TLV320ADC3100

ZHCSHY2 – MARCH 2018

适用于声控系统和便携式音频的 **TLV320ADC3100** 低功耗立体声 **ADC**

1 特性

- 立体声音频 ADC：
  - 92dBA 信噪比
  - 支持从 8kHz 到 96kHz 的 ADC 采样率
- 具有可编程系数和内置处理块的灵活数字滤波：
  - 针对语音的低延迟无限脉冲响应 (IIR) 滤波器
  - 针对音频的线性相位有限脉冲响应 (FIR) 滤波器
  - 多达 5 个附加的可编程双二阶滤波器
  - 可编程高通滤波器
- 四个具有可配置自动增益控制 (AGC) 功能的音频输入：
  - 在单端或者全差分配置中可编程
  - 可选三态，用于轻松与其他音频器件进行互操作
- 低功耗并具有广泛模块功率控制：
  - 6mW 单声道录制，8kHz
  - 11mW 立体声录制，8kHz
  - 10mW 单声道录制，48kHz
  - 17mW 立体声录制，48kHz
- 可编程麦克风偏置
- 用于时钟生成的可编程锁相环路 (PLL)
- I²C 控制总线
- 音频串行数据总线支持 I²S、左平衡和右平衡、DSP、PCM 和 TDM 模式
- 电源：
  - 模拟：2.7V 至 3.6V
  - 数字：内核：1.65V 至 1.95V，I/O：1.1V–3.6V
- 封装：4mm × 4mm，24 引脚 RGE (VQFN)

2 应用

- 声控系统
- 智能扬声器、支持语音的助理
- 便携式低功耗音频系统
- 噪声消除系统
- 适用于数字音频的前端语音或音频处理器

3 说明

TLV320ADC3100 是一款低功耗、立体声音频模数转换器 (ADC)，此器件支持 8kHz 至 96kHz 的采样率并具有一个可提供高达 40dB 模拟增益或自动增益控制 (AGC) 的集成可编程增益放大器。还提供粗糙衰减为 0dB，-6dB，或者关闭的前端输入。此输入在一个单端组合或者完全差分配置中可编程。通过 I²C 接口可提供广泛的基于寄存器的功率控制，从而启用单声道或者立体声录音。TLV320ADC3100 集成了可编程通道增益、数字音量控制、锁相环 (PLL)、可编程双二阶滤波器和低延迟滤波模式。利用可以根据具体应用需求进行选择的预编程内置处理块 (PRB)，可以优化性能和功耗。TLV320ADC3100 的低功耗和灵活性特性使其非常适合电池供电便携式设备。TLV320ADC3100 与 TLV320ADC3101 在外形和软件上兼容。

器件信息 (1)

器件型号	封装	封装尺寸（标称值）
TLV320ADC3100	VQFN (24)	4.00mm x 4.00mm

(1) 如需了解所有可用封装，请参阅数据表末尾的可订购产品附录。

注：之前版本的页码可能与当前版本有所不同。

日期	修订版本	说明
2018 年 3 月	*	最初发布版本。

5 说明 （续）

AGC 可在宽范围的启动（7ms 至 1.4s）和衰减（50ms 至 22.4s）时间内进行编程。包含一项用于避免噪声抽吸的可编程噪声门功能。提供了针对语音和电话进行优化的低延迟中断识别寄存器 (IIR) 滤波器，并且提供了针对音频进行优化的线性相位有限脉冲响应 (FIR) 滤波器。还提供了可编程 IIR 滤波器，这些滤波器可用于声音均衡或者消除噪声分量。可以对音频串行总线进行编程，以支持 I²S、左平衡、右平衡、数字信号处理器 (DSP)、脉冲编码调制 (PCM) 和时分多路复用 (TDM) 模式。音频总线可以在主/从模式下运行。

包括一个用于灵活时钟生成的可编程集成 PLL，并且为来自各种可用 MCLK 的所有标准音频速率提供支持，这些 MCLK 的工作频率从 512kHz 到 50MHz 不等，其中包括最常用的 12MHz、13MHz、16MHz、19.2MHz 和 19.68MHz 系统时钟频率。

6 Pin Configuration and Functions

RGE Package
24-Pin VQFN With Exposed Thermal Pad
Top View
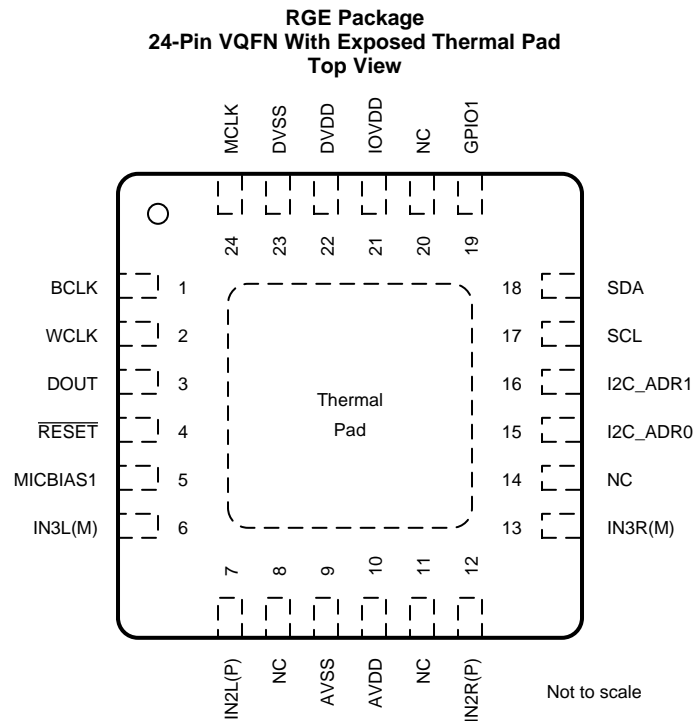

Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
AVDD	10	P	Analog voltage supply, 2.7 V–3.6 V
AVSS	9	P	Analog ground supply, 0 V
BCLK	1	I/O	Audio serial data bus bit clock
DOUT	3	O	Audio serial data bus data output
DVDD	22	P	Digital core voltage supply, 1.65 V–1.95 V
DVSS	23	P	Digital ground supply, 0 V
GPIO1	19	I/O	General-purpose input/output 1, multifunction pin based on register programming
I2C_ADR0	15	I	LSB of I^2C bus address
I2C_ADR1	16	I	LSB + 1 of I^2C bus address
IN2L(P)	7	I	Microphone or line analog input (left-channel single-ended or differential plus)
IN2R(P)	12	I	Microphone or line analog input (right-channel single-ended or differential plus)
IN3L(M)	6	I	Microphone or line analog input (left-channel single-ended or differential minus)
IN3R(M)	13	I	Microphone or line analog input (right-channel single-ended or differential minus)
IOVDD	21	P	I/O voltage supply, 1.1 V–3.6 V
MCLK	24	I	Master clock input
MICBIAS1	5	O	MICBIAS1 bias voltage output
NC	8, 11, 14, 20	—	No connection
RESET	4	I	Reset
SCL	17	I/O	I^2C serial clock
SDA	18	I/O	I^2C serial data input/output
WCLK	2	I/O	Audio serial data bus word clock
Thermal pad	Pad	—	Connect the thermal pad to AVSS.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted) [1][2]

		MIN	MAX	UNIT
	AVDD to AVSS	−0.3	3.9	V
	IOVDD to DVSS	−0.3	3.9	V
	DVDD to DVSS	−0.3	2.5	V
	Digital input voltage to DVSS	−0.3	IOVDD + 0.3	V
	Analog input voltage to AVSS	−0.3	AVDD + 0.3	V
	Operating temperature	−40	85	°C
T_J Max	Junction temperature		105	°C
	Power dissipation	$(T_J \text{ Max} - T_A) / \theta_{JA}$		W
T_{stg}	Storage temperature	−65	125	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) ESD complacence tested to EIA/JESD22-A114-B and passed.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 [1]	±1000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 [2]	±250	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
AVDD	Analog supply voltage [1]	2.7	3.3	3.6	V
DVDD	Digital core supply voltage [1]	1.65	1.8	1.95	V
IOVDD	Digital I/O supply voltage [1]	1.1	1.8	3.6	V
V_I	Analog full-scale, 0-dB input voltage (AVDD = 3.3 V)		0.707		Vrms
	Digital output load capacitance			10	pF
T_A	Operating free-air temperature	−40		85	°C

(1) Analog voltage values are with respect to AVSS; digital voltage values are with respect to DVSS.

7.4 Thermal Information

	THERMAL METRIC [1]	TLV320ADC3100	UNIT
		RGE (VQFN)	
		24 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	33.9	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	34.1	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	11.5	°C/W
ψ_{JT}	Junction-to-top characterization parameter	0.4	°C/W
ψ_{JB}	Junction-to-board characterization parameter	11.5	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	3.2	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report.

7.5 Electrical Characteristics

at 25°C, AVDD = 3.3 V, IOVDD = 1.8 V, DVDD = 1.8 V, f_S = 48-kHz, and 16-bit audio data (unless otherwise noted)

	PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
AUDIO ADC						
	Input signal level (0-dB)	Single-ended input		0.707		Vrms
	Input common-mode voltage	Single-ended input		1.35		Vrms
SNR	Signal-to-noise ratio, A-weighted [1][2]	f_S = 48 kHz, 0-dB PGA gain, IN1 inputs selected and AC-shorted to ground	80	92		dB
	Dynamic range, A-weighted [1][2]	f_S = 48 kHz; 1-kHz, –60-dB, full-scale input applied at IN1 inputs; 0-dB PGA gain		92		dB
THD	Total harmonic distortion	f_S = 48 kHz; 1-kHz, –2-dB, full-scale input applied at IN1 inputs; 0-dB PGA gain		–90	–75	dB
				0.003%	0.017%	
PSRR	Power-supply rejection ratio	234 Hz, 100 mV_{PP} on AVDD, single-ended input		46		dB
		234 Hz, 100 mV_{PP} on AVDD, differential input		68		
	ADC channel separation	1 kHz, –2-dB IN2L to IN2R		–73		dB
	ADC gain error	1 kHz input, 0-dB PGA gain		0.7		dB
	ADC programmable-gain amplifier maximum gain	1-kHz input tone, R_{SOURCE} < 50 Ω		40		dB
	ADC programmable-gain amplifier step size			0.502		dB
	Input resistance	IN1 inputs, routed to single ADC, input mix attenuation = 0 dB		35		kΩ
		IN2 inputs, input mix attenuation = 0 dB		35		
		IN1 inputs, input mix attenuation = –6 dB		62.5		
		IN2 inputs, input mix attenuation = –6 dB		62.5		
	Input capacitance			10		pF
	Input level control minimum attenuation setting			0		dB
	Input level control maximum attenuation setting			6		dB
	Input level control attenuation step size			6		dB

(1) Ratio of output level with 1-kHz, full-scale, sine-wave input, to the output level with the inputs short-circuited, measured A-weighted over a 20-Hz to 20-kHz bandwidth using an audio analyzer.
(2) All performance measurements done with 20-kHz, low-pass filter and, where noted, A-weighted filter. Failure to use such a filter may result in higher THD and lower SNR and dynamic range readings than shown in the *Electrical Characteristics* table. The low-pass filter removes out-of-band noise that, although not audible, may affect dynamic specification values.

Electrical Characteristics (continued)

at 25°C, AVDD = 3.3 V, IOVDD = 1.8 V, DVDD = 1.8 V, f_S = 48-kHz, and 16-bit audio data (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
ADC DIGITAL DECIMATION FILTER (f_S = 48 kHz)						
	Filter gain from 0 f_S to 0.39 f_S	Filter A, AOSR = 128 or 64		±0.1		dB
	Filter gain from 0.55 f_S to 64 f_S	Filter A, AOSR = 128 or 64		−73		dB
	Filter group delay	Filter A, AOSR = 128 or 64		17 / f_S		s
	Filter gain from 0 f_S to 0.39 f_S	Filter B, AOSR = 64		±0.1		dB
	Filter gain from 0.60 f_S to 32 f_S	Filter B, AOSR = 64		−46		dB
	Filter group delay	Filter B, AOSR = 64		11 / f_S		s
	Filter gain from 0 f_S to 0.39 f_S	Filter C, AOSR = 32		±0.033		dB
	Filter gain from 0.28 f_S to 16 f_S	Filter C, AOSR = 32		−60		dB
	Filter group delay	Filter C, AOSR = 32		11 / f_S		s
MICROPHONE BIAS						
	Bias voltage	Programmable settings, load = 750 Ω		2		V
			2.25	2.5	2.75	
				AVDD – 0.2		
	Current sourcing	2.5-V setting			4	mA
	Integrated noise	BW = 20 Hz to 20 kHz, A-weighted, 1-µF capacitor between MICBIAS and AGND		3.3		µV rms
DIGITAL I/O						
V_{IL}	Input low level	I_{IL} = 5 µA	−0.3		0.3 × IOVDD	V
V_{IH}	Input high level[3]	I_{IH} = 5 µA	0.7 × IOVDD			V
V_{OL}	Output low level	I_{IH} = 2 TTL loads			0.1 × IOVDD	V
V_{OH}	Output high level	I_{OH} = 2 TTL loads	0.8 × IOVDD			V
SUPPLY CURRENT (f_S = 48 kHz, AVDD = 3.3 V, DVDD = IOVDD = 1.8 V)						
Mono record	AVDD	PLL and AGC off		2		mA
	DVDD			1.9		
Stereo record	AVDD	PLL and AGC off		4		mA
	DVDD			2.1		
PLL	AVDD	Additional power consumed when PLL is powered		1.1		mA
	DVDD			0.8		
Power down	AVDD	All supply voltages applied, all blocks programmed in lowest power state		0.04		µA
	DVDD			0.7		

(3)   When IOVDD < 1.6 V, the minimum V_{IH} is 1.1 V.

7.6 Timing Requirements: I²S, LJF, RJF Timing in Master Mode

specified at 25°C, DVDD = 1.8 V, all timing specifications are measured at characterization; see 图 1 for a timing diagram

		IOVDD = 1.8 V		IOVDD = 3.3 V		UNIT
		MIN	**MAX**	**MIN**	**MAX**	
t_d(WS)	BCLK, WCLK delay time		20		15	ns
t_d(DO-WS)	BCLK, WCLK to DOUT delay time		25		20	ns
t_d(DO-BCLK)	BCLK to DOUT delay time		20		15	ns
t_r	Rise time		20		15	ns
t_f	Fall time		20		15	ns

7.7 Timing Requirements: DSP Timing in Master Mode

specified at 25°C, DVDD = 1.8 V, all timing specifications are measured at characterization; see 图 2 for a timing diagram

		IOVDD = 1.8 V		IOVDD = 3.3 V		UNIT
		MIN	**MAX**	**MIN**	**MAX**	
t_d(WS)	BCLK, WCLK delay time		25		15	ns
t_d(DO-BCLK)	BCLK to DOUT delay time		25		15	ns
t_r	Rise time		20		15	ns
t_f	Fall time		20		15	ns

7.8 Timing Requirements: I²S, LJF, RJF Timing in Slave Mode

specified at 25°C, DVDD = 1.8 V, all timing specifications are measured at characterization; see 图 3 for a timing diagram

		IOVDD = 1.8 V		IOVDD = 3.3 V		UNIT
		MIN	**MAX**	**MIN**	**MAX**	
t_H(BCLK)	BCLK high period	35		35		ns
t_L(BCLK)	BCLK low period	35		35		ns
t_s(WS)	BCLK, WCLK setup time	10		6		ns
t_h(WS)	BCLK, WCLK hold time	10		6		ns
t_d(DO-WS)	BCLK, WCLK to DOUT delay time (for LJF mode only)		30		30	ns
t_d(DO-BCLK)	BCLK to DOUT delay time		25		20	ns
t_r	Rise time		16		8	ns
t_f	Fall time		16		8	ns

7.9 Timing Requirements: DSP Timing in Slave Mode

specified at 25°C, DVDD = 1.8 V, all timing specifications are measured at characterization; see 图 4 for a timing diagram

		IOVDD = 1.8 V		IOVDD = 3.3 V		UNIT
		MIN	**MAX**	**MIN**	**MAX**	
t_H(BCLK)	BCLK high period	35		35		ns

8 Detailed Description

8.1 Overview

The TLV320ADC3100 is a flexible, low-power, stereo audio analog-to-digital converter (ADC) with extensive feature integration, intended for applications in voice-activated systems, portable computing, communication, and entertainment applications. The device integrates a host of features to reduce cost, board space, and power consumption in space-constrained, battery-powered, portable applications. The TLV320ADC3100 is form-factor and software compatible with the more feature-rich TLV320ADC3101, which has additional features such as a programmable miniDSP.

The TLV320ADC3100 consists of the following blocks:

- Stereo audio multibit delta-sigma ADC (8 kHz–96 kHz)
- Programmable digital filter engines including biquads
- Register-configurable combinations of up to four single-ended or two differential audio inputs
- Fully programmable phase-locked loop (PLL) with extensive ADC clock-source and divider options for maximum end-system design flexibility

Communication to the TLV320ADC3100 for control is via a two-wire I²C interface. The I²C interface supports both standard and fast communication modes.

## 8.2 Functional Block Diagram
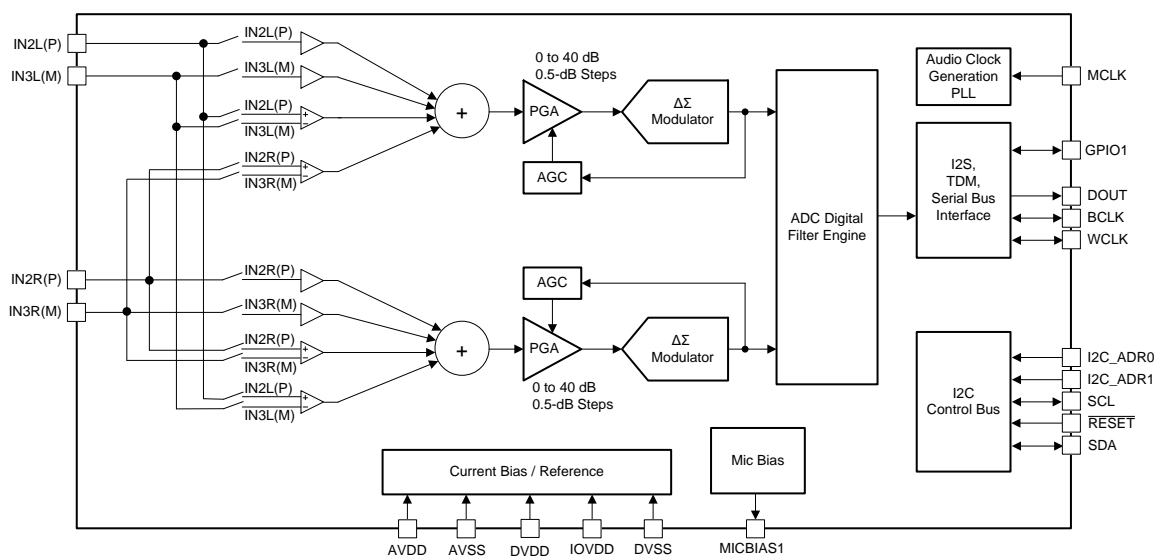

8.3 Feature Description

8.3.1 Hardware Reset

The TLV320ADC3100 requires a hardware reset after power up for proper operation. After all power supplies are at their specified values, the $\overline{\text{RESET}}$ pin must be driven low for at least 10 ns. If this reset sequence is not performed, the TLV320ADC3100 may not respond properly to register reads or writes.

8.3.2 PLL Start-up

When the PLL is powered on, a start-up delay of approximately 10 ms occurs after the power-up command of the PLL and before the clocks are available to the TLV320ADC3100. This delay is to ensure stable operation of the PLL and clock-divider logic.

Feature Description (接下页)

8.3.3 Software Power Down

By default, all circuit blocks are powered down following a reset condition. Hardware power up of each circuit block can be controlled by writing to the appropriate control register. This approach allows the lowest power-supply current for the functionality required. However, when a block is powered down, all register settings are maintained as long as power is applied to the device.

8.3.4 Audio Data Converters

The TLV320ADC3100 supports the following standard audio sampling rates: 8 kHz, 11.025 kHz, 12 kHz, 16 kHz, 22.05 kHz, 24 kHz, 32 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, and 96 kHz. The converters can also operate at different sampling rates in various combinations, as described in this section.

The TLV320ADC3100 supports a wide range of options for generating clocks for the ADC section as well as the digital interface section and the other control blocks; see 图 27. The ADC clocks require a source reference clock. The clock can be provided on the device pins MCLK and BCLK. The source reference clock for the ADC section can be chosen by programming the ADC_CLKIN value on page 0, register 4, bits 1:0. The ADC_CLKIN can then be routed through highly flexible clock dividers (see 图 27) to generate various clocks required for the ADC and programmable digital filter sections. In the event that the desired audio or programmable digital filter clocks cannot be generated from the external reference clocks on MCLK and BCLK, the TLV320ADC3100 also provides the option of using an on-chip PLL that supports a wide range of fractional multiplication values to generate the required system clocks. Starting from ADC_CLKIN, the TLV320ADC3100 provides several programmable clock dividers to support a variety of sampling rates for the ADC and the clocks for the programmable digital filter section.

8.3.5 Digital Audio Data Serial Interface

Audio data are transferred between the host processor and the TLV320ADC3100 via the digital-audio serial-data interface, or audio bus. The audio bus on this device is flexible, including left- or right-justified data options, support for I^{2}S or pulse code modulation (PCM) protocols, programmable data-length options, a time-division multiplexing (TDM) mode for multichannel operation, flexible master and slave configurability for each bus clock line, and the ability to directly communicate with multiple devices within a system.

The audio serial interface on the TLV320ADC3100 has an extensive I/O control for communication with two independent processors for audio data. The processors can communicate with the device one at a time. This feature is enabled by register programming of the various pin selections.

The audio bus of the TLV320ADC3100 can be configured for left- or right-justified, I^{2}S, DSP, or TDM modes of operation, where communication with standard telephony PCM interfaces is supported within the TDM mode. These modes are all MSB-first, with the data width programmable in 16, 20, 24, or 32 bits by configuring page 0, register 27, bits 5:4. In addition, the word clock and bit clock can be independently configured in either master or slave mode for flexible connectivity to a wide variety of processors. The word clock is used to define the beginning of a frame, and can be programmed as either a pulse or a square-wave signal. The frequency of this clock corresponds to the maximum-selected ADC sampling frequency.

The bit clock is used to clock in and out the digital audio data across the serial bus. When in master mode, this signal can be programmed to generate variable clock pulses by controlling the bit-clock divider in page 0, register 30; see 图 27. Accommodating various word lengths as well as supporting the case when multiple TLV320ADC3100s share the same audio bus may require that the number of bit-clock pulses in a frame be adjusted.

The TLV320ADC3100 also includes a feature to offset the position of the start of a data transfer with respect to the word clock. There are two configurations that allow using either a single offset for both channels or to use separate offsets. The Ch_Offset_1 reference represents the value in page 0, register 28 and Ch_Offset_2 represents the value in page 0, register 37. When page 0, register 38, bit 0 is set to zero (time-slot-based channel assignment is disabled), the offset of both channels is controlled, in terms of number of bit clocks, by the programming in page 0, register 28 (Ch_Offset_1). When page 0, register 38, bit 0 = 1 (time-slot-based channel assignment enabled), the first channel is controlled, in terms of number of bit clocks, by the programming in page 0, register 28 (Ch_Offset_1), and the second channel is controlled, in terms of number of bit clocks, by the programming in page 0, register 37 (Ch_Offset_2), where register 37 programs the delay between the first word and the second word. Also, the relative order of the two channels can be swapped, depending on the programmable register bit (page 0, register 38, bit 4) that enables swapping of the channels.

Feature Description (接下页)

The TLV320ADC3100 also supports a feature for inverting the bit clock polarity used for transferring the audio data as compared to the default clock polarity used. This feature can be used independently of the audio interface mode chosen. The bit clock polarity can be configured by writing to page 0, register 29, bit 3.

The TLV320ADC3100 further includes programmability (page 0, register 27, bit 0) to place DOUT in the high-impedance state at the end of data transfer (that is, at the end of the bit cycle corresponding to the LSB of a channel). By combining this capability with the ability to program at what bit clock in a frame the audio data begins, TDM can be accomplished, resulting in multiple ADCs able to use a single audio serial data bus. To further enhance the tri-state capability, the TLV320ADC3100 can be put in a high-impedance state a half bit cycle earlier by setting page 0, register 38, bit 1 to 1. When the audio serial data bus is powered down while configured in master mode, the pins associated with the interface are put into a high-impedance output state.

Either or both of the two channels can be disabled in LJF, I²S, and DSP modes by using page 0, register 38, bits 3:2. 图 10 shows the interface timing when both channels are enabled and early tri-stating is enabled. 图 11 shows the effect of setting page 0, register 38, bit 2, first channel disabled, and setting page 0, register 27, bit 0 to 1, which enables placing DOUT in the high-impedance state. If placing DOUT in the high-impedance state is disabled, then the DOUT signal is driven to logic level 0.
图 10. **Both Channels Enabled, Early Tri-Stating Enabled**
图 11. **First Channel Disabled, Second Channel Enabled, Tri-Stating Enabled**

The sync signal for the ADC filter is not generated based on the disabled channel. The sync signal for the filter corresponds to the beginning of the earlier of the two channels. If the first channel is disabled, the filter sync is generated at the beginning of the second channel, if enabled. If both channels are disabled, there is no output to the serial bus, and the filter sync corresponds to the beginning of the frame.

By default, when the word clocks and bit clocks are generated by the TLV320ADC3100, these clocks are active only when the ADC is powered up within the device. This internal clock gating is done to save power. However, the internal clock gating architecture also supports a feature wherein both the word clocks and bit clocks can be active even when the codec in the device is powered down. This feature is useful when using the TDM mode with multiple codecs on the same bus or when word clocks or bit clocks are used in the same system as general-purpose clocks.

Feature Description (接下页)

8.3.5.1 *Right-Justified Mode*

In right-justified mode, the LSB of the left channel is valid on the rising edge of the bit clock preceding the falling edge of word clock. Similarly, the LSB of the right channel is valid on the rising edge of the bit clock preceding the rising edge of the word clock. 图 12 shows the right-justified mode timing.
图 **12. Right-Justified Mode Timing Diagram**

For right-justified mode, the number of bit clocks per frame must be greater than twice the programmed word-length of the data.

> 注
> The time-slot-based mode is not available in the right-justified mode.

8.3.5.2 *Left-Justified Mode*

In left-justified mode, the MSB of the right channel is valid on the rising edge of the bit clock following the falling edge of the word clock. Similarly, the MSB of the left channel is valid on the rising edge of the bit clock following the rising edge of the word clock. 图 13 shows the standard timing of the left-justified mode.
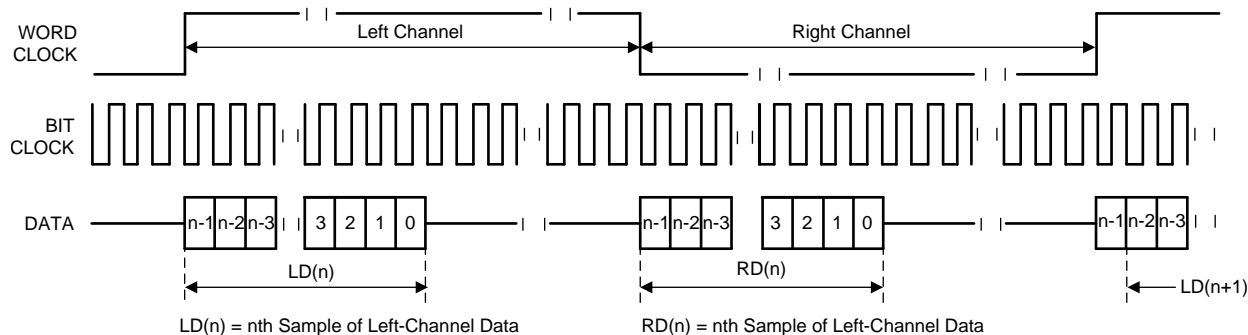

图 **13. Left-Justified Mode (Standard Timing)**

Feature Description (接下页)

图 14 shows the left-justified mode with Ch_Offset_1 = 1.
图 14. Left-Justified Mode With Ch_Offset_1 = 1

图 15 shows the left-justified mode with Ch_Offset_1 = 0 and bit clock inverted.
图 15. Left-Justified Mode With Ch_Offset_1 = 0, Bit Clock Inverted

For left-justified mode, the number of bit clocks per frame must be greater than twice the programmed word length of the data. Also, the programmed offset value must be less than the number of bit clocks per frame by at least the programmed word length of the data.

When the time-slot-based channel assignment is disabled (page 0, register 38, bit 0 = 0), the left and right channels have the same offset Ch_Offset_1 (page 0, register 28), and each edge of the word clock starts data transfer for one of the two channels, depending on whether or not channel swapping is enabled. Data bits are valid on the rising edges of the bit clock. With the time-slot-based channel assignment enabled (page 0, register 38, bit 0 = 1), the left and right channels have independent offsets (Ch_Offset_1 and Ch_Offset_2). The rising edge of the word clock starts data transfer for the first channel after a delay of its programmed offset (Ch_Offset_1) for this channel. Data transfer for the second channel starts after a delay of its programmed offset (Ch_Offset_2) from the LSB of the first-channel data. The falling edge of the word clock is not used.

With no channel swapping, the MSB of the left channel is valid on the (Ch_Offset_1 + 1)th rising edge of the bit clock following the rising edge of the word clock. Consequently, the MSB of the right channel is valid on the (Ch_Offset_1 + 1)th rising edge of the bit clock following the falling edge of the word clock. The timing diagram of 图 14 illustrates the operation in this case, with an offset of 1. Because channel swapping is not enabled, the left-channel data are before the right-channel data. With channel swapping enabled, the MSB of the right channel is valid on the (Ch_Offset_1 + 1)th rising edge of the bit clock following the rising edge of the word clock. Thus, the MSB of the left channel is valid on the (Ch_Offset_1 + 1)th rising edge of the bit clock following the falling edge of the word clock. The timing diagram of 图 16 depicts the operation in this case, with an offset of 1. As shown in the diagram, the right-channel data of a frame are before the left-channel data of that frame because of channel swapping. Otherwise, the behavior is similar to the case where channel swapping is disabled. The MSB of the right-channel data is valid on the second rising edge of the bit clock after the rising edge of the word clock, as a result of an offset of 1. Similarly, the MSB of the left-channel data is valid on the second rising edge of the bit clock after the falling edge of the word clock.

Feature Description (接下页)
图 **16. Left-Justified Mode With Ch_Offset_1 = 1, Channel Swapping Enabled**

When the time-based-slot mode is enabled with no channel swapping, the MSB of the left channel is valid on the (Offset1 + 1)th rising edge of the bit clock following the rising edge of the word clock. Thus, the MSB of the right channel is valid on the (Ch_Offset_2 + 1)th rising edge of the bit clock following the LSB of the left channel.

图 17 shows the operation with time-based-slot mode enabled, Ch_Offset_1 = 0, and Ch_Offset_2 = 1. The MSB of the left channel is valid on the first rising edge of the bit clock after the rising edge of the word clock. Data transfer for the right channel does not wait for the falling edge of the word clock, and the MSB of the right channel is valid on the second rising edge of the bit clock after the LSB of the left channel.
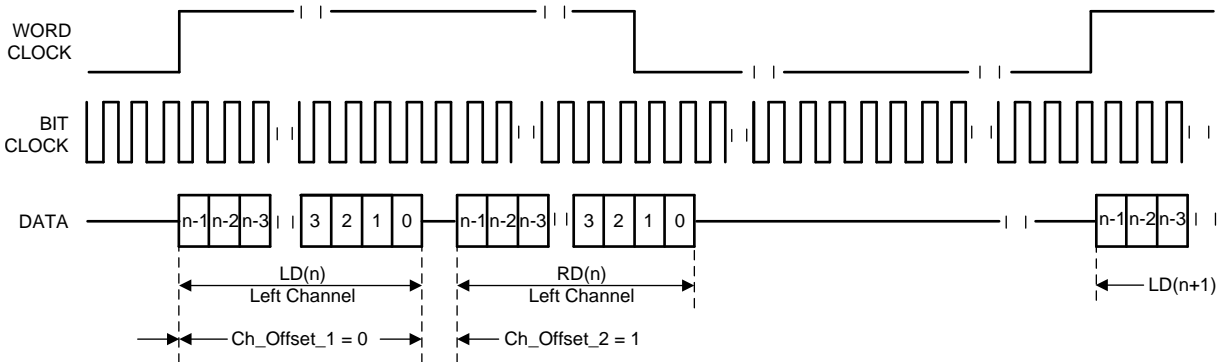

图 **17. Left-Justified Mode, Time-Based-Slot Mode Enabled, Ch_Offset_1 = 0, Ch_Offset_2 = 1**

When the time-based-slot mode is enabled and channel swapping is enabled, the MSB of the right channel is valid on the (Ch_Offset_1 + 1)th rising edge of the bit clock following the rising edge of the word clock. Thus, the MSB of the left channel is valid on the (Ch_Offset_2 + 1)th rising edge of the bit clock following the LSB of the right channel. 图 18 illustrates the operation in this mode with Ch_Offset_1 = 0 and Ch_Offset_2 = 1. The MSB of the right channel is valid on the first rising edge of the bit clock after the rising edge of the word clock. Data transfer for the left channel starts following the completion of data transfer for the right channel without waiting for the falling edge of the word clock. The MSB of the left channel is valid on the second rising edge of the bit clock after the LSB of the right channel.

图 18. Left-Justified Mode, Time-Based-Slot Mode Enabled, Ch_Offset_1 = 0, Ch_Offset_2 = 1, Channel Swapping Enabled

8.3.5.3 I²S Mode

In I²S mode, the MSB of the left channel is valid on the second rising edge of the bit clock after the falling edge of the word clock. Similarly, the MSB of the right channel is valid on the second rising edge of the bit clock after the rising edge of the word clock. 图 19 shows the standard I²S timing.
图 19. I²S Mode (Standard Timing)

图 20 shows the I²S mode timing with Ch_Offset_1 = 2.
图 20. I²S Mode With Ch_Offset_1 = 2

Feature Description (接下页)

图 21 shows the I²S mode timing with Ch_Offset_1 = 0 and the bit clock inverted.
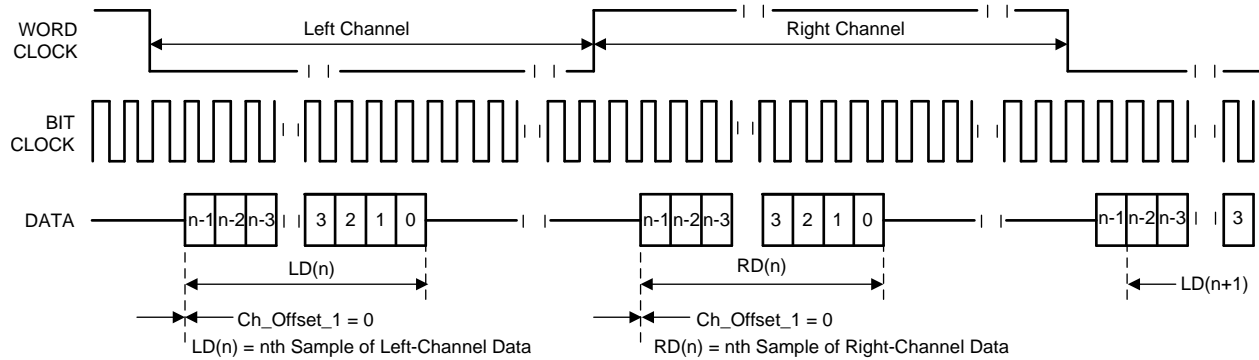

图 21. I²S Mode With Ch_Offset_1 = 0, Bit Clock Inverted

For the I²S mode, the number of bit clocks per channel must be greater than or equal to the programmed word length of the data. Also, the programmed offset value must be less than the number of bit clocks per frame by at least the programmed word length of the data.

8.3.5.4 DSP Mode

In DSP mode, the rising edge of the word clock starts the data transfer with the left-channel data first and is immediately followed by the right-channel data. Each data bit is valid on the falling edge of the bit clock. 图 22 shows the standard timing for the DSP mode.
图 22. DSP Mode (Standard Timing)

图 23 shows the DSP mode timing with Ch_Offset_1 = 1.
图 23. DSP Mode With Ch_Offset_1 = 1

Feature Description (接下页)

图 24 shows the DSP mode timing with Ch_Offset_1 = 0 and the bit clock inverted.
图 24. DSP Mode With Ch_Offset_1 = 0, Bit Clock Inverted

For DSP mode, the number of bit clocks per frame must be greater than twice the programmed word length of the data. Also, the programmed offset value must be less than the number of bit clocks per frame by at least the programmed word length of the data.

图 25 shows the DSP time-slot-based mode without channel swapping, and with Ch_Offset_1 = 0 and Ch_Offset_2 = 3. The MSB of the left channel data is valid on the first falling edge of the bit clock after the rising edge of the word clock. Because the right channel has an offset of 3, the MSB of its data is valid on the third falling edge of the bit clock after the LSB of the left-channel data. As in the case of other modes, the serial output bus is put in the high-impedance state, if tri-stating of the output is enabled, during all extra bit-clock cycles in the frame.
图 25. DSP Mode, Time-Slot-Based Mode Enabled, Ch_Offset_1 = 0, Ch_Offset_2 = 3

Feature Description (接下页)

图 26 shows the timing diagram for the DSP mode with left and right channels swapped, Ch_Offset_1 = 0, and Ch_Offset_2 = 3. The MSB of the right channel is valid on the first falling edge of the bit clock after the rising edge of the word clock. Similarly, the MSB of the left channel is valid three bit-clock cycles after the LSB of right channel because the offset for the left channel is 3.
图 26. DSP Mode, Time-Slot-Based Mode Enabled, Ch_Offset_1 = 0, Ch_Offset_2 = 3, Channel Swap Enabled

8.3.6 Audio Clock Generation

The audio converters in the fully programmable filter mode of the TLV320ADC3100 require an internal audio master clock at a frequency of ≥ N × f_S, where N = IADC (page 0, register 21) when filter mode (page 0, register 61) equals zero; otherwise, N equals the instruction count from the ADC processing blocks (see 表 6). The master clock is obtained from an external clock signal applied to the device.

The device can accept an MCLK input from 512 kHz to 50 MHz, which can then be passed through either a programmable divider or a PLL to get the proper internal audio master clock required by the device. The BCLK input can also be used to generate the internal audio master clock.

A primary concern is proper operation of the TLV320ADC3100 at various sample rates with the limited MCLK frequencies available in the system. This device includes a programmable PLL to accommodate such situations. The integrated PLL can generate audio clocks from a wide variety of possible MCLK inputs, with particular focus paid to the standard MCLK rates already widely used.

When the PLL is enabled:

f_S = (PLLCLK_IN × K × R) / (NADC × MADC × AOSR × P)

where

- P = 1, 2, 3,…, 8
- R = 1, 2, …, 16
- K = J.D
- J = 1, 2, 3, …, 63
- D = 0000, 0001, 0002, 0003, …, 9998, 9999
- PLLCLK_IN can be MCLK or BCLK, selected by page 0, register 4, bits 3:2   (1)

P, R, J, and D are register programmable. J is the integer portion of K (the numbers to the left of the decimal point), whereas D is the fractional portion of K (the numbers to the right of the decimal point, assuming four digits of precision).

Examples:

If K = 8.5, then J = 8, D = 5000
If K = 7.12, then J = 7, D = 1200
If K = 14.03, then J = 14, D = 0300
If K = 6.0004, then J = 6, D = 0004

Feature Description (接下页)

When the PLL is enabled and D = 0000, the following conditions must be satisfied to meet specified performance:

512 kHz ≤ (PLLCLK_IN / P) ≤ 20 MHz
80 MHz ≤ (PLLCLK_IN × K × R / P) ≤ 110 MHz
4 ≤ J ≤ 55

When the PLL is enabled and D ≠ 0000, the following conditions must be satisfied to meet specified performance:

10 MHz ≤ PLLCLK_IN / P ≤ 20 MHz
80 MHz ≤ PLLCLK_IN × K × R / P ≤ 110 MHz
4 ≤ J ≤ 11
R = 1

Example:

For MCLK = 12 MHz, f_S = 44.1 kHz, NADC = 8, MADC = 2, and AOSR = 128:
Select P = 1, R = 1, K = 7.5264, which results in J = 7, D = 5264

Example:

For MCLK = 12 MHz, f_S = 48 kHz , NADC = 8, MADC = 2, and AOSR = 128:
Select P = 1, R = 1, K = 8.192, which results in J = 8, D = 1920

表 1 lists several example cases of typical MCLK rates and how to program the PLL to achieve sample rates of f_S = 44.1 kHz or 48 kHz with NADC = 8, MADC = 2, and AOSR = 128.

表 1. Typical MCLK Rates

MCLK (MHz)	P	R	J	D	ACHIEVED f_S	% ERROR
f_S = 44.1 kHz						
2.8224	1	1	32	0	44,100.00	0.0000
5.6448	1	1	16	0	44,100.00	0.0000

16.0	1	1	6	1440	48,000.00	0.0000
19.2	1	1	5	1200	48,000.00	0.0000
19.68	1	1	4	9951	47,999.79	−0.0004
48.0	4	1	8	1920	48,000.00	0.0000

图 27 shows a detailed diagram of the audio clock section of the TLV320ADC3100.

图 27. Audio Clock Generation Processing
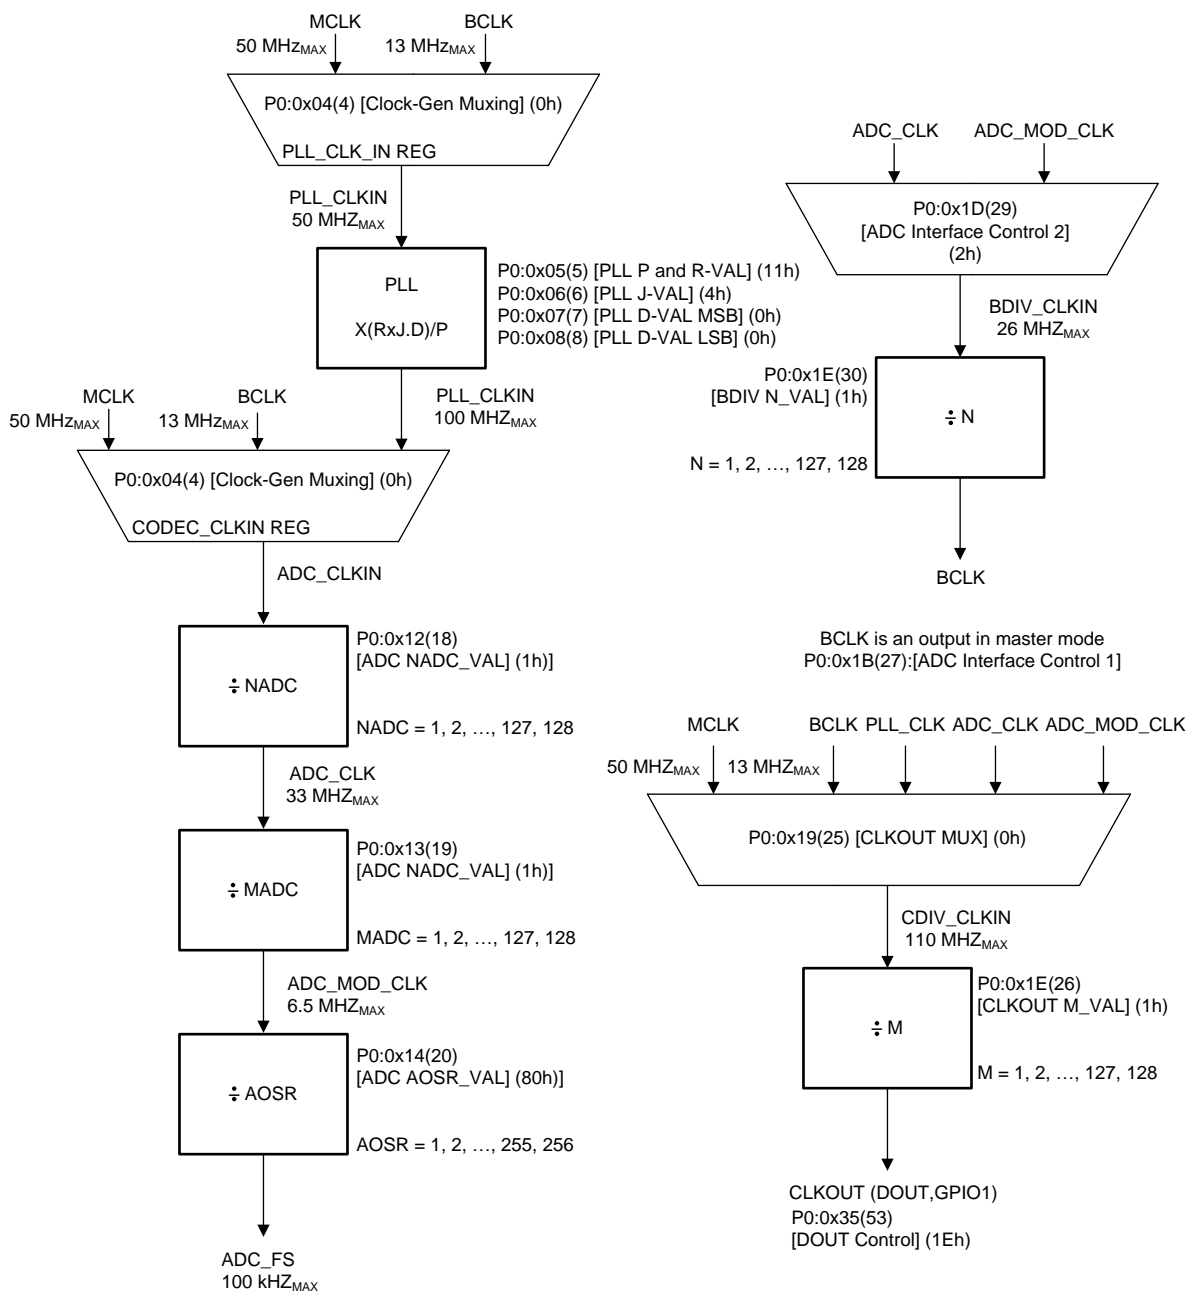

NOTE: MADC × AOSR ≥ IADC, where IADC is the number of instructions (instruction count) for the ADC MAC engine. IADC is programmable from 2, 4,…, 510. The convention used in this figure is page number: register number (reset value).

8.3.7 Stereo Audio ADC

The TLV320ADC3100 includes a stereo audio ADC that uses a delta-sigma modulator with 128-times oversampling in single-rate mode, followed by a digital decimation filter. The ADC supports sampling rates from 8 kHz to 48 kHz in single-rate mode, and up to 96 kHz in dual-rate mode. Whenever the ADC is in operation, the device requires that an audio master clock be provided and appropriate audio clock generation be set up within the device.

In order to provide optimal system power dissipation, the stereo ADC can be powered one channel at a time, to support when only mono record capability is required. In addition, both channels can be fully or partially powered down.

The integrated digital decimation filter removes high-frequency content and down-samples the audio data from an initial sampling rate of 128 f_S to the final output sampling rate of f_S. The decimation filter provides a linear phase output response with a group delay of 17 / f_S. The –3-dB bandwidth of the decimation filter extends to 0.45 f_S and scales with the sample rate (f_S). The filter has a minimum 73-dB attenuation over the stop band from 0.55 f_S to 64 f_S. Independent digital high-pass filters are also included with each ADC channel, with a corner frequency that can be set independently by programmable coefficients or can be disabled entirely.

Because of the oversampling nature of the audio ADC and the integrated digital decimation filtering, requirements for analog antialiasing filtering are relaxed. The TLV320ADC3100 integrates a second-order analog antialiasing filter with 20-dB attenuation at 1 MHz. This filter, combined with the digital decimation filter, provides sufficient antialiasing filtering without requiring additional external components.

The ADC is preceded by a programmable gain amplifier (PGA) that allows analog gain control from 0 dB to 40 dB in steps of 0.5 dB. The PGA gain changes are implemented with an internal soft-stepping algorithm that only changes the actual volume level by one 0.5-dB step every one or two ADC output samples, depending on the register programming (see register page 0, register 81). This soft-stepping specifies that volume control changes occur smoothly with no audible artifacts. On reset, the PGA gain defaults to a mute condition, and upon power down, the PGA soft-steps the volume to mute before shutting down. A read-only flag is set whenever the gain applied by the PGA equals the desired value set by the register. The soft-stepping control can also be disabled by programming a register bit.

8.3.8 Audio Analog Inputs

8.3.8.1 Digital Volume Control

The TLV320ADC3100 also has a digital volume-control block with a range from –12 dB to 20 dB (as shown in 表 2) in steps of 0.5 dB. This block is set by programming page 0, registers 83 and 84 for the left and right channels, respectively.

表 2. Digital Volume Control for the ADC

DESIRED GAIN (dB)	LEFT, RIGHT CHANNEL PAGE 0, REGISTERS 83 AND 84, BITS 6:0
−12	110 1000
−11.5	110 1001
−11	110 1010
...	...
−0.5	111 1111
0	000 0000 (default)
0.5	000 0001
...	...
19.5	010 0111
20	010 1000

During volume control changes, the soft-stepping feature is used to avoid audible artifacts. The soft-stepping rate can be set to either 1 or 2 gain steps per sample. Soft-stepping can also be entirely disabled. This soft-stepping is configured via page 0, register 81, bits 1:0, and is common to soft-stepping control for the analog PGA. During power-down of an ADC channel, this volume control soft-steps down to –12 dB before powering down. Resulting from the soft-stepping control, soon after changing the volume control setting or powering down the ADC channel, the actual applied gain may be different from the one programmed through the control register. The TLV320ADC3100 provides feedback through the read-only flags in page 0, register 36, bit 7 for the left channel and page 0, register 36, bit 3 for the right channel.

8.3.8.2 Fine Digital Gain Adjustment

Additionally, the gain in each channel is finely adjustable in steps of 0.1 dB. This feature is useful when trying to match the gain between channels. By programming page 0, register 82, the gain can be adjusted from 0 dB to –0.4 dB in steps of 0.1 dB. This feature, in combination with the regular digital volume control, allows the gains through the left and right channels be matched in the range of –0.5 dB to 0.5 dB with a resolution of 0.1 dB.

8.3.8.3 AGC

The TLV320ADC3100 includes automatic gain control (AGC) for ADC recording. AGC can be used to maintain a nominally constant output level when recording speech. As opposed to manually setting the PGA gain, in the AGC mode, the circuitry automatically adjusts the PGA gain as the input signal becomes overly loud or very weak, such as when a person speaking into a microphone moves closer to or farther from the microphone. The AGC algorithm has several programmable parameters (including target gain, attack and decay time constants, noise threshold, and maximum PGA applicable) that allow the algorithm to be fine-tuned for any particular application. The algorithm uses the absolute average of the signal (which is the average of the absolute value of the signal) as a measure of the nominal amplitude of the output signal. Because the gain can be changed at the sample interval time, the AGC algorithm operates at the ADC sample rate.

- **Target level** represents the nominal output level at which the AGC attempts to hold the ADC output signal level. The TLV320ADC3100 allows programming of eight different target levels that can be programmed from –5.5 dB to –24 dB relative to a full-scale signal. Because the TLV320ADC3100 reacts to the signal absolute average and not to peak levels, TI recommends that the target level be set with enough margin to avoid clipping at the occurrence of loud sounds.
- **Attack time** determines how quickly the AGC circuitry reduces the PGA gain when the output signal level exceeds the target level resulting from an increase in input signal level. A wide range of attack-time programmability is supported in terms of number of samples (that is, the number of ADC sample-frequency clock cycles).
- **Decay time** determines how quickly the PGA gain is increased when the output signal level falls below the target level resulting from a reduction in input signal level. A wide range of decay-time programmability is supported in terms of number of samples (that is, the number of ADC sample-frequency clock cycles).
- **Noise threshold**. If the input signal level falls below the noise threshold, the AGC considers the duration that the signal level remains below the threshold as silence, and thus brings down the gain to 0 dB in steps of 0.5 dB every sample period and sets the noise-threshold flag. The gain stays at 0 dB unless the input signal average rises above the noise threshold setting, thus preventing noise from being amplified in the absence of a signal. The noise threshold level in the AGC algorithm is programmable from –30 dB to –90 dB of full-scale. When the AGC noise threshold is set to –70 dB, –80 db, or –90 dB, the maximum applicable microphone input PGA setting must be greater than or equal to 11.5 dB, 21.5 dB, or 31.5 dB, respectively. This operation includes hysteresis and debounce to prevent the AGC gain from cycling between high gain and 0 dB when signals are near the noise threshold level. The noise (or silence) detection feature can also be entirely disabled.
- **Maximum applicable PGA** allows the maximum gain applied by the AGC to be restricted. This restriction can be used for limiting PGA gain in situations where environmental noise is greater than the programmed noise threshold. Microphone input maximum PGA can be programmed from 0 dB to 40 dB in steps of 0.5 dB.
- **Hysteresis**, as the name suggests, determines a window around the noise threshold that must be exceeded to detect if the recorded signal is indeed either noise or signal. If the energy of the recorded signal is initially greater than the noise threshold, then the AGC recognizes the signal as noise only when the energy of the recorded signal falls below the noise threshold by a value given by hysteresis. Similarly, after the recorded signal is recognized as noise, for the AGC to recognize the sound as a signal, its energy must exceed the noise threshold by a value given by the hysteresis setting. In order to prevent the AGC from jumping between noise and signal states (which can happen when the energy of the recorded signal is very close to the noise

threshold), a non-zero hysteresis value must be chosen. The hysteresis feature can also be disabled.

- **Debounce time (noise and signal)** determines the hysteresis in time domain for noise detection. The AGC continuously calculates the energy of the recorded signal. If the calculated energy is less than the set noise threshold, then the AGC does not increase the input gain to achieve the target level. However, to handle audible artifacts that can occur when the energy of the input signal is very close to the noise threshold, the AGC checks if the energy of the recorded signal is less than the noise threshold for a duration greater than the noise debounce time. Similarly, the AGC starts increasing the input-signal gain to reach the target level when the calculated energy of the input signal is greater than the noise threshold. Again, to avoid audible artifacts when the input-signal energy is very close to noise threshold, the energy of the input signal must continuously exceed the noise threshold value for the signal debounce time. If the debounce times are kept very small, then audible artifacts can result by rapidly enabling and disabling the AGC function. At the same time, if the debounce time is kept too large, then the AGC can take more time to respond to changes in input signal levels with respect to the noise threshold. Both noise and signal debounce time can be disabled.
- The **AGC noise threshold flag** is a read-only flag indicating that the input signal has levels lower than the noise threshold, and thus is detected as noise (or silence). In such a condition, the AGC applies a gain of 0 dB.
- **Gain applied by the AGC** is a read-only register setting that gives a real-time feedback to the system on the gain applied by the AGC to the recorded signal. This setting, along with the target setting, can be used to determine the input signal level. In a steady state situation:

    Target level (dB) = gain applied by AGC (dB) + input signal level (dB)

When the AGC noise threshold flag is set, then the status of the gain applied by the AGC is not valid.

- **The AGC saturation flag** is a read-only flag indicating that the ADC output signal has not reached its target level. However, the AGC is unable to increase the gain further because the required gain is higher than the maximum allowed PGA gain. Such a situation can happen when the input signal has very low energy and the noise threshold is also set very low. When the AGC noise threshold flag is set, the status of the AGC saturation flag must be ignored.
- **The ADC saturation flag** is a read-only flag indicating an overflow condition in the ADC channel. On overflow, the signal is clipped and distortion results. This distortion typically happens when the AGC target level is kept very high and the energy in the input signal increases faster than the attack time.
- **An AGC low-pass filter** is used to help determine the average level of the input signal. This average level is compared to the programmed detection levels in the AGC to provide the correct functionality. This low-pass filter is in the form of a first-order IIR filter. Two 8-bit registers are used to form the 16-bit digital coefficient, as shown in the *Register Maps* section. In this way, a total of six registers are programmed to form the three IIR coefficients. 公式 2 shows how the transfer function of the filter is implemented for signal-level detection:

$$H(z) = \frac{N_0 + N_1 z^{-1}}{2^{15} - D_1 z^{-1}}$$

where

- Coefficient N0 can be programmed by writing into page 4, registers 2 and 3
- Coefficient N1 can be programmed by writing into page 4, registers 4 and 5
- Coefficient D1 can be programmed by writing into page 4, registers 6 and 7
- N0, N1, and D1 are 16-bit, 2s-complement numbers, and their default values implement a low-pass filter with cutoff at $0.002735 \times \mathrm{ADC\_f_S}$ (2)

表 3 lists various AGC programming options. The AGC can be used only if the analog microphone input is routed to the ADC channel.

图 28 illustrates the input and output signals along with the decay and attack times of the AGC.

图 28. AGC Characteristics

The TLV320ADC3100 includes two analog audio input pins, which can be configured as one fully-differential pair and one single-ended input, or as three single-ended audio inputs. These pins connect through series resistors and switches to the virtual ground terminals of two fully differential operational amplifiers (one per ADC and PGA channel). By selecting to turn on only one set of switches per operational amplifier at a time, the inputs can be effectively multiplexed to each ADC PGA channel.

By selecting to turn on multiple sets of switches per operational amplifier at a time, mixing can also be achieved. Mixing of multiple inputs can easily lead to PGA outputs that exceed the range of the internal operational amplifiers, resulting in saturation and clipping of the mixed output signal. Whenever mixing is being implemented, take adequate precautions to avoid such a saturation case from occurring. In general, the mixed signal must not exceed 2 V_{PP} (single-ended) or 4 V_{PP} (differential).

In most mixing applications, there is also a general requirement to adjust the levels of the individual signals being mixed. For example, if a soft signal and a large signal are to be mixed and played together, the soft signal generally must be amplified to a level comparable to the large signal before mixing. In order to accommodate this requirement, the TLV320ADC3100 includes an input level control on each of the individual inputs before they are mixed or multiplexed into the ADC PGAs, with programmable attenuation at 0 dB, –6 dB, or off.

注

This input-level control is not intended to be a volume control, but instead used for coarse level setting. Finer soft-stepping of the input level is implemented in this device by the ADC PGA.

图 29 shows various available configurations for the audio input.
图 29. TLV320ADC3100 Available Audio Input Path Configurations

表 4. TLV320ADC3100 Audio Signals

AUDIO SIGNALS AVAILABLE TO THE LEFT ADC		AUDIO SIGNALS AVAILABLE TO THE RIGHT ADC	
SINGLE-ENDED INPUTS	DIFFERENTIAL INPUTS	SINGLE-ENDED INPUTS	DIFFERENTIAL INPUTS
IN2L(P)	IN2L(P), IN3L(M)	IN2R(P)	IN2R(P), IN3R(M)
IN3L(M)	IN2R(P), IN3R(M)	IN3R(M)	IN2L(P), IN3L(M)

Inputs can be selected as single-ended instead of fully differential, and mixing or multiplexing into the ADC PGAs is also possible in this mode. However, an input pair cannot be selected as fully differential for connection to one ADC PGA and simultaneously selected as single-ended for connection to the other ADC PGA channel. However, an input can be selected or mixed into both the left and right channel PGAs, as long as the PGA has the same configuration for both channels (either both single-ended or both fully differential).

8.3.9 Input Impedance and VCM Control

The TLV320ADC3100 includes several programmable settings to control the analog input pins, particularly when the pins are not selected for connection to an ADC PGA. The default option allows unselected inputs to be put into a high-impedance state. However, the pins on the device do include protection diode circuits connected to AVDD and AVSS. Thus, if any voltage is driven onto a pin approximately one diode drop (~0.6 V) above AVDD or one diode drop below AVSS, these protection diodes begin conducting current, resulting in an effective impedance that no longer appears as a high-impedance state.

Another programmable option for unselected analog inputs is to weakly hold those inputs at the common-mode input voltage of the ADC PGA (determined by an internal band-gap voltage reference). This feature is useful to keep the AC-coupling capacitors connected to the analog inputs biased up at a normal DC level, thus avoiding the need for them to charge up suddenly when the input is changed from being unselected to selected for connection to an ADC PGA. This option is controlled in page 1, register 52 through page 1, register 57. This option must be disabled when an input is selected for connection to an ADC PGA or selected for the analog input bypass path, because the input can corrupt the recorded input signal if left operational when an input is selected.

In most cases, the analog input pins on the TLV320ADC3100 must be AC-coupled to analog input sources, the only exception generally being if an ADC is used for DC voltage measurement. The AC-coupling capacitor causes a high-pass filter pole to be inserted into the analog signal path, so the size of the capacitor must be chosen to move that filter pole sufficiently low in frequency to cause minimal effect on the processed analog signal. The input impedance of the analog inputs, when selected for connection to an ADC PGA, varies with the setting of the input-level control, starting at approximately 35 kΩ with an input-level control setting of 0 dB, and 62.5-kΩ when the input-level control is set at –6 dB. For example, using a 0.1-µF, AC-coupling capacitor at an analog input results in a high-pass filter pole of 45.5 Hz when the 0-dB, input-level control setting is selected. 表 5 lists various mixer gains and microphone PGA ranges to set a high-pass corner for the application.

表 5. Single-Ended Input Impedance vs PGA Ranges[1]

MIXER GAIN (dB)	MICROPHONE PGA RANGE (dB)	INPUT IMPEDANCE (Ω)
0	0–5.5	35,000
0	6–11.5	38,889
0	12–17.5	42,000
0	18–23.5	44,074
0	24–29.5	45,294
0	30–35.5	45,960
0	36–40	46,308
–6	0–5.5	62,222
–6	6–11.5	70,000
–6	12–17.5	77,778
–6	18–23.5	84,000
–6	24–29.5	88,148
–6	30–35.5	90,588
–6	36–40	91,919

(1) Valid when only one input is enabled.

8.3.10 MICBIAS Generation

The TLV320ADC3100 includes a programmable microphone bias output (MICBIAS1) capable of providing output voltages of 2 V or 2.5 V (both derived from the on-chip, band-gap voltage) with 4-mA, output-current drive capability. In addition, the MICBIAS output can be programmed to switch to AVDD directly through an on-chip switch, or powered down completely when not needed, for power savings. This function is controlled by register programming in page 1, register 51.

8.3.11 ADC Decimation Filtering and Signal Processing

The TLV320ADC3100 ADC channel includes a built-in digital decimation filter to process the oversampled data from the delta-sigma modulator to generate digital data at the Nyquist sampling rate with high dynamic range. The decimation filter can be chosen from three different types, depending on the required frequency response, group delay, and sampling rate.

8.3.11.1 Processing Blocks

The TLV320ADC3100 offers a range of processing blocks that implement various signal processing capabilities along with decimation filtering. These processing blocks provide a choice of how much and what type of signal processing is used and which decimation filter is applied.

The signal processing blocks available are:
- First-order IIR
- Scalable number of biquad filters
- Variable-tap FIR filter
- AGC

The processing blocks are tuned for common cases and can achieve high antialias filtering or low group delay in combination with various signal processing effects such as audio effects and frequency shaping. The available first-order IIR, biquad, and FIR filters have fully user-programmable coefficients. The ADC processing blocks can be selected by writing to page 0, register 61. The default (reset) processing block is PRB_R1. 表 6 lists the available processing blocks for the ADC.

表 6. ADC Processing Blocks

PROCESSING BLOCKS	CHANNEL	DECIMATION FILTER	FIRST-ORDER IIR AVAILABLE	NUMBER OF BIQUADS	FIR	REQUIRED AOSR VALUE	INSTR CTR
PRB_R1	Stereo	A	Yes	0	No	128, 64	188
PRB_R2	Stereo	A	Yes	5	No	128, 64	240
PRB_R3	Stereo	A	Yes	0	25-tap	128, 64	236

8.3.11.3 *User-Programmable Filters*

Depending on the selected processing block, different types and orders of digital filtering are available. A first-order IIR filter is always available, and is useful to filter out possible DC components of the signal efficiently. Up to five biquad sections, or alternatively up to 25-tap FIR filters, are available for specific processing blocks. The coefficients of the available filters are arranged as sequentially indexed coefficients in two banks. If adaptive filtering is chosen, the coefficient banks can be switched while the processor is running.

The coefficients of these filters, as shown in 表 7, are each 16 bits wide, in 2s-complement format, and occupy two consecutive 8-bit registers in the register space. Specifically, the filter coefficients, shown in 图 39, are in 1.15 (one dot 15) format with a range from –1.0 (0x8000) to 0.999969482421875 (0x7FFF).

表 7. ADC First-Order IIR Filter Coefficients

FILTER	FILTER COEFFICIENT	ADC COEFFICIENT, LEFT CHANNEL	ADC COEFFICIENT, RIGHT CHANNEL
First-order IIR	N0	C4 (page 4, registers 8, 9)	C36 (page 4, registers 72, 73)
	N1	C5 (page 4, registers 10, 11)	C37 (page 4, registers 74, 75)
	D1	C6 (page 4, registers 12, 13)	C38 (page 4, registers 76, 77)
图 39. 2s-Complement Coefficient Format

8.3.11.3.1 First-Order IIR Section

公式 3 gives the transfer function for the first-order IIR filter.

$$H(z) = \frac{N_0 + N_1 z^{-1}}{2^{15} - D_1 z^{-1}}$$

(3)

The frequency response for the first-order IIR section with default coefficients is flat at a gain of 0 dB.

8.3.11.3.2　Biquad Section

公式 4 gives the transfer function of each biquad filter.

$$H(z) = \frac{N_0 + 2 \times N_1 z^{-1} + N_2 z^{-2}}{2^{15} - 2 \times D_1 z^{-1} - D_2 z^{-2}}$$

(4)

The frequency response for each of the biquad sections with default coefficients is flat at a gain of 0 dB. 表 8 lists the available coefficients for the five biquad filters.

表 8. ADC Biquad Filter Coefficients

FILTER	FILTER COEFFICIENT	ADC COEFFICIENT, LEFT CHANNEL	ADC COEFFICIENT, RIGHT CHANNEL
BIQUAD A	N0	C7 (page 4, registers 14, 15)	C39 (page 4, registers 78, 79)
	N1	C8 (page 4, registers 16, 17)	C40 (page 4, registers 80, 81)

8.3.11.3.3 FIR Section

Six of the available ADC processing blocks offer FIR filters for signal processing. PRB_R9 and PRB_R12 feature a 20-tap FIR filter, whereas the processing blocks PRB_R3, PRB_R6, PRB_R15, and PRB_R18 feature a 25-tap FIR filter. 公式 5 gives the transfer function of the Mth order FIR filter that is reconfigurable based on the processing block chosen.

$$H(z) = \sum_{n=0}^{M} FIR_n z^{-n}$$

$$M = 24 \text{ for PRB\_R3, PRB\_R6, PRB\_R15, and PRB\_R18}$$

$$M = 19 \text{ for PRB\_R9 and PRB\_R12}$$

(5)

The coefficients of the FIR filters correspond to the ADC coefficient space as listed in 表 9 and are 16-bit, 2s-complement format. There is no default transfer function for the FIR filter. When the FIR filter is used, all applicable coefficients must be programmed.

表 9. ADC FIR Filter Coefficients

FILTER COEFFICIENT	ADC COEFFICIENT, LEFT CHANNEL	ADC COEFFICIENT, RIGHT CHANNEL
FIR0	C7 (page 4, registers 14, 15)	C39 (page 4, registers 78, 79)
FIR1	C8 (page 4, registers 16, 17)	C40 (page 4, registers 80, 81)
FIR2	C9 (page 4, registers 18, 19)	C41 (page 4, registers 82, 83)

8.3.11.4 Decimation Filter

The TLV320ADC3100 offers three different types of decimation filters. The integrated digital decimation filter removes high-frequency content and downsamples the audio data from an initial sampling rate of AOSR × f_S to the final output sampling rate of f_S. Decimation filtering is achieved using a higher-order cascaded integrator-comb (CIC) filter followed by linear-phase FIR filters. The decimation filter cannot be chosen by itself; this filter is implicitly set through the chosen processing block.

This section describes the properties of the available filters A, B, and C.

8.3.11.4.1 Decimation Filter A

This filter is intended for use at sampling rates up to 48 kHz. When configuring this filter, the oversampling ratio of the ADC can either be 128 or 64. For highest performance, the oversampling ratio must be set to 128. Filter A can also be used for 96 kHz at an AOSR of 64. 表 10 specifies the performance of filter A. 图 40 shows the frequency response for filter A.

表 10. Specification for ADC Decimation Filter A

PARAMETER	CONDITION	VALUE (Typical)	UNIT
AOSR = 128			
Filter gain pass band	0 f_S–0.39 f_S	0.062	dB
Filter gain stop band	0.55 f_S–64 f_S	−73	dB
Filter group delay		17 / f_S	s
Pass-band ripple, 8 kSPS	0 f_S–0.39 f_S	0.062	dB
Pass-band ripple, 44.18 kSPS	0 f_S–0.39 f_S	0.05	dB
Pass-band ripple, 48 kSPS	0 f_S–0.39 f_S	0.05	dB
AOSR = 64			
Filter gain pass band	0 f_S–0.39 f_S	0.062	dB
Filter gain stop band	0.55 f_S–32 f_S	−73	dB
Filter group delay		17 / f_S	s
Pass-band ripple, 8 kSPS	0 f_S–0.39 f_S	0.062	dB
Pass-band ripple, 44.18 kSPS	0 f_S–0.39 f_S	0.05	dB
Pass-band ripple, 48 kSPS	0 f_S–0.39 f_S	0.05	dB
Pass-band ripple, 96 kSPS	0 kHz–20 kHz	0.1	dB
ADC channel response for decimation filter A
(red line corresponds to −73 dB)

图 40. ADC Decimation Filter A, Frequency Response

8.3.11.4.2 Decimation Filter B

Filter B is intended to support sampling rates up to 96 kHz at an oversampling ratio of 64. 表 11 specifies the performance of filter B. 图 41 shows the frequency response for filter B.

表 11. Specification for ADC Decimation Filter B

PARAMETER	CONDITION	VALUE (Typical)	UNIT
AOSR = 64			
Filter gain pass band	$0\ f_S$–$0.39\ f_S$	±0.077	dB
Filter gain stop band	$0.6\ f_S$–$32\ f_S$	–46	dB
Filter group delay		$11\ /\ f_S$	s
Pass-band ripple, 8 kSPS	$0\ f_S$–$0.39\ f_S$	0.076	dB
Pass-band ripple, 44.18 kSPS	$0\ f_S$–$0.39\ f_S$	0.06	dB
Pass-band ripple, 48 kSPS	$0\ f_S$–$0.39\ f_S$	0.06	dB
Pass-band ripple, 96 kSPS	0 kHz–20 kHz	0.11	dB
ADC channel response for decimation filter B
(red line corresponds to –44 dB)

图 41. ADC Decimation Filter B, Frequency Response

8.3.11.4.3 Decimation Filter C

Filter type C, along with an AOSR of 32, is specially designed for 192-kSPS operation of the ADC. The pass band, which extends up to 0.11 × f_S (corresponds to 21 kHz), is suited for audio applications. 表 12 specifies the performance of filter C. 图 42 shows the frequency response for filter C.

表 12. Specifications for ADC Decimation Filter C

PARAMETER	CONDITION	VALUE (Typical)	UNIT
Filter gain from 0 f_S to 0.11 f_S	0 f_S–0.11 f_S	±0.033	dB
Filter gain from 0.28 f_S to 16 f_S	0.28 f_S–16 f_S	–60	dB
Filter group delay		11 / f_S	s
Pass-band ripple, 8 kSPS	0 f_S–0.11 f_S	0.033	dB
Pass-band ripple, 44.18 kSPS	0 f_S–0.11 f_S	0.033	dB
Pass-band ripple, 48 kSPS	0 f_S–0.11 f_S	0.032	dB
Pass-band ripple, 96 kSPS	0 f_S–0.11 f_S	0.032	dB
Pass-band ripple, 192 kSPS	0 kHz–20 kHz	0.086	dB
ADC channel response for decimation filter C
(red line corresponds to –60 dB)

图 42. ADC Decimation Filter C, Frequency Response

8.3.11.5 ADC Data Interface

The decimation filter and signal processing block in the ADC channel passes 32-bit data words to the audio serial interface one time every frame (WCLK). During each frame (WCLK), a pair of data words (for the left and right channels) is passed. The audio serial interface rounds the data to the required word length of the interface before converting to serial data per the different modes for audio serial interface.

8.3.12 TLV320ADC3100 Comparison

表 13 lists a comparison between the TLV320ADC3100, TLV320ADC3101, and TLV320ADC3001. The TLV320ADC3100 is form-factor and software compatible with the TLV320ADC3101.

表 13. Device Comparison Table

FEATURES	TLV320ADC3101	TLV320ADC3001	TLV320ADC3100
Number of ADCs	2	2	2
Number of inputs/outputs	6, digital I / f	3, digital I / f	4, digital I / f
Resolution (bits)	24	24	24
Control interface	I²C	I²C	I²C
Digital audio interface	LJ, RJ, I2S, DSP, TDM	LJ, RJ, I2S, DSP, TDM	LJ, RJ, I2S, DSP, TDM
Digital microphone support	Yes	No	No
Number of GPIOs	2	0	1
Number of Microphone bias	2	1	1
Package	4-mm × 4-mm, 24-pin QFN	2.24-mm × 2.16-mm, 16-pin DSBGA (WCSP)	4-mm × 4-mm, 24-pin QFN

8.4 Device Functional Modes

8.4.1 Recording Mode

The recording mode is activated when the ADC blocks are enabled. The record path operates from 8 kHz to 48 kHz in single-rate mode and up to 96 kHz in dual-rate mode. This mode contains programmable input channel configurations supporting single-ended and differential setups. In order to provide optimal system power management, the stereo recording path can be powered up one channel at time, to support when only mono record capability is required. Digital signal processing blocks can remove audible noise that may be introduced by mechanical coupling. The TLV320ADC3100 includes automatic gain control (AGC).

8.5 Programming

8.5.1 Digital Control Serial Interface

8.5.1.1 I²C Control Mode

The TLV320ADC3100 supports the I²C control protocol and is capable of both standard and fast modes. Standard mode is up to 100 kHz and fast mode is up to 400 kHz. When in I²C control mode, the TLV320ADC3100 can be configured for one of four different addresses, using the I2C_ADR1 and I2C_ADR0 pins, which control the two LSBs of the device address. The five MSBs of the device address are fixed as 0011 0 and cannot be changed, whereas the two LSBs are given by I2C_ADR1:I2C_ADR0. 表 14 lists the four possible device addresses resulting from this configuration.

表 14. I²C Slave Device Addresses for I2C_ADR1, I2C_ADR0 Settings

I2C_ADR1	I2C_ADR0	DEVICE ADDRESS
0	0	0011 000
0	1	0011 001
1	0	0011 010
1	1	0011 011

I²C is a two-wire, open-drain interface supporting multiple devices and masters on a single bus. Devices on the I²C bus only drive the bus lines low by connecting them to ground; they never drive the bus lines high. Instead, the bus wires are pulled high by pullup resistors, so the bus wires are high when no device is driving them low. This way, two devices cannot conflict; if two devices drive the bus simultaneously, there is no driver contention.

Communication on the I²C bus always takes place between two devices, one acting as the master and the other acting as the slave. Both masters and slaves can read and write, but slaves can only do so under the direction of the master. Some I²C devices can act as masters or slaves, but the TLV320ADC3100 can only act as a slave device.

An I²C bus consists of two lines, SDA and SCL. SDA carries data; SCL provides the clock. All data are transmitted across the I²C bus in groups of eight bits. To send a bit on the I²C bus, the SDA line is driven to the appropriate level when SCL is low (a low on SDA indicates the bit is 0; a high indicates the bit is 1). When the SDA line has settled, the SCL line is brought high, then low. This pulse on SCL clocks the SDA bit into the receiver shift register.

The I²C bus is bidirectional: the SDA line is used both for transmitting and receiving data. When a master reads from a slave, the slave drives the data line; when a master sends to a slave, the master drives the data line. Under normal circumstances, the master drives the clock line.

Most of the time the bus is idle, no communication is taking place, and both lines are high. When communication is taking place, the bus is active. Only master devices can start a communication by causing a START condition on the bus. Normally, the data line is only allowed to change state when the clock line is low. If the data line changes state when the clock line is high, the state is either a START condition or its counterpart, a STOP condition. A START condition is when the clock line is high and the data line goes from high to low. A STOP condition is when the clock line is high and the data line goes from low to high.

After the master issues a START condition, the master sends a byte indicating the slave device to communicate with. This byte is called the *address byte*. Each device on an I²C bus has a unique 7-bit address that is used to respond with. (Slaves can also have 10-bit addresses; see the I²C specification for details.) The master sends an address in the address byte, together with a bit that indicates whether the slave device is to be read from or written to.

Every byte transmitted on the I²C bus, whether address or data, is acknowledged with an acknowledge bit. When a master has finished sending a byte (eight data bits) to a slave, the master stops driving SDA and waits for the slave to acknowledge the byte. The slave acknowledges the byte by pulling SDA low. The master then sends a clock pulse to clock the acknowledge bit. Similarly, when a master has finished reading a byte, the master pulls SDA low to acknowledge this read to the slave. The master then sends a clock pulse to clock the bit.

A not-acknowledge is performed by leaving SDA high during an acknowledge cycle. If the master attempts to address a device not present on the bus, then the master receives a not-acknowledge because no device is present at that address to pull the line low.

When a master has finished communicating with a slave, the master may issue a STOP condition. When a STOP condition is issued, the bus becomes idle again. A master may also issue another START condition. If a START condition is issued when the bus is active, this condition is called a *repeated START condition*.

The TLV320ADC3100 also responds to and acknowledges a general call, which consists of the master issuing a command with a slave address byte of 00h. 图 43 and 图 44 show timing diagrams for I²C write and read operations, respectively.
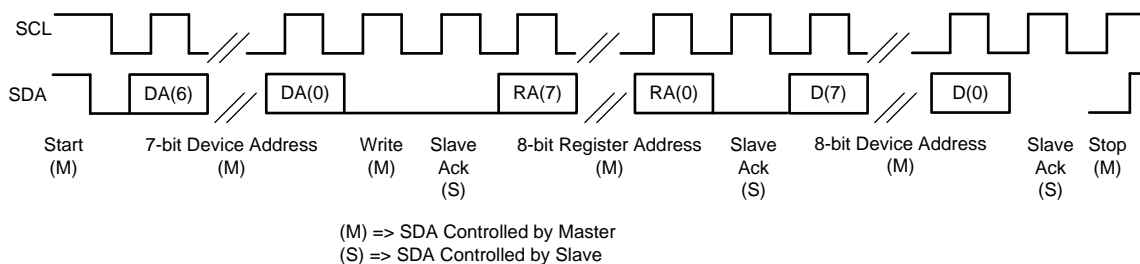

图 43. I²C Write
图 44. I²C Read

In the case of an I^{2}C register write, if the master does not issue a STOP condition, then the device enters auto-increment mode. So in the next eight clocks, the data on SDA are treated as the data for the next incremental register.

Similarly, after the device has transmitted the 8-bit data from the addressed register for an I^{2}C register read, and if the master issues an acknowledge, the slave then takes control of the SDA bus and transmits the next eight clocks of data for the next incremental register.

8.6 Register Maps

8.6.1 Control Registers

This section describes the control registers for the TLV320ADC3100 in detail. All registers are eight bits in width, with bit 7 referring to the most-significant bit of each register and bit 0 referring to the least-significant bit.

Pages 0, 1, 4, 5, and 32–47 are available. All other pages are reserved. Do not read from or write to reserved pages.

The procedure for register access is:
- Select page N (write data *N* to register 0 regardless of the current page number)
- Read or write data from or to valid registers in page N
- Select new page M (write data *M* to register 0 regardless of the current page number)
- Read or write data from or to valid registers in page M
- Repeat as needed

表 63. Register 59: ADC CIC Filter Gain Control Field Descriptions

Bit	Field	Type	Reset	Description
7:4	L-CIC FILT GAIN	R/W	0100h	Left CIC filter gain[1]
3:0	R-CIC FILT GAIN	R/W	0100h	Right CIC filter gain[1]

(1) For proper operation, the CIC gain must be ≤ 1.
If AOSR (page 0, register 20) = 64 and [1 ≤ Filter Mode (page 0, register 61) ≤ 6], then the reset value of 4 results in CIC gain = 1.
Otherwise, the CIC gain = [AOSR / (64 × Digital Filter Engine Decimation)]^4 × 2$^{(\text{CIC Filter Gain Control})}$ for 0 ≤ CIC Filter Gain Control ≤ 12,
and if CIC Filter Gain Control = 15, CIC gain is automatically set such that for 7 ≤ (AOSR / Digital Filter Engine Decimation) ≤ 64,
0.5 < CIC gain ≤ 1.

The remaining page 4 registers are either reserved registers or are used for setting coefficients for the various filters in the processing blocks. Reserved registers must not be written to.

The filter coefficient registers are arranged in pairs, with two adjacent 8-bit registers containing the 16-bit coefficient for a single filter. The 16-bit integer contained in the MSB and LSB registers for a coefficient are interpreted as a 2s-complement integer, with possible values ranging from −32,768 to 32,767. When programming any coefficient value for a filter, the MSB register must always be written first, immediately followed by the LSB register. Even if only the MSB or LSB portion of the coefficient changes, both registers must be written in this sequence. 表 109 is a list of the page 4 registers, excluding the previously described register 0.

表 109. Page 4 Registers

REGISTER NUMBER	RESET VALUE	REGISTER NAME
1	XXXX XXXX	Reserved. Do not write to this register.
2	0000 0001	Coefficient N0(15:8) for AGC LPF (first-order IIR) used as averager to detect level[1]
3	0001 0111	Coefficient N0(7:0) for AGC LPF (first-order IIR) used as averager to detect level
4	0000 0001	Coefficient N1(15:8) for AGC LPF (first-order IIR) used as averager to detect level
5	0001 0111	Coefficient N1(7:0) for AGC LPF (first-order IIR) used as averager to detect level
6	0111 1101	Coefficient D1(15:8) for AGC LPF (first-order IIR) used as averager to detect level

9 Application and Implementation

9.1 Application Information

图 137 shows the required external components and system level connections for proper operation of the device in several popular use cases.
图 137. Typical Connections

Each of these configurations can be realized using the evaluation modules (EVMs) for the device. As previously discussed in the *Recording Mode* section, the TLV320ADC3100 is form-factor and software compatible with the TLV320ADC3101. Therefore, both the TLV320ADC3101 and the TLV320ADC3100 use the same EVM, the TLV320ADC3101-K. These flexible modules allow full evaluation of the device in the most common modes of operation. Any design variation can be supported by TI through schematic and layout reviews. Visit http://e2e.ti.com for design assistance and join the audio amplifier discussion forum for additional information.

9.2 Typical Application
图 138. Application With Two Analog Microphones Using a Shared MICBIAS

9.2.1 Design Requirements

表 110 lists the design parameters for this application.

表 110. Design Parameters

KEY PARAMETER	SPECIFICATION
AVDD	3.3 V
AVDD supply current	> 6 mA (PLL on, AGC off, digital filter engine off, stereo record, f_S = 48 kHz)
DVDD	1.8 V
DVDD supply current	> 4 mA (PLL on, AGC off, digital filter engine off, stereo record, f_S = 48 kHz)
IOVDD	1.8 V
Maximum MICBIAS current	4 mA (MICBIAS voltage 2.5 V)

9.2.2 Detailed Design Procedure

This section describes the necessary steps to configure the TLV320ADC3100.

9.2.2.1 Step 1

The system clock source (master clock) and the targeted ADC sampling frequency must be identified.

Depending on the targeted performance, the decimation filter type (A, B, or C) and AOSR value can be determined:

- Filter A must be used for 48-kHz high-performance operation; AOSR must be a multiple of 8
- Filter B must be used for up to 96-kHz operations; AOSR must be a multiple of 4
- Filter C must be used for up to 192-kHz operations; AOSR must be a multiple of 2

In all cases, 公式 6 limits the AOSR range:

$$2.8 \text{ MHz} < \text{AOSR} \times \text{ADC\_fs} < 6.2 \text{ MHz} \tag{6}$$

Based on the identified filter type and the required signal-processing capabilities, the appropriate processing block can be determined from the list of available processing blocks (PRB_R1 to PRB_R18).

Based on the available master clock, the chosen AOSR and the targeted sampling rate, the clock divider values NADC and MADC can be determined. If necessary, the internal PLL can add a large degree of flexibility.

公式 7 describes that, in summary, ADC_CLKIN (derived directly from the system clock source or from the internal PLL) divided by MADC, NADC, and AOSR must be equal to the ADC sampling rate ADC_fs. The ADC_CLKIN clock signal is shared with the DAC clock-generation block.

$$ADC\_CLKIN = NADC \times MADC \times AOSR \times ADC\_fs \tag{7}$$

To a large degree, NADC and MADC can be chosen independently in the range of 1 to 128. In general, as long as 公式 8 is met, NADC must be as large as possible:

$$MADC \times AOSR \geq INSTR\_CTR \tag{8}$$

RC is a function of the chosen processing block and is listed in 表 6.

The common-mode voltage setting of the device is determined by the available analog power supply.

At this point, the PRB_Rx, AOSR, NADC, MADC, and input and output common-mode values device-specific parameters are known. If the PLL is used, the PLL parameters P, J, D, and R are determined as well.

9.2.2.2 Step 2

Setting up the device via register programming:

The following list gives a sequence of items that must be executed in the time between powering the device up and reading data from the device:

1. Define starting point:
    a. Power up applicable external hardware power supplies
    b. Set register page to 0
    c. Initiate SW reset
2. Program clock settings:
    a. Program PLL clock dividers P, J, D, and R (if PLL is used)
    b. Power up PLL (if PLL is used)
    c. Program and power up NADC
    d. Program and power up MADC
    e. Program OSR value
    f. Program I2S word length if required (for example, 20 bits)
    g. Program the processing block to be used
3. Program analog blocks:
    a. Set register page to 1
    b. Program MICBIAS, if applicable
    c. Program MICPGA
    d. Program routing of inputs and common mode to ADC input
    e. Unmute analog PGAs and set analog gain
4. Program ADC:
    a. Set register page to 0
    b. Power up ADC channel
    c. Unmute digital volume control and set gain

9.2.2.3 Example Register Setup to Record Analog Data Through ADC to Digital Out

A typical EVM I^{2}C register control script follows to show how to set up the TLV320ADC3100 in record mode with f_S = 44.1 kHz and MCLK = 11.2896 MHz.

```
# Key: w 30 XX YY ==> write to I2C address 0x30, to register 0xXX, data 0xYY
#                # ==> comment delimiter
#
# The following list gives an example sequence of items that must be executed in the time
# between powering the device up and reading data from the device. Note that there are
# other valid sequences depending on which features are used.
#
# ADC3101EVM Key Jumper Settings and Audio Connections:
# 1. Remove Jumpers W12 and W13
# 2. Insert Jumpers W4 and W5
# 3. Insert a 3.5mm stereo audio plug into J9 for
#    single-ended input IN1L(P) - left channel and
#    single-ended input IN1R(M) - right channel
################################################################
# 1. Define starting point:
#    (a) Power up appicable external hardware power supplies
#    (b) Set register page to 0
#
w 30 00 00
#    (c) Initiate SW Reset
#
w 30 01 01
#
# 2. Program Clock Settings
#    (a) Program PLL clock dividers P,J,D,R (if PLL is necessary)
#
# In EVM, the ADC3001 receives: MCLK = 11.2896 MHz,
# BCLK = 2.8224 MHz, WCLK = 44.1 kHz
#
# Sinve the sample rate is a multiple of the input MCLK then
# no PLL is needed thereby saving power. Use Default (Reset) Settings:
# ADC_CLKIN = MCLK, P=1, R=1, J=4, D=0000
w 30 04 00
w 30 05 11
w 30 06 04
w 30 07 00
w 30 08 00
#
#    (b) Power up PLL (if PLL is necessary) - Not Used in this Example
w 30 05 11

9.2.2.4 MICBIAS

The TLV320ADC3100 has a built-in bias voltage output for the biasing of microphones. No intentional capacitors must be connected directly to the MICBIAS output for filtering.

9.2.2.5 Decoupling Capacitors

The TLV320ADC3100 requires adequate power-supply decoupling to ensure that the noise and total harmonic distortion (THD) are low. A good ceramic capacitor, typically 0.1 µF, placed as close as possible to the device AVDD, IOVDD, and DVDD lead works best. Placing this decoupling capacitor close to the TLV320ADC3100 is important for the performance of the converter. For filtering lower-frequency noise signals, a 1-µF or greater capacitor placed near the device also helps.

9.2.3 Application Curves

图 139. Line Input to ADC FFT Plot

图 140. Input-Referred Noise vs PGA Gain
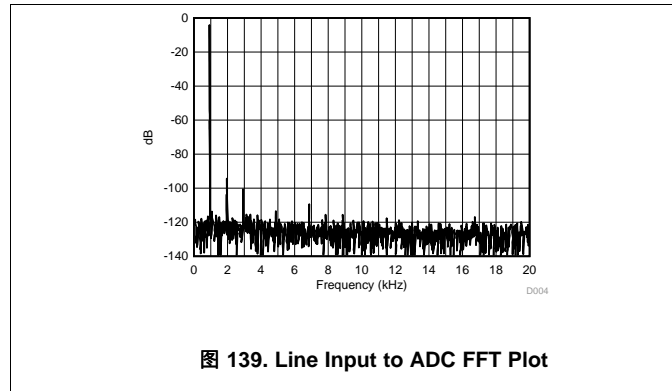

10 Power Supply Recommendations

The power supplies are designed to operate from 2.7 V to 3.6 V for AVDD, from 1.65 V to 1.95 V for DVDD and from 1.1 V to 3.6 V for IOVDD. Any value out of these ranges must be avoided to ensure the correct behavior of the device. The power supplies must be well regulated. Placing a decoupling capacitor close to the TLV320ADC3100 improves the performance of the device. A low equivalent-series-resistance (ESR) ceramic capacitor with a value of 0.1 µF is a typical choice. If the TLV320ADC3100 is used in highly noise-sensitive circuits, TI recommends adding a small LC filter on the VDD connections.

11 Layout

11.1 Layout Guidelines

Each system design and PCB layout is unique. The layout must be carefully reviewed in the context of a specific PCB design. However, the following guidelines can optimize the TLV320ADC3100 performance:

The decoupling capacitors for the power supplies must be placed close to the device terminals. 图 137 shows the recommended decoupling capacitors for the TLV320ADC3100.

Route analog differential audio signals differentially on the PCB for better noise immunity. Avoid crossing digital and analog signals to avoid undesirable crosstalk.

Analog and digital grounds must be separated to prevent possible digital noise from affecting the analog performance of the board.

12.5 静电放电警告

ESD 可能会损坏该集成电路。德州仪器 (TI) 建议通过适当的预防措施处理所有集成电路。如果不遵守正确的处理措施和安装程序，可能会损坏集成电路。

ESD 的损坏小至导致微小的性能降级，大至整个器件故障。 精密的集成电路可能更容易受到损坏，这是因为非常细微的参数更改都可能会导致器件与其发布的规格不相符。

SLYZ022 — *TI Glossary*.

This glossary lists and explains terms, acronyms, and definitions.

13 机械、封装和可订购信息

以下页面包含机械、封装和可订购信息。这些信息是指定器件的最新可用数据。数据如有变更，恕不另行通知，且不会对此文档进行修订。如需获取此数据表的浏览器版本，请查阅左侧的导航栏。

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TLV320ADC3100IRGER	ACTIVE	VQFN	RGE	24	3000	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	ADC 3100	Samples
TLV320ADC3100IRGET	ACTIVE	VQFN	RGE	24	250	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	ADC 3100	Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.
