

# ***J721E DRA829/TDA4VM/AM68P Processors Silicon Revision 1.1 Texas Instruments Families of Products***

*Technical Reference Manual*

---

Literature Number: SPRUIL1D  
MAY 2019 – REVISED DECEMBER 2024

# Table of Contents

<b>1 Introduction</b>	<b>79</b>
1.1 Device Overview	80
1.2 Device Block Diagram	82
1.3 Device Main Domain	85
1.3.1 Arm Cortex-A72 Subsystem	87
1.3.2 Arm Cortex-R5F Processor	87
1.3.3 C66x DSP Subsystem	87
1.3.4 C71x DSP Subsystem	88
1.3.5 Graphics Processing Unit	88
1.3.6 Multi-Standard HD Video Decoder	89
1.3.7 Multi-Standard HD Video Encoder	89
1.3.8 Vision Pre-processing Accelerator	90
1.3.9 Depth and Motion Perception Accelerator	90
1.3.10 Navigator Subsystem	91
1.3.11 Region-based Address Translation Module	93
1.3.12 Data Routing Unit	93
1.3.13 Display Subsystem	93
1.3.14 Camera Subsystem	96
1.3.15 Shared D-PHY Transmitter	97
1.3.16 Video Processing Front End	97
1.3.17 Multicore Shared Memory Controller	97
1.3.18 DDR Subsystem	98
1.3.19 Region-based Address Translation Module	98
1.3.20 General Purpose Input/Output Interface	98
1.3.21 Inter-Integrated Circuit Interface	98
1.3.22 Improved Inter-Integrated Circuit Interface	99
1.3.23 Multi-channel Serial Peripheral Interface	99
1.3.24 Universal Asynchronous Receiver/Transmitter	99
1.3.25 Gigabit Ethernet Switch	99
1.3.26 Peripheral Component Interconnect Express Subsystem	100
1.3.27 Universal Serial Bus (USB) Subsystem	100
1.3.28 SerDes	101
1.3.29 General Purpose Memory Controller with Error Location Module	102
1.3.30 Multimedia Card/Secure Digital Interface	103
1.3.31 Universal Flash Storage Interface	103
1.3.32 Enhanced Capture Module	104
1.3.33 Enhanced Pulse-Width Modulation Module	104
1.3.34 Enhanced Quadrature Encoder Pulse Module	104
1.3.35 Controller Area Network	104
1.3.36 Audio Tracking Logic	105
1.3.37 Multi-channel Audio Serial Port	105
1.3.38 Timers	105
1.3.39 Internal Diagnostics Modules	106
1.4 Device MCU Domain	107
1.4.1 MCU Arm Cortex-R5F Processor	108
1.4.2 MCU Region-based Address Translation Module	109
1.4.3 MCU Navigator Subsystem	109
1.4.4 MCU Analog-to-Digital Converter	110
1.4.5 MCU Inter-Integrated Circuit Interface	110

1.4.6 MCU Improved Inter-Integrated Circuit Interface.....	111
1.4.7 MCU Multi-channel Serial Peripheral Interface.....	111
1.4.8 MCU Universal Asynchronous Receiver/Transmitter.....	111
1.4.9 MCU Gigabit Ethernet Switch.....	111
1.4.10 MCU Octal Serial Peripheral Interface and HyperBus Memory Controller as a Flash Subsystem.....	112
1.4.11 MCU Controller Area Network.....	113
1.4.12 MCU Timers.....	113
1.4.13 MCU Internal Diagnostics Modules.....	113
1.5 Device WKUP Domain.....	114
1.5.1 WKUP Device Management and Security Controller.....	115
1.5.2 WKUP General Purpose Input/Output Interface.....	115
1.5.3 WKUP Inter-Integrated Circuit Interface.....	115
1.5.4 WKUP Universal Asynchronous Receiver/Transmitter.....	116
1.5.5 WKUP Internal Diagnostics Modules.....	116
1.6 Device Identification.....	117
<b>2 Memory Map.....</b>	<b>118</b>
2.1 MAIN Domain Memory Map.....	119
2.2 MCU Domain Memory Map.....	173
2.3 WKUP Domain Memory Map.....	177
2.4 Processors View Memory Map.....	178
2.5 Region-based Address Translation.....	179
<b>3 System Interconnect.....</b>	<b>181</b>
3.1 System Interconnect Overview.....	182
3.2 System Interconnect Integration.....	184
3.2.1 Interconnect Integration in WKUP Domain.....	184
3.2.2 Interconnect Integration in MCU Domain.....	185
3.2.3 Interconnect Integration in MAIN Domain.....	186
3.3 System Interconnect Functional Description.....	189
3.3.1 Master-Slave Connections.....	189
3.3.2 Quality of Service (QoS).....	221
3.3.3 Route ID.....	226
3.3.4 Initiator-Side Security Controls and Firewalls.....	227
3.3.5 VBUSM_TIMEOUT_GASKET (MCU_TIMEOUT_64B2).....	251
<b>4 Initialization.....</b>	<b>269</b>
4.1 Initialization Overview.....	270
4.1.1 ROM Code Overview.....	270
4.1.2 Bootloader Modes.....	271
4.1.3 Terminology.....	271
4.2 Boot Process.....	273
4.2.1 MCU ROM Code Architecture.....	273
4.2.2 DMSC ROM Description.....	274
4.2.3 Boot Process Flow.....	274
4.2.4 MCU Only vs Normal Boot.....	277
4.3 Boot Mode Pins.....	279
4.3.1 MCU_BOOTMODE Pin Mapping.....	280
4.3.2 BOOTMODE Pin Mapping.....	282
4.3.3 No-boot/Dev-boot Configuration.....	284
4.3.4 OSPI Boot Device Configuration.....	285
4.3.5 xSPI Boot Device Configuration.....	285
4.3.6 QSPI Boot Device Configuration.....	290
4.3.7 SPI Boot Device Configuration.....	291
4.3.8 I2C Boot Device Configuration.....	292
4.3.9 MMC/SD Card Boot Device Configuration.....	293
4.3.10 Ethernet Boot Device Configuration.....	294
4.3.11 USB Boot Device Configuration.....	296
4.3.12 PCIe Boot Device Configuration.....	297
4.3.13 UART Boot Device Configuration.....	298
4.3.14 GPMC NOR Boot Device Configuration.....	299
4.3.15 eMMC Boot Device Configuration.....	303
4.3.16 PLL Configuration.....	304
4.4 Boot Parameter Tables.....	306

4.4.1 Common Header.....	306
4.4.2 PLL Setup.....	307
4.4.3 PCIe Boot Parameter Table.....	308
4.4.4 I2C Boot Parameter Table.....	308
4.4.5 OSPI/QSPI/SPI/xSPI Boot Parameter Table.....	309
4.4.6 GPMC NOR Boot Parameter Table.....	311
4.4.7 Ethernet Boot Parameter Table.....	311
4.4.8 USB Boot Parameter Table.....	313
4.4.9 MMCSD Boot Parameter Table.....	313
4.4.10 UART Boot Parameter Table.....	314
4.5 Boot Image Format.....	315
4.5.1 Overall Structure.....	315
4.5.2 X.509 Certificate.....	315
4.5.3 Organizational Identifier (OID).....	315
4.5.4 X.509 Extensions Specific to Boot.....	316
4.5.5 Generating X.509 Certificates.....	316
4.5.6 Image Data.....	318
4.6 Boot Modes.....	319
4.6.1 I2C Bootloader Operation.....	319
4.6.2 SPI Bootloader Operation.....	319
4.6.3 QSPI Bootloader Operation.....	320
4.6.4 OSPI Bootloader Operation.....	320
4.6.5 PCIe Bootloader Operation.....	320
4.6.6 GPMC NOR Bootloader Operation.....	320
4.6.7 Ethernet Bootloader Operation.....	321
4.6.8 USB Bootloader Operation.....	322
4.6.9 MMCSD Bootloader Operation.....	323
4.6.10 UART Bootloader Operation.....	323
4.7 Boot Memory Maps.....	325
4.7.1 Memory Layout/MPU.....	325
4.7.2 Global Memory Addresses Used by ROM Code.....	325
4.7.3 Memory Reserved by ROM Code.....	326
<b>5 Device Configuration.....</b>	<b>327</b>
5.1 Control Module (CTRL_MMR).....	328
5.1.1 WKUP_CTRL_MMR0.....	329
5.1.2 MCU_CTRL_MMR0.....	337
5.1.3 CTRL_MMR0.....	344
5.2 Power.....	360
5.2.1 Power Management Overview.....	360
5.2.2 Power Management Subsystems.....	361
5.2.3 Device Power States.....	441
5.2.4 Dynamic Power Management.....	459
5.2.5 Thermal Management.....	461
5.3 Reset.....	462
5.3.1 Reset Overview.....	462
5.3.2 Reset Sources.....	463
5.3.3 Reset Status.....	464
5.3.4 Reset Control.....	464
5.3.5 BOOTMODE Pins.....	465
5.3.6 Reset Sequences.....	466
5.3.7 PLL Behavior on Reset.....	470
5.4 Clocking.....	472
5.4.1 Overview.....	472
5.4.2 Clock Inputs.....	474
5.4.3 Clock Outputs.....	476
5.4.4 Device Oscillators.....	479
5.4.5 PLLs.....	482
<b>6 Processors and Accelerators.....</b>	<b>508</b>
6.1 Compute Cluster.....	509
6.1.1 Compute Cluster Overview.....	509
6.1.2 Compute Cluster Functional Description.....	510

6.2 Dual-A72 MPU Subsystem.....	517
6.2.1 A72SS Overview.....	517
6.2.2 A72SS Integration.....	519
6.2.3 A72SS Functional Description.....	521
6.3 Dual-R5F MCU Subsystem.....	531
6.3.1 R5FSS Overview.....	531
6.3.2 R5FSS Integration.....	534
6.3.3 R5FSS Functional Description.....	543
6.4 C66x DSP Subsystem.....	563
6.5 C71x DSP Subsystem.....	598
6.5.1 C71SS Overview.....	598
6.5.2 C71SS Integration.....	601
6.5.3 C71SS Functional Description.....	602
6.6 Graphics Accelerator (GPU).....	609
6.6.1 GPU Overview.....	609
6.6.2 GPU Integration.....	611
6.6.3 GPU Functional Description.....	614
6.7 Multi-Standard HD Video Decoder (DECODER).....	616
6.7.1 DECODER Overview.....	616
6.7.2 DECODER Integration.....	618
6.7.3 DECODER Functional Description.....	620
6.8 Multi-Standard HD Video Encoder (ENCODER).....	621
6.8.1 ENCODER Overview.....	621
6.8.2 ENCODER Integration.....	623
6.8.3 ENCODER Functional Description.....	625
6.9 Vision Pre-processing Accelerator (VPAC).....	626
6.9.1 VPAC Overview.....	626
6.9.2 VPAC Integration.....	630
6.9.3 VPAC Subsystem Level.....	633
6.9.4 VPAC Vision Imaging Subsystem (VISS).....	644
6.9.5 VPAC Lens Distortion Correction (LDC) Module.....	719
6.9.6 VPAC Multi-Scaler (MSC).....	743
6.9.7 VPAC Noise Filter (NF).....	765
6.10 Depth and Motion Perception Accelerator (DMPAC).....	779
6.10.1 DMPAC Overview.....	779
6.10.2 DMPAC Integration.....	782
6.10.3 DMPAC Functional Description.....	785
6.10.4 DMPAC Programming Guide.....	805
<b>7 Interprocessor Communication.....</b>	<b>813</b>
7.1 Mailbox.....	814
7.1.1 Mailbox Overview.....	814
7.1.2 Mailbox Integration.....	815
7.1.3 Mailbox Functional Description.....	819
7.1.4 Mailbox Programming Guide.....	823
7.2 Spinlock.....	825
7.2.1 Spinlock Overview.....	825
7.2.2 Spinlock Integration.....	826
7.2.3 Spinlock Functional Description.....	827
7.2.4 Spinlock Programming Guide.....	829
<b>8 Memory Controllers.....</b>	<b>831</b>
8.1 Multicore Shared Memory Controller (MSMC).....	832
8.1.1 MSMC Overview.....	832
8.1.2 MSMC Integration.....	834
8.1.3 MSMC Functional Description.....	837
8.2 DDR Subsystem (DDRSS).....	848
8.2.1 DDRSS Overview.....	848
8.2.2 DDRSS Environment.....	851
8.2.3 DDRSS Integration.....	856
8.2.4 DDRSS Functional Description.....	859
8.3 Virtualization Subsystem (VirtSS).....	902
8.3.1 VirtSS Overview.....	903

8.3.2 Peripheral Virtualization Unit (PVU).....	916
8.3.3 Page Based Address Translation Unit (PAT).....	924
8.4 Region-based Address Translation (RAT) Module.....	930
8.4.1 RAT Functional Description.....	930
<b>9 Interrupts</b> .....	933
9.1 Interrupt Architecture.....	934
9.2 Interrupt Controllers.....	936
9.2.1 Generic Interrupt Controller (GIC).....	936
9.2.2 Cluster Level Event Controller (CLEC).....	944
9.2.3 Other Interrupt Controllers.....	953
9.3 Interrupt Routers.....	954
9.3.1 INTRTR Overview.....	954
9.3.2 INTRTR Integration.....	955
9.4 Interrupt Sources.....	966
9.4.1 WKUP Domain Interrupt Maps.....	966
9.4.2 MCU Domain Interrupt Maps.....	973
9.4.3 MAIN Domain Interrupt Maps.....	991
<b>10 Data Movement Architecture (DMA)</b> .....	1119
10.1 DMA Architecture.....	1120
10.1.1 Overview.....	1120
10.1.2 DMA Hardware/Software Interface.....	1129
10.1.3 Operational Description.....	1165
10.2 Navigator Subsystem (NAVSS).....	1186
10.2.1 Main Navigator Subsystem (NAVSS).....	1187
10.2.2 MCU Navigator Subsystem (MCU NAVSS).....	1203
10.2.3 Unified DMA Controller (UDMA).....	1212
10.2.4 Ring Accelerator (RINGACC).....	1228
10.2.5 Proxy.....	1241
10.2.6 Secure Proxy.....	1247
10.2.7 Interrupt Aggregator (INTR_AGGR).....	1254
10.2.8 Packet Streaming Interface Link (PSI-L).....	1262
10.2.9 PSIL Subsystem (PSILSS).....	1267
10.2.10 NAVSS North Bridge (NB).....	1271
10.3 Peripheral DMA (PDMA).....	1276
10.3.1 PDMA Controller.....	1276
10.3.2 PDMA Sources.....	1297
10.4 Data Routing Unit (DRU).....	1307
10.4.1 DRU Overview.....	1307
10.4.2 DRU Integration.....	1309
10.4.3 DRU Functional Description.....	1312
<b>11 Time Sync</b> .....	1320
11.1 Time Sync Module (CPTS).....	1321
11.1.1 CPTS Overview.....	1321
11.1.2 CPTS Integration.....	1323
11.1.3 CPTS Functional Description.....	1325
11.2 Timer Manager.....	1332
11.2.1 Timer Manager Overview.....	1332
11.2.2 Timer Manager Integration.....	1334
11.2.3 Timer Manager Functional Description.....	1335
11.2.4 Timer Manager Programming Guide.....	1338
11.3 Time Sync and Compare Events.....	1340
11.3.1 Time Sync Architecture.....	1340
11.3.2 Time Sync Routers.....	1342
11.3.3 Time Sync Event Sources.....	1356
<b>12 Peripherals</b> .....	1366
12.1 General Connectivity Peripherals.....	1367
12.1.1 Analog-to-Digital Converter (ADC).....	1367
12.1.2 General-Purpose Interface (GPIO).....	1386
12.1.3 Inter-Integrated Circuit (I2C) Interface.....	1408
12.1.4 Improved Inter-Integrated Circuit (I3C) Interface.....	1445
12.1.5 Multichannel Serial Peripheral Interface (MCSPI).....	1472

12.1.6 Universal Asynchronous Receiver/Transmitter (UART).....	1534
12.2 High-speed Serial Interfaces.....	1614
12.2.1 Gigabit Ethernet MAC (MCU_CPSW0).....	1615
12.2.2 Gigabit Ethernet Switch (CPSW0).....	1716
12.2.3 Peripheral Component Interconnect Express (PCIe) Subsystem.....	1829
12.2.4 Universal Serial Bus (USB) Subsystem.....	1874
12.2.5 2-L Serializer/Deserializer (SerDes).....	1890
12.2.6 4-L Serializer/Deserializer (SerDes).....	1910
12.3 Memory Interfaces.....	1920
12.3.1 Flash Subsystem (FSS).....	1921
12.3.2 Octal Serial Peripheral Interface (OSPI).....	1933
12.3.3 HyperBus Interface.....	1966
12.3.4 General-Purpose Memory Controller (GPMC).....	1978
12.3.5 Error Location Module (ELM).....	2088
12.3.6 Multimedia Card Secure Digital (MMCSD) Interface.....	2102
12.3.7 Universal Flash Storage (UFS) Interface.....	2189
12.4 Industrial and Control Interfaces.....	2212
12.4.1 Enhanced Capture (ECAP) Module.....	2212
12.4.2 Enhanced Pulse Width Modulation (EPWM) Module.....	2245
12.4.3 Enhanced Quadrature Encoder Pulse (EQEP) Module.....	2337
12.4.4 Controller Area Network (MCAN).....	2369
12.5 Audio Interfaces.....	2435
12.5.1 Audio Tracking Logic (ATL).....	2436
12.5.2 Multichannel Audio Serial Port (MCASP).....	2438
12.6 Display Subsystem (DSS) and Peripherals.....	2513
12.6.1 DSS Overview.....	2513
12.6.2 DSS Environment.....	2520
12.6.3 DSS Integration.....	2533
12.6.4 Display Subsystem Controller (DISPC) with Frame Buffer Decompression Core (FBDC).....	2545
12.6.5 MIPI Display Serial Interface (DSI) Controller.....	3162
12.6.6 Embedded DisplayPort (eDP) Transmitter.....	3225
12.7 Camera Subsystem.....	3254
12.7.1 Camera Streaming Interface Receiver (CSI_RX_IF).....	3255
12.7.2 MIPI D-PHY Receiver (DPHY_RX).....	3283
12.7.3 Camera Streaming Interface Transmitter (CSI_TX_IF).....	3297
12.8 Shared MIPI D-PHY Transmitter (DPHY_TX).....	3317
12.8.1 DPHY_TX Subsystem Overview.....	3317
12.8.2 DPHY_TX Environment.....	3319
12.8.3 DPHY_TX Integration.....	3322
12.9 Video Processing Front End (VPFE).....	3324
12.9.1 VPFE Overview.....	3324
12.9.2 VPFE Environment.....	3326
12.9.3 VPFE Integration.....	3328
12.9.4 VPFE Functional Description.....	3331
12.10 Timer Modules.....	3354
12.10.1 Global Timebase Counter (GTC).....	3354
12.10.2 Windowed Watchdog Timer (WWDT).....	3359
12.10.3 Timers.....	3378
12.11 Internal Diagnostics Modules.....	3430
12.11.1 Dual Clock Comparator (DCC).....	3430
12.11.2 Error Signaling Module (ESM).....	3481
12.11.3 Memory Cyclic Redundancy Check (MCRC) Controller.....	3505
12.11.4 ECC Aggregator.....	3521
<b>13 On-Chip Debug.....</b>	<b>3529</b>
13.1 Introduction to SoC Debug Framework.....	3530
<b>Revision History.....</b>	<b>3532</b>

## Export Control Notice

Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from disclosing party under nondisclosure obligations (if any), or any direct product of such technology, to any destination to which such export or re-export

is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorization from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws.

This chapter introduces the features, subsystems, and architecture of the J721E Family of high-performance Systems-on-Chip (SoC).

---

**Note**

This document describes the superset architecture, processors and peripherals of the J721E DRA829/TDA4VM SoCs, which are part of the K3 Multicore SoC architecture platform. Not all features are available on each family of devices. The superset J721E device is available for preproduction software development. Software should constrain the features used to match the intended production device. For more information on the specific features, processors and peripherals available on a particular device, refer to the Device Comparison table in the corresponding device-specific Datasheet.

The DRA829/TDA4VM processors are hereinafter commonly referred to as *device* or *SoC*.

TI limits support for this family of SoCs to features that are supported via Software Development Kits (SDK). The SDK “build sheet” is available for download as part of each SDK and should be referenced to understand the subset of SoC hardware functionality that is available in software:

## 1.1 Device Overview

The DRA829 and TDA4VM SoCs are part of the K3 Multicore SoC architecture platform. The SoCs are targeted for automotive applications and aim to meet the complex processing needs of modern embedded products.

They are designed as a low power, high performance and highly integrated device architecture, adding significant enhancement on processing power, graphics capability, video and imaging processing, virtualization and coherent memory support. In addition, these SoCs support state of the art security and functional safety features.

Some of the main distinguished characteristics of the device are:

- 64-bit architecture with virtualization and coherent memory support, which leverages full processing capability of 64-bit Arm® Cortex®-A72
- Fully programmable industrial communication subsystems to enable future-proof designs for customers that need to adopt the new Gigabit Time-sensitive Networks (TSN) standards, but still need full support on legacy protocols and continuous system optimization over the product deployment
- Integration of vision hardware processing accelerators to facilitate extensive processing requirements in low power budget for automotive ADAS and machine vision applications
- Integration of a general-purpose microcontroller unit (MCU) with a dual Arm® Cortex®-R5F MCU subsystem, available for general purpose use as two cores or in lockstep, intended to help customers achieve functional safety goals for their end products
- Integration of a next-generation fixed and floating-point C71x Digital Signal Processor (DSP) that significantly boosts power over a broad range of general signal processing tasks for both general applications and automotive functions which also incorporates advanced techniques to improve control code efficiency and ease of programming such as branch prediction, protected pipeline, precise exception and virtual memory management
- Tightly coupled Matrix Multiplication Accelerator (MMA) that extends the C71x DSP architecture's scalar and vector facilities enabling deep learning and enhance vision, analytics and wide range of general applications. The achieved total TOPS (Tera Operations Per Second) performance significantly differentiates the device for single board computer in machine vision and deep learning applications
- Key display features including flexibility to interface with different panel types (eDP, DSI, DPI) with multi-layer hardware composition
- Integration of hardware features that help applications to achieve functional safety mechanisms
- Robust security architecture with sandboxed DMSC controller managing all secure configurations with high performance client-server messaging scheme between secure DMSC and all cores
- Simplified solution for power supply management, enabling lower cost system solution (on-die bias LDOs and power good comparators for minimal power sequencing requirements consistent with low cost supply design)

The device is composed of the following main subsystems, across different domains of the SoC, among others:

- One dual-core 64-bit Arm Cortex-A72 microprocessor subsystem at up to 2.0 GHz and up to 24K DMIPS (Dhrystone Million Instructions per Second)
- Up to three Microcontroller Units (MCU), based on dual-core Arm Cortex-R5F processor running at up to 1.0 GHz, up to 12K DMIPS
- Up to two TMS320C66x DSP CorePac modules running at up to 1.35 GHz, up to 40 GFLOPS
- One C71x floating point, vector DSP running at up to up to 1.0 GHz, up to 80 GFLOPS
- One deep-learning MMA, up to 8 TOPS (8b) at 1.0 GHz
- Up to two gigabit dual-core Programmable Real-Time Unit and Industrial Communication Subsystems (PRU\_ICSSG)
- Two Navigator Subsystems (NAVSS) for data movement and control
- One multi-pipeline Display Subsystem (DSS) with one MIPI® Display Serial Interface Controller (DSI) and shared MIPI D-PHY Transmitter (DPHY\_TX), one Embedded DisplayPort Transmitter (EDP) with shared Serializer/Deserializer (SERDES), and two MIPI Display Pixel Interface (DPI) ports
- Two Camera Streaming Interface Receivers (CSI\_RX\_IF) with dedicated MIPI D-PHYs (DPHY\_RX)
- One Camera Streaming Interface Transmitter (CSI\_TX\_IF) with MIPI D-PHY Transmitter (DPHY\_TX) shared with DSI

- One Vision Processing Accelerator (VPAC) with image signal processor
- One Depth and Motion Processing Accelerator (DMPAC)
- One dual-core multi-standard HD Video Decoder (DECODER)
- One dual-core multi-standard HD Video Encoder (ENCODER)
- One Graphics Processing Unit (GPU)
- One Device Management and Security Controller (DMSC)

The device provides a rich set of peripherals such as:

- General connectivity peripherals, including:
  - Two 12-bit general purpose Analog-to-Digital Converters (ADC)
  - Ten Inter-Integrated Circuit (I2C) interfaces
  - Three Improved Inter-Integrated Circuit (I3C) controllers
  - Eleven master/slave Multichannel Serial Peripheral Interfaces (MCSPI)
  - Twelve configurable Universal Asynchronous Receiver/Transmitter (UART) interfaces
  - Ten General-Purpose Input/Output (GPIO) modules
- High-speed interfaces, including:
  - Two Gigabit Ethernet Switch (CPSW) modules
  - Two Dual-Role-Device (DRD) Universal Serial Bus Subsystems (USBSS) with integrated PHY
  - Four Peripheral Component Interconnect express (PCIe) Gen3 subsystems
- Flash memory interfaces, including:
  - One Octal SPI (OSPI) interface and one Quad SPI (QSPI) or one QSPI and one HyperBus™
  - One General Purpose Memory Controller (GPMC) with Error Location Module (ELM) and 8- or 16-bit-wide data bus width (supports parallel NOR or NAND FLASH devices)
  - Three Multimedia Card/Secure Digital (MMCSD) controllers
  - One Universal Flash Storage (UFS) interface
- Industrial and control interfaces, including:
  - Sixteen Controller Area Network (MCAN) interfaces with flexible data rate support
  - Three Enhanced Capture (ECAP) modules
  - Six Enhanced Pulse-Width Modulation (EPWM) subsystems
  - Three Enhanced Quadrature Encoder Pulse (EQEP) modules
- Audio peripherals, including:
  - One Audio Tracking Logic (ATL)
  - Twelve Multichannel Audio Serial Port (MCASP) modules supporting up to 16 channels with independent TX/RX clock/sync domain
- One Video Processing Front End (VPFE) interface module

The device also integrates:

- Power distribution, reset controls and clock management components
- Power-management techniques for device power consumption minimization:
  - Adaptive Voltage Scaling (AVS)
  - Dynamic Frequency Scaling (DFS)
  - Gated clocks
  - Multiple voltage domains
  - Independently controlled power domains for major modules
  - Voltage and Temperature Management (VTM) module
  - Power-on Reset Generators (PRG)
  - Power Sleep Controllers (PSC)
- Optimized interconnect (CBASS) architecture to enable latency-critical real time network and IO applications
- Control modules (CTRL\_MMRs) mainly associated with device top-level configurations such as:
  - IO Pad and pin multiplexing configuration
  - PLL control and associated High-Speed Dividers (HSDIV)
  - Clock selection
  - Analog function controls

- Multicore Shared Memory Controller (MSMC)
- DDR Subsystem (DDRSS) with Error Correcting Code (ECC), supporting LPDDR4
- 1KB RAM with ECC support for C71x boot vectors
- 2KB RAM with ECC support for A72 and R5F boot vectors
- 512KB On-Chip SRAM protected by ECC
- One Global Time Counter (GTC) module
- Thirty 32-bit counter timers with compare and capture modes
- Debug and trace capabilities

The device includes different modules for functional safety requirements support:

- MCU island with dual lock step Arm Cortex-R5F
- Safety enabled interconnect with implemented features to help with Freedom From Interference (FFI)
- Twelve Real Time Interrupt (RTI) modules with Windowed Watchdog Timer (WWDT) functionality to monitor processor cores
- Sixteen Dual-Clock Comparators (DCC) to monitor clocking sources during run-time
- Three Error Signaling Modules (ESM) to enable error monitoring
- Temperature monitoring sensors
- ECC on all critical memories
- Dedicated hardware Memory Cyclic Redundancy Check (MCRC) blocks

The device supports the following main security functionalities among others:

- Secure Boot Management
- Public Key Accelerator (PKA) for large vector math operation
- Cryptographic acceleration (AES, 3DES, MD5, SHA1, SHA2-224, 256, 512 operation)
- Trusted Execution Environment (TEE)
- Secure storage support
- On-the-fly encryption and authentication support for OSPI interface

The device is partitioned into three functional domains, each containing specific processing cores and peripherals:

- Wake-up (WKUP) domain
- Microcontroller (MCU) domain
- MAIN domain

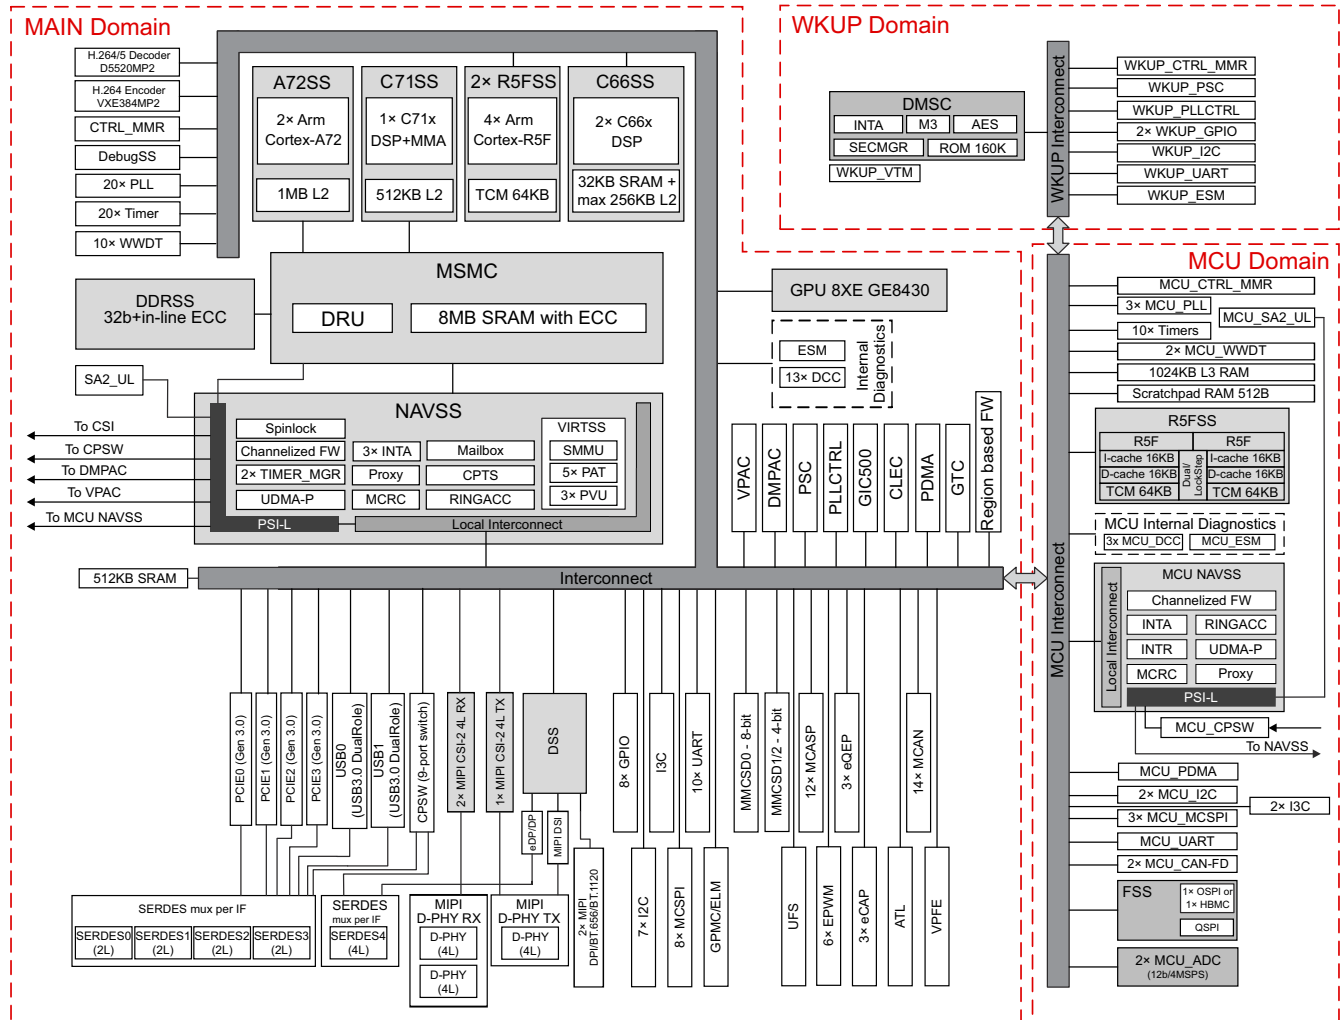

This domain fragmentation enables the device to achieve lower power dissipation profiles by allowing the power supplies to unused domains to be completely turned off and allows efficient addressing of safety requirements.

### Note

The MCU and WKUP domains are combined into a common MCU/WKUP domain in this family of devices, but for compatibility with other K3 platform SoCs, the domain naming and separation are maintained throughout this document (where applicable).

### Note

The supported set of features and peripherals is device part number dependent. For more information, see the device-specific Datasheet.

## 1.3 Device Main Domain

This section describes the modules integrated in the device MAIN domain.

[Figure 1-2](#) is a block diagram of the device MAIN domain.

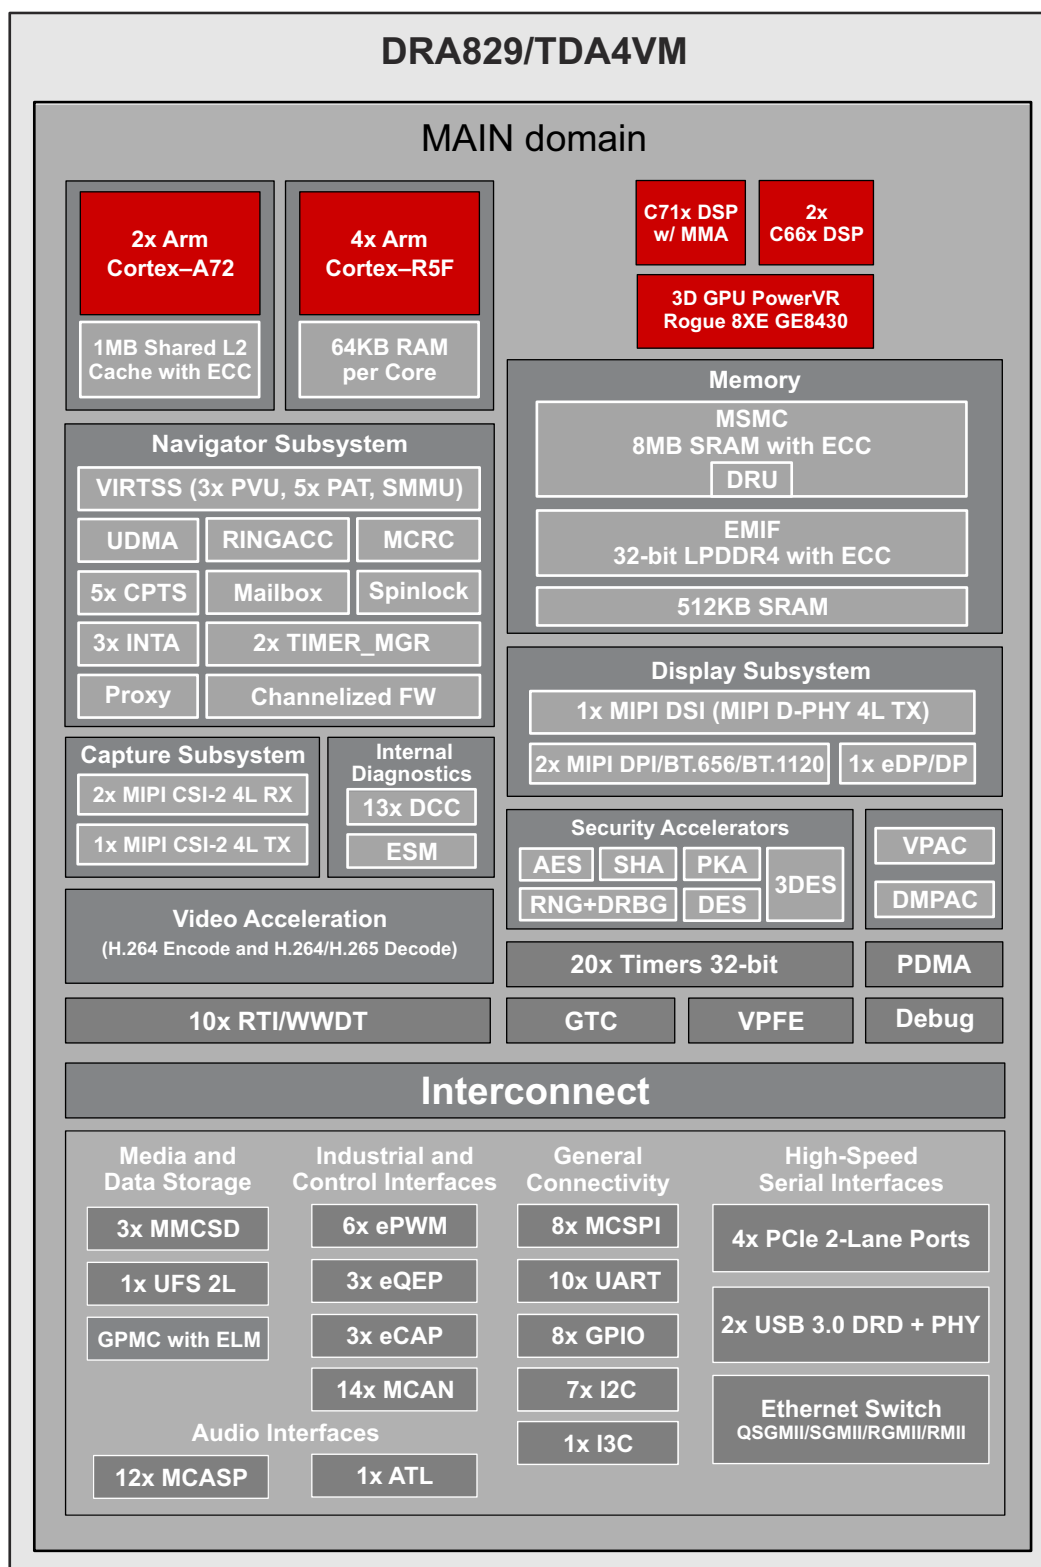

Figure 1-2. Device Main Domain Block Diagram

### Note

The supported set of features and peripherals is device part number dependent. For more information, see the device-specific Datasheet.

#### 1.3.1 Arm Cortex-A72 Subsystem

The SoC implements one dual-core Arm Cortex-A72 Microprocessor Unit (MPU). Each core has the following main features:

- Full Armv8-A architecture compliancy
- Advanced Single Instruction Multiple Data (SIMD) and floating point extension (Arm Neon™)
- Armv8 Cryptography Extensions
- Superscalar, variable length, out-of-order pipeline
- 48KB program and 32KB data Level 1 (L1) Cache
- 1MB shared Level 2 (L2) Cache
- ECC protection for L1 data cache and L2 Cache
- Parity protection for L1 Instruction Cache
- Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB) RAMs, return stack, and indirect predictor
- Arm General Interrupt Controller (GICv3) architecture
- Support for up to four timers within each Cortex-A72 core
- 512-bit wide, synchronous or asynchronous VBUSM.C master interface
- Arm CoreSight™ Debug and Trace Architecture
- Advanced power management for low power optimization
- SoC level dedicated RTI windowed watchdog timer per core

#### 1.3.2 Arm Cortex-R5F Processor

Integrated in MAIN domain are two instances of the dual-core Arm Cortex-R5F processor. Each dual-core instance supports the following main features:

- Armv7-R architecture
- Two modes of operation, boot-time configurable:
  - Split mode: two independently operating cores (Asymmetric Multi Processing, no coherence)
  - Lock (lockstep) mode: one main operating core with the other operating in lockstep
- 16KB instruction and 16KB data SECDED ECC protected L1 cache per core in split mode
- 64KB of Tightly Coupled Memory (TCM) per core
- Full-Precision Floating Point (VFPv3)
- 8 breakpoints, 8 watch points
- 16-region Memory Protection Unit (MPU)
- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface
- Performance Monitoring Unit (PMU)
- 32-bit to 48-bit Region-based Address Translation (RAT) on memory access masters
- Integrated Vectored Interrupt Manager (VIM)
- Interfaces:
  - 64-bit VBUSM master pair (1 read, 1 write) for L3 memory accesses (per core)
  - 64-bit VBUSM slave for TCM access (per core)
  - 32-bit VBUSM master pair (1 read, 1 write) for peripheral access
  - 32-bit VBUSP master for peripheral access (per core)
  - 32-bit VBUSP slave configuration port (per core)
  - 32-bit VBUSP slave debug port

#### 1.3.3 C66x DSP Subsystem

Integrated in MAIN domain are two instances of C66x DSP based on the TI's standard TMS320C66x DSP CorePac module. Each C66x DSP supports the following main features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program memory controller (PMC) with 32KB L1 program memory (L1P), configurable as cache and/or SRAM
- Data memory controller (DMC) with 32KB L1 data memory (L1D), configurable as cache and/or SRAM
- Unified memory controller (UMC) with 288KB L2 memory, only part of which is cacheable
- Internal DMA (IDMA) engine
- External memory controller (EMC)
- Extended memory controller (XMC)
- Address extension/translation (32-bit to 48-bit)
- Memory protection for multiple segments and all internal L1/L2 RAMs
- Error detection and correction
- Integrated C66x CorePac interrupt controller (INTC)
- Debug/emulation capabilities

---

### Note

The C66x L1P memory is disabled (not supported) in this device.

---

## 1.3.4 C71x DSP Subsystem

Integrated single instance of C71x DSP supports the following main features:

- True 64-bit C71x CPU core with:
  - Instruction fetch unit
  - Instruction dispatch unit
  - Instruction decode unit
  - CPU dual data path with one 64-bit scalar side (side A) and one 512-bit vector side (side B)
  - CPU control logic
  - Test, debug, and interrupt logic
  - Enhanced Instruction Set Architecture (ISA)
  - OpenCL features
- Matrix Multiply Accelerator (MMA) as a special functional unit in C71x CorePac CPU
- L1 Program Memory Controller (PMC) with 32KB L1P memory, all cache
- L1 Data Memory Controller (DMC) with 48KB L1D memory, configurable as cache and/or SRAM
- L2 Unified Memory Controller (UMC) with 512KB L2 memory, configurable as cache and/or SRAM
- Multi-dimensional Streaming Engine (SE) - flexible, high bandwidth mechanism for reading large quantities of data into C71x DSP
- CorePac Memory Management Unit (CMMU)
- Power-down controller
- Debug capabilities

## 1.3.5 Graphics Processing Unit

Integrated in MAIN domain is one instance of Graphics Processing Unit (GPU) which accelerates 2-Dimensional (2D) and 3-Dimensional (3D) graphics and compute applications. It supports the following main features:

- Single core architectures based on PowerVR® Series8XE GE8430 with shared system level cache of 64KB
- Tile-based deferred rendering architecture
- Multi-threaded Unified Shading Cluster (USC) engines incorporating pixel, vertex and compute shader functionality
- Fully virtualized memory addressing for OS operation in a unified memory architecture (up to 64 GB physical address space and 1 TB virtual address space)
- PowerVR Texture Compression
- Advanced DMA driven operation for minimum host CPU interaction

- Support of Frame Buffer Compression (FBC) and Frame Buffer Compression Decompression (FBDC) features
- Programmable high-quality image anti-aliasing
- Hardware virtualization and hardware security
- API Support: RenderScript

### 1.3.6 Multi-Standard HD Video Decoder

Integrated in MAIN domain dual-core multi-standard HD Video Decoder (DECODER) is based on D5520MP2 PowerVR VPU (video processor unit). It has the following main features, among others:

- Decoding support of:
  - 1x 4Kp60 or
  - 2x 4Kp30 or
  - 4x 1080p60 or
  - 8x 1080p30
- Decoding formats supported:
  - H.265
  - H.264
  - WMV-9
  - VC-1
  - MPEG-2
  - H.263
  - DivX
  - AVC
  - RealVideo
  - VP8
  - VP6
  - Sorenson
  - JPEG
- Hardware scaling
- Rotation support: 90°, 180° and 270°
- Support of secure playback

### 1.3.7 Multi-Standard HD Video Encoder

Integrated in MAIN domain dual-core multi-standard HD Video Encoder (ENCODER) is based on VXE384MP2 PowerVR VPU (video processor unit). It has the following main features, among others:

- Encoding support of:
  - 1x 1080p60 video stream encoding or
  - 2x or 3x 1080p30 video stream encodings
- Encoding formats supported:
  - H.264 MVC
  - H.264 HP
  - H.264 MP
  - H.264 BP
  - MPEG-4 SP
  - H.263 BP
  - Still images in MPEG2 MP
  - Still images in JPEG
- Support of multiple slices per frame (H.264) under software control
- Search range of +/-128 horizontally and +/-104 vertically
- Integrated scaler
- Dedicated hardware support for
  - Integer motion estimation

- Sup-pel motion estimation
- Intra search
- Transform and inverse transform
- Quantization and inverse quantization
- Motion vector prediction and estimation
- Zigzag Scan, Run Length and Variable Length Encoding

### 1.3.8 Vision Pre-processing Accelerator

The Vision Pre-processing Accelerator (VPAC) provides a set of common vision primitive functions, performing various pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation, and offloads these common tasks from the main SoC processors (ARM, DSP, etc.). The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS) which provides raw data image processing such as:
  - Wide Dynamic Range (WDR) merge
  - Defect Pixel Correction (DPC)
  - Lens Shading Correction (LSC)
  - Global/Local Brightness and Contrast Enhancement (GLBCE)
  - Advanced Spatial Noise Filter (NSF4V)
  - Edge Enhancement (EE)
  - Demosaicing
  - Color conversion
- Lens Distortion Correction (LDC) block, which provides data reading from memory (DDR or on-chip) and applies perspective transformation as well as correction of lens distortion (including fisheye lenses).
- Multi-Scalar (MSC) block reads data from memory (DDR or on-chip) to internal shared level 2 (SL2) memory and generates up to 10 scaled outputs from one or two inputs, with various scaling ratios.
- Noise Filter (NF) block reads data from memory (DDR or on-chip) to internal SL2 memory and does Bilateral filtering to remove noise.
- Hardware Thread Scheduler (HTS) provides inter-processor communication among various VPAC sub-modules (VISS, LDC, MSC and NF) as well as with the local DMA Engine (UTC).
- Internal Shared Level 2 (SL2) memory for data exchange across VPAC sub-modules (VISS, LDC, MSC and NF) and from DDR/MSMC, using the K3 Data Movement Architecture (DMA) mechanism
- Load/Store Engine (LSE) which performs data load and store tasks on a the SL2 memory for the hardware accelerator algorithm cores

### 1.3.9 Depth and Motion Perception Accelerator

The Depth and Motion Perception Accelerator (DMPAC) computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common local memory, DMA, external messaging and control infrastructure. The DMPAC provides the following main features, among others:

- Image resolution up to 2MPix (maximum horizontal resolution up to 2048 pixels; maximum vertical resolution up to 1024 pixels)
- Maximum throughput up to 220MPix/sec for DOF, and up to 84-100MPix/sec for SDE
- Simultaneous operation of Stereo (1MPix@30fps) and Optical flow (1MP@30fps)
- 12-bit fully packed luminance data input pixel data format (other formats supported through conversion)
- Packed 16-bit (disparity) or 32-bit (flow vector) output data formats
- Shared Level 2 (SL2) memory sub-system, which serves the data transfer of the DOF and SDE blocks
- Unified Transfer Controller (UTC), which serves as a DMA engine
- Hardware Thread Scheduler (HTS) block for messaging and control mechanism
- Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the Stereo and Optical Flow hardware threads

### 1.3.10 Navigator Subsystem

Instantiated in the MAIN domain one Navigator subsystem named NAVSS can be used for efficient transfer of data support between software, firmware and hardware in all combinations. It consists of the following main modules:

- Unified DMA Controller with the following main modes and features:
  - K3 DMA Architecture compliant Tx/Rx port implementation
  - K3 DMA Architecture compliant Packet-Oriented DMA Functionality (UDMA-P)
  - K3 DMA Architecture compliant Third Party Channel Controller
  - K3 DMA Architecture compliant Unified Transfer Controller
  - K3 DMA Architecture compliant Unified DMA channels which all share the execution hardware using time division multiplexing
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
  - Supports 1024 independent memory-mapped ring structures
  - Supports various modes for each ring based on usage and compatibility
  - Provides single-word deep shared incoming Transfer Response FIFO
  - Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities
- Proxy module with the following main features:
  - Provides proxy buffers to store large data bursts that a host can only access in smaller amounts
  - Keeps the large data coherent until the complete data has been accessed
  - Allows interleaved access between multiple hosts using multiple proxies
  - Supports a pre-configured number of target resources to proxy with pre-configured number of channels, size of each channel, and address offset per each target
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
  - Supports a number of threads, where each has their own independent proxy function
  - Supports a programmable fixed queue for each proxy thread
  - Supports multiple producers all writing to the same queue
  - Supports programmable thresholds for when to generate events
  - Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Interrupt Aggregator modules provide a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
  - 64-bit VBUSP slave using 64-bit registers
  - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Provide a set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
  - Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Provides a set of GEVI 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces
- Virtualization Subsystem hardware modules with the following main features and blocks:
  - Implements all virtualization translation components
  - Implements NAVSS connectivity between Accelerator Cluster (AC), peripherals Module Subsystem (MODSS), Unified DMA (UDMA-P), and North Bridge (NB) ports
  - Supports 5 Page-based Address Translation (PAT) modules and their configuration
  - Supports 3 PVUs and their configuration
  - Supports 1 Arm SMMUv3 Translation Buffer Unit (TBU) and its configuration
  - Supports Arm SMMUv3 Translation Control Unit (TCU)
  - Supports external Arm AMBA® Distributed Translation Interface (DTI) connections

- Supports SMMU DTI interconnect
- Bridges all ARM AXI or APB interfaces to CBA VBUSM and VBUSP busses
- Peripheral Virtualization Unit module which provides TLBs (Translation Look-aside Buffers) for static virtual address translation on a CBA VBUSM bus with the following main features:
  - Implements a channelized TLB for virtual address translation
  - Supports a pre-configured number of entries per TLB channel
  - Supports TLB chaining to extend the search but at a latency penalty
  - Supports a 48-bit address size
  - Supports page sizes of 4KB, 16KB, 64KB, 2MB, 32MB, 512MB, 1GB, and 16GB
  - Support TLBs in software mode, where they are maintained by software only
  - Produces a fault interrupt when the TLB misses or upon a permission error
- Page-based Address Translation unit which performs page-based address translation on a CBA VBUSM bus with the following main features:
  - Implements a VBUSM retiming bridge with page based address translation
  - Supports up to 16384 pages, each occupying a programmable 4-KB, 16-KB, 64-KB, or 1-MB of address space
  - Supports a 48-bit output address size
  - Allows fast programming of the table, or fast generic SRAM access when the table is disabled
  - Supports *transaction* ID re-assignment
- Mailbox module to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism with the following main features:
  - 12 clusters
  - 32-bit message width
  - Message reception and queue-not-full notification using interrupts
  - Non-intrusive emulation
- Spinlock module (256 hardware semaphores) for synchronizing the processes running on multiple processors in the device.
- Two Timer Manager modules to support timing operations for the processes running on multiple processors, each with the following main features:
  - 1024 × 32-bit RAM-based independent timers (2048 in total)
  - Event interface to an interrupt aggregation module in the NAVSS subsystem with events triggering when a timer expires or when an expired timer is reset or deactivated
  - Host access to determine which timer(s) expired
  - 32 registers with individual timeout status (one bit per timer)
  - Groups of 16 timers separated into pages of 4-K address space
  - Timer bits within each page to read expiration status for each timer when software only has access to that page
  - 10 μs time to cycle through all of the timers
  - Host access to reset individual timers
  - Periodic hardware timers – a timer may be set to automatically reprogram itself upon expiration without software intervention.
- Time Sync modules to facilitate host control of time sync operations, each with the following main features:
  - Supports a selection of multiple external clock sources
  - Software control of time sync events via interrupt or polling
  - Supports 8 hardware timestamp push inputs
  - Supports timestamp counter compare output
  - Supports timestamp counter bit output
  - Supports 6 timestamp generator function outputs
  - 32-bit and 64-bit timestamp modes
- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system with the following main features:
  - Four channels to perform background signature verification on any memory subsystem

- Data compression on 8-, 16-, 32-, and 64-bit data size
- Dedicated CRC value register per channel which contains the pre-determined CRC value
- Timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation: Auto, Semi-CPU, and Full-CPU
- Timeout interrupt generation if CRC is not performed within the time limit
- Per channel DMA request generation to initiate CRC value transfer

### 1.3.11 Region-based Address Translation Module

Integrated in MAIN domain thirteen instances of RAT module perform a region based address translation of a 32-bit input address into a 48-bit output address. Each RAT module provides the following main features:

- 16 regions with dedicated registers for attributes configuration:
  - Region base address
  - Region size
  - Translated base address
- Address translation for only enabled regions
- Region boundary crossing transactions error generation

### 1.3.12 Data Routing Unit

The Data Routing Unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests which enables performing of high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. It behaves like a DMA transfer controller, moving data at MPU frequency and has the following main features:

- Programmable configuration registers for direct transfer request submission
- Read and write command queues
- Programmable priority for each queue
- Two dedicated ports (one read and one write) to generate independent read and write commands
- Support for region based and channelized firewall
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
- Error detection and Correction

### 1.3.13 Display Subsystem

Instantiated in the MAIN domain Display Subsystem (DSS) is a flexible composition-enabled display subsystem that supports multiple high resolution display outputs. It consists of the following main modules:

- Display Controller (DISPC), with the following main features:
  - Support of multi-layer blending and transparency for each of display outputs
  - Supports write-back pipeline with scaling to enable memory-to-memory composition and/or to capture a display output for Ethernet video encoding
  - Supports gamma correction and programmable color control in both source and destination pipelines
  - Embedded DMA Controller with the following main features:
    - Support for 1D-only DMA transfers
    - Support for 48b addressable memory space
    - Support for memory fragmentation through external PAT at SoC level
    - Integrated shared buffer management for pipelines within the same DMA controller group
    - Programmable DMA requests management
    - Support for source image flip along X and Y-axis
    - Support for secure access to firewall protected frame buffer in DDR memory
  - Two input display processing Video Pipelines, each supporting:
    - Wide range of input RGB source pixel formats
    - Wide range of input YUV source pixel formats

- Programmable poly-phase filter (scaler)
- Programmable color space conversion
- Programmable Brightness/Contrast/Hue/Saturation
- Programmable Gamma Correction LUT
- Luma Key generation
- 10-bit processing pipeline
- Two input display processing Video Lite Pipelines, each supporting:
  - Wide range of input RGB source pixel formats
  - Wide range of input YUV source pixel formats
  - YUV420 to YUV422 chroma up-sampling using an average filter
  - YUV422 to YUV444 chroma up-sampling using a 4-tap filter based on Catmull-Rom algorithm
  - Programmable color space conversion
  - Programmable Brightness/Contrast/Hue/Saturation
  - Programmable Gamma Correction LUT
  - Luma Key generation
  - 10-bit processing pipeline
- One Write-back (WB) pipeline, supporting:
  - Wide range of destination RGB pixel formats
  - Wide range of destination YUV pixel formats
  - Programmable poly-phase filter (scaler)
  - Output capture and Memory-to-memory (M2M) operation modes
- Four Overlay Managers (OVR), each supporting:
  - Input pixel format: ARGB48-12121212
  - Output pixel format: ARGB48-12121212
  - Overlay of the input pipelines
  - Up to 5 input layers blending
  - Transparency color key
  - Alpha blending support: Embedded pixel alpha (ARGB and RGBA), global pixel, and combination of global pixel and pixel alpha
  - Z-order programmable (full flexibility)
  - Color bar test pattern insertion
  - Any overlay output can be selected to drive the Write-back pipeline
- Four Video Port (VP) display outputs, each supporting:
  - 36-bit per pixel on the RGB output interface
  - Independent programmable timing generator, supporting up to 600 MHz pixel clock video formats
  - Independent programmable 10-bit gamma correction
  - Independent programmable multiple cycles output format on 8/9/12/16-bit interface
  - Selection between RGB and YUV422 output pixel
  - Configurable VP output mode
- Internal diagnostic features:
  - Supports up to 4 programmable (position/size) check regions on the DISPC video port display outputs
  - Support for 1 check region on each input video pipeline output
  - MISR (Multiple Input Signature Register) used on each check region to perform data correctness check and/or freeze frame detection
- Local power features:
  - Low power saving modes
  - On-the-fly Dynamic Frequency Scaling (DFS) support
  - Capability to associate all buffers a single pipeline for a display self-refresh
- System interconnect ports:
  - Two 128-bit VBUSM master interfaces for data read/write
  - One 32-bit VBUSP slave interface for configuration

- Frame Buffer Decompression Core (FBDC), that performs a decompression on lossless compressed images on a tile-by-tile basis.
- MIPI Display Serial Interface (DSI) transmitter host controller, with the following main features:
  - Compliance with MIPI DSI 1.3.1 and previous protocol specifications
  - Compliance with Stereoscopic Display Format (SDF) specification
  - Video and command operational modes
  - Both burst and non-burst modes for video mode data transmission
  - Up to 4 virtual channels via command mode
  - Bi-directional communication and escape mode
  - Pixel clock rate range: 25-330 MHz
  - Programmable display resolutions
  - 16/18/24/30/36-bit RGB input data formats for video mode
  - RGB16, RGB18 packed, and RGB24 input data formats for command mode
  - All generic data types defined by MIPI
  - Display Command Set (DCS) transparent to the protocol engine
  - ECC on the APB interface
  - Data splitter for 2-, 3-, or 4-data lane configuration
  - Connection to a single MIPI D-PHY complex I/O through an 8-bit Protocol Peripheral Interface (PPI)
  - Tearing effect (TE) input signals for command mode display
  - Bus contention recovery
  - Video mode pattern generator: color bar pattern image and D-PHY BET testing pattern
  - APB slave interface with 32-bit data and address for configuration
- The MIPI DSI Physical Layer (D-PHY) module with the following main features:
  - Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
  - 1, 2 or 4 data lanes, in addition to clock signaling
  - Maximum data rate up to 2.5 Gbps per data lane
  - Protocol Peripheral Interface (PPI)
  - HS continuous and burst mode
  - Low-Power (LP), Ultra-Lower Power Mode (ULPM), and Shutdown modes
  - Forward direction and reverse direction escape modes
  - Automatic termination control in both high-speed and low-power modes
  - Single 32-bit VBUSP slave interface
- Embedded DisplayPort (eDP) transmitter host controller with the following main features:
  - Compliance with VESA® DisplayPort™ (DP) 1.3 (with 1.4 DSC/FEC support) specification
  - Compliance with VESA Embedded DisplayPort (eDP) 1.4 specification
  - Static configuration of either DP or eDP mode
  - Link rates up to High Bit Rate 3 (HBR3)
  - Pixel clock rate range: 25-600 MHz
  - 8, 10, and 12 bpc (bits per component), in RGB/YCbCr444 colorimetry formats (CEA-861 compliant) and YCbCr422 (via simple decimation)
  - Data splitter for 1-, 2-, or 4-data lane configuration
  - Single Stream Transport (SST)
  - Multiple Stream Transport (MST)
  - High-bandwidth Digital Content Protection (HDCP) data encryption via an embedded HDCP core
  - Display Stream Compression (DSC) encoded stream data transport via an embedded DSC core
  - Forward Error Correction (FEC) encoder with/without DSC enabled in DP mode
  - Single Stream Transport (SST)
  - Audio transport features
  - Metadata transport via Main Stream Attribute (MSA) packet or via SDP
  - APB slave ports for TX/PHY controller configuration
  - SAPB (secure) slave port for secure connection
  - Video source muxing options

- One 32-bit VBUSP slave interface used for configuration
- ECC on the critical memories
- Parity check on the configuration interface
- Encoder self-check diagnostics support in the DSC core
- Injection of ECC and parity errors
- eDP (Physical Layer) SERDES and Aux PHY modules with the following main features:
  - DP1.3, HBR3 and eDP1.4a HBR3 throughput
  - 1, 2, or 4 lanes at 1.62Gbps, 2.7Gbps, 5.4Gbps, and 8.1Gbps per lane
  - Additional link rates (2.16, 2.43, 3.24, 4.32Gbps) per lane in eDP mode
  - Reduced differential voltage swing (0.2/0.25/0.30/0.35/0.40/0.45) in eDP mode
  - Hot Plug Detect (HPD) for connection detection and interrupt from sink
  - Integrated Low Jitter, Fixed Bandwidth PLL
  - DisplayPort physical layer functionalities:
    - Scrambler
    - 8/10-bit encoder (within the eDP transmitter)
    - Inter Lane Skew Insertion
    - Training Pattern Generation – TPS1,2,3,4 PRBS7 and 80-bit custom training pattern generation (bypassing the scrambler and encoder)
- 1 Mbps AUX PHY for link training, DPCD register access, HDCP authentication and EDID access

### 1.3.14 Camera Subsystem

Camera Subsystem unites two camera streaming interfaces – receiver and transmitter, allowing the device to stream video inputs from multiple cameras to the video processing accelerator (VPAC) or to internal memory and to output CSI-2 protocol image data to any device that supports MIPI CSI-2 protocol. Main modules are as follows:

- Camera Streaming Interface Receiver (CSI\_RX\_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+ and MIPI CSI-2 v2.0
  - Supports up to 16 virtual channels per input
  - Supports one 4MP camera or eight 2MP camera streams
  - Supports data rate up to 2.5 Gbps per lane (wire rate)
  - Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Receiver (DPHY\_RX)
  - Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
  - Supports four independent (simultaneous) output streams:
    - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator
    - One (up to 4 channels) PPI 16-bit pixel retransmission interface to Camera Streaming Interface Transmitter (CSI\_TX\_IF)
    - One (up to 32 Channels) DMA interface through a 128-bit Packet Streaming Interface Link (PSI\_L) connection to NAVSS for transfers to memory:
- Functional and data path error interrupts
- ECC support
- MIPI D-PHY Receiver (DPHY\_RX) with the following main features:
  - Allows the device to input video streams from external sensor cameras and other CSI2 compliant sources
  - Compliant to MIPI D-PHY standard v1.2
  - Supports up to 4 data and 1 clock lanes
  - Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
  - Clock lane Control / Interface logic type: CIL-SCNN for HS and low power receiving
  - Data lane Control / Interface logic type: CIL-SFAN for HS and low power receiving
  - Data lanes can be independently operated in HS or ULP mode
  - Swapping of DP/DN signals within each clock/data pair
- Camera Streaming Interface Transmitter (CSI\_TX\_IF) with the following main features:
  - Compliant to MIPI CSI-2 v1.3+, MIPI CSI-2 v2.0, and MIPI D-PHY v1.2
  - Data rate up to 2.5 Gbps per lane (wire rate)

- Supports 1, 2, 3, or 4 Data Lane connections to MIPI D-PHY Transmitter (DPHY\_TX)
- Over 25 different programmable formats including YUV420, YUV422, RGB, Raw, and User Defined
- Support of 16 virtual channels
- Support of four configurable input streams

### 1.3.15 Shared D-PHY Transmitter

The DPHY\_TX module provides an option for video output interfacing by implementing a four lane, MIPI D-PHY Transmitter. DPHY\_TX module supports the following main features:

- Compliancy to MIPI D-PHY Standard version 1.2
- Supports up to 4 data lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Supports Escape mode
- Data Lanes can be independently operated in HS or ULP mode
- Includes a CMN block with reference generators / resistor calibration and an integrated PLL
- Fault detection

### 1.3.16 Video Processing Front End

Video Processing Front End (VPFE) is an input interface module that receives raw (unprocessed) image/video data or YUV digital video data from external imaging peripherals (such as image sensors, video decoders, etc.) and performs DMA transfers to store the captured data in the system DDR memory. VPFE module supports the following features:

- Includes a buffer memory for interfacing to the DMA at the chip level and preventing the Charge-Coupled Device Controller (CCDC) from overflowing
- Support for conventional Bayer pattern and Foveon sensor formats
- Generates HD/VD timing signals and field ID to an external timing generator or can synchronize to the external timing generator
- Support for progressive (non-interlaced) and interlaced sensors
- Support for up to 110-MHz sensor clock
- Support for REC656/CCIR-656 standard (YCbCr 422 format, either 8- or 16-bit)
- Support for YCbCr 422 format, either 8- or 16-bit with discrete HSYNC and VSYNC signals
- Support for up to 16-bit input
- Generates optical black clamping signals
- Support for digital clamping and black level compensation
- Support for 10-bit to 8-bit A-law compression
- Support for a low-pass filter prior to writing to DDR
- Support for generating output to range from 16-bits to 8-bits wide
- Support for down-sampling via programmable culling patterns
- Ability to control output to the DDR via an external write enable signal
- Support for up to 16K pixels (image size) in both the horizontal and vertical directions
- Region-based Address Translation (RAT) module for converting legacy 32-bit to 48-bit addressing scheme in the write DMA path

### 1.3.17 Multicore Shared Memory Controller

Multicore Shared Memory Controller (MSMC) provides high-bandwidth resource access both to and from all of the connected processing elements and the rest of the system and supports the following main features:

- 8MB (4 banks x 2MB) SRAM with ECC
- 512-bit processor port bus and 40-bit physical address bus
- Coherent unified bi-directional interfaces to connect to processors or device masters
- One infrastructure master interface
- Single external memory master interface
- Support of distributed virtual system
- Internal DMA engine – DRU (Data Routing Unit)
- Bandwidth management with starvation bound

- Two-level Quality-of-Service (QoS) support for real-time/non-real-time split
- Security firewall for SRAM/cache and external memory
- ECC error protection
- One interconnect messaging interface that supports DMA/pre-fetch requests to DRU
- Trace and debug features
- Support of dynamic clock gating on all logic units

### 1.3.18 DDR Subsystem

Integrated in MAIN domain one instance of DDR Subsystem (DDRSS) is used as an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS provides the following main features:

- Support of LPDDR4 memory type
- 32-bit memory bus interface with in-line ECC
- Up to 8 GB memory address range
- System bus interface: little endian only with 512-bit data width
- Configuration bus Interface: little endian only with 32-bit data width
- Support of dual rank configuration
- Support of automatic idle power saving mode when no or low activity is detected
- Class of Service (CoS) - three latency classes supported
- Prioritized refresh scheduling
- Statistical counters for performance management

### 1.3.19 Region-based Address Translation Module

Integrated in MAIN domain thirteen instances of Region-based Address Translation (RAT) module perform a region based address translation of a 32-bit input address into a 48-bit output address. Each RAT module provides the following main features:

- 16 regions with dedicated registers for attributes configuration:
  - Region base address
  - Region size
  - Translated base address
- Address translation for only enabled regions
- Region boundary crossing transactions error generation

### 1.3.20 General Purpose Input/Output Interface

Eight General Purpose Input/Output (GPIO) modules integrated in MAIN domain provide dedicated general-purpose pins that can be configured as either inputs or outputs. Modules main features are:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

### 1.3.21 Inter-Integrated Circuit Interface

Device MAIN domain contains seven multi-master Inter-Integrated Circuit (I2C) interfaces, each with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-master transmitter/slave receiver and receiver/slave transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

### 1.3.22 Improved Inter-Integrated Circuit Interface

Device MAIN domain contains one multi-master Improved Inter-Integrated Circuit (I3C) module with the following main features:

- Supports Single Data Rate (SDR) and High Data Rate – Dual Data Rate (HD-DDR) communication modes
- Support of Common Command Codes (CCC)
- Hot-Join capability
- In Band Interrupts (IBI)
- Support of Dynamic Address Assignment (DAA)
- Support of Static Addressing (SA)
- FIFO Buffers
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves

### 1.3.23 Multi-channel Serial Peripheral Interface

Integrated in MAIN domain eight Multi-channel Serial Peripheral Interface (MCSPI) modules have the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Support of different master multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

### 1.3.24 Universal Asynchronous Receiver/Transmitter

Integrated into MAIN domain are ten configurable Universal Asynchronous Receiver/Transmitter (UART) interfaces with the following main features:

- 16C750-compatible
- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

### 1.3.25 Gigabit Ethernet Switch

Integrated in the MAIN domain one instance of 9-port Gigabit Ethernet Switch (CPSW) subsystem provides Ethernet packet communication for the device. CPSW provides the following features:

- Eight Ethernet ports with selectable SGMII, RGMII and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Support of eight priority level Quality Of Service (QOS) - 802.1p
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Differentiated Services Code Point (DSCP) Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (802.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)

- Store and Forward Switching
- Non-Blocking switch fabric
- Support of Time Sensitive Network - IEEE P802.3br/D2.0 Interspersing Express Traffic and IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE) with 1024 ALE table entries
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

### 1.3.26 Peripheral Component Interconnect Express Subsystem

Integrated in the MAIN domain are four Peripheral Component Interconnect express (PCIe) subsystems with shared SerDes lines, each providing the following main features:

- Compliant to PCI-Express® Base Specification, Revision 4.0 (Version 0.7)
- One or two-lane configuration with up to 8.0 Gbps/lane (Gen3). Can be used as 2-lane controller, configurable in 1x1 or 1x2 mode.
- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- Dual mode: Root Port (RP) or End Point (EP) operation modes, selectable via bootstrap pins
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4KB
- Address Translation Services (ATS)
- Single-root I/O Virtualization (SR-IOV) with Physical Functions (PF) and Virtual Functions (VF) in End Point mode – 6 PF and 16 VF
- Four virtual channels (VC)
- Maximum number of non-posted outstanding transactions: 32
- Resizable Base Address Registers (BAR) capability
- Separate Reference Clock with Independent Spread (SRIS)
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

### 1.3.27 Universal Serial Bus (USB) Subsystem

Instantiated in MAIN domain two Universal Serial Bus (USB) subsystems with integrated PHY have the following main features:

- Dual-Role Device (DRD) capability
- Support of USB2.0 (up to 480 Mbps) standard
- Support of USB3.0 (5 Gbps) standard
- Support of Peripheral (aka Device) mode at Super Speed (SS at 5 Gbps), High Speed (HS at 480 Mbps), and Full Speed (FS at 12 Mbps)
- Support of Host mode at SS (5 Gbps), HS (480 Mbps), FS (12 Mbps), and Low Speed (LS at 1.5 Mbps)
- Support of static peripheral and static host operations
- Support of Host Negotiation Protocol (HNP)
- Support of USB3 low power protocol states (U0, U1, U2, and U3)
- USB Type-C connector with internal data lane swapping
- Each USB instance contains a single xHCI compliant with xHCI 1.0 specification with internal DMA controller

- Shared SerDes for USB 3.0 operation
- ECC on internal RAMs
- Embedded USB 2.0 PHY:
  - Fully compliant with UTMI+ Level 3 specification revision 1.0
  - Supports HS, FS and LS data rates
  - Charger Downstream Port (CDP) as per Battery Charging Specification, Revision 1.2
  - Supports USB low-power states: suspend and link power management (LPM)
  - Supports multiple reference clocks for PLL
  - Supports PLL standalone and bypass features

### 1.3.28 SerDes

Integrated in the MAIN domain are five instances of high-speed differential interface implemented with Serializer/Deserializer (SERDES) Multi-protocol Multi-link modules:

- The 2L SerDes instantiations which are an implementation of a multi-protocol PCIe/USB/Ethernet PHY, consisting of a PIPE compliant multi-protocol (PCIe Gen1/2/3 and USB 3.0/3.1) PCS, IEEE 802.3 clause 72 link training modules, supporting different components (TAP controller, APB interface, PHY power control and Clock/Reset controller), and Physical Medium Attachment (PMA)
- The 4L SerDes is an implementation of a multi-protocol PHY, consisting of a PIPE compliant multi-protocol Physical Coding Sublayer (PCS), supporting components (TAP controller, APB interface, PHY power control and Clock/Reset controller), and PMA.

Device supports four 2L SerDes modules, each with the following main features:

- Two bidirectional lanes
- Supported lane configurations: x1 and x2
- Supported standards:
  - PCIe Gen 1, 2 and 3
  - USB 3.1 Gen 1
  - Ethernet - SGMII/QSGMII
- Supports 'L1 PM Sub-states with CLKREQ' ECN
- Raw SerDes / Ethernet PHY 32/20-bit data interface with separate Rx and Tx source synchronous clocks
- For automotive safety applications, supports logic to monitor for successful PHY power state/data rate changes and generate an interrupt upon failure
- Provides option to automatically re-configure the PHY for a non-default configuration upon start-up (PHY auto-configuration)
- Supports multitude of high-speed data rates including (Gb/s): 1.25, 1.5, 2.5, 3.0, 3.125, 5.0, 6.0, 6.25, 8.0
- PHY (PMA integrated with PCS):
  - ECNs included: L1 PM Sub-states CLKREQ; SRIS
  - USB3.1 per Universal Serial Bus 3.1 Specification, Revision 1.0
  - QSGMII Specification revision 1.2
- Selectable serial pin polarity reversal for both transmit and receive paths
- Up to two reference clock sources for mixed standard multi-lane link applications
- Capable of equalizing up to 30dB total loss channels
- Receiver data recovery path:
  - Includes 5-tap DFE with adaptive training.
  - Supports far-end transmit pre-cursor and post-cursor adaptive training
  - Includes adaptive offset correction and gain control
  - Periodic on-the-fly training updates maintain optimization with drifting environment
- Receiver clock recovery path:
  - Tracks frequency offset of +/-5700ppm or greater where +/- 700 PPM is considered static and the remainder is from spread-spectrum techniques (SSC)
  - Includes CTLE with adaptive equalization
  - Includes adaptive phase offset correction

- Supports on-the-fly eye and bathtub curve diagramming with 8-bit voltage amplitude resolution and up to 1/64 UI time resolution
- Data path built-in self-test (BIST) with programmable pattern generation and error detection
- Serial bit stream and parallel word loopback for both line and parallel side
- Analog Test Bus (ATB) for internal node monitoring during characterization
- 8-bit ADC provides digitized ATB measurement results over configuration bus
- Supports DC and AC JTAG (boundary scan) per IEEE 1149.6
- Automatic calibration of pin termination resistors

Device supports one 4L SerDes with the following main features:

- Four bidirectional lanes
- Supported lane configurations: all lane configurations from x1 to x4
- Supported standards:
  - SGMII/QSGMII
  - Embedded DisplayPort Tx (UI\_Rate\_1 - UI\_Rate\_8)
- Single protocol, independent multiple links (where N is the number of lanes) support for:
  - eDP Tx link can be 1, 2, or 4 lanes
  - N SGMII links.
- Simultaneous multi-protocol support for various combinations (including Multiple Ethernet links + 1x eDP Tx link)
- Raw SerDes interface with separate Tx and Rx source synchronous clocks
- Supports PCIe 'L1 PM Sub-states with CLKREQ'
- For automotive safety applications, supports logic to monitor for successful PHY power state/data rate changes and generate an interrupt upon failure
- Dual on-chip PLLs which accepts a wide range of reference clocks
- Supports spread spectrum generation (up to 5000 PPM)
- PLL lock status
- Single off-chip resistor required
- Automatic calibration for on-chip termination resistors
- 20-bit/16-bit parallel data transceiver interface
- Support for external differential reference clock
- Support for internal single-ended reference clock
- Decision feedback equalization with 3-tap adaptive decision feedback equalization with adaptive CTLE and offset correction
- Supports bifurcation link combinations from 1 to 4 lanes per link
- Robust clock/data recovery tracks static frequency offset of +/- 350 PPM, and spread spectrum up to 5000 PPM
- Support for IEEE 1149.6 boundary scan
- Serial and parallel loop-back functions
- BIST functions for manufacturing test including multiple pattern generator/error detector
- Analog Test Bus for test and characterization
- 8-bit digitized ATB measurement system
- On demand eye/bathtub curve measurement capability

### 1.3.29 General Purpose Memory Controller with Error Location Module

Integrated in MAIN domain is one instance of General-Purpose Memory Controller (GPMC) with Error Location Module (ELM). Dedicated for interfacing with external memory devices it has the following main features:

- Support of 8- or 16-bit-wide data path to external memory devices
- Supports up to 4 independent chip-select regions of programmable size and programmable base addresses on 16MB, 32MB, 64MB, or 128MB boundary in a total address space of 1GB
- Support of the following wide range of external memories/devices:
  - Asynchronous or synchronous 8-bit wide memory or device (non-burst device)

- Asynchronous or synchronous 16-bit wide memory or device
- 16-bit non-multiplexed NOR flash device
- 16-bit address and data multiplexed NOR flash device
- 8-bit and 16-bit NAND flash device
- 16-bit pseudo-SRAM (pSRAM) device
- Supports various interface protocols when communicating with external memory or external devices:
  - Asynchronous read/write access
  - Asynchronous read page access (4, 8, and 16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4, 8, and 16 Word16)
  - Synchronous read burst access with wrap capability (4, 8, and 16 Word16)
- Supports up to 16-bit on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- ELM module which used in a conjunction with the GPMC and provides ECC calculation (up to 16-bit) for NAND support and ability to work in both page-based and continuous modes, has the following main features:
  - 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
  - Eight simultaneous processing contexts
  - Page-based and continuous modes
  - Interrupt generation on error-location process completion

### 1.3.30 Multimedia Card/Secure Digital Interface

Device MAIN domain supports three Multimedia Card/Secure Digital (MMCSD) controllers with the following main features:

- One controller with 8-bit wide data bus
- Two controllers with 4-bit wide data bus
- Support of eMMC5.1 Host Specification (JESD84-B51)
- Support of SD Host Controller Standard Specification - SDIO 4.0
- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3
- Multimedia card features:
  - Backward compatible with earlier eMMC standards
  - SDR, 3.3 V / 1.8 V, 4-bit bus width, 0-26 MHz, 13 MB/s
  - SDR, 3.3 V / 1.8 V, 1-bit bus width, 0-26 MHz, 3.25 MB/s
  - SDR, 3.3 V / 1.8 V, 4-bit bus width, 0-52 MHz, 26 MB/s
  - SDR, 3.3 V / 1.8 V, 1-bit bus width, 0-52 MHz, 6.5 MB/s
  - DDR, 3.3 V / 1.8 V, 4-bit bus width, 0-52 MHz, 52 MB/s
  - SDR, 1.8 V, 0-200 MHz, 4-bit bus width, 100 MB/s
- SD card support: SDIO, SDR12, SDR25, SDR50, DDR50
- System bus interface: CBA 4.0 VBUSM master port with 64-bit data width and 64-bit address, little endian only
- Configuration bus interface: CBA 4.0 VBUSM with 32-bit data width, 32-bit aligned accesses only, linear incrementing addressing mode, little endian only

### 1.3.31 Universal Flash Storage Interface

Device MAIN domain supports one standard-based serial interface engine - Universal Flash Storage (UFS) interface with an integrated M-PHY. UFS provides the following main features:

- Support of Universal Flash Storage Host (UFS2.1, JESD220C)
- Support of Universal Flash Storage Host Controller Interface (UFSHCI, JESD223C)
- Support of UFS interconnect - MIPI UniPro (v.1.60, 2013) and MIPI M-PHY (v3.1, 2014)
- Supports speeds 1.46 Gbps (Gear 1), 2.91 Gbps (Gear 2) and 5.83 Gbps (Gear 3), 2-lanes

- Support of all UFS mandatory SCSI commands required by JEDEC specification
- Master bus Interface: one 64-bit master interface for data transfers, 48-bit address width, embedded DMA within the host controller with support of little-endian mode only
- Configuration Bus Interface: one 32-bit slave interface for configuration access, support of linear incrementing addressing mode and only aligned accesses
- ECC support on internal RAMs
- M-PHY Features: supports reference clocks of 19.2 MHz and 26 MHz

### 1.3.32 Enhanced Capture Module

Integrated in the MAIN domain three Enhanced Capture (ECAP) modules provide accurate timing for different events. When not being used for event capture, its resources can be used to generate a single channel of asymmetrical PWM waveforms (configurable as either one capture input, or as one auxiliary PWM output). Each ECAP module supports the following main features:

- 32-bit time base counter
- 4 x 32 bits event time-stamp capture registers
- 4 stage sequencer (Mod4 counter), synchronized to external events
- Independent edge polarity selection for up to four sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- Interrupt capabilities on any of the four capture events
- Support of different capture modes (single shot capture, continuous mode capture, absolute timestamp capture or delta mode time-stamp capture)

### 1.3.33 Enhanced Pulse-Width Modulation Module

Integrated into MAIN domain are six Enhanced Pulse-Width Modulation (EPWM) modules, each with the following main features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two independent PWM outputs that can be used in different configurations (with single-edge operation, with dual-edge symmetric operation or one independent PWM output with dual-edge asymmetric operation)
- Asynchronous override control of PWM signals during fault conditions
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both latched and un-latched fault conditions
- Events enabling to trigger both CPU interrupts and start of ADC conversions

### 1.3.34 Enhanced Quadrature Encoder Pulse Module

Integrated in MAIN domain are three 32-bit Enhanced Quadrature Encoder Pulse (EQEP) modules for position, speed, and frequency measurements support. Each of the modules has the following main features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low speed measurement
- Unit time base for speed/frequency measurement
- Watchdog timer for detecting stalls

### 1.3.35 Controller Area Network

Fourteen Controller Area Network (MCAN) interfaces integrated into MAIN domain and supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications have the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support for DRA829 and TDA4VM families of devices
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers

- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

### 1.3.36 Audio Tracking Logic

Instantiated in MAIN domain one Audio Tracking Logic (ATL) module, which is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock, supports the following main features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local Audio Word Select [AWS] and Baseband Word Select [BWS])
- Each instance selects between 28 mux choices for BWS and 30 mux choices for AWS
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing
- Selection between interface or functional clock to run error counting timers and to derive modulated clock outputs
- Clock and reset management: receives clock and reset signals from the device PSC module
- Hardware reset
- Local software reset

### 1.3.37 Multi-channel Audio Serial Port

Instantiated in MAIN domain are twelve instances of Multi-channel Audio Serial Ports (MCASP). The MCASP is a general purpose audio serial port, useful for Time-Division Multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component Digital audio Interface Transmission (DIT). MCASP modules have the following main features:

- Connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and Sony/Philips Digital Interface (S/PDIF) transmit physical layer components
- Support of Time Division Multiplexed (TDM) interface, Inter-IC Sound (I2S) standard, and similar bit stream formats
- Integrated Digital Audio Interface Transmitter (DIT) with enhanced channel status/user data RAM and support of S/PDIF, IEC60958-1, and AES-3 formats
- Independent serializer for each AXRx channel of each MCASP module
- A single 32-bit buffer per serializer for transmit and receive operations
- Support for two DMA requests (one per direction)
- One transmit and one receive interrupt requests common for all serializers
- Two independent clock generator modules for transmit and receive allowing the MCASP to receive and transmit at different rates
- Support of up to 16 serial data pins on MCASP0, up to 12 serial data pins on MCASP1, 8 serial data pins on MCASP10 and MCASP11, 6 serial data pins on MCASP2 and 4 serial data pins on MCASP3 through MCASP9
- MCASP10 internal connection to eDP for audio support

### 1.3.38 Timers

Three different types of timer modules are instantiated in the MAIN domain:

- One instance of Global Time Counter (GTC) module that can be used for time synchronization and debug trace time stamping with the following main features:
  - 64-bit up counter
  - No rollover during the lifetime of the device
  - Compatible with Armv8 system counter requirements

- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols
- Ten instances of Real Time Interrupt (RTI) windowed watchdog module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processors cores
- Twenty instances of Timer module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code
  - Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer

### 1.3.39 Internal Diagnostics Modules

Instantiated in MAIN domain are different internal diagnostics modules which provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

- Thirteen instances of Dual Clock Comparator (DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement
- One instance of Error Signaling Module (ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Error pin to signal severe device failure
  - Configurable time base for error signal
  - Error forcing capability
  - Internal redundant flops on safety critical fields
- Multiple ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
  - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
  - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
  - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error
  - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)
  - Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)

- Single bit error detection via parity checking results in a non-correctable error interrupt
- Memory Cyclic Redundancy Check (MCRC) module used to perform CRC to verify the integrity of a memory system – part of the NAVSS

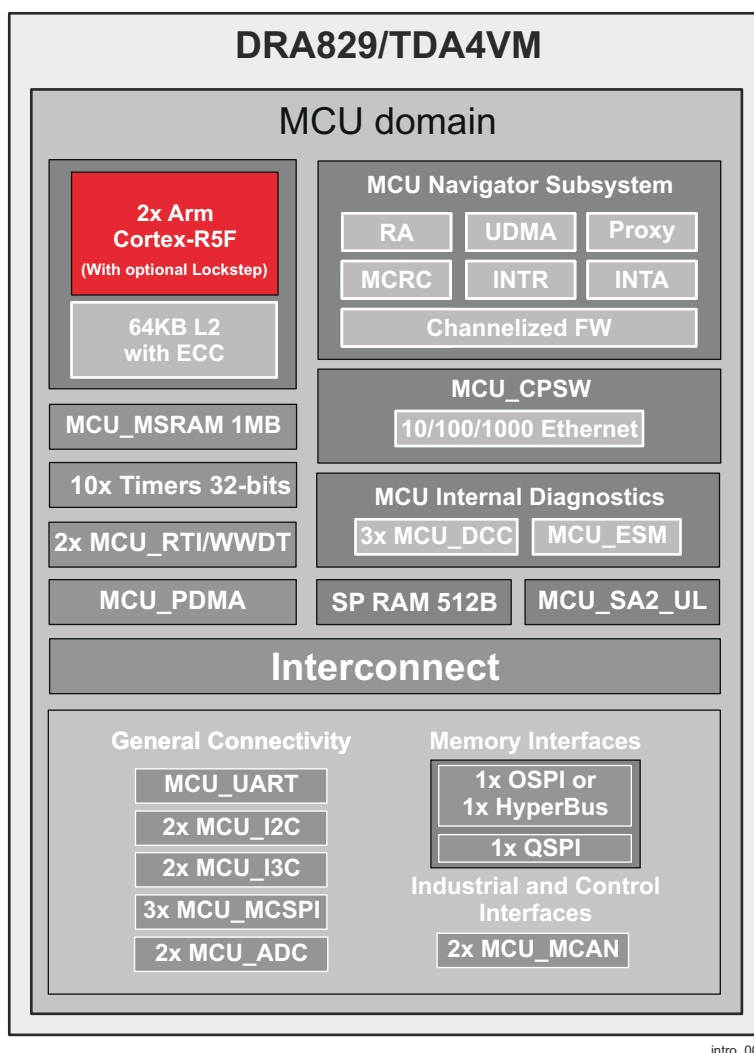

## 1.4 Device MCU Domain

The Microcontroller Unit Subsystem is a “chip-in-a-chip” concept and operates using a separate voltage supply, clock sources and resets and includes the components needed for device management. This allows the MCU to function continuously regardless of the state of the rest of the device, including periods in which the rest of the device is held in reset or powered down. Most communication between the MCU island and the rest of the SoC can (and, in a safety case, should) be conducted via internal SPI connections. These connections allow for safe communications to isolate the MCU island from faults in the rest of the SoC. The MCU island integrates communication peripherals such as MCSPI and MCAN which are expected to be used for safety critical communication, so if the main SoC goes down, the MCU island can communicate this information to the rest of the system. Isolation of the MCU Dual-Core Arm Cortex-R5F Microprocessor Subsystem helps to provide Freedom from Interference (FFI).

The MCU subsystem has integrated:

- 192 KB of read-only memory used for first stage booting (MCU ROM)
- 1024KB L3 RAM for program/data storage with the following features:
  - Supports various ECC features available via the ECC aggregator modules
  - Supports linear and cache-line wrap addressing modes
  - Supports configurable data-path widths of 32, 64, 128, 256 and 512 bits
  - Supports configurable FIFO depths for command, write data, read data and write status
- Configurable Scratchpad RAM (512 bytes) aimed for storing debug and context information across chip resets

[Figure 1-3](#) shows the block diagram of the device MCU domain.

intro\_002

**Figure 1-3. Device MCU Domain Block Diagram**

### Note

The supported set of features and peripherals is device part number dependent. For more information, see the device-specific Datasheet.

### 1.4.1 MCU Arm Cortex-R5F Processor

Integrated in MCU domain one instance of Arm dual-core Cortex-R5F processor supports the following main features:

- Armv7-R architecture
- Two modes of operation, boot-time configurable:
  - Split mode: two independently operating cores (Asymmetric Multi Processing, no coherence)
  - Lock (lockstep) mode: one main operating core with the other operating in lockstep
- 16KB instruction and 16KB data SECDED ECC protected L1 cache per core in split mode
- 64KB of Tightly Coupled Memory (TCM) per core
- Full-Precision Floating Point (VFPv3)
- 8 breakpoints, 8 watch points
- 16-region Memory Protection Unit (MPU)

- CoreSight Debug Access Port (DAP)
- CoreSight ETM-R5 interface
- Performance Monitoring Unit (PMU)
- 32-bit to 48-bit Region-based Address Translation (RAT) on memory access masters
- Integrated Vectored Interrupt Manager (VIM)
- Interfaces:
  - 64-bit VBUSM master pair (1 read, 1 write) for L3 memory accesses (per core)
  - 64-bit VBUSM slave for TCM access (per core)
  - 32-bit VBUSM master pair (1 read, 1 write) for peripheral access
  - 32-bit VBUSP master for peripheral access (per core)
  - 32-bit VBUSP slave configuration port (per core)
  - 32-bit VBUSP slave debug port

### 1.4.2 MCU Region-based Address Translation Module

Integrated in MCU domain two instances of Region-based Address Translation module perform a region based address translation of a 32-bit input address into a 48-bit output address. Each RAT module provides the following main features:

- 16 regions with dedicated registers for attributes configuration:
  - Region base address
  - Region size
  - Translated base address
- Address translation for only enabled regions
- Region boundary crossing transactions error generation

### 1.4.3 MCU Navigator Subsystem

Instantiated in the MCU domain one Navigator subsystem named MCU\_NAVSS can be used for efficient transfer of data support between software, firmware and hardware in all combinations. It consists of the following main modules:

- Unified DMA Controller with the following main modes and features:
  - K3 DMA Architecture compliant Tx/Rx port implementation
  - K3 DMA Architecture compliant Packet-Oriented DMA Functionality (UDMA-P)
  - K3 DMA Architecture compliant Third Party Channel Controller
  - K3 DMA Architecture compliant Unified Transfer Controller
  - K3 DMA Architecture compliant Unified DMA channels which all share the execution hardware using time division multiplexing
- Ring Accelerator provides hardware acceleration to enable straightforward passing of work between a producer and a consumer and has the following main features:
  - Supports 286 independent memory-mapped ring structures
  - Supports various modes for each ring based on usage and compatibility
  - Provides single-word deep shared incoming Transfer Response FIFO
  - Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities
- Proxy module with the following main features:
  - Provides proxy buffers to store large data bursts that a host can only access in smaller amounts
  - Keeps the large data coherent until the complete data has been accessed
  - Allows interleaved access between multiple hosts using multiple proxies
  - Supports a pre-configured number of target resources to proxy with pre-configured number of channels, size of each channel, and address offset per each target
- Secure proxy module is a modified version of the proxy module and in addition has the following main features:
  - Supports a number of threads, where each has their own independent proxy function
  - Supports a programmable fixed queue for each proxy thread
  - Supports multiple producers all writing to the same queue

- Supports programmable thresholds for when to generate events
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Interrupt Aggregator module provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Main features are as follows:
  - 64-bit VBUSP slave using 64-bit registers
  - Provide a set of TI Interrupt Architecture compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks
  - Provide a set of Global Event Input (GEVI) counters which can count events delivered via an ingress Event Transport Lane (ETL)
  - Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Provides a set of GEVI 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces
- Time Sync module to facilitate host control of time sync operations with the following main features:
  - Supports a selection of multiple external clock sources
  - Software control of time sync events via interrupt or polling
  - Supports 8 hardware timestamp push inputs
  - Supports timestamp counter compare output
  - Supports timestamp counter bit output
  - Supports 6 timestamp generator function outputs
  - 32-bit and 64-bit timestamp modes
- Memory Cyclic Redundancy Check module performs CRC to verify the integrity of a memory system with the following main features:
  - Four channels to perform background signature verification on any memory subsystem
  - Data compression on 8-, 16-, 32-, and 64-bit data size
  - Dedicated CRC value register per channel which contains the pre-determined CRC value
  - Timed base event trigger from timer to initiate DMA data transfer
  - Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
  - Three modes of operation: Auto, Semi-CPU, and Full-CPU
  - Timeout interrupt generation if CRC is not performed within the time limit
  - Per channel DMA request generation to initiate CRC value transfer

#### 1.4.4 MCU Analog-to-Digital Converter

Analog-to-Digital Converter (MCU\_ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels). Integrated in the MCU domain are two instances, each with the following main features:

- 4 MSPS rate with a 60 MHz sample clock
- Single-ended or differential input options
- Each ADC module can be configured and transformed into digital test inputs
- Programmable 16 steps Finite State Machine (FSM) sequencer

#### 1.4.5 MCU Inter-Integrated Circuit Interface

Device MCU domain contains two multi-master Inter-Integrated Circuit (MCU\_I2C) interfaces, each with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1
- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-master transmitter/slave receiver and receiver/slave transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms

- Low power consumption

#### **1.4.6 MCU Improved Inter-Integrated Circuit Interface**

Device MCU domain contains two multi-master Improved Inter-Integrated Circuit (MCU\_I3C) modules, each with the following main features:

- Supports Single Data Rate (SDR) and High Data Rate – Dual Data Rate (HD-DDR) communication modes
- Support of Common Command Codes (CCC)
- Hot-Join capability
- In Band Interrupts (IBI)
- Support of Dynamic Address Assignment (DAA)
- Support of Static Addressing (SA)
- FIFO Buffers
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves

#### **1.4.7 MCU Multi-channel Serial Peripheral Interface**

Integrated in MCU domain three Multi-channel Serial Peripheral Interface (MCU\_MCSPI) modules where each has the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of MCSPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Support of different master multichannel modes
- Single interrupt line for multiple interrupt source events
- Support of start-bit write command
- Support of start-bit pause and break sequence
- Built-in FIFO available for a single channel

#### **1.4.8 MCU Universal Asynchronous Receiver/Transmitter**

Integrated into MCU domain is one 16C750-compatible and configurable Universal Asynchronous Receiver/Transmitter (MCU\_UART) interface with the following main features:

- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

#### **1.4.9 MCU Gigabit Ethernet Switch**

Integrated in the MCU domain is one instance of Gigabit Ethernet Switch (MCU\_CPSW) subsystem which provides Ethernet packet communication for the device. MCU\_CPSW has the following main features:

- One Ethernet port with selectable RGMII or RMII interfaces and an internal Communications Port Programming Interface (CPPI) port
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Support of eight priority level Quality Of Service (QOS) - 802.1p
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)
- Differentiated Services Code Point (DSCP) Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Priority Based Flow Control (802.3x) Support
- Wire rate switching (802.1d)

- Store and Forward Switching
- Non-Blocking switch fabric
- Support of Time Sensitive Network - IEEE P802.3br/D2.0 Interspersing Express Traffic and IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE) with 64 ALE table entries
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Ethernet Mac transmit to Ethernet Mac receive Loopback mode (digital loopback) supported
- Maximum frame size of 2024 bytes
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Host port CPPI Streaming Packet Interface
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

#### **1.4.10 MCU Octal Serial Peripheral Interface and HyperBus Memory Controller as a Flash Subsystem**

Integrated in MCU domain one Flash Subsystem (MCU\_FSS) provides access to external flash devices via Octal Serial Peripheral Interface (OSPI) and HyperBus interface along with encryption/decryption, authentication, and in-line ECC protection. MCU\_FSS supports the following main features:

- Provides one OSPI and one QSPI or one QSPI and one HyperBus flash interfaces
- Primary OSPI0/HyperBus interfaces support:
  - Execute in place (XIP) operation
  - 32-byte Block Copy (BC) operation
  - ECC and/or authentication with four configurable authentication regions and authentication on 32-byte or 64-byte blocks
- Secondary 4-bits OSPI1 interface supports:
  - 32-byte BC operation
  - ECC
- OSPI interfaces support:
  - Up to 4 devices using different chip selects
  - Single, dual, quad (QSPI mode), or octal (on OSPI0 only) I/O instructions
  - Dual Quad-SPI mode for fast boot applications
  - Memory mapped 'direct' and software triggered 'indirect' modes of operation
  - Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
  - DDR Mode and Data Terminal Ready DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
  - Programmable write protected regions
  - Programmable delays between transactions
  - Programmable baud rate generator to generate OSPI clocks
  - Programmable interrupt generation
  - Programmable data decoder for enabling continuous addressing mode for each of connected devices and auto-detection of boundaries between devices
  - Bidirectional CRC on Multiple-SPI interface and handling of ECC errors for flash devices with embedded correction engine mechanisms
- HyperBus interface supports:
  - Up to 2 devices using two memory chip selects
  - Connection to Cypress® HyperFlash™ or HyperRAM™ devices
  - Up to 166 MHz maximum memory bus operation for reads
  - Up to 16 outstanding read transactions
  - Linear incrementing mode for reads and writes

- Asynchronous bus clock

#### 1.4.11 MCU Controller Area Network

Two Controller Area Network interfaces integrated into MCU domain (MCU\_MCAN) and supporting both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications have the following main features:

- Conforms with CAN Protocol version 2.0 part A, B and ISO 11898-1:2015
- Full CAN FD (up to 64 data bytes) support
- SAE J1939 support
- AUTOSAR support for DRA829 and TDA4VM families of devices
- Up to 32 dedicated transmit buffers and 64 dedicated receive buffers
- Two configurable receive FIFOs, up to 64 elements each
- Configurable transmit FIFO, up to 32 elements
- Configurable transmit queue, up to 32 elements
- Configurable transmit event FIFO, up to 32 elements
- Up to 128 filter elements
- Maskable interrupts, two interrupt lines
- Timestamp Counter

#### 1.4.12 MCU Timers

Two different types of timer modules are instantiated in the MCU domain:

- Two instances of Real Time Interrupt (MCU\_RTI) windowed watchdog module providing timer functionality for operation systems and benchmarking code with the following main features:
  - Two independent 64 bit counter blocks
  - Four configurable compare registers for generating operating system ticks
  - Free running counter 0 can be incremented by either the internal pre-scale counter or by an external event
  - Selectable RTI clock input (derived from any of the available clock sources)
  - Windowed Watchdog Timer (WWDT) feature
  - Some RTI modules are pre-dedicated to specific processor cores
- Ten instances of Timer module with support of the following main features:
  - Free running 32-bit upward counter
  - Generates a 1-ms tick with a 32.768-kHz functional clock
  - Interrupts generated on overflow, compare and capture
  - Supported modes of operation: compare and capture, auto-reload and start-stop
  - Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
  - Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
  - On-the-fly read/write register (while counting) for systems operation and benchmarking code
  - Each odd numbered timer instance may be optionally cascaded with the previous even numbered timer instance to form up to a 64-bit timer

#### 1.4.13 MCU Internal Diagnostics Modules

Instantiated in MCU domain are different internal diagnostics modules which provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

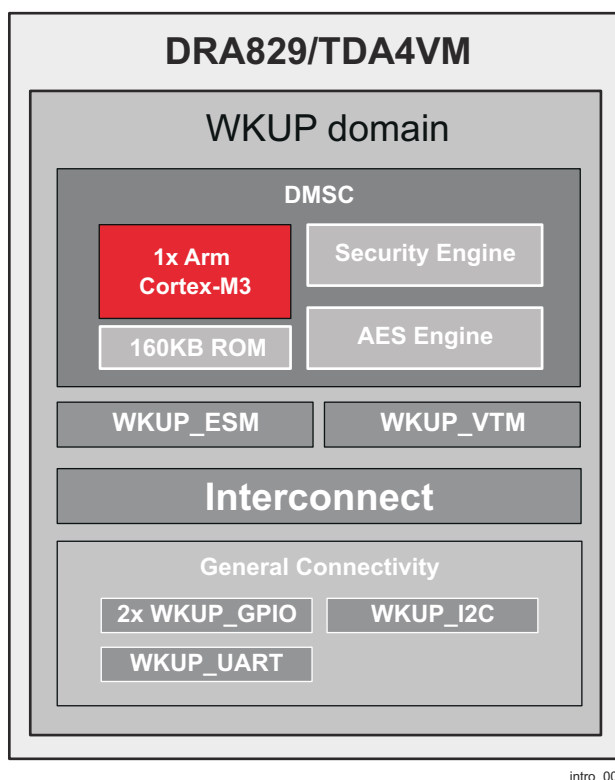

- Three instances of Dual Clock Comparator (MCU\_DCC) modules, used to determine the accuracy of a clock signal during the time execution of an application, each having the following main features:
  - Two independent counter blocks count clock pulses from each clock source
  - Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
  - Configurable time base for error signal
  - Error signal generation when one of the clocks is out of spec
  - Clock frequency measurement
- One instance of Error Signaling Module (MCU\_ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:

- Up to 1024 level or pulse error event inputs
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
- Configurable time base for error signal
- Error forcing capability
- Internal redundant flops on safety critical fields
- Multiple ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
  - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
  - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
  - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error
  - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)
  - Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)
  - Single bit error detection via parity checking results in a non-correctable error interrupt
- Memory Cyclic Redundancy Check module used to perform CRC to verify the integrity of a memory system – part of MCU\_NAVSS

## 1.5 Device WKUP Domain

Wake-up Subsystem (WKUPSS) is defined as an isolated domain to control operating states of the device. It supports low-power modes of operations and safety precautions during power transitions. Located in the WKUPSS are dedicated subsystems for device management and security functions.

Figure 1-4 shows the block diagram of the device WKUP domain.

**Figure 1-4. Device WKUP Domain Block Diagram**

### Note

The supported set of features and peripherals is device part number dependent. For more information, see the device-specific Datasheet.

#### 1.5.1 WKUP Device Management and Security Controller

Integrated in WKUP domain is the Device Management and Security Controller (WKUP\_DMSC) which provides control over the device boot sequencing, device management, power management, and security. With the factory-sealed firmware, DMSC main functions include:

- Device management
- On-chip power management and wake-up control
- Device boot configuration and sequence
- Secure boot setup
- Decryption routines
- Firewall control for isolation and Security
- Runtime Security Management and resource allocation

Arm Cortex-M3 based DMSC acts as a system security master and protects critical security assets during run-time. As part of booting a High Security (HS) device, DMSC uses on-chip keys to establish root-of-trust and authenticate images to reinforce trust. DMSC controls the power management of device, hence is responsible to bring device cleanly out of reset and enforce clock and reset rules. DMSC power management functions are critical to bring device to low power modes and sense wakeup events to bring device back to active state. DMSC acts also as main boot processor and as such is the very first subsystem that is brought out of reset after device power-on-reset

Main components of the DMSC are:

- Arm Cortex-M3 processor core (ARMv7-M architecture profile)
- 160 KB ROM to allow boot sequence, authentication and provide security service (M3 accessible only)
- Two separate local memory banks for Instruction code (I-code) and Data space (D-code) with single error correction and double error detection
- Firewall enabled 32-bit VBUSP CBASS interconnect
- Interrupt Aggregator with support of up to 80 interrupt inputs to the DMSC
- Four dual-mode 32-bit timers
- One RTI/WWDT module capable of issuing warm reset to the SoC
- DMSC control module - contains various control, configuration and status MMRs for power management functions
- Debug and trace related modules
- Security Manager module for device security management, device type control (GP, EMU, HS), emulation and JTAG control, and key management
- AES engine with 128, 192 and 256-bits support and DPA/EMA countermeasures

#### 1.5.2 WKUP General Purpose Input/Output Interface

Two General Purpose Input/Output (WKUP\_GPIO) modules integrated in WKUP domain provide dedicated general-purpose pins that can be configured as either inputs or outputs. Modules main features are:

- Support of 9 banks x 16 GPIO pins
- Support of up to 9 banks of interrupt capable GPIOs
- Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO pin
- Set/clear functionality per individual GPIO pin

#### 1.5.3 WKUP Inter-Integrated Circuit Interface

Device WKUP domain contains one multi-master Inter-Integrated Circuit (WKUP\_I2C) interface with the following main features:

- Compliancy to the Philips I2C-bus specification version 2.1

- Support of standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Support of 7-bit and 10-bit device addressing modes
- Support of multi-master transmitter/slave receiver and receiver/slave transmitter modes
- Built-in FIFOs with programmable size of 8 to 64 bytes for buffered read or write
- 8-bit-wide data access
- Support of Auto Idle, Idle Request/Idle Acknowledge handshake, and Asynchronous Wakeup mechanisms
- Low power consumption

#### 1.5.4 WKUP Universal Asynchronous Receiver/Transmitter

Integrated into WKUP domain is one 16C750-compatible and configurable Universal Asynchronous Receiver/Transmitter (WKUP\_UART) interface with the following main features:

- Support of RS-485 external transceiver auto flow control
- Dual 64-byte FIFOs – one per each received and transmitted data paths
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Baud rates up to 3.6 Mbps with 48 MHz functional clock
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Support of IrDA 1.4 Slow Infrared (SIR), Medium Infrared (MIR), and Fast Infrared (FIR) communications
- Support of Consumer Infrared Remote control mode (CIR) with programmable data encoding

#### 1.5.5 WKUP Internal Diagnostics Modules

Instantiated in WKUP domain are different internal diagnostics modules which provide monitoring and diagnostic functions required to achieve certain safety compliance levels:

- One Error Signaling Module (WKUP\_ESM) for safety-related events and/or errors aggregation from throughout the device into one location supports the following main features:
  - Up to 1024 level or pulse error event inputs
  - Selectable low and high priority interrupt error pin prioritization of each error event
  - Error pin to signal severe device failure
  - Configurable time base for error signal
  - Error forcing capability
  - Internal redundant flops on safety critical fields
- Multiple ECC aggregator modules supporting ECC mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED). Applied to different memories in many of the subsystems, each of the ECC aggregators has the following main features:
  - Reduces memory software errors via single error correction (SEC) and double error detection (DED)
  - Provides a mechanism to control and monitor the ECC RAMs in a module or subsystem
  - Supports software readable status of ECC errors (single and double-bit) and associated info such as RAM address and data bit or bits that are in error
  - Aggregates level pending status from the ECC RAMs in two interrupts to the device CPU – interrupt for correctable error (SEC) and interrupt for uncorrectable error (DED)
  - Supports up to 256 ECC endpoints (either ECC RAM or interconnect ECC component)
  - Single bit error detection via parity checking results in a non-correctable error interrupt

## 1.6 Device Identification

The manufacturer identity, the boundary scan part number, and the silicon revision of the device can be read in the CTRLMMR\_WKUP\_JTAGID register. See [Table 1-2](#) and [Table 1-3](#), for more information.

**Table 1-2. Device JTAG ID**

CTRLMMR_WKUP_JTAGID Register Field	Value	Comment
[31-28] VARIANT	See <a href="#">Table 1-3</a>	Silicon Revision (SR) identifier.
[27-12] PARTNO	See <a href="#">Table 1-3</a>	Part number for boundary scan.
[11-1] MFG	0x17	Manufacturer identity (TI).
[0] LSB	0x1	Always reads 1.

**Table 1-3. Device JTAG ID Values**

Silicon Type	VARIANT	PARTNO	CTRLMMR_WKUP_JTAGID Register Value
DRA829 SR1.0 TDA4VM SR1.0	0x0	0xBB64	0x0BB6402F
DRA829 SR1.1 TDA4VM SR1.1	0x1	0xBB64	0x1BB6402F
DRA829 SR2.0 TDA4VM SR2.0	0x2	0xBB64	0x2BB6402F

This chapter summarizes the memory map address regions for the device.

---

**Note**

NAVSS0\_DDR0 and NAVSS0\_DDR1 are used for load balancing and real time/ non-real time traffic separation. Max addressable DDR memory across the two paths is 8 GB.

---

## 2.2 MCU Domain Memory Map

Table 2-3 shows the MCU domain memory map.

### Note

The memory locations not shown in Table 2-3 are either unallocated or reserved and not used. Accesses to these locations are not recommended and should be avoided.

## 2.5 Region-based Address Translation

The SoC memory map view shown in [Section 2.1](#), [Section 2.2](#) and [Section 2.3](#) is used by the processors in COMPUTE\_CLUSTER0 but there are processors which support only 32-bit addressing and cannot access higher address ranges. For these processors RAT modules are integrated to remap the 32-bit addresses to

48-bit addresses allowing higher address range accesses. The "RAT\_REGION" regions shown in [Table 2-5](#) through [Table 2-8](#) are dedicated to RAT remapping.

For more information about the RAT module, see [Section 8.4 Region-based Address Translation \(RAT\) Module](#).

## Chapter 3

# System Interconnect

---

The following sections describe the device system interconnect.

<b>3.1 System Interconnect Overview.....</b>	<b>182</b>
<b>3.2 System Interconnect Integration.....</b>	<b>184</b>
<b>3.3 System Interconnect Functional Description.....</b>	<b>189</b>

### 3.1 System Interconnect Overview

All modules and subsystems in the device communicate with each other through the system interconnect for any memory map accesses. It is partitioned into the following sections:

- CBASS0 interconnect
- INFRA\_CBASS0 interconnect
- MCU\_CBASS0 interconnect
- WKUP\_CBASS0 interconnect

These interconnects are used for data transfers and configuration. They are composed by switch fabrics enabling fast internal data movement. They also provide low-latency and concurrent data transfers between master and slave peripherals.

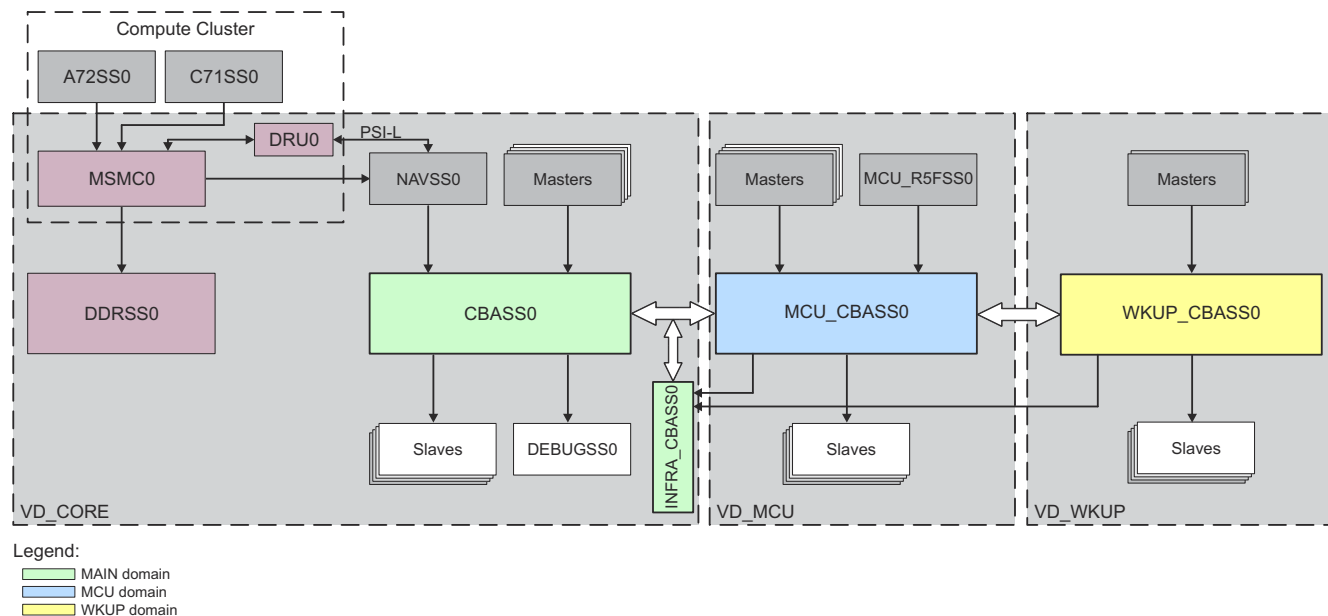

The CBASS0 is further partitioned in the following sub-interconnects:

- CBASS\_HC2\_0
- CBASS\_AC0
- CBASS\_DATADEBUG0
- CBASS\_HC0
- CBASS\_CSI0
- CBASS\_HC\_CFG0
- CBASS\_MCASP\_G0\_0
- CBASS\_MCASP\_G1\_0
- CBASS\_RC0
- CBASS\_RC\_CFG0
- CBASS\_AASRC0
- CBASS\_IPPHY0

Most of the device modules are connected to the CBASS0 interconnect that is located in VD\_CORE. These modules, INFRA\_CBASS0 and CBASS0 are part of the device MAIN domain. MCU\_CBASS0 resides in VD\_MCU and connects all modules from the MCU domain. WKUP\_CBASS0 is located in VD\_WKUP and is for modules in the WKUP domain. INFRA\_CBASS0 contains almost all infrastructure and internal diagnostic components and also peripherals not power managed in the MAIN domain.

[Figure 3-1](#) shows the device system interconnect. All modules and subsystems can be classified into two categories: masters and slaves. The masters are capable of initiating read and write transfers in the system. The

slaves on the other hand depend on the masters to perform transfers to and from them. They cannot generate read/write requests but can respond to these requests generating interrupts or DMA requests.

intconn-001

**Figure 3-1. Device System Interconnect Overview**

## 3.2 System Interconnect Integration

This section describes system interconnect integration in the device, including information about clocks, resets, and hardware requests.

### 3.2.1 Interconnect Integration in WKUP Domain

Table 3-1 through Table 3-3 summarize the integration of WKUP\_CBASS0 in device WKUP domain.

**Table 3-1. WKUP\_CBASS0 Integration Attributes**

Module Instance	Attributes		
	Power Sleep Controller	Power Domain	Module Domain
WKUP_CBASS0	WKUP_PSC0	PD0	LPSC0
WKUP_CBASS_FW0	WKUP_PSC0	PD0	LPSC0

**Table 3-2. WKUP\_CBASS0 Clocks and Resets**

Clocks			
Module Instance	Source Clock Signal	Source	Description
WKUP_CBASS0	MCU_SYSCLK0/3	WKUP_PLLCTRL0	WKUP_CBASS0 clocks
	MCU_SYSCLK0/6	WKUP_PLLCTRL0	
	MCU_SYSCLK0/12	WKUP_PLLCTRL0	
WKUP_CBASS_FW0	MCU_PLL_CLKOUT/3	MCU_PLL0	Clock for all WKUP_CBASS0 firewalls
Resets			
Module Instance	Source Reset Signal	Source	Description
WKUP_CBASS0	MOD_G_RST	LPSC0	WKUP_CBASS0 reset
WKUP_CBASS_FW0	MOD_G_RST	LPSC0	Reset for all WKUP_CBASS0 firewalls

**Table 3-3. WKUP\_CBASS0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
WKUP_CBASS0	WKUP_COMMON_ERR_INTR	GIC500_SPI_IN_952	GIC500	WKUP CBASS null endpoint error interrupt	Level
		R5FSS0_INTRTR0_IN_156	R5FSS0_INTRTR0

DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
MCU_CBASS0	-	-	-	-	-

### Note

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

### 3.2.3 Interconnect Integration in MAIN Domain

[Table 3-7](#) through [Table 3-9](#) summarize the integration of CBASS0 in device MAIN domain.

**Table 3-7. CBASS0 Integration Attributes**

Module Instance	Attributes		
	Power Sleep Controller	Power Domain	Module Domain
CBASS0	PSC0	PD0	LPSC0
INFRA_CBASS0	PSC0	PD0	LPSC2

**Table 3-7. CBASS0 Integration Attributes (continued)**

CBASS_FW0	PSC0	PD0	LPSC0
-----------	------	-----	-------

**Table 3-8. CBASS0 Clocks and Resets**

Clocks			
Module Instance	Source Clock Signal	Source	Description
CBASS0	MAIN_SYSCLK0	PLLCTRL0	CBASS0 and INFRA_CBASS0 clocks
INFRA_CBASS0	MAIN_SYSCLK0/2	PLLCTRL0	
	MAIN_SYSCLK0/4	PLLCTRL0	
CBASS_FW0	MAIN_SYSCLK0 or MAIN_SYSCLK0/2	PLLCTRL0	Clocks for all CBASS0 firewalls
Resets			
Module Instance	Source Reset Signal	Source	Description
CBASS0	MOD_G_RST	LPSC0	CBASS0 reset
INFRA_CBASS0	MOD_G_RST	LPSC2	INFRA_CBASS0 reset
CBASS_FW0	MOD_G_RST	LPSC0	Reset for all CBASS0 firewalls

**Table 3-9. CBASS0 Hardware Requests**

Interrupt Requests

**DMA Events**

Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
CBASS0	-	-	-	-	-

**Note**

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

### 3.3 System Interconnect Functional Description

#### 3.3.1 Master-Slave Connections

Table 3-10 through Table 3-19 list the master and slave end point connections on the CBASS0. A cell may contain one of the following:

- Y – There is a connection between this master and that slave
- N – There is no connection between this master and that slave.

**Table 3-10. CBASS0 Connectivity Matrix (Part 1)**

Table 3-20 and Table 3-21 list the master and slave end point connections on the MCU\_CBASS0. A cell may contain one of the following:

- Y – There is a connection between this master and that slave
- N – There is no connection between this master and that slave.

Table 3-22 lists the master and slave end point connections on the WKUP\_CBASS0. A cell may contain one of the following:

- Y – There is a connection between this master and that slave
- N – There is no connection between this master and that slave.

### 3.3.2 Quality of Service (QoS)

The device interconnect provides two mechanisms to achieve quality of service (QoS): parallel routing based on order ID and arbitration based on priority. The order ID has two main usages: to order execution of transactions and parallel paths selection. The parallel paths are defined as multiple paths between master and slave. If two or more slaves share same physical memory map assignment, it is considered parallel paths.

The CBASS\_MAP\_i[7-4] ORDERID bit field is for transactions for each master and each channel of the master. This allows different mapping not only for each master, but also for each channel of the master, if multiple channels are supported. The CBASS\_MAP\_i[7-4] ORDERID bit field specifies the initial order ID value. The ORDERIDx bit fields in CBASS\_GRP\_MAP1\_j and CBASS\_GRP\_MAP2\_j registers take the initial order ID value and result in a final order ID value, which is nothing more than a 4-bit identifier used for path routing. The final order ID is used to differentiate the paths to a slave and thus allowing load balancing of the traffic over each path.

The interconnect performs traffic routing and switching from a number of masters to a number of slaves. The masters send transactions. The interconnect decodes which slave is being accessed based on special signals and memory map and routes that transaction to the slave. The interconnect also arbitrates for a slave when there are multiple transactions being requested simultaneously. The arbitration is based on transaction priority. Once a transaction is selected, the interconnect sends the transaction to the slave. The transaction priority is controlled per master and per channel of the master through the CBASS\_MAP\_i[14-12] EPRIORITY bit field. The priority setting for each master can be done by any processor. Increasing the priority level for certain master can help the transaction from that master to have advantage on winning arbitration, therefore improving the latency and bandwidth for the transactions from that master.

Since the order ID is controlled from configuration registers, the user can re-partition the traffic among parallel paths to achieve better load balance adjusted for specific use cases. As order ID has routing implication for both command and return data, its configuration must not be changed during run time. Otherwise, the return data may be routed to wrong path and cause system hang. To avoid this, the system must be put into idle state with no traffic on the interconnect before reprogramming procedure.

There are many QoS register blocks each of which is master related only. [Table 3-24](#) through [Table 3-37](#) show the mapping between masters and QoS block physical addresses. "N/A" in column "**QoS Block Physical Address**" means that the corresponding master does not have QoS registers at device level. Local QoS registers may still be available.

#### Note

Route ID is not related to QoS. For route ID description, see [Section 3.3.3](#).

#### Note

There are no master modules on the INFRA\_CBASS0 interconnect.

The interconnect inside NAVSS0 uses order ID to provide multiple (at least two) parallel paths to DDR and a separate set of multiple (at least two) parallel paths to SRAM. NAVSS0 also provides multiple (at least two) parallel paths for the DMA traffic to SoC level, which can provide isolated DMA traffic paths. For more information, see *Navigator Subsystem (NAVSS)*.

The MSMC does not use order ID for routing purpose to provide separate physical paths for transaction. Instead, it provides two threads to isolate two classes of transactions: thread 0 and thread 2. The arbitration between these two threads is based on credits, and thread 2 has priority over thread 0 when both threads have credits available for transfer. In addition, there is bandwidth management scheme based on transaction priority and bandwidth starvation prevention mechanism. For more information, see *Multicore Shared Memory Controller (MSMC)*.

By default all masters send transactions with order ID = 0. All transactions with the same order ID execute in order if they are sent to the same slave or going through a common bridge. On the SoC level interconnect, the order ID is used to partition the transactions to MSMC and DDR data space into parallel routing paths. Further, the north bridge inside NAVSS0 provides multiple parallel paths to the compute cluster. Each path is separated by order ID value. All read commands towards MSMC and DDR sharing the same order ID and sharing the same master path from SoC side (including NAVSS0) provide read return data in order back to the master port. The write response can be returned out of order for the same order ID value. Therefore, programming order ID has implications on overall system performance as well as achieving QoS for certain class of traffic. Multiple configurations are needed to make sure that the QoS goal is met.

For any write to address range 0x4500\_0000 to 0x45FF\_FFFF, it is recommended to read back the value after the write to make sure the write landed. The registers in this regions are mainly for firewall configuration, ISC/DMA credential configuration, QoS MMR configuration.

On QoS MMR configuration, in order to configure certain transaction to be the highest priority, the priority field needs to be set to zero for that transaction. In order to make sure that priority field is indeed to set to zero, the following sequence should be followed:

1. Read the priority field, if it is non-zero value, follow a write to overwrite priority field to be 0x0.

2. If read back priority field is zero, write to QoS MMR register to set priority field to be 0x7. Read back the same priority field. If the read back value is 0x7, write to QoS MMR register to set priority field to be 0x0. If the read back value is 0x0, it means this register is not implemented and priority setting is not working.

### **3.3.3 Route ID**

The route ID is used by the interconnect to route return status and data back to the transaction initiator. Each master has one or multiple unique route IDs assigned to it. The route ID has no other usage. There are no software controls for the route ID.

### 3.3.4 Initiator-Side Security Controls and Firewalls

Firewalls (FW) and Initiator-side Security Controls (ISC) are important interconnect components that enable hardware isolation for freedom from interference or security uses. ISCs enable every transaction to be identified and tagged to precisely assign the source ID. Firewalls are downstream (target) components that provide the ability to filtering transactions based on the sideband information.

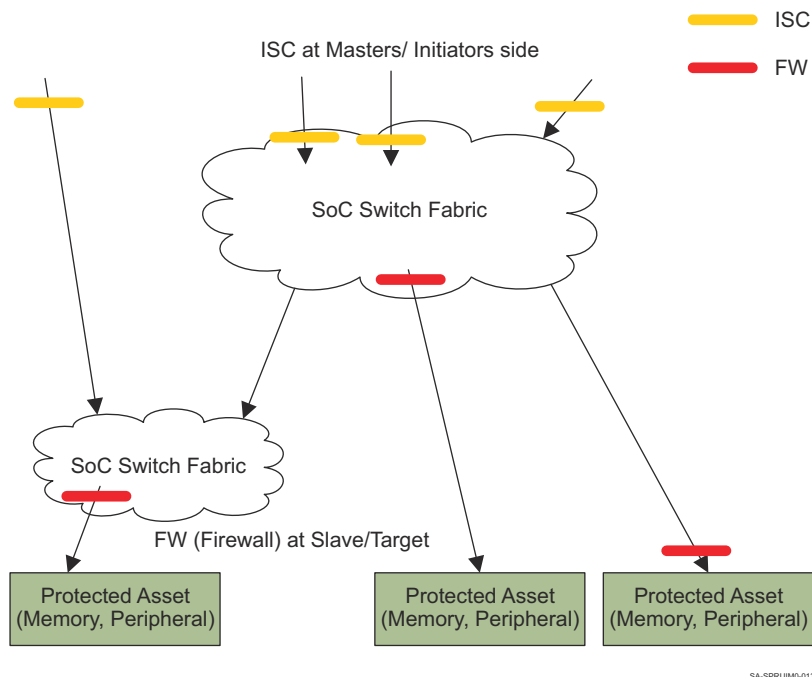

The device protection depends on firewalls. They are used to protect data and configuration spaces by managing the accesses to these memory regions. There are two types of firewalls - region based and channelized. There aren't channelized firewalls on system level. Only NAVSS0, MCU\_NAVSS0 and DRU0 have channelized firewalls for the various DMA channels. Only region based firewalls are available on system level. See [Section 3.3.4.2.2.1](#) and [Section 3.3.4.2.3.1](#) for description of the region based and channelized firewalls.

Almost all slaves have a firewall right before the transaction reaches them. There are few exceptions such as WKUP\_DMSC0, VPAC0, DMPAC0, NAVSS0 and MCU\_NAVSS0 slave ports. These subsystems contain local interconnect with own firewalls inside the subsystem itself. The firewalls inside compute cluster (for A72SS0, C71SS0 and DRU) are also an exception. They are put on the master instead on the slave port side. To enable access for that master port to the slaves these master side firewalls must individually be programmed. Note that there is also a second firewall for C71SS0 that is put on the slave port side.

On devices supporting secure boot and secure DMSC, these components allow the SoC to support multi-tier security and provide segregation of secure and non-secure worlds. All configuration of ISCs and FWs are under exclusive control of DMSC, using a dedicated interconnect.

The number of ISC and Firewall blocks and placement of these blocks are based on the topology of each device. ISC and Firewall blocks are placed in host modules (AXI to VBUSM.C Bridge); or part of the interconnect (for example: CBASS).

Figure 3-2 presents a generic view of ISCs and Firewalls in SoC.

**Figure 3-2. ISC and Firewall in SoC**

### 3.3.4.1 Initiator-Side Security Controls (ISC)

Initiator-Side Security Control (ISC) modules are hosted at the initiator side where the transactions are sourced. ISC controls the security sideband attributes that are applied to outgoing transactions and have ability to override security values under exclusive control of DMSC.

ISC Capabilities:

- Attach Priv-ID to each bus transaction.
- Priv-ID is a source ID attached to identify the source of a transaction in the system.
- By default, each initiator in the system has a unique Priv-ID.
- Multiple modules can be assigned the same Priv-ID to form logical groups.
- Assert, De-assert or pass-through secure bit.
- Assert, De-assert or pass through Priv-bits.

ISCs are connected to the dedicated security VBUSP interconnect and can be exclusively configured by DMSC. ISC optionally can support region and channel number based security control, where, based on incoming channel or address, the associated security controls, are applied.

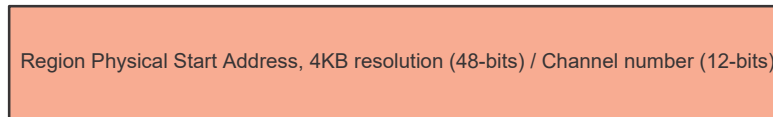

Figure 3-3 presents ISC config registers per region.

ISC Control Regs **per** region

E = Enable Region (0xA = Enabled)  
L = Lock Config  
C = Use Channel number, not address  
D = Default region indicator  
S = Make outgoing transaction secure (0xA = Enabled)  
N = Make outgoing transaction Non-secure  
R = Reserved  
P = Do not replace Priv-ID, pass through PrivID  
NOPRIV = Clear Outgoing PRIV Attribute  
PRIV = Set Outgoing PRIV Attribute

Lower 12-bits valid in case of channel number

Not valid in case of channel number

**Figure 3-3. ISC Config Registers per Region**

Priv-ID is used to identify the logical source of transaction and is attached by ISC. The Priv-IDs are allocated based on subsystem as part of platform definition.

#### Note

See Appendix Spreadsheet for ISC and Priv-ID details.

#### 3.3.4.1.1 Special System Level Priv-ID

This section describes Special Priv-IDs that must not be assigned to any ISC. These Priv-ID when encountered by various blocks like firewall have special meaning.

Table 3-38 presents Special Priv-IDs.

**Table 3-38. Special Priv-IDs**

Special Priv-IDs	Hex Value	Decimal Value
System Reserved Priv-ID	0xC1, 0xC2, 0xC4, 0xC6, 0xC7	193, 194, 196, 198, 199
Wild card Priv ID	0xC3	195
Block Priv ID	0xC5	197
DMA Reserved Priv-ID	0xC0	192

(1) Value "ch" means one ISC setting per one channel as this is a channelized ISC.

### 3.3.4.2 Firewalls (FW)

Firewalls play an important role in implementing overall SoC security by providing a means to allow or restrict access to device resources to any given master entity or Secure/Non-Secure/Priv/User world. Firewalls are placed at various data path points throughout the SoC to control access to protected asset (Peripheral, memory and so forth).

Firewalls ensure that assets can be protected and are only accessible by allowed master and in selected operation mode (Secure, Non-Secure, Priv, User, write, read and so forth). In case of firewall violations, the transaction is dropped and the appropriate violation code is registered with associated parameters.

There are three types of firewalls, Peripheral firewalls, Memory firewalls (referred as one group **Region Based Firewall** in the device-specific TRM) and Channelized firewalls.

Each Firewall module in the SoC has a unique Firewall ID that allows software to decode the source of each violation. The Firewall IDs are allocated based on subsystem as part of platform definition. The full SoC view of Firewall IDs for various Firewall modules are captured in each device spec.

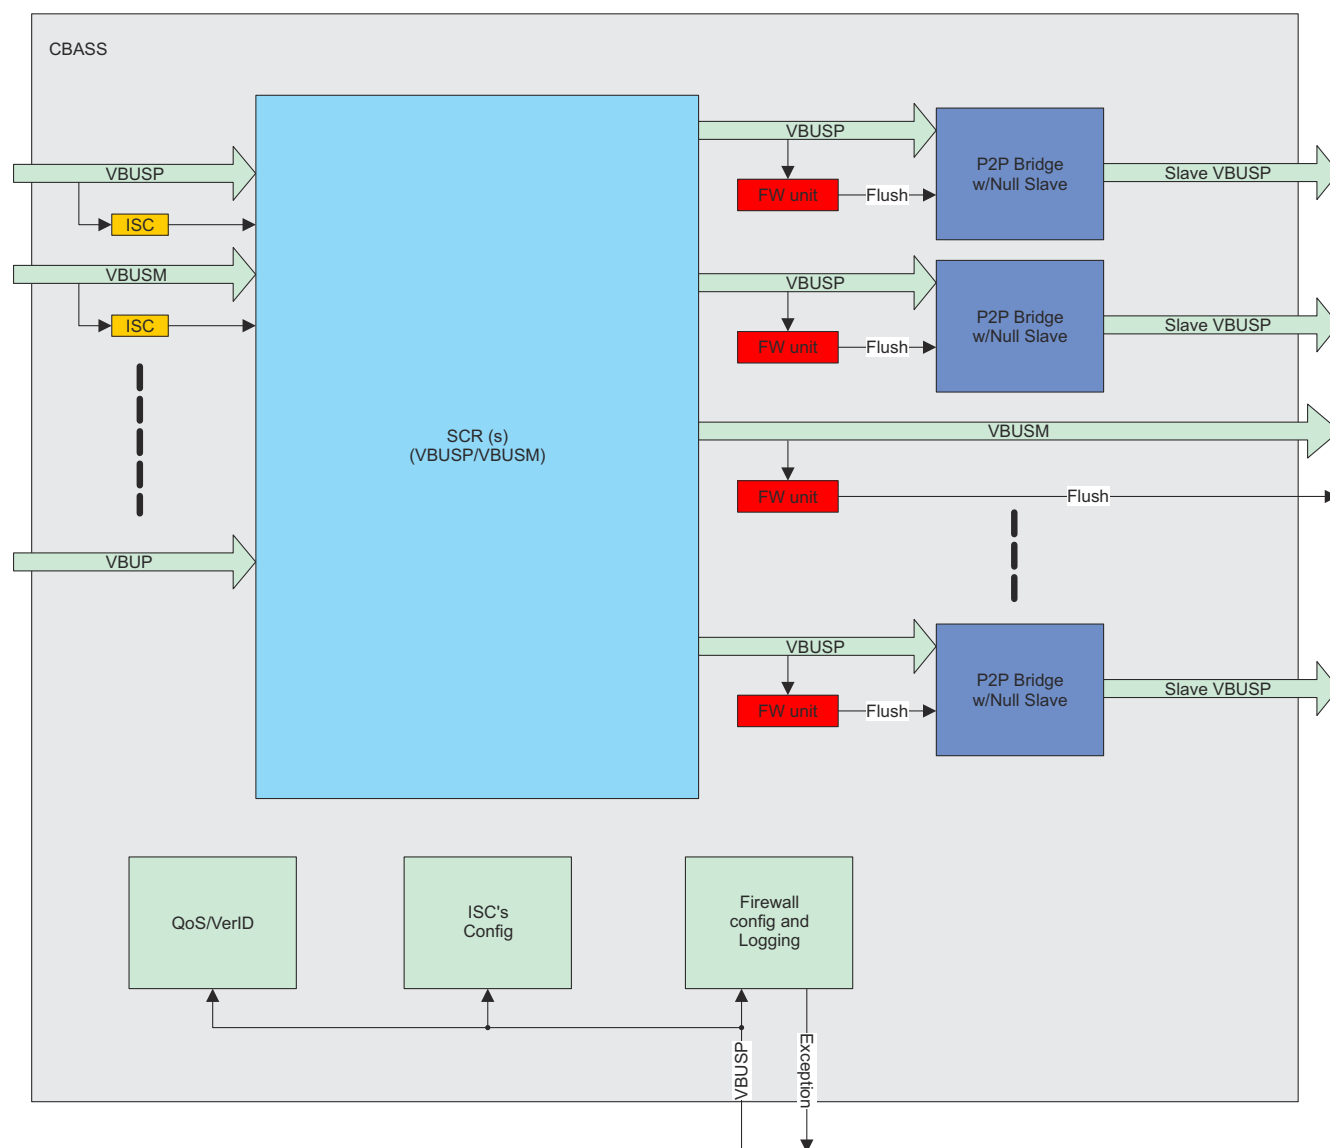

#### 3.3.4.2.1 Peripheral Firewalls (FW)

Peripheral firewall modules are placed in front of peripherals like UART, SPI and so forth. They protect access to the peripheral registers/memory and typically have firewall regions as number of regions supported by module that is being protected.

All Peripheral firewalls support 3 Priv-ID slots that allow multiple masters/initiators to access protected peripherals.

The peripheral firewall is configured using dedicated VBUSP port to CBASS that connects to DMSC private VBUSP interconnect.

[Figure 3-4](#) presents Peripheral Firewall.

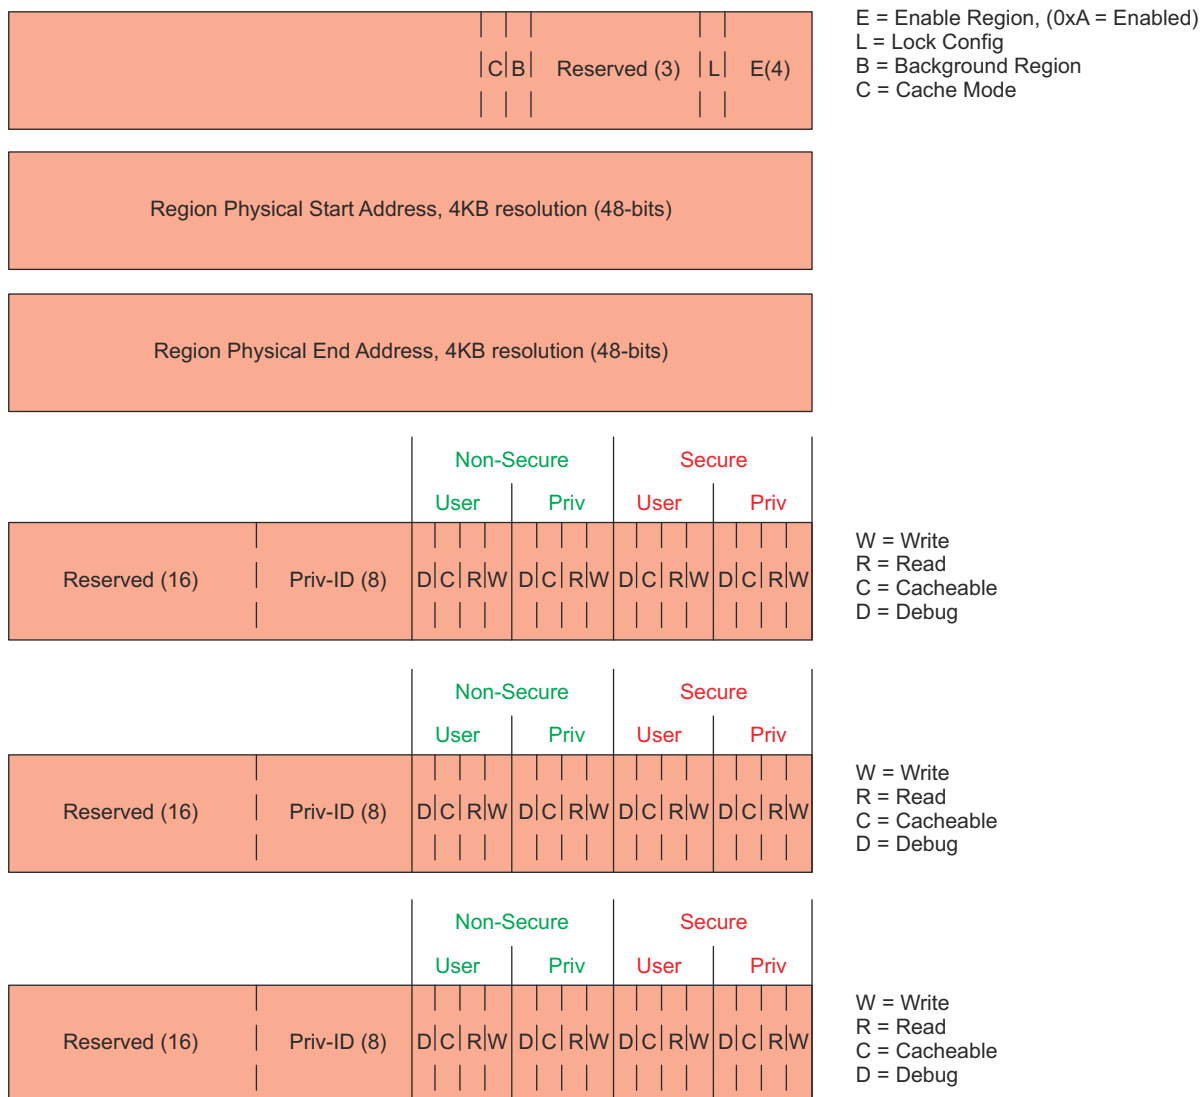

SA-SPRUI1D-015

**Figure 3-4. Peripheral Firewall**

Each region is defined by start and end physical address and associated permission/control register as shown in [Figure 3-5](#).

Firewall Control Regs **per** region

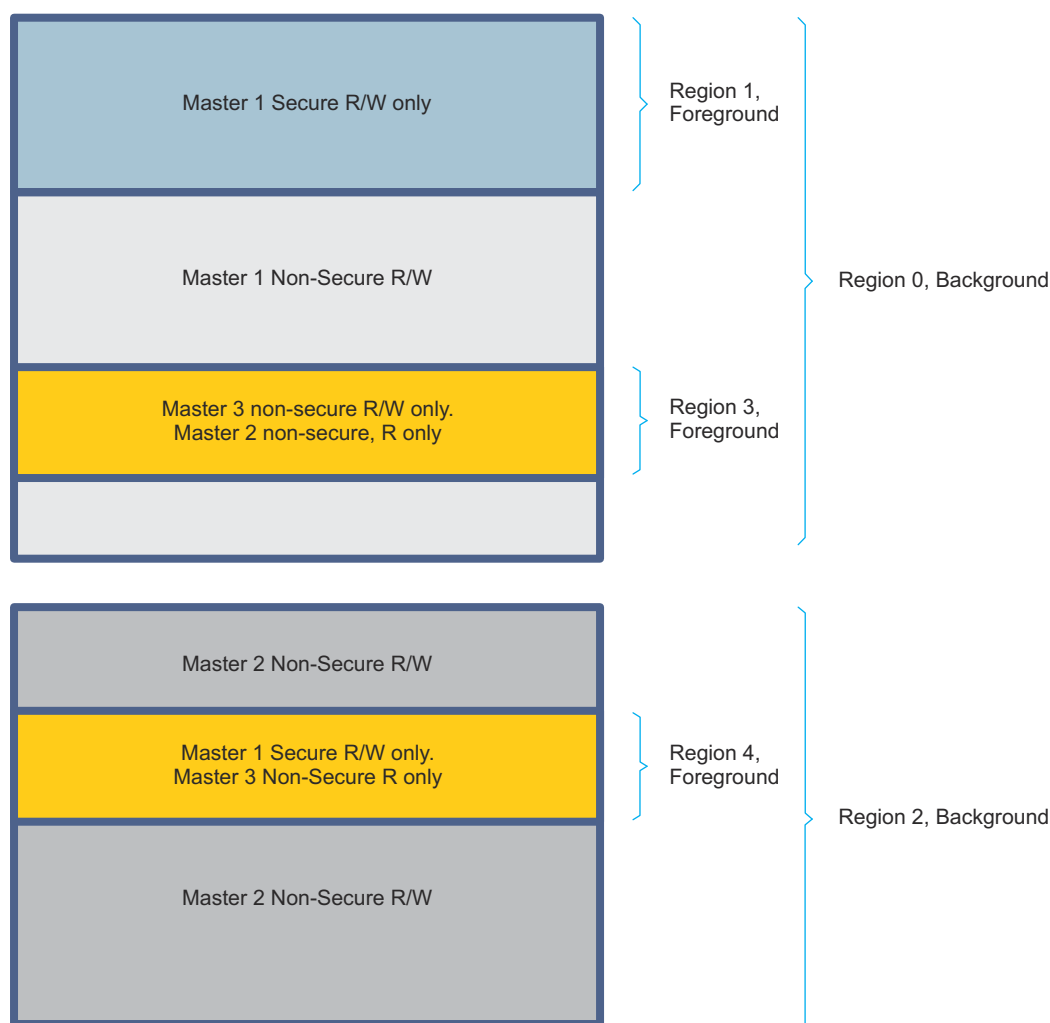

SA-SPRUI00-016

**Figure 3-5. Peripheral Firewall Config Registers per Regions**

A Peripheral's Firewall module can have one or more regions. In case there is more than 1 region, the registers are duplicated for each region.

If multiple regions are supported, a firewall configuration can be defined as either a Background or Foreground region depending on the setting of the Background (B) bit. Foreground regions can overlap background regions and their Firewall settings take precedence over the Background settings when there is overlap. However, background regions cannot overlap each other and foreground regions cannot overlap each other. A firewall error will result in case a memory transaction is made to the improper overlap regions.

Figure 3-6 presents peripherals firewall regions.

SA-SPRUID-017

**Figure 3-6. Peripherals Firewall Regions**

In the above case, Region 0 and Region 2 are background regions (background bit set in control register). Region 1, Region 3 and Region 4 are **not** background (foreground) regions. In case the incoming transaction hits in address in Region 1, the permissions of Region 1 are applied to filter incoming transaction, thereby completely ignoring the permission of the background Region 0.

Table 3-40 through Table 3-54 show the initiator and target firewalls, firewall IDs, physical base address of the corresponding firewall, number of firewall regions, and areas covered by the firewall. The firewall ID uniquely identifies each firewall. In case of firewall violation this ID is logged and can be read through the CBASS\_EXCEPTION\_LOGGING\_HEADER0[23-8] SRC\_ID field.

### 3.3.4.2.2 Memory or Region-based Firewalls

Memory/Data firewalls are designed to protect Memory (SRAM/DDR and so forth) and data regions (GPMC and so forth). Memory/Data firewalls have a defined firewall region count so that the memory can be partitioned into multiple firewall regions.

The architecture of Memory/Data firewalls is similar to Peripheral Firewalls, however, the Memory/Data firewall can have either 1 or 3 Priv-ID slots per region, with associated permissions. The number of Priv-ID slots is determined based on placement of firewall block. Each region in this type of firewall is defined by a physical start and end address.

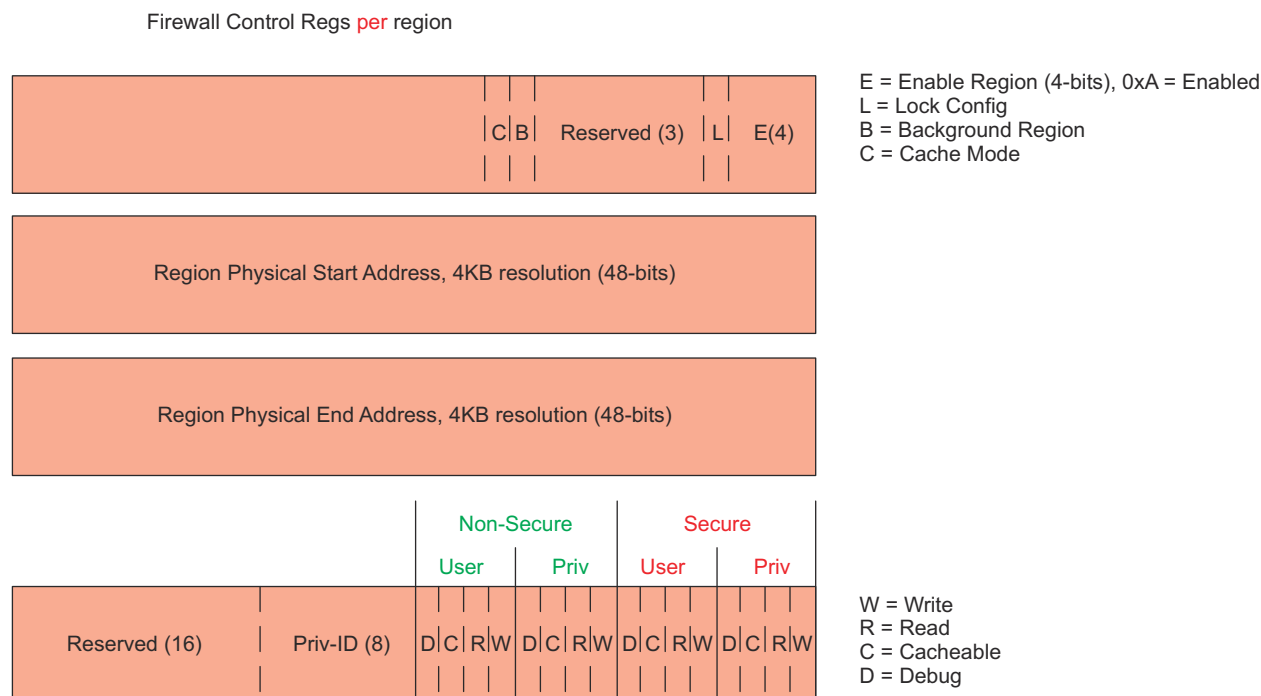

Figure 3-7 presents Memory/Data firewall config registers with 3 Priv-ID slots per region.

## Firewall Control Regs **per** region

### Figure 3-7. Memory/Data Firewall Config Registers with 3 Priv-ID slot per Region

Figure 3-8 presents Memory/Data firewall config registers with 1 Priv-ID slot per region.

SA-SPRUI1D-019

**Figure 3-8. Memory/Data Firewall Config Registers with 1 Priv-ID slot per Region**

The Memory/Data firewall is configured using dedicated VBUSP port to CBASS/AXI to VBUSM.C Bridge/DRU that connects to DMSC private VBUSP interconnect.

Memory/Data Firewalls also support background regions as in peripheral firewalls.

### 3.3.4.2.2.1 Region Based Firewall Functional Description

The region based firewall provides a memory region based protection and isolation mechanism. For each defined memory region, it checks the transaction attributes such as secure vs non-secure, debug vs non-debug, supervisor vs user mode, read vs write and so on. The transaction is dropped, if it does not match the configuration and appropriate violation code is registered with offending parameters.

Host modules (for example, AXI2VBUSMC bridge or CBASSes) provide transaction attributes that are checked by the firewalls, which then determine if the transaction should be blocked or passed. The firewall implements filtering algorithm that compares these host incoming transaction parameters against the region policy to give block indication to the host. Firewall region registers configure the filtering mechanism which includes setting region address range, region permission registers and region control register. There are also firewall exception registers used for violation reporting and logging.

The region based firewall supports multiple regions. Each one is defined by address range and associated access permission. The minimum memory region size is 4KB. The firewall concurrently checks the incoming transaction against all enabled regions looking for violations.

Each firewall is associated with the following registers:

- CBASS\_FW\_REGION\_i\_CONTROL

- CBASS\_FW\_REGION\_i\_PERMISSION\_0 to CBASS\_FW\_REGION\_i\_PERMISSION\_2
- CBASS\_FW\_REGION\_i\_START\_ADDRESS\_L and CBASS\_FW\_REGION\_i\_START\_ADDRESS\_H
- CBASS\_FW\_REGION\_i\_END\_ADDRESS\_L and CBASS\_FW\_REGION\_i\_END\_ADDRESS\_H

Each region is defined by start and end physical address and associated permission and control registers. A firewall can have 1-24 regions. In case there is more than 1 region, then these registers are duplicated for all regions. Setting the CBASS\_FW\_REGION\_i\_CONTROL[3-0] ENABLE field to 0xA enables the region and makes firewall check active for this region. Setting to 0x1 the CBASS\_FW\_REGION\_i\_CONTROL[8] BACKGROUND bit indicates to the firewall that the region is background region. Setting to 0x1 the CBASS\_FW\_REGION\_i\_CONTROL[9] CACHE\_MODE bit ignores cacheable check, so that it cannot fail. In this case the access check is performed based on the READ and WRITE bits in CBASS\_FW\_REGION\_i\_PERMISSION\_x. Clearing CACHE\_MODE enables the cacheable check, so that cacheable transactions are allowed only when the corresponding cacheable permission bit (CBASS\_FW\_REGION\_i\_PERMISSION\_x [y\_CACHEABLE]) is set. If the CBASS\_FW\_REGION\_i\_CONTROL[4] LOCK bit is set to 0x1, then the region configuration cannot be changed at all. This is one-time change. This bit is typically used for primary master to consume and lock its resources and then pass firewall control to secondary master.

In case two regions overlap, the CBASS\_FW\_REGION\_i\_CONTROL[8] BACKGROUND bit is used to select the appropriate permission to be used. The region whose BACKGROUND bit is 0x0 (foreground) takes precedence and its permissions are taken into effect. The background region is ignored.

#### Note

There can be only one background region per firewall. Foreground regions can have overlapping addresses only with the background region.

It is a software mistake to have overlapping regions with the BACKGROUND bit set to the same value (either background or foreground). Software must be careful to not configure two overlapping regions with the BACKGROUND bit set to the same value.

The firewall also checks if the transaction crosses a 4KB boundary. If so, the transaction is blocked regardless of any matching regions.

When a region is set to be debugable through the corresponding CBASS\_FW\_REGION\_i\_PERMISSION\_x [y\_DEBUG] bit, the firewall ignores the read and write checks for any debug transactions, so that it cannot fail. This allows debug breakpoints to be written out to code even in read-only regions.

When a region is set to be cacheable through the corresponding CBASS\_FW\_REGION\_i\_PERMISSION\_x [y\_CACHEABLE] bit and CACHE\_MODE = 0x0, the firewall ignores the read and write checks for any transaction (cacheable or not), so that it cannot fail due to these checks. This allows a write allocated cache to read a cache line even in write-only regions. Due to caches not protecting user and supervisor data from each other, the firewall allows cacheable access to the region when either the user cacheable permission or the supervisor cacheable permission is set.

The firewall notifies the host that the transaction is blocked in case of the following violation conditions:

- All regions are disabled.
- Incoming address does not hit any region.
- Non-secure incoming read transaction attempting to access configured secure-only write/read region.
- Non-secure incoming write transaction attempting to access configured secure-only write/read region.
- Secure incoming read transaction attempting to access configured non-secure-only write/read region.
- Secure incoming write transaction attempting to access configured non-secure region.
- Incoming secure write transaction attempting to access configured secure read region. This check is ignored if the region is configured as cacheable.
- Incoming secure read transaction attempting to access configured secure write region. This check is ignored if the region is configured as cacheable.

- Incoming non-secure write transaction attempting to access configured non-secure read region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure read transaction attempting to access configured non-secure write region. This check is ignored if the region is configured as cacheable.
- Incoming non-secure debug access to non-debugable secure region.
- Incoming non-secure debug access to non-debugable non-secure region.
- Incoming secure debug access to non-debugable secure region.
- Incoming secure debug access to non-debugable non-secure region.
- Incoming cacheable transaction attempting to access non-cacheable configured region.

All violation parameters caused the exception are logged in the firewall exception registers described in *Firewall Exception Registers*. Table 3-55 shows the mapping between the register fields and violation parameters. If the CBASS\_EXCEPTION\_LOGGING\_CONTROL[0] DISABLE\_F bit is set to 0x1, logging is disabled.

If violation occurs, the corresponding firewall notifies WKUP\_DMSC0 driving high a dedicated signal. The notification (that is, the signal) can be masked by setting to 0x1 the CBASS\_EXCEPTION\_LOGGING\_CONTROL[1] DISABLE\_PEND bit. The firewall exception notification signal gets automatically cleared when the CBASS\_EXCEPTION\_LOGGING\_DATA3 register is read. That signal can be manually set via the CBASS\_EXCEPTION\_PEND\_SET[0] PEND\_SET bit and cleared via the CBASS\_EXCEPTION\_PEND\_CLEAR[0] PEND\_CLR bit. Reading one of these two bits returns the status of the signal (that is, violation occurred or not).

**Table 3-55. Firewall Violation Parameters**

Field	Value	Description
CBASS_EXCEPTION_LOGGING_HEADER0[31-24] TYPE_F	0x1	Exception type for firewall violation. This is fixed for the SoC firewalls and is used by software to detect that this corresponding violation comes from a firewall.
CBASS_EXCEPTION_LOGGING_HEADER0[23-8] SRC_ID	0x-	Firewall ID. Unique for each firewall. This is used to identify the exact firewall that issued violation so that software detects the precise source.
CBASS_EXCEPTION_LOGGING_HEADER0[7-0] DEST_ID	0x-	Destination ID of node where the firewall violation has be to routed.
CBASS_EXCEPTION_LOGGING_HEADER1[31-24] GROUP	0x0	Exception group. This is used to group exceptions to category. All firewall exceptions are in one group.
CBASS_EXCEPTION_LOGGING_HEADER1[23-16] CODE	Exception code:	
	0x0	Reserved.
	0x1	No region enabled.
	0x2	Incoming address does not hit any active region and transaction is dropped.
	0x3	Reserved.
	0x4	Cacheable error. A cacheable transaction attempting to read/write non-cached marked region.
	0x5	Debug error. A debug transaction attempting to read/write a non-allowed debug region.
	0x6	Read error. A Read transaction attempting to read from non-allowed read region.
	0x7	Write error. A Write transaction attempting to write from non-allowed write region.
	0x8	4KB crossing error. A transaction attempting to cross a 4KB boundary.
CBASS_EXCEPTION_LOGGING_DATA0[31-0] ADDR_L	0x-	Lower 32 address bits (31:0) of the incoming transaction
CBASS_EXCEPTION_LOGGING_DATA1[15-0] ADDR_H	0x-	Upper 16 address bits (47:32) of the incoming transaction

**Table 3-55. Firewall Violation Parameters (continued)**

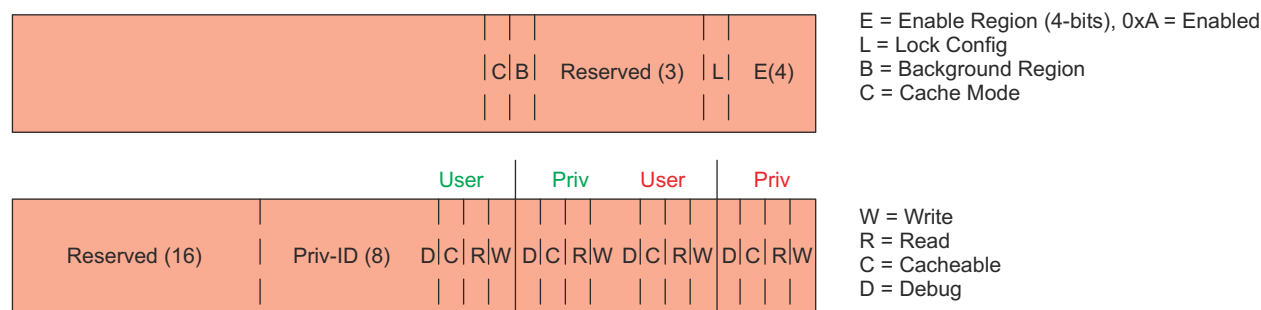

Field	Value	Description
CBASS_EXCEPTION_LOGGING_DATA2[7-0] PRIV_ID	Not used	Incoming transaction parameters
CBASS_EXCEPTION_LOGGING_DATA2[8] SECURE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[9] PRIV	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[10] CACHEABLE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[11] DEBUG	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[12] READ	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[13] WRITE	0x-	
CBASS_EXCEPTION_LOGGING_DATA2[27-16] ROUTEID	0x-	
CBASS_EXCEPTION_LOGGING_DATA3[9-0] BYTECNT	0x-	Byte count of the incoming transaction

### 3.3.4.2.3 Channelized Firewalls

A Channelized firewall is designed to protect modules that have logical channels (Ring Accelerator and so forth, for example). These firewalls operate at the resolution of a channel and have no association with physical addresses. Each channel is defined as a logical control entity.

In case of channelized firewalls, the number of regions are less than or equal to number of logical channels and each typical channel/region is very small memory space (typically in Bytes, like 16 bytes). A channel is owned by one processing entity, hence only 1 Priv-ID slot is provided for each Channelized firewall along with associated permissions.

## Firewall Control Regs **per** region

SA-SPR11M0-020

The Channelized firewall is configured using dedicated VBUSP port to CBASS/Bridges that connects to DMSC private VBUSP interconnect.

## Note

For more information about the interconnect firewalls, see *Interconnect Firewalls*.

The channelized firewall protects an address space that consists of multiple channels where each channel needs its own permissions. This is in contrast to the region based firewall which implements a number of regions that can protect a programmed address range. The channelized firewall extends this to a larger number of ranges that can be protected, but each range is no longer programmable and is instead fixed to a particular channel address range. This allows each channel to be owned and protected individually. The channels within same memory region have same size. The system can allocate each channel to a particular owner or owner groups with certain permissions and guarantee that others cannot access that channel. This protection is useful for either accessing data resources, or control for each resource. The channelized firewall provides an efficient way to implement access protection and isolation requiring finer granularity than the region based firewall.

Same as the region based firewall, the channelized firewall may also support multiple regions. Each region contains a number of channels that need to be protected individually and has size in bytes equal to the channel's data to protect. This allows multiple regions so that the firewall can protect a module containing multiple sets of registers that are each channelized and need separate protections, such as data access as well as control setup.

The transaction addresses are compared against region addresses to identify which region is being accessed. Then the offset within the region is used to identify the particular channel being accessed. If a valid channelized region is not decoded during the firewall check, then the transaction is passed through unmodified because the module may have other regions which are not channelized, but accesses to them are already protected by a region based firewall so the channelized one should not block them.

The permission check is performed just like for a region based firewall. The channelized firewall checks for user or supervisor privileged levels. It also checks for transactions that cross important boundaries and gives errors if violated. The first check is for a transaction crossing a 4KB address boundary. This is illegal on the bus, so the firewall checks for compliance. The second check is if the transaction crosses a channel boundary. The channelized firewall blocks a transaction accessing multiple channels in the same burst, as it cannot check the permission for the entire range of channels. The channelized firewall also supports error logging when a transaction fails the checks. It sends information about the type of error and the transaction that caused it.

The channelized firewall is associated with the following registers:

- \*\_CH\_i\_CONTROL, where "i" can be from 0 to 63 and denotes the channel. For example, see *Data Routing Unit (DRU)*. This register is equivalent to the CBASS\_FW\_REGION\_i\_CONTROL register of the region based firewall.
- \*\_CH\_i\_PERMISSION\_x, where "i" can be from 0 to 63 and denotes the channel and "x" can be 0 to 2. For example, see *Data Routing Unit (DRU)*. This register is equivalent to the CBASS\_FW\_REGION\_i\_PERMISSION\_x register of the region based firewall.

#### 3.3.4.2.3.2 Null Error Reporting

The interconnect supports capturing null slave errors for reporting. A null slave error occurs when a transaction does not address any slaves based on the address map, resulting in the transaction returning error status. The null errors are captured into registers and an interrupt is generated. There is only one set of reporting registers, so only one error can be captured until cleared by software. The report captures some details of the transaction, such as the Route ID to identify the master involved and the address accessed. See *Null Error Reporting Registers* for details about the null error reporting registers.

### 3.3.5 VBUSM\_TIMEOUT\_GASKET (MCU\_TIMEOUT\_64B2)

#### 3.3.5.1 Overview and Feature List

##### 3.3.5.1.1 Features Supported

- Tracks and times out VBUSM transactions
- Reports an error via interrupt
- Logs information about the transaction for debug
- Provides appropriate responses on read/status interface so issuing initiator may proceed
- Reports an error if an unexpected response arrives
- Software and Hardware flushing of outstanding transactions
- Number of outstanding write and read transactions:
- MCU FW to Main FW: num\_writes = 2, num\_reads = 2
- FSS: num\_writes = 32, num\_reads = 32
- MCU Island to RC: num\_writes = 9, num\_reads = 15
- MCU to MAIN\_INFRA: num\_writes = 2, num\_reads = 2

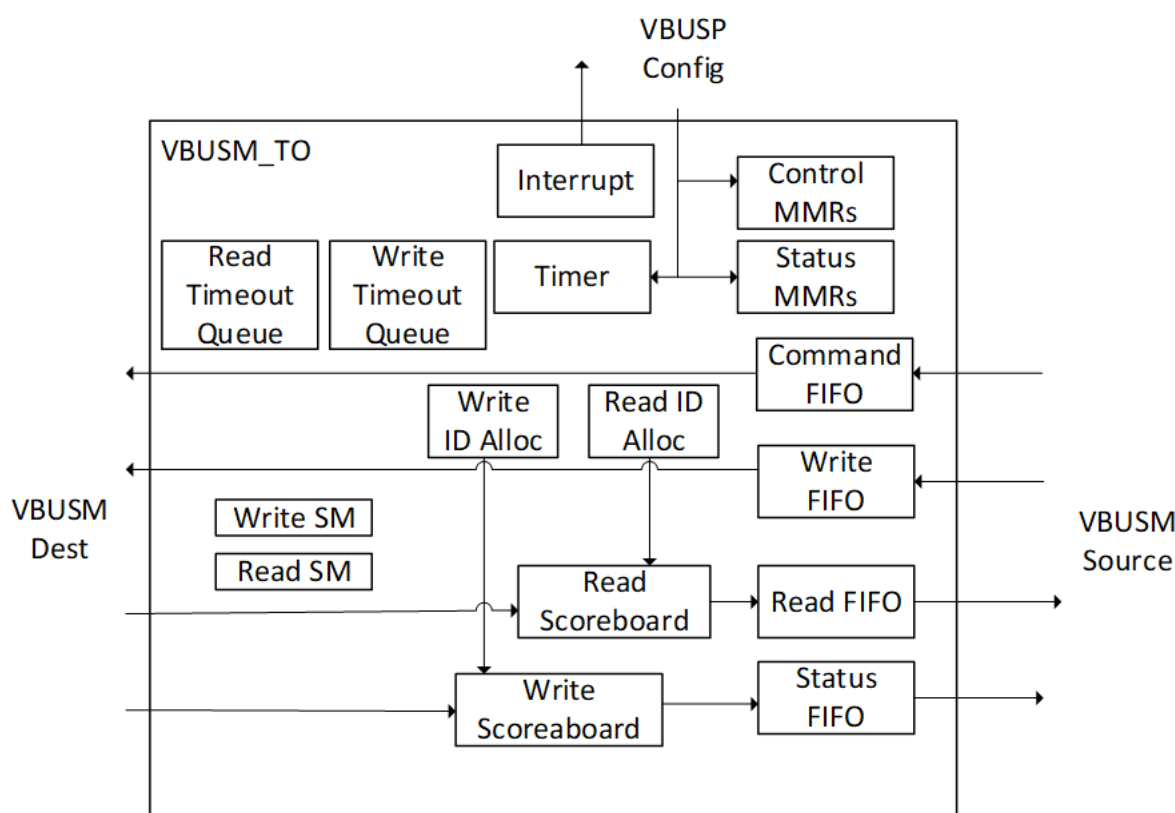

##### 3.3.5.1.2 Features Not Supported

- Protocol Checking
- Credit Mode
- Store and Forward
- Unaligned command and write data

#### 3.3.5.2 Functional Description

##### 3.3.5.2.1 Functional Operation

### 3.3.5.2.1.1 Overview

**Figure 3-10. VBUSM Block Diagram**

The VBUSM Timeout Gasket tracks transactions outstanding on a VBUSM 4.0 initiator interface. If a transaction has been outstanding for more than a programmed time, the transaction is considered timed-out (with the expectation that the target is hung and will not return a response). The gasket will then signal an error to the system and provide responses (with appropriate error status) so that the initiator can proceed and will not be hung as well.

### 3.3.5.2.1.2 FIFOs

There is a shallow FIFO on the source side for each of command, write data, write status, and read data to ease timing integration and reduce stalls.

### 3.3.5.2.1.3 ID Allocator

To track outstanding transactions, the gasket replaces the Command ID with a tag which it can then track. The ID Allocator allocates a free tag for each new transaction. If there are no free IDs to allocate, the command and write busses are stalled. Whenever a returned transaction is completed, the tag is freed.

### 3.3.5.2.1.4 Timer

There is a 30-bit free-running timer inside of the gasket. There is also a 2-bit eon bit. Whenever the timer is equal to or greater than the programmed timeout value (Timeout Value Register (Base Address + 0x14)), the timer is reset to 0 and the eon increments (when 3, the eon will roll-over to 0).

When a command is presented (the creq is asserted on the destination side) the command is given an eon value of the current eon minus 1 (for example, if the eon is currently 0, then the transaction is assigned an eon of 3). Thus each command has a minimum of 2 and a maximum of 3 eons before it times out. If the command is not accepted (cready does not assert) by the time the eon rolls around to the command eon, this is considered a Command Timeout. In this case:

- The creq will be de-asserted
- The command will be pushed onto the timeout queue
  - The gasket will return proper responses with a timeout status and appropriate interrupts and reporting as detailed in this spec
- The gasket will automatically transition to Software Flush mode:
  - If a command is not accepted, it is assumed that the target infrastructure is hung, at which point issuing more commands is of no use.
  - Software may disable software flush mode

Each transaction, once issued (cready is asserted), is assigned the current eon minus 1 (for example, if the eon is currently 0, then the transaction is assigned an eon of 3). Thus each transaction has a timeout of a minimum of 2 eons and a maximum of 3 (see Note below). If all of the responses for the transaction have not returned by the eon is equal to the transaction eon, this is considered a Transaction Timeout. In this case:

- The command will be pushed onto the timeout queue
  - The gasket returns proper responses with a timeout status, and appropriate interrupts and reporting as detailed in this spec.

The timer only increments when the gasket is enabled.

---

#### Note

To avoid violating bus protocol rules of not interrupt in-progress physical read bursts, if a read burst has been partially returned but an older command times out in the middle of this burst, that older command may be prevented from timing out until the current burst completes. Theoretically this may delay a read transaction timeout until up to 6 eons. However, this should be *extremely rare*, as a target is unlikely to return only part of a physical burst and then wait to complete that burst (this would be inefficient, as targets typically return a physical burst contiguously and split it in to logical bursts if more time is needed for subsequent data).

---

##### 3.3.5.2.1.5 Timeout Queue

There is a timeout queue each for reads and writes. Whenever a new transaction is submitted it is pushed onto the timeout queue with the correct eon (see [Section 3.3.5.2.1.4](#)). Whenever a transaction completes, it is popped off of the timeout queue. Whenever the head element of a timeout queue has an eon equal to the current eon, that transaction is considered timed-out. It is flushed by proxying back responses.

##### 3.3.5.2.1.6 Write Scoreboard

The write scoreboard keeps track of all write transactions currently in-flight through the gasket. The write scoreboard can keep track of <num\_writes> write transactions at a time (specified at configuration time, see [Section 3.3.5.5.1](#)). If a new write transaction comes in and the write scoreboard is full, the command bus (including all writes and reads) and the write data bus are stalled until a slot becomes available. The write scoreboard tracks the following information about all write commands that come through.

- OrderID
- RouteID
- CID
- Current Bytecnt
- Original Bytecnt
- Address
- Eon

When a write status is received on the status bus, the write scoreboard compares the tag (stored in the SID) to find the associated transaction. If the transaction matches one being tracked by the write scoreboard, then the status is passed to the egress FIFO and sbytecnt is subtracted from the current bytecnt. If the current bytecnt becomes 0, then the transaction is evicted from the write scoreboard and the tag is returned. If there are bytes left, then it is kept.

If the write status does not match a tracked transaction, then an Unexpected Response error is generated, the information about the response is logged (see [Section 3.3.5.2.1.12](#)), and the status is discarded (not forwarded to the egress FIFO). Probable reasons for an unexpected response are:

- A response to a transaction that has already been flushed due to timeout
- An error on the destination side

If the Timeout Queue is not empty and the next element in the queue is a write, the scoreboard issues a response so that the initiator is not hung:

1. Stall the write status interface until the following steps are done.
2. Issue a Transaction Timeout Interrupt.
3. Log the information about the transaction (See [Timeout Error Reporting](#)).
4. Issue a response to the write status egress FIFO.
  - a. sid/sorderid/srouteid set appropriately
  - b. sbytecnt set to the remaining outstanding bytes
  - c. sstatus set to 3'd3 (Timeout Error)
5. Evict the transaction from the write scoreboard.
6. Pop the item from the Timeout Queue.

### 3.3.5.2.1.7 Read Scoreboard

The read scoreboard keeps track of all read transactions currently in-flight through the gasket. The read scoreboard can keep track of <num\_reads> read transactions at a time (specified at configuration time, see [Section 3.3.5.5.1](#)). If a new read transaction comes in and the read scoreboard is full, the command bus (including all writes and reads) is stalled until a slot becomes available. The read scoreboard tracks the following information about all ad commands that come through.

- OrderID
- RouteID
- CID
- Current Bytecount
- Original Bytecnt
- Read Data Alignment
- Address
- Eon

When read data is received on the read data bus, the read scoreboard compares the tag (stored in the RID) to find the associated transaction. If the transaction matches one being tracked by the read scoreboard, then the data is passed to the read egress FIFO and rbytecnt is subtracted from the current bytecnt. If the current bytecnt becomes 0, then the transaction is evicted from the read scoreboard and the tag is returned. If there are bytes left, then it is kept.

If the read data does not match a tracked transaction, then an Unexpected Response error is generated, the information about the response is logged (see [Section 3.3.5.2.1.12](#)), and the read data is discarded (not forwarded to the egress FIFO). Probable reasons for an unexpected response are:

- A response to a transaction that has already been flushed due to timeout
- An error on the destination side

If the Timeout Queue is not empty and the next element in the queue is a read, the read scoreboard issues responses so that the initiator is not hung:

1. Stall the read data interface until the following steps are done.
2. Issue a Transaction Timeout Interrupt.
3. Log the information about the transaction (see [Section 3.3.5.2.1.10](#)).
4. Issue a series of read responses to the read data egress FIFO until the read is complete.
  - a. RID/RORDERID/RROUTEID set appropriately
  - b. RBYTECNT set appropriately

- c. RSTATUS set to 3'd3 (Timeout Error)
- d. RDATA set to 0
- 5. Evict the transaction from the read scoreboard.
- 6. Pop the item from the Timeout Queue.

#### 3.3.5.2.1.8 Flush Mode

In addition to flushing individual commands that timeout, there are two ways to force the flushing of all commands (flush mode): software and hardware. Software flush is initiated by writing to the Flush Register (Base Address + 0x10). Hardware flush is initiated whenever the flush input is asserted.

When in flush mode:

- All currently outstanding transactions will be flushed as per the descriptions in [Section 3.3.5.2.1.6](#) and [Section 3.3.5.2.1.7](#).
- All new incoming commands are not forwarded to the destination, but they are put into the appropriate scoreboard, pushed into the Timeout Queue, and subsequently flushed.
- All incoming responses from the destination side are discarded.

In addition, if a command times out before it is ever accepted on the destination side of the bridge, the gasket automatically enters Software flush mode (Flush Register (Base Address + 0x10) flush field set to 4'b1111). Software may use this MMR to subsequently turn flush mode off.

#### 3.3.5.2.1.9 Flushing

When a transaction is flushed (because it has timed out or the gasket is in flush mode), the gasket proxies back transactions to the initiator. When the transaction is completely flushed, it is popped from the relevant scoreboard. If, after a transaction has started (or completed) flushing, a response comes back for that transaction, it triggers an Unexpected Response.

If a transaction has been flushed, the ID is re-allocated to a new transaction, then a response comes for the old, timed-out transaction, it can cause faults in the system. For this reason, the timeout value should be sufficiently large that, if reached, it is expected that a response for the original transaction never returns.

For writes, the gasket sends a single write status transaction for all of the remaining bytes in the transaction. The status will have sstatus set to 0x3 (Timeout Error).

For reads, the gasket sends however many read data phases are required to fulfill the remaining bytes of the command. The data will be all 0 and the rstatus set to 0x3 (Timeout Error).

#### 3.3.5.2.1.10 Timeout Error Reporting

If a transaction times out and a Transaction Timeout Interrupt is asserted (and there are no currently outstanding Interrupts) then the following registers are loaded with the information about the transaction that timed out:

- Dir/orderid
- Routeid/id
- Original Bytecnt / Current Bytecnt
- Address0
- Address1

The Timeout Error Info Register (Base Address + 0x30) register keeps track of how many Transaction Timeout Interrupts have occurred since the last one was serviced. When a Transaction Timeout Interrupt occurs, the value is incremented (until saturated). If a Transaction Timeout Interrupt occurs and there is already one pending, then the counter is incremented by one, but the reporting information for the new transaction is lost.

#### 3.3.5.2.1.11 Command Timeout Error Reporting

If a transaction times out not because all of the responses didn't come back but because the command was never accepted in the first place (ready does not come back), this is a Command Timeout. A command timeout ultimately leads to two interrupts, one when the command times out and is pushed onto the timeout queue, and a second when the transaction times out from the queue. When the transaction timeout happens, the same information is recorded for reporting purposes.

### 3.3.5.2.1.12 Unexpected Response Reporting

If an Unexpected Response Interrupt is asserted (and there are no currently outstanding interrupts), then the following registers are loaded with information about the unexpected response:

- Dir/orderid
- Routeid/cid
- Bytecnt

The Unexpected Response Info Register (Base Address + 0x34) register keeps track of how many Unexpected Transaction Interrupts have occurred since the last one was serviced. Whenever an Unexpected Transaction Interrupt occurs, the value is incremented (until saturated). If an Unexpected Transaction Interrupt occurs and there is already one pending, then the counter is incremented by one, but the reporting information for the new transaction is lost.

### 3.3.5.2.1.13 Latency and Stalls

The gasket inserts 1 cycle of latency in each forward direction (1 on command, 1 on write data) and 2 on responses (2 on read data, 2 on write status). In addition, the following stall conditions may occur.

- If a write command comes in and there are no free slots in the write scoreboard, the entire command bus and write data bus stalls.
- If a read command comes in and there are no free slots in the read scoreboard, the entire command bus stalls.
- If a write transaction is being timed out, then the write status bus stalls while the write scoreboard flushes the command.
- If a read transaction is being timed out, then the read data bus stalls while the read scoreboard flushes the command.

### 3.3.5.2.1.14 Bypass

The gasket is disabled by default. When disabled (see Enable Register (Base Address + 0x0C)), the gasket operates in bypass mode and just passes all commands, data, and responses through untouched (though the latency is still added and the CID is still remapped so that order can be preserved in the case where the gasket is enabled or disabled with transactions in flight). In Bypass mode, there are no timed out transactions and thus no timeout interrupts. However, if an unexpected response is received, the unexpected response logic will still work as normal (including issuing an interrupt).

### 3.3.5.2.1.15 Safety

The gasket supports the following features for functional safety:

- CBA safety signaling on source and destination interfaces (if enabled with <safe\_bus> parameter)
- CBA safety signaling on configuration interface (if enabled with <safe> parameter)
- ECC protection on scoreboard RAMs (if enabled with <safe> parameter)
- Parity protection on scoreboard flops (if enabled with <safe> parameter)
- Parity protection or multi-bit field protection on configuration MMRs (if enabled with <safe> parameter)
- Parity protection on the free-running timer (if enabled with <safe> parameter)

An uncorrected error reported on any of the protected fields indicates a potentially dangerous fault, and the system integrator should take appropriate action (such as transition to a safe state).

A fault in the free-running timer may cause errors by prematurely timing out transactions, but it may also be recoverable by taking the following steps.

1. Disable the gasket.
2. Wait for scoreboards to become empty. If they don't become empty for a long time, this may indicate that there are other issues in the system. The system integrator can use Software Flush, but additional intervention is probably required (such as transition to a safe state or system reset).
3. Write a 0 to the Timer Register (Base Address + 0x18) to reset the timer.
4. Enable the gasket.

### 3.3.5.3 Interrupt Conditions

Table 3-56 shows the interrupts generated by the module.

**Table 3-56. Interrupts**

Module Instance	Module Interrupt Signal	Destination Interrupt Name	Destination	Description	Type
MCU_TIMEOUT_64B2	MCU_TIMEOUT_64B2_TRANS_ERR_LVL_0	MCU_ESM0_LVL_IN_76	MCU_ESM0	MCU_TIMEOUT_64B2 interrupt request	Level

When an interrupt is received, software should read the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24) to determine what type of interrupt it is.

#### 3.3.5.3.1 Transaction Error Interrupt

The Transaction Error Interrupt signals that the gasket has detected an error on a transaction. The gasket returns an appropriate response to the source side, so the source will not immediately violate a safety goal, but it is assumed that something uncorrected has happened in the system. The system must treat this as a dangerous event and react accordingly. The specific response is the responsibility of the system integrator, but possibilities are discussed below. There are three possible causes of the Transaction Error Interrupt: transaction timeout, unexpected response, and command timeout. Software should query the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24) to determine the cause.

##### 3.3.5.3.1.1 Transaction Timeout

If all of the responses to a transaction have not been received within the time allotted (programmed by the Timeout Value Register (Base Address + 0x14)) or if a transaction was never accepted (Command Timeout) and placed on the timeout queue, then a transaction is considered to have timed out. The interrupt indicates that the gasket is flushing the transaction and that information has been logged about the transaction that timed out in the following registers:

- Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
- Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
- Error Transaction Bytecnt Register (Base Address + 0x40)
- Error Transaction Upper Address Register (Base Address + 0x44)
- Error Transaction Lower Address Register (Base Address + 0x48)

When servicing a Transaction Timeout Error, software should perform the following steps:

1. Read the Timeout Error Info Register (Base Address + 0x30) to determine how many transaction timeouts have occurred since last serviced.
2. Read the Error Transaction Valid/Dir/ID Register (Base Address + 0x38). If the valid field is 0 or the type field is Unexpected Response, then these registers do not contain any information about the timed out transaction, skip to step 4.
3. Read the information from the following registers:
  - Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
  - Error Transaction Bytecnt Register (Base Address + 0x40)
  - Error Transaction Upper Address Register (Base Address + 0x44)
  - Error Transaction Lower Address Register (Base Address + 0x48)
  - Error Transaction Lower Address Register (Base Address + 0x48)
4. Write the number of timed out events serviced this ISR (read in step 1) to the Timeout Error Info Register (Base Address + 0x30).
5. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24).

If the write in step 4 does not decrement the value to 0 (because a new transaction has timed out), then the interrupt will re-issue after the write in step 5.

This section only describes how to service the interrupt. The system integrator must decide what actions to take based on this information. Suggestions include:

- Log the information for debug purposes
- Determine the target that is unresponsive and take appropriate action
  - Reset target
  - Reset main SoC
  - Reset whole device

### 3.3.5.3.1.2 Unexpected Response

If the gasket receives a response that it was not expecting then this interrupt is triggered. See [Section 3.3.5.2.1.12](#) for a discussion of unexpected responses. When this interrupt is triggered, information about the unexpected response will be in the following registers:

- Error Transaction Valid/Dir/ID Register (Base Address + 0x38)
- Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
- Error Transaction Bytecnt Register (Base Address + 0x40)

When servicing an Unexpected Response Error, software should perform the following steps:

1. Read the Unexpected Response Info Register (Base Address + 0x34) to determine how many unexpected responses have occurred since last serviced.
2. Read the Error Transaction Valid/Dir/ID Register (Base Address + 0x38). If the valid field is 0 or the type field is Timeout Error, then these registers do not contain any information about the unexpected response, skip to step 4.
3. Read the information from the following registers:
  - Error Transaction RouteID/OrderID Register (Base Address + 0x3C)
  - Error Transaction Bytecnt Register (Base Address + 0x40)
4. Write the number of unexpected responses serviced this ISR (read in step 1) to the Unexpected Response Info Register (Base Address + 0x34).
5. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24).

If the write in step 4 does not decrement the value to 0 (because a new unexpected response has arrived), then the interrupt re-issues after the write in step 5.

This section only describes how to service the interrupt. The system integrator must decide what actions to take based on this information. Suggestions include:

- Log the information for debug purposes.
- Determine the target that is unresponsive and take appropriate action:
  - Reset target.
  - Reset main SoC.
  - Reset whole device.

### 3.3.5.3.1.3 Command Timeout

A Command Timeout happens when a command is presented on the destination side (creq) but never accepted (cready) within the allotted time. See [Section 3.3.5.2.1.11](#). When this happens, a Command Timeout interrupt is issued. When servicing a Command Timeout Error, software should perform the following step:

1. Clear the interrupt by writing to the appropriate bit in the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24).

When a Command Timeout occurs, the gasket automatically transitions to Software Flush mode (see [Section 3.3.5.2.1.8](#)). The system can assume that the target infrastructure is hung and take appropriate action.

Suggested actions include:

- Transitioning to a safe state.
- Re-setting the target domain to eliminate the hang.
- Re-enable the gasket (disable software flush) and attempt further access.

### 3.3.5.4 Memory Map

**Table 3-57. Module Memory Map**

Address Offset	Register
0x00	Revision Register
0x04	Configuration Register
0x08	Info Register
0x0C	Enable Register
0x10	Flush Register
0x14	Timeout Value Register
0x18	Timer Register
0x1C	Reserved
0x20	Error Interrupt Raw Status/Set Register
0x24	Error Interrupt Enabled Status/Clear Register
0x28	Error Interrupt Mask Set Register
0x2C	Error Interrupt Mask Clear Register
0x30	Timeout Error Info Register
0x34	Unexpected Response Info Register
0x38	Error Transaction Valid/Dir/ID Register
0x3C	Error Transaction RouteID/OrderID Register
0x40	Error Transaction Bytecnt Register
0x44	Error Transaction Upper Address Register
0x48	Error Transaction Lower Address Register
0x4C	Error Transaction Timestamp Register

#### 3.3.5.4.1 Revision Register (Base Address + 0x00)

The Revision Register contains the major and minor revisions for the VBUSM Timeout Gasket.

Bits	Field	Type	Reset	Description
31:30	scheme	r	01	Always read as 01. Writes have no effect.
29:28	rsvd	r	10	Always read as 00.
27:16	func	r	0x606	Always read as the assigned func id.
15:11	rtl	r	0x4	RTL version of the module. The "R" value in the X.Y.R.Z as defined by K3.
10:8	major	r	0x1	Major revision of module. The "X" value in the X.Y.R.Z defined in K3.
7:6	custom	r	Hard coded	Special version.
5:0	minor	r	0x0	Minor revision of module. The "Y" value in the X.Y.R.Z defined in K3

#### 3.3.5.4.2 Configuration Register (Base Address + 0x04)

The Configuration Register contains information about the configuration of the gasket.

Bits	Field	Type	Reset	Description
31:24	Reserved	r	0x0	Reserved. Read as 0.
23:16	writes	r	<num_writes>	This is the total number of slots in the write scoreboard.
15:8	Reserved	r	0x0	Reserved. Read as 0.
7:0	reads	r	<num_reads>	This is the total number of slots in the read scoreboard

### 3.3.5.4.3 Info Register (Base Address + 0x08)

The Info Register contains information about the current status of the gasket.

Bits	Field	Type	Reset	Description
31:25	Reserved	r	0x0	Reserved. Read as 0.
24:16	cur_writes	r	0x0	This is the current number of occupied slots in the write scoreboard.
15:9	Reserved	r	0x0	Reserved. Read as 0.
8:0	cur_reads	r	0x0	This is the current number of occupied slots in the read scoreboard

### 3.3.5.4.4 Enable Register (Base Address + 0x0C)

The Enable Register contains the enable control of the gasket.

Bits	Field	Type	Reset	Description
31:4	Reserved	r	0x0	Reserved. Read as 0.
3:0	enable	r/w	0x0	This controls whether the gasket is enabled or not. See <a href="#">Section 3.3.5.2.1.14</a> . <ul style="list-style-type: none"> <li>4'b0000 – Disabled</li> <li>4'b0001-4'b1111 – Enabled</li> </ul>

### 3.3.5.4.5 Flush Register (Base Address + 0x10)

The Flush Register contains the flush control of the gasket.

Bits	Field	Type	Reset	Description
31	ext_flush	r	*	This indicates the value of the flush input synchronized to the gasket clock
31:4	Reserved	r	0x0	Reserved. Read as 0.
3:0	flush	r/w	0x0000	This is the software control for whether the gasket is in flush mode or not. See <a href="#">Section 3.3.5.2.1.8</a> . <ul style="list-style-type: none"> <li>4'b0000-4'b1110 – Normal Mode</li> <li>4'b1111 – Flush Mode</li> </ul> <p>Note that this field can be automatically set to 4'b1111 (Flush Mode) in the event of a Command Timeout (see <a href="#">Section 3.3.5.2.1.4</a>)</p>

### 3.3.5.4.6 Timeout Value Register (Base Address + 0x14)

The Timeout Value Register contains the timeout value for scoreboarded transactions.

Bits	Field	Type	Reset	Description
31:30	Reserved	r	0x0	Reserved. Read as 0.

Bits	Field	Type	Reset	Description
29:0	timeout	r/w	0x3FFF_FFFF	<p>This is the number of cycles in each eon (see <a href="#">Section 3.3.5.2.1.4</a>). Each transaction can be outstanding for a minimum of 2 and a maximum of 3 eons before it is considered timed out. Note that if this value is changed while there are outstanding transactions it may affect the timeout of those transactions.</p> <ul style="list-style-type: none"> <li>If the value is written to be greater than the current value, then all outstanding transactions may live longer based on the new timeout value.</li> <li>If the value is written to be lower than the current value, then all outstanding transactions may live shorter based on the new timeout value <ul style="list-style-type: none"> <li>If the new timeout value written is equal to or larger than the current timer value, the timer will be reset to 0 and the eon will flip. This may cause currently outstanding transactions to time out faster.</li> </ul> </li> </ul> <p>Note: This field can only be written if byte enables 3:0 are set. Byte writes will be ignored.</p>

#### 3.3.5.4.7 Timer Register (Base Address + 0x18)

The Timer Register contains the current value for free-running timer.

Bits	Field	Type	Reset	Description
31:30	eon	r	0x0	This is the current eon. It toggles each time the timer field is reset to 0. See <a href="#">Section 3.3.5.2.1.4</a> .
29:0	timer	r/wtc	0x0	<p>This is the current value of the free-running counter. It increments once per clock cycle if the gasket is enabled. When the value is equal to or greater than the timeout value in the Timeout Value Register (Base Address + 0x10), it will be reset to 0 and begin incrementing again. This value only increments when the gasket is enabled.</p> <p>If the gasket is disabled (Enable Register (Base Address + 0x08)) and a zero is written to this field, the timer will reset to 0 and be ready to increment when the gasket is re-enabled. The eon will also be reset to 0.</p> <p>If the gasket is enabled, writes have no effect. See <a href="#">Section 3.3.5.2.1.4</a>.</p>

#### 3.3.5.4.8 Error Interrupt Raw Status/Set Register (Base Address + 0x20)

The Error Interrupt Raw Status Register contains the raw status of the gasket interrupts

Bits	Field	Type	Reset	Description
31:3	Reserved	r	0x0	Reserved. Read as 0.

Bits	Field	Type	Reset	Description
2	cmd	r/w1ts	0x0	This field represents the raw status of the Command Timeout Error. Read 0 – No pending command timeout interrupt 1 – Pending command timeout interrupt Write 0 – No effect 1 – Set command timeout interrupt
1	unexp	r/w1ts	0x0	This field represents the raw status of the Unexpected Response Error. Read 0 – No pending unexpected response interrupt 1 – Pending unexpected response interrupt Write 0 – No effect 1 – Set unexpected response interrupt
0	timeout	r/w1ts	0x0	This field represents the raw status of the Timeout Error Interrupt. Read 0 – No pending timeout interrupt 1 – Pending timeout interrupt Write 0 – No effect 1 – Set timeout interrupt

### 3.3.5.4.9 Error Interrupt Enabled Status/Clear Register (Base Address + 0x24)

The Error Interrupt Raw Status Register contains the raw status of the gasket interrupts.

Bits	Field	Type	Reset	Description
31:3	Reserved	r	0x0	Reserved. Read as 0.
2	cmd	r/w1tc	0x0	This field represents the masked status of the Command Timeout Error. Read 0 – No pending command timeout interrupt 1 – Pending command timeout interrupt Write 0 – No effect 1 – Clear command timeout interrupt
1	unexp	r/w1tc	0x0	This field represents the masked status of the Unexpected Response Error. Read 0 – No pending unmasked unexpected response interrupt 1 – Pending unmasked unexpected response interrupt Write 0 – No effect 1 – Clear unexpected response interrupt

Bits	Field	Type	Reset	Description
0	timeout	r/w1tc	0x0	This field represents the masked status of the Timeout Error Interrupt. Read 0 – No pending unmasked timeout interrupt 1 – Pending unmasked timeout interrupt Write 0 – No effect 1 – Clear timeout interrupt

#### 3.3.5.4.10 Error Interrupt Mask Set Register (Base Address + 0x28)

The Error Interrupt Mask Set is used to enabled interrupts.

Bits	Field	Type	Reset	Description
31:3	Reserved	r	0x0	Reserved. Read as 0.
2	cmd	r/w1ts	0x1	This field is used to set the mask for the Command Timeout Error. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Enable interrupt (mask set)
1	unexp	r/w1ts	0x1	This field is used to The Error Interrupt Mask Set is used to enabled interrupts. set the mask for the Unexpected Response Error. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Enable interrupt (mask set)
0	timeout	r/w1ts	0x1	This field is used to set the mask for the Timeout Interrupt. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Enable interrupt (mask set)

#### 3.3.5.4.11 Error Interrupt Mask Clear Register (Base Address + 0x2C)

The Error Interrupt Mask Clear Register is used to disable interrupts.

Bits	Field	Type	Reset	Description
31:3	Reserved	r	0x0	Reserved. Read as 0.

Bits	Field	Type	Reset	Description
2	cmd	r/w1tc	0x1	This field is used to clear the mask for the Command Timeout Error. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Disable interrupt (mask clear)
1	unexp	r/w1tc	0x1	This field is used to clear the mask for the Unexpected Response Error. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Disable interrupt (mask clear)
0	timeout	r/w1tc	0x1	This field is used to clear the mask for the Timeout Interrupt. Read 0 – Interrupt is disabled (mask cleared) 1 – Interrupt is enabled (mask set) Write 0 – No effect 1 – Disable interrupt (mask clear)

### 3.3.5.4.12 Timeout Error Info Register (Base Address + 0x30)

The Timeout Error Info Register contains information about the number of Timeout errors that have occurred.

Bits	Field	Type	Reset	Description
31:2	Reserved	r	0x0	Reserved. Read as 0.
1:0	timeouts	r/wtd	0x0	This field contains information about how many transactions have timed out since the last one was serviced. Writing to this register decrements the contents by the value written. For instance, if the value is 2 and a 1 is written, the value will decrement to 1. If this field is non-0 when the interrupt is cleared by writing to the Error Interrupt Enabled Status/ Clear Register (Base Address + 0x24) the interrupt will be re-issued. The value saturates at 3, so if there are more than three pending it will be unknown exactly how many have occurred. If the value is saturated at 3 and a value of 3 is written, the value will turn to 0. Read 0 – No pending timeout interrupts 1 – One pending timeout interrupt 2 – Two pending timeout interrupts 3 – Three or more pending timeout interrupts

### 3.3.5.4.13 Unexpected Response Info Register (Base Address + 0x34)

The Unexpected Response Info Register contains information about the number of Timeout errors that have occurred.

Bits	Field	Type	Reset	Description
31:2	Reserved	r	0x0	Reserved. Read as 0.
1:0	unexps	r/wtd	0x0	<p>This field contains information about how many unexpected responses have been received since the last one was serviced. Writing to this register decrements the contents by the value written. For instance, if the value is 2 and a 1 is written, the value will decrement to 1. If this field is non-0 when the interrupt is cleared by writing to the Error Interrupt Enabled Status/Clear Register (Base Address + 0x24) the interrupt will be re-issued.</p> <p>The value saturates at 3, so if there are more than three pending it will be unknown exactly how many have occurred. If the value is saturated at 3 and a value of 3 is written, the value will turn to 0.</p> <p>Read</p> <p>0 – No pending unexpected response interrupts</p> <p>1 – One pending unexpected response interrupt</p> <p>2 – Two pending unexpected response interrupts</p> <p>3 – Three or more pending unexpected response interrupts</p>

### 3.3.5.4.14 Error Transaction Valid/Dir/RouteID Register (Base Address + 0x38)

This register contains the type, direction, and transaction ID of the transaction error that was captured.

Bits	Field	Type	Reset	Description
31:28	Reserved	r	0x0	Reserved. Read as 0.
27:16	rid	r	0x0	Route ID – This indicates the Route ID of the captured transaction
15:12	Reserved	r	0x0	Reserved. Read as 0.
11:8	oid	r	0x0	Order ID – This indicates the Order ID of the capture transaction
7:4	Reserved	r	0x0	Reserved. Read as 0.
2	dir	r	0x0	<p>Direction – This indicates whether the captured transaction was a read or a write</p> <p>0 – Write</p> <p>1 – Read</p>
1	type	r	0x0	<p>Type – This indicates what type of error these registers contain information about</p> <p>0 – Transaction Timeout</p> <p>1 – Unexpected Response</p>

Bits	Field	Type	Reset	Description
0	valid	r	0x0	<p>If this field is a 1, then the contents of this and the below registers is considered valid. I.e. it contains the information about the transaction that was captured. If this field is 0 then this and the other listed registers are not valid. This is because there is either no error pending, or the error pending did not have any captured information because there was an error pending in front of it that had already captured information.</p> <ul style="list-style-type: none"> <li>0 – Invalid</li> <li>1 – Valid</li> </ul>

### 3.3.5.4.15 Error Transaction Tag/CommandID Register (Base Address + 0x3C)

This register contains the routeid and orderid of the transaction error that was captured.

Bits	Field	Type	Reset	Description
31:28	Reserved	r	0x0	Reserved. Read as 0.
27:16	tag	r	0x0	Tag – This indicates the CID/RID/SID of the transaction on the destination side of the gasket. This is the tag assigned to the transaction. For an Unexpected Transaction Error, this field is whatever the sid/rid of the transaction was. For a Timeout Error, this is the tag (replacement CID) that was used.
15:12	Reserved	r	0x0	Reserved. Read as 0.
11:0	cid	r	0x0	Command ID – This indicates the original Command ID (SID/RID) of the command. This field is only valid on a Timeout Error, not on an Unexpected Transaction Error.

### 3.3.5.4.16 Error Transaction Bytecnt Register (Base Address + 0x40)

This register contains the byte count of the transaction error that was captured.

Bits	Field	Type	Reset	Description
31:26	Reserved	r	0x0	Reserved. Read as 0.
25:16	cbytecnt	r	0x0	Current Byte Count – If this is a timed out transaction, this is the number of bytes that were not returned as of the time the transaction timed out. If this is an unexpected response transaction, then this field is not applicable.
15:10	Reserved	r	0x0	Reserved. Read as 0.
9:0	obytecnt	r	0x0	Original Byte Count – If this is a timed out transaction, then this field represents the CBYTECNT value of the original command. If this is an unexpected response transaction, then this field contains the value of the bytecnt of the unexpected transaction (sbytecnt or rbytecnt).

### 3.3.5.4.17 Error Transaction Upper Address Register (Base Address + 0x44)

This register contains the upper address bits of the transaction error that was captured. If the address is 32-bits or smaller, this field will be all 0. *N* is the number of bits on the source/dest address bus minus 33.

Bits	Field	Type	Reset	Description
31:N	Reserved	r	0x0	Reserved. Read as 0.
N-1:0	addr_u	r	0x0	Upper Address bits – If the captured transaction was a Timeout Error, this field represents the lower address bits N-1:32] of the original transaction. If the error was an Unexpected Response error, then this field is not applicable.

#### 3.3.5.4.18 Error Transaction Lower Address Register (Base Address + 0x48)

This register contains the lower address bits of the transaction error that was captured.

Bits	Field	Type	Reset	Description
31:0	addr_l	r	0x0	Lower Address bits – If the captured transaction was a Timeout Error, this field represents the lower address bits [31:0] of the original transaction. If the error was an Unexpected Response error, then this field is not applicable.  If the address width is less than 32, then the bits above the address range will be read as 0.

#### 3.3.5.5 Integration Overview

##### 3.3.5.5.1 Parameterization Requirements

**Table 3-58. Module Parameters**

Parameter	Value
num_writes	This is the number of outstanding write transactions that the write scoreboard can handle at once. When the scoreboard is full, all subsequent commands will be stalled, so this value should be picked appropriately for throughput. See <a href="#">Section 3.3.5.2.1.6</a> . <ul style="list-style-type: none"> <li>1 – 1024 (Default 4)</li> </ul>
num_reads	This is the number of outstanding read transactions that the read scoreboard can handle at once. When the scoreboard is full, all subsequent commands will be stalled, so this value should be picked appropriately for throughput. See <a href="#">Section 3.3.5.2.1.7</a> . <ul style="list-style-type: none"> <li>1 – 1024 (Default 4)</li> </ul>
safe	Add CBA Safety Signaling on the config bus and internal flop protection. Include EDC controller and export sVbus interface(s) <ul style="list-style-type: none"> <li>0 – No Safety Signals</li> <li>1 – Safety Signals Included (Default)</li> </ul>
safe_bus	Add CBA Safety Signaling on the source and destination VBUSM interfaces <ul style="list-style-type: none"> <li>0 – No Safety Signals</li> <li>1 – Safety Signals Included (Default)</li> </ul>
src_name	This is the prefix for the signals on the source bus
dst_name	This is the prefix for the signals on the destination bus
osigs	Space separate list of optional signals on the CBA interfaces
data_width	Width of the data bus. Default 32
addr_width	Width of the address bus. Default 32
region_cnt	Number of CBA Regions. Default 1

**Table 3-58. Module Parameters (continued)**

Parameter	Value
pipe	Enable EDC Pipe Stage. Default 0 (off)

### 3.3.5.6 I/O Description

#### 3.3.5.6.1 Clockstop Idle

The gasket only returns clockstop idle when there are no outstanding transactions in any of the FIFOs or in the scoreboard. The free-running timer may still be running (but pauses if the clock pauses).

#### 3.3.5.6.2 Flush

The flush signal is expected to indicate that the destination side is down. It is synchronized internally.

#### 3.3.5.6.3 Module I/O

[Table 3-59](#) shows the interrupts from the module.

**Table 3-59. Interrupt Requests**

Module Instance	Module Interrupt Signal	Destination Interrupt Name	Destination	Description	Type
MCU_TIMEOUT_64B2	MCU_TIMEOUT_64B2_TRANS_ERR_LVL_0	MCU_ESM0_LVL_IN_76	MCU_ESM0	MCU_TIMEOUT_64B2 interrupt request	Level

If <safe> is enabled, the following sVbus signals in [Table 3-60](#) are present.

**Table 3-60. EDC Controller Interface**

Pin Name	Type	Function
edc_ctrl_strb	In	Strobe
edc_ctrl_txd	In	Transmit Data
edc_ctrl_rxd	Out	Receive Data
edc_ctrl_pend[1:0]	Out	Event Pending

### 3.3.5.7 User's Guide

#### 3.3.5.7.1 Programmer's Guide

##### 3.3.5.7.1.1 Initialization

Software should take the following steps when initializing the gasket.

1. Enable/Disable gasket as desired (Default enabled - Enable Register (Base Address + 0x08)).
2. Set the timeout value as desired (Default max - Timeout Value Register (Base Address + 0x10)).
3. Enable/Disable interrupts as desired (Default enabled - Error Interrupt Enabled Status/Clear Register (Base Address + 0x24)).

##### 3.3.5.7.1.2 Software Flush

If the system determines that it must flush all outstanding transactions (for instance, because the main SoC is in an error condition and is going to be reset), software may do this by writing to the Flush Register (Base Address + 0x0C). When all transactions are flushed, software should exit Flush mode. If the destination side is in reset, this should trigger hardware flush, keeping the gasket returning any transactions that arrive. The system should also use the CBA disconnect interface to keep transactions from going to the gasket when the destination side is taken down.

This chapter describes the steps for non-secure device initialization.

<b>4.1 Initialization Overview.....</b>	<b>270</b>

## 4.1 Initialization Overview

Figure 4-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip(s)
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software (SBL)
- **Initial software:** Software that loads, prepares, and passes control to application software or to the high-level operating system (HLOS)
- **High-Level Operating System** or bare-metal application which runs on main processor(s)

init-003

**Figure 4-1. Initialization Process**

The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins, the associated configuration registers, and memory structures that are vital to the correct initialization of the device.

### 4.1.1 ROM Code Overview

ROM bootloader (or ROM Code) is a software that resides in a on-chip read-only memory (ROM) to assist the customer in transferring and executing their application code. The device has two ROM codes operating in tandem – the MCU ROM code, and the DMSC ROM code.

In order to accommodate various system scenarios, the ROM Code supports several boot modes. These boot modes can be broadly classified as:

- Host boot modes
- Memory boot modes.

During a host boot, the device is configured to receive code from a host via the selected interface. Either the host writes the application code directly into internal memory or the ROM Code receives the application code on the selected interface and stores it in internal memory.

During a memory boot, the device transfers code from non-volatile memory to internal memory for execution.

In all boot modes, the entire boot operation can be partitioned into two sections:

1. Hardware initialization phase
2. Boot process.

During initialization, the ROM Code configures the device resources (PLLs, peripherals, pins) as needed to support the boot process. The resources used depend on the boot mode requirements.

During the boot process the boot image can be loaded into device memory and executed, or executed in place, depending on the boot peripheral. DMSC will perform code verification and allow, or forbid, the image execution.

Main configuration source for boot after power-up are the BOOTMODE pins sampled automatically after reset release and stored in device status registers. At ROM Code startup, these pin values are read from the registers to create the boot peripheral list and the boot configuration tables used later to initialize and startup the PLLs and boot peripherals.

The ROM Code also provides a multi-stage boot mechanism.

### 4.1.2 Bootloader Modes

Table 4-1 shows the boot modes supported by ROM code.

**Table 4-1. ROM Code Boot Modes**

Boot Mode	Boot Media/Host	Peripheral	Domain <sup>(1)</sup>	Can be a Backup Mode? <sup>(2)</sup>	Notes
No-boot/Dev-boot	No media or host	None	N/A	N	No boot or development boot – debug modes
OSPI	OSPI flash	MCU_FSS0_OSPI0	MCU	N	On OSPI port
QSPI	QSPI flash/EEPROM	MCU_FSS0_OSPI0 or MCU_FSS0_OSPI1	MCU	N	On OSPI port
SPI	SPI EEPROM	MCU_FSS0_OSPI0 or MCU_FSS0_OSPI1	MCU	Y <sup>(3)</sup>	On OSPI port
I2C	I <sup>2</sup> C EEPROM External host	MCU_I2C0	MCU	Y	I2C module is master I2C module is slave
MMCSD	MMC/SD card	MMCSD0 or MMCSD1	MAIN	Y <sup>(3)</sup>	Boot from User Data Area (UDA) or file system
eMMC	eMMC flash	MMCSD0 or MMCSD1	MAIN	N	Boot from boot partition with auto-fall back to file system
Ethernet	External host	MCU_CPSW0	MCU	Y <sup>(3)</sup>	In BOOTP mode. RGMII or RMII PHY
PCIe	External host	PCIE0 or PCIE1	MAIN	N	-
UART	External host	MCU_UART0 or WKUP_UART0	MCU	Y	XMODEM protocol
GPMC NOR	NOR flash	GPMC0	MAIN	N	-
USB	External host	USB0 or USB1	MAIN	Y <sup>(3)</sup>	USB device mode boot using DFU (device firmware upgrade)

(1) MCU peripherals are available for boot even when main domain is not powered.

(2) The peripheral can be selected also as a backup boot mode. A backup mode is tried if primary boot mode fails.

(3) When in normal boot flow (MCU Only = 0)

#### Note

Because different devices support different sets of peripherals, see the *device-specific Datasheet* to obtain the list of peripherals supported in your device.

### 4.1.3 Terminology

- **Boot Mode Pins:** Boot mode pins provide vital information to ROM code for boot. These pins must be properly set up before power ramp.
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase.
- **Boot Header:** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase.
- **eFuse:** A one-time programmable memory location usually set at the factory.
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device (SoC) or a non-secure device.
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software. This can be the SBL (secondary bootloader) responsible for loading an OS.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory.

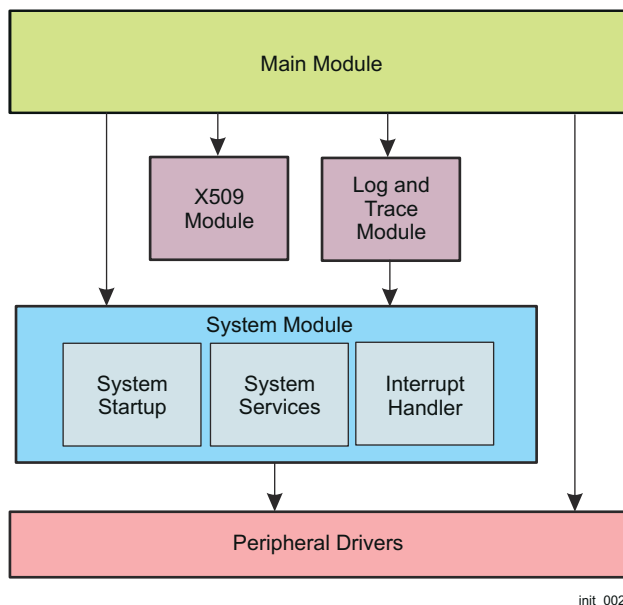

- **Master CPU:** The Arm® Cortex® CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory.
- **ROM Code:** or ROM bootloader (RBL), the on-chip software in device ROM that executes first and implements booting.
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the device ROM code.
- **OCMC RAM memory:** On-chip RAM memory used by ROM code during boot and also for loading the booting image. ROM code is using MCU\_MSRAM0
- **Booting Parameter Table:** A logical structure stored in the on-chip RAM memory and contains information for the boot, such as the boot file name or an address to boot from.

## 4.2 Boot Process

### 4.2.1 MCU ROM Code Architecture

The MCU ROM code has the following components (see also [Figure 4-2](#)):

- Main
- Buffer manager
- X.509
- Log and Trace
- System
- Protocol
- Driver

**Figure 4-2. MCU ROM Code Architecture**

#### 4.2.1.1 Main Module

The Main module contains the top level execution loop. This loop repeats until a boot image has been received or directed to sleep by the DMSC. The main loop has three different execution sub-paths based on the boot peripheral.

- **Image Path** This path is used by the GPMC NOR, USB-DFU, PCIe, OSPI, and QSPI boot modes. In these cases the image data can be directly read by both, MCU and DMSC, in place.
- **Block Path** This path is used by the SPI, I2C, UART, eMMC, Ethernet and MMC/SD cards in raw mode. In this mode data is received from the peripheral in blocks. Blocks are accumulated in the boot buffer until a full X.509 certificate header has been received, at which point this full certificate and any subsequent blocks are passed to the DMSC as they arrive.
- **Filesystem Path** This path is used by the MMC/SD cards in filesystem mode. This mode executes exactly like in the block path, except that the boot image location is defined by a filesystem.

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

#### 4.2.1.2 X509 Module

The X509 module parses the boot header. The boot header is an X.509 certificate as defined in [RFC5280](#). Extensions specific to boot are described in [Section 4.5.2, X.509 Certificate](#).

This module also includes an OID decoder as well as defines OID values as C #define constants for any values that can be used during boot.

#### 4.2.1.3 Buffer Manager Module

The buffer manager module is used to allocate buffers to hold boot data. The MCU code allocates a buffer when it is ready to read a block of data from the boot peripheral. Once the data is read the buffer ownership is passed to the DMSC. When the DMSC has completed processing the data in the buffer ownership is returned to the MCU, which then frees the buffer.

#### 4.2.1.4 Log and Trace Module

The Log and Trace modules are not integral to the boot process. Instead, they provide ability to record operation of the ROM code and track unexpected occurrences.

Log and trace function is currently TI internal.

#### 4.2.1.5 System Module

The system module provides services to other modules. These services are not directly related to boot drivers. The system module is the only module that operates in the supervisor mode of the MCU (a few services will run in user). The system module supports the following functions:

- Interrupt enable, disable, and service
- IPC
- Power
- Pinmux
- Clock
- Task switch

The main level is able to detect if a received boot image is in the correct format and reject non-conforming images.

#### 4.2.1.6 Protocol Module

The protocol modules provide implementation of high-level data transfer protocols. The BOOTP/TFTP and XMODEM protocols reside in this layer. These modules provide services as defined in well-known standards.

#### 4.2.1.7 Driver Module

The driver module implements the low level peripheral drivers.

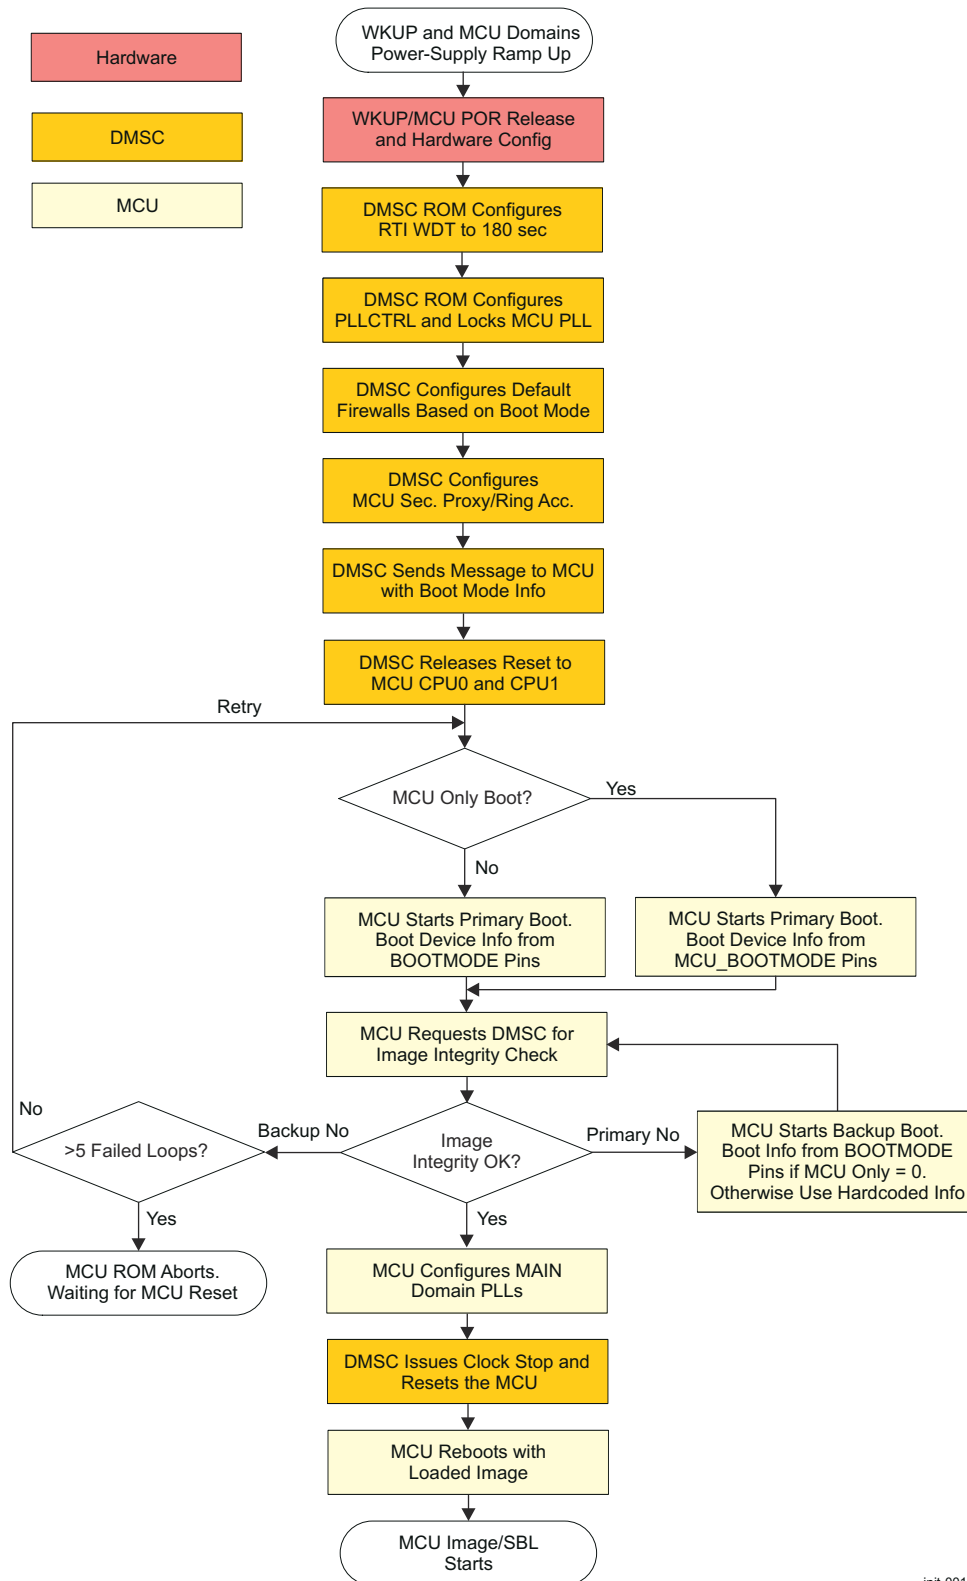

### 4.2.2 DMSC ROM Description

In a general-purpose (GP) device, DMSC ROM performs the following functions:

- Device management
- Configures the boot vectors (in BOOT\_CFG) and controls reset release of MCU core. That is, DMSC is the boot master of MCU core.
- IPC configuration via MCU\_NAVSS rings and Secure Proxy
- PLL configuration (MCU subsystem and SA2UL)
- X509 certificate parsing
- SA2UL configuration to SHA512 for image integrity checks
- Test flow support – Wait-In-Reset commands
- DMSC firmware loading

### 4.2.3 Boot Process Flow

The MCU boot process flow is shown in [Figure 4-3](#).

init-001

**Figure 4-3. Boot Process**

The values of (MCU\_)BOOTMODE pins are latched into the Device Status registers (CTRLMMR\_MAIN\_DEVSTAT and CTRLMMR\_WKUP\_DEVSTAT) by hardware as the device comes out of

global cold reset. When MCU Only boot was selected, only MCU\_BOOTMODE pins are taken into account and only MCUSS set of peripherals are available for boot. For more information how to set BOOTMODE and MCU\_BOOTMODE pins, see [Section 4.3, Boot Mode Pins](#).

The DMSC is the boot master of MCU. DMSC performs the necessary configurations and releases MCU's reset for CPU0 and CPU1 simultaneously even when in split mode.

---

#### Note

DMSC releases MCU's reset for CPU0 and CPU1 simultaneously regardless if MCU CPUs are in lockstep or split mode.

---

The MCU checks the boot mode pins and then configures the appropriate peripheral interface to get access to a boot image. A cursory check of the image is made, and the image is passed to DMSC. DMSC ROM then will perform code verification and route the boot image to the on-chip RAM. Once the image has been received, MCU enters a clean state and idles. DMSC ROM code will assert reset to the MCU, redirect the boot vector to the newly loaded image, and release the reset. This restarts the MCU with the MCU ROM code fully disconnected.

The MCU ROM code executes only on initial power up (POR). On subsequent (warm) resets, the reset vector base address will point to run-time loaded code (the SBL), and not ROM.

---

#### Note

DMSC ROM sets up a 3-minute watchdog timer (MCU\_RTI0) timeout. During this time, the MCU boot needs to get completed, otherwise a WDT reset will occur. Once the MCU image is loaded (SBL/SPL), DMSC ROM will restart the watchdog timer for additional 3 minutes upon entering the MCU SBL. The customer-provided MCU image needs to load and install the TI-provided SYSFW image into the DMSC, which will manage the watchdog timer during run time.

---

---

#### Note

The following system conditions must be met at POR to perform device boot:

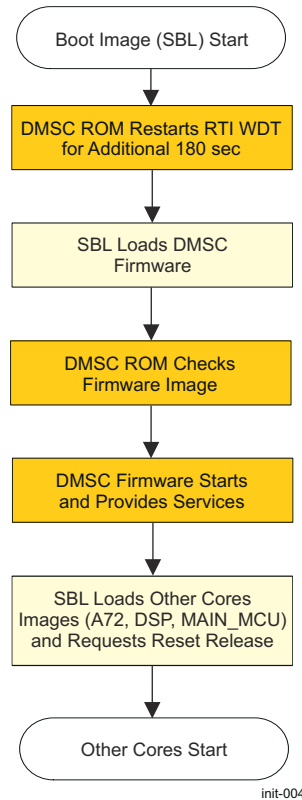

- USB cable plug must be inserted
- Ethernet PHY is powered up and out of reset
- The SD card cage must be powered before entering the SD card boot mode. A SD/MMC card with pre-loaded image must be inserted
- Memory devices must be up and ready (power ramped up and reset completed) at device startup:
  - eMMC
  - OSPI/QSPI flash
  - SPI or I<sup>2</sup>C EEPROM
  - NOR flash

Failing to meet these requirements may result in boot fail and performing a backup boot (if available for that mode).

---

[Figure 4-4](#) describes the external bootloader (SBL) typical tasks.

**Figure 4-4. External Bootloader Tasks**

Upon MCU reset and SBL execution start, DMSC ROM restarts the RTI watchdog timer for additional 180 seconds of timeout. During that time, SBL must load the DMSC firmware provided by TI otherwise a MCU reset will occur as a preventive measure against software misbehavior.

One of the SBL's main tasks is to load the DMSC firmware. Only after this task is performed, SBL can load the other processor (A72s, R5s, or optional DSPs) image and request a reset release from DMSC firmware for those cores.

#### 4.2.4 MCU Only vs Normal Boot

Users can select a special (MCU only) boot flow, which can boot the MCU, even if the main domain is unpowered. The MCU-only boot differences versus the normal boot are described below:

**Normal Boot** — Requires minimum of:

- VDDS\*\_MCU
- VDD\_MCU
- and VDD\_CORE, VDD\_CPU

voltage rails ON. Other voltage rails are optional.

Power domains for WKUP, MCUSS and Core domain are ON. Power domains required for the specified boot mode may be turned-on by the boot ROM code, if they are OFF by default.

**MCU-Only Boot** — Requires minimum of:

- VDDS\*\_MCU
- VDD\_MCU

voltage rails ON. Other voltage rails are optional. Power domains for WKUP and MCUSS are ON (only R5 is switchable). Core domain is unknown (may be powered or unpowered). Only limited set of boot modes involving

MCUSS peripherals are supported. Power domains required for the specified boot mode may be turned-on by the boot ROM code, if they are OFF by default

### 4.3 Boot Mode Pins

Boot Mode pins provide means to select the boot mode and options before the device is powered up. After every POR, they are the main source to populate the Boot Parameter Tables. See [Section 4.4, Boot Parameter Tables](#) for table list and description.

Boot mode pins can be divided into the following categories:

- **MCU\_BOOTMODE[02:00]** – Denote system clock frequency (WKUP\_HFOSC0) to ROM code for PLL configuration.
- **MCU\_BOOTMODE[05:03]** – Select the requested boot (primary) mode after POR, that is, the peripheral/memory to boot from. These are the only pins which direct boot on MCU Only boot mode
- **MCU\_BOOTMODE06** – MCU Only boot mode. In MCU Only boot, ROM code skips BOOTMODE pins and attempts boot only from MCU peripherals
- **MCU\_BOOTMODE[09:08]** – These pins can select tests to be performed on power-up (POST). POST runs in hardware, before the ROM code starts
- **BOOTMODE0** – This pin allows for additional primary boot modes to be selected when in non-MCU Only (normal) mode
- **BOOTMODE[3:1]** – Select the backup boot mode, that is, the peripheral/memory to boot from, if primary boot device failed.
- **BOOTMODE[6:4]** – These pins provide optional configurations for primary boot and are used in conjunction with the boot mode selected. See [Section 4.3.2.3](#) and the corresponding boot mode section.
- **BOOTMODE7** – This pin provides optional configurations for the backup boot devices. See [Section 4.3.2.4](#) and the corresponding boot mode section.

---

#### Note

It is user's responsibility to set the boot mode pins (via pullups or pulldowns, and jumpers/switches) depending on the desired boot scenario.

System board must provide means to switch bootmode pin settings easily. In a field design, some pins may be hardcoded to 0 or 1 but only after careful evaluation (for example, if using MCU Only pin = 1).

---

#### Note

CTRLMMR\_MAIN\_DEVSTAT register reflects the BOOTMODE pin values sampled at internal POR release.

CTRLMMR\_WKUP\_DEVSTAT register reflects the MCU\_BOOTMODE pin values sampled at internal POR release.

---

### 4.3.1 MCU\_BOOTMODE Pin Mapping

The MCU\_BOOTMODE pins are the only pins sampled in MCU-only boot mode. MCU\_BOOTMODE pin mapping is shown in [Table 4-2](#).

**Table 4-2. MCU\_BOOTMODE Pin Mapping**

9	8	7	6	5	4	3	2	1	0
POST Config		Reserved <sup>(1)</sup>	MCU Only	Primary Boot Mode A			PLL Config		

(1) Set to 0 (via pulldown to vss)

[Table 4-3](#) describes the MCU\_BOOTMODE pins that need to be set according to the system clock provided to the device.

The ROM Code will configure any PLLs required during the boot process. The ROM Code does not have the ability to select HFOSC1 (in main domain) during initial boot, however the selection can be done through the boot certificate (see [Section 4.5](#), *Boot Image Format*).

**Table 4-3. PLL Reference Clock Selection**

PLL Config Pins			Ref Clock (MHz)
MCU 2	MCU 1	MCU 0	
0	0	0	19.2
0	0	1	20
0	1	0	24
0	1	1	25
1	0	0	26
1	0	1	27 <sup>(2)</sup>
1	1	0	Reserved
1	1	1	No PLL setup <sup>(1)</sup>

(1) Only no-boot, I2C, and SPI modes are expected to function with PLL config = 7 (No PLL setup)

(2) USB DFU boot mode is not supported with the reference clock of 27 MHz

If MCU Only mode (boot from MCU domain only) needs to be selected, the MCU Only pin must be set to 1 (see [Table 4-4](#)).

**Table 4-4. MCU Only Configuration**

MCU Only Pin	MCU Only Selection
MCU 6	
0	Normal boot mode. Both MCU_BOOTMODE and BOOTMODE pins are read by ROM code
1	MCU Only boot mode. Only MCU_BOOTMODE pins are read by ROM code. Boot can proceed only from MCU peripherals

[Table 4-5](#) lists the boot modes (both primary and backup), available when MCU Only boot was selected. For normal boot modes, refer to [Table 4-8](#) and [Table 4-9](#)

**Table 4-5. Boot Mode Selection When MCU Only = 1**

Primary Boot Mode A Pins			Primary Boot Mode Selected	Backup Boot Mode Assigned <sup>(1)</sup>
MCU 5	MCU 4	MCU 3		
0	0	1	OSPI	UART
0	1	0	QSPI	UART
0	1	1	SPI	UART
1	0	0	Ethernet RGMII	I2C
1	0	1	Ethernet RMII	I2C
1	1	0	I2C	UART

**Table 4-5. Boot Mode Selection When MCU Only = 1 (continued)**

Primary Boot Mode A Pins			Primary Boot Mode Selected	Backup Boot Mode Assigned <sup>(1)</sup>
MCU 5	MCU 4	MCU 3		
1	1	1	UART	I2C

- (1) When MCU Only = 1, backup mode is assigned per primary mode. In general, non-flash primary boot modes are backed up with flash modes, and flash primary modes use non-flash for backup.

Power-On Self-Test sequence is executed as directed by pins shown in [Table 4-6](#). Dedicated eFuse bits may override the POST pins. See register CTRLMMR\_WKUP\_POST\_OPT in section *WKUP\_CTRL\_MMR0 Registers* and POST section in the Safety Manual for details.

**Table 4-6. POST Selection**

POST Config Pins		POST Sequence
MCU 9	MCU 8	
0	0	DMSC LBIST followed by MCU LBIST followed by PBIST <sup>(2)</sup>
0	1	DMSC LBIST and MCU LBIST in parallel followed by PBIST <sup>(2)</sup>
1	0	Reserved <sup>(2)</sup>
1	1	POST bypass <sup>(1)</sup>

- (1) eFuse may has been programmed so that these pins are overridden and a POST sequence is always executed (no bypass possible).  
(2) This sequence may has been replaced by another via eFuse settings. See register CTRLMMR\_WKUP\_POST\_OPT in section *WKUP\_CTRL\_MMR0 Registers* and POST section in SW Safety Manual, for details.

### 4.3.2 BOOTMODE Pin Mapping

In normal boot operation (MCU Only = 0), the ROM execution is directed also through the main boot mode pins. This provides more flexibility and more booting peripherals to boot from. The Main domain must be powered and functional when MCU Only = 0.

Main boot mode pins are shown in [Table 4-7](#).

**Table 4-7. BOOTMODE Pin Mapping**

7	6	5	4	3	2	1	0
Backup Boot Mode Config	Primary Boot Mode Config			Backup Boot Mode			Primary Boot Mode B

#### 4.3.2.1 Primary Boot Mode Selection

The primary boot mode is the first mode attempted after reset. [Table 4-8](#) lists all possible primary boot modes. Boot modes with Boot Mode B = 1 are available during normal boot only.

**Table 4-8. Primary Boot Mode Selection When MCU Only = 0**

Primary Boot Mode B Pin	Primary Boot Mode A Pins			Boot Mode Selected
0	MCU 5	MCU 4	MCU 3	
0	0	0	1	OSPI
0	0	1	0	QSPI
0	0	1	1	SPI
0	1	0	0	Ethernet RGMII
0	1	0	1	Ethernet RMII
0	1	1	0	I2C
0	1	1	1	UART
1	0	0	0	MMC/SD card
1	0	0	1	eMMC
1	0	1	0	USB
1	1	0	0	GPIC NOR
1	1	0	1	PCIe
1	1	1	0	Reserved
1	1	1	1	No-boot/Dev boot

#### 4.3.2.2 Backup Boot Mode Selection When MCU Only = 0

With MCU Only = 0, the backup boot mode is selected via pins within the main BOOTMODE map. [Table 4-9](#) lists all possible backup boot modes when MCU Only = 0. For backup boot modes when MCU Only = 1, please refer to [Table 4-5](#).

**Table 4-9. Backup Mode Selection (MCU Only=0)**

Backup Boot Mode Pins			Backup Boot Mode Selected
3	2	1	
0	0	0	None (no backup boot will be attempted)
0	0	1	USB – Device (DFU)
0	1	0	Reserved
0	1	1	UART
1	0	0	Ethernet
1	0	1	MMC/SD card
1	1	0	SPI

**Table 4-9. Backup Mode Selection (MCU Only=0) (continued)**

Backup Boot Mode Pins			Backup Boot Mode Selected
3	2	1	
1	1	1	I2C

#### 4.3.2.3 Primary Boot Mode Configuration

When in normal boot flow (MCU Only = 0), it is possible to modify certain peripheral settings, such as chip-select, bus speed, and others, depending on the peripheral selected.

The mapping of configuration pins per boot mode is shown in [Table 4-10](#). See the respective sections for details.

**Table 4-10. Primary Boot Mode Configuration**

Primary Boot Mode Config Pins			Primary Boot Mode B Pin	Primary Boot Mode A Pins			Primary Boot Mode
6	5	4	0	MCU 5	MCU 4	MCU 3	
Speed	Iclk	Csel	0	0	0	1	OSPI
Port	Iclk	Csel	0	0	1	0	QSPI
Port	Mode	Csel	0	0	1	1	SPI
Clkout	Delay	Link stat	0	1	0	0	Ethernet RGMII
Clkout	Clk src		0	1	0	1	Ethernet RMII
Bus reset	Mode	Addr	0	1	1	0	I2C
		Port	0	1	1	1	UART or No boot
Port	Bus width	Fs/raw	1	0	0	0	MMC/SD card
Port	Bus width	Voltage	1	0	0	1	eMMC
Port	Mode	Lane Swap	1	0	1	0	USB
AD Mux		Csel	1	1	0	0	GPMP NOR
Port	N lanes	sref	1	1	0	1	PCIe
			1	1	1	0	Reserved (PG1.0 only)
sfdp (PG1.1 only)	pincmd	mode	1	1	1	0	xSPI
Split	Arm/Thumb	No/Dev	1	1	1	1	No-boot/Dev boot

#### 4.3.2.4 Backup Boot Mode Configuration

When in normal boot flow (MCU Only = 0), it is possible to modify certain peripheral settings, such as chip-select, bus speed, and others depending on the peripheral selected.

The mapping of the backup configuration pin per boot mode selected is shown in [Table 4-11](#). See the respective sections for details.

**Table 4-11. Backup Boot Mode Configuration**

Backup Boot Mode Config Pin	Backup Boot Mode Pins			Backup Boot Mode
7	3	2	1	
	0	0	0	None (no backup boot will be attempted)
Port	0	0	1	USB – Device (DFU)
Port	0	1	0	Reserved
Port	0	1	1	UART
I/F	1	0	0	Ethernet
Port	1	0	1	MMC/SD card
Port	1	1	0	SPI
Nide	1	1	1	I2C

### 4.3.3 No-boot/Dev-boot Configuration

[Table 4-12](#) shows configuration pins assignment to functions when No-boot/Dev-boot was selected. In this mode, ROM code is bypassed and user is allowed to run his own code for development or debug.

MCU-only mode is not compatible with no-boot/dev-boot since the DebugSS is in the main domain.

**Table 4-12. No-boot/Dev-boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Split	0	Split/Lockstep configuration of MCU R5 cores derived from eFuse	N/A
		1	MCU R5 cores forced to split mode	
5	Arm/Thumb	0	ARM mode reset vectors	N/A
		1	Thumb mode reset vectors	
4	No/Dev	0	Development Boot	N/A
		1	No boot	

During the *Development boot* ( $BOOTMODE[4] = 0$ ), the DMSC ROM code will act as if boot of the primary image has completed, and the DMSC ROM will be waiting for a *Firmware load* message from MCU R5. Thus user can load a standard u-boot/SPL image to the R5 RAM. U-boot/SPL will then load the DMSC firmware and complete the full boot.

In *No-boot* ( $BOOTMODE[4] = 1$ ), both the DMSC and MCU R5 ROMs are bypassed and both CPUs are held in a dummy branch-to-self loop. No-boot is the most minimal device touch state by the ROM - only minimal hardware configurations are done and none of the PLLs is locked/configured. No-boot is suitable if user wants to load his own PLL, Pad config, and other basic settings.

#### 4.3.4 OSPI Boot Device Configuration

Octal SPI flash memories support various protocols, and OSPI boot mode of the device only supports a specific protocol defined below. *Additionally, if the flash memory is complaint with JEDEC xSPI standards JESD251 and JESD216D, refer to xSPI boot mode described in Section 4.3.5 (applicable only in PG1.1).* The OSPI protocol is described according to bit-width (1 or 8) and data rate (S or D for \*S\*ingle Data rate or \*D\*ouble Data rate) for the Command/Address/Data segments of the protocol. The OSPI boot mode supports 1S-1S-8S mode. The Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued for OSPI mode is 0x8b, followed by zero for address and 8 dummy cycles. The frequencies of operation is 33 MHz. The OSPI boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the OSPI boot mode.

Table 4-13 shows configuration pins assignment to functions when boot mode is the Octal SPI.

**Table 4-13. OSPI Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Speed	0	33 MHz using manual tap selection	0
		1	Reserved	
5	Iclk	0	Iclock source external	0
		1	Iclock source internal	
4	Csel	0	CS 0	0
		1	CS 1	

Table 4-14 summarizes the OSPI pin configuration done by ROM code for OSPI boot device.

**Table 4-14. OSPI Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_OSPI0_CLK0	MCU_OSPI0_CLK	Disable	Up	0	Disable	Enable	0
MCU_OSPI0_LBCLK0	MCU_OSPI0_LBCLK0	Disable	Up	0	Enable	Enable	0
MCU_OSPI0_DQS	MCU_OSPI0_DQS	Disable	Up	0	Enable	Disable	0
MCU_OSPI0_D0	MCU_OSPI0_D0	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D1	MCU_OSPI0_D1	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D2	MCU_OSPI0_D2	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D3	MCU_OSPI0_D3	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D4	MCU_OSPI0_D4	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D5	MCU_OSPI0_D5	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D6	MCU_OSPI0_D6	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D7	MCU_OSPI0_D7	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_CSn0	MCU_OSPI0_CSn0	Enable	Up	0	Disable	Enable	0
MCU_OSPI0_CSn1	MCU_OSPI0_CSn1	Enable	Up	0	Disable	Enable	0
MCU_OSPI1_LBCLK0	MCU_OSPI0_CSn2	Enable	Up	0	Disable	Enable	1
MCU_OSPI1_DQS	MCU_OSPI0_CSn3	Enable	Up	0	Disable	Enable	1

#### 4.3.5 xSPI Boot Device Configuration

The xSPI protocol defines 1S-1S-1S mode for general backwards compatibility, and 8D-8D-8D for maximum throughput (where bit-width (1 or 8) and data rate (S or D for \*S\*ingle Data rate or \*D\*ouble Data rate)).

For 1S-1S-1S mode of operation (Bit-width =1, Single Data Rate): the Command and Address issued are 8 bits and 24 bits, respectively. The Read Command issued is 0x0b, followed by zero for address and 8 dummy cycles. The frequency of operation supported is 50 MHz.

For 8D-8D-8D mode of operation (Bit-width =8, Double Data Rate): the Command and Address issued are 8 bits and 32 bits, respectively. The Read Command issued is 0x0b or 0xee, followed by zero for address, 16 or 20 dummy cycles. The frequency of operation supported is 25 MHz. Additionally, the flash is expected to be configured in 8D mode out of POR through the nonvolatile configuration register.

For SFDP mode, ROM starts operation in 1S-1S-1S mode, then reads the SFDP header from flash memory to get the 8D-8D-8D switching sequence, Read Command, CMD Extension, and Byte Order. SFDP parsing of ROM is described below and on successful parsing ROM, issues the 8D-8D-8D command switching sequence. It then reads the boot image in 8D-8D-8D mode with the read command specified in the SFDP header.

The following boot mode pin configuration and corresponding pin usage and mux configuration are shown below. This is the xSPI boot mode.

**Table 4-15. MCU\_BOOTMODE Pin Map OSPI**

9	8	7	6	5	4	3	2	1	0
Rsvd (not for boot use)	Rsvd	MCU Only	Primary Boot Mode A				PLL Config		
X	X	X	X	1	1	0	X	X	X

**Table 4-16. BOOTMODE Pin Map OSPI**

7	6	5	4	3	2	1	0
Backup Boot Mode Config	Primary Boot Mode Config			Backup Boot Mode			Primary Boot B
X	0/1	0/1	0/1	X	X	X	1

**Table 4-17. xSPI Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	SFDP	0	SFDP (Serial Flash Discovery Parameter) Disabled	0
		1	SFDP Enabled	
5	Pin Cmd	0	0x0B Read Command	0
		1	0xEE Read Command	
4	Mode	0	SPI-STR (1S-1S-1S) at 50 MHz	0
		1	OCTAL-DTR (8D-8D-8D) at 25 MHz	

**Table 4-18. xSPI Pin Usage**

Package Name	Function Name	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel	Pad configuration Register
MCU_OSPI0_CLK0	MCU_OSPI0_CLK	Disable	Up	0	Disable	Enable	0	WKUP_PADCONFIG_0

MCU_OSPI1_CSn0	MCU_OSPI1_CSn0	Enable	Up	0	Disable	Enable	0
MCU_OSPI1_CSn1	MCU_OSPI1_CSn1	Enable	Up	0	Disable	Enable	0

### 4.3.7 SPI Boot Device Configuration

Table 4-22 shows configuration pins assignment to functions when boot mode is the SPI on OSPI port mode. The SPI bus will be run at 4.156 MHz.

**Table 4-22. SPI Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6 (7) <sup>(1)</sup>	Port	0	Port 0	0
		1	Port 1	
5	Mode	0	SPI Mode 0	0
		1	SPI Mode 3	
4	Csel	0	CS 0	0
		1	CS 1	

(1) When SPI is the backup mode and MCU Only=0

Table 4-23 summarizes the OSPI pin configuration done by ROM code for SPI boot device on port 0.

**Table 4-23. SPI Port 0 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_OSPI0_CLK0	MCU_OSPI0_CLK	Disable	Up	0	Disable	Enable	0
MCU_OSPI0_LBCLK0	MCU_OSPI0_LBCLK0	Disable	Up	0	Enable	Enable	0
MCU_OSPI0_DQS	MCU_OSPI0_DQS	Disable	Up	0	Enable	Disable	0
MCU_OSPI0_D0	MCU_OSPI0_D0	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_D1	MCU_OSPI0_D1	Enable	Up	0	Enable	Enable	0
MCU_OSPI0_CSn0	MCU_OSPI0_CSn0	Enable	Up	0	Disable	Enable	0
MCU_OSPI0_CSn1	MCU_OSPI0_CSn1	Enable	Up	0	Disable	Enable	0
MCU_OSPI1_LBCLK0	MCU_OSPI0_CSn2	Enable	Up	0	Disable	Enable	1
MCU_OSPI1_DQS	MCU_OSPI0_CSn3	Enable	Up	0	Disable	Enable	1

Table 4-24 summarizes the OSPI pin configuration done by ROM code for SPI boot device on port 1.

**Table 4-24. SPI Port 1 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_OSPI1_CLK0	MCU_OSPI1_CLK	Disable	Up	0	Disable	Enable	0
MCU_OSPI1_LBCLK0	MCU_OSPI1_LBCLK0	Disable	Up	0	Enable	Enable	0
MCU_OSPI1_D0	MCU_OSPI1_D0	Enable	Up	0	Enable	Enable	0
MCU_OSPI1_D1	MCU_OSPI1_D1	Enable	Up	0	Enable	Enable	0
MCU_OSPI1_CSn0	MCU_OSPI1_CSn0	Enable	Up	0	Disable	Enable	0
MCU_OSPI1_CSn1	MCU_OSPI1_CSn1	Enable	Up	0	Disable	Enable	0

### 4.3.8 I2C Boot Device Configuration

Table 4-25 shows configuration pins assignment to functions when boot mode is the I2C mode.

**Table 4-25. I2C Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Bus reset	0	Hung bus reset attempt after 1 ms	0
		1	No hung bus reset attempted	
5 (7) <sup>(1)</sup>	Mode	0	SoC I2C module is master (boot from flash/EEPROM)	0
		1	SoC I2C module is slave	
4	Address	0	0x50 (master mode, EEPROM's address), 0x10 (slave mode, own address)	0
		1	0x51 (master mode, EEPROM's address), 0x11 (slave mode, own address)	

(1) When I2C is the backup mode and MCU Only=0

The I<sup>2</sup>C bus is considered inactive if the data line is low and clock remains high for the specified timeout time. Recovery consists of driving the clock a stop condition is detected. A stop condition is a transition on the data line from 0 to 1 while the clock line is high. If the clock line is stuck low there is no way to take control of the bus.

Table 4-26 summarizes the I2C pin configuration done by ROM code for I<sup>2</sup>C boot device.

**Table 4-26. I2C Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_I2C0_SCL	MCU_I2C0_SCL	Enable	Up	0	Enable	Enable	0
MCU_I2C0_SDA	MCU_I2C0_SDA	Enable	Up	0	Enable	Enable	0

### 4.3.9 MMC/SD Card Boot Device Configuration

Table 4-27 shows configuration pins assignment to functions when boot mode is the MMC/SD card mode.

**Table 4-27. MMC/SD Card Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6 (7) <sup>(1)</sup>	Port	0	Port 0	N/A
		1	Port 1	
5	Bus Width	0	4 bit	N/A
		1	1 bit	
4	FS/Raw	0	Filesystem mode	N/A
		1	Raw Mode	

(1) When MMCSD is the backup mode

Table 4-28 summarizes the MMC pin configuration done by ROM code for MMC/SD Card boot device on port 1.

#### Note

Note that MMC Port 0 has no pin mux.

**Table 4-28. MMC/SD Card Port 1 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MMC1_DAT3 <sup>(1)</sup>	MMC1_DAT3	Enable	Up	0	Enable	Enable	0
MMC1_DAT2 <sup>(1)</sup>	MMC1_DAT2	Enable	Up	0	Enable	Enable	0
MMC1_DAT1 <sup>(1)</sup>	MMC1_DAT1	Enable	Up	0	Enable	Enable	0
MMC1_DAT0	MMC1_DAT0	Enable	Up	0	Enable	Enable	0
MMC1_CLK	MMC1_CLK	Disable	Up	0	Disable	Enable	0
MMC1_CMD	MMC1_CMD	Enable	Up	0	Enable	Enable	0
MMC1_SDCD	MMC1_SDCD	Enable	Up	0	Enable	Disable	0

(1) In 1-bit mode, only MMC1\_DAT0 is configured.

### 4.3.10 Ethernet Boot Device Configuration

Table 4-29 shows configuration pins assignment to functions when boot mode is the Ethernet RGMII mode.

**Table 4-29. Ethernet RGMII Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Clkout	0	25 MHz clock not generated on MCU CLKOUT	0
		1	25 MHz clock generated on MCU CLKOUT	
5	Delay	0	RGMII with internal Tx delay	0
		1	RGMII with external Tx delay	
4	Link stat	0	PHY scan used for speed/duplex setup	0
		1	RGMII status register used for speed/duplex setup	

Table 4-30 shows configuration pins assignment to functions when boot mode is the Ethernet RMII mode.

**Table 4-30. Ethernet RMII Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Clk out	0	50 MHz clock not generated on MCU CLKOUT	0
		1	50 MHz clock generated on MCU CLKOUT	
5	Clk src	0	External clock source	0
		1	Internal clock source	
4	Reserved	X	Not used	N/A

Table 4-31 shows configuration pins assignment to functions when boot mode is the Ethernet is the backup mode.

**Table 4-31. Ethernet Backup Boot Configuration Field**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
7 <sup>(1)</sup>	Interface	0	RGMII with internal Tx delay	N/A
		1	RMII with external clock source	

(1) When Ethernet is the backup mode

Table 4-32 summarizes the RGMII pin configuration done by ROM code for Ethernet boot device on RGMII port.

**Table 4-32. RGMII Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_RGMII1_TX_CTL	MCU_RGMII1_TX_CTL	Disable	Down	0	Disable	Enable	0
MCU_RGMII1_RX_CTL	MCU_RGMII1_RX_CTL	Disable	Down	0	Enable	Disable	0
MCU_RGMII1_TD3	MCU_RGMII1_TD3	Disable	Down	0	Disable	Enable	0
MCU_RGMII1_TD2	MCU_RGMII1_TD2	Disable	Down	0	Disable	Enable	0
MCU_RGMII1_TD1	MCU_RGMII1_TD1	Disable	Down	0	Disable	Enable	0
MCU_RGMII1_TD0	MCU_RGMII1_TD0	Disable	Down	0	Disable	Enable	0
MCU_RGMII1_TXC	MCU_RGMII1_TXC	Disable	Down	0	Enable	Enable	0
MCU_RGMII1_RXC	MCU_RGMII1_RXC	Disable	Down	0	Enable	Disable	0
MCU_RGMII1_RD3	MCU_RGMII1_RD3	Disable	Down	0	Enable	Disable	0
MCU_RGMII1_RD2	MCU_RGMII1_RD2	Disable	Down	0	Enable	Disable	0
MCU_RGMII1_RD1	MCU_RGMII1_RD1	Disable	Down	0	Enable	Disable	0
MCU_RGMII1_RD0	MCU_RGMII1_RD0	Disable	Down	0	Enable	Disable	0
MCU_MDIO0_MDIO	MCU_MDIO0_MDIO	Enable	Up	0	Enable	Enable	0

**Table 4-32. RGMII Pin Usage (continued)**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_MDIO0_MDC	MCU_MDIO0_MDC	Enable	Up	0	Disable	Enable	0
WKUP_GPIO_11	MCU_CLKOUT0	Disable	Down	0	Disable	Enable	6

Table 4-33 summarizes the RMII pin configuration done by ROM code for Ethernet boot device on RMII port.

**Table 4-33. RMII Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MCU_RGMII1_TX_CTL	MCU_RMII1_CRSDV	Disable	Down	0	Enable	Disable	1
MCU_RGMII1_RX_CTL	MCU_RMII1_RX_ER	Disable	Down	0	Enable	Disable	1
MCU_RGMII1_TD1	MCU_RMII1_TXD1	Disable	Down	0	Disable	Enable	1
MCU_RGMII1_TD0	MCU_RMII1_TXD0	Disable	Down	0	Disable	Enable	1
MCU_RGMII1_TXC	MCU_RMII1_TX_EN	Disable	Down	0	Disable	Enable	1
MCU_RGMII1_RXC	MCU_RMII1_REF_CLK	Disable	Down	0	Enable	Enable	1
MCU_RGMII1_RD1	MCU_RMII1_RXD1	Disable	Down	0	Enable	Disable	1
MCU_RGMII1_RD0	MCU_RMII1_RXD0	Disable	Down	0	Enable	Disable	1
WKUP_GPIO_11	MCU_CLKOUT0	Disable	Down	0	Disable	Enable	6
MCU_MDIO0_MDIO	MCU_MDIO0_MDIO	Enable	Up	0	Enable	Enable	0
MCU_MDIO0_MDC	MCU_MDIO0_MDC	Enable	Up	0	Disable	Enable	0

### 4.3.11 USB Boot Device Configuration

Table 4-34 shows configuration pins assignment to functions when boot mode is the USB mode.

**Table 4-34. USB Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6 (7) <sup>(1)</sup>	Port	0	Port 0	N/A
		1	Port 1	
5	Mode	0	DFU (USB device mode)	N/A
		1	Reserved	
4	Lane Swap	0	D+/D- lines are not swapped	N/A
		1	D+/D- lines are swapped	

(1) When USB is the backup mode

Table 4-35 summarizes the USB pin configuration done by ROM code for USB boot device on port 0.

**Table 4-35. USB Port 0 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
USB0_DRVVBUS	USB0_DRVVBUS	Enable	Down	0	Disable	Enable	0

Table 4-36 summarizes the USB pin configuration done by ROM code for USB boot device on port 1.

**Table 4-36. USB Port 1 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
USB0_DRVVBUS	USB1_DRVVBUS	Enable	Down	0	Disable	Enable	1

#### Note

Note that other USB pins do not have pin mux options.

### 4.3.12 PCIe Boot Device Configuration

Table 4-37 shows configuration pins assignment to functions when boot mode is the PCIe mode.

**Table 4-37. PCIe Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Port	0	Port 0	N/A
		1	Port 1	
5	N Lanes	0	Max lanes	N/A
		1	Reserved	
4	Clocking	0	From external pins	N/A
		1	From internal source	

#### Note

Note that PCIe (SERDES) pins do not have pin mux options.

### 4.3.13 UART Boot Device Configuration

ROM Code always configures the UART port to 115200 kbaud, 8-n-1 mode, and the XMODEM protocol is used to transfer the boot data.

**Table 4-38. UART Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Reserved	-	Not used	N/A
5	Reserved	-	Not used	N/A
4 (7) <sup>(1)</sup>	Port	0	MCU UART (port 0)	0
		1	WKUP UART (port 1)	

(1) When UART is the backup mode and MCU Only=0

Table 4-39 summarizes the UART pin configuration done by ROM code for UART host on port 0.

**Table 4-39. UART Port 0 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
WKUP_GPIO0_12	MCU_UART_TXD	Enable	Up	0	Disable	Enable	0
WKUP_GPIO0_13	MCU_UART_RXD	Enable	Up	0	Enable	Disable	0

Table 4-40 summarizes the UART pin configuration done by ROM code for UART host on port 1.

**Table 4-40. UART Port 1 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
WKUP_UART_TXD	WKUP_UART_TXD	Enable	Up	0	Disable	Enable	0
WKUP_UART_RXD	WKUP_UART_RXD	Enable	Up	0	Enable	Disable	0

#### 4.3.14 GPMC NOR Boot Device Configuration

Table 4-41 shows configuration pins assignment to functions when boot mode is the GPMC NOR mode.

**Table 4-41. GPMC NOR Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6-5	A/D Mux	0	Non-mux	N/A
		1	Reserved	
		2	Reserved	
		3	Non-mux	
4	Csel	0	Chip select 0	N/A
		1	Chip select 1	

Table 4-42 summarizes the GPMC pin configuration done by ROM code for GPMC non-muxed memory.

**Table 4-42. GPMC non-muxed Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
PRG0_PRU0_GPO5	GPMC0_AD0	Disable	Down	0	Enable	Enable	8
PRG0_PRU0_GPO7	GPMC0_AD1	Disable	Down	0	Enable	Enable	8
PRG0_PRU0_GPO8	GPMC0_AD2	Disable	Down	0	Enable	Enable	8
PRG0_PRU0_GPO9	GPMC0_AD3	Disable	Down	0	Enable	Enable	8
PRG0_PRU0_GPO10	GPMC0_AD4	Disable	Down	0	Enable	Enable	8

### 4.3.15 eMMC Boot Device Configuration

Table 4-45 shows configuration pins assignment to functions when boot mode is the eMMC mode.

**Table 4-45. eMMC Boot Configuration Fields**

BOOTMODE Pins	Field	Value	Description	MCU Only=1 Value
6	Port	0	Port 0	N/A
		1	Port 1	
5	Bus Width	0	Max width by port (8-bit on port 0, 4-bit on port 1)	N/A
		1	1-bit only	
4	Voltage	0	1.8V	N/A
		1	3.3V	

Table 4-43 summarizes the MMC pin configuration done by ROM code for eMMC on port 1.

#### Note

Note that MMC Port 0 has no pin mux options.

**Table 4-46. eMMC Port 1 Pin Usage**

Device Pin	Module Signal	Pull Enable	Pull Direction	Driver Index	Rx En/Dis	Tx En/Dis	Pinmux Sel
MMC1_DAT3	MMC1_DAT3	Enable	Up	0	Enable	Enable	0
MMC1_DAT2	MMC1_DAT2	Enable	Up	0	Enable	Enable	0
MMC1_DAT1	MMC1_DAT1	Enable	Up	0	Enable	Enable	0
MMC1_DAT0	MMC1_DAT0	Enable	Up	0	Enable	Enable	0
MMC1_CLK	MMC1_CLK	Disable	Up	0	Disable	Enable	0
MMC1_CMD	MMC1_CMD	Enable	Up	0	Enable	Enable	0
MMC1_SDCD	MMC1_SDCD	Enable	Up	0	Enable	Disable	0

#### 4.3.15.1 eMMC Flash

To support eMMC boot mode across a device warm reset, eMMC flash has the following requirements:

1. The reset line must be connected to the eMMC flash input reset pin.
2. The eMMC flash ext\_csd[162] RST\_n\_ENABLE must be set to the expected configuration for the warm-reset signal to propagate to the flash device for the boot process to succeed. Possible configurations are shown in Table 4-47.

#### Note

For warm\_reset eMMC boot to function correctly, 0x1 must be written to RST\_n\_ENABLE in the ext\_csd[162] Register. This will enable the RST\_n signal.

**Table 4-47. ext\_csd[162] Register**

Bit	Field	Type	Description
7:2	Reserved		Reserved
1:0	RST_n_ENABLE	R/W	0x0: RST_n signal is temporarily disabled (default) 0x1: RST_n signal is permanently enabled 0x2 RST_n signal is permanently disabled 0x3: Reserved

### 4.3.16 PLL Configuration

ROM code must be aware of the reference clock provided to PLLs. That is, the speed of the quartz crystal, or the clock supplied by an external clock oscillator. On how to indicate the PLL reference clock, see , *PLL Reference Clock Selection*.

See [Section 5.4, Clock Management](#), for the PLL reference clock scheme.

ROM code configures only PLLs which are required during boot. Therefore, if a PLL is required for the backup boot mode but not the primary boot mode, and if the backup boot mode never executes, then the PLLs required for backup boot are not enabled. [Table 4-48](#) lists the enabled PLLs according to module or boot peripheral.

**Table 4-48. PLL Configuration by Boot Mode**

MCU_PLL0	MCU_PLL1	MCU_PLL2	Main PLL0	Main PLL1	Main PLL2	Main PLL3	Boot Mode
✓	✓						OSPI/QSPI/SPI
✓		✓					Ethernet
✓	✓						I2C
✓	✓						UART
✓			✓				MMCSD
✓			✓	✓			USB
✓			✓				GPCM NOR
✓			✓		✓		PCIe

#### Note

All clock frequencies are in megahertz.

#### 4.3.16.1 MCU\_PLL0, MCU\_PLL2, Main PLL0, and Main PLL3

[Table 4-49](#) summarizes the ROM code settings used to configure MCU\_PLL0, MCU\_PLL2, Main PLL0, and Main PLL3 for the supported input clocks.

**Table 4-49. PLL Configuration for MCU\_PLL0, MCU\_PLL2, Main PLL0, and Main PLL3**

2000 MHz VCO frequency								
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv	
19.2	1	19.2	104	2796202	2000	$3.97 \times 10^{-8}$	0 or 1	
20	1	20	100	0	2000	0	0 or 1	
24	1	24	83	5592405	2000	$1.99 \times 10^{-8}$	0 or 1	
25	1	25	80	0	2000	0	0 or 1	
26	1	26	76	15486661	2000	$5.50 \times 10^{-8}$	0 or 1	
27	1	27	74	1242757	2000	$4.42 \times 10^{-8}$	0 or 1	

#### 4.3.16.2 MCU\_PLL1

The MCU\_PLL1 is a fractional PLL configured with a VCO frequency of 2400 MHz.

**Table 4-50. PLL Configuration for MCU\_PLL1**

2400 MHz VCO frequency								
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv	
19.2	1	19.2	125	0	2400	0	0	
20	1	20	120	0	2400	0	0	
24	1	24	100	0	2400	0	0	
25	1	96	192	0	2400	0	0	
26	1	26	92	5162220	2400	$1.8 \times 10^{-8}$	0	

**Table 4-50. PLL Configuration for MCU\_PLL1 (continued)**

2400 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
27	1	27	88	14913081	2400	$5.53 \times 10^{-8}$	0

#### 4.3.16.3 Main PLL1

The main PLL is a fractional PLL configured with a VCO frequency of 1920 MHz.

**Table 4-51. PLL Configuration for Main PLL1**

1920 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	100	0	1920	0	0
20	1	20	96	0	1920	0	0
24	1	24	80	0	1920	0	0
25	1	25	76	13421773	1920	$4.77 \times 10^{-8}$	0
26	1	26	73	14196106	1920	$5.04 \times 10^{-8}$	0
27	1	27	71	1864135	1920	$6.62 \times 10^{-8}$	0

#### 4.3.16.4 Main PLL2

Main PLL2 is an fractional PLL configured with a VCO frequency of 1800 MHz.

**Table 4-52. PLL Configuration for Main PLL 2**

1800 MHz VCO frequency							
Ref clk	Refdiv	Pfd freq	Fbdiv	Frac	Vco	Delta	Postdiv
19.2	1	19.2	93	12582912	1800	0	0
20	1	20	90	0	1800	0	0
24	1	24	75	0	1800	0	0
25	1	25	72	0	1800	0	0
26	1	26	69	3871665	1800	$1.38 \times 10^{-8}$	0
27	1	27	66	11184811	1800	$3.97 \times 10^{-8}$	0

#### 4.3.16.5

##### Note

Note that the bringup and configuration of bootmode-specific PLLs by ROM code will result in a bootmode-specific device clocking setup which for example has an impact on which peripheral modules can readily be clocked and used by SBL/SPL prior to loading and bringing up System Firmware (SYSFW).

## 4.4 Boot Parameter Tables

The boot parameter tables direct the main module boot process. On cold boot the tables are created based on pin strapped values (see [Section 4.3, Boot Mode Pins](#)) and built-in data. The ROM Code supports two parameter tables stored as an array in a fixed memory address in the MSRAM, each of size 512 bytes. The ROM will attempt to boot using the primary table. On boot failure, ROM Code will retry using the second table.

Using two tables handles two cases.

- The first is in initial board manufacture where the primary boot table specifies boot from a flash device, and the flash is blank. ROM Code would then switch to the secondary boot mode which would receive the image externally (Ethernet, USB, PCIe, UART) and this image would flash the boot image.
- The second case is failure due to total flash corruption. In all flash parameter tables there exist backup addresses within the primary boot mode. This covers the problem of a flash update failure with a backup image present on the same flash device.

The boot tables reside at a fixed location in memory which is described in [Section 4.7.2, Global Memory Addresses Used by ROM Code](#).

### 4.4.1 Common Header

These boot parameter tables have certain parameters common across all the boot modes, while the rest of the parameters are unique to the boot modes. The common entries in the boot parameter table are shown in [Table 4-53](#).

**Table 4-53. Boot Parameter Table Common Header**

Byte Offset	Size (bytes)	Name	Description
0	2	Length	The length of the table
2	2	Checksum	Ones complement checksum over length bytes in the table. If 0 the checksum is not validated.
4	2	Peripheral	Identifies the boot peripheral and format of the table after the common header. See <a href="#">Table 4-54</a>
6	2	Reserved	Reserved
8	4	Timeout	Timeout for this boot mode, in milliseconds
12	4	Magic	Magic value 0x01AD0911
16	40	PLL Config 0	PLL Configuration 0. See <a href="#">Table 4-55</a>
56	40	PLL Config 1	PLL Configuration 1
96	40	PLL Config 2	PLL Configuration 2
136	40	PLL Config 3	PLL Configuration 3
176	40	PLL Config 4	PLL Configuration 4
216	40	PLL Config 5	PLL Configuration 5

[Table 4-54](#) lists the possible boot modes used in the boot parameter tables.

**Table 4-54. Boot Peripheral Selection**

Peripheral Field Value	Description
0	Sleep (No boot)
10	Ethernet Reserved
20	Ethernet BOOTP/TFTP (general)
21	Ethernet RGMII specific
22	Ethernet RMII specific
30	PCIe
31	PCIe 1-lane
32	PCIe 2-lane
40	I2C

**Table 4-54. Boot Peripheral Selection (continued)**

Peripheral Field Value	Description
50	SPI
60	UART
70	USB DFU
71	USB Reserved
72	USB Reserved
80	QSPI
85	OSPI
90	Hyperflash Reserved
100	MMC/SD Card (general)
101	eMMC (general)
102	MMC 1-bit
103	MMC 4-bit
104	MMC 8-bit
110	GPMC
120	UFS Reserved
130	xSPI

#### 4.4.2 PLL Setup

Table 4-55 through describe the PLL configuration fields.

**Table 4-55. Boot Parameter Table PLL Configuration**

Byte Offset	Size (bytes)	Name	Description
0	1	Domain/cfg	See Table 4-56
1	1	PLL number	PLL number indexed from 0. See , for PLL numbers.
2	1	Input source	See Table 4-58
3	1	PLL Type	This field must be 1 to indicate an SCPLL
4	4	Input Ref Clock	The PLL input clock, in Q16.16 format
8	4	Feed back divider, integer part	Integer value of feedback divider
12	4	Feed back divider, fractional part	Fractional portion of feedback divider. Total divider is the Integer part + (Fractional part / 2 <sup>24</sup> )
16	1	Ref divider	Input clock pre-divider
17	1	Post divider 1	Output post divider 1
18	1	Post divider 2	Output post divider 2
19	1	Reserved	Reserved
20	2	Hsdiv Enable	Bit map. A set bit indicates that the corresponding hsdiv is enabled.
22	2	Reserved	Reserved
24	16	Hsdiv[16]	Array of hs divider values.

**Table 4-56. PLL Domain and Enable Configuration**

7	6	5	4	3	2	1	0
Reserved		Enable		Reserved		Domain	

**Table 4-57. PLL Domain and Enable Field Description**

Field	Value	Description
Enable	0	PLL not configured
	1	PLL enabled only if currently disabled or in bypass
	2	PLL is unconditionally enabled. If currently enabled with a different configuration the PLL is first disabled

**Table 4-57. PLL Domain and Enable Field Description (continued)**

Field	Value	Description
Domain	3	PLL is unconditionally disabled
	0	PLL is in the MCU domain
	1	PLL is in the MAIN domain

**Table 4-58. PLL Reference Source Bit Fields**

7	6	5	4	3	2	1	0
Source Type				Source Index			

**Table 4-59. PLL Reference Source Field Description**

Field	Value	Description
Source Type	0	Source is HFOSC
	1	Source is external pin
	2	Reserved
	3-7	Reserved
Source Index	0-31	Source index (HFOSC[0-31] or pin[0-31], depending on Source Type) HFOSC[0] – WKUP_HFOSC0 HFOSC[1] – HFOSC1 (in MAIN domain) PIN[1] – EXT_REFCLK1 pin (not all PLLs, see <a href="#">Section 5.4, Clocking</a> )

#### 4.4.3 PCIe Boot Parameter Table

[Table 4-60](#) shows the boot parameter table for PCIe boot. Must be preceded with the common boot parameters described in [Table 4-53](#).

**Table 4-60. PCIe Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	portNum	From pins	Physical port number
260	4	AddrWid	64	PCIe address width
264	4	LinkRate	8000	Link rate in MHz
268	4	RefClkKHz	100000	Serdes reference clock in kHz
272	4	Nlanes	From pins	Number of PCIe lanes configured (link width)
276	4	Rsvd	4	Reserved
280	4	Rsvd	256	Reserved
284	4	Rsvd	256	Reserved
288	4	Rsvd	0	Reserved
292	4	Rsvd	0	Reserved
296	4	Vendor ID	0x104C	PCIe Vendor ID value (read from control registers)
300	4	Device ID	0xB00D	PCIe Device ID value (read from control registers)
304	4	Class code/revision ID	0x04800001	PCIe class code and revision ID value
308	4	Internal Clock	From Pins	If non-zero, internal (SoC) ref clock is used
312	4	sscEnable	1	Enable spread spectrum clock
316	4	RefSrc	From Pins	Selects serdes reference clock internal source. Refer to , <i>Reference Clock Distribution</i> for details.

#### 4.4.4 I2C Boot Parameter Table

[Table 4-61](#) shows the boot parameter table for I2C boot. Must be preceded with the common boot parameters described in [Table 4-53](#).

**Table 4-61. I2C Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode	From Pins	0x4E = I2C Master, 0x72 = I2C slave
258	1	Dev Addr	From Pins	I2C address when slave mode (0x10 or 0x11)
259	1	Reserved	0	Reserved
260	4	Mod Clock	0	I2C Module input clock. If 0, it is computed by ROM code.
264	2	Bus Freq	400	I2C Master mode bus frequency, in kHz
266	2	Bus Addr	From Pins	I2C Master mode storage device's address (0x50 or 0x51)
268	2	Read Index	0	Index to the active read offset (0 or 1)
270	2	Read Offset 0	0x0000	I2C Master mode read offset
272	2	Read Offset 1	0x8000	I2C Master mode backup read offset
274	2	Reserved	0	Reserved
276	2	Reserved	0	Reserved
280	2	Busy Timeout	From pins	Number of $\mu$ s before a bus recovery is attempted. In units of microseconds in Q3 number format. Value of 0 disables bus recovery attempts.

#### 4.4.5 OSPI/QSPI/SPI/xSPI Boot Parameter Table

Table 4-62 shows the boot parameter table for OSPI, QSPI, or SPI boot. Table 4-63 shows the boot parameter table for xSPI. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-62. OSPI/QSPI/SPI Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero, the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 2, 4, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1, 2, 4, 8)
260	1	Data Width	From Pins	Number of pins used to received data (1, 2, 4, 8)
261	1	Address Size	24	16 (SPI only), 24, and 32 bits are the valid address sizes
262	1	Mode	0	OSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0–3)
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable DQS
269	1	Reserved	0	Reserved
270	2	Module Freq	0	The OSPI module frequency after PLL enable, in kHz. If 0, ROM code uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The OSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	4	Tap Delay	0xFFFFFFFF	The read tap selection. If 0xFFFFFFFF, the ROM code will scan the taps to find the best delay. The result will then overwrite the value in this table.
284	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
288	4	notDAC	From pins	When 0, DAC mode is used

**Table 4-62. OSPI/QSPI/SPI Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
292	4	Read Index	0	Index to the active read address (0-1)
296	4	Read Addr 0	0x000000	The initial flash read address
300	4	Read Addr 1	0x400000 (0x4000 SPI)	Backup read address
304	4	Reserved	0	Reserved
308	4	Reserved	0	Reserved

**Table 4-63. xSPI Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	0	Physical port number
257	1	Mode on	From Pins	If non-zero the mode byte will be sent
258	1	Instruct Width	From Pins	Number of pins used to send instructions (1, 8)
259	1	Address Width	From Pins	Number of pins used to send address (1,8)
260	1	Data Width	From Pins	Number of pins used to received data (1,8)
261	1	Address Size	24	24 or 32 bits are the valid address sizes
262	1	Mode	0	QSPI clock polarity and phase mode
263	1	CSEL	From Pins	Chip select number (0-n) not the bitfield
264	1	Read Cmd	From Pins	Command used to read read data
265	1	Mode byte	0	Value used for the mode byte (when active)
266	1	Dummy Cycles	From pins	Number of dummy cycles sent after the read command
267	1	clkRecovery	From pins	Clock recovery
268	1	dqsEnable	0	Enable dqs
269	1	ddrEnable	From pins	OSPI DDR mode operation
270	2	Module Freq	0	The QSPI module frequency after PLL enable, in kHz. If 0 the ROM uses the value from the module clock tables.
272	4	Bus Frequency	From pins	The QSPI bus frequency, in kHz
276	4	Delay	0x08080808 or 0x01010101	The chip select read delays. Default value is based on the read command
280	1	SFDP	From Pins	Enables SFDP parser for 1S-1S-1S to 8D-8D-8D switching

**Table 4-63. xSPI Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
282	4	Tap Delay	0xffffffff	The read tap selection. If 0xffffffff the ROM will scan the taps to find the best delay. The result will then overwrite the value in this table.
286	4	Internal Clk	From pins	0 = external (dqs) 1 = internal
290	4	indac	From pins	When 0 XIP mode is used
294	4	Read Index	0	Index to the active read address
298	4	Read Addr 0	0	The initial flash read address
302	4	Read Addr 1	0x400000	Backup read address

#### 4.4.6 GPMC NOR Boot Parameter Table

Table 4-64 shows the boot parameter table for GPMC NOR boot. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-64. GPMC NOR Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	refClkKHz	0	The module functional clock frequency, in kHz. 0 = ROM code computes the value.
260	4	csSizeMb	64	The size of each chip-select, in MB
264	1	Csel	From pins	The chip-select to use (0-3)
265	1	adMux	From pins	The address/data multiplexing used. 0 = A/D parallel, 1 = A/A/D mux, 2 = A/D mux
266	1	Width	16	Data bus width
267	1	Reserved	0	Reserved
268	4	Read index	0	The currently active read offset (0-1)
272	4	Read offset 0	0x000000	Read address offset 0
276	4	Read offset 1	0x400000	Backup read address offset 1
280	4	Reserved	0	Reserved
284	4	Reserved	0	Reserved

#### 4.4.7 Ethernet Boot Parameter Table

Table 4-65 is shown segmented into four sections:

1. The first section contains information required to configure the device hardware
2. The second section contains information used by the top level Ethernet module to execute the boot
3. The third section contains information for the Ethernet stack code.
4. The fourth section contains information for creating the BOOTP packet (vendor string, ID string and debug string), and holds information returned in the BOOTP response (Default route and file name)

Table 4-65 shows the boot parameter table for Ethernet boot. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-65. Ethernet Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
Hardware Configuration Options				

**Table 4-65. Ethernet Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	2	Mod Freq	0	Module clock frequency, kHz. If 0, ROM code computes the value.
258	1	Port Num	0	Physical port number
259	1	Interface	From Pins	0 = RGMII with internal delay 1 = RGMII with external delay 2 = RMII
260	1	Init Level	0	0 = Initialize only not enabled modules 1 = Full ethernet sub-system initialization
261	1	Clock out enable	From pins	0x10 = MCU_CLKOUT enable 0x11 = MCU_CLKOUT disable
262	1	Clk out freq	From pins	0x20 = MCU_CLKOUT 25 MHz (RGMII) 0x21 = MCU_CLKOUT 50 MHz (RMII)
263	1	RMII Clk In	From pins	0x60 = RMII internal (SoC) clock 0x61 = RMII external clock
264	1	Port Enable	0x01	Bit map. A set bit indicates that the corresponding physical port will be enabled
265	1	Phy Query	From pins	0x30 = speed/duplex determined from RGMII status register 0x31 = MDIO used to query PHY 0x32 = Use fixed speed/duplex values from offset 266/267.
266	1	Speed		0x40 = full speed (1Gbit for RGMII, 100Mbit for RMII) 0x41 = slow speed (100Mbit for RGMII, 10Mbit for RMII)
267	1	Duplex		0x50 = full duplex 0x51 = half duplex
Main Level Boot Control				
268	1	Bootp enable	1	0 = Image information already in this structure 1 = Use BOOTP to get boot image information
269	1	Reserved	0	Reserved
270	2	Bootp Timeout	4000	BOOTP timeout in milli-seconds
272	2	TFTP timeout	1000	TFTP timeout in milli-seconds
274	2	Bootp retries	10	Number of BOOTP retries before fail
276	2	TFTP retries	10	Number of TFTP retries before fail
278	2	Reserved	0	Reserved
Network Stack Configuration (plus TFTP server ID)				
280	6	MAC Address	From E-fuse	MAC address of the device
286	2	Reserved	0	Reserved
288	4	Device IP	0	IP address of the device. Valid only if BOOTP not enabled
292	4	Net Mask	0	Net mask. Valid only if BOOTP not enabled
296	4	Tftp server IP	0	TFTP server IP. Valid only if BOOTP not enabled
BOOTP send and receive Information				
300	20	Vendor String	"TI K3 Bootp Boot"	BOOTP request vendor string. Valid only if BOOTP not enabled
320	9	Client ID	1-mac-address-0	Client ID. See <a href="#">RFC1700</a>
329	1	ID len	7	Client ID length
330	45	Debug array	SOC ID up to size available	Debug array output
375	1	Debug len	Varies	The number of valid bytes in debug array
376	4	Next hop	0	Next hop IP address. Valid only if bootp not enabled
380	4	Default Route	0	IP default route IP address. Valid only if bootp not enabled
384	128	Boot filename	0	Boot filename. Valid only if bootp not enabled

#### 4.4.8 USB Boot Parameter Table

Table 4-66 shows the boot parameter table for USB boot. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-66. USB Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	4	Port	From pins	Physical port number. Always set to 0.
260	4	Reseved	0	Reseved
264	4	Base address 0	From pins (port)	Base address of USB subsystem (CMN)
268	4	Base address 1	From pins (port)	Base address of controller
272	4	phyBaseAddress	From pins (port)	Base address of USB PHY module
276	4	modRefClkKHz	varies	Module reference clock, in kHz
280	4	Vendor ID	0x0451	USB vendor ID. Read from control registers.
284	4	Product ID	0x6163	USB product ID. Read from control registers.
288	4	String Table addr	0x4182BCA8	Pointer to the string table in RAM
292	2	Vendor String offset	0	Offset to vendor string in string table
298	2	Prod string offset	32	Offset to product string in string table
300	2	Serial num string offset	64	Offset to serial number string in string table
302	2	Timeout	5000	USB timeout in milliseconds
304	2	Mode	1	1 = DFU ≠1 = Reserved
305	1	Lane reverse	0	Host mode only. Boot file name in Unicode characters
306	2	Reseved	0	Reseved
308	4	Block size	4096	DFU block size

#### 4.4.9 MMCSD Boot Parameter Table

Table 4-67 shows the boot parameter table for eMMC, MMC or SD card boot. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-67. MMCSD Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Port	From Pins	Physical port number
257	1	eMMC	From Pins	0 = SD/MMC, else eMMC
258	1	bootAck	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode the controller expects a boot ack from the eMMC
259	1	Media	1 for eMMC 0 for SD/MMC	0 = auto detect card type 1 = MMC 2 = SD
260	1	busWidth	8 for eMMC From Pins for SD/MMC	Number of data pins (1, 4, or 8). If 0, max supported pins of the port are used.
261	1	bootAlt	1 for eMMC 0 for SD/MMC	If 1 and in eMMC mode, the controller uses the alt boot method (CMD1 with arg 0xFFFF_FFFA) to initiate data transfer
262	1	sigVolt	0x18 for port0 0x33 for port1	Sets the signal voltage for the controller. 0x18 = 1.8V 0x33 = 3.3V
263	1	Reserved	0	Reserved
264	4	Max Bus Freq	0	Max bus frequency in kHz. If 0, the value is determined by reading the CSD register from the card (still maxes out at 25 MHz)

**Table 4-67. MMCSD Boot Parameter Table (continued)**

Byte Offset	Size (bytes)	Name	Default Value	Description
268	4	refClkKHz	0	Module reference clock frequency, in kHz. If 0, the ROM code computes the value.
272	4	respTimeout	40000	The timeout period on initial card read, in milli-seconds, Q3 number format
276	128	Filename	"\tiboot3.bin"	For SD/MMC, boot filename in 16-bit Unicode characters (max 64)
404	4	Mode	0x1144D091	0x1144D091 = file system boot 0x1144C180 = raw image boot
408	4	CardIsInit	0	0 = card not yet initialized 1 = card has been initialized
412	4	Rsvd	0	Reserved
416	4	RawIndex	0	Current active read offset (0 or 1)
420	4	Rsvd	0	Reserved
424	4	Raw Offset 0	0x000000	Raw read offset
428	4	Raw Offset 1	0x400000	Backup raw read offset
432	4	Rsvd	0	Reserved
436	4	Rsvd	0	Reserved

#### 4.4.10 UART Boot Parameter Table

Table 4-68 shows the boot parameter table for UART boot. Must be preceded with the common boot parameters described in Table 4-53.

**Table 4-68. UART Boot Parameter Table**

Byte Offset	Size (bytes)	Name	Default Value	Description
256	1	Magic	0x49	Required Magic value
257	1	Protocol	63 (0x3F)	Specifies the transfer protocol = XMODEM
258	2	Reserved	0	Reserved
260	1	Max error Count	10	Error count resulting in boot abort
261	1	Ack timeout	3	Timeout in seconds on ack
262	1	Char timeout	20	Inter-character timeout in milliseconds
263	1	Reserved	0	Reserved
264	4	Port	From Pins	Physical port number
268	4	Mod Ref Clk	48000	Module reference clock, in kHz
272	4	Data Rate	115200	Baud rate (bps)
276	1	Parity	0	0=none, 1=odd, 2=even
277	1	Data bits	8	Only 8 data bit width is supported
278	1	Stop bits	2	Stop bits in Q7.1 format (2 = 1 stop bit)
279	1	Flow Control	0	0=none, 1= RTS/CTS
280	1	Over sample	16	Only 16× and 13× oversample are supported
281	1	Magic 2	0xB7	Required magic value

## 4.5 Boot Image Format

### 4.5.1 Overall Structure

The boot image consists of an X.509 Certificate, followed immediately by a boot image blob.

X.509 Certificate (Variable Size) (Optional)
Boot Image Blob (Variable Size)

### 4.5.2 X.509 Certificate

The X.509 certificate is described in [RFC5280](#). Section 4.1 of the specification describes the format.

The X.509 fields relevant to the public boot (taken from RFC5280) are shown below.

```

Certificate ::= SEQUENCE {
    tbsCertificate      TBSCertificate,
    signatureAlgorithm  AlgorithmIdentifier,
    signatureValue      BIT STRING }
TBSCertificate ::= SEQUENCE {
    version             [0] EXPLICIT Version DEFAULT v1,
    serialNumber        CertificateSerialNumber,
    signature           AlgorithmIdentifier,
    issuer              Name,
    validity            Validity,
    subject             Name,
    subjectPublicKeyInfo SubjectPublicKeyInfo,
    issuerUniqueID      [1] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    subjectUniqueID     [2] IMPLICIT UniqueIdentifier OPTIONAL,
                        -- If present, version MUST be v2 or v3
    extensions          [3] EXPLICIT Extensions OPTIONAL
                        -- If present, version MUST be v3
}
Extensions ::= SEQUENCE SIZE (1..MAX) OF Extension
Extension ::= SEQUENCE {
    extnID              OBJECT IDENTIFIER,
    critical            BOOLEAN DEFAULT FALSE,
    extnValue           OCTET STRING
                        -- contains the DER encoding of an ASN.1 value
                        -- corresponding to the extension type identified
                        -- by extnID
}

```

In general, an X.509 certificate contains a public key which has been signed by a private key. The public ROM code does not directly use the keys. In non-secure devices, the public key value is in general a don't care condition. The exception is certificates containing a degenerate RSA public key. GP devices with a degenerate RSA key allow for integrity checking of most (but not all) of the certificate.

The public MCU ROM only needs to extract some of information from the X.509 formatted structure:

- The total size of the X.509 Certificate
- The total size of the boot image

The total size of the X.509 Certificate is determined by reading the length of the sequence containing the certificate. The length of the image is determined by parsing the certificate to find the extension field which holds the image length.

The ROM defines several extensions that are used only by TI for boot. These are placed in the extensions field of the TBS certificate.

### 4.5.3 Organizational Identifier (OID)

OID (organizational identifier) values are represented as a tree structure. TI has the following node registered:

1.3.6.1.4.1.294: iso(1), identified-organization(3), dod(6), internet(1), private(4), enterprise(1), Texas Instruments(294)

ROM code adds the following branch after *Texas Instruments: device-boot(1)*. The OID values shown in this section are leaves off the device boot branch.

#### 4.5.4 X.509 Extensions Specific to Boot

These values are not defined in any standard, but created by TI for boot.

##### 4.5.4.1 Boot Info (OID 1.3.6.1.4.1.294.1.1)

This extension must be present on all boot images. It is from this extension that the image length is extracted.

```
bootInfo ::= SEQUENCE {
    cert_type:  INTEGER,      -- identifies the certificate type
    boot_core:  INTEGER,      -- identifies the boot core
    core_opts:  INTEGER,      -- 32 or 64 bit boot core target
    load_addr:  OCTET STRING, -- Global address image destination
    image_size: INTEGER,      -- Image size in bytes
}
```

**Table 4-69. Certificate Type Values**

Value	Description
0x0000_0001	Primary boot image
0x0000_0002	Firmware image

**Table 4-70. Boot Core Values**

Value	Description
0x00	Firmware (DMSC) image
0x08	DMSC certificate
0x10	MCU image
0x20	Reserved

**Table 4-71. Core Options Bit Fields**

31	2	1	0
Reserved		Split	Mode

**Table 4-72. Core Options Field Description**

Bits	Field	Value	Description
1	Split	0	Dual MCU set to lockstep (two cores in lockstep)
		1	Dual MCU set to split mode (two independent cores)
0	Mode	0	MCU starts execution in Arm® mode
		1	MCU starts execution in Thumb® mode

##### 4.5.4.2 Image Integrity (OID 1.3.6.1.4.1.294.1.2)

```
imageIntegrity ::= SEQUENCE {
    sha_type:  OID,      -- Identifies the SHA type
    hash:      OCTET STRING -- The SHA of the boot image
}
```

#### 4.5.5 Generating X.509 Certificates

X.509 Certificates are generated using OpenSSL and a configuration script to supply values in the extension fields.

#### 4.5.5.1 Key Generation

The SBL must always be signed with a given OpenSSL key - Secure and GP devices. Secure must have encryption and authentication, GP device must only have authentication. The key used for authentication can be random or specific. If a random key is generated and SBL is signed with this, the ROM will copy the SBL image for authentication using memcpy. With this key, ROM code will be directed to use DMA to load the SBL for authentication which saves boot time.

##### 4.5.5.1.1 Degenerate RSA Keys

Degenerate RSA keys are valid RSA keys with the private exponent set to 1. This results in the signature field being equal to the digest, since in RSA:

$$\text{Signature} = \text{digest}^{\text{privExp}} \bmod n^{\text{privExp}} \bmod n^{\text{privExp}} \quad (1)$$

Where  $n$  is the key size. Since the hash used is SHA-512 and the signature is an ASN.1 sequence containing the OID defining which has been used as well as the hash value, the degenerate RSA must have a value of  $n$  greater than the maximum digest size. Typically 1024-bit is chosen.

The following sequence is used to generate degenerate RSA keys:

1. Create a random RSA key:

```
openssl genrsa -out key.pem 1024
```

2. Convert to text:

```
openssl rsa -in key.pem -text -noout > key.txt
```

3. Create an asn1 template for the degenerate key called degenerateKey.txt. Simply copy the values for modulus, prime (listed as  $p$  in key.txt), prime 2 (listed as  $q$ ), and coefficient (listed as  $\text{coeff}$ ). Set the public and private key exponents to 1, as well as the values for  $e1$  and  $e2$ . See the example below.
4. Convert the template to DER:

```
openssl asn1parse -genconf degenerateKey.txt -out degenerateKey.der
```

5. Sanity check the key:

```
openssl rsa -in degenerateKey.der -inform der -text -check
```

6. If there are no errors create the degenerate key pem file:

```
openssl rsa -in degenerateKey.der -inform der -outform pem -out degenerateKey.pem
```

An example degenerateKey.txt file is shown.

```
asn1=SEQUENCE:rsa_key
[rsa_key]
version=INTEGER:0
modulus=INTEGER:<copied from key.txt>
pubExp=INTEGER:1
privExp=INTEGER:1
p=INTEGER:<copied from key.txt>
q=INTEGER:<copied from key.txt>
e1=INTEGER:1
e2=INTEGER:1
coeff=INTEGER:<copied from key.txt>
```

Note that when copying the multi-byte fields from key.txt it is necessary to remove the colons, concatenate the lines and add a preceding 0x.

### 4.5.5.2 Configuration Script

An example openssl configuration script is shown below. Not all extensions are required, but all possible are shown.

```
[ req ]
distinguished_name = req_distinguished_name
x509_extensions = v3_ca
prompt = no
dirstring_type = nobmp
[ req_distinguished_name ]
C = GB
ST = HI
L = Boston
O = Texas Instruments., Inc.
OU = DSP
CN = Bob
emailAddress = Bob@hou.ti.com
[ v3_ca ]
basicConstraints = CA:true
1.3.6.1.4.1.294.1.1 = ASN1:SEQUENCE:boot_seq
1.3.6.1.4.1.294.1.2 = ASN1:SEQUENCE:image_integrity
1.3.6.1.4.1.294.1.3 = ASN1:SEQUENCE:swrv
1.3.6.1.4.1.294.1.4 = ASN1:SEQUENCE:encryption
1.3.6.1.4.1.294.1.5 = ASN1:SEQUENCE:key_derivation
1.3.6.1.4.1.294.1.7 = ANSI:SEQUENCE:pllControl
1.3.6.1.4.1.294.1.8 = ANSI:SEQUENCE:debug
[ boot_seq ]
certType = INTEGER:1
bootCore = INTEGER:16
bootArchWidth = INTEGER:32
destAddr = FORMAT:HEX,OCT:bc934b00
imageSize = INTEGER:0x00004860
[ image_integrity ]
shaType = OID:1.3.14.3.2.26
shaValue = FORMAT:HEX,OCT:4cf4d59ef77b5d9ab28d2ceb3c9fe83cb52ae6d2
[ swrv ]
rollback = INTEGER:0x00010001
[ encryption ]
Iv = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
Rstring = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff101112131415161718191a1b1c1d1e1f
Icount = INTEGER:1
Salt = FORMAT:HEX,OCT:00112233445566778899aabbccddeeff
[ pllControl ]
pll0_num = INTEGER:0
pll0_cfg = FORMAT:HEX,OCT:00345678900
pll1_num = INTEGER:1
pll0_cfg = FORMAT:HEX,OCT:00345678900
[ debug ]
uid = FORMAT:HEX,OCT:00345678900
type = INTEGER:1
dbgE = INTEGER:0
secDbgEn = INTEGER:0
```

The certificate is then generated using the following openssl command:

```
openssl req -new -x509 -key <private_key_pem_file> -nodes -out <output_x.509_pem_file> -config
<config_file> -sha512
```

If a delegate key is being signed, then add the option -signkey <sign\_key\_pem\_file> to the command above.

### 4.5.6 Image Data

The image data (blob) is considered simply as a byte stream. On devices that are multiple bytes wide (for example, PCIe) the image must be formatted so that all multi-byte fields match the endianness of the device. The MCU will always run in little endian mode.

## 4.6 Boot Modes

### 4.6.1 I2C Bootloader Operation

#### 4.6.1.1 I2C Initialization Process

In the I2C boot mode, the ROM Code configures the MCU\_I2C0 peripheral.

MCU\_I2C0 can operate either in master mode or in slave mode. In the master mode, the boot master drives the I2C slave device where the image is stored. In the slave mode, the data transfer is driven by an external I2C master device. The master device is usually another SoC device or a FPGA.

A detailed summary of the I2C boot parameter table and the BOOTMODE pins definitions are listed in [Section 4.4.4, I2C Boot Parameter Table](#) and [Section 4.3.8, I2C Boot Device Configuration](#).

##### 4.6.1.1.1 Block Size

ROM code will read 0x800 bytes before processing the data. The last block must be padded to the next 0x800 byte boundary and it must be padded with zeros.

##### 4.6.1.1.2

The boot code does not support byte address to bus address wrapping. So the maximum image size that can be access is 64 kbytes. What this means is that if the read address is 0xFF00, the read size is 0x200 and the I2C bus address is 0x50, then 0x100 bytes will be read from 0xFF00 at bus address 0x50, followed by 0x100 bytes from 0x0000 at bus address 0x50. The bus address does not increment when the address rolls over.

#### 4.6.1.2 I2C Loading Process

##### 4.6.1.2.1 Loading a Boot Image From EEPROM

In this mode, the MCU\_I2C0 peripheral is configured as I2C master.

ROM Code will start reading from the I2C EEPROM at the specified I2C bus address. This read will be done beginning at the specified base address offset. Data will be read in 2-KB chunks. The data will be stored at the address specified in the boot header. It will continue reading image data until a complete image has been read. When the complete image has been read, the ROM Code will branch to the start address of the image.

##### 4.6.1.2.2 Loading Image In Slave Mode

The ROM Code also provides the option to set the I2C to slave mode and connect to external master device, which can then send the image to boot from. The default slave address is set to the value specified in the boot configuration in [Section 4.4.4, I2C Boot Parameter Table](#).

ROM Code will initialize the MCU\_I2C0 hardware and then start polling the specified I2C port for data. As data is read from the I2C port, it will be stored at the address specified in the boot header. The ROM Code will continue polling for and reading data until a complete image has been read. Data will be read and processed in 2-Kbyte chunks. The I2C master should pad the image with zeroes to be a multiple of this size. When the complete image has been read, the ROM Code will branch to the base address of the image.

### 4.6.2 SPI Bootloader Operation

#### 4.6.2.1 SPI Initialization Process

In the SPI boot mode, the ROM Code initializes the OSPI peripheral to SPI bus at 4.156 MHz. The image is read from the EEPROM connected to the corresponding OSPI port and chip-select. The the starting offset to be read can be provided by the user through the BOOTMODE pins ([Section 4.3.7, SPI Boot Device Configuration](#)). A detailed summary of the SPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, OSPI/QSPI/SPI Boot Parameter Table](#).

#### 4.6.2.2 SPI Loading Process

The SPI boot loading process is similar to the loading process explained in [Section 4.6.1.2.1, Loading a Boot Image From EEPROM](#), except that the image is read from a NOR flash. The data formats supported are also the same as in [Section 4.6.1.2, I2C Loading Process](#). All the other loading processes that are detailed for I2C master mode work for the SPI boot mode, too.

### 4.6.3 QSPI Bootloader Operation

#### 4.6.3.1 QSPI Initialization Process

In the QSPI boot mode, the ROM Code initializes the OSPI peripheral in DAC mode. The image is read from the QSPI flash connected to the selected chip-select. See [Section 4.3.6, QSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the QSPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, QSPI Boot Parameter Table](#).

#### 4.6.3.2 QSPI Loading Process

QSPI boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

### 4.6.4 OSPI Bootloader Operation

#### 4.6.4.1 OSPI Initialization Process

In the OSPI boot mode, the ROM Code initializes the OSPI peripheral in DAC mode. The image is read from the OSPI flash connected to the selected chip-select. See [Section 4.3.4, OSPI Boot Device Configuration](#) for OSPI port settings.

A detailed summary of the OSPI boot parameter table and the boot configuration definitions are listed in [Section 4.4.5, OSPI Boot Parameter Table](#).

#### 4.6.4.2 OSPI Loading Process

OSPI boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

### 4.6.5 PCIe Bootloader Operation

#### 4.6.5.1 PCIe Initialization Process

In the PCIe boot mode, the ROM Code configures the PCIe and SerDes from information it obtains from the boot parameter table, see [Section 4.4.3, PCIe Boot Parameter Table](#)

#### 4.6.5.2 PCIe Loading Process

PCIe boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

### 4.6.6 GPMC NOR Bootloader Operation

#### 4.6.6.1 GPMC NOR Initialization Process

In this mode, the ROM Code configures the GPMC interface based on the configuration parameters specified in the boot parameter table for the GPMC NOR boot mode, see [Section 4.4.6, GPMC NOR Boot Parameter Table](#). The boot parameter structure definition for the GPMC NOR boot mode and the parts of this table that can be configured by the BOOTMODE pins are detailed in [Section 4.3.14, GPMC NOR Boot Device Configuration](#).

The default timings cannot be used since they are based on a 19.2 MHz module clock. The GPMC module is clocked by Main PLL0 (MAIN\_SYSCLK0) divided by 2, which is 250 MHz. This is the FCLK input to the module, yielding a 4-ns period. The following configurations are setup by boot:

**Table 4-73. GPMC NOR Timing Configuration**

Field	Default		ROM Code	
	Value	Time (ns)	Value	Time (ns)
CSONTime	1	4	1	4
CSRdOffTime	16	64	28	112
ADVOnTime	4	16	8	32
ADVRdOffTime	5	20	11	44
OEOOnTime	6	24	13	52

**Table 4-73. GPMC NOR Timing Configuration (continued)**

Field	Default		ROM Code	
	Value	Time (ns)	Value	Time (ns)
OEOffTime	16	64	28	112
RdAccessTime	15	60	27	108
RdCycleTime	17	68	30	120
AdvAadMuxOnTime	1	4	1	4
AdvAadMuxOffTime	2	8	4	16
OeAadMuxOnTime	1	4	1	4
OeAadMuxOffTime	3	12	6	24

#### 4.6.6.2 GPMC NOR Loading Process

GPMC NOR boot mode is not executable-in-place (XIP). ROM code first copies boot image into on-chip RAM and then executes it.

#### 4.6.7 Ethernet Bootloader Operation

##### 4.6.7.1 Ethernet Initialization Process

When the device is set to boot through the Ethernet mode, the ROM Code configures PHY, NAVSS, and the CPSW. These initial configurations, as well as the interface mode (RMII, RGMII), are determined by querying the BOOTMODE pins, see [Section 4.3.10, Ethernet Boot Device Configuration](#), and the boot parameter table for the Ethernet boot, see [Section 4.4.7, Ethernet Boot Parameter Table](#).

The queue manager is setup to route the packets to queues polled by the ROM Code.

##### 4.6.7.2 Ethernet Loading Process

After device configuration, the bootloader performs a standard BOOTP/TFTP boot. The device sends a BOOTP request with its MAC address to a host TFTP server to be assigned an IP from a pool of addresses. After this connection is established, the device is able to receive image data encapsulated in Ethernet packets, see [Section 4.6.7.2.1](#). Data received is stripped of its network headers and the boot data is stored in internal RAM. When the transfer completes and the image is found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

##### 4.6.7.2.1 Ethernet Boot Data Formats

Ethernet boot uses the BOOTP/TFTP protocol for downloads. Only IPv4 is supported.

###### 4.6.7.2.1.1 Limitations

- Received packets cannot be IP fragmented (should not be a problem in most systems since the BOOTP/TFTP packets have fixed lengths of small size)
- Only DIX Ethernet headers are supported.
- 802.3 with SNAP/LLC not supported
- DIX Ethernet with VLAN not supported
- 802.3 with VLAN and SNAP/LLC not supported

###### 4.6.7.2.1.2 BOOTP Request

###### 4.6.7.2.1.2.1 MAC Header (DIX)

- Destination MAC = value from parameter table (default is broadcast)
- Source MAC = value from parameter table (default is e-fuse value)
- Type = IPv4 (0x0800)

###### 4.6.7.2.1.2.2 IPv4 Header

- Version = 4
- Header length = 0
- TOS = 0

- Len = computed during operation
- ID = 0x0001
- Flags + Fragment offset = 0
- TTL = 0x10
- Protocol = UDP (17)
- Header checksum = Computed during operation
- SRC IP = 0.0.0.0
- Dest IP = 255.255.255.255

#### 4.6.7.2.1.2.3 UDP Header

- Source port = BOOTP client (68 decimal)
- Destination Port = BOOTP server (67 decimal)
- Length = computed during operation
- Checksum = computed during operation

#### 4.6.7.2.1.2.4 BOOTP Payload

- Opcode = Request (1)
- HW Type = Ethernet (1)
- HW Addr Len = 6
- Hop Count = 0
- Transaction ID = 1
- Number of seconds = 0
- Client IP = 0.0.0.0
- Your IP = 0.0.0.0
- Server IP = 0.0.0.0
- Gateway IP = 0.0.0.0
- Client HW Address = Device MAC address (from parameter table)
- Server hostname = NULL
- Filename = NULL
- Option 60, Vendor ID string, from parameter table
- Option 61, Client ID string, from parameter table

#### 4.6.7.2.1.2.5 TFTP

There are no ROM code specific TFTP configurations.

#### 4.6.7.3 Ethernet Hand Over Process

Once the ROM Code receives the valid packet, it decodes it to get the image sections and loads them in the appropriate memory location. After the image is loaded and validated, the ROM Code starts the boot image execution.

#### 4.6.8 USB Bootloader Operation

The USB boot mode is used to read the boot image from external USB host .

See [Section 4.3.11, USB Boot Device Configuration](#) and [Section 4.4.8, USB Boot Parameter Table](#) for the available configuration options.

More information about USB DFU protocol can be found at [http://www.usb.org/developers/docs/devclass\\_docs/DFU\\_1.1.pdf](http://www.usb.org/developers/docs/devclass_docs/DFU_1.1.pdf).

After successful enumeration, the ROM Code will start reading from the external host as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

#### 4.6.8.1 USB-Specific Attributes

##### 4.6.8.1.1 DFU Device Mode

- Vendor ID = 0x451
- Product ID = 0x6162
- Device ID = 0

#### 4.6.9 MMCSD Bootloader Operation

Only single data rate with backward compatible interface timing is supported.

See [Section 4.3.9, MMCSD Boot Device Configuration](#) and [Section 4.4.9, MMCSD Boot Parameter Table](#) for the available configuration options.

If the card type is set to autodetect, then an initial discovery phase is performed:

1. Send CMD 0. (GO IDLE, both for MMC and SD)
2. Send CMD 55. If the card responds then the card type is assumed to be SD and the boot attempt fails (the device do not support SD boot). On timeout the code sends CMD 1. If there is a response then the card type is MMC.

The ROM Code will start reading from the MMCSD memory boot sector, or filesystem, as specified by the BOOTMODE pins. It will continue reading data from the memory and storing it in internal RAM until a complete image has been read. When the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

#### 4.6.10 UART Bootloader Operation

##### 4.6.10.1 Initialization Process

In the UART boot mode, the selected UART module (port) is the only peripheral configured. The baud rate, data, parity, and stop bits are configured based on the information in the UART boot parameter table. The boot parameter table definitions and the boot configuration values that can be set are in [Section 4.3.13, UART Boot Device Configuration](#) and [Section 4.4.10, UART Boot Parameter Table](#).

Once the ROM Code configures the UART, it sends the UART pings for few seconds, which can be seen in the host. The pings consist of an ASCII capital C character. The UART boot mode supports only the CRC mode of XMODEM and does not support CHECKSUM mode.

##### 4.6.10.2 UART Loading Process

Before the ping from the device stops, load the boot image from the host using the XMODEM protocol.

##### 4.6.10.2.1 UART XMODEM

The XMODEM protocol is used to transfer boot data. Only CRC mode is supported (not checksum), with both 128- and 1024-byte block sizes. The general, format of received frames is shown in [Table 4-74](#) and [Table 4-75](#).

**Table 4-74. XMODEM 1024- and 128-byte Data Frames**

STX	Block Num	Inv Block Num	1024 data bytes			CRC	CRC
SOH	Block Num	Inv Block Num	128 data bytes	CRC	CRC		

**Table 4-75. XMODEM Data Frame Fields**

Field	Value	Description
STX	0x02	The start character for 1024-byte CRC data blocks
SOH	0x01	The start character for 128-byte CRC data block
Block Num	0x01-0xFF – 0x00	The block number. The first block has value 1, and the block number wraps around 0xFF to 0
Inv Block Num	0xFE-0x00	The inverse block number (bit inverse of the block number)
CRC	Calculated	The 16-bit CRC generated from the polynomial 0x1021

The XMODEM protocol is implemented as a half-duplex protocol as shown in [Table 4-76](#).

**Table 4-76. Example of XMODEM Transfer protocol**

Transmitter Sends		Receiver Sends
	←	Ping ('C')
Frame 1	→	
	←	ACK (or NACK)
Frame 2	→	
	←	ACK (or NACK)
EOT	→	
	←	ACK (or NACK)

#### 4.6.10.3 UART Hand-Over Process

Once the complete image has been read and found in good integrity, the ROM Code will branch to the address defined in the Boot Info field of the boot header.

## 4.7 Boot Memory Maps

### 4.7.1 Memory Layout/MPU

Table 4-77 shows an overview of the MPU configuration. In the R5 MPU, higher numbered regions have priority, therefore in Table 4-77, where two regions overlap, the region on the right defines the memory attributes.

**Table 4-77. Memory Layout/MPU**

Memory Address	Regions			
0x0000_0000	Region 0 non-executable full access	Region 10		
0x0000_003F				
...				
0x4101_0000		Region 3 TCM User access	Region 4 TCM Priv access	
0x4101_0FFF				
0x4101_1000				
0x4101_7FFF				
...				
0x4180_0000		Region 1 ROM User access	Region 2 ROM Priv access	
0x4180_7FFF				
0x4180_8000				
0x4183_FFFF				
...				
0x41C0_0000		Region 5 RAM All access non-cacheable		
0x41CB_FFFF				
0x41CC_0000			Region 6 cacheable	
0x41CD_FFFF				
0x41CE_0000			Region 7 cacheable	
0x41CE_FFFF				
0x41CF_0000			Region 8 non-cacheable non-executable	
0x41CF_DFFF				
0x41CF_E000				Region 9 cacheable
0x41CF_FFFF				
...				
0xFFFF_FFFF				

### 4.7.2 Global Memory Addresses Used by ROM Code

The ROM code uses several global memory addresses that are useful for debugging. They are shown in Table 4-78.

**Table 4-78. Global Memory Addresses**

Group	Address	Size (bytes)	Content
Version	0x4182_FF80	64	ROM code version (stored in ROM)
Free MSRAM	0x41C0_0000	768k	Loadable space for SBL
Warning/Error Logs	0x41CF_E000	512	Warning entries in cold boot
Warning/Error Logs	0x41CF_E200	512	Severe entries in cold boot
Warning/Error Logs	0x41CF_E400	256	Critical entries in cold boot
Message Logs	0x41CF_E580	512	Circular message buffer
Message Logs	0x41CF_E780	20	Circular message context log
Warning/Error Logs	0x41CF_E800	512	Warning entries in warm boot
Warning/Error Logs	0x41CF_EA00	512	Severe entries in warm boot

**Table 4-78. Global Memory Addresses (continued)**

Group	Address	Size (bytes)	Content
Warning/Error Logs	0x41CF_EC00	256	Critical entries in warm boot
Warning/Error Logs	0x41CF_ED00	40	Cold boot log context
Warning/Error Logs	0x41CF_ED28	40	Warm boot log context
Warning/Error Logs	0x41CF_ED50	4	Active context pointer (not index) to one of the cold or warm contexts
Trace	0x41CF_ED80	24	Boot trace context
Trace	0x41CF_ED98	1024	Boot trace entry buffers
Parameter Tables	0x41CF_FBFC	4	Parameter table index (currently active table, 0 or 1)
Parameter Tables	0x41CF_FC00	512	Parameter table 0
Parameter Tables	0x41CF_FE00	512	Parameter table 1

The ROM code version information is a structure shown in [Table 4-79](#)

**Table 4-79. ROM Code Version**

Field	Address	Size (bytes)	Value for PG1
Version Number	0x4182_FF80	4	0x00010000 (1.0.0)
Version Date	0x4182_FF84	8	"02/24/19"
Device Name	0x4182_FF8C	12	"j7es"
Commit ID	0x4182_FF98	40	"ff0ea75aac317ea6042724fe775412bca006e697"

#### 4.7.3 Memory Reserved by ROM Code

ROM code reserves all of TCM B (BTCM) and the upper memory address of on-chip RAM (MCU\_MSRAM0). The initial section of MCU\_MSRAM0 is available for the booted image. This is the only memory available for the boot image since neither MSMC nor TCM A (ATCM) is powered up or available for the boot image.

[Table 4-80](#) shows ROM code memory usage.

**Table 4-80. Memory Reserved By ROM Code**

Memory	Address	ROM Code Usage
TCM B (BTCM)	0x0000	Reserved by ROM Code
	0x7FFF	
MCU_MSRAM0	0x41C0_0000	Free for boot image
	0x41CB_FFFF	
	0x41CC_0000	Reserved by ROM Code
	0x41CF_FFFF	

5.1 Control Module (CTRL_MMR).....	328
5.2 Power.....	360
5.3 Reset.....	462
5.4 Clocking.....	472

## 5.1 Control Module (CTRL\_MMR)

The CTRL\_MMR is a module on the device that controls top-level device behavior in various states. It contains registers for configuration, bootstrap signals, I/O pad multiplexing, clock selection, and many others. There are three CTRL\_MMR modules in this device - CTRL\_MMR0 which resides in VD\_CORE, MCU\_CTRL\_MMR0 in VD\_MCU and WKUP\_CTRL\_MMR0 in the VD\_WKUP voltage domain.

There are also two other modules (SEC\_MMR0 and MCU\_SEC\_MMR0) that have registers to control the configuration of the MAIN domain R5 and C66 processors and the MCU domain processors.

The following sections describe all these modules.

### 5.1.1 WKUP\_CTRL\_MMR0

The following sections describe the WKUP\_CTRL\_MMR0 module.

#### 5.1.1.1 WKUP\_CTRL\_MMR0 Overview

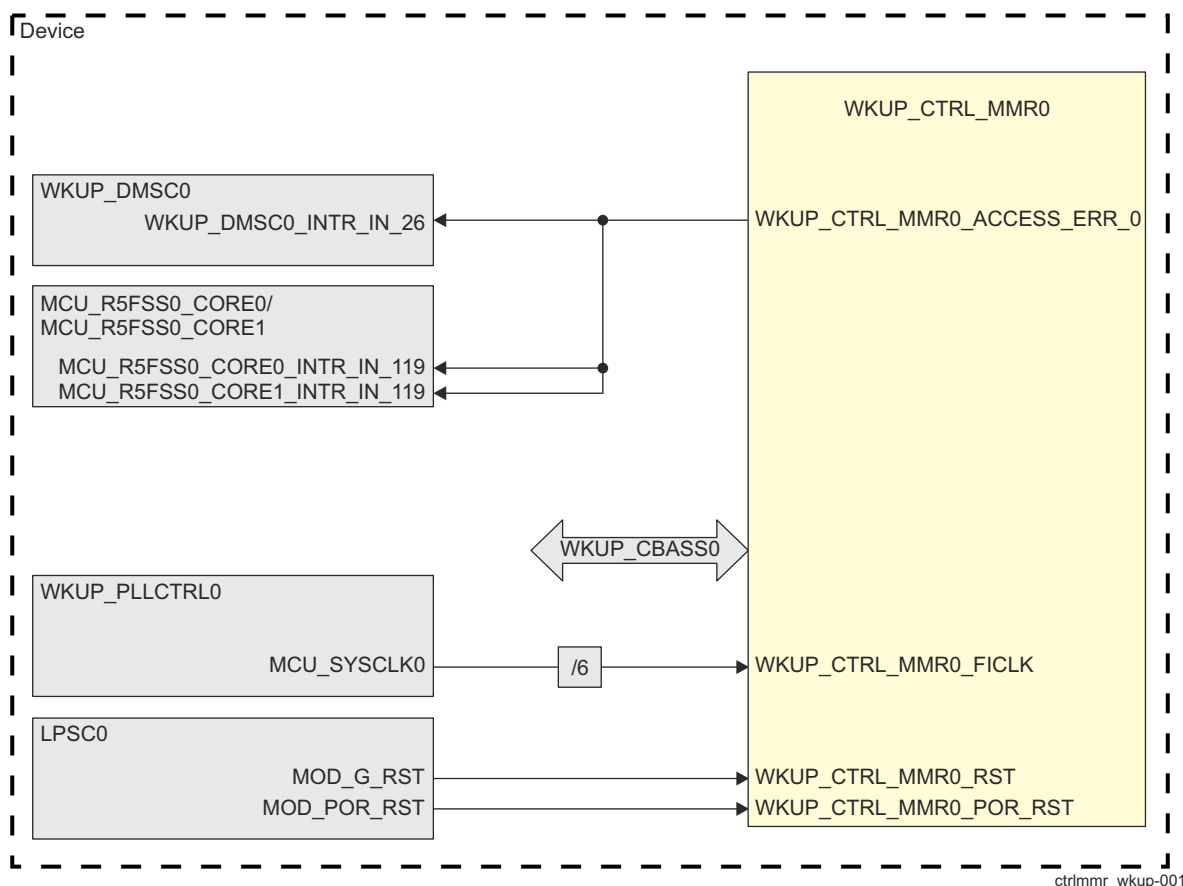

The WKUP\_CTRL\_MMR0 module has registers associated mainly with:

- [Device pad configuration](#)
- [Kick protection \(register write protection\)](#)
- [WKUP\\_CTRL\\_MMR0 module interrupts](#)
- [Clock selection](#)
- [Device features](#)
- [POK Modules](#)
- [Reset related registers](#)
- [PRG Modules](#)
- [Voltage glitch detectors](#)
- [I/O debounce control](#)
- and a few other registers and register groups.

### 5.1.1.2 WKUP\_CTRL\_MMR0 Integration

This section describes WKUP\_CTRL\_MMR0 integration in the device, including information about clocks, resets, and hardware requests.

A single WKUP\_CTRL\_MMR0 module is integrated in the device WKUP domain. [Figure 5-1](#) shows the integration of WKUP\_CTRL\_MMR0.

**Figure 5-1. WKUP\_CTRL\_MMR0 Integration**

[Table 5-1](#) through [Table 5-3](#) summarize the integration of the WKUP\_CTRL\_MMR0 module in the device WKUP domain.

**Table 5-1. WKUP\_CTRL\_MMR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
WKUP_CTRL_MMR0	WKUP_PSC0	PD0	LPSC0	WKUP_CBASS0

**Table 5-2. WKUP\_CTRL\_MMR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
WKUP_CTRL_MMR0	WKUP_CTRL_MMR0_FICLK	MCU_SYSCCLK0/6	WKUP_PLLECTRLO	Functional and interface clock for the WKUP_CTRL_MMR0 module with frequency equal to MCU_SYSCCLK0 divided by 6.
Resets				

**Table 5-2. WKUP\_CTRL\_MMR0 Clocks and Resets (continued)**

Module Instance	Module Reset Input	Source Reset Signal	Source	Description
WKUP_CTRL_MMR0	WKUP_CTRL_MMR0_RST	MOD_G_RST	LPSC0	Module level main reset
	WKUP_CTRL_MMR0_POR_RST	MOD_POR_RST	LPSC0	Module power-on reset

**Table 5-3. WKUP\_CTRL\_MMR0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
WKUP_CTRL_MM R0	WKUP_CTRL_MMR0_ACCESS_ ERR_0	WKUP_DMSC0_INTR_IN_26	WKUP_DMSC0	Interrupt indicating protection, addressing, lock violation.	Level
		MCU_R5FSS0_CORE0_INTR _IN_119	MCU_R5FSS0_COR E0		
		MCU_R5FSS0_CORE1_INTR _IN_119	MCU_R5FSS0_COR E1		
DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
WKUP_CTRL_MM - R0	-	-	-	-	-

### Note

For more information about WKUP\_CTRL\_MMR0\_ACCESS\_ERR\_0, see [Section 5.1.1.3.1.3](#).

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

### 5.1.1.3 WKUP\_CTRL\_MMR0 Functional Description

#### 5.1.1.3.1 Description for WKUP\_CTRL\_MMR0 Register Types

The following sub-sections provide summary and description for most of the registers which are part of the WKUP\_CTRL\_MMR0 module memory space. The rest of the registers are described in the corresponding chapters where the functionality associated with particular WKUP\_CTRL\_MMR0 register is covered in more detail.

##### 5.1.1.3.1.1 Pad Configuration Registers

The pad multiplexing scheme is same as described in [Section 5.1.3.3.1.1](#). For more details, refer to that section. The only difference is that the CTRLMMR\_WKUP\_PADCONFIG0 to CTRLMMR\_WKUP\_PADCONFIG93 registers control the signal multiplexing of modules in the device MCU and WKUP domains.

##### 5.1.1.3.1.2 Kick Protection Registers

The functionality of the WKUP\_CTRL\_MMR0 kick protection registers is same as described in [Section 5.1.3.3.1.2](#). For more details, refer to that section.

[Table 5-4](#) summarizes the WKUP\_CTRL\_MMR0 kick protection registers.

**Table 5-4. WKUP\_CTRL\_MMR0 Partition Unlock Values**

Register	Partition <sup>(1)</sup>	Unlock Value	Offset Range
CTRLMMR_WKUP_LOCK0_KICK0	Partition 0	68EF 3490h	0000h to 1FFFh
CTRLMMR_WKUP_LOCK0_KICK1	Partition 0	D172 BC5Ah	
CTRLMMR_WKUP_LOCK1_KICK0	Partition 1	68EF 3490h	4000h to 5FFFh
CTRLMMR_WKUP_LOCK1_KICK1	Partition 1	D172 BC5Ah	
CTRLMMR_WKUP_LOCK2_KICK0	Partition 2	68EF 3490h	8000h to 9FFFh
CTRLMMR_WKUP_LOCK2_KICK1	Partition 2	D172 BC5Ah	
CTRLMMR_WKUP_LOCK3_KICK0	Partition 3	68EF 3490h	C000h to DFFFh
CTRLMMR_WKUP_LOCK3_KICK1	Partition 3	D172 BC5Ah	
CTRLMMR_WKUP_LOCK6_KICK0	Partition 6	68EF 3490h	1 8000h to 1 9FFFh
CTRLMMR_WKUP_LOCK6_KICK1	Partition 6	D172 BC5Ah	
CTRLMMR_WKUP_LOCK7_KICK0	Partition 7	68EF 3490h	1 C000h to 1 DFFFh
CTRLMMR_WKUP_LOCK7_KICK1	Partition 7	D172 BC5Ah	

(1) Not listed partitions are reserved and not used.

##### 5.1.1.3.1.3 WKUP\_CTRL\_MMR0 Module Interrupts

The WKUP\_CTRL\_MMR0 module has one interrupt request - the WKUP\_CTRL\_MMR0\_ACCESS\_ERR\_0. The interrupt behavior is same as described in [Section 5.1.3.3.1.3](#). For more details, refer to that section. When reading replace the corresponding registers with the following:

- CTRLMMR\_WKUP\_INTR\_RAW\_STAT
- CTRLMMR\_WKUP\_INTR\_STAT\_CLR
- CTRLMMR\_WKUP\_INTR\_EN\_SET
- CTRLMMR\_WKUP\_INTR\_EN\_CLR
- CTRLMMR\_WKUP\_FAULT\_ADDR
- CTRLMMR\_WKUP\_FAULT\_TYPE
- CTRLMMR\_WKUP\_FAULT\_ATTR
- CTRLMMR\_WKUP\_FAULT\_CLR

#### 5.1.1.3.1.4 Clock Selection Registers

There are registers within the WKUP\_CTRL\_MMR0 module address space that are used to select clocks for the MAIN PLLs and several other modules. [Table 5-5](#) summarizes these registers. Related information can also be found in *Clocking*.

**Table 5-5. Summary of the WKUP\_CTRL\_MMR0 Clock Selection Registers**

Register Name	Register Name
CTRLMMR_WKUP_MCU_PLL_CLKSEL	CTRLMMR_WKUP_MAIN_PLL13_CLKSEL
CTRLMMR_WKUP_PER_CLKSEL	CTRLMMR_WKUP_MAIN_PLL14_CLKSEL
CTRLMMR_WKUP_USART_CLKSEL	CTRLMMR_WKUP_MAIN_PLL15_CLKSEL
CTRLMMR_WKUP_GPIO_CLKSEL	CTRLMMR_WKUP_MAIN_PLL16_CLKSEL
CTRLMMR_WKUP_MAIN_PLL0_CLKSEL	CTRLMMR_WKUP_MAIN_PLL17_CLKSEL
CTRLMMR_WKUP_MAIN_PLL1_CLKSEL	CTRLMMR_WKUP_MAIN_PLL18_CLKSEL
CTRLMMR_WKUP_MAIN_PLL2_CLKSEL	CTRLMMR_WKUP_MAIN_PLL19_CLKSEL
CTRLMMR_WKUP_MAIN_PLL3_CLKSEL	CTRLMMR_WKUP_MAIN_PLL23_CLKSEL
CTRLMMR_WKUP_MAIN_PLL4_CLKSEL	CTRLMMR_WKUP_MAIN_PLL24_CLKSEL
CTRLMMR_WKUP_MAIN_PLL5_CLKSEL	CTRLMMR_WKUP_MAIN_PLL25_CLKSEL
CTRLMMR_WKUP_MAIN_PLL6_CLKSEL	CTRLMMR_WKUP_MAIN_SYCLK_CTRL
CTRLMMR_WKUP_MAIN_PLL7_CLKSEL	CTRLMMR_WKUP_MCU_SPI0_CLKSEL
CTRLMMR_WKUP_MAIN_PLL8_CLKSEL	CTRLMMR_WKUP_MCU_SPI1_CLKSEL
CTRLMMR_WKUP_MAIN_PLL12_CLKSEL	

#### 5.1.1.3.1.5 Device Feature Registers

The following registers within the WKUP\_CTRL\_MMR0 module address space provide status information regarding specific device features:

- CTRLMMR\_WKUP\_DEVICE\_FEATURE0
- CTRLMMR\_WKUP\_DEVICE\_FEATURE1
- CTRLMMR\_WKUP\_DEVICE\_FEATURE2
- CTRLMMR\_WKUP\_DEVICE\_FEATURE3
- CTRLMMR\_WKUP\_DEVICE\_FEATURE4
- CTRLMMR\_WKUP\_DEVICE\_FEATURE5
- CTRLMMR\_WKUP\_DEVICE\_FEATURE6

#### 5.1.1.3.1.6 POK Module Registers

[Table 5-6](#) summarizes the registers associated with the device POK modules.

**Table 5-6. Summary of the POK Registers**

Register Name	Register Name
CTRLMMR_WKUP_POK_VDDA_PMIC_IN_CTRL	CTRLMMR_WKUP_POK_VDD_CORE_UV_CTRL
CTRLMMR_WKUP_POK_VDDSHV_WKUP_GEN_UV_CTRL	CTRLMMR_WKUP_POK_VDD_CPU_UV_CTRL
CTRLMMR_WKUP_POK_VDDR_MCU_UV_CTRL	CTRLMMR_WKUP_POK_VMON_EXT_UV_CTRL
CTRLMMR_WKUP_POK_VDD_MCU_OV_CTRL	CTRLMMR_WKUP_POK_VDDR_CORE_UV_CTRL
CTRLMMR_WKUP_POK_VDDSHV_WKUP_GEN_OV_CTRL	CTRLMMR_WKUP_POK_VDD_CORE_OV_CTRL
CTRLMMR_WKUP_POK_VDDR_MCU_OV_CTRL	CTRLMMR_WKUP_POK_VDD_CPU_OV_CTRL
CTRLMMR_WKUP_POR_POKHV_UV_CTRL	CTRLMMR_WKUP_POK_VMON_EXT_OV_CTRL
CTRLMMR_WKUP_POR_POKLV_UV_CTRL	CTRLMMR_WKUP_POK_VDDR_CORE_OV_CTRL
CTRLMMR_WKUP_POR_POKHV_OV_CTRL	

#### 5.1.1.3.1.7 Power and Reset Related Registers

The following are the reset related registers within the WKUP\_CTRL\_MMR0 module address space:

- CTRLMMR\_WKUP\_POR\_CTRL
- CTRLMMR\_WKUP\_POR\_STAT
- CTRLMMR\_WKUP\_RESET\_SRC\_STAT
- CTRLMMR\_WKUP\_MAIN\_POR\_TO\_CTRL
- CTRLMMR\_WKUP\_POR\_RST\_CTRL
- CTRLMMR\_WKUP\_MAIN\_WARM\_RST\_CTRL
- CTRLMMR\_WKUP\_RST\_STAT
- CTRLMMR\_WKUP\_MCU\_WARM\_RST\_CTRL

#### 5.1.1.3.1.8 PRG Related Registers

The following are the PRG related registers within the WKUP\_CTRL\_MMR0 module address space:

- CTRLMMR\_WKUP\_PRG0\_CTRL
- CTRLMMR\_WKUP\_PRG0\_STAT
- CTRLMMR\_WKUP\_PRG1\_CTRL
- CTRLMMR\_WKUP\_PRG1\_STAT
- CTRLMMR\_WKUP\_MAIN\_PRG\_CTRL
- CTRLMMR\_WKUP\_MAIN\_PRG\_STAT

#### 5.1.1.3.1.9 Voltage Glitch Detect Control and Status Registers

There are glitch detector circuits monitoring the voltage of the device voltage domains. WKUP\_CTRL\_MMR0 has registers that provide control and status information associated with these glitch detectors. [Table 5-7](#) summarizes the voltage glitch detect control and status registers.

**Table 5-7. Summary of the Voltage Glitch Detect Registers**

Register Name	Register Name
CTRLMMR_WKUP_VDD_CPU_GLDTC_CTRL	CTRLMMR_WKUP_VDDR_CPU_GLDTC_STAT
CTRLMMR_WKUP_VDD_CORE_GLDTC_CTRL	CTRLMMR_WKUP_VDDR_CORE_GLDTC_STAT
CTRLMMR_WKUP_VDDR_CPU_GLDTC_CTRL	CTRLMMR_WKUP_VDD_MCU_GLDTC_CTRL
CTRLMMR_WKUP_VDDR_CORE_GLDTC_CTRL	CTRLMMR_WKUP_VDDR_MCU_GLDTC_CTRL
CTRLMMR_WKUP_VDD_CPU_GLDTC_STAT	CTRLMMR_WKUP_VDD_MCU_GLDTC_STAT
CTRLMMR_WKUP_VDD_CORE_GLDTC_STAT	CTRLMMR_WKUP_VDDR_MCU_GLDTC_STAT

#### 5.1.1.3.1.10 I/O Debounce Control Registers

Some device pads have debounce logic. The following WKUP\_CTRL\_MMR0 registers are used to configure the debounce period:

- CTRLMMR\_WKUP\_DBOUNCE\_CFG1
- CTRLMMR\_WKUP\_DBOUNCE\_CFG2
- CTRLMMR\_WKUP\_DBOUNCE\_CFG3
- CTRLMMR\_WKUP\_DBOUNCE\_CFG4
- CTRLMMR\_WKUP\_DBOUNCE\_CFG5
- CTRLMMR\_WKUP\_DBOUNCE\_CFG6

The CTRLMMR\_WKUP\_DBOUNCE\_CFG1 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE\_SEL fields set to 1h. The CTRLMMR\_WKUP\_DBOUNCE\_CFG2 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE\_SEL fields set to 2h and so on. The CTRLMMR\_WKUP\_DBOUNCE\_CFG6 register contains the debounce period for pads with PADCONFIGx[13-11] DEBOUNCE\_SEL fields set to 6h.

---

**Note**

The debounce logic is not associated with all signals that can be multiplexed on a pad. Only certain signals can use it.

---

For information about the PADCONFIGx registers, see *Pad Configuration Registers*.

[Table 5-8](#) shows the debounce period values to load in the CTRLMMR\_WKUP\_DBOUNCE\_CFGx[5-0] DB\_CFG field.

---

**Note**

The debounce clock selection should happen before the consumer of the debounced signals is enabled as the clock multiplexers for the debounce logic are NOT glitch-free.

---

**Table 5-8. Debounce Period Values**

CTRLMMR_WKUP_DBOUNCE_CF Gx[5-0] DB_CFG Decimal Value	GPIO Case (32.768kHz (1))	EQEP Case (20MHz <sup>(1)</sup> )	CTRLMMR_WKUP_DBOUNCE_CF Gx[5-0] DB_CFG Decimal Value	GPIO Case (20MHz <sup>(1)</sup> )	EQEP Case (250MHz <sup>(1)</sup> )
	Delay[ms]	Delay[μs]		Delay[μs]	Delay[ns]
0	bypassed	bypassed	32	0.05	4

30	140.63	230.4	62	230.4	18.432
31	156.25	256	63	256	20.48

(1) These are the debounce logic clock frequencies.

### 5.1.2 MCU\_CTRL\_MMR0

The following sections describe the MCU\_CTRL\_MMR0 module.

#### 5.1.2.1 MCU\_CTRL\_MMR0 Overview

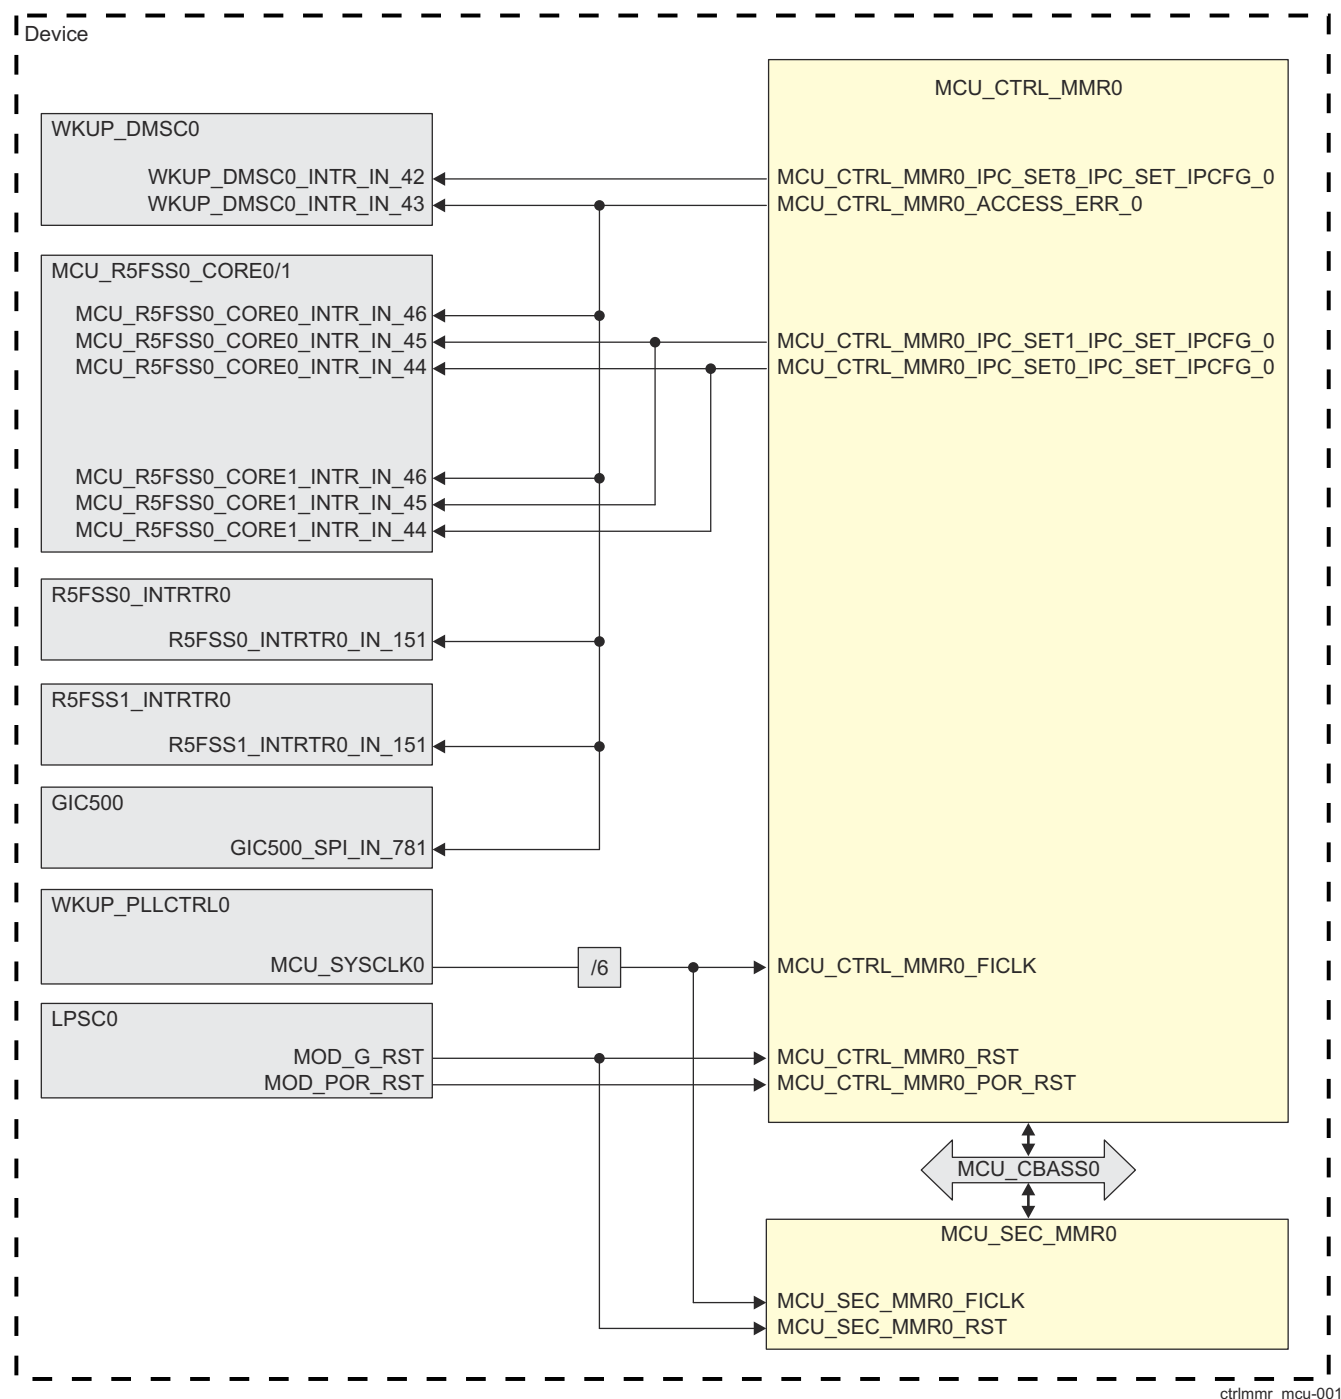

The MCU\_CTRL\_MMR0 module has registers associated mainly with:

- [Kick protection \(register write protection\)](#)
- [MCU\\_CTRL\\_MMR0 module interrupts](#)
- [Inter-processor communication](#)
- [Timer I/O multiplexing](#)
- [Clock muxing and division](#)
- [MCU\\_CPSW0 MAC address](#)
- and a few other registers and register groups.

### 5.1.2.2 MCU\_CTRL\_MMR0 Integration

This section describes MCU\_CTRL\_MMR0 and MCU\_SEC\_MMR0 integration in the device, including information about clocks, resets, and hardware requests.

One MCU\_CTRL\_MMR0 and one MCU\_SEC\_MMR0 modules are integrated in the device MCU domain. [Figure 5-2](#) shows their integration.

**Figure 5-2. MCU\_CTRL\_MMR0 and MCU\_SEC\_MMR0 Integration**

Table 5-9 through Table 5-11 summarize the integration of the MCU\_CTRL\_MMR0 and MCU\_SEC\_MMR0 modules in the device MCU domain.

**Table 5-9. MCU\_CTRL\_MMR0 and MCU\_SEC\_MMR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_CTRL_MMR0 MCU_SEC_MMR0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

**Table 5-10. MCU\_CTRL\_MMR0 and MCU\_SEC\_MMR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_CTRL_MMR0	MCU_CTRL_MMR0_FICLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	Functional and interface clock for the MCU_CTRL_MMR0 module with frequency equal to MCU_SYSCCLK0 divided by 6.
MCU_SEC_MMR0	MCU_SEC_MMR0_FICLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	Functional and interface clock for the MCU_SEC_MMR0 module with frequency equal to MCU_SYSCCLK0 divided by 6.

Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MCU_CTRL_MMR0	MCU_CTRL_MMR0_RST	MOD_G_RST	LPSC0	Module level main reset
	MCU_CTRL_MMR0_POR_RST	MOD_POR_RST	LPSC0	Module power-on reset
MCU_SEC_MMR0	MCU_SEC_MMR0_RST	MOD_G_RST	LPSC0	MCU_SEC_MMR0 module reset

**Table 5-11. MCU\_CTRL\_MMR0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
MCU_CTRL_MM R0	MCU_CTRL_MMR0_ACCES S_ERR_0	GIC500_SPI_IN_781	GIC500	Interrupt indicating protection, addressing, lock violation.	Level
		WKUP_DMSC0_INTR_IN_43	WKUP_DMSC0

	MCU_CTRL_MMR0_IPC_SE T1_IPC_SET_IPCFG_0	MCU_R5FSS0_CORE1_INTR_IN_44	MCU_R5FSS0_CORE1	Interrupt generated by writing 1h to CTRLMMR_MCU_IPC_SET1[0].	Level
		MCU_R5FSS0_CORE0_INTR_IN_45	MCU_R5FSS0_CORE0		
	MCU_CTRL_MMR0_IPC_SE T8_IPC_SET_IPCFG_0	MCU_R5FSS0_CORE1_INTR_IN_45	MCU_R5FSS0_CORE1	Interrupt generated by writing 1h to CTRLMMR_MCU_IPC_SET8[0].	Level

**Table 5-11. MCU\_CTRL\_MMR0 Hardware Requests (continued)**

DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
MCU_CTRL_MM R0	-	-	-	-	-

### Note

For more information about MCU\_CTRL\_MMR0\_ACCESS\_ERR\_0, see [Section 5.1.2.3.1.2](#).

For more information about MCU\_IPC\_INTx, see [Section 5.1.2.3.1.3](#).

### 5.1.2.3 MCU\_CTRL\_MMR0 Functional Description

#### 5.1.2.3.1 Description for MCU\_CTRL\_MMR0 Register Types

The following sub-sections provide summary and description for most of the registers which are part of the MCU\_CTRL\_MMR0 module memory space. The rest of the registers are described in the corresponding chapters where the functionality associated with particular MCU\_CTRL\_MMR0 register is covered in more detail.

##### 5.1.2.3.1.1 Kick Protection Registers

The functionality of the MCU\_CTRL\_MMR0 kick protection registers is same as described in [Section 5.1.3.3.1.2](#). For more details, refer to that section.

[Table 5-12](#) summarizes the MCU\_CTRL\_MMR0 kick protection registers.

**Table 5-12. MCU\_CTRL\_MMR0 Partition Unlock Values**

Register	Partition <sup>(1)</sup>	Unlock Value	Offset Range
CTRLMMR_MCU_LOCK0_KICK0	Partition 0	68EF 3490h	0000h to 1FFFh
CTRLMMR_MCU_LOCK0_KICK1	Partition 0	D172 BC5Ah	
CTRLMMR_MCU_LOCK1_KICK0	Partition 1	68EF 3490h	4000h to 5FFFh
CTRLMMR_MCU_LOCK1_KICK1	Partition 1	D172 BC5Ah	
CTRLMMR_MCU_LOCK2_KICK0	Partition 2	68EF 3490h	8000h to 9FFFh
CTRLMMR_MCU_LOCK2_KICK1	Partition 2	D172 BC5Ah	
CTRLMMR_MCU_LOCK3_KICK0	Partition 3	68EF 3490h	C000h to DFFFh
CTRLMMR_MCU_LOCK3_KICK1	Partition 3	D172 BC5Ah	

(1) Not listed partitions are reserved and not used.

##### 5.1.2.3.1.2 MCU\_CTRL\_MMR0 Module Interrupts

The MCU\_CTRL\_MMR0 module has one interrupt request - the MCU\_CTRL\_MMR0\_ACCESS\_ERR\_0. The interrupt behavior is same as described in [Section 5.1.3.3.1.3](#). For more details, refer to that section. When reading replace the corresponding registers with the following:

- CTRLMMR\_MCU\_INTR\_RAW\_STAT
- CTRLMMR\_MCU\_INTR\_STAT\_CLR
- CTRLMMR\_MCU\_INTR\_EN\_SET
- CTRLMMR\_MCU\_INTR\_EN\_CLR
- CTRLMMR\_MCU\_FAULT\_ADDR
- CTRLMMR\_MCU\_FAULT\_TYPE
- CTRLMMR\_MCU\_FAULT\_ATTR
- CTRLMMR\_MCU\_FAULT\_CLR

##### 5.1.2.3.1.3 Inter-processor Communication Registers

The inter-processor communication (IPC) registers are used for generating interrupts to the device cores. The IPC scheme is same as described in [Section 5.1.3.3.1.4](#). For more details, refer to that section.

[Table 5-13](#) summarizes the IPC registers.

**Table 5-13. Summary of the MCU\_CTRL\_MMR0 IPC Registers**

IPC Register	Writing 1h to bit 0 results in:	Writing 1h to one of the bits [31-4] results in:
CTRLMMR_MCU_IPC_SET0	<ul style="list-style-type: none"> <li>• interrupt generation to MCU R5 Core 0</li> <li>• setting the IPC_SET bit to 1h</li> <li>• setting the corresponding IPC_CLR bit to 1h</li> </ul>	setting that bit and the corresponding IPC_SRC_CLR bit to 1h
CTRLMMR_MCU_IPC_SET1	<ul style="list-style-type: none"> <li>• interrupt generation to MCU R5 Core 1</li> <li>• setting the IPC_SET bit to 1h</li> <li>• setting the corresponding IPC_CLR bit to 1h</li> </ul>	setting that bit and the corresponding IPC_SRC_CLR bit to 1h

**Table 5-13. Summary of the MCU\_CTRL\_MMR0 IPC Registers (continued)**

IPC Register	Writing 1h to bit 0 results in:	Writing 1h to one of the bits [31-4] results in:
CTRLMMR_MCU_IPC_SET8	<ul style="list-style-type: none"> <li>interrupt generation to WKUP_DMSC0</li> <li>setting the IPC_SET bit to 1h</li> <li>setting the corresponding IPC_CLR bit to 1h</li> </ul>	setting that bit and the corresponding IPC_SRC_CLR bit to 1h
CTRLMMR_MCU_IPC_CLR0	<ul style="list-style-type: none"> <li>clearing the interrupt to MCU R5 Core 0</li> <li>clearing the IPC_CLR bit</li> <li>clearing the corresponding IPC_SET bit</li> </ul>	clearing (set to 0h) that bit and the corresponding IPC_SRC_SET bit
CTRLMMR_MCU_IPC_CLR1	<ul style="list-style-type: none"> <li>clearing the interrupt to MCU R5 Core 1</li> <li>clearing the IPC_CLR bit</li> <li>clearing the corresponding IPC_SET bit</li> </ul>	clearing (set to 0h) that bit and the corresponding IPC_SRC_SET bit
CTRLMMR_MCU_IPC_CLR8	<ul style="list-style-type: none"> <li>clearing the interrupt to WKUP_DMSC0</li> <li>clearing the IPC_CLR bit</li> <li>clearing the corresponding IPC_SET bit</li> </ul>	clearing (set to 0h) that bit and the corresponding IPC_SRC_SET bit

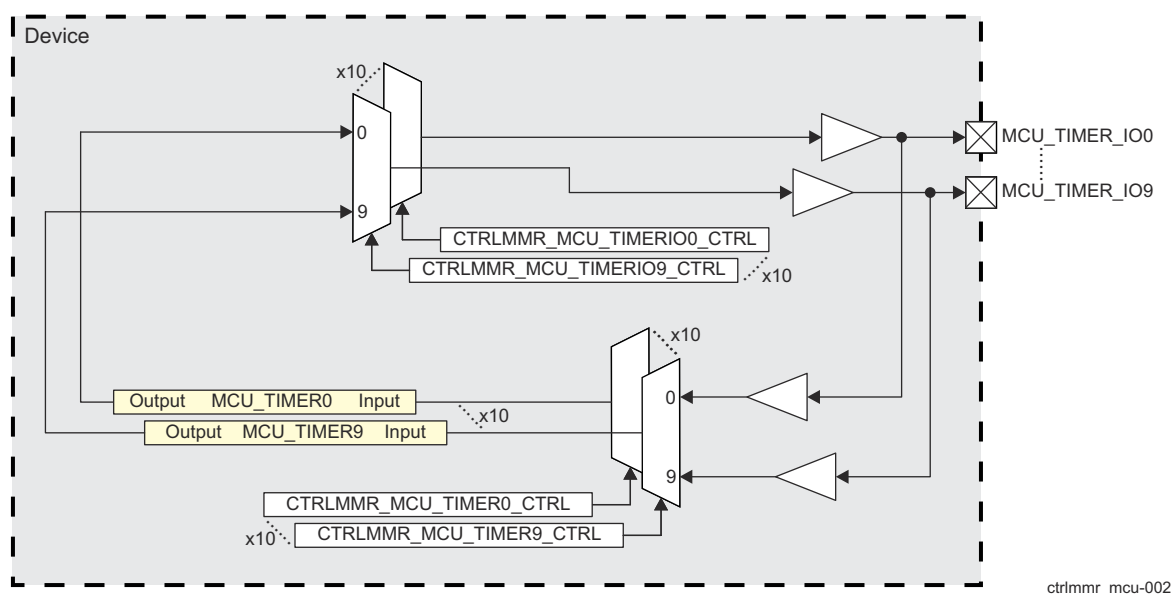

### Note

For latency reasons the IPC registers are not write protected by KICK registers which means that they can be written to without a need for performing unlocking procedure as described in *Kick Protection Registers*.

#### 5.1.2.3.1.4 Timer I/O Muxing Control Registers

Not all timer inputs and outputs are pinned out of the device. Through the MCU timer I/O muxing registers the inputs and outputs of the MCU domain timers can be made available on the MCU\_TIMER\_IO[9:0] device pads.

Each timer input can be configured to be driven by one of the MCU\_TIMER\_IO[9:0] pads through the corresponding bits in the CTRLMMR\_MCU\_TIMER0\_CTRL to CTRLMMR\_MCU\_TIMER9\_CTRL registers. Each of the MCU\_TIMER\_IO[9:0] pads can be configured to be driven by any of the timer outputs through the corresponding bits in the CTRLMMR\_MCU\_TIMERIO0\_CTRL to CTRLMMR\_MCU\_TIMERIO9\_CTRL registers. Figure 5-3 shows the TIMER I/O multiplexing scheme for the MCU domain.

**Figure 5-3. MCU Domain TIMER I/O Multiplexing Scheme**

For more information about each timer, see *Timers*.

#### 5.1.2.3.1.5 Clock Muxing and Division Registers

There are registers within the MCU\_CTRL\_MMR0 module address space dedicated to clock muxing and division for some device modules. [Table 5-14](#) summarizes these registers. Related information can also be found in *Clocking*.

**Table 5-14. Summary of the MCU\_CTRL\_MMR0 Clock Muxing and Division Registers**

Register Name	Register Name	Register Name
CTRLMMR_MCU_CLKOUT0_CTRL	CTRLMMR_MCU_ENET_CLKSEL	CTRLMMR_MCU_TIMER6_CLKSEL
CTRLMMR_MCU_EFUSE_CLKSEL	CTRLMMR_MCU_R5_CORE0_CLKSEL	CTRLMMR_MCU_TIMER7_CLKSEL
CTRLMMR_MCU_MCAN0_CLKSEL	CTRLMMR_MCU_TIMER0_CLKSEL	CTRLMMR_MCU_TIMER8_CLKSEL
CTRLMMR_MCU_MCAN1_CLKSEL	CTRLMMR_MCU_TIMER1_CLKSEL	CTRLMMR_MCU_TIMER9_CLKSEL
CTRLMMR_MCU_OSPI0_CLKSEL	CTRLMMR_MCU_TIMER2_CLKSEL	CTRLMMR_MCU_RTIO_CLKSEL
CTRLMMR_MCU_OSPI1_CLKSEL	CTRLMMR_MCU_TIMER3_CLKSEL	CTRLMMR_MCU_RT11_CLKSEL
CTRLMMR_MCU_ADC0_CLKSEL	CTRLMMR_MCU_TIMER4_CLKSEL	CTRLMMR_MCU_USART_CLKSEL
CTRLMMR_MCU_ADC1_CLKSEL	CTRLMMR_MCU_TIMER5_CLKSEL	

#### 5.1.2.3.1.6 MCU\_CPSW0 MAC Address Registers

Each device has a unique 48-bit MAC address which is stored in the MCU\_CTRL\_MMR0 registers shown in [Table 5-15](#).

**Table 5-15. MCU\_CPSW0 MAC Address Registers**

Bit Field	Description
CTRLMMR_MCU_MAC_ID0[31-0] MACID_LO	Contains the first, second, third and fourth octets of the MCU_CPSW0 MAC address
CTRLMMR_MCU_MAC_ID1[15-0] MACID_HI	Contains the fifth and sixth octets of the MCU_CPSW0 MAC address

### 5.1.3 CTRL\_MMR0

The following sections describe the CTRL\_MMR0 module.

#### 5.1.3.1 CTRL\_MMR0 Overview

The CTRL\_MMR0 module has registers associated mainly with:

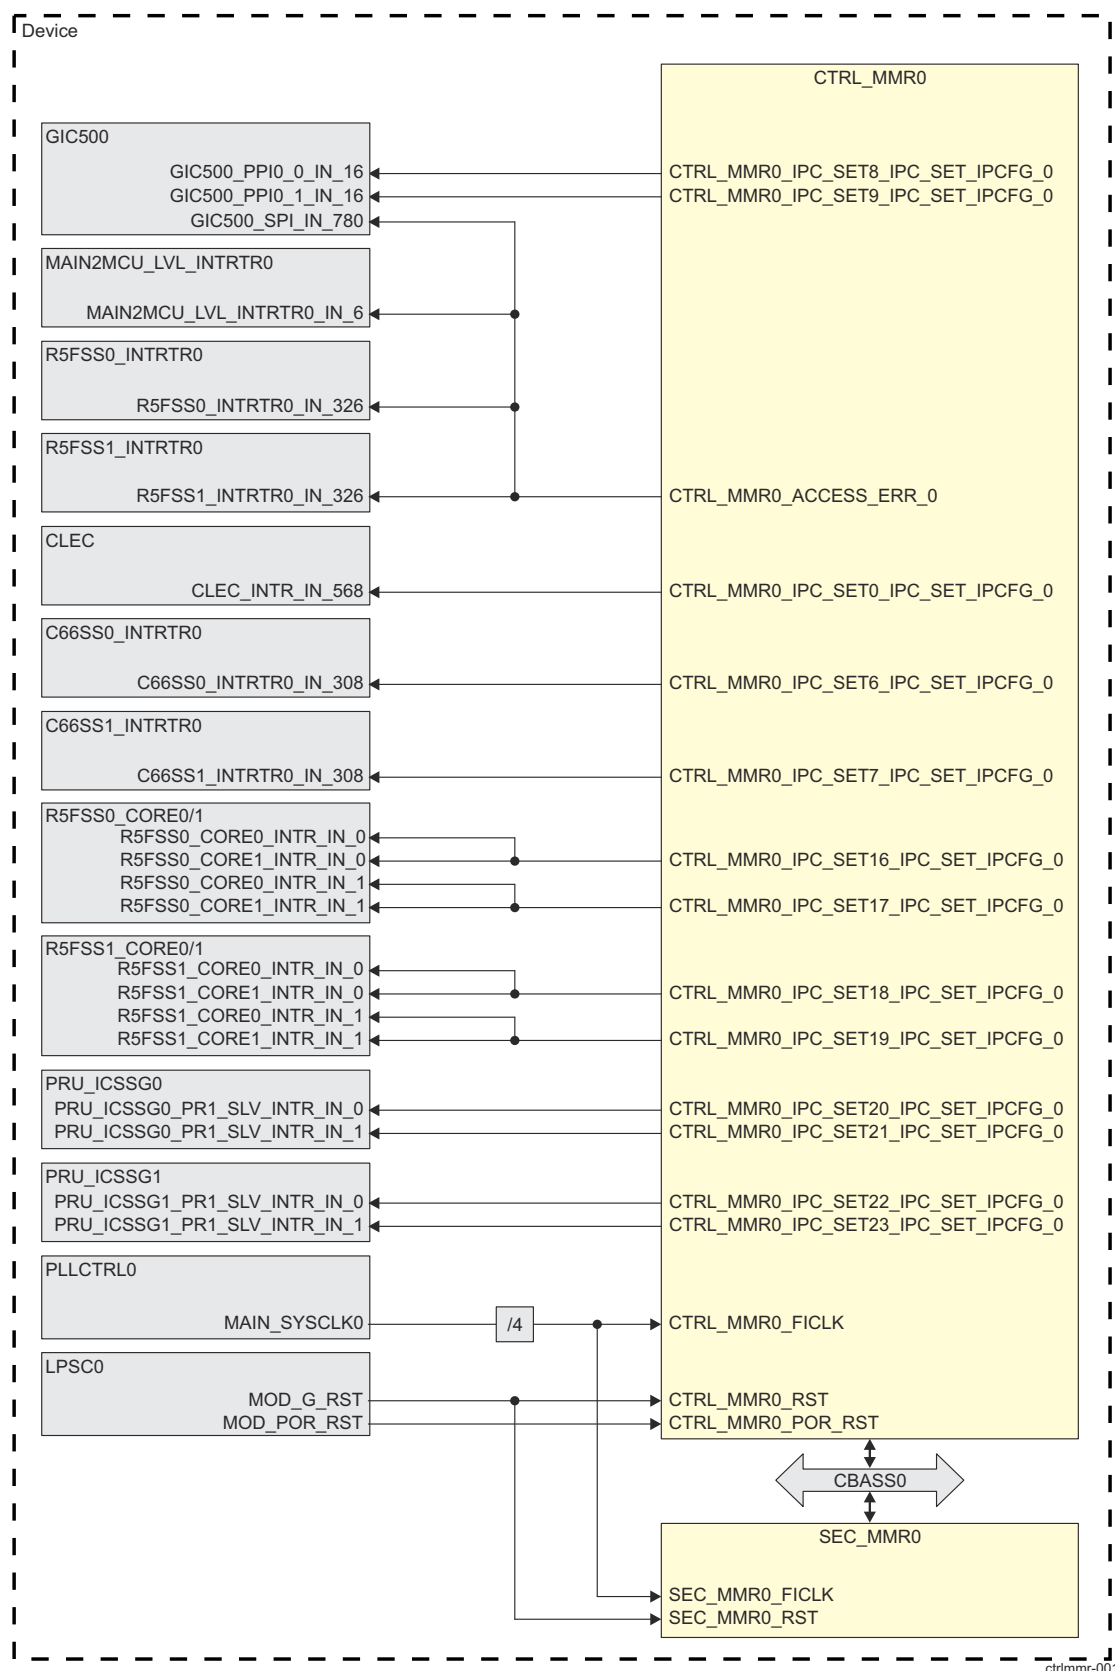

- [Device pad configuration](#)
- [Kick protection \(register write protection\)](#)
- [CTRL\\_MMR0 module interrupts](#)
- [Inter-processor communication](#)
- [Timer I/O multiplexing](#)
- [EHRPWM/EQEP control and status](#)
- [PRU\\_ICSSG control](#)
- [Clock muxing and division](#)
- [Ethernet port operation control](#)
- [PCIe operation control](#)
- [SERDES lane function control](#)
- [DDRSS dynamic frequency change](#)
- and a few other registers and register groups.

### 5.1.3.2 CTRL\_MMR0 Integration

This section describes CTRL\_MMR0 and SEC\_MMR0 integration in the device, including information about clocks, resets, and hardware requests.

One CTRL\_MMR0 and one SEC\_MMR0 modules are integrated in the device MAIN domain. [Figure 5-4](#) shows their integration.

**Figure 5-4. CTRL\_MMR0 and SEC\_MMR0 Integration**

Table 5-16 through Table 5-18 summarize the integration of the CTRL\_MMR0 and SEC\_MMR0 modules in the device MAIN domain.

**Table 5-16. CTRL\_MMR0 and SEC\_MMR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
CTRL_MMR0 SEC_MMR0	PSC0	PD0	LPSC0	CBASS0

**Table 5-17. CTRL\_MMR0 and SEC\_MMR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
CTRL_MMR0	CTRL_MMR0_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	Functional and interface clock for the CTRL_MMR0 module with frequency equal to MAIN_SYSCCLK0 divided by 4.
SEC_MMR0	SEC_MMR0_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	Functional and interface clock for the SEC_MMR0 module with frequency equal to MAIN_SYSCCLK0 divided by 4.

Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
CTRL_MMR0	CTRL_MMR0_RST	MOD_G_RST	LPSC0	Module level main reset
	CTRL_MMR0_POR_RST	MOD_POR_RST	LPSC0	Module power-on reset
SEC_MMR0	SEC_MMR0_RST	MOD_G_RST	LPSC0	SEC_MMR0 module reset

**Table 5-18. CTRL\_MMR0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

**Note**

For more information about CTRL\_MMR0\_ACCESS\_ERR\_0, see [Section 5.1.3.3.1.3](#).

### 5.1.3.3 CTRL\_MMR0 Functional Description

#### 5.1.3.3.1 Description for CTRL\_MMR0 Register Types

The following sub-sections provide summary and description for most of the registers which are part of the CTRL\_MMR0 module memory space. The rest of the registers are described in the corresponding chapters where the functionality associated with particular CTRL\_MMR0 register is covered in more detail.

##### 5.1.3.3.1.1 Pad Configuration Registers

The pad configuration registers are used to configure most of the device pads. Each pad configuration register (CTRLMMR\_PADCONFIG0 to CTRLMMR\_PADCONFIG172) is associated only with one pad and has bits as described in [Table 5-19](#).

**Table 5-19. Description Of The Pad Configuration Register Bits**

Bit	Field <sup>(1)</sup>	Type	Description
31	LOCK	R/W	Pad configuration register lock bit. 0h - The corresponding pad configuration register is unlocked. Its value can be modified. Further writes are allowed. 1h - The corresponding pad configuration register is locked. Its value can not be modified. Further writes are not allowed.
30	WKUP_EVT	R	Wakeup event status 0h - No wake event on pin 1h - Wake event occurred on pin
29	WKUP_EN	R/W	Wakeup enable 0h - Wakeup operation disabled 1h - Wakeup operation enabled
28-27	RESERVED	R	Reserved
26	DSOUT_VAL	R/W	Specifies the output logic value for a pad when device is in Deep Sleep mode. 0h - Output value is 0 1h - Output value is 1
25	DSOUT_DIS	R/W	Deep Sleep output disable 0h - Output enabled 1h - Output disabled
24	DS_EN	R/W	Deep Sleep override control 0h - I/O keeps its previous state when Deep Sleep mode is active 1h - I/O state is forced to OFF mode value when Deep Sleep mode is active
23	ISO_BYP	R/W	Isolation Bypass 0h - I/O isolation is preserved 1h - I/O isolation is bypassed
22	ISO_OVR	R/W	Isolation Override 0h - I/O isolation is preserved 1h - I/O isolation is overridden
21	TX_DIS	R/W	Disables the driver for a pad 0h - Driver is enabled 1h - Driver is disabled

**Table 5-19. Description Of The Pad Configuration Register Bits (continued)**

Bit	Field <sup>(1)</sup>	Type	Description
20-19	DRV_STR	R/W	<p>Drive Strength Control.</p> <p>Selects the drive strength value for LVCMOS pins. (Does not apply to other pin types). Nominal drive strength is recommended and is the value used for data manual AC timing . Fast or Slow modes can be used where necessary, and should be validated using IBIS simulations to determine the appropriate timing derate from the data manual.</p> <p>0h - Nominal (recommended)  1h - Fast  2h - Slow  3h - Reserved</p>
18	RXACTIVE	R/W	<p>Input enable for a pad</p> <p>0h - Receiver disabled  1h - Receiver enabled</p>
17-16	RESERVED	R	Reserved
15	FORCE_DS_EN	R/W	<p>Enable pad Deep Sleep controls by overriding DMSC gating</p> <p>0h - Deep Sleep pad controls are gated by the DMSC  1h - Deep Sleep pad controls are activated. DMSC gating logic is overridden.</p>
14	ST_EN	R/W	<p>Receiver Schmitt Trigger enable</p> <p>0h - Schmitt trigger input disabled  1h - Schmitt trigger input enabled</p>
13-11	DEBOUNCE_SEL	R/W	<p>Selects the debounce period for a pad. For more information, see <a href="#">Section 5.1.1.3.1.10</a>.</p> <p>0h: Debounce period of 0  1h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG1[5-0] DB_CFG field  2h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG2[5-0] DB_CFG field  3h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG3[5-0] DB_CFG field  4h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG4[5-0] DB_CFG field  5h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG5[5-0] DB_CFG field  6h: Debounce period as specified via the CTRLMMR_WKUP_DBOUNCE_CFG6[5-0] DB_CFG field  7h: Reserved</p>
10-6	RESERVED	R	Reserved
5-4	VGPI0_SEL	R/W	<p>Virtual MAIN_GPIO instance select.</p> <p>These bits select which instance of GPIO is used for this I/O pad. This allows protection between two different processor virtual worlds. These bits have no effect if GPIO mode (MUXMODE = 7h) is not selected for the pad.</p> <p>0h - Implement GPIO in GPIO_0/1 instance  1h - Implement GPIO in GPIO_2/3 instance  2h - Implement GPIO in GPIO_4/5 instance  3h - Implement GPIO in GPIO_6/7 instance</p>

**Table 5-19. Description Of The Pad Configuration Register Bits (continued)**

Bit	Field <sup>(1)</sup>	Type	Description
3-0	MUXMODE	R/W	Selects the desired multiplexing mode for a pad 0h - Mux Mode 0 1h - Mux Mode 1 2h - Mux Mode 2 3h - Mux Mode 3 4h - Mux Mode 4 5h - Mux Mode 5 6h - Mux Mode 6 7h - Mux Mode 7 8h - Mux Mode 8 9h - Mux Mode 9 Ah - Mux Mode 10 Bh - Mux Mode 11 Ch - Mux Mode 12 Dh - Mux Mode 13 Eh - Mux Mode 14 Fh - Mux Mode 15

(1) Some bits may not be present in all PADCONFIGx registers.

Many of the device pads support pad multiplexing. This means that their function can be independently chosen from two or more options. The selection of functions available on each pad is enumerated in table “*Pin Multiplexing*” of the device-specific Datasheet. The desired function is selected via the MUXMODE field of the associated pad configuration register.

The CTRLMMR\_PADCONFIG0 to CTRLMMR\_PADCONFIG172 registers control the signal multiplexing of modules in the device MAIN domain.

#### 5.1.3.3.1.2 Kick Protection Registers

The CTRL\_MMR0 module has a protection mechanism which prevents spurious writes from changing the values of its registers. The LOCKi\_KICK0 and LOCKi\_KICK1 registers are used for this purpose. A write is required first to the LOCKi\_KICK0[31-1] KEY field and then to the LOCKi\_KICK1[31-0] KEY field with exact data values to unlock the protection mechanism. Once released then all registers within Partition “i” having write permissions can be written to. The read only registers are still read only. An indication for unlocked Partition “i” is when the LOCKi\_KICK0[0] UNLOCKED bit is set to 1h. When the protection mechanism is locked (indicated by LOCKi\_KICK0[0] UNLOCKED = 0h) none of the registers within Partition “i” can be written to. They can only be read.

Table 5-20 shows the values that must be written to the LOCKi\_KICK0 and LOCKi\_KICK1 registers to unlock each partition. Writing any other data value to either of these registers locks the protection mechanism and blocks any writes to the registers that reside in Partition “i”.

**Table 5-20. Partition Unlock Values**

Register	Partition <sup>(1)</sup>	Unlock Value	Offset Range
CTRLMMR_LOCK0_KICK0	Partition 0	68EF 3490h	0000h to 1FFFh
CTRLMMR_LOCK0_KICK1	Partition 0	D172 BC5Ah	
CTRLMMR_LOCK1_KICK0	Partition 1	68EF 3490h	4000h to 5FFFh
CTRLMMR_LOCK1_KICK1	Partition 1	D172 BC5Ah	
CTRLMMR_LOCK2_KICK0	Partition 2	68EF 3490h	8000h to 9FFFh
CTRLMMR_LOCK2_KICK1	Partition 2	D172 BC5Ah	
CTRLMMR_LOCK3_KICK0	Partition 3	68EF 3490h	C000h to DFFFh
CTRLMMR_LOCK3_KICK1	Partition 3	D172 BC5Ah	

**Table 5-20. Partition Unlock Values (continued)**

Register	Partition <sup>(1)</sup>	Unlock Value	Offset Range
CTRLMMR_LOCK5_KICK0	Partition 5	68EF 3490h	1 4000h to 1 5FFFh
CTRLMMR_LOCK5_KICK1	Partition 5	D172 BC5Ah	
CTRLMMR_LOCK6_KICK0	Partition 6	68EF 3490h	1 8000h to 1 9FFFh
CTRLMMR_LOCK6_KICK1	Partition 6	D172 BC5Ah	
CTRLMMR_LOCK7_KICK0	Partition 7	68EF 3490h	1 C000h to 1 DFFFh
CTRLMMR_LOCK7_KICK1	Partition 7	D172 BC5Ah	

(1) Not listed partitions are reserved and not used.

### Note

In order to ensure that all registers from all partitions are write protected, software must always re-lock the protection mechanism after completing the register writes.

The following registers are exceptions and are not write protected by the LOCK<sub>i</sub>\_KICK0 and LOCK<sub>i</sub>\_KICK1 registers:

- The *Inter-processor Communication Registers*
- The *Kick Protection Registers* described in this section.

The *Inter-processor Communication Registers* registers are not write protected in order to reduce the access latency.

#### 5.1.3.3.1.3 CTRL\_MMR0 Module Interrupts

The CTRL\_MMR0 module has one interrupt request, the CTRL\_MMR0\_ACCESS\_ERR\_0, which is associated with the following registers:

- CTRLMMR\_INTR\_RAW\_STAT — interrupt raw status register
- CTRLMMR\_INTR\_STAT\_CLR — interrupt status register
- CTRLMMR\_INTR\_EN\_SET — interrupt enable register
- CTRLMMR\_INTR\_EN\_CLR — interrupt disable register

The following applies for the interrupt behavior of the CTRL\_MMR0 module:

- The CTRL\_MMR0 module asserts its interrupt line only if the interrupts are enabled by setting to 1h the corresponding bits in the CTRLMMR\_INTR\_EN\_SET register. These interrupts can be disabled by setting to 1h the corresponding bits in the CTRLMMR\_INTR\_EN\_CLR register.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by setting to 1h the corresponding bit in the CTRLMMR\_INTR\_STAT\_CLR register which also clears the corresponding bit in the CTRLMMR\_INTR\_RAW\_STAT register. The status flags in the CTRLMMR\_INTR\_RAW\_STAT register are set even if the corresponding interrupt is disabled unlike those in the CTRLMMR\_INTR\_STAT\_CLR register, which are set only if the corresponding interrupt is enabled.
- An interrupt is also generated by the CTRL\_MMR0, if certain bit in the CTRLMMR\_INTR\_RAW\_STAT register is set to 1h and the corresponding interrupt is enabled through the CTRLMMR\_INTR\_EN\_SET register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled the corresponding raw flag in the CTRLMMR\_INTR\_RAW\_STAT register is set to 1h when an IRQ condition occurs.
- Even if interrupts are not enabled, a status bit in the CTRLMMR\_INTR\_RAW\_STAT register can also be cleared by setting to 1h the corresponding bit in the CTRLMMR\_INTR\_STAT\_CLR register.

Table 5-21 lists the interrupt events which can assert the (CTRL\_MMR0\_ACCESS\_ERR\_0) interrupt line.

**Table 5-21. CTRL\_MMR0 Events**

Event Flag	Event Mask	Description
CTRLMMR_INTR_RAW_STAT[2] LOCK_ERR CTRLMMR_INTR_STAT_CLR[2] EN_LOCK_ERR	CTRLMMR_INTR_EN_SET[2] LOCK_ERR_EN_SET CTRLMMR_INTR_EN_CLR[2] LOCK_ERR_EN_CLR	Lock violation interrupt. Occurs when writing to a register in a locked CTRL_MMR0 partition.
CTRLMMR_INTR_RAW_STAT[1] ADDR_ERR CTRLMMR_INTR_STAT_CLR[1] EN_ADDR_ERR	CTRLMMR_INTR_EN_SET[1] ADDR_ERR_EN_SET CTRLMMR_INTR_EN_CLR[1] ADDR_ERR_EN_CLR	Addressing violation interrupt. Occurs when accessing an illegal address inside the CTRL_MMR0 module.
CTRLMMR_INTR_RAW_STAT[0] PROT_ERR CTRLMMR_INTR_STAT_CLR[0] EN_PROT_ERR	CTRLMMR_INTR_EN_SET[0] PROT_ERR_EN_SET CTRLMMR_INTR_EN_CLR[0] PROT_ERR_EN_CLR	Protection violation interrupt. Occurs when a register is accessed without the required secure/privilege level permissions.

When an error event as described in [Table 5-21](#) occurs, the error associated details are captured in the CTRLMMR\_FAULT\_ADDR, CTRLMMR\_FAULT\_TYPE and CTRLMMR\_FAULT\_ATTR registers. CTRLMMR\_FAULT\_ADDR contains the address of the first fault access. CTRLMMR\_FAULT\_TYPE and CTRLMMR\_FAULT\_ATTR contain status attributes associated with the first fault access. To clear the contents of these three registers and allow them to latch the attributes of the next fault the CTRLMMR\_FAULT\_CLR[0] CLEAR bit must be set to 1h.

#### 5.1.3.3.1.4 Inter-processor Communication Registers

The inter-processor communication registers are used for generating interrupts to the device cores. Any master having access to the CTRL\_MMR0 registers can generate an interrupt by writing 1h to the CTRLMMR\_IPC\_SETx[0] bits. The interrupt is cleared when 1h is written to the CTRLMMR\_IPC\_CLRx[0] bits. For example, writing 1h to CTRLMMR\_IPC\_SET8[0] IPC\_SET generates an interrupt to A72 core 0, and writing 1h to CTRLMMR\_IPC\_CLR8[0] IPC\_CLR clears this event. These registers provide also a *Source ID* facility through the CTRLMMR\_IPC\_SETx[31-4] IPC\_SRC\_SET and CTRLMMR\_IPC\_CLRx[31-4] IPC\_SRC\_CLR bit fields by which up to 28 different sources of interrupts can be identified. Allocation of the source bits to source processor and meaning is entirely based on software convention. Virtually, anything can be a source for these fields as this is completely controlled by software.

Writing 1h to an IPC\_SRC\_SET bit sets to 1h both the IPC\_SRC\_SET and corresponding IPC\_SRC\_CLR bit. Writing 1h to an IPC\_SRC\_CLR bit sets to 0h (clears) both the IPC\_SRC\_CLR and corresponding IPC\_SRC\_SET bit. The same logic applies also to the IPC\_SETx[0] IPC\_SET and IPC\_CLRx[0] IPC\_CLR bits. [Table 5-22](#) summarizes the inter-processor communication (IPC) registers.

**Table 5-22. Summary of the IPC Registers**

IPC Register	Writing 1h to bit 0 results in:	Writing 1h to one of the bits [31-4] results in:
CTRLMMR_IPC_SET0	<ul style="list-style-type: none"> <li>interrupt generation to C71x core 0</li> <li>setting the IPC_SET bit to 1h</li> <li>setting the corresponding IPC_CLR bit to 1h</li> </ul>	setting that bit and the corresponding IPC_SRC_CLR bit to 1h

#### Note

For latency reasons the IPC registers are not write protected by KICK registers which means that they can be written to without a need for performing unlocking procedure as described in *Kick Protection Registers*.

#### 5.1.3.3.1.5 Timer I/O Muxing Control Registers

Not all timer inputs and outputs are pinned out of the device. Through the timer I/O muxing registers the inputs and outputs of the MAIN domain timers can be made available on the TIMER\_IO[7:0] device pads.

Each timer input can be configured to be driven by one of the TIMER\_IO[7:0] pads through the corresponding bits in the CTRLMMR\_TIMER0\_CTRL to CTRLMMR\_TIMER19\_CTRL registers. Each of the TIMER\_IO[7:0] pads can be configured to be driven by any of the timer outputs through the corresponding bits in the CTRLMMR\_TIMERIO0\_CTRL to CTRLMMR\_TIMERIO7\_CTRL registers. [Figure 5-5](#) shows the TIMER I/O multiplexing scheme for the MAIN domain.

**Figure 5-5. MAIN Domain TIMER I/O Multiplexing Scheme**

For more information about each timer, see *Timers*.

#### 5.1.3.3.1.6 EHRPWM/EQEP Control and Status Registers

The CTRL\_MMR0 registers which provide control and status information for the EHRPWM/EQEP modules are shown in [Table 5-23](#).

**Table 5-23. Summary of the EHRPWM/EQEP Control and Status Registers**

Register Name	Description	Associated Functionality Described in:
CTRLMMR_EPWM0_CTRL CTRLMMR_EPWM1_CTRL CTRLMMR_EPWM2_CTRL CTRLMMR_EPWM3_CTRL CTRLMMR_EPWM4_CTRL CTRLMMR_EPWM5_CTRL	Time base clock, source of PWM synchronization input and other controls for the EHRPWM <sup>(1)</sup> module	<i>EPWM<sup>(1)</sup> Modules Time Base Clock Gating and Daisy-Chain Connectivity between EPWM Modules in Enhanced Pulse Width Modulation (EPWM) Module</i>
CTRLMMR_SOCA_SEL CTRLMMR_SOCB_SEL	Start of Conversion output source	<i>ADC start of conversion signals (PWM_SOCA and PWM_SOCB) in Enhanced Pulse Width Modulation (EPWM) Module</i>
CTRLMMR_EQEP_STAT	Provides EQEP <sup>x</sup> phase error status information	<i>EPWM Integration Device Specific EQEP Features in Enhanced Quadrature Encoder Pulse (EQEP) Module</i>

(1) The terms "EPWM" and "EHRPWM" are interchangeable in this section.

#### 5.1.3.3.1.7 PRU\_ICSSG Control Registers

There are registers within the CTRL\_MMR0 module address space related to several PRU\_ICSSG features. These registers are shown in [Table 5-24](#).

**Table 5-24. PRU\_ICSSG Control Registers**

Register Name	Register Name
CTRLMMR_ICSSG0_CTRL0	CTRLMMR_ICSSG1_CTRL0
CTRLMMR_ICSSG0_CTRL1	CTRLMMR_ICSSG1_CTRL1

### 5.1.3.3.1.8 Clock Muxing and Division Registers

There are registers within the CTRL\_MMR0 module address space dedicated to clock muxing and division for some device modules. [Table 5-25](#) summarizes these registers. Related information can also be found in [Section 5.4 Clocking](#).

**Table 5-25. Summary of the Clock Muxing and Division Registers**

Register Name	Register Name	Register Name
CTRLMMR_OBSCLK0_CTRL	CTRLMMR_SPI6_CLKSEL	CTRLMMR_ATL_AWS1_SEL

## 5.2 Power

This chapter describes the power-management architecture implemented in the device.

The Power Management is presented in several general sections - Power Management Subsystems, including both System and Control Modules; Device Power States; Dynamic and Thermal Management.

### 5.2.1 Power Management Overview

Power management architecture of the device is built over three levels of power controls: clock-, power-, and voltage supplies to the subsystem modules, namely domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch).

A set of Power Domains (PD) are defined for the device, where clock and power supplies to the domain may be controlled by Power Sleep Controllers (PSC), see [Section 5.2.2.2.1, Power Sleep Controller and Local Power Sleep Controllers](#). This section describes functionality of PSC, as well as list of power domains, control registers and hierarchical dependencies of PDs.

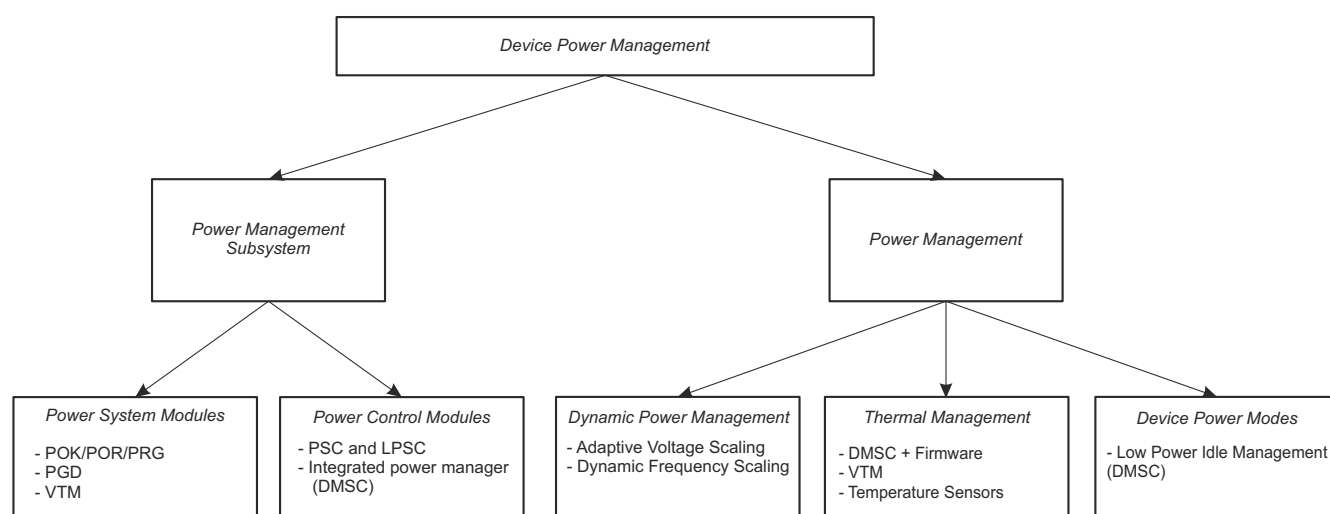

One or multiple power domains may share a single power supply, this level of grouping are referred as Voltage Domains (VD). Some voltage domains may be turned off by externally switching off the power supplies to these domains. [Section 5.2.2.2.1.3.1, WKUP\\_PSC0 Device-Specific Information](#), and [Section 5.2.2.2.1.3.1, PSC0 Device-Specific Information](#), give list of VDs and corresponding PDs on them.

Device power states are defined based on the combination of VD and PD ON/OFF states, as described in [Section 5.2.3, Device Power States](#)

Initial configuration of the device clocking tree and power domains, as well as power state transitions, may be complex due to hierarchical dependencies. Thus a Device Management and Security Controller (DMSC) is integrated to off-load some of these tasks from main controllers. DMSC also serves as a wake-up controller and generator, maintaining minimum hardware state machines when all programmable cores are turned off. Power management functions of the DMSC are described in [Section 5.2.2.2.2, Integrated Power Management \(DMSC\)](#), for functional reference. Standard applications shall use the DMSC Firmware APIs to perform high-level power management functions.

Additional hardware modules for temperature sensing, thermal management, power monitoring, and reset functions related to power ramping, are described in [Section 5.2.2.1, Power System Modules](#).

[Figure 5-6](#) shows the overview of the common power management of the device.

power-001

**Figure 5-6. Overview of Common Power Management**

## 5.2.2 Power Management Subsystems

### 5.2.2.1 Power Management Unit

The Power Management Unit in consists of a Reference system and a Safety system.

- **Reference System:**

The Reference system generates internally used power supply and reference rails. It ensures reliable power on sequencing with the PMU and generates a reset signal based on coarse voltage level checks given to the external power supplies. The Reference system also contains the 1.8V LDO which generates a 1.8V output on the VDDA18\_LDO pin. The 1.8V on VDDA18\_LDO can be connected to VDDA18 and VDDA18\_OSC\_PLL on the board to provide the 1.8V supply to the Analog Circuit and PLL. This connection has to be done external to the device as there is no internal connection path for VDDA18\_LDO to source either VDDA18 or VDDA\_OSC\_PLL.

Using the 1.8V LDO as the VDDA18 source allows the 1.8V LDO to source multiple internal blocks. These blocks include the internal ADC voltage reference buffers as well as other analog loads. Because the ADC reference buffers are sourced internally through the VDDA18 input, the VDDA18\_LDO output should not be connected as source for the ADC VREFHI inputs.

- **Safety System:**

The Safety System contains the safety comparators and temperature sensor to monitor the system supplies and temperature. The glitch filtered output of the voltage monitors are connected to the Error Signaling Module (ESM) and provide an error signal if the supply is not within the voltage thresholds set for the individual monitored supplies.

#### 5.2.2.1.1 Power OK (POK) Modules

---

#### Note

All POK modules are inWKUP domain regardless of the domain of the voltage they monitor.

---

---

#### Note

In this family of devices, the Power-on-reset module is used only for voltage monitoring, as three additional POK modules. For more information about POK functionality in POR module - voltage being monitored and type (under voltage or over voltage), see [Power on Reset \(POR\) Module](#).

---

**Table 5-30. POK Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_POK0	✓	-	-
WKUP_POK1	✓	-	-
WKUP_POK2	✓	-	-
WKUP_POK3	✓	-	-
WKUP_POK4	✓	-	-
WKUP_POK5	✓	-	-
WKUP_POK6	✓	-	-
WKUP_POK7	✓	-	-
WKUP_POK8	✓	-	-
WKUP_POK9	✓	-	-
WKUP_POK10	✓	-	-
WKUP_POK11	✓	-	-
WKUP_POK12	✓	-	-
WKUP_POK13	✓	-	-

POK modules are responsible for accurately detecting the voltage levels. Each module is trimmed to account for process and temperature variations. The trim values are provided by eFuse chains enabled by a POR/Reset Generator (PRG) module.

Two types of POK modules are implemented in this family of devices - POK and POK\_SA. See [Table 5-31](#) about the type of a POK and the voltage it is monitoring. More information about the two types of POKs is given further in this section.

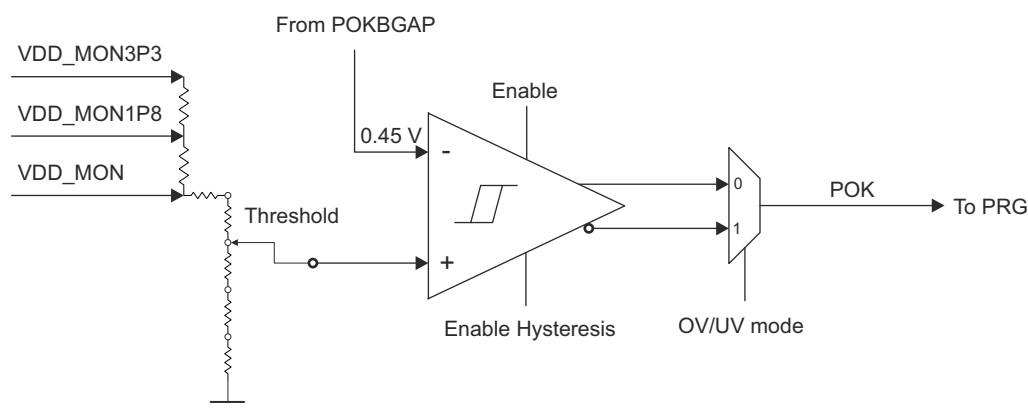

**Table 5-31. POK Modules Type and Monitored Voltage**

Module Instance	Connected to PRG	Type	Voltage Monitored	OV/UV <sup>(1)</sup>
WKUP_POK0	WKUP_PRG0	POK_SA	VMON_ER_VSYS pin <sup>(2)</sup>	UV
WKUP_POK1	WKUP_PRG0	POK	VDDSHV0_MCU	UV
WKUP_POK2	WKUP_PRG0	POK	VDDAR_MCU	UV
WKUP_POK3	WKUP_PRG0	POK	VDD_MCU	OV
WKUP_POK4	WKUP_PRG0	POK	VDDSHV0_MCU	OV
WKUP_POK5	WKUP_PRG0	POK	VDDAR_MCU	OV
WKUP_POK6	WKUP_PRG2	POK	VDD_CORE	UV
WKUP_POK7	WKUP_PRG2	POK	VDD_CPU	UV
WKUP_POK8	WKUP_PRG2	POK	VMON_IR_VEXT pin	UV
WKUP_POK9	WKUP_PRG2	POK	VDDAR_CORE	UV
WKUP_POK10	WKUP_PRG2	POK	VDD_CORE	OV
WKUP_POK11	WKUP_PRG2	POK	VDD_CPU	OV
WKUP_POK12	WKUP_PRG2	POK	VMON_IR_VEXT pin	OV
WKUP_POK13	WKUP_PRG2	POK	VDDAR_CORE	OV

(1) UV: POK is set for under voltage detection, OV: POK is set for over voltage detection.

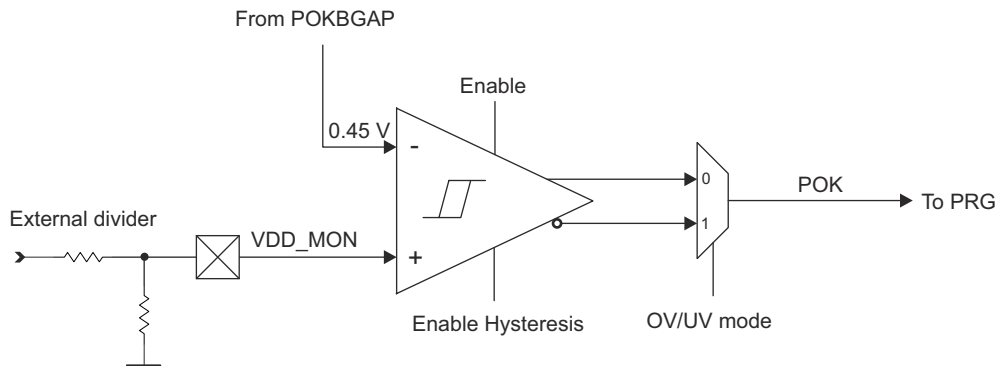

(2) Typically used to monitor PMIC's VSYS voltage.

[Figure 5-7](#) and [Figure 5-8](#) represent the block diagrams of the two POK types.

pok-001

**Figure 5-7. POK Block Diagram**

pok-002

**Figure 5-8. POK\_SA Block Diagram**

Vref for both POK and POK\_SA types in Figure 5-7 and Figure 5-8 is supplied from POR module, see [Power on Reset \(POR\) Module](#).

#### 5.2.2.1.1.1 POK Programming Model

Table 5-32 and Table 5-33 show the programmable features for the POK modules based on the block diagrams shown in Figure 5-7 and Figure 5-8. Furthermore, each POK module has its own dedicated register to set its programmable features. Table 5-34 lists those registers.

**Table 5-32. POK Programmable Features**

Programmable Feature	Register Bitfield of the POK Dedicated Register
POK hysteresis	[31] HYST_EN
POK over or under voltage detection mode	[7] OVER_VOLT_DET
POK programmable resistors for voltage comparator	[6-0] POK_TRIM

**Table 5-33. POK\_SA Programmable Features**

Programmable Feature	Register Bitfield of the POK Dedicated Register
POK hysteresis	[31] HYST_EN
POK over or under voltage detection mode	[0] OVER_VOLT_DET

WKUP_POK10	VDD_CORE (OV)	CTRLMMR_WKUP_POK_VDD_CORE_OV_CTRL
WKUP_POK11	VDD_CPU (OV)	CTRLMMR_WKUP_POK_VDD_CPU_OV_CTRL
WKUP_POK12	VMON_IR_VEXT pin (OV)	CTRLMMR_WKUP_POK_VMON_EXT_OV_CTRL

**Table 5-34. POK Control Registers (continued)**

POK	Voltage Monitored <sup>(1)</sup>	Register <sup>(2)</sup>
WKUP_POK13	VDDAR_CORE (OV)	CTRLMMR_WKUP_POK_VDDR_CORE_OV_CTRL

- (1) UV means POK is set for under voltage detection, OV means POK is set for over voltage detection.  
(2) For more information about control and status registers, see *Control Module (CTRL\_MMR)*.

#### Note

All POKs given in [Table 5-34](#) are enabled via corresponding bit in CTRLMMR\_WKUP\_PRG0\_CTRL and CTRLMMR\_WKUP\_MAIN\_PRG\_CTRL. Status of the POKs can be monitored via CTRLMMR\_WKUP\_PRG0\_STAT and CTRLMMR\_WKUP\_MAIN\_PRG\_STAT. For more information about control registers, see *Control Module (CTRL\_MMR)*.

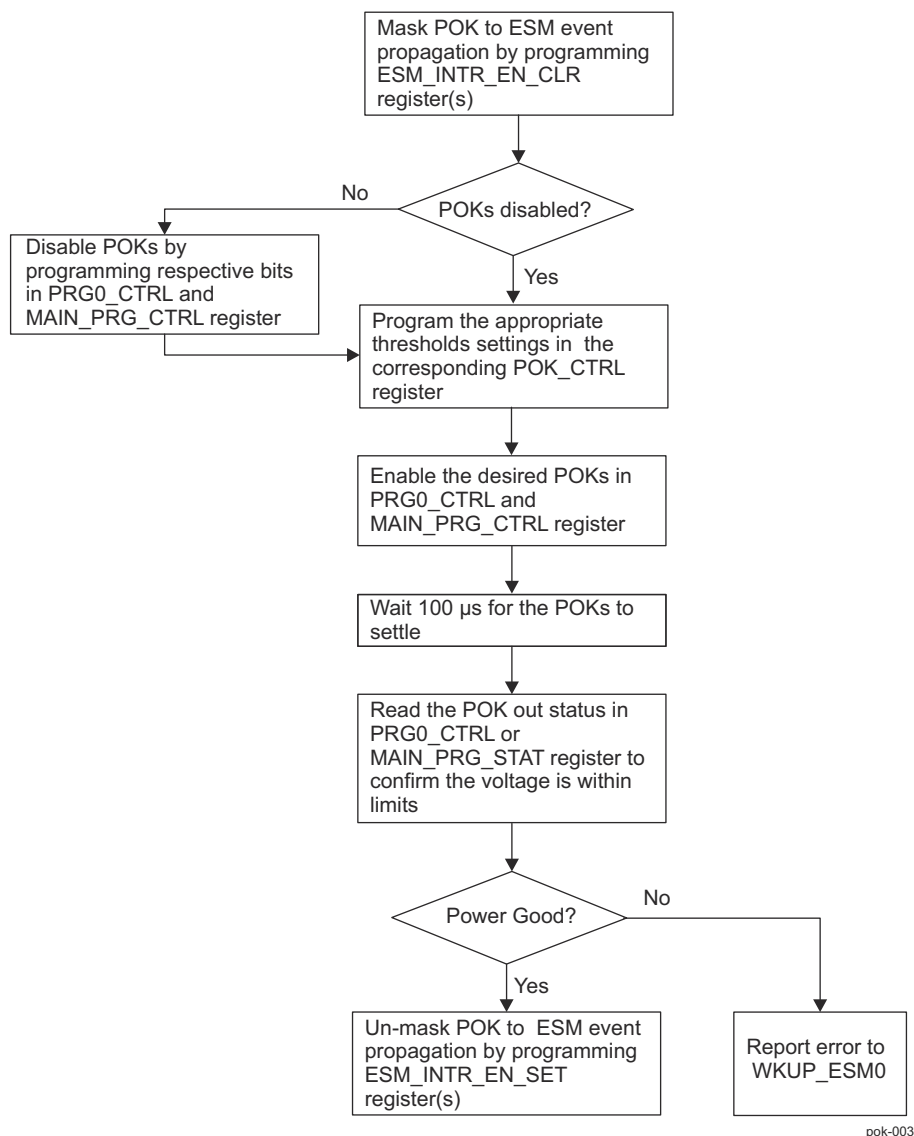

The possible values of the monitored voltage differ among the POK types, see [Table 5-35](#). If the voltage values are programmable, they are set through [6-0] POK\_TRIM bitfield in the corresponding POK control register, see [Table 5-34](#).

**Table 5-35. Values of the Possible Monitored Voltages**

POK Type	Monitored Voltage Values
POK	3.3 V, 1.8 V, core voltages from 0.6 V to 1.5 V
POK_SA	0.45 V (allows for external resistor divider for a wide range of scaled voltages)

### POK Threshold Setting Programming Sequence

After initial boot, it is the responsibility of software to program the appropriate POK threshold settings and then enable the POK monitoring for desired supply rails. The sequence shown in [Figure 5-9](#) has to be followed.

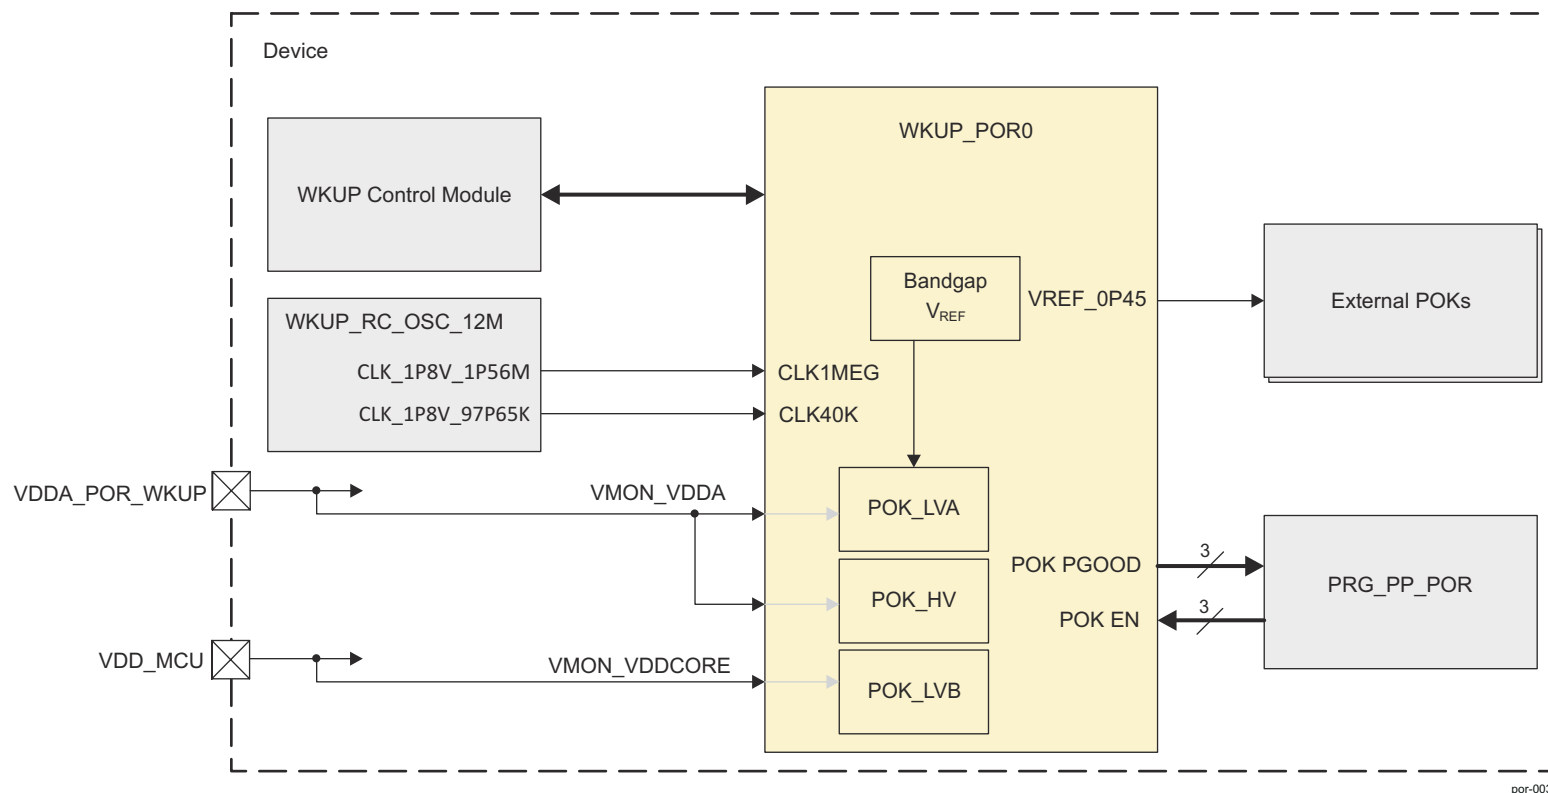

**Figure 5-9. POK Programming Model**

### 5.2.2.1.2.2 POR Integration

The device supports one instance of a Power on Reset (POR) module - WKUP\_POR0. WKUP\_POR0 is located in WKUP domain. [Figure 5-11](#) shows the integration of WKUP\_POR0.

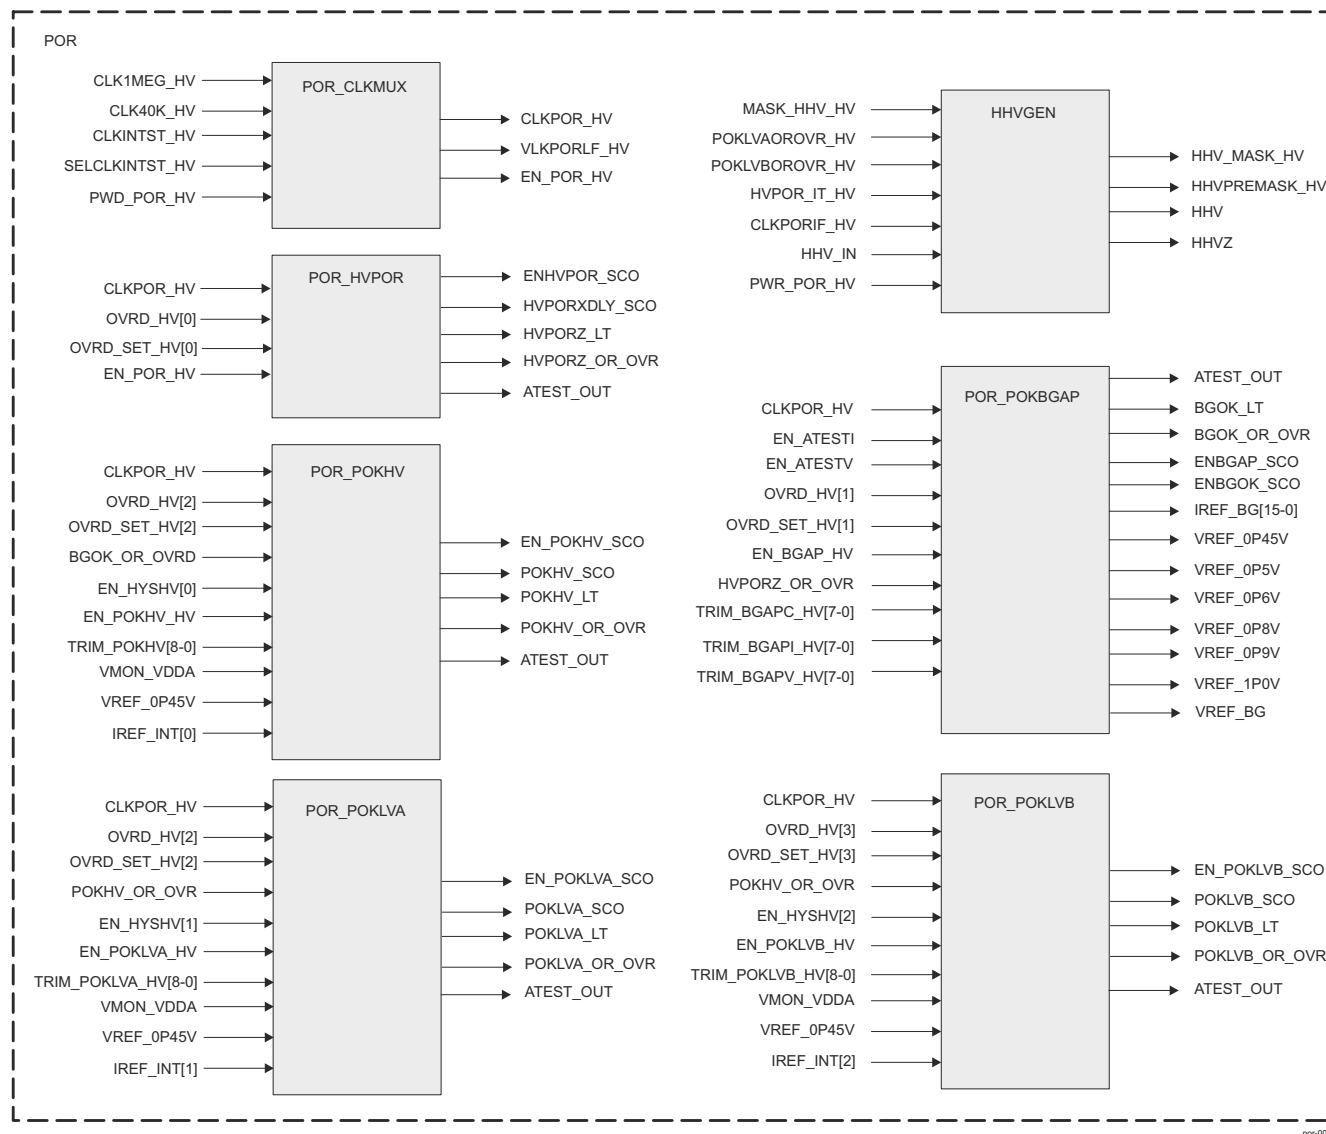

**Figure 5-11. POR Integration**

**Table 5-37. POR Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
WKUP_POR0	CLK1MEG	CLK_1P8V_1P56M	WKUP_RC_OSC_12M	Clock from RCOSC
	CLK40K	CLK_1P8V_97P65K	WKUP_RC_OSC_12M	Clock from RCOSC

### 5.2.2.1.2.3 POR Functional Description

Figure 5-12 shows the block diagram of a POR module.

**Figure 5-12. POR Block Diagram**

The modules in the block diagrams are:

- POR\_HVPOR, system supply POR is used to reset the custom logic at power-up and keep it in reset until system supply is sufficiently high for logic cells to operate reliably.
- Bandgap (POR\_POKBAP, shortly named as BGAP) provides reference for the comparator within POR module and also provides reference to external supply monitor circuits. This circuit also includes a Bandgap OK (BGOK) check to ensure bandgap is within expected range. This is a very crude check to ensure BG is not stuck at ground or supply levels.
- System Supply Power OK comparators, POR\_POKHV and POR\_POKLVA, shortly named as POHVH and POKLVA, check the system supply for under voltage and over voltage detection, respectively. POR\_POKHV is enabled after a wait time following BGOK assertion in order to allow BG to settle to expected accuracy. POR\_POKLVA is enabled once POR\_POKHV is set.
- POR\_POKLVB, shortly named POKLVB, checks VDD supply for under voltage detection.

System power ramp-up and reset deassertion sequence is:

1. VDD (and all other supplies) is ramped up ahead of the system supply, VDDA.
2. As VDDA ramps up internal signals follows this ramp, but as soon as supply is sufficiently high for operation of HVPOR circuit HVPORZ signal will be driven to low (reset) state. At the same time HHV signal that is used for level shifter isolation is pulled high.
3. Once VDDA ramps up to the HVPOR threshold, HVPORZ toggles high. HVPOR threshold is set by the minimum supply level required for the proper operation of the custom digital circuits. Width HVPORZ should be wide enough to properly reset the custom digital circuits
4. HVPORZ goes through an analog delay to provide additional time for the reset. Once HVPORZ\_DLY toggles high, HVPORZ synchronized with CLKPOR\_HV to produce HVPORZ\_OR\_OVR signal that is used to generate EN\_BGAP.
5. BGAP circuitry includes a BGOK circuitry that is set once BGAP is settled. BGOK gets synchronized with clock to produce BGOK\_OR\_OVR signal that is used to generate EN\_POKHV.
6. POKHV checks VDDA supply against the BGAP reference and if it is above the threshold level POKHV is set that gets synchronized to clock to produce POKHV\_OR\_OVR signal. POKHV\_OR\_OVR is used to generate EN\_POKLVA and EN\_POKLVB that enables the comparator that checks VMON\_VDDA (vdda) for over voltage and VMON\_VDDCORE (vdd) for under voltage detection.
7. POKLVA and POKLVB check VMON\_VDDA (VDDA) and VMON\_VDDCORE, against bandgap reference and produce synchronized output signals POKLVA\_OR\_OVR and POKLVB\_OR\_OVR. This is the last step in voltage checks within the POR\_IP. POKLVA\_OR\_OVR and POKLVB\_OR\_OVR is fed to the HHVGEN block that combines these two to generate pre HHV signal and further processes the combined signal to implement HHV masking functionality and a minimum of 250- $\mu$ s delay before de-asserting the HHV.
8. HHV signal is then level shifted to VDD domain to generate the reset signal, SOC\_PORZ for SoC.

#### Note

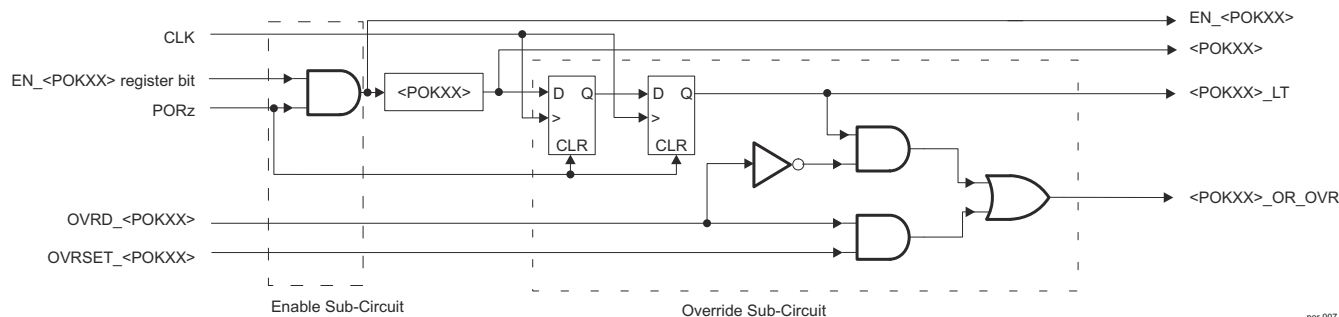

In this family of devices, only the POK functionality of the POR module is used. That is, in step 8, HHV signal is not resetting the SoC.

POR systems response to system power supply ramp down is:

1. Once VDDA cross below the threshold of the POK\_VDDA, POK flags failure and synchronously issues reset to the core domain and asserts HHV. At the same time, in anticipation of failure in VBG state machine resets system back to the step 5 of the above-described system power ramp-up and reset deassertion sequence.
2. As the supply ramps down further, it crosses system POR threshold and a full system reset is issued. As system reboots, the POR starts its operation from the step 1 of the above-described system power ramp-up and reset deassertion sequence.

#### POR Sub-Block Enable and Override

The core of the POR sub-blocks, PORHV, BGAP (BGOK is the comparator output), POKHV and POKLVA and POKLVB have a wrapper around them that controls the enable for these blocks and also process the comparator outputs according to the override. The wrapper architecture is common for all subblocks and is depicted in [Figure 5-13](#) BGAP (BGOK is the comparator output), POKHV, POKLVA and POKLVB.

<POKXX> - is either of BGAP, POKHV, POKLVA and POKLVB

**Figure 5-13. POKHV Wrapper**

Controls, enable, override and override set signal, are not effective until HHV is released.

## Debug and Power-Down Modes

### Note

In this family of devices only POK functionality of POR module is used.

Debug and powerdown mode of the POR module are enabled through PORDEBUGEN\_HV, and PWD\_POR\_HV device pins (both VDDA/1.8V signal), respectively. Truth table for operation modes is given in [Table 5-38](#).

Debug mode enables the override controls for the comparators by forcing the level shifters for these control signals out of HHV state.

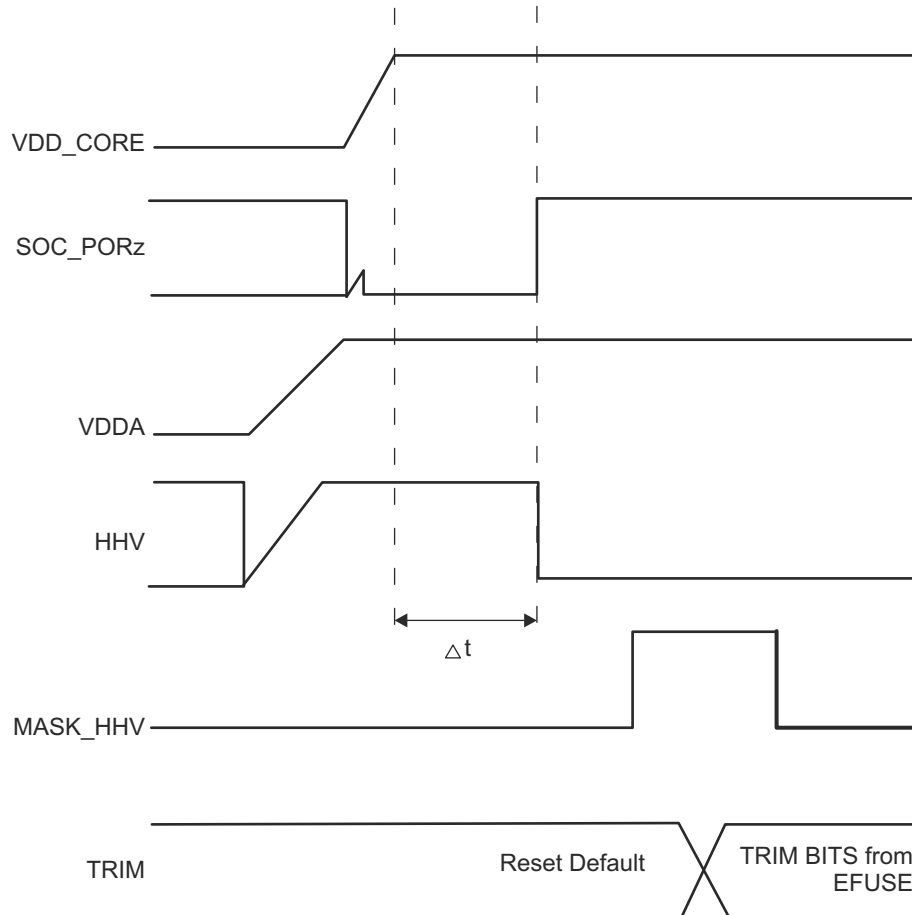

During powerdown PORHV block is disabled at its output is forced to logic low forcing all following blocks into disable state. Also, the HHV signal is forced to logic low and SOC\_PORZ is forced to logic high. During powerdown mode if debug mode is also enabled, subblocks of the POR module may be enabled through override control signals, but SOC\_PORZ and HHV state cannot be modified.

**Table 5-38. POR Operational Mode**

PORDEBUGEN_HV	PWD_POR_HV	VDDA	VDD	HHV	SOC_PORZ	POR Module State
Z	Z	OFF	OFF	Z	Z	Not Powered
Z	Z	OFF	ON	Z	0	Reverse ISO Not Powered
0	0	ON	OFF	1	X	Functional
0	0	ON	ON	0	1	Functional
0	1	ON	ON	0	1	Powerdown
1	0	ON	ON	0	1	DebugMode Operational
1	1	ON	ON	0	1	Mixed Mode (POR_HV powerdown Debug Enable)

## HHV/SOC\_PORZ Masking and Trimming

POR module allows HHV/SOC\_PORZ outputs to be masked after initial reset de-assertion as shown in [Figure 5-14](#). Masking feature of the HHV/SOC\_PORZ should be used before applying the EFUSE trim values in order to avoid re-assertion of the reset due to the transient associated with the new trim values. This feature should be used during functional mode testing of the POR on ATE or bench. HHV Mask may be selected to be applied during normal operation in order to access internal comparator outputs

**Figure 5-14. HHV masking and trimming**

### External (HHVIN\_HV) HHV/SOC\_PORZ Pin Functionality

The POR module gates the internal generated reset signal with the external pin input (HHVIN\_HV) just before outputting HHV.SOC\_PORZ signals. If external reset feature is not available then HHVIN\_HV port of the POR module should be tied low.

### POK operational modes in POR

Modes of operations for the POK blocks in the POR module can be controlled through control signals, HHV, EN\_POK, POK\_SET\_THRESHOLD[8]. [Table 5-39](#) defines the modes of operation.

**Table 5-39. POK Operational Mode**

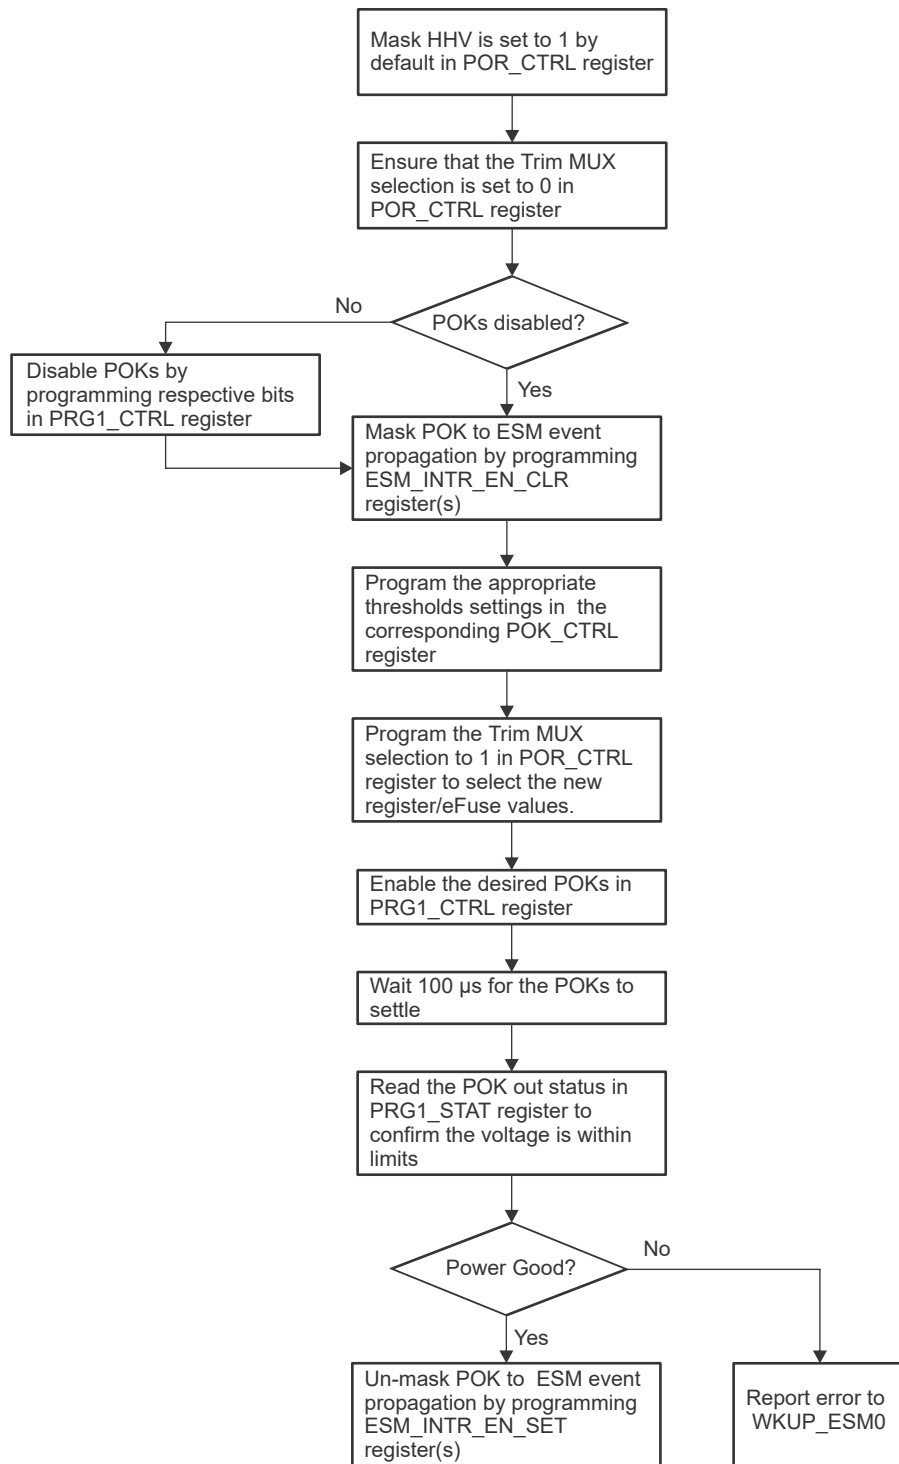

HHV	EN_POK	ENPOK18 (internal)	POK_SET_THRES HOLD<8>	POK_OUT	Comments
1	x	0	x	0	HHV State
1	X	1	0	UVD	Power Up supply Checks
1	X	1	1	OVD	Power Up supply Checks
0	0	0	0	1	Disable State for UVD
0	0	0	1	1	Disable State for OVD
0	1		0	UVD	UVD Mode POK_OUT=1 if power is good.
0	1		1	OVD	OVD Mode POK_OUT=1 if power is good.

#### 5.2.2.1.2.4 POR Programming Model

The three internal POKs for the POR module and their hystereses can be independently enabled from CTRLMMR\_WKUP\_POR\_POKHV\_UV\_CTRL, CTRLMMR\_WKUP\_POR\_POKLV\_UV\_CTRL, CTRLMMR\_WKUP\_POR\_POKHV\_OV\_CTRL, and CTRLMMR\_WKUP\_POR\_BANDGAP\_CTRL. For more information about control registers, see *Control Module (CTRL\_MMR)*.

The three POKs in the POR module are enabled via corresponding bit in CTRLMMR\_WKUP\_WKUP\_PRG1\_CTRL. Their current state can be monitored via corresponding bit in CTRLMMR\_WKUP\_WKUP\_PRG1\_CTRL.

[Figure 5-15](#) shows the programming sequence for the three POKs in the POR module.

**Figure 5-15. POKs in POR Module Programming**

### 5.2.2.1.3 PoR/Reset Generator (PRG) Modules

#### 5.2.2.1.3.1 PRG Overview

A PRG module is responsible for implementing enable/disable controls and event/interrupt masking logic on all POK outputs. [Table 5-40](#) shows PRG modules allocation within device domains.

**Table 5-40. PRG Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_PRG0	✓	-	-
WKUP_PRG1	✓	-	-
WKUP_PRG2	✓	-	-

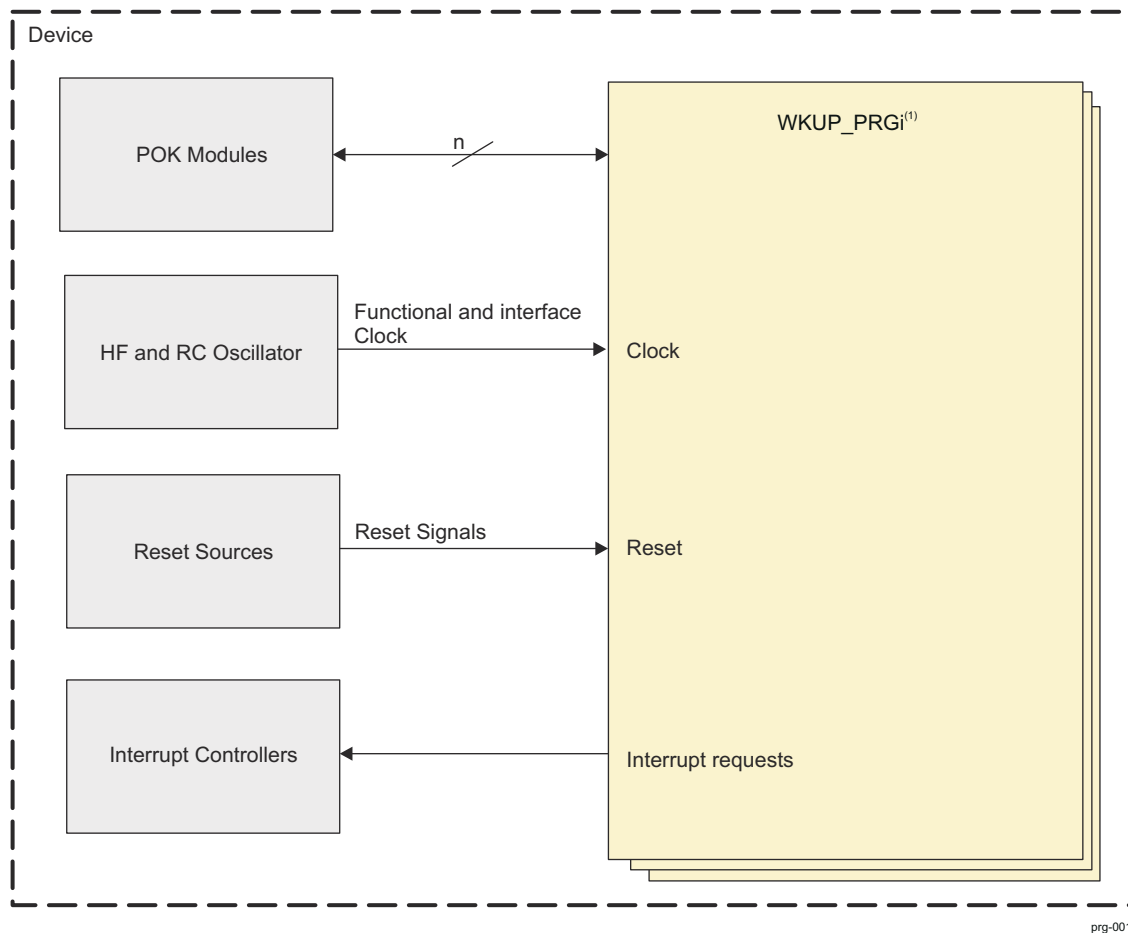

[Table 5-41](#) shows the device domains to which are PRG dedicated for.

**Table 5-41. Dedicated Domains**

Domain/Module	PRG Module
WKUP/MCU	WKUP_PRG0
MCU	WKUP_PRG1 <sup>(1)</sup>
MAIN	WKUP_PRG2

(1) The internal three POKs of POR module are connected to WKUP\_PRG1.

Figure 5-16 shows the PRG module overview.

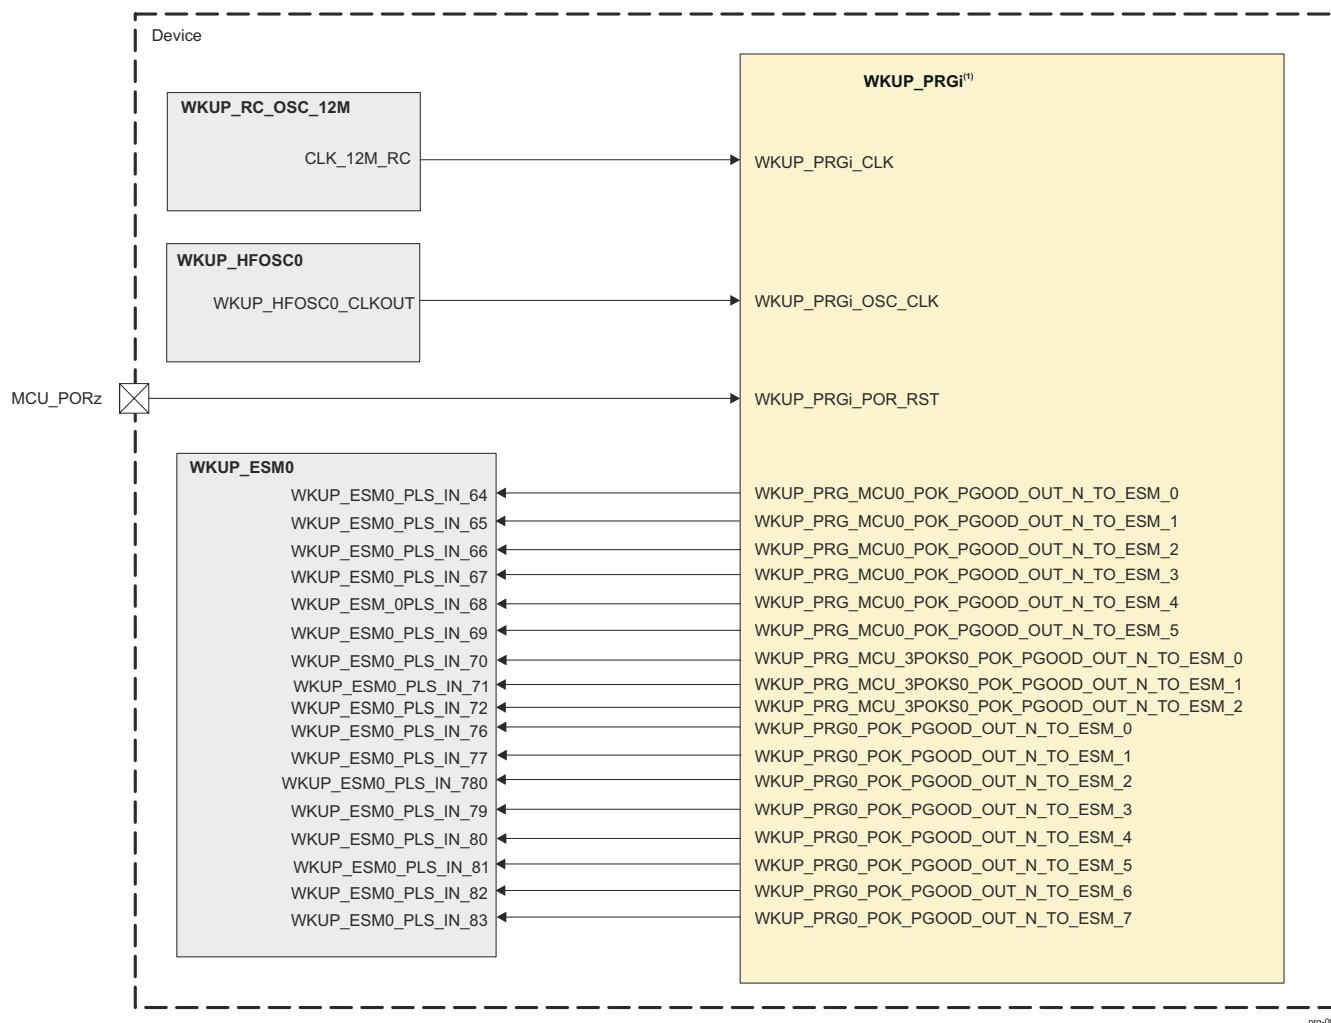

(<sup>1</sup>) i = 0, 1, or 2

**Figure 5-16. PRG Overview**

#### 5.2.2.1.3.2 PRG Integration

Figure 5-17 shows the integration of PRG modules.

(1) i = 0, 1, 2

**Figure 5-17. PRG Integration**

Table 5-42 through Table 5-44 summarize the integration of the PRG modules in the device.

**Table 5-42. PRG Integration Attributes**

Module Instance	Attributes	
	Power Sleep Controller	Power Domain
WKUP_PRG0	No PSC interface	PD0 (WKUP_PSC0)
WKUP_PRG1	No PSC interface	PD0 (WKUP_PSC0)
WKUP_PRG1	No PSC interface	PD0 (WKUP_PSC0)

#### 5.2.2.1.3.3 PRG Programming Model

The PRG modules registers used to control and monitor the status of POKs modules are:

- CTRLMMR\_WKUP\_PRG0\_CTRL
- CTRLMMR\_WKUP\_PRG0\_STAT
- CTRLMMR\_WKUP\_PRG1\_CTRL
- CTRLMMR\_WKUP\_PRG1\_STAT
- CTRLMMR\_WKUP\_MAIN\_PRG\_CTRL
- CTRLMMR\_WKUP\_MAIN\_PRG\_STAT

For more information about control registers, see *Control Module (CTRL\_MMR)*.

#### 5.2.2.1.4 Power Glitch Detect (PGD) Modules

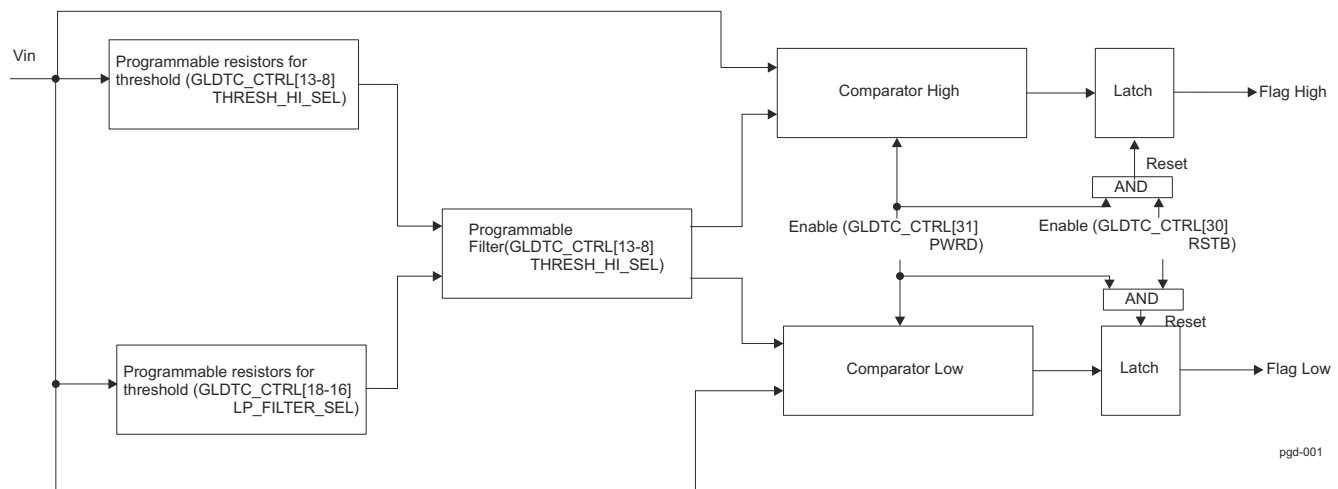

A Power Glitch Detect (PGD) circuit is used to detect short duration “glitches” on the core and MPU power supplies. The PGD provides a low output when no glitch is detected and a high output when a glitch is detected.

Table 5-45 shows PGD modules allocation within device domains.

**Table 5-45. PGD Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MCU_PGD0	-	✓	-
MCU_PGD1	-	✓	-
PGD0	-	-	✓
PGD1	-	-	✓
PGD2	-	-	✓
PGD3	-	-	✓

Figure 5-18 shows the PGD block diagram.

**Figure 5-18. PGD Block Diagram**

Table 5-46 summarize the PGD integration.

**Table 5-46. PGD Integration Summary**

Module Instance	Monitored Voltage	PGD Control Register	PGD Status Register

	VDDR_CORE_GLDTC_STAT_THRESH_LOW_FLAG <sup>(1)</sup>	WKUP_ESM_LVL_EVT_IN_26	WKUP_ESM0	PGD2 Threshold Low Flag level interrupt	Level
PGD3	VDDR_CPU_GLDTC_STAT_THRESH_HI_FLAG <sup>(1)</sup>	WKUP_ESM_LVL_EVT_IN_31	WKUP_ESM0	PGD3 Threshold High Flag level interrupt	Level
	VDDR_CPU_GLDTC_STAT_THRESH_LOW_FLAG <sup>(1)</sup>	WKUP_ESM_LVL_EVT_IN_30	WKUP_ESM0	PGD3 Threshold Low Flag level interrupt	Level

(1) The interrupt flag is mapped also to the corresponding status register, shown in [Table 5-47](#).

### Note

A flag status bit in corresponding STAT register is cleared by clearing the [30] RSTB bit in the corresponding CTRL register, see for STAT and CTRL registers for a certain PGD module.

### 5.2.2.1.5 Voltage and Thermal Manager (VTM)

#### 5.2.2.1.5.1 VTM Overview

This section describes the Voltage and Thermal Manager (VTM) module in the device.

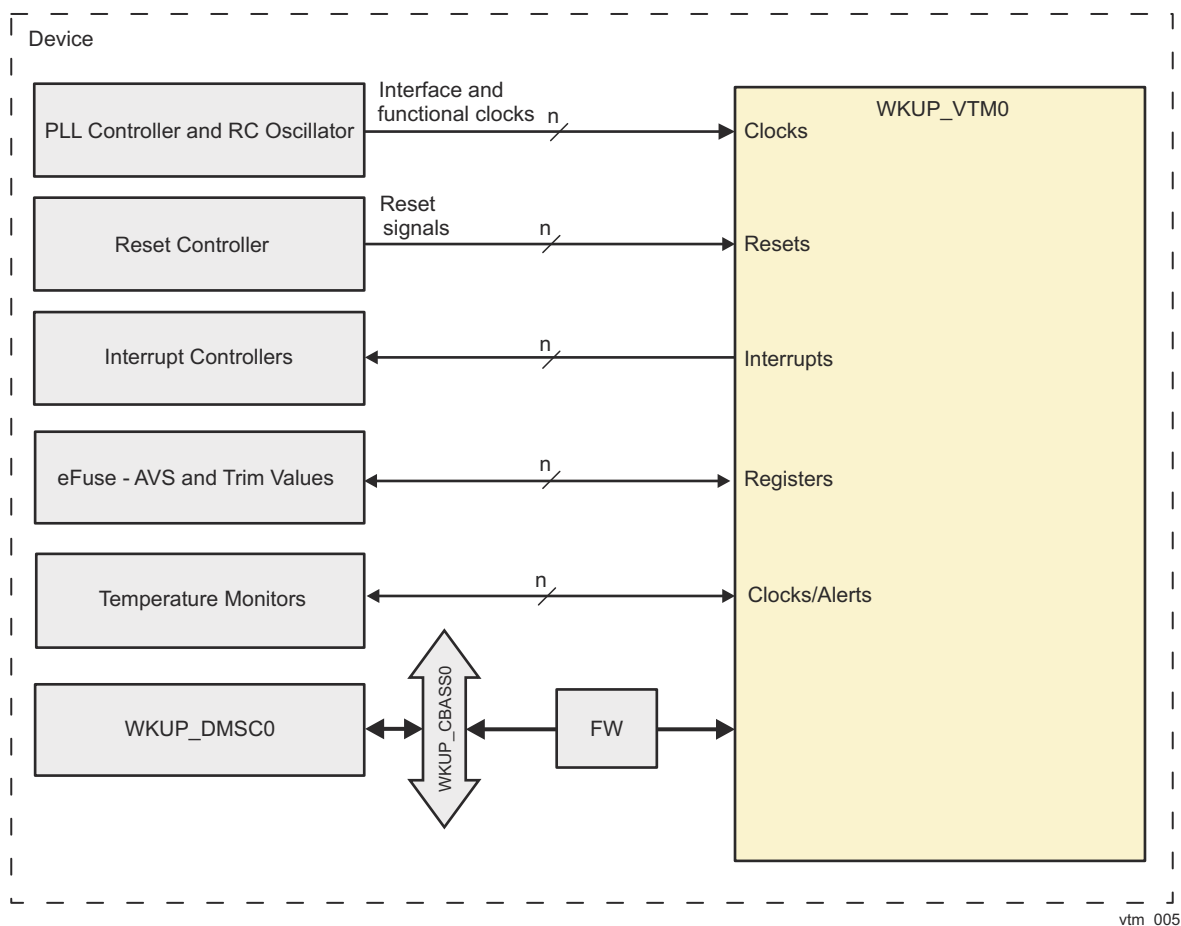

VTM provides the control, status as well as interrupt and event generation related to integrated temperature sensors and thermal events programmed by the user. VTM also contains a set of memory mapped registers that store device-specific operating voltages (AVSVNOM) set during device testing. These values may be used for the system AVS software to adjust operating voltages for the device to achieve optimal operating power.

The device supports one VTM module - WKUP\_VTM0. Table 5-48 shows VTM module allocation within device domains.

**Table 5-48. VTM Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_VTM0	✓	-	-

Figure 5-19 shows VTM module allocation within device domains.

**Figure 5-19. VTM Overview**

#### 5.2.2.1.5.1.1 VTM Features

VTM module supports the following features:

- AVS-Class0 only
- Supports up to 8 temperature monitors

- Programming of temperature-crossing thresholds
- Signals when programmed thresholds are exceeded - up to 3 alerts:
  - Three full reference 10-bit temperature threshold points, THPT1, THPT2 and THPT0.
- Supports up to 8 temperature monitors
- Allows resolution of 0.5°C for temperature reading and threshold point temperature alert/interrupt generation.
- Supports PMIC/LDO set-up with Class-0 VDD-VID settings
- Support of tentative customization of OPP voltage per device (in support of multiple OPPs)
- AVS-voltage or thermal management for up to 8 voltage domains
- Maximum temperature alert
- Supports one shot sampling mode and continuous monitoring mode for the sensors

---

**Note**

The VTM of this family of devices has only 5 temperature sensors.

---

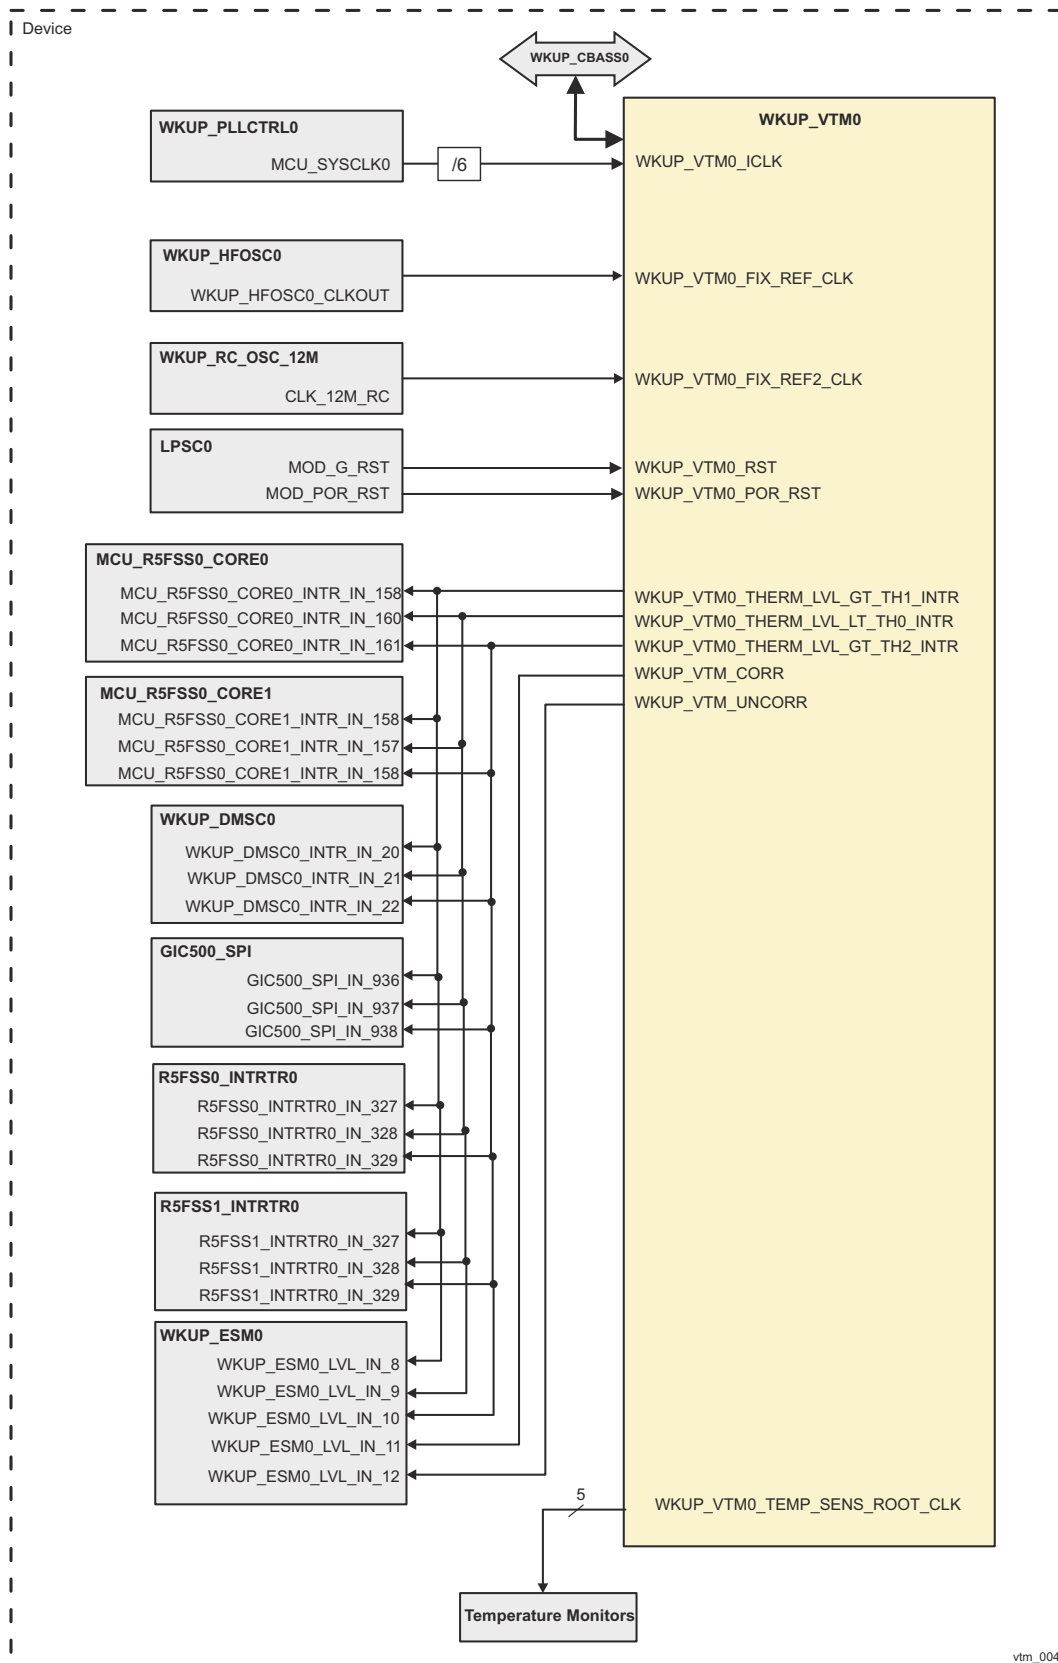

**5.2.2.1.5.1.2 VTM Not Supported Features**

- No support for AVS-Class0 with temperature compensation (AVS0 + TC)
- No integrated I2C inside VTM
- No direct hardware triggering of I2C transactions by VTM
- No support for voltage and thermal management of IO voltage domains
- No oversampling of the temperature reading
- No support for eFuse defaults of all register values

**5.2.2.1.5.2 VTM Integration**

A single VTM module is integrated in the device WKUP domain. [Figure 5-20](#) shows the integration of WKUP\_VTM0.

In this family of devices, five temperature monitors are used.

**Figure 5-20. WKUP\_VTM0 Integration**

Table 5-49 through Table 5-51 summarize the integration of WKUP\_VTM0 in device WKUP domain.

**Table 5-49. WKUP\_VTM0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
WKUP_VTM0	WKUP_PSC0	PD0	LPSC0	WKUP_CBASS0

**Table 5-50. WKUP\_VTM0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
WKUP_VTM0	WKUP_VTM0_ICLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	WKUP_VTM interface clock
	WKUP_VTM0_FIX_R EF_CLK	WKUP_HFOSC0_CLKOUT	WKUP_HFOSC0	Reference clock, used for the sensors

For more information about logical processing of the internal interrupts of VTM, see [Section 5.2.2.1.5.3.2, VTM Temperature Driven Alerts and Interrupts](#).

### 5.2.2.1.5.3 VTM Functional Description

#### 5.2.2.1.5.3.1 VTM Temperature Status and Thermal Management

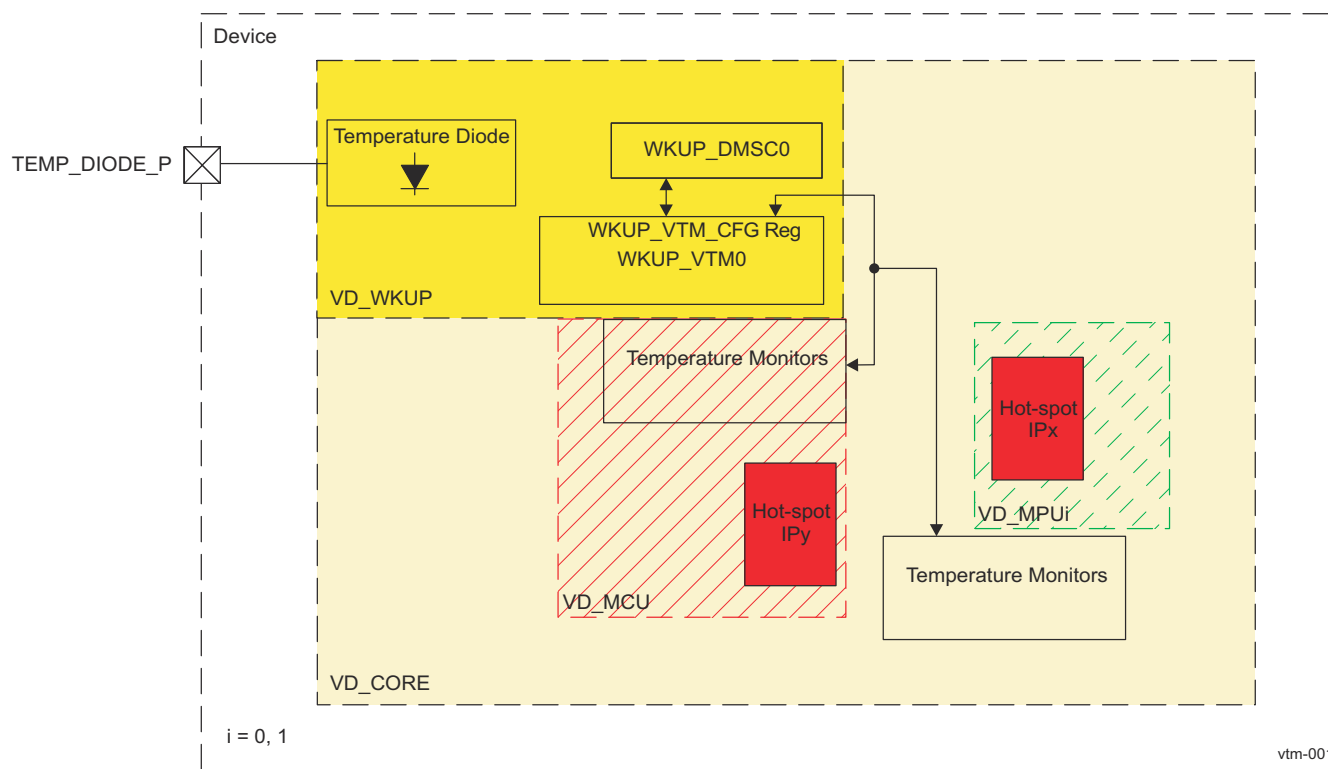

VTM module provides temperature reading and interrupt/alert information for thermal management.

Figure 5-21 shows a high level view of modules required to implement AVS-Class0 and thermal management in the device, VTM included.

VTM controls the temperature monitors in the die. A single VTM can control up to 8 monitors via its registers. The VTM enables the sensors periodically to keep the reported data continually updated because the device sensors are not periodical. The temperature value coming back from the monitor is captured and reported by the VTM registers. The VTM keeps the sensors in reset state when not enabled to save power and reduce sensor usage to maximize the sensor life.

#### Note

This device has 5 integrated temperature monitors.

**Figure 5-21. Top-level IPs for AVS-Class0 and Thermal Management**

#### Note

A temperature diode sensor is used to measure silicon junction temperature, for more information about temperature diode, see the device-specific Datasheet.

#### 5.2.2.1.5.3.1.1 10-bit Temperature Values Versus Temperature

Table 5-52 shows a table lookup method for translating code to temperature from temperature monitors which correspond to the temperature measured read from the VTM0\_VTM\_TMPSENS\_STAT\_J [9-0] DATA\_OUT bitfields. Table 5-52 also provides the values for the temperatures coded in VTM0\_VTM\_MISC\_CTRL2 [25-16] MAXT\_OUTRG\_ALERT\_THR0 and VTM0\_VTM\_MISC\_CTRL2 [9-0] MAXT\_OUTRG\_ALERT\_THR thresholds.

**Table 5-52. Temperature Translation Table**

Parameter Type	Value								
Temperature [°C] (rounded)	-40	-25	0	25	50	75	100	125	150
Temperature [°C] (unrounded)	-40.03	-24.95	0.01	25.02	49.94	75.03	100.02	124.97	150.00
DATA_OUT Code	28	77	164	260	366	485	620	773	949

**Table 5-53** shows a table that gives coefficients of polynomial to calculate code or temperature. The equation to calculate code or temperature is:

$$y = a4 \times x^4 + a3 \times x^3 + a2 \times x^2 + a1 \times x + a0$$

**Table 5-53. Equation Method to Calculate Code or Temperature**

Function	Unit	Coefficient				
		a4	a3	a2	a1	a0
Code = f(Temperature)	Decimal value of code	4.9847E-08	1.6972E-05	6.8759E-03	3.6509E+00	1.6407E+02
Temperature = f(Code)	°C	-9.2627E-12	6.0373E-08	-1.7058E-04	3.2512E-01	-4.9002E+01

#### 5.2.2.1.5.3.2 VTM Temperature Driven Alerts and Interrupts

Each temperature-monitor register group of VTM can be configured to sample the temperature of its corresponding temperature monitor and trigger up to 3 alert (level) signals:

- GT\_TH1\_ALERT (overtemperature alert comparator result) - generated by the 10-bit temperature threshold-point1 (THPT1). Set in VTM\_TMPSENSx\_TH[25-16] TH1\_VAL.
- GT\_TH2\_ALERT (overtemperature alert comparator result) - 10-bit incremental poing generated by threshold-point2 (THPT2). Set in VTM\_TMPSENSx\_TH2[9-0] TH2\_VAL.
- LT\_TH0\_ALERT (undertemperature alert comparator result) - 10-bit incremental poing generated by threshold-point0 (THPT0). Set in VTM\_TMPSENSx\_TH[9-0] TH0\_VAL.

#### Note

The following inequality shall always be valid: THPT2 > THPT1 > THPT0.

#### Note

The device also supports absolute maximum alert (when the die temperature exceeds the programmed temperature in WKUP\_VTM\_MISC\_CTRL2[9-0] MAXT\_OUTRG\_ALERT\_THR) - THERM\_MAXTEMP\_OUTRANGE\_ALERT. For more information about how to handle it, see [Section 5.2.2.1.5.3.7.1, VTM Maximum Temperature Outrange Alert](#).

The level interrupts can be used as follows:

- GT\_TH1\_INT: An early alert for firmware/software to start doing high-temperature thermal management.
- GT\_TH2\_INT: A late interrupt whose level high can be used to trigger a hardware-voltage domain reset.
- LT\_TH0\_INT: A follow-up interrupt to GT\_TH1\_INT which will report to the firmware/software that the temperature has drop to a safe level to eliminate the thermal-management actions triggered in GT\_TH1\_INT.

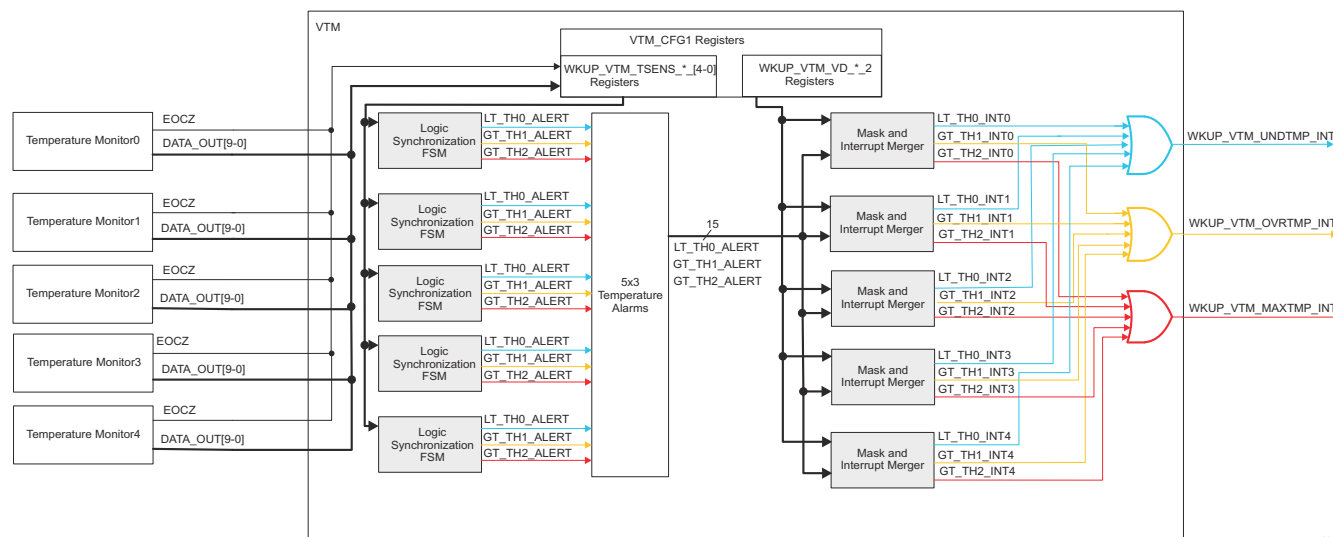

LT\_TH0\_INT, if enabled, will get triggered always when the temperature being read is less than THPT0, regardless of whether GT\_TH1\_INT and GT\_TH2\_INT are enabled, or have ever been triggered. And therefore if LT\_TH0\_INT has to be generated, then firmware/software is responsible to enable the LT\_TH0\_INT only as part of the interrupt service routine of GT\_TH1\_INT and GT\_TH2\_INT. Otherwise it will keep triggering when is not needed.

Each voltage-domain register group can be set to enable and generate the 3 interrupts related to that particular voltage domain. For enabling and disabling the three types of interrupts see the corresponding group of registers:

- for GT\_TH1\_INT - WKUP\_VTM\_GT\_TH1\_INT\_RAW\_STAT\_SET, WKUP\_VTM\_GT\_TH1\_INT\_EN\_STAT\_CLR, WKUP\_VTM\_GT\_TH1\_INT\_EN\_SET, WKUP\_VTM\_GT\_TH1\_INT\_EN\_CLR
- for GT\_TH2\_INT - WKUP\_VTM\_GT\_TH2\_INT\_RAW\_STAT\_SET, WKUP\_VTM\_GT\_TH2\_INT\_EN\_STAT\_CLR, WKUP\_VTM\_GT\_TH2\_INT\_EN\_SET, WKUP\_VTM\_GT\_TH2\_INT\_EN\_CLR
- for LT\_TH0\_INT - WKUP\_VTM\_LT\_TH0\_INT\_RAW\_STAT\_SET, WKUP\_VTM\_LT\_TH0\_INT\_EN\_STAT\_CLR, WKUP\_VTM\_LT\_TH0\_INT\_EN\_SET, WKUP\_VTM\_LT\_TH0\_INT\_EN\_CLR.

All 3 alerts from the 5 temperature monitors are available as inputs of the mask and alert merging logic block of each voltage domain, such that the temperature monitors that are relevant to each voltage domain can be selected as the contributors to the generation of the 3 combined interrupts in each voltage domain (5 shown in sketch; 3 ). This logic is presented in Figure 5-22. The THERM\_MAXTEMP\_OUTRANGE\_ALERT is not shown in this figure. Notice that the same temperature sensor can contribute to more than one voltage domain and each voltage domain can have multiple sensors contributing to the interrupt generation in that VD, see WKUP\_VTM\_VD\_EVT\_SET\_j and WKUP\_VTM\_VD\_EVT\_CLR\_j registers.

**Figure 5-22. VTM Alert and Interrupt Generation**

The interrupts need to be active even when the functional clock is off. In this mode they will be driven by the sensor clock.

#### Note

The interrupts are only active when the sensor is in continuous mode. A one-shot sampling of the sensor will not trigger any interrupts.

Table 5-54 presents the connection of VTM TEMPSENSOR registers groups to voltage domains.

**Table 5-54. VTM TEMPSENSOR Register Groups Mapping to Voltage Domains**

Register Group	Voltage Domain
WKUP_VTM_TMPSENS_*_0	Sensor in VD_WKUP.
WKUP_VTM_TMPSENS_*_1	Sensor in VD_CORE near near MPU region.
WKUP_VTM_TMPSENS2_*_2	Sensor in VD_CC near C7x region.

**Table 5-54. VTM TEMPSensor Register Groups Mapping to Voltage Domains  
(continued)**

WKUP_VTM_TMPSENS_*_3	Sensor in VD_CORE near GPU region.
WKUP_VTM_TMPSENS_*_4	Sensor in VD_CORE near CPSW0 and R5FSS region.
WKUP_VTM_TMPSENS_*[7-6]	Not-used.

There are only 3 interrupts that come out of the VTM module: THERM\_LVL\_LT\_TH0\_INTR, THERM\_LVL\_GT\_TH1\_INTR, THERM\_LVL\_GT\_TH2\_INTR. The interrupt contributions of the 5 voltage domain groups are ORed together to only produce the 3 interrupts that go out. Once an interrupt is detected via DMSC/Compute\_cluster, the firmware/software will check which of the 5 voltage domains is the source of the interrupt.

#### Note

Software shall read the corresponding flags in each of the connected voltage domains to identify which voltage domain is active.

#### 5.2.2.1.5.3.3 VTM VID Voltage Domains

Table 5-55 presents the connection of VTM VD registers groups to voltage domains.

**Table 5-55. VTM VD Register Groups Mapping to Voltage Domains**

Register Group	Voltage Domain
WKUP_VTM_*_VD_*[1-0]	Not-used.
WKUP_VTM_*_VD_*_2	Maps to VD_CC
WKUP_VTM_*_VD_*[7-3]	Not-used.

Table 5-56 shows the relation between the VID bit-field values and voltage.

**Table 5-56. VID Bit-field Values and Their Corresponding Voltage**

0x3A	0.74	0x58	0.89	0x76	1.04		

**5.2.2.1.5.3.4 VTM Clocking**

The VTM has 2 reference clock inputs, WKUP\_VTM0\_FIX\_REF\_CLK and WKUP\_VTM0\_FIX\_REF2\_CLK. The WKUP\_VTM0\_FIX\_REF\_CLK is the high precision clock that is used for the sensors. The WKUP\_VTM0\_FIX\_REF2\_CLK is a lower precision clock that can be used during low power scenarios to keep the sensors running when the WKUP\_VTM0\_FIX\_REF\_CLK is shut off. WKUP\_VTM\_CLK\_CTRL[31] TSENS\_CLK\_SEL and WKUP\_VTM\_CLK\_CTRL[4-0] TSENS\_CLK\_DIV are used to switch between the clocks and to choose the divider value. All the sensors in all VDs controlled by this VTM will run off of the same reference clock.

**Note**

Software must disable all sensors before switching the reference clock.

For more information about propagation sequence of the sensor changes, see [Section 5.2.2.1.5.3.7.3, Sensors Programming Sequences](#).

**5.2.2.1.5.3.5 VTM Retention Interface**

VTM has a general purpose retention interface, consistent of 16 sets of 3 signals that can operate totally independently in order to provide retention for 16 signals in the SoC:

- LPMODE\_SLEEP\_RETIN[15:0]
- LPMODE\_SLEEP\_RETEN[15:0]
- LPMODE\_SLEEP\_RETOUT[15:0]

The input LPMODE\_SLEEP\_RETIN[n] is sampled and synchronized continuously while LPMODE\_SLEEP\_RETEN[n] = 0. The synchronized output is send out via LPMODE\_SLEEP\_RETOUT[n]. Once LPMODE\_SLEEP\_RETEN[n] = 1, then the synchronizer will latch the value and continue providing that latched value via LPMODE\_SLEEP\_RETOUT[n].

**5.2.2.1.5.3.6 VTM ECC Aggregator****Note**

For more information about ECC Aggregator functionality, see *ECC Aggregator*.

### 5.2.2.1.5.3.7 VTM Programming Model

#### 5.2.2.1.5.3.7.1 VTM Maximum Temperature Outrange Alert

THERM\_MAXTEMP\_OUTRANGE\_ALERT is used at the device level in order to generate device warm reset. The alert is asserted when the device overheats and exceeds the maximum temperature limit specified for the device, namely 125°C.

The following is the sequence to assert the THERM\_MAXTEMP\_OUTRANGE\_ALERT:

1. For the output to go active ('1'), the VTM has to be configured to operate with at least one of its temperature sensors enabled, and WKUP\_VTM\_TMPSENS\_CTRL\_j[11] MAXT\_OUTRG\_EN = 1 for the corresponding enabled sensor.
2. In addition, WKUP\_VTM\_MISC\_CTRL[0] ANYMAXT\_OUTRG\_ALERT\_EN has to be set to '1'.
3. With the previous configuration set and at least one of the temperature sensors properly configured, and enabled, if the temperature of the die ever exceeds the programmed value in WKUP\_VTM\_MISC\_CTRL2, the VTM output will be driven '1' once the sensor detects the programmed maximum temperature.
4. At the device level the VTM output, THERM\_MAXTEMP\_OUTRANGE\_ALERT, will drive the PLL controllers into warm reset state with the PLL controllers entering CHIP\_0\_RST condition, at the same time that all the PLLs go into clock bypass mode.
5. By the actions described in No.4, the device will considerably reduce its power consumption, which over the passing of a few seconds will cause the device to reduce its temperature.
6. The VTM sensor continues to read the temperature and once the code corresponding to the programmed value in WKUP\_VTM\_MISC\_CTRL2[25-16] MAXT\_OUTRG\_ALERT\_THR0 is detected the VTM drives THERM\_MAXTEMP\_OUTRANGE\_ALERT = 0.
7. After No.6 is fulfilled, the PLL controllers no longer have the THERM\_MAXTEMP\_OUTRANGE\_ALERT driving the CHIP\_0\_RST request and thus the PLL controllers bring the SoC out of reset and the boot sequence re-starts. At the same time the PLLs get out of bypass mode and start with their target programmed frequencies for the boot process.

#### Note

THERM\_MAXTEMP\_OUTRANGE\_ALERT output of VTM is mapped to WKUP\_VTM\_MISC\_CTRL[0] ANY\_MAXT\_OUTRG\_ALERT\_EN.

Notice that exceeding of the programmed value in WKUP\_VTM\_MISC\_CTRL2[9-0] MAXT\_OUTRG\_ALERT\_THR boundary doesn't result in a PORz (cold reset) event, but instead a CHIP\_0\_RST event. Otherwise if cold reset is applied to the MCU/WKUP domains of the device, the VTM will be fully reset and the output THERM\_MAXTEMP\_OUTRANGE\_ALERT will be cleared to '0' immediately.

#### 5.2.2.1.5.3.7.2 Temperature Monitor during Low Power Modes

For more information about device Low Power Modes (LPM), see *Device Power States*.

The following sequence has to be follow in LPM:

1. During MCU\_ONLY LPM VD\_CORE is OFF and VD\_MCU and VD\_WKUP are ON, so:
  - WKUP\_VTM\_TMPSENS\_CTRL\_1[1] TMPSOFF needs to be programmed for the sensor to be disabled and WKUP\_VTM\_TMPSENS\_CTRL\_1, and VTM\_TMPSENS\_TRIM\_1 registers settings for this sensor to go to its reset state.
2. If the exit from low power modes in the device results in the VD\_CORE also being ON, then at that point the remaining TMPSENS modules can be enabled (WKUP\_VTM\_TMPSENS\_CTRL\_1, WKUP\_VTM\_TMPSENS\_TRIM\_1 registers).

#### 5.2.2.1.5.3.7.3 Sensors Programming Sequences

##### Sensors Control Modifications Sequence:

1. Write changes to registers.
2. Wait for 900ns to 1us (long enough for sensor period of slowest 1.15 MHz sensor clock plus some extra).
3. New changes can be written to registers.

### Sensors TRIM Pins Modifications Sequence:

1. Clear WKUP\_VTM\_TMPSENS\_CTRL\_j[6] CLRZ to disable the sensor, so that it has the ENA input low.
2. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin .
3. Update the WKUP\_VTM\_TMPSENS\_TRIM\_j registers.
4. Wait for 900ns to 1us for the sensor clock to toggle and register to updated TRIM pins while ENA is low.
5. Now the sensor can be enabled normally.

### Reset Sensors Sequence:

1. Set the WKUP\_VTM\_TMPSENS\_CTRL\_j[6] CLRZ bit to enable the sensor (so that it has the ENA input high).
2. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
3. Clear WKUP\_VTM\_TMPSENS\_CTRL\_j[6] CLRZ to disable and reset the sensor (as it requires an ENA transition from 1 to 0 to reset initially) .
4. Wait for 900ns to 1us for the sensor clock to toggle and register the updated ENA pin.
5. Now the sensor can be configured and enabled normally.

#### 5.2.2.1.5.3.8 AVS-Class0

Adaptive Voltage Scaling (AVS) Class 0 is a procedure for lowering the voltage on certain device power rails. AVS Class 0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

AVS can be enabled by system software after primary boot. Refer to *AVS Support* on how to enable AVS based on these registers.

#### 5.2.2.1.6 Distributed Power Clock and Reset Controller (DPCR)

DPCR module is instantiated at the chip level for every power managed sub-chip to support power management features, local clock alignment, DFT power management overrides, isolation controls for self-test and clocking for LBIST. It is also help standardizing interfaces between moduels/sub-chips and central power management, clocking and reset infrastructure at the chip-level.

DPCR contains following sub-modules:

- Distributed Clock Aligner - aligns clock dividers inside power managed block/sub-chip whenever the block goes through power-down/power-up sequence.
- Distributed Clock Aligner for other PLLs - similar functionality as the Distributed Clock Aligner and is used for sub-chips clocked by other PLLs in addition to main/core PLL.
- Distributed RAM Power Controller - is used for power management sequencing for embedded memories. It supports up to eight separate memory groups.
- Distributed Power Chain Controller - controls sequencing of power switch chains inside power managed sub-chips.

All of the above modules are entirely hardware modules, the exception is Distributed RAM Power Controller. It has RAM\_SLEEPMODE pins that are conntrolled via PSC (see corresponding WKUP\_PSC0\_PDCTL\_y[14-12] PDMODE or PSC0\_PDCTL\_y[14-12] PDMODE). [Table 5-57](#) shows the memory power state dependend on the value of the bitfields in PSC registers.

**Table 5-57. RAM\_SLEEPMODE Settings for Memory Power States**

RAM_SLEEPMODE Value	Memory Power State
0x0	Core Off, RAM Array Off, RAM Periphery Off
0x1	Core Off, RAM Array Retention, RAM Periphery off (DeepSleep)
0x2	Reserved <sup>(1)</sup>
0x3	Reserved
0x4	Core Retention, RAM Array Off, RAM Periphery Off

**Table 5-57. RAM\_SLEEPMODE Settings for Memory Power States (continued)**

RAM_SLEEPMODE Value	Memory Power State
0x5	Core Retention, RAM Array Retention, RAM Periphery Off (DeepSleep)
0x6	Reserved
0x7	Reserved
0x8	Core On, RAM Array Off, RAM Periphery Off
0x9	Core On, RAM Array Retention, RAM Periphery Off (DeepSleep)
0xA	Core On, RAM Array Retention, RAM Periphery Off (LightSleep)
0xB	Core On, RAM Array Retention, RAM Periphery On
0xC	Reserved
0xD	Reserved
0xE	Reserved
0xF	Core On, RAM Array On, RAM Periphery On

(1) Reserved values default to 0xF (Core On, RAM Array and Periphery On)

### 5.2.2.2 Power Control Modules

The Power Control Modules are divided into two section, dependent on their functionality - Power Sleep Controller and Local Power Sleep section and Integrated Power Management (DMSC) section.

#### 5.2.2.2.1 Power Sleep Controller and Local Power Sleep Controllers

The Power Sleep Controller (PSC) includes a Global Power Sleep Controller (GPSC) and a number of Local Power Sleep Controllers (LPSC) that control overall device power by turning off unused power domains and gating off clocks to individual peripherals and modules. The PSC provides the user with an interface to control several important power and clock operations.

The device has two PSC - WKUP\_PSC0 and PSC0 in WKUPSS and MAIN SoC, respectively.

##### 5.2.2.2.1.1 PSC Terminology

Term	Definition
<b>LPSC</b>	Local Power Sleep Controller; one per module (domain)
<b>GPSC</b>	Global Power/Sleep Controller; manages the LPSCs
<b>PSC</b>	Power Sleep Controller, including one GPSC and multiple LPSCs

##### 5.2.2.2.1.2 PSC Features

The PSC includes the following features:

- Provides software interface to:
  - Control module power on or off
  - Control module clock on or off
- Supports emulation features: power, clock, and reset.

For more information on how to control the PSC see [Section 5.2.2.2.1.5, PSC: Executing State Transitions and PSC Registers](#).

#### Note

PSC functions are controlled via DMSC. For more information how to use DMSC, see TISCI API available at ti.com.

##### 5.2.2.2.1.3 PSC: Device Power-Management Layout

The device is divided into a number of separate voltage domains each containing specific processing cores and peripherals. This division enables the device to achieve lower power dissipation profiles by allowing the power supplies to unused domains to be completely turned off.

Each PSC in the device has several power domains that can be turned on for operation or off to minimize power dissipation. The Global Power Sleep Controller (GPSC) is used to control the power gating of various power domains.

Clock gating to each logic block is managed by the Local Power Sleep Controllers (LPSCs). For modules with a dedicated clock or multiple clocks, the LPSC communicates with the PLL controller to enable and disable that module's clock(s) at the source. For modules that share a clock with other modules, the LPSC controls the clock gating logic for each module.

##### 5.2.2.2.1.3.1 WKUP\_PSC0 Device-Specific Information

[Table 5-58](#) provides the device-level view with module asSoCiations to the clock, power, and voltage domains.

**Table 5-58. WKUP\_PSC0 Power Management Device-Level Layout**

VD Name	PD Name	PD Index	LPSC Name	LPSC Index	Modules

			LPSC_MCU_R5FF0_1	20	MCU_RT0I1, MCU_R5FF0_CORE1
			LPSC_MCU_R5FF0FSS_PBI0ST_0	21	MCU_R5FF0_PBI0ST

### Note

For details on power domain state transitions, please refer to [Section 5.2.2.2.1.5, Executing State Transitions](#).

[Table 5-59](#) presents presents Power Domain features for WKUP\_PSC0.

**Table 5-59. WKUP\_PSC0 Power Domain Features**

PD index	PD name	GP(always on)/PD/ PDM(memory power domain only)	Default Power Domain state	PD State Software Controlled
0	GP_CORE_CTL_WKUP	GP <sup>(1)</sup>	AO <sup>(3)</sup>	NO
1	PD_MCU_R5FF0FSS	PD <sup>(2)</sup>	ON	YES

(1) Group with common power - means that there are no power switches. The group is considered always-on.

(2) Power switched domain - means this is a full power switched domain, there are logic power-switches and memory power-switches if there are memories.

(3) AO = AlwaysOn

[Table 5-60](#) presents LPSCs features.

**Table 5-60. WKUP\_PSC0 LPSC Features**

LPSC Index	LPSC Name	Default LPSC State	Efuse Disable Availability	LPSC State Software Controlled	Reset Isolation

**Note**

For details on module state transitions, please refer to [Section 5.2.2.1.5, Executing State Transitions](#).

**Note**

For information about LPSC Dependencies, see [Section 5.2.2.1.3.3, LPSC Dependencies Overview](#).

### 5.2.2.2.1.3.3 LPSC Dependences Overview

Table 5-64, Table 5-65, Table 5-66, Table 5-67, and Table 5-68 depict the dependences among the LPSC in both PSCs - WKUP\_PSC0 and PSC0. The matrices are used in the following way:

- Enabling a LPSC - to check if another LPSC has to be enabled before a specific LPSC, take the specific LPSC column (find its name in one of the LPSC Dependences tables) and check if there is Y mark in this parts of the LPSC Dependences tables. All LPSC makred as Y should be enabled before enabling the specific LPSC.
- Disabling a LPSC - to disable a LPSC, take the specific LPSC row and check if there is Y mark in all five parts of the LPSC Dependences tables. All LPSC makred as Y should be disabled before enabling the specific LPSC.

In red are the LPSC that are always on. In green are those that are default on. For more information about default state and reset isolation of the LPSC see Table 5-60 and Table 5-63. For more information about reset isolation see *Reset*.

#### 5.2.2.2.1.4 PSC: Power Domain and Module States

The PSC organizes device modules into different power domains and into different module domains (clock domains). Note that there is no relationship between a power domain and a module domain. These are completely separate entities and may be controlled separately.

##### 5.2.2.2.1.4.1 Power Domain States

A power domain can be only in one of the two states (ON or OFF), defined as follows:

- **ON:** Power to the power domain is on. Logic/memories are awake.
- **OFF:** Power to the power domain is off. Logic/memories are turned off.

The AlwaysOn power domain in WKUP domain is always in the ON state when the device is powered on. The AlwaysOn power domain in MAIN domain is software controlled and is in OFF state in MCU-ONLY and DeepSleep modes. The other power domains can be in either the ON or OFF state; that is, the logic/memory for a specific module can remain powered down if it is not used.

##### 5.2.2.2.1.4.2 Module States

A module can be in one of the following states: *Disable*, *Enable*, *SwRstDisable*, or *SyncRst*. As shown in [Table 5-69](#), these states correspond to combinations of module reset asserted or de-asserted and module clock on or off. Note that module reset is defined as to a full reset of a given module, such that all hardware is put back into its default state.

**Table 5-69. Module States**

Module State	Module Reset	Module Clock	Disabled Request to Interconnect	VBUS Request
Disable	De-asserted	OFF	Asserted	Re-directed to Infrastructure NULL endpoint.
Enable	De-asserted	ON	De-asserted	VBUS requests are served.
SwRstDisable	Asserted	OFF	Asserted	Re-directed to Infrastructure NULL endpoint.
SyncRst	Asserted	ON	Asserted	Re-directed to Infrastructure NULL endpoint.

##### 5.2.2.2.1.4.3 Local Reset

In addition to module reset described in the previous section, some modules can be reset using a special local reset, see [Table 5-70](#) and [Table 5-71](#). When local reset is asserted, the internal memories (L1P, L1D, and L2) for the core are still accessible. The local reset resets only the corresponding module, not the rest of the chip. Local reset is intended to be used by the watchdog timers to reset the processor core in the event of an error. The procedures for asserting and de-asserting local reset are as follows (y denotes the module domain number):

1. Set WKUP\_PSC0\_MDCTL\_y[8] LRST or PSC0\_MDCTL\_y[8] LRST to 0x0 to assert local reset.
2. Set WKUP\_PSC0\_MDCTL\_y[8] LRST or PSC0\_MDCTL\_y[8] LRST to 0x1 to de-assert local reset.

**Table 5-70. Local Reset of Modules Controlled by WKUP\_PSC0**

#### 5.2.2.2.1.5 PSC: Executing State Transitions

This section describes how to execute state transitions for power domains and modules. Examples show how to enable only power domains, only module domains, or a combination. Although the user has complete control of the sequencing, see [Section 5.2.2.2.1.5.4, Recommendations for Power Domain/Module Sequencing](#) for recommendations.

##### 5.2.2.2.1.5.1 Power Domain State Transitions

This section describes the basic procedure for transitioning the state of a power domain.

#### Note

The PD\_WKUP power domain is always in the ON state when the device is powered-on, and therefore it is not possible to transition this domain to the OFF state. Conversely, the other domains are in the OFF or ON state when the device is powered-on. Transitions between ON and OFF states need to follow the procedure below. See the device-specific Datasheet and respective module Technical Reference Manual chapter for any other considerations especially while turning off the power domain.

The procedure for power domain state transitions is shown below (x denotes the power domain number, y denotes the module domain number):

1. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to clear to 0. Wait for any previously initiated transitions to finish before initiating a new transition.
2. Set WKUP\_PSC0\_PDCTL\_y[0] NEXT or PSC0\_PDCTL\_y[0] NEXT for an ON (1) or OFF (0) transition. NOTE: When WKUP\_PSC0\_PTCMD[x] GO or PSC0\_PTCMD[x] GO is set to 1 in the next step, the PDCTLx[0] NEXT field of this power domain and the WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT field of the module in this power domain are evaluated. Therefore, the WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT field may be set for multiple modules before executing this step.
3. Set WKUP\_PSC0\_PTCMD[x] GO or PSC0\_PTCMD[x] GO to 1 to initiate the state transition(s). The PSC turns on or off the logic/memory for that particular domain.
4. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to self-clear to 0. The domain is safely in the new state only after WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT is cleared to 0.

##### 5.2.2.2.1.5.2 Module State Transitions

This section describes the procedure for transitioning the module state.

### Note

The following procedure is applicable for all LPSC-controlled modules. To transition the module state, one must be aware of several system considerations. Transitions between Enable and Disable states need to follow the procedure below. See the device-specific Datasheet and peripheral chapter for any other considerations especially while transitioning a module to Disable state. Also, before transitioning a module to Enable, if the logic/memories are not in the PD\_WKUP and GP\_CORE\_CTL power domains, they must be turned on before or in parallel with the transition. See [Section 5.2.2.2.1.5.1, Power Domain State Transitions](#).

The procedure for module state transitions is shown below (x denotes the power domain number, y denotes the module domain number):

1. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to clear to 0x0. Wait for any previously initiated transitions to finish before initiating a new transition.
2. Set WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT to Enable (0x3) or Disable (0x0). Note that transitions in multiple WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT fields may be set in this step as long as the corresponding power domain is on.
3. Set WKUP\_PSC0\_PTCMD[x] GO or PSC0\_PTCMD[x] GO to 1 to initiate the transition(s).
4. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to self-clear to 0. The module is safely in the new state only after WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT clears to 0.

#### 5.2.2.2.1.5.3 Concurrent Power Domain/Module State Transitions

This section describes the basic procedure for transitioning the state of a power domain and module domain for modules that are not in the AlwaysOn domain. This may be done separately as described in the sections above, if desired.

The procedure for concurrent power domain/module state transitions is shown below (x denotes the power domain number, y denotes the module domain number):

1. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to clear to 0. Wait for any previously initiated transitions to finish before initiating a new transition.
2. Set WKUP\_PSC0\_PDCTL\_y[0] NEXT or PSC0\_PDCTL\_y[0] NEXT for an ON (1) transition.
3. Set WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT to Enable (0x3). Note that transitions in multiple WKUP\_PSC0\_MDCTL\_y[4-0] NEXT or PSC0\_MDCTL\_y[4-0] NEXT fields may be set in this step as long as the corresponding power domain is on.
4. Set WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to 1 to initiate the state transition(s). The PSC will turn on the logic/memory for that particular domain, starts the module clock, then de-asserts the module reset.
5. Wait for WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT to self-clear to 0. The module is safely in the new state only after WKUP\_PSC0\_PTSTAT[x] GOSTAT or PSC0\_PTSTAT[x] GOSTAT clears to 0.

#### 5.2.2.2.1.5.4 Recommendations for Power Domain/Module Sequencing

As noted in [Section 5.2.2.2.1.4, Power Domain and Module States Defined](#) and [Section 5.2.2.2.1.5, Executing State Transitions](#), a particular peripheral's power domain must be enabled before the module is enabled.

Unless there is a system-level reason to perform each function separately, the recommendation is to use the sequence listed in rather than individual sequencing. Even though a single write to the appropriate GO bit starts the power domain and module transition, it is still sequenced such that the memory/logic is certain to turn on before the module is enabled. Thus, there is no ill effect in performing these together.

It is important to know that when a power domain is enabled, all logic/memories for that module are immediately turned on and moved to an active state. This means that there will be a spike in current consumption at that particular time. In other words, di/dt will be affected. To minimize the effect on di/dt of enabling power domains, it is recommended to power up modules one at a time. It is also recommended that all modules be initialized early

in the application to avoid a large spike in  $di/dt$  during normal operation where the application may already be drawing a substantial amount of current from the supply.

#### 5.2.2.2.1.6 PSC: Emulation Support in the PSC

The PSC supports commands that allow emulation tools to have some control over the state of power domains and modules.

In particular, the PSC supports the following emulation commands:

- Power on and enable features:
  - **Force Power:** Allows emulation to force the power domain into an ON state.
  - **Force Active:** Allows emulation to force the power domain into an ON state and force the module into the Enable state.
- Reset features:
  - **Assert Reset:** Allows emulation to assert the module's local reset.
  - **Wait Reset:** Allows emulation to keep local reset asserted for an extended period of time after software initiates local reset de-assert.
  - **Block Reset:** Allows emulation to block software initiated local and module resets.

Local reset applies only to the domains listed in [Table 5-70](#) and [Table 5-71](#); module reset applies to all other domains.

#### 5.2.2.2.1.7 PSC: A72SS, MSMC, MCU Cortex-R5F, C71SS0, and C66SS Subsystem Power-Up and Power-Down Sequences

##### 5.2.2.2.1.7.1 ARMi\_COREn Power State Transition

Each ARMi\_COREn has its own power domain, see [Table 5-61](#). Each (PD\_A72\_k) of these power domains can be transitioned independently. [Table 5-72](#) lists the possible A72 Core power states. See also [Figure 5-23](#) for the power states of a core. No ARMi\_COREn can transition out of the ARMi\_COREn\_OFF or ARMi\_COREn\_RESET states unless respective CC\_ARMSS is in the A72SS\_ON state.

ARMi\_COREn can be in either WFI or WFE state after executing a WFI (Wait for Interrupt) or WFE (Wait For Event) Instruction, in which the block is On, but has additional clock gating applied to lower power.

**Table 5-72. A72 Core Power States**

Power Domain (PD_A72_n)	L2 Domain	L2 RAM Domain	Processors State
OFF	OFF	OFF	OFF
L2 Dormant Mode <b>Not supported in this family of devices.</b>	OFF	ON	OFF
		RET <sup>(1)</sup>	
L2 Retention Mode <b>Not supported in this family of devices.</b>	ON	RET	WFx <sup>(1)</sup>
			RET
			OFF
ON	ON	ON	ON
			WFx
			RET
			OFF

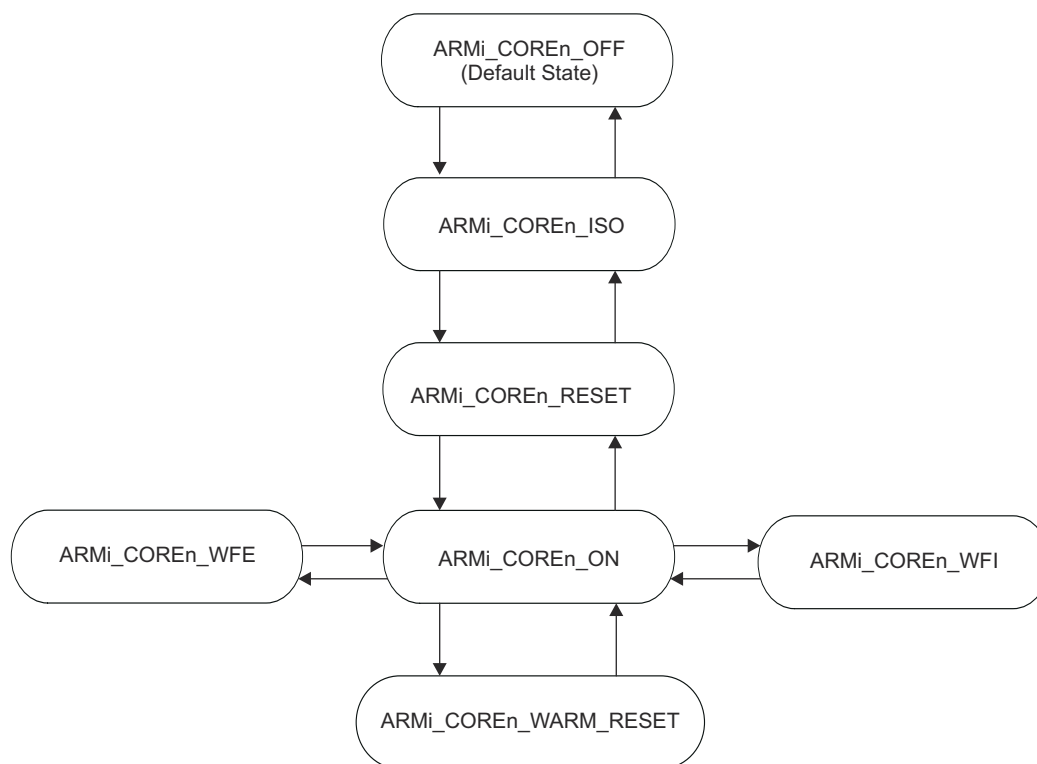

(1) RET = Retention; WFx is either WFI or WFE

#### Note

Note that this family of device does not support retention. For more information about the Arm A72 core transitions among the power states, see Power Management Section in Arm® Cortex®-A72 MPCore Processor Technical Reference Manual, available at <http://infocenter.arm.com/help/index.jsp>.

### Note

Cold reset signal of the ARMi\_COREn of A72SS is directly mapped to PORz reset on PSC0. The primary reset signals are directly mapped to MOD\_G\_RST on PSC0.

power-004

**Figure 5-23. ARMi\_COREn Power Transitions**

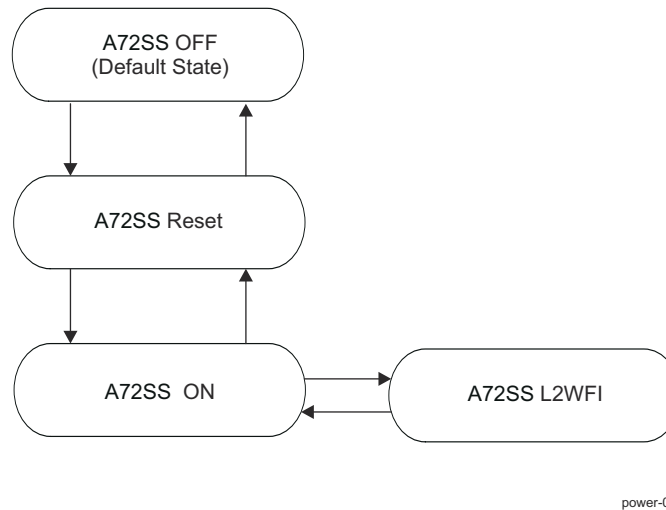

#### 5.2.2.1.7.2 A72SS Power State Transition

Each A72SS has its own power domain, see [Table 5-61](#). Each (PD\_A72\_Cluster\_i) of these power domains can be transitioned independently. See [Figure 5-23](#) for the power states of the A72SS.

If at least one ARMi\_COREn is ON, the respective CC\_ARMSS power domain has to be ON. The sequencing shall ensure that all cores except Core 0 are powered down (in ARMi\_COREn\_ISO or ARMi\_COREn\_OFF state) and CORE 0 is in ARMi\_CORE0\_RESET state before respective CC\_ARMSS domain can be powered down.

### Note

For more information about the Arm A72 cluster transitions among the power states, see Power Management Section in Arm® Cortex®-A72 MPCore Processor Technical Reference Manual, available at <http://infocenter.arm.com/help/index.jsp>.

**Figure 5-24. A72SS Power Transitions**

#### 5.2.2.1.7.3 GIC0 Sequencing to Support A72SS Power Management

When a CC\_ARMSS is to be powered down or with gated clocks, system shall disable sending any type of interrupts - LPI/PPI/SPI, to that A72SS. Also, sending any transactions over the AXI streaming interface to the A72SS shall be disabled.

GIC0 wake-up signal is connected to WKUP\_DMSC0. WKUP\_DMSC0 will have to wake-up the A72SS if a specific core is expected to service an interrupt and the core is powerdown or with gated clock.

#### 5.2.2.1.7.4 Power management features supported by C7x Corepac

Table 5-73 lists the supported power states of C7x Corepac.

**Table 5-73. Power Management Support by C7x**

Memory	Logic	Clock/Reset	C7x Corepac
OFF	OFF	Clockgated + reset	Supported
OFF	ON	Clockgated	Not supported
OFF	ON	Clockgated + reset	Supported
Retention (reton/retgood in tagrams's, not RTA)	ON	Clockgated	Supported
Retention	OFF	-	Not supported
Retention	ON	Reset	Not supported

#### 5.2.2.1.7.5 C7x CorePac Clkstop/Powerdown/Disconnect Sequencing

1. C7x PBIST CLKSTOP/ACK handshaking should be complete.
2. Software to program DRU to disable any L2 pre-warm or MMU pre-warm:
  - a. DRU DTR/pre-warm initiated by that core: Software in the C7x corepac should ensure completion.
  - b. DRU DTR/pre-warm initiated by other cores
3. Programmer executes specific sequence to initiate disconnect in response to a secure interrupt:
  - a. System software to reprogram CLEC router to disable events to C7x CorePac
  - b. Streaming Engine (SE) open streams should have been closed.
  - c. Flush L1D cache with MVC L1D ECR instructions.
  - d. Flush L2 cache with MVC L2 ECR instructions and set L2\$ size = 0 (any pre-warms from system will not generate MDMA traffic).
  - e. Execute IDLE instruction. The IDLE instruction monitor idle status of L1I, L1D, SE, CMMU, MMA blocks and send out an overall idle status to powerdown controller by monitoring the following:

- i. Loads/Stores: The CPU keeps track of load/store operations itself to know when they have completed.
  - ii. Instruction Fetch: The CPU tells the PMC to stop instruction prefetching and keeps track of when the PMC has stopped fetching new instructions.
  - iii. Streaming Engine: The CPU monitor the TSR register SE\_ACTIVE bits to ensure all streaming engines have been closed. Also, in the case of a CMO or cache pre-warm stream, the SE will send an “SCOHERENCE\_ACTIVE” signal to the CPU to let CPU know that all transactions that it initiates to L2 has completed.
  - iv. CPU\_IDLE asserted
  - v. CorePac level idle asserted. This signal is readable through the DMSC memory-mapped “corepac power management status register”. This signal represents a combination of the below idle signals:
    1. CPU\_IDLE
    2. UMC\_IDLE.
4. System asserts MSMC\_\*\_CPU\_PWR\_SCR\_DISABLE\_REQ to Compute Cluserter.
  5. Compute Cluserter level asserts MSMC MSMC\*\_CPU\_PWR\_SCR\_DISABLE\_REQ
    - This ensures that MSMC will not send any snoops/SDMA into C7x corepac
    - New transactions from MSMC into C7x CorePac will be stalled.
  6. System waits for MSMC\_\*\_CPU\_PWR\_SCR\_DISABLE\_ACK from MSMC\_CORE and asserts MSMC\_\*\_CPU\_PWR\_SCR\_DISABLE\_DONE
    - Ensures that all outstanding transactions to C7x are complete.
    - All new transactions to C7x CorePac are terminated with error status in MSMC.
  7. System asserts COREPAC\_CLKSTOP\_REQ (could be asserted anytime earlier as well).
  8. C7x CorePac asserts COREPAC\_CLKSTOP\_ACK
    - Qualified with idle of all corepac components and CLKSTOP\_ACK of debug components.
  9. C7x CorePac can be clockgated.

---

#### Note

Once the CorePac is disconnected from MSMC, it can be clockgated or powered-down. If clockgated, clocks can be restarted and CLEC events can be reprogrammed to wakeup the core.

System has to ensure that CLEC events to a C7x CorePac are disabled prior to clockgating or powerdown of that corepac.

---

#### Note

For more information about C7x signals and registers, see [Section 6.5, C71x DSP Subsystem](#).

---

##### 5.2.2.2.1.7.6 MSMC0 Clkstop/Powerdown/Disconnect Sequencing

The following sequence has to be performed in order to gate the MSMC0 clock:

1. All A72SS connected to MSMC0 shall be in clkstop (or) powerdown state:
  - a. Ensure that all Direct-TR initiated by the respective core is complete (by polling TR complete register).
  - b. A72SS powerdown sequencing are described in the respective sections in Arm® Cortex®-A72 MPCore Processor Technical Reference Manual, available at <http://infocenter.arm.com/help/index.jsp>.
  - c. This ensures that MSMC\_\*\_CPU\_PWR\_SCR\_DISABLE\_ACK is asserted for all CorePacs (and EN\_ACK if connected to an Arm CorePac are IDLE).
  - d. Note that L3 cache may have dirty lines at this point and needs to be written back to DDRSS0 RAM.
2. DRU has to be taken into idle state:
  - a. System software ensures that DRU does not initiate any new requests.
  - b. UDMA-P initiated TR need to be completed.
  - c. System de-asserts the PSIL link slave port of NAVSS0 to DRU.
3. System ensures that VBUSP\_CFG, VBUSP\_DBG, and VBUSP\_DMSC slave ports are disconnected in CBASS0.

4. System software guarantees that SoC0/SoC1 ports do not initiate any transactions to DDRSS0 or MSMC0 SRAM.
5. System software to disable MSMC0 scrubber.
6. System software to change L3 cache size to 0 by writing to MSMC0 CACHE\_CTRL register:
  - a. Note: This operation has to done by secure software running in WKUP\_DMSC0 only. User code shall not be allowed to change L3 cache size.
  - b. Results in L3 cache flush to DDRSS0.
  - c. Software to poll MSMC0 CACHE\_CTRL register to ensure that L3 cache size change is complete.
7. PSC0 disconnects DDRSS0 slave interfaces of MSMC0 and MSMC0 core asserts `MSMC_*_EMIF_PWR_SCR_DISABLE_ACK`.
8. PSC0 ensures SoC0 slave port from NAVSS0 to MSMC0 is disconnected at NAVSS0. Note that this will result in WKUP\_DMSC0 not being able to access MSMC0 control registers.
9. PSC0 disconnects SoC0/SoC1 slave interfaces of MSMC0 and MSMC0 core asserts `MSMC_*_SoC*_PWR_SCR_DISABLE_ACK`.
10. System asserts `MSMC_CLKSTOP_REQ`.
11. `MSMC_WRAP` asserts `MSMC_CLKSTOP_ACK`. This factors in idle of all the `MSMC0_WRAP` components as well:
  - a. `MSMC_CORE_IDLE`, `DRU_IDLE`
  - b. `VBUSP_DBG`, `VBUSP_CFG`, `VBUSP_DMSC` interfaces idle
  - c. `DRU_PSIL_LINK` (output of MSMC) is '0' – denotes disconnected.
12. System can gate the clocks to `MSMC_WRAP`.

#### 5.2.2.2.1.7.7 MCU Cortex-R5F Power Modes

Table 5-74 describes the possible power modes of MCU Cortex-R5F.

**Table 5-74. MCU Cortex-R5F Core Power States**

Mode	CPU Clock Gated	CPU Logic Powered	CPU RAMs powered	Exit to Run Mode Requires
RUN	NO	YES	YES	-
STANDBY	When Idle	YES	YES	Pipeline restart
DORMANT Not supported in this family of devices.	YES	NO	YES	Pipeline restart. Restore registers and configuration from memory
OFF	YES	NO	NO	Pipeline restart. Restore registers and configuration from memory. Invalidate caches and reinitialize caches and TCMs. DMSC intervention.

#### 5.2.2.2.1.7.8 C66x\_DSPSS Power Sequences

Power-on corepac sequence follows this order:

1. The processor C66x\_DSPSS is off.
2. The processor is first powered up by turning on the power switch. At this step, the clock remains off.
3. Asynchronous `clk_divalign` reset is asserted to reset the clocks.
4. `ASYNCLCK_DIVALIGN` reset is deserted, all clocks will start toggling at the desired frequencies.
  - For C66x\_DSPSS, the input clock is `C66_CLK1_CLK` and `PLL_CTRL_CLK`
5. After clock is brought up, POR reset should take place and set debug, PBIST logic in starting state before de-asserted. After POR reset is de-asserted for n cycle which guaranteed the reset took effect, the processor CorePac is powered up, therefore, `ISO_ON` can be de-asserted.
6. Then the processor or core functional logic should be brought to life by de-assert the `CLKSTOP_REQ`, `CLKSTOP_ACK` will follow
7. Finally, the warm `MOD_G_RST` is de-asserted a few cycles to start the processor function.

DSP clock, reset and Power management sequencing in detail:

Power-up:

1. The processor corepac is off.
2. The processor is first powered up by turning on the power switch.
3. ASYNC\_CLK\_DIVALIGN reset is asserted, all clocks will start toggling at the desired frequencies.
4. CLK\_EN should be asserted for a few cycles then deasserted while the corepac is still in reset to bring everything to reset values (acknowledge will follow).
5. After clocks have been brought up, POR\_RST should be deasserted for the corepac.
6. ISO\_EN should be deasserted to disable the isolation cells.

Corepac enable:

1. CLK\_EN should be asserted for a few cycles then deasserted while the corepac is still in reset to bring everything to reset values (acknowledge will follow)
2. MOD\_G\_RST should be deasserted to bring the corepac out of reset.
3. CLK\_EN should be asserted to give the module functional clocks (acknowledge will follow)
4. CLKSTOP\_REQ should be deasserted (and the acknowledge will follow).

SW\_RST\_DISABLE:

1. Processor is put in idle mode by IDLE instruction.
2. Assert CLKSTOP\_REQ in corepac (processor will ensure system is idle before responding with acknowledge).
3. Deassert CLK\_EN to clockgate the corepac (acknowledge will follow).
4. Assert MOD\_G\_RST to put the corepac in reset mode.

Power-down:

1. Configure the PDCCMD register to enable power down mode
2. Enable CPU interrupt(s) corresponding with wakeup and disable all others
3. Execute IDLE instruction
4. Assert CLKSTOP\_REQ in corepac (processor will ensure system is idle before responding with ack)

---

#### Note

C66x DSP Pre-fetch Should Be Disabled before Entering Power Down Mode.

---

---

#### Note

For more information about C66x signals and registers, see [Section 6.4, C66x DSP Subsystem](#).

---

The DSP may hang after multiple iterations of going into C66x Corepac Power-Down and wake up from external events.

The C66x XMC (External Memory Controller) can have outstanding pre-fetch requests when C66x Corepac transitions to a Power Down state. The XMC clocks are gated internally during this transition. While XMC clocks are gated, outstanding pre-fetch request responses are not seen by the XMC which leads to an inconsistent state between the XMC and the L3 Interconnect. When the DSP wakes up, this can manifest as different symptoms within the DSP subsystem, including Cache corruption, incorrect data being returned to the CPU, and can eventually lead to a DSP hang condition.

The steps to avoid this issue are as given below:

1. Ensure the code which places the DSP C66x Corepac to Power Down State (power down entry procedure shown below) is placed in the DSP C66x L2 RAM memory.
2. Set the IDLE bit in PDCCMD register during initialization.
3. Inside the power down entry procedure include the following software sequence:
  - a. Execute MFENCE instruction.

- b. Write 1 to XPF\_CMD.INV (address 0x0800\_0300).
- c. Read XPFACS (address 0x0800\_0304).
- d. Execute IDLE instruction.

While executing multi-threaded DSP software with C66x Corepac Power Down caution should be observed to not allow the power down entry sequence to be preempted and switch context.

#### 5.2.2.2.2 Integrated Power Management (DMSC)

##### 5.2.2.2.2.1 DMSC Power Management Overview

The device has one DMSC module located in WKUP domain - WKUP\_DMSC0, that controls the Power Management. [Figure 5-25](#) describes the top-level diagram of WKUP\_DMSC0 module, including the Power Management interfaces.

**Figure 5-25. Overview of Device Management and Security Control (WKUP\_DMSC0)**

#### 5.2.2.2.1.1 DMSC Power Management Features

DMSC power management supports:

- DMSC control:
  - Contains various control, configuration and status registers for power management functions
- Main features of oscillators control:
  - Controls the main oscillator power down
  - Controls the gating of the POR RC oscillator root clock of the main oscillator to avoid high frequency clock propagation during oscillator wake-up
- DMSC memory power management
  - Power-off of ROM during sleep modes
  - RAM retention during sleep modes
- IO power management
  - Controls IO isolation while going into standby mode
  - Controls IO wake-up capability
- External signals for power control
  - Support for 64 general purpose inputs which can be used by Cortex-M3
- Slave VBUSP port to directly connect to Power Sleep Controller (PSC).

---

**Note**

Power resource management of the device is done via firmware running on DMSC.

---

---

**Note**

For more information how to use DMSC, see TISCI API available at [ti.com](http://ti.com).

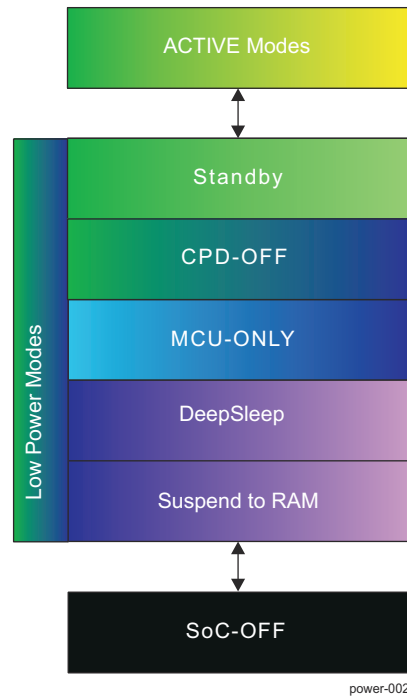

---

### 5.2.3 Device Power States

#### 5.2.3.1 Overview of Device Low-Power Modes

The device supports multiple power modes described in the sections below. The lower power consumption comes at the cost of longer time for recovery to a running mode.

Figure 5-26 depicts the valid power modes for the device.

**Figure 5-26. Power Modes**

Device supports the following power states:

- SoC-OFF: entire device is off by switching off voltage rails externally. External DDR memory may be optionally in Self-Refresh (SR).
- SuspendToRAM: all power rails are OFF except for DDR IO. External DDR memory may be optionally in self-refresh.
- DeepSleep: all processor core power domains are OFF (voltage domain ON). Only WKUP power domains are ON. Some top-level modules that does not have power domains, are ON.
- MCU-ONLY: WKUP and MCU voltage domains are ON, and MAIN SoC side voltage domains are OFF except for 1.8 V IO rail. External DDR memory is in SR optionally.
- Core Power Domain OFF (CPD-OFF): all voltage domains are ON, MAIN SoC side all power domains are OFF. CPD-OFF is alternative to the MCU-ONLY, in case there are restrictions to turn off MAIN SoC side voltage domains.
- Standby: Main processor cores in WFI/WFE, rest of active subsystems idles. .
- Active: main status and control registers are ON, processors and subsystems are ON, based on use cases.

See *Power Estimation Application Note*, for more information about power saved in each low power mode.

#### 5.2.3.2 Voltage Domains

Table 5-75 shows the state of power supply voltages in each low power mode.

**Table 5-75. Voltage Domains State in Low Power Modes**

Power Modes	Voltage domains						
	VD_WKUP/MCU	VD_CORE	VD_CC	Other WKUP (IO, Analog)	Other MCU (IO, Analog)	Other SoC (IO, Analog)	DDREMIF and PHY
SoC-OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
SuspendToRAM	ON	OFF	OFF	OFF	OFF	OFF	ON
DeepSleep	ON	ON	ON	ON	ON	ON	ON
MCU-ONLY	ON	OFF	OFF	ON	ON	ON/OFF	ON
CPD-OFF	ON	ON	ON	ON	ON	ON	ON
Standby	ON	ON	ON	ON	ON	ON	ON

### 5.2.3.3 Power Domains

Table 5-76 shows the state of power domains in each low power mode.

**Table 5-76. Power Domains State in Low Power Modes**

Power Modes	Power Domains															
	GP_COR_E_CTL_WKUP	PD_MCU_R5F0FS	GP_COR_E_CTL	PD_MCA_NSS	PD_DSS	PD_ICSS	PD_9GSS	PD_SERDES_0	PD_SERDES_1	PD_SERDES_2	PD_SERDES_3	PD_SE_RDES_4	PD_SE_RDES_5	PD_TIMER	PD_C7_1x_0	PD_C7_1x_1
SoC-OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
SuspendToRAM	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
DeepSleep	ON	OFF	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	OFF	OFF
MCU-ONLY	ON	ON	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
CPD-OFF	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	OFF	OFF
Standby	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON

**Table 5-77. Power Domains State in Low Power Modes**

Power Modes	Power Domains															
	PD_A72_C_LUSTER_0	PD_A72_0	PD_A72_1	PD_A72_C_LUSTER_1	PD_A72_2	PD_A72_3	PD_GPU_COM	PD_GPU_CORE	PD_C66x_0	PD_C66x_1	PD_R5FSS_0	PD_R5FSS_1	PD_DECODE	PD_ENCODE	PD_DMPAC	PD_VPAC
SoC-OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
SuspendToRAM	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
DeepSleep	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
MCU-ONLY	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
CPD-OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF	OFF
Standby	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON	ON

### 5.2.3.4 Clock Sources States

Table 5-78 shows the state of global clocks in each low power mode.

**Table 5-78. Global Clock States in Low Power Modes**

Power Modes	Clocks		
	WKUP_HFOSC0	HFOSC1 (if available)	DPLLs
SoC-OFF	OFF	OFF	OFF
SuspendToRAM	OFF	OFF	OFF

**Table 5-78. Global Clock States in Low Power Modes (continued)**

Power Modes	Clocks		
	WKUP_HFOSC0	HFOSC1 (if available)	DPLLs
DeepSleep	OFF	OFF	OFF
MCU-ONLY	ON	ON	Single DPLL locked
CPD-OFF	ON	ON	Single DPLL locked
Standby	ON	ON	Bypass / Low Frequency

### 5.2.3.5 Wake-up Sources

Table 5-79 shows Wake-up Sources in each low power mode.

#### Note

MCU-ONLY state is not considered as a state that needs a wake-up source as processor is alive. A72SS and/or R5FSS can be in WFI and any interrupt which is routable to R5F or WKUP\_DMSC0 could cause exit from this state.

**Table 5-79. Wake-up Sources in Low Power Modes**

Power Modes	Wake-up source
SoC-OFF	MCU_PORz.
SuspendToRAM	TBD
DeepSleep	WKUP_DMSC0 Timers (any), WKUP_UART0, WKUP_GPIO0, WKUP_GPIO1, WKUP_I2C .
CPD-OFF	WKUP_GPIO0, WKUP_GPIO1, WKUP_UART0, WKUP_I2C0, WKUP_TIMERS. All instances of the following peripherals in MCU domain - UART, I2C, SPI, MCAN, Timers.
Standby	All peripherals with interrupts routed to GIC.

### 5.2.3.6 Device Power States and Transitions

The LPMs always transition from run state. If the device software decides to transition from one low power mode to another low power mode, it needs to go through the run state first.

Normally, the software initiates transition to low power mode and interrupts/events are the exit trigger.

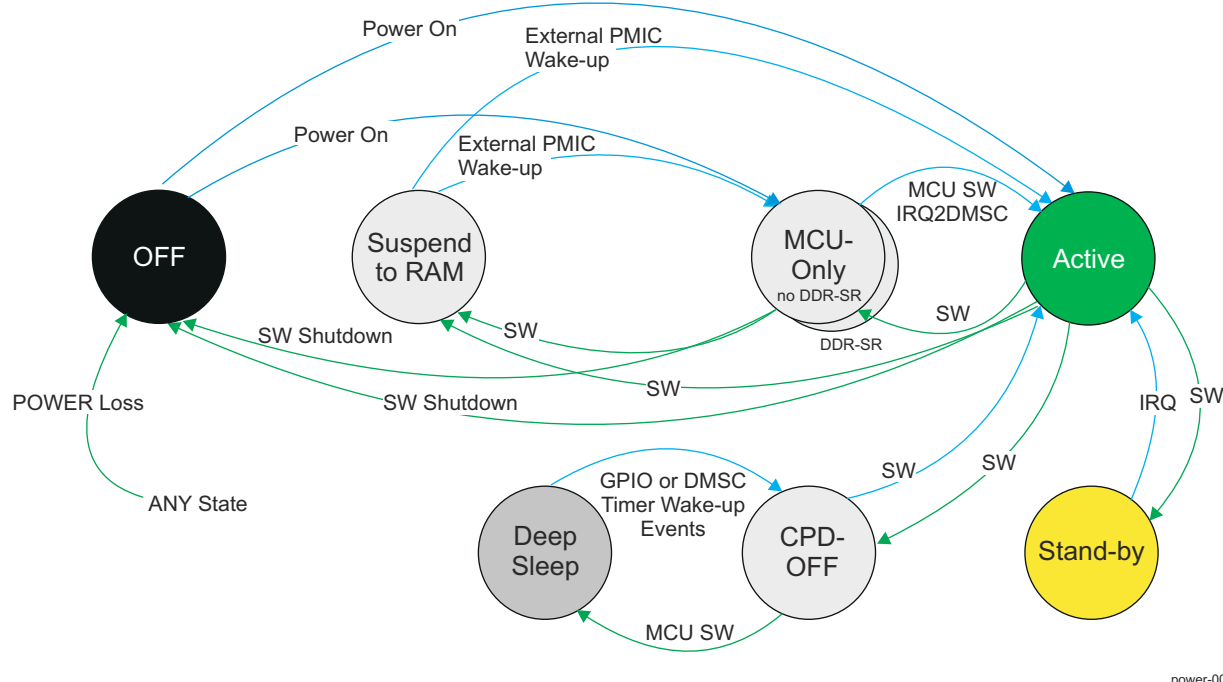

Figure 5-27 shows the state diagram of transitions between LPMs.

#### Note

The state diagram represents higher layer logical requesters, as any actual operation are actualized by WKUP\_DMSC0 firmware.

For more information about wake-up requesters, see Table 5-79, *Wake-up Sources and Debug Capability in Low Power Modes*.

**Figure 5-27. Transition between Low Power Modes**

#### Note

For details on power domain and module state transitions, please refer to [Section 5.2.2.2.1.5, Executing State Transitions](#).

#### Note

CTRLMMR\_WKUP\_DEEPSLEEP\_CTRL is used to force all WKUP and MAIN IOs into DeepSleep mode, for more information about control registers, see *Control Module (CTRL\_MMR)*.

The device supports the below transitioning schemes to low power states. No voltage domain manipulations. Only power domains:

- ACTIVE->Standby
- ACTIVE->CPD-OFF
- ACTIVE->DeepSleep, device effectively goes through CPD-OFF

Requiring voltage domain and supply management:

- ACTIVE->MCU-ONLY
- ACTIVE->SuspendToRAM
- MCU-ONLY->SuspendToRAM

#### 5.2.3.6.1 LPM Entry Sequences

[Table 5-80](#) lists all the possible steps in entering LPM. In the tables further down used are the following abbreviations:

- HLOS stands for High-Level Operational System.
- RTOS stands for Real-Time Operational System.
- PM stands for Power Management.
- FW stands for Firmware.
- PM-FW stands for Power Management - Firmware.

- DMSC-FW stands for DMSC - Firmware.
- SW stands for Software.

**Table 5-80. LPM Entry Sequence**

Step Label	Responsible HW/SW	Step description
ACT-0-0	Various	SoC fully ACTIVE
ACT-1-0	HLOS + PM - FW	Identify conditions to enter low power mode
ACT-1-0.1	HLOS + PM - FW	HLOS/RTOS + DMSC + DMSC-FW PM policy identifies conditions to enter Standby
ACT-1-0.2	HLOS + PM - FW	HLOS/RTOS + DMSC + DMSC-FW PM policy identifies conditions to enter CPD-OFF or DeepSleep
ACT-1-0.3	HLOS + PM - FW	HLOS/RTOS + DMSC + DMSC-FW PM policy: identifies conditions to enter MCU-ONLY
ACT-1-0.4	HLOS + PM - FW	HLOS/RTOS + DMSC + DMSC-FW PM policy: identifies conditions to enter SuspendToRAM
ACT-1-0.5	HLOS + PM - FW	HLOS/RTOS + DMSC + DMSC-FW PM policy: identifies conditions to enter Software Shutdown
ACT-2-0	SW	-Virtual-machines running in each core have completed all their tasks and any task involving other modules. - Virtual-machines running in each core have released all peripherals. - Virtual machines are either down or on standby.
ACT-6-1-1	SW(C71x)	- Save C71x core context in DDR. - Set C71x in IDLE instruction and memory system ready for c71x to be POWER-OFF. - Turn off power domain for C71x as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a> ).
ACT-6-2a	SW(A72) + FW	- Save A72 core context in DDR. - Set A72 core_0,1,2,3 into WFI and ready to be POWER-OFF as well as . - Set-up A72_CLUSTER_0 and A72_CLUSTER_1 ready to complete POWER-OFF of each of its 2 cores. - Turn off power domains PD_A72_0, PD_A72_1, PD_A72_2, PD_A72_3 as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a> ). - Set-up A72_CLUSTER_0 and A72_CLUSTER_1 ready to for both clusters to POWER-OFF. - Turn off power domains PD_A72_CLUSTER_0 and PD_A72_1 as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a> ).
ACT-6-4	SW	- When going from MCU-ONLY mode to SuspendToRAM no context can be saved to DDR. - Instead a limited amount of MCU context could be saved to external NOR-Flash via FSS.
ACT-7-2	SW(A72) + FW	- Set A72_CORE_0, A72_CORE_1, A72_CORE_2, A72_CORE_3 into WFI.
ACT-8-2	FW	Disable (SwRstDis), LPSC_MAIN_DEBUG and LPSC_MCU_DBG as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a> ).
ACT-10-1	FW	-Save acceleratorpac context to DDR, MAIN_ACCELLERATOR modules like ENCODER, DECODER, DMPAC. - Prepare accelerators for CLKSTOP and POWER-OFF state. - POWER-OFF power domains for acceleratorpac as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a> ).

**Table 5-80. LPM Entry Sequence (continued)**

Step Label	Responsible HW/SW	Step description
ACT-10-2-3	SW-FW	<ul style="list-style-type: none"> <li>- Save context from remaining MAIN power-domains that could be turned OFF depending on usage scenario.</li> <li>- POWER-OFF all other power-domains in MAIN domain that could be POWERED-OFF, excluding PD0 since that is always-on and locked.</li> <li>- For PD domains of type PDRIO, they also could be powered-OFF during Low-Power Modes as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> <li>- To be able to be powered-OFF the reset isolated modules all their RST_ISO bits needs to be cleaned inside PSC for all the LPSC components of a given power domain.</li> <li>- At this point the LPSCs associated with PD0 are still enabled.</li> <li>- Power OFF domains and disable LPSCs as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-10-4-1	FW	<ul style="list-style-type: none"> <li>- Save MSMC-CFG to DDR.</li> <li>- Save any other context required to DDR from the top-of the Compute Cluster and MSMC.</li> <li>- Save limit set of WR register values from CTRL_MMR0 to DDR.</li> </ul>
ACT-10-4-2	FW	<ul style="list-style-type: none"> <li>- Save CTRLMMR_MAIN_DEVSTAT in DMSC RAM.</li> <li>- Save CTRLMMR_MAIN_BOOTCFG register from CTRL_MMR0 in DMSC RAM.</li> </ul>
ACT-11-01	SW(R5x) + FW	<ul style="list-style-type: none"> <li>- R5FSSs context save to DDR.</li> <li>- Perform cache manage and WFI sequence for R5FSSs in order to get it ready for POWER-OFF.</li> <li>- Turn off power domains for R5FSSs clusters PD_R5FSS_0 and PD_R5FSS_1 as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-11-4a	SW(C66x) + FW	<ul style="list-style-type: none"> <li>- C66x context save to DDR.</li> <li>- Set C66x in IDLE instruction and memory system ready for C66x to be POWER-OFF.</li> <li>- POWER-OFF C66x (PD_C66x_0 and PD_C66x_1) as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-11-05	FW	<ul style="list-style-type: none"> <li>- Save DDR config to DMSC-RAM.</li> <li>-Set LPSCs for DDR in SwRstDis state.</li> <li>- For PD0 (GP_CORE_CTL) (the only PD still ON) in PSC0, set ALL remaining LPSCs in SwRstDis state (except LPSC0 which is locked) as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-11-06	FW	<ul style="list-style-type: none"> <li>- Set the following LPSC to SwRstDis: LPSC_MAIN2WKUPMCU</li> <li>- Disable all the HSDIVs in MAIN. Except the one providing clock MAIN_PLL0_HSDIV0_CLKOUT to PLLCTRL , namely HSDIV0 of PLL0.</li> <li>- Disable all the PLLs in MAIN. Except PLL0.</li> <li>- Now set PLLCTRL (MAIN_PLL0_HSDIV0_CLKOUT) in bypass mode.</li> <li>- Disable PLL0.</li> <li>- Set all of the following LPSCs, in WKUP_PSC0, to SwRstDis as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>): LPSC_DEBUG2DMSC, LPSC_WKUPMCU2MAIN.</li> <li>- If it wasn't already, switch WKUP_HFOSC0 to HFOSC1 as input reference to PLL0, by writing CTRLMMR_WKUP_MAIN_PLL0_CLKSEL[0] CLK_SEL = 1.</li> <li>- POWER-OFF HFOSC1 by writing to CTRLMMR_WKUP_HFOSC1_CTRL[7] PD_C = 1 in WKUP_CTRL_MMR0.</li> </ul>
ACT-12-00	FW	Place DDR in Self Refresh Mode
ACT-12-02	FW	MCU_ONLY.MCU_R5FF0FSS_ACTIVE >> Place DDR in Self Refresh Mode
ACT-13-01	FW(DMSC)	<p>Set all the other LPSCs of WKUP_PSC0 except PD0 (GP_CORE_CTL_WKUP) to SwRstDis state as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>), except for the ones below:</p> <ul style="list-style-type: none"> <li>- Keep enable the LPSCs LPSC_WKUP_ALWAYSON, LPSC_DMSC, LPSC_WKUP_GPIO.</li> </ul>

**Table 5-80. LPM Entry Sequence (continued)**

Step Label	Responsible HW/SW	Step description
ACT-13-02	FW(DMSC)	<p>-If the WKUP_GPIOs need to detect wake-up events independently of the WKUP_IO-PM-DCH, then GPIOs need to remain fully functional and clocked during DeepSleep.</p> <p>- To do that do the following:</p> <ul style="list-style-type: none"> <li>Set WKUP_GPIO_CTRL[0] = 1'b1 . This will make sure that even when CLK_EN=0 is applied to GPIO the clock will still be running.</li> <li>Set LPSC_wkup_gpio in CLKSTOP-DISABLE state (NOT SwRstDis state).</li> <li>Go to WKUP_MMR module and switch the GPIO functional clock to 32 Khz.</li> <li>WKUP_GPIO_CLKSEL[1:0] = 2'b10.</li> <li>Or for a second type of test it could be switched to the 12.5Mhz RC clock.</li> <li>WKUP_GPIO_CLKSEL[1:0] = 2'b11.</li> </ul>
ACT-14-01	FW-DMSC	<p><b>For Modes with R5FSS OFF, except MCU-ONLY.R5FSS-OFF&gt;&gt;</b></p> <ul style="list-style-type: none"> <li>MCU_R5FF0FSS context save to DDR.</li> <li>Perform cache manage and WFI/WFE sequence for MCU_R5FF0FSS in order to get it ready for POWER-OFF.</li> <li>Turn off power domain - PD_MCU_R5FF0FSS, for MCU_R5FF0FSS as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-14-02	FW-DMSC	<p><b>For MCU_ONLY.R5FSS-OFF &gt;&gt;</b></p> <ul style="list-style-type: none"> <li>MCU_R5FF0FSS context save to Flash.</li> <li>Perform cache manage and WFI/WFE sequence for MCU_R5FF0FSS in order to get it ready for POWER-OFF.</li> <li>Turn off power domain - PD_MCU_R5FF0FSS, for MCU_R5FF0FSS as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-15-1	FW	MCU_R5FF0FSS enters WFI/WFE mode
ACT-14-3	FW	<p><b>ForModes with R5FSS OFF &gt;&gt;</b></p> <ul style="list-style-type: none"> <li>DMSC off power domain for MCU_R5FF0FSS as per PSC dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> </ul>
ACT-21	FW(DMSC)	DMSC sends commands to PMIC via WKUP_I2C0 to turn off all the supply, so device goes to OFF state.
ACT-22-1	FW(DMSC)	DMSC sends command to PMIC via WKUP_I2C0 to set desired wakeup events inside PMIC which will trigger wake-up from SuspendToRAM.
ACT-22-2	FW(DMSC)	Send command to PMIC via WKUP_I2C0 to assert from the board DDR_RET chip input.
ACT-22-3	FW(DMSC)	DMSC sends command to PMIC via WKUP_I2C0 to turn off all the supply except the supply to DDR IO (and except RTC supply inside PMIC), for PMIC/SoC to enter SuspendToRAM mode (PMIC-LP_State).
ACT-16-1	FW(DMSC)	If enable, disable the following LPSCs: LPSC_MCU_DEBUG, LPSC_MCU_TEST.
ACT-16-2	FW(DMSC)	Before entering MCU_ONLY mode disable all VTM temperature sensors that are on the SOC_MAIN portion of the SoC: VTM_TMPSENS1-4. At the same time make sure that the TEMP sensor in the VD_WKUP is enabled and running to keep monitoring temperature: VTM_TMPSENS0
ACT-17-1	FW	<ul style="list-style-type: none"> <li>Save to DMSC-RAM and disable POK modules related to SoC_MAIN core portion of the SoC via WKUP_CTRL_MMR0 module: POK_VDD_CORE_UV_CTRL, POK_VDD_CPU_UV_CTRL, POK_VDDR_CORE_UV_CTRL, POK_VMON_EXT_UV_CTRL, POK_VDD_CORE_OV_CTRL, POK_VDD_CPU_OV_CTRL, POK_VDDR_CORE_OV_CTRL, POK_VMON_EXT_OV_CTRL</li> <li>First save and disable their contribution to ESM events</li> <li>Next save and disable their contribution to PRG reset, CTRLMMR_WKUP_MAIN_PRG_CTRL all POK_*_EN = 0.</li> </ul>
ACT-17-2	FW	<ul style="list-style-type: none"> <li>Disable any still enable POK modules.</li> <li>Disable any ESM event generation going OFF-Chip.</li> </ul>

**Table 5-80. LPM Entry Sequence (continued)**

Step Label	Responsible HW/SW	Step description
ACT-17-2-2	FW	<p>- DMSC asserts PMIC_POWER_EN1 (the pin for SoC to communicate with PMIC) to turn-off the power supplies to VDD_CORE and VDD_CPU and IO-supplies that feed - USB, SERDES and PLLs in MAIN.</p> <p>or</p> <p>- DMSC sends commands to PMIC via WKUP_I2C0 to turn-off the power supplies to VDD_CORE and VDD_CPU and IO-supplies that feed - USB, SERDES and PLLs in MAIN.</p>
ACT-18	FW	DMSC informs PMIC to shut off supply to WKUP/MCU domain and only keep supply to DDR IO to enter SuspendToRAM state (PMIC-LP_State)
ACT-19-1	FW	<p>- Via WKUP_CTRL_MMR0 module, remove the reset-isolation blocking on the MAIN_PORZ propagation: CTRLMMR_WKUP_POR_RST_CTRL[0] POR_RST_ISO_DONE_Z = 0.</p> <p>- Via WKUP_CTRL_MMR0 module apply PORz to SoC_MAIN: CTRLMMR_WKUP_POR_RST_CTRL[19-16] SW_MAIN_POR = 4'b0110 .</p>
ACT-19-2	FW	Set CTRLMMR_WKUP_MAIN_VDOM_CTRL[0] MAIN_VD_OFF = 1 in WKUP_CTRL_MMR0 module prior to powering off the main voltage domain to ensure proper signal isolation.
ACT-25-00	SW+FW	START MAIN-IO-Power-Management daisy-chain (IO-PM-DCH) low power mode entry sequence via FW:
ACT-25-01	SW+FW	<p>MAIN-IO-Power-Management daisy-chain (IO-PM-DCH) low power mode entry sequence via FW:</p> <p>- Prior to the DMSC IO-PM-DCH sequence, Software-driver and R5F-FW determines what are the deep sleep (DS) configuration values to be set in the CTRLMMR_PADCONFIGi (i = 0 to 172) for all MAIN-IOs, and sets those registers.</p> <p>- Those same configuration values will apply regardless if it is any LowPowerMode entry that uses MAIN-IO-PM daisy-chain. There is only one DS setting in the PADCFG register.</p> <p>NOTE: If the END-TARGET LOW POWER MODE is either of MCU-ONLY or SuspendToRAM modes then:</p> <ul style="list-style-type: none"> <li>• Save all the CTRLMMR_PADCONFIGi (i = 0 to 172) for all MAIN-IOs to DDR (Context Save).</li> <li>• Additionally, for the very limited set of IOs that could be used as wake-up events, save all their registers context to DMSC-RAM.</li> </ul>
ACT-25-02a	FW(DMSC)	<p>Main-IO-PM-DCH:</p> <p>Kick-Off propagation of all the CTRLMMR_PADCONFIGi (i = 0 to 172) registers selections for Wake-up event enables ([29] WKUP_EN bit), and iso-bypass ([23] ISO_BYP bit) to all IOs in main-region IO-PM-DCH. Read-modify write to DMSC power registers, see DMSC addendum for more information.</p>
ACT-25-02b	FW(DMSC)	<p>Main-IO-PM-DCH: Kick-Off propagation of all the CTRLMMR_PADCONFIGi (i = 0 to 172) registers selections for Wake-up event enables ([29] WKUP_EN bit) to all IOs in main-region IO-PM-DCH. When the VDD_CORE is OFF NO-ISOBYPASS is supported. Read-modify write to DMSC power registers, see DMSC addendum for more information.</p>
ACT-25-03	FW(DMSC)	<p>Main-IO-PM-DCH: Kick-Off propagation of all the DeepSleep selection settings for IO inputs pupdsel, pi, gz from CTRLMMR_PADCONFIGi (i = 0 to 172) registers to all IOs in main-region IO-PM-DCH. Write WKUP_CTRL_MMR0 CTRLMMR_WKUP_DEEPSLEEP_CTRL[8] FORSE_DS_MAIN to force the deep sleep value onto pins.</p>
ACT-25-04	FW(DMSC)	<p>Main-IO-PM-DCH: Latch the wakeup event enabled in all IOs whose PADCFG register has WUEN bit set by toggling the WUCLK. WUCLK is toggled by writing '1' to a register in DMSC. WUCLK_CTRL_1 ( B[8] ) then poling until PMCTRL_IO_1.WUCLK_STATUS_1 ( B[9] ) = '1'. Next is to drive WUCLK=0 by writing '0' to MMR bit PMCTRL_IO_1.WUCLK_CTRL_1 ( B[8] ) then poling until PMCTRL_IO_1.WUCLK_STATUS_1 ( B[9] ) = '0'.</p>
ACT-25-05	FW(DMSC)	<p>Main-IO-PM-DCH: Kick-Off isolation and isolation sequence of all IOs in main-region IO-PM-DCH. Read-modify write to DMSC PMCTRL_IO_1, writing 1'b1 to bit PMCTRL_IO_1[24].</p>

**Table 5-80. LPM Entry Sequence (continued)**

Step Label	Responsible HW/SW	Step description
ACT-25-10	SW+FW	DMSC start to set WkupMcu IO into daisy-chain low power mode: - Prior to the DMSC's Wkup-MCU IO-PM-DCH sequence, Software-driver + R5-FW determines what are the deep sleep (DS) configuration values to be set in the Wkup PAD-CFG for all Wkup-IOs, and sets those registers. - Those same config values will apply regardless if it is any LowPowerMode entry that uses Wkup-IO-PM daisy-chain. There is only one DS setting in the PADCFG MMRs.
ACT-25-11	FW(DMSC)	Wkup-IO-Power-Management daisy-chain (Wkup-IO-PM-DCH) low power mode entry sequence via FW: Wait for completion of Isolation in Main-IO-PM-DCH. Keep polling bit PMCTRL_IO_1[25] until it shows '1' to indicate completion of isolation sequence for Main-IO-PM-DCH.
ACT-25-12	FW(DMSC)	Wkup-IO-PM-DCH: Kick-Off propagation of all the CTRLMMR_WKUP_PADCONFIGi (i = 0 to 93) registers selections for Wake-up event enables ([29] WKUP_EN bit), and iso-bypass ([23] ISO_BYP bit) to all IOs in Wkup-region IO-PM-DCH. Read-modify write to DMSC register PMCTRL_IO_0, writing 2'b11 to bits PMCTRL_IO_0[16, 6]
ACT-25-13	FW(DMSC)	Wkup-IO-PM-DCH: Kick-Off propagation of all the DeepSleep selection settings for IO inputs pupdsel, pi, gz from CTRLMMR_WKUP_PADCONFIGi (i = 0 to 93) to all IOs in Wkup-region IO-PM-DCH. Write 0x00000001 to DMSC register FW_CTRL_OUT0_SET.
ACT-25-14	FW(DMSC)	Wkup-IO-PM-DCH: Latch the wakeup event enabled in all IOs whose PADCFG has WUEN bit set by toggling the WUCLK. WUCLK is toggled by writing '1' to MMR bit PMCTRL_IO_0.WUCLK_CTRL_0 ( B[8] ) then poling until PMCTRL_IO_0.WUCLK_STATUS_0 ( B[9] ) = '1'. Next is to drive WUCLK=0 by writing '0' to MMR bit PMCTRL_IO_0.WUCLK_CTRL_0 ( B[8] ) then poling until PMCTRL_IO_0.WUCLK_STATUS_0 ( B[9] ) = '0'.
ACT-25-15	FW(DMSC)	Wkup-IO-PM-DCH: Kick-Off isolation and isolation sequence of all IOs in Wkup-region IO-PM-DCH. Configure WKUP_CTRL_MMR POR_RST_CTRL as needed Read-modify write to DMSC's MMR PMCTRL_IO_0, writing 1'b1 to bit PMCTRL_IO_0[24].
ACT-25-16	FW(DMSC)	Wkup-IO-PM-DCH: Wait for completion of Isolation in Wkup-IO-PM-DCH. Keep polling bit PMCTRL_IO_0[25] until it shows '1' to indicate completion of isolation sequence for Wkup-IO-PM-DCH. At this point the DMSC-M3 will finish/complete the low-power mode code sequence to the point it goes into WFI state. The entering of M3 into WFI causes the DMSC internal low power sequence to kick-in and DMSC will complete it and wait until a wake-up event.
ACT-26	FW	Set LPSC_DEBUG2DMSC, LPSC_WKUPMCU2MAIN, LPSC_MAIN2WKUPMCU to SwRstDis as per PSC dependency constrains (see <a href="#">Section 5.2.2.1.3.3, LPSC Dependencies Overview</a> ).
ACT-28-01	DMSC-FW	(If OFF-Mode or SuspendToRAM-Mode skip this) DMSC-FW config DMSC in LPM0. - Kick LPM Entry in DMSC by setting WFI in DMSC's M3.
ACT-29-01	DMSC-FW	(If OFF-Mode or SuspendToRAM-Mode skip this) -Configure DMSC for LPM4 or LPM3. - This should include enabling the interrupts and wake-up events that are desired to cause a wakeup out of the LPM. - The IO-PM daisy-chains for both Main-IO-PM-DCH and WKUP-IO-PM-DCH must be included among the wake-up events.
ACT-29-02	DMSC-FW	(If OFF-Mode or SuspendToRAM-Mode skip this) -Switch the input clock for WKUP_PLLCTRL0 from MCU_PLL0/HSDIV_CLKOUT to WKUP_HFOSC0_CLKOUT. - Set WKUP_PLL_CTRL register PLLCTL[0] PLEN = 0 and PLLCTL[5] PLENSRC = 1. - The IO-PM daisy-chains for both Main-IO-PM-DCH and WKUP-IO-PM-DCH must be included among the wake-up events. - Set MCU_PLL0 in bypass mode.
ACT-29-03	DMSC-FW	(If OFF-Mode or SuspendToRAM-Mode skip this) -Kick LPM Entry in DMSC by setting WFI in DMSC's M3.

### Note

NOTICE that there are a few steps in [Table 5-82](#) ACTIVE to CPD-OFF part of the table which should be skip if the transition is from ACTIVE to DeepSleep. If the device is already in CPD-OFF and need to transition to DeepSleep, then the content of R5F can't be save to DDR and will have to be saved to FLASH. Alternatively the context of R5F will be lost and the MCU\_R5FF0FSS in next wakeup if it stays in CPD-OFF state the R5Fwill start from scratch without context restored.

### 5.2.3.6.2 LPM Exit Sequences

Table 5-86 lists all available steps used in exiting LPM.

**Table 5-86. LPM Exit Step Labels**

Step Label	Responsible HW/SW	Step description
LPM_Ex-01	SoC	SoC and PMIC are in SuspendToRAM mode.
LPM_Ex-02	PMIC	PMIC detects an external wakeup event from SuspendToRAM, it can be any, but not limited to the events below: <ul style="list-style-type: none"> <li>PMIC RTC timer event</li> <li>GPI wakeup event</li> <li>CAN-RX pin activity</li> </ul>
LPM_Ex-03	PMIC	PMIC wakeup and enables power supply to full SoC.
LPM_Ex-03a	PMIC	PMIC wakeup and enables power supply to MCU domain and MCU-I/Os.
LPM_Ex-04.1a	SoC	WKUP/MCU goes through PORz reset and starts ROM boot sequence.
LPM_Ex-04.1b	SW(MCU_R5FF0Fx)	R5FSS boots to SBL.
LPM_Ex-04.1c	SW(MCU_R5FF0Fx)	SBL sends command to PMIC via WKUP_I2C0 to check SuspendToRAM flag to identify if this is COLD or SuspendToRAM-boot.
LPM_Ex-04.2	SoC	Main domain goes through PORz reset
LPM_Ex-05	SW(MCU_R5FF0Fx)	SBL detects device recovered from SuspendToRAM.
LPM_Ex-05.1a	SW(MCU_R5FF0Fx)	SBL reads from boot-strap boot-mode registers that this is MCU-ONLY boot.
LPM_Ex-05.1b	SW(MCU_R5FF0Fx)	SBL reads from boot-strap boot-mode registers that this is full-SoC boot.
LPM_Ex-05.2	SW(MCU_R5FF0Fx)	SBL does restore to MCU domain (no DDR available).
LPM_Ex-06	FW/SW(MCU_R5FF0Fx)	<ul style="list-style-type: none"> <li>Restore required context to main domain from DDR and RESUME.</li> <li>DMSC (or potentially R5F) sets to power-up all PDs and ENABLE all the LPSCs (or as required per usage case and per as seen per context saving information).</li> <li>Sequence power-up and LPSC enable as per dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependences Overview</a>).</li> <li>Restore required context to MAIN domain from DDR and RESUME.</li> </ul>
LPM_Ex-07-0	Start MCU-Only R5FSS-OFF	<ul style="list-style-type: none"> <li>PD_MCU_R5FF0FSS = OFF</li> <li>LPSC_WKUP_GPIO is in DISABLE (not SwRstDis) state, such that it could generate wake-up events</li> <li>LPSC_WKUP_ALWAYSON and LPSC_DMSC are in ENABLE state</li> <li>All other LPSCs are in SwRstDis state</li> <li>DMSC in LPM4 or LPM3.</li> </ul>
LPM_Ex-07-1	Start MCU-Only	MCU is in functional mode, PLLCNTRL in clock bypass mode, MCU_R5FF0F in WFI/WFE, DMSC in LPM0(WFI).

**Table 5-86. LPM Exit Step Labels (continued)**

Step Label	Responsible HW/SW	Step description
LPM_Ex-07-2	IO	<p>One of the IOs enable to detect wakeup events is toggled from the board.</p> <ul style="list-style-type: none"> <li>- Event will propagate asynchronous through all of the IO-PM daisy chain (DCH) and eventually reaches DMSC.</li> <li>- The IO-PM wake-up event corresponding to each of the 2 IO-PM-DCH were set prior to enter LPM4/3.</li> <li>- The DMSC ASYNC-starts driving WKUP_HFOSC0 to enable state and PWR-ON</li> <li>- The DMSC wake-up FSM running of the 32-kHz RC oscillator starts the wake-up of DMSC.</li> <li>- DMSC eventually exits LPM4/3 and the interrupt map to the IO-PM-DCHs will cause M3 to exit WFI.</li> <li>- M3 executes corresponding wakeup ISR</li> </ul>
LPM_Ex-10	FW	DMSC puts main IO back to normal state. When peripherals are initialized, CTRLMMR_WKUP_DEEPSLEEP_CTRL override for main domain can be released to allow IO to be controlled by core logic again.
LPM_Ex-11	DMSC-FW	<ul style="list-style-type: none"> <li>-DMSC Powers-ON PD_MCU_R5FF0FSS and enables R5x as per PSC dependency constrains (see <a href="#">Section 5.2.2.1.3.3, LPSC Dependences Overview</a>).</li> <li>-MCU-R5x reboot</li> </ul>
LPM_Ex-12	MCU SW	MCU_R5FF0F SW decides to SoC transition to active mode by requesting to DMSC.
LPM_Ex-13	FW	DMSC powers up the power domains in the main domain to enter active mode.
LPM_Ex-14	FW/SW(MCU_R5FF0Fx)	<p>Wake-up events CASE-1:</p> <ul style="list-style-type: none"> <li>- CASE1: An interrupt defined for the purpose of wake-up from active peripherals, as per the list below, is detected in the MCU_R5FF0FSS.</li> </ul> <p>If MCU_R5FF0F is in WFI/WFE mode, it exits WFI/WFE mode and respond to interrupt. When MCU_R5FF0F is ACTIVE or WFI the interrupt can be from any of the peripherals or timer events in MCU map to MCU_R5FF0F:</p> <p>Examples - I2C, UART, ADC, SPI etc.</p>
LPM_Ex-14-2	DMSC-FW	<p>Wake-up events CASE-2 and 3: For the below wakeup cases only DMSC can detect the wake-up condition.</p> <ul style="list-style-type: none"> <li>- CASE2: When R5F is OFF or in CLKSTOP only interrupts map to DMSC could cause wakeup.</li> <li>- CASE3: Even if R5F is ON, when the wake-up event is map to be detected by the IO-PM daisy chain either in WKUP/MCU or MAIN, only DMSC can detect such event.</li> </ul>
LPM_Ex-15-2-1	FW/SW(MCU_R5FF0Fx)	<p>Wake-up events CASE-1:</p> <p>R5F ON and enabled and out of WFI/WFE executing ISR. The ISR will also ID if SoC_MAIN needs to be ON.</p>
LPM_Ex-15-2-2	DMSC-FW	<p>Wake-up events CASE-3:</p> <ul style="list-style-type: none"> <li>- R5F is ON, but wake-up event is only map as an interrupt and wake-up event for DMSC to detect it.</li> <li>- DMSC runs ISR which depending on the WKUP source might not require to turn ON SoC_MAIN.</li> <li>- If wakeup source is from WKUP-IO-PM-DCH then DMSC needs to check all CTRLMMR_WKUP_PADCONFIGi (i = 0 to 93) registers to figure out the peripheral whose IO caused the wkup event</li> <li>- If wakeup source is from MAIN-IO-PM-DCH then DMSC will need to power-ON SoC_MAIN.</li> </ul>
LPM_Ex-15-2-3	DMSC-FW	<p>Wake-up events CASE-2:</p> <ul style="list-style-type: none"> <li>- R5F is OFF, wake-up event is only map as an interrupt and wake-up event for DMSC to detect it.</li> <li>- DMSC runs ISR which depending on the WKUP source might not require to turn ON SoC_MAIN.</li> <li>- If wakeup source is from MAIN-IO-PM-DCH then DMSC will have to power-on SoC_MAIN.</li> </ul>
LPM_Ex-15-2-5	FW/SW(MCU_R5FF0Fx)	<p>If SoC_MAIN needs to be ON there are 2 cases:</p> <ul style="list-style-type: none"> <li>-If PMIC_PIN_CTRL: PMIC control is via pin MCU_R5FF0x core will send request message to DMSC to power-ON main.</li> <li>-Else If PMIC_I2C_CTRL: then MCU_R5FF0x will run the PMIC driver itself and message to DMSC once main is ON for the FW to stay in sync.</li> </ul>

**Table 5-86. LPM Exit Step Labels (continued)**

Step Label	Responsible HW/SW	Step description
LPM_Ex-15-2-6	DMSC-FW	<ul style="list-style-type: none"> <li>- Set MMR inside WKUP_PLLCTRL0 PLLCTL[0] PLEN = 1 and PLLCTL[5] PLENSRC = 1.</li> <li>- Switch the input clock for WKUP_PLLCTRL0 from WKUP_HFOSC0_CLKOUT to MCU_PLL0/HSDIV_CLKOUT.</li> <li>- By now WKUP_PLLCTRL0 should be out of bypass mode and running of MCU_PLL0.</li> <li>- If required as part of the context restore, turn-ON/Enable HFOSC1.</li> <li>- If required as part of the context restore, turn-ON/Enable MCU_PLL1 and MCU_PLL2.</li> </ul>
LPM_Ex-15-2-7	FW	DMSC (or potentially R5F) sets to ENABLE all the LPSCs (or as required per usage case) in the WKUP_PSC based on dependency constrains (see <a href="#">Section 5.2.2.2.1.3.3, LPSC Dependencies Overview</a> ). With the exception of the LPSCs listed below, which will be enable at a later step: <ul style="list-style-type: none"> <li>- LPSC_WKUPMCU2MAIN, LPSC_MAIN2WKUPMCU, LPSC_DEBUG2DMSC, LPSC_MCU_DEBUG.</li> </ul>
LPM_Ex-15-2-8	DMSC-FW	DMSC to remove wkup-IO-PM-DCH from isolation mode and move them to functional mode. When peripherals are initialized, CTRLMMR_WKUP_DEEPSLEEP_CTRL override for WKUP can be released to allow IO to be controlled by core logic again.
LPM_Ex-15-2-9	FW	<ul style="list-style-type: none"> <li>-Via WKUP_CTRL_MMR0 module, confirm removal of the reset-isolation blocking on the main_porz propagation: CTRLMMR_WKUP_POR_RST_CTRL[0] POR_RST_ISO_DONE_Z = 0.</li> <li>-Via WKUP_CTRL_MMR0 module apply PORz to SoC_MAIN: CTRLMMR_WKUP_POR_RST_CTRL[19-16] SW_MAIN_POR = 4'b0110 .</li> </ul>
LPM_Ex-16-1	FW	DMSC sets CTRLMMR_WKUP_MAIN_PWR_CTRL[0] PWR_EN to turn on the main voltage domain. This information is further transported through pin to PMIC to turn on the main voltage domain supply.
LPM_Ex-16-2	FW	<ul style="list-style-type: none"> <li>-Clear PGOOD status bit in POK modules related to SoC_MAIN core portion of the SoC via WKUP_CTRL_MMR0 module: CTRLMMR_WKUP_MAIN_PRG_STAT[31] POK_CLR = 1.</li> <li>POK_VDD_CORE_UV_CTRL, POK_VDD_CPU_UV_CTRL,</li> <li>POK_VDDR_CORE_UV_CTRL, POK_VMON_EXT_UV_CTRL</li> <li>POK_VDD_CORE_OV_CTRL, POK_VDD_CPU_OV_CTRL,</li> <li>POK_VDDR_CORE_OV_CTRL, POK_VMON_EXT_OV_CTRL</li> </ul>
LPM_Ex-16-3	FW	<ul style="list-style-type: none"> <li>-Poll until all POK UV and OV status bitts indicate PGOOD status for all POK modules related to SoC_MAIN core portion of the SoC via WKUP_CTRL_MMR0 module: CTRLMMR_WKUP_MAIN_PRG_STAT corresponding POK_*_OV/UV = 1.</li> <li>POK_VDD_CORE_UV_CTRL, POK_VDD_CPU_UV_CTRL,</li> <li>POK_VDDR_CORE_UV_CTRL, POK_VMON_EXT_UV_CTRL</li> <li>POK_VDD_CORE_OV_CTRL, POK_VDD_CPU_OV_CTRL,</li> <li>POK_VDDR_CORE_OV_CTRL, POK_VMON_EXT_OV_CTRL</li> </ul>

### 5.2.3.6.3 IO Retention

IO retention is supported on MCU\_GENERAL and CANUART IOs, MCU Scratch Memory, SerDes PHY, and DDR PHY.

- The control of the retention of LVCMOS IOs is performed via the corresponding PADCONFIG register listed in *Control Module (CTRL\_MMR)*. For more information about the exact PADCONFIG register see Pin Multiplexing Table in the device-specific Datasheet.
- MCU-Scratch-Memory - TBD
- The control of the retention of SERDES PHY is performed via CTRLMMR\_SERDESx\_CTRL[8] RET\_EN, x = 0 to 4. For more information about control registers, see *Control Module (CTRL\_MMR)*.
- The control of DDRSS retention is controlled via external DDR\_RET pin.

## 5.2.4 Dynamic Power Management

### 5.2.4.1 AVS Support

The device supports only Adaptive Voltage Scaling (AVS) Class 0. This is a procedure for lowering the voltage on certain device power rails. AVS-Class0 attempts to normalize the power consumption across all devices. The optimal voltage for each AVS supported rail of each device is determined after analysis in the factory, based on the strength of the device during manufacturing. This value is written in the device eFuse where it can be read through dedicated registers.

The following supplies support AVS-Class0:

- VDD\_CC

The AVS voltage for a supply is an E-fuse VID value located in the corresponding WKUP\_VTM\_VD\_OPPVID\_j register in the VTM module. [Table 5-56](#) lists the mapping of the supplies to the VTM control registers. Separate VID values are fused for the different OPPs that the supply supports. For more information about OPPs supported by a supply in the device, see the device-specific DataSheet.

The AVS functionality can be enabled and performed by software after the primary boot of the device is finished. Typically, the voltage adjustment of AVS operation is done as secondary boot software.

### 5.2.4.2 Dynamic Frequency Scaling (DFS) Operations

DFS is supported for all major cores (no change in voltage) such as MPU/GPU/C7x/C66x DSP.

Processor cores that have dedicated voltage supply and asynchronous operating frequency from the main SoC support:

- Independent AVS voltage setting based on Vmin of cores on the domain (Compute Cluster / VDD\_CC components only).
- Dynamic scaling of processor operating frequency without change of operating voltages.

**Table 5-93. Device Family OPP**

Voltage Domain	Module	OPP_NOM Frequency, MHz
VDD_CC (Fixed/AVS/DFS)	MPU0	2000

### 5.2.5 Thermal Management

The modules that perform thermal management are:

- On-die temperature Monitor with Integrated multiple sensors
- One thermal diode
- VTM
- DMSC firmware.

For information about VTM, see [Voltage and Thermal Manager \(VTM\)](#).

For more information how to use DMSC, see the [TISCI API](#).

## 5.3 Reset

This chapter describes the device reset management.

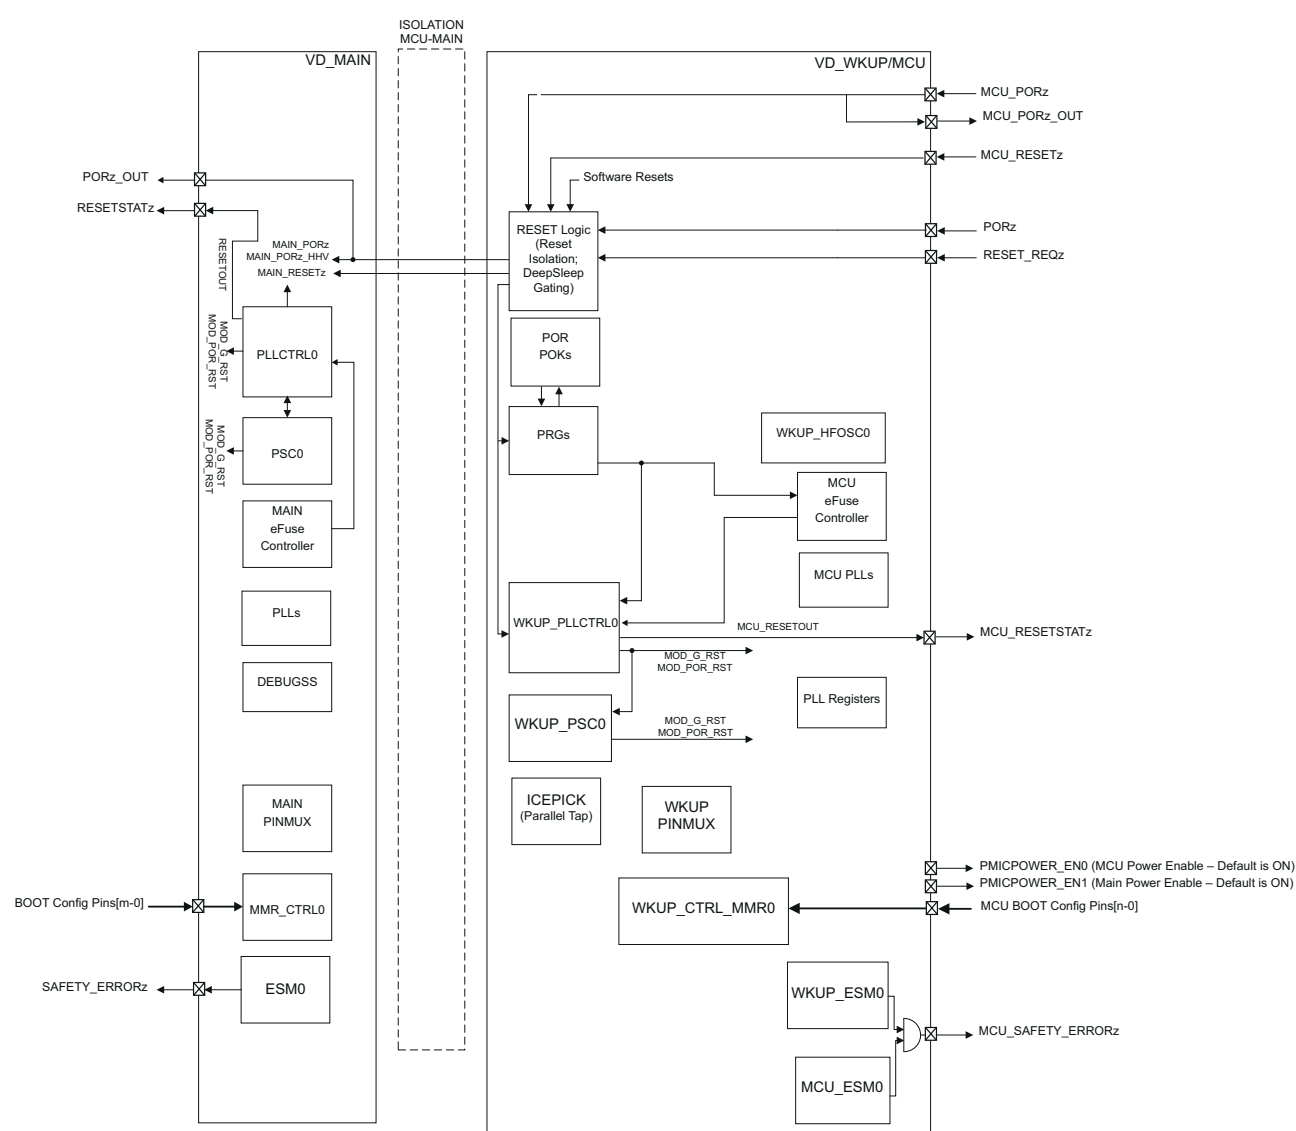

### Terminology

- DMSC - Device Management Security Controller
- PSC - Power Sleep Controller
- LPSC - Local Power Sleep Controller
- ESM - Error Signaling Module
- Isolation – the module is exempted from reset

#### 5.3.1 Reset Overview

Resets bring the device or part of the device to a known state after events such as power-up or hardware or software requests.

Figure 5-28 shows an overview of the reset architecture.

**Figure 5-28. Reset Architecture**

### Note

For power modules used in the reset see:

- For internal PORz detection, see *Power on Reset (POR) Module*, in *Power*.
- For Power Reset Generator (PRG), see *Power Reset Generator (PRG) Modules*, in *Power*.
- For POK, see *POK Modules*, in *Power*.
- For Power Glitch Detector (PGD), see *Power Glitch Detector (PGD) Modules*, in *Power*.

### Note

For information about Boot modes and Boot configuration pins, see *Initialization*.

### Note

MOD\_POR\_RST[n] and MOD\_G\_RST[n] are connected to certain modules. For more information which is the number of the LPSC of a certain module, see its specific chapter.

## 5.3.2 Reset Sources

Table 5-95 summarizes the resets supported by device.

**Table 5-95. Reset Supported in the Device**

Reset Source	Type	Sequence (Effect)
MCU_PORz	Input (control) pin Master Power-on-Reset input (active low) to the entire device. Effects all domains – WKUP, MCU, and MAIN No isolation possible.	See <a href="#">Section 5.3.6.2, MCU_PORz Sequence</a> .
MCU_RESEZz	Input (control) pin Master Warm Reset input (active low) to the entire device. Effects all domains – WKUP, MCU, and MAIN Modules configured for isolation in the MAIN domain are isolated although the WKUP/MCU domain is not isolated from the MAIN domain.	See <a href="#">Section 5.3.6.3, MCU_RESEZz Sequence</a> .
PORz	Input (control) pin Power-on-Reset input (active low) to the MAIN domain. Effects MAIN domain WKUP/MCU should be isolated from the MAIN domain	See <a href="#">Section 5.3.6.4, PORz Sequence</a> .
RESET_REQz	Input (control) pin Warm Reset Request input (active low) to the MAIN domain Effects MAIN domain WKUP/MCU should be isolated from the MAIN domain. Additionally, modules within the MAIN domain may be isolated.	See <a href="#">Section 5.3.6.5, RESET_REQz Sequence</a> .
SW_MCU_WARMRST	Software reset: equivalent to MCU_RESEZz pin CTRLMMR_WKUP_MCU_WARM_RST_CTRL <sup>(1)</sup>	See <a href="#">Section 5.3.6.3, MCU_RESEZz Sequence</a> .
SW_MAIN_POR	Software reset: equivalent to PORz pin CTRLMMR_WKUP_POR_RST_CTRL <sup>(1)</sup>	See <a href="#">Section 5.3.6.4, PORz Sequence</a> .
SW_MAIN_WARMRST	Software reset: equivalent to RESET_REQz pin CTRLMMR_WKUP_MAIN_WARM_RST_CTRL <sup>(1)</sup>	See <a href="#">Section 5.3.6.5, RESET_REQz Sequence</a> .
WKUP_DMSC0 COLD RST	Internal event: equivalent to MCU_RESEZz	See <a href="#">Section 5.3.6.3, MCU_RESEZz Sequence</a> .
WKUP_DMSC0 WARM RST	Internal event: equivalent to MCU_RESEZz	See <a href="#">Section 5.3.6.3, MCU_RESEZz Sequence</a> .

**Table 5-95. Reset Supported in the Device (continued)**

Reset Source	Type	Sequence (Effect)
Thermal Over-temperature (VTM)	Internal event: equivalent to MCU_RESETz (except that PLL behavior is different)	See <a href="#">Section 5.3.6.3, MCU_RESETz Sequence</a> .
Debug Reset		
Local Resets	Local reset is a reset that is applied to any given module in a module domain or to a CPU and/or its megamodule (any tightly coupled controllers delivered with the CPU) and their associated local watchdog timers.	

(1) These registers are part of the WKUP CTRL\_MMR domain, see *Control Module (CTRL\_MMR)*.

### 5.3.3 Reset Status

[Table 5-96](#) summarizes the reset status of the device.

**Table 5-96. Reset Status**

Reset Status	Type/Description
MCU_PORz_OUT	Output pin Propagated from the MCU_PORz input
MCU_RESETSTATz	Output pin Indicates release of internal reset on the WKUP/MCU domain Released synchronous with start of WKUP_DMSC0 ROM code execution.
PORz_OUT	Output pin Indicates PORz state in MAIN domain (delayed from PORz)
RESETSTATz	Output pin Indicates release of internal reset on the MAIN domain
THERMAL_RST	Software bit in CTRLMMR_WKUP_RESET_SRC_STAT <sup>(1)</sup>
DEBUGSS_RST	
COLD_OUT_RST	
WARM_OUT_RST	
PORZ_PIN	
RESET_REQZ_PIN	
MCU_RSTZ_PIN	
SW_MAIN_POR	
SW_MAIN_WARMRST	
SW_MCU_WARMRST	
MAIN_RST_DONE	Software bit in
MCU_RST_DONE	CTRLMMR_WKUP_RST_STAT <sup>(1)</sup>

(1) These registers are part of the WKUP CTRL\_MMR domain, see *Control Module (CTRL\_MMR)*.

### 5.3.4 Reset Control

[Table 5-97](#) lists the reset control registers.

**Table 5-97. Reset Control**

Reset Control	Control Register <sup>(1)</sup>
WKUP_DMSC0 Timeout control	CTRLMMR_WKUP_MAIN_POR_TO_CTRL (0 – 500 $\mu$ s in 100 $\mu$ s increments)
POR_RST_ISO_DONE_Z	CTRLMMR_WKUP_POR_RST_CTRL
SOC_WARMRST_ISO_DONE_Z	CTRLMMR_WKUP_MAIN_WARM_RST_CTRL

(1) These registers are part of the WKUP CTRL\_MMR domain, see *Control Module (CTRL\_MMR)*.

### 5.3.5 BOOTMODE Pins

The MCU\_BOOTMODE pins and BOOTMODE direct the MCU\_R5FSS boot (first stage boot). MCU\_BOOTMODE pins are latched based upon the rising edge of MCU\_PORz. BOOTMODE pins are latched based upon the rising edge of PORz\_OUT.

For more details on Bootmode pins, see *Initialization*.

### 5.3.6 Reset Sequences

#### 5.3.6.1 MCU\_PORz Overview

On MCU\_PORz,

- the WKUP\_DMSC0 is powered and clocked;
- the MCU\_R5FSS0 is powered but not clocked;
- all processors (except PRU\_ICSSG) on the MAIN side are powered down (and clock-gated):
  - C71x cores
  - C66x cores
  - Dual A72 MPU Sub-systems
  - GPU
  - R5FSS
  - HD Video Encoder/Decoder
  - Vision Pre-processing accelerator
  - Depth and Motion perception accelerator
- PRU\_ICSSG is in an Always On domain but is clock gated.

The general behavior for coming out of an MCU\_PORz reset is:

- Hardware initialization

**ROM Boot Loader (or ROM Code):** the purpose of the ROM Boot Loader is to load and check integrity of the Secondary Boot Loader (or application image).

- WKUP\_DMSC0 Code executes, setting up MCU\_R5FSS0 clocks and configuring security. WKUP\_DMSC0 code passes Boot info to MCU\_R5FSS0 and releases the MCU\_R5FSS0 clocks.
- MCU\_R5FSS0 ROM reads MCU\_BOOTMODE pins and if the boot is not specified as MCU-Only, the MCU\_R5FSS0 ROM also reads the BOOTMODE pins. The Bootmode pins define the peripherals involved in the boot and the associated media (see ROM Code boot modes). The media holds the secondary boot loader (SBL) or the entire application image. The WKUP\_DMSC0 firmware needs to be incorporated in this code. For MCU\_R5FSS ROM functional description, refer to *Initialization*.
- Once the Secondary Boot Loader has been verified, the WKUP\_DMSC0 issues a clock stop to the MCU\_R5FSS0 and resets the MCU\_R5FSS0.

**Secondary Boot Loader:** the secondary boot loader configures the device for application.

The previous description gives the high-level behavior for the MCU\_PORz reset. Other resets are almost a subset of this procedure. [Section 5.3.6.2](#), [Section 5.3.6.3](#), [Section 5.3.6.4](#), and [Section 5.3.6.5](#) explain this sequence in more detail.

#### 5.3.6.2 MCU\_PORz Sequence

MCU\_PORz and PORz must be held low until:

- All supplies have ramped to proper levels
- WKUP\_HFOSC0 has a stable amplitude that propagates clocks into the core

If the supplies and clock are already stable, MCU\_PORz and/or PORz must be held active (low) for a minimum of 1.2  $\mu$ s.

1. When MCU\_PORz is asserted low, WKUP\_CTRL\_MMR0 and MCU\_CTRL\_MMR0 registers are reset; a bit within the WKUP\_CTRL\_MMR0 registers is reset which allows PORz to propagate to the MAIN domain without delay. In the MAIN domain, CTRL\_MMR0 registers are reset.
2. The MCU\_BOOTMODE pins are latched on the rising edge of MCU\_PORz. The BOOTMODE pins are latched on the rising edge of PORz.
3. The release of MCU\_PORz begins a read of fuse values to register files; several different chains of e-fuse values are registered in parallel read sequences. Values are consumed by different blocks at various points in this sequence. In parallel and based upon the release of PORz, the MAIN domain e-fuse controller initiates a read of its e-fuse values.

4. LBIST/PBIST checks of the WKUP\_DMSC0 and MCU\_R5FSS0 cores and memories are run in the WKUP/MCU domain; in the MAIN domain, the BIST engines are controlled by the application software.
5. WKUP\_PSC0 is initialized (and PSC0 in the MAIN domain is initialized); concretely, the PSC modules (both WKUP\_PSC0 and PSC0) configure default power states and LPSC (clocking) states.
6. After power domain and clock domain initialization is completed, PSC modules release resets to the device (MOD\_POR\_RST, MOD\_G\_RST).
7. WKUP\_DMSC0 is removed from reset; WKUP\_DMSC0 ROM code execution begins. At this time MCU\_RESETSTATz is de-asserted.
8. WKUP\_DMSC0 executes WKUP\_DMSC0 ROM.
  - a. Configures MCU\_PLL0, MCU\_PLL0\_HSDIV1, and WKUP\_PLLCTRL0 (proper clock frequency for MCU\_R5FSS0).
  - b. Configures firewalls and message manager.
  - c. Uses the message manager to pass Boot info to MCU\_R5FSS0 ROM.
9. Based upon MCU\_BOOTMODE[06],
  - a. if MCU\_BOOTMODE[06] = 0, the user has requested a normal boot. Wait for MAIN to be released from reset (duration limited by WKUP\_DMSC0 timeout).
  - b. if MCU\_BOOTMODE[06] = 1, MCU-Only boot is requested. There is no timeout nor dependency upon MAIN release from power on reset.
10. MCU\_R5FSS0\_CORE0 is released from reset and begins to execute ROM
  - a. Based upon the value of MCU\_BOOTMODE pins (and MAIN domain BOOTMODE pins if MCU\_BOOTMODE[06] = 0), the R5F ROM code configures peripherals and PLLs to enable loading the external code.
  - b. Secondary boot-loader is loaded from external memory
  - c. MCU ROM requests WKUP\_DMSC0 for loaded code authentication
  - d. WKUP\_DMSC0 stops clocks to MCU\_R5FSS0
  - e. WKUP\_DMSC0 issues an MCU\_R5FSS0 reset
  - f. MCU\_R5FSS0\_CORE0 begins executing secondary boot-loader.

At the end of this sequence, MCU\_R5FSS0 is executing the secondary bootloader. The control of the device now passes to the customer code.

---

#### Note

On warm resets (except those caused by a VTM Thermal over-temperature), the output of various PLLs are either bypassed or left unaffected. For more details, see [Section 5.3.7, PLL Behavior on Reset](#).

---

---

#### Note

Reset Isolated domains are isolated during a MCU\_RESETz (or any warm reset) event.

---

### 5.3.6.3 MCU\_RESETz Sequence

MCU\_RESETz release requires:

- All supplies have ramped to proper levels
- WKUP\_HFOSC0 has a stable amplitude that propagates clocks into the core

MCU\_RESETz must be held active (low) for a minimum of 1.2  $\mu$ s.

When MCU\_RESETz is asserted low, it is also immediately passed to the MAIN domain (similar to MCU\_PORz asserting PORz).

1. Much of the device is reset. Blocks that are not reset:
  - a. Internal 12.5 MHz oscillator
  - b. External HF oscillator
  - c. External LF oscillator

- d. Power monitoring circuitry (Bandgap, POR, POK, PGD, PRG)
- e. I/O cells and I/O pad configuration registers
- f. SERDES
- g. efuse Controller/storage
- h. PLLs
- i. Voltage Temperature Module
- j. Global Timebase Counter (GTC)
- k. Boot Mode Latches
- l. Debug Components
- m. PSRAM

Another group of modules is partially reset:

- a. PSC
  - b. WKUP\_DMSC0
  - c. Debug
  - d. STM
  - e. MCU\_CPSW0 (CPSW2G)
  - f. CPSW0 (CPSW9G)
  - g. Probe
2. When MCU\_RESETz is released, PSC modules release MOD\_G\_RST to the device.
  3. WKUP\_DMSC0 is removed from reset; WKUP\_DMSC0 ROM code execution begins. At this time MCU\_RESETSTATz is de-asserted.
  4. WKUP\_DMSC0 executes ROM.
    - a. Configures MCU PLL0, MCU PLL0 HSDIV1, and WKUP PLLCTRL0 (proper clock frequency for MCU\_R5FSS0).
    - b. Configures firewalls and message manager.
    - c. Uses the message manager to pass Boot info to MCU
  5. Based upon MCU\_BOOTMODE[06],
    - a. if MCU\_BOOTMODE[06] = 0, the user has requested a normal boot. Wait for MAIN to be released from reset (duration limited by WKUP\_DMSC0 timeout).
    - b. if MCU\_BOOTMODE[06] = 1, MCU-Only boot is requested. There is no timeout nor dependency upon MAIN release from power on reset.
  6. MCU\_R5FSS0\_CORE0 is released from reset and begins to execute ROM
    - a. Based upon the value of MCU\_BOOTMODE pins (and MAIN domain BOOTMODE pins if MCU\_BOOTMODE[06] = 0), the MCU ROM code configures peripherals and PLLs to enable loading the external code.
    - b. Secondary boot-loader is loaded from external memory
    - c. MCU ROM requests WKUP\_DMSC0 for loaded code authentication
    - d. WKUP\_DMSC0 stops clocks to MCU\_R5FSS0
    - e. WKUP\_DMSC0 issues MCU reset
    - f. MCU\_R5FSS0\_CORE0 begins executing secondary boot-loader.

At the end of this sequence, MCU\_R5FSS0 is executing the secondary bootloader. The control of the device now passes to the customer code.

#### 5.3.6.4 PORz Sequence

PORz release requires:

- All supplies have ramped to proper levels
- WKUP\_HFOSC0 has a stable amplitude that propagates clocks into the core

PORz must be held active (low) for a minimum of 1.2  $\mu$ s.

If PORz is asserted with MCU\_PORz, then PORz propagates to the MAIN domain immediately.

If PORz is asserted independent of MCU\_PORz, then the user code must have setup:

- CTRLMMR\_WKUP\_POR\_RST\_CTRL[0] POR\_RST\_ISO\_DONE\_Z (high) in order to block the PORz from immediate propagation and
- CTRLMMR\_WKUP\_MAIN\_POR\_TO\_CTRL[2:0] TIMEOUT\_PER in order to configure the timeout, after which PORz is unconditionally propagated to MAIN domain.

PORz sequence is:

1. When PORz is asserted low, hardware in the WKUP/MCU domain recognizes the PORz and generates an interrupt to WKUP\_DMSC0 and MCU. Reset hardware latches the PORz low level.
2. User software is responsible for isolating WKUP/MCU domain from the MAIN domain. The details of the isolation are application specific and are carried out in software. Connections between the WKUP/MCU domain and the MAIN domain include:
  - LPSC\_WKUPMCU2MAIN - LPSC4 (WKUP\_PSC0)
  - LPSC\_MAIN2WKUPMCU - LPSC5 (WKUP\_PSC0)
  - Communications channel: MCSPI3 is connected as a master to MCU\_MCSPI1; MCSPI4 is directly connected as a slave to MCU\_MCSPI2.
  - WKUP\_GPIOMUX\_INTRTR0
  - MAIN2MCU\_LVL\_INTRTR0
  - MAIN2MCU\_PLS\_INTRTR0
  - WKUP\_ESM0
  - MCU\_ESM0

When the isolation is complete, MCU\_R5FSS0 or WKUP\_DMSC0 must write CTRLMMR\_WKUP\_POR\_RST\_CTRL[0] POR\_RST\_ISO\_DONE\_Z low to allow the PORz signal to propagate.

3. The BOOTMODE pins are latched on the rising edge of PORz.
4. The release of PORz begins a read of eFuse values to register files; several different chains of e-fuse values are registered in parallel read sequences. Values are consumed by different blocks at various points in this sequence.
5. PSC0 is initialized; specifically, PSC0 module configures default power states and LPSC (clocking) states.
6. After power domain / clock domain initialization is completed, PSC modules release resets to the device (MOD\_POR\_RST, MOD\_G\_RST).
7. CTRLMMR\_WKUP\_RST\_STAT[0] MAIN\_RST\_DONE is asserted.

At the end of this sequence, MCU\_R5FSS can read the CTRLMMR\_WKUP\_RST\_STAT[0] MAIN\_RST\_DONE bit and begin re-configuring the MAIN domain.

### 5.3.6.5 RESET\_REQz Sequence

RESET\_REQz release requires:

- All supplies have ramped to proper levels
- WKUP\_HFOSC0 has a stable amplitude that propagates clocks into the core

RESET\_REQz must be held active (low) for a minimum of 1.2  $\mu$ s.

Like the PORz sequence, it is necessary to have configured CTRLMMR\_WKUP\_MAIN\_WARM\_RST\_CTRL[0] SOC\_WARMRST\_ISO\_DONE\_Z high in order to block the reset request from immediately propagating. Unlike the PORz sequence, there is no timeout. Also, unlike the PORz sequence, some clock domains within given power domains can be configured to ignore the RESET\_REQz signal.

1. When RESET\_REQz is asserted low, hardware in the WKUP/MCU domain recognizes the RESET\_REQz and generates an interrupt to WKUP\_DMSC0 and MCU\_R5FSS0. Reset hardware latches the RESET\_REQz low level.
2. User software is responsible for isolating WKUP/MCU domain from the MAIN domain. The details of the isolation are application specific and are carried out in software. Connections between the WKUP/MCU domain and the MAIN domain include:
  - LPSC\_WKUPMCU2MAIN - LPSC4 (WKUP\_PSC0)
  - LPSC\_MAIN2WKUPMCU - LPSC5 (WKUP\_PSC0)

- Communications channel: MCSPI3 is connected as a master to MCU\_MCSP11; MCSPI4 is directly connected as a slave to MCU\_MCSP12.
- WKUP\_GPIOMUX\_INTRTR0
- MAIN2MCU\_LVL\_INTRTR0
- MAIN2MCU\_PLS\_INTRTR0
- WKUP\_ESM0
- MCU\_ESM0

When the isolation is complete, MCU\_R5FSS0 or WKUP\_DMSC0 must write CTRLMMR\_WKUP\_MAIN\_WARM\_RST\_CTRL[0] SOC\_WARMRST\_ISO\_DONE\_Z low to allow the RESET\_REQz signal to propagate.

3. Power domains are not reset by RESET\_REQz if-and-only-if a LPSC in the power domain is configured to be reset isolated. Otherwise, power domains and clock domains are reset by RESET\_REQz.

#### Note

As an example of how to read tables in the PSC: Device Power-Management Layout Section, in *Power*, PSC0 Power Management Device-Level Layout shows that PD\_R5FSS\_0 is assigned Power Domain Index 24 with LPSCs 93, 94, and 95 controlling clocks/resets to circuitry within this power domain. PSC0 Power Domain Features shows that power domain 24 is OFF by default (if isolation does not block the reset). PSC0 LPSC Features shows that LPSC 93, 94, and 95 are OFF by default *but* LPSC 93 and 94 can be configured for reset isolation.

If Reset isolation is selected for LPSC 93 and 94, resets and clocks are not affected by the RESET\_REQz signal. Power Domain 24 cannot be reset when the LPSCs are active. Note that LPSC 95 **is** reset.

If Reset isolation is not selected for either LPSC 93 or 94, resets propagate to LPSC 93, 94, and 95; the clocks are stopped to these LPSCs (since their default state is OFF). Power Domain 24 is reset to its OFF state.

4. After power domain / clock domain initialization is completed, PSC modules release resets to the non-isolated parts of the device (MOD\_POR\_RST, MOD\_G\_RST).
5. CTRLMMR\_WKUP\_RST\_STAT[0] MAIN\_RST\_DONE is asserted.

At the end of this sequence, MCU\_R5FSS0 can read the CTRLMMR\_WKUP\_MAIN\_WARM\_RST\_CTRL[0] SOC\_WARMRST\_ISO\_DONE\_Z bit and begin re-configuring the MAIN domain.

#### Note

On warm resets (except those caused by a VTM Thermal over-temperature), the output of various PLLs are either bypassed or left unaffected. For more details, see [Section 5.3.7, PLL Behavior on Reset](#).

### 5.3.7 PLL Behavior on Reset

[Table 5-98](#) summarizes the PLL behavior on reset.

**Table 5-98. PLL Behavior on Reset**

Reset Type	PLL Behavior	
	MCU Domain PLLs	MAIN Domain PLLs
MCU_PORz	All PLLs are reset	All PLLs are reset
PORz	All PLLs are unaffected	All PLLs are reset
MCU_RESETz or RESET_REQz (or other warm resets except VTM Thermal over-temperature event)	All PLL outputs are bypassed (to the reference input frequency into the PLL), see <a href="#">Table 5-99</a> .	Some PLL outputs are bypassed (to the reference input frequency into the PLL) and other PLLs are unaffected, see <a href="#">Table 5-99</a> .
Warm reset triggered by a VTM thermal over-temperature event	All PLL outputs are bypassed	All PLL outputs are bypassed

**Table 5-99. PLL Behavior on Warm Resets, Except VTM Event**

Not-bypassed (unaffected)	Bypassed
PLL1	MCU_PLL0
PLL2	MCU_PLL1
PLL3	MCU_PLL2
PLL16	PLL0
PLL17	PLL4
PLL18	PLL5
PLL19	PLL6
PLL23	PLL7
	PLL8
	PLL12
	PLL13
	PLL14
	PLL15
	PLL24
	PLL25

The warm reset event bypasses the PLL (that are to be bypassed) while the warm reset is asserted; after the warm reset is released, the PLL switches from bypass to using the PLL again. If the user wants to maintain bypassed PLLs in the bypass mode (for example, to control current slews on the board in a reset event); there are control bits to configure the PLL in this way:

- For MCU\_PLL\_[2:0]:  
CTRLMMR\_WKUP\_MCU\_PLL\_CLKSEL[23] BYP\_WARM\_RST = 0  
CTRLMMR\_WKUP\_MCU\_PLL\_CLKSEL[31] BYPASS\_SW\_OVRD = 1
- For bypassed PLLs in the MAIN domain:  
CTRLMMR\_WKUP\_MAIN\_PLLn\_CLKSEL[23] BYP\_WARM\_RST = 0  
CTRLMMR\_WKUP\_MAIN\_PLLn\_CLKSEL[31] BYPASS\_SW\_OVRD = 1

The behavior with PLLs configured as defined above is:

- the BYPASS\_SW\_OVRD bit ( = 1) enables the following behavior:
  - the PLL currently is not in bypass mode (for example, the PLL clock propagates) because BYP\_WARM\_RST is 0
  - when a warm reset occurs, the PLLs configured to bypass automatically set the BYP\_WARM\_RST to 1. This setting (with BYPASS\_SW\_OVRD = 1) maintains the bypass state after the warm reset is released.

When software is ready to use the PLL, the BYP\_WARM\_RST is cleared back to 0.

## 5.4 Clocking

This chapter describes the clock architecture of the device.

---

### Note

For a detailed visual representation of the distribution and management of the device clocks at the device level, see the clock interactive software for the device - Clock Tree Tool (CTT) .

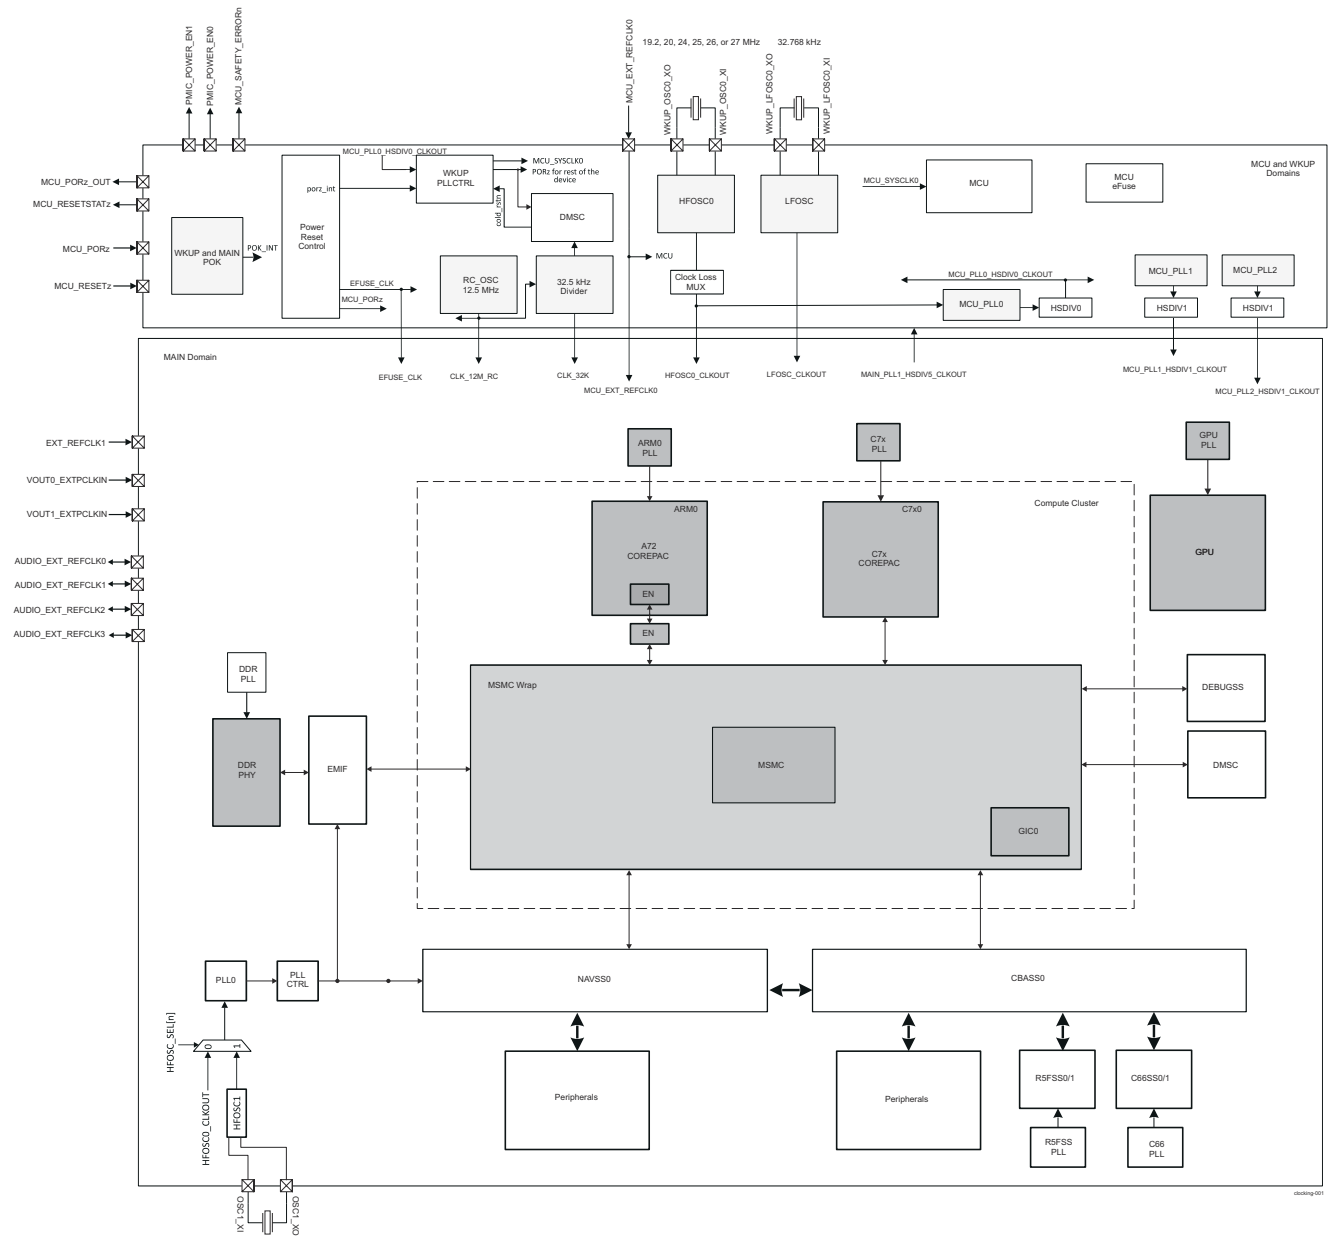

---

### 5.4.1 Overview

To satisfy the various subsystems requirements, the device features multiple clock sources and clock generators:

- External Crystal Drivers
- Internal Oscillator
- Phase-Locked Loop circuits (PLLs)
- Dividers

[Figure 5-29](#) shows the device top-level clock diagram. The clocking is divided into two clocking domains - WKUP/MCU, and MAIN.

### Figure 5-29. Top-Level Clock Diagram

## 5.4.2 Clock Inputs

### 5.4.2.1 Overview

Various external clock inputs are needed to drive the device. Summary of these input clock signals is given below. Some of those inputs are bidirectional and are marked as inputs/outputs in the summary:

- High frequency oscillators
  - WKUP\_OSC0\_XO/WKUP\_OSC0\_XI — external main crystal interface pins of the internal oscillator which sources a reference clock. Provides reference clock to PLLs within WKUP/MCU and MAIN domain.
  - OSC1\_XO/OSC1\_XI — external main crystal interface pins connected to internal oscillator which sources reference clock. Provides reference clock to PLLs within MAIN domain. This high-frequency oscillator is used to provide audio clock frequencies to MCASPs.
- Low frequency oscillator
  - WKUP\_LFOSC\_XO/WKUP\_LFOSC\_XI — external main crystal interface pins connected to internal oscillator which sources reference clock provides a clock for low power operation.
- General purpose clock inputs
  - MCU\_EXT\_REFCLK0 — optional external system clock input (MCU domain).
  - EXT\_REFCLK1 — optional external system clock input (MAIN domain). Optionally PLL4 (AUDIO0 PLL), PLL15 (AUDIO0 PLL) and MCASP can be sourced by EXT\_REFCLK1 (sourced externally).
- External video pixel clock inputs
  - VOUT0\_EXTPCLKIN — optional for the DPI0 port of DSS.
  - VOUT1\_EXTPCLKIN — optional for the DPI1 port of DSS.
- External CPTS reference clock inputs
  - MCU\_CPTS0\_RFT\_CLK — CPTS reference clock inputs for MCU\_CPTS\_RFT\_CLK.
  - CPTS0\_RFT\_CLK — CPTS reference clock inputs for CPTS\_RFT\_CLK.
- External audio reference clock input/output pins. For more information which clocks may be sourced as an outputs to the pins, see [Section 12.5.2, Multichannel Audio Serial Port \(MCASP\)](#).
  - AUDIO\_EXT\_REFCLK0
  - AUDIO\_EXT\_REFCLK1
  - AUDIO\_EXT\_REFCLK2
  - AUDIO\_EXT\_REFCLK3

#### Note

Other clock inputs that are routed directly to the subsystems are described in the respective subsystem chapters.

### 5.4.2.2 Mapping of Clock Inputs

[Table 5-100](#) lists the mapping for the device clock inputs.

**Table 5-100. Mapping for Input Sources**

Domain	Clock	Ball Mapping	Frequency List / Range	Type
WKUP	WKUP_HFOSC0_CLK	WKUP_OSC0_XI WKUP_OSC0_XO	19.2, 20, 24, 25, 26, or 27 MHz	External Clock / Crystal Pins
	WKUP_LFOSC0_CLKOUT	WKUP_LFOSC_XI WKUP_LFOSC_XO	32.768 kHz	External Clock / Crystal Pins
	MCU_EXT_REFCLK0	MCU_EXT_REFCLK0	up to 100 MHz	LVC MOS
	MCU_CPTS_RFT_CLK	MCU_CPTS0_RFT_CLK	up to 100 MHz	LVC MOS
MAIN	HFOSC1_CLK	OSC1_XI OSC1_XO	19.2, 20, 24, 25, 26, or 27 MHz For audio applications: 22.5792 MHz or 24.576 MHz	External Clock / Crystal Pins
	EXT_REFCLK1	EXT_REFCLK1	up to 100 MHz	LVC MOS
	VOUT0_EXTPCLKIN	VOUT0_EXTPCLKIN	up to 150 MHz	LVC MOS

**Table 5-100. Mapping for Input Sources (continued)**

Domain	Clock	Ball Mapping	Frequency List / Range	Type
	VOUT1_EXTCLKIN	VOUT1_EXTCLKIN	up to 150 MHz	LVC MOS
	CPTS_RFT_CLK	CPTS0_RFT_CLK	up to 150 MHz	LVC MOS
	AUDIO_EXT_REFCLK0	AUDIO_EXT_REFCLK0	up to 80 MHz	LVC MOS
	AUDIO_EXT_REFCLK1	AUDIO_EXT_REFCLK1	up to 80 MHz	LVC MOS
	AUDIO_EXT_REFCLK2	AUDIO_EXT_REFCLK2	up to 80 MHz	LVC MOS
	AUDIO_EXT_REFCLK3	AUDIO_EXT_REFCLK3	up to 80 MHz	LVC MOS

[Table 5-101](#) lists the internal RC-oscillator sources.

**Table 5-101. Internal RC Oscillator Input Sources**

Domain	RC Oscillator	Clock	Frequency
WKUP	WKUP_RC_OSC_12M	CLK_12M_RC	12.5 MHz

### 5.4.3 Clock Outputs

The device provides several system clock outputs. Summary of these output clock signals is as follows:

- MCU\_SYCLKOUT0
- MCU\_OBSCLK0
- SYCLKOUT0
- OBSCLK0, OBSCLK1, OBSCLK2

Other clock outputs, that are routed directly from subsystems to device pins, are described in the respective module chapter.

Observation clock pins - MCU\_OBSCLK0, OBSCLK0, OBSCLK1, and OBSCLK2 serve the following purposes:

- During testing, PLLs on the device are configured to output all operating frequencies desired by each module to characterize PLL performance.
- System debug: during debug, clocks from various PLLs can be inspected for possible clues. Example clock glitches, lock loss etc.

#### Note

Maximum frequency supported on both MCU\_OBSCLK0, OBSCLK0, OBSCLK1, and OBSCLK2 pins is 200 MHz. Hence the divider at the output of each OBSCLK mux must be programmed to meet this limitation.

Unlike the OBSCLK pins which can select several different clocks for output, system clock pins (MCU\_SYCLKOUT0 and SYCLKOUT0) are hardwired to dedicated clock resources (see [Section 5.4.3.2](#))

#### 5.4.3.1 Observation Clock Pins

##### 5.4.3.1.1 MCU\_OBSCLK0 Pin

MCU\_OBSCLK0 output is controlled by CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL register in the WKUP\_CTRL\_MMR0 module; for more information about control registers, see *Control Module (CTRL\_MMR)*. Two muxes are connected in series - MCU\_OBSCLK0\_MUX0 and MCU\_OBSCLK0\_MUX1, see [Figure 5-30](#).

**Figure 5-30. MCU\_OBSCLK0 Muxes Diagram**

How to select the output of MCU\_OBSCLK0\_MUX1 is described in [Table 5-102](#).

**Table 5-102. MCU\_OBSCLK0\_MUX1 Output Clock Selection**

CTRLMMR_WKUP_MCU_OBSCLK_CTRL <sup>(2)</sup> [3-0] CLK_SEL	MCU_OBSCLK0_MUX1 Output Clock Selection <sup>(1)</sup>
0x0	CLK_12M_RC
0x1	0 (GND) <sup>(3)</sup>
0x2	MCU_PLL0_HSDIV0_CLKOUT
0x3	WKUP_PLLCTL_OBSCLK (MCU_PLL0 input reference clock)
0x4	MCU_PLL1_HSDIV1_CLKOUT

**Table 5-102. MCU\_OBSCLK0\_MUX1 Output Clock Selection (continued)**

CTRLMMR_WKUP_MCU_OBSCLK_CTRL <sup>(2)</sup> [3-0] CLK_SEL	MCU_OBSCLK0_MUX1 Output Clock Selection <sup>(1)</sup>
0x5	MCU_PLL1_HSDIV2_CLKOUT
0x6	MCU_PLL1_HSDIV3_CLKOUT
0x7	MCU_PLL1_HSDIV4_CLKOUT
0x8	MCU_PLL2_HSDIV0_CLKOUT
0x9	CLK_32K
0xA	MCU_PLL2_HSDIV1_CLKOUT
0xB	MCU_PLL2_HSDIV2_CLKOUT
0xC	MCU_PLL2_HSDIV3_CLKOUT
0xD	MCU_PLL2_HSDIV4_CLKOUT
0xE	WKUP_HFOSC0_CLKOUT
0xF	WKUP_LFOSC0_CLKOUT

(1) Software-controlled 4-bit divider is used to obtain the divided versions of the clocks passed to MCU\_OBSCLK1 mux

(2) For more information about control registers, see *Control Module (CTRL\_MMR)*.

(3) GND - ground

The value of the software-controlled 4-bit divider is determined by register CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL[11-8] MCU\_OBSCLK\_CTRL\_CLK\_DIV in the WKUP\_CTRL\_MMR0 module; for more information about control registers, see *Control Module (CTRL\_MMR)*.

#### Note

MCU\_OBSCLK1\_MUX0 is provided as a low jitter output for WKUP\_HFOSC0\_CLK. In this configuration, CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL[3:0] should be configured as 0001b (1, selecting a logical low signal) and CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL[24] should be configured as 1.

#### 5.4.3.1.2

#### Note

MCU\_OBSCLK1\_MUX0 is provided as a low jitter output for WKUP\_HFOSC0\_CLK. In this configuration, CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL[3:0] should be configured as 0001b (1, selecting a logical low signal) and CTRLMMR\_WKUP\_MCU\_OBSCLK\_CTRL[24] should be configured as 1.

#### 5.4.3.1.3 OBSCLK0, OBSCLK1, and OBSCLK2 Pins

The OBSCLK0, OBSCLK1, and OBSCLK2 output pins are controlled simultaneously, so that the three pins are connected to the same signal. OBSCLK0, OBSCLK1, and OBSCLK2 outputs are controlled by CTRLMMR\_OBSCLK0\_CTRL register in the CTRL\_MMR0 module; for more information about control registers, see *Control Module (CTRL\_MMR)*. [Figure 5-31](#) shows a block diagram of internal OBSCLK0 mux connections.

#### Note

OBSCLK2 has lot more jitter due to PD limitations/long routing. If the intent is to use OBSCLK2 to do anything beyond just observe clock toggle, customers should switch to OBSCLK0 or OBSCLK1.

**Figure 5-31. OBSCLK0 Muxes Diagram**

**Table 5-103. OBSCCLK0\_MUX1\_CLKOUT**

CTRLMMR_OBSCCLK1_CTRL <sup>(1)</sup> [1-0] CLK_SEL	OBSCCLK0_MUX1_CLKOUT Selection
0x0	MAIN_PLL7_HSDIV0_CLKOUT / 4
0x1	MAIN_PLL8_HSDIV0_CLKOUT / 8
0x2	MAIN_PLL13_HSDIV0_CLKOUT / 4
0x3	0 (GND) <sup>(2)</sup>

(1) For more information about control registers, see *Control Module (CTRL\_MMR)*.

(2) GND - ground

**Table 5-104. OBSCCLK0, OBSCCLK1, and OBSCCLK2 Clock Selection**

CTRLMMR_OBSCCLK0_CTRL <sup>(2)</sup> [4-0] CLK_SEL	OBSCCLK0, OBSCCLK1, and OBSCCLK2 Selection <sup>(1)</sup>
0x0	MAIN_PLL0_HSDIV0_CLKOUT
0x1	MAIN_PLL1_HSDIV0_CLKOUT
0x2	MAIN_PLL2_HSDIV0_CLKOUT
0x3	MAIN_PLL3_HSDIV0_CLKOUT
0x4	MAIN_PLL4_HSDIV0_CLKOUT
0x5	MAIN_PLL5_HSDIV0_CLKOUT
0x6	MAIN_PLL6_HSDIV0_CLKOUT
0x7	0 (GND) <sup>(3)</sup>
0x8	0 (GND) <sup>(3)</sup>
0x9	0 (GND) <sup>(3)</sup>
0xA	0 (GND) <sup>(3)</sup>
0xB	0 (GND) <sup>(3)</sup>
0xC	MAIN_PLL12_HSDIV0_CLKOUT
0xD	Input from OBSCCLK0_MUX1_CLKOUT
0xE	MAIN_PLL14_HSDIV0_CLKOUT
0xF	MAIN_PLL15_HSDIV0_CLKOUT
0x10	MAIN_PLL16_HSDIV0_CLKOUT
0x11	MAIN_PLL17_HSDIV0_CLKOUT
0x12	MAIN_PLL18_HSDIV0_CLKOUT
0x13	MAIN_PLL19_HSDIV0_CLKOUT
0x14	UFS MPHY_TX_REF_SYMBOLCLK
0x15	UFS MPHY_M31_VCO_19P2M_CLK
0x16	UFS MPHY_M31_VCO_26M_CLK
0x17	MAIN_PLL23_HSDIV0_CLKOUT
0x18	MAIN_PLL24_HSDIV0_CLKOUT
0x19	MAIN_PLL25_HSDIV0_CLKOUT
0x1A	CPTS_GENF3
0x1B	CLK_12M_RC
0x1C	LFXOSC_CLKOUT
0x1D	PLLCTRL_OBSCCLK (PLL0 input reference clock)
0x1E	HFOSC1_CLK
0x1F	WKUP_HFOSC0_CLKOUT

(1) Software-controlled 8-bit divider is used to obtain the divided versions of the clocks passed to output pins

(2) For more information about control registers, see *Control Module (CTRL\_MMR)*.

(3) GND - ground

The value of the software-controlled 8-bit divider is determined by register CTRLMMR\_OBSCCLK0\_CTRL[15-8] OBSCCLK\_CTRL\_CLK\_DIV; for more information about control registers, see *Control Module (CTRL\_MMR)*.

### 5.4.3.2 System Clock Pins

#### 5.4.3.2.1 MCU\_SYSCLKOUT0

MCU\_SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (MCU\_SYSCLKOUT0).

#### Note

MCU\_SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

#### 5.4.3.2.2 SYSCLKOUT0

SYSCLK0 is divided by 4 and then send out of the device as a LVCMOS clock signal (SYSCLKOUT0). This signal can be used to test if the specific device clock is functioning or not.

#### Note

SYSCLKOUT0 cannot be used as a clock source for external devices on the board.

### 5.4.4 Device Oscillators

The device has the possibility to source clocks of two external high-frequency oscillators - WKUP\_HFOSC0 and HFOSC1 and one external low-frequency oscillator - WKUP\_LFOSC0. The device has one internal RC oscillator - WKUP\_RC\_OSC\_12M.

#### 5.4.4.1 Device Oscillators Integration

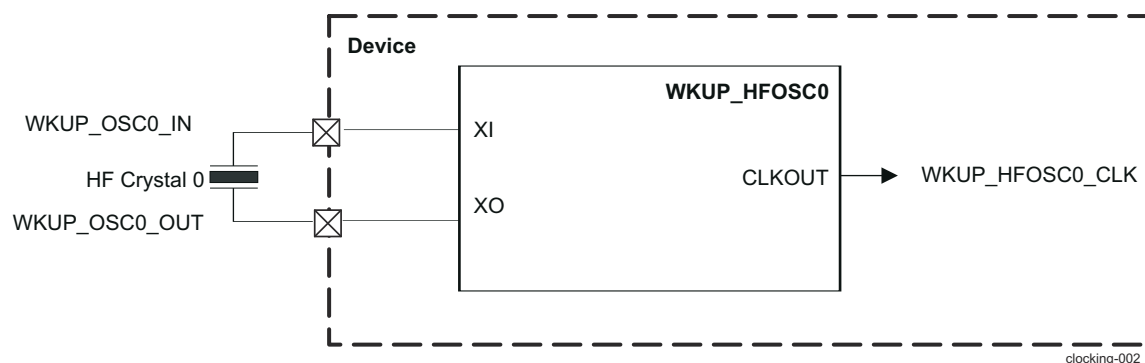

##### 5.4.4.1.1 Oscillators with External Crystal

By default, WKUP\_LFOSC0 and HFOSC1 are disabled, while WKUP\_HFOSC0 is enabled after PORz.

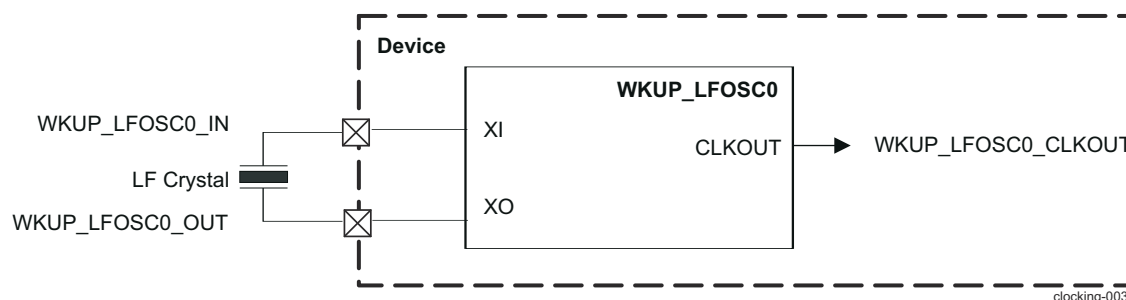

Program CTRLMMR\_WKUP\_LFXOSC\_CTRL register to enable WKUP\_LFOSC0 oscillator.

CTRLMMR\_WKUP\_LFXOSC\_TRIM[18-16] I\_MULT requires configuration based upon the load capacitance of the low-frequency crystal circuit.

All device oscillators with external crystals support a bypass mode. In this mode, an external clock can be driven on the XI Pin.

**Figure 5-32. WKUP\_HFOSC0 Integration Diagram**

**Figure 5-33. WKUP\_LFOSC0 Integration Diagram**

**Figure 5-34. HFOSC1 Integration Diagram**

#### 5.4.4.1.2 Internal RC Oscillator

WKUP\_RC\_OSC\_12M is always oscillate mode.

The RC clock output (WKUP\_RC\_OSC\_12M) is used by the on-chip Reset Glue logic, Power Reset Generator (PRG) circuits, WKUP\_HFOSC0 Loss Circuits, Dual Clock Comparator (DCC) and Timer Modules. Its frequency is targeted at 12.55MHz +/-10%.

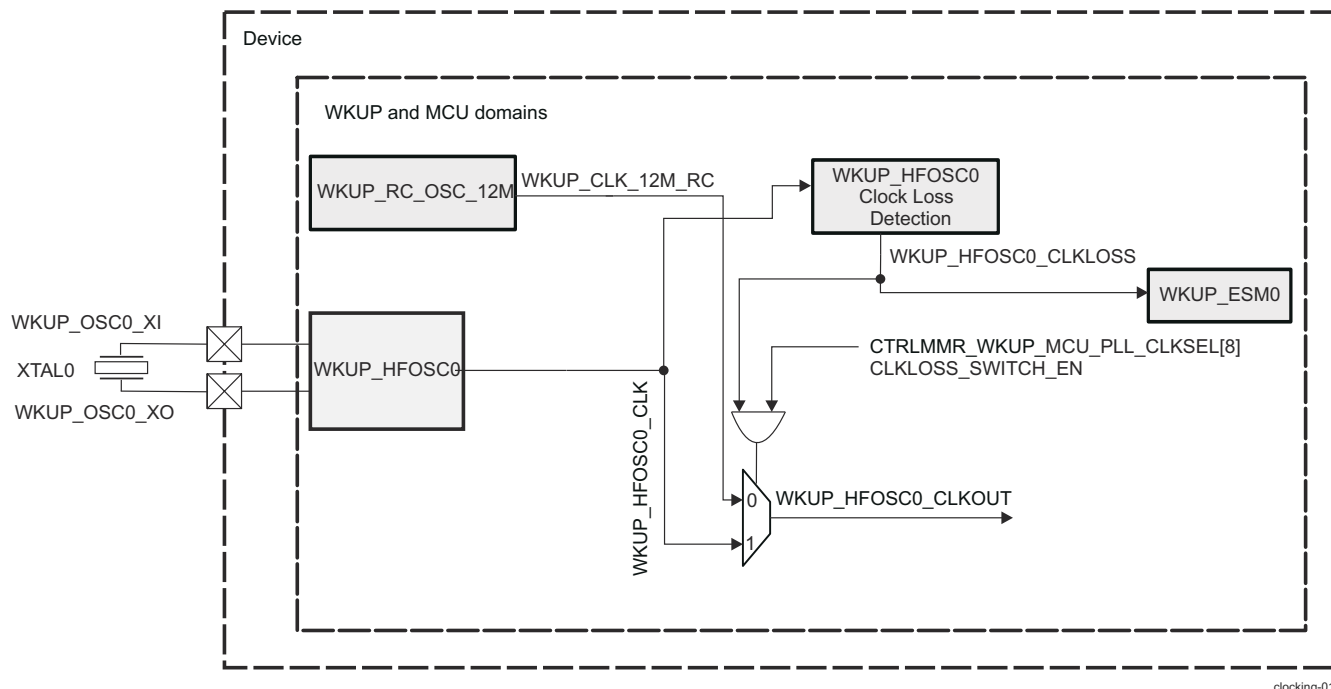

#### Note

An output clock of WKUP\_RC\_OSC\_12M is further divided down to generate a 32-kHz clock (CLK\_32K). This clock is used by WKUP\_DMSC0 and Timer Modules.

If an application needs accurate 32.768-kHz clock, then use WKUP\_LFOSC0 (32.768 kHz) output clock.

#### 5.4.4.2 Oscillator Clock Loss Detection

The device supports WKUP\_HFOSC0 clock loss circuitry to detect when WKUP\_HFOSC0\_CLK stops toggling. If CTRLMMR\_WKUP\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWCH\_EN is set and WKUP\_HFOSC0\_CLK stops toggling condition is detected, the reference clock is switched from WKUP\_HFOSC0\_CLKOUT to WKUP\_CLK\_12M\_RC to allow the device to operate with a slower clock. The WKUP\_HFOSC0\_CLK stops toggling condition is reported as an error to WKUP\_ESM0 regardless of the value of CTRLMMR\_WKUP\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWCH\_EN. Integration diagram of WKUP\_HFOSC0 clock loss detection is presented in [Figure 5-35](#).

**Figure 5-35. WKUP\_HFOSC0 Clock Loss Detection Integration Diagram**

WKUP\_ESM0 can optionally generate an interrupt to WKUP\_DMSC0 and MCU\_R5FSS so they can save some critical contents such as error logging to scratch pad memory or external flash. ESM must also be configured to report this error on the SAFETY\_ERRORn pin.

WKUP\_HFOSC0 clock loss is a catastrophic failure since this clock is the most critical system clock. During the clock loss condition an external system intervention is required.

The clock loss mux is not a glitch free mux. The mux control is synchronized to the CLK\_12M\_RC clock. Since WKUP\_HFOSC0\_CLK has stopped switching the mux should transition to RC Clock without producing glitches.

Hence it is important to ensure that MCU\_SAFETY\_ERRORn is pulled low during this error condition. In clock-loss condition, the device reports the error to the external device through MCU\_SAFETY\_ERRORn pin - the pin is driven Low. The recovery mechanism is up to the external system (such as a PMIC to take action). For example, it can try a full system power cycle to see if the system recovers. If the system does not recover then, it has to take some other action such as to check system clocks, external crystal, supply rails.

PLL will lose the lock when clock loss is detected. During this time 12.5-MHz RC clock is output through the bypass muxes. The PLL will relock to a new frequency based on 12.5 MHz.

In an event of clock glitch which may potentially hang the device, then the WKUP\_DMSC0 watchdog timer will expire and will generate an internal reset for the whole device.

### 5.4.5 PLLs

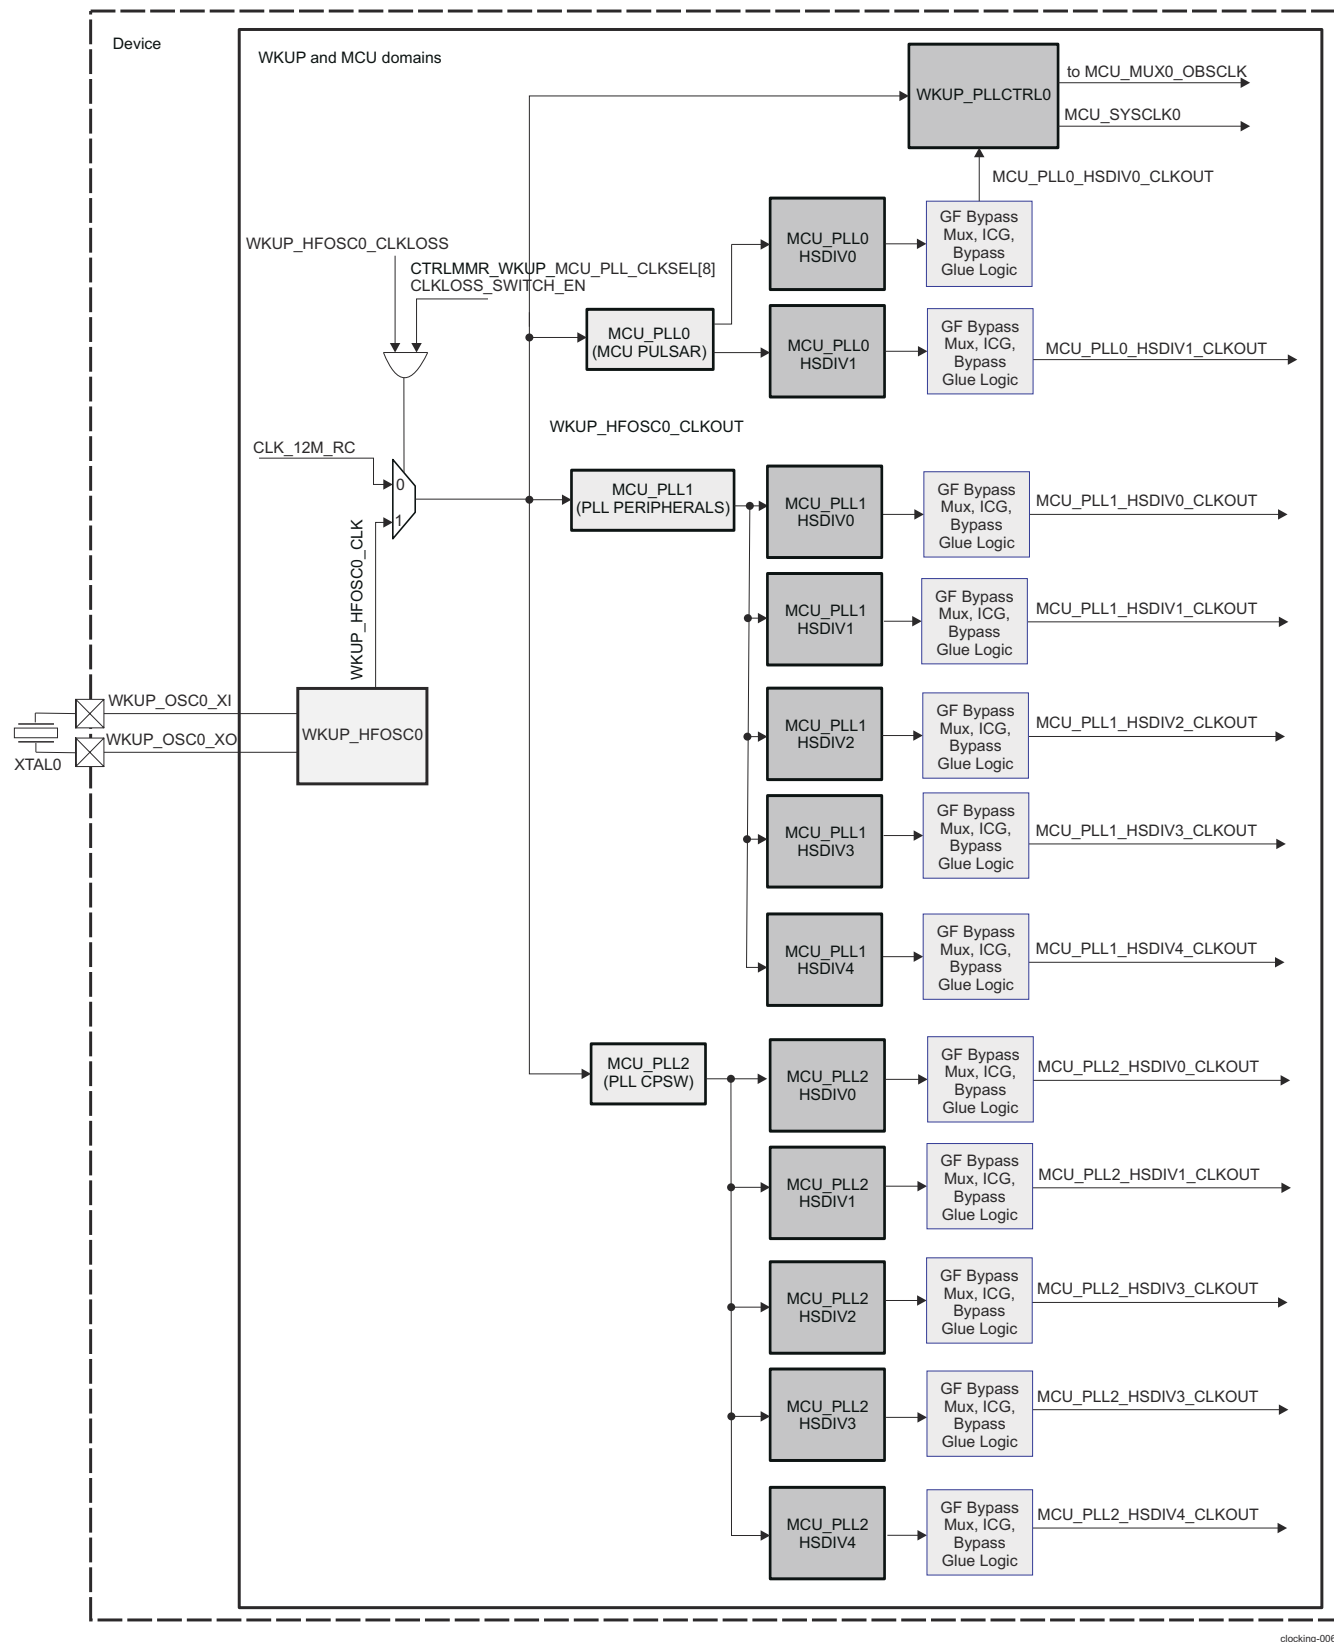

Phase-Locked Loop circuits (PLLs) in the device are clock generator PLLs, which multiply the lower-frequency reference clock up to the operating frequency of the respective subsystem(s).

#### 5.4.5.1 WKUP and MCU Domains PLL Overview

There are total three PLLs in the device in WKUP/MCU domain:

- MCU\_PLL0 (MCU R5FSS PLL) with WKUP\_PLLCTRL0
- MCU\_PLL1 (MCU PERIPHERAL PLL)
- MCU\_PLL2 (MCU Command Platform Ethernet Switch (CPSW) PLL).

Overview of the device PLLs with their reference clock options in WKUP/MCU domain is shown on [Figure 5-36](#). For more specific information about PLLs see [Section 5.4.5.5, PLLs Device-Specific Information](#).

docking-006

Figure 5-36. WKUP/MCU Domain PLLs Integration

#### 5.4.5.2 MAIN Domain PLLs Overview

There are total twenty PLLs in the device in MAIN domain:

- PLL0 (MAIN PLL) with PLLCTRL0
- PLL1 (PER0 PLL)
- PLL2 (PER1 PLL)
- PLL3 (CPSW9G PLL)
- PLL4 (AUDIO0 PLL)
- PLL5 (VIDEO PLL)
- PLL6 (GPU PLL)
- PLL7 (C7x PLL)
- PLL8 (ARM0 PLL)
- PLL12 (DDR PLL)
- PLL13 (C66 PLL)

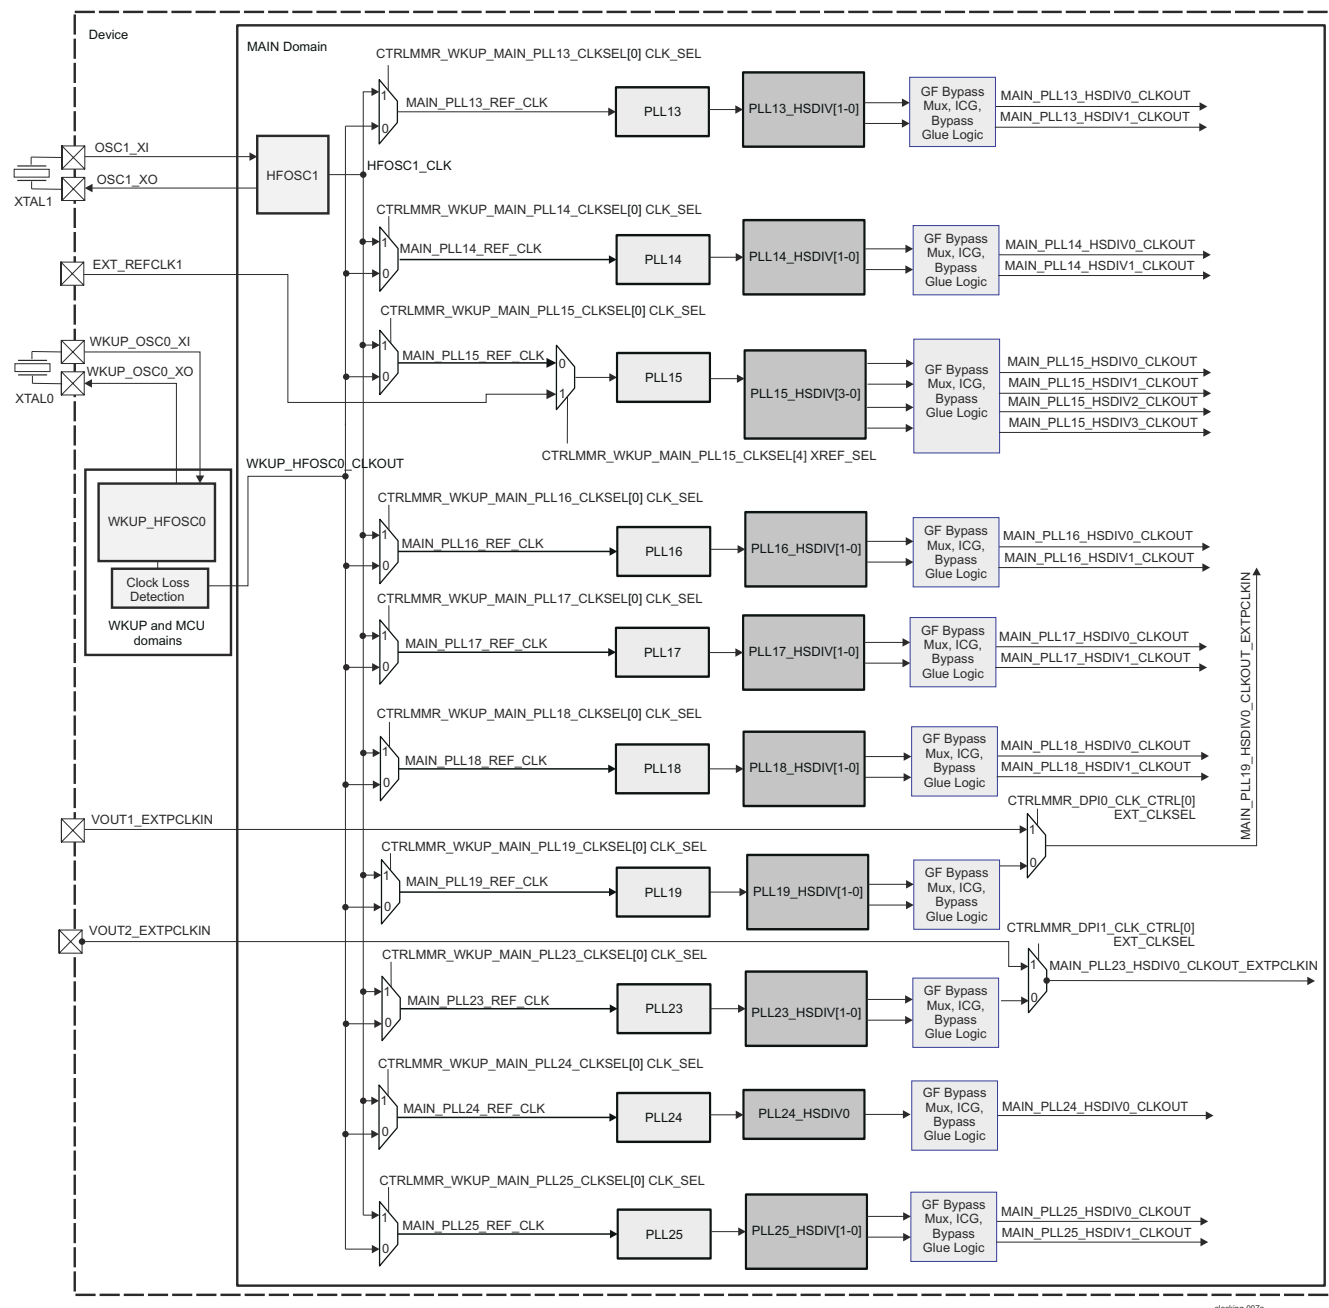

Figure 5-38. MAIN Domain PLLs Integration - Part 2

### 5.4.5.3 PLL Reference Clocks

#### 5.4.5.3.1 PLLs in MCU Domain

The reference clocks MCU\_PLL0\_REF\_CLK, MCU\_PLL1\_REF\_CLK and MCU\_PLL2\_REF\_CLK for the PLLs in MCU domain is chosen between the internal high-frequency (HF) oscillator with external crystal, WKUP\_HFOSC0, and 12.5-MHz free-running RC oscillator. The selection for all PLLs is made through CTRLMMR\_WKUP\_MCU\_PLL\_CLKSEL[8] CLKLOSS\_SWCH\_EN, see [Table 5-105](#).

Table 5-105. PLL MCU Domain Reference Clock Selection - WKUP\_HFOSC0\_CLKOUT Selection

CTRLMMR_WKUP_MCU_PLL_CLKSEL <sup>(2)</sup> [8] CLKLOSS_SWCH_EN	MCU_PLLn_REF_CLK <sup>(1)</sup>
0 (default)	WKUP_HFOSC0_CLK

**Table 5-105. PLL MCU Domain Reference Clock Selection - WKUP\_HFOSC0\_CLKOUT Selection (continued)**

CTRLMMR_WKUP_MCU_PLL_CLKSEL <sup>(2)</sup> [8] CLKLOSS_SWCH_EN	MCU_PLLn_REF_CLK <sup>(1)</sup>
1	WKUP_CLK_12M_RC if clock loss is detected or WKUP_HFOSC0_CLK if clock loss is not detected

(1) n = 0, 1, 2

(2) For more information about control registers, see *Control Module (CTRL\_MMR)*.

#### 5.4.5.3.2 PLLs in MAIN Domain

Each PLL in MAIN domain has a dedicated register CTRLMMR\_WKUP\_MAIN\_PLLn\_CLKSEL in WKUP\_CTRL\_MMR0 to choose its reference clock.

MAIN\_PLLn\_REF\_CLK (n = 0 to 8, 12 to 19, 23 to 25) clock source is selected by means of CTRLMMR\_WKUP\_MAIN\_PLLn\_CLKSEL[0] CLK\_SEL bit; for more information about control registers, see *Control Module (CTRL\_MMR)*. The encoding of CLK\_SEL is shown in [Table 5-106](#).

**Table 5-106. PLL MAIN Domain Reference Clock Selection**

CTRLMMR_WKUP_MAIN_PLLn_CLKSEL <sup>(1)</sup> [0] CLK_SEL	MAIN_PLLn_REF_CLK Selection <sup>(1)</sup>
0 (default)	WKUP_HFOSC0_CLK
1	HFOSC1_CLK

(1) n = 0 to 8, 12 to 19, 23 to 25

PLL4 (AUDIO0 PLL) and PLL15 (AUDIO1 PLL) input reference clocks have additional selection via mux configured in the CTRLMMR\_WKUP\_MAIN\_PLL4\_CLKSEL[4] XREF\_SEL and the CTRLMMR\_WKUP\_MAIN\_PLL15\_CLKSEL[4] XREF\_SEL, respectively, in WKUP\_CTRL\_MMR0 (see [Table 5-107](#) and [Table 5-108](#)); for more information about control registers, see *Control Module (CTRL\_MMR)*.

**Table 5-107. PLL4 (AUDIO0 PLL) Clock Selection**

CTRLMMR_WKUP_MAIN_PLL4_CLKSEL[4] XREF_SEL	PLL4 (AUDIO0 PLL) Ref Selection
0 (default)	MAIN_PLL4_REF_CLK already selected via MAIN_PLL4_REF_CLK[0] CLK_SEL
1	EXT_REFCLK1 (external clock input on device pins)

**Table 5-108. PLL15 (AUDIO1 PLL) Clock Selection**

CTRLMMR_WKUP_MAIN_PLL15_CLKSEL[4] XREF_SEL	PLL15 (AUDIO1 PLL) Ref Selection
0 (default)	MAIN_PLL15_REF_CLK already selected via MAIN_PLL15_REF_CLK[0] CLK_SEL
1	EXT_REFCLK1 (external clock input on device pins)

#### 5.4.5.4 Generic PLL Overview

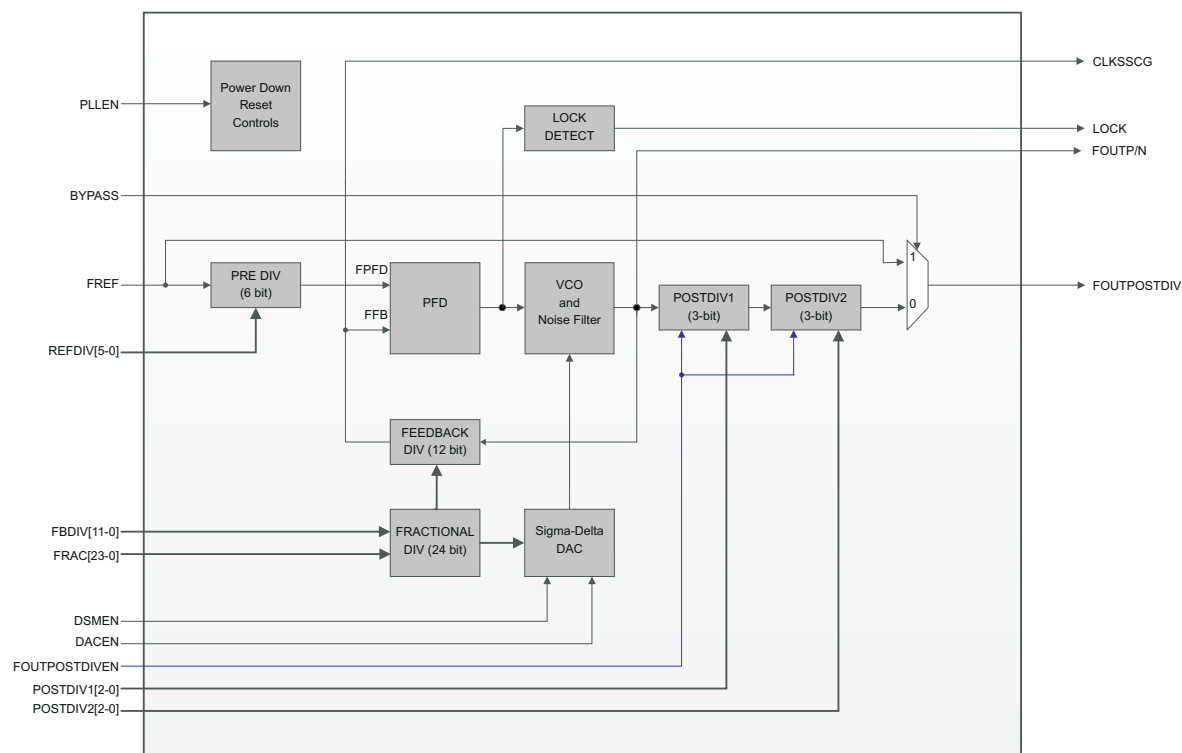

To generate high-frequency clocks, the device supports multiple on-chip PLLs controlled directly by the Top-level Clocking. They are of three types: Standard fractional PLL (PLLTS16FFCLAFRAC2), Fractional PLL with Calibration (PLLTS16FFCLAFRACF) and De-skew PLL with Calibration (PLLTS16FFCLVDESKEWC) PLLs.

#### Note

This chapter discusses only the PLLs that are directly controlled by the Top-level Clocking. The other PLLs embedded in and managed by other subsystems are described in their respective subsystems.

#### 5.4.5.4.1 PLLs Output Clocks Parameters

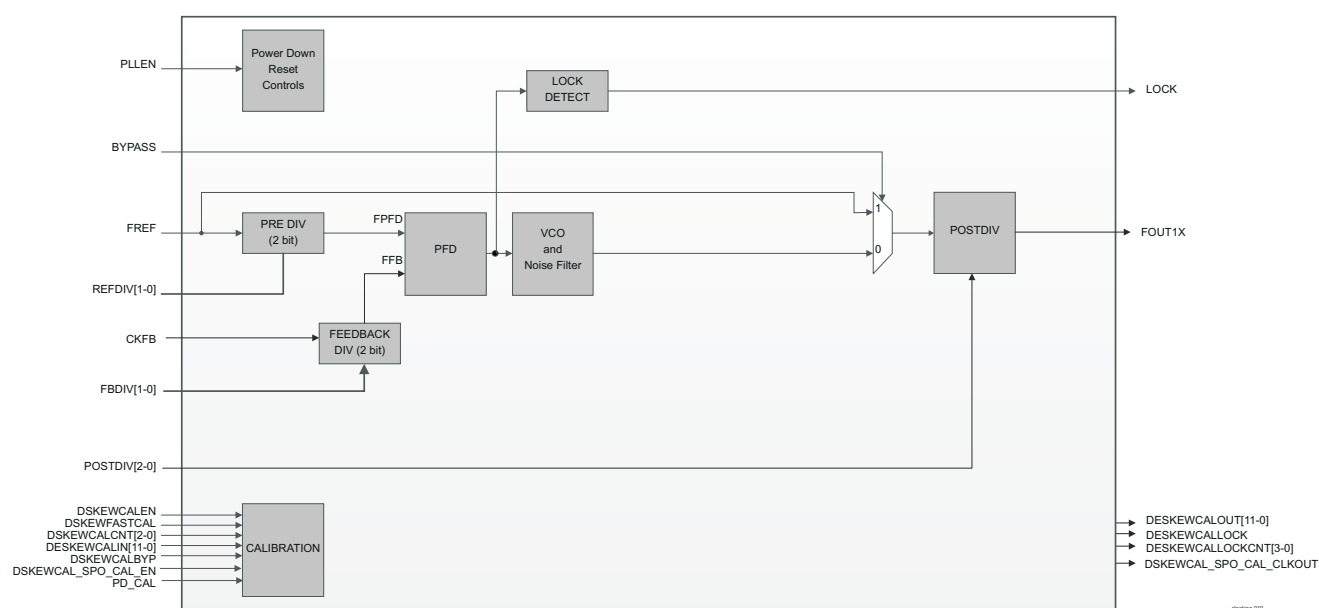

Figure 5-39, Figure 5-40, and Figure 5-41 show the functional architecture of a generic PLL for PLLTS16FFCLAFRAC2, PLLTS16FFCLAFRACF, and PLLTS16FFCLVDESKEWC types, respectively.

clocking-008

**Figure 5-39. Generic PLL Functional Diagram for PLLTS16FFCLAFRAC2 Type**

**Figure 5-40. Generic PLL Functional Diagram for PLLTS16FFCLAFRACF Type**

clocking-010

**Figure 5-41. Generic PLL Functional Diagram for PLLTS16FFCLVDESKEWC Type**

#### 5.4.5.4.1.1 PLLs Input Clocks

As shown in [Figure 5-40](#) and [Figure 5-41](#) for each type of PLL, the two possible input clocks are:

- FREF: Reference clock input is used to generate the synthesized clock but can also be used as the bypass clock for some outputs of the PLL whenever the PLL enters bypass mode. It is mandatory for the PLL clock synthesis.
- CKFB: Feedback clock input. Used only in PLLTS16FFCLVDESKEWC type. The CKFB input is internally connected, see [Figure 5-41](#).

#### 5.4.5.4.1.2 PLL Output Clocks

##### 5.4.5.4.1.2.1 PLLTS16FFCLAFRAC2 Type Output Clocks

[Table 5-109](#) describes the output clocks of PLLTS16FFCLAFRAC2.

**Table 5-109. PLLTS16FFCLAFRAC2 Output Clocks**

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	$((FREF / REFDIV) * (FBDIV + FRAC))$
FOUTN	Negative phase VCO output (no post divider)	$((FREF / REFDIV) * (FBDIV + FRAC))$
FOUTPOSTDIV	VCO-divided clock output.	$FOUTP / (POSTDIV1 * POSTDIV2)$
CLKSSCG	Clock to SSMOD	$(FREF / REFDIV)$

Where:

- REFDIV is the software-configured division ratio binary value.
- FBDIV is the software-configured division ratio binary value.
- FRAC is the software-configured fractional division.
- POSTDIV1 is the software-configured division ratio binary value.
- POSTDIV2 is the software-configured division ratio binary value.

#### Note

POSTDIV1 and POSTDIV2 valid values are from 1 to 7. To ensure correct operation, POSTDIV1 must always be programmed to a value equal to or greater than POSTDIV2.

#### Note

For device-specific information about clock output parameters and synthesized clocks, see [Table 5-117](#) and [Table 5-119](#).

##### 5.4.5.4.1.2.2 PLLTS16FFCLAFRACF Type Output Clocks

[Table 5-110](#) describes the output clocks of PLLTS16FFCLAFRACF.

**Table 5-110. PLLTS16FFCLAFRACF Output Clocks**

Output	Description	Frequency
FOUTP	Positive phase VCO output (no post divider)	$(FREF / REFDIV) * (FBDIV + FRAC)$
FOUTN	Negative phase VCO output (no post divider)	$(FREF / REFDIV) * (FBDIV + FRAC)$
FOUTPOSTDIV	VCO-divided clock output.	$FOUTP / (POSTDIV1 * POSTDIV2)$
CLKSSCG	Clock to SSMOD	$(FREF / REFDIV)$

Where:

- REFDIV is the software-configured division ratio binary value.
- FBDIV is the software-configured division ratio binary value.
- FRAC is the software-configured fractional division.
- POSTDIV1 is the software-configured division ratio binary value.
- POSTDIV2 is the software-configured division ratio binary value.

---

**Note**

POSTDIV1 and POSTDIV2 valid values are from 1 to 7. To ensure correct operation, POSTDIV1 must always be programmed to a value equal to or greater than POSTDIV2.

---

---

**Note**

For device-specific information about clock output parameters and synthesized clocks, see [Table 5-117](#) and [Table 5-119](#).

---

#### 5.4.5.4.1.2.3 PLLTS16FFCLVDESKEWC Type Output Clocks

[Table 5-111](#) describes the output clocks of PLLTS16FFCLVDESKEWC.

**Table 5-111. PLLTS16FFCLVDESKEWC Output Clocks**

Output	Description	Frequency
FOUT1X	Output Clock	(FREF / REFDIV * FBDIV)

Where:

- REFDIV is the software-configured division ratio binary value.
- FBDIV is the software-configured division ratio binary value.

---

**Note**

REFDIV and FBDIV valid values are 1, 2, and 4.

POSTDIV valid values are 1, 2, 4, 8, 16, 32, 64, and 128.

---

---

**Note**

For device-specific information about clock output parameters and synthesized clocks, see [Table 5-118](#) and [Table 5-120](#).

---

#### 5.4.5.4.1.2.4 PLL Lock

PLL module outputs a lock status signal to indicate that the PLL has achieved frequency lock. When the PLL detects no cycle slips between the feedback clock (FFB) and reference clock FPDF (FREF/ REFDIV[5-0]) for 128 consecutive cycles, it asserts the lock signal high. When the PLL detects any cycle slip, lock signal will go low and stays low until it detects no cycle slip for 128 consecutive cycles. This lock signal is captured in <PLL\_name>\_STAT[0] LOCK bit. Software can read this bit to determine if the PLL has achieved frequency lock before selecting the PLL clock through external bypass mux.

When PLL losses lock, there is a hardware mechanism to automatically bypass the PLL clock to the reference clock (FREF) using the external glitch free mux. BYP\_ON\_LOCKLOSS bit in <PLL\_name>\_CTRL register enables this automatic bypass mode on PLL lock loss. When the PLL re-locks, the glitch free mux switches to PLL clock out.

The PLL lock signal is also routed to ESM module for error reporting. ESM can be configured to generate interrupts to MCU\_R5FSS/R5FSS and WKUP\_DMSC0 and assert Low on SAFETY\_ERRORn pin on PLL Lock loss for further action.

Table 5-112 summarizes the PLL lock signals in the device (all level type).

**Table 5-112. PLL Lock Signal Summary**

PLL Instance	PLL Lock Signal (Source)	ESM Error Input (Destination)
PLL0 (MAIN PLL)	PLLFRAC2_SSMOD0_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_0
PLL1 (PER0 PLL)	PLLFRAC2_SSMOD1_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_1
PLL2 (PER1 PLL)	PLLFRAC2_SSMOD2_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_2
PLL3 (CPSW9G PLL)	PLLFRAC2_SSMOD3_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_3
PLL4 (AUDIO0 PLL)	PLLFRAC2_SSMOD4_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_4
PLL5 (VIDEO PLL)	PLLFRAC2_SSMOD5_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_5
PLL6 (GPU PLL)	PLLFRAC2_SSMOD6_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_6
PLL7 (C7x PLL)	PLLFRAC2_SSMOD7_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_7
PLL8 (ARM0 PLL)	PLLFRAC2_SSMOD8_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_8
PLL12 (DDR PLL)	PLLFRAC2_SSMOD12_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_12
PLL13 (C66 PLL)	PLLFRAC2_SSMOD13_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_13
PLL14 (R5FSS PLL)	PLLFRAC2_SSMOD14_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_14
PLL15 (AUDIO1 PLL)	PLLFRAC2_SSMOD15_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_15
PLL16 (DSS PLL0)	PLLFRAC2_SSMOD16_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_16
PLL17 (DSS PLL1)	PLLFRAC2_SSMOD17_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_17
PLL18 (DSS PLL2)	PLLFRAC2_SSMOD18_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_18
PLL19 (DSS PLL3)	PLLFRAC2_SSMOD19_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_19
PLL23 (DSS PLL7)	PLLFRAC2_SSMOD23_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_23
PLL24 (MLB PLL)	PLLDDESKEW24_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_24
PLL25 (VISION PLL)	PLLFRAC2_SSMOD25_LOCKLOSS_IPCFG_0	ESM0_LVL_IN_25

#### 5.4.5.4.1.2.5 HSDIVIDER

A PLL may contain up to 16 HSDIVIDER modules to produce more clocks with divided ratio based on the PLL synthesized clock frequency. HSDIVIDER provides only one output. The HSDIVIDER output clock frequency is given by the equations in Table 5-113.

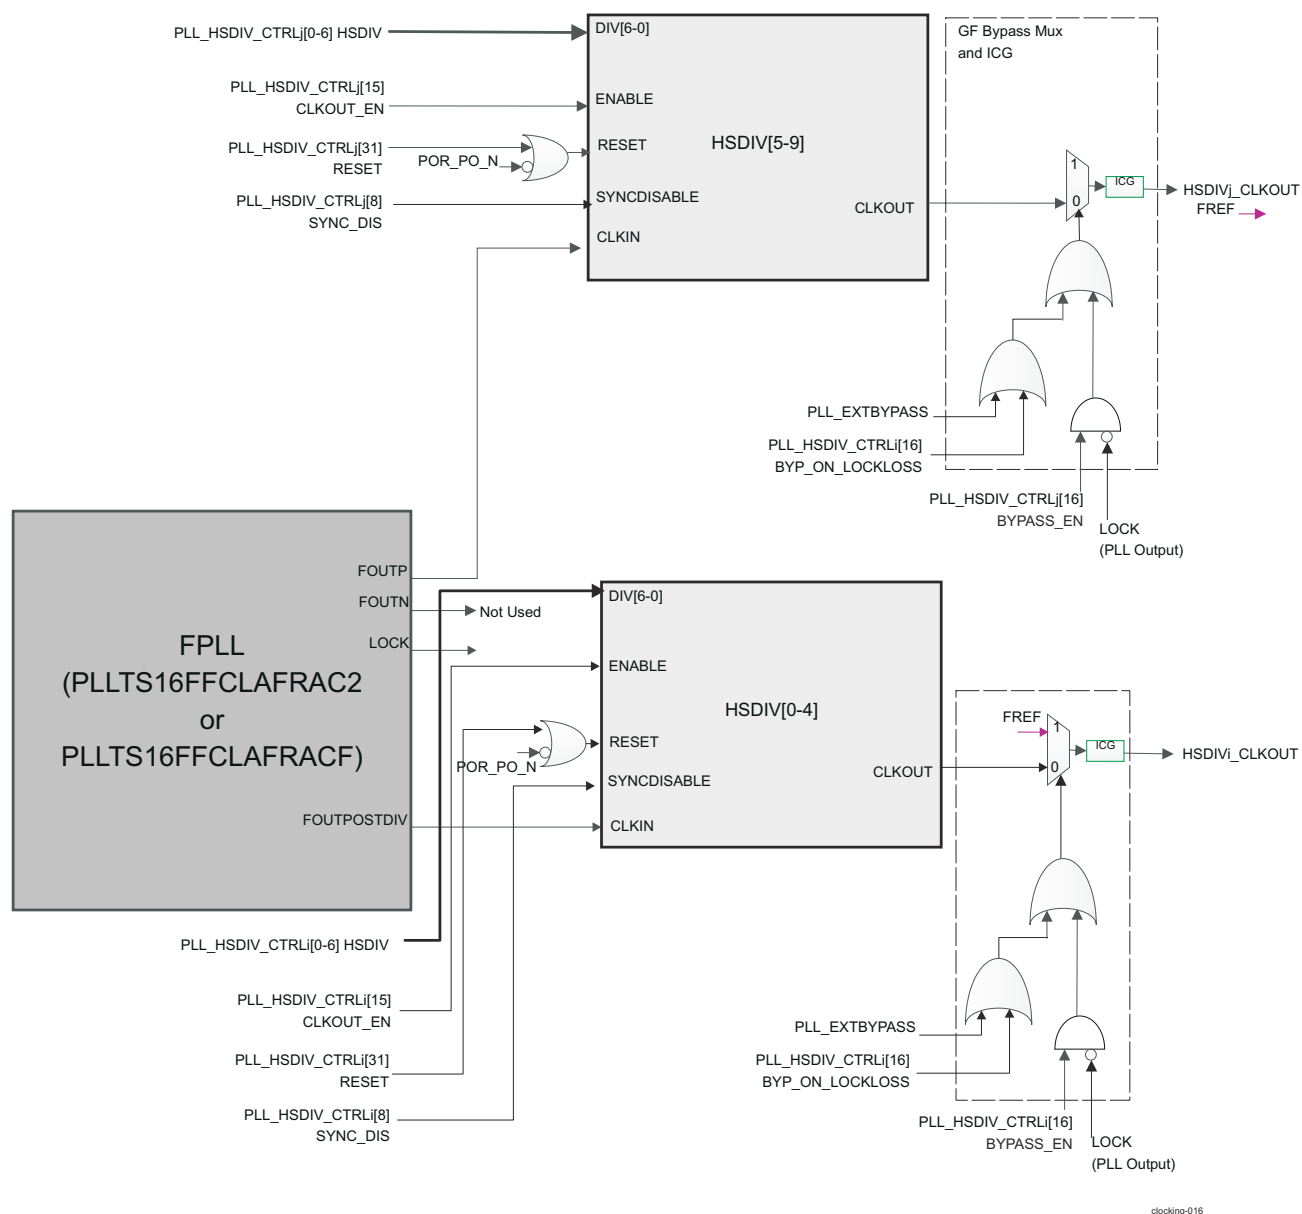

**Table 5-113. HSDIV\_CLKOUT Frequency With PLL State**

Equation	PLL Mode
$HSDIV\_CLKOUT = FOUTP / (HSDIV + 1)$	Locked
$HSDIV\_CLKOUT = FREF$	Before lock or during reload

Where:

- FOUTP is the PLL lock frequency. In case of PLLTS16FFCLVDESKEWC PLL, FOUTP is substituted with FOUT1X.
- HSDIV is the software-configured division ratio binary value.

Figure 5-42 and Figure 5-43 describe the connection between a HSDIV and a specific type of PLL. Signals related only to this connections are shown in both figures.

(1)<sub>i</sub> = 0 to 4; <sub>j</sub> = 5 to 9

**Figure 5-42. PLLTS16FFCLAFRAC2 / PLLTS16FFCLAFRACF and HSDIV Connection**

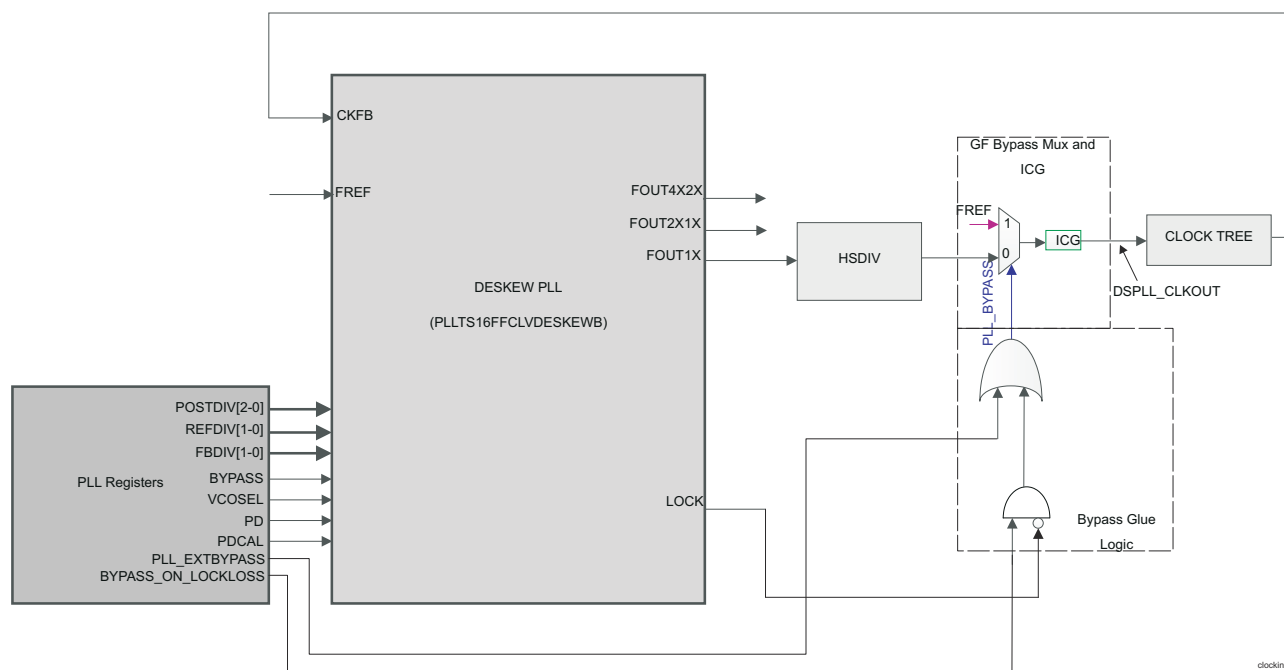

Figure 5-43. PLLTS16FFCLVDESKEWC and HSDIV Connection

#### 5.4.5.4.1.2.6 ICG Module

ICG module ensures that when a particular HSDIV is not enabled the HSDIV clock output is gated off. This is a hardware module with no software control.

#### 5.4.5.4.1.2.7 PLL Power Down

PLLTS16FFCLVDESKEWC has a power down feature. The PLL can be powered down via DSPLL24\_CTRL[4] PD\_EN.

PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF are disabled with MCU\_PLLn\_CTRL[15] PLL\_EN or PLLn\_CTRL[15] PLL\_EN.

#### 5.4.5.4.1.2.8 PLL Calibration

PLLTS16FFCLAFRACF and PLLTS16FFCLVDESKEWC have calibration feature. The calibration settings are done via <PLL\_Name>\_CAL\_CTRL register. The calibration status can be monitored by reading <PLL\_Name>\_CAL\_STAT register. For more information about device-specific information about calibration feature, see [Table 5-121](#).

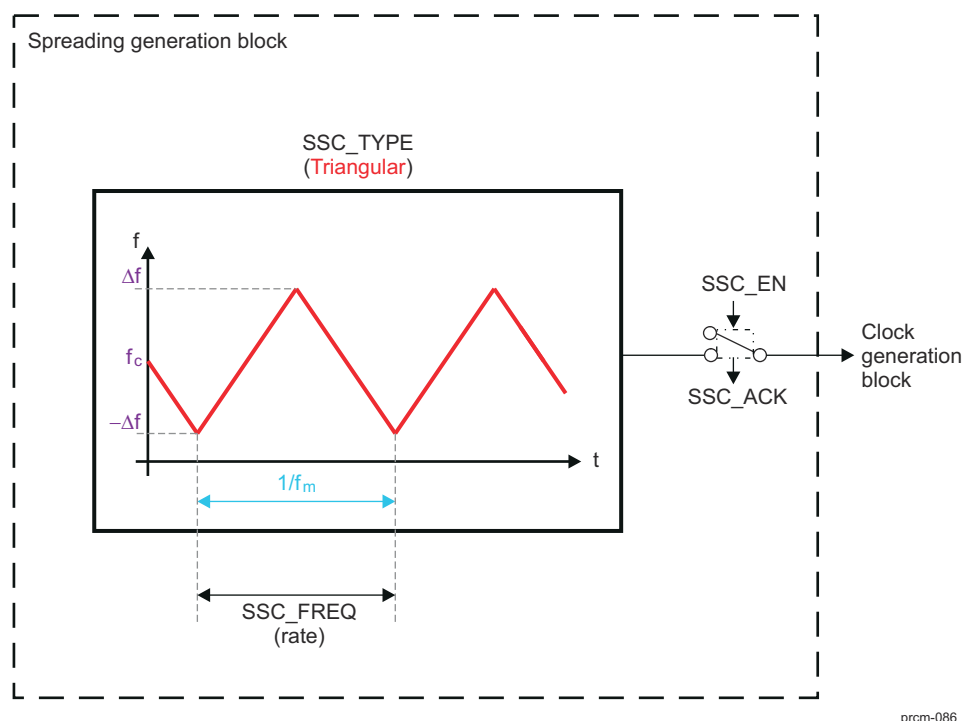

#### 5.4.5.4.2 PLL Spread Spectrum Modulation Module

Spread Spectrum Modulation (SSMOD) modules on the device reduces Electro Magnetic Interference (EMI). It is a fully-digital circuit, used to modulate the frequency of the selected fractional PLLs. Programming options include selection of center spread or down spread, modulation depth, and modulation shape. The default modulation profile is triangular.

All PLLs in this family of device have SSMOD module, except for PLL24, which is the only PLL of PLLTS16FFCLVDESKEWC type.

SSMOD in the PLL is performed by changing the feedback divider (FRAC and FBDIV) in a triangular pattern. This varies the frequency of the output clock in a triangular pattern. The frequency of this pattern is the modulation frequency ( $f_m$ ). It is programmed as a ratio of the CLKIN/4.

[Figure 5-44](#) shows a diagram of the spreading generation block.

prcm-086

**Figure 5-44. Spreading Generation Block Diagram**

**Note**

$f_c$  is the original output clock frequency.

$f_m$  is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal to add some controlled deviation to the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces EMI. SSMOD\_DOWNSPREAD can control the position of the generated signal. It is controlled by the <PLL\_name>\_CTRL[4] DOWNSPREAD\_EN bit of the corresponding registers. If the DOWNSPREAD\_EN bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0.

The value of SSMOD\_FREQ controls the rate of the generated signal. It can be programmed as a ratio of the reference clock:  $f_{ref} / 4$ . The value that must be programmed is calculated as follows:  
ModFreqDivider =  $f_{ref} / (4 \times f_m)$ , where  $f_m < f_{ref} / 70$ ,  $f_{ref} = f_{inp} / (1+N)$ , and  $f_{inp}$  is the input clock for the PLL.

**5.4.5.4.2.1 Definition of SSMOD**

The aim of the SSMOD is to add a variation to the frequency of an original clock, which spreads the generated interference over a larger band of frequencies.

In theory, SSMOD means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 MHz at one time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be spread out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating an SSMOD by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.

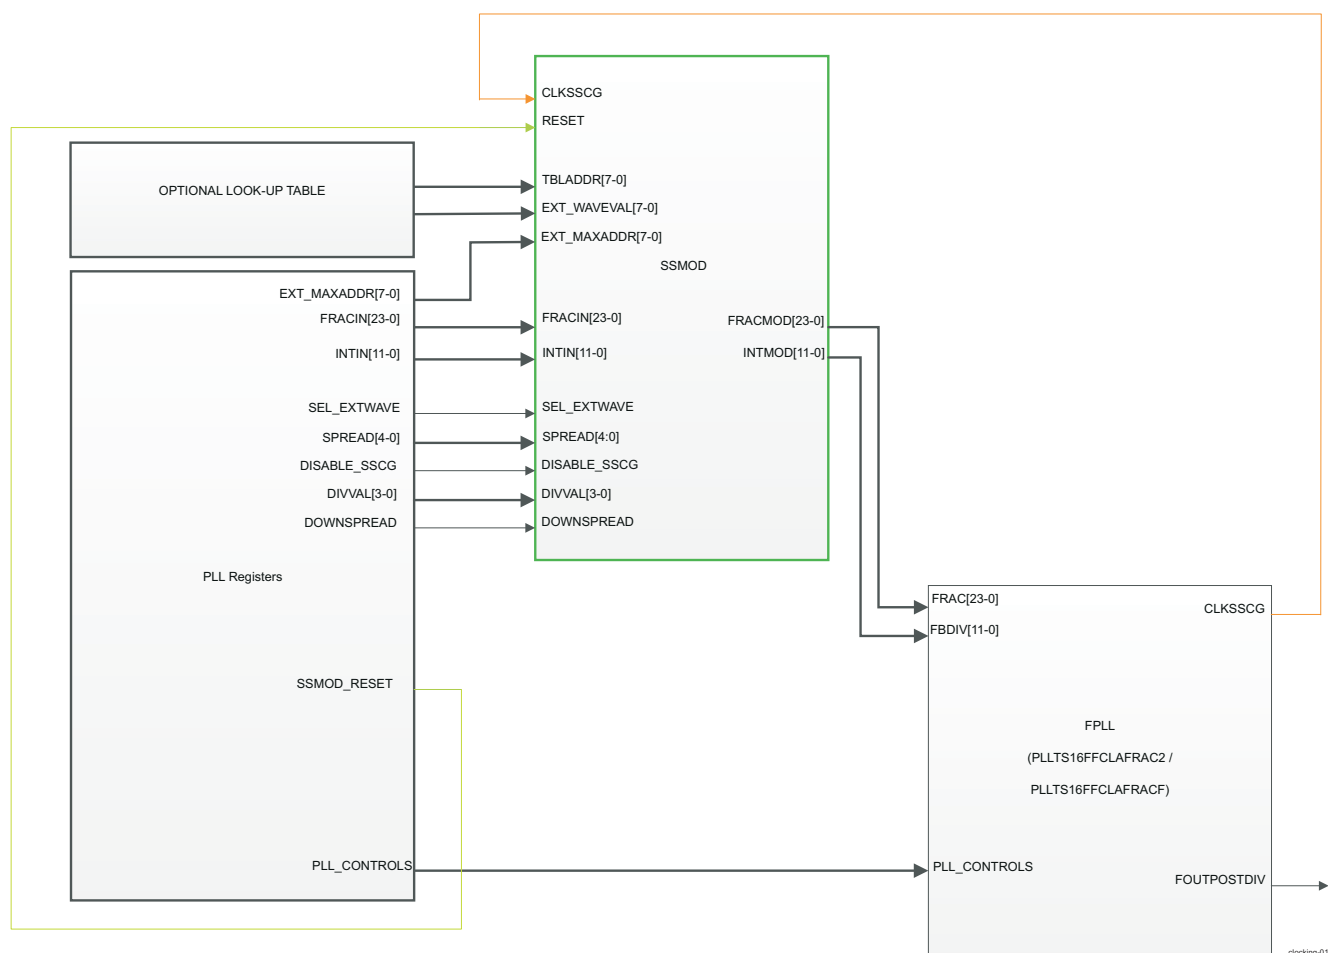

#### 5.4.5.4.2.2 SSMOD Configuration

Table 5-114 describes the PLL SSMOD control bitfields. Figure 5-45 describes the connection between a SSMOD and a PLL.

**Table 5-114. SSMOD related bitfields**

Parameter	Register	Description
SSMOD enable control	<PLL_name>n_SS_CTRL[31] <sup>(1)</sup> BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[31] BYPASS_EN)	Enable/disable the PLL SSMOD feature.
Wave table maximum address	<PLL_name>n_SS_CTRL[25-18] <sup>(1)</sup> WV_TBL_MAXADDR (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[25-18] WV_TBL_MAXADDR)	Wave table maximum address. Indicates the maximum number of address bits used to access the external wave table. These bits are not used if <PLL_name>n_SS_CTRL[0] WAVE_SEL = 0
Type of spread	<PLL_name>n_SS_CTRL[4] <sup>(1)</sup> DOWNSPREAD_EN (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[4] DOWNSPREAD_EN)	Selects center spread or down spread clock variance
Wave table selection	<PLL_name>n_SS_CTRL[0] <sup>(1)</sup> WAVE_SEL (For example, MCU_PLL0 - MCU_PLL0_SS_CTRL[0] WAVE_SEL)	Wave pattern select External wave table should only be selected
Modulation divider	<PLL_name>n_SS_SPREAD[19-16] <sup>(1)</sup> MOD_DIV (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[19-16] MOD_DIV)	Input clock divider. This divider sets the modulation frequency.
Spread Depth	<PLL_name>n_SS_SPREAD[4-0] <sup>(1)</sup> SPREAD (For example, MCU_PLL0 - MCU_PLL0_SS_SPREAD[4-0] SPREAD)	Sets the spread modulation depth.

(1) n = 0, 1, 2 for MCU domain and n = 0 - 8, 12 - 19, 23, and 25 for MAIN domain

**Figure 5-45. PLL and SSMOD Connection**

### 5.4.5.5 PLLs Device-Specific Information

Table 5-115 lists the basic information of each of the three MCU PLLs.

**Table 5-115. Basic Information of MCU\_PLL0, MCU\_PLL1, and MCU\_PLL2**

PLL name	Type	SSMOD Available	HSDIV Available	Input clock	Comments
MCU_PLL0	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0 and HSDIV1	WKUP_HFOSC0_CLKOUT	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
MCU_PLL1	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, and HSDIV4	WKUP_HFOSC0_CLKOUT	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
MCU_PLL2	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, and HSDIV4	WKUP_HFOSC0_CLKOUT	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>

(1) See *Generic PLL Functional Diagram for PLLTS16FFCLAFRAC2 type* for overview of the PLL.

(2) See [Section 5.4.5.5.2](#) for synthesised clock parameters.

(3) See [Section 5.4.5.5.3](#) for clock output parameters.

Table 5-116 lists the basic information of each of the MAIN PLLs.

**Table 5-116. Basic Information of MAIN Domain PLLs**

PLL name	Type	SSMOD Available	HSDIV Available	Input clock	Comments
PLL0	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4, HSDIV5, HSDIV6, HSDIV7, and HSDIV8	MAIN_PLL0_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL1	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV5, HSDIV6, HSDIV7, and HSDIV8	MAIN_PLL1_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL2	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, HSDIV4, HSDIV5, HSDIV6, and HSDIV7	MAIN_PLL2_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL3	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, HSDIV3, and HSDIV4	MAIN_PLL3_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL4	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, and HSDIV3	MAIN_PLL4_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL5	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0 and HSDIV1	MAIN_PLL5_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL6	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0	MAIN_PLL6_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL7	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMD related bitfields/bits	HSDIV0	MAIN_PLL7_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>

**Table 5-116. Basic Information of MAIN Domain PLLs (continued)**

PLL name	Type	SSMOD Available	HSDIV Available	Input clock	Comments
PLL8	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0	MAIN_PLL8_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL12	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0	MAIN_PLL12_REF_CLK	See <a href="#">(4)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL13	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0 and HSDIV1	MAIN_PLL13_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL14	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0 and HSDIV1	MAIN_PLL14_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL15	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0, HSDIV1, HSDIV2, and HSDIV3	MAIN_PLL15_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL16	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0 and HSDIV1	MAIN_PLL16_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>
PLL17	PLLTS16FFCLAFRAC2	Yes, see <a href="#">Table 5-114</a> for more information on SSMOD related bitfields/bits	HSDIV0 and HSDIV1	MAIN_PLL17_REF_CLK	See <a href="#">(1)</a> , <a href="#">(2)</a> , and <a href="#">(3)</a>

- (2) See [Section 5.4.5.5.2](#) for synthesized clock parameters.
- (3) See [Section 5.4.5.5.3](#) for clock output parameters.
- (4) See [Figure 5-40](#), *Generic PLL Functional Diagram for PLLTS16FFCLAFRAC2F type* for overview of the PLL.
- (5) See *Generic PLL Functional Diagram for PLLTS16FFCLVDESKEWC type* for overview of the PLL.

#### 5.4.5.5.1 SSMOD Related Bitfields Table

[Table 5-114](#) lists SSMOD related bitfields for all three types of PLLs.

#### 5.4.5.5.2 Clock Synthesis Inputs to the PLLs

Table 5-117 lists the clock synthesis parameters for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF types.

**Table 5-117. Clock synthesis Parameters for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF Types**

Parameter Name	Register
FBDIV	<PLL_name>_FREQ_CTRL0[11-0] FB_DIV_INT (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL0[11-0] FB_DIV_INT)
FRAC	<PLL_name>_FREQ_CTRL1[23-0] FB_DIV_FRAC (For example, MCU_PLL0 - MCU_PLL0_FREQ_CTRL1[23-0] FB_DIV_FRAC)
POSTDIV2	<PLL_name>_DIV_CTRL[26-24] POST_DIV2 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[26-24] POST_DIV2)
POSTDIV1	<PLL_name>_DIV_CTRL[18-16] POST_DIV1 (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[18-16] POST_DIV1)
REFDIV	<PLL_name>_DIV_CTRL[5-0] REF_DIV (For example, MCU_PLL0 - MCU_PLL0_DIV_CTRL[5-0] REF_DIV)

Table 5-118 lists the clock synthesis parameters for PLLTS16FFCLVDESKEWC type.

#### Note

For PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF types - POSTDIV1 and POSTDIV2 values are from 1 to 7. To ensure correct operation, POSTDIV1 must always be programmed to a value equal to or greater than POSTDIV2.

**Table 5-118. Clock synthesis Parameters for PLLTS16FFCLVDESKEWC Type**

Parameter Name	Register
FBDIV	<PLL_name>_DIV_CTRL[13-12] FB_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[13-12] FB_DIV)
POSTDIV	<PLL_name>_DIV_CTRL[10-8] POST_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[10-8] POST_DIV)
REFDIV	<PLL_name>_DIV_CTRL[1-0] REF_DIV (For example, PLL24 - PLL24_PLL_DIV_CTRL[1-0] REF_DIV)

#### Note

For PLLTS16FFCLVDESKEWC type:

- REFDIV and FBDIV valid values are 1, 2, and 4.
- POSTDIV valid values are 1, 2, 4, 8, 16, 32, 64, and 128.

#### 5.4.5.5.3 Clock Output Parameter

Table 5-119 lists the control/status bit fields for output clocks.

**Table 5-119. Clock Output Parameter for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF Types**

Clock Output/Divider	Parameter Name	Control/Status Bit Field
<PLL_name>_CLKOUT, <PLL_name>_HSDIV_CLKOUT <sup>(1)</sup>	Control	<PLL_name>_CTRL[31] BYPASS_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[31] BYPASS_EN)

**Table 5-119. Clock Output Parameter for PLLTS16FFCLAFRAC2 and PLLTS16FFCLAFRACF Types (continued)**

Clock Output/Divider	Parameter Name	Control/Status Bit Field
<PLL_name>_HSDIVj_CLKOUT <sup>(1)</sup>	Control	<PLL_name>_HSDIV_CTRLj[15] CLKOUT_EN (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL0[5] CLKOUT_EN and MCU_PLL0_HSDIV_CTRL1[5] CLKOUT_EN)
<PLL_name>_HSDIVj_CLKOUT <sup>(1)</sup>	Divider control	<PLL_name>_HSDIV_CTRLj[6-0] HSDIV (For example, MCU_PLL0 - MCU_PLL0_HSDIV_CTRL0[6-0] HSDIV and MCU_PLL0_HSDIV_CTRL1[6-0] HSDIV)
PLL bypass mux	Control	<PLL_name>_CTRL[16] BYP_ON_LOCKLOSS (For example, MCU_PLL0 - MCU_PLL0_CTRL[16] BYP_ON_LOCKLOSS)
Enable 4-phase clock generator	Control	<PLL_name>_CTRL[5] CLK_4PH_EN (ignored if <PLL_name>_CTRL[4] CLK_POSTDIV_EN = 0) (For example, MCU_PLL0 - MCU_PLL0_CTRL[5] CLK_4PH_EN)
Post divide CLK enable	Control	<PLL_name>_CTRL[4] CLK_POSTDIV_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[4] CLK_POSTDIV_EN)
Delta-Sigma modulator enable	Control	<PLL_name>_CTRL[1] DSM_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[1] DSM_EN)
Enable fractional noise canceling DAC	Control	<PLL_name>_CTRL[0] DAC_EN (For example, MCU_PLL0 - MCU_PLL0_CTRL[0] DAC_EN)

(1) j is the number of HSDIV for the current PLL.

**Table 5-120. Clock Output Parameter for PLLTS16FFCLVDESKEWC Type**

Clock Output/Divider	Parameter Name	Control/Status Bit Field
<PLL_name>_CLK_OUT, <PLL_name>_HSDIVj_CLK_OUT	Control	<PLL_name>_CTRL[31] BYPASS_EN (For example, PLL24 - PLL24_CTRL[31] BYPASS_EN)

#### 5.4.5.5.4 Calibration Related Bitfields

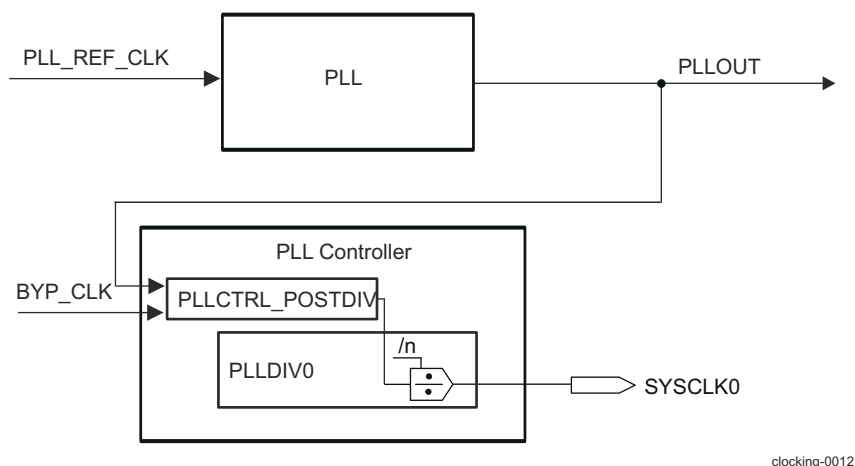

Table 5-121 lists the calibration related bitfields/bits.

**Table 5-121. Recalibration Feature Parameters**

Recalibration feature	Parameter Name	Control/Status Bit Field
Calibration enable to actively adjust for input skew	Control	<PLL_name>_CAL_CTRL[31] CAL_EN (For example, PLL12 - PLL12_CAL_CTRL[31] CAL_EN)
Fast calibration enabled	Control	<PLL_name>_CAL_CTRL[20] FAST_CAL (For example, PLL12 - PLL12_CAL_CTRL[20] FAST_CAL)
Calibration loop programmable counter	Control	<PLL_name>_CAL_CTRL[18-16] CAL_CNT (For example, PLL12 - PLL12_CAL_CTRL[18-16] CAL_CNT)
Calibration bypass	Control	<PLL_name>_CAL_CTRL[15] CAL_BYP (For example, PLL12 - PLL12_CAL_CTRL[15] CAL_BYP)
Calibration input	Control	<PLL_name>_CAL_CTRL[11-0] CAL_IN (For example, PLL12 - PLL12_CAL_CTRL[11-0] CAL_IN)
Output of the calibration block	Status	<PLL_name>_CAL_STAT[11-0] CAL_OUT (For example, PLL12 - PLL12_CAL_STAT[11-0] CAL_OUT)

#### 5.4.5.6 PLL and PLL Controller Connection

Two PLL Controllers are implemented in the device - PLLCTRL0 and WKUP\_PLL\_CTRL0. They are respectively related to PLL0 and MCU\_PLL0. The PLL Controllers manage the clock ratios, alignment, and gating for the system clocks.

**Figure 5-46. PLL and PLL Controller**

#### Note

PLLCTRL\_POSTDIV is not supported in this family of devices.

#### Note

The PLL Controllers registers can be accessed by any master in the device.

A SYSCLK0 clock out of a PLLCTRL is the only synchronous clock in that domain. That means  
- MCU\_SYSCLK0 out of WKUP\_PLLCTRL is the synchronous CBASS clock in MCU domain and  
SYSCLK0 out of Main PLLCTRL is the synchronous CBASS clock in Main domain.

#### 5.4.5.7 System Clocks Operating Frequency Ranges

Table 5-122 lists the operating frequency ranges for the system clocks of the device.

**Table 5-122. System Clocks Operating Frequency Range**

System Clocks	Minimum Operating Frequency (MHz)
MCU_PLL0 (MCU TBD PLL) with WKUP_PLLCTRL0	TBD
MCU_PLL1 (MCU PERIPHERAL PLL)	TBD
MCU_PLL2 (MCU CPSW PLL)	TBD
PLL0 (MAIN PLL) with PLLCTRL0	TBD
PLL1 (PER0 PLL)	TBD
PLL2 (PER1 PLL)	TBD
PLL3 (CPSW9G PLL)	TBD
PLL4 (AUDIO0 PLL)	TBD
PLL5 (VIDEO PLL)	TBD
PLL6 (GPU PLL)	TBD
PLL7 (C7x PLL)	TBD
PLL8 (ARM0 PLL)	TBD
PLL12 (DDR PLL)	TBD

**Table 5-122. System Clocks Operating Frequency Range (continued)**

System Clocks	Minimum Operating Frequency (MHz)
PLL13 (C66 PLL)	TBD
PLL14 (PULSAR PLL)	TBD
PLL15 (AUDIO1 PLL)	TBD
PLL16 (DSS PLL0)	TBD
PLL17 (DSS PLL1)	TBD
PLL18 (DSS PLL2)	TBD
PLL19 (DSS PLL3)	TBD
PLL23 (DSS PLL7)	TBD
PLL24 (MLB PLL)	TBD
PLL25 (VISION PLL)	TBD

(1) Supported input reference clock frequencies to the PLL are 19.2/24/25/26 MHz only.

(2) Interconnect clock on DSS is CPU/4. This will range from 100 MHz to 250 MHz.

(3) When Main PLL is configured to 400 MHz mode, DSS can only support a max pixel clock of 74.25 MHz. For lower resolution displays the DSS clock can be lower than 74.25 MHz.

#### 5.4.5.8 Recommended Clock and Control Signal Transition Behavior

All clocks and strobe signals must transition between  $V_{IH}$  and  $V_{IL}$  (or between  $V_{IL}$  and  $V_{IH}$ ) in a monotonic manner. Monotonic transitions are more easily ensured with faster switching signals. Slower input transitions are more susceptible to glitches due to noise, and special care must be taken for slow input clocks.

#### 5.4.5.9 Interface Clock Specifications

##### Interface Clock Terminology

The interface clock is used at the system level to sequence the data and to control transfers accordingly with the interface protocol.

##### Interface Clock Frequency

The two interface clock characteristics are:

- The maximum clock frequency
- The maximum operating frequency

The interface clock frequency documented here is the maximum clock frequency, which corresponds to the maximum frequency programmable on this output clock. This frequency defines the maximum limit supported by the Device IC and does not take into account any system consideration (PCB, peripherals).

The system designer must take into account these system considerations and the Device IC timing characteristics to properly define the maximum operating frequency that corresponds to the maximum frequency supported to transfer the data on this interface.

#### 5.4.5.10 PLL, PLLCTRL, and HSDIV Controllers Programming Guide

##### 5.4.5.10.1 PLL Initialization

##### 5.4.5.10.1.1 Kick Protection Mechanism

#### Note

PLL configuration registers are write-protected at power-up. Software must first un-lock the PLLn\_LOCKKEY0 and PLLn\_LOCKKEY1 registers prior to writing to any chip-level registers.

The un-lock process shall follow the steps:

1. Write value 0x68EF3490 to PLLn\_LOCKKEY0 register.
2. Write value 0xD172BC5A to PLLn\_LOCKKEY1 register.

After these two steps a write access to the PLL registers is allowed. Writing any other data value to either of these two registers locks the kicker mechanism and blocks any writes to the PLL registers.

---

#### Note

In order to ensure that all PLL registers are write protected, software must always re-lock the kicker mechanism after completing the register writes.

---

#### 5.4.5.10.1.2 PLL Initialization to PLL Mode

---

#### Note

For validated set of parameters that can be programmed to PLLs, please refer to the device-specific Datasheet.

---

Initially, the device powers up in PLL bypass mode. The bypass mux is a glitch free mux and is located outside the PLL module. PLL\_EXTBYPASS bit controls the bypass mux section. During Power-up, the bypass mux defaults to select FREF clock (PLL clock bypass mode).

During boot, WKUP\_DMSC0 ROM programs the MCU\_PLL0 to a valid frequency based on the crystal frequency and BOOTMODE pin settings. WKUP\_DMSC0 then waits for PLL to be locked by checking the PLL LOCK status bit. WKUP\_DMSC0 ROM programs PLL\_EXTBYPASS bit to '0' to disable the bypass mode to propagate MCU\_PLL0 clock to WKUP\_PLLCTRL0. At this point WKUP\_DMSC0 brings MCU\_R5FSS out of reset to complete the reset of the boot process. R5FSS software configures the remaining PLLs and bring them out of bypass mode.

The following shows the PLL initialization sequence.

1. Wait until supplies are stable and PORz is de-asserted. By this time the reference clock source must be up and running.
2. Default controls settings:
  - By default PLEN signal is Low provided by <PLL\_name>\_CTRL register default state. This signal behaves like a reset control to the PLL.
  - By default PLL\_INTBYPASS signal is low provided by <PLL\_name>\_CTRL register default state.
  - By default PLL\_EXTBYPASS signal is high provided by PLL MMR CTRL default state. PLL clock will be bypassed externally by a glitch free mux. The output of the mux will be the reference clock FREF.
  - LOCK output of PLL will be Low.
3. Program the PLL to a valid setting that runs the VCO within the specified range. The following bits/bitfields must be programmed appropriately by software: DSMEN, DACEN, FOUTPOSTDIVEN, FOUT4PHASEEN, REFDIV[5-0], FBDIV[11-0], FRAC[23-0], POSTDIV1[2-0], POSTDIV2[2-0].
4. Wait for 1  $\mu$ s to allow the PLL internal reset to complete (PLL powerdown switch pulls the loop filter voltage from rail-to-rail, which ensures the PLL will be completely powered down from any state).
5. Assert PLEN to a High (by writing a '1' into PLEN bit in <PLL\_name>\_CTRL register).
6. Wait for PLL Lock output to go high. Software can read the LOCK bit in <PLL\_name>\_STATS register to check if PLL has locked.
7. De-assert PLL\_EXTBYPASS signal to a Low by writing 0 into BYPASS\_EN bit in <PLL\_name>\_CTRL register.
8. Glitch free mux safely switches to the PLL clock output.

**Changing PLL setting:** During normal operation, before changing PLL settings, the PLL clock must be bypassed by setting PLL\_EXTBYPASS control to a high. Then follow steps 2 to 8 from the above sequence.

#### 5.4.5.10.1.3 PLL Programming Requirements

- A PLL VCO frequency must be set to > 1500 MHz
  - For best PLL performance, maximize VCO frequency where possible.
- A PLL must always operate in Fractional Mode (DACEN and DSMEN set to '1'). This is true even when the FBDIV is a integer.
- A PLL Reference clock frequency must be > 10 MHz.
- REFDIV[5:0] must be set to "000001".
- DESKEWC and FRACF PLLs must always be used with continuous calibration mode turned on and follow the calibration procedure.

#### 5.4.5.10.2 HSDIV PLL Programming

<PLL\_Name>\_HSDIV\_CTRLK[15] CLKOUT\_EN = 0 cleanly disables the HSDIV output clock

<PLL\_Name>\_HSDIV\_CTRLK[6:0] HSDIV = <value> for divider

<PLL\_Name>\_HSDIV\_CTRLK[8] SYNC\_DIS = 0 insures that the divider changes occur synchronously to the internal divider of the HSDIV block.

when the clock is required,

<PLL\_Name>\_HSDIV\_CTRLK[15] CLKOUT\_EN = 1 cleanly enables the HSDIV output clock

#### 5.4.5.10.3 PLL Controllers Programming - Dividers PLLDIVn and GO Operation

The GO operation is required to change the divider ratios of the PLLDIVn PLLDIVn registers. [Section 5.4.5.10.3.1, GO Operation](#), discusses the GO operation. [Section 5.4.5.10.3.2, Software Steps to Modify PLLDIVn Ratios](#), provides the software steps required to change the divider ratios.

##### 5.4.5.10.3.1 GO Operation

The GO operation writes to the RATIO field in the PLLDIVn PLLDIVn. Registers do not change the dividers' divide ratios immediately. The PLLDIV dividers change to the new RATIO rates only during a GO operation. This section discusses the GO operation and alignment of the SYSCLKs.

The PLL Controller clock align control register (ALNCTL) determines which SYSCLKs must be aligned. Before a GO operation, program ALNCTL so that the appropriate clocks are aligned during the GO operation.

A GO operation is initiated by setting the GOSET bit in PLLCMD to 1. During a GO operation:

- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL and SYS *n* bit in DCHANGE set to 1 is paused at the low edge. Then the PLL Controller restarts all these SYSCLKs simultaneously, aligned at the rising edge. When the SYSCLKs are restarted, SYSCLK *n* toggles at the rate programmed in the RATIO field in PLLDIVn PLLDIVn.
- Any SYSCLK *n* with the corresponding ALN *n* bit in ALNCTL cleared and the SYS *n* bit in DCHANGE set immediately changes to the new rate programmed in the RATIO field.
- The GOSTAT bit in PLLSTAT is set throughout the duration of a GO operation.

#### CAUTION

To help prevent errors, all device operation must be stopped before the GO operation.

#### 5.4.5.10.3.2 Software Steps to Modify PLLDIV Ratios

Perform the following steps to modify PLLDIV.

1. Check that the GOSTAT bit in PLLSTAT is cleared to show that no GO operation is currently in progress.
2. Program the RATIO field in PLLDIVn to the desired new divide-down rate. If the RATIO field changed, the PLL Controller will flag the change in the corresponding bit of DCHANGE.
3. Set the respective ALN *n* bits in ALNCTL to align any SYSCLKs after the GO operation.
4. Set the GOSET bit in PLLCMD to initiate the GO operation to change the divide values and align the SYSCLKs as programmed.

5. Read the GOSTAT bit in PLLSTAT to make sure the bit returns to 0 to indicate that the GO operation has completed.

#### 5.4.5.10.4 Entire Sequence for Programming PLLCTRL, HSDIV, and PLL

Table 5-123 shows the entire sequence of programming PLLCTRL, HSDIV, and PLL from an unknown state to a defined non-spread-spectrum state.

**Table 5-123. Programming Sequence of PLLCTRL, HSDIV, and PLL**

Step	Description
Unlock PLL registers	<PLL_Name>_LOCKKEY0 (= 0x68EF3490) <PLL_Name>_LOCKKEY1 (= 0xD172BC5A)
If PLL0	Configure PLLCTRL block into bypass mode PLLCTL[0] PPLEN = 0 PLLCTL[5] PPLENSRC = 0
Configure external bypass so that no transient clock propagates	<PLL_Name>_CTRL[31] BYPASS_EN = 1
Delay	
Disable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 0
Delay	
Disable PLL	<PLL_Name>_CTRL[15] PLL_EN = 0
Delay	
Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 1
If PLL0	Check PLLSTAT[0] GOSTAT to make sure that divider change is not currently in-progress GOSTAT should equal 0. Clear GOSET bit PLLCMD[0] GOSET = 0 Configure divider in PLLCTRL to /1 PLLDIV1 = 0x8000 (enable divider and divide by 1) PLLDIV2 = 0x00 (disable divider and divide by 1) Set alignment control bits ALNCTL = 3 Set GOSET bit to initiate the divider change PLLCMD[0] GOSET = 1 Check PLLSTAT[0] GOSTAT to make sure that divider change has completed GOSTAT should equal 0.
Configure HSDIV(s) divider value	<PLL_Name>_HSDIV_CTRLk[6-0] HSDIV (=val)
Clear HSDIV(s) SYNC_DIS	<PLL_Name>_HSDIV_CTRLk[8] SYNC_DIS = 0
Delay	
Clear Reset HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[31] RESET = 0
Configure PLL multiplier	Integer portion of divider <PLL_Name>_FREQ_CTRL0[11-0] (=val) Fractional portion of divider <PLL_Name>_FREQ_CTRL1[23-0] (=val)
Configure PLL dividers	Reference clock divider <PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1 Post divider 1 <PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1 Post divider 2 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1
Configure "random" PLL controls	<PLL_Name>_CTRL[8] INTL_BYP_EN = 0 <PLL_Name>_CTRL[5] CLK_4PH_EN = 0 <PLL_Name>_DIV_CTRL[26-24] POST_DIV2 = 1

**Table 5-123. Programming Sequence of PLLCTRL, HSDIV, and PLL (continued)**

Step	Description
	<PLL_Name>_DIV_CTRL[18-16] POST_DIV1 = 1
	<PLL_Name>_DIV_CTRL[5-0] REF_DIV = 1
	<PLL_Name>_CTRL[1] DSM_EN = 1
	<PLL_Name>_CTRL[0] DAC_EN = 1
	<PLL_Name>_SS_CTRL[31] BYPASS_EN (SSMOD) = 1
	<PLL_Name>_CTRL[4] CLK_POSTDIV_EN – if PLL has more than 5 HSDIV blocks, 1; else 0.
	<PLL_Name>_CTRL[16] BYP_ON_LOCKLOSS (= {0, 1})
Delay	
Enable PLL	<PLL_Name>_CTRL[15] PLL_EN = 1
Wait for Lock	Wait for MCU_PLL0_STAT[0] LOCK = 1
Enable HSDIV(s)	<PLL_Name>_HSDIV_CTRLk[15] CLKOUT_EN = 1
Delay	
Configure external bypass to pass PLL	<PLL_Name>_CTRL[31] BYPASS_EN = 0
Delay	
If PLL0	Configure PLLCTRL block into PLL mode PLLCTL[0] PLEN = 0
Lock PLL registers	<PLL_Name>_LOCKKEY0 (= any value) <PLL_Name>_LOCKKEY1 (= any value)

## 6.1 Compute Cluster

This section describes the Compute Cluster (COMPUTE\_CLUSTER0).

### 6.1.1 Compute Cluster Overview

The COMPUTE\_CLUSTER0 encompasses the Arm® Cortex®-A72 subsystem, C71x DSP subsystem, Cluster Level Event Controller (CLEC), Generic Interrupt Controller (GIC), Multicore Shared Memory Controller (MSMC), Data Routing Unit (DRU), AXI to VBUSM.C bridge, ECC aggregators and debug components. Figure 6-1 shows an overview of the COMPUTE\_CLUSTER0 and its surrounding modules.

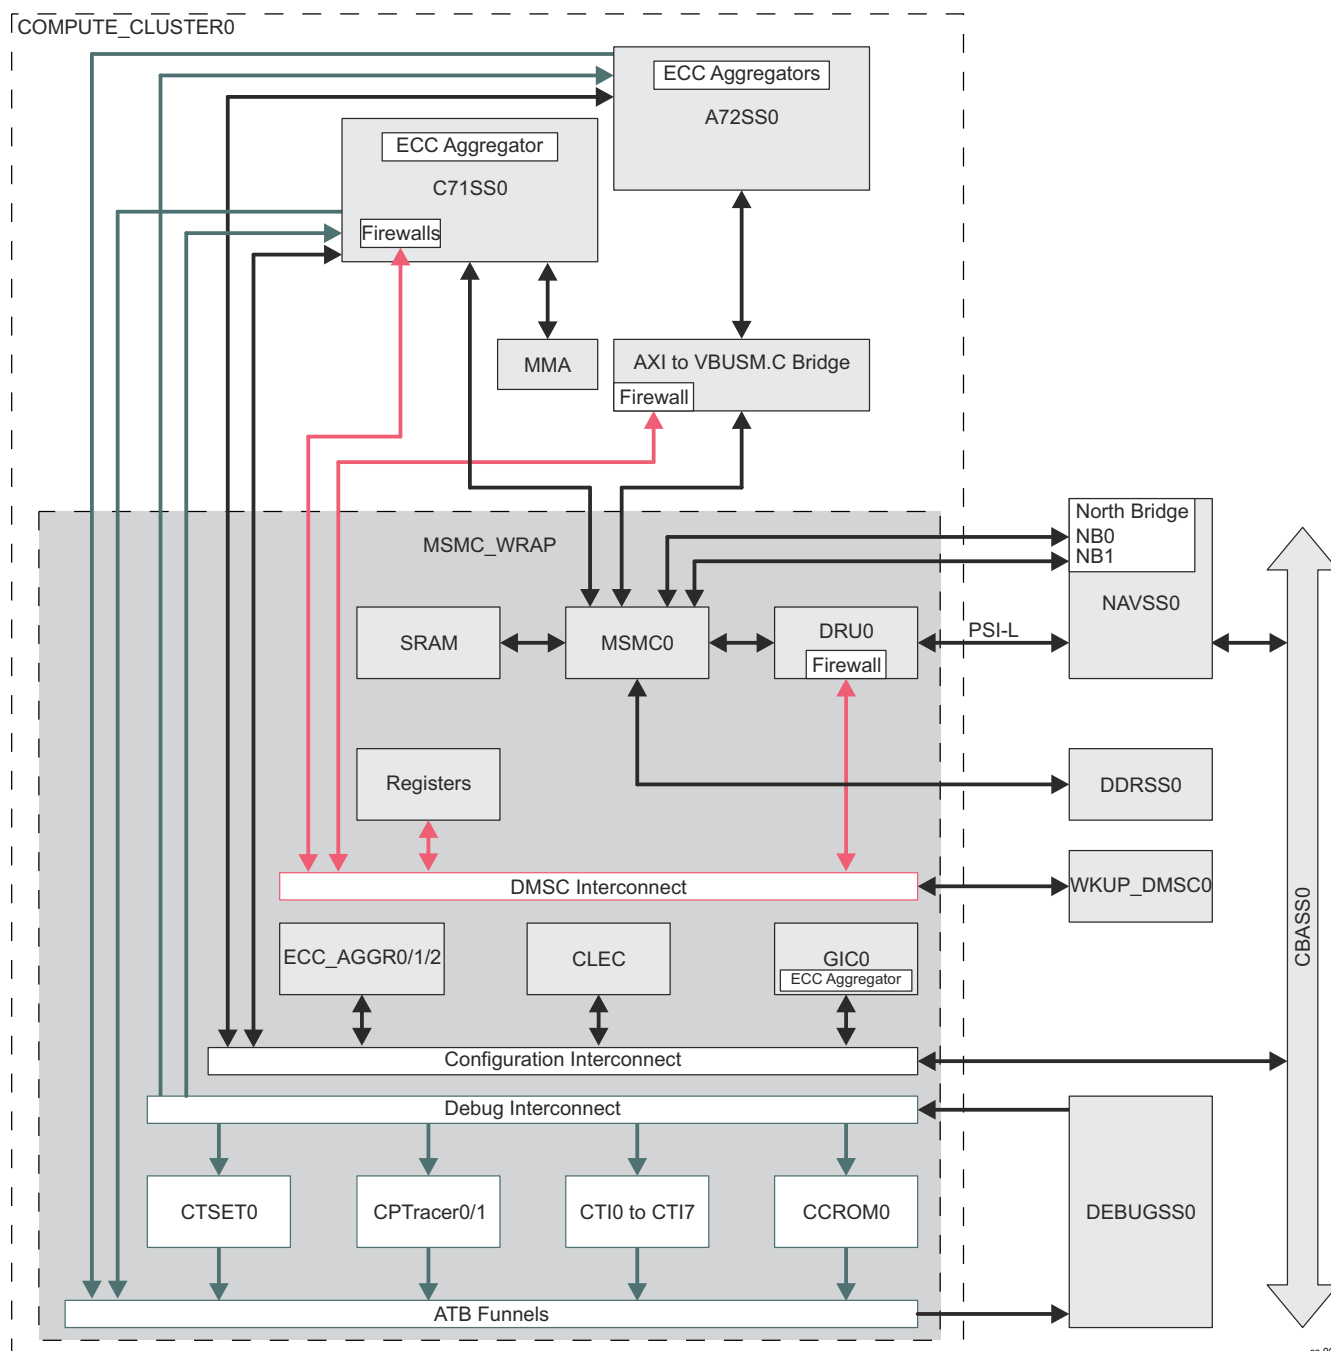

Figure 6-1. COMPUTE\_CLUSTER0 Overview

## 6.1.2 Compute Cluster Functional Description

For information about supported features, integration and functional description of the main COMPUTE\_CLUSTER0 modules, see:

- [Section 6.2 Dual-A72 MPU Subsystem](#)
- [Section 6.5 C71x DSP Subsystem](#)
- [Section 8.1 Multicore Shared Memory Controller \(MSMC\)](#)
- [Section 10.4 Data Routing Unit \(DRU\)](#)
- [Chapter 9 Interrupts](#)

### 6.1.2.1 Compute Cluster Memory Regions

[Table 6-1](#) provides a summary of the COMPUTE\_CLUSTER0 memory regions as seen from the system, WKUP\_DMSC0 and debug external APB.

**Table 6-1. COMPUTE\_CLUSTER0 Memory Regions**

Region	Start Address	End Address	Region Size

### 6.1.2.2 Compute Cluster Firewalls

The following firewalls are present in COMPUTE\_CLUSTER0:

- Region based firewall for A72SS0 integrated in its AXI2VBUSMC bridge
- Two region based firewalls for C71SS0
- Region based firewall for DRU0
- Channelized firewall for DRU0

The A72SS0 firewall protects the traffic generated from the A72SS0 and is placed on the master port side unlike most device firewalls that are on the slave port side. This firewall has to be programed to enable the A72 master port access to the needed slaves.

The first C71SS0 region based firewall (C71SS0 MDMA) protects the traffic generated from the C71SS0 and same as A72SS0 is placed on the master port side. The second C71SS0 region based firewall protects the access to the C71SS0 L2 SRAM and is placed on the slave port side.

The DRU region based firewall is intended to protect the DRU configuration registers within a programmatically specified range. The DRU channelized firewall protects the following:

- The real time configuration registers for each channel
- The TR submission registers for each channel

- The data transfers for each channel

For more information about the DRU firewalls, see [Section 10.4.3.4 DRU Firewalls](#).

The A72SS0 and C71SS0 region based firewalls are same as the other device region based firewalls. For more information about their functionality, see [Section 3.3.4 Interconnect Firewalls](#) in [Chapter 3 System Interconnect](#).

### 6.1.2.3 Compute Cluster ECC Aggregators

As shown in [Figure 6-1](#) the COMPUTE\_CLUSTER0 consists of different modules, several interconnects and ECC aggregators. The memories (internal data buffers, command buffers, queue buffers, other FIFOs, configuration registers, etc.) associated with these blocks are ECC protected to increase functional reliability.

There are three ECC aggregators in the A72SS0, one in the C71SS0, one in GIC0, and three ECC aggregators in MSMC\_WRAP. [Table 6-2](#) through [Table 6-5](#) show the mapping between the end points, their memories protected by ECC and the RAM IDs. The mapping for the ECC aggregators in A72SS0 is shown in [Section 6.2.3.9 A72SS ECC Aggregators](#). The debug components are not ECC protected.

The RAM ID is written to the ECC\_VECTOR[10-0] ECC\_VECTOR field. For information about the ECC aggregator functionality, see [Section 12.11.4 ECC Aggregator](#).

## 6.2 Dual-A72 MPU Subsystem

This section describes the Dual-A72 Microprocessor Unit (MPU) Subsystem (A72SS) in the device.

### 6.2.1 A72SS Overview

#### 6.2.1.1 A72SS Introduction

The device implements one Dual-core Arm® Cortex®-A72 MPU, which is integrated inside the Compute Cluster, along with other modules. The Cortex-A72 cores are general-purpose processors that can be used for running customer applications.

The A72SS is built around the Arm Cortex-A72 MPCore (A72 cluster), which is provided by Arm and configured by TI. It is based on the symmetric multiprocessor (SMP) architecture, and thus it delivers high performance and optimal power management and debug capabilities.

The A72 processor is a multi-issue out-of-order superscalar execution engine with integrated L1 instruction and data caches, compatible with Armv8-A architecture. The Armv8-A architecture brings a number of new features. These include 64-bit data processing, extended virtual addressing and 64-bit general purpose registers.

The A72 processor features an in-order, 8-stage, dual-issue pipeline, and improved integer, Arm Neon™, Floating-Point Unit (FPU) and memory performance. It supports two execution states: AArch32 and AArch64. The AArch64 state gives the A72 CPU its ability to execute 64-bit applications, while the AArch32 state allows the processor to execute existing Armv7-A applications.

For more details on the Compute Cluster and its internal architecture, see *Compute Cluster*.

There is a single A72SS module in the device. [Table 6-6](#) shows A72SS allocation within device domains.

**Table 6-6. A72SS Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
A72SS0	–	–	✓

#### 6.2.1.2 A72SS Features

The A72SS supports the following key features:

- Arm Dual-A72 Cluster (Cortex-A72 MPCore) level features:
  - A72 CPU
    - Full Armv8-A architecture compliance
      - AArch32 and AArch64 execution states
        - AArch32 for full backward compatibility with Armv7
        - AArch64 for 64b support and new architectural features
      - All exception levels EL0-3
      - A32 instruction set (previously Arm instruction set)
      - T32 instruction set (previously Thumb instruction set)
      - A64 instruction set
    - Advanced SIMD and floating point extensions (Neon)
    - Armv8 cryptography extensions
    - Superscalar, variable length, out-of-order pipeline
    - Dynamic branch prediction with Branch Target Buffer (BTB) and Global History Buffer (GHB) RAMs, return stack, and indirect predictor
  - A72 L1/L2 cache memory and MMU
    - 48-entry, fully associative, L1 instruction TLB with native support for 4KB, 64KB, and 1MB page sizes
    - 32-entry, fully associative, L1 data TLB with support for 4KB, 64KB, and 1MB page sizes
    - 4-way, set associative, unified 1K entry L2 TLB per processor
    - 48KB L1 Instruction Cache per processor with parity protection
    - 32KB L1 Data Cache per processor with ECC protection

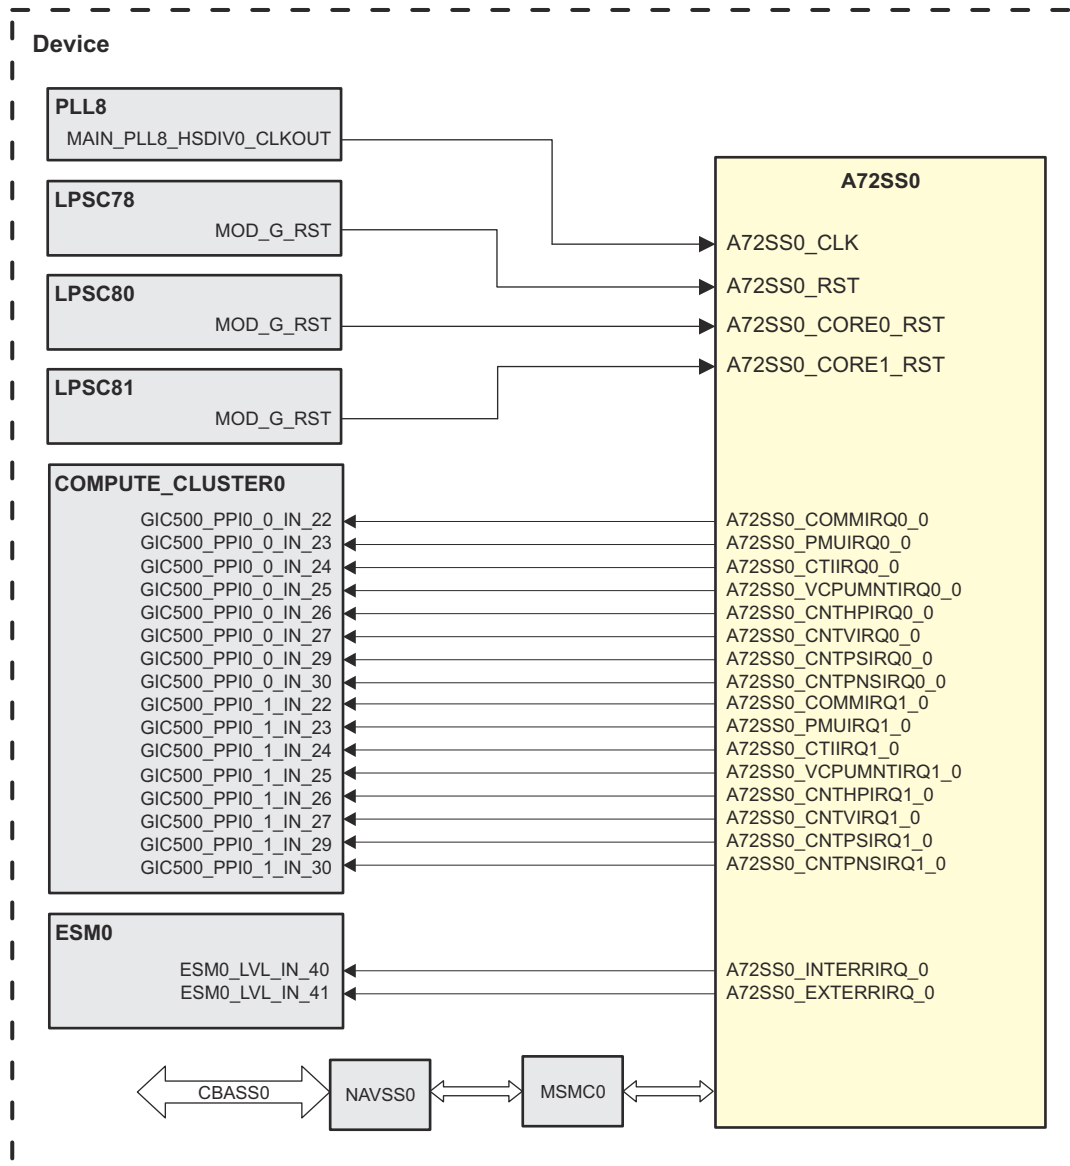

- 1MB Shared L2 Cache with ECC protection
  - Arm GICv3 architecture
  - Generic timers
  - Debug
    - Arm CoreSight™ architecture
    - Embedded Trace Macrocell (ETM)
    - Performance Monitor Unit (PMUv3 architecture)
- TI A72SS subsystem level features:
  - 512-bit wide, asynchronous VBUSM.C master interface
    - AXI2VBUSM\_MASTER bridge
    - Cache pre-warming via use of ACP port
  - Timebase input interfaces
    - 64-bit graycoded global time
    - 48-bit graycoded debug time
  - 32-bit VBUSP slave interface for debug (internally converted to APB)
  - 32-bit ATB output port for debug/trace
  - Interface with Arm GIC-500 interrupt controller
  - Support for ECC on internal RAMs via ECC aggregators
- SoC level features:
  - Supports the SoC multi-core cache coherency architecture
  - Dedicated A72SS clocking (Arm PLL) for full flexibility in performance trade-offs
  - Advanced power management with fine-grained control of individual A72 CPU power domains, coarse grained cluster-level power management, and low-power standby modes (WFI/WFE modes)
  - Dedicated RTI windowed watchdog timer per core

## 6.2.2 A72SS Integration

This section describes the A72SS integration in the device, including information about clocks, resets, and hardware requests.

Figure 6-2 shows the A72SS integration.

**Figure 6-2. A72SS Integration**

Table 6-7 through Table 6-9 summarize the A72SS integration.

**Table 6-7. A72SS Integration Attributes**

Module Instance		Attributes

## 6.2.3 A72SS Functional Description

### 6.2.3.1 A72SS Block Diagram

Figure 6-3 shows the block diagram of the A72SS subsystem.

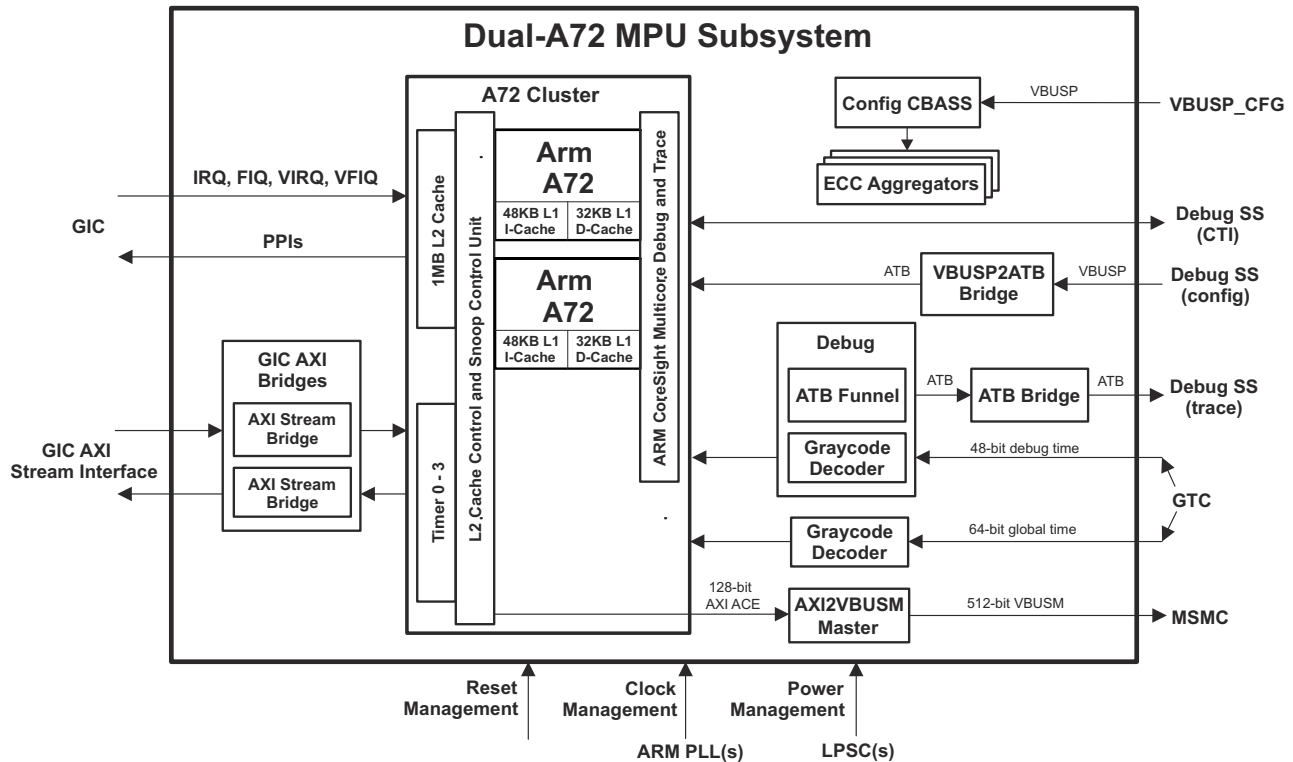

Figure 6-3. A72SS Block Diagram

### 6.2.3.2 A72SS A72 Cluster

The A72 cluster is provided by Arm and configured by TI. Table 6-10 summarizes the configuration of the A72 cluster for this device.

Table 6-10. A72 Cluster Configuration

Parameter	Value
Core type	A72 <sup>(1)</sup>
Number of cores	2
Bus width	512
L1 instruction cache size	48K
L1 data cache size	32K
L2 cache size	1M
ECC protection for L2 cache	Included
ECC/parity protection for CPU cache	Included
Advanced SIMD and Floating Point Extension	Included
Cryptography extension	Included
L2 FEQ size	28

(1) The A72 core revision used in this device is r1p0.

### 6.2.3.3 A72SS Interfaces and Async Bridges

The A72SS has the following main interfaces:

- 512-bit wide VBUSM.C master interface
  - Supported by AXI2VBUSM\_MASTER Bridge, which performs the following primary functions (among others):
    - Provides an asynchronous voltage domain crossing boundary for the AXI ACE master and ACP slave ports
    - Provides protocol conversion between AXI ACE (128-bit) and CBA VBUSM.C (512-bit)
    - Provides support for cache pre-warming
- 64-bit graycoded system input time
  - Graycode value provided by Global Timebase Counter (GTC)
  - Dedicated decoder (64-bit input) for graycode-to-binary conversion
- 48-bit graycoded debug input time
  - Graycode value provided by GTC
  - Dedicated decoder (48-bit input) for graycode-to-binary conversion
- 32-bit VBUSP slave interface for configuration of ECC aggregators
- 32-bit VBUSP slave interface for debug
  - Supported by VBUSP2APB Bridge, which performs VBUSP-to-APB conversion (for controlling the Arm A72 Cluster internal debug logic)
- 32-bit ATB output port for debug/trace
  - Supported by ATB Bridge, which performs clock and voltage level conversion on the combined ATB interface
  - Connected to the Debug Subsystem
- Cross Trigger Interface (CTI) for debug
  - Connected to the Debug Subsystem
- Interface(s) with Arm GIC-500 Interrupt Controller
  - Supported by GIC AXI Streaming Bridge, which performs clock and voltage level conversion on the AXI streaming protocol
  - Interrupts (PPIs) from Arm A72 Cluster to GIC-500
  - Interrupts (IRQ, FIQ, VIRQ, VFIQ) from GIC-500 to Arm A72 Cluster
- Power/clock interface(s)
  - Dedicated PLL for Arm A72 Cluster
  - Dedicated LPSC for Arm A72 Cluster, and also for each A72 core

### 6.2.3.4 A72SS Interrupts

#### 6.2.3.4.1 A72SS Interrupt Inputs

The A72 CPU receives interrupts at its inputs (IRQ, FIQ, VIRQ, VFIQ) via the dedicated Arm GIC-500 Interrupt Controller which is integrated inside the Compute Cluster and is tightly-coupled to the A72. The GIC-500 supports both A72 cores in the system. The GIC-500 is compliant to the Arm GICv3 specification and supports four types of interrupts:

- *Software Generated Interrupts (SGI)*
  - There are 16 SGIs (ID0-ID15)
  - These are inter-processor interrupts
- *Private Peripheral Interrupts (PPI)*
  - There are 16 PPIs (ID16-ID31)
  - These are wired interrupts dedicated to a specific CPU
  - Many are reserved to specific functions via convention
- *Shared Peripheral Interrupts (SPIs)*
  - There are 960 SPIs (ID32-ID991)
  - These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC-500

- *Locality-Specific Peripheral Interrupts (LPI)*
  - There are 57344 LPIs
  - These interrupts are used for message-based interrupts from a peripheral

The mapping of PPIs and SPIs to the GIC-500 interrupt inputs can be found in TBD.

#### Note

For a brief list of features supported by the GIC-500 module, see *Generic Interrupt Controller (GIC)*.  
For detailed description of the GIC-500 module, see the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

#### 6.2.3.4.2 A72SS Interrupt Outputs

Table 6-11 lists the interrupts generated by the A72SS

**Table 6-11. A72SS Interrupt Outputs**

TI Interrupt Name <sup>(1)</sup>	Arm Interrupt Name	Interrupt Description
<b>A72 Core Interrupts (PPIs)<sup>(2)</sup></b>		
A72SS0_VCPUMNTIRQy_0	nVCPUMNTIRQ	This interrupt indicates that a virtual CPU interface on the corresponding core needs serviced. This interrupt is serviced by software switching to the virtual CPU and finding what specific service needs done.
A72SS0_CNTHPIRQy_0	nCNTHPIRQ	This interrupt indicates a physical timer event at the EL2 (hypervisor) exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL2 and service accordingly.
A72SS0_CNTPNSIRQy_0	nCNTPNSIRQ	This interrupt indicates a physical timer event at the EL1 non-secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 non-secure and service accordingly.
A72SS0_CNTPSIRQy_0	nCNTPSIRQ	This interrupt indicates a physical timer event at the EL1 secure exception level. Service of this interrupt is dependent on what the timer was set for. Software should take exception to EL1 secure and service accordingly.
A72SS0_CNTVIRQy_0	nCNTVIRQ	This interrupt indicates a virtual timer event. Service of this interrupt is dependent on what the timer was set for. Software should take exception and service accordingly.
A72SS0_PMIIRQy_0	nPMUIRQ	This interrupt is generated by the Performance Monitor Unit (PMU). The PMU can generate an interrupt based on several conditions, depending on programming. Software should take exception and query the PMU as to the cause of the interrupt, and act accordingly.
A72SS0_COMMIRQy_0	nCOMMIRQ	Communications channel receive or transmit interrupt
A72SS0_CTIIRQy_0	CTIIRQ	Cross Trigger Interface (CTI) interrupt
<b>A72 Cluster Interrupts</b>		
A72SS0_EXTERRIRQ_0	nEXTERRIRQ	This error indicates that an error has occurred on the memory bus. It is considered an external abort (or asynchronous error), because it cannot be attributed to a specific instruction. Depending on the system, software may try to recover, or reset the system.
A72SS0_INTERRIRQ_0	nINTERRIRQ	This error indicates an unrecoverable error in the cache system (L1 or L2 data RAM, L2 tag RAM, or SCU L1 duplicate tag RAM). It is considered an external abort (or asynchronous error), because it cannot be attributed to a specific instruction. Depending on the system, software can try to recover, or reset.

(1) In this column, y is the A72 core index (0 or 1)

(2) These are *per core* interrupts

---

### Note

The mapping of these interrupts in the system is summarized in *A72SS Integration*, and can also be found in *Interrupts*.

For more detailed description of these interrupts and their handling, see the *Arm® Cortex®-A72 MPCore Processor Technical Reference Manual*.

---

## 6.2.3.5 A72SS Power Management, Clocking and Reset

### 6.2.3.5.1 A72SS Power Management

The A72 cluster and each A72 CPU reside in a separate power domain, as follows:

- PD14 (PD\_A72\_CLUSTER\_0): Power domain of A72 cluster
- PD15 (PD\_A72\_0): Power domain of A72SS0\_CORE0
- PD16 (PD\_A72\_1): Power domain of A72SS0\_CORE1

There is a dedicated Local Power Sleep Controller (LPSC) for the A72 cluster and for each A72 core, as well. The LPSC assignment is as follows:

- LPSC78 (LPSC\_A72\_CLUSTER\_0): Dedicated for A72 cluster
- LPSC80 (LPSC\_A72\_0): Dedicated for A72SS0\_CORE0
- LPSC81 (LPSC\_A72\_1): Dedicated for A72SS0\_CORE1

For more details on these LPSCs, including power-up/down sequences, see *Power*.

### 6.2.3.5.2 A72SS Clocking

There is a dedicated PLL for the A72 cluster: PLL8 (ARM0 PLL). For more details on this PLL, see *Clocking*.

### 6.2.3.6 A72SS Debug Support

The A72SS supports the standard Arm CoreSight debug architecture. Details on Arm debug can be found *On-chip Debug*, and the relevant Arm specifications.

### 6.2.3.7 A72SS Timestamps

The A72SS has two timebase input interfaces:

- 64-bit global timestamp: Used for synchronizing the Arm internal timers. This is done via the Arm CNTVALUEB[63:0] bus
- 48-bit debug timestamp: Can be embedded in Arm trace streams at periodic and strategic locations, allowing the temporal relationship of different trace sources to be determined

Both of them are fed by the Global Timebase Counter (GTC), which provides a 64-bit graycode value. The MPU includes two graycode decoders (for global time and debug time, respectively), which take the asynchronous graycoded times, synchronize them to the appropriate clock, and convert them to binary time, as required by Arm.

---

### Note

Both graycode decoders are 64-bit but the one dedicated to debug time has a 48-bit input (the upper 16 bits are tied to 0).

---

For more details on the GTC, see *Global Timebase Counter (GTC)*.

### 6.2.3.8 A72SS Watchdog

The A72SS does not have an integrated watchdog timer. Instead, this feature is provided externally by the Real Time Interrupt (RTI) module, which implements a windowed watchdog timer capable of issuing warm reset to the SoC, when necessary.

There are two RTI modules in the MAIN domain that are assigned to the A72 cores:

- RTI0 used as windowed watchdog for A72SS0\_CORE0
- RTI1 used as windowed watchdog for A72SS0\_CORE1

For more details on the RTI windowed watchdog feature, see *Real Time Interrupt Module (RTI)*.

### 6.2.3.9 A72SS Internal Diagnostics

The A72SS integrates three ECC aggregators for internal diagnostics and to stimulate errors in associated RAMs for ECC testing purposes:

- A72SS0\_CORE0\_ECC\_AGGR: ECC aggregator for A72SS0\_CORE0 level
- A72SS0\_CORE1\_ECC\_AGGR: ECC aggregator for A72SS0\_CORE1 level
- A72SS0\_CLUSTER\_ECC\_AGGR: ECC aggregator for A72\_CLUSTER (L2) level

#### 6.2.3.9.1 A72SS ECC Aggregators During Low Power States

When a CPU core is in WFI/WFE, the corresponding CPU ECC aggregator MMR region is not accessible and will return error status. Similarly, when L2 is in WFI, the L2 ECC aggregator MMR region is not accessible and will return error status.

#### 6.2.3.9.2 A72SS CBASS Diagnostics

A72SS0\_CORE0\_ECC\_AGGR integrates all the SVBUS slave endpoints for A72SS0\_CORE0.

**Table 6-12. A72SS0\_CORE0\_ECC\_AGGR RAM ID Mapping for Interface Diagnostics**

Endpoint	Memory ID	Controller
A72SS0_CORE0	24	EDC controller for A72SS0_CORE0_ECC_AGGR

A72SS0\_CORE1\_ECC\_AGGR integrates all the SVBUS slave endpoints for A72SS0\_CORE1.

**Table 6-13. A72SS0\_CORE1\_ECC\_AGGR RAM ID Mapping for Interface Diagnostics**

Endpoint	Memory ID	Controller
A72SS0_CORE1	24	EDC controller for A72SS0_CORE1_ECC_AGGR

A72SS0\_CLUSTER\_ECC\_AGGR integrates all the SVBUS slave endpoints for CBASS and cluster.

**Table 6-14. A72SS0\_CLUSTER\_ECC\_AGGR RAM ID Mapping for Interface Diagnostics**

Endpoint	Memory ID	Controller
A72SS0_CLUSTER	32	EDC controller for A72SS0_CLUSTER_ECC_AGGR
	33-41	Internal bridges

#### 6.2.3.9.3 A72SS SRAM Diagnostics

The A72 cluster natively supports ECC/parity protection on some of its internal SRAMs. However, error injection for the memories is not natively supported by the A72 cluster. Instead, this capability is added at A72SS level via ECC aggregator. This is a valuable TI addition to the Arm native implementation.

[Table 6-15](#) shows the A72SS SRAM ECC support details.

**Table 6-15. A72SS SRAM ECC Support**

A72 RAM	ARM Native Support	TI Error Injection Support
L1 I-Cache Data RAM	Parity protection	Single error injection <sup>(1)</sup>
L1 I-Cache Tag RAM	Parity protection	Single error injection <sup>(1)</sup>
L1 I-Cache BTB RAM	No support	N/A
L1 I-Cache GHB RAM	No support	N/A
L1 I-Cache IP RAM	No support	N/A
L1 D-Cache Data RAM	ECC	Single and double error injection <sup>(1)</sup>
L1 D-Cache Tag RAM	ECC	Single and double error injection <sup>(1)</sup>
L1 PF PHT RAM	No support	N/A

**Table 6-15. A72SS SRAM ECC Support (continued)**

A72 RAM	ARM Native Support	TI Error Injection Support
L2 TLB RAM	Parity	Single error injection <sup>(1)</sup>
L2 Snoop Tag RAM	ECC	Single and double error injection <sup>(2)</sup>
L2 Tag RAM	ECC	Single and double error injection <sup>(2)</sup>
L2 Data RAM	ECC	Single and double error injection <sup>(2)</sup>
L2 Dirty RAM	ECC	Single and double error injection <sup>(2)</sup>
L2 Inclusion PLRU RAM	ECC	Single and double error injection <sup>(2)</sup>

(1) Supported by A72SS0\_CORE0/1\_ECC\_AGGR

(2) Supported by A72SS0\_CLUSTER\_ECC\_AGGR

**6.2.3.9.4 A72SS SRAM ECC Aggregator Configurations**

There are several schemas of memory protection employed inside of the processors. [Table 6-16](#) and [Table 6-17](#) describe the schema and arrangement. This describes what bits are protected, how they are protected, the behavior when an error is detected and what bits can be disturbed for ECC testing purposes. This also lists the RAM\_ID associated with each memory to the corresponding ECC aggregator.

The key for the protection schemes is as follows:

- Parity: Parity bit(s) to protect data
- ECC: Error Correction Code to protect data
- SECEDED: Single Error Correction, Double Error Detection

**Table 6-16. A72SS0\_CORE0/1\_ECC\_AGGR Mapping**

Memory	Protection	Parity/ECC Granularity	RAM Arrangement	RAM_ID	Notes
L1 I-Cache Data	Parity	1 parity bit / 16 bits of Instruction data	[71] – Parity of all odd bits of [63:32] and [67] [70] – Parity of all even bits of [63:32] and [66] [69] – Parity of all odd bits of [31:0] and [65] [68] – Parity of all even bits of [31:0] and [64]	0-5	Parity error invalidates the offending cache line, force a fetch from the L2 cache on the next access. No aborts are generated, location of error is reported in the A72 CPUMERR register.
L1 I-Cache Tag	Parity	2 parity bits / 36 bits tag entry	[107] – Parity of all odd bits of [104:72] [71] – Parity of all odd bits of [68:36] [35] – Parity of all odd bits of [32:0] [106] – Parity of all even bits of [104:72] [70] – Parity of all even bits of [68:36] [34] – Parity of all even bits of [32:0] [105], [69], [33] – Valid bit [104:72], [68:36], [32:0] – Tag	6-7	Parity error invalidates the offending cache line, force a fetch from the L2 cache on the next access. No aborts are generated, location of error is reported in the A72 CPUMERR register.
L1 D-cache Data	ECC SECEDED	32-bit word	[155:149] – ECC [148:117] – Data [116:110] – ECC [109:78] – Data [77:71] – ECC [70:39] – Data [38:32] – ECC [31:0] – Data	8-15	Single bit errors are corrected in the background and the line is removed from the cache as part of the correction process. No exception or interrupt is generated, but the A72 MERR register is updated to indicate a non-fatal error. Double bit errors are detected and an imprecise data abort is triggered and the line is evicted from the cache.

**Table 6-16. A72SS0\_CORE0/1\_ECC\_AGGR Mapping (continued)**

Memory	Protection	Parity/ECC Granularity	RAM Arrangement	RAM_ID	Notes
L1 D-Cache Tag	ECC SECEDED	Tag for a single cache line	[39:33] – ECC for [32:2] Tag and [1:0] State	16-19	Single bit errors are corrected in the background and the line is removed from the cache as part of the correction process. No exception or interrupt is generated, but the A72 MERR register is updated to indicate a nonfatal error. Double bit errors are detected and an imprecise data abort is triggered and the line is evicted from the cache.
L2 TLB	Parity		[129] – Parity Bit [128:0] – TLB data	20-23	Error detection results in entry invalidated, new pagewalk to refetch.

**Table 6-17. A72SS0\_CLUSTER\_ECC\_AGGR Mapping**

Memory	Protection	RAM Arrangement	RAM_ID	Notes
L2 Tag	ECC SECEDED	Odd way: [77:71] – ECC for [70:41] Tag and [40:39] State  Even Way: [38:32] – ECC for [31:2] Tag and [1:0] State	12-27	Accesses resulting in an L2 cache hit, where a single-bit error is detected on the data array, the L2 memory system supports in-line ECC correction. Uncorrected data is forwarded to the requesting unit, and in parallel, the ECC circuitry checks for accuracy. If a single-bit error is detected, any uncorrected data returned within two cycles before the error indicator must be discarded.
L2 Data	ECC SECEDED	[143:128] – ECC [127:0] - Data	4-11	Accesses resulting in an L2 cache hit, where a single-bit error is detected on the Data array, the L2 memory system supports in-line ECC correction. Uncorrected data is forwarded to the requesting unit, and in parallel, the ECC circuitry checks for accuracy. If a single-bit error is detected, any uncorrected data returned within two cycles before the error indicator must be discarded.
L2 Snoop Tag RAM	ECC SECEDED	[79:73] – ECC for [72:42] Tag and [41:40] State  [39:33] – ECC for [32:2] Tag and [1:0] State	0-3	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.
L2 Inclusion PLRU RAM	ECC SECEDED	[38:32] – ECC for [30:16] PLRU and [15:0] Inclusion	30-31	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.

**Table 6-17. A72SS0\_CLUSTER\_ECC\_AGGR Mapping (continued)**

Memory	Protection	RAM Arrangement	RAM_ID	Notes
L2 Dirty RAM	ECC SECDED	[47:44] – ECC	28-29	For single-bit ECC errors detected, the request is flushed from the L2 pipeline and is forced to reissue. The tag bank where the single-bit error occurred, performs a read-modify-write sequence to correct the single-bit error in the array. The request is then reissued.

### 6.2.3.10 A72SS Cache Pre-Warming

Cache pre-warming is a method by which data/instructions that will be needed in the near future can be loaded into the L2 cache before the MPU itself does a fetch. The goal is for the cache to have the data ready before the MPU actually needs it, so that software does not need to stall waiting for cache fetches. The mechanism is the MPU's ACP port combined with the Data Routing Unit (DRU).

The basic steps are as follows:

1. Software identifies some data or instruction it knows it will need in the near future
2. Software sets up a DRU pre-warm transfer for this data
3. DRU performs reads through the ACP port of the MPU (through AXI2VBUSM\_MASTER)
4. MPU initiates reads over the memory interface that load the data into L2 cache
5. MPU returns the read data through the ACP port
  - AXI2VBUSM\_MASTER discards this data (there is no need for the DRU to see it)

Now, when software tries to access this data, it will hit in the L2 cache.

For details on DRU programming to perform cache pre-warming, see *Multicore Shared Memory Controller (MSMC)*.

### 6.2.3.11 A72SS Boot

For Armv8 cores such as A72, two boot modes are supported: legacy 32-bit address boot mode, and 64-bit address boot mode. The selection is asserted before the A72 core is out of reset and is based on the configuration of the following Compute Cluster register:

- CC\_CP\_CONFIG\_0[3-0] AARCH bit field

When the A72 core is configured for a 32-bit address boot mode, the boot vector is fixed at address 0x0000\_0000, which corresponds to the start address of the 2KB boot RAM (PSRAM2KECC0\_RAM).

When the A72 core is configured for a 64-bit address boot mode, the boot vector is determined by the RVBARADDRx tie-off signal, which is configured via associated Compute Cluster registers:

- For A72SS0\_CORE0: CC\_RST\_VEC\_LO\_CP0\_0 and CC\_RST\_VEC\_HI\_CP0\_0
- For A72SS0\_CORE1: CC\_RST\_VEC\_LO\_CP1\_0 and CC\_RST\_VEC\_HI\_CP1\_0

The Compute Cluster RVBARADDRx setting is latched into the A72 RVBAR register, where reset is applied. Once reset is released, the A72 RVBAR register becomes read-only and the latched value is used as a boot vector location.

[Table 6-18](#) summarizes the A72 boot mode specifics.

**Table 6-18. A72 Boot Mode Specifics**

32-bit Address Boot Mode	64-bit Address Boot Mode
Boot vector is part of vector table	Boot vector is not part of vector table
Boot vector has a fixed address: 0x0000_0000. It corresponds to the 2KB boot RAM (PSRAM2KECC0_RAM)	Boot vector is determined by RVBARADDRx[39:2] tie-off setting per core. <sup>(1)</sup>
Location of the vector table is fixed by default (0x0000_0000)	No default location of vector table
No need to program A72 VBAR register if vector table stays at the default address	Each A72 core boot code must program VBAR_ELn core registers to initialize its location of the vector tables for the various Armv8 exception levels
Vector table is 32B	Vector table is 128B
Vector table location can be reprogrammed after boot	Vector table location is unknown until it is programmed after reset

(1) Although the associated Compute Cluster register provides support for a 50-bit wide reset base vector, the actual support is for a 40-bit reset base vector per SoC restriction.

#### 6.2.3.12 A72SS IPC with Other CPUs

The A72 cores can communicate with other device cores (R5F MCU, C66x DSP, C7x DSP, etc) by supporting interrupt generation to and from these cores. The interprocessor communication (IPC) interrupts are assigned in the corresponding Control Module memory-mapped registers (MMRs) called IPC\_SETx / IPC\_CLRx. For more information, see *Control Module (CTRL\_MMR)*.

## 6.3 Dual-R5F MCU Subsystem

This chapter describes the dual-R5F Microcontroller Unit (MCU) Subsystem (R5FSS) in the device.

### 6.3.1 R5FSS Overview

The R5FSS is a dual-core implementation of the Arm® Cortex®-R5F processor configured for split/lock operation. It also includes accompanying memories (L1 caches and tightly-coupled memories), standard Arm CoreSight™ debug and trace architecture, integrated vectored interrupt manager (VIM), ECC aggregators, and various other modules for protocol conversion and address translation for easy integration into the SoC.

#### Note

The Cortex-R5F processor is a Cortex-R5 processor that includes the optional floating point unit (FPU) extension. In this TRM, all references to the Cortex-R5 processor by default apply to the Cortex-R5F processor.

There are three R5FSS subsystems in the device. [Table 6-19](#) shows R5FSS allocation across device domains.

**Table 6-19. R5FSS Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MCU_R5FSS0	–	✓	–
R5FSS0	–	–	✓
R5FSS1	–	–	✓

#### 6.3.1.1 R5FSS Features

Each R5FSS supports the following features:

- Dual-core Arm Cortex-R5F
  - Core revision: r1p3
  - Armv7-R profile
  - Split/lock operation
    - Split mode: Two independently operating cores (asymmetric multi processing, no coherence)
    - Lock (lockstep) mode: One main operating core with the other operating in lockstep
    - Boot-time configurable to be in split or lock mode
  - L1 memory system
    - 16KB instruction cache
      - 4x4KB ways
      - SECDED ECC protected per 64 bits
    - 16KB data cache
      - 4x4KB ways
      - SECDED ECC protected per 32 bits
    - 64KB tightly-coupled memory (TCM) per CPU
      - SECDED ECC protected per 32 bits
      - Readable/writable from system
      - Split into A and B banks (with B further splitting into B0 and B1 interleaved banks)
        - 32KB TCMA (ATCM)
        - 16KB TCMB0 (B0TCM)
        - 16KB TCMB1 (B1TCM)
  - Low interrupt latency with restartable instructions
  - Non-maskable interrupt (NMI)
  - Full-precision floating point (VFPv3)
  - 16 region memory protection unit (MPU)
  - 8 breakpoints

- 8 watchpoints
- Dynamic branch prediction with global history buffer and 4-entry return stack
- CoreSight debug access port (DAP)
- CoreSight embedded trace macrocell (ETM-R5) interface
- Performance monitoring unit (PMU)
- Interfaces
  - 64-bit VBUSM master pair (1 read, 1 write) for L3 memory accesses (per core)
  - 64-bit VBUSM slave for TCM access (per core)
    - Also allows access to cache for debug purposes
  - 32-bit VBUSM master pair (1 read, 1 write) for peripheral access
    - Note: This port is only supported for R5FSS0 and R5FSS1; it is not supported for MCU\_R5FSS0
  - 32-bit VBUSP master for peripheral access (per core)
  - 32-bit VBUSP slave configuration port (per core)
  - 32-bit VBUSP slave debug port
    - Allows access to all R5FSS internal debug logic

---

### Note

VBUSP is a pended protocol such that only a single transaction can be outstanding at any given time. Transactions are completed on VBUSP entirely before the next transaction is presented on the interface.

VBUSM allows multiple transactions to be outstanding which increases bus throughput.

- 
- Synchronous clock domain crossing on all interfaces
    - Interfaces can run at an integer division of the core frequency
  - Error detection logic (in lockstep mode only)
  - 32-bit to 48-bit region-based address translation (RAT) on memory access masters
    - 16 regions
      - Base address + size
      - Must be size aligned
  - Integrated vectored interrupt manager (VIM)
    - 512 interrupts per core
      - Only interrupts connected to R5F core 0 are available in lock mode
      - Each interrupt programmable as either IRQ or FIQ
      - Each interrupt has a programmable enable mask
      - Each interrupt has a programmable 4-bit priority
    - Priority interrupt supported
    - Vectored interrupt interface
      - Compatible with R5F VIC port
      - Programmable 32-bit vector address per interrupt
        - Address is SECEDED error protected
        - Default vector addresses provided on DED
      - Split or lockstep capable
      - Software interrupt generation
  - Integrated ECC aggregators
    - Support for error injection to all supported ECC memory blocks to test ECC functionality (add-on function from TI)
    - One ECC aggregator per core to cover all RAMs and caches associated with that core
  - Standard Arm CoreSight debug and trace architecture at the R5FSS level
    - Cross triggering: Supported by cross trigger interface (CTI) (per CPU) and cross trigger matrix (CTM) components
    - Processor trace: Supported by embedded trace macrocell (ETM) (per CPU) and advanced trace bus (ATB) funnel components
  - Boot

- From ROM or external memory
- From TCM

See [Section 6.3.3](#) for a functional block diagram and more details on the R5FSS.

#### 6.3.1.2 R5FSS Not Supported Features

The R5FSS does *not* support the following native R5F features in this device:

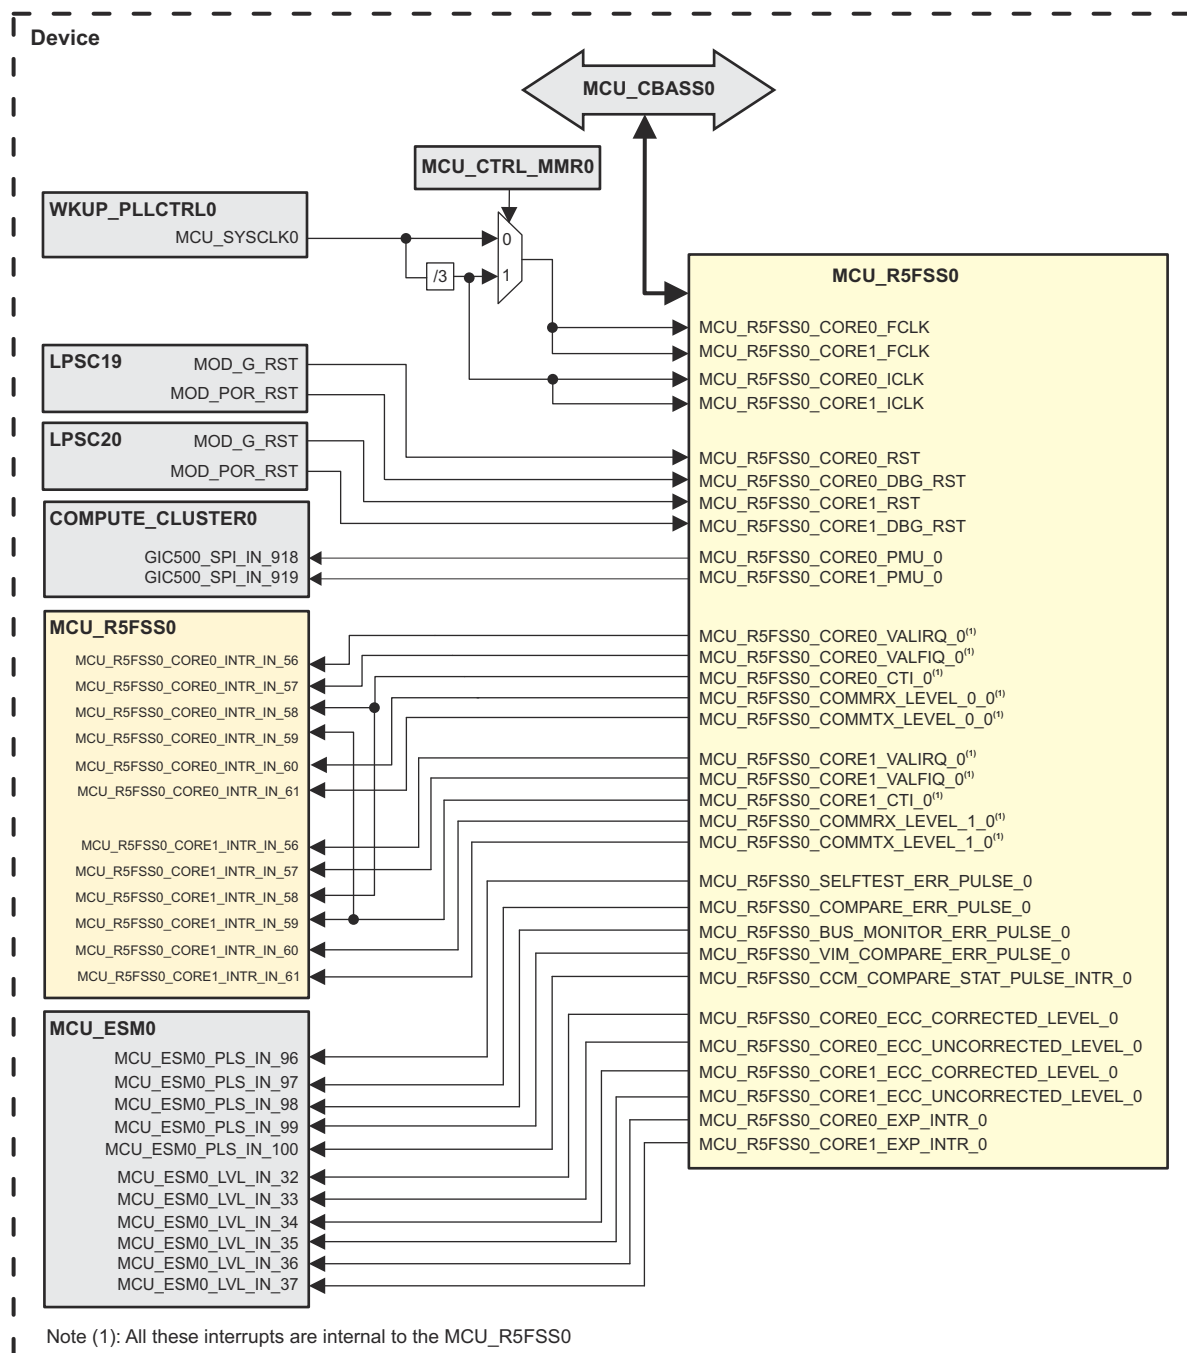

- ACP port (no coherence)
- Bus parity / ECC

## 6.3.2 R5FSS Integration

This section describes the R5FSS integration in the device, including information about clocks, resets, and hardware requests.

### 6.3.2.1 R5FSS Integration in MCU Domain

There is a single R5FSS subsystem integrated in the device MCU domain - MCU\_R5FSS0. Figure 6-4 shows the MCU\_R5FSS0 integration.

**Figure 6-4. MCU\_R5FSS0 Integration**

Table 6-20 through Table 6-22 summarize the MCU\_R5FSS0 integration.

**Table 6-20. MCU\_R5FSS0 Integration Attributes**

Module Instance		Attributes			
		Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_R5FSS0	MCU_R5FSS0_CORE0	WKUP_PSC0	PD1	LPSC19	MCU_CBASS0
	MCU_R5FSS0_CORE1	WKUP_PSC0	PD1	LPSC20	MCU_CBASS0

**Table 6-21. MCU\_R5FSS0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_R5FSS0	MCU_R5FSS0_CORE0_FCLK	MCU_SYSCLK0 (default) or MCU_SYSCLK0/3 <sup>(1)</sup>	WKUP_PLLCT RL0	MCU_R5FSS0_CORE0 functional clock
	MCU_R5FSS0_CORE0_ICLK	MCU_SYSCLK0/3	WKUP_PLLCT RL0	MCU_R5FSS0_CORE0 interface clock
	MCU_R5FSS0_CORE1_FCLK	MCU_SYSCLK0 (default) or MCU_SYSCLK0/3 <sup>(1)</sup>	WKUP_PLLCT RL0	MCU_R5FSS0_CORE1 functional clock
	MCU_R5FSS0_CORE1_ICLK	MCU_SYSCLK0/3	WKUP_PLLCT RL0	MCU_R5FSS0_CORE1 interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MCU_R5FSS0	MCU_R5FSS0_CORE0_RST	MOD_G_RST	LPSC19	MCU_R5FSS0_CORE0 main reset
	MCU_R5FSS0_CORE0_DBG_RST	MOD_POR_RST	LPSC19	MCU_R5FSS0_CORE0 debug reset (APB excluded)
	MCU_R5FSS0_CORE1_RST	MOD_G_RST	LPSC20	MCU_R5FSS0_CORE1 main reset
	MCU_R5FSS0_CORE1_DBG_RST	MOD_POR_RST	LPSC20	MCU_R5FSS0_CORE1 debug reset (APB excluded)

(1) Source clock selection is done via Control Module register (CTRLMMR\_MCU\_R5\_CORE0\_CLKSEL). MCU\_R5FSS0\_CORE1 always receives the same clock as MCU\_R5FSS0\_CORE0 based on this register.

**Table 6-22. MCU\_R5FSS0 Hardware Requests**

### 6.3.2.2 R5FSS Integration in MAIN Domain

There are two R5FSS subsystems integrated in the device MAIN domain - R5FSS0 and R5FSS1. [Figure 6-5](#) and [Figure 6-6](#) show the integration of R5FSS0 and R5FSS1, respectively.

**Figure 6-5. R5FSS0 Integration**

**Figure 6-6. R5FSS1 Integration**
**Table 6-23. R5FSS0/1 Integration Attributes**

Module Instance		Attributes

restriction is that CPU0 must be in a higher power/reset state than CPU1. For instance, CPU1 cannot be out of reset if CPU0 is not.

In lockstep mode, the core logic from CPU1 is used as redundant logic to check for errors in CPU0. The CPU1 interfaces and RAMs are not used. Comparison logic automatically checks the redundant logic against the primary logic and flags any errors.

For a brief list of features supported by the R5F processor in this device, see [Section 6.3.1.1](#). For more detailed description of this processor, see the *Arm Cortex-R5 Technical Reference Manual*.

#### 6.3.3.2.1 L1 Caches

The R5F has a Harvard cache architecture, which means it has an independent L1 instruction cache (16KB) and L1 data cache (16KB). The instruction cache is protected by SECDED ECC per 64 bits. The data cache is protected by SECDED ECC per 32 bits.

#### 6.3.3.2.2 Tightly-Coupled Memories (TCMs)

The R5F has two tightly-coupled memories (TCMs), ATCM and BTCM. The BTCM is further broken down into two interleaved banks, B0TCM and B1TCM.

TCMs are low-latency, tightly integrated memories for the R5F to use. Either TCM can be used for any combination of instruction and/or data. TCM performance is equal to performance on instructions/data that are in cache. However, TCMs have some additional advantages over cache. TCMs can be loaded with instructions that do not cache well (such as ISRs) or preloaded with code by an external source, before that code is needed, to save cache miss time. TCMs are also a good place for blocks of data for intense processing. They can be loaded (or pre-loaded by an external source) before the data is needed, saving cache miss time. The data can then be directly accessed by an external source, instead of needing to do cache evicts.

As mentioned, TCMs can be accessed (either read or written) by an external source over the TCM VBUSM slave interface. This allows instructions or data to be preloaded, or for data to be read out after the R5F has processed it. The VBUSM slave has a lower priority to accessing TCMs than the R5F but care must be taken to keep an external source from reading or writing TCM data that the R5F is working on. This handshaking is external to any of the R5FSS hardware.

TCMs are protected by ECC per 32 bits. For this to work, ECC must be enabled before data is written in to the TCMs (either externally or from the R5F). ECC is enabled via the following R5F system control bits: ACTLR.ATCMPCEN, ACTLR.B0TCMPCEN, and ACTLR.B1TCMPCEN, respectively.

Whether or not the TCMs are enabled is controlled by the ENABLE bit in the corresponding ATCM/BTCM region register. The default (reset) value of this bit is determined by the CPU<sub>n</sub>\_INITRAMA and CPU<sub>n</sub>\_INITRAMB bootstraps, respectively. Both ATCM and BTCM are configured for a size of 32KB in this device. Note that the BTCM size is the total of both B0TCM and B1TCM (16KB each).

If a TCM is not enabled, then it does not appear in the R5F's memory view, but it can be accessed by an external source. If a TCM is enabled, then its place in the R5F memory map is determined by a combination of bootstrap signal and system register. If the CPU<sub>n</sub>\_LOCZRAMA bootstrap signal is high, then the initial base address of ATCM is 0x0000\_0000 and the initial address of BTCM is 20'h41010. If the CPU<sub>n</sub>\_LOCZRAMA bootstrap signal is low, then the initial base address of BTCM is 0x0000\_0000 and the initial base address of ATCM is 20'h41010.

#### Note

This base address of 0x41010 for ATCM/BTCM based on the CPU<sub>n</sub>\_LOCZRAMA bootstrap only affects the R5F's memory view. The SoC will see the ATCM/BTCM based on the TCM slave interface regions, as defined in [Section 6.3.3.2](#). The base address of either TCM may be overwritten via the ATCM or BTCM region register. Care must be taken not to move the base address of a TCM when it may be being accessed.

It is possible to preload a TCM with instructions and boot from it. See [Section 6.3.3.12](#) for details on TCM booting.

### 6.3.3.2.3 R5FSS Special Signals

[Table 6-26](#) through [Table 6-28](#) list some R5FSS features associated with special signals. Note that in lockstep mode only those for CPU0 apply.

**Table 6-26. MCU\_R5FSS0 Special Features**

Feature	Comment
Cluster affinity group ID	R5F cluster 0 (ID = 0x0)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MCU_SEC_MMR register setting. Defaults to Arm mode
Split or lockstep mode 0 = Split mode 1 = Lockstep mode	Controlled via MCU_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU <sub>n</sub> execution halt when coming out of reset (CPU <sub>n</sub> _HALT)	Controlled via MCU_SEC_MMR register setting. Defaults to halted state
CPU <sub>n</sub> exception vectors base address	Controlled via MCU_SEC_MMR register setting. Defaults to ROM address 0x0000_4110_0000
CPU <sub>n</sub> VIM base address	0x40F8_0000
CPU <sub>n</sub> RAT base address	0x40F9_0000
CPU <sub>n</sub> RAT accesses ID	0x2 (CPU0); 0x3 (CPU1)
CPU <sub>n</sub> ATCM enable at reset (CPU <sub>n</sub> _INITRAMA)	Controlled via MCU_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MCU_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MCU_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MCU_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	VBUSM port not used
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_4000_0000 MCU peripheral base address
CPU <sub>n</sub> VBUSP peripheral port size	16MB for MCUSP peripherals (0x0_4000_0000 to 0x0_40FF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	VBUSM port not used
CPU <sub>n</sub> VBUSM normal peripheral port size	VBUSM port not used
CPU <sub>n</sub> VBUSM virtual peripheral port base address	VBUSM port not used
CPU <sub>n</sub> VBUSM virtual peripheral port size	VBUSM port not used
CPU <sub>n</sub> clock stopped indication	Status logged into MCU_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MCU_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MCU_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MCU_SEC_MMR register setting. Defaults to 0

**Table 6-27. R5FSS0 Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 1 (ID = 0x1)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode

**Table 6-27. R5FSS0 Special Features (continued)**

Feature	Comment
Split or lockstep mode 0 = Split mode 1 = Lockstep mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU <sub>n</sub> execution halt when coming out of reset (CPU <sub>n</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>n</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>n</sub> VIM base address	0x0FF8_0000
CPU <sub>n</sub> RAT base address	0x0FF9_0000
CPU <sub>n</sub> RAT accesses ID	0x4 (CPU0); 0x5 (CPU1)
CPU <sub>n</sub> ATCM enable at reset (CPU <sub>n</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_0C00_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_0C00_0000 to 0x0_0FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals
CPU <sub>n</sub> VBUSM normal peripheral port size	16MB for MAIN peripherals (0x0_0200_0000 to 0x0_02FF_FFFF)
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals
CPU <sub>n</sub> VBUSM virtual peripheral port size	16MB for MAIN peripherals (0x0_0200_0000 to 0x0_02FF_FFFF)
CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

**Table 6-28. R5FSS1 Special Features**

Feature	Comment
Cluster affinity group ID	R5F Cluster 2 (ID = 0x2)
Exception handling state at reset 0 = Arm 1 = Thumb	Controlled via MAIN_SEC_MMR register setting. Defaults to Arm mode
Split or lockstep mode 0 = Split mode 1 = Lockstep mode	Controlled via MAIN_SEC_MMR register setting. Defaults to a value defined by eFuse
CPU <sub>n</sub> execution halt when coming out of reset (CPU <sub>n</sub> _HALT)	Controlled via MAIN_SEC_MMR register setting. Defaults to halted state
CPU <sub>n</sub> exception vectors base address	Controlled via MAIN_SEC_MMR register setting. Defaults to Bootvector RAM address 0x0000_0000_0200
CPU <sub>n</sub> VIM base address	0x0FF8_0000
CPU <sub>n</sub> RAT base address	0x0FF9_0000
CPU <sub>n</sub> RAT accesses ID	0x6 (CPU0); 0x7 (CPU1)

**Table 6-28. R5FSS1 Special Features (continued)**

Feature	Comment
CPU <sub>n</sub> ATCM enable at reset (CPU <sub>n</sub> _INITRAMA)	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> BTCM enable at reset (CPU <sub>n</sub> _INITRAMB)	Controlled via MAIN_SEC_MMR register setting. Defaults to enabled state
CPU <sub>n</sub> A/BTCM reset base address indicator (CPU <sub>n</sub> _LOCZRAMA) 0 = B at 0x0 1 = A at 0x0	Controlled via MAIN_SEC_MMR register setting. Defaults to 1
CPU <sub>n</sub> non-maskable fast interrupts enable	Controlled via MAIN_SEC_MMR register setting. Defaults to disabled state
CPU <sub>n</sub> VBUSM peripheral port enabled at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port enable at reset	Enabled
CPU <sub>n</sub> VBUSP peripheral port base address	Mapped to 0x0_0C00_0000 for low latency MAIN peripherals
CPU <sub>n</sub> VBUSP peripheral port size	64MB for MAIN peripherals (0x0_0C00_0000 to 0x0_0FFF_FFFF)
CPU <sub>n</sub> VBUSM normal peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals
CPU <sub>n</sub> VBUSM normal peripheral port size	16MB for MAIN peripherals (0x0_0200_0000 to 0x0_02FF_FFFF)
CPU <sub>n</sub> VBUSM virtual peripheral port base address	Mapped to 0x0200_0000 for MAIN peripherals

CPU <sub>n</sub> clock stopped indication	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFI state	Status logged into MAIN_SEC_MMR register bit
CPU <sub>n</sub> WFE state	Status logged into MAIN_SEC_MMR register bit
CPU clockstop behavior 0: CPU clocks stopped in standby 1: CPU clocks not stopped in standby	Controlled via MAIN_SEC_MMR register setting. Defaults to 0

### 6.3.3.3 R5FSS Interfaces

#### 6.3.3.3.1 Master Interfaces

The R5FSS has several master interfaces per core:

- 64-bit VBUSM master pair (1 read – “RMST”, 1 write – “WMST”) for L3 memory accesses; this is the main memory interface
  - Includes region-based address translation (RAT)
- 32-bit VBUSM master pair (1 read – “PRMST”, 1 write – “PWMST”) for peripheral access
  - Enabled at reset
  - Note: This port is only supported for R5FSS0 and R5FSS1; it is not supported for MCU\_R5FSS0
- 32-bit VBUSP master “PMST” for peripheral access
  - Includes logic that provides the R5F CPU with a private access to VIM and RAT
  - Enabled at reset

#### 6.3.3.3.2 Slave Interfaces

The R5FSS has several slave interfaces that define its internal memory space:

- 32-bit VBUSP configuration slave (per core)
  - Region [0]: ECC aggregator block
  - Region [1]: Lockstep comparator block (CCMR5); this region is only applicable to CORE0
- 64-bit TCM slave (per core)
  - Region [0]: ATCM
  - Region [1]: BTCM
  - Region [2]: Instruction cache RAMs
  - Region [3]: Data cache RAMs
- 32-bit VBUSP debug slave
  - Provides access to all R5FSS internal debug logic

Regions [0] and [1] of the TCM slave interface provide direct access to the TCM RAMs. Access to the RAMs is arbitrated with access from the R5F's L1 memory system. Excessive access while the R5F is also attempting access will degrade performance.

Regions [2] and [3] of the TCM slave interface provide access to the cache RAMs for testing purposes. Access to the cache RAMs can only be done while the caches are disabled and should only be done for test purposes.

In addition to the slave interfaces, there are peripherals (RAT and VIM) that are only accessible by the R5F. The R5F has an access to these modules via the VBUSP peripheral interface.

### 6.3.3.4 R5FSS Power, Clocking and Reset

#### 6.3.3.4.1 R5FSS Power

The following R5FSS power considerations should be noted:

- R5FSS has a single power domain for all its internal logic
- When operating in split mode, CPU0 must be in a higher power/reset state than CPU1.

For more details on R5FSS power management, including power-up and power-down sequences, see [Section 5.2, Power](#).

#### 6.3.3.4.2 R5FSS Clocking

The R5FSS has four clock inputs:

- CPU0\_CLK: This is the clock for CPU0 logic
- CPU1\_CLK: This is the clock for CPU1 logic
- CPU0\_ICLK: This is the clock for CPU0 interfaces
- CPU1\_ICLK: This is the clock for CPU1 interfaces

CPU0\_CLK and CPU1\_CLK are the clocks for all of the internal CPU logic. They are provided separately so that:

- In split mode, CPU1's clock may be turned off, while CPU0 is still in active mode
- In lock mode, they are sourced separately

CPU0\_ICLK and CPU1\_ICLK are the clocks for all of the interfaces for their associated CPU (for example: VBUSM and VBUSP bridges, exception generation, debug and trace logic). They are provided separately so that CPU1\_ICLK can be gated if CPU1 is in a lower power state, while CPU0 is ON, or when in lock mode.

The interface clock is an integer ratio of the CPU clock. The exact ratio for each R5F is provided in [Section 6.3.2](#).

#### 6.3.3.4.2.1 Changing MCU\_R5FSS0 CPU Clock Frequency

For each MCU\_R5FSS0 CPU, the interface clock is an integer ratio of the CPU0 clock. The exact core to interface clock ratio is configured via associated Control Module register:

- CTRLMMR\_MCU\_R5\_CORE0\_CLKSEL for both MCU\_R5FSS0 cores

The interface clock has a fixed frequency, so this register is essentially used to select the CPU clock frequency. Due to some design limitation, the core frequency switch for the MCU\_R5FSS0 may cause clock misalignment. To avoid this clock misalignment, the below software sequence should be implemented by a core other than MCU\_R5FSS0\_CORE0 or MCU\_R5FSS0\_CORE1 when changing the CPU clock frequency:

1. Power down MCU\_R5FSS0
2. Change the core to interface ratio by modifying the associated CTRL\_MMR register
3. Power up MCU\_R5FSS0 and follow the bring up sequence based on split or lockstep mode

Note that the sequence above is a static configuration change and any context in the MCU\_R5FSS0 will be not be preserved. There is no dynamic clock reconfiguration available.

#### 6.3.3.4.3 R5FSS Reset

The R5FSS has four reset inputs:

- CPU0\_RST: This is the reset for the non-debug logic of CPU0

- CPU0\_DBG\_RST: This resets the CPU0 debug logic, excluding the APB interface
- CPU1\_RST: This is the reset for the non-debug logic of CPU1
- CPU1\_DBG\_RST: This resets the CPU1 debug logic, excluding the APB interface

In addition to the reset signals, there are two halt signals:

- CPU0\_HALT
- CPU1\_HALT

These halt signals keep the CPUs from fetching instructions when they come out of reset. The main use is to have the CPUs halted until the TCMs are loaded (when booting from TCM), though halt could be used for any other purpose.

### 6.3.3.5 R5FSS Lockstep Error Detection Logic

When bootstrapped to lockstep mode, there is a logic that compares the outputs of the two cores. Whenever an error is detected, an interrupt is asserted. A logic is also included to test the comparison logic.

In lockstep mode, the logic from CPU1 is used to check CPU0. CPU1's RAMs and L1 memory system are not used. Instead, all inputs to CPU0 are copied, delayed by two cycles, and fed into CPU1's logic. All outputs from CPU0 are copied, delayed by two cycles, and compared to the outputs of CPU1.

The lockstep error detection logic in the R5FSS is implemented via the CPU compare module (CCMR5). The CCMR5 performs two main functions:

- CPU output compare: Compares the core compare bus outputs of the two R5F processor cores in lockstep mode
- Inactivity monitoring: This is to detect any transaction initiated by the diagnostic R5F core (CPU1) in lockstep mode. The diagnostic core is expected *not* to initiate any transaction in lockstep mode

#### 6.3.3.5.1 CPU Output Compare Block

To implement a lockstep CPU cluster, a diagnostic checker block is included. The diagnostic checker block compares the CPU compare outputs on every cycle. A difference in the CPU output signals is indicated by an error signal.

As the CPUs are working with a two-cycle phase difference, there should be no compare errors generated when the CPUs are reset two cycles apart. For the various CPU interfaces, the comparison will start on the first valid transaction on key control signals.

##### 6.3.3.5.1.1 Operating Modes

The CPU compare block can run in one out of four operating modes:

- Compare active block
- Self test
- Error forcing
- Self test error forcing

To select an operating mode for the CPU compare block, a dedicated key must be written to the key register R5FSS\_CCMKEYR1. R5FSS\_CCMSR1 is the status register associated with this block.

Table 6-29 provides details on the operating modes of the CPU compare block.

**Table 6-29. CPU Compare Block Operating Modes**

Mode	Key <sup>(1)</sup>	Self Test Error Signal	Compare Error Signal	CMPE1 <sup>(2)</sup>	STC1 <sup>(3)</sup>	STET1 <sup>(4)</sup>	STE1 <sup>(5)</sup>
Compare block active	0000	Enabled	Enabled	Enabled	Disabled	Disabled	Disabled
Self test	0110	Enabled	Disabled	Disabled	Enabled	Enabled	Enabled
Error forcing	1001	Error	Error	Disabled	Disabled	Disabled	Disabled
Self test error forcing	1111	Error	Enabled	Enabled	Disabled	Disabled	Disabled

(1) R5FSS\_CCMKEYR1[3:0] MKEY1 bit field

- (2) R5FSS\_CCMSR1[16] CMPE1: Compare error flag
- (3) R5FSS\_CCMSR1[8] STC1: Self test complete flag
- (4) R5FSS\_CCMSR1[1] STET1: Self test error type flag
- (5) R5FSS\_CCMSR1[0] STE1: Self test error flag

#### 6.3.3.5.1.2 Compare Block Active Mode

In compare block active mode, the output signals of both CPUs are compared, and any difference in the outputs is indicated by the compare error signal (CPU\_BUS\_CMP\_ERR\_INT). Additionally, as indicated in [Table 6-29](#), the self test error signal (SELFTEST\_ERR\_INT) is also asserted.

---

#### Note

The self test error signal is shared by both the CCMR5's CPU compare and inactivity monitor blocks.

---

#### Note

Not all flops inside the R5F CPU(s) are initialized at reset. To avoid an erroneous CCMR5 compare error, the application software needs to ensure that the CPU registers of both CPUs are initialized with the same values before the registers are used. This is to ensure that the programmer's model CPU registers of both CPU are initialized properly.

---

#### 6.3.3.5.1.3 Self Test Mode

In self test mode, the CCMR5 compare block is checked for faults by applying internally generated series of test patterns. During self test, the core compare disabled signal is deactivated. If a fault on the CCMR5 module gets detected, a self test error is generated.

When self test mode is entered, the CCMR5 module will generate predetermined test patterns to look for any hardware faults inside it. If a fault is detected, then a self test error flag (STE1) is set, a self test error signal is asserted, and the self test is terminated immediately after entering compare mismatch mode. If no fault is found during self test, the self test complete flag (STC1) will be set. The user needs to poll the R5FSS\_CCMSR1 status register to find out the self test status. In both cases – self test terminated and self test completed – the CCMR5 will remain in self test mode and will be idle, and therefore the R5FSS\_CCMKEYR1 key register will show the self test key until the mode is switched by writing another key to this register. During the self test operation, the compare error signal output is inactive, irrespective of the compare result. When switched out of self test mode, the core compare disabled signal is de-asserted.

There are two types of patterns generated by CCMR5 during self test mode: compare match test, and compare mismatch test. The CCMR5 first generates compare match test patterns followed by compare mismatch test patterns. During self test, each test pattern is applied on CPU output signal ports of the CCMR5's compare block and clocked for one cycle.

Self test of CPU output compare logic is done with respect to CPU clock. As mentioned, self test error is indicated by the SELFTEST\_ERR\_INT signal. Whether the self test failed during compare match test or compare mismatch test is indicated by the self test error type flag (STET1) in the R5FSS\_CCMSR1 status register. When the block's self test is completed, the corresponding self test complete flag (STC1) is set.

---

#### Note

During self test, both CPUs can execute normally, but the compare logic will not be checking any CPU signals. Also, during self test, only the compare unit logic is tested. The self test is not interruptible.

---

#### 6.3.3.5.1.4 Compare Match Test

During compare match test, there are four different test patterns generated to stimulate the hardware. An identical vector is applied to both input ports (CPU0 and CPU1 output signals, which are inputs to the CCMR5 block) at the same time expecting a compare match. These patterns cause the self test logic to exercise every CPU output signal. This test can be independently enabled by programming the CCMR5 registers. If the compare unit produces a compare mismatch then the self test error flag is set and the self test error signal is

generated. If an error is detected during compare match, then CCMR5 enters compare mismatch mode before terminating the test.

The four test patterns are:

- All 0's on both CPUs
- All 1's on both CPUs
- 0xA's on both CPUs
- 0x5's on both CPUs

These four test patterns will take four clock cycles to complete.

Table 6-30 illustrates the compare match test sequence. The core compare disabled signal is asserted on entry and de-asserted when complete.

**Table 6-30. Compare Match Test Sequence**

CPU0 Signal Position									CPU1 Signal Position									Cycle
n:8	7	6	5	4	3	2	1	0	n:8	7	6	5	4	3	2	1	0	
0x5	0	1	0	1	0	1	0	1	0x5	0	1	0	1	0	1	0	1	0
0xA	1	0	1	0	1	0	1	0	0xA	1	0	1	0	1	0	1	0	1
0's	0	0	0	0	0	0	0	0	0's	0	0	0	0	0	0	0	0	2
1's	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	1	1	3

#### 6.3.3.5.1.5 Compare Mismatch Test

In compare mismatch test, the number of test patterns is equal to two times the number of CPU output signals to compare in compare mode active. The core compare disabled signal is asserted on entry and de-asserted when complete. An 'all-ones' vector is applied to the CCMR5's CPU0 input port and the same pattern is also applied to the CCMR5's CPU1 input port but with one bit flipped starting from signal position 0. The un-equal vector should cause the CCMR5 module to expect a compare mismatch at signal position 0. Note that a mismatch is an expected good result, while a match will indicate hardware fault. When a fault is detected, which means that a compare match is produced by the compare logic, the self test error flag is set and the self test error signal is asserted.

The above compare mismatch test algorithm repeats itself again in a domino fashion with next signal position flipped, while forcing all other signals to logic level '1'. This process is repeated until every single signal position is verified on both CPU signal ports.

The compare mismatch test is terminated if a compare match is detected and the module becomes idle. The compare mismatch test ensures that the compare unit is able to detect a mismatch on every CPU signal being compared.

Table 6-31 illustrates the compare mismatch test sequence.

**Table 6-31. Compare Mismatch Test Sequence**

CPU0 Signal Position										CPU1 Signal Position										Cycle
n	...	7	6	5	4	3	2	1	0	n	...	7	6	5	4	3	2	1	0	
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	1	0	0
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	0	1	1
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	0	1	1	2
1	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	0	1	1	1	3
...																				
1	1's	1	1	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1	1	n-1
1	1's	1	1	1	1	1	1	1	1	0	1's	1	1	1	1	1	1	1	1	n
1	1's	1	1	1	1	1	1	1	0	1	1's	1	1	1	1	1	1	1	1	n+1
1	1's	1	1	1	1	1	1	0	1	1	1's	1	1	1	1	1	1	1	1	n+2

**Table 6-31. Compare Mismatch Test Sequence (continued)**

CPU0 Signal Position										CPU1 Signal Position										Cycle
n	...	7	6	5	4	3	2	1	0	n	...	7	6	5	4	3	2	1	0	
1	1's	1	1	1	1	1	0	1	1	1	1's	1	1	1	1	1	1	1	1	n+3
1	1's	1	1	1	1	0	1	1	1	1	1's	1	1	1	1	1	1	1	1	n+4
...																				
0	1's	1	1	1	1	1	1	1	1	1	1's	1	1	1	1	1	1	1	1	2n

#### 6.3.3.5.1.6 Error Forcing Mode

In error forcing mode, a test pattern is applied to the CPU related inputs of the compare logic to force an error at the compare error signal of the compare unit. The core compare disabled signal is asserted on entry and de-asserted when complete.

This mode is enabled by writing the dedicated key in the R5FSS\_CCMKEYR1 key register (see [Table 6-29](#)). The error signal is generated by asserting the CPU\_BUS\_CMP\_ERR\_INT signal.

Error forcing mode is similar to the compare mismatch test operation of self test mode, in which an un-equal vector is injected into the CCMR5 CPU signal ports. Instead of setting a self test error flag and asserting self test error signal, the error forcing mode forces the compare mismatch to set the compare error flag (CMPE1) and assert the compare error signal.

Only one hardcoded test pattern is applied into CCMR5 during error forcing mode. A repeated 0x5 pattern is applied to CPU0 signal port, while a repeated 0xA pattern is applied to the CPU1 signal port. The error forcing mode takes one cycle to complete. Hence, the failing signature is presented for one clock cycle and the mode is automatically switched to lockstep mode and the R5FSS\_CCMKEYR1 key register will show the lockstep key (0000). During this cycle the CPUs are not compared. The user should expect to receive the error signal from CCMR5 module once the error forcing mode is entered. If no error signal is set, then a hardware fault is present.

#### 6.3.3.5.1.7 Self Test Error Forcing Mode

In self test error forcing mode, an error is forced at the self test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle. The core compare disabled signal is asserted on entry and de-asserted when complete.

#### 6.3.3.5.2 Inactivity Monitor Block

Another function of the CCMR5 module is to monitor the inputs of bus matrix coming from the diagnostic R5F core (CPU1) in lockstep mode, to detect any transaction initiated by diagnostic core. Output signals from the diagnostic core, which indicate a valid transaction on a master interface, are compared against their clamped values. If any signal value is different from its clamped value, an error signal is generated.

[Table 6-32](#) shows the R5F diagnostic core output signals, which are being monitored to detect any activity in the processor bus.

**Table 6-32. Inactivity Monitor Block Signals**

Signal Name	Interface	Description	Clamp Value
AWVALIDM1	L2 AXI Master	Indicates write address and control are valid	0
ARVALIDM1	L2 AXI Master	Indicates read address and control are valid	0
AWVALIDP1	AXI PP <sup>(1)</sup>	Indicates write address and control are valid	0
ARVALIDP1	AXI PP <sup>(1)</sup>	Indicates read address and control are valid	0
HTRANSP1[1:0]	AHB PP	Indicates the type of transfer – idle (00), busy (01), non-sequential (10), sequential (11)	0
BVALIDS1	AXI Slave	Indicates valid write response is available	0
RVALIDS1	AXI Slave	Indicates Read Data Channel Address and Control are valid	0
ATCEN01	ATCM	Enable for ATCM lower word	0
ATCEN11	ATCM	Enable for ATCM upper word	0

**Table 6-32. Inactivity Monitor Block Signals (continued)**

Signal Name	Interface	Description	Clamp Value
B0TCEN01	B0TCM	Enable for B0TCM lower word	0
B0TCEN11	B0TCM	Enable for B0TCM upper word	0
B1TCEN01	B1TCM	Enable for B1TCM lower word	0
B1TCEN11	B1TCM	Enable for B1TCM upper word	0

(1) Not supported for MCU\_R5FSS0

More details on these signals can be found in the *Arm Cortex-R5 Technical Reference Manual*.

The error response in case of a detected transaction is indicated by the INACTIVITY\_ERR\_INT signal.

#### 6.3.3.5.2.1 Operating Modes

The inactivity monitor block can run in one out of four operating modes:

- Compare active block
- Self test
- Error forcing
- Self test error forcing

To select an operating mode for the inactivity monitor block, a dedicated key must be written to the key register R5FSS\_CCMKEYR3. R5FSS\_CCMSR3 is the status register associated with this block.

Table 6-33 provides details on the operating modes of the inactivity monitor block.

**Table 6-33. Inactivity Monitor Block Operating Modes**

Mode	Key <sup>(1)</sup>	Self Test Error Signal	Compare Error Signal <sup>(2)</sup>	CMPE3 <sup>(3)</sup>	STC3 <sup>(4)</sup>	STET3 <sup>(5)</sup>	STE3 <sup>(6)</sup>
Compare block active	0000	Enabled	Enabled	Enabled	Disabled	Disabled	Disabled
Self test	0110	Enabled	Disabled	Disabled	Enabled	Enabled	Enabled
Error forcing	1001	Error	Error	Disabled	Disabled	Disabled	Disabled
Self test error forcing	1111	Error	Enabled	Enabled	Disabled	Disabled	Disabled

(1) CCMKEYR3[3:0] MKEY3 bit field

(2) Corresponds to bus monitor error signal for inactivity monitoring

(3) CCMSR3[16] CMPE3: Compare error (bus monitor error) flag

(4) CCMSR3[8] STC3: Self test complete flag

(5) CCMSR3[1] STET3: Self test error type flag

(6) CCMSR3[0] STE3: Self test error flag

#### 6.3.3.5.2.2 Compare Block Active Mode

In compare block active mode, the output signals of CPU1 (after clamping) are compared against their clamped values, and a mismatch is indicated by the bus monitor error signal. Additionally, as indicated in Table 6-33, the self test error signal is also asserted.

#### Note

The self test error signal is shared by both the CCMR5's CPU compare and inactivity monitor blocks.

#### 6.3.3.5.2.3 Self Test Mode

Inactivity monitor has a self test feature and self test is done by applying a predetermined set of internally generated test patterns on the Inactivity Monitor inputs. For the fault detection, the comparison is done against the clamped values. The generated patterns are same as output compare block test patterns, but they are applied on every HCLK cycles. Any fault detected is indicated by the self test error signal. If no fault is found during self test, the self test complete flag (STC3) will be set. The user needs to poll the R5FSS\_CCMSR3 status register to find out the self test status. In both cases – self test terminated and self test completed

– inactivity monitor will remain in self test mode and will be idle, and therefore the R5FSS\_CCMKEYR3 key register will show the self test key until the mode is switched by writing another key to this register.

### Note

Bus monitor error is disabled during self test mode.

Two types of test patterns are applied for inactivity monitor self test:

- Compare match pattern
- Compare mismatch pattern

Self test takes 16 cycles to complete. Self test error is indicated by the SELFTEST\_ERR\_INT signal. Whether the self test failed during compare match test or compare mismatch test is indicated by the self test error type flag (STET3) in the R5FSS\_CCMSR3 status register. When the block's self test is completed, the corresponding self test complete flag (STC3) is set.

#### 6.3.3.5.2.4 Compare Match Test

In compare match test, patterns are applied such that no compare error is generated. Because the comparison is done against the clamped values, and all compared signals are clamped to zero, only one test pattern is applicable for compare match test. A pattern of 'all-zeros' is applied for compare match test. If a compare mismatch is found, then self test error flag (STE3) is set and self test error is asserted. If an error is detected during compare match, then CCMR5 enters compare mismatch mode before terminating the test. If no mismatch is found, compare mismatch test is done next.

#### 6.3.3.5.2.5 Compare Mismatch Test

In compare mismatch test, a series of un-equal test patterns are applied on inactivity monitor inputs. Un-equal vectors are expected to generate a compare mismatch and a compare match indicates a fault. If a compare match is found, self test error flag is set and a self test error is indicated. Self test is terminated as well. If all patterns are generating mismatch, self test complete flag (STC3) is set.

Table 6-34 shows the patterns used for compare mismatch test.

**Table 6-34. Inactivity Monitor Compare Mismatch Patterns**

Inactivity Monitor Compare Mismatch Patterns												Cycle
11	10	9	8	7	6	5	4	3	2	1	0	
0	0	0	0	0	0	0	0	0	0	0	1	0
0	0	0	0	0	0	0	0	0	0	1	0	1
0	0	0	0	0	0	0	0	0	1	0	0	2
0	0	0	0	0	0	0	0	1	0	0	0	3
0	0	0	0	0	0	0	1	0	0	0	0	4
0	0	0	0	0	0	1	0	0	0	0	0	5
0	0	0	0	0	1	0	0	0	0	0	0	6
0	0	0	0	1	0	0	0	0	0	0	0	7
0	0	0	1	0	0	0	0	0	0	0	0	8
0	0	1	0	0	0	0	0	0	0	0	0	9
0	1	0	0	0	0	0	0	0	0	0	0	10
1	0	0	0	0	0	0	0	0	0	0	0	11

#### 6.3.3.5.2.6 Error Forcing Mode

In error forcing mode, a test pattern is applied to inactivity monitor inputs of the compare logic to force an error at the compare error signal of the compare unit. Only one hardcoded test pattern of 'all-ones' is applied into CCMR5 during error forcing mode. The error forcing mode takes one cycle to complete. Hence, the failing

signature is presented for one clock cycle and the mode is automatically switched to lockstep mode and the R5FSS\_CCMKEYR3 key register will show the lockstep key (0000). During this cycle the bus monitoring is disabled.

#### 6.3.3.5.2.7 Self Test Error Forcing Mode

In self test error forcing mode, an error is forced at the self test error signal. The compare unit is still running in lockstep mode and the key is switched to lockstep after one clock cycle.

#### 6.3.3.5.3 Polarity Inversion Logic

As already mentioned, there is logic (implemented via XOR) to test the comparison logic itself. The CCMR5 block can be configured to be in self test to check the integrity of the final XOR error generation logic, and can be switched back to functional compare mode after self test completion. To ensure that switching back to functional mode has happened, user can program CCMR5 polarity control register (R5FSS\_CCMPOLCNTRL) to invert the polarity of eight CPU output signals, which will cause an error generation (CCM\_STAT\_ERR\_INT). The eight signals that are chosen to be able to control the polarity are: AWWALIDMm, RVALIDSm, ATCEN0m, BOTCEN0m, BITCWEm, IRQACKm, AWWALIDPm, HWRITEP. See the *Arm Cortex-R5 Technical Reference Manual* for details on these signals.

The XOR inversion is placed between the two back-to-back delay flops of CPU1 outputs. Note that the XOR inversion logic is a diagnostic feature. If user does not observe CCM\_STAT\_ERR\_INT error generation after programming the CCMPOLCNTRL[7:0] POL\_INV inversion bits, this means that:

1. All eight signals of the inversion logics (XOR) are faulty and CCM\_STAT\_ERR\_INT is not asserted. This is a very difficult case to hit but theoretically it could happen if a hard fault gets accumulated over times on these polarity inversion XOR gates; OR
2. The CCMR5 block has not switched back to functional mode yet

User can perform self test again to identify whether the issue is #1 or #2. If the second self test passes that means the issue is #1.

### 6.3.3.6 R5FSS Vectored Interrupt Manager (VIM)

#### 6.3.3.6.1 VIM Overview

The VIM aggregates device interrupts and sends them to the R5F CPU(s). It can be used in either split or lockstep configuration. In split, it has two independent interrupt cores, one per CPU. In lockstep, CPU1 acts as a diagnostic on CPU0; only CPU0's outputs are used but all outputs are compared to CPU1 to provide diagnostic coverage.

The VIM module supports the following features:

- 512 interrupt inputs per R5F core
- Each interrupt has its own 4-bit programmable priority
  - Defined via the R5FSS\_VIM\_PRI\_INT\_j register
  - The VIM provides support for priority interruption of interrupts
- Each interrupt has its own enable mask
  - Interrupt enable is done via the R5FSS\_VIM\_INTR\_EN\_SET\_j register
  - Interrupt disable is done via the R5FSS\_VIM\_INTR\_EN\_CLR\_j register
- Each interrupt can be programmed as either an IRQ or FIQ
  - Defined via the R5FSS\_VIM\_INTMAP\_j register
- Each interrupt has its own programmable 32-bit vector address associated with it
  - Defined via the R5FSS\_VIM\_VEC\_INT\_j register
  - Protected with SECDDED
- One IRQn and one FIQn output per core
- Vectored interrupt interface
  - Compatible with R5F VIC port
- Default vector provided when a double-bit error is detected
- Split or lockstep capable

- In lockstep mode, only interrupts connected to VIM interrupt core 0 are available
- Software interrupt generation

### 6.3.3.6.2 VIM Interrupt Inputs

The VIM supports 512 interrupt inputs per core. Each interrupt can be either a level or a pulse (both active-high). The interrupt mapping for the two R5F cores can be found in [Section 9.4, Interrupt Sources](#).

### 6.3.3.6.3 VIM Interrupt Outputs

The VIM has two interrupt outputs per core:

- **CoreN\_IRQn**: This is a normal interrupt for core *N* (active-low level). It can be serviced via the VIC interface or through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an IRQ (via the R5FSS\_VIM\_INTMAP\_j register) and is enabled (via the R5FSS\_VIM\_INTR\_EN\_SET\_j register), then it will cause an IRQ to assert
- **CoreN\_FIQn**: This is a fast (or non-maskable) interrupt for core *N* (active-low level). FIQs always have priority over IRQs. An FIQ can be serviced through the MMR interface. Whenever an interrupt input goes high, if that interrupt is mapped as an FIQ and is enabled, then it will cause an FIQ to assert

### 6.3.3.6.4 VIM Interrupt Vector Table (VIM RAM)

For each VIM interrupt core, there is an associated interrupt vector table (VIM RAM) that is used to store the address of ISRs. During register vectored interrupt and hardware vectored interrupt, VIM accesses the interrupt vector table using the vector value to fetch the address of the corresponding ISR. Note that both interrupt vector tables are identical in their memory organization.

The VIM RAM is basically comprised of a set of interrupt vector registers (R5FSS\_VIM\_VEC\_INT\_j). Hence, the interrupt vector table is organized in 512 words of 30 bits, with a base address corresponding to the physical address of the first register in the group.

#### Note

The lower two bits of the 32-bit interrupt vector are always 0s.

[Figure 6-8](#) shows the VIM RAM interrupt vector map.

VIM RAM Address Space	VIM RAM Entries
Base Address + 0h	Interrupt 0 Vector
Base Address + 4h	Interrupt 1 Vector
Base Address + 8h	Interrupt 2 Vector
Base Address + 7F8h	Interrupt 510 Vector
Base Address + 7FCh	Interrupt 511 Vector

**Figure 6-8. VIM RAM Interrupt Vector Map**

The interrupt vector table has protection by ECC to indicate corruption due to soft errors. The ECC logic inside VIM supports SECDED. See [Table 6-35](#) for the VIM RAM ID in the ECC aggregator map.

#### 6.3.3.6.5 VIM Interrupt Prioritization

The VIM supports the interruption of the currently active interrupt by one with a higher priority. FIQs and IRQs are completely separate but both use the same mechanism.

When an interrupt goes from pending to active (FIQ: reading the R5FSS\_VIM\_FIQVEC register; IRQ: reading the R5FSS\_VIM\_IRQVEC register, or the *coreN\_IRQACK* going high), then the interrupt is loaded into the corresponding active register (R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ), and all interrupts of an equal or lesser priority are masked (discarded). If prior to this interrupt being cleared (by writing to the R5FSS\_VIM\_FIQVEC register, or R5FSS\_VIM\_IRQVEC register) another interrupt of higher priority arrives, then the FIQn/IRQn will be asserted and that interrupt made pending as normal. If the CPU switches this interrupt to active (by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register), then the currently active interrupt will be pushed onto a stack. When an interrupt is cleared by reading the R5FSS\_VIM\_FIQVEC / R5FSS\_VIM\_IRQVEC register, if there are any interrupts on the stack, the first entry is popped off and put back into the R5FSS\_VIM\_ACTFIQ / R5FSS\_VIM\_ACTIRQ register, so that software may continue where it left off.

#### 6.3.3.6.6 VIM ECC Support

The memory that holds the interrupt vector for each interrupt is protected by SECDED ECC. Single-bit errors are corrected and written back. Double-bit errors are not corrected. If a double-bit error occurs while trying to load a vector, then the R5FSS\_VIM\_DEDVEC register is used to provide the default vector for the *coreN\_IRQADDRV* signal, the R5FSS\_VIM\_IRQVEC register, and the R5FSS\_VIM\_FIQVEC register. The R5FSS\_VIM\_DEDVEC should point to an ISR that handles the fact that there was an uncorrectable error in the interrupt handling.

Some possible remediating actions would be to:

1. Reconstruct the vector table and re-start the application
  - a. Potentially switch to a completely software interrupt handler in the mean time
2. Restart the application from scratch
3. Reset the device
4. Sit in a loop (or WFI) while something external (for example, the ESM) responds to the DED interrupt that will be generated

It is up to the user and the application to determine the appropriate action.

---

#### Note

An interrupt that has an uncorrectable vector error (and thus uses the DED vector) will still have the priority of the original interrupt. This makes it possible for a higher priority interrupt to supersede the handling of the error.

Control and reporting are done by the R5FSS ECC aggregator.

---

#### 6.3.3.6.7 VIM Lockstep Mode

In lockstep mode, CPU1 is used as a diagnostic for CPU0. In this mode, only the interrupt inputs for CPU0 are used. Besides to CPU0, these interrupt inputs are also internally routed to CPU1 (through the level-sync / edge-detect logic dedicated to CPU1, and additionally through some delay circuits). The outputs from both VIM interrupt cores are then sent to the R5FSS CCMR5 module through dedicated compare buses (with CPU0's outputs delayed). The CCMR5 module is responsible for comparing the two sets of output signals and for reporting any mismatches by generating an interrupt (VIM\_BUS\_CMP\_ERR\_INT).

---

#### Note

In lockstep mode, only the RAM dedicated to CPU0 is used, so software *must not* do anything with the ECC interface on the RAM dedicated to CPU1.

---

### 6.3.3.6.8 VIM IDLE State

The VIM will indicate IDLE when there are no pending unmasked interrupts or MMR accesses. The VIM does not have a clock stop interface.

### 6.3.3.6.9 VIM Interrupt Handling

There are multiple ways to service an interrupt depending on how much of the hardware assistance offered by the VIM the software wants to take advantage of.

For IRQs, it is recommended to use the procedure in [Section 6.3.3.6.9.1](#), but the procedures in [Section 6.3.3.6.9.2](#) or [Section 6.3.3.6.9.3](#) (if a user wants to implement a fully software prioritization scheme) may be used as alternatives.

For FIQs, it is recommended to use the procedure in [Section 6.3.3.6.9.4](#), but the procedure in [Section 6.3.3.6.9.5](#) may be used as an alternative.

---

#### Note

These descriptions do not include steps such as stack pushes and state retention that software must take in order to return from the ISR. It is assumed that the programmer is aware of these steps.

---

#### 6.3.3.6.9.1 Servicing IRQ Through Vector Interface

If the associated CPU has the vector (VIC) interface enabled, then the following method is used for servicing IRQs:

1. Hardware handshake
  - a. CPU asserts *coreN\_IRQACK* high
  - b. VIM asserts *coreN\_IRQADDRV* to indicate that the *coreN\_IRQADDR* bus is stable with the correct vector address
  - c. CPU reads *coreN\_IRQADDR*, jumps to that address, and de-asserts *coreN\_IRQACK* low
  - d. VIM de-asserts *coreN\_IRQn* and *coreN\_IRQADDRV*, VIM masks (discards) all IRQs with the same or lower priority
  - e. VIM loads the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field (which corresponds to the vector address) into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, which causes the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register
    - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_IRQSTS\_j register, or R5FSS\_VIM\_STS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 6.3.3.6.9.2 Servicing IRQ Through MMR Interface

When an IRQ interrupt is received, the CPU should follow these steps if not using the vector interface:

1. Read the R5FSS\_VIM\_IRQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_IRQn* output. If another interrupt of a higher priority becomes available, the *coreN\_IRQn* will re-assert, allowing priority interruption of an interrupt
  - b. Reading this register will cause the value from the R5FSS\_VIM\_PRIIRQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTIRQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTIRQ[31] VALID bit to be set
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
4. Write any value to the R5FSS\_VIM\_IRQVEC register
  - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
  - b. This will also clear the R5FSS\_VIM\_ACTIRQ[31] VALID bit

#### 6.3.3.6.9.3 Servicing IRQ Through MMR Interface (Alternative)

If a user does not want to use the R5FSS\_VIM\_IRQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_IRQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_PRIIRQ register to determine which interrupt is the highest priority IRQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_IRQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_IRQSTS\_j register and use a software prioritization scheme to determine which IRQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_IRQSTS\_j register

#### 6.3.3.6.9.4 Servicing FIQ

When an FIQ interrupt is received, the CPU should follow these steps:

1. Read the R5FSS\_VIM\_FIQVEC register and jump to that address to service the ISR
  - a. Reading this register will mask (discard) all interrupts of an equal or lower priority and de-assert the *coreN\_FIQn* output. If another interrupt of a higher priority becomes available, the *coreN\_FIQn* will re-assert, allowing priority interruption of an interrupt.

- b. Reading this register will cause the value from the R5FSS\_VIM\_PRIFIQ[9:0] NUM bit field to be loaded into the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field, and the R5FSS\_VIM\_ACTFIQ[31] VALID bit to be set
  2. Service the interrupt
  3. Depending on whether the original source of the interrupt was a pulse or a level (determined by reading the R5FSS\_VIM\_ACTFIQ[9:0] NUM bit field to determine number, and reading the appropriate bit in the R5FSS\_VIM\_INTTYPE\_j register to determine type)
    - a. Pulse
      - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
      - ii. Clear the interrupt at the source. This way, the source can generate another pulse, if it needs to, and the VIM will process this as a new interrupt
    - b. Level
      - i. Clear the interrupt at the source
      - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register. This way, the level should be gone at the input to the VIM, it will avoid falsely re-calling the interrupt. If the source maintains the level, then it means there is another interrupt
  4. Write any value to the R5FSS\_VIM\_FIQVEC register
    - a. This will clear the priority mask and will cause all interrupts to be re-evaluated for the new highest priority interrupt
    - b. This will also clear the R5FSS\_VIM\_ACTFIQ[31] VALID bit

#### 6.3.3.6.9.5 Servicing FIQ (Alternative)

If a user does not want to use the R5FSS\_VIM\_FIQVEC register, the VIM may be used as a more traditional interrupt controller. Note that in this mode, there is no hardware priority masking (because the R5FSS\_VIM\_FIQVEC register is never read). Software would be responsible for doing all priority operations.

1. Determine which interrupt to service
  - a. Read the R5FSS\_VIM\_PRIFIQ register to determine which interrupt is the highest priority FIQ currently asserted, OR
  - b. Optionally read the R5FSS\_VIM\_FIQGSTS register to determine which groups have IRQs pending, then read the R5FSS\_VIM\_FIQSTS\_j register and use a software prioritization scheme to determine which FIQ to service
2. Service the interrupt
3. Depending on whether the original source of the interrupt was a pulse or a level
  - a. Pulse
    - i. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register
    - ii. Clear the interrupt at the source.
  - b. Level
    - i. Clear the interrupt at the source
    - ii. Clear the status by writing a '1' to the appropriate bit in the R5FSS\_VIM\_STS\_j register, or R5FSS\_VIM\_FIQSTS\_j register.

#### 6.3.3.7 R5FSS Region Address Translation (RAT)

The R5F is a 32-bit processor, which means it can only access 4GB of directly addressable memory. The R5FSS includes a region-based address translation (RAT) unit per core, which allows the R5F to access higher address ranges. The R5FSS RAT module translates a 32-bit input address into a 48-bit output address. It supports 16 regions. For more details on RAT functionality, refer to [Section 8.4, Region-based Address Translation \(RAT\) Module](#).

### 6.3.3.8 R5FSS ECC Support

The R5F provides native ECC and parity support on all related memories, generating and checking the redundancy automatically. The methods for checking and reporting errors are available in the *Arm Cortex-R5 Technical Reference Manual*.

The R5FSS adds the capability of testing this logic by allowing errors (single and double bit) to be injected into memories (for testing purposes) via an ECC aggregator (per core). Note that because the R5FSS ECC aggregator is only used in error-injection mode, it only supports a subset of the generic ECC aggregator functionality in the device.

For a detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of R5FSS CPU0 and CPU1 ECC aggregators, see *R5FSS\_CPU0\_ECC\_AGGR\_CFG\_REGS Registers* and *R5FSS\_CPU1\_ECC\_AGGR\_CFG\_REGS Registers*, respectively.

[Table 6-35](#) provides the RAM ID for each core. This is needed for bit field [10-0] ECC\_VECTOR in the corresponding R5FSS\_CPU0\_VECTOR / R5FSS\_CPU1\_VECTOR register (part of the ECC aggregator register space).

**Table 6-35. RAM ID Map for ECC Aggregator (Per Core)**

RAM ID	Memory Name
0	CPU0/1 ITAG RAM0
1	CPU0/1 ITAG RAM1
2	CPU0/1 ITAG RAM2
3	CPU0/1 ITAG RAM3

### 6.3.3.9 R5FSS Memory View

The memory view of each R5F (that is, the memory map as seen by each R5F) is a function of several things:

- Exception vector bootstrap: The R5F exception table (including boot vector) is always 32 bytes at address 0x00000000 as seen by the R5F. If not booting from a TCM, then boot is done over the main memory interface. The exception vector bootstrap is under software control, which allows these 32 bytes at address 0x00000000 to be remapped somewhere else in the SoC memory map.
- TCM locations: TCMs can be enabled or disabled and located at different places in the memory map, depending on bootstrap configuration. For more details, see [Table 6-26](#), and [Section 6.3.3.2.2](#).
- Peripheral interface locations: The R5F natively supports three interfaces for peripheral access. Each can be enabled/disabled and located based on bootstrap configuration. Note that the VBUSP peripheral interface must be enabled in order to use RAT and VIM.
- RAT base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- VIM base address: This is determined by a bootstrap. This address is located within the VBUSP peripheral interface address space.
- RAT programming: The RAT can take regions of memory accessible by the main memory interface and map them to different addresses.

The combination of the above determines what the R5F sees where in the memory map, and over what interface different transactions come out. Every transaction that does not directly address a TCM or a peripheral interface comes over the main memory interface. Transactions on the main memory interface can be further remapped with the RAT.

See [Chapter 2, Memory Map](#), for the complete R5F memory view for this device.

### 6.3.3.10 R5FSS Interrupts

Interrupt outputs: FPIXcm, FPUFCm, FPOFCm, FPDZCm, FPIDCm, and FPIOCm from R5F are not connected. Consequently, the only way to check the status of the cumulative exception status flags is by reading the FPSCR register.

### 6.3.3.11 R5FSS Debug and Trace

The R5FSS supports standard Arm CoreSight debug and trace architecture. For more details, see the *On-chip Debug* chapter.

### 6.3.3.12 R5FSS Boot Options

There are two methods of booting the R5F, or rather, two methods of placing the exception vectors (of which the boot vector is one).

The first method is to have the exception vectors external to the R5F. The user can place the exception vectors at the address indicated by the exception vector bootstrap and then program the boot vector there. When the processor exits reset, it will fetch the boot vector from this location.

The second method is to boot from a TCM. To do this, software should take the following steps:

1. Assert the correct bootstraps
  - a. To boot from ATCM, set CPUUn\_INITRAMA (or CPUUn\_INITRAMB to boot from BTCM)
  - b. Assert CPUUn\_LOCZRAMA properly for the desired TCM
2. Assert CPUUn\_HALT
3. Release the CPU from reset
4. Load the desired code into the TCM via the TCM slave port
  - a. Exception vectors should be located at address 0x00000000 of the TCM
5. De-assert CPUUn\_HALT

## 6.4 C66x DSP Subsystem

This section describes the C66x Digital Signal Processor Subsystem (C66SS) in the device.

### Note

The purpose of this chapter is to provide a basic overview of the C66x DSP and to specify its SoC integration. For full functional description of C66x DSP, refer to the documents listed in [Section 6.4.4](#).

### 6.4.1 C66SS Overview

The C66x subsystem is based on the TI's standard TMS320C66x DSP CorePac module. It includes subsystem logic to ease the C66x CorePac integration into the SoC, while maximizing software reuse from previous devices.

The C66x DSP extends the performance of the C64x+ and C674x DSPs through enhancements and new features. Many of the new features target increased performance for vector processing. The C64x+ and C674x DSPs support 2-way SIMD operations for 16-bit data and 4-way SIMD operations for 8-bit data. On C66x DSP, the vector processing capability is improved by extending the width of the SIMD instructions.

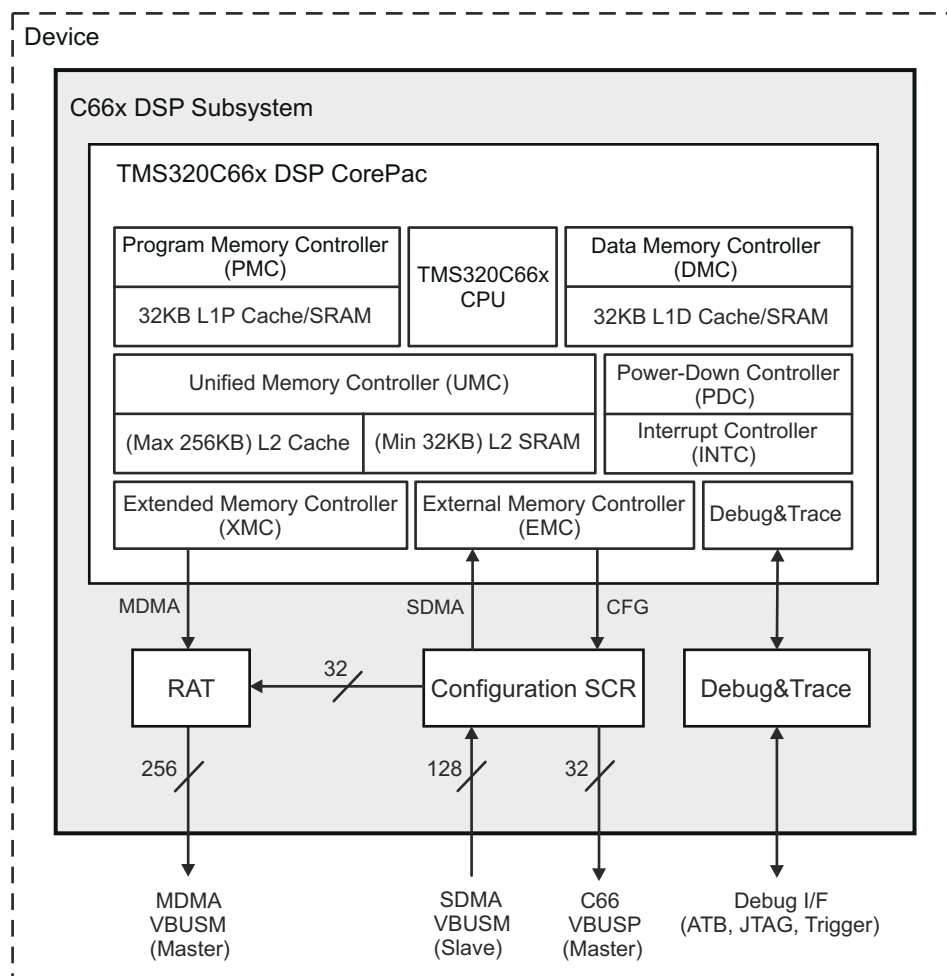

The C66x DSP can execute instructions that operate on 128-bit vectors. For example, the QMPY32 instruction is able to perform the element-to-element multiplication between two vectors of four 32-bit data each. The C66x DSP also supports SIMD for floating-point operations. Improved vector processing capability (each instruction can process multiple data in parallel) combined with the natural instruction level parallelism of C6000 architecture (for example, execution of up to eight instructions per cycle) results in a very high level of parallelism that can be exploited by DSP programmers through the use of TI's optimized C/C++ compiler.

There are two functionally identical C66SS modules in the device. [Table 6-36](#) shows C66SS modules allocation within device domains.

**Table 6-36. C66SS Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
C66SS0	–	–	✓
C66SS1	–	–	✓

[Figure 6-9](#) shows an overview of the C66SS.

**Figure 6-9. C66SS Overview**

## 6.4.2 C66SS Features

The C66SS supports the following features:

- Fixed/Floating-point C66x CPU based on a superset of the C64x+ and C67x+ ISA
- Program memory controller (PMC):
  - 32KB L1 program memory (L1P), configurable as cache and/or SRAM
  - When configured as a cache, L1P is a direct-mapped cache with a 32-byte cache line
  - L1P page size is 2KB
  - L1P memory controller provides bandwidth management, memory protection, and power-down functions

### Note

The C66x L1P SRAM option is disabled (not supported) in this device. Hence, C66x L1P is always configured as full cache.

- Data memory controller (DMC):
  - 32KB L1 data memory (L1D), configurable as cache and/or SRAM
  - When configured as a cache, L1D is a 2-way set-associative cache with a 64-byte cache line
  - L1D page size is 2KB
  - L1D memory controller provides bandwidth management, memory protection, and power-down functions
- Unified memory controller (UMC):
  - 288KB L2 memory, only part of which is cacheable

- Maximum 256KB can be configured as cache or SRAM
- 32KB is always mapped as SRAM
- When configured as a cache, L2 is a 4-way set associative cache with a 128-byte cache line
- L2 page size is 16KB
- L2 memory controller supports hardware prefetching and also provides bandwidth management, memory protection, and power-down functions
- Internal DMA (IDMA) engine
- External memory controller (EMC):
  - One 128-bit VBUSM slave port from main SCR
  - One 32-bit VBUSP master port to configuration SCR
- Extended memory controller (XMC):
  - One 256-bit VBUSM master port to main SCR
- Multi-stream prefetch buffer
- Address extension/translation (32-bit to 48-bit) on MDMA port using region address translation (RAT)
  - 16 regions
- Memory protection for multiple segments
- Memory protection for all internal L1/L2 RAMs
- Error detection for L1P data and tag RAMs
- Error detection and correction for L1D data and tag RAMs
- Error detection and correction for all L2 data and tag RAMs
- Hardware management for L2 SRAM and L1D cache coherency
- Integrated C66x CorePac interrupt controller (INTC) that works in conjunction with dedicated chip-level interrupt router for distribution of system interrupts to the C66x core
- Integrated leakage and dynamic power management
- Debug/emulation capabilities:
  - Support for stop mode, real-time and monitor mode debug capabilities
  - Support for processor instruction trace and system trace (printf-style debug)

### 6.4.3 C66SS Unsupported Features

The C66SS does *not* support the following:

- XMC memory protection and address extension (MPAX) 36-bit addressing. Note that:
  - RAT module is used for address translation instead. Translation is 32-bit to 48-bit
  - MPAX is supported for memory protection within the C66x CorePac
- "Full logic/RAM retention" mode featuring wake-up on both interrupt and DMA event (logic in "always on" domain). Only OFF mode is supported by C66SS, requiring full boot
- Cache coherency with MSMC (connection is through CBASS and not directly)

### 6.4.4 C66x DSP Reference Documents

The following TI documents provide more detailed description of C66x DSP:

- *TMS320C66x DSP CorePac User Guide* ([SPRUGW0](#))
- *TMS320C66x DSP CPU and Instruction Set Reference Guide* ([SPRUGH7](#)).
- *TMS320C66x DSP Cache User Guide* ([SPRUGY8](#)).

## 6.4.5 C66SS Integration

This section describes the C66SS integration in the device, including information about clocks, resets, and hardware requests.

Figure 6-10 and Figure 6-11 show the C66SS0 and C66SS1 integration, respectively.

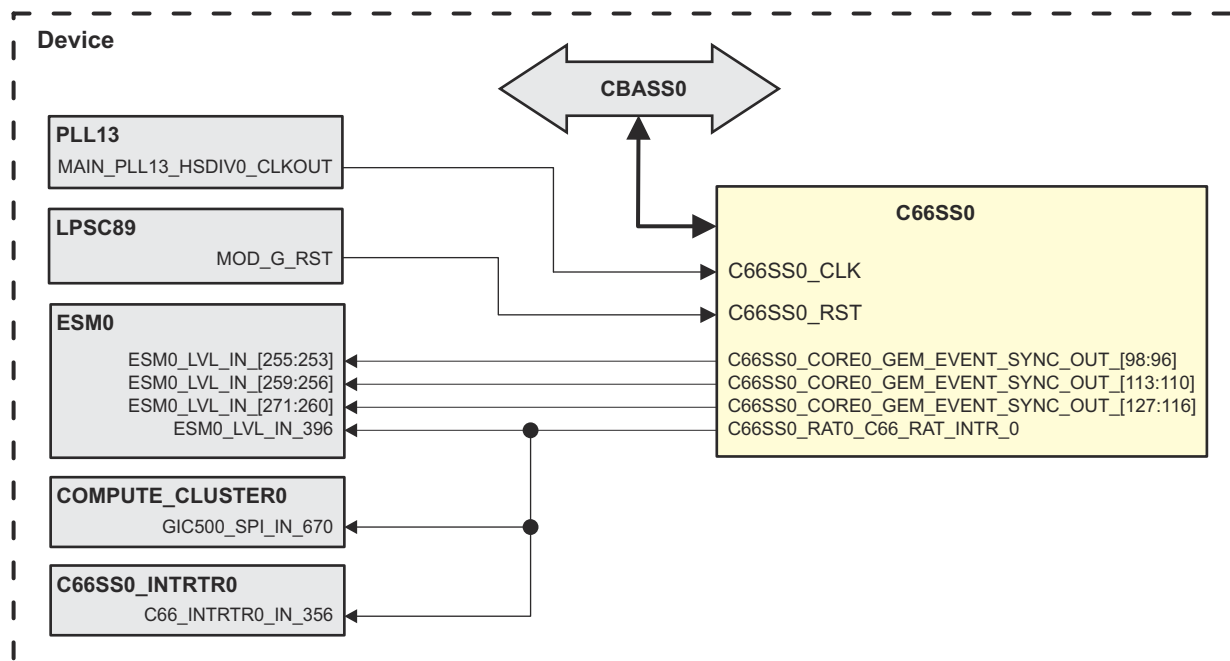

Figure 6-10. C66SS0 Integration

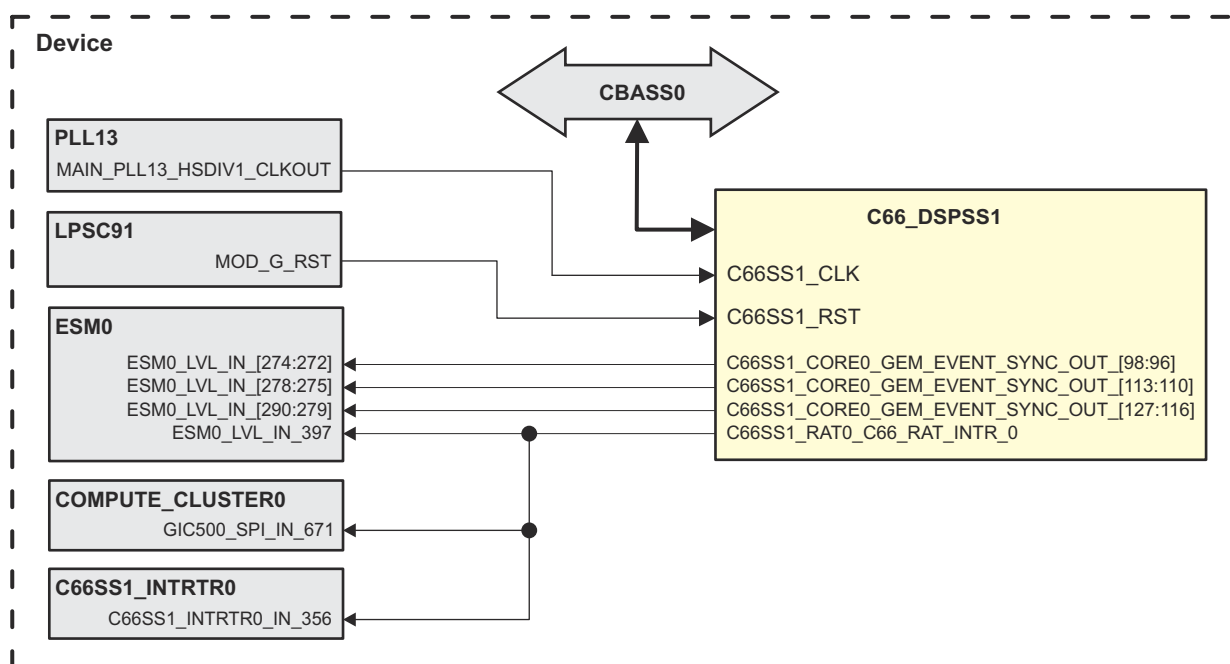

Figure 6-11. C66SS1 Integration

Table 6-37 through Table 6-39 summarize the C66SS integration.

**Table 6-37. C66SS Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
C66SS0	PSC0	PD22	LPSC89	CBASS0
C66SS1	PSC0	PD23	LPSC91	CBASS0

## 6.4.6 C66SS Functional Description

## 6.4.7 C66SS Cache Configuration

### Note

The purpose of this section is to provide an overview of the C66x cache memory architecture and to specify its configuration in this device. Details on the C66x cache functionality can be found in the *TMS320C66x DSP Cache User Guide* ([SPRUGY8](#)).

The device contains a 288KB level-2 memory (L2), a 32KB level-1 program memory (L1P), and a 32KB level-1 data memory (L1D). Each memory has a unique location in the memory map (see [Chapter 2, Memory Map](#)).

After device reset, L1P and L1D cache are configured as all cache, by default. The L1P and L1D cache can be reconfigured via software through the L1PMODE field of the L1P Configuration Register (L1PMODE) and the L1DMODE field of the L1D Configuration Register (L1DCFG) of the C66x CorePac. L1D is a 2-way set-associative cache, while L1P is a direct-mapped cache.

## 6.4.8 L1P Memory Configuration

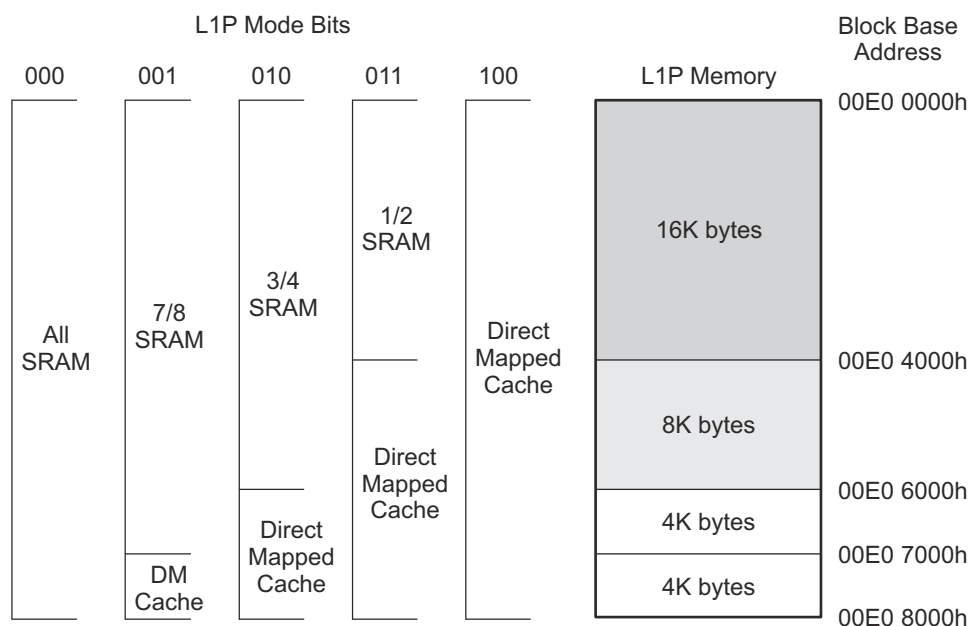

### Note

The C66x L1P SRAM option is disabled (not supported) in this device. Hence, C66x L1P is always configured as full cache.

The L1P memory configuration for this device is as follows:

- Region 0 size is 0KB (disabled)
- Region 1 size is 32KB with no wait states

[Figure 6-12](#) shows the available SRAM/cache configurations for L1P.

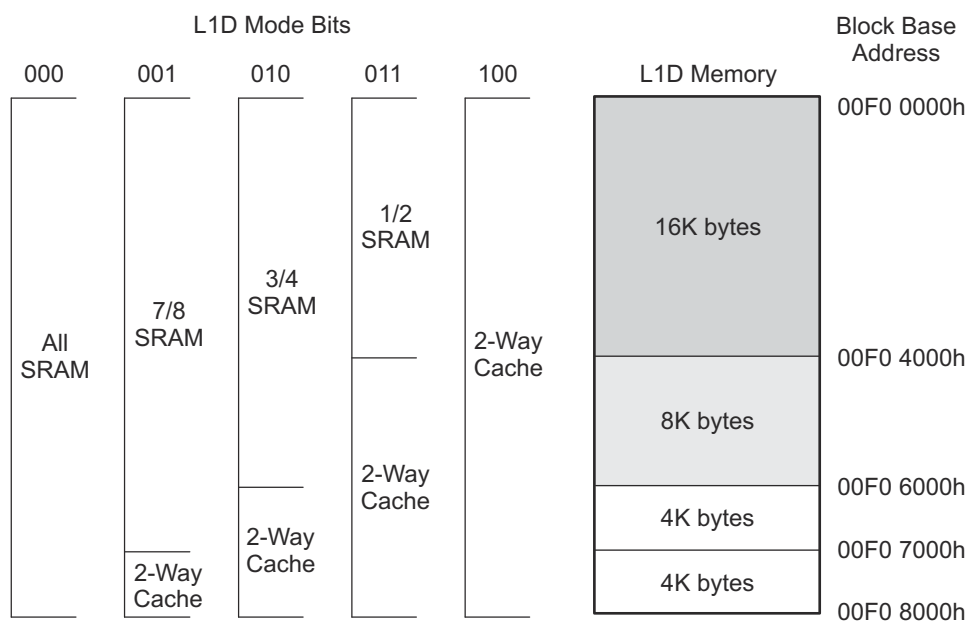

**Figure 6-12. L1P Memory Configurations**

## 6.4.9 L1D Memory Configuration

The L1D memory configuration for this device is as follows:

- Region 0 size is 0KB (disabled)
- Region 1 size is 32KB with no wait states.

Figure 6-13 shows the available SRAM/cache configurations for L1D.

**Figure 6-13. L1D Memory Configurations**

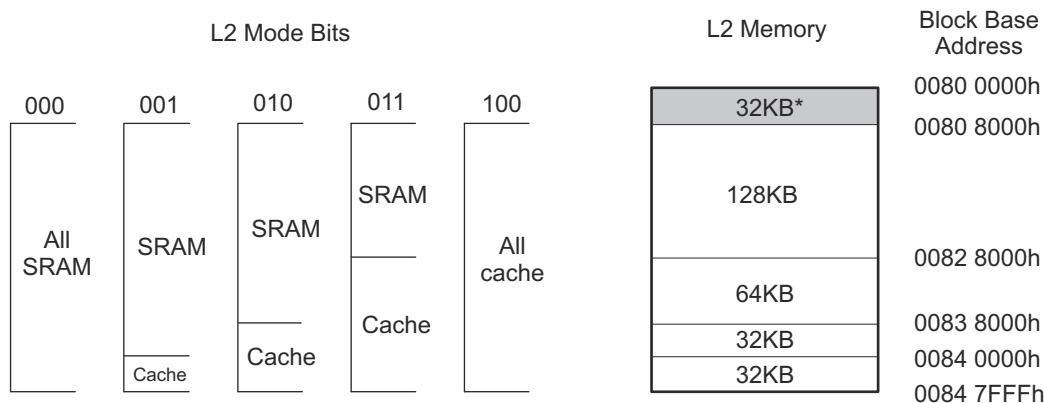

#### 6.4.10 L2 Memory Configuration

The L2 memory configuration for this device is as follows:

- 288KB of memory
- Local starting address is 0080 0000h

256KB of L2 memory can be configured as all SRAM, all 4-way set-associative cache, or a mix of the two. The other 32KB are always SRAM. The amount of L2 memory that is configured as cache is controlled through the L2MODE field of the L2 Configuration Register (L2CFG) of the C66x CorePac.

Figure 6-14 shows the available SRAM/cache configurations for L2. By default, L2 is configured as all SRAM after device reset.

\*Note: The 32KB gray-shaded block is all SRAM, non-cacheable, non-configurable by L2MODE

**Figure 6-14. L2 Memory Configurations**

### 6.4.11 C66SS ECC/Parity Support

The device supports ECC/parity on all C66x CorePac internal SRAMs. All the ECC/parity features are enabled by default (that is, after device reset). Software can disable the features per SRAM type if not required.

Table 6-40 summarizes the ECC/parity support in C66x CorePac.

**Table 6-40. C66SS ECC/Parity Support**

C66SS Memory	ECC/Parity Support
L1P Data RAM	Parity
L1P Tag RAM	Parity
L1D Data RAM	ECC-SECDED
L1D Tag RAM	ECC-SECDED
L2 Data RAM	ECC-SECDED
L2 Tag RAM	ECC-SECDED

### 6.4.12 C66SS Region Address Translation

The C66SS implements a region-based address translation (RAT) in order to extend the addressing capability of the C66x CPU from 32-bit to 48-bit. The RAT supports 16 regions, each having dedicated MMRs that define its attributes: base address (32-bit), size (up to 4GB), and translated address (48-bit). Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

For more details on RAT operation, see the *Region Address Translation* chapter.

### 6.4.13 C66SS Boot Configuration

In this device, the C66x boots from system memory instead of booting from ROM. The boot vector that defines the C66x fetch address is controlled by the following MAIN\_SEC\_MMR registers:

- For C66SS0: CLSTR2\_CORE0\_BOOTVECT\_LO[21:0] GEM\_ISTP\_RST\_VAL
- For C66SS1: CLSTR3\_CORE0\_BOOTVECT\_LO[21:0] GEM\_ISTP\_RST\_VAL

DMSC is the only master that can change the boot vector value, if needed. By default, the boot vector points to the C66x L2 SRAM at 0080 0000h.

In general, a device CPU host (typically R5F) loads a boot image to a given system memory location, sets the GEM\_ISTP\_RST\_VAL bit field to that address location, and then releases the C66x from reset. At that point, the C66x will begin fetching code from that location.

#### Note

If the GEM\_ISTP\_RST\_VAL value is modified, the change will be taken into account by C66x upon the next reset.

C66x is by default booted as non-secure mode. Due to address alignment requirement of boot vector value for C66x, a 2KB boot RAM (PSRAM2KECC) is added at SoC level. It is shared by the following CPU cores in the device: C66x, Cortex-A72 and Cortex-R5F.

### 6.4.14 C66SS Memory View

The C66x view of the address space is provided in the *Memory Map* chapter. Note that although most of the C66SS internal space is only accessible by the C66x, some modules (such as L1D and L2 memories) are also accessible by other SoC masters.

### 6.4.15 C66SS Interrupt Conditions

The C66SS supports the following features for interrupts:

- 1 NMI input event
- 128 input events
- 128 output events

### 6.4.16 C66SS Interrupt Inputs

The INTC integrated within the C66x CorePac provides flexible management of system events. The 128 input events include both internally-generated events (within the C66x CorePac) and chip-level events. In addition to these 128 events, the INTC also receives the non-maskable event and routes it straight through to the C66x DSP.

The 128 system events are either event inputs or event combinations generated by the event combiner. The event combiner logic has the capability of grouping multiple event inputs to four possible event outputs. These outputs are then provided to the interrupt selector and treated as additional system events.

The C66SS interrupt map can be found in the *Interrupts* chapter.

### 6.4.17 C66SS Interrupt Outputs

The C66x CorePac provides a 128-bit event output bus that can be used to either generates events under software control, or can convey the state of the corresponding functional interrupt/event input. [Table 6-39](#) shows which event outputs are used in this device and what is their mapping.

### 6.4.18 C66SS Clocking Considerations

The main functional clock for the C66SS is derived from a chip-level PLL. The clock rate (DIV2, DIV3, or DIV4) for the subsystem logic and the bus interfaces is set via the following MAIN\_SEC\_MMR registers:

- For C66SS0: CLSTR2\_CFG[1:0] SSCLK\_MODE
- For C66SS1: CLSTR3\_CFG[1:0] SSCLK\_MODE

The SSCLK\_MODE configuration is also propagated to the C66x CorePac and it affects the clock rates for XMC\_MDMA, EMC\_SDMA, and EMC\_CFG.

### 6.4.19 C66SS Power-Up/Down Sequences

The power-up and power-down sequences for the C66SS can be found in the *Power* chapter.

### 6.4.20 C66SS Endianness Support

The following MAIN\_SEC\_MMR registers provide the capability to select the endianness of the C66x core:

- For C66SS0: CLSTR2\_CORE0\_CFG[16] BIG\_ENDIAN
- For C66SS1: CLSTR3\_CORE0\_CFG[16] BIG\_ENDIAN

Note that while the C66x CPU core can operate in big-endian mode, the final output at the C66SS boundary is in little-endian format, as the rest of the chip is always little-endian. A logic internal to the C66SS is used to swizzle the data when the C66x is set to big-endian mode.

### 6.4.21 C66SS Debug Support

The C66SS supports the following debug features:

- Invasive debug
  - Halt mode debug
  - Real-time debug

- Monitor mode debug
- Non-invasive debug
  - Trace
- Advanced event triggering (AET)

For more details, see the *On-Chip Debug* chapter.

## 6.4.22 C66SS Registers

## 6.4.23 C66x CorePac Registers

[Table 6-42](#) lists the memory-mapped registers for the C66x CorePac. All register offset addresses not listed in [Table 6-42](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-41. C66x CorePac Instances**

Instance	Base Address
C66_COREPAC_ICFG	0100 0000h <sup>(1)</sup> <sup>(2)</sup>

- (1) C66SS0/1 private memory-mapped register space. This region is only accessible by its associated C66x core; it is not accessible by any other SoC master. The base address is the same for each C66x memory view.
- (2) Although the base address for this region is 0100 0000h, the first register is at address 0180 0000h. The [0100 0000h - 0180 0000h] space is reserved.

### Note

This section provides only a register summary for the C66x CorePac. The registers listed in [Table 6-42](#) are described in detail in *TMS320C66x DSP CorePac User Guide* ([SPRUGW0](#)).

**Table 6-42. C66x CorePac Registers**

Offset <sup>(1)</sup>	Acronym	Register Name	C66_COREPAC_ICFG Physical Address
0h to Ch	EVTFLAG0 to EVTFLAG3	Event Flag Register 0-3	0180 0000h to 0180 000Ch

(1) All offsets in this table are based on the address of the first register in the ICFG region (0180 0000h).

## 6.4.24 C66x RAT Registers

Table 6-44 lists the memory-mapped registers for the C66x RAT registers. All register offset addresses not listed in Table 6-44 should be considered as reserved locations and the register contents should not be modified.

**Table 6-43. C66x RAT Instances**

Instance	Base Address
C66_COREPAC_C66_RATCFG	07FF 0000h <sup>(1)</sup>

- (1) C66SS0/1 private memory-mapped register space. This region is only accessible by its associated C66x core; it is not accessible by any other SoC master. The base address is the same for each C66x memory view.

**Table 6-44. C66x RAT Registers**

Offset	Acronym	Register Name	C66_COREPAC_C66_RATCFG Physical Address

#### 6.4.25 C66\_RAT\_PID Register (Offset = 0h) [reset = 66803100h]

C66\_RAT\_PID is shown in [Figure 6-15](#) and described in [Table 6-46](#).

Return to [Summary Table](#).

This register contains the major and minor revisions for the module.

**Table 6-45. C66\_RAT\_PID Instances**

Instance	Physical Address
C66_COREPAC_C66_RATCFG	07FF 0000h

**Figure 6-15. C66\_RAT\_PID Register**

15-8	ADDRS	R	2h	Number of addresses.
7-0	REGIONS	R	10h	Number of regions.

### 6.4.27 C66\_RAT\_CTRL\_j Register (Offset = 20h) [reset = 0h]

C66\_RAT\_CTRL\_j is shown in [Figure 6-17](#) and described in [Table 6-50](#).

Return to [Summary Table](#).

This region controls the size and the enable for a region.

Offset = 20h + (j \* 10h); where j = 0h to Fh.

**Table 6-49. C66\_RAT\_CTRL\_j Instances**

Instance	Physical Address
C66_COREPAC_C66_RATCFG	07FF 0020h

30-6	RESERVED	R	0h	Reserved.
5-0	SIZE	R/W	0h	Size of the region in address bits. 0h = 1B 1h = 2B 2h = 4B ... 20h = 4GB

#### 6.4.28 C66\_RAT\_BASE\_j Register (Offset = 24h) [reset = 0h]

C66\_RAT\_BASE\_j is shown in [Figure 6-18](#) and described in [Table 6-52](#).

Return to [Summary Table](#).

This register is used for the base address for a region. This is the source address for matching to a region.

Offset = 24h + (j \* 10h); where j = 0h to Fh.

**Table 6-51. C66\_RAT\_BASE\_j Instances**

Instance	Physical Address
C66_COREPAC_C66_RATCFG	07FF 0024h

Bit	Field	Type	Reset	Description
31-0	BASE	R/W	0h	Base address for the region. It must be aligned to the programmed size.

#### 6.4.29 C66\_RAT\_TRANS\_L\_j Register (Offset = 28h) [reset = 0h]

C66\_RAT\_TRANS\_L\_j is shown in [Figure 6-19](#) and described in [Table 6-54](#).

Return to [Summary Table](#).

This register contains the translated lower address bits for a region.

Offset = 28h + (j \* 10h); where j = 0h to Fh.

**Table 6-53. C66\_RAT\_TRANS\_L\_j Instances**

Instance	Physical Address
C66_COREPAC_C66_RATCFG	07FF 0028h

31-1	RESERVED	R	0h	Reserved.
0	ENABLE_CLR	R/W1C	0h	Write a 1 to clear the exception interrupt enable signal.

#### 6.4.43 C66\_RAT\_EOI\_REG Register (Offset = 850h) [reset = 0h]

C66\_RAT\_EOI\_REG is shown in [Figure 6-33](#) and described in [Table 6-82](#).

Return to [Summary Table](#).

##### EOI Register

The EOI register is used to re-trigger the pulse interrupt signal to ensure that any nested interrupt events are serviced. The software interrupt handler must write to the EOI register at the end of the current interrupt processing routine, so that new events can re-trigger the pulse interrupt signal again. For level interrupt signals the EOI register is not functional and must not be used.

**Table 6-81. C66\_RAT\_EOI\_REG Instances**

## 6.5 C71x DSP Subsystem

This section describes the C71x Digital Signal Processor Subsystem (C71SS) in the device.

### 6.5.1 C71SS Overview

The TMS320C71x is the next-generation fixed and floating-point DSP platform. The C71x DSP is a new core in the Texas Instruments' DSP family. The C71x DSP supports vector signal processing, providing significant lift in DSP processing power over a broad range of general signal processing tasks in comparison to the C6x DSP family. In addition, the C71x provides several specialized functions which accelerate targeted functions by more than 30 times. Besides expanding vector processing capabilities, the new C71x core also incorporates advanced techniques to improve control code efficiency and ease of programming such as branch prediction, protected pipeline, precise exception and virtual memory management.

The C71x builds on the C6x's legacy but it is not binary compatible with any previous C6x DSPs. Many of the C71x architecture features are new and unique. The C71x is designed as a platform with these characteristics:

- True 64-bit machine with 64-bit memory addressing (64-bit virtual memory addressing, 40-bit physical addressing) and single-cycle 64-bit base arithmetic operations
- Achieves 4 to 32 times DSP processing capacity compared to C66x
- Preserves out-of-the-box performance parity for C code which has been optimized for C66x with a few exceptions
- Provides a direct software migration path from C66x
- Provides direct architecture support for accelerating OpenCL

There is a single C71SS module in the device. It is tightly coupled with a matrix multiply accelerator (MMA).

[Table 6-83](#) shows C71SS allocation within device domains.

**Table 6-83. C71SS Allocation within Device Domains**

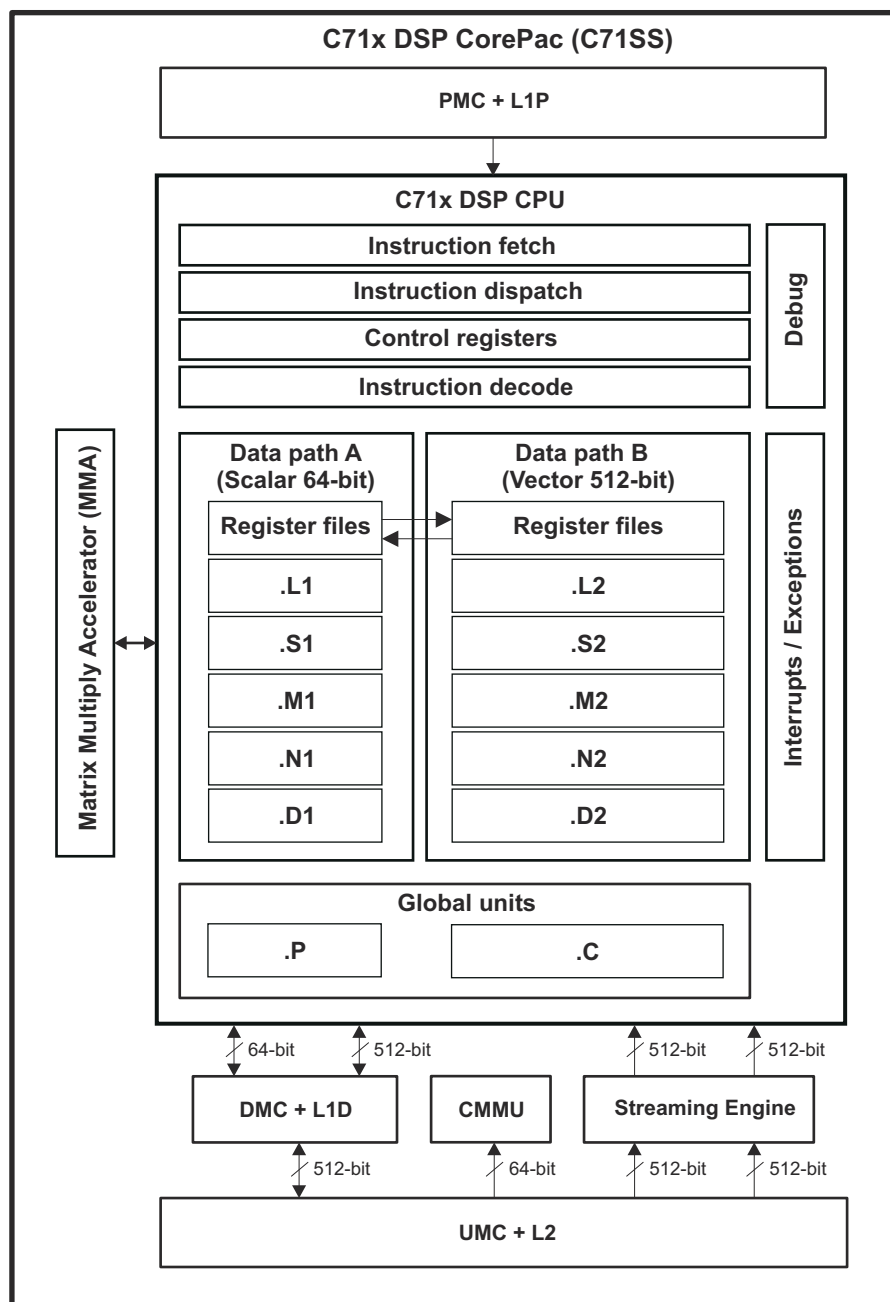

Module Instance	Domain		
	WKUP	MCU	MAIN
C71SS0 (+ MMA)	–	–	✓

#### Note

The C71SS is also referred to as C71x CorePac.

[Figure 6-34](#) shows an overview of the C71SS.

**Figure 6-34. C71SS Overview**

#### 6.5.1.1 C71SS Features

The C71SS (C71x CorePac) supports the following key features:

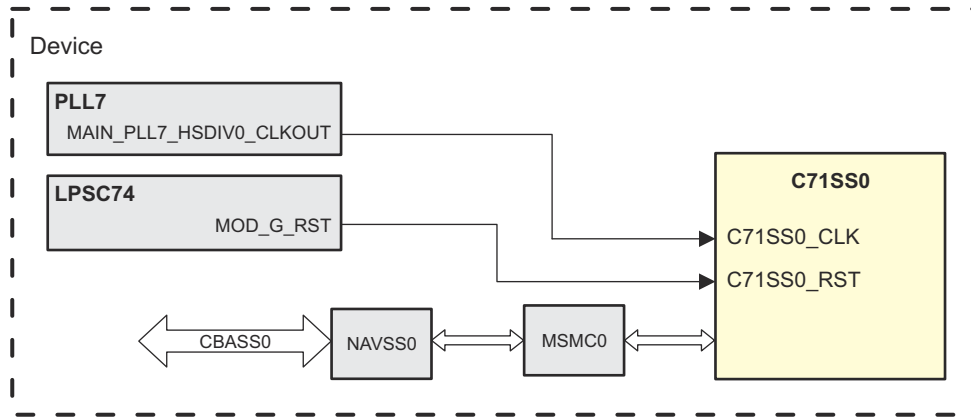

- C71x CPU
- Matrix multiplication accelerator (MMA)
- Hierarchical cache memory system
  - Level 1 (L1):
    - L1 program memory controller (PMC) with associated L1 program memory (L1P)
    - L1 data memory controller (DMC) with associated L1 data memory (L1D), either L1 data cache or L1 scratch memory
  - Level 2 (L2):

- L2 unified memory controller (UMC) with associated L2 memory, either L2 cache or L2 scratch memory
- Streaming engine (SE)
- CorePac memory management unit (CMMU), fully compliant with Armv8-A memory architecture
- Power/clock/reset management unit
- ECC/parity support
  - ECC protection of L2 memory and L1D memory
  - Parity protection of L1P memory
- PBIST and LBIST support
- Cluster Level Event Controller (CLEC) CPU interface
- C71x debug subsystem
- Extended configuration register (ECR) interface for register access (instead of MMR)

### 6.5.2 C71SS Integration

This section describes the C71SS integration in the device, including information about clocks, resets, and hardware requests.

Figure 6-35 shows the C71SS0 integration.

**Figure 6-35. C71SS0 Integration**

Table 6-84 through Table 6-85 summarize the C71SS integration.

**Table 6-84. C71SS Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
C71SS0	PSC0	PD12	LPSC74	CBASS0 <sup>(1)</sup>

(1) Accessed through MSMC0.

**Table 6-85. C71SS Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
C71SS0	C71SS0_CLK	MAIN_PLL7_HSDIV0_CLKOUT	PLL7	C71SS0 main functional clock
Resets

C71SS0	C71SS0_RST	MOD_G_RST	LPSC74	C71SS0 hardware reset

### 6.5.3 C71SS Functional Description

#### Note

This chapter provides only a brief description of C71SS supported features. Full description of C71x DSP functionality is provided in standalone TI documentation.

#### 6.5.3.1 C71x DSP CPU

The C71x CPU is a true 64-bit core which provides the following key features:

- Instruction fetch unit
- Instruction dispatch unit, advanced instruction packing
- Instruction decode unit
- CPU dual datapath
  - One 64-bit scalar side (side A) and one 512-bit vector side (side B)
  - Side A includes the following functional units
    - Four main scalar processing units (.L1, .S1, .M1, .N1) capable of operating on up to 64-bit wide data
    - Two units (.D1, .D2) for address calculations, enabling parallel load/store operations
    - The following operations can be executed at the same time in a single clock cycle
      - One non-aligned 64-bit load or store operation
      - Two 64-bit arithmetic/logical operations (non-multiply arithmetic instructions)
      - One 128-bit multiply operation
  - Side B includes the following functional units
    - Five main vector processing units (.L2, .S2, .M2, .N2, .C) capable of operating on up to 512-bit wide vector data
    - A predication processing unit (.P) for vector predication
    - The following vector operations can be executed at the same time in a single clock cycle
      - One non-aligned 512-bit load or store operation
      - Two 512-bit arithmetic/logical operations (non-multiply arithmetic instructions)
      - One 1024-bit multiply operation
      - One 512-bit correlation operation or regular arithmetic operation
      - One vector predicate manipulation operation
  - Vector side B can perform up to 128×16-bit fixed-point multiply-accumulate (MAC), 4.0 times the MAC capacity compared to C66x
  - Vector side B can perform up to 80 single precision FLOPs/cycle or 32 double precision FLOPs/cycle, 5.0 times the floating point compared to C66x
  - The C71x CPU can load or store in parallel 64 bits and 512 bits of data per clock cycle, more than four times the bandwidth compared to C66x. In addition, a novel streaming data interface can read an additional 1024 bits of data per clock cycle, providing a total of 12 times more bandwidth compared to the C66x
  - Large set of machine registers:
    - Up to 16×512-bit global vector registers
    - Up to 16×64-bit global scalar registers
    - Local registers
  - Register file cross paths
    - Two cross paths, 64-bit each
    - Allow functional units from one data path to access a 64-bit operand from the opposite side global register file
    - The cross paths can not access the local register files directly
- CPU control logic
  - Support for two security states
    - Secure state: CPU can access both secure and non-secure space
    - Non-secure state: CPU can only access non-secure space, and cannot access secure space

- Support for six privilege and execution levels for security and virtualization support with banked control registers for full isolation and protection
  - Secure root supervisor
  - Secure root user
  - Non-secure root supervisor
  - Non-secure root user
  - Non-secure guest supervisor
  - Non-secure guest user
- Pipeline can operate in both unprotected and protected modes
  - Unprotected mode: Traditional C6x VLIW DSP operating mode with exposed instruction delay slots
  - Protected mode: Control code execution mode where instructions delay slots are not exposed
- Scoreboarding mechanism to help hide memory system stalls and to allow the compiler to generate more efficient control codes
- Supports recoverable interrupts and internal precise exception
  - No need to disable interrupts during multiple assignment code. In-flight results in multiple-assignment code are recorded by pipeline capture queues. These queues allow all programs to be interrupted at any arbitrary cycle, even during software pipelined loops, and then to be restarted correctly upon return from the interrupt or exception handler
  - Pipeline capture queues may be unloaded and reloaded, allowing the OS to swap out tasks regardless of whether the task was operating in protected or unprotected pipeline mode
  - Programmable event priority, hardware automatic event mask based on priority levels
  - Hardware performs automatic stacking at even handler entry and automatic unstacking at event exiting
- Nested loop counters (NLC): Hardware mechanism to facilitate low-overhead loop collapsing by providing the computations associated with nested loop counters and predicates, avoid the needs of using explicit instructions
- Test, debug, and interrupt logic
- Enhanced instruction set architecture (ISA)
  - Single-cycle 64-bit arithmetic, logical, and shift instructions
  - Improvements to load/store instructions
    - Endian aware vector load instructions
    - Unpacking load / packing store instructions
    - Vector load/store with element reversal
    - Vector load with data duplications
  - Specialized instructions to speed up key benchmarks
    - Horizontal MAX/MIN search acceleration instructions
    - Horizontal ADD, SUB instructions
    - Dedicated FIR instructions
    - Sliding window sum of absolute differences (SAD)
    - Maskable complex dot products
  - Circular comparison instructions to accelerate Viterbi
  - New and improved atomic instructions to replace LL/SC/CL combination
  - Increases orthogonality between 32-bit, 64-bit, and vector operations compared to C66x
  - Supports binlog instruction for vision algorithms
  - Specialized instructions only allowed to execute at required privilege level and secure state
- C71x OpenCL features
  - Full compliance with IEEE 754 floating point standard
    - Support subnormal numbers
  - DVM support
    - Support fencing for uTLB transactions

The matrix multiply accelerator (MMA) is included as a special functional unit in the C71x CorePac and is tightly coupled to CPU operation.

### 6.5.3.2 C71x DSP Matrix Multiply Accelerator

The matrix multiply accelerator (MMA) provides the following key features:

- Support for fully connected layer using matrix multiply with arbitrary dimension
- Support for convolution layer using 2D convolution with matrix multiply with read panel
- Support for ReLU non-linearity layer OTF
- Support for high utilization (>85%) for typical convolutional neural network (CNN), such as AlexNet, ResNet, and others
- Ability to support any CNN network topologies limited only by memory size and bandwidth
- Coupled with C71x CPU using DSP chassis for data formatting
- MMA and C71x CPU are on a shared power domain
  - MMA cannot be independently powered off or clock gated at LPSC level (although it has extensive clock gating within the IP)

### 6.5.3.3 C71x DSP Cache Memory System

The C71x CorePac implements a hierarchical cache memory system with the following levels:

- Level 1 (L1):
  - L1 program memory controller (PMC) with associated L1 program memory (L1P)
  - L1 data memory controller (DMC) with associated L1 data memory (L1D)
- Level 2 (L2):
  - L2 unified memory controller (UMC) with associated L2 memory

#### 6.5.3.3.1 C71x DSP L1 Program Memory

The L1P cache controller supports a fixed cache size of 32KB. The purpose of the L1P cache is to maximize performance of the code execution. L1P cache is necessary to facilitate fetching program code at a fast clock rate in order to maintain a large system memory. The cache is responsible for hiding the latency associated with executing code from the slower system memory.

The L1P memory system provides the following key features:

- L1 program memory controller (PMC) with 32KB L1P memory, all cache (no support for L1P SRAM)
- L1P cache
  - 4-way set associative
  - 64-byte line size
  - Virtually indexed, virtually tagged (48-bit virtual address)
  - Auto-prefetching on L1P misses from L2
- Prefetch and branch prediction
- ECC SECDED support
- Software initiated coherence operations
  - Single cycle invalidate with support for three modes: all cache lines, only user cache lines, only supervisor cache lines
- Virtual memory
  - Virtual-to-physical addressing on misses
  - Micro-TLB (uTLB) to handle address translation and for code protection
- Extended control register (ECR) access
  - L1P ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

#### 6.5.3.3.2 C71x DSP L1 Data Memory

The L1D includes a non-blocking cache controller, which has a main cache and a small fully associative victim cache. Main cache is read-allocate and supports write-back and write-through. Victim cache services read and write hit directly with no performance overhead as main cache.

The purpose of the L1D memory/cache is to maximize performance of the data processing. The cache is necessary to facilitate reading and writing data at the full CPU clock rate, while still having a large system

memory. It is the cache's responsibility to hide much of the latency associated with reading from and writing to the slower system memory. The L1D memory includes two logical sections:

- L1D partition 0: Can support 32KB (max) / 8KB (min) of cache. Cache may only reside in partition 0. A cache size of 0KB is not supported, which means that disabling L1D cache functionality is not possible
- L1D partition 1: Can support 40KB (max) / 16KB (min) of SRAM (may include LUT and histogram)

---

#### Note

The minimum cache size (8KB) can only be achieved via L1DMODE register programming.

---

The L1D memory system provides the following key features:

- L1 data memory controller (DMC) with 48KB L1D memory, configurable as cache and/or SRAM
- L1D partition 0 (cache/SRAM) + L1D partition 1 (SRAM only)
- L1D cache
  - 32KB cache (max), configurable down to 8KB cache (min)
  - Dual datapath (DP0 + DP1) support
  - Direct-mapped (1-way set-associative) main cache
  - 128-byte cache line size
  - Read-allocate cache
  - Support for both write-back and write-through modes
  - Support for victim cache
    - 16 cache lines, fully associative
  - Physically indexed, physically tagged (40-bit physical address)
  - Support for speculative loads
  - Hit under miss
  - Posted write miss support
  - Write merging on all outstanding write transactions inside L1D
- L1D SRAM
  - 16KB (min), configurable up to 40KB (max)
  - Accessible from CPU or DMA
- Lookup table (LUT) and histogram
  - LUT
    - Up to 4 sets of look up tables can be specified simultaneously
    - Supports interpolation mode
    - Indices are unsigned values at 32-bit lanes of the source register
    - Look up table elements can be signed or unsigned, bytes, half-words or words
  - Histogram
    - Up to 4 sets of histograms can be specified simultaneously
    - Supports regular and weighted histogram operations
    - Indices are unsigned values at 32-bit lanes of the source register
    - Histogram weights are at 32-bit lanes of the source register
    - Histogram weights can only be signed bytes or signed half-words
    - Histogram bin data saturates to the minimum or maximum values of its data bin type
- Bandwidth
  - 1024-bit data throughput
  - 16×64-bit banks
- ECC SECDED support
- Coherence
  - Full MESI support
  - Support for global cache coherence operations
  - Snoops and cache maintenance operation support from L2
  - Snoops for L2 SRAM, MSMC SRAM and external (DDR) addresses

- Virtual memory support
  - Support for wider (40-bit) physical address
- ECR access
  - L1D ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

### 6.5.3.3.3 C71x DSP L2 Memory

The L2 memory system provides the following key features:

- L2 unified memory controller (UMC) with 512KB L2 memory, configurable as cache and/or SRAM
  - L2 cache
    - 8-way set-associative
    - 128-byte cache line size
    - Write-allocate cache
    - Support for both write-back and write-through modes
    - Physically indexed, physically tagged (40-bit physical address)
    - Supports 2×64-byte streams from one streaming engine
    - External MMR and MDMA accesses on an unified interface to MSMC
    - Caches MMU page tables
    - Cache pre-warming from SE and/or MSMC
  - L2 SRAM
    - Security firewall on L2 SRAM accesses
    - DMA access to L2 SRAM on merged MSMC I/F
  - Bandwidth
    - 2048-bit data throughput (see [Section 6.5.3.4, C71x DSP Streaming Engine](#))
    - 4×512-bit banks, with 2 virtual banks each
  - ECC SECDED support
  - Coherence
    - Full MESI support
    - Support for global coherence operations
    - Snoops for L2 SRAM, MSMC SRAM and external (DDR) addresses
    - User coherence commands from SE
    - Full coherence between L1D cache, SE, L2 SRAM, MSMC SRAM and DDR
  - ECR access
    - L2 ECR registers are not memory mapped and instead are mapped to a MOVC CPU instruction

### 6.5.3.4 C71x DSP Streaming Engine

The streaming engine (SE) supports the following key features:

- Provides a flexible, high bandwidth mechanism for reading large quantities of data into C71x CPU
- Supplies two 512-bit data streams (S0, S1) directly from L2 to the vector units
- Provides two stream address generators, supporting the two data streams
  - Flexible multi-dimensional address calculators
  - Provide offset addresses for load and store instructions
- Supports element promotion, decimation, duplication, transpose loads, predication
- LEZR feature can be enabled to return N number of zero vectors to CPU after selected dimension ends. LEZR and transposed mode are not supported together. LEZR is still supported when transposed mode is disabled..
- Provides 6D addressing
  - Access patterns up to 6D can be programmed ahead
  - 6D data is presented as 512-bit vector per cycle
- Communicates with L2 memory controller for requests beyond L2 (MSMC, DDR)
- Coherent with L1D data at stream open/close boundaries
- ECC SECDED support

The SE can sustain 1024-bits/cycle total bandwidth (512 bits/cycle on each of two streams) to the DSP CPU. When combined with its 512-bit/cycle vector load unit and 512-bit/cycle store unit, the DSP CPU can access 2048 bits/cycle of data.

#### 6.5.3.5 C71x DSP CorePac Memory Management Unit

The CorePac Memory Management Unit (CMMU) extends the C71x architecture with support for address translation, access permission and protections and memory attributes determination and checking. It is implemented per C71x cluster as a two-level TLB structure. The CMMU works with the C71x L1 caches, stream buffers in each processor and CorePac memory system of CorePac cluster to translate virtual addresses to physical addresses, controls tablewalk hardware that accesses translation tables in main memory. The CMMU enables fine-grained memory system control through a set of virtual-to-physical address mappings and memory attributes held in the L1 level micro translation look-aside buffer (uTLB) and CorePac cluster level translation look-aside buffers (TLBs).

The CMMU provides the following key features:

- Supports AArch32 LPAE and AArch64 page table format
  - Programmable levels of page table translation
  - 4KB, 16KB, 64KB translation granules
- Supports multiple page sizes: 4KB, 16KB, 64KB, 2MB, 32MB, 512MB, 1GB, 16GB
- Supports both hardware and software managed table walks
- Hierarchical Table Lookaside Buffer (TLB) caching page entries, intermediate page walk pointers for optimum address translation performance
  - Micro-TLB (uTLB) as first level TLB
    - 16-entry fully associative dual interface L1 data uTLB
    - 8-entry fully associative L1 instruction uTLB
  - CorePac (L2) TLB as second level TLB
    - 512-entry 4-way associative TLB cache, caching both instruction and data page translations with virtual-to-physical address mapping
    - Intermediate table walk caches to reduce memory access during multi-level page walk
    - Allows caching and sharing of intermediate table walks and page tables in the system cache hierarchy
- Security extensions that facilitate the development of secure applications
- Soft-error protection on all RAM and data storage structures

#### 6.5.3.6 C71x DSP ECC Support

[Table 6-86](#) provides the RAM ID for the C71x DSP ECC aggregator.

**Table 6-86. RAM ID Map for C71x DSP ECC Aggregator**

RAM ID	Endpoint
0	C71x Corepac
1	CBASS P2P
2	CBASS SCR
3	CBASS SCR
4	Reserved
5	Reserved
6	UMC pipe 0
7	UMC pipe 0
8	UMC pipe 1
9	UMC pipe 1
10	UMC pipe 2
11	UMC pipe 2
12	UMC pipe 3

**Table 6-86. RAM ID Map for C71x DSP ECC Aggregator (continued)**

RAM ID	Endpoint
13	UMC pipe 3
14	DMC
15	DMC tag RAM
16	SE, stream 0
17	SE, stream 1
18	PMC

#### 6.5.3.7 C71x DSP Boot Configuration

In this device, the C71x boots from system memory instead of booting from ROM. A 1KB boot RAM (PSRAM1KECC) is used to store boot vectors for the C71x CPU.

#### 6.5.3.8 C71x DSP Power-Up/Down Sequences

The power-up and power-down sequences for the C71SS can be found in *Power*.

#### 6.5.3.9 C71x DSP Interrupt Control

The cluster level event controller (CLEC) serves the role of an interrupt controller for the C71x DSP. For more details, see *Interrupts*.

## 6.6 Graphics Accelerator (GPU)

This chapter describes the integration of the Graphics Processing Unit (GPU) subsystem in the device.

### 6.6.1 GPU Overview

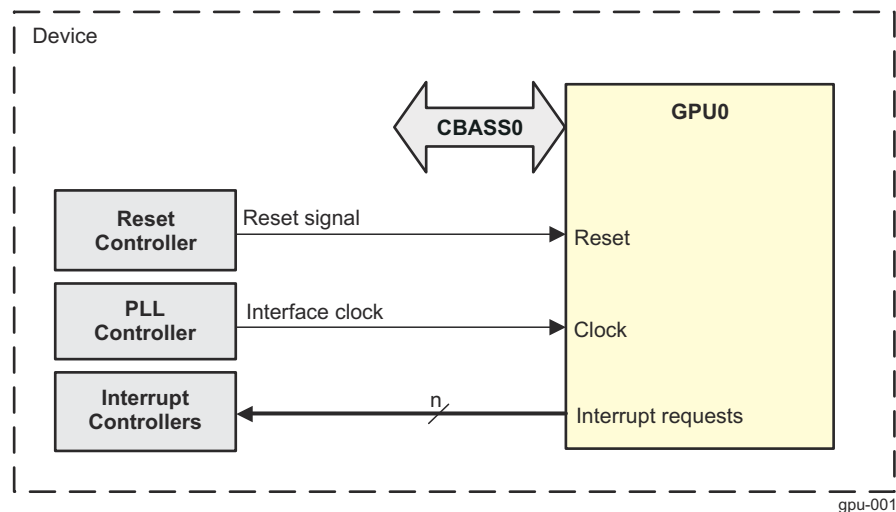

The Graphics Processing Unit (GPU) accelerates 3-dimensional (3D) and 2-dimensional (2D) graphics and compute applications.

The GPU is based on the PowerVR® Series8XE GE8430 core from Imagination Technologies.

The GPU module is a scalable architecture which efficiently processes a number of different workload concurrently:

- 3D Graphic Workload, which involves vertex data and pixel data processing for rendering of 3D scenes.
- 2D Graphic Workload, which involves pixel data processing for rendering 2D objects.
- Compute Applications Workload, which involves general purpose data processing.

Figure 6-36 shows the GPU module overview.

**Figure 6-36. GPU Module Overview**

#### 6.6.1.1 GPU Features Overview

- APIs support:
  - OpenGL® - ES 3.2
  - OpenCL™ - 1.2 EP
  - Vulkan 1.2
- Single-core GPU architecture is consisting of:
  - 1 × PowerVR® Series8XE GE8430 core
- Unified Shading Clusters (USCs):
  - Multithreaded engine incorporating vertex shader, pixel shader and compute shader functionality
  - Incorporates an ALU architecture with high SIMD efficiency
- Tile-based deferred rendering architecture with concurrent processing of multiple tiles
- 96GFLOPS and 6GPix/s at 750MHz clock
- Hardware virtualization
- Hardware security
- FBC and FBDC (Frame Buffer Compression/Decompression)
- Dedicated MIPS processor for firmware execution
- Advanced DMA driven operation for minimum host CPU interaction
- Programmable high quality image anti-aliasing
- Fully virtualized memory addressing in a unified memory architecture:

- Up to 64 GB physical address space
- Up to 1 TB virtual address space

**6.6.1.2 GPU Not Supported Features**

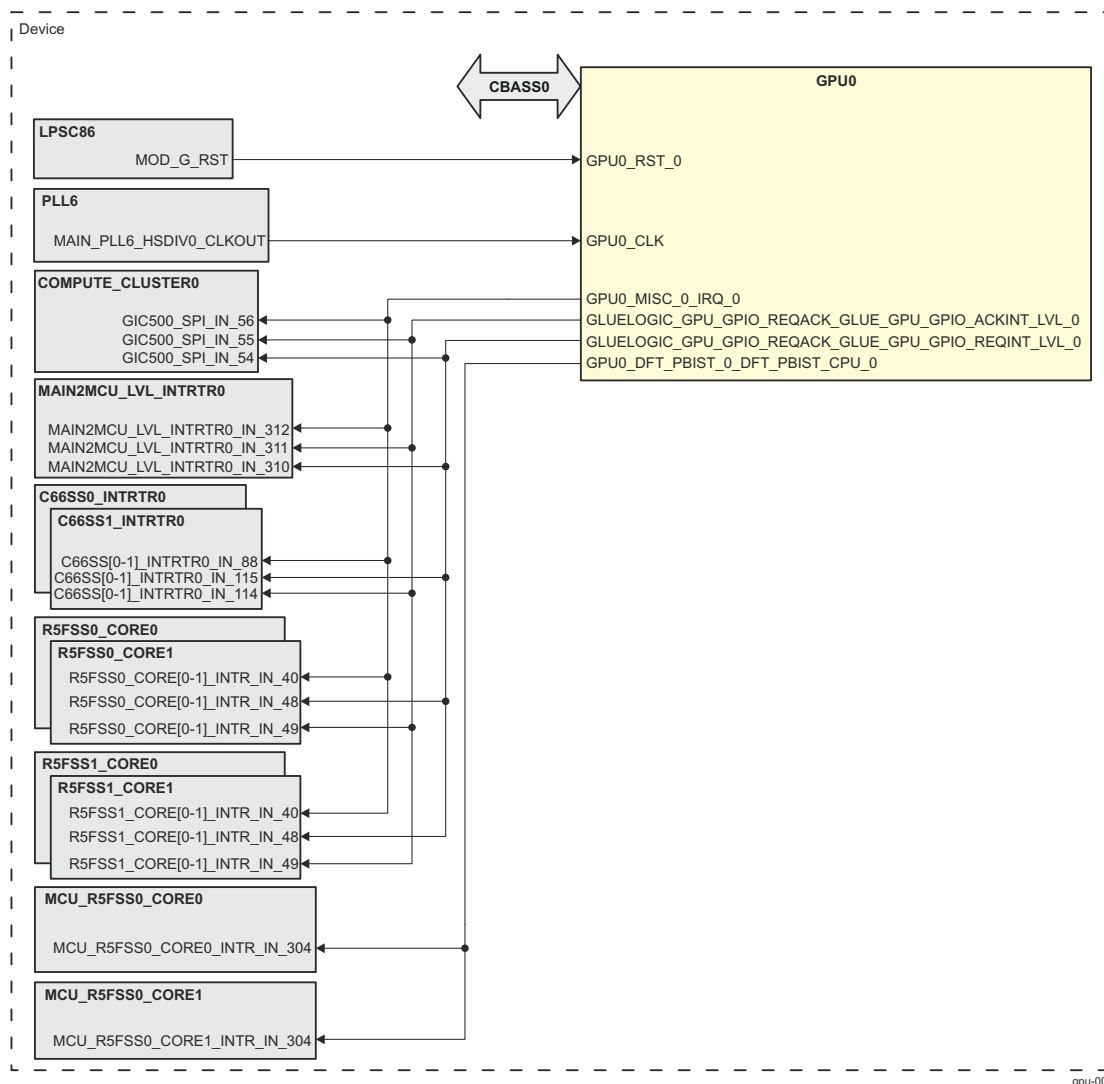

- Memory coherency
- ECC support on memories
- ECC support on bus interfaces

## 6.6.2 GPU Integration

This section describes GPU0 integration in the device, including information about clocks, resets, and hardware requests.

### 6.6.2.1 GPU Integration in MAIN Domain

There is one GPU0 module integrated in the device MAIN domain. [Figure 6-37](#) shows the integration of GPU0.

**Figure 6-37. GPU0 Integration**

[Table 6-87](#) through [Table 6-89](#) summarize the integration of GPU0 in the device MAIN domain.

**Table 6-87. GPU0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

### 6.6.3 GPU Functional Description

#### 6.6.3.1 GPU Block Diagram

The GPU architecture comprises the following elements:

- A power, clock, and data interface logic
- A GPU core, partitioned into the following sub-blocks:
  - SLC\_SIDEKICK
  - RASCAL
  - DUST0 and DUST1

Figure 6-38 shows the GPU top-level block diagram.

**Figure 6-38. GPU Block Diagram**

The GPU module has 1 × GPU core. The wrapper around GPU core enables it integrates into device.

The GPU module is connected to the CBASS0 interconnect by:

- Two 256-bit data master interfaces for data transfer (read and write separate).
- One 32-bit data slave interface for GPU core configuration.

GPIO offers an additional communication channel between CPU and GPU. For more information on the GPIO registers, see [Section 5.1, Control Module \(CTRL\\_MMR\)](#).

The GPU module is based on tile-based deferred rendering (TBDR) and processes data in two phases:

1. The first phase is the *Vertex Processing Phase*, which involves vertex operations such as transformation and vertex lighting, as well as dividing a 3D scene into tiles.
2. The second phase is the *Pixel Processing Phase*, which involves pixel operations such as rasterization, texturing and shading of pixels.

Sub-block SLC\_SIDEKICK incorporates System Level Cache (SLC), MIPS processor, FBC, and FBDC. The SLC\_SIDEKICK handle the reset and clock control of the RASCAL, DUST0, and DUST1 blocks, including during the power transition state.

Sub-block RASCAL incorporates rasterization step.

Sub-blocks DUST0 and DUST1 incorporates Unified Shading Cluster (USC) and Texture Processing Unit (TPU).

#### 6.6.3.2 GPU Clock Configuration

The GPU subsystem operates from one clock from dedicated PLL for core operations (GPU0\_CLK).

When no longer needed by the GPU subsystem, GPU0\_CLK can be cut by software.

For additional information, see [Table 6-88](#), *GPU0 Clocks and Resets*.

#### 6.6.3.3 GPU Reset

The GPU subsystem has its own reset domain. Reset of the GPU is performed by activating the GPU0\_RST\_0 signal.

Reset domains refer to:

- GPU0\_RST\_0 resets RASCAL, DUST0, DUST1 blocks, SLC\_SIDEKICK sub-block and power, clock, and data interface logic from GPU core.

For additional information, see [Table 6-88](#), *GPU0 Clocks and Resets*.

#### 6.6.3.4 GPU Power Management

The GPU subsystem has its own power domains (GPU\_COMMON and GPU\_CORE).

Power domains refer to:

- SLC\_SIDEKICK and Wrapper blocks are part of GPU\_COMMON power domain.
- RASCAL, DUST0 and DUST1 blocks are part of GPU\_CORE power domain.

For additional information, see [Table 6-87](#), *GPU0 Integration Attributes*.

#### 6.6.3.5 GPU Interrupt Requests

The GPU subsystem can generate four interrupt signals -

GPU0\_MISC\_0\_IRQ\_0, GLUELOGIC\_GPU\_GPIO\_REQACK\_GLUE\_GPU\_GPIO\_ACKINT\_LVL\_0,  
GLUELOGIC\_GPU\_GPIO\_REQACK\_GLUE\_GPU\_GPIO\_REQINT\_LVL\_0,  
GPU0\_DFT\_PBI0\_DFT\_PBI0\_CPU\_0.

For additional information, see [Table 6-89](#), *GPU0 Hardware Requests*.

## 6.7 Multi-Standard HD Video Decoder (DECODER)

This section describes the dual-core multi-standard HD video decoder DECODER module in the device.

The DECODER module is a D5520MP2 dual-core PowerVR® VPU (video processor unit) from Imagination Technologies.

### 6.7.1 DECODER Overview

The DECODER is capable of supporting:

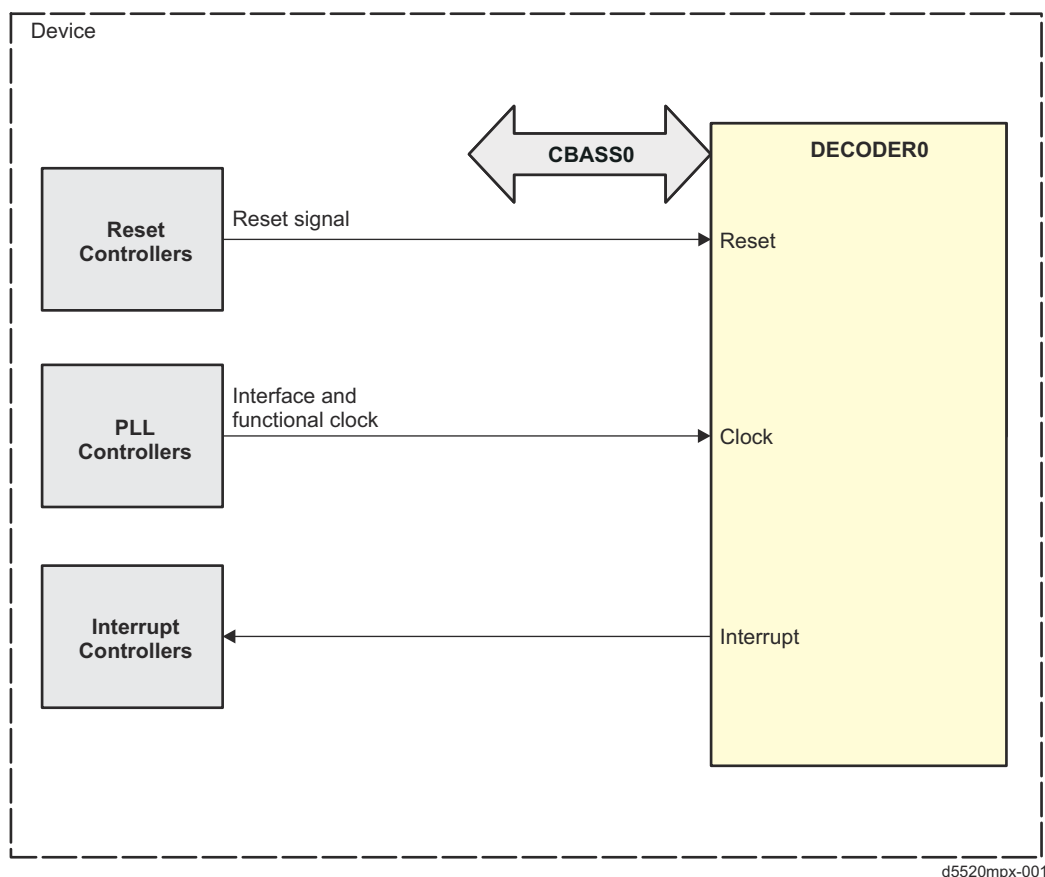

- 1x 4kp60 decode or
- 2x 4kp30 decodes or
- 4x 1080p60 decodes or
- 8x 1080p30 decodes

The device has one instance of the DECODER module. [Table 6-90](#) shows DECODER module allocation within device domains.

**Table 6-90. DECODER Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DECODER0	-	-	✓

[Figure 6-39](#) shows the DECODER module overview.

**Figure 6-39. DECODER Module Overview**

#### 6.7.1.1 DECODER Features

The DECODER decoder supports the following decoding schemes:

- HEVC
- H.264
- MPEG-4
- WMV-9
- VC-1
- MPEG-2
- H.263
- DivX
- AVS
- RealVideo
- VP8
- VP6
- Sorenson
- JPEG

The DECODER also features:

- Hardware scaling
- 90°, 180°, 270° rotation support
  - Software driver runs on main host processor (no dedicated middle-ware processor is required as in previous decoder generation)
- Support secure playback (differentiated access to secure data space secure streams), enforced via device level firewalls controlled by DMSC.

#### 6.7.1.2 DECODER Not Supported Features

The DECODER does not support the following features:

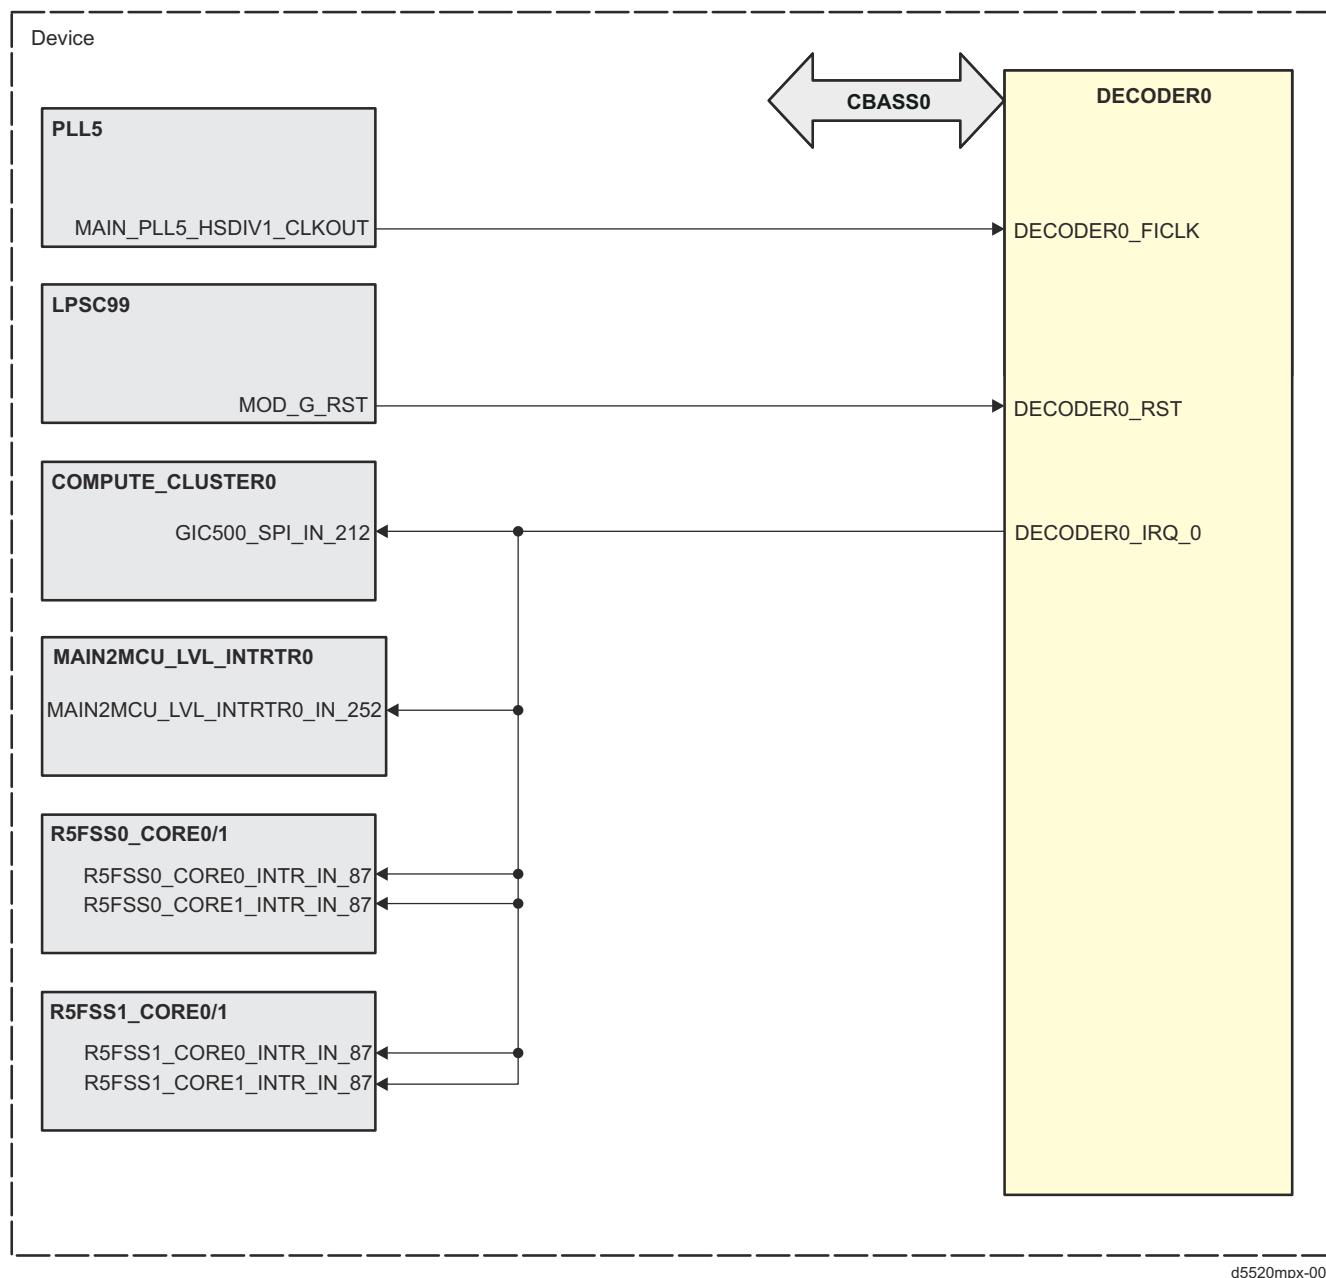

- ECC of memories
- Cache support

## 6.7.2 DECODER Integration

This section describes the DECODER integration in the device, including information about clocks, resets, and hardware requests.

### 6.7.2.1 DECODER Integration in MAIN Domain

There is one DECODER module integrated in the device MAIN domain. [Figure 6-40](#) shows the integration of DECODER module.

**Figure 6-40. DECODER Integration**

[Table 6-91](#) through [Table 6-93](#) summarize the integration of DECODER in the device MAIN domain.

**Table 6-91. DECODER Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DECODER0	PSC0	PD26	LPSC99	CBASS0

**Table 6-92. DECODER Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DECODER0	DECODER0_FICLK	MAIN_PLL5_HSDIV1_CLKOUT	PLL5	DECODER0 interface and functional clock

Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description

**Table 6-93. DECODER Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DECODER0	DECODER0_IRQ_0	GIC500_SPI_IN_212	COMPUTE_CLUSTER0	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level
		MAIN2MCU_LVL_INTRTR0_IN_252	MAIN2MCU_LVL_INTRTR0	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level
		R5FSS0_CORE0_INTR_IN_87	R5FSS0_CORE0	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level
		R5FSS0_CORE1_INTR_IN_87	R5FSS0_CORE1	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level
		R5FSS1_CORE0_INTR_IN_87	R5FSS1_CORE0	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level
		R5FSS1_CORE1_INTR_IN_87	R5FSS1_CORE1	DECODER0 signal for various interrupt conditions. The source of the interrupt can be found by polling the interrupt status registers.	Level

### Note

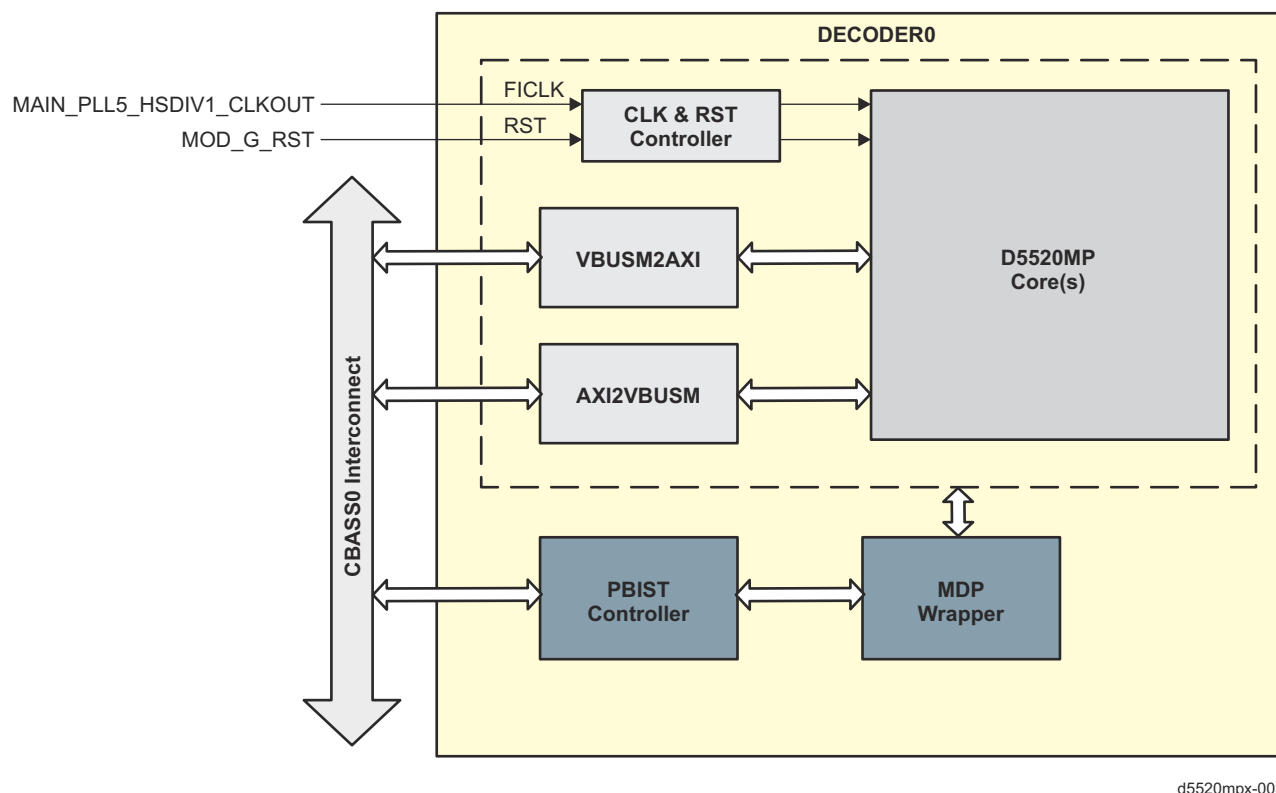

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

### 6.7.3 DECODER Functional Description

The DECODER is a multi-format video decoder which is based on D5520MP video decoder IP. The DECODER has AXI3 interfaces for both slave configuration and master data transfer. The DECODER has embedded processor which parses the bit-stream headers and does the hardware management to reduce the load requirements on the main host processor. Figure 6-41 shows the DECODER high level functional block architecture diagram.

d5520mpx-003

**Figure 6-41. DECODER Functional Block Diagram**

#### 6.7.3.1 DECODER Clock Configuration

The DECODER has single clock DECODER0\_FICLK. All the logic processing, data master interface and slave configuration interface will work on same clock.

#### 6.7.3.2 DECODER Reset

The DECODER has its own reset domain. Global reset of the DECODER is performed by activating the DECODER0\_RST signal in the LPSC99 domain.

#### 6.7.3.3 DECODER Interrupts

The DECODER has one interrupt signal DECODER0\_IRQ\_0. The decoder interrupt is generated by the D5520 core to signal various interrupt conditions.

## 6.8 Multi-Standard HD Video Encoder (ENCODER)

This section describes the dual-core multi-standard HD video encoder ENCODER module in the device.

The ENCODER module is a VXE384MP2 core PowerVR® VPU (video processor unit) from Imagination Technologies.

### 6.8.1 ENCODER Overview

The ENCODER is capable of supporting:

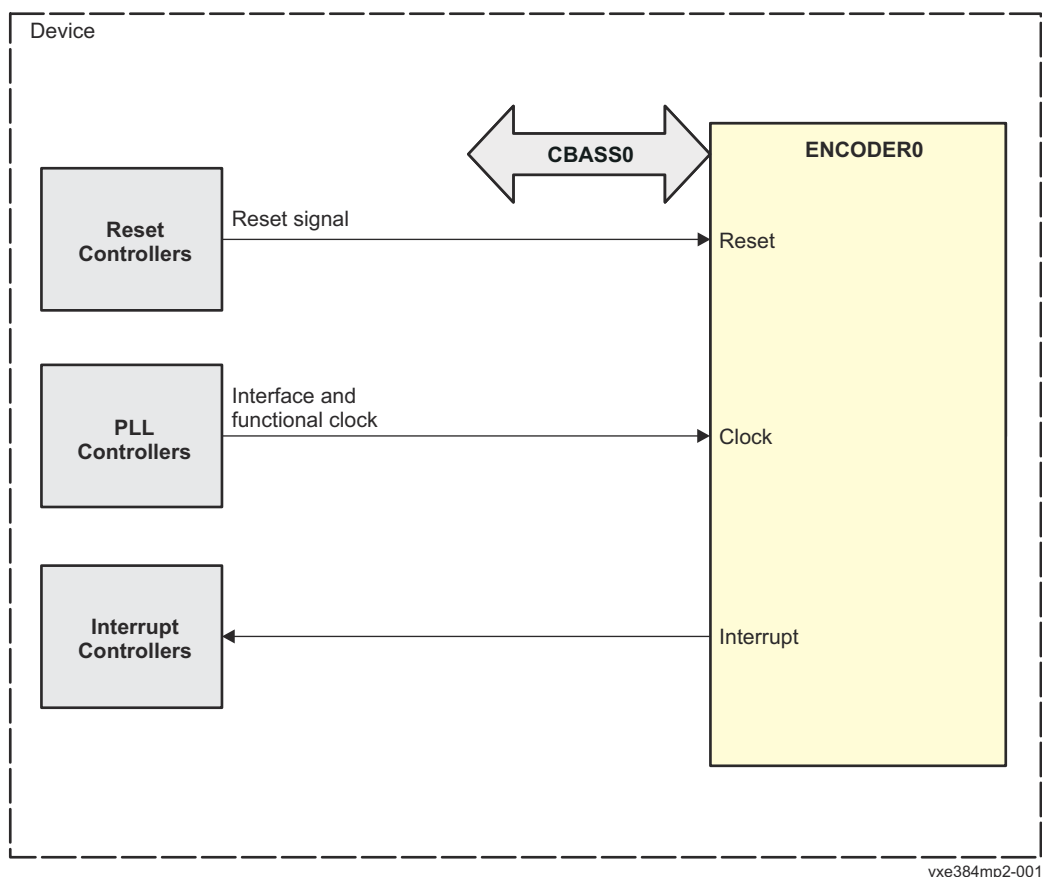

- 1x 1080p60 video stream encoding or
- 2x or 3x 1080p30 video stream encodings

The device has one instance of the ENCODER module. [Table 6-94](#) shows ENCODER module allocation within device domains.

**Table 6-94. ENCODER Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
ENCODER0	-	-	✓

[Figure 6-42](#) shows the ENCODER module overview.

**Figure 6-42. ENCODER Module Overview**

#### 6.8.1.1 ENCODER Features

The ENCODER encoder supports the following encoding schemes:

- H.264 MVC

- H.264 HP
- H.264 MP
- H.264 BP
- MPEG-4 SP
- H.263 BP

It also encodes still images in these formats:

- MPEG2 MP
- JPEG

The ENCODER also features:

- Support of multiple slices per frame (H.264) under software control
- Search range of +/-128 horizontally and +/-104 vertically
- Integrated scaler
- Dedicated hardware support for:
  - Integer motion estimation
  - Sup-pel motion estimation
  - Intra search
  - Transform and inverse transform
  - Quantization and inverse quantization
  - Motion vector prediction and estimation
  - Zigzag scan, run length and variable length encoding

#### **6.8.1.2 ENCODER Not Supported Features**

The ENCODER does not support the following features:

- ECC of memories
- Image rotation

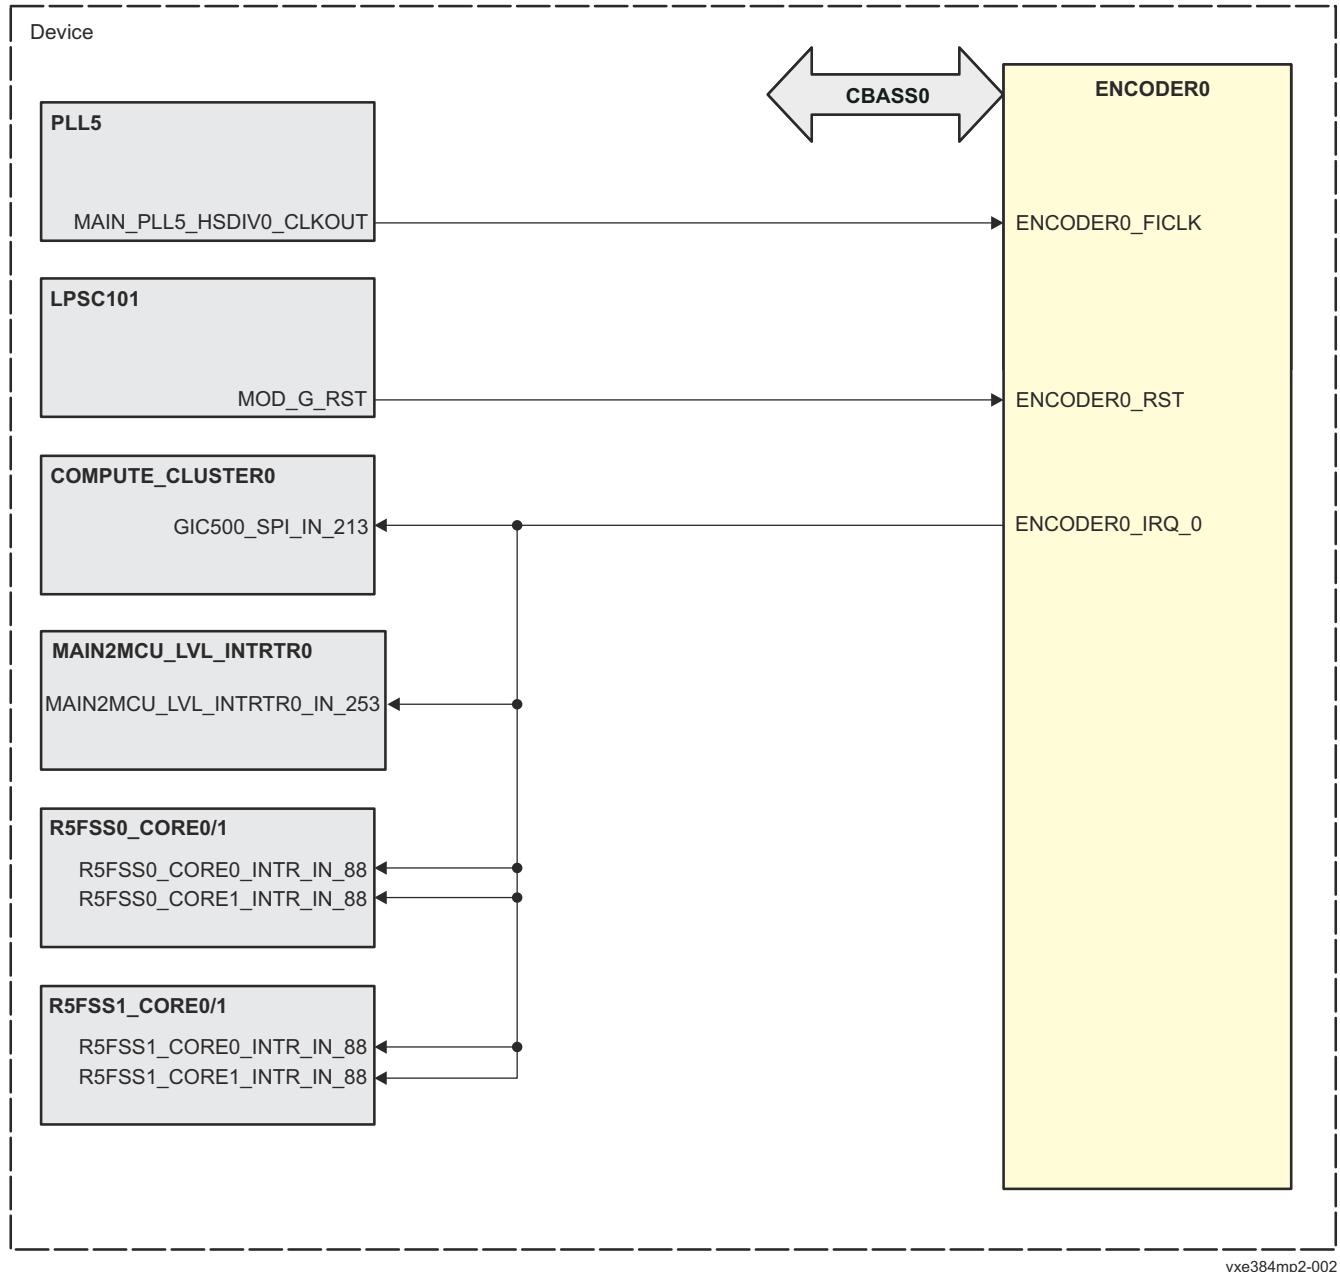

## 6.8.2 ENCODER Integration

This section describes the ENCODER integration in the device, including information about clocks, resets, and hardware requests.

### 6.8.2.1 ENCODER Integration in MAIN Domain

There is one ENCODER module integrated in the device MAIN domain. [Figure 6-43](#) shows the integration of ENCODER module.

**Figure 6-43. ENCODER Integration**

[Table 6-95](#) through [Table 6-97](#) summarize the integration of ENCODER in the device MAIN domain.

**Table 6-95. ENCODER Integration Attributes**

Module Instance	Attributes

### 6.8.3 ENCODER Functional Description

The ENCODER is a multi-format video encoder which is based on VXE384MP2 video encoder core IP. The ENCODER has AXI3 interfaces for both slave configuration and master data transfer. Figure 6-44 shows the ENCODER high level functional block architecture diagram.

**Figure 6-44. ENCODER Functional Block Diagram**

#### 6.8.3.1 ENCODER Clock Configuration

The ENCODER has single clock ENCODER0\_FICLK. All the logic processing, data master interface and slave configuration interface will work on same clock.

#### 6.8.3.2 ENCODER Reset

The ENCODER has its own reset domain. Global reset of the ENCODER is performed by activating the ENCODER0\_RST signal.

#### 6.8.3.3 ENCODER Interrupts

The ENCODER has one interrupt signal ENCODER0\_IRQ\_0. The encoder interrupt is generated by the VXE384 core to signal various interrupt conditions.

## 6.9 Vision Pre-processing Accelerator (VPAC)

This chapter describes the Vision Pre-processing Accelerator (VPAC) in the device.

### 6.9.1 VPAC Overview

The Vision Pre-processing Accelerator (VPAC) subsystem is a set of common vision primitive functions, performing pixel data processing tasks, such as: color processing and enhancement, noise filtering, wide dynamic range (WDR) processing, lens distortion correction, pixel remap for de-warping, on-the-fly scale generation, on-the-fly pyramid generation. The VPAC offloads these common tasks from the main SoC processors (ARM, DSP, etc.), so these CPUs can be utilized for differentiated high-level algorithms. The VPAC is designed to support multiple cameras by working in time-multiplexing mode. The VPAC also includes an imaging pipe, which can be integrated on-the-fly with external camera sensor, as well as does memory-to-memory (M2M) processing on pixel data.

The VPAC subsystem provides 4 processing blocks: Vision Imaging Sub-System (VISS), Lens Distortion Correction (LDC), Multi-Scalar (MSC) and Noise Filter (NF), along with Hardware Thread Scheduler (HTS), Load Store Engin (LSE), and 512 KB of internal L2 memory

The device includes a single instantiation of the VPAC subsystem. [Table 6-98](#) shows the VPAC allocation across device domains.

**Table 6-98. VPAC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
VPAC0	-	-	✓

[Figure 6-45](#) provides an overview of the VPAC subsystem.

vpac-001

**Figure 6-45. VPAC Overview**

### 6.9.1.1 VPAC Features

The VPAC includes the following processing and infrastructure sub-modules:

- **Vision Imaging Sub-System (VISS).** The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), Spatial Noise Filtering, demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
  - Performance is up to 1 pixel/cycle
  - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b) (see [Section 6.9.3.6](#))
  - Processing up to 4096 pixels/line (8MP frame)
  - Support for concurrent 12-bit and 8-bit YUV output
  - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC etc.)
  - Support for other color spaces:
    - RGB output
    - Support for color saturation and gray scale for HSV/HSL, etc.

- Support for multiple WDR/HDR formats:
  - Combined Companded format (up to 16-bit companded)
  - Separated Exposures – up to 3 frame Motion Adaptive HDR Merge
  - Staggered HDR
  - Digital Lateral Overlap (DLO)
- Support of statistics for Auto-Exposure/Auto-White-Balance or Auto-Focus (configurable option to select either AE/AWB or AF)
- Support for Flexible CFA for generating multi-plane output for any 2x2 RAW format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up to 3 directions per color plane
  - Adaptive threshold based on intensity measure
- Support for multiple color format output generation
  - Supports traditional 12-bit YUV output
  - Support of 8-bit YUV output (see [Section 6.9.3.6](#))
  - Supports RGB output (8-bit only)
  - Supports saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear output
- Global/Local Brightness and Contrast Enhancement module (16-bit)
- Spatial Noise Filter (NSF4V)
  - Supports raw input image in generic 2x2 color pattern format including Bayer pattern
  - Supports 16-bit raw input image
  - Spatially adaptive noise level threshold
  - Configurable soft or hard thresholding
  - Supports elliptical lens shading gain adjustment of adaptive noise threshold with 2 sets of independent settings
  - White Balance gain
  - Signal level detection with flexible cross-color-channel or independent averaging
- Option to bypass visual enhancement functions (NSF4V and GLBCE)
- Edge Enhancement (EE)
  - Enhance the visual quality of the image (Luma only)
  - Edge enhancer filter and the edge sharpener filter can be combined by configuration
  - Option to bypass visual enhancement functions (CAC, NSF4V, and GLBCE)
- Lens Distortion Correction (LDC) block. The LDC engine is YUV domain processor designed to perform perspective and geometric transforms. This can be used for creating several effects, including but not limited to:
  - Lens Distortion Correction, including Fish Eye Lenses
  - Epipolar rectification for Stereo
  - Generic perspective transforms for rotation scaling or Augmented Reality like effects

The output of the LDC block can be sent to external memory (DDR) or sent to other VPAC sub-module (Scalar, Noise filter) for further pre-processing via local shared memory (SL2). The LDC block provides the following main features:

- Performance up to 1 cycle/pixel (bilinear) and 2 cycles/pixel (bicubic)
- Autonomous memory-to-memory operation
- Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Supported formats (see [Section 6.9.3.6](#)):
  - YUV420 12-bit packet input and YUV420 12-bit packed output
  - YUV420 12-bit unpacked input and YUV420 12-bit unpacked output
  - YUV420 8-bit packet input and YUV420 8-bit packed output
  - YUV422 8-bit packed input and YUV420 8-bit packed output

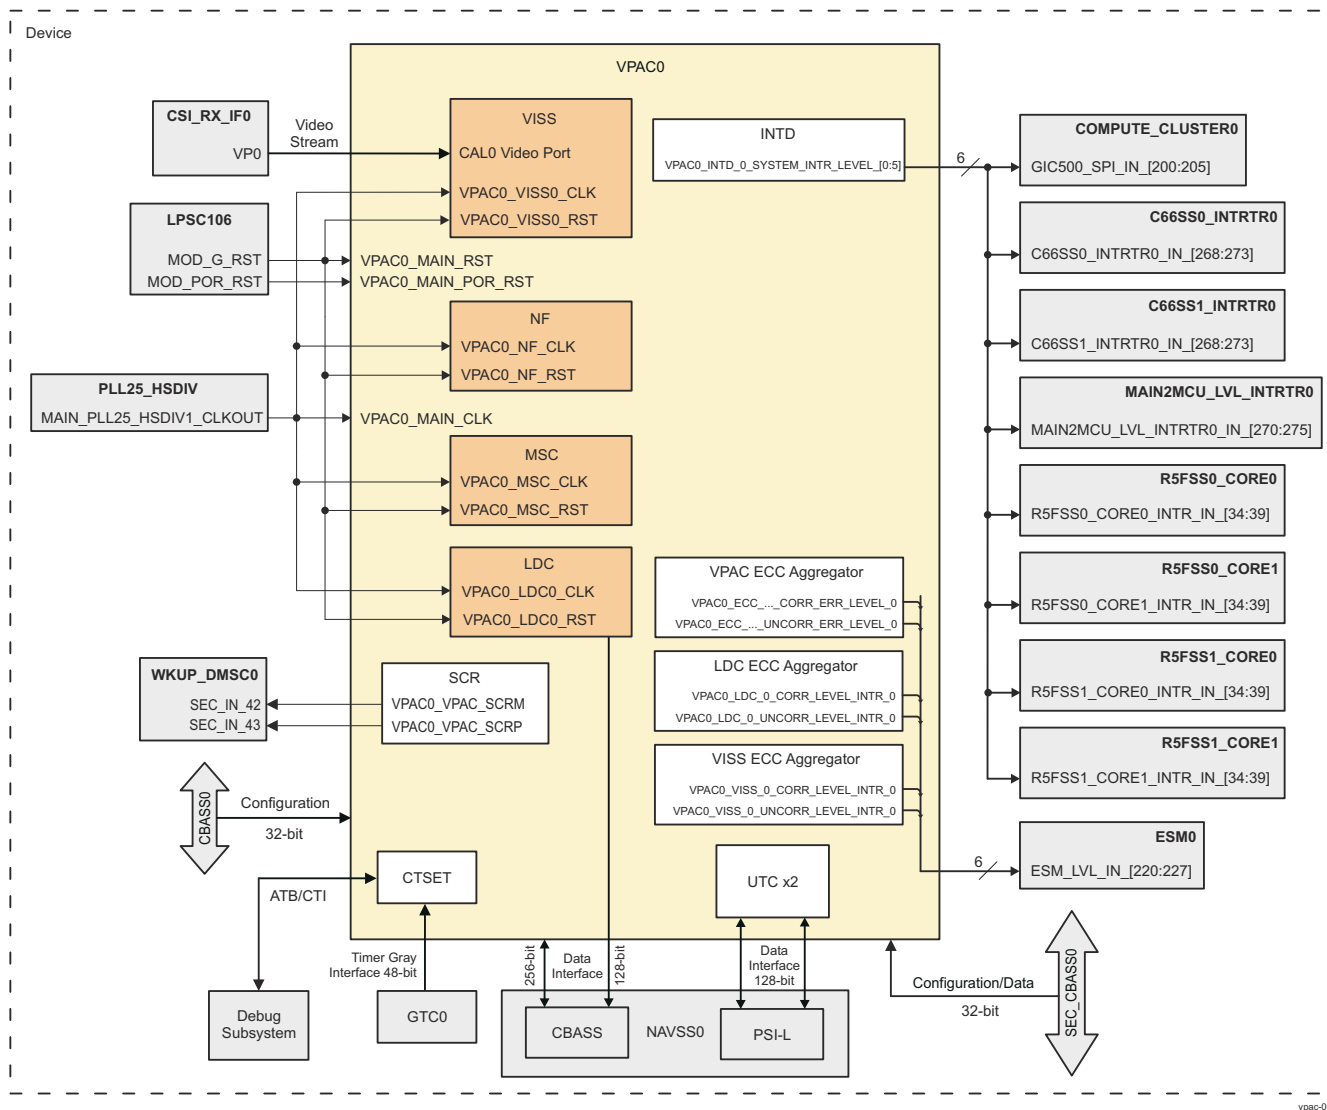

- YUV422 8-bit packed input and YUV422 8-bit packed output
  - Supports up to 8192 x 8192 image dimension
  - Pixel Interpolation
    - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
    - Bilinear interpolation mode to offer double throughput
  - Support of Luma Only or Chroma Only Mode
  - Supports variable block size frame processing (9 regions)
- Multi-Scalar (MSC) block. The MSC block reads data from memory (DDR or on-chip) to shared memory (SL2) and generates up to 10 scaled outputs from a given input with various scaling ratios (between 1x and x0.25). The output of the MSC block can be sent to external memory (DDR) from the local shared memory (SL2), or can be further noise filtered using the VPAC Noise Filter (NF) block. The MSC supports two independent threads (scalars), which combined can generate up to max 10 scales. The MSC block provides the following main features:
  - Multi-scaling capable: 10 simultaneous scaled outputs from 1 or 2 input planes; up to 2 simultaneous processing thread with total of 10 scaled output with 1 to N and 1 to M configurations (where N+M <=10)
  - Each scaling engine can be configured to perform Pyramid or inter-octave scale generation
  - Scaling ratio supported: 1x ~ x/4 (with 1x scaling, MSC can perform a 3~5-tap generic separable convolution filtering)
  - 5-tap separable filter kernel implementation
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Poly phase implementation with support of 64 or 32 phases poly phase support
  - 4 sets of 5-tap x 32 phase coefficients (two can be combined to support 5-tap x 64 phase coefficients and one of set can hold additional 5-tap customer filter coefficients for non-resizing filter)
  - 2 additional sets of 5-tap Gaussian filter coefficients (single-phase) dedicated for Pyramid (Octave) generation
  - Coefficients in 10-bit (S10Q8 format - signed value of 10 bits with 8-bit fraction)
  - Separate initial horizontal and vertical phase programming option
  - Support for two planes of data processing
    - Data in a plane can be uniform (for example, Y plane) or interleaved (Cb/Cr interleaved)
  - 8-bit or 12-bit component data
  - Performance up to 1 input pixel/cycle
  - Output data rate is dependent on downscaling ratio
  - Programmable input and output ROI (or clipping) for each scaler
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (frame resolution support is not constrained by MSC line buffer)
- Noise Filter (NF). The NF block reads data from memory (DDR or on-chip) to shared memory (SL2) and does Bilateral filtering to remove noise. The output of the NF block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using the MSC block. The NF block provides the following main features:
  - Support for bilateral and general filtering
  - Supports filter size up to 5x5
  - Supports true 2D bilateral filtering
  - Supports filter size up to 5x5 of programmable static weights
  - LUT based bilateral weights generation (8-bit for weight)
  - Supported formats: one plane (interleaved plane and non-interleaved) YUV 420, 12-bit or 8-bit
  - Performance up to 1 pixel/cycle
- Hardware Thread Scheduler (HTS). The HTS block used for inter-processor communication among various VPAC sub-modules (VISS, LDC, Scalar, and NF) and with the local DMA Engine (UTC). The HTS block provides the following main features:
  - Scheduling the HWA threads and associated tasks
  - Enables rate-controlled task execution
  - Support running several independent threads asynchronously in the sub-system
  - Debug functions:
    - Halting HWA threads at logical task boundary

- Handling pipeline suspend and subsequent abort by software intervention
- Shared Level 2 (SL2) memory. The SL2 is used as intermediate storage for Hardware Accelerator (HWA) to exchange data across VPAC sub-modules (that is, VISS, LDC, MSC, and NF) and from DDR/System Memory. VPAC supports Realtime and Non-Realtime processing threads simultaneously.

### 6.9.2 VPAC Integration

This section describes the VPAC integration in the device MAIN domain, including information about clocks, resets, and hardware requests.

There is one VPAC subsystem integrated in the device MAIN domain - VPAC0. [Figure 6-46](#) shows the integration of VPAC.

**Figure 6-46. VPAC Integration**

[Table 6-99](#) through [Table 6-101](#) summarize the integration of VPAC in the device MAIN domain.

**Table 6-99. VPAC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

**Table 6-99. VPAC Integration Attributes (continued)**

VPAC0	PSC0	PD29	LPSC106	CBASS0 NAVSS0_CBASS NAVSS0_PSI_L SEC_CBASS0

### 6.9.3 VPAC Subsystem Level

This section covers VPAC subsystem-level details.

#### 6.9.3.1 VPAC Subsystem Clocks

Each block within the VPAC subsystem receives its own clocking signal:

- MAIN\_CLK is the operation clock for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, INTD, etc.
- VISS0\_CLK is the operation clock for the VISS and its sub-modules
- LDC0\_CLK is the operation clock for the LDC module
- MSC\_CLK is the operation clock for the MSC module
- NF\_CLK is the operation clock for the NF module

For more details on the source of each clock at SoC level, see *VPAC Integration*.

#### 6.9.3.2 VPAC Subsystem Resets

Each block within the VPAC subsystem can be reset through its own HW reset signal:

- MAIN\_RST is the reset for all infrastructure modules, such as UTC/DRU, HTS, ECC Aggregator, etc.
- VISS0\_RST is the reset for the VISS and its sub-modules
- LDC0\_RST is the reset for the LDC module
- MSC\_RST is the reset for the MSC module
- NF\_RST is the reset for the NF module

For more details on the source of each reset signal at SoC level, see *VPAC Integration*.

#### 6.9.3.3 VPAC Subsystem Interrupts

The VPAC subsystem outputs six physical system interrupt lines: VPAC\_LEVEL\_0\_INTR through VPAC\_LEVEL\_5\_INTR. For more information on how the interrupt lines are connected at SoC level, see *VPAC Integration*. The interrupt aggregation within the VPAC subsystem is done using the internal INTD module. Each interrupt line can be mapped to the same list of source interrupt events generated by the modules within the VPAC subsystem.

[Table 6-102](#) shows the INTD interrupt control registers for each VPAC interrupt line. Each interrupt line has a separate set of registers for level and pulse input event types. Each bit in a register corresponds to a particular interrupt event. For more details on the mapping of interrupt events to INTD register bits, see [Table-XXX](#) further below.

- The ENABLE registers enable the mapping of the internal VPAC interrupt events, generated by a module within the VPAC subsystem, to the VPAC output system interrupt lines. Writing a '1' in a register bit position allows the corresponding module interrupt event to trigger the respective system interrupt. Writing a '0' in the same bit position blocks the module interrupt event from triggering the system interrupt.
- The ENABLE\_CLR registers disables the mapping of the internal VPAC interrupt events to the VPAC output system interrupt lines.
- The STATUS registers are used to capture which VPAC sub-module interrupt events, that have been mapped to a system interrupt, are active and pending. This status is used when multiple module interrupts are grouped into a single system interrupt, so the software can read the status register to determine exactly which module interrupt has caused the system interrupt.
  - For level interrupts, the status is based on the active level of the module interrupt input, and when the input is inactive then the status is inactive as well.
  - For pulsed interrupts, the status is set upon the pulse and reflects a pending status and software must clear the pending status since the module does not indicate the inactive status (unlike a level interrupt, which does).
- The STATUS\_CLR registers allows software to clear the pending status of interrupt events. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts.

**Table 6-102. VPAC Subsystem Interrupt Control Registers**

The VISS interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_0 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_0 registers. [Table 6-103](#) provides more details on the VISS interrupt events. All VISS interrupts are single pulse event signals.

**Table 6-103. VPAC Subsystem VISS Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	RAWFE_CFG_ERR_INTR	Config read or write memory access occurred during functional operation and likely corrupted functional operation. VISS merges all config error sources from RawFE and refer to RawFE spec for the entire error source list.
1	RAWFE_AEW_PULSE_INTR	H3A AEW interrupt.
2	RAWFE_AF_PULSE_INTR	H3A AF interrupt.
3	RAWFE_H3A_PULSE_INTR	H3A interrupt.
4	RAWFE_H3A_BUF_OVRFLOW_PULSE_INTR	H3A output buffer overflow.
5	NSF4V_LINEMEM_CFG_ERR_INTR	VBUSP diagnostic read access of RAM, while NSF data using RAM for functional purpose.
6	NSF4V_HBLANK_ERR_INTR	Horizontal Blanking too short between lines.
7	NSF4V_VBLANK_ERR_INTR	Vertical Blanking too short between frames.
8	GLBCE_CFG_ERR_INTR	Either non-shadowed registers written or static memories are accessed during active window.
9	GLBCE_FILT_START_INTR	GLBCE started filtering. This interrupt is issued at the rising edge of filtering signal.
10	GLBCE_FILT_DONE_INTR	GLBCE ended filtering. This interrupt is issued at the falling edge of filtering signal.
11	GLBCE_HSYNC_ERR_INTR	Generated when delayed HS/HE signals doesn't match with derived signals from GLBCE core.

**Table 6-103. VPAC Subsystem VISS Interrupt Events (continued)**

Register Bit	Interrupt Event Name	Description
12	GLBCE_VSYNC_ERR_INTR	Generated when delayed VS/VE signals doesn't match with derived signals from GLBCE core.
13	GLBCE_VP_ERR_INTR	This interrupt is issued, if there is a data input while filtering is high.
14	FCFA_CFG_ERR_INTR	Either non-shadowed registers written or line memories are accessed during active window.
15	FCC_CFG_ERR_INTR	Configuration access to registers/memories has corrupted functional operation. Configuration read or write memory access occurred during functional operation. Merged independent error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.
16	FCC_OUTIF_OVF_ERR_INTR	FIFO overflow on FIFO for Y12 LSE I/F. Merged all FCC output overflow error sources at VISS. Refer to Section <i>VISS Flexible Color Processing (FCP)</i> for all sources.
17	FCC_HIST_READ_ERR_INTR	Host was not able to read the entire histogram mem between VS-VE window (triggered when the first access to histogram has been performed but the last has not been performed).
18	EE_CFG_ERR	Configuration happened to EE regions causing corruption during frame processing.
19	EE_SYNCOVF_ERR	EE horizontal synchronization FIFO overflow interrupt.
20	LSE_FR_DONE_EVT_INTR	LSE frame done interrupt.
21	LSE_SL2_RD_ERR_INTR	Set whenever there is an error response on VBUSM read command for any input channel.
22	LSE_SL2_WR_ERR_INTR	Set whenever there is an error response on VBUSM write command for any output channel.
23	LSE_CAL_VP_ERR_INTR	Set whenever one of the following input frame errors is detected at VPORT_INPUT.
24	LSE_OUT_FR_START_EVT_INTR	Output Frame Start (from VISS top level).

The LDC interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_1 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_1 registers. [Table 6-104](#) provides more details on the LDC interrupt events. All LDC interrupts are single pulse event signals.

**Table 6-104. VPAC Subsystem LDC Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	LDC_PIX_IBLK_OUTOFBOUND_INTR	Back mapped pixel co-ordinate goes out of the pre-computed input pixel bounding box.
1	LDC_MESH_IBLK_OUTOFBOUND_INTR	Block mesh co-ordinate goes out of the pre-computed mesh bounding box.
2	LDC_PIX_IBLK_MEMOVF_INTR	Input Pixel block memory overflow.
3	LDC_MESH_IBLK_MEMOVF_INTR	Mesh block memory overflow.
4	LDC_IFR_OUTOFBOUND_INTR	Back mapped input co-ordinate goes out of input frame range.
5	LDC_INT_SZOVF_INTR	Affine and perspective transform precision overflow error.
6	LDC_FR_DONE_EVT_INTR	Frame done LDC.
7	LDC_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
8	LDC_VBUSM_RD_ERR_INTR	Error on Input VBUSM Read interface.

The MSC interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_2 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_2 registers. [Table 6-105](#) provides more details on the MSC interrupt events. All MSC interrupts are single pulse event signals.

**Table 6-105. VPAC Subsystem MSC Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	MSC_LSE_FR_DONE_EVT_0_INTR	Frame done MSC processing thread 0.
1	MSC_LSE_FR_DONE_EVT_1_INTR	Frame done MSC processing thread 1.
2	MSC_LSE_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.
3	MSC_LSE_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.

The NF interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_2 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_2 registers. [Table 6-106](#) provides more details on the NF interrupt events. All NF interrupts are single pulse event signals.

**Table 6-106. VPAC Subsystem NF Interrupt Events**

Register Bit	Interrupt Event Name	Description
8	NF_FR_DONE_INTR	Frame done NF.
9	NF_SL2_WR_ERR_INTR	Error on SL2 VBSUM Write interface.
10	NF_SL2_RD_ERR_INTR	Error on SL2 VBSUM Read interface.

The HTS interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_3 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_3 registers. [Table 6-107](#) provides more details on the HTS interrupt events. All HTS interrupts are single pulse event signals, save for the SPARE\_PEND\_xxx interrupts, which can be both single pulse events and level events.

**Table 6-107. VPAC Subsystem HTS Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	PIPE_DONE_0	Pipeline 0 done.
1	PIPE_DONE_1	Pipeline 1 done.
2	PIPE_DONE_2	Pipeline 2 done.
3	PIPE_DONE_3	Pipeline 3 done.
4	PIPE_DONE_4	Pipeline 4 done.
5	PIPE_DONE_5	Pipeline 5 done.
6	PIPE_DONE_6	Pipeline 6 done.
7	TDONE	HWA0 thread done.
8	RESERVED	Reserved.
9	TDONE	HWA2 thread done.
10	RESERVED	Reserved.
11	TDONE	HWA4 thread done.
12	TDONE	HWA5 thread done.
13	TDONE	HWA6 thread done.
14	SPARE_DEC_0	Spare 0 scheduler decrement pulse (ehost mode).
15	SPARE_DEC_1	Spare 1 scheduler decrement pulse (ehost mode).
16	SPARE_PEND_0_PULSE	Spare 0 scheduler pend assertion (ehost mode).
17	SPARE_PEND_0_LEVEL	Spare 0 scheduler pend assertion (ehost mode).
18	SPARE_PEND_1_PULSE	Spare 1 scheduler pend assertion (ehost mode).
19	SPARE_PEND_1_LEVEL	Spare 1 scheduler pend assertion (ehost mode).
20	WATCHDOGTIMER_ERR_0	Watchdog Timeout Error for HWA0.
21	RESERVED	Reserved.
22	WATCHDOGTIMER_ERR_2	Watchdog Timeout Error for HWA2.
23	RESERVED	Reserved.
24	WATCHDOGTIMER_ERR_4	Watchdog Timeout Error for HWA4.

**Table 6-107. VPAC Subsystem HTS Interrupt Events (continued)**

Register Bit	Interrupt Event Name	Description
25	WATCHDOGTIMER_ERR_5	Watchdog Timeout Error for HWA5.
26	WATCHDOGTIMER_ERR_6	Watchdog Timeout Error for HWA6.

The UTC interrupt events indicating TR complete are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_4 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_4 registers for UTC0, and VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_5 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_5 plus VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_6 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_6 registers for UTC1. [Table 6-108](#) provides more details on the UTC TR complete interrupt events. All UTC TR complete interrupts are single pulse event signals.

**Table 6-108. VPAC Subsystem UTC TR Complete Interrupt Events**

Register Bit	Interrupt Event Name	Description
31-0	UTC0_COMPLETE_INTR[31:0]	TR complete interrupt.
31-0 plus 31-0	UTC1_COMPLETE_INTR[63:0]	TR complete interrupt.

The UTC interrupt events indicating error are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_7 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_7 registers for both UTC0 and UTC1. [Table 6-109](#) provides more details on the UTC error interrupt events. All UTC error interrupts are single pulse event signals.

**Table 6-109. VPAC Subsystem UTC Error Interrupt Events**

Register Bit	Interrupt Event Name	Description
0	UTC0_ERR	UTC0 error.
1	UTC1_ERR	UTC1 error.
2	UTC0_PROT_ERR_INTR	UTC0 protocol violation.
3	UTC1_PROT_ERR_INTR	UTC1 protocol violation.

The CTSET interrupt events are mapped to register bits within the VPAC\_INTD\_xxx\_VPAC\_OUT\_0\_7 through VPAC\_INTD\_xxx\_VPAC\_OUT\_5\_7 registers. [Table 6-110](#) provides more details on the CTSET events. All CTSET error interrupts are single pulse event signals.

**Table 6-110. VPAC Subsystem CTSET Interrupt Events**

Register Bit	Interrupt Event Name	Description
4	CTM_PULSE_INTR	Counter Timer Module (CTM) pulse interrupt.

#### 6.9.3.4 VPAC Subsystem SL2 Memory Infrastructure

The SL2 memory subsystem implements an interconnect between DMA and HWAs initiators. It contains 512KB Shared L2 memory to acts temporary local memory to transfer data between external memory and HWAs.

The SL2 memory does not implement ECC, as it contains mostly pixel data.

#### 6.9.3.5 VPAC Subsystem DMA Infrastructure

Two UTC instances are used inside the VPAC subsystem. UTC0 deals with real time (RT) transfer , and UTC1 is used for non-realtime (NRT) transfer. Both UTC0 and UTC1 data transfer channels are used for DMA transfers in and out of the VPAC SL2 memory. All 32 channels of the UTC0 are mapped on *channel\_number* = [95:64] and are recommended to be used for real time data transfer only. All 64 channels of UTC1 are mapped on *channel\_number* = [63:0] and are recommended to be used for all other DMA transfer needs of the VPAC subsystem.

All data movement transactions at VPAC subsystem boundary are multiples of aligned 128-byte transfers.

### 6.9.3.6 VPAC Subsystem Data Formats Support

Table 6-111 summarizes the data formats supported in VPAC Subsystem.

**Table 6-111. VPAC Subsystem Data Formats Support**

No	Module	Input			Output		
		Bit-depth	Chroma (NV12)	Packing	Bit-depth	Chroma (NV12)	Packing
1	VISS	12	RAW	no	12 & 8	420	yes
2		14	RAW	no	12 & 8	420	yes
3		16	RAW	no	12 & 8	420	yes
4		8	RAW	yes	8	420	yes
5		12	RAW	yes	12 & 8	420	yes
5		All of the above			8	422	yes
6	LDC	8	422	yes	8	420	yes
7		8	422	yes	8	422	yes
8		8	420	yes	8	420	yes
9		12	420	yes/no	12	420	yes
10		12	420	yes/no	12 & 8	420	no
11	MSC	12	Planar	yes	12	planar	yes
12		8	Planar	yes	8	planar	yes
13	NF	12	Y/UV (NV12)	yes	12	UV (NV12)	yes

### 6.9.3.7 VPAC Subsystem Debug Features

The VPAC subsystem is a combination of multiple asynchronous pipelines running concurrently. The Counter, Timer and System Event Trace (CTSET) module within the VPAC subsystem provides the following main features:

- Monitoring up to 255 VPAC events.
- ATB interface compliant trace packets (synchronous to VPAC clock domain).
- Counter (count=8) and Timer (count=4).
- All debug events can be configured to be either selected for trace packet, timer or counter features.
- In one of the combination, debug events can be selected to for timer event out to be used to generate external CTI compliant trigger.

For more information on the CTSET module operation, see Chapter *On-Chip Debug*.

Table 6-112 lists the VPAC subsystem events that are mapped on the CTSET module.

**Table 6-112. VPAC Subsystem CTSET Event List**

Index	Event Name	HWA	Event Type	Event Description
0	viss_err	VISS0	pulse	VISS Related Error message (config, ovf, sync, blank, access, vp) <sup>(1)</sup>
1	rawfe_h3a_pulse_intr	VISS0	pulse	H3A interrupt
2	rawfe_dbg_ctl_vs_event	VISS0	pulse	Verticle start in the beginning of the RAWFE pipeline
3	rawfe_dbg_ctl_ve_event	VISS0	pulse	Verticle end in the beginning of the RAWFE pipeline
4	rawfe_dbg_ctl_hs_event	VISS0	pulse	Horizontal start in the beginning of the RAWFE pipeline
5	rawfe_dbg_ctl_he_event	VISS0	pulse	Horizaontal end in the beginning of the RAWFE pipeline
6	rawfe_dbg_ctl_lse_slv_stall_event	VISS0	pulse	RAWFE is stalling lse slave interface due to FCP or MTC stall
7	rawfe_dbg_ctl_lse_mst_stall_event	VISS0	pulse	H3A master interface to LSE is stalled

**Table 6-112. VPAC Subsystem CTSET Event List (continued)**

Index	Event Name	HWA	Event Type	Event Description
8	rawfe_dbg_ctl_lse_intf_stall_event	VISS0	pulse	Within a frame (VS to VE at RFE i/p) LSE is not sending data to RFE
9	rawfe_dbg_ctl_x_y_match_event	VISS0	pulse	X,Y pixel position has reached the start of RAWFE pipeline
10	rawfe_dbg_ctl_dpc_otf_corr_event	VISS0	pulse	DPC OTF corrected a pixel position
11	rawfe_dbg_ctl_pipe_adv_event	VISS0	pulse	Active pipeline advancement
12	nsf4v_in_hs_event	VISS0	pulse	Start of Active Line at NSF4V input
13	nsf4v_in_vs_event	VISS0	pulse	Start of Active Frame at NSF4V input
14	nsf4v_in_he_event	VISS0	pulse	End of Active Line at NSF4V output
15	nsf4v_in_ve_event	VISS0	pulse	End of Active Frame at NSF4V output
16	glbce_filt_start_intr	VISS0	pulse	GLBCE filtering start ( generated at the rising edge of filtering signal)
17	glbce_filt_done_intr	VISS0	pulse	GLBCE filtering done (generated at falling edge of filtering signal)
18	glbce_sol_event	VISS0	pulse	Start of Active Line at GLBCE input
19	glbce_sof_event	VISS0	pulse	Start of Active Frame at GLBCE input
20	glbce_eol_event	VISS0	pulse	End of Active Line at GLBCE output
21	glbce_eof_event	VISS0	pulse	End of Active Frame at GLBCE output
22	fcfa_sol_event	VISS0	pulse	Start of line processing for CFA input
23	fcfa_sof_event	VISS0	pulse	Start of frame processing for CFA input
24	fcc_stall_event	VISS0	pulse	Stall has occurred on any one of the output LSE interfaces
25	fcc_eol_if_y12_event	VISS0	pulse	End of line on Y12 LSE I/f (only generated for valid lines)
26	fcc_eof_if_y12_event	VISS0	pulse	End of frame on Y12 LSE I/f
27	fcc_eol_if_uv12_event	VISS0	pulse	End of line on UV12 LSE I/f (only generated for valid lines)
28	fcc_eof_if_uv12_event	VISS0	pulse	End of frame on UV12 LSE I/f
29	fcc_eol_if_y8r8_event	VISS0	pulse	End of line on Y8R8 LSE I/f (only generated for valid lines)
30	fcc_eof_if_y8r8_event	VISS0	pulse	End of frame on Y8R8 LSE I/f
31	fcc_eol_if_c8g8_event	VISS0	pulse	End of line on C8G8 LSE I/f (only generated for valid lines)
32	fcc_eof_if_c8g8_event	VISS0	pulse	End of frame on C8G8 LSE I/f
33	fcc_eol_if_s8b8_event	VISS0	pulse	End of line on S8B8 LSE I/f (only generated for valid lines)
34	fcc_eof_if_s8b8_event	VISS0	pulse	End of frame on S8B8 LSE I/f
35	fcc_flexcc_eop_event	VISS0	pulse	End of processing (EOP) for FlexCC
36	lse_fr_done_evt_intr	VISS0	pulse	Frame processing done event
37	lse_out_fr_start_evt_intr	VISS0	pulse	Travelled Frame Start from LSE Core
39	ldc_err	LCD0	pulse	LDC processing error <sup>(2)</sup>
40	mesh_iblk_fetch_start_event	LCD0	pulse	Input mesh block fetch start event
41	mesh_iblk_fetch_done_event	LCD0	pulse	Input mesh block fetch completion event
42	pix_iblk_fetch_start_event	LCD0	pulse	Input pixel block fetch start event (Active for both Y and C)
43	pix_iblk_fetch_done_event	LCD0	pulse	Input pixel block fetch done event (Active for both Y and C)
44	frame_start_event	LCD0	pulse	Frame processing start event

**Table 6-112. VPAC Subsystem CTSET Event List (continued)**

Index	Event Name	HWA	Event Type	Event Description
45	lse_stall_event	LCD0	pulse	LSE write stall event
46	coreblk_proc_done_event	LCD0	pulse	LDC Core Block processing done
47	coreblk_wr_done_event	LCD0	pulse	LDC Core block write complete on C12 channel
48	coreyblk_wr_done_event	LCD0	pulse	LDC Core block write complete on Y12 channel
49	vpac_ldc_fr_done_evt_intr	LCD0	pulse	Frame processing done event
51	msc_err	MSC	pulse	Error Response for VBUSM read/Write SL2 access (msc_lse_sl2_rd_err_intr    msc_lse_sl2_wr_err_intr)
52	msc_lse_fr_done_evt_0_intr	MSC	pulse	Frame processing done event for MSC Thread0
53	msc_lse_fr_done_evt_1_intr	MSC	pulse	Frame processing done event for MSC Thread1
55	nf_err	NF	pulse	Error Response for VBUSM read/Write SL2 access (vpac_nf_sl2_wr_err_intr    vpac_nf_sl2_rd_err_intr)
56	vpac_nf_fr_done_evt_intr	NF	pulse	Frame processing start event

254:239	[utc1,utc0] {wrrreq,1'b0,wrrreq stall,wrrreq valid creq, rd rreq stall, rd valid rreq, rd creq stall, rd valid creq}	HTS	pulse	MMR config to select external ctset events or UTC SL2 access control signals

- (1) The signals combined to generate the viss\_err event are: rawfe\_cfg\_err\_intr || glbce\_cfg\_err\_intr || fcfa\_cfg\_err\_intr || fcc\_cfg\_err\_intr || ee\_cfg\_err || nsfv4\_line\_cfg\_err || rawfe\_h3a\_buf\_overflow\_pulse\_intr || nsf4v\_hblank\_err\_intr || nsf4v\_vblank\_err\_intr || glbce\_vp\_err\_intr || glbce\_hsync\_err\_intr || glbce\_vsync\_err\_intr || fcc\_outif\_ovf\_err\_intr || fcc\_hist\_read\_err\_intr || ee\_syncovf\_err\_intr || lse\_sl2\_rd\_err\_intr || lse\_sl2\_wr\_err\_intr || lse\_cal\_vp\_err\_intr.
- (2) The signals combined to generate the ldc\_err event: pix\_iblk\_outofbound\_intr || mesh\_iblk\_outofbound\_intr || pix\_iblk\_memovf\_intr || mesh\_iblk\_memovf\_intr || ifr\_outofbound\_intr || int\_szovf\_intr || vpac\_ldc\_sl2\_wr\_err\_intr || vpac\_ldc\_vbusm\_rd\_err\_intr.

The VPAC subsystem also supports halting an execution pipeline using external or user halt request. Halting a pipeline is achieved by not granting thread start to HWA. Once halted, VPAC waits for an external sync trigger or config resume to restart execution. VISS, MSC and NF modules halt at line boundary, and LDC halts at block boundary.

The VPAC subsystem supports generic debug capability/features and ARM cross trigger interface for debug triggers:

- Halting the HWA threads on debug request input at logical trigger boundary.
- Continue/restart VPAC from halted state (step/continue) based on external sync trigger and HTS\_DBG\_CNTL register.
- Debug compliant dbg\_attn output after processing external halt request and when VPAC halts debug enabled pipelines.
- CTI (Cross Trigger Interface) compliant out halted trigger after processing external halt request and reaching halted state of VPAC.
- Stalling all pipelines of VPAC (with configurable option to disable impact of debug features on a pipeline).
- Indicate to Host through readable debug\_rdy bit in HTS to indicate readiness of HWA resource in case of halted (dbgattn asserted)

The VPAC subsystem debug capability supported is as captured in the HTS\_DBG\_CAP register. Ext\_halt, ext\_sync, hwa\_halted are CTI (Cross Trigger Interface) mapped async trigger interface (refer to the async protocol of trigger interface in the ARM® CoreSight™ Architecture Specification).

The VISS module, when used in OTF mode, must not be included as debuggable module within VPAC. VISS must be disabled (HTS: debug pipeline disable) to respond to halt request, otherwise behavior is undefined. The VISS module, when used in memory to memory mode, can be halted. But VISS LUTs must not be read during halted state, as it can corrupt the design pipeline.

#### 6.9.3.8 VPAC Subsystem Security Features

The VPAC subsystem implements region basead firewall on slave endpoints within config CBASS and SL2 CBASS. Both CBASS is driven by independent DMSC FW interface from SoC level. All internal masters on SL2 SCR are configured with ISC. [Figure 6-47](#) provides FW/ISC summary.

Module	Interconnet	Security component	Parameter	Endpoints	FW_ID( dec)	FW/ISC/QoS config address offset(hex)	privID reset value( dec)
VPAC	SCRP	Region FW	2 region	ECC AGG	6048	0	
			1 region	VPAC_TOP	6049	400	
			8 region	INTD	6050	800	
			8 region	HTS	6051	C00	
			1 region	CTSET	6052	1000

## 6.9.4 VPAC Vision Imaging Subsystem (VISS)

This chapter describes the Vision Imaging Subsystem (VISS).

### 6.9.4.1 VISS Top Level

This section describes the Vision ISS (VISS) top level details.

#### 6.9.4.1.1 VISS Features

The VPAC includes the following processing and infrastructure sub-modules:

- Vision Imaging Sub-System (VISS). The vision imaging pipe does image processing on raw data which includes Wide Dynamic Range (WDR) merge, Defect Pixel Correction (DPC), Lens Shading Correction (LSC), Global/Local Brightness and Contrast Enhancement (GLBCE), demosaicing, color conversion, and Edge Enhancement (EE). It can operate on sensor data either on-the-fly or in memory-to-memory mode. The VISS provides the following main features:
  - Performance is 1 pixel per cycle
  - Up to 16-bit input RAW formats (8b, 12b, 14b, 16b)
  - Support for concurrent 12-bit and 8-bit YUV output
  - Support for generic 2x2 RAW format (Bayer, RCCB, RCCC etc.)
  - Support for other color spaces:
    - RGB output
    - Support for color saturation and gray scale for HSV/HSL, etc. (Hue is not supported)

#### 6.9.4.1.2 VISS Block Diagram

The VISS module does on-the-fly processing on raw pixels captured from camera sensor (via CSI RX module). It also does memory to memory processing (via DDR memory) for data captured from other sources at SoC level. [Figure 6-48](#) is simplified block diagram of VISS top level.

**Figure 6-48. VISS Block Diagram**

The VISS consists of the following Hardware Accelerators (HWAs):

- RFE (RAW-FE): The RAW Frond End HW block does RAW pixel (that is, Bayer, RCCC, RGBW, etc.) processing on captured image data from sensor and pass-on to NSF4V, GLBCE block, and then to Flexible Color Processing (FCP) HW block for demosaicing and color conversion.
- NSF4V: Spatial Noise Filter supporting generic 2x2 pixel format with 16-bit pixel size. The NSF4V module can be bypassed in the applications where visual enhancement is not desired.

- GLBCE: The GLBCE module is used for dynamic range control within image for visual quality. If contrast enhancement on input image is required for visual quality, the RFE output is processed by the NSF4v and GLBCE blocks. Otherwise, the RFE output is bypassed to FCP.
- FCP: The Flexible Color Processing HW receives data from the GLBCE and does demosaicing and color conversion. The output of FCP is sent to VPAC shared memory to be written into DDR for the rest of the vision processing by programmable processors (for example, DSP or Arm), or other Vision HW blocks (for example, DMPAC).
- LSE: The Load and Store Engine is an infrastructure block, which performs the following functions:
  - CAL video port: The CSI RX module at SoC level receives CSI-2 sensor data, extracts pixels and drives the result data on its video port interface. The video port is mapped onto one of LSE input interfaces for on-the-fly image processing to reduce DDR bandwidth and latency. The LSE also provides horizontal and vertical blanking cycles to allow core data path to settle at proper boundary of line and frame.
  - SL2 memory access: This module supports load/store data from/to SL2 using VBUSM interface. Loaded data from SL2 are passed on to unpacker function of LSE for RFE. Packed data after FCP/H3A processing is written into SL2.
  - Pixel pack/unpack: Source data (512-bit) for RFE processing is loaded from SL2 and passed onto unpacker function for pixel extraction. Extracted pixels are driven on to the video port of RFE. Similarly, the FCP produced pixels are passed through packer function for eventual write into SL2. The H3A generated data is pseudo mapped as pixels of 32-bit for packing purpose and directly driven by the RFE.
  - Event control: The HTS events are generated at line level. These events are routed to LSE to start the processing. For each consumed line, the HTS needs a *task done* indication. For some initial lines of image, there would not be any valid data output. Similarly, the H3A generated data will be at paxel/window height number of lines. For initial lines not producing any valid data, the HTS needs to be indicated with separate mask bits for each output streams. For these initial lines, when there is no valid output due to lines delay inside VISS, the LSE still generates mask output to HTS indicating lack of proper output data.

#### 6.9.4.1.3 VISS Data Flow within VPAC

VISS receives data from sensor through:

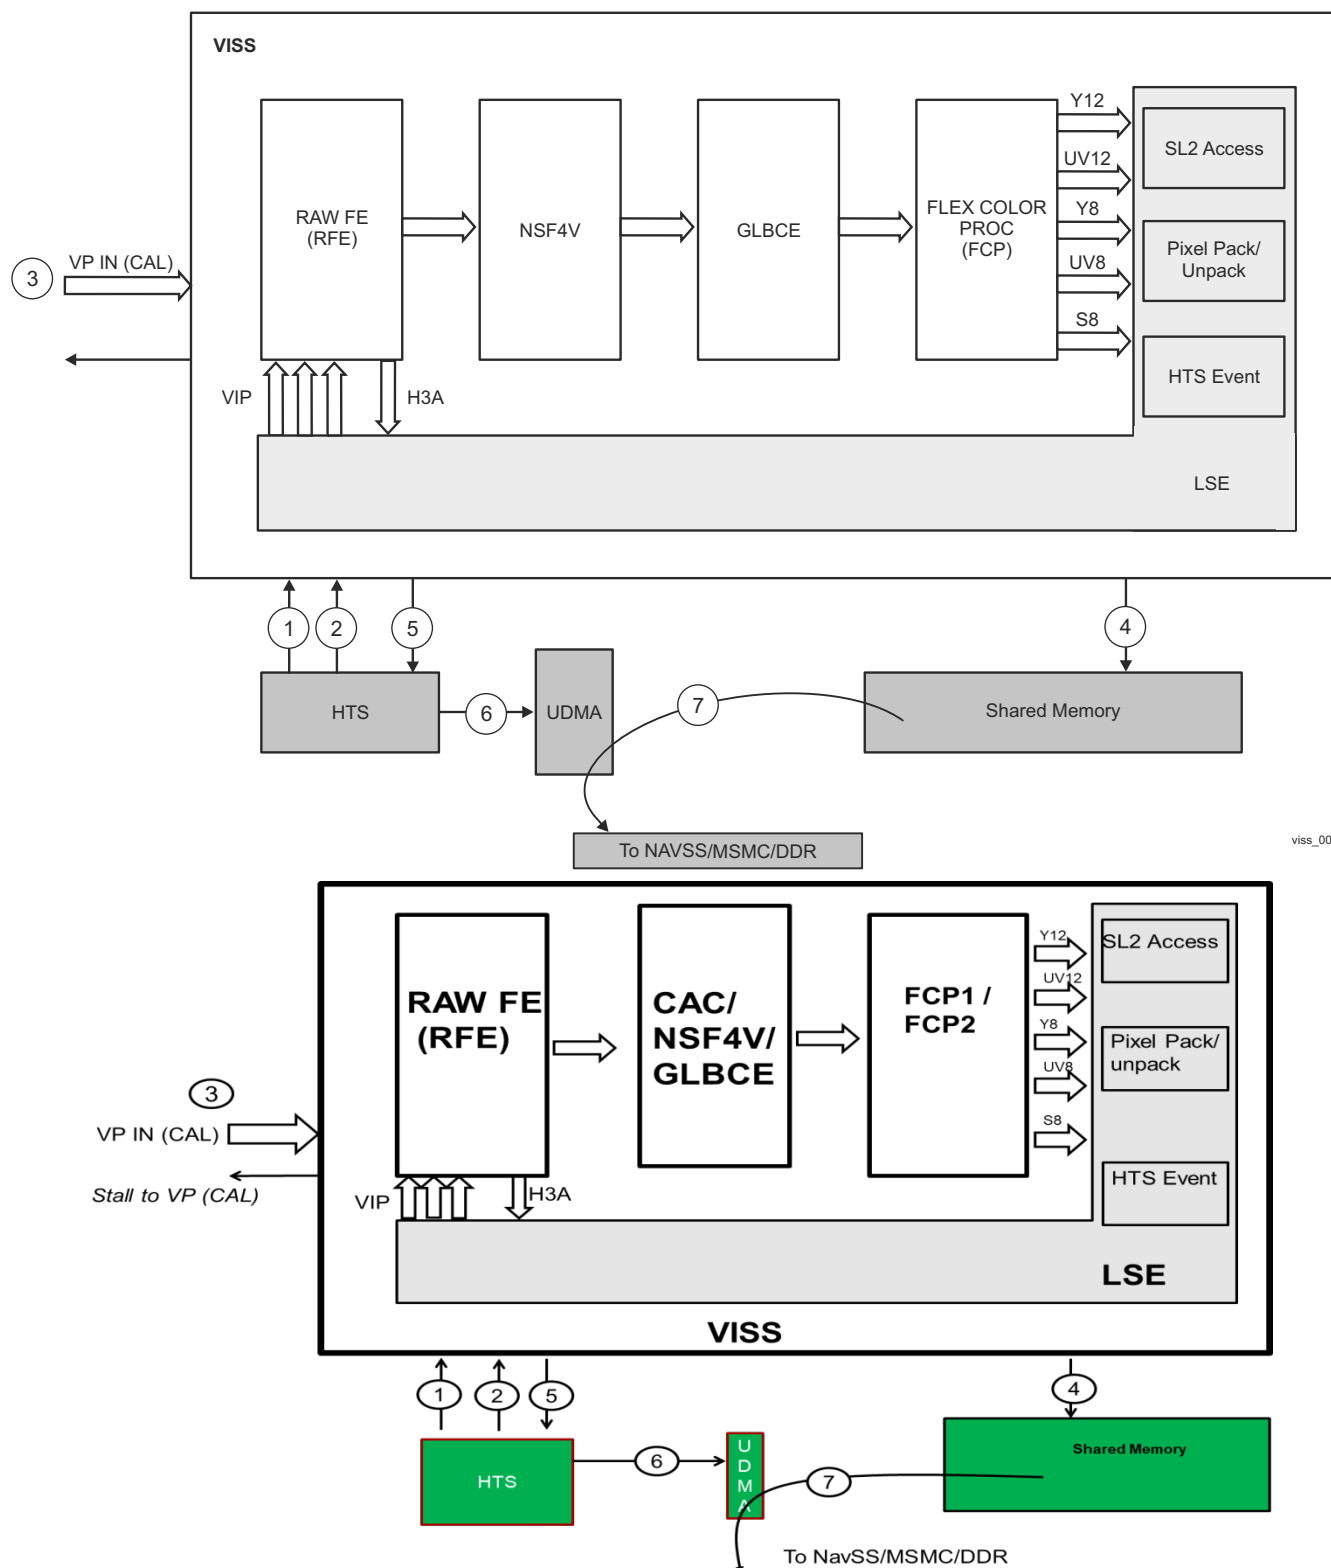

- CSI RX video port for OTF processing (Sensor -> CSI RX -> LSE -> RFE -> FCP)
- DMA of VPAC (Sensor -> CAL -> DDR -> VPAC\_SL2 -> LSE -> RFE -> FCP)

##### 6.9.4.1.3.1 VISS On-the-fly Processing

The VISS operation is controlled through a single HTS thread. For details of the HTS operation refer to Section *VPAC Hardware Thread Scheduler (HTS)*. The VISS configuration is valid for a single or multiple frame. External-host manages VISS configuration at end of each frame, if required. The HTS controls image processing between lines and handles managing shared memory for VISS inputs/outputs. Sub-frame processing is not natively supported. SW must configure VISS and HTS to start initialization process before enabling sensor capture. After the initialization sequence, the HTS will generate a start trigger to VISS. The generation of the start trigger depends on the availability of H3A data out buffer and FCP data out buffer inside the SL2 memory.

At this stage, the LSE waits for CSI RX video port (VP) to start sending valid pixels. As and when VP data starts streaming in, it is routed to the RFE video port. As RFE and FCP are running in streaming mode, the FCP indicates to LSE about completion of one line of operation. After receiving valid data out, the HTS will trigger UDMA for data store into DDR. Each 'thread done' accompanies output mask for all output buffers. Mask bits indicate to HTS about validity of output buffer as for each thread done all output buffers do not need to be produced. The HTS will issue next start after checking all output buffers availability. The streaming data from CSI RX is storable upto 2KB storage inside VP memory of CSI RX. Any temporary stall can be absorbed, but prolonged stall is buffer overflow inside CSI RX. In VPAC, VISS produced data is transferred using Real Time fabric of NAVSS/MSMC and low predictable latency needs to be guaranteed.

**Figure 6-49. VISS On-the-fly Operation**

The following OTF operation steps are illustrated in [Figure 6-49](#):

1. *Init* from HTS to initialize VISS.

2. Thread start. Step 1+2 prior to enabling CSI RX + PHY + sensor.
3. Video port data streaming. Unit of operation inside VISS at line level.
4. Output data produced by FCP and H3A at line level. H3A will produce data only at those lines which aligns with paxel\_height/window\_height.
5. Production of 1 line depends on consumption of 1 line on VP interface. 'Thread done' triggered after completion of 1 processed line write into SL2. In case there is no valid data to be written into SL2, 'thread done' is generated after consumption of 1 line of data from VP. Note: *Horizontal blanking will be configured inside LSE to facilitate writing complete line out of FCP.*
6. HTS triggers DMA to store output buffer from SL2 to DDR.
7. DMA loads data from SL2 and writes into DDR.

The following assumptions are made for the OTF operation described above:

- UDMA write is mapped onto Real Time Thread for guaranteed QoS. Channel done by UDMA must be generated after completion of write into DDR. Next thread start depend on availability of minimum one buffer for each output line in SL2. More buffers in SL2 can take care of instantaneous drop in UDMA transfer capacity.
- Cycle gap between HTS done and next start must be minimal. CSI RX VP interface will be stalled whenever LSE input buffer on VP interface reaches near full condition.
- Configurable vertical latency times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, even though last line of current frame is already fed into RFE.
- Buffer dependencies:
  - H3A output buffer (AE or AF)
  - FCP output buffer (Y12, YV12, Y8, UV8, S8)

#### 6.9.4.1.3.1.1 Non-WDR or Companded WDR Sensors

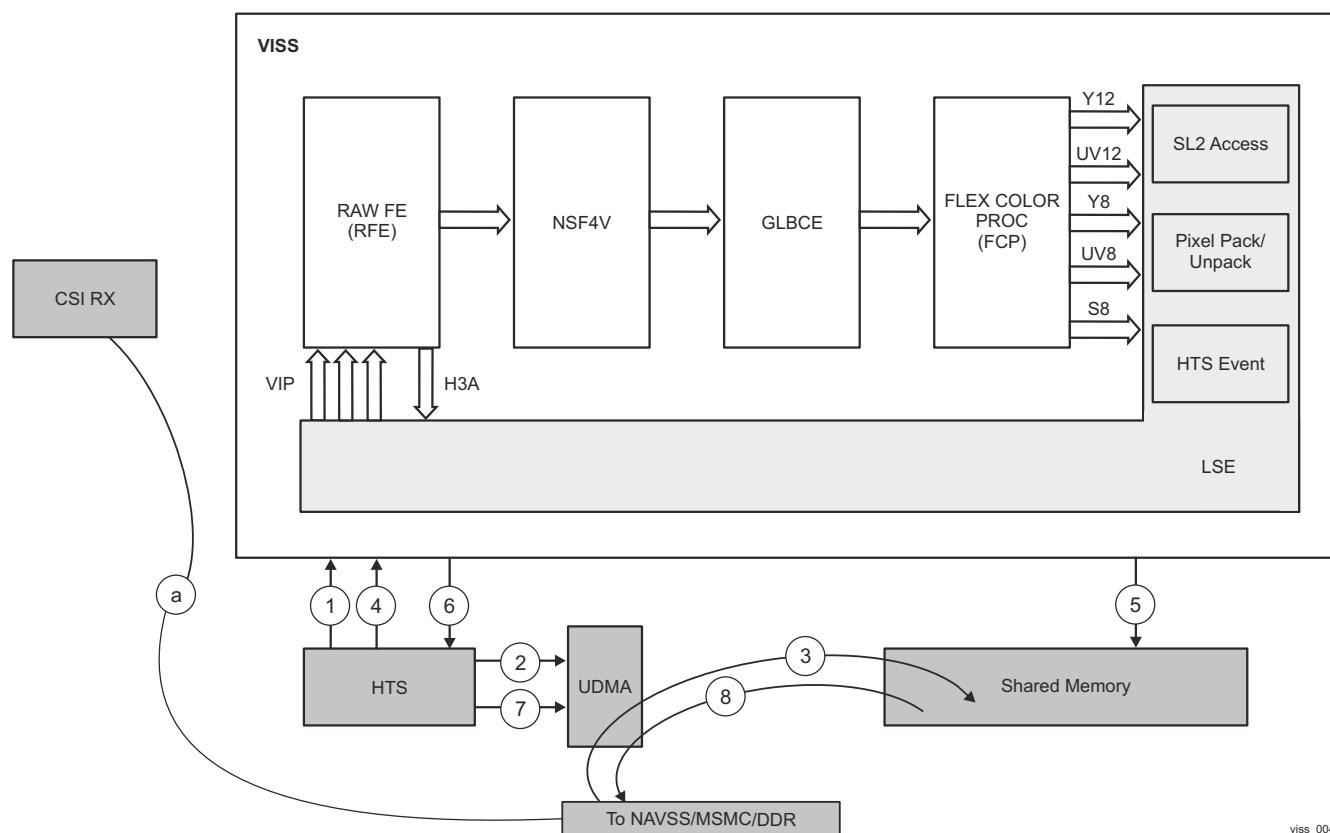

VISS is enabled for single input data when either sensor does not support WDR or sensor does on-chip WDR merge and pass on merged data after companding to 12 bit / 14 bits as shown in [Figure 6-50](#).

**Figure 6-50. VISS Non-WDR/Companded: High Level**

#### 6.9.4.1.3.2 VISS Memory to Memory Image Processing

CSI RX writes CSI-2 received pixel data into DDR. Once a frame is written, host is triggered to initiate VISS processing. HTS will go through 'init' sequence to initialize VISS and its SL2 pointers. As UDMA is head of pipeline for memory to memory mode of image processing, its scheduler inside HTS needs to be configured for generating "frame height" number of triggers to fetch image lines one by one. This is essential to bring determinism in pipeline as there is no producer for UDMA load thread.

**Figure 6-51. VISS Memory to Memory Operation**

The following memory to memory operation steps are illustrated in [Figure 6-51](#):

1. CSI-2 stream captured via CSI RX into DDR. This traffic must be routed through Real Time fabric of NAVSS/MSMC. CSI RX capture happens independent of VISS processing.
1. *Init* from HTS to initialize VISS.
2. HTS triggers UDMA to fetch data for processing. There could be max 3 independent input data.
3. UDMA loads the data and stores into SL2.
4. Upon completion of all input buffer loading (at line level) UDMA channel 'done' event triggers VISS thread start (still needs to ensure there are buffer available for writing VISS output data).
5. VISS produces line #N corresponding to loading of line #N + vertical\_latency.
6. 'Tdone' triggered to HTS.
7. HTS triggers UDMA for output buffer transfer into DDR.
8. UDMA loads data from SL2 and write into DDR.

The following assumptions are made for the memory to memory operation described above:

- CSI RX write is mapped onto hard real time fabric of NavSS/MSMC.
- Configurable vertical blanking times 'Tstart' generated by HTS to let RFE + NSF4V + GLBCE + FCP flush its internal pipe, eventhough last line of current frame is already fed into RFE.
- Buffer dependencies:
  - RFE input buffer (exp0, exp1, exp2)
  - H3A output Buffer (AE or AF)
  - FCP output Buffer (Y12, UV12, Y8, UV8, S8)

#### 6.9.4.1.4 VISS Data Formats Support

[Table 6-113](#) lists the data formats supported by VISS. VISS does not support YUV Input. In case of external YUV Sensor, CSI RX directly writes into DDR and the data is subsequently processed by the rest of VPAC.

**Table 6-113. VISS Data Formats**

Direction	Pixel Width	Pixel Container Width (M2M)	Packing	Video port (OTF)	Comments
VISS Input	RAW12/14/16	16b	No	16b / pixel	1. Companded data/External ISP 2. MSB bits are padded with zeros within fixed width pipeline
	RAW8	8b	Yes	16b / pixel	
	RAW12	12b	Yes	16b / pixel	
VISS Output	YUV420 (12b) NV12	12b	Yes	N/A	
	YUV420 (12b) NV12	16b	No	N/A	
	YUV420 (8b) NV12	8b	Yes	N/A	
	YUV422 (8b) UYVY/YUY2/NV16	8b	Yes	N/A	
	RGB (planar)	8b	Yes	N/A	With RGB output, limited YUV data outputs are available (only 12-bit YUV data is available)
	S8	8bit	Yes	N/A	

#### 6.9.4.1.5 VISS VPORT Interface

The video port (VPORT) interface is used to stream the pixel data from up stream to down stream module. In VISS, the VPORT interface is used to receive data from CSI RX (in streaming mode) and in between VISS sub-modules (RFE -> NSF4V -> GLBCE -> FCP).

The VPORT supports stall signal (VP\_STALL) and also either one pixel or 2 pixel data per cycle.

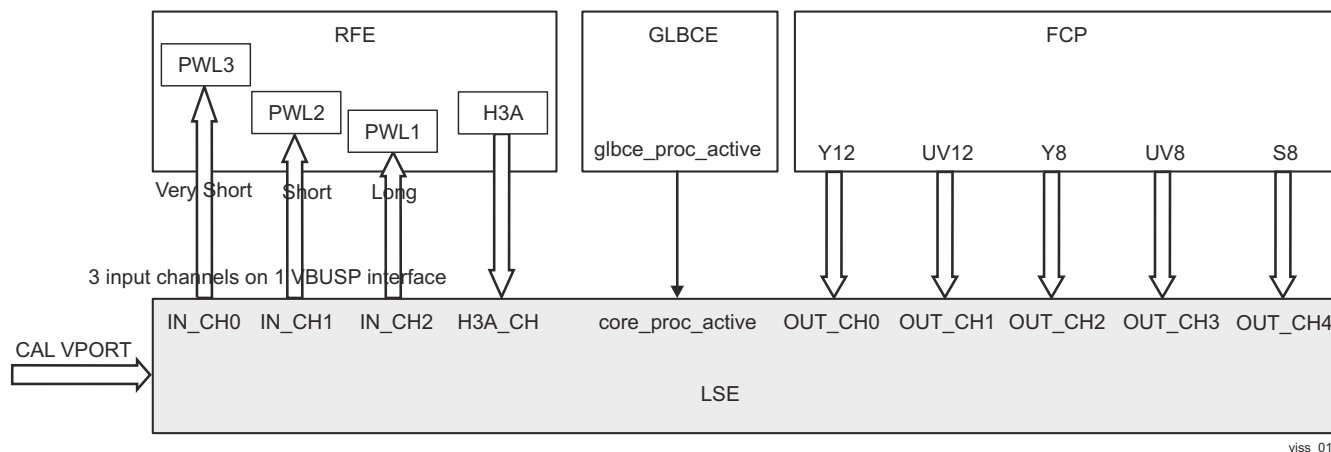

The pixel data (VP\_DATA) received on the VPORT is organized in 32 bits as follows:

- VP\_DATA[15:0] = pixel (n)
- VP\_DATA[31:16] = pixel (n+1). This is ignored, when VPORT\_TWO\_PIXEL = 0
- MSBs are padded with 0's when less than 16 bits are used.

#### 6.9.4.1.6 VISS Submodule Integration Specifics

##### 6.9.4.1.6.1 LSE Integration

Figure 6-52 captures the channel integration between LSE and rest of VISS submodules. Though digram shows three input channels between LSE to RFE, 3 channels data is transferred using single VBUSP interface.

**Figure 6-52. VISS LSE Channel Integration**

LSE supports YUV422 interleaving only on 8-bit data.

The LSE configuration for VISS can be read in VISS\_LSE\_STATUS\_PARAM register fields.

For more information on LSE module operation, see Chapter *Load and Store Engine (LSE)*.

#### **6.9.4.1.6.2 GLBCE Integration**

GLBCE is Global/Local Brightness and Contrast Enhancement module.

The GLBCE module supports the following main features:

- One pixel/cycle operation
- Up to 4096 pixels/line (line size)
- Bayer image
- When GLBCE is off, the RFE/NSF4V output is bypassed to FCP

For more information on GLBCE operation, see [Section 6.9.4.5, VISS Global/Local Brightness and Contrast Enhancement \(GLBCE\) Module](#).

##### **6.9.4.1.6.2.1 GLBCE Startup**

GLBCE requires approximately 5400 clock pulses after startup before it could receive data on its video port. Therefore, before RFE -> GLBCE -> FCP path could be used after a GLBCE reset, the SW shall use the following sequence to provide those required clock pulses:

- Prior to enabling rest of VISS pipe, configure VISS clock control to allow free running clock to GLBCE.
- Wait for the 'glbce\_filtering\_done' event. It indicates that GLBCE has received enough PCLK pulses for internal initialization and that it is now ready to receive pixels.
- Configure GLBCE clock to normal mode. Enable the rest of VISS pipeline.

GLBCE has a minimum input restriction of 480x240 pixels. The input frame must be at least this size.

GLBCE LUTs must not be changed during the active frames. They can only be updated in vertical blanking. GLBCE\_LUT\_FI may be changed frame by frame depending on the GLBCE tuning method. Other LUTs (GLBCE\_REV\_PERCEPT\_LUT\_xx, GLBCE\_FWD\_PERCEPT\_LUT\_xx, and GLBCE\_WDR\_GAMMA\_LUT\_xx) are not expected to be updated dynamically except in very limited case.

##### **6.9.4.1.6.2.2 GLBCE Bypass**

When the GLBCE is disabled (by VISS\_CNTL[0] GLBCE\_EN = 0), any access targeted to GLBCE registers or GLBCE statistics memory will respond with error status, and 'glbce\_cfg\_err' interrupt will be generated.

##### **6.9.4.1.7 VISS Stall Handling**

VISS can handle momentarily stall condition created due to lack of enough band width. Streaming mode is described in the following sections.

##### **6.9.4.1.7.1 Stall Handling for Streaming Mode**

Streaming stall handling is similar to memory to memory mode, except that final effect will be reflected in generating stall to the VPORT interface. Upon stall assertion, VISS expects no more than 2 VPORT pixel clock cycles.

##### **6.9.4.1.8 VISS Interrupts**

The VISS submodules generate the interrupt events described in *Section VPAC Subsystem Interrupts*.

##### **6.9.4.1.8.1 Interrupts Merging**

The configuration error interrupts are merged at VISS level. The following list describe the configuration error eventss and the corresponding merged interrupts.

- RAWFE\_CFG\_ERR\_INTR: Generated when configuration interface access the RFE end points, while frame processing is active. Merged interrupts from RFE:
  - lut1\_cfg\_err\_intr
  - lut2\_cfg\_err\_intr

- lut3\_cfg\_err\_intr
- wdr\_lut\_cfg\_err\_intr
- dpc\_line\_cfg\_err\_intr
- dpc\_lut\_cfg\_err\_intr
- h3a\_lut\_cfg\_err\_intr
- h3a\_line\_cfg\_err\_intr
- GLBCE\_CFG\_ERR\_INTR: Generated when the configuration interface access the GLBCE register region or statistics memory, while frame processing is active. Merged interrupts from GLBCE:
  - glbce\_statmem\_cfg\_err\_intr
  - glbce\_mmr\_cfg\_err\_intr
- FCFA\_CFG\_ERR\_INTR: Generated when the configuration interface access the CFA register region, or LUT or line memory, while frame processing is active. Merged interrupts from CFA:
  - lut\_cfg\_err\_intr
  - cfa\_mmr\_err\_intr
  - cfa\_pix\_err\_intr
- FCC\_OUTIF\_OVF\_ERR\_INTR: Generated when any of the FCC output interfaces overflows. Merged interrupts from CC:
  - overflow\_if\_y12\_intr
  - overflow\_if\_uv12\_intr
  - overflow\_if\_y8r8\_intr
  - overflow\_if\_c8g8\_intr
  - overflow\_if\_s8b8\_intr
- FCC\_CFG\_ERR\_INTR: Generated when the configuration interface access FCC register region or its LUTs, while frame processing is active. Merged interrupts from FCC:
  - contrast0\_cfg\_err\_intr
  - contrast1\_cfg\_err\_intr
  - contrast2\_cfg\_err\_intr
  - lut\_12to80\_cfg\_err\_intr
  - lut\_12to81\_cfg\_err\_intr
  - lut\_12to82\_cfg\_err\_intr
- EE\_CFG\_ERR\_INTR: Configuration happened to EE regions causing corruption during frame processing. Merged EE sources are:
  - eelut\_cfg\_err\_intr
  - ee\_pix\_err\_intr
- EE\_SYNCOVF\_ERR\_INTR:
  - ee\_hz\_align12\_intr
  - ee\_hz\_align8\_intr

#### 6.9.4.1.8.2 Handling of Configuration Error Interrupts

Table 6-114 give hints on handling configuration error interrupts.

**Table 6-114. VISS Configuration Error Interrupts Handling**

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
	RAWFE	

**Table 6-114. VISS Configuration Error Interrupts Handling (continued)**

Memory	Error Generation Window	HWA-level Register Status Clearing Mechanism
PWL1_LUT, PWL2_LUT, PWL3_LUT	Config read access during active line OR write access during active frame.	Write '1' to corresponding bit in RAWFE_INT_STAT register.
WDR_LUT		
H3A_LUT		
H3A_ACCM		
H3A_LINE		
DPC_LUT	Config read/write access during active frame at H3A boundary.	
DPC_LINE	Config read/write access during active frame.	
LSC Table	Config read access during active line OR write access during active frame.	
	Config read/write access during active frame. Active frame in lsc case is VS at pwl to VE at lsc input delayed by 1 cycle.	
NSF4V		
NSF4V_LINE	Config read/write access when datapath is accessing the corresponding memory on the same cycle.	No register status in NSF4V.
GLBCE		
GLBCE non-shadowed registers	Config write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' to GLBCE_INT_STAT[0] MMR_CFG_ERR register bit.
GLBCE_STAT	Config read/write access during active frame. Active frame window is from VS_IN to Filter done.	Write '1' into GLBCE_INT_STAT[1] STATMEM_CFG_ERR register bit.
GLBCE_LINE	Not mapped to config.	N/A
CFA		
CFA FIR Filter registers	Config write access during active frame.	Write '1' to CFA_INT_STATUS[2] CFA_MMR_ERR register bit.
CFA_LUT	Config read/write access during active frame.	Write '1' into CFA_INT_STATUS[0] LUT_CFG_ERR register bit.
CFA_LINE	Config read/write access during active frame.	Write '1' to CFA_INT_STATUS[1] CFA_PIX_ERR register bit.
FCC		
LUT_CONTRAST	Config access (read/write) occurs during active line when the LUT is enabled.	Write '1' to corresponding bit in FCC_FLEXCC_INT_STATUS register.
HISTOGRAM	Config access has occurred to the first location but not to the last location till the start of next frame implying that full histogram was not read.	
LUT_COLOR	Config access (read/write) occurs during active line when the LUT is enabled.	
CC_LINE	No error generation logic.	N/A
EE		
EE_LINE	Config accesses during active frame.	Write '1' to EE_INT_STATUS[1] EE_PIX_ERR register bit.
LUT	Config accesses during active frame.	Write '1' to EE_INT_STATUS[0] EELUT_CFG_ERR register bit.

#### 6.9.4.1.9 VISS Error Correcting Code (ECC) Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

One or more memories within VISS are ECC protected using an ECC Memory Wrapper which implements Single Error Correction and Double Error Detection (SECDDED).

The ECC wrapper provides Single Error Detection and Correction (SED/SEC). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC wrapper also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC wrapper also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

An ECC Aggregator at the VISS level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the host (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their ECC register set.

The following VISS memories are ECC protected:

- GLBCE statistics memory.
- RAWFE non pixel line buffer memories. See Section *VISS RAW Frond-End (RAWFE)*, for more information.
- FCP non pixel line buffer memories

For more information on the ECC Aggregator operation, see Section *ECC Aggregator* in Chapter *Safety Modules*.

#### 6.9.4.1.10 VISS Programmer's Guide

##### 6.9.4.1.10.1 VISS Initialization Sequence

VISS initialization is part of any other HWA initialization on VPAC. Prior to starting HWA initialization through HTS, VISS must be configured in below order.

1. Configure RFE registers, GLBCE registers, NSF4V registers and FCP registers:
  - The VISS\_CNTL[0] GLBCE\_EN register bit needs to be set, in order to configure the GLBCE registers.
2. Select input / output stream properties inside LSE.
3. After reset and prior to enabling LSE, apply the following configuration:
  - a. Make sure VISS\_CNTL[0] GLBCE\_EN bit is '1'.
  - b. Enable IRQ for interrupt event 'glbce\_filtering\_done'.
  - c. Set VISS\_GLBCECONFIG[0] GLBCE\_PCLKFREE register bit to '1'.
  - d. Wait for interrupt 'glbce\_filtering\_done'.
  - e. Clear VISS\_GLBCECONFIG[0] GLBCE\_PCLKFREE register bit.
4. Enable LSE input and output buffer lines.
5. Enable pipeline and schedulers associated with VISS HTS configuration (pipeline enable must happen after enabling all attached schedulers).
6. Enabling HTS will trigger init sequence which will initialize LSE, RFE and FCP. This will also trigger head of pipe for NAVSS UDMA fetch (in case of memory to memory operation). Otherwise, VISS waits for streaming data from CSI RX.
7. After initializing VISS/VPAC, configure and enable CSI RX, CSI RX PHY and camera sensor in order.
8. Once streaming data starts, it will continue till the end of frame. Blanking (set in VISS\_LSE\_CFG[31-22] VP\_HBLNK\_CNT register field) must be configured more than VISS blanking needs (see *VISS Blanking Requirements*).
9. Once a complete frame is fully written into DDR, the HTS module comes back to init state and restart from step #6. For some usecase, LSE input/out enables after each frame might be considered as well (step #5).
10. After each 'frame\_done', if the configuration needs to be changed, it must be done within vertical blanking period for not shadowed registers (refer to Sections *VISS RAW Frond-End (RAWFE)* and *VISS Flexible Color Processing (FCP) Module*, for more details).
11. At any stage, if there is a need to stop the streaming interface, the HTS must first be paused and then aborted, and then reset and re-configure the entire VISS as part or recovery from abort.

**6.9.4.1.10.2 VISS Configuration Restrictions**

Frame size restriction:

- If GLBCE is enabled in the VISS pipeline, the minimum frame required is 480x240 pixels.
- If GLBCE is disabled in the VISS pipeline, the minimum frame required is 64x16 pixels.
- Frame width and height has to be even.
- Histogram can only be enabled when the frame width is 256 pixels minimum.

LSE H3A channel enabling restriction:

- When the H3A output channel is enabled in LSE, at least one other output channel needs to be enabled.

**6.9.4.1.10.3 VISS Real-time Operating Requirements**

SW needs to configure UTC/UDMA channel registers for write out buffers.

SW needs to reconfigure RAWFE LSE LUT, if needed, and any other non-shadowed registers during vertical blanking period only. Some control bits would be shadowed, which can be configured during a complete frame.

#### 6.9.4.2 VISS Load Store Engine (LSE)

For more information on the VISS LSE module operation, see [Section 6.9.4.1.6.1](#), *LSE Integration*, and *Load Store Engine (LSE)*.

### 6.9.4.3 VISS RAW Frond-End (RAWFE)

This section describes the Vision Imaging Sub-system (VISS) RAW Frond-End (RAWFE) module in the device.

#### 6.9.4.3.1 RAWFE Overview

The RAWFE is a set of raw pixel processing functions to enhance the RAW image signal received from the sensor. The key application of the RAWFE is in the ADAS space where in it is used for both analytics as well as visual use cases.

##### 6.9.4.3.1.1 RAWFE Supported Features

Each RAWFE module implements the following features:

- Support for any 2x2 RAW data pattern.
- Support for merge up to 3 separate exposures.
- PWL (piecewise linear) and LUT based de-companding at the front end of each exposure channel
- Support for WDR merge, including 2 exposure merge, 3 exposure merge and 2 exposure hybrid (12 bit and 16 bit) merge.
- Support for companding LUT from 24 bits down to 12 bits.
  - LUTs support higher precision in lower end.
- Support for LUT as well as adaptive Defect Pixel Correction.
- Support for table based lens shading correction.
- Support for 3A statistics
  - Statistics can be generated on independent exposures or merged data after tone map.

#### 6.9.4.3.2 RAWFE Functional Description

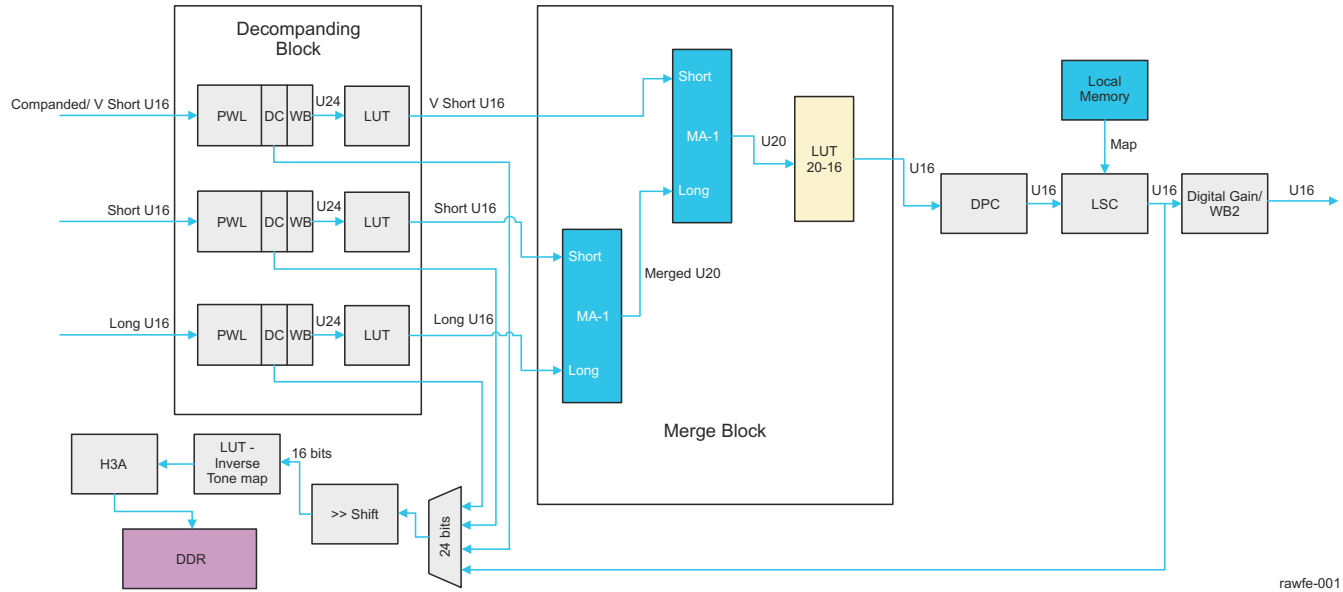

##### 6.9.4.3.2.1 RAWFE Functional Operation

The RAWFE processes captured image data from sensor and passes the data to the Flexible Color processing module (FCP) for demosaicing and color conversion.

[Figure 6-53](#) shows a high level conceptual block diagram of the RAWFE module.

The RAWFE consists of the following main components

- Decompaning block: This is used to decompand the sensor compressed raw to native bit depth. The same block can be used for tone mapping as well. The decompanding block can take sensor compressed RAW data and can decompand to up to 24 bits.
- WDR Merge: Each instance of the WDR merge block can take in 2 independent exposures (up to 16 bits) and generate up to 20 bit data.
- LSC Block: The block performs lens shading correction by applying gains stored in a look up memory.
- DPC: The block performs defect pixel correction using either LUT based memory or adaptive defect correction.
- H3A: The H3A block generates 2 different set of statistics, one for AWB and AE and the other for auto focus.

**Figure 6-53. RAWFE Block Diagram**

#### 6.9.4.3.2 RAWFE ECC for RAMs

Table 6-115 lists the RAWFE ECC RAMs

**Table 6-115. Table 3: RAM ECC capabilities**

Module	# Rams	ECC
PWL LUT1	2	ECC, with single bit correction, including writeback.
PWL LUT2	2	ECC, with single bit correction, including writeback.
PWL LUT3	2	ECC, with single bit correction, including writeback.
WDR LUT	2	ECC, with single bit correction, including writeback.
H3A LUT	2	ECC, with single bit correction, including writeback.
DPC (line buffer)	4	No ecc
LSC LUT	1	ECC, with single bit correction, including writeback.
LSC GAIN	1	ECC, with single bit correction, including writeback.
H3A accum	1	No ecc
H3A line	1	No ecc

#### 6.9.4.3.3 RAWFE Interrupts

The following section lists the RAWFE interrupts

##### 6.9.4.3.3.1 RAWFE CPU Interrupts

Table 6-116 lists the interrupts generated by the RAWFE sub-modules.

**Table 6-116. RAWFE Interrupts**

Interrupt	Description
LUT1_CFG_ERR	Config access to LUT1 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LUT2_CFG_ERR	Config access to LUT2 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.

**Table 6-116. RAWFE Interrupts (continued)**

Interrupt	Description
LUT3_CFG_ERR	Config access to LUT3 ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if cfg access occurs during active line. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
WDR_LUT_CFG_ERR	Config access to WDR LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_LUT_CFG_ERR	Config access to H3A LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any (read/write) cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
H3A_ACCM_CFG_ERR	Config access to H3A accum ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
H3A_LINE_CFG_ERR	Config access to H3A line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LUT_CFG_ERR	Config access to DPC LUT ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame.
DPC_LINE_CFG_ERR	Config access to DPC line ram has corrupted functional operation, config read or write memory access occurred during functional operation. Only asserted if any cfg access occurs during active line OR write occurs in horizontal blanking within a frame.
LSC_CFG_ERR	Config access to LSC ram has corrupted functional operation, config read or write memory access occurred during functional operation. Asserted if any cfg access occurs during active frame. Active frame in lsc case is VS at pwl to ve at lsc input delayed by 1 cycle.
H3A_AEW	h3a aew interrupt.
H3A_AF	h3a af interrupt
H3A	h3a interrupt
H3A_BUF_OVRFLOW_PULSE_INTR	Generated when an overflow occurs in the H3a output buffer

#### 6.9.4.3.3.2 RAWFE Debug Events

**Table 6-117** lists the RAWFE debug events. Debug events are used for hardware debug as well as performance measurement. They are not intended to be used as interrupts where the cpu needs to process them.

**Table 6-117. RAWFE Debug events**

Event	Description
VS_EVENT	ventricle start in the beginning of the rawfe pipeline
VE_EVENT	ventricle end at the end of the rawfe pipeline
HS_EVENT	horizontal start in the beginning of the rawfe pipeline
HE_EVENT	horizontal end at the end of the rawfe pipeline
LSE_SLAVE_STALL	rawfe is stalling lse slave interface due to ext or mtc stall
LSE_MASTER_STALL	lse master interface is stalled
LSE_INTERFACE_IDLE	within a frame lse is not sending data
X_Y_EVENT_MATCH	x-y pixel position has reached the start of rawfe pipeline
DPC_OTF_CORR_EVENT	dpc of corrected a pixel position
PIPE_ADV_EVENT	active pipeline advancement

#### 6.9.4.3.4 RAWFE Sub-Modules Details

The following sections describe in detail the sub-modules present within the RAWFE module.

##### 6.9.4.3.4.1 RAWFE Decompaning Block

The decompaning block is responsible for decompaning pwl (or LUT) compressed data back to its linear bit width. The decompaning block can generate up to 24 bits of data, however the data needs to be tone mapped down to 16 bits before additional processing can take place. There are 3 instances of the Decompaning block each implementing the same functionality.

The input interface of the decompaning block is 16 bits.

Figure 6-54 shows a high level block diagram of the decompaning block.

**Figure 6-54. RAWFE Decompaning Block Diagram**

##### 6.9.4.3.4.1.1 RAWFE Mask & Shift

The mask and shift block is used to mask out any control bits present in the data. The 'Mask' is a 16 bit configuration register which will perform a bit wise 'and' operation on the incoming data. (For example for sensor data with data in 12 bits and 4 bits of control information, the mask value would be programmed to 0xFFF). The Mask operation is followed by a shift operation. The 'Shift' field is a 3 bit configuration register which can perform a right shift (>>) from 0 to 7 bits.

##### 6.9.4.3.4.1.2 RAWFE Piece Wise Linear Operation

The PWL block is used to apply a piece-wise-linear gain on the incoming pixel data and is generally used to uncompress sensor compressed data. The knee points of the PWL curve should be programmed to correspond with the compression knee points used by the sensor configuration.

The PWL block supports an input size from 8 – 16 bits and can support an output up to 24 bits.

Figure 6-55 depicts a PWL curve applied on incoming data

**Figure 6-55. RAWFE PWL Curve implementation**

The PWL block implements the following equation assuming the input lies in the nth segment.

$$\text{Out\_Pixel} = ((X - \text{ThrX}_n) \times \text{Slope}) + \text{ThrY}_n \quad (2)$$

The figure below shows the PWL block architecture

**Figure 6-56. RAWFE PWL Block Diagram**

The Wdr\_clip parameter can be set to clip the output at the desired bit width (typically 20 bits).

#### 6.9.4.3.4.1.3 RAWFE Offset/WB-1 Block

This block is used for applying White balance correction in linear domain as well as for subtracting the DC offset using the signed 24 bit offsets. The functionality is similar to the WB2 block. Note, there is a tap out point to H3A after the offset application, but prior to the gain block. This allows the H3A to receive DC subtracted (but not WB corrected) data.

#### 6.9.4.3.4.1.4 RAWFE LUT Based compression

The LUT based compression is used for addressing multiple use cases.

- The primary function of the LUT is to take the PWL decompounded data (up to 24 bits and after DC subtraction) and compress it using an  $x^n$  curve to a bitwidth of 16 bits. This is required since the downstream path is only capable of supporting up to 16 bits of data.
- It can be used to decompand data when the compression curve cannot be addressed using 3 knee points or if the compression is true curve instead of PWL. In this scenario the DC subtraction IP is disabled and the LUT is used to implement both the decompression as well as the DC subtraction functionality.

The LUT compression is modified from the implementation in previous generation ISPs. The previous LUTs had 512 entries leading to a step size of  $2^{20}/512 = 2048$ . As such there were only 2 LUT points in the critical low range (0-4095) of the image. The LUT implementation is optimized for a 20-bit decompounded data and allows for a step size of 32 in the critical range (lower 12 bits) and a step size of 2048 in the successive ranges.

The Non Linear LUT implementation supports 3 zones for the input range

- For bitWidth < 12 bits, the LUT offers a linear range with a step size of 32. (Only the first 128 locations (plus 129th location for supporting interpolation) are utilized in this mode)
- For bitWidths between 13 and 20: This is the most common operating zone for the LUT. In this mode, the range between 0 and 4k is split in 128 locations with a step size of 32. Beyond 4k range, the step is variable and is set to 2k for the highest bit width of 20 and subsequently reduces by half as the bitwidth is reduced (E.g. 1k for 19 bits etc)
- For bitwidths between 21 and 24: In this operation zone, the first 128 locations are used with a varying step size based on bit width such that the step size is 64 for 21 bits of data and doubles with increase in bitWidth. (E.g. 128 for 22 bits etc). The remaining locations implement a varying step size between 4k (for 21 bits) and 32k (for 24 bits).
  - Example-1: Bitwidth=21 bits:
    - Range 0-8k-> Step size = 64;
    - Range 8k-  $2^{21}$  -> Step Size = 4096
  - Example-2: Bitwidth = 22 bits

- Range 0 -16k -> Step Size = 128
- Range 16k – 2<sup>22</sup> -> Step\_Size = 8192
- Example 3: Bitwidth = 24 bits
  - Range 0 – 64K -> Step Size = 512
  - Range 64K - 2<sup>24</sup> -> Step Size = 32k

The LUT logic provides a generic table which can support any bit width and can be used in different regions in the RAWFE as well as other modules.

The LUT3 supports shadowing for very short frame only. If the MMR shadow enable is set then the LUT2 is used on the LUT3 data.

#### 6.9.4.3.4.2 RAWFE WDR Merge Block

The merge block supports merging up to 3 exposures to generate a cumulative 20 bit frame.

The merge block is based on 2 instances of the Motion-Adaptive merge block, each of which is independently capable of supporting the merging of 2 exposures (10 – 16 bits each) to a combined bit width of up to 20 bits. In a more generic scenario the merge block should be designed and verified to support the following scenarios

- Merge 2 exposures of 10 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 16 bits
- Merge 2 exposures of 12 bits each to 20 bits
- Merge 2 exposures (12 bit and 16 bit) to 20 bits.
- Merge 2 exposures of 16 bit each to 20 bits.

Using two instances of the motion adaptive merge block provides the functionality to merge up to 3 independent exposures, each of 12 bits, to a combined bitwidth of 20 bits. The block also provides capability to only merge 2 exposures using a combination of mux and clipping blocks.

The merge block comprises of two instances of the motion adaptive merge (MA1/MA2) as well as an LUT based companding block and mux structures to enable different data flow. To keep the design complexity under control some restrictions are applied to the data connectivity on the merge blocks. A key restriction is that for the two exposure merge only the MA-2 block should be used and the MA-2 should be used along with MA-1 for 3 exposure merge. Further the position of the long and short exposures on each block are fixed. [Table 6-118](#) summarizes some of the possible combinations which can be realized using the logic. (Note, this is not an exhaustive list from a DV perspective).

The MA block when set to bypass/disabled mode, will pass the input stream marked as 'short' (refer to [Figure 6-53](#)) to the output.

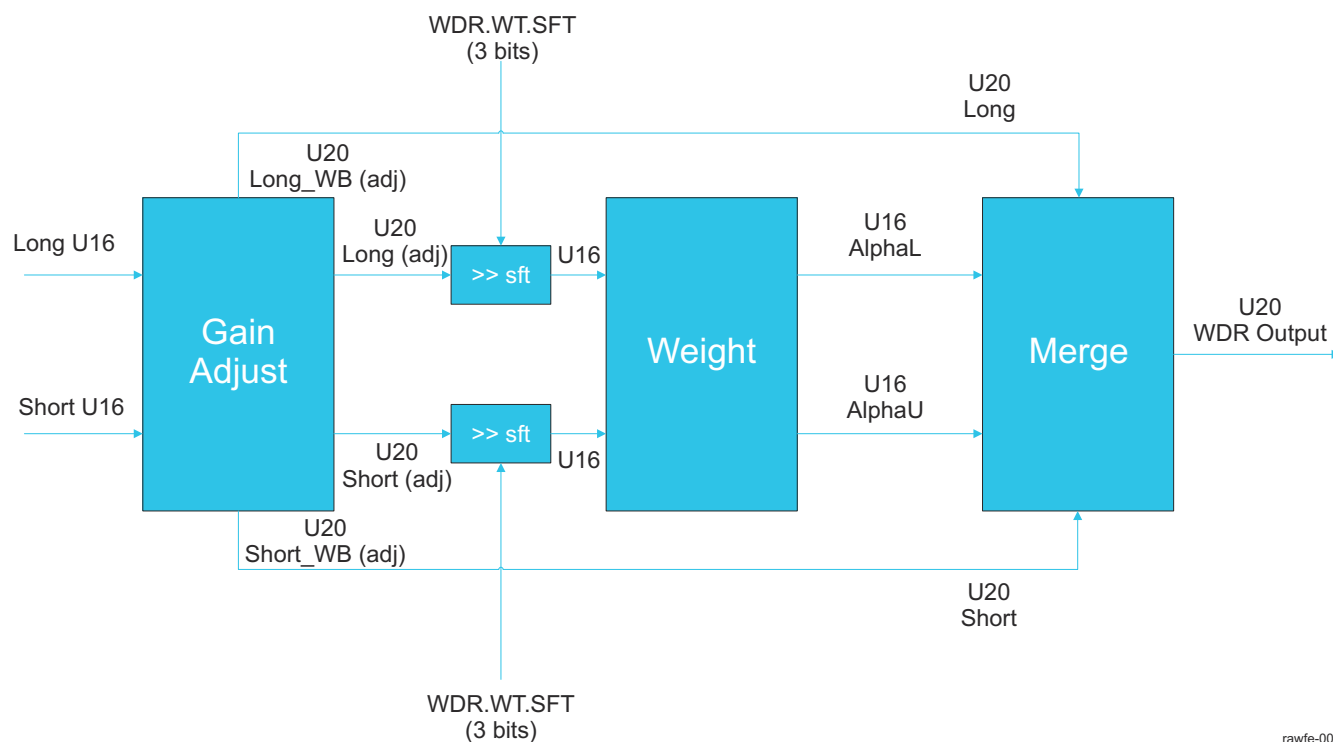

**Table 6-118. Figure 7:RAWFE Different merge modes**

Merge Mode	MA-1	MA-2	LUT
2 Exposures (12 bit) to 20 bit	Bypassed	Merge Long / Short	Use VS and Short Exposures Set to 20-16
2 Exposures (12 bit) to 16 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures Bypassed
2 Exposures (12 bit) to 16 bit with tone mapping	Bypassed	Merge Long /Short	Use VS and Short Exposures Set to 16-16 mode
2 Exposures (12 & 16) to 20 bit	Bypassed	Merge Long /Short	Use VS and Short Exposures Set to 20-16
3 Exposures (12 bit each) to 20 bit	Merge Long and Short	Merge VS / MA-1 output	Use all 3 exposures Set to 20-16
Single exposure companded	Bypass	Bypass	Use VS exposure only Bypassed

#### 6.9.4.3.4.2.1 RAWFE WDR Motion Adaptive Merge (MA1 / MA2)

This section provides the detailed description of the two instances of the motion adaptive merge.

Figure 6-57 shows the high level block diagram of the MA merge block

rawfe-007

**Figure 6-57. RAWFE WDR Motion Adaptive Merge**

The MA block receives two inputs each of which can be up to 16 bits. As mentioned earlier, the ordering of the long and the short exposure cannot be changed and should be positioned as it's depicted in the figure above. The MA block consists of 3 main sub-blocks, which are described in the following sub-sections.

#### 6.9.4.3.4.2 RAWFE Companding LUT

The companding LUT is used to perform a global tone mapping on the image and reduce the bit depth from 20 bits down to 16 bits. The LUT is implemented as a non uniformly spaced memory, with higher precision in the lower range of the image intensity. The LUT architecture is similar to that used for the decompanding LUT in the previous section.

#### 6.9.4.3.4.3 RAWFE Defective Pixel Correction (DPC) Block

The defect pixel correction (DPC) block is responsible for correcting defective pixels present on the sensor as an artifact of the manufacturing process. The defect pixel detection can either be LUT based or on the fly (OTF – DPC). For LUT based DPC, the defect map is stored in a memory.

Figure 6-58 shows a high level block diagram of the DPC module. The DPC comprises of two different methods of performing the functionality, each of which is highlighted below. The LUT based defect correction mechanism requires the sensor to be calibrated and the defect positioned stored in memory, whereas the Adaptive DPC automatically detects defects and corrects them. If required the LUT DPC and adaptive DPC can be enabled together in sequence.

**Figure 6-58. RAWFE DPC Block Diagram**

#### 6.9.4.3.4.3.1 RAWFE LUT Based DPC

LUT based defect pixel correction provides the highest level of accuracy since all defects can be identified perfectly without any false positives. The LUT based DPC mechanism however suffers from the limitation that the sensor has to be calibrated (each sample has to be individually calibrated) and that can add cost to the testing and qualification process. Some automotive grade sensor vendors provide the defect pixel locations already in an on chip memory and that can additionally be utilized to program the defect LUT without adding the cost. The LUT size for the DPC is constrained to 256 entries, since it is assume for a sensor of 2 -3 Mpix resolution, 256 entries are more than sufficient. Each entry in the LUT is 29 bits with 13 bits for x coordinate, 13 bits for Y coordinate and 3 bits for the method. Figure 6-59 illustrates the organization of the LUT memory

rawfe-017

**Figure 6-59. RAWFE DPC LUT Memory Organization**

A sample table is provided below for 7 entries. The LUT is specified in left to right and top to down fashion (Raster Scan order). As such design only has to look at the current LUT pointer to be able to determine if the current location is a defect or not.

**Table 6-119. Figure 14: RAWFE Sample DPC Table**

10	1400	0	
236	1107	1	
236	1200	1	
488	10	1	
488	100	2	
800	138	3	
900	1000	1	
900	1100	3	

The method filed pertains to how the defect pixel is treated once it has been detected. Several possibilities arise including copying from one of the neighbors or using an average of the neighbors. The table below summarizes different methods that can be programmed for treating defect pixels.

**Table 6-120. Figure 15:RAWFE LUT DPC Method(s)**

Method Value	Functional equivalent
0	Replace with Black or white dot based on config
1	Dout = d4
2	Dout = d5
3	Dout = (d4 + d5)/2
4	Dout = (d2 + d7)/2
5	Dout = d2
6	Dout = d7
7	Dout = ((d2 + d7)/2 + (d4 + d5)/2)/2

The pixel arrangement and numbering convention is depicted in the image below with 'd0' being considered the center pixel.

Figure 6-60. RAWFE DPC Pixel numbering convention

When the DPC method is set to '0', the output is either a black or a white pixel (depending on a separate configuration register). With this method, the LUT dpc can be used in conjunction with OTF DPC in a way that the LUT programmed defects are almost always identified by the adaptive DPC. This can be used to accurately correct for all known defects and then using adaptive DPC to correct for temperature or other operating condition based defects. (Defect pixels are strongly correlated with analog gain).

#### 6.9.4.3.4.3.2 RAWFE On-The-Fly (OTF) DPC

The LUT based DPC suffers from the drawback that each sensor die has to be calibrated for defects. The calibration process adds cost to the sensor dies, as such the preferred DPC method relies on automatically detecting the defects based on thresholds.

The OTF DPC algorithm detects defective pixels by comparing the current pixel (d0 on the left of the figure below) against its 8 neighboring pixels with the same color (d1 ~ d8 on the left of the figure below). Let's use dmax and dmin to denote the maximum and minimum of d1 ~ d8 respectively. If the current pixel d0 is greater than the sum of dmax and a detection threshold T (i.e.,  $d0 > d_{max} + T$ ) as shown on the right of the figure below, then the current pixel is considered a defect and its value is replaced by dmax. Similarly, if  $d0 < d_{min} - T$ , then the current pixel is replaced by dmin.

Figure 6-61. RAWFE OTF DPC

The detection threshold T is made adaptive by calculating the local image intensity and using a programmable look-up-table. The local intensity is approximated by the average of the second largest and the second smallest pixel values among d1 ~ d8 (dmax2 and dmin2 respectively in the figure above). With this average value, the threshold T is obtained from the look-up-table with linear interpolation. The look-up-table contains the detection thresholds (U16) at the average values of 0, 512, 1024, 2048, 4096, 8192, 16384, 32768 and the corresponding slope values (S12Q8) for linear interpolation.

#### 6.9.4.3.4.4 RAWFE Lens Shading Correction (LSC) and Digital Gain (DG) Block

The lens shading module corrects for the lens fall off (loss of light) at the corners of the lens. [Figure 6-62](#) shows a sample image of this phenomenon and the corresponding result after treating with LSC operation.

**Figure 6-62. RAWFE Before and After LSC**

The image on the left shows a block at the center of the lens and a corresponding block at the edge of the lens. Both blocks are equally illuminated, as such should appear equally bright on the image. However, due to lens fall off, the block at the edge appears significantly darker than the block at the center. The image on the right shows the corresponding result after LSC gains have been applied.

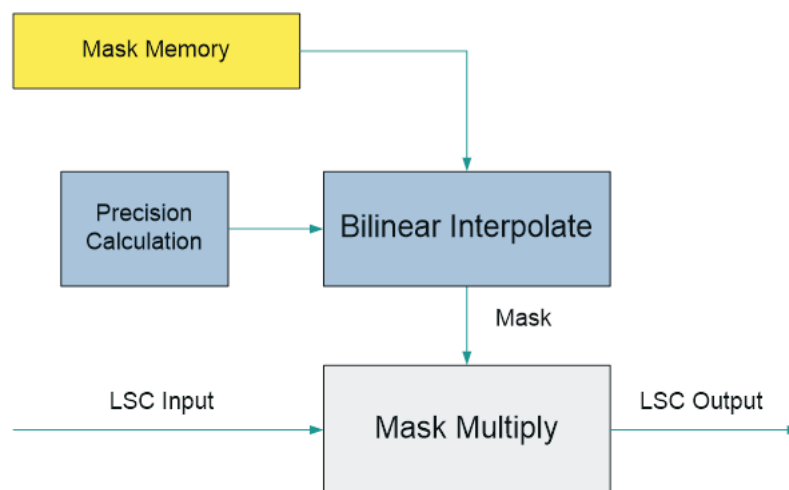

This block (2D-LSC) contains lens shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image is conceived to be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in internal MEMORY down-sampled, and is accessed and up-sampled by the LSC module to pixel resolution before being applied to the pixel data. The key difference from previous generation LSC is that the gain map is stored internally in the memory instead of relying on DRAM fetch.

The LSC module does not implement any Region of Interest (ROI) functionality and the LSC gain mask is applied on the entire image. Further, only an 8 bit gain is stored in the mask. The gain can be stored in different formats depending on the range. The 8 bits of gain can be used to represent different ranges based on the `lscfg.GAIN_FORMAT` register as per the table below

- 0 : U8Q8 -> 0 to 0.996
- 1 : U8Q8 +1 -> 1 to 1.996
- 2 : U8Q7 -> 0 to 1.992
- 3 : U8Q7 +1 -> 1 to 2.992
- 4 : U8Q6 -> 0 to 2.984
- 5 : U8Q6 +1 -> 1 to 3.984
- 6 : U8Q5 -> 0 to 6.968
- 7 : U8Q5 +1 -> 1 to 7.968

### Note

The offset field is removed from the implementation of the LUT and only the gain field is retained. This is different than previous implementations.

rawfe-021

**Figure 6-63. RAWFE LSC block diagram**

#### 6.9.4.3.4.4.1 RAWFE LSC Features Supported

- Gain map is MxN down-sampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {8,16,32,64,128 } independently.
- The size of the internal memory is based on a 2Mpix sensor with 16x32 downscaling ratio. As such the size is approximately 19 Kbytes-( 4758 locations with 4 Bytes/location) -> Each entry has gains for all 4 colors. This corresponds to a sensor resolution of 1928 x 1208
- Support 8-bit entry in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up)

Figure 6-62 illustrates the LSC active region and map up-scaling feature. (The maps are stored independently per color channel)

#### 6.9.4.3.4.4.2 RAWFE LSC Image Framing with Respect to Gain Map Samples

The gain maps are stored MxM downsampled, and needs to be upsampled by LSC hardware before being applied to the image. It is most straightforward for LSC hardware if the gain map grid is aligned with the input image grid. In other words, first pixel corresponds to a source gain map entry, rather than being upsampled through interpolation. Figure 6-64 shows the LSC active region with respect to the gain map grid.

**Figure 6-64. RAWFE LSC active region with respect to gain map samples**

For an image frame size of  $W \times H$  (output and input are the same size), gain map being  $M \times N$  downsampled, it needs  $(\text{ceil}(W / M) + 1) \times (\text{ceil}(H / N) + 1) \times 4$  bytes of gain map data in internal memory. (NOTE:  $\text{ceil}()$  represents the ceiling function).

The LSC module is designed to work with Bayer CFA data, having R/Gr/Gb/B color pattern. For the purpose of functional description, we assume Red is the starting color, but any other starting color or other  $2 \times 2$  color pattern can be used by placing color gains in the appropriate order.

Each  $2 \times 2$  set of samples is stored together in a 32-bit word in internal memory. For R/Gr/Gb/B CFA data and  $8 \times 8$  downsampled gains, the following order is assumed in the gain map, using conventional (X, Y) coordinate notation (X for horizontal offset and Y for vertical offset):

Line 0: R(0,0) Gr(1,0) Gb(0,1) B(1,1) R(8,0) Gr(9,0) Gb(8,1) B(9,1)...

Line 1: R(0,8) Gr(1,8) Gb(0,9) B(1,9) R(8,8) Gr(9,8) Gb(8,9) B(9,9)...

#### 6.9.4.3.4.5 RAWFE Gain & Offset Block

The gain block allow 2 primary functions

- Allow for digital gain to be applied if the image is too dark even after analog gain and exposure time have been set to the maximum
- Independent gain setting for each color channel in 13 bit format U13Q9 with 9 bits of fraction.
  - Allows a gain value from 0 to 31.996 in steps of  $1/256$ .

The Gain block can be configured to apply an offset on top of the gain. This is to support the log compressed image mode, where in the traditional WB Gain becomes an offset.

#### 6.9.4.3.4.6 RAWFE H3A

##### 6.9.4.3.4.6.1 RAWFE H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting statistics about the raw image. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:

The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:

- Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
- Accumulation mode in a paxel

- Accumulation of horizontal and vertical focus value in a paxel
- Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
- Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
- Programmable width and height for the paxel/window
- Programmable red, green, and blue position within a  $2 \times 2$  matrix
- Separate horizontal start for paxel and filtering
- Programmable vertical and horizontal line increments within a paxel
- Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
- Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.

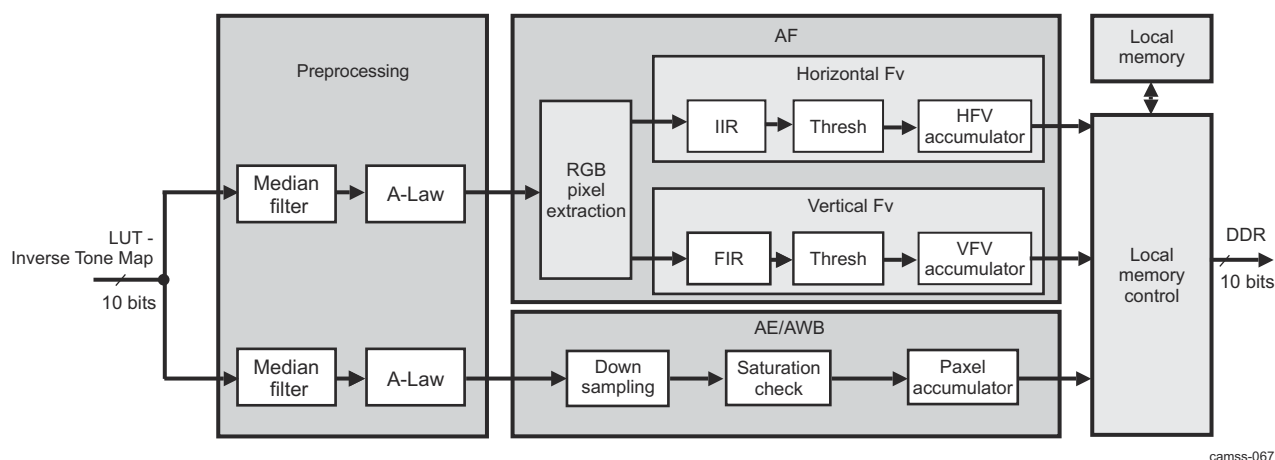

• Auto exposure and auto white balance (AE/AWB) engine:

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

- Accumulate clipped pixels along with all nonsaturated pixels in each window per color
- Accumulate the sum of squared pixels in each window per color
- Minimum and maximum pixel values in each window per color
- Support for up to 36 horizontal windows with sum + { sum\_sq or min+max } output
- Support for up to 56 horizontal windows with sum output
- Support for up to 128 vertical windows
- Programmable width and height for the windows. All windows in the frame are the same size.
- Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
- Programmable horizontal sampling points in a window
- Programmable vertical sampling points in a window
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 4096 pixels.

#### 6.9.4.3.4.6.2 RAWFE H3A Top-Level Block Diagram

The block diagram in Figure 6-65 shows the process of the AF and AE/AWB data paths through the H3A module.

camss-067

**Figure 6-65. RAWFE H3A Top-Level Block Diagram**

#### 6.9.4.3.4.6.3 RAWFE H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the VISS\_RAWFE\_H3A\_LINE\_START register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 4096 pixels. After 4096 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 4096 clock cycles, then the active region ends immediately and the counter waits for the VISS\_RAWFE\_H3A\_LINE\_START register count to be reached again. For the vertical position the VISS\_RAWFE\_H3A\_LINE\_START[31:16] SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 6-66 shows the RAWFE H3A frame format settings.

**Figure 6-66. RAWFE H3A Frame Format Settings**

#### Note

(Frame width on VP) - (VISS\_RAWFE\_H3A\_LINE\_START[15:0] LINE\_START) must be less than or equal to 4096, because the H3A memory lines are limited to 4096 pixels.

#### 6.9.4.3.4.6.4 RAWFE H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the VISS\_RAWFE\_H3A\_PCR[1] AF\_ALAW\_EN bit) and the AE/AWB engine (the VISS\_RAWFE\_H3A\_PCR[17] AEW\_ALAW\_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the VISS\_RAWFE\_H3A\_PCR[2] AF\_MED\_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The

horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i – 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i – 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the VISS\_RAWFE\_H3A\_PCR[10:3] MED\_TH bit field.

#### **6.9.4.3.4.6.5 RAWFE H3A Autofocus Engine**

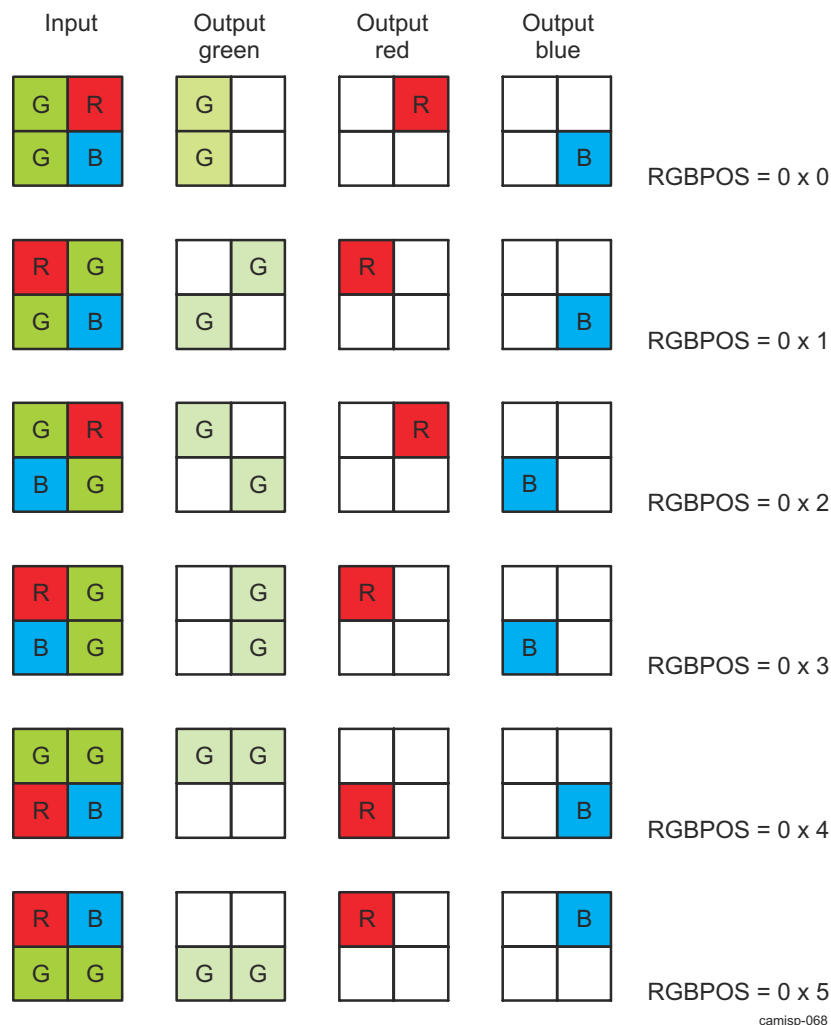

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV<sup>2</sup> are produced. The FV and FV<sup>2</sup> values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

##### **6.9.4.3.4.6.5.1 RAWFE H3A Paxel Extraction**

From the paxel starting coordinate (the VISS\_RAWFE\_H3A\_AFPAXSTART[27:16] PAXSH and VISS\_RAWFE\_H3A\_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the paxel grid, with respect to first pixel of the input image frame.

The paxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if VISS\_RAWFE\_H3A\_PCR[20] AF\_VF\_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the VISS\_RAWFE\_H3A\_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. [Figure 6-67](#) shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

**Figure 6-67. RAWFE H3A Red, Green, and Blue Pixel Extraction Examples**

Each paxel is VISS\_RAWFE\_H3A\_AFPAX1[23:16] PAXW × VISS\_RAWFE\_H3A\_AFPAX1[7:0] PAXH (width × height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every VISS\_RAWFE\_H3A\_AFPAX2[16:13] AFINCV lines. Vertical FV can skip columns, operating on one every VISS\_RAWFE\_H3A\_AFPAX2[20:17] AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) ≥ 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column VISS\_RAWFE\_H3A\_AFIIRSH[11:0] IIRSH.

Figure 6-68 shows the RAWFE H3A horizontal/vertical fv paxel configuration.

**Figure 6-68. RAWFE H3A Horizontal/Vertical FV Poxel Configuration**

**Note**

$$(\text{VISS\_RAWFE\_H3A\_AFPAXSTART}[27:16] \text{ PAXSH}) + (\text{VISS\_RAWFE\_H3A\_AFPAX2}[5:0] \text{ PAXHC}) \\ \times (\text{VISS\_RAWFE\_H3A\_AFPAX1}[23:16] \text{ PAXW}) \leq [(\text{Frame width on VP}) - \\ (\text{VISS\_RAWFE\_H3A\_LINE\_START}[15:0] \text{ LINE\_START})] \leq 4096$$

Table 6-121 lists the bit fields that configure the size and number of paxels.

**Table 6-121. RAWFE H3A Poxel Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AFPAX1[23:16] PAXW	8	Poxel width (in pixels)
VISS_RAWFE_H3A_AFPAX1[7:0] PAXH	8	Poxel height (in lines)
VISS_RAWFE_H3A_AFPAX2[5:0] PAXHC	6	Poxel count for horizontal direction
VISS_RAWFE_H3A_AFPAX2[12:6] PAXVC	7	Poxel count for vertical direction
VISS_RAWFE_H3A_AFPAX2[16:13] AFINCV	4	Line increments in a poxel
VISS_RAWFE_H3A_AFPAX2[20:17] AFINCH	4	Column increments in a poxel
VISS_RAWFE_H3A_AFPAXSTART[27:16] PAXSH	12	Poxel start position H
VISS_RAWFE_H3A_AFPAXSTART[11:0] PAXSV	12	Poxel start position V
VISS_RAWFE_H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the VISS\_RAWFE\_H3A\_ADVANCED[31:15] ID bit field, then VISS\_RAWFE\_H3A\_ADVANCED[0] AF\_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV\_1 and HFV\_2.

#### 6.9.4.3.4.6.5.2 RAWFE H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range –128 to 127 or –512 to 511.

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide

with 6 bits of decimal, S12Q6 (VISS\_RAWFE\_H3A\_AFCOEF010 to VISS\_RAWFE\_H3A\_AFCOEF0010 for SET0, and VISS\_RAWFE\_H3A\_AFCOEF110 to VISS\_RAWFE\_H3A\_AFCOEF1010 for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the VISS\_RAWFE\_H3A\_AFIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is  $m$  bits (signed) and the required output value is  $n$  bits, clipping transforms the input to between  $-2^1$  and  $2^1$ . Values lower than  $-2^1$  are set to  $-2^1$ , and values higher than  $2^1$  are set to  $2^1$ .

#### 6.9.4.3.4.6.5.3 RAWFE H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 6-121 lists the register fields that configure the size and number of paxels:

- In peak mode (VISS\_RAWFE\_H3A\_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (VISS\_RAWFE\_H3A\_PCR[14] FVMODE = 0x0), all HFV<sub>n</sub> are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV<sub>n</sub> (HFV<sub>n\_peak</sub> for peak mode or HFV<sub>n\_sum</sub> for sum mode)
- HFV\_count<sub>n</sub>
- HFV\_sq<sub>n</sub> (HFV\_sq<sub>n\_peak</sub> for peak mode or HFV\_sq<sub>n\_sum</sub> for sum mode)

$n = 1$  or  $2$  for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
    rowpeak_n = 0;
    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
        if (aIIRout_n >= threshold_n)
        {
            hfval = aIIRout_n - threshold_n;
            HFV_count_n++;
        }
        else hfval = 0;
        if (hfval > rowpeak_n)
        {
            rowpeak_n = HFV_n;
        }
        HFV_n_sum += hfval;
        HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
    } // Finished looping on values in a row
    HFV_n_peak += rowpeak_n;
    HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}
```

- threshold<sub>n</sub> is VISS\_RAWFE\_H3A\_HVF\_THR[15:0] HTHR1 and VISS\_RAWFE\_H3A\_HVF\_THR[31:16] HTHR2, respectively.
- IIRout<sub>n</sub> is the IIRout<sub>1</sub> and IIRout<sub>2</sub> outputs, respectively.
- HFV\_count<sub>n</sub> and HFV\_sq<sub>n</sub> are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
  - HFV<sub>n</sub> = HFV<sub>n\_sum</sub>
  - HFV\_sq<sub>n</sub> = HFV\_sq<sub>n\_sum</sub>
- In peak mode:

- HFV\_n = HFV\_n\_peak
- HFV\_sq\_n = HFV\_sq\_n\_peak

#### 6.9.4.3.4.6.5.4 RAWFE H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1\_x, where x = 0 to 4, in the VISS\_RAWFE\_H3A\_VFV\_CFG1 and VISS\_RAWFE\_H3A\_VFV\_CFG2 registers for FIR 1, and VCOEF2\_x, where x = 0 to 4, in the VISS\_RAWFE\_H3A\_VFV\_CFG3 and VISS\_RAWFE\_H3A\_VFV\_CFG4 registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold VISS\_RAWFE\_H3A\_VFV\_CFG2[31:16] VTHR1 for FIR 1, and VISS\_RAWFE\_H3A\_VFV\_CFG4[31:16] VTHR2 for FIR 2, and square logic to produce VFV\_n and VFV\_sq\_n.

#### 6.9.4.3.4.6.5.5 RAWFE H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

[Table 6-121](#) lists the bitfields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV\_n
- VFV\_count\_n
- VFV\_sq\_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;
if (aFIRout_n >= threshold_n)
{
    VFV_n = aFIRout_n - threshold_n
    VFV_count_n++;
}
else VFV_n = 0;
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold\_n is VISS\_RAWFE\_H3A\_VFV\_CFG2[31:16] VTHR1 and VISS\_RAWFE\_H3A\_VFV\_CFG4[31:16] VTHR2, respectively.
- FIRout\_n is the FIRout\_1 and FIRout\_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

#### 6.9.4.3.4.6.6 RAWFE H3A AE/AWB Engine

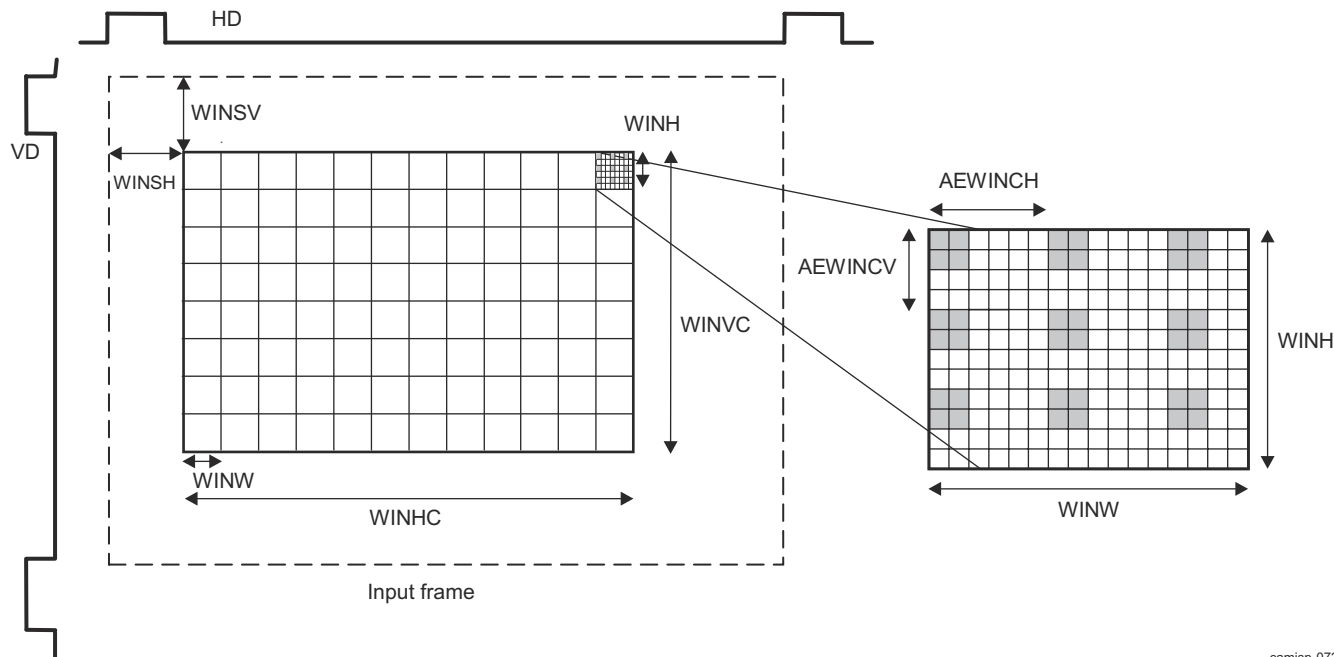

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x0
- Min/max mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: VISS\_RAWFE\_H3A\_AEWCFG[9:8] AEFMT = 0x2

#### 6.9.4.3.4.6.1 RAWFE H3A Sub\_sampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in Figure 6-69. Each window is further sampled down to a set of  $2 \times 2$  blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in Figure 6-69.

camisp-072

**Figure 6-69. RAWFE H3A AE/AWB Window Configurations**

Table 6-122 lists the bit fields that configure the window and block sizes, counts, and starting positions.

**Table 6-122. RAWFE H3A AE/AWB Window Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

#### 6.9.4.3.4.6.2 RAWFE H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the VISS\_RAWFE\_H3A\_AEWINBLK[27:16] WINSV bit field, and the height is specified in the VISS\_RAWFE\_H3A\_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 6-70 shows a black row of windows before rows of windows.

camisp-075

**Figure 6-70. RAWFE H3A Black Row of Windows Before Regular Rows of Windows**

Table 6-123 lists the bit fields that configure the window and block sizes, counts, and starting positions.

**Table 6-123. RAWFE H3A AE/AWB Window With Additional Black Row Register Field Descriptions**

Bit Field	Bit Width	Description
VISS_RAWFE_H3A_AEWIN1[20:13] WINW	7	Window width (in pixels)
VISS_RAWFE_H3A_AEWIN1[31:24] WINH	7	Window height (in lines)
VISS_RAWFE_H3A_AEWIN1[5:0] WINHC	6	Window count for horizontal direction
VISS_RAWFE_H3A_AEWIN1[12:6] WINVC	7	Window count for vertical direction
VISS_RAWFE_H3A_AEWINSTART[11:0] WINSH	12	Window start position H
VISS_RAWFE_H3A_AEWINSTART[27:16] WINSV	12	Window start position V
VISS_RAWFE_H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
VISS_RAWFE_H3A_AEWSUBWIN[11:8] AEWINC	4	Vertical distance between subsamples
VISS_RAWFE_H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
VISS_RAWFE_H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

#### 6.9.4.3.4.6.3 RAWFE H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the VISS\_RAWFE\_H3A\_PCR[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the  $2 \times 2$  block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

#### 6.9.4.3.4.6.4 RAWFE H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every  $2 \times 2$  pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a  $2 \times 2$  pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the  $2 \times 2$  pixel grid is associated with a color R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See [Section 6.9.4.3.4.6.4](#) for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the VISS\_RAWFE\_H3A\_AEWCFG[3:0] SUMSHFT bit field.

#### 6.9.4.3.4.6.7 RAWFE H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the VISS\_RAWFE\_H3A\_AFBUFST[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the VISS\_RAWFE\_H3A\_AFBUFST[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of pixels or windows. This requires that each horizontal row of pixels or windows starts and ends on a 32-byte boundary. If a horizontal row of pixels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

[Table 6-124](#) shows the packet formats for AF with vertical AF enabled.

**Table 6-124. RAWFE H3A AF Packet Format With Vertical AF Enabled**

Buffer Start Address (Byte Address)	31	16	15	0

#### 6.9.4.3.4.6.8 RAWFE H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The VISS\_RAWFE\_H3A\_PCR[15] BUSYAF and/or VISS\_RAWFE\_H3A\_PCR[18] BUSYAEAWB status bits are set when the start of frame occurs (if the VISS\_RAWFE\_H3A\_PCR[0] AF\_EN and/or VISS\_RAWFE\_H3A\_PCR[16] AEW\_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The VISS\_RAWFE\_H3A\_PCR[15] BUSYAF and/or VISS\_RAWFE\_H3A\_PCR[18] BUSYAEAWB status bits may be polled to determine the end of frame status.

#### 6.9.4.3.4.6.9 RAWFE H3A Interface Mux

The H3A logic also implements an LUT or Shift /clip block. The LUT logic is same as the decompanding LUT in the previous section(s) with some minor modifications. The input bit width to the LUT cannot exceed 16 and the LUT entry size is only 10 bits, since the H3A logic works on 10 bit data.

The logic also implements a shift and clipU10 functionality for converting data from up to 24 bits down to 10. The shift parameter has to be programmed to implement the desired shift value. The shift register programming must ensure that the output of the shift is not greater than 16bits when the LUT is enabled and it should not be greater than 10 bits when the LUT is disabled.

#### 6.9.4.3.4.6.10 RAWFE H3A interface to LSE

The H3A interface to LSE is VBUSP. It uses channel id to indicate data or control information. Please refer to LSE functional spec on control information mapping to channel id bits.

#### 6.9.4.3.4.6.11 RAWFE H3A Erratas

The following hardware restrictions apply and need to be taken care of by software:

1. When AF is enabled software can not use the first or last pixels in the window. Start at position 2 end at line -2.
2. When AEW is enabled software can not use the first pixel in a window. Start at position 2.
3.  $(PAXW+1) \% (AFINCH+1) \neq 1$  when VF enabled (PAXW and AFINCH are raw MMR parameters)

#### 6.9.4.3.5 RAWFE Programmer's Guide

##### 6.9.4.3.5.1 RAWFE Core programming details

There are multiple use cases that can be enabled with this module, however broadly the use case are broken in to two categories, one for Companded Data sensors and the other for Separate Exposures sensors. The following fields should be programmed correctly for the IP to function

- PWL Core
- Set slopes and thresholds as per sensor settings only for Companded sensors
- Decompanding LUT
- This LUT is used for global tone map of decompounded data from 24 bits to 16 bits. (This is typically not used for separate exposures sensor)

- Merge Logic
- Program the merge block based on the exposure ratios of the incoming data.
- This block is typically not used for companded sensors.
- LUT after merge should be programmed to tone map from 20 bits down to 16 (Separate exposure sensors only)
- DPC/ LSC
- Set as per tuning parameters for both companded/separate exposures sensors
- H3A LUT and settings
- Use LUT if H3A input comes after LSC. Program LUT to apply inverse global curve.
- Use shift if data is coming from exposures directly.

#### **6.9.4.3.5.2 RAWFE Initialization Sequence**

See [Section 6.9.3](#), *VPAC Subsystem* for details.

#### **6.9.4.3.5.3 RAWFE Real-time Operating Requirements**

See [Section 6.9.3](#), *VPAC Subsystem* for details.

#### 6.9.4.4 VISS Spatial Noise Filter (NSF4V)

##### 6.9.4.4.1 NSF4V Introduction

###### 6.9.4.4.1.1 NSF4V Features

For a list of features supported by the NSF4V module, see Section *VPAC Features*.

Some additional NSF4V parameters include:

- Input image format: any 2x2 raw color pattern
- Frame Width: limited to 4096
- Throughput:
  - 1 pixel in/out per clock
- Back Pressure Mechanism:
  - Input clock gating
  - Vert line sync
    - 7 extra lines of clocks plus enough clocks to flush pipeline

###### 6.9.4.4.1.2 NSF4V Not Supported Features

NSF4V does not support the following features:

- Edge Enhancement
- YUV formats
- Module bypass (it is implemented at top subsystem level)

###### 6.9.4.4.2 NSF4V Overview

The advanced noise filter NSF4v decomposes the input image into low-frequency, mid-frequency, and high-frequency bands first and then filter out the noise in frequency domain. NSF4v can adapt its noise filtering strength to local image intensity according to the user programmable noise threshold registers. NSF4 is also able to adjust its strength according to the amount of previously applied lens shading correction gains with a user programmable approximate radial model.

###### 6.9.4.4.2.1 Decomposition Kernel Representation

With combination of just level 1, levels 1+2, and levels 1+2+3, horizontally and vertically, the result feature detection filter kernels are shown in [Figure 6-71](#). Note that all coefficients are powers of 2, and therefore do not require multiplication.

$$\begin{aligned}
 F1 &= \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix} /4 \\
 F2 &= \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix} /4 \\
 F3 &= \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} /4 \\
 F4 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \end{bmatrix} /16 \\
 F5 &= \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix} /16 \\
 F6 &= \begin{bmatrix} 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & -1 \\ -1 & -1 & 1 & 1 \\ -1 & -1 & 1 & 1 \end{bmatrix} /16 \\
 F7 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F8 &= \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 \end{bmatrix} /64 \\
 F9 &= \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \\ -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 \end{bmatrix} /64
 \end{aligned}$$

nsf4v-002

**Figure 6-71. NSF4V Kernel Representation for Decomposition Filters**

G1...9 are the counter-part reconstruction kernels. Each of G1...9 is a row-wise and column-wise mirror of the counterpart F function.

The kernel representation in [Figure 6-72](#) illustrates a filter alignment.

nsf4v-003

**Figure 6-72. NSF4V Kernel Representation Filter Alignment**

Figure 6-72 is showing an academic 8x8 pixel image frame which has been border extended on all 4 edges. Superposed onto this border extended frame (shown in dotted lines) is the kernel alignment for all 3 different kernel sizes for each of the three levels:

- Level 1: 2x2 kernel
- Level 2: 4x4 kernel
- Level 3: 8x8 kernel

For each of the 9 different kernels, a matrix of (width + 7) x (height + 7) decomposition values result. All of these result matrixes are exactly aligned.

nsf4v-004

**Figure 6-73. NSF4V Example F1 Kernel Result**

The kernel alignment is top-left aligned for the first pixel. Which translates in the recursive approach as a X-Y shift. In order to be mathematically aligned in the Recursive approach, the Level 1 output needs to be shifted 6 positions in both the X and Y direction relative to the Level 3 output. Additionally, the Level 2 output needs to be shifted 4 positions in both the X and Y direction relative to the Level 3 output. These shifts are critical such that Level 1, 2, and 3 values are cycle aligned when presented to the thresholding circuit.

One can reach the same conclusion by looking at the figure and thinking about which line delay or which horizontal pipelined pixel position is used in order for the kernels to output their results in the same pipeline cycle.

#### 6.9.4.4.3 NSF4V Lens Shading Correction Compensation

The Lens Shading Correction (LSC) is implemented prior to NSF. This is not an optimal order of operation and therefore an adjustment factor is implemented to compensate for the order of operations. The LSCC (Lens Shading Correction Compensation) first approximates the gain of LSC and calculates both that gain and it's inverse. Within the T<sub>n</sub> calculation, the inverse gain is applied to the LL2 average, then the T<sub>n</sub> is calculated. Last, the result is multiplied by the gain. In this way, the LSC is approximately reversed temporarily in order that T<sub>n</sub> is calculated properly.

LSCC calculates the radius (distance) from the center of the image, then uses a programmable curve to look up the gain value.

While calculating the radius, the center on the frame is programmable. Also a correction gain (kh and kv) separately for X and Y are programmable which allows for elliptical shaped lenses. Because the SQRT is such an expensive function, the resulting radius is used in the SQR form and as such has a very large dynamic range. A programmable shift value effectively selects which portion of this dynamic range is to use for the curve lookup.

The curve lookup is a 16 segment curve. The SQR(Radius) is lookup on the X axis and the resulting gain is supplied on the Y axis.

#### 6.9.4.4.4 NSF4V Noise Threshold Adaptation to Local Image Intensity

Figure 6-74 shows the local image intensity to noise threshold  $T_n$  mapping via the 12-segment interpolated lookup. Twelve sets of  $(X, Y, S)$ ,  $S$  = slope, are provided per curve, one set per color plane, with the first  $X$  coordinate fixed at zero.

**Figure 6-74. NSF4V Local Image Intensity to Noise Threshold Piece-wise Linear Function**

The slopes should be implemented with signed value, as some image sensors might require higher noise threshold at the low intensity range than high intensity range.

### 6.9.4.5 VISS Global/Local Brightness and Contrast Enhancement (GLBCE) Module

#### 6.9.4.5.1 GLBCE Overview

The Global Local Brightness Contrast Enhancement module performs dynamic range compression or tone mapping of an input image based on a model of the human visual system. It is used to produce most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations.

#### 6.9.4.5.2 GLBCE Interface

Data flow control of GLBCE module is done by PCLK. GLBCE processes the image cycle by cycle, and output the data after certain cycles of latency.

#### 6.9.4.5.3 GLBCE Core

The GLBCE Core is an iridix® core which performs "dynamic range compression" or "tone mapping" on an input image based on a model of the human visual system. It is used in a camera pipeline to produce the most natural images under a wide range of capture conditions, typically by revealing shadow detail which would otherwise be under-exposed in high contrast situations. The purpose of the transform is to map the image content from an input source such that it remains fully visible on an output display without loss of content. Note that iridix is specifically designed to preserve color, sharpness and boost contrast of the source image.

The iridix core is based on space-variant or pixel-by-pixel processing algorithms which construct a family of transforms based on the analysis of image content. The algorithms inside iridix are adaptive, meaning that a single set of parameters can be set to process any source image or any video sequence under different lighting conditions.

Iridix generates effective tone curves by analyzing the regions surrounding each pixel. The tone curves generated by iridix are based on an asymmetry curve which is then shaped and controlled by a number of parameters that control the gain limitation weighting towards shadows, mid tones and highlights.

##### 6.9.4.5.3.1 GLBCE Core Key Parameters

[Table 6-128](#) shows the key parameters within the iridix core. It is recommended that all parameters be set statically to their recommended values other than the iridix strength parameter, which should be controlled dynamically with scene content. The calculation of iridix strength is explained in [Section 6.9.4.5.3.2](#).

**Table 6-128. GLBCE Core Key Parameters**

Parameter	Description
iridix strength	This register sets iridix processing strength.
	0x00: Video data will not be processed at all, and will pass to the output unchanged.
	0xFF: Maximum processing strength.
Variance space	This register affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). If this parameter is set to zero, the sensitivity to small areas is maximized (i.e. the transform becomes more local). When this parameter is set to 0xF, the transform deemphasizes small local details, and the transform becomes more global
Variance intensity	For a high-contrast image with shadows and highlights, a small value will cause iridix to adjust shadows and highlights almost independently. A large variance causes iridix to become progressively more global, meaning that the presence of highlights affects the processing of shadows and vice-versa.
Slope min limit	This register is used to restrict the slope of the tone curve generated by iridix. When this parameter is set to 0x00, the tone curve slope generated by iridix is not limited.
	When this value is set to 0xFF, iridix will not generate a tone curve with a slope less than 3/4. Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-128
Slope max limit	This register is used to restrict the slope of the tone-curve generated by iridix. When this parameter is set to 0xFF, the tone curve slope generated by iridix is not limited.
	When this value is set to 0x00, iridix will not generate a tone-curve with slope greater than 16/15 (48°). Intermediate values of slope limit are linear interpolation between minimum and maximum values.
	The recommended range of this parameter is 0-160. For noisy images, lower values should be used.

**Table 6-128. GLBCE Core Key Parameters (continued)**

Parameter	Description
Black level	The value stored in this register will be used as the zero level for iridix processing in all data channels. Data below this value will not be processed and remain unchanged.
White level	The value stored in this register will be used as the white level for iridix processing in all data channels. Data above this value will not be processed and remain unchanged.
Asymmetry LUT	This look-up-table is 33 words, each of which is 16-bits. The asymmetry function is used to balance the iridix effect between the dark and bright regions of the image.
Forward perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is presented to the core, this look-up-table must be used to map the linear data to the perceptual space so that iridix can perform its perceptual functions.
Reverse perceptual LUT	The iridix core works in a perceptually uniform space and thus when linear data is required from the output of the core, this look-up-table must be used to map the data from the perceptual space back to linear space for further processing in the pipeline.

#### 6.9.4.5.3.2 GLBCE Iridix Strength Calculation

This section describes how the dynamic parameter, iridix strength, is calculated.

#### Note

Dynamic range of a digital camera can be described as the ratio of maximum light intensity measurable (at pixel saturation), to minimum light intensity measurable (but above read-out noise). This is a very important concept to consider when computing iridix strength, because the gain applied by iridix is also proportional to the visible boost of noise in the image. The maximum gain applied by iridix should be determined by the dynamic range of the camera system. This is governed by the equation presented in this section.

With iridix strength is zero, all tone curves are linear for all images. As iridix strength is increased, the variation between curves in shadows, mid tones and highlights increases, resulting in increasing compression of global dynamic range.

Iridix strength is calculated as follows:

$$\text{iridix strength} = \text{Max} \left( 0, \text{Min} \left( \frac{\text{IR\_Gain\_Target} - 1}{\text{IR\_Gain\_Max} - 1}, f(\text{analog gain}) \right) \right) * 255$$

glbce-843

**Figure 6-75. GLBCE Iridix Strength Formula**

Where:

- IR\_Gain\_Target is the desired iridix gain to be applied to the image. This is calculated from the image's histogram on a per-frame basis by the auto exposure algorithm (in RAWFE H3A module). The histogram is analysed to compute an exposure ratio for the desired global histogram shift. This computed exposure ratio is then used to feed a look-up-table which in turn generates the IR\_Gain\_Target parameter.
- IR\_GainMax is the maximum iridix gain. If the fwd\_percep\_lut is disabled, then the IR\_GainMax should be set to 64, and if the fwd\_percep\_lut is enabled, then the IR\_Gainmax should be set to 16.
- f(analog gain) is a function that determines the maximum iridix strength in relation to noise. f(analog gain) is characterised as follows:

**Figure 6-76. GLBCE Iridix f(Analog Gain) Function**

$f(\text{analog gain})$  should only be used when the RAWFE is in linear mode. Otherwise, it should be set to 1

#### **6.9.4.5.3.3 GLBCE Iridix Configuration Registers**

##### **6.9.4.5.3.3.1 GLBCE Iridix Frame Width**

Frame Width is the number of pixels in an active line and is controlled from GLBCE\_FRAME\_WIDTH[15:0] VAL. Recommended value 2560 (decimal)

##### **6.9.4.5.3.3.2 GLBCE Iridix Frame Height**

Frame Height is the number of active lines in a frame and is controlled from GLBCE\_FRAME\_HEIGHT[15:0] VAL. Recommended value 1920 (decimal)

##### **6.9.4.5.3.3.3 GLBCE Iridix Control 0**

This is the main control register for the iridix core is GLBCE\_CONTROL0 where GLBCE is enabled/disabled and the type of processing algorithm is selected.

##### **6.9.4.5.3.3.4 GLBCE Iridix Control 1**

This register is reserved for debugging purposes. Recommended value 6 (decimal)

##### **6.9.4.5.3.3.5 GLBCE Iridix Strength**

GLBCE\_STRENGTH\_IR[7:0] VAL register sets the processing strength of the iridix core. Recommended value 128 (decimal)

##### **6.9.4.5.3.3.6 GLBCE Iridix Variance**

The GLBCE\_VARIANCE parameter affects the sensitivity of the transform to different areas of the image, and can be increased in order to emphasize small regions (e.g. faces). GLBCE\_VARIANCE[7:4] VARIANCEINTENSITY recommended value 12 (decimal). GLBCE\_VARIANCE[3:0] VARIANCESPACE recommended value 7 (decimal).

##### **6.9.4.5.3.3.7 GLBCE Iridix Dither**

When the number of color gradations of a display device is small (for example 6 bits per color), pixel dithering can make gradients look smother. Dithering of the least significant bits is applied and then these bits can be later truncated. The three least significant bits (D2, D1, D0) of this GLBCE\_DITHER register are responsible for the strength of dithering. There are 4 possible levels of dithering. Recommended value 0 (decimal)

#### 6.9.4.5.3.3.8 GLBCE Iridix Amplification Limit

The parameters dark amplification limit and bright amplification limit are used to restrict the luminance space in which iridix can adaptively generate tone curves for each pixel. GLBCE\_LIMIT\_AMPL[7:4] BRIGHTAMPLIFICATIONLIMIT recommended value 0 (decimal). GLBCE\_LIMIT\_AMPL[3:0] DARKAMPLIFICATIONLIMIT recommended value 0 (decimal).

#### 6.9.4.5.3.3.9 GLBCE Iridix Slope Min and Max

GLBCE\_SLOPE\_MIN[7:0] SLOPEMINLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 64 (decimal).

GLBCE\_SLOPE\_MAX[7:0] SLOPEMAXLIMIT register is used to restrict the slope of the tone curve generated by iridix. Recommended value 72 (decimal).

#### 6.9.4.5.3.3.10 GLBCE Iridix Black Level

The value stored in the Black Level register GLBCE\_BLACK\_LEVEL[15:0] VAL will be used as the zero level for iridix processing in all data channels. Data below the Black level will not be processed and remain unchanged. Recommended value 0 (decimal).

#### 6.9.4.5.3.3.11 GLBCE Iridix White Level

The value stored in White Level register GLBCE\_WHITE\_LEVEL[15:0] VAL will be used as white level for iridix processing in all data channels. Data above White level will not be processed and stay unchanged. Recommended value 65535 (decimal).

#### 6.9.4.5.3.3.12 GLBCE Iridix Asymmetry Function Look-up-table

The Asymmetry function is used to balance the iridix effect between the dark and bright regions of the image. The Asymmetry Function Lookup Table geometry is 33 words, each of which is 16-bits wide.

GLBCE\_LUT\_FI\_00

GLBCE\_LUT\_FI\_01

... repeat until...

GLBCE\_LUT\_FI\_32

Recommended values (decimal):

0:5377:10218:14600:18585:22224:25561:28631:31466:34092:36530:38801:40921:42904

:61429:62322:63176:63995:64781:65535

The C-code for generating the Asymmetry LUT is shown below:

```
#include <math.h>
int AsymmetryTable[33];
void GenerateAsymmetry(int Asymmetry, int SecondPole)
{
    double x = (double(Asymmetry)+1)/257 * 2 - 1;
    int ai = (int)floor(0.5 + 255 * (1- 1/(1000*x*x*x) + x - ((x >= 0)*2)));
    double as = fabs(double(ai) / 255);
    double dp = double(SecondPole) / 255;
    int ii;
    for (ii = 0 ; ii < 33 ; ++ii)
    {
        if(ai >= 0)
        {
            x = double(ii) / 32;
        }
        else
        {
            x = double(32 - ii) / 32;
        }
        int y = (int)floor((dp+(1-dp)*pow((fabs(1-dp-x)/dp), 3)) * (x*(as+1)/(as+x) ) *
            65535.0 + 0.5);
        y = y < 0 ? 0 : y > 65535 ? 65535 : y;

        if (ai < 0)
        {

```

```

        y = 65535 - y;
    }
    AsymmetryTable[ii] = y;
}

```

#### 6.9.4.5.3.3.13 GLBCE Iridix Forward and Reverse Perceptual Functions Look-up-tables

The iridix core works in a perceptually uniform space and thus when linear data is presented to the core it needs to be processed with special perceptual functions. These are implemented as two perceptual LUTs namely: Forward Perceptual LUT and Reverse Perceptual LUT. Each LUT is made up of sixty-five 32-bit words.

GLBCE\_REV\_PERCEPT\_LUT\_00  
GLBCE\_REV\_PERCEPT\_LUT\_01

#### 6.9.4.5.4 GLBCE Embedded Memory

GLBCE needs 2 lines of line memories and 1 set of cache memories.

**Table 6-129. GLBCE Memories**

Memory Type	Qty	Size	Clock	ECC Supported	Description
DELAY LINE	1	2122 x 64 (GLBCE_LINE_SIZE /2+10)x64	FCLK	No	GLBCE line memory
STATMEM	8 banks	16 bit x 1024	FCLK	Yes	GLBCE Cache memory (computes and stores the statistics from the frame)

#### 6.9.4.5.5 GLBCE General Processing

GLBCE block needs appropriate statistics information to be stored to its cache memory in prior to processing incoming frame. Usually, this takes a two-pass process.

1. GLBCE is configured for input frame-A
2. Frame-A is given to GLBCE
3. GLBCE processes the input frame-A
4. GLBCE generates statistic (statistics-A) data based on frame-A in vertical blanking period
5. (Optional process) statistics-A is read from cache memory and moved to SDRAM
6. GLBCE is configured for input frame-B
7. Frame-B is given to GLBCE
8. GLBCE processes the input frame-B with the statistics-A generated from frame-A
9. GLBCE generates statistics-B based on frame-B in vertical blanking period
10. (Optional process) statistics-B is read from cache memory and moved to SDRAM

Alternatively, GLBCE can process in the following manner

1. Pre-calculated Statistics-C is copied to GLBCE cache memory from SDRAM
2. GLBCE is programmed for input frame-D
3. Frame-D is given to GLBCE
4. GLBCE processes frame-D based on statistics-C
5. GLBCE generates statistics-D based on frame-D in vertical blanking period
6. (Optional process) statistics-D is read from cache memory and moved to SDRAM

In [Section 6.9.4.5.6](#), some examples closer to real world use cases are explained based on the above two processes.

#### 6.9.4.5.6 GLBCE Continuous Frame Processing

This is a very basic case, which does not need transferring statistics between cache memory and SDRAM. The most common example is video capture. In this case, the most straight forward way to run GLBCE, is to generate statistics from N-th frame, and apply it to (N+1)-th frame. The effect from using statistics of different frame should be small if the difference between frames is small. For example, it is expected this does not generate artifact, if the video frame rate is 30fps or larger. Below this rate, the single frame processing programming model explained in [Section 6.9.4.5.7](#) should be considered.

In the case of continuous frame processing, GLBCE is operated in the following manner:

1. GLBCE is programmed for incoming frame

2. Input frame comes in
3. GLBCE processes Input frame based on the statistics from the previous frame
4. GLBCE generates statistics based on the current input frame in the vertical blanking period
5. Repeat Step 1 through 4 as required

For the first frame of a set of sequential frames, Strength parameter should be 0, so GLBCE does not affect the image based on wrong statistics. SW may need to increase the strength value gradually after the first frame.

#### **6.9.4.5.7 GLBCE Single Image Processing**

For a single image, GLBCE needs to process the image twice, once for statistics generation, and once for actual GLBCE process.

1. GLBCE is configured for the input image.
2. The image is given to GLBCE. (Output image from GLBCE should be suppressed, for example, by disabling the next module in the path)
3. Statistics is generated in vertical blanking period.
4. The input image is given to GLBCE again. Output image with right GLBCE is generated.

Also, GLBCE can take in small size image in the first pass to reduce processing time.

5. A small size version (IMG-S) of the input image (IMG-IN) is generated.
6. GLBCE is configured for the small size image (IMG-S).
7. The small size image (IMG-S) is given to GLBCE.
8. Statistics for the small size image is generated in vertical blanking period.
9. GLBCE is configured for the original input image (IMG-IN).
10. The original input image (IMG-IN) is given to GLBCE.

### 6.9.4.6 VISS Flexible Color Processing (FCP) Module

#### 6.9.4.6.1 FCP Overview

The Flexible Color Processing module is responsible for performing CFA Interpolation as well as performing a host of color processing functions for generating different color outputs.

##### 6.9.4.6.1.1 FCP Features Supported

The FCP include the following main features:

- Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats
  - Can generate up to 4 independent color planes
  - Support for up to 3 directions per color plane
  - Adaptive Threshold based on intensity measure
- Support for multiple color format output generation:
  - Support 12-bit YUV output
  - Supports RGB output
  - Supports Saturation outputs (8 bits only)
  - Supports Grayscale/Luma/IR/Clear output.
- Support for 16 to 12 compression (LUT based) at the entry of the block
- Support for flexible output format generation including YUV as well as RGB, SV, and so forth.
- Single cycle/pixel performance

##### 6.9.4.6.2 FCP Functional Description

The Flexible Color Processor (FCP) receives data from RAW-FE and does demosaicing and color conversion. The output of FCP is sent to external memory.

**Figure 6-77. FCP Block Diagram**

The FCP consists of the following major sub-blocks for supporting different sensor and output formats:

- LUT based compression: used to reduce the bit width from 16 bits to 12 bits while still preserving the dynamic range.
- Flexible CFA: this block takes in as input any 2x2 raw sensor pattern and is capable of generating up to 4 full resolution color planes.
- Flexible Color Conversion (Flexible CC): this block takes in the output of the Flexible CFA and generates multiple standard as well as custom data formats.
- Flexible Edge Enhancer (Flexible EE): this block can take the output of the Color Conversion and align the Y and UV channels as well as enhance the edges in the luma channel.

##### 6.9.4.6.3 FCP Submodule Details

###### 6.9.4.6.3.1 Flexible CFA / Demosaicing

###### 6.9.4.6.3.1.1 Feature-set

The Flexible CFA include the following main features:

- Support for Flexible CFA for generating multi-plane output for any 2x2 raw format sensor configuration.
  - Supports RCBC, RCCC, Bayer, RGBC as well as other formats.

- Can generate up to 4 independent color planes.
- Supports Clear (C) pixel.
- Supports Infrared (IR) pixels.
- Edge aware CFA interpolation.
- Software programmable filter for interpolation up to 4 color channels.
- Support for up to 4 phases and 3 directions per color channel.
- Software controlled algorithm for direction selection.
- Adaptive threshold calculation for direction selection.
- Support of up to 2 sets of programmable mask based gradient selection

#### 6.9.4.6.3.1.2 Block Diagram of Flexible CFA

The Flexible CFA module follows the VPORT (internal) interface for both the input/output to the RAW-FE or Flexible CC module.

##### 6.9.4.6.3.1.2.1 Gradient/Threshold Calculation

The Flexible CFA incorporates 2 sets of gradient and direction selection logic. Typically for symmetric 2x2 patterns like Bayer, only a single set is sufficient; however in sensors wherein one of the channels is working on a different data type, the second set can be used for that channel. An example of such sensors is the RGB-IR sensor, wherein the 2x2 pattern consists of one pixel of each color channel and one pixel of the IR channel. In this case, mixing the gradients and intensity of the color channels with the IR channel could be meaningless.

The gradient selection uses bit masks to select the desired pixel position for calculating the horizontal and the vertical gradient.

Figure 6-78 shows the notation for the bit-mask values. The same notation is used for vertical masks as well and the notation implies that setting a '1' in any field of the bit Mask enables the absolute difference of those 2 pixels to be summed in the gradient calculation.

FCP\_007

**Figure 6-78. Gradient Bit Masks**

Similar masks are also used to calculate the intensity (see Figure 6-79), however instead of taking the absolute difference, the bit masks are used to sum up the pixels in those locations.

FCP\_008

**Figure 6-79. Intensity Bit Mask**

The 4 bit Intensity mask is used to choose which pixels in the 6 rows should be used for creating the intensity sum. The same masks are used for every 2x2 window within the 6x6 buffer. (Thus setting all 4 bits to '1' will be equivalent to summing up the entire 6x6 window.) A programmable shift is then used to bring the intensity down to the 0-16k range. The maximum value of intensity can be 6x6 x4k = 144k, so the maximum value of shift is 4 (divide by 16). The shift value can be programmed to any value between 0 and 4 and should be chosen based

on the mask. Note that dependent on the shift value, it's possible that the full range of 0-16k of the intensity may not be reached, hence the adaptive threshold should be programmed accordingly.

The adaptive threshold calculation uses the calculated intensity. For more information, see [Section 6.9.4.6.3.1.2.2, Software Controlled Direction Selection](#).

#### 6.9.4.6.3.1.2.2 Software Controlled Direction Selection

Software can control or guide direction selection at frame or sequence level as shown in [Figure 6-80](#).

FCP\_009

**Figure 6-80. Software Controlled Direction Selection**

[Table 6-130](#) summarizes number of option available to software.

**Table 6-130. Summary of HSX Spaces**

Mode	Name	Details
0	Horizontal	Dir = 0
1	Vertical	Dir = 1
2	HV	Dir = 2
3	HV_Threshold (Fixed threshold is MMR)	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise
4	HV_AdaptiveThreshold	in Dir = 0: $\text{gradH} \geq \text{gradV} + \text{threshold}$ in Dir = 1: $\text{gradV} \geq \text{gradH} + \text{threshold}$ in Dir = 2: Otherwise

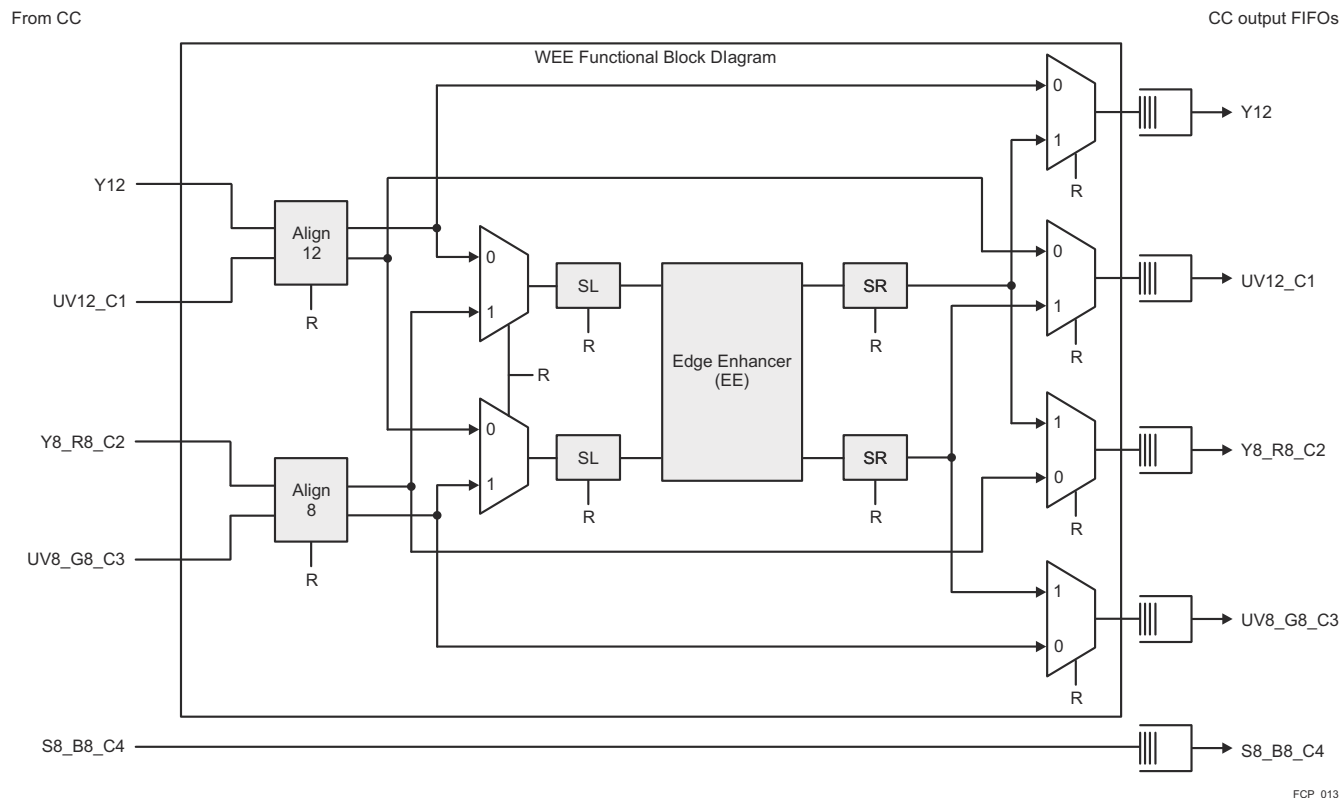

For calculation of adaptive threshold, 7 options are used. Each one defines a threshold to be used as a different intensity level as it follows:

- Entry-0 -> Intensity = 0
- Entry-1 -> Intensity = 512
- Entry-2 -> Intensity = 1024
- Entry-3 -> Intensity = 2048
- Entry 4 -> Intensity = 4096
- Entry 5 -> Intensity = 8192
- Entry 6 -> Intensity = 16384

The adaptive threshold can then be calculated as a linear interpolation between 2 successive entries based on the given intensity.

#### 6.9.4.6.3.2 Edge Enhancer Module Wrapper (WEE)

Figure 6-81 shows a high level block diagram of the Edge Enhancer (EE) module wrapper. For more information about the Edge Enhancer algorithm, see *Edge Enhancer (EE)*. The wrapper places the Edge Enhancer within the FCP structure along with associated muxes.

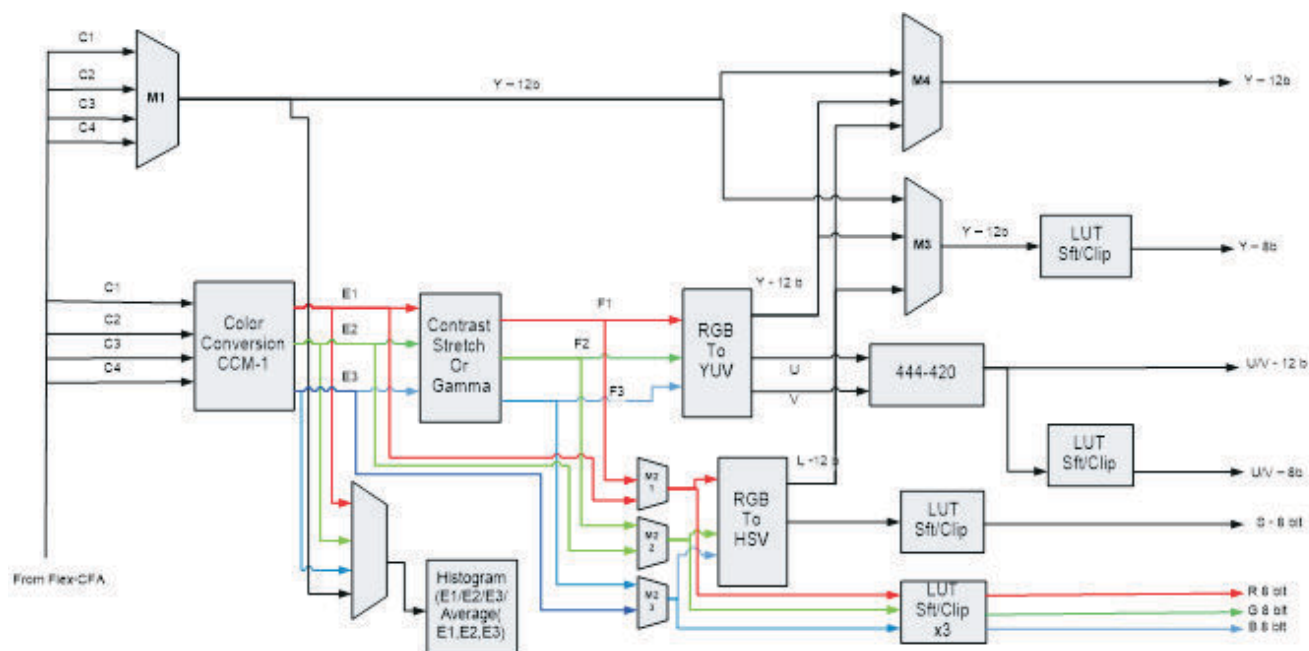

**Figure 6-81. Block Diagram of Edge Enhancer Module Wrapper**

##### 6.9.4.6.3.2.1 EE - Edge Enhancer Block

The Edge Enhancer module is used to enhance the visual quality of the image by increasing its sharpness. The module only works on Y (Luma) data and uses a combination of 2D High-Pass Filtering to detect edges and then apply them on the input image.

##### 6.9.4.6.3.3 Flexible Color Conversion (CC)

Figure 6-82 shows a high level block diagram of the Flexible Color Conversion (CC) module.

**Figure 6-82. Flexible CC Block Diagram (Logical View)**

The Flexible CC enables multiple use cases and allows different color formats to be generated.

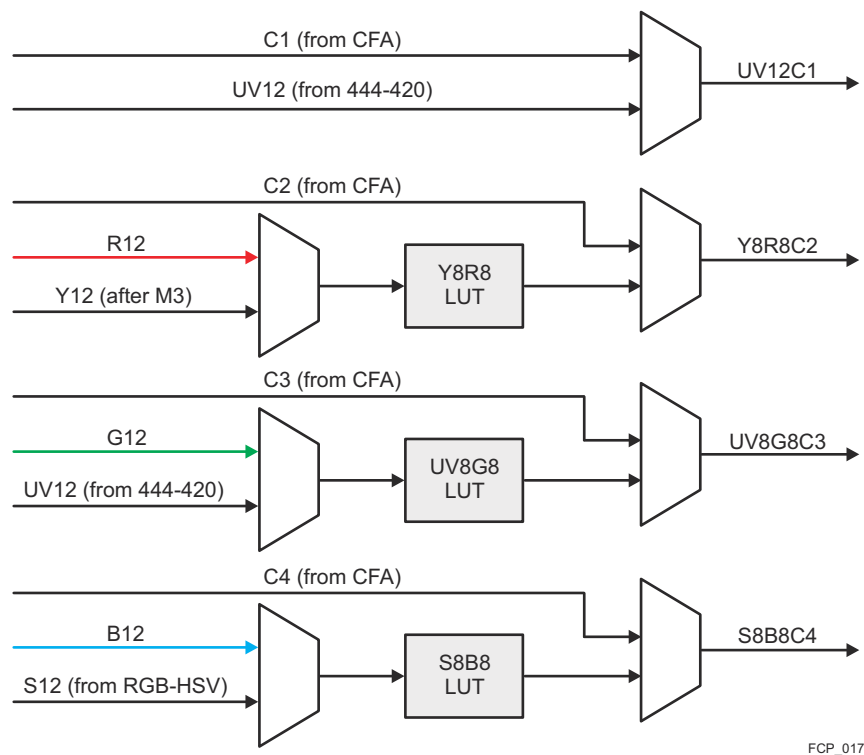

The Flexible CC module follows the VPORT (Internal) Interface for both the input to the Flexible CC module.

#### 6.9.4.6.3.3.1 Interface Mux

The Flexible CC logical block diagram has 5 primary outputs connecting to the LSE modules in the VISS. For more information about LSE modules, see *Load Store Engine (LSE)*. A multiplex scheme is used to connect multiple outputs on to 5 interfaces using the interface Mux. The Flexible CC output can optionally also allow data from Flexible CFA to be tapped out on to one of the primary interfaces. Note that 12-8 LUTs are shared between the RGB generation and the Y/UV 8-bit generation logic.

Figure 6-83 shows the details of the interface mux. There are only 3 LUTs shared in different mode and only 5 concurrent output streams can be activated at any point of time. For 8-bit outputs, the data is stored in the MSB 11-4 bits of the 12-bit bus. Further, the Y12 output is dedicated and not multiplexed with other interface signals.

**Figure 6-83. Flexible CC Interface Mux**

#### 6.9.4.6.3.3.2 Color Conversion (CCM-1)

The Color Conversion (CCM-1) is defined using the mathematical equations from [Figure 6-84](#).

$$\begin{aligned} E1(x, y) &= W11 \times C1(x, y) + W12 \times C2(x, y) + W13 \times C3(x, y) + W14 \times C4(x, y) + Offset\_1 \\ E2(x, y) &= W21 \times C1(x, y) + W22 \times C2(x, y) + W23 \times C3(x, y) + W24 \times C4(x, y) + Offset\_2 \\ E3(x, y) &= W31 \times C1(x, y) + W32 \times C2(x, y) + W33 \times C3(x, y) + W34 \times C4(x, y) + Offset\_3 \end{aligned}$$

**Figure 6-84. CCM-1**

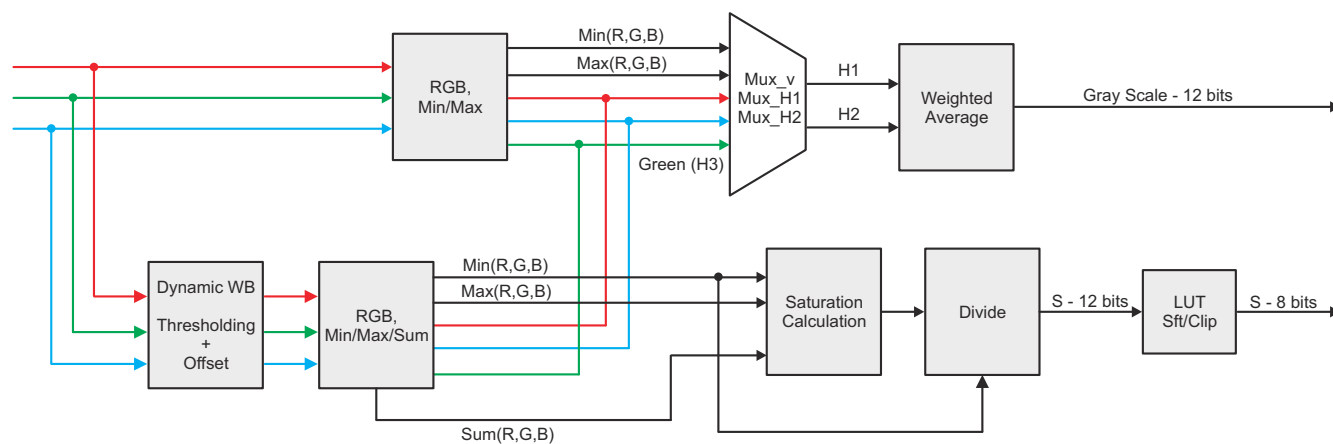

The CCM matrices weights ( $W^{**}$ ) are 12 bit signed each (S12Q8) representing a range from -8 to +7.996 with 8 bits of fraction. The offsets are 13 bit signed notation (S13Q11) representing a range of -4096 to +4095. The offset is effectively shifted by one (left shifted/ multiplied by 2) before being applied. The effective range of offset is -2 to +1.995 with 11 bits of fraction.

The 4 component CCM allows for a power combination of color format generation to be addressed.

#### 6.9.4.6.3.3.3 RGB to HSX Conversion

The RGB-HSV module is used for converting color spaces and creating custom luminance data plane. This way the 8-bit Saturation and 12-bit Luminance (L or V) plane are generated.

[Figure 6-85](#) shows the block which generates the Luminance / Gray Scale Plane as well as the Saturation (8-bit) plane.

FCP\_019

Figure 6-85. S & V Generation

#### 6.9.4.6.3.3.3.1 Weighted Average Block

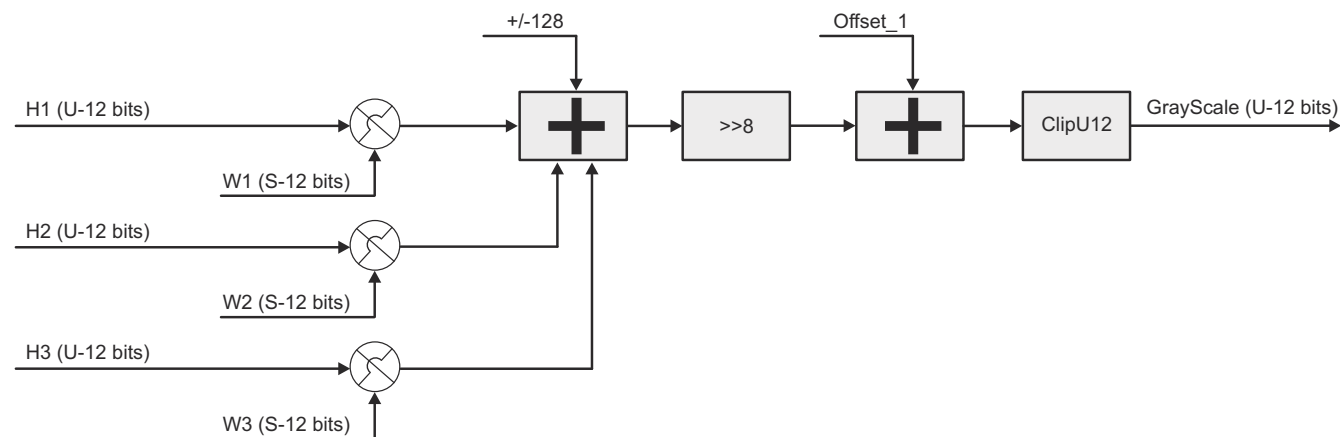

The Weighted Average block implements the equation shown on Figure 6-86.

$$GrayScale(x, y) = W1 \times H1(x, y) + W2 \times H2(x, y) + W3 \times H3(x, y) + Offset\_1$$

Figure 6-86. Gray Scale Computation

In the equation on Figure 6-86 the Weights (W1\*) are 12 bits signed with a range of -8 to +7.9996 in S12Q8 format. The offset is Signed 13 bits in S13Q11 format with a range of -2 to +1.995.

Figure 6-87 depicts the architecture of the Weighted Average block:

FCP\_020

Figure 6-87. Weighted Average Block

The mux before the matrix chooses whether the native R/B channels are transmitted or alternatively the Min/Max (RGB) from the Min-Max block are transmitted. Further, the calculation of V can work on either the non-WB corrected data or the WB corrected version. For more information about WB correction, see Section 6.9.4.6.3.3.3.2, Saturation Block.

The combination of the Min-Max block, the mux and the Weighted Matrix allows any of the Gray Scale calculation as shown in Table 6-131.

**Table 6-131. Summary of HSX Spaces**

No	Formula	Configuration
Grey scale (HSI)	$(R+G+B) / 3$	H1 = R, H2 = B; Offset_1 = 0; W1 = W2 = W3 = 1/3 = 85;
Gray Scale (HSV)	Max(RGB)	H1 = Max(RGB); H2 = NA Offset_1 = 0; W2/W3 = 0; W1 = 1 (256);
Gey Scale HSL	$(\text{Max}(\text{RGB}) + \text{Min}(\text{RGB})) / 2$	H1 = Max(RGB), H2 = Min(RGB); W1 = W2 = 0.5 (128) Offset_1 = 0; W3 = 0;
		H1 = R, H2 = G; W1 = W3 = 0.25 (64); W2 = 0.5 (128) Offset_1 = 0

**Table 6-132. Grey Scale and Saturation Calculation**

No	HSI Color Space	HSV Color Space	SHL Color Space	Customer Requirements
Grey Scale Computation	$(R+G+B) / 3$	Max(R,G,B)	$(\text{Max}(\text{R,G,B}) + \text{Min}(\text{R,G,B})) / 2$	$(R+2*G+B) / 3$
Saturation (S) Computation	$1 - (\text{Min}(\text{R,G,B}) / (R+G+B))$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / \text{Max}(\text{R,G,B})$	$(\text{Max}(\text{R,G,B}) - \text{Min}(\text{R,G,B})) / 255 - \text{Gray value}$	S = Max(R,G,B) - Min(R,G,B)
Hue (H) Computation	Complex formula involving (R-G) (R-B) & (G-B)	Division formula livolving (R-G) (R-B) & (G-B)	Complex formula involving all component	Separate output for (R-G) and Yellowness

#### 6.9.4.6.3.3.2 Saturation Block

The Saturation block first applies a dynamic white balance offset to correct the saturation plane when the image is in log domain and is used for analytics data flow. Once the WB offset is applied, the saturation calculation proceeds as described below. Note that the White balance offset is only applied if the independent pixel values are below a threshold (VISS\_FCP\_FCC\_RGBHSV\_WB\_LINLOGTHR\_1/2). Further, even the minimum of RGB is compared against a threshold (VISS\_FCP\_FCC\_RGBHSV\_WB\_LINLOGTHR\_2[27-16] SATMINTHR bit field) and the higher of the two is used. The saturation calculation always uses the data with the WB correction applied, however the V calculation can choose between WB corrected or uncorrected data using VISS\_FCP\_FCC\_CFG\_1[26] MUXRGBHSV\_MUX\_V.

Table 6-132 shows the condensed form for the Grey Scale and Saturation calculation. In the Flexible CC the saturation calculation is supported using two modes based on the VISS\_FCP\_FCC\_CFG\_2[6] HSVSATMODE bit as follows.

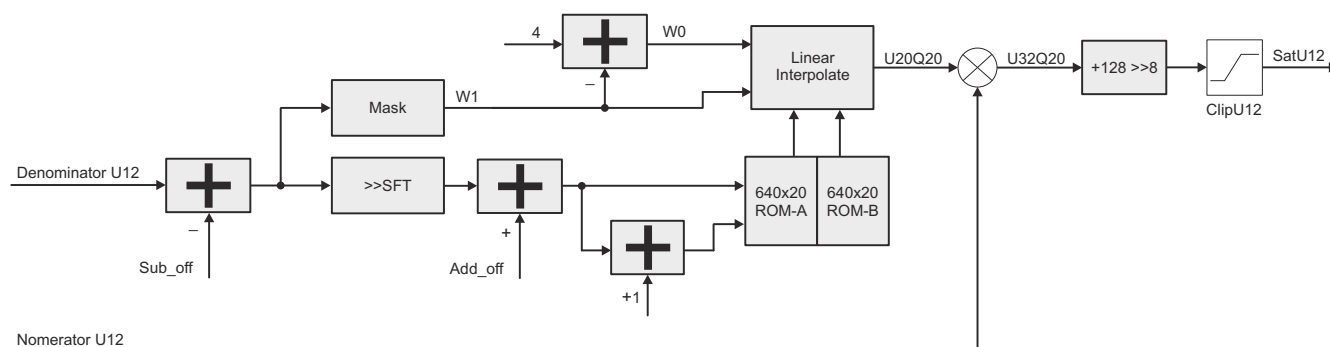

- HSVSATMODE = 0: Max(RGB) - Min(RGB)
- HSVSATMODE = 1: SUM(RGB) - Min(RGB)

Similarly the denominator for the dvision is chosen using the following selection on the VISS\_FCP\_FCC\_CFG\_2[5-4] HSVSATDIVMODE bit field.

- HSVSATDIVMODE = 0: No division, denominator = 1
- HSVSATDIVMODE = 1: Max(RGB)
- HSVSATDIVMODE = 2: 4095 – Gray value (computed in Figure 6-86)
- HSVSATDIVMODE = 3: Sum(RGB)

#### 6.9.4.6.3.3.3 Division Block

The division operation is implemented to calculate 1/x followed by a multiplication with the value. The input to the LUT is 12-bit unsigned value and the output is 8-bits fraction representing 1/x calculation. The divide LUT is implemented as a non-linear ROM with 1216 (1280 for aligning to 128 size boundary) entries and up to 2 segments to reduce error. Ideally to implement a full ROM for an input space of 12 bits would require 4k entires, however to save space and reduce error, the ROM is partitioned such that it is full resolution for the first 256 entries where the curve is highly non linear, whereas the next 4k - 256 entires have a step size of 4. Each ROM entry has a bit size of 20 bits in U20Q20.

FCP\_022

**Figure 6-88. Division LUT**

These are the parameters that need to be calculated based on the range of the input.

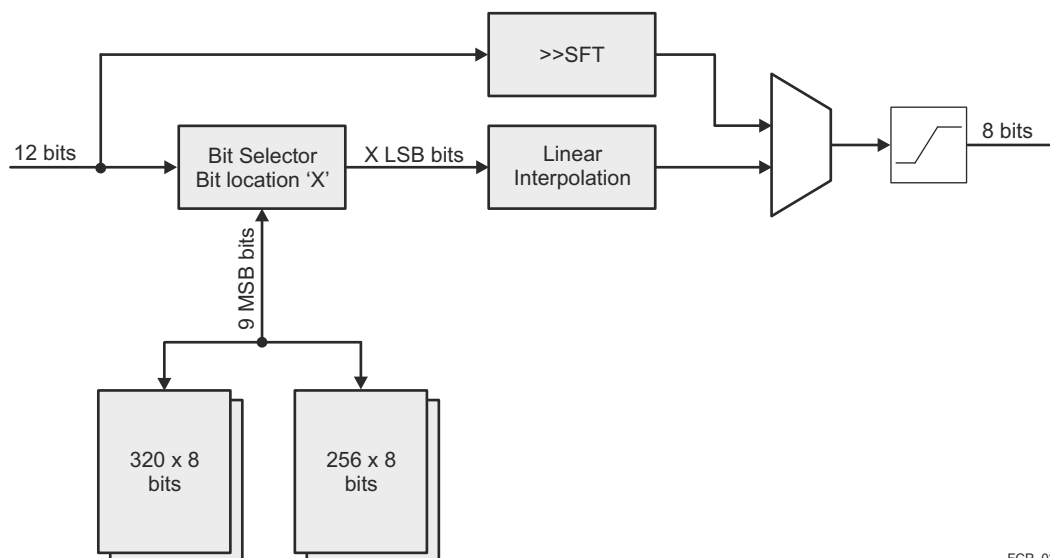

- SFT: '0' if input <256, 2 otherwise
- Mask: '0' if input <256, 4 otherwise
- Add\_off: '0' if input <256, 256 otherwise
- Sub\_off: '0' if input <256, 256 otherwise

The 'shift' parameter at the end is a configuration register which needs to be programmed. Typical programming value is 8 to generate a result in Q12 format (such that the range is 0 to1). This is usually the case when the denominator is greater than the numerator.

#### 6.9.4.6.3.3.4 LUT Based 12 to 8 Downsampling

In the final step the generated saturation value (12 bit) or the incoming RGB values (12 bit) needs to be scaled down to 8 bits using the linear LUT with 513 entries.

Figure 6-89 is a high level block diagram of the LUT block. It shows the weight calculation for the LUT assuming the incoming data can be of any bit depth between 8 and 12 bits.

FCP\_023

**Figure 6-89. LUT Based 12-8 Compression**

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only  $4095/512 = 8$ .

Figure 6-90 shows the high level block diagram of the interpolation process. The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different usecases. However, since the

step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that.

A shift operation can be performed instead of LUT to reduce bitwidth from 12 down to 8 bits.

FCP\_024

**Figure 6-90. Linear Interpolation on LUT**

The code below shows the addressing for the LUT as well as the weight calculation logic for supporting multiple bit widths at the input from 8 – 12 bits.

#### 12-8 Bit LUT Curve

```

CASE BIT_SEL
12 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
11 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
10 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
9 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
8 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//wt0 is always calculated at 8 - wt1
wt0 = 8 - wt1
  
```

The input bit width (BIT\_SEL) is specified using a dedicated register for generating Y8 output. However for other paths (RGB/UV/Sat) the 8 bit conversion is done using either 12 bits (if data is tapped prior to contrast block) as the bitwidth or the clipping value after contrast block (VISS\_FCP\_FCC\_CFG\_2[12-9] CONTRASTBITCLIP, if data is tapped after contrast block).

#### 6.9.4.6.3.3.4 Histogram

The histogram can work on either one of the color components after the CCM-1 or the fourth color component routed directly from the Flexible CFA. The Histogram can also work on internally generated Luma value using simple averaging of RGB components. The Histogram module supports a local memory which can be read by the host processor. The Histogram provides data which can be used by the software to generate tone curves for the Contrast Stretch LUT.

The input to the Histogram module is calculated based on the control MMR as it follows:

- 0: R
- 1: G
- 2: B
- 3: MuxC1\_4
- 4:  $(R+2 \cdot G+B) / 4$

The histogram module downsamples the image in the horizontal direction by a factor of 2 using simple averaging filter. This ensures that the memory access requirements of the module are limited to 1 read + 1 write access every 2 cycles (1 access/cycle) and thus can be achieved using a simple memory architecture.

The histogram module requires a ping-pong memory which is mapped to the configuration bus. This allows for histogram operation to run in concurrent with the Read operation from the host. For ease of software complexity, both the Ping/Pong memories map to the same address and it is the responsibility of the design to ensure that the muxing logic always take care of the correct access from both the host and the module. To detect error conditions, if the host is not able to read fast enough from the memory, an error interrupt should be generated whenever the host has initiated a read transfer from the first location of the memory but has not initiated a read transfer from the last location of the memory.

The Histogram module has 2 banks of memories each of 256x20 bits which are used in ping pong fashion. The input pixel has to be downshifted to match the bin size. The Histogram module has separate registers for creating an ROI using horizontal/vertical start postions as well as horizontal/vertical size.

Typically the ROI registers (VISS\_FCP\_FCC\_CFG\_HIST\_1 and VISS\_FCP\_FCC\_CFG\_HIST\_2) have to be set that at least one line is skipped for histogram calculation. The one line of time can be used by the histogram module to set the value of each of the bins to zero. This also puts a constraint on the histogram ROI to have a minmum width of 256 pixels.

FCP\_026

**Figure 6-91. Histogram Module**

#### 6.9.4.6.3.3.5 Contrast Stretch / Gamma

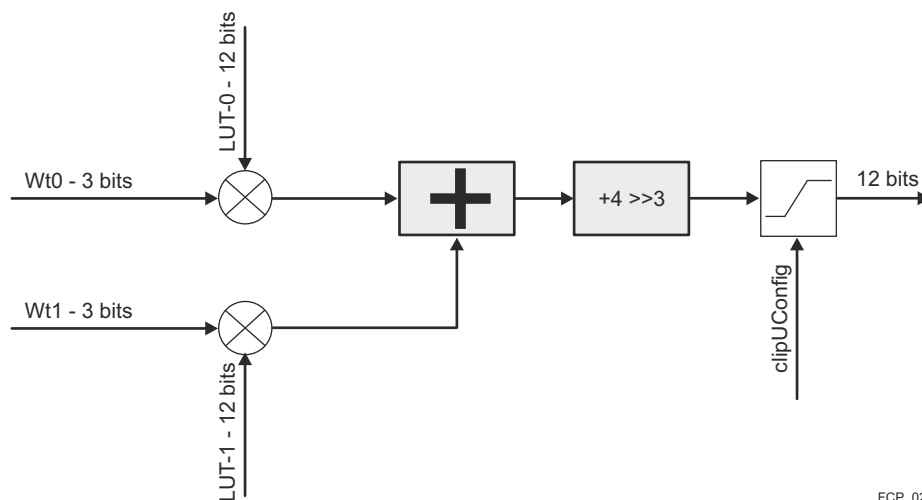

The logic of the Contrast/Gamma unit is based on the same as that of the 12-8 bit conversion LUTs. There are 3 copies of the logic, one for each color channel. The standard data flow allows for a 12 bit input and 12 bit unsigned output, however different bit width combinations are possible using the select bit of the LUT and the clip value. Each entry of the LUT table is 12 bits.

Figure 6-92 and Figure 6-93 show the block diagram and implementation of linear interpolation for the Contrast Stretch/Gamma module.

FCP\_027

**Figure 6-92. Contrast Enhancement Module**

FCP\_028

**Figure 6-93. Contrast Enhancement Linera Interpolation**

The code below shows the LUT addressing scheme which is similar to the 12-8 bit conversion module. The configurable clip at the end of processing allows for less than 12 bit output to be supported directly from the module.

#### Contrast Enhancement, LUT Addressing

```
CASE BIT_SEL
0 (12 bit data): Addr = Inp[3:11]; wt1 = Inp[2:0]
1 (11 bit data): Addr = Inp[2:10]; wt1 = Inp[1:0] & '0'
2 (10 bit data): Addr = Inp[1:9]; wt1 = Inp[0] & '00'
3 (9 bit data): Addr = Inp[0:8]; wt1 = '000'
4 (8 bit data): Addr = Inp[0:7]; wt1 = '000';
//Wt0 is always calculated at 8 - wt1
Wt0 = 8 - wt1
```

#### 6.9.4.6.3.3.6 RGB-YUV Conversion

The RGB-YUV conversion is a matrix based conversion from 12-bit RGB to 12-bit YUV. The output after conversion is YUV444.

The conversion is carried out using the equation on [Figure 6-94](#).

$$Y(x,y) = WRY \times R(x,y) + WGY \times G(x,y) + WBY \times B(x,y) + Offset\_1$$

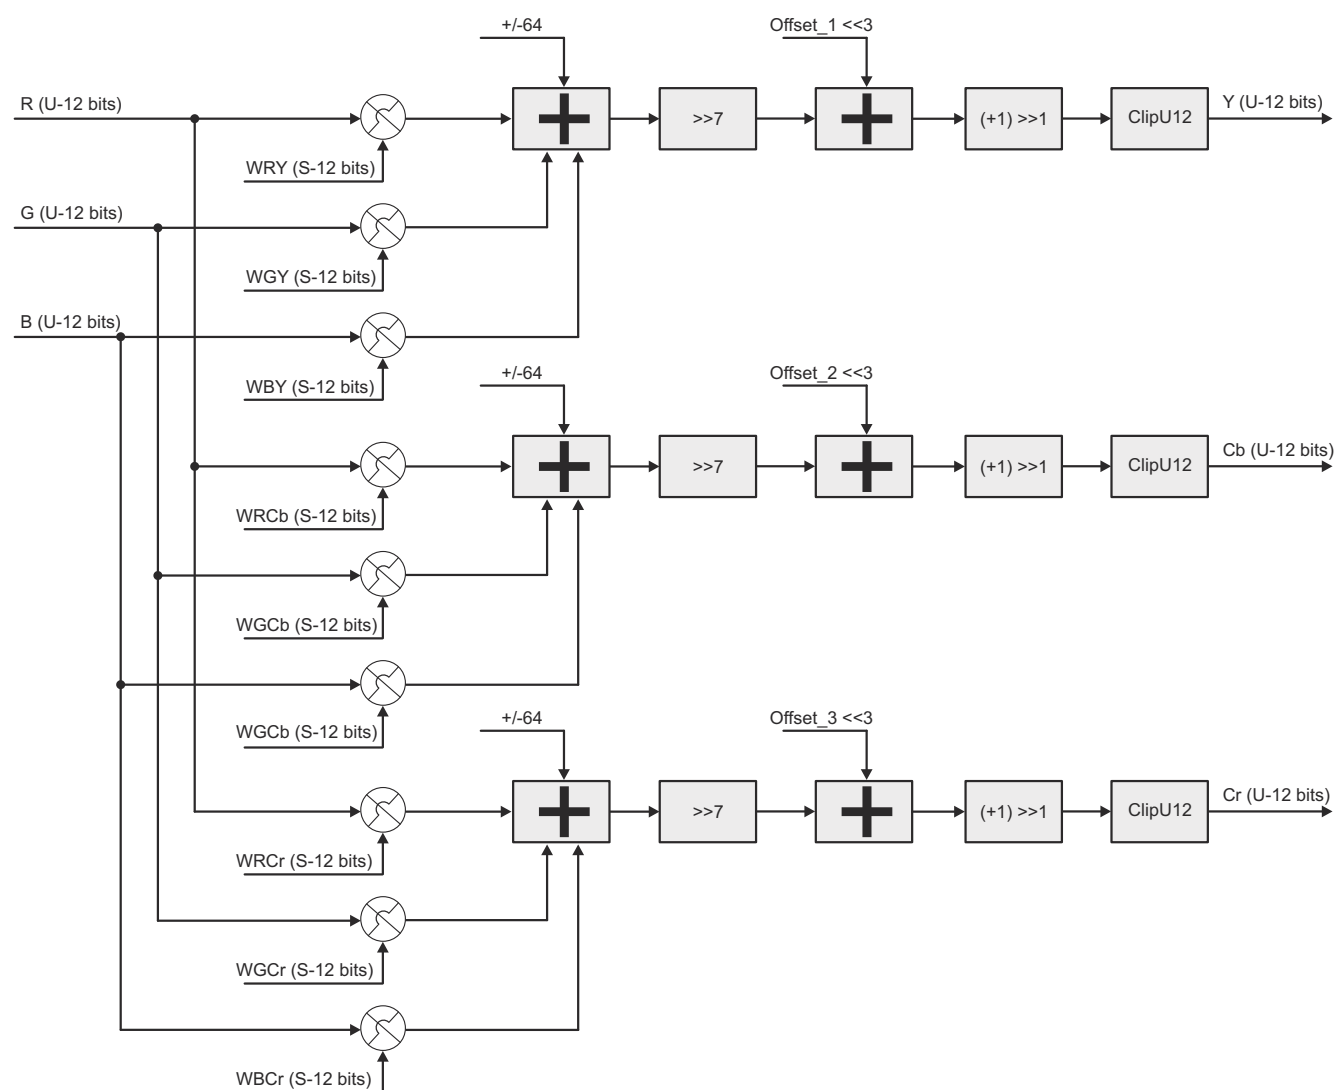

$$Cb(x,y) = WRCb \times R(x,y) + WGCb \times G(x,y) + WBCb \times B(x,y) + Offset\_2$$

$$Cr(x,y) = WRCr \times R(x,y) + WGCr \times G(x,y) + WBCr \times B(x,y) + Offset\_3$$

**Figure 6-94. RGB-to-YUV Conversion**

In this equation, the weights are signed 12 bits (S12Q8) with 8 bit of fraction precision, representing a range of -8 to +7.996. The offsets are signed 13 bits.

Figure 6-95 shows the implementation of the RGB to YUV module. The output after conversion is YUV444, as such it is followed by a chroma downsampling stage where in the Chroma resolution is reduced by half in both the horizontal and vertical direction.

FCP\_030

**Figure 6-95. RGB to YUV**

#### 6.9.4.6.3.4 444-422/420 Chroma Down-sampler

This module down-samples the chroma components from 444-420 format; effectively reducing the chroma resolution to 50% in both the horizontal and vertical direction.

The downsampling is performed using a 3 Tap filtering [1 2 1] followed by decimation. The conversion logic generates chroma in co-sited/co-located format in both the horizontal and vertical direction.

Figure 6-96 shows the block diagram of the format conversion module. The Chroma output can be optionally downshifted from 12 bits to 8 bits using the LUT/SFT module. Only one copy of the Horizontal averaging filter is required since there is a decimation step following the filtering. Only even locations of both Cb/Cr are retained while the odd locations are decimated, however from design perspective the Hz Averager module works on Cb on even cycles and Cr on odd cycles.

FCP\_031

**Figure 6-96. 444 to 420 Module**

Additionally another mode of operation is to support planar YUV422 mode. In this case the chroma is only downsampled in the horizontal direction and the vertical averaging/downsampling is disabled.

The mode is referred to pseudo 422 since actual 422 mode requires the data to be interleaved between the Y and the chroma channels. In this case the interleaving of Y & C is handled by LSE whereas the Flexible CC module will only generate Y & Cb/Cr (interleaved) planes separately.

#### 6.9.4.6.4 FCP Interrupts

The FCP module has three interrupts, as it follows:

- LUT\_CFG\_ERR - 16-12 LUT is written during active window
- CFA\_PIX\_ERR - Access to line memories by CFG during active window
- CFA\_MMR\_ERR - Non-Shadowed registers are written during active window

There are two additional events:

- SOL\_EVENT - Start of line processing for Flexible CFA, triggered when the line enters the Flexible CFA
- SOF\_EVENT - Start of frame processing for Flexible CFA, triggered when the frame enters the Flexible CFA

For information about the FCP interrupt events, see Section *VISS Top Level Functional Description*.

#### 6.9.4.6.5 FCP Programmer's Guide

##### 6.9.4.6.5.1 HWA Core Programming Details

The following fields should be programmed correctly for the FCP module to function.

- Input LUT
  - Use the LUT to reduce the bitwidth of the data to 12 bits so that it can pass through the Flexible CFA pipe.
  - If the GLBCE module is disabled, set the bit width and enable the LUT.
- Flexible CFA
  - Program the Flexible CFA kernels based on the input data pattern. Program only 3 channels for Bayer sensors and up to 4 for other non-standard formats like RGB-IR.
  - Set up the correct thresholds (use only one set for Bayer type sensors and two sets for non-standard formats like RGB-IR).
- Flexible CC
  - Set up the Flexible CC for either visual or analytics data flow.

- For visual, program the CCM-1 to be used as RGB2RGB and Contrast to be used as Gamma with clip at 10 bits. Only the 8-bit outputs are used and the Y8/C8 data is generated using shift down from 10 to 8 (instead of LUT).
- For analytics, CCM-1 is programmed depending on sensor input format and the histogram is used to populate the contrast table. 12-bit outputs are used however Y8/C8 can be generated using 12 to 8 LUT based downshifting. The correct Saturation generation parameters should also be set.

### 6.9.4.7 VISS Edge Enhancer (EE)

This section describes the Edge Enhancer module.

#### 6.9.4.7.1 Edge Enhancer Introduction

The Edge Enhancer module is used to enhance the visual quality of the image by increasing the sharpness of the image. The module only works on Y (Luma) data and uses a combination of 2D HPF (High-Pass Filter) filtering to detect edges and then apply them on the input image.

The Edge Enhancer consists of two separate blocks internally, the edge enhancer filter and the edge sharpener filter. The module can be programmed to either select the output of one of the filters or to use a blend of both.

Figure 6-97 below shows a conceptual block diagram of the edge enhancer filter. The input data is assumed to be a 12 bits/pixel. The EE module is tuned to process 8-bit images (MSB aligned) but has support to process 10-bit and 12-bit images as well.

Figure 6-97. Edge Enhancer Block Diagram

#### 6.9.4.7.1.1 Edge Enhancer Filter

The edge enhancer filter works on a  $5 \times 5$  HPF filter (M) with programmable coefficients. The filter is symmetric as such only  $3 \times 3$  coefficients are programmable.

Here, M is a  $5 \times 5$  matrix with programmable coefficients specified by VISS\_FCP\_EE\_YEE\_COEF\_Ri\_Cj (i and j are 0, 1, or 2). The shift value (shf<sub>HPF</sub>) is specified by VISS\_FCP\_EE\_YEE\_SHIFT[5-0] YEE\_SHIFT.

$$HPF(h, v) = \left( \sum_{j=-2}^2 \sum_{i=-2}^2 M_{i,j} Y(h+i, v+j) \right) \gg shf_{HPF}$$

$$M = \begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

**Figure 6-98. Edge Enhancer Linear Filter**

The HPF value is shrink by a threshold value,  $threshold_{HPF}$  ( $u6 = 10$ ), specified by VISS\_FCP\_EE\_YEE\_E\_THR register, and clipped to signed 14 bits to get the index for the LUT. The MSB 12 bits of the index are used for the LUT address (4k locations) whereas the LSB 2 bits acts as weight to the linear interpolation logic.

$$index = clip(shrink(HPF, threshold_{HPF}), -8k, 8k)$$

$$shrink(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$clip(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

**Figure 6-99. Edge Enhancer Indexing**

The edge enhancement intensity is looked up from the LUT, where A is the MSB 12 bits of the index.

$$E_{int} = Interpolate(LUT[A], LUT[A+1])$$

**Figure 6-100. Edge Intensity LUT Formula**

The  $5 \times 5$  HPF filter is not fully programmable, rather only the top left quadrant is programmable coefficients. The rest of the kernel is symmetric along the y and the x axis.

**Figure 6-101** below depicts how the kernels are implemented, with the kernel locations marked inside the boxes. The green color shows the kernels that are programmable.

**Figure 6-101. 5 × 5 HPF Filter**

The border conditions are handled by data duplication on each of the borders when the desired pixel goes out of range.

The output of the LUT is the final output of the edge enhancer filter.

#### 6.9.4.7.1.2 Edge Sharpener Filter

Figure 6-102 below shows a high level block diagram of the edge sharpener function.

**Figure 6-102. Edge Sharpener Function**

In edge sharpener filter module, enabled when VISS\_FCP\_EE\_YEE\_MERGESEL[0] YEE\_MERGESEL = 1, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the following 2D linear filter with fixed coefficients shown in Figure 6-103.

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = \text{clip} \left( \text{shrink} \left( g \times \left( \sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i, v+j) \right) \gg 3 \right), threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH}$$

**Figure 6-103. Edge Sharpener Details**

The gain ( $g$ ) and threshold values for shrink/clip function ( $threshold_{LOW}$ ,  $threshold_{HIGH}$ ) are determined by register values (VISS\_FCP\_EE\_YES\_E\_GAIN, VISS\_FCP\_EE\_YES\_E\_THR1, VISS\_FCP\_EE\_YES\_E\_THR2). The precision of  $g$  is in U12Q6,  $threshold_{LOW}$  is in U16Q6 and that of  $threshold_{HIGH}$  is in U10.

This edge intensity is then clipped by a threshold value in the formula shown in [Figure 6-104](#).

$$S_{int} = \begin{cases} \text{clip}(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

**Figure 6-104. Edge Intensity Clipping Formula**

The threshold value ( $grad$ ) is a function of the activity around the target pixel, which is derived from gradient values. Gain ( $g_{grad}$ ) and offset ( $g_{base}$ ) are specified by VISS\_FCP\_EE\_YES\_G\_GAIN and VISS\_FCP\_EE\_YES\_G\_OFT.

$$grad = g_{grad} (\min(gx_L, gx_R) + \min(gy_T, gy_B)) \gg 6 + g_{base}$$

$$gx_L = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{xL}(i,j) \cdot y(h+i, v+j) \right)$$

$$gx_R = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{xR}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_T = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{yT}(i,j) \cdot y(h+i, v+j) \right)$$

$$gy_B = \text{abs} \left( \sum_{j=-1}^1 \sum_{i=-1}^1 G_{yB}(i,j) \cdot y(h+i, v+j) \right)$$

$$G_{xL} = \frac{1}{4} \begin{pmatrix} 1 & -1 & 0 \\ 2 & -2 & 0 \\ 1 & -1 & 0 \end{pmatrix}$$

$$G_{xR} = \frac{1}{4} \begin{pmatrix} 0 & 1 & -1 \\ 0 & 2 & -2 \\ 0 & 1 & -1 \end{pmatrix}$$

$$G_{yT} = \frac{1}{4} \begin{pmatrix} 1 & 2 & 1 \\ -1 & -2 & -1 \\ 0 & 0 & 0 \end{pmatrix}$$

$$G_{yB} = \frac{1}{4} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \\ -1 & -2 & -1 \end{pmatrix}$$

**Figure 6-105. Edge Threshold Value Formula**

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

#### 6.9.4.7.1.3 Merge Block

The output from edge enhancer filter and edge sharpener filter are merged with the following function.

$$E_{merge} = \begin{cases} E_{int} + S_{int} & VISS\_FCP\_EE\_YEE\_MERGESEL[0]YEE\_MERGESEL = 0 \\ \text{absmax}(E_{int}, S_{int}) & VISS\_FCP\_EE\_YEE\_MERGESEL[0]YEE\_MERGESEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & \text{abs}(y) \leq \text{abs}(x) \\ y & \text{otherwise} \end{cases}$$

**Figure 6-106. Edge Enhancer and Sharpener Merger Formula**

The  $E_{merge}$  value is added to the Y input value to make the final output.

The contribution of each of the filters can be modified. The edge sharpener filter block can be turned off or reduced in strength using the gain fields. The edge enhancer filter block can be disabled using the LUT.

#### 6.9.4.7.2 Edge Enhancer Programming Model

Table 6-133 captures the programming parameters and the programming model of the Edge Enhancer module.

#### Note

UMQN implies M bits with N bits of fraction and M-N bits of Integer.

For more information, see *Edge Enhancer Registers*.

**Table 6-133. Edge Enhancer Programming Parameters**

Parameter Name	New Precision	Tuning Methodology
VISS_FCP_EE_EE_CFG_0[12-0] WIDTH	13 bits	Width of the image
VISS_FCP_EE_EE_CFG_0[28-16] HEIGHT	13 bits	Height of the image
VISS_FCP_EE_EE_ENABLE[0] YEE_ENABLE	1	Enable Module
VISS_FCP_EE_YEE_SHIFT[5-0] YEE_SHIFT	U6	-
VISS_FCP_EE_YEE_COEF_R0/1/2_C0/1/2[9-0] YEE_COEF_R0/1/2_C0/1/2	Signed 10	-
VISS_FCP_EE_YEE_E_THR[9-0] YEE_E_THR	U10	Shrink Threshold before LUT, scale by 16×
VISS_FCP_EE_YEE_MERGESEL[0] YEE_MERGESEL	1 bit	Mergesel: Off(0), On(1)
VISS_FCP_EE_YES_E_HAL[0] YES_E_HAL	1 bit	Halo Reduction; Off(0)/On(1)
VISS_FCP_EE_YES_G_GAIN[7-0] YES_G_GAIN	U8Q6	Usually 1.5 times YES_E_GAIN
VISS_FCP_EE_YES_G_OFT[9-0] YES_G_OFT	U10	Scale by 16
VISS_FCP_EE_YES_E_GAIN[11-0] YES_E_GAIN	U12Q6	Same as previous
VISS_FCP_EE_YES_E_THR1[15-0] YES_E_THR1	U16Q6	Scale by 16
VISS_FCP_EE_YES_E_THR2[9-0] YES_E_THR2	U10	Scale by 16

### 6.9.5 VPAC Lens Distortion Correction (LDC) Module

This section describes the Lens Distortion Correction (LDC) module.

#### 6.9.5.1 LDC Overview

The LDC module deals with lens geometric distortion issues in the camera system. The distortion can be common optical distortions, such as barrel, pin-cushion, or fisheye distortion. LDC is not limited to just these types of distortions. Affine transformation support is also added to support the image and video stabilization application, where multiple images of the same scene need to be aligned. Perspective warp is an extension to affine transform and offers additional capabilities. Perspective transformations can align two images that are captured from different camera viewpoints or locations. This can also be used to rectify the left and right images of a stereo camera to reduce the complexity of a disparity computation. Perspective transformations can also generate new viewpoints.

##### 6.9.5.1.1 LDC Features

- Autonomous memory-to-memory operation
  - Tile based processing
- Generic mesh based distortion model to correct multiple distortion types
- Perspective warp transformation for perspective correction; affine transform is a subset of perspective warp and supports scaling and rotation
- Support multiple input and output YUV data formats:
  - Among the supported data formats are UYVY (YCbCr 422), NV12 (YCbCr 420) and NV21 (YCbCr 420)
- Support up to 8192 x 8192 image dimension
- Pixel Interpolation
  - Bi-cubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode to offer double throughput
- Performance
  - 1 cyc/pixel (bilinear)
  - 2 cyc/pixel (Bi-cubic)
- Support to process either Luma only or Chroma only modes in YUV420 input data format to save bandwidth
- Support for independent block size in multiple regions (up to 9 regions)
- Dual output channels for programmable output pixel size
- ECC support on Mesh Data internal storage memories and width conversion LUTs on dual output channel
- Interface to HTS module for block level synchronization with other IPs
- Circular addressing support for Output Write (for SL2 interface) and Input Read
- Event for Block/Frame completion and Error scenarios

#### 6.9.5.2 LDC Functional Description

##### 6.9.5.2.1 LDC Block Diagram

Most digital cameras suffer from some degree of nonlinear geometric distortion. A spatial transformation is required to correct the distortion. In automotive applications, cameras use wide angle lenses, including fisheye lenses to provide 180+° field of view. To visually present the scene to the user in an easy-to-consume representation, these distortions need to be corrected

Back mapping gives coordinates of the distorted image as a function of coordinates of the undistorted output image. Correction involves back-mapping each output pixel to a location in the source distorted image, and thus the corrected image is fully populated. As the distorted pixel locations mostly fall onto fractional coordinates, correction involves interpolation.

As shown in [Figure 6-107](#), the LDC consists of a back mapping block, a x/y offset table, image buffer interface, buffer, an interpolation block, and SL2 interface.

[Figure 6-107](#) is a block diagram of the LDC.

**Figure 6-107. LDC Block Diagram**

Given the coordinates of the undistorted image, the corresponding coordinates of the distorted image are calculated by combining the output coordinates and the offsets from the offset table. Distorted pixels are read from the image buffer, and buffered for the bilinear interpolation. After the interpolation, corrected image is written back to the SL2 memory.

The LDC processes the image in small two-dimensional (2D) blocks. The software configures appropriate parameters, then initiates the LDC function by writing to an LDC register. The LDC controls the sequencing through 2D blocks, DMA transfers, and computation to process an entire image autonomously. Interrupt, if enabled, is asserted at the completion of the image.

The LDC write is controlled by HTS at block level.

To start the LDC, software must set the VPAC\_LDC\_CTRL[0] LDC\_EN bit to 1. The VPAC\_LDC\_CTRL[2] BUSY bit is a status that reflects LDC activity.

#### 6.9.5.2.2 LDC Clocks

Complete VPAC LDC operates on single clock (that is, VPAC0\_LDC0\_CLK). Except the signals that are coming from LPSC, all other LDC sub-block clock domains are synchronous to VPAC0\_LDC0\_CLK.

#### 6.9.5.2.3 LDC Interrupts

LDC generates interrupt events and these are made available to the VPAC. VPAC implements compatible interrupt function via the interrupt aggregator, see chapter [Section 6.9.3 VPAC Subsystem](#).

All the interrupts are active high and pulsed for one VPAC0\_VISS0\_CLK cycle. Following interrupts events are generated. Out of these only ECC interrupt should be treated as real interrupt and others are used as events for the interrupt aggregator at VPAC level.

**Table 6-134. LDC Interrupt Events**

Interrupt Event	Type	Category	Description
PIX_IBLK_OUTOFBOUND	pulse	func	PIX_IBLK_OUTOFBOUND pulse interrupt event

**Table 6-134. LDC Interrupt Events (continued)**

Interrupt Event	Type	Category	Description
MESH_IBLK_OUTOFBOUND	pulse	func	MESH_IBLK_OUTOFBOUND pulse interrupt event
IFR_OUTOFBOUND	pulse	func	IFR_OUTOFBOUND pulse interrupt event
INT_SZOVF	pulse	func	INT_SZOVF pulse interrupt event
VPAC_LDC_FR_DONE_EVT	pulse	func	LSE frame done event
VPAC_LDC_SL2_WR_ERR	pulse	func	LSE SL2 VBUSM Write Error interrupt event
PIX_IBLK_MEMOVF	pulse	func	Input pixel block internal memory overflow event
MESH_IBLK_MEMOVF	pulse	func	Input mesh block internal memory overflow event
VPAC_LDC_VBUSM_RD_ERR	pulse	func	Error event on VBUSM Read Interface
UNCORR_PULSE	pulse	error	ECC Aggregator uncorrectable error, pulse
UNCORR_LEVEL	level	error	ECC Aggregator uncorrectable error, level
CORR_PULSE	pulse	error	ECC Aggregator correctable error, pulse
CORR_LEVEL	level	error	ECC Aggregator correctable error, level

#### 6.9.5.2.3.1 LDC Interrupt Events Description

##### 6.9.5.2.3.1.1 PIX\_IBLK\_OUTOFBOUND

Generated when back mapping of block non-corner pixel co-ordinate goes out of the pre-computed input bounding box (i.e. data required for processing is not available in private pixel storage). This event is generated for the first occurrence of error in each frame. Upon this error, PIX\_PAD setting needs to be reviewed. Upon pixel out of bound, pixel co-ordinate will be clipped to the pre-fetched block boundary. Usually no special treatment is required on this error event. Only few pixels are expected to be have this condition..

##### 6.9.5.2.3.1.2 MESH\_IBLK\_OUTOFBOUND

Generated when mesh data required for non-corner mesh co-ordinate goes out of the pre-computed mesh bounding box (i.e. mesh data required for processing is not available in internal mesh storage). This event is generated for the first occurrence of error in each frame. This error condition is handled inside design by clipping the mesh data location to the pre-fetched block boundary. No special treatment is expected on this error event.

##### 6.9.5.2.3.1.3 IFR\_OUTOFBOUND

Generated when back mapped input pixel co-ordinate goes out of valid input frame boundary or co-ordinates post Perspective warping goes out of valid Mesh frame size (Frame size for which mesh data is available). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the co-ordinates to valid frame boundary. It is recommended to review the source of the error to make sure that it is expected.

##### 6.9.5.2.3.1.4 INT\_SZOVF

Generated when intermediate variables of affine or perspective transform operation goes above what hardware supports (U16Q3). This event is generated for the first occurrence of error in each frame. In the event of error condition, design will clip the variables the size to what HW supports. Upon this error, Affine and Perspective coefficients need to be reviewed.

##### 6.9.5.2.3.1.5 VPAC\_LDC\_FR\_DONE\_EVT

Generated on once complete output frame is written into SL2.

#### 6.9.5.2.3.1.6 VPAC\_LDC\_SL2\_WR\_ERR

This event is generated whenever the LDC SL2 Output VBUSM Interface write status is something other than 0 (success).

#### 6.9.5.2.3.1.7 PIX\_IBLK\_MEMOVF

Generated when input pixel block memory storage requirement is more than internal pixel memory or each side of input block size goes above 1023. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size setting needs to be reviewed.

#### 6.9.5.2.3.1.8 MESH\_IBLK\_MEMOVF

Generated when Mesh block internal storage requirement is more than internal Mesh memory or either side of input block size goes above 1010. This event will be generated once per block in case of error. In the event of error condition, one or more output pixel blocks corruption. Upon this error, Output Block size or Affine/Pwarp parameters or mesh sub-sampling factor setting needs to be reviewed.

#### 6.9.5.2.3.1.9 VPAC\_LDC\_VBUSM\_RD\_ERR

This event is generated whenever the LDC Read VBUSM Interface status is something other than 0 (success).

#### 6.9.5.2.4 LDC Affine Transform

The LDC first performs an affine transform, which can be used for rotations and scaling, as shown in [Figure 6-108](#). The output of the pixel coordinate is used as the input address to the affine transform.

ldc-010

**Figure 6-108. LDC Affine Transformation**

The mapping from destination coordinate to the source coordinate is expressed as:

$$h_{aff} = a \times h_u + b \times v_u + c$$

$$v_{aff} = d \times h_u + e \times v_u + f$$

This transform allows full rotation, expansion, contraction, and translation. The parameters {a, b, d, e} are in S16Q12 (signed number on 14 bits with 2 bits for integer and 12 bits of fraction) format, and parameters {c, f}

are in S16Q3 format (signed number on 16 bits with 13 bits for integer and 3 bits of fraction). These parameters must be set in following bit fields:

- a = VPAC\_LDC\_AFF\_AB[15:0] A
- b = VPAC\_LDC\_AFF\_AB[31:16] B
- c = VPAC\_LDC\_AFF\_CD[15:0] C
- d = VPAC\_LDC\_AFF\_CD[31:16] D
- e = VPAC\_LDC\_AFF\_EF[15:0] E
- f = VPAC\_LDC\_AFF\_EF[31:16] F

#### 6.9.5.2.5 LDC Perspective Transformation

When a camera is viewing a scene from two different positions or when multiple cameras are viewing the scene from different positions, a transformation between the two viewing angles is needed to align the images. Under specific conditions, the class of geometric transformations known as homography, or planar-perspective transformation, will capture the geometric relationship between the images accurately. Common applications of homography transforms are to align (or stitch) multiple frames of the same scene to compute a panoramic output image. A second application is the alignment of planar surfaces in the world. Finally, perspective transforms are also useful in computing depth maps from a stereo image pair. By rectifying the two views, the search to compute disparity between the two views is simplified to a 1-D search problem. The homography is defined by a 3x3 transformation matrix, as in

$$h_{aff} = a * h_u + b * v_u + c \quad (3)$$

$$v_{aff} = d * h_u + e * v_u + f \quad (4)$$

$$z = \max(0, g * h_u + h * v_u + 1) \quad (5)$$

$$h_p = h_{aff} / z \quad (6)$$

$$v_p = v_{aff} / z. \quad (7)$$

The affine transform is a subset of the perspective transformation. By setting  $g = h = 0$ ,  $h_p = h_{aff}$  and  $v_p = v_{aff}$ .

In image alignment applications, the homography matrices are computed by locating corresponding points in the two frames and estimating the matrix parameters to transform the set of points in one frame onto the corresponding points in the second frame. In the stereo rectification application, the matrix is determined (pre-computed) at the calibration step and remains fixed.

When LDC is requested to provide a change in the frame size between the input and output, the affine/perspective parameters must be programmed to implement the coordinate scaling (see for programming details). In the following sections, the mesh table is used to program distortion correction. The table sizes are defined based on the total output frame size.

#### 6.9.5.2.6 LDC Lens Distortion Back Mapping

In YCbCr mode, the offset table defines a (x,y) vector for a regular grid of output points. The grid can be fully sampled or down sampled. A fully sampled grid will define an offset vector for every output pixel, defining exactly where to fetch the input data to compute the output pixel. This is the most precise definition and can capture rapidly changing offset tables. The drawback is that it will require a large amount of memory bandwidth as the LDC engine will be reading offset values for every output pixel. Since most offset tables are not expected to change rapidly in a small spatial region, LDC supports reading a subsampled offset table. Offset tables can be subsampled by powers of two in both horizontal and vertical directions and the subsampling factor is set in the register, VPAC\_LDC\_MESHTABLE\_CFG[2-0] M. This mode conserves memory bandwidth by reducing the amount of data read to describe the offset vectors, but requires more hardware to interpolate the missing offset vectors. LDC supports bilinear interpolation to interpolate missing offset vectors.

The mapping procedure is described by the following series of equations. Given an output pixel at location, we compute the input pixel location.

$$x_c = \text{CLIP}(x_o, 0, 8 \times W - 1), \text{ W: Mesh Frame Width} \quad (8)$$

$$y_c = \text{CLIP}(y_o, 0, 8 \times H - 1), \text{ H: Mesh Frame Height} \quad (9)$$

$$\text{Mask} = (1 \ll (3 + M)) - 1 \quad (10)$$

$$i_{x0} = (x_c \gg (3 + M)), f_x = x_c \& \text{Mask} \quad (11)$$

$$i_{y0} = (y_c \gg (3 + M)), f_y = y_c \& \text{Mask} \quad (12)$$

Clip new locations to previously fetched mesh block boundaries.

$$i_x = \text{CLIP}(i_{x0}, \text{block\_startmx}, \text{block\_endmx} - 1) \quad (13)$$

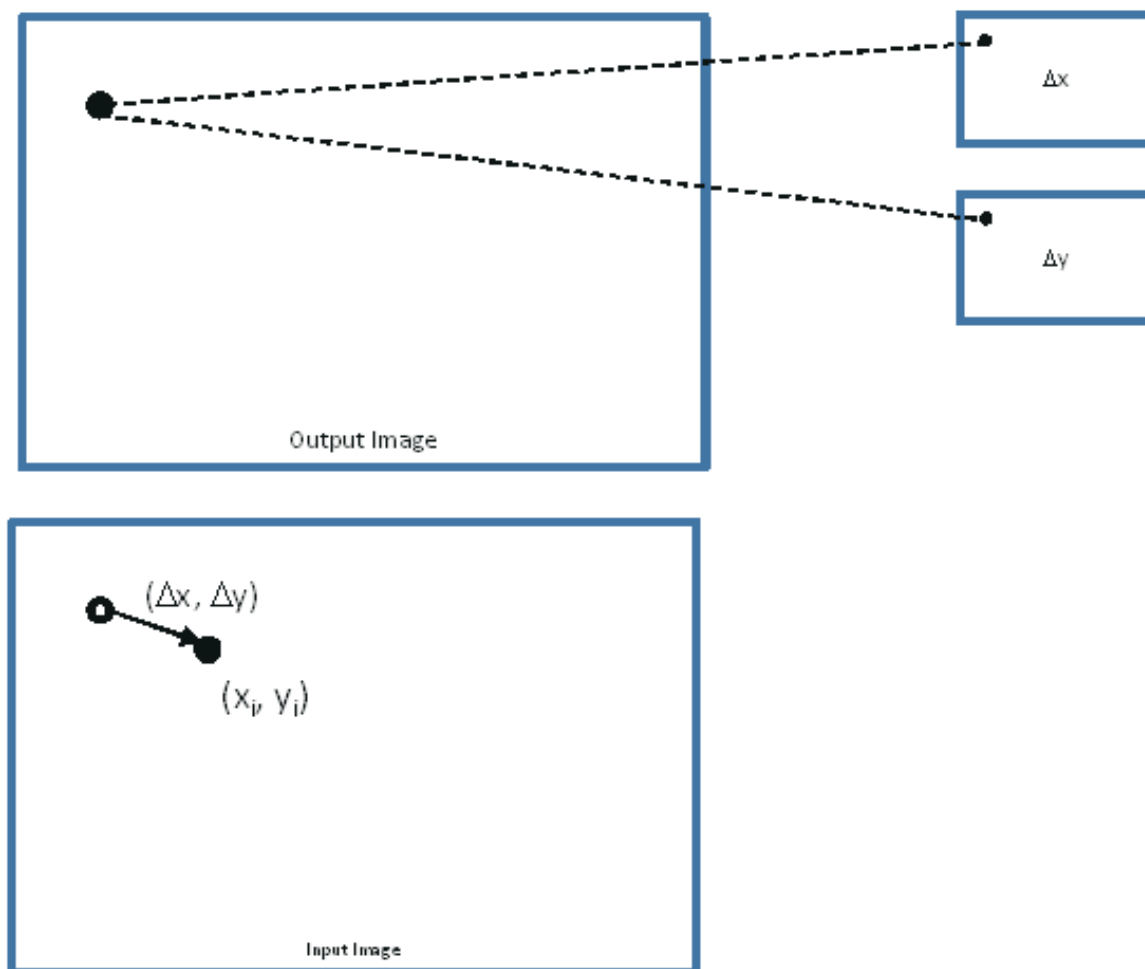

$$i_y = \text{CLIP}(i_{y0}, \text{block\_startmy}, \text{block\_endmy} - 1) \quad (14)$$

$$\begin{aligned}
 \text{Ofst0} &= \text{READ32}(\text{OfstTable}[i_x, i_y]) \\
 \Delta x_0 &= \text{MSB16}(\text{Ofst0}) \\
 \Delta y_0 &= \text{LSB16}(\text{Ofst0}) \\
 \\
 \text{Ofst1} &= \text{READ32}(\text{OfstTable}[i_x + 1, i_y]) \\
 \Delta x_1 &= \text{MSB16}(\text{Ofst1}) \\
 \Delta y_1 &= \text{LSB16}(\text{Ofst1}) \\
 \\
 \text{Ofst2} &= \text{READ32}(\text{OfstTable}[i_x, i_y + 1]) \\

 \end{aligned}$$

Idc-023

**Figure 6-109. LDC Lens Distortion Back Mapping Offset Calculation**

Graphically, this procedure is shown in [Figure 6-110](#).

ldc-024

**Figure 6-110. LDC Back Mapping Procedure Using Offset Table**

The input coordinate  $(x_i, y_i)$  refers to final input frame co-ordinates and is used to fetch the appropriate input pixels for interpolation. The interpolation procedure is described in . Before fetching  $data(x_i, y_i)$ , is clipped to the input frame boundary.

#### 6.9.5.2.6.1 LDC Mesh Table Storage Format

The size of the mesh table is dependent on the Total output frame size. The size must be:

$$\text{Table Width} = \text{CEIL}((\text{Mesh Frame Width})/2^M) + 1 \quad (15)$$

$$\text{Table Height} = \text{CEIL}((\text{Mesh Frame Height})/2^M) + 1. \quad (16)$$

Mesh frame width and height are specified by registers: VPAC\_LDC\_MESH\_FRSZ[13-0] W and VPAC\_LDC\_MESH\_FRSZ[29-16] H. The downsampling factor, M, is specified by register VPAC\_LDC\_MESHTABLE\_CFG[2] M.

The mesh table should be stored with delta(x) and delta(y) offsets interleaved and stored in raster order. Each offset is S16Q3, so a table entry is 32-bits, including both delta(x) and delta(y). The location of the mesh table is configured by registers VPAC\_LDC\_MESH\_BASE\_H and VPAC\_LDC\_MESH\_BASE\_I. The buffer width ( $\geq$  Table Width), is provided by VPAC\_LDC\_MESH\_OFST[15-0] OFST. The mesh table must be aligned on a 16-byte boundary.

### 6.9.5.2.7 LDC Pixel Interpolation

In UYVY and NV12 mode, the pixel interpolation type can be set to bi-cubic interpolation for best quality or bilinear interpolation for faster performance.

As the coordinates ( $h_d, v_d$ ) calculated by the back-mapping function are not generally integer values, bi-cubic or bilinear interpolation is applied to the distorted pixels.

Depending on register configuration, bi-cubic or bilinear interpolation is used to interpolate the output Y pixels:

- VPAC\_LDC\_CFG[6] YINT\_TYP = 0, bi-cubic interpolation for Y, bilinear for other components
- VPAC\_LDC\_CFG[6] YINT\_TYP = 1, bi-linear interpolation for all components

In the case of bi-cubic interpolation, the distorted pixel is interpolated from the 16 Y pixels in the 4 x 4 grid around the distorted location, as shown in [Figure 6-111](#). Bi-cubic interpolation is used first along the horizontal direction, then the vertical direction.

**Figure 6-111. LDC Bi-cubic Interpolation for Y**

If bi-linear interpolation is selected, the distorted pixel is interpolated from the four Y pixels in the 2 x 2 grid around the distorted location, as shown in [Figure 6-112](#).

**Figure 6-112. LDC Bi-linear Interpolation for Y**

For Cb and Cr components, simple bilinear interpolation is used. Each distorted pixel is interpolated from the four same-color pixels on the 2 x 2 grid around the distorted location. For UYVY data, the Cb/Cr grid is not square, but is 2x wider compared to the height. This is shown in [Figure 6-113](#).

**Figure 6-113. LDC Bilinear Interpolation for CB/Cr in UYVY and NV12 Format**

### 6.9.5.2.8 LDC Buffer Management

Nonlinear nature of the Back Mapping suggests 2-D processing to make more efficient use of external memory bandwidth. Since the mapping computation is non-trivial, the hardware requires the software to provide a number of data management parameters to assist hardware with data transfers.

#### 6.9.5.2.8.1 LDC Buffer Management

Once mesh block fetch is completed, final input co-ordinates are calculated by applying back mapping on previously calculated perspective warp corner pixel co-ordinates. Additional padding is applied on top of these back mapped corner co-ordinates based on the interpolation type.

The LDC processes a block of VPAC\_LDC\_OUT\_BLKSZ[7:0] OBW x VPAC\_LDC\_OUT\_BLKSZ[15:8] OBH (output block width by output block height) pixels at a time in a raster-scan order throughout the image. OBW is constrained to be a multiple of a base width, depending on the operating mode. This is described in [Table 6-135](#). OBH should be even. The LDC uses four corners of the output block plus some padding to fetch the input block. Due to extreme scenarios, there will be scenarios where above bounding box calculated by hardware doesn't cover all the input data required to generate particular output block. To cover those cases, software needs to supply additional PixelPad, the amount of padding in input block in all directions. Software must supply OBW, OBH, and VPAC\_LDC\_OUT\_BLKSZ[19:16] PIXPAD, the amount of padding in input pixels. Software must guarantee that, for EVERY output pixel in the OBW x OBH output block, the input pixels required are bounded by back mapping of the four corners plus/minus the padding. More precisely, the input block is determined by:

- $IBX\_start = \min(\text{truncate}(\text{distortx}(\text{corner1})), \text{truncate}(\text{distortx}(\text{corner3}))) - \text{HwPad} - \text{PixelPad}$
- $IBX\_end = \max(\text{truncate}(\text{distortx}(\text{corner2})), \text{truncate}(\text{distortx}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$
- $IBY\_start = \min(\text{truncate}(\text{distorty}(\text{corner1})), \text{truncate}(\text{distorty}(\text{corner2}))) - \text{HwPad} - \text{PixelPad}$
- $IBY\_end = \max(\text{truncate}(\text{distorty}(\text{corner3})), \text{truncate}(\text{distorty}(\text{corner4}))) + \text{HwPad} + \text{PixelPad}$

where corner1, corner2, corner3, and corner4 are upper-left, upper-right, lower-left, and lower-right corners of the OBW x OBH output block, and distortx(.), distorty(.) are X and Y distorted coordinates of the corners. Distorted coordinates computed by the back-mapping process described in [Section 6.9.5.2.6, LDC Lens Distortion Back-Mapping](#). [Figure 6-114](#) shows the input block bound calculation. [Table 6-135](#) lists the OBW requirements.

Figure 6-114. LDC Input Block Bound

Table 6-135. LDC OBW Requirements

Data Format	OBW must be a multiple of
YUV422	8
YUV420	8

Typically for geometric distortion, the LDC\_BLOCK[19:16] PIXPAD bit field must be 4 to accommodate neighbor sets for all colors. Software must set the PIXPAD bit field correctly.

OBH and OBW must be large enough for efficient operation of the lens distortion operation. As shown in [Table 6-135](#), OBW is constrained to ensure efficient external memory write. Another constraint is that input block size,  $(IBX\_end - IBX\_start + 1) \times (IBY\_end - IBY\_start + 1)$ , for EVERY input block of the image, must fit the allocated input buffer. These parameters must not be specified pessimistically (OBH, OBW too small, or PixelPad too large). Pessimistic parameter setting degrades performance and incurs unnecessary external memory transfer.

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image (See Multi-pass Frame processing).

An intermediate event, *hts\_tdone*, is also provided on completion of each macro block output write. This allows the LDC operation to be pipelined with other tasks. The LDC output write stall after this event, waiting for a pulse on the *hts\_tstart* signal to begin writing the next macro block.

#### 6.9.5.2.9 LDC Multi Region with Variable Block size

Distortion in wide angle lenses causes output block size to be very small due to extreme scaling in particular regions of the Image. This could be caused by high field-of-view or viewing position. The range of “Ratio of Output block to input pixel block size” is very high across the frame.

In order to solve this, LDC supports dividing the frame into multiple regions and output block size can be programmed independently for each region. Frame can be divided up to 9 regions. Frame can be divided into maximum of three slices horizontally and maximum of three slices vertically as shown in [Figure 6-115](#). All the regions in a vertical slice share the common horizontal start location and all the regions in a horizontal slice share the common vertical start location. Width of vertical slices can be configured using VPAC\_LDC\_REGN\_W12\_SZ[13-0] W1, VPAC\_LDC\_REGN\_W12\_SZ[29-16] W2 and PAC\_LDC\_REGN\_W3\_SZ[13-0] W3 register fields. Height of horizontal slices can be configured using VPAC\_LDC\_REGN\_H12\_SZ[13-0] H1, VPAC\_LDC\_REGN\_H12\_SZ[29-16] H2 and VPAC\_LDC\_REGN\_H3\_SZ[13-0] H3 register fields.

Idc-027

**Figure 6-116. LDC Region Skipping Example**

#### 6.9.5.2.9.2 LDC Support for sub-set of 3x3 regions

HW supports dividing the frame into sub-set of 3x3 regions. Following combinations of regions are supported.

- 3 vertical slices
  - $RW1 = x$ ,  $RW2 = y$  and  $RW3 = z$
- 2 vertical slices
  - $RW1 = x$ ,  $RW2 = y$  and  $RW3 = 0$
  - Last region width has to be zero
- 1 vertical slice
  - $RW1 = x$ ,  $RW2 = 0$  and  $RW3 = 0$
  - Last two regions width has to be zero
- 3 horizontal slices
  - $RH1 = x$ ,  $RH2 = y$  and  $RH3 = z$
- 2 horizontal slices
  - $RH1 = x$ ,  $RH2 = y$  and  $RH3 = 0$
  - Last region height has to be zero
- 1 horizontal slice
  - $RH1 = x$ ,  $RH2 = 0$  and  $RH3 = 0$
  - Last two regions height has to be zero

As shown in [Figure 6-117](#), 2x2 region partitioning can be done by programming  $RW3=RH3=0$ .

#### Note

Region numbering remains as in 3x3 region partitioning with R3, R6-R8 being null regions.

ldc-028

**Figure 6-117. LDC 2x2 Region Partitioning Example**

#### 6.9.5.2.9.3 LDC Limitations of Multi Region Scheme

Following features can't be supported when multi region processing is enabled.

- Circular buffer support can't be enabled on Input data fetch
- HTS synchronization can't be enabled on Input data fetch
- LDC can't be joined with other HWAs in the VPAC. LDC output needs to be written to external memory.
- HTS can't make use of multiple BPR buffers available in SL2 circular buffer

#### 6.9.5.2.9.4 LDC Multi Region Block Constrains

- $RW1 + RW2 + RW3$  must be equal to OFW
- $RH1 + RH2 + RH3$  must be equal to OFH
- SW to program the LSE buffer Stride, at-least the size of largest output block width among all regions.
- SW to program buffer height at-least twice the maximum block height among all regions

#### 6.9.5.2.10 LDC Multi-pass Frame processing

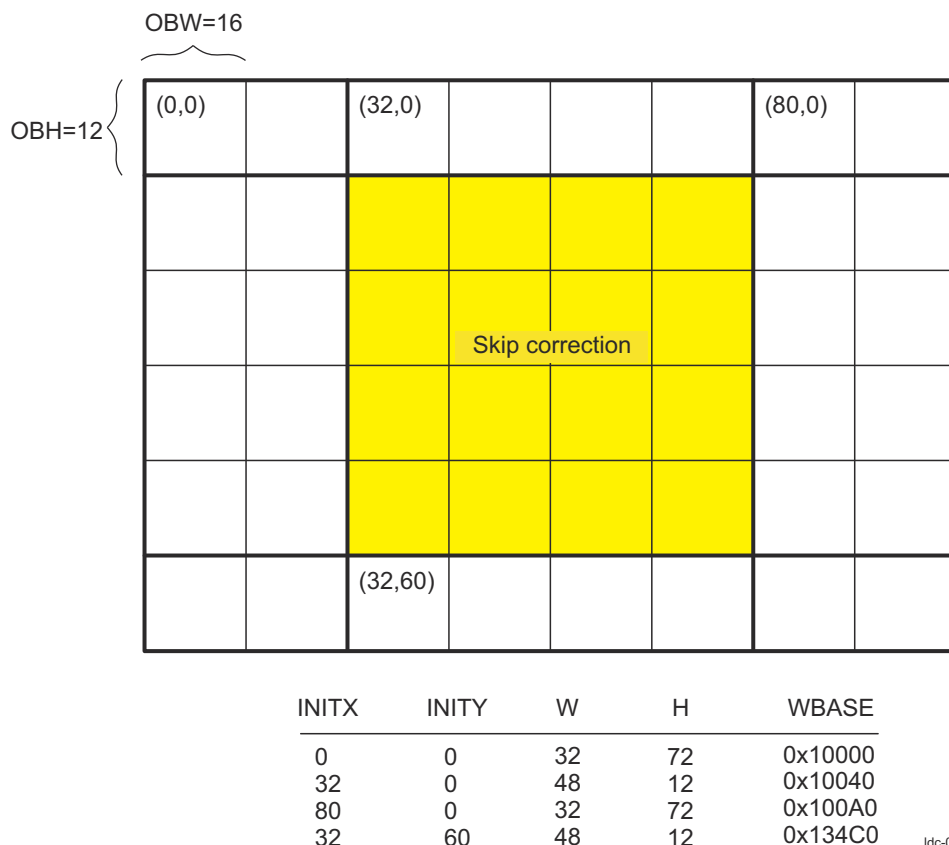

The LDC can process a portion of the image, rather than the entire image. This saves time by letting an image process through multiple software/LDC interactions to correct only a portion of the image.

An intermediate interrupt can occur after processing each macro block. This lets the LDC operation be pipelined with other tasks.

To process only a portion of the image, the following parameters are required:

- VPAC\_LDC\_INITXY[12:0] INITX: X coordinate of upper-left corner of output frame
- VPAC\_LDC\_INITXY[28:16] INITY: Y coordinate of upper-left corner of output frame
- VPAC\_LDC\_INPUT\_FRSZ[13:0] W: Width of output frame
- VPAC\_LDC\_INPUT\_FRSZ[29:16] H: Height of output frame
- FrameBase SDRAM address of upper-left corner of output frame (Y and Cb/Cr base needed in case of YCbCr420)
- FrameOfst SDRAM frame width (in bytes)

Figure 6-118 is an example of multiple-pass processing with middle-of-the-image skipped.

**Figure 6-118. LDC Multiple-Pass Correction Example**

The LDC does not copy skipped blocks from the input frame to the output frame (necessary task unless output frame = input frame); software must set up and initiate this memory copy.

A note on in-place operation to conserve external memory: Depending on the offset table and configuration parameters, it may not be feasible to point the output image at the input image and have corrected pixels overwriting the source image. Software must determine whether it is feasible to overwrite, and allocate a separate frame buffer when it is not feasible. The LDC does not care if the input and output image pointers coincide, nor does it check any dependency violations.

The starting address of the input frame, corresponding to input coordinate (0, 0), is specified in the LDC\_RD\_BASE[31:0] RBASE bit field and offset in the LDC\_RD\_OFST[15:0] ROFST bit field ((Y and Cb/Cr base required for YCbCr4:2:0: LDC\_420C\_RD\_BASE[31:0] RBASE)). The LDC does not clips input block to input frame size if any of the input block falls outside the input frame.

#### Note

- Any number of input blocks CAN fall partially or totally outside the input frame by assuming coordinates that are outside valid range (negative or exceeding maximum image width defined by the line offset).
- If any output pixel refers to any input pixel outside the input frame, the computed value for that output pixel would be same as neighbor pixel which falls into valid input frame. The other output pixels can still have correct outcomes.

#### 6.9.5.2.11 LDC Input/Output Data Formats

Table 6-136 captures valid number of LDC input and output data mode/format combinations.

**Table 6-136. LDC Supported Data Format Combinations**

Input		Output	
Data Mode	Data format	Data Mode	Data format
420 420_Y 420_UV	8-bit	Same as input	8bit
	12-bit - packed		12-bit - packed
	12-bit - unpacked		12-bit - packed
	12-bit - packed		12-bit - unpacked
422	8-bit	420	8-bit (on channel[2/3] using LUT)
			8-bit (on channel[0/1] with shift)
			8-bit (on channel[2/3] using LUT)
			8-bit
422	8-bit	422	12-bit – packed
			8-bit

Output data mode will be same as input data mode except when input data is 422, output data can also be converted to 420. In the case of input data format is 8-bit and output data format is 12-bit packed, valid data range is only 8-bit. Output data formatted into 12-bit packed format with 4 MSB bits being all zeros.

The following list contains the register fields used to configure data modes and formats:

- Input data mode - VPAC\_LDC\_CTRL[4-3] IP\_DATAMODE
- Input data format - VPAC\_LDC\_CTRL[6-5] IP\_DFMT
- Output Luma data format – VPAC\_LDC\_LSE\_BUF\_CFG\_j (j = 0, 2) PIX\_FMT\_PW
- Output Chroma data format – VPAC\_LDC\_LSE\_BUF\_CFG\_j (j = 1, 3) PIX\_FMT\_PW

LDC supports YCbCr 422 in the UYVY input data format. The sample grid for YCbCr 422\_UYVY is shown in [Figure 6-119](#).

ldc-029

**Figure 6-119. LDC Sample Grids for UYVY**

UYVY data are stored in 8-bit per color components as shown in [Table 6-137](#).

**Table 6-137. LDC UYVY 8-bit Per Color Components**

31			0
Y(1)	Cr(0)	Y(0)	Cb(0)

The sample grid for YUV420 NV12 is shown in [Figure 6-120](#).

ldc-029

**Figure 6-120. LDC Sample Grids for NV12**

YCbCr 420 data are stored 8-bit per color components, and in two planes, Y by itself and Cb/Cr interleaved as shown in [Table 6-138](#)

**Table 6-138. LDC YCbCr 420 data stored 8-bit per color components**

31			0
(Y plane) Y(3)	Y(2)	Y(1)	Y(0)
(Cb/Cr plane) Cr(2)	Cb(2)	Cr(0)	Cb(0)

3	1	3	0	2	9	2	8	2	7	2	6	2	5	2	4	2	3	2	2	1	2	0	1	9	8	7	6	5	4	3	2	1	0			
Y2[7:0]												Y1												Y0												+0x0
Y5[3:0]				Y4												Y3												Y2[11:8]				+0x4				
Y7								Y6												Y5[11:4]								+0x8								
Y10[7:0]												Y9												Y8												+0C
Y13[3:0]				Y12												Y11												Y10[11:8]				+10				
Y15												Y14												Y13[11:4]								+14				

3	1	3	0	2	9	2	8	2	7	2	6	2	5	2	4	2	3	2	2	1	2	0	1	9	8	7	6	5	4	3	2	1	0					
Cb1[7:0]																Cr0										Cb0												+0x0
Cr2[3:0]				Cb2										Cr1										Cb1[11:8]				+0x4										
Cr3										Cb3										Cr2[11:4]								+0x8										
Cb5[7:0]										Cr4										Cb4								+0C										
Cr6[3:0]				Cb6										Cr5										Cb5[11:8]				+10										
Cr7										Cb7										Cr6[11:4]								+14										

ldc-031

**Figure 6-121. LDC YUV420 (2-plane 12-bit Fully Packed Format)**

#### 6.9.5.2.12 LDC YUV422 to YUV420 Conversion

Supporting input YUV422 format enables external sensors providing the YUV data directly. YUV422 to YUV420 conversion is done after pixel interpolation and achieved by dropping odd Chroma lines in the block. This retains the Chroma co-sited relation with Luma as at LDC input.

Idc-032

**Figure 6-122. LDC YUV422 to YUV420 Conversion**

#### 6.9.5.2.13 LDC SL2 Interface (LSE)

LDC Output write interface is handled by LSE sub-module. LSE (Load Store Engine) module is a common component integrated in VPAC to perform data load and store tasks on the SL2 memory for the HWA algorithm core.

VBUSP interface is be used to transfer the data from LDC Core to LSE.

For more LSE details, see *Load Store Engine (LSE)*.

##### 6.9.5.2.13.1 LDC PSA (Parallel Signature Analysis)

LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA's internal paths. When enabled, every valid pixel data from the CORE is sampled by a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. Note that data used for PSA is raw data from the CORE rather than data written into SL2 with container alignment. For LDC, PSA signature is calculated in the same order as CORE data transfer to LSE which is 3D block order as against frame order. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC\_LDC\_LSE\_PSA\_SIGNATURE\_y y=0..#\_of\_Output Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature. The read-only register keeps the last saved value until a reset (set to 0) or is replaced by another frame data signature.

##### 6.9.5.2.14 LDC LUT Mapped Dual Output

LDC produces parallel 8-bit and 12-bit outputs to support surround view and ADAS applications concurrently. LDC produces parallel 8-bit output from 12-bit input using LUT based implementation. This 8-bit output is written into SL2 using LSE output channels (channel[2] for Luma and channel[3] for Chroma). Though use case requires 8-bit output, hardware is designed to be generic which supports any 8-12bit to 8-12bit conversion.

12 or 8 bit generated by data interpolation block is mapped to 8 to 12 bits using a LUT based mapping. The LUT is similar to the LUTs used in VISS and is a linear LUT with 513 entries.

The LUTs are sized to provide 513 locations of data, to enable linear interpolation for all locations. The internal weights are sized as 3 bits since the maximum delta between 2 steps is only  $4095/512 = 8$ . The logic is designed to scale for bit width and can support anything from 8 to 12 bits of input to support different use cases. However, since the step size is different depending on the input bit width, the bit selection and weight calculation logic is designed to account for that. LSE Shift operation can be instead of LUT to reduce bit width from 12 down to 8.

The input bit width (IN\_BITDEPTH explained above) is specified using a dedicated register. Output is clipped to programmable clip value ( $2^{\text{BitClip}-1}$ ). Combination of IN\_BITDEPTH, LUT values and Clip value programation allows any 8-12bit to 8-12bit conversion.

#### 6.9.5.2.15 LDC Band Width Controller

A Bandwidth Limiter is required to limit the mean BW that LDC can request over the VBUSM Read interface. The software sets the maximum allowed bytes per cycle in the register, VPAC\_LDC\_VBUSMR\_CFG[27-16] BW\_CTRL.

To determine the maximum allowed bytes per cycle, the software needs to know the configuration of LDC, which determines the maximum input block size. Given a specific configuration, the `ldc_findMaxInputBuffer` utility provided with the functional C model, can be used to give the maximum input block size. The performance requirements determine the maximum number of cycles allowed per block.

#### 6.9.5.2.16 LDC Input Block Fetch Limit

In order to limit the band width hogging by LDC in case of wrong mesh table data, maximum amount of input block pixel data being fetched will be capped at maximum internal memory available for respective data (Note: Luma and Chroma has different size internal buffers).

In YUV420\* modes, limit is imposed by Luma data. Pixel data fetch is stopped on detecting the overflow condition and interrupt event is generated. Maximum of 2 requests can be issued upon overflow detection. In case of mesh data, only interrupt event is generated on detecting overflow condition and there is no stalling of fetch. These events are generated for the first overflow case per frame.

#### 6.9.5.2.17 LDC HTS Interface

The HTS interface is used to synchronize between blocks in VPAC Subsystem. In the case of LDC, it controls the start of LDC operation by issuing `hts_init`. LDC will be waiting for `hts_init` once it is enabled, so LDC is expected to be enabled before issuing `hts_init`.

HTS also controls the LDC output write which will indirectly control all LDC operations (that is, fetch and processing). LDC will start writing output pixel data when only it receives `hts_tstart` for that particular block. Once all output data is written, LDC will generate `hts_tdone` (also `hts_eop` if it is last block of the frame).

#### 6.9.5.2.18 LDC VBUSM Read Interface

VBUSM Read interface has following features

- Data Width – 128 Bit
- Address width – 48 Bit
- Maximum of number of Tags – 32
  - Design can be constrained to use lesser number of Tags
- Maximum Command Size: Programmable
  - 32/64/128/256 Bytes
  - Command will split at maximum command size address boundary
- Chanid Encode: `chanid[1:0]` identify the source/type of the data interface is requesting. `Chanid[11:2]` is tied low.
  - Chanid[1:0] decoding
    - 00 – Mesh Data.
    - 01 – Luma data in 420 mode/422 data.
    - 10 – Chroma data in 420 mode.

### 6.9.5.3 LDC Programmers Guide

#### 6.9.5.3.1 LDC Programming Geometric Distortion Mode

Geometric distortions, barrel and pincushion distortion, can be corrected on UYVY and NV12 data formats. The Mesh based back mapping is used in this mode. An additional affine transform can be configured at the same time.

1. Check and wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0).
2. Set VPAC\_LDC\_CTRL[4-3] IP\_DATAMODE for UYVY (0) or NV12 data (2). Program VPAC\_LDC\_CTRL[6-5] IP\_DFMT to required data storage format.
3. Set VPAC\_LDC\_CTRL[1] LDMAPEN = 1 to enable lens distortion back mapping.

4. Set the input frame base address in VPAC\_LDC\_RD\_BASE\_H / VPAC\_LDC\_RD\_BASE\_L registers. Note that the frame base address must be aligned on a 16-byte boundary. In case of YUV420, YUV422SP, Y1\_Y2 and Y1\_Y2Y3 modes, configure VPAC\_LDC\_RD\_420C\_BASE\_H / VPAC\_LDC\_RD\_420C\_BASE\_L registers for Chroma Data.
5. Set the input frame line offset in VPAC\_LDC\_RD\_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
  - a. Set VPAC\_LDC\_CTRL[9] IP\_CIRCEN = 1.
  - b. LDC computes the row number and applies modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in VPAC\_LDC\_RD\_OFST[29-16] MOD register field. In YUV420 modes, the number of rows in the buffer is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[15-8] OBH and VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[7:0] OBW. Note the constraints on OBW in [Table 6-135](#).
8. Set the pixel pad in VPAC\_LDC\_REGION\_OUT\_BLKSZ\_j[19-16] PIXPAD.
9. Set the input frame size in VPAC\_LDC\_INPUT\_FRSZ[29-16] H and VPAC\_LDC\_INPUT\_FRSZ[13-0] W.
10. Set the output frame size in VPAC\_LDC\_MESH\_FRSZ[29-16] H and VPAC\_LDC\_MESH\_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in VPAC\_LDC\_COMPUTE\_FRSZ[29-16] H and VPAC\_LDC\_COMPUTE\_FRSZ[13-0] W.
12. Set the starting output point in VPAC\_LDC\_INITXY[12-0] INITX and VPAC\_LDC\_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.9.5.3.4](#).
14. Set the mesh offset table pointer to the correct address (VPAC\_LDC\_MESH\_BASE\_H / VPAC\_LDC\_MESH\_BASE\_I[31-0] ADDR and VPAC\_LDC\_MESH\_OFST[15-0] OFST). Set the table down sampling factor for MxM down sampling in VPAC\_LDC\_MESHTABLE\_CFG[2-0] M.
15. Set the Y plane interpolation type to bilinear or bi-cubic in VPAC\_LDC\_CFG[6] YINT\_TYP.
16. If also using affine transform, set the six affine transform parameters in VPAC\_LDC\_AFF\_AB.A, VPAC\_LDC\_AFF\_AB.B, VPAC\_LDC\_AFF\_CD.C, VPAC\_LDC\_AFF\_CD.D, VPAC\_LDC\_AFF\_EF.E, and VPAC\_LDC\_AFF\_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.
17. If also using perspective transform, enable VPAC\_LDC\_CTRL[7] PWARPEN and set VPAC\_LDC\_PWARP\_GH[15-0] G and VPAC\_LDC\_PWARP\_GH[31-16] H. If perspective transform is not used, disable VPAC\_LDC\_CTRL[7] PWARPEN and set VPAC\_LDC\_PWARP\_GH[15-0] G = 0 and VPAC\_LDC\_PWARP\_GH[31-16] H = 0.
18. Set VPAC\_LDC\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
19. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
20. Wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 6.9.5.3.2 LDC Programming Rotational Video Stabilization (Affine Transformation)

In the rotational video stabilization use case, consecutive frames capturing the same scene are aligned to minimize camera shake. Camera motions cause the frames to have translation or rotation differences. Thus, the frames need to be aligned to maintain a stable output video. The affine transform offers control to account for scaling, rotation, and translation transforms. For example, the rotation use case can be parameterized with the following affine transform parameters:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} c \\ f \end{bmatrix}$$

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o - h_o \cos(\theta) - v_o \sin(\theta) \\ v_o - v_o \cos(\theta) - h_o \sin(\theta) \end{bmatrix}$$

ldc-035

where theta is the angle of rotation. In the scaling case, the affine transform uses:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} \alpha & 0 \\ 0 & \alpha \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} h_o(1-\alpha) \\ v_o(1-\alpha) \end{bmatrix}$$

Idc-036

where alpha is the scale factor. Translation uses an identity matrix along with the translation vector as the affine transform parameters, as in:

$$\begin{bmatrix} h_{aff} \\ v_{aff} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} h_d \\ v_d \end{bmatrix} + \begin{bmatrix} T_h \\ T_v \end{bmatrix}$$

Idc-037

where  $T_h$  and  $T_v$  are the translation parameters. More complex transforms can be derived and the affine transformation is general so that optimization routines may be used to provide the best parameters to align two frames. In all affine transforms, the perspective warp parameters,  $g$  and  $h$ , should be set to 0.

The following steps need to be performed by the application to initialize and run LDC to perform affine transform.

1. Check and wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0).
2. Set VPAC\_LDC\_CTRL[4-3] IP\_DATAMODE and VPAC\_LDC\_CTRL[6-5] IP\_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the affine transform, set VPAC\_LDC\_CTRL[1] LDMAOPEN = 1. Otherwise, set VPAC\_LDC\_CTRL[1] LDMAOPEN = 0.
4. Set the input frame base address in VPAC\_LDC\_RD\_BASE\_H / VPAC\_LDC\_RD\_BASE\_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in VPAC\_LDC\_RD\_OFST[15-0] OFST.
6. If reading the input image from a circular buffer:
  - a. Set VPAC\_LDC\_CTRL[9] IP\_CIRCEN = 1.
  - b. If using row address, LDC computes the row number and applies a modulo operation. The absolute address in the buffer is computed from this wrap-around row and the column number and then data is fetched from the circular buffer. Set the circular buffer size in VPAC\_LDC\_RD\_OFST[29-16] MOD. In YUV420 modes, the number of rows in the Y buffer is MOD and the number of rows in the Cb/Cr buffers is MOD/2. In others modes, the number of rows in the buffer is MOD for both Y buffer and Cb/Cr buffer.
7. Set the tile size in VPAC\_LDC\_OUT\_BLK SZ[15-8] OBH and VPAC\_LDC\_OUT\_BLK SZ[7-0] OBW. Note the constraints on OBW in [Table 6-135](#).
8. Set the pixel pad in VPAC\_LDC\_OUT\_BLK SZ[19-16] PIXPAD.
9. Set the input frame size in VPAC\_LDC\_INPUT\_FRSZ[29-16] H and VPAC\_LDC\_INPUT\_FRSZ[13-0] W.
10. Set the output frame size in VPAC\_LDC\_MESH\_FRSZ[29-16] H and VPAC\_LDC\_MESH\_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
11. Set the output compute frame size in VPAC\_LDC\_COMPUTE\_FRSZ[29-16] H and VPAC\_LDC\_COMPUTE\_FRSZ[13-0] W.
12. Set the starting output point in VPAC\_LDC\_INITXY[12-0] INITX and VPAC\_LDC\_INITXY[28-16] INITY.
13. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.9.5.3.4](#).
14. If the data format is NV12, set the 420 UV input plane base address in VPAC\_LDC\_RD\_420C\_BASE\_H / VPAC\_LDC\_RD\_420C\_BASE\_I. This address must be 16-byte aligned.
15. Set the mesh offset table pointer to the correct address (VPAC\_LDC\_MESH\_BASE\_H / VPAC\_LDC\_MESH\_BASE\_I and VPAC\_LDC\_MESH\_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE\_CFG.M.
16. Set the Y plane interpolation type to bilinear or bicubic in VPAC\_LDC\_CFG[6] YINT\_TYP.
17. Set the six affine transform parameters in VPAC\_LDC\_AFF\_AB.A, VPAC\_LDC\_AFF\_AB.B, VPAC\_LDC\_AFF\_CD.C, VPAC\_LDC\_AFF\_CD.D, VPAC\_LDC\_AFF\_EF.E, and VPAC\_LDC\_AFF\_EF.F. If

affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, and F = 0.

18. Disable perspective warp transform with VPAC\_LDC\_CTRL[7] PWARPEN = 0. Set the two perspective transform parameters VPAC\_LDC\_PWARP\_GH[15-0] G = 0 and VPAC\_LDC\_PWARP\_GH[31-16] H = 0.
19. Set VPAC\_LDC\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
20. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
21. Wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 6.9.5.3.3 LDC Programming Perspective Transformation

Perspective transforms are used to align the image data of two different cameras viewing the same scene from different positions. It can also be used in the case of stereo image rectification to align the epipolar lines of the left/right image pair with their scan lines.

The following steps need to be performed by the application to initialize and run LDC to perform perspective transform.

1. Check and wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0).
2. Set VPAC\_LDC\_CTRL[4-3] IP\_DATAMODE and VPAC\_LDC\_CTRL[6-5] IP\_DFMT to required data mode and format.
3. If lens distortion correction is performed at the same time as the perspective transform, set VPAC\_LDC\_CTRL[1] LDMAPEN = 1. Otherwise, set LDMAPEN = 0.
4. Set the input frame base address in VPAC\_LDC\_RD\_BASE\_H / VPAC\_LDC\_RD\_BASE\_I. Note that the frame base address must be aligned on a 16-byte boundary.
5. Set the input frame line offset in VPAC\_LDC\_RD\_OFST[15-0] OFST.
6. Set the tile size in VPAC\_LDC\_OUT\_BLKSZ[15-8] OBH and VPAC\_LDC\_OUT\_BLKSZ[7-0] OBW. Note the constraints on OBW in [Table 6-135](#).
7. Set the pixel pad in VPAC\_LDC\_OUT\_BLKSZ[19-16] PIXPAD.
8. Set the input frame size in VPAC\_LDC\_INPUT\_FRSZ[29-16] H and VPAC\_LDC\_INPUT\_FRSZ[13-0] W.
9. Set the output frame size in VPAC\_LDC\_MESH\_FRSZ[29-16] H and VPAC\_LDC\_MESH\_FRSZ[13-0] W. Mesh data has to be present for entire frame after transform.
10. Set the output compute frame size in VPAC\_LDC\_COMPUTE\_FRSZ[29-16] H and VPAC\_LDC\_COMPUTE\_FRSZ[13-0] W.
11. Set the starting output point in VPAC\_LDC\_INITXY[12-0] INITX and VPAC\_LDC\_INITXY[28-16] INITY.
12. Configure SL2 Interface programming registers. Details of LSE configuration is captured in [Section 6.9.5.3.4](#).
13. If the data format is NV12, set the 420 UV input plane base address in VPAC\_LDC\_RD\_420C\_BASE\_H / VPAC\_LDC\_RD\_420C\_BASE\_I. This address must be 16-byte aligned.
14. Set the mesh offset table pointer to the correct address (VPAC\_LDC\_MESH\_BASE\_H / VPAC\_LDC\_MESH\_BASE\_I and VPAC\_LDC\_MESH\_OFST. Set the table down sampling factor for MxM down sampling in MESHTABLE\_CFG.M.
15. Set the Y plane interpolation type to bilinear or bicubic in VPAC\_LDC\_CFG[6] YINT\_TYP.
16. Set the eight perspective transform parameters in VPAC\_LDC\_AFF\_AB.A, VPAC\_LDC\_AFF\_AB.B, VPAC\_LDC\_AFF\_CD.C, VPAC\_LDC\_AFF\_CD.D, VPAC\_LDC\_AFF\_EF.E, and VPAC\_LDC\_AFF\_EF.F. If affine transform is not used, then these need to be set to the following values: A = 4096, B = 0, C = 0, D = 0, E = 4096, F = 0, G = 0 and H = 0. Enable VPAC\_LDC\_CTRL[7] PWARPEN = 1.
17. Set VPAC\_LDC\_CTRL[0] LDC\_EN = 1 to start the LDC operation.
18. Start the HTS init sequencing. LDC fetch/processing is gated with hts\_init.
19. Wait for VPAC\_LDC\_CTRL[2] BUSY to become IDLE (0) or wait for the end of frame completion interrupt.

#### 6.9.5.3.4 LDC Programming LSE

Following provides the LSE general programming guideline.

It also captures an additional secondary specific use case configuration values for some registers.

- Frame Size = 1920x1080
- Output Block size = 64x32
- Luma data being consumed by MSC and Chroma is written out by UDMA
  - Block to line conversion done for Luma data via SL2.

- Chroma data is written out at block level.
  - Circular buffer size just to do ping-pong between LDC – MSC(Y) and LDC – UDMA(C)
  - 12-bit pixel data
1. Pixel Data Format
    - a. VPAC\_LDC\_LSE\_BUF\_CFG\_j (PIX\_FMT\_PW, PIX\_FMT\_CNTRSZ, and PIX\_FMT\_ALIGN) parameters define the pixel output data format for this output channel.
    - b. Common data formats:
      - i. Fully packed 12-bit : PIX\_FMT\_PW=1, PIX\_FMT\_CNTRSZ=1, PIX\_FMT\_ALIGN=0
      - ii. 12-bit unpacked (MSB aligned) : PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ=2, PIX\_FMT\_ALIGN=1
  2. Output SL2 Circular Buffer Configuration
    - a. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j (buf\_stride) – define the line stride size (must be 64 byte multiple)
      - i. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE = 2880 (1920 \* 1.5)
      - ii. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE = 96 (64 \* 1.5)
    - b. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j (cbuf\_size) – define the size of the circular buffer in the SL2 (number of lines)
      - i. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE = 68 (2\*OBH+4)
      - ii. VPAC\_LDC\_LSE\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE = 64 (2\*OBH)
  3. Output SL2 Circular Buffer 2D mode Configuration (applicable for LDC only - TBD)
    - a. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j (buf\_blk\_width) – defines the number of bytes equivalent to OBW (output block width) pixels.
      - i. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j.buf\_blk\_width = 96 (64\*1.5)
    - b. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j (cbuf\_bpr) – defines the number of 2D blocks per row in the SL2 circular buffer.
      - i. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN = 30
      - ii. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN = 1
  4. Base Address and Channel Enable:
    - a. VPAC\_LDC\_LSE\_BUF\_BA\_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
    - b. VPAC\_LDC\_LSE\_BUF\_BA\_j[31] ENABLE – enables this output channel.

#### 6.9.5.3.5 LDC Programming Restrictions and Special Cases

The following list of LDC programming restrictions should be considered:

1. VPAC\_LDC\_LSE\_BUF\_ATTR1\_j[25-16] CBUF\_BPR\_CHAN supports 1023 number of block per row. Hence, with output block width of 8, maximum line size supported in SL2 memory is 8184 pixels.
2. In 422 mode, always program as data format as 8-bit (design does not select data format automatically based on mode)
3. Due to hardware limitations, make sure that input block size (height and width) does not cross 1023 (pixels/lines).
  - The hardware generates either PIX\_IBLK\_MEMOVF or MESH\_IBLK\_MEMOVF events in this case.
4. VPAC\_LDC\_CTRL[0] LDC\_EN should be high before issuing hts\_init.

## 6.9.6 VPAC Multi-Scaler (MSC)

### 6.9.6.1 MSC Overview

VPAC\_MSC (VPAC Multi-Scaler, hereinafter simply referred to also as MSC) is a Hardware Acceleration (HWA) module in Vision Pre-processing Accelerator (VPAC) . MSC supports two sets of multi-output scaling filters to accelerate generation of pyramid (Octave) and intra-octave scales required by Optical Flow processing and DSP vision algorithms.

#### 6.9.6.1.1 MSC Features

- 10 scaled outputs independently mapped to 1 or 2 processing threads (any number up to 10 scaler outputs can be mapped to one thread, while the remaining scaler outputs can be mapped to the other thread)
- Programmable scaling engine:
  - Pyramid or intra-octave scale generation
  - $1x \sim x/4$  image downscaling
  - $1x$  generic separable convolution filtering
  - On-the-fly (OTF) or memory-to-memory (M2M) operation with line buffers in SL2 (thus, frame width not constrained by internal line buffer width).
- Polyphase filters:
  - 5-tap separable filter kernel structure
  - Programmable kernel sizes for vertical/horizontal filter (3, 4, or 5)
  - Polyphase implementation with support of 64 or 32 phases
  - Independent programming of vertical/horizontal filters with initial phase programming option
- Filter Coefficients (shared by all scalers):
  - Coefficients in signed 10-bit number (typically 1-bit integer with 8 fractional bits)
  - Programmable Coefficient shift size to set precision of coefficient number (shift size represents the fractional bit width)
  - 2 dedicated sets of 5-tap single phase filter coefficients (for example, Gaussian) for Pyramid (Octave) generation or custom convolution filtering.
  - 4 sets of 5-tap x 32 phase coefficients
    - Two can be combined to support 5-tap x 64-phase filters
    - First can be configured to hold additional 5-tap single-phase convolution filters for non-resizing application.
- Input/output format support:
  - Each thread can support the following input source formats:
    - One plane (uniform or interleaved format - Y, CbCr interleaved, R)
  - Each Input channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
  - Each Output channel supports 8/12-bit pixel data in 8/12/16-bit pixel container with programmable LSB/MSB alignment
- Performance:
  - 1 cycle/pixel per plane
  - Input line skip for thread performing only pyramid-generation (50% less processing time)
- Other features:
  - Programmable Input and Output Region of Interest (ROI) (or clipping) for each scaler
  - Support for Vertical and Horizontal edge Padding (replication) for both luma/chroma data plane inputs
- Functional Safety Support: CRC frame data signature capture on all output channels for fault detection in the data path.

#### 6.9.6.1.2 MSC Not Supported Features

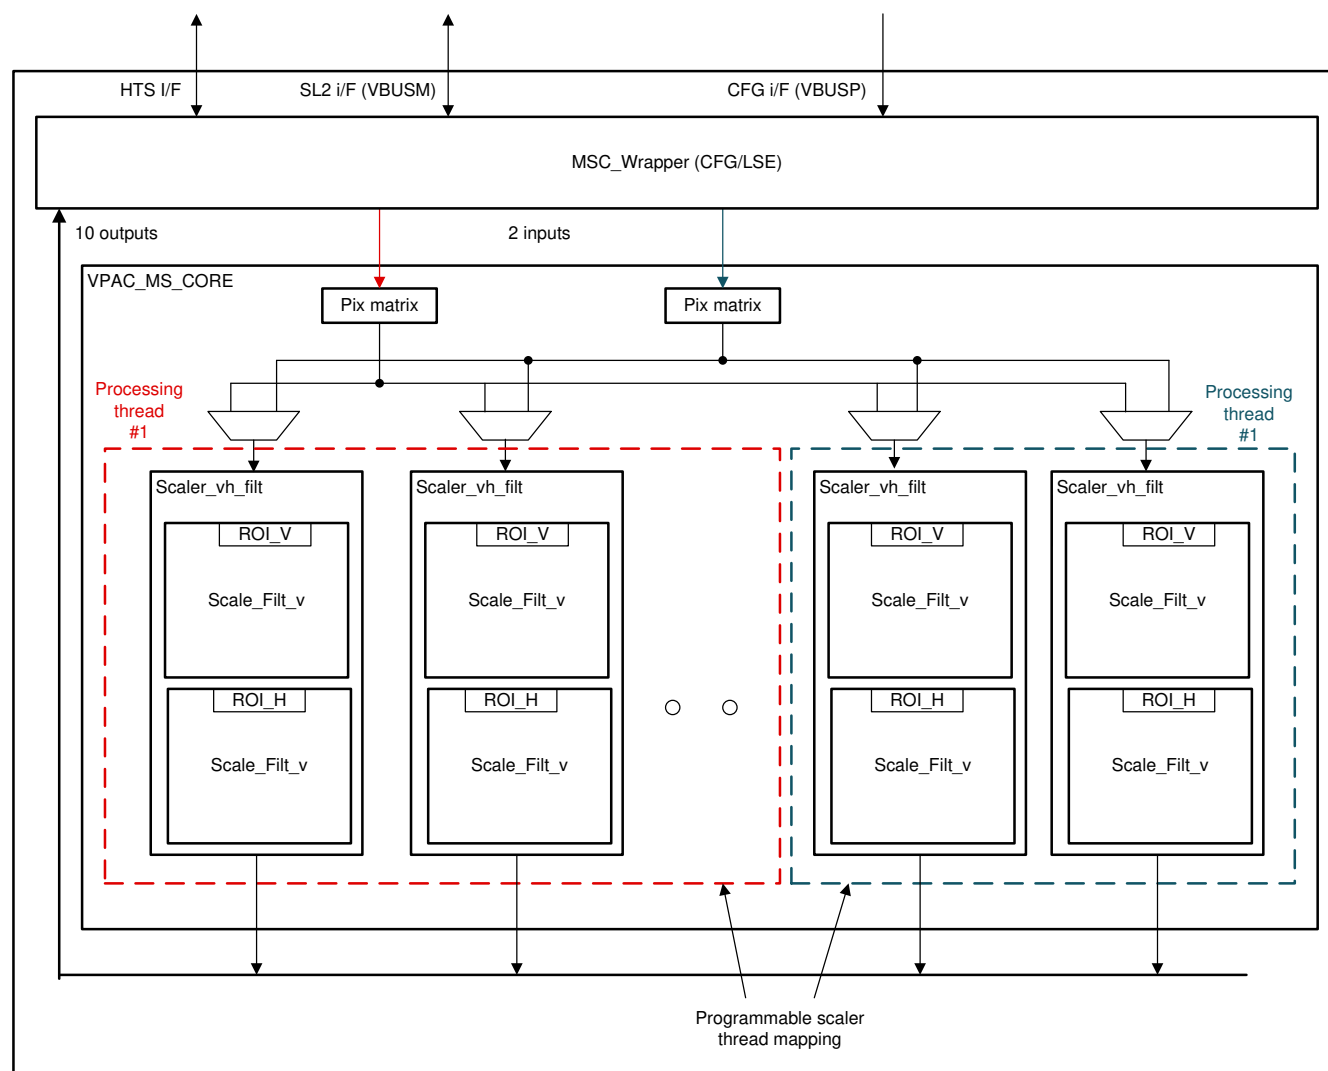

- More than 2 input threads or 10 outputs
- Block based operation for scalar
- Multi-component (RGB) Scaling
- Error checks for out of bound parameters

## 6.9.6.2 MSC Functional Description

### 6.9.6.2.1 MSC Functional Overview

VPAC\_MSC consists of 10 programmable resizers performing multi-thread/multi-scaling operations (1-input to N-outputs and 1-input to M-outputs where  $N+M$  is 10 or less). Each processing thread of MSC HWA reads its input plane data from a Shared Memory buffers (SL2) circular line buffers, performs multi-scaling operations (ratios between X and 0.25X) on the selected thread channel input, and writes out results to SL2 circular line buffers. In case of OTF operation, the source data is generated from another HWA. In case of M2M operation, the source data is read from the DDR memory. Data transfers from/to SL2 to/from external memory (or another HWA) are handled by VPAC level DMA controller with transfer request events coming from VPAC top level HWA Thread Scheduler (HTS), see *HWA Threads Scheduler (HTS)*.

A typical configuration of the MSC module uses one input plane data to generate 7 intra-octave scales and the next octave image. Multi-pass processing is then utilized to generate up to next 6 or 7 sets of scales/octaves. Since the resolution after each octave is essentially reduced by 4x, the performance requirement for generating an infinite number of scales is bounded by 1.33x of the base input image pixel rate. The second input can be used to enable a pyramid generation processing for another input data or a set of scales/pyramid generation for chroma data as long as the total number of scales needed by both threads is 10 or less. Each resizer in a processing thread can access any coefficient set.

**Figure 6-123. Block Diagram of Multi-Scaler Filter Core**

For details on MSC integration in VPAC, see [Section 6.9.3, VPAC Subsystem Level](#).

#### **6.9.6.2.1.1 MSC Submodule Details**

The MSC\_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs following functions:

- Provides interface to SL2 circular buffers via a common VBUSM master interface
- Manages input and output channel updates in sync with HTS
- Provides data unpacking for core and packing for SL2 interface
- Manages LSE specific configuration registers

The MSC\_CORE performs all filtering operations for various 2-in/10-out multi-scaling/multi-thread configurations. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

The internal data transfers between the MSC\_LSE and MSC\_CORE are done over VBUSP write-only streaming interfaces.

##### **6.9.6.2.1.1.1 MSC Load Store Engine (MSC\_LSE)**

##### **6.9.6.2.1.1.1.1 MSC\_LSE Overview**

[Figure 6-124](#) shows the MSC\_LSC block diagram.

The MSC LSE supports following VPAC LSE features:

- Up to 2 processing threads supported (a thread is a processing chain with its own HTS start/done).
- Input channel features:
  - One SL2 input channel per thread with following features for the input channel:
    - Single data plane support
    - 8/12 packed and 12-bit unpacked source format support
    - Up to 5 lines - input kernel height support
    - 1D addressing mode only with CBUF address handling
    - Input Line Skip Support
    - Vertical boundary Edge Padding (Replication only) support
    - Channel enable
    - Video frame data with frame sync signals over a common vbusp streaming write-master interface

- Output Channel Features:
  - Up to 10 SL2 output channels (pixel data output only)
  - Single data plane support for each output channel
  - Programmable thread mapping for each output channel
  - 8/12 packed and 12-bit unpacked output pixel data format support
  - 1D addressing mode support with CBUF address handling
  - Channel enable
  - Video frame data with frame sync signals (along with optional in-band control signals) over a separate vbusp streaming write-slave interface
- HTS synchronization support
- LSE internal data bypass mode support
  - Input channel 0 can be configured to bypass/loopback mode the data to the core and/or directly to the output channel 9 (bypassing the core).

#### 6.9.6.2.1.1.2 MSC\_LSE Internal Data Loopback Channel

The MSC\_LSE provides a data loopback channel.

When enabled (VPAC\_MSC\_LSE\_CFG\_LSE[0] LOOPBACK\_EN), the LSE sends the “loopback-enabled” input channel unpacked data directly to the designated output channel packing logic without going through the HWA\_CORE. The looped back data can be packed in a different format in the output channel to perform a data format conversion or can be packed in the same format as the input.

When the loopback mode is enabled, the “loopback” designated output channel is no longer available for HWA\_CORE output data transfer. But, the input channel can still operate normally to read in the data for the HWA\_CORE (provided that the other output channel is used for transferring out the HWA\_CORE output data) by setting VPAC\_MSC\_LSE\_CFG\_LSE[1] LOOPBACK\_CORE\_EN. In this mode, the input channel flow is throttled by both the core and the loopback data path.

The data flow of the loopback mode is also controlled by the HTS synchronization signals.

#### 6.9.6.2.1.1.3 MSC\_LSE PSA Support

As a safety function, LSE integrates a CRC signature capture mechanism on each output channel data to verify the integrity of the HWA internal paths. When enabled (VPAC\_MSC\_LSE\_CFG\_LSE[8] PSA\_EN), every valid transfer frame data from the MSC is passed through a CRC module to update the signature for the channel before the data is packed and sent to the SL2 buffer. At the end of frame condition, the final signature is saved in a separate read-only signature register (VPAC\_MSC\_LSE\_PSA\_SIGNATURE\_y[31-0] VAUE = 0,...,Number\_of\_Output\_Channel-1) till the next end of frame condition for software to read and compare it against the golden reference signature.

The PSA signature register is based on the following IEEE 802.3 standard 32-bit CRC polynomial:

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The PSA module is inserted in the LSE data path as shown in [Figure 6-124](#).

#### 6.9.6.2.1.1.4 MSC\_LSE Feature Detailed Description

For detailed LSE feature description, see *Load Store Engine (LSE)*.

#### 6.9.6.2.1.1.2 MSC\_CORE (HWA Core)

The MSC\_CORE (HWA\_CORE) is configured as two multi-scaling engines each of which can perform 1-to many (multi) scaling operations on an independent input source. The number of outputs (scaler filters) assigned to each multi-scaling engine is user-configurable.

#### 6.9.6.2.1.1.2.1 MSC\_CORE Overview

[Figure 6-125](#) shows the architectural overview of the MSC\_CORE. Each reconfigurable multi-scaling engine in the MSC\_CORE receives its input frame data from its own dedicated VP (vbusp write only slave) interface. VP\_IN\_0 port is used for the thread #0 (multi-scaling engine-0) and VP\_IN\_1 port is used for the thread

#1 (multi-scaling engine-1). The `THREAD_MAP` parameter of the `MSC_LSE` output channel configuration register (`VPAC_MSC_LSE_DST_BUF_CFG_j[7] THREAD_MAP`) controls which input port is connected to which scaling filter (filter\_0 ~ filter\_9).

**Figure 6-125. MSC\_CORE Block Diagram**

The scaling filter implements the vertical-before-horizontal architecture in order to avoid intermediate result line buffers that would be needed in the horizontal-before-vertical configuration. This architecture also allows the source frame width to be not restricted by internal line buffer sizes.

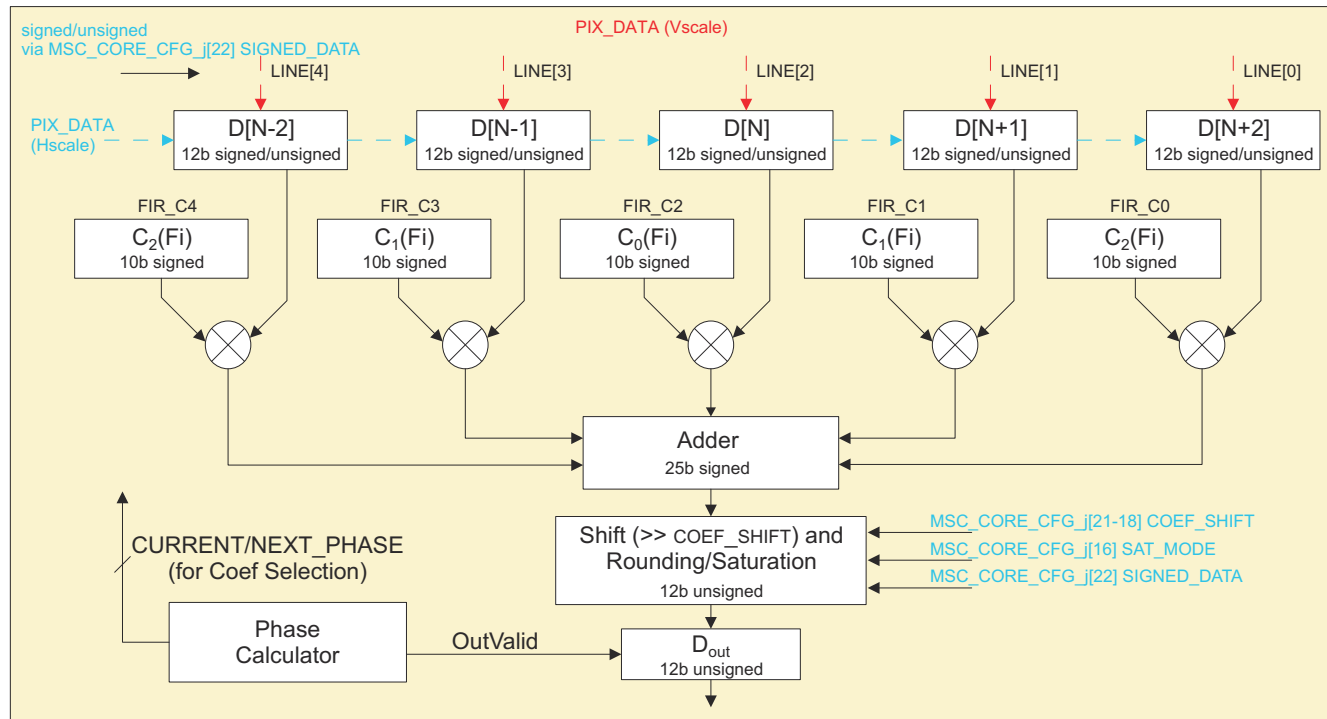

Each scaling filter in the `MSC_CORE` consists of 5-tap (32/64-phase) Polyphase filter based vertical and horizontal resizers. At the input of each resizer, a ROI checker determines the input start position (that is, marks the input data as valid). Output of each resizer is then trimmed to the configured output size of the scaling filter in each respective direction.

For `MSC`, the vertical input edge padding is performed in the `MSC_LSE` while the horizontal input boundary padding is done within the `MSC_CORE` before the horizontal resizer.

#### 6.9.6.2.1.1.2.2 Polyphase Filter of Vertical/Horizontal Resizers

##### 6.9.6.2.1.1.2.2.1 Filter Data Path Logic

Figure 6-126 shows the micro-architecture of the polyphase filter data path. The 5-tap filter structure can be programmed to perform a 5-tap Gaussian filter (for Octave generation) or a 4-tap bi-cubic downscaling filter (for scale generation). Or, it can be configured to perform a custom convolution filter without resizing. Filter coefficients for any unused taps should be set to 0. For example, in case of a 4-tap filtering, `C2(Fi)` filter coefficient should be set to 0. For 3-tap filtering, `C-2(Fi)` and `C2(Fi)` filter coefficients should be set to 0.

**Figure 6-126. Polyphase Filter Micro-Architecture**

### Kernel Size Configuration

There is no separate configuration required to set the filter kernel size (number of taps) within the polyphase filter. The filter always works as a 5-tap filter but requires unused taps to be masked using the zero coefficients.

### Coefficient Precision Selection

The precision of the coefficients is user-configurable using VPAC\_MSC\_CORE\_CFG\_j[21-18] COEF\_SHIFT which determines the number of fractional bits of the coefficient.

### Unsigned/Signed Data Type support

Typically for image resizing, the input and output data are in unsigned (positive) integer numbers in the range of [0..4095]. But, in some non-image convolution filtering (for example, Sobel filter), the input and output data may be in signed integer data format. The MSC supports a user-selectable data type mode bit (VPAC\_MSC\_CORE\_CFG\_j[22] SIGNED\_DATA) per resizer to specify whether the input/output data is in signed or unsigned data format. The selection determines the input range and output clipping limits as shown below:

VPAC\_MSC\_CORE\_CFG\_0[22] SIGNED\_DATA = 0 -> [0..4095]

VPAC\_MSC\_CORE\_CFG\_0[22] SIGNED\_DATA = 1 -> [-2048..2047]

Note that all filters in the same processing thread should have the SIGNED\_DATA bit set to a same value.

### Rounding Logic

The rounding is done by “adding 0.5 and dropping fractional bits”. This achieves the following:

For data  $\geq 0$ : “round to nearest, ties away from zero”

For data  $< 0$ : “round to nearest, ties toward zero”

### Output Saturation Logic

For some non-image unsigned data filtering, the result of the final adder could be negative numbers. To avoid clipping all negative numbers to 0, the MSC filter data processing supports a mode

(VPAC\_MSC\_CORE\_CFG\_j[22] SAT\_MODE = 1) to offset the result by 2048 and then clip the final result to [0..4095] in the output saturation logic to preserve the full data range.

### Edge Pixel Replication

Pixel replication in vertical direction (edge line replication) is done in the MSC\_LSE.

Pixel replication in horizontal direction (edge pixel replication) is performed in the horizontal filter. For chroma data plane, Cb/Cr pixel replication is done independently with edge Cb/Cr data respectively.

#### 6.9.6.2.1.2.2.2 Filter Parameters

[Table 6-139](#) lists the parameters used to define the configuration of the resizing (downsampling) vertical/horizontal filters.

**Table 6-139. Parameters of the Resizing (Downsampling) Vertical/Horizontal Filters**

Parameter	Bit Precision	Description
FIRINC_V VPAC_MSC_CORE_FIRINC_j[30-16] VS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Vertical Resizing Ratio value (vertical filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling) +1 in the above equation is optional. +1 forces non-repeating coefficients in integer ratio scaling cases.
FIRINC_H VPAC_MSC_CORE_FIRINC_j[14-0] HS	U15Q12 (Unsigned 15b number with 12-bit fraction)	Horizontal Resizing Ratio value (Horizontal filter increment) Valid Range: 4096 (1x scaling) < FIRINC_V < 16384 (1/4x scaling)
ACC_INIT_V VPAC_MSC_CORE_ACC_INIT_j[27-16] VS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Vertical Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095
ACC_INIT_H VPAC_MSC_CORE_ACC_INIT_j[11-0] HS	U12Q12 (Unsigned 12b number with 12b fraction)	Initial Horizontal Resizer Phase Valid Range: 0 < ACC_INIT_V < 4095

Additionally, [Table 6-140](#) lists the mode parameters defined the filter operation and coefficient selection.

**Table 6-140. Filter Mode and Coefficient Selection via VPAC\_MSC\_CORE\_CFG\_j Registers**

Parameter	Bit Width	Description
SIGNED_DATA VPAC_MSC_CORE_CFG_j[22] SIGNED_DATA	1-bit	Integer type of input and output frame data: 0 : Unsigned 12-bit (default) 1 : Signed 12-bit
UV_MODE VPAC_MSC_CORE_CFG_j[17] UV_MODE	1-bit	Source data interleave format: 0 - non-interleaved (Y data) 1 - interleaved (UV data)
SP_VS_COEF_SEL VPAC_MSC_CORE_CFG_j[15-12] SP_VS_COEF_SEL	4-bits	Single Phase – Vertical Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N < 10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.

**Table 6-140. Filter Mode and Coefficient Selection via VPAC\_MSC\_CORE\_CFG\_j Registers (continued)**

Parameter	Bit Width	Description
SP_HS_COEF_SEL VPAC_MSC_CORE_CFG_j[10-7] SP_HS_COEF_SEL	4-bits	Single Phase – Horizontal Filter Coef Selection N : 5-tap/32-phase Filter Coef Set #0 (Entry N+10) where N=0-9 10 : Gaussian Filter #0 11 : Gaussian Filter #1 12-15 : Invalid When FilterMode=0 and N < 10, then the multi-phase coef set #0 is dedicated for one or more single phase filters.
VS_COEF_SEL VPAC_MSC_CORE_CFG_j[5-4] VS_COEF_SEL	2-bits	Multi-phase Vertical Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
HS_COEF_SEL VPAC_MSC_CORE_CFG_j[3-2] HS_COEF_SEL	2-bits	Multi-phase Horizontal Coef Selection 00 : 5-tap/32-phase Filter coef set #0 01 : 5-tap/32-phase Filter coef set #1 10 : 5-tap/32-phase Filter coef set #2 11 : 5-tap/32-phase Filter coef set #3
PHASE_MODE VPAC_MSC_CORE_CFG_j[1] PHASE_MODE	1-bit	Filter Phase mode selection 0 - 64 phases 1 - 32 phases
FILTER_MODE VPAC_MSC_CORE_CFG_j[0] FILTER_MODE	1-bit	Filter Mode 0 – Single Phase Filter (for example, Gaussian Filter for Pyramid) 1 – Multi-phase Scaling Filter
FILT_SAT_MODE VPAC_MSC_CORE_CFG_j[16] SAT_MODE	1-bit	Filter Output Saturation Mode 0 - [0..4095] clipping 1 - [-2048.. 2047] clip followed by +2048 This parameter is used only when signed_data = 0 (unsigned data type).
COEF_SHIFT VPAC_MSC_CORE_CFG_j[21-18] COEF_SHIFT	4-bits	Coef Shift Size: configures the precision of the 10-bit signed filter coefficients (valid Shift range: 5~9) : 5: Shift by 5 (5-bit fraction) 6: Shift by 6 (6-bit fraction) 7: Shift by 7 (7-bit fraction) 8: Shift by 8 (8-bit fraction) 9: Shift by 9 (9-bit fraction) Integer size = 9 - #_of_fraction_bits

#### 6.9.6.2.1.1.2.2.3 Single-Phase Filter Parameters

For a single-phase filter configuration (VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE = 0), software must ensure that FIRINC parameters (VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS and VPAC\_MSC\_CORE\_FIRINC\_j[14-0] HS) are programmed with one of the following values only:

- 0x4000 (1/4 X resizing)
- 0x2000 (1/2 X resizing)
- 0x1000 (1X – no scaling)

VPAC\_MSC\_CORE\_ACC\_INIT\_j[27-16] VS and VPAC\_MSC\_CORE\_ACC\_INIT\_j[11-0] HS configuration values are ignored by the MSC hardware (internally set to 0x0) when VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE = 0. If any phase offsets are needed, the starting pixel/line locations of the frame and the filter coefficient values should be adjusted to implement the desired phase shift.

#### **6.9.6.2.1.2.2.4 Interleaved Mode Handling**

When the input is in the interleaved data format (for example, YUV420 Chroma data), the horizontal filter supports two sets of 5-input buffers (Cb and Cr buffers) and alternates filtering operation between two. Phase calculation and coefficient updates are done every other sample. Edge replications at the start of the line and at the end of the line are handled separately for Cb and Cr data.

There is no change in how the vertical filter handles an interleaved data format source.

#### **6.9.6.2.1.2.2.5 Input Skip Line Support**

When a processing thread is only performing an octave generation (1/2x single phase resizing), the next input lines can be offset by 2 lines since the output is only generated every other input line times. By skipping lines (VPAC\_MSC\_LSE\_SRC\_CFG\_j[7] SRC\_LN\_INC\_2), the SL2 access is reduced in half for this mode and the cycle time to complete an Octave generation is equal to 1/2 of the input frame size.

Line N: Read Line N-2, N-1, N, N+1, N+2

Line N+1: Skip

Line N+2: Read Line N, N+1, N+2, N+3, N+4

Line N+3: Skip

Even though “N+1” line processing is skipped, all source lines are still required for proper filtering. Therefore, the DMA transfer from DDR to SL2 should include all lines. VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS should be set to 4096 (1x resizing) to compensate for source line skip (if it is doing a 1/2 resizing).

Horizontal Skip is done normally as 1/2 x resizing by the core HScale Filter.

#### **6.9.6.2.1.2.3 Scaler Filter Thread Mapping**

The scaling filter\_# (# = 0..9) is enabled and its input is connected to one of the processing thread source VP ports (VP\_IN\_0 or VP\_IN\_1) by configuring the output channel #n buffer configuration:

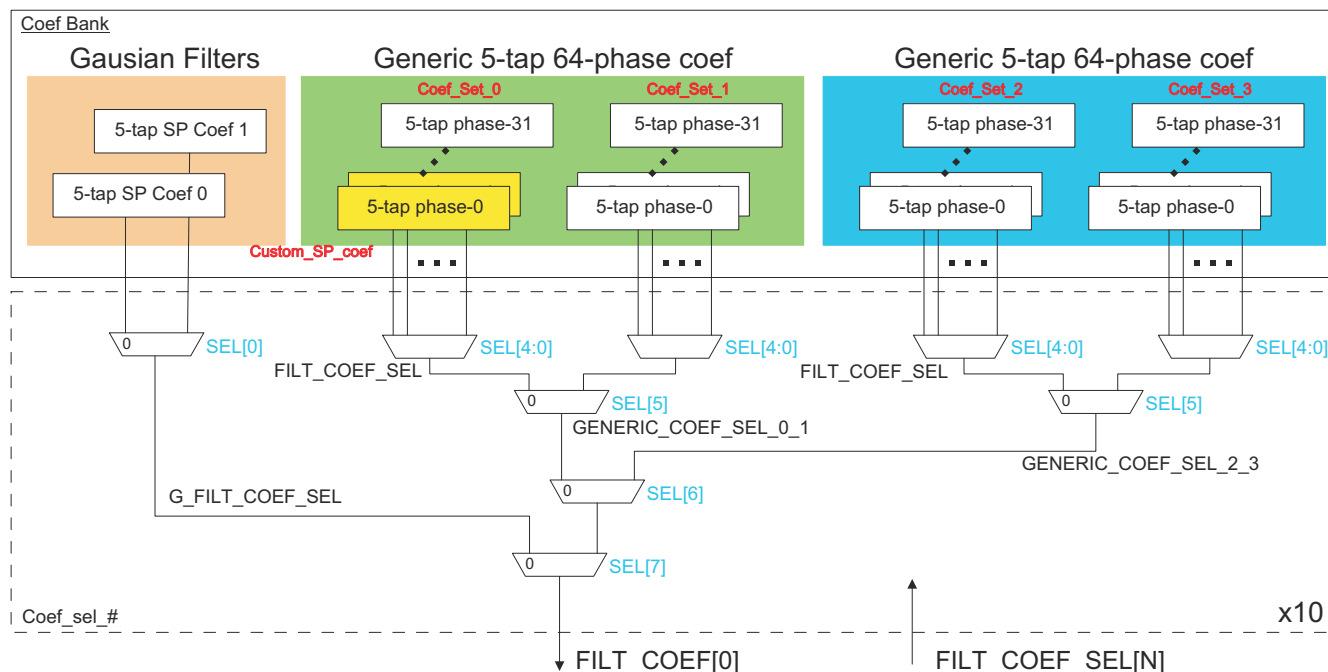

VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[7] THREAD\_MAP: 0 maps the filter to VP\_IN\_0, 1 maps to the VP\_IN\_1.

VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[TBD] ENABLE: enables both filter and output channel

By mapping each output to a thread explicitly in the output channel configuration register, MSC guarantees that a filter can only be connected to one processing thread.

#### **6.9.6.2.1.2.4 Filter Coefficients**

Since each resizer needs to access the common coefficients independently, the coefficients are stored in registers (instead of memory). Each resizer selects directly from these register using the coefficient selection scheme as shown in [Figure 6-127](#). The same mux is used to select either vertical or horizontal coefficients.

**Figure 6-127. Coefficient Selection**

#### 6.9.6.2.1.2.4.1 Filter Coefficient Parameter Configuration

Each coefficient table entry consists of 5 coefficients stored in two memory mapped configuration registers - VPAC\_MSC\_CORE\_C210\_j and VPAC\_MSC\_CORE\_C43\_j. FIR\_C4-0 parameters map to C-2, C-1, C0, C1, and C2 coefficients (see [Figure 6-125](#)).

#### 6.9.6.2.1.2.4.2 3/4/5-Tap Filter Configuration

All filters operate in 5-tap filter mode – requiring 5-tap coefficients regardless of the filter usage. For less-than-5 tap filter configurations, coefficients corresponding to the unused taps should be set to 0.

For example, FIR\_C0 and FIR\_C4 will need to be set to 0x0 for a 3-tap configuration.

For 4-tap configuration, FIR\_C0 will need to be set to 0x0.

#### 6.9.6.2.1.2.5 Input/Output ROI Trimmers

Each scaler filter implements the ROI scaling as shown below with input and output trimmers. The input trimmer simply marks the beginning of the ROI to indicate where the valid source pixels and lines start in the source image. Doing the source ROI marker allows the exact specification of a sub-image in a common source image (no position or size restriction) while keeping the original boundary pixels (that is, not use the replicated pixels/lines).

The output trimmers then uses destination size parameters (VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH) to trim out the exact final output image sizes.

VPAC\_MSC does not perform output size correction by stuffing extra pixels in the case the programmed VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH exceeds the actual output size of the scaler. In this case, VPAC\_MSC simply outputs the actual size.

#### 6.9.6.2.2 Resizer Algorithm Details

This section describes the algorithm details of the Horizontal and Vertical Down-Scaling engines.

##### 6.9.6.2.2.1 Multiple Scales Generations

For a high number of scales needed by vision image processing algorithm (for example, 32 or more), there are many options in generating the multiple scales as shown in [Figure 6-128](#). Among the options, the “linear rescale

from octave resolution” gives the best tradeoff in video quality and design simplicity. The MSC implements 1-to-N multi-rescaling (that is, from one base image to multi-intra-scales and the next octave image generation) as shown as option B in [Figure 6-128](#).

**Figure 6-128. Multiple Scale Generation**

#### 6.9.6.2.2.2 Polyphase Filter

Both vertical and horizontal resizers in MSC hardware are implemented using a programmable Polyphase filter structure supporting 5-tap kernel with either 64 or 32 phases.

##### 6.9.6.2.2.2.1 Interpolation/Resampling

[Figure 6-129](#) illustrates the interpolation principle. The assumptions are that the input pixels are evenly spaced. The distance between each input pixel is assumed to be 1. The magnification ratio is given by  $64/N$  and  $p/64$  is the initial phase of the output data. The output pixels are evenly spaced as well. The distance between each output pixel is given by  $N/64$  (in the example below,  $N > 64$ ). The position of the  $n$ -th output pixel is given by  $(n \times N + p) / 64$ .

**Figure 6-129. Interpolation Principle**

Figure 6-130 illustrates the interpolation principle at the n-th output pixel ( $o_n$ ) at position  $x_n$ . Interpolation method with  $m$  and  $d$  parameters, are described as:

$$m = \text{floor}((n \times N + p) / 64)$$

$$d = ((n \times N + p) / 64) - m$$

Figure 6-130 illustrates the concept when the filters are configured in 4-tap mode for non-integer rescaling (the first coefficient corresponding to  $O_{m-2}$  is set to zero).

**Figure 6-130. Interpolation Process**

Figure 6-131 illustrates another explanation of the concept of a Polyphase filter using a simple 2-tap linear filter in a design which supports 5 phases.

**Figure 6-131. Polyphase Filtering**

For each one of the 5 phases, the weights (or filter coefficients) are different and after the 5 phases the weights start repeating, see [Figure 6-131](#).

[Figure 6-132](#) depicts the architecture for the independent polyphase filter unit.

**Figure 6-132. Polyphase Filter Unit**

Both the horizontal and vertical filter described earlier are an instance of the Polyphase filter unit, though only the vertical filter requires line memories (implemented in SL2 memory space). In all, there will be 20 instances of the Polyphase filter unit, 2 filters per channel and 10 total channels in the VPAC\_MSC module.

#### 6.9.6.2.2.2 Phase Calculation and Re-sampler

The phase calculation block calculates the current phase which in turn is used for selecting the right coefficient set and for the output qualifier in the Re-sampler block. The Re-sampler engine then decides whether or not the output created by the interpolation unit is a valid output or not.

#### 6.9.6.2.2.3 Shared Coefficient Buffers

The MSC module supports up to 4 sets of multi-phase coefficients for generic non-integer resizing and up to 10 sets of single-phase coefficients (5x1 entries) for Octave generation and integer resizing applications. The multi-phase coefficients can also be configured in one of two following options:

- 4 sets of 5-tap x 32 phase coefficients
- 1 set of 5-tap x 64 phase coefficients and 2 sets of 5-tap x 32 phase coefficients
- 2 sets of 5-tap x 64 phase coefficients

The 32 phase configuration option allows using independent coefficients for vertical and horizontal resizer to achieve aspect ratio change during the scaling.

#### 6.9.6.2.2.4 Border Pixel Padding

The MSC module replicates missing lines and pixels at top/bottom and left/right sides of the input frame for non-interleaved (luma) and interleaved (chroma) data.

The missing lines at the top/bottom are replicated in the LSE sub-module prior to the vertical scaler and the missing pixels at the left/right sides of each line are replicated in the core prior to the horizontal scaler. For more information about LSE module, see *Load Store Engine (LSE)*.

Replication scheme simply repeats the edge line or pixel to create missing lines/pixels. [Figure 6-133](#) shows horizontal pixel replication.

**Figure 6-133. Horizontal Pixel Replication**

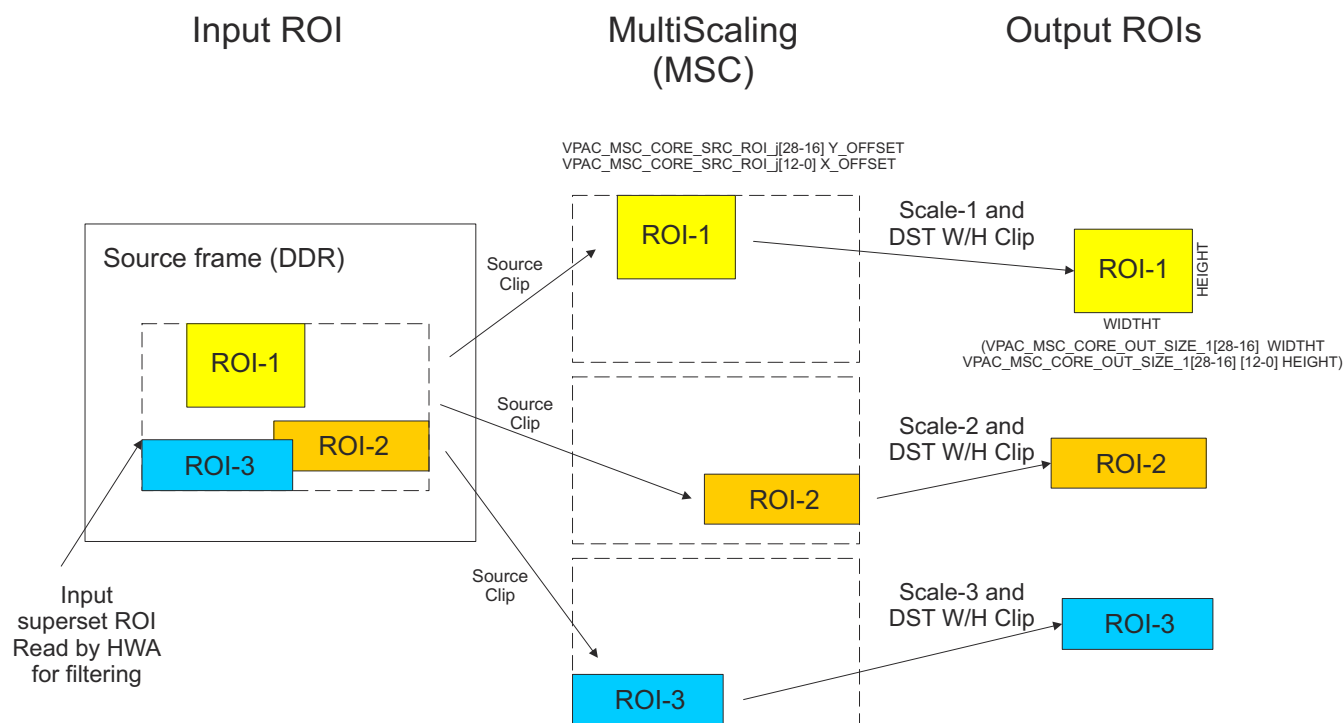

If a scaling is performed on a sub-frame (ROI) within the input frame, no replicated lines/pixels will be used since the lines/pixels outside the sub-frame are already present in the input frame.

For interleaved data format, the horizontal replication is done separately for U and V data. For U-data, edge U-pixel will be replicated. For V-data, edge V-pixel will be replicated. There is no distinction in the vertical edge padding.

#### 6.9.6.2.2.3 ROI Handling

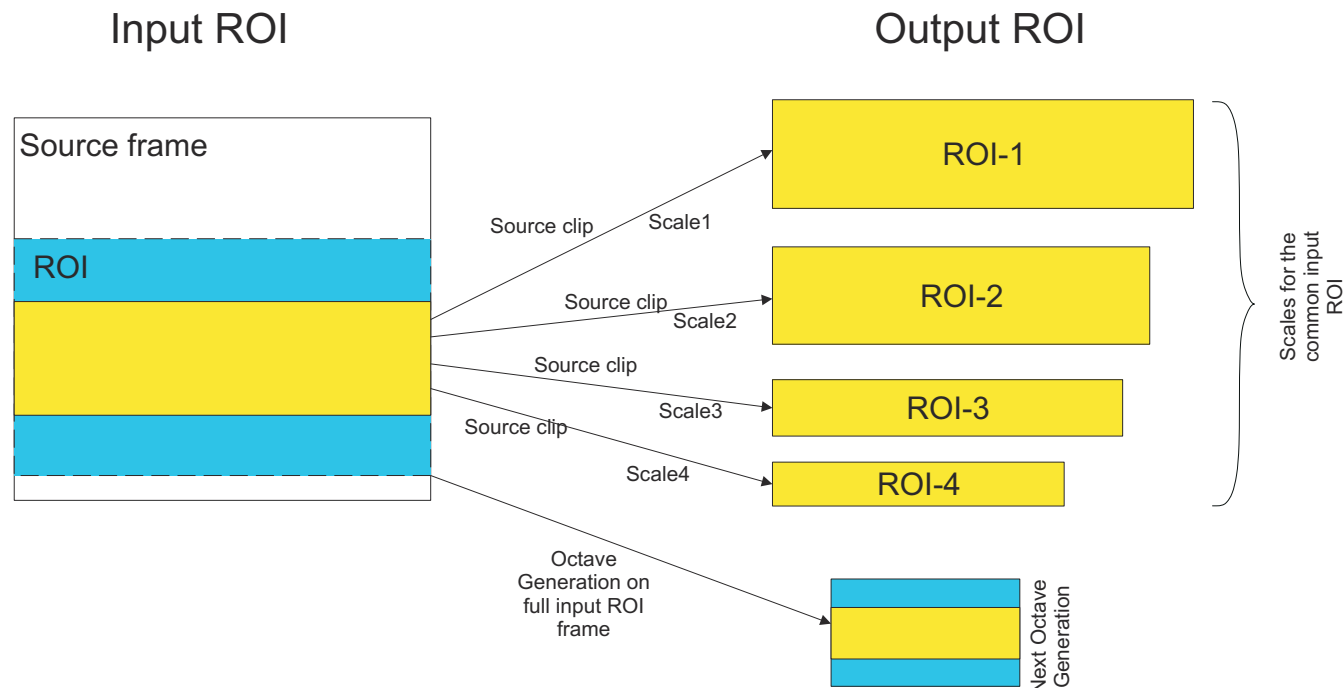

- ROI supported during scaling generation
  - Only one ROI at Input Frame and one ROI at Output frame per scale
  - ROI definitions (for input as well as all output scales) can be changed at every input frame under software control.
  - ROI for each scale (for output) can be different among scales (as well as with respect to the input). It is set under software Control.
  - The key purpose of ROI is DDR bandwidth reduction. There is additional help by reduction on processing power on DSP and hardware.
- The input ROI is a superset area considering following two scenarios.
  - Multiple ROIs in given Input Frame, if there are multiple ROI for input frame
  - Input Frame area from Overlapped ROI across scales

[Figure 6-134](#) shows an example of multiple ROIs in the source superset ROI area.

**Figure 6-134. Multiple-ROI Support Illustration**

Figure 6-135 illustrates another application of generating output ROIs with different scales from a common source region.

**Figure 6-135. Multiple-ROI From a Common Source ROI**

By defining output ROIs, only the data within ROI in the “superset ROI” scaled output image is saved thus reducing the DDR traffic significantly.

### 6.9.6.2.3 MSC Data Formats Supported

Table 6-141 summarizes data format supported by MSC.

**Table 6-141. MSC Input/Output Data Formats**

Module (IO)	Bit-Depth	Chroma Format	Packing
MSC Input	8-bit	YUV420	Fully Packed
	12-bit	YUV420	Fully Packed
	12-bit	YUV420	Unpacked in 16-bit
MSC Output	8-bit	YUV420	Fully Packed
	12-bit	YUV420	Fully Packed
	12-bit	YUV420	Unpacked in 16-bit

Table 6-142 and Table 6-143 show the pixel data memory organization for YUV420 (2-plane 12-bit fully packed format).

**Table 6-142. YUV420 (2-plane 12-bit Fully Packed Format), First Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Y2[7:0]								Y1								Y0								+0 x0								
Y5[3:0]								Y4								Y3								Y2[11:8]								+0 x4
Y7								Y6								Y5[11:4]								+0 x8								
Y10[7:0]								Y9								Y8								+0 C								
Y13[3:0]								Y12								Y11								Y10[11:8]								+1 0
Y15								Y14								Y13[11:4]								+1 4								

**Table 6-143. YUV420 (2-plane 12-bit Fully Packed Format), Second Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Cb1[7:0]								Cr0								Cb0																+0 x0
Cr2[3:0]								Cb2								Cr1								Cb1[11:8]								+0 x4
Cr3																Cb3								Cr2[11:4]								+0 x8
Cb5[7:0]								Cr4								Cb4																+0 C
Cr6[3:0]								Cb6								Cr5								Cb5[11:8]								+1 0
Cr7																Cb7								Cr6[11:4]								+1 4

Table 6-144 and Table 6-145 show the pixel data memory organization for YUV420 (2-plane 8-bit fully packed format)

**Table 6-144. YUV420 (2-plane 8-bit Fully Packed Format), YUV 4:2:0 – NV12, First Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Y3								Y2								Y1								Y0								+0 x0
Y7								Y6								Y5								Y4								+0 x4

**Table 6-144. YUV420 (2-plane 8-bit Fully Packed Format), YUV 4:2:0 – NV12, First Plane (continued)**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Y11								Y10								Y9								Y8								+0 x8
Y15								Y14								Y13								Y12								+0 xC

**Table 6-145. YUV420 (2-plane 8-bit Fully Packed format), YUV 4:2:0 – NV12, Second Plane**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Cr1								Cb1								Cr0								Cb0								+0 x0
Cr3								Cb3								Cb2								Cb2								+0 x4
Cr5								Cb5								Cr4								Cb4								+0 x8
Cr7								Cb7								Cb6								Cb6								+0 xC

**Note**

MSC supports both NV12 and NV21 chroma component ordering. Since there is no color processing, the ordering of Cb and Cr is irrelevant. Simply, if a NV12 chroma plane is the input, the output will be a NV12 chroma plane.

**12-bit unpacked format (16-bit container) with LSB/MSB alignments is shown below**

[Table 6-146](#) and [Table 6-147](#) show the pixel data memory organization for YUV420 (2-plane 12-bit unpacked format – LSB aligned)

### 6.9.6.3 MSC Interrupt Conditions

#### 6.9.6.3.1 CPU Interrupts

Table 6-150 lists the interrupts generated by the MSC module.

**Table 6-150. Interrupts**

Interrupt	Type	Description
VPAC_MSC_LSE_FR_DONE_E VT_0	Pulse	Frame Processing complete for all filters in the processing thread 0.
VPAC_MSC_LSE_FR_DONE_E VT_1	Pulse	Frame Processing complete for all filters in the processing thread 1.
VPAC_MSC_LSE_SL2_RD_ERR	Pulse	Set whenever there is an error response on VBUSM read command request for any input channel
VPAC_MSC_LSE_SL2_WR_ER R	Pulse	Set whenever there is an error response on VBUSM write command request for any output channel

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic. The MSC has no mask/set/clear registers for these events. For more information see [Section 6.9.3, VPAC Subsystem](#).

#### 6.9.6.3.2 Interrupt Event Description

##### 6.9.6.3.2.1 VPAC\_MSC\_LSE\_FR\_DONE\_EVT\_0/1 Events

These events are generated when all filters associated with the thread 0 or 1 complete the frame processing. This is set when input EOF (end of frame) event and output EOF (end of frame) events are detected.

##### 6.9.6.3.2.2 VPAC\_MSC\_LSE\_SL2\_RD\_ERR Interrupt Event

This event is generated whenever the VBUSM read status is something other than 0 (success).

The VPAC status register VPAC\_MSC\_STATUS\_ERROR[4-0] VM\_RD\_ERR stores the last non-zero RSTATUS value and the input channel number for user to see what type of error has occurred on which channel.

**Table 6-151. Encoding for RSTATUS**

RSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive read fail

##### 6.9.6.3.2.3 VPAC\_MSC\_LSE\_SL2\_WR\_ERR Interrupt Event

This event is generated whenever the VBUSM write status is something other than 0 (success).

The VPAC status register VPAC\_MSC\_STATUS\_ERROR[14-8] VM\_WR\_ERR stores the last non-zero WSTATUS value and the output channel number for user to see what type of error has occurred on which channel.

**Table 6-152. Encoding for WSTATUS**

WSTATUS	Meaning
0	Success
1	Addressing error
2	Protection error
3	Timeout error
4	Data error
5	Unsupported Addressing Mode error
6	RESERVED
7	Exclusive write fail

#### 6.9.6.4 MSC Performance

Since the resizer performs only downscaling operations, the throughput of scaler is mostly dictated by the input processing rate – 1 input pixel per 1 clock cycle. Once the data is made available to the scaler filter after the initial set up and data fetching, the scaler should be fully active except for few cycles at the end of each line to flush the line.

If a processing thread is performing a pyramid generation only, the vertical line skip feature can be enabled to reduce the frame processing time approximately by ½.

#### 6.9.6.5 MSC Clocking

Complete VPAC\_MSC module operates on single clock - VPAC0\_MSC\_CLK.

#### 6.9.6.6 MSC Reset

VPAC\_MSC has one synchronous active low reset input. The entire module is reset by this reset.

#### 6.9.6.7 MSC Programmer's Guide

##### 6.9.6.7.1 Programming Model

##### 6.9.6.7.1.1 MSC Programming Guidelines

MSC does not support shadow registers for its configuration registers. All changes must be done prior to the HTS.INIT request for a frame processing.

Input and output channels are individually enabled. It is expected that at least one input and output channels are enabled for each HTS thread enabled.

The MSC does not check for proper programming of all configuration parameters. It is strictly software responsibility to ensure programming of MSC (Core and LSE) registers do not cause conflict with each other.

##### 6.9.6.7.1.2 MSC\_Core Programming Details

All filters enabled for a multi-scaling thread are programmed via:

- VPAC\_MSC\_CORE\_CFG\_j[0] FILTER\_MODE; Coefficient Set Selection - VPAC\_MSC\_CORE\_CFG\_j[3-2] HS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[5-4] VS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[10-7] SP\_HS\_COEF\_SEL, VPAC\_MSC\_CORE\_CFG\_j[15-12] SP\_VS\_COEF\_SEL; and filter tap size parameters VPAC\_MSC\_CORE\_CFG\_j[11] SP\_VS\_COEF\_SRC and VPAC\_MSC\_CORE\_CFG\_j[6] SP\_HS\_COEF\_SRC.
- Coefficients set in VPAC\_MSC\_CORE\_C210\_j, VPAC\_MSC\_CORE\_C43\_j, VPAC\_MSC\_CORE\_C210\_j\_k, VPAC\_MSC\_CORE\_C43\_j\_k registers.
- ROI source offset - VPAC\_MSC\_CORE\_SRC\_ROI\_j[28-16] Y\_OFFSET and VPAC\_MSC\_CORE\_SRC\_ROI\_j[12-0] X\_OFFSET, and size. The size of ROI depends on the X and Y

offsets. For full-size set the offsets to 0. Note that the ROI\_SIZE may or may not be same as the MSC frame size (set in MSC\_FRAME\_SIZE\_j[28-16] HEIGHT and MSC\_FRAME\_SIZE\_j[12-0] WIDTH) - depending on whether ROI is full or sub-frame sized.

- Output size - VPAC\_MSC\_CORE\_OUT\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_CORE\_OUT\_SIZE\_j[12-0] WIDTH.
- Filter parameters - VPAC\_MSC\_CORE\_FIRINC\_j[14-0] HS, VPAC\_MSC\_CORE\_FIRINC\_j[30-16] VS, VPAC\_MSC\_CORE\_ACC\_INIT\_j[27-16] VS, and VPAC\_MSC\_CORE\_ACC\_INIT\_j[11-0] HS.

Filter thread mapping is done with output channel configuration parameters (MSC\_BUF\_CFG\_j[7] THREAD\_MAP). Specifying the mapping in one register for each channel prevents any resource conflict.

#### 6.9.6.7.1.3 MSC\_LSE Programming Details

Two processing threads can be activated independently.

##### 6.9.6.7.1.3.1 Input Thread Configuration:

1. Pixel Data Format
  - a. VPAC\_MSC\_LSE\_SRC\_CFG\_j[1-0] PIX\_FMT\_PW, VPAC\_MSC\_LSE\_SRC\_CFG\_j[3-2] PIX\_FMT\_CNTRSZ, and VPAC\_MSC\_LSE\_SRC\_CFG\_j[4] PIX\_FMT\_ALIGN parameters define the pixel input data format for all input channels of the thread.
  - b. Common data formats:
    - i. Fully packed 12-bit: PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ = 1, PIX\_FMT\_ALIGN = 0
    - ii. Fully packed 8-bit: PIX\_FMT\_PW = 0, PIX\_FMT\_CNTRSZ = 0, PIX\_FMT\_ALIGN = 0
2. Pixel Input Matrix Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_CFG\_j[15-12] KERN\_LN\_OFFSET defines the starting line offset number of the input pixel matrix (for 5-tap filter configuration, offset = 0, for 4-tap configuration, offset = 1)
  - b. VPAC\_MSC\_LSE\_SRC\_CFG\_j[11-8] KERN\_SZ\_HEIGHT defines the height of the input pixel matrix (for example, MSC = 5, VISS = 1, NF = 5)
  - c. VPAC\_MSC\_LSE\_SRC\_CFG\_j[21-19] KERN\_TPAD\_SZ, and VPAC\_MSC\_LSE\_SRC\_CFG\_j[18-16] KERN\_BPAD\_SZ defines the number of padding lines required at top and bottom of the frame (for example, for 5-tap filter configuration for MSC, both of these parameters are set to 2. For 4-tap filter configuration for MSC, TPAD\_SZ = 1 while BPAD\_SZ = 2).
3. Source Frame Size
  - a. VPAC\_MSC\_LSE\_SRC\_FRAME\_SIZE\_j[28-16] HEIGHT and VPAC\_MSC\_LSE\_SRC\_FRAME\_SIZE\_j[12-0] WIDTH – define the width and height (pixels/lines) of the source video frame.
4. Source SL2 Circular Buffer Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[15-6] BUF\_STRIDE – defines the line stride size (must be 64 byte multiple)
  - b. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[24-16] CBUF\_SIZE – define the size of the circular buffer in the SL2 (number of lines)
  - c. VPAC\_MSC\_LSE\_SRC\_BUF\_ATTR\_j[31-25] START\_NIB\_OFFSET – defines the line start offset in smaller resolution (start address within the first SL2 512-bit word in 4-bit resolution).
5. Source BA and Enable Configuration
  - a. VPAC\_MSC\_LSE\_SRC\_i\_BUF\_BA\_y[23-6] ADDR – defines the SL2 base address of the Circular buffer for the input channel. VPAC\_MSC\_LSE\_SRC\_i\_BUF\_BA\_y[31] ENABLE – enables the input channel.

##### 6.9.6.7.1.3.2 Output Channel Configuration

1. Pixel Data Format
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[1-0] PIX\_FMT\_PW, VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[3-2] PIX\_FMT\_CNTRSZ, and VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[4] PIX\_FMT\_ALIGN parameters define the pixel output data format for this output channel.
  - b. Common data formats:
    - i. Fully packed 12-bit: PIX\_FMT\_PW = 1, PIX\_FMT\_CNTRSZ = 1, PIX\_FMT\_ALIGN = 0
    - ii. Fully packed 8-bit: PIX\_FMT\_PW = 0, PIX\_FMT\_CNTRSZ = 0, PIX\_FMT\_ALIGN = 0

2. Output Thread Map
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_CFG\_j[7] THREAD\_MAP defines the output channel thread mapping.
3. Output SL2 Circular Buffer Configuration
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_ATTR0\_j[15-6] BUF\_STRIDE – define the line stride size (must be 64 byte multiple)
  - b. VPAC\_MSC\_LSE\_DST\_BUF\_ATTR0\_j[24-16] CBUF\_SIZE – define the size of the circular buffer in the SL2 (number of lines)
4. Base Address and Channel Enable:
  - a. VPAC\_MSC\_LSE\_DST\_BUF\_BA\_j[23-6] ADDR – defines the SL2 base address of the Circular buffer for this output channel.
  - b. VPAC\_MSC\_LSE\_DST\_BUF\_BA\_j[31] ENABLE – enables this output channel.

#### 6.9.6.7.1.4 MSC HTS Programming Details

There is no configuration required for HTS interface in the MSC\_HWA. All programming is done in the separate HTS module. It is expected that at least one input and output channel is enabled for each HTS thread. For more details on programming HTS, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

#### 6.9.6.7.1.5 MSC Data Transfer Programming Details

Refer to *VPAC Subsystem Programmer's Guide*.

#### 6.9.6.7.1.6 LSE Interrupt Programming

MSC does not have any interrupt MASK/SET/CLEAR registers. Interrupts are pulse output events that go to the VPAC top level interrupt aggregation logic. For more information about the aggregation logic, see [Section 6.9.3](#), *VPAC Subsystem*.

MSC does, however, provide a set of statuses for VBUSM interface errors. These status are mapped to VPAC\_MSC\_STATUS\_ERROR and they are cleared by writing all 1's to the status bit field.

#### 6.9.6.7.2 Initialization Sequence

For details, see [Section 6.9.3](#), *VPAC Subsystem Level*.

#### 6.9.6.7.3 Real-Time Operating Requirements

For details, see [Section 6.9.3](#), *VPAC Subsystem Level*.

#### 6.9.6.7.4 Power Up/Down Sequence

For details, see [Section 6.9.3](#), *VPAC Subsystem Level*.

### 6.9.7 VPAC Noise Filter (NF)

#### 6.9.7.1 NF Overview

The noise filter in VPAC is used for filtering out spatial noise without impacting edges in image.

##### 6.9.7.1.1 NF Supported Features

- Bilateral filtering:
  - Supports filter size up to 5×5
  - Supports true 2D Bilateral filtering
- Generic filtering:
  - Supports filter size up to 5×5 of programmable static weights
- LUT based Bilateral weights generation:
  - 8-bit for weight
- Supported formats:
  - YUV420, 12-bit
  - One plan (interleaved plane and non-interleaved)
- Performance: 1 cycle/pixel
- Line based Input and Output
- Memory-to-memory operation
- Support for ROI:
  - Both Input and Output can be handled via DMA

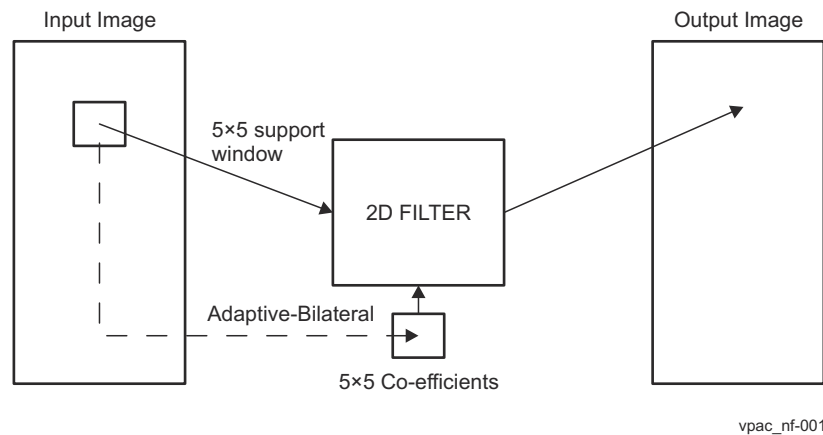

#### 6.9.7.2 NF Functional Description

##### 6.9.7.2.1 Functional Operation

The noise filter hardware (NF HW) block reads data from memory (DDR or on-chip) to shared memory (SL2 with the help of DMA) and does Bilateral filtering to remove noise. The output of NF HW block can be sent to external memory (DDR) from shared memory (SL2) or can be further re-sized using Scalar hardware.

##### 6.9.7.2.1.1 Overview

Figure 6-136 shows a block diagram of Bilateral noise filter with support for filtering size up to 5×5.

**Figure 6-136. Bilateral Noise Filter Block Diagram**

##### 6.9.7.2.1.2 Algorithm Details

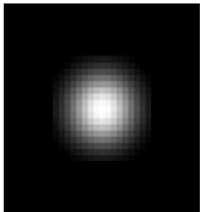

The basic equation for Bilateral filtering is shown in Figure 6-137.

$$BF[I]_p = \frac{1}{W_p} \sum_{q \in S} G_{\sigma_s}(\|p - q\|) G_{\sigma_r}(\|I_p - I_q\|) I_q$$

vpac\_nf-003

**Figure 6-137. Bilateral Filtering Equation**

The range and space parameters are shown in [Figure 6-138](#).

$$BF[I]_p = \frac{1}{W_p} \sum_{q \in S} G_{\sigma_s}(\|p - q\|) G_{\sigma_r}(\|I_p - I_q\|) I_q$$

vpac\_nf-004

**Figure 6-138. Range and Space Parameters**

Range and space parameters:

- space ss: spatial extent of the kernel, size of the considered neighborhood.
- range sr: "minimum" amplitude of an edge.

### 6.9.7.3 NF Interrupts

#### 6.9.7.3.1 CPU Interrupts

The following interrupts are generated by the NF module (see [Table 6-153](#)):

**Table 6-153. Interrupts**

Interrupt	Description
NF_FRAME_DONE	Frame processing complete.
NF_SL2_READ_ERROR	Set whenever there is an error response on VBUSM read command request for any input channel.
NF_SL2_WRITE_ERROR	Set whenever there is an error response on VBUSM write command request for any output channel.

All interrupts are single pulse event signals that are mapped to the VPAC level interrupt aggregation logic.

### 6.9.7.3.2 Interrupt Event Description

#### 6.9.7.3.2.1 NF\_FRAME\_DONE Event

These events are generated when noise filtering is complete for entire frame. This is set when input end of frame (EOF) event and output EOF events are detected.

#### 6.9.7.3.2.2 NF\_SL2\_READ\_ERROR Event

This event is generated whenever the VBUSM read status is something other than '0' (success).

The VPAC status register (VPAC\_NF\_LSE\_STATUS\_ERROR) stores the last non-zero rstatus value for user to see which type of error has occurred.

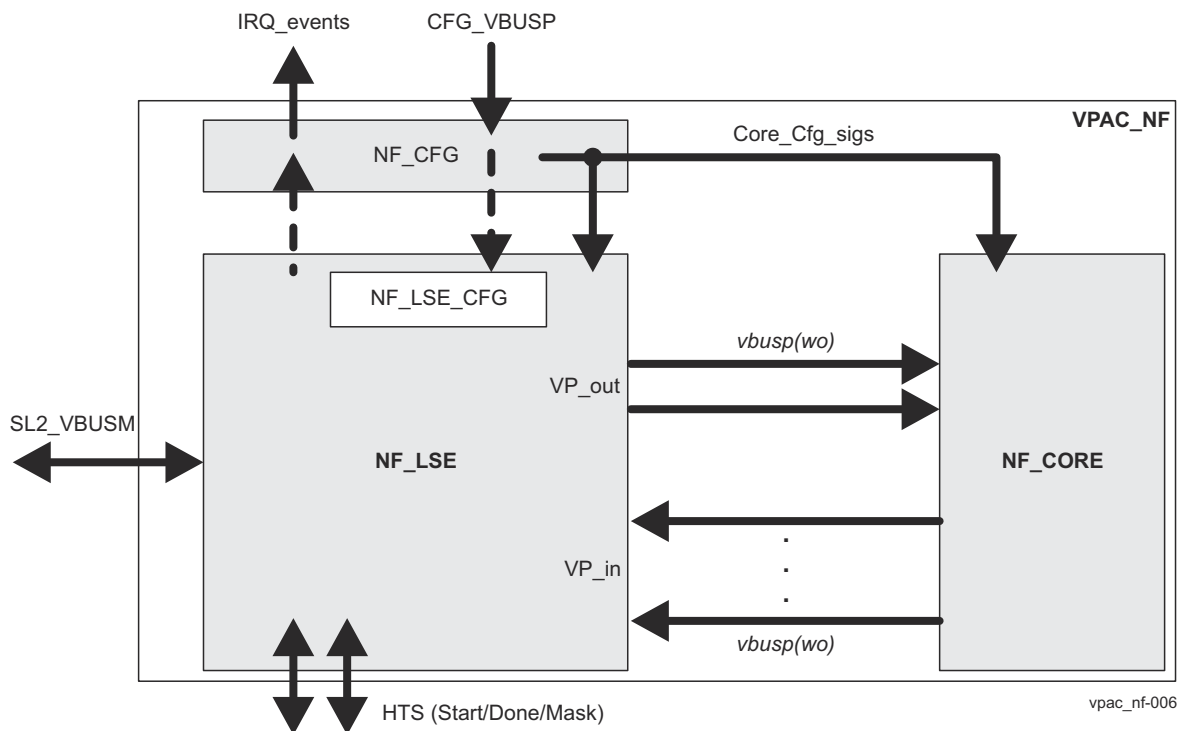

#### 6.9.7.3.2.3 NF\_SL2\_WRITE\_ERROR Event

This event is generated whenever the VBUSM write status is something other than '0' (success).

The VPAC status register (VPAC\_NF\_LSE\_STATUS\_ERROR) stores the last non-zero sstatus value for user to see which type of error has occurred.

### 6.9.7.4 NF Submodule Details

Following the common hardware partition strategy of VPAC HWA, the Noise Filter is partitioned as shown in Figure 6-139.

**Figure 6-139. NF Hardware Partition**

The NF\_CFG manages all configuration registers for the NF (top and core) via a common VBUSB slave interface.

The NF\_LSE (Load Store Engine) handles all interfacing to the SL2 memory space and performs the following functions:

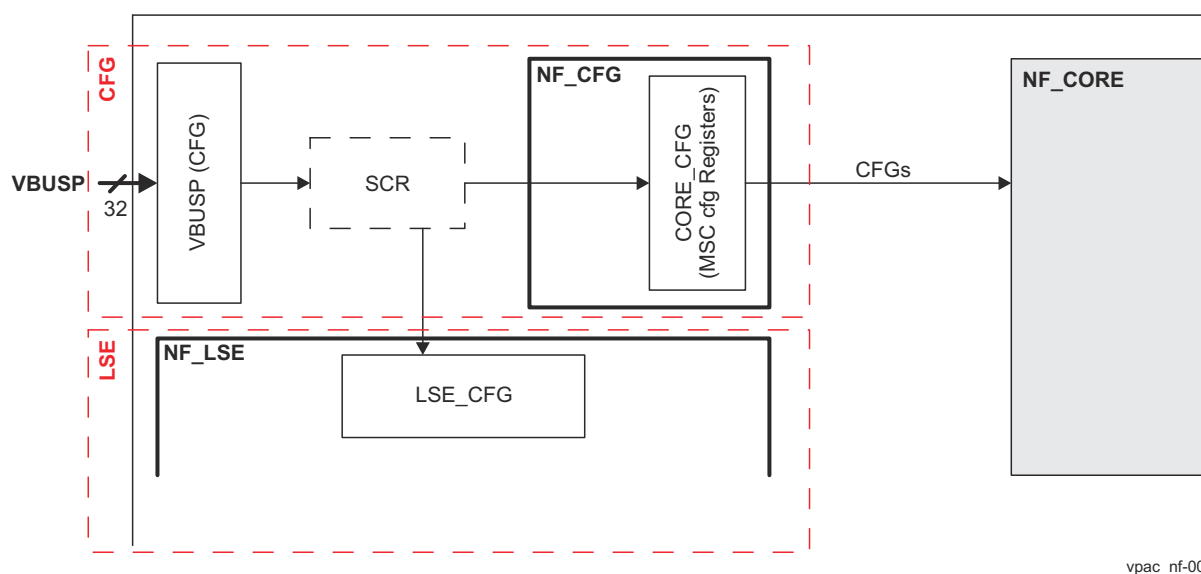

- Provides interface to SL2 circular buffers via a common VBUSM master interface.
- Manages input and output channel updates in sync with Hardware Thread Scheduler (HTS).
- Provides data unpacking for core and packing for SL2 interface.
- Manages LSE specific configuration registers.

The NF\_CORE performs noise filtering operations on given input and produces output. It has no direct connection to external interface and it works on a frame data coming in and out in raster scan order.

#### 6.9.7.4.1 NF\_CFG

The NF configuration registers consist of LSE configuration registers (see *VPAC\_NF\_LSE Registers*) and CORE configuration registers (see *VPAC\_NF\_CORE Registers*).

Figure 6-140 shows NF\_CFG block diagram.

**Figure 6-140. NF\_CFG Block Diagram**

#### 6.9.7.4.2 NF\_LSE

The NF integrates a VPAC\_LSE (Load Store Engine) .

##### 6.9.7.4.2.1 NF\_LSE Overview

The NF\_LSE supports the following VPAC\_LSE features:

- Input channel features:
  - One SL2 input channel with following features for the input channel:
    - Up to 5 lines - input kernel height support
    - Any source pixel start position support with Line Start Offset (in nibble-address resolution)
    - Input Line Skip support
    - Vertical boundary Edge Padding (Replication only) support
- Output Channel Features:
  - Only one SL2 output channels (pixel data output only)
  - Single data plane support for each output channel with no special chroma data interleaving support on the output
- Hardware Thread Scheduler (HTS) synchronization support
  - Start/Done task synchronization signal handling
  - Programmable Done-mask generation schemes
  - End of processing (EOP) generation

##### 6.9.7.4.2.2 NF\_LSE Feature Detailed Description

For detailed LSE feature description, refer to *Load Store Engine (LSE) Overview*.

#### 6.9.7.4.3 Synchronization With HTS

Scheduling of data transfer in the SL2 interface is controlled by the HTS controller integrated at the VPAC top level. A dedicated HTS is integrated per processing thread to manage start and done flow control signals and to issue DMA service events to trigger DDR from/to SL2 transfers and SL2 from/to HWA.

The following flow control scheme is used:

/\* initialization \*/

1. @ Frame Start up: (HTS) INIT → Frame Initialization

/\* First two line processing \*/

---

#### Note

'N' is input kernel height.

---

1. @ N-2 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and all output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
4. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task

/\* Middle Lines processing \*/

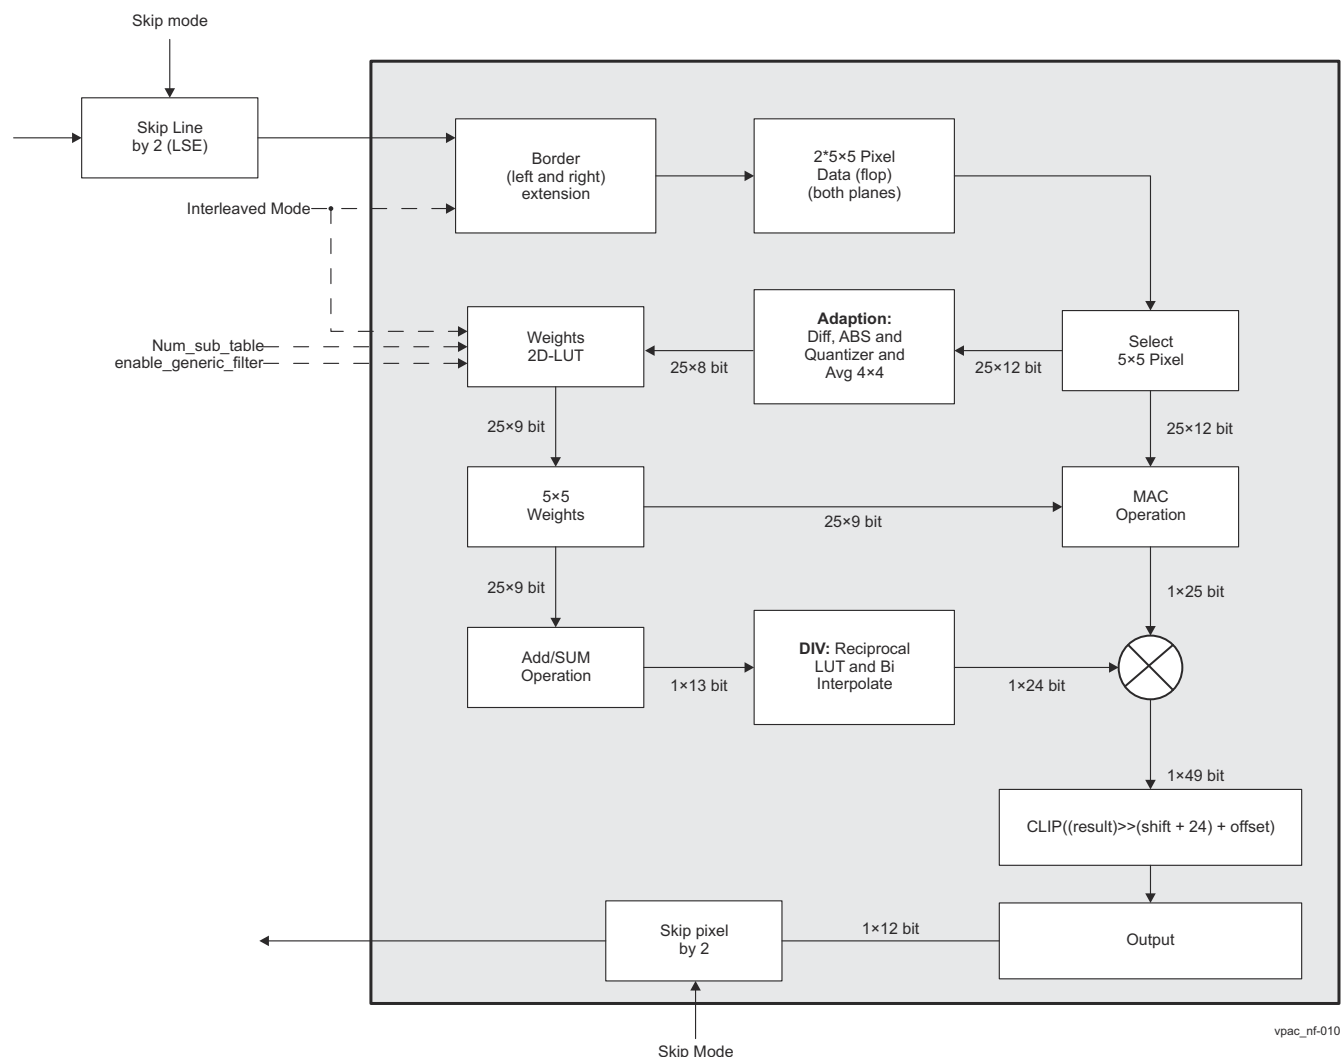

1. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. Repeat (6) and (7) until Frame\_H-3 lines

/\* Last two line processing \*/

1. @ N-1 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
2. @ Input Line Consumed and output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
3. @ N-2 input lines available and output buffer line available: (HTS) START → Starts filter Line processing (initial line) tasks
4. @ Input Line Consumed and all output Done: (PixCntlFSM) DONE → Indicates completion of the line processing task
5. @EOP: (PixCntlFSM) EOP

#### 6.9.7.4.4 Noise Filter Core Block Diagram

Figure 6-141 shows the core of the Noise filter. The line buffers are stored in SL2.

**Figure 6-141. NF-CORE Block Diagram**

There are two modes of filtering:

1. Bilateral filtering mode: The overall weights are computed based on center pixels. These are 8-bit unsigned weights. The center weight is read from MMR as 8-bit unsigned. The 9th bit for all weight is hardwired to '0'. The MAC operation is signed multiply with addition. As MSB for weight is set '0', it will be act as unsigned multiplier of 12-bit pixel to 8-bit unsigned weight.
2. Generic filtering mode: In this mode, all weights are 9-bit signed value read LUT from initial 24 values read as 9-bit signed value from every 2 bytes (16 bits) locations.

#### 6.9.7.4.4.1 Space Weight Details

Figure 6-142 shows spatial distance from central pixel to decide spatial weight.

4	3	2	3	4
3	1	0	1	3
2	0		0	2
3	1	0	1	3
4	3	2	3	4

vpac\_nf-011

**Figure 6-142. Space Distance For 5×5 Pixels**

- Total number pixels = 25
  1. Number of pixel at distance 0 = 4
  2. Number of pixel at distance 1 = 4
  3. Number of pixel at distance 2 = 4
  4. Number of pixel at distance 3 = 8
  5. Number of pixel at distance 4 = 4
- Space range (five, 0-4)
- Please note that Center pixel has 9-bit programmable MMR register for fixed weight

#### 6.9.7.4.4.2 Weight Calculation Logic

##### 6.9.7.4.4.2.1 Combined LUT For Space And Range Weights

In this approach, Bilateral weight is computed for each center pixel based on the input (guide) image:

- $i$ : center pixel index,  $j$ : neighbor pixel index
- $I_i$ : center pixel input image intensity,  $I_j$ : neighbor pixel input image intensity

$$W_{i,j}^{bf} = \frac{1}{K_i} \exp\left(-\frac{|i-j|^2}{\sigma_s^2}\right) \exp\left(-\frac{|I_i - I_j|^2}{\sigma_c^2}\right),$$

**Division LUT**

**Combined LUT**

vpac\_nf-012

**Figure 6-143. LUT For Combined Weight For Space And Range**

The following are details of this approach:

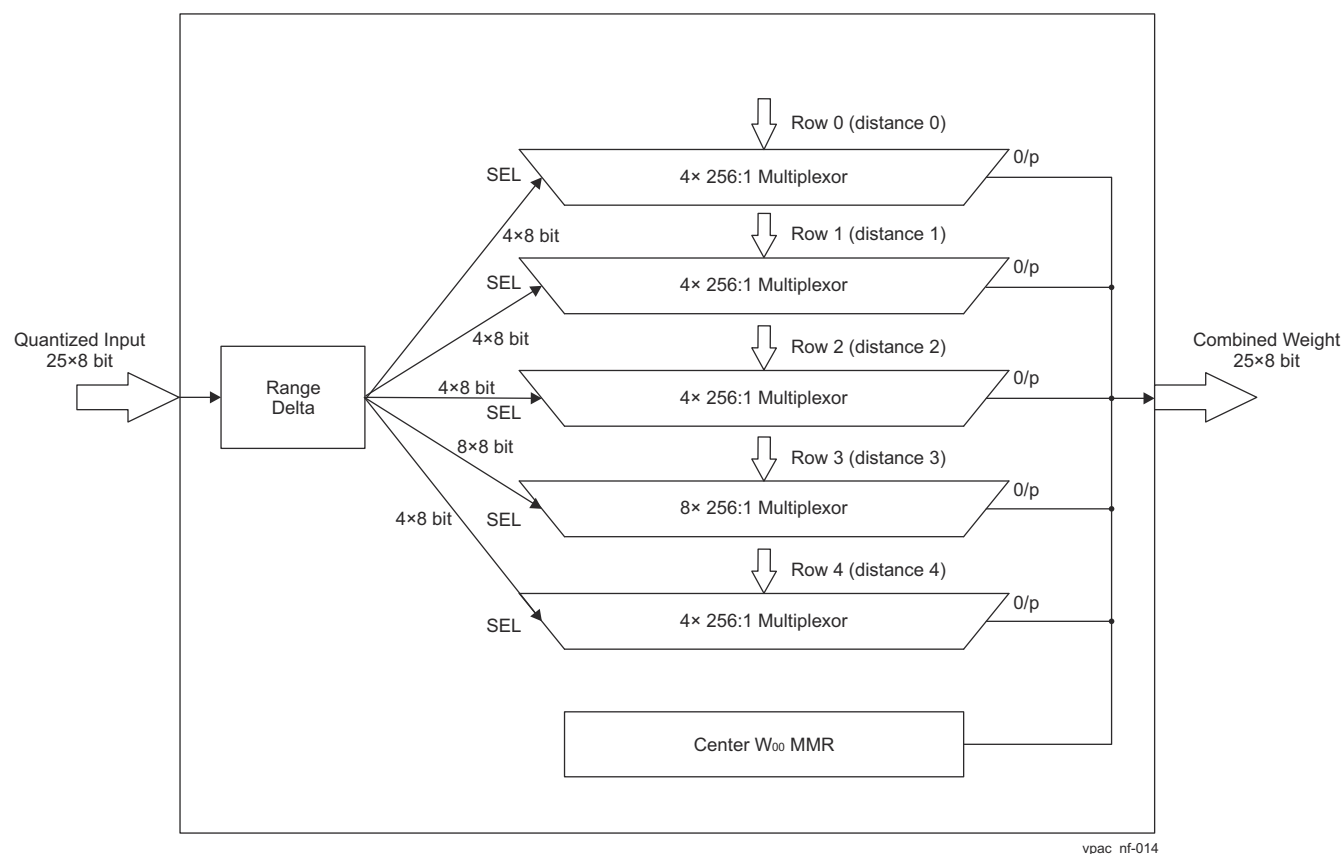

- $(i-j)$  is 3-bit for 5×5: use 3 bits
- $(I_i - I_j)$  is 13-bits: quantize to 8 bits
- Pre-compute  $W_{i,j}$  as 8-bit values including normalization and put in a 2D lookup table
- $LUT[i][j]$ :  $i$  is 3-bit pix index,  $j$  is 8-bit image intensity diff
- Lookup value is 8-bit
- Total storage:  $5 \times 256 \times 8b = 1280$  Bytes
- Can be reduced further based on symmetric nature of range
- For  $1/K_i$  (refer to [Section 6.9.7.4.4.3](#))

The LUT organization is shown in [Figure 6-144](#).

**Figure 6-144. LUT Organization For Combined Weights**

Figure 6-145 shows details of weight LUT logic for this approach.

**Figure 6-145. Weight LUT Logic**

#### 6.9.7.4.4.3 Reciprocal Calculation Logic

1/Ki calculation is done using Reciprocal table.

The following are details of Reciprocal table:

- Table is located in ROM (all values are hardwired)
- 24 bits per entry
- The first 512 entries are not quantized
- The remaining entries are quantized by 16 with Bilinear interpolation during lookup two neighbouring values
- Total of 993 entries

#### 6.9.7.4.4.4 Border Handling

##### 6.9.7.4.4.4.1 Border Handling (Simple)

The noise filter will support boarder extension. It will process two pixel copy in each directions for padding. The output frame size will be equal to input frame size as shown in [Figure 6-146](#). The output there will be border pixels (two in each direction) will be unfiltered, while rest of middle frame is noise filtered. Please note that the output frame size (or resolution) will be identical to input frame (resolution).

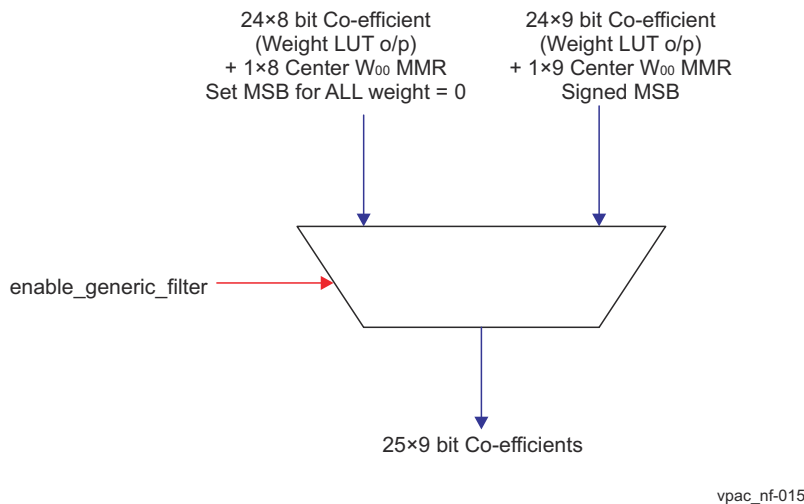

**Figure 6-146. Border Handling**

#### 6.9.7.4.5 Usage As Generic 2D Filter Engine

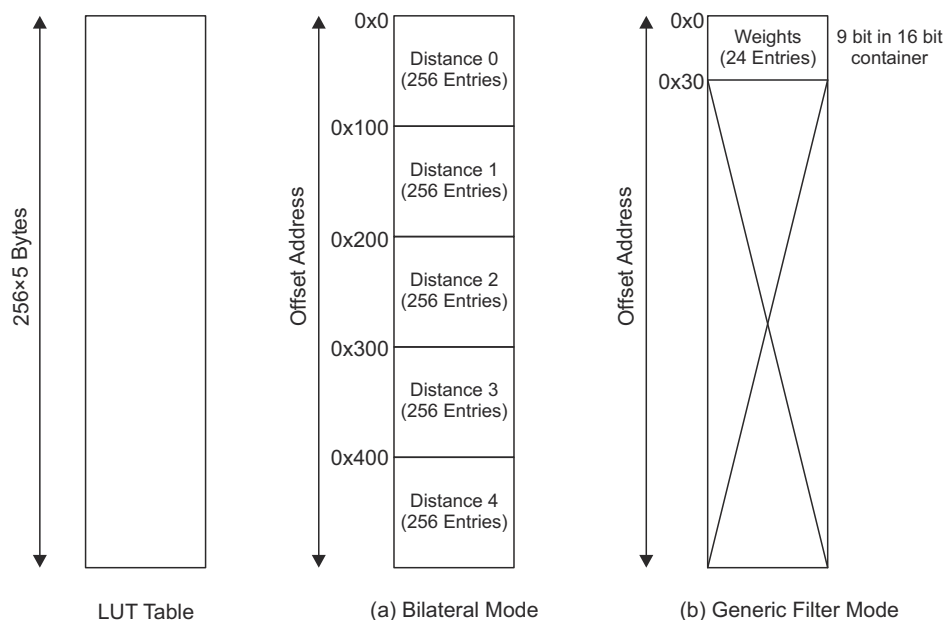

The given noise filter can be used as generic 2D 5×5 filter core. This mode is enabled by selecting `ENABLE_GENERIC_FILTER` in `CNTR` MMR. In this case, software needs to set necessary MMR to provide co-efficients for 2D convolution. The overall decision for 5×5 co-efficient is shown in [Figure 6-147](#).

Note the order of the weight is Column first then Row second `C0_R0`, `C1_R0`, ... , `C4_R5`, `C5_R5`.

**Figure 6-147. 5×5 Weight (Generic 2D Filtering)**

Figure 6-148 shows the usage of Weight or Range LUT for Generic Filtering Mode.

vpac\_nf-017

**Figure 6-148. Weight LUT Usage In Generic Mode**

#### 6.9.7.4.6 Adaptive Bilateral Weight Support

The hardware supports adaptive Bilateral filtering using `num_sub_tables > 0`. The `num_sub_table = 1` means 2 tables withing LUT per distance, `num_sub_table = 2` means 4 sub\_table within LUT per distance and `num_sub_table = 3` means 8 sub\_tables per distance. The tables are stored as interlaved within each distance. For example in case `num_sub_table = 1`, there are two LUT within each distance with even entries coming from LUT1 and odd entries coming from table 2 as shown in Figure 6-149.

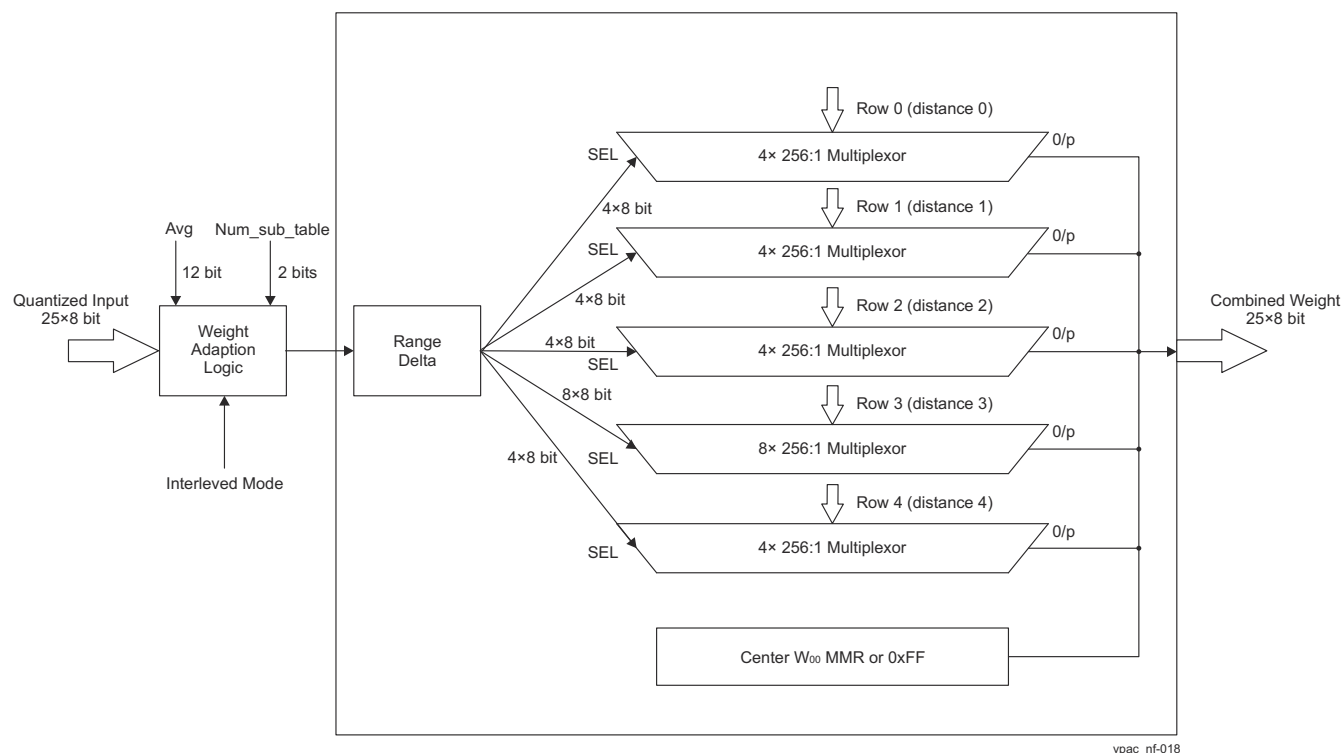

vpac\_nf-018

**Figure 6-149. Interleaved Entries In Table**

The adaptation logic consist using 4×4 average of 5×5 window (top left corner) and `num_sub_tables` from MMR as shown below using combo logic below:

- Mask "`num_sub_tables`" LSB bits out of 8 bits.
- $\text{LSB Bits} = \text{Average\_4x4} \gg (12 - \text{num\_sub\_tables})$
- 8 bits for LUT look up =  $(8 - \text{num\_sub\_table}) \ll \text{num\_sub\_table} + \text{LSB Bits}$
- Please note that this is constant LSB bits for all 25 pixels that will be replaced for all 25×8 pixels.

**Figure 6-150. Adaptive Bilateral Filtering**

#### 6.9.7.4.7 Chroma Handling (Interleaved Mode)

Please note that the given hardware module can support either Luma (Non-Interleaved mode) OR Chroma mode (Interleaved mode) at a time. It can't support two data plane (Luma + Chroma) simultaneously.

When the input is in the interleaved data format (for example: YUV420 Chroma data), the filter core keeps two sets of 5-input samples (Cb and Cr buffers) and alternates filtering operation between two. In this case, core does deinterleaving and maintains two set of data of 6x5 for both planes as shown in block diagram of core. The parameters for Chroma needs to be programmed at every frame differently compared to Luma.

Note software can always do a "force" select which sub table to use by clearing `adaptive_mode` then `sub_table_select` defines which table to use, otherwise below defines which sub table is selected.

- Mask "num\_sub\_tables" LSB bits out of 8 bits.
- $\text{LSB Bits} = \text{Average\_4x4} \gg (12 - \text{num\_sub\_tables})$
- If (`num_sub_tables != 1`):
  - 8 bits for LUT look up =  $(8 - \text{num\_sub\_table}) \ll \text{num\_sub\_table} + \text{LSB Bits}$

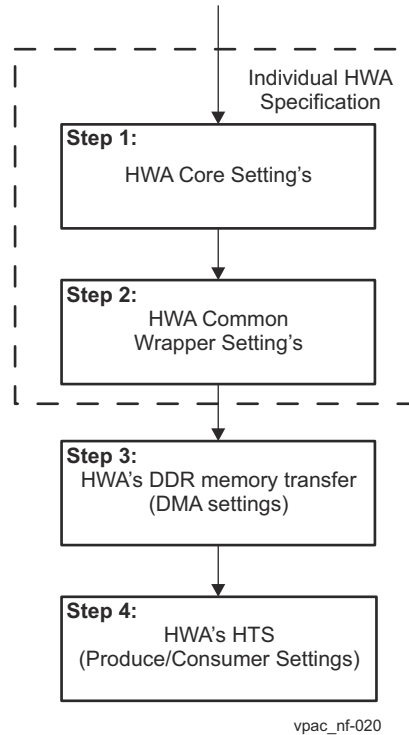

Else:

- 8 bits for LUT look up =  $(8 - \text{inputPlaneInterleaving}) \ll \text{inputPlaneInterleaving} + \text{LSB Bits}$
- Please note that this is constant LSB bits for all 25 pixels that will be replaced for all 25x8 pixels.

#### 6.9.7.5 NF Programmer's Guide

##### 6.9.7.5.1 Programming Model

The full programming of the module, consist of the following four steps (see [Figure 6-151](#)):

**Figure 6-151. Programming Steps**

#### 6.9.7.5.1.1 HWA Core Programming Details

There are two use-cases:

- Bilateral Noise Filter Mode: The following core MMR needs to be programmed to enable Bilateral noise filter mode:
  - Set Weight LUT (8-bit unsigned) tables (5×256 values corresponding to various distance from distance in MMR (0x100 onwards))
  - Set Control register fields (Center weight to maximum - 0×255, offset, shift, ...)
  - Set generic\_filter\_mode to '0'
- Generic 2D Convolution (filtering) Mode: The following core MMR needs to be programmed to enable Bilateral noise filter mode:
  - Set Weight LUT (9 bit unsigned) tables (24 values (each 9-bit signed) in 16 bit container from start of LUT
  - Set Control register fields (Center weight, offset, shift, ...)
  - Set generic\_filter\_mode to '1'

#### 6.9.7.5.1.2 NF SL2 Wrapper Interface Programming Details

The following MMR needs to be programmed as per overall Data flow as well as algorithm needs:

- Set Input (SRC) side SL2 configuration, buffer base address, attributes and sizes
- Set Output (DST) side SL2 configuration, buffer base address, attributes and sizes

#### 6.9.7.5.1.3 HWA HTS Programming Details

For more details of programming, refer to HTS and Section VPAC Subsystem.

Although following are Hardcoded configuration for given HWA (Noise filter (NF)) for HTS:

- Consumer score board: Transaction aggregation
- Number of lines of delay = 5
- ...

**6.9.7.5.1.4 HWA Data Transfer Programming Details**

For more details, refer to the VPAC Top/UTC specification.

## 6.10 Depth and Motion Perception Accelerator (DMPAC)

This chapter describes the Depth and Motion Perception Accelerator (DMPAC) in the device.

### 6.10.1 DMPAC Overview

The Depth and Motion Perception Accelerator (DMPAC) is a power efficient hardware accelerator that computes dense stereo depth maps (*depth*) and dense optical flow vectors (*motion*) from camera inputs.

The image/video sensor-based environmental perception (also known as scene understanding) is at the core of many emerging applications in automotive, industrial and consumer electronics. Typically, this involves detection of all objects in the scene along with their 3D position and motion with regards to the observer or the car by analyzing one or many related input video streams. Various computer vision algorithms are used to achieve these tasks.

A very robust method of obtaining the 3D depth from images is to use two cameras in a stereo setup - two cameras with known relative positions and camera parameters. The two images of the same scene, captured from two different camera poses/perspectives, are analyzed to find disparities among every pixel positions in the images. This is known as the Stereo Disparity map. The disparity values of every pixel can be used to obtain the 3D positions of the object/space they belong to via triangulation.

On the other hand, by analyzing two images from a single camera, captured at two different time instances (that is, two temporal frames in a video), one can determine where each pixel in a past frame moved to in the future frame. This is known as the Optical Flow vector. The flow vectors for each pixel position can be used to obtain 3D structure of the scene, identify moving objects and determine their relative speed and direction of motion.

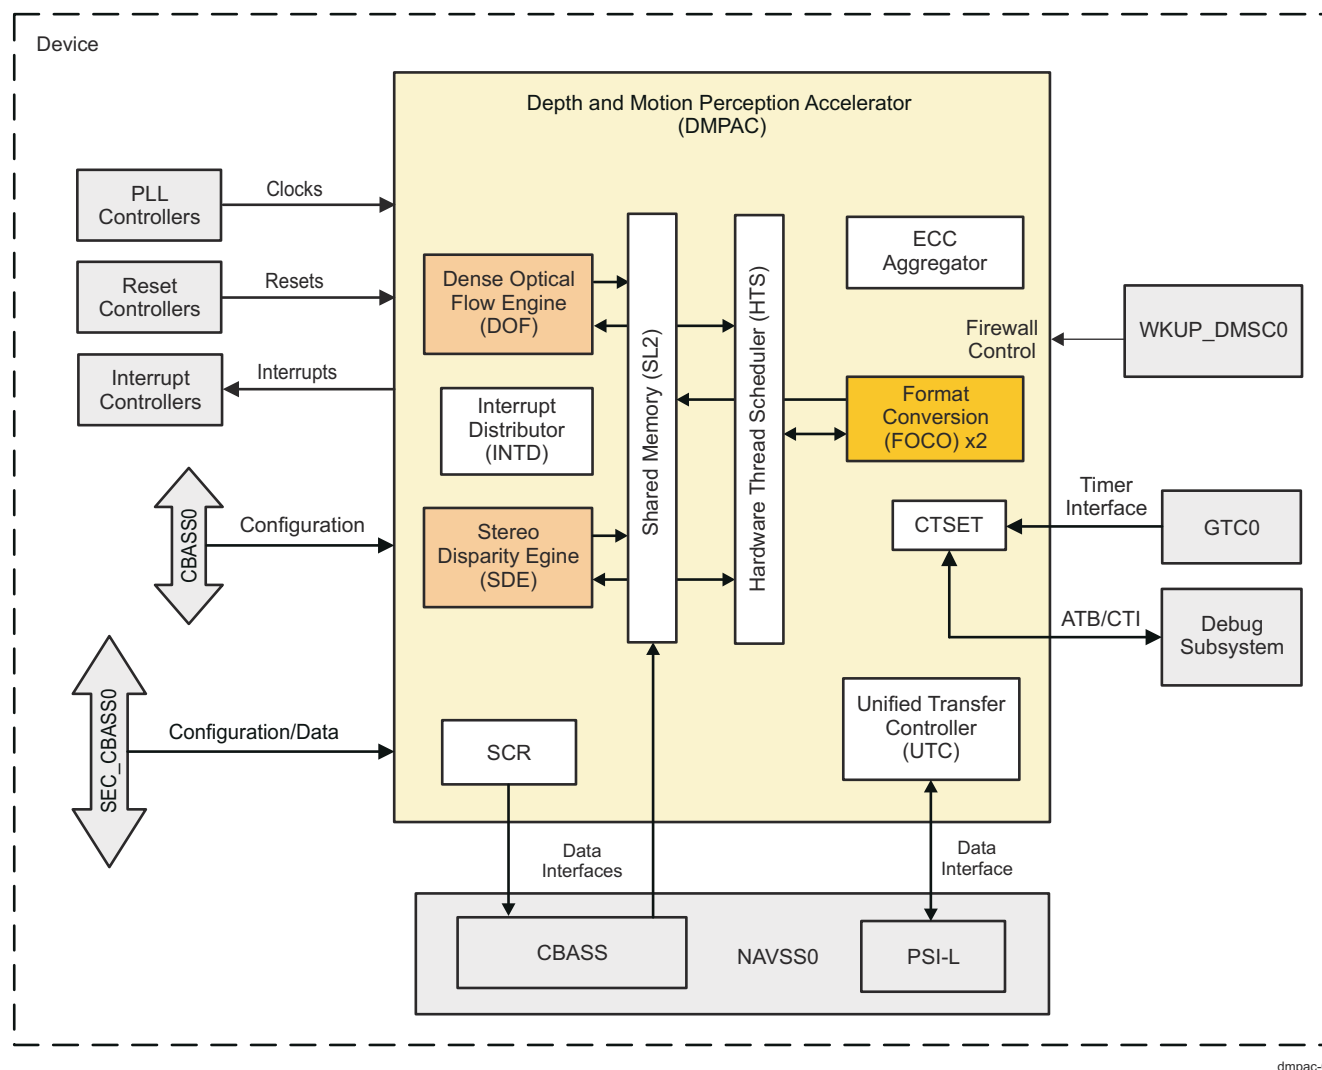

The DMPAC is dedicated to the aforesaid image processing tasks. The stereo and optical flow processing is partitioned into two top level sub-blocks: the Dense Optical Flow (DOF) engine and the Stereo Disparity Engine (SDE). The DOF and SDE blocks share a common shared local memory, DMA, external messaging and control infrastructure.

The device includes a single instantiations of the DMPAC. [Table 6-154](#) shows the DMPAC allocation across device domains.

**Table 6-154. DMPAC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
DMPAC0	-	-	✓

[Figure 6-152](#) provides an overview of the DMPAC.

dmpac-001

**Figure 6-152. DMPAC Overview**

### 6.10.1.1 DMPAC Features

The DMPAC supports the following main features:

- Input image resolution up to 2 MPix with maximum horizontal resolution of up to 2048 pixels and maximum vertical resolution of up to 1024 pixels
- Input pixel format of 12-bit fully packed luminance data, and other formats using the integrated Format Conversion (FOCO) module
- Pixel level output packed in 16bpp and 32bpp formats for stereo disparity estimates and optical flow estimates, respectively
- Simultaneous operation of SDE and DOF, each processing inputs of up to 1 MPix image resolution (1 MPix = 1280 × 720 pixels)
- Resolution vs. frame rate scalability (higher frame rate at lower resolution)
- A Dense Optical Flow (DOF) engine: The DOF engine implements Texas Instruments' proprietary algorithm for estimation/calculation of the optical flow between the input image pair. The algorithm uses hierarchical coarse-to-fine block search strategy leveraging image pyramids in which proprietary binary pixel descriptors are used for pixel correspondence determination. In the scheme accuracy and smoothness of the flow map is enforced using optical flow estimates of the causal neighbors of a pixel in the given and higher (lower resolution) pyramid level (pixels are processed in raster scan order in a pyramid level to refine existing optical flow estimates). The DOF engine supports:

- Optical flow vector lengths up to +/- 191 pixels in horizontal direction and +/- 62 pixels in vertical direction for each input pixel
- Dense flow vector map for each input pixel
- Optical flow vector precision of 1/16<sup>th</sup> of inter pixel distance
- Post filtering of the optical flow estimates using 2D median filtering
- 16 level confidence score for every output flow vector
- A Stereo Disparity Engine (SDE): The SDE implements Texas Instruments' proprietary algorithm in order to find the disparity map between the input image pair. The SDE supports:
  - Disparity search range (SR) of 64/128/192. It can support either "0 to SR-1" or "-3 to SR-4"
  - 1/16<sup>th</sup> pixel accurate sub-pixel level disparity estimate
  - Disparity estimate post processing using 2D median filtering
  - 8 level confidence score for each disparity output
- Common top level infrastructure:
  - Shared Level 2 (SL2) memory sub-system, which serves both DOF and SDE blocks, along with the FOCO modules when required as an intermediate storage exchange data across sub-modules (FOCO to DOF/SDE) and from DDR/System Memory
  - A Unified Transfer Controller (UTC), which serves as a DMA engine
  - Messaging and control mechanism via a Hardware Thread Scheduler (HTS) block
  - A Counter, Timer and System Event Trace (CTSET) module, which provides event tracing capability for the SDE and DOF hardware threads

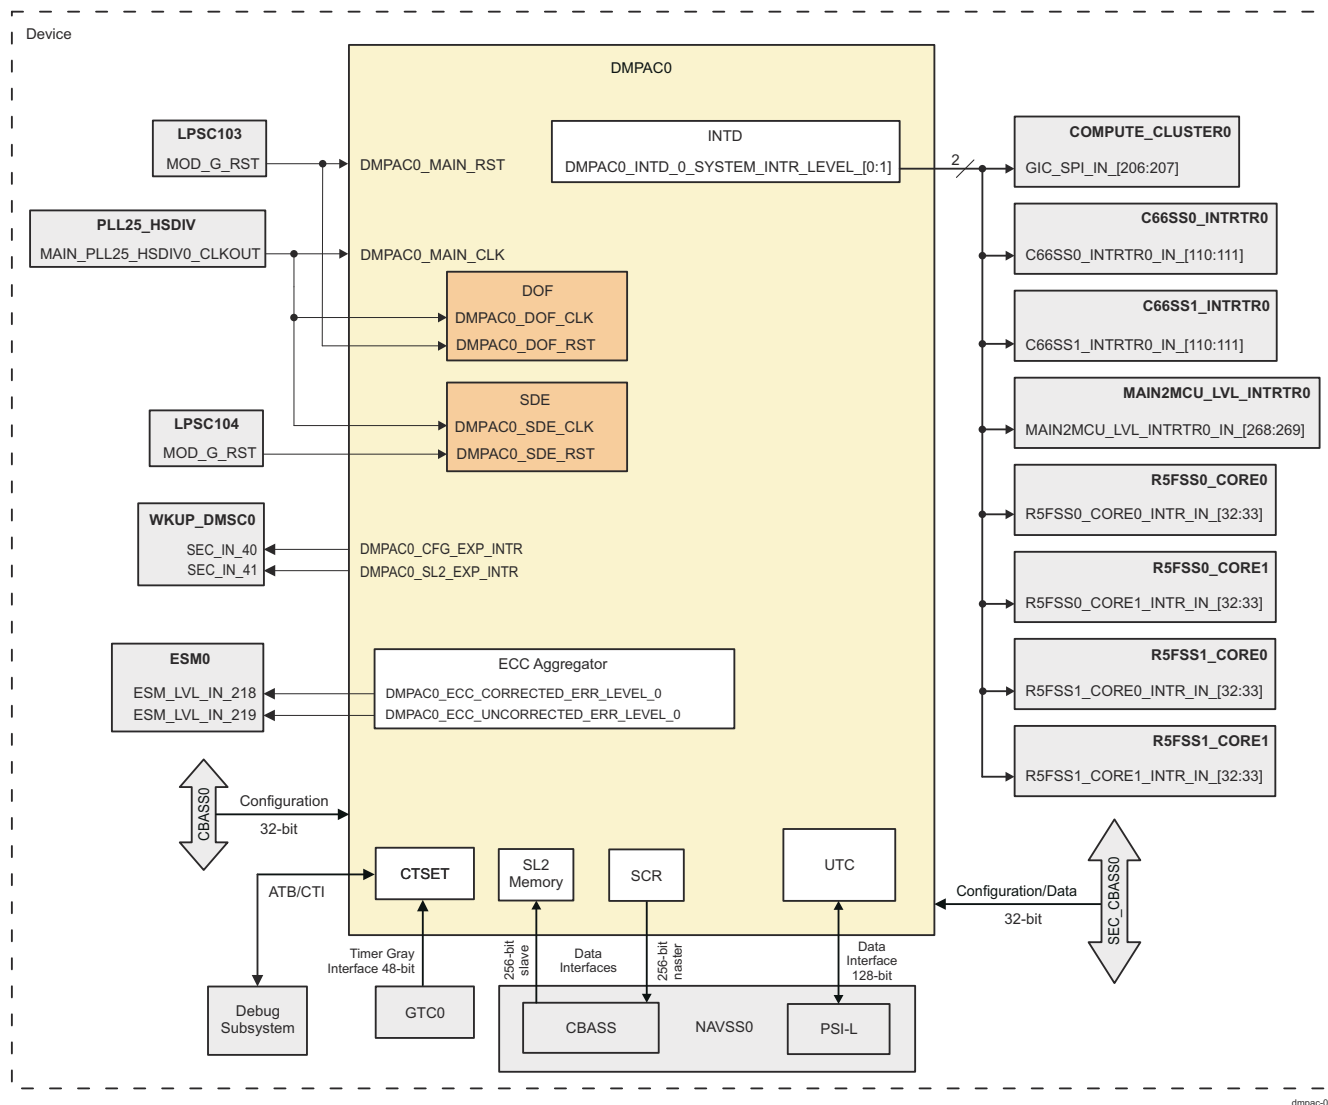

The DMPAC does not support (but relies on other HWAs/processors on the SoC to perform these tasks):

- Epipolar rectification of the stereo input images
- Image pyramid generation for the optical flow input images

### 6.10.2 DMPAC Integration

This section describes the DMPAC integration in the device MAIN domain, including information about clocks, resets, and hardware requests.

There is one DMPAC integrated in the device MAIN domain - DMPAC0. Figure 6-153 shows the integration of DMPAC0.

**Figure 6-153. DMPAC Integration**

Table 6-155 through Table 6-157 summarize the integration of DMPAC0 in the device MAIN domain.

**Table 6-155. DMPAC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DMPAC0 (TOP Level and DOF)			LPSC103	CBASS0
DMPAC0 (SDE)	PSC0	PD28	LPSC104	NAVSS0_CBASS NAVSS0_PSI_L SEC_CBASS0

**Table 6-156. DMPAC Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DMPAC0	DMPAC0_MAIN_CLK	MAIN_PLL25_HSDIV0_CLKOUT	PLL25_HSDIV	DMPAC0 main functional clock.
	DMPAC0_SDE_CLK			DMPAC0 SDE functional clock.
	DMPAC0_DOF_CLK			DMPAC0 DOF functional clock.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
DMPAC0	DMPAC0_MAIN_DOF_RST	MOD_G_RST	LPSC103	DMPAC0 main and DOF reset
	DMPAC0_SDE_RST	MOD_G_RST	LPSC104	DMPAC0 SDE reset

### Note

The DMPAC and VPAC clocks are derived from the same PLL and as a result, the following maximum clock frequency restrictions apply:

- When the VPAC is set to maximum clock frequency = 720 MHz, the DMPAC clock frequency is limited to 480 MHz.

**Table 6-157. DMPAC Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type

DMPAC0_SL2_EXP_INTR	SEC_IN_41		DMPAC0 firewall exception pending interrupt for the SL2 interconnect	N/A

### 6.10.3 DMPAC Functional Description

#### 6.10.3.1 DMPAC Block Diagram

Figure 6-154 shows a simplified block diagram of the DMPAC subsystem. The Stereo and Optical flow processing is partitioned into two top level blocks (SDE and DOF) which share a common L2 memory subsystem, DMA, external messaging and control infrastructure.

**Figure 6-154. DMPAC Block Diagram**

#### 6.10.3.2 DMPAC Data Formats and Image Resolution

##### 6.10.3.2.1 Resolution and Frame Rate

The stereo and optical flow processing in DMPAC is designed to support scalability with regards to input image resolution and achievable frame rate.

This section contains examples for 520MHz operating clock. For lower clock frequencies, the frame rate should be scaled accordingly.

The input resolution and frame rate support for stereo processing is shown in Table 6-158.

**Table 6-158. DMPAC Input Resolution and Frame Rate Support for Stereo Processing**

Imager Configuration	Resolution			Mpix	Fps	Comments
	Width	Height	Restrictions			
2MP Imager	2048	1024	See (2)	2.10	40	Baseline performance
2MP Imager with cropped ROI <sup>(1)</sup>	2048	512		1.05	80	Example of achievable scalability.
1MP Imager with cropped ROI	1024	512		0.52	160	
	1280	640		0.82	102	

(1) ROI = Region of Interest

- (2)
- Width must be  $128 + 16 \cdot n$ , where  $0 \leq n \leq 120$
  - Height must be  $64 + 16 \cdot m$ , where  $0 \leq m \leq 60$

The input resolution and frame rate support for optical flow processing is shown in [Table 6-159](#).

**Table 6-159. DMPAC Input Resolution and Frame Rate Support for Optical Flow Processing**

Imager Configuration	Resolution			Mpix	Fps	Comments
	Width	Height	Restrictions			
2MP Imager	2048	1024	Width and Height must be multiple of 32	2.10	100	Baseline performance
2MP Imager with cropped ROI	2048	512		1.05	200	Example of achievable scalability.
1MP Imager with cropped ROI	1024	512		0.52	400	
	1280	640		0.82	256	

#### 6.10.3.2.2 Input Data Formats

The DMPAC supports both 8-bit and fully packed 12-bit luma data formats. The DOF and SDE blocks only accept fully packed 12-bit luma data format. When processing of 8-bit luma data input formats is required, the format conversion (FOCO) blocks need to be enabled, as they can convert 8-bit data into 12-bit fully packed format for both stereo and optical flow processing inside DMPAC sub-system. The fully packed 12-bit data organization goes on till the end of the line. Every line always starts at a 64-byte aligned boundary in SL2 memory. In the system DDR, it is advised that every line starts at a new DDR burst (for example, 128 bytes for 64-bit LPDDR4).

**Table 6-160. DMPAC Input Pixel Data Format**

MSB																												LSB			
127																												0			
4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b	4b		
Byte 15		Byte 14		Byte 13		Byte 12		Byte 11		Byte 10		Byte 9		Byte 8		Byte 7		Byte 6		Byte 5		Byte 4		Byte 3		Byte 2		Byte 1		Byte 0	
		Pixel 9		Pixel 8		Pixel 7		Pixel 6		Pixel 5		Pixel 4		Pixel 3		Pixel 2		Pixel 1		Pixel 0											

The image luminance data can be placed anywhere in the SoC memory system that is accessible by the DMA engine attached to the DMPAC.

#### 6.10.3.3 DMPAC Top Level Data Flow

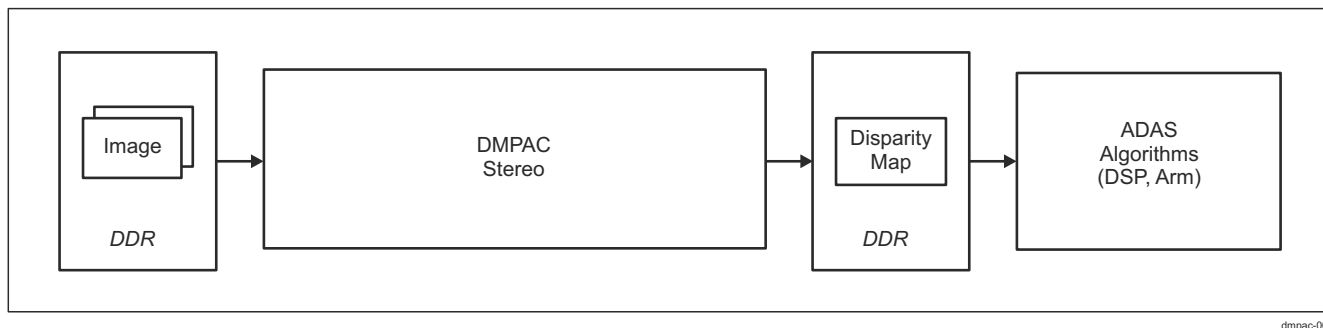

[Figure 6-155](#) through [Figure 6-158](#) illustrate an example of the SoC level dataflow for Stereo and Optical flow processing in a typical system implementation, where DMPAC has been integrated along with a Vision Imaging Sub-system (VISS) and a Vision Preprocessing Accelerator (VPAC).

The processing pipeline between these blocks can be synchronized at frame level or at a lower granularity of slice level (multiple full image rows) depending of SoC level control and data bandwidth capabilities.

**Figure 6-158. DMPAC SoC Level Dataflow for Optical Flow Processing**

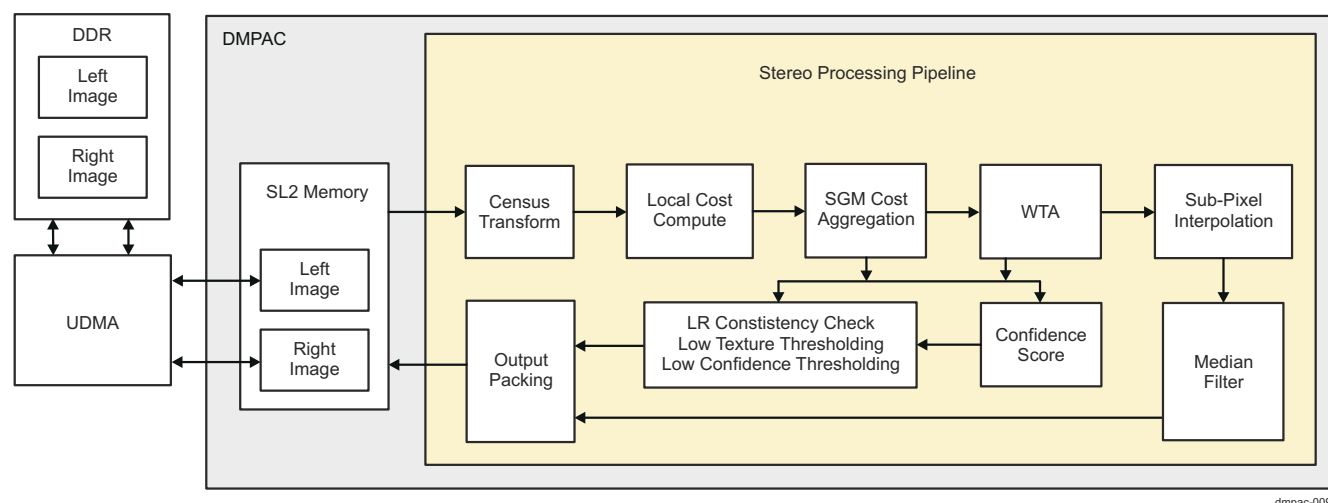

#### 6.10.3.4 DMPAC Stereo Functional Overview

The DMPAC implements Texas Instruments' proprietary algorithm in order to find the disparity map between the input image pair. The algorithm is based on Semi Global Matching method that is optimized and adapted to fit into real time, low power processing requirements without any significant loss of quality.

This section outlines the overall functionality of the Stereo Disparity Engine (SDE).

##### 6.10.3.4.1 Stereo Processing Dataflow

Figure 6-159 illustrates the functional view of dataflow for stereo processing within the DMPAC. The input image (with required image pre-processing including epipolar rectification done) is stored in external SDRAM (DDR). The DMPAC UTC fetches the input image pair luminance data in its level 2 memory sub-system and then processes through its pipeline. The final output from stereo module is written back to shared L2 memory which is transferred back to external SDRAM (DDR).

**Figure 6-159. DMPAC Functional View of Stereo Processing Dataflow**

#### 6.10.3.4.2 Disparity Range

The disparity ranges supported by the DMPAC SDE module are as follows:

- Disparity search range (SR) of 64/128/192. It can support either “0 to SR-1” or “-3 to SR-4”.
- Negative disparity -3 is supported for correcting camera calibration errors
- Disparity output is provided for each input pixels, that is, at 100% density (except for the border pixels)

#### 6.10.3.4.3 Epipolar Rectification

The DMPAC SDE does not implement support for epipolar rectification on input images. Epipolar rectification must be done in external modules (such as VPAC LDC) and the rectified input image must be fed as input to the DMPAC.

#### 6.10.3.4.4 Disparity Search Method

The following search strategy is employed by the DMPAC SDE module to establish pixel correspondence between the input image pairs:

- 1D search along the image scan line is applied, that is, the correspondence of a pixel in the right image is searched in the same image row in the left image.
- Disparity search is done for every pixel position in the right image without skipping any pixel in the search range.

#### 6.10.3.4.5 Cost Computation Method

The DMPAC SDE aggregates local cost in a custom semi global method. It follows the following steps:

- Input image intensity data is first transformed into Census domain by Census Transform . Census transformation is performed over an 9x9 pixel neighborhood window.
- The local matching cost between two image pixel positions are measured by the Hamming Distance of the corresponding census signature.
- Local costs are then aggregated using a custom semi global matching (SGM) method.
- Similar to standard SGM methods, penalty terms (P1, P2) for disparity changes in the local neighborhood is used.
- The penalty terms P1, P2 are used in a non-adaptive way, that is, they remain constant for the entire frame processing.

#### 6.10.3.4.6 Cost Plane Compression Method

In order to reduce on-chip storage of intermediate aggregated path costs, the DMPAC SDE employs a compression-decompression scheme.

#### 6.10.3.4.7 Sub-Pixel Interpolation Method

For increase precision or 'depth resolution' of the output disparity map, integer pixel disparity map from SGM processing step is further refined to a sub-pixel accurate disparity estimate.

- Sub-pixel accuracy of 1/16th pixel is implemented, encoded in 4 bits of fractional precision in the final output.

#### 6.10.3.4.8 Raw Disparity Output Cleaning Method

The raw output disparity results out of SGM contains several inconsistencies, errors and noise which is cleaned by the following post-processing steps:

- "Left-Right consistency check" is applied to find out exceptional pixel position where correspondence from Left-to-Right search does not match the correspondence from Right-to-Left search. A improvised 'fast method' or approximation is used to avoid full left to right and right to left disparity search.
- A "Low Texture Thresholding" method is applied to filter out pixels with low texture in the neighborhood.

#### Note

The above cleaning methods update the confidence values associated with the pixel positions and do not update the actual disparity values.

#### 6.10.3.4.9 Confidence Score Computation Method

All stereo algorithms, by virtue of the underlying assumption they make, have an inherent limitation on accuracy of the determined disparity map. Confidence score is a metric indicating the inherent correctness/inaccuracy of the each disparity value in the disparity map. The DMPAC SDE generates confidence map as follows:

- Confidence score value shall be 3 bits, 8 levels.

#### 6.10.3.4.10 Disparity Map Post Filtering Method

In order to remove impulsive estimation noise, the DMPAC SDE implements a final filter to remove noise from the generated disparity map:

- 2D 5x5 Median Filter (non-weighted) is used as post-processing filter.
- All samples within the filter kernel shall be considered for median filtering.

#### Note

The raw disparity map from the output of the SGM process is filtered, while the Confidence map is not filtered.

#### 6.10.3.4.11 Disparity Output Data Packing Format

The final disparity value and corresponding confidence score is packed as follows, before being sent out of DMPAC:

- Disparity output is 16-bit packed format.
- Disparity output format is: (MSB)[IntegerBits.FractionalBits.ConfidenceBits](LSB), where:
  - IntegerBits is 9 (support disparity range -3 to +255)
  - FractionalBits is 4 (support 1/16th pixel precision)
  - ConfidenceBits is 3 (8 levels of confidence value)

**Table 6-161. DMPAC Stereo Output Data Format**

Table 1. New Delta-16 Stereo Output Data Format					
15	7	6	3	2	0
IntegerBits		FractionalBits		ConfidenceBits	
9.4b signed number 1b sign, 8b int mag, 4b fraction				3b int	

#### 6.10.3.5 DMPAC Optical Flow Functional Overview

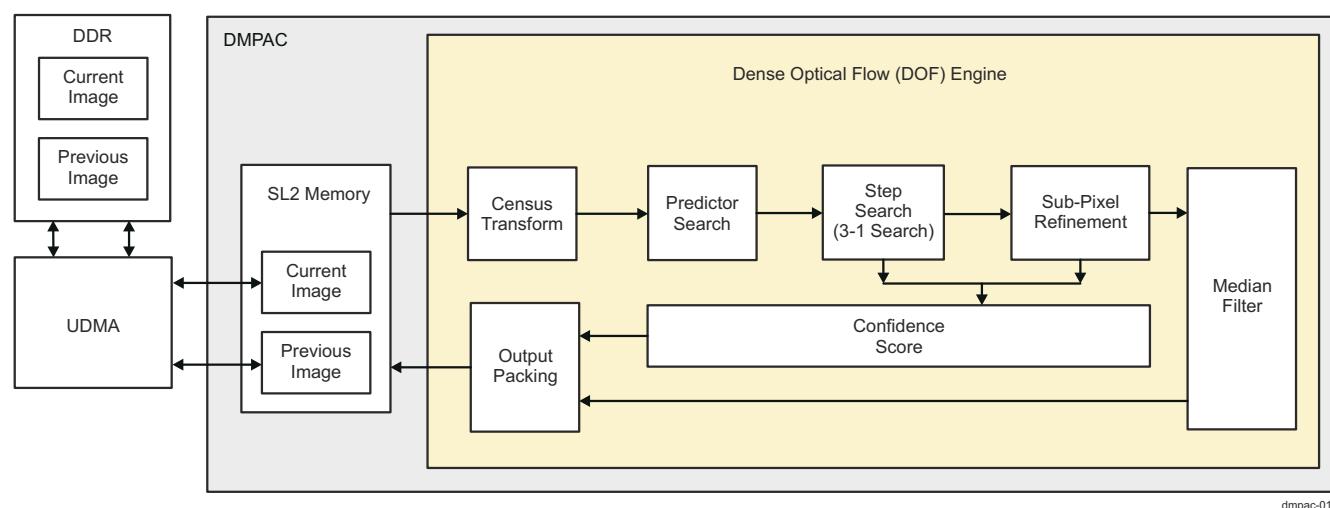

The DMPAC implements Texas Instruments' proprietary algorithm to find the optical flow vector map between the input image pair. The optical flow estimation process implemented in the DMPAC has been formulated

by combining pyramidal block matching (PBM) method with differential technique based optical flow method proposed by Lucas-Kanade(LK). In this formulation the PBM method performs optical flow estimation with integer pixel resolution and followed by an iteration of the LK method used to refine the obtained estimate and obtain optical flow estimate with fractional pixel precision. The PBM method starts the optical flow estimation at the highest pyramid level using spatial predictors and step search method to obtain accurate motion estimation. These optical flow estimates are then appropriately scaled up and refined (again using spatial predictors and step search method) at each of the lower pyramid levels sequentially. At base pyramid level the predictor configuration can be altered to include temporal predictors or auxiliary predictors, however step search remains the same. At base pyramid level, once PBM process completes, an iteration of LK step is used to refine the obtained flow estimates. During predictor evaluation and step search the PBM method uses binary census transform for pixel description and hamming distance as the optimization function. The 2D post filtering of the optical flow estimates can also be performed at output of each of the pyramid levels including base level. The algorithm has been optimized to fit into real time, low power processing requirements with highly precise and accurate estimates.

This section outlines the overall functionality of the Dense Optical Flow (DOF) core.

#### 6.10.3.5.1 Optical Flow Processing Dataflow

Figure 6-160 illustrates the functional view of dataflow for optical flow processing within the DMPAC. The input image pyramids (with required image pre-processing) are stored in external SDRAM (DDR). The DMPAC UTC/UDMA fetches the image pyramid luminance data in its shared L2 memory sub-system and then processes through its pipeline. The final output from the DOF module is written back to the shared DOF L2 memory, which is transferred back to the external SDRAM (DDR).

**Figure 6-160. DMPAC Functional View of Optical Flow Processing Dataflow**

#### 6.10.3.5.2 Flow Vector Range

The DMPAC optical flow core supports motion search region large enough for:

- Max flow vector range of -191 to +191 (horizontal) and -62 to +62 (vertical).
- Supports asymmetric vertical search range - different positive (which is downwards) than negative (which is upwards) vertical search range.
- Flow Vector output shall be of 100% density (flow vector for every pixel).

### Note

There is a further restriction on the combined maximum range for HSR and VSR. For example:

$|HSR| = 191$ , then  $|VSR| \leq 56$

$|VSR| = 62$ , then  $|HSR| \leq 170$

#### 6.10.3.5.3 Block Matching Process

The block matching process is based on motion predictors and two step coarse-to-fine refinement. Where:

- Predictor search stage evaluates configured optical flow predictors and selects the best predictor that minimizes the block matching cost.
- DMPAC defines a list 7 motion predictors that are supported and can be configured at pyramid level. These are referred to as TopLeft, Top, TopRight, Left, PyramidalLeft, PyramidalCurrent and Temporal predictors.
  - DMPAC allows use of upto 5 motion predictors for a pixel and 2 of these can be configured at each pyramid level and other three are fixed.
  - Upper pyramid levels (L5-L1) can use any 2 of Left, PyramidalLeft and PyramidalCurrent predictors.
  - Base pyramid level (L0) can use any 2 of Left, PyramidalLeft PyramidalCurrent and Temporal predictors.
- Two step coarse to fine step search method refines optical flow estimates around winner predictor. A configurable motion smoothness factor value allows the block matching process to control the smoothness of the flow field.

#### 6.10.3.5.4 Image Pyramid Generation Method

The DMPAC optical flow processing requires multi-level Gaussian Image Pyramids for implementing coarse-to-fine refinement method during pixel correspondence search. However, the DMPAC does not implement the logic required to build this image pyramid. It requires some SoC level external logic to build and store the image pyramid in external SDRAM (DDR).

The DMPAC optical flow processing requires/uses the following features for the image pyramid:

- Up to 6 levels of Pyramid (base + 5 octaves) shall be supported.
- Each higher octave is  $\frac{1}{2}$  in width and  $\frac{1}{2}$  in height with regard to its predecessor.
- Gaussian Smoothing followed by  $/2$  down sampling is required to generate next octave.

As shown in [Figure 6-157](#), *DMPAC SoC Level Dataflow for Optical Flow Pre-Processing*, the sclare module (MSC) in VPAC is responsible to generate the image pyramid.

#### 6.10.3.5.5 Cost Computation Method

The DMPAC uses the following methods to derive an effective and robust cost function for predictor search and hierarchical step search stages:

- Cost function used is 'Hamming Distance over Census Transform'.
- Motion smoothness factor (MSF) is fixed for the entire frame processing.

#### 6.10.3.5.6 Sub-Pixel Refinement Method

The DMPAC optical flow uses differential technique to refine flow vector estimates to sub-pixel precision:

- Lucas-Kanade (LK) method is used for computing sub-pixel accurate flow vectors.

#### 6.10.3.5.7 Confidence Score Computation Method

The DMPAC optical flow processing core uses sophisticated methods to compute an accurate and robust measure of the 'estimation confidence' of the computed flow vector and assigns a confidence score to each flow vector based on that.

- Both image and flow field features are used to compute confidence score.
- Following features are used as the basis of confidence measure calculation:
  1. Winner Cost
  2. Gradient in the feature descriptor space calculated using hamming distance

3. Flow gradient of horizontal flow
  4. Flow gradient of vertical flow
  5. Filtered Cost
  6. Filtered gradient
  7. Filtered gradient of horizontal flow
  8. Filtered gradient of vertical flow
- Fixed 16 independent decision trees are supported for adaptive weight computation.
  - Weights are combined linearly and scaled to the supported confidence value range.
  - Confidence score value is quantized to 4 bits, 16 levels.

#### 6.10.3.5.8 Flow Vector Post Filtering Method

The DMPAC implements robust and iterative outlier rejection technique after processing each level of image pyramid during optical flow processing. The following methods are used:

- Estimated flow vectors are filtered after each pyramid level.
- Horizontal and vertical component of the flow vector are filtered separately.
- 2D 5x5 Median Filter shall be supported as post-processing filter.
- All samples within the filter kernel shall be considered for median filtering.

#### 6.10.3.5.9 Flow Vector Output Data Packing Format

The DMPAC optical flow output is saved off to DDR (via the DMPAC SL2 using UTC/UDMA) in a packed format. The parameters are as follows:

- For Base Layer, the flow vector output is 32-bit packed format.
- The flow vector output format is: (MSB) [IntegerBitsU, FractionalBitsU, IntegerBitsV, FractionalBitsV, ConfidenceBits] (LSB), where:
  - IntegerBitsU is 9 bits, and IntegerBitsV is 7 bits (support for +/- 191 H flow vectors and +/- 63 V flow vectors).
  - FractionalBitsU, FractionalBitsV is 4 bits each (support for 1/16th pixel of precision).
  - ConfidenceBits is 4 bits (16 levels)

**Table 6-162. DMPAC Optical Flow Output Data Format for Base Layer**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### 6.10.3.5.10 Sparse Optical Flow Support

The DMPAC produces dense optical flow output by default. In order to facilitate smaller amount of output data that is easier to process in an external DSP/Arm during a Sparse Optical Flow and/or Tracking algorithm, the DMPAC supports a sparse flow vector output generation based on an input binary image map.

#### 6.10.3.6 DMPAC Format Conversion (FOCO) Module Operation

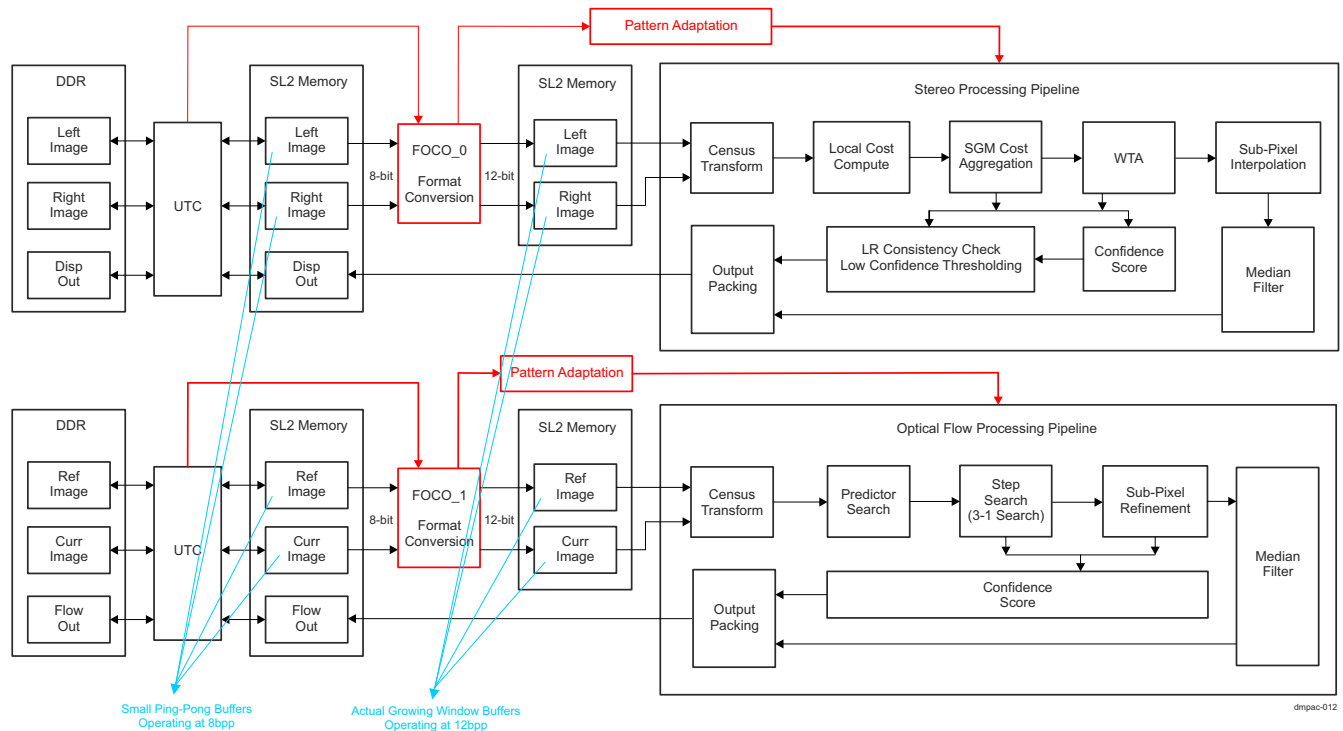

The SDE and DOF engines always work only on pixel data that is organized in a fully packed 12-bit format. These accelerators do not support any other input pixel data formats. To support other data formats, two format conversion modules (FOCO\_0 and FOCO\_1) are included inside the DMPAC sub-system. The FOCO converts

other data formats into the data format supported by the SDE and DOF engines. Figure 6-161 shows how the format conversion engine sits inside the DMPAC sub-system.

**Figure 6-161. DMPAC with Format Conversion Engine (FOCO)**

The FOCO operates in a SL2 memory-to-memory processing fashion. The DMA engine brings the data into the SL2 which is then read by the FOCO, converted and written back into SL2 to be consumed by the SDE and DOF engines. Figure 6-162 shows the data flow with the format conversion engines.

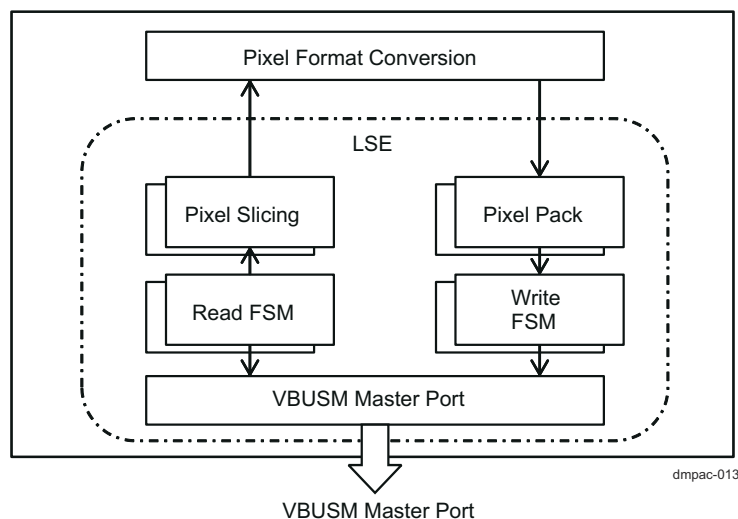

**Figure 6-162. DMPAC Data Flow with FOCO**

### Note

There is only one SL2 memory instance. The two SL2 Memory blocks share correspond to two logic partitions.

#### 6.10.3.6.1 FOCO Implementation Details

Figure 6-163 shows a logical block diagram of a format conversion engine.

**Figure 6-163. DMPAC FOCO Logical Block Diagram**

All the FOCO sub-components mentioned above, except the Pixel Format Conversion sub-component, are implemented using a Load Store Engine (LSE). The operating granularity of FOCO is always one pixel line. Since the input operation granularity of the SDE and DOF engines is different from one pixel line, there is a pattern adapter inside the HTS to enable connection between the FOCO and these engines.

Only 2 input and 2 output channels in each FOCO (one channel for base and reference image) are needed for the DOF and SDE operation. However, there are totally 4 input and 4 output channels in each FOCO instance to enable newer processing flows in the future.

The LSE inside FOCO has the following characteristics:

- 4 Read Channels supporting 8-bit packed, 12-bit packed + MSB/LSB aligned, 16-bit.
- 4 Write Channels supporting 8-bit packed, 12-bit packed + MSB/LSB aligned, 16-bit.
- Single threaded operation.

For more details on LSE operation, see *Load Store Engine (LSE)*.

#### 6.10.3.6.2 FOCO Core Details

The format conversion core implements a generic round-shift-mask pipelined structure. The idea is to get various different types of format conversion by configuring different values for round, shift and mask registers dedicated for each input-output channel pair.

There are two 32-bit configuration registers, DMPAC\_FOCO\_0\_CH\_CTRL\_j/DMPAC\_FOCO\_1\_CH\_CTRL\_j and DMPAC\_FOCO\_0\_CH\_COUNT\_j/DMPAC\_FOCO\_1\_CH\_COUNT\_j, for each input-output channel pair inside the FOCO core. [Section 6.10.4, DMPAC Programming Guide](#), contains two example FOCO configurations for converting different types of pixel format.

#### 6.10.3.7 DMPAC Clocks

The DMPAC receives the following clocking signals. For more information on the source of the clocks at SoC level, see *DMPAC Integration*.

- The MAIN\_CLK is the clock for the DMPAC top level infrastructure blocks.

- The DOF\_CLK is the clock for the DOF block.
- The SDE\_CLK is the clock for the SDE block.

#### 6.10.3.8 DMPAC Resets

The DMPAC receives the following hardware reset signals. For more information which is their source at SoC level, see *DMPAC Integration*.

- The MAIN\_DOF\_RST is the reset signal for the DMPAC top level infrastructure blocks, as well as for the DOF block.
- The SDE\_RST is the reset signal for the SDE block.

#### 6.10.3.9 DMPAC Interrupts

The DMPAC outputs several interrupt lines. For more information how they are connected at SoC level, see *DMPAC Integration*.

- DMPAC0\_INTD\_0\_SYSTEM\_INTR\_LEVEL\_0 and DMPAC0\_INTD\_0\_SYSTEM\_INTR\_LEVEL\_1 interrupt lines

The CP\_INTD block inside DMAPC is used to aggregate several internal interrupt event sources into 2 output interrupt lines: DMPAC0\_INTD\_0\_SYSTEM\_INTR\_LEVEL\_0 and DMPAC0\_INTD\_0\_SYSTEM\_INTR\_LEVEL\_1. The mapping of internal events to each line is controlled via a separate set of CP\_INTD registers.

Table 6-164 shows how the internal interrupt event sources are mapped on the CP\_INTD registers for the DMPAC0\_INTD\_0\_SYSTEM\_INTR\_LEVEL\_0 line.

**Note**

In [Table 6-164](#) and [Table 6-165](#), the bit positions corresponding to SPARE\_PEND\_0\_L and SPARE\_PEND\_1\_L should not be used in registers controlling pulse outputs. Instead, the bit positions corresponding to SPARE\_PEND\_0\_P and SPARE\_PEND\_1\_P should be used to control SPARE\_PEND\_0 and SPARE\_PEND\_1 interrupts, respectively. These registers are:

- \*\_ENABLE\_REG\_PULSE\_DMPAC\_OUT\_\*
- \*\_ENABLE\_CLR\_REG\_PULSE\_DMPAC\_OUT\_\*
- \*\_STATUS\_REG\_PULSE\_DMPAC\_OUT\_\*
- \*\_STATUS\_CLR\_REG\_PULSE\_DMPAC\_OUT\_\*

Similarly, the bit positions corresponding to SPARE\_PEND\_0\_P and SPARE\_PEND\_1\_P should not be used in registers controlling level outputs. Instead, the bit positions corresponding to SPARE\_PEND\_0\_L and SPARE\_PEND\_1\_L should be used to control SPARE\_PEND\_0 and SPARE\_PEND\_1 interrupts, respectively. These registers are:

- \*\_ENABLE\_REG\_LEVEL\_DMPAC\_OUT\_\*
- \*\_ENABLE\_CLR\_REG\_LEVEL\_DMPAC\_OUT\_\*
- \*\_STATUS\_REG\_LEVEL\_DMPAC\_OUT\_\*
- \*\_STATUS\_CLR\_REG\_LEVEL\_DMPAC\_OUT\_\*

- DMPAC0\_ECC\_CORRECTED\_ERR\_LEVEL\_0 and DMPAC0\_ECC\_UNCORRECTED\_ERR\_LEVEL\_0 interrupt lines

The ECC Aggregator block within the DMPAC aggregates the pending status from the ECC protected RAMs into two output interrupt lines: DMPAC0\_ECC\_CORRECTED\_ERR\_LEVEL\_0 for correctable errors, and DMPAC0\_ECC\_UNCORRECTED\_ERR\_LEVEL\_0 for uncorrectable errors. For more information on the ECC memory protection, see [Section 6.10.3.16, DMPAC Memory Error Protection](#).

**6.10.3.10 DMPAC SL2 Memory Subsystem**

A common shared level 2 (SL2) memory sub-system serves the input output data for both SDE and DOF cores. Same memory is also used by the FOCO module, when required, and it also mapped to SoC address map for external usage. This SL2 memory sub-system has the following configuration:

- 512KB SRAM; No ECC implemented

SL2 size allocation restrictions:

SDE SL2 memory Calculation (M1+M2+M3+M4)

- Internal Memory

M1= (Image Width/8u)\*2u\*8u\*8u;

```

if(sl2AllocPrms->searchRange == 192)
{
M1 = M1 * 3u;
}
else if(sl2AllocPrms->searchRange == 128)
{
M1 = M1 * 2u;
}
- Reference Frame (M2)/Current Frame (M3)
pitch = ((Image Width)*3/2) + 63 & 0xFFFFF0; // 64 byte aligned
if(0u == ((pitch)%256u))
{
pitch += 64u;
}
M3 = M2 = pitch*24;
- Disparity Buffer (M4)
M4 = (Image Width)*2*10*2;
DOF SI2 memoeru Calculation (M1+M2+M3+M4+M5)
- Reference Frame (M1)/Current Frame (M2)
pitch = ((Image Width)*3/2) + 63 & 0xFFFFF0; // 64 byte aligned
if(0u == ((pitch)%256))
{
pitch += 64u;
}
M1 = pitch * (((topSR + 7) & 0xFFFFF0) + 2
+ ((botSR + 10) & 0xFFFFF0)
+ 2);
M2 = pitch * (6 + 2 + 8 + 2);
- Temporal predictor (M3)
M3 = (((Image Width) * 4) + 63) & 0xFFFFF0 * 2;
- Pyramidal Predictor (M4)
M4 = (((Image Width) + 63) & 0xFFFFF0) * 2;
- Output Flow Vector (M5)
M5 = (((Image Width) * 4) + 63) & 0xFFFFF0 * 4;

```

### 6.10.3.11 DMPAC Common DMA

The UTC module is used as the DMA for DMPAC. The UTC implements a Channel Controller (CC) as the programming interface and Transfer Controller (TC) for managing DMA transfers. The UTC used for DMPAC is optimized for transfer types such as 2D/3D/4D that are typical of DMPAC access patterns. The following features/parameters are implemented for the UTC module instantiated for DMPAC:

- 32 events; no QDMA requirement
- 32 TR entries

The DMPAC UTC channel controller supports DMA transfer events to read or write following data:

1. Stereo Base Input
2. Stereo Reference Input
3. Stereo Disparity Output
4. Optical Flow Current Input
5. Optical Flow Reference Input
6. Optical Flow Top Pyramid Flow Vector Input
7. Optical Flow Temporal Flow Vector Input
8. Optical Flow Sparse Processing Binary Map Input
9. Optical Flow Vector Output

These data transfer events would be mapped to one or more TR entries within UTC through its programming. All DMPAC data transfers are deterministic in nature and hence it does not require any interaction from the software in between a frame processing. The TR entries should be programmed in such a way that they operate on a circular buffer in SL2 and a full frame level buffer in DDR. For more details about the number and programming of TR entries, see [Section 6.10.4, DMPAC Programming Guide](#).

All data movement transactions at DMPAC boundary are in multiples of aligned 128-byte transfers.

*Chanid* signal on VBUSM Data Master interface carries the UTC channel number which initiated the transfer.

### 6.10.3.12 DMPAC Messaging and Control

The DMPAC SDE and DOF cores run independent hardware processing and data transfer (via UTC/UDMA) threads in order to process stereo and optical flow simultaneously. The thread management is flexible and supports different top level settings of resolution, frame rate, DDR data buffer address etc.

The HTS module for DMPAC is used to implement the thread management and control triggering of processing threads within the DMPAC. It is also used to manage message transfer and control between DMPAC and external SoC level components like VPAC and DSP. For more details on the HTS for DMPAC, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

#### 6.10.3.12.1 DOF Node Scheduler

The DOF engine uses the HWA0 node schedulers in the DMPAC HTS.

The scheduler implements 5 consumer sockets:

1. Reference Frame Read (UTC)
2. Current Frame Read (UTC)
3. Temporal Flow Vector Read (UTC)
4. Pyramidal Flow Vector Read (UTC)
5. Sparse Flow Binary Map Read (UTC)

Some of these consumer sockets will be disabled during different data processing flows. For example, in case of dense processing, the socket #5 would be disabled, as there would be no sparse map read.

The scheduler implements 1 producer socket:

1. Flow Vector Write (UTC)

Before the start of the optical flow processing, the first 71 image lines of reference frame must be aggregated to start the processing of the first paxel row and this progressively increases to 142 image lines in steady state. Similarly, for the current frame, 9 image lines must be aggregated before the start of the processing of the first

paxel row and then progressively increases to 15 lines in steady state. To enable this, the reference frame and current frame read DMA producer scheduler implements transaction aggregator to aggregate enough number of image lines to start the optical flow operation.

#### **6.10.3.12.2 SDE Node Scheduler**

The SDE core uses the HWA1 node schedulers in the DMPAC HTS.

The scheduler implements 2 consumer sockets:

1. Reference Frame Read (UTC)
2. Base Frame Read (UTC)

The scheduler implements 1 producer socket:

1. Stereo Disparity Write (UTC)

Before the start of the stereo disparity processing, the first 16 image lines of both reference and base frame must be aggregated to start the processing of the first row of blocks and then 8 additional image lines in steady state for the subsequent row of blocks. To enable this, the reference and base frame read DMA producer scheduler implements transaction aggregator to aggregate enough number of image lines to start the optical flow operation.

The SDE inherently operates on blocks and reads the inputs and writes the outputs in terms of blocks. The HTS manages the stereo triggers at block level. While the output DMA for stereo disparity happens at block level, the inputs from DDR are read at line level. To handle the difference in pattern between DMA and compute on the input side, there is a pattern adapter implemented inside the reference and base frame read DMA producer scheduler which adapts the lines based growing window fetched from UTC into several blocks to be computed by the SDE. This pattern adaptation is just a way to handle the start of the stereo disparity engine, it does not alter the data organization of these input buffers in SL2.

#### **6.10.3.13 DMPAC Hardware Security**

The DMPAC implements firewalls inside its configuration interconnect and SL2 interconnect to prevent any rogue master to control and corrupt the data and operation of the DMPAC. The firewalls only allows accesses for commands with appropriate previledges (defined by the VBUS privID). [Figure 6-164](#) gives a comprehensive picture of all the hardware security components inside the DMPAC.

#### 6.10.3.13.1 Configuration Interconnect

Copyright © 2024 Texas Instruments Incorporated

**Table 6-166. DMPAC Configuration Interconnect FW Details**

Interconnect	Security component	Parameter	Endpoints	DMSC VBUSP Offset	Regions	Num privIDs	FW ID	privID Reset Value (dec)
Config VBUSP CBASS	Region FW	1 region	DMPAC_TOP	0x400	1	3	5985	0
		4 region	INTD	0x800	4	3	5986	0
		4 region	HTS	0xC00	4	3	5987	0
		1 region	ECC Aggr	0x0	1	3	5984	0
		1 region	CTSET	0x1000	1	3	5988	0
		1 region	FOCO_0	0x1400	1	3	5989	0

		1 region	DOF	0x1C00	1	3	5991	0
		1 region	SDE	0x2000	1	3	5992	0
		4 region	UTC	0x2400	4	3	5992	0

### 6.10.3.13.2 SL2 Interconnect

The DMPAC SL2 interconnect has 4 end-points, each one corresponding to one of the 4 banks of SL2. Each of these end-points have a 4-region region-based firewall instance. Each of the regions in all of the SL2 interconnect firewalls have capability to allow the access from a maximum of 3 privIDs.

Of all the master ports on SL2, only the ones originating from the UTC (via the DMA interconnect) associate a privID with the commands. The master ports originating from the functional compute blocks like DOF, SDE, and FOCO engines do not associate a privID with the commands that they issue. For that purpose, an ISC is instantiated inside SL2 for each of these functional compute masters. These ISCs operate in a channelized mode with just one channel. There is no differentiation between various commands on a master port. A LUT inside ISC would associate a privID to all the commands based on what is configured by the DMSC at SoC level.

[Table 6-167](#) captures the details about all these instances and their IDs and offsets.

**Table 6-167. DMPAC SL2 Interconnect FW and ISC Details**

Interconnect	Security component	Parameter	Endpoints	DMSC VBUSP Offset	Regions	Num privIDs	FW ID	privID Reset Value (dec)

		4-region	SL2 Bank3	0xC00	4	3	6019	0

### 6.10.3.14 DMPAC Debug

The DMPAC HTS implements the host debug interfaces required for the SoC level debug manager. This provides the hardware thread level execution control and debug visibility capability to the host debugger.

The DMPAC also implements extensive benchmarking and real time event trace support via the Counter, Timer and System Event Trace (CTSET) module. An extensive set of event of interest within the stereo and optical flow processing cores and DMA completion events are mapped to the CTSET module, thus providing both benchmarking and event trace capabilities to DMPAC.

[Table 6-168](#) captures how the DMPAC internal events are hooked up with the CTSET module.

**Table 6-168. DMPAC CTSET Events List**

Index	Event Name	Event Type	Event Description
0	dof_hts_init	Pulse	DOF initialization request
1	dof_hts_init_tdone	Pulse	Acknowledgement of DOF init req
2	dof_hts_tstart	Pulse	DOF Thread start
3	dof_hts_tdone	Pulse	DOF Thread done
4	dof_hts_tdone_mask	Pulse	DOF output data mask, inline with tdone
5	dof_hts_eop	Pulse	DOF End of Frame processing
6	dof_hts_debug_rdy	Level	DOF Halt ready Status. 1 - Halted state, 0 - Functional state
7	dof_clkgate	Level	MPB all clk gate
8	dof_se_prefetch	Level	DOF SE is pre-fetching
9	dof_se_stall	Level	DOF SE is stalled
10	dof_stall	Level	MPB clk gate due to empty buffers
63:11	Reserved	-	-
64	sde_hts_init	Pulse	SDE initialization request
65	sde_hts_init_tdone	Pulse	Acknowledgement of SDE init req
66	sde_hts_tstart	Pulse	SDE Thread start
67	sde_hts_tdone	Pulse	SDE Thread done
68	sde_hts_tdone_mask	Pulse	SDE output data mask, inline with tdone
69	sde_hts_eop	Pulse	SDE End of Frame processing
70	sde_hts_debug_rdy	Level	SDE Halt ready Status. 1 - Halted state, 0 - Functional state
71	sde_stall	Level	SDE active high back pressure -or- stall
199:108	Reserved	-	-
159:128	dma_channel_start[31:0]	Pulse	DMPAC DMA Start triggers from HTS to UTC
191:160	dma_channel_done[31:0]	Pulse	DMPAC DMA Done events from UTC to HTS
223:192	dru_ctset_intr	Pulse	
254:218	Reserved	-	-

### 6.10.3.15 DMPAC Internal Diagnostic Features

The DMPAC implements several internal diagnostic features:

- Fault coverage on standard logic
  - Parallel Signature Analyzer (PSA) based signature generation for all critical address and data bus interfaces (internal and external) to enable faster "functional BIST" on logic gates and registers.
    - PSA are 32-bit CRC based
    - PSA is implemented within DOF, SDE, and FOCO sub-modules
- Error detection, diagnostics and recovery
  - Dedicated Watchdog Timers compute processing thread to detect hang condition; upon detection the DMPAC generates interrupt to external host
  - Support for external host access to registers while suspended due to error

#### Note

The external host (software) driven reset to DMPAC is the only guaranteed way of recovering from an error (due to any source).

If the input data and configuration to DMPAC operation is pre-determined (used for periodic testing), then output data also gets known. In such a situation, complete output buffer comparison can be avoided by enabling PSA

on output buffer. The PSA generates a 32-bit CRC value which can be compared to a pre-calculated value, thus avoiding complete output buffer comparison. The DOF and SDE cores implement PSA internal to them.

#### 6.10.3.16 DMPAC Memory Error Protection

The ECC Aggregator module integrated within the DMPAC provides a mechanism to control and monitor certain internal ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. The ECC Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error.

The memories within the DMPAC that are ECC protected are:

- UTC block memories:
  - dru\_queue\_buffer0 RAM
  - dru\_queue\_buffer1 RAM
  - dru\_queue\_buffer2 RAM
  - dru\_state\_buffer0 RAM
  - dru\_response\_buffer0 RAM

For more information on ECC Aggregator operation, see *ECC Aggregator*.

#### 6.10.4 DMPAC Programming Guide

The DMPAC implements two pipelines within it. A pipeline is combination of several input DMA, compute and output DMA. These two pipelines are:

1. Optical Flow Pipeline
2. Stereo Disparity Pipeline

The two pipelines can operate independent of each other.

In the following sub-sections, the convention for describing register and its bit-fields is as follows:

module\_name -> register\_name -> bit\_field

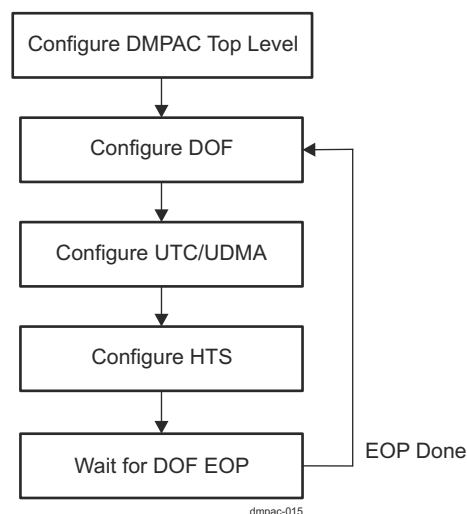

#### CAUTION

No access of any type, either read or write, should be made to the DOF and SDE internal memory space when the respective modules are operationally active (that is, between the initialization and end of pipeline). This would result in an unknown behavior. If the contents of the internal memory space are to be read, for debug purpose, then the respective module needs to be suspended first and only upon full suspension, this memory space should be read out. No writes should ever be done to the internal memory space as it would result in an unknown behavior.

To simplify the programming sequences in this section, the variables in [DMPAC 12bpp Optical Flow Processing Initialization Sequence](#) are defined.

##### 6.10.4.1 DMPAC Optical Flow Initialization Sequence - 12-bit Packed Input Pixel Data

The sequence in [Figure 6-165](#) describes a high level initialization sequence for Optical Flow processing when input images (current and reference) are organized in a fully packed 12-bit format. A pyramid of images is created by the MSC inside VPAC for every frame before it can be fed to the DMPAC Optical Flow processing engine. The sequence below needs to be repeated for every level of such a pyramid. The parameters pertaining to frame resolution, input and output dependencies, data movement and algorithm needs to be updated for every level.

**Figure 6-165. DMPAC 12bpp Optical Flow Processing Initialization Sequence**
**Table 6-169. DMPAC Programming Guide Terminology**

Variable	Equation	Comments
RefTop	$\text{multiple\_of\_2}(\text{vsr\_n}+6)$	/* 6=census tr + hamming dist */

CurCurr	2	
CurBott	8	/* 6=census tr + hamming dist; 1=adv-pred; 1= round */
CurThreshold	$\text{CurTop} + \text{CurCurr} + \text{CurBott}$	
mf_en	Median Filter Enable	

#### 6.10.4.1.1 Optical Flow 12bb - DMPAC Top Level Configuration

```

Set ENABLE->DMPAC_EN to '1'. // Enable DMPAC Module
Set ENABLE->DOF_EN to '1'. // Enable Optical Flow Processing Module
  
```

#### 6.10.4.1.2 Optical Flow 12bb - UTC Configuration

The Optical Flow engine needs a maximum of 5 input buffers to be fetched by UTC before it can start its processing. It produces one output which need to be sent out into DDR by the UTC.

##### 6.10.4.1.2.1 Reference Frame Growing Window Fetch

The reference frame growing window fetches happen in the granularity of two lines. The UTC needs to be configured to bring two consecutive lines on every event trigger. Only after several DMA event triggers, a sufficient amount of data would have been accumulated, which would trigger DOF operation. The SL2 buffer is sized to hold a maximum 146 lines (assuming  $\text{vsr\_p} = \text{vsp\_n} = 63$ ), so it must wrap around at that granularity. While setting up the destination side transfer parameters, care must be taken to achieve staggering. In other words, two vertically adjacent pixels should come from different SL2 banks. For example, in case the image width is 2048 pixels, this would mean 3KB of data per line. Without any staggering, two vertically adjacent pixels would fall in the same memory bank of DMPAC SL2. This can cause SL2 access problems considering DOF reference frame growing window access pattern. To avoid this situation, a dummy SL2 word (64 bytes) need to be inserted at the end of every line. This will make vertically adjacent pixels to come from different banks. If the

image width is such that staggering happens naturally, the addition of dummy SL2 word does not need to be done.

#### 6.10.4.1.2.2 Current Frame Growing Window Fetch

The current frame growing window fetches happen in the granularity of two lines. The UTC needs to be configured to bring two consecutive lines on every event trigger. Only after several DMA event triggers, a sufficient amount of data would have been accumulated, which would trigger DOF operation. The SL2 buffer is sized to hold a maximum 18 lines, so it must wrap around at that granularity. While setting up the destination side transfer parameters, care must be taken to achieve staggering. In other words, two vertically adjacent pixels should come from different SL2 banks. For example, in case the image width is 2048 pixels, this would mean 3KB of data per line. Without any staggering, two vertically adjacent pixels would fall in the same memory bank (or bank pair) of DMPAC SL2. This can cause SL2 access problems considering DOF current frame growing window access pattern. To avoid this situation, a dummy SL2 word (64 bytes) need to be inserted at the end of every line. This will make vertically adjacent pixels to come from different banks. If the image width is such that staggering happens naturally, the addition of dummy SL2 word does not need to be done.

#### 6.10.4.1.2.3 Temporal Predictor Fetch

There needs to be at least a ping-pong (2 deep) buffer in SL2 for temporal predictor fetch. This fetch is only needed while processing the base layer of the pyramid. This fetch needs to be disabled for other layer processing. Since a paxel level predictor evaluation is performed, only alternate (even) lines needs to be fetched for this buffer from the external memory. The UTC source side fetch parameters need to be programmed appropriately. Every line of this buffer needs to start from a new SL2 word. There cannot be any overlap with the previous word.

#### 6.10.4.1.2.4 Pyramidal Predictor Fetch

There needs to be at least a ping-pong (2 deep) buffer in SL2 for pyramidal predictor fetch. This fetch is not needed while processing the top most layer of the pyramid. This fetch needs to be enabled for other layer processing. Every line of this buffer needs to start from a new SL2 word. There cannot be any overlap with the previous word.

#### 6.10.4.1.2.5 Sparse Optical Flow Binary Map Fetch

There needs to be at least a ping-pong (2 deep) buffer in SL2 for sparse optical flow binary map fetch. This fetch is not needed when sparse processing is turned off. The UTC needs to be configured to bring two consecutive lines of this map on every event trigger. Every line of this buffer needs to start from a new SL2 word. There cannot be any overlap with the previous word.

#### 6.10.4.1.2.6 Flow Vector Output

There needs to be at least a ping-pong (2 deep) buffer in SL2 for flow vector output. The size of the buffer can vary between the sparse and dense optical flow processing. The UTC needs to be configured to send out two consecutive lines of this map on every event trigger. Every line of this buffer will start from a new SL2 word.

#### 6.10.4.1.3 Optical Flow 12bb - HTS Configuration

The HWA0 schedule in HTS is used for the DOF. The HTS programming is as follows:

```
// RFGW Fetch
HTS->DMA0_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->DMA0_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA0_SCHEDULER_CONTROL->dma_channel_no = 0; // Assign appropriate DMA channel
HTS->DMA0_HOP->hop = 1;
HTS->DMA0_HOP->hop_thread_count = ImgHeight/2;
HTS->DMA0_PROD0_CONTROL->prod_en = 1;
HTS->DMA0_PROD0_CONTROL->cons_select = 0;
HTS->DMA0_PROD0_BUF_CONTROL->depth = (RefThreshold + 2)/2;
HTS->DMA0_PROD0_BUF_CONTROL->count_dec = 1;

if(RefThreshold > ImgHeight)
{
    HTS->DMA0_PROD0_BUF_CONTROL->threshold = ImgHeight/2;
}
```

```

    if((refBot + 2u) < dofConfig->height)
    {
        HTS->DMA0_PROD0_COUNT->count_preload = (ImgHeight - RefBot - 2)/2;
    }
    else
    {
        HTS->DMA0_PROD0_COUNT->count_preload = 0;
    }
    if(refBot < dofConfig->height)
    {
        HTS->DMA0_PROD0_COUNT->count_postload = RefBot/2 + mf_en
    }
    else
    {
        HTS->DMA0_PROD0_COUNT->count_postload = (ImgHeight - RefCurr)/2 + mf_en
    }
}
else
{
    HTS->DMA0_PROD0_BUF_CONTROL->threshold = (RefThreshold)/2;
    HTS->DMA0_PROD0_COUNT->count_preload = RefTop/2
    HTS->DMA0_PROD0_COUNT->count_postload = RefBot/2 + mf_en
}

// CFGW Fetch
HTS->DMA1_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->DMA1_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA1_SCHEDULER_CONTROL->dma_channel_no = 1; // Assign appropriate DMA channel
HTS->DMA1_HOP->hop = 1;
HTS->DMA1_HOP->hop_thread_count = ImgHeight/2;
HTS->DMA1_PROD0_CONTROL->prod_en = 1;
HTS->DMA1_PROD0_CONTROL->cons_select = 0;
HTS->DMA1_PROD0_BUF_CONTROL->depth = (CurThreshold + 2)/2;
HTS->DMA1_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA1_PROD0_BUF_CONTROL->threshold = (CurThreshold)/2;
HTS->DMA1_PROD0_COUNT->count_preload = CurTop/2;
HTS->DMA1_PROD0_COUNT->count_postload = CurBot/2 + mf_en;

// Temporal predictor fetch
HTS->DMA2_SCHEDULER_CONTROL->sch_en = 1; // Only for Base pyramid
HTS->DMA2_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA2_SCHEDULER_CONTROL->dma_channel_no = 2; // Assign appropriate DMA channel
HTS->DMA2_HOP->hop = 1;
HTS->DMA2_HOP->hop_thread_count = ImgHeight/2;
HTS->DMA2_PROD0_CONTROL->prod_en = 1;
HTS->DMA2_PROD0_CONTROL->cons_select = 0;
HTS->DMA2_PROD0_BUF_CONTROL->depth = 2;
HTS->DMA2_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA2_PROD0_BUF_CONTROL->threshold = 1;
HTS->DMA2_PROD0_COUNT->count_preload = 0;
HTS->DMA2_PROD0_COUNT->count_postload = mf_en;

// Pyramidal predictor fetch
HTS->DMA3_SCHEDULER_CONTROL->sch_en = 1; // Only if Pyramid predictor enabled
HTS->DMA3_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA3_SCHEDULER_CONTROL->dma_channel_no = 3; // Assign appropriate DMA channel
HTS->DMA3_HOP->hop = 1;
HTS->DMA3_HOP->hop_thread_count = ImgHeight/2;
HTS->DMA3_PROD0_CONTROL->prod_en = 1;
HTS->DMA3_PROD0_CONTROL->cons_select = 0;
HTS->DMA3_PROD0_BUF_CONTROL->depth = 2;
HTS->DMA3_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA3_PROD0_BUF_CONTROL->threshold = 1;
HTS->DMA3_PROD0_COUNT->count_preload = 0;
HTS->DMA3_PROD0_COUNT->count_postload = mf_en;

// Sparse binary map fetch
HTS->DMA4_SCHEDULER_CONTROL->sch_en = 1; // Only if SOF enabled
HTS->DMA4_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA4_SCHEDULER_CONTROL->dma_channel_no = 4; // Assign appropriate DMA channel
HTS->DMA4_HOP->hop = 1;
HTS->DMA4_HOP->hop_thread_count = ImgHeight/2;
HTS->DMA4_PROD0_CONTROL->prod_en = 1;
HTS->DMA4_PROD0_CONTROL->cons_select = 0;
if(mf_en)

```

```

{
    HTS->DMA4_PROD0_BUF_CONTROL->depth = 2;
}
else
{
    HTS->DMA4_PROD0_BUF_CONTROL->depth = 3;
}
HTS->DMA4_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA4_PROD0_BUF_CONTROL->threshold = 1;
HTS->DMA4_PROD0_COUNT->count_preload = 0;
HTS->DMA4_PROD0_COUNT->count_postload = mf_en;

// HWA0 Scheduler Programming
HTS->HWA0_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->HWA0_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0

#### 6.10.4.2 DMPAC Stereo Disparity Initialization Sequence - 12-bit Packed Input Pixel Data

Figure 6-166 describes a high level initialization sequence for Stereo Disparity processing when input images (both left and right view) are organized in a fully packed 12-bit format. Rectified left and right images are created by the LDC module inside VPAC for every frame before it can be fed to the Stereo Disparity processing engine. The sequence below needs to be repeated for every frame. The parameters pertaining to frame resolution, data movement and algorithm needs to be updated for every frame as needed.

**Figure 6-166. DMPAC 12bpp Stereo Disparity Processing Initialization Sequence**

#### 6.10.4.2.1 Stereo Disparity 12bpp - DMPAC Top Configuration

```

Set ENABLE->DMPAC_EN to '1'. // Enable DMPAC Module
Set ENABLE->SDE_EN to '1'. // Enable Stereo Disparity Processing Module
  
```

If the input data and configuration to DMPAC operation is pre-determined (used for periodic testing), then output data also gets known. In such a situation, complete output buffer comparison can be avoided by enabling PSA on output buffer. The PSA generates a 32-bit CRC value which can be compared to a pre-calculated value, thus avoiding complete output buffer comparison. The SDE module implements a PSA function.

Upon end of pipe, *SDE->PSA\_SIGNATURE->crc\_sts* would reflect the 32-bit CRC value.

#### 6.10.4.2.2 Stereo Disparity 12bpp - DMA Configuration

The Stereo Disparity engine needs 2 input buffers to be fetched by the UTC before it can start its processing. It produces one output which needs to be sent out into DDR by the UTC.

##### 6.10.4.2.2.1 Reference Frame Growing Window Fetch

The reference frame growing window fetches happen in the granularity of 8 lines as the height of the SDE processing block is 8. The UTC needs to be configured to bring 8 consecutive lines on every event trigger. Only after 2 DMA event triggers, a sufficient amount of data (16 lines) would have been accumulated which would trigger the SDE operation. The SL2 buffer is sized to hold a maximum 24 lines, so it must wrap around at that granularity. Although it is not quite mandatory, while setting up the destination side transfer parameters, care must be taken to achieve staggering, only if SL2 size permits. In other words, two vertically adjacent pixels should come from different SL2 banks. For example, in case the image width is 2048 pixels, this would mean 3KB of data per line. Without any staggering, two vertically adjacent pixels would fall in the same memory bank of DMPAC SL2. This can cause SL2 access problems considering SDE reference frame growing window access pattern. To avoid this situation, a dummy SL2 word (64 bytes) needs to be inserted at the end of every line. This will make vertically adjacent pixels to come from different banks. If the image width is such that staggering happens naturally, the addition of a dummy SL2 word does not need to be done.

##### 6.10.4.2.2.2 Base Frame Growing Window Fetch

The base frame growing window fetches happen in the granularity of 8 lines. The UTC needs to be configured to bring 8 consecutive lines on every event trigger. Only after 2 DMA event triggers, a sufficient amount of data would have been accumulated, which would trigger the SDE operation. The SL2 buffer is sized to hold a maximum 24 lines, so it must wrap around at that granularity. Although it is not quite mandatory, while setting up the destination side transfer parameters, care must be taken to achieve staggering, only if SL2 size permits. In other words, two vertically adjacent pixels should come from different SL2 banks. For example, in case the

image width is 2048 pixels, this would mean 3KB of data per line. Without any staggering, two vertically adjacent pixels would fall in the same memory bank (or bank pair) of DMPAC SL2. This can cause SL2 access problems considering SDE base frame growing window access pattern. To avoid this situation, a dummy SL2 word (64 bytes) needs to be inserted at the end of every line. This will make vertically adjacent pixels to come from different banks. If the image width is such that staggering happens naturally, the addition of a dummy SL2 word does not need to be done.

#### 6.10.4.2.2.3 Stereo Disparity Output

There needs to be at least a ping-pong (2 deep) buffer in SL2 for the disparity output. The size of the output can vary based on the location of the processed block in the frame. The height of the block will have one particular value for the first row of blocks in the image. Then, in steady state, the height would have a different value for the central part of the image rows. It would finally have a different height for the last row of blocks. The UTC needs to be configured appropriately to handle this. One possible way is to use 3 linked TR entries in UTC for these three image regions. The UTC needs to send out a block on every event trigger. Every block of this buffer will start from a new SL2 word.

#### 6.10.4.2.3 Stereo Disparity 12bpp - HTS Configuration

The HWA1 scheduler in HTS is used for the SDE. The HTS programming is as follows:

```
// RFGW Fetch
HTS->DMA8_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->DMA8_SCHEDULER_CONTROL->pipeline_num = 1; // Belongs to pipeline 1
HTS->DMA8_SCHEDULER_CONTROL->dma_channel_no = 6; // Assign appropriate DMA channel
HTS->DMA8_HOP->hop = 1;
HTS->DMA8_HOP->hop_thread_count = ImgHeight/8;
HTS->DMA8_PROD0_CONTROL->prod_en = 1;
HTS->DMA8_PROD0_CONTROL->cons_select = 0;
HTS->DMA8_PROD0_BUF_CONTROL->depth = 3;
HTS->DMA8_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA8_PROD0_BUF_CONTROL->threshold = 2;
HTS->DMA8_PROD0_COUNT->count_preload = 0;
HTS->DMA8_PROD0_COUNT->count_postload = 0;
HTS->DMA8_PA0_CONTROL->pa_enable = 1; // Enable Pattern Adapter
HTS->DMA8_PA0_CONTROL->pa_dec_cntl = 1; // post pattern adaptation, decrement ps count by count_dec
HTS->DMA8_PA0_CONTROL->pa_buf_cntl = 0; // Apply threshold, count_preload and count_postload on
prodcount

psMaxCnt = Imgwidth/64;
if((64 * psMaxCnt) != Imgwidth)
{
    psMaxCnt++;
}

HTS->DMA8_PA0_CONTROL->pa_ps_maxcount = Imgwidth; // Assuming frame width of 2048 and block width
of 64
HTS->DMA8_PA0_CONTROL->pa_cs_maxcount = 2; // Pattern Adapter starts when we have 16 lines in GW
HTS->DMA8_PROD0_BUF_CONTROL->count_dec = 1; // Overwrite 8 line in GW once the entire

// BFGW Fetch
HTS->DMA9_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->DMA9_SCHEDULER_CONTROL->pipeline_num = 1; // Belongs to pipeline 1
HTS->DMA9_SCHEDULER_CONTROL->dma_channel_no = 6; // Assign appropriate DMA channel
HTS->DMA9_HOP->hop = 1;
HTS->DMA9_HOP->hop_thread_count = ImgHeight/8;
HTS->DMA9_PROD0_CONTROL->prod_en = 1;
HTS->DMA9_PROD0_CONTROL->cons_select = 0;
HTS->DMA9_PROD0_BUF_CONTROL->depth = 3;
HTS->DMA9_PROD0_BUF_CONTROL->count_dec = 1;
HTS->DMA9_PROD0_BUF_CONTROL->threshold = 2;
HTS->DMA9_PROD0_COUNT->count_preload = 0;
HTS->DMA9_PROD0_COUNT->count_postload = 0;

psMaxCnt = Imgwidth/64;
if((64 * psMaxCnt) != Imgwidth)
{
    psMaxCnt++;
}
```

```

HTS->DMA9_PA0_CONTROL->pa_ps_maxcount = Imgwidth; // Assuming frame width of 2048 and block width
of 64
HTS->DMA9_PA0_CONTROL->pa_cs_maxcount = 2; // Pattern Adapter starts when we have 16 lines in GW
HTS->DMA9_PROD0_BUF_CONTROL->count_dec = 1; // Overwrite 8 line in GW once the entire

// HWA1 Scheduler Programming
HTS->HWA1_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->HWA1_SCHEDULER_CONTROL->pipeline_num = 1; // Belongs to pipeline
HTS->HWA1_WDTIMER->watchdog_timer_en = 0; //Activate WD
HTS->HWA1_HOP->hop = 0;
HTS->HWA1_BW_LIMITER->BW_limiter_en = 0;

// HWA0 consumer and producer control
HTS->HWA1_CONS0_CONTROL->cons_en = 1; // Enable RFGW Fetch
HTS->HWA1_CONS1_CONTROL->cons_en = 1; // Enable CFGW Fetch

HTS->HWA1_CONS0_CONTROL->prod_select = 0;
HTS->HWA1_CONS1_CONTROL->prod_select = 0;

HTS->HWA1_PROD0_CONTROL->prod_en = 1; // Enable Producer socket
HTS->HWA1_PROD0_CONTROL->cons_select = 0; // Fixed to DMA
HTS->HWA1_PROD0_BUF_CONTROL->depth = 2;
HTS->HWA1_PROD0_BUF_CONTROL->threshold = 1;
HTS->HWA1_PROD0_BUF_CONTROL->count_dec = 1;
HTS->HWA1_PROD0_COUNT->count_preload = 0;
HTS->HWA1_PROD0_COUNT->count_postload = 0;

// Flow vector output
HTS->DMA256_SCHEDULER_CONTROL->sch_en = 1; // scheduler enable
HTS->DMA256_SCHEDULER_CONTROL->pipeline_num = 0; // Belongs to pipeline 0
HTS->DMA256_SCHEDULER_CONTROL->dma_channel_no = 8; // Assign appropriate DMA channel
HTS->DMA256_CONS0_CONTROL->cons_en = 1;
HTS->DMA256_CONS0_CONTROL->prod_select = 0;

// Enable Pipeline
HTS->PIPELINE_CONTROL_1->pipe_en = 1; // Enable DOF pipeline# 1

```

#### 6.10.4.3 DMPAC End of Pipeline Processing

The DMPAC can have a maximum of 2 active pipelines at any given time. For more details on the end of pipeline processing for both of these pipelines, see *Hardware Accelerator (HWA) Thread Scheduler (HTS)*.

#### 6.10.4.4 DMPAC Debug Restrictions

During Halt request based debug of the SDE module, not all internal memories can be read, if the requirement is to resume or single-step to completion with correct output. Accessing the SDE BPCC memory would corrupt the processing of SDE, once it is read.

This SDE memory can still be accessed to probe the contents and debug. If a single step is required, the test must be run again without probing the memory.

No such restrictions exist for the DOF memories.

Chapter 7

Interprocessor Communication

---

This chapter describes the interprocessor communication modules in the device.

7.1 Mailbox.....	814
7.2 Spinlock.....	825

## 7.1 Mailbox

This chapter describes the mailbox module in the device.

### 7.1.1 Mailbox Overview

Mailbox module serves to facilitate the communication between the various on-chip processors of the device by providing a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors (users) through a set of registers and associated interrupt signals.

The device implements the following:

- One system (NAVSS) mailbox module:
  - Number of clusters: 12
  - Used for communication between: Compute Cluster Arm (CC\_ARMSS), MCU\_ARMSS, and PRU\_ICSSG subsystems
  - Reference names: MAILBOX0

Table 7-1 shows the Mailbox allocation across device domains.

**Table 7-1. Mailbox Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MAILBOX0	-	-	✓ (NAVSS)

#### 7.1.1.1 Mailbox Features

Each mailbox module supports the following features:

- Parameters configured at design time (see Table 7-2):
  - Number of mailbox clusters
    - Each mailbox cluster has the same configuration
    - Clusters are accessed via separate VBUS regions. Clusters can be treated as mailbox module instances.
  - Number of users
  - Number of mailbox message queues
  - Number of messages (FIFO depth) for each message queue
- 32-bit message width
- Partial writes do not advance the FIFO pointers
- Message reception and queue-not-full notification using interrupts
- Non-intrusive emulation

#### 7.1.1.2 Mailbox Parameters

Table 7-2 shows the configuration of the mailbox module in the device.

**Table 7-2. Mailbox Configuration Parameters**

Module Instance	Parameters			
	Users (Processors)	Clusters <sup>(1)</sup>	Message Queues <sup>(2)</sup>	Number of Messages <sup>(3)</sup>
MAILBOX0	4	12	16	4

(1) Number of mailbox clusters

(2) Number of mailbox message queues (mailboxes per cluster)

(3) Number of messages (FIFO depth) for each message queue

#### 7.1.1.3 Mailbox Not Supported Features

The following features are not supported by the module:

- Hardware protection to prevent users from reading FIFO mailboxes that it doesn't own as receiver or writing to FIFO mailboxes that it doesn't own as sender.

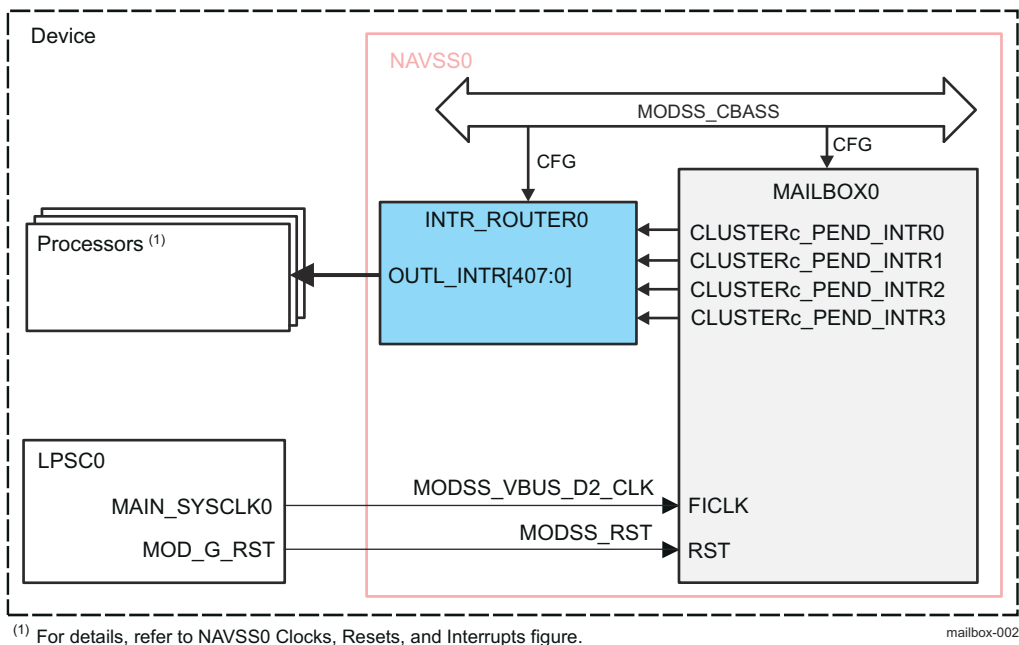

## 7.1.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

### 7.1.2.1 System Mailbox Integration

Figure 7-1 shows the MAILBOX integration in the NAVSS. MAILBOX module contains a number of mailbox clusters. Each cluster generates one interrupt per user (processor).

**Figure 7-1. Mailbox Integration**

c = 0 to 11

Table 7-3 through Table 7-5 summarize the MAILBOX integration in the device.

**Table 7-3. Mailbox Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MAILBOX0	PSC0	GP	LPSC0	MODSS_CBASS

**Table 7-4. Mailbox Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MAILBOX0	MAILBOX0_FICLK	MODSS_VBUS_D2_CLK	MAIN_SYSCLK0	MAILBOX0 clock. This clock is used for all interface and functional operations.

Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MAILBOX0	MAILBOX0_RST	MODSS_RST	LPSC0	MAILBOX0 hardware reset

### 7.1.3 Mailbox Functional Description

The mailbox module provides a means of communication through message queues among the users. The individual mailbox modules, or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX\_IRQ\_ENABLE\_SET\_j (or MAILBOX\_IRQ\_ENABLE\_CLR\_j) register.

#### Note

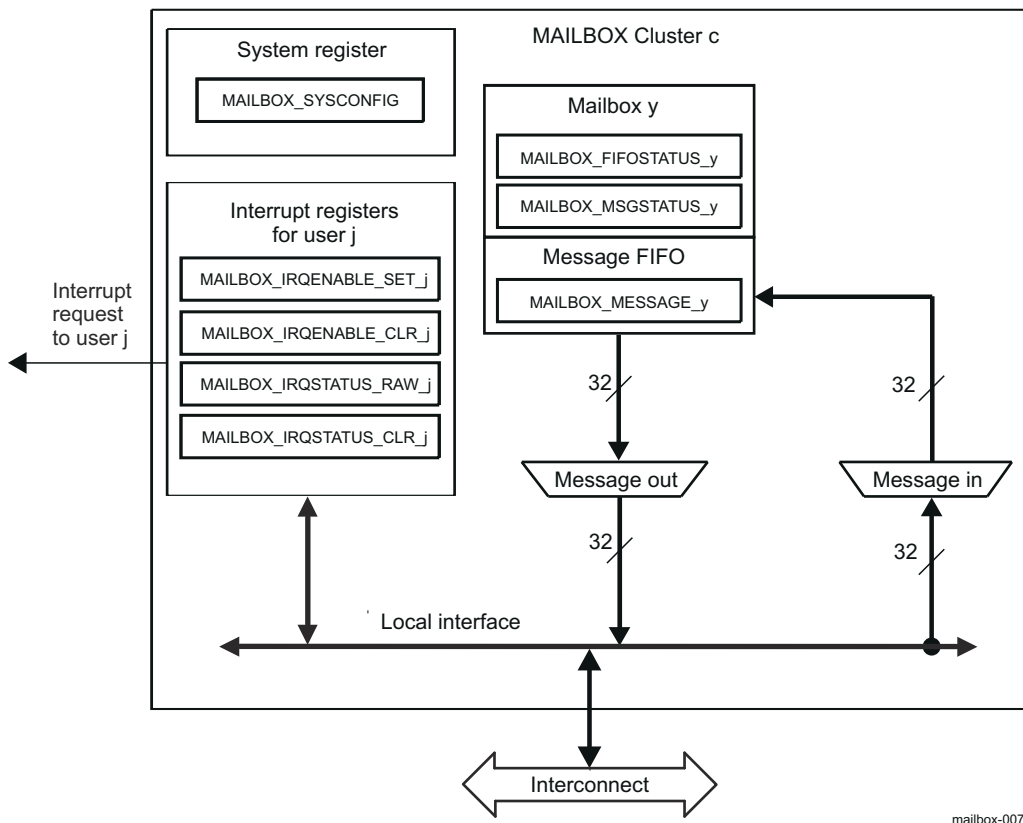

It is software responsibility to select a user by mapping (via INTR\_ROUTER0) the corresponding mailbox interrupt to the interrupt controller of the appropriate processor subsystem.

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.

Each MAILBOX\_IRQ\_STATUS\_RAW\_j/MAILBOX\_IRQ\_STATUS\_CLR\_j interrupt status register corresponds to a particular user.

#### 7.1.3.1 Mailbox Block Diagram

Figure 7-2 shows the mailbox internal block diagram.

**Figure 7-2. Mailbox Block Diagram**

c = 0 to 11

j = 0 to 3

y = 0 to 15

### 7.1.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX\_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX\_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

### 7.1.3.3 Mailbox Power Management

The clkstop\_idle will be asserted if all of the following are true:

- The VBUSP interface is inactive
- All mailboxes are empty
- There are no enabled events or outstanding interrupts

An enabled event means there is pending action required from one of the users, and it means one or more mailboxes still expect data.

### 7.1.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

Table 7-6 lists the event flags, and their mask, that can cause module interrupts.

**Table 7-6. Interrupt Events**

Non-Maskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQ_STATUS_RAW_j[0+y*2]	MAILBOX_IRQ_STATUS_CLR_j[0+y*2]	MAILBOX_IRQ_ENABLE_CLR_j[0+y*2]	MAILBOX_IRQ_ENABLE_SET_j[0+y*2]	Mailbox y receives a new message.
NEWMSGSTATUSMBY	NEWMSG_STATUSMBY	NEWMSG_STATUSMBY	NEWMSG_STATUSMBY	
MAILBOX_IRQ_STATUS_RAW_j[1+y*2]	MAILBOX_IRQ_STATUS_CLR_j[1+y*2]	MAILBOX_IRQ_ENABLE_CLR_j[1+y*2]	MAILBOX_IRQ_ENABLE_SET_j[1+y*2]	Mailbox y message queue is not full.
NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	NOTFULLSTATUSMBY	

(1) MAILBOX\_IRQ\_STATUS\_RAW\_j register is mostly used for debug purposes.

#### CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX\_IRQ\_STATUS\_CLR\_j register.

Writing a logical 1 in a bit of the MAILBOX\_IRQ\_STATUS\_CLR\_j register will also clear to 0 the corresponding bit in the appropriate MAILBOX\_IRQ\_STATUS\_RAW\_j register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX\_IRQ\_ENABLE\_SET\_j register. Events are reported in the appropriate MAILBOX\_IRQ\_STATUS\_CLR\_j and MAILBOX\_IRQ\_STATUS\_RAW\_j registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX\_IRQ\_ENABLE\_CLR\_j register. Events are only reported in the appropriate MAILBOX\_IRQ\_STATUS\_RAW\_j register.

In case of the MAILBOX\_IRQ\_STATUS\_RAW\_j register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 7.1.3.5 Mailbox Assignment

#### 7.1.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX\_IRQ\_ENABLE\_SET\_j register. The receiver reads the MAILBOX\_MESSAGE\_y register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX\_FIFO\_STATUS\_y and/or MAILBOX\_MSG\_STATUS\_y registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX\_IRQ\_ENABLE\_SET\_j register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX\_FIFO\_STATUS\_y or MAILBOX\_MSG\_STATUS\_y registers
- Write the message to the corresponding MAILBOX\_MESSAGE\_y register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX\_IRQ\_ENABLE\_SET\_j register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX\_IRQ\_STATUS\_CLR\_j register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX\_IRQ\_STATUS\_CLR\_j register acknowledges, and subsequently clears, an interrupt.

#### CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

### 7.1.3.6 Sending and Receiving Messages

#### 7.1.3.6.1 Description

When a 32-bit message is written to the MAILBOX\_MESSAGE\_y register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX\_FIFO\_STATUS\_y register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX\_MESSAGE\_y register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX\_MESSAGE\_y register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX\_MSG\_STATUS\_y register.

### 7.1.3.7 Example of Communication

Figure 7-3 shows an example of communication between two processors.

mailbox-008

**Figure 7-3. Example of Communication**

## 7.1.4 Mailbox Programming Guide

### 7.1.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

#### 7.1.4.1.1 Global Initialization

##### 7.1.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 7.1.2, Mailbox Integration](#), for further information.

**Table 7-7. Global Initialization of Surrounding Modules for MAILBOX**

Surrounding Modules	Comments
LPSC	The MAILBOX functional and interface clock must be enabled.
Interrupt Controllers	Processor's (user's) interrupt controller must be configured to enable the interrupt request generation.
INTR_ROUTER0	INTR_ROUTER0 configuration must be done to allow module IRQs to be mapped to required INTC input. For more information see <i>Interrupt Routers</i> .

#### 7.1.4.1.1.2 Mailbox Global Initialization

##### 7.1.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 7-8. Mailbox Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFT_RESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFT_RESET	=0x0

#### 7.1.4.1.2 Mailbox Operational Modes Configuration

##### 7.1.4.1.2.1 Mailbox Processing modes

##### 7.1.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

**Table 7-9. Sending a Message (Polling Method)**

Step	Register/Bit Field/Programming Model	Value
IF: Is FIFO full?	MAILBOX_FIFO_STATUS_y[0] FULL	=0x1
Wait until at least one message slot is available	MAILBOX_FIFO_STATUS_y[0] FULL	=0x0
<b>ELSE</b>		
Write message	MAILBOX_MESSAGE_y[31:0] VALUE	0x-

Step	Register/Bit Field/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQ_STATUS_CLR_j[0 + y*2]	0x1
IF: Number of messages is not equal to 0?	MAILBOX_MSG_STATUS_y[2:0] NUM_MESSAGES	≠0x0
Read message	MAILBOX_MESSAGE_y[31:0] VALUE	0x--
<b>ELSE</b>		
Write 1 to acknowledge interrupt	MAILBOX_IRQ_STATUS_CLR_j[0 + y*2]	0x1
<b>ENDIF</b>		

## 7.2 Spinlock

This chapter describes the Spinlock module of the device.

### 7.2.1 Spinlock Overview

The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device.

The Spinlock module implements 256 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 7-4 shows an overview of the Spinlock module.

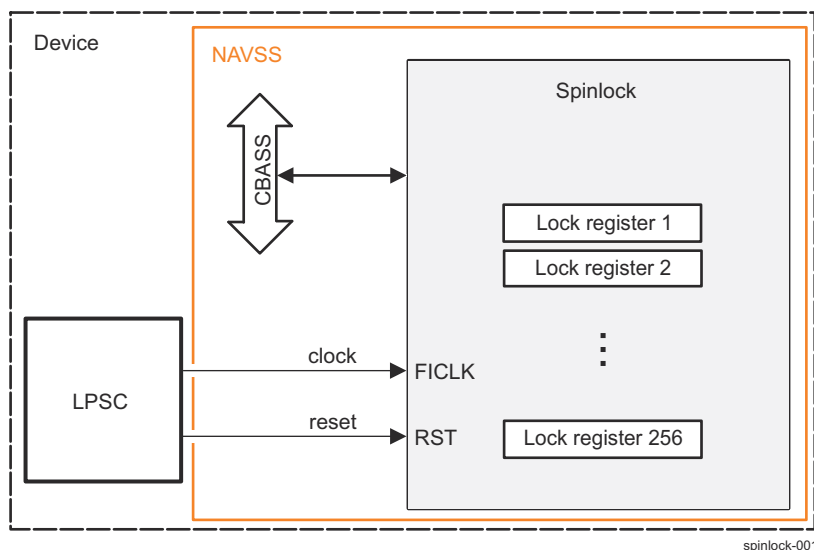

Figure 7-4. Spinlock Overview

Table 7-15. Spinlock Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
SPINLOCK0	-	-	✓ (NAVSS)

#### 7.2.1.1 Spinlock Not Supported Features

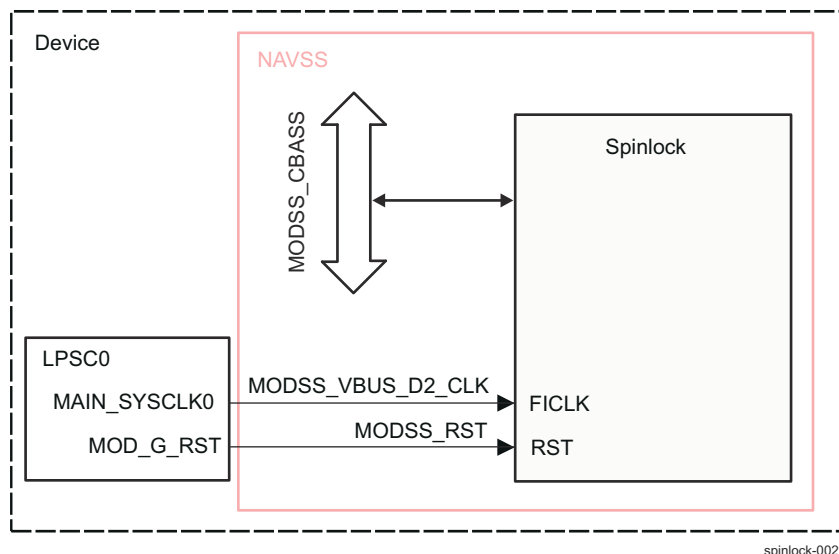

The following features are not supported by the module:

- Ownership enforcement. There is no support to ensure that a lock register is locked and unlocked by the same process
- There is no support for checking that the same VBUS initiator that acquired the lock is the one that is freeing the lock
- There is no support for fairness or congestion control.

## 7.2.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 7-5 shows the Spinlock integration.

**Figure 7-5. Spinlock Integration**

Table 7-16 and Table 7-17 summarize the integration of the module in the device.

**Table 7-16. Spinlock Integration Attributes**

SPINLOCK0	-	-	-	No PDMA channels to external DMA engines	-

### 7.2.3 Spinlock Functional Description

#### 7.2.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK\_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Note that reading back the value of SPINLOCK\_SYSCONFIG[1] SOFTRESET bit will always return 0.

#### 7.2.3.2 Spinlock Power Management

The Spinlock module supports the Power Idle interface. Software must arrange to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

1. Software must check that all controllers that may be using the Spinlock module are either:
  - a. Already powered off (all in-use flags are 0)
  - b. Notified that Spinlock is not available and the notification is acknowledged
2. If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK\_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any controller that is still active. Alternatively, you may decide to wait a timeout period to allow any active controller to clean up its locks before powering down.

The Spinlock module may now be powered off.

#### 7.2.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

#### 7.2.3.4 Spinlock Functional Operation

The Spinlock module supports 256 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK\_LOCK\_REG\_i[0] TAKEN bit. There are two states: Taken (SPINLOCK\_LOCK\_REG\_y[0] TAKEN = 1) or Not Taken (SPINLOCK\_LOCK\_REG\_y[0] TAKEN = 0), where y = 0h to FFh.

When the status of lock y (where y = 0 to 255) is Not Taken (free), a read from the SPINLOCK\_LOCK\_REG\_y register returns 0 and sets the lock to Taken (locked). When the status of lock y is Taken, a read returns 1 and does not change the state of the lock.

A write to the SPINLOCK\_LOCK\_REG\_y register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

Figure 7-6 shows the SPINLOCK\_LOCK\_REG\_y register state diagram.

**Figure 7-6. Lock Register State Diagram**

#### Note

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

## 7.2.4 Spinlock Programming Guide

### 7.2.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 7.2.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

**Table 7-19. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC	Spinlock functional and interface clock must be enabled. For more information, see <i>Clocking</i>

#### 7.2.4.1.2 Basic Spinlock Operations

The main Spinlock operations are:

- Clear all the Taken spinlocks by writing 0 to SPINLOCK\_LOCK\_REG\_y (only after a system bug recovery)
- Take a spinlock by reading the SPINLOCK\_LOCK\_REG\_i[0] TAKEN bit
- Release spinlock by writing 0 to SPINLOCK\_LOCK\_REG\_i[0] TAKEN bit

##### 7.2.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

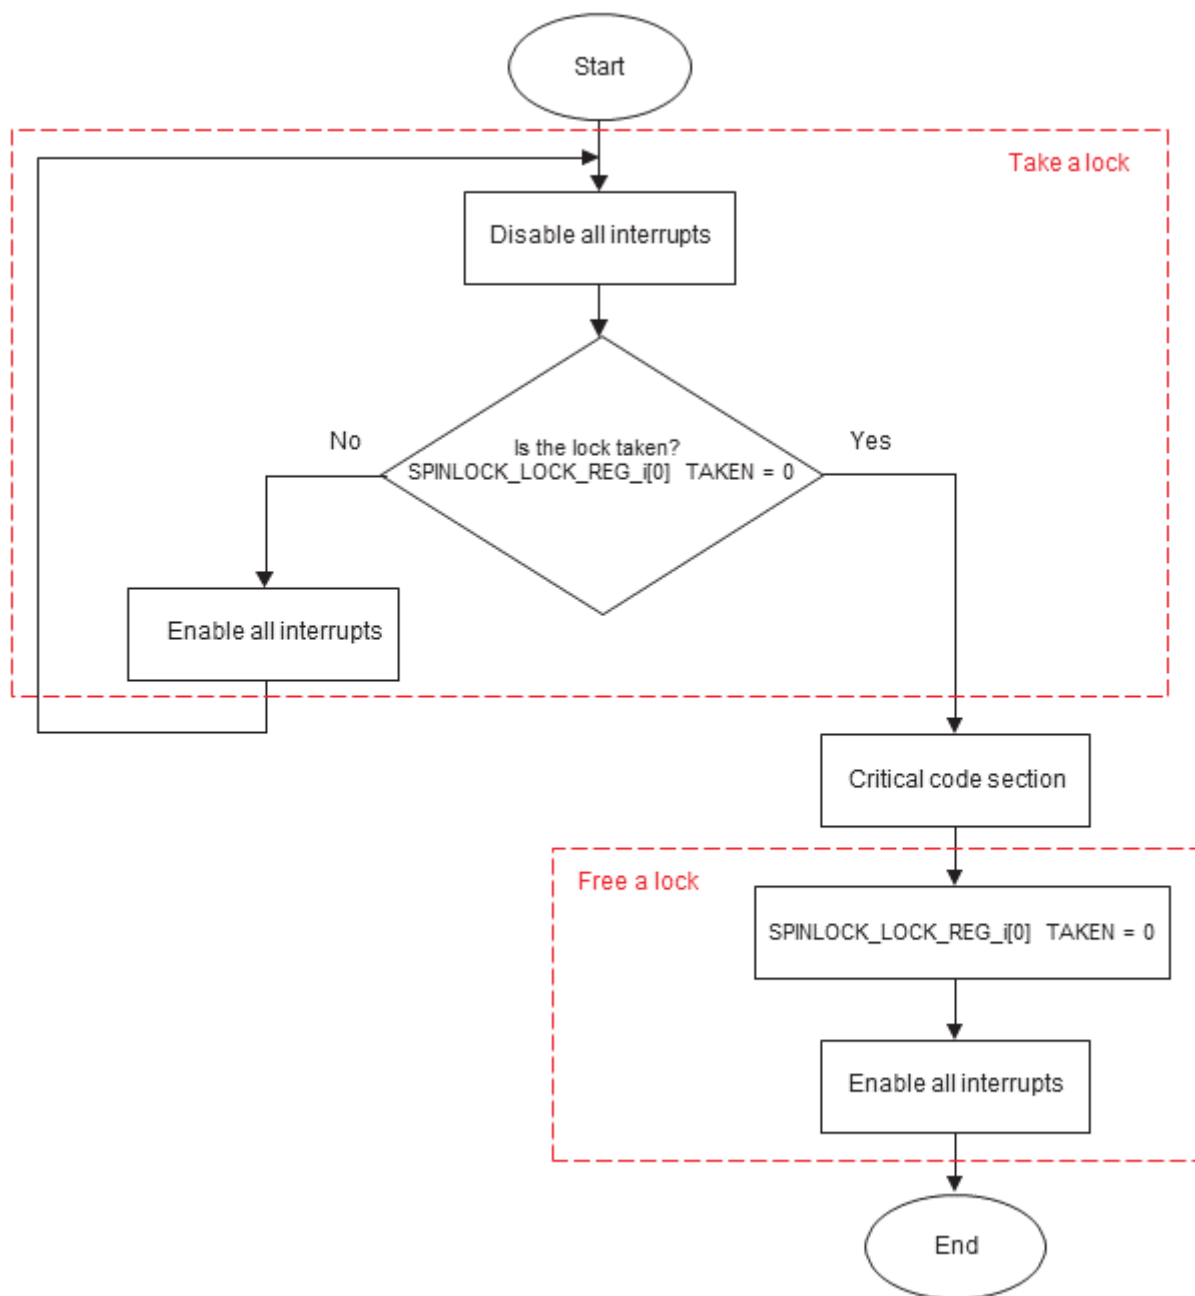

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK\_LOCK\_REG\_y registers at system startup to insure that all locks are initialized to Not Taken.

**Table 7-20. Spinlock System Bug Recovery**

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = 1?	SPINLOCK_SYSTATUS[0] IU0	=1
Free the 256 locks	SPINLOCK_LOCK_REG_y[0] TAKEN (y = 0 to 255)	0x0
END		

##### 7.2.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software must disable interrupts. Then it must read the SPINLOCK\_LOCK\_REG\_y[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it must proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition must be reattempted. To prevent unknown interrupt disabled time, interrupts must be re-enabled and then disabled before reattempting to acquire the lock. [Figure 7-7](#) shows the described above procedure.

**Figure 7-7. Take and Release Spinlock**
**Table 7-21. Register Call Summary**

Register Name
SPINLOCK_LOCK_REG_y[0] TAKEN

**Table 7-22. Subprocess Call Summary**

Subprocess Name	Description
Disable (Mask) All Interrupts	For information about disabling/enabling all interrupts in an Arm® processor, refer to Arm <i>Technical Reference Manual</i> , available at <a href="http://infocenter.arm.com/help/index.jsp">infocenter.arm.com/help/index.jsp</a> .
Enable (Unmask) All Interrupts	For information about disabling/enabling all interrupts in other processors, refer to the corresponding processor chapter.

This chapter describes the memory controllers in the device.

<b>8.1 Multicore Shared Memory Controller (MSMC)</b>	<b>832</b>
<b>8.2 DDR Subsystem (DDRSS)</b>	<b>848</b>
<b>8.3 Virtualization Subsystem (VirtSS)</b>	<b>902</b>
<b>8.4 Region-based Address Translation (RAT) Module</b>	<b>930</b>

## 8.1 Multicore Shared Memory Controller (MSMC)

This section describes the Multicore Shared Memory Controller (MSMC) for the device.

### 8.1.1 MSMC Overview

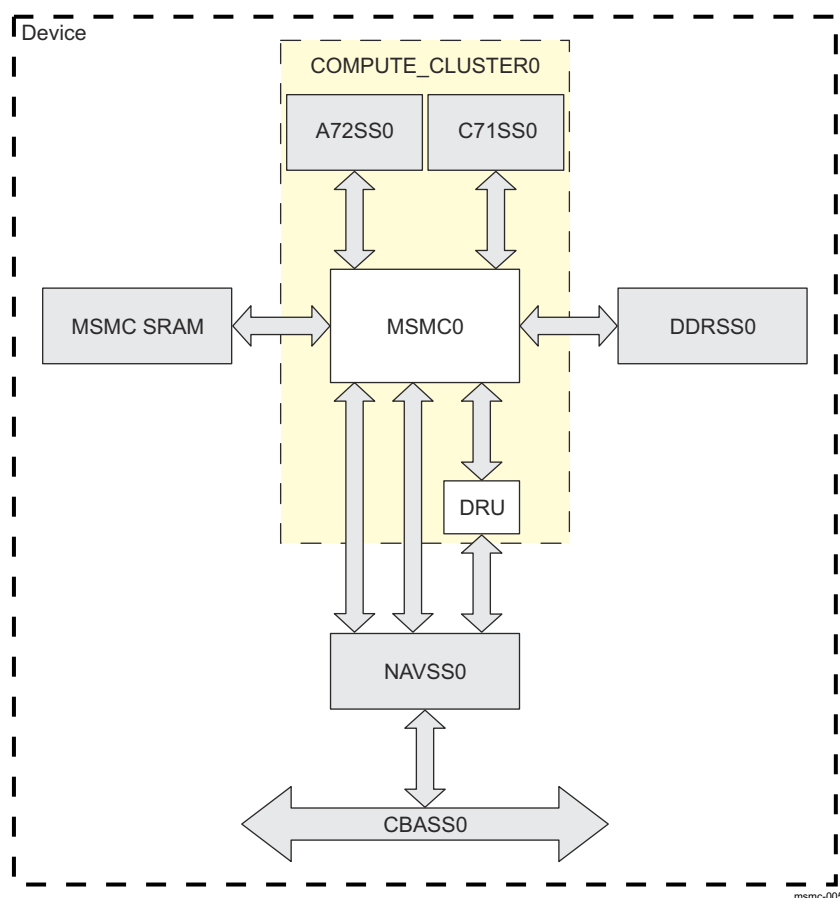

The Multicore Shared Memory Controller (MSMC) forms the heart of the compute cluster (COMPUTE\_CLUSTER0) providing high-bandwidth resource access both to and from all of the connected processing elements and the rest of the system. MSMC serves as the data-movement backbone of the compute cluster.

Table 8-1 shows MSMC modules allocation within device domains.

**Table 8-1. MSMC Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MSMC	-	-	✓

Figure 8-1 shows an overview of the MSMC and its surrounding modules.

**Figure 8-1. MSMC Overview**

MSMC supports the following features:

- 8MB (4 banks x 2MB) SRAM with ECC:
  - Shared coherent level 2/level 3 memory-mapped SRAM
  - Shared coherent level 3 cache
- 512-bit processor port bus and 40-bit physical address bus

- Coherent unified bi-directional interfaces to connect to processors or device masters
- One infrastructure master interface
- Single external memory master interface
- Supports distributed virtual system
- Supports internal DMA engine – DRU (Data Routing Unit)
  - DMA in/out L2 SRAM, MSMC, DDR and system
  - L2, L3 cache pre-warming and post flushing
- Bandwidth management with starvation bound
- Two-level QoS support for real-time/nonreal-time split
- Security firewall flush support for SRAM/cache and external memory
- Functional reliability:
  - SEC/DED protection on all data and tag memories with hardware scrubbing
  - SEC/DED protection on all data pipelines
  - Data memory address hamming protection
  - Coherent interconnect transaction metadata parity protection
- One interconnect messaging interface that supports DMA/prefetch requests to DRU
- Trace and debugging support
- Supports dynamic clock gating on all logic units
- MSMC is always on when VD\_CORE is on

#### 8.1.1.1 MSMC Not Supported Features

MSMC does not support the following:

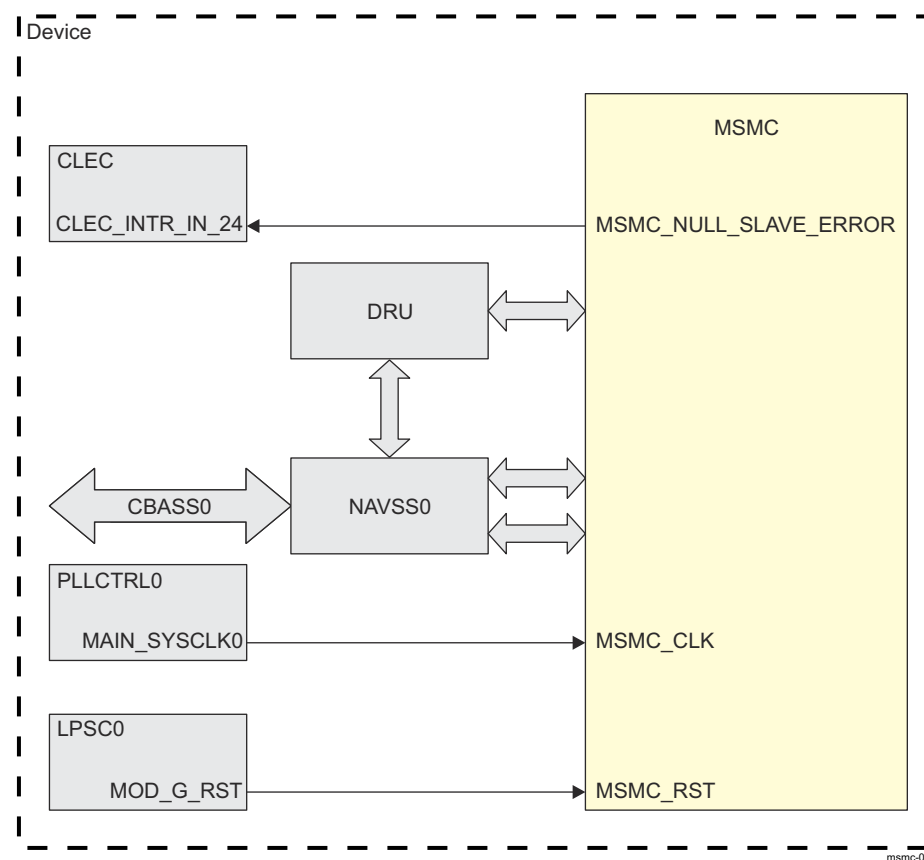

- RAM address decode protection
- Direct cache resize changes from one non-zero cache size configuration to another non-zero cache size configuration. In this case software is required to manually transition down to zero cache size configuration first, followed by a second transition from zero cache size configuration to the new non-zero cache size configuration.
- MSMC SRAM or SDRAM traffic during an MSMC cache resize transition. The traffic during this transition has undefined behavior.

## 8.1.2 MSMC Integration

This section describes MSMC integration in the device, including information about clocks, resets, and hardware requests.

### 8.1.2.1 MSMC Integration in MAIN Domain

A single MSMC module is integrated in the device MAIN domain. [Figure 8-2](#) shows the integration of MSMC.

**Figure 8-2. MSMC Integration**

Table 8-2 through Table 8-4 summarize the integration of MSMC in device MAIN domain.

**Table 8-2. MSMC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MSMC	PSC0	PD0	LPSC0	CBASS0 (Accessed through NAVSS0 NB0 <sup>(1)</sup> and NB1 <sup>(1)</sup> )

## 8.1.2.2

---

**Note**

For more information about the MSMC interrupts, see [Section 8.1.3.8](#).

For more information on the interconnects, see [Chapter 3](#), *System Interconnect*.

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5](#), *Device Configuration*.

For more information on the device interrupt controllers, see [Section 9.2](#), *Interrupt Controllers*.

---

### 8.1.3 MSMC Functional Description

#### 8.1.3.1 MSMC Block Diagram

Figure 8-3 shows a high-level view of the MSMC module that includes the main interfaces, memory, and subunits.

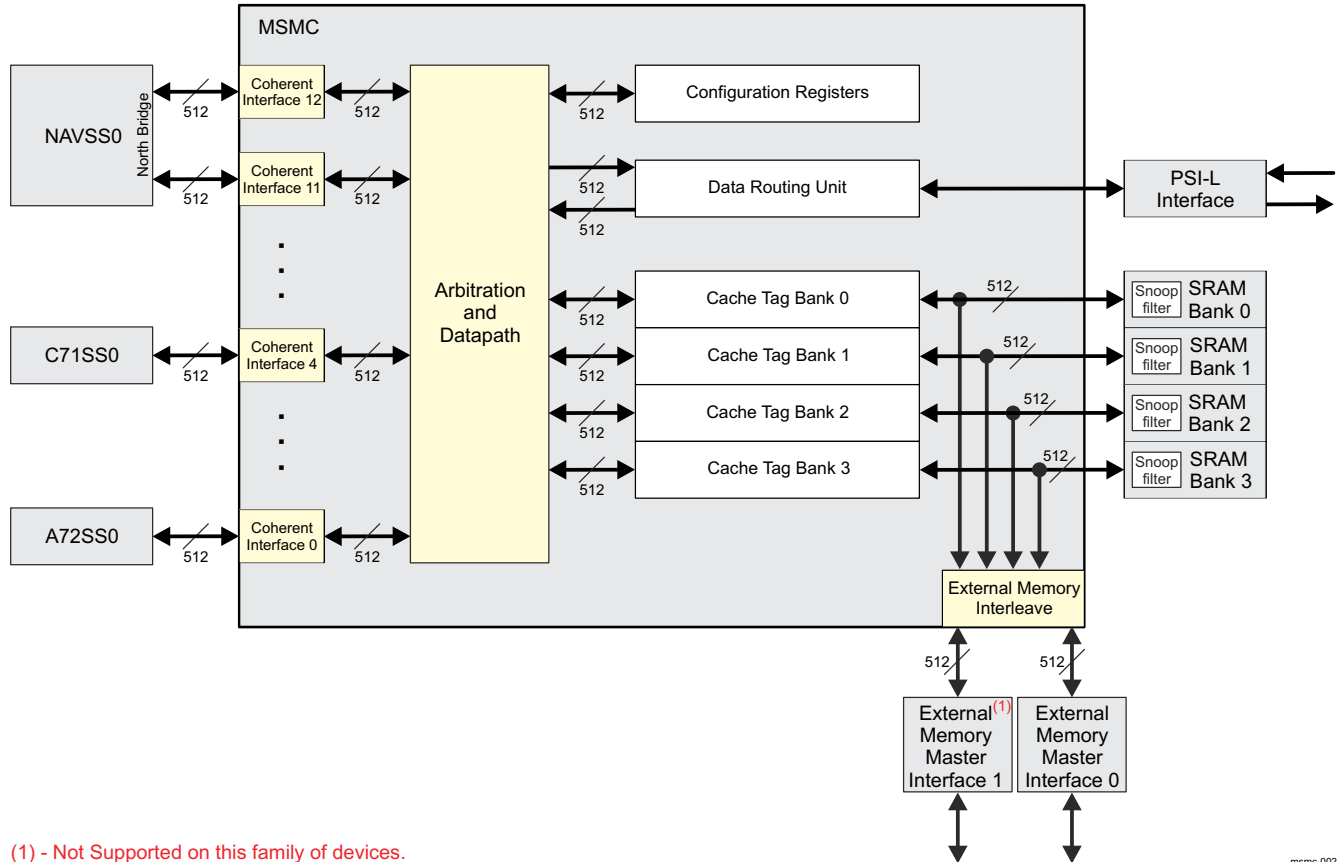

Figure 8-3. MSMC Functional Block Diagram

MSMC directly incorporates on-chip SRAM controllers to provide the compute cluster with low-latency memory. In addition, the individual memory banks can maintain coherence with the connected caching masters as well as the system slave ports.

#### 8.1.3.2 MSMC On-Chip Memory Banking

MSMC on-chip SRAM supports physical and virtual banking to maximize the available bandwidth to all masters. The total SRAM space is divided into four physical banks, and each physical bank contains two virtual sub-banks. These virtual banks provide access to that physical memory bank every MSMC\_CLK cycle.

Figure 8-4 shows the MSMC memory organization. Each SRAM bank provides 64 bytes per MSMC\_CLK cycle.

Figure 8-4. MSMC Memory Organization

### 8.1.3.3 MSMC Snoop Filter and Data Cache

Each MSMC SRAM bank implements the memory-mapped SRAM snoop filter in its own memory structure similar to a cache tag memory. The snoop filter tracks atomic coherent blocks at the same granularity as the level 3 cache for external memory: 128 bytes.

MSMC also implements a combined snoop filter and level 3 cache for the connected external memory space. As with the memory-mapped SRAM, the snoop filter exists to optimize performance of coherent external memory data cached in the attached level 1 and level 2 coherent caches. The external memory snoop filter is a 32-way set-associative cache structure which tracks coherent data at the same granularity as the SRAM snoop filter: 128 bytes.

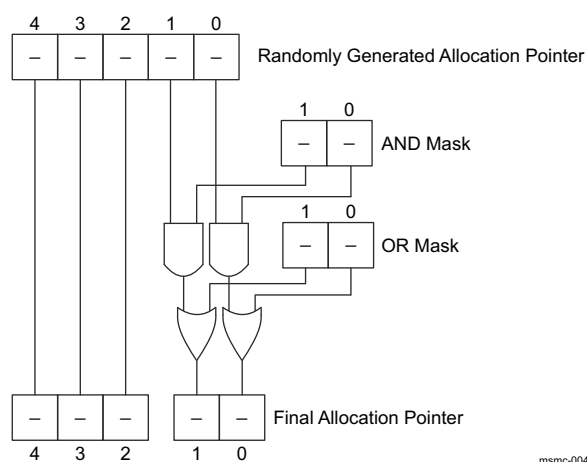

SoC and DRU transactions use snoop filter allocation policy which directs allocations strictly into the data-backed portion (ways) of the L3 cache. Random way selection only occurs when the targeted data-backed or non-data-backed portion (ways) of the L3 cache set are fully occupied. This applies also to CPU transactions, if the `MSMC_CACHE_CTRL[10] ALLOCATION_POLICY` bit is set to 0x0. When the `MSMC_CACHE_CTRL[10] ALLOCATION_POLICY` bit is set to 0x1, all CPU transactions use a randomized allocation policy which can select between both data-backed and non-data-backed ways.

The level 3 snoop filter/cache randomly chooses a way to replace when allocating a new cache line. The foundation of this random replacement is a 24-bit maximal period Linear Feedback Shift Register (LFSR) tuned to minimize any bias. The state of the LFSR supplies two to five bit allocation pointers depending on the configured cache size/number of ways. Each bank houses its own separately initialized LFSR which updates upon each allocation. For debugging purposes, MSMC supplies a linear mode replacement policy which initializes to the configured number of ways, eventually decrement to zero with allocations, and wrap back around to the total number of ways. Software can enable the linear replacement policy by writing 0x1 to the `MSMC_CACHE_CTRL[8] REPLACEMENT_POLICY` bit.

#### 8.1.3.3.1 Way Partitioning

The random replacement implementation attempts to minimize any allocation bias throughout the ways for a large number of allocations. However, it can be useful to introduce purposeful bias to help keep the state of certain tasks resident in the cache. To serve this end, MSMC supports programmable way-partitioning based on real-time versus nonreal-time traffic.

To accomplish this without introducing other unpredictable bias MSMC provides groups of AND-OR masks which can be attached to a group of IDs. The AND-OR masks consist of two fields: a two-bit AND field and a two-bit OR field. MSMC applies these two fields to the lower two bits of the randomly chosen allocation way. [Figure 8-5](#) shows how MSMC calculates the final allocation pointer using the initial random state and the user-defined AND-OR mask.

**Figure 8-5. Way Partition Allocation Pointer Generation**

The two-bit masks allow rough partitioning for quadrants of the cache. Depending on the configured cache size, the cache consists of 0-7 groups of 4 ways each, for a maximum of 32 ways. The upper 3 bits in the allocation pointer determine which group of 4 ways. The final two bits determine selection between the 4 ways within that group. [Table 8-5](#) describes the possible values for the AND-OR mask and the resulting available ways.

**Table 8-5. AND-OR Mask Way Selection**

Way 3	Way 2	Way 1	Way 0	AND Mask	OR Mask
X	X	X	X	11	00
X	X			-1	10
		X	X	01	00
X		X		1-	01
	X		X	10	00
X				--	11
	X			-0	10
		X		0-	01
			X	00	00

The AND-OR masks are programmed via the following bit fields:

- MSMC\_RT\_WAY\_SELECT[6-5] OR\_MASK
- MSMC\_RT\_WAY\_SELECT[1-0] AND\_MASK
- MSMC\_NRT\_WAY\_SELECT[6-5] OR\_MASK
- MSMC\_NRT\_WAY\_SELECT[1-0] AND\_MASK

#### 8.1.3.3.2 Cache Size Configuration and Associativity

MSMC has registers to provide software control to determine which portion of the on-chip SRAM will be used as cache data store. To maximize this flexibility, the associativity of the level 3 data cache scales with the desired cache size. The 32 ways in each snoop filter set are separated into 8 groups of 4 ways each as shown in [Table 8-6](#).

**Table 8-6. Cache Way Grouping**

	Group 0	Group 1	Group 2	Group 3
Way 0	0	4	8	12
Way 1	1	5	9	13
Way 2	2	6	10	14
Way 3	3	7	11	15
	Group 4	Group 5	Group 6	Group 7
Way 0	16	20	24	28
Way 1	17	21	25	29
Way 2	18	22	26	30
Way 3	19	23	27	31

The MSMC\_CACHE\_CTRL[3-0] CACHE\_SIZE bit field controls the cache size by selecting how many way groups are backed with data. [Table 8-7](#) describes the encodings of the CACHE\_SIZE field.

**Table 8-7. Cache Size Field Encodings**

CACHE_SIZE	Number of Active Way Groups	Total Active Data Ways
0x0	0	0 ways
0x1	1	4 ways
0x2	2	8 ways
0x3	3	12 ways
0x4	4	16 ways

**Table 8-7. Cache Size Field Encodings (continued)**

CACHE_SIZE	Number of Active Way Groups	Total Active Data Ways
0x5	5	20 ways
0x6	6	24 ways
0x7	7	28 ways
0x8	8	32 ways

Writing a new value to the CACHE\_SIZE field begins the cache size transition process. The MSMC hardware sets the MSMC\_CACHE\_CTRL[4] SZ\_TRANSITION bit to 0x1 during this transition process. When the transition process completes hardware sets SZ\_TRANSITION to 0x0. During this transition time window:

- Further writes to the CACHE\_SIZE field are ignored
- Reads to the CACHE\_SIZE field reflect the previous field value.

After setting a new CACHE\_SIZE value, software can poll the SZ\_TRANSITION bit to know when the transition is complete. At that point the new CACHE\_SIZE value can be read in the MSMC\_CACHE\_CTRL[3-0] CACHE\_SIZE bit field.

As the cache scales up in size, the memory-mapped space shrinks by the same amount, appearing as though the cache grows from the top of the memory mapped region down. This provides a single contiguous memory-mapped window starting from the SRAM base address. The memory space occupied by the cache is no longer accessible as memory-mapped SRAM and any accesses to this space return an addressing error.

#### 8.1.3.4 MSMC Access Protection Checks

To support potential software polling/reconfiguration for functional reliability, MSMC does not trigger error status for configuration accesses to unimplemented addresses. All reads of unimplemented addresses return data as zero and writes are ignored. This model should support a simple DMA "read, compare, and write-back" model for checking the MSMC configuration state.

#### 8.1.3.5 MSMC Null Slave

MSMC implements a null slave endpoint to handle accesses which cannot be sent to their intended destination. This can happen for several reasons listed in [Table 8-8](#). Commands routed to null slave return to the originating master with the appropriate response status listed in [Table 8-8](#). MSMC prioritizes protection error status over addressing error status when both can be applied to a single command.

**Table 8-8. Null Slave Response Status**

Description	Response Status
Firewall Flush	Protection Error
Invalid Memory Range	Addressing Error
Coherent Command to DMA	Success
Disabled Endpoint	Addressing Error
Real-time to DMA	Addressing Error

MSMC captures command information and triggers an event when routing unexpected command to null slave. Any of the conditions in [Table 8-8](#) which respond with a faulted response status (except firewall failures) triggers null slave error interrupt and logs appropriate command information to the MSMC\_NULL\_SLV\_STAT0 and MSMC\_NULL\_SLV\_STAT1 registers. The following bit fields capture that command information:

- ADDR
- BYTECNT
- ROUTEID
- PRIVID
- OPCODE
- MEMTYPE
- EMU

- SEC
- PRIV

For more information about the MSMC interrupts, see [Section 8.1.3.8](#).

MSMC captures a single null slave error event into the MSMC\_NULL\_SLV\_STAT0 and MSMC\_NULL\_SLV\_STAT1 registers.

#### 8.1.3.6 MSMC Resource Arbitration

When access requests arrive at the MSMC slave ports, the requests may target the same endpoint and hence need arbitration. These endpoint arbiters implement a multi-layer fairness arbitration scheme with starvation bounds to allow the user control to partition system bandwidth.

In each arbitration cycle, each arbiter prioritizes all active requests using the following prioritized layers until it selects a unique winner:

1. Transaction-tagged priority - Each active requestor pushes out a priority based on all of the currently active transactions in its pipeline. The highest priority requestors are chosen.
2. Fair-Share State - The arbiter selects the requestor(s) with the highest internal Fairshare state.
3. Static Priority - Finally, the arbiter uses a static priority to break any remaining ties after levels 1 and 2.

In addition to the three levels the arbiter tracks a starvation count for each requestor to each arbiter. Every time a request wins arbitration, all loser requests have their starvation count decremented. Every time a requestor wins arbitration for an active request, the starvation count resets to the initial state. If the starvation count reaches zero, that requestor priority level elevates to the highest priority level. Once the starved active request wins arbitration the priority level reverts back to the normal value. These starvation bounds can be programmed via the MSMC\_SBNDCOH0 through MSMC\_SBNDCOH12 registers.

#### Note

Not all MSMC\_SBNDCOHx registers are used on this device.

The three-layer arbitration scheme is not sufficient to ensure a bound on the minimum bandwidth experienced by lower priority requests relative to higher priority requests. Consequently, a starvation bound can be defined to limit that minimum bandwidth experienced by the lower priority requests relative to higher priority requests.

Since MSMC introduces multiple virtual channels feeding the same physical arbiter, the starvation mechanism is expanded to specify bounds for these channels.

**Table 8-9. Starvation Bound Definitions**

Port	Channel	Resource Target	Register Name and Field
Cache coherent 0	Real-time	External memory	MSMC_SBNDCOH0[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH0[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH0[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH0[7-0] SBNDM_NRT
Cache coherent 4	Real-time	External memory	MSMC_SBNDCOH4[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH4[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH4[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH4[7-0] SBNDM_NRT
Cache coherent 11	Real-time	External memory	MSMC_SBNDCOH11[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH11[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH11[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH11[7-0] SBNDM_NRT

**Table 8-9. Starvation Bound Definitions (continued)**

Port	Channel	Resource Target	Register Name and Field
Cache coherent 12	Real-time	External memory	MSMC_SBNDCOH12[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDCOH12[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDCOH12[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDCOH12[7-0] SBNDM_NRT
DRU	Real-time	External memory	MSMC_SBNDDRU[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDDRU[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDDRU[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDDRU[7-0] SBNDM_NRT
Responses Snoops	Real-time	External memory	MSMC_SBNDRRESP[55-48] SBNDE_RT
		On-chip resources	MSMC_SBNDRRESP[39-32] SBNDM_RT
	Non-real-time	External memory	MSMC_SBNDRRESP[23-16] SBNDE_NRT
		On-chip resources	MSMC_SBNDRRESP[7-0] SBNDM_NRT

The starvation bounds specified through the registers in [Table 8-9](#) apply to each trip an access requires through an arbitration point. The number of potential arbitrations should be considered when programming the starvation bounds. The following are few common examples of round-trip command arbitration for reads:

- Non-coherent SRAM read: Command central arbitration > Data SRAM arbitration > Response central arbitration
- Coherent SRAM read: Command central arbitration > Snoop central arbitration > Snoop response central arbitration > Read response central arbitration

Depending on whether caching and coherence are enabled and the state of the system, the number of potential arbitrations for a given access may vary and starvation should be considered accordingly.

#### 8.1.3.7 MSMC Error Detection and Correction

MSMC protects both on-chip memory resources and data busses throughout the MSMC pipelines. A mixture of SEC/DED (single-error correct/double-error detect) hamming code and simple parity protect the on-chip memory resources.

#### Note

MSMC aligns to the device architecture for system reliability using ECC aggregators to report detected parity and EDC faults both from scrubbing and functional access. The MSMC associated ECC aggregators are part of COMPUTE\_CLUSTER0. For more information, see [Section 6.1.2.3 Compute Cluster ECC Aggregators](#) in [Section 6.1 Compute Cluster](#).

For information about the ECC aggregator functionality, see [Section 12.11.4 ECC Aggregator](#).

##### 8.1.3.7.1 On-chip SRAM and Pipeline Data Protection

The on-chip data memory and data bus pipelines share the same Hamming EDC strategy to maximize protection across MSMC. Two EDC data/hamming pairs combine to form each 64 bytes of data. When functional accesses read data from the memory the EDC code travels through the MSMC pipeline with the data protecting all of those data pipelines in addition to the memory. Consumers of the protected data pairs should perform the EDC check and correction as needed before utilizing the data.

MSMC does not protect stored memory data all of the time. This requires memory initialization after reset to avoid spurious errors. In addition, read-modify-write combine cycle is also needed in case of any write access to the memory that does not commit to a full EDC quanta.

MSMC stores each 532-bit data + hamming code separately in the on-chip SRAM in the following way:

- SRAM[255:0] -> 256-bit Data Word 0
- SRAM[265:256] -> 10-bit Hamming Word 0
- SRAM[266:521] -> 256-bit Data Word 1
- SRAM[531:522] -> 10-bit Hamming Word 1

#### 8.1.3.7.2 On-chip SRAM L3 Cache Tag and Snoop Filter Protection

The level 3 cache/snoop filter tags stored in on-chip SRAM are also SEC/DED protected similarly to the data storage. Due to timing closure including all of the tag bits for a given set into one hamming data + code word is not possible. Instead, the 32 ways are broken into 8 groups of 4 ways each comprising hamming data (100 bits) + code (9 bits). The MSMC core logic outputs 8 logical SRAM interfaces for the tag memories based on the EDC protection quanta sizes. The hamming protection bits are stored at the most significant bit positions of the total data + hamming word inside the logical memory instance.

#### 8.1.3.7.3 On-chip SRAM Memory Mapped SRAM Snoop Filter Protection

MSMC stores the memory mapped SRAM snoop filter state in a separate memory from the tags and protects this information with simple parity. Each snoop filter entry requires five data bits and eight coherent blocks are stored together as a parity data word, resulting in one parity bit to every 40 data bits. The parity bit resides at the most significant bit position in the total parity + data word.

#### 8.1.3.7.4 Background Parity Refresh (Scrubbing)

The MSMC has scrubbing engine that periodically cycles through each location of each memory bank in the MSMC, reading and correcting the data, recalculating the parity bits for the data and storing the data and parity information.

The frequency with which each scrubbing cycle is initiated and the delay between each burst by the scrubbing engine is programmed using the MSMC\_SMEDCC register. The MSMC\_SMEDCC[7-0] REFDEL bitfield controls the number of MSMC\_CLK cycles between each scrub. To prevent the bursts from the scrubbing engine from posing a significant performance impact, the value in the REFDEL field is pre-scaled by 1024 in functional mode. A value of 0 is interpreted to be the same as a value of 1. At reset, REFDEL = 0 and a new scrub burst is issued 1024 cycles after the previous one ends. The operation of the scrubbing engine is enabled by default at reset but may be disabled by setting the MSMC\_SMEDCC[31] SEN bit to 0x0.

#### 8.1.3.8 MSMC Interrupts

The MSMC has the following registers for interrupt control:

- MSMC\_SMIRSTAT - Raw interrupt status
- MSMC\_SMIRWS - Raw interrupt software set
- MSMC\_SMIRC - Raw interrupt software clear
- MSMC\_SMIESTAT - Enable interrupt status
- MSMC\_SMIIEWS - Enable interrupt software set
- MSMC\_SMIIEC - Enable interrupt software clear
- MSMC\_SMESTAT - Raw and Enabled Interrupt Status

Each bit in these registers represents a single event or interrupt supported by MSMC, which generates only one interrupt. This is the null slave error interrupt (MSMC\_NULL\_SLAVE\_ERROR). MSMC sets this event when routing a command through the MSMC null slave port which results in an unsuccessful response status. Commands failing firewall checks do not trigger the null slave error interrupt event in MSMC.

##### 8.1.3.8.1 Raw Interrupt Registers

MSMC sets the associated bit in the MSMC\_SMIRSTAT register when a software or hardware event occurs. Software can trigger the event by setting the corresponding bit in the MSMC\_SMIRWS register. MSMC keeps the MSMC\_SMIRSTAT bit asserted until software clears it by setting the corresponding bit in MSMC\_SMIRC. Both MSMC\_SMIRWS and MSMC\_SMIRC are write-only registers and do not implement any actual state.

### 8.1.3.8.2 Interrupt Enable Registers

Software can enable an event by setting the associated bit in the MSMC\_SMIEWS register, and MSMC will assert the same bit in the MSMC\_SMIESTAT register in response. The bit of MSMC\_SMIESTAT remains asserted until software disables the event by setting the corresponding bit in the MSMC\_SMIEC register. Both MSMC\_SMIEWS and MSMC\_SMIEC are write-only registers and do not implement any actual state.

### 8.1.3.8.3 Triggered and Enabled Interrupts

The MSMC\_SMIESTAT register is a read-only reflection of events that are both triggered and enabled. It is a combination of MSMC\_SMIRSTAT and MSMC\_SMIESTAT.

### 8.1.3.9 MSMC Memory Regions

Device masters access MSMC controlled resources through two memory map windows - internal and external.

[Table 8-10](#) shows all MSMC associated memory regions including detailed breakdown of the MSMC internal memory mapped window.

**Table 8-10. MSMC Memory Regions**

Region	Start Address	End Address	Region Size
Internal memory mapped window			
MSMC Coherent Interface for A72SS0	0x00 6000 0000	0x00 60FF FFFF	16 MB
MSMC Coherent Interface for C71SS0	0x00 6400 0000	0x00 64FF FFFF	16 MB
MSMC Coherent Interface for the NB0 Port of North Bridge in NAVSS0	0x00 6B00 0000	0x00 6BFF FFFF	16 MB
MSMC Coherent Interface for the NB1 Port of North Bridge in NAVSS0	0x00 6C00 0000	0x00 6CFF FFFF	16 MB
DRU Configuration Registers	0x00 6D00 0000	0x00 6DFF FFFF	16 MB
MSMC Configuration Registers <sup>(1)</sup>	0x00 6E00 0000	0x00 6EFF FFFF	16 MB
MSMC SRAM	0x00 7000 0000	0x00 707F FFFF	8 MB
External memory mapped window			
2 GB External SDRAM Space	0x00 8000 0000	0x00 FFFF FFFF	2 GB
8 GB External SDRAM Space <sup>(2)</sup>	0x08 0000 0000	0x09 FFFF FFFF	8 GB
Other MSMC associated memory regions			
Compute Cluster ECC Aggregator 0 Configuration Registers	0x4D 2000 0000	0x4D 2000 03FF	1 KB
Compute Cluster ECC Aggregator 1 Configuration Registers	0x4D 2000 0400	0x4D 2000 07FF	1 KB
Compute Cluster ECC Aggregator 2 Configuration Registers	0x4D 2000 0800	0x4D 2000 0BFF	1 KB

(1) The MSMC configuration space supports 1-, 2-, 4- and 8-byte aligned reads and 4- and 8-byte aligned writes.

(2) The first 2 GB of this region are inaccessible.

As shown in [Table 8-10](#) software accesses the memory-mapped on-chip SRAM as part of the MSMC memory mapped space.

### 8.1.3.10 MSMC Hardware Coherence

MSMC supports hardware cache coherence between CPU cache-coherent masters and peripherals accessing MSMC through the system slave ports for shared SRAM and DDR data range spaces. Hardware coherence support abstracts away the cache memory systems of supported components from software, simplifying software implementation.

MSMC does not support memory coherence for the following spaces:

- DDRSS configuration space
- MSMC configuration space

- System-on-chip master port peripherals/memory
- CPU local resources such as memory-mapped level 2 SRAM
- Any other memory not directly connected to MSMC

To stay coherent with each other, caches inside coherent masters typically track more states than the traditional valid/dirty combinations. MSMC uses the ACE coherence protocol which supports these five MOESI states:

- Modified - Cache line is unique (no other caches currently have it) and dirty
- Owned - Cache line is shared (other caches may have it) and dirty
- Exclusive - Cache line is unique (no other caches have it) and clean
- Shared - Cache line is shared (other caches may have it) and clean
- Invalid - No allocated line

In order to maintain coherence between cached masters, MSMC can initiate requests to coherent masters for shared regions of memory. These requests are referred to as "snoop requests".

The following example demonstrates how coherence is maintained between DMA and CPU, when DMA writes to shareable memory space.

1. DMA (noncaching master) issues a write to shareable space.
2. MSMC coherence controller issues Invalidate and Writeback snoop to all CPUs.
3. All CPUs invalidate the line from their cache and respond with dirty data if necessary
4. MSMC merges the DMA write data with the victim and commits to memory.

The following example demonstrates how coherence is maintained between DMA and CPU, when DMA reads from shareable memory space.

1. DMA issues a read to shareable space.
2. MSMC coherence controller issues a ReadOnce snoop to the CPU.
3. CPU responds with cached data.
4. MSMC returns the read data to DMA.

#### 8.1.3.10.1 Snoop Filter Broadcast Mode

As described in [Section 8.1.3.3](#) MSMC implements inclusive snoop filters for both memory-mapped SRAM and external memory shared space to limit the amount of required snoop traffic. Both the SRAM and external snoop filters encode the following states for each coherent memory block in their respective filtering structures:

- INVALID - This memory block must be in Invalid state in all coherent CPUs. Since the external snoop filter is inclusive of all cached coherent data, a miss in the snoop filter is functionally equivalent to this state.
- CPU\_SHARED - This memory block may be cached in Shared or Owned state in the associated coherent CPU.
- CPU\_UNIQUE - This memory block may be cached in Shared, Owned, Exclusive, or Modified state in the associated coherent CPU.
- BROADCAST\_SHARED - This memory block may be cached in Shared or Owned states in multiple coherent CPUs.
- BROADCAST\_UNIQUE - This memory block may be cached in Shared, Owned, Exclusive, or Modified states in multiple coherent CPUs. Typically lines only reach this state when MSMC encounters a snoop filter parity error or broadcast mode is enabled.

As a safeguard MSMC provides a "Broadcast Mode" configuration that forces MSMC to treat all snoop filter entries as BROADCAST\_UNIQUE. This results in snoops generated to all applicable coherent masters for snoop filter hits. This mode can be toggled on and off, but the user should be aware that the snoop filter becomes no longer strictly inclusive once enabled since snoop filter entries accessed during this mode are no longer accurately tracking line ownership. Coherency is still maintained in this mode, though additional potentially unnecessary snoop activity may occur. To enable the broadcast mode feature the MSMC\_COHCTRL[0] BCM bit should be set to 0x1.

### 8.1.3.11 MSMC Quality-of-Service

As an orthogonal axis to arbitration priority MSMC provides two classes of traffic, real-time (RT) and nonreal-time (NRT), to maintain quality-of-service (QoS) guarantees and alleviate head-of-line blocking issues. The currently implemented dataflows supported by the QoS hardware are:

- SoC coherent slave - MSMC SRAM
- SoC coherent slave - External memory
- DRU coherent slave - MSMC SRAM
- DRU coherent slave - External memory

At a high-level priority and QoS represent orthogonal axes controlling the latency (priority) and bandwidth protection (QoS) for multiple data flows routed through the MSMC. To accomplish this MSMC provides a dedicated buffering at each arbitration point that can only be consumed by RT traffic. This way NRT traffic cannot completely starve out RT requests.

The SoC coherent, DRU coherent, and external memory interfaces need dedicated credits to support QoS. Each of these interfaces implements additional threading to exchange these dedicated credits.

**Table 8-11. QoS Threading**

Thread Index	[0]	[2]
SoC Coherent Slave	CPU	RT_CPU
DRU Coherent Slave	CPU	RT_CPU
External Memory Master	CPU	RT_CPU

The RT\_CPU thread provides a completely separate pool of credits, where necessary, to implement the dedicated buffers for RT traffic.

#### Note

There is no software control over the MSMC QoS hardware.

#### Note

Interfaces which do not support QoS features denote all traffic as nonreal-time.

### 8.1.3.12 MSMC Memory Regions Protection

There is no built-in firewall to protect the on-chip and external memory regions. MSMC relies on the system distributed firewall structure to protect these memory windows. MSMC receives a "pass/fail" attribute on each of its entry points including the DRU interfaces which it uses to route the transaction to either the addressed endpoint (pass) or to the internal null slave (fail). Transactions carrying the "fail" return Protection Error on read or write status. Since these failed transactions route through the null slave endpoint no snoops, allocations, or other hardware side-effects occur as a result of these transactions.

### 8.1.3.13 MSMC Cache Tag View

MSMC implements debug hardware to allow software to query the state of the SRAM snoop filter and L3 cache tag/snoop filter. Software can query the tag structures using the MSMC\_DBGTAGCTL and MSMC\_DBGTAGVIEW registers in the following sequence:

1. Write the desired tag or snoop filter information to the MSMC\_DBGTAGCTL register and wait for status return
2. Read the MSMC\_DBGTAGVIEW register to collect the values populated from step 1

The write in step 1 triggers population of the MSMC\_DBGTAGVIEW register with the appropriate values from the tag or snoop filter memory. The following are important notes about this feature:

- Writing invalid values into the MSMC\_DBGTAGCTL register results in undefined values in the MSMC\_DBGTAGVIEW register.
- All writes to MSMC\_DBGTAGCTL triggers re-population of MSMC\_DBGTAGVIEW, regardless of whether MSMC\_DBGTAGVIEW has been read since the last write to MSMC\_DBGTAGCTL
- This feature is intended for debug use when the system is halted or quiet. If software writes MSMC\_DBGTAGCTL during active operation MSMC will find an empty cycle on the tag/snoop filter memory to read the contents and return to MSMC\_DBGTAGVIEW. However, if there are accesses in flight which operate on the desired tag or snoop filter block the contents of MSMC\_DBGTAGVIEW will reflect whatever was in the memory at the time of read.
- Security considerations for cache tag view must be comprehended in the firewalls present before all MSMC request interfaces. MSMC does not perform additional security checks.

## 8.2 DDR Subsystem (DDRSS)

This section describes the DDR Subsystem (DDRSS) for the device.

### 8.2.1 DDRSS Overview

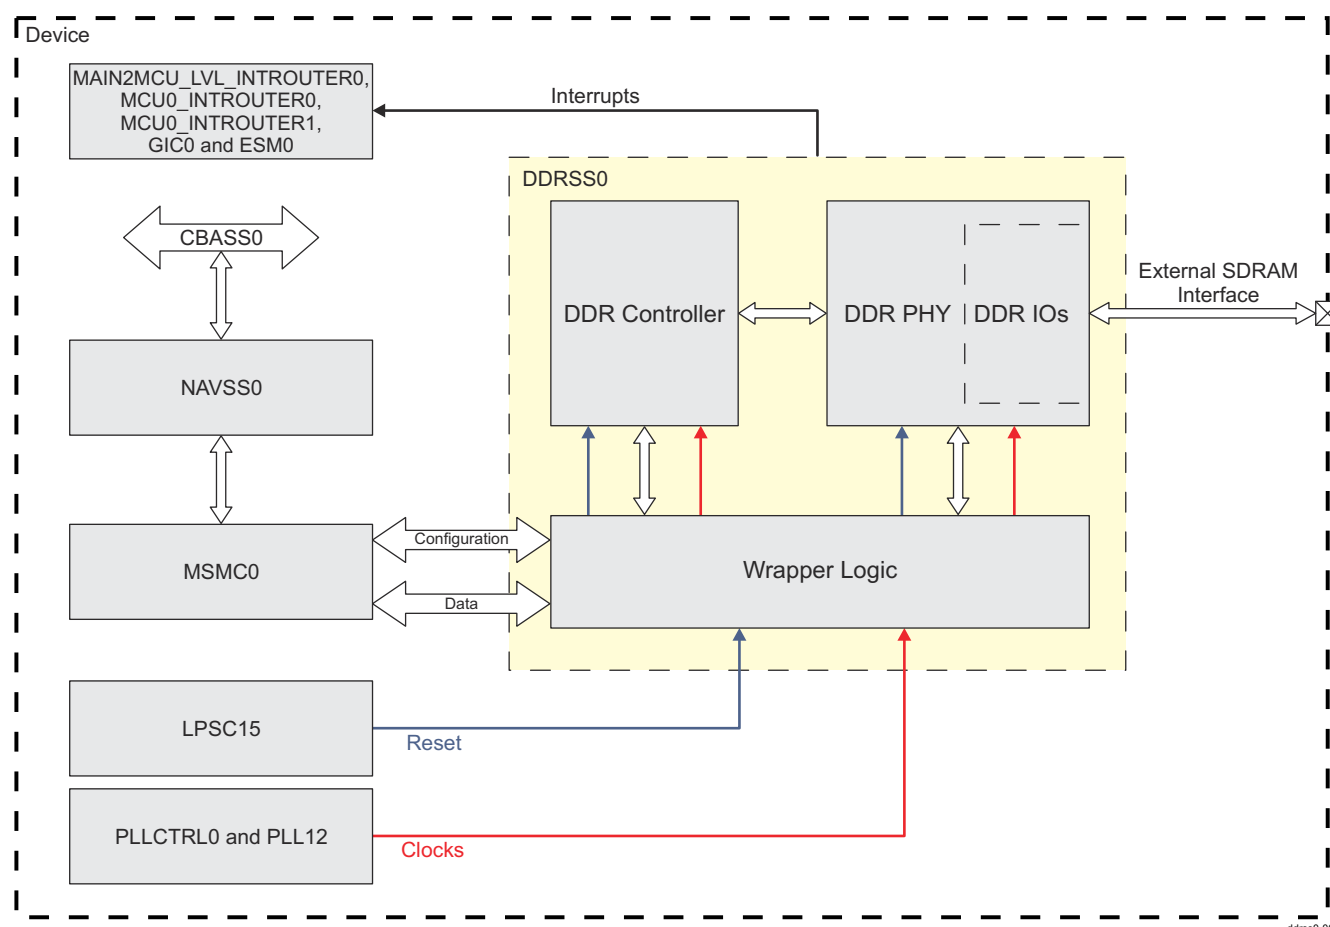

The DDR subsystem in this device comprises DDR controller, DDR PHY and wrapper logic to integrate these blocks in the device. The DDR subsystem is referred to as DDRSS0 and is used to provide an interface to external SDRAM devices which can be utilized for storing program or data. DDRSS0 is accessed via MSMC, and not directly through the system interconnect.

Table 8-12 shows DDRSS modules allocation within device domains.

**Table 8-12. DDRSS Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DDRSS0	-	-	✓

Figure 8-6 shows an overview of the DDRSS0 and its surrounding modules.

**Figure 8-6. DDRSS Overview**

The DDRSS0 supports:

- Memory Types:
  - LPDDR4
- Memory Bus Features:

- 32-bit width with in-line ECC
- Up to 2 ranks (in one package)
- SDRAM address range up to 8 GB
- System Bus Interface:
  - 512-bit data width
  - Little endian only
  - Address aliasing prevention to block accesses to unpopulated SDRAM region
  - Clock asynchronous to DDR clock
- Configuration Bus Interface:
  - 32-bit data width
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
  - Clock asynchronous to DDR clock
- Key Features:
  - Full coherency across all commands
  - Bank interleaving
  - Priority based scheduling
  - Scheduling based on bank openness
  - Class of Service (CoS) - Three latency classes supported
  - Read/write scheduling to avoid turn-around time
  - Prioritized refresh scheduling
  - Dynamic change of refresh rate via software for extended temperatures
  - Statistical counters for performance management
- SDRAM ECC Features:
  - In-line ECC
  - Read-modify-write ECC for sub-word writes
  - ECC address error logging
  - Statistical counters for counting ECC errors
  - Injecting ECC errors during normal operation for validation
- Low Power Features:
  - Self-refresh entry and exit via software or hardware clock stop request
  - System bus clock stop via hardware clock stop request when controller is idle
  - Automatic idle power saving mode when no or low activity is detected
  - DDR and system bus clock frequency change using self-refresh via software or hardware clock stop request
  - Turning off SoC power after DDR is put into self-refresh (DDR reset and CKE I/O retention)
  - Tri-stating of all DDR I/O cells via software while driving CKE and RSTN pins during self-refresh
  - LPDDR4 Frequency Set Point (FSP)
  - I/O retention managed by an external device through dedicated pin
- Functional Reliability Features:
  - ECC on data pipe
  - Parity on address and command pipes
  - Data EDC on the master port interface
  - Command parity on the master port interface
  - Data EDC on the configuration port interface
  - Command parity on the configuration port interface
  - MSMC2DDR bridge AXI bus timeout
- DDR PHY Features:
  - Automatic and software controllable initialization and calibration (ZQ) for the DDR PHY and I/O cells
  - Automatic and software controllable delay line calibrations with Voltage and Temperature (VT) compensation

- Automatic and software controllable write levelling with VT compensation
- Automatic read DQS gate training per rank with VT compensation
- Automatic and software controllable DQ/DQS eye training per rank
- Automatic and software controllable read and write data bit deskew
- Automatic and software controllable Command/Address (CA) levelling with VT compensation for LPDDR4
- Automatic and software controllable CA bit deskew for LPDDR4
- Refreshes to SDRAM during leveling and training
- No seeding requirement based on board topology for any of the leveling and training algorithms
- Dynamic/automatic I/O Receiver disable when read transfer is not on going
- Capability of disabling data macros and I/O cells when not in use

#### 8.2.1.1 DDRSS Not Supported Features

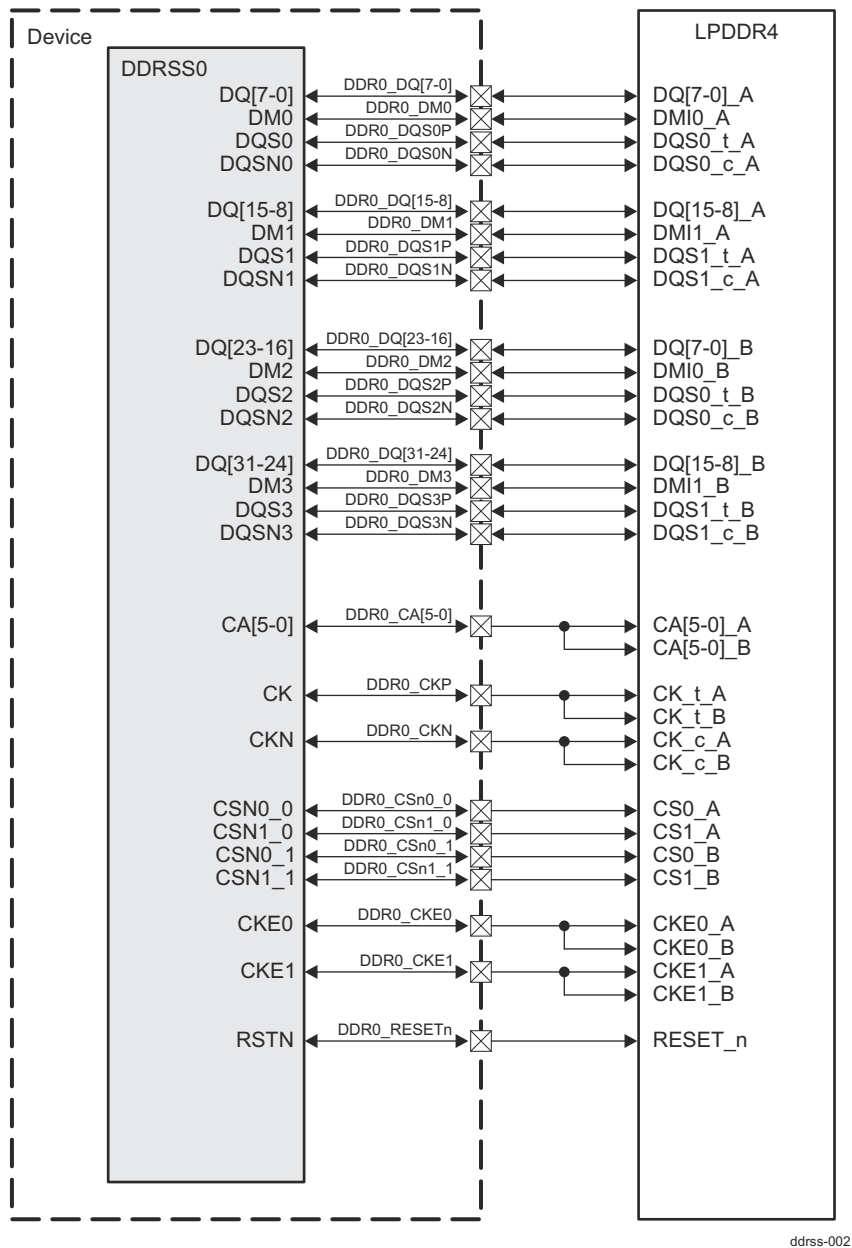

DDRSS0 does not support the following:

- DDR3 SDRAMs
- DDR3L SDRAMs
- DDR3U SDRAMs
- DDR4 SDRAMs
- DIMM
- 1/4 width (8-bit) mode via software configuration
- Data bus obfuscation or any other kind of encryption
- Fail-safe reset I/O to maintain reset state during SoC power OFF
- Independent, 16-bit, two-channel operation for LPDDR4
- The ECC engine of the DDR controller
- No support for byte mode, or memories with more than 17 row address bits

## 8.2.2 DDRSS Environment

This section describes the DDRSS0 external connections (environment).

Figure 8-7 shows an example connection to dual rank LPDDR4 x32 device.

ddrss-002

Figure 8-7. LPDDR4 Connection

Table 8-13 describes the DDRSS0 I/O signals used for connection to SDRAM devices.

**Table 8-13. DDRSS0 I/O signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
RSTN	DDR0 RSTN	I/O	SDRAM reset	0x0
CKE[1-0]	DDR0 CKE[1-0]	I/O	SDRAM CKE[1-0] signals	0x0
CK	DDR0 CKP	I/O	SDRAM differential clock pair	0x0
CKN	DDR0 CKN			0x1

**Table 8-13. DDRSS0 I/O signals (continued)**

Module Pin	D e v i c e L e v e l S i g n a l	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
CSN0_0	D D R 0   C S n 0   0	I/O	SDRAM chip select 0 (two copies of CS0) <sup>(3)</sup>	0x0
CSN0_1	D D R 0   C S n 0   1			0x0
CSN1_0	D D R 0   C S n 1   0	I/O		0x0
CSN1_1	D D R 0   C S n 1   1			0x0

**Table 8-13. DDRSS0 I/O signals (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
CA[5-0]	DDR0 [CA[5-0]	I/O	SDRAM address and command bus	HiZ
DQS[3-0]	DDR0 [DQS[3-0]P	I/O	SDRAM data strobe	HiZ
DQSN[3-0]	DDR0 [DQS[3-0]N	I/O	SDRAM data strobe invert	HiZ
DQ[31-0]	DDR0 [DQ[31-0]	I/O	SDRAM data bus	HiZ

**Table 8-13. DDRSS0 I/O signals (continued)**

Module Pin	D e v i c e L e v e l S i g n a l	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
DM[3-0]	D D R 0 [ D M [ 3 - 0 ]	I/O	SDRAM data mask/DBI	HiZ
RET	D D R [ R E T	I/O	External I/O retention enable	-

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Chip select for each channel is controlled independently during CA training, but they run in locked-step during normal operation.

#### Note

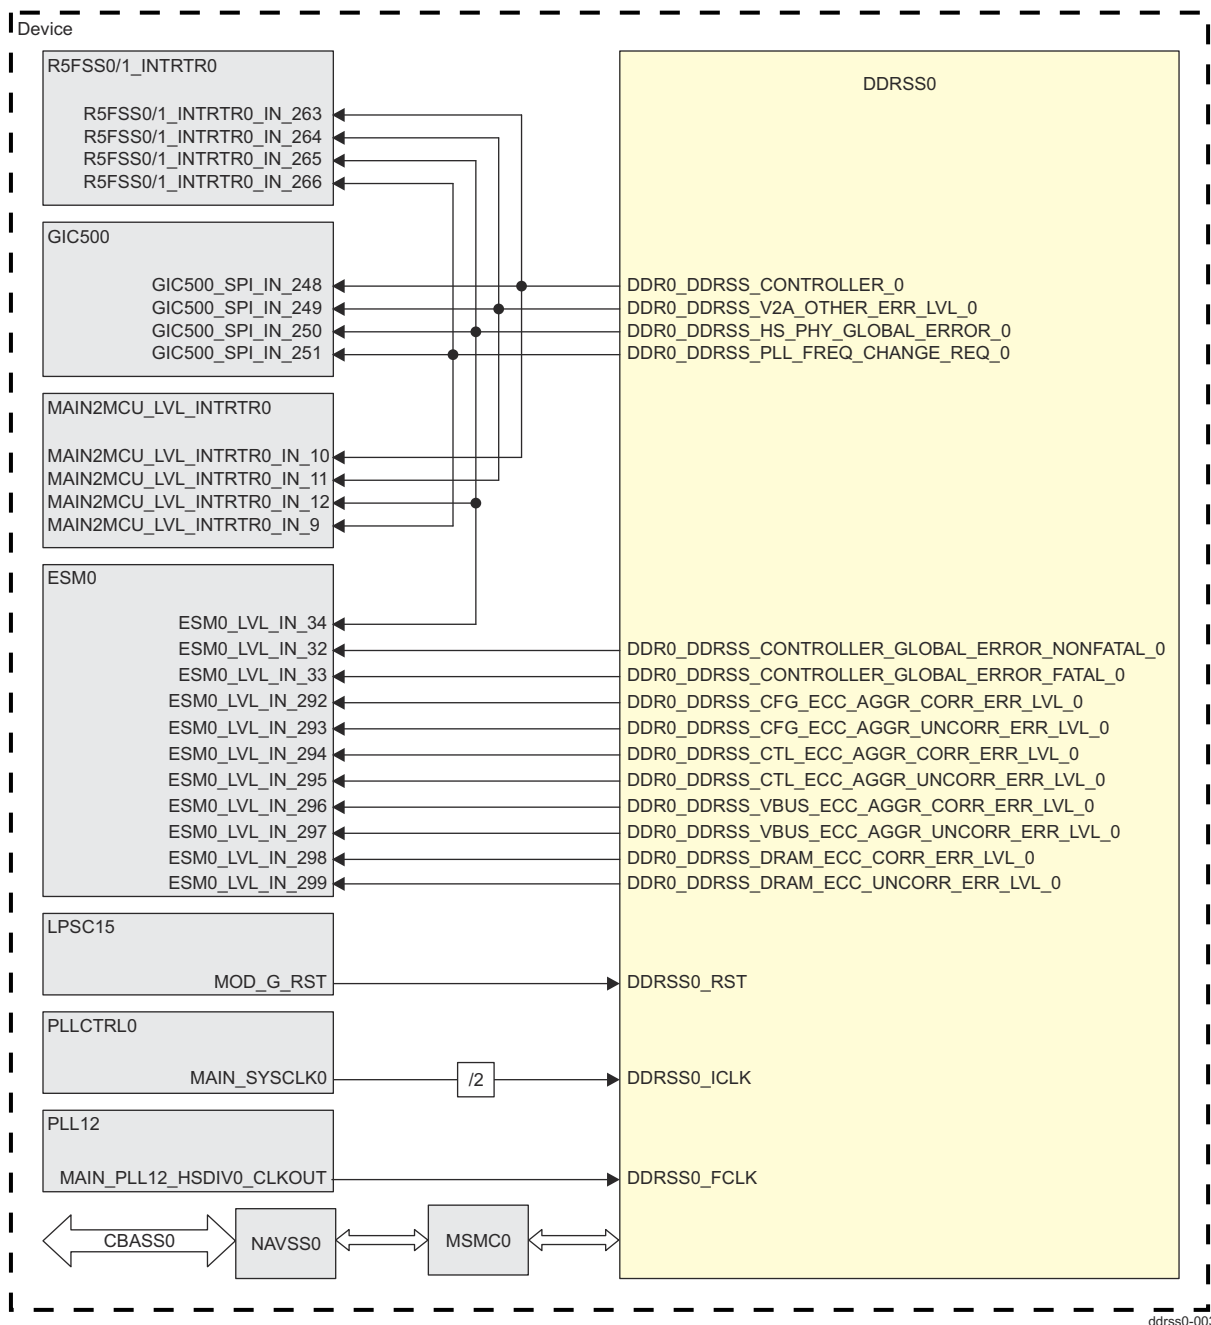

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 8.2.3 DDRSS Integration

This section describes DDRSS0 integration in the device, including information about clocks, resets, and hardware requests.

#### 8.2.3.1 DDRSS Integration in MAIN Domain

A single DDRSS0 module is integrated in the device MAIN domain. [Figure 8-8](#) shows the integration of DDRSS0.

**Figure 8-8. DDRSS0 Integration**

Table 8-14 through Table 8-16 summarize the integration of DDRSS0 in device MAIN domain.

**Table 8-14. DDRSS0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DDRSS0	PSC0	PD0	LPSC15	CBASS0 (Accessed through MSMC)

**Table 8-15. DDRSS0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DDRSS0	DDRSS0_ICLK	MAIN_SYSCCLK0/2	PLLCTRL0	DDRSS0 configuration interface clock
	DDRSS0_FCLK	MAIN_PLL12_HSDIV0_CLKO UT	PLL12	DDRSS0 functional clock. It supplies the SDRAM clock.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
DDRSS0	DDRSS0_RST	MOD_G_RST	LPSC15	DDRSS0 reset

**Table 8-16. DDRSS0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DDRSS0	DDR0_DDRSS_CONTROLLER_GLOBAL_ERROR_NONFATAL_0	ESM0_LVL_IN_32	ESM0	DDR controller interrupt associated with bit [0] of the DDRSS_CTL_437[31-24] GLOBAL_ERROR_INFO field	Level
	DDR0_DDRSS_CONTROLLER_GLOBAL_ERROR_FATAL_0	ESM0_LVL_IN_33	ESM0	DDR controller interrupt associated with bits [7-1] of the DDRSS_CTL_437[31-24] GLOBAL_ERROR_INFO field	Level
	DDR0_DDRSS_CFG_ECC_AGGR_CORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_292	ESM0	DDRSS0_ECC_AGGR_CFG correctable error interrupt	Level
	DDR0_DDRSS_CFG_ECC_AGGR_UNCORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_293	ESM0	DDRSS0_ECC_AGGR_CFG non-correctable error interrupt	Level
	DDR0_DDRSS_CTL_ECC_AGGR_CORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_294	ESM0	DDRSS0_ECC_AGGR_CTL correctable error interrupt	Level
	DDR0_DDRSS_CTL_ECC_AGGR_UNCORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_295	ESM0	DDRSS0_ECC_AGGR_CTL non-correctable error interrupt	Level
	DDR0_DDRSS_VBUS_ECC_AGGR_CORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_296	ESM0	DDRSS0_ECC_AGGR_VBUS correctable error interrupt	Level
	DDR0_DDRSS_VBUS_ECC_AGGR_UNCORRECTABLE_ERROR_LVL_0	ESM0_LVL_IN_297	ESM0	DDRSS0_ECC_AGGR_VBUS non-correctable error interrupt	Level

## 8.2.4 DDRSS Functional Description

### 8.2.4.1 DDRSS MSMC2DDR Bridge

The MSMC2DDR bridge is part of the DDRSS and connects the DDR controller and MSMC data paths.

#### 8.2.4.1.1 VBUSM.C Threads

##### Note

VBUS (VBUSM and VBUSP) is the device interconnect communication protocol. The letter "C" in "VBUSM.C" stands for Coherence Extension and denotes the interface is dedicated to COMPUTE\_CLUSTER0. The VBUS protocol is beyond the scope of the device documentation as it is purely hardware oriented. For details about the device interconnect and the associated software controls, see *System Interconnect*.

The MSMC2DDR bridge supports two threads on the VBUSM.C interface. They are as follows:

- High Priority Thread (HPT) - traffic received on VBUSM.C thread 2 belongs to HPT.
- Low Priority Thread (LPT) - traffic received on VBUSM.C thread 2 belongs to LPT.

HPT has priority over LPT. Therefore, the execution of commands from the command FIFO can be out-of-order. As a result, the read data can also be returned out-of-order. This ensures that the HPT will be guaranteed execution even when LPT is fully blocked.

The MSMC2DDR bridge maintains data coherency across threads. Therefore, any HPT transactions that depend on the LPT transactions due to address conflicts are blocked until execution of the corresponding LPT transactions. This might result in a scenario where HPT can be blocked because of blockage on LPT. Once the LPT blockage has cleared, the blockage on the dependent HPT commands is also cleared.

HPT transactions can use global credits as well as thread 2 credits. LPT transactions can only use global credits.

On the command interface, the MSMC2DDR bridge gives back global credits on the VBUSM.C interface only if the available credits on the command queue in the DDR controller are greater than the DDRSS\_V2A\_CTL\_REG[16-12] CRIT\_THRESH field.

On the read data return interface, HPT traffic is prioritized over LPT traffic. The MSMC2DDR bridge sends HPT read data if there is at least 1 global or 1 thread 2 credit available.

The MSMC2DDR bridge sends LPT read data if there is no HPT data to send, and:

- There are at least 2 global credits available, or
- There is at least 1 global credit available and it is the last data phase

#### 8.2.4.1.2 Class of Service (CoS)

Commands arriving on LPT and HPT to the DDRSS0 carry the VBUSM.C priority whereas the DDR controller uses another priority. The MSMC2DDR bridge has the following registers for flexible mapping of the VBUSM.C priority to DDR controllers's priority:

- Range match registers:
  - DDRSS\_V2A\_R1\_MAT\_REG
  - DDRSS\_V2A\_R2\_MAT\_REG
  - DDRSS\_V2A\_R3\_MAT\_REG
- Priority map registers:
  - DDRSS\_V2A\_LPT\_DEF\_PRI\_MAP\_REG
  - DDRSS\_V2A\_LPT\_R1\_PRI\_MAP\_REG
  - DDRSS\_V2A\_LPT\_R2\_PRI\_MAP\_REG
  - DDRSS\_V2A\_LPT\_R3\_PRI\_MAP\_REG
  - DDRSS\_V2A\_HPT\_DEF\_PRI\_MAP\_REG
  - DDRSS\_V2A\_HPT\_R1\_PRI\_MAP\_REG
  - DDRSS\_V2A\_HPT\_R2\_PRI\_MAP\_REG

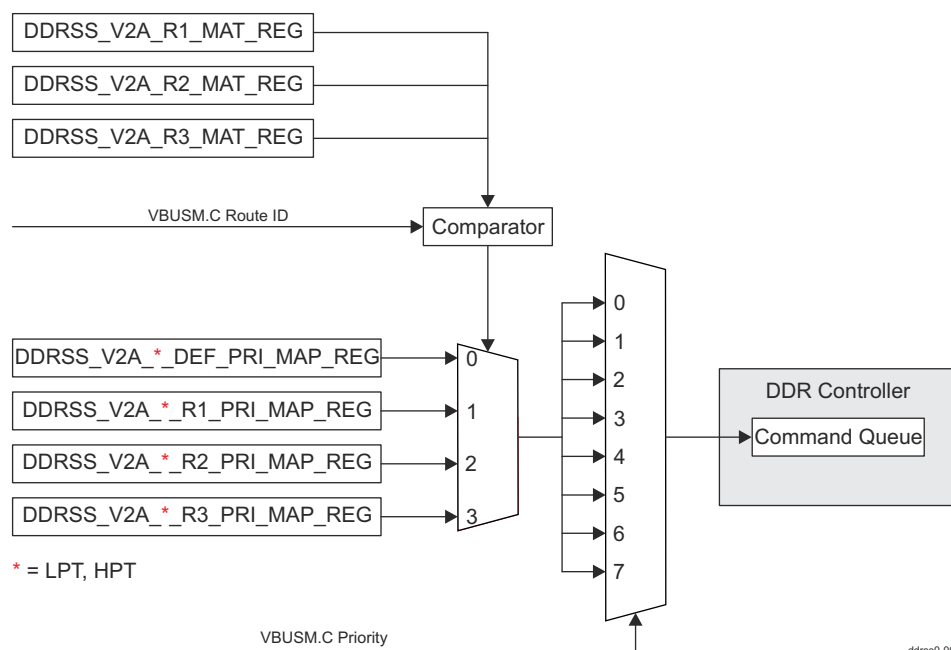

#### – DDRSS\_V2A\_HPT\_R3\_PRI\_MAP\_REG

This allows the system to essentially create different classes of service based on the initiator (Route ID) and the priority of the commands.

Each thread has a set of corresponding priority map registers to map the incoming priority on that thread to appropriate priority for the DDR controller as shown in Figure 8-9. The default values of these registers are such that inherently the HPT traffic has higher priority than the LPT traffic inside the DDR controller, but these settings can be changed via software per system needs.

#### Note

For information about Route ID, see *Route ID* in *System Interconnect*.

**Figure 8-9. DDRSS CoS Mapping Diagram**

#### 8.2.4.1.3 AXI Write Data All-Strobes

The DDR controller data path is connected to the MSMC2DDR bridge through AXI interface. To enable higher performance and lower latency, the bridge drives the AXI AWALLSTRB signal to a "1" when the AXI write data do not have any byte enable holes. This allows the DDR controller to accept and start processing the write command as soon as possible without waiting for all data. The DDRSS\_CTL\_377[16] AXI0\_ALL\_STROBES\_USED\_ENABLE bit must be set to a 0x1 to utilize this feature. The controller ignores the AWALLSTRB signal if AXI0\_ALL\_STROBES\_USED\_ENABLE is set to 0x0.

#### 8.2.4.1.4 Inline ECC for SDRAM Data

For SDRAM data integrity, the MSMC2DDR bridge supports inline ECC on the data written to or read from the SDRAM. ECC is enabled by programming the bits in the DDRSS\_ECC\_CTRL\_REG register. ECC is stored together with the data so that a dedicated SDRAM device for ECC is not required. When using this inline ECC feature the inline ECC inside the DDR controller must be disabled by setting to 0x0 the DDRSS\_CTL\_206[17-16] ECC\_ENABLE field.

8-bit single error correction double error detection (SECCDED) ECC is calculated over 64-bit data quanta. For every 512-byte data block 64 bytes of ECC is stored inline. Thus 1/9th of the total SDRAM space is used for ECC storage and the rest 8/9th is available for system use. From system point of view that 8/9th of the SDRAM

data space are seen as consecutive byte addresses. Even if there are non-ECC protected regions the previously described 1/9th-8/9th rule still applies and consecutive byte addresses are seen from system point of view.

The ECC is calculated for all accesses that are within the address ranges protected by ECC. The address ranges are specified through the following registers:

- DDRSS\_ECC\_R0\_STR\_ADDR\_REG
- DDRSS\_ECC\_R0\_END\_ADDR\_REG
- DDRSS\_ECC\_R1\_STR\_ADDR\_REG
- DDRSS\_ECC\_R1\_END\_ADDR\_REG
- DDRSS\_ECC\_R2\_STR\_ADDR\_REG
- DDRSS\_ECC\_R2\_END\_ADDR\_REG

The ECC is read and verified during reads if both the DDRSS\_ECC\_CTRL\_REG[0] ECC\_EN and DDRSS\_ECC\_CTRL\_REG[2] ECC\_CK bits are set to 0x1. For 1-bit ECC error, the MSMC2DDR bridge corrects the data and returns it to the requestor. Although the error is corrected on the returned data, the SDRAM is not corrected. It is responsibility of the system software to correct the ECC error at that location.

It is also responsibility of the system software to pre-load the ECC protected region with known data before functional reads and writes are performed. This can be done by writing to the SDRAM with ECC enabled (DDRSS\_ECC\_CTRL\_REG[0] ECC\_EN = 0x1 and DDRSS\_ECC\_CTRL\_REG[1] RMW\_EN = 0x1) and ECC check disabled (DDRSS\_ECC\_CTRL\_REG[2] ECC\_CK = 0x0). Once the data is loaded in the SDRAM, ECC check must be enabled (DDRSS\_ECC\_CTRL\_REG[2] ECC\_CK = 0x1) before using the DDR interface.

#### 8.2.4.1.4.1 ECC Cache

The MSMC2DDR bridge implements a 128-line deep ECC cache for improving inline ECC performance. Each cache line can be allocated to an initiator in the system based on its Route ID. The Route ID allocation to cache line can be done by writing to the DDRSS\_ECC\_RID\_INDX\_REG and DDRSS\_ECC\_RID\_VAL\_REG registers. Since the bridge uses unallocated cache lines for all read accesses without Route ID allocation, one or more locations in the cache should be kept unallocated for better performance. To ensure that at least one cache line remains unallocated, in the case all cache lines are allocated by software, the bridge automatically unallocates the 127th cache line. Write accesses without Route ID allocation result in ECC and data writes to the SDRAM, when the DDRSS\_ECC\_CTRL\_REG[4] WR\_ALLOC bit is set to 0x0. When DDRSS\_ECC\_CTRL\_REG[4] WR\_ALLOC is set to 0x1, an unassigned cache-line is allocated to write accesses without Route ID allocation.

#### 8.2.4.1.4.2 ECC Statistics

For 1-bit ECC error, the MSMC2DDR bridge logs the address location for the error in an internal 2-level deep FIFO. It stores the first two 1-bit ECC errors. The DDRSS\_ECC\_1B\_ERR\_ADR\_LOG\_REG register shows the address on top of the internal FIFO. Software should write 0x1 to the DDRSS\_ECC\_1B\_ERR\_ADR\_LOG\_REG[28-0] ECC\_1B\_ERR\_ADR field to pop the FIFO and display the next address stored. The FIFO is loaded with the address for the next 1-bit ECC error if it is not full. If a single address is associated with more than one ECC error, that address is logged twice.

The number of 1-bit ECC errors can be counted using the DDRSS\_ECC\_1B\_ERR\_CNT\_REG register. The MSMC2DDR bridge also supports programming a threshold in the DDRSS\_ECC\_1B\_ERR\_THRSH\_REG register. When the 1-bit error count is equal to or greater than the programmed threshold, the bridge sets the DDRSS\_V2A\_INT\_RAW\_REG[3] ECC1BERR bit and also triggers the DDR0\_DDRSS\_DRAM\_ECC\_CORR\_ERR\_LVL\_0 interrupt. When servicing the interrupt, software needs to clear the error count otherwise further interrupts will not be triggered. For 2-bit ECC errors, the bridge sets the DDRSS\_V2A\_INT\_RAW\_REG[4] ECC2BERR bit and also triggers the DDR0\_DDRSS\_DRAM\_ECC\_UNCORR\_ERR\_LVL\_0 interrupt. The bridge does not correct the data for these uncorrectable errors. Along with generating the interrupt, the bridge also reports an error to the requesting initiator and sends all zeros for the data. The bridge also logs the address location for the error in the DDRSS\_ECC\_2B\_ERR\_ADR\_LOG\_REG register.

The MSMC2DDR bridge sets the DDRSS\_V2A\_INT\_RAW\_REG[5] ECCM1BERR bit and triggers the DDR0\_DDRSS\_DRAM\_ECC\_UNCORR\_ERR\_LVL\_0 interrupt whenever it receives multiple 1-bit errors in

different data words of the same SDRAM burst. This is done because the probability of receiving multiple 1-bit errors in different data words of the same SDRAM burst is very low. If this occurs, the chances are that there were multi-bit errors in each data word. Therefore, for reliability, pessimistic approach is taken to report these as a fatal error. The threshold for the number of 1-bit errors that result in an uncorrected error, reporting can be set by writing to the DDRSS\_ECC\_CTRL\_REG[12-8] COR\_ECC\_THRESH field. For reliability, the threshold is always kept at 0/1 meaning 1-bit error in 2 or more data words is reported as a 2-bit error. For debug, the threshold can be changed to a higher value. Note that since these are multiple 1-bit errors, the statistic logging is done in the DDRSS\_ECC\_1B\_ERR\_CNT\_REG and DDRSS\_ECC\_1B\_ERR\_ADR\_LOG\_REG registers.

#### 8.2.4.1.5 Opcode Checking

The MSMC2DDR bridge checks the VBUSM.C opcode received for unsupported opcodes and flags error for debug purposes. Only opcode values for read and write operations are supported.

If an unsupported VBUSM.C opcode is received for an access, the bridge sets the DDRSS\_V2A\_INT\_RAW\_REG[0] OERR bit to 0x1 and triggers the DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0 interrupt. The opcode and the Route ID for the command caused error are logged in the DDRSS\_V2A\_OERR\_LOG\_REG[17-12] OERR\_OP\_CODE and DDRSS\_V2A\_OERR\_LOG\_REG[11-0] OERR\_ROUTE\_ID fields.

Since the bridge does not know how to process the command with an unsupported opcode, it discards the command and does not respond with any status on the write status or the read status buses.

#### 8.2.4.1.6 Address Alias Prevention

The MSMC2DDR bridge checks the VBUSM.C address received against the valid SDRAM address space programmed in the DDRSS\_V2A\_CTL\_REG register. If the VBUSM.C address for an access falls outside the programmed range the bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[1] AERR bit and also triggers the DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0 interrupt. The address and the Route ID for the command caused error are logged in the DDRSS\_V2A\_AERR\_LOG1\_REG and DDRSS\_V2A\_AERR\_LOG2\_REG registers.

The valid address range can be programmed using the DDRSS\_V2A\_CTL\_REG[9-5] SDRAM\_IDX and DDRSS\_V2A\_CTL\_REG[4-0] REGION\_IDX fields. [Table 8-17](#) summarizes the scenarios for determining valid address range and interrupt generation.

**Table 8-17. REGION\_IDX and SDRAM\_IDX Scenarios**

Condition	Description
REGION_IDX = SDRAM_IDX	DDR region size is equal to the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX < SDRAM_IDX	DDR region size is less than the connected SDRAM size. It is SoC responsibility to ensure that the addresses received by the DDR subsystem do not fall outside the region size. No address error is generated if the address received falls outside the region size.
REGION_IDX > SDRAM_IDX	DDR region size is greater than the connected SDRAM size. Address error is generated if the address received falls outside the connected SDRAM size.

A write access outside the programmed range is discarded. A write error associated status is sent back to the VBUSM.C interface.

A read access outside the programmed range is executed on the SDRAM interface as a normal read, but data will contain all zeroes before forwarding it to the VBUSM.C interface. A read error associated status is sent back to the VBUSM.C interface along with the read data containing all zeroes.

When inline ECC is enabled, the available SDRAM size is reduced by 1/9th of the size programmed in the SDRAM\_IDX field. Therefore, the bridge reports an error if an access falls outside the reduced SDRAM size when inline ECC is enabled. The reduced SDRAM size limit applies to all accesses, both to the protected and non-protected ECC regions.

#### 8.2.4.1.7 Data Error Detection and Correction

The MSMC2DDR bridge performs data error detection and correction (EDC) on write data received. The EDC is performed over 256-bit data quanta and uses a Hamming code algorithm supporting single error correction and double error detection.

If the write data has a single bit error the bridge indicates a single bit error through the ECC aggregator interrupts. The write data will be corrected and written to the SDRAM. The address, the error position, and the Route ID for the command caused error are logged in the DDRSS\_V2A\_1B\_ERR\_LOG1\_REG and DDRSS\_V2A\_1B\_ERR\_LOG2\_REG registers. The number of 1-bit EDC errors is kept in the DDRSS\_V2A\_1B\_ERR\_CNT\_REG register.

If the write data has a double bit error the bridge indicates a double bit error through the ECC aggregator interrupts. The write will be executed on the SDRAM interface as a normal write and the data inside the SDRAM will be corrupted. The address and the route ID for the command caused the error are logged in the DDRSS\_V2A\_2B\_ERR\_LOG1\_REG and DDRSS\_V2A\_2B\_ERR\_LOG2\_REG registers. The bridge does not respond with a write error associated status for 2-bit EDC errors.

The bridge implements four EDC checkers that check EDC on each 256-bit quanta of a 1024-bit data word, in a single clock cycle. Therefore, when ECC errors occur on multiple 256-bit quanta in the same 1024-bit word, the error reported and logged is for the least significant 256-bits. If different quanta in the same 1024-bit word have single and double bit errors simultaneously, both errors are reported via interrupts but the address and Route ID associated with only the double bit error are logged.

The bridge generates an EDC code for the read data and sends it along with its read response for checking by the receiving system master.

#### 8.2.4.1.8 AXI Bus Timeout

The MSMC2DDR bridge has a timeout counter that expires when no AXI transaction can be sent to the DDR controller or no AXI response is received from the controller for a programmed time interval. The counter only counts when there are pending commands in the bridge and the AXI bus is idle. Therefore, the bridge will not time out during low-power modes. The time interval can be programmed by writing to the DDRSS\_V2A\_BUS\_TO[23-0] BUS\_TIMER field.

Upon the expiry of the counter, the bridge terminates all pending commands in its internal FIFOs, returns error responses, sets the DDRSS\_V2A\_INT\_RAW\_REG[2] TOERR bit and triggers the DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0 interrupt.

After a timeout occurs, the bridge terminates any new commands received and returns error response. Writing a value of 0x0 to the DDRSS\_V2A\_BUS\_TO[23-0] BUS\_TIMER field exits the timeout mode. The other method to exit the timeout mode is to reset the DDRSS0, thus resetting the MSMC2DDR bridge, the DDR controller, and the DDR PHY.

#### 8.2.4.2 DDRSS Interrupts

The DDRSS0 generates the following interrupts:

- DDR0\_DDRSS\_PLL\_FREQ\_CHANGE\_REQ\_0
- DDR controller interrupts:
  - DDR0\_DDRSS\_CONTROLLER\_GLOBAL\_ERROR\_NONFATAL\_0
  - DDR0\_DDRSS\_CONTROLLER\_GLOBAL\_ERROR\_FATAL\_0
  - DDR0\_DDRSS\_CONTROLLER\_0
- DDR PHY interrupts:
  - DDR0\_DDRSS\_HS\_PHY\_GLOBAL\_ERROR\_0
- ECC aggregators interrupts:
  - DDR0\_DDRSS\_CTL\_ECC\_AGGR\_CORR\_ERR\_LVL\_0
  - DDR0\_DDRSS\_CTL\_ECC\_AGGR\_UNCORR\_ERR\_LVL\_0
  - DDR0\_DDRSS\_VBUS\_ECC\_AGGR\_CORR\_ERR\_LVL\_0

- DDR0\_DDRSS\_VBUS\_ECC\_AGGR\_UNCORR\_ERR\_LVL\_0
- DDR0\_DDRSS\_CFG\_ECC\_AGGR\_CORR\_ERR\_LVL\_0
- DDR0\_DDRSS\_CFG\_ECC\_AGGR\_UNCORR\_ERR\_LVL\_0
- MSMC2DDR bridge interrupts:
  - DDR0\_DDRSS\_DRAM\_ECC\_CORR\_ERR\_LVL\_0
  - DDR0\_DDRSS\_DRAM\_ECC\_UNCORR\_ERR\_LVL\_0
  - DDR0\_DDRSS\_V2A\_OTHER\_ERR\_LVL\_0

The MSMC2DDR bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[0] OERR bit, if the VBUSM.C access has an unsupported opcode.

The MSMC2DDR bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[1] AERR bit, if the VBUSM.C address for an access that falls outside the DDR space programmed in the DDRSS\_V2A\_CTL\_REG register.

The MSMC2DDR bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[2] TOERR bit, if it detects a hang on its interface to the DDR controller.

The MSMC2DDR bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[3] ECC1BERR bit, if the threshold for 1-bit ECC errors is met.

The MSMC2DDR bridge sets to 0x1 the DDRSS\_V2A\_INT\_RAW\_REG[4] ECC2BERR bit, in case of 2-bit errors for a read access performed within the SDRAM address range protected by ECC.

The DDRSS0 asserts particular interrupt line only if the interrupts are enabled by writing 0x1 to the corresponding bit in the DDRSS\_V2A\_INT\_SET\_REG register. The interrupts can be disabled by writing 0x1 to the corresponding bit in the DDRSS\_V2A\_INT\_CLR\_REG register.

When interrupts are enabled, the corresponding bits in the DDRSS\_V2A\_INT\_STAT\_REG register are also set if an interrupt condition occurs. The interrupts can be cleared once serviced by writing 0x1 to the corresponding bit in the DDRSS\_V2A\_INT\_STAT\_REG register as well as writing to the DDRSS\_V2A\_EOI\_REG register.

[Table 8-18](#) shows the events that are generated by the MSMC2DDR bridge.

**Table 8-18. MSMC2DDR Bridge Events**

Event Flag	Event Mask	Description
DDRSS_V2A_INT_RAW_REG[4] ECC2BERR DDRSS_V2A_INT_STAT_REG[4] ECC2BERR	DDRSS_V2A_INT_SET_REG[4] ECC2BERR_EN DDRSS_V2A_INT_CLR_REG[4] ECC2BERR_EN	Generated in case of 2-bit errors for a read access within the ECC protected SDRAM address range. For more information, see <a href="#">Section 8.2.4.1.4.2</a> .
DDRSS_V2A_INT_RAW_REG[3] ECC1BERR DDRSS_V2A_INT_STAT_REG[3] ECC1BERR	DDRSS_V2A_INT_SET_REG[3] ECC1BERR_EN DDRSS_V2A_INT_CLR_REG[3] ECC1BERR_EN	Generated in case of meeting the threshold for 1-bit ECC errors. For more information, see <a href="#">Section 8.2.4.1.4.2</a> .
DDRSS_V2A_INT_RAW_REG[2] TOERR DDRSS_V2A_INT_STAT_REG[2] TOERR	DDRSS_V2A_INT_SET_REG[2] TOERR_EN DDRSS_V2A_INT_CLR_REG[2] TOERR_EN	Generated in case of a hang of the interface between the MSMC2DDR bridge and the DDR controller. For more information, see <a href="#">Section 8.2.4.1.8</a> .
DDRSS_V2A_INT_RAW_REG[1] AERR DDRSS_V2A_INT_STAT_REG[1] AERR	DDRSS_V2A_INT_SET_REG[1] AERR_EN DDRSS_V2A_INT_CLR_REG[1] AERR_EN	Generated if the VBUSM.C address for an access falls outside the programmed range. For more information, see <a href="#">Section 8.2.4.1.6</a> .
DDRSS_V2A_INT_RAW_REG[0] OERR DDRSS_V2A_INT_STAT_REG[0] OERR	DDRSS_V2A_INT_SET_REG[0] OERR_EN DDRSS_V2A_INT_CLR_REG[0] OERR_EN	Generated if an unsupported VBUSM.C opcode is received for an access. For more information, see <a href="#">Section 8.2.4.1.5</a> .

### 8.2.4.3 DDRSS Memory Regions

Table 8-19 shows all memory regions associated with the DDRSS0.

**Table 8-19. DDRSS0 Memory Regions**

Region	Start Address	End Address	Region Size
DDRSS0 wrapper logic registers	0x00 0298 0000	0x00 0298 01FF	512 B
DDR controller registers	0x00 0299 0000	0x00 0299 1FFF	8 KB
DDR PHY independent module registers	0x00 0299 2000	0x00 0299 3FFF	8 KB
DDR PHY registers	0x00 0299 4000	0x00 0299 7FFF	16 KB
DDRSS0_ECC_AGGR_CTL registers	0x4D 200B 0000	0x4D 200B 03FF	1 KB
DDRSS0_ECC_AGGR_VBUS registers	0x4D 200B 0400	0x4D 200B 07FF	1 KB
DDRSS0_ECC_AGGR_CFG registers	0x4D 200B 0800	0x4D 200B 0BFF	1 KB
External SDRAM data space - region 0 (32-bit low memory space)	0x00 8000 0000	0x00 FFFF FFFF	2 GB
External SDRAM data space - region 1 (high memory space) <sup>(1)</sup>	0x08 0000 0000	0x09 FFFF FFFF	8 GB

(1) The first 2 GB of this region are inaccessible.

### 8.2.4.4 DDRSS ECC Support

The DDRSS0 aligns to the device architecture for system reliability and uses the following ECC aggregators for detection and reporting of ECC errors:

- DDRSS0\_ECC\_AGGR\_CTL
- DDRSS0\_ECC\_AGGR\_VBUS
- DDRSS0\_ECC\_AGGR\_CFG

For information about the ECC aggregator functionality, see *ECC Aggregator*.

### 8.2.4.5 DDRSS Dynamic Frequency Change Interface

This interface is used for handshaking between DDRSS0 and CTRL\_MMR0 to dynamically change DDR clock frequency to support LPDDR4 Frequency Set Point (FSP). The frequency change can be initiated either by a SoC processor or by the DDRSS0.

The associated CTRL\_MMR0 registers for processor initiated frequency change are:

- CTRLMMR\_CHNG\_DDR4\_FSP\_REQ
- CTRLMMR\_CHNG\_DDR4\_FSP\_ACK

The associated CTRL\_MMR0 registers for DDRSS0 initiated frequency change are:

- CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ
- CTRLMMR\_DDR4\_FSP\_CLKCHNG\_ACK

The sequence for an SoC processor initiated frequency change is as follows:

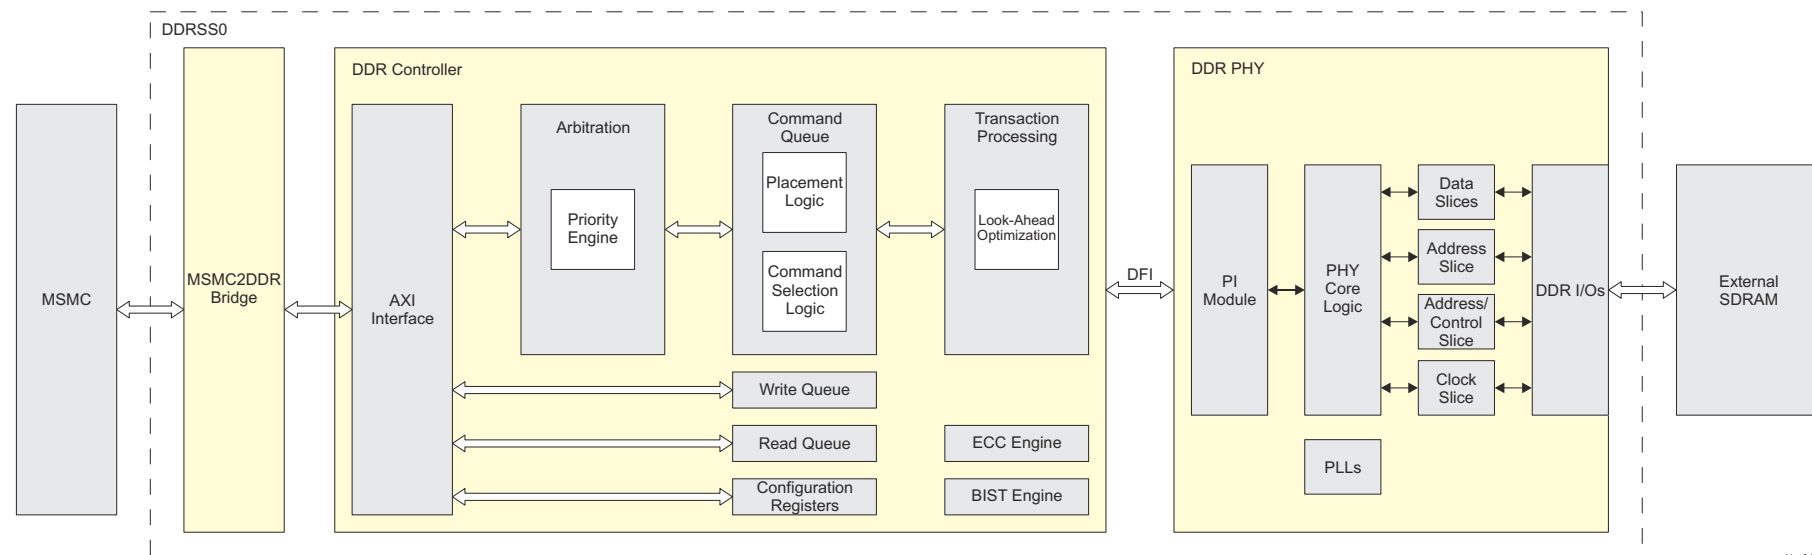

1. The processor writes the desired frequency to the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[1-0] REQ\_TYPE field.
2. The processor sets to 0x1 the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[8] REQ bit to initiate frequency change.
3. The processor programs PLL12 according to the CTRLMMR\_CHNG\_DDR4\_FSP\_REQ[1-0] REQ\_TYPE value.
4. The processor polls the CTRLMMR\_CHNG\_DDR4\_FSP\_ACK[7] ACK and CTRLMMR\_CHNG\_DDR4\_FSP\_ACK[0] ERROR bits to check if the frequency change has been completed successfully.

The sequence for DDRSS0 initiated frequency change is as follows:

1. DDRSS0 requests frequency change by asserting the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[7] REQ bit and the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[1-0] REQ\_TYPE field. The REQ bit is also connected to the DDR0\_DDRSS\_PLL\_FREQ\_CHANGE\_REQ\_0 interrupt.
2. Software reads the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_REQ[1-0] REQ\_TYPE value and programs PLL12 accordingly.
3. After the DDRSS0\_FCLK has been changed software should set to 0x1 the CTRLMMR\_DDR4\_FSP\_CLKCHNG\_ACK[0] ACK bit.

#### 8.2.4.6 DDR Controller Functional Description

Figure 8-10 shows the DDR controller blocks along with the DDR PHY and MSMC2DDR bridge.

The ECC Engine block of the DDR controller is not supported.

BIST Engine is not supported.

**Figure 8-10. DDR Controller Functional Blocks**

#### 8.2.4.6.1 DDR PHY Interface (DFI)

The DDR controller and DDR PHY are connected via DDR PHY Interface (DFI) which is used for transferring control information and data between the PHY and the controller. There are DFI programmable parameters which software can interact with through some of the DDR controller (see *DDR Controller Registers*), PI (see *PI Registers*) and DDR PHY (see *DDR PHY Registers*) registers. For more information about DFI, see <http://www.ddr-phy.org/>.

#### 8.2.4.6.2 Command Queue

The DDR controller contains a command queue which uses a placement algorithm to determine the order of commands to be placed into the command queue. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at a time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. The placement logic also attempts to maximize efficiency of the DDR controller through command grouping and bank splitting.

##### 8.2.4.6.2.1 Placement Logic

The placement logic is a 2-stage queue which determines the order of commands that run in the DDR controller. The placement logic follows rules for determining placement of new commands into the queue, relative to the contents of the command queue at that time. Placement is determined by considering coherency, address collisions, source collisions, data collisions, user assigned priority, latency, age, and command type to offer low latency for critical masters while optimizing bandwidth for all masters. A second reordering stage allows ready-to-run commands to start even if the head-of-queue command is not yet ready to run. Some of the rules used in the placement logic can be individually enabled or disabled via the DDRSS\_CTL\_274 through DDRSS\_CTL\_277 registers. In addition, the queue can be disabled completely, resulting in an in-line queue that services requests in the order that they arrive.

The DDR controller also has a full look-ahead facility that reduces the effect of page misses by pre-conditioning rows for upcoming requests by using “spare” cycles in preceding transactions.

##### 8.2.4.6.2.2 Command Selection Logic

After a command is in the command queue, command selection logic determines the method of pulling commands from the queue for running. On each clock cycle, the selection logic scans the entries of the command queue for determining the command to run. Commands for running are based on bank readiness, availability of at least 1 burst of data (writes), availability of storage for at least 1 burst of data (reads), bus turnaround timing, and conflicts. Similar to the placement rules, a command does not run before a command that was placed ahead of it in the command queue if it conflicts with address, source ID, or bank commands. Lower priority commands can run ahead of higher priority commands if the higher priority commands are not ready to run, as long as they do not conflict with commands that are ahead in the command queue.

##### 8.2.4.6.3 Low Power Control

The DDR controller contains an arbitration block that has software programmable interface for low power control. Placement of and removal from the various memory low power modes is controlled through programming of registers in the DDR controller. The user can also monitor the status of the memory devices through a programmable register. This interface supports a lock option allowing software to execute additional commands through this interface without worrying about state changes through other interfaces.

##### 8.2.4.6.4 Transaction Processing

The transaction command processing logic is used to process the commands in the command queue. The logic organizes the commands to the memories in such a way that data throughput is maximized. Bank opening and closing cycles are used for data transfers. The logic reviews the entire command queue for look-ahead of which banks have to be accessed in the future and ensures that the programmed memory timing conditions are met. This flexibility allows the controller to be tuned to extract the maximum performance out of memories. During processing, the controller examines the commands and issues the appropriate set of signals to the memory.

##### 8.2.4.6.5 BIST Engine

---

#### Note

BIST Engine is not supported.

---

The DDR controller has a BIST engine that supports MOV13N and limited MOV1 algorithms, a self-refresh retention test, an idle retention test and a memory initialization test for detecting the following faults:

- All address decoder faults
- All memory cell stuck-at faults
- All transition faults
- Most unlinked inversion coupling faults
- Most unlinked idem potent coupling faults
- Most idem potent coupling that are linked with inversion coupling faults

The DDR controller also supports BIST on ECC lanes for out-of-band ECC configuration. The following are the BIST related registers:

- DDRSS\_CTL\_194 through DDRSS\_CTL\_205
- DDRSS\_CTL\_302 through DDRSS\_CTL\_311

#### 8.2.4.6.6 ECC Engine

##### Note

The ECC Engine block of the DDR controller is not supported.

The ECC engine can confirm the data accuracy and remove or identify bit errors if they occur. It checks for errors in both the data and the check code on all read transactions. The DDR controller can detect single-bit and double-bit data errors and can correct single-bit errors. The ECC engine supports interrupts, register storage of ECC error signatures, signaling of ECC errors, ECC scrubbing and write-back, automatic ECC corruption and ECC error forcing. The DDR controller supports inline ECC, which means a portion of the memory device connected to the controller is reserved for storing the ECC check codes and is not available for user data storage. ECC can be enabled or disabled through the DDRSS\_CTL\_206[17-16] ECC\_ENABLE field. When enabled, all read data is checked for ECC (and optionally corrected) and ECC is computed and stored on all write data. Single-bit errors can be corrected and double-bit errors can be flagged. ECC information is not returned and ECC scrubbing is supported to maintain memory contents. The DDRSS\_CTL\_206 through DDRSS\_CTL\_227 registers contain the ECC related software controls.

#### 8.2.4.6.7 Address Mapping

The DDR controller automatically maps SoC addresses to the SDRAM memory in a contiguous block. Addressing starts at address 0x0 and ends at the highest available address according to the size and number of SDRAM memories present. This mapping depends on the programmed values in the DDR controller registers and is based on the actual size of the available SDRAM memories. The size is configured via the DDRSS\_CTL\_286[2-0] MEMDATA\_RATIO\_0 and DDRSS\_CTL\_287[10-8] MEMDATA\_RATIO\_1 fields and that must be initialized at power-up.

#### 8.2.4.6.8 Paging Policy

The DDR controller offers a flexible paging policy that allows open page operation, closed page operation, or an auto-precharge-per-command option that allows both modes simultaneously. Auto-precharge-per-command allows marking a particular master or transaction (for example, a CPU cache) as a closed-page transaction. This type of transaction reduces power and improves latency for the next transaction to a different row in the same SDRAM bank. Other transactions can be marked as open page transactions. This type of transaction reduces power and improves latency and bandwidth to the next transaction to the same row in the same SDRAM bank.

#### 8.2.4.6.9 DDR Controller Initialization

Once the power to the SDRAM and SoC is stable, the DDR controller must be initialized. It then automatically initializes the external memory. The general steps to initialize the DDR controller are as follows:

1. Reset the DDRSS0 through the DDRSS0\_RST signal. This resets all DDR controller registers.
2. Issue write register commands to configure the SDRAM protocols and the settings for the DDR controller. Keep the DDRSS\_CTL\_0[0] START bit to 0x0 during this initialization step.
3. Set to 0x1 the DDRSS\_CTL\_0[0] START bit. This triggers the controller to execute initialization sequence using the settings written to its registers. If the DDRSS\_CTL\_88[0] PWRUP\_SREFRESH\_EXIT bit is set to 0x0, the DDR controller issues MRWs and requests a ZQCL.

The DDR controller waits for the DDR PHY to assert the `dfi_init_complete` signal, which indicates that the PHY and SDRAM are ready to accept commands. When this signal asserts, the controller begins its initialization routine. The DDR controller sets to 0x1 bit [9] in the `DDRSS_CTL_293[31-0] INT_STATUS_0` field when initialization is complete and it is ready to accept commands.

For information about the DDR PHY initialization, see [Section 8.2.4.7.5](#).

#### **8.2.4.6.10 Programming LPDDR4 Memories**

LPDDR4 memories are specified to run at high frequency and include additional features such as CA training, write leveling, and ODT. At these high speeds, the DDR PHY also supports read data-eye training and gate training. Leveling and training operations are all performed through the PI module.

##### **8.2.4.6.10.1 Frequency Set Point (FSP)**

LPDDR4 memories use frequency set points to allow the memory to easily switch between two different frequencies without ever being in an un-trained state. There are two frequency set points - frequency set point 0 and frequency set point 1.

FSP is controlled through the following bits:

- `DDRSS_CTL_192[0] DFS_ALWAYS_WRITE_FSP`
- `DDRSS_CTL_163[16] DISABLE_UPDATE_TVRCG`
- `DDRSS_CTL_192[16] FSP_OP_CURRENT`
- `DDRSS_CTL_191[24] FSP_PHY_UPDATE_MRW`
- `DDRSS_CTL_192[8] FSP_STATUS`
- `DDRSS_CTL_192[24] FSP_WR_CURRENT`
- `DDRSS_CTL_193[17-16] FSP0_FRC`
- `DDRSS_CTL_193[25-24] FSP1_FRC`
- `DDRSS_CTL_190[8] MR_FSP_DATA_VALID_F0`
- `DDRSS_CTL_190[16] MR_FSP_DATA_VALID_F1`
- `DDRSS_CTL_190[24] MR_FSP_DATA_VALID_F2`
- `DDRSS_CTL_166[4-0] TCKFSPE_F0`
- `DDRSS_CTL_168[4-0] TCKFSPE_F1`
- `DDRSS_CTL_171[4-0] TCKFSPE_F2`
- `DDRSS_CTL_166[12-8] TCKFSPX_F0`
- `DDRSS_CTL_168[28-24] TCKFSPX_F1`
- `DDRSS_CTL_171[12-8] TCKFSPX_F2`
- `DDRSS_CTL_166[31-16] TVREF_LONG_F0`
- `DDRSS_CTL_169[15-0] TVREF_LONG_F1`
- `DDRSS_CTL_171[31-16] TVREF_LONG_FN`

##### **8.2.4.6.10.1.1 FSP Mode Register Programming During Initialization**

Before initialization, the user should program the FSP-related mode registers (MR1, MR2, MR3, MR11, MR12, MR13, MR14 and MR22) with the relevant values, and the `DDRSS_CTL_21[28-24] DFIBUS_FREQ_F2`, `DDRSS_CTL_21[20-16] DFIBUS_FREQ_F1` and `DDRSS_CTL_21[12-8] DFIBUS_FREQ_F0` fields with the frequency set to use. These mode registers are programmed through the following fields:

- `DDRSS_CTL_175[7-0] MR1_DATA_F0_0`
- `DDRSS_CTL_175[23-16] MR1_DATA_F1_0`
- `DDRSS_CTL_176[7-0] MR1_DATA_F2_0`
- `DDRSS_CTL_182[23-16] MR1_DATA_F0_1`
- `DDRSS_CTL_183[7-0] MR1_DATA_F1_1`
- `DDRSS_CTL_183[23-16] MR1_DATA_F2_1`
- `DDRSS_CTL_175[15-8] MR2_DATA_F0_0`
- `DDRSS_CTL_175[31-24] MR2_DATA_F1_0`
- `DDRSS_CTL_176[15-8] MR2_DATA_F2_0`

- DDRSS\_CTL\_182[31-24] MR2\_DATA\_F0\_1
- DDRSS\_CTL\_183[15-8] MR2\_DATA\_F1\_1
- DDRSS\_CTL\_183[31-24] MR2\_DATA\_F2\_1
- DDRSS\_CTL\_176[31-24] MR3\_DATA\_F0\_0
- DDRSS\_CTL\_177[7-0] MR3\_DATA\_F1\_0
- DDRSS\_CTL\_177[15-8] MR3\_DATA\_F2\_0
- DDRSS\_CTL\_184[15-8] MR3\_DATA\_F0\_1
- DDRSS\_CTL\_184[23-16] MR3\_DATA\_F1\_1
- DDRSS\_CTL\_184[31-24] MR3\_DATA\_F2\_1
- DDRSS\_CTL\_178[23-16] MR11\_DATA\_F0\_0
- DDRSS\_CTL\_178[31-24] MR11\_DATA\_F1\_0
- DDRSS\_CTL\_179[7-0] MR11\_DATA\_F2\_0
- DDRSS\_CTL\_186[7-0] MR11\_DATA\_F0\_1
- DDRSS\_CTL\_186[15-8] MR11\_DATA\_F1\_1
- DDRSS\_CTL\_186[23-16] MR11\_DATA\_F2\_1
- DDRSS\_CTL\_179[15-8] MR12\_DATA\_F0\_0
- DDRSS\_CTL\_179[23-16] MR12\_DATA\_F1\_0
- DDRSS\_CTL\_179[31-24] MR12\_DATA\_F2\_0
- DDRSS\_CTL\_186[31-24] MR12\_DATA\_F0\_1
- DDRSS\_CTL\_187[7-0] MR12\_DATA\_F1\_1
- DDRSS\_CTL\_187[15-8] MR12\_DATA\_F2\_1
- DDRSS\_CTL\_180[7-0] MR13\_DATA\_0
- DDRSS\_CTL\_180[15-8] MR14\_DATA\_F0\_0
- DDRSS\_CTL\_180[23-16] MR14\_DATA\_F1\_0
- DDRSS\_CTL\_180[31-24] MR14\_DATA\_F2\_0
- DDRSS\_CTL\_187[31-24] MR14\_DATA\_F0\_1
- DDRSS\_CTL\_188[7-0] MR14\_DATA\_F1\_1
- DDRSS\_CTL\_188[15-8] MR14\_DATA\_F2\_1
- DDRSS\_CTL\_181[31-24] MR22\_DATA\_F0\_0
- DDRSS\_CTL\_182[7-0] MR22\_DATA\_F1\_0
- DDRSS\_CTL\_182[15-8] MR22\_DATA\_F2\_0
- DDRSS\_CTL\_189[15-8] MR22\_DATA\_F0\_1
- DDRSS\_CTL\_189[23-16] MR22\_DATA\_F1\_1
- DDRSS\_CTL\_189[31-24] MR22\_DATA\_F2\_1

In addition, the following fields must also be programmed before asserting the DDRSS\_CTL\_0[0] START bit:

- DDRSS\_CTL\_165[25-16] TFC\_F0
- DDRSS\_CTL\_166[4-0] TCKFSPE\_F0
- DDRSS\_CTL\_166[12-8] TCKFSPX\_F0
- DDRSS\_CTL\_164[25-16] TVRCG\_ENABLE\_F0
- DDRSS\_CTL\_165[9-0] TVRCG\_DISABLE\_F0
- DDRSS\_CTL\_168[9-0] TFC\_F1
- DDRSS\_CTL\_168[20-16] TCKFSPE\_F1
- DDRSS\_CTL\_160[28-24] TCKFSPX\_F1
- DDRSS\_CTL\_167[9-0] TVRCG\_ENABLE\_F1
- DDRSS\_CTL\_167[25-16] TVRCG\_DISABLE\_F1
- DDRSS\_CTL\_170[25-16] TFC\_F2
- DDRSS\_CTL\_171[4-0] TCKFSPE\_F2
- DDRSS\_CTL\_171[12-8] TCKFSPX\_F2
- DDRSS\_CTL\_169[25-16] TVRCG\_ENABLE\_F2
- DDRSS\_CTL\_170[9-0] TVRCG\_DISABLE\_F2
- DDRSS\_CTL\_21[1-0] DFIBUS\_BOOT\_FREQ
- DDRSS\_CTL\_20[25-24] DFIBUS\_FREQ\_INIT

- DDRSS\_CTL\_149[24] DFS\_ENABLE
- DDRSS\_CTL\_191[24] FSP\_PHY\_UPDATE\_MRW

The following bits may or may not be modified, depending on what operations are needed after a frequency change occurs:

- DDRSS\_CTL\_192[0] DFS\_ALWAYS\_WRITE\_FSP
- DDRSS\_CTL\_89[16] DFS\_ZQ\_EN

Once the DDRSS\_CTL\_0[0] START bit is asserted, the DDR controller programs the mode registers in the memory devices with these values using the FSP-OP and FSP-WR values from the DDRSS\_CTL\_180[7-0] MR13\_DATA\_0 field. Once initialization is complete, either the PHY, PI, or controller will have updated the frequency set points with the needed values.

#### 8.2.4.6.10.1.2 FSP Mode Register Programming During Normal Operation

During normal operation, the DDR controller may modify the FSP mode register values in memory. To do this, the user should program the DDRSS\_CTL\_164[1-0] MRW\_DFS\_UPDATE\_FRC field with the frequency set that the DDR controller is using and program the appropriate new values in the FSP-related mode registers previously listed. Since there are two copies of each of these mode registers in the memory device (other than MR13), the user should also identify the appropriate frequency set points for operation and writing in the DDRSS\_CTL\_192[16] FSP\_OP\_CURRENT and DDRSS\_CTL\_192[24] FSP\_WR\_CURRENT bits.

Generally, the user should not modify the mode registers for the frequency set being used, and therefore should program the DDRSS\_CTL\_192[24] FSP\_WR\_CURRENT with the opposite value of the DDRSS\_CTL\_192[16] FSP\_OP\_CURRENT bit.

Once established the values to write, the frequency set in the DDR controller to use, and the frequency set points, the user should program the DDRSS\_CTL\_159[26-0] WRITE\_MODEREG field for the operation:

- Set bit [24] to 1h for all chips to be written with new values, or identify the target chip select in bits [15-8].
- Set bit [26] to 1h for a FSP-write operation. A write to this bit targets the mode registers MR1, MR2, MR3, MR11 and MR22 for writing. MR12 and MR14 are also written if the DDRSS\_CTL\_191[24] FSP\_PHY\_UPDATE\_MRW bit is set to 0h.
- Set bit [25] to 1h to trigger the operation.

All of these bits may be programmed simultaneously.

#### Note

When the DDRSS\_CTL\_159[26-0] WRITE\_MODEREG field is written with bit [26] set to 1h, the corresponding MR13 mode register is updated automatically with the value in the DDRSS\_CTL\_180[7-0] MR13\_DATA\_0 or DDRSS\_CTL\_187[23-16] MR13\_DATA\_1 fields, except that the value in the DDRSS\_CTL\_192[24] FSP\_WR\_CURRENT bit will define the value written in MR13 [6] and the value in the DDRSS\_CTL\_192[16] FSP\_OP\_CURRENT bit will define the value written in MR13 [7]. This write occurs before the other mode register writes, which means that the user may inadvertently write the wrong frequency set point mode or switch to the new frequency set point.

#### 8.2.4.6.10.1.3 FSP Mode Register Programming During Dynamic Frequency Scaling

During a hardware DFS operation, the FSP mode registers are used to switch from one frequency set to the other. Before a hardware frequency change can be requested, the following must be programmed:

- DDRSS\_CTL\_193[17-16] FSP0\_FRC
- DDRSS\_CTL\_193[25-24] FSP1\_FRC
- DDRSS\_CTL\_192[24] FSP\_WR\_CURRENT
- DDRSS\_CTL\_192[16] FSP\_OP\_CURRENT
- DDRSS\_CTL\_190[24] MR\_FSP\_DATA\_VALID\_F2
- DDRSS\_CTL\_190[16] MR\_FSP\_DATA\_VALID\_F1
- DDRSS\_CTL\_190[8] MR\_FSP\_DATA\_VALID\_F0

FSP mode register writes are required as part of the DFS operation. To accomplish this, three mode register writes are issued to MR13, and additional mode register write to each of the FSP mode registers. These commands are issued at three times:

1. After frequency change entry and before the memory is placed into self refresh the first mode register write to MR13 is issued. This writes the value from the DDRSS\_CTL\_180[7-0] MR13\_DATA\_0 and DDRSS\_CTL\_187[23-16] MR13\_DATA\_1 fields for all bits other than the FSP-WR bit which will be defined as opposite of the FSP-OP bit. Then mode register writes to all the other FSP mode registers are issued.
2. After the memory is in self-refresh, the MR13 is written again. This write causes the FSP-OP bit to toggle, and to set the VRCG bit. At this point, the frequency change should take place.
3. After the frequency change, one final mode register write to MR13 is performed to clear the VRCG bit. The DFS operation will update the FSP mode registers and the DDRSS\_CTL\_192[8] FSP\_STATUS bit once it is complete.

#### 8.2.4.6.10.2 Data Bus Inversion (DBI)

LPDDR4 memories support data bus inversion (DBI) for signal integrity and power savings. The DDR controller can support DBI on the read or write path, or on both. DBI functions by ensuring that in each data byte, there are no more than four '1' bits. This can be used to confirm data transmission, and also for power savings.

DBI is controlled through the following:

- The DDRSS\_CTL\_291[16] RD\_DBI\_EN bit
- The DDRSS\_CTL\_291[8] WR\_DBI\_EN bit

Before enabling controller-level data bus inversion, the DBI mode must be enabled in the memories through a write to bits [7-6] of MR3. The system behavior depends on the value of the memory mode register bits, the DDRSS\_CTL\_291[16] RD\_DBI\_EN or DDRSS\_CTL\_291[8] WR\_DBI\_EN bit, and the value of each byte of data.

If the DDRSS\_CTL\_291[8] WR\_DBI\_EN bit is set to 1h, the user should ensure that the memory mode register WR DBI bit is also set to 1h. When both of these bits are set, the DDR controller examines each byte of the incoming write data and identifies the number of '1' bits within each byte. If a byte of data has 5 or more '1' bits, the DDR controller automatically flips the data bits in that byte and drives the dfi\_wrddata\_mask/dfi\_wrddata\_mask\_p1 signal that corresponds to that byte to '1'. If the number of '1' bits within a byte is 4 or less or the DDRSS\_CTL\_291[8] WR\_DBI\_EN bit is set to 0h, then the data is sent to the DRAMs unchanged. On the DRAM, if the dfi\_wrddata\_mask/dfi\_wrddata\_mask\_p1 signal is driven to '1', the DRAM re-inverts that byte before storing the data and if the dfi\_wrddata\_mask/dfi\_wrddata\_mask\_p1 signal is set to '0', the DRAM stores the data as received.

For the read path, if the memory mode register RD DBI bit is set to 1h, the DDRSS\_CTL\_291[16] RD\_DBI\_EN bit should also be set to 1h. When both of these bits are set, the DDR controller examines the input signal dfi\_rddata\_dbi\_n/dfi\_rddata\_dbi\_n\_w1. If the signal is driven to '1' for a byte, the DDR controller inverts the associated byte before sending it to the requestor. If the dfi\_rddata\_dbi\_n/dfi\_rddata\_dbi\_n\_w1 signal is held to '0' for a byte, the data is sent out to the requestor unchanged.

#### 8.2.4.6.10.3 On-Die Termination

LPDDR4 memories provide two different types of on-die termination (ODT) - ODT for the DQ and ODT for the CA buses.

##### 8.2.4.6.10.3.1 LPDDR4 DQ ODT

LPDDR4 supports termination for the DQ and DQS input signals, but this termination does not utilize an ODT input pin. Instead, the ODT is controlled by the command. The functionality is enabled through bits [2-0] of mode register MR11, where a value of 0h disables the ODT functionality. The DQ ODT settings can be programmed through the following fields:

- DDRSS\_CTL\_178[23-16] MR11\_DATA\_F0\_0
- DDRSS\_CTL\_186[7-0] MR11\_DATA\_F0\_1
- DDRSS\_CTL\_178[31-24] MR11\_DATA\_F1\_0
- DDRSS\_CTL\_186[15-8] MR11\_DATA\_F1\_1

- DDRSS\_CTL\_179[7-0] MR11\_DATA\_F2\_0
- DDRSS\_CTL\_186[23-16] MR11\_DATA\_F2\_1

These field values are written to the associated mode registers when the DDR controller issues a MRW to the memory.

When DQ ODT is enabled, RTT is asserted with a write or masked write command.

#### **8.2.4.6.10.3 LPDDR4 CA ODT**

LPDDR4 can terminate the CA bus, including the CS and CLK signals. The value on the ODT input pin, ODT\_CA, on the DRAM and the settings in the mode registers determine if CA ODT is enabled in the memories and the RTT termination resistance. The functionality is enabled through bits [6-4] of mode register MR11, where the value of 0h disables ODT functionality. Bits [5-3] of MR22 control individual aspects of the CA ODT when ODT is not disabled. The CA ODT settings can be programmed through the following fields:

- DDRSS\_CTL\_178[23-16] MR11\_DATA\_F0\_0
- DDRSS\_CTL\_178[31-24] MR11\_DATA\_F1\_0
- DDRSS\_CTL\_179[7-0] MR11\_DATA\_F2\_0
- DDRSS\_CTL\_186[7-0] MR11\_DATA\_F0\_1
- DDRSS\_CTL\_186[15-8] MR11\_DATA\_F1\_1
- DDRSS\_CTL\_186[23-16] MR11\_DATA\_F2\_1
- DDRSS\_CTL\_181[31-24] MR22\_DATA\_F0\_0
- DDRSS\_CTL\_182[7-0] MR22\_DATA\_F1\_0
- DDRSS\_CTL\_182[15-8] MR22\_DATA\_F2\_0
- DDRSS\_CTL\_189[15-8] MR22\_DATA\_F0\_1
- DDRSS\_CTL\_189[23-16] MR22\_DATA\_F1\_1
- DDRSS\_CTL\_189[31-24] MR22\_DATA\_F2\_1

These field values are written to the associated mode registers when the DDR controller issues a MRW to the memory.

#### **8.2.4.6.10.4 Byte Lane Swapping**

The DDR controller supports byte lane swapping on the board or a DIMM for better timing or routing. In most cases, this swapping is invisible to the user as data byte lanes are swapped when data is being written, and then unswapped as data is read. However, mode register reads does not un-swap the data. Therefore, the user must be aware of the location of the 0<sup>th</sup> byte of the data in order to process the information from the mode registers correctly.

Whether byte lane swapping is used or not, the user must program the following fields:

- DDRSS\_CTL\_286[11-8] DEVICE0\_BYTE0\_CS0
- DDRSS\_CTL\_286[19-16] DEVICE1\_BYTE0\_CS0
- DDRSS\_CTL\_286[27-24] DEVICE2\_BYTE0\_CS0
- DDRSS\_CTL\_287[3-0] DEVICE3\_BYTE0\_CS0
- DDRSS\_CTL\_287[19-16] DEVICE0\_BYTE0\_CS1
- DDRSS\_CTL\_287[27-24] DEVICE1\_BYTE0\_CS1
- DDRSS\_CTL\_288[3-0] DEVICE2\_BYTE0\_CS1
- DDRSS\_CTL\_288[11-8] DEVICE3\_BYTE0\_CS1

Unique parameters are provided for each chip select to allow for different byte swapping on each chip select. Each field contains one bit for each byte of the memory data bus. If a device is not being used, the DEVICEx\_BYTE0\_CSy field should be programmed to 0h, but if the device is being used, then only one bit of the DEVICEx\_BYTE0\_CSy field should be set to 1h.

#### **8.2.4.6.10.5 DQS Interval Oscillator**

The DDR controller includes a feature to control the internal DQS clock tree oscillator in the LPDDR4 memories. This oscillator is used to track the delay variance of the DQS clock tree that will occur over time due to temperature and voltage. This feature allows the oscillator to be initiated and results read. If the result is outside

of the programmed allowable variance, the DDR controller informs the PHY. The DDR controller does not perform any training functions as a part of or a result of this oscillator measurement - the PHY is expected to handle all training requirements.

The DQS oscillator is controlled through the following fields:

- DDRSS\_CTL\_26[16] DQS\_OSC\_ENABLE
- DDRSS\_CTL\_28[31-24] DQS\_OSC\_HIGH\_THRESHOLD
- DDRSS\_CTL\_28[23-16] DQS\_OSC\_NORM\_THRESHOLD
- DDRSS\_CTL\_27[14-0] DQS\_OSC\_PERIOD
- DDRSS\_CTL\_29[15-8] DQS\_OSC\_PROMOTE\_THRESHOLD

- DDRSS\_CTL\_28[7-0] TOSCO\_F1
- DDRSS\_CTL\_28[15-8] TOSCO\_F2

Once the DDR controller has been initialized, before the controller reaches its terminal power-on state, a request is generated to the oscillator module to set the initial base values. These values are read from the memories and stored in the OSC\_BASE\_VALUE\_x\_CSy fields.

Following a frequency change, the base values to be used for comparison must be updated. As part of the operation, the frequency change task generates a subtask request to the DQS oscillator. This request, like the initialization request, will run the oscillator and then load the resulting values into the OSC\_BASE\_VALUE\_x\_CSy fields.

Once the base values have been updated, the DDR controller sets to 1h bit [31] in the DDRSS\_CTL\_293[31-0] INT\_STATUS\_0 field indicating DQS oscillator base value update interrupt.

#### 8.2.4.6.10.5.1 Oscillator State Machine

A state machine inside the DDR controller tracks oscillator-related commands and wait times. The basic flow is as follows:

1. If the oscillator function is enabled by setting the DDRSS\_CTL\_26[16] DQS\_OSC\_ENABLE bit to 1h, the process begins when a request is received to run the oscillator function. This request can be issued automatically during the initialization process, during a frequency change process, as a software request by setting the DDRSS\_CTL\_30[0] DQS\_OSC\_REQUEST bit to 1h, or through a programmable periodic timer (the DDRSS\_CTL\_28[23-16] DQS\_OSC\_NORM\_THRESHOLD, DDRSS\_CTL\_28[31-24] DQS\_OSC\_HIGH\_THRESHOLD, or DDRSS\_CTL\_29[7-0] DQS\_OSC\_TIMEOUT fields). Once this process has started, the memory is not allowed to enter any low power modes until complete.
2. If the request is through initialization, MR23 is written with the value of the DDRSS\_CTL\_190[7-0] MR23\_DATA field defining the number of cycles to run the oscillator.
3. An MPC is issued to start the oscillator. If there are multiple DRAM devices on a rank, the MPC is issued to all devices on the rank at the same time, and then the state machine proceeds to the next rank and issues MPCs to that rank, and so on.

4. The state machine waits the cycles defined by the DDRSS\_CTL\_27[14-0] DQS\_OSC\_PERIOD field and the cycles specified in the DDRSS\_CTL\_27[31-24] TOSCO\_F0, DDRSS\_CTL\_28[7-0] TOSCO\_F1, and DDRSS\_CTL\_28[15-8] TOSCO\_F2 fields to allow the operation to complete and the results to be stored.
5. The state machine issues a read to MR18.
6. The state machine waits the number of cycles specified in the DDRSS\_CTL\_51[27-24] TMRR field, and then stores the result in a temporary location. If there are multiple DRAM devices on a rank, the MRR captures the mode register content for all devices on that rank.
7. The state machine issues a read to MR19.
8. The state machine waits the number of cycles specified in the DDRSS\_CTL\_51[27-24] TMRR field, and then stores the result in a temporary location. If there are multiple DRAM devices on a rank, the MRR captures the mode register content for all devices on that rank.
9. The values read in MR18 and MR19 represent the LSB and MSB of the DQS oscillator count. The DDR controller combines them and compares the result. If multiple devices exist on a rank, the comparison is made between each device and the base value.
  - a. If this is the initial read or a read related to a DFS operation, the values are stored in the OSC\_BASE\_VALUE\_x\_CSy fields. The DDR controller drives a 1h value on the dfi\_function signal and asserts the dfi\_function\_valid signal for the number of cycles defined by the DDRSS\_CTL\_27[19-16] FUNC\_VALID\_CYCLES field.
  - b. If the value is FFFFh, an overflow condition occurred during the measurement process. The DDR controller sets to 1h bit [0] in the DDRSS\_CTL\_294[12-0] INT\_STATUS\_1 field indicating DQS oscillator measurement overflow interrupt and ignores the value.
  - c. If the difference between the measured value and the base value is lower than or equal to the value programmed in the DDRSS\_CTL\_29[31-16] OSC\_VARIANCE\_LIMIT field, the DDR controller returns to idle state. If the request was issued through software, the DDR controller sets to 1h bit [30] in the DDRSS\_CTL\_293[31-0] INT\_STATUS\_0 field indicating DQS oscillator request complete interrupt.
  - d. If the difference between the measured value and the base value is greater than the value programmed in the DDRSS\_CTL\_29[31-16] OSC\_VARIANCE\_LIMIT field, the DDR controller sets to 1h bit [1] in the DDRSS\_CTL\_294[12-0] INT\_STATUS\_1 field indicating DQS oscillator out of variance interrupt. The DDR controller also drives a 2h value on the dfi\_function signal and asserts the dfi\_function\_valid signal for the number of cycles defined by the DDRSS\_CTL\_27[19-16] FUNC\_VALID\_CYCLES field. The measured value will replace the base value for any device for which the measured value is outside the variance. This base value update does not set to 1h bit [31] in the DDRSS\_CTL\_293[31-0] INT\_STATUS\_0 field.

#### 8.2.4.6.10.6 Per-Bank Refresh (PBR)

Refresh commands are important memory operations to preserve memory contents, but they are also disruptive to system transaction flow. To minimize the impact, the DDR controller implements refresh on a per-bank basis. This does increase the quantity of refresh commands, but allows banks that are not targeted by the refresh to be accessed for read and write commands.

PBR is controlled through the following fields:

- DDRSS\_CTL\_228[12-8] AREF\_MAX\_CREDIT
- DDRSS\_CTL\_228[4-0] AREF\_MAX\_DEFICIT
- DDRSS\_CTL\_227[20-16] AREF\_NORM\_THRESHOLD
- DDRSS\_CTL\_71[28-24] AREF\_PBR\_CONT\_DIS\_THRESHOLD
- DDRSS\_CTL\_71[20-16] AREF\_PBR\_CONT\_EN\_THRESHOLD
- DDRSS\_CTL\_71[3-0] PBR\_BANK\_SELECT\_DELAY
- DDRSS\_CTL\_71[8] PBR\_CONT\_REQ\_EN
- DDRSS\_CTL\_67[0] PBR\_EN
- DDRSS\_CTL\_70[31-16] PBR\_MAX\_BANK\_WAIT
- DDRSS\_CTL\_67[8] PBR\_NUMERIC\_ORDER
- DDRSS\_CTL\_59[16] TREF\_ENABLE
- DDRSS\_CTL\_68[15-0] TREFI\_PB\_F0

- DDRSS\_CTL\_69[15-0] TREFI\_PB\_F1
- DDRSS\_CTL\_70[15-0] TREFI\_PB\_F2

#### 8.2.4.6.10.6.1 Normal Operation

Per-bank refresh commands may be issued to all banks or to a single bank, and may be issued to each bank in any order if programmed for this behavior. However, all banks must be refreshed before the same bank can be issued a new per-bank refresh command. The DDR controller can issue the commands in any order, and subsequent per-bank refresh sequences can be a completely different order than the last command. The order of banks is specified via the DDRSS\_CTL\_67[8] PBR\_NUMERIC\_ORDER bit. It is potentially advantageous to execute out-of-numerical order to prevent an active bank from stalling refresh operations to any other banks.

The PBR logic is part of the auto-refresh logic. The auto-refresh logic is responsible for maintaining the debit / credit counts for refresh that ensure that refresh commands are occurring as needed. The DRAM allows the user to postpone a maximum of 8 refresh commands which means that the user can wait as much as 9 x TREFI\_PB\_Fx cycles before issuing a refresh command. The DDR controller keeps track of how many refreshes it has skipped (DDRSS\_CTL\_228[4-0] AREF\_MAX\_DEFICIT) or advanced (DDRSS\_CTL\_228[12-8] AREF\_MAX\_CREDIT) and ensures that the DRAM requirements are satisfied. The PBR logic issues refresh commands to single banks if enabled via the DDRSS\_CTL\_67[0] PBR\_EN bit and in accordance with the programmed values. The DDRSS\_CTL\_59[16] TREF\_ENABLE bit must also be set to 1h for the PBR logic to work. The auto-refresh logic issues refresh commands to all banks and high priority refresh commands if the refresh count falls below a certain threshold.

When a refresh is required, the PBR logic issues a per-bank refresh command to a specific bank. If that bank is currently being accessed by the DDR controller core, the command will be held off. If the command is held off beyond the number of cycles specified in the DDRSS\_CTL\_70[31-16] PBR\_MAX\_BANK\_WAIT field, the PBR logic inhibits the active process in the DDR controller core, closes the bank, executes the PBR command and then un-inhibits the core to allow the interrupted process to continue. Once the bank is free, the PBR command is issued. The bank will be blocked from accesses within the number of clocks programmed into the DDRSS\_CTL\_71[3-0] PBR\_BANK\_SELECT\_DELAY field and the refresh will occur and then release the bank.

#### 8.2.4.6.10.6.2 Continuous Refresh Request Mode

The PBR logic can be temporarily modified to continuously assert refresh requests. This option may be desirable when the auto-refresh logic is running at a deficit and the user wishes to run per-bank refreshes instead of auto-refreshes to restore the refresh count.

Setting the DDRSS\_CTL\_71[8] PBR\_CONT\_REQ\_EN bit to 1h enables this mode. Automatic mode falls between the normal priority and high priority commands in terms of priority. When enabled, if the number of all-bank refresh commands pending exceeds the value programmed into the DDRSS\_CTL\_71[20-16] AREF\_PBR\_CONT\_EN\_THRESHOLD field, then the DDR controller automatically begins issuing per-bank refresh commands. As refreshes occur, the pending command count drops. Once that value meets the value programmed in the DDRSS\_CTL\_71[28-24] AREF\_PBR\_CONT\_DIS\_THRESHOLD field, the DDR controller stops automatically issuing per-bank refresh commands.

If however the refresh command pending count exceeds the value programmed into the DDRSS\_CTL\_227[20-16] AREF\_NORM\_THRESHOLD field, the DDR controller temporarily suspends the PBR logic, and the auto-refresh logic issues all-bank refresh commands until the refresh logic catches up. Once caught up, the PBR logic is resumed.

#### 8.2.4.7 DDR PHY Functional Description

The DDR PHY provides functionality to interface the DDR controller to SDRAM devices. The PHY has a slice based and DQS-delay architecture. It contains data, address, address/control and clock slices and uses programmable clock delay lines to align write data, read data capture, and DQS gating from the I/O pads across the DFI interface to the DDR controller.

#### 8.2.4.7.1 Data Slice

The data slice transfers data between the DDR controller and the SDRAM devices. The data slice is a module that interfaces to the DQ, DM, and DQS signals of the SDRAM and is duplicated as many times as necessary to create the current SoC SDRAM data width.

The write data path logic (from DFI to pads) and the read data path logic (from pads to DFI) are contained within the data slice. Termination and directional controls for the data path related I/Os are also contained in this slice.

#### 8.2.4.7.2 Address Slice

The address slice transfers address information between the DDR controller and the SDRAM devices and contains 6 address bits.

The address write data path logic (from DFI to pads) and the read data path logic (loopback only) are contained within the address slice. Termination and directional controls for the address path related I/Os also exist in this slice.

##### 8.2.4.7.2.1 Address Swapping

The address slice has the ability to programmably change which DFI address bits that are connected to the I/O pads. Address signals can be swapped within an address slice without restrictions. The swapping is done via the DDRSS\_PHY\_1053[23-0] PHY\_ADR\_ADDDR\_SEL\_0 field.

#### 8.2.4.7.3 Address/Control Slice

The address/control slice is a module that interfaces to the control, command, and address connections of the SDRAM and is duplicated as many times as necessary to create the appropriate width for the SoC. The address/control signals within a slice have per bit delay line control.

#### 8.2.4.7.4 Clock Slice

The clock slice creates the clock signal used by the SDRAM. The slice also disables the clock when instructed by the DDR controller through the DFI bus. When the clock is disabled, the CK pin drives low and the CKN drives high. Duty cycle correction is also applied in the memory clock slice.

#### 8.2.4.7.5 DDR PHY Initialization

Once the power to the SDRAM and SoC is stable, the DDR PHY must be reset and initialized before normal traffic can commence. Once the initialization has completed, the DDR PHY asserts the dfi\_init\_complete signal to notify the DDR controller that the PHY and SDRAM are ready to accept commands.

The procedure to initialize the DDR PHY is as follows:

1. Reset the DDRSS0 through the DDRSS0\_RST signal. This resets all DDR PHY registers.
2. Program all needed PHY registers.
3. The dfi\_init\_start is then asserted by the DDR controller. The PHY slice master delay lines locks and then the PHY asserts the dfi\_init\_complete signal. This indicates that the PHY and SDRAM are ready to accept commands. The PHY is now ready for normal traffic.

For information about the DDR controller initialization, see [Section 8.2.4.6.9](#).

#### 8.2.4.7.6 DDR PHY Dynamic Frequency Scaling (DFS)

The DDR PHY supports Dynamic Frequency Scaling (DFS) as defined by the DFI specification. This feature allows the PHY to be configured for multiple frequency sets, and have the DFI bus dynamically specify which frequency set to use at a given time. Before using a frequency set in normal operation, leveling operation should be performed on that set. Failure to do so may result in invalid operation. Once leveling has been performed with each frequency set, the user can freely switch between frequencies without need to repeat the leveling, unless the leveling environment requires periodic updates for voltage and temperature compensation.

This DDR PHY contains registers for each frequency set. This feature creates a lookup table that may be accessed through the DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX and DDRSS\_PHY\_1281[8]

PHY\_FREQ\_SEL\_MULTICAST\_EN fields, which gives a flexibility in controlling these frequency set registers with a simple register interface. This fact should be taken into account when reading and writing these registers.

The DDRSS\_PHY\_1280[1-0] PHY\_FREQ\_SEL and DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX fields operate independently, but if the PHY\_FREQ\_SEL\_INDEX field specifies a frequency set different than the one currently being used, accidental write to or read from invalid registers may happen.

Reads from frequency based registers return only the value that correlates to the frequency set identified in the DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX field. For writes to the frequency based registers, the resulting write depends on the value of the DDRSS\_PHY\_1281[8] PHY\_FREQ\_SEL\_MULTICAST\_EN bit. If it is set to 0x1, all frequency sets are concurrently written. If the PHY\_FREQ\_SEL\_MULTICAST\_EN bit is set to 0x0, only the frequency set identified in the PHY\_FREQ\_SEL\_INDEX field is written.

For example, consider a write to DDRSS\_PHY\_130[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_0 with the following settings:

- DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX = 0x0001 (frequency set 1)
- DDRSS\_PHY\_1281[8] PHY\_FREQ\_SEL\_MULTICAST\_EN = 0x0.

In this case, only the frequency set 1 version of the DDRSS\_PHY\_130[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_0 field is written. If the same settings are used, but with PHY\_FREQ\_SEL\_MULTICAST\_EN = 0x1, then all frequency-indexed versions of PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_0 are written.

#### 8.2.4.7.7 Chip Select and Frequency Based Register Settings

Some register settings within the PHY are chip select based. The DDRSS\_PHY\_6[0] PHY\_PER\_CS\_TRAINING\_INDEX\_0 bit allows access to a particular chip select copy. The PHY\_PER\_CS\_TRAINING\_INDEX\_0 bit is associated with data slice 0. The following bits are associated with the other data slices:

- DDRSS\_PHY\_262[0] PHY\_PER\_CS\_TRAINING\_INDEX\_1
- DDRSS\_PHY\_518[0] PHY\_PER\_CS\_TRAINING\_INDEX\_2
- DDRSS\_PHY\_774[0] PHY\_PER\_CS\_TRAINING\_INDEX\_3

When writing to chip select based registers, if the DDRSS\_PHY\_5[24] PHY\_PER\_CS\_TRAINING\_MULTICAST\_EN\_0 bit is set to 0x1, then all chip select copies receive the same data. The PHY\_PER\_CS\_TRAINING\_MULTICAST\_EN\_0 bit is associated with data slice 0. The following bits are associated with the other data slices:

- DDRSS\_PHY\_261[24] PHY\_PER\_CS\_TRAINING\_MULTICAST\_EN\_1
- DDRSS\_PHY\_517[24] PHY\_PER\_CS\_TRAINING\_MULTICAST\_EN\_2
- DDRSS\_PHY\_773[24] PHY\_PER\_CS\_TRAINING\_MULTICAST\_EN\_3

Some register settings in the PHY are frequency based. As already described, the DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX field allows access to a particular frequency copy. When writing to frequency based registers, if the DDRSS\_PHY\_1281[8] PHY\_FREQ\_SEL\_MULTICAST\_EN bit is set to 0x1, then all frequency copies receive the same data. [Table 8-20](#) shows the frequency based register settings.

DDRSS_PHY_1412[31-0] PHY_PAD_CLK_DRIVE	
DDRSS_PHY_1413[17-0] PHY_PAD_CLK_DRIVE2	

Some register settings in the PHY are both chip select based and frequency based. For them, the PHY\_PER\_CS\_TRAINING\_INDEX\_0/1/2/3 bits and the DDRSS\_PHY\_1281[17-16] PHY\_FREQ\_SEL\_INDEX field apply to the register access. The DDRSS\_PHY\_1281[8] PHY\_FREQ\_SEL\_MULTICAST\_EN bit applies as well. [Table 8-21](#) shows the chip select based and frequency based register settings.

#### 8.2.4.7.8 Low-Power Modes

The DDR PHY provides a means to reduce the operational power when it is not actively transferring read or write data for an extended period of time. This is done using the DFI low power interface. Using this interface, the DDR controller communicates to the PHY that it may enter its own low-power state and informs the PHY how quickly it requires the PHY to recover if a low-power state is entered. This DDR PHY has the following power modes:

- **Idle:** This is a period in which no read or write activity is being performed by the DDR controller. The PHY is not in any low power state, and is ready to accept commands at any time.
- **Read/Write:** This describes the time period when the PHY is actively performing a read or write operation triggered by the DDR controller.
- **Light Sleep:** This is a low-power state in which the master delay lines and their logic receive a clock, but all other slice logic is gated off. The PHY PLLs remain in an active state. Register reads and writes to data and address slices are not permitted. The PHY returns quickly to functional operation after an exit from light sleep. After exiting the PHY initializes the slave delay settings automatically. The master delay line macro maintains lock. This mode is entered if the dfi\_lp\_wakeup signal is driven with a value less than or equal to the programmed value in bits [3:0] of the the DDRSS\_PHY\_1318[15-8] PHY\_LP\_WAKEUP field. If low power idle state is enabled, the value must also be greater than the value of bits [7:4] in the DDRSS\_PHY\_1318[15-8] PHY\_LP\_WAKEUP field.
- **Deep Sleep:** This is an ultra low-power state in which clocking to the data, address, and address/control slices is disabled. The PLLs are in a power down state. Pad calibration functions are frozen. When in this mode, no DFI accesses or register reads and writes can be performed. This mode is entered if the dfi\_lp\_wakeup signal is driven with a value greater than the programmed value in bits [3:0] of the the DDRSS\_PHY\_1318[15-8] PHY\_LP\_WAKEUP field.
- **Low Power Idle:** This is a low power version of idle where the data slices are placed in a light sleep mode while still allowing accesses to the data slice register address space. The DDRSS\_PHY\_1318[16] PHY\_LS\_IDLE\_EN bit enables this low power idle state. The mode is entered if the dfi\_lp\_wakeup signal is driven with a value less than or equal to the programmed value of bits [7:4] in the DDRSS\_PHY\_1318[15-8] PHY\_LP\_WAKEUP field.

In general, if the SDRAM is placed into a power-down mode, the DDR PHY should enter light sleep. If the SDRAM is placed in a self-refresh mode, the DDR PHY could enter deep sleep.

The DDRSS\_PHY\_1319[9-0] PHY\_LP\_CTRLUPD\_CNTR\_CFG field controls the number of clock controller cycles between de-assertion of the dfi\_lp\_req signal and de-assertion of the dfi\_lp\_ack signal during exit of light sleep and low power idle modes.

Within each data slice, the DQ, DM and DQS I/O's are disabled when not being written to or read from. The gate feedback pads are constantly enabled to control the read DQS gate open logic. The following fields control disabling the gate feedback pad for the corresponding slice during deep sleep mode:

- DDRSS\_PHY\_79[26-24] PHY\_FDBK\_PWR\_CTRL\_0
- DDRSS\_PHY\_335[26-24] PHY\_FDBK\_PWR\_CTRL\_1
- DDRSS\_PHY\_591[26-24] PHY\_FDBK\_PWR\_CTRL\_2
- DDRSS\_PHY\_847[26-24] PHY\_FDBK\_PWR\_CTRL\_3

#### 8.2.4.7.9 Training Support

Training of the DDR PHY and SDRAM is necessary to support high-speed operation. The general training flow as follows:

1. I/O calibration
2. CA/CS training (VREF CA)
3. Write leveling
4. Read DQS gate training
5. Read data eye training
6. Write data eye training (VREF DQ)

##### 8.2.4.7.9.1 Write Leveling

When the write leveling algorithm has completed, the final write DQS delay settings can be found in the following fields:

- DDRSS\_PHY\_120[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_376[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_632[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_888[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_121[1-0] PHY\_WRLVL\_THRESHOLD\_ADJUST\_0
- DDRSS\_PHY\_377[1-0] PHY\_WRLVL\_THRESHOLD\_ADJUST\_1
- DDRSS\_PHY\_633[1-0] PHY\_WRLVL\_THRESHOLD\_ADJUST\_2
- DDRSS\_PHY\_889[1-0] PHY\_WRLVL\_THRESHOLD\_ADJUST\_3

After write leveling is complete, the following fields can be checked to obtain the leveling status:

- DDRSS\_PHY\_50[16-0] PHY\_WRLVL\_STATUS\_OBS\_0
- DDRSS\_PHY\_306[16-0] PHY\_WRLVL\_STATUS\_OBS\_1
- DDRSS\_PHY\_562[16-0] PHY\_WRLVL\_STATUS\_OBS\_2
- DDRSS\_PHY\_818[16-0] PHY\_WRLVL\_STATUS\_OBS\_3

After write leveling is complete, software can always override the results by writing directly to the following fields:

- DDRSS\_PHY\_120[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_376[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_632[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_888[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_3

If the clock path to the SDRAM is longer than the DQS path to the SDRAM, the leveling result from the first SDRAM along the memory clock path always returns a small value greater than zero because the DQS signal needs to be moved slightly to the right to line up with the memory clock. If the clock path to the SDRAM is shorter than the DQS path to the SDRAM, the DQS signal may need to be moved close to a cycle before it lines up with the memory clock. The leveling result indicates to the slice that the DQS needs to be delayed almost a cycle. This would then result in the write data being a cycle later than expected by the SDRAM based on when the write command is received. In reality, the DQS needs to be negatively delayed to align to the memory clock in the proper cycle. To create this “negative” delay, the command bus needs to be delayed one cycle so that when the DQS is delayed almost one cycle, the DQS appears “early” with respect to the write command. For example, if the memory clock path for slice 0 is expected to be about 1/16th cycle shorter than the DQS path, a write leveling result of 0x1E0 would be expected. The DDRSS\_PHY\_131[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_0 field enables the data slice 0 to understand if this is an expected delay or if this is a “negative” delay condition. When the result contained in DDRSS\_PHY\_120[25-16] PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_0 field is greater than the DDRSS\_PHY\_131[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_0 field, the command bus is delayed by one cycle. [Table 8-22](#) shows examples of programming this field for various expected delays. The following fields are associated with the other data slices:

- DDRSS\_PHY\_387[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_1
- DDRSS\_PHY\_643[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_2
- DDRSS\_PHY\_889[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_3

**Table 8-22. PHY Write Level Delay Values**

Expected Delay	PHY_WRLVL_DELAY_EARLY_THRESHOLD_ <b>x</b> <b>x</b> = 0, 1, 2, 3	Command Bus Impact
0.25 cycle	0x200 (off)	None
1.00 cycle	0x200 (off)	None
0.00 cycles	0x1E0	1 cycle delay if result is > 0x1E0

The DDRSS\_PHY\_132[16] PHY\_WRLVL\_EARLY\_FORCE\_ZERO\_0 bit works with the DDRSS\_PHY\_131[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_0 field for slice 0. The following fields are associated with the other slices:

- DDRSS\_PHY\_388[16] PHY\_WRLVL\_EARLY\_FORCE\_ZERO\_1 and DDRSS\_PHY\_387[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_1
- DDRSS\_PHY\_644[16] PHY\_WRLVL\_EARLY\_FORCE\_ZERO\_2 and DDRSS\_PHY\_643[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_2
- DDRSS\_PHY\_900[16] PHY\_WRLVL\_EARLY\_FORCE\_ZERO\_3 and DDRSS\_PHY\_899[25-16] PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_3

When the write leveling result satisfies the early threshold condition, the DQS is ideally aligned to clock but there is a cycle of latency added to the command path. Setting the PHY\_WRLVL\_EARLY\_FORCE\_ZERO\_ **x** bit to 0x1 forces the PHY\_CLK\_WRDQS\_SLAVE\_DELAY\_ **x** value to 0x0 so there is no command latency impact.

The PHY\_WRLVL\_THRESHOLD\_ADJUST\_ **x** fields contain the results of the PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_ **x** and PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_ **x** calculations from the write leveling process. This allows for direct observation of the leveling results. It also allows to rewrite leveling results if desired. This can be useful in case leveling is performed once and the same results are used in the future. The PHY\_WRLVL\_DELAY\_EARLY\_THRESHOLD\_ **x** and PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_ **x** results can be applied through the PHY\_WRLVL\_THRESHOLD\_ADJUST\_ **x** fields without having to go through the leveling process again.

The previously mentioned PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_ **x** fields are accessed through the following registers:

- DDRSS\_PHY\_132[9-0] PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_0
- DDRSS\_PHY\_388[9-0] PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_1
- DDRSS\_PHY\_644[9-0] PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_2
- DDRSS\_PHY\_900[9-0] PHY\_WRLVL\_DELAY\_PERIOD\_THRESHOLD\_3

#### 8.2.4.7.9.2 Read Gate Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS\_PHY\_130[25-16] PHY\_RDDQS\_GATE\_SLAVE\_DELAY\_0 (cycle fraction)
- DDRSS\_PHY\_386[25-16] PHY\_RDDQS\_GATE\_SLAVE\_DELAY\_1 (cycle fraction)
- DDRSS\_PHY\_642[25-16] PHY\_RDDQS\_GATE\_SLAVE\_DELAY\_2 (cycle fraction)
- DDRSS\_PHY\_898[25-16] PHY\_RDDQS\_GATE\_SLAVE\_DELAY\_3 (cycle fraction)
- DDRSS\_PHY\_131[3-0] PHY\_RDDQS\_LATENCY\_ADJUST\_0 (cycle offset)
- DDRSS\_PHY\_387[3-0] PHY\_RDDQS\_LATENCY\_ADJUST\_1 (cycle offset)
- DDRSS\_PHY\_643[3-0] PHY\_RDDQS\_LATENCY\_ADJUST\_2 (cycle offset)
- DDRSS\_PHY\_899[3-0] PHY\_RDDQS\_LATENCY\_ADJUST\_3 (cycle offset)

After read gate training is complete, the following fields can be checked to obtain the training status:

- DDRSS\_PHY\_54[17-0] PHY\_GTLVL\_STATUS\_OBS\_0
- DDRSS\_PHY\_310[17-0] PHY\_GTLVL\_STATUS\_OBS\_1
- DDRSS\_PHY\_566[17-0] PHY\_GTLVL\_STATUS\_OBS\_2
- DDRSS\_PHY\_822[17-0] PHY\_GTLVL\_STATUS\_OBS\_3

After read gate training is complete, software can always override the results by writing directly to the PHY\_RDDQS\_GATE\_SLAVE\_DELAY\_x and PHY\_RDDQS\_LATENCY\_ADJUST\_x fields.

#### 8.2.4.7.9.3 Read Data Eye Training

When the read gate training algorithm has completed, the final read DQS slave delay settings can be found in the following fields:

- DDRSS\_PHY\_121[17-8] PHY\_RDDQS\_DQ0\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_122[25-16] PHY\_RDDQS\_DQ1\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_123[25-16] PHY\_RDDQS\_DQ2\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_124[25-16] PHY\_RDDQS\_DQ3\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_125[25-16] PHY\_RDDQS\_DQ4\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_126[25-16] PHY\_RDDQS\_DQ5\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_127[25-16] PHY\_RDDQS\_DQ6\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_128[25-16] PHY\_RDDQS\_DQ7\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_377[17-8] PHY\_RDDQS\_DQ0\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_378[25-16] PHY\_RDDQS\_DQ1\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_379[25-16] PHY\_RDDQS\_DQ2\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_380[25-16] PHY\_RDDQS\_DQ3\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_381[25-16] PHY\_RDDQS\_DQ4\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_382[25-16] PHY\_RDDQS\_DQ5\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_383[25-16] PHY\_RDDQS\_DQ6\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_384[25-16] PHY\_RDDQS\_DQ7\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_633[17-8] PHY\_RDDQS\_DQ0\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_634[25-16] PHY\_RDDQS\_DQ1\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_635[25-16] PHY\_RDDQS\_DQ2\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_636[25-16] PHY\_RDDQS\_DQ3\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_637[25-16] PHY\_RDDQS\_DQ4\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_638[25-16] PHY\_RDDQS\_DQ5\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_639[25-16] PHY\_RDDQS\_DQ6\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_640[25-16] PHY\_RDDQS\_DQ7\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_889[17-8] PHY\_RDDQS\_DQ0\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_890[25-16] PHY\_RDDQS\_DQ1\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_891[25-16] PHY\_RDDQS\_DQ2\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_892[25-16] PHY\_RDDQS\_DQ3\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_893[25-16] PHY\_RDDQS\_DQ4\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_894[25-16] PHY\_RDDQS\_DQ5\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_895[25-16] PHY\_RDDQS\_DQ6\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_896[25-16] PHY\_RDDQS\_DQ7\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_122[9-0] PHY\_RDDQS\_DQ0\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_123[9-0] PHY\_RDDQS\_DQ1\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_124[9-0] PHY\_RDDQS\_DQ2\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_125[9-0] PHY\_RDDQS\_DQ3\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_126[9-0] PHY\_RDDQS\_DQ4\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_127[9-0] PHY\_RDDQS\_DQ5\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_128[9-0] PHY\_RDDQS\_DQ6\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_129[9-0] PHY\_RDDQS\_DQ7\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_378[9-0] PHY\_RDDQS\_DQ0\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_379[9-0] PHY\_RDDQS\_DQ1\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_380[9-0] PHY\_RDDQS\_DQ2\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_381[9-0] PHY\_RDDQS\_DQ3\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_382[9-0] PHY\_RDDQS\_DQ4\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_383[9-0] PHY\_RDDQS\_DQ5\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_384[9-0] PHY\_RDDQS\_DQ6\_FALL\_SLAVE\_DELAY\_1

- DDRSS\_PHY\_385[9-0] PHY\_RDDQS\_DQ7\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_634[9-0] PHY\_RDDQS\_DQ0\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_635[9-0] PHY\_RDDQS\_DQ1\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_636[9-0] PHY\_RDDQS\_DQ2\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_637[9-0] PHY\_RDDQS\_DQ3\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_638[9-0] PHY\_RDDQS\_DQ4\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_639[9-0] PHY\_RDDQS\_DQ5\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_640[9-0] PHY\_RDDQS\_DQ6\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_641[9-0] PHY\_RDDQS\_DQ7\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_890[9-0] PHY\_RDDQS\_DQ0\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_891[9-0] PHY\_RDDQS\_DQ1\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_892[9-0] PHY\_RDDQS\_DQ2\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_893[9-0] PHY\_RDDQS\_DQ3\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_894[9-0] PHY\_RDDQS\_DQ4\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_895[9-0] PHY\_RDDQS\_DQ5\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_896[9-0] PHY\_RDDQS\_DQ6\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_897[9-0] PHY\_RDDQS\_DQ7\_FALL\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_129[25-16] PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_385[25-16] PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_641[25-16] PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_897[25-16] PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_3
- DDRSS\_PHY\_130[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_386[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_642[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_2
- DDRSS\_PHY\_898[9-0] PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_3

Read data eye training for LPDDR4 devices does return data on the DM pin so the DBI data is trained along with the other DQ pins. In this case, the PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_x and PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_x fields receive their own unique values.

After read data eye training is complete, no error condition is noted in the read leveling status fields. The RISE and FALL field results in the previously described registers can be checked to look for values that appear out of place (for example, near 0x000, near 0x100 or greater) or to look for a DQ that is much different than the rest. After read data eye training is complete, software can always override the results by writing directly to the PHY\_RDDQS\_DQy\_RISE\_SLAVE\_DELAY\_x, PHY\_RDDQS\_DQy\_FALL\_SLAVE\_DELAY\_x, PHY\_RDDQS\_DM\_RISE\_SLAVE\_DELAY\_x and PHY\_RDDQS\_DM\_FALL\_SLAVE\_DELAY\_x fields.

#### 8.2.4.7.9.4 Write DQ Training

The data that is written to the SDRAM during training is created within the data slice. The following data pattern options are available:

- Clock pattern - An alternating pattern of "1" and "0" is applied to each DQ/DM. The phase of the 1/0 pattern is identical on the DQ/DM pins.
- LFSR pattern - The same LFSR pattern that is used for data loopback can be applied to the DQ/DM pins. The LFSR is reset at the start of the pattern and each burst of data is different according to the progression of the LFSR.
- User defined pattern - A user defined pattern can also be applied to the DQ/DM pins. Independent data for each bit covering a full burst of 16 can be loaded into register fields to supply the training data. The same data pattern is repeated for every burst. The pattern is defined through the following fields:
  - DDRSS\_PHY\_36[31-0] PHY\_USER\_PATT0\_0
  - DDRSS\_PHY\_292[31-0] PHY\_USER\_PATT0\_1
  - DDRSS\_PHY\_548[31-0] PHY\_USER\_PATT0\_2
  - DDRSS\_PHY\_804[31-0] PHY\_USER\_PATT0\_3
  - DDRSS\_PHY\_37[31-0] PHY\_USER\_PATT1\_0

- DDRSS\_PHY\_293[31-0] PHY\_USER\_PATT1\_1
- DDRSS\_PHY\_549[31-0] PHY\_USER\_PATT1\_2
- DDRSS\_PHY\_805[31-0] PHY\_USER\_PATT1\_3
- DDRSS\_PHY\_38[31-0] PHY\_USER\_PATT2\_0
- DDRSS\_PHY\_294[31-0] PHY\_USER\_PATT2\_1
- DDRSS\_PHY\_550[31-0] PHY\_USER\_PATT2\_2
- DDRSS\_PHY\_806[31-0] PHY\_USER\_PATT2\_3
- DDRSS\_PHY\_39[31-0] PHY\_USER\_PATT3\_0
- DDRSS\_PHY\_295[31-0] PHY\_USER\_PATT3\_1
- DDRSS\_PHY\_551[31-0] PHY\_USER\_PATT3\_2
- DDRSS\_PHY\_807[31-0] PHY\_USER\_PATT3\_3
- DDRSS\_PHY\_40[15-0] PHY\_USER\_PATT4\_0
- DDRSS\_PHY\_296[15-0] PHY\_USER\_PATT4\_1
- DDRSS\_PHY\_552[15-0] PHY\_USER\_PATT4\_2
- DDRSS\_PHY\_808[15-0] PHY\_USER\_PATT4\_3

These patterns can be used in any combination and if multiple patterns are requested, the final results are based on the largest leading edge found and the smallest trailing edge found across the patterns selected.

#### 8.2.4.7.9.5 CA Training

CA bits can be swizzled between any bit positions via the DDRSS\_PHY\_1053[23-0] PHY\_ADR\_ADDR\_SEL\_0 field.

When the memory subsystem consists of more than one LPDDR device on the full bus width (two 16 bit devices on a 32 bit bus), all devices receive the same CA bits at some timing relative to each other depending on board placement and routing. In these cases, the DDR PHY can only supply a single CA training value for all devices to use together. Since each device may not receive ideal timing, the CA timing margin is reduced in the overall memory subsystem. Either a single one (any of them) or any combination of the devices participating in the training can be individually selected via the DDRSS\_PHY\_1357[20-16] PHY\_CALVL\_DEVICE\_MAP field.

In case of two channels, each one can be assigned to a specific chip select and data slices. The DDRSS\_PHY\_1293[31-24] PHY\_CALVL\_CS\_MAP field is used to map each CS rank to the appropriate DQ slice for training data return.

Bit 1 of the DDRSS\_PHY\_1038[25-24] PHY\_ADR\_CALVL\_RANK\_CTRL\_0 field enables current training results to be taken into account along with new training results, instead of discarding previous results. This can be used to train each rank or channel and construct an aggregate for all of them. Each rank or channel then receives the same CA training timing that is the best case possible for all of them. This may result in the setup/hold margin for the CA bits being narrower than any single rank or channel could achieve by itself.

#### Note

When multiple frequency sets are supported, then all ranks for a given frequency set must be trained before changing to a new frequency. Failure to do so results in rank aggregation not being performed completely with possible data corruption due to rank training being improper.

In case of multiple channels each rank of a channel must use the same CA swizzle. Each rank of a channel must also use the same DQ swizzle.

If the memory device DQ bits are not received in the same order at the PHY as the LPDDR device sent them, then the DQ data has been swizzled, and must be reordered back to its original form before CA training can interpret the results. The following fields specify the DQ swizzling in the corresponding data slice:

- DDRSS\_PHY\_114[31-0] PHY\_DQ\_DM\_SWIZZLE0\_0
- DDRSS\_PHY\_370[31-0] PHY\_DQ\_DM\_SWIZZLE0\_1
- DDRSS\_PHY\_626[31-0] PHY\_DQ\_DM\_SWIZZLE0\_2
- DDRSS\_PHY\_882[31-0] PHY\_DQ\_DM\_SWIZZLE0\_3

- DDRSS\_PHY\_115[3-0] PHY\_DQ\_DM\_SWIZZLE1\_0
- DDRSS\_PHY\_371[3-0] PHY\_DQ\_DM\_SWIZZLE1\_1
- DDRSS\_PHY\_627[3-0] PHY\_DQ\_DM\_SWIZZLE1\_2
- DDRSS\_PHY\_883[3-0] PHY\_DQ\_DM\_SWIZZLE1\_3

The PHY\_DQ\_DM\_SWIZZLE0\_x fields contain the bit position to map the received read DQ bits for proper comparison with the training pattern bits.

After CA training is complete the DDRSS\_PHY\_1043[31-0] PHY\_ADR\_CALVL\_OBS1\_0 field can be read to obtain training status information.

After CA training is complete, software can always override the results by writing to the following fields:

- DDRSS\_PHY\_1065[18-8] PHY\_ADR0\_CLK\_WR\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1066[10-0] PHY\_ADR1\_CLK\_WR\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1067[10-0] PHY\_ADR2\_CLK\_WR\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1068[10-0] PHY\_ADR3\_CLK\_WR\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1069[10-0] PHY\_ADR4\_CLK\_WR\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1070[10-0] PHY\_ADR5\_CLK\_WR\_SLAVE\_DELAY\_0

#### Note

The PHY\_ADRx\_CLK\_WR\_SLAVE\_DELAY\_0 fields can be programmed between 0x000 and 0x600. While training is permitted to set these fields below 0x0C0, the final result is always greater than 0x0C0. If software overrides training results, values less than 0x0C0 should never be programmed. The same restriction applies also to the PHY\_GRPy\_SLAVE\_DELAY\_x fields.

#### 8.2.4.7.9.6 CS Training

When the CS training algorithm has completed, the final CS slave delay settings can be found in the following fields:

- DDRSS\_PHY\_1399[10-0] PHY\_GRP0\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1399[26-16] PHY\_GRP1\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1400[10-0] PHY\_GRP2\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1400[26-16] PHY\_GRP3\_SLAVE\_DELAY\_0
- DDRSS\_PHY\_1401[10-0] PHY\_GRP0\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_1402[10-0] PHY\_GRP1\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_1403[10-0] PHY\_GRP2\_SLAVE\_DELAY\_1
- DDRSS\_PHY\_1404[10-0] PHY\_GRP3\_SLAVE\_DELAY\_1

After CS training is complete, the DDRSS\_PHY\_1289[31-0] PHY\_CSLVL\_OBS1 field can be read to obtain training status information.

After CS training is complete, software can always override the results by writing directly to the PHY\_GRPy\_SLAVE\_DELAY\_x fields.

#### 8.2.4.7.10 Data Bus Inversion (DBI)

Data bus inversion is supported in the DDR PHY. The PHY only passes the DBI information between the DDR controller and SDRAM devices. It does not perform DBI generation and decode. If the DDRSS\_PHY\_102[8] PHY\_DBI\_MODE\_0 bit is set to 0x1 the SDRAM DBI information for slice 0 is passed to the DDR controller. The following bits are associated with the other slices:

- DDRSS\_PHY\_358[8] PHY\_DBI\_MODE\_1
- DDRSS\_PHY\_614[8] PHY\_DBI\_MODE\_2
- DDRSS\_PHY\_870[8] PHY\_DBI\_MODE\_3

#### 8.2.4.7.11 I/O Pad Calibration

I/O pad calibration runs at initialization time by default but it can also be programmed to operate in a background mode after initialization. Bits [3:1] of the DDRSS\_PHY\_1330[12-0] PHY\_CAL\_MODE\_0 field

enable the periodic calibration mechanism and determine the base clock frequency of the interval counter. The DDRSS\_PHY\_1331[31-0] PHY\_CAL\_INTERVAL\_COUNT\_0 field then sets a timer to indicate how frequently calibration is performed. When the timer expires, the calibration runs in background, independent of other traffic running through the PHY. When the calibration is complete, the updated PVTP/PVTN/PVTR codes are transferred to the PHY I/O cells. Whether or not the update of the memory clock PVTP/PVTN/PVTR codes is applied at the same time as the remaining I/O cells is controlled through the DDRSS\_PHY\_1298[8] PHY\_CONTINUOUS\_CLK\_CAL\_UPDATE bit. If the automatic update of the memory clock codes is disabled through the PHY\_CONTINUOUS\_CLK\_CAL\_UPDATE bit, the DDRSS\_PHY\_1298[0] SC\_PHY\_UPDATE\_CLK\_CAL\_VALUES bit can be used to trigger a manual update.

#### 8.2.4.7.12 DQS Error

A DQS error results from a mismatch between the expected number of read DQS pulses and the actual number of read DQS pulses. Counters exist at DDR PHY level to track the number of DQS errors in each data slice. Counter information can be obtained by reading the following fields:

- DDRSS\_PHY\_1363[31-0] PHY\_DS0\_DQS\_ERR\_COUNTER
- DDRSS\_PHY\_1364[31-0] PHY\_DS1\_DQS\_ERR\_COUNTER
- DDRSS\_PHY\_1365[31-0] PHY\_DS2\_DQS\_ERR\_COUNTER
- DDRSS\_PHY\_1366[31-0] PHY\_DS3\_DQS\_ERR\_COUNTER

The DQS error signals from each data slice are accumulated at PHY level and can be used to generate a dfi\_error signal. Bit 2 of the DDRSS\_PHY\_1361[26-24] PHY\_ERR\_MASK\_EN field is used to mask the DQS error from generating a dfi\_error or being reported on dfi\_error\_info[2].

#### 8.2.4.8 PI Functional Description

The PHY Independent (PI) module is part of the DDR PHY and can perform PHY independent leveling without involvement of the DDR controller. The PI can also initialize the SDRAM independent of the DDR controller. The PI module provides an interface between the PHY core logic and the DDR controller.

##### 8.2.4.8.1 PI Initialization

The PI module can be used to perform SDRAM initialization before training instead of the DDR controller. The following steps represent the main actions of the initialization process:

1. Set to 0x1 the DDRSS\_PI\_139[8] PI\_DRAM\_INIT\_EN bit.
2. Enable the PI by setting to 0x1 the DDRSS\_PI\_0[0] PI\_START bit.
3. Enable the DDR controller.
4. The PI, DDR controller and PHY core are involved in a process of specific hardware communication between them that does not require software intervention.
5. The PI starts the power-up sequence which includes the SDRAM initialization timing, the SDRAM mode register programming and training.
6. After completion of the power-up sequence, the PI notifies the DDR controller through the dfi\_init\_complete signal.
7. The DDR controller can now access the SDRAM.

## 8.3 Virtualization Subsystem (VirtSS)

This chapter describes the features and functions of the Virtualization Subsystem (VirtSS) hardware modules in the device.

### 8.3.1 VirtSS Overview

The VirtSS is instantiated in the main NAVSS.

#### 8.3.1.1 VirtSS Features

The VirtSS provides all the translation components supported in K3 for virtualization as well as NAVSS connectivity between the AC, MODSS, UDMASS, and NB ports. The virtualization components include PATs, PVUs, and Arm® SMMUv3 components, TBU and TCU. The number of each component, as well as the configuration of each component, can be seen in [Section 8.3.1.3, VirtSS Configuration](#). VirtSS instances the components and any required bridges and provides the CBA busses, connected into the main NAVSS CBASS. All routing to the VirtSS is defined in the NAVSS CBASS.

There is one VirtSS in the device and it is part of the main Navigator Subsystem (NAVSS0).

The VirtSS supports the following functions and features:

- Implements all virtualization translation components in a subsystem
- Implements NAVSS connectivity between AC, MODSS, UDMASS, and NB ports
- Supports 5× PATs (Page-based Address Translator), see [Section 8.3.3](#)
- Supports 3× PVUs (Peripheral Virtualization Unit), see [Section 8.3.2](#)
- Supports a SMMU TBU (Arm SMMUv3 Translation look-aside Buffer Unit)
- Supports a SMMU TCU (Arm SMMUv3 Translation Controller Unit)
- Supports a SMMU DTI ( Arm® AMBA® Distributed Translation Interface) interconnect
- Supports external DTI connections
- Bridges all AXI or APB interfaces to CBA VBUSM and VBUSP busses.

For SMMU TBU and SMMU TCU functional description please refer to Arm documentation at <http://infocenter.arm.com>.

#### 8.3.1.2 Functional Description

The Arm® System Memory Management Unit (SMMU) provides facilities to translate addresses of transactions mastered by non-processor modules in the device. For embedded automotive applications, SMMU is not used to increase hardware utilization through datacenter-like virtualization, but for enhanced software reliability and safety by rigid partitioning of chip-level resources.

The block diagram of the VirtSS, Virtualization Subsystem, that implements SMMU is described in [Figure 8-11](#).

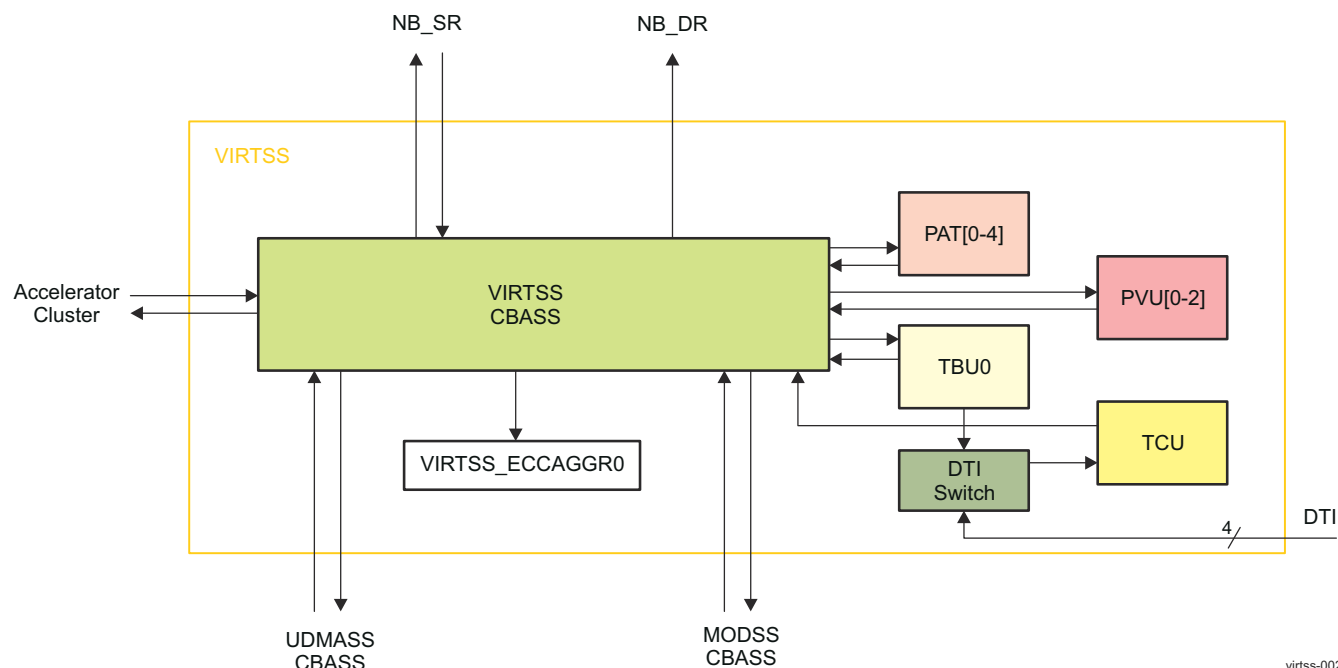

Figure 8-11. VirtSS Block Diagram

### 8.3.1.2.1 Ports

The VirtSS has 4 sets of ports, in and out, for the AC, MODSS, UDMASS, and NB. Each set includes a configurable number of possibly parallel ports where *orderid* defines the port to use for the transaction. If the port group matches a slave port group then those masters only connect to those slaves, otherwise all masters connect to the slaves without matching group names. The ports can carry PA, IPA, or VA addresses and route to the slave ports or the virtualization components. The NAVSS must define these as parallel ports using the same *orderid* mappings. It should also map the PAT physical addresses to these ports. These ports support the following table of accesses - [Table 8-23](#).

Table 8-23. Port Table of Accesses

Atype	Path
PA	Access to slave port
PA	Access to PAT
IPA	Access to PAT (must hit PAT range), then to PVU
IPA	Access to PVU
VA	Access to SMMU

### 8.3.1.2.2 CBASS

The VirtSS uses a CBASS to support decoding transactions to the slaves and PATs, which are address based, or to the PVUs which is *atype* and *orderid* based, or to the TBUs which are *atype* and *orderid* based. To support this all input transactions of IPA *atype* that hit the PAT address range are converted to PA so that the CBASS can decode the address to a PAT region, and then the *atype* is restored going into the PAT. Any other IPA transaction will go to a PVU. And any VA transaction will go to a TBU. PAT, PVU, and TBU output transactions go back to this CBASS so that they can be decoded again. This allows an IPA transaction to go first to a PAT and then to a PVU. The PVU and TBU output transactions will target the slave based on the resulting translated address. DMA transactions that are just to PVU can use private DMA PVUs if configured. DMA transactions that access the PAT will transition like they were non-DMA transactions and use the IO PVU components.

### 8.3.1.2.3 PAT

The VirtSS contains PATs, which are page based address translation units. The PAT is address based, so only translations addressing the PAT will reach the PAT input bus. The PAT is then programmed for the page size and page translations. The PAT will then map the input address to a page and translate the address of the output transaction to the programmed physical address. The PAT output bus goes back to the VirtSS CBASS to be routed to the new target.

#### 8.3.1.2.3.1 Bandwidth Splitting

If a single PAT cannot support the required bandwidth, then multiple PAT instances must be used. Since the PAT is physically addressed, any bandwidth splitting must be done by address. That means the peripherals accessing the PAT must use the correct address mapping so that they are routed to the correct PAT. There may be some gaps in the PAT address map if the page sizes of the PATs are not programmed to the largest size, since the fixed SoC address map must support the largest PAT sizes.

### 8.3.1.2.4 PVU

The VirtSS contains PVUs, which are peripheral virtualization units. The PVU is IPA, intermediate physically addressed, so only translations using that address type will reach the PVU input bus. The PVU is then programmed for each *virtid* table, per VM, and all the translations, which are similar to LPAE pages. The PVU will then map the input address to a table and page and translate the address of the output transaction to the programmed physical address. The PVU output bus goes right back to the VirtSS CBASS to be routed to the new target.

#### 8.3.1.2.4.1 Bandwidth Splitting

If a single PVU cannot support the required bandwidth, then multiple PVU instances must be used. Since the PVU does not have any address decode, using an IPA, then any splitting is done based on the bus *orderid* value. That means the peripherals accessing the PVU must be set to use the correct *orderid* so that they are routed to the correct PVU.

### 8.3.1.2.5 TBU

The VirtSS contains SMMU TBUs, which are TLBs, translation look aside buffer units. The TBU is virtually addressed, so only translations using that address type will reach the TBU input bus. The TBU normally uses the *virtid* CBA signal as the AXI *streamid* signal to identify the VM for the translation. There is a bridge from the VBUSM bus to the AXI bus of the TBU. The TBU will perform the virtual address lookup and on a hit, or on a miss it will request the translation from the TCU, described later, via the DTI bus, also described later. The TBU will then translate the address of the output transaction based on the SMMU programmed page tables to the programmed physical address. The TBU output bus goes through another bridge from AXI to VBUSM and then goes back to the NAVSS CBASS to be routed to the target.

#### 8.3.1.2.5.1 Bandwidth Splitting

If a single TBU cannot support the required bandwidth, then multiple TBU instances must be used. Since the TBU does not have any address decode, using a VA, then any splitting is done based on the bus *orderid* value. That means the peripherals accessing the TBU must be set to use the correct *orderid* so that they are routed to the correct TBU.

#### 8.3.1.2.5.2 Initialization Delay Requirement

In order to initialize the TBL RAMs for ECC codes, there must be no transactions to the TBU for at least 32 TBU clock cycles after reset while the RAM is busy. During this time the software must not enable any IOs for SMMU usage.

### 8.3.1.2.6 TCU

The VirtSS contains an SMMU TCU, translation controller unit. TCU takes translation requests from all the TBUs via the DTI bus and walks the SMMU page tables in memory, if there are any TBUs enabled. The TCU has an output AXI bus to access memory, and this is bridged to VBUSM which then goes to the NAVSS CBASS to access the memory. The TCU is programmed to map the VM to SMMU page tables in memory, as well as

other features, via a VBUSP port bridge to APB. Due to the bridge not supporting byte enables, all TCU register access must be full 32-bit words, and it does not support individual byte writes.

### 8.3.1.2.7 DTI Interconnect

The VirtSS contains an SMMU DTI, distributed translation interface, to interconnect the TBU requests to the TCU. The interconnect simply switches all the TBU DTI busses to the single TCU bus and delivers the TCU responses. These busses are then connected to TBU and TCU.

### 8.3.1.2.8 External DTI Ports

The VirtSS contains external SMMU DTI ports to connect external subsystems that have DTI support, such as PCIe. The number of ports can be seen in [Table 8-26](#), *VirtSS Global Parameters*.

### 8.3.1.2.9 DMA Split

The VirtSS supports reserving some of the components for DMA only usage, to keep the DMA and peripheral usage from interfering with each other. Only the DMA ports will be able to access the DMA private PVUs or TBUs. All the TBUs still connect inside the VirtSS to the single TCU via the DTI interconnect.

### 8.3.1.2.10 Port Routing Rules

Since the ports are all split based on *orderid*, there are normally fixed connections to components as well as the final output port that a transaction will follow. [Table 8-24](#) details the rules that are applied to a transaction from the various input ports, where X is the port matching the transaction *orderid*. The only less consistent path is when the DMA source accesses the PAT, and then the output route becomes the IO path (due to problems routing from PAT to either IO or DMA PVUs), or when the VirtSS is configured for less DMA PVUs and the transactions will route to the DMA PVU if it exists for that *orderid* and if not then the IO PVU for that *orderid*. Note that the PAT and PVU contain registers that can modify the *orderid* of a transaction, and if these features are enabled, then the output port for those transactions will be modified as well, so these rules would no longer apply.

**Table 8-24. Port Routing Rules**

Input Port	Components
<non-dma>_mstX	PAT and/or IO PVU
dma_mstX	IO PVU only (if not private DMA PVU for that orderid)
dma_mstX	DMA PVU only
dma_mstX	PAT and IO PVU
<non-dma>_mstX	IO TBU
dma_mstX	DMA TBU

There are also paths that are explicitly blocked, either because they could cause deadlock or because the path is not possible. The impossible paths are due to the PVU and SMMU translations always resulting in physical addresses, which cannot target a PVU or SMMU since those only receive intermediate or virtual transactions. [Table 8-25](#) shows all the blocked paths, and any transactions that attempt to target these paths inside the VirtSS will return errors.

**Table 8-25. Blocked Paths**

Source Port or Component	Target Port or Component that is Blocked
PAT output	PAT input (could deadlock)
PVU output	PVU or SMMU input (impossible)
SMMU output	PVU or SMMU input (impossible)

If the system is using PAT to PVU paths, then the PVU tables are not allowed to map to physical addresses which map to a PAT. This is because it can cause a loop for transactions going to PAT to PVU back to PAT, which

could cause a deadlock. Software must avoid this condition by not allowing the PVU to map any translations back to a PAT range.

### 8.3.1.3 VirtSS Configuration

This section describes the hardware configuration of VirtSS.

[Table 8-26](#) shows the global VirtSS settings that are enabled.

**Table 8-26. VirtSS Global Parameters**

Parameter	Setting	Description
data_width	256	Data bus width in bits.
fault_addr	0x0000310cf000	Fault address location to send faulting transactions, so that they route to a known location to return errors.
pat_small_start	0x004800000000	Base address for the first small PAT.
pat_large_start	0x004900000000	Base address for the first large PAT.
num_ext_dtis	4	Number of external DTI ports.
tbu_burst_size	256	Max burst size for TBU input transactions for AXI bridge sizing.
tbu_id_width	4	Width in bits for TBU AXI ID pins based on toggling orderid range for AXI bridge sizing.
tbu_buffers	enabled	TBU Buffers for transaction offload are enabled.
safe	enabled	Safety is enabled.

#### 8.3.1.3.1 PAT Parameters

[Table 8-27](#) shows the PAT instance configuration.

**Table 8-27. PAT Parameters**

PAT Instance	Number of Pages	Large	Source ID	Config FW	RouteID
NAVSS0_PAT0	16384	0	0	0x0000:6:3:4736	224
NAVSS0_PAT1	16384	0	0	0x0400:6:3:4737	225
NAVSS0_PAT2	16384	0	0	0x0800:6:3:4738	226
NAVSS0_PAT3	2048	1	1	0x0c00:6:3:4739	227
NAVSS0_PAT4	2048	1	1	0x1000:6:3:4740	228

#### 8.3.1.3.2 PVU Parameters

[Table 8-28](#) shows the PVU instance configuration.

**Table 8-28. PVU Parameters**

PVU Instance	TLB Channels/ VirtIDs	Entries per TLB Channel	Source ID	Config FW	RouteID	OrderID range
NAVSS0_IO_PV U0	64	8	16	0x2000::3:4744	208	0-7
NAVSS0_IO_PV U1	64	8	17	0x2400::3:4745	209	8-15
NAVSS0_DMA_ PVU1	64	8	19	0x2c00::3:4747	211	8-15

#### 8.3.1.3.3 TBU Parameters

[Table 8-29](#) shows the TBU instance configuration.

**Table 8-29. TBU Parameters**

TBU Instance	Write Buffer Depth	Latency FIFO Depth	Translate Slots	Read Outstanding Transaction Depth	Write Outstanding Transaction Depth	Micro TLB Depth	Main TLB Depth	RouteIDs	OrderID range
IO_TBU0	64	4	4	64	64	12	128	232-233	0-15

**8.3.1.3.4 TCU Parameters**

[Table 8-30](#) shows the TCU configuration.

**Table 8-30. TCU Parameters**

Walk Cache Stage 1 Depth (L0, L1, L2, L3)	Walk Cache Stage 2 Depth (L0, L1, L2, L3)	Configuration Cache Depth	Translation Slots	Page Table Walk Slots	Cache Table Walk Slots	Config FW	RouteIDs
128, 128, 1024, 1024	128, 128, 1024, 1024	16	32	32	8	0x4000::3:4752	248-249

**8.3.1.3.5 ECC Aggregator Parameters**

[Table 8-31](#) shows the ECC Aggregator configuration.

**Table 8-31. ECC Aggregator Parameters**

Config Base	Config FW
0x000031002000	0x4400::3:4753

### 8.3.1.4 Theory of Operation

For SOC components outside the NAVSS and Compute Cluster (CC), the device provides a pool of address mapping resources composed of Arm SMMUv3 TBU instances, TI PVU instances and TI PAT instances. At system configuration time, software programs the SOC infrastructure (including SOC CBASS and NAVSS CBASS) such that I/O modules and hardware accelerators are associated with specific address mapping resources. I/O modules may also be configured to master transactions directly through NAVSS CBASS with trusted physical addresses by setting the transaction's CBA ATYPE bits either in the specific module's configuration or with the SOC CBASS port logic.

UDMA has its own dedicated set of four PVU address mapping resource modules that are in series with the connections from UDMA.

Components in the compute cluster that master transactions implement the Armv8 two-level translation scheme or equivalent functionality using PAT and PVU modules.

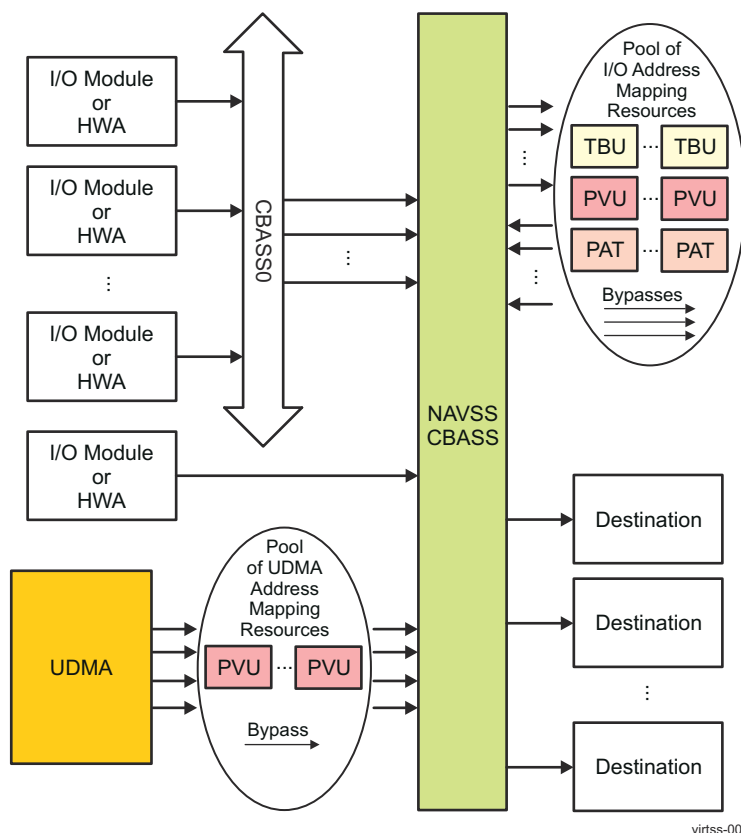

The options for transactions mastered by I/O, HWA or UDMA are summarized in [Table 8-32](#).

**Table 8-32. Transaction Options**

Source	Hop 1	Hop 2	Hop 3	Hop 4	Hop 5	Hop 6	Hop 7	Notes
I/O device	SOC switch	CBASS	Destination					Trusted physical address
I/O device	SOC switch	CBASS	TBU	CBASS	Destination			Non-realtime transaction
I/O device	SOC switch	CBASS	PAT	CBASS	Destination			Real-time, trusted transaction
I/O device	SOC switch	CBASS	PVU	CBASS	Destination			Real-time, trusted transaction
I/O device	SOC switch	CBASS	PAT	CBASS	PVU	CBASS	Destination	Real-time, trusted transaction
HWA	CBASS	Destination						Trusted physical address
HWA	CBASS	TBU	CBASS	Destination				Non-realtime transaction
HWA	CBASS	PAT	CBASS	Destination				Real-time, trusted transaction
HWA	CBASS	PVU	CBASS	Destination				Real-time, trusted transaction
HWA	CBASS	PAT	CBASS	PVU	CBASS	Destination		Real-time, trusted transaction
UDMA	CBASS	Destination						Trusted physical address
UDMA	CBASS	TBU	CBASS	Destination				Non-realtime transaction
UDMA	PVU	CBASS	Destination					Real-time, trusted transaction
UDMA	CBASS <sup>(1)</sup>	PAT	CBASS	Destination				Real-time, trusted transaction
UDMA	CBASS <sup>(1)</sup>	PAT	CBASS	PVU	CBASS	Destination		Real-time, trusted transaction

- (1) One connection into CBASS is provided for UDMA connections to bypass PVU translation and go through CBASS to a PAT instance. This path is a configuration-time option and only supports 25% of the UDMA to CBASS bandwidth.

[Figure 8-12](#) shows an overview of VirtSS operation.

**Figure 8-12. Functional Diagram**

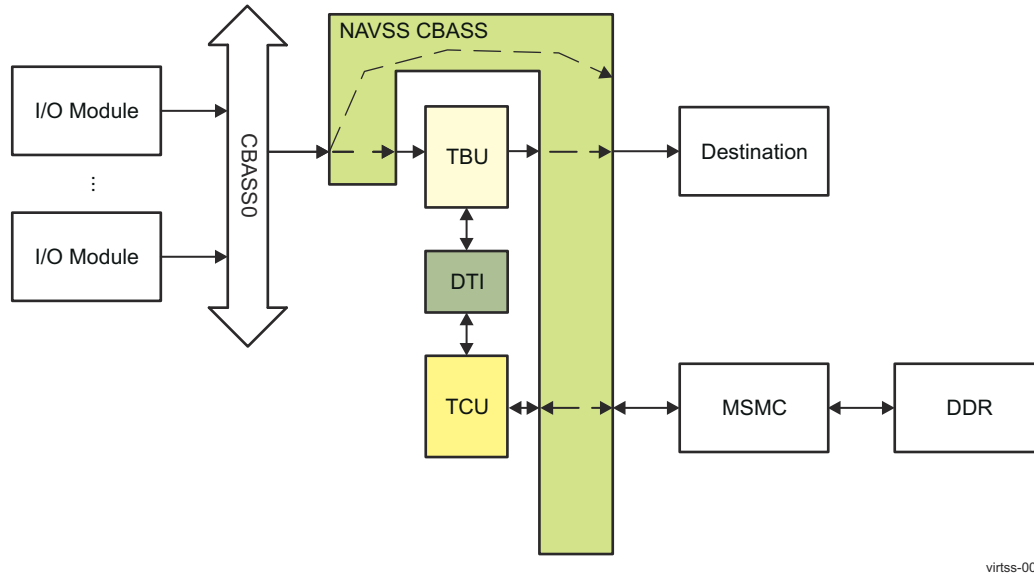

Aggregated requests from I/O or HWA modules are mapped directly to NAVSS CBASS ports. When using I/O address translation, normal switching in NAVSS CBASS passes transactions to dedicated CBASS ports connected to the address mapping resource ports. The logic on the path through each TBU, PVU or PAT module reads transactions, performs translations, optionally modifies transaction side-band information, and sends translated transactions back into the interconnect to be switched to the transaction's next destination.

The address mapping resource modules have a moderate number of cached or stored translations that can service translations with low latency. All of the TBU instances connect to a single TCU through the DTI protocol. When a TBU lookup miss occurs, a request is sent from the TBU using the DTI protocol over an AXI switch interconnect to the TCU. The requested translation may be cached in the TCU. If the translation is not present, table walking state machines load the translation, typically in multiple memory accesses, from tables via additional transactions through CBASS and MSMC with DDR memory.

Exception events can occur when PAT or PVU lookups are requested but there is not a matching memory range.

The architecture and microarchitecture of the TBU and TCU are specified by Arm documentation [<http://infocenter.arm.com>].

**Figure 8-13. Functional Example**

The address mapping resource modules have limited command bandwidth. The peak command rate of the TBU, PVU and PAT is one command per clock cycle, at the CBASS clock rate. There is some level of hit-under-miss support in the TBU allow commands to proceed through the TBU while misses are being serviced by the TCU. Depending on the TBU access pattern, the command bandwidth may be much less than the peak rate.

Software assignment of I/O modules or HWAs to address translation resource requires some estimation of the bandwidth or command rate of the specific I/O modules in the system, the characteristics of the address sequence per virtual machine (which may include multiple channels), the page sizes used for the address translation and the number of VMs expected to use the I/O modules. As a crude rule-of-thumb, a specific TBU should support near peak rate if  $3 \times \sum_i (VM_i \times Channels_i)$  for the virtual machines and each virtual machine's channels is less than 128.

Latencies grow roughly by orders of magnitude as translations proceed from the TBU through TCU. Accesses that hit the TBU uTLB or miss the TBU uTLB and hit the TBU MTLB have a throughput of one access per cycle. There is a < 100 cycle penalty on TBU uTLB miss that misses in TBU MTLB and hits in TCU. Subsequent accesses may not observe this penalty because of hit under miss processing. There is a < 1000 cycle penalty on TBU uTLB miss that misses in TBU MTLB and misses in TCU MTLB and require table walk. Hit-under-miss behavior is not beneficial in this case.

**Table 8-33. Address Translation Resource Summary**

Mapping Resource	Peak bandwidth supported (assuming 256b interconnect at 500MHz) over all instances
1 TBU for I/O, UDMA and HWA modules	16 GB/s
4 PAT (parallel small and large size instances) for I/O and HWA modules	64 GB/s
4 PVU for I/O and HWA modules	64 GB/s
4 PVU for UDMA	64 GB/s

This architecture depends on proper configuration to reach performance targets. The software configuration of the SOC and NAVSS components that control the mapping of I/O devices and hardware accelerators to address mapping resources must minimize contention for the limited TBU entries. Failure to load balance the TBU instances has several undesirable consequences. First, the latency of the initial hop through NAVSS CBASS to the TBU is modulated by the throughput of the TBU pair. Frequent TBU misses that require TCU lookups reduce the TBU throughput and can increase the congestion in CBASS. Second, long term severe congestion

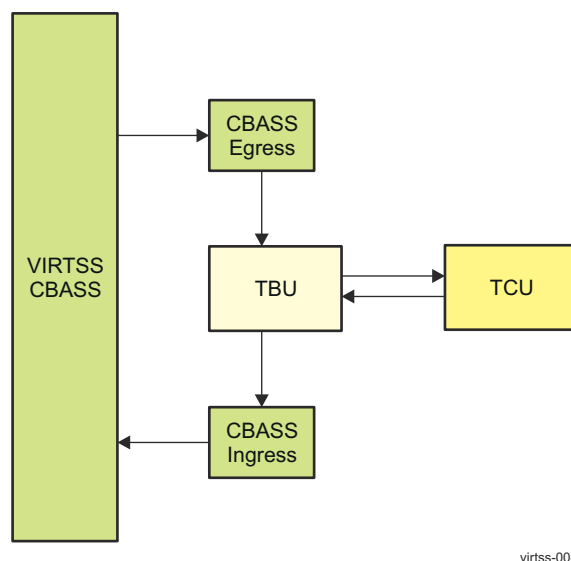

in links results in head-of-line (HOL) blocking for the other I/O devices or hardware accelerators that have been aggregated onto the same CBASS input port. This results in undesirable performance interference between I/O devices or hardware accelerators.

In addition to performance considerations, this architecture depends on proper configuration to avoid deadlocks. If all the available hit-under-miss capacity in the TBU and TCU are exhausted and there is a TBU miss that must be handled by the TCU and the TCU must access memory, that path to memory must not be obstructed by the transaction that is waiting on the TCU response to the TBU. If this obstruction occurs then there will be no forward progress on that TBU transaction and a deadlock will occur. For deadlock-free operation, the TCU path through CBASS to MSMC and DDR cannot share resources with any path from and I/O device or hardware accelerator to a TBU instance.

#### 8.3.1.4.1 TBU Address Translation Module

The TBU module reads transactions from CBASS, performs permission checks and address translations from virtual addresses then returns translated physical address transactions to CBASS. The architectural 2-stage translation and intermediate physical addresses (IPA) and the are not visible or exported to the rest of the system.

TBU is segregated from PAT and PVU paths to avoid short-term interference due to TBU blocking conditions on real-time traffic.

**Figure 8-14. TBU Functional Diagram**

On the path through the TBU, egress logic from CBASS converts the transactions to the format expected by the TBU. Internally, TBU provides payload-wide buffering and arbitration to support reordering as a result of TBU misses. Additionally, per Arm documentation, the TBU contains a bypass path that copies the input transaction to the output without translation or permission checking. Once the TBU has completed operating on a transaction, CBASS ingress logic converts the TBU output to format expected by CBASS and the transaction is transported to its final destination.

#### 8.3.1.4.2 DTI

Arm has defined the DTI (Distributed Translation Interface) message protocol to convey translation requests and responses between the TBUs and TCU. The protocol was defined to allow for a variety of transport mechanisms. The device uses AXI for DTI transport. Standard AXI bus components multiplex the TBU DTI requests onto a single command bus that the TCU reads. To maintain single-cycle TCU throughput, an AXI read channel returns DTI responses to the TBUs.

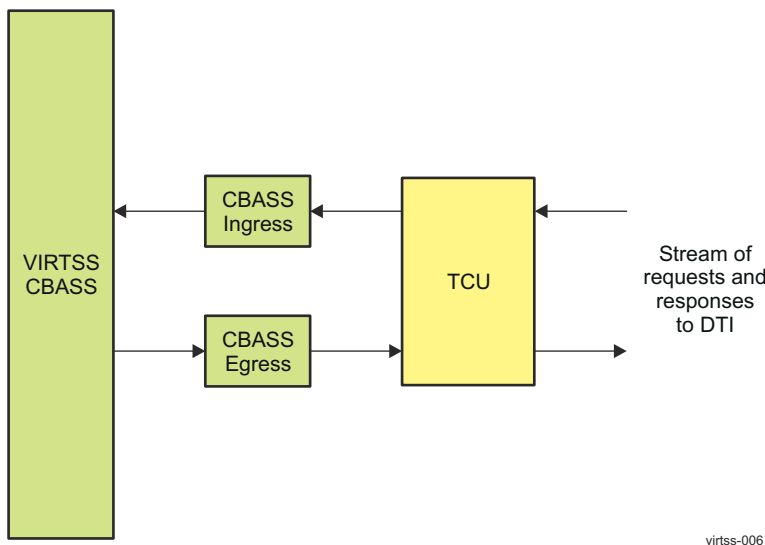

**Figure 8-15. DTI Functional Diagram**

#### 8.3.1.4.3 TCU

The Translation Control Unit (TCU) reads a stream of DTI-protocol translation requests from the distributed TBUs and returns translation information either from the TCU's local cache or from tables in memory. The TCU is wrapped in a module that includes the CBASS transaction push and pull interfaces. TCU operations that require table walking use these interfaces to access DDR memory where the in-memory page tables are stored.

Additionally, TCU handles Address Translation Service (ATS) for PCIe and the equivalent function for USB.

The K3 architecture does not support hardware coherence between any cached page table information in the TCU and operations on memory from the compute cluster. If an agent in the compute cluster modifies page tables, some mechanism must be used to initiate TCU invalidation. TCU invalidations automatically handle the subsequent TBU invalidations. This behavior is consistent with the Arm SMMU system architecture definition.

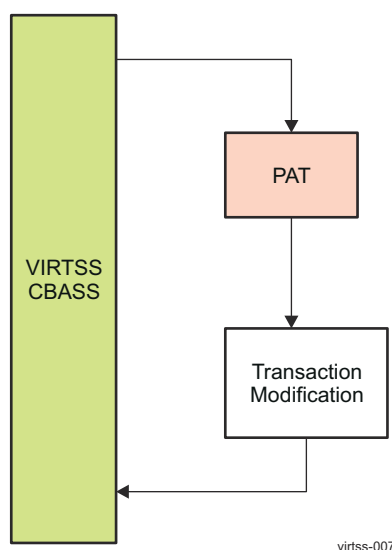

**Figure 8-16. TCU Functional Diagram**

#### 8.3.1.4.4

#### 8.3.1.4.5 PAT Address Translation Module

The PAT module reads transactions from CBASS, performs address translations from physical address or intermediate physical addresses using address lookup, then returns the same type (physical or intermediate physical) address transactions to CBASS. Details on PAT operation can be found in [Section 8.3.3, Page Based Address Translation Unit \(PAT\)](#).

**Figure 8-17. PAT Functional Diagram**

After address translation, the transaction passes through a transaction modification block that can change sideband information such as OrderID to divert the transaction to other modules for further translation (typically a PVU module). This transaction modification may use K3-specific data stored as page attributes in the PAT. Transaction modification can be globally disabled for all PAT instances with a single register write.

#### **8.3.1.4.5.1 Run-Time PAT Configuration**

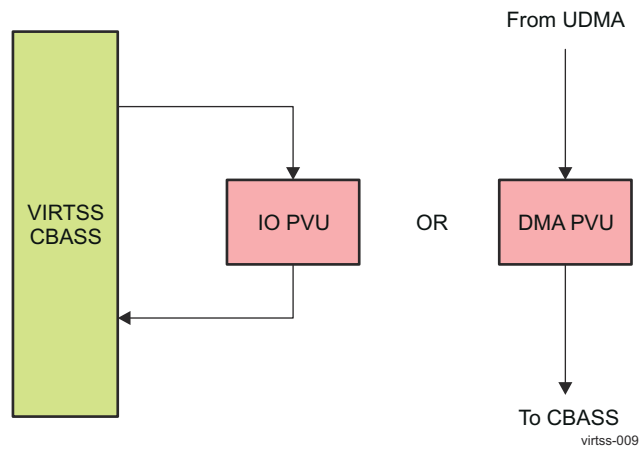

The registers in PAT that define the address spaces are mapped into the physical address space in contiguous regions. Software, probably a hypervisor, can use DMA to accelerate updates to PAT. However, these DMA writes are not indivisible. An address transaction to a region mapped by an incoming or over-written address range may result in a corrupted translation. The hypervisor must configure PAT before virtual machines using those mapping are allowed to perform memory translation through a PAT instance.

A subset of a PAT instance's registers are used for control and configuration. Each PAT instance has an independent copy of these registers. Except for the transaction modification control described above, software that wants to globally apply some configuration or operating mode to all PAT instances must iterate through all the PAT instances.

There is no special handshake mechanism in PAT can be used determine when the page updates through DMA are complete. The hypervisor must use the normal DMA completion indication to determine when the entries are updated and it is safe to allow traffic through the PAT using a new configuration.

#### **8.3.1.4.6 PVU Address Translation Module**

The PVU module reads transactions from CBASS or UDMA, and performs address translations on partitions of memory regions indexed by the transaction's VirtID. PVU checks page permissions, completes the translation and returns the translated transaction to CBASS for switching to the destination. Details of PVU operation can be found in [Section 8.3.2, Peripheral Virtualization Unit \(PVU\)](#).

**Figure 8-18. PVU Functional Diagram**

The PVU has a fixed number of contexts and pages per context. There are 64 contexts in each PVU instance, each containing 8 variably-sized pages.

The PVU does not implement table walking. An address sent to PVU that cannot be associated with a page is an error condition.

## 8.3.2 Peripheral Virtualization Unit (PVU)

This chapter describes the PVU module, part of the main NAVSS.

### 8.3.2.1 PVU Overview

The Peripheral Virtualization Unit (PVU) module provides TLBs (translation look-aside buffers) for a static virtual address translation on a CBA VBUSM bus.

Figure 8-19 shows a top-level overview of the PVU module.

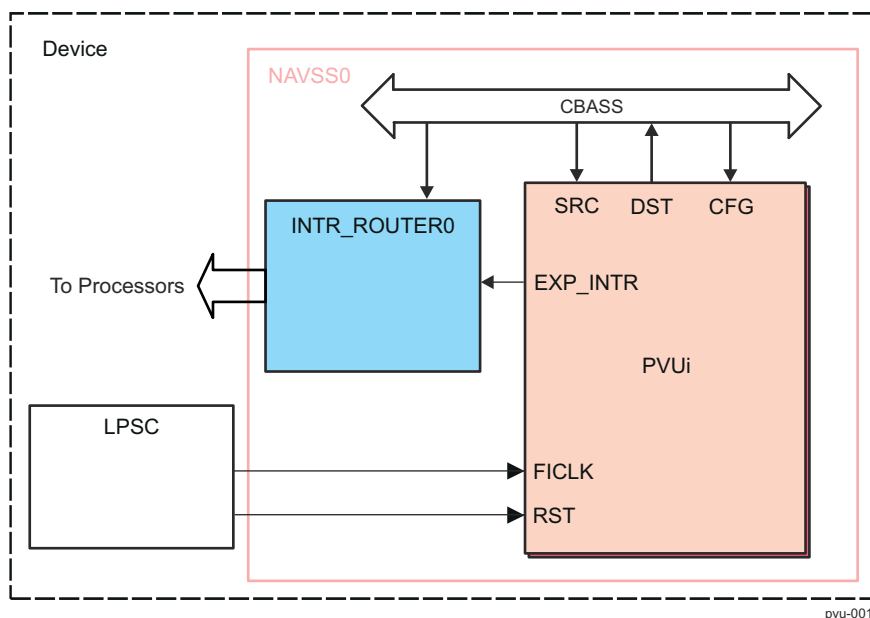

Figure 8-19. PVU Overview

#### 8.3.2.1.1 PVU Features

Each PVU supports the following features:

- Implements a channelized TLB for virtual address translation
- Supports a pre-configured number of virtIDs (channels). See [Section 8.3.2.1.2](#).
- Supports mapping of virtIDs to TLBs with a programmable number of DMA channel support
- Supports a pre-configured number of entries per channel of the TLB. See [Section 8.3.2.1.2](#)
- Supports TLB chaining to extend the search but at a latency penalty
- Supports a 48-bit address size
- Supports page sizes of 4 KB, 16 KB, 64 KB, 2 MB, 32 MB, 512 MB, 1 GB, and 16 GB
- Support TLBs in software mode, where they are maintained by software only
- Produces a fault interrupt when the TLB misses or upon a permission error.

#### 8.3.2.1.2 PVU Parameters

Table 8-34 shows the PVU configuration parameters set during SoC design.

Table 8-34. PVU Configuration Parameters

Module Instance	Parameters					
	TLB Channels <sup>(1)</sup>	Entries per TLB Channel <sup>(1)</sup>	Source ID	Config FW	RouteID	OrderID range <sup>(2)</sup>
NAVSS0_IO_PVU0	64	8	16	0x2000::3:4744	208	0-7 (IO and DMA)
NAVSS0_IO_PVU1	64	8	17	0x2400::3:4745	209	8-15 (IO)

**Table 8-34. PVU Configuration Parameters (continued)**

NAVSS0_DMA_PVU1	64	8	19	0x2c00::3:4747	211	8-15 (DMA)
-----------------	----	---	----	----------------	-----	------------

- (1) Can be read off from the PVU\_CONFIG read-only register.
- (2) Depending on the value of orderID of the transaction, and type of master, it will be routed to one of the PVU instances. Here, DMA indicates any transaction from NAVSS UDMA and IO indicates any other master excluding UDMA

#### 8.3.2.1.3 PVU Not Supported Features

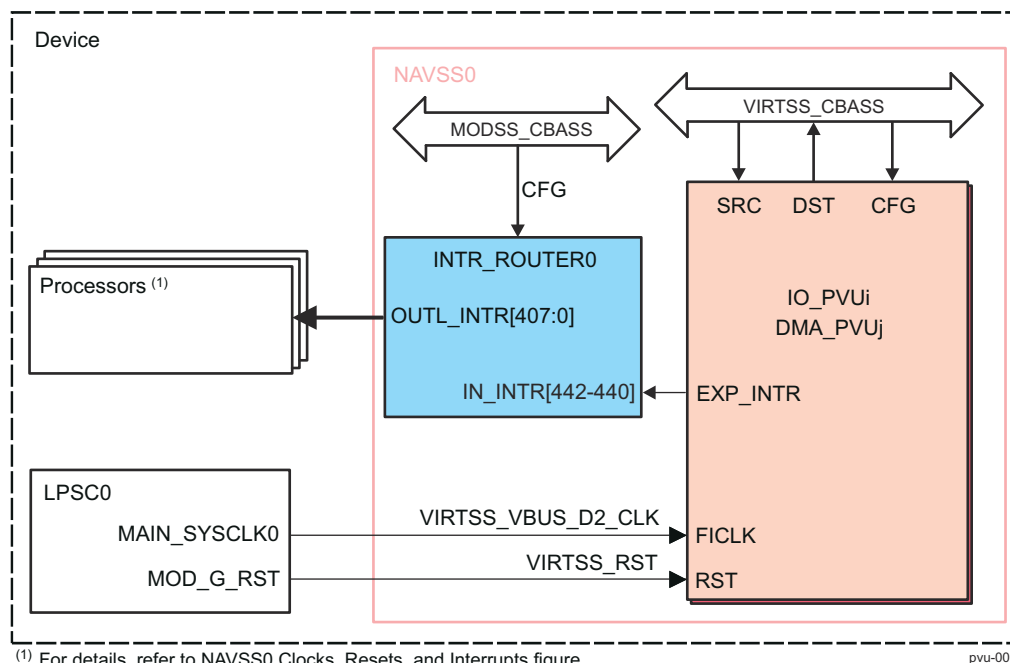

The following features are not supported by the module:

- Does not generate bus error responses
- Does not support transactions that cross a 4-KB boundary
- Does not support back fill from any MMU, hardware, or software.

### 8.3.2.2 PVU Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 8-20 shows the PVU integration in the device.

**Figure 8-20. PVU Integration**

i = 0 or 1

j = 1

Table 8-35 and Table 8-36 summarize the integration of the module in the device.

**Table 8-35. PVU Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
NAVSS0_IO_PVU0	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_IO_PVU1	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_DMA_PVU1	PSC0	GP	LPSC0	VIRTSS_CBASS

**Table 8-36. PVU Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
NAVSS0_IO_PVU0	FICLK	VIRTSS_VBUS_D2_CLK	MAIN_SYSCLK0	This clock is used for all interface and functional operations.
NAVSS0_IO_PVU1	FICLK	VIRTSS_VBUS_D2_CLK	MAIN_SYSCLK0	This clock is used for all interface and functional operations.
NAVSS0_DMA_PVU1	FICLK	VIRTSS_VBUS_D2_CLK	MAIN_SYSCLK0	This clock is used for all interface and functional operations.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
NAVSS0_IO_PVU0	RST	VIRTSS_RST	LPSC0	PVU hardware reset
NAVSS0_IO_PVU1	RST	VIRTSS_RST	LPSC0	PVU hardware reset

NAVSS0_DMA_PV U1	RST	VIRTSS_RST	LPSC0	PVU hardware reset
---------------------	-----	------------	-------	--------------------

**Table 8-37. PVU Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
NAVSS0_IO_PVU0	EXP_INTR	IN_INTR[442]	INTR_ROUTER0	Fault interrupt when the TLB misses or a permission error was found	Level
NAVSS0_IO_PVU1	EXP_INTR	IN_INTR[441]	INTR_ROUTER0	Fault interrupt when the TLB misses or a permission error was found	Level
NAVSS0_DMA_PV U1	EXP_INTR	IN_INTR[440]	INTR_ROUTER0	Fault interrupt when the TLB misses or a permission error was found	Level
DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
NAVSS0_IO_PVU0	-	-	-	No PDMA channels to external DMA engines	-
NAVSS0_IO_PVU1	-	-	-	No PDMA channels to external DMA engines	-
NAVSS0_DMA_PV U1	-	-	-	No PDMA channels to external DMA engines	-

### 8.3.2.3 PVU Functional Description

#### 8.3.2.3.1 Functional Operation Overview

The Peripheral Virtualization Unit, PVU, module provides TLBs, translation look-aside buffers, for a static virtual address translation on a CBA VBUSM bus. This is in contrast to a dynamic translation TLB that works with an MMU, such as the Arm® processor SMMU. The module acts as a VBUSM retiming bridge that also performs the address translation. Each of the TLBs has its own set of private entries. It is a static translation because all the entries must be programmed by software and there is no hardware to fetch new translation entries when a transaction does not match any of the provided entries.
