

TLV181x 和 TLV182x 系列 40V 轨至轨输入比较器，具有推挽或开漏输出选项

1 特性

- 2.4V 至 40V 宽电源电压范围
- 轨到轨输入
- 已知启动的上电复位 (POR)
- 低输入偏移电压为 500 μ V
- 420ns 典型传播延迟
- 每通道的低静态电流为 5 μ A
- 低输入偏置电流 150fA
- 推挽输出选项 (TLV181x)
- 开漏输出选项 (TLV182x)
- -40°C 到 +125°C 的完整温度范围
- 2kV ESD 保护
- 功能安全型
 - 可提供用于功能安全系统设计的文档

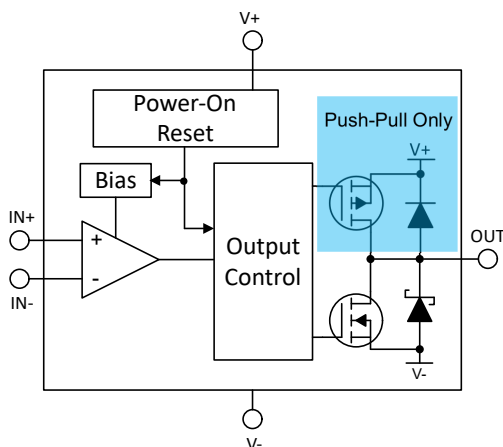

2 应用

- 电器
- 工厂自动化和控制
- 电机驱动器
- 信息娱乐系统与仪表组

3 说明

TLV181x 和 TLV182x 是一个 40V 单通道、双通道和四通道比较器系列，具有多个输出选项。该系列提供具有推挽或开漏输出选项的轨至轨输入。该系列具有出色的速度功率组合，传播延迟为 420ns，整个电源电压范围为 2.4V 至 40V，每个通道的静态电源电流仅为 5 μ A。

所有器件都包含上电复位 (POR) 功能。这可确保输出处于已知状态，直到达到最小电源电压，然后输出才对

TLV18xx 方框图

输入做出响应，从而防止系统上电和断电期间出现错误输出。

TLV181x 比较器具有推挽式输出级，能够灌/拉毫安级电流，同时可对 LED 进行控制或驱动容性负载（例如 MOSFET 栅极）。

TLV182x 比较器具有开漏输出级，可在独立于比较器电源电压的情况下上拉至 40V。

器件信息

器件型号	封装 ⁽¹⁾	本体尺寸 (标称值) ⁽²⁾
TLV1811、 TLV1821 (单通道)	SC-70 (6)	1.25mm x 2.00mm
	SOT-23 (5)	1.60mm x 2.90mm
TLV1811L、 TLV1821L (单通道 - 交替引脚 排列)	SC-70 (5)	1.25mm x 2.00mm
	SOT-23 (5)	1.60mm x 2.90mm
TLV1812、 TLV1822 (双通道)	SOIC (8)	3.91mm x 4.90mm
	TSSOP (8)	3.00mm x 4.40mm
	VSSOP (8)	3.00mm x 3.00mm
	WSON (8)	2.00mm x 2.00mm
TLV1814、 TLV1824 (四通道)	SOT-23 (8)	1.60mm x 2.90mm
	SOIC (14)	3.91mm x 8.65mm
	TSSOP (14)	4.40mm x 5.00mm
	SOT-23 (14)	4.20mm x 2.00mm
	WQFN (16)	3.00mm x 3.00mm

(1) 如需了解所有可用封装，请参阅数据表末尾的可订购产品附录。

(2) 封装尺寸 (长 x 宽) 为标称值，并包括引脚 (如适用)。

(1) Some manufacturers transpose the names of channels 1 and 2. Electrically the pinouts are identical, just a difference in channel naming convention.

5 Specifications

5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
Supply voltage: $V_S = (V+) - (V-)$	- 0.3	42	V
Input pins (IN+, IN-) from (V-) ⁽²⁾	- 0.3	(V+) + 0.3	V
Current into Input pins (IN+, IN-)	- 10	10	mA
Output (OUT) voltage (Open-Drain) from (V-) ⁽³⁾	- 0.3	42	V
Output (OUT) voltage (Push-Pull) from (V-)	- 0.3	(V+) + 0.3	V
Output (OUT) current ^{(4) (5) (6)}	-10	10	mA
Junction temperature, T_J		150	°C
Storage temperature, T_{stg}	- 65	150	°C

- Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute Maximum Ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If used outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not be fully functional, and this may affect device reliability, functionality, performance, and shorten the device lifetime.
- Input terminals are diode-clamped to (V-). Input signals that can swing more than 0.3V beyond the supply rails must be current-limited to 10mA or less.
- Output (OUT) for open drain can be greater than (V+) and inputs (IN+, IN-) as long as it is within the - 0.3V to 42V range
- The output is diode-clamped to (V-) for both output options, and diode clamped to (V+) for the push-pull output option. The open drain version does not have a clamp to V+. Please see the *Outputs* and *ESD Protection* section of the *Application Information* Section for more information.
- Output sinking and sourcing current is internally limited to <35mA when operating within the Absolute Maximum output voltage limits. The Absolute Maximum Output Current limit specified here is the maximum current through the clamp structure when exceeding the supply voltage below (V-) for both output options, or above (V+) for the push-pull option.
- Short-circuit from output to (V-) or (V+). Continuous output short circuits at elevated supply voltages can result in excessive heating and exceeding the maximum allowed junction temperature, leading to eventual device destruction.

5.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process.
- JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
Supply voltage: $V_S = (V+) - (V-)$		2.4	40	V
Input voltage range from (V-)		- 0.2	(V+) + 0.2	V
Output voltage range from (V-)	Open Drain	- 0.2	40	V
Output voltage range from (V-)	Push Pull	- 0.2	(V+) + 0.2	V

5.4 Thermal Information - Single

5.7 Electrical Characteristics

For V_S (Total Supply Voltage) = $(V+) - (V-) = 12V$, $V_{CM} = V_S / 2$ at $T_A = 25^\circ C$ (Unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
OFFSET VOLTAGE						
V_{OS}	Input offset voltage		-3	±0.5	3	mV
PSRR	Power supply rejection ratio	$V_S = 2.4V$ to $40V$, $V_{CM} = (V-)$		100		dB
POWER SUPPLY						
I_Q	Quiescent current per comparator, No Load	Output Low, $T_A = 25^\circ C$		5	6.5	μA
I_Q	Quiescent current per comparator, No Load	Output High, $T_A = 25^\circ C$		7	9	μA
V_{POR}	Power On Reset Voltage			1.7		V
INPUT BIAS CURRENT						
I_B	Input bias current ⁽¹⁾			150		fA
I_{OS}	Input offset current ⁽¹⁾			10		fA
INPUT CAPACITANCE						
C_{ID}	Input Capacitance, Differential			2		pF
C_{IC}	Input Capacitance, Common Mode			8		pF
INPUT COMMON MODE RANGE						
OUTPUT						
I_{OL}	Short-circuit current	Sinking	15	30		mA
I_{OH}	Short-circuit current	Sourcing (for Push-Pull only)	15	30		mA

(1) This parameter is ensured by design and/or characterization and is not tested in production .

5.8 Switching Characteristics

For V_S (Total Supply Voltage) = $(V+) - (V-) = 12V$, $V_{CM} = V_S / 2$ at $T_A = 25^\circ C$ (Unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
OUTPUT						
T_{PD-HL}	Propagation delay time, high-to-low	$V_{OD} = 10mV, C_L = 50pF$		900		ns
T_{PD-HL}	Propagation delay time, high-to-low	$V_{OD} = 100mV, C_L = 50pF$		450		ns
T_{PD-LH}	Propagation delay time, low-to-high, push-pull output	$V_{OD} = 10mV, C_L = 50pF$		900		ns
T_{PD-LH}	Propagation delay time, low-to-high, push-pull output	$V_{OD} = 100mV, C_L = 50pF$		420		ns
T_{RISE}	Output Rise Time, 20% to 80%, push-pull output	$C_L = 50pF$		15		ns
T_{FALL}	Output Fall Time, 80% to 20%	$C_L = 50pF$		15		ns
F_{TOGGLE}	Toggle Frequency	$V_{ID} = 100mV, C_L = 50pF$		500		kHz
POWER ON TIME						
P_{ON}	Power on-time			200		μs

6 Typical Characteristics

$T_A = 25^\circ\text{C}$, $V_S = 12\text{V}$, $R_{\text{PULLUP}} = 2.5\text{k}$, $C_L = 20\text{pF}$, $V_{\text{CM}} = 0\text{V}$, $V_{\text{UNDERDRIVE}} = 100\text{mV}$, $V_{\text{OVERDRIVE}} = 100\text{mV}$ unless otherwise noted.

7 Detailed Description

7.1 Overview

The TLV181x and TLV182x devices are micro-power comparators with push-pull and open-drain output options. Operating down to 2.4V while only consuming only 5µA per channel, the TLV181x and TLV182x are well suited for portable, automotive and industrial applications. An internal power-on reset circuit is designed so that the output remains in a known state during power-up and power-down.

7.2 Functional Block Diagrams

图 7-1. TLV182x Open-Drain Block Diagram

图 7-2. TLV181x Push-Pull Block Diagram

7.3 Feature Description

TLV18xx Family Options

The TLV18xx family consists of several output and pinout options, all featuring 40V operation, micro-power 5µA supply currents, 420ns propagation delay, and a Power-On Reset (POR) function.

The TLV18xx family has two output options:

The TLV181x has a **push-pull** (sink-source) output.

The TLV182x has a **open-drain** (sink only) output, capable of being pulled-up to any voltage up to 40V, independent of comparator supply voltage.

The TLV1811L and TLV1821L are alternate pinouts of the TLV1811 and TLV1821 that allow upgrading older devices such as the TLV7211, TLV7221, LMC7211 and LMC7221 family.

7.4 Device Functional Modes

7.4.1 Inputs

7.4.1.1 TLV18xx Rail-to-Rail Input

The TLV18xx input voltage range extends from 200mV below V- to 200mV above V+. The differential input voltage (V_{ID}) can be any voltage within these limits. No phase-inversion of the comparator output occurs when the input voltages stay within the specified range.

The Rail-to-Rail input does have an ESD clamp to the V+ supply line and therefore the input voltage must not exceed the supply voltages by more than 200mV. TI does not recommend applying signals to the rail to rail inputs with no supply voltage.

7.4.1.2 ESD Protection

The TLV182x open-drain option ESD protection consists of a snapback ESD clamp between the output and V- to allow the output to be pulled above V+ to a maximum of 40V. For the inputs, there is a "lower" ESD clamp between V- and the inputs and there is also a parasitic "upper" ESD soft-clamp diode between the input and V+ with a 5k Ω equivalent resistance (as shown in [图 7-1](#)). These are not traditional ESD cells and current must be limited to 1mA or less across this upper diode junction and resistance. External diode clamping is recommended if the input voltage can exceed V+ during operation.

The TLV181x push-pull inputs and output ESD protection contains a conventional diode-type "upper" ESD clamp between the I/O pins and V+, and a "lower" ESD clamp between the I/O pins and V-. The inputs or output must not exceed the supply rails by more than 200mV.

If the inputs are to be connected to a low impedance source, such as a power supply or buffered reference line, TI recommends adding a current-limiting resistor in series with the input to limit any currents when the clamps conduct. The current must be limited 10mA or less, though TI recommends limiting the current to 1mA or less. This series resistance can be part of any resistive input dividers or networks.

7.4.1.3 Unused Inputs

If a channel is not to be used, DO NOT tie the inputs together. Due to the high equivalent bandwidth and low offset voltage, tying the inputs directly together can cause high frequency chatter as the device triggers on its own internal wideband noise. Instead, the inputs must be tied to any available voltage that resides within the specified input voltage range and provides a minimum of 50mV differential voltage. For example, one input can be grounded and the other input connected to a reference voltage, or even V+ (as long as the input is directly connected to the V+ pin to avoid transients).

7.4.2 Outputs

7.4.2.1 TLV181x Push-Pull Output

The TLV181x features a push-pull output stage capable of both sinking and sourcing current. This allows driving loads such as LED's and MOSFET gates, as well as eliminating the need for a power-wasting external pull-up resistor. The push-pull output must never be connected to another output.

Directly shorting the output to the opposite supply rail (V+ when output "low" or V- when output "High") can result in thermal runaway and eventual device destruction at high (>12 V) supply voltages. If output shorts are possible, a series current limiting resistor is recommended to limit the power dissipation.

Unused push-pull outputs must be left floating, and never tied to a supply, ground, or another output.

7.4.2.2 TLV182x Open-Drain Output

The TLV182x features an open-drain (also commonly called open collector) sinking-only output stage enabling the output logic levels to be pulled up to an external voltage from 0V up to 40V, independent of the comparator supply voltage (V+). The open-drain output allows logical OR'ing of multiple open drain outputs and logic level translation. TI recommends setting the pull-up resistor current to between 100uA and 1mA. Lower value pull-up resistor values can help increase the rising edge rise-time, but at the expense of increasing V_{OL} and higher power dissipation. The rise-time is dependent on the time constant of the total pull-up resistance and total load capacitance. Large value pull-up resistors (>1 M Ω) creates an exponential rising edge due to the output RC time constant and increase the rise-time.

Directly shorting the output to V+ can result in thermal runaway and eventual device destruction at high (>12V) pull-up voltages. If output shorts are possible, a series current limiting resistor is recommended to limit the power dissipation.

Unused open drain outputs can be left floating, or can be tied to the V- pin if floating pins are not desired.

7.4.3 Power-On Reset (POR)

The TLV18xx family has an internal Power-on-Reset (POR) circuit for known start-up or power-down conditions. While the power supply (V_+) is ramping up or ramping down, the POR circuitry is activated for up to $200\mu\text{s}$ after the minimum supply voltage threshold of 2.4V is crossed, or immediately when the supply voltage drops below 2.4V . When the supply voltage is equal to or greater than the minimum supply voltage, and after the delay period, the comparator output reflects the state of the differential input (V_{ID}).

For the TLV181x push-pull output devices, the output is held low during the POR period (t_{on}).

For the TLV182x open drain output option the POR circuit keeps the output high impedance (Hi-Z) during the POR period (t_{on}).

图 7-3. Power-On Reset Timing Diagram

Note: The output voltage rises with the pull-up voltage during the POR period.

7.4.4 Hysteresis

The TLV18xx family does not have internal hysteresis. Due to the wide effective bandwidth and low input offset voltage, there is a possibility for the output to "chatter" when the absolute differential voltage is near zero as the comparator triggers on internal wideband noise. This is normal comparator behavior and is expected. TI recommends that the user add external hysteresis if slow moving signals are expected. See 节 8.1.2 in the following section.

8 Application and Implementation

备注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

8.1.1 Basic Comparator Definitions

8.1.1.1 Operation

The basic comparator compares the input voltage (V_{IN}) on one input to a reference voltage (V_{REF}) on the other input. In the 图 8-1 example below, if V_{IN} is less than V_{REF} , the output voltage (V_O) is logic low (V_{OL}). If V_{IN} is greater than V_{REF} , the output voltage (V_O) is at logic high (V_{OH}). 表 8-1 summarizes the output conditions. The output logic can be inverted by simply swapping the input pins.

表 8-1. Output Conditions

Inputs Condition	Output
$IN+ > IN-$	HIGH (V_{OH})
$IN+ = IN-$	Indeterminate (chatters - see Hysteresis)
$IN+ < IN-$	LOW (V_{OL})

8.1.1.2 Propagation Delay

There is a delay between from when the input crosses the reference voltage and the output responds. This is called the Propagation Delay. Propagation delay can be different between high-to-low and low-to-high input transitions. This is shown as t_{pLH} and t_{pHL} in 图 8-1 and is measured from the mid-point of the input to the midpoint of the output. Likewise, propagation varies with what is called Overdrive (V_{OD}) and Underdrive (V_{UD}) voltage levels (see section below).

图 8-1. Comparator Timing Diagram

8.1.1.3 Overdrive and Underdrive Voltage

The overdrive voltage, V_{OD} , is the amount of input voltage beyond the reference voltage (and not the total input peak-to-peak voltage). The overdrive voltage is 100mV as shown in the 图 8-1 example. Similarly, underdrive voltage, V_{UD} , is how far below REF the input starts. The overdrive and underdrive voltages influence the propagation delay (t_p). See curves in the Typical Characteristics section for more details. The smaller the overdrive voltage, the longer the propagation delay, particularly when $<100\text{mV}$. If the fastest speeds are desired, apply the highest amount of overdrive possible. Contrary to overdrive voltage, larger underdrive voltage causes t_p to increase. This is particularly important in applications where rail-to-rail input swings are present at the comparator inputs. The result can be skewed propagation delay (difference between t_{pLH} and t_{pHL}). As a low power comparator, it is not recommended to use this comparator family if variation in propagation delay is critical.

The risetime (t_r) and falltime (t_f) is the time from the 20% and 80% points of the output waveform.

8.1.2 Hysteresis

The basic comparator configuration can oscillate or produce a noisy "chatter" output if the applied differential input voltage is near the comparator's offset voltage. This usually occurs when the input signal is moving very slowly across the switching threshold of the comparator.

This problem can be prevented by the addition of hysteresis or positive feedback.

The hysteresis transfer curve is shown in 图 8-2. This curve is a function of three components: V_{TH} , V_{OS} , and V_{HYST} :

- V_{TH} is the actual set voltage or threshold trip voltage.
- V_{OS} is the internal offset voltage between V_{IN+} and V_{IN-} . This voltage is added to V_{TH} to form the actual trip point at which the comparator must respond to change output states.
- V_{HYST} is the hysteresis (or trip window) that is designed to reduce comparator sensitivity to noise.

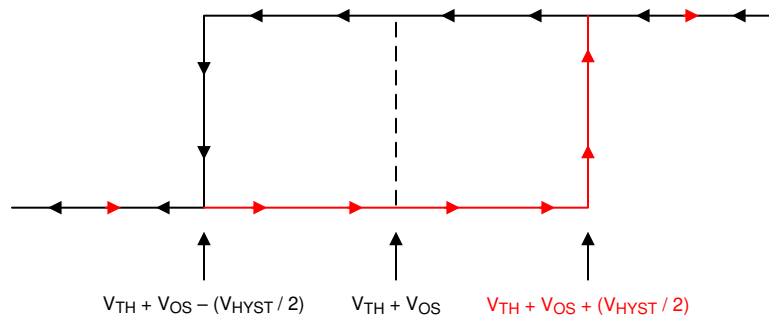

图 8-2. Hysteresis Transfer Curve

For more information, please see Application Note SBOA219 "[Comparator with and without hysteresis circuit](#)".

8.1.2.1 Inverting Comparator With Hysteresis

The inverting comparator with hysteresis requires a three-resistor network that is referenced to the comparator supply voltage (V_{CC}), as shown in 图 8-3.

图 8-3. TLV181xin an Inverting Configuration With Hysteresis

The equivalent resistor networks when the output is high and low are shown in 图 8-3.

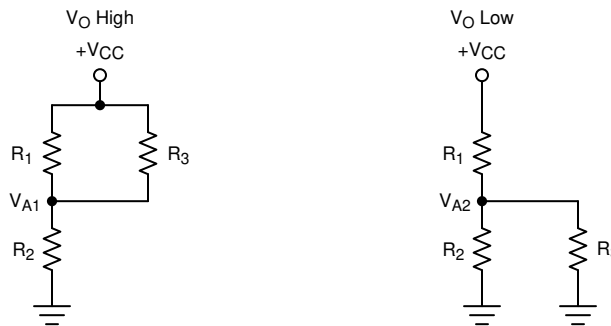

图 8-4. Inverting Configuration Resistor Equivalent Networks

When V_{IN} is less than V_A , the output voltage is high (for simplicity, assume V_O switches as high as V_{CC}). The three network resistors can be represented as $R1 \parallel R3$ in series with $R2$, as shown in 图 8-4.

方程式 1 below defines the high-to-low trip voltage (V_{A1}).

$$V_{A1} = V_{CC} \times \frac{R2}{(R1 \parallel R3) + R2} \quad (1)$$

When V_{IN} is greater than V_A , the output voltage is low. In this case, the three network resistors can be presented as $R2 \parallel R3$ in series with $R1$, as shown in 方程式 2.

Use 方程式 2 to define the low to high trip voltage (V_{A2}).

$$V_{A2} = V_{CC} \times \frac{R2 \parallel R3}{R1 + (R2 \parallel R3)} \quad (2)$$

方程式 3 defines the total hysteresis provided by the network.

$$\Delta V_A = V_{A1} - V_{A2} \quad (3)$$

8.1.2.2 Non-Inverting Comparator With Hysteresis

A non-inverting comparator with hysteresis requires a two-resistor network and a voltage reference (V_{REF}) at the inverting input, as shown in 图 8-5,

图 8-5. TLV181x in a Non-Inverting Configuration With Hysteresis

The equivalent resistor networks when the output is high and low are shown in 图 8-6.

图 8-6. Non-Inverting Configuration Resistor Networks

When V_{IN} is less than V_{REF} , the output is low. For the output to switch from low to high, V_{IN} must rise above the V_{IN1} threshold. Use 方程式 4 to calculate V_{IN1} .

$$V_{IN1} = R1 \times \frac{V_{REF}}{R2} + V_{REF} \quad (4)$$

When V_{IN} is greater than V_{REF} , the output is high. For the comparator to switch back to a low state, V_{IN} must drop below V_{IN2} . Use 方程式 5 to calculate V_{IN2} .

$$V_{IN2} = \frac{V_{REF} (R1 + R2) - V_{CC} \times R1}{R2} \quad (5)$$

The hysteresis of this circuit is the difference between V_{IN1} and V_{IN2} , as shown in 方程式 6.

$$\Delta V_{IN} = V_{CC} \times \frac{R1}{R2} \quad (6)$$

For more information, please see Application Notes SNOA997 "Inverting comparator with hysteresis circuit" and SBOA313 "Non-Inverting Comparator With Hysteresis Circuit".

8.1.2.3 Inverting and Non-Inverting Hysteresis using Open-Drain Output

An open drain output device, such as the TLV182x, can also be used, but the output pull-up resistor must also be taken into account in the calculations. The pull-up resistor is seen in series with the feedback resistor when the output is high. Thus, the feedback resistor is actually seen as $R2 + R_{PULLUP}$. TI recommends that the pull-up resistor be at least 10 times less than the feedback resistor value.

8.2 Typical Applications

8.2.1 Window Comparator

Window comparators are commonly used to detect undervoltage and overvoltage conditions. 图 8-7 shows a simple window comparator circuit. Window comparators require open drain outputs (TLV182x) if the outputs are directly connected together.

图 8-7. Window Comparator

8.2.1.1 Design Requirements

For this design, follow these design requirements:

- Alert (logic low output) when an input signal is less than 1.1V
- Alert (logic low output) when an input signal is greater than 2.2V
- Alert signal is active low
- Operate from a 3.3V power supply

8.2.1.2 Detailed Design Procedure

Configure the circuit as shown in 图 8-7. Connect V_{CC} to a 3.3V power supply and V_{EE} to ground. Make R_1 , R_2 and R_3 each $10\text{M}\Omega$ resistors. These three resistors are used to create the positive and negative thresholds for the window comparator (V_{TH+} and V_{TH-}).

With each resistor being equal, V_{TH+} is 2.2V and V_{TH-} is 1.1V. Large resistor values such as $10\text{M}\Omega$ are used to minimize power consumption. The resistor values can be recalculated to provide the desired trip point values.

The sensor output voltage is applied to the inverting and noninverting inputs of the two comparators. Using two open-drain output comparators allows the two comparator outputs to be Wire-OR'ed together.

The respective comparator outputs are low when the sensor is less than 1.1V or greater than 2.2V. The respective comparator outputs are high when the sensor is in the range of 1.1V to 2.2V (within the "window"), as shown in 图 8-8.

8.2.1.3 Application Curve

图 8-8. Window Comparator Results

For more information, please see Application note SBOA221 "[Window comparator circuit](#)".

8.2.2 Square-Wave Oscillator

Square-wave oscillator can be used as low cost timing reference or system supervisory clock source. A push-pull output (TLV181x) is recommended for best symmetry.

图 8-9. Square-Wave Oscillator

8.2.2.1 Design Requirements

The square-wave period is determined by the RC time constant of the capacitor C_1 and resistor R_4 . The maximum frequency is limited by propagation delay of the device and the capacitance load on the output. The low input bias current allows a lower capacitor value and larger resistor value combination for a given oscillator frequency, which helps to reduce BOM cost and board space. TI recommends that R_4 be over several kilo-ohms to minimize loading the output.

8.2.2.2 Detailed Design Procedure

The oscillation frequency is determined by the resistor and capacitor values. The following calculation provides details of the steps.

图 8-10. Square-Wave Oscillator Timing Thresholds

First consider the output of Figure 图 8-9 as high, which indicates the inverted input V_C is lower than the noninverting input (V_A). This causes the C_1 to be charged through R_4 , and the voltage V_C increases until equal to the noninverting input. The value of V_A at the point is calculated by 方程式 7.

$$V_{A1} = \frac{V_{CC} \times R_2}{R_2 + R_1 + R_3} \quad (7)$$

if $R_1 = R_2 = R_3$, then $V_{A1} = 2V_{CC}/3$

At this time the comparator output trips pulling down the output to the negative rail. The value of V_A at this point is calculated by 方程式 8.

$$V_{A2} = \frac{V_{CC}(R_2 \parallel R_3)}{R_1 + R_2 \parallel R_3} \quad (8)$$

if $R_1 = R_2 = R_3$, then $V_{A2} = V_{CC}/3$

The C_1 now discharges through the R_4 , and the voltage V_{CC} decreases until reaching V_{A2} . At this point, the output switches back to the starting state. The oscillation period equals to the time duration for C_1 from $2V_{CC}/3$ to $V_{CC}/3$ then back to $2V_{CC}/3$, which is given by $R_4 C_1 \times \ln 2$ for each trip. Therefore, the total time duration is calculated as $2R_4 C_1 \times \ln 2$.

The oscillation frequency can be obtained by 方程式 9:

$$f = 1 / (2 R_4 \times C_1 \times \ln 2) \quad (9)$$

8.2.2.3 Application Curve

图 8-11 shows the simulated results of an oscillator using the following component values:

- $R_1 = R_2 = R_3 = R_4 = 100k \Omega$
- $C_1 = 100pF, C_L = 20pF$
- $V^+ = 5V, V^- = GND$
- C_{stray} (not shown) from V_A TO GND = $10pF$

图 8-11. Square-Wave Oscillator Output Waveform

8.2.3 Adjustable Pulse Width Generator

图 8-12 is a variation on the square wave oscillator that allows adjusting the pulse widths.

R_4 and R_5 provide separate charge and discharge paths for the capacitor C depending on the output state.

图 8-12. Adjustable Pulse Width Generator

The charge path is set through R_5 and D_2 when the output is high. Similarly, the discharge path for the capacitor is set by R_4 and D_1 when the output is low.

The pulse width t_1 is determined by the RC time constant of R_5 and C . Thus, the time t_2 between the pulses can be changed by varying R_4 , and the pulse width can be altered by R_5 . The frequency of the output can be changed by varying both R_4 and R_5 . At low voltages, the effects of the diode forward drop (0.8V, or 0.15V for Shottky) must be taken into account by altering output high and low voltages in the calculations.

8.2.4 Time Delay Generator

The circuit shown in 图 8-13 provides output signals at a prescribed time interval from a time reference and automatically resets the output low when the input returns to 0V. This is useful for sequencing a "power on" signal to trigger a controlled start-up of power supplies.

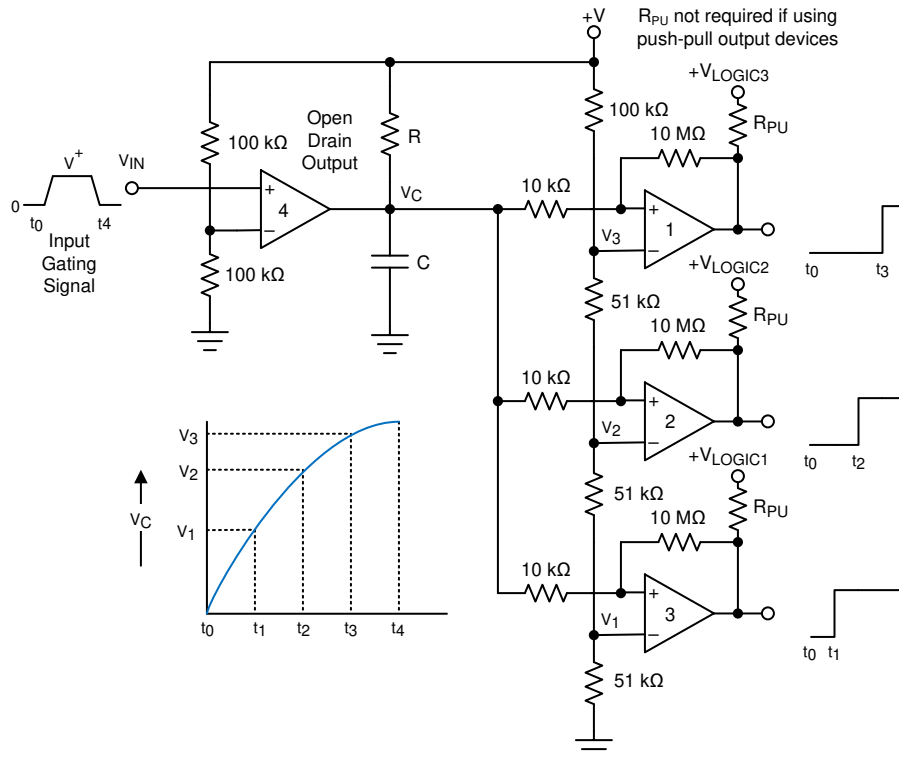

图 8-13. Time Delay Generator

Consider the case of $V_{IN} = 0$. The output of comparator 4 is also at ground, "shorting" the capacitor and holding the node at 0V. This implies that the outputs of comparators 1, 2, and 3 are also at 0V. When an input signal is applied, the output of open drain comparator 4 goes High-Z and C charges exponentially through R. This is indicated in the graph. The output voltages of comparators 1, 2, and 3 switch to the high state in sequence when V_C rises above the reference voltages V_1 , V_2 and V_3 . A small amount of hysteresis has been provided by the $10k\Omega$ and $10M\Omega$ resistors to insure fast switching when the RC time constant is chosen to give long delay times. A good starting point is $R = 100k\Omega$ and $C = 0.01\mu F$ to $1\mu F$.

All outputs immediately go low when V_{IN} falls to 0V, due to the comparator output going low and immediately discharging the capacitor.

Comparator 4 must be a open-drain type output (TLV182x), whereas comparators 1 though 3 can be either open drain or push-pull output, depending on system requirements. R_{PU} is not required for push-pull output devices.

8.2.5 Logic Level Shifter

The output of the TLV182x is the uncommitted drain of the output transistor. Many open-drain outputs can be tied together to provide an output OR'ing function if desired.

图 8-14. Universal Logic Level Shifter

The two $10k\Omega$ resistors bias the input to half of the input logic supply level to set the threshold in the mid-point of the input logic levels. Only one shared output pull-up resistor is needed and can be connected to any pull-up voltage between 0V and 5.5V. The pullup voltage (V_{LOGIC}) must match the driven logic input "high" level.

8.2.6 One-Shot Multivibrator

图 8-15. One-Shot Multivibrator

A monostable multivibrator has one stable state in which the circuit can remain indefinitely. The circuit can be triggered externally to another quasi-stable state. A monostable multivibrator can thus be used to generate a pulse of desired width.

The desired pulse width is set by adjusting the values of C_2 and R_4 . The resistor divider of R_1 and R_2 can be used to determine the magnitude of the input trigger pulse. The output changes state when $V_1 < V_2$. Diode D_2

provides a rapid discharge path for capacitor C_2 to reset at the end of the pulse. The diode also prevents the non-inverting input from being driven below ground.

8.2.7 Bi-Stable Multivibrator

图 8-16. Bi-Stable Multivibrator

A bi-stable multivibrator has two stable states. The reference voltage is set up by the voltage divider of R_2 and R_3 . A pulse applied to the SET terminal switches the output of the comparator high. The resistor divider of R_1 and R_4 now sets the non-inverting input to a voltage greater than the reference voltage. A pulse applied to RESET toggles the output low.

8.2.8 Zero Crossing Detector

图 8-17. Zero Crossing Detector

A voltage divider of R_4 and R_5 establishes a reference voltage V_1 at the non-inverting input. By making the series resistance of R_1 and R_2 equal to R_5 , the comparator output switches when $V_{IN} = 0V$. Diode D_1 clamps V_3 near ground. The voltage divider of R_2 and R_3 then prevents V_2 from going below ground. A small amount of hysteresis is setup to maintain rapid output voltage transitions.

8.2.9 Pulse Slicer

A Pulse Slicer is a variation of the Zero Crossing Detector and is used to detect the zero crossings on an input signal with a varying baseline level. This circuit works best with symmetrical waveforms. The RC network of R_1 and C_1 establishes an mean reference voltage V_{REF} , which tracks the mean amplitude of the V_{IN} signal. The non-inverting input is directly connected to V_{REF} through R_2 . R_2 and R_3 are used to produce hysteresis to keep transitions free of spurious toggles. The time constant is a tradeoff between long-term symmetry and response time to changes in amplitude.

If the waveform is data, the data can be encoded in the recommended NRZ (Non-Return to Zero) format to maintain proper average baseline. Asymmetrical inputs can suffer from timing distortions caused by the changing V_{REF} average voltage.

图 8-18. Pulse Slicer

For this design, follow these design requirements:

- The RC constant value (R_2 and C_1) must support the targeted data rate to maintain a valid tripping threshold.
- The hysteresis introduced with R_2 and R_{43} helps to avoid spurious output toggles.

The TLV182x can also be used, but with the addition of a pull-up resistor on the output (not shown for clarity).

图 8-19 shows the results of a 9600 baud data signal riding on a varying baseline.

图 8-19. Pulse Slicer Waveforms

8.3 Power Supply Recommendations

Due to the fast output edge rates, bypass capacitors are critical on the supply pin to prevent supply ringing and false triggers and oscillations. Bypass the supply directly at *each* device with a low ESR 0.1 μF ceramic bypass capacitor directly between V_{CC} pin and ground pins. Narrow, peak currents will be drawn during the output transition time, particularly for the push-pull output device. These narrow pulses can cause un-bypassed supply lines and poor grounds to ring, possibly causing variation that can eat into the input voltage range and create an inaccurate comparison or even oscillations.

The device can be powered from both "split" supplies ($V+$ and $V-$), or "single" supplies ($V+$ and GND), with GND applied to the $V-$ pin. Input signals must stay within the specified input range (between $V+$ and $V-$) for either type. Note that with a "split" supply the output swings "low" (V_{OL}) to $V-$ potential and not GND.

8.4 Layout

8.4.1 Layout Guidelines

For accurate comparator applications, a clean, stable power supply is important to minimize output glitches. Output rise and fall times are in the tens of nanoseconds, and must be treated as high speed logic devices. The bypass capacitor should be as close to the supply pin as possible and connected to a solid ground plane, and preferably directly between the V_{CC} and GND pins.

Minimize coupling between outputs and inputs to prevent output oscillations. Do not run output and input traces in parallel unless there is a V_{CC} or GND trace between output to reduce coupling. When series resistance is added to inputs, place resistor close to the device. A low value (≤ 100 ohms) resistor can also be added in series with the output to dampen any ringing or reflections on long, non-impedance controlled traces. For best edge shapes, controlled impedance traces with back-terminations should be used when routing long distances.

8.4.2 Layout Example

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
