

ZHCS839A - MARCH 2012 - REVISED MARCH 2012

# 带有集成高侧金属氧化物场效应晶体管 (MOSFET) 的 3A 双路非同步转换

查询样品: TPS54386-Q1

# 特性

- 符合汽车应用要求
- 具有符合 AEC-Q100 的下列结果:

RUMENTS

- 器件温度 2 级: -40℃ 至 +105℃ 的环境运行温 度范围
- 器件人体模型 (HBM) 静电放电 (ESD) 分类等级
- 器件充电器件模型 (CDM) ESD 分类等级 C3B
- 4.5V 至 28V 的输入范围
- 输出电压范围介于 0.8V 和输入电压的 90% 之间
- 输出电流高达 3A
- 固定开关频率: 600kHz
- 过流保护的三个可选电平(输出2)
- 0.8V 1.5% 电压基准
- 2.1ms 内部软启动
- 双路脉宽调制 (PWM) 输出 180° 异相位
- 可通过一个单一引脚来选择比率计或者顺序启动模
- 85mΩ 内部高侧 MOSFET
- 电流模式控制
- 内部补偿
- 逐脉冲过流保护
- 148°C 上的热关断
- 14 引脚 PowerPAD ™ 散热型薄型小外形尺寸 (HTSSOP) 封装

# 应用范围

- 为数字信号处理器 (DSP) 供电
- 消费类电子产品

# 说明

TPS54386-Q1 是一款双输出、非同步降压转换器,此 转换器能够支持运行在 4.5V 至 28V 输入电源电压范 围内的 3A 输出应用,并且要求输出电压在 0.8V 至输 入电压 90% 的范围内。

借助于内部确定的运行频率、软启动时间、和控制环路 补偿,这些转换器在所需外部组件大大减少的情况下提 供很多特性。 通道-1 过流保护被设定在 4.5A 上, 然 而,通过将一个引脚接地、连接至 BP,或者保持悬空 可选择通道-2 过流保护电平。 设置电平被用于允许针 对应用(此类应用不需要两个输出的完全负载能力)的 外部组件按比例增减。

输出可以被独立启用,或者可以被配置为支持比率计或 者顺序启动排序。 此外,两个输出也可以由不同的电 源供电。

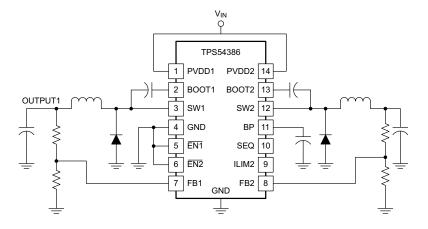

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

TERMIN	NAL	1/0	DECORPORTION
NAME	NO.	1/0	DESCRIPTION
BOOT1	2	I	Input supply to the high-side gate driver for output 1. Connect a 22-nF to 82-nF capacitor from this pin to SW1. This capacitor is charged from the BP pin voltage through an internal switch. The switch is turned ON during the OFF time of the converter. To slow down the turn ON of the internal FET, a small resistor (1 $\Omega$ to 3 $\Omega$ ) may be placed in series with the bootstrap capacitor.
BOOT2	13	I	Input supply to the high-side gate driver for output 2. Connect a 22-nF to 82-nF capacitor from this pin to SW2. This capacitor is charged from the BP pin voltage through an internal switch. The switch is turned ON during the OFF time of the converter. To slow down the turn ON of the internal FET, a small resistor (1 $\Omega$ to 3 $\Omega$ ) may be placed in series with the bootstrap capacitor.
ВР	11	_	Regulated voltage to charge the bootstrap capacitors. Bypass this pin to GND with a low-ESR (4.7-µF to 10-µF X7R or X5R) ceramic capacitor.
EN1	5	1	Active-low enable input for output 1. If the voltage on this pin is greater than 1.55 V, output 1 is disabled (high-side switch is OFF). A voltage of less than 0.9 V enables output 1 and allows soft-start of output 1 to begin. An internal current source drives this pin to PVDD2 if left floating. Connect this pin to GND for always ON operation.
EN2	6	I	Active-low enable input for output 2. If the voltage on this pin is greater than 1.55 V, output 2 is disabled (high-side switch is OFF). A voltage of less than 0.9 V enables Output 2 and allows soft start of Output 2 to begin. An internal current source drives this pin to PVDD2 if left floating. Connect this pin to GND for always ON operation.
FB1	7	1	Voltage feedback pin for output 1. The internal transconductance error amplifier adjusts the PWM for output 1 to regulate the voltage at this pin to the internal 0.8-V reference. A series resistor divider from output 1 to ground, with the center connection tied to this pin, determines the value of the regulated output voltage. Compensation for the feedback loop is provided internally to the device. See the Feedback Loop and Inductor-Capacitor (L-C) Filter Selection section for further information.
FB2	8	I	Voltage feedback pin for output 2. The internal transconductance error amplifier adjusts the PWM for output 2 to regulate the voltage at this pin to the internal 0.8-V reference. A series resistor divider from output 2 to ground, with the center connection tied to this pin, determines the value of the regulated output voltage. Compensation for the feedback loop is provided internally to the device. See the Feedback Loop and Inductor-Capacitor ( L-C) Filter Selection section for further information.
GND	4	_	Ground pin for the device. Connect directly to the thermal pad.
ILIM2	9	1	Current limit adjust pin for output 2 only. This function is intended to allow a user with asymmetrical load currents (output 1 load current much greater than output 2 load current) to optimize component scaling of the lower-current output while maintaining proper component derating in a overcurrent fault condition. The discrete levels are available as shown in Table 3, Current Limit Threshold Adjustment for Output 2. Note: An internal 2-resistor divider (150-k $\Omega$ each) connects BP to ILIM2 and to GND.
PVDD1	1	I	Power input to the output 1 high-side MOSFET only. This pin should be locally bypassed to GND with a low-ESR ceramic capacitor of 10-µF or greater.
PVDD2	14	I	The PVDD2 pin provides power to the device control circuitry, provides the pull-up for the $\overline{\text{EN1}}$ and $\overline{\text{EN2}}$ pins and provides power to the output 2 high-side MOSFET. This pin should be locally bypassed to GND with a low-ESR ceramic capacitor of 10-µF or greater. The UVLO function monitors PVDD2 and enables the device when PVDD2 is greater than 4.1 V.

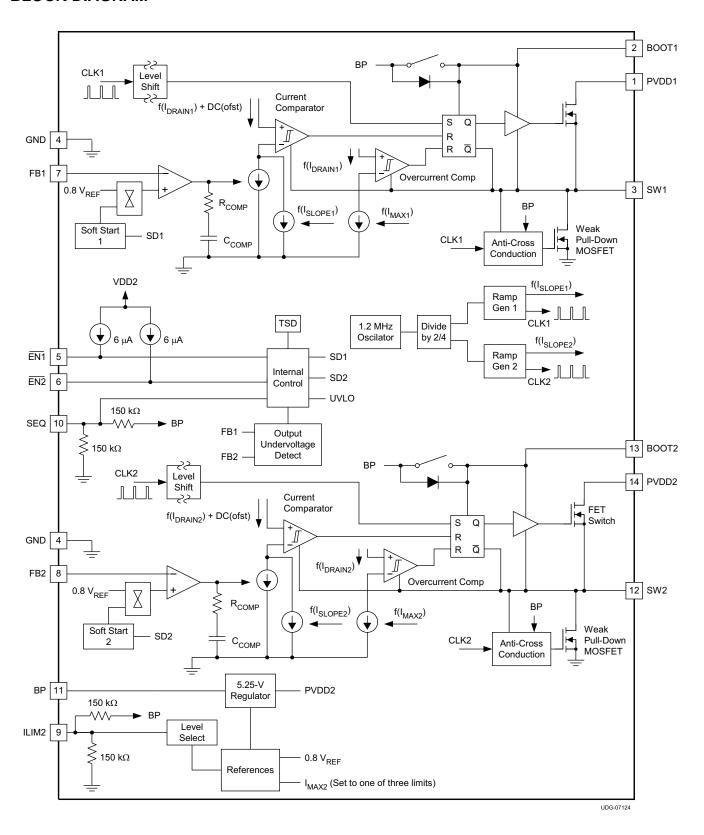

# **TERMINAL FUNCTIONS (continued)**

# **TERMINAL FUNCTIONS (continued)**

TERMIN	IINAL		DESCRIPTION			
NAME	NO.	I/O	DESCRIPTION			
			This pin configures the output start-up mode. If the SEQ pin is connected to BP, then when output 2 is enabled, output 1 is allowed to start after output 2 has reached regulation; that is, sequential startup where output 1 is slave to output 2. If $\overline{\text{EN2}}$ is allowed to go high after the outputs have been operating, then both outputs are disabled immediately, and the output voltages decay according to the load that is present. For this sequence configuration, tie $\overline{\text{EN1}}$ to ground.			
SEQ	EQ 10	10 I	If the SEQ pin is connected to GND, then when output 1 is enabled, output 2 is allowed to start after output 1 has reached regulation; that is, sequential start-up where output 2 is slave to output 1. If $\overline{\text{EN1}}$ is allowed to go high after the outputs have been operating, then both outputs are disabled immediately, and the output voltages decay according to the load that is present. For this sequence configuration, tie $\overline{\text{EN2}}$ to ground.			
			If left floating, output 1 and output 2 start ratiometrically when both outputs are enabled at the same time. They soft-start at a rate determined by their final output voltage and enter regulation at the same time. If the $\overline{\text{EN1}}$ and $\overline{\text{EN2}}$ pins are allowed to operate independently, then the two outputs also operate independently. NOTE: An internal two-resistor (150-k $\Omega$ each) divider connects BP to SEQ and to GND. See the Sequence States table.			
SW1	3	0	Source (switching) output for output 1 PWM. A snubber is recommended to reduce ringing on this node. See SW Node Ringing for further information.			
SW2	12	0	Source (switching) output for output 2 PWM. A snubber is recommended to reduce ringing on this node. See SW Node Ringing for further information.			
Thermal pad	_	_	This pad must be tied externally to a ground plane and the GND pin.			

# **BLOCK DIAGRAM**

#### APPLICATION INFORMATION

#### **FUNCTIONAL DESCRIPTION**

The TPS54386-Q1 is a dual-output, non-synchronous converter. Each PWM channel contains an internally compensated error amplifier, current-mode pulse-width modulator (PWM), switch MOSFET, enable, and fault-protection circuitry. Common to the two channels are the internal voltage regulator, voltage reference, clock oscillator, and output-voltage sequencing functions.

#### **DESIGN HINT**

The TPS54386-Q1 contains internal slope compensation and loop compensation components; therefore, the external L-C filter must be selected appropriately so that the resulting control loop meets criteria for stability. This approach differs from an externally-compensated controller, where the L-C filter is generally selected first, and the compensation network is found afterwards. (See the *Feedback Loop and L-C Filter Selection* section.)

#### **NOTE**

Unless otherwise noted, a label with a lowercase x appended implies the term applies to both outputs of the two modulator channels. For example, the term  $\overline{ENx}$  implies both  $\overline{EN1}$  and  $\overline{EN2}$ . Unless otherwise noted, all parametric values given are typical. See the *Electrical Characteristics* for minimum and maximum values. Calculations should be performed with tolerance values taken into consideration.

### **Voltage Reference**

The band-gap cell common to both outputs, trimmed to 800 mV.

#### Oscillator

The oscillator frequency is internally fixed at two times the SWx node switching frequency. The two outputs are internally configured to operate on alternating switch cycles (that is, 180° out of phase).

#### Input Undervoltage Lockout (UVLO) and Startup

When the voltage at the PVDD2 pin is less than 4.1 V, a portion of the internal bias circuitry is operational, and all other functions are held OFF. All of the internal MOSFETs are also held OFF. When the PVDD2 voltage rises above the UVLO turnon threshold, the <u>state</u> of the enable pins determines the remainder of the internal start-up sequence. If either output is enabled (ENx pulled low), the BP regulator turns on, charging the BP capacitor with a 20-mA current. When the BP <u>pin is greater than 4 V, PWM is enabled and soft-start begins, depending on the SEQ mode of operation and the EN1 and EN2 settings.</u>

Note that the internal regulator and control circuitry are powered from PVDD2. The voltage on PVDD1 may be higher or lower than PVDD2. (See the *Dual Supply Operation* section.)

# **Enable and Timed Turnon of the Outputs**

Each output has a dedicated (active-low) enable pin. If left floating, an internal current source pulls the pin to PVDD2. By grounding, or by pulling the  $\overline{\text{ENx}}$  pin to below approximately 1.2 V with an external circuit, the associated output is enabled and soft-start is initiated.

If both enable pins are left in the *high* state, the device operates in a shutdown mode, where the BP regulator is shut down and minimal functions are active. The total standby current from both PVDD pins is approximately 70 µA at the 12-V input supply.

An R-C circuit connected to an  $\overline{ENx}$  pin may be used to delay the turnon of the associated output after power is applied to PVDDx (see Figure 16). After power is applied to PVDD2, the voltage on the  $\overline{ENx}$  pin slowly decays towards ground. Once the voltage decays to approximately 1.2 V, then the output is enabled and the startup sequence begins. If it is desired to enable the outputs of the device immediately upon the application of power to PVDD2, then omit these two components and tie the  $\overline{ENx}$  pin to GND directly.

If an R-C circuit is used to delay the turnon of the output, the resistor value  $\underline{m}$  ust be much less than 1.2 V / 6  $\mu A$  or 200 k $\Omega$ . A suggested value is 51 k $\Omega$ . This resistor value allows the  $\overline{ENx}$  voltage to decay below the 1.2-V threshold while the 6- $\mu A$  bias current flows.

The capacitor value required to delay the start-up time (after the application of PVDD2) is shown in Equation 1.

$$C = \frac{t_{DELAY}}{R \times \ell n \bigg(\frac{V_{IN} - 2 \times I_{ENx} \times R}{V_{TH} - I_{ENx} \times R}\bigg)} farads$$

#### where:

- R and C are the timing components.
- V<sub>TH</sub> is the 1.2-V enable threshold voltage.
- I ENx is the 6-μA enable-pin biasing current.

(1)

Other enable-pin functionality is dictated by the state of the SEQ pin. (See the *Output Voltage Sequencing* section.)

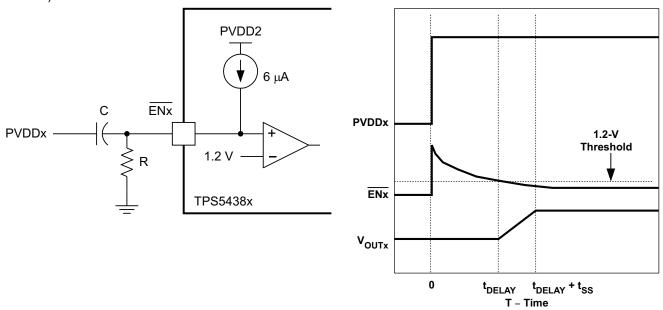

Figure 16. Start-Up Delay Schematic

Figure 17. Start-Up Delay With R-C on Enable

#### **DESIGN HINT**

If delayed output-voltage start-up is not necessary, simply connect  $\overline{\text{EN1}}$  and  $\overline{\text{EN2}}$  to GND. This configuration allows the outputs to start immediately on valid application of PVDD2.

If  $\overline{\text{ENx}}$  is allowed to go *high* after output x has been in regulation, the upper MOSFET shuts off, and the output decays at a rate determined by the output capacitor and the load. The internal pulldown MOSFET remains in the OFF state. (See the *Bootstrap for N-Channel MOSFET* section.)

# **Output-Voltage Sequencing**

The TPS54386-Q1 allows single-pin programming of output-voltage start-up sequencing. During power on, the state of the SEQ pin is detected. Based on whether the pin is tied to BP, to GND, or left floating, the outputs behave as described in Table 2.

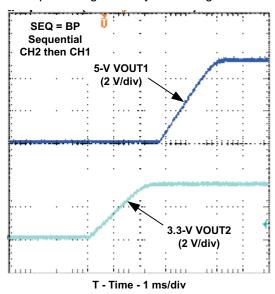

### **Table 2. Sequence States**

SEQ PIN STATE	MODE	EN1	EN2		
BP		Ignored by the device.when $V = V = V = V = V = V = V = V = V = V $			
	Sequential, output 2 then output 1	Sequential, output 2 then output 1  Tie EN1 to < enable threshold voltage for BP to be active when V <sub>EN2</sub> > enable threshold voltage			
		Tie $\overline{\text{EN1}}$ to > enable threshold voltage for low quiescent current (BP inactive) when $V_{\overline{\text{EN2}}}$ > enable threshold voltage			
			Ignored by the device.when V <sub>EN1</sub> < enable threshold voltage		
GND	Sequential, output 1 then output 2	Active	Tie $\overline{\text{EN2}}$ to < enable threshold voltage for BP to be active when $V_{\overline{\text{EN1}}}$ > enable threshold voltage		
			Tie $\overline{\text{EN2}}$ to > enable threshold voltage for low quiescent current (BP inactive) when V $\overline{\text{EN1}}$ > enable threshold voltage		
(floating)	Independent or ratiometric, output 1 and output 2	Active. EN1 and EN2 must be tied together for Ratio-metric startup.	Active. EN1 and EN2 must be tied together for ratiometric start-up.		

If the SEQ pin is connected to BP, then when output 2 is enabled, output 1 is allowed to start approximately 400 µs after output 2 has reached regulation; that is, sequential start-up where output 1 is slave to output 2. If EN2 is allowed to go high after the outputs have been operating, then both outputs are disabled immediately, and the output voltages decay according to the load that is present.

If the SEQ pin is connected to GND, then when output 1 is enabled, output 2 is allowed to start approximately 400 µs after output 1 has reached regulation; that is, sequential start-up where output 2 is slave to output 1. If EN1 is allowed to go high after the outputs have been operating, then both outputs are disabled immediately, and the output voltages decay according to the load that is present.

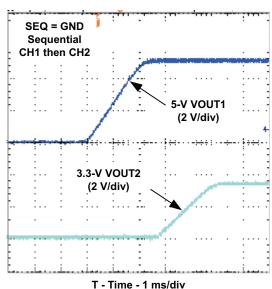

Figure 18. SEQ Pin Tied to BP

Figure 19. SEQ Pin Tied to GND

#### NOTE

An R-C network connected to the  $\overline{\text{ENx}}$  pin may be used in addition to the SEQ pin in sequential mode to delay the start-up of the first output voltage. This approach may be necessary in systems with a large number of output voltages and elaborate voltage-sequencing requirements. See *Enable and Timed Turn On of the Outputs*.

If the SEQ pin is left floating, output 1 and output 2 each start ratiometrically when both outputs are enabled at the same time. Output 1 and output 2 soft-start at a rate that is determined by the respective final output voltages and enter regulation at the same time. If the EN1 and EN2 pins are allowed to operate independently, then the two outputs also operate independently.

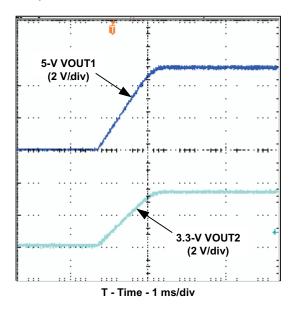

Figure 20. SEQ Pin Floating

#### **Soft Start**

Each output has a dedicated soft-start circuit. The soft-start voltage is an internal digital reference ramp to one of two noninverting inputs of the error amplifier. The other input is the (internal) precision 0.8-V reference. The total ramp time for the FB voltage to charge from 0 V to 0.8 V is about 2.1 ms. During a soft-start interval, the TPS54386-Q1 output slowly increases the voltage to the noninverting input of the error amplifier. In this way, the output voltage ramps up slowly until the voltage on the noninverting input to the error amplifier remains at the reference voltage. At that time, the voltage at the noninverting input to the error amplifier remains at the reference voltage.

#### **NOTE**

To avoid a disturbance in the output voltage during the stepping of the digital soft-start, a minimum output capacitance of 50  $\mu$ F is recommended. See *Feedback Loop and Inductor-Capacitor (L-C) Filter Selection*. Once the filter and compensation components have been established, laboratory measurements of the physical design should be performed to confirm converter stability.

During the soft-start interval, pulse-by-pulse current limiting is in effect. If an overcurrent pulse is detected, six PWM pulses are skipped to allow the inductor current to decay before another PWM pulse is applied. (See the *Output Overload Protection* section.) There is no pulse-skipping if a current-limit pulse is not detected.

### **DESIGN HINT**

If the rate of rise of the input voltage (PVDDx) is such that the input voltage is too low to support the desired regulation voltage by the time soft-start has completed, then the output UV circuit may trip and cause a *hiccup* in the output voltage. In this case, use a timed-delay start-up from the  $\overline{\text{ENx}}$  pin to delay the start-up of the output until the PVDDx voltage has the capability of supporting the desired regulation voltage. See *Operating Near Maximum Duty Cycle* and *Maximum Output Capacitance* for related information.

(2)

# **Output Voltage Regulation**

Each output has a dedicated feedback loop comprising a voltage-setting divider, an error amplifier, a pulse-width modulator, and a switching MOSFET. The regulation output voltage is determined by a resistor divider connecting the output node, the FBx pin, and GND (see Figure 21). Assuming the value of the upper resistor of the voltage-setting divider is known, the value of the lower divider resistor for a desired output voltage is calculated by Equation 2.

$$R2 = R1 \times \left[ \frac{V_{REF}}{V_{OUT} - V_{REF}} \right]$$

#### where

• V<sub>REF</sub> is the internal 0.8-V reference voltage.

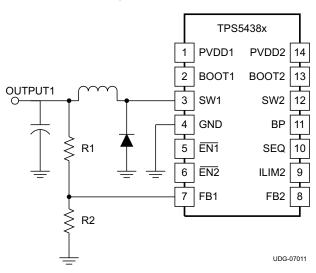

Figure 21. Feedback Network for Channel 1

## **DESIGN HINT**

There is a leakage current of up to 12  $\mu A$  out of the SW pin when a single output of the TPS54386-Q1 is disabled. Keeping the series impedance of R1 + R2 less than 50 k $\Omega$  prevents the output from floating above the reference voltage while the controller output is in the OFF state.

# Feedback Loop and Inductor-Capacitor (L-C) Filter Selection

In the feedback signal path, the output voltage-setting divider is followed by an internal  $g_M$ -type error amplifier with a typical transconductance of 30  $\mu$ s. An internal series-connected R-C circuit from the  $g_M$  amplifier output to ground serves as the compensation network for the converter. The signal from the error amplifier output is then buffered and combined with a slope compensation signal before it is mirrored to be referenced to the SW node. Here, it is compared with the current feedback signal to create a pulse-width-modulated (PWM) signal to drive the upper MOSFET switch. A simplified equivalent circuit of the signal control path is depicted in Figure 22.

#### NOTE

Noise coupling from the SWx node to internal circuitry of BOOTx may impact narrow pulse-width operation, especially at load currents less than 1 A. See SW Node Ringing for further information on reducing noise on the SWx node.

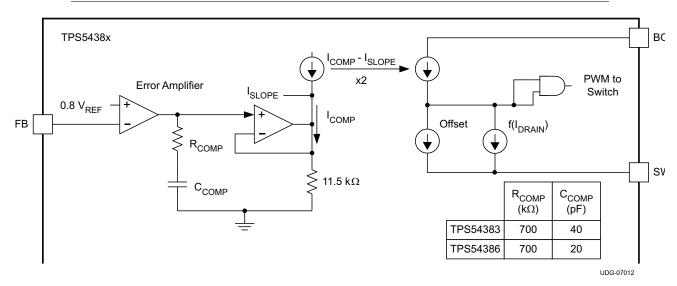

Figure 22. Feedback-Loop Equivalent Circuit

A more conventional small-signal equivalent block diagram is shown in Figure 23. Here, the full closed-loop signal path is shown. Because the TPS54386-Q1 contains internal slope-compensation and loop-compensation components, the external L-C filter must be selected appropriately so that the resulting control loop meets criteria for stability. This approach differs from an externally-compensated controller, where the L-C filter is generally selected first, and the compensation network is found afterwards. To find the appropriate L and C filter combination, the output-to-Vc signal path plots (see the next section) of gain and phase are used along with other design criteria to aid in finding the combination that best results in a stable feedback loop.

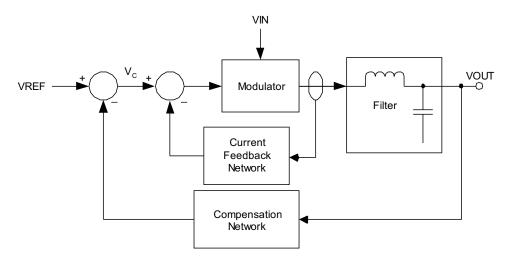

Figure 23. Small-Signal Equivalent Block Diagram

# Inductor-Capacitor (L-C) Selection

The following figures plot the TPS54386-Q1 output-to-Vc gain and phase versus frequency for various duty cycles (10%, 30%, 50%, 70%, 90%) at three (200 mA, 400 mA, 600 mA) peak-to-peak ripple-current levels. The loop response curve selected to compensate the loop is based on the duty cycle of the application and the ripple current in the inductor. Once the curve has been selected and the inductor value has been calculated, the output capacitor is found by calculating the L-C resonant frequency required to compensate the feedback loop. A brief example follows the curves.

Note that the internal error-amplifier compensation is optimized for output capacitors with an ESR zero frequency between 20 kHz and 60 kHz. See the following sections for further details.

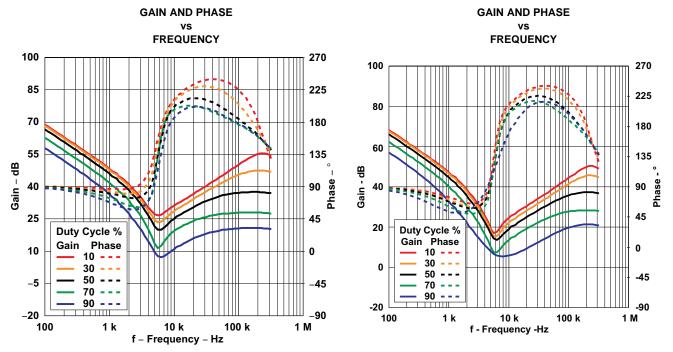

Figure 24. TPS54386-Q1 at 200-mApp Ripple Current

Figure 25. TPS54386-Q1 at 400-mApp Ripple Current

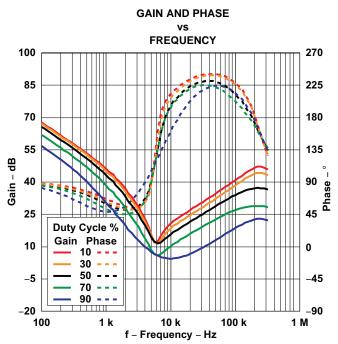

Figure 26. TPS54386-Q1 at 600-mApp Ripple Current

### **Maximum Output Capacitance**

With internal pulse-by-pulse current limiting and a fixed soft-start time, there is a maximum output capacitance which may be used before start-up problems begin to occur. If the output capacitance is large enough so that the device enters a current-limit protection mode during startup, then there is a possibility that the output will never reach regulation. Instead, the TPS54386-Q1 simply shuts down and attempts a restart as if the output were short-circuited to ground. The maximum output capacitance (including bypass capacitance distributed at the load) is given by Equation 3:

$$C_{OUTmax} = \frac{t_{SS}}{V_{REF}} \left[ I_{CLx} - V_{REF} (1 + \frac{R1}{R2}) (1 - \frac{V_{REF} (1 + \frac{R1}{R2}) \times T_{S}}{2 \times V_{IN} \times L} + \frac{1}{R_{LOAD}}) \right]$$
(3)

#### **Minimum Output Capacitance**

Ensure the value of capacitance selected for closed-loop stability is compatible with the requirements of *Soft Start*.

#### Modifying The Feedback Loop

Within the limits of the internal compensation, there is flexibility in the selection of the inductor and output-capacitor values. A smaller inductor increases ripple current, and raises the resonant frequency, thereby incerasing the required amount of output capacitance. A smaller capacitor could also be used, increasing the resonant frequency, and increasing the overall loop bandwidth—perhaps at the expense of adequate phase margin.

The internal compensation of the TPS54x8x is designed for capacitors with an ESR zero frequency between 20 kHz and 60 kHz. It is possible, with additional feedback compensation components, to use capacitors with higher or lower ESR zero frequencies. For either case, the components C1 and R3 (see Figure 30) are added to recompensate the feedback loop for stability. In this configuration, a low frequency pole is followed by a higher-frequency zero. The placement of this pole-zero pair is dependent on the type of output capacitor used and the desired closed-loop frequency response.

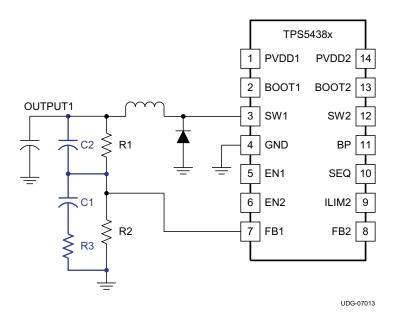

Figure 27. Optional Loop Compensation Components

#### NOTE

Once the filter and compensation components have been established, laboratory measurements of the physical design should be performed to confirm converter stability.

# Using High-ESR Output Capacitors

If a high-ESR capacitor is used in the output filter, a zero appears in the loop response that could lead to instability. To compensate, a small R-C series connected network is placed in parallel with the lower voltage-setting divider resistor (see Figure 27). The values of the components are determined such that a pole is placed at the same frequency as the ESR zero and a new zero is placed at a frequency location conducive to good loop stability.

The value of the resistor is calculated using a ratio of impedances to match the ratio of ESR zero frequency to the desired zero frequency.

$$R3 = \frac{R2}{\left(\left(\frac{f_{ZERO(desired)}}{f_{ESR(zero)}}\right) - 1\right)}$$

### where:

- $f_{\text{ESR(zero)}}$  is the ESR zero frequency of the output capacitor.
- f<sub>ZERO(desired)</sub> is the desired frequency of the zero added to the feedback. This frequency should be placed between 20 kHz and 60 kHz to ensure good loop stability.

The value of the capacitor is calculated in Equation 5.

$$C1 = \frac{1}{2\pi \times R_{EQ} \times f_{ESR(zero)}}$$

where:

R<sub>EQ</sub> is an equivalent impedance created by the parallel combination of the voltage-setting divider resistors (R1 and R2) in series with R3.

$$R_{EQ} = R3 + \frac{1}{\left(\left(\frac{1}{R1}\right) + \left(\frac{1}{R2}\right)\right)}$$
(6)

# Using All Ceramic Output Capacitors

With low-ESR ceramic capacitors, there may not be enough phase margin at the crossover frequency. In this case (see Figure 27), resistor R3 is set equal to 1/2 R2. This lowers the gain by 6 dB, reduces the crossover frequency, and improves phase margin.

The value of C1 is found by determining the frequency at which to place the low-frequency pole. The minimum frequency at which to place the pole is 1 kHz. Any lower, and the time constant will be too slow and interfere with the internal soft-start (see Soft Start). The upper bound for the pole frequency is determined by the operating frequency of the converter. It is 3 kHz for the TPS54x83, and 6 kHz for the TPS54x86. C1 is then found from Equation 7. Keep component tolerances in mind when selecting the desired pole frequency.

$$C1 = \frac{1}{2\pi \times R_{EQ} \times f_{POLE(desired)}}$$

where:

- f POLE(desired) is the desired pole frequency between 1 kHz and 3 kHz (TPS54x83) or 1 kHz and 6 kHz (TPS54x86).
- R<sub>EQ</sub> is an equivalent impedance created by the parallel combination of the voltage-setting divider resistors (R1 and R2) in series with R3.

$$R_{EQ} = R3 + \frac{1}{\left(\left(\frac{1}{R1}\right) + \left(\frac{1}{R2}\right)\right)}$$
(8)

If it is necessary to increase phase margin, place a capacitor in parallel with the upper voltage-setting divider resistor (C2 in Equation 9).

$$C2 = \frac{1}{2\pi \times f_{C} \times R1} \times \sqrt{1 + \frac{R1}{\left(\frac{\left(R2 \times R3\right)}{\left(R2 + R3\right)}\right)}}$$

where

•  $f_{\rm C}$  is the unity-gain crossover frequency, (approximately 50 kHz for most designs following these guidelines).

# Example: TPS54386-Q1 Buck Converter Operating at 12-V Input, 3.3-V Output and 400-mA<sub>(P-P)</sub> Ripple Current

First, the steady-state duty cycle is calculated. Assuming the rectifier diode has a voltage drop of 0.5 V, the duty cycle is approximated using Equation 10.

$$\delta = \frac{V_{\text{OUT}} + V_{\text{DIODE}}}{V_{\text{IN}} + V_{\text{DIODE}}} = \frac{3.3 + 0.5}{12 + 0.5} = 30\%$$
(10)

The filter inductor is then calculated; see Equation 11.

$$L = \frac{V_{IN} - V_{OUT}}{\Delta I_L} \times \delta \times T_S = \frac{12 - 3.3}{0.4} \times 0.3 \times \frac{1}{600000} = 10.9 \,\mu\text{H} \tag{11}$$

A custom-designed inductor may be used for the application, or a standard value close to the calculated value may be used. For this example, a standard 10-µH inductor is used. Using Figure 25, find the 30% duty cycle curve. The 30% duty cycle curve has a down slope from low frequency and rises at approximately 6 kHz. This curve is the resonant frequency that must be compensated. Any frequency within an octave of the peak may be used in calculating the capacitor value. In this example, 6 kHz is used.

$$C = \frac{1}{L \times (2 \times \pi \times f_{RES})^2} = \frac{1}{10 \times 10^{-6} \times (2 \times 3.14 \times 6000)^2} = 70 \,\mu\text{F}$$
(12)

A 68- $\mu$ F capacitor should be used as a bulk capacitor, with up to 10  $\mu$ F of ceramic bypass capacitance. To ensure the ESR zero does not significantly impact the loop response, the ESR of the bulk capacitor should be placed a decade above the resonant frequency.

$$R_{ESR} < \frac{1}{2 \times \pi \times 10 \times f_{RES} \times C} = \frac{1}{2 \times 3.14 \times 10 \times 6000 \times 68 \times (10)^{-6}} \approx 40 \text{ m}\Omega$$
(13)

The resulting loop gain and phase are shown in Figure 28. Based on measurement, loop crossover is 45 kHz with a phase margin of 60 degrees.

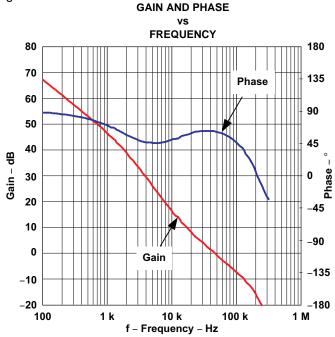

Figure 28. Example Loop Result

### **Bootstrap for the N-Channel MOSFET**

A bootstrap circuit provides a voltage source higher than the input voltage and of sufficient energy to fully enhance the switching MOSFET each switching cycle. The PWM duty cycle is limited to a maximum of 90%, allowing an external bootstrap capacitor to charge through an internal synchronous switch (between BP and BOOTx) during every cycle. When the PWM switch is commanded to turn ON, the energy used to drive the MOSFET gate is derived from the voltage on this capacitor.

To allow the bootstrap capacitor to charge each switching cycle, an internal pulldown MOSFET (from SW to GND) is turned ON for approximately 140 ns at the beginning of each switching cycle. In this way, if, during light load operation, there is insufficient energy for the SW node to drive to ground naturally, this MOSFET forces the SW node toward ground and allows the bootstrap capacitor to charge.

Because this is a charge transfer circuit, care must be taken in selecting the value of the bootstrap capacitor. It must be sized such that the energy stored in the capacitor on a per-cycle basis is greater than the gate charge requirement of the MOSFET being used.

#### **DESIGN HINT**

For the bootstrap capacitor, use a ceramic capacitor with a value between 22 nF and 82 nF.

#### NOTE

For 5-V input applications, connect PVDDx to BP directly. This connection bypasses the internal control-circuit regulator and provides maximum voltage to the gate-drive circuitry. In this configuration, shutdown mode IDD<sub>SDN</sub> is the same as quiescent IDD<sub>Q</sub>.

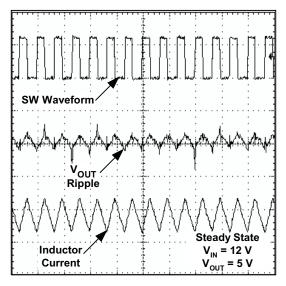

# **Light Load Operation**

There is no special circuitry for pulse skipping at light loads. The normal characteristic of a nonsynchronous converter is to operate in the *discontinuous-conduction mode* (DCM) at an average load current less than one-half of the inductor peak-to-peak ripple current. Note that the amplitude of the ripple current is a function of input voltage, output voltage, inductor value, and operating frequency, as shown in Equation 14.

$$I_{DCM} = \frac{1}{2} \times \frac{V_{IN} - V_{OUT}}{L} \times \delta \times T_{S}$$
(14)

Further, during discontinuous-mode operation the commanded pulse duration may become narrower than the capability of the converter to resolve. To maintain the output voltage within regulation, skipping switching pulses at light load conditions is a natural byproduct of that mode. This condition may occur if the output capacitor is charged to a value greater than the output regulation voltage and there is insufficient load to discharge the capacitor. A byproduct of pulse skipping is an increase in the peak-to-peak output ripple voltage.

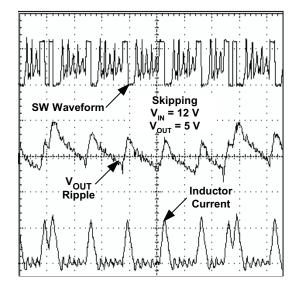

Figure 29. Steady State

Figure 30. Skipping

#### **DESIGN HINT**

If additional output capacitance is required to reduce the output-voltage ripple during DCM operation, be sure to recheck the *Feedback Loop and Inductor-Capacitor (L-C) Filter Selection* and *Maximum Output Capacitance* sections.

### **SW Node Ringing**

A portion of the control circuitry is referenced to the SW node. To ensure jitter-free operation, it is necessary to decrease the voltage waveform ringing at the SW node to less than 5 volts peak and of a duration of less than 30-ns. In addition to following good printed-circuit board (PCB) layout practices, there are a couple of design techniques for reducing ringing and noise.

#### SW Node Snubber

Voltage ringing observable at the SW node is caused by fast switching edges and parasitic inductance and capacitance. If the ringing results in excessive voltage on the SW node, or erratic operation of the converter, an R-C snubber may be used to dampen the ringing and ensure proper operation over the full load range.

#### **DESIGN HINT**

A series-connected R-C snubber (C = between 330 pF and 1 nF, R = 10  $\Omega$ ) connected from SW to GND reduces the ringing on the SW node.

#### **Bootstrap Resistor**

A small resistor in series with the bootstrap capacitor reduces the turnon time of the internal MOSFET, thereby reducing the rising-edge ringing of the SW node.

# **DESIGN HINT**

A resistor with a value between 1  $\Omega$  and 3  $\Omega$  may be placed in series with the bootstrap capacitor to reduce ringing on the SW node.

#### **DESIGN HINT**

Placeholders for these components should be placed on the initial prototype PCBs in case they are needed.

### **Output Overload Protection**

In the event of an overcurrent during soft-start on either output (such as starting into an output short), pulse-by-pulse current limiting and PWM frequency division are in effect for that output until the internal soft-start timer ends. At the end of the soft-start time, a UV condition is declared and a fault is declared. During this fault condition, both PWM outputs are disabled and the small pulldown MOSFETs (from SWx to GND) are turned ON. This process ensures that both outputs discharge to GND in the event that overcurrent is on one output while the other is not loaded. The converter then enters a *hiccup*-mode time-out before attempting to restart. *Frequency division* means if an overcurrent pulse is detected, six clock cycles are skipped before the next PWM pulse is initiated, effectively dividing the operating frequency by six and preventing excessive current buildup in the inductor.

In the event of an overcurrent on either output after the output reaches regulation, pulse-by-pulse current limit is in effect for that output. In addition, an output undervoltage (UV) comparator monitors the FBx voltage (that follows the output voltage) to declare a fault if the output drops below 85% of regulation. During this fault condition, both PWM outputs are disabled and the small pulldown MOSFETs (from SWx to GND) are turned ON. This design ensures that both outputs discharge to GND, in the event that overcurrent is on one output while the other is not loaded. The converter then enters a *hiccup*-mode timeout before attempting to restart.

The overcurrent threshold for output 1 is set nominally at 4.5 A. The overcurrent level of output 2 is determined by the state of the ILIM2 pin. The ILIM setting of output 2 is not latched in place and may be changed during operation of the converter.

Table 3. Current Limit Threshold Adjustment for Output 2

ILIM2 Connection	OCP Threshold for Output 2
BP	4.5-A nominal setting
(floating)	3-A nominal setting
GND	1.5-A nominal setting

#### **DESIGN HINT**

The OCP threshold refers to the peak current in the internal switch. Be sure to add one-half of the peak inductor ripple current to the dc load current in determining how close the actual operating point is to the OCP threshold.

### **Operating Near Maximum Duty Cycle**

If the TPS54386-Q1 operates at maximum duty cycle, and if the input voltage is insufficient to support the output voltage (at full load or during a load-current transient), then there is a possibility that the output voltage will fall from regulation and trip the output UV comparator. If this should occur, the TPS54386-Q1 protection circuitry declares a fault and enters a shut-down-and-restart cycle.

#### **DESIGN HINT**

Ensure that under ALL conditions of line and load regulation, there is sufficient duty cycle to maintain output-voltage regulation.

To calculate the operating duty cycle, use Equation 15.

$$\delta = \frac{V_{OUT} + V_{DIODE}}{V_{IN} + V_{DIODE}}$$

where

• V<sub>DIODE</sub> is the voltage drop of the rectifier diode.

(15)

# **Dual-Supply Operation**

It is possible to operate a TPS54386-Q1 from two supply voltages. If this application is desired, then the sequencing of the supplies must be such that PVDD2 is above the UVLO voltage before PVDD1 begins to rise. This level requirement ensures that the internal regulator and the control circuitry are in operation before PVDD1 supplies energy to the output. In addition, output 1 must be held in the disabled state (EN1 high) until there is sufficient voltage on PVDD1 to support output 1 in regulation. (See the *Operating Near Maximum Duty Cycle* section.)

The preferred sequence of events is:

- 1. PVDD2 rises above the input UVLO voltage.
- 2. PVDD1 rises with output 1 disabled until PVDD1 rises above the level to support output 1 regulation. With these two conditions satisfied, there is no restriction on PVDD2 to be greater than or less than PVDD1.

#### **DESIGN HINT**

An R-C delay on  $\overline{\text{EN1}}$  may be used to delay the start-up of output 1 for a long-enough period of time to ensure that PVDD1 can support the output 1 load.

# **Cascading Supply Operation**

It is possible to source PVDD1 from output 2 as depicted in Figure 31 and Figure 32. This configuration may be preferred if the input voltage is high, relative to the voltage on output 1.

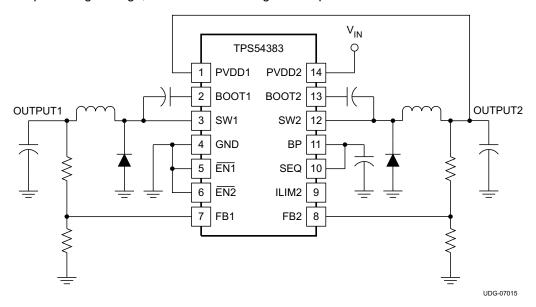

Figure 31. Schematic Showing Cascading PVDD1 From Output 2

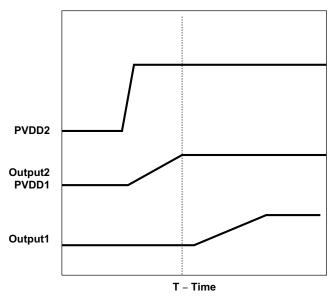

Figure 32. Waveforms Resulting From Cascading PVDD1 From Output 2

In this configuration, the following conditions must be maintained:

- 1. Output 2 must be of a voltage high enough to maintain regulation of output 1 under all load conditions.
- 2. The sum of the current drawn by output 2 load plus the current into PVDD1 must be less than the overload protection current level of output 2.
- 3. The method of output sequencing must be such that the voltage on output 2 is sufficient to support output 1 before output 1 is enabled. This requrement may be accomplished by:
  - (a) a delay of the enable function
  - (b) selecting sequential sequencing of output 1 starting after output 2 is in regulation

# **Multiphase Operation**

The TPS54386-Q1 is not designed to operate as a two-channel multiphase converter. See <a href="http://www.power.ti.com">http://www.power.ti.com</a> for appropriate device selection.

# Bypass and Filtering

As with any integrated circuit, supply bypassing is important for jitter-free operation. To improve the noise immunity of the converter, ceramic bypass capacitors must be placed as close to the package as possible.

- 1. PVDD1 to GND: Use a 10-µF ceramic capacitor.
- 2. PVDD2 to GND: Use a 10-µF ceramic capacitor.
- 3. BP to GND: Use a 4.7-µF to 10-µF ceramic capacitor.

### **Overtemperature Protection and Junction Temperature Rise**

The overtemperature thermal protection limits the maximum power to be dissipated at a given operating ambient temperature. In other words, at a given device power dissipation, the maximum ambient operating temperature is limited by the maximum allowable junction operating temperature. The device junction temperature is a function of power dissipation and the thermal impedance from the junction to ambient. If the internal die temperature should reach the thermal shutdown level, the TPS54386-Q1 shuts off both PWMs and remains in this state until the die temperature drops below the hysteresis value, at which time the device restarts.

The first step to determine the device junction temperature is to calculate the power dissipation. The power dissipation is dominated by the two switching MOSFETs and the BP internal regulator. The power dissipated by each MOSFET is composed of conduction losses and output (switching) losses incurred while driving the external rectifier diode. To find the conduction loss, first find the rms current through the upper switch MOSFET.

$$I_{RMS(outputx)} = \sqrt{D \times \left( \left(I_{OUTPUTx}\right)^2 + \left( \frac{\left(\Delta I_{OUTPUTx}\right)^2}{12} \right) \right)}$$

where

- D is the duty cycle.
- I<sub>OUTPUTx</sub> is the dc output current.
- ΔI<sub>OUTPUTx</sub> is the peak ripple current in the inductor for output x. (16)

Notice the impact of the operating duty cycle on the result.

Multiplying the result by the  $R_{DS(on)}$  of the MOSFET gives the conduction loss.

$$P_{D(cond)} = I_{RMS(outputx)}^{2} \times R_{DS(on)}$$
(17)

The switching loss is approximated by:

$$P_{D(SW)} = \left[ \frac{\left( V_{IN} \right)^2 \times C_J \times f_S}{2} \right]$$

where

- where C<sub>J</sub> is the parallel capacitance of the rectifier diode and snubber (if any).
- $f_{\rm S}$  is the switching frequency. (18)

The total power dissipation is found by summing the power loss for both MOSFETs plus the loss in the internal regulator.

$$P_{D} = P_{D(cond)output1} + P_{D(SW)output1} + P_{D(cond)output2} + P_{D(SW)output2} + V_{IN} \times Iq$$
(19)

The temperature rise of the device junction depends on the thermal impedance from the junction to the mounting pad (see the *Package Dissipation Ratings* table), plus the thermal impedance from the thermal pad to ambient. The thermal impedance from the thermal pad to ambient depends on the PCB layout (thermal-pad interface to the PCB, the exposed pad area) and airflow (if any). See the *PCB Layout Guidelines, Additional References* section.

The operating junction temperature is shown in Equation 20.

$$T_{J} = T_{A} + P_{D} \times \left(\theta_{TH(pkg)} + \theta_{TH(pad-amb)}\right)$$
(20)

#### **Power Derating**

The TPS54386-Q1 delivers full current at ambient temperatures up to 85°C if the thermal impedance from the thermal pad maintains the junction temperature below the thermal shutdown level. At higher ambient temperatures, the device power dissipation must be reduced to maintain the junction temperature at or below the thermal shutdown level. Figure 33 illustrates the power derating for elevated ambient temperature under various airflow conditions. Note that these curves assume that the thermal pad is properly soldered to the recommended board. (See the *References* section for further information.)

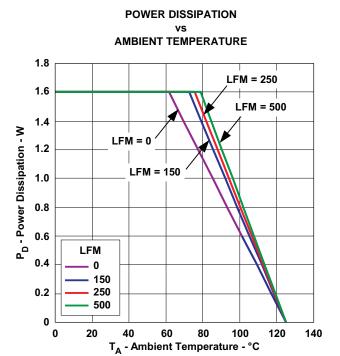

Figure 33. Power-Derating Curves

### PowerPAD Package

The PowerPAD package provides low thermal impedance for heat removal from the device. The thermal pad derives its name and low thermal impedance from the large bonding pad on the bottom of the device. The circuit board must have an area of solder-tinned-copper underneath the package. The dimensions of this area depend on the size of the PowerPAD package. Thermal vias connect this area to internal or external copper planes and should have a drill diameter sufficiently small so that the via hole is effectively plugged when the barrel of the via is plated with copper. This plug is needed to prevent wicking the solder away from the interface between the package body and the solder-tinned area under the device during solder reflow. Drill diameters of 0.33 mm (13 mils) work well when 1-oz. copper is plated at the surface of the board while simultaneously plating the barrel of the via. If the thermal vias are not plugged when the copper plating is performed, then a solder mask material should be used to cap the vias with a diameter equal to the via diameter of 0.1 mm minimum. This capping prevents the solder from being wicked through the thermal vias and potentially creating a solder void under the package. (See the *Additional References* section.)

#### **PCB Layout Guidelines**

The layout guidelines presented here are illustrated in the PCB layout examples given in Figure 34 and Figure 35.

- The thermal pad must be connected to a low-current (signal) ground plane having a large copper surface area to dissipate heat. Extend the copper surface well beyond the IC package area to maximize thermal transfer of heat away from the IC.
- Connect the GND pin to the thermal pad through a 10-mil (0.010-in, or 0.254-mm) wide trace.
- Place the ceramic input capacitors close to PVDD1 and PVDD2; connect using short, wide traces.
- Maintain a tight loop of wide traces from SW1 or SW2 through the switch node, inductor, output capacitor, and rectifier diode. Avoid using vias in this loop.
- Use a wide ground connection from the input capacitor to the rectifier diode, placed as close to the power path as possible. Placement directly under the diode and the switch node is recommended.
- Locate the bootstrap capacitor close to the BOOT pin to minimize the gate-drive loop.
- Locate voltage-setting resistors and any feedback components over the ground plane and away from the switch node and the rectifier diode to the input-capacitor ground connection.
- Locate snubber components (if used) close to the rectifier diode with minimal loop area.

www.ti.com.cn

- Locate the BP bypass capacitor very close to the IC; a minimal loop area is recommended.
- Locate the output ceramic capacitor close to the inductor output terminal between the inductor and any electrolytic capacitors, if used.

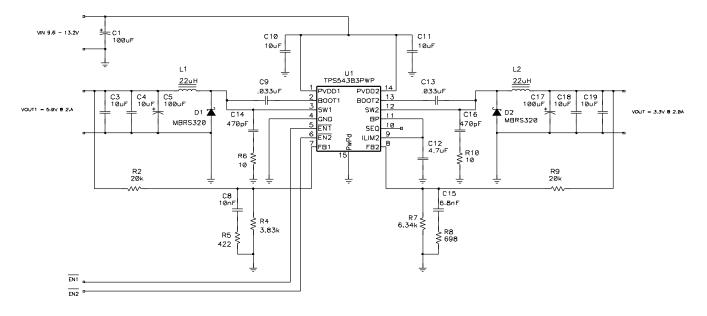

Figure 36. Design Example Schematic

# **Design Procedure**

## **Duty Cycle Estimation**

The first step is to estimate the duty cycle of each switching FET.

$$D_{\text{max}} \approx \frac{V_{\text{OUT}} + V_{\text{FD}}}{V_{\text{IN(min)}} + V_{\text{FD}}}$$
(21)

$$D_{min} \approx \frac{V_{OUT} + V_{FD}}{V_{IN(max)} + V_{FD}}$$
(22)

Using an assumed forward drop of 0.5 V for a Schottky rectifier diode, the channel 1 duty cycle is approximately 40.1% (minimum) to 48.7% (maximum), while the channel 2 duty cycle is approximately 27.7% (minimum) to 32.2% (maximum).

#### **Inductor Selection**

The peak-to-peak ripple is limited to 30% of the maximum output current. This places the peak current far enough from the minimum overcurrent trip level to ensure reliable operation.

For both channel 1 and channel 2, the maximum inductor ripple current is 600 mA. The inductor size is estimated in Equation 23.

$$L_{min} \approx \frac{V_{IN(max)} - V_{OUT}}{I_{LRIP(max)}} \times D_{min} \times \frac{1}{f_{SW}}$$
(23)

The inductor values are

- L1 = 18.3 µH
- L2 = 15.3 µH

The next-higher standard inductor value of 22 µH is used for both inductors.

The resulting ripple currents are:

$$I_{RIPPLE} \approx \frac{V_{IN(max)} - V_{OUT}}{L} \times D_{min} \times \frac{1}{f_{SW}}$$
(24)

Peak-to-peak ripple currents of 0.498 A and 0.416 A are estimated for channel 1 and channel 2, respectively.

The rms current through an inductor is approximated by Equation 25.

$$I_{L(rms)} = \sqrt{\left(I_{L(avg)}\right)^2 + \frac{1}{12}\left(I_{RIPPLE}\right)^2}$$
(25)

and is approximately 2 A for both channels.

The peak inductor current is found using:

$$I_{L(peak)} \approx I_{OUT(max)} + \frac{1}{2}I_{RIPPLE}$$
 (26)

An inductor with a minimum rms current rating of 2 A and minimum saturation current rating of 2.25 A is required. A Coilcraft MSS1278-223ML 22-µH, 6.8-A inductor is selected.

# **Rectifier Diode Selection**

A Schottky diode is selected as a rectifier diode for its low forward-voltage drop. Allowing 20% over VIN for ringing on the switch node, the required minimum reverse-breakdown voltage of the rectifier diode is:

$$V_{(BR)R(min)} \ge 1.2 \times V_{IN} \tag{27}$$

www.ti.com.cn

The diode must have reverse breakdown voltage greater than 15.8 V, therefore a 20-V device is used.

The average current in the rectifier diode is estimated by Equation 28.

$$I_{D(avg)} \approx I_{OUT(max)} \times (1-D)$$
(28)

For this design, 1.2-A (average) and 2.25 A (peak) is estimated for channel 1 and 1.5-A (average) and 2.21-A (peak) for channel 2.

An MBRS320, 20-V, 3-A diode in an SMC package is selected for both channels. This diode has a forward voltage drop of 0.4 V at 2 A.

The power dissipation in the diode is estimated by Equation 29.

$$P_{D(max)} \approx V_{FM} \times I_{D(avg)}$$
 (29)

For this design, the full-load power dissipation is estimated to be 480 mW in D1, and 580 mW in D2.

### **Output Capacitor Selection**

The TPS54386-Q1 internal compensation limits the selection of the output capacitors. From , the internal compensation has a double zero resonance at about 3 kHz. The output capacitor is selected by Equation 30.

$$C_{OUT} = \frac{1}{4 \times \pi^2 \times (f_{RES})^2 \times L}$$
(30)

Solving for C<sub>OUT</sub> using

- f<sub>RES</sub> = 3 kHz
- L = 22 µH

The resulting is  $C_{OUT}$  = 128  $\mu$ F. The output ripple voltage of the converter is composed of the ripple voltage across the output capacitance and the ripple voltage across the ESR of the output capacitor. To find the maximum ESR allowable to meet the output ripple requirements, the total ripple is partitioned and the equation solved to find the ESR.

$$ESR_{(max)} = \frac{V_{RIPPLE(tot)} - V_{RIPPLE(cap)}}{I_{RIPPLE}} = \frac{V_{RIPPLE(tot)}}{I_{RIPPLE}} - \frac{D}{f_{S} \times C_{OUT}}$$
(31)

Based on 128  $\mu$ F of capacitance, 300-kHz switching frequency, and 50-mV ripple voltage, plus rounding up the ripple current to 0.5 A and the duty cycle to 50%, the capacitive portion of the ripple voltage is 6.5 mV, leaving a maximum allowable ESR of 87 m $\Omega$ .

To meet the ripple-voltage requirements, a low-cost 100- $\mu$ F electrolytic capacitor with 400 m $\Omega$  ESR (C5, C17) and two 10- $\mu$ F ceramic capacitors (C3 and C4; and C18 and C19) with 2.5-m $\Omega$  ESR are selected. From the data sheets for the ceramic capacitors, the parallel combination provides an impedance of 28 m $\Omega$  at 300 kHz for 14 mV of ripple.

# **Voltage Setting**

The primary feedback divider resistors (R2, R9) from VOUT to FB should be between 10 k $\Omega$  and 50 k $\Omega$  to maintain a balance between power dissipation and noise sensitivity. For this design, 20 k $\Omega$  is selected.

The lower resistors, R4 and R7 are found using the following equations.

$$R4 = \frac{V_{FB} \times R2}{V_{OUT1} - V_{FB}}$$
(32)

$$R7 = \frac{V_{FB} \times R9}{V_{OUT2} - V_{FB}}$$
(33)

- $R2 = R9 = 20 \text{ k}\Omega$
- V<sub>FB</sub> = 0.8 V

- R4 = 3.8 kΩ (3.83 kΩ standard value is used)
- R7 = 6.4 k $\Omega$  (6.34 k $\Omega$  standard value is used)

# **Compensation Capacitors**

Checking the ESR zero of the output capacitors:

$$f_{\text{ESR(zero)}} = \frac{1}{2 \times \pi \times C \times \text{ESR}}$$

- C = 100 μF
- ESR =  $400 \text{ m}\Omega$

Because the ESR zero of the main output capacitor is less than 20 kHz, an R-C filter is added in parallel with R4 and R7 to compensate for the ESR of the electrolytic capacitor and add a zero of approximately 40 kHz.

$$R5 = \frac{R4}{\left(\left(\frac{f_{ZERO(desired)}}{f_{ESR(zero)}}\right) - 1\right)}$$

- f<sub>ESR(zero)</sub> = 4 kHz
- f<sub>ESR(desired)</sub> = 40 kHz
- R4 =  $3.83 \text{ k}\Omega$
- R5 = 424  $\Omega$  (422  $\Omega$  selected)
- $R7 = 6.34 \text{ k}\Omega$

$$R_{EQ} = R5 + \frac{1}{\left(\left(\frac{1}{R2}\right) + \left(\frac{1}{R4}\right)\right)}$$

- $R2 = R9 = 20 \text{ k}\Omega$
- $R_{EQ1} = 3.63 \text{ k}\Omega$

• 
$$R_{EQ2} = 5.51 \text{ k}\Omega$$
 (36)

$$C8 = \frac{1}{2 \times \pi \times R_{EQ} \times f_{ESR(zero)}}$$

• C8 = 10.9 nF (10 nF selected)

# **Input Capacitor Selection**

The TPS54386-Q1 data sheet recommends a minimum 10-µF ceramic input capacitor on each PVDD pin. These capacitors must be capable of handling the rms ripple current of the converter. The rms current in the input capacitors is estimated by Equation 38.

$$I_{RMS(outputx)} = \sqrt{D \times \left( \left( I_{OUTPUTx} \right)^2 + \left( \frac{\left( \Delta I_{OUTPUTx} \right)^2}{12} \right) \right)}$$
(38)

•  $I_{RMS(CIN)} = 0.43 \text{ A}$ 

One 1210 10- $\mu$ F, 25-V, X5R ceramic capacitor with 2-m $\Omega$  ESR and a 2-A rms current rating is selected for each PVDD input. Higher-voltage capacitors are selected to minimize capacitance loss at the dc bias voltage to ensure the capacitors maintain sufficient capacitance at the working voltage.

#### **Bootstrap Capacitor**

To ensure proper charging of the high-side FET gate and limit the ripple voltage on the boost capacitor, a 33-nF bootstrap capacitor is used.

#### ILIM

Current limit must be set above the peak inductor current  $I_{L(peak)}$ . Comparing  $I_{L(peak)}$  to the available minimum current limits, ILIM is connected to BP for the highest current-limit level.

#### **SEQ**

The SEQ pin is left floating, leaving the enable pins to function independently. If the enable pins are tied together, the two supplies start up ratiometrically. Alternatively, SEQ could be connected to BP or GND to provide sequential start-up.

#### **Power Dissipation**

The power dissipation in the TPS54386-Q1 is composed of FET conduction losses, switching losses, and internal regulator losses. The rms FET current is found using Equation 39.

$$I_{RMS(outputx)} = \sqrt{D \times \left( \left( I_{OUTPUTx} \right)^2 + \left( \frac{\left( \Delta I_{OUTPUTx} \right)^2}{12} \right) \right)}$$
(39)

This results in 1.05 -A rms for channel 1 and 0.87 A rms for channel 2.

Conduction losses are estimated by:

$$P_{CON} = R_{DS(on)} \times \left(Q_{SW(rms)}\right)^{2}$$
(40)

Conduction losses of 198 mW and 136 mW are estimated for channel 1 and channel 2 respectively.

The switching losses are estimated in Equation 41.

$$P_{SW} \approx \frac{\left(V_{IN(max)}\right)^2 \times \left(C_{DJ} + C_{OSS}\right) \times f_{SW}}{2} \tag{41}$$

From the data sheet of the MBRS320, the junction capacitance is 658 pF. Because this is large compared to the output capacitance of the TPS54x8x, the FET capacitance is neglected, leaving switching losses of 17 mW for each channel.

The regulator losses are estimated in Equation 42.

$$P_{REG} \approx I_{DD} \times V_{IN(max)} + I_{BP} \times \left(V_{IN(max)} - V_{BP}\right)$$
(42)

With no external load on BP ( $I_{BP} = 0$ ), the power dissipation of the regulator is 66 mW.

Total power dissipation in the device is the sum of conduction and switching for both channels, plus regulator losses.

The total power dissipation is  $P_{DISS} = 0.198 + 0.136 + 0.017 + 0.017 + 0.066 = 434$  mW.

#### **Design Example Test Results**

The following results are from the TPS54386-Q1-001 EVM.

#### Example 2: 24 V to 12 V and 24 V to 5 V

For a higher input voltage, both a snubber and bootstrap resistors are added to reduce ringing on the switch node and a 30-V Schottky diode is selected. A higher-resistance feedback network is chosen for the 12-V output to reduce the feedback current.

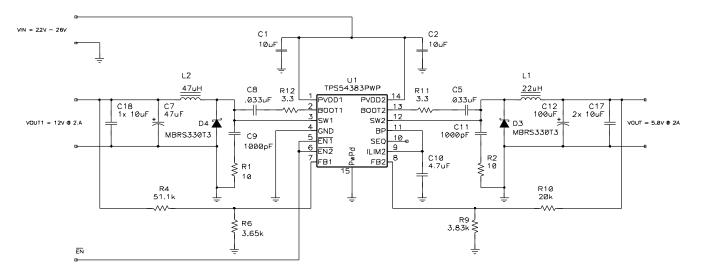

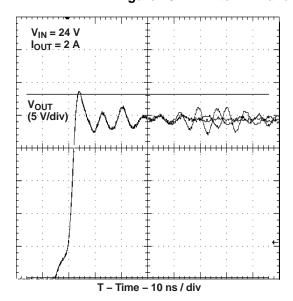

Figure 43. 24 V to 12 V and 24 V to 5 V Using the TPS54386-Q1

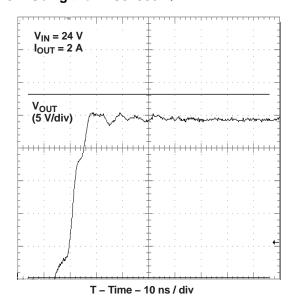

Figure 44. Switch Node Ringing Without Snubber and Boost Resistor

Figure 45. Switch Node Ringing With Snubber and Boost Resistor

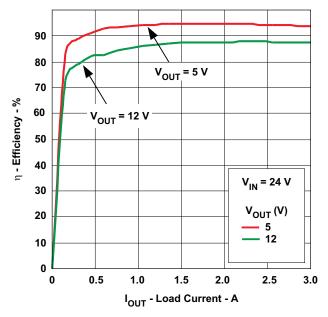

Figure 46. Efficiency vs Load Current

## Example 3: 5 V to 3.3 V and 5 V to 1.2 V

For a low-input-voltage application, the TPS54386-Q1 is selected for reduced size, and all ceramic output capacitors are used. 22-µF input capacitors are selected to reduce input ripple and lead capacitors are placed in the feedback to boost phase margin.

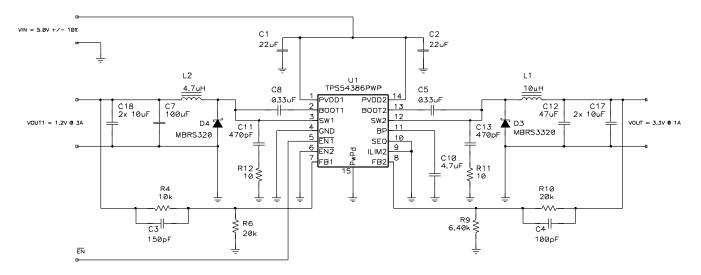

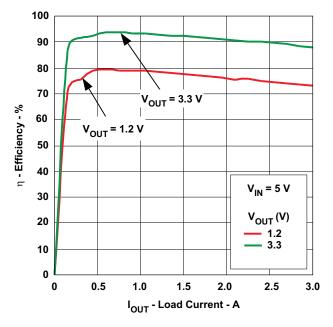

Figure 47. 5 V to 3.3 V and 5 V to 1.2 V

## Package Outline and Recommended PCB Footprint

The following pages outline the mechanical dimensions of the 14-Pin PWP package and provide recommendations for PCB layout.

## PACKAGE OPTION ADDENDUM

10-Dec-2020

#### **PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan	Lead finish/ Ball material	MSL Peak Temp	Op Temp (°C)	Device Marking (4/5)	Samples
TPS54386TPWPRQ1	ACTIVE	HTSSOP	PWP	14	2000	RoHS & Green	NIPDAU	Level-3-260C-168 HR	-40 to 105	54386T	Samples

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead finish/Ball material Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
