## 6.4 Connections for Unused Pins

表 6-3 lists the correct termination of unused pins.

**表 6-3. Connection of Unused Pins**

PIN <sup>(1)</sup>	POTENTIAL	COMMENT
PAX	Open	Set corresponding pin functions to GPIO (PINCMx.PF = 0x1) and configure unused pins to output low or input with internal pullup or pulldown resistor.
NRST	VCC	NRST is an active-low reset signal. Pull high to VCC or the device cannot start. For more information, see 节 9.1.

(1) Any unused pin with a function that is shared with general-purpose I/O must follow the "PAX" unused pin connection guidelines.

E <sub>G</sub>	Gain error	VDD reference, 10-bit <sup>(2)</sup>	-5		5	LSB
		VDD reference, 12-bit <sup>(2)</sup>	-25		25	LSB

- (1) Total Unadjusted Error (TUE) can be calculated from E<sub>I</sub>, E<sub>O</sub>, and E<sub>G</sub> using the following formula: TUE = √(E<sub>I</sub><sup>2</sup> + |E<sub>O</sub>|<sup>2</sup> + E<sub>G</sub><sup>2</sup>)  
Note: You must convert all of the errors into the same unit, usually LSB, for the above equation to be accurate
- (2) VDD reference specifications are measured with V<sub>R+</sub> = VDD and V<sub>R-</sub> = VSS = 0V.

(3) Offset error achieves +/-3mV after software calibration

### 7.11.4 Typical Connection Diagram

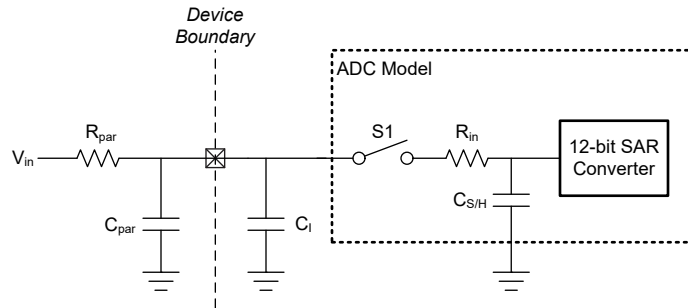

图 7-2. ADC Input Network

1. Refer to [ADC Electrical Characteristics](#) for the values of  $R_{in}$  and  $C_{S/H}$
2. Refer to [Digital IO Electrical Characteristics](#) for the value of  $C_I$
3.  $C_{par}$  and  $R_{par}$  represent the parasitic capacitance and resistance of the external ADC input circuitry

Use the following equations to solve for the minimum sampling time (T) required for an ADC conversion:

1.  $\tau = (R_{par} + R_{in}) \times C_{S/H} + R_{par} \times (C_{par} + C_I)$
2.  $K = \ln(2^n / \text{Settling error}) - \ln((C_{par} + C_I) / C_{S/H})$
3.  $T$  (minimum sampling time) =  $K \times \tau$

## 8 Detailed Description

The following sections describe all of the components that make up the devices in this data sheet. The peripherals integrated into these devices are configured by software through Memory Mapped Registers (MMRs). For more details, see the corresponding chapter of the [MSPM0 C-Series 24MHz Microcontrollers Technical Reference Manual](#).

### 8.1 CPU

The CPU subsystem (MCPUSS) implements an Arm Cortex-M0+ CPU, a system timer, and interrupt management features. The Arm Cortex-M0+ is a cost-optimized 32-bit CPU that delivers high performance and low power to embedded applications. Key features of the CPU Sub System include:

- Arm Cortex-M0+ CPU supports clock frequencies from 32kHz to 24MHz
  - ARMv6-M Thumb instruction set (little endian) with 32-cycle 32x32 slow multiply instruction
- Nested vectored interrupt controller (NVIC) with 4 programmable priority levels and tail chaining

### 8.2 Operating Modes

MSPM0C MCUs provide five main operating modes (power modes) to allow for optimization of the device power consumption based on application requirements. In order of decreasing power, the modes are: RUN, SLEEP, STOP, STANDBY, and SHUTDOWN. The CPU is active executing code in RUN mode. Peripheral interrupt events can wake the device from SLEEP, STOP, or STANDBY mode to the RUN mode. SHUTDOWN mode completely disables the internal core regulator to minimize power consumption, and wake is only possible via NRST or SWD. RUN, SLEEP, STOP, and STANDBY modes also include several configurable policy options (for example, RUN.x) for balancing performance with power consumption.

To further balance performance and power consumption, MSPM0C devices implement two power domains: **PD1** (for the CPU, memories, and high performance peripherals), and **PD0** (for low speed, low power peripherals).

- **PD1** is always powered in RUN and SLEEP modes, but is disabled in all other modes.
- **PD0** is always powered in RUN, SLEEP, STOP, and STANDBY modes.
- PD1 and PD0 are both disabled in SHUTDOWN mode.

#### 8.2.1 Functionality by Operating Mode (MSPM0C110x)

表 8-1 lists the supported functionality in each operating mode.

Functional key:

- **EN**: The function is enabled in the specified mode.
- **DIS**: The function is disabled (either clock or power gated) in the specified mode, but the function's configuration is retained.
- **OPT**: The function is optional in the specified mode, and remains enabled if configured to be enabled.
- **NS**: The function is not automatically disabled in the specified mode, but use of the function is not supported.
- **OFF**: The function is fully powered off in the specified mode, and no configuration information is retained.

If STOP0 is entered from RUN2 (SYSOSC was disabled and MCLK was sourced from LFCLK), SYSOSC remains disabled as it was in RUN2, and ULPCLK remains at 32kHz as it was in RUN2.
- (2) When using the STANDBY1 policy for STANDBY, only TIMG8, TIMG14 and TIMA0 are clocked. Other PD0 peripherals can generate an asynchronous fast clock request upon external activity but are not actively clocked.

### 8.3 Power Management Unit (PMU)

The power management unit (PMU) generates the internally regulated core supplies for the device and provides supervision of the external supply (VDD). The PMU also contains the bandgap voltage reference used by the PMU itself as well as analog peripherals. Key features of the PMU include:

- Power-on reset (POR) supply monitor

- Brown-out reset (BOR) supply monitor with early warning capability using three programmable thresholds
- Core regulator with support for RUN, SLEEP, STOP, and STANDBY operating modes to dynamically balance performance with power consumption
- Parity-protected trim to immediately generate a power-on reset (POR) in the event that a power management trim is corrupted

For more details, see the PMU chapter of the [MSPM0 C-Series 24MHz Microcontrollers Technical Reference Manual](#).

## 8.4 Clock Module (CKM)

The clock module provides the following oscillators:

- **LFOSC**: Internal low-frequency oscillator (32kHz)
- **SYSOSC**: Internal high-frequency oscillator (24MHz)
- **LFCKIN**: low-frequency digital clock input (32KHz)
- **HFCKIN**: high-frequency digital clock input (4 to 24MHz)

The following clocks are distributed by the clock module for use by the processor, bus, and peripherals:

- **MCLK**: Main system clock for PD1 peripherals, derived from SYSOSC or LFCLK, active in RUN and SLEEP modes
- **CPUCLK**: Clock for the processor (derived from MCLK), active in RUN mode
- **ULPCLK**: Ultra-low power clock for PD0 peripherals, active in RUN, SLEEP, STOP, and STANDBY modes
- **MFCLK**: 4MHz fixed mid-frequency clock for peripherals, available in RUN, SLEEP, and STOP modes
- **LFCLK**: 32kHz fixed low-frequency clock for peripherals or MCLK, active in RUN, SLEEP, STOP, and STANDBY modes
- **ADCCLK**: ADC clock, available in RUN, SLEEP and STOP modes
- **CLK\_OUT**: Used to output a clock externally, available in RUN, SLEEP, STOP, and STANDBY modes

For more details, see the CKM chapter of the [MSPM0 C-Series 24MHz Microcontrollers Technical Reference Manual](#).

## 8.5 DMA

The direct memory access (DMA) controller allows movement of data from one memory address to another without CPU intervention. For example, the DMA can be used to move data from ADC conversion memory to SRAM. The DMA reduces system power consumption by allowing the CPU to remain in low power mode, without having to awaken to move data to or from a peripheral.

The DMA in these devices support the following key features:

- 1 DMA transfer channel
- Direct peripheral to DMA trigger is supported only from ADC.
- Byte (8-bit), short word (16-bit), word (32-bit) and long word (64-bit) or mixed byte and word transfer capability
- Transfer counter block size supports up to 64k transfers of any data type
- Configurable DMA transfer trigger selection

表 8-2 lists the available triggers for the DMA which are configured using the DMATCTL.DMATSEL control bits in the DMA memory mapped registers.

表 8-2. DMA Trigger Mapping

TRIGGER 0:6	SOURCE
0	Software

2	Generic Subscriber 1 (FSUB_1)

## 8.6 Events

The event manager transfers digital events from one entity (for example, a peripheral) to another (for example, a second peripheral, the DMA or the CPU). The event manager implements event transfer through a defined set of event publishers (generators) and subscribers (receivers) that are interconnected through an event fabric containing a combination of static and programmable routes.

Events that are transferred by the event manager include:

- Peripheral event transferred to the CPU as an interrupt request (IRQ) (Static Event)
  - Example: GPIO interrupt is sent to the CPU
- Peripheral event transferred to the DMA as a DMA trigger (DMA Event)
  - Example: ADC trigger to DMA to request a DMA transfer
- Peripheral event transferred to another peripheral to directly trigger an action in hardware (Generic Event)
  - Example: TIMx timer peripheral publishes a periodic event to the ADC subscriber port, and the ADC uses the event to trigger start-of-sampling

For more details, see the Event chapter of the [MSPM0 C-Series 24MHz Microcontrollers Technical Reference Manual](#).

**表 8-3. Generic Event Channels**

A generic route is a point-to-point (1:1) route in which the peripheral publishing the event is configured to use the available generic route channel to publish the event to another entity. An entity can be another peripheral, a generic DMA trigger event, or a generic CPU event.

CHANID	Generic Route Channel Selection	Channel Type

1	Generic event channel 1 selected	1 : 1

### 8.8 Flash Memory

A single bank of nonvolatile flash memory is provided for storing executable program code and application data.

Key features of the flash include:

- In-circuit program and erase operations supported across the entire recommended supply range
- Small 1KB sector sizes (minimum erase resolution of 1KB)
- Up to 100000 program and erase cycles

For a complete description of the flash memory, see the NVM chapter of the [MSPM0 C-Series 24MHz Microcontrollers Technical Reference Manual](#).

### 8.9 SRAM

MSPM0Cxx MCUs include a low-power high-performance SRAM memory with zero wait state access across the supported CPU frequency range of the device. SRAM memory can be used for storing volatile information such as the call stack, heap, global data, and code. The SRAM memory content is fully retained in RUN, SLEEP, STOP, and STANDBY operating modes and is lost in SHUTDOWN mode. A write protection mechanism is provided to allow the application to dynamically write protect the SRAM memory with 1KB resolution. Write protection is useful when placing executable code into SRAM to provide a level of protection against unintentional overwrites of code by either the CPU or DMA. Placing code in SRAM can improve performance of critical loops by enabling zero wait state operation and lower power consumption.

### 8.10 GPIO

The general purpose input/output (GPIO) peripheral lets the application write data out and read data in through the device pins. Through the use of the Port A GPIO peripheral, these devices support up to 18 GPIO pins.

The key features of the GPIO module include:

- 0 wait state MMR access from CPU
- Set, clear, or toggle multiple bits without the need of a read-modify-write construct in software
- "FastWake" feature enables low-power wakeup from STOP and STANDBY modes for any GPIO port
- User controlled input filtering

## 8.11 IOMUX

The IOMUX peripheral enables IO pad configuration and controls digital data flow to and from the device pins. The key features of the IOMUX include:

## 9 Applications, Implementation, and Layout

### 备注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

### 9.1 Typical Application

#### 9.1.1 Schematic

TI recommends connecting a combination of a 10- $\mu$ F and a 0.1- $\mu$ F low-ESR ceramic decoupling capacitor to the VDD and VSS pins. Higher-value capacitors can be used but can affect the supply rail ramp-up time. Decoupling capacitors must be placed as close as possible to the pins (within a few millimeters).

PA1 and NRST are double bonded for some variants. If it's used as a NRST, it must connect an external 47-k $\Omega$  pullup resistor with a 10-nF pulldown capacitor.

For 5V-tolerant open drain (ODIO), a pullup resistor is required to output high for I2C and UART functions if the ODIO are used.

图 9-1. Typical Application Schematic

## 10 Device and Documentation Support

TI offers an extensive line of development tools. Tools and software to evaluate the performance of the device, generate code, and develop solutions are listed below.

### 10.1 Device Nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all MSP MCU devices and support tools. Each MSP MCU commercial family member has one of two prefixes: MSP or X. These prefixes represent evolutionary stages of product development from engineering prototypes (X) through fully qualified production devices (MSP).

**X** - Experimental device that is not necessarily representative of the final device's electrical specifications

**MSP** - Fully qualified production device

**X** devices are shipped against the following disclaimer:

"Developmental product is intended for internal evaluation purposes." MSP devices have been characterized fully, and the quality and reliability of the device have been demonstrated fully. TI's standard warranty applies. Predictions show that prototype devices (X) have a greater failure rate than the standard production devices. TI recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

TI device nomenclature also includes a suffix with the device family name. This suffix indicates the temperature range, package type, and distribution format. [图 10-1](#) provides a legend for reading the complete device name.

Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

<sup>(5)</sup> Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
