64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **TIME\_STAMP** are used (**CPSW\_CPTS\_EVENT\_0\_REG** and **CPSW\_CPTS\_EVENT\_3\_REG**). In 32-bit mode only the lower 32-bits (**CPSW\_CPTS\_EVENT\_0\_REG**) are used.

**Figure 12-174. CPTS\_COMP Output in Toggle and Non-Toggle Mode**

#### 12.2.2.4.7.10 Timestamp Sync Output

The **CPTS\_SYNC** output is a selected bit of the [31:0]**TIME\_STAMP** counter value. One of bits 17-31 can be selected in **CPSW\_CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL**. The **CPTS\_SYNC** output is disabled when **CPSW\_CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL** is zero.

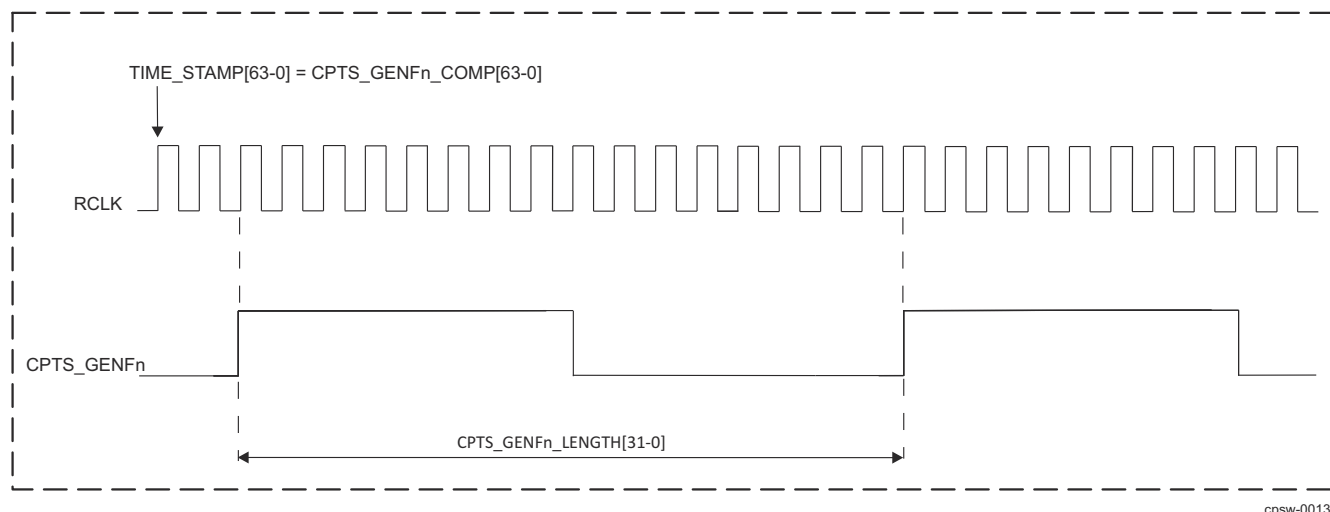

If the selected counter bit is 1 at the time when **TS\_SYNC\_SEL** value is written then a rising edge will not occur on the **CPTS\_SYNC** output. A rising edge will occur on the **CPTS\_SYNC** output upon the next transition to 1 of the selected counter bit. The **TS\_SYNC\_SEL** value must be written to zero before changing to a different non-zero value. No events are generated due to the **CPTS\_SYNC** operation. The **CPTS\_SYNC** output is two **CPTS\_RFT\_CLK** periods after the actual count value.

#### 12.2.2.4.7.11 Timestamp GENFn Output

The **CPTS\_GENFn** outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The **CPTS\_GENFn** output cycle is **CPSW\_GENF0\_LENGTH\_REG/ CPSW\_GENF1\_LENGTH\_REG[31:0] LENGTH CPTS\_RFT\_CLK** periods (which is different than **CPTS\_COMP** operation). [Figure 12-175](#) represents the **CPTS\_GENFn** output signal.

The **CPTS\_GENFn** output cycle is **CPSW\_GENF0\_LENGTH\_REG/ CPSW\_GENF1\_LENGTH\_REG[31:0] CPTS\_RFT\_CLK** periods beginning when the 64-bit **TIME\_STAMP** value compares with the 64-bit **GENFn\_COMP** value (**CPSW\_GENF0\_COMP\_LOW\_REG** and **CPSW\_GENF0\_COMP\_HIGH\_REG** registers) and the length value is non-zero. The **CPTS\_GENFn** output cycle repeats thereafter every **CPSW\_GENF0\_LENGTH\_REG/ CPSW\_GENF1\_LENGTH\_REG[31:0] CPTS\_RFT\_CLK** periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the **CPSW\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY** bit is low. No compare events and no **CPTS\_EVNT** interrupts are generated.

**Figure 12-175. CPTS\_GENFn Output Signal Diagram**

#### 12.2.2.4.7.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS\_RFT\_CLK from the CPSW\_GENF0\_LENGTH\_REG/ CPSW\_GENF1\_LENGTH\_REG[31-0] value. A value of 1h will add 1 CPTS\_RFT\_CLK to the CPSW\_GENF0\_LENGTH\_REG/ CPSW\_GENF1\_LENGTH\_REG[31-0] value. The CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

#### 12.2.2.4.7.11.2 GENFn PPM

The CPTS\_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW\_GENF0\_PPM\_LOW\_REG/ CPSW\_GENF0\_PPM\_HIGH\_REG enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS\_RFT\_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW\_GENF0\_CONTROL\_REG/ CPSW\_GENF1\_CONTROL\_REG[0] PPM\_DIR bit. When PPM\_DIR bit is set a single CPTS\_RFT\_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM\_DIR bit is cleared a single CPTS\_RFT\_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

#### Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF\_PPM[41-0] (through CPSW\_GENF0\_PPM\_LOW\_REG and CPSW\_GENF0\_PPM\_HIGH\_REG) is:  
 $1,000,000/100 = 10,000(\text{decimal})$

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for GENF\_PPM[41-0] (through CPSW\_GENF0\_PPM\_LOW\_REG and CPSW\_GENF0\_PPM\_HIGH\_REG) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

#### 12.2.2.4.7.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

#### 12.2.2.4.7.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event

- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

#### **12.2.2.4.7.13.1 Time Stamp Push Event**

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the [0]TS\_PUSH bit of the CPSW\_CPTS\_TS\_PUSH\_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW\_CPTS\_EVENT\_3\_REG register) of the timestamp are zero in 32-bit mode.

#### **12.2.2.4.7.13.2 Time Stamp Counter Rollover Event (32-bit mode only)**

The CPTS module contains a 32-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

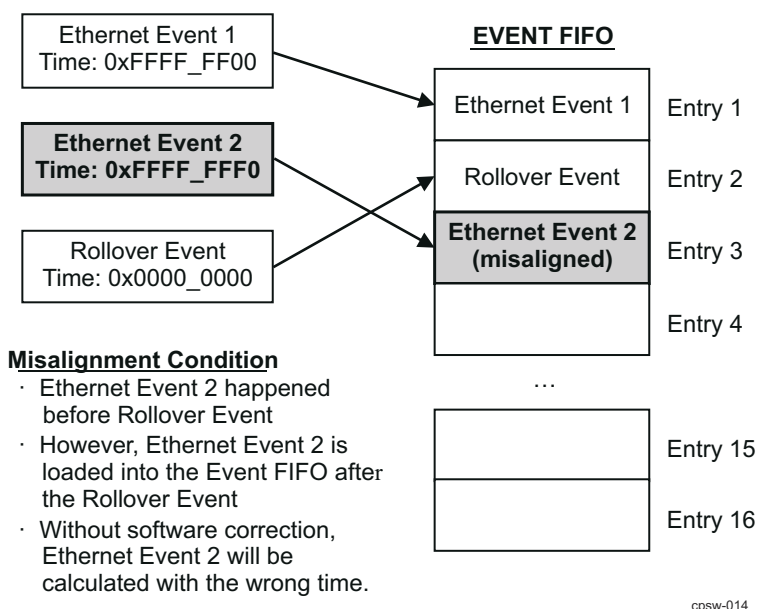

#### **12.2.2.4.7.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)**

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW\_CPTS\_EVENT\_0\_REG[31:0] TIME\_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 12-176](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

**Figure 12-176. Event FIFO Misalignment Condition**

#### 12.2.2.4.7.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs ( CPTS\_HW[1:4]\_TS\_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in [Figure 12-172](#). The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the CPSW\_CPTS\_EVENT\_1\_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS\_RFT\_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW\_CPTS\_CONTROL\_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 12.2.2.4.7.13.5 Ethernet Port Events

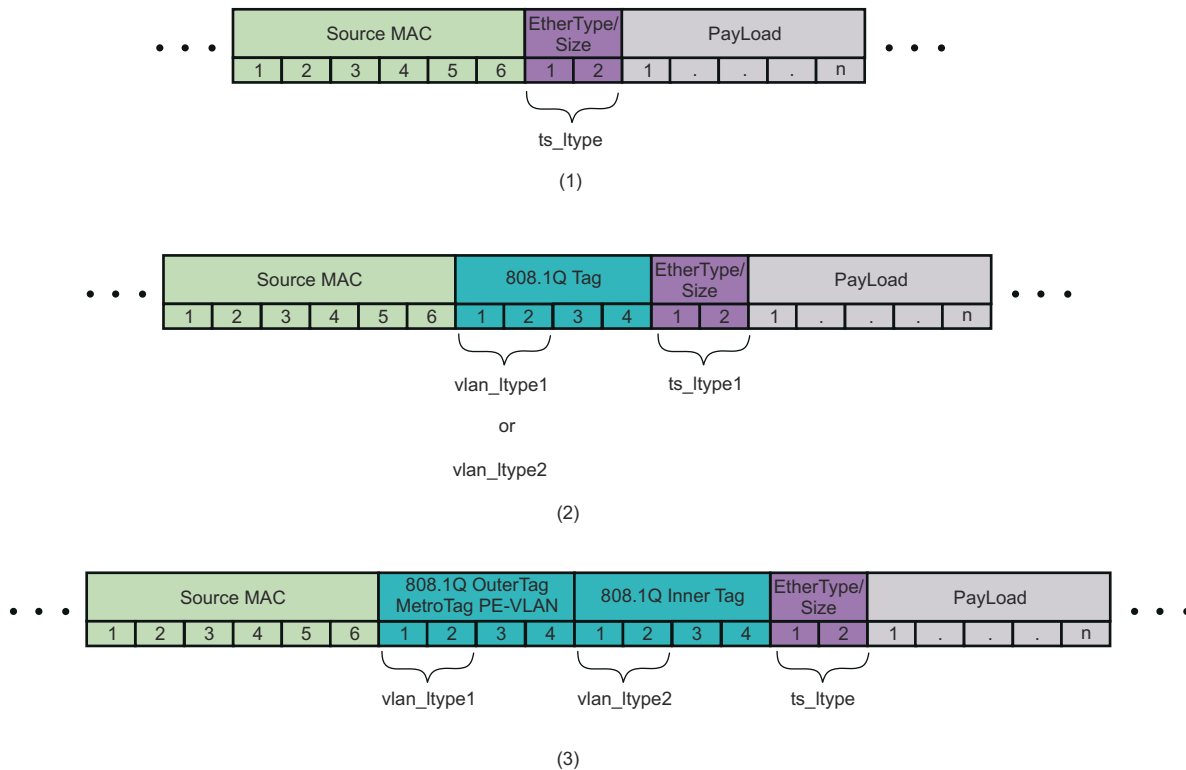

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in [Figure 12-177](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS\_LTYPE1 field in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG\_k or the TS\_LTYPE2 field in CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 12-177](#). To indicate to the CPTS hardware that a virtual LAN is in use, the TS\_TX\_VLAN\_LTYPE1\_EN (or TS\_TX\_VLAN\_LTYPE2\_EN) enable bit must be set in the

CPSW\_PN\_TS\_CTL\_REG\_k register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS\_VLAN\_LTYPE1 (or TS\_VLAN\_LTYPE2 depending on which enable bit was set) field in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 12-177. In this case, both TS\_VLAN\_LTYPE1 and TS\_VLAN\_LTYPE2 must be enabled. The outer tag must match the value of the TS\_VLAN\_LTYPE1 field, and the inner tag must match the value of the TS\_VLAN\_LTYPE2 field.

cpsw-015

#### 12.2.2.4.7.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS\_RFT\_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

#### Annex D (IPv4)

1. Receive annex D time sync is enabled (TS\_RX\_ANNEX\_D\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register).

2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

#### Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is cleared to 0h, or byte 22 contains any value if CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is cleared to 0h and Bytes 30 through 33 contain:
  - a. Decimal 224.0.1.129 and the TS\_129 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - b. Decimal 224.0.1.130 and the TS\_130 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - c. Decimal 224.0.1.131 and the TS\_131 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - d. Decimal 224.0.1.132 and the TS\_132 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - e. Decimal 224.0.0.107 and the TS\_107 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set

-OR-

The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set and Bytes 30 through 33 contain any values.

8. Bytes 36 and 37 contain:
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set -OR-
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG\_k register.
11. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

#### Annex E (IPv6)

1. Receive annex E time sync is enabled (TS\_RX\_ANNEX\_E\_EN bit is set in the switch CPSW\_PN\_TS\_CTL\_REG\_k register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x86dd.
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x86dd

- c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x86dd
- d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is cleared to 0h, or byte 21 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 21 is the TTL/HOP field.
6. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is cleared to 0 and Bytes 38 through 53 contain:
  - a. FF0M:0:0:0:0:0:0:0:0181 and the TS\_129 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - b. FF0M:0:0:0:0:0:0:0:0182 and the TS\_130 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - c. FF0M:0:0:0:0:0:0:0:0183 and the TS\_131 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - d. FF0M:0:0:0:0:0:0:0:0184 and the TS\_132 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set, or
  - e. FF0M:0:0:0:0:0:0:0:006B and the TS\_107 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set

#### Note

All values above are 16-bit hex numbers where M is enabled in the TS\_MCAST\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG\_k register.

-OR-

The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register is set to 1h and Bytes 38 through 53 contain any value.

7. Bytes 56 and 57 contain (UDP Header in bytes 54 through 61):
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW\_PN\_TS\_CTL2\_REG\_k register is set, or
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW\_PN\_TS\_CTL2\_REG\_k register is set.
8. The PTP message begins in byte 62.
9. The packet message type is enabled in the MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL2\_REG\_k register.
10. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

#### Annex F (IEEE 802.3)

1. Receive Annex F time sync is enabled (TS\_RX\_ANNEX\_F\_EN is set in the switch CPSW\_PN\_TS\_CTL\_REG\_k register).
2. One of the sequences below is true:
  - a. The first packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG\_k register. LTYPE 1 should be used when only one time sync LTYPE is to be enabled.
  - b. The first packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register and LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register.
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG\_k register

- d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register.
- e. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG\_k register.
- f. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register.
- g. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG\_k register.
- h. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG\_k register.
5. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

#### 12.2.2.4.7.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use to the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

#### Annex D (IPv4)

1. Transmit time sync is enabled (TS\_TX\_ANNEX\_D\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG\_k register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG\_k register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG\_k register

3. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG\_k register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS\_RFT\_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

**Table 12-231. Values of Message Type Field**

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW\_CPTS\_EVENT\_1\_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW\_CPTS\_EVENT\_0\_REG (and CPSW\_CPTS\_EVENT\_3\_REG) register contains the time stamp value when the packet arrived at the corresponding port.

#### 12.2.2.4.7.13.5.3

**Table 12-232. Values of Message Type Field**

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4:7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E:F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW\_CPTS\_EVENT\_1\_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW\_CPTS\_EVENT\_0\_REG (and CPSW\_CPTS\_EVENT\_3\_REG) register contains the time stamp value when the packet arrived at the corresponding port.

#### 12.2.2.4.7.14 Timestamp Compare Event

##### Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

##### 12.2.2.4.7.14.1 32-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register and the CPSW\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

##### 12.2.2.4.7.14.2 64-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG and CPSW\_CPTS\_EVENT\_3\_REG) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG and CPSW\_CPTS\_TS\_COMP\_HIGH\_VAL\_REG registers and the CPSW\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

##### 12.2.2.4.7.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP\_EN bit and sends the DOMAIN, MESSAGE\_TYPE, and SEQUENCE\_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW\_9G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

##### 12.2.2.4.7.16 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW\_CPTS\_INT\_ENABLE\_REG register.
2. Upon interrupt, read the CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG registers values.
3. Set the CPSW\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW\_CPTS\_INT\_ENABLE\_REG
2. Upon interrupt, enter the CPTS service routine.
3. Read the CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG registers values.

4. Set the CPSW\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four CPTS\_RFT\_CLK periods plus four CPPI\_ICLK periods.
6. Read the TS\_PEND\_RAW bit in the CPSW\_CPTS\_INTSTAT\_RAW\_REG register to determine if another valid event is in the event FIFO. If bit TS\_PEND\_RAW is asserted, go to step 3. If bit TS\_PEND\_RAW is not asserted proceed with step 7.
7. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the CPSW\_CPTS\_INTSTAT\_RAW\_REG register to determine if a valid event is on the event FIFO.

#### 12.2.2.4.8 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the NAVSS. The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

##### 12.2.2.4.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW\_9G Egress)

The CPSW2G has a single transmit packet streaming interface. All Ethernet packet data destined for the host (Port 0) is transferred on the transmit packet streaming interface. The transmit packet streaming interface is equivalent to an Ethernet MAC output with the difference being that 128-bit streaming interface data is output. Egress packet data is packed on the 128-bit data bus with all words having 16-bytes except possibly the last packet data word which is the word previous to the EOP word. INFO Word 0–3 is transferred on SOP. The EOP word contains the packet status 0–3 (data type 24) which includes the timestamp and checksum data. Packets are not dropped on the transmit streaming interface due to pushback, but packets may be dropped in the associated priority FIFO.

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPSW\_PN\_RX\_MAXLEN\_REG\_k[13-0] RX\_MAXLEN byte value of the ingress port (only the CPSW\_PN\_RX\_MAXLEN\_REG\_k number of bytes are kept if long packets are transferred due to CPSW\_PN\_MAC\_CONTROL\_REG\_k register copy error frames set - RX\_CEF\_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPSW\_PN\_MAC\_CONTROL\_REG\_k[24] RX\_CMF\_EN bit set.

The error encoding on the TXST\_PKT\_ERR[3:0] output is shown in [Table 12-233](#):

**Table 12-233. Error Encoding on the TXST\_PKT\_ERR[3:0] Output**

TXST_PKT_ERR[3:0]	Description
0000	No Error
0001	CRC Error
0010	Code or alignment error
0011	Short (no code/align/crc error)
0100	FragCRC (short with crc error)
0101	Frag Code/Align (short with code/align error)
0110	Long
0111	Jabber CRC (long with crc error)
1000	Jabber Code/Align (long with code/align error)
1001	Mac ontrl packet (CPSW_PN_MAC_CONTROL_REG[24] RX_CMF_EN set on ingress Ethernet port)
1010	Mac control CRC

**Table 12-233. Error Encoding on the TXST\_PKT\_ERR[3:0] Output (continued)**

TXST_PKT_ERR[3:0]	Description
1011	Mac control Code/Align
1100	Mac control short/frag (short MAC control frame with CRC/Code/Align)
1101	Mac control long/jabber (long MAC control frame with CRC/Code/Align)
1110	Reserved
1111	Reserved

The CPPI Port 0 transmit packet streaming interface has a single output thread. If a packet transmission has begun then the entire packet will be transmitted before the next packet is sent (packet data from multiple packets are not interleaved on the transmit streaming interface). The default egress flow is the port number minus 1, concatenated with the 3-bit Port 0 transmit FIFO hardware switch priority. For example, a packet that was received on port 4 with a Port 0 transmit FIFO hardware switch priority of 5 would be sent on flow 29 (decimal) or flow 0b0011101 (binary). Priority remapping on ingress and Port 0 transmit egress effects the output flow.

INFO Words () are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 12-178. TX INFO Word 0 Format**

Bit	Field	Description
31-27	PKT_TYPE	Always set to 0b00111. Host PD (Packet Descriptor) Word 2. Packet Type: bits[31-27].
26-24	RESERVED	Reserved.
23	PASS_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.
22	CRC_TYPE	The packet CRC type. The type of CRC passed is determined by CRC_TYPE field in the CPSW_PN_MAC_CONTROL_REG_k register (not by the type of CRC the packet had on Ethernet port ingress). Host PD Word 1. Protocol Specific Flags: bits[27-24]. 0h: Ethernet CRC 1h: Castagnoli CRC
21-8	RESERVED	Reserved.
7-0	FLOW_ID	This is the packet output transmit streaming interface flow. The default flow ID can be overridden by ALE classification (Thread mapping). The switch default flow is the 3-bit "From Port" value concatenated with the 3-bit "Switch Priority" {From_Port[2:0], Switch_Priority[2:0]} as shown below: Host PD (Packet Descriptor) Word 1. Flow ID: bits[13-0]. 0h: The packet was received on Ethernet port 1 1h: The packet was received on Ethernet port 2 Switch Priority – The actual hardware switch priority that the packet was stored in on the CPPI transmit FIFO.

#### 12.2.2.4.8.2 CPPI Receive Packet Streaming Interface (CPSW Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS\_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0\_RX\_PASS\_CRC\_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO\_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer than the value in CPSW\_P0\_RX\_MAXLEN\_REG[13:0] RX\_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0\_RX\_PAD bit in the CPSW\_CONTROL\_REG register is set and if PASS\_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS\_CRC info bit is set regardless of P0\_RX\_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

### Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]\_TCFG.tx\_filt\_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

**Figure 12-186. RX INFO Word 0 Format**

CHEC KSUM _INV	RESE RVED	CHECKSUM_BYTECOUNT													

Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

### 12.2.2.4.8.3 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S\_CN\_SWITCH bit in the CPSW\_CONTROL\_REG register must be set for the Outer VLAN L type to be supported.

#### 12.2.2.4.8.3.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

##### 12.2.2.4.8.3.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

##### 12.2.2.4.8.3.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).
- Byte 24 = 0x06 for TCP protocol.

##### 12.2.2.4.8.3.1.3 IPV6 UDP

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

**12.2.2.4.8.3.1.4 IPV6 TCP**

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

**12.2.2.4.8.4 CPPI Receive Checksum Offload**

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX\_CHECKSUM\_EN bit in the CPSW\_P0\_CONTROL\_REG register must be set for receive checksum operation to be enabled. When bit RX\_CHECKSUM\_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM\_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

**12.2.2.4.8.5 Egress Packet Operations**

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations (CPSW\_ALE\_EGRESSOP). IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

#### 12.2.2.4.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

##### 12.2.2.4.9.1 MDIO Frame Formats

Table 12-234 shows the address, Table 12-235 shows the read format and Table 12-236 shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

**Table 12-234. MDIO Clause 45 Address Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

**Table 12-235. MDIO Clause 45 Read Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

**Table 12-236. MDIO Clause 45 Write Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction. The MDIO CPSW\_MDIO\_USER\_ADDR0\_REG register must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

#### Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

#### Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 00 pattern.

#### Operation Code

The operation code for an address transaction is 00. The operation code for a read is 11, while the operation code for a write is a 01.

#### PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

#### MMD Number

The MMD number is the 5 bits allowing 32 unique values. The first bit transmitted is the MSB.

#### Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall

drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

### Address

The address field is 16 bits on address operations. The first bit transmitted is the MSB of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the MDIO CPSW\_MDIO\_USER\_ADDR0\_REG/ CPSW\_MDIO\_USER\_ADDR1\_REG register values as the 16-bit address.

### Data

The Data field is 16 bits on read and write operations. The first bit transmitted and received is the MSB of the data word.

#### 12.2.2.4.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the CPSW\_MDIO\_CONTROL\_REG register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO CPSW\_MDIO\_LINK\_REG register. Individual PHY's can be enabled or disabled for polling the associated bit in the CPSW\_MDIO\_POLL\_EN\_REG register. The CPSW\_MDIO\_LINK\_REG and CPSW\_MDIO\_ALIVE\_REG register bit values are updated on the poll of each PHY. The LINKSEL bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO CPSW\_MDIO\_LINK\_INT\_RAW\_REG register and the MDIO CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register, if enabled by the LINKINT\_ENABLE bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register.

The MDIO CPSW\_MDIO\_ALIVE\_REG register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO CPSW\_MDIO\_ALIVE\_REG register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a CPSW\_MDIO\_USER\_ACCESS\_REG\_k register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW field in the CPSW\_MDIO\_USER\_INT\_RAW\_REG register corresponding to the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register being used. The corresponding bit in the CPSW\_MDIO\_USER\_INT\_MASKED\_REG register may also be set depending on the mask setting in the MDIO CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG and CPSW\_MDIO\_USER\_INT\_MASK\_CLEAR\_REG registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different CPSW\_MDIO\_USER\_ACCESS\_REG\_k registers. The host should check the status of the GO bit in the MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW\_PN\_MAC\_CONTROL\_REG\_k register in the corresponding MAC.

#### 12.2.2.5 CPSW0 Programming Guide

##### 12.2.2.5.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, RGMII, SGMII, QSGMII or QSGMII\_SUB ) Mode.  
See CTRL\_MMR0\_ENET1\_CTRL[2-0] PORT\_MODE\_SEL to CTRL\_MMR0\_ENET8\_CTRL[2-0] PORT\_MODE\_SEL registers.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*

4. Ensure that at least 2000 CPPI\_ICLK periods are run after reset is de-asserted.
5. Configure the CPSW\_CONTROL\_REG register
6. Configure the Ethernet Port Source Address registers (CPSW\_PN\_SA\_L\_REG\_k and CPSW\_PN\_SA\_H\_REG\_k)
7. Configure the CPSW statistic port enable register CPSW\_STAT\_PORT\_EN\_REG
8. Configure the ALE ([Section 12.2.2.4.6.1, Address Lookup Engine](#))
9. Configure the MDIO ([Section 12.2.2.5.3.1, Initializing the MDIO Module](#))
10. Configure Ethernet port, as per the desired mode of operations

#### **12.2.2.5.2 Ethernet MAC Reset or XGMII/GMII Mode Change Configuration**

To reset the Ethernet port, the host must perform the following:

1. Set CMD\_IDLE bit to 1h in the Ethernet port control registers: CPSW\_PN\_MAC\_CONTROL\_REG\_k.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status registers: CPSW\_PN\_MAC\_STATUS\_REG\_k.
3. Set SOFT\_RESET bit to 1h in the Ethernet port software reset registers: CPSW\_PN\_MAC\_SOFT\_RESET\_REG\_k.
4. Wait for SOFT\_RESET bit in the CPSW\_PN\_MAC\_SOFT\_RESET\_REG\_k registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.

#### **12.2.2.5.3 MDIO Software Interface**

##### **12.2.2.5.3.1 Initializing the MDIO Module**

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW\_MDIO\_CONTROL\_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW\_MDIO\_CONTROL\_REG.
3. The MDIO PHY alive status register (MDIO CPSW\_MDIO\_ALIVE\_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW\_MDIO\_LINK\_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k, where k = 0 or 1), and set the LINKINT\_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG) to use the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1).

##### **12.2.2.5.3.2 Writing Data To a PHY Register**

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

### 12.2.2.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW\_MDIO\_USER\_ACCESS\_REG\_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

### 12.2.3 Peripheral Component Interconnect Express (PCIe) Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) subsystem.

#### 12.2.3.1 PCIe Subsystem Overview

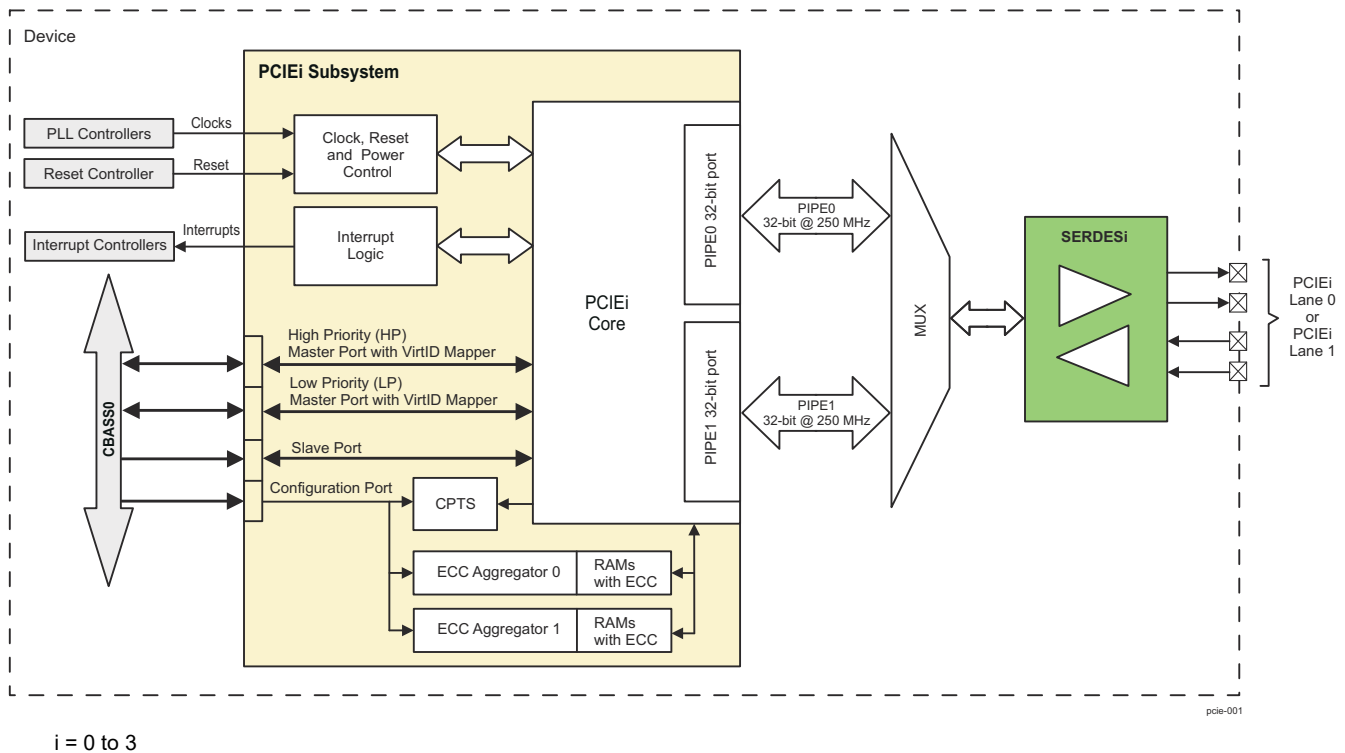

The Peripheral Component Interconnect Express (PCIe) subsystem is built around a multi-lane dual-mode PCIe controller that provides low pin-count, high reliability, and high-speed data transfers at rates of up to 8.0 Gbps per lane for serial links on backplanes and printed wiring boards.

The device includes four instantiations of PCIe subsystem named PCIE0, PCIE1, PCIE2 and PCIE3. [Table 12-237](#) shows the PCIe subsystem allocation within device domains:

**Table 12-237. PCIe Subsystem Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
PCIE0	-	-	✓
PCIE1	-	-	✓
PCIE2	-	-	✓
PCIE3	-	-	✓

[Figure 12-190](#) provides PCIe subsystems overview.

**Figure 12-190. PCIe Subsystems Overview**

#### 12.2.3.1.1 PCIe Subsystem Features

Each PCIe subsystem supports the following main features:

- Compliance to PCIe® Base Specification, Revision 4.0 (Version 0.7)
- One or two-lane configuration with up to 8.0 Gbps/lane (Gen3). Can be used as 2-lane controller, configurable in 1x1 or 1x2 mode.

- Gen3 (8 Gbps 128/130-bit encoding), Gen2 (5 Gbps 8/10-bit encoding), and Gen1 (2.5 Gbps 8/10-bit encoding) with auto-negotiation
- Dual mode: Root Port (RP) or End Point (EP) operation modes, selectable via bootstrap pins
- Dynamic PIPE width change when switching between Gen1/2/3 modes
- Constant 32-bit PIPE width for Gen1/2/3 modes
- Maximum payload size of 256 bytes
- Maximum remote read request size of 4K bytes
- Address Translation Services (ATS)
- Single-root I/O Virtualization (SR-IOV) with Physical Functions (PF) and Virtual Functions (VF) in End Point mode
  - Six Physical Functions (PF)
  - Sixteen Virtual Functions (4 VF for each of PF0, PF1, PF2, and PF3; 0 VF for PF4 and PF5)
- Four virtual channels (VC)
- PCI Power Management states are:
  - L1 Active State Power Management
  - L1 Power Management substates support
  - D1 Device Power Management state
- Maximum number of non-posted outstanding transactions: 32
- Resizable BAR capability
- Legacy, MSI and MSI-X Interrupt Support
- 32 outbound address translation regions
- Precision time measurement (PTM)

#### **12.2.3.1.2 PCIe Subsystem Not Supported Features**

The PCIe subsystems do not support the following features:

- Gen4 (16GT/s) operation
- 2-lane controller, configurable in 2x1 mode
- PCIe beacon for in-band wake
- Vendor Messaging
- I/O access in inbound direction in RP or EP mode
- Addressing modes other than incremental for burst transactions. As a result, the PCIe addresses cannot be in cacheable memory space.
- L2 power state
- Hot-plug
- Separate Reference Clock with Independent Spread (SRIS)

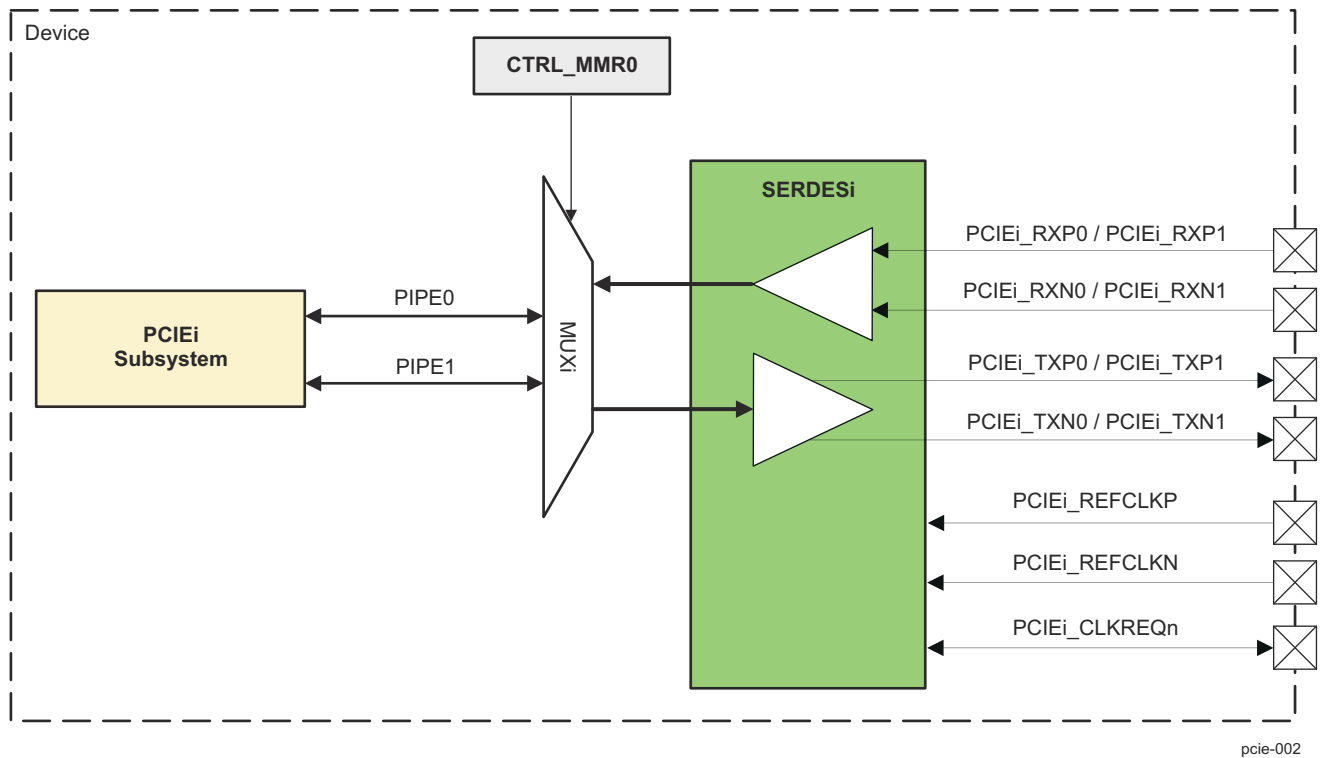

### 12.2.3.2 PCIe Subsystem Environment

This section describes the PCIe subsystem application fields from an environment point of view (external connections).

#### CAUTION

The PCIe subsystems do not have any direct external interface pins. PCIe data transactions are implemented through the corresponding SERDES interface pins.

**Figure 12-191. PCIe Subsystem Enviroment**

[Table 12-238](#) describes the SERDES signal names at device level related to PCIe subsystems, and specifies their functions. For more information on the SERDES operation and interface signals, refer to *Serializer/Deserializer (SerDes)*.

**Table 12-238. PCIe Subsystem I/O Signals**

Device Level Signal	I/O <sup>(1)</sup>	Description
<b>PCIE0 Subsystem</b>		
PCIE0_RXN0	I	PCle Lane 0 Receive Differential Data (-)

PCIE3_REFCLKN	I	PCIe differential reference clock (-)
PCIE3_REFCLKP	I	PCIe differential reference clock (+)
PCIE3_CLKREQn	I/O	PCIe active-low clock request

(1) I = Input; O = Output.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.2.3.3 PCIe Subsystem Integration

This section describes PCIe subsystems integration in the device MAIN domain, including information about clocks, resets, and hardware requests.

There are four PCIe subsystems integrated in the device MAIN domain - PCIE0, PCIE1, PCIE2 and PCIE3. Figure 12-192 shows the integration of PCIE0 and PCIE1.

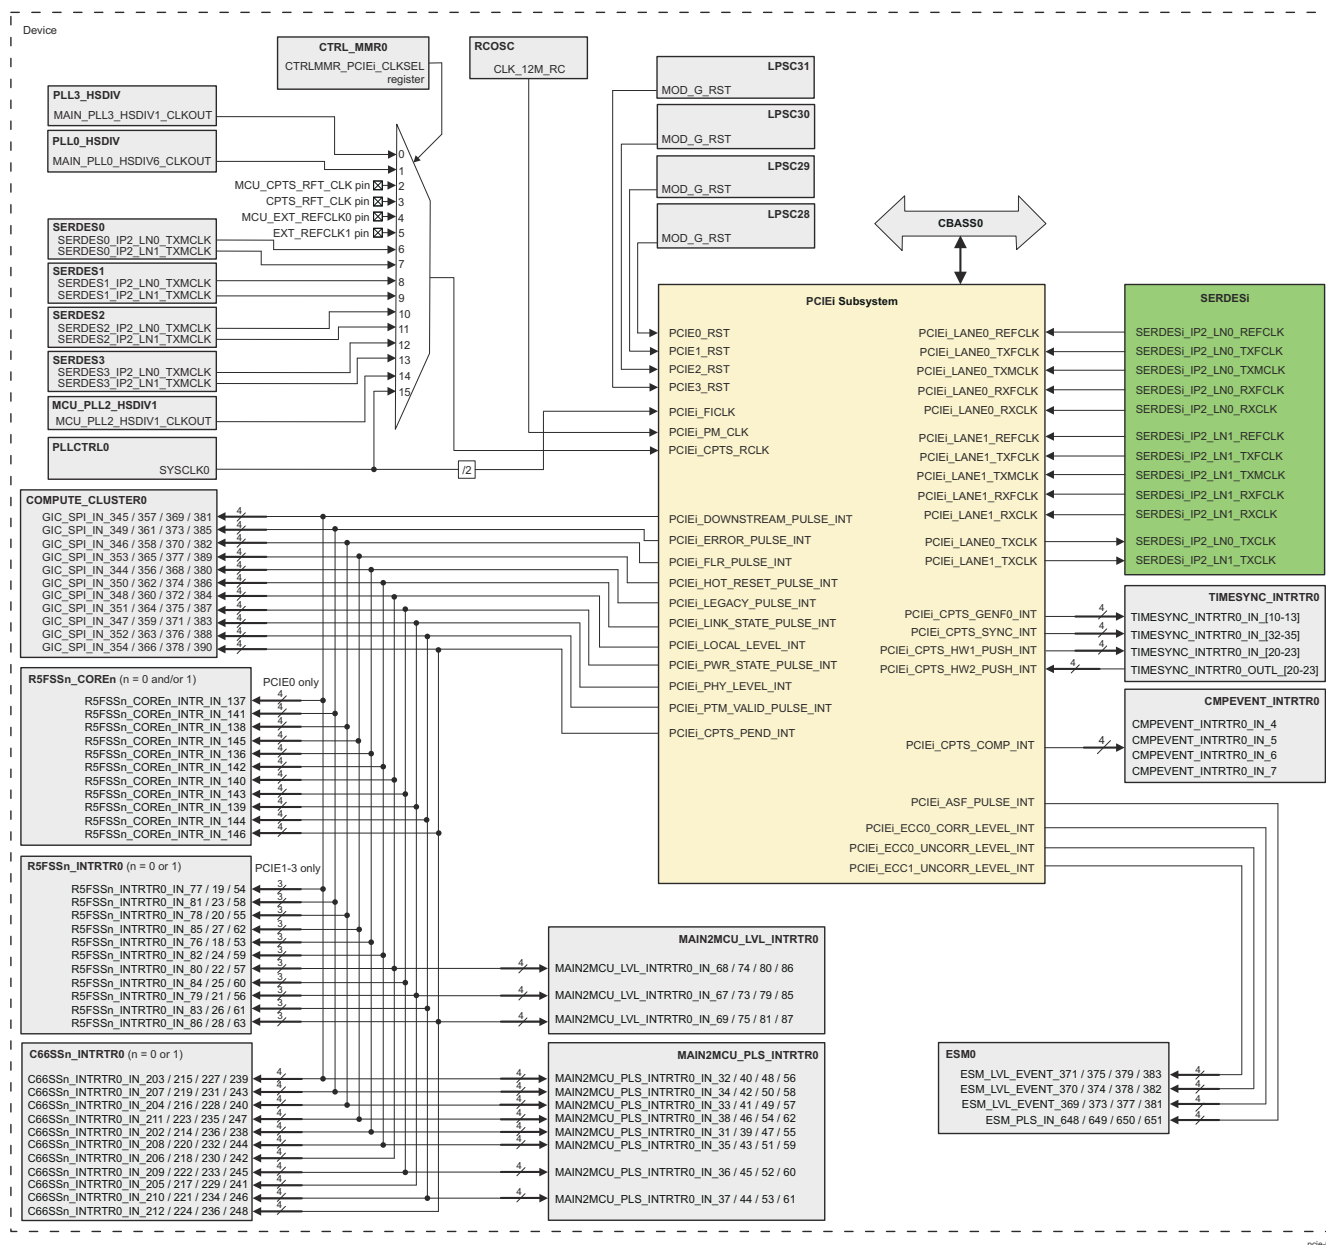

Figure 12-192. PCIe Subsystem Integration

Table 12-239 through Table 12-241 summarize the integration of PCIE0, PCIE1, PCIE2, and PCIE3 in device MAIN domain.

**Table 12-239. PCIe Subsystem Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
PCIE0	PSC0	PD0	LPSC28	CBASS0
PCIE1	PSC0	PD0	LPSC29	CBASS0
PCIE2	PSC0	PD0	LPSC30	CBASS0
PCIE3	PSC0	PD0	LPSC31	CBASS0

**Table 12-240. PCIe Subsystem Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

MAIN_SYSCLK0	PLLCTRL0			
PCIE2_LANE0_REFCLK	SERDES2_IP2_LN0_REFCLK	SERDES2	PCIE2 PIPE lane 0 reference clock from SERDES2	
PCIE2_LANE0_TXFCLK	SERDES2_IP2_LN0_TXFCLK		PCIE2 PIPE lane 0 TX full rate clock from SERDES2	
PCIE2_LANE0_TXMCLK	SERDES2_IP2_LN0_TXMCLK		PCIE2 core clock from SERDES2 via lane 0	
PCIE2_LANE0_RXFCLK	SERDES2_IP2_LN0_RXFCLK		PCIE2 PIPE lane 0 RX full rate clock from SERDES2	
PCIE2_LANE0_RXCLK	SERDES2_IP2_LN0_RXCLK		PCIE2 PIPE lane 0 RX clock from SERDES2	
PCIE2_LANE1_REFCLK	SERDES2_IP2_LN1_REFCLK	SERDES2	PCIE2 PIPE lane 1 reference clock from SERDES2	
PCIE2_LANE1_TXFCLK	SERDES2_IP2_LN1_TXFCLK		PCIE2 PIPE lane 1 TX full rate clock from SERDES2	
PCIE2_LANE1_TXMCLK	SERDES2_IP2_LN1_TXMCLK		PCIE2 core clock from SERDES2 via lane 1	
PCIE2_LANE1_RXFCLK	SERDES2_IP2_LN1_RXFCLK		PCIE2 PIPE lane 1 RX full rate clock from SERDES2	
PCIE2_LANE1_RXCLK	SERDES2_IP2_LN1_RXCLK		PCIE2 PIPE lane 1 RX clock from SERDES2	
SERDES2	SERDES2_IP2_LN0_TX CLK	PCIE2_LANE0_TXCLK	PCIE2	PCIE2 PIPE lane 0 transmit clock to SERDES2
	SERDES2_IP2_LN1_TX CLK	PCIE2_LANE1_TXCLK		PCIE2 PIPE lane 1 transmit clock to SERDES2
PCIE3	PCIE3_FICLK	SYSCLK0 / 2	PLLCTRL0	PCIE3 functional and interface clock
	PCIE3_PM_CLK	CLK_12M_RC	RCOSC	PCIE3 clock from RC oscillator

**Table 12-240. PCIe Subsystem Clocks and Resets (continued)**

PCIE3_CPTS_RCLK	MAIN_PLL3_HSDIV1_CLKOUT	PLL3_HSDIV	PCIE3 CPTS reference clock (RCLK). The CPTS RCLK clock frequency should be greater than or equal to the PCIE FICLK clock frequency. Otherwise, the software will have to add some wait cycles before a correct event is generated by the CPTS module. The selection of the source signal (see <a href="#">Figure 12-192, PCIe Subsystem Integration</a> ) can be done via the CTRLMMR_PCIE3_CLKSEL[3-0] CPTS_CLKSEL register field in the device Control Module.	
	MAIN_PLL0_HSDIV6_CLKOUT	PLL0_HSDIV		
	MCU_CPTS_RFT_CLK	I/O pin

### Note

PCIe Subsystem interrupts are further described in [Section 12.2.3.4.4, PCIe Subsystem Interrupts](#).

For more information on the interconnects in device MAIN domain, see [Chapter 3, System Interconnect](#).

For more information on the power, reset and clock management in device MAIN domain, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the interrupt controllers in device MAIN domain, see [Chapter 9, Interrupts](#).

For more information on the time sync and compare events routers, see [Section 11.3, Time Sync and Compare Events](#).

### 12.2.3.4 PCIe Subsystem Functional Description

This chapter describes the functionality of the PCIe Gen4 controller module. It provides register description and a PCIe module configuration example.

#### 12.2.3.4.1 PCIe Subsystem Block Diagram

The block diagram of PCIe subsystem is shown in Figure 12-193. The subsystem comprises of these major components – the PCIe Core with AXI interfaces, bridges to connect to the system CBASS0 interconnect master and slave interfaces, bridges to connect the system CBASS0 configuration interfaces, additional logic to implement the Precision Time Measurement (PTM), user configuration and interrupt, and RAMs to support the controller FIFOs.

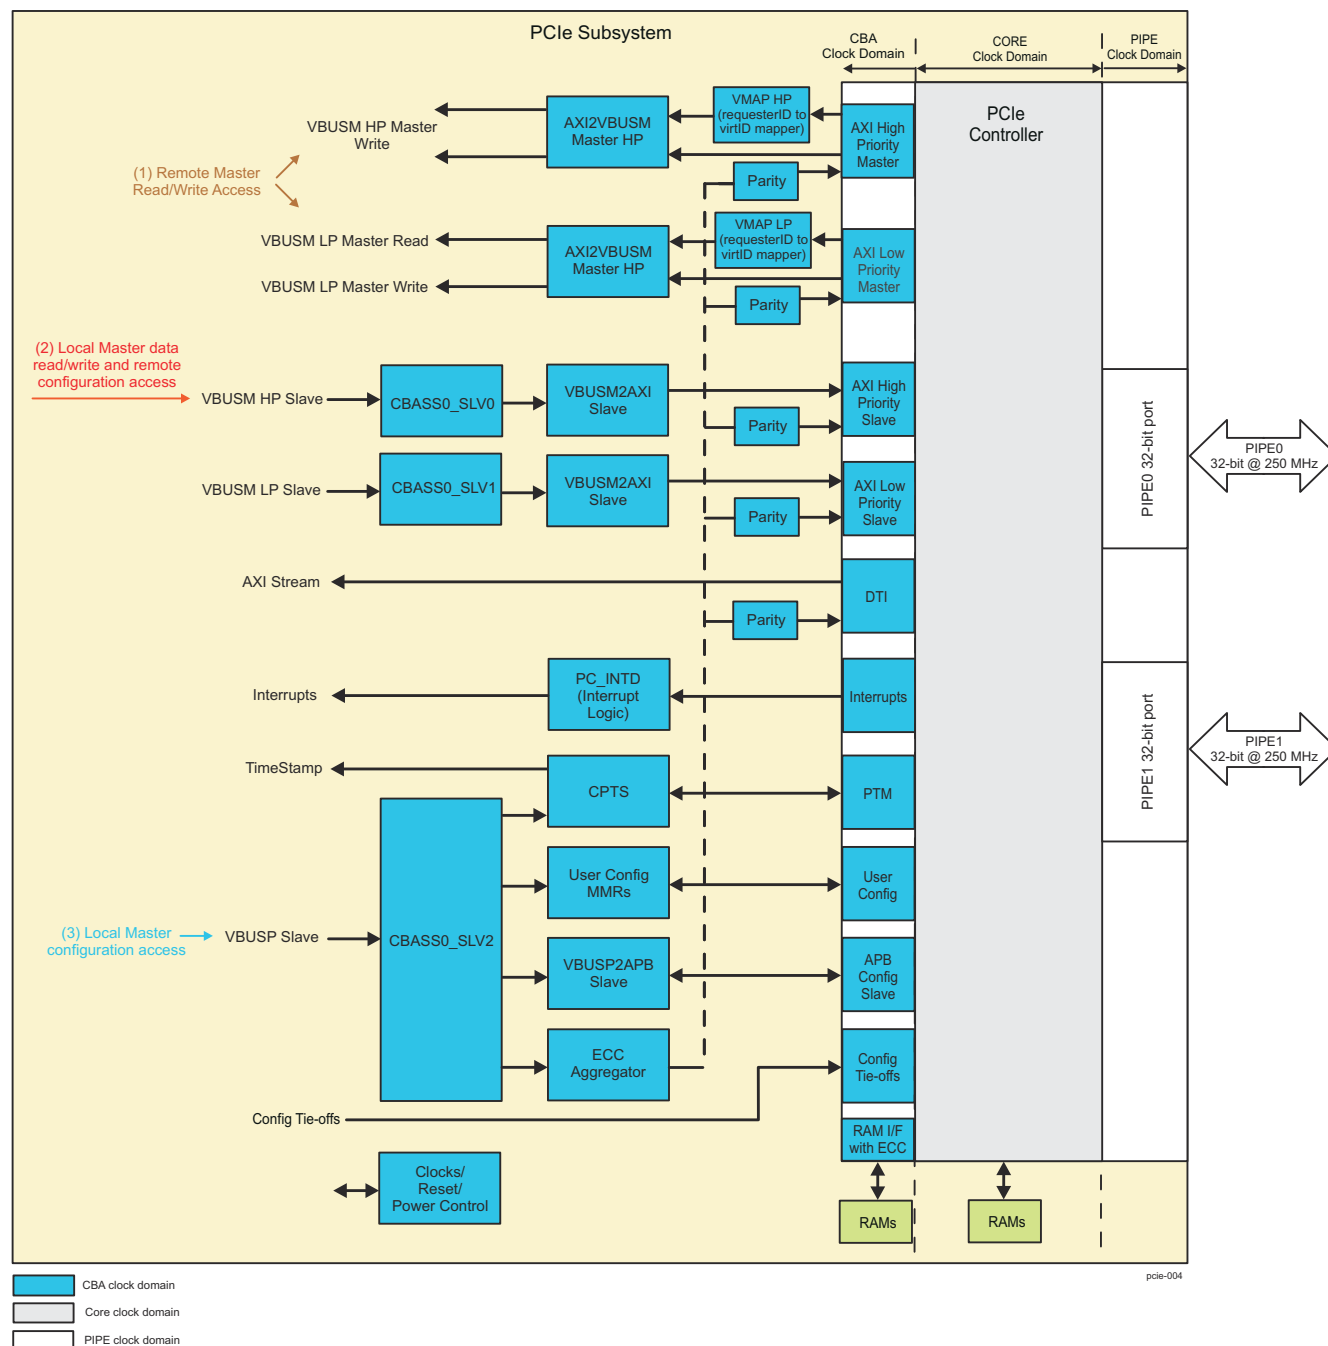

Figure 12-193 also shows example data flows in the PCIe subsystem, where:

1. A remote master issues read or write access over PCIe to the local device. This will create a command to be issued on the PCIe VBUSM master read or write interface.
2. A master in the local device wants to access a resource on the remote device over PCIe link or access the PCIe configuration registers (local or remote). This will create a transaction over the PCIe VBUSM slave interface.
3. A local master accesses registers in the PCIe Controller, ECC Aggregator or CPTS block. The PCIe VBUSM slave will be used for this transaction.

#### 12.2.3.4.1.1 PCIe Core Module

The PCIe Core module supports dual mode of operation - it can be configured as an End Point (EP) and also as a Root Port (RP). The operational mode is selected with PCIe\_MODE\_SELECT bit. Typically, it is expected that these bits be driven from a SoC level register that is programmed during initial power up based on settings in the SoC boot configuration or a non-volatile storage such as eFuse or Flash memory. The table below lists the encodings available.

It is not expected that pcie\_mode\_select would have to change during a full power cycle of the device. It is more likely that the operational mode of a SoC will stay as EP or RP for a particular end product's life cycle. The chip level circuitry is expected to provide the hardware input to set RP or EP mode and not switch back during operation and forth without a reset cycle.

The PCIe core module supports four virtual channels (VC) and four transfer classes (TC). The VCs can be used to implement Quality-of-Service (QoS) mechanism by enabling priority or round-robin arbitration. Typically, the highest numbered enabled VC is assigned the highest priority.

The PCIe core module is configured to support Single Root I/O virtualization (SR-IOV). It supports 6 Physical Functions (PF) and 16 Virtual Functions (VF).

There are two AXI4.0 master ports and two AXI4.0 slave port in the PCIe core. The two AXI master and slave ports are labeled high-priority and low-priority. Ingress data traffic that is assigned the highest priority (highest VC) will be delivered on the high-priority AXI master port. Data on the other VCs will be delivered on the low priority AXI master port. Similarly, egress data that is presented on the high-priority slave port will be assigned the highest VC by the PCIe core. Data presented on the low priority AXI slave port will be assigned lower VCs. This will enable the system to transfer the high and low priority data streams to different destinations based on the latency requirements. Having the two AXI master ports will also prevent low priority traffic from blocking the high priority traffic.

#### 12.2.3.4.1.2 PCIe PHY Interface

The PCIe subsystem incorporates a PCIe compliant PHY (PIPE) interface to connect to a SERDES-based PHY. The PCIe PHY module consist of a SERDES module and a PCIe PCS (Physical Coding Subblock) module. The SERDES module converts parallel data into PCIe serial signals and the PCIe PCS module provides an industry standard PIPE Interface to PCIe MAC. The frequency of the PIPE interface can be 62.5MHz, 125MHz, 250MHz or 500MHz depending on whether the system is operating in Gen1, Gen2, Gen3 or Gen4 modes. The width of the PIPE interface remains constant at 32-bits for all modes of operation. For more information on the SERDES module, see *Serializer/Deserializer (SerDes)*.

#### 12.2.3.4.1.3 CBA Infrastructure

The PCIe subsystem includes two CBASS modules (CBASS\_SLV0/1 and CBASS\_SLV2) to provide access to the various sub-components.

The CBASS\_SLV0/1 is used to access the PCIe egress data region through the VBUSM2AXI bridge and the AXI slave port of the PCIe controller. There are three data regions implemented in the CBASS\_SLV0/1. The PCIE\_DAT0 region provides a region with 27 bits of address and PCIE\_DAT1 region provides a region with 32 bits of address. These regions are provided to ensure separate memory spaces for 32-bit and 64-bit maps at the SoC level. The PCIE\_DAT2 region provides a region with 48 bits of address. This is used to route all requests with *case/* not equal to zero to the PCIe controller slave port. The destination for all these three regions is the

AXI slave port of the PCIe controller. CBASS\_SLV0 is used for high priority access; CBASS\_SLV1 is used for low priority access.

The CBASS\_SLV2 provides multiple regions to access the VBUSP configuration ports of the sub-components of the PCIe sub-system like the PCIe controller configuration port, USER\_CFG, VMAP, CPTS and the ECC aggregators. Having multiple regions on the VBUSP configuration port enables the SoC infrastructure to have hardware firewalls that can provide secure access to configuration registers.

The SERDES PLL should be initialized prior to accessing the PCIe core and ECC\_AGGR1 configuration registers. Any accesses to these two regions prior to initializing the SERDES PLL will complete with a read/write status error in CBASS\_SLV2.

#### **12.2.3.4.1.4 VBUSM to AXI Bridges**

A VBUSM2AXI protocol conversion bridge is attached to the each AXI slave port. This bridge translates all incoming data requests and sends them to the AXI slave port of the PCIe controller core. Wherever required, it also generates side band signals that the AXI bridge needs based upon the address and the address space of the transaction on the device's native bus.

#### **12.2.3.4.1.5 AXI to VBUSM Bridges**

Each of the two AXI master ports of the PCIe core has an AXI2VBUSM bridge that is used for high speed data transfer during data read/write transactions originated by remote devices over the PCIe link. This bridge provides the protocol translation between the AXI master interface of the PCIe controller core and the VBUSM interface used in this device.

#### **12.2.3.4.1.6 VBUSP to APB Bridge**

A VBUSP2APB bridge is used to convert the device VBUSP configuration access to the APB protocol supported by the PCIe controller core.

#### **12.2.3.4.1.7 Custom Logic**

The PCIe subsystem includes custom logic to implement Precision Time Management (PTM), interrupts and user configuration registers. The details of this logic are described in later sections of this document.

#### **12.2.3.4.2 PCIe Subsystem Reset Schemes**

This section describes the reset schemes supported by PCIe Base Specification and the way these resets are supported by the PCIe Subsystem. PCIe Base Specification specifies two mechanisms for performing reset – Conventional Reset mechanism and Functional Level Reset mechanism.

##### **12.2.3.4.2.1 PCIe Subsystem Conventional Reset**

There are three distinct types of Conventional Reset and each of these causes the hardware state machines, hardware logic, port states and configuration registers to be initialized to their default values.

1. Cold Reset – The reset occurring at power-up of the device is referred to as Cold Reset. Cold Reset is triggered by the PERSTn signal being asserted. PERSTn signal is an auxiliary signal in PCIe Specification and can be used at power on reset for the device that has PCIe as its primary bus interface to rest of the system. The device is allowed to generate its own power-on reset as long as the PCIe requirements for PERSTn are met. See PCIe Base Specifications for details.
2. Warm Reset – A reset can be triggered by the hardware without the removal of power from the device. This reset is referred to as Warm Reset. The hardware implementation is not specified by the PCIe Specification.
3. Hot Reset – The PCIe Specifications provides an in-band mechanism to propagate a Conventional Reset across a Link. This reset, called the Hot Reset, propagates via the transmission of TS1 Ordered Sets. In general, Hot Reset is software controlled procedure and can only be issued by Root Port in a PCIe network as the propagation is downstream only. PCIe subsystem translates the received in-band hot reset into an interrupt that can then be used by software to reset the PCIe subsystem.

After a conventional reset, the software must wait at least 100 ms before attempting any PCIe transaction on the device that has been reset. If the downstream device does not respond to transaction packets, it must not give up until 1 second plus an additional 50% (0.5 second) time is lapsed.

#### 12.2.3.4.2.2 PCIe Subsystem Function Level Reset

Function Level Reset (FLR) is an optional in-band reset mechanism that is used to reset one particular function in a PCIe device. The PCIe core will initiate the appropriate function level reset process when it receives the FLR message. The PCIE\_CORE\_EP\_I\_PCIE\_DEV\_CAP[28] FLRC bit indicates, if a function-level reset is active.

#### 12.2.3.4.2.3 Reset Isolation

It can be important to isolate reset of PCIe subsystem from reset of the rest of the device. The procedure to implement this depends upon what functionality the PCIe subsystem is providing – Root Port or End Point.

##### 12.2.3.4.2.3.1 Root Port Reset with Device Not Reset

When PCIe subsystem is operating as a Root Port, it is the master controller on the PCIe subsystem. When PCIe subsystem is to be reset in this operating mode, the link to the downstream device will get disconnected. To accomplish this reset, the PCIe subsystem RP should issue a hot reset to End Point or Switch downstream. It should also stop any ongoing transactions. Then, a PCIe subsystem reset can be issued. The sequence of events is outlined below:

1. Stop transactions at system and application level. This is recommended for graceful suspension of activity at system level. It is not required by PCIe subsystem though. Not choosing to gracefully stop transaction would cause some of the outstanding transactions to complete in error and it may be harmful from software stability standpoint.
2. Disable “Bus Master Enable” for End Points (see [Section 12.2.3.4.6.2, PCIe Transaction Limitations](#)). Note that a hand shake with EP Software may be required as not all End Point application software will automatically become aware of this disable action from RP.
3. Optionally, issue Hot Reset to End Point devices via PCIE\_USER\_RSTCMD[0] INIT\_HOT\_RESET bit . Note that the link will be getting disconnected. So, a reset may be happening regardless of the Hot Reset command from RP. It depends on the architecture of the other (external) device. In devices with PCIe subsystem, link disconnection automatically results in a reset request interrupt. A PCIe subsystem reset is required to get the memory buffers out of internal flush modes.
4. Initiate Clock Stop sequence and wait for Acknowledgement. For more information, see [Section 12.2.3.4.3.1, CBA Power Management](#).
5. Issue reset to PCIe subsystem (local reset).
6. Reinitialize PCIe subsystem and downstream devices. PCIe bus enumeration must be performed again.

Note that it is possible for Root Port to occasionally see the downstream device going down for some reason and disconnecting. Such events typically occur due to an internal error condition in the End Point. When such an event occurs, the sequence of events for the Root Port will be as follows:

1. The PCIe subsystem in RP mode will issue the “Reset Request” interrupt when it detects link getting disconnected unexpectedly.
2. The PCIe subsystem will flush all master transactions and any completion data from pending transactions. It will also start completing slave transactions with error completions.
3. After servicing the interrupt and disabling further interrupts, the system software must reset PCIe subsystem Root Port (see steps #4 and later specified previously in this section).

##### 12.2.3.4.2.3.2 Device Reset with Root Port Not Reset

As a Root Port, PCIe core is the master of PCIe subsystem. If the device hardware and the software is reset and re-initialized, the system does not get additional benefit of keeping the PCIe subsystem alive as all context information is lost. So, this mode is not supported.

##### 12.2.3.4.2.3.3 End Point Device Reset with Root Port Not Reset

It may be desirable to isolate the reset only to PCIe subsystem when it is operating as an End Point. Such resets may be implemented when a Hot Reset command is received from upstream device (Root Port or Switch). The sequence to be followed is as outlined below.

1. Hot Reset is received. The “Request Reset” interrupt is triggered.

2. The PCIe subsystem will automatically enter Flush Mode. The PCIe Link Training and Status State Machine (LTSSM) will be disabled automatically.
3. PCIe subsystem will complete all master transactions and any completion data from pending transactions will be accepted and discarded. It will also start issuing error response for new slave transactions.
4. Upon receipt of the reset interrupt from PCIe subsystem, the system software must immediately start preparing for shut down of PCIe subsystem. The DMA or software process accessing PCIe subsystem should gracefully suspend operations. Otherwise, step #3 may continue for unduly long time and Root Port may assume that the EP is non-responsive to its link re-training attempts.
5. Read the Reset Command register (PCIE\_USER\_RSTCMD) to check if the bridge activity flush bit is zero. This indicates that it is safe to issue warm reset to PCIe subsystem.
6. Initiate Clock Stop sequence. This will ensure no outstanding transactions exist.
7. Issue a PCIe subsystem Reset.
8. Resume initialization sequence.

#### **12.2.3.4.2.3.4 Device Reset with End Point Device Not Reset**

As an End Point, the PCIe subsystem does not need to stay operational when the device reset is happening. Upon detecting the link disconnection, the upstream port will re-train the link when Root Port issues a link retrain command to itself or to a switch port next to the EP.

If it is required that the PCIe subsystem be operational (without any transactions though), the End Point must negotiate with the other devices (primarily Root Port) to stop activity. Otherwise, if the End Point goes into force idle/standby or clock stop modes without properly managing the process, there will be timeouts or errors on incoming read transactions and writes will be completely lost. In such situation, the Root Port will encounter excessive errors and may issue a hot reset to the End Point anyway.

#### **12.2.3.4.2.4 PCIe Reset Limitations**

Once a reset situation occurs, the PCIe subsystem prepares for reset assertion from the device level reset controller. In this mode, all outbound write transactions are discarded and all outbound reads are returned with error. Similarly, all inbound reads/writes are discarded and any pending reads are completed but data is discarded. Additionally, any register reads on local or remote registers regions are returned in error even though data may be correct. Register writes on local registers are executed correctly.

Whenever the reset interrupt is asserted by PCIe subsystem, the host controller should clear the interrupt, perform a clock stop request/ack sequence and issue a local reset to PCIe subsystem.

#### **12.2.3.4.2.5 PCIe Reset Requirements**

Whenever link goes from connected to disconnected state, the PCIe subsystem requires re-initialization based on the events occurring in PCIe core. A request for reset is typically going to be issued and will manifest as a reset request interrupt. Since loopback requires transitions through link connect and disconnect, it will generate reset request interrupts. Typically, issuing the warm reset (module reset for CBA) would be sufficient.

#### **12.2.3.4.3 PCIe Subsystem Power Management**

PCIe has multiple power management protocols. Some of them are invoked by the hardware, such as Active State Power Management (ASPM), while others are activated at higher levels via software.

The PCIe core supports D0, D1 and D3-Hot power states.

Link power states L0, L0s, L1, L1s are supported.

L0s entry and exit is managed by the PCIe core if ASPM L0s is enabled.

L1 entry and exit is also managed by the PCIe core if ASPM L1 is enabled. Software can force the exit from L1 by writing to the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit in the PCIe subsystem. Entry into L1 can also be blocked by setting the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 bit.

L1s support requires that the CLKREQ pin be connected to the remote peer. L1s power state is entered when the link is in L1 and CLKREQ pin is de-asserted. Software can force the exit from

L1s by writing to either the PCIE\_USER\_PMCMD[0] CLIENT\_REQ\_EXIT\_L1 or PCIE\_USER\_PMCMD[1] CLIENT\_REQ\_EXIT\_L1\_SUBSTATE bits in the PCIe subsystem.

#### 12.2.3.4.3.1 CBA Power Management

The power management for PCIe subsystem with CBA interface is primarily accomplished through the clock stop protocol. Any time the clock stop protocol is initiated, the PCIe subsystem will acknowledge after making sure that there are no outstanding transactions. If there are any pending transactions in the subsystem, then the clock stop acknowledgement procedure cannot be completed. Therefore, it is necessary that the system software first suspend activity on the serial link as well as on the CBA interface. To do so, it is expected that the devices communicating with the device on which clock stop procedure is to be performed agree to stop transactions targeted to the device in question. Similarly, it is required that the outgoing transactions also be stopped to successfully complete the clock stop sequence. The PCIe subsystem will guarantee that in the event there are pending transactions that are still in process of draining will prevent the clock-stop acknowledgement to be issued to CBA subsystem power management logic.

#### Note

The PCIe subsystem does not have ability to terminate the clock stop state. Therefore, any wakeup sequence can only be initiated through other means such as software driven timers or software detected events occurring outside of PCIe subsystem.

#### 12.2.3.4.4 PCIe Subsystem Interrupts

The PCIe subsystem provides a number of interrupts, the PCIe controller interrupt, CPTS interrupt, and interrupts generated in the PCIe subsystem using device Interrupt Distributor (CP\_INTD).

The CP\_INTD module is used to generate and aggregate interrupts from various status signals of the PCIe core. Interrupts from the PCIe core and CPTS modules are ported out directly to the subsystem boundary without any aggregation. [Table 12-242](#) shows the details of the interrupt outputs

**Table 12-242. PCIe Core Interrupt Events**

Name	Width	Type	Polarity	Category	Clock	Reset	Description
PCIE_LEGACY_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCIe legacy interrupt. INTA_OUT, INTB_OUT, INTC_OUT and INTD_OUT status outputs from the PCIe core are aggregated. Note: Valid in RP mode only.
PCIE_ERROR_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCIe error interrupt. FATAL_ERROR_OUT, NON_FATAL_ERROR_OUT and CORRECTABLE_ERROR_OUT status outputs from the PCIe core are aggregated. Note: Valid in both RP and EP modes.
PCIE_ASF_PULSE	1	Pulse	High	Internal Diagnostics	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCIe active internal diagnostics interrupt. All active internal diagnostics status signals (asf_*) from the PCIe core are aggregated. Note: Valid in both RP and EP modes.
PCIE_FLR_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCIe Function Level interrupt. FLR_IN_PROGRESS[5:0] and VF_FLR_IN_PROGRESS[15:0] status outputs from the PCIe core are aggregated. Note: Valid in EP mode only.

**Table 12-242. PCIe Core Interrupt Events (continued)**

Name	Width	Type	Polarity	Category	Clock	Reset	Description
PCIE_DOWNSTREAM_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie downstream interrupt.</p> <ul style="list-style-type: none"> <li>F0_VSEC_INTERRUPT_OUT,</li> <li>F1_VSEC_INTERRUPT_OUT,</li> <li>F2_VSEC_INTERRUPT_OUT,</li> <li>F3_VSEC_INTERRUPT_OUT,</li> <li>F4_VSEC_INTERRUPT_OUT and</li> <li>F5_VSEC_INTERRUPT_OUT</li> </ul> <p>status outputs from the PCie controller are aggregated. Note: Valid in EP mode only</p>
PCIE_HOT_RESET_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie hot reset interrupt. HOT_RESET_OUT status output from the PCie controller is aggregated. Note: Valid in EP mode only.</p>
PCIE_LINK_STATE_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie link state interrupt. LINK_DOWN_RESET_OUT status from the PCie core is aggregated. Note: Valid in both RP and EP modes.</p>
PCIE_PWR_STATE_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie power state interrupt. POWER_STATE_CHANGE and DPA_INTERRUPT[5:0] status output from the PCie core are aggregated. Note: Valid in both EP and RP modes.</p>
PCIE_LOCAL_LEVEL	1	Level	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie local interrupt The LOCAL_INTERRUPT from the PCie controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.</p>
PCIE_PHY_LEVEL	1	Level	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie PHY interrupt. The PHY_INTERRUPT_OUT from the PCie controller is brought out directly without any aggregation. Note: Valid in both RP and EP modes.</p>
PCIE_PTM_VALID_PULSE	1	Pulse	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie PTM valid interrupt PTM_LOCAL_TIMER_OUT_VALID status output from the PCie controller is aggregated. Note: Valid only in EP mode.</p>
PCIE_ECC0_UNCORR_PULSE	1	Pulse	High	Internal Diagnostics	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie ECC Aggregator0 uncorrected pulse interrupt.</p>
PCIE_ECC0_UNCORR_LEVEL	1	Level	High	Internal Diagnostics	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	<p>PCie ECC Aggregator0 uncorrected level interrupt.</p>

**Table 12-242. PCIe Core Interrupt Events (continued)**

Name	Width	Type	Polarity	Category	Clock	Reset	Description
PCIE_ECC0_CORR_PULSE	1	Pulse	High	Internal Diagnostics	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCle ECC Aggregator0 corrected pulse interrupt.
PCIE_ECC0_CORR_LEVEL	1	Level	High	Internal Diagnostics	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCle ECC Aggregator0 corrected level interrupt.
PCIE_ECC1_UNCORR_PULSE	1	Pulse	High	Internal Diagnostics	PCIE_LANE0_TX_MCLK	PCIE_RST_MOD_G_RST_N	PCle ECC Aggregator1 uncorrected pulse interrupt.
PCIE_ECC1_UNCORR_LEVEL	1	Level	High	Internal Diagnostics	PCIE_LANE0_TX_MCLK	PCIE_RST_MOD_G_RST_N	PCle ECC Aggregator1 uncorrected level interrupt.
PCIE_CPTS_PEND_INTR	1	Level	High	Func	PCIE_CBA_CLK	PCIE_RST_MOD_G_RST_N	PCle CPTS level interrupt. The EVNT_PEND_INTR from the CPTS module is brought out directly without aggregation.

#### 12.2.3.4.4.1 Interrupt Generation in EP Mode

When PCIe subsystem is operating as an End Point (EP), either the legacy interrupts, MSI or MSI-X interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RP device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

##### 12.2.3.4.4.1.1 Legacy Interrupt Generation in EP Mode

The End Point (EP) can trigger generation of a PCI Legacy Interrupt at the Root Port via an in-band Assert\_INTx / Deassert\_INTx messages (where x = A, B, C, or D). Software can write to the PCIE\_USER\_LEGACY\_INTR\_SET register to trigger the required INTx (where x = A, B, C, or D) assert and de-assert message from the PCIe core. Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

#### Note

The interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

##### 12.2.3.4.4.1.2 MSI and MSI-X Interrupt Generation

In the case of MSI interrupts signaling, the interrupt conditions are communicated from the EP to the RP via messages. Thus, upon the occurrence of an interrupt condition, a message is sent by the EP with information that identifies the origin of the interrupt. Each message is in the form of a memory write request, containing an address and a data value to be written. Each PCI function supported by a device can be assigned a separate memory address, thus providing separate virtual channels for signaling interrupts generated by each function. In addition, the MSI mechanism allows a maximum of 32 distinct data patterns in the messages generated by each PCI function, and each pattern can be assigned to an interrupt condition within the function.

In the case of MSI-X interrupts signaling, the operation is similar to the MSI mode, except that the mechanism allows a much larger number of distinct interrupt conditions as many as 2048 per function to be communicated, and enables a distinct address to be defined for each of these conditions. This mechanism requires two tables to be stored in the EP memory. The MSI-X table contains the address/data patterns to be used for each interrupt condition (as many as 2048 per function) as well as individual enable/mask bits, and the Pending Bit Array (PBA) stores the status of each interrupt condition. Interrupt conditions are communicated from the EP to the RP via messages (write requests), as in the case of the MSI mode.

#### 12.2.3.4.4.2 PCIe Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than these are used to map to interrupts.

##### 12.2.3.4.4.2.1 PCIe Core Downstream Interrupts

The Vendor Specific Capability signals of the PCIe core, F0\_VSEC\_INTERRUPT\_OUT, F1\_VSEC\_INTERRUPT\_OUT, F2\_VSEC\_INTERRUPT\_OUT, F3\_VSEC\_INTERRUPT\_OUT, F4\_VSEC\_INTERRUPT\_OUT and F5\_VSEC\_INTERRUPT\_OUT, are used to generate interrupts to the EP from the RP. F0\_VSEC\_INTERRUPT\_OUT represents the interrupt for the EP Physical Function 0, F1\_VSEC\_INTERRUPT\_OUT is the interrupt output for EP Physical Function 1 and so on. These signals are aggregated into the PCIE\_DOWNSTREAM\_PULSE interrupt to the local host.

The RP can write to the Vendor specific control registers to assert these signals at the EP and this will trigger the PCIE\_DOWNSTREAM\_PULSE interrupt to the EP host.

##### 12.2.3.4.4.2.2 PCIe Core Function Level Reset Interrupts

The PCIE\_FLR\_PULSE interrupt is asserted to indicate to the host that the PCIe controller has received a function-level reset request from the remote side. The PCIE\_FLR\_PULSE interrupt is an aggregation of the FLR\_IN\_PROGRESS[5:0] and VF\_FLR\_IN\_PROGRESS[15:0] signals from the PCIe core. Each bit of FLR\_IN\_PROGRESS[5:0] represents Physical Function0 through 5 and each bit of the VF\_FLR\_IN\_PROGRESS[15:0] represents Virtual Function0 through 15.

Upon assertion of the function level reset interrupt, software will need to write to the PCIE\_USER\_FLR\_DONE[5:0] FLR\_DONE bit field within 100ms to acknowledge to the PCIe core that all the application level processing related to the function level reset is complete. Similarly, software will need to acknowledge virtual function level reset completion by writing to the PCIE\_USER\_VF\_FLR\_DONE[15:0] VF\_FLR\_DONE bit field within 100ms of the virtual function level reset being asserted.

##### 12.2.3.4.4.2.3 PCIe Core Power Management Event Interrupts

The PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by the POWER\_STATE\_CHANGE\_INTERRUPT output of the PCIe core. This interrupt is asserted when the power state of a physical or virtual function is being changed to D1 or D3 state by writing into their Power Management Control register (PCIE\_CORE\_PFn\_I\_PWR\_MGMT\_CTRL\_STAT\_REP or PCIE\_CORE\_VFm\_I\_PWR\_MGMT\_CTRL\_STAT\_REP, respectively).

Software can check the PCIE\_USER\_LINKSTATUS[23-16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM register field to determine the physical function for which power state change occurred. The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK register bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

The PCIE\_DPA\_PULSE interrupt is generated by aggregating the PCIe controller DPA\_INTRs interrupt status outputs. This interrupt is asserted in EP mode when there is a configuration write to the dynamic power allocation control register (PCIE\_CORE\_PFn\_I\_DPA\_CTRL\_STATUS\_REG) to modify the DPA power state of the device. The DPA\_INTR0 is asserted for such an event for PF0, the DPA\_INTR1 for PF1 and so on.

##### 12.2.3.4.4.2.4 PCIe Core Hot Reset Request Interrupt

When the link is down, the Root Port may request reset of the End Point. This request is terminated as an PCIE\_HOT\_RESET\_PULSE interrupt to the End Point host software. All outstanding transactions are completed in error on slave port and further transactions are not generated on the master port. Once the transactions are completely stopped, the software should issue a local reset to PCIe subsystem. The re-initialization process may then be started.

The PCIE\_HOT\_RESET\_PULSE interrupt is generated from the HOT\_RESET\_OUT output of the PCIe core.

#### **12.2.3.4.4.2.5 PTM Valid Interrupt**

In EP mode, the PCIe subsystem will generate the `pcie_ptm_valid_pulse` interrupt to the local CPU after a PTM dialog between the PTM requester (EP) and the PTM responder (RP). The PTM valid interrupt indicates to the CPU in the EP that the local timers have been updated with the timestamp data obtained from the RP. The CPU can read the timer registers inside the EP to determine the current timebase.

The `pcie_ptm_valid_pulse` interrupt is generated from the `PTM_LOCAL_TIMER_OUT_VALID` signal from the PCIe core.

#### **12.2.3.4.4.3 PCIe Interrupt Generation in RP Mode**

As per PCIe Base Specifications, Root Port ports only receive interrupts. There is no mechanism to generate interrupts from RP port to EP mode as per PCIe specification.

However, PCIe subsystem does support generation of interrupts from RP to EP. The downstream interrupts described in [Section 12.2.3.4.4.2.1, PCIe Core Downstream Interrupts](#) provides a mechanism for the RP to generate software triggered interrupts to the EP.

#### **12.2.3.4.4.4 PCIe Interrupt Reception in RP Mode**

##### **12.2.3.4.4.4.1 PCIe Legacy Interrupt Reception in RP Mode**

The RP can receive any of the four legacy INTx interrupts from the EP. These will trigger the `PCIE_LEGACY_PULSE` interrupt to the host CPU.

The `PCIE_LEGACY_PULSE` interrupt is an aggregation `INTA_OUT`, `INTB_OUT`, `INTC_OUT` and `INTD_OUT` signals from the PCIe core.

##### **12.2.3.4.4.4.2 MSI/MSI-X Interrupt Reception in RP Mode**

The PCIe core decodes all MSI and MSI-X messages received from the link and forwards them on the low-priority AXI master interface. These messages must then be routed to the system interrupt controller by the SoC interconnect (CBASS0).

##### **12.2.3.4.4.4.3 Advanced Error Reporting Interrupt**

If enabled by software at the time of enumeration, PCIe subsystem will generate this interrupt to indicate occurrence of errors of various levels of severity. The software can choose not to enable Advanced Error Reporting but if it enables, it must process the interrupt as per PCIe Specifications.

The advanced error reporting interrupt is signaled by the `PCIE_ERROR_PULSE` interrupt. The `PCIE_ERROR_PULSE` is an aggregation of the `FATAL_ERROR_OUT`, `NON_FATAL_ERROR_OUT` and `CORRECTABLE_ERROR_OUT` from the PCIe core.

#### **12.2.3.4.4.5 PCIe Interrupt Reception in RP and EP Mode**

These interrupts are common to both RP and EP modes of operation.

##### **12.2.3.4.4.5.1 PCIe Local Interrupt**

The `LOCAL_INTERRUPT` from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.3.4.4.5.2 PHY Interrupt**

The `PHY_INTERRUPT_OUT` from the PCIe controller is ported out directly to the PCIe subsystem boundary. For more details, see the PCIe specification

##### **12.2.3.4.4.5.3 Link down Interrupt**

If the PHY link is disconnected, the `PCIE_LINK_STATE_PULSE` interrupt will be generated. The expected course of action is to reset the entire PCIe subsystem and restart. All application states must also be initialized so that the operations can resume following the reset and renegotiation of the link.

The `PCIE_LINK_STATE_PULSE` interrupt is generated from the `LINK_DOWN_RESET_OUT` output of the PCIe core.

#### **12.2.3.4.4.5.4 Transaction Error Interrupts**

If there is a timeout on PCIe or an abort, PCIE\_PHY\_LOCAL\_LEVEL interrupt will be issued. The PCIE\_PHY\_LOCAL\_LEVEL interrupt is generated by the aggregation of the LOCAL\_INTERRUPT and PHY\_INTERRUPT\_OUT signals from the PCIe core. For more details, see the PCIe specification.

#### **12.2.3.4.4.5.5 Power Management Event Interrupt**

This PCIE\_PWR\_STATE\_PULSE interrupt is generated to let the software know of the power management events. The PCIE\_PWR\_STATE\_PULSE interrupt is generated by aggregating the POWER\_STATE\_CHANGE\_INTERRUPT and DPA\_INTERRUPT outputs of the PCIe core.

In EP mode, software can check the PCIE\_USER\_LINKSTATUS[23-16] POWER\_STATE\_CHANGE\_FUNCTION\_NUM bit field to determine the physical function for which power state change occurred.

The PCIE\_USER\_PMCMD[2] POWER\_STATE\_CHANGE\_ACK bit can be used to acknowledge the POWER\_STATE\_CHANGE\_INTERRUPT.

#### **12.2.3.4.4.5.6 Active Internal Diagnostics Interrupts**

The active internal diagnostics interrupt is signaled by the PCIE\_ASF\_PULSE interrupt. This is an aggregation of the ASF\_CSR\_ERR, ASF\_DAP\_ERR, ASF\_INTEGRITY\_ERR, ASF\_INT\_FATAL, ASF\_INT\_NONFATAL, ASF\_PROTOCOL\_ERR, ASF\_SRAM\_CORR\_ERR, ASF\_SRAM\_UNCORR\_ERR, and ASF\_TRANS\_TO\_ERR signals from the PCIe core.

#### **12.2.3.4.4.6 ECC Aggregator Interrupts**

The PCIE\_ECC0\_UNCORR\_PULSE/PCIE\_ECC0\_UNCORR\_LEVEL and PCIE\_ECC0\_CORR\_PULSE/PCIE\_ECC0\_CORR\_LEVEL interrupts are asserted by the CBA clock domain ECC Aggregator. The PCIE\_ECC1\_UNCORR\_PULSE/PCIE\_ECC1\_UNCORR\_LEVEL interrupts are asserted by the Core clock domain ECC Aggregator. The Core clock domain ECC Aggregator correctable interrupts are not exported since this aggregator is only connected to the parity injection logic and the correctable interrupts for this module will never fire.

#### **12.2.3.4.4.7 CPTS Interrupts**

The PCIE\_CPTS\_PEND\_INT interrupt is asserted by the CPTS module in the PCIe subsystem to signal a TimeStamp event. Please refer to the CPTS module specifications for details on these interrupts.

#### **12.2.3.4.5 PCIe Subsystem DMA Support**

The PCIe Subsystem has different requirements based upon whether it is operated in Root Port (RP) or End Point (EP) mode. The PCIe subsystem does not have DMA capabilities built into it. It has internal slave and master ports connected to the device-level interconnect.

An external DMA engine can make burst data read/writes on the slave port and the master port on PCIe subsystem can initiate reads/writes to memory on behalf of a remote PCIe device.

The PCIe subsystem does not specify the DMA protocol that is used for data transfers. The software implementations on the two ends of the PCIe link implement a data transfer protocol that is compatible with each other.

As a result, there will be several software drivers required – one driver that will manage the PCIe subsystem in RP mode and another set of drivers that will run on the RP side and will manage each of the End Points connected to the PCIe subsystem RP.

Similarly, when PCIe subsystem is operating as an End Point, there are two drivers – one to manage the PCIe subsystem from the device side and another driver that will run on the device operating as the Root Port.

##### **12.2.3.4.5.1 PCIe DMA Support in Root Port Mode**

When operating in Root Port mode, a DMA controller internal to the device (outside PCIe subsystem) can perform DMA to and from any remote device located on the PCIe subsystem. The memory address of such

devices is available to the software via the PCIe bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCIe side.

#### **12.2.3.4.5.2 PCIe DMA Support in End Point Mode**

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. Any PCIe transactions destined for the device from the upstream ports will get transferred to the master port on the PCIe subsystem. Similarly, any transactions originating from the software will be sent over to PCIe link.

In End Point mode, the PCIe subsystem provides address translation functionality. It is possible to map memory accesses originating on PCIe side to memory accesses with different address on the CBA bus side. These address ranges are configurable through application registers.

#### **12.2.3.4.6 PCIe Transactions**

##### **12.2.3.4.6.1 PCIe Supported Transactions**

PCIe subsystem supports the following transactions:

1. Memory Read/Write in inbound/outbound direction in Root Port (RP) and End Point (EP) modes.
2. I/O Read/Write in outbound direction in RP mode.
3. Configuration Read/Write in outbound direction in RP mode.
4. Configuration Read/Write in inbound direction in EP mode.
5. Message Transactions for interrupts and power management in RP and EP modes.

The following transactions are not supported:

1. Locked Read transactions and associated messages.
2. Inbound I/O Transaction Layer Packets (TLPs).
3. User defined messages.

##### **12.2.3.4.6.2 PCIe Transaction Limitations**

There are some limitations that must be adhered to while issuing transactions to PCIe subsystem internal bus interface.

- System Initialization

#### **CAUTION**

The PCIe subsystem operation is completely dependent upon the availability of the SERDES module for PCIe transactions. The SERDES module must be configured and corresponding PLLs must be locked before the PCIe subsystem is able to process any data transactions. Any data accesses to the PCIe subsystem prior to this initialization may result in an internal bus hang condition.

- Remote Configuration and I/O Requests

Since the remote configuration and I/O transaction windows are directly mapped to internal bus space, the software must care to not access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

- Byte Strobe Limitations

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater than 32-bit, the TLP (Transaction Layer Packets) size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

- Burst Type Limitations

The PCIe core and respectively the PCIe subsystem does not support 'fixed' or 'wrap' burst types on its Slave or Master port. Transactions that require any burst type other than incremental burst type will result in unspecified behavior, possibly bus lock up.

- Transaction Address Alignment

The PCIe subsystem imposes a limitation of a maximum of 128-byte outbound read/write command. However, if the starting address is not aligned to an 8-byte boundary, then the maximum transaction size is reduced to 120 bytes. This limitation is placed to avoid arithmetic overflow in computing transaction length from CBA to AXI. Unspecified behavior will occur if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

- Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). The PCIe core will not interleave read responses, if the outbound read command/transaction size does not exceed the maximum transaction size configured in the PCIe core.

#### **12.2.3.4.7 PCIe Subsystem Address Translation**

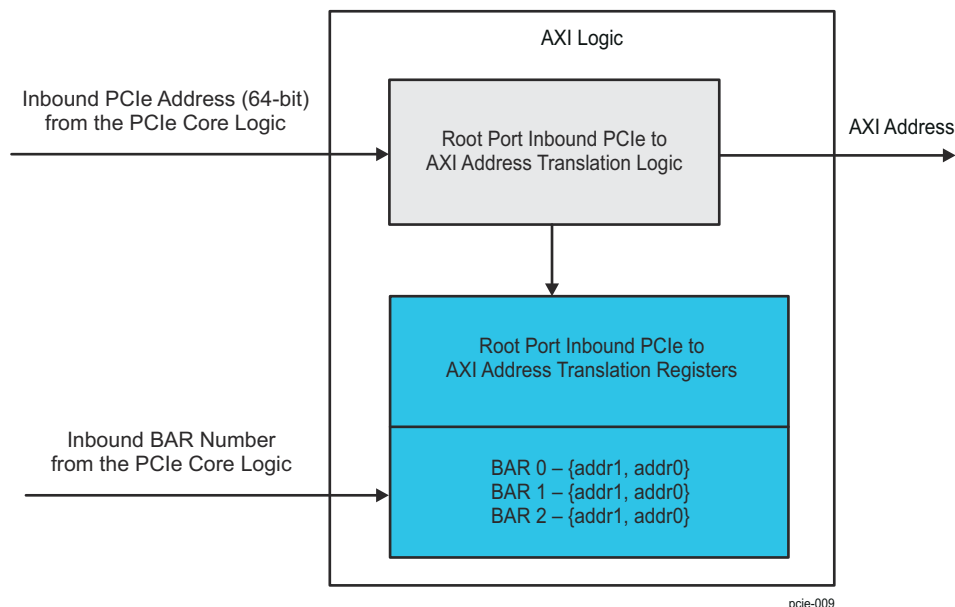

The PCIe subsystem uses the address translation registers in the PCIe core to translate outbound system addresses to PCIe space and inbound PCIe address to a valid system address. Note that internal address translation is different from the Address Translation Services (ATS).

##### **12.2.3.4.7.1 PCIe Inbound Address Translation**

###### **12.2.3.4.7.1.1 Root Port Inbound PCIe to AXI Address Translation**

The Root Port inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the BAR match of the incoming TLP. In Root Port mode there are 2 bars, so BAR 0 and BAR1 registers are implemented. There is a BAR7 register which is used as a no match BAR address translation register. In Root Port mode there are 2 bars but a BAR value of 7 will be indicated by HAL2AXI when BAR matching is disabled. Any address that does not match the Root Port BARs will be sent out as a BAR7 TLP. Each BAR register is implemented as two 32-bit registers which are named addr0 and addr1. The "Root Port Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "Root Port Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the inbound PCIe address to form the AXI address. An addr0 [5:0] + 1 number of lower bits are passed from the inbound PCIe address to AXI address. In other words, the number of bits taken from inbound PCIe address is given by the addr0[5:0] + 1 value.

**Figure 12-194. PCIE Root Port Inbound PCIe to AXI Address Translation**

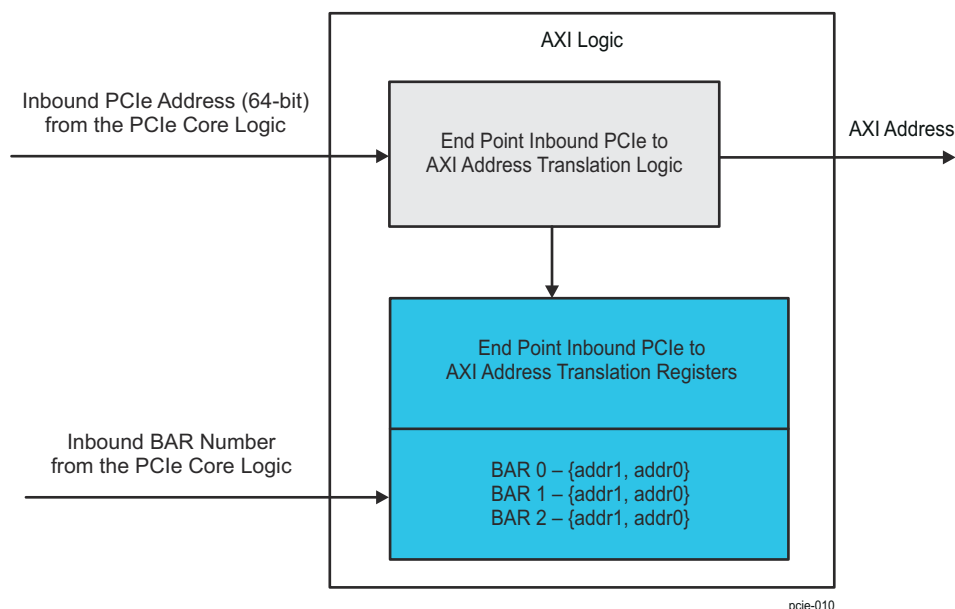

A set of registers corresponding to one Root Port BAR is shown in [Table 12-243](#).

**Table 12-243. PCIE Root Port Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
addr1	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0	31:8	Lower [31:8] bits of the AXI address.	24'd0
	7:6	Reserved	2'd0
	5:0	Number of address bits passed through from PCIe to AXI. The PCIe controller passes the programmed value + 1 bits from PCIe to AXI. Minimum value to be programmed into this field is 7 as the lower 8 bits of the base address programmed in these registers (AXI) are replaced by zeros by the Root Port Inbound PCIe to AXI Address Translation Logic.	6'd0

#### 12.2.3.4.7.1.2 End Point Inbound PCIe to AXI Address Translation

The End Point Inbound PCIe to AXI address translation is performed on memory and IO TLPs. The selection of which address translation registers to use in the translation process is dependent on the function number and BAR match of the incoming TLP. In End Point mode there are 7 bars per function, so 7 sets of registers are implemented per function, each BAR having two 32-bit registers (addr0 and addr1). The "End Point Inbound PCIe to AXI Address Translation Logic" takes the upper bits from the "End Point Inbound PCIe to AXI Address Translation Registers" and the lower bits are taken from the Inbound PCIe Address to form the AXI address. The number of bits to pass from Inbound PCIe Address to AXI is decided by the Inbound BAR aperture.

**Figure 12-195. PCIE End Point Inbound PCIe to AXI Address Translation**

A set of registers corresponding to one End Point BAR is shown in [Table 12-244](#).

**Table 12-244. PCIE End Point Inbound PCIe to AXI Address Translation Registers for one BAR**

Register Name	Bits	Description	Default Value
addr1	31:0	Upper [63:32] bits of the AXI address.	32'd0
addr0	31:0	Lower [31:0] bits of the AXI address.	32'd0

#### 12.2.3.4.7.2 PCIe Outbound Address Translation

The PCIe Subsystem allows mapping of PCIe addresses to/from the internal bus addresses of the device. This is accomplished by using internal address translation unit (iATU) in the PCIe core. For each outbound read/write request, the address translation module within PCIe subsystem can convert a VBUSM address to a PCIe address of memory Read/Write type.

If a transaction is large enough that it goes past the address translation region, unspecified behavior may occur. The address translation only works at the time a command is issued. So, a memory write, for example, will not automatically go to next translation region, if it starts in the previous one and is bigger than the remaining size in the starting translation region.

The “Dynamic Method: Sideband Descriptor Based” outbound address translation mechanism is used to bypass the outbound address translation unit under certain conditions.

##### 12.2.3.4.7.2.1 PCIe Outbound Address Translation Bypass

The PCIe subsystem supports bypassing the outbound address translation in the PCIe controller when the casel value on the VBUSM high-priority or VBUSM low-priority interfaces is non-zero.

When the system DMA sets the casel value for any transaction to non-zero, the ATU bypass logic in the PCIe subsystem drives the AXI\_AWUSER or AXI\_ARUSER signals to disable the address translation unit in the PCIe controller. The PCIe TLP address for that transaction will be the same as the input CBA address and there will be no translation from the system address to the PCIe address.

The following values are driven on the AXI\_AWUSER/AXI\_ARUSER by the PCIe subsystem when casel is not equal to 0.

**Table 12-245. AXI\_A\*USER Sideband Signal Mapping**

AXI_A*USER field	Description	Value
AXI_A*USER[3:0]	Mem write	0h (for read) 2h (for write)
AXI_A*USER[4]	No snoop	0h
AXI_A*USER[5]	Relaxed ordering	0h
AXI_A*USER[6]	ID based ordering	0h
AXI_A*USER[8:7]	AT bits	2h
AXI_A*USER[15:9]	Reserved	0h
AXI_A*USER[16]	Reserved	0h
AXI_A*USER[19:17]	TC	0h (for low-priority I/F) 3h (for high-priority I/F)
AXI_A*USER[20]	Poison Write TLP	0h
AXI_A*USER[21]	Insert Read ECRC	0h
AXI_A*USER[22]	Reserved	0h
AXI_A*USER[23]	Requester ID Enable	0h
AXI_A*USER[31:24]	Requester ID – Function number + Device number	0h
AXI_A*USER[39:32]	Requester ID – Bus number	0h
AXI_A*USER[47:40]	Reserved	0h
AXI_A*USER[60:48]	Reserved	0h
AXI_A*USER[63:61]	Reserved	0h
AXI_A*USER[84:64]	Reserved	0h
AXI_A*USER[85]	PASID	0h
AXI_A*USER[105:86]	PASID value	0h
AXI_A*USER[106]	Privilege mode	0h
AXI_A*USER[107]	Execute mode	0h
AXI_A*USER[108]	Reserved	0h
AXI_A*USER[127:109]	Reserved	0h
AXI_A*USER[3:0]	Sideband valid	1h

#### 12.2.3.4.8 PCIe Subsystem Virtualization Support

The PCIe subsystem supports multiple virtualization related features as described below.

##### 12.2.3.4.8.1 EP SR-IOV support

In End Point (EP) mode, the PCIe subsystem supports Single Root I/O Virtualization (SR-IOV) with four physical functions (PF) and four virtual functions (VF) per physical function for PF0-PF3 only.

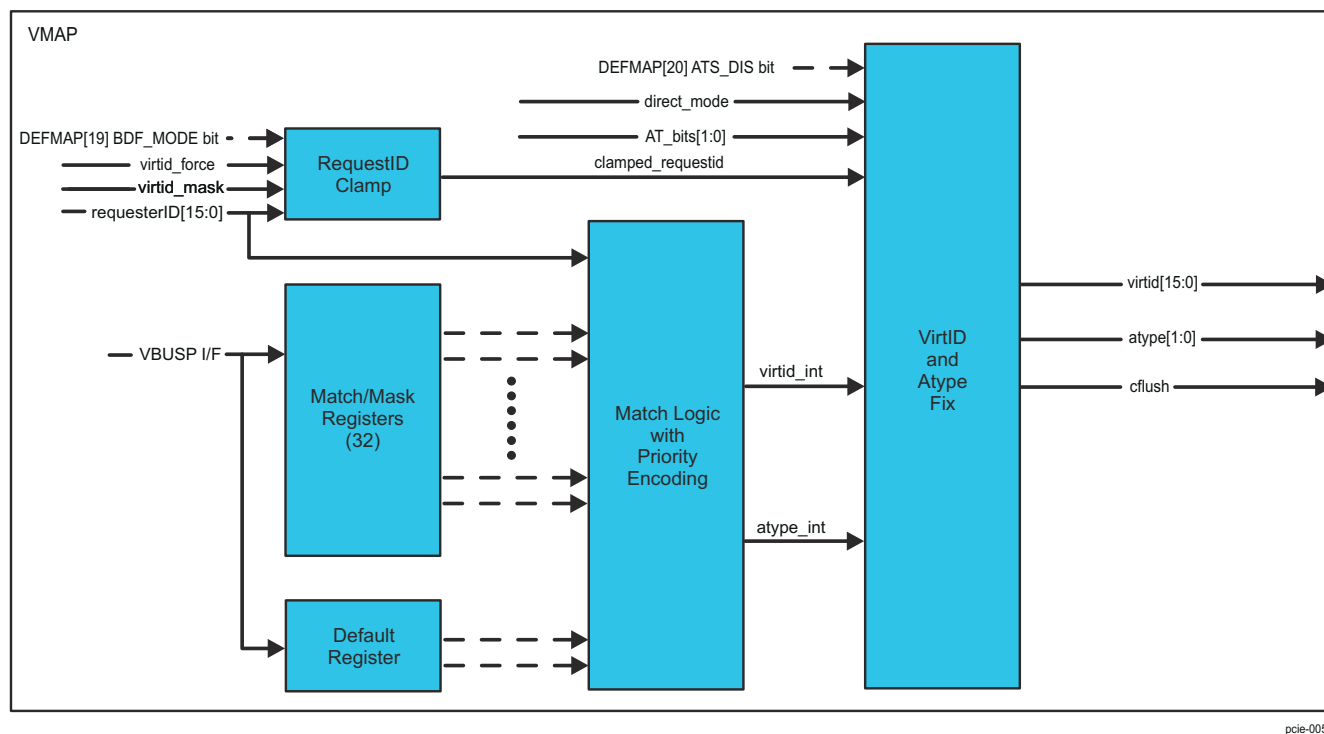

##### 12.2.3.4.8.2 RP ATS support

In Root Port (RP) mode, the PCIe subsystem has an AXI streaming interface (DTI) to connect to the system level SMMU. Address Translation Messages (ATS) from the End Point is routed to the SMMU over the DTI interface. The translated address and any invalidation requests from the SMMU, sent to the PCIe over the DTI interface, is converted to ATS messages and sent to the End Point.

##### 12.2.3.4.8.3 VirtID Mapping

The PCIe subsystem includes the VMAP module that can be programed to map (convert) the incoming 16-bit PCIe requestID + 2-bit PCIe AT bits to the 16-bit CBA virtID + 2-bit CBA atype attributes.

Figure 12-196 shows the block diagram of the VMAP module. The blocks shown in the diagram are replicated for the read and write AXI channels. However, there is only one set of configuration registers in the VMAP module and these are shared by both the read and write channel logic.

**Figure 12-196. PCIe Subsystem VirtID Mapper**

The RequestID Clamp block is used to clamp the incoming requestID to a maximum value. This block compares the incoming PCIe requestID[15:12] masked with the virtid\_mask[3:0] to an expected value. Bit [19] BDF\_MODE in PCIE\_VMAP\_DEFMAP is used to set the value to virtid\_force[3:0] or 4'h0. The clamped\_requestid is set to the maximum value of FFFFh if the comparison is false. The clamped\_requestid value is later used downstream by the PVU or SMMU in the SoC.

Each of the VMAP modules includes a set of 32 match and mask registers. Software can enable the registers to be used for the mapping by setting the [0] EN bit in PCIE\_VMAP\_CTRL\_j registers. Software can also program the [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers to indicate the incoming PCIe requestid that needs to be matched. The [11-0] VID and [17-16] ATYPE bit fields in PCIE\_VMAP\_VIRTID\_j registers are used to program the required CBA virtID and Atype fields in case of a match. In order to prevent a spurious match, the [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers should be set up before the [0] EN bit in PCIE\_VMAP\_CTRL\_j registers is set. The same sets of registers are used for both read and write transactions.

The Match logic with Priority Encoding block compares the incoming PCIe requestID with the values programmed in the VMAP control registers and sets the value of the virtid\_int and atype\_int variables. For every incoming PCIe transaction, the incoming PCIe requestID[11:0] bits are masked with the PCIE\_VMAP\_REQID\_j[31-16] MASK bit field and compared against each of the thirty two values indicated by PCIE\_VMAP\_REQID\_j[15-0] RID that are enabled. The location of the first match of this comparison operation is used to select the [11-0] VID and [17-16] ATYPE bit fields in PCIE\_VMAP\_VIRTID\_j registers. This is used as the virtid\_int and atype\_int values for the downstream logic. In case none of the enabled [15-0] RID and [31-16] MASK bit fields in PCIE\_VMAP\_REQID\_j registers pairs match the incoming requestID, the value in [11-0] DEF\_VID and [17-16] DEF\_ATYPE bit fields in PCIE\_VMAP\_DEFMAP registers is used.

The VirtID and Atype Fix block uses the incoming PCIe AT\_bits along with the matched and clamped values of the requestID from the downstream blocks to set the final values of the virtID, catype and cflush attributes for the particular CBA transaction. The values of the virtID, catype and cflush are determined based on the following criteria:

1. If the incoming PCIe TLP has a translated address, as indicated by the PCIe AT\_bits equal to 2 and if the match operation results in an expected atype value of 2 and Address Translation Services (ATS) is enabled in the system, as indicated by the PCIE\_VMAP\_DEFMAP[20] ATS\_DIS register bit, the virtID is set to the *clamped\_requestid* and the *catype* value is set to 2. This enables the PCIe subsystem to pass along the full incoming requestID[15:0] to the upstream SMMU/PVU. The incoming transaction is flushed if it fails this criteria by setting the cflush attribute to 1. The PCIe EP initiating this transaction will be sent a Completion Abort (CA) response for a read request, if the transaction is flushed.
2. If the incoming PCIe TLP does not have a translated address, as indicated by the PCIe AT\_bits equal to 0, the virtID can be set to the output of the mask/match registers or the *clamped\_requestid*. The *catype* attribute for this transaction can be set to the value from the mask/match registers.

### Note

The PCIE implementation in the device uses the *direct\_mode* workaround. This forces the *cvirtID* and *catype* to 0 when the incoming transaction matches the criteria outlined in (1) above.

The system Interconnect only supports 12-bits of *virtid*. As a result, only *virtid*[11:0] from the PCIe VMAP module will be used in the system and *virtid*[15:12] is not connected.

The pseudo-code for the virtID mapping algorithm implemented is described below.

```
// Requestid Clamp
// Note: only the low 4 bits of virtid_force & virtid_mask are used in the current PCIe wrapper
// virtid_mask[7:4] should always be 1
// virtid_mask[n] of 1 means use the virtid_force value for this bit
// virtid_mask[n] of 0 means use the requestID value for this bit, virtid_force[n] should be 0
// Bit [19] BDF_MODE in PCIE_VMAP_DEFMAP specifies if we are using
// 0 based bus numbers (0) or offset bus numbers (1)
expected_value[3:0] = PCIE_VMAP_DEFMAP[19] BDF_MODE ? virtid_force[3:0] : 4'h0;
if (requestID[15:12] & virtid_mask[3:0] == expected_value[3:0] )
{
    clamped_requestID[15:0] = requestID[15:0];
}
else
{
    clamped_requestID[15:0] = FFFFh;
}
// Match Logic with Priority Encoding
for n in 0 to 31 do
if (PCIE_VMAP_CTRL_j[0] EN == 1h &&
(requestID & PCIE_VMAP_REQID_j[31:16] MASK) == PCIE_VMAP_REQID_j[15:0] RID )
{
    found[n] = true;
}
```

```
else
{
found[n] = false;
}
done
// priority encoder for 32 results from above
// uses lowest numbered match
// also outputs a bool specifying if any match was found
all_miss = true;
for n in 0 to 31 do
if (found[n])
{
virtid_int[11:0] = PCIE_VMAP_VIRTID_j[11-0] VID;
atype_int[1:0] = PCIE_VMAP_VIRTID_j[17-16] ATYPE;
all_miss = false;
break;
}
done
// Use the default if no match is found
if (all_miss)
{
virtid_int[11:0] = PCIE_VMAP_DEFMAP[11-0] DEF_VID;
atype_int[1:0] = PCIE_VMAP_DEFMAP[17-16] DEF_ATYPE;
}
// VirtID and Atype Fix
if (AT_bits == 0x2) // Is this a pre-translated address?
{
// Is this EP using SMMU and is ATS enabled?
if (atype_int == 2h && PCIE_VMAP_DEFMAP[20] == 0h )
{
if (direct_mode == 1h) //
{
// yes, send directly to destination address
atype[1:0] = 2'h0; // Direct
virtid[15:0] = 16'h0; // should not matter
flush = 1'b0; // don't turn on the flush bit
```

```
at_cba = 1'b0; // Not used
}
else
{
// no, send to SMMU TBU for processing
atype[1:0] = 2'h2; // //SMMU
virtid[15:0] = clamped_requestID[15:0]; //Use the correct StreamID
flush = 1'b0; // don't turn on the flush bit
at_cba = 1'b1; // Indicate a pre-translated address
}
}
else
{
// All other cases should error the transaction for pre-translated transaction
// PVU & Direct should not see any pre-translated requests
// SMMU with ATS disables also errors
atype[1:0] = 2'h2; // use VirtSS to force the error
virtid[15:0] = 16'h0; // should not matter
flush = 1'b1; // force the error
at_cba = 1'b1; // should not matter
}
}
else
{
// This transaction is not pre-translated
atype[1:0] = atype_int //use the atype from the register
flush = 1'b0; // don't force an n error
at_cba = 1'b0; // this is not pre-e- translated
if (atype_int == 2'h2)
{
// this is SMMU, use the clamped RequestID
virtid[15:0] = clamped_requestID[15:0];
}
else
{
// this is not SMMU, use the value from the register
```

```

virtid[11:0] = virtid_int[11:0];
virtid[15:12] = 4'h0;
}
}

```

#### 12.2.3.4.9 PCIe Subsystem Quality-of-Service (QoS)

The Quality-of-Service (QoS) mechanism in the PCIe subsystem uses the Virtual Channel/Traffic Class (VC/TC) feature in the PCIe core in conjunction with the CBA QoS capabilities.

For ingress traffic, transactions that use the highest enabled virtual channel will be directed to the high priority master interface. Transactions using all other virtual channels will be directed to the low priority master interface.

In addition, the TC information from each transaction on the AXI master information is mapped to the CCHANID signal of the VBUSM master interface. The system level interconnect can use the CCHANID along with the orderid for QoS purposes. [Table 12-246](#) shows the TC mapping to the 12-bit CCHANID of each VBUSM master interface.

**Table 12-246. QoS Ingress CCHANID Mapping**

TC Value	CCHANID[11:0]
0	{9'd0, 3'b000}
1	{9'd0, 3'b001}
2	{9'd0, 3'b010}
3	{9'd0, 3'b011}
4	{9'd0, 3'b110}
5	{9'd0, 3'b101}
6	{9'd0, 3'b110}
7	{9'd0, 3'b111}

For egress traffic, the data presented on the VBUSM high priority port will be assigned the highest enabled VC. This will ensure that data on the high priority port will get priority on the PCIe link. All data presented on the VBUSM low priority port will be assigned lower VCs.

#### 12.2.3.4.10 PCIe Subsystem Precision Time Measurement (PTM)

Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

PTM defines the following components:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint.
- PTM Responder - A Function capable of using PTM to supply PTM Master Time associated with a RP.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root – The source of PTM Master Time for a PTM hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

When using PTM between two components on a Link, the EP sends PTM requests to the RP on the same link. During each dialog, the RP populates the PTM Response message based on timestamps stored during previous PTM dialogs. Once each component has historical timestamps from the preceding dialog, the EP can combine its timestamps with those passed in the PTM Response message to calculate the PTM Master Time.

The PCIe core implements all of the features required to handle the PTM conversation between the requestor and responder in hardware. In addition, the Timestamp module (CPTS) is connected to the timestamp interface of the PCIe core so that events can be logged.

#### 12.2.3.4.11 PCIe Subsystem Loopback

The PCIe subsystem provides loopback support through PIPE interface (Link Layer).

##### 12.2.3.4.11.1 PCIe PIPE Loopback

The procedure depends upon whether the device is operating in RP or EP Mode. In either case, the PCIe subsystem can be loopback master or loopback slave as outlined in PCIe specifications. A loopback master is the component requesting loopback and transmitting the data. A loopback slave is the component looping back the data.

#### Note

The PIPE loopback mode cannot be used for looping back transactions.

##### 12.2.3.4.11.1.1 PIPE Loopback Master Mode

The loopback path when PCIe subsystem is loopback master is:

PCIe subsystem (loopback master) -> PIPE (TX) -> PCIe Link -> Loopback -> PCIe Link -> PIPE (RX) -> PCIe subsystem

##### 12.2.3.4.11.1.2 PIPE Loopback Slave Mode

The loopback path when PCIe subsystem is loopback slave is:

Remote device -> PCIe Link -> PIPE (RX) -> Loopback -> PIPE (TX) -> PCIe Link -> Remote device

If the PCIe subsystem is a loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as loopback master and it will transition PCIe subsystem into loopback slave state following which the inbound transactions will be loopback to the test equipment. There is no programming required on PCIe subsystem to enter loopback in slave mode. PHY support is not required to use this loopback mode.

##### 12.2.3.4.12 PCIe Subsystem Error Handling

As an End Point, PCIe subsystem reports errors to root complex so that corrective action may be taken. These messages become error interrupts on the Root Port side. In addition, the errors that are detected by the PCIe subsystem locally are also reported to software via interrupts.

Note that for several errors of the same type that are detected in close succession, the PCIe subsystem will not necessarily send as many error messages to Root Port. It is guaranteed to send at least one such error message.

##### 12.2.3.4.12.1 PCIe AXI to/from VBUSM Bus Error Mapping

[Table 12-247](#) and [Table 12-248](#) show the bus error mapping to/from the AXI interface on the PCIe controller to the system VBUSM interfaces.

The AXI2VBUSM bridge maps the bus errors on the ingress AXI interface to the VBUSM master interface as shown in the table below.

**Table 12-247. AXI to VBUSM Bus Error Mapping**

VBUSM		AXI	
Code	Error	Code	Error
0 (decimal)	Success	0h	OKAY
1 (decimal)	N/A	3h	N/A
2-3 (decimal) 7 (decimal)	All Others	2h	SLVERR

The VBUSM2AXI bridge maps the bus errors on the egress VBUSM slave interface to the AXI interface as shown in the table below.

**Table 12-248. VBUSM to AXI Bus Error Mapping**

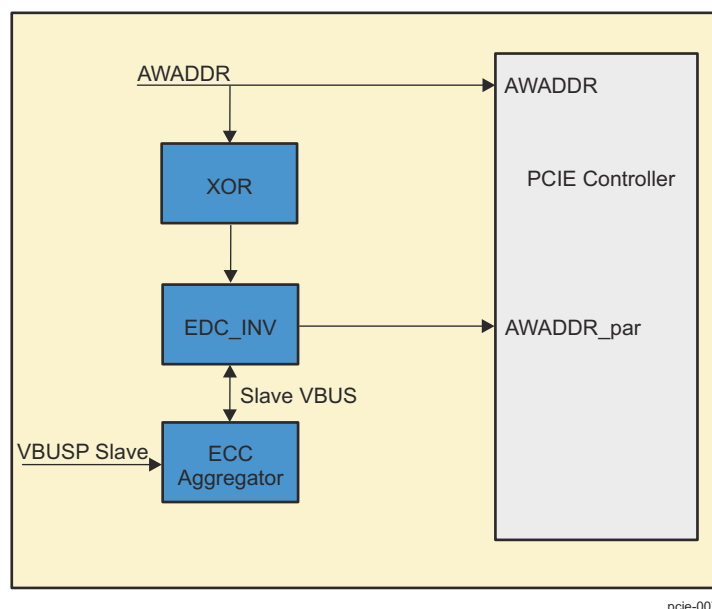

AXI		VBUSM	
Code	Error	Code	Error
N/A	N/A	2 (decimal)	Protection Error
0h	OKAY	0 (decimal)	Success
3h	DECERR	1 (decimal)	Addressing Error
2h	SLVERR	1 (decimal)	Addressing Error

### 12.2.3.4.13 PCIe Subsystem Internal Diagnostics Features

#### 12.2.3.4.13.1 PCIe Parity

All the parity inputs on the PCIe controller core are driven by the EDC\_INV module. This allows the parity input to the PCIe controller to be inverted and thus inject an error. [Figure 12-197](#) shows the parity logic on the AXI AWADDR port as an example. The parity of the AWADDR inputs to the PCIe controller are calculated as an XOR and this is fed into the PCIe controller using the EDC\_INV block. The input AWADDR\_par can be inverted using commands from the ECC Aggregator to enable error injection. Similar logic is present on all other parity inputs to the PCIe controller.

Checking input parity and output parity are handled inside the PCIe controller. Any errors in parity are signaled using the PCIe active internal diagnostics interrupt (PCIE\_ASF\_PEND).

**Figure 12-197. Parity Logic on AXI AWADDR Input**

#### 12.2.3.4.13.2 ECC Aggregators

The PCIe subsystem instantiates two ECC Aggregators: AXI\_ECC\_AGGR and CORE\_ECC\_AGGR.

AXI\_ECC\_AGGR is connected to the RAMs in PCIe CBA Clock Domain and CORE\_ECC\_AGGR is connected to the RAMs in the PIPE Clock Domain.

The ECC Aggregator modules integrated within the PCIe subsystem provide a mechanism to control and monitor the ECC RAMs via Single Error Correction (SEC) and Double Error Detection (DED) functions. Each ECC Aggregator module gathers level pending status from the ECC RAMs into two interrupts to system level. One interrupt is for correctable errors (SEC) and the other one for uncorrectable errors (DED). The ECC

Aggregator supports software readable status of ECC single/double-bit errors and associated information such as RAM address and data bit(s) that are in error. Write back correction for async read RAMs is not supported.

For more information on the ECC Aggregator operation, see [Section 12.11.4, ECC Aggregator](#).

#### 12.2.3.4.13.3 RAM ECC inversion

The RAM ECC logic inside the PCIe controller can be tested using the ECC inversion logic.

#### 12.2.3.4.14 LTSSM State Encoding

[Table 12-249](#) is used when the PCIe/M-PCIe core is configured to be operating in PCIe mode.

[Table 12-249](#) provides the encoding of the LTSSM states on the LTSSM\_STATE output of the core, as well the state read from the Physical Layer Configuration Register 0.

**Table 12-249. LTSSM State Encoding**

LTSSM State Name	Value (hex)

## 12.2.4 Universal Serial Bus (USB) Subsystem

This section describes the USB 3.0 Dual-Role-Device (DRD) interface subsystem of the device.

### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

### 12.2.4.1 USB Overview

Similar to earlier versions of USB bus, USB 3.0 is a general-purpose cable bus, supporting data exchange between a host device and a wide range of simultaneously accessible peripherals.

The device supports these USB subsystems:

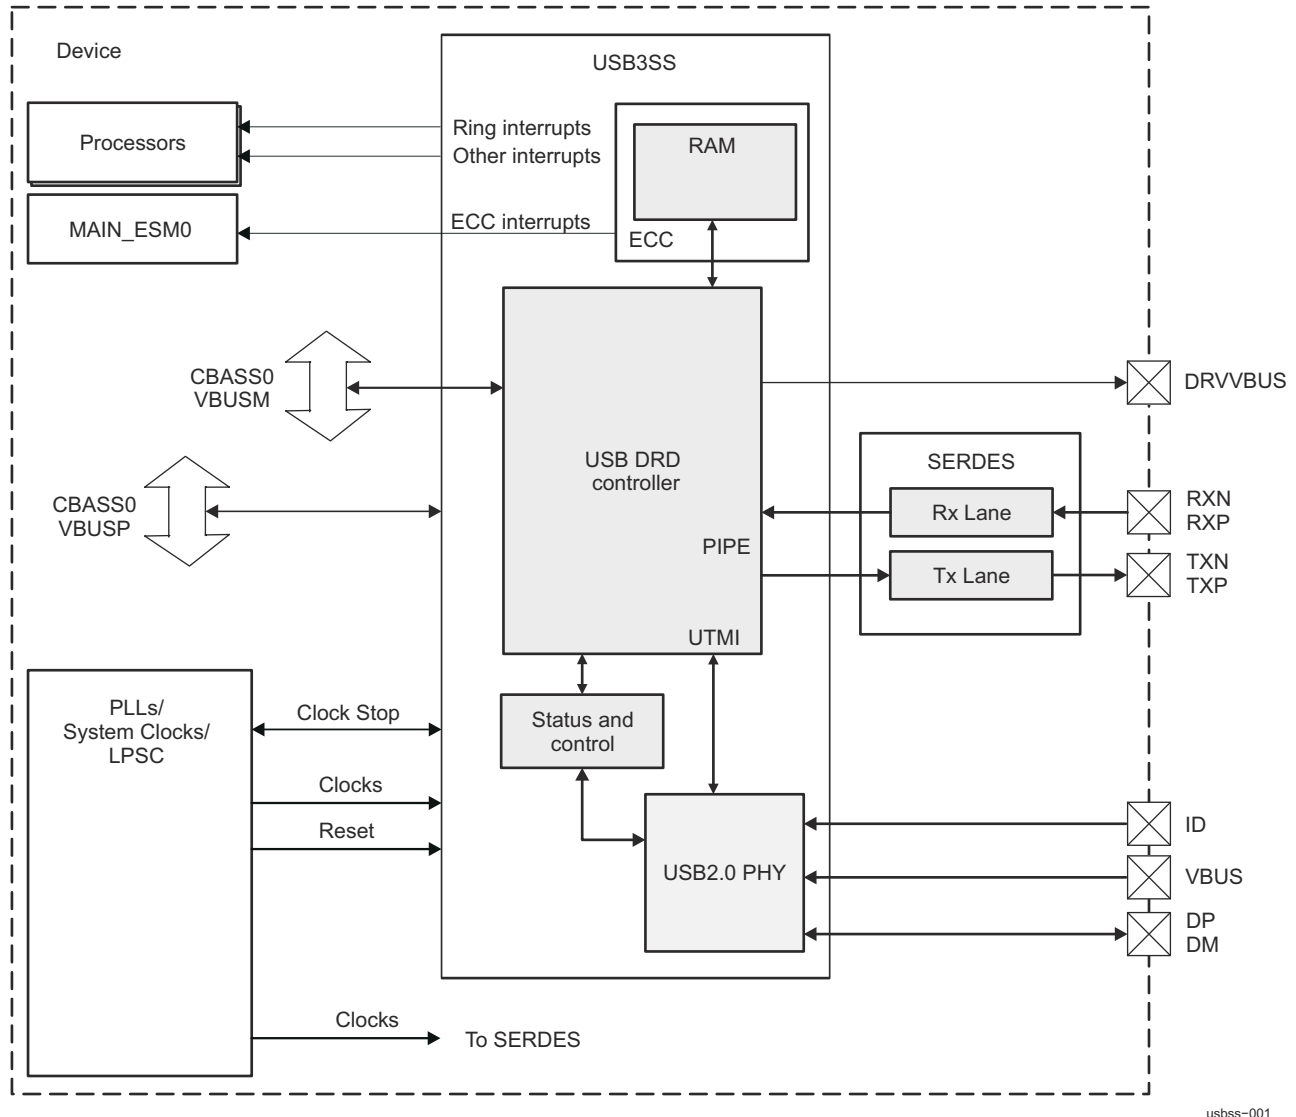

- USB3SS0 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS <sup>1</sup>(USB2.0) PHY
- USB3SS1 is SuperSpeed (SS) USB 3.0 Dual-Role-Device (DRD) subsystem with on-chip SS (USB3.0) PHY and HS/FS/LS (USB2.0) PHY

**Table 12-250. USB Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
USB3SS0	-	-	✓
USB3SS1	-	-	✓

Figure 12-198 shows the USB subsystem highlights.

<sup>1</sup> LowSpeed (LS) is supported only in host mode, in both USB3SS0 and USB3SS1.

usbss-001

**Figure 12-198. USB Subsystem Overview**

#### 12.2.4.1.1 USB Features

The USB Dual-Role-Device (DRD) subsystem, supports the following USB features:

- General features:
  - Supports Peripheral (aka Device) mode at Superspeed (5 Gbps), Highspeed (480 Mbps), and Fullspeed (12 Mbps)
  - Supports Host mode at Superspeed (5 Gbps), Highspeed (480 Mbps), Fullspeed (12 Mbps), and Low-speed (1.5 Mbps)
  - Static peripheral operation
  - Static host operation
  - Compliant with USB 3.1 Gen1 Specification
  - Limited OTG 2.0 functionality
  - Supports VBUS and ID detection
  - Host Negotiation Protocol (HNP) support
  - Charger Downstream Port (CDP) as per Battery Charging Specification, Revision 1.2
- Each controller instance contains single xHCI with the following features:

- Compatible to the xHCI specification (revision 1.0)
- Supports 15 Transmit (TX), 15 Receive (RX) endpoints (EPs), and one EP0 endpoint which is bidirectional
- Internal scatter-gather DMA controller
- Dynamic data buffering
- USB3 power saving states (U1, U2, and U3) and USB2 L1/L2
- 64 slots supported with 32 endpoints per slot, for host operation
- Operation flexibility:
  - Uniform programming model for SS, HS, FS, and LS operation
  - Multiple interrupt lines:
    - 8 interrupts associated with 8 programmable Event Rings for multi-core support
    - Interrupt for OTG events
- Functional safety:
  - Internal RAM with ECC
  - Hardware transaction timeout monitor
- Supports VBUS and ID detection in the USB2.0 PHY
- External requirements and I/O features:
  - Requires an external charge pump or power switch for VBUS 5-V generation
  - Requires an external circuitry or PMIC to start the battery charging upon Battery Charger (BC) detected event
  - Requires external high-precision resistors for USB2.0 PHY and SERDES termination calibration
  - Supports internal data lane swapping for Type C connector. All other Type C features, like cable detection and CC configuration, have to be implemented using external circuitry
  - Supports short circuit protection to GND and short-term short circuit protection to VBUS on data pins

#### 12.2.4.1.2 USB Not Supported Features

The following are USB features which are not supported in the current device:

- OTG 3.0 functionality
- HSIC (High Speed Inter-Chip) and SSIC interface
- ULPI Interface for external PHY
- SRP and ADP protocols
- Hibernation
- Cache-line wrap addressing mode on both bus interfaces
- Debug trace interface
- xHCI IO virtualization
- MSI support

#### 12.2.4.1.3 USB Terminology

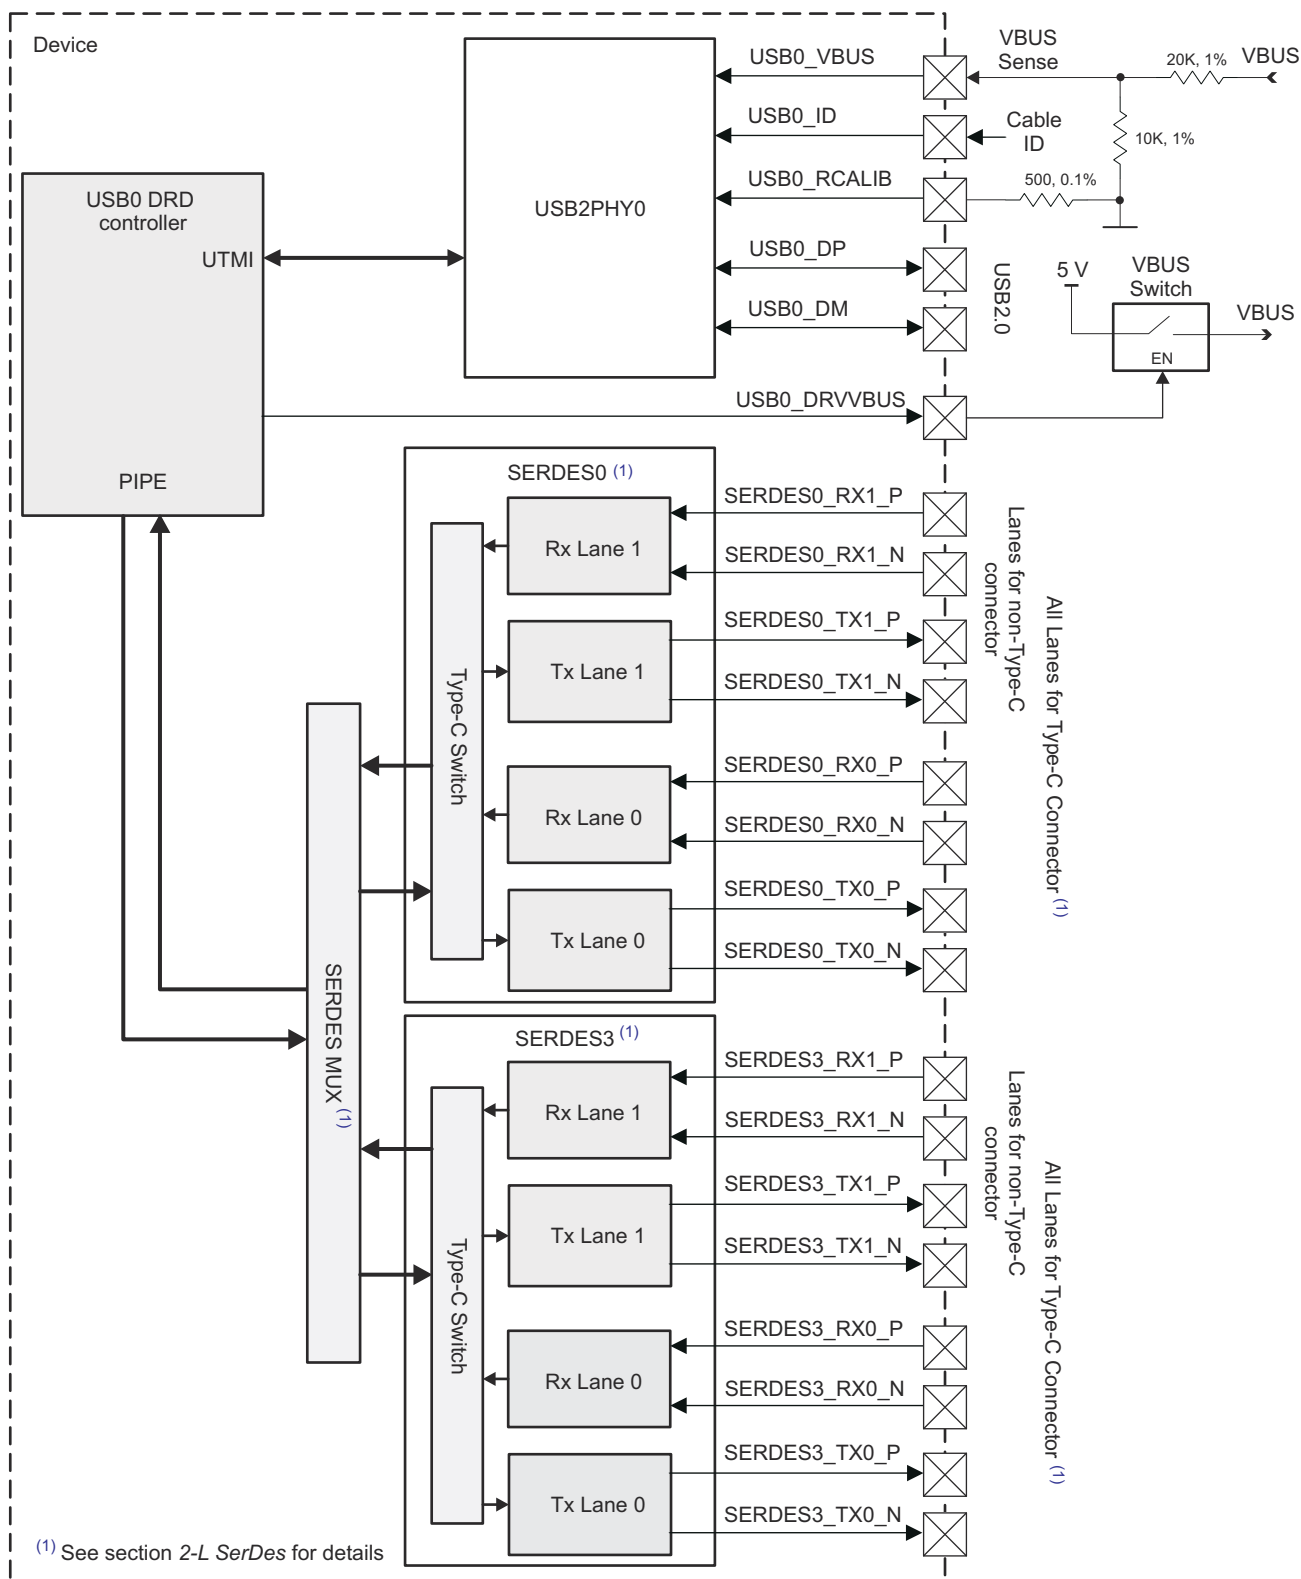

The following acronyms and abbreviations are related to USB.

Term	Definition
<b>ADP</b>	Attach Detection Protocol: detects USB OTG attach/detach events.
<b>DRD</b>	Dual Role Device: USB Host and Peripheral capable.
<b>DS</b>	Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).
<b>EP</b>	Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.
<b>FS</b>	Full-Speed USB data rate (12 Mbps).
<b>HNP</b>	Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.
<b>HS</b>	High-Speed USB data rate (480 Mbps).
<b>ITP</b>	Isochronous Timestamp Packet: USB SS micro-frame boundary packets.
<b>LMP</b>	Link Management Packet.
<b>LS</b>	Low-Speed USB data rate (1.5 Mbps).

Term	Definition
<b>OTG</b>	On-The-Go extension to USB protocol.
<b>PHY</b>	Physical Layer Device.
<b>SS</b>	Super-Speed USB data rate. 5 Gbps (USB3.0 or USB3.1 Gen1)
<b>US</b>	Upstream facing from a device (or hub) to the host (or a hub).
<b>USB IF</b>	USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. <a href="http://www.usb.org">http://www.usb.org</a>
<b>xHC</b>	Host Controller, designates the USB hardware that implements the xHCI specification.
<b>xHCI</b>	eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

## 12.2.4.2 USB Environment

Figure 12-199 shows the I/O interface signals of the USB3SS0 subsystem.

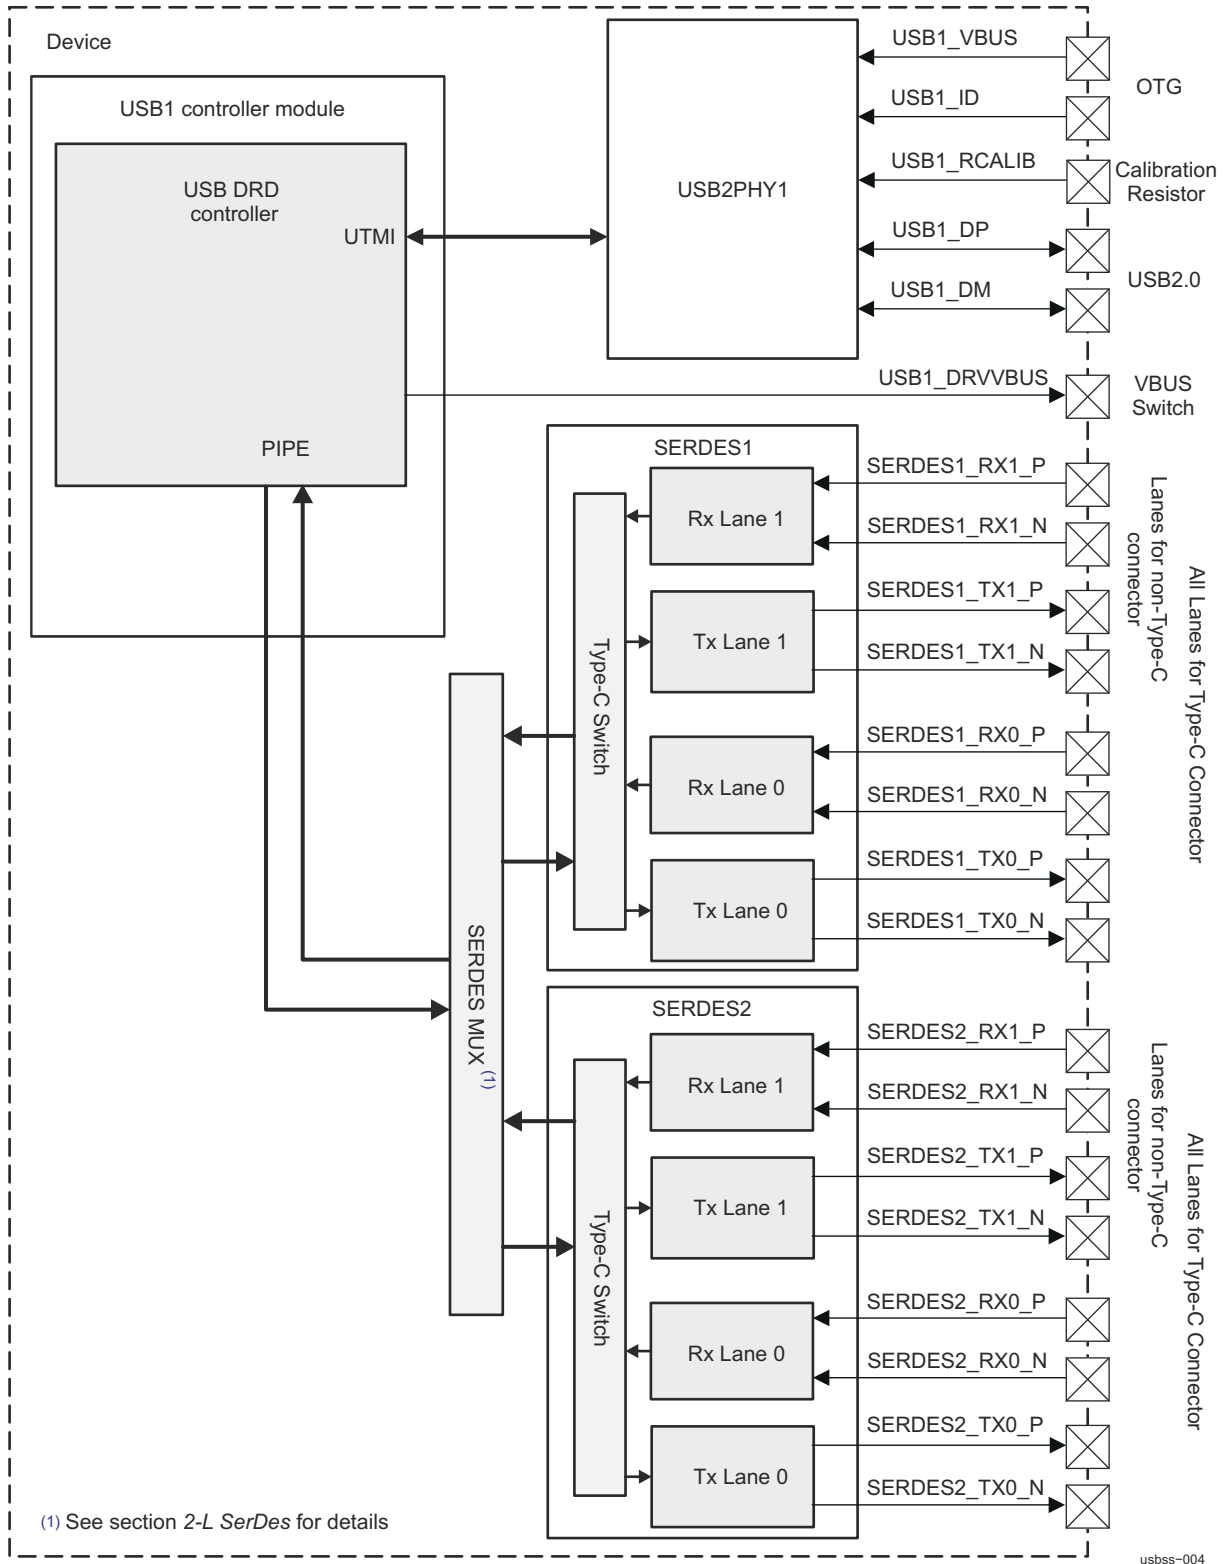

usbss-003

Figure 12-199. USB3SS0 Subsystem Environment

Figure 12-200 shows the I/O interface signals of the USB3SS1 subsystem.

**Figure 12-200. USB3SS1 Subsystem Environment**

Table 12-251 describes the external signals of the USB3SS0 subsystem.

**Table 12-251. USB3SS0 Input/Output Description**

Device Pin	Module or PHY Signal	I/O <sup>(1)</sup>	Description	Value at Reset
USB0_DP	DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)	HiZ
USB0_DM	DM	I/O		HiZ
SERDES0_RX1_P (SERDES0_RX0_P) or <sup>(2)</sup> SERDES3_RX1_P (SERDES3_RX0_P)	RX_P_LN1 <sup>(3)</sup> (RX_P_LN0) <sup>(4)</sup>	I	USB3.0 differential data receive lane (RX+ pin)	HiZ
SERDES0_RX1_N (SERDES0_RX0_N) or <sup>(2)</sup> SERDES3_RX1_N (SERDES3_RX0_N)	RX_N_LN1 <sup>(3)</sup> (RX_N_LN0) <sup>(4)</sup>	I	USB3.0 differential data receive lane (RX- pin)	HiZ
SERDES0_TX1_P (SERDES0_TX0_P) or <sup>(2)</sup> SERDES3_TX1_P (SERDES3_TX0_P)	TX_P_LN1 <sup>(3)</sup> (TX_P_LN0) <sup>(4)</sup>	O	USB3.0 differential data transmit lane (TX+ pin)	HiZ
SERDES0_TX1_N (SERDES0_TX0_N) or <sup>(2)</sup> SERDES3_TX1_N (SERDES3_TX0_N)	TX_N_LN1 <sup>(3)</sup> (TX_N_LN0) <sup>(4)</sup>	O	USB3.0 differential data transmit lane (TX- pin)	HiZ
SERDES0_REXT or <sup>(2)</sup> SERDES3_REXT	CMN_REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm $\pm$ 1% accurate off-chip resistor connected from this pin to ground.	HiZ
USB0_ID	ID	A/I	USB cable identifier (A/B-device). Analog ID pin sense with internal pull-up	HiZ
USB0_VBUS	VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm	HiZ
USB0_DRVVBUS	DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate	0
USB0_RCALIB	RTRIM	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm $\pm$ 1% off-chip resistor connected from this pin to ground	HiZ

(1) I = Input; O = Output; A = Analog

(2) USB3SS0 Superspeed can go to either SERDES0 or SERDES3. Refer to 2-L *Serializer/Deserializer (SerDes)* for more details.

(3) Lane 1 is active always, regardless if non-Type C or Type C connector is being used.

(4) Lane 0 is active only if Type C connector is being used.

Table 12-252 describes the external signals of the USB3SS1 subsystem.

**Table 12-252. USB3SS1 Input/Output Description**

Device Pin	Module or PHY Signal	I/O <sup>(1)</sup>	Description	Value at Reset
USB1_DP	DP	I/O	USB2.0 data pins. These are HS/FS/LS bidirectional differential data lane (D+/D-)	HiZ
USB1_DM	DM	I/O		HiZ
SERDES1_RX1_P (SERDES1_RX0_P) or <sup>(2)</sup> SERDES2_RX1_P (SERDES2_RX0_P)	RX_P_LN1 <sup>(3)</sup> (RX_P_LN0) <sup>(4)</sup>	I	USB3.0 differential data receive lane (RX+ pin)	HiZ

**Table 12-252. USB3SS1 Input/Output Description (continued)**

Device Pin	Module or PHY Signal	I/O <sup>(1)</sup>	Description	Value at Reset
SERDES1_RX1_N (SERDES1_RX0_N) or <sup>(2)</sup> SERDES2_RX1_N (SERDES2_RX0_N)	RX_N_LN1 <sup>(3)</sup> (RX_N_LN0) <sup>(4)</sup>	I	USB3.0 differential data receive lane (RX- pin)	HiZ
SERDES1_TX1_P (SERDES1_TX0_P) or <sup>(2)</sup> SERDES2_TX1_P (SERDES2_TX0_P)	TX_P_LN1 <sup>(3)</sup> (TX_P_LN0) <sup>(4)</sup>	O	USB3.0 differential data transmit lane (TX+ pin)	HiZ
SERDES1_TX1_N (SERDES1_TX0_N) or <sup>(2)</sup> SERDES2_TX1_N (SERDES2_TX0_N)	TX_N_LN1 <sup>(3)</sup> (TX_N_LN0) <sup>(4)</sup>	O	USB3.0 differential data transmit lane (TX- pin)	HiZ
SERDES1_REXT or <sup>(2)</sup> SERDES2_REXT	CMN_REXT	A/I	USB3.0 SerDes external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.	HiZ
USB1_ID	ID	A/I	USB cable identifier (host/device). Analog ID pin sense with internal pull-up	HiZ
USB1_VBUS	VBUS	A/I	An 3.3-V analog input for monitoring the voltage on VBUS (VBUS sense). 5-V VBUS must be applied via an external resistive divider /3. For example, R1 = 20 kOhm and R2 = 10 kOhm	HiZ
USB1_DRVVBUS	DRVVBUS	O	A digital output signal for VBUS Power Supply Enabling. Used to enable an external charge pump or power switch to supply +5V power to the VBUS port, when appropriate	0
USB1_RCALIB	RTRIM	A/I	External resistor for USB2.0 PHY calibration. Requires a 500 Ohm $\pm 1\%$ off-chip resistor connected from this pin to ground	HiZ

(1) I = Input; O = Output; A = Analog

(2) USB3SS1 SuperSpeed can go to either SERDES1 or SERDES2. Refer to 2-L *Serializer/Deserializer (SerDes)* for more details.

(3) Lane 1 is active always, regardless if non-Type C or Type C connector is being used.

(4) Lane 0 is active only if Type C connector is being used.

### 12.2.4.3 USB Integration

This section describes USB module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 12-201](#) and [Figure 12-202](#) show the integration of the USB subsystem in the device.

For Superspeed SerDes integration details, please refer to in *Serializer/Deserializer (SerDes)*.

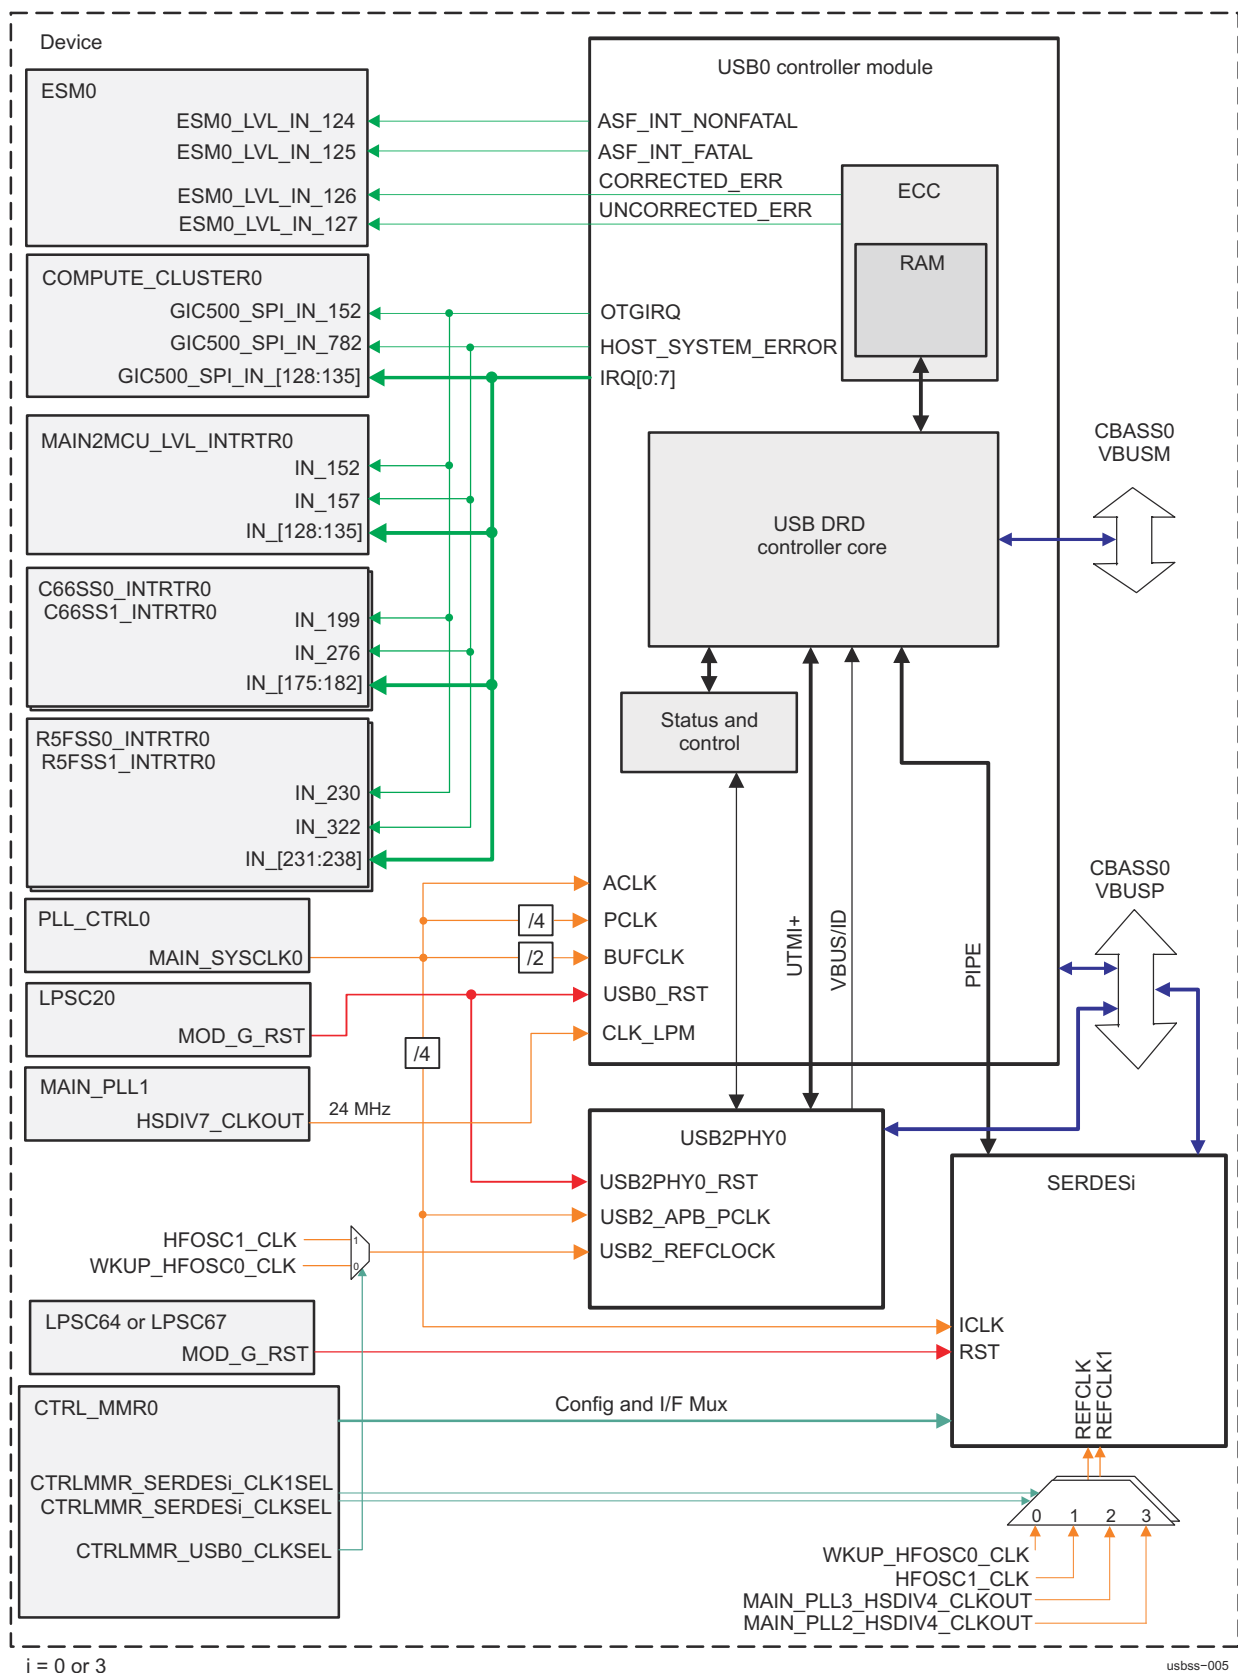

Figure 12-201. USB3SS0 Integration

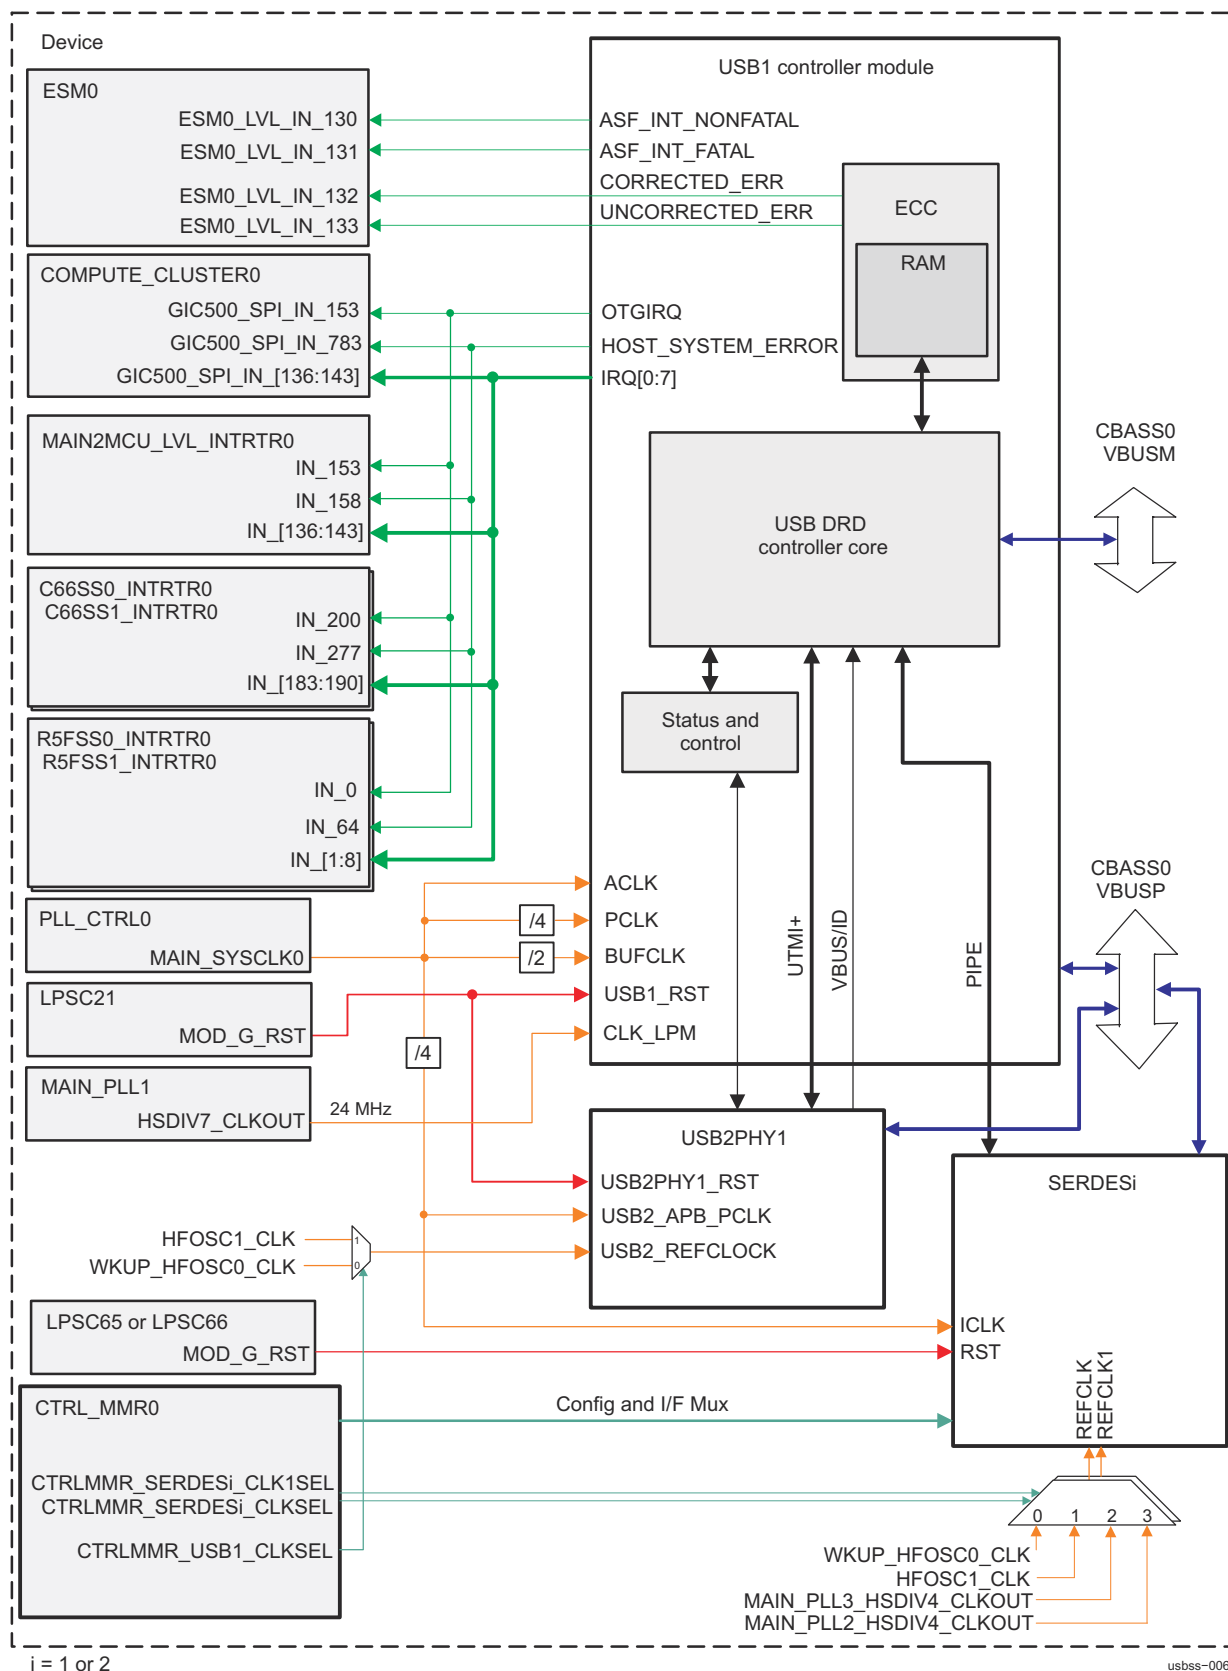

Figure 12-202. USB3SS1 Integration

Table 12-253 through Table 12-255 summarize the integration of USBSS.

**Table 12-253. USB Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
USB3SS0	PSC0	PD0	LPSC20	CBASS0
USB3SS1	PSC0	PD0	LPSC21	CBASS0

**Table 12-254. USB Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
USB3SS0	ACLK	MAIN_SYSCLK0	PLL_CTRL0	VBUSM interface clock
	PCLK	MAIN_SYSCLK0/4	PLL_CTRL0	VBUSP interface clock
	BUFCLK	MAIN_SYSCLK0/2	PLL_CTRL0	VBUSM bridge clock
	CLK_LPM	MAIN_PLL1_HSDIV7_C LKOUT	MAIN_PLL1	Low power clock (24 MHz). This clock has to be free running when USB is enabled.
USB2PHY0	USB2_REFCLOCK	WKUP_HFOSC0_CLK	WKUP_HFOSC0	USB2PHY reference clock. HFOSC selected via CTRLMMR_USB0_CLKSEL. Frequency value must be indicated to PHY via USB3P0SS_STATIC_CONFIG.
		HFOSC1_CLK	HFOSC1	
USB3SS1	USB2_APB_PCLK	MAIN_SYSCLK0/4	PLL_CTRL0	USB2PHY VBUSP interface clock
	ACLK	MAIN_SYSCLK0	PLL_CTRL0	VBUSM interface clock
	PCLK	MAIN_SYSCLK0/4	PLL_CTRL0	VBUSP interface clock
	BUFCLK	MAIN_SYSCLK0/2	PLL_CTRL0	VBUSM bridge clock
	CLK_LPM	MAIN_PLL1_HSDIV7_C LKOUT	MAIN_PLL1	Low power clock (24 MHz). This clock has to be free running when USB is enabled.
USB2PHY1	USB2_REFCLOCK	WKUP_HFOSC0_CLK	WKUP_HFOSC0	USB2PHY reference clock. HFOSC selected via CTRLMMR_USB1_CLKSEL. Frequency value must be indicated to PHY via USB3P0SS_STATIC_CONFIG.
		HFOSC1_CLK	HFOSC1	
	USB2_APB_PCLK	MAIN_SYSCLK0/4	PLL_CTRL0	USB2PHY VBUSP interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
USB3SS0	USB0_RST	MOD_G_RST	LPSC20	USB3SS0 hardware reset
USB3SS1	USB1_RST	MOD_G_RST	LPSC21	USB3SS1 hardware reset

**Table 12-255. USB Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt	Destination Interrupt Input	Destination	Description	Type
USB3SS0	IRQ_[0:7]	GIC500_SPI_IN_[128:135]	COMPUTE_CLUSTER0	8 event ring interrupts in host mode. In device mode, IRQ[6] is device USB interrupt and IRQ[7] is device wakeup request.	Level

USB3SS0 and USB3SS1	-	-	-	No PDMA channels to external DMA engines. USB has an internal DMA controller.	-

## 12.2.4.4 USB Functional Description

### Note

This chapter serves to describe the integration of the third-party USB controller and should not be considered sufficient for those wishing to modify the existing Linux or RTOS USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux or RTOS USB driver(s), or create new drivers, contact TI for more information on how to obtain the third-party documentation under NDA.

The USB3SS subsystem contains the USB3.0 Dual Role Device (DRD) controller module and a USB2.0 PHY module. A wrapper module is controlling some top-level functions like Host and Device role switch and reset release.

The USB controller uses USB2PHY for USB2.0 operation and one of the device SERDESes for USB3.0 speeds. The SERDES also contains lane swap feature for USB Type-C plug flipping support.

### 12.2.4.4.1 USB Type-C Connector Support

Lane swapping for Type-C connector support is performed within the SERDES wrapper module. Type-C CC detection and configuration has to be performed by external ICs. Type-C device attachment/detachment and cable orientation have to be communicated using I2C, GPIO, or a similar method.

For USB Type-C support, the SERDES wrapper and SERDES must be programmed for USB protocol on both lane 0 and lane 1. Software must hold PHY in reset and then write to the LN10\_SWAP bit to mux the PIPE interface to the other lane. Also the SuperSpeed port in the controller has to be in disabled state when programming LN10\_SWAP.

### 12.2.4.4.2 USB Controller Reset

USB controller has three resets going in, called preset\_n, pwrup\_rst\_n, and aresetn.

- preset\_n comes from the mod\_g\_rst\_n input coming from LPSC
- pwrup\_rst\_n is PWRUP\_RST\_N register bit in the USB wrapper module (USB3P0SS\_W1). This reset has to be deasserted before accessing controller registers. The default value for pwrup\_rst\_n is 0 (reset asserted). This reset goes to the default asserted state when mod\_g\_rst\_n reset is asserted.
- areset\_n comes from PWRUP\_RST\_N register bit, but the deassertion is synchronized to ACLK.

### 12.2.4.4.3 Overcurrent Detection

The overcurrent detection circuit is external to the device. Software must specify an overcurrent condition to the controller whenever the overcurrent signal is received from the detection circuit. Software must set the OVERCURRENT\_N bit to 0 in the USB3P0SS\_W1 register when overcurrent was detected.

### 12.2.4.4.4 Top-Level Initialization Sequence

The following initialization sequence has to be followed before configuring the controller for USB operation:

1. Software must select and configure the SERDES for USB operation. Some of the registers are shown in [Table 12-256](#). Refer to *Serializer/Deserializer (SerDes)* for more details. USB2.0 PHY contains default configuration that normally does not need change.

**Table 12-256. USB3.0 Register Configuration**

Bitfields not listed should be left at default value

Register	Bit Field/ Programming Model	Value
RX_CREQ_FLTR_B_PREG__RX_CREQ_FLTR_A_MODE0_PREG_j	[7:6] CREQ_CRFLTR_GAIN1_MODE_0_PREG	2h
	[5:3] CREQ_CRFLTR_GAIN2_MODE0_PREG	3h
	[2:1] CREQ_CRFLTR_ACCUMSAT2_MODE0_PREG	1h
DEQ_PHALIGN_CTRL_j	[1:0] DEQ_PHALIGN_SAMPSIZE_PREG	3h
SDFILT_H2L_A_PREG	SIGDET_SUPPORT_PREG_j[15:0]	6013h (Default)

- Software must configure the pseudo-static settings in USB3P0SS\_W1 register
- Software must set PWRUP\_RST\_N to 1 in order to deassert controller reset
- Software must wait for controller to be ready in the respective mode selected by reading the respective status bits.

After the above sequence, software can access controller registers.

## 12.2.5 2-L Serializer/Deserializer (SerDes)

This section describes the 2-Lane Serializer/Deserializer (SerDeses) in the device.

### 12.2.5.1 2-L SerDes Overview

SerDes'es goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
  - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
  - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.

The device contains four two-lane SerDeses: SERDES0 through SERDES3.

For four-lane SerDes (SERDES4), please see [Section 12.2.6, 4-L Serializer/Deserializer \(SerDes\)](#).

**Table 12-257. SerDes Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
SERDES0	-	-	✓
SERDES1	-	-	✓
SERDES2	-	-	✓
SERDES3	-	-	✓
SERDES4 (4-L)	-	-	✓

[Figure 12-203](#) through [Figure 12-206](#) show the SerDes highlights.

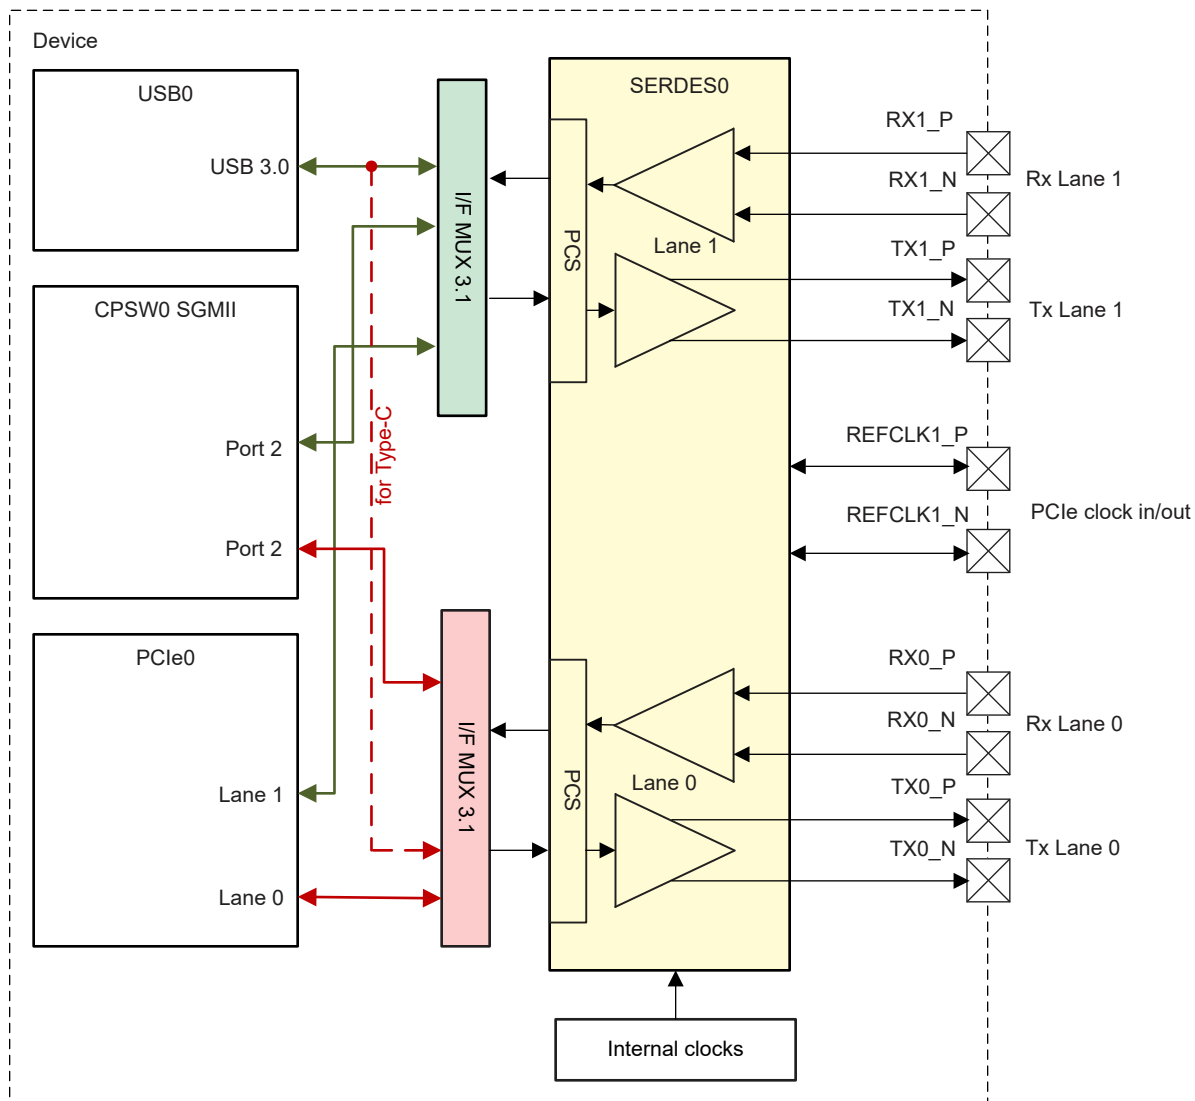

Figure 12-203. SERDES0 Overview

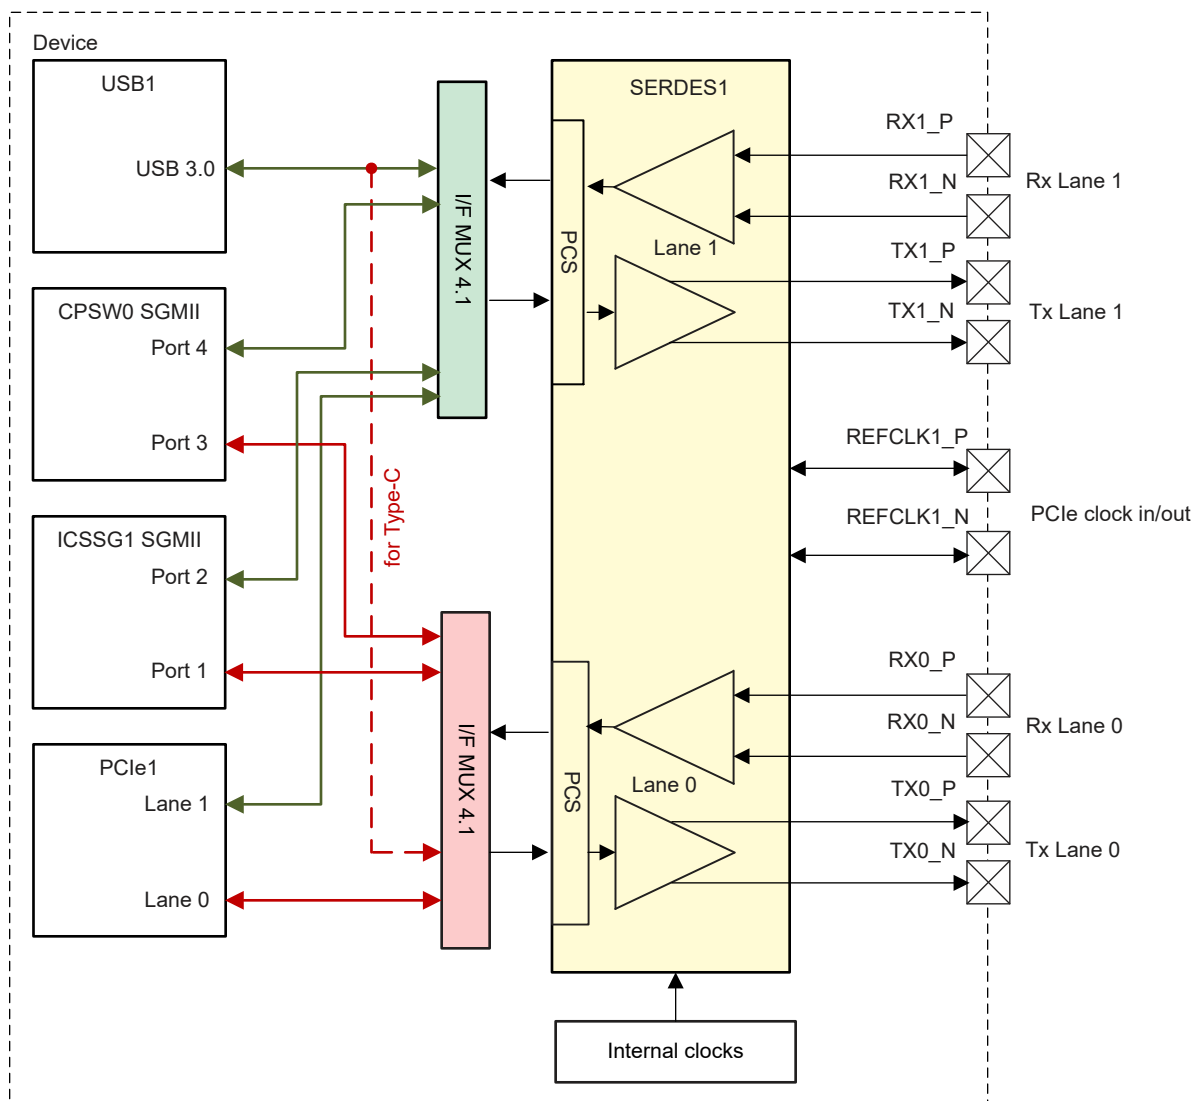

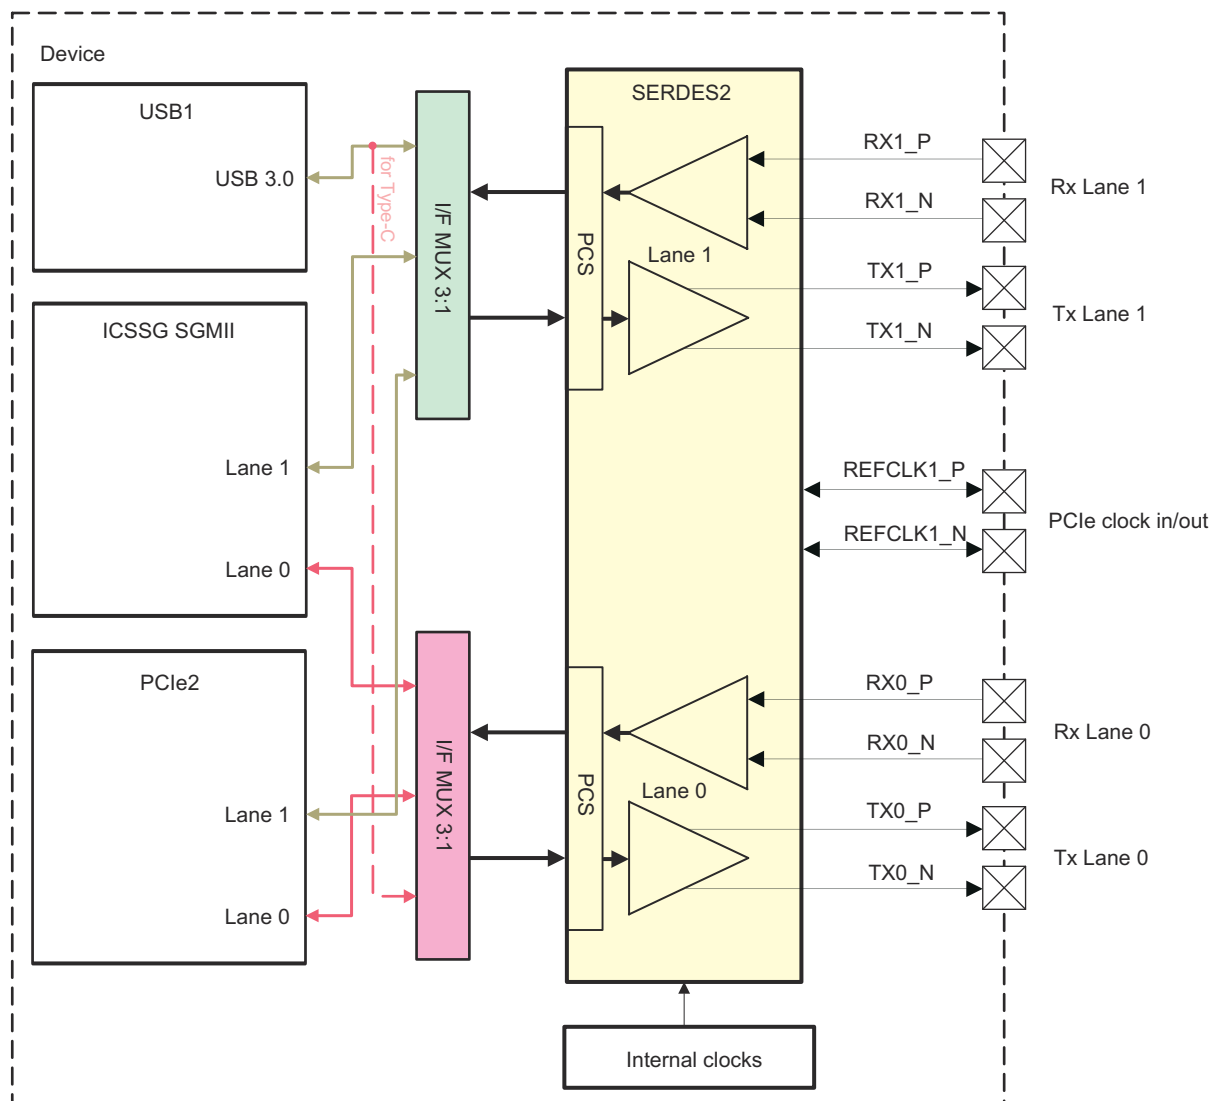

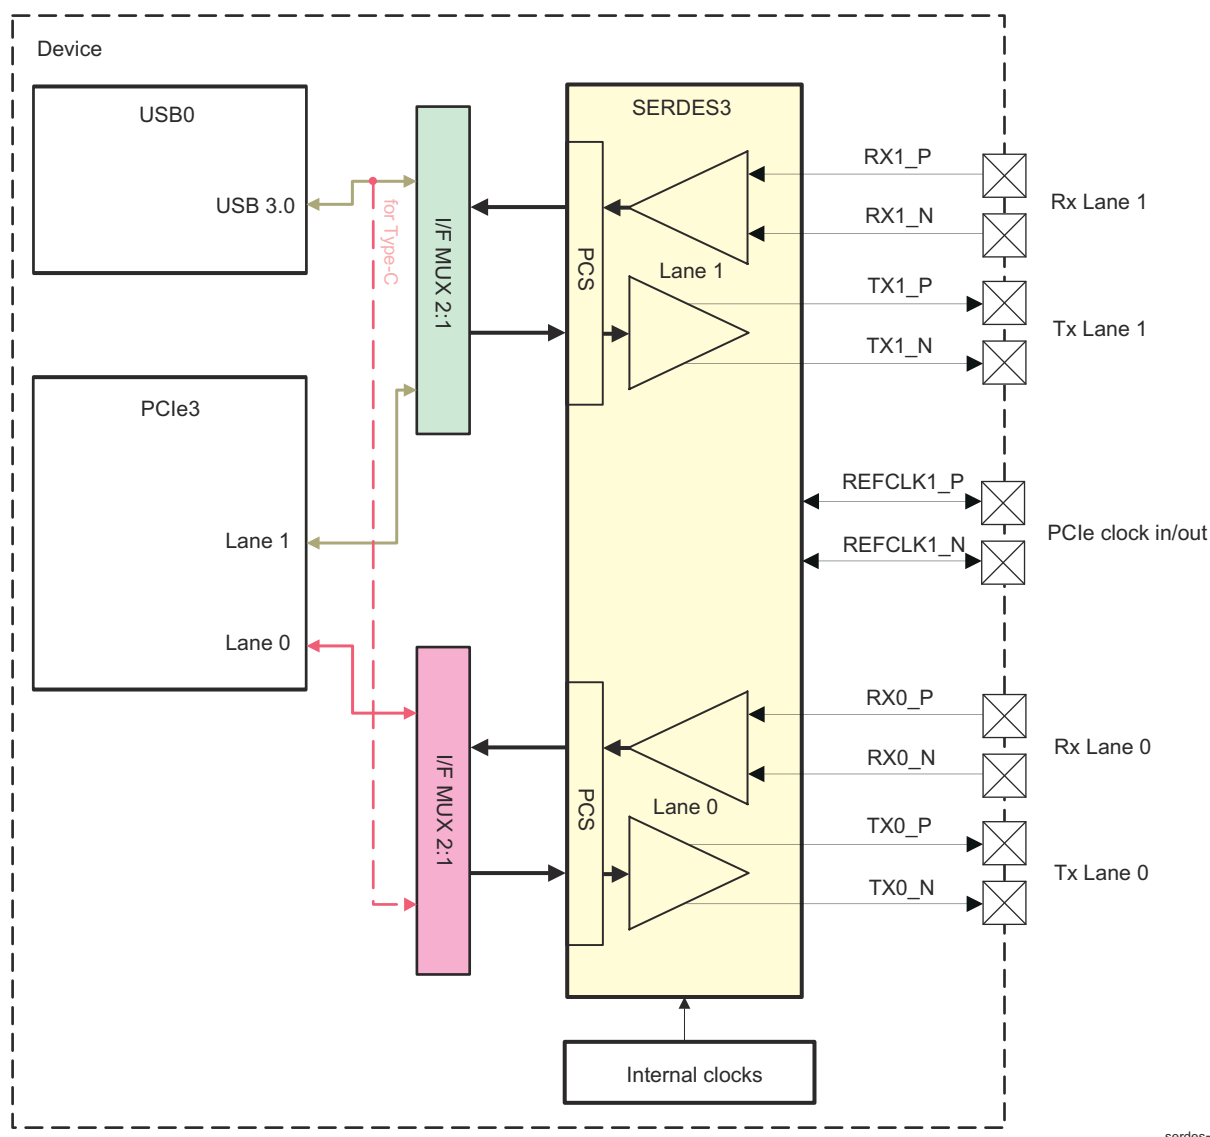

Figure 12-204. SERDES1 Overview

serdes-003

Figure 12-205. SERDES2 Overview

serdes-004

**Figure 12-206. SERDES3 Overview**

#### 12.2.5.1.1 2-L SerDes Features

The SERDES module features include:

- Dual lane PHY containing:
  - Transmit and Receive I/Os
  - Serializer
  - Deserializer
  - Clock and data recovery (CDR) unit
- Common Module (CMN)
  - PLLs
  - Master bias
  - Automatic calibration of pin termination resistors
  - Reference clock input buffers
  - Reset and startup management
- Physical Coding Sub-block (PCS)
  - PCIe per PCI Express Base Specification Revision 4.0, February 19, 2014

- ECNs included: L1 PM Substates CLKREQ; SRIS.
- USB3.1 per Universal Serial Bus 3.1 Specification, Revision 1.0, July 26, 2013
- QSGMII Specification revision 1.2
- Symbol alignment
- Selectable serial pin polarity reversal for both transmit and receive paths
- Bit stream reordering
- Physical Media Attachment (PMA) layer
  - Transmit equalization
  - Receive equalization
  - Data path BIST with programmable pattern generation and error detection
  - Serial bit stream and parallel word loopback for both line and parallel side
  - 8-bit ADC provides digitized ATB measurement results
  - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (one Tx and one Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock
- Rx comma align block
  - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate
  - Supports comma detection that is not sensitive to false commas using all 8B10B character combinations

#### 12.2.5.1.2 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance <sup>2</sup>, see the device-specific Datasheet.

- SGMII: This is electrically compliant with SGMII revision 1.8 with the following clarifications:
  - It does not implement the separate clock signaling
  - Electrical compatibility does not guarantee interoperability with devices.
- QSGMII: This is electrically compliant with QSGMII revision 1.2 with the following clarifications:
  - It does not implement the separate clock signaling
  - Electrical compatibility does not guarantee interoperability with devices.
- PCIe: This is electrically compliant with version 4.0.
- USB: This is electrically compliant with USB 3.1.

**Table 12-258. SerDes Supported Standards**

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)	Bus Width (bits)
PCI Express 4.0 Gen1	2.5	19.2, 20, 24, 25, 26, 27, 31.25, 100	8
PCI Express 4.0 Gen2	5.0	19.2, 20, 24, 25, 26, 27, 31.25, 100	16
PCI Express 4.0 Gen3	8.0	19.2, 20, 24, 25, 26, 27, 31.25, 100	32
SGMII	1.25	19.2, 20, 24, 25, 26, 27, 62.5, 100	10
SGMII	2.5	19.2, 20, 24, 25, 26, 27, 62.5, 100	10
USB 3.1 Gen1 SuperSpeed	5.0	19.2, 20, 24, 25, 26, 27, 100	16

<sup>2</sup> Electrical compatibility does not guarantee interoperability with devices

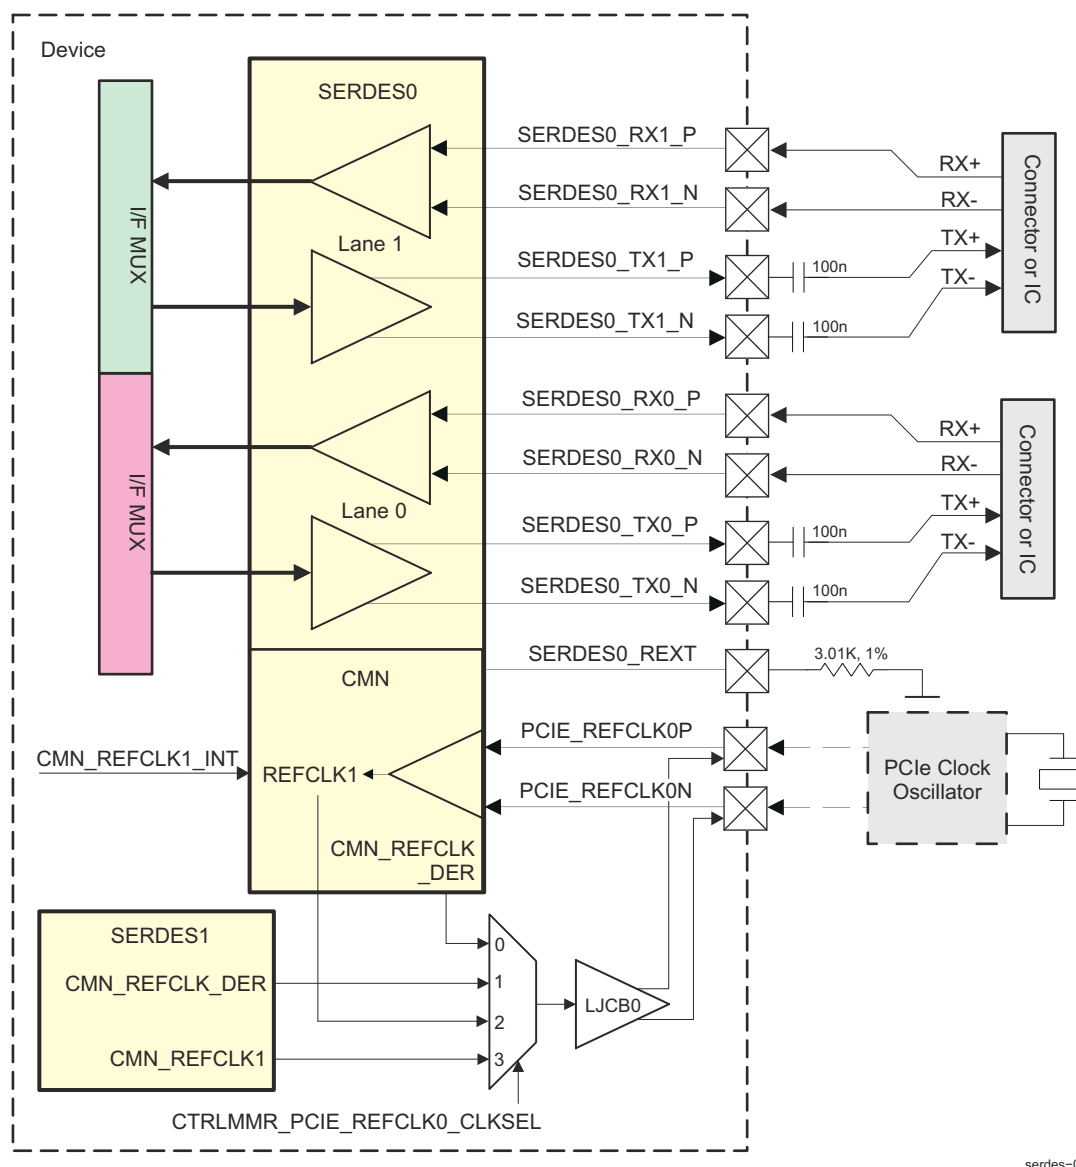

## 12.2.5.2 2-L SerDes Environment

### 12.2.5.2.1 2-L SerDes I/Os

#### Note

Although containing some of the basic external components, [Figure 12-207](#) to [Figure 12-210](#) must not be considered as an exhaustive guide for the PCB designer. TI provides additional documents for those who are willing to design PCBs and/or fine tune the SerDes.

[Figure 12-207](#) shows the I/O interface pins of SerDes.

serdes-006

**Figure 12-207. SERDES0 Environment**

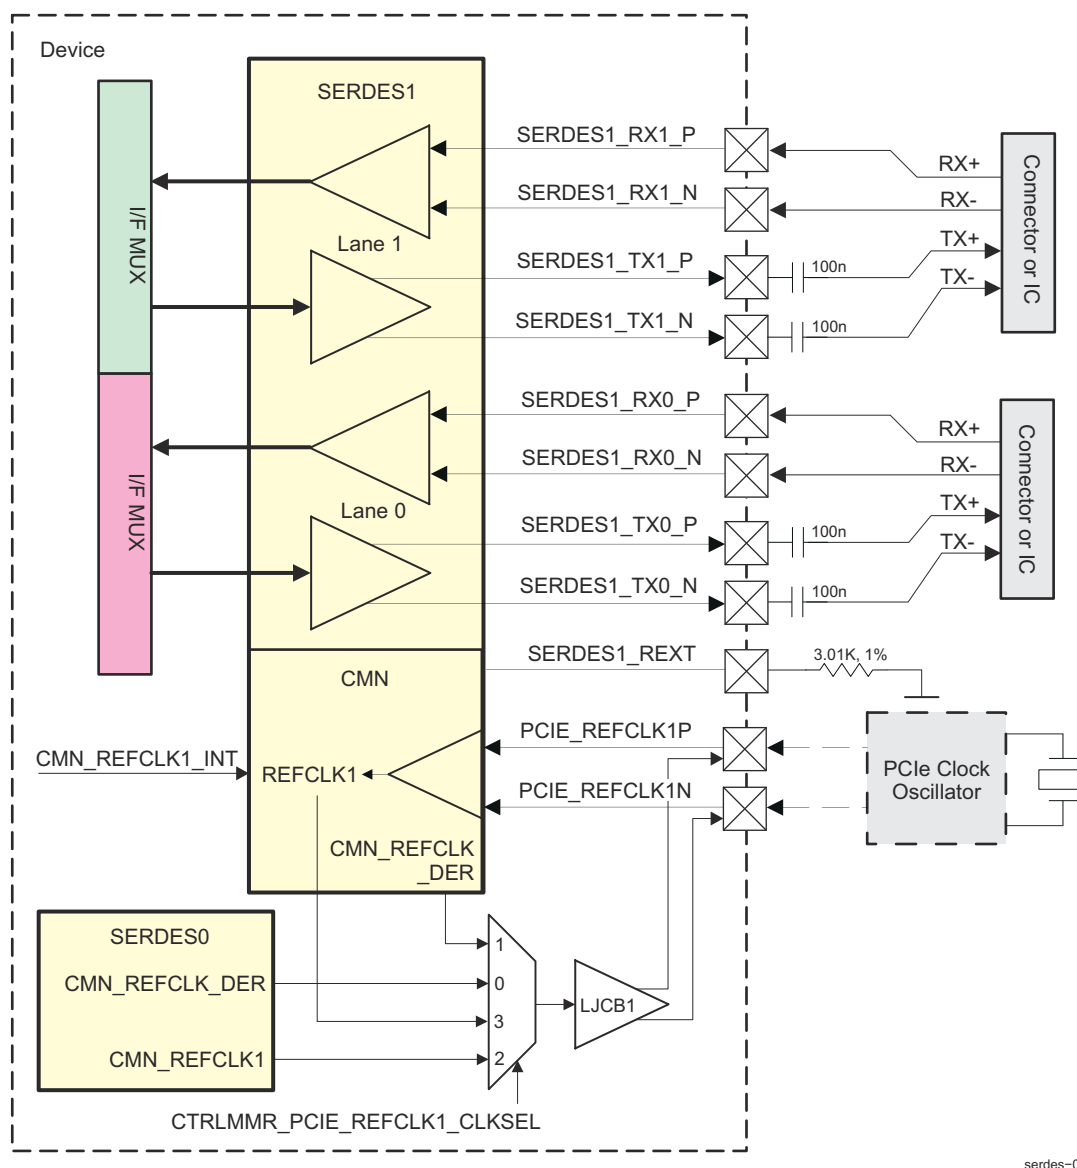

[Table 12-259](#) describes the external signals of SERDES0 module.

**Table 12-259. SERDES0 Input/Output Description**

Device Pin	Module Signal	I/O <sup>(1)</sup>	Description	Value at Reset
SERDES0_RX0_P	RX_P_LN0	I	SerDes differential data receive pins. Lane 0	HiZ
SERDES0_RX0_N	RX_M_LN0			
SERDES0_TX0_P	TX_P_LN0	O	SerDes differential data transmit pins. Lane 0	HiZ

### 12.2.5.3 2-L SerDes Integration

This section describes SerDes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 12-211 shows the integration of the SerDes modules in the device.

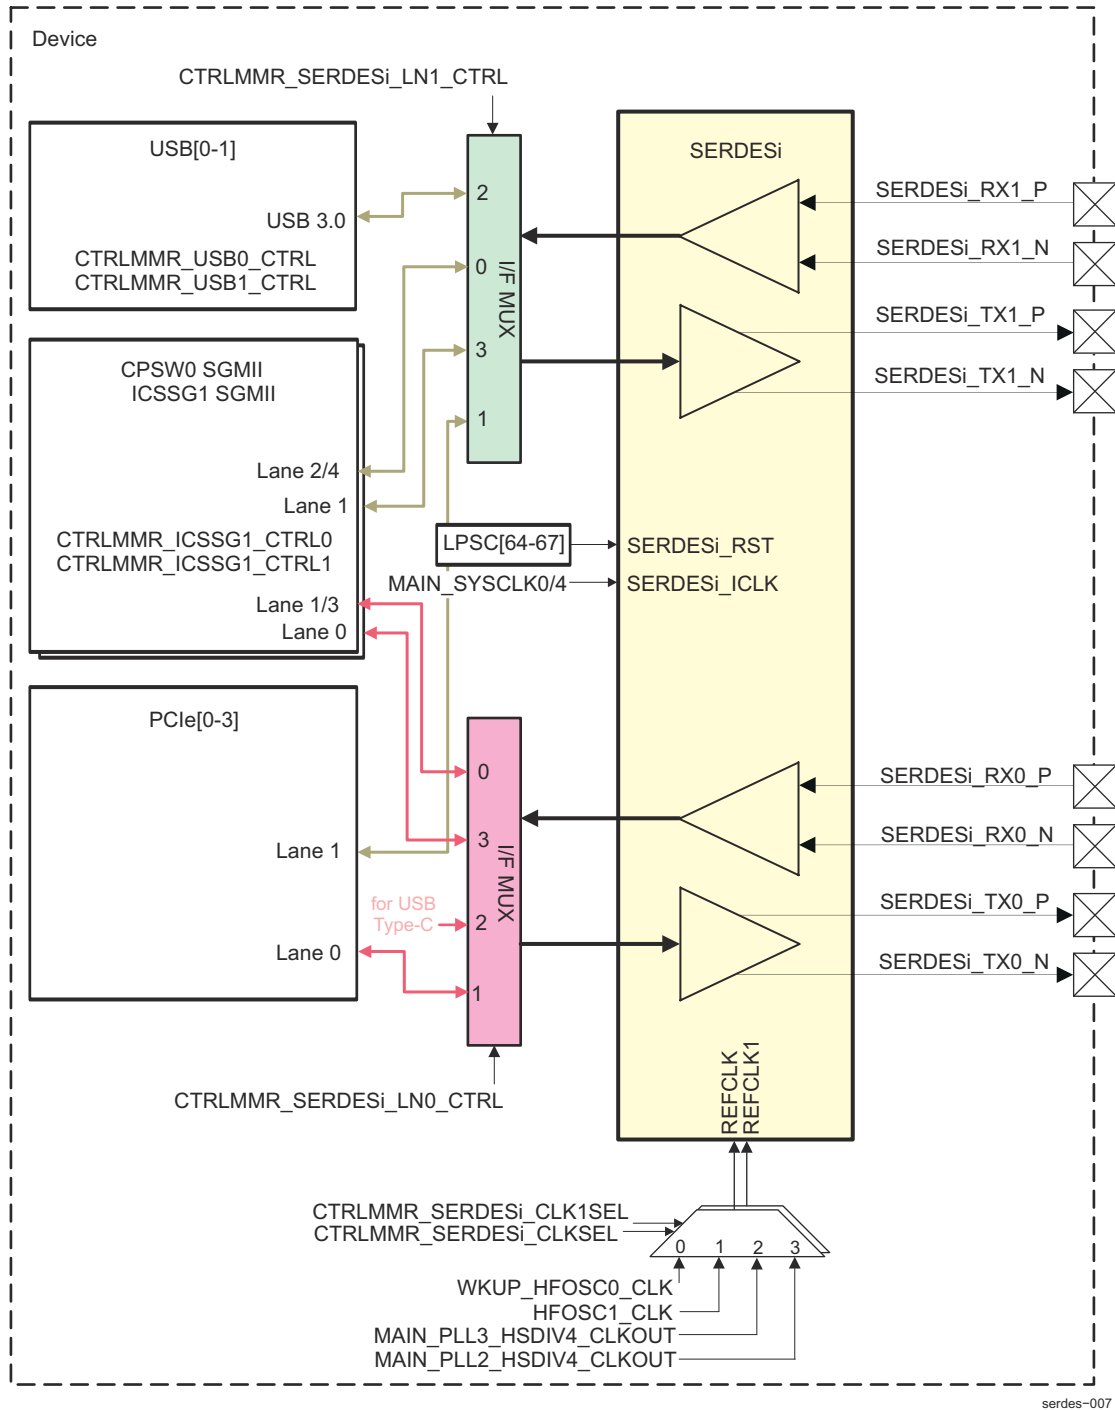

Figure 12-211. 2-L SerDes Integration

i = 0 to 3

Table 12-263 through Table 12-265 summarize the integration of SerDes in device MAIN domain.

**Table 12-263. 2-L SerDes Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
SERDES0	PSC0	PD5	LPSC64	CBASS0

### Note

For more information on the interconnects in device, see [Chapter 3, System Interconnects](#).

For more information on the power, reset and clock management in device MAIN domain, see the corresponding sections within [Chapter 5, Device Configuration](#).

### 12.2.5.3.1 2-L WIZ Settings

This section describes the quazi-static settings that software must perform after global resets. These settings are made via registers in the CTRL\_MMR0 module. For CTRL\_MMR0 description, please refer to [Section 5.1, Control Module \(CTRL\\_MMR\)](#).

#### 12.2.5.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- USB0 (USB 3.1 Gen1)
- USB1 (USB 3.1 Gen1)
- PCIe0 (one- or two-lane)
- PCIe1 (one- or two-lane)
- PCIe2 (one- or two-lane)
- PCIe3 (one- or two-lane)
- CPSW0 SGMII (one- to four-lane)
- CPSW0 QSGMII
- ICSSG1 SGMII (one- or two-lane)

[Table 12-266](#) describes the interface combinations supported by SERDES0.

**Table 12-266. SERDES0 Supported Configurations**

Interface Alias	CTRLMMR_SERDES0_LN0_CTRL		CTRLMMR_SERDES0_LN1_CTRL	
	[1:0] LANE_FUNC_SEL	Interface on Lane 0	[1:0] LANE_FUNC_SEL	Interface on Lane 1
IP1	0x0	CPSW0 Q/SGMII Lane 1	0x0	CPSW0 Q/SGMII Lane 2
IP2	0x1	PCIe0 Lane 0	0x1	PCIe0 Lane 1
IP3	0x2	-(1)	0x2	USB0
IP4	0x3	-	0x3	-

(1) Reserved for USB0 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See [Section 12.2.4, USB](#).

[Table 12-267](#) describes the interface combinations supported by SERDES1.

**Table 12-267. SERDES1 Supported Configurations**

Interface Alias	CTRLMMR_SERDES1_LN0_CTRL		CTRLMMR_SERDES1_LN1_CTRL	
	[1:0] LANE_FUNC_SEL	Interface on Lane 0	[1:0] LANE_FUNC_SEL	Interface on Lane 1
IP1	0x0	CPSW0 Q/SGMII Lane 3	0x0	CPSW0 Q/SGMII Lane 4
IP2	0x1	PCIe1 Lane 0	0x1	PCIe1 Lane 1
IP3	0x2	-(1)	0x2	USB1
IP4	0x3	ICSSG1 SGMII Lane 0	0x3	ICSSG1 SGMII Lane 1

(1) Reserved for USB1 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See [Section 12.2.4, USB](#).

[Table 12-268](#) describes the interface combinations supported by SERDES2.

**Table 12-268. SERDES2 Supported Configurations**

Interface Alias	CTRLMMR_SERDES2_LN0_CTRL		CTRLMMR_SERDES2_LN1_CTRL	
	[1:0] LANE_FUNC_SEL	Interface on Lane 0	[1:0] LANE_FUNC_SEL	Interface on Lane 1
IP1	0x0	-	0x0	-
IP2	0x1	PCIe2 Lane 0	0x1	PCIe2 Lane 1
IP3	0x2	-(1)	0x2	USB1
IP4	0x3	ICSSG1 SGMII Lane 0	0x3	ICSSG1 SGMII Lane 1

(1) Reserved for USB1 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See [Section 12.2.4, USB](#).

Table 12-269 describes the interface combinations supported by SERDES3.

**Table 12-269. SERDES3 Supported Configurations**

Interface Alias	CTRLMMR_SERDES3_LN0_CTRL		CTRLMMR_SERDES3_LN1_CTRL	
	[1:0] LANE_FUNC_SEL	Interface on Lane 0	[1:0] LANE_FUNC_SEL	Interface on Lane 1
IP1	0x0	-	0x0	-
IP2	0x1	PCIe3 Lane 0	0x1	PCIe3 Lane 1
IP3	0x2	-(1)	0x2	USB0
IP4	0x3	-	0x3	-

(1) Reserved for USB0 for type-C connector lane swap. That is, select this function if Type C was implemented in the design. See [Section 12.2.4, USB](#).

As seen in [Table 12-266](#) to [Table 12-269](#), USB0, USB1, and ICSSG1 SGMII can be routed to two different lanes. To avoid routing to two lanes at the same time, an additional muxing exists.

[Table 12-270](#) to [Table 12-273](#) describes the additional muxing for USB0, USB1, and ICSSG1 SGMII lane 0, and lane 1.

#### Note

Settings in [Table 12-270](#) to [Table 12-273](#) must be aligned with the settings made in [Table 12-266](#) to [Table 12-269](#).

**Table 12-270. USB0 Muxing to Serdeses**

#### 12.2.5.3.1.2 Internal Reference Clock Selection

The device clock tree provides the SerDeses with identical clock options but with independent selection control for each SerDes.

Table 12-274 and Table 12-275 describe the internal reference clock options for SERDES0 through SERDES3, REFCLK and REFCLK1 inputs.

**Table 12-274. 2-L SerDes Internal Reference Clock Selection (REFCLK)**

SERDES0: CTRLMMR_SERDES0_CLKSEL SERDES1: CTRLMMR_SERDES1_CLKSEL SERDES2: CTRLMMR_SERDES2_CLKSEL SERDES3: CTRLMMR_SERDES3_CLKSEL	
[1:0] CORE_REFCLK_SEL	Internal Clock to SERDES Core

## 12.2.5.4 2-L SerDes Functional Description

### 12.2.5.4.1 2-L SerDes Block Diagram

Figure 12-212 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one Tx/Rx lane is shown.

**Figure 12-212. SerDes and WIZ Block Diagram**

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (PCIe, USB3.0, and SGMII).

## 12.2.6 4-L Serializer/Deserializer (SerDes)

This section describes the 4-Lane Serializer/Deserializer (SerDes) in the device.

### 12.2.6.1 4-L SerDes Overview

SerDes'es goal is to convert device (SoC) parallel data into serialized data that can be output over a high-speed electrical interface. In the opposite direction, SerDes converts high-speed serial data into parallel data that can be processed by the device. To this end, the SerDes contains a variety of functional blocks to handle both the external analog interface as well as the internal digital logic.

Most important building blocks of SerDes are:

- Physical Media Attachment (PMA):
  - Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer, and Clock and Data Recovery (CDR) unit.
  - Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes, and muxes SerDes to peripherals.

The device contains one quad-lane SerDes: SERDES4.

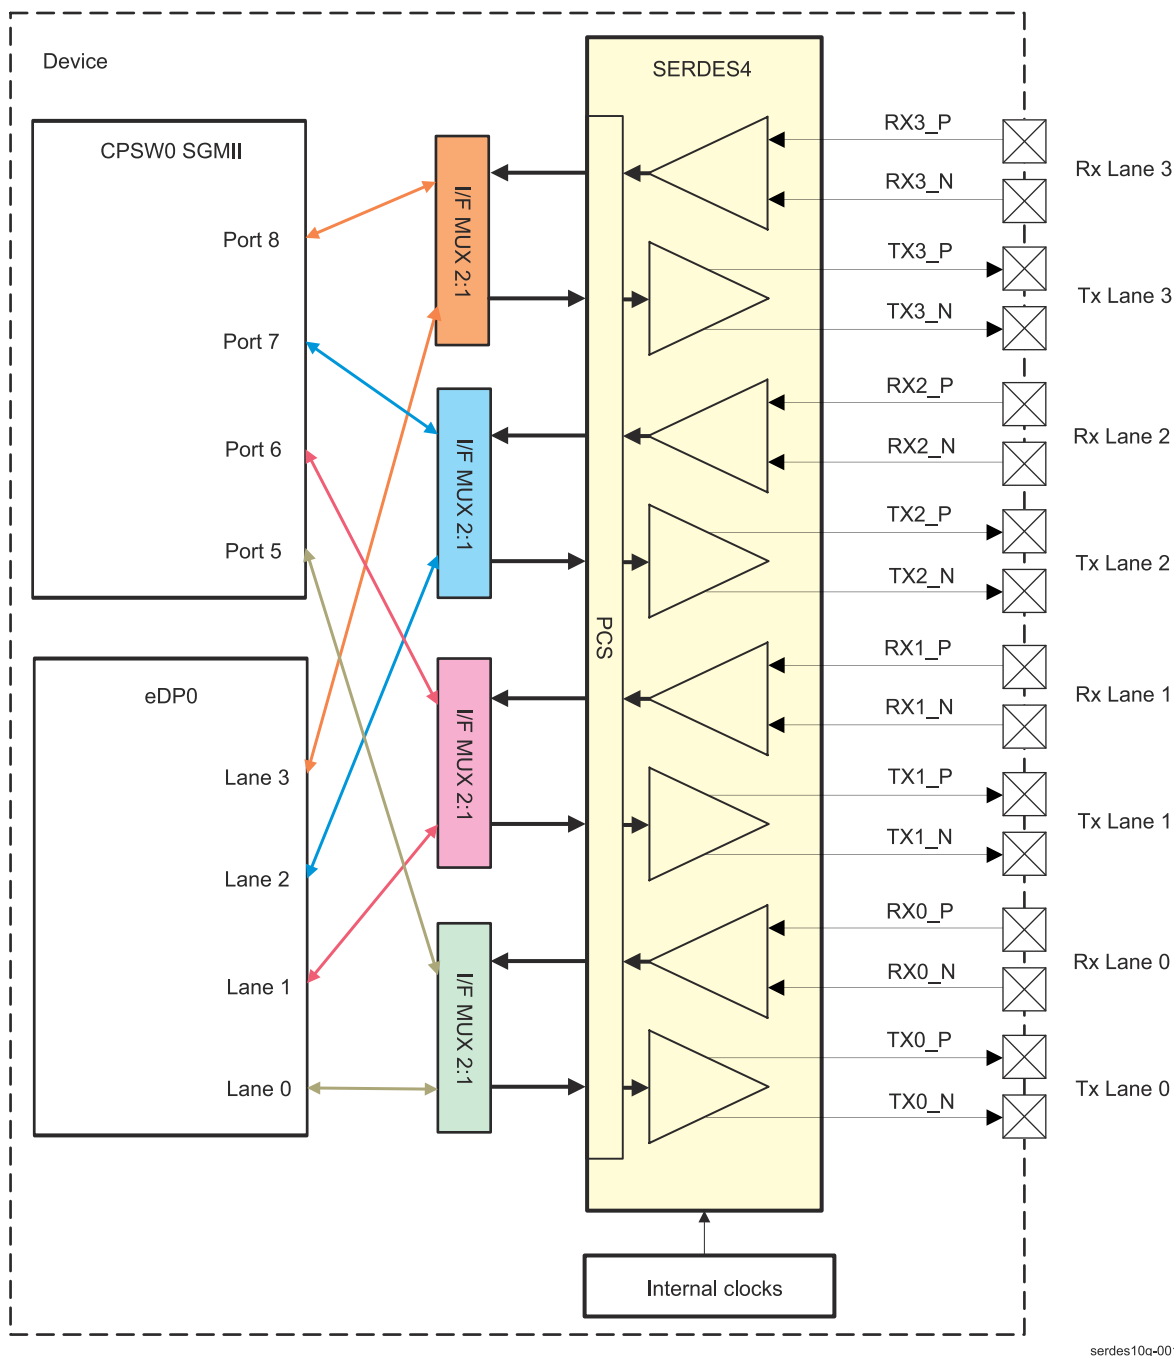

For two-lane SerDeses (SERDES[0-3]), please refer to [Section 12.2.5, 2-L Serializer/Deserializer \(SerDes\)](#).

**Table 12-276. SerDes Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
SERDES0 (2-L)	-	-	✓
SERDES1 (2-L)	-	-	✓
SERDES2 (2-L)	-	-	✓
SERDES3 (2-L)	-	-	✓
SERDES4	-	-	✓

[Figure 12-213](#) shows 4-Lane SerDes highlights.

serdes10g-001

Figure 12-213. SERDES4 Overview

#### 12.2.6.1.1 4-L SerDes Features

The SERDES module features include:

- Quad lane PHY containing:
  - Transmit and Receive I/Os
  - Serializer
  - Deserializer
  - Clock and data recovery (CDR) unit
- Common Module (CMN)
  - PLLs

- Master bias
- Automatic calibration of pin termination resistors
- Reference clock input buffers
- Reset and startup management
- Physical Coding Sub-block (PCS)
  - Embedded DisplayPort (eDP1.4) Tx (UI\_Rate\_1 - UI\_Rate\_8)
    -
  - QSGMII Specification revision 1.2
  - Symbol alignment
  - Selectable serial pin polarity reversal for both transmit and receive paths
  - Bit stream reordering
- Physical Media Attachment (PMA) layer
  - Transmit equalization
  - Receive equalization
  - Data path BIST with programmable pattern generation and error detection
  - Serial bit stream and parallel word loopback for both line and parallel side
  - 8-bit ADC provides digitized ATB measurement results
  - Supports DC and AC JTAG (boundary scan) per IEEE 1149.6

The SERDES mux (WIZ) module supports the following features:

- Multiplexes device interfaces onto a single SERDES lane (one Tx and one Rx)
- Provides registers to implement SERDES control and status functions and alignment delays
- Clock generator block for providing MAC transmit clock
- Rx comma align block
  - Performs de-stuffing the Rx data stream in the event that the Rx rate is different from the Tx rate
  - Supports comma detection that is not sensitive to false commas using all 8B10B character combinations

#### 12.2.6.1.2 Industry Standards Compatibility

All SerDes interfaces are configured as point-to-point connections. It is assumed that the connection is made between the SoC and another device that is compliant to the appropriate industry standard. The list of supported standards is given below.

This chapter deals with the physical layer and, therefore, it is the electrical specifications in these standards that are relevant. For more information regarding protocol compliance <sup>3</sup>, see the device-specific Datasheet.

- SGMII: This is electrically compliant with SGMII revision 1.8 with the following clarifications:
  - It does not implement the separate clock signaling
  - Electrical compatibility does not guarantee interoperability with devices.
- QSGMII: This is electrically compliant with QSGMII revision 1.2 with the following clarifications:
  - It does not implement the separate clock signaling
  - Electrical compatibility does not guarantee interoperability with devices.
- Embedded DisplayPort Tx (UI\_Rate\_1 - UI\_Rate\_8)

**Table 12-277. 4-L SerDes Supported Standards**

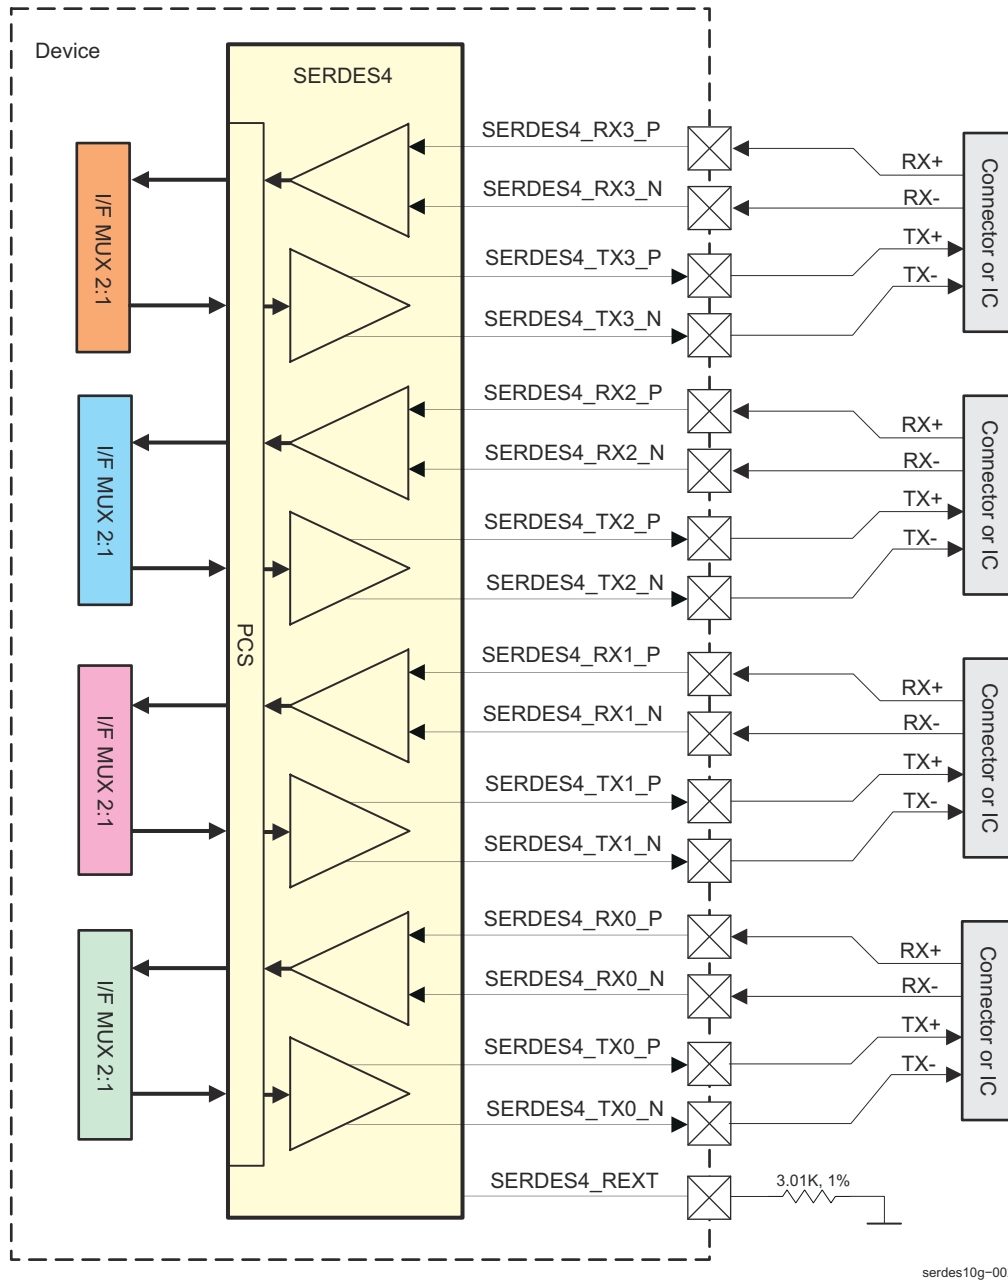

Standard	Bit Rate (Gbps)	Reference Clock Frequency (MHz)	Bus Width (bits)
SGMII	1.25	19.2, 20, 24, 25, 26, 27, 100, 125	10
SGMII	2.5	19.2, 20, 24, 25, 26, 27, 100, 125	10
eDP	25.92 (total)	19.2, 20, 24, 25, 26, 27, 100	10

<sup>3</sup> Electrical compatibility does not guarantee interoperability with devices

## 12.2.6.2 4-L SerDes Environment

### 12.2.6.2.1 4-L SerDes I/Os

Figure 12-214 shows the I/O interface signals of SERDES.

serdes10g-002

**Figure 12-214. 4-L SerDes Environment**

#### Note

Although containing some of the basic external components, [Figure 12-214](#) must not be considered as an exhaustive guide for the PCB designer. TI provides additional documents for those who are willing to design PCBs and/or fine tune the SerDes.

[Table 12-278](#) describes the external signals of SERDES4 module.

**Table 12-278. 4-L SerDes Input/Output Description**

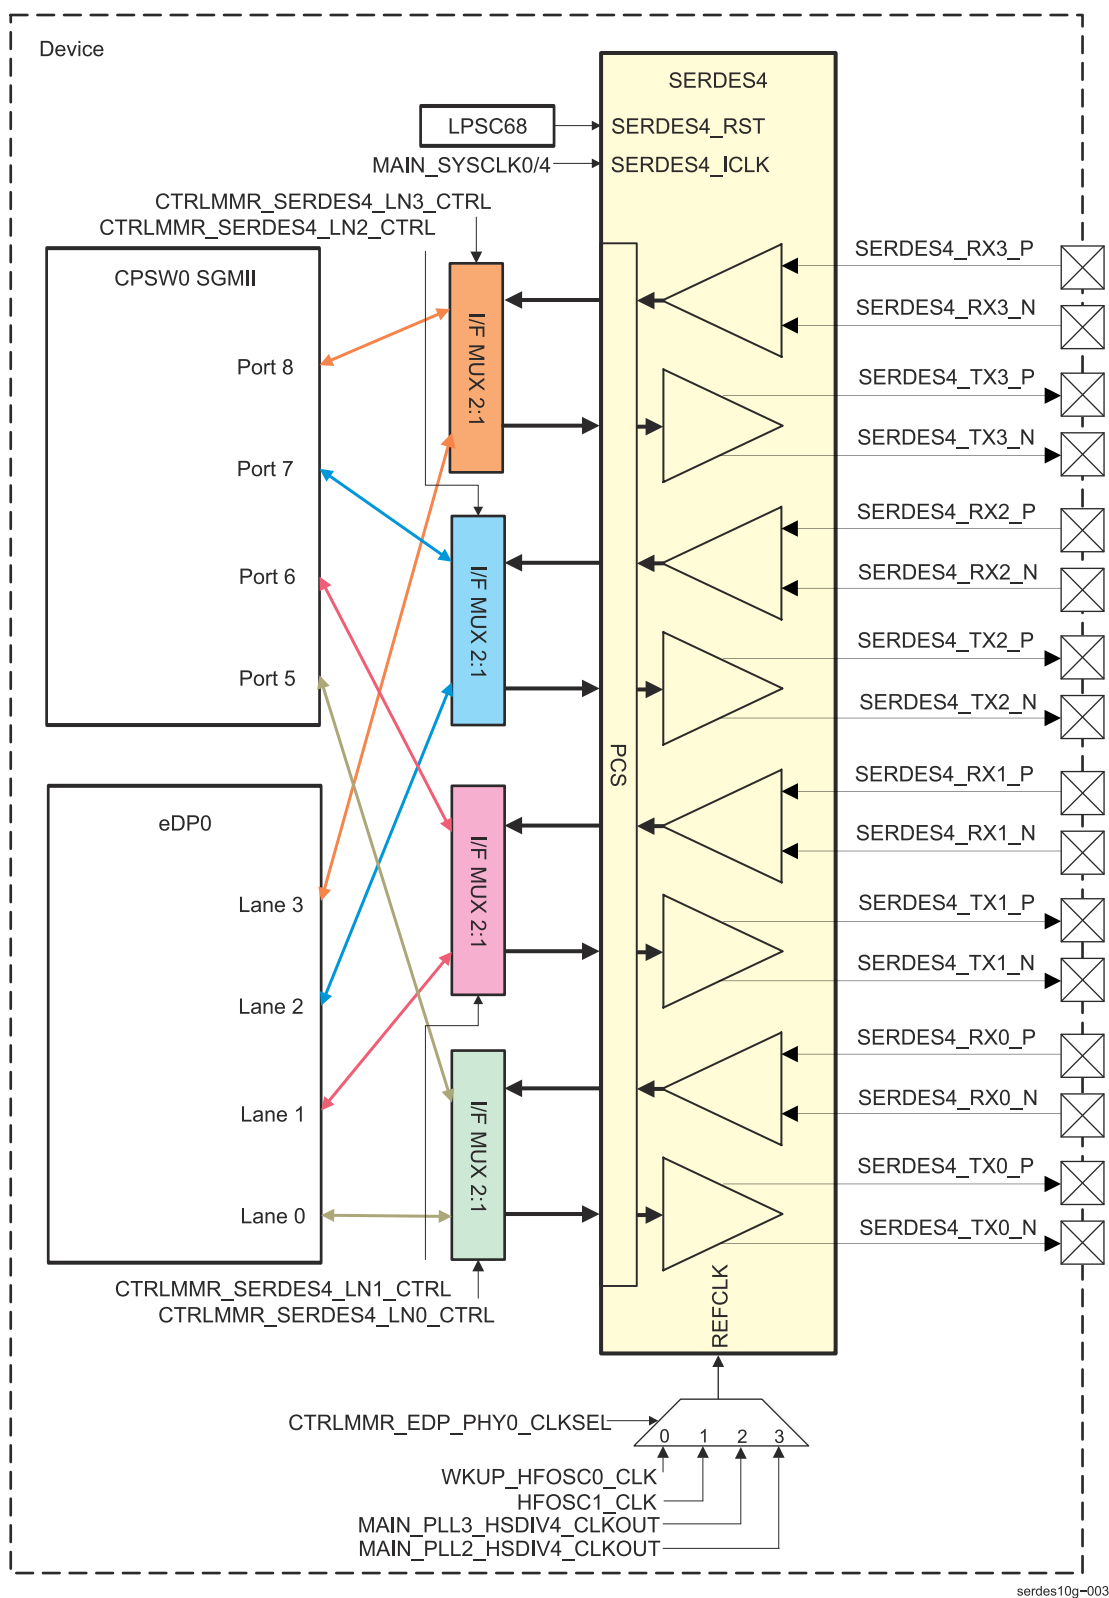

Device Pin	Module Signal	I/O <sup>(1)</sup>	Description	Value at Reset

SERDES4_REXT	CMN_REXT	A/I	PMA external calibration resistor. Requires a 3.01 kOhm $\pm 1\%$ accurate off-chip resistor connected from this pin to ground.	HiZ

(1) I = Input; O = Output; A = Analog

### 12.2.6.3 4-L SerDes Integration

This section describes SerDes module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 12-215](#) shows the integration of the SerDes modules in the device.

**Figure 12-215. 4-L SerDes Integration**

Table 12-279 through Table 12-281 summarize the integration of SerDes in device MAIN domain.

**Table 12-279. 4-L SerDes Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
SERDES4	PSC0	PD9	LPSC68	CBASS0

**Table 12-280. 4-L SerDes Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
SERDES4	SERDES4_ICLK	MAIN_SYSCLK0/4	PLL_CTRL0	VBUS interface clock

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
SERDES4	-	-	-	No interrupt requests to interrupt controllers	-
DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
SERDES4	-	-	-	No PDMA channels to external DMA engines	-

### Note

For more information on the interconnects in device, see [Chapter 3, System Interconnects](#).

For more information on the power, reset and clock management in device MAIN domain, see the corresponding sections within [Chapter 5, Device Configuration](#).

### 12.2.6.3.1 4-L WIZ Settings

This section describes the quazi-static settings that software must perform after global resets. These settings are made via registers in the CTRL\_MMR0 module. For CTRL\_MMR0 description, please refer to [Section 5.1, Control Module \(CTRL\\_MMR\)](#).

#### 12.2.6.3.1.1 Interface Selection

SerDeses provide PHY functions for the following high-speed interfaces:

- CPSW0 SGMII (one- to four-lane)
- CPSW0 QSGMII
- eDP (two- or four-lane)

[Table 12-282](#) describes the interface combinations supported by SERDES4.

**Table 12-282. SERDES4 Supported Configurations**

CTRLMMR_SERDES4_LN0_CT RL [1:0]		CTRLMMR_SERDES4_LN1_CT RL [1:0]		CTRLMMR_SERDES4_LN2_CT RL [1:0]		CTRLMMR_SERDES4_LN3_CT RL [1:0]

#### 12.2.6.3.1.2 Internal Reference Clock Selection

The device clock tree provides the SerDeses with identical clock options but with independent selection control for each SerDes.

[Table 12-283](#) describes the internal reference clock options for SERDES4.

**Table 12-283. 4-L SerDes Internal Reference Clock Selection**

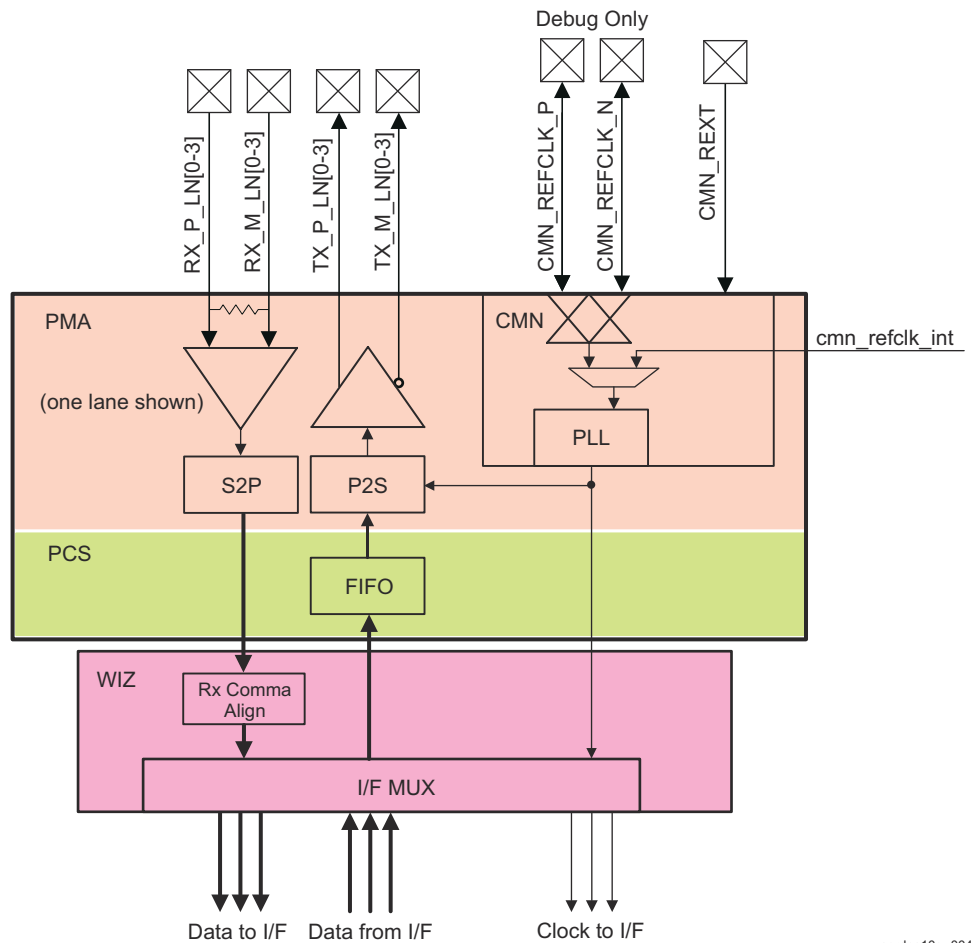

CTRLMMR_EDP_PHY0_CLKSEL	
[1:0] CLK_SEL	Internal Clock to SERDES Core
0x0	WKUP_HFOSC0_CLKOUT
0x1	HFOSC1_CLKOUT
0x2	MAIN_PLL3_HSDIV4_CLKOUT
0x3	MAIN_PLL2_HSDIV4_CLKOUT

## 12.2.6.4 4-L SerDes Functional Description

### 12.2.6.4.1 4-L SerDes Block Diagram

Figure 12-216 is a top-level, non-exhaustive diagram of SerDes and WIZ wrapper. Note that only one (Tx + Rx) lane is shown.

**Figure 12-216. 4-L SerDes and WIZ Block Diagram**

Building blocks of SerDes include:

- Lanes: The lanes handle all inputs and outputs from the serial interface, and contain the Tx/Rx I/Os, serializer/deserializer (P2S/S2P), and Clock and Data Recovery (CDR) unit. Each SerDes contains one Tx and Rx lane.
- Common module (CMN): The CMN handles peripheral and Tx clocking of the SerDes. It consists of internal PLLs and external reference clock input buffer, reset, and startup circuitry.
- Lanes and CMN are parts of the Physical Media Attachment (PMA) layer.
- Physical Coding Sub-block (PCS): The PCS is responsible for translating data from/to the parallel interface, as well as data encoding/decoding and symbol alignment.
- WIZ: The WIZ acts as a wrapper for the SerDes, and can both send control signals to and report status signals from the SerDes (register interface), and muxes SerDes to peripherals (eDP and SGMII).

## 12.3 Memory Interfaces

This section describes the memory interfaces in the device.

### 12.3.1 Flash Subsystem (FSS)

This section describes the Flash Subsystem (FSS) in the device.

#### 12.3.1.1 FSS Overview

The Flash Subsystem (FSS) provides access to external flash devices via Octal SPI (OSPI) and HyperBus™ interface.

The FSS includes two OSPIs and one HyperBus interface. For more information, see *Octal Serial Peripheral Interface (OSPI)* and [Section 12.3.3, HyperBus Interface](#).

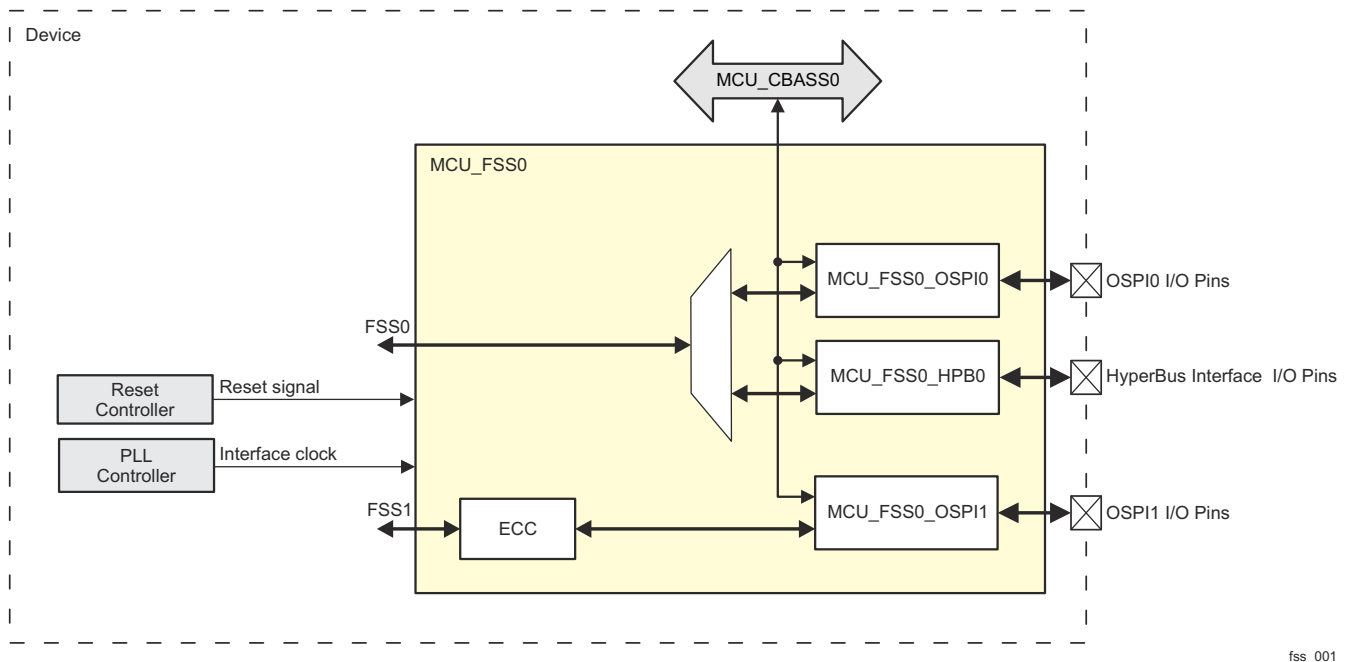

[Table 12-284](#) shows FSS allocation across device domains.

**Table 12-284. FSS Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0	-	✓	-

[Figure 12-217](#) shows the FSS overview.

The first FSS path (FSS0) has access to either OSPI0 or HyperBus interface. The second FSS path (FSS1) has access only to OSPI1 and can be configured with or without ECC.

fss\_001

**Figure 12-217. FSS Overview**

#### 12.3.1.1.1 FSS Features

The FSS has the following features:

- Two simultaneous flash interfaces:
  - Two OSPIs (OSPI0 and OSPI1) OR
  - One HyperBus interface and one OSPI (OSPI1)
- Primary OSPI0/HyperBus interface supports:
  - Execute in place (XIP) operation
  - 32-byte block copy (BC) operation

- Secondary OSPI1 interface supports:
  - 32-byte block copy (BC) operation
  - ECC
- OSPIs support single, dual, quad, or octal SPI devices
- OSPIs support up to 4 devices
- HyperBus interface supports up to 2 devices
- The OSPIs and HyperBus interface have independent power management for low power operations

**12.3.1.1.2 FSS Not Supported Features**

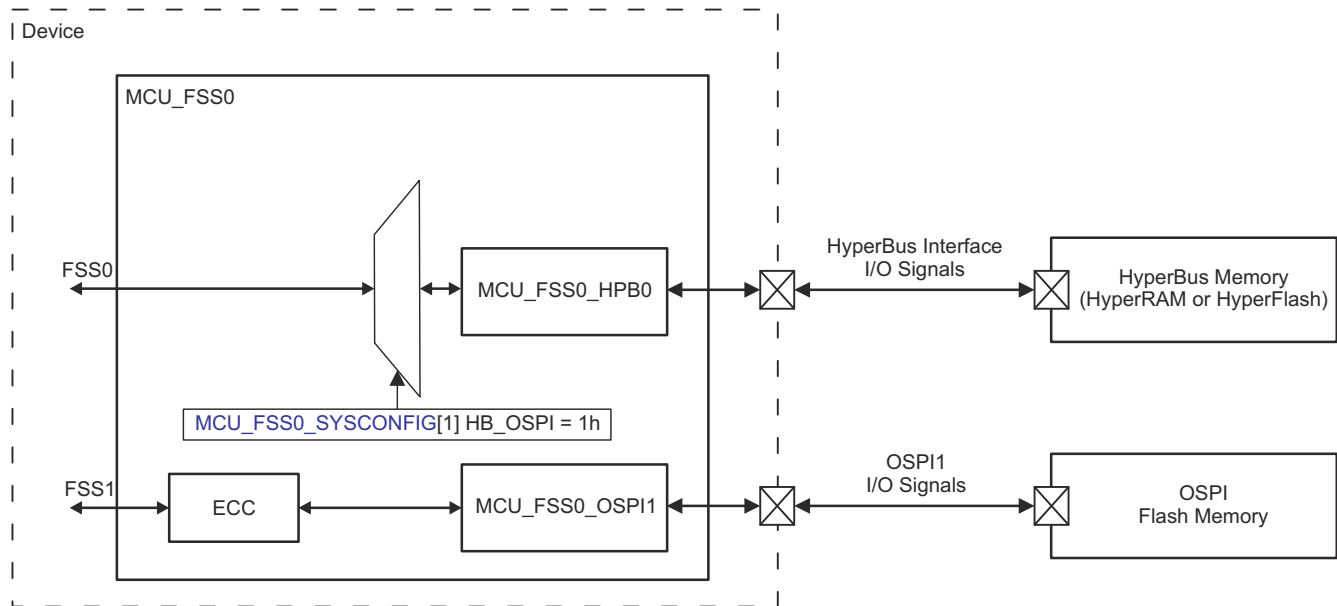

- DMA is not supported for OSPI0 and OSPI1 in INDAC mode

### 12.3.1.2 FSS Environment

The FSS is hereinafter also referred to as MCU\_FSS0.

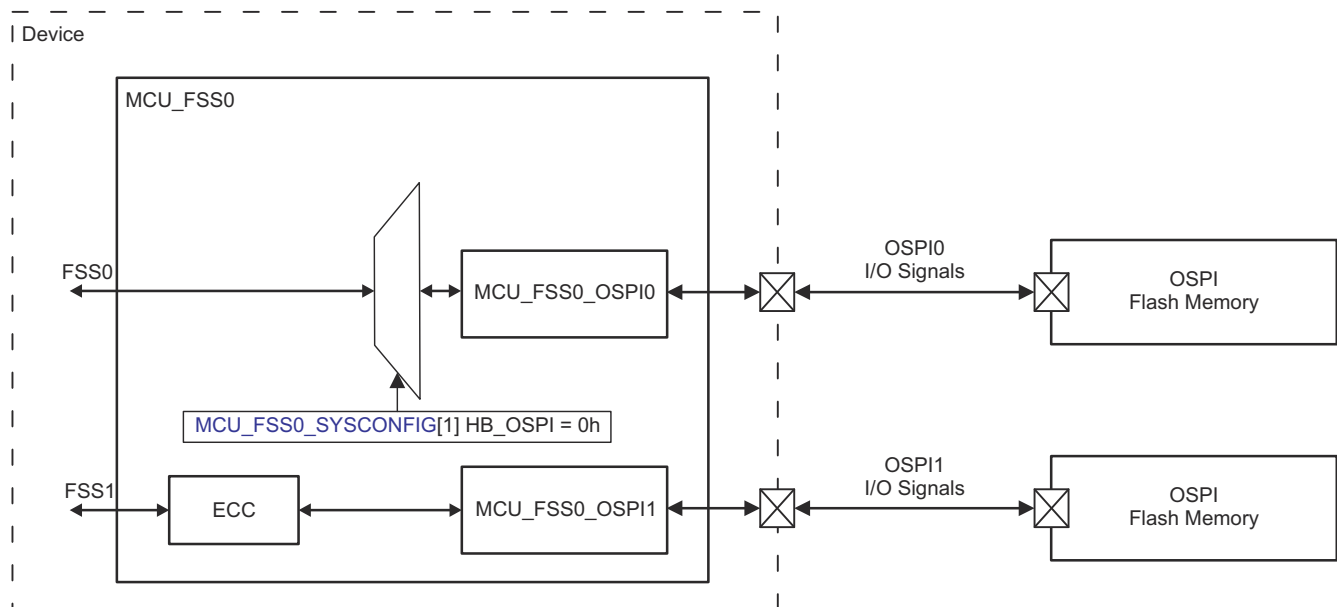

#### 12.3.1.2.1 FSS Typical Application

Figure 12-218 and Figure 12-219 show typical MCU\_FSS0 applications (two simultaneous FSS interfaces).

fss\_002

**Figure 12-218. MCU\_FSS0 Typical Application - HyperBus Interface and OSPI1**

fss\_002

**Figure 12-219. MCU\_FSS0 Typical Application - OSPI0 and OSPI1**

[Table 12-285](#) describes the MCU\_FSS0 I/O signals.

**Table 12-285. MCU\_FSS0 I/O Signals**

FSS Interface	I/O Signals
OSPIs (OSPI0 and OSPI1)	For more information about OSPIs I/O signals, see <i>OSPI I/O Signals</i> .
HyperBus interface	For more information about HyperBus interface I/O signals, see <a href="#">Table 12-305</a> .

---

**Note**

For more information on the OSPI environment, see *OSPI Environment*.

For more information on the HyperBus environment, see *HyperBus Environment*.

---

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

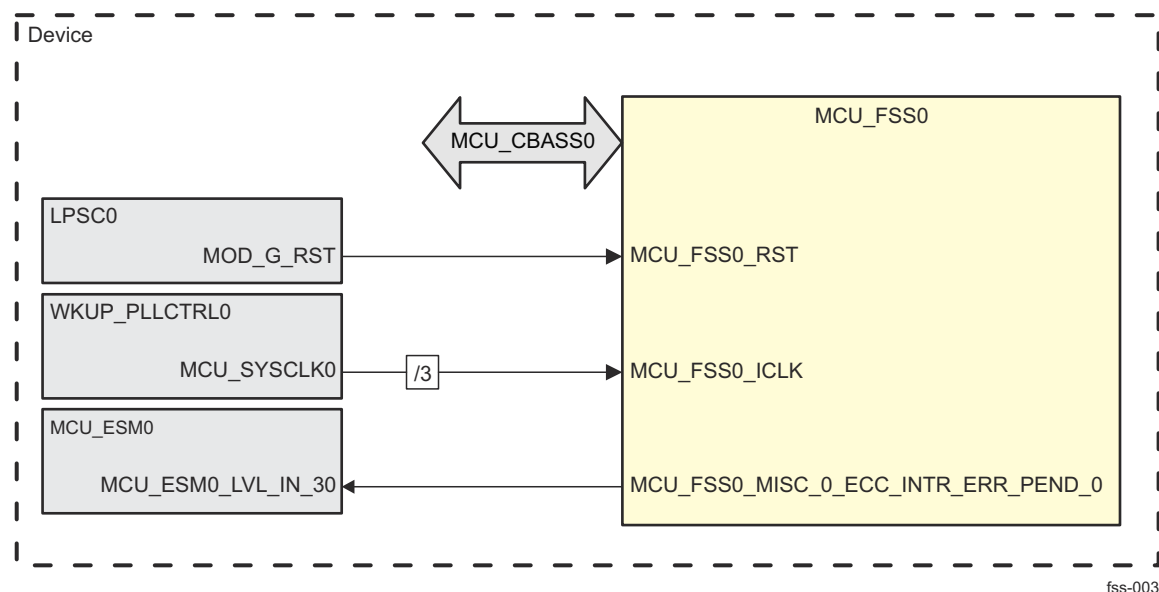

---

### 12.3.1.3 FSS Integration

This section describes the FSS integration in the device, including information about clocks, resets, and hardware requests.

#### 12.3.1.3.1 FSS Integration in MCU Domain

There is one FSS integrated in the device MCU domain - MCU\_FSS0. [Figure 12-220](#) shows the integration of MCU\_FSS0.

**Figure 12-220. MCU\_FSS0 Integration**

[Table 12-286](#) through [Table 12-288](#) summarize the integration of MCU\_FSS0 in the device MCU domain.

**Table 12-286. MCU\_FSS0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_FSS0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

### 12.3.1.4 FSS Functional Description

#### 12.3.1.4.1 FSS Block Diagram

The FSS provides access to external Flash and RAM devices. It supports XIP (Execute-in-Place) and BC (Block Copy) operations.

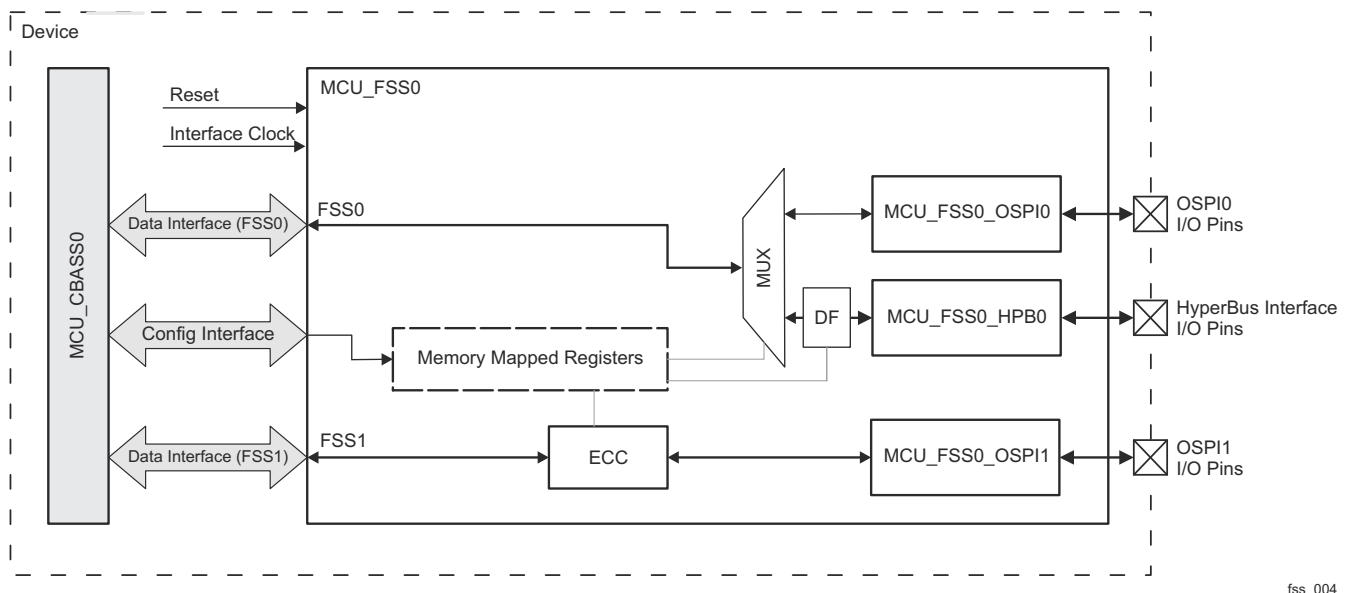

The FSS consists of two OSPIs and one HyperBus interface. There are two FSS paths - FSS0 and FSS1 (see [Figure 12-221](#)). The first path (FSS0) includes OSPI0 and HyperBus interface. The second path (FSS1) includes OSPI1. These two FSS paths can be used simultaneously (see *FSS Typical Application*).

[Table 12-289](#) shows the FSS allowed interface combinations.

**Table 12-289. FSS Allowed Interface Combinations**

Combination	Primary Interface (FSS0)	Secondary Interface (FSS1)
1.	OSPI0 (MCU_FSS0_OSPI0)	Not Used
2.	HyperBus Interface (MCU_FSS0_HPB0)	Not Used
3.	OSPI0 (MCU_FSS0_OSPI0)	OSPI1 (MCU_FSS0_OSPI1)
4.	HyperBus Interface (MCU_FSS0_HPB0)	OSPI1 (MCU_FSS0_OSPI1)
5.	Not Used	OSPI1 (MCU_FSS0_OSPI1)

[Figure 12-221](#) shows the FSS block diagram.

**Figure 12-221. FSS Block Diagram**

#### FSS Blocks:

- **MCU\_CBASS0:** The MCU\_CBASS0 interconnect allows FSS to communicate with the device modules and subsystems.
- **Data Interface (FSS0):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to either the OSPI0 or HyperBus interface.
- **Data Interface (FSS1):** It is 64-bit data/32-bit address multi issue data interface with coherent in-band bypass. It provides accessibility to the OSPI1.
- **Config Interface:** It is used for configuration of the memory mapped registers within the FSS.
- **Interface Clock and Reset:**
  - For more information, see *MCU\_FSS0 Clocks and Resets*.
  - For more information, see *MCU\_FSS0\_OSPI Clocks and Resets*.

- For more information, see *MCU\_FSS0\_HPBO Clocks and Resets*.
- Memory Mapped Registers: This block conditionally includes registers from the following blocks: FSS, ECC, MUX, and DF. The configuration of these registers defines which combination of FSS interfaces is selected (see [Table 12-289](#)) and also which FSS features and operation modes are used. For more information, see *MCU\_FSS0\_SYSCONFIG*.
- MUX: The Muxing (MUX) block is used as a software controlled switch in the primary FSS (FSS0) interface. It defines which interface to be used (OSPI0 or HyperBus interface). The MUX block can switch only when the traffic is idle. The software has responsibility to cause the traffic to be stopped.
- DF: The Dynamic Fragmenter (DF) module is responsible for fragmenting write data to the flash region so that all writes to the flash region are done in 16-bits chunks (a requirement for HyperFlash). It passes all other transaction through unaffected.
- ECC: The Single Error Correction and Double Error Detection (SECEDED) mechanism is used. Each 32-byte block is protected by four SECEDED bytes. The secondary FSS1 interface includes a stand-alone ECC module which can be used for OSPI1 only. For more information, see *ECC Support*.
- FSS Interfaces:
  - *MCU\_FSS0\_OSPI0*: The OSPI0 is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
  - *MCU\_FSS0\_OSPI1*: The OSPI1 is part of the secondary FSS interface (FSS1). It can be configured with or without ECC.
  - *MCU\_FSS0\_HPBO*: The HyperBus interface is part of the primary FSS interface (FSS0). It can be configured to use ECC and/or OTFE module.
- FSS I/O Pins:
  - OSPI1 I/O Pins: All used *MCU\_FSS0\_OSPI1* interface pins (for more information, see *OSPI I/O Signals*).
  - HyperBus I/O Pins: All used *MCU\_FSS0\_HPBO* interface pins (for more information, see *HyperBus I/O Signals*).

#### 12.3.1.4.2 FSS ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

For more information about ECC, refer to *ECC Aggregator*.

For FSS1 path when the stand-alone ECC module is used:

- The input for the ECC module is 32-byte data block.
- The ECC module generates ECC codes for the 32-byte data block.
- The ECC module packs data + ECC, reformats the address and sends this to the flash controller (OSPI1 flash controller).

For more information, see *ECC Calculation*.

##### 12.3.1.4.2.1 FSS ECC Calculation

The ECC calculation is generated or checked on the concatenated structure {BIT('1'),BLOCK\_ADDRESS[26-0],WORD1[127-0],WORD0[127-0]} broken into four 71-bit chunks stored in the ECC word. The ECC word has four 8-bits values. Each value checks a 71-bit segment of the concatenated structure.

Details:

- The 71-bit portion uses a standard 7-bit ECC calculation plus a parity bit (8-bit value).
- The WORD0[127-0] is the first 128-bit word of a block and the WORD1[127-0] is the second 128-bit word of the data block.
- The BLOCK\_ADDRESS[26-0] is the upper 27 bits of the requested byte address known as the block address.

- If the MCU\_FSS0\_SYSCONFIG[3] ECC\_DISABLE\_ADR bit is set, the BLOCK\_ADDRESS[26-0] is assumed zero so that it does not affect the ECC calculation.
- If the ECC detects a double error, the returned data is cleared to zero.
- Both SEC and DED are reported to the ECC registers.

For more information about ECC registers, see *FSS Registers*.

#### 12.3.1.4.3 FSS Modes of Operation

Table 12-289 presents the possible combinations of FSS interfaces.

Both paths (FSS0 and FSS1) support XIP and BC modes.

#### 12.3.1.4.4 FSS Read Operations

The ECC module can read any byte or block of bytes. If the region is ECC protected, the ECC module reads the block and returns the appropriate bytes requested. If not in an ECC protected region, only the requested bytes are read.

##### 12.3.1.4.4.1 OSPI Read Pipeline Mode

The OSPIs support a pipeline mode. In this mode if requests are supplied back to back, the OSPIs provide data at a higher rate. When consecutive blocks are read whether in or out of regions with ECC, the ECC module reads the entire block including the unused ECC word and only return the necessary portion so that the OSPI maintains the pipelining operation. Reading a single non ECC protected and non 32-byte request or non consecutive block causes the OSPI pipeline to flush. For more information, see *PHY Pipeline Mode*.

##### 12.3.1.4.5 FSS Memory Address Translation

The ECC module stores ECC in the target memory. This creates the need to translate the address from the requestor to the memory. The translation is fixed for a given memory. If the memory contains ECC, the entire memory will reserve an ECC word for each 32-byte block.

Table 12-290 defines the memory address equation for a given input address.

The configuration mode for a given memory is not ever expected to change once setup. Although regions could be changed, the fundamental modes are considered to be static.

**Table 12-290. Memory Address Equation**

ECC Mode	Authentication Mode	Memory Block Address	64 MB Blocks Available
No	No	Input Address/32×32	64
Yes	No	Input Address/32×36	56.8

If the memory is configured to have ECC, the total blocks are reduced by 11 %. That is 11 % of the flash is reserved for ECC data regardless if any regions for ECC are used.

#### 12.3.1.4.6 FSS0 and FSS1 Regions

Both FSS interfaces (from FSS0 and FSS1 paths) have three regions:

Both FSS interfaces (from FSS0 and FSS1 paths) have three regions:

- Region 0 is used for XIP, DMA read or DMA write of flash or RAM which contains ECC protected data.
- Region 1 is used for a smaller boot region of 64 MB or 128 MB. It is similar to Region 0, but can select any 64 MB or 128 MB block from Region 0.
- Region 3 is used to enable HyperBus programming (by writing flash key patterns). Region 3 can also be used to program the flash with ECC protected data and to clear ECC errors when the flash takes a bit hit (to clear a single bit error, it may be necessary to re-write an entire block of the flash). Region 3 can also be used to validate ECC block programming.

#### 12.3.1.4.6.1 FSS0 and FSS1 Regions Boot Size Configuration

The boot size for FSS0 (OSPI0/HyperBus interface) and FSS1 (OSPI1) defaults to 64 MB but can be configured to be 128 MB. Selection of boot block which will be used is also configurable. For more information see CTRLMMR\_MCU\_FSS\_CTRL register in *Control Module (CTRL\_MMR)*.

#### 12.3.1.4.7 FSS Memory Regions

Table 12-291 shows the FSS memory regions.

**Table 12-291. FSS Memory Regions**

Address Range		Size	Description
FSS0 (HyperBus interface or OSPI0)	FSS1 (OSPI1)		
0x04 0000 0000 to 0x04 FFFF FFFF	0x06 0000 0000 to 0x06 FFFF FFFF	4 GB	External Memory Space (Region 0)
0x00 5000 0000 to 0x00 57FF FFFF	0x00 5800 0000 to 0x00 5FFF FFFF	128 MB	Boot Space (Region 1)
0x05 0000 0000 to 0x05 FFFF FFFF	0x07 0000 0000 to 0x07 FFFF FFFF	4 GB	External Memory Space (Region 3)

### 12.3.1.5 FSS Programming Guide

#### 12.3.1.5.1 FSS Initialization Sequence

Initialization steps:

- Configure the main boot parameters for FSS0 or FSS1):
  - Select the boot block to be used.
  - Select the size of the boot block to be used.
- Enable FSS in PSC.
- Configure the FSS interface which will be used:
  - For FSS0 - OSPI0 or HyperBus interface.
  - For FSS1 - OSPI1.
- Enable the selected FSS interface in PSC.
- Configure the FSS interface:
  - For more information about OSPI configuration, please see *Octal Serial Peripheral Interface (OSPI)*.
  - For more information about HyperBus interface configuration, please see *HyperBus Interface*.
- Configure the ECC region start address and size:
  - MCU\_FSS0\_ECC\_RGSTRT\_j
  - MCU\_FSS0\_ECC\_RGSIZ\_j
- Enable the ECC option if the target flash device has ECC encoded within.
- If the target device is HyperFlash/SRAM configure fragmentation address boundary:
  - Flash device requires fragmentation.
  - SRAM device does not require fragmentation.
- Enable error interrupts (see MCU\_FSS0\_ENABLE\_SET).

#### 12.3.1.5.2 FSS Real-Time Operation

The CPU or DMA can read any location in the memory map and ECC will occur based on the region selection and size configuration.

In the event of an ECC single error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If a single error occurs, the CPU can scrub the flash block to determine if the error is permanent and requires reprogramming.

In the event of an ECC double error detect, the 32-byte block address and associated error bits are stored and an interrupt is generated (if enabled). The CPU can then service the interrupt and determine the error type. If the double error detect is within the flash, the region is corrupt and have to be treated as unused.

For ECC double error detect the bus status will also be set. This prevents the CPU from executing the erroneous data.

#### **12.3.1.5.3 FSS Power Up/Down Sequence**

There are four PSC controls for the FSS: the FSS itself, OSPI0, HyperBus interface, and OSPI1. The CPU enables the appropriate interfaces before using FSS0 or FSS1 of the FSS.

The FSS0 can be used for HyperBus interface or OSPI0 and only the interface in use has to be enabled. Software should ensure the selected interface is enabled prior to FSS0 transactions.

The FSS1 can only be used to access OSPI1. The FSS1 transaction may be blocked depending on the power state of the OSPI1.

Normal Power Down Sequence:

- Block any new transaction to the particular interface - FSS0 or FSS1.
- Power down the target FSS interface.
- In the event when all targets are powered down, the FSS can then be powered down.

### 12.3.2 Octal Serial Peripheral Interface (OSPI)

This section describes the Octal Serial Peripheral Interface (OSPI) module for the device.

#### 12.3.2.1 OSPI Overview

The Octal Serial Peripheral Interface (OSPI) module is a kind of Serial Peripheral Interface (SPI) module which allows single, dual, quad, or octal read and write access to external flash devices.

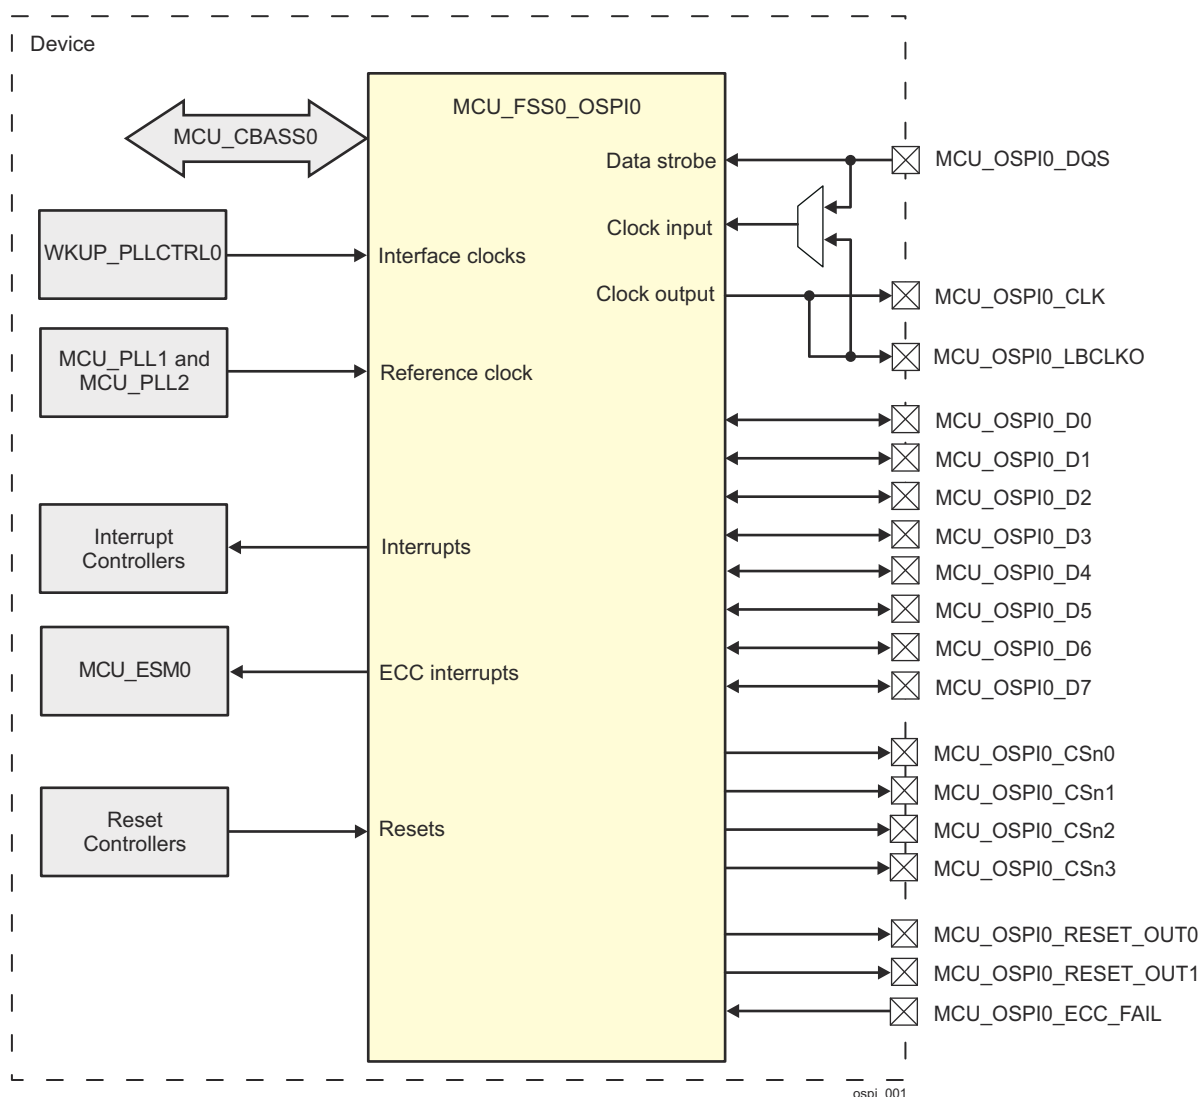

The OSPI module is used to transfer data, either in a memory mapped direct mode (for example a processor wishing to execute code directly from external flash memory), or in an indirect mode where the module is set-up to silently perform some requested operation, signaling completion via interrupts or status registers. For indirect operations, data is transferred between system memory and external flash memory via an internal SRAM which is loaded for writes and unloaded for reads by a device controller at low latency system speeds. Interrupts or status registers are used to identify the specific times at which this SRAM is accessed using user programmable configuration registers.

[Table 12-292](#) shows the OSPI allocation across device domains.

**Table 12-292. OSPI Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0_OSPI0	-	✓	-

[Figure 12-222](#) shows the OSPI module overview.

**Figure 12-222. OSPI Overview**

### 12.3.2.1.1 OSPI Features

The OSPI module has the following features:

- Support for single, dual, quad (QSPI mode) or octal I/O bus widths.
- Memory mapped 'direct' mode of operation for performing flash data transfers and executing code from flash memory.
- Software triggered 'indirect' mode of operation for performing low latency and non-processor intensive flash data transfers.
- Local SRAM of configurable size to reduce advanced high-performance bus overhead and buffer flash data during indirect transfers.
- Set of software advanced peripheral bus accessible flash control registers to perform any flash command, including data transfers up to 8-bytes at a time.
- Additional addressable memory bank to accommodate more than 8-bytes at a time.
- Support for XIP, sometimes referred to as continuous mode.
- Support for DDR Mode and DTR protocol (including Octal DDR protocol with DQS for Octal-SPI devices)
- Programmable device sizes.
- Programmable write protected regions to block system writes from taking effect.

- Programmable delays between transactions.
- Legacy mode allowing software direct access to low level transmit and receive FIFOs, bypassing the higher layer processes.
- An independent reference clock to decouple bus clock from SPI clock – allows slow system clocks.
- Programmable baud rate generator to generate OSPI clocks.
- Features included to improve high speed read data capture mechanism.
- Option to use adapted clocks or DQS to further improve read data capturing.
- Programmable interrupt generation.
- Up to four external device selects - OSPI and QSPI devices can be mixed
- Programmable data decoder, enables continuous addressing mode for each of the connected devices and auto-detection of boundaries between devices.
- Supports BOOT mode.
- Bidirectional CRC on Multiple-SPI interface.
- Handling ECC errors for flash devices with embedded correction engine.
- Full integration with PHY module dedicated to more flexible and power efficient transfers.
- Supports RESET\_OUT[1-0] and ECC\_FAIL pins for external flash devices where ECC is checked on the flash.
- Automatic Flash device status polling for programming operation (Auto HW Polling)

#### **12.3.2.1.2 OSPI Not Supported Features**

The following features are not supported on this family of devices:

- Pulse events not used.
- In Octal-SPI and Quad-SPI mode, Mode 1, 2, and 3 are not supported.
- Flash device status polling for programming operation using STIG

### 12.3.2.2 OSPI Environment

The FSS0\_OSPI0 module is hereinafter referred to as OSPI module.

This section describes the OSPI external connections (environment).

The OSPI module is primarily intended for fast booting from Octal- and Quad-SPI flash memories. [Figure 12-223](#) shows a typical connection of the OSPI module to an external Octal-SPI flash memory.

**Figure 12-223. OSPI Connected to an External Octal-SPI Flash Memory**

[Table 12-293](#) lists and describes the FSS0\_OSPI I/O signals.

**Table 12-293. OSPI I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>FSS0_OSPI0</b>				
DQ0	OSPI0_D0	IO	FSS0_OSPI0 data input/output 0	HiZ
DQ1	OSPI0_D1	IO	FSS0_OSPI0 data input/output 1	HiZ
DQ2	OSPI0_D2	IO	FSS0_OSPI0 data input/output 2	HiZ
DQ3	OSPI0_D3	IO	FSS0_OSPI0 data input/output 3	HiZ
DQ4	OSPI0_D4	IO	FSS0_OSPI0 data input/output 4	HiZ
DQ5	OSPI0_D5	IO	FSS0_OSPI0 data input/output 5	HiZ
DQ6	OSPI0_D6	IO	FSS0_OSPI0 data input/output 6	HiZ
DQ7	OSPI0_D7	IO	FSS0_OSPI0 data input/output 7	HiZ
N_SS_OUT0	OSPI0_CS <sub>n</sub> 0	O	FSS0_OSPI0 external flash device chip select 0	0x1
N_SS_OUT1	OSPI0_CS <sub>n</sub> 1	O	FSS0_OSPI0 external flash device chip select 1	0x1
N_SS_OUT2	OSPI0_CS <sub>n</sub> 2	O	FSS0_OSPI0 external flash device chip select 2	0x1
N_SS_OUT3	OSPI0_CS <sub>n</sub> 3	O	FSS0_OSPI0 external flash device chip select 3	0x1
OCLK	OSPI0_CLK	O	FSS0_OSPI0 clock output for the external flash device	0x0
	OSPI0_LBCLKO	O	FSS0_OSPI0 external loopback output	0x0
DQS	OSPI0_DQS	I <sup>(3)</sup>	FSS0_OSPI0 data strobe / external loopback input	Don't care
RESET_OUT0	OSPI0_RESET_OUT0	O <sup>(4)</sup>	FSS0_OSPI0 reset output 0 for the external flash device. Pin is active low.	0x1
RESET_OUT1	OSPI0_RESET_OUT1	O <sup>(4)</sup>	FSS0_OSPI0 reset output 1 for the external flash device. Pin is active low.	0x1
ECC_FAIL	OSPI0_ECC_FAIL	I	FSS0_OSPI0 ECC status from the external flash device	0x1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR\_OSPI0\_CLKSEL[4] LOOPCLK\_SEL bit in *Control Module (CTRL\_MMR)*.

(4) When OSPI flash memory is not used for Boot, the RESET\_OUT[1:0] signals can be used to reset the OSPI flash. If OSPI flash is used for Boot, the flash needs to be reset in tandem with SoC PORz, thus the OSPI0\_RESET\_OUT[0:1] signal should not be used.

[Table 12-294](#) describes the OSPI I/O connectivity to external SPI devices.

**Table 12-294. OSPI I/O Connectivity to External SPI Devices**

Module Pin	I/O <sup>(1)</sup>	Description			
		4-pin <sup>(1)</sup> SPI - Single Read/Write (SIO) (DATA_XFER_TYPE_EXT_MODE_FLD=0x0)	4-pin <sup>(1)</sup> SPI - Dual Read/Write (DATA_XFER_TYPE_EXT_MODE_FLD=0x1)	6-pin <sup>(1)</sup> SPI - Quad Read/Write (DATA_XFER_TYPE_EXT_MODE_FLD=0x2)	11-pin <sup>(1)</sup> SPI - Octal Read/Write (DATA_XFER_TYPE_EXT_MODE_FLD=0x3)

RESET_OUT1	O	External SPI device reset 1. Pin is active low.			
ECC_FAIL	I	External SPI device ECC failure indication			

(1) This is the pin count at the external SPI flash memory side.

(2) When used as an external loopback input, the DQS signal can alternatively be referred to as LBCLKI. The LBCLKI clock input signal is a looped back version of the LBCLKO clock output signal and facilitates easier timing closure at higher speeds. The loopback has to be at board level in order to support higher OSPI speeds. The source of the loopback clock is defined by CTRLMMR\_OSPI0\_CLKSEL[4] LOOPCLK\_SEL bit in *Control Module (CTRL\_MMR)*.

#### Note

For OSPI0\_CLK, OSPI0\_LBCLKO, and OSPI0\_DQS signals to work properly, the RXACTIVE bit of the appropriate registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.3.2.3 OSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.3.2.3.1 OSPI Integration in MCU Domain

There is one OSPI module integrated in the device domain - FSS0\_OSPI0. [Figure 12-224](#) shows its integration in the device.

**Figure 12-224. FSS0\_OSPI Integration**

[Table 12-295](#) through [Table 12-297](#) summarize the integration of FSS0\_OSPI0 in device domain.

**Table 12-295. FSS0\_OSPI Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
FSS0_OSPI0	PSC0	PD0		CBASS0

### 12.3.2.4 OSPI Functional Description

#### 12.3.2.4.1 OSPI Block Diagram

Figure 12-225 shows the OSPI module block diagram.

**Figure 12-225. OSPI Block Diagram**

The OSPI module is composed of three main blocks. The first one is the OSPI controller, the second one is the low level SPI protocol controller, and the third one is the integrated PHY.

The OSPI module has the following two target interfaces:

- Data target interface intended for data transfer.
- Configuration target interface intended for accessing the programmable set of registers.

##### 12.3.2.4.1.1 Data Target Interface

The data interface is used for data transfer to external flash devices in direct and indirect mode of operation. The data target controller validates incoming data accesses, responds to invalid requests, performs any required byte and halfword reordering, blocks writes that violate the programmed write protection rules (only for direct access) and forwards the transfer request to either the direct access controller (DAC) or the indirect access controller (INDAC).

The data interface bus is 32-bits wide. Therefore only byte, halfword and word accesses are permitted. When the controller is configured to work in SPI Octal DDR Mode or Octal DDR Protocol (where 2 bytes are collected within single SPI clock cycle what exceeds the size of 1 byte transfer request), 8 bit transfer size is not allowed.

#### Note

Cache line wrap accesses over the data target port should be word aligned.

Data target port doesn't support cache line wrap bursts of 128 bytes.

#### 12.3.2.4.1.2 Configuration Target Interface

The configuration interface is used to configure the OSPI module and perform software controlled flash accesses using the OSPI\_FLASH\_CMD\_CTRL\_REG register (for more information refer to [Section 12.3.2.4.11, Software Triggered Instruction Generator \(STIG\)](#)). Depending on the address it routes the incoming interconnect transfer to the Low level SPI protocol controller or to the ECC aggregator. The configuration port is also used to interact with the OSPI configuration and SRAM ECC registers.

#### Note

The configuration interface supports only 32-bit accesses. For single byte or halfword manipulations software should perform read-modify-write operations.

#### 12.3.2.4.1.3 OSPI Clock Domains

The OSPI module has two main clock sources for the Octal-SPI controller.

- For interface clocks
- For reference clock

The source for the interface clocks corresponds to the configuration and data buses. The data bus clock (OSPI\_HCLK) is the main system clock used to transfer data over the data bus between a controller on the system interconnect and the OSPI module. The data bus clock also drives the internal OSPI SRAM. The configuration bus clock (OSPI\_PCLK) is used to access the OSPI configuration register and perform basic configuration and for interrupt handling. The OSPI reference clock (OSPI\_RCLK) drives the SPI transmit and receive logic in the OSPI module. It is also used to generate the output SPI protocol clock (OSPI\_OCLK) and for oversampling of the input data. Using the reference clock (OSPI\_RCLK) allows the OSPI module to decouple the frequency of the SPI flash device from the device system clocks, thereby providing more flexible clocking solution.

#### Note

There is no particular clock ratio requirement between configuration (OSPI\_PCLK) and data bus (OSPI\_HCLK) clocks.

#### 12.3.2.4.2 OSPI Modes

#### Note

Some of the OSPI features described in this section may not be supported on this family of devices. For more information, see *OSPI Not Supported Features*.

The OSPI module supports four SPI modes. These modes are defined through the OSPI\_CONFIG\_REG[1] SEL\_CLK\_POL\_FLD and OSPI\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD bits. The SEL\_CLK\_POL\_FLD bit defines the clock polarity and the SEL\_CLK\_PHASE\_FLD bit defines the data launch and data capture relation to the OSPI clock edges. [Table 12-298](#) gives a brief description of these modes.

**Table 12-298. OSPI Modes**

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
0	0	0	Clock inactive state: low Data launch edge: clock falling edge Data capture edge: clock rising edge
1	0	1	Clock inactive state: low Data launch edge: clock rising edge Data capture edge: clock falling edge

**Table 12-298. OSPI Modes (continued)**

SPI Mode	SEL_CLK_POL_FLD	SEL_CLK_PHASE_FLD	Description
2	1	0	Clock inactive state: high
			Data launch edge: clock rising edge
			Data capture edge: clock falling edge
3	1	1	Clock inactive state: high
			Data launch edge: clock falling edge
			Data capture edge: clock rising edge

Octal flash devices provide DQS signal which allows source synchronous capture, but for Quad flash devices the OSPI module has a loopback mode. In this loopback mode the clock, looped back at board level, is used for registering the input data, and the edge used is same as the launch edge, thus giving a full cycle path (for more information, see [Section 12.3.2.4.2.1, Read Data Capture](#)).

#### 12.3.2.4.2.1 Read Data Capture

[Figure 12-226](#) shows the Read Data Capture Logic in the OSPI module.

**Figure 12-226. Read Data Capture Logic**

The PHY module includes a DLL which allows adjustment of the sampling edge with respect to the incoming data to achieve maximum frequency. There are three sources for the sampling signal:

- The reference clock
- Output SPI clock external loopback
- The DQS (only available in Octal Flash devices)

The loopback mode (only for Quad flash devices) can work in two cases. The first one is when OSPI\_CONFIG\_REG[2] SEL\_CLK\_PHASE\_FLD=0. When SEL\_CLK\_PHASE\_FLD=1 there aren't enough clock falling edges for the register pipeline to catch the last data driven, thus causing a functional failure. Additionally, since the capture edge is falling edge, it gives a full cycle input path only in SPI mode 0, that is when SEL\_CLK\_POL\_FLD=0 and SEL\_CLK\_PHASE\_FLD=0. Thus SPI mode 0 is the first of two modes that support high MHz operation (greater than 50 MHz). The second mode is when SEL\_CLK\_PHASE\_FLD=1 and SEL\_CLK\_PHASE\_FLD=1 (SPI mode 3). In this case the missing clock falling edge is compensated inside the OSPI controller when using the incorporated PHY module by inverting the loopback clock.

The loopback mode is enabled by writing 0x0 to OSPI\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD. The taps are selected by programming OSPI\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD field. The taps delay the read data capturing logic by the programmed number of OSPI\_RCLK cycles.

#### 12.3.2.4.2.1.1 Mechanisms of Data Capturing

There are two mechanisms of data capturing in the OSPI module. They can be combined in some parts to ensure reliable sampling solution independent on the system requirements and the controller configuration. The mechanisms are as follows:

- Data capturing mechanism using taps
- Data capturing mechanism using PHY module.

#### 12.3.2.4.2.1.2 Data Capturing Mechanism Using Taps

This section describes the data capturing mechanism where sampling point is adjusted for one of the reference clock edges inside divided OSPI clock.

After POR, the adapted loopback clock circuit and the OSPI\_RCLK delay register line both wake in a disabled state. The OSPI\_RD\_DATA\_CAPTURE\_REG register provides the control for the mechanism using taps.

OSPI\_RD\_DATA\_CAPTURE\_REG[5] SAMPLE\_EDGE\_SEL\_FLD bit selects the edge of the reference clock, on which data outputs from flash memory are sampled.

OSPI\_RD\_DATA\_CAPTURE\_REG[4-1] DELAY\_FLD bit field controls the additional number of read data capture cycles (this is the fast reference clock, running at least x4 of the device clock) that should be applied to the internal read data capture circuit. The large clock-to-out delay of the flash memory together with trace delays as well as other device delays may impose a maximum flash clock frequency which is less than the flash memory device itself can operate at. To compensate, software shall set this register to a value that guarantees robust data captures.

#### **12.3.2.4.2.1.3 Data Capturing Mechanism Using PHY Module**

PHY module is responsible for data capturing. More detailed description of all internal PHY sampling mechanisms is included in [Section 12.3.2.4.16.2, Read Data Capturing by the PHY Module](#).

#### **12.3.2.4.2.2 External Pull Down on DQS**

Per the OSPI protocol, the FLASH device drives DQS while CS is asserted. When CS is not asserted the FLASH device presents HiZ on DQS. When configured to use DQS, the controller uses the DQS as a clock, which samples the incoming data into a FIFO. Noise on the DQS when it is HiZ can cause spurious false triggering of the FIFO and filling it with invalid data. There is no way to clear this data except to reset the OSPI module.

To avoid this issue, it is recommended to add a pull down on the DQS line.

During device wakeup, before the IO ring is configured properly, the CS to the FLASH device is HiZ. Depending on the actual level of the CS line the FLASH device might drive the DQS High, Low or HiZ. A pull down on DQS forces the DQS input to Low, but the DQS might still be High or in the presence of noise there might be transitions between Low and High. This again can cause the same issue of capturing garbage data in the Controller FIFO.

To avoid this issue it is recommended to release the OSPI from reset only after the IO ring is configured properly.

#### **12.3.2.4.3 OSPI Power Management**

##### **Note**

The OSPI module does not provide any hardware signal for busy or idle status. Software need to ensure that the OSPI module is idle before clocks can be shut off by reading the OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.

OSPI\_PCLK and OSPI\_HCLK share the same clock stop request/acknowledge and clock enable/acknowledge interface.

#### **12.3.2.4.4 Auto HW Polling**

The OSPI controller is capable of automatically testing the Flash device busy bit to guarantee no reads or writes are ignored by the flash when it is busy burning in programmed data.

At the end of a programming transaction, the Flash device goes into a burn-in state and becomes busy.

When Auto HW Polling is enabled, the OSPI controller keeps track of programming transactions and will initiate a Flash status read polling transactions automatically, until Flash indicates it is not busy, before any additional data read or programming operations are sent to the flash device. See OSPI\_WRITE\_COMPLETION\_CTRL\_REG register and the associated registers.

The OSPI controller requires that the OSPI\_WRITE\_COMPLETION\_CTRL\_REG[23-16] POLL\_COUNT\_FLD field should always be set with values greater or equal to 3 ( $\geq 3$ ).

#### **12.3.2.4.5 Flash Reset**

OSPI provides Flash reset out ports. These ports are active low and controlled thru OSPI\_CONFIG\_REG register.

The controller provide Flash reset out ports. These ports are active low and controlled thru the Config\_reg(0x0)[5].reset\_cfg\_fld and cofnig\_reg(0x0)[6].reset\_pin\_fld.

The register fields control the `ospi_reset_out[3:0]` mentioned in section 7.1.24 of the functional spec.

#### 12.3.2.4.6 OSPI Memory Regions

Table 12-299 shows the OSPI memory map in MCU domain.

**Table 12-299. OSPI Memory Map**

Address Range	Size	Description
<b>MCU_FSS0_OSPI0</b>		
0x00 4704 0000 to 0x00 4704 0100	256 B	Configuration registers space
0x00 4704 4000 to 0x00 4704 4200	512 B	Global control registers space
0x00 4706 8000 to 0x00 4706 8400	1 KB	OSPI_ECC_AGGR registers space

#### Note

For more information about the memory space, see *FSS Memory Regions*.

#### 12.3.2.4.7 OSPI Interrupt Requests

The OSPI module generates three interrupts. The ECC interrupts (`FSS0_OSPI_0_OSPI_ECC_CORR_LVL_INTR_0` and `FSS0_OSPI_0_OSPI_ECC_UNCORR_LVL_INTR_0`) are generated by the OSPI ECC aggregator.

The other interrupt (`FSS0_OSPI_0_OSPI_LVL_INTR_0`) is generated by the OSPI module.

Table 12-300 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

**Table 12-300. OSPI Events**

Event Flag	Event Mask	Description
OSPI_IRQ_STATUS_REG[0] MODE_M_FAIL_FLD	OSPI_IRQ_MASK_REG[0] MODE_M_FAIL_MASK_FLD	Event Flag and Event Mask for the OSPI Interrupts.

OSPI_ECC_AGGR_STATUS_CLR[3-2] TIMEOUT	OSPI_ECC_AGGR_ENABLE_CLR[1] TIMEOUT	

#### 12.3.2.4.8 OSPI Data Interface

##### 12.3.2.4.8.1 Data Interface Address Remapping

The incoming data interface address, by default, maps directly to the address sent serially to the FLASH device. If the FLASH device has a 24-bit address, then the 24 LSB's of the data address is forwarded. A remap feature is available to remap all incoming data addresses to ADDRESS + N, where N is the value stored in the OSPI\_REMAP\_ADDR\_REG[31-0] VALUE\_FLD bit field. It is enabled via the OSPI\_CONFIG\_REG[16] ENB\_AHB\_ADDR\_REMAP\_FLD bit. This feature could be used when software needs to move boot code to another FLASH region.

##### 12.3.2.4.8.2 Write Protection

In order to protect the FLASH device, a software controlled write protection feature is supported. Any data write detected (by using DAC), pointing to an area of the FLASH that is protected, is not permitted.

A programmable region of the FLASH device, defined as a number of FLASH 'blocks' starting from a particular block number can be protected. Three programmable registers are provided. The first OSPI\_LOWER\_WR\_PROT\_REG register defines the FLASH block that is located at the bottom of the region to be protected. The second OSPI\_UPPER\_WR\_PROT\_REG register defines the FLASH block that is located at the top of the region to be protected. The third OSPI\_WR\_PROT\_CTRL\_REG register is a control register consisting of 2 bits. The OSPI\_WR\_PROT\_CTRL\_REG[0] INV\_FLD bit allows software to invert the region that is being protected, causing the programmed region to become the only areas of FLASH memory that is not protected from writes. The OSPI\_WR\_PROT\_CTRL\_REG[1] ENB\_FLD bit is the write protection enable bit. When this bit is set to 0, the FLASH device is unprotected.

For implementation, the data interface must map the incoming address into its associated FLASH block. A block can be between 1 and 65 KB, programmed via the OSPI\_DEV\_SIZE\_CONFIG\_REG register.

##### 12.3.2.4.8.3 Access Forwarding

For legal accesses, the data interface will forward all accesses to one of two access controllers - the direct access and the indirect access controllers. Assuming DAC has been enabled via the OSPI\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTRL\_FLD bit, then by default all accesses will be forwarded to this controller. Before any accesses can be forwarded to INDAC, it must first be configured by software. This process is fully explained in [Section 12.3.2.4.10, Indirect Controller \(INDAC\)](#). If DAC is disabled, any incoming access that cannot be

forwarded to INDAC will be completed immediately with an error. If DAC is enabled, the same access will be forwarded and serviced by DAC.

#### **12.3.2.4.9 OSPI Direct Access Controller (DAC)**

Direct access refers to the operation where data interface accesses directly trigger a read or write to FLASH memory. It is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and will be serviced by the DAC. Note that accesses that use DAC do not use the embedded SRAM. The data transfer stops when read or write burst is carried out. The amount of wait states applied will be dependent on the latency through the controller. Latency is kept to a minimum when the use of XIP read instructions are enabled (see OSPI\_CONFIG\_REG[18] ENTER\_XIP\_MODE\_IMM\_FLD and OSPI\_CONFIG\_REG[17] ENTER\_XIP\_MODE\_FLD bits).

#### **12.3.2.4.10 OSPI Indirect Access Controller (INDAC)**

##### **12.3.2.4.10.1 Indirect Read Controller**

The aim of the indirect mode of operation is to read significant numbers of bytes from FLASH memory without requiring a data interface access to trigger it. Instead indirect operations are controlled and triggered by software via specific control/configuration Indirect Read Transfer registers (OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG, OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG, OSPI\_INDIRECT\_READ\_XFER\_START\_REG, and OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG). This block will communicate with an embedded low level SPI protocol state machine module to perform an efficient and optimized FLASH read burst, placing the read data into the local SRAM module ready for fast and low latency delivery to any external controller.

By default, the Indirect Read controller is disabled. Before enabling it, software must configure how much data is required and the start address. The start address and total number of bytes to be fetched is defined in OSPI\_INDIRECT\_READ\_XFER\_START\_REG and OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. For more information refer to [Section 12.3.2.4.10.3, Indirect Access Queuing](#).

The total number of bytes to read in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the size of requests. In the case of SRAM overrun, the controller will back pressure FLASH reads until space becomes available in the SRAM. Back pressuring the reads on the SPI interface is handled by completing any current read burst, waiting until space in the SRAM becomes available and then issuing a new read burst at the address where the previous terminated burst ended.

An external controller will be able to fetch the data that the controller has read from external FLASH memory by issuing data interface reads to the OSPI module. The address of the incoming read access must be in the range of indirect trigger address programmed via the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register to indirect trigger address +  $2^{**}(\text{indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the indirect range to grant SRAM as source. Each valid Indirect Read will cause the internal SRAM to be popped, thereby decoupling the incoming read access address from the FLASH address – that is not direct mapped. Therefore the indirect trigger address does not have any relationship with the FLASH address. It is just to indicate that data should take the SRAM as source instead of the FLASH memory array after triggering of any valid Indirect Read. The FLASH address for Indirect Read is taken from the OSPI\_INDIRECT\_READ\_XFER\_START\_REG register. Assuming the requested data is present in the SRAM at the point the data interface access is received by the OSPI module, then the data will be fetched from the SRAM and the response to the read burst will be achieved with minimum latency. Once the data has been read from the SRAM, the OSPI module will free up the associated resource in the SRAM.

If a read access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a read access is received whose address is within the range described above but the requested data is not immediately present in the SRAM then wait states will be applied until the data has been read from FLASH and pushed to the SRAM.

If a read burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external controller is only permitted to issue 32-bit data interface reads until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final read, the external controller may issue a 16-bit (Halfword) or byte access to complete the transfer. It is also permitted for the external controller to always issue a 32-bit Word read on the last indirect access. The controller will pad the upper bits of the response with zero. The current expectation is that the SRAM will be kept fairly full while the read operation is carried out. The fill level of the SRAM is directly readable by software reading the OSPI\_SRAM\_FILL\_REG register.

An indirect operation may be cancelled at any time by setting 1 to OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus controller should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via configuration registers and then decide for itself when the data should be fetched from the local SRAM. The fill level watermark register (see OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level passes this watermark, an interrupt is generated. If the watermark value is > 0, the watermark interrupt is also generated when the final byte of data has been read by the OSPI module and placed in the SRAM, even if the actual SRAM fill level has not risen above the watermark. This last feature is useful to avoid software tracking how much data has been read and resetting the watermark value for the last few bytes of an indirect read transfer.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an Indirect Read operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect read operation. OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[2] RD\_STATUS\_FLD bit is available to check the status.

#### 12.3.2.4.10.1 Indirect Read Transfer Process

The following sequence can be followed:

1. Setup OSPI\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_INDIRECT\_READ\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. If the watermark interrupt feature is to be used, set the OSPI\_INDIRECT\_READ\_XFER\_WATERMARK\_REG register which will cause an interrupt to be generated when the fill level increases beyond the watermark level. Setting the watermark can be useful indication to software when to read the next part of the indirect read transfer. Note that if the watermark is set to a value other than zero, the watermark interrupt will always trigger once the final byte of indirect transfer has been fetched and placed in the embedded SRAM, even if the watermark value is higher than the actual completed fill level.
7. Trigger Indirect Read access by setting the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit to 1.
8. If the watermark interrupt feature is to be used, wait for watermark interrupt. Else poll the SRAM fill level via the OSPI\_SRAM\_FILL\_REG register to decide when sufficient data is in the SRAM to trigger data fetches.

9. Read the expected amount of data from SRAM. If there is still more data to fetch in order to complete the indirect read transfer, then loop back to step 8. Otherwise continue to step 10.
10. The completion status of the Indirect Read operation can be polled via the OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD bit.
11. An Indirect Complete interrupt will be generated when the Indirect read operation has completed.

#### 12.3.2.4.10.2 Indirect Write Controller

The aim of the indirect mode of operation is to perform bulk transfer of data from the processor into a FLASH memory in the most efficient manner. The fewest possible write cycles inside the FLASH device will be carried out for the indirect transfer, thus maximizing the life of the device. Indirect write operation can be thought of from a software perspective as the inverse of the indirect read. It is controlled and triggered by software via specific control/configuration Indirect Write Transfer registers (for more information see the following registers: OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG, OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG, OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG, and OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG). This block will await delivery of the write data via the external data interface controller, placing it in the local SRAM before communicating with the existing legacy SPI core to perform an efficient and optimized FLASH write burst.

By default, the indirect write controller is disabled. Before enabling it, the software must configure how much data is required and the start address. The start address and total number of bytes to be written is defined in OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG and OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG registers, respectively. Up to two indirect operations can be programmed at any one time. The second operation can be triggered while the first is in progress. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. The Indirect write queuing is very similar to indirect read queuing. For more information refer to [Section 12.3.2.4.10.3, Indirect Access Queuing](#).

The total number of bytes to write in an indirect operation is not limited by the size of the SRAM. The size of SRAM will only limit the amount of data that can be accepted from the external controller. In the case of an SRAM overrun, the controller will back pressure the data interface with wait states. Note the fill level of the SRAM is readable via programmable OSPI\_SRAM\_FILL\_REG register and this can be used to avoid this situation.

An external controller will provide the write data and will transfer this to the OSPI module by issuing data interface writes. The address of the incoming write access must be in the range of Indirect trigger address programmed via the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register to Indirect trigger address +  $2^{**}(\text{Indirect trigger address range}) - 1$ . Default value of the range is equal to 16 locations. This allows a 16-beat burst to be applied starting from the Indirect trigger address. The smaller bursts are possible to handle effectively as well with this approach. Furthermore it is not strict requirement to push consecutive address sequence. Actual address just has to be in the Indirect Range to grant SRAM as source. Each write will cause the internal SRAM to be pushed, thereby decoupling the incoming write access address from the FLASH address – that is not direct mapped. Therefore Indirect trigger address does not have any relationship with FLASH address. It is just to indicate that data should take SRAM as source instead of FLASH Memory array after triggering of any valid Indirect Write. The FLASH address for Indirect Write is taken from the OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register. Assuming the SRAM is not full at the point the data interface access is received by the OSPI module, then the data will be pushed to the SRAM with minimum latency.

If a write access is received whose address is not within the range described above then that access will not be completed using the indirect controller. It will instead be serviced by the direct access controller.

If a write access is received whose address is within the range described above but the SRAM is full then wait states will be applied until some or all of the data has been pushed from the SRAM to the FLASH.

If a write burst is received whose access elements traverse the Indirect trigger range, then the accesses within the Indirect trigger range will be processed by the indirect controller, and the rest will be taken by the direct access controller. This is likely to be a software configuration error.

The external controller is only permitted to issue 32-bit data interface writes until the last word of an indirect transfer. This helps keep the SRAM control logic less complex. On the final write, the external controller may issue a 32-bit word, 16-bit (halfword) or a byte access to complete the transfer. If the number of bytes to write is less than 4 on the last transfer, the controller is still permitted to issue a 32-bit transfer. In these cases, the extra bytes are discarded by the controller.

When the SRAM holds a number of bytes equal to or greater than the size of a FLASH page (which itself is programmed into the OSPI module, with a default of 256 bytes) or when the SRAM holds all remaining bytes of the currently executing indirect transfer, the OSPI module will initiate a write burst to the flash command generator.

An indirect operation may be cancelled at any time by setting 1 to the OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[1] CANCEL\_FLD bit.

Any bus controller should be allowed to initiate an indirect access. The OSPI module provide software access mechanism to the SRAM fill-level directly via the configuration registers and then decide for itself when the data should be written to the local SRAM. The fill level watermark register (see OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register) is provided. When the SRAM fill level falls below this watermark, an interrupt is generated.

Two further interrupt sources are provided to help understand the status of an indirect operation. Firstly, an interrupt is generated when an indirect operation has completed. Secondly, an interrupt is generated if an indirect write operation was requested but could not be accepted due to the fact 2 indirect operations have already been buffered by the OSPI module.

Setting the OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit starts an indirect write operation. The OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[2] WR\_STATUS\_FLD bit is available to check the status.

#### 12.3.2.4.10.2.1 Indirect Write Transfer Process

The following sequence can be followed:

1. Setup OSPI\_CONFIG\_REG register.
2. Setup the indirect transfer's FLASH start address in the OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register.
3. Setup the number of bytes to be transferred in the OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register.
4. Setup the indirect transfer's trigger address in the OSPI\_IND\_AHB\_ADDR\_TRIGGER\_REG register.
5. Setup the indirect transfer's trigger address range in the OSPI\_INDIRECT\_TRIGGER\_ADDR\_RANGE\_REG register.
6. It is functionally valid for software to simply write all the data to the SRAM in one block transfer. However, if the total number of bytes to write is greater than the size of the partitioned SRAM, then it is quite likely the SRAM will become full causing the OSPI to back-pressure the system data bus for a considerable time. This time is based on the FLASH data-rate and the page-write time of the device. To avoid sending all the write data in one block transfer, software can make use of the watermark interrupt to identify a convenient time to send data a page at a time to the SRAM module. Alternatively, software can poll the SRAM fill level register directly to identify how empty the SRAM is at any one time in order to make a judgment as to when the most practical time to send the next part of the transfer.
7. If the watermark interrupt feature is to be used, set the OSPI\_INDIRECT\_WRITE\_XFER\_WATERMARK\_REG register which will cause an interrupt to be generated when the fill level falls below the watermark. The watermark should be set to a number between zero and a page size. That is if the page size is 256 bytes, then setting the watermark to a value between 10 and 250 is reasonable and will cause the interrupt to trigger when the fill level drops below the programmed number. Setting the watermark can be useful to provide an indication to software when to write the next page of data to the SRAM.
8. Trigger Indirect Write access by setting OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit.

9. If the remaining number of bytes still to be transferred into the SRAM for the current indirect transfer is greater than a FLASH page, then write 1 FLASH page worth of data to the SRAM. Otherwise send the remaining data from the indirect transfer to SRAM.
10. If all the data in the indirect transfer has now been sent to the SRAM, then go to 12 and await indirect complete status. Otherwise if there is more data still to be transferred then either:
  - If the watermark interrupt feature is being used, then wait for watermark interrupt.
  - Alternatively the SRAM fill level can be interrogated to identify a convenient time to send more data.
11. Loop back to 9.
12. Optional: The completion status of the Indirect write operation can be polled via OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[5] IND\_OPS\_DONE\_STATUS\_FLD.
13. An Indirect Complete interrupt will be generated when the Indirect write operation has completed.

#### **12.3.2.4.10.3 Indirect Access Queuing**

Software is permitted to queue up to two indirect transfers for both the indirect write controller and the indirect read controller. Supporting two indirect operations allows a short turnaround time between the completion of one indirect operation and the start of the second. Any attempt to queue more than two operations will cause an interrupt to be generated. To take advantage of this feature, software should attempt to keep both indirect programming slots full at all times.

From the software perspective, indirect access queuing is achieved by triggering bit 0 of the indirect transfer control register (OSPI\_INDIRECT\_READ\_XFER\_CTRL\_REG[0] START\_FLD bit or OSPI\_INDIRECT\_WRITE\_XFER\_CTRL\_REG[0] START\_FLD bit) twice in short succession. The indirect number of bytes register (OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG or OSPI\_INDIRECT\_WRITE\_XFER\_NUM\_BYTES\_REG register) and the indirect FLASH start address register (OSPI\_INDIRECT\_READ\_XFER\_START\_REG or OSPI\_INDIRECT\_WRITE\_XFER\_START\_REG register) must be setup with the relevant transfer data before START\_FLD bit can be triggered for each transfer. Since these registers will change regularly, the hardware must keep sampled versions of these registers for the duration of the indirect transfer.

The internal register block will only issue an indirect start trigger to the key underlying datapath blocks one at a time. There are 2 independent datapath blocks in the indirect access controller that will receive and independently sample this information. The first is the datapath block on the data bus side of the SRAM. For indirect reads, this is a read interface, for indirect writes, it is a write interface. The second is the datapath block on the FLASH side of the SRAM. For indirect reads, this is a write interface, for indirect writes, it is a read interface. Both blocks will process the indirect transfers at different times. For example, for an indirect read operation, the datapath block on the FLASH side of the SRAM will be able to start processing the second queued transfer as soon as the last byte of the first transfer has been written to the SRAM. Before commencing the second transfer, this block must resample the OSPI\_INDIRECT\_READ\_XFER\_NUM\_BYTES\_REG and OSPI\_INDIRECT\_READ\_XFER\_START\_REG registers. Similarly, the datapath block on the bus side will resample the same registers locally when it has forwarded all the FLASH data associated with the first indirect transfer from the SRAM onto the data bus.

#### **12.3.2.4.10.4 Consecutive Writes and Reads Using Indirect Transfers**

It is permitted for software to trigger an indirect read operation while an indirect write operation is in progress. Similarly it is permitted to trigger an indirect write while an indirect read operation is in progress. Indirect write operations will take overall precedence.

#### **12.3.2.4.10.5 Accessing the SRAM**

The SRAM depth is separated in two segments. The lower segment is reserved for indirect read use. The upper segment is for indirect write use only. The size of each segment is programmable via the OSPI\_SRAM\_PARTITION\_CFG\_REG register. This feature allows to allocate how many bits of the SRAM address bus are allocated to indirect read. By default, this is set so that exactly half of the SRAM is portioned for use by the indirect read controller. To ensure the read data bus is not directly fed by the SRAM read data through combinatorial logic, an extra bank of holding registers is included in the indirect read data path. These registers act as an extra location to be added to the allocated number of SRAM locations for indirect read.

To illustrate how the SRAM (and the extra bank of holding registers) can be allocated between indirect read and write, the following example is provided. The depth of the SRAM in this example is configured to be 8 bits. This is equal to 256 locations.

- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x00, then 256 locations are allocated to indirect writes and 1 location to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x01, then 255 locations are allocated to indirect writes and 2 locations to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0x02, then 254 locations are allocated to indirect writes and 3 locations to indirect reads.
- And so on until.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFD, then 3 locations are allocated to indirect writes and 254 locations to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFE, then 2 locations are allocated to indirect writes and 255 locations to indirect reads.
- If the OSPI\_SRAM\_PARTITION\_CFG\_REG[7-0] ADDR\_FLD field is set to 0xFF, then 1 location is allocated to indirect writes and 256 locations to indirect reads.

### Note

A value of 0xFF or 0x00 in the OSPI\_SRAM\_PARTITION\_CFG\_REG register should be avoided by software, as only the bottom 8 bits of the SRAM fill level are accessible through software (up to 255 limit) via the OSPI\_SRAM\_FILL\_REG register. If the fill level reaches 256 on either the indirect read or write side, it will appear when reading the Fill Level to be 0.

There are four SRAM sources that are arbitrated and muxed onto the single SRAM port. Up to three sources can access this port at any one time. The sources are described as follows:

- Indirect Write, Write source. This is located on the data bus side of the SRAM.
- Indirect Write, Read source. This is located on the FLASH side of the SRAM.
- Indirect Read, Write source. This is located on the FLASH side of the SRAM.
- Indirect Read, Read source. This is located on the data bus side of the SRAM.

A fixed priority arbitration scheme is implemented. [Table 12-301](#) shows priority allocated to these sources.

**Table 12-301. SRAM Access Priority**

SRAM Access Priority		
Indirect Write	Write to SRAM (from System Data Bus)	3rd (exclusive with Data Bus Read Request)
	Read from SRAM (from OSPI Module)	2nd
Indirect Read	Write to SRAM (from OSPI Module)	1st
	Read from SRAM (from System Data Bus)	3rd (exclusive with Data Bus Write Request)

### Note

With the exception of the write port during an Indirect Read operation (on the FLASH side of the SRAM), the logic driving all four sources must not assume single cycle completion. Writes to the SRAM during an indirect read must be allowed to complete immediately to avoid data loss. Therefore this port is given maximum priority.

#### 12.3.2.4.11 OSPI Software-Triggered Instruction Generator (STIG)

The DAC and INDAC are used to transfer data. In order to access the volatile and non-volatile configuration registers, the legacy SPI Status register, other status/protection registers as well as to perform ERASE functions, a separate software controller is required. The software triggered instruction generator (STIG) is controlled using the OSPI\_FLASH\_CMD\_CTRL\_REG register by setting

up the command to issue to the FLASH device. This is a generic controller and can be used to perform any instruction that the FLASH device supports from the extended SPI protocol. Configuring of instructions which are not compliant with the specification of the FLASH devices could cause unpredicted behavior of the controller. OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bits should be set different than OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD. The OSPI\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit is used to trigger the command. The OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit is used by software to poll the status of the command execution. For reads, when the command has been serviced (OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit toggles from '1' to '0'), up to 8 bytes of read data will be placed in the OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG registers. For writes, the write data should be placed in the OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG registers.

The completion of the STIG request could be also checked by the corresponding interrupt. The occurrence of the interrupt indicates that the controller is ready for accepting a new STIG request. It is important to notice that completion of the STIG request is not equivalent to completion it on SPI side. For example, if STIG is configured to the command composed of data to transmit only, the data is taken from the corresponding STIG register fields and put into TX FIFO. Since all bytes to write are known, another STIG can be queued before serialization of the current one is completed.

There are some commands which require more data to read than 8 bytes (for example READ ID command). The additional STIG Memory Bank is implemented in order to accommodate these data if needed. The STIG Memory Bank (internal component of the controller) is controlled by the OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit. If enabled, the number of bytes to read in the STIG is extended to 16 as defined in OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field. It should be noticed that there are very few commands (excluding Read Array ones which are not intended to handle effectively in STIG Mode but in Direct/Indirect Modes) which return more than 8 bytes to the controller. If the maximum number of bytes to Read using STIG in target application is less than 16, the depth of the STIG Memory Bank can be set smaller what will result in saving noticeable part of the area.

If number of bytes to Read in the STIG as defined in OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[18-16] NB\_OF\_STIG\_READ\_BYTES\_FLD bit field exceeds the Memory Bank Depth, remaining data will overwrite the STIG Memory Bank locations starting from its first address. OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG keep the last 8 bytes read from the Flash Device by STIG when Memory Bank is enabled. Therefore, for example if the user wants to get just a single byte from the last eight bytes from long continuous read SPI data chain, there is no need to access the STIG Memory Bank since data can be taken from suitable Flash Command Read Data register. In order to access more data, STIG Memory Bank data request should be triggered. It is controlled by the OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG and works analogously for triggering STIG from the functional standpoint.

OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[0] TRIGGER\_MEM\_BANK\_REQ\_FLD bit is used to trigger the command, bit OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[1] MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD is used by software to poll the status of the command execution. When MEM\_BANK\_REQ\_IN\_PROGRESS\_FLD bit toggles from "1" to "0", the byte of data (OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[15-8] MEM\_BANK\_READ\_DATA\_FLD) from corresponding address (OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG[28-20] MEM\_BANK\_ADDR\_FLD bit field) is valid. The address should be set before triggering the STIG Memory Bank access. Each consecutive STIG access overwrites the previous one so that the data in the Bank always fit into byte index fetched by the last STIG access configured to use the Memory Bank (first incoming byte equals first address of the Memory Bank, second one equals the second address and so on).

#### 12.3.2.4.11.1 Servicing a STIG Request

A STIG request will cause the OSPI Flash controller to interrogate the OSPI\_FLASH\_CMD\_CTRL\_REG register to determine what and how many bytes it should send to the FLASH device. The OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD field of this register indicate the instruction to be sent and is always pushed first. If there is an address to send, then the address (the size

of which is also programmed in the same register) is sent next. The address itself is stored in the OSPI\_FLASH\_CMD\_ADDR\_REG register. If Mode bits are enabled by OSPI\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD bit. OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field are being sent right after address. If OSPI\_FLASH\_CMD\_CTRL\_REG[18] ENB\_MODE\_BIT\_FLD and OSPI\_CONFIG\_REG[29] CRC\_ENABLE\_FLD are both enabled, STIG will replace XIP Mode bits (not applicable for CRC aware SPI interface) for automatically calculated address CRC byte. Therefore, to execute CRC aware STIGs (meaning the commands requiring sending address CRC byte), ENB\_MODE\_BIT\_FLD bit should always be set. If there are any dummy cycles to send (the size of which is also programmed in OSPI\_FLASH\_CMD\_CTRL\_REG register) then those are sent next. If there is data to write or read (the size of which is also programmed in OSPI\_FLASH\_CMD\_CTRL\_REG register) then for the case of writes, up to 8 bytes can be sent (as stored in the Flash Command Write Data registers, OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG registers) next. In the read case, when the read data has been collected from the FLASH device, the OSPI Flash Controller stores that in the Flash Command Read Data Registers (OSPI\_FLASH\_RD\_DATA\_LOWER\_REG and OSPI\_FLASH\_RD\_DATA\_UPPER\_REG registers). Up to 8 bytes can be get if OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD bit is disabled or up to 512 when enabled. When the OSPI Flash controller starts to service a STIG request, it sets the OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit to indicate a command execution is in progress. When the OSPI Flash controller is in the auto-polling state, servicing a STIG request is slightly different. Most of devices are largely inaccessible after a program operation until the device has completed that write. Some group of them has a possibility to suspend programming page. It can be controlled by the OSPI\_POLLING\_FLASH\_STATUS\_REG[8] DEVICE\_STATUS\_VALID\_FLD bit, which indicate active auto-polling phase. After requesting a STIG, the OSPI Flash Controller immediately issues appropriate OPCODE to Memory. During servicing a STIG (in auto-polling phase) the status bit of command execution remains steady and other parts of transfer such as ADDRESS or DUMMY BITS, and so forth, are disabled (to issued Program Suspend Command is needed OPCODE only). There is a programmable option to add delay between every repetitive poll operation (delay is defined by OSPI\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field). This feature is implemented to free up SPI bandwidth if needed.

---

#### Note

The OSPI data is sent LSB first, while address is sent MSB first.

---

---

#### Note

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

---

### 12.3.2.4.11.2

---

#### Note

The OSPI data is sent LSB first, while address is sent MSB first.

---

---

#### Note

The STIG complete status bit gets cleared before the actual flash access completes. Software should wait for about 700 ns if there is any dependency on actual access completion.

---

### 12.3.2.4.12 OSPI Arbitration Between Direct / Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a simple fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

- The Indirect Access Write
- The Direct Access Write

- The STIG
- The Direct Access Read
- The Indirect Access Read

#### 12.3.2.4.13 OSPI Command Translation

Requests issued by the direct access controller, the indirect access controller or the STIG will be translated into a sequence of byte transfers to send downstream (before serialization to the FLASH device). These sequences depend on the requested transfer but an example of a typical 1-byte non sequential READ is shown below:

INSTRUCTION OPCODE -> ADDRESS -> Mode Byte -> Dummy Bytes -> 1 byte of don't care

For sequential accesses, an extra byte of data per read is pushed to the FLASH device on the back of the above sequence assuming it can be done so with no gap between each transferred byte.

When PHY mode is enabled and consequently no clock divider is configured, latency caused by multi domain synchronization may make an extra byte insufficient to avoid the transfer gap. To ensure the sequential access non-interrupted and keep the maximum performance of the controller, PHY Pipeline Mode is implemented. When enabled, number of don't care bytes is calculated based on the configuration.

The actual sequence sent to the FLASH device depends on the requested transfers, whether the transfer is non-sequential or sequential, whether the device has been configured in XIP mode and the state of the main Device Instruction Type programmable registers (OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG).

For writes, the write enable latch (or WEL) within the FLASH device itself must be high before a write sequence can be issued. The OSPI Flash Controller will automatically issue the write enable latch command before triggering a write command via the direct or indirect access controllers (DAC/INDAC) – that is the user does not need to perform this operation. For increasing flexibility and performance user can turn off this feature by setting the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[8] WEL\_DIS\_FLD bit. The opcode for WREN is typically 0x06 and is common between devices.

When write requests from the direct or indirect access controllers are no longer being received and all outstanding requests have been sent, the FLASH device will automatically start the page program write cycle. Any incoming request at this time will be held in wait states until the cycle has completed. The OSPI Flash Controller will automatically poll the FLASH device legacy SPI status register to identify when the write cycle has completed. This is achieved by sending the RDSR opcode to the FLASH device and waiting until the device itself has indicated the write cycle has completed (until the Write in Progress bit has cleared to zero and the write enable latch bit has also cleared to zero or device is ready bit has set to one). The WREN and the RDSR device instructions are the only ones that are sent by the controller under the hood. For any other specific instruction that the user determines should be sent to the device (for example if the device needs to be unprotected before a write command is issued), these should be handled separately by issuing FLASH commands via the STIG.

There is an option to trigger HOLD or RESET feature on I/Os of the Flash Device. The HOLD one is generally common across the devices and takes an alternative function of DQ3 pin (applicable when device operates neither in Quad SPI mode nor DDR). The transfer can be hold and then resumed by dedicated software trigger field (OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD). The devices which have the HOLD feature on DQ3 usually need another dedicated pin for hardware reset and ones without HOLD feature usually have alternative reset on DQ3 what makes the additional reset pin being redundant. The controller supports both variants and reset selection register field (OSPI\_CONFIG\_REG[6] RESET\_CFG\_FLD) allows the user to configure which hardware reset solution is implemented in the device under usage.

After configuration is done, it is possible to trigger HOLD or RESET features using I/Os (OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD or OSPI\_CONFIG\_REG[5] RESET\_PIN\_FLD bits). After HOLD activation the controller is introduced into waiting state and any other operations should not be requested before de-asserting of HOLD configuration bit. The HOLD feature is useful when any SPI transaction needs to be prolonged in order to adjust it into specific point in time. Note that any HOLD trigger issued during active SPI transaction may be synchronized into reference clock domain at the time the SPI transfer turns to be finished. In this case, there is nothing to hold so the low level SPI logic will not activate HOLD on DQ3. To check if HOLD

request suspended the transfer OSPI\_CONFIG\_REG[31] IDLE\_FLD bit can be polled for. If SPI is not in the IDLE state, the transfer was successfully suspended. It is important for the software to take care of resetting OSPI\_CONFIG\_REG[4] HOLD\_PIN\_FLD bit before newly triggered SPI transaction. In case HOLD request is set before the beginning of the transfer it will be HOLD right after it starts what may not always be a goal. The hardware RESET needs to be activated when CS is high (no valid transaction is present on SPI bus). It can be checked by polling of OSPI\_CONFIG\_REG[31]. If the controller is in the IDLE state and no other transfer requests are queued to perform, the hardware RESET can be triggered. The RESET feature is useful when any write, program or erase operation needs to be cancelled. No transfer request is permitted before driving the reset back to being inactive. Triggering HOLD or RESET on DQ3 at the time the device is configured to work in Quad SPI mode or DDR will overwrite transfer data on DQ3 with '0'. This behavior is considered as a software error so it is advisable for the system to make sure that the flash device was introduced to suitable SPI mode (that is by polling its configuration register) before triggering alternative DQ3 function. There are four independent reset outputs implemented to separate between multiple devices connected to the controller (up to 4 are supported). The decision which reset output is to be activated after triggering OSPI\_CONFIG\_REG[5] RESET\_PIN\_FLD bit is made based on OSPI\_CONFIG\_REG[9] PERIPH\_SEL\_DEC\_FLD and OSPI\_CONFIG\_REG[13-10] PERIPH\_CS\_LINES\_FLD bits. Reset output OSPI\_ECC\_VECTOR is to be directly driven into corresponding dedicated RESET pins of the devices with separated RESET pin and alternatively, Reset output OSPI\_ECC\_VECTOR is to be control OSPI\_ECC\_VECTOR of the DQ3 RESET devices enabling separating of DQ3 Controller Outputs on SoC integration level.

The controller supports all combinations of CPHA and CPOL for Serial Clock. It allows the controller to support any SPI target devices not limited to Flash Memories. Multiple-SPI flash devices use just a subset of these combinations depending on the Transfer Mode as defined in [Table 12-302](#).

**Table 12-302. Flash SPI Modes**

(SEL_CLK_POL_FLD, SEL_CLK_PHASE_FLD)	Edge Mode	Support
0x00 (SPI MODE 0)	SDR	Yes
0x01 (SPI MODE 1)	SDR	No
0x10 (SPI MODE 2)	SDR	No
0x11 (SPI MODE 3)	SDR	No
0x00 (SPI MODE 0)	DDR	Yes
0x01 (SPI MODE 1)	DDR	No
0x10 (SPI MODE 2)	DDR	No
0x11 (SPI MODE 3)	DDR	No

#### 12.3.2.4.14 Selecting the Flash Instruction Type

In order to send the correct READ and WRITE opcodes, software should initialize the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers. These registers include fields to setup the required instruction opcodes that is intended to be used to access the FLASH (default is basic READ and basic page program) as well as the instruction type, edge mode (DDR or SDR) and whether the instruction uses single, dual, quad or octal pins for address and data transfer. Providing this level of control to the user provides a future proofed generic solution. To ensure the controller can operate from a reset state, the registers will be reset to an opcode compatible with SIO devices what can be modified using BOOT feature.

Despite being applicable for both READs and WRITEs, the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[9-8] INSTR\_TYPE\_FLD field only appears once – it is not included in the OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG register. If software sets this to anything other than '0', then the address transfer type and the data transfer type bits of both OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers become don't care. It is made available to allow software to support the less common FLASH instructions where the opcode, address and data are sent on 2 or 4 lanes (the opcode from most instructions are sent serially to the FLASH device, even for dual/quad instructions).

There are devices capable of handling Read Operations in Dual Data Rate Mode (DDR) (it is also called Dual Transfer Rate Mode (DTR)). That means they can issue and capture the data on both rising and falling edges during working with dedicated command type. This enables the controller to maintain throughput at twice lower frequency of OSPI clock. The Device Read Instruction Register has DDR enable bit which informs Octal-SPI Flash Controller that opcode written into Read Opcode field is capable with DDR command type. The other field defined in OSPI\_RD\_DATA\_CAPTURE\_REG[19-16] DDR\_READ\_DELAY\_FLD which enables the controller to shift the transmitted data in DDR mode. By default, data are shifted by 1 clock cycle to ensure hold timing greater than 0 during DDR transactions. It may not be sufficient for high reference clock frequency in accordance with the high dividers.

Table 12-303 shows how software should configure the OSPI module for selected specific READ and WRITE instruction supported by the abovementioned device.

**Table 12-303. READ and WRITE Instruction Configuration**

READ							
OPCODE	OPCODE sent over how many lanes / edge mode?	ADDRESS / DUMMY / MODE sent over how many lanes / edge mode?	DATA bytes sent over how many lanes / edge mode?	Instruction Type (OSPI_DEV_INSTR_RD_CONFIG_REG[9-8] INSTR_TYPE_FLD)	Address transfer type (OSPI_DEV_INSTR_RD_CONFIG_REG[13-12] ADDR_XFER_TYPE_STD_MODE_FLD)	Data transfer type (OSPI_DEV_INSTR_RD_CONFIG_REG[17-16] DATA_XFER_TYPE_EXT_MODE_FLD)	DDR bit enable (OSPI_DEV_INSTR_RD_CONFIG_REG[10] DDR_EN_FLD)
READ	1/SDR	1/SDR	1/SDR	0	0	0	0

**Note**

This data are applicable for both 3-byte or 4-byte address variants of the commands if did not indicate otherwise.

### Note

In DTR protocol all transfer phases (including opcode) take DDR edge mode independently on the command under execution. DTR protocol is to be enabled by OSPI\_CONFIG\_REG[24] ENABLE\_DTR\_PROTOCOL\_FLD bit. It has higher priority than DDR Mode enable bit from OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[10] DDR\_EN\_FLD.

#### 12.3.2.4.15 OSPI Data Integrity

The CRC aware SPI transfer can be performed when both controller and device are configured to work in the Octal DDR Protocol.

For write transactions (the controller transmits data throughout all transfer), the controller is responsible for sending address CRC byte (XOR of all address bytes) following address bytes and TX data CRC byte (XOR of all data bytes to write) following data chunk with size as defined in OSPI\_MODE\_BIT\_CONFIG\_REG[10-8] CHUNK\_SIZE\_FLD bit field. All CRC data are being calculated and sent automatically by the controller and the external device is responsible for reacting accordingly on any possible interpolation on the Flash interface. For read transactions, the controller is also responsible for sending address CRC byte (like for write) and for getting and progressing RX data CRC byte returning by the Flash Device after each chunk with size as defined in OSPI\_MODE\_BIT\_CONFIG\_REG[10-8] CHUNK\_SIZE\_FLD bit field. At the time when the Flash Device is returning data back to the controller, the controller dynamically calculates checksum byte by byte. Once the chunk is completed, CRC returned from Flash Device should fit to dynamically calculated CRC by the controller. In case of any deviation, controller reports CRC error to the system by corresponding interrupt (CRC error interrupt). The controller also provides the last captured CRC data in RX data chunk (defined in OSPI\_MODE\_BIT\_CONFIG\_REG[31-24] RX\_CRC\_DATA\_LOW\_FLD and OSPI\_MODE\_BIT\_CONFIG\_REG[23-16] RX\_CRC\_DATA\_UP\_FLD bit fields) to give the software driver the opportunity to further detecting any data corruption on system interfaces. The CRC data valid interrupt informs the system about the accessibility of the new RX CRC data in the registers. Once the system gets the full data word, it can calculate CRC by itself. At the time it collects all data words in chunk and then gets the CRC data valid interrupt, it can compare these data and react accordingly.

Some devices also have embedded ECC mechanism allowing them to report data abnormal conditions on their ECC Correction Signal output. At the time this output turns low, the device expect the OSPI controller to read status register of the device in order to get more details about the source of detected abnormal situation. The OSPI controller investigates ECC status on its ECC\_FAIL input and generates an interrupt when detecting this signal being low.

#### 12.3.2.4.16 OSPI PHY Module

OSPI module fully integrates PHY module dedicated to more flexible and power efficient transfers.

The PHY module communicates with the OSPI Flash controller via the aforementioned PHY Interface and handles data transfer on low-level stage of design hierarchy. However, when the OSPI\_RCLK is configured to be equal to the SPI clock instead of alternative approach using clock divider, there is just one OSPI\_RCLK cycle (not 4 or more) within single SPI period or half period for DDR Mode (SPI Control Module works on reference clock). Given that OSPI\_RCLK is the input clock for RX FIFO and the output one for TX FIFO, the PHY solution incurs more restrictive requirement for value of system clock in order to synchronize data without SPI transfer interruption. For example, when the controller operates in DDR 1× octal Mode, 2 bytes of data (equivalent to one RX FIFO location) is gathered within just single OSPI\_RCLK cycle. The controller cannot predict next data access while operating in the Direct Mode (meaning its size or whether it is sequential to the previous one or not). As a result, if the OSPI\_HCLK is not significantly greater than OSPI\_RCLK, the SPI transfer has to be suspended until the Flash Command Generator forwards new data to TX FIFO.

An optional PHY Pipeline Mode is implemented to avoid the necessity of stable clocking of the system clock for the Direct Mode when the PHY mode is enabled and to keep maximum performance while ensuring correct operation of the OSPI controller with the PHY using low frequencies from all its domains. This mode is a trade-off between large software overhead when operating in the Indirect Mode and the described limitations

present in the Direct Mode. For more information about PHY Pipeline Mode, see [Section 12.3.2.4.16.1, PHY Pipeline Mode](#).

When DDR 2× Mode is granted based on configuration – SPI transfer is automatically performed using the PHY module even if the OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD is de-asserted. SDR 2× commands are handled with PHY module paths being bypassed. Nevertheless, dividers of 2, 4 or 6 for DDR and divider of 2 for SDR should not be configured based on controller requirements and these configurations are perceived as a software error.

The following steps are an example of software algorithm of adapting the OSPI controller with the PHY module incorporated to work in octal 1× clock DDR Protocol. Note that all necessary configuration steps described in [Section 12.3.2.5.2, Configuring the OSPI Controller for Optimal Use](#) shall be completed before the algorithm.

1. Set PHY mode enable (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD bit) and DDR protocol (OSPI\_CONFIG\_REG[24] ENABLE\_DTR\_PROTOCOL\_FLD bit). It is assumed that device is configured to work in DDR Protocol.
2. Before setting the DLL parameters, software calibration could be needed.  
OSPI\_PHY\_MASTER\_CONTROL\_REG[23] PHY\_MASTER\_BYPASS\_MODE\_FLD bit controls the bypass mode of the controller and target DLLs. If this bit is set, the DLL bypass mode is enabled. This mode is intended to be used only for debug. When set to 0, a Controller operational mode is selected, when set to 1 the Bypass mode is selected.

DLL works in normal mode of operation where the target delay line settings are used as fractional delay of the controller delay line encoder reading of the number of delays in one cycle.

Controller DLL is disabled with only 1 delay element in its delay line. The target delay lines decode delays in absolute delay elements rather than as fractional delays.

- DLL Bypass Mode (follow only if operating in this mode):
  - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD bit field.
  - Re-synchronize DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set PHY bypass mode enable through OSPI\_PHY\_MASTER\_CONTROL\_REG[23] PHY\_MASTER\_BYPASS\_MODE\_FLD bit.
- DLL Controller Mode (follow only if operating in this mode):
  - Drive DLL reset bit OSPI\_PHY\_CONFIGURATION\_REG[30] PHY\_CONFIG\_RESET\_FLD into low.
  - Calculate initial delay value for the Controller DLL according to the OSPI\_PHY\_MASTER\_CONTROL\_REG[6-0] PHY\_MASTER\_INITIAL\_DELAY\_FLD bit field.
  - Depending on frequency of reference clock, calculate how many delay elements should be used to shift this clock by 25% of its period (best case for DDR transfers from setup/hold timings standpoint). Note that delay could be slightly different in a real design. TX Delay is configured in OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD bit field.
  - Re-synchronize DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set DLL reset bit back to high (since both bits are within the same register, it is acceptable to set both bits simultaneously).
  - Poll OSPI\_DLL\_OBSERVABLE\_LOWER\_REG[15] DLL\_OBSERVABLE\_LOWER\_LOOPBACK\_LOCK\_FLD bit. When set – lock is done.
  - Re-synchronize Target DLLs by asserting OSPI\_PHY\_CONFIGURATION\_REG[31] PHY\_CONFIG\_RESYNC\_FLD bit (If this bit is already set by previous re-synchronization, toggle sequence from "0" to "1" must be generated in order to trigger re-synchronization DLL logic) and set TX DLL Delay (OSPI\_PHY\_CONFIGURATION\_REG[22-16] PHY\_CONFIG\_TX\_DLL\_DELAY\_FLD)

- and RX DLL Delay (OSPI\_PHY\_CONFIGURATION\_REG[6-0] PHY\_CONFIG\_RX\_DLL\_DELAY\_FLD) fields which are equivalent to percentage clock offsets now. It is recommended to wait for the new configuration being propagated by 20 reference clock cycles before triggering the next SPI transfer.
- Consider Read Data from location where its value is predictable. This step can be performed in different ways, depending on the device. Parameter Page, ID, Status, Data from OTP region or Data from location of Flash Array the value of which is known can act as the pattern.
  - Trigger Read request chosen from above options.
  - Check correctness of data and store that information:
    - Increment value of RX clock delay – it is configurable in the OSPI\_PHY\_CONFIGURATION\_REG[6-0] PHY\_CONFIG\_RX\_DLL\_DELAY\_FLD bit field.
    - Re-synchronize DLLs.
    - Trigger valid Read request.
    - Check correctness of data and store information.
    - If range boundary of RX clock delay is achieved, go to step 3. Otherwise go back to step "Increment value of RX clock delay".
  - 3. Set RX clock delay value for one from the middle of valid range based on information in storage.
  - 4. Re-synchronize DLLs.
  - 5. Set OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG for Octal Read DDR Configuration (each transfer phase should be configured to work in Octal mode, Number of Dummy cycles should be set as specified in the documentation of the device or more when because of additional read paths delays of actual systems data is predicted to be flopped by PHY module with delay excesses actual cycle of SPI clock generated by the controller).
  - 6. Enable Pipeline mode in the OSPI\_CONFIG\_REG[25] PIPELINE\_PHY\_FLD bit.
  - 7. Perform Sequential Read of Data consistent with conditions indicated within [Section 12.3.2.4.16.1, PHY Pipeline Mode](#).
  - 8. After de-asserting the data target select signal by software – poll OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.
  - 9. When it is asserted to high – next transfer request can be triggered.

#### 12.3.2.4.16.1 PHY Pipeline Mode

This mode is used for Direct Read Mode of operation. If any other operations are intended to be executed, it is recommended to disable PHY Pipeline Mode and re-enable for subsequent Direct Reads in PHY mode. Since there is comprehensive software mechanism controlling Read data transfers in Indirect Mode, pipeline of data interface accesses is not effective for this mode. Enable PHY Pipeline feature when at least four 4-byte-sized data words are predicted to be read in sequentially. The Flash Command Generator pipelines and puts them into TX FIFO which causes CS to remain active because low level SPI protocol controller controls TX FIFO fill level. In order to correctly trigger Direct Read in Pipeline Mode TX FIFO must be empty. Therefore first polling of OSPI\_CONFIG\_REG[31] IDLE\_FLD bit needs to be done. The sequential data transfer will be interrupted when the data target select signal of the data interface is asserted to low. This information is also detected by Data Target Module which informs the Flash Command Generator that the next access is invalid and a TX FIFO locations can be flushed transparently for the system.

In PHY Pipeline Mode it is recommended for Data Controller not to introduce wait states in between consecutive occurrences of the data interface signal that indicates transfer has finished. It will ensure regular transfer rate on data side. Introducing wait states gradually slows data transfer rate down and may finally cause SPI transfer interruption because of TX FIFO data starvation. The system, however, may need to introduce some number of wait states after completion of sequential transfer (composed of 4-byte sized data words) for progressing the data. The dedicated buffer is implemented in Data Target Controller which collects all incoming data during wait states injection. In order to keep SPI transfer uninterrupted, number of wait states should be as little as possible. The higher the OSPI\_HCLK/ OSPI\_RCLK ratio the more wait states can be introduced without SPI transfer interruption. In case the system is able to launch a new transfer before wait states overflow, buffered data transfer to the host will continue. It compensates slowed down transfer by introducing wait states. In case the system is not able to launch a new transfer before wait states overflow, next incoming transfer is considered non-sequential and is executed after all pipelined data is flushed.

This mode can be enabled when following conditions are met:

- OSPI\_HCLK > OSPI\_RCLK (Comparing the slow data clock with the fast reference one makes Pipeline Mode ineffective – Suspend of SPI Transfer would be possible. Consequently, this condition has to be met to operate in this mode.)
- Only 4-byte sized Data Words are permitted (This ensures more data clock cycles for synchronization of FIFOs between consecutive pulses of the signal indicating transfer has finished.)
- The transfer with introduced wait states or non-sequential transfers can only be triggered in between at least four 4-byte sized Data Bursts sequential accesses (16 Bytes) to be sure that Data Controller can trust buffered incoming data during wait states injection.
- Do not use Pipeline Mode along with Continuous Mode (XIP). Benefit of XIP is limited for bulk data transfers intended to execute in Pipeline Mode.

#### **12.3.2.4.16.2 Read Data Capturing by the PHY Module**

Read Data Capturing by the PHY module is useful, as the user is not responsible for the design dedicated DLL being compatible with the Octal-SPI Flash Controller. Another benefit is an option to adjust both SPI clock and sampling clock in a very wide range to fit them into individual requirements of any system. If loopback clock (OSPI\_RD\_DATA\_CAPTURE\_REG[0] BYPASS\_FLD) and PHY mode (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the loopback clock is driven into RX DLL instead of gated reference clock. Because of the architecture of DLL, loopback clock needs to be provided in SPI Mode 0. If DQS (OSPI\_RD\_DATA\_CAPTURE\_REG[8] DQS\_ENABLE\_FLD) and PHY mode (OSPI\_CONFIG\_REG[3] PHY\_MODE\_ENABLE\_FLD) are both enabled, the DQS is driven into RX DLL instead of gated reference clock.

### 12.3.2.5 OSPI Programming Guide

#### 12.3.2.5.1 Configuring the OSPI Controller for Use After Reset

The OSPI controller has been designed to wake up in a state that is suitable for performing basic reads and writes using the direct access controller. The BASIC read (opcode 0x03) and BASIC write (opcode 0x02) instructions are operations supported by all target devices. The controller also wakes up with a baud rate divider setting of divide-by-32. Assuming the reference clock is operating at 400 MHz after reset, then this means the effective SPI clock is just 12.5 MHz. This should be slow enough to meet all timing requirements of all target devices without any further device programming.

If the target device does not use 3 address bytes, the device size configuration register must be modified to the appropriate size.

If software plans to write to the device, and the number of bytes per device page is not equal to 256, then the device size configuration register must also be modified.

While not a requirement, it is prudent for software to enable the write protect feature prior to enabling the OSPI controller. This will block any data writes from taking effect. To do so, the protection registers (OSPI\_LOWER\_WR\_PROT\_REG, OSPI\_UPPER\_WR\_PROT\_REG and OSPI\_WR\_PROT\_CTRL\_REG) should be setup and the number of bytes per device block in the device size configuration register should also be setup.

After Power-on Reset (POR), software can read from and write to the FLASH device (albeit slowly). Enabling/Disabling the controller and DAC is achieved with just one write to corresponding fields of the OSPI\_CONFIG\_REG register. User shall take note to maintain the default values of the baud rate divisor and the default state of SEL\_CLK\_POL\_FLD/ SEL\_CLK\_PHASE\_FLD bits of this register. A write data value of 0x00780081 is recommended.

#### 12.3.2.5.2 Configuring the OSPI Controller for Optimal Use

##### Note

When using the OSPI Controller, the opcodes in OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[7-0] RD\_OPCODE\_NON\_XIP\_FLD, OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG[7-0] WR\_OPCODE\_FLD and OSPI\_WRITE\_COMPLETION\_CTRL\_REG[7-0] OPCODE\_FLD bit fields shall not match the opcode in the OSPI\_FLASH\_CMD\_CTRL\_REG[31-24] CMD\_OPCODE\_FLD bit field.

For high speed transfers PHY mode can be enabled and for optimal configuration PHY Pipeline mode is recommended. For more information, see [Section 12.3.2.4.16.1, PHY Pipeline Mode](#).

To access the flash optimally, software must configure the controller accurately:

1. Wait until any pending STIG or INDAC operation has completed or poll OSPI\_CONFIG\_REG[31] IDLE\_FLD bit.
2. Disable the DAC through OSPI\_CONFIG\_REG[7] ENB\_DIR\_ACC\_CTLR\_FLD bit. It is permitted, but not necessary to also disable the OSPI controller completely via OSPI\_CONFIG\_REG[0] ENB\_SPI\_FLD bit.
3. Update the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG and OSPI\_DEV\_INSTR\_WR\_CONFIG\_REG registers for the instruction type you wish to use for indirect and direct writes and reads.
4. Update the OSPI\_MODE\_BIT\_CONFIG\_REG[7-0] MODE\_FLD bit field if mode bits have been enabled in the OSPI\_DEV\_INSTR\_RD\_CONFIG\_REG[20] MODE\_BIT\_ENABLE\_FLD bit.
5. Update the OSPI\_DEV\_SIZE\_CONFIG\_REG if the contents are incorrect. Note parts or all of this register may have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used. If the default values are correct for the target device, or if some of the values (not including the number address bytes) were incorrect but device writes were not permitted.
6. Update the OSPI\_DEV\_DELAY\_REG. This register allows the user to tweak how the chip select is driven after each FLASH access. This is required as each device may have different timing requirements. As

the serial clock frequency is increased, these timing requirements become more important. Note the numbers programmed in this register are based on the period of reference clock. Example: A device needs 50ns minimum time before CS can be re-asserted after it has been de-asserted. By default, the controller will only provide a minimum of 1 SCLK period. When the device is operating at 100 MHz, the SCLK period is only 10ns, so 40ns extra is required. Since the register defines the number of reference clock cycles to add, and reference clock is running at 400 MHz (2.5ns period), then the user should program a value of at least 16 to the OSPI\_DEV\_DELAY\_REG[31-24] D\_NSS\_FLD. This delay can be extended during auto-polling phase. There is possibility to define the polling repetition delay in the OSPI\_WRITE\_COMPLETION\_CTRL\_REG[31-24] POLL\_REP\_DELAY\_FLD bit field.

7. Update the OSPI\_REMAP\_ADDR\_REG register, if required. Affects DAC path only.
8. Setup and enable write protection registers (OSPI\_LOWER\_WR\_PROT\_REG, OSPI\_UPPER\_WR\_PROT\_REG and OSPI\_WR\_PROT\_CTRL\_REG) if they are required and if they have not already been setup from post initialization.
9. Enable required interrupts via the OSPI\_IRQ\_MASK\_REG register.
10. Setup the baud rate divisor in the OSPI\_CONFIG\_REG[22-19] MSTR\_BAUD\_DIV\_FLD to define the required clock frequency of the target device.
11. Update the OSPI\_RD\_DATA\_CAPTURE\_REG register. This register will delay when the read data is captured and can help when the read data path from the device to the controller is long and the device clock frequency is high. An update to this register may not be necessary.
12. Enable the OSPI controller and the DAC via the OSPI\_CONFIG\_REG.

#### 12.3.2.5.3 Using the Flash Command Control Register (STIG Operation)

The OSPI\_FLASH\_CMD\_CTRL\_REG register provides software means to access the FLASH device in a flexible and programmable manner. This is known as a STIG operation (Software Triggered Instruction Generator). The instruction opcode, number of address bytes (if any), the address itself, number of dummy cycles (if any), number of write data bytes (if any), the write data itself and the number of read data bytes (if any) can be programmed. Once these have been programmed, software can trigger the command via OSPI\_FLASH\_CMD\_CTRL\_REG[0] CMD\_EXEC\_FLD bit and wait for its acceptance by polling OSPI\_FLASH\_CMD\_CTRL\_REG[1] CMD\_EXEC\_STATUS\_FLD bit. When CMD\_EXEC\_STATUS\_FLD bit turns de-asserted, another STIG can be triggered. This method of accessing the FLASH is the typical mechanism that software would use to access the FLASH device's registers, as well as for performing ERASE operations. It can also be used to access the FLASH array itself, although the maximum of 8 data bytes may be read or written at any one time, defined in the Flash Command Write and Read Data registers (OSPI\_FLASH\_RD\_DATA\_LOWER\_REG, OSPI\_FLASH\_RD\_DATA\_UPPER\_REG, OSPI\_FLASH\_WR\_DATA\_LOWER\_REG and OSPI\_FLASH\_WR\_DATA\_UPPER\_REG). This number of bytes can be extended for Read Data commands using additional STIG Memory Bank controlled by OSPI\_FLASH\_CMD\_CTRL\_REG[2] STIG\_MEM\_BANK\_EN\_FLD and OSPI\_FLASH\_COMMAND\_CTRL\_MEM\_REG.

Commands issued using this interface have a higher priority than all other READ accesses coming from data interface, and will therefore interrupt any READ commands being requested by the indirect or direct controllers.

#### 12.3.2.5.4 Using SPI Legacy Mode

SPI legacy mode allows software to access the internal TX-FIFO and RX-FIFO directly, thus bypassing the direct, indirect and STIG controllers.

Legacy mode allows the user to issue any FLASH instruction to the device, but does place a heavy software overhead in order to manage the fill levels of the FIFO's effectively. This is because the legacy SPI core is bi-directional in nature, with data continuously being transferred in either direction while the chip select is enabled. Even if the driver only wishes to read data from the FLASH device, dummy data must be written out to ensure the chip select stays active, and vice versa for write transactions.

Since the TX-FIFO and RX-FIFO are of limited depth, software has a responsibility to maintain the FIFO levels to ensure the TX-FIFO does not become exhausted during the instruction execution and the RX-FIFO doesn't overflow. This can place a lot of overhead on software. Interrupts are provided to indicate when the fill levels

pass programmable watermarks, which are themselves programmable registers `OSPI_TX_THRESH_REG` and `OSPI_RX_THRESH_REG`.

The limited depth may impose the limitation over execution of some specific SPI commands in legacy mode. Note that the controller interprets all transmitted bytes as valid. For example, if the Flash Device was configured to return valid data after many dummy cycles, the TX FIFO could become full before the controller sends all of dummy data.

#### **12.3.2.5.5 Entering XIP Mode from POR**

XIP is a mode that can be entered in a non-volatile way if the device has XIP enabled as a non-volatile configuration setting. Software will not be able to discover the state of XIP from POR via FLASH status register reads as the only operation a FLASH device will recognize when XIP mode is enabled is an XIP read operation.

If it is already known that the device will enter XIP from POR, then the `OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD` and `OSPI_CONFIG_REG[18] ENTER_XIP_MODE_IMM_FLD` bits should be set in initial boot.

If it is not already known that the device will enter XIP from POR, and XIP from POR may be supported by the attached FLASH device, then software can attempt to exit XIP mode by issuing an XIP exit command using a STIG command (via the `OSPI_FLASH_CMD_CTRL_REG` register). To do this, software must be aware of the mode bit requirements of that device, as XIP entry and exit changes per device.

#### **12.3.2.5.6 Entering XIP Mode Otherwise**

XIP mode is supported in most FLASH devices. Some of them use signature bits that are sent to the device immediately following the address bytes, other use signature bits and also require a FLASH device configuration register write to enable XIP. For the FLASH devices that must be compliant to the OSPI controller, the following steps can be taken by software to enter XIP mode:

1. Disable the DAC and INDAC (`OSPI_CONFIG_REG[7] ENB_DIR_ACC_CTLR_FLD`) to ensure no new data read accesses will be sent to the FLASH device.
2. (Optional) Configure the `OSPI_FLASH_CMD_CTRL_REG` to issue a VCR write to FLASH memory, because XIP mode must first be enabled for some devices.
3. Configure the XIP mode bits in the `OSPI_MODE_BIT_CONFIG_REG[7-0] MODE_FLD` bit field.
4. Enable the local controllers XIP mode by setting `OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD` bit.
5. Re-enable the DAC and, if required, the INDAC.

#### **12.3.2.5.7 Exiting XIP Mode**

To exit XIP mode, software should first disable the DAC and INDAC to ensure no new data read accesses will be sent to the FLASH device. It should then set mode bits to other than the established in the corresponding Flash Device specifications. These are dependent on the FLASH device and manufacturer. Software should then reset `OSPI_CONFIG_REG[17] ENTER_XIP_MODE_FLD`.

Note the FLASH device must see a READ instruction before it can disable its internal XIP mode state, so this means XIP mode will internally stay active until the next READ instruction is serviced. User must take care to ensure that XIP mode is disabled before the end of any READ sequence.

### 12.3.3 HyperBus Interface

This section describes the HyperBus module in the device.

#### 12.3.3.1 HyperBus Overview

The HyperBus module is a part of the device Flash Subsystem (FSS). For more information about FSS, see [Section 12.3.1, Flash Subsystem \(FSS\)](#).

The HyperBus module is a low pin count memory interface that provides high read/write performance. The HyperBus module connects to HyperBus memory (HyperFlash or HyperRAM) and uses simple HyperBus protocol for read and write transactions.

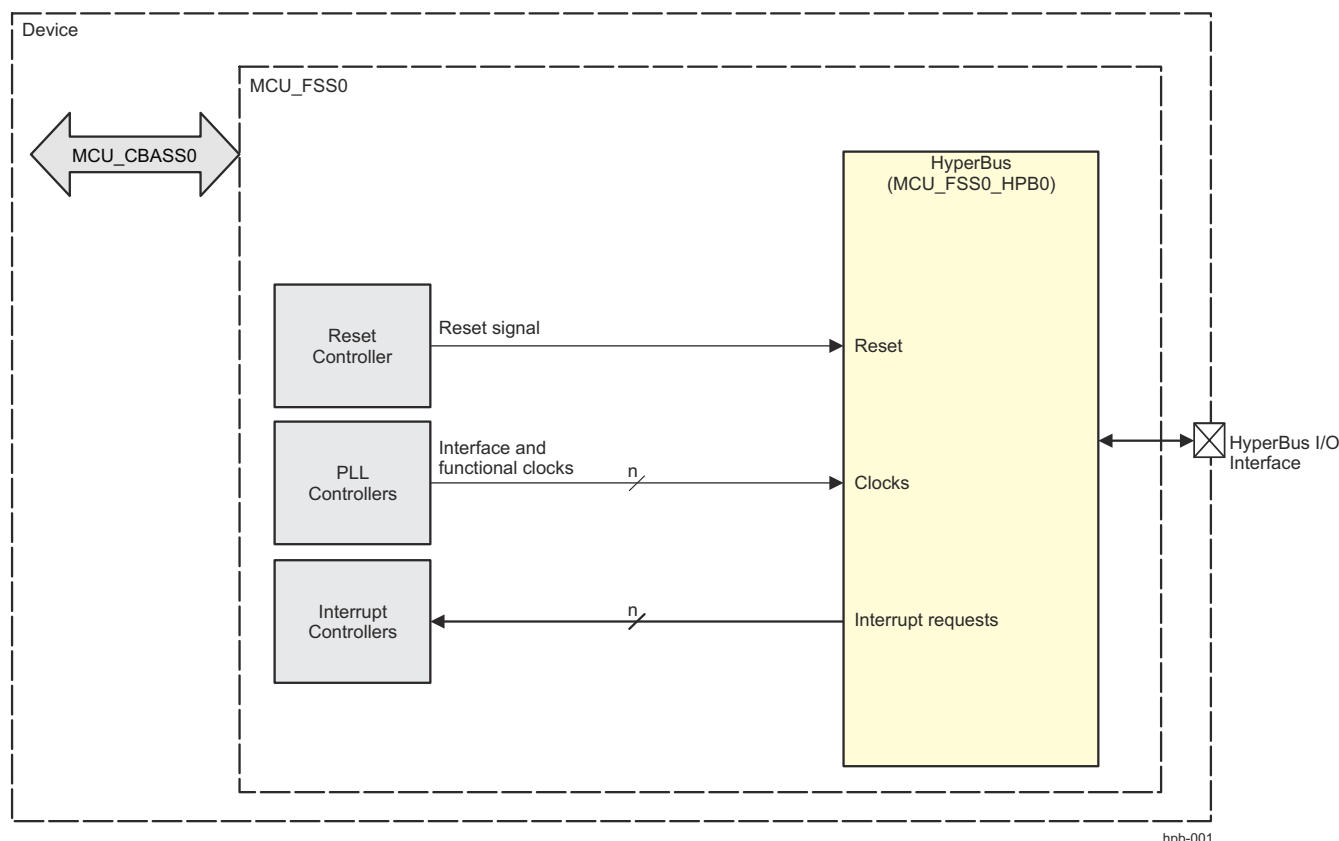

There is one HyperBus™ module inside the device. The HyperBus module includes one HyperBus Memory Controller (HBMC).

[Table 12-304](#) shows HyperBus allocation across device domains.

**Table 12-304. HyperBus Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_FSS0_HPBO	-	✓	-

[Figure 12-227](#) shows the HyperBus module overview.

**Figure 12-227. HyperBus Module Overview**

#### 12.3.3.1.1 HyperBus Features

- Support for Cypress® HyperFlash and HyperRAM
- Up to 166 MHz maximum memory bus operation for reads

- Supports up to 166 MHz dual data rate (333 MBps) flash devices for system requiring rapid boot or instant-on displays
- Supports up to 333 MBps external pseudo-RAM (HyperRAM) for systems

**Note:** For more information, see section Timing and Switching Characteristics in the device-specific Datasheet.

- Low pin count interface with LVCMOS I/O pins (can be muxed with other FSS interfaces (OSPIS))
- Two memory chip selects
- Linear incrementing mode for reads and writes
- Up to 16 outstanding read transactions (see [Section 12.3.3.4.5](#), *HyperBus True Continuous Read (TCR) Mode*)
- Asynchronous bus clock

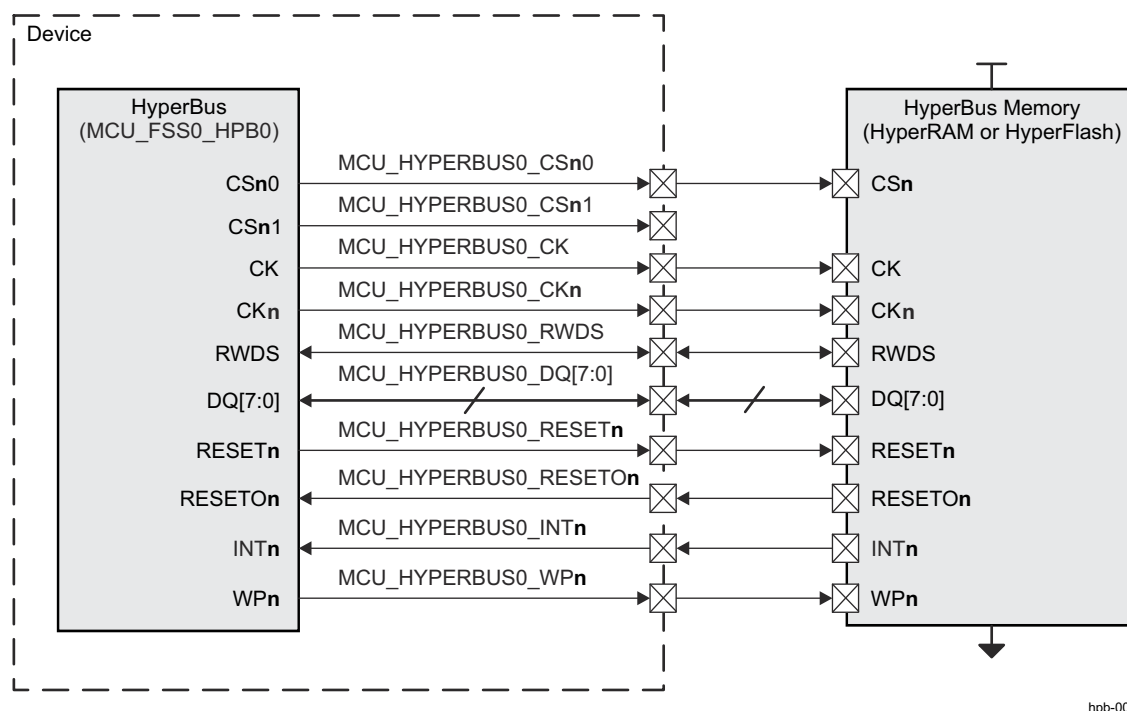

#### **12.3.3.1.2 HyperBus Not Supported Features**

- Cache-line wrap and fixed address modes for reads or writes
- General Purpose Output register (MCU\_FSS0\_HPBO\_MC\_GPOR) of the HBMC is not used

### 12.3.3.2 HyperBus Environment

This section describes the HyperBus external connections (environment).

Figure 12-228 shows the HyperBus connected to HyperRAM or HyperFlash.

**Figure 12-228. HyperBus Connected to HyperRAM or HyperFlash**

Table 12-305 describes the HyperBus I/O signals.

**Table 12-305. HyperBus I/O Signals**

Module Pin	Device Level Signal <sup>(1)</sup>	I/O <sup>(2)</sup>	Description	Module Pin Reset Value
<b>MCU_FSS0_HPB0</b>				
CK	MCU_HYPERBUS0_CK	O	HyperBus Clock Output (differential)	0x0
CKn	MCU_HYPERBUS0_CKn	O	HyperBus Inverted Clock Output (differential)	0x1
RWDS	MCU_HYPERBUS0_RWDS	I/O/HiZ	HyperBus Read/Write Data Strobe	0x1

RESETn	MCU_HYPERBUS0_RESETn	O	HyperBus Reset Output	0x1
RESETOn	MCU_HYPERBUS0_RESETOn	I	Reset State Indicator (output from HyperBus memory)	0x1
INTn	MCU_HYPERBUS0_INTn	I	Memory Interrupt (output from HyperBus memory)	0x1
WPn <sup>(3)</sup>	MCU_HYPERBUS0_WPn	O	HyperBus Write Protect (output to HyperBus memory)	0x1

(1) n - Active Low

(2) I = Input; O = Output; HiZ = High Impedance

(3) WPn pin is not used on Cypress flash devices.

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

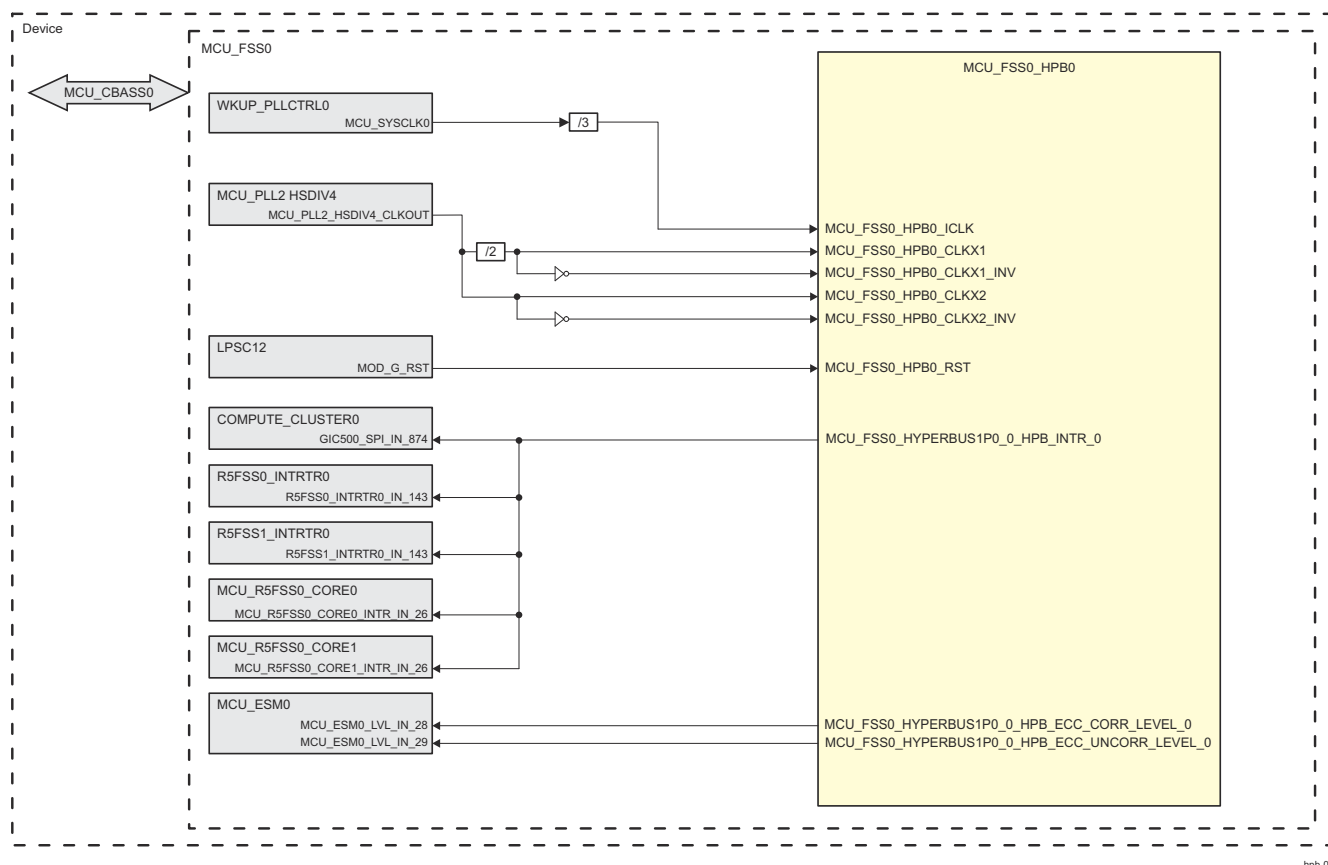

---

### 12.3.3.3 HyperBus Integration

This section describes the HyperBus integration in the device, including information about clocks, resets, and hardware requests.

#### 12.3.3.3.1 HyperBus Integration in MCU Domain

There is one HyperBus module integrated in the device MCU domain - MCU\_FSS0\_HPBO. Figure 12-229 shows the integration of MCU\_FSS0\_HPBO.

**Figure 12-229. MCU\_FSS0\_HPBO Integration**

Table 12-306 through Table 12-308 summarize the integration of MCU\_FSS0\_HPBO in the device MCU domain.

**Table 12-306. MCU\_FSS0\_HPBO Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

### 12.3.3.4 HyperBus Functional Description

The HyperBus module is a high throughput memory interface. It is a part of the device FSS and provides execute in place (XIP) operation and block copy access to HyperBus memory devices (HyperRAM and HyperFlash). The FSS enables in-line ECC protection and authentication features for the HyperBus module.

For more information about FSS, see *Flash Subsystem (FSS)*.

The HyperBus module is compliant to the *Cypress HyperBus™ Specification v1.2*.

Figure 12-230 shows the HyperBus module block diagram.

**Figure 12-230. HyperBus Module Block Diagram**

Basic Blocks:

- HBMC: The HyperBus Memory Controller (HBMC) is the main part (the core) of the HyperBus Subsystem and provides accessibility to external HyperBus memory (HyperFlash or HyperRAM) using simple HyperBus protocol for data read and write transfers.
  - The Data Port on the HBMC is used for CBASS data slave interface to access the external HyperBus memory.
  - The CFG Port on the HBMC is used for configuration of the HBMC registers.
- HyperBus I/O Interface: The HyperBus I/O Interface includes all used interface pins (for more information, see *HyperBus I/O Signals*).
- Memory IF: The Memory IF block implements the following functionality:
  - Convert single-rate command and data output from the HBMC to double-rate (DDR)
  - Use DLL to delay the incoming read data strobe from the memory
- FIFO Memories with ECC: There are internal HyperBus FIFOs implemented with memories that are used during read and write transactions. These FIFO memories are ECC protected (for more information about the FIFOs, see [Section 12.3.3.4.3, HyperBus Internal FIFOs](#)).
- ECC Aggregator: The ECC Aggregator facilitates aggregating and reporting internal HyperBus FIFO memory errors (for more information, see [Section 12.3.3.4.2, HyperBus ECC Support](#)).
- HBMC Registers: This block includes set of all used HBMC registers.
- HyperBus Subsystem Registers: This block implements memory-mapped registers at the HyperBus Subsystem level.
- ECC Aggregator Registers: This block includes all used ECC Aggregator registers.

For more information about all HyperBus registers, see *HyperBus Registers*.

- MCU\_CBASS0: The MCU\_CBASS0 interconnect implements the clock domain crossing bridges needed to separate the two main clock domains: MCU\_CBASS0 clock domain and Memory clock domain.
- Data Slave IF: The Data Slave IF on the interconnect is a 32-bit wide interface and is used to access an external HyperBus memory via the Data Port on the HBMC. The data interface supports linear incrementing addresses only. Cache-line wrap and fixed addressing modes are not supported.
- Config Slave IF: The Config Slave IF on the interconnect is a 32-bit wide interface and is used to access the HBMC registers (via the CFG Port on the HBMC), HyperBus Subsystem registers, and ECC Aggregator registers. The config interface also supports linear incrementing address mode only.

For more information about supported and not supported HyperBus features, see *HyperBus Overview*.

- Clocks: For more information about HyperBus Clocks, see *MCU\_FSS0\_HBP0 Clocks and Resets*.
- Subsystem Reset: The reset signal to the Subsystem Reset block provides reset to the all HyperBus Subsystem parts (for more information about HyperBus Resets, see *MCU\_FSS0\_HBP0 Clocks and Resets*).
- Interrupts: For more information, see *MCU\_FSS0\_HBP0 Clocks and Resets* and *HyperBus Interrupts*.

#### 12.3.3.4.1 HyperBus Interrupts

The HyperBus module sources one active high level HyperBus interrupt and two active high level ECC Aggregator interrupts (see *MCU\_FSS0\_HBP0 Hardware Requests*).

The HyperBus interrupt is generated based on the HyperBus memory's active low level interrupt. In the HyperBus Subsystem this active low level interrupt is converted to active high level HyperBus interrupt (see RESETOn pin in *Hyperbus I/O Signals*).

The ECC Aggregator interrupts are generated based on the ECC errors (single (correctable) and double (uncorrectable) bit errors) in the embedded HyperBus memories (for more information, see *HyperBus ECC Support*).

#### 12.3.3.4.2 HyperBus ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

The embedded HyperBus memories are ECC protected.

#### 12.3.3.4.2.1 ECC Aggregator

##### Note

For more information about ECC Aggregator, refer to [Section 12.11.4, ECC Aggregator](#).

For more information about ECC Aggregator Registers, refer to *HyperBus Registers*.

#### 12.3.3.4.3 HyperBus Internal FIFOs

There are 10 FIFO buffers in the module that help improve performance. [Table 12-309](#) shows the HyperBus FIFOs details.

**Table 12-309. HyperBus FIFOs**

Buffer Name	Size (Width x Depth)
Address (ADR) FIFO	Two port RAM – 16 x 46-bit
Write data (WDAT) FIFO	Two port RAM – 256 x 40-bit
Write status (BDAT) FIFO	Two port RAM – 16 x 2-bit
Read data (RDAT) FIFO	Two port RAM – 128 x 40-bit
Receive (RX) FIFO	Two port RAM – 256 x 20-bit
Address write (AW) FIFO	Two port RAM – 16 x 44-bit
Write ID (WID) FIFO	Two port RAM – 16 x 2-bit
Address write ID (AWID) FIFO	Two port RAM – 16 x 14-bit
Address read (AR) FIFO	Two port RAM – 16 x 44-bit
Address read ID (ARID) FIFO	Two port RAM – 16 x 18-bit

#### 12.3.3.4.4 HyperBus Data Regions

For more information about HyperBus data regions, refer to [Section 12.3.1.4.7, FSS Memory Regions](#).

#### 12.3.3.4.5 HyperBus True Continuous Read (TCR) Mode

The HBMC supports True Continuous Read (TCR) operation for HyperFlash. This feature is able to improve HyperFlash read performance.

When this feature is enabled, the HBMC can merge multiple up to 16 max burst read commands that are present in its command FIFO into a single memory read transaction to the HyperFlash memory. As a result, the command input and initial latency for the latter burst read commands are saved, which leads to improved throughput.

### 12.3.3.5 HyperBus Programming Guide

#### 12.3.3.5.1 HyperBus Initialization Sequence

The HBMC provides two sets of Memory Base Address, Memory Configuration and Memory Timing registers to access devices connected to the two external chip selects. The following programming guidelines need to use the correct set of registers depending on which chip select is accessed.

The HBMC compares the input address bits [31-24] to the value programmed in the MCU\_FSS0\_HPB0\_MC\_MBAR\_y registers to determine the external chip select that is accessed.

##### 12.3.3.5.1.1 HyperFlash Access

**Table 12-310. HyperFlash Access Sequence**

Step	Description
1.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit .
2.	<p>Lock MDLL:</p> <ul style="list-style-type: none"> <li>- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPB0 Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.</li> <li>- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of Flash data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal Flash access .</li> <li>- The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .</li> </ul>
3.	<p>Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y):</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 1h, to enable HBMC to merge multiple accesses with sequential addresses into a single memory access. This will improve memory throughput.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h, to set 'Memory space' instead 'CR space'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 0h, to set 'HyperFlash' instead 'HyperRAM'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.</li> </ul>
4.	Initialize Memory Timing register (MCU_FSS0_HPB0_MC_MTR_y) based on timing of the memory device being used.
5.	<p>Initialize Memory Base Address register (MCU_FSS0_HPB0_MC_MBAR_y):</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MBAR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperFlash can be accessed. The HBMC will initiate HyperFlash access to any memory mapped access in this range.</li> </ul>
6.	Check the MCU_FSS0_HPB0_MC_CSR[10] RRSTOERR bit in Controller Status register to ensure that the HyperFlash is out of reset.
7.	Normal HyperFlash access can be performed after this.
8.	The HyperFlash device registers and CFI (Common Flash Interface) region can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table.
9.	The HyperFlash memory data array can be read as memory mapped access.
10.	The HyperFlash write sequence needs to be followed to update contents of the memory array.

### 12.3.3.5.1.2 HyperRAM Access

**Table 12-311. HyperRAM Access Sequence**

Step	Description
1.	Wait 150 $\mu$ s for RAM to power up after reset. The HyperRAM does not provide any feedback on reset/ready state to the HBMC .
2.	Ensure that the FIFO RAM auto-initialization is complete by reading the MCU_FSS0_HPB0_SS_RAM_STAT_REG[0] INIT_DONE bit .
3.	<p>Lock MDLL:</p> <ul style="list-style-type: none"> <li>- To ensure that the MDLL in the HyperBus is locked, the reset to the HyperBus module should be de-asserted only after all the clock inputs are stable at the desired operating frequency (see <i>MCU_FSS0_HPB0 Clocks and Resets</i>). The MDLL can lose the lock if the frequencies of the clock inputs to the HyperBus module are changed during operation.</li> <li>- To ensure that the MDLL is stabilized, the following sequence is required. Boot code should attempt to read 64 bytes of RAM data, for 16 iterations, and if the data is the same in 4 successive iterations, the DLL can be considered to be stabilized and the software proceed with normal RAM access .</li> <li>- The MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK and MCU_FSS0_HPB0_SS_DLL_STAT_REG[1] SDL_LOCK bits can be used to determine if the master delay line and slave delay line have locked, respectively .</li> </ul>
4.	<p>Initialize Memory Configuration register (MCU_FSS0_HPB0_MC_MCR_y):</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MCR_y[31] MAXEN bit and MCU_FSS0_HPB0_MC_MCR_y[26-18] MAXLEN bit field based on burst transaction length to memory.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[17] TCMO = 0h, since HBMC does not support command merging for HyperRAM accesses.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[16] ACS = 0h, to set 'No asymmetry cache system support'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[5] CRT = 0h or 1h, depending on what needs to be accessed (memory or register space).</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[4] DEVTYPE = 1h, to set 'HyperRAM' instead 'HyperFlash'.</li> <li>- MCU_FSS0_HPB0_MC_MCR_y[1-0] WRAPSIZE = 00h, since the HBMC does not support wrap bursts.</li> </ul>
5.	Initialize MCU_FSS0_HPB0_MC_MTR_y register based on timing of the memory device being used.
6.	<p>Initialize MCU_FSS0_HPB0_MC_MCR_y register:</p> <ul style="list-style-type: none"> <li>- MCU_FSS0_HPB0_MC_MCR_y[31-24] A_MSB = 8 MSB bits of memory address space. This will define the start of the 16 MB address region in the system memory where the HyperRAM can be accessed. The controller will initiate HyperRAM access to any memory mapped access in this range.</li> </ul>
7.	Check the MCU_FSS0_HPB0_SS_DLL_STAT_REG[0] MDLL_LOCK bit to ensure the Master DLL is locked.
8.	Normal HyperRAM access can be performed after this.
9.	The HyperRAM device registers can be accessed by read/write transactions to the offset from the base address as specified in the device command summary table with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to register space.
10.	The HyperRAM memory data array can be read/written to as memory mapped access with MCU_FSS0_HPB0_MC_MCR_y[5] CRT bit set to memory space.

#### Note

HyperRAM devices have a 150  $\mu$ s startup time. Software needs to wait this duration after reset to initiate transactions to a HyperRAM device.

### 12.3.3.5.2 HyperBus Real-time Operating Requirements

The HBMC may assert the memory interrupt based on the status of the memory transaction. Software needs to handle this interrupt using the MCU\_FSS0\_HPB0\_MC\_ISR register. The MCU\_FSS0\_HPB0\_MC\_ISR register can provide the status information to determine the cause of the interrupt.

#### **12.3.3.5.3 HyperBus Power Up/Down Sequence**

Software needs to ensure that there are no pending transactions before stopping clock and/or power to the HBMC.

### 12.3.4 General-Purpose Memory Controller (GPMC)

This section describes the General-Purpose Memory Controller (GPMC) for the device.

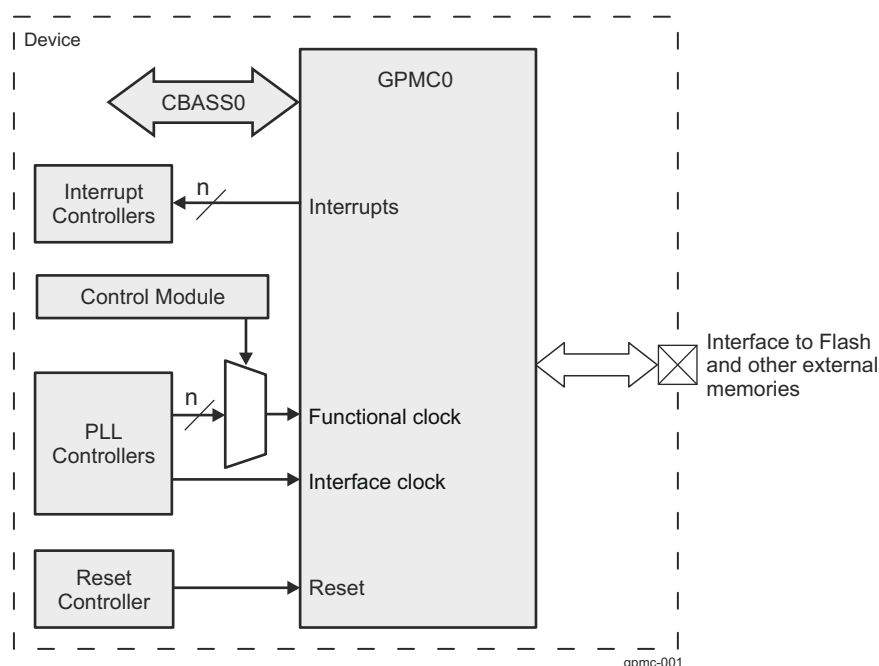

#### 12.3.4.1 GPMC Overview

The General-Purpose Memory Controller is a unified memory controller dedicated for interfacing with external memory devices like:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in non-multiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

shows the GPMC module allocation within device domains.

Figure 12-231 shows the GPMC0 module overview.

**Figure 12-231. GPMC0 Overview**

#### 12.3.4.1.1 GPMC Features

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to 4 chip select regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports on-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ( $t = 4, 8, \text{ or } 16$ ) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth usage
- The clock to the external memory is provided from GPMC\_FCLK divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters with a timing granularity of one GPMC\_FCLK clock cycle.

- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write-posting engine associated with DMA controller at system level to achieve full performance from the NAND device with minimum effect on NOR/SRAM concurrent access
- 32-bit interconnect slave interface which supports non-wrapping and wrapping burst of up to 16x32 bits.

The GPMC supports the following various access types:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8 and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8 and 16 Word16)
- Address-data-multiplexed (AD) access
- Address-address-data (AAD) multiplexed access
- Little-endian access only

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (non burst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit non-multiplexed NOR flash device
- External 16-bit address and data multiplexed NOR Flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

---

#### **Note**

Page mode is available only in non-multiplexed mode.

---

#### **12.3.4.1.2 GPMC Not Supported Features**

The following features are not supported on this family of devices:

- DMA mode is not supported.
- Asynchronous page write mode is not supported.
- Multiple write access in asynchronous mode is not supported.
- Multiple read access in asynchronous mode is not supported in address/data-multiplexed and AAD-multiplexed modes.

### 12.3.4.2 GPMC Environment

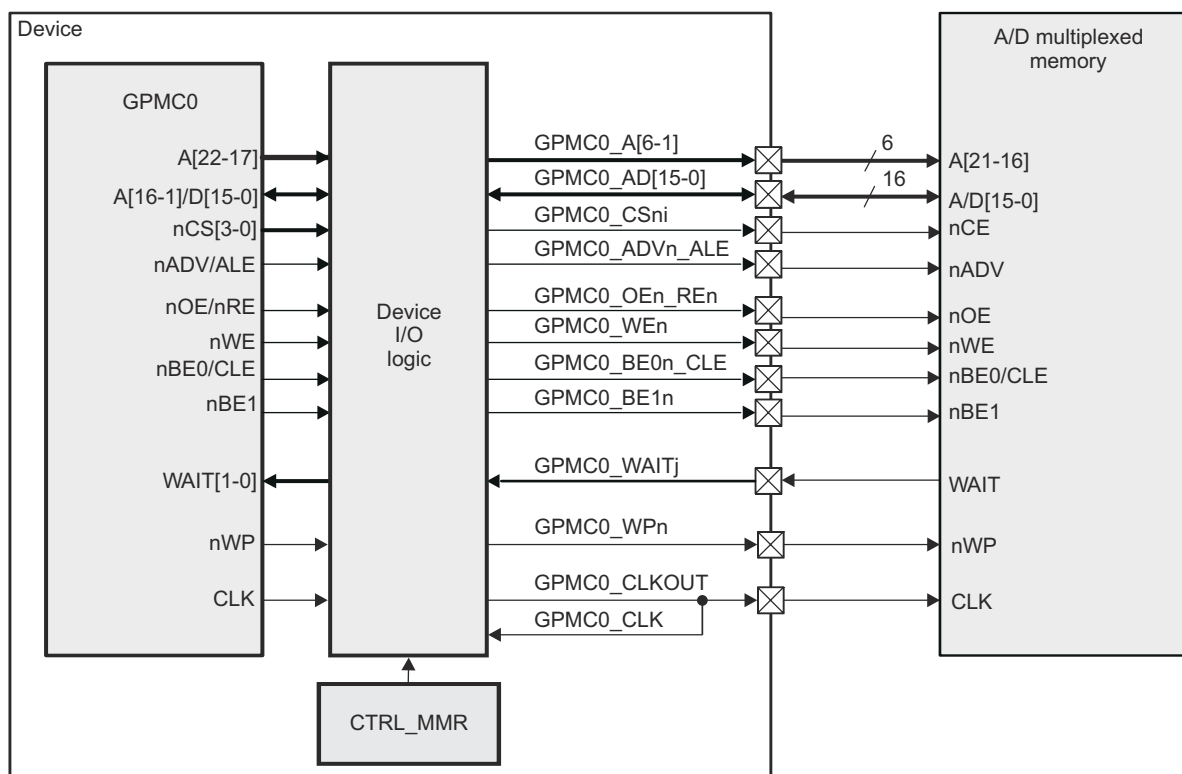

The GPMC0 module is hereinafter referred to as GPMC.

This section describes the GPMC0 external connections (environment).

#### 12.3.4.2.1 GPMC Modes

This section shows four GPMC0 external connection options:

- [Figure 12-232](#) shows a connection between the GPMC0 and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed but this protocol uses fewer address pins) external memory device.
- [Figure 12-233](#) shows a connection between the GPMC0 and a 16-bit synchronous non-multiplexed external memory device.
- [Figure 12-234](#) shows a connection between the GPMC0 and an 8-bit synchronous non-multiplexed external memory device.
- [Figure 12-235](#) shows a connection between the GPMC0 and an 8-bit NAND device.

#### 12.3.4.2.2 GPMC I/O Signals

Table 12-312 lists the GPMC subsystem input/output (I/O) pins.

**Table 12-312. GPMC I/O Signals (Master Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>GPMC0</b>				
A[22-0]	GPMC0_A[22-0]	O	23-bit output address bus	-
A[16-1]/D[15-0]	GPMC0_AD[15-0]	I/O	Multiplexed address/data	-
nCS[3-0]	GPMC0_CS[n][3-0]	O	Chip-selects (active low)	-
CLK	GPMC0_CLKOUT	O	Clock generated for the external memory or device. For more information, see <a href="#">Figure 12-236</a> .	-
RET_CLK				
N/A	GPMC0_FCLK_MUX	O	Free running clock. GPMC functional clock (GPMC0_FCLK) propagated on a device pad. For more information on the GPMC0_FCLK_MUX integration, see <a href="#">Figure 12-236</a> .	-
nADV/ALE	GPMC0_ADVn_ALE	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.	-
nOE/nRE	GPMC0_OEn_REn	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.	-
nWE	GPMC0_WEn	O	Write enable (active low)	-
nBE0/CLE	GPMC0_BE0n_CLE	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.	-
nBE1	GPMC0_BE1n	O	Upper-byte enable (active low)	-
WAIT[1-0]	GPMC0_WAIT[1-0]	I	External wait signal for NOR and NAND protocol memories. Can be mapped on any of the chip-selects.	-
nWP	GPMC0_WPn	O	Write protect (active low)	-
DIR	GPMC0_DIR	O	This signal can be used to control an external buffer direction. Also controls the signal direction of D[15-0]. Low during transmit (for write access: data OUT from GPMC0 to memory). High during receive (for read access: data IN from memory to GPMC0).	-

(1) I = Input; O = Output; I/O - Bidirectional

(2) HiZ = High Impedance

#### Note

For GPMC output clock signal (CLK) to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

Table 12-313 shows the use of address and data GPMC pins based on the type of external device.

**Table 12-313. GPMC Pin Multiplexing Options**

<b>GPMC Pin</b>	<b>Multiplexed Address Data 16-Bit Device</b>	<b>non-multiplexed Address Data 16-Bit Device (incomplete 28-bit address range)</b>	<b>non-multiplexed Address Data 8-Bit Device (incomplete 28-bit address range)</b>	<b>16-Bit NAND Device</b>	<b>8-Bit NAND Device</b>

(1) Used to effectively address 8-bit (only) non-multiplexed memories

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x0.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

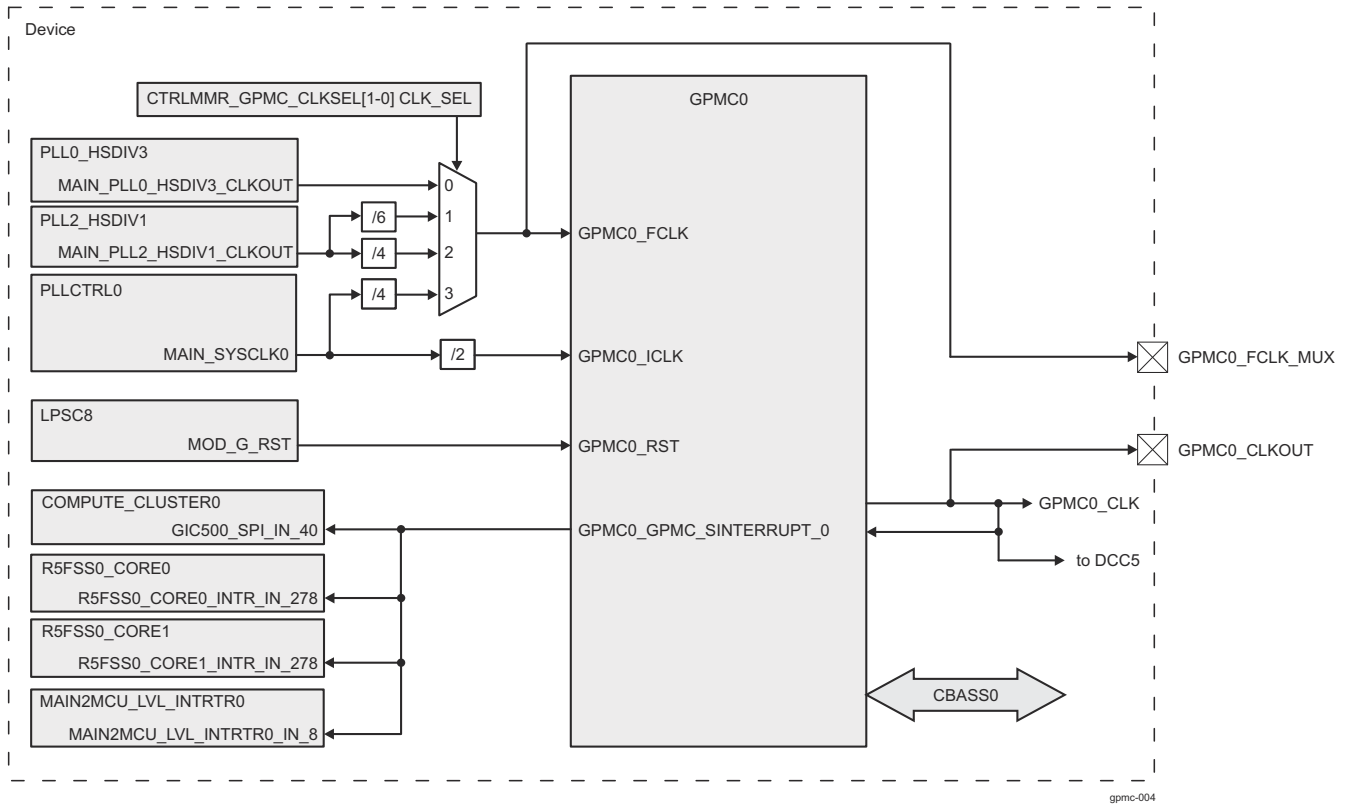

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field (where i = 0 to 3).

#### 12.3.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.3.4.3.1 GPMC Integration in MAIN Domain

A single GPMC module is integrated in the device MAIN domain - GPMC0. Figure 12-236 shows the GPMC0 integration.

**Figure 12-236. GPMC0 Integration**

Table 12-314 through Table 12-316 summarize the integration of GPMC0 in device MAIN domain.

**Table 12-314. GPMC0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
GPMC0	PSC0	PD0	LPSC8	CBASS0

**Table 12-315. GPMC0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
GPMC0	GPMC0_FCLK	MAIN_PLL0_HSDIV3_CLKO UT	PLL0_HSDIV3	GPMC0 Functional Clock. For more information about clock multiplexing, see CTRLMMR_GPMC_CLKSEL[1-0] CLK_SEL in <i>Control Module (CTRL_MMR)</i> .

		MAIN2MCU_LVL_INTRTR0_IN_8	MAIN2MCU_LVL_INTR TR0	GPMC0 Interrupt Request	

### Note

GPMC0 interrupts are further described in [Section 12.3.4.4.4](#), *GPMC Interrupt Requests*.

#### 12.3.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the four configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external WAIT pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

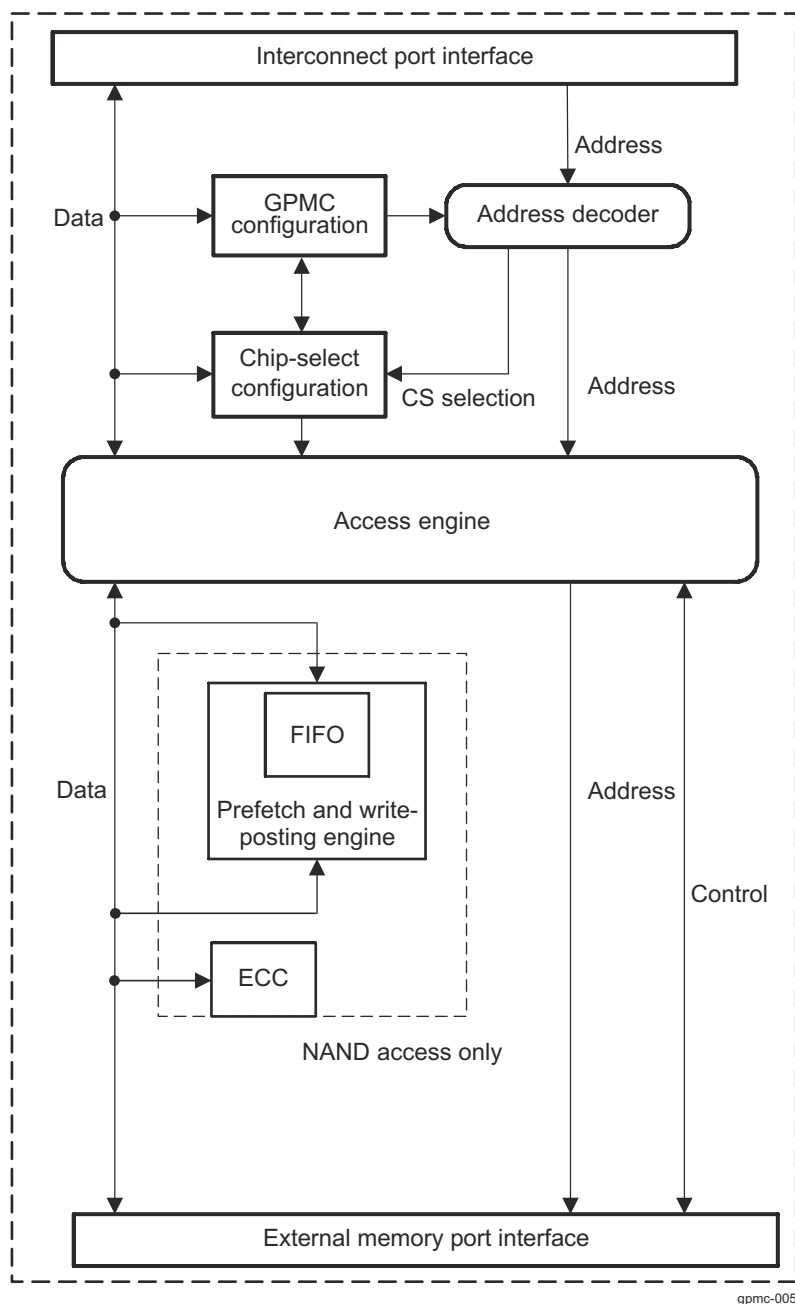

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

##### 12.3.4.4.1 GPMC Block Diagram

[Figure 12-237](#) shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

**Figure 12-237. GPMC Block Diagram**

The GPMC can access various external devices. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

#### 12.3.4.4.2 GPMC Clock Configuration

Table 12-317 describes the GPMC clocks.

**Table 12-317. GPMC Clocks**

Signal	I/O <sup>(1)</sup>	Description
GPMC_FCLK	I	Functional clock
GPMC_ICLK	I	Interface clock
CLK (GPMC_CLKOUT pin)	O	External clock provided to synchronous external memory devices and to DCC5 in the device.

(1) I = Input; O = Output; I/O - Bidirectional

The GPMC output clock (CLK) is generated by the GPMC from the internal GPMC\_FCLK clock. The source of the GPMC\_FCLK is described in *GPMC0 Clocks*. The GPMC output clock is configured using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), as shown in [Table 12-318](#).

**Table 12-318. GPMC Output Clock Configuration**

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC Output Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

When using synchronous interface protocols, the GPMC output clock (CLK), toggles only during the read or write access cycle. In some applications, it may be desirable to have a continuous clock running at the GPMC interface clock frequency for clocking attached devices. This option is enabled by an optional clock path from GPMC functional clock input (GPMC\_FCLK) to GPMC\_FCLK\_MUX. And output of this mux can be selected by CLKOUT\_SEL bit field for GPMC\_CONTROL Register present in MSS\_CTRL. For more details, see MSS\_CTRL chapter in GPMC Global Configuration.

Note that when using such synchronous interface protocols with the continuous clock option, user should ensure that the GPMC outputs are timed to the same frequency (GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0).

#### 12.3.4.4.3 GPMC Power Management

[Table 12-319](#) describes the local power-management features available for the GPMC module.

**Table 12-319. GPMC Local Power-Management Features**

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_ICLK clock upon the internal activity.
Target idle modes	GPMC_SYSCONFIG[4-3] IDLEMODE	Force-idle, no-idle and smart-idle modes are available.

#### 12.3.4.4.4 GPMC Interrupt Requests

The GPMC generates one interrupt request (see *GPMC0 Hardware Requests*).

[Table 12-320](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 12-320. GPMC Interrupt Events**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.

**Table 12-320. GPMC Interrupt Events (continued)**

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

#### 12.3.4.4.5 GPMC Interconnect Port Interface

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The GPMC interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC\_CONFIG1\_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

#### 12.3.4.4.6 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-non-multiplexed memories or devices is supported with an address range of 4MB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.

- 8-bit-wide NOR devices do not use GPMC I/O: GPMC\_AD[15-8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: GPMC\_A[22-0].
- 8-bit-wide NAND devices do not use GPMC I/O: GPMC\_A[22-0] and GPMC I/O: GPMC\_AD[15-8].

#### 12.3.4.4.6.1 GPMC I/O Configuration Setting

##### Note

In this section and the following sections, the *i* in GPMC\_CONFIGx\_i stands for the GPMC chip-select *i*, where *i* = 0 to 3.

To select a NAND device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b10
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b01

To select an address/data-non-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0b00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA = 0b00

#### 12.3.4.4.7 GPMC Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and four sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

##### 12.3.4.4.7.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 128MB address space. For more information, see *Memory Map*.

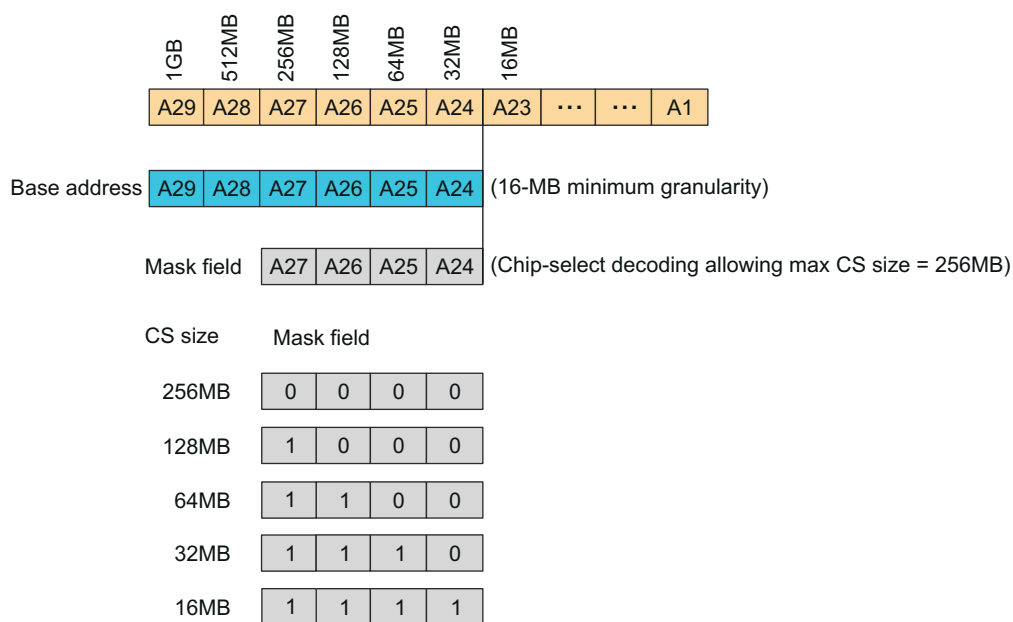

##### Note

Even though GPMC supports total address space of 1GB, only 128MB are physically available in this device.

The GPMC 128MB address space can be divided into a maximum of four chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MB to 256MB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in [Figure 12-238](#) (with A0 as the device system byte-address line). The base address is programmed through the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC\_CONFIG7\_i[11-8] MASKADDRESS bit field.

gpmc-006

**Figure 12-238. Chip-Select Address Mapping and Decoding Mask**

For example, to map the 128MB address space (from 2000 0000h to 27FF FFFFh), the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field should be set to 28h.

Eg : 68000000h = 0110\_1000\_0000\_0000\_0000\_0000\_0000b

Base Address[29:24] = 10\_1000 = 28h

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC\_CONFIG7\_i[6] CSVALID bit (where i stands for the GPMC chip-select i, where i = 0 to 3). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

### CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines at the value specified in the device-specific Datasheet.

#### 12.3.4.4.7.2 Access Protocol

##### 12.3.4.4.7.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC\_CONFIG1\_i[11-10] DEVICETYPE parameter (where i = 0 to 3) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

### Note

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 12.3.4.4.11, GPMC NAND Device Basic Programming Model](#), and [Section 12.3.4.4.11.1, NAND Memory Device in Byte or Word16 Stream Mode](#).

#### 12.3.4.4.7.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC\_CONFIG1\_i[13-12] DEVICESIZE bit field (where i = 0 to 3) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

##### 12.3.4.4.7.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field (where i = 0 to 3). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See *GPMC Integration*.

### Note

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See [Section 12.3.4.4.11, NAND Device Basic Programming Model](#).

#### 12.3.4.4.7.3 External Signals

##### 12.3.4.4.7.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external GPMC\_WAIT pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features two input WAIT pins: GPMC\_WAIT1, and GPMC\_WAIT0. These pins allow control of external devices with different WAIT pin polarity. They also allow the overlap of WAIT pin assertion from different devices without affecting access to devices for which the WAIT pin is not asserted.

- The GPMC\_CONFIG1\_i[17-16] WAITPINSELECT bit field (where i = 0 to 3) selects which input GPMC\_WAIT pin is used for the device attached to the corresponding chip-select.

- The polarity of the WAIT pin is defined through the WAITxPINPOLARITY bit of the GPMC\_CONFIG register. A WAIT pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a WAIT pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the WAIT pin of the external memory device, based on the access type: read or write.

- The GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether or not the WAIT pin must be monitored during read accesses.
- The GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether or not the WAIT pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the WAIT pin of the external memory device asynchronously or synchronously with the GPMC output clock, depending on the access type: synchronous or asynchronous (the GPMC\_CONFIG1\_i[29] READTYPE and GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 12.3.4.4.7.3.1.1 Wait Monitoring During Asynchronous Read Access

When WAIT pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with WAIT pin monitoring enabled, the WAIT pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through WAIT pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the WAIT pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

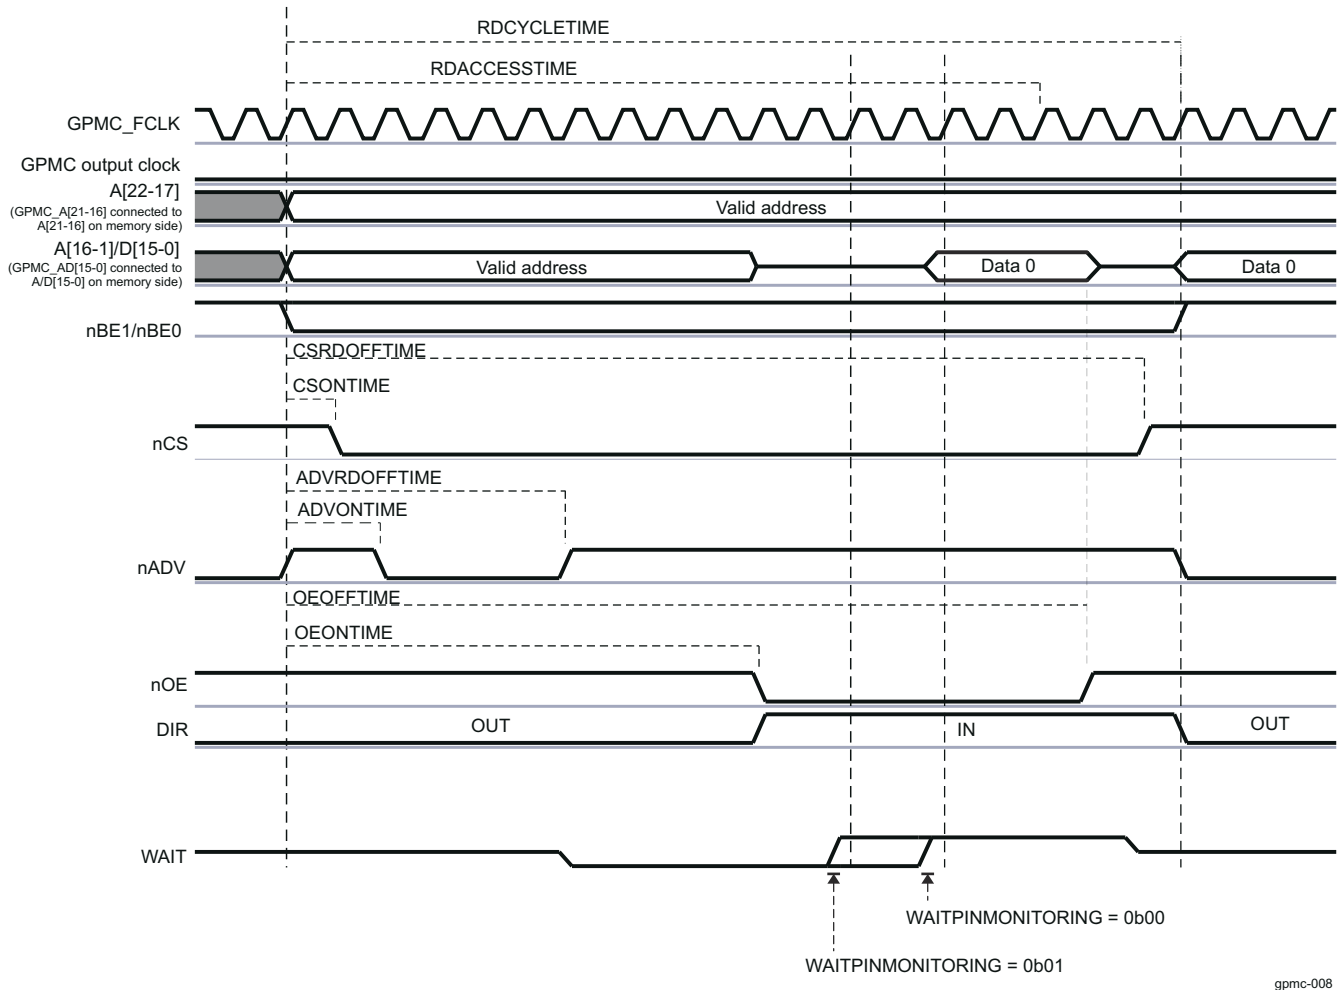

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

#### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and no GPMC output clock is provided to the external device. Still, because GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 12-239 shows wait behavior during an asynchronous single read access.

**Figure 12-239. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

#### Note

The WAIT signal is active low. GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME = 0b00, or 0b01.

#### 12.3.4.7.3.1.2 Wait Monitoring During Asynchronous Write Access

When WAIT pin monitoring is enabled for write accesses (GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the WAIT pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write

time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3).

#### Note

- The WAITMONITORINGTIME parameter does not delay the WAIT pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC output clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 12.3.4.4.7.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with WAIT pin monitoring enabled, the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC output clock cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME bit field (where i = 0 to 3), and is expressed as a number of GPMC output clock cycles.

In synchronous mode, when WAIT pin monitoring is enabled (the GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the WAIT pin must be at a valid level, either asserted or deasserted:

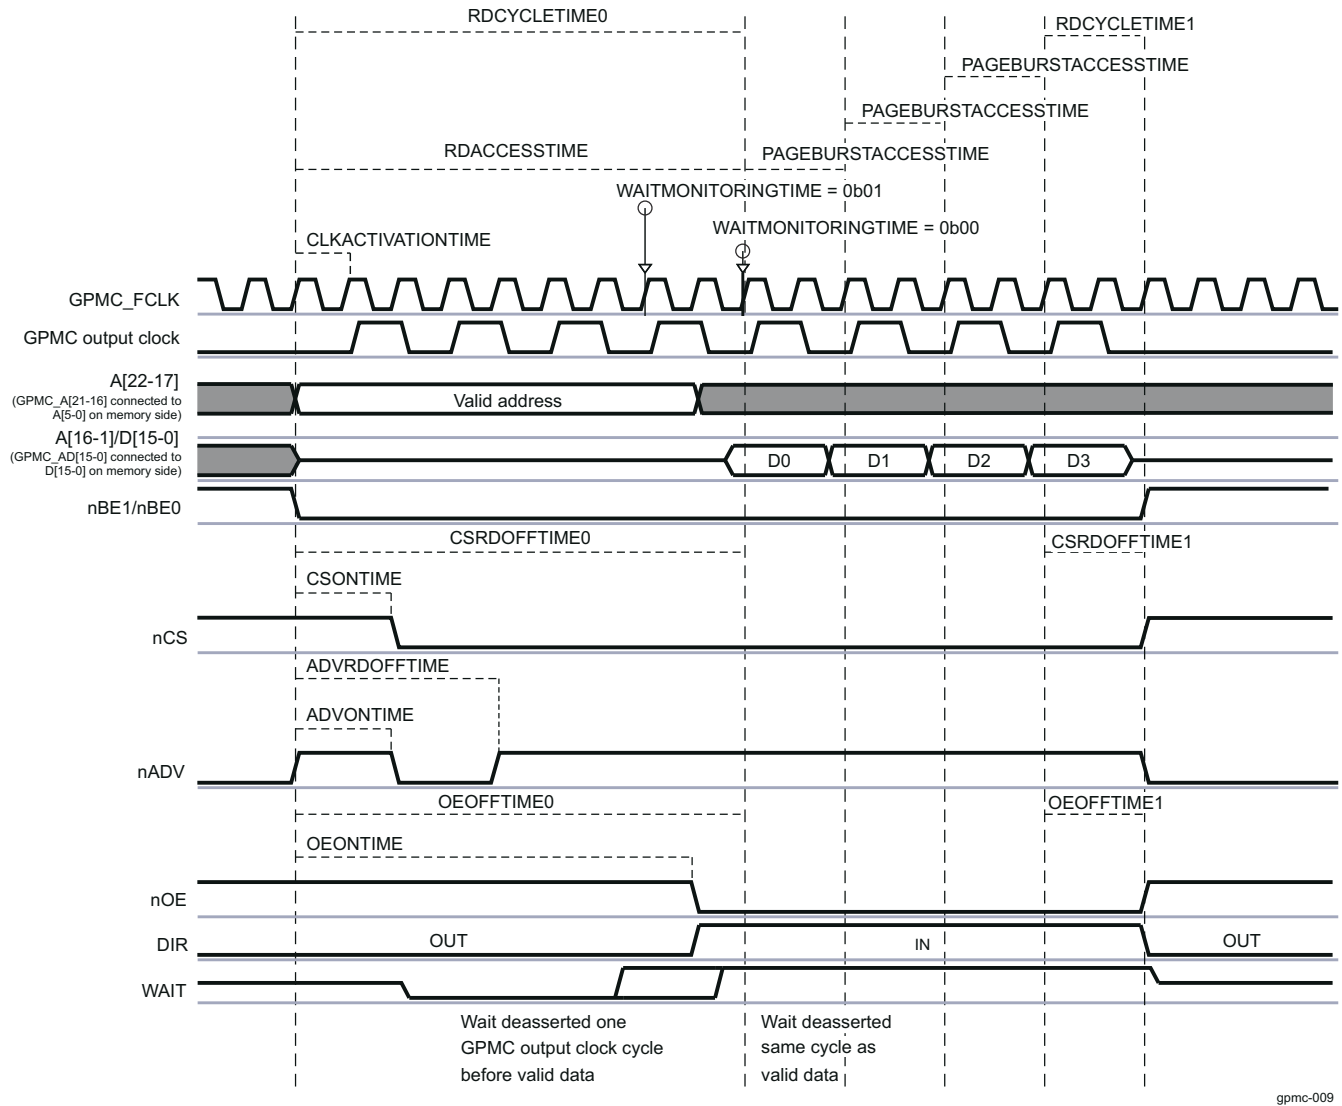

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 12-240 shows wait behavior during a synchronous read burst access.

**Figure 12-240. Wait Behavior During a Synchronous Read Burst Access**

**Note**

The WAIT signal is active low. WAITMONITORINGTIME = 0b00, 0b01.

**12.3.4.4.7.3.1.4 Wait Monitoring During Synchronous Write Access**

During synchronous accesses with WAIT pin monitoring enabled (the GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit), the WAIT pin is captured synchronously with GPMC output clock, using the rising edge of this clock.

If enabled, external WAIT pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC output clock capture edge of the effective memory device.

WAIT-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

#### Note

WAIT monitoring is supported for all configurations except GPMC\_CONFIG1\_i[19-18]  
WAITMONITORINGTIME = 0x0 (where i = 0 to 3) for write bursts with a clock divider of 1 or 2  
(the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

#### 12.3.4.4.7.3.1.5 Wait With NAND Device

For information about the use of the WAIT pin for communication with a NAND flash external device, see [Section 12.3.4.4.11.2, NAND Device-Ready Pin](#).

#### 12.3.4.4.7.3.1.6 Idle Cycle Control Between Successive Accesses

##### 12.3.4.4.7.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC\_CONFIG6\_i[11-8] BUSTURNAROUND bit field (where i = 0 to 3).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

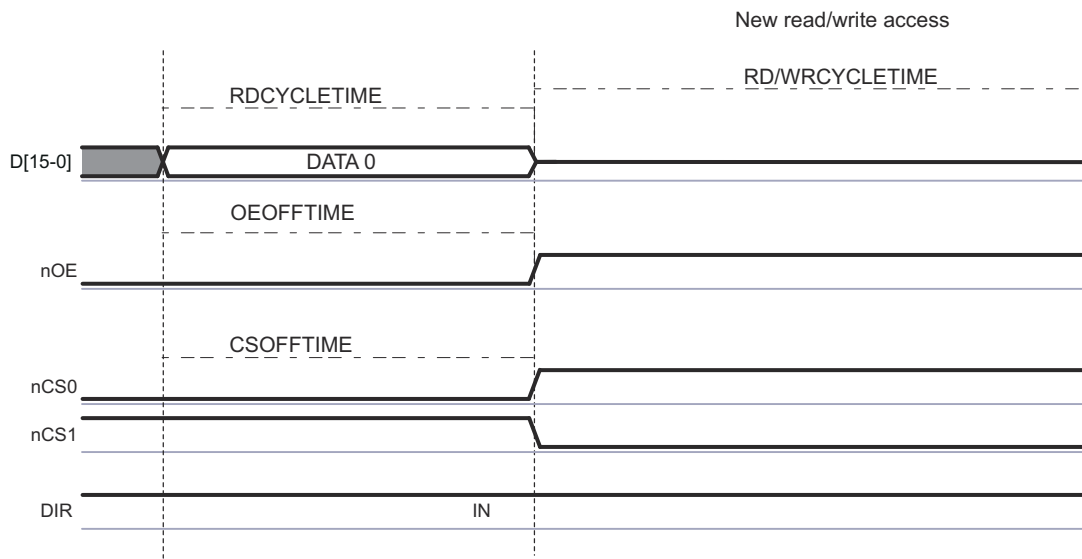

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

#### Note

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC\_CONFIG6\_i[11:8] CYCLE2CYCLEDELAY bit field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see [Figure 12-241](#) through [Figure 12-243](#)).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

gpmc-049

**Figure 12-241. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)**

gpmc-050

**Figure 12-242. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround**

**Figure 12-243. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround**

#### 12.3.4.4.7.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN bit (where i = 0 to 3) enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the GPMC\_CONFIG6\_i[11-8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC\_CONFIG1\_i[30] READMULTIPLE = 0 or GPMC\_CONFIG1\_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC output clock (CLK)) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC output clock at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 12.3.4.4.7.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select.

CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

### Note

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC\_CONFIG6\_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see [Section 3.4.4.7.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#).

[Table 12-321](#) describes the configuration required for idle cycle insertion.

**Table 12-321. Idle Cycle Insertion Configuration**

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 12.3.4.4.7.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select i, where i = 0 to 3). Increasing all access timing parameters allows support of slow devices.

#### 12.3.4.4.7.3.2 DIR Pin

The DIR pin is used to control I/O direction on the GPMC data bus GPMC\_D[15-0]. Depending on pad multiplexing, this signal can be output and used externally to the device, if required. The DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the DIR pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC\_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC\_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the DIR pin is OUT (see [Section 12.3.4.4.8.10, Bus Keeping Support](#)). In non-multiplexed devices, the DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

#### 12.3.4.4.7.3.3 Reset

No reset signal is sent to the external memory device by the GPMC.

GPMC\_RST is the reset signal for the GPMC module. It is connected and controlled by LPSC8 in VD\_CORE. That reset signal initializes the internal state-machine and the internal configuration registers.

#### 12.3.4.4.7.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The nWP output pin value is controlled through the GPMC\_CONFIG[4] WRITEPROTECT bit which is common for all chip selects.

#### 12.3.4.4.7.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses.

#### 12.3.4.4.7.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC\_ERR\_TYPE register and the address of the illegal access is stored in the GPMC\_ERR\_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC\_ERR\_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC\_ERR\_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.

- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the `GPMC_TIMEOUT_CONTROL` register and enabled with the `GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE` bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. An interrupt generation is handled at interconnect level.

#### 12.3.4.4.8 GPMC Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about `GPMC_CLKOUT` and `GPMC_FCLK`, see [Section 12.3.4.4.8.6, GPMC\\_CLKOUT](#).

#### Note

In the following sections, the start access time refers to the time at which the access begins.

##### 12.3.4.4.8.1 Read Cycle Time and Write Cycle Time (*RDCYCLETIME* / *WRCYCLETIME*)

The `GPMC_CONFIG5_i[4-0] RDCYCLETIME` and `GPMC_CONFIG5_i[12-8] WRCYCLETIME` bit fields (where  $i = 0$  to 3) define the address bus and byte-enable valid time for read and write accesses. To ensure a correct duty cycle of GPMC output clock between accesses, `RDCYCLETIME` and `WRCYCLETIME` are expressed in `GPMC_FCLK` cycles and must be multiples of the GPMC output clock cycle. The `RDCYCLETIME` and `WRCYCLETIME` bit fields can be set with a granularity of 1 or 2 through the `GPMC_CONFIG5_i[4] TIMEPARAGRANULARITY` bit.

When `RDCYCLETIME` or `WRCYCLETIME` completes, if they are not already deasserted, all control signals (`nCS`, `nADV/ALE`, `nOE/RE`, `nWE`, and `BE0/CLE`) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

#### Note

All control signals (`CS`, `ADV#/ALE`, `BE0#/CLE`, `WE#`, and GPMC output clock) are kept inactive (`ADV#/ALE`, `BE0#/CLE`, and GPMC output clock at low level; and `CS`, `OE#/RE`, and `WE` at high level) during the idle `GPMC_FCLK` cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (`GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN = 0` or `GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSSEN = 0`, where  $i = 0$  to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (`nCS`, `nADV/ALE`, `nBE0/CLE`, `nWE`, and `nOE/RE`) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, `CYCLE2CYCLESAMECSSEN = 1` or `CYCLE2CYCLEDIFFCSSEN = 1`), the control signals are forced to their respective default reset values for the number of `GPMC_FCLK` cycles defined in `CYCLE2CYCLEDELAY`.

#### **12.3.4.4.8.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)**

The GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME (read access) and GPMC\_CONFIG2\_i[20-16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG2\_i[7] CSEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. CSEXTRADELAY is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **12.3.4.4.8.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)**

The GPMC\_CONFIG3\_i[3-0] ADVONTIME field (where i = 0 to 3) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME (read access) and GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG3\_i[7] ADVEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC output clock and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME, GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME, and GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV

pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see [Section 12.3.4.4.11](#), *GPMC NAND Access Description*.

#### **12.3.4.4.8.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)**

The GPMC\_CONFIG4\_i[3-0] OEONTIME bit field (where i = 0 to 3) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user must ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[7] OEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **Note**

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

#### **12.3.4.4.8.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)**

The GPMC\_CONFIG4\_i[19-16] WEONTIME bit field (where i = 0 to 3) defines the nWE signal-assertion time relative to start access time. The GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[23] WEEXTRADELAY bit. This half-GPMC\_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC output clock. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 12.3.4.4.8.6 GPMC\_CLKOUT

The GPMC output clock generated for external synchronous memory or device is GPMC\_CLKOUT.

- The GPMC\_CLKOUT clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field (where i = 0 to 3), with a guaranteed 50-percent duty cycle. For information about the duty cycle error, see the device-specific Datasheet.
- The GPMC\_CLKOUT clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLKOUT activation.
- The GPMC\_CLKOUT clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLKOUT clock is kept low when access is defined as asynchronous.

#### CAUTION

When the cycle time completes, the GPMC\_CLKOUT may be high because of the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLKOUT clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

#### Note

To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME - CLKACTIVATIONTIME)$  must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .
- The PAGEBURSTACCESSTIME value must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .

#### 12.3.4.4.8.7 GPMC Output Clock and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC output clock edge can be controlled in the following ways:

- For the GPMC output clock signal, the GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field (where i = 0 to 3) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC output clock allows setup and hold control of the control-signal assertion and deassertion times.
- When the GPMC output clock runs at the GPMC\_FCLK frequency so that GPMC output clock edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by a half-GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

#### 12.3.4.4.8.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME and GPMC\_CONFIG6\_i[28-24] WRACCESSTIME bit fields (where i = 0 to 3). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

#### 12.3.4.4.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field (where i = 0 to 3) defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC\_FCLK rising edge corresponding to the GPMC output clock rising edge used for the first data capture.

GPMC output clock, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC output clock.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see [Section 12.3.4.4.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.4.4.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC\_CONFIG6\_i[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the GPMC\_WAIT pin is at a valid state two GPMC output clock cycles before WRACCESSTIME completes. For more information about wait monitoring, see [Section 12.3.4.4.7.3.1, WAIT Pin Monitoring Control](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from the start access time to the GPMC output clock rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC output clock edge for a synchronous write access. For more information about wait monitoring, see [Section 12.3.4.4.7.3.1, WAIT Pin Monitoring Control](#).

#### 12.3.4.4.8.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field (where i = 0 to 3) can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit.

##### 12.3.4.4.8.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access. For more information about wait monitoring, see [Section 12.3.4.4.7.3.1, WAIT Pin Monitoring Control](#).

##### 12.3.4.4.8.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC output clock edge in synchronous write mode. For more information about wait monitoring, see [Section 12.3.4.4.7.3.1](#), *WAIT Pin Monitoring Control*.

#### **12.3.4.4.8.10 Bus Keeping Support**

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

#### **12.3.4.4.9 GPMC NOR Access Description**

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC\_CONFIG1\_i[29] READTYPE bit (where i = 0 to 3). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC\_CONFIG1\_i[27] WRITETYPE bit where (i = 0 to 3).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC\_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC output clock (CLK), RdAccessTime, WrAccessTime, and WAIT pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

---

#### **Note**

The address bus and nBE[1-0] are fixed for the duration of a synchronous burst read access, but they are updated for each byte of an asynchronous page-read access.

---

#### **12.3.4.4.9.1 Asynchronous Access Description**

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC output clock is not provided outside the GPMC and is kept low.

##### **12.3.4.4.9.1.1 Access on Address/Data Multiplexed Devices**

##### **12.3.4.4.9.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device**

[Figure 12-244](#) shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 12-244. Asynchronous Single Read on an Address/Data-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-361](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.4.7.2.3, Address/Data-Multiplexing Interface](#).

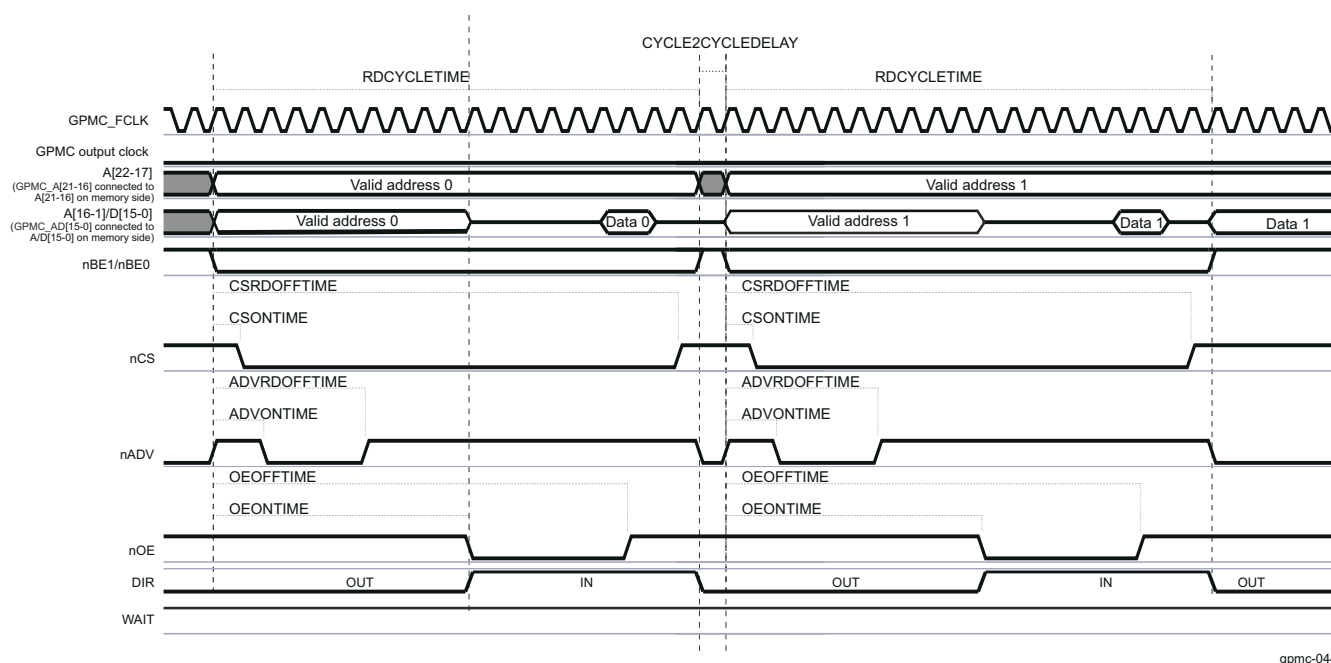

Address bits (A[16-1] from a GPMC perspective, A[15-0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC\_A[22-16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 12.3.4.4.9.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The GPMC\_CONFIG6\_i[11-8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

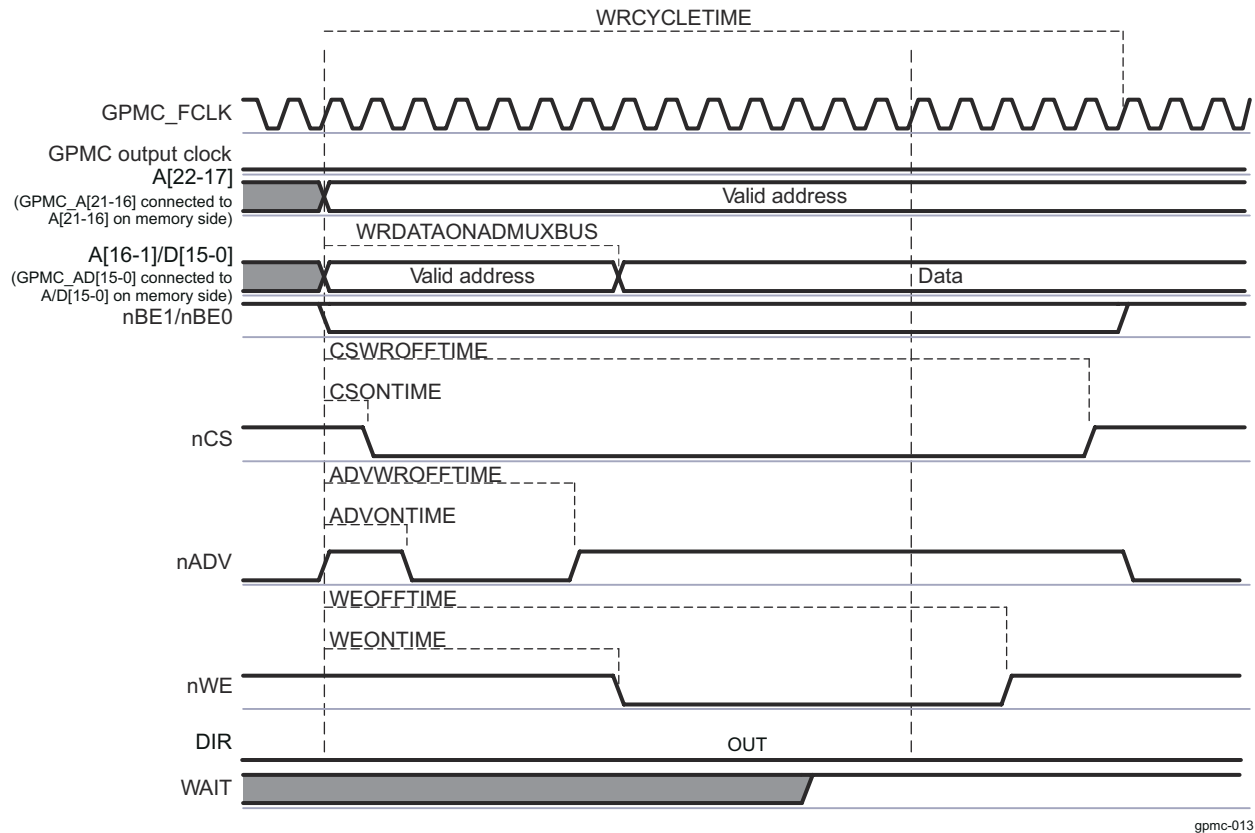

**Figure 12-245. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)**

#### 12.3.4.4.9.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

[Figure 12-246](#) shows an asynchronous single-write operation on an address/data-multiplexed device.

**Figure 12-246. Asynchronous Single-Write on an Address/Data-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-361](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 12.3.4.4.7.2.3, Address/Data-Multiplexing Interface](#).

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC\_CONFIG5\_i[12-8] WRCYCLETIME parameter.

Address bits A[16-1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[22-17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS time.

#### Note

Multiple write access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 12.3.4.4.8.10, Bus Keeping Support](#).

### 12.3.4.4.9.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC\_CONFIG1\_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.4.9.3, Asynchronous and Synchronous Accesses in non-multiplexed Mode](#).

### 12.3.4.4.9.1.2 Access on Address/Address/Data-Multiplexed Devices

#### 12.3.4.4.9.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 12-247 shows an asynchronous single-read operation on an AAD-multiplexed device.

**Figure 12-247. Asynchronous Single Read on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-361](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE

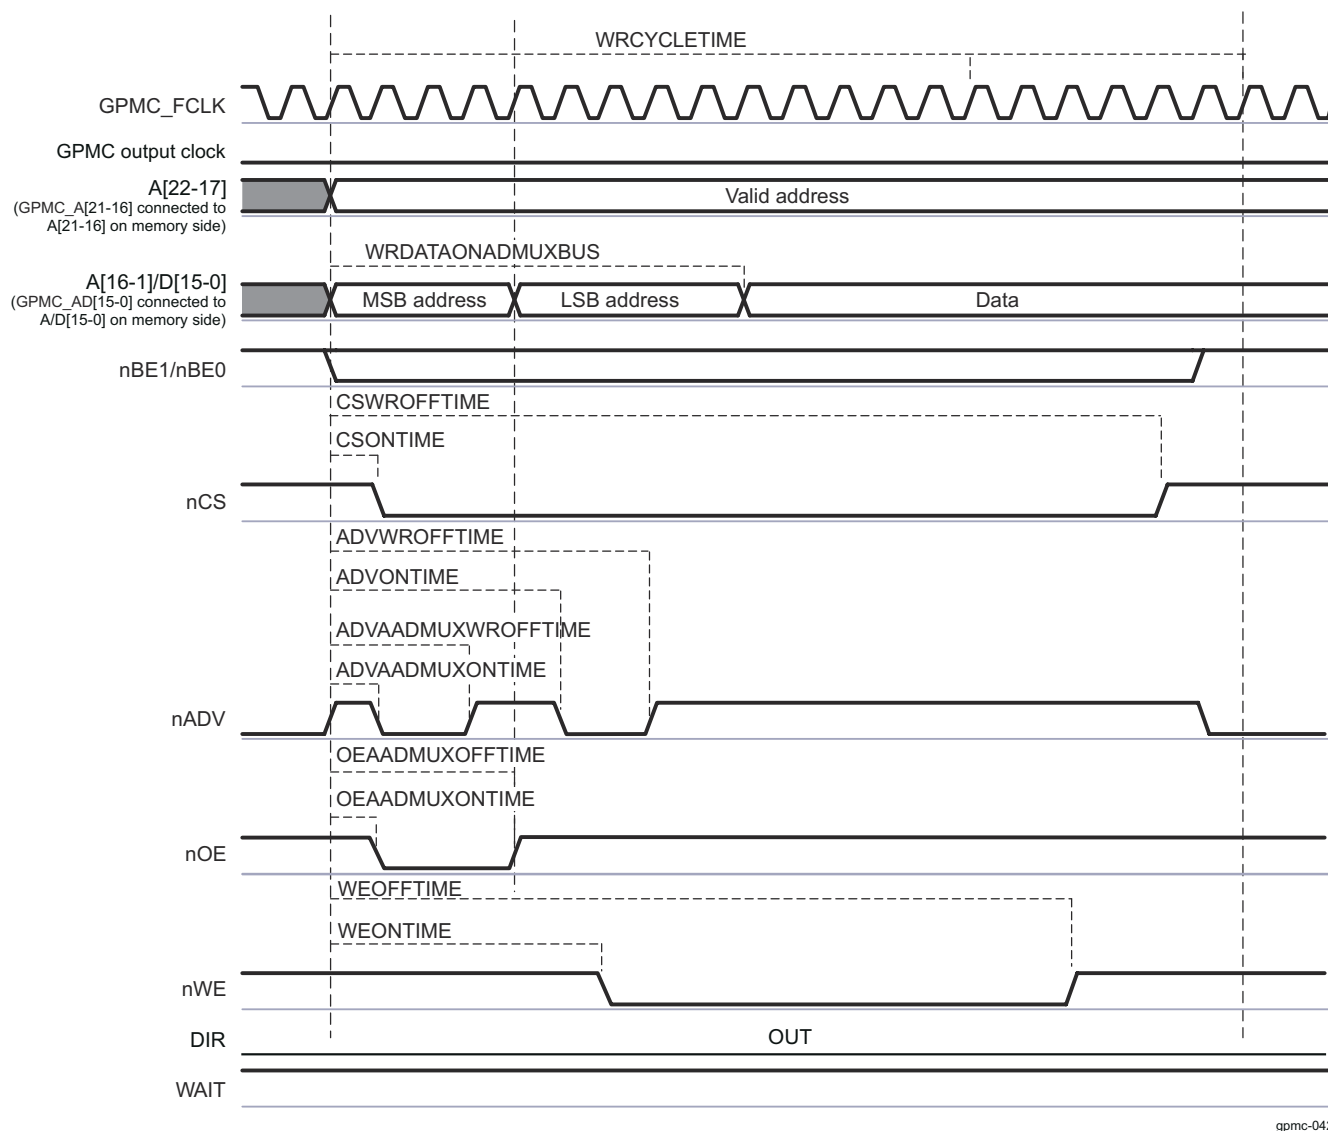

driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

#### **12.3.4.4.9.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device**

Figure 12-248 shows an asynchronous single-write operation on an AAD-multiplexed device.

gpmc-042

**Figure 12-248. Asynchronous Single Write on an AAD-Multiplexed Device**

For formulas to calculate timing parameters, see [Section 12.3.4.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-361](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See [Table 12-352, NAND Memory Type](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:

- nOE assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
- nOE deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS parameter.

#### **12.3.4.4.9.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device**

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC\_CONFIG1\_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 12.3.4.4.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

#### **12.3.4.4.9.2 Synchronous Access Description**

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (non-multiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 12.3.4.4.9.3, Asynchronous and Synchronous Accessed in non-multiplexed Mode](#).

In synchronous operations:

- The GPMC\_CLKOUT clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLKOUT clock is derived from the GPMC\_FCLK clock using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 3.
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME bit field specifies that the GPMC\_CLKOUT is provided outside the GPMC for 0 to 2 GPMC\_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

#### **12.3.4.4.9.2.1 Synchronous Single Read**

[Figure 12-249](#) and [Figure 12-250](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

gpmc-015

**Figure 12-249. Synchronous Single Read (GPMCCLKDIVIDER = 0)**

gpmc-016

**Figure 12-250. Synchronous Single Read (GPMCCLKDIVIDER = 1)**

For formulas to calculate timing parameters, see [Section 12.3.4.5.6.1, GPMC Timing Parameters Formulas](#).

[Table 12-361](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.4.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.4.8.10, Bus Keeping Support](#).

#### **12.3.4.4.9.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)**

[Figure 12-251](#) and [Figure 12-252](#) show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

gpmc-018

**Figure 12-251. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)**

gpmc-019

**Figure 12-252. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**

When the GPMC\_CONFIG5\_i[20-16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See [Table 12-347, NOR Memory Type](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC\_CLKOUT cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC\_CONFIG5\_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-252](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 12.3.4.4.8.10, Bus Keeping Support](#).

Burst wraparound is enabled through the GPMC\_CONFIG1\_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word linear burst access to wrap within its burst-length boundary through the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field.

#### 12.3.4.4.9.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

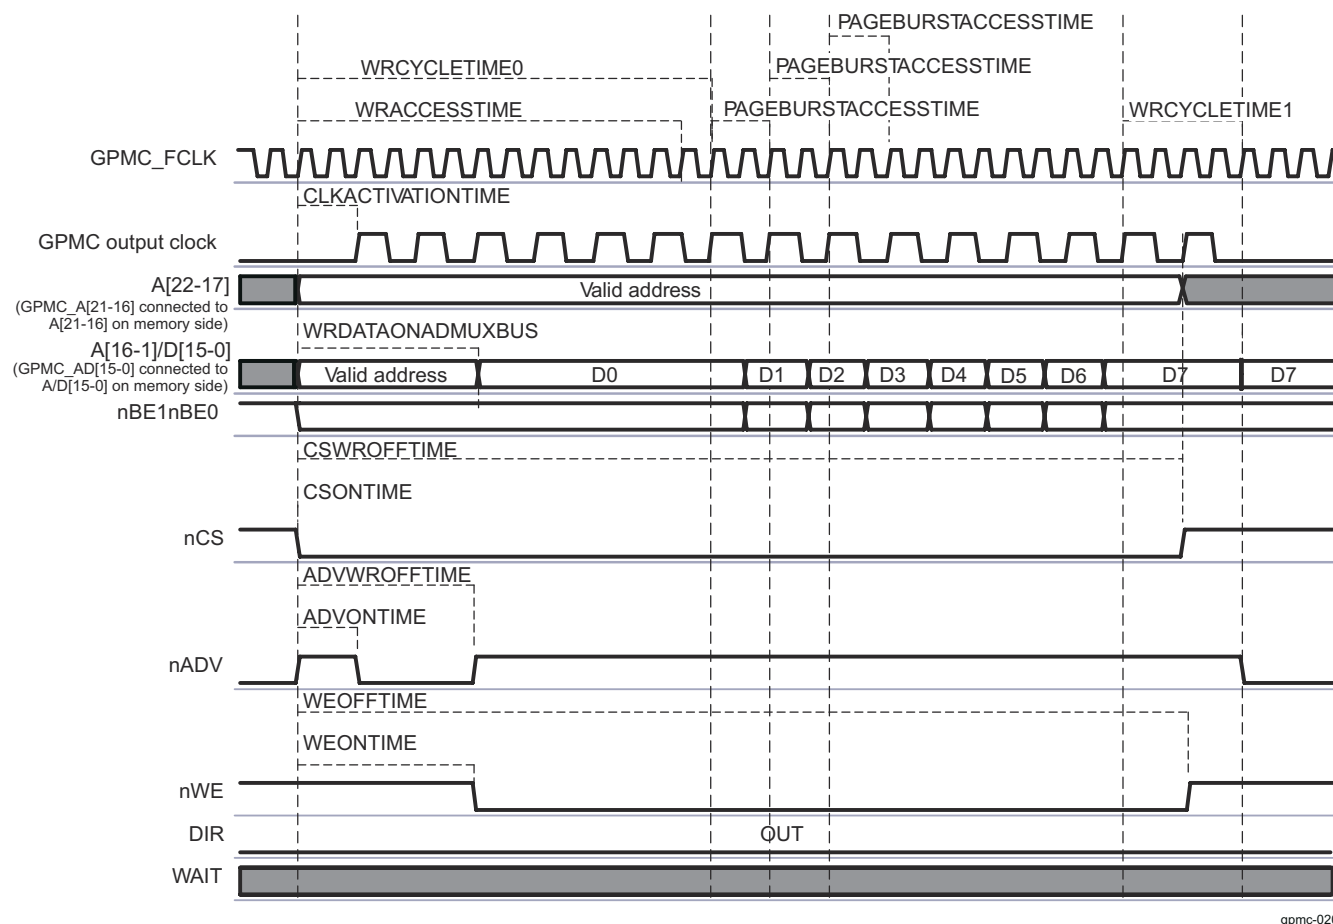

**Figure 12-253. Synchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16-1]) until the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

#### 12.3.4.4.9.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 12-254 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 12-254. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

Figure 12-255 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

**Figure 12-255. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode**

The first data of the burst is driven on the A/D bus at the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS bit field.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see [Section 12.3.4.4.7.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME bit field (where i = 0 to 3) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC\_CONFIG2\_i[20-16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME bit field.

- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME bit field.

#### Note

The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC\_CONFIG4\_i[15-13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until GPMC\_CONFIG5\_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC\_CONFIG6\_i[28-24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC\_CONFIG5\_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 12-254](#), the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 12.3.4.4.8.10, Bus Keeping Support](#).

#### 12.3.4.4.9.3 Asynchronous and Synchronous Accesses in non-multiplexed Mode

Page mode is available only in non-multiplexed mode.

- Asynchronous single-read operation on a non-multiplexed device
- Asynchronous single-write operation on a non-multiplexed device
- Asynchronous multiple- (page mode) read operation on a non-multiplexed device
- Synchronous operations on a non-multiplexed device

##### 12.3.4.4.9.3.1 Asynchronous Single-Read Operation on non-multiplexed Device

[Figure 12-256](#) shows an asynchronous single-read operation on a non-multiplexed device.

**Figure 12-256. Asynchronous Single Read on an Address/Data-non-multiplexed Device**

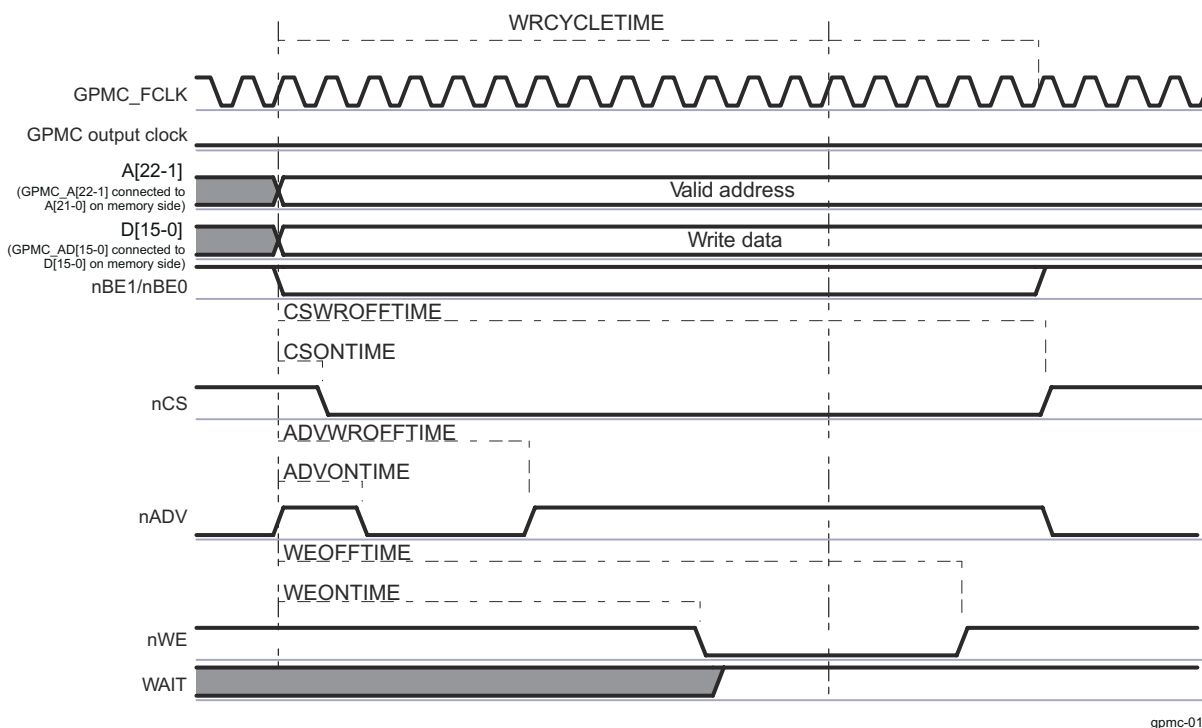

The 22-bit address (For a 16-bit data memory device, hence GPMC A[0] is not necessary to be output) is driven onto the address bus A[22-1] and the 16-bit data is driven onto the data bus D[15-0].

Read data is latched at GPMC\_CONFIG1\_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC\_CONFIG1\_5[4-0] RDCYCLETIME parameter.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-352, NAND Memory Type](#)).

#### 12.3.4.4.9.3.2 Asynchronous Single-Write Operation on non-multiplexed Device

[Figure 12-257](#) shows an asynchronous single-write operation on a non-multiplexed device.

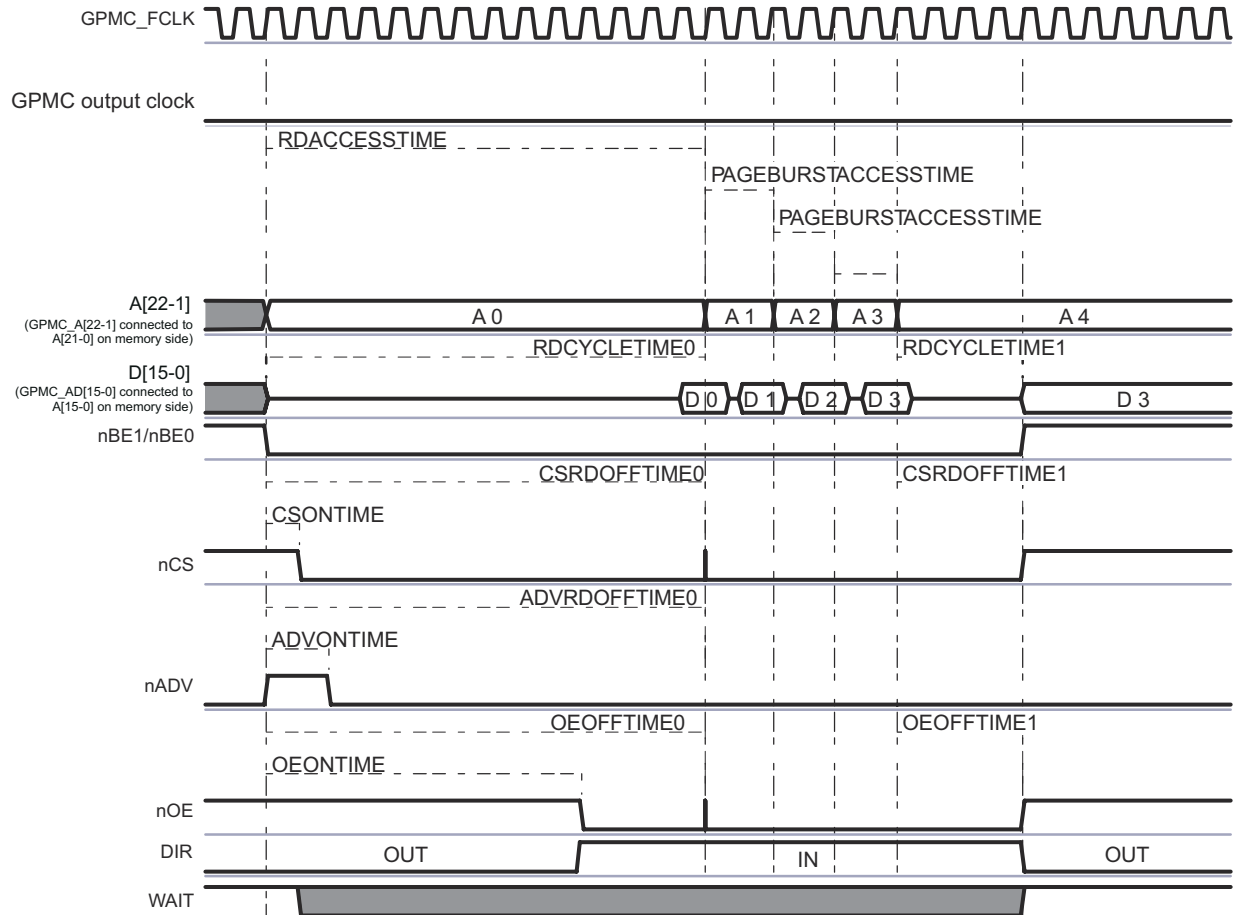

**Figure 12-257. Asynchronous Single Write on an Address/Data-non-multiplexed Device**

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-352](#)).

#### 12.3.4.4.9.3.3 Asynchronous Multiple (Page Mode) Read Operation on non-multiplexed Device

[Figure 12-258](#) shows an asynchronous multiple-read operation on a non-multiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

gpmc-014

**Figure 12-258. Asynchronous Multiple (Page Mode) Read**

### Note

The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see [Table 12-352](#)).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC\_CONFIG5\_i[20-16] RDACCESSTIME completion time (where i = 0 to 3). The end of the access is defined by the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME bit field.

- In [Figure 12-258](#), the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 12.3.4.4.9.3.4 Synchronous Operations on a non-multiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 12.3.4.5.3](#), *GPMC Configuration in NOR Mode*.

#### 12.3.4.4.9.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC\_CONFIG1\_i[30] READMULTIPLE and GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bits (where i = 0 to 3) are associated with the READTYPE and WRITETYPE parameters.

#### Note

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

#### 12.3.4.4.9.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 3). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC\_CONFIG1\_i[31] WRAPBURST bit (where i = 0 to 3) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only

fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), WAIT pin monitoring must be enabled to dynamically control data access completion within the burst.

#### Note

When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

#### 12.3.4.4.10 GPMC pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC\_CONFIG1\_i[11-10] DEVICETYPE bit field (where i = 0 to 3) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 12.3.4.4.11 GPMC NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

### 12.3.4.4.11.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model depends on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 12.3.4.4.11.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC\_CONFIG7\_i register (where i = 0 to 3) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

#### CAUTION

To allow correct command, address, and data-access controls, the GPMC\_CONFIG1\_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in [Table 12-322](#). Failure to comply with these settings corrupts the NAND interface protocol.

**Table 12-322. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] <sup>(1)</sup>	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26-25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24-23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19-18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17-16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13-12]	0b00 or 0b01	8- or 16-bit interface

**Table 12-322. Chip-Select Configuration for NAND Interfacing (continued)**

Bit Field	Register	Value	Comments
DEVICETYPE	GPMC_CONFIG1_i[11-10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9-8]	0b00	non-multiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1-0]	Don't care	Asynchronous mode

(1)  $i = 0$  to 3

The GPMC\_CONFIG1\_i to GPMC\_CONFIG4\_i registers (where  $i = 0$  to 3) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

#### 12.3.4.4.11.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations (where  $i = 0$  to 3) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i register locations must be posted for faster operations (where  $i = 0$  to 3). The GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC\_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers (where  $i = 0$  to 3) are 32-bit word locations, which means any 32- or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDRESS\_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC\_NAND\_COMMAND\_i and a GPMC\_NAND\_ADDRESS\_i (where  $i = 0$  to 3) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

#### 12.3.4.4.11.1.3 Command Latch Cycle

Writing data at the GPMC\_NAND\_COMMAND\_i location (where  $i = 0$  to 3) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.

- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 12-259 shows the NAND command latch cycle.

**Figure 12-259. NAND Command Latch Cycle**

#### Note

CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

#### 12.3.4.4.11.1.4 Address Latch Cycle

Writing data at the GPMC\_NAND\_ADDRESS\_i location (where i = 0 to 3) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 12-260 shows the NAND address latch cycle.

Figure 12-260. NAND Address Latch Cycle

**Note**

ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

**12.3.4.4.11.1.5 NAND Device Data Read and Write Phase Control in Stream Mode**

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC\_NAND\_DATA\_i location (where i = 0 to 3) mapped in the chip-select-associated control register region. GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 12-261 shows the NAND data read cycle.

**Figure 12-261. NAND Data Read Cycle**

Writing data to the GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 12-262 shows the NAND data write cycle.

**Figure 12-262. NAND Data Write Cycle**

#### 12.3.4.4.11.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see [Section 12.3.4.4.11.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

#### **12.3.4.4.11.1.7 Read and Write Access Size Adaptation**

##### **12.3.4.4.11.1.7.1 8-Bit-Wide NAND Device**

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

##### **12.3.4.4.11.1.7.2 16-Bit-Wide NAND Device**

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### 12.3.4.4.11.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

#### Note

If a read access to a NAND flash is done using WAIT monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the WAIT pin monitoring for read and write accesses (that is, set the GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING and GPMC\_CONFIG1\_i[22] WAITREADMONITORING bits to 0, where i = 0 to 3), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 1) of the GPMC\_STATUS.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC\_IRQENABLE register bits[11-8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC\_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

##### 12.3.4.4.11.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC\_STATUS[9-8] WAITxSTATUS bit (where x = 0 to 1). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### 12.3.4.4.11.2.2 Ready Pin Monitored by Hardware Interrupt

Each GPMC\_WAIT input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC\_CONFIG[9-8] WAITxPINPOLARITY bits (where x = 0 to 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 1) of the GPMC\_IRQSTATUS register according to the GPMC\_WAIT pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC\_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC\_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC\_IRQSTATUS register according to the GPMC\_WAIT pin used for NAND device ready signal monitoring.

#### 12.3.4.4.11.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC\_ECC\_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhuri-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC\_ECC\_CONFIG[3-1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

##### 12.3.4.4.11.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

##### 12.3.4.4.11.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC\_ECCj\_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC\_ECCj\_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC\_ECC\_CONTROL[3-0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC\_ECCj\_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC\_ECCj\_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC\_ECC\_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC\_ECCj\_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZe bits (where j = 1 to 9) in the GPMC\_ECC\_SIZE\_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC\_ECCj\_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC\_ECCj\_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZe bits are set to 0, and the ECC9RESULTSIZe bit is set to 1.

#### 12.3.4.4.11.3.1.2 ECC Enabling

The GPMC\_ECC\_CONFIG[3-1] ECCCS bit field selects the allocated chip-select. The GPMC\_ECC\_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- ECCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZe (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 12-323](#) describes the ECC enable settings.

**Table 12-323. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

**Table 12-323. ECC Enable Settings (continued)**

Bit Field	Register	Value	Comments
ECSSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECSSIZE1
ECSSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECSSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

#### 12.3.4.4.11.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 12-263 and Figure 12-264. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

**Figure 12-263. Hamming Code Accumulation Algorithm (1/2)**

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254

P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

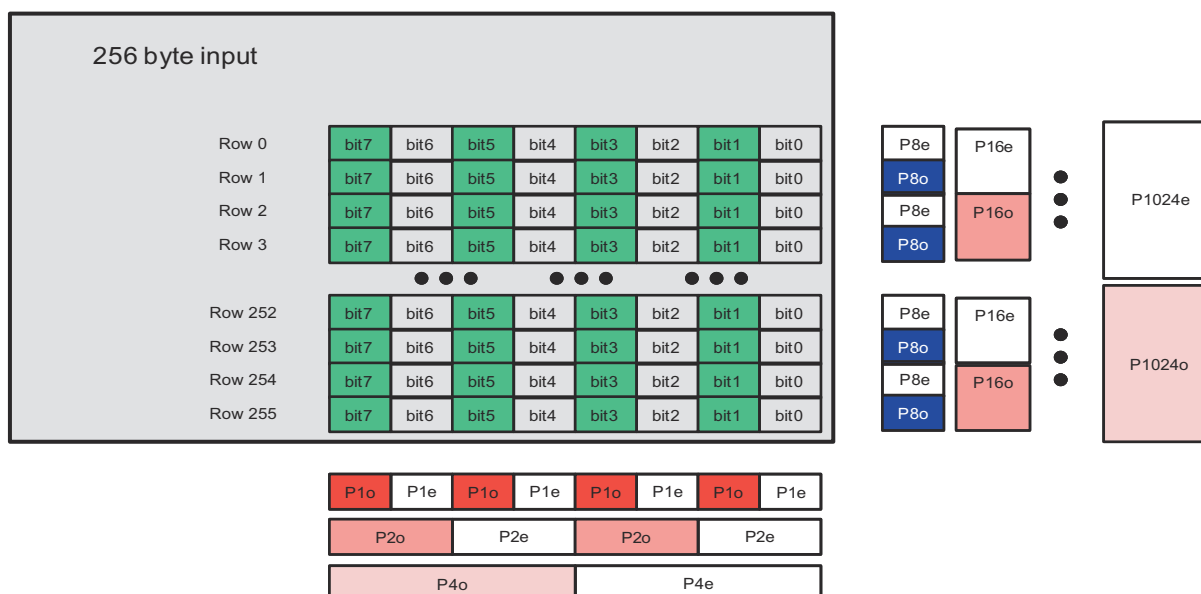

gpmc-027

**Figure 12-264. Hamming Code Accumulation Algorithm (2/2)**

Unused parity bits in the result registers are set to 0.

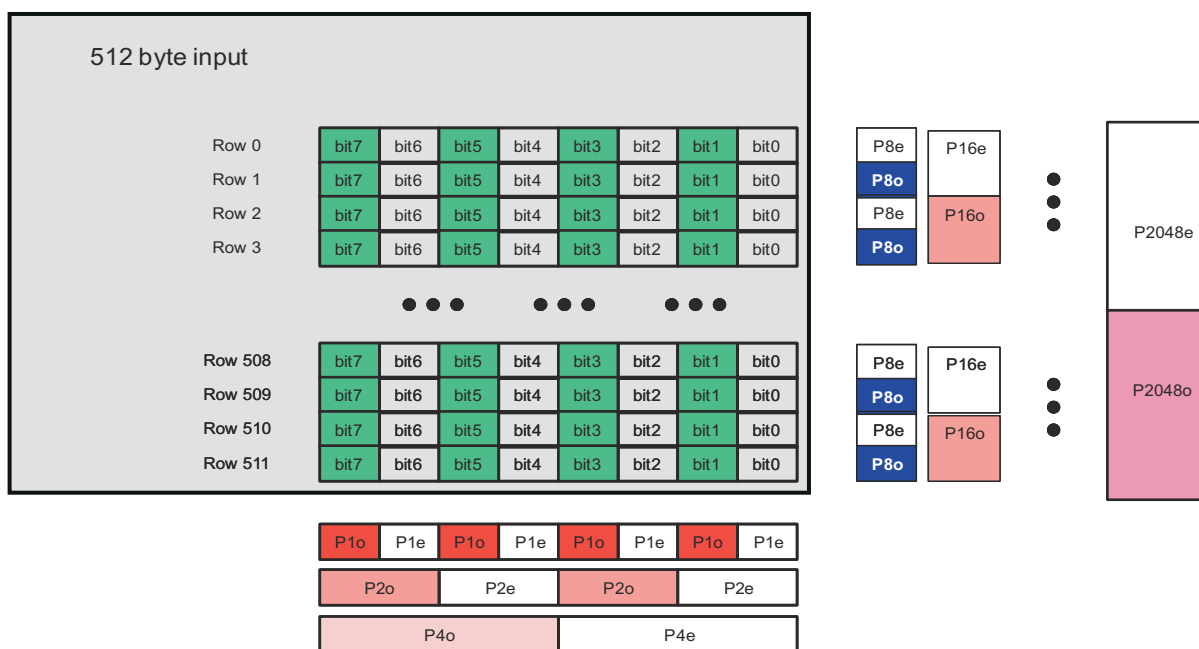

Figure 12-265 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

gpmc-028

**Figure 12-265. ECC Computation for a 256-Byte Data Stream (Read or Write)**

Figure 12-266 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

gpmc-029

**Figure 12-266. ECC Computation for a 512-Byte Data Stream (Read or Write)**

For a 2-KB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC\_ECCj\_RESULT registers (where j = 1 to 9).

#### 12.3.4.4.11.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 12.3.4.4.11.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

#### 12.3.4.4.11.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC\_ECC\_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. [Figure 12-267](#) and [Figure 12-268](#) show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

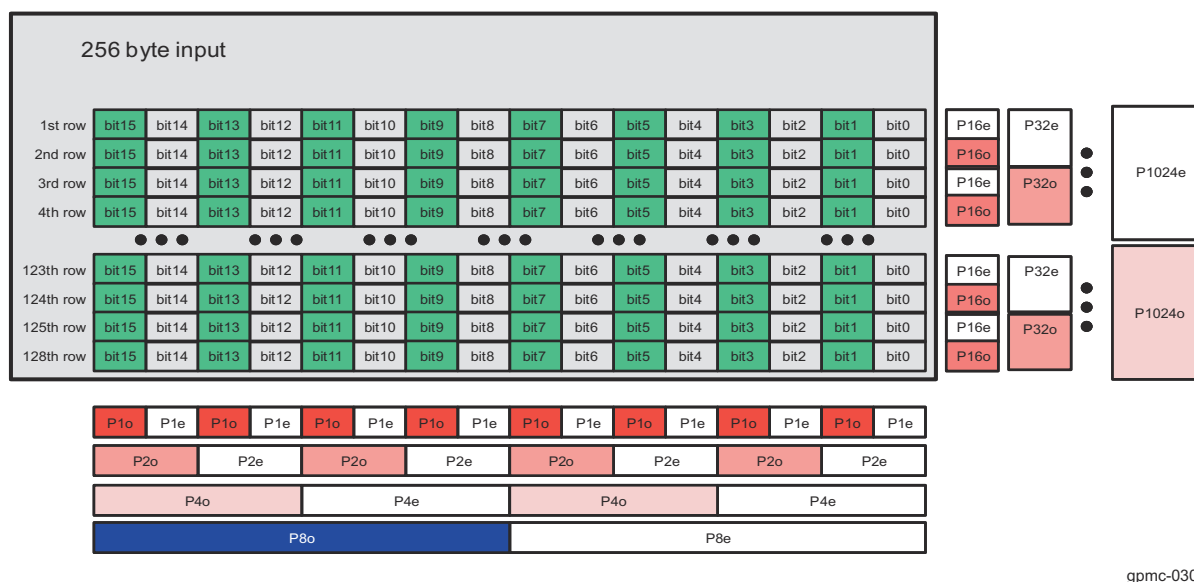

Figure 12-267. 128 Word16 ECC Computation

Figure 12-268. 256 Word16 ECC Computation

#### 12.3.4.4.11.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

##### 12.3.4.4.11.3.2.1 Requirements

- Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
  - Typical page write sequence:
    - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.
- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.
- 2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
- 3. Each page can hold up to 4KB of data, spare bytes not included. This means up to  $8 \times 512$ -byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
- 5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

#### 12.3.4.4.11.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In a standard case, 512 bytes of data (that is,  $2^{12}$  bits = 4096 bits) are seen as a polynomial of degree  $2^{12} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$ , as described in [Table 12-324](#).

**Table 12-324. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$			ECC $R(x)$		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) \times 8) - 1 = 4119$ , for a total of  $3 + 13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where  $i = 0$  to 3):

- GPMC\_BCH\_RESULT0\_i
- GPMC\_BCH\_RESULT1\_i
- GPMC\_BCH\_RESULT2\_i
- GPMC\_BCH\_RESULT3\_i

#### 12.3.4.4.11.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LSB) represents a segment of polynomial  $b_7 * x^{(7+i)} + b_6 * x^{(6+i)} + \dots + b_0 * x^i$

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

### Note

The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 12-325 and Table 12-326 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset module 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and M(2<sup>12</sup>–1) of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

**Table 12-325. Aligned Message Byte Mapping in 8-Bit NAND**

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

**Table 12-326. Aligned Message Byte Mapping in 16-Bit NAND**

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 12-327 through Table 12-332 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

**Table 12-327. Aligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

**Table 12-328. Misaligned Nibble Mapping of Message in 8-Bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S + 1) / 2 – 2	Nibble 2	Nibble 1

**Table 12-328. Misaligned Nibble Mapping of Message in 8-Bit NAND (continued)**

Byte Offset	8-Bit Word
$(S + 1) / 2 - 1$	Nibble 0 (LSB)

**Table 12-329. Aligned Nibble Mapping of Message in 16-Bit NAND**

	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$S/2 - 4$	Nibble 5	Nibble 4	Nibble 7	Nibble 6
$S/2 - 2$	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

**Table 12-330. Misaligned Nibble Mapping of Message in 16-Bit NAND (1 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 1) / 2 - 4$	Nibble 4	Nibble 3	Nibble 6	Nibble 5
$(S + 1) / 2 - 2$	Nibble 0 (LSB)		Nibble 2	Nibble 1

**Table 12-331. Misaligned Nibble Mapping of Message in 16-Bit NAND (2 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 2) / 2 - 4$	Nibble 3	Nibble 2	Nibble 5	Nibble 4
$(S + 2) / 2 - 2$			Nibble 1	Nibble 0 (LSB)

**Table 12-332. Misaligned Nibble Mapping of Message in 16-Bit NAND (3 Unused Nibbles)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Least Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...	...	...	...
$(S + 3) / 2 - 4$	Nibble 2	Nibble 1	Nibble 4	Nibble 3
$(S + 3) / 2 - 2$			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

#### 12.3.4.4.11.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword

(concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 12.3.4.4.11.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see [Section 12.3.4.4.11.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

##### 12.3.4.4.11.3.2.2.3.1 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1. In the same example, 5 nibbles to process + 3 to discard = 8 nibbles =  $2 \times 16$ -bit accesses. Software must set:

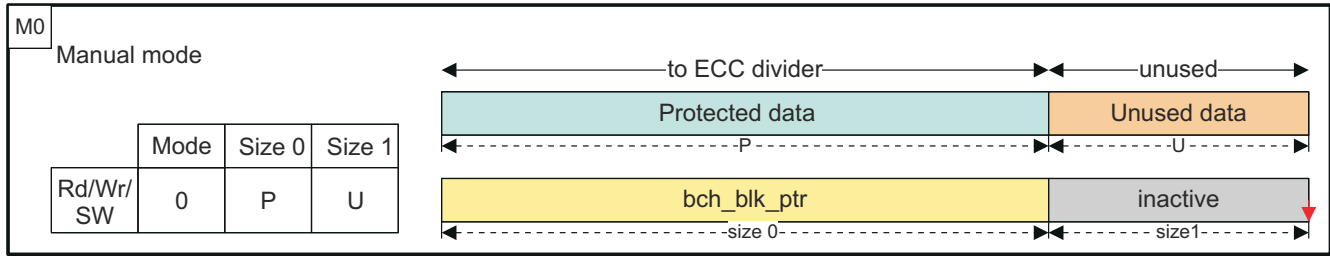

- GPMC\_ECC\_SIZE\_CONFIG[21-12] ECCSIZE0 = 0x5
- GPMC\_ECC\_SIZE\_CONFIG[31-22] ECCSIZE1 = 0x3

---

#### Note

In the following figures, size and size0 are the same parameter.

---

gpmc-032

**Figure 12-269. Manual Mode Sequence and Mapping**

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

#### 12.3.4.4.11.3.2.2.3.2 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.4.4.11.3.2.2.3.3 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

#### 12.3.4.4.11.3.2.2.3.4 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.4.4.11.3.2.2.3.5 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.4.4.11.3.2.2.3.6 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.4.4.11.3.2.2.3.7 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.4.4.11.3.2.2.3.8 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

#### 12.3.4.4.11.3.2.2.3.9 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

#### 12.3.4.4.11.3.2.2.3.10 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.4.4.11.3.2.2.3.11 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

#### 12.3.4.4.11.3.2.2.3.12 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

#### 12.3.4.4.11.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 3.4.4.11.3.2.2.1, Memory Mapping of Data Message](#).

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 12-270 through Figure 12-272, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of  $n = 2^{13} - 1 = 8191$  bits; that codeword (higher-order bits) is all-zero and implicit during computations.

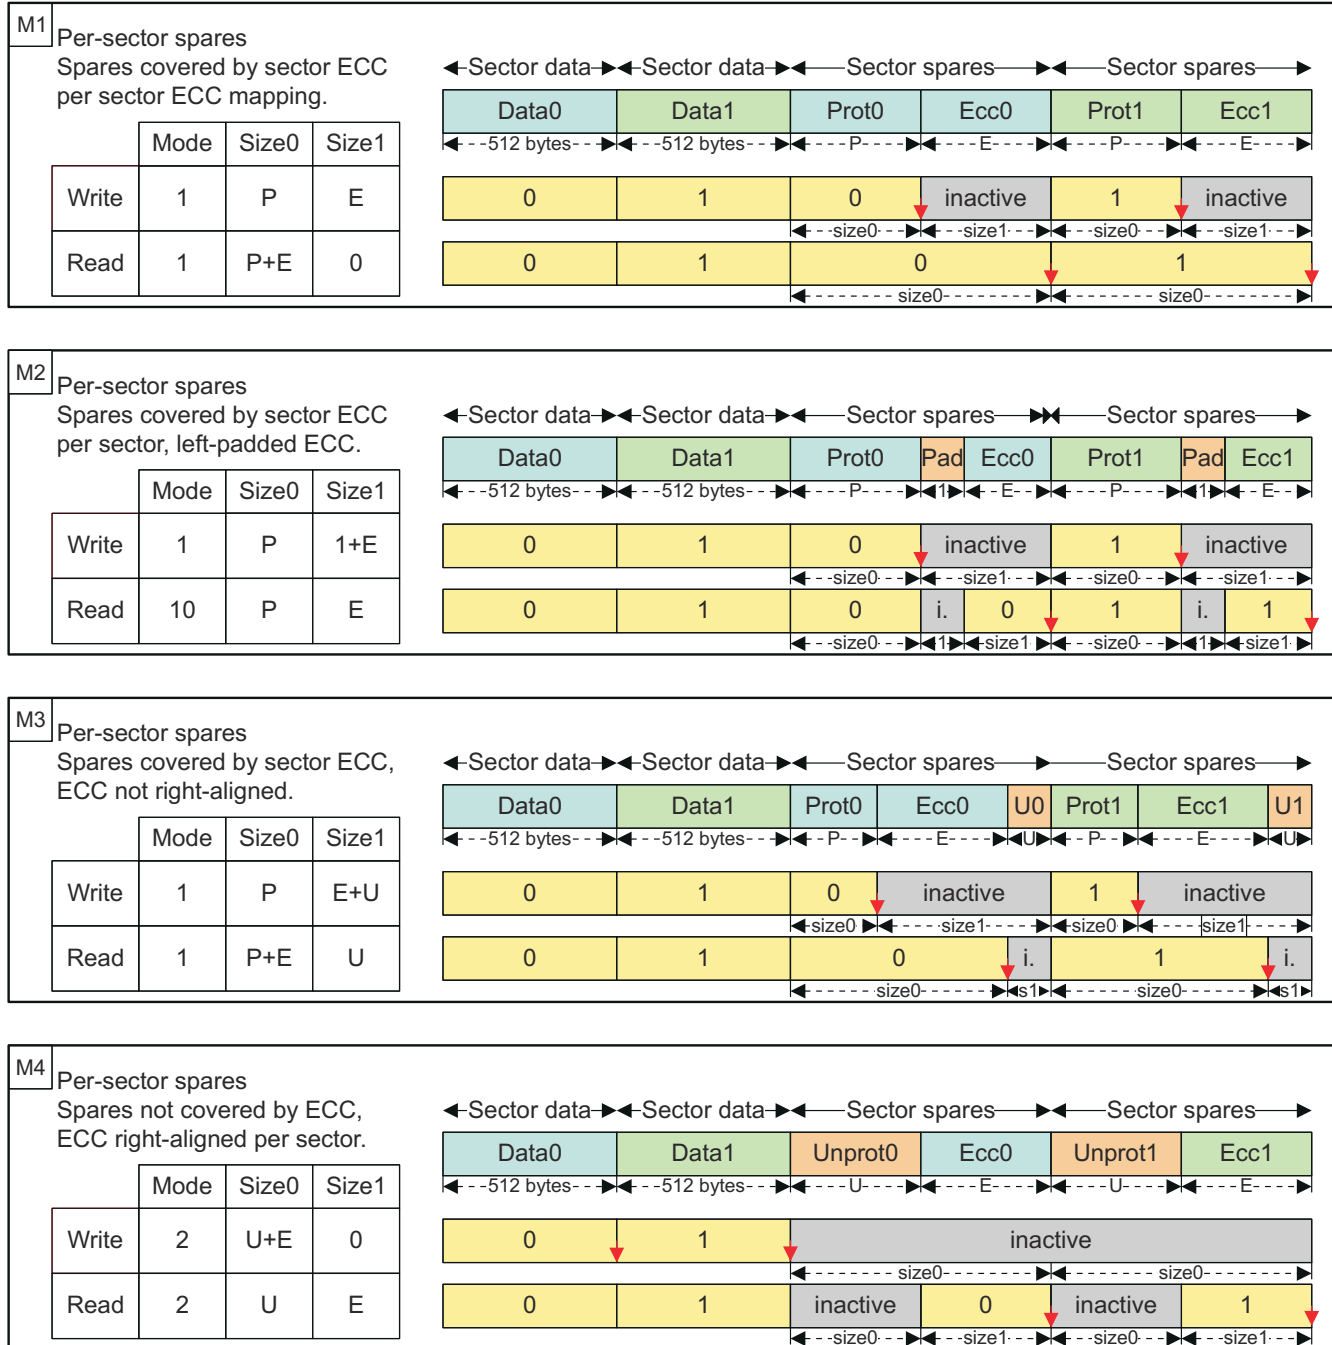

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword:  $(512) + P + E$
  - Other sectors:  $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords  $(512) + E$

#### 12.3.4.4.11.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

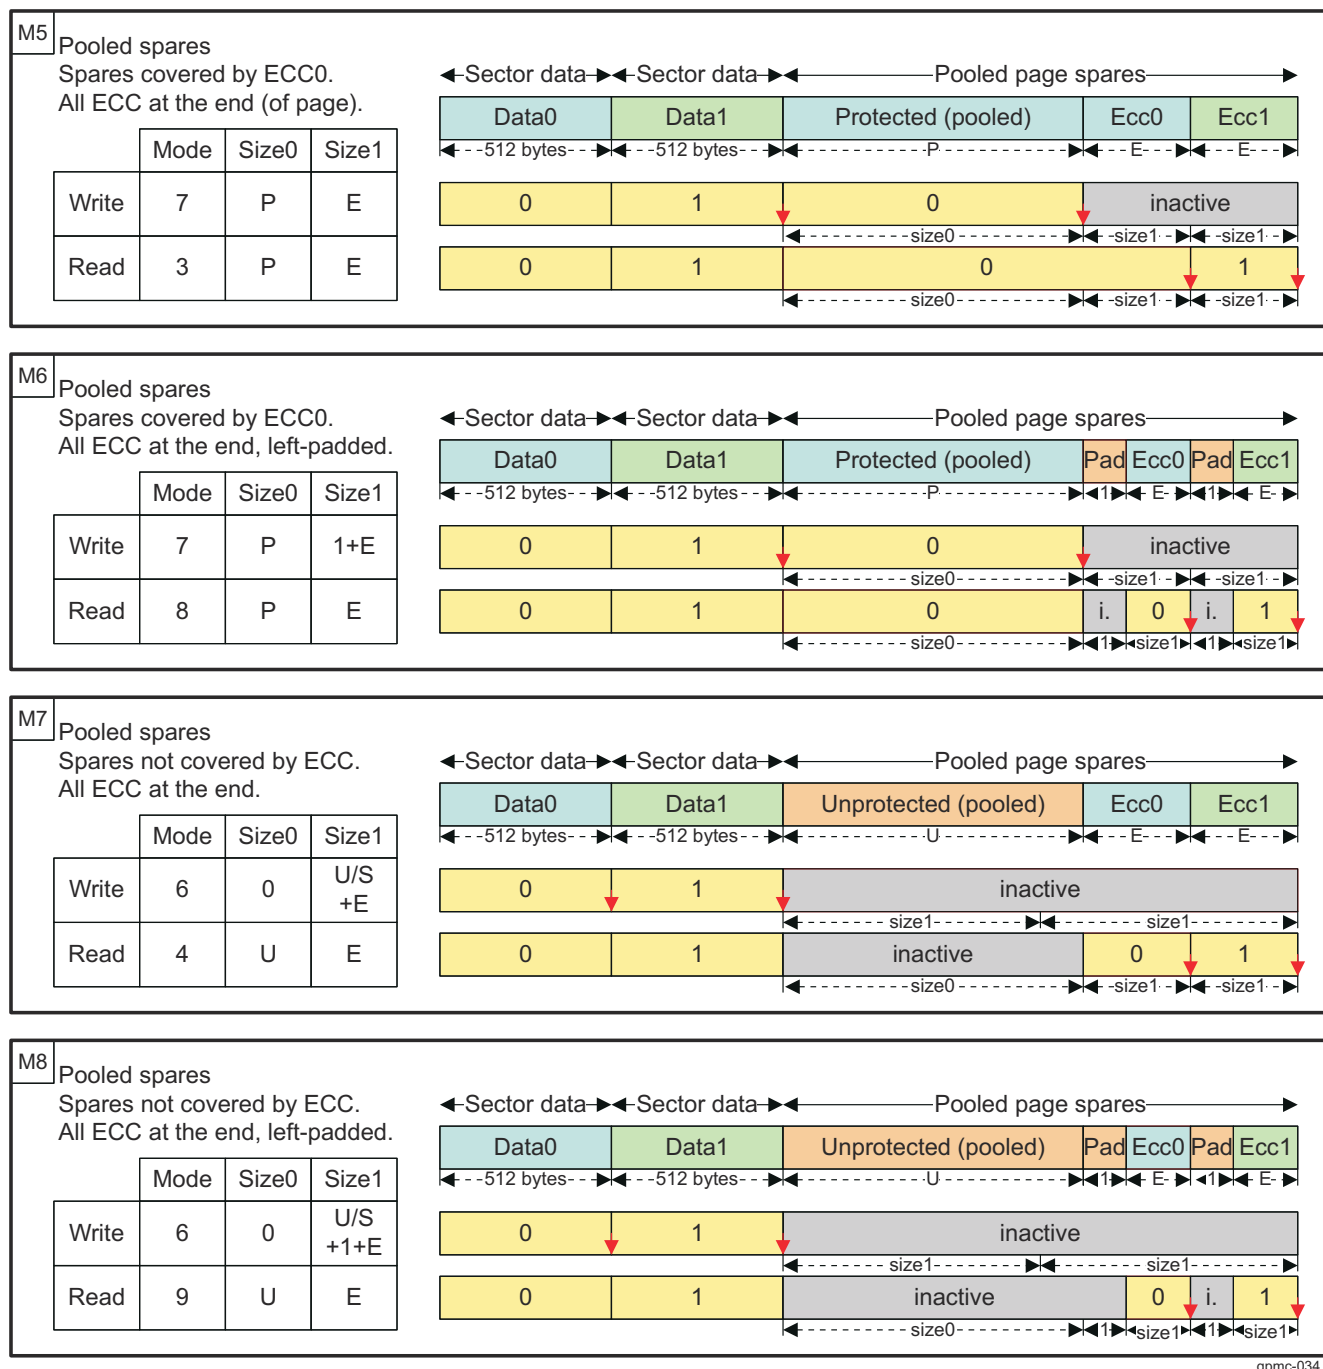

gpmc-033

**Figure 12-270. NAND Page Mapping and ECC: Per-Sector Schemes**

#### 12.3.4.4.11.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

gpmc-034

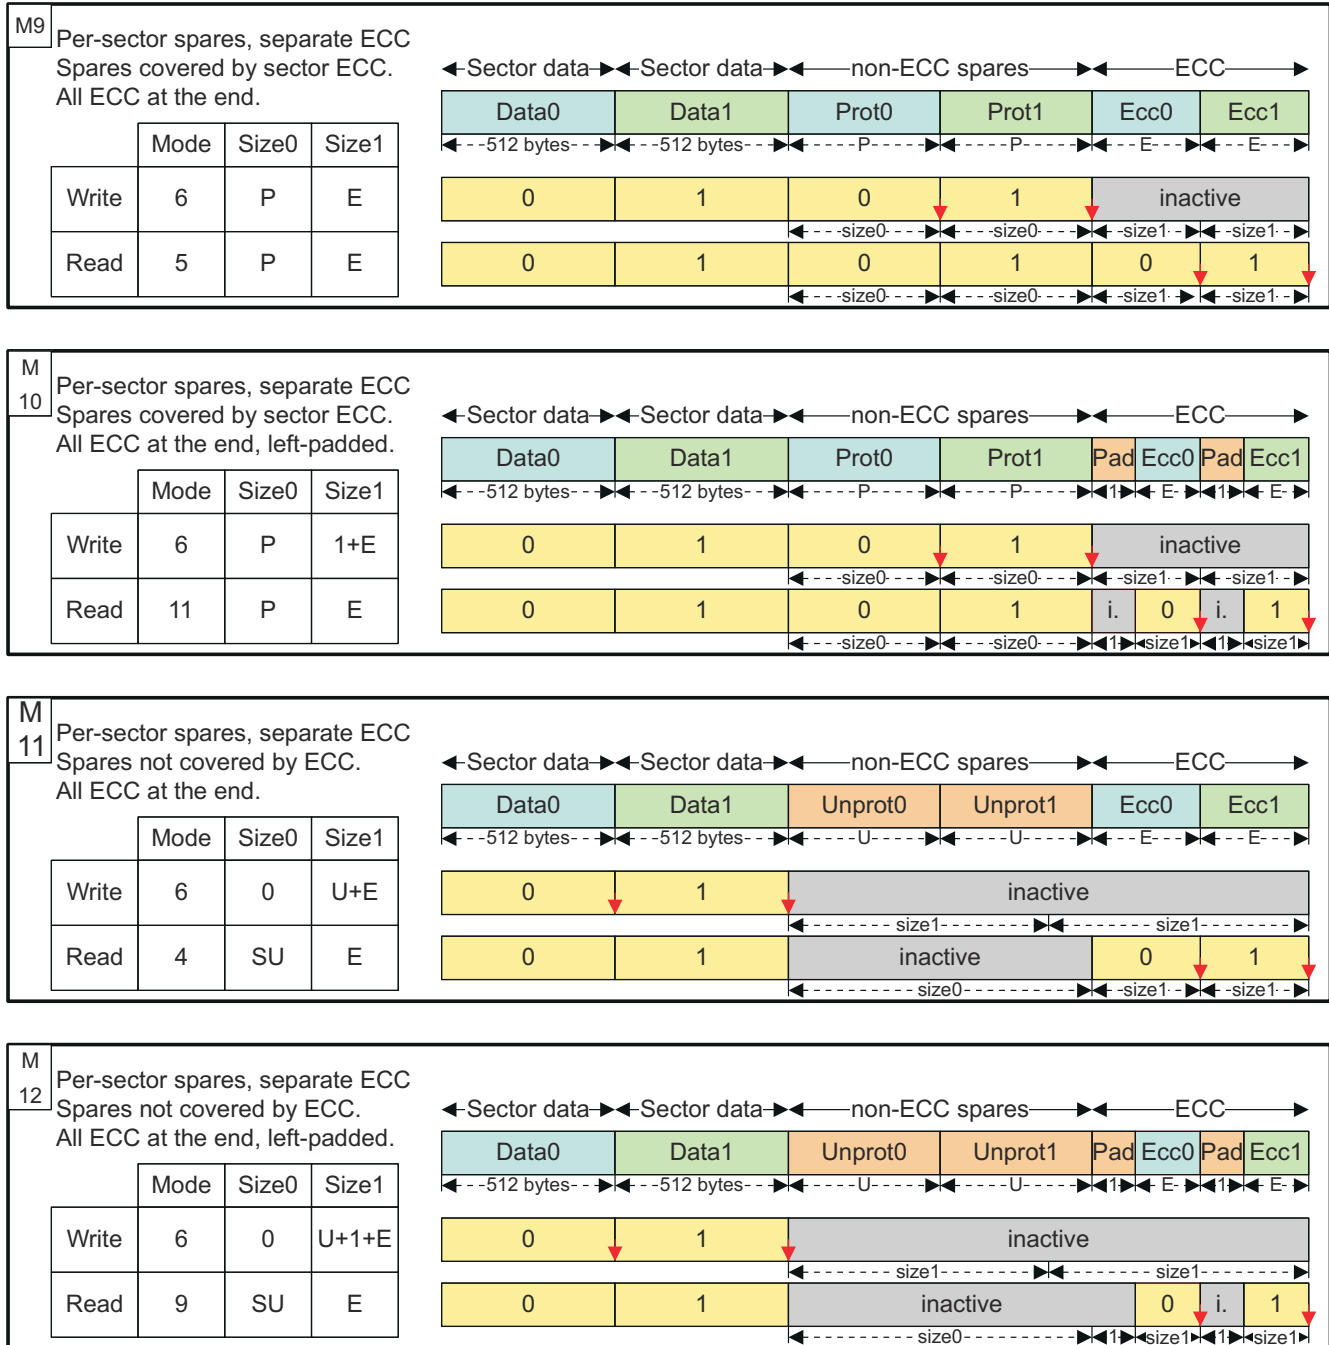

**Figure 12-271. NAND Page Mapping and ECC: Pooled Spare Schemes**

#### 12.3.4.4.11.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

gpmc\_035

**Figure 12-272. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC**

#### 12.3.4.4.11.4 Prefetch and Write-Posting Engine

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

NAND device data access cycles are usually much slower than the CPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long

read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the interconnect interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by a device host processor through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by a device DMA module through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine depends on the NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write-posting engine access to the GPMC bus for a number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

---

#### Note

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

---

#### 12.3.4.4.11.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC\_PREFETCH\_CONFIG1[26-24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 3):

- GPMC\_NAND\_COMMAND\_i
- GPMC\_NAND\_ADDRESS\_i
- GPMC\_NAND\_DATA\_i

The FIFO entry on the interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC\_PREFETCH\_STATUS[30-24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 12.3.4.4.11.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see [Section 12.3.4.4.11.2.2, Ready Pin Monitored by Hardware Interrupt](#)). The GPMC\_PREFETCH\_CONFIG1[5-4] WAITPINSELECTOR bit field selects which GPMC\_WAIT pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT bit field.

Table 12-333 describes the prefetch mode configuration.

**Table 12-333. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17-16]	0 to 1	Selects WAIT pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 12.3.4.4.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine</a> .
CYCLOOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.4.4.11.4.3 FIFO Control in Prefetch Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be drained directly by a device host processor or a DMA module channel.

In draining mode, the FIFO status can be monitored through the GPMC\_PREFETCH\_STATUS[30-24] FIFOPOINTER bit field or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, all the available bytes must be read, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must

be cleared. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

#### Note

The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 12.3.4.4.11.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC\_PREFETCH\_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the NAND software driver must issue the second cycle program command and monitor

the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 12-334 describes the write-posting configuration.

**Table 12-334. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26-24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14-8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13-0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See <a href="#">Section 12.3.4.4.11.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine</a> .
CYCLOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30-28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

#### 12.3.4.4.11.4.5 FIFO Control in Write-Posting Mode

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

The FIFO can be filled directly by a device host processor or a DMA module channel.

In filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC\_PREFETCH\_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC\_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, enough bytes must be written to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC\_PREFETCH\_STATUS[13-0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC\_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC\_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the TERMINALCOUNTSTATUS bit must be cleared. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

### Note

The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, DMA or CPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

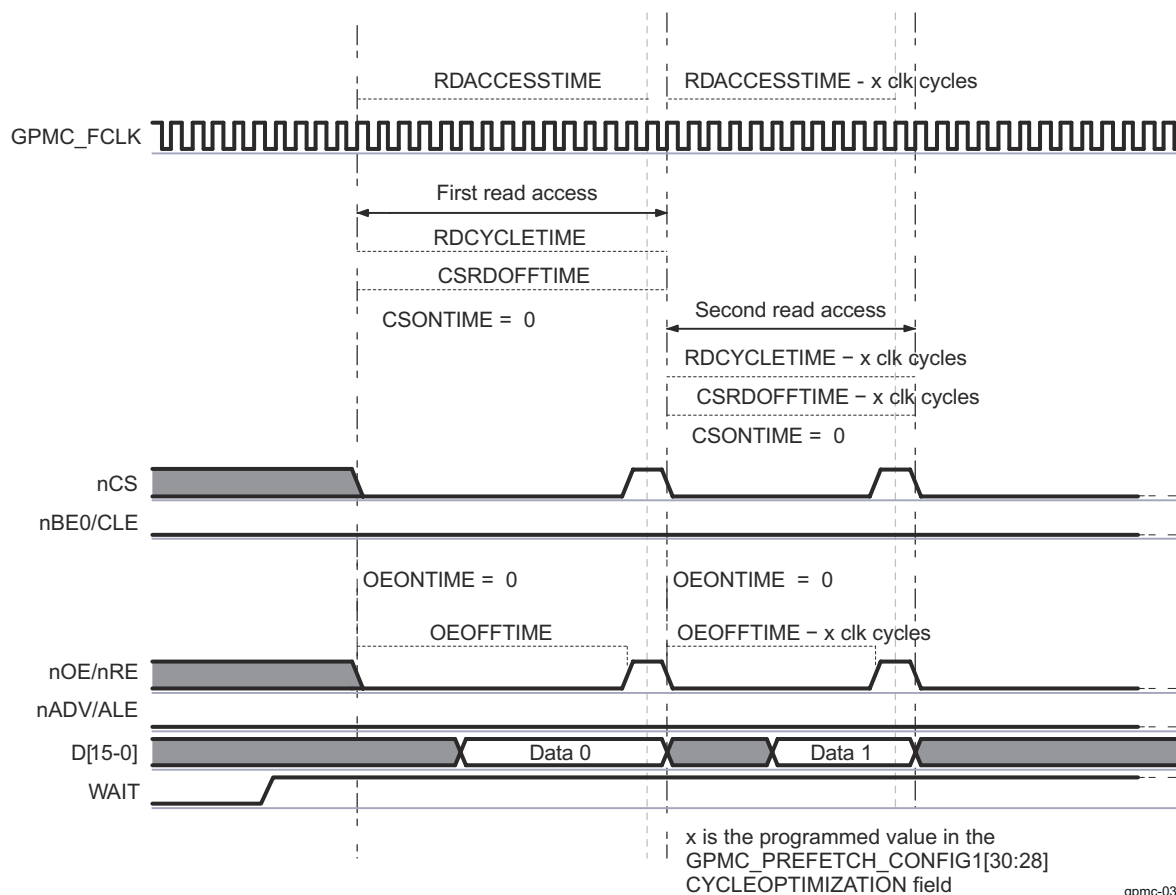

#### 12.3.4.4.11.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSN is set. This capability is limited to the prefetch and write-posting engine accesses, and accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC\_NAND\_DATA\_i location, where i = 0 to 3) are never optimized.

The GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field defines the number of GPMC\_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 12-273 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION bit field.

gpmc-036

**Figure 12-273. NAND Read Cycle Optimization Timing Description**

#### 12.3.4.4.11.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

#### 12.3.4.4.12 GPMC Use Cases and Tips

##### 12.3.4.4.12.1 How to Set GPMC Timing Parameters for Typical Accesses

###### 12.3.4.4.12.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or non-multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

###### 12.3.4.4.12.1.2 Typical GPMC Setup

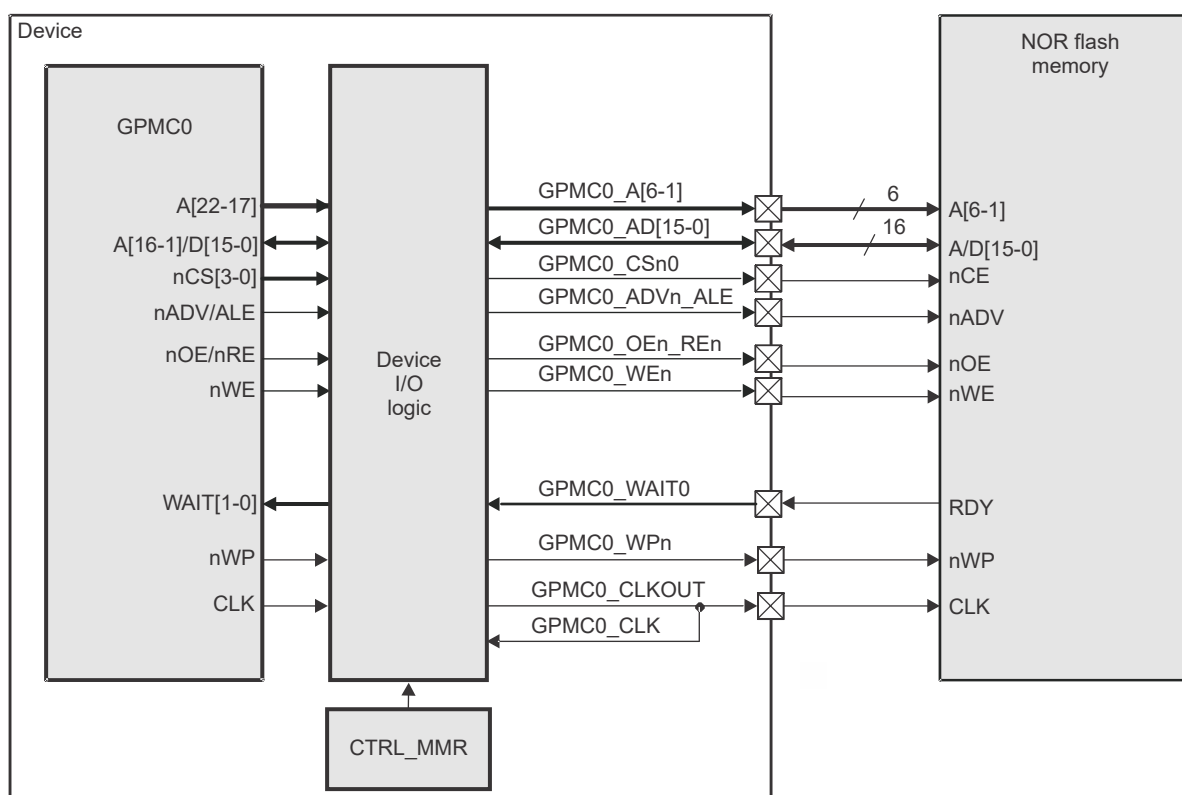

[Table 12-335](#) lists some of the I/Os of the GPMC module.

**Table 12-335. Typical GPMC Setup Signals**

Module Pin	I/O <sup>(1)</sup>	Description
GPMC0_FCLK	Internal	Functional clock. Acts as the time reference.
GPMC0_ICLK	Internal	Interface clock. Acts as the time reference.
GPMC0_CLKOUT	O	External clock provided to the external device for synchronous operations
GPMC0_A[21-16]	O	Address
GPMC0_AD[15-0]	I/O	Data-multiplexed with addresses A[16-1] on memory side
GPMC0_CSn[3-0]	O	Chip-selects
GPMC0_ADVn_ALE	O	Address valid enable
GPMC0_OEn_REn	O	Output enable (read access only)
GPMC0_WEn	O	Write enable (write access only)
GPMC0_WAIT[1-0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) I = Input; O = Output

[Figure 12-274](#) shows the typical connection between the GPMC module and an attached NOR Flash memory.

**Figure 12-274. GPMC Connection to an External NOR Flash Memory**

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

#### 12.3.4.4.12.1.2.1 GPMC Configuration for Synchronous Burst Read Access

##### Note

The examples in [Section 12.3.4.4.12.1.2.1](#) through [Section 12.3.4.4.12.1.2.3](#) are based on a clock rate of 104 MHz. See the device-specific Datasheet for the maximum frequency appropriate for this device and the memory datasheet for the maximum frequency for the particular memory device.

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

[Table 12-336](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 12-337](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 12-275](#) shows the synchronous burst read access.

**Table 12-336. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3

**Table 12-336. Useful Timing Parameters on the Memory Side (continued)**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5.2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nADV pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ( $T = 9.615$  ns). The read access time between two bursts of data is  $tBACC = 5.2$  ns. Therefore, data setup time is a clock period –  $tBACC = 4.415$  ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

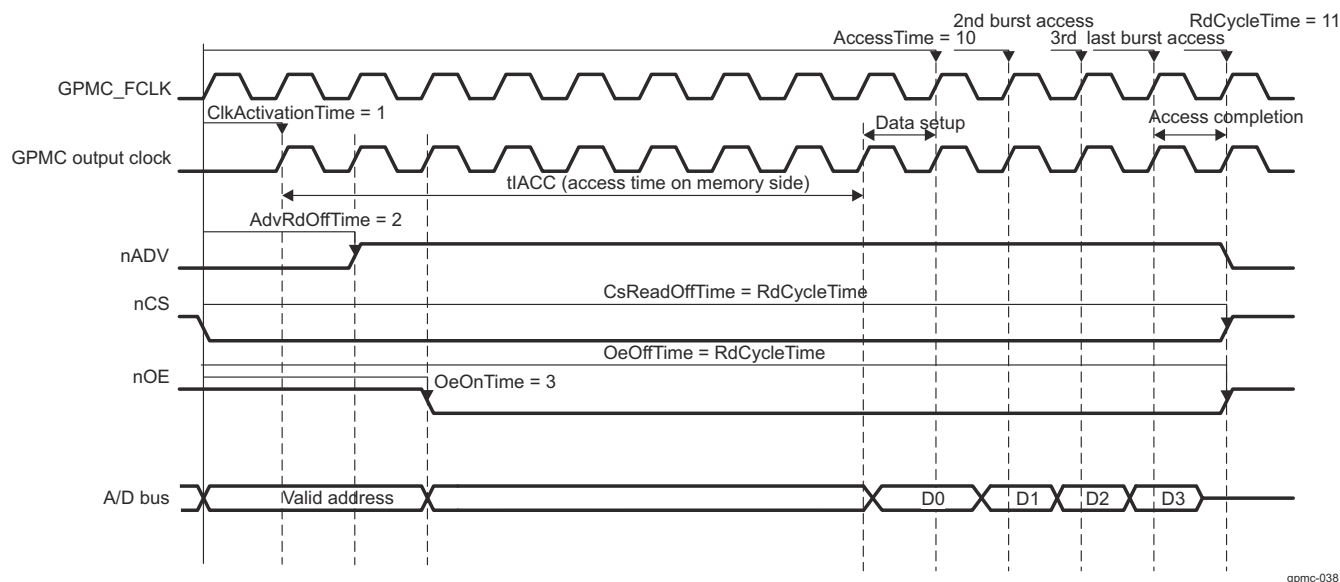

**Table 12-337. Calculating GPMC Timing Parameters**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	$\min(tCES, tACS)$	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$	94.03: (9.615 + 80 + 4.415)	10: $\text{roundmax}(94.03 / 9.615)$	RDACCESSTIME = 0xA
PageBurst RdAccessTime	$\text{roundmax}(tBACC)$	$\text{roundmax}(5.2)$	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	$\text{RdAccess time} + \max(tCEZ, tOEZ)$	101.03: (94.03 + 7)	11	RDCYCLETIME = 0xB
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	–	11	CSRDOFFTIME = 0xB
AdvOnTime	tAVC <sup>(1)</sup>	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC <sup>(2)</sup>	12	2	ADVRDOFFTIME = 0x2
OeOnTime <sup>(3)</sup>	$(\text{ClkActivationTime} + tACH) < \text{OeOnTime}(\text{ClkActivationTime} + tIACC)$	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0xB

(1) The external clock provided to the NOR flash is not yet available.

(2)  $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$ ; thus,  $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$ .

(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

**Figure 12-275. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.4.4.12.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ( $f = 104 \text{ MHz}$ ;  $T = 9.615 \text{ ns}$ ).

Table 12-338 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 12-339 shows how to calculate timings for the GPMC using the memory parameters.

Figure 12-276 shows the asynchronous read access.

**Table 12-338. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 12-338: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

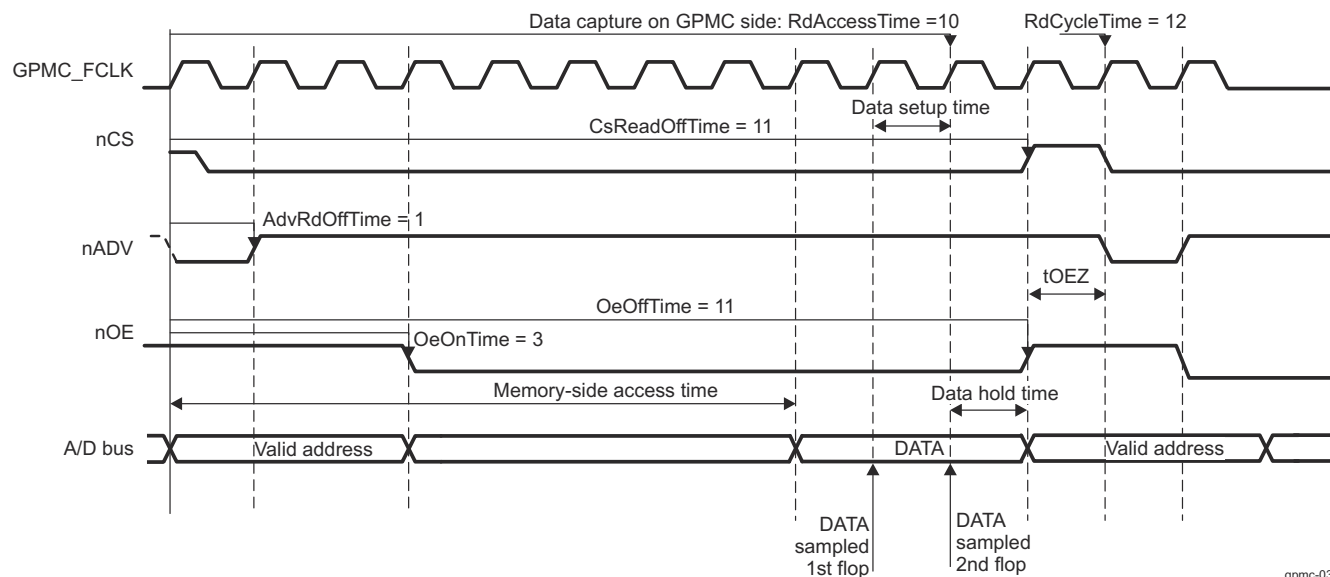

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, RdAccessTime + 1).
4. To complete the access, nOE/nCS signals are driven to High-Z. RdAccessTime + 1 + tOEZ is the read cycle time.

5. Addresses can now be relatched and a new read cycle begun.

**Table 12-339. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime		n/a (asynchronous mode)		
RdAccessTime	round max (tCE)	80	10	RDACCESSTIME = 0xA
PageBurstAccessTime	N/A (single access)			
RdCycleTime	RdAccessTime + 1 cycle + tOEZ	96.615	12	RDCYCLETIME = 0xC
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	RdAccessTime + 1 cycle	89.615	11	CSRDOFFTIME = 0xB
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0x1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x1
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	RdAccessTime + 1 cycle	89.615	11	OEOFFTIME = 0xB

gpmc-039

**Figure 12-276. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

#### 12.3.4.4.12.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9.615 ns).

Table 12-341 shows how to calculate timings for the GPMC using the memory parameters.

Table 12-340 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 12-277 shows the asynchronous single write access.

**Table 12-340. AC Characteristics for Asynchronous Single Write (Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20

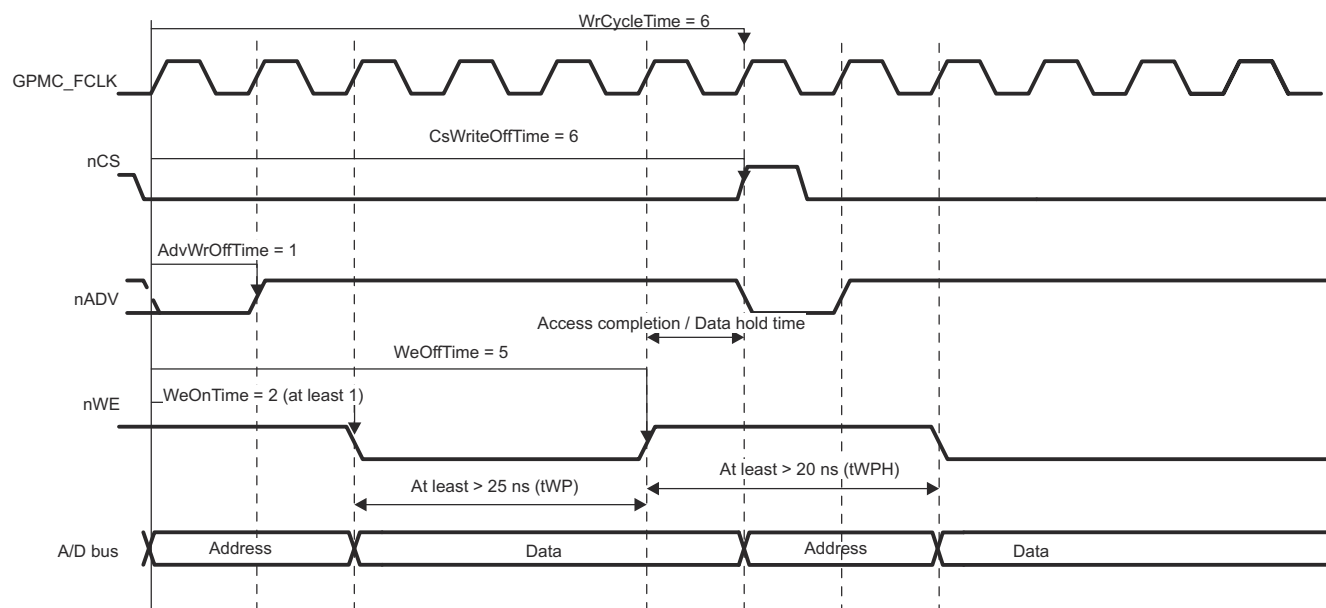

**Table 12-340. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is  $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion, the GPMC requires one cycle of data hold time (nCS deassertion). For more information, see the device-specific Datasheet.

**Table 12-341. GPMC Timing Parameters for Asynchronous Single Write**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime		N/A (asynchronous mode)		
WdAccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime		N/A (single access)		
WrCycleTime	WeOffTime + AccessCompletion	57.615	6	WRCYCLETIME = 0x6
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57.615	6	CSWROFFTIME = 0x6
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x1
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x5

gpmc-040

**Figure 12-277. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

#### 12.3.4.4.12.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

#### 12.3.4.4.12.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, and so on)
- 8- and 16-bit NAND flash devices

##### 12.3.4.4.12.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

**Table 12-342. Supported Memory Interfaces**

(1) Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

#### 12.3.4.4.12.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 12-343 summarizes the NAND interface signals level applied to external device or memories.

**Table 12-343. NAND Interface Bus Operations Summary**

Bus Operation	CLE	ALE	nCE	nWE <sup>(1)</sup>	nRE <sup>(1)</sup>	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H <sup>(2)</sup>	H <sup>(2)</sup>	H <sup>(2)</sup>	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L

(1) RE stands for rising edge; FE stands for falling edge

(2) Can be nCE high, or WE and nRE high.

#### 12.3.4.4.12.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

[Table 12-344](#) summarizes the level of the NOR interface signals applied to external devices or memories.

**Table 12-344. NOR Interface Bus Operations Summary**

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15-0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

#### 12.3.4.4.12.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

FPGA (Field-Programmable Gate Array) is a low-power integrated circuit based on an array of programmable logic blocks.

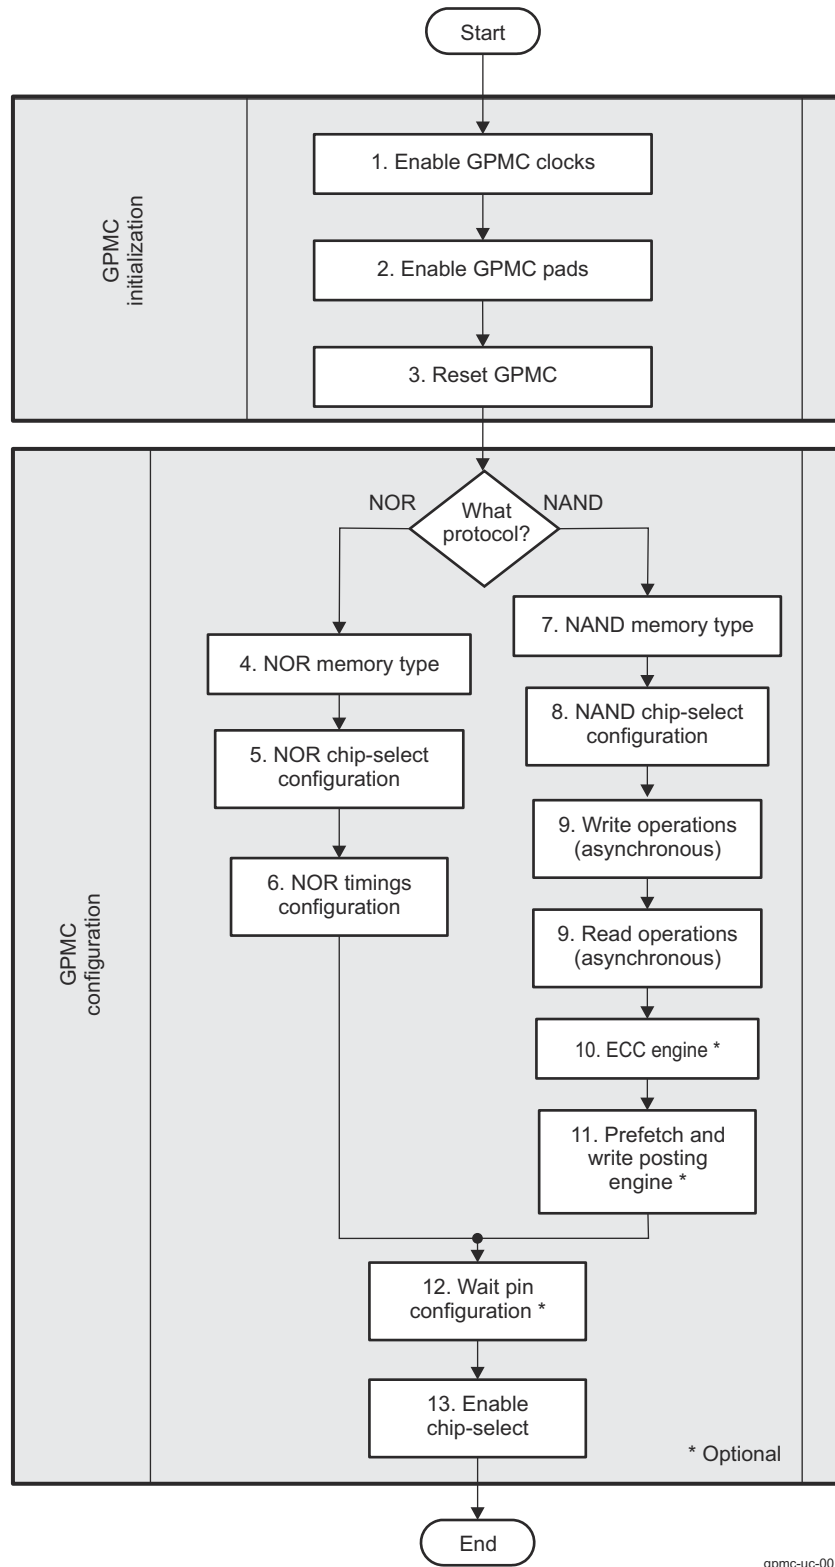

pSRAM (pseudo-static random access memory) is a low-power memory device. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It has synchronous write capability.

### 12.3.4.5 GPMC Basic Programming Model

#### 12.3.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

[Figure 12-278](#) and [Table 12-345](#) through [Table 12-346](#) show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

**Figure 12-278. Programming Model Top-Level Diagram**

**Table 12-345. GPMC Configuration in NOR Mode**

Step	Description
NOR Memory Type	See <a href="#">Table 12-347</a> .

**Table 12-345. GPMC Configuration in NOR Mode (continued)**

Step	Description
NOR Chip-Select Configuration	See <a href="#">Table 12-348</a> .

Enable Chip-Select	See <a href="#">Table 12-358</a> .

### 12.3.4.5.2 GPMC Initialization

GPMC can be reset via software bit in LPSC. For more information, see *Reset*.

### 12.3.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

**Table 12-347. NOR Memory Type**

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9-8] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency <sup>(1)</sup> .	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time <sup>(1)</sup> .	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations <sup>(1)</sup> .	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or non-multiplexed asynchronous for multiple access one)

**Table 12-348. NOR Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-349. NOR Timings Configuration**

Subprocess Name	Register/Bit Field	Value

When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

#### 12.3.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

#### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

**Table 12-352. NAND Memory Type**

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11-10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9-8] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See <a href="#">Section 12.3.4.5.5, Set Memory Access</a> .	x

**Table 12-353. NAND Chip-Select Configuration**

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16MB).	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 12-354. Asynchronous Read and Write Operations**

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See <a href="#">Section 12.3.4.5.6, GPMC Timing Parameters</a> .	

**Table 12-355. ECC Engine**

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x <sup>(2)</sup>
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[21-12] ECCSIZE0 and [31-22] ECCSIZE1	x <sup>(1)</sup>
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x

**Table 12-355. ECC Engine (continued)**

Subprocess Name	Register/Bit Field	Value
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_CONFIG[6-4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) Depends on the size of each sector in the NAND page

(2) This parameter depends on the numbers of sectors in a page.

**Table 12-356. Prefetch and Write-Posting Engine**

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue an interrupt request.	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select interrupt synchronization mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30-28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

**Table 12-357. WAIT Pin Configuration**

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which WAIT pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

**Table 12-358. Enable Chip-Select**

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

#### 12.3.4.5.5 Set Memory Access

##### Note

Some of the GPMC features described in this section may not be supported on this family of devices. For more information, see *GPMC Not Supported Features*.

This section describes the bit field to configure to set the GPMC in various memory modes. [Table 12-359](#) and [Table 12-360](#) provide check lists for mode parameters and access type parameters, respectively.

**Table 12-359. Mode Parameters Check List**

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	Don't care	0x1 <sup>(1)</sup>	Not Supported	0x0	Don't care	0x1	Don't care
GPMC_CONFIG1_i	29	READTYPE	0x0	Don't care	0x0 <sup>(1)</sup>	Not Supported	0x1	Don't care	0x1	Don't care
GPMC_CONFIG1_i	28	WRITEMULTIPLE	Don't care	0x0	- <sup>(1)</sup>	Not Supported	Don't care	0x0	Don't care	0x1
GPMC_CONFIG1_i	27	WRITETYPE	Don't care	0x0	- <sup>(1)</sup>	Not Supported	Don't care	0x1	Don't care	0x1

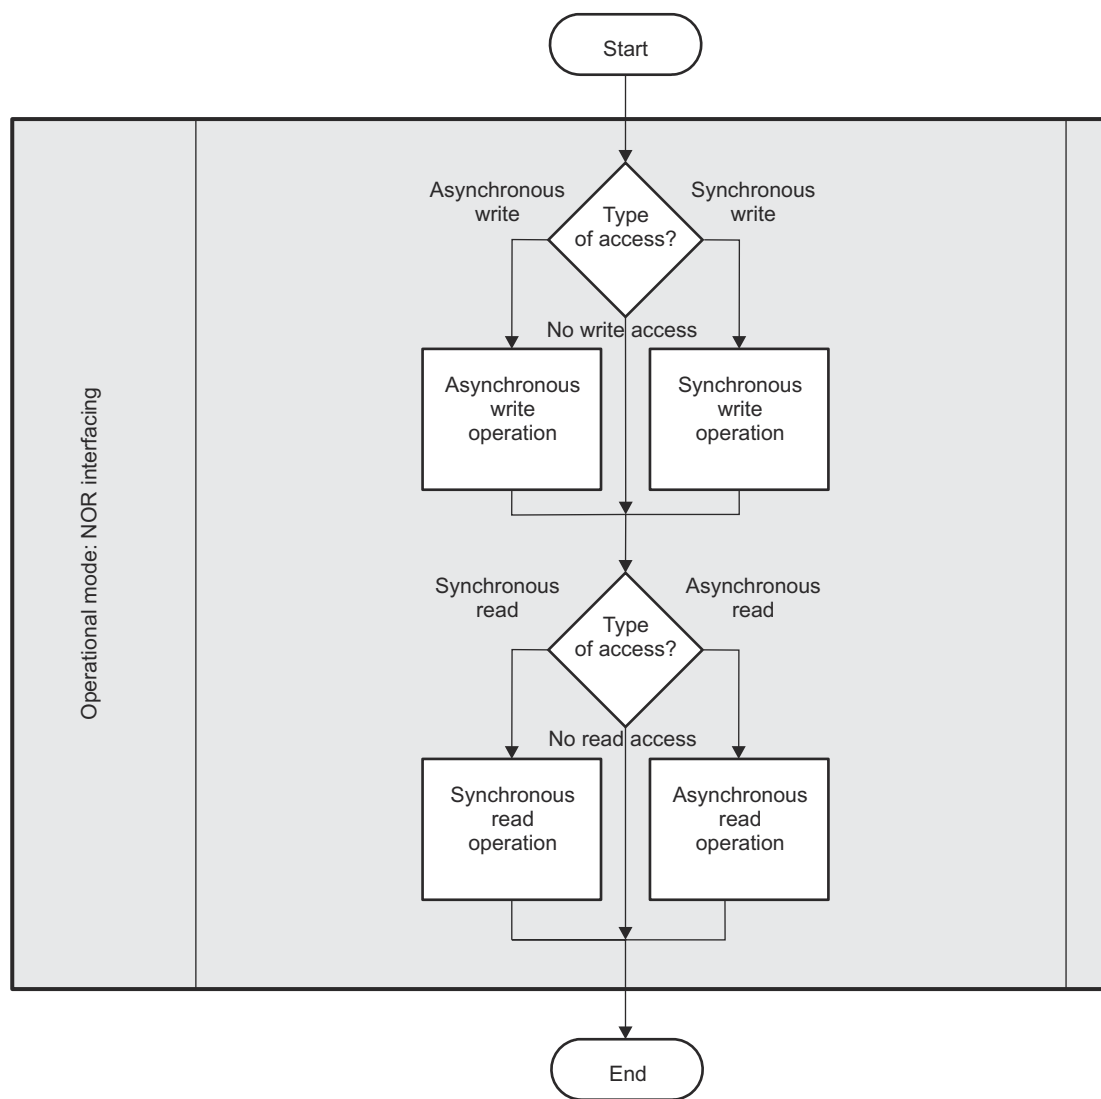

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in non-multiplexed mode.

**Table 12-360. Access Type Parameters Check List**

Register	Bit	Name	Access Type		
			non-multiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	0x0	0x2	0x1

#### 12.3.4.5.6 GPMC Timing Parameters

Figure 12-279 shows a programming model diagram for the NOR interfacing timing parameters.

gpmc-uc-002

**Figure 12-279. NOR Interfacing Timing Parameters Diagram**

Table 12-361 lists the bit fields to configure adequate timing parameters in various memory modes.

**Table 12-361. Timing Parameters**

Register	Bit	Name	Asynchronous			Synchronous				Non-multiplexed	Access/ Data-Multiplexed	Access Type
			Single Read Accesses	Single Write Accesses	Multiplexed Read (Page) Accesses	Single Read Accesses	Single Write Accesses	Multiplexed Read (Burst) Accesses	Multiplexed Write (Burst) Accesses			
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y

### 12.3.4.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

For complete information, such as OPP and board effects on timings, see the device-specific Datasheet.

#### 12.3.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x2. [Table 12-362](#) describes the NAND timing parameters.

**Table 12-362. NAND Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – GPMC_WEn valid time
B	ns	Delay time – GPMC_CS valid to GPMC_WEn valid
C	ns	Delay time – GPMC_BE0n_CLE/GPMC_ADVn_ALE high to GPMC_WEn valid
D	ns	Delay time – GPMC_AD[15-0] valid to GPMC_WEn valid
E	ns	Delay time – GPMC_WEn invalid to GPMC_AD[15-0] invalid
F	ns	Delay time – GPMC_WEn invalid to GPMC_BE0n_CLE/GPMC_ADVn_ALE invalid
G	ns	Delay time – GPMC_WEn invalid to GPMC_CS invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – GPMC_CS valid to GPMC_OEn_REn valid
J	ns	Setup time – GPMC_AD[15-0] valid to GPMC_OEn_REn invalid
K	ns	Pulse duration – GPMC_OEn_REn valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – GPMC_OEn_REn invalid to GPMC_CS invalid

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

$$\begin{aligned}
 A &= (\text{WEOffTime} - \text{WEOntime}) * (\text{TimeParaGranularity} + 1) * \text{GPMC\_FCLK period} \\
 B &= ((\text{WEOntime} - \text{CSOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC\_FCLK period} \\
 C &= ((\text{WEOntime} - \text{ADVOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{WEEExtraDelay} - \text{ADVExtraDelay})) * \text{GPMC\_FCLK period} \\
 D &= (\text{WEOntime} * (\text{TimeParaGranularity} + 1) + 0.5 * \text{WEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 E &= (\text{WrCycleTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) - 0.5 * \text{WEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 F &= (\text{ADVWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{ADVExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC\_FCLK period} \\
 G &= (\text{CSWrOffTime} - \text{WEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{WEEExtraDelay})) * \text{GPMC\_FCLK period} \\
 H &= \text{WrCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 I &= ((\text{OEOnTime} - \text{CSOnTime}) * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{OEEExtraDelay} - \text{CSEExtraDelay})) * \text{GPMC\_FCLK period} \\
 J &= ((\text{RdAccessTime} - \text{OEOffTime}) * (\text{TimeParaGranularity} + 1) - 0.5 * \text{OEEExtraDelay}) * \text{GPMC\_FCLK period} \\
 K &= (\text{OEOffTime} - \text{OEOnTime}) * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 L &= \text{RdCycleTime} * (1 + \text{TimeParaGranularity}) * \text{GPMC\_FCLK period} \\
 M &= (\text{CSRdOffTime} - \text{OEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSEExtraDelay} - \text{OEEExtraDelay})) * \text{GPMC\_FCLK period}
 \end{aligned}$$

[Figure 12-280](#) shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

**Figure 12-280. NAND Command Latch Cycle Timing Simplified Example**

#### 12.3.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. [Table 12-363](#) describes the synchronous NOR formulas.

**Table 12-363. Synchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – address bus valid to CLK first edge Delay time – nBE0 / nBE1 valid to CLK first edge
C	ns	Pulse duration – nBE0 / nBE1 low
D	ns	Delay time – CLK rising edge to nBE0 / nBE1 invalid Delay time – CLK rising edge to nADV/ALE invalid
E	ns	Delay time – CLK rising edge to nCS invalid Delay time – CLK rising edge to nOE/nRE invalid
F	ns	Delay time – CLK rising edge to nCS transition
G	ns	Delay time – CLK rising edge to nADV/ALE transition
H	ns	Delay time – CLK rising edge to nOE/nRE transition
I	ns	Delay time – CLK rising edge to nWE transition
J	ns	Delay time – CLK rising edge to A[16-1]/D[15-0] data bus transition Delay time – CLK rising edge to nBE0 / nBE1 transition
K	ns	Pulse duration – nADV/ALE low
L	ns	Delay time – WAIT invalid to first data latching CLK edge

The configuration parameters are calculated through the following formulas. For more information, see the device-specific Datasheet.

1. For single read accesses:

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$C = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$$

$$D = (\text{RDCYCLETIME} - \text{RDACCESSTIME}) * \text{GPMC\_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - \text{RDACCESSTIME}) * \text{GPMC\_FCLK period}$$

2. For burst read accesses (where n is the page burst access number):
 
$$A = (CSRDOFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$

$$C = (RDCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$

$$D = (RDCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$$

$$E = (CSRDOFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$$
3. For burst write accesses (where n is the page burst access number):
 
$$A = (CSWROFFTIME - CSONTIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$

$$C = (WRCYCLETIME + (n - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$$

$$D = (WRCYCLETIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$$

$$E = (CSWROFFTIME - (RDACCESSTIME + (n - 1) * PAGEBURSTACCESSTIME)) * GPMC\_FCLK \text{ period}$$
4. For all accesses:
 

For nCS falling edge (chip-select activated):

  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$$
  - Case where GPMCFCLKDIVIDER = 0x1:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)}$$

$$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$$
  - Case where GPMCFCLKDIVIDER = 0x2:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3}$$

$$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3}$$

$$F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3}$$

For nCS rising edge (chip-select deactivated) in reading mode:

  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$$
  - Case where GPMCFCLKDIVIDER = 0x1:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)}$$

$$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$$
  - Case where GPMCFCLKDIVIDER = 0x2:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3}$$

$$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3}$$

$$F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3}$$

For nCS rising edge (chip-select deactivated) in writing mode:

  - Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period}$$
  - Case where GPMCFCLKDIVIDER = 0x1:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)}$$

$$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$$
  - Case where GPMCFCLKDIVIDER = 0x2:
 
$$F = 0.5 * CSEXTRADELAY * GPMC\_FCLK \text{ period, when (CSWROFFTIME - CLKACTIVATIONTIME) is a multiple of 3}$$

$F = (1 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $F = (2 + 0.5 * CSEXTRADELAY) * GPMC\_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV falling edge (nADV activated):

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are even})$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are even})$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are even})$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:  
 $G = 0.5 * ADVEXTRADELAY * GPMC\_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $G = (1 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $G = (2 + 0.5 * ADVEXTRADELAY) * GPMC\_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nOE falling edge (nOE activated):

- Case where GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are even})$

- $$H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nOE rising edge (nOE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are even})$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $H = 0.5 * OEEXTRADELAY * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nWE falling edge (nWE activated):

- Case where  $GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are even})$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nWE rising edge (nWE deactivated):

- Case where  $GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER = 0x0$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period}$
- Case where  $GPMCFCLKDIVIDER = 0x1$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are even})$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period otherwise.}$
- Case where  $GPMCFCLKDIVIDER = 0x2$ :  
 $I = 0.5 * WEEXTRADELAY * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$   
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$   
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC\_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$

For nADV low pulse duration:

- Read operation:

- $K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$
- Write operation:  
 $K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$

For WAIT invalid to first data latching GPMC output clock edge:

- $L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC\_FCLK \text{ period} + GPMC \text{ output clock period}$

Figure 12-281 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

gpmc-046

**Figure 12-281. Synchronous NOR Single Read Simplified Example**

#### 12.3.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC\_CONFIG1\_i[11-10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 12-364 describes the asynchronous NOR formulas.

**Table 12-364. Asynchronous NOR Formulas Description**

Configuration Parameter	Unit	Description
A	ns	Pulse duration – nCS low
B	ns	Delay time – nCS valid to nADV/ALE invalid
C	ns	Delay time – nCS valid to nOE/nRE invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – nCS valid to nWE valid
F	ns	Delay time – nCS valid to nWE invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before nOE/nRE high

**Table 12-364. Asynchronous NOR Formulas Description (continued)**

Configuration Parameter	Unit	Description
I	ns	Delay time – nCS valid to nOE/nRE invalid (burst read)
J	ns	Delay time – address bus valid to nCS valid
		Delay time – data bus valid to nCS valid
		Delay time – nBE0 / nBE1 valid to nCS valid
K	ns	Delay time – nCS valid to nADV/ALE valid
L	ns	Delay time – nCS valid to nOE/nRE valid
M	ns	Delay time – nCS valid to first data latching edge
N	ns	Pulse duration – nBE0 / nBE1 valid time
O	ns	Delay time – nCS valid to nADV/ALE valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive. For more information, see the device-specific Datasheet.

- nCS low pulse:  
For single read:  $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$   
For burst read:  $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number  
For single write:  $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$   
For burst write:  $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$ , where N = page burst access number
- nCS valid to nADV/ALE invalid delay:  
For reading:  $B = ((\text{ADVROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$   
For writing:  $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $C = ((\text{OEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC\_FCLK period}$
- $H = ((\text{OEOFFTIME} - \text{RDACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC\_FCLK period}$
- $I = ((\text{OEOFFTIME} + (N - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$ , where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC\_FCLK period}$
- $M = ((\text{RDACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC\_FCLK period}$
- nBE0 /nBE1 pulse:  
For single read:  $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC\_FCLK period}$

For burst read:  $N = (RDCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number

For burst write:  $N = (WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC\_FCLK \text{ period}$ , where N = page burst access number

- $O = ((WRCYCLETIME + (N - 1) * PAGEBURSTACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY - CSEXTRADELAY)) * GPMC\_FCLK \text{ period}$

Figure 12-282 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

**Figure 12-282. Asynchronous NOR Single Write Simplified Example**

#### Note

Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

### 12.3.5 Error Location Module (ELM)

This section describes the Error Location Module (ELM) for the device.

#### 12.3.5.1 ELM Overview

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. A host processor can then correct the data block by flipping the bits to which the ELM error-location outputs point.

When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller. ELM can be also used to support parallel NOR flash or NAND flash.

The General-Purpose Memory Controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM depends on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

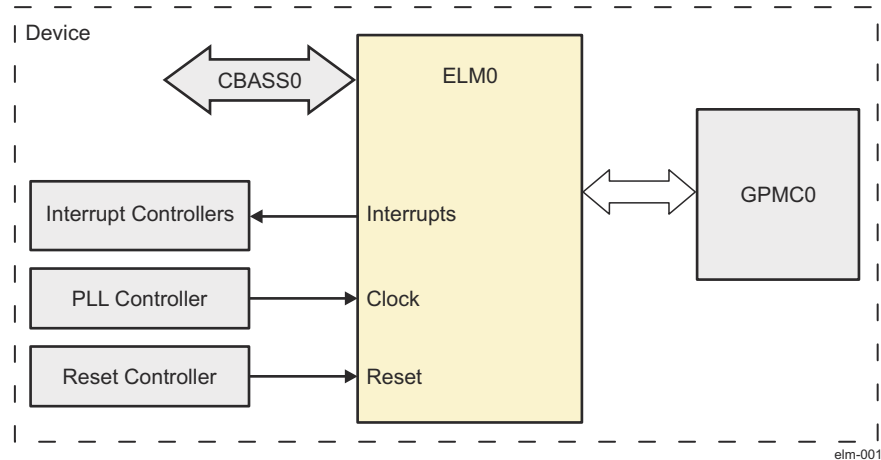

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

Table 12-365 shows the ELM allocation across device domains.

**Table 12-365. ELM Allocation Across Device Domains**

Instance	WKUP	MCU	MAIN
	Domain		
ELM0	-	-	✓

Figure 12-283 shows the ELM0 module overview.

**Figure 12-283. ELM0 Overview**

#### 12.3.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location, based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode.

#### 12.3.5.1.2 ELM Not Supported Features

The following features are not supported on this family of devices:

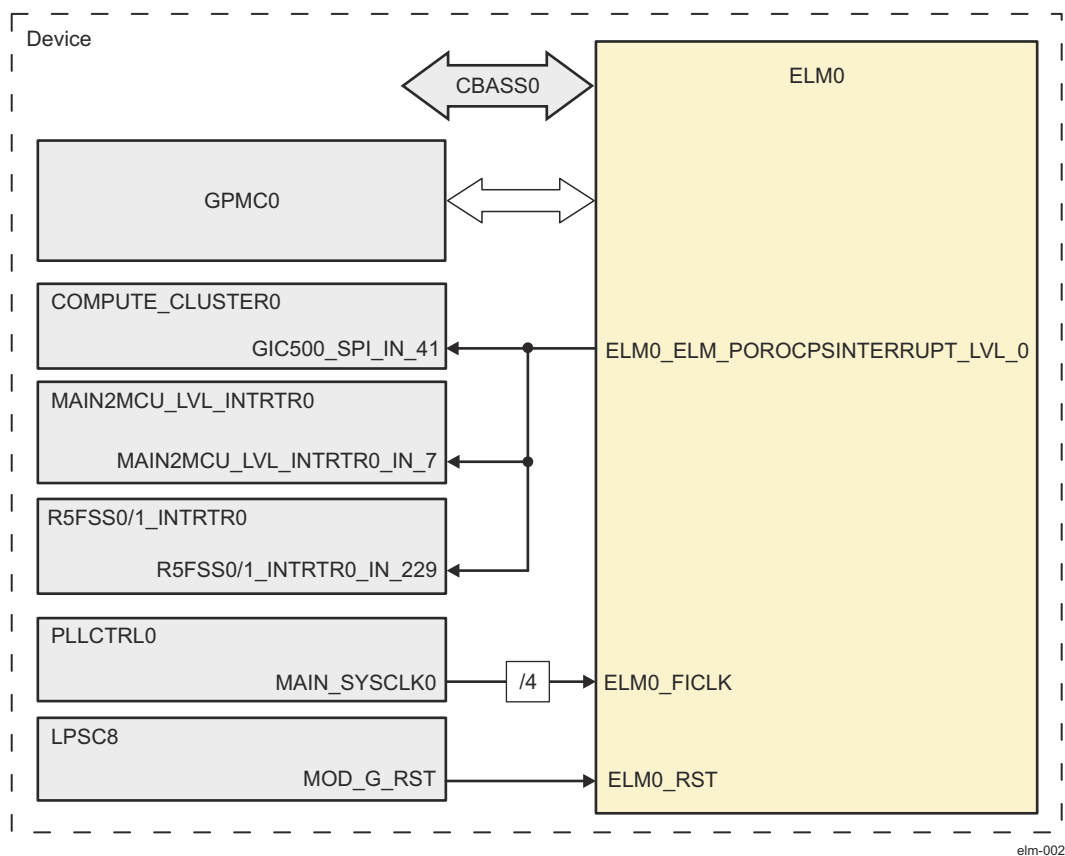

- Local power management of clock activity

### 12.3.5.2 ELM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.3.5.2.1 ELM Integration in MAIN Domain

A single ELM module is integrated in the device MAIN domain - ELM0. Figure 12-284 shows the ELM0 integration.

**Figure 12-284. ELM0 Integration**

Table 12-366 through Table 12-368 summarize the integration of ELM0 in device MAIN domain.

**Table 12-366. ELM0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
ELM0	PSC0	PD0	LPSC8	CBASS0

**Table 12-367. ELM0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
ELM0	ELM0_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	ELM0 functional and interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
ELM0	ELM0_RST	MOD_G_RST	LPSC8	ELM0 hardware reset

**Table 12-368. ELM0 Hardware Requests**

Interrupt Requests				
--------------------	--	--	--	--

**Table 12-368. ELM0 Hardware Requests (continued)**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
ELM0	ELM0_ELM_POROCPSINTERR UPT_LVL_0	GIC500_SPI_IN_41	COMPUTE_CLUSTER0	Error-location process complete interrupt	Level
		R5FSS0_INTRTR0_IN_29	R5FSS0_INTRTR0	Error-location process complete interrupt	Level
		R5FSS1_INTRTR0_IN_29	R5FSS1_INTRTR0	Error-location process complete interrupt	Level
		MAIN2MCU_LVL_INTRTR0_IN_7	MAIN2MCU_LVL_INTRTR0	Error-location process complete interrupt	Level

### 12.3.5.3 ELM Functional Description

The ELM0 module is hereinafter referred to as ELM.

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

#### 12.3.5.3.1 ELM Software Reset

To perform a software reset, set the ELM\_SYSCONFIG[1] SOFTRESET bit to 1. The ELM\_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM\_SYSCONFIG[1] SOFTRESET bit is automatically reset.

#### 12.3.5.3.2 ELM Power Management

##### Note

Some of the ELM features described in this section may not be supported on this family of devices. For more information, see *ELM Not Supported Features*.

Table 12-369 describes the power-management features available to the ELM.

**Table 12-369. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FICLK clock upon the interface activity.
Idle modes	ELM_SYSCONFIG[4-3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained.

#### 12.3.5.3.3 ELM Interrupt Requests

Table 12-370 lists the event flags, and their masks, that can cause module interrupts asserting the ELM0\_ELM\_POROCPSINTERRUPT\_LVL\_0 signal.

**Table 12-370. ELM Events**

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

### 12.3.5.3.4 ELM Processing Initialization

ELM\_LOCATION\_CONFIG global setting parameters must be set before using the error-location engine. The ELM\_LOCATION\_CONFIG[1-0] ECC\_BCH\_LEVEL bit field defines the error-correction level used (4-, 8-, or 16-bit error correction). The ELM\_LOCATION\_CONFIG[26-16] ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM\_PAGE\_CTRL[i] SECTOR\_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM\_IRQENABLE[i] LOCATION\_MASK\_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM\_IRQENABLE[8] PAGE\_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM\_SYNDROME\_FRAGMENT\_0\_i to ELM\_SYNDROME\_FRAGMENT\_6\_i. The first six registers can be written in any order, but ELM\_SYNDROME\_FRAGMENT\_6\_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit).

As soon as one validity bit is asserted (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM\_LOCATION\_STATUS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit is set.

### 12.3.5.3.5 ELM Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM\_LOCATION\_STATUS\_i[8] ECC\_CORRECTABLE bit is set to 1 and the ELM\_LOCATION\_STATUS\_i[4-0] ECC\_NB\_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM\_LOCATION\_STATUS\_i[8] ECC\_CORRECTABLE bit is set to 0 while the ELM\_LOCATION\_STATUS\_i[4-0] ECC\_NB\_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC\_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC\_ERROR\_LOCATION bit field. The first error detected is logged in the ELM\_ERROR\_LOCATION\_0\_i[12-0] ECC\_ERROR\_LOCATION bit field; the second is logged in the ELM\_ERROR\_LOCATION\_1\_i[12-0] ECC\_ERROR\_LOCATION bit field, and so on.

Table 12-371 describes the ELM\_LOCATION\_STATUS\_i value decoding.

**Table 12-371. ELM\_LOCATION\_STATUS\_i Value Decoding**

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
-----------------------	---------------------	--------	---------------------------	-----------------

**Table 12-371. ELM\_LOCATION\_STATUS\_i Value Decoding (continued)**

1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

### 12.3.5.3.6 ELM Processing Completion

When the processing for a given syndrome polynomial completes, its ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit is reset. It must not be set again until the exit status registers, ELM\_LOCATION\_STATUS\_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM\_LOCATION\_STATUS\_i register, and error locations are stored in order in the ECC\_ERROR\_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM\_PAGE\_CTRL are reset), an interrupt is triggered whenever a ELM\_IRQSTATUS[i] LOC\_VALID\_i bit is asserted. Software must read the ELM\_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM\_LOCATION\_STATUS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i). When done, software must clear the corresponding ELM\_IRQSTATUS[i] LOC\_VALID\_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM\_IRQSTATUS[8] PAGE\_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM\_IRQENABLE[i] LOCATION\_MASK\_i bits are cleared. A page is defined using the ELM\_PAGE\_CTRL register. Each SECTOR\_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM\_IRQSTATUS[i] LOC\_VALID\_i bits. The module triggers an ELM\_IRQSTATUS[8] PAGE\_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM\_IRQSTATUS register must be cleared by using a single atomic-write access.

### Note

Do not modify page setting parameters in the ELM\_PAGE\_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM\_PAGE\_CTRL[i] SECTOR\_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM\_IRQSTATUS bits to check for their status.

### 12.3.5.4 ELM Basic Programming Model

#### 12.3.5.4.1 ELM Low-Level Programming Model

##### 12.3.5.4.1.1 Processing Initialization

**Table 12-372. ELM Processing Initialization**

Step	Register/Bit Field/Programming Model	Value
Resets the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management.	ELM_SYSCONFIG[4-3] SIDLEMODE	Set value
Defines the error-correction level used.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length.	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode.	ELM_PAGE_CTRL	Set value
<b>IF</b> continuous mode is used:	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enable interrupt for syndrome polynomial i.	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
<b>ELSE</b> (page mode is used):	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value
<b>ENDIF</b>		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

##### 12.3.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 12-373](#) and [Table 12-374](#) describe the processing completion for continuous and page modes, respectively.

**Table 12-373. ELM Processing Completion for Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM0_ELM_POROCPSINTERRUPT_LVL_0 interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
<b>IF</b> the process fails (too many errors):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x0) and after the exit status register check (ELM\_LOCATION\_STATUS\_i).

**Table 12-374. ELM Processing Completion for Page Mode**

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM0_ELM_POROCPSINTERRUPT_LVL_0 interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
<b>IF</b> the process fails (too many errors): It is software dependent.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
<b>ELSE</b> (process successful, the engine completes):	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12-0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12-0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12-0] ECC_ERROR_LOCATION	
<b>ENDIF</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTATUS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 12.3.5.4.1.3

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTATUS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 12.3.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see [Table 12-375](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980.

**Table 12-375. Use Case: Continuous Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module.	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 8 bits.	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x1
Define the maximum buffer length: 528 bytes (2 × 528 = 1056).	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420
Set the ELM in continuous mode.	ELM_PAGE_CTRL	0
Enable interrupt for syndrome polynomial 0.	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1

**Table 12-375. Use Case: Continuous Mode (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiate the computation process.	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: ELM0_ELM_POROCPSINTERRUPT_LVL_0 is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4-0] ECC_NB_ERRORS (where i = 0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 12-376](#) are given in decimal format.

**Table 12-376. 16-Bit NAND Sector Buffer Address Map**

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176

259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24

**Table 12-376. 16-Bit NAND Sector Buffer Address Map (continued)**

263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8
-----	---	---	---	---	---	---	---	---	----	----	----	----	----	----	---	---

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

#### 12.3.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for a 16-bit error-correction capability in page mode (see [Table 12-377](#)). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 12-377. Use Case: Page Mode**

Step	Register/Bit Field/Programming Model	Value
Reset the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the target interface power management: Smart idle is used.	ELM_SYSCONFIG[4-3] SIDLEMODE	0x2
Define the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1-0] ECC_BCH_LEVEL	0x2
Define the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26-16] ECC_SIZE	0x420

	ELM_ERROR_LOCATION_1_i (where i = 1)	0x1036
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (where i = 1)	0x3E8
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

### 12.3.6 Multimedia Card Secure Digital (MMCSD) Interface

This section describes the MMCSD modules in the device.

#### 12.3.6.1 MMCSD Overview

There are three MMCSD modules inside the device - MMCSD0, MMCSD1 and MMCSD2. Each MMCSD module includes one MMCSD Host Controller.

Each controller has the following data bus width:

- MMCSD0 - 8-bit wide data bus
- MMCSD1 - 4-bit wide data bus
- MMCSD2 - 4-bit wide data bus

Table 12-378 shows MMCSD allocation across device domains.

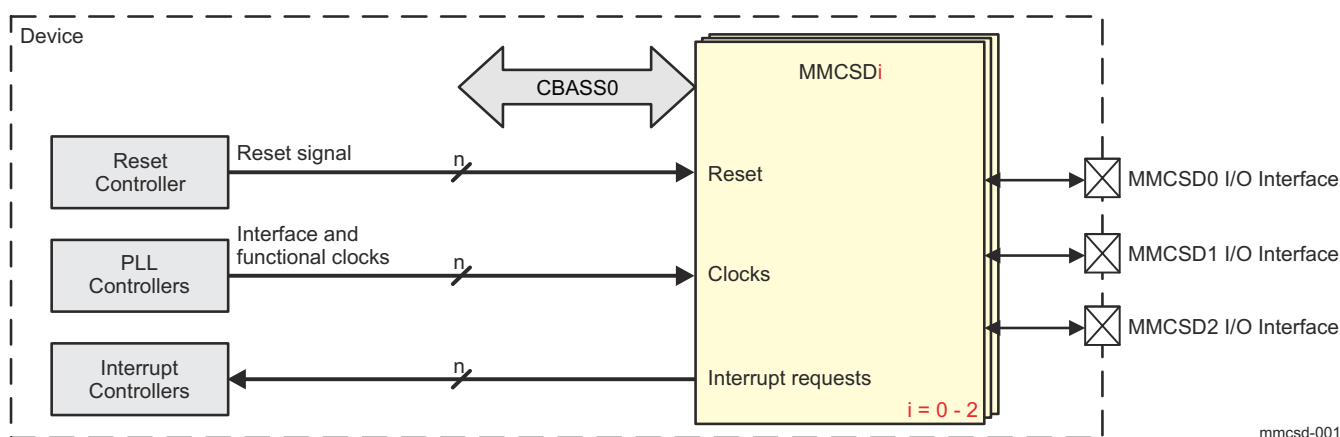

**Table 12-378. MMCSD Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MMCSD0	-	-	✓
MMCSD1	-	-	✓
MMCSD2	-	-	✓

The MMCSD Host Controller provides an interface to eMMC 5.1 (embedded MultiMedia Card), SD 4.10 (Secure Digital), and SDIO 4.0 (Secure Digital IO) devices. The MMCSD Host Controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit insertion, and checking for syntactical correctness.

The MMCSD Host Controller provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method. In programmed IO method, the device CPU transfers data using the Buffer Data Port register (MMCSD0\_DATA\_PORT / MMCSD12\_DATA\_PORT). In DMA data transfer method, the MMCSD Host Controller can read or write memory without device CPU intervention.

Figure 12-285 shows the MMCSDi module overview (where i = 0 to 2).

**Figure 12-285. MMCSDi Module Overview**

mmcsd-001

### 12.3.6.1.1 MMCSD Features

Each MMCSD Host Controller supports:

- Integrated DMA controller supporting SD Advanced DMA - ADMA2 and ADMA3 (for more information about ADMA support, see [Section 12.3.6.4.5, Advanced DMA](#))
- System Bus Interface:
  - 64-bit data width (master interface)
  - 64-bit address
  - Clock asynchronous to MMCSD clock (MMCi\_CLK)
  - Little endian only
- Configuration Bus Interface:
  - 32-bit data width (slave interface)
  - Linear incrementing addressing mode
  - 32-bit aligned accesses only
  - Little endian only
- Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level (MMCSD1/MMCSD2 only)

MMCSD0 Host Controller (eMMC interface):

- MultiMedia Card Support:
  - eMMC Electrical Standard 5.1 (JESD84-B51)
  - Backward compatible with earlier eMMC standards
  - Legacy MMC SDR:
    - 1.8 V, 8-bit bus width, 0-25 MHz, 25 MBps
    - 1.8 V, 4-bit bus width, 0-25 MHz, 12.5 MBps
    - 1.8 V, 1-bit bus width, 0-25 MHz, 3.125 MBps
  - High Speed SDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 50 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 25 MBps
    - 1.8 V, 1-bit bus width, 0-50 MHz, 6.25 MBps
  - High Speed DDR:
    - 1.8 V, 8-bit bus width, 0-50 MHz, 100 MBps
    - 1.8 V, 4-bit bus width, 0-50 MHz, 50 MBps
  - HS200 SDR:
    - 1.8 V, 0-200 MHz, 8-bit bus width, 200 MBps
    - 1.8 V, 0-200 MHz, 4-bit bus width, 100 MBps

MMCSD1/MMCSD2 Host Controller (SD/SDIO interface):

- 
- Secure Digital Card Support:
  - Backward compatible with earlier SD card specifications
  - SD Host Controller Standard Specification 4.10 and SD Physical Layer Specification v3.01
  - SDIO Specification v3.00
  - Default Speed mode: 3.3 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - High Speed mode: 3.3 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR12: UHS-I 1.8 V signaling, frequency up to 25 MHz, up to 12.5 MBps
  - SDR25: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 25 MBps
  - SDR50: UHS-I 1.8 V signaling, frequency up to 100 MHz, up to 50 MBps
  - DDR50: UHS-I 1.8 V signaling, frequency up to 50 MHz, up to 50 MBps

### 12.3.6.1.2 MMCSD Not Supported Features

MMCSD0 Host Controller:

- MultiMedia Card:

- 3.3 V, 3.0 V and 1.2 V
- Secure Digital Card and SDIO
- Muxing of other LVCMOS interfaces onto the MMCSD interface at the SoC level
- HS400 DDR:
  - 1.8 V, 0-200 MHz, 8-bit bus width, 400 MBps

MMCSD1/MMCSD2 Host Controller:

- MultiMedia Card
- Secure Digital Card:
  - UHS-II
  - SDR104: UHS-I 1.8 V signaling, frequency up to 200 MHz, up to 100 MBps

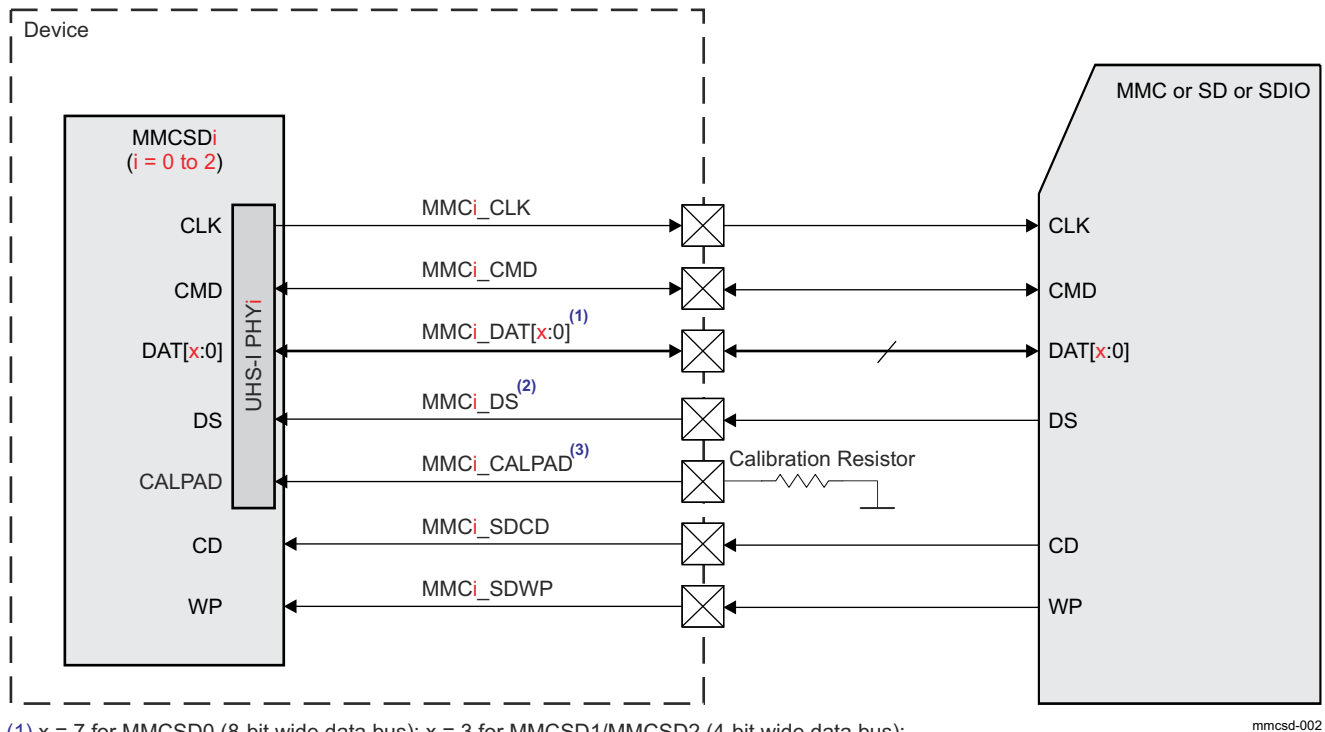

### 12.3.6.2 MMCSD Environment

The MMCSD0, MMCSD1 and MMCSD2 modules are hereinafter referred to as MMCSDi module.

This section describes the MMCSDi external connections (environment).

The MMCSD0 can be used for connection to 1, 4, or 8-bit devices (dedicated for connection to eMMC devices). The MMCSD1/MMCSD2 can be used for connection to 1 or 4-bit devices (dedicated for connection to SD or SDIO devices). For each MMCSD an integrated UHS-I PHY provides interface to external device.

Figure 12-286 shows the MMCSDi (where i = 0 to 2) connected to MMC, SD, or SDIO device.

**Figure 12-286. MMCSDi Connected to MMC, SD, or SDIO Device**

Table 12-379 describes the MMCSDi I/O signals.

**Table 12-379. MMCSDi I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
<b>MMCSD0</b>				
CLK	MMC0_CLK <sup>(3)</sup>	O	External Clock	0x0
CMD	MMC0_CMD	I/O	Command Line	0x0
DAT[7:0]	MMC0_DAT[7:0]	I/O	Data Signals	0x0
DS	MMC0_DS	I	Data Strobe	0x0
CALPAD	MMC0_CALPAD <sup>(2)</sup>	A	PHY Calibration Resistor	HiZ
<b>MMCSD1</b>				
CLK	MMC1_CLK	O	External Clock	0x0
CMD	MMC1_CMD	I/O	Command Line	0x0
DAT[3:0]	MMC1_DAT[3:0]	I/O	Data Signals	0x0
WP	MMC1_SDWP	I	SD Card Write Protect	0x1
CD	MMC1_SDCD	I	SD Card Detect	0x0
<b>MMCSD2</b>				
CLK	MMC2_CLK	O	External Clock	0x0
CMD	MMC2_CMD	I/O	Command Line	0x0
DAT[3:0]	MMC2_DAT[3:0]	I/O	Data Signals	0x0
WP	MMC2_SDWP	I	SD Card Write Protect	0x1
CD	MMC2_SDCD	I	SD Card Detect	0x0

(1) I = Input; O = Output; HiZ = High Impedance; A = Analog

(2) An external 10 kΩ ±1% resistor must be connected between this pin and VSS. No external voltage should be applied to this pin.

(3) This output signal is also used as a retiming input. It is also recommended to place a 33 Ω resistor in series (close to the SoC) to avoid signal reflections.

#### Note

For MMC1\_CLK signal to work properly, the RXACTIVE bit of the CTRLMMR0\_PADCONFIG171 register should be set to 0x1 because of retiming purposes.

For MMC2\_CLK signal to work properly, the RXACTIVE bit of the CTRLMMR0\_PADCONFIG172 register should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), refer to the device-specific Datasheet.

### 12.3.6.2.1 Protocol and Data Format

The bus protocol between the MMCSD Host Controller and the card is message-based. Each message is represented by one of the following parts:

- **Command:** A command starts an operation. The command is transferred serially from the MMCSD Host Controller to the card on the CMD line.
- **Response:** A response is an answer to a command. The response is sent from the card to the MMCSD Host Controller. It is transferred serially on the CMD line.
- **Data:** Data are transferred from the MMCSD Host Controller to the card or from the card to the MMCSD Host Controller using the data lines.
- **Busy:** The DAT[0] signal is maintained low by the card as far as it is programming the data received.
- **CRC status:** The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

#### 12.3.6.2.1.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

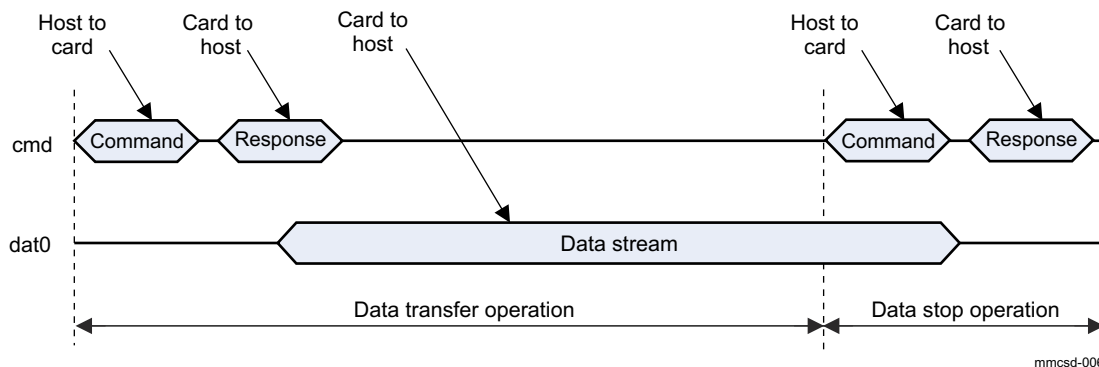

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO devices, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

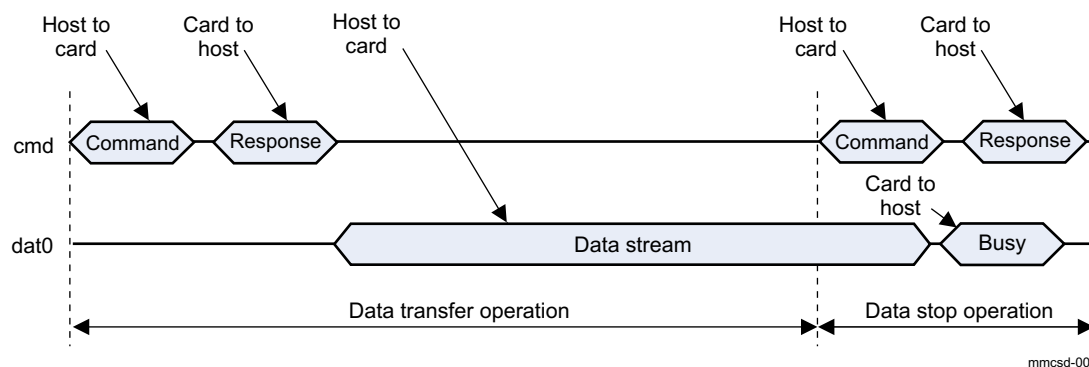

Figure 12-287 and Figure 12-288 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the CMD line.

#### Note

Stream commands are supported only by MMCs.

**Figure 12-287. Sequential Read Operation (MMCs Only)**

**Figure 12-288. Sequential Write Operation (MMCs Only)**

Figure 12-289 and Figure 12-290 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the CMD line. These operations are available for all kinds of devices (MMC, SD, SDIO).

**Figure 12-289. Multiple Block Read Operation**

mmcsd-009

**Figure 12-290. Multiple Block Write Operation With Card Busy Signal**

**Note**

- The card busy signal is not always generated by the card. Refer to [Figure 12-289](#) and [Figure 12-290](#), that show a particular case.
- Software must perform a software reset (see MMCS00\_SOFTWARE\_RESET / MMCS12\_SOFTWARE\_RESET register) after a data time-out to ensure that MMCi\_CLK is stopped.
- For multiblock transfer, and especially for MMC devices, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMCs supports this feature).

**12.3.6.2.1.2 Data Format**

**12.3.6.2.1.2.1 Coding Scheme for Command Token**

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 12-291](#)).

mmcsd-010

**Figure 12-291. Command Token Format**

**12.3.6.2.1.2.2 Coding Scheme for Response Token**

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see [Figure 12-292](#) and [Figure 12-293](#)). Depending on the type of commands sent to the card, the MMCS00\_COMMAND / MMCS12\_COMMAND register must be configured differently to

avoid false CRC or index errors to be flagged on command response (see [Table 12-380](#)). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

**Figure 12-292. Response Token Format (R1/R1b, R3, R4, R5/R5b, R6, R7)**

**Figure 12-293. Response Token Format (R2)**

**Table 12-380. Relationship Between Configuration and Name of Response Type**

Response Type MMCSD0_COMMAND[1-0] RESP_TYPE_SEL / MMCSD12_COMMAND[1-0] RESP_TYPE_SEL	Index Check Enable MMCSD0_COMMAND[4] CMD_INDEX_CHK_ENA / MMCSD12_COMMAND[4] CMD_INDEX_CHK_ENA	CRC Check Enable MMCSD0_COMMAND[3] CMD_CRC_CHK_ENA / MMCSD12_COMMAND[3] CMD_CRC_CHK_ENA	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

### 12.3.6.2.1.2.3 Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 12-294](#) through [Figure 12-296](#)).

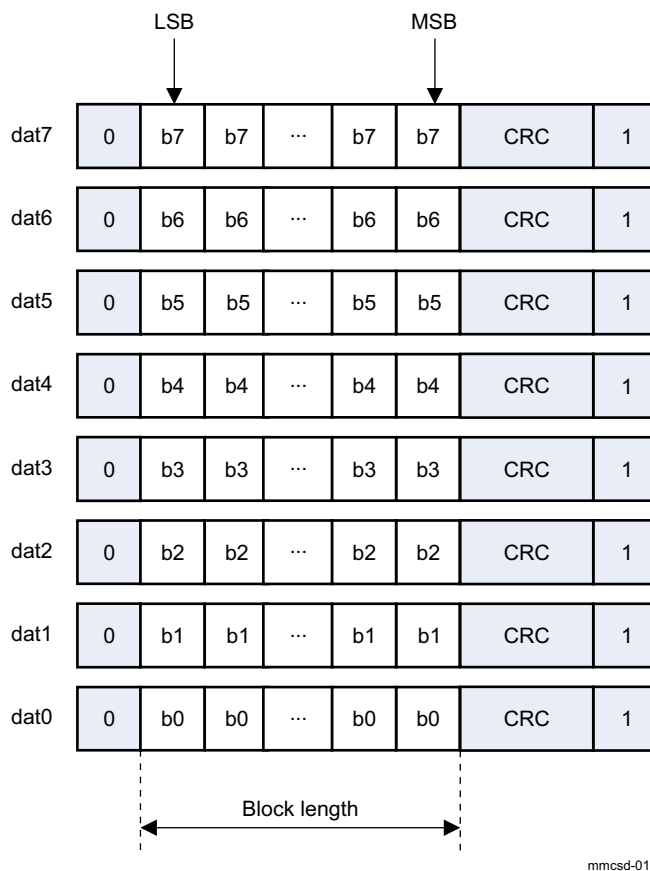

**Figure 12-294. Data Token Format for 1-Bit Transfers**

**Figure 12-295. Data Token Format for 4-Bit Transfers**

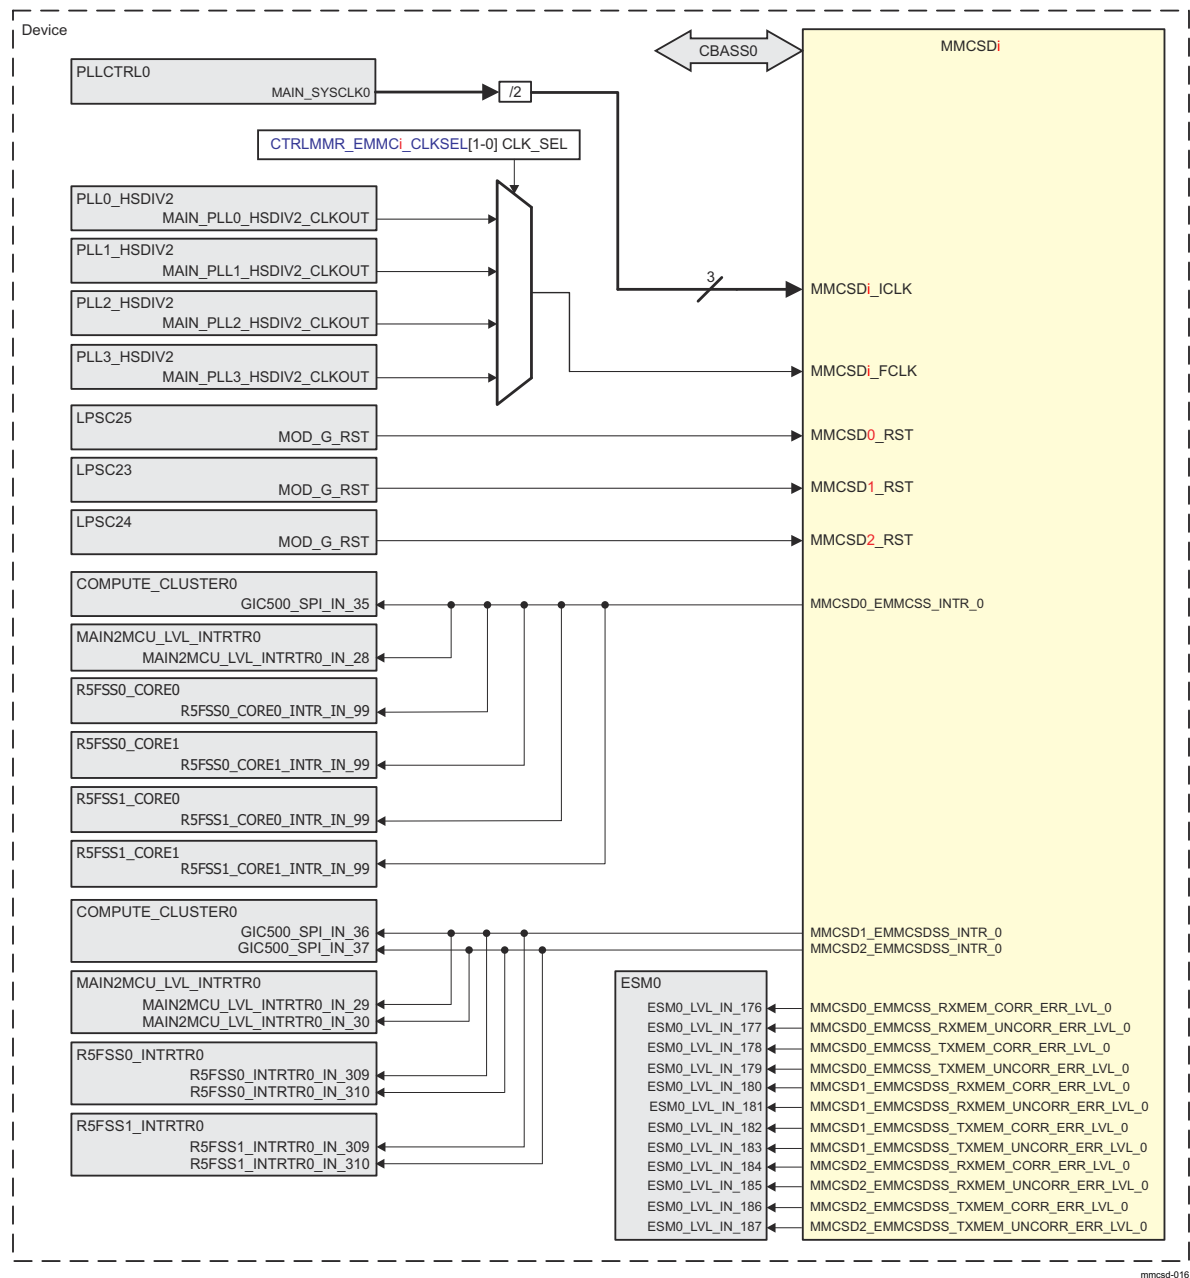

**Figure 12-296. Data Token Format for 8-Bit Transfers**

### 12.3.6.3 MMCSD Integration

This section describes the MMCSD integration in the device, including information about clocks, resets, and hardware requests.

#### 12.3.6.3.1 MMCSD Integration in MAIN Domain

There are three MMCSD modules integrated in the device MAIN domain - MMCSD0, MMCSD1 and MMCSD2. [Figure 12-297](#) shows the integration of MMCSD0, MMCSD1 and MMCSD2.

mmcscd-016

A.  $i = 0 \text{ to } 2$

**Table 12-381. MMCSD Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MMCSD0	PSC0	PD0	LPSC25	CBASS0
MMCSD1	PSC0	PD0	LPSC23	CBASS0
MMCSD2	PSC0	PD0	LPSC24	CBASS0

**Table 12-382. MMCSD Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MMCSD0	MMCSD0_ICLK	MAIN_SYSCLK0/2	PLLCTRL0	MMCSD0 Interface Clock
	MMCSD0_FCLK	MAIN_PLL0_HSDIV2_CLKOUT (MMCSD0 default selection)	PLL0_HSDIV2	MMCSD0 Functional Clock (for more information about clock multiplexing, see CTRLMMR_EMMC0_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_EMMC0_CLKSEL[1-0] CLK_SEL = 0, MAIN_PLL0_HSDIV2_CLKOUT is selected)
		MAIN_PLL1_HSDIV2_CLKOUT (MMCSD1 default selection)	PLL1_HSDIV2	
		MAIN_PLL2_HSDIV2_CLKOUT (MMCSD2 default selection)	PLL2_HSDIV2	
		MAIN_PLL3_HSDIV2_CLKOUT (can be used by any MMCSD)	PLL3_HSDIV2

## 12.3.6.4 MMCSD Functional Description

### 12.3.6.4.1 Block Diagram

Figure 12-298 shows the MMCSDi module block diagram (where i = 0 to 2).

- (1) i = 0 to 2  
 (2) x = 7 for MMCSD0 (8-bit wide data bus); x = 3 for MMCSD1/MMCSD2 (4-bit wide data bus);  
 (3) Used for HS400 mode (MMCSD0 Only);

**Figure 12-298. MMCSDi Module Block Diagram**

#### Basic Blocks:

- MMCSD Host Controller:** The MMCSD Host Controller is situated in the MMCSD Subsystem and provides accessibility to external MMC/SD/SDIO devices using a Programmed IO method or DMA data transfer method.
- UHS-I PHY:** The integrated UHS-I PHY provides an interface between the MMCSD Host Controller and external MMC/SD/SDIO devices.
- MMCSDi Interface:** The MMCSDi Interface includes all used interface pins (for more information, see [Table 12-379](#)).
- Master Port:** Provides a 64-bit wide read/write interface between the device and the MMCSD Subsystem internal SRAM.
- Slave Port:** Provides a 32-bit wide interface between the device and the MMCSD Subsystem and MMCSD Host Controller parts.
- MMCSD Host Controller Registers:** This block includes set of all MMCSD Host Controller registers.
- MMCSD Subsystem and PHY Registers:** This block implements memory-mapped registers at the MMCSD Subsystem level and memory-mapped registers to control and program the MMCSD PHY.
- ECC Aggregator:** The ECC Aggregator block facilitates aggregating and reporting internal SRAM ECC errors (for more information, see [Section 12.3.6.4.4, ECC Support](#)).
- Internal SRAM with ECC:** The internal SRAM block is used for data storage during read/write transactions.
- DMA Controller:** Manages the data transfer between the device memory and the MMCSD Subsystem internal SRAM.
- System Clocks:** There are asynchronous relationship between the interface (system) clock and functional clock (for more information, see [Table 12-382](#)).
- System Reset:** The reset to the MMCSD Subsystem provides reset to the all MMCSD Subsystem parts (for more information, see [Table 12-382](#)).

- Interrupts: The MMCSD Subsystem sources one MMCSD Host Controller interrupt and four ECC Aggregator interrupts (for more information, see [Table 12-383](#) and [Section 12.3.6.4.3, Interrupt Requests](#)).

For more information about all MMCSD registers, see *MMCSD Registers*.

The MMCSD Host Controller can use a Programmed IO method (PIO) or DMA data transfer method to access external MMC/SD/SDIO devices.

The slave port is used for device CPU access to the MMCSD Host Controller register set. The MMCSD Host Controller register set provides the communication between the device CPU and the MMCSD Host Controller. In PIO method the device CPU transfers data using the MMCSD0\_DATA\_PORT / MMCSD12\_DATA\_PORT register. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the slave port, the MMCSD0\_DATA\_PORT / MMCSD12\_DATA\_PORT register in the MMCSD Host Controller, and the PHY.

The master port is used for connection to the DMA controller (for more information about ADMA support, see [Section 12.3.6.4.5, Advanced DMA](#) and MMCSD0\_CAPABILITIES / MMCSD12\_CAPABILITIES register). In DMA data transfer method the DMA controller uses the master port to transfer data between the device memory and the MMCSD Subsystem internal SRAM. The other side of the internal SRAM is connected to the MMCSD Host Controller. The data flow from the device memory to the external MMC/SD/SDIO device (and vice versa) is through the master port, internal SRAM, MMCSD Host Controller, and the PHY. The DMA controller manages the read/write operations from/to the internal SRAM without device CPU intervention.

#### 12.3.6.4.2 Memory Regions

[Table 12-384](#) shows MMCSDi module memory map.

**Table 12-384. MMCSDi Module Memory Map**

Address Range			Size	Description
MMCSD0	MMCSD1	MMCSD2		
0x04F80000 - 0x04F80FFF	0x04FB0000 - 0x04FB0FFF	0x04F98000 - 0x04F98FFF	4 KB	MMCSD Host Controller registers region
0x04F88000 - 0x04F883FF	0x04FB8000 - 0x04FB83FF	0x04F90000 - 0x04F903FF	1 KB	MMCSD Subsystem registers region
0x02A24000 - 0x02A243FF	0x02A26000 - 0x02A263FF	0x02A71000 - 0x02A713FF	1 KB	ECC Aggregator Receive RAM registers region
0x02A25000 - 0x02A253FF	0x02A27000 - 0x02A273FF	0x02A70000 - 0x02A703FF	1 KB	ECC Aggregator Transmit RAM registers region

#### 12.3.6.4.3 Interrupt Requests

Each MMCSD instance sources one active high level MMCSD Host Controller interrupt and four active high level ECC Aggregator interrupts (see [Table 12-383](#)). The MMCSD Host Controller interrupt is generated based on the bit values in the MMCSD0\_NORMAL\_INTR\_STS / MMCSD12\_NORMAL\_INTR\_STS and MMCSD0\_NORMAL\_INTR\_STS\_ENA / MMCSD12\_NORMAL\_INTR\_STS\_ENA registers. The ECC Aggregator interrupts are generated based on the ECC errors - single and double bit errors (for more information about ECC Aggregator interrupts, see [Section 12.3.6.4.4, ECC Support](#)).

#### 12.3.6.4.4 ECC Support

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

There are two SRAM memories (transmit SRAM and receive SRAM) within each MMCSD instance. These two memories are ECC protected.

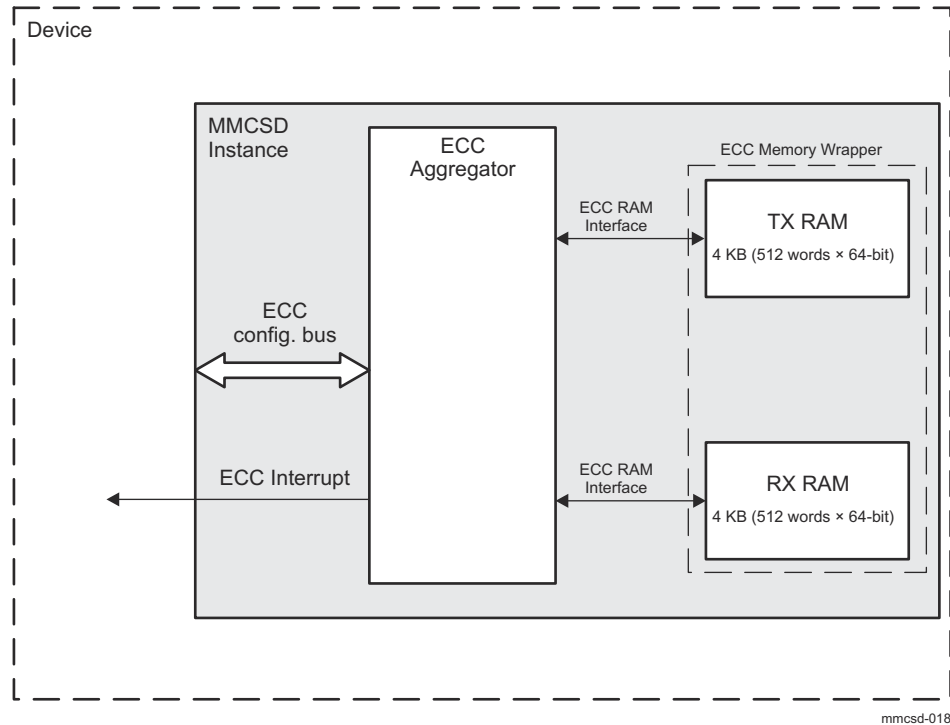

The SEC logic detects and corrects a single bit error (single bit error per ECC word or per ECC data segment). The DED logic only detects (does not correct) double errors (double bit errors per ECC word or per ECC data segment).

#### 12.3.6.4.4.1 ECC Aggregator

There are two SRAMs (each with size 4 KB - 512 words × 64-bit) in each MMCSD Subsystem. One SRAM dedicated for transmit and one SRAM dedicated for receive operations.

Figure 12-299 shows the ECC Aggregator block diagram.

**Figure 12-299. ECC Aggregator Block Diagram**

#### Note

For more information about ECC Aggregator, refer to *ECC Aggregator*.

For more information about ECC Aggregator Registers, refer to *MMCSD Registers*.

#### 12.3.6.4.5 Advanced DMA

The MMCSD modules support SD Advanced DMA – ADMA2 and ADMA3.

#### Note

For more information, refer to the SD Association specification titled "*SD Host Controller Simplified Specification, Part A2, Version 4.10*".

#### 12.3.6.4.6 eMMC PHY BIST

##### 12.3.6.4.6.1 BIST Overview

To verify the eMMC5.1 PHY functionality, the BIST function is built on top of the eMMC5.1 PHY that can either be controlled from SOC registers or from special Vendor Registers defined in the TI's eMMC5.1 Host Controller. The functionality of the BIST is to be able to test various functions of the PHY (without using the eMMC protocol/ software stack) and provide the results of the testing to the diagnostic software.

The 128-byte Test Pattern is as follows:

[illegible]

In non-HS200 Modes, the testing is performed for one time with programmed Tx Phase and Rx Phase values. In HS200 Mode, the testing is performed 32-times and it is expected that some of the iterations will have data mismatch because of the RxPhase Timing. The BIST engine iterates through all 32-phases of Rx Clock and provides the result of data/cmd line compare for each of the phases in a 32-bit status vector.

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

#### **12.3.6.4.6.2.3 HS Mode with TXDLY using Delay Chain**

This is the High Speed (HS) mode where the eMMC CLK is set to 50 MHz. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the TX Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode.

The DLL is disabled in this mode.

#### **12.3.6.4.6.2.4 DDR50 Mode with TXDLY using DLL**

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the TX Clock Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases. The Phase shifting on the RX path is disabled in this mode.

#### **12.3.6.4.6.2.5 DDR50 Mode with TXDLY using Delay Chain**

This is the DDR50 mode where the eMMC CLK is set to 50 MHz. The data is driven on both the edges of the clock. To emulate the Interface timing, a Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. In this mode, the Tx Clock Phase shift is being performed by using one of the first 16-taps of the Tx Delay Chain Phases. The Phase shifting on the RX path is disabled in this mode. The DLL is disabled in this mode.

#### **12.3.6.4.6.2.6 HS200 Mode with TX/RXDLY using DLL**

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted TX Clock. The amount of phase shift can be from 1 to 16 Taps. The RxClock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the DLL TXCLK Phases and the RX Phase shift is being performed by using one of the 32 taps of the DLL RXCLK Phases.

#### **12.3.6.4.6.2.7 HS200 Mode with TX/RXDLY using Delay Chain**

This is the HS200 mode where the eMMC CLK is set to 200 MHz. To emulate the Interface timing, a small Hold time is inserted on Transmit data lines by using the Phase shifted Tx Clock. The amount of phase shift can be from 1 to 16 Taps. The Rx Clock Phase is adjusted from 1 to 32 Phases to check the data at different phases. In this mode, the TX Phase shift is being performed by using one of the first 16-taps of the Delay Chain Phases and the RX Phase shift is being performed by using one of the 32 taps of the Delay Chain Phases.

The DLL is disabled in this mode.

#### **12.3.6.4.6.2.8 HS400 Mode**

In this mode, the Receive data is captured using the STRB line. To support this mode, the AFE is configured such that the STRB is toggled during the time when the fixed pattern transmission (including the START/END). The Receive STRB line is phase shifted by 90 and 180 degrees by the DLL. As the data is captured using the STRB, there is no need to enable the RX Clock Phases, and these can be disabled. To maintain the timing, the TX Phase can be adjusted accordingly.

#### **12.3.6.4.6.3 BIST Functionality**

The BIST engine inside the eMMC PHY leverages the Tuning Pattern to verify the functionality of the PHY (including the IOs and the DLL). The BIST engine is controlled from SOC and the eMMC Host Controller should be disabled during the BIST Mode. The BIST can be run at different modes (Clock Speeds) and the result of the BIST operation is presented to the SOC.

In normal mode, the PHY Transmit Data path operates on the MMCS0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL. This clock is provided by the eMMC Host Controller and the frequency of this clock is varied based on the operating mode. The following are the various frequencies used in various modes.

- Default Speed: 25 MHz
- High Speed: 25 MHz
- DDR52: 50 MHz
- HS200: 200 MHz
- HS400: 200 MHz

This clock is generated by the eMMC Host Controller and under direct control of the software through the Clock Control Register @0x2C of the Host Controller Register Set. The eMMC Host Controller uses the XIN\_CLK (the reference clock to the Host Controller, which is usually 200 MHz) and uses the Clock Divider Value and the Clock Enable Control.

The BIST Engine runs on the same MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL. Though the Host Controller is disabled during the BIST operation, the software should program the Clock Control Register so that the MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL is generated for the BIST engine.

#### 12.3.6.4.6.4 Signal Interface

The BIST logic is controlled by a set of signals which can be from a set of registers that are software accessible. The following are the signals for BIST Functions.

**Table 12-385. BIST Logic Signals**

Signal	Direction	Description
MMCSD0_SS_PHY_CTRL_6_REG[31].BISTENABLE	Input	<b>BIST Enable</b> When set the BIST Controller controls the DFE and overwrites the data path signals from the Host Controller Interface. When this is cleared, the Host Controller signals are connected to the DFE and BIST is disabled.
MMCSD0_SS_PHY_CTRL_6_REG[27:24].BISTMODE	Input	<b>BIST Mode</b> This selects one of the specified BIST Modes for running the BIST sequence. The following are the encoding for the mode: 4'b0000: HS200 Mode with DLL 4'b0001: HS200 Mode with DLY_CHAIN 4'b0010: HS400 Mode (STROBE Mode) 4'b0011: DDR52 Mode with DLL 4'b0100: DDR52 Mode with DLY_CHAIN 4'b0101: HS Mode with DLL 4'b0110: HS Mode with DLY_CHAIN 4'b0111: DS Mode (with DLY_CHAIN)
MMCSD0_SS_PHY_CTRL_6_REG[30].BISTSTART	Input	<b>BIST Start</b> The rising edge of this signal is used to start the BIST function on the specified BIST Mode. When the BIST is complete the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE output is asserted. Before setting this signal, the SOC must make sure that the MMCSD0_SS_PHY_STAT_1_REG[3].BISTDONE is low (deasserted).
MMCSD0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS	Output	<b>BIST Status</b> This is the status of the BIST Testing. In non HS200 Mode, the Bit[0] indicates whether the BIST Passed or not. In HS200 modes, the 32-bit indicates the Pattern Match at each of the 32-taps on RxClk Path.

**Table 12-385. BIST Logic Signals (continued)**

Signal	Direction	Description
MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE	Output	<b>BIST Done</b> This is asserted when the BIST completes its sequence. The result of the test is presented in the MMCSDB0_SS_PHY_STAT_2_REG[31:0].BISTSTATUS output. This is asserted until the MMCSDB0_SS_PHY_CTRL_6_REG[30].BISTSTART is deasserted at which point the MMCSDB0_SS_PHY_STAT_1_REG[3].BISTDONE is also cleared.

#### 12.3.6.4.6.5 Programming Flow

For the BIST operation, the OD\_EN/REN/PU/OD controls to the CMD/STRB/DAT lines should be programmed as follows:

- OD\_EN: 1'b0
- REN: 1'b0
- PU: 1'b1
- OD: 1'b0

##### 12.3.6.4.6.5.1 DS Mode

The following are the various settings required for performing the BIST in Default Speed timing.

##### 12.3.6.4.6.5.1.1 Configuration

- MMCSDB0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 25 MHz.
- PHY's DLL should be disabled.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0111.
- MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b0.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to 4'b0000.
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSDB0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

##### 12.3.6.4.6.5.1.2 BIST Programming

1. Set the MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSDB0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSDB0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSDB0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

##### 12.3.6.4.6.5.2 HS Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in HS Mode with DLY Chain.

##### 12.3.6.4.6.5.2.1 Configuration

- MMCSDB0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.

- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0110.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

#### 12.3.6.4.6.5.2.2 BIST Programming

1. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.5.3 HS Mode with DLL

The following are the various settings required for performing the BIST in HS Mode with DLL.

##### 12.3.6.4.6.5.3.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be Enabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0101.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 50 MHz Mode.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.4.6.5.3.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.5.4 DDR52 Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in DDR52 Mode with DLY Chain.

##### 12.3.6.4.6.5.4.1 Configuration

- MMCSO0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz.
- PHY's DLL should be disabled.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0100.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to on of the tap Value based on Timing Closure.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.4.6.5.4.2 BIST Programming

1. Set the MMCSO0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSO0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

4. Clear the MMCSO0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.5.5 DDR52 Mode with DLL

The following are the various settings required for performing the BIST in DDR52 Mode with DLL.

##### 12.3.6.4.6.5.5.1 Configuration

- MMCSO0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 50 MHz
- PHY's DLL should be Enabled.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0011.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSO0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 50MHz Mode.

If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.4.6.5.5.2 BIST Programming

1. Wait for MMCSO0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSO0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSO0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

```
BIST PASS
```

```
else
```

```
BIST FAIL;
```

```
endif
```

5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.5.6 HS200 Mode with DLY\_CHAIN

The following are the various settings required for performing the BIST in HS200 Mode with DLY Chain.

##### 12.3.6.4.6.5.6.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0001.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0

\*In this mode, the BIST Engine cycles thru all the 32 taps, so there is no need of controlling the Input Tap Delay.

##### 12.3.6.4.6.5.6.2 BIST Programming

1. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
2. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
3. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*31:0+ Bit and run the "HS200 Bist Result Check Procedure"
4. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.5.7 HS200 Mode with DLL

The following are the various settings required for performing the BIST in HS200 Mode with DLL.

##### 12.3.6.4.6.5.7.1 Configuration

- MMCSD0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be disabled.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0000.
- MMCSD0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA\* to 1'b0.
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL\* to 5'b00000
- MMCSD0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSD0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 200 MHz Mode.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

##### 12.3.6.4.6.5.7.2 BIST Programming

1. Wait for MMCSD0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSD0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSD0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*31:0+ Bit and run the "HS200 Bist Result Check Procedure".
5. Clear the MMCSD0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

### 12.3.6.4.6.5.8 HS400 Mode with DLL

The following are the various settings required for performing the BIST in HS400 Mode with DLL.

#### 12.3.6.4.6.5.8.1 Configuration

- MMCSO0\_CLOCK\_CONTROL[15:8].SDCLK\_FRQSEL should be set to 200 MHz.
- PHY's DLL should be enabled.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[27:24].BISTMODE should be set to 4'b0010.
- MMCSO0\_SS\_PHY\_CTRL\_6\_REG[31].BISTENABLE should be set to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[20].OTAPDLYENA to 1'b1.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[15:12].OTAPDLYSEL to one of the tap values based on Timing Closure.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[8].ITAPDLYENA to 1'b0
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[4:0].ITAPDLYSEL to 5'b00000
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[9].ITAPCHGWIN to 1'b0
- MMCSO0\_SS\_PHY\_CTRL\_5\_REG[10:8].FRQSEL should be set for 200 MHz Mode.
- MMCSO0\_SS\_PHY\_CTRL\_4\_REG[31:24].STRBSEL should be set to appropriate values based on based on STRB timing closure.

\* If Timing closure requires usage of Input Tap Enable and Tap Select should be set appropriately.

#### 12.3.6.4.6.5.8.2 BIST Programming

1. Wait for MMCSO0\_SS\_PHY\_STAT\_1\_REG[0].DLLRDY to be 1'b1 (DLL is Ready)
2. Set the MMCSO0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b1.
3. Wait until the MMCSO0\_SS\_PHY\_STAT\_1\_REG[3].BISTDONE is set to 1'b1.
4. Read the MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS[0] Bit and check the value.

If (MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS\*0+==1'b1) then

BIST PASS

else

BIST FAIL;

endif

5. Clear the MMCSO0\_SS\_PHY\_CTRL\_6\_REG[30].BISTSTART to 1'b0.

#### 12.3.6.4.6.6 HS200 BIST Result Check Procedure

In HS200 Mode, the BIST engine in the PHY runs Tuning Pattern test 32 times, with different TAP values selected, for each iteration. The result from the 32 iterations is presented on the MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS output. It is expected that some of the TAP values will have timing issues and results in pattern mismatch when compared with the received pattern for those taps. The PASS/FAIL for the HS200 Mode is based on the following theory.

Of the 32 taps, the Data Capture EYE for certain taps will result in mismatches, but these will be sequential tap values. Thus, in a full 32 iterations, a sequence of taps results in data mismatches. Also, based on the timing closure, the number of taps with pattern mismatch should be approximately 1/4th of the number of taps with pattern match. This 1/4th count is not absolute, as this involves various factors such as the timing closure, PVT variation, and so forth. Anywhere from 4 to 16 invalid sequential taps is normal.

For example, if 8 of the 32 sequential taps have the data mismatches, the following would be the resulting MMCSO0\_SS\_PHY\_STAT\_2\_REG[31:0].BISTSTATUS output based which of the 8 sequential taps the mismatches are. The following is the notation used:

- 1: Pattern matched at this tap
- 0: Pattern match failed at this tap

3	3	2	2	2	2	2	2	2	2	2	2	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0		
1	0	9	8	7	6	5	4	3	2	1	0	9	8	7	6	5	4	3	2	1	0	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0

### 12.3.6.5 MMCSD Programming Guide

#### 12.3.6.5.1 Sequences

This section defines basic sequence flow chart divided into several sub sequences.

#### Note

This section is applicable for MMCSD0, MMCSD1 and MMCSD2 but MMCSD0 registers are used in the content.

#### Note

UHSII is not supported. For more information, see [Section 12.3.6.1.2, Not Supported Features](#).

"Wait for interrupts" is used in the flow chart. This means the Host Driver waits until specified interrupts are asserted. If already asserted, then fall through that step in the flow chart. Timeout checking shall be always required to detect no interrupt generated but this is not described in the flow chart.

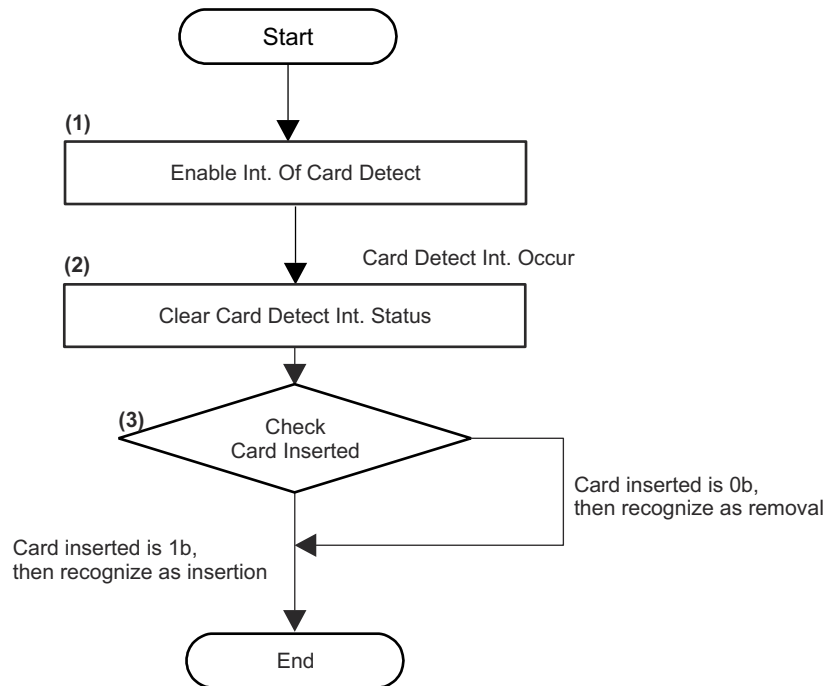

This specification uses the double box like [Figure 12-301](#), (the step (1) in [Figure 12-305](#)), it means that the other flows, which already are shown, shall be performed. Therefore, the interrupt may be included in the other flows.

mmcsd-019

**Figure 12-301. Double Box Notation**

#### 12.3.6.5.1.1 SD Card Detection

mmcsd-020

**Figure 12-302. SD Card Detect Sequence**

(1) The host driver should wait for 1 second after power is applied to the Host Controller before executing card initialization sequence.

The flow chart for detecting a SD card is shown in [Figure 12-302](#).

Each step is executed as follows:

To enable interrupt for card detection, write 1 to the following bits:

- MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[6] CARD\_INSERTION
- MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL
- MMCSD0\_NORMAL\_INTR\_SIG\_ENA[7] CARD\_REMOVAL

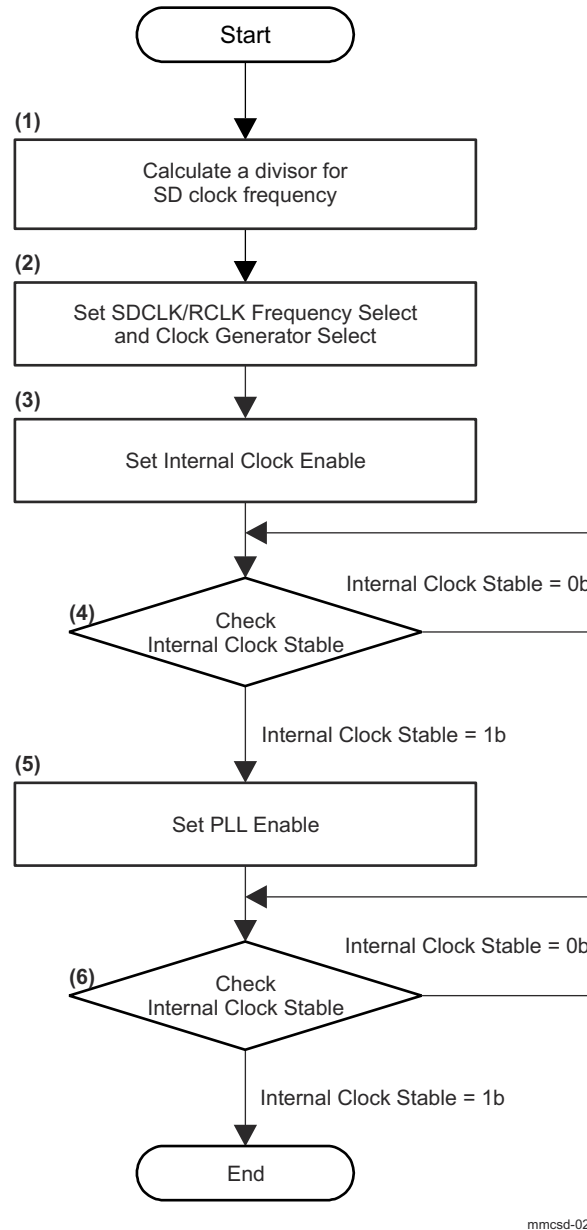

(1) When the Host Driver detects the card insertion or removal, clear its interrupt statuses. If Card Insertion interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[6] CARD\_INSERTION bit. If Card Removal interrupt is generated, write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[7] CARD\_REMOVAL bit.

(2) Check MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 1, the Host Driver can supply the power and the clock to the SD card. In the case where MMCSD0\_PRESENTSTATE[16] CARD\_INSERTED bit is 0, the other executing processes of the Host Driver shall be immediately closed.

If miniSD adaptor is used for standard SD slot and miniSD card is inserted or extracted from the adaptor, card detect interrupt may not be generated. When host does not receive response to any commands, miniSD card is extracted or in idle state, the host should try to re-initialize the card. In this case, all card information shall be re-loaded.

### 12.3.6.5.1.2 SD Clock Control

#### 12.3.6.5.1.2.1 Internal Clock Setup Sequence

mmcsd-021

**Figure 12-303. Internal Clock Setup Sequence**

The sequence for supplying SD Clock to a SD card is described in [Figure 12-303](#). From Version 4.10, MMCS0\_CLOCK\_CONTROL[3] PLL\_ENA bit is added. This sequence is also applicable to prior versions which do not support MMCS0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(1) Calculate a divisor to determine SD Clock frequency for legacy IF or RCLK frequency for UHS-II IF by reading MMCS0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ and MMCS0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit fields. If non-zero value is set to MMCS0\_CAPABILITIES[55-48] CLOCK\_MULTIPLIER bit field, Programmable Clock Mode can be used (for more information, see MMCS0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit). If MMCS0\_CAPABILITIES[15-8] BASE\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

(2) Set MMCSD0\_CLOCK\_CONTROL[15-8] SDCLK\_FRQSEL bit field and MMCSD0\_CLOCK\_CONTROL[5] CLKGEN\_SEL bit in accordance with the calculated result of step (1).

If MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set, these bits are set by Host Controller automatically as specified in the Preset Value register (MMCSD0\_PRESET\_VALUE0 - MMCSD0\_PRESET\_VALUE10).

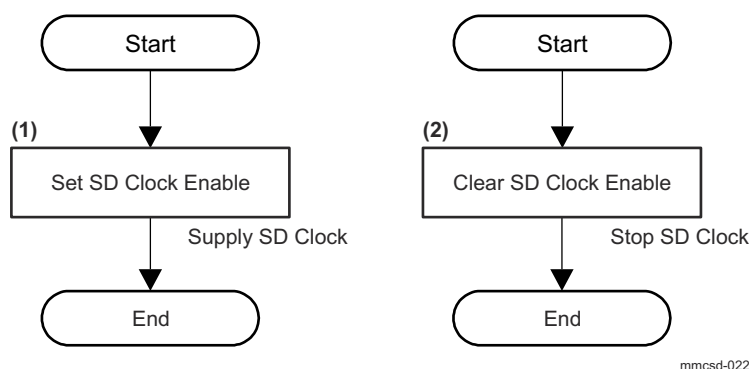

(3) Set MMCSD0\_CLOCK\_CONTROL[0] INT\_CLK\_ENA bit.

(4) Check MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit. Repeat this step until this status is 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

(5) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit. This step does not affect Host Controllers which do not support MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit.

(6) If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is supported, PLL locked may be checked by this status (if MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this status is supposed to indicate 1 by step (3)). Clock will be stable in shorter time but timeout of this loop is defined as 150 ms.

#### 12.3.6.5.1.2.2 SD Clock Supply and Stop Sequence

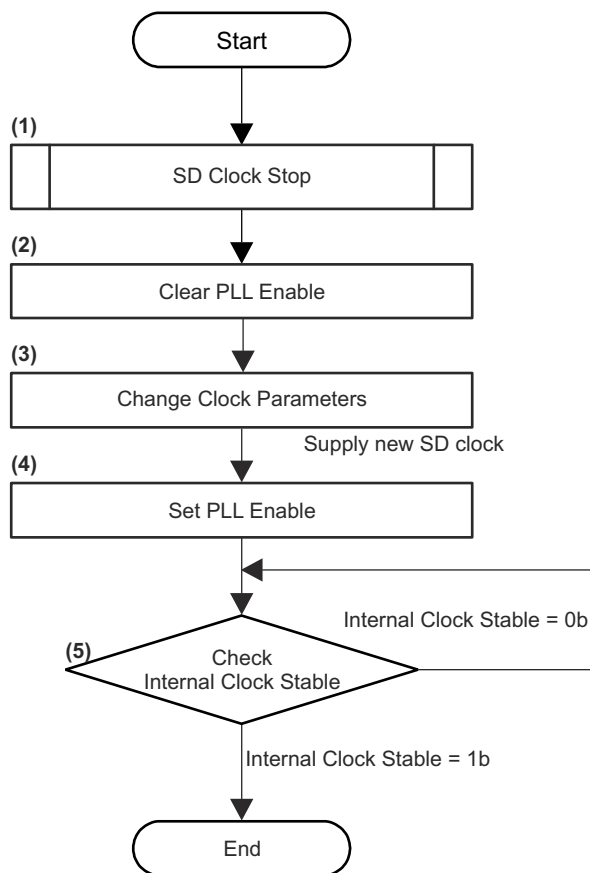

**Figure 12-304. SD Clock Supply and Stop Sequence**

The flow chart for stopping the SD Clock is shown in [Figure 12-304](#). The Host Driver shall not stop the SD Clock when a SD transaction is occurring on the SD Bus -- namely, when either MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT or MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1.

(1) Setup Internal Clock (see [Figure 12-303](#)). Then set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 1. Then, the Host Controller starts supplying the SD Clock.

(2) Set MMCSD0\_CLOCK\_CONTROL[2] SD\_CLK\_ENA bit to 0. Then, the Host Controller stops supplying the SD Clock. Internal Clock is still oscillating.

### 12.3.6.5.1.2.3 SD Clock Frequency Change Sequence

mmcsd-023

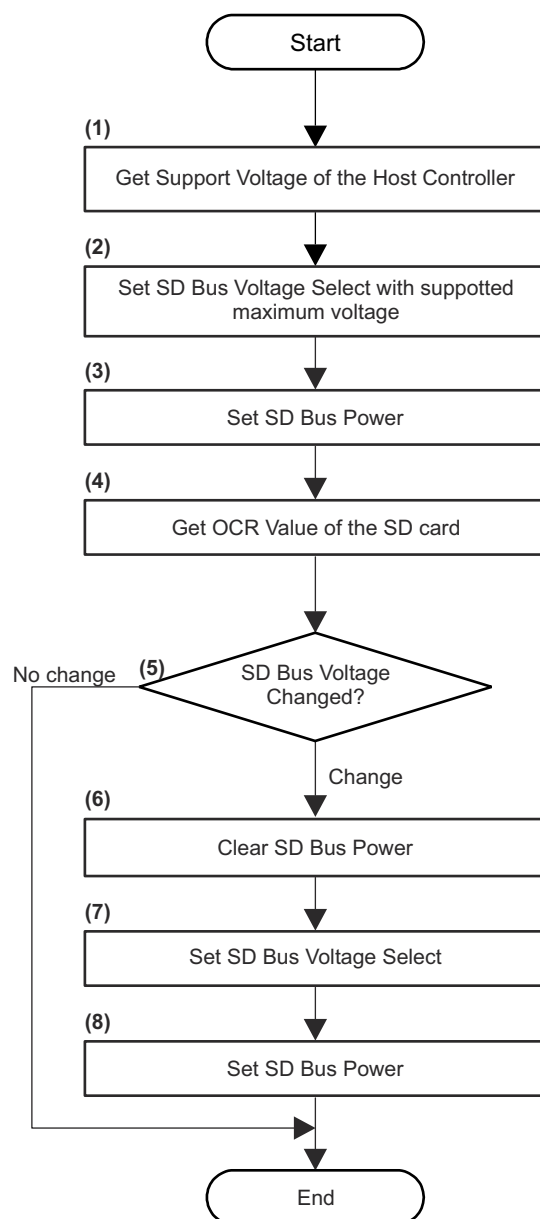

**Figure 12-305. SD Clock Change Sequence**

The sequence for changing SD Clock frequency is shown in [Figure 12-305](#).

- (1) Execute the SD Clock Stop Sequence (see [Figure 12-304](#)). If SD Clock supply to card is already stopped, skip this step.
- (2) Clear MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 0. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step has no effect and may be skipped.
- (3) When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 0, change clock parameters in the MMCSD0\_CLOCK\_CONTROL register. When MMCSD0\_HOST\_CONTROL2[15] PRESET\_VALUE\_ENA bit is set to 1, select Bus Speed Mode as described.
- (4) Set MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit to 1. If MMCSD0\_CLOCK\_CONTROL[3] PLL\_ENA bit is not supported, this step this step has no effect and may be skipped.
- (5) Wait until MMCSD0\_CLOCK\_CONTROL[1] INT\_CLK\_STABLE bit is set to 1. Clock will be stable in shorter time but timeout of this loop is defined as 150 ms. SD Clock Supply Sequence is required to provide clock to device (see [Figure 12-304](#)).

### 12.3.6.5.1.3 SD Bus Power Control

The sequence for controlling the SD Bus Power is described in [Figure 12-306](#).

mmcsd-024

**Figure 12-306. SD Bus Power Control Sequence**

- (1) By reading the MMCSD0\_CAPABILITIES register, get the support voltage of the Host Controller.
- (2) Set MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field with maximum voltage that the Host Controller supports.
- (3) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 1.
- (4) Get the OCR value of all function internal of SD card.
- (5) Judge whether SD Bus voltage needs to be changed or not. In case where SD Bus voltage needs to be changed, go to step (6). In case where SD Bus voltage does not need to be changed, go to "End".
- (6) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit to 0 for clearing this bit. The card requires voltage rising from 0 volt to detect it correctly. The Host Driver shall

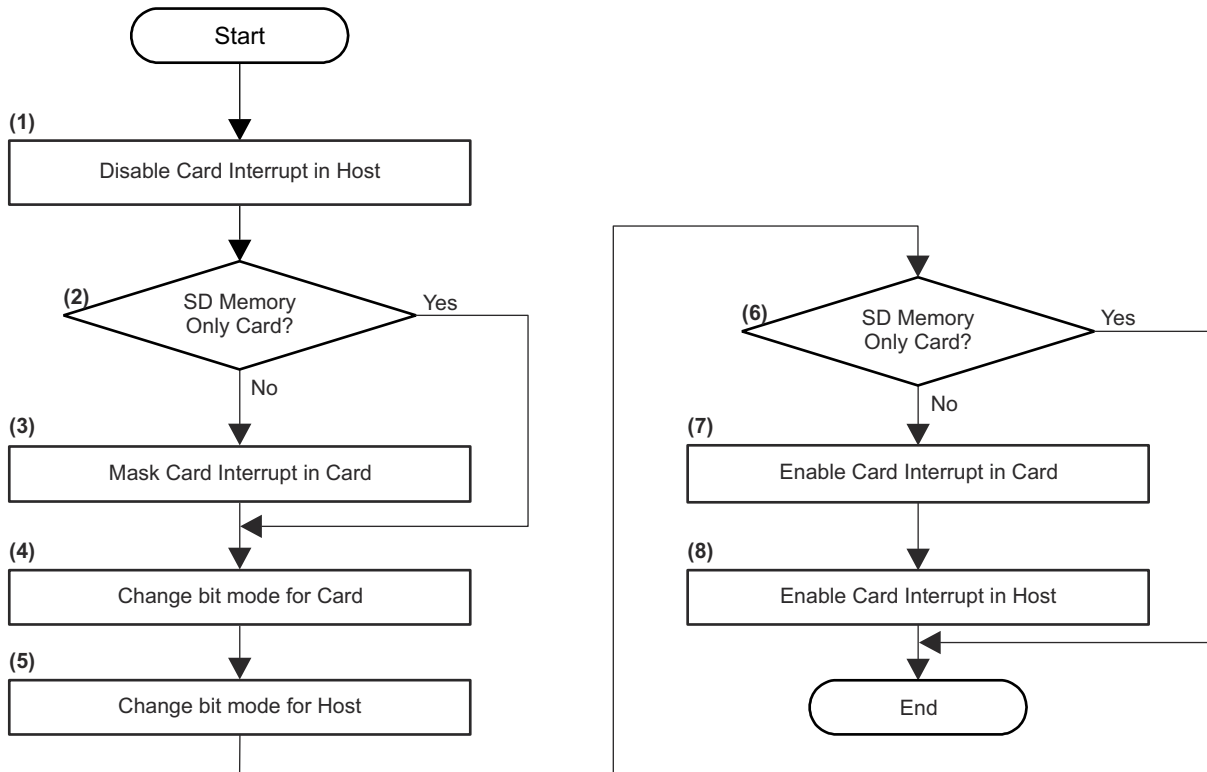

clear MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER bit before changing voltage by setting MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(7) Set MMCSD0\_POWER\_CONTROL[3-1] SD\_BUS\_VOLTAGE bit field.

(8) Set MMCSD0\_POWER\_CONTROL[0] SD\_BUS\_POWER to 1.

**Note:** Step (2) and step (3) can be executed at same time. And also, step (7) and step (8) can be executed at same time.

#### 12.3.6.5.1.4 Changing Bus Width

mmscd-025

**Figure 12-307. Change Bus Width Sequence**

The sequence for changing bit mode on SD Bus is shown in [Figure 12-307](#).

(1) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 0 for masking incorrect interrupts that may occur while changing the bus width.

(2) In case of SD memory only card, go to step (4). In case of other card, go to step (3).

(3) Set "IENM" of the CCCR in a SDIO or SD combo card to 0 by CMD52.

(4) Change the bus width mode for a SD card. SD Memory Card bus width is changed by ACMD6 and SDIO card bus width is changed by setting Bus Width of Bus Interface Control register in CCCR.

(5) In case of changing to 4-bit mode, set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 1. In another case (1-bit mode), set this bit to 0.

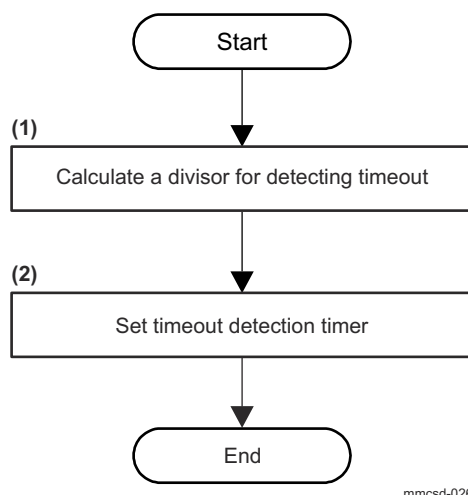

(6) In case of SD memory only card, go to the "End". In case of other card, go to step (7).

(7) Set "IENM" of the CCCR in a SDIO or SD combo card to 1 by CMD52.

(8) Set MMCSD0\_NORMAL\_INTR\_STS\_ENA[8] CARD\_INTERRUPT bit to 1.

Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

#### 12.3.6.5.1.5 Timeout Setting on DAT Line

mmcsd-026

**Figure 12-308. Timeout Setting Sequence**

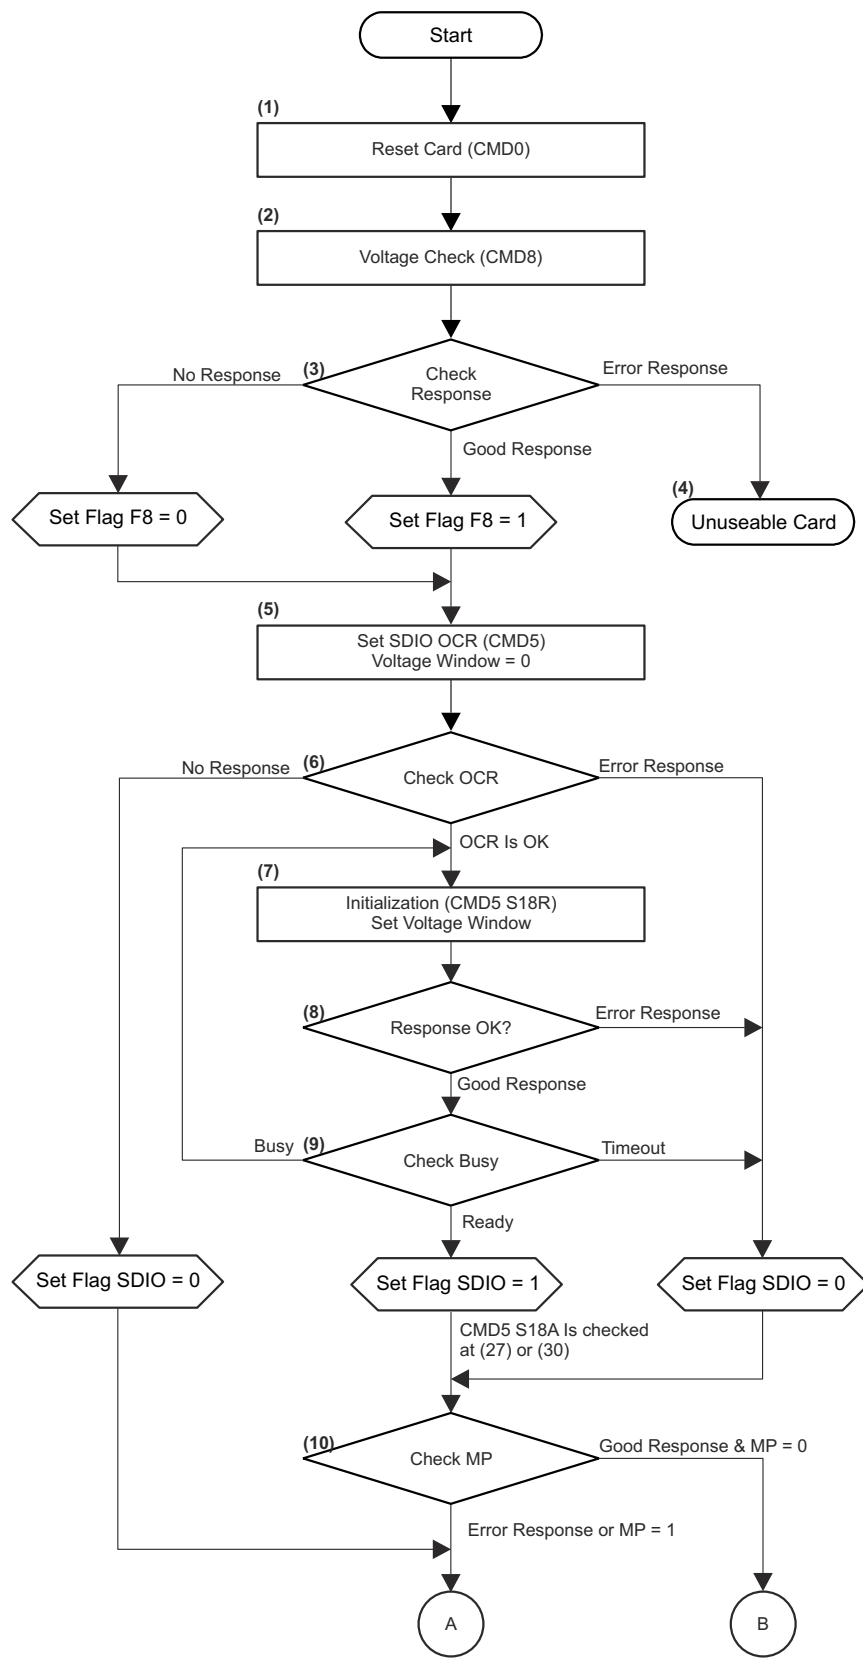

In order to detect timeout errors on DAT line, the Host Driver shall execute the following two steps before any SD transaction. For more information regarding SD transactions:

(1) Calculate a divisor to detect timeout errors by reading MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field and MMCSD0\_CAPABILITIES[7] TIMEOUT\_CLK\_UNIT bit. If MMCSD0\_CAPABILITIES[5-0] TIMEOUT\_CLK\_FREQ bit field is 00 0000b, the Host System shall provide this information to the Host Driver by another method.

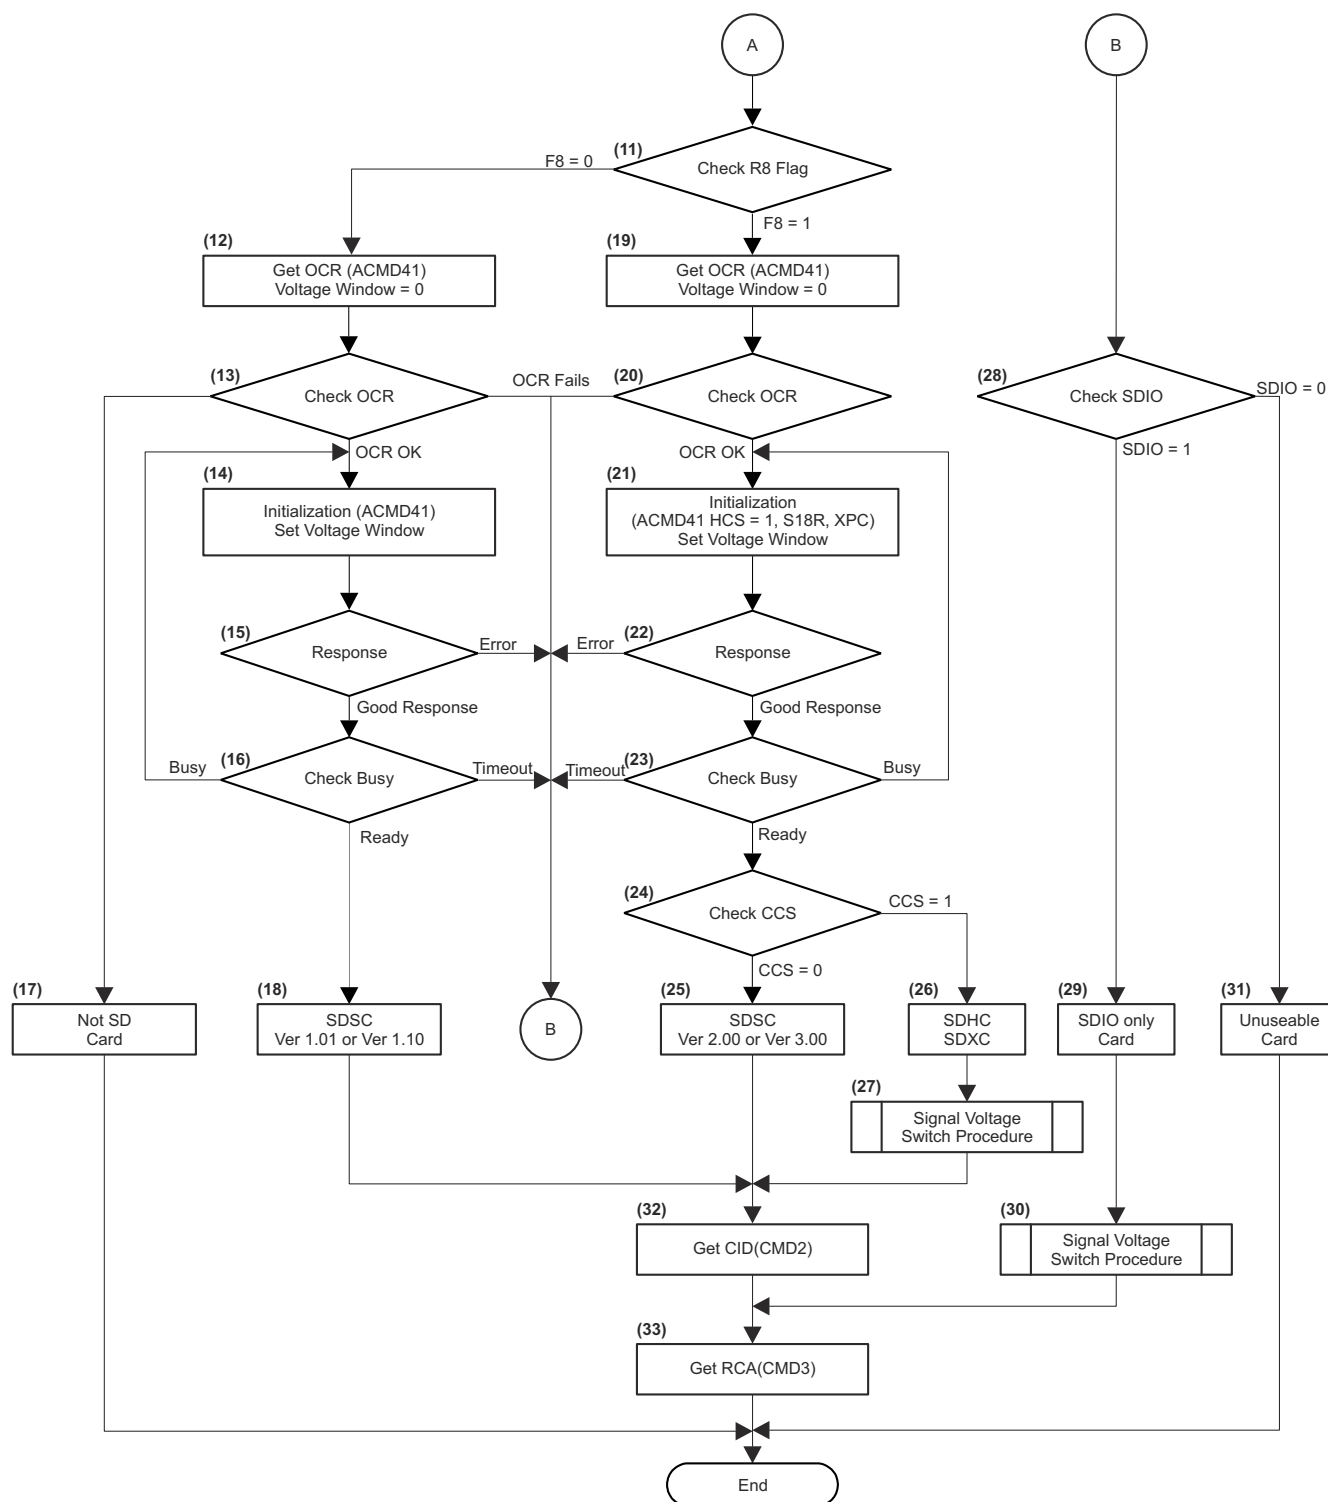

(2) Set MMCSD0\_TIMEOUT\_CONTROL[3-0] COUNTER\_VALUE bit field in accordance with the value from step (1) above.

#### 12.3.6.5.1.6 Card Initialization and Identification (for SD I/F)

Figure 12-309 and Figure 12-310 shows initialization and card identification sequence for the Standard Capacity SD Memory Card (SDSC), the High Capacity SD Memory Card (SDHC) and the Extended Capacity SD Memory Card (SDXC) that was based on the Physical Layer Version 3.01. Refer to the latest sequence.

**Figure 12-309. Card Initialization and Identification (1)**

mmcsd-028

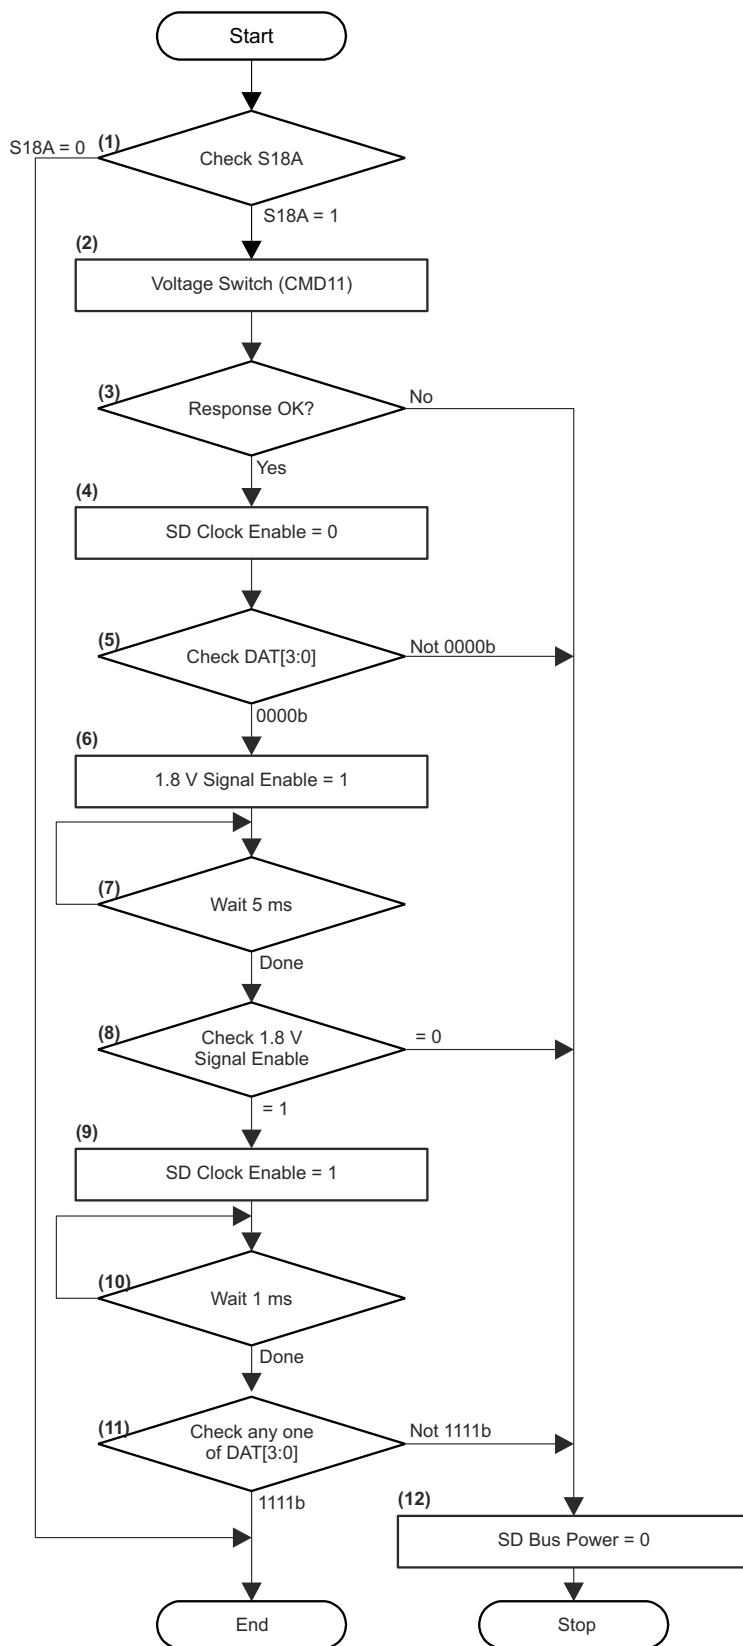

**Figure 12-310. Card Initialization and Identification (2)**

- (1) SD Bus mode is selected by CMD0 (Keep Pin 1 to high during CMD0 execution).
- (2) New CMD8 shall be issued after CMD0 to support High Capacity SD Memory Card.

- (3) Voltage check command enables the Hosts to support future low voltage specification. However, at this time, only one voltage is defined. Legacy cards and Not SD cards do not respond to CMD8. In this case, set F8 to 0 (F8 is CMD8 valid flag used in step (11)) and go to Step (5). Only Version 2.00 or higher cards can respond to CMD8. The host needs to check whether CRC of the response is valid and whether VHS and check pattern in the argument are equal to VCA and check pattern in the response. Passing all these checks results in CMD8 response OK. In this case, set F8 to 1 and go to step (5). If one of the checks is failed, go to step (4).
- (4) Initialization is stopped by CMD8 fails. The Host Driver should retry step (1) to (3) one more time (this is not described in the figure).
- (5) SDIO OCR is available by issuing CMD5 with setting voltage window (bit 23 to 0) in the argument to 0. SDIO initialization is not started.
- (6) No response means the card does not have SDIO function. Set SDIO flag to 0 and go to step (11). If the card responds to CMD5 and the response is OK, go to step (7). If the response is error, set SDIO flag to 0 and go to step (10). SDIO flag indicates whether SDIO functions are initialized or not.
- (7) The SDIO portion starts initialization by CMD5 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (8) If no response or error response is receive, set SDIO flag to 0 and go to step (10). If good response is received, go to step (9).
- (9) Check busy status in the response. If busy is released, set SDIO flag to 1 and go to step (10). Repeat from step (7) while busy is indicated. Detecting timeout of 1 second exits the loop. In this case, set SDIO flag to 0 and go to step (10).
- (10) Good response in this step means that all responses received at (6) and (8) are valid. When response is good, MP (memory present) flag in the response can be checked. If the response valid and MP = 0, go to step (28). Otherwise, go to step (11).
- (11) Check F8 flag set in step (3). If CMD8 is executed correctly (F8 = 1), go to step (19). Otherwise, go to step (12).
- (12) OCR is available by issuing ACMD41 with the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. The response of CMD55 (ACMD41) may indicate illegal command error due to some SD cards do not recognized CMD8. The Host Driver should ignore this error or issue CMD0 before ACMD41 to clear this error status.
- (13) If response of CMD55 is not received, the card is not SD cards and goes to (17). If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (14). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.
- (14) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (15) If no response or error response is received, go to step (28). If good response is received, go to step (16).
- (16) Check busy status in the response. If busy is released, go to step (18). Repeat from step (14) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).
- (17) The host recognizes that the card is not SD memory card and quits SD card initialization.
- (18) The host recognizes that the card is Version 1.xx Standard Capacity SD Memory Card. Go to Step (30).
- (19) OCR is available by issuing ACMD41 with setting the voltage window (bit 23 to 0) in the argument is set to 0. Memory initialization is not started. Setting of HCS does not affect this operation.

- (20) If the card responds to CMD55, it may also respond to CMD41. If the responses of ACMD41 are OK, go to Step (21). Otherwise, go to step (28). Locked card can be detected by the card status in the response of CMD55.
- (21) The memory portion starts initialization by Issuing ACMD41 with setting the supply voltage to the voltage window. UHS-I supported host sets S18R to 1. If the host can supply more than 150mA, XPC is set to 1. HCS in the argument is set to 1, which indicates supporting High Capacity Memory Card. If the supplied voltage is not matched with voltage window of card, the card goes into inactive state and does not return the response.
- (22) If no response or error response is received, go to step (28). If good response is received, go to step (23).
- (23) Check busy status in the response. If busy is released, go to step (24). Repeat from step (21) while busy is indicated. The interval of ACMD41 shall be less than 50 ms. Detecting timeout of 1 second exits the loop and go to step (28).
- (24) CCS in the response is valid after busy is released. If CCS = 0, it indicates the Standard Capacity SD Memory Card and go to step (25). If CCS = 1, it indicates the High Capacity SD Memory Card or Extended Capacity Memory Card and go to Step (26).
- (25) The host recognizes that the card is Ver2.00 or Ver3.00 Standard Capacity SD Memory Card. Optimal functions defined in Version 2.00 or higher are available. Go to Step (32).
- (26) The host recognizes that the card is the High Capacity SD Memory Card or Extended Capacity Memory Card.
- (27) Perform the signal voltage switch procedure and go to step (32).
- (28) Check SDIO flag. If SDIO = 1, go to step (28). Otherwise, go to step (31).
- (29) The host recognizes that the card is SDIO only card and go to step (30).
- (30) Perform the signal voltage switch procedure and go to step (33).
- (31) The host recognizes that the card is unusable.
- (32) In case of memory card, CMD2 is issued to get CID and Go to Step (31).
- (33) CMD3 is issued to get RCA. If the RCA number is 0, the Host should issue CMD3 again.

### 12.3.6.5.1.6.1 Signal Voltage Switch Procedure (for UHS-I)

mmcsd-029

**Figure 12-311. Signal Voltage Switch Procedure**

- (1) If S18A of CMD5 or S18A of ACMD41 is set to 1, signal voltage switch is performed according to the following steps. Otherwise, exits from this procedure.
- (2) Issue CMD11.
- (3) Check response and if an error is detected, go to step (12).
- (4) Stop providing SD clock to the card.
- (5) Check DAT[3:0] level. If the level is 0000b, the card is ready to start voltage switch sequence. Otherwise, go to (12) to quit the sequence.
- (6) Set MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit.
- (7) Wait 5 ms. 1.8 V voltage regulator shall be stable within this period.
- (8) If MMCSD0\_HOST\_CONTROL2[3] V1P8\_SIGNAL\_ENA bit is cleared by Host Controller, go to step (12).
- (9) Provide SD Clock to the card again.
- (10) Wait 1 ms.
- (11) Check DAT[3:0] level. If the level is 1111b, switch to 1.8 V signal level is completed successfully. Otherwise, go to (12).
- (12) If an error occurs during voltage switch procedure, stop providing the power to the card. In this case, Host Driver should retry initialization procedure by setting S18R to 0 at step (7) and (21) in [Figure 12-309](#) and [Figure 12-310](#).

#### **12.3.6.5.1.7 SD Transaction Generation**

This section describes the sequences how to generate and control various kinds of SD transactions. SD transactions are classified into three cases:

- (1) Transactions that do not use the DAT line.
- (2) Transactions that use the DAT line only for the busy signal.
- (3) Transactions that use the DAT line for transferring data.

In this specification the first and the second case's transactions are classified as "Transaction Control without Data Transfer using DAT Line", the third case's transaction is classified as "Transaction Control with Data Transfer using DAT Line". Refer to the latest SD Physical Layer Specification and SDIO Specification for more detail about SD commands specification.

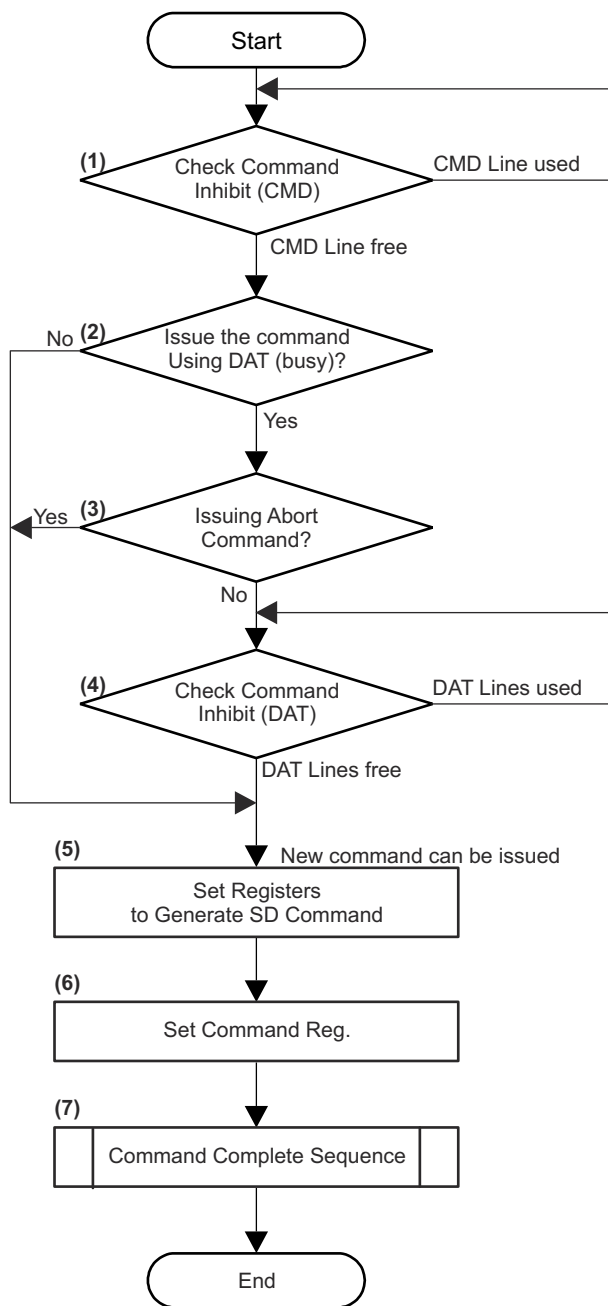

##### **12.3.6.5.1.7.1 Transaction Control without Data Transfer Using DAT Line**

In this section, the sequence for how to issue SD Command and how to complete SD Command is explained. [Figure 12-312](#) shows the sequence to issue a SD Command and [Figure 12-313](#) shows the sequence to finalize a SD Command.

##### **12.3.6.5.1.7.1.1 The Sequence to Issue a SD Command**

The sequence to issue the SD Command is detailed in [Figure 12-312](#).

mmcscd-030

**Figure 12-312. SD Command Issue Sequence**

(1) Check MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 0. That is, when MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is 1, the Host Driver shall not issue a SD Command.

(2) If the Host Driver issues a SD Command using DAT lines including busy signal, go to step (3). If without using DAT lines including busy signal, go to step (5).

(3) If the Host Driver is issuing an abort command, go to step (5). In the case of nonabort command, go to step (4).

(4) Check MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit. Repeat this step until MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit is set to 0.

(5) Set registers except the MMCSD0\_COMMAND register.

(6) Set the MMCSD0\_COMMAND register.

**Note:** Writing the upper byte [3] in the MMCSD0\_COMMAND register causes the Host Controller to issue a SD command to the SD card.

(7) Perform Command Completion Sequence in accordance.

#### **12.3.6.5.1.7.1.2 The Sequence to Finalize a Command**

[Figure 12-313](#) shows the sequence to finalize a SD Command when response check is disabled. There is a possibility that some errors (Command Index/End bit/CRC/Timeout Error) occur during this sequence. If response check is enabled, error is indicated by Response Error Interrupt.

mmcsd-031

**Figure 12-313. Command Complete Sequence**

#### 12.3.6.5.1.7.1.3

(1) If MMCS0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit is set to 1 (response check is enabled), go to stop (4) else wait for the Command Complete Interrupt (MMCS0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE). If the Command Complete Interrupt has occurred, go to step (2).

(2) Write 1 to MMCS0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(3) Read the Response register (see MMCS0\_RESPONSE\_0 - MMCS0\_RESPONSE\_7) and get necessary information of the issued command.

- (4) Judge whether the command uses the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) or not. If it uses Transfer Complete, go to step (5). If not, go to step (7).
- (5) Wait for the Transfer Complete Interrupt. If the Transfer Complete Interrupt has occurred, go to step (6).
- (6) Write 1 to MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.
- (7) Check for errors in Response Data (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7). If there is no error, go to step (8). If there is an error, go to step (9).
- (8) Return Status of "No Error".
- (9) Return Status of "Response Contents Error".

**Note1:** While waiting for the Transfer Complete interrupt, the Host Driver shall only issue commands that do not use the busy signal.

**Note2:** The Host Driver shall judge the Auto CMD12 complete by monitoring Transfer Complete.

**Note3:** When the last block of un-protected area is read using memory multiple block read command (CMD18), OUT\_OF\_RANGE error may occur even if the sequence is correct. The Host Driver should ignore it. This error will appear in the response of Auto CMD12 or in the response of the next memory command.

#### **12.3.6.5.1.7.2 Transaction Control with Data Transfer Using DAT Line**

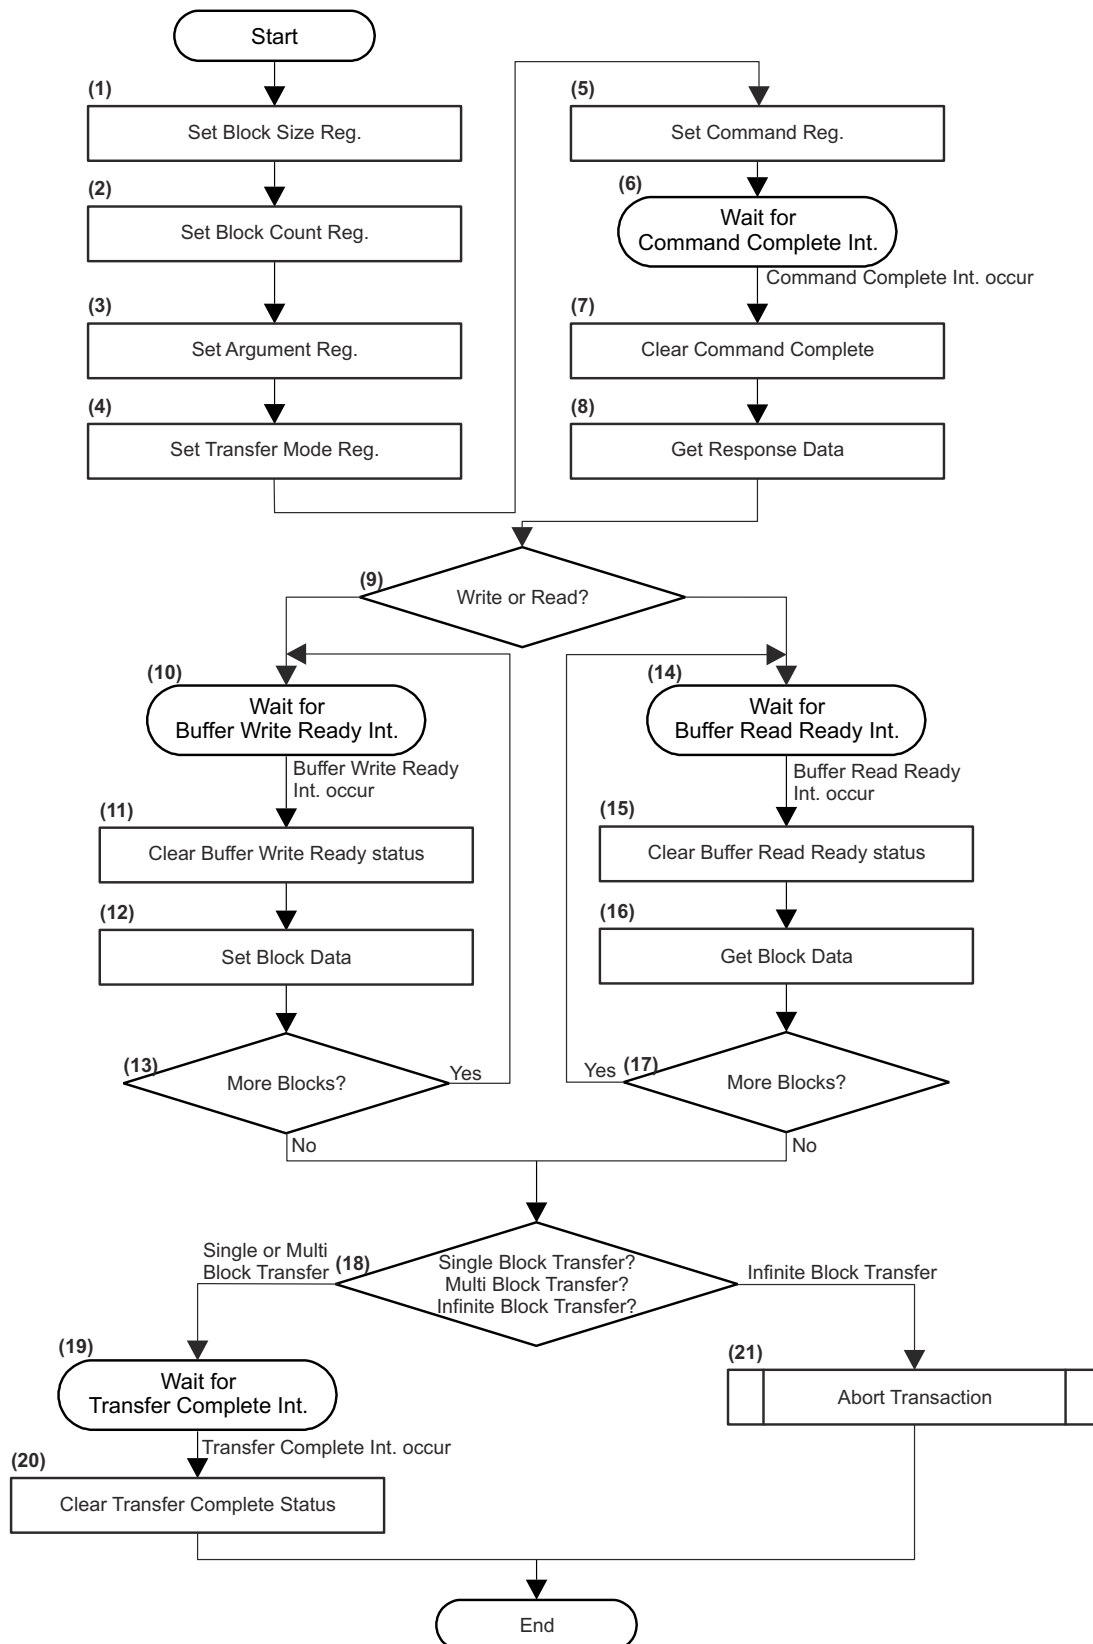

Depending on whether DMA (optional) is used or not, there are two execution methods.

In addition, the sequences for SD transfers are classified into following three kinds according to how the number of blocks is specified:

- (1) Single Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified is always one.
- (2) Multiple Block Transfer: The number of blocks is specified to the Host Controller before the transfer. The number of blocks specified shall be one or more.
- (3) Infinite Block Transfer: The number of blocks is not specified to the Host Controller before the transfer. This transfer is continued until an abort transaction is executed. This abort transaction is performed by CMD12 in the case of a SD memory card and by CMD52 in the case of a SDIO card.

##### **12.3.6.5.1.7.2.1 Not using DMA**

The sequence for not using DMA is shown in [Figure 12-314](#).

mmscd-032

**Figure 12-314. Transaction Control with Data Transfer Using DAT Line Sequence (Not using DMA)**

- (1) Set the value corresponding to the executed data byte length of one block to the MMCSD0\_BLOCK\_SIZE register.
- (2) Set the value corresponding to the executed data block count to the MMCSD0\_BLOCK\_COUNT register in accordance with [Table 12-386](#).

**Table 12-386. Determination of Transfer Type**

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Not Zero	Multiple Transfer
1	1	Zero	Stop Multiple Transfer

- (3) Set the argument value to Argument register (MMCSD0\_ARGUMENT1\_LO and MMCSD0\_ARGUMENT1\_HI).

- (4) Set the value to the MMCSD0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSD0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to [Table 12-386](#).

If response check is enabled (MMCSD0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCSD0\_TRANSFER\_MODE[6] RESP\_TYPE).

- (5) Set the value to MMCSD0\_COMMAND register.

**Note:** When writing the upper byte [3] of MMCSD0\_COMMAND register, SD command is issued.

- (6) If response check is enabled, go to stop (9) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

- (7) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit for clearing this bit.

- (8) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

- (9) In the case where this sequence is for write to a card, go to step (10). In case of read from a card, go to step (14).

- (10) Then wait for Buffer Write Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY).

- (11) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[4] BUF\_WR\_READY bit for clearing this bit.

- (12) Write block data (in according to the number of bytes specified at the step (1)) to MMCSD0\_DATA\_PORT register.

- (13) Repeat until all blocks are sent and then go to step (18).

- (14) Then wait for the Buffer Read Ready Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY).

- (15) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[5] BUF\_RD\_READY bit for clearing this bit.

- (16) Read block data (in according to the number of bytes specified at the step (1)) from the MMCSD0\_DATA\_PORT register.

- (17) Repeat until all blocks are received and then go to step (18).

- (18) If this sequence is for Single or Multiple Block Transfer, go to step (19). In case of Infinite Block Transfer, go to step (21).

- (19) Wait for Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).

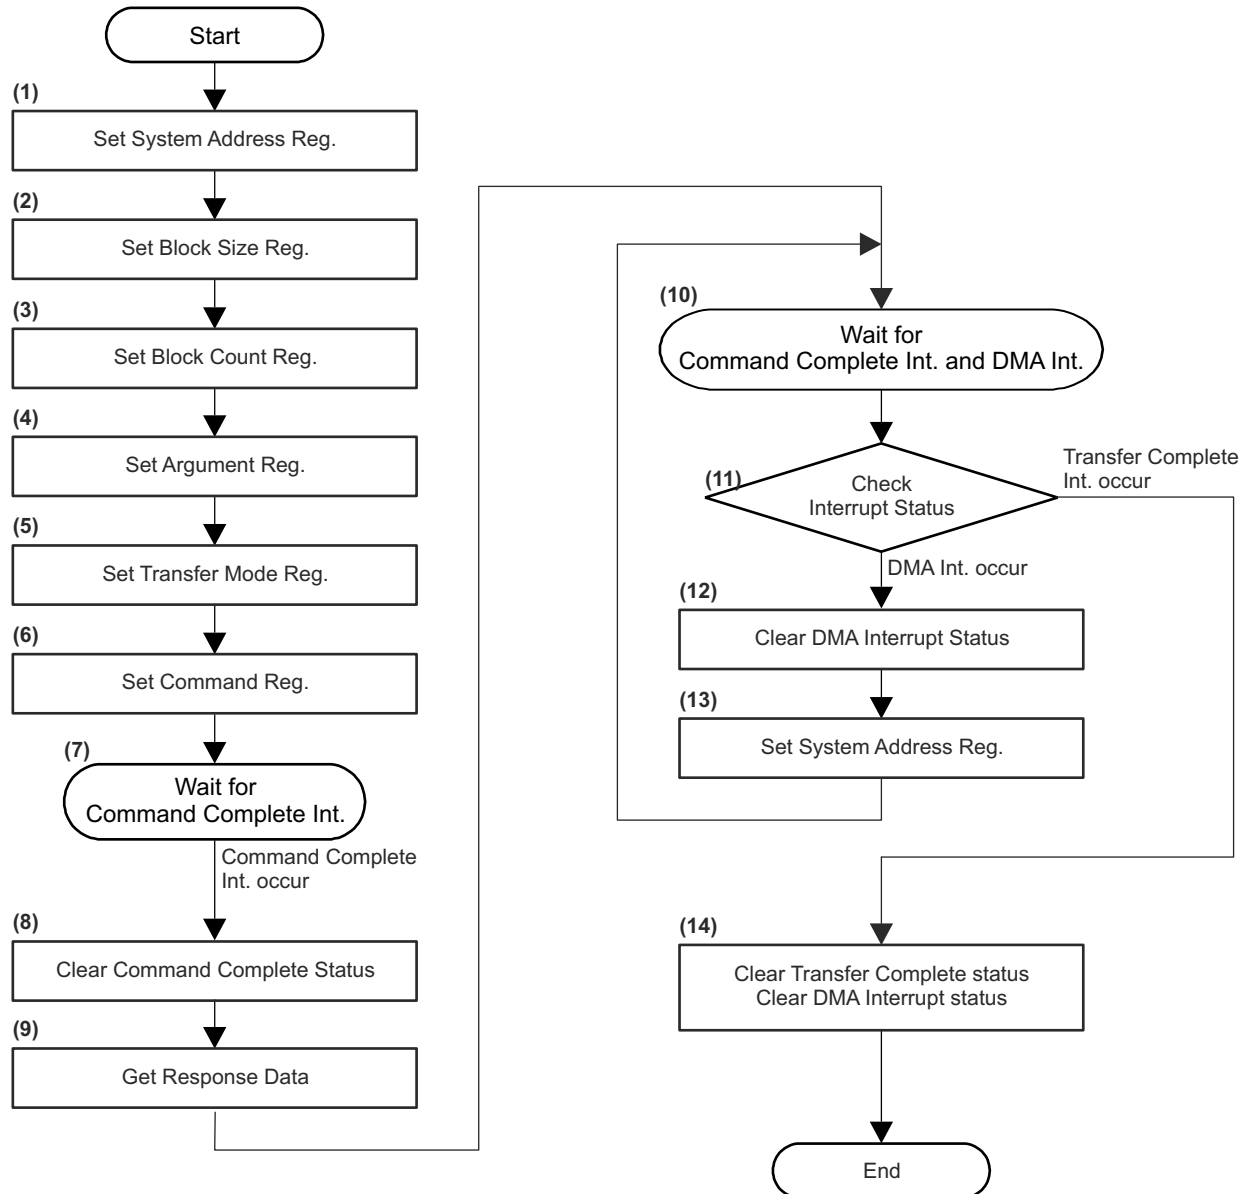

(20) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit for clearing this bit.

(21) Perform the sequence for Abort Transaction in accordance with [Section 12.3.6.5.1.8, Abort Transaction](#).

**Note:** Step (1) and Step (2) can be executed at same time. Step (4) and Step (5) can be executed at same time.

#### 12.3.6.5.1.7.2.2 Using SDMA

The sequence for using SDMA is shown in [Figure 12-315](#).

mmcsd-033

**Figure 12-315. Transaction Control with Data Transfer Using DAT Line Sequence (Using SDMA)**

(1) Data location of system memory is set to the SDMA System Address register if MMCSD0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 0 or set to the MMCSD0\_ADMA\_SYS\_ADDRESS register if MMCSD0\_HOST\_CONTROL2[12] HOST\_VER40\_ENA = 1.

(2) Set the value corresponding to the executed data byte length of one block in the MMCSD0\_BLOCK\_SIZE register.

(3) Set the value corresponding to the executed data block count in the MMCSDB0\_BLOCK\_COUNT register in accordance with [Table 12-386](#).

(4) Set the argument value to the Argument register (MMCSDB0\_ARGUMENT1\_LO and MMCSDB0\_ARGUMENT1\_HI).

(5) Set the value to the MMCSDB0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSDB0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to [Table 12-386](#). If response check is enabled (MMCSDB0\_TRANSFER\_MODE[7] RESP\_ERR\_CHK\_ENA = 1), set MMCSDB0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5.

(6) Set the value to the MMCSDB0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSDB0\_COMMAND register, the SD command is issued and SDMA is started.

(7) If response check is enabled, go to stop (10) else wait for the Command Complete Interrupt (MMCSDB0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(8) Write 1 to the MMCSDB0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(9) Read Response register (MMCSDB0\_RESPONSE\_0 - MMCSDB0\_RESPONSE\_7) and get necessary information of the issued command.

(10) Wait for the Transfer Complete Interrupt (MMCSDB0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and DMA Interrupt (MMCSDB0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT).

(11) If MMCSDB0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (14) else if MMCSDB0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit is set to 1, go to Step (12). The MMCSDB0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is higher priority than the MMCSDB0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit.

(12) Write 1 to the MMCSDB0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

(13) Set the next system address of the next data position to the System Address register (MMCSDB0\_ADMA\_SYS\_ADDRESS) and go to Step (10).

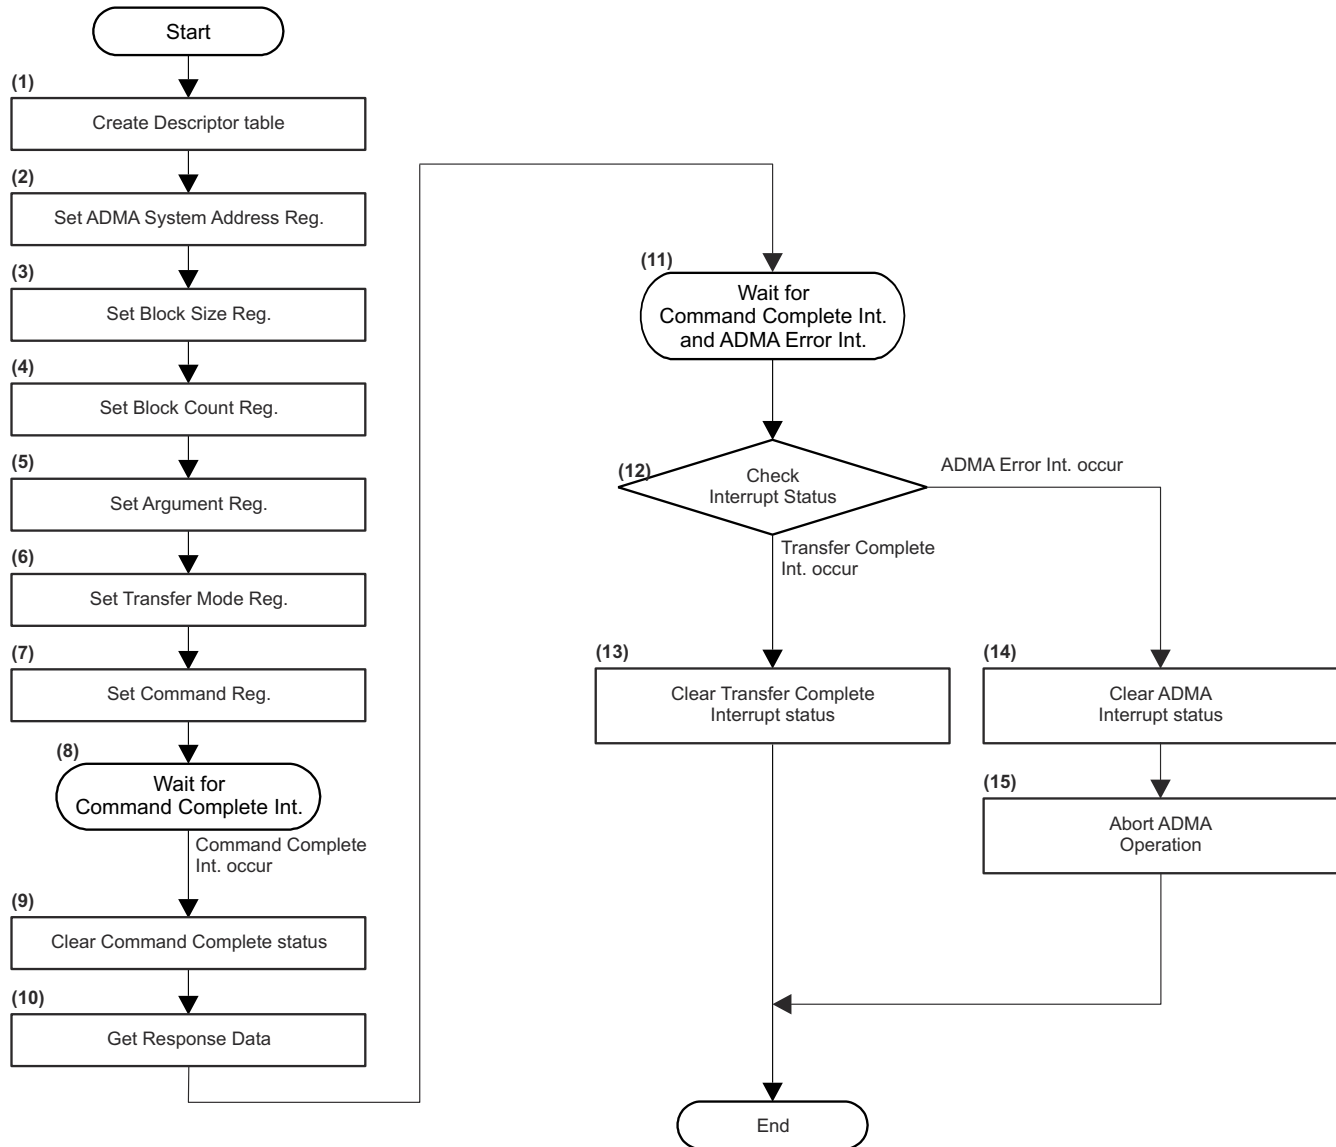

(14) Write 1 to the MMCSDB0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit and MMCSDB0\_NORMAL\_INTR\_STS\_ENA[3] DMA\_INTERRUPT bit to clear this bit.

**Note:** Step (2) and Step (3) can be executed simultaneously. Step (5) and Step (6) can also be executed simultaneously.

#### 12.3.6.5.1.7.2.3 Using ADMA

The sequence for using ADMA is shown in [Figure 12-316](#).

mmcsd-034

**Figure 12-316. Transaction Control with Data Transfer Using DAT Line Sequence (Using ADMA)**

- (1) Create Descriptor table for ADMA in the system memory.
- (2) Set the Descriptor address for ADMA in the MMCSDD0\_ADMA\_SYS\_ADDRESS register.
- (3) Set the value corresponding to the executed data byte length of one block in the MMCSDD0\_BLOCK\_SIZE register.
- (4) Set the value corresponding to the executed data block count in the MMCSDD0\_BLOCK\_COUNT register in accordance with [Table 12-386](#).
- (5) Set the argument value to the Argument register (MMCSDD0\_ARGUMENT1\_LO and MMCSDD0\_ARGUMENT1\_HI).
- (6) Set the value to the MMCSDD0\_TRANSFER\_MODE register. The Host Driver determines Multi/Single Block Select, Block Count Enable, Data Transfer Direction, Auto CMD12 Enable and DMA Enable in the MMCSDD0\_TRANSFER\_MODE register. Multi/Single Block Select and Block Count Enable are determined according to [Table 12-386](#). If response check is enabled (MMCSDD0\_TRANSFER\_MODE[7]

RESP\_ERR\_CHK\_ENA = 1), set MMCSD0\_TRANSFER\_MODE[8] RESP\_INTR\_DIS bit to 1 and select Response Type R1/R5 (MMCSD0\_TRANSFER\_MODE[6] RESP\_TYPE).

(7) Set the value to the MMCSD0\_COMMAND register.

**Note:** When writing to the upper byte [3] of the MMCSD0\_COMMAND register, the SD command is issued and DMA is started.

(8) If response check is enabled, go to stop (11) else wait for the Command Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit).

(9) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS[0] CMD\_COMPLETE bit to clear this bit.

(10) Read Response register (MMCSD0\_RESPONSE\_0 - MMCSD0\_RESPONSE\_7) and get necessary information of the issued command.

(11) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE) and ADMA Error Interrupt (MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE).

(12) If MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit is set to 1, go to Step (13) else if MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field is set to 1, go to Step (14).

(13) Write 1 to the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to clear this bit.

(14) Write 1 to the MMCSD0\_ADMA\_ERR\_STATUS[1-0] ADMA\_ERR\_STATE bit field to clear this bit.

(15) Abort ADMA operation. SD card operation should be stopped by issuing abort command. If necessary, the Host Driver checks MMCSD0\_ADMA\_ERR\_STATUS register to detect why ADMA error is generated.

**Note:** Step (3) and Step (4) can be executed simultaneously. Step (6) and Step (7) can also be executed simultaneously.

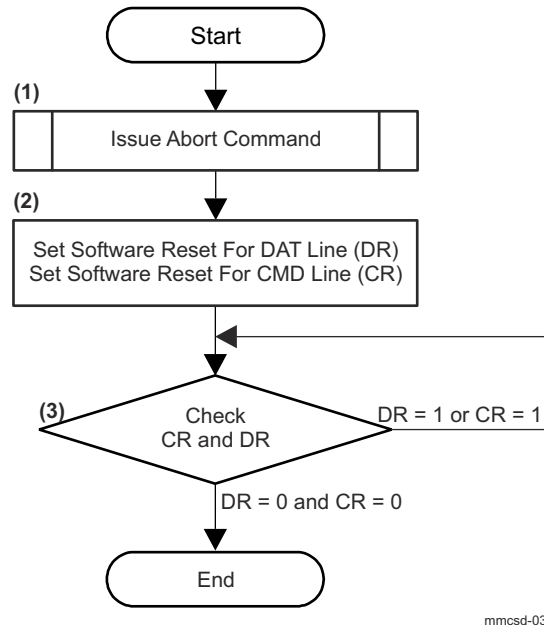

#### 12.3.6.5.1.8 Abort Transaction

An abort transaction is performed by issuing CMD12 for a SD memory card and by issuing CMD52 for a SDIO card. There are two cases where the Host Driver needs to do an Abort Transaction. The first case is when the Host Driver stops Infinite Block Transfers. The second case is when the Host Driver stops transfers while a Multiple Block Transfer is executing.

There are two ways to issue an Abort Command. The first is an asynchronous abort. The second is a synchronous abort. In an asynchronous abort sequence, the Host Driver can issue an Abort Command at any time unless MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit is set to 1. In a synchronous abort, the Host Driver shall issue an Abort Command after the data transfer stopped by using MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

##### 12.3.6.5.1.8.1 Asynchronous Abort

The sequence for Asynchronous Abort is shown in [Figure 12-317](#).

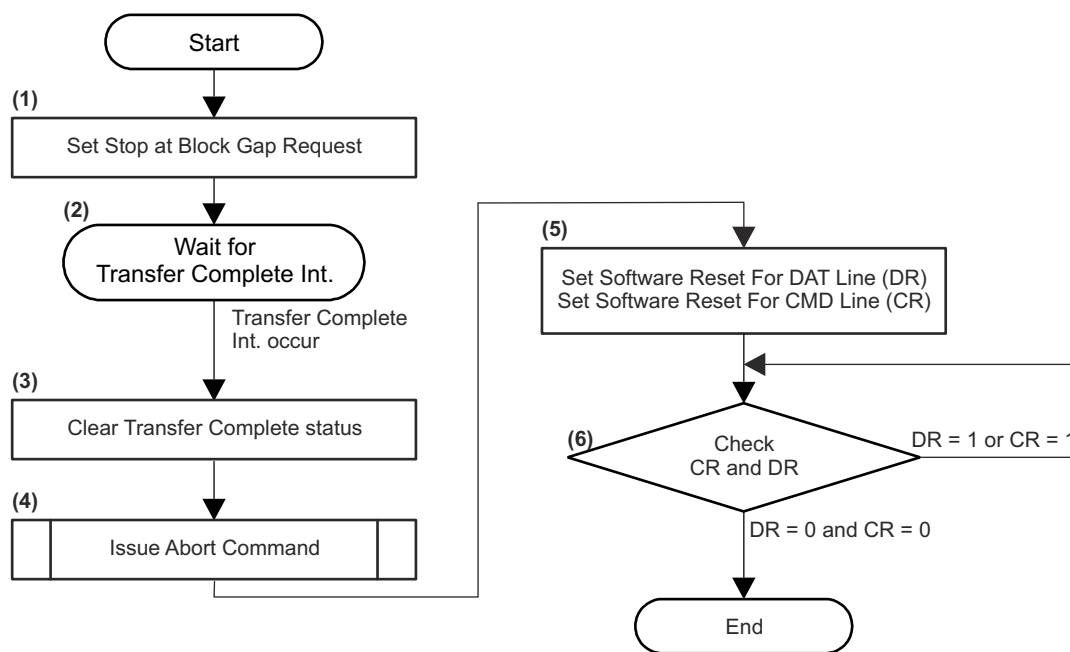

mmcsd-035

**Figure 12-317. Asynchronous Abort Sequence**

- (1) Issue Abort Command in accordance.
- (2) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.
- (3) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (3).

### 12.3.6.5.1.8.2 Synchronous Abort

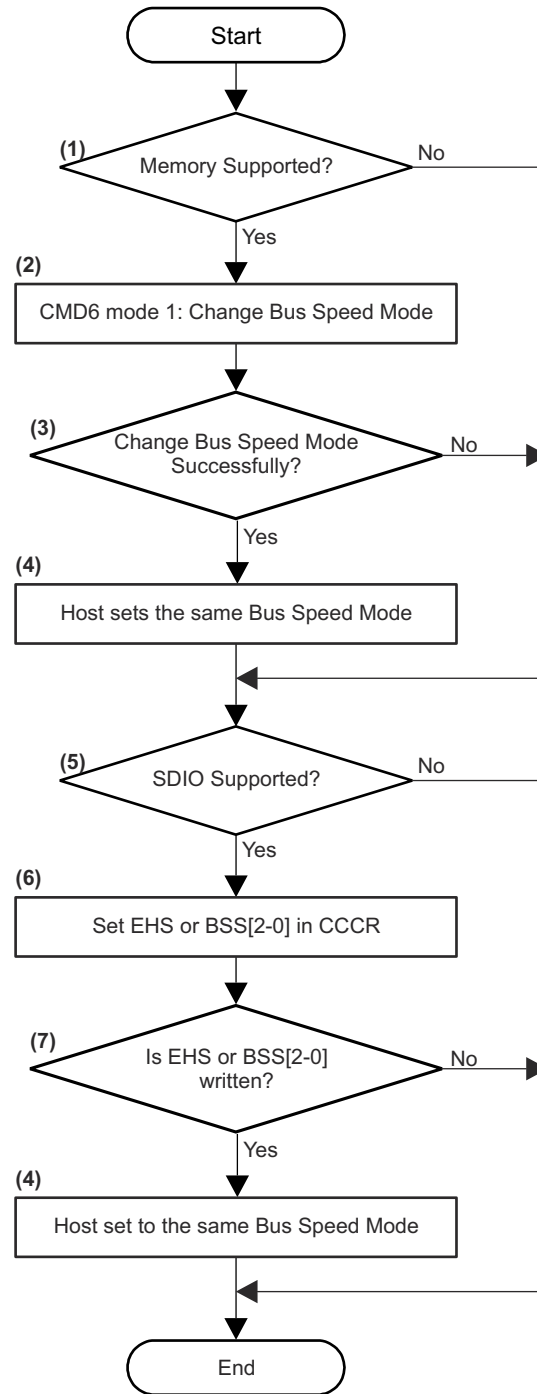

mmcsd-036

**Figure 12-318. Synchronous Abort Sequence**

- (1) Set the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop SD transactions.
- (2) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (3) Set the MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (4) Issue the Abort Command
- (5) Set both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 to do software reset.
- (6) Check both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If both MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit and MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit are 0, go to "End". If either MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit or MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 1, go to step (6).

### 12.3.6.5.1.9 Changing Bus Speed Mode

This section describes the sequence for switching the bus speed mode: Default Speed, High Speed mode and UHS-I mode. The switch command (CMD6) is used to change memory card bus speed mode. The EHS bit (SDIO Version 2.00) or BSS[2-0] bits (SDIO Version 3.00) in the CCCR register is used to change the bus speed mode for SDIO card. In case of Combo card, either of the switch method changes both memory and IO bus speed mode. This means the first switch is effective. Refer to the Physical Layer Specification Version 3.0x and the SDIO Specification Version 3.00 for more information about switching bus speed. [Figure 12-319](#) shows the sequence for switching bus speed mode for Combo Card. Note that if the card is locked, bus width cannot be changed. Unlock the card is required before changing bus width.

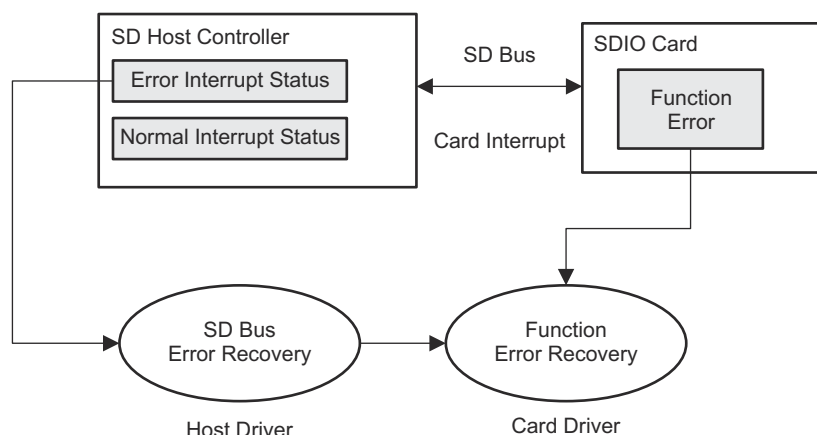

mmcsd-037

**Figure 12-319. Changing Bus Speed Mode**

- (1) The Host Driver checks if the card supports memory. If not supported, go to (5).
- (2) Issue CMD6 with mode 1 to change bus speed mode (Default, High Speed mode or UHS-I mode).
- (3) Check the response of CMD6. If the card does not supports CMD6 (no response) or bus speed is not changed successfully, go to step (5). In this case, the card is in Default Speed mode.
- (4) The Host Driver changes the Host Controller bus speed mode to the same mode.

- (5) The Host Driver checks if the card supports SDIO. If not supported, go to the end.
- (6) Issue CMD52 to write EHS bit or BSS[2-0] bits in CCCR to change bus speed mode (the same bus speed mode of (2) shall be set).
- (7) If EHS or BSS[2-0] are not changed successfully, go to the end.
- (8) The Host Driver changes the Host Controller bus speed to the same mode. In case of Combo card, bus speed is already changed at step (4) and this step does not affect changing bus speed.

#### 12.3.6.5.1.10 Error Recovery

mmcsd-038

**Figure 12-320. Error Report and Recovery**

Figure 12-320 shows concept of error report and its recovery. The Host Controller has 2 interrupt status registers. If an error occurs in the SD Bus transaction, one of the bits is set in the MMCSDB0\_ERROR\_INTR\_STS register. If the function errors occur in the SDIO card, the card interrupt informs these function errors and the Card interrupt is set in the MMCSDB0\_NORMAL\_INTR\_STS\_ENA register (the Card Interrupt is used to inform not only error statuses but also normal information. For example, to inform function ready). The Card Driver shall do function error recovery because the Host Driver does not know how to control the function. In the case that function error occurs due to SD Bus error, SD Bus error recovery is required before function error recovery. Abort command is used to recover SD Bus, and then the Host Driver should save error statuses related to SD Bus errors before issuing abort command and transfer these statuses to the Card Driver. These statuses may be used to recover function error. Following explanations are related to SD Bus error recovery. This specification does not specify the function error recovery.

When an error occurs during data transfer in 2L-HD UHS-II mode, there will be the case that Host Controller cannot drive D0 lane in input mode due to DIR LSS for retrieving lane direction is not detected. In this case, Host Driver cannot issue abort command for recovery. Then if DIR LSS is not detected, Host Controller sets MMCSDB0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit. Host Driver should execute power cycle if MMCSDB0\_UHS2\_ERR\_INTR\_STS[17] DEADLOCK\_TIMEOUT bit is detected to recover from this error. Furthermore, if this type of error is detected several times in 2L-HD, Host Driver should use FD mode rather than using 2L-HD.

Implementation Note:

If the Card Driver cannot recover the function errors, the Host Driver should try following methods.

- (9) Using IOEx for SDIO card

IOEx may be used as the reset per function basis. Sequence is as follows:

Clear IOEx = 0 and wait until IORx = 0 and then set IOEx = 1 again. SDIO may be recovered when IORx = 1.

- (10) Using reset command for memory and SDIO card Re-initialization sequence is required.

(11) Off and on power supply for the SD Bus.

The card may be recovered by the power on reset. Re-initialization sequence is required.

The two cases where the Host Driver needs the "Error Recovery" sequence are classified as follows:

(1) Error Interrupt Recovery:

If error interrupt is indicated by the MMCSD0\_ERROR\_INTR\_STS register, the Host Driver shall apply this sequence.

(2) Auto CMD12 Error Recovery:

If there are errors in Auto CMD12, the Host Driver shall apply this sequence. In terms of Return Status, Auto CMD12 Error Recovery is classified into 4 cases. It is shown in Figure 12-321. If error occurs during memory write transfer, strongly recommend using ACMD22 and then in the following recovery sequence, retry to send remaining blocks not written.

**Figure 12-321. Return Status of Auto CMD12 Error Recovery**

Implementation Note:

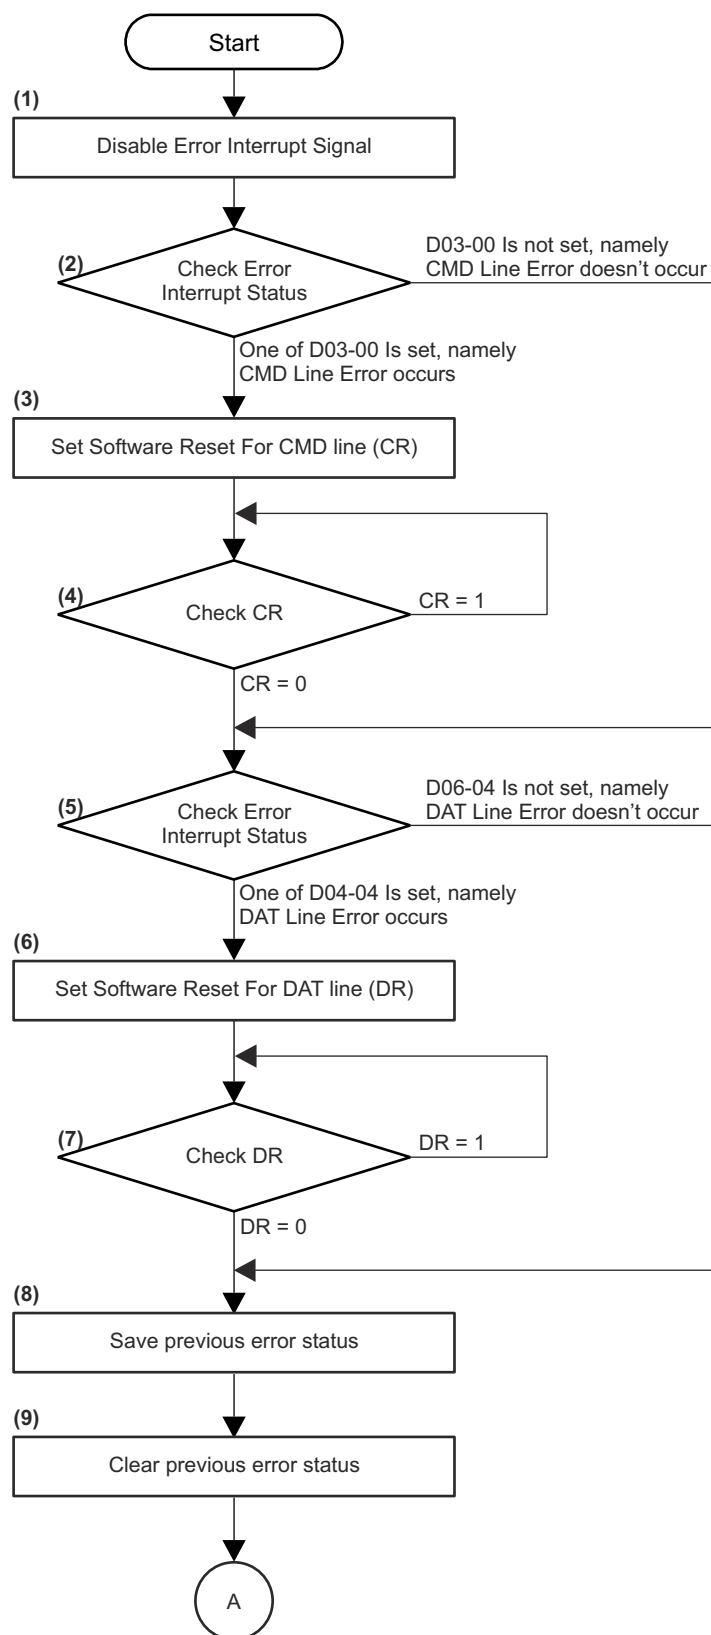

Abort command is used to recover from SD Bus error. SDIO transaction abort using CMD52 returns response but in the case of memory transaction abort using CMD12, response returns depending on the memory card state. If no response returns after issue CMD12, the Host Driver should check card state using CMD13. If the state is "tran" in the CURRENT\_STATE, consider CMD12 is successful.

Implementation Note:

The following sequence is one possible error recovery flow. There may be another methods, sometimes using interrupts or polling. It can be possible to use another flows, based on Host System requirements.

In these error recovery sequences, return statuses for the next sequence. When the Host Controller cannot issue the next command due to SD Bus error, the error recovery sequences return "Non-recoverable" status. In this case, the Host System may cut off power to the SD Bus and then power on SD Bus and initialize both the Host Controller and the SD card again.

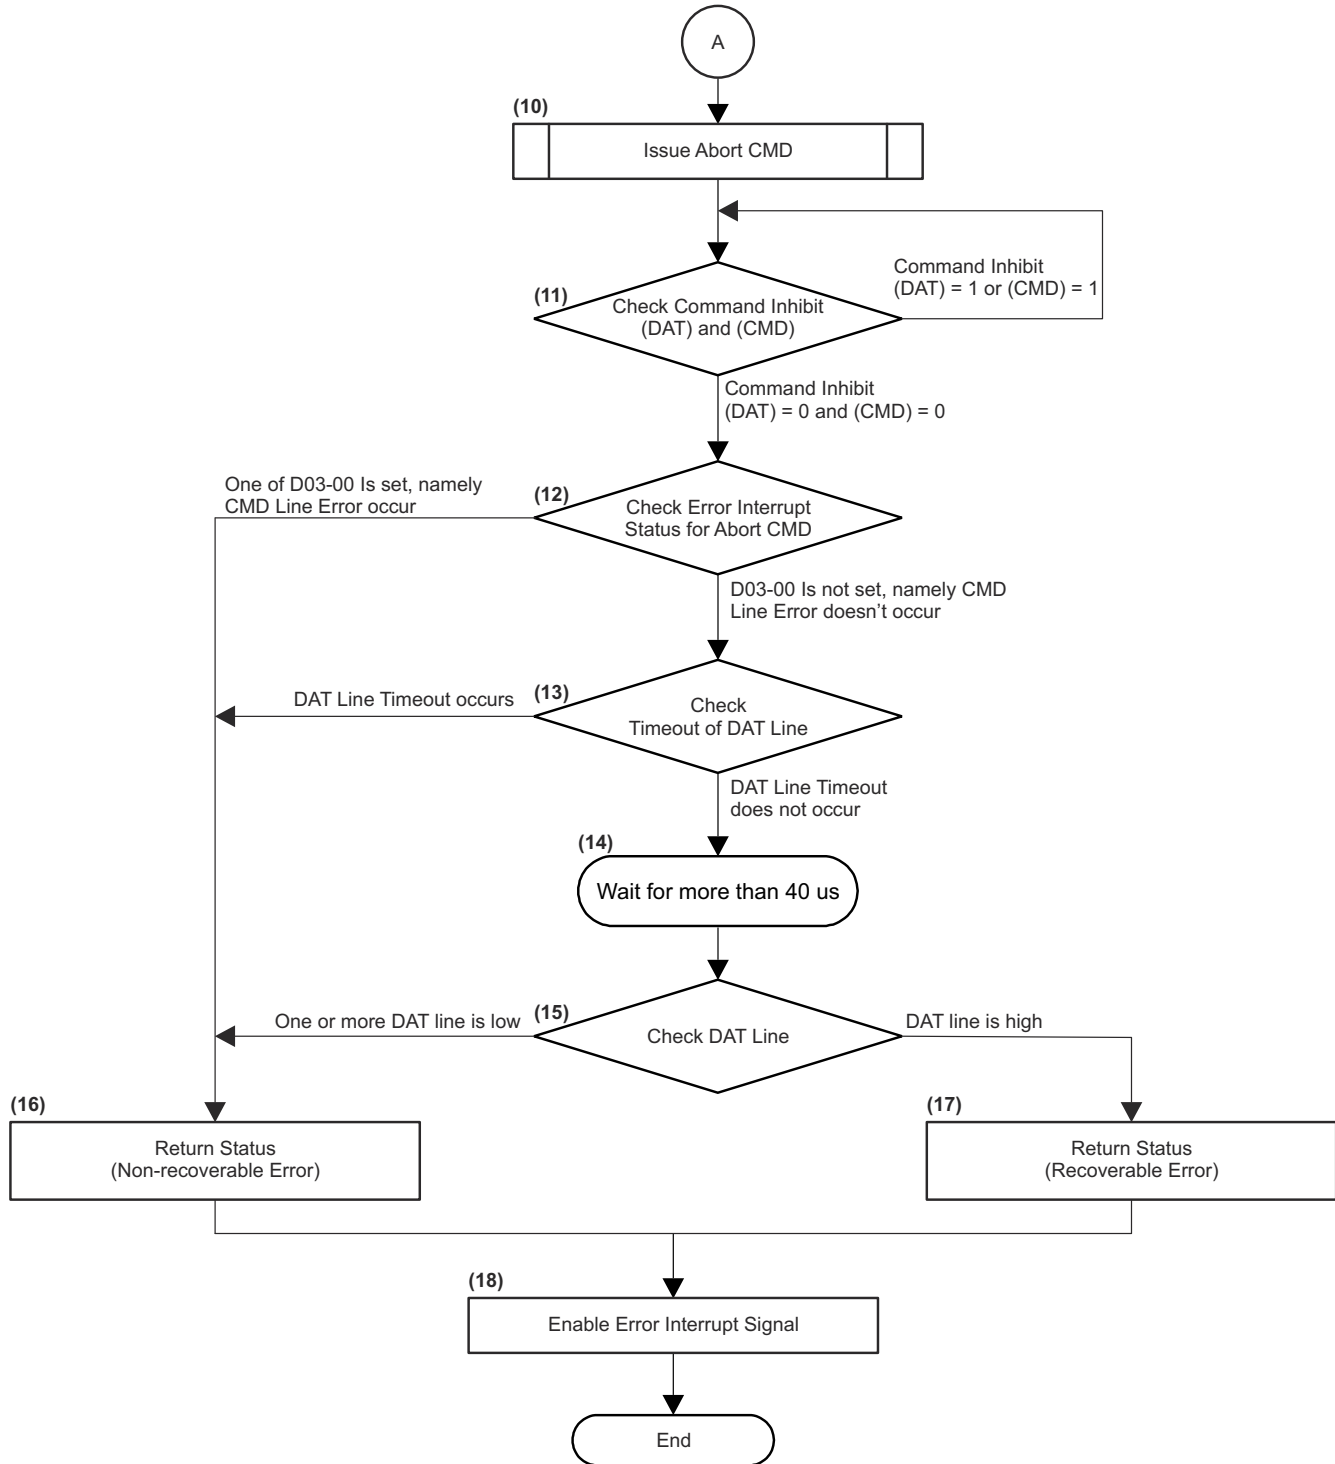

### 12.3.6.5.1.10.1 Error Interrupt Recovery

mmcsd-040

**Figure 12-322. Error Interrupt Recovery Sequence (1)**

mmcsd-041

**Figure 12-323. Error Interrupt Recovery Sequence (2)**

- (1) Disable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).
- (2) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D03-00) is set to 1, go to step (3). If none are set to 1 (all are 0), go to step (5).
- (3) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1.

- (4) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (5). If it is 1, go to step (4).
- (5) Check bits D06-04 in the MMCSD0\_ERROR\_INTR\_STS register. If one of these bits (D06-04) is set to 1, go to step (6). If none are set to 1 (all are 0), go to step (8).
- (6) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Save previous error status.
- (9) Clear previous error status with setting them to 1.
- (10) Issue Abort Command.
- (11) MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit. Repeat this step until both MMCSD0\_PRESENTSTATE[1] INHIBIT\_DAT bit and MMCSD0\_PRESENTSTATE[0] INHIBIT\_CMD bit are set to 0.
- (12) Check bits D03-00 in the MMCSD0\_ERROR\_INTR\_STS register for Abort Command. If one of these bits is set to 1, go to step (16). If none of these bits are set to 1 (all are 0), go to step (13).
- (13) Check MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT bit. If this bit is set to 1, go to step (16). If it is 0, go to step (14).
- (14) Wait for more than 40 us.
- (15) By monitoring the DAT [3:0] Line Signal Level in the MMCSD0\_PRESENTSTATE register, judge whether the level of the DAT line is low or not. If one or more DAT lines are low, go to step (16). If the DAT lines are high, go to step (17).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status of "Recoverable Error".
- (18) Enable the Error Interrupt Signal (MMCSD0\_ERROR\_INTR\_SIG\_ENA).

### 12.3.6.5.1.10.2 Auto CMD12 Error Recovery

mmcsd-042

**Figure 12-324. Auto CMD12 Error Recovery**

The sequence for Auto CMD12 Error Recovery is shown in [Figure 12-324](#). Following four cases A-D shall be covered.

A: An error occurred in CMD\_wo\_DAT, but not in the SD memory transfer.

B: An error occurred in CMD\_wo\_DAT, and also occurred in the SD memory transfer.

C: An error did not occur in CMD\_wo\_DAT, but an error occurred in the SD memory transfer.

D: CMD\_wo\_DAT was not issued, and an error occurred in the SD memory transfer.

- (1) Check MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is set to 1, go to step (2). If this bit is set to 0, go to step (6). In addition, the Host Driver shall define PCMD flag, which changes to 1 if MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit is set to 1.
- (2) Wait for Error Interrupt Recovery for CMD\_wo\_DAT.
- (3) Check "Return Status". In the case of "Non-recoverable Error", go to step (16). In the case of "Recoverable Error", go to step (4).
- (4) Issue CMD12.
- (5) If the CMD line errors occur for the CMD12 (one of D03-00 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Non-recoverable Error" and go to step (16). If not CMD line error and busy timeout error occur (D04 is set in the MMCSD0\_ERROR\_INTR\_STS register), "Return Status" is "Recoverable Error" and go to step (11). Otherwise, "Return Status" is "No error" and go to step (17).
- (6) Set MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit to 1 for software reset of the CMD line.
- (7) Check MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit. If MMCSD0\_SOFTWARE\_RESET[1] SWRST\_FOR\_CMD bit is 0, go to step (8). If it is 1, go to step (7).
- (8) Issue CMD12. Acceptance of CMD12 depends on the state of the card. CMD12 may make the card to return to tran state. If the card is already in tran state, the card does not response to CMD12.
- (9) Check "Return Status" for CMD12. If "Return Status" returns "Non-recoverable Error", go to step (16). In the case of "Recoverable Error" or "No error", go to step (10).
- (10) Check the MMCSD0\_AUTOCMD\_ERR\_STS[0] ACMD12\_NOT\_EXEC bit. If this bit is 0, go to step (11). If it is 1, go to step (14).
- (11) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (12) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (13). If it is 1, go to step (12).
- (13) Check the PCMD flag. If PCMD is 1, go to step (18). If it is 0, go to step (19).
- (14) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (15) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to step (20). If it is 1, go to step (15).
- (16) Return Status of "Non-recoverable Error".
- (17) Return Status that an error has occurred in CMD\_wo\_DAT, but not in the SD memory transfer.
- (18) Return Status that an error has occurred in both CMD\_wo\_DAT, and the SD memory transfer.
- (19) Return Status that an error has not occurred in CMD\_wo\_DAT, but has occurred in the SD memory transfer.
- (20) Return Status that CMD\_wo\_DAT has not been issued, and an error has occurred in the SD memory transfer.

#### 12.3.6.5.1.11 Wakeup Control (Optional)

After the Host System goes into standby mode, the Host System can resume from standby via a wakeup event initiated by one of the following three events:

- (1) Interrupt from a SD card: If an SD card interrupt occurs, the Host System can resume from standby mode. If the Host System uses this wakeup factor, SD Bus power shall be kept on.
- (2) Insertion of SD card: If a SD card is inserted, the Host System can resume from standby mode.
- (3) Removal of SD card: If a SD card is removed, the Host System can resume from standby mode.

The sequence for preparing wakeup before the Host System goes into standby mode is shown in [Figure 12-325](#).

**Figure 12-325. Wakeup Control before Standby Mode**

(1) Set MMCSD0\_HOST\_CONTROL1[1] DATA\_WIDTH bit to 0.

(2) Execute SD Clock Stop Sequence as described in [Section 12.3.6.5.1.2.2](#), *SD Clock Supply and Stop Sequence*.

(3) Clear the MMCSD0\_NORMAL\_INTR\_STS register and the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register, and then set the enable bits of each wakeup event factor to 1 in the MMCSD0\_WAKEUP\_CONTROL register and set the bits of MMCSD0\_ERROR\_INTR\_STS\_ENA register to use wakeup.

The sequence for wakeup once in standby mode is shown in [Figure 12-326](#).

**Figure 12-326. Wakeup from Standby**

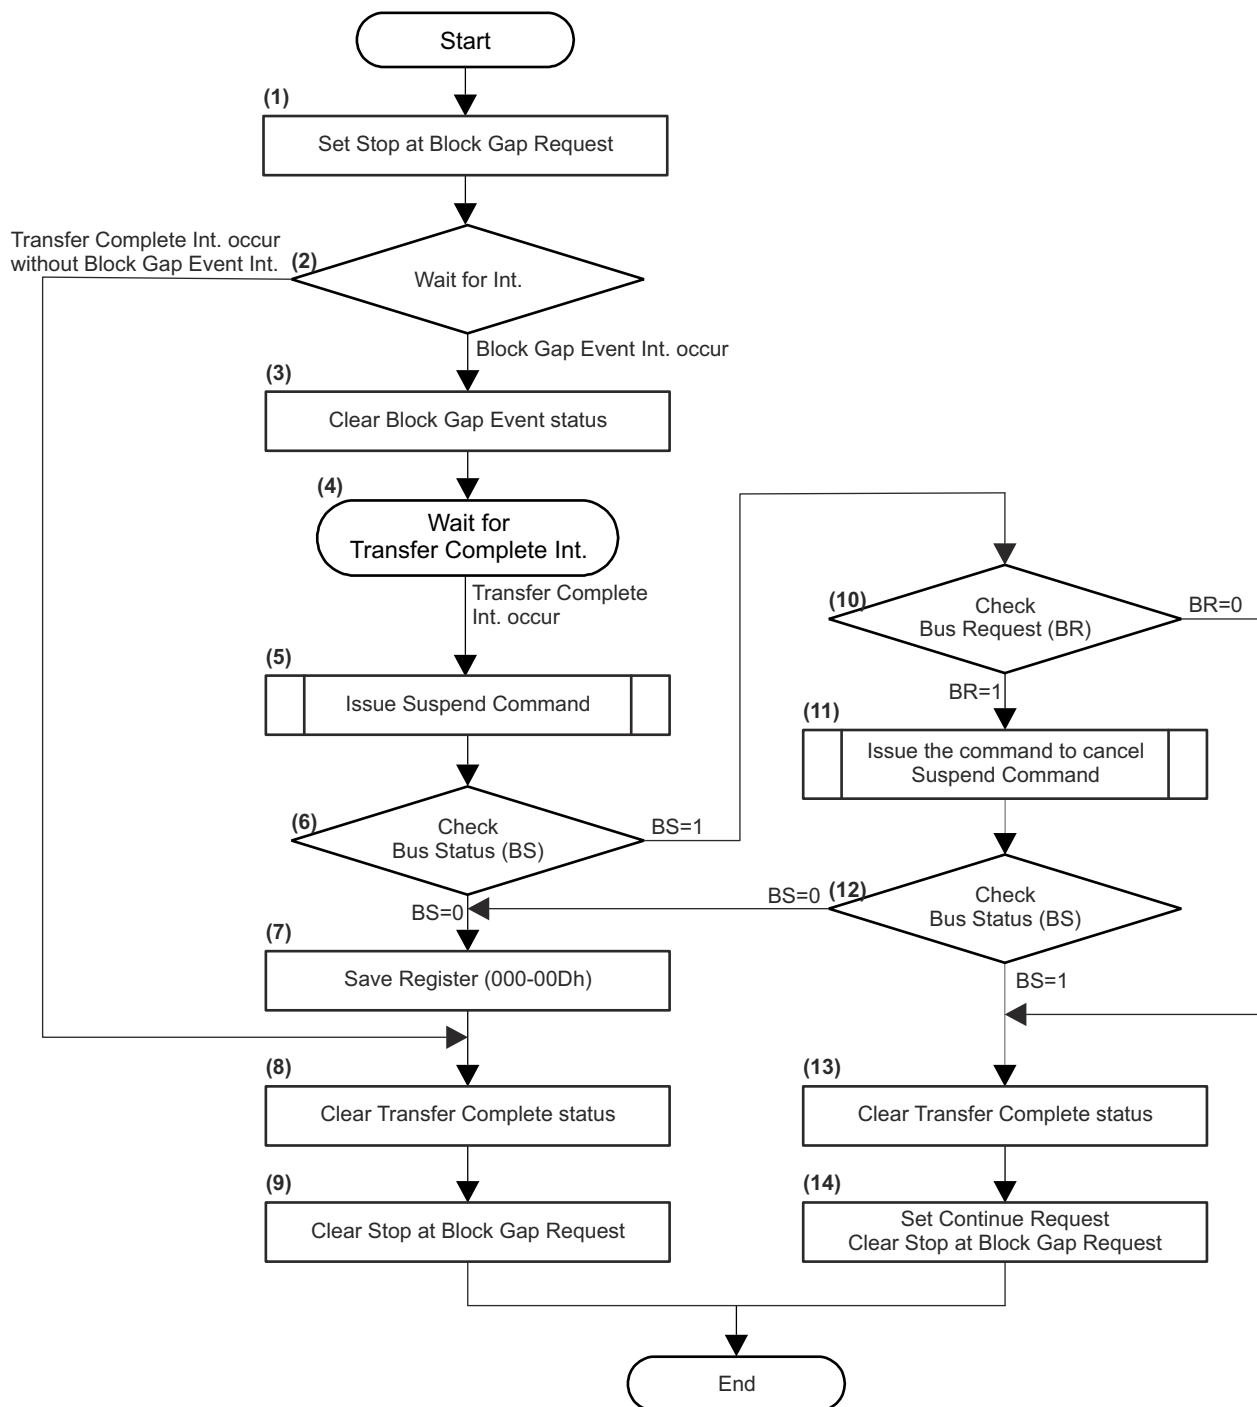

(1) Wait for wakeup event.

- (2) Set the enable bits of each wakeup event factor to 0 in the MMCSD0\_WAKEUP\_CONTROL register and then clear event statuses in the MMCSD0\_NORMAL\_INTR\_STS register. If necessary, set the MMCSD0\_NORMAL\_INTR\_SIG\_ENA register.
- (3) Execute SD Clock Supply Sequence (see [Section 12.3.6.5.1.2.2](#), *SD Clock Supply and Stop Sequence*).
- (4) Set the SD Bus width (see [Section 12.3.6.5.1.4](#), *Changing Bus Width*).

#### **12.3.6.5.1.12 Suspend/Resume (Optional, Not Supported from Version 4.00)**

If a SD card supports suspend and resume functionality, then the Host Controller can initiate suspend and resume. It is necessary for both the Host Controller and the SD card to support the function of "Read Wait". ADMA operation does not support this function.

### 12.3.6.5.1.12.1 Suspend Sequence

mmcsd-045

**Figure 12-327. The Sequence for Suspend**

(1) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 1 to stop the SD transaction.

(2) Wait for an Interrupt. If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 0 and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit is set to 1, go to step (8). If MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit is set to 1, go to step (3).

- (3) Set MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit to 1 to clear this bit.
- (4) Wait for the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS\_ENA[1] XFER\_COMPLETE).
- (5) Issue the Suspend Command in accordance with [Section 12.3.6.5.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (6) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (10).
- (7) Save the register .
- (8) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (9) Set MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to 0 to clear this bit.
- (10) Check the BR value of the response data. If BR is 1, go to step (11). If BR is 0, go to step (13).
- (11) Issues the command to cancel the previous suspend command in accordance with [Section 12.3.6.5.1.7.1](#), *Transaction Control without Data Transfer Using DAT Line*.
- (12) Check the BS value of the response data. If BS is 0, go to step (7). If BS is 1, go to step (13).
- (13) Set MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit to 1 to clear this bit.
- (14) Set MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 to continue the transaction. At the same time, write 0 to MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit to clear this bit.

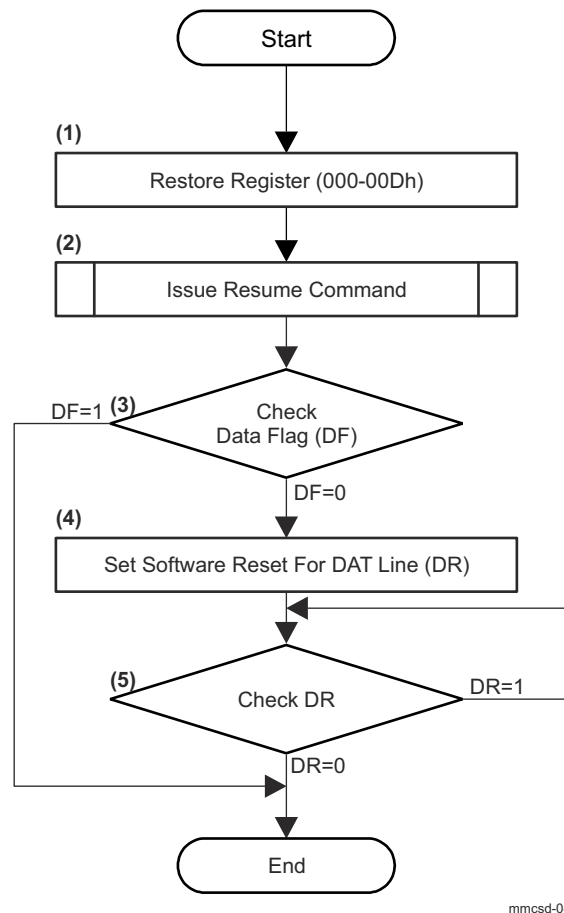

Conditions			Suspend/Resume Function	
Host Suspend/Resume Support	Card Suspend/Resume Support	Card Read Wait Support	Write Suspend/Resume	Read Suspend/Resume
Not supported	Don't care	Don't care	Cannot be used	Cannot be used
Supported	Not supported	Don't care	Cannot be used	Cannot be used
Supported	Supported	Not supported	Can be used	Cannot be used
Supported	Supported	Supported	Can be used	Can be used

mmcsd-046

**Figure 12-328. Suspend/Resume Condition**

### 12.3.6.5.1.12.2 Resume Sequence

mmcsd-047

**Figure 12-329. The Sequence for Resume**

- (1) Restore the register .
- (2) Issue the Resume Command .
- (3) Check the DF value of the response data. If DF is 0, go to step (4). If DF is 1, go to "End".
- (4) Set MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit to 1 for software reset of the DAT line.
- (5) Check MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit. If MMCSD0\_SOFTWARE\_RESET[2] SWRST\_FOR\_DAT bit is 0, go to "End". If it is 1, go to step (5).

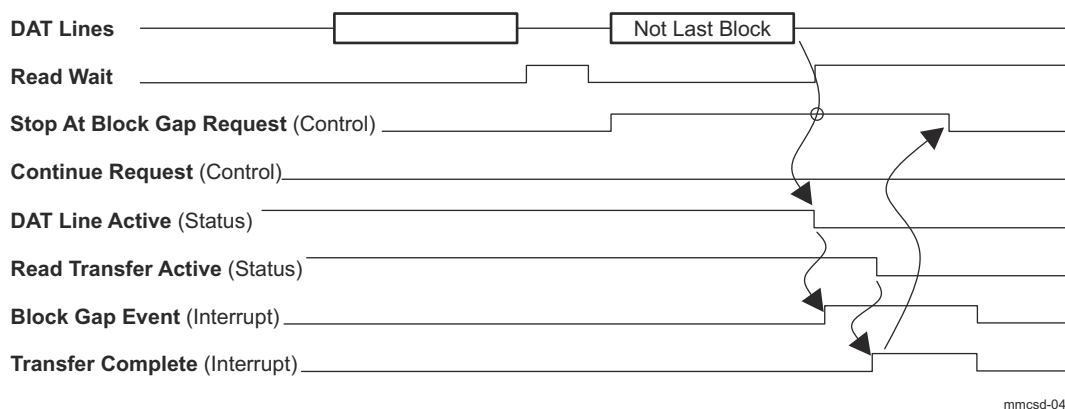

### 12.3.6.5.1.12.3 Stop At Block Gap/Continue Timing for Read Transaction

The timing of Stop At Block Gap Request and Continue Request. The Transfer Complete interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is always generated by setting MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit where data transfer is stopped. However, generation of the Block Gap Event interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is dependent on whether the last data block is sent or not. Block Gap Event is not generated If all data blocks are transferred (the last block is transferred). It is not necessary to enable Block Gap Event interrupt. The status can be checked when transfer complete interrupt is detected. It is not necessary to use Continue Request (MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE) if Block Gap Event status is not set because there is no further data to be transferred. If Read Wait is not supported, Host Controller stops SD Clock at the block gap.

Implementation Note:

The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL, MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE, MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bits shall be set and cleared by the Host Controller.

The MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set and cleared by the Host Driver. The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit shall be set by the Host Driver and be cleared by the Host Controller. The MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit and MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit shall be set by the Host Controller and be cleared by the Host Driver.

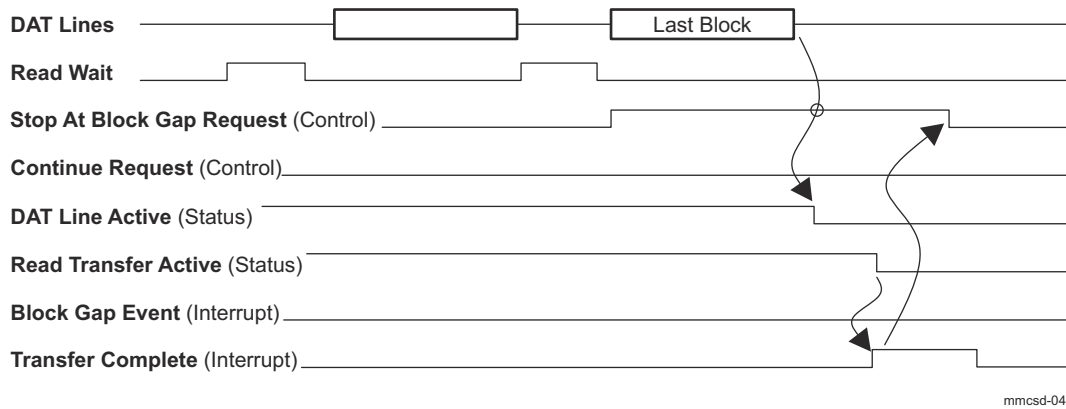

**Figure 12-330. Wait Read Transfer by Stop At Block Gap Request**

The Host Controller can accept a Stop At Block Gap Request (MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP) when all the following conditions are met.

- (1) It is at the block gap.
- (2) The Host Controller can assert read wait or it is already asserted.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit is set to 1.

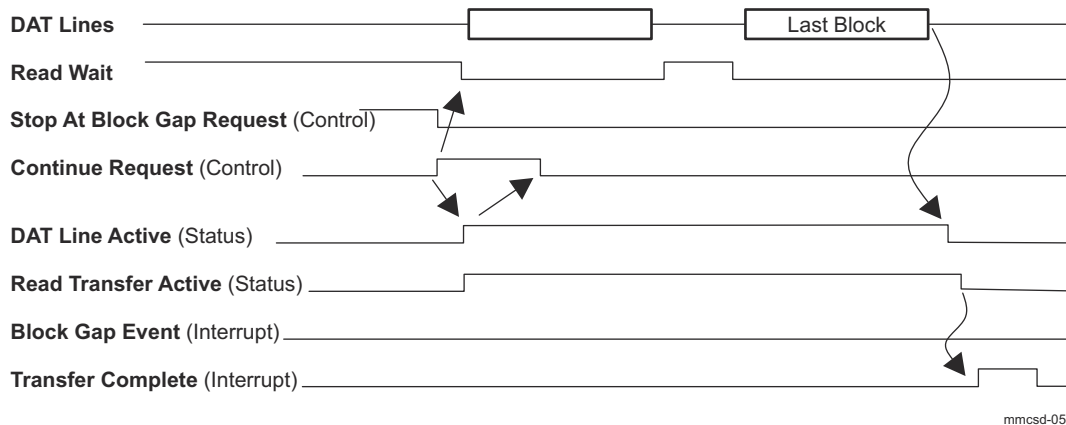

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit:

- (1) Clear MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT).
- (2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE).
- (3) After accepting MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit, clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-331. Stop At Block Gap Request is Not Accepted at the Last Block of the Read Transfer**

If the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and stops the transaction normally. The Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit status is not set to 1, the driver shall clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-332. Continue Read Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

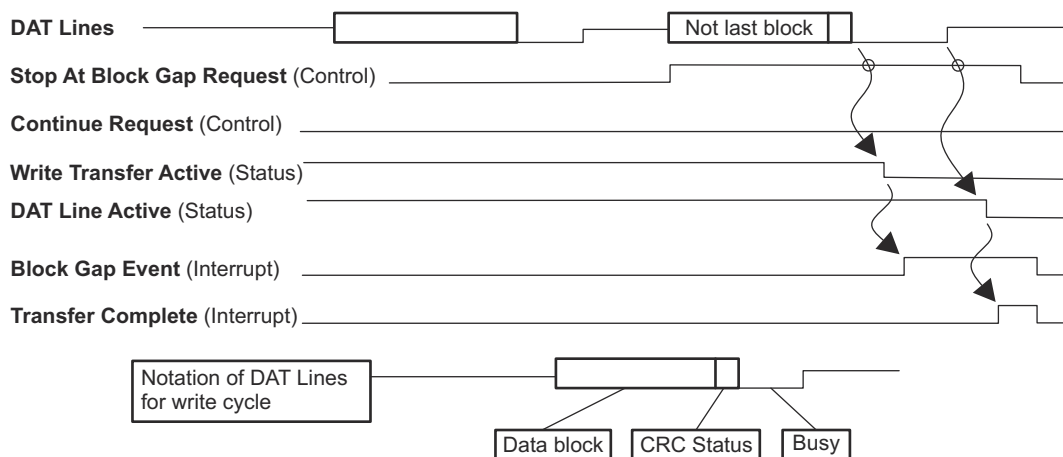

- (1) Release MMCSD0\_BLOCK\_GAP\_CONTROL[2] RDWAIT\_CTRL bit (if the data block can accept the next data).
- (2) Set the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit.
- (3) The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (2).

The end of the read transfer is specified by data length.

- (1) Clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and do not generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).

(2) After all valid data has been read (No valid read data remains in the Host Controller), clear the MMCSD0\_PRESENTSTATE[9] RD\_XFER\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

#### 12.3.6.5.1.2.4 Stop At Block Gap/Continue Timing for Write Transaction

mmcsd-051

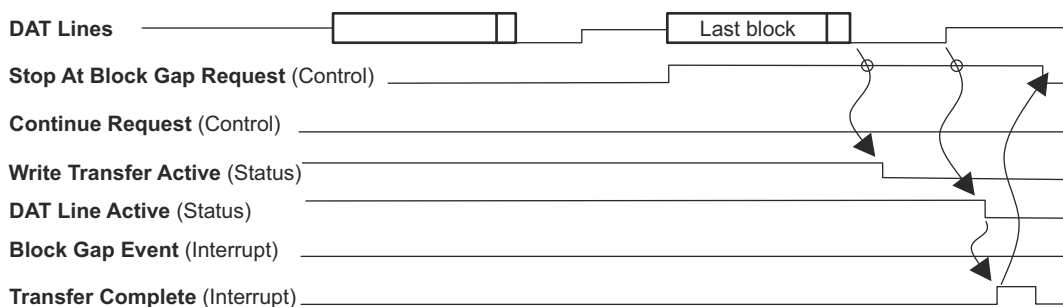

**Figure 12-333. Wait Write Transfer by Stop At Block Gap Request**

The Host Controller can accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit when matches all following conditions:

- (1) It is at the block gap.
- (2) No valid write data remains in the Host Controller.

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

- (1) Clear the MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit and generate the Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT bit).
- (2) After the busy signal is released, clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generate the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).
- (3) After accepting the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit), clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

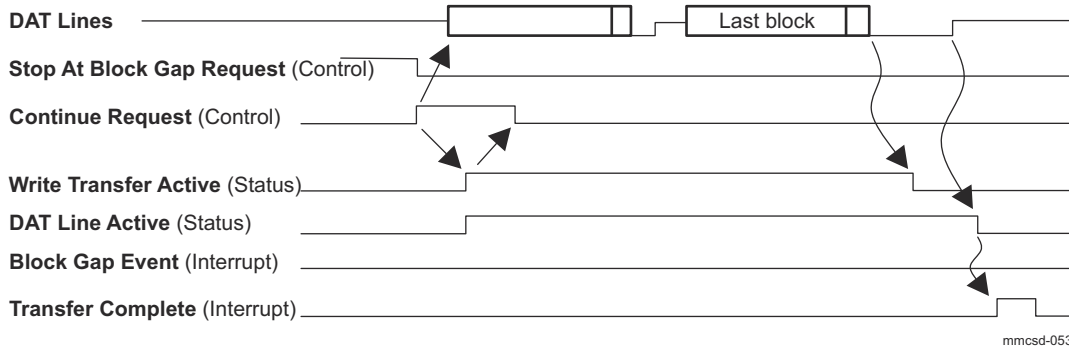

mmcsd-052

**Figure 12-334. Stop At Block Gap Request is Not Accepted at the Last Block of the Write Transfer**

If the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit is set to 1 during the last block transfer, the Host Controller shall not accept the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit and terminates the transaction normally. The Block Gap Event Interrupt (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVENT) is not generated. When the Transfer

Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE) is generated, and if the MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVEN bit is not set to 1, the driver shall clear the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit.

**Figure 12-335. Continue Write Transfer by Continue Request**

To restart a stopped data transfer, set the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit to 1 (the MMCSD0\_BLOCK\_GAP\_CONTROL[0] STOP\_AT\_BLK\_GAP bit shall be set to 0).

After accepting the MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit:

(1) Set the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit.

(2) The MMCSD0\_BLOCK\_GAP\_CONTROL[1] CONTINUE bit is automatically cleared by (1).

The end of transfer is specified by data length.

(1) Clear the MMCSD0\_PRESENTSTATE[8] WR\_XFER\_ACTIVE bit, and do not generate the (MMCSD0\_NORMAL\_INTR\_STS[2] BLK\_GAP\_EVEN).

(2) After the busy signal is released, clear the MMCSD0\_PRESENTSTATE[2] DATA\_LINE\_ACTIVE bit and generates the Transfer Complete Interrupt (MMCSD0\_NORMAL\_INTR\_STS[1] XFER\_COMPLETE bit).

### 12.3.6.5.2 Driver Flow Sequence

#### Note

This section is applicable for MMCSD0, MMCSD1 and MMCSD2 but MMCSD0 registers are used in the content.

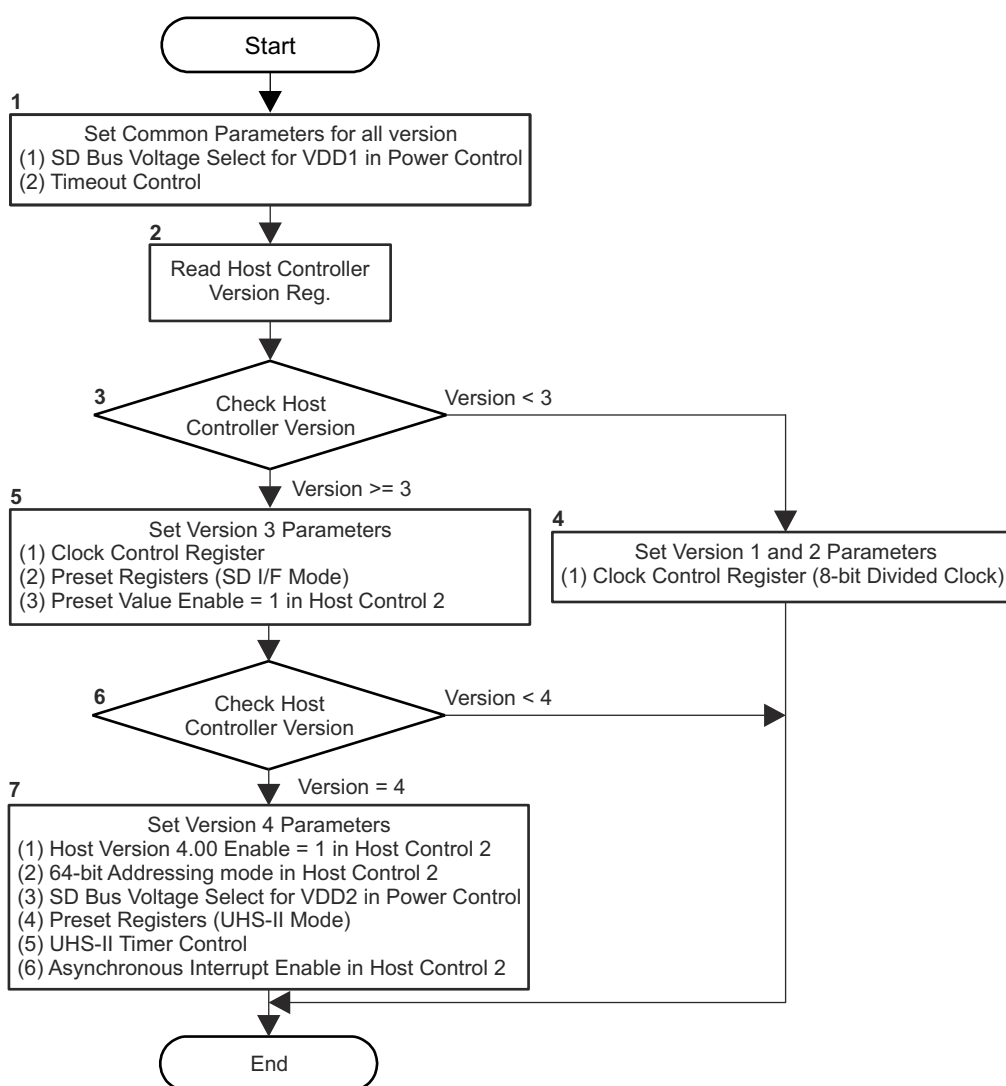

#### Note

UHSII is not supported. For more information, see [Section 12.3.6.1.2, Not Supported Features](#).

#### 12.3.6.5.2.1 Host Controller Setup and Card Detection

##### 12.3.6.5.2.1.1 Host Controller Setup Sequence

Figure 12-336 and Table 12-387 show a Host Controller setup sequence.

mmcsd-054

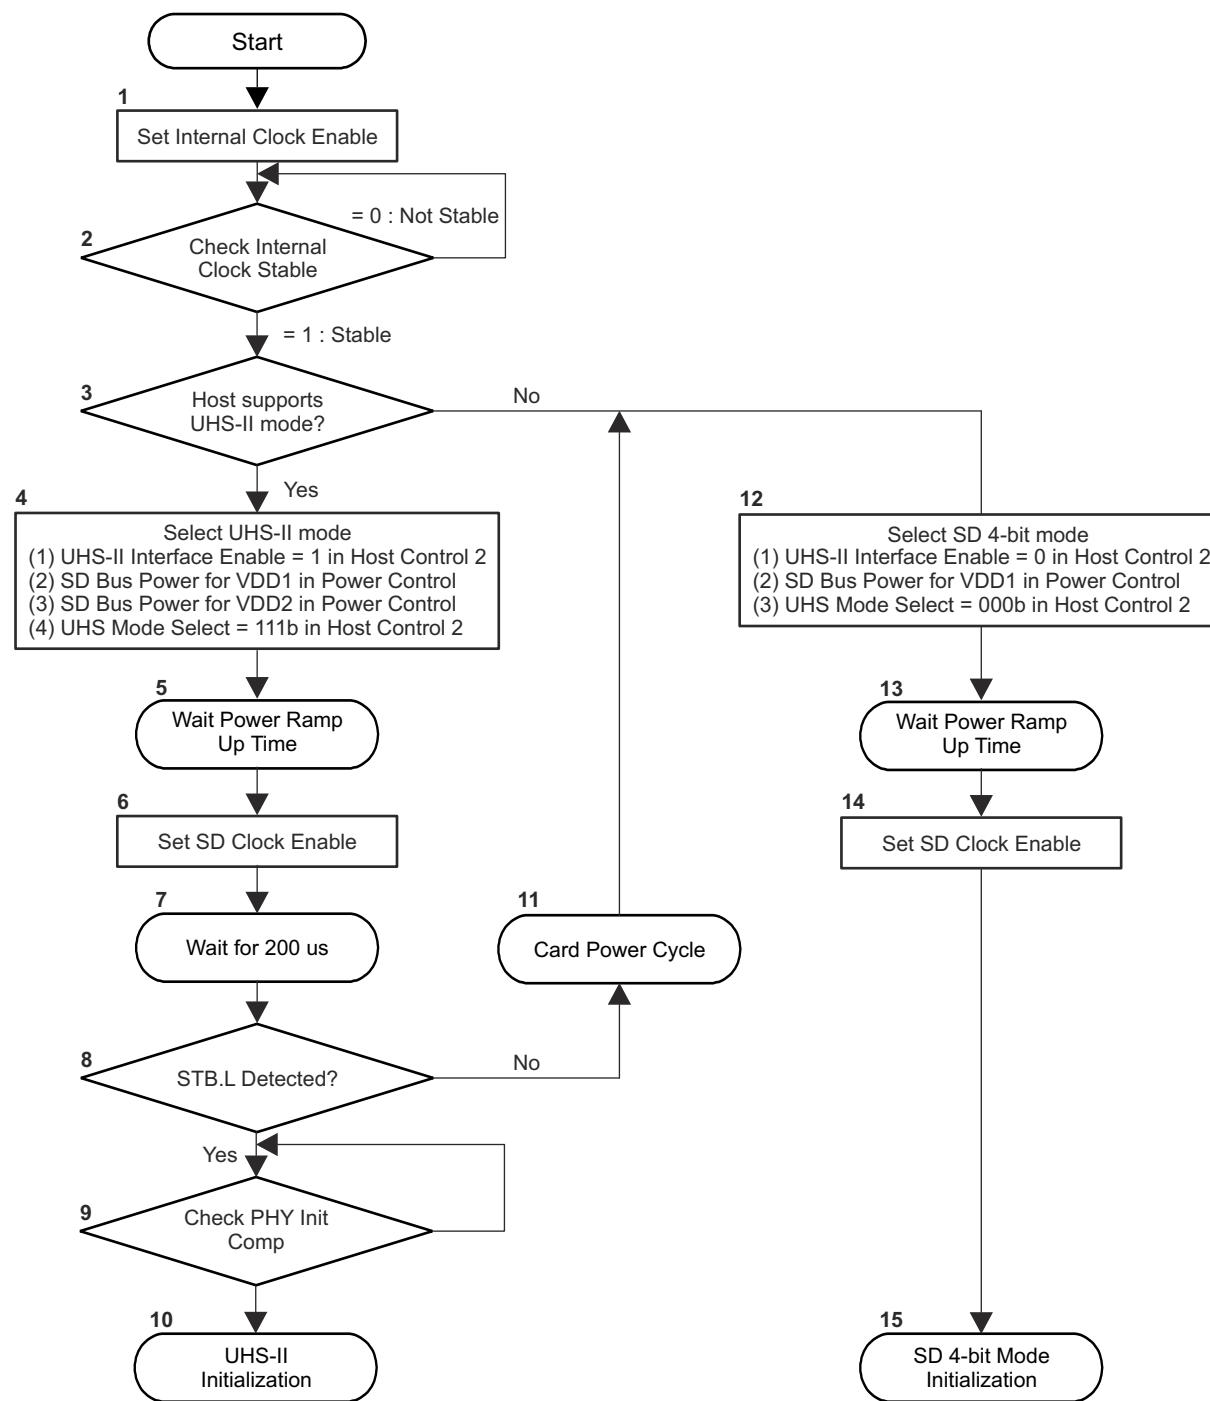

**Figure 12-336. Host Controller Setup Sequence**

**Table 12-387. Host Controller Setup Sequence**

Step	Description
1	Set parameters for all Host Controller version. Set the MMCSD0_POWER_CONTROL[3-1] SD_BUS_VOLTAGE and MMCSD0_TIMEOUT_CONTROL[3-0] COUNTER_VALUE bit fields.
2	Read the MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM bit field.
3	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is less than version 3, go to step (4), if it is version 3 or later go to step (5).
4	Set the MMCSD0_CLOCK_CONTROL register using 8-bit Divided Clock mode.
5	Set Version 3 parameters. The MMCSD0_CLOCK_CONTROL register is sets in 10-bit Divided Clock Mode or Programmable Clock Mode. If Clock Multiplier in the MMCSD0_CAPABILITIES register is not zero, Programmable Clock Mode should be used. If Preset Value is used, set Preset Values of SD I/F Modes in the Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set the MMCSD0_HOST_CONTROL2[15] PRESET_VALUE_ENA bit to 1.
6	If Specification Version number (MMCSD0_HOST_CONTROLLER_VER[7-0] SPEC_VER_NUM) is version 4, go to step (7), if it is less than version 4, exits.
7	Set Version 4 parameters. Set the MMCSD0_HOST_CONTROL2[12] HOST_VER40_ENA bit to 1. If the MMCSD0_CAPABILITIES[27] ADDR_64BIT_SUPPORT_V4 bit is set to 1, set the MMCSD0_HOST_CONTROL2[13] BIT64_ADDRESSING bit to 1. If UHS-II Support is set to 1 and 1.8 V VDD2 Support is set to 1 in the MMCSD0_CAPABILITIES register, set SD Bus Voltage Select for VDD2 to 1.8 V mode in the MMCSD0_POWER_CONTROL register, set preset value for UHS-II Mode to Preset Value register (MMCSD0_PRESET_VALUE0 - MMCSD0_PRESET_VALUE10) and set Timeout Counter Value for CMD_RES and Timeout Counter Value for Deadlock in the MMCSD0_UHS2_TIMER_CONTROL register based on Timeout Clock Frequency and Timeout Clock Unit in the MMCSD0_CAPABILITIES register. If Asynchronous Interrupt Support in the MMCSD0_CAPABILITIES register is set to 1, set Asynchronous Interrupt Enable to 1 in the MMCSD0_HOST_CONTROL2 register.

#### 12.3.6.5.2.1.2 Card Interface Detection Sequence

This procedure is invoked by the Card Insertion interrupt. [Figure 12-337](#) and [Table 12-388](#) show a card interface detection sequence.

mmcsd-055

**Figure 12-337. Card Interface Detection Sequence**
**Table 12-388. Card Interface Detection Sequence**

Step	Description
1	Set Internal Clock Enable to 1 in the MMCSDD0_CLOCK_CONTROL register.
2	Wait until Internal Clock Stable is set to 1 in the MMCSDD0_CLOCK_CONTROL register.
3	If Host Supports UHS-II, go to step (4) else go to step (12).
4	Try to initialize a card to UHS-II mode. Set UHS-II Interface Enable to 1 in the MMCSDD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 and SD Bus Power for VDD2 to 1 in the MMCSDD0_POWER_CONTROL register, and set UHS Mode Select to 111b in the MMCSDD0_HOST_CONTROL2 register.

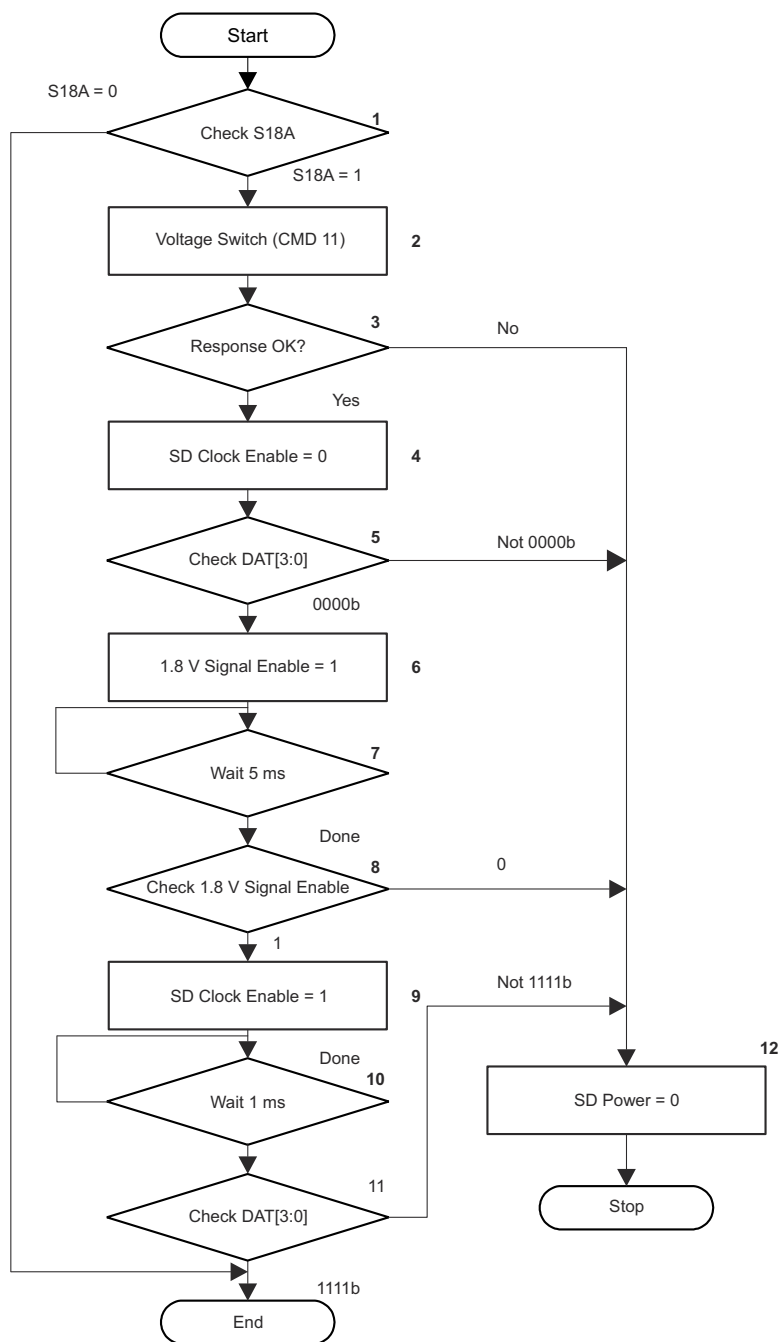

**Table 12-388. Card Interface Detection Sequence (continued)**

Step	Description
5	Wait power ramp up time. It is dependent on a Host System.
6	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
7	Wait 200 $\mu$ s to check a card supports UHS-II mode.
8	Check STB.L Detection in the MMCSD0_PRESENTSTATE register. If UHS-II IF is detected, go to step (9). If UHS-II IF is not detected, go to step (11).
9	Wait until Lane Synchronization in the MMCSD0_PRESENTSTATE register is set to 1 (PHY Initialization is completed).
10	Perform UHS-II initialization.
11	Perform card power cycle.
12	Try to initialize a card to SD 4-bit mode. Set UHS-II Interface Enable to 0 in the MMCSD0_HOST_CONTROL2 register, set SD Bus Power for VDD1 to 1 in the MMCSD0_POWER_CONTROL register, and set UHS Mode Select to 000b in the MMCSD0_HOST_CONTROL2 register.
13	Wait power ramp up time. It is dependent on a Host System.
14	Set SD Clock Enable to 1 in the MMCSD0_CLOCK_CONTROL register.
15	Perform SD 4-bit mode initialization. Refer to <a href="#">Section 12.3.6.5.1.6</a> , <i>Card Initialization and Identification (for SD I/F)</i> .

### 12.3.6.5.2.2 Boot Operation

The boot operation sequence is shown in [Figure 12-338](#).

mmcsd-056

**Figure 12-338. Boot Operation Sequence**

#### 12.3.6.5.2.2.1 Normal Boot Operation: (For Legacy eMMC 5.0)

The Host driver writes the boot timeout value into MMCSD0\_BOOT\_TIMEOUT\_CONTROL register as per the eMMC4.3+ spec.

When the Host driver sets the "BOOT\_ENABLE" to 1 in MMCSD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit to "1" in MMCSD0\_TRANSFER\_MODE register, the Host controller drives the CMD line to "0" for boot operation.

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver

(MMCSD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK). If the Host controller doesn't receive the boot acknowledgement from the device within the timeout value, the Host controller will assert the data timeout error interrupt (MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

After servicing the boot acknowledge interrupt or data timeout error interrupt, the driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The Host controller terminates the boot operation when the programmed number of blocks is transferred to the System. The Driver can write "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can also be terminated in between the boot transfer (the Driver can set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, the Host controller asserts soft reset for CMD line and DATA line internally once the driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE), to reset all the state machines to idle state.

There is no need to perform error recovery sequence in case data timeout interrupt occurs during boot operation (ignore sending abort command, soft reset and just clear the timeout interrupt and proceed with the boot flow).

If the device sends wrong acknowledgement to the Host, the Host controller will assert Data CRC Error interrupt (MMCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC) on the Driver. In this case, the Host driver has to stop the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller will assert Data End Bit Error interrupt (MMCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver.

The Host driver stops the boot mode operation by setting "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

#### 12.3.6.5.2.2.2 Alternate Boot Operation (For Legacy eMMC 5.0):

The Host driver writes the boot timeout value as per the eMMC4.3+ spec into MMCSD0\_BOOT\_TIMEOUT\_CONTROL register.

If the "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" is set to 1 in MMCSD0\_BLOCK\_GAP\_CONTROL register and "DATA\_XFER\_DIR" bit is set to 1 in MMCSD0\_TRANSFER\_MODE register, the host controller drives the CMD0 (0xFFFFFFFF) on the CMD line.

The system shall wait for command complete interrupt before "RCV\_BOOT\_ACK" interrupt (MMCSD0\_NORMAL\_INTR\_STS[13] RCV\_BOOT\_ACK).

If the Host controller is configured to wait for boot acknowledgement from the eMMC4.3+ device, the controller receives the boot acknowledgement and asserts the "RCV\_BOOT\_ACK" interrupt to the driver.

The eMMC4.3+ device starts sending the boot data on the data line and Host controller sends the same to system whenever a block of data is received from device. The System needs to send CMD0 to inform the device about the boot operation complete. The system shall program MMCSD0\_COMMAND register with argument "00000000h" for the CMD0 and waits for command complete.

The Host controller terminates the boot operation when the programmed number of blocks are transferred to the System and the Driver shall send CMD0 to eMMC card and then program "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register.

The boot operation can be terminated at any time (the Driver can send CMD0 and set the "BOOT\_ENABLE" as "0" anytime to disable the boot operation). After the boot termination, all state machines in the Host controller need to move to IDLE state. The Host controller asserts the soft reset for CMD and data line internally when the

driver clears the BOOT\_COMPLETE interrupt (MMCSD0\_NORMAL\_INTR\_STS[14] BOOT\_COMPLETE) and all the state machine goes to the idle state.

If the Host controller doesn't receive the acknowledgement from the device within timeout value the Host controller will assert the data timeout error interrupt (MMCSD0\_ERROR\_INTR\_STS[4] DATA\_TIMEOUT).

The driver programs the MMCSD0\_BOOT\_TIMEOUT\_CONTROL register with boot data timeout value.

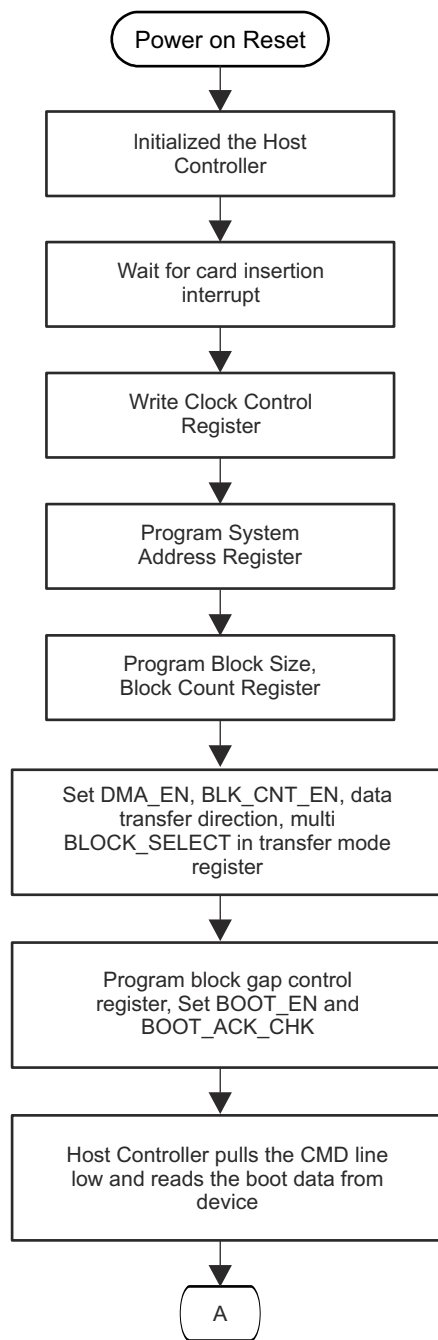

There is no need to perform error recovery sequence in case of data timeout interrupt as mentioned above. If the device sends wrong acknowledgement to the Host, then Host controller will assert Data CRC Error interrupt to the Driver (MMCSD0\_ERROR\_INTR\_STS[5] DATA\_CRC). The Host driver has to stop the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

If the device sends end bit as "0" in acknowledgement to the Host, the Host controller asserts Data End Bit Error interrupt (MMCSD0\_ERROR\_INTR\_STS[6] DATA\_ENDBIT) on the Driver. The Host driver stops the boot mode operation by setting "ALT\_BOOT\_MODE" and "BOOT\_ENABLE" as "0" in MMCSD0\_BLOCK\_GAP\_CONTROL register and write soft reset for CMD and data line.

**Note:** Enable the MMCSD0\_BLOCK\_GAP\_CONTROL[7] BOOT\_ACK\_ENA bit during boot operation. If failed, the controller will not wait for boot acknowledge from the card and send out data CRC error when the card sends boot acknowledgement first and followed by boot data.

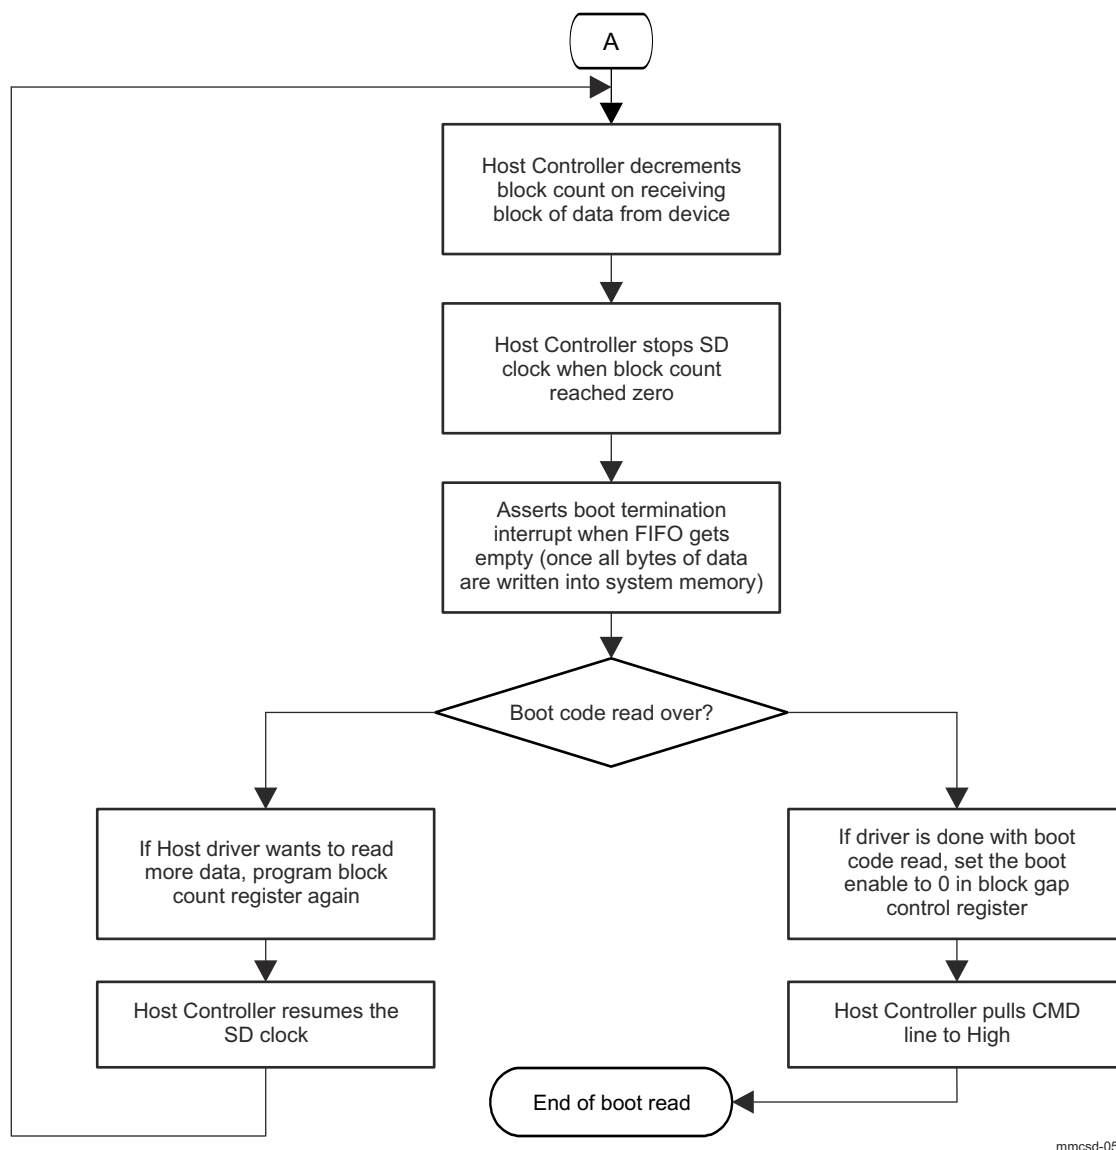

#### **12.3.6.5.2.2.3 Boot Code Chunk Read Operation (For Legacy eMMC 5.0):**

The following figure explains the boot code read done as chunks of data (the Driver can read the boot data as 2K, 4K, 1K and 8K etc. instead of 128K at a time)

mmcsd-057

**Figure 12-339. Boot Code Access Flow Diagram (1)**

**Figure 12-340. Boot Code Access Flow Diagram (2)**

#### 12.3.6.5.2.3 Retuning procedure (For Legacy Interface)

##### 12.3.6.5.2.3.1 Sampling Clock Tuning

The SD bus can be operating in high clock frequency mode and then the data window from the card on CMD and DAT[3:0] lines gets smaller. The position of the data window will vary depending on the card and host system implementation. Therefore, the Host Controller shall support a tuning circuit when SDR104 or SDR50.

The Host Controller shall support a tuning circuit when SDR104 or SDR50 (if Use Tuning for SDR50 is set to 1 in the MMCSDD0\_CAPABILITIES register) is supported by executing the tuning procedure and adjusting the sampling clock. Execute Tuning and Sampling Clock Select in the MMCSDD0\_HOST\_CONTROL2 register are used to control the tuning circuit.

##### 12.3.6.5.2.3.2 Tuning Modes

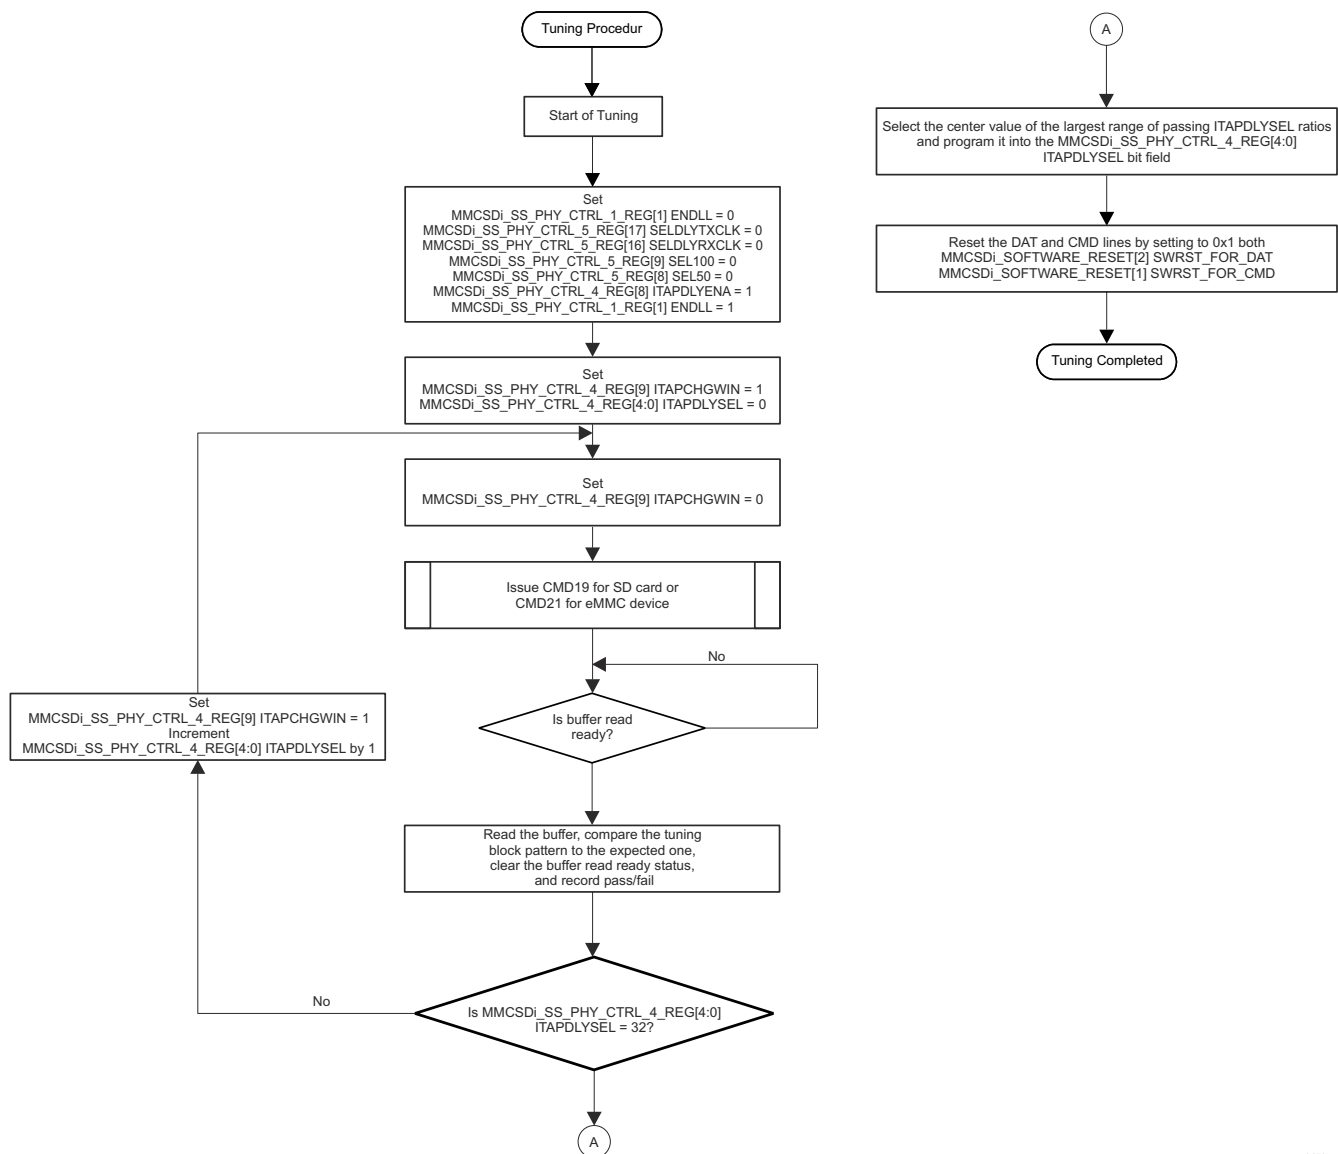

The re-tuning timing is specified by two methods: Re-Tuning Request generated by Host Controller and expiration of a re-tuning timer prepared by Host Driver.

(1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MB.

(2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled.

### 12.3.6.5.2.3.3 Re-Tuning Mode 2

The [Figure 12-341](#) defines sampling clock tuning procedure supported by Host Controller. In default, for lower frequency operation, fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using SDR104, sampling clock tuning is required. Start of sampling clock tuning is requested by setting Execute Tuning to 1 and Sampling Clock Select to 0.

**Figure 12-341. MMCSD Clock Tuning**

mmcsd-059sm

Host driver issue CMD19 repeatedly until the host controller resets Execute Tuning to 0. Host Controller resets Execute Tuning to 0 when tuning is completed or tuning is not completed within 40 times. Host Driver can abort this loop by 40 times CMD19 issue or 150 ms time-out.

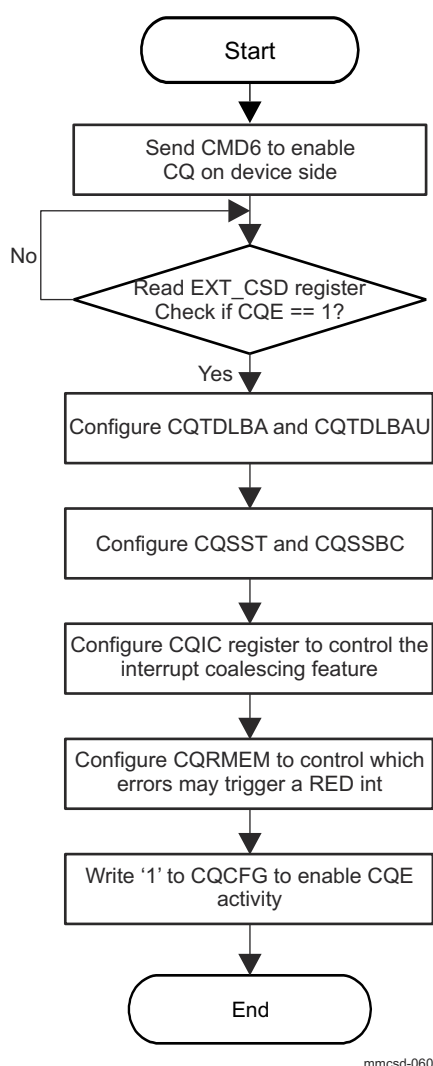

If tuning is completed successfully, Host Controller set Sampling Clock Select to 1 and this means the Host Controller start to use tuned sampling clock. If tuning is failed, Host Controller keeps Sampling Clock Select to 0. By writing Sampling Clock Select to 0, sampling clock is switched from tuned sampling clock to fixed sampling clock. Re-tuning time would be smaller than the first tuning time. CMD19 response errors are not indicated while tuning is performed.

The clock tuning tap delay values are selected using Variable sampling point detection. Fixed tap delay value is used for fixed tuning clock method.

#### 12.3.6.5.2.4 Command Queuing Driver Flow Sequence

##### 12.3.6.5.2.4.1 Command Queuing Initialization Sequence

Figure 12-342 and Table 12-389 show a Command Queuing initialization sequence.

**Figure 12-342. Command Queuing Initialization Sequence**

**Table 12-389. Command Queuing Initialization Sequence**

Step	Description
1	Initialize and enable Command Queueing in the device.

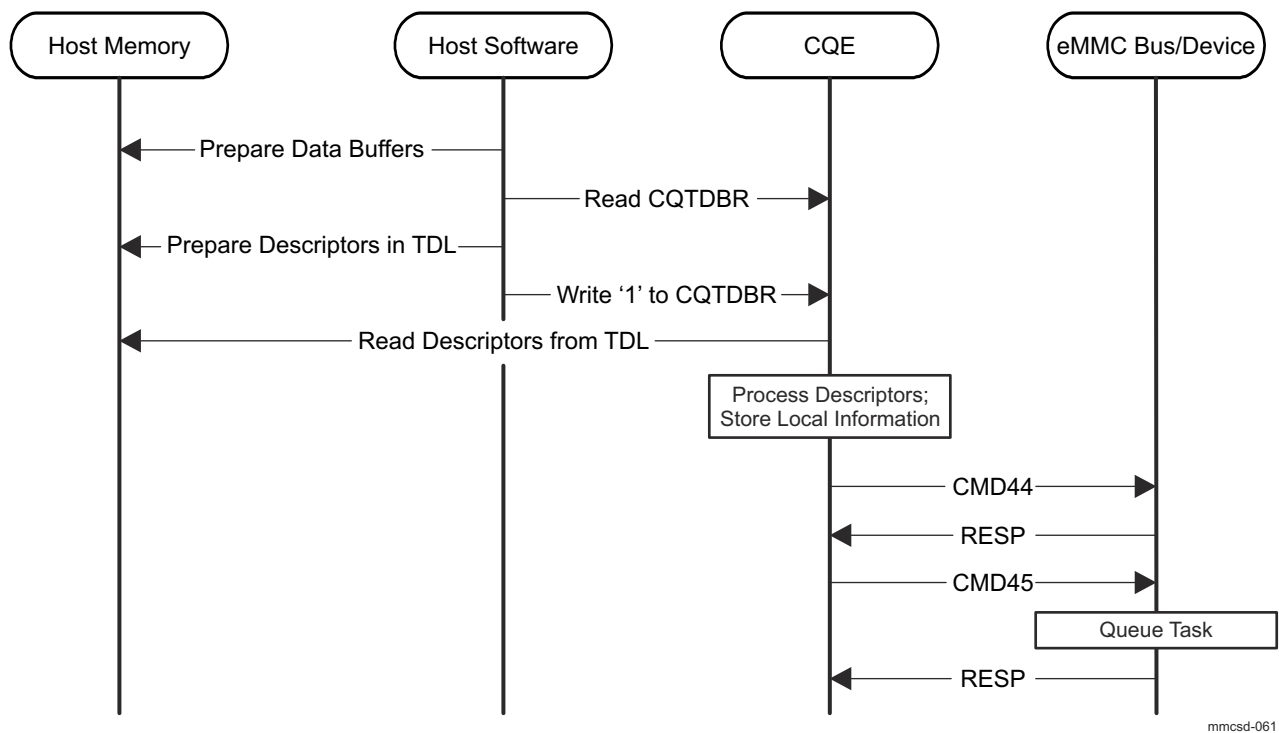

**Table 12-389. Command Queuing Initialization Sequence (continued)**

Step	Description
2	Configure Task Descriptor size in MMCSD0_CQ_CONFIG register.
3	Configure MMCSD0_CQ_TDL_BASE_ADDR and MMCSD0_CQ_TDL_BASE_ADDR_UPBITS registers to point to the memory location allocated to the TDL in host memory.
4	Configure CQSST and CQSSBC to control when SEND_QUEUE_STATUS commands are sent to the device by CQE.
5	Configure MMCSD0_CQ_INTR_COALESCING register to control the interrupt coalescing feature: enable/disable, set interrupt count and timer protection.
6	Configure MMCSD0_CQ_RESP_ERR_MASK register to control which errors may trigger a RED interrupt (if different from reset values).
7	Write '1' to MMCSD0_CQ_CONFIG register to enable CQE activity.

#### 12.3.6.5.2.4.2 Task Issuance Sequence

Figure 12-343 and Table 12-390 show a task issuance sequence.

mmcsd-061

**Figure 12-343. Task Issuance Sequence**
**Table 12-390. Task Issuance Sequence**

Step	Description
1	Find an empty transfer request slot by reading the MMCSD0_CQ_TASK_DOOR_BELL register. An empty transfer request slot has its respective bit cleared to '0' in the MMCSD0_CQ_TASK_DOOR_BELL register.

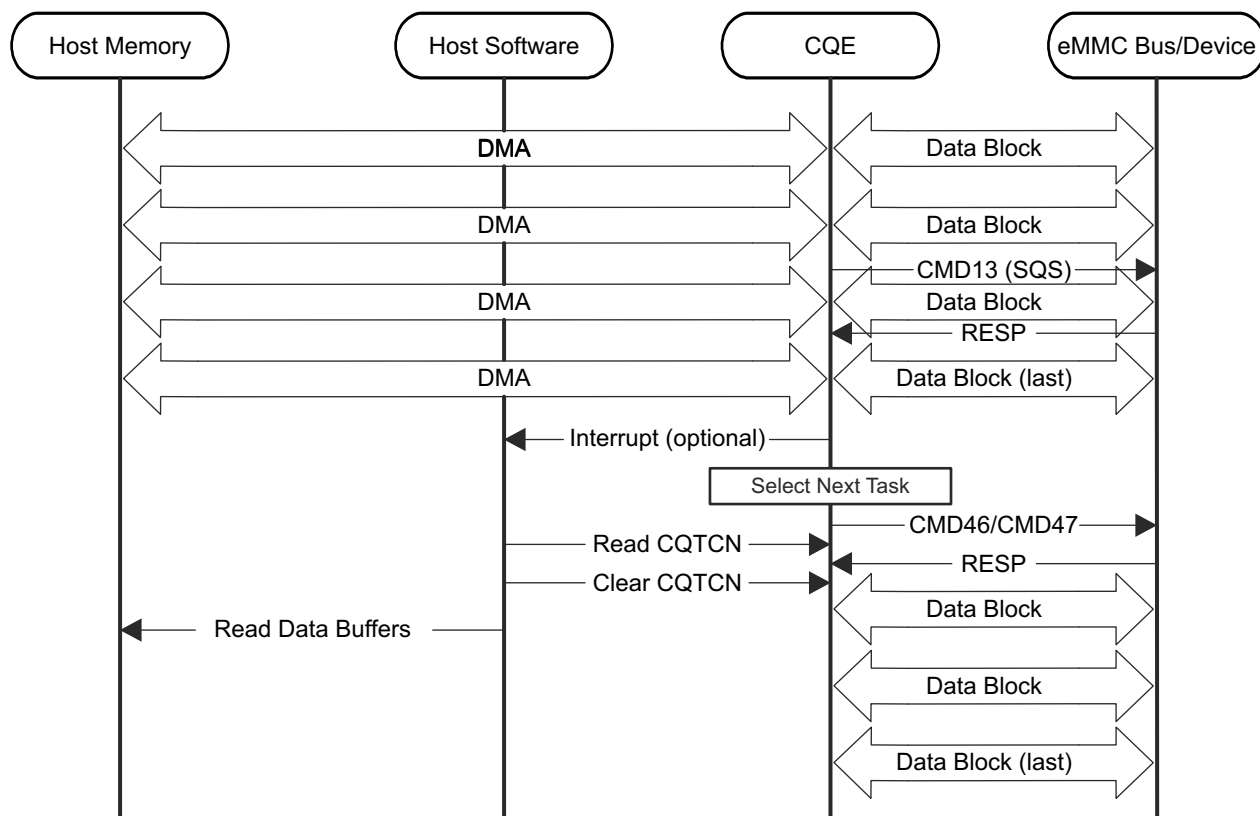

**Table 12-390. Task Issuance Sequence (continued)**

Step	Description
2	Build a Task Descriptor at the 1st entry of the empty slot. Task Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, as required for Task Descriptors.</li> <li>3. Int = 1, if an interrupt on completion is required. Otherwise, Int = 0.</li> <li>4. Act = b101, to indicate a Task Descriptor .</li> <li>5. Data Direction = 1 for read commands, and 0 for write commands.</li> <li>6. Priority = 1 for high priority, and 0 for simple requests.</li> <li>7. QBR = 1 if Queue Barrier functionality is required. 0 otherwise.</li> <li>8. Forced Programming, Context ID, Tag Request, Reliable Write, Block Count, and Block Address programmed according to application requirements.</li> </ul>
3	Build a Transfer Descriptor at the 2nd entry of the empty slot. Transfer Descriptor field values: <ul style="list-style-type: none"> <li>1. Valid = 1, to indicate the descriptor is effective.</li> <li>2. End = 1, if a TRAN descriptor is used, to indicate the task only has one data buffer. End = 0 if LINK descriptor is used.</li> <li>3. Int = 0. Ignore in Command queueing.</li> <li>4. Act = b100, for TRAN descriptors, pointing directly to the task's single data buffer. Act = 401 b110, for LINK descriptors, point to a scatter/gather list (indirect).</li> <li>5. Address and Length programmed according to the data buffer supplied by the application.</li> </ul>
4	If more than one transfer is requested, repeat step 1-3 for all needed transfers.
5	Set MMCSD0_CQ_TASK_DOOR_BELL register to indicate to the CQE that one or more transfer requests are ready to be sent to the attached device. Host software shall only write a '1' to the bit position that corresponds to new tasks; all other bit positions within MMCSD0_CQ_TASK_DOOR_BELL register should be written with a '0', which indicates no change to their current values.

#### 12.3.6.5.2.4.3 Task Execution and Completion Sequence

The CQE is responsible for task execution, communication with the device and moving the data to the buffers in the host memory.

Figure 12-344 and Table 12-391 show a task execution and completion sequence.

mmcsd-062

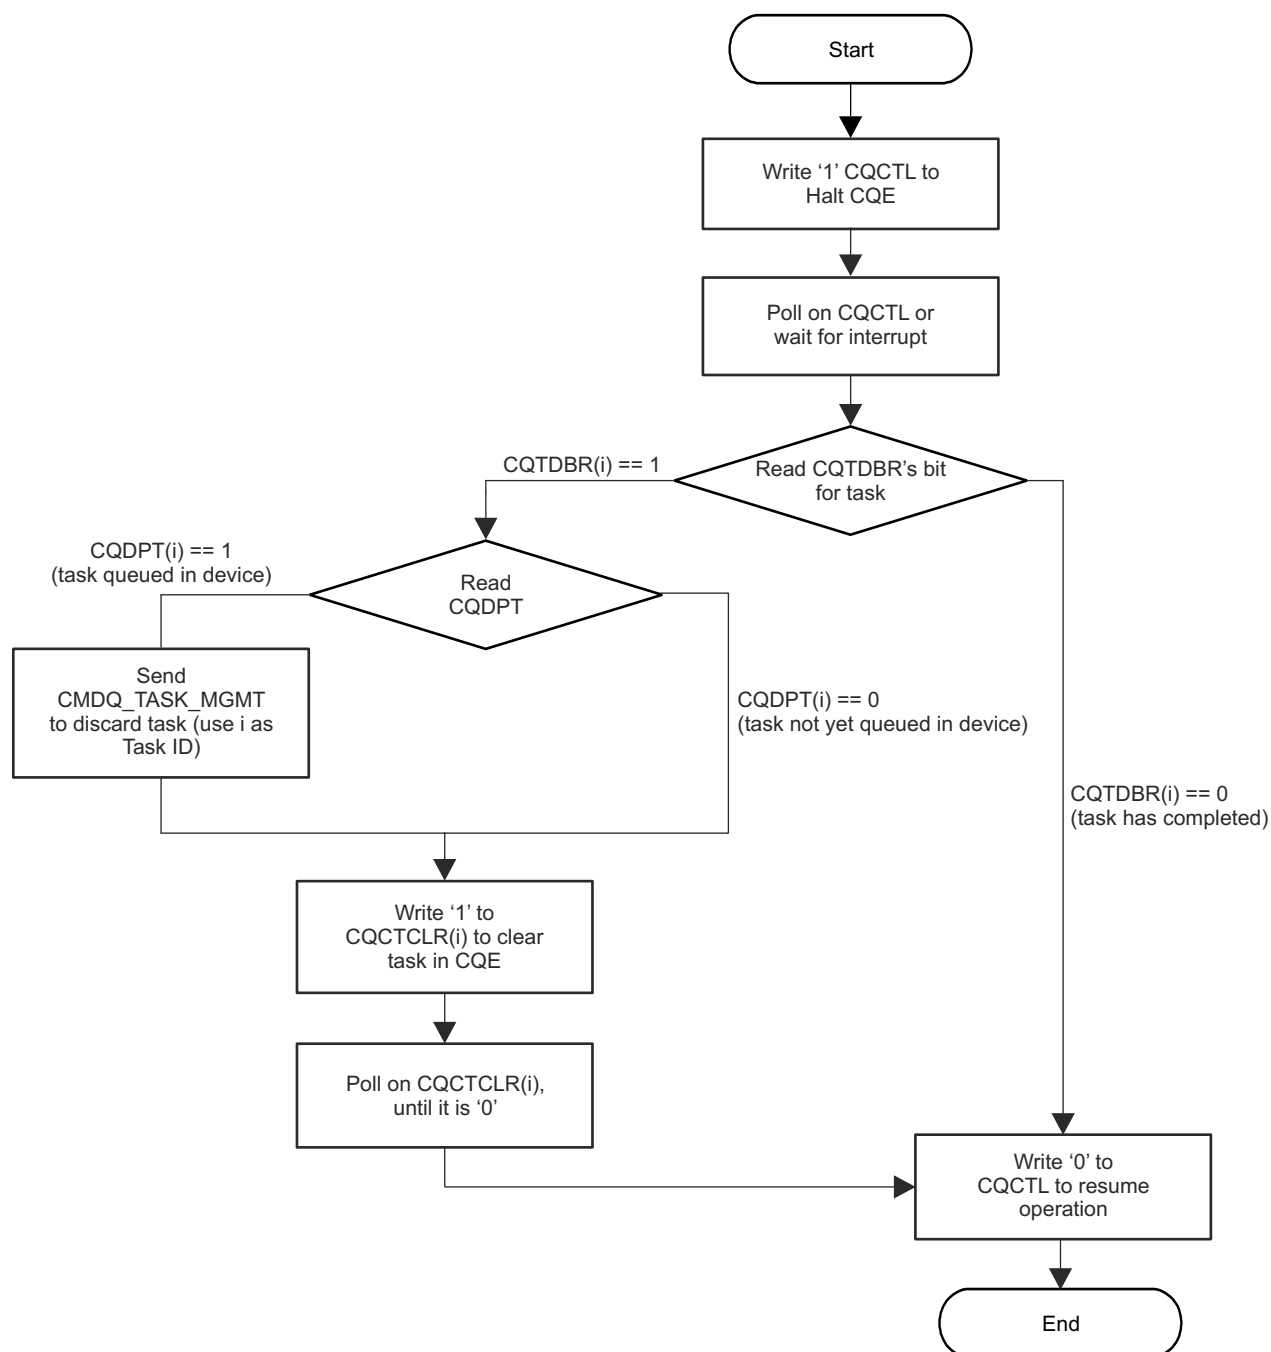

**Figure 12-344. Task Execution and Completion Sequence**

**Table 12-391. Task Execution and Completion Sequence**

Step	Description
1	Once the tasks are queued on the device side CQE sends CMD13 to determine the queue status. The queue status lets the CQE know which tasks are ready for execution.
2	The response to CMD13 may indicate no task is ready in which case the CQE is required to send CMD13 again at a later time as controlled CQSST register.
3	If a task is ready for execution then the host sends EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) to the device with the task id ordering it to execute a task.
4	When the task execution is completed, an interrupt may be generated, if requested, or as determined by Interrupt Coalescing mechanism.
5	The host software reads MMCSD0_CQ_TASK_COMP_NOTIF register to determine which task(s) has(have) been completed. Each bit set in MMCSD0_CQ_TASK_COMP_NOTIF register represents by index which task has completed but hasn't yet been served by software.
6	For every task completed clear the appropriate MMCSD0_CQ_TASK_COMP_NOTIF register bit.
7	Repeat steps 1-6 for the pending tasks.

#### 12.3.6.5.2.4.4 Task Discard and Clear Sequence

Figure 12-345 and Table 12-392 show a task discard and clear sequence.

mmscd-063

**Figure 12-345. Task Discard and Clear Sequence**
**Table 12-392. Task Discard and Clear Sequence**

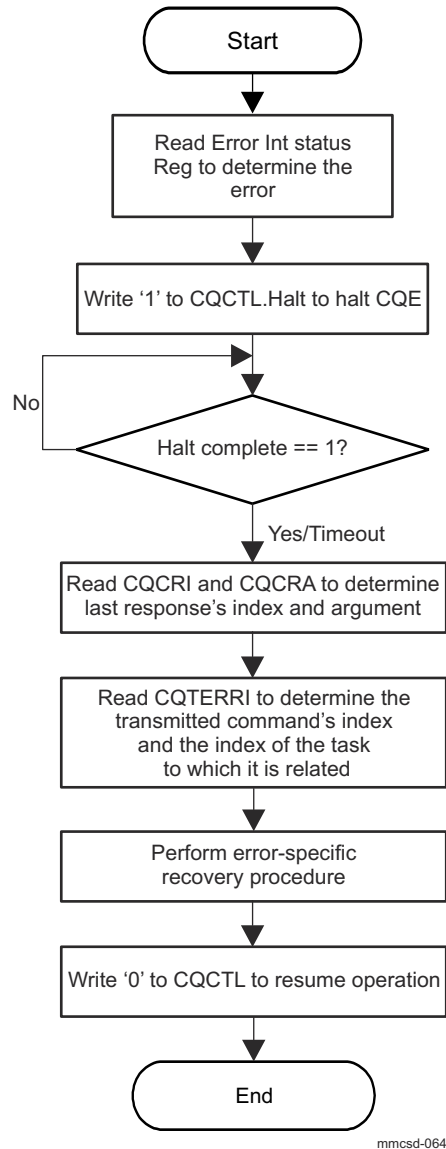

Step	Description
1	While CQE is enabled write '1' to MMCS0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
2	Poll on MMCS0_CQ_INTR_STS[0] HALT_COMPLETE bit.
3	Read MMCS0_CQ_TASK_DOOR_BELL register to determine if the task to be discarded is set to 1.
4	Read MMCS0_CQ_DEV_PENDING_TASKS register to check if the task is queued in the device.
5	Send CMDQ_TASK_MGMT(CMD48) to discard task using the task id as the argument.
6	Write '1' to CQCTCLR[i] to clear task in CQE.

**Table 12-392. Task Discard and Clear Sequence (continued)**

Step	Description
7	Poll on CQCTCLR[i] until it is '0'.
8	Write '0' to MMCSD0_CQ_CONTROL register to resume CQE.

#### 12.3.6.5.2.4.5 Error Detect and Recovery when CQ is enabled

Figure 12-346 and Table 12-393 show an error detect and recovery sequence.

**Figure 12-346. Error Detect and Recovery Sequence**
**Table 12-393. Error Detect and Recovery Sequence**

Step	Description
1	Read eMMC host controller MMCSD0_ERROR_INTR_STS register and determine error is related to CQE.
2	Write '1' to MMCSD0_CQ_CONTROL[0] HALT_BIT bit to halt CQE.
3	Wait for MMCSD0_CQ_CONTROL[0] HALT_BIT bit to read '1'. In some error cases, this may not happen, so software should proceed to the next step after a sufficient time-out.

**Table 12-393. Error Detect and Recovery Sequence (continued)**

Step	Description
4	Read MMCSD0_CQ_CMD_RESP_INDEX and MMCSD0_CQ_CMD_RESP_ARG registers to determine last response's index and argument.
5	Read MMCSD0_CQ_TASK_ERR_INFO register to determine the transmitted command's index and the index of the task to which it is related.
6	Perform error-specific recovery procedure.
7	Write '0' to MMCSD0_CQ_CONTROL register to resume operation.

### 12.3.7 Universal Flash Storage (UFS) Interface

This section describes the Universal Flash Storage (UFS) interface in the device.

#### 12.3.7.1 UFS Overview

The Universal Flash Storage (UFS) interface is a standard-based serial interface engine.

There is one UFS module inside the device - UFS0. The UFS module includes one UFS 2.1 host controller (HC) with an integrated M-PHY.

The UFS module complies with the standards as listed in [Table 12-394](#).

**Table 12-394. UFS Standards**

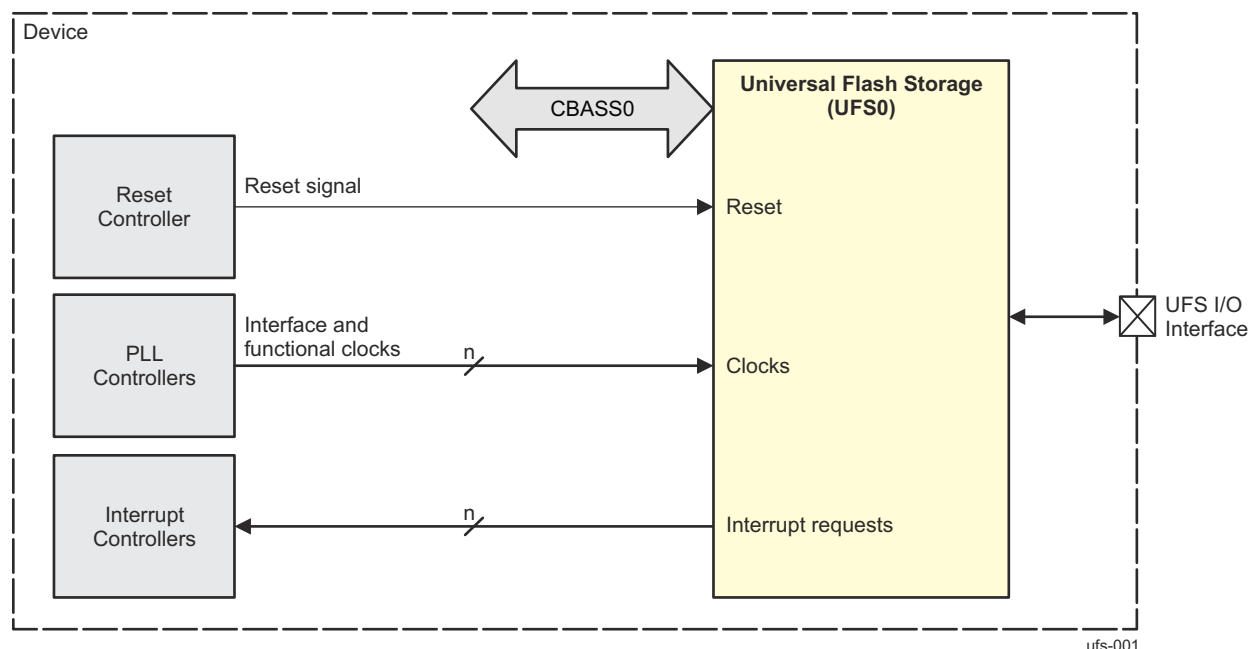

Document	Version	Description
JESD220-1A	v1.1	Universal Flash Storage (UFS) Unified Memory Extension
JESD220-2	v1.0	Universal Flash Storage (UFS) Card Extension
JESD220C	v2.1, March 2016	Universal Flash Storage (UFS)
JESD223-1B	v1.1A	Universal Flash Storage Host Controller Interface (UFSHCI) Unified Memory Extension
JESD223C	v2.1, March 2016	Universal Flash Storage Host Controller Interface (UFSHCI)
JESD224	March 2013	Universal Flash Storage (UFS) Test
	November, 2001	Federal Information Processing Standards (FIPS) 197 Advanced Encryption Standard (AES)
	v3.1, 2014	MIPI® Alliance Specification for M-PHY
	v1.60, 2013	MIPI Alliance Specification for Unified Protocol (UniProSM)
	Revision 24, August 2010	Small Computer System Interface (SCSI) Block Commands - 3
	Revision 27, October 2010	SCSI Primary Commands - 4

[Table 12-395](#) shows the UFS allocation across device domains.

**Table 12-395. UFS Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
UFS0	-	-	✓

[Figure 12-347](#) shows the UFS module overview.

**Figure 12-347. UFS Module Overview**

#### 12.3.7.1.1 UFS Features

##### Key Features:

- Supports Universal Flash Storage Host (UFS2.1, JESD220C)
- Supports Universal Flash Storage Host Controller Interface (UFSHCI, JESD223C)
- Supports UFS interconnect - MIPI UniPro and MIPI M-PHY
- Supports Gear 1: 1.46 Gbps, 2-lanes
- Supports Gear 2: 2.91 Gbps, 2-lanes
- Supports Gear 3: 5.83 Gbps, 2-lanes
- Supports all UFS mandatory SCSI commands required by JEDEC specification
- Supports power-on reset (POR), hardware (HW) reset, EndPoint reset, Logical Unit reset, and Warm reset

##### Master Bus Interfaces:

- Supports one 64-bit master interface (CBA4.0 VBUSM) for data transfers
- Supports 48-bit address width on the master interface
- Include embedded DMA controller within the host controller
- Supports little-endian mode only

##### Configuration Bus Interfaces:

- Supports one 32-bit slave interface (CBA4.0 VBUSP) for configuration access
- Supports linear incrementing addressing mode
- Supports aligned accesses only

Supports ECC on internal RAM's

##### M-PHY Features:

- Supports reference clock of 19.2 MHz and 26 MHz

### 12.3.7.2 UFS Environment

This section describes the UFS external connections (environment).

Figure 12-348 shows the UFS I/O interface signals.

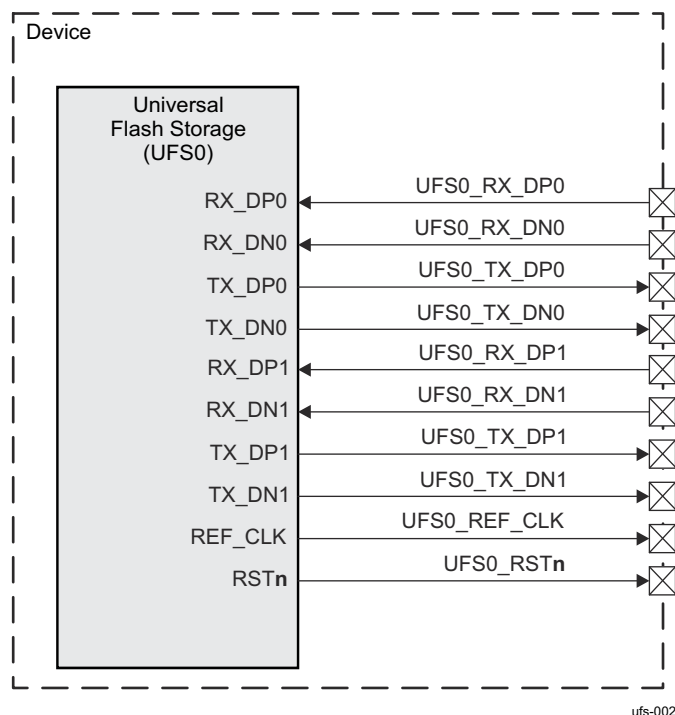

Figure 12-348. UFS I/O Interface Signals

Table 12-396 describes the UFS I/O signals.

Table 12-396. UFS I/O Signals

Module Pin	Device Level Signal	I/O <sup>(2)</sup>	Description	Module Pin Reset Value
<b>UFS0</b>				
RX_DP0	UFS0_RX_DP0	I	UFS Lane0 RX Data Positive	0x0
RX_DN0	UFS0_RX_DN0	I	UFS Lane0 RX Data Negative	0x0
TX_DP0	UFS0_TX_DP0	O	UFS Lane0 TX Data Positive	0x0
TX_DN0	UFS0_TX_DN0	O	UFS Lane0 TX Data Negative	0x0
RX_DP1	UFS0_RX_DP1	I	UFS Lane1 RX Data Positive	0x0
RX_DN1	UFS0_RX_DN1	I	UFS Lane1 RX Data Negative	0x0
TX_DP1	UFS0_TX_DP1	O	UFS Lane1 TX Data Positive	0x0
TX_DN1	UFS0_TX_DN1	O	UFS Lane1 TX Data Negative	0x0
REF_CLK	UFS0_REF_CLK	O	UFS Reference Clock Signal to Slave	0x0
RSTn	UFS0_RSTn <sup>(1)</sup>	O	UFS Reset Signal to Slave	0x0

(1) n - Active Low

(2) I = Input; O = Output

#### Note

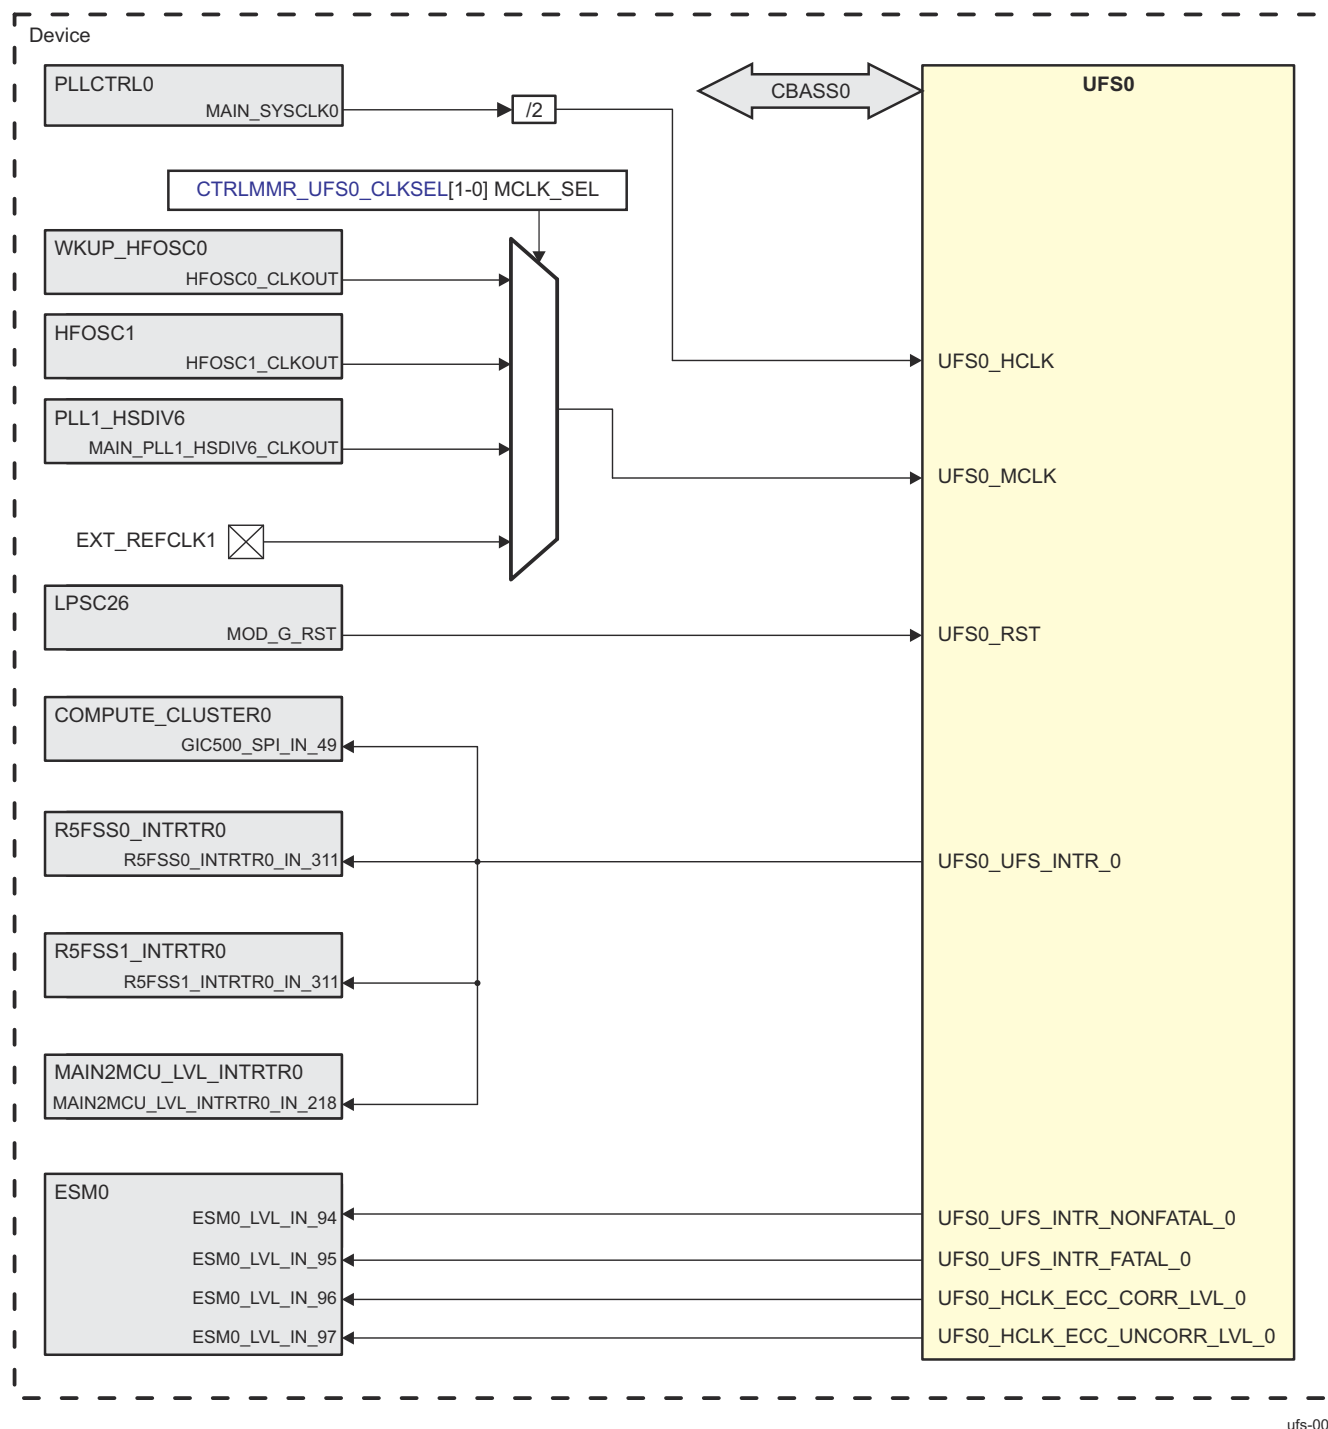

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

### 12.3.7.3 UFS Integration

This section describes the UFS integration in the device, including information about clocks, resets, and hardware requests.

#### 12.3.7.3.1 UFS Integration in MAIN Domain

There is one UFS module integrated in the device MAIN domain - UFS0. Figure 12-349 shows the integration of UFS0.

ufs-003

**Figure 12-349. UFS0 Integration**

Table 12-397 through Table 12-399 summarize the integration of UFS0 in the device MAIN domain.

**Table 12-397. UFS0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
UFS0	PSC0	PD0	LPSC26	CBASS0

**Table 12-398. UFS0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
UFS0	UFS0_HCLK	MAIN_SYSCLK0/2	PLLCTRL0	UFS0 Interface Clock
	UFS0_MCLK	HFOSC0_CLKOUT	WKUP_HFOSC0	UFS0 Reference Clock for the M-PHY (for more information about clock multiplexing, see CTRLMMR_UFS0_CLKSEL[1-0] MCLK_SEL bit field in
		HFOSC1_CLKOUT	HFOSC1	Control Module (CTRL_MMR).

### 12.3.7.4 UFS Functional Description

#### 12.3.7.4.1 UFS Block Diagrams

The UFS subsystem includes one UFS 2.1 host controller with an integrated M-PHY. The UFS host controller is a standard-based serial interface engine.

The UFS host controller is compliant with the *Universal Flash Storage (UFS) Specification* and *UFS Host Controller Interface (UFSHCI) Specification* (see [Table 12-394](#)).

Figure 12-350 shows the UFS subsystem block diagram.

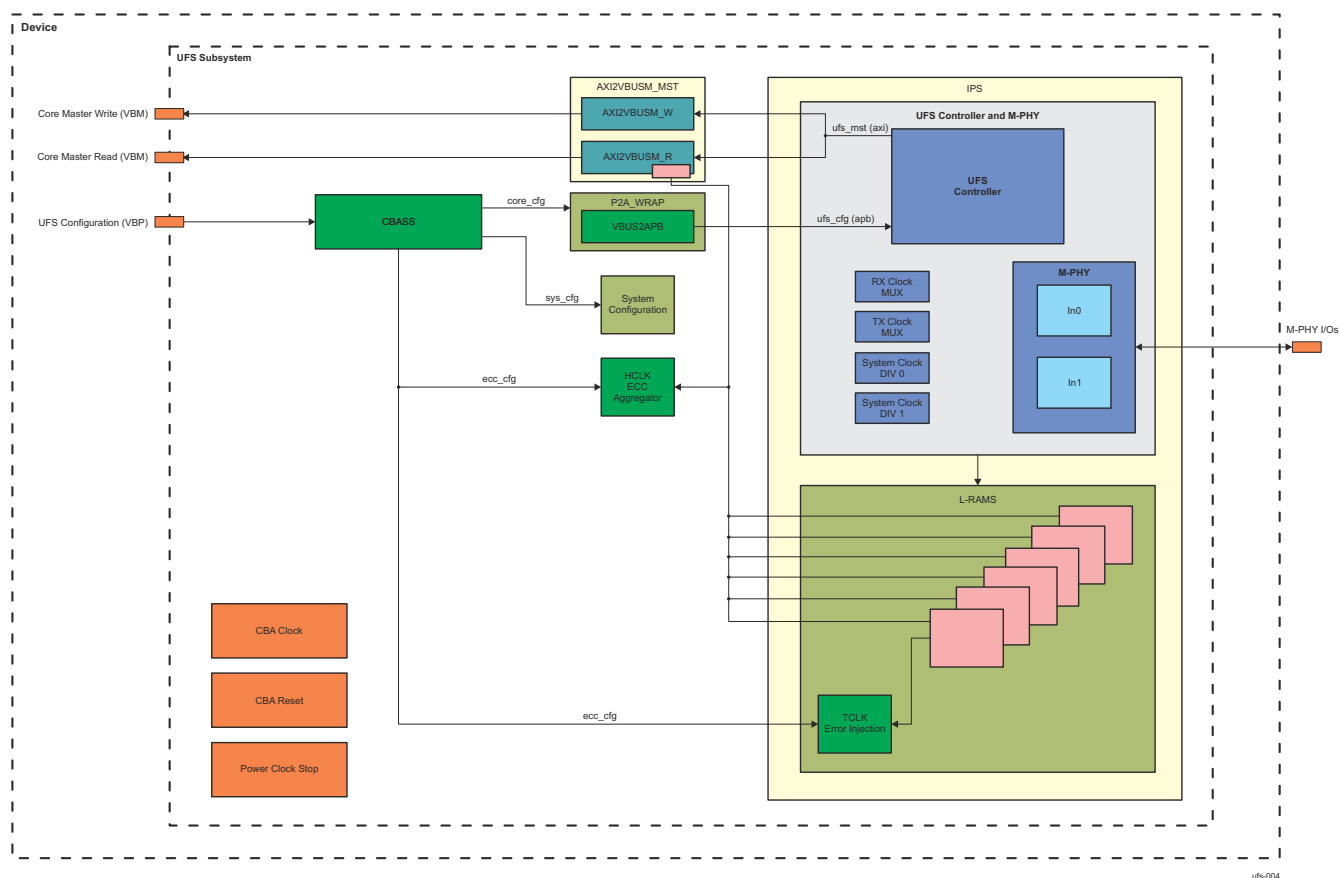

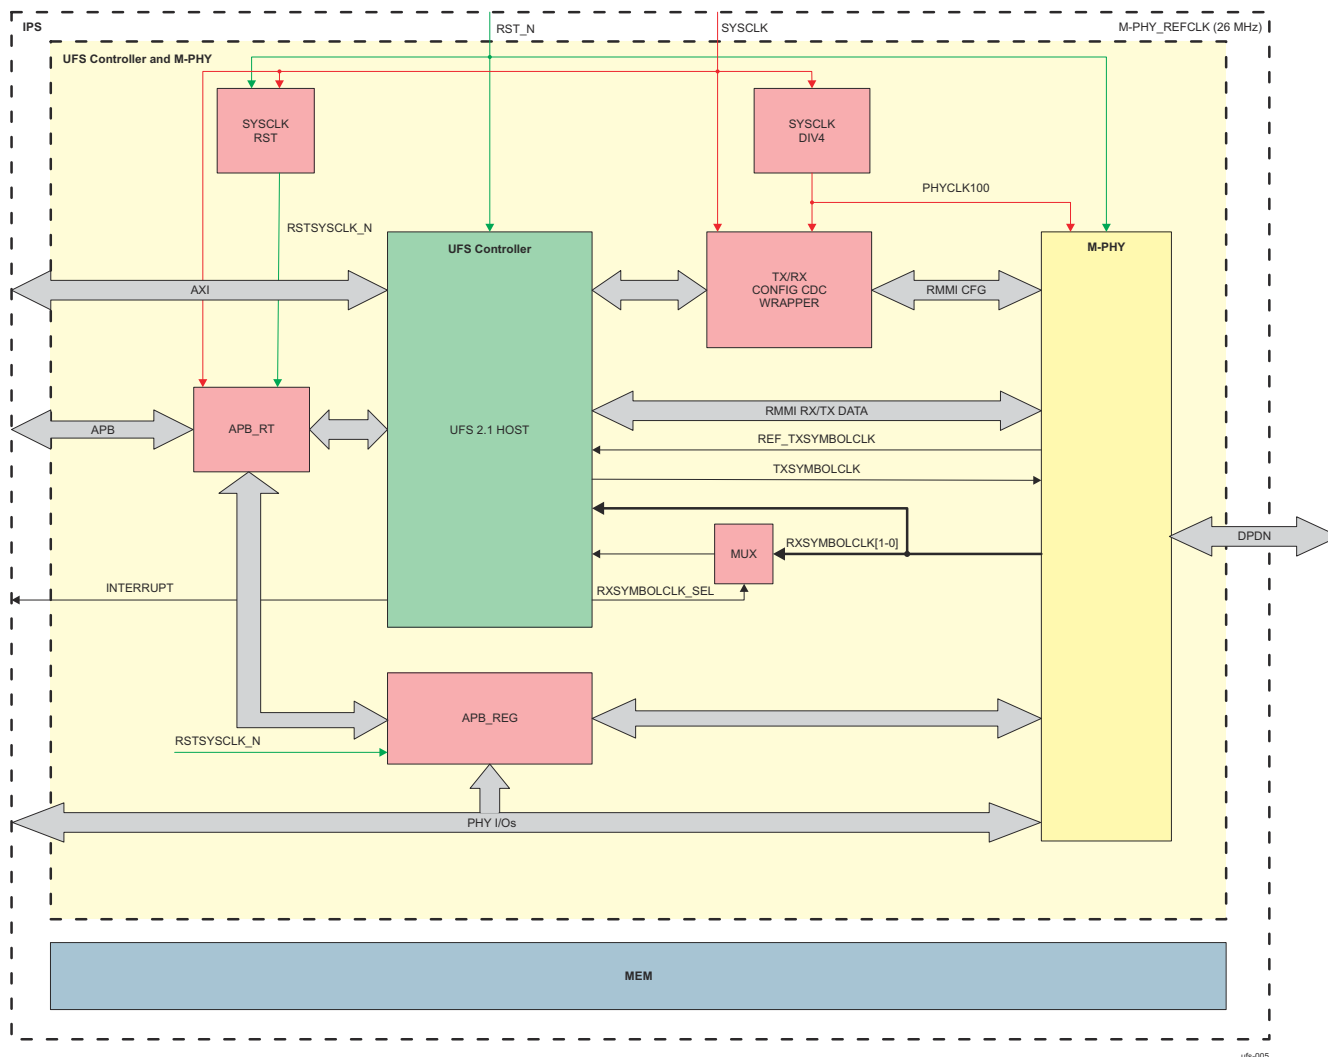

Figure 12-350. UFS Subsystem Block Diagram

Figure 12-351 presents an example of UFS Integrated Protocol Stack (IPS) subsystem.

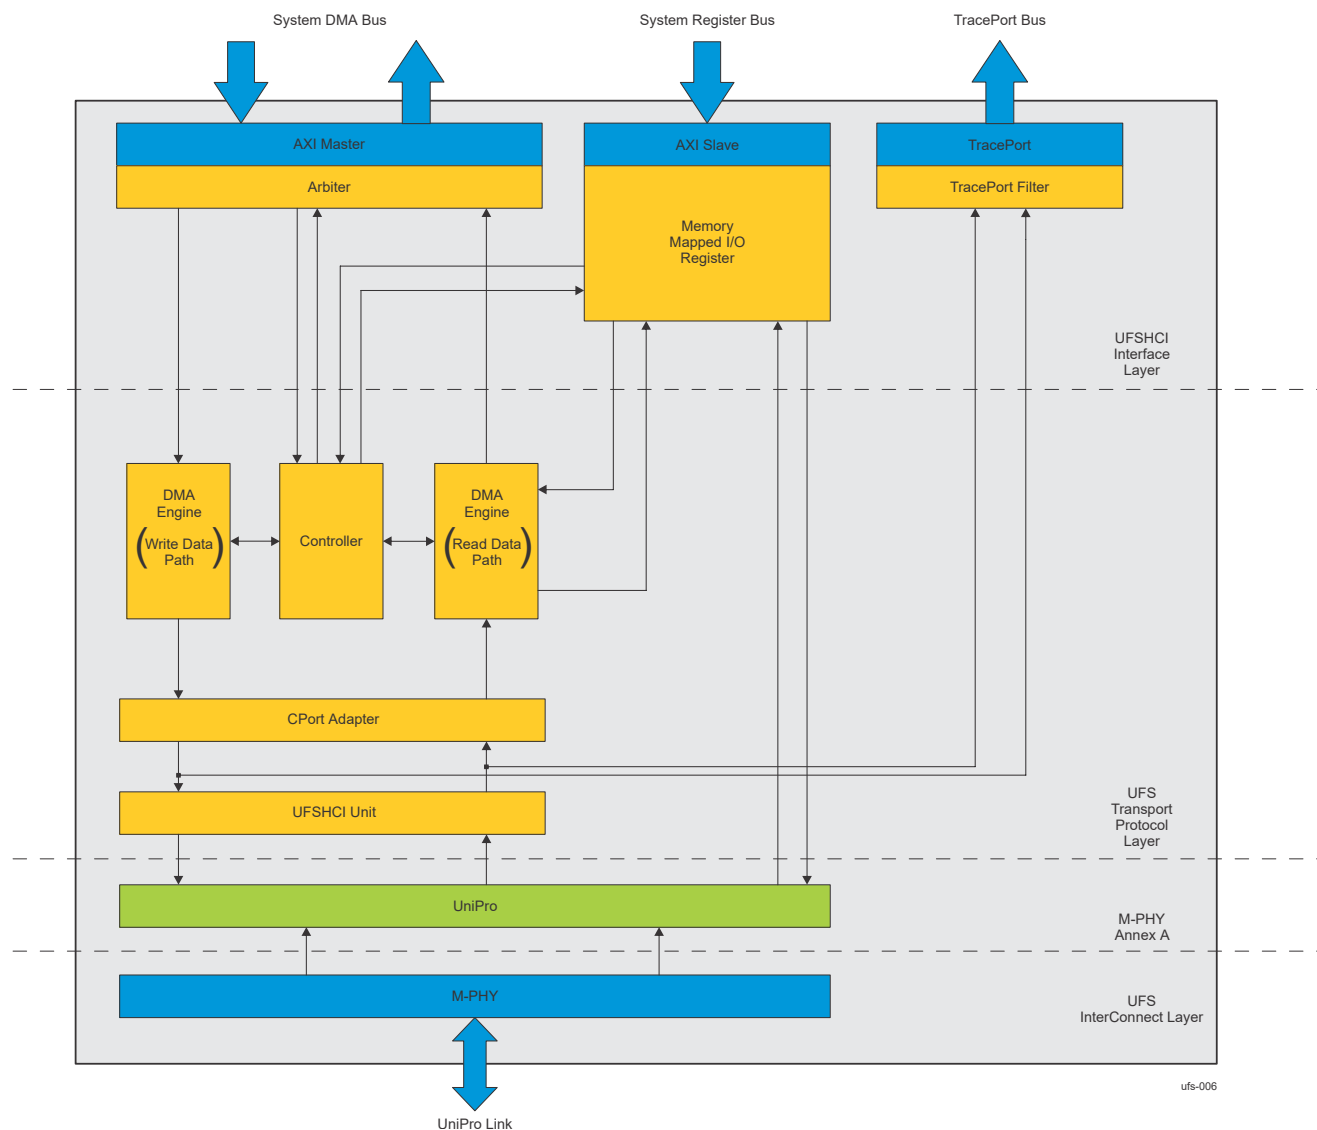

The UFS host controller is provided with additional hierarchy to support M-PHY integration.

These additional levels of hierarchy make up the IPS. Both the UFS host controller and the M-PHY share the same control interface (APB) and in further description is assumed they are mapped into single area in APB subsystem.

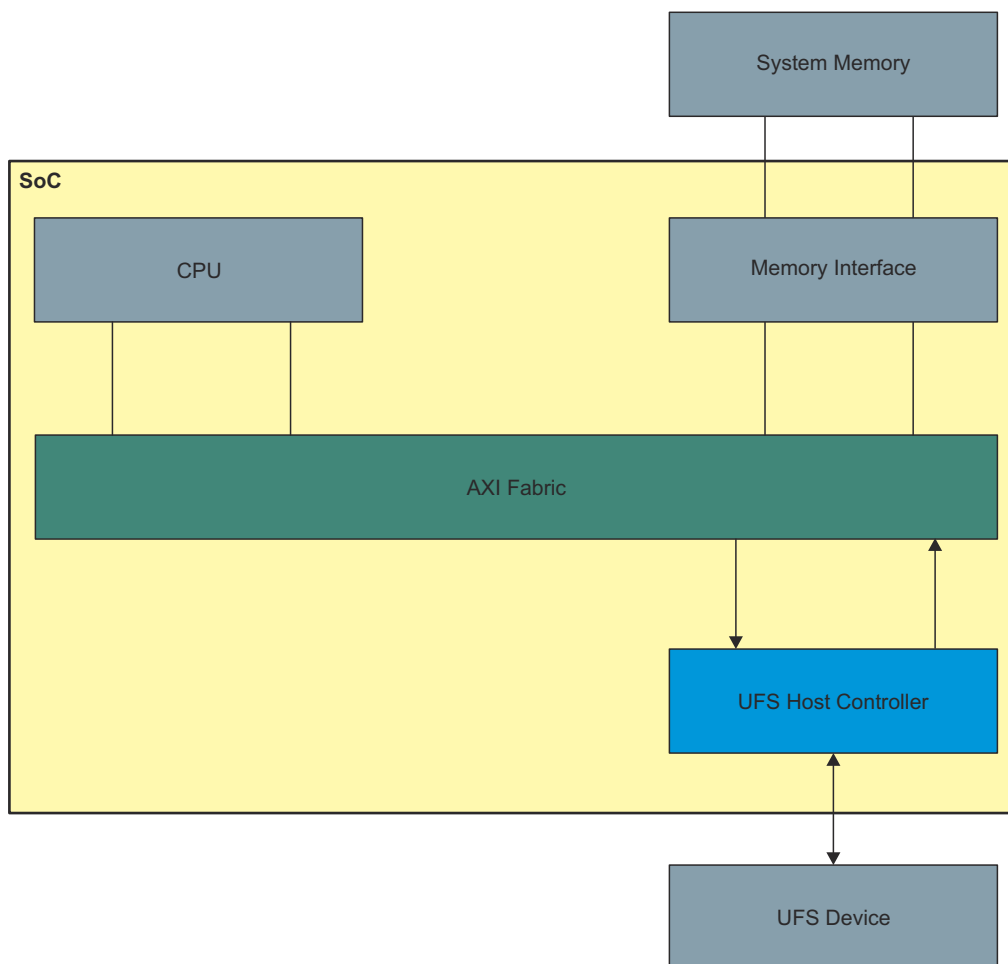

**Figure 12-351. UFS IPS Subsystem**

Figure 12-352 shows UFS controller block diagram.

**Figure 12-352. UFS Controller Block Diagram**

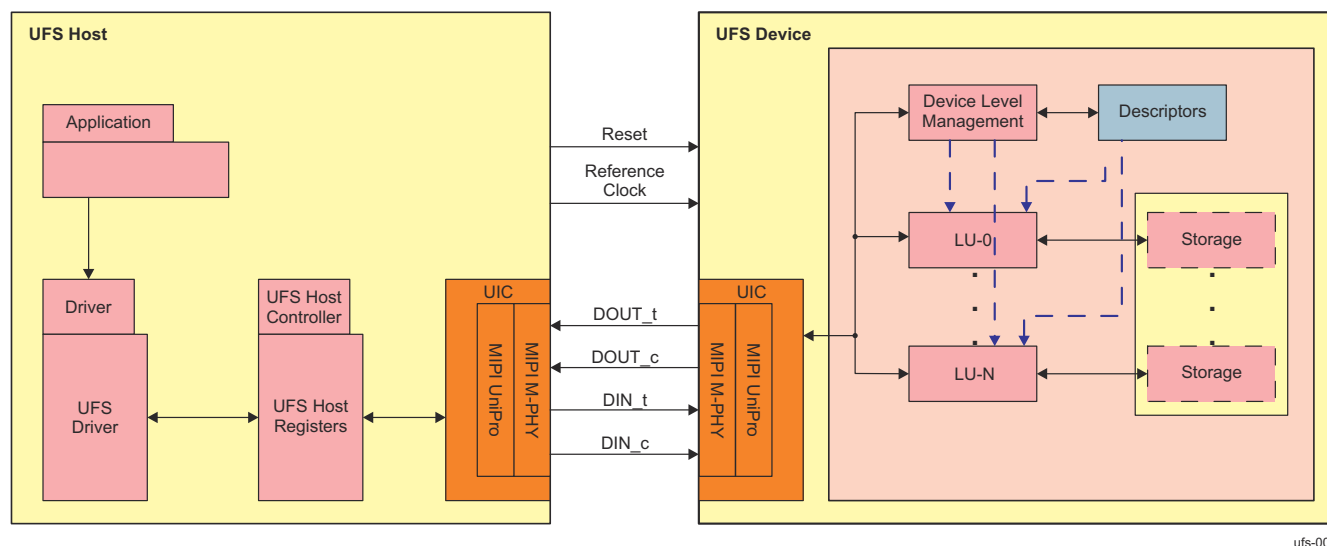

Figure 12-353 presents an example of UFS system level block diagram.

ufs-007

**Figure 12-353. UFS System Level Block Diagram**

Figure 12-354 shows UFS system model. The application layer of the UFS host controller connects to a UniPro protocol stack and M-PHY, both of which can be considered part of the UFS host controller.

**Figure 12-354. UFS System Model**

#### 12.3.7.4.2 UFS ECC Support

The UFS module supports Error Correcting Code (ECC). The ECC is a mechanism for providing increased system reliability via reduction of memory software errors by allowing single bit errors to be detected and corrected (SEC) and double bit errors to be detected (DED).

#### Note

For more information about ECC Aggregator, refer to *ECC Aggregator*.

For more information about UFS ECC Aggregator Registers, refer to *UFS0\_HCLK\_ECC\_AGGR\_CFG Registers*.

#### 12.3.7.5 UFS Programming Guide

#### Note

It is assumed that the reader of this section has an in-depth understanding of the following documents:

- JEDEC Standard Universal Flash Storage Unified Host Controller Interface
- JEDEC Standard Universal Flash Storage
- MIPI Alliance Specification for M-PHY
- MIPI Alliance Specification for Unified Protocol (UniPro®)
- SCSI Architecture Model

##### 12.3.7.5.1 UFS Start-Up Sequence

The initialization of the UFS host controller can be split up into the following four phases:

- Configuring and initializing the UniPro stack. This step can be further split up into the following tasks:
  - Initiate module enable and link startup
  - Set power mode related attributes
  - Start power mode change procedure
  - Set local and peer Layer 2 attributes
- Configuring the UFS host controller

- Initializing the UFS external device
- Refining the UFS host controller setup and configuring the host software driver

---

#### Note

While certain attributes and features of the external device may not be known from the start, commands and transaction will use default values known to work (minimal subset, probably lower performance).

---

#### 12.3.7.5.1.1 UniPro Initialization

##### 12.3.7.5.1.1.1 UniPro Layer 2 Configuration

Layer 2 configuration can be separated into two parts: thresholds and timers.

The calculation and selection of these attribute values have major influence on the performance of a UniPro system as they program the generation of AFC frames. Careful selection of these values is therefore very important. [Section 12.3.7.5.1.1.1.1](#) and [Section 12.3.7.5.1.1.1.5](#) describe these attributes in detail and give some advice on their configuration values.

---

#### Note

AFC frames for acknowledge generation are generated independently from AFC frames for credit exchange.

---

##### 12.3.7.5.1.1.1.1 Layer 2 Threshold Value Calculation

Layer 2 defines three configurable threshold values:

- DL\_TC0TXFCThreshold (see [Section 12.3.7.5.1.1.1.2](#))
- DL\_AFC0CreditThreshold (see [Section 12.3.7.5.1.1.1.3](#))
- DL\_C0OutAckThreshold (see [Section 12.3.7.5.1.1.1.4](#))

These threshold values are used to control AFC frame and credit transmission between the two devices on the link.

##### 12.3.7.5.1.1.1.2 DL\_TC0TXFCThreshold

A change in DL\_TC0TXFCThreshold influences the required level of available credits (1 credit = 32 bytes) in a transmitter before the Protection Timer is started to request an update of credit information.

For example, if this threshold value for TC0 is locally set to 10 credits, the local TX will start the Protection Timer when less than 10 credits are available for sending data to the peer device. If the Protection Timer expires, the local TX sends an AFC0 frame to the peer device with CReq set to 1 to request an update of the peer RX credit information. When the peer device answers with an AFC0 frame at any time, the Protection Timer is restarted if there are still 10 or fewer credits available or stopped otherwise.

This mechanism should prevent that the local TX runs out of credits and needs to stall its data transmissions, when for any reason the credit update was lost or not sent in time.

As a general guideline, this threshold value can be set to its maximum value (1 less than the maximum number of credits of the receive buffer for the corresponding TC, which is stored in the attribute DL\_PeerTC0RxInitCreditVal). With this setting the local TX will try to get an update of the local credit information as long as it has not all possible credits available. The overhead for sending the AFC frames depends on the counter value of the Protection Timer, but should not have a negative impact on the link performance.

**DLTCxTXFCThreshold = DLPeerTxTXInitCrediVal - 1;**

### 12.3.7.5.1.1.3 DL\_AFC0CreditThreshold

This threshold value is the counterpart of the DL\_TC0TXFCThreshold value in the receiver. It defines the amount of credits, which have become available since the last credit update but are not communicated to the peer device yet, before an AFC credit update is triggered.

For example, if this value is set to 5 credits, the device will not update its credit information to the peer device before at least 5×32 bytes are read from the receive buffer of the corresponding traffic class since the last credit update.

Changing this attribute to a lower value will increase the number of AFC frames sent for only updating credit information. A higher value however, might lead to a stall for data transmission on the peer device as not enough credits might be available. The maximum value is defined by the size of the RxBuffer in credits. A higher value for the threshold attribute would break credit handling.

As a guideline, setting this attribute to the credit value corresponding to the maximum size of a frame for this traffic class (MaxFrameSizeTC0), should give reasonable results. In this case, the receiver sends its credit update when at least one additional frame of MaxFrameSizeTC0 can be stored in its buffer.

**DL\_AFC0CreditThreshold = MaxFrameSizeTC0[credits];**

### 12.3.7.5.1.1.4 DL\_TC0OutAckThreshold

This attribute defines the number of frames (+1) to be received before an AFC frame is sent to the peer device.

For example, if this attribute is set to 2, the device will send an AFC frame back when three frames were received for the corresponding traffic class. Setting this attribute to a lower value will increase the number of AFC frames on the link. A higher value might have negative impact on the transmitter, if its own TX buffer reaches its limit as too many unacknowledged frames are stored.

As a guideline, this value should be set according to the two related buffers on each side of the link. The maximum number of frames that can be stored in the smaller buffer (peer TX or local RX) defines the upper bound for this attribute. A value at least 1 or two frames lower gives the AFC frame some time to traverse to the peer side.

**DL\_TC0OutAckThresholdmax = min(PeerTXBufferSizeTC0, LocalRxBufferSizeTC0)[frames];**

### 12.3.7.5.1.1.1.5 Layer 2 Timer Value Calculation

Layer 2 uses three timers to keep the link operational in case of wrong configuration or unstable communication with the peer device. These timers can be separately configured using three attributes:

- DL\_FC0ProtectionTimeOutVal (see [Section 12.3.7.5.1.1.1.6](#))
- DL\_TC0ReplayTimeOutVal (see [Section 12.3.7.5.1.1.1.7](#))
- DL\_AFC0ReqTimeOutVal (see [Section 12.3.7.5.1.1.1.7](#))

#### 12.3.7.5.1.1.1.6 DL\_FC0ProtectionTimeOutVal

The Protection Timer is used in conjunction with DL\_TC0TCXFCThreshold described in [Section 12.3.7.5.1.1.1.1](#). Its purpose is to "protect" the link against the loss of an AFC frame and the resulting stall in communication, if required credits were not delivered.

This timer is running whenever less credits than DL\_TC0TCXFCThreshold are available. After expiration, the local UniPro sends an AFC frame to the peer device requesting a credit information update (CReq set to 1). When this AFC request is sent, the timer is restarted. If the peer device does not respond within the second timer period, the link is automatically reinitialized, as the request seems to be lost.

The configuration of the Protection Timer has very little impact on the system performance. If the timer is set to a low value, the amount of AFC request frames may increase (depending on the threshold value). A too high value results in longer periods of inactivity if the link gets broken.

As a consequence setting this timeout value to any value between 512 and 1023 should result in a good compromise between additional AFC frame generation and latency in case of errors:

$$512 \leq \text{DL\_FC0ProtectionTimeOutVal} \leq 1023;$$

#### 12.3.7.5.1.1.1.7 DL\_TC0ReplayTimeOutVal and DL\_AFC0ReqTimeOut

The Replay Timer of one device is closely connected to the Request Timer on the other device of the link. In general, one Replay Timer for each traffic class is running when transmitted frames are not acknowledged yet and is reset every time a new frame is sent or one or more frames are acknowledged. This timer protects the protocol against lost AFC or NAC frames. When for a period of DL\_TC0ReplayTimeOutVal  $\mu$ s when no AFC is received and no new frame is sent for this traffic class, the timer expires and the link is re-initialized automatically and a retransmission is started.

An UFS device has two methods of generating an AFC frame for acknowledging data reception. The **DL\_TC0OutAck - Threshold value + 1** defines the number of received frames before an AFC is automatically generated. In addition, the AFC Request Timer at the receiver is used to trigger AFC generation before the Replay Timer at the transmitter is expired even when the DL\_TC0OutAckThreshold value is not reached.

To secure proper operation, the AFC Request Timer needs to be programmed to a significantly smaller value than the Replay Timer on the other side. The configuring application should take care that the Replay Timer value includes the AFC Request value, internal processing of a new AFC frame generation, and transmission over the link. To be on the safe side, the local Request Timer should be programmed with a value twice the remote AFC Request Timer value. With this rule the allowed accuracy of the timers of  $\pm 10\%$  should also be accounted for.

The AFC Request Timer should also have a quite high minimum value in order to not generate more AFC frames than actually needed. The following formula gives a general guideline for programming these two timer values.

$$1024 \leq 2 \times \text{DL\_AFC0RequestTimeOutVal} \leq \text{DL\_TC0ReplayTimeOutCal} \leq 4095;$$

#### 12.3.7.5.1.1.2 UniPro CPort Connection Management

For this particular case of UFS, as application layer, the connections are setup statically by having reset values for the UFS host controller and a UFS device predefined at reset. The predefined reset values are given in [Table 12-400](#).

Note that these reset values are different from the default reset values given by the *MIPI UniPro Specification* but are in line with the reset values given by the *JEDEC UFS Specification*. Furthermore, the reset values for the device are only assumed reset values.

**Table 12-400. Reset Values for Some UniPro Attributes**

UniPro Attribute	Reset Value of the UFS Host Controller	Expected UFS Device Reset Value
N_DeviceID	0	1
N_DeviceID_valid	TRUE	TRUE
T_PeerDeviceID	1	0
T_PeerCPortID	0	0
T_TrafficClass	0	0
T_CPortFlags	6 (E2E_FC off, CSD off, CSV off)	6 (E2E_FC off, CSD off, CSV off)
T_ConnectionState	1 (CONNECTED)	1 (CONNECTED)

At link startup and after exiting from the Auto-Hibernate state the UFS host controller will set the UniPro CPort attributes as shown in the following sequence:

CPort 0 Configuration:

- 4020h **T\_ConnectionState** 0h
- 4021h **T\_PeerDeviceID** 1h
- 4022h **T\_PeerCPortID** 0h
- 4023h **T\_TrafficClass** 0h
- 4025h **T\_CPortFlags** 6h
- 4020h **T\_ConnectionState** 1h

Additionally, if the value of the UFS\_XCNF[17-16] PCPCONFEX bit field is set to 3h, the UFS host controller will configure also the CPorts of the PEER device as follows:

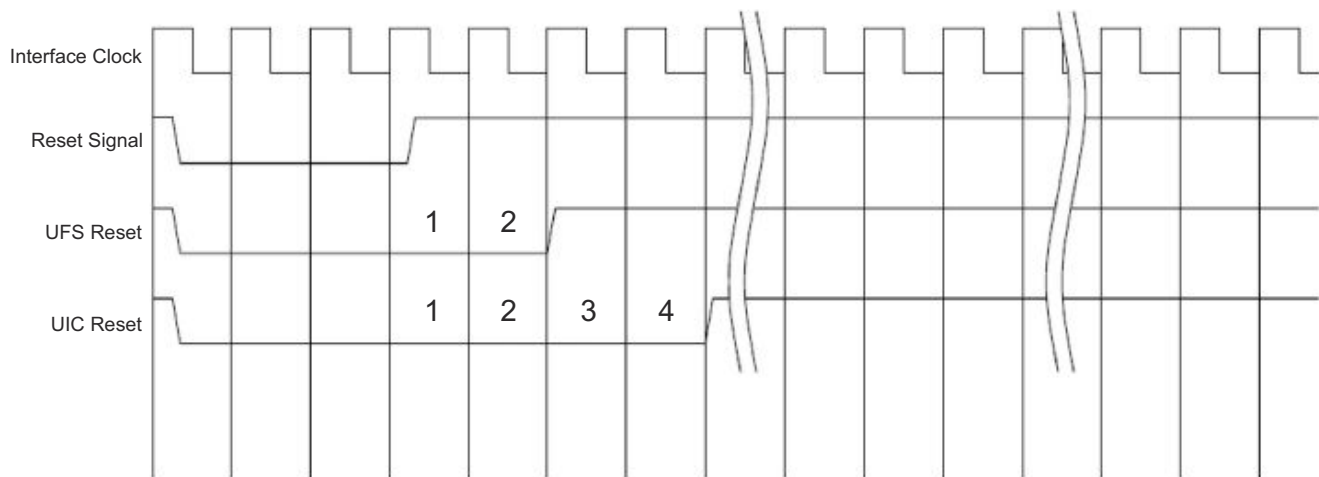

If the value of the UFS\_XCNF[17-16] PCPCONFEX bit field is set to 2h, the UFS host controller will poll the T\_ConnectionState attribute of CPort0 of the PEER device. Only CPort0 will be polled.

#### 12.3.7.5.1.2 UFS Host Controller Initialization

The following procedure shall be applied to initialize the UFS host controller:

1. Assert reset signal. For more information about the UFS reset signal, see *UFS0 Clocks and Resets*.
2. De-assert reset signal and wait for at least 4 interface clock cycles (see [Figure 12-355](#)). For more information about the UFS interface clock, see *UFS0 Clocks and Resets*.
3. Write appropriate value into the FS\_HCLKDIV register.
4. Write a 1h to the FS\_SS\_CTRL[0] RST\_N\_PCS bit to take UFS slave device out of reset.
5. Write a 1h to the UFS\_HCE register in order to enable the UFS host controller. This triggers an autonomous basic initialization of the local UIC layer. The initialization sequence shall consist of a *DME\_RESET* and a *DME\_ENABLE* command. Further commands, such as *DME\_SET* commands may be added, depending on the implementation needs. During the basic initialization sequence, the UFS\_HCE register is read as 0h.
6. Wait until the UFS\_HCE register is read as 1h before continuing. This indicates that the basic initialization sequence is completed.
7. Additional commands, such as *DME\_SET* commands may be sent from the system host to the UFS host controller to provide configuration flexibility.
8. Optionally set the UFS\_IE[10] UCCE bit to 1h in order to enable the interrupt (UFS\_IS[10] UCCS).
9. Send *DME\_LINKSTARTUP* command to start the link startup procedure.
10. Completion of the *DME\_LINKSTARTUP* command sets the UFS\_IS[10] UCCS bit and may flag an interrupt to the system host if the UFS\_IE[10] UCCE bit is set. This interrupt will be flagged independently from the GenericErrorCode.
11. In case the GenericErrorCode of the completed *DME\_LINKSTARTUP* command is *SUCCESS*, the UFS\_HCS[0] DP bit is set in addition to the UFS\_IS[10] UCCS bit.

12. Check the value of the UFS\_HCS[0] DP bit and make sure that there is a device attached to the Link. If presence of a device is detected, go to step **13**; otherwise, resend the *DME\_LINKSTARTUP* command after the UFS\_IS[7] ULLS bit has been set to 1h (go to step **8**). The UFS\_IS[7] ULLS bit equal 1h indicates that the UFS Device is ready for a link startup.
13. Enable additional interrupts by programming the UFS\_IE register.
14. Initialize the Interrupt Aggregation Control register (UFS\_UTRIACR) with the desired values for the threshold (UFS\_UTRIACR[12-8] IACTH) and timeout (UFS\_UTRIACR[7-0] IATOVAL).
15. For example, write value 81010664h to initialize with the following parameters:
  - The UFS\_UTRIACR[31] IAEN bit is set.
  - The UFS\_UTRIACR[24] IAPWEN bit is set.
  - The UFS\_UTRIACR[16] CTR bit is set.
  - The UFS\_UTRIACR[12-8] IACTH bit field is set to 6h.
  - The UFS\_UTRIACR[7-0] IATOVAL bit field is set to 64h (4.0 ms).
16. **Note:** The UFS\_UTRIACR register initialization may be executed at any time when the Run/Stop register (FS\_UTRLRSR) is not enabled or when no requests are outstanding.
17. Complete the UFS host controller configuration via *UIC* command interface if required.
18. Allocate and initialize UTP Task Management Request List.
19. Program the UTP Task Management Request List Base Address (UFS\_UTMRLBA) with a 32-bit address pointing to the starting address of the UTP Task Management Request List created at the step **15**.
20. Allocate and initialize UTP Transfer Request List.
21. Program the UTP Transfer Request List Base Address (UFS\_UTRLBA) with a 32-bit address pointing to the starting address of the UTP Transfer Request List created at the step **17**.
22. Enable the UTP Task Management Request List by setting the UTP Task Management Request List Run Stop register (UFS\_UTMRLRSR) to 1h. This operation allows the UFS host controller to begin accepting UTP Task Management Request via the UTP Task Management Request Door Bell mechanism (UFS\_UTMRLDBR).
23. Enable the UTP Transfer Request List by setting the UTP Transfer Request List Run Stop register (UFS\_UTRLRSR) to 1h. This operation allows the UFS host controller to begin accepting UTP Transfer Request via the UTP Transfer Request Door Bell mechanism (UFS\_UTRLDBR).
24. At this point, the UFS host controller is up and running.

ufs-009

**Figure 12-355. UFS Host Controller Reset Waveform**

#### 12.3.7.5.1.3 HCE Bit

When the Host Controller Enable (UFS\_HCE) bit transitions from 0h to 1h, the UFS host controller will go through an initialization sequence that is outlined as follows:

- Warm hardware reset of the UFS host controller
- *DME\_RESET* (Warm)
- *DME\_ENABLE*
- *LINK\_STARTUP*

As a part of the Link Startup procedure, the UFS interface will configure the CPort Attributes of the local and eventually the peer UniPro. Refer to [Section 12.3.7.5.1.1.2, UniPro CPort Connection Management](#).

### 12.3.7.5.2 UFS Host Controller Programming

#### 12.3.7.5.2.1 UFS Software Model

This section provides details on the transactions, protocol elements, and data structures which need to be used to control the UFS host controller, MIPI UniPro stack, and external device. The transactions are built by the system hosts and sent to the UFS controller via the UTP Transfer Request List, the UTP Task Management Request List, and the UTP Command Descriptors.

While some transactions are already prepared as UPIU packets by the host software, for some other transactions (mainly the transfer of the raw data), the UPIU packets need to be constructed first. The construction takes place on the fly in the UFS Controller as listed in [Table 12-401](#).

**Table 12-401. UFS Host Controller Commands**

Command	Format	Action
UTP Command	UTP Transfer Request List	Send to device
DME Command	Register Access	Access UniPro stack
Task Management Command	UTP Task Management Request List	Send to device

To send commands to the UFS host controller, UniPro stack, and UFS device, the system host needs to perform a series of setup and configurations steps. The following list gives a brief summary on the necessary sequence:

- Find an empty slot in the UTP Transfer Request List (UTP Task Management Request List) by reading the *UFS\_UTRDLDBR* (*UFS\_UTMRLDBR*) register.
- Program the required transactions in the UTP Transfer Request List (UTP Task Management Request List) and depending on the transfer setup a UTP Command Descriptor.
- Then setup the appropriate bit in the *UFS\_UTRDLDBR* (*UFS\_UTMRLDBR*) register.

For a detailed description, refer to [Section 12.3.7.5.2.2, UFS Theory of Operation](#).

The UFS host controller starts processing the UTP Transfer Request List and UTP Task Management Request List.

Once the UFS host controller has finished processing a command, it updates the status field in the UTP Transfer Request List (UTP Task Management Request List) or UTP Command Descriptor respectively.

The UFS Transport Protocol (UTP) commands are commands based on UPIU packets. To set up the communication, both the transaction lists as well as the command descriptors need to be programmed.

#### 12.3.7.5.2.1.1 UFS Layers

The UFS interface is based on master/slave architecture. Direct device-to-device communication is not supported. The information flow is packet based and the packets are sent in a request/response method where the Initiator sends a request to a Target and the Target must always respond. There is only one UFS host controller on the physical interface and most requests are typically initiated by the UFS host controller. The requests initiated by UFS device could be an interrupt or any other request for service actions.

The communication between the UFS host controller and the device is layer oriented. The UFS specification defines the following layers:

- UFS communication is layered communication architecture. The information is packetized at different layer with the appropriate header.
- UFS InterConnect Layer (UIC) - the UIC Layer is based on MIPI M-PHY and the MIPI UniPro stack:

segments does not end on a 32-bit boundary, then additional padding with 0h data will be added to round up the UPIU to the next 32-bit address boundary.

#### 12.3.7.5.2.1.2.2 UFS Protocol

As described earlier, the communication between the host system host and the external device is based on UPIU packets. These packets are used to define the following protocols:

- UTP: the SCSI Architecture Model (SAM) is used as general architectural model for the UFS SCSI. This model uses the SCSI command set and the SAM Task Management features to establish the communication between the system host and the UFS device. For the UFS implementation a reduced SCSI command set is used.
- Native UFS communication: native UFS commands are used to communicate with the UFS host controller and the MIPI UniPro stack outside of the SCSI protocol.

#### 12.3.7.5.2.1.3 UFS Host Data Structure

Most of the communication between host software and the UFS host controller or the UFS device respectively is via system memory tables, descriptors and buffers. These memory locations describe commands to be executed, the data transfer operations that are part of the commands, store status information coming back from the device and provide buffer space for data transactions.

#### Note

For additional information on host data structures and programming procedures, refer to *Universal Flash Storage Host Controller Interface (UFSHCI)*, JESD223C.

#### 12.3.7.5.2.2 UFS Theory Of Operation

As described in [Section 12.3.7.5.2.1.3, UFS Host Data Structure](#), the host software presents a list of commands to the UFS host controller. Independent from the system host, this list is then being processed by the UFS host controller which asserts an interrupt line in case a command finishes.

On order to post new commands to the UFS host controller, the system host needs to find empty slots in the command list. In case no empty slot is available, the host thread needs to wait until a command finishes and the driver software has made a new slot available.

Nevertheless, the UFS host controller continuously looks at the UFS\_UTRLDBR and UFS\_UTMRLDBR registers to determine if there are commands ready to be processed. The processing order depends on three factors:

- Time at which the bit(s) inside the UFS\_UTRLDBR and UFS\_UTMRLDBR registers have been asserted.
- Index inside the UFS\_UTRLDBR and UFS\_UTMRLDBR registers.
- Command type (UTP or Task Management).

The processing rules are as follows:

1. Task Management commands have higher priority than UTP commands.
2. Commands with lower time stamp have higher priority than commands with higher time stamps.
3. Within the same time stamp, commands with lower doorbell register index have higher priority than commands with a higher doorbell register index.

While there is no indicator about active commands, it is not possible to know in advance when a particular command is being processed, or how the command will remain in the command list respectively.

To add an additional level of uncertainty, any UFS device is allowed to accept more than one command and is allowed to process those commands out-of-order. As a consequence, commands placed in the command list need to be robust enough to get arbitrarily re-ordered. In cases where this may cause problems, only one command at a time may be placed into the command list.

[Section 12.3.7.5.2.2.1, Building a UTP Transfer Request](#) provide more detail on the low-level driver to explain how the communication and data transfer is handled between system host, the UFS host controller, and UFS device.

### 12.3.7.5.2.2.1 Building A UTP Transfer Request

Typically a command for the UFS host controller consists of a UTP Transfer Request List entry and a command table element. Thus, the host software needs to start by finding an empty slot inside the UTP Transfer Request List first.

Here are the basic steps for setting up the command list:

- Find an empty command list slot by reading the UFS\_UTRLDBR register.
- In case there are no empty slots, wait and try again.
- In case there is at least one empty slot, start setting up the UTP Transfer Request Descriptor:
  - Write CT: define command type.
  - Write DD: define data direction.
  - Write I: define whether or not an interrupt has to be generated.
  - Initialize OCS with the value Fh.
- Allocate space inside the system memory for an UTP Command Descriptor.
- Initialize Command UPIU field of the UTP Command Descriptor:
  - Write TTY: transaction type, here 1h.
  - Write FL: specific flags for this command.
  - Write LUN: the SCSI address this command is directed to.
  - Write TT: task tag, a unique number to identify the task.
  - Write CST: command set type, 0h for SCSI commands.
  - Write TEL: total EHS Length, always 0h.
  - Write DSL: data segment length, always 0h.
  - Write EDTL: expected data transfer length. This field indicates the amount of data to be transferred between the Initiator and Target (read or write). Data is stored in system memory.
  - Write CDB: write the SCSI command into the following 16 bytes.
- Initialize Response UPIU field of the UTP Command Descriptor with zero.
- Initialize PRD field of the UTP Command Descriptor with the required data scatter/gather buffer information.
- Now the UTP Command Descriptor has been set up and the UTP Transfer Request List Descriptor needs to be completed:
  - Write UCDBA: base address of the UTP Command Descriptor.
  - Write UCDBAU: upper 32 bit of the UCDBA, always 0h.
  - Program field RUO with the offset (from the starting address of UCD) of Response UPIU within UCD.
  - Program field RUL with the length of Response UPIU.
  - Program field PRDTO with the offset (from the starting address of UCD) of the PRD table within UCD if required.
  - Program field PRDTL with the length of the PRD table if required.
- Repeat this procedure for all commands which need to be set up.
- Check the UFS\_UTRLRSR register and make sure it is read 1h before continuing.
- Set UTP Transfer Request Interrupt Aggregation Control Register (UFS\_UTRIACR) enable bit to 1h to enable the interrupt.
- Set Counter and Timer Reset (UFS\_UTRIACR[16] CTR) bit to 1h to reset the counter and timer associated with the interrupt.
- Program field Interrupt aggregation counter threshold (UFS\_UTRIACR[12-8] IACTH) with the number of command completions that are required to generate an interrupt.
- Program field Interrupt aggregation timeout value (UFS\_UTRIACR[7-0] IATOVAL) with the maximum time allowed between a response arrival to the UFS host controller and the generation of an interrupt.
- Set the UFS\_UTRLDBR register to ring the doorbell register to indicate to the UFS host controller that one or more transfer requests are ready to be sent to the attached device. The host software shall only write a 1h to the bit position that corresponding to the new command. All other bit positions within the UFS\_UTRLDBR register should be written with a 0h, which indicates no change to their current values.

Now the UFS host controller will take over and process the command list without further software interaction.

#### 12.3.7.5.2.2.2 Processing UTP Task Management Request Completion

The host software processes the interrupt generated by the UFS host controller for command completion. In the interrupt service routine, the host software checks the UFS\_IS register to determine if there is an interrupt pending. If the UFS host controller has an interrupt pending:

- The host software determines the cause of the interrupt by reading the UFS\_IS register. If the UFS\_IS[9] UTMRCs bit is set this indicates that a UTP Task Management Request has completed.
- The host software clears appropriate bits in the UFS\_IS register corresponding to the cause of the interrupt.
- The host software reads the UFS\_UTMRLDBR register, and compares the current value to the list of commands previously issued by the host software that are still outstanding. The host software completes with success any outstanding command whose corresponding bit has been cleared in the respective register. The UFS\_UTMRLDBR register is a volatile. The software should only use its value to determine commands that have completed, not to determine which commands have previously been issued.
- If there were errors, noted in the UFS\_IS register, the host software performs error recovery actions.

#### 12.3.7.5.2.2.3 Building UTP Task Management Request

Typically a command for the UFS host controller consists of a UTP Transfer Request List entry and a command table element. Thus, the host software needs to start by finding an empty slot inside the UTP Task Management Request List first.

Basic steps for setting up the Task Management Request:

- Find an empty command list slot by reading the UFS\_UTMRLDBR register.
- In case there are no empty slots, wait and try again.
- In case there is at least one empty slot, start setting up the UTP Task Management Request Descriptor:
  - Write I: define whether or not an interrupt has to be generated.
  - Initialize OCS with the value Fh.
- Allocate space inside the system memory for an UTP Command Descriptor.
- Repeat the above procedure for all task management commands that need to be set up.
- Check UTP Task Management Request List Run Stop register (UFS\_UTMRLRSR) and make sure it is read 1h before continuing.
- Set UTP Transfer Request Interrupt Aggregation Control register (UFS\_UTRIACR) enable bit to 1h to enable the interrupt.
- Set the UFS\_IE[9] UTMRCe bit to 1h to enable the interrupt.
- Set UTP Task Management Request List Doorbell register (UFS\_UTMRLDBR) to ring the doorbell register to indicate to the UFS host controller that one or more transfer requests are ready to be sent to the attached device. The host software shall only write a 1h to the bit position that corresponding to the new command. All other bit positions within the UFS\_UTMRLDBR register should be written with a 0h, which indicates no change to their current values.

Now the UFS host controller will take over and process the command list without further software interaction.

#### 12.3.7.5.2.2.4 Processing UTP Transfer Request Completion

Control will be given back to the software by assertion of the Transfer Request Completion Status interrupt (UFS\_IS[0] UTRCS). The UFS\_IS[0] UTRCS bit is set when at least one of the following 4 conditions is met:

- The UTRD.I bit is set (Interrupt Command).
- The counter, after incrementing, reaches the value configured in the UFS\_UTRIACR[12-8] IACTH bit field.
- The IA (Interrupt Aggregation) timer reaches the value configured in the UFS\_UTRIACR[7-0] IATOVAL bit field (this event may occur at any time, not necessarily coupled with request completion).
- The Overall Command Status (OCS) of the completed command is unequal to "SUCCESS".

An interrupt is generated by the write operation if the completion interrupt is not masked (disabled) by the UFS\_IE[0] UTRCE bit.

The host software processes the interrupt generated by the UFS host controller for command completion. In the interrupt service routine, the host software checks the UFS\_IS register to determine if there is an interrupt pending. If the UFS host controller has an interrupt pending:

1. If there were errors, noted in the UFS\_IS register, the host software performs error recovery actions.
2. In the case of the Transfer Request Completion Status interrupt (UFS\_IS[0] UTRCS), the host software clears the interrupt and then may use one of two methods to determine which UTP transfer requests (TRs) have completed:
  - a. Read the UFS\_UTRLDBR register, and compare the current value to the list of commands previously issued by the host software that are still outstanding. For any transfer request which is outstanding, a value of 0h in bit *i* (where *i* is the UTRL slot through which the TR is issued) of the UFS\_UTRLDBR register means that the TR has completed. The UFS\_UTRLDBR register is a volatile. The software should only use its value to determine commands that have completed, not to determine which commands have previously been issued.
  - b. Read the UTP Transfer Request List Completion Notification register (UFS\_UTRLCNR). For any TR, a value of 1h in bit *i* (where *i* is the UTRL slot through which the TR is issued) of the UFS\_UTRLCNR register means that the TR has completed.
3. For every TR *i* whose completion is detected, the software repeats the following steps:
  - a. Processes the request completion as required by higher OS layers (for example: file system).
  - b. Clears bit *i* of the UFS\_UTRLCNR register, by writing 1h to it.
  - c. Marks slot *i* as available for reuse (software only).
4. After processing all previously detected TRs, the software may reset and restart Interrupt Aggregation mechanism by writing 80010000h to the UFS\_UTRIACR register.
5. The software determines if new TRs have completed since step 2, by repeating one of the two methods described in step 2. If new TRs have completed, the software repeats the sequence from step 3.

#### 12.3.7.5.2.2.5 UFS Host Processing

The host processing of the commands initiated by the system host is done independent of the system host and software. The exact steps the UFS host controller will perform may vary, but the baseline steps for a read/write operation are given below:

- The UFS host controller will read the selected command list entry with one 4-beat burst.
- Depending on the command type, further actions are taken. In case the command is read/write:
  - The UFS host controller will fetch the first part of the UPIU (till the data segment) in 4-beat bursts. This will bring the header information and the SCSI command into the controller.
  - The UFS host controller will read the first PRD entry with a 2-beat burst.
  - Now the UFS host controller will set up its internal data structure and variables.
  - To start the device communication, the UFS host controller will send the already fetched UPIU packet to the device.
- Now the device will initiate the data transfer phase by sending Ready-To-Transfer (RTT) UPIUs to the UFS host controller.
  - The device either sends a RTT UPIU (in case of a write) or directly a Data In UPIU (in case of a read). The size of the Data In UPIU is not predefined.
  - The UFS host controller either sends back the requested data with a Data Out UPIU, or takes the data and stores it in an internal buffer.

The above transactions between the UFS host controller and the device are executed until all data is transferred or an error occurred.

In parallel to the transactions between the UFS host controller and device, the data is transferred between the UFS host controller and system memory.

- On receiving the Response UPIU, the UFS host controller updates the Transfer Response field of the UTP Command Descriptor with the received UPIU.
- Once a command has been completed, depending on the Interrupt Enable register (UFS\_IE), an interrupt may be asserted to signal the system host that the transfer is done.

#### 12.3.7.5.2.2.6 UFS Response Management And Command Completion

Although not a command, the management of command completion, response management, and error handling can be considered to be related to the command interface.

There are essentially three steps to perform when a response UPIU arrives:

- Analyzing the packet.
- Storing of the sense data which might be part of the response packet.
- Modification of the Response UPIU field in the related UPIU command table entry.

As a last step and depending on the command setup, the UFS host controller will set the interrupt flag.

### 12.3.7.5.3 UFS PHY Programming

This section details specific steps on how to program the M-PHY.

The M-PHY registers can be used to configure and read the status of the M-PHY. These M-PHY registers are part of the common UFS host controller address space . For detailed description of the UFS and M-PHY registers, refer to *UFS0\_P2A\_WRAP\_CFG\_VBP\_UFSHCI Registers*.

UFS and M-PHY address spaces:

- UFS address space: 04E8 0000h – 04E8 1103h
- M-PHY address space: 04E8 1104h – 04E8 1193h

The M-PHY configuration and status bits are connected directly either to the top-level ports or to the M-PHY register bank or to both exclusively.

The UFS\_MPHY\_MMIO\_A[0] MMIO\_A configuration bit is being used to choose if the dual-connection M-PHY configuration bits are connected to the registers or to IOs. After the reset, the UFS\_MPHY\_MMIO\_A register value is 0h, so the M-PHY configuration bits are connected to the IOs by default. These bits are listed in [Table 12-402](#).

**Table 12-402. The Dual Connection M-PHY Configuration Bits**

UFS_MPHYCFG_VCONTROL		UFS_MPHYCFG_MISC		UFS_MPHY_M MIO_A = 1	UFS_MPHY_M MIO_A = 0
Offset	1188h	Offset	1184h		
Bits	Name	Bits	Name		
16	VCONTROL_LA_SA_SEL	29	CMN_MPX_EN_MMIO	Registers	I/Os
11-10	VCONTROL_DEEMP_SEL	28-26	CMN_MPX_SEL_MMIO		
9-0	VCONTROL	25	TX0_TEST_15_MMIO		
		24	TX1_TEST_15_MMIO		
		17	REFCLK_NOGATED		
		16-15	REFCLK_FREQ_SEL		
		6-0	DEBUG_SEL		

#### Note

To enlarge the M-PHY HS-Gear mode initialization time, set M-PHY configuration for the digital part register (UFS\_MPHYCFG\_XCFGD1) to 01000000h.

The UFS\_MPHY\_MMIO\_A register will be stuck at zero in test mode in order to prevent toggling any of the dependent M-PHY input ports during scan procedure.

### 12.3.7.5.4 UFS Hibernate Timings Considerations

Software should take care of the following hibernate timings specifics:

1. An additional 22us needs to be added to the default TActivate time after establishing a link. This can be achieved by adjusting the host's *PA\_Granularity* and *PA\_TActivate* attributes in the Unipro layer as follows:

```
If (PA_Granularity == 6)
    PA_Granularity == 1;
```

```

        PA_TActivate = PA_TActivate*100 + 22;
else if (PA_Granularity == 5)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*32 + 22;
else if (PA_Granularity == 4)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*16 + 22;
else if (PA_Granularity == 3)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*8 + 22;
else if (PA_Granularity == 2)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate*4 + 22;
else if (PA_Granularity == 1)
    PA_Granularity == 1;
    PA_TActivate = PA_TActivate + 22;

```

2. The TActivate time at hibernate exit on the peer side needs to be increased, by changing the *RX\_Advanced\_Min\_ActivateTime\_Capability* attribute default value from 0x04 to 0x0A in the M-PHY layer on host side.
3. The connection of differential termination resistance needs to be enabled, by setting to '1' the *Termination\_Force\_Enable* attribute in the M-PHY layer on host side.

## 12.4 Industrial and Control Interfaces

This section describes the industrial and control interfaces in the device.

### 12.4.1 Enhanced Capture (ECAP) Module

This section describes the Enhanced Capture (ECAP) module in the device.

#### 12.4.1.1 ECAP Overview

The Enhanced Capture (ECAP) module can be used for:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

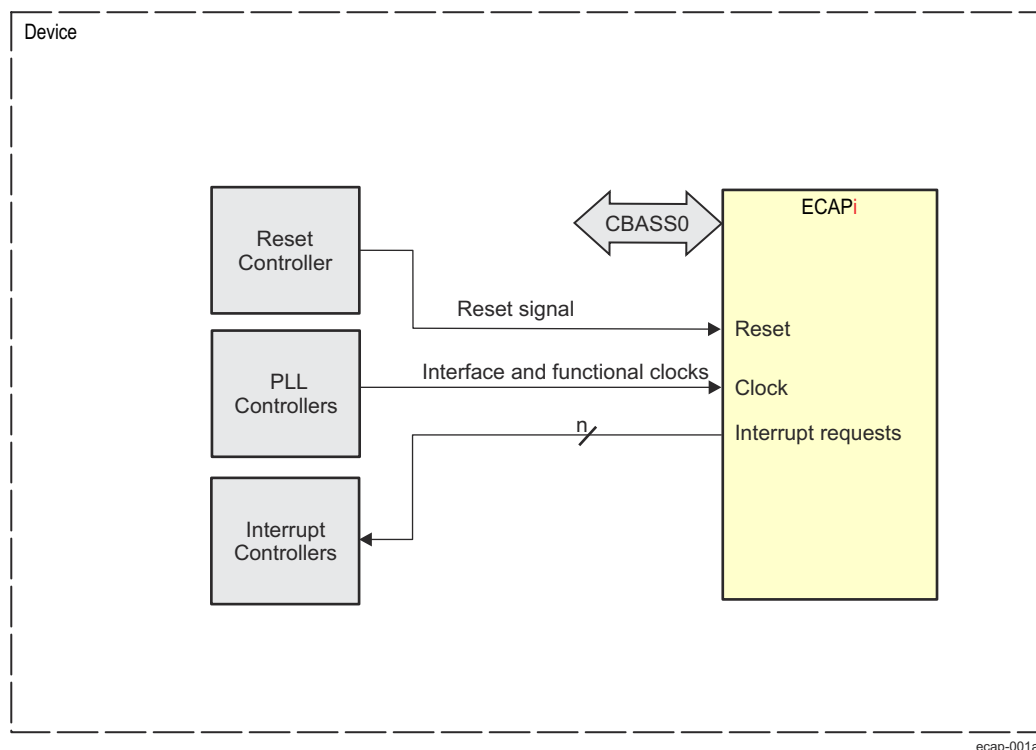

The device has three instances of the ECAP module.

Table 12-403 shows the ECAP allocation across device domains.

**Table 12-403. ECAP Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
ECAP0	-	-	✓
ECAP1	-	-	✓
ECAP2	-	-	✓

Figure 12-357 shows the ECAP modules overview.

A.  $i = 0 \text{ to } 2$

**Figure 12-357. ECAP Overview**

#### **12.4.1.1.1 ECAP Features**

The ECAP module includes the following features:

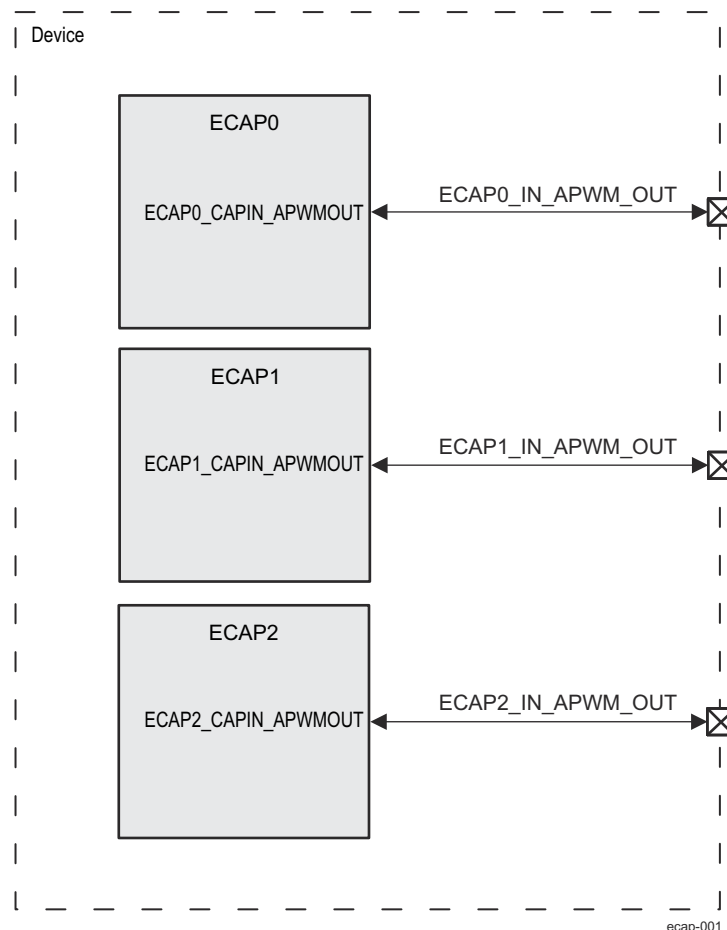

- 32-bit time base counter
- 4 × 32 bits event time-stamp capture registers (ECAP\_CAP1 through ECAP\_CAP4)
- 4-stage sequencer (Mod4 counter), synchronized to external events (ECAPx pin edges)
- Independent edge polarity (rising / falling edge) selection for all 4 sequenced time-stamp capture events
- Input capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Interrupt capabilities on any of the 4 capture events
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

## 12.4.1.2 ECAP Environment

### 12.4.1.2.1 ECAP I/O Interface

This section describes the ECAP external connections (environment).

Figure 12-358 shows the ECAP interface signals.

**Figure 12-358. ECAP External Interface I/Os**

Table 12-404 describes the ECAP I/O signals.

**Table 12-404. ECAP I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>ECAP0</b>				
ECAP0_CAPIN_APWMOUT	ECAP0_IN_APWM_OUT	I/O	ECAP0 Capture input / PWM output	HiZ
<b>ECAP1</b>				
ECAP1_CAPIN_APWMOUT	ECAP1_IN_APWM_OUT	I/O	ECAP1 Capture input / PWM output	HiZ
<b>ECAP2</b>				
ECAP2_CAPIN_APWMOUT	ECAP2_IN_APWM_OUT	I/O	ECAP2 Capture input / PWM output	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

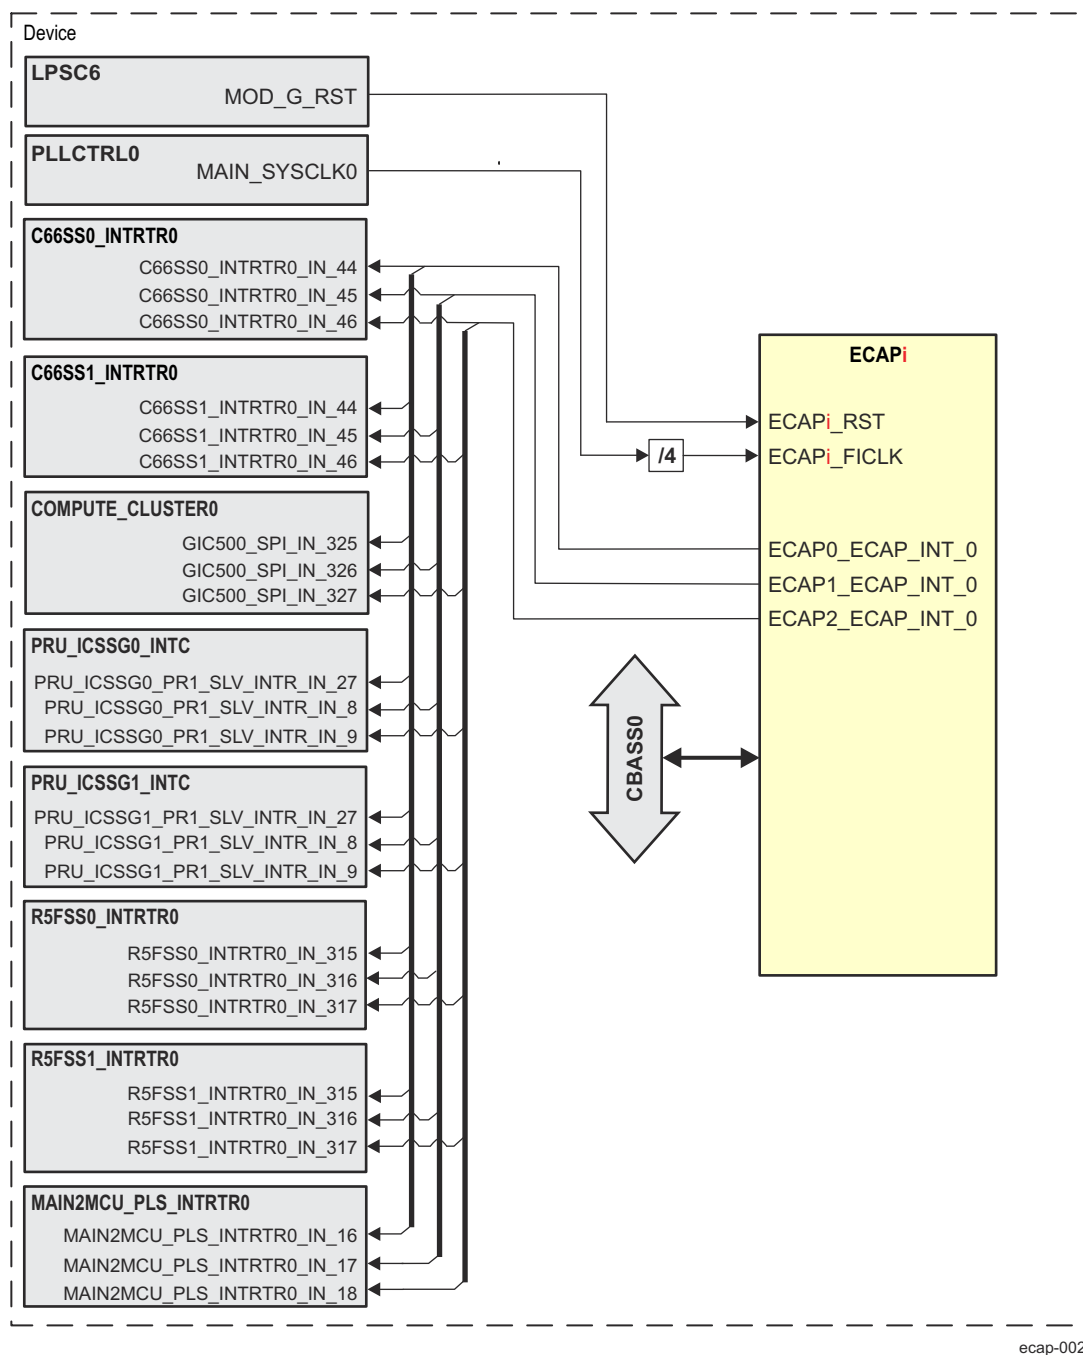

---

### 12.4.1.3 ECAP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 12-359 shows the ECAP integration.

There are three instances of the Enhanced Capture (ECAP) module integrated in the device.

A.  $i = 0 \text{ to } 2$

**Figure 12-359. ECAP Integration**

Table 12-405 through Table 12-407 summarize the integration of ECAP0, ECAP1 and ECAP2 modules in device MAIN domain.

**Table 12-405. ECAP Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
ECAP0	PSC0	PD0	LPSC6	CBASS0
ECAP1	PSC0	PD0	LPSC6	CBASS0
ECAP2	PSC0	PD0	LPSC6	CBASS0

**Table 12-406. ECAP Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
ECAP0	ECAP0_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	ECAP0 functional and interface clock
ECAP1	ECAP1_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	ECAP1 functional and interface clock
ECAP2	ECAP2_FICLK	MAIN_SYSCCLK0/4	PLLCTRL0	ECAP2 functional and interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
ECAP0	ECAP0_RST	MOD_G_RST	LPSC6	Module Reset

#### 12.4.1.3.1 Daisy-Chain Connectivity between ECAP Modules

The ECAP modules provide input synchronisation signals to allow them to be synchronized to other modules or events. On the device, these signals are connected in a daisy-chain fashion for the ECAP0 to ECAP2 module as shown in [Figure 12-360](#). The ECAP capture events come from external input pins.

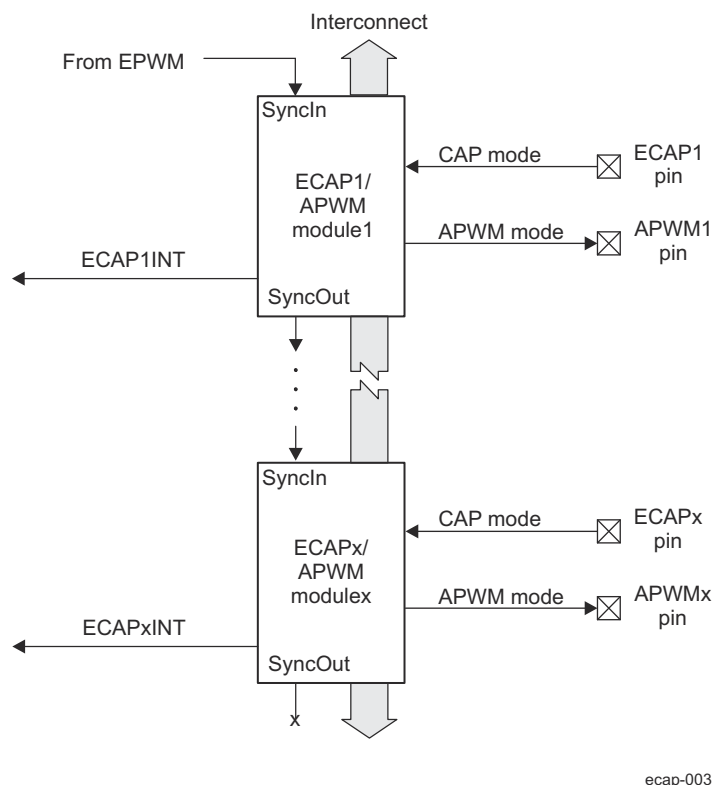

**Figure 12-360. ECAP Daisy-Chain Connectivity**

### 12.4.1.4 ECAP Functional Description

The ECAP module represents one complete capture channel, which has the following independent key resources:

- Dedicated input capture pin
- 32 events selection mapping capability to the input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (ECAP\_CAP1 through ECAP\_CAP4)
- 4-stage sequencer (Mod4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (ECAP\_CAP1 through ECAP\_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

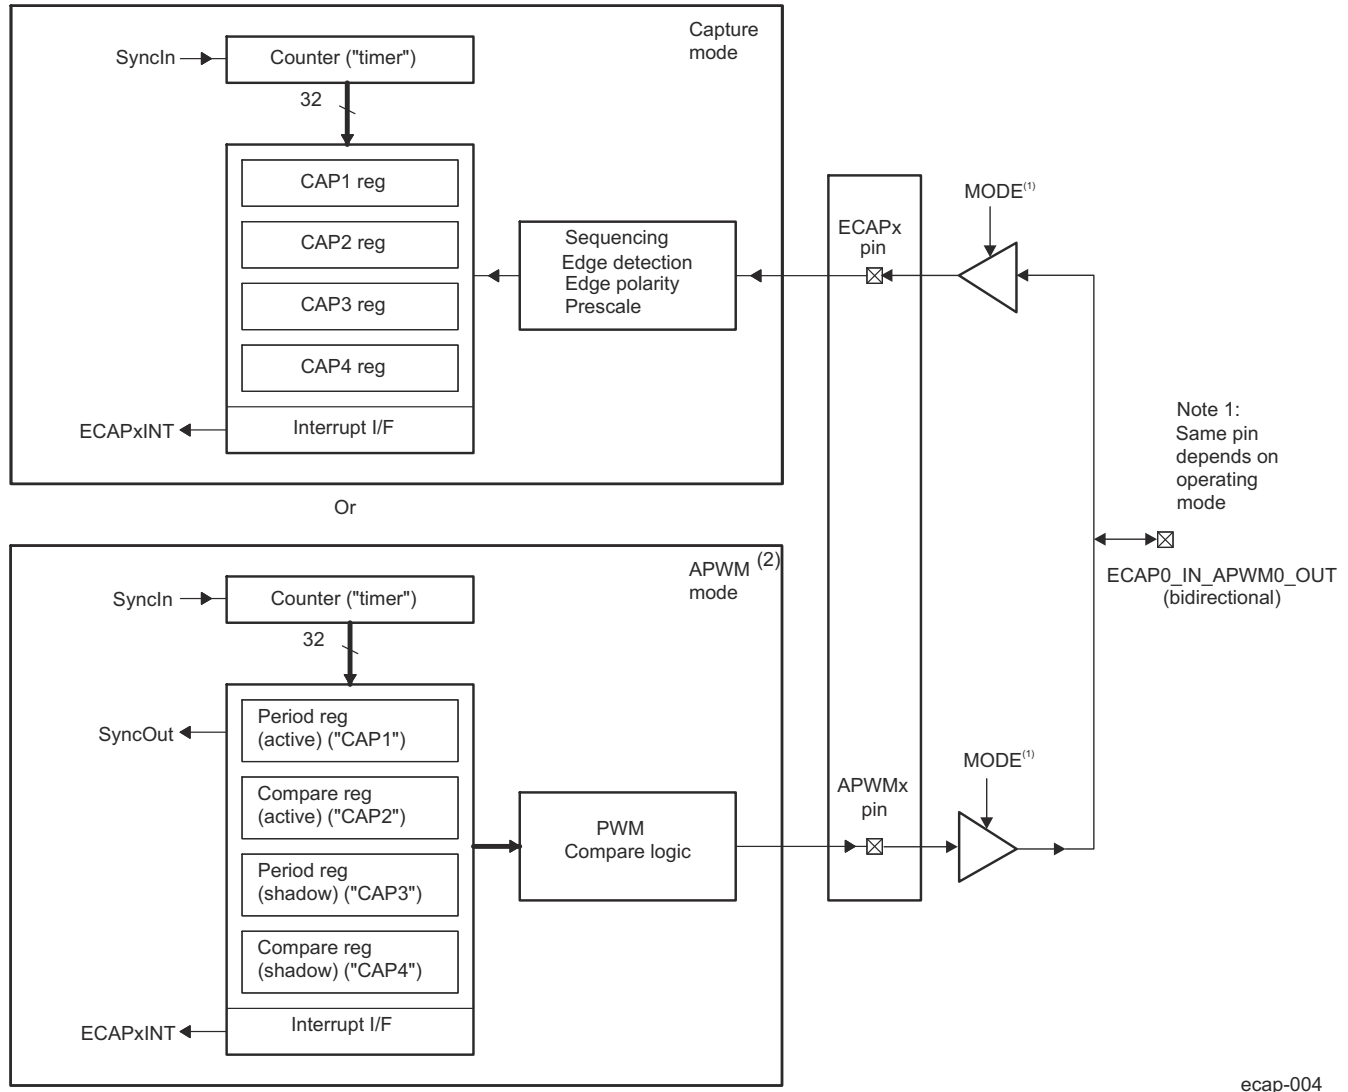

Multiple identical ECAP modules can be contained in a system as shown in [Figure 12-361](#). For actual number of the ECAP modules integrated in the device, refer to the *ECAP Integration*. The letter x within a signal or module name is used to indicate a generic ECAP instance on a device. For example, output interrupt request, ECAP1INT belongs to ECAP1, ECAP2INT belongs to ECAP2, and so forth.

**Figure 12-361. Multiple ECAP Modules**

#### 12.4.1.4.1 Capture and APWM Operating Modes

The ECAP module resources can be used to implement a single-channel PWM generator (with 32-bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The ECAP\_CAP1 and ECAP\_CAP2 registers become the active period and compare registers, respectively, while the ECAP\_CAP3 and ECAP\_CAP4 registers become the period and capture shadow registers, respectively. [Figure 12-362](#) is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

ecap-004

- A single pin is shared between CAP and APWM functions. In capture mode, it is an input. In APWM mode, it is an output.
- In APWM mode, writing any value to the ECAP\_CAP1/ECAP\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) invokes the shadow mode.

**Figure 12-362. Capture and APWM Modes of Operation**

Figure 12-363 shows the various components that implement the capture function.

### Figure 12-363. Capture Function Diagram

An input capture signal (pulse train) can be prescaled by  $N = 2-62$  (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. [Figure 12-364](#) shows a functional diagram and [Figure 12-365](#) shows the operation of the prescale function.

ecap-006

- A. When a prescale value of 1 is chosen (ECAP\_ECCTL[13-9] EVTFLTPS = 0b0000) the input capture signal by-passes the prescale logic completely.

**Figure 12-364. Event Prescale Control**

ecap-007

**Figure 12-365. Prescale Function Waveforms**

#### 12.4.1.4.1.1.2 ECAP Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Mod4 sequencer.
- The edge event is gated to its respective CAP $n$  register by the Mod4 counter. The CAP $n$  register is loaded on the falling edge.

#### 12.4.1.4.1.1.3 ECAP Continuous/One-Shot Control

- The Mod4 (2-bit) counter is incremented via edge qualified events CEVT1 through CEVT4 (see the ECAP\_ECINT\_EN\_FLG register).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output; when equal the Mod4 counter stops and inhibits further loads of the ECAP\_CAP1 through ECAP\_CAP4 registers. This occurs during one-shot operation.

The continuous/one-shot block (Figure 12-366) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the ECAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of the ECAP\_CAP1 through ECAP\_CAP4 registers (time-stamps).

Re-arming prepares the ECAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of the ECAP\_CAP1 through ECAP\_CAP4 registers again, providing the ECAP\_ECCTL[8] CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0), the one-shot action is ignored, and capture values continue to be written to the ECAP\_CAP1 through ECAP\_CAP4 registers in a circular buffer sequence.

ecap-008

**Figure 12-366. ECAP Continuous/One-shot Block Diagram**

#### 12.4.1.4.1.1.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via the control ECAP\_ECCTL[8] CAPLDEN bit. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

The ECAP\_CAP1 and ECAP\_CAP2 registers become the active period and compare registers, respectively, in APWM mode.

The ECAP\_CAP3 and ECAP\_CAP4 registers become the respective shadow registers (APRD and ACMP) for the ECAP\_CAP1 and ECAP\_CAP2 registers during APWM operation.

#### 12.4.1.4.1.1.6 ECAP Interrupt Control

An interrupt can be generated on capture events CEVT1 through CEVT4, CNTOVF (see the ECAP\_ECINT\_EN\_FLG[21] CNTOVF\_FLG bit) or APWM events (TSCNT = PRD, TSCNT = CMP). See [Figure 12-368](#).

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the ECAP<sub>n</sub> module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, TSCNT = PRD, TSCNT = CMP) can be generated. The interrupt enable register (ECAP\_ECINT\_EN\_FLG) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECAP\_ECINT\_EN\_FLG) indicates if any interrupt event has been latched and contains the global interrupt flag ECAP\_ECINT\_EN\_FLG[16] INT\_FLG bit. An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1h, and the INT\_FLG flag bit is 0h. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECAP\_ECINT\_CLR\_FRC) before any other interrupt pulses are generated. The interrupt force register (ECAP\_ECINT\_CLR\_FRC) can force an interrupt event. This is useful for test purposes.

#### 12.4.1.4.1.1.7 ECAP Shadow Load and Lockout Control

In capture mode, this logic inhibits (locks out) any shadow loading of the ECAP\_CAP1 or ECAP\_CAP2 registers from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to the ECAP\_CAP1 or ECAP\_CAP2 register immediately upon writing a new value.
- On period equal, CTR[31-0] = PRD[31-0]

#### Note

The CEVT1\_FLG, CEVT2\_FLG, CEVT3\_FLG, CEVT4\_FLG flags are only active in capture mode (ECAP\_ECCTL[25] CAP\_APWM == 0h). The TSCNT = PRD, TSCNT = CMP flags are only valid in APWM mode (ECAP\_ECCTL[25] CAP\_APWM == 1h). CNTOVF\_FLG flag is valid in both modes.

Copyright © 2024 Texas Instruments Incorporated

#### 12.4.1.4.1.2 ECAP APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When the ECAP\_CAP1/ECAP\_CAP2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via the shadow registers - APRD and ACMP (ECAP\_CAP3/ECAP\_CAP4). The shadow register contents are transferred over to ECAP\_CAP1/ECAP\_CAP2 registers either immediately upon a write, or on a TSCNT = PRD trigger.
- In APWM mode, writing to the ECAP\_CAP1/ECAP\_CAP2 active registers will also write the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) will invoke the shadow mode.
- During initialization, software must write the PRD and CMP values to the active registers. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, software should use only shadow registers.

**Figure 12-369. PWM Waveform Details of ECAP APWM Mode Operation**

The behavior of APWM active-high mode (APWMPOL == 0) is:

CMP = 0x00000000, output low for duration of period (0% duty)

CMP = 0x00000001, output high 1 cycle

CMP = 0x00000002, output high 2 cycles

CMP = PERIOD, output high except for 1 cycle (<100% duty)

CMP = PERIOD+1, output high for complete period (100% duty)

CMP > PERIOD+1, output high for complete period

The behavior of APWM active-low mode (APWMPOL == 1) is:

CMP = 0x00000000, output high for duration of period (0% duty)

CMP = 0x00000001, output low 1 cycle

CMP = 0x00000002, output low 2 cycles

CMP = PERIOD, output low except for 1 cycle (<100% duty)

CMP = PERIOD+1, output low for complete period (100% duty)

CMP > PERIOD+1, output low for complete period

#### 12.4.1.4.2 Summary of ECAP Functional Registers

[Table 12-408](#) shows the ECAP module control and status register set. All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode.

#### Note

In APWM mode, writing to the ECAP\_CAP1/ECAP\_CAP2 active registers also writes the same value to the corresponding shadow registers (ECAP\_CAP3/ECAP\_CAP4). This emulates immediate mode. Writing to the shadow registers (ECAP\_CAP3/ECAP\_CAP4) invokes the shadow mode.

**Table 12-408. ECAP Control and Status Functional Registers**

Offset	Register Name	Description	Size (×16)
0h	ECAP_TSCNT	Time-Stamp Counter Register	2
4h	ECAP_CNTPHS	Counter Phase Offset Value Register	2
8h	ECAP_CAP1	Capture 1 Register	2
Ch	ECAP_CAP2	Capture 2 Register	2
10h	ECAP_CAP3	Capture 3 Register	2
14h	ECAP_CAP4	Capture 4 Register	2
28h	ECAP_ECCTL	Capture Control Register	2
2Ch	ECAP_ECINT_EN_FLG	Capture Interrupt Enable and Flag Register	2
30h	ECAP_ECINT_CLR_FRC	Capture Interrupt Clear and Forcing Register	2
5Ch	ECAP_PID	Revision ID Register	2

#### Note

For more information on the ECAP registers, see *ECAP Registers*.

### 12.4.1.5 ECAP Use Cases

The following sections will provide applications examples and code snippets to show how to configure and operate the ECAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//=====
// CAPXPOL bits
#define EC_RISING           0x0
#define EC_FALLING         0x1
// CTRRSTx bits
#define EC_ABS_MODE        0x0
#define EC_DELTA_MODE      0x1
// PRESCALE bits
#define EC_BYPASS          0x0
#define EC_DIV1            0x0
#define EC_DIV2            0x1
#define EC_DIV4            0x2
#define EC_DIV6            0x3
#define EC_DIV8            0x4
#define EC_DIV10           0x5
// ECCTL2 ( ECAP Control Reg 2)
//=====
// CONT/ONESHOT bit
#define EC_CONTINUOUS       0x0
#define EC_ONESHOT         0x1
// STOPVALUE bit
#define EC_EVENT1          0x0
#define EC_EVENT2          0x1
#define EC_EVENT3          0x2
#define EC_EVENT4          0x3
// RE-ARM bit
#define EC_ARM              0x1
// TSCTRSTOP bit
#define EC_FREEZE          0x0
#define EC_RUN              0x1
// SYNC0_SEL bit
#define EC_SYNCIN          0x0
#define EC_CTR_PRD         0x1
#define EC_SYNC0_DIS       0x2
// CAP/APWM mode bit
#define EC_CAP_MODE        0x0
#define EC_APWM_MODE       0x1
// APWMPOL bit
#define EC_ACTV_HI         0x0
#define EC_ACTV_LO         0x1
// Generic
#define EC_DISABLE          0x0
#define EC_ENABLE          0x1
#define EC_FORCE            0x1
```

#### 12.4.1.5.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 12-370 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 12-370), if this occurs, the CNTOVF\_FLG (counter overflow) flag is set, and an interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4-th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAP $n$  registers.

**Figure 12-370. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect**

**Table 12-409. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS

ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-1. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;      // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;      // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;      // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;      // Fetch Time-Stamp captured at t4
Period1 = TSt2-TSt1;         // Calculate 1st period
Period2 = TSt3-TSt2;         // Calculate 2nd period
Period3 = TSt4-TSt3;         // Calculate 3rd period
```

#### 12.4.1.5.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 12-371 the ECAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 =  $t_3 - t_1$ , Period2 =  $t_5 - t_3$ , ...etc. Duty Cycle1 (on-time %) =  $(t_2 - t_1) / \text{Period1} \times 100\%$ , etc. Duty Cycle1 (off-time %) =  $(t_3 - t_2) / \text{Period1} \times 100\%$ , etc.

Figure 12-371. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect

**Table 12-410. ECAP Initialization for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-2. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger**

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers
// Run Time ( e.g. CEVT4 triggered ISR call)
//=====
TSt1 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at t1
TSt2 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at t2
TSt3 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at t3
TSt4 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at t4
Period1 = TSt3-TSt1;      // Calculate 1st period
DutyOnTime1 = TSt2-TSt1;   // Calculate On time
DutyOffTime1 = TSt3-TSt2;  // Calculate Off time
```

#### 12.4.1.5.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 12-372 shows how the ECAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CNTOVF\_FLG (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAP<sub>n</sub> contents directly give timing data without the need for CPU calculations: Period1 = T<sub>1</sub>, Period2 = T<sub>2</sub>,...etc. As shown in Figure 12-372, the CEVT1 event is a good trigger point to read the timing data, T<sub>1</sub>, T<sub>2</sub>, T<sub>3</sub>, T<sub>4</sub> are all valid here.

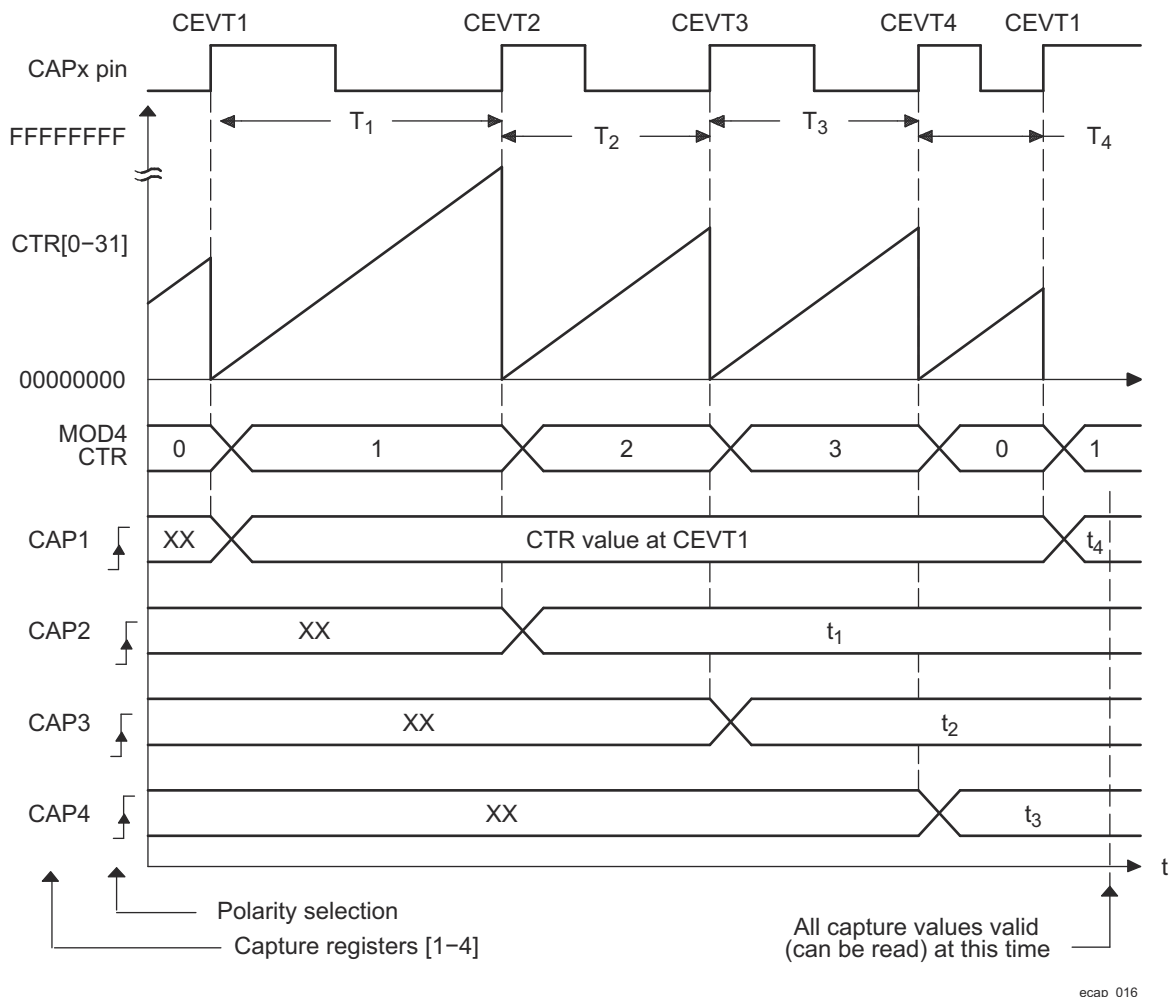

Figure 12-372. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect

**Table 12-411. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

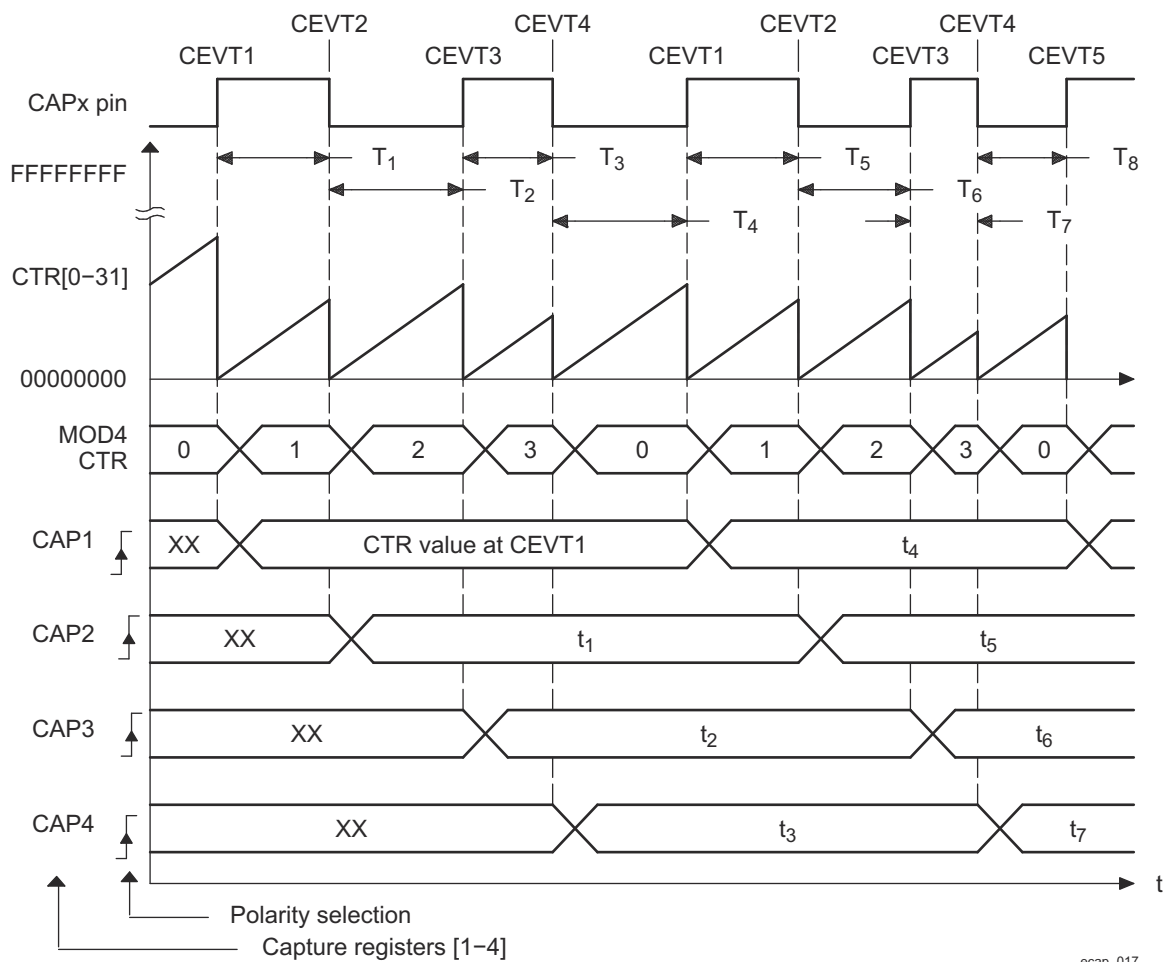

**Example 12-3. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger**

```
// Code snippet for CAP mode Delta Time, Rising edge trigger
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Period value.
Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
```

#### 12.4.1.5.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 12-373 the ECAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 =  $T_1 + T_2$ , Period2 =  $T_3 + T_4$ , ...etc Duty Cycle1 (on-time %) =  $T_1 / \text{Period1} \times 100\%$ , etc Duty Cycle1 (off-time %) =  $T_2 / \text{Period1} \times 100\%$ , etc.

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

**Figure 12-373. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect**

**Table 12-412. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers**

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCl_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-4. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers**

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers
// Run Time ( e.g. CEVT1 triggered ISR call)
//=====
// Note: here Time-stamp directly represents the Duty cycle values.
DutyOnTime1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
DutyOffTime1 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
DutyOnTime2 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
DutyOffTime2 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
Period1 = DutyOnTime1 + DutyOffTime1;
Period2 = DutyOnTime2 + DutyOffTime2;
```

### 12.4.1.5.5 Application of the APWM Mode

#### 12.4.1.5.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the ECAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM $n$ . The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

**Figure 12-374. PWM Waveform Details of APWM Mode Operation**

**Table 12-413. ECAP Initialization for APWM Mode**

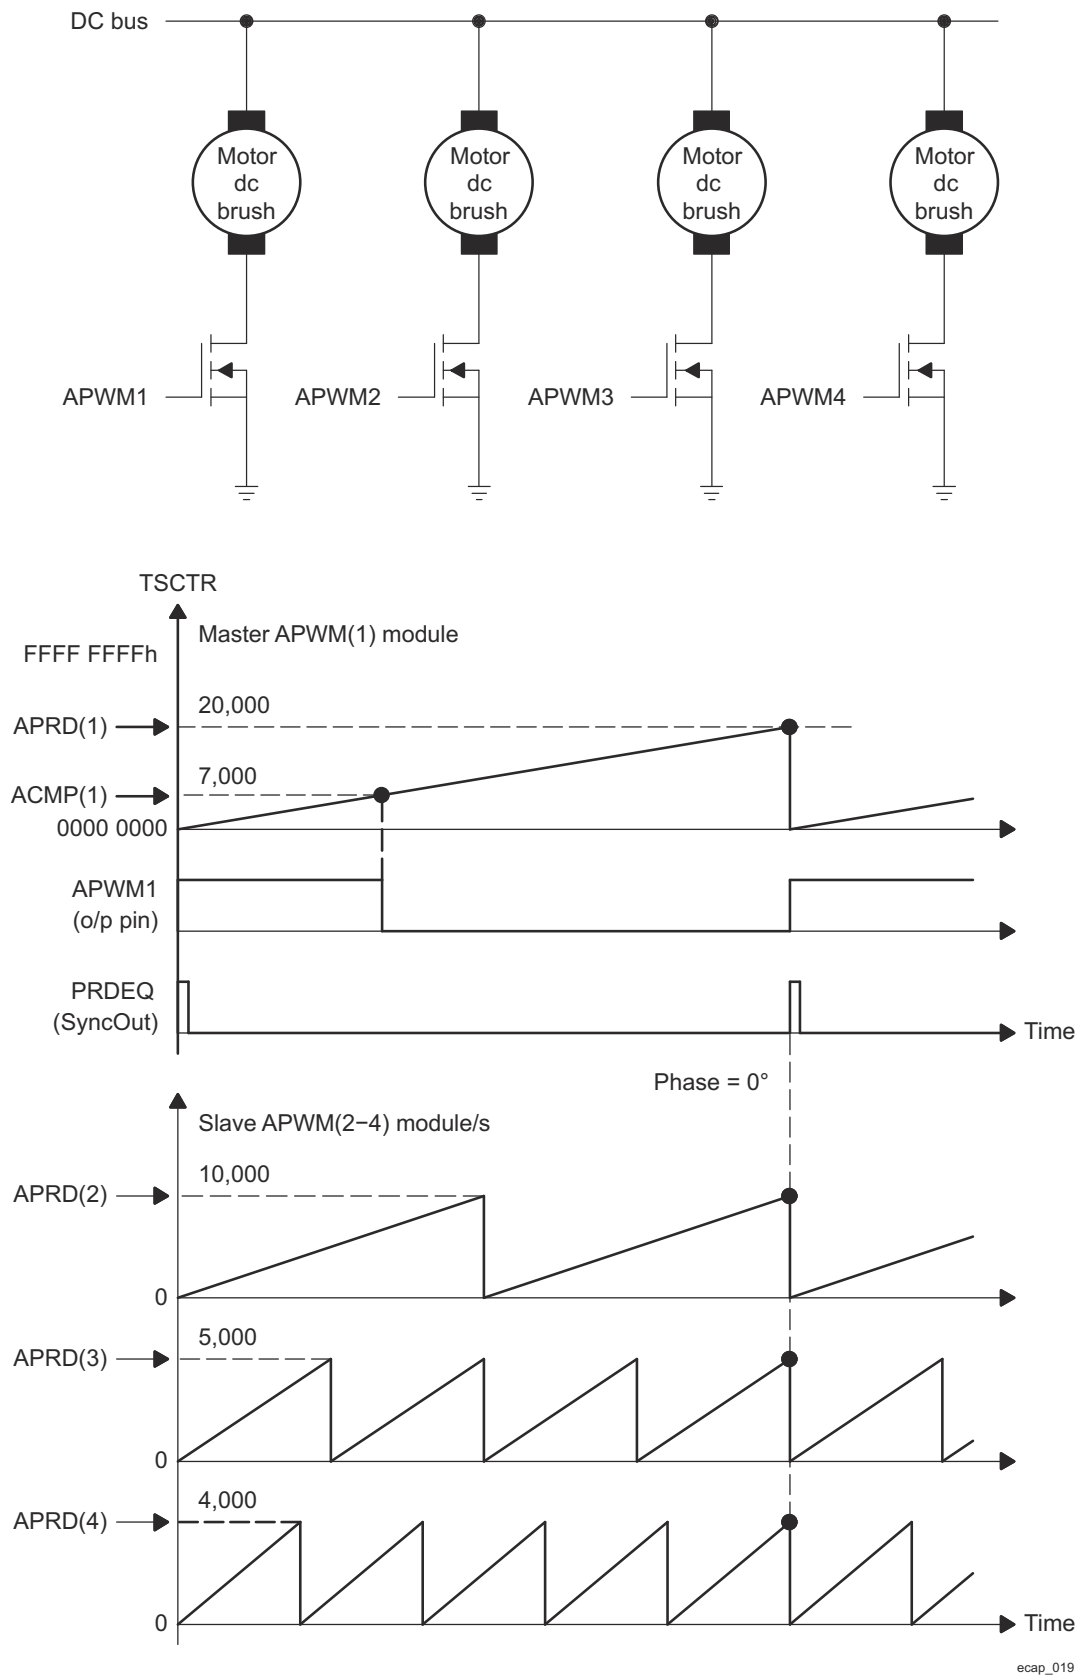

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCL_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-5. Code Snippet for APWM Mode**

```
// Code snippet for APWM mode Example 1
// Run Time (Instant 1, e.g. ISR call)
//=====
ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value
// Run Time (Instant 2, e.g. another ISR call)
//=====
ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

**12.4.1.5.5.2 Multichannel PWM Generation with Synchronization Example**

Figure 12-375 takes advantage of the synchronization feature between the ECAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one ECAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency ( $F1 = 1/20,000$ ) requirement. Here Slave2 Freq =  $2 \times F1$ , Slave3 Freq =  $4 \times F1$  and Slave4 Freq =  $5 \times F1$ . Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

**Figure 12-375. Multichannel PWM Example Using 4 ECAP Modules**

**Table 12-414. ECAP1 Initialization for Multichannel PWM Generation with Synchronization**

Register	Bit	Value

ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCl_EN	EC_ENABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

**Example 12-6. Code Snippet for Multichannel PWM Generation with Synchronization**

```
// Code snippet for APWM mode Example 2
// Run Time (Note: Example execution of one run-time instant)
//=====
ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

#### 12.4.1.5.5.3 Multichannel PWM Generation with Phase Control Example

In [Figure 12-376](#), the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by  $120^\circ$  from each other. Hence if "Leg" 1 (controlled by APWM1) is the reference Leg (or phase), that is,  $0^\circ$ , then Leg 2 need  $120^\circ$  off-set and Leg 3 needs  $240^\circ$  off-set. The waveforms in [Figure 12-376](#) show the timing relationship between each of the phases (Legs). Note ECAP1 module is the Master and issues a SyncOut pulse to the slaves (modules 2, 3) whenever  $TSCTR = \text{Period value}$ .

**Figure 12-376. Multiphase (channel) Interleaved PWM Example Using 3 ECAP Modules**

**Example 12-7. Code Snippet for Multichannel PWM Generation with Phase Control**

```
// Code snippet for APWM mode Example 3
// Run Time (Note: Example execution of one run-time instant)
//=====
// All phases are set to the same duty cycle
ECAP1Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP2Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
ECAP3Regs.CAP2 = 700;    // Set Duty cycle i.e. compare value = 700
```

**12.4.2 Enhanced Pulse Width Modulation (EPWM) Module**

This chapter describes the Enhanced PWM (EPWM) module in the device.

**12.4.2.1 EPWM Overview**

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The EPWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the EPWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In the further description the letter x within a signal or module name is used to indicate a generic EPWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the EPWMx instance. Thus, EPWM1A and EPWM1B belong to EPWM1, EPWM2A and EPWM2B belong to EPWM2, and so forth.

The EPWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given EPWM module functionality can be extended with the so called **High-Resolution Pulse Width Modulator**. Refer to the [Section 12.4.2.3](#), to determine which EPWM instances include the HRPWM feature. The HRPWM functionalities are described in [Section 12.4.2.4.9](#).

As also described in [Section 12.4.2.3.2](#), the EPWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the EPWM integration allows this synchronization scheme to be extended to the capture peripheral modules (ECAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

The device has six instances of the EPWM modules.

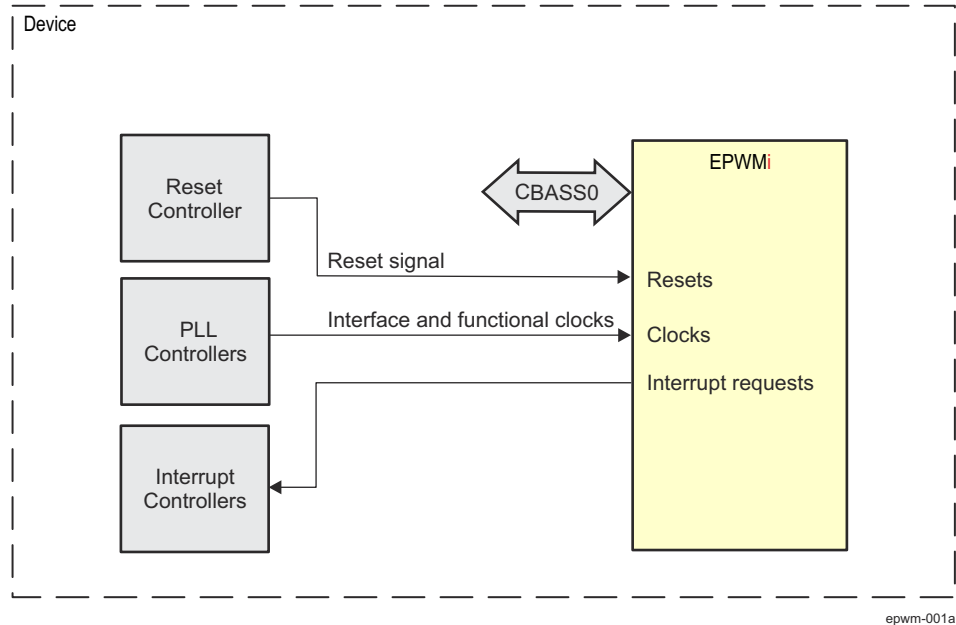

[Table 12-421](#) shows the EPWM allocation across device domains.

**Table 12-421. EPWM Allocation Across Device Domains**

Instance	Domain

**Figure 12-377. EPWM Overview**

#### 12.4.2.1.1 EPWM Features

Each EPWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software
- Programmable phase-control support for lag or lead operation relative to other EPWM modules
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Allows events to trigger both CPU interrupts and ADC start of conversions
- Programmable event prescaling minimizes CPU overhead on interrupts
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives
- High-resolution module with programmable delay line:
  - Programmable on a per PWM period basis
  - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all.

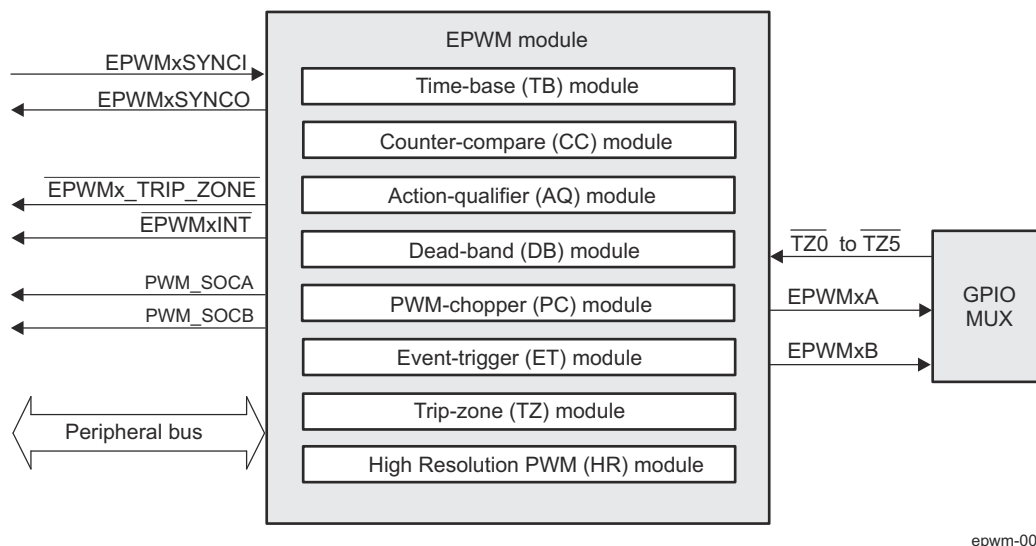

Each EPWM module is connected to the input/output signals shown in [Figure 12-378](#). The signals are described in detail in subsequent sections.

The order in which the EPWM modules are connected may differ from what is shown in [Figure 12-378](#). See *Daisy-Chain Connectivity between EPWM Modules* for the actual synchronization scheme implemented in the device. Each EPWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 12-379](#).

epwm-001

**Figure 12-378. Multiple EPWM Modules**

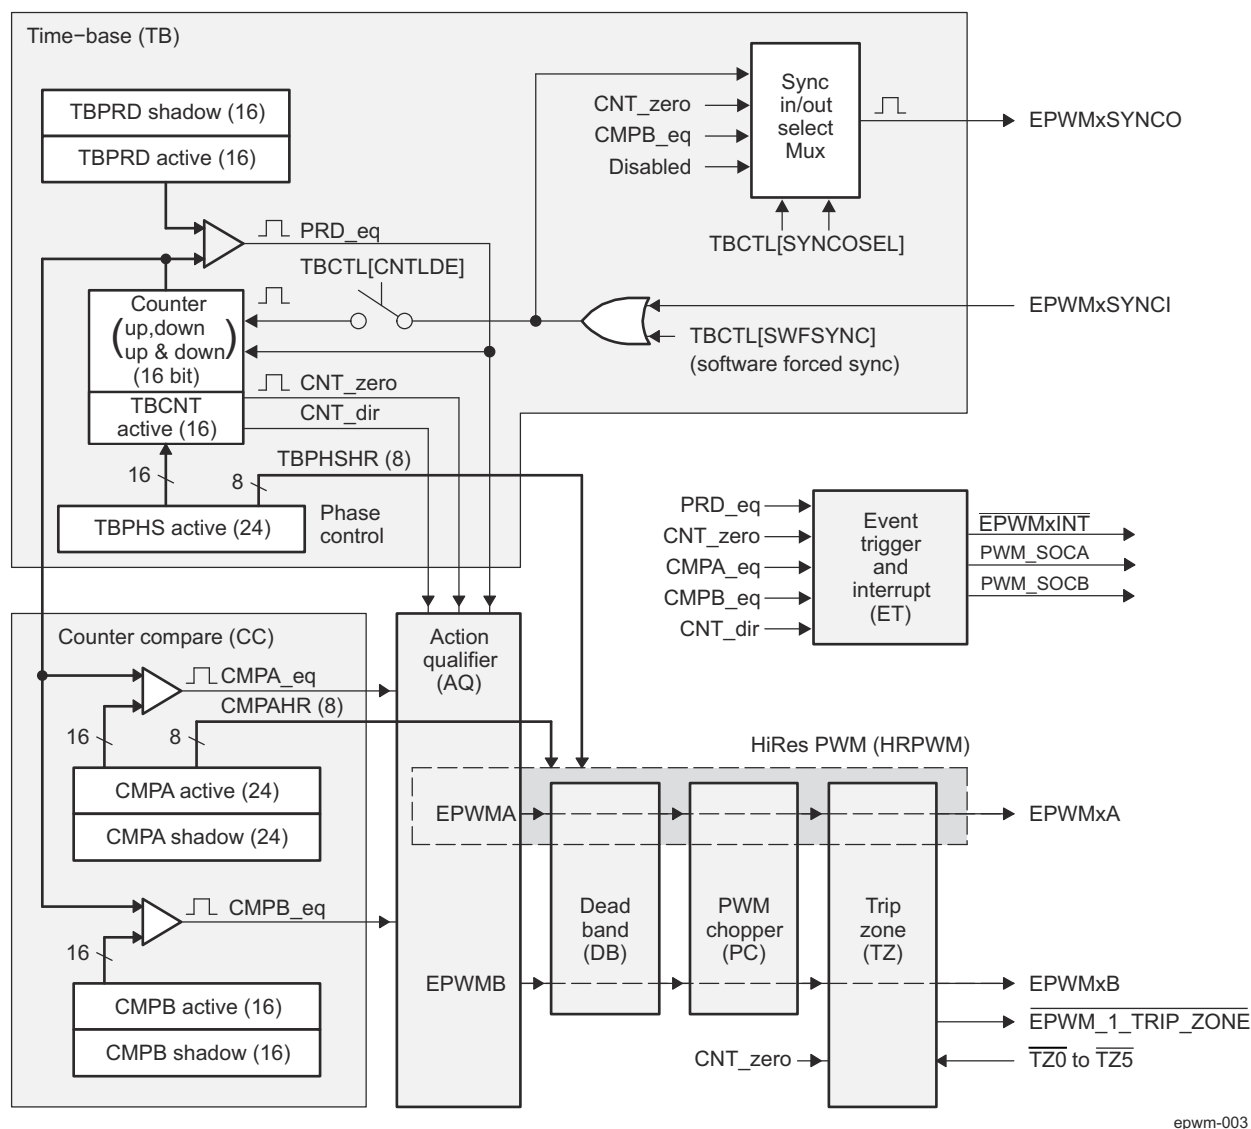

**Figure 12-379. Submodules and Signal Connections for an EPWM Module**

Figure 12-380 shows more internal details of a single EPWM module. The main signals used by the EPWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for the device.
- **Trip-zone signals (TZ0 to TZ5).** These input signals alert the EPWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the EPWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins for EPWM0 (EPWM module 0) and EPWM3. The EPWM5 synchronization output (EPWM5SYNCO) is also connected to the input SYNCIN of the Enhanced Capture Module (ECAP0).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).** Each EPWM module has two ADC start of conversion signals (one for each sequencer). Any EPWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the EPWM.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the EPWM register file.

Figure 12-380 also shows the key internal submodule interconnect signals. Each submodule is described in Section 12.4.2.4.

**Figure 12-380. EPWM Submodules and Critical Internal Signal Interconnects**

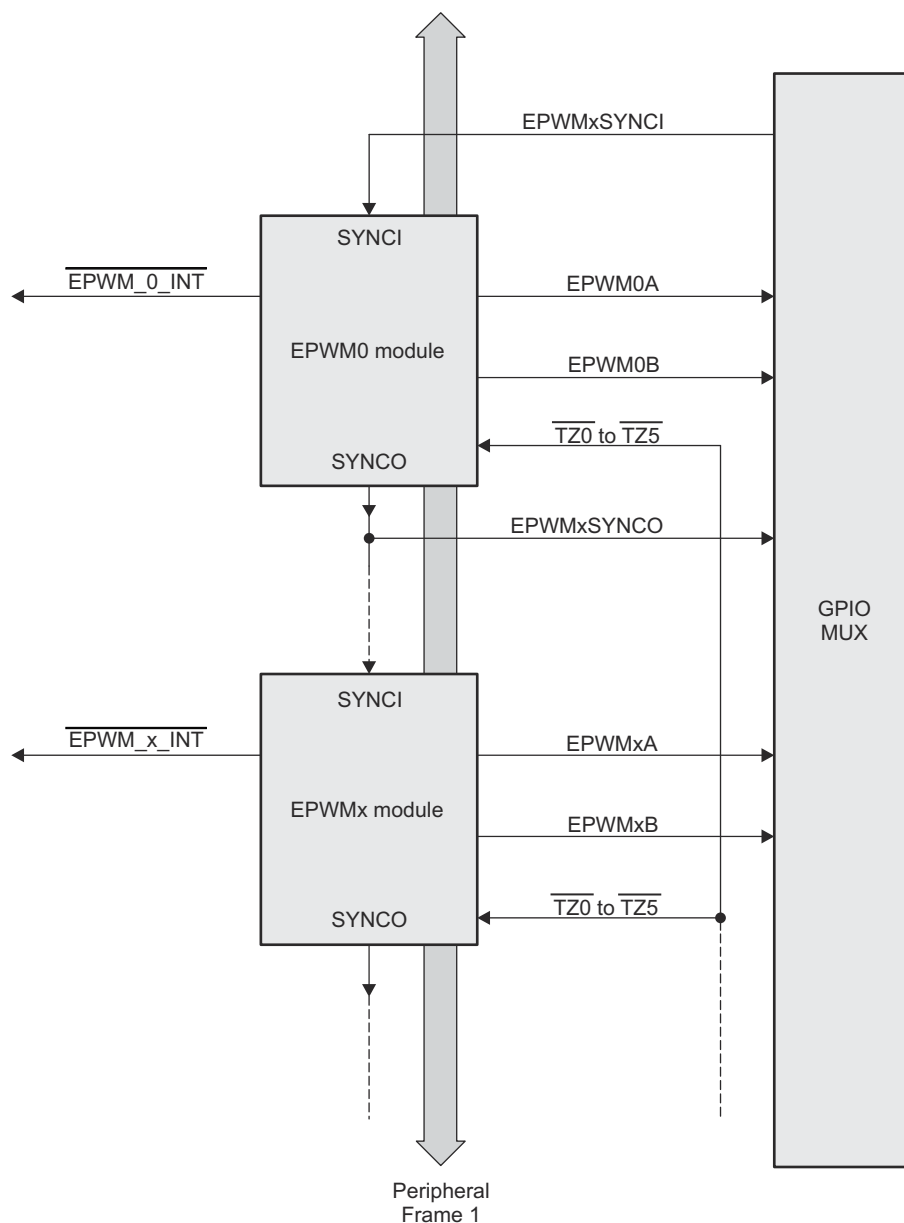

#### 12.4.2.1.2 EPWM Not Supported Features

- EPWM digital comparator modules are not supported

#### 12.4.2.1.3

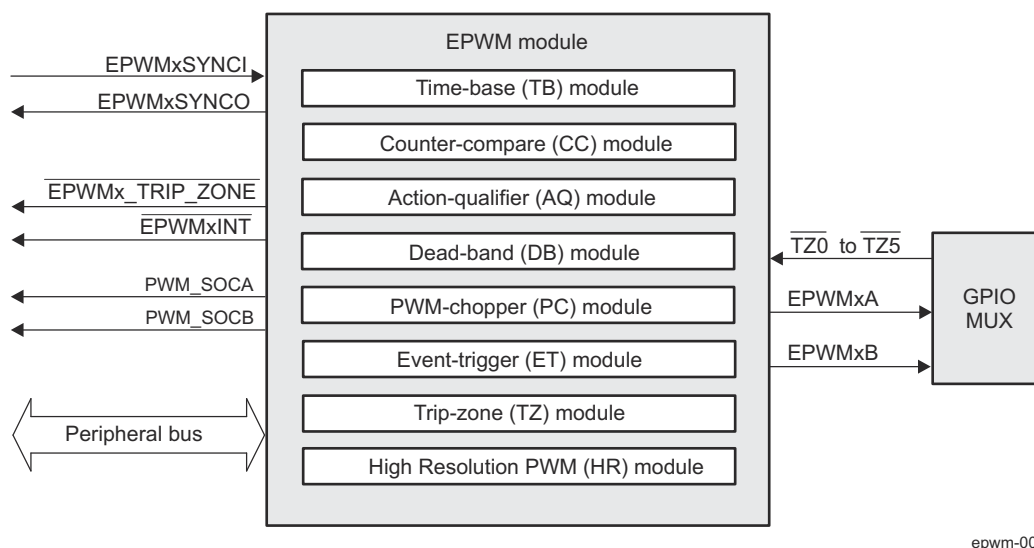

Each EPWM module is connected to the input/output signals shown in [Figure 12-381](#). The signals are described in detail in subsequent sections.

The order in which the EPWM modules are connected may differ from what is shown in [Figure 12-381](#). See [Section 12.4.2.3.2](#) for the actual synchronization scheme implemented in the device. Each EPWM module consists of eight submodules and is connected within a system via the signals shown in [Figure 12-382](#).

### Figure 12-381. Multiple EPWM Modules

epwm-001

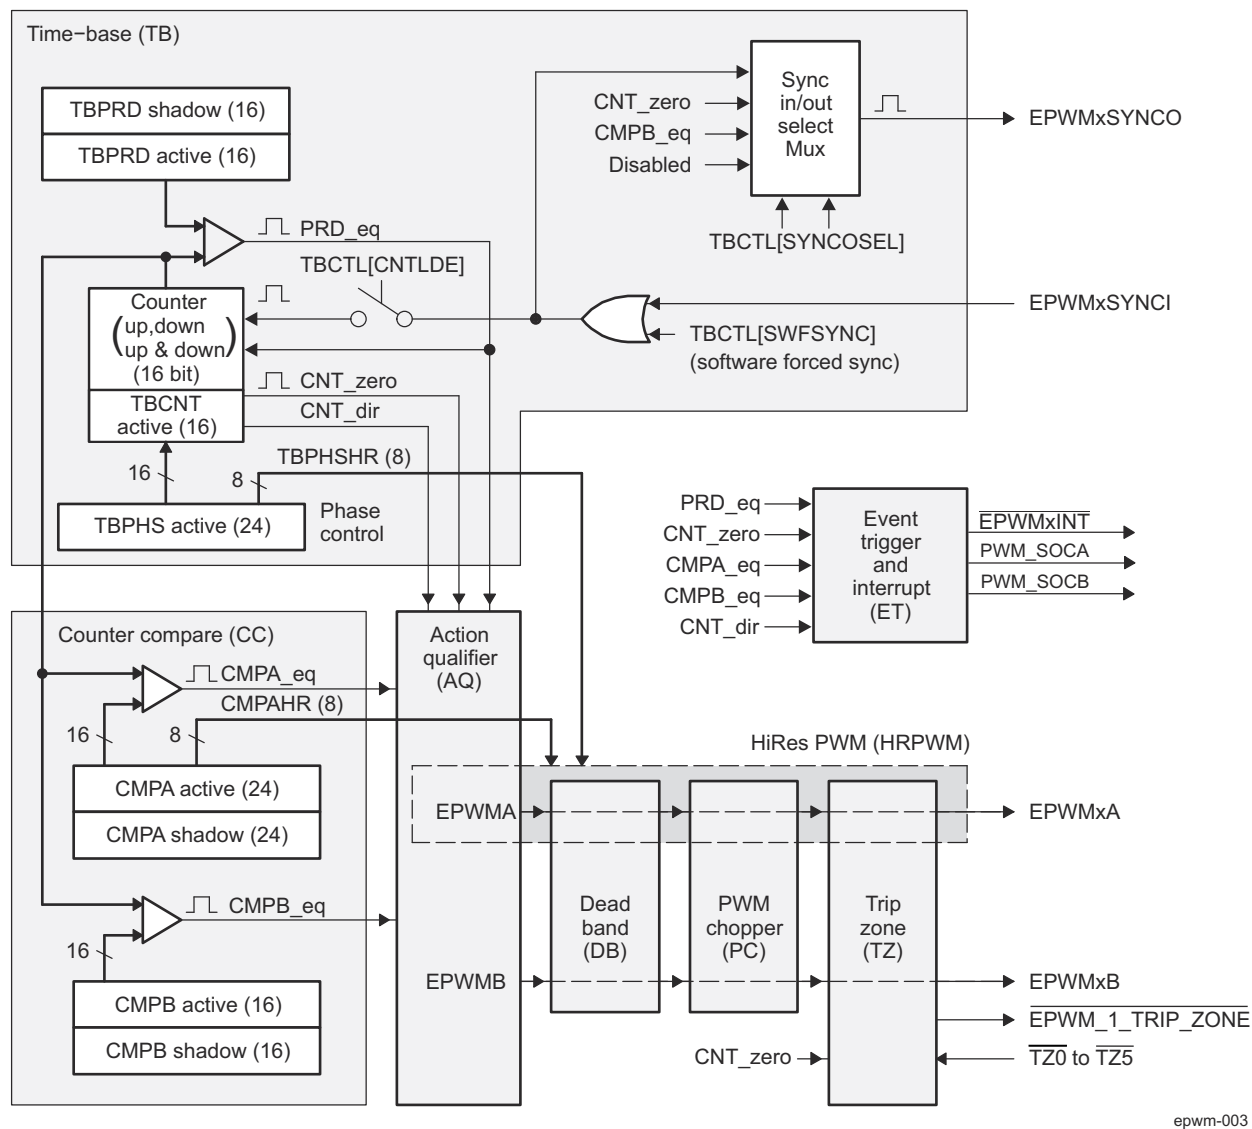

epwm-002

**Figure 12-382. Submodules and Signal Connections for an EPWM Module**

Figure 12-383 shows more internal details of a single EPWM module. The main signals used by the EPWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for the device.
- **Trip-zone signals (TZ0 to TZ5).** These input signals alert the EPWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.
- **Time-base synchronization input (EPWMxSYNCl) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the EPWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins for EPWM0 (EPWM module 0) and EPWM3. The EPWM5 synchronization output (EPWM5SYNCO) is also connected to the input SYNCIN of the Enhanced Capture Module (ECAP0).
- **ADC start-of-conversion signals (EPWMxSOCA and EPWMxSOCB).** Each EPWM module has two ADC start of conversion signals (one for each sequencer). Any EPWM module can trigger a start of conversion for either sequencer. Which event triggers the start of conversion is configured in the Event-Trigger submodule of the EPWM.
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the EPWM register file.

Figure 12-383 also shows the key internal submodule interconnect signals. Each submodule is described in Section 12.4.2.4.

PWM_SOC_A	EHRPWM_SOC_A	O	EPWM start of conversion output A	OZ
PWM_SOC_B	EHRPWM_SOC_B	O	EPWM start of conversion output B	OZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

### 12.4.2.3 EPWM Integration

This section describes the EPWM module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 12-385](#) shows the EPWM integration.

There are 6 instances of the EPWM integrated in the device. Each of the Enhanced Pulse Width Modulator (EPWM) includes an Enhanced High Resolution Modulator (eHRPWM).

The high-resolution functionality is implemented only on the EPWMxA output. EPWMxB output has conventional PWM capabilities.

At system level the EPWM0 through EPWM5 integration features are listed below:

- A 32-bit slave configuration port on the CBASS0 interconnect
- A single functional clock from PLLCTRL0 shared between all 5 EPWM modules
- 2 hardware events per EPWM, that is a total of 12 events. From these events each EPWM:
  - generates 2 interrupts to the device COMPUTE\_CLUSTER0, PRU\_ICSSG0\_INTC, PRU\_ICSSG1\_INTC and MAIN2MCU\_INTRTR\_PLS
- A synchronization input/output daisy chain-like connection exists between the EPWM0 through EPWM5. For more details, refer to [Section 12.4.2.3.2, Daisy-Chain Connectivity between EPWM Modules](#).

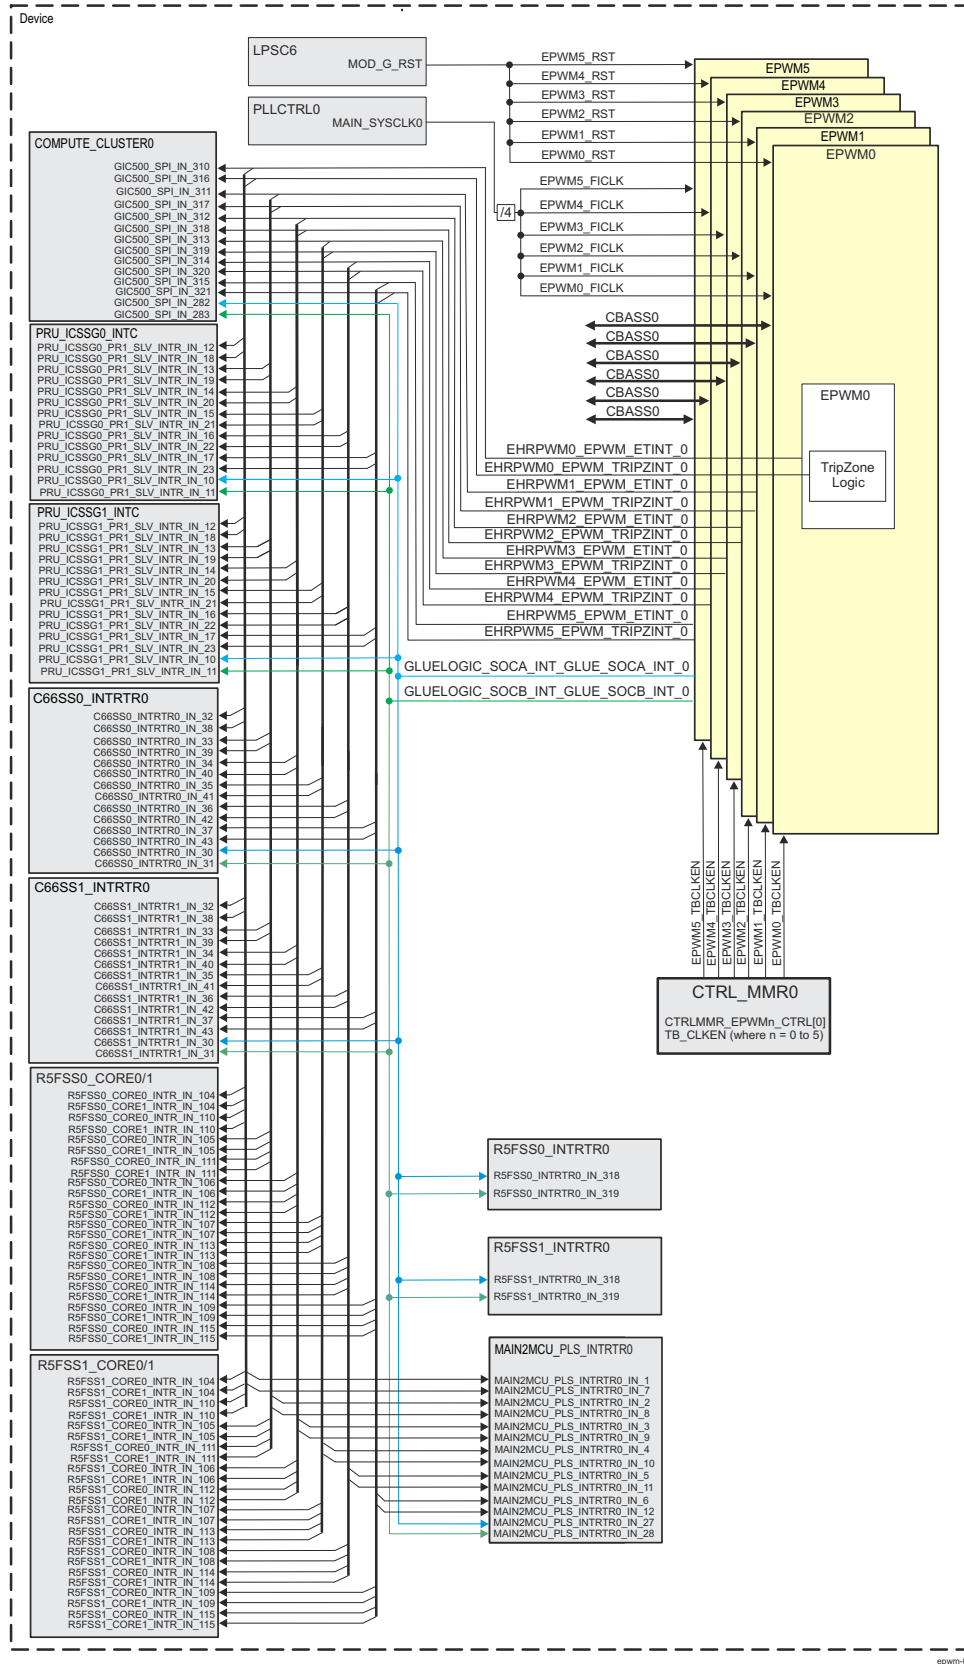

Figure 12-385. EPWM Integration

Table 12-423 through Table 12-425 summarize the integration of the module in the device.

**Table 12-423. EPWM Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

#### 12.4.2.3.1 Device Specific EPWM Features

A High-Resolution PWM (HRPWM) modulator is added to each of the device EPWM modules.

---

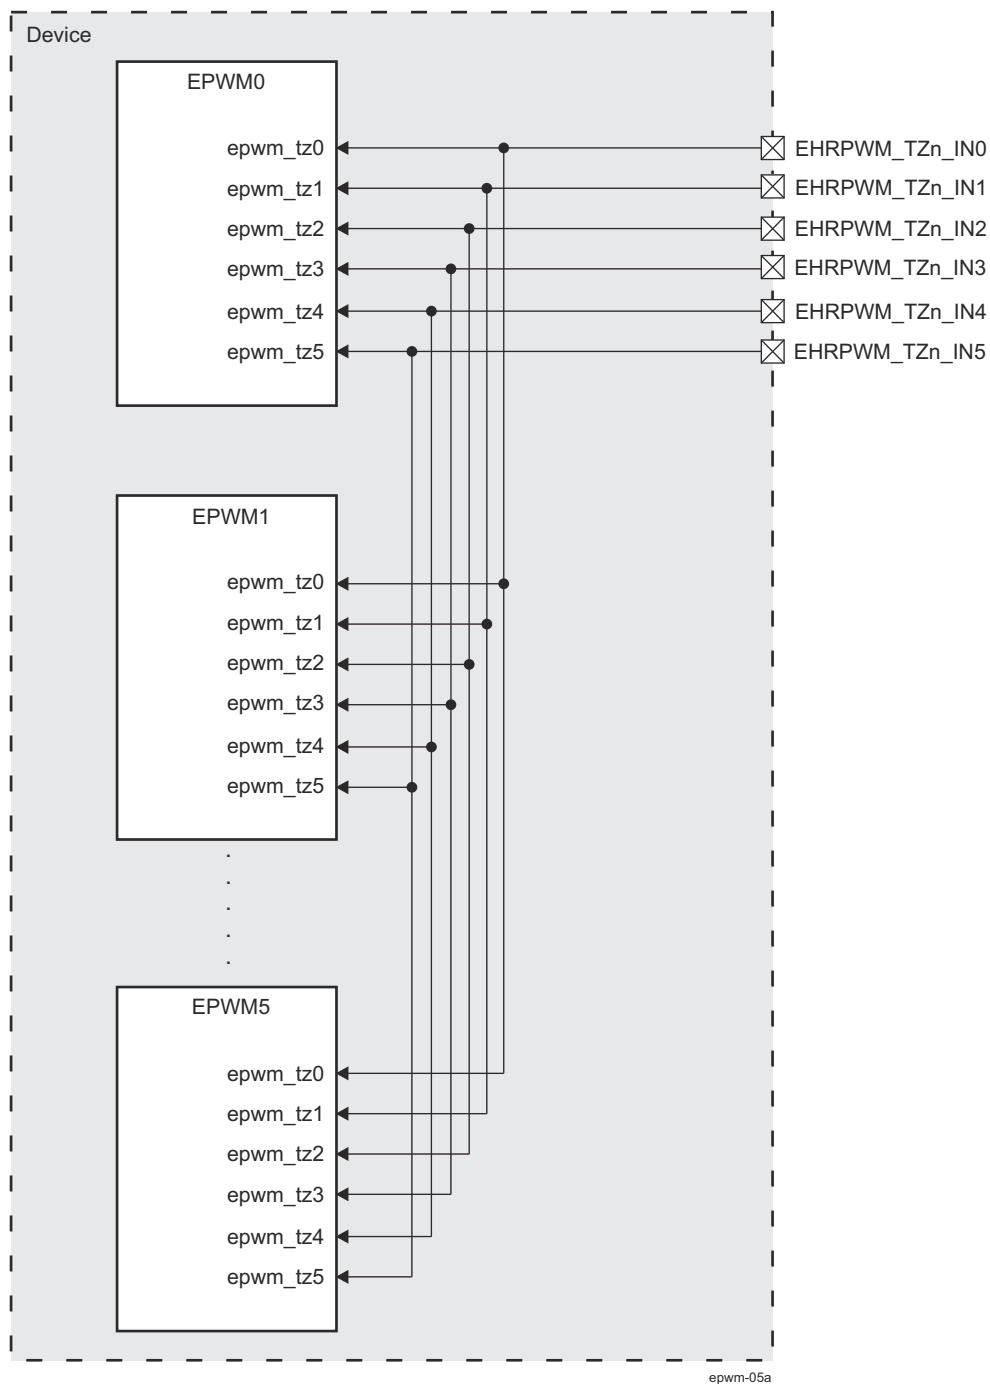

##### Note

The HRPWM option applies only to the EPWMxA output channel. The EPWMxB channel has conventional capabilities. For more details on HRPWM features of EPWM modules refer to the [Section 12.4.2.4.9](#).

---

The EPWM module interface has some restrictions in functionality as listed below:

- **For EPWM comparators — only the outputs (ehrpwmxA and ehripwmxB, where x = 0 to 5) are available at chip level**
- **Each EPWM supports 6 tripzone event inputs and each of those inputs from all six of the EPWMs are tied to a common tripzone\_input pin so that any EPWM can be triggered by any of the six tripzone inputs as shown in [Figure 12-386](#).**

**Figure 12-386. EPWM Tripzone Connectivity Detail**

The EPWM functional interface signals which are NOT available to user are summarized in [Table 12-426](#).

**Table 12-426. Device Limitations for the EPWM Functional Interfaces**

Module Interface	Signal	Description	Comment
<b>EPWM_n</b> (where n = 0 to 5 for the device)	EPWM_COMP_EPWMDCMAH	EPWM Comparator A input (HIGH)	Not available at chip boundary (can not be used)
	EPWM_COMP_EPWMDCMAL	EPWM Comparator A input (LOW)	
	EPWM_COMP_EPWMDCMBH	EPWM Comparator B input (HIGH)	
	EPWM_COMP_EPWMDCMBL	EPWM Comparator B input (LOW)	
	EPWM_TRIP_TZ_O[5:0]	EPWM Tripzone outputs	
	EPWM_TRIP_TZ_OEN[5:0]	EPWM Tripzone outputs enable	

### Note

Only the SYNCI input and SYNCO output signals of EPWM0 and EPWM3 modules are available at chip-level. Respective names of the signals are: EHRPWM0\_SYNCI and EHRPWM0\_SYNCO (for EPWM0) and EHRPWM3\_SYNCI and EHRPWM3\_SYNCO (for EPWM3). For more information, see [Section 12.4.2.2, EPWM Environment](#).

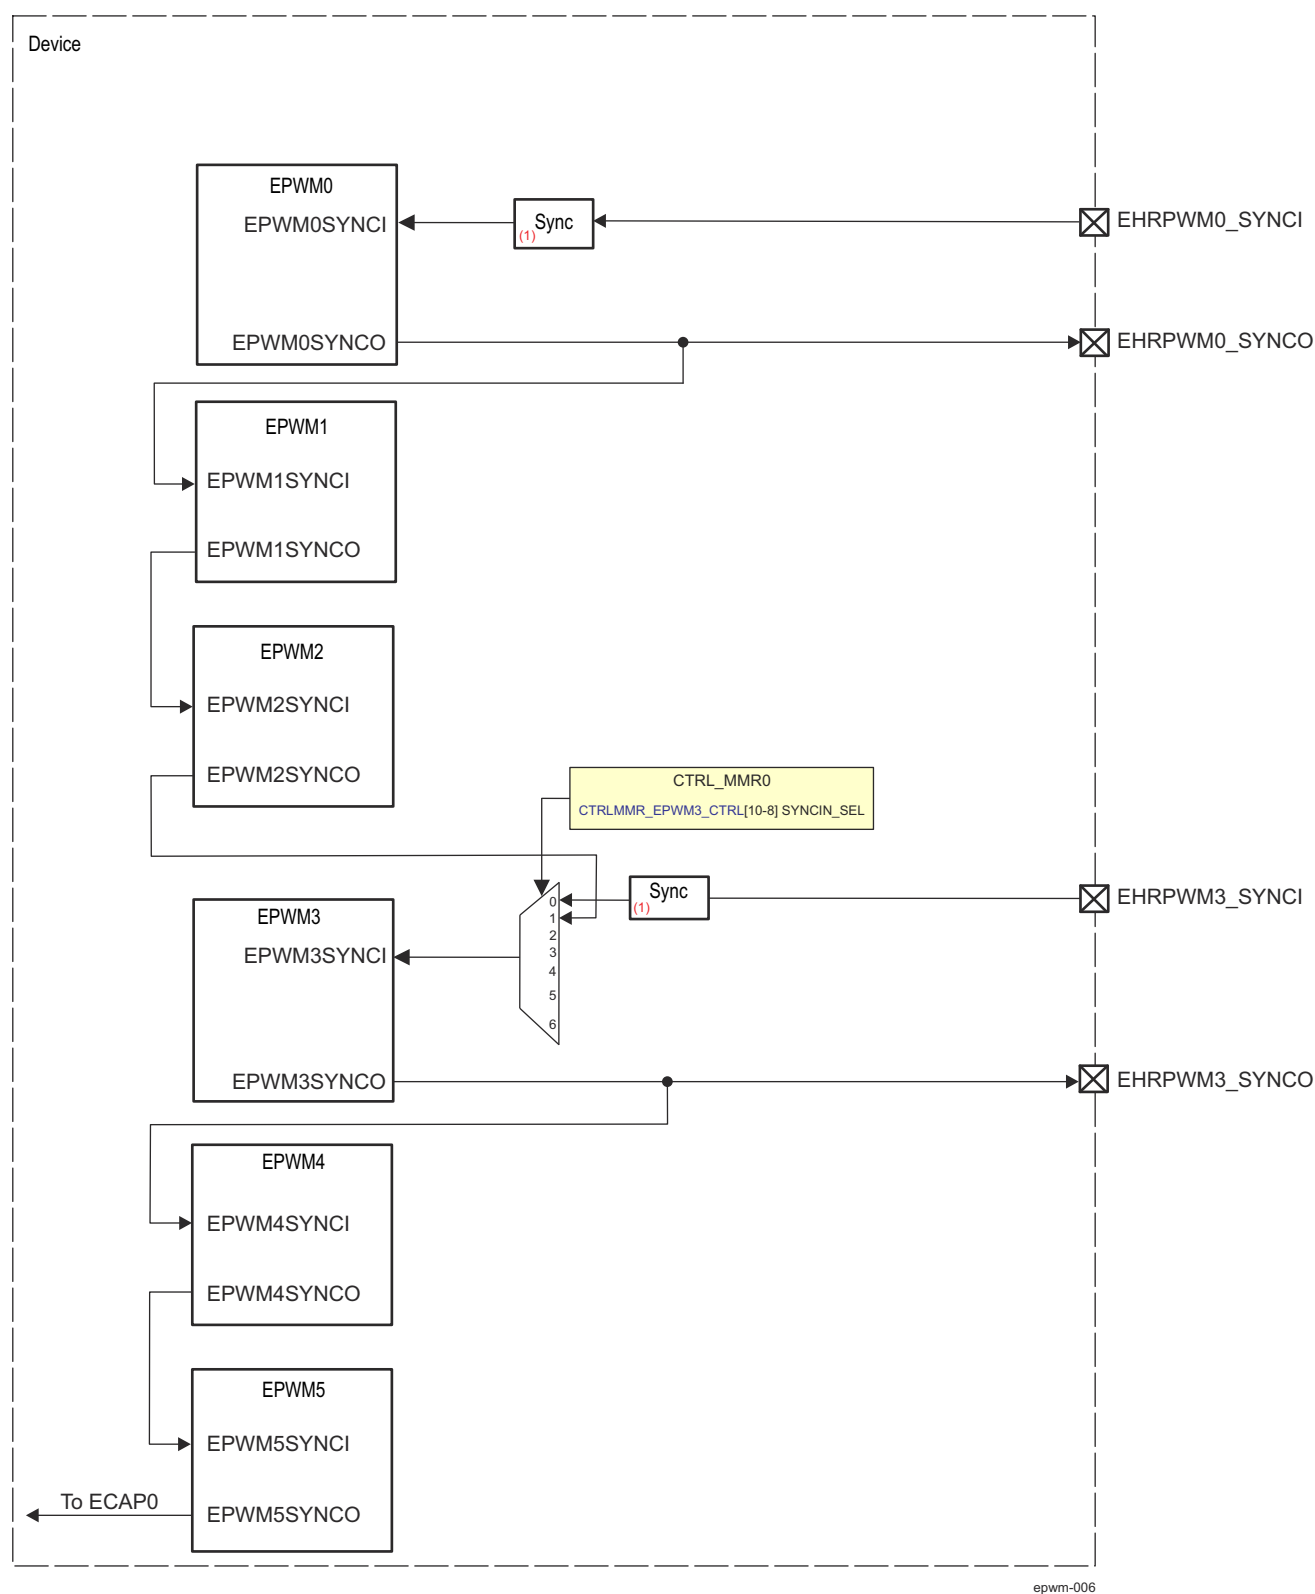

#### 12.4.2.3.2 Daisy-Chain Connectivity between EPWM Modules

For synchronization to other modules or events EPWMs are provided with synchronization signals. In the device, these signals are connected in a daisy-chain fashion as shown in [Figure 12-387](#). The EPWM0 input synchronization signal is terminated at a device pad (EHRPWM0\_SYNCI signal), such that device external sync events can be directly applied only to the EPWM0 submodule. Additionally, the EPWM0 input synchronization scheme can be extended through PRU\_ICSSG Host interrupts (ICSSG\_n\_HOST\_INT6, where n = 0 to 1), routed through device PRU\_ICSSG modules. The EPWM3 through EPWM5 modules can be synchronized either from a separate external signal on the EHRPWM3\_SYNCI pin or from EPWM2 output synchronization signal. Additionally, the EPWM3 input synchronization scheme can be extended through PRU\_ICSSG Host interrupts (ICSSG\_n\_HOST\_INT7, where n = 0 to 1). The EPWM3 input synchronization signal is selected using the corresponding SYNCIN\_SEL bit field of the CTRLMMR\_EPWM3\_CTRL register in the CTRL\_MMR0 module. A synchronization output is available from the EPWM0 on the EHRPWM0\_SYNCO output pin and from EPWM3 on the EHRPWM3\_SYNCO pin. PWM0\_SYNC\_OUT and PWM3\_SYNC\_OUT output events are internally routed to the Interrupt Controllers (INTC) for each of the PRU\_ICSSG modules in this device.

#### Note

The EPWM0 EPWM0SYNCI signal (device EHRPWM0\_SYNCI input signal) triggers the event of the EPWM0 Phase Register being loaded into the Counter register (TBPHS -> TBCNT). This event is synchronous to the EPWM0 **time-base clock** (TBCLK).

The EPWM0 EPWM0SYNCO (device EHRPWM0\_SYNCO output signal) is implicitly synchronous to the time-base clock, as this signal has a programmable source of event (in the EPWM\_TBCTL[5-4] SYNCOSSEL bit field) triggered synchronously to the EPWM0 TBCLK.

**Figure 12-387. Daisy-Chain Connectivity between EPWM Modules**

---

**Note**

The EPWM0SYNCl and EPWM3SYNCl inputs of EPWM0 and EPWM3 modules can be connected to one of several external event sources. These sources must be synchronized to the EPWM clock domain to prevent propagation of metastable state. A synchronizer (signified with (1) Sync of the figure above) has been implemented in the path to resolve this potential issue. However, the synchronizer inserts a delay which may need to be accounted in some applications of the EPWM module.

---

#### 12.4.2.3.3 ADC start of conversion signals (PWM\_SOCA and PWM\_SOCB)

Each EPWM module provides start of conversion events (PWM\_SOCA and PWM\_SOCB), that can be used to start conversion of external ADC module. In this device all PWM\_SOCA and all PWM\_SOCB events are ORed together and hence any of the 6 EPWMs can initiate an ADC start of conversion. These events are then multiplexed with an PRU\_ICSSG[0-1] host interrupts (ICSSG\_x\_HOST\_INTn, where x = 0 to 1 and n = 1 or 2), allowing either PRU\_ICSSG[0-1] or EPWM0 through EPWM5 modules to trigger the PWM\_SOCA/PWM\_SOCB event pins (EHRPWM\_SOCA and EHRPWM\_SOCB). The PWM\_SOCA and PWM\_SOCB event output signals are also routed back to the PRU\_ICSSGn (where n = 0 to 1) modules as interrupts as shown in [Figure 12-388](#)

---

#### Note

ICSSG\_x\_HOST\_INTn (where x = 0 to 1 and n = 1 or 2) interrupts are mapped to Host-3 and Host-4 of the PRU\_ICSSG Interrupt Controller.

---

**Figure 12-388. Interconnectivity of ADC start of conversion**

#### 12.4.2.3.4 EPWM Modules Time Base Clock Gating

Each EPWM module has an EPWMTBCLKEN module input used to individually **enable / disable its EPWM time-base clock**. The EPWM time-base clock enable input comes from the EPWMn\_CTRL (where n = 0 to 5) register in CTRL\_MMR0 module, as follows:

- EPWM0 -> CTRLMMR\_EPWM0\_CTRL[0] TB\_CLKEN bit
- EPWM1 -> CTRLMMR\_EPWM1\_CTRL[0] TB\_CLKEN bit
- EPWM2 -> CTRLMMR\_EPWM2\_CTRL[0] TB\_CLKEN bit
- EPWM3 -> CTRLMMR\_EPWM3\_CTRL[0] TB\_CLKEN bit
- EPWM4 -> CTRLMMR\_EPWM4\_CTRL[0] TB\_CLKEN bit
- EPWM5 -> CTRLMMR\_EPWM5\_CTRL[0] TB\_CLKEN bit.

This individual TBCLKEN control can be used to align the EPWM time base clock. TB\_CLKEN bit set to 0h, holds the TBCLK generation counter in its reset state. When TB\_CLKEN is set to 1h, then the TBCLK generation counter is allowed to count.

#### 12.4.2.4 EPWM Functional Description

8 submodules are included in each EPWM peripheral. Each of these submodules performs specific tasks that can be configured by software.

##### 12.4.2.4.1 EPWM Submodule Features

[Table 12-427](#) lists the eight key submodules together with a list of their main configuration parameters.

**Table 12-427. Submodule Configuration Parameters**

Submodule	Configuration Parameter or Option
Time-base (TB)	<ul style="list-style-type: none"> <li>Scale the time-base clock (TBCLK) relative to the system clock (FICLK).</li> <li>Configure the PWM time-base counter (TBCNT) frequency or period.</li> <li>Time-base counter mode selection: <ul style="list-style-type: none"> <li>count-up mode: used for asymmetric PWM</li> <li>count-down mode: used for asymmetric PWM</li> <li>count-up-and-down mode: used for symmetric PWM</li> </ul> </li> <li>Configure the time-base phase relative to another EPWM module.</li> <li>Synchronize the time-base counter between modules through hardware or software.</li> <li>Configure the direction (up or down) of the time-base counter after a synchronization event.</li> <li>Configure how the time-base counter will behave when the device is halted by an emulator.</li> <li>Specify the source for the synchronization output of the EPWM module: <ul style="list-style-type: none"> <li>Synchronization input signal</li> <li>Time-base counter equal to zero</li> <li>Time-base counter equal to counter-compare B (CMPB)</li> <li>No output synchronization signal generated</li> </ul> </li> </ul>
Counter-compare (CC)	<ul style="list-style-type: none"> <li>Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB</li> <li>Specify the time at which switching events occur on the EPWMxA or EPWMxB output</li> </ul>
Action-qualifier (AQ)	<ul style="list-style-type: none"> <li>Specify the type of action taken when a time-base or counter-compare submodule event occurs: <ul style="list-style-type: none"> <li>No action taken</li> <li>Output EPWMxA and/or EPWMxB switched high</li> <li>Output EPWMxA and/or EPWMxB switched low</li> <li>Output EPWMxA and/or EPWMxB toggled</li> </ul> </li> <li>Force the PWM output state through software control</li> <li>Configure and control the PWM dead-band through software</li> </ul>
Dead-band (DB)	<ul style="list-style-type: none"> <li>Control of traditional complementary dead-band relationship between upper and lower switches</li> <li>Specify the output rising-edge-delay value</li> <li>Specify the output falling-edge delay value</li> <li>Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification</li> </ul>
PWM-chopper (PC)	<ul style="list-style-type: none"> <li>Create a chopping (carrier) frequency</li> <li>Pulse width of the first pulse in the chopped pulse train</li> <li>Duty cycle of the second and subsequent pulses</li> <li>Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.</li> </ul>

**Table 12-427. Submodule Configuration Parameters (continued)**

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	<ul style="list-style-type: none"> <li>Configure the EPWM module to react to one, all, or none of the trip-zone pins</li> <li>Specify the tripping action taken when a fault occurs: <ul style="list-style-type: none"> <li>Force EPWMxA and/or EPWMxB high</li> <li>Force EPWMxA and/or EPWMxB low</li> <li>Force EPWMxA and/or EPWMxB to a high-impedance state</li> <li>Configure EPWMxA and/or EPWMxB to ignore any trip condition</li> </ul> </li> <li>Configure how often the EPWM will react to the trip-zone pin: <ul style="list-style-type: none"> <li>One-shot</li> <li>Cycle-by-cycle</li> </ul> </li> <li>Enable the trip-zone to initiate an interrupt</li> <li>Bypass the trip-zone module entirely</li> </ul>
Event-trigger (ET)	<ul style="list-style-type: none"> <li>Enable the EPWM events that will trigger an interrupt.</li> <li>Specify the rate at which events cause triggers (every occurrence or every second or third occurrence)</li> <li>Poll, set, or clear event flags</li> </ul>
High-Resolution PWM (HRPWM)	<ul style="list-style-type: none"> <li>Enable extended time resolution capabilities</li> <li>Configure finer time granularity control or edge positioning</li> </ul>

Some examples on various EPWM module configurations are shown below. These examples use the constant definitions shown in [Example 12-8](#).

#### 12.4.2.4.2 EPWM Time-Base (TB) Submodule

This section describes the Time-Base (TB) submodule in the PWM module.

##### 12.4.2.4.2.1 Overview

Each EPWM module has its own time-base submodule that determines all of the timing events. Built-in synchronization logic allows the time-base of multiple EPWM modules (EPWMx) to work together as a single system. [Figure 12-389](#) illustrates the time-base module's place within the EPWM.

**Figure 12-389. EPWM Time-Base Submodule**

The TB module generates the period (or frequency) of the PWM output waveforms and consists of a 16-bit counter that can be configured for up, down or up and down counting. The time base for the counter is a pre-scaled version of the system clock (FICLK/n) which can be programmed for a pre-scale of 1, that is same as system clock.

TB module features:

- Specify the EPWMx time-base counter (TBCNT) frequency or period in the EPWM\_TBCNT register to control how often events occur.
- Manage time-base synchronization with other EPWMx modules.
- Maintain a phase relationship with other EPWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - PRD\_eq (Time-base counter (EPWM\_TBCNT register) equal to the specified period in EPWM\_TBPRD register (that is TBCNT = TBPRD)).
  - CNT\_zero (Time-base counter equal to zero (TBCNT = 0000h)).
- Configure the rate of the time-base clock; a prescaled version of the CPU m clock (FICLK). This allows the time-base counter to increment/decrement at a slower rate.

##### 12.4.2.4.2.2 Controlling and Monitoring the EPWM Time-Base Submodule

[Table 12-428](#) lists the registers used to control and monitor the time-base submodule.

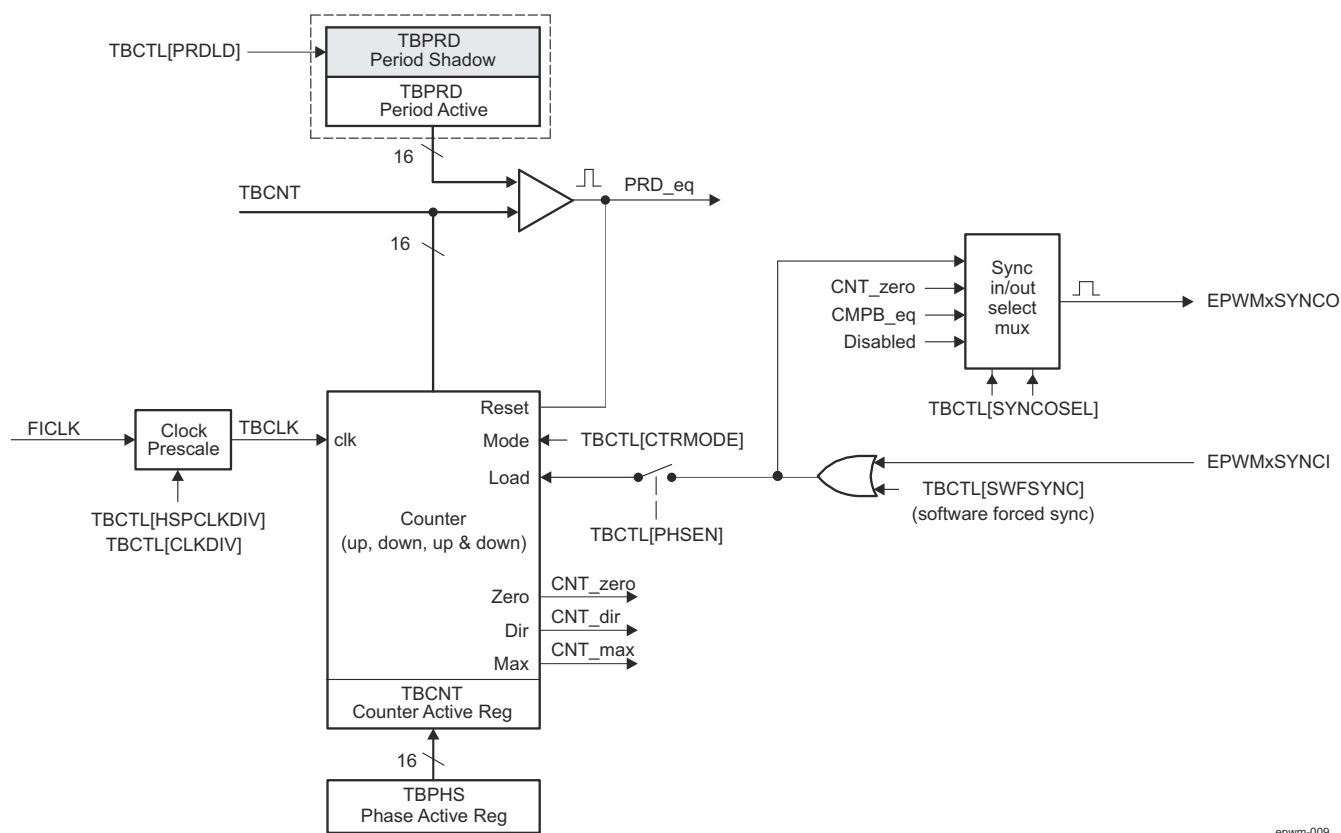

### Table 12-428. EPWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register <sup>(1)</sup>	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

- (1) This register is available only on EPWM instances that include the high-resolution extension (HRPWM). On EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

Figure 12-390 shows the critical signals and registers of the time-base submodule. Table 12-429 provides descriptions of the key signals associated with the time-base submodule.

### Figure 12-390. EPWM Time-Base Submodule Signals and Registers

### Table 12-429. EPWM Time-Base Submodule Key Signals

Signal	Description
EPWMxSYNCl	Time-base synchronization input.  Input pulse used to synchronize the time-base counter with the counter of another EPWM module earlier in the synchronization chain. An EPWM peripheral can be configured to use or ignore this signal. For the first EPWM module (EPWM0) this signal comes from a device pin. For subsequent EPWM modules this signal is passed from another EPWM peripheral. For example, EPWM2SYNCl is generated by the EPWM1 peripheral and the EPWM3SYNCl is generated (optional through internal multiplexer) by EPWM2 or from a device pin. See <a href="#">Section 12.4.2.4.2.3.2</a> for information on the synchronization order of a particular device.

**Table 12-429. EPWM Time-Base Submodule Key Signals (continued)**

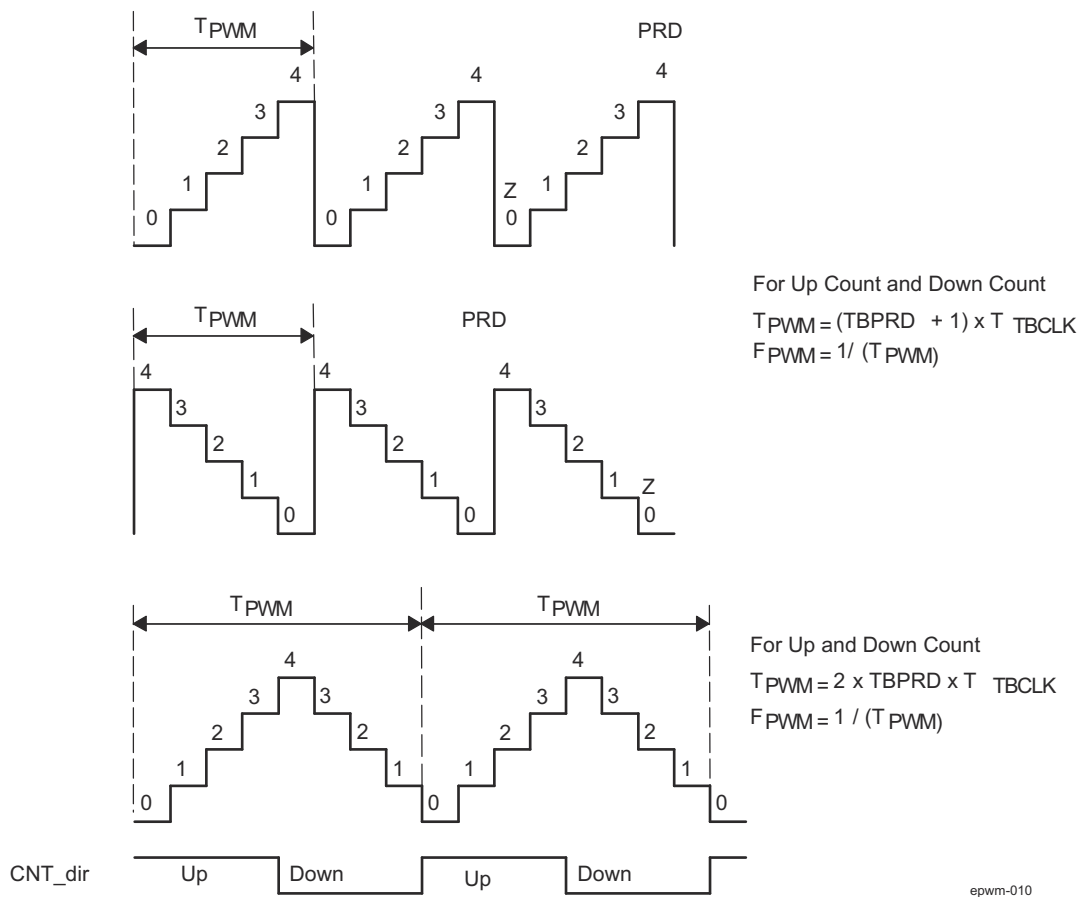

Signal	Description
EPWMxSYNCO	Time-base synchronization output.  This output pulse is used to synchronize the counter of an EPWM module later in the synchronization chain. The EPWM module generates this signal from one of three event sources: <ol style="list-style-type: none"> <li>1. EPWMxSYNCl (Synchronization input pulse)</li> <li>2. TBCNT = 0: The time-base counter (EPWM_TBCNT register) equal to zero (TBCNT = 0000h).</li> <li>3. TBCNT = CMPB: The time-base counter (EPWM_TBCNT register) equal to the counter-compare B register — EPWM_CMPB (that is bitfield TBCNT = bitfield CMPB).</li> </ol>
PRD_eq	Time-base counter equal to the specified period.  This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CNT_zero	Time-base counter equal to zero.  This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CMPB_eq	Time-base counter equal to active counter-compare B register (TBCNT = CMPB).  This event is generated by the counter-compare submodule and used by the synchronization out logic.
CNT_dir	Time-base counter direction.  Indicates the current direction of the EPWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CNT_max	Time-base counter equal max value (TBCNT = FFFFh).  Generated event when the EPWM_TBCNT register value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock.  This is a prescaled version of the system clock — FICLK and is used by all submodules within the EPWMn. This clock determines the rate at which time-base counter increments or decrements.

#### 12.4.2.4.2.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period register (EPWM\_TBPRD) and the mode of the time-base counter. [Figure 12-391](#) shows the period ( $T_{pwm}$ ) and frequency ( $F_{pwm}$ ) relationships for the up-count, down-count, and up-down-count time-base counter modes when the period is set to 4 (EPWM\_TBPRD[15:0] TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (FICLK).

The time-base counter has three modes of operation selected by the time-base control register (EPWM\_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset back to the period value and it repeats this pattern.

**Figure 12-391. EPWM Time-Base Frequency and Period**

#### 12.4.2.4.2.3.1 EPWM Time-Base Period Shadow Register

The time-base period register (EPWM\_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the EPWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM\_TBCTL[3] PRDL bit. This bit enables and disables the EPWM\_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM\_TBPRD shadow register is enabled when EPWM\_TBCTL[3] PRDL = 0h. Reads from and writes to the EPWM\_TBPRD register memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM\_TBPRD (Active) ← EPWM\_TBPRD (shadow)) when the time-base counter register (EPWM\_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM\_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM\_TBCTL[3] PRDL = 1h), then a read from or a write to the TBPRD memory address goes directly to the active register.

#### 12.4.2.4.2.3.2 EPWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the EPWM modules on a device. Each EPWM module has a synchronization input (EPWMxSYNCl) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (EPWM0) comes from an external pin. For the device EPWM environment sync pin details refer to *EPWM Environment*. The possible synchronization connections for the remaining EPWM modules is shown in [Figure 12-392](#).

epwm-011

**Figure 12-392. EPWM Time-Base Counter Synchronization Scheme 1**

Each EPWM module can be configured to use or ignore the synchronization input. If the EPWM\_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the EPWM module (EPWM\_TBCNT register) will be automatically loaded with the phase register (EPWM\_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCl: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM\_TBPHS → EPWM\_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1h to the EPWM\_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCl.

This feature enables the EPWM module to be automatically synchronized to the time base of another EPWM module. Lead or lag phase control can be added to the waveforms generated by different EPWM modules to synchronize them. In up-down-count mode, the EPWM\_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See [Figure 12-393](#) through [Figure 12-396](#) for examples.

Clearing the EPWM\_TBCTL[2] PHSEN bit configures the EPWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other EPWM modules. In this way, a controller time-base (for example, EPWM1) and downstream modules (EPWM2–EPWMx) can be set and they may select to run in synchronization with the controller.

#### 12.4.2.4.2.4 Phase Locking the Time-Base Clocks of Multiple EPWM Modules

As already described in *EPWM Modules Time-Base Clock Gating*, TB\_CLKEN bit in the EPWMn\_CTRL (where n = 0 to 5) register of the device CTRL\_MMR0 can be used to individually control or globally synchronize the time-base clocks of all enabled EPWM modules on a device. When all TB\_CLKEN bits are set to 0b0, the

time-base clocks of all EPWMx (where x = 0 to 5) modules are stopped (default). When all TB\_CLKEN bits are simultaneously set in software to 0b1, all EPWMx modules time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM\_TBCTL register of each EPWM module must be set identically. The proper procedure for enabling the EPWM clocks is as follows:

1. Enable the EPWM module clocks.
2. Set TB\_CLKEN = 0. This will stop the time-base clock within any enabled EPWMx module.
3. Configure the prescaler values and desired EPWM modes per each involved EPWMx.
4. Simultaneously set TB\_CLKEN bits to 0b1.

#### 12.4.2.4.2.5 EPWM Time-Base Counter Modes and Timing Waveforms

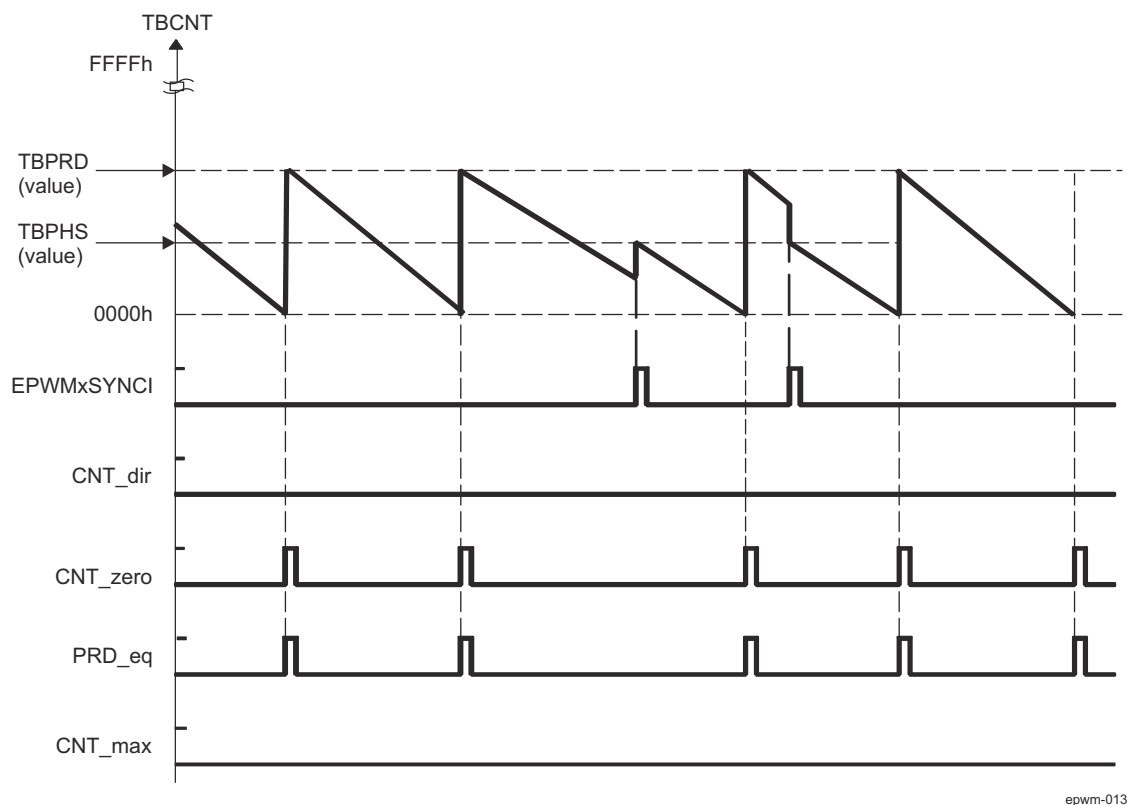

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

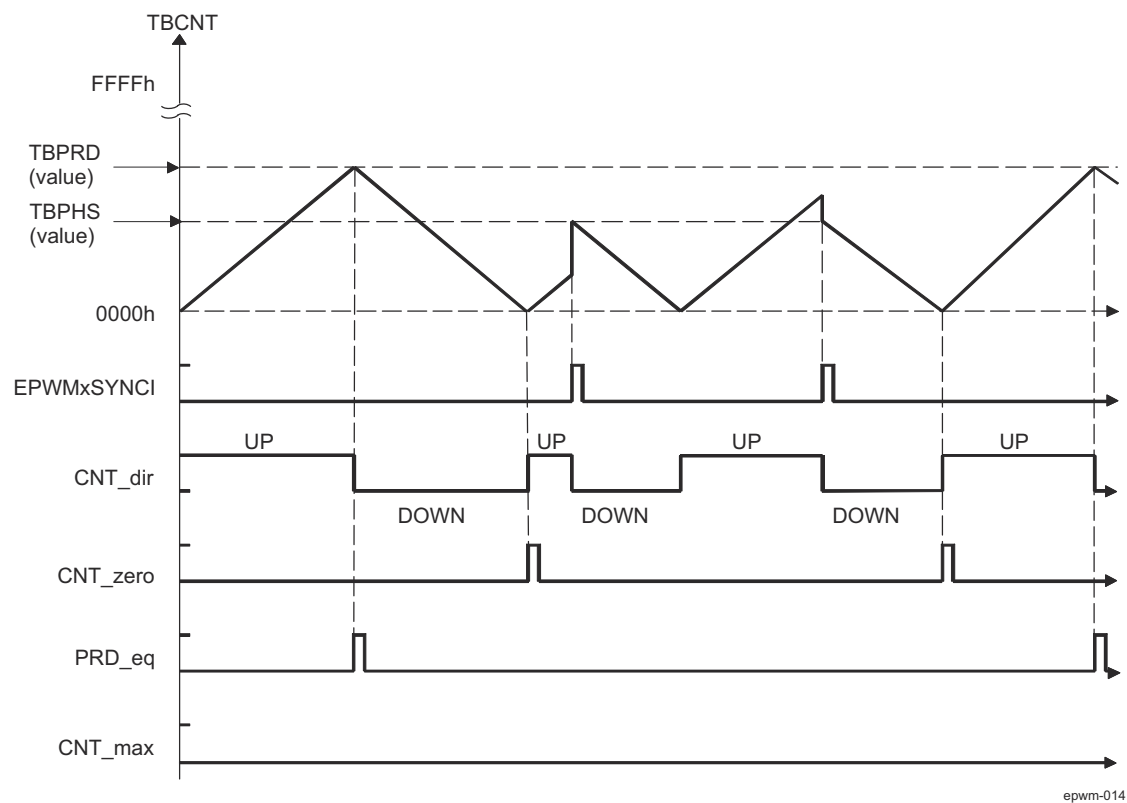

To illustrate the operation of the first three modes, [Figure 12-393](#) to [Figure 12-396](#) show when events are generated and how the time-base responds to an EPWMxSYNCl signal.

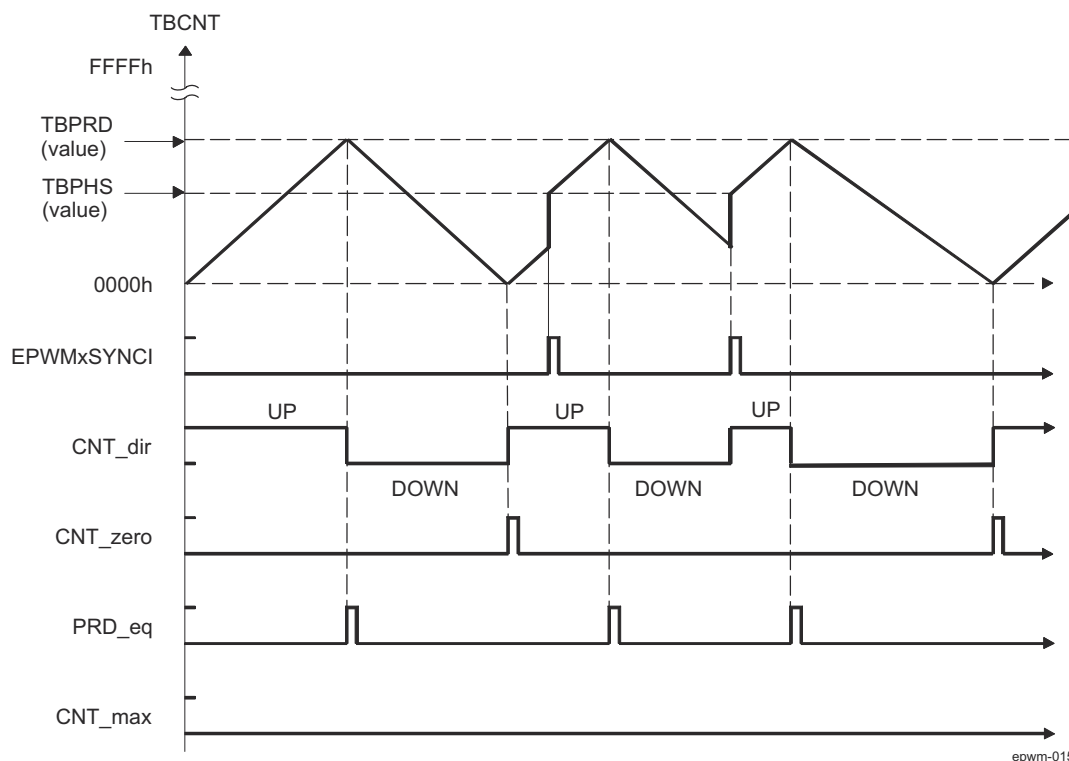

**Figure 12-393. EPWM Time-Base Up-Count Mode Waveforms**

**Figure 12-394. EPWM Time-Base Down-Count Mode Waveforms**

**Figure 12-395. EPWM Time-Base Up-Down-Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 0 Count Down on Synchronization Event**

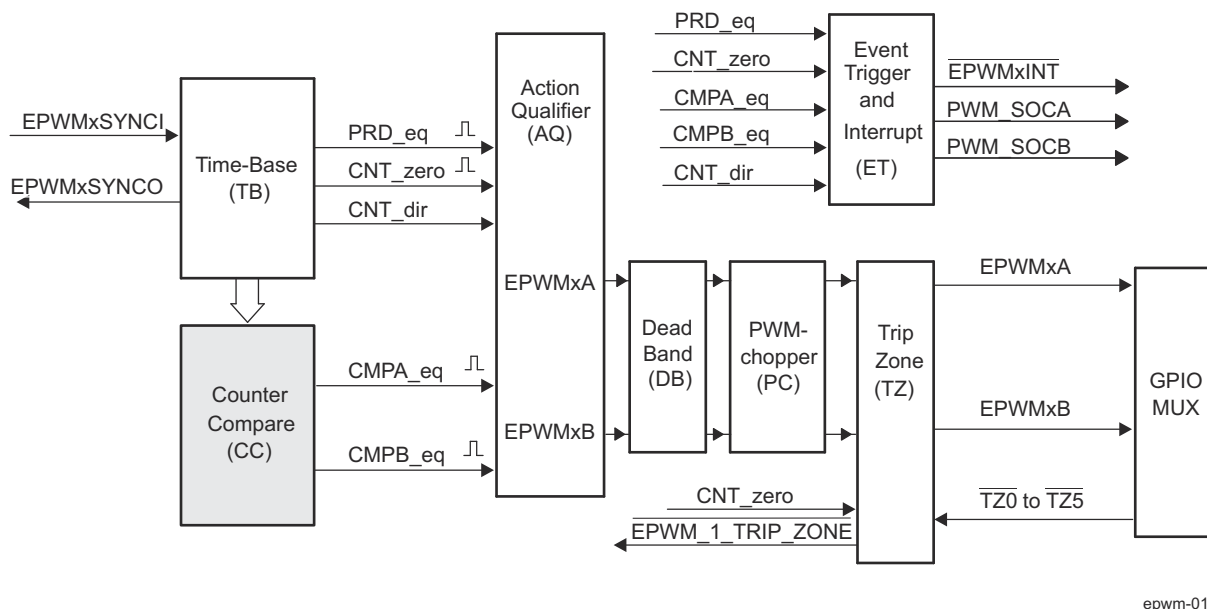

**Figure 12-396. EPWM Time-Base Up-Down Count Waveforms, EPWM\_TBCTL[13] PHSDIR = 1 Count Up on Synchronization Event**

### 12.4.2.4.3 EPWM Counter-Compare (CC) Submodule

This section describes the Counter-Compare (CC) submodule in the PWM module.

#### 12.4.2.4.3.1 Overview

Figure 12-397 illustrates the counter-compare submodule within the EPWM. Figure 12-398 shows the basic structure of the counter-compare submodule.

epwm-016

**Figure 12-397. EPWM Counter-Compare Submodule**

CC module features:

- Generates events based on programmable time stamps using the EPWM\_CMPA and EPWM\_CMPB registers
  - CMPA\_eq (Time-base counter equals counter-compare A register (TBCNT = CMPA)).
  - CMPB\_eq (Time-base counter equals counter-compare B register (TBCNT = CMPB)).
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle.

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (EPWM\_CMPA) and counter-compare B (EPWM\_CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

#### 12.4.2.4.3.2 Controlling and Monitoring the EPWM Counter-Compare Submodule

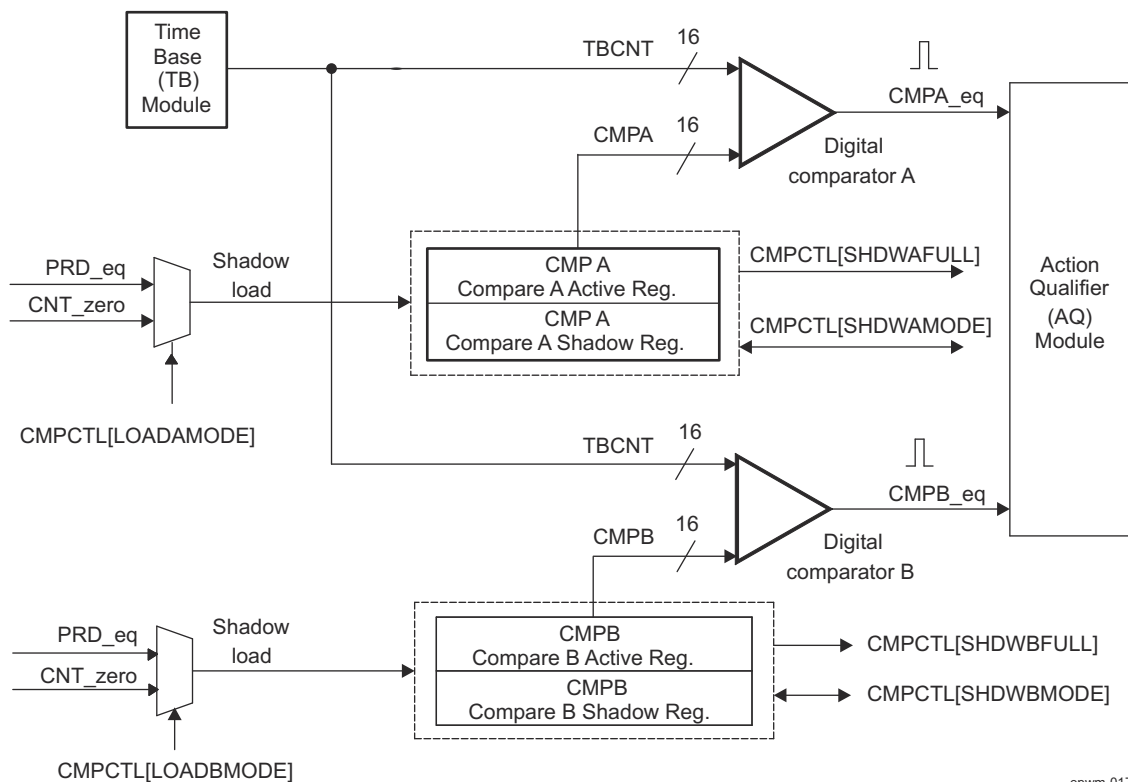

Table 12-430 lists the registers used to control and monitor the counter-compare submodule. Table 12-431 lists the key signals associated with the counter-compare submodule.

**Table 12-430. EPWM Counter-Compare Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_CMPCTL	Counter-Compare Control Register.	Eh	No
HRPWM_CMPAHR	HRPWM Counter-Compare A Extension Register <sup>(1)</sup>	10h	Yes
EPWM_CMPA	Counter-Compare A Register	12h	Yes
EPWM_CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on the EPWM modules with the high-resolution extension (HRPWM). On the EPWM modules that do not include the HRPWM, this location is reserved. See *EPWM Integration* to determine which EPWM instances include this feature.

epwm-017

**Figure 12-398. EPWM Counter-Compare Submodule Signals and Registers**

**Table 12-431. EPWM Counter-Compare Submodule Key Signals**

Signal	Description of Event	Register Bitfields Compared
CMPA_eq	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
PRD_eq	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

### 12.4.2.4.3.3 Operational Highlights for the EPWM Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CMPA: Time-base counter equal to counter-compare A register (EPWM\_TBCNT = EPWM\_CMPA).
2. CMPB: Time-base counter equal to counter-compare B register (EPWM\_TBCNT = EPWM\_CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to [Section 12.4.2.4.4](#) for more details.

The counter-compare EPWM\_CMPA and EPWM\_CMPB registers each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the EPWM\_CMPCTL[4] SHDWAMODE and EPWM\_CMPCTL[6] SHDWBMODE bits. These bits enable and disable the EPWM\_CMPA shadow register and EPWM\_CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Load Mode:**

The shadow mode for the EPWM\_CMPA register is enabled by clearing the EPWM\_CMPCTL[4] SHDWAMODE bit and the shadow register for EPWM\_CMPB register is enabled by clearing the EPWM\_CMPCTL[6] SHDWBMODE bit. Shadow mode is enabled by default for both EPWM\_CMPA and EPWM\_CMPB register.

If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

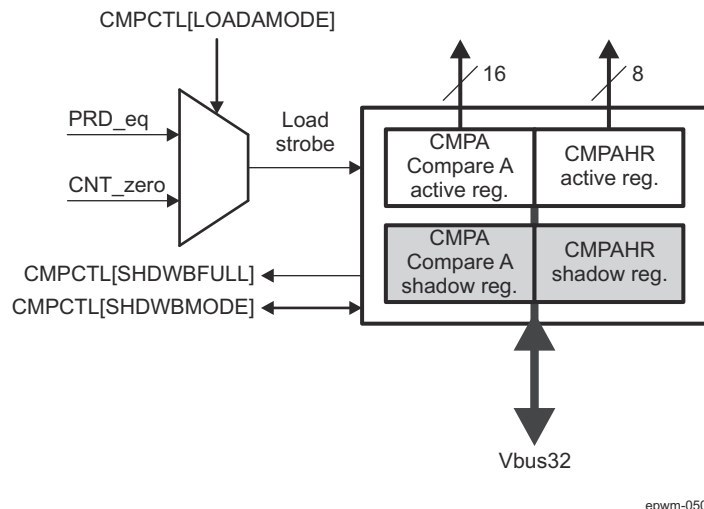

- PRD\_eq: Time-base counter equal to the period (TBCNT = TBPRD).
- CNT\_zero: Time-base counter equal to zero (TBCNT = 0000h)
- Both PRD\_eq and CNT\_zero events occurrence

Which of these three events will drive the counter compare module is specified by the EPWM\_CMPCTL[1-0] LOADAMODE and EPWM\_CMPCTL[3-2] LOADBMODE register bit fields. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.

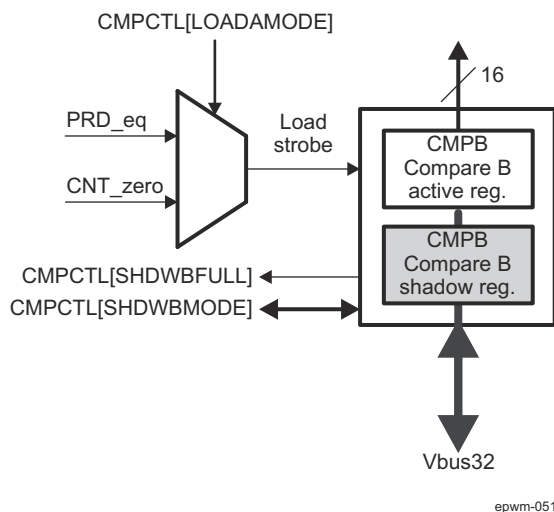

- **Immediate Load Mode:**

If immediate load mode is selected (EPWM\_CMPCTL[4] SHDWAMODE = 1h or EPWM\_CMPCTL[6] SHDWBMODE = 1h), then a read from or a write to the register will go directly to the active register.

[Figure 12-399](#) and [Figure 12-400](#) show Compare A and B Dual Shadow registers.

**Figure 12-399. Compare A Dual Shadow register**

**Figure 12-400. Compare B Dual Shadow register**

#### Note

In HRPWM mode the user must perform a single 32-bit write access to both the HRPWM\_CMPAHR and EPWM\_CMPA registers. Two 16-bit accesses are not allowed.

#### 12.4.2.4.3.4 EPWM Counter-Compare Submodule Timing Waveforms

As described in [Section 12.4.2.4.2](#), the Time Base (TB) module can be configured to operate in 3 distinct count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

The timing diagrams in [Figure 12-401](#) to [Figure 12-404](#) show how CMPA and CMPB events are generated in each of the 3 count modes and how the EPWMxSYNCI signal interacts.

An EPWMxSYNCl external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

**Figure 12-401. EPWM Counter-Compare Event Waveforms in Up-Count Mode**

**Figure 12-402. EPWM Counter-Compare Events in Down-Count Mode**

**Figure 12-403. EPWM Counter-Compare Events in Up-Down-Count Mode, EPWM\_TBCTL[13] PHSDIR = 0  
Count Down on Synchronization Event**

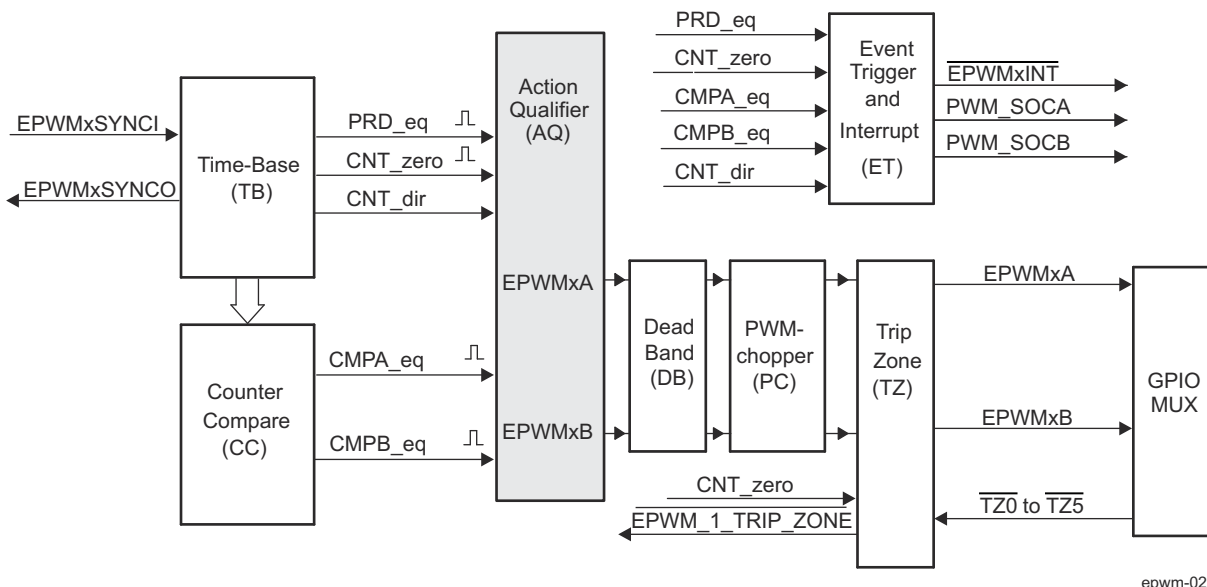

**Figure 12-404. EPWM Counter-Compare Events in Up-Down-Count Mode, EPWM\_TBCTL[13] PHSDIR = 1  
Count Up on Synchronization Event**

#### 12.4.2.4.4 EPWM Action-Qualifier (AQ) Submodule

This section describes the Action-Qualifier (AQ) submodule in the PWM module.

##### 12.4.2.4.4.1 Overview

Figure 12-405 shows the action-qualifier (AQ) submodule in the EPWM system. This submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

epwm-022

**Figure 12-405. EPWM Action-Qualifier Submodule**

AQ module features:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - PRD\_eq**: Time-base counter equal to the period (TBCNT = TBPRD)
  - CNT\_zero**: Time-base counter equal to zero (TBCNT = 0000h)
  - CMPA\_eq**: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CMPB\_eq**: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing

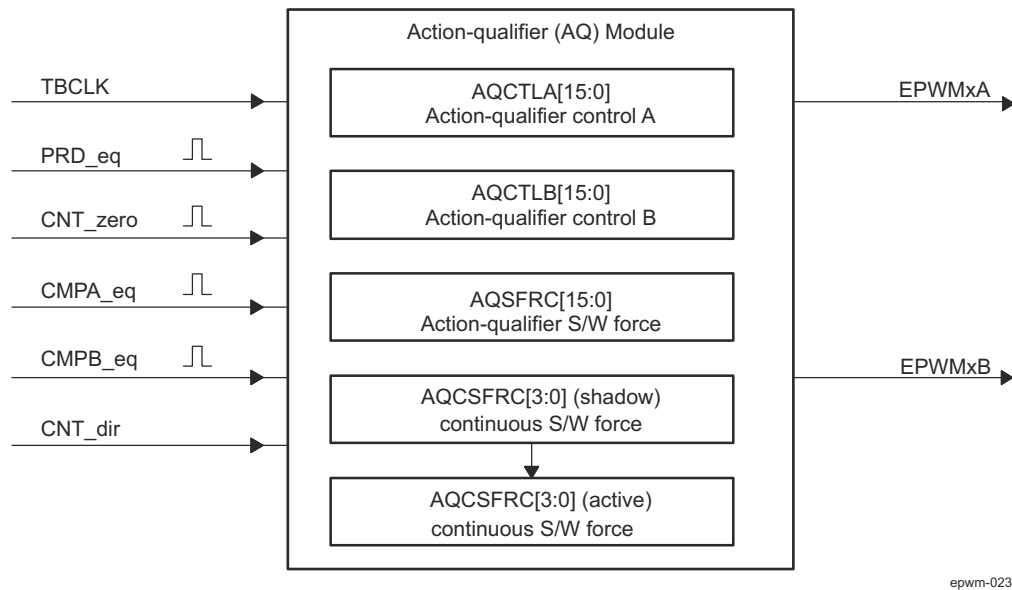

##### 12.4.2.4.4.2 Controlling and Monitoring the EPWM Action-Qualifier Submodule

Table 12-432 lists the registers used to control and monitor the action-qualifier submodule.

**Table 12-432. EPWM Action-Qualifier Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
EPWM_AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
EPWM_AQSFRC	Action-Qualifier Software Force Register	1Ah	No
EPWM_AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers as shown in Figure 12-406. The possible input events are summarized again in Table 12-433.

**Figure 12-406. EPWM Action-Qualifier Submodule Inputs and Outputs**

**Table 12-433. EPWM Action-Qualifier Submodule Possible Input Events**

Signal	Description	Register Bitfield Compared
PRD_eq	Time-base counter equal to the period value	TBCNT = TBPRD
CNT_zero	Time-base counter equal to zero	TBCNT = 0000h
CMPA_eq	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CMPB_eq	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by EPWM\_AQSFRC and EPWM\_AQCSFRC registers.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the Event\_Trigger (ET) submodule description in [Section 12.4.2.4.8](#) for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in [Figure 12-407](#). Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
<div>SW ×</div>	<div>Z ×</div>	<div>CA ×</div>	<div>CB ×</div>	<div>P ×</div>	Do Nothing
<div>SW ↓</div>	<div>Z ↓</div>	<div>CA ↓</div>	<div>CB ↓</div>	<div>P ↓</div>	Clear Low
<div>SW ↑</div>	<div>Z ↑</div>	<div>CA ↑</div>	<div>CB ↑</div>	<div>P ↑</div>	Set High
<div>SW T</div>	<div>Z T</div>	<div>CA T</div>	<div>CB T</div>	<div>P T</div>	Toggle

epwm-024

**Figure 12-407. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs**

#### 12.4.2.4.4.3 EPWM Action-Qualifier Event Priority

It is possible for the EPWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is: events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in [Table 12-434](#). A priority level 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

**Table 12-434. EPWM Action-Qualifier Event Priority for Up-Down-Count Mode**

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD in EPWM_TBPRD active register)
5	Counter equals CMPB on down-count (CBD) <sup>(1)</sup>	Counter equals CMPB on up-count (CBU) <sup>(1)</sup>
6 (Lowest)	Counter equals CMPA on down-count (CAD) <sup>(1)</sup>	Counter equals CMPA on up-count (CBU) <sup>(1)</sup>

(1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

[Table 12-435](#) shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

**Table 12-435. EPWM Action-Qualifier Event Priority for Up-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

[Table 12-436](#) shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

**Table 12-436. EPWM Action-Qualifier Event Priority for Down-Count Mode**

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in [Table 12-437](#).

**Table 12-437. Behavior if CMPA/CMPB is Greater than the Period**

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB $\leq$ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $>$ TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB $<$ TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB $<$ TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is $\geq$ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB $<$ TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB $\geq$ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

#### 12.4.2.4.4.4 Waveforms for Common EPWM Configurations

##### Note

The waveforms in this chapter show the EPWMs behavior for a static compare register value. In a running system, the active compare registers (EPWM\_CMPA and EPWM\_CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place — either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

##### Use up-down-count mode to generate a symmetric PWM:

- If EPWM\_CMPA / EPWM\_CMPB is loaded on zero, then use EPWM\_CMPA / EPWM\_CMPB values greater than or equal to 1.
- If EPWM\_CMPA / EPWM\_CMPB is loaded on period, then use EPWM\_CMPA / EPWM\_CMPB values less than or equal to TBPRD - 1.

This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

##### Use up-down-count mode to generate an asymmetric PWM:

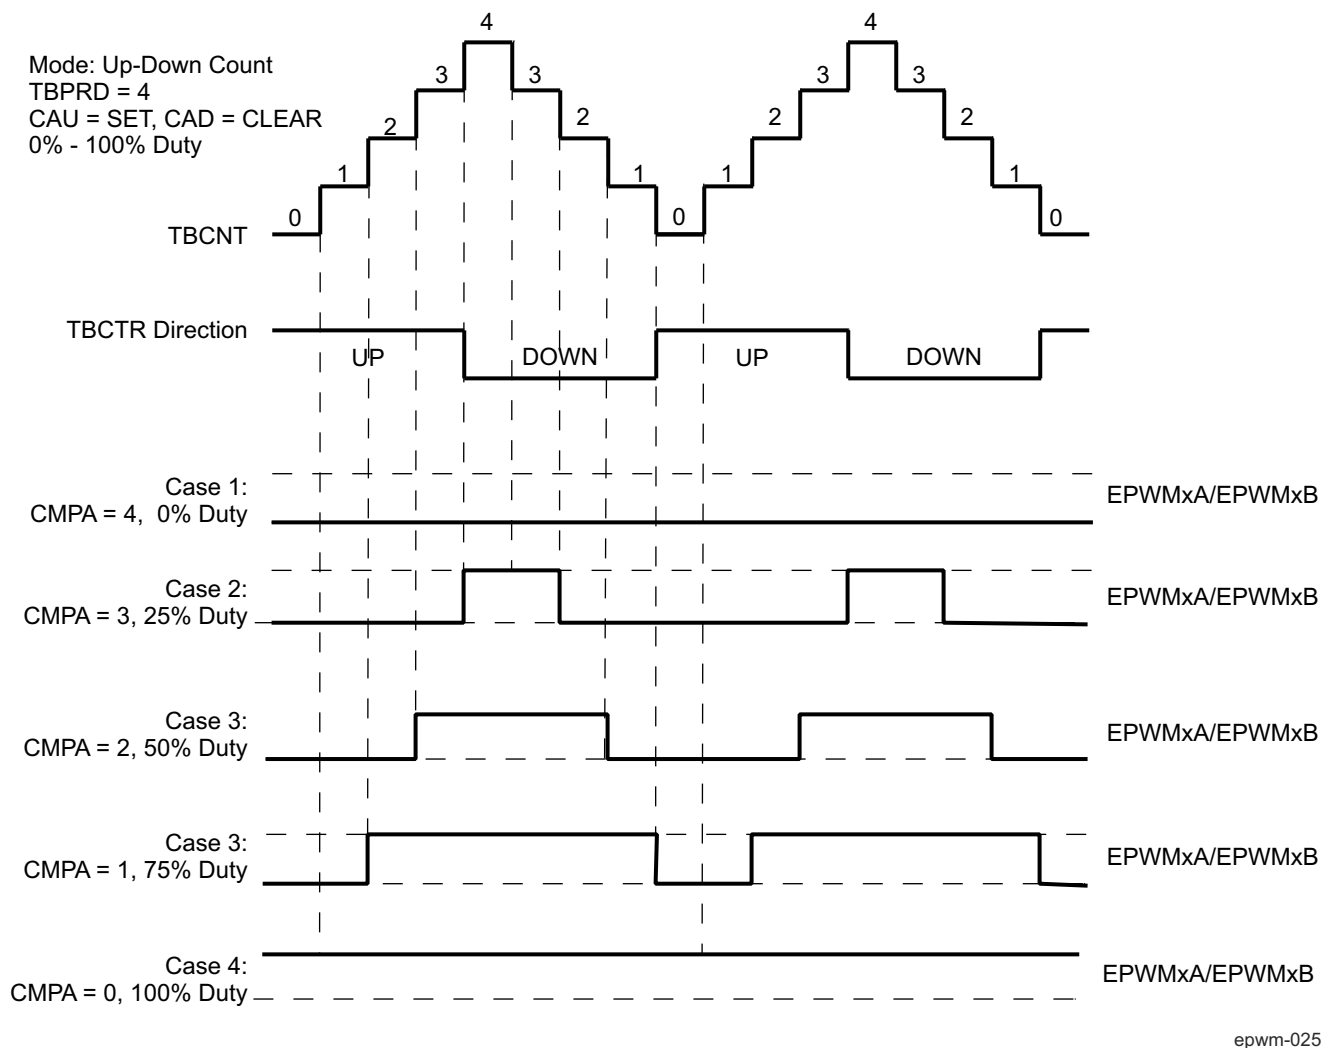

- To achieve 50-0% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50-0% PWM duty.

##### When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load EPWM\_CMPA / EPWM\_CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 12-408 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When  $CMPA = 0$ , the PWM signal is low for the entire period giving the 0% duty waveform. When  $EPWM\_CMPA = EPWM\_TBPRD$ , the PWM signal is high achieving 100% duty.

When using this configuration in practice, if  $CMPA/CMPB$  is loaded on zero, then use  $CMPA/CMPB$  values greater than or equal to 1. If  $CMPA/CMPB$  is loaded on period, then use  $CMPA/CMPB$  values less than or equal to  $TBPRD - 1$ . This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

**Figure 12-408. EPWM Up-Down-Count Mode Symmetrical Waveform**

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers (EPWM\_TBPRD, EPWM\_CMPA, and EPWM\_CMPB). The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from EPWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

- Figure 12-409. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB — Active High**

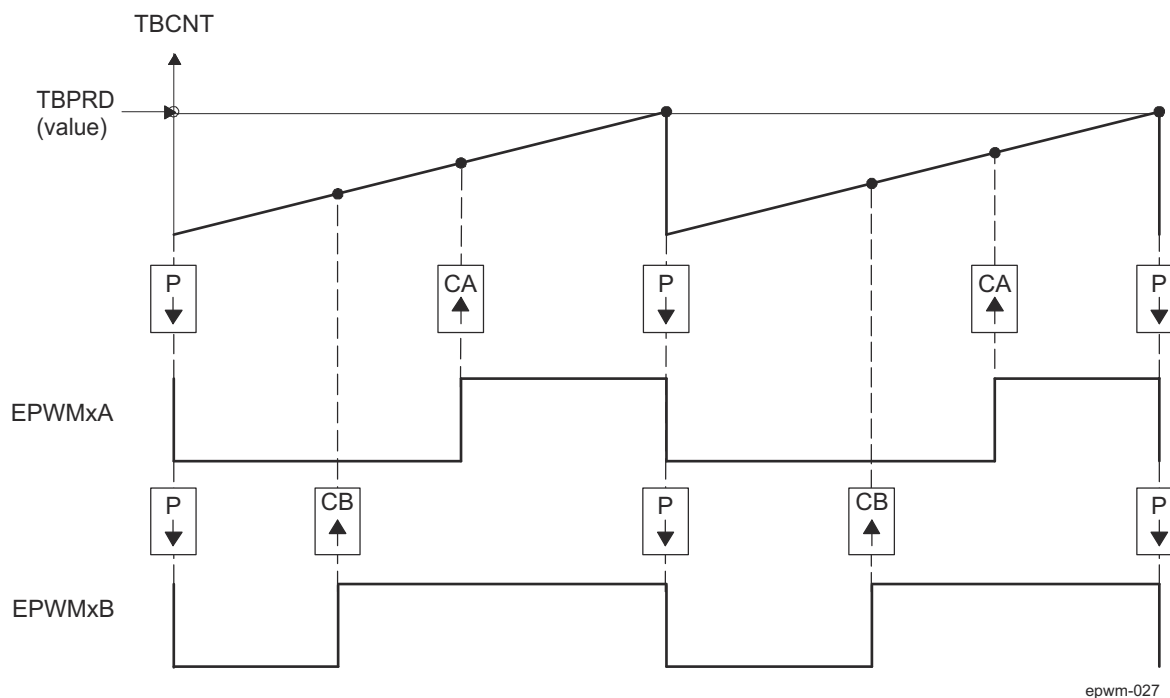

**Table 12-438. EPWMx Initialization for Figure 12-409**

Register	Bitfield	Value	Comments
EPWM_TBPRD	TBPRD	600 (258h)	Period = 601 TBCLK counts
EPWM_TBPHS	TBPHS	0	Clear Phase Register to 0
EPWM_TBCNT	TBCNT	0	Clear TB counter
EPWM_TBCTL	CTRMODE	TB_UP	Phase loading disabled
	PHSEN	TB_DISABLE	
	PRDLD	TB_SHADOW

Table 12-440 and Table 12-441 contains initialization and runtime register configurations for the waveforms in Figure 12-410.

- PWM period =  $(TBPRD + 1) \times T_{TBCLK}$
- Duty modulation for EPWMxA is set by CMPA, and is active low (that is, the low time duty is proportional to CMPA).
- Duty modulation for EPWMxB is set by CMPB and is active low (that is, the low time duty is proportional to CMPB).
- The Do Nothing actions ( X ) are shown for completeness here, but will not be shown on subsequent diagrams.
- Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

#### 12.4.2.4.5 EPWM Dead-Band Generator (DB) Submodule

This section describes the Dead-Band Generator (DB) submodule in the PWM module.

##### 12.4.2.4.5.1 Overview

Figure 12-415 illustrates the dead-band generator submodule within the EPWM module.

**Figure 12-415. Dead-Band Generator Submodule**

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the EPWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in Figure 12-415)

##### 12.4.2.4.5.2 Controlling and Monitoring the EPWM Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

**Table 12-450. Dead-Band Generator Submodule Registers**

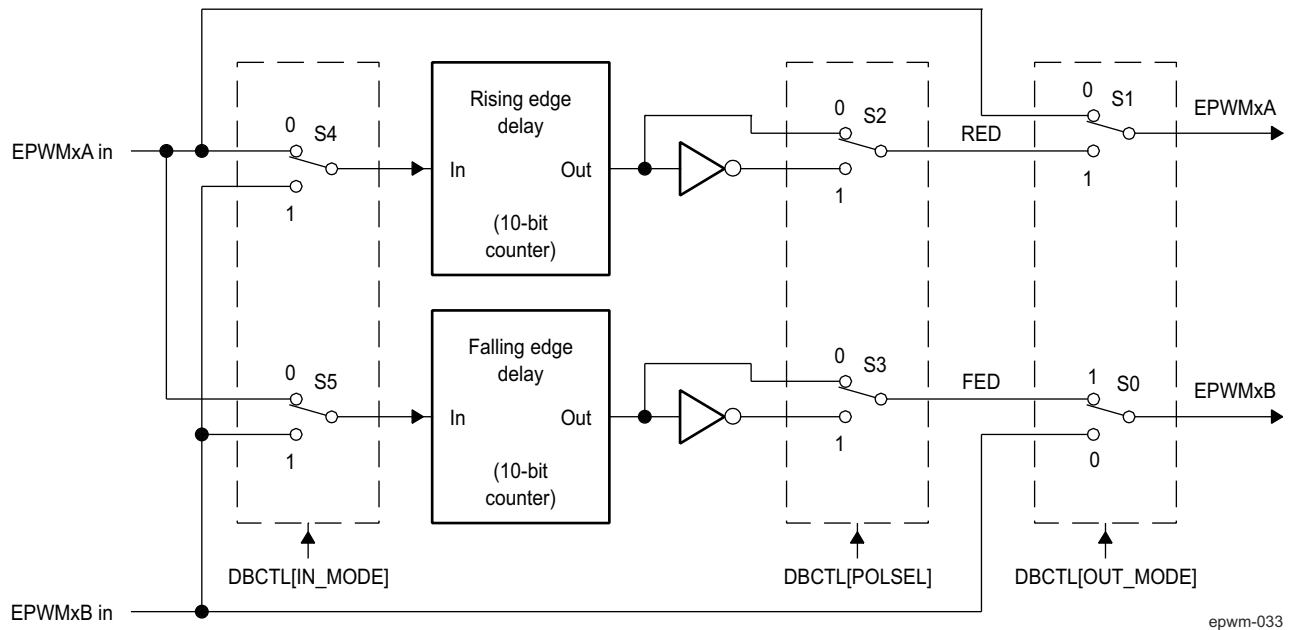

Acronym	Register Description	Address Offset	Shadowed
EPWM_DBCTL	Dead-Band Control Register	1Eh	No
EPWM_DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
EPWM_DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

#### 12.4.2.4.5.3 Operational Highlights for the EPWM Dead-Band Generator Submodule

The dead-band submodule has two groups of independent selection options as shown in Figure 12-416.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the EPWM\_DBCTL[5-4] IN\_MODE control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the EPWM\_DBCTL[1-0] OUT\_MODE bit fields. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (EPWM\_DBCTL[3-2] POLSEL) allows to be specified whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

**Figure 12-416. Configuration Options for the EPWM Dead-Band Generator Submodule**

Although all combinations are supported, not all are typical usage modes. [Table 12-451](#) lists some classical dead-band configurations. These modes assume that the EPWM\_DBCTL[5-4] IN\_MODE is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in [Table 12-451](#) fall into the following categories:

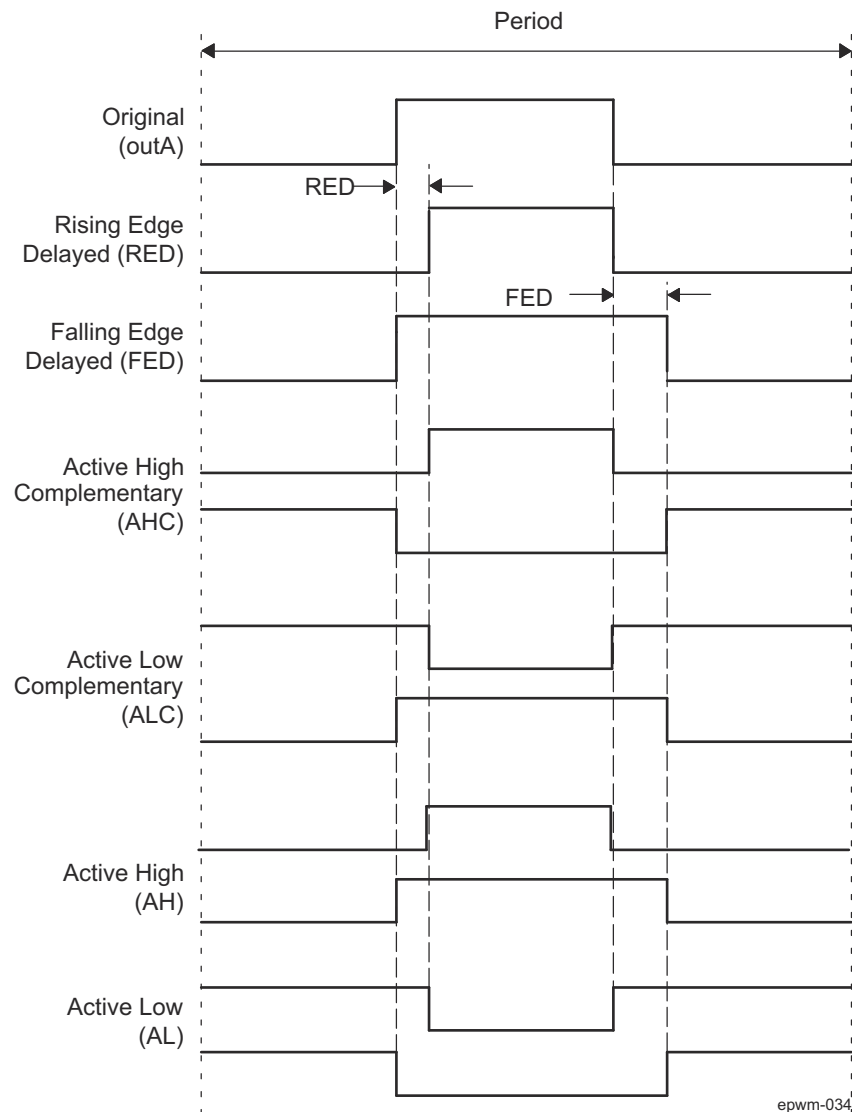

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows to be fully disabled the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in [Figure 12-417](#). Note that to generate equivalent waveforms to [Figure 12-417](#), configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in [Table 12-451](#) show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

**Table 12-451. Classical Dead-Band Operating Modes**

Mode	Mode Description <sup>(1)</sup>	EPWM_DBCTL[3-2] POLSEL		EPWM_DBCTL[1-0] OUT_MODE	
		S3	S2	S1	S0
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

(1) These are classical dead-band modes and assume that EPWM\_DBCTL[5-4] IN\_MODE = 0b00. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN\_MODE configuration.

[Figure 12-417](#) shows waveforms for typical cases where 0% < duty < 100%.

**Figure 12-417. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)**

The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the EPWM\_DBRED and EPWM\_DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formulas to calculate falling-edge-delay and rising-edge-delay are:

$$FED = EPWM\_DBFED \times T_{TBCLK}$$

$$RED = EPWM\_DBRED \times T_{TBCLK}$$

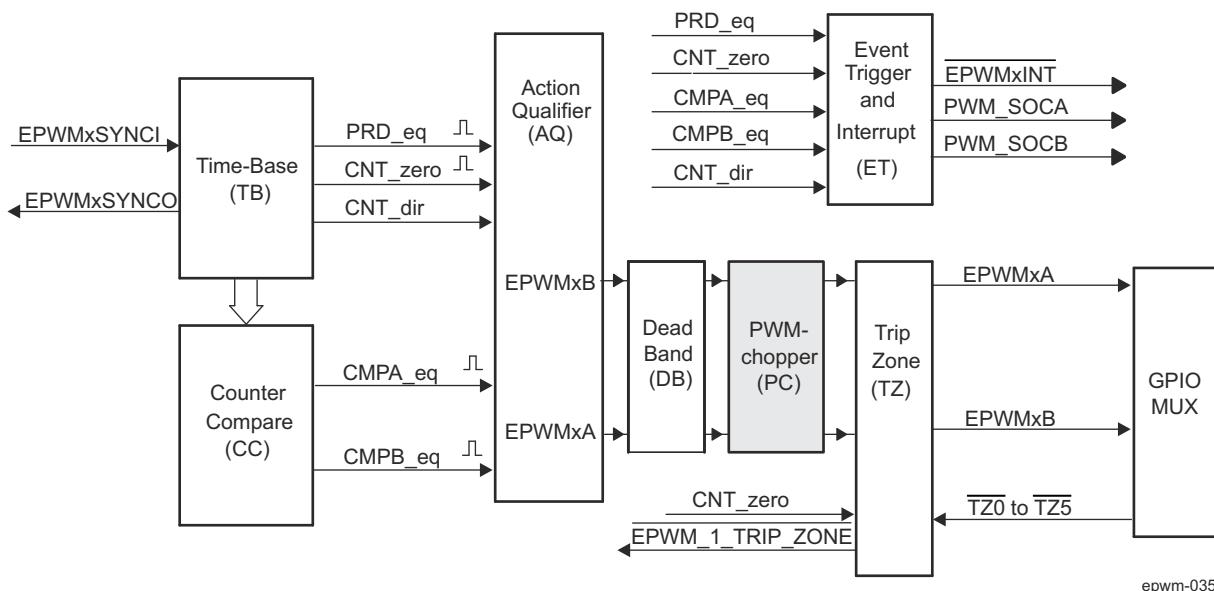

Where  $T_{TBCLK}$  is the period of TBCLK, the prescaled version of FICLK.

#### 12.4.2.4.6 EPWM-Chopper (PC) Submodule

This section describes the PWM-Chopper (PC) submodule in the PWM module.

##### 12.4.2.4.6.1 Overview

Figure 12-418 illustrates the PWM-chopper (PC) submodule within the EPWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if a pulse transformer-based gate drivers to control the power switching elements is needed.

**Figure 12-418. PWM-Chopper Submodule**

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

##### 12.4.2.4.6.2

PC module key features:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

##### 12.4.2.4.6.3 Controlling the EPWM-Chopper Submodule

The EPWM-chopper submodule operation is controlled via the register in [Table 12-452](#).

**Table 12-452. EPWM-Chopper Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_PCCTL	PWM-chopper Control Register	3Ch	No

#### 12.4.2.4.6.4 Operational Highlights for the EPWM-Chopper Submodule

Figure 12-419 shows the operational details of the EPWM-chopper submodule. The carrier clock is derived from FICLK. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the EPWM\_PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

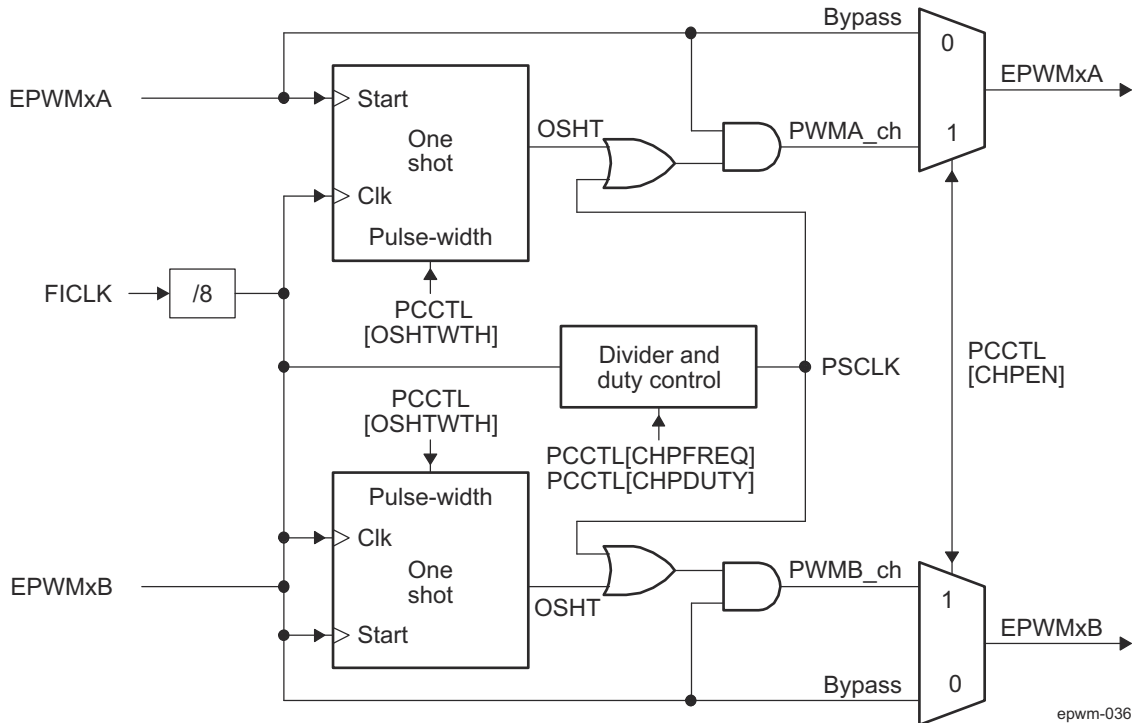

Figure 12-419. PWM-Chopper Submodule Signals and Registers

#### 12.4.2.4.6.5 EPWM-Chopper Waveforms

Figure 12-420 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

**Figure 12-420. Simple EPWM-Chopper Submodule Waveforms Showing Chopping Action Only**

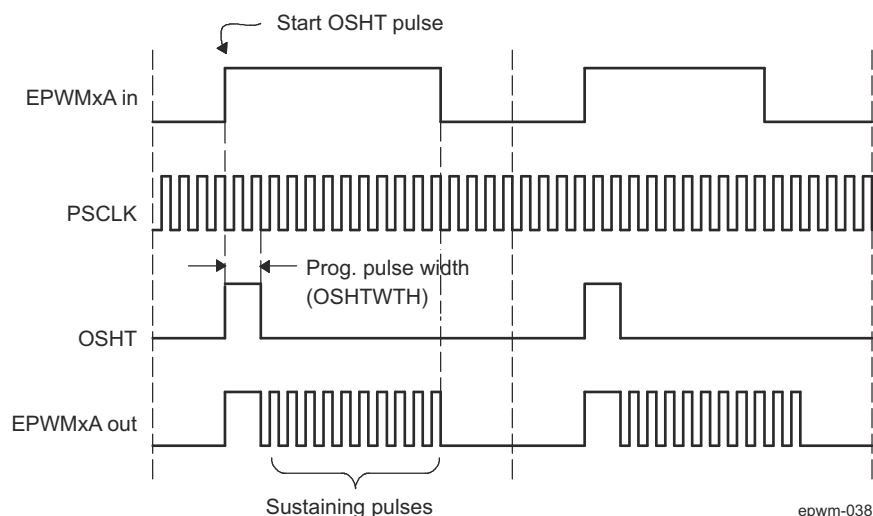

#### 12.4.2.4.6.5.1 EPWM-Chopper One-Shot Pulse

The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{FICLK} \times 8 \times OSHTWTH$$

Where  $T_{FICLK}$  is the period of the system clock (FICLK) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 12-421 shows the first and subsequent sustaining pulses.

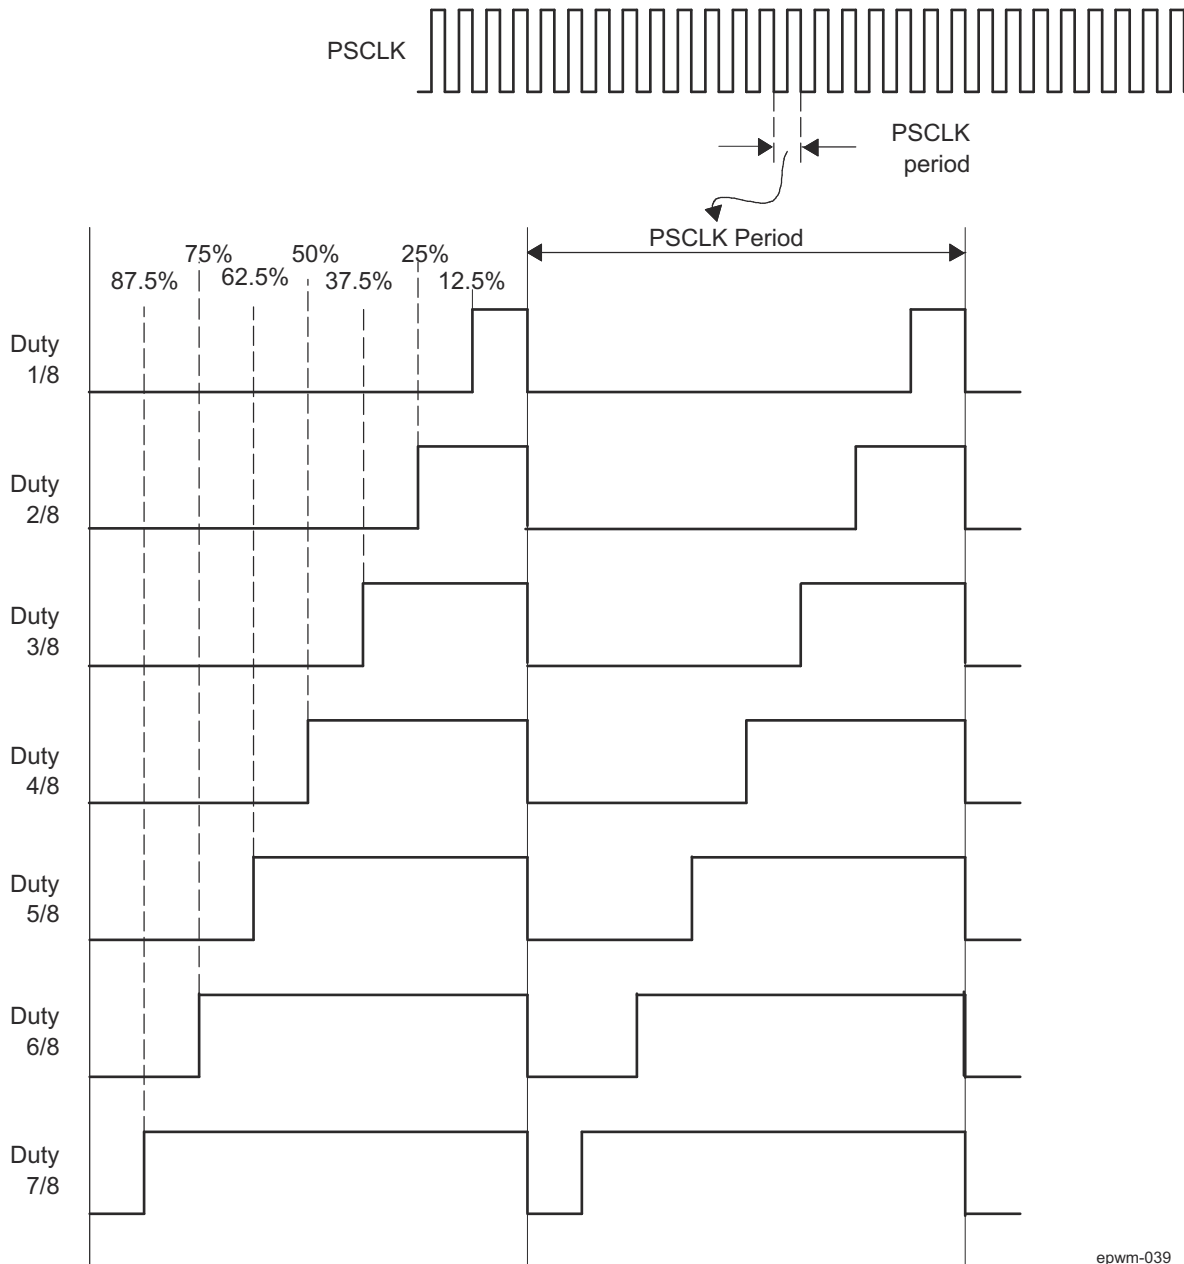

**Figure 12-421. EPWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses**

#### 12.4.2.4.6.5.2 EPWM-Chopper Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 12-422 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5 to 87.5%.

epwm-039

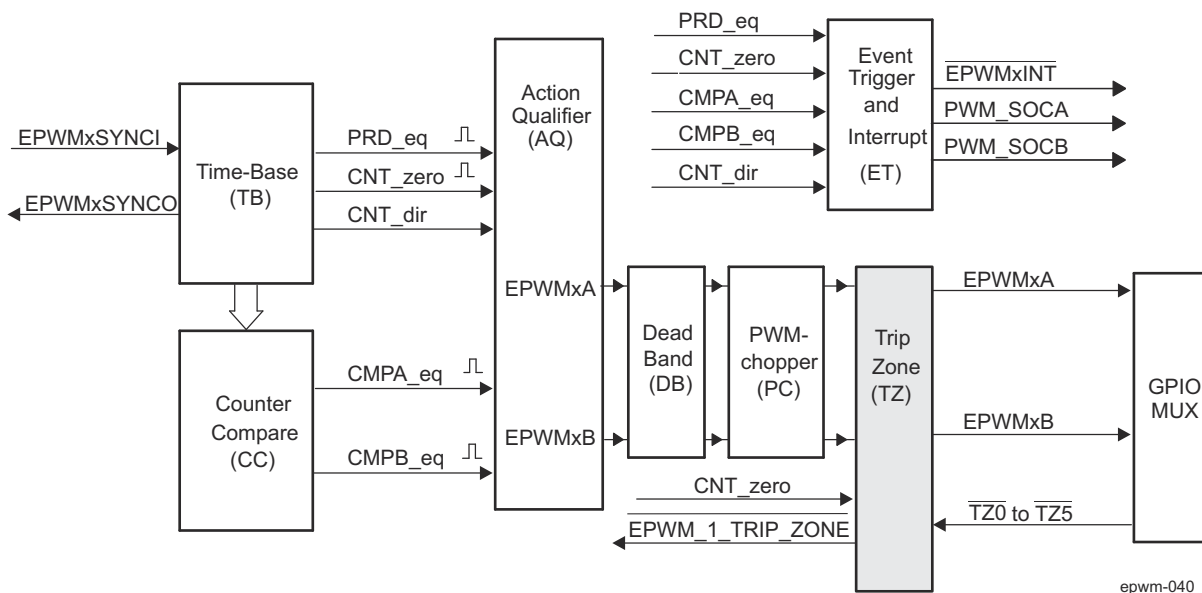

**Figure 12-422. EPWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses**

#### 12.4.2.4.7 EPWM Trip-Zone (TZ) Submodule

This section describes the Trip-Zone (TZ) submodule in the PWM module.

##### 12.4.2.4.7.1 Overview

Figure 12-423 shows how the trip-zone (TZ) submodule fits within the EPWM module. Each EPWM module is connected to six  $\overline{TZ}$  signals ( $\overline{TZ0}$  to  $\overline{TZ5}$ ) that are sourced from the GPIO MUX. These signals indicate external fault or trip conditions, and the EPWM outputs can be programmed to respond accordingly when faults occur. See *EPWM Integration* to determine the number of trip-zone pins available for the device.

**Figure 12-423. EPWM Trip-Zone Submodule**

The key functions of the trip-zone submodule are:

- Trip inputs  $\overline{TZ0}$  to  $\overline{TZ5}$  can be flexibly mapped to any EPWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

#### Note

For each EPWMx module, 6 tripzone input events are supported ( $\overline{EPWMx\_TRIP\_TZ[5:0]}$ ). Each tripzone input for all EPWMx modules (where x = 0 to 5) are tied to a common tripzone input pin, so that any EPWMx can be triggered by any of the six tripzone inputs.

#### 12.4.2.4.7.2 Controlling and Monitoring the EPWM Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

**Table 12-453. EPWM Trip-Zone Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_TZSEL	Trip-Zone Select Register <sup>(1)</sup>	24h	No
EPWM_TZCTL	Trip-Zone Control Register <sup>(1)</sup>	28h	No
EPWM_TZEINT	Trip-Zone Enable Interrupt Register <sup>(1)</sup>	2Ah	No
EPWM_TZFLG	Trip-Zone Flag Register <sup>(1)</sup>	2Ch	No
EPWM_TZCLR	Trip-Zone Clear Register <sup>(1)</sup>	2Eh	No
EPWM_TZFRC	Trip-Zone Force Register <sup>(1)</sup>	30h	No

(1) All trip-zone registers are EALLOW protected and can be modified only after executing the EALLOW instruction.

#### 12.4.2.4.7.3 Operational Highlights for the EPWM Trip-Zone Submodule

The trip-zone signals at pin  $\overline{TZ0}$  to  $\overline{TZ5}$  is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each EPWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular EPWM module is determined by the EPWM\_TZSEL register for that specific EPWM module. The trip-zone signal may or may not be synchronized to the system clock (FICLK). A minimum of 1 FICLK low pulse on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs is sufficient to trigger a fault condition in the EPWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs.

The  $\overline{TZ0}$  to  $\overline{TZ5}$  inputs can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a EPWM module. The configuration is determined by the EPWM\_TZSEL[5-0] CBCK and EPWM\_TZSEL[13-8] OSHTk bit field (where k = 0 to 5 corresponds to the trip pin), respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 12-454 lists the possible actions. In addition, the cycle-by-cycle trip event flag (EPWM\_TZFLG[1] CBC) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register.

The specified condition on the pins is automatically cleared when the EPWM time-base counter reaches zero (EPWM\_TBCNT[15-0] TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The EPWM\_TZFLG[1] CBC flag bit will remain set until it is manually cleared by writing to the EPWM\_TZCLR[1] CBC bit. If the cycle-by-cycle trip event is still present when the EPWM\_TZFLG[1] CBC bit is cleared, then it will again be immediately set.

- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the EPWM\_TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 12-454 lists the possible actions. In addition, the one-shot trip event flag (EPWM\_TZFLG[2] OST) is set and a EPWMxTZINT interrupt is generated if it is enabled in the EPWM\_TZEINT register. The one-shot trip condition must be cleared manually by writing to the EPWM\_TZCLR[2] OST bit.

The action taken when a trip event occurs can be configured individually for each of the EPWM output pins by way of the EPWM\_TZCTL[1-0] TZA and EPWM\_TZCTL[3-2] TZB register bit field. One of four possible actions, shown in Table 12-454, can be taken on a trip event.

**Table 12-454. Possible Actions On an EPWM Trip Event**

EPWM_TZCTL[1-0] TZA and/or EPWM_TZCTL[3-2] TZB	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

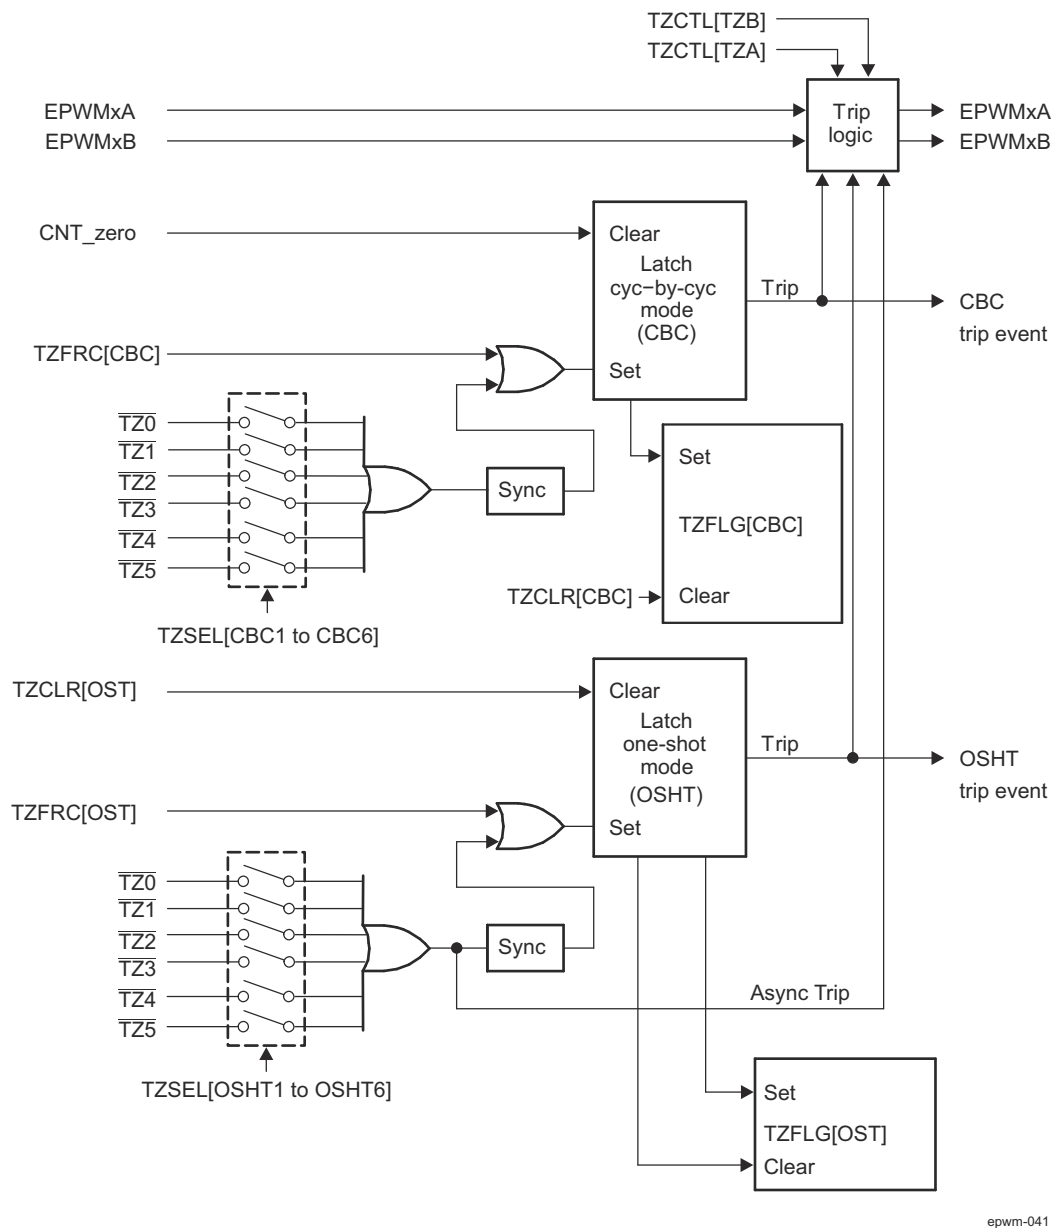

### Example of EPWM Trip-Zone Configurations

A one-shot trip event on  $\overline{TZ0}$  pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

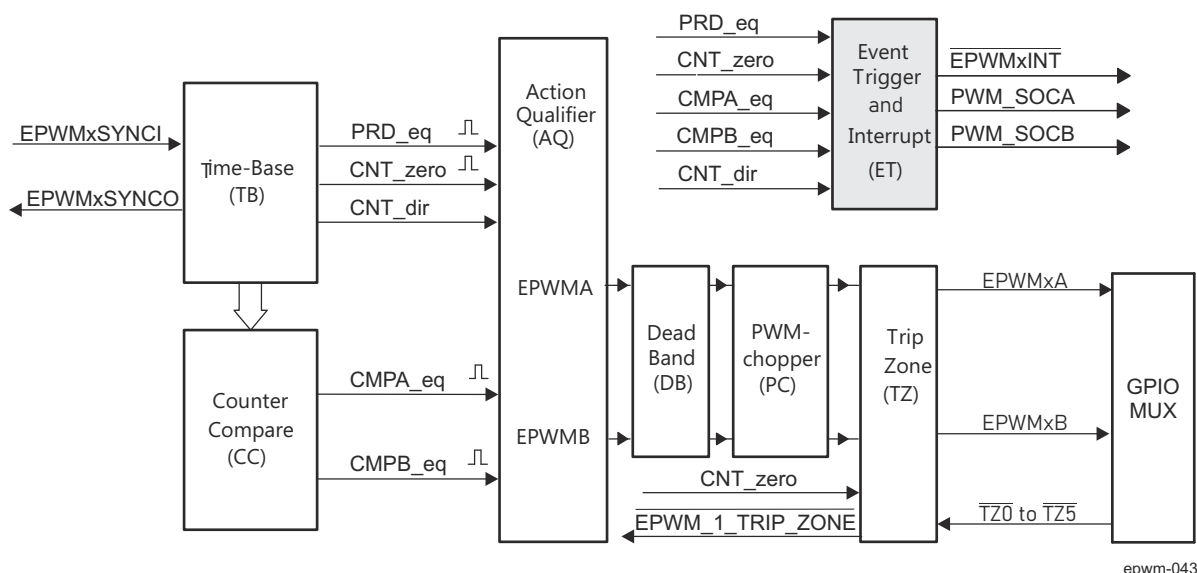

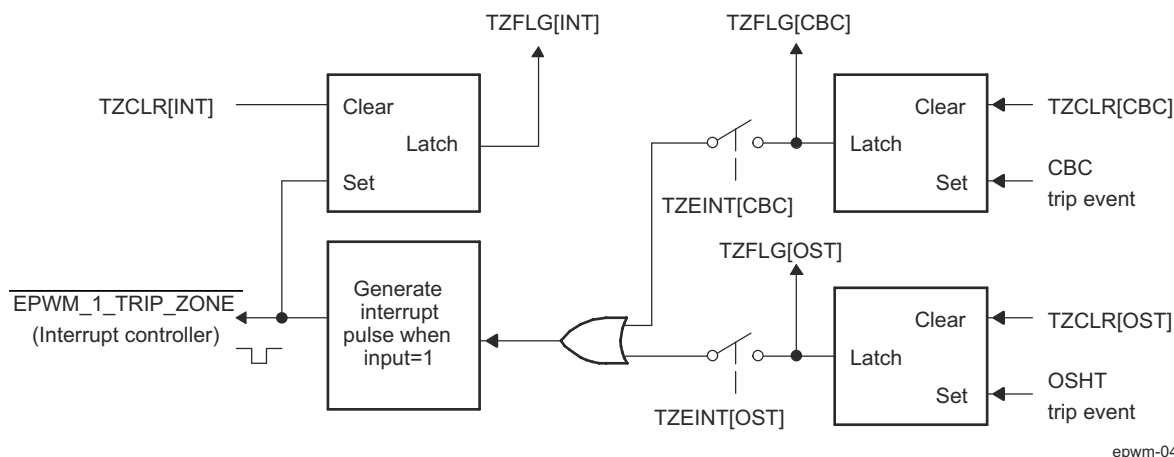

- Configure the EPWM1 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM1
  - EPWM\_TZCTL[1-0] TZA = 2: EPWM1A will be forced low on a trip event
  - EPWM\_TZCTL[3-2] TZB = 2: EPWM1B will be forced low on a trip event
- Configure the EPWM2 registers as follows:
  - EPWM\_TZSEL[8] OSHT1 = 1: enables  $\overline{TZ}$  as a one-shot event source for EPWM2
  - EPWM\_TZCTL[1-0] TZA = 1: EPWM2A will be forced high on a trip event
  - EPWM\_TZCTL[3-2] TZB = 1: EPWM2B will be forced high on a trip event

#### 12.4.2.4.7.4 Generating EPWM Trip-Event Interrupts

Figure 12-424 and Figure 12-425 illustrate the trip-zone submodule control and interrupt logic, respectively.

**Figure 12-424. EPWM Trip-Zone Submodule Mode Control Logic**

#### 12.4.2.4.8.2 Controlling and Monitoring the EPWM Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in [Table 12-455](#):

**Table 12-455. EPWM Event-Trigger Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
EPWM_ETSEL	Event-Trigger Selection Register	32h	No
EPWM_ETPS	Event-Trigger Prescale Register	34h	No
EPWM_ETFLG	Event-Trigger Flag Register	36h	No
EPWM_ETCLR	Event-Trigger Clear Register	38h	No
EPWM_ETFRC	Event-Trigger Force Register	3Ah	No

#### 12.4.2.4.8.3 Operational Overview of the EPWM Event-Trigger Submodule

Each EPWM module has one interrupt request line as shown in [Figure 12-427](#). Mapping interrupt lines to device host interrupt controllers is device specific and is covered in *EPWM Integration*.

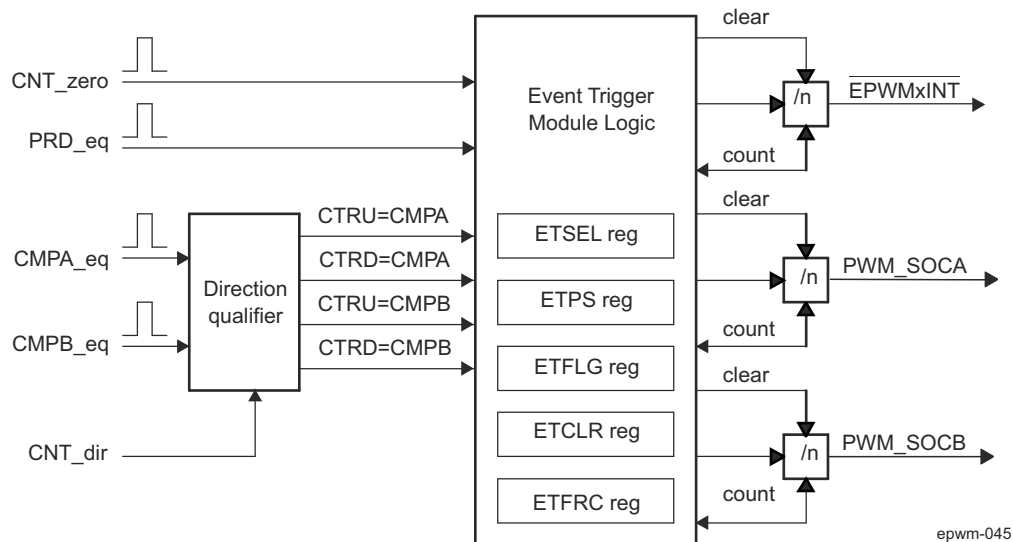

epwm-044

**Figure 12-427. EPWM Event-Trigger Submodule Inter-Connectivity to Interrupt Controller**

The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in [Figure 12-428](#)) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

epwm-045

**Figure 12-428. EPWM Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs**

- **ETSEL** — This selects which of the possible events will trigger an interrupt.
- **ETPS** — This programs the event prescaling options previously mentioned.
- **ETFLG** — These are flag bits indicating status of the selected and prescaled events.
- **ETCLR** — These bits allow to clear the flag bits in the EPWM\_ETFLG register via software.
- **ETFRC** — These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in [Figure 12-429](#).

[Figure 12-429](#) shows the event-trigger's interrupt generation logic. The interrupt-period (EPWM\_ETPS[1-0] INTPRD) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (EPWM\_ETSEL[2-0] INTSEL) bits. The event can be one of the following:

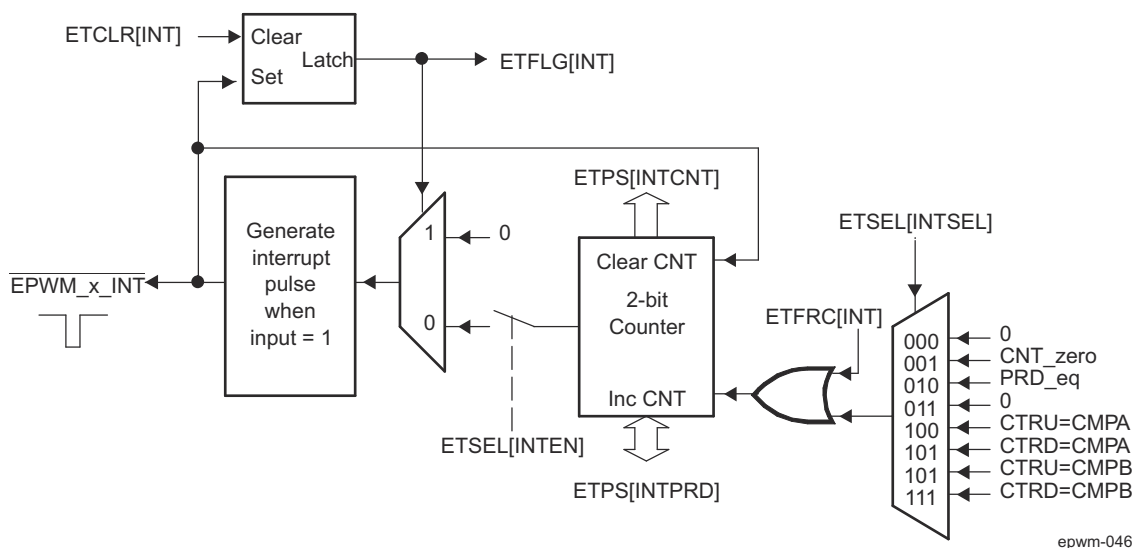

- Time-base counter equal to zero (EPWM\_TBCNT[15-0] TBCNT = 0000h).
- Time-base counter equal to period (EPWM\_TBCNT[15-0] TBCNT = EPWM\_TBPRD[15-0] TBPRD).
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (EPWM\_CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (EPWM\_CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (EPWM\_ETPS[3-2] INTCNT) register bits. That is, when the specified event occurs the EPWM\_ETPS[3-2] INTCNT bits are incremented until they reach the value specified by the EPWM\_ETPS[1-0] INTPRD bit field. When EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

When EPWM\_ETPS[3-2] INTCNT reaches EPWM\_ETPS[1-0] INTPRD, one of the following behaviors will occur:

- If interrupts are enabled, EPWM\_ETSEL[3] INTEN = 1h and the interrupt flag is clear, EPWM\_ETFLG[0] INT = 0h, then an interrupt pulse is generated and the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, and the event counter is cleared EPWM\_ETPS[3-2] INTCNT = 0h. The counter will begin counting events again.
- If interrupts are disabled, EPWM\_ETSEL[3] INTEN = 0, or the interrupt flag is set, EPWM\_ETFLG[0] INT = 1h, the counter stops counting events when it reaches the period value EPWM\_ETPS[3-2] INTCNT = EPWM\_ETPS[1-0] INTPRD.
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[0] INT flag is cleared. This allows for one interrupt to be pending while one is serviced.

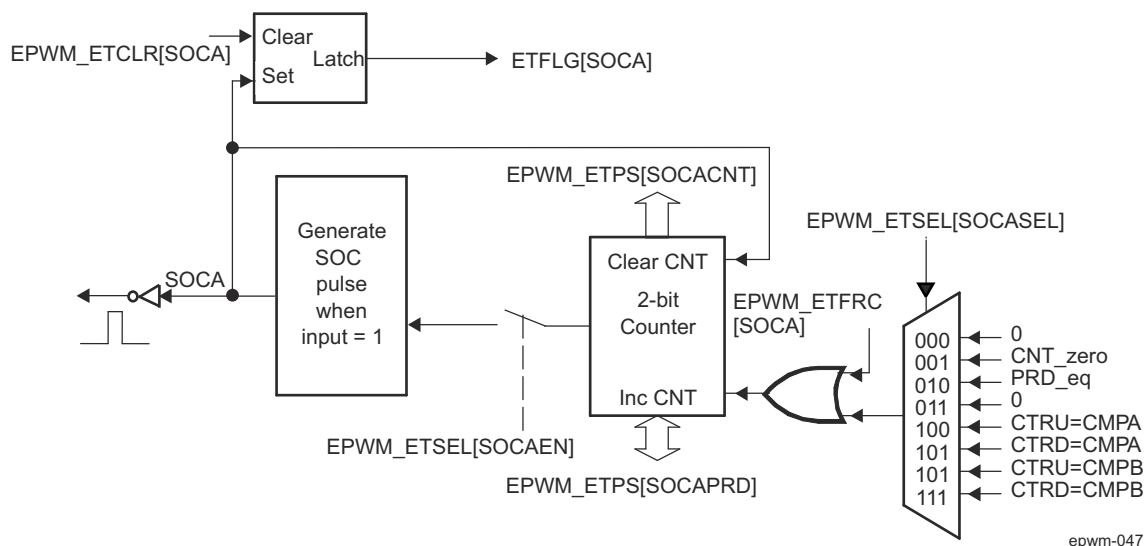

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1h to the EPWM ETFRC[0] INT bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0h, the counter is disabled and hence no events will be detected and the EPWM ETFRC[0] INT bit is also ignored.

**Figure 12-429. EPWM Event-Trigger Interrupt Generator**

#### 12.4.2.4.8.4

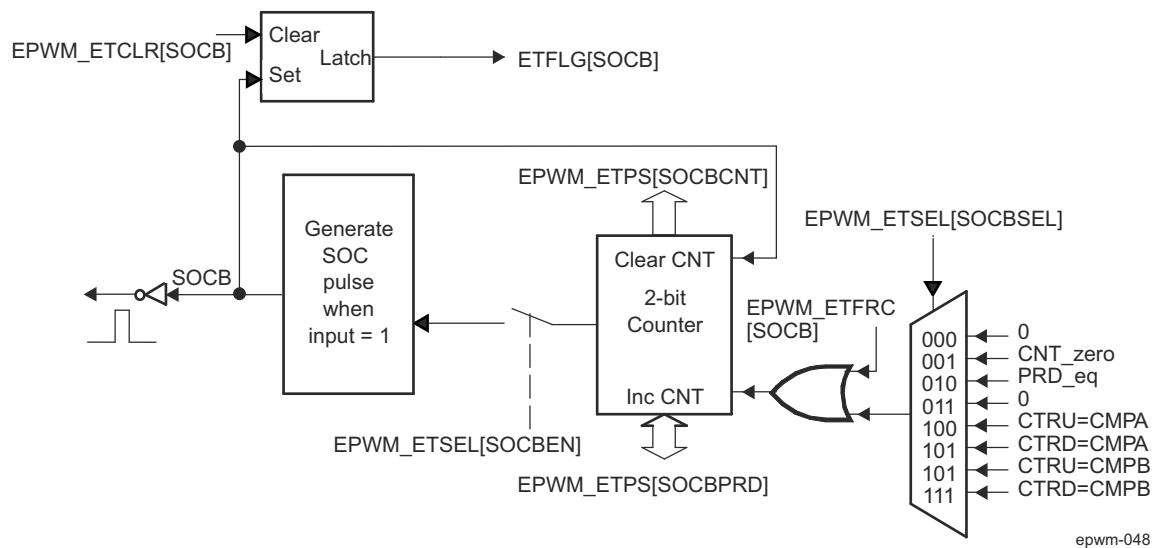

Figure 12-430 shows the operation of the event-trigger's start-of-conversion-A (SOCA) pulse generator. The EPWM\_ETPS[11-10] SOCA\_CNT counter and EPWM\_ETPS[9-8] SOCA\_PRD period values behave similarly to the interrupt generator except that the pulses are continuously generated. That is, the pulse flag EPWM\_ETFLG[2] SOCA is latched when a pulse is generated, but it does not stop further pulse generation. The enable/disable EPWM\_ETSEL[11] SOCAEN bit stops pulse generation, but input events can still be counted until the period value is reached as with the interrupt generation logic. The event that will trigger an SOCA and SOCB pulse can be configured separately in the EPWM\_ETSEL[10-8] SOCASEL and EPWM\_ETSEL[14-12] SOCBSEL bit field. The possible events are the same events that can be specified for the interrupt generation logic.

**Figure 12-430. EPWM Event-Trigger SOCA Pulse Generator**

Figure 12-431 shows the operation of the event-trigger's start-of-conversion-B (SOCB) pulse generator. The event-trigger's SOCB pulse generator operates the same way as the SOCA.

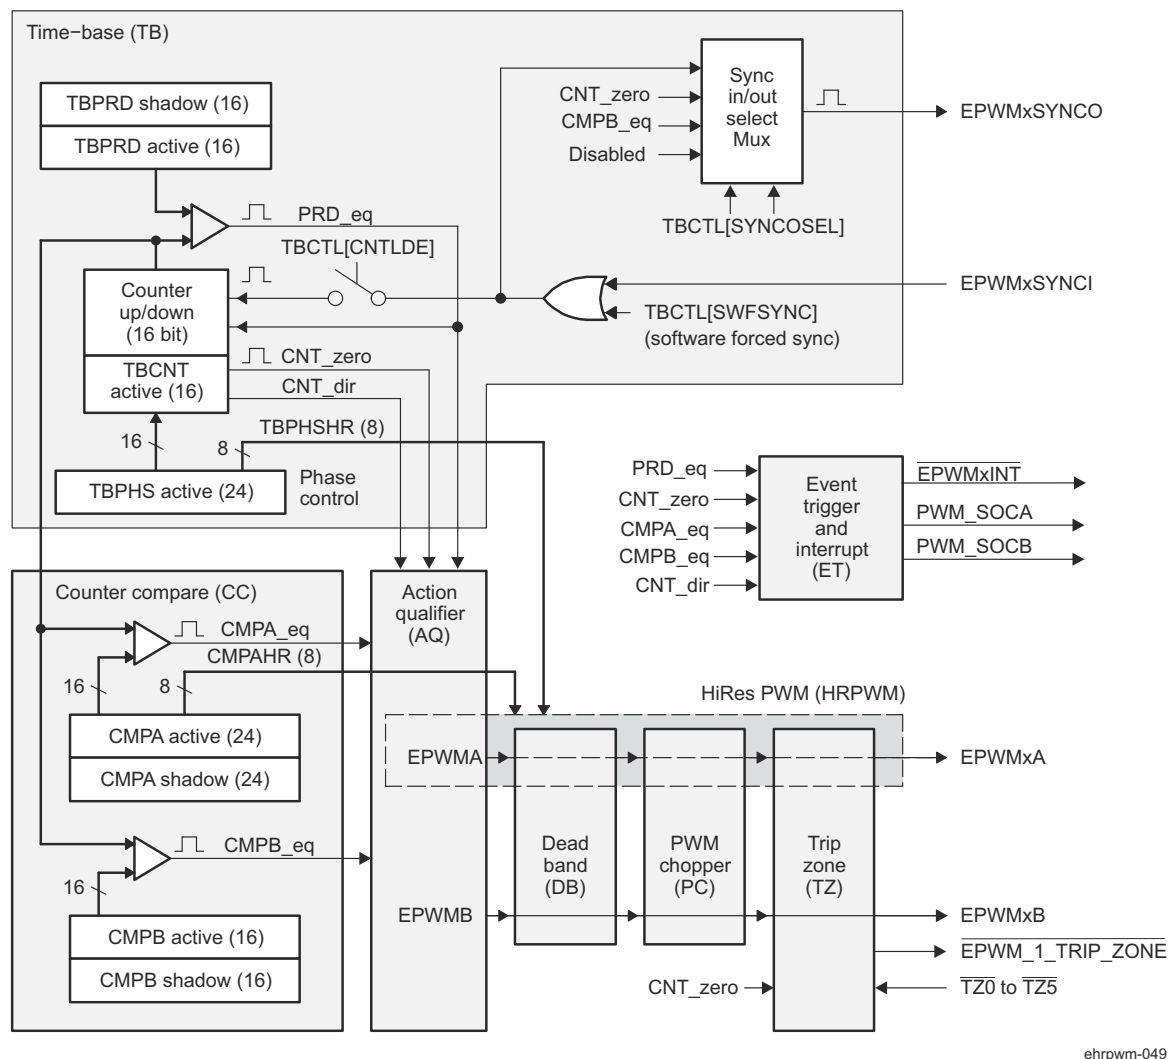

**Figure 12-431. EPWM Event-Trigger SOCB Pulse Generator**

#### 12.4.2.4.9 EPWM High Resolution (HRPWM) Submodule

This section describes the High-Resolution PWM (HRPWM) submodule in the PWM module.

##### 12.4.2.4.9.1 Overview

Figure 12-432 shows the high-resolution PWM (HRPWM) submodule in the EPWM system. Some devices include the high-resolution PWM submodule, see *EPWM Integration* to determine which EPWM instances include this feature.

**Figure 12-432. HRPWM System Interface**

The high-resolution pulse-width modulator (HRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits.

The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. **EPWMxB output has conventional PWM capabilities**

The EPWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in [Figure 12-433](#), the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

**Figure 12-433. Resolution Calculations for Conventionally Generated PWM**

Use HRPWM when the required PWM operating frequency does not offer sufficient resolution in PWM mode. As an example of improved performance offered by HRPWM, [Table 12-456](#) shows resolution in bits for various PWM frequencies. [Table 12-456](#) values assume a MEP step size of 180 ps. See the device-specific Datasheet for typical and maximum performance specifications for the MEP.

**Table 12-456. Resolution for PWM and HRPWM**

PWM Frequency (kHz)	Regular Resolution (PWM)		High Resolution (HRPWM)	
	Bits	%	Bits	%
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

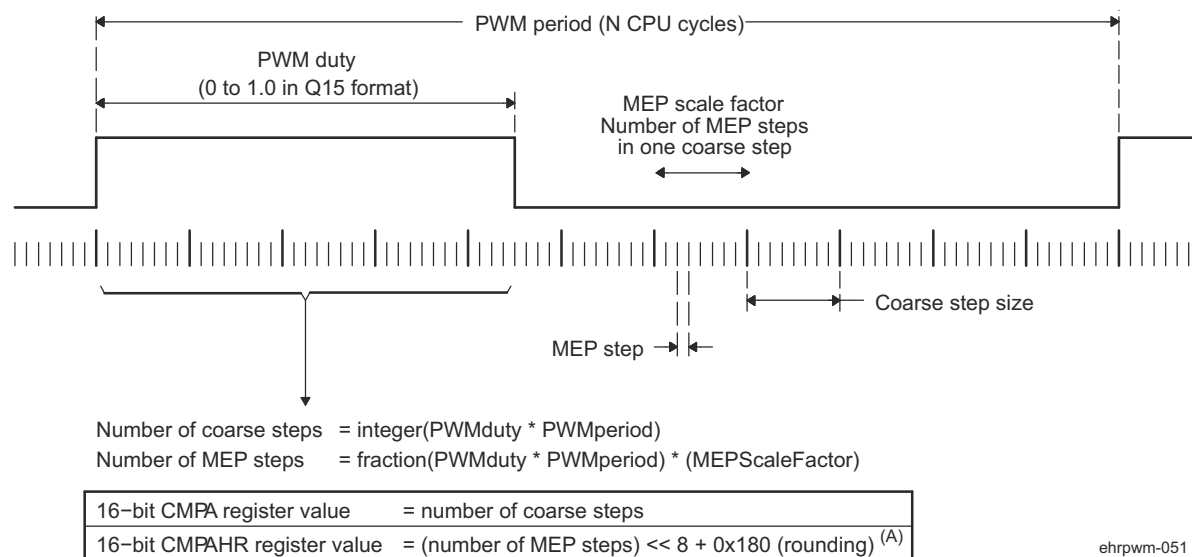

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

#### 12.4.2.4.9.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

[Figure 12-434](#) shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (HRPWM\_CMPAHR).

A. For MEP range and rounding adjustment.

**Figure 12-434. Operating Logic Using MEP**

To generate an HRPWM waveform of a given frequency and polarity, the user needs to configure the TBM (Time-Base Module), CCM (Counter-Compare Module), and AQM (Action-Qualifier Module) registers. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

#### 12.4.2.4.9.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit EPWM\_TBPHS and EPWM\_CMPA registers used to control PWM operation.

- HRPWM\_TBPHSHR — Time-Base Phase High-Resolution Register
- HRPWM\_CMPAHR — Counter-Compare A High-Resolution Register.

Table 12-457 lists the registers used to control and monitor the high-resolution PWM submodule.

**Table 12-457. HRPWM Submodule Registers**

Acronym	Register Description	Address Offset	Shadowed
HRPWM_TBPHSHR	Extension Register for HRPWM Phase	4h	No
HRPWM_CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRPWM_HRCTL	HRPWM Configuration Register	40h	No

#### 12.4.2.4.9.4 Configuring the High-Resolution PWM Submodule

Once the EPWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRPWM\_HRCTL register located at offset address 40h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the HRPWM\_CMPAHR register (duty cycle control) or the HRPWM\_TBPHSHR register (phase control). RE or FE control mode should be used with the HRPWM\_CMPAHR register. BE control mode should be used with the HRPWM\_TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the HRPWM\_CMPAHR register and should be chosen to be the

same as the regular load option for the CMPA register. If the HRPWM\_TBPHSHR register is used, then this option has no effect.

#### 12.4.2.4.9.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM (Time-Base Module) and CCM (Counter-Compare Module) registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. [Table 12-458](#) shows the typical range of operating frequencies supported by the HRPWM.

**Table 12-458. Relationship Between MEP Steps, PWM Frequency and Resolution**

System (MHz)	MEP Steps Per FICLK <sup>(1)</sup> (2) (3)	PWM Minimum (Hz) <sup>(4)</sup>	PWM Maximum (MHz)	Resolution at Maximum (Bits) <sup>(5)</sup>
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

- (1) System frequency = FICLK, that is, CPU clock. TBCLK = FICLK.
- (2) Table data based on a MEP time resolution of 180 ps (this is an example value).
- (3) MEP steps applied =  $T_{FICLK}/180$  ps in this example.
- (4) PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.
- (5) Resolution in bits is given for the maximum PWM frequency stated.

### 12.4.2.4.9.5.1 HRPWM Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, and so forth) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. Figure 12-435 shows that duty cycle of 40% (a compare value of 32 counts) is the closest to 40.5%. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 12-459.

Utilizing MEP allows to achieve an edge position much closer to the desired point of 324 ns. Table 12-459 shows that in addition to the CMPA value, 22 steps of the MEP (HRPWM\_CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

**Figure 12-435. Required PWM Waveform for a Requested Duty = 40.5%**

**Table 12-459. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)**

CMPA (count) <sup>(1) (2) (3)</sup>	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

(1) System clock, FICLK and TBCLK = 100 MHz, 10 ns

(2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

(3) Assumed MEP step size for the above example = 180 ps

#### 12.4.2.4.9.5.2 HRPWM Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (EPWM\_CMPA) and MEP (HRPWM\_CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, FICLK	=	10 ns (100 MHz)
PWM frequency	=	1.25 MHz (1/800 ns)
Required PWM duty cycle, <b>PWMDuty</b>	=	0.405 (40.5%)
PWM period in terms of coarse steps, <b>PWMperiod</b> (800 ns/10 ns)	=	80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), <b>MEP_SF</b>	=	55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value)	=	180h

#### Step 1: Percentage Integer Duty value conversion for EPWM\_CMPA register

EPWM_CMPA register value	=	$\text{int}(\text{PWMDuty} \times \text{PWMperiod})$ ; int means integer part
	=	$\text{int}(0.405 \times 80)$
	=	$\text{int}(32.4)$
EPWM_CMPA register value	=	32 (20h)

#### Step 2: Fractional value conversion for HRPWM\_CMPAHR register

HRPWM_CMPAHR register value	=	$(\text{frac}(\text{PWMDuty} \times \text{PWMperiod}) \times \text{MEP\_SF}) \ll 8) + 180\text{h}$ ; frac means fractional part
	=	$(\text{frac}(32.4) \times 55 \ll 8) + 180\text{h}$ ; Shift is to move the value as CMPAHR high byte
	=	$((0.4 \times 55) \ll 8) + 180\text{h}$
	=	$(22 \ll 8) + 180\text{h}$
	=	$22 \times 256 + 180\text{h}$ ; Shifting left by 8 is the same multiplying by 256.
	=	$5632 + 180\text{h}$
	=	$1600\text{h} + 180\text{h}$
HRPWM_CMPAHR value	=	1780h; HRPWM_CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

### 12.4.2.4.9.5.3 HRPWM Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 FICLK cycles after the period starts.

Duty cycle range limitations are illustrated in Figure 12-436. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

**Figure 12-436. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz**

If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 12-437. In this case low percent duty limitation is no longer an issue.

**Figure 12-437. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz**

### 12.4.2.4.10 EPWM / HRPWM Functional Register Groups

The Table 12-460 lists the groups of EPWM and the high-resolution PWM module registers according to their functionalities.

**Table 12-460. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule**

Register Name	Offset	Size (×16)	Shadow	Register Description
<b>Time-Base (TB) Submodule Registers</b>				
EPWM_TBCTL	0h	1	No	Time-Base Control Register

**Table 12-460. EPWM / HRPWM Module Control and Status Registers Grouped by Submodule (continued)**

Register Name	Offset	Size (×16)	Shadow	Register Description
EPWM_TBSTS	2h	1	No	Time-Base Status Register
EPWM_TBPHS	6h	1	No	Time-Base Phase Register
EPWM_TBCNT	8h	1	No	Time-Base Counter Register
EPWM_TBPRD	Ah	1	Yes	Time-Base Period Register
<b>Counter-Compare (CC) Submodule Registers</b>				
EPWM_CMPCTL	Eh	1	No	Counter-Compare Control Register
EPWM_CMPA	12h	1	Yes	Counter-Compare A Register
EPWM_CMPB	14h	1	Yes	Counter-Compare B Register
<b>Action-Qualifier (AQ) Submodule Registers</b>				
EPWM_AQCTLA	16h	1	No	Action-Qualifier Control Register for Output A (EPWMxA)
EPWM_AQCTLB	18h	1	No	Action-Qualifier Control Register for Output B (EPWMxB)
EPWM_AQSFRC	1Ah	1	No	Action-Qualifier Software Force Register
EPWM_AQCSFRC	1Ch	1	Yes	Action-Qualifier Continuous S/W Force Register Set
<b>Dead-Band (DB) Generator Submodule Registers</b>				
EPWM_DBCTL	1Eh	1	No	Dead-Band Generator Control Register
EPWM_DBRED	20h	1	No	Dead-Band Generator Rising Edge Delay Count Register
EPWM_DBFED	22h	1	No	Dead-Band Generator Falling Edge Delay Count Register
<b>Trip-Zone (TZ) Submodule Registers</b>				
EPWM_TZSEL	24h	1	No	Trip-Zone Select Register
EPWM_TZCTL	28h	1	No	Trip-Zone Control Register <sup>(1)</sup>
EPWM_TZEINT	2Ah	1	No	Trip-Zone Enable Interrupt Register <sup>(1)</sup>
EPWM_TZFLG	2Ch	1	No	Trip-Zone Flag Register <sup>(1)</sup>
EPWM_TZCLR	2Eh	1	No	Trip-Zone Clear Register <sup>(1)</sup>
EPWM_TZFRC	30h	1	No	Trip-Zone Force Register <sup>(1)</sup>
<b>Event-Trigger (ET) Submodule Registers</b>				
EPWM_ETSEL	32h	1	No	Event-Trigger Selection Register
EPWM_ETPS	34h	1	No	Event-Trigger Pre-Scale Register
EPWM_ETFLG	36h	1	No	Event-Trigger Flag Register
EPWM_ETCLR	38h	1	No	Event-Trigger Clear Register
EPWM_ETFRC	3Ah	1	No	Event-Trigger Force Register
<b>PWM-Chopper Submodule Registers</b>				
EPWM_PCCTL	3Ch	1	No	PWM-Chopper Control Register
<b>High-Resolution PWM (HRPWM) Submodule Registers</b>				
HRPWM_TBPHSHR	4h	1	No	Extension for HRPWM Phase Register
HRPWM_CMPAHR	10h	1	No	Extension for HRPWM Counter-Compare A Register
HRPWM_HRCTL	40h	1	No	HRPWM Control Register

(1) EALLOW protected registers.

#### 12.4.2.4.11 Proper EPWM Interrupt Initialization Procedure

When the EPWM peripheral clock is enabled it is possible that interrupt flags may be set due to spurious events as the EPWM registers not being properly initialized. The proper procedure for initializing the EPWM peripheral is:

1. Disable global interrupts (CPU INTM flag)

2. Disable EPWM interrupts
3. Initialize peripheral registers
4. Clear any spurious EPWM flags
5. Enable EPWM interrupts
6. Enable global interrupts

### 12.4.3 Enhanced Quadrature Encoder Pulse (EQEP) Module

This section describes the Enhanced Quadrature Encoder Pulse (EQEP) module in the device.

#### 12.4.3.1 EQEP Overview

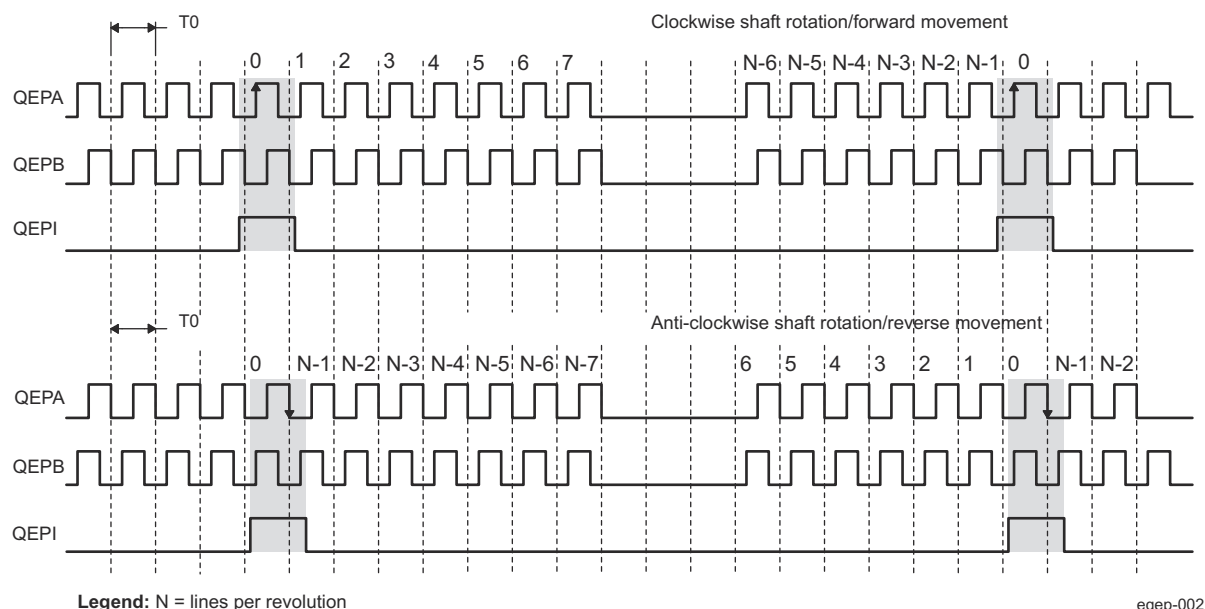

The Enhanced Quadrature Encoder Pulse (EQEP) peripheral is used for direct interface with a linear or rotary incremental encoder to get position, direction and speed information from a rotating machine for use in high performance motion and position control system. The disk of an incremental encoder is patterned with a single track of slots patterns, as shown in [Figure 12-438](#). These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position and zero reference.

**Figure 12-438. Optical Encoder Disk**

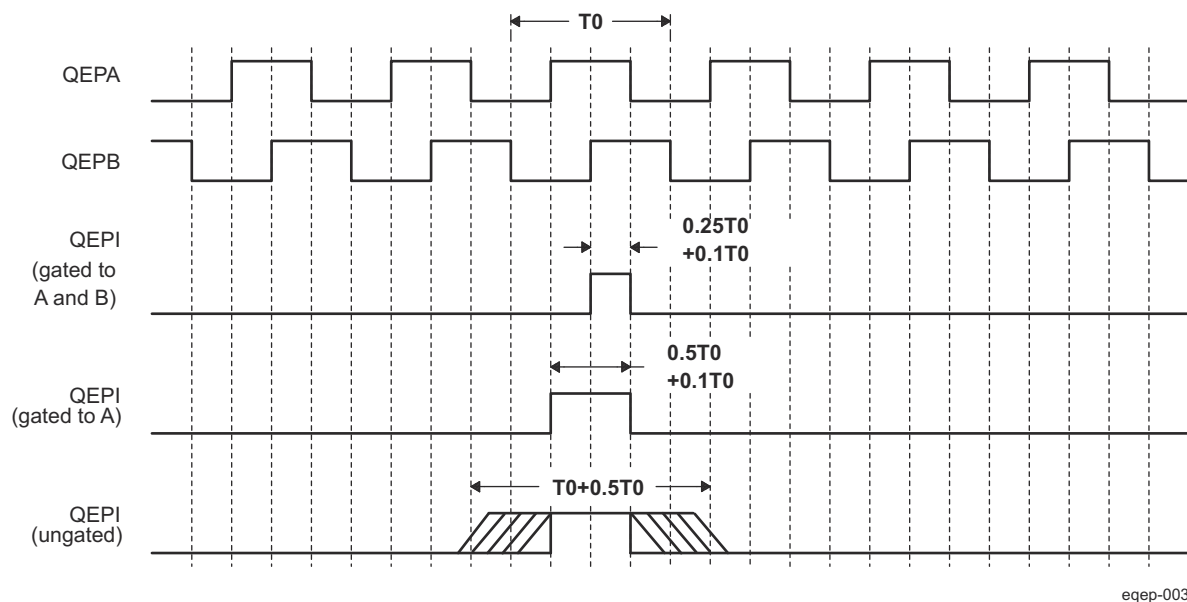

To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vice versa as shown in [Figure 12-439](#).

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 kHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

**Figure 12-439. QEP Encoder Output Signal for Forward/Reverse Movement**

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 12-440. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

**Figure 12-440. Index Pulse Example**

Some typical applications for rotary encoders range from fax machines to motor controllers, and even robot localization. Rotary sensors are fundamental to the robotics and motion control systems found today. The optical shaft encoder can be used to improve a robot in various ways. The encoder can measure rotational distance traveled and speed, which can be used to monitor, for example, the angular position of a robot gripper arm or the speed of a robot.

**General Issues:** Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$V(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{eqep-004} \quad (19)$$

$$V(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad \text{eqep-005} \quad (20)$$

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k - 1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$t(k)$ : Time instant " $k$ "

$t(k-1)$ : Time instant " $k - 1$ "

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement.

[Equation 19](#) is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity  $[x(k) - x(k-1)]$  is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant  $1/T$  (where  $T$  is the constant time between unit time events and is known in advance).

Estimation based on [Equation 19](#) has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period  $T$ . For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, [Equation 20](#) provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. [Equation 20](#) can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation of [Equation 19](#). A combination of relatively large motor speeds and high sensor resolution makes the time interval  $\Delta T$  small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use [Equation 20](#) at low speed and have the software switch over to [Equation 19](#) when the motor speed rises above some specified threshold.

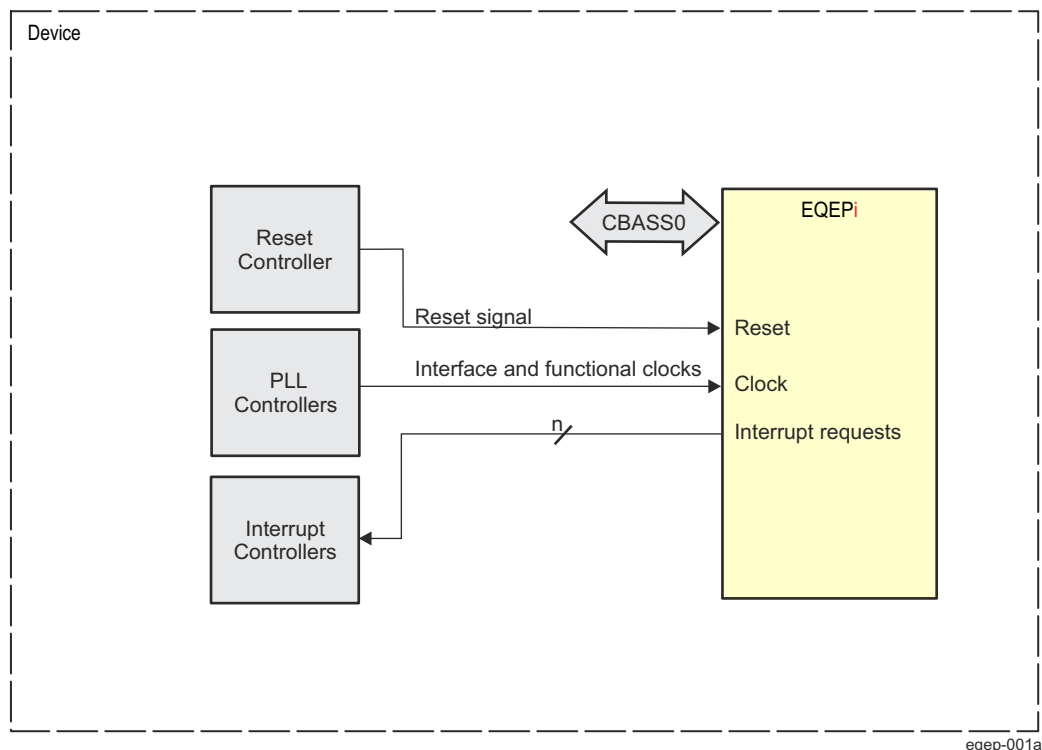

The device has three instances of the EQEP modules.

Table 12-461 shows the EQEP allocation across device domains.

**Table 12-461. EQEP Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
EQEP0	-	-	✓
EQEP1	-	-	✓
EQEP2	-	-	✓

Figure 12-441 shows the EQEP module overview.

A.  $i = 0 \text{ to } 2$

**Figure 12-441. EQEP Overview**

#### 12.4.3.1.1 EQEP Features

The EQEP module includes the following features:

- Input synchronization
- Three stage/six stage digital noise filter
- Quadrature decoder unit
- Position counter and control unit for position measurement
- Quadrature edge capture unit for low-speed measurement
- Unit time base for speed and frequency measurement
- Watchdog timer for detecting stalls
- EQEP inputs (A/B/INDEX and STROBE) are available at chip level
- EQEP phase error output is also available. The status of the phase error can be observed by software through the CTRLMMR\_EQEP\_STAT register in the CTRL\_MMR0 module.

#### 12.4.3.1.2 EQEP Not Supported Features

The following EQEP features are not supported:

- EQEP quadrature outputs (A and B) are not pinned out

For more information about EQEP module restrictions in functionality, see *Device Specific EQEP Features*.

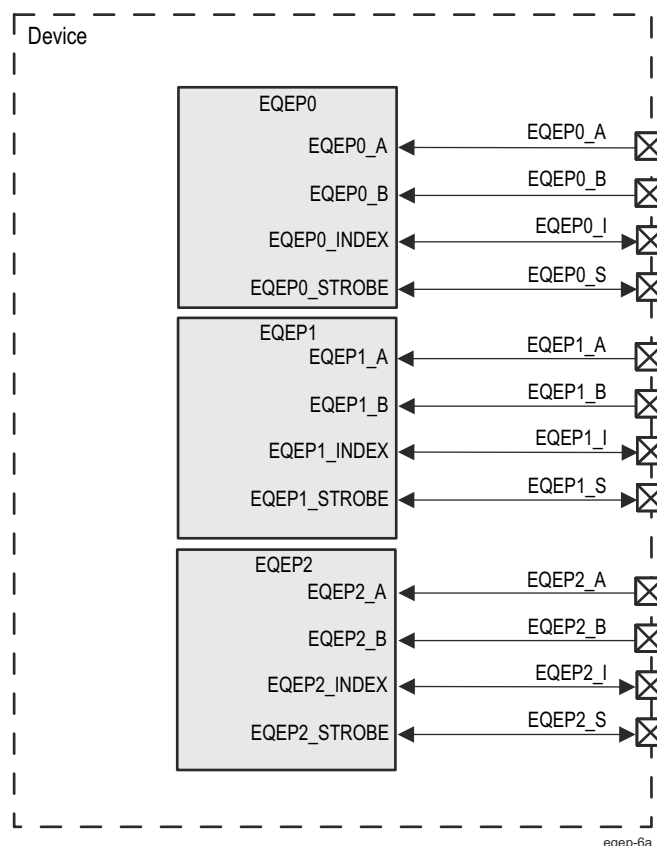

### 12.4.3.2 EQEP Environment

#### 12.4.3.2.1 EQEP I/O Interface

The EQEP<sub>i</sub> (where  $i = 0$  to 2) module is hereinafter referred to as EQEP module.

This section describes the EQEP external connections (environment).

Figure 12-442 shows the EQEP interface signals.

**Figure 12-442. EQEP External Interface I/Os**

Table 12-462 describes the EQEP I/O signals.

**Table 12-462. EQEP I/O Signals**

Module Pin	Device Level Signal Name	I/O Type <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>EQEP0</b>				
EQEP0_A	EQEP0_A	I	EQEP0 Quadrature input A	HiZ
EQEP0_B	EQEP0_B	I	EQEP0 Quadrature input B	HiZ
EQEP0_INDEX	EQEP0_I	I/O <sup>(3)</sup>	EQEP0 Index input/output	HiZ
EQEP0_STROBE	EQEP0_S	I/O <sup>(3)</sup>	EQEP0 Strobe input/output	HiZ
<b>EQEP1</b>				
EQEP1_A	EQEP1_A	I	EQEP1 Quadrature input A	HiZ
EQEP1_B	EQEP1_B	I	EQEP1 Quadrature input B	HiZ
EQEP1_INDEX	EQEP1_I	I/O <sup>(3)</sup>	EQEP1 Index input/output	HiZ
EQEP1_STROBE	EQEP1_S	I/O <sup>(3)</sup>	EQEP1 Strobe input/output	HiZ
<b>EQEP2</b>				
EQEP2_A	EQEP2_A	I	EQEP2 Quadrature input A	HiZ

**Table 12-462. EQEP I/O Signals (continued)**

Module Pin	Device Level Signal Name	I/O Type <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
EQEP2_B	EQEP2_B	I	EQEP2 Quadrature input B	HiZ
EQEP2_INDEX	EQEP2_I	I/O <sup>(3)</sup>	EQEP2 Index input/output	HiZ
EQEP2_STROBE	EQEP2_S	I/O <sup>(3)</sup>	EQEP2 Strobe input/output	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Output functionality is not supported. Only inputs are pinned out. For more information see *Device Specific EQEP Features*.

### Note

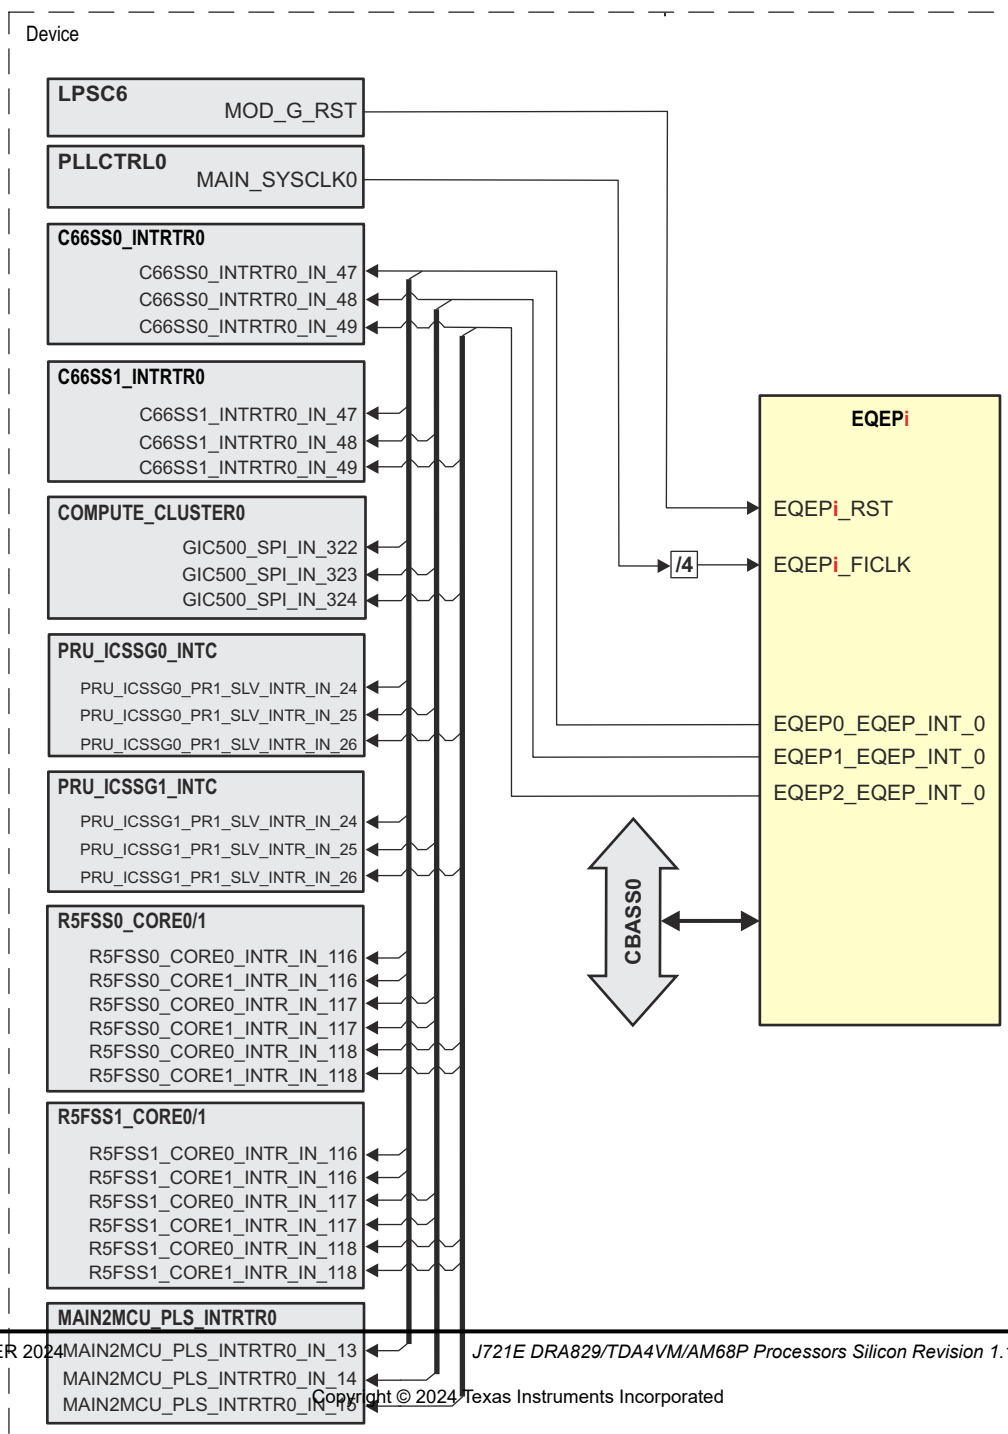

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

### 12.4.3.3 EQEP Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

There are three EQEP modules integrated in the device MAIN domain - EQEP0, EQEP1 and EQEP2.

[Figure 12-443](#) shows the integration of EQEPi.

**Table 12-463. EQEP Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
EQEP0	PSC0	PD0	LPSC6	CBASS0
EQEP1	PSC0	PD0	LPSC6	CBASS0
EQEP2	PSC0	PD0	LPSC6	CBASS0

**Table 12-464. EQEP Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
EQEP0	EQEP0_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	EQEP0 functional and interface clock
EQEP1	EQEP1_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	EQEP1 functional and interface clock
EQEP2	EQEP2_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	EQEP2 functional and interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
EQEP0	EQEP0_RST	MOD_G_RST	LPSC6	Module Reset

### 12.4.3.3.1 Device Specific EQEP Features

The EQEP module interface has some restrictions in functionality. The EQEP restrictions are, as follows:

- **Only EQEP inputs (A / B / INDEX and STROBE) are available to user at chip level**
- **EQEP phase error output (EQEP\_ERR\_PHASE\_ERR) is also available**
  - The status of the phase error can be observed by software using the CTRLMMR\_EQEP\_STAT register in the CTRL\_MMR0 module.

The EQEP functional interface signals which are NOT available to user are summarized in [Table 12-466](#).

**Table 12-466. Device Limitations for the EQEP Functional Interfaces**

Module Interface	Signal	Description	Comment
<b>EQEPi</b> (where i = 0 to 2 for the device)	EQEP_EQEPA_O	EQEP quadrature A output	Not available at chip boundary (can not be used)
	EQEP_EQEPB_O	EQEP quadrature B output	
	EQEP_EQEPA_OEN	EQEP quadrature A output enable	
	EQEP_EQEPB_OEN	EQEP quadrature B output enable	

### 12.4.3.4 EQEP Functional Description

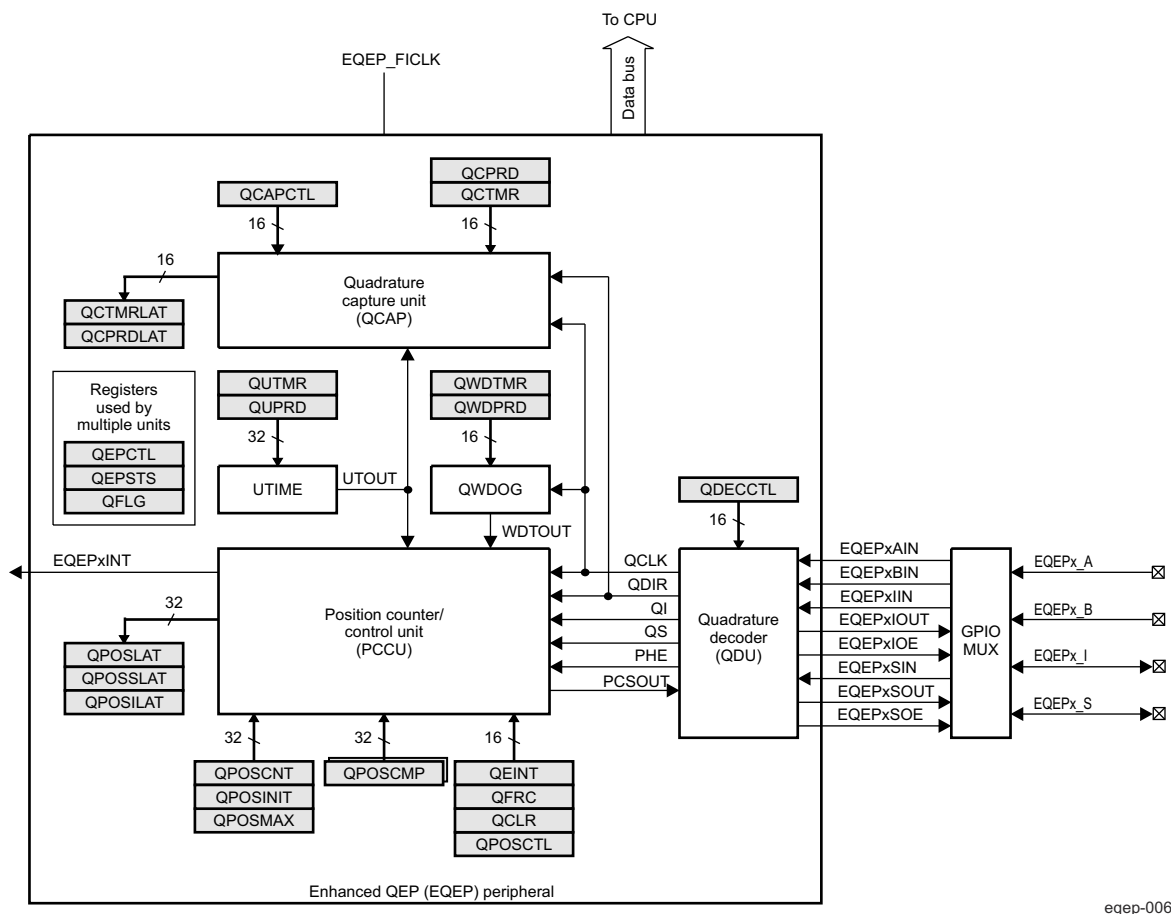

This section provides the EQEP functional description and corresponding functional details about EQEPx inputs.

#### Note

Multiple identical EQEP modules can be contained in a system. For actual number of EQEP modules integrated in the device, refer to *EQEP Integration*. The letter x within a signal or module name is used to indicate a generic EQEP instance on a device. For example, output interrupt request, EQEP0\_EQEP\_INT\_0 belongs to EQEP0, EQEP1\_EQEP\_INT\_0 belongs to EQEP1, and so forth.

The EQEP peripheral contains the following major functional units (as shown in Figure 12-444):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Three stage/six stage digital noise filter
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG).

**Figure 12-444. Functional Block Diagram of the EQEP Peripheral**

#### 12.4.3.4.1 EQEP Inputs

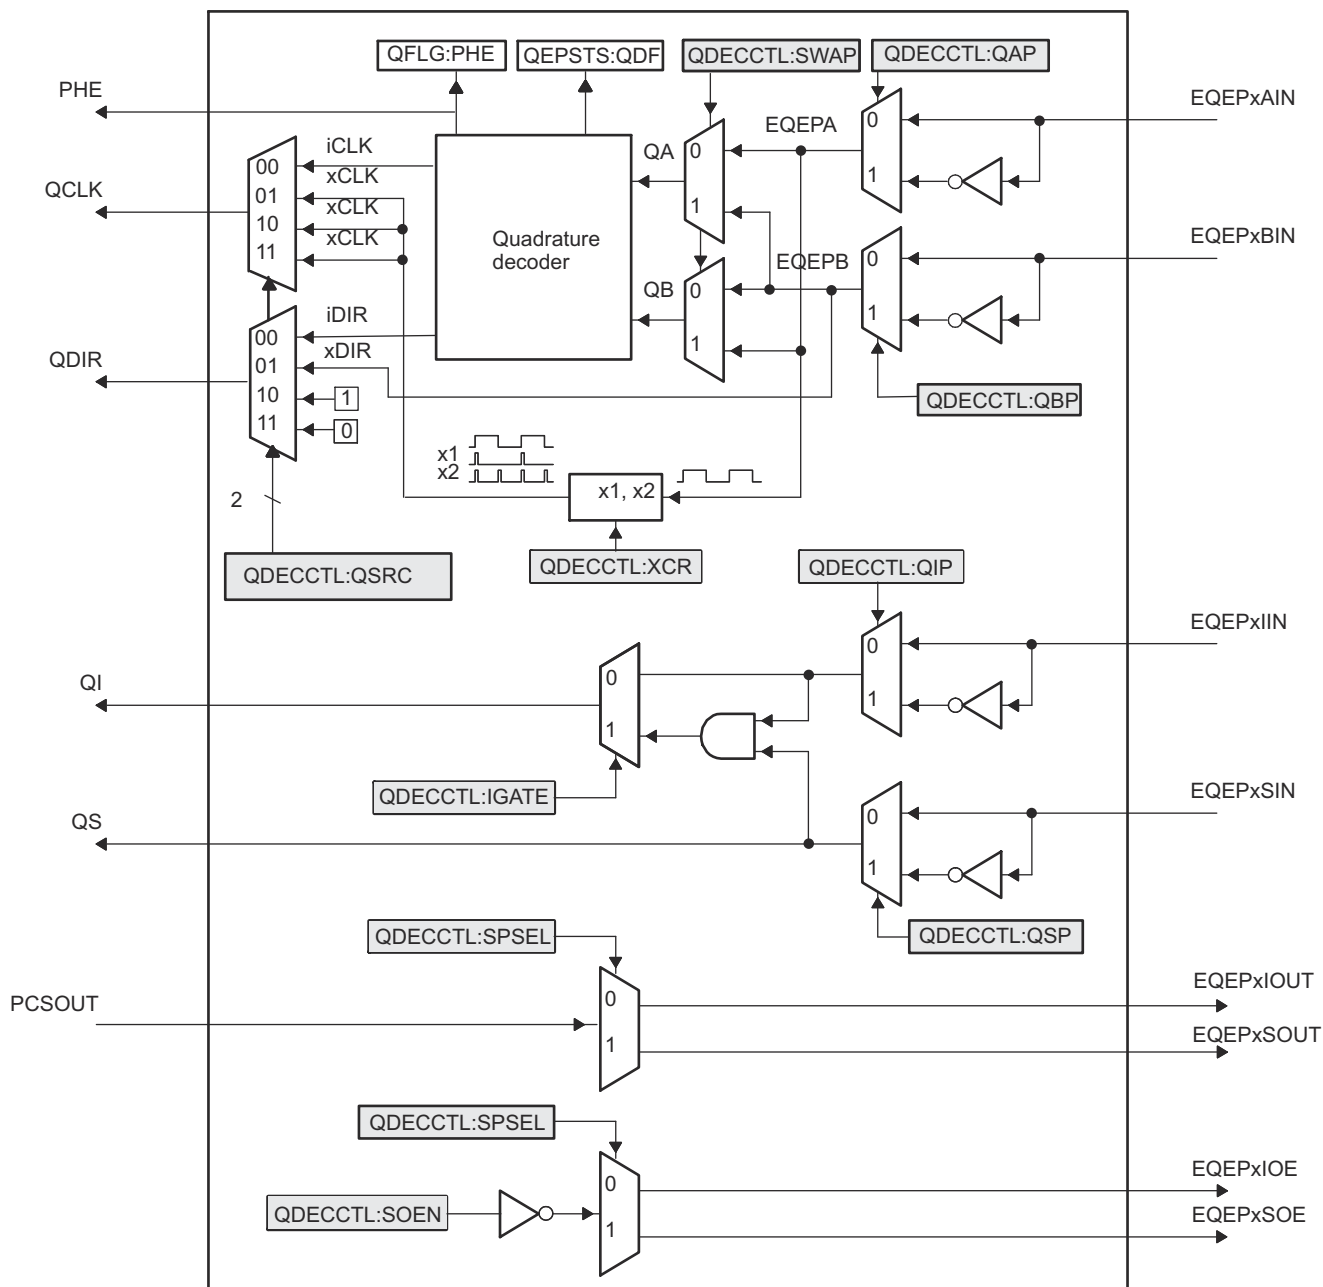

The EQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

- EQEPx\_A and EQEPx\_B: These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock mode: The EQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of EQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The EQEPx\_A pin provides the clock input and the EQEPx\_B pin provides the direction input.
- EQEPx\_I: Index or Zero Marker: The EQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the EQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- EQEPx\_S: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

#### 12.4.3.4.2 EQEP Quadrature Decoder Unit (QDU)

Figure 12-445 shows a functional block diagram of the QDU.

eqep-007

**Figure 12-445. Functional Block Diagram of Decoder Unit**

#### 12.4.3.4.2.1 EQEP Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode.

##### 12.4.3.4.2.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

#### Direction Decoding

The direction decoding logic of the EQEP circuit determines which one of the sequences (EQEPA, EQEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the EQEP status register (EQEP\_QEP\_STS\_CT). [Table 12-467](#) and [Figure 12-446](#) show the direction decoding logic in truth table and state machine form. Both edges of the EQEPA and EQEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the EQEP logic is four times that of each input sequence. [Figure 12-447](#) shows the direction decoding and clock generation from the EQEP input signals.

#### Phase Error Flag

In normal operating conditions, quadrature inputs EQEPA and EQEPB will be 90 degrees out of phase. The phase error flag (QPEI\_FLG) is set in the EQEP\_QINT\_EN\_FLG register when edge transition is detected simultaneously on the EQEPA and EQEPB signals to optionally generate interrupts. State transitions marked by dashed lines in [Figure 12-446](#) are invalid transitions that generate a phase error.

#### Count Multiplication

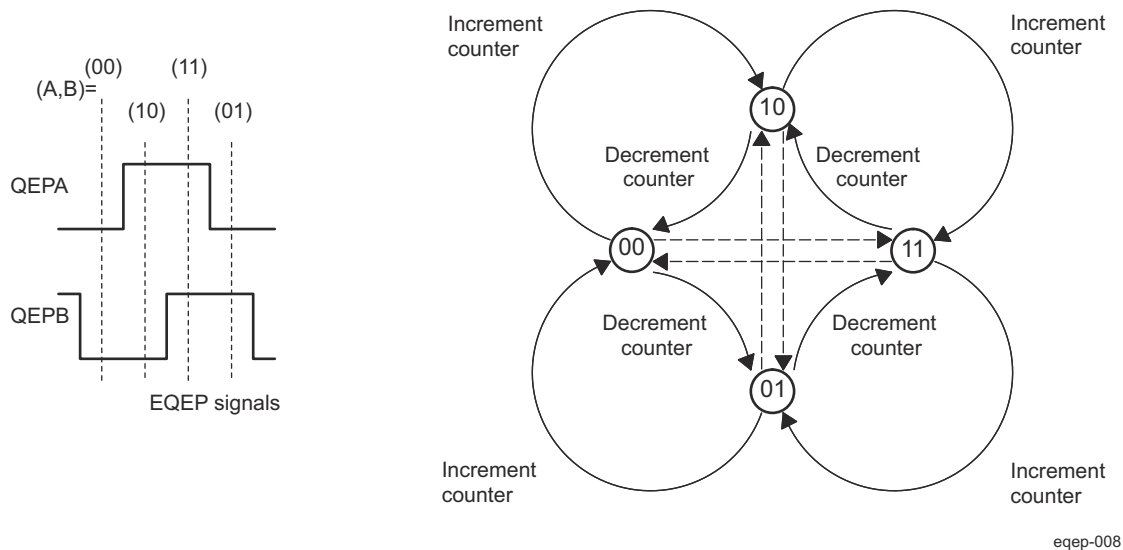

The EQEP position counter provides 4× times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both EQEP input clocks (EQEPA and EQEPB) as shown in [Figure 12-447](#).

#### Reverse Count

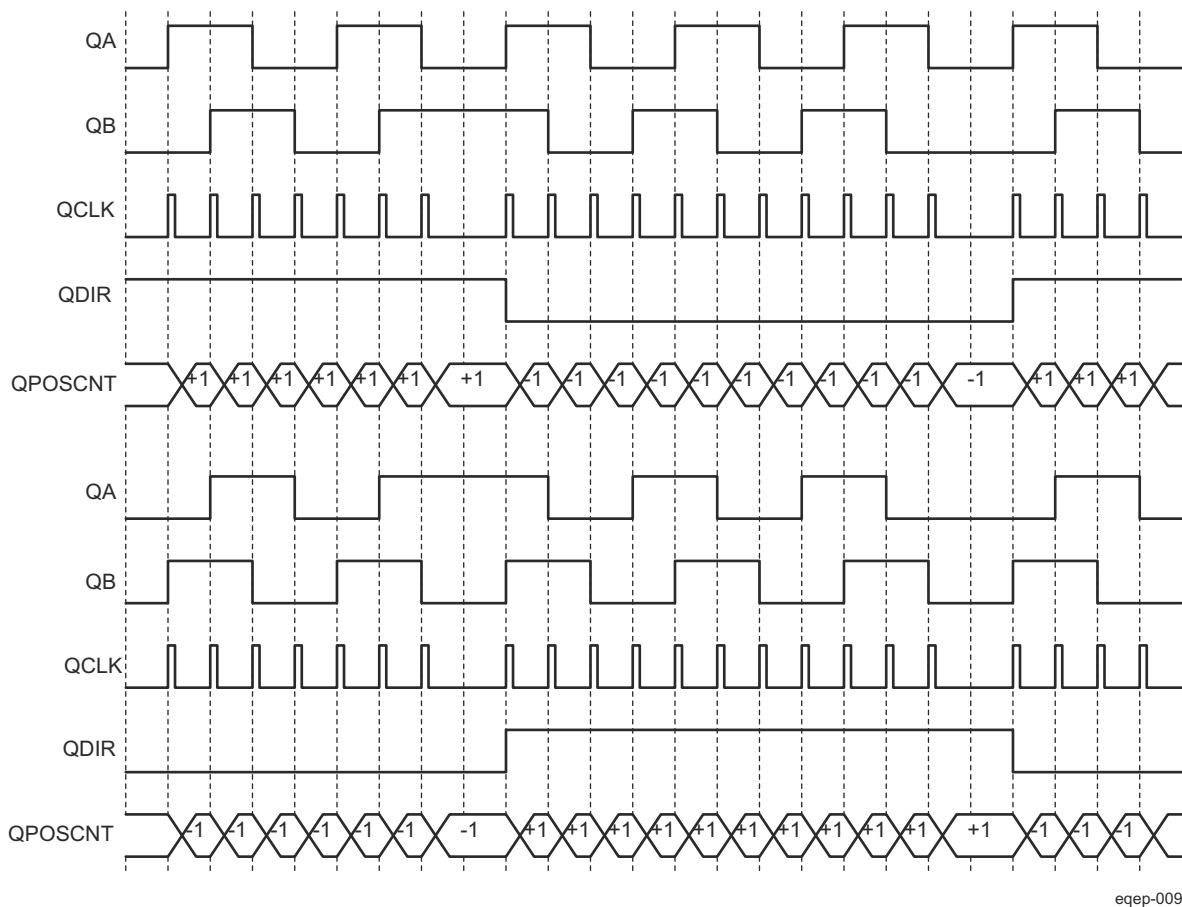

In normal quadrature count operation, EQEPA input is fed to the QA input of the quadrature decoder and the EQEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

**Table 12-467. Quadrature Decoder Truth Table**

Previous Edge	Present Edge	QDIR	QPOSCNT
QA↑	QB↑	UP	Increment
	QB↓	DOWN	Decrement
	QA↓	TOGGLE	Increment or Decrement
QA↓	QB↓	UP	Increment
	QB↑	DOWN	Decrement
	QA↑	TOGGLE	Increment or Decrement
QB↑	QA↑	DOWN	Increment
	QA↓	UP	Decrement
	QB↓	TOGGLE	Increment or Decrement
QB↓	QA↓	DOWN	Increment
	QA↑	UP	Decrement
	QB↑	TOGGLE	Increment or Decrement

**Figure 12-446. Quadrature Decoder State Machine**

**Figure 12-447. Quadrature-clock and Direction Decoding**

#### 12.4.3.4.2.1.2 EQEP Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. EQEPA input will provide the clock for position counter and the EQEPB input will have the direction information. The position counter is incremented on every rising edge of a EQEPA input when the direction input is high and decremented when the direction input is low.

#### 12.4.3.4.2.1.3 EQEP Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.3.4.2.1.4 EQEP Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the EQEPA input. Setting of the XCR bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables clock generation to the position counter on both edges of a EQEPA input, thereby increasing the measurement resolution by 2× factor.

#### 12.4.3.4.2.2 EQEP Input Polarity Selection

Each EQEP input can be inverted using the in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL[8-5]) control bits. As an example, setting of the QIP bit in EQEP\_QDEC\_QEP\_CTL inverts the index input.

#### 12.4.3.4.2.3 EQEP Position-Compare Sync Output

The EQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (EQEP\_QPOSCNT) and the position-compare register (EQEP\_QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the EQEP decoder and control register (EQEP\_QDEC\_QEP\_CTL) enables the position-compare sync output and the SPSEL bit in EQEP\_QDEC\_QEP\_CTL selects either an EQEP index pin or an EQEP strobe pin.

#### 12.4.3.4.3 EQEP Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (EQEP\_QDEC\_QEP\_CTL and EQEP\_QCAP\_QPOS\_CTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

##### 12.4.3.4.3.1 EQEP Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement).

In all the above operating modes, position counter is reset to 0 on overflow and to QPOS MAX bifield value in EQEP\_QPOS MAX register on underflow. Overflow occurs when the position counter counts up after QPOS MAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in EQEP\_QINT\_EN\_FLG register.

#### 12.4.3.4.3.1.1 EQEP Position Counter Reset on Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM] = 0b00)

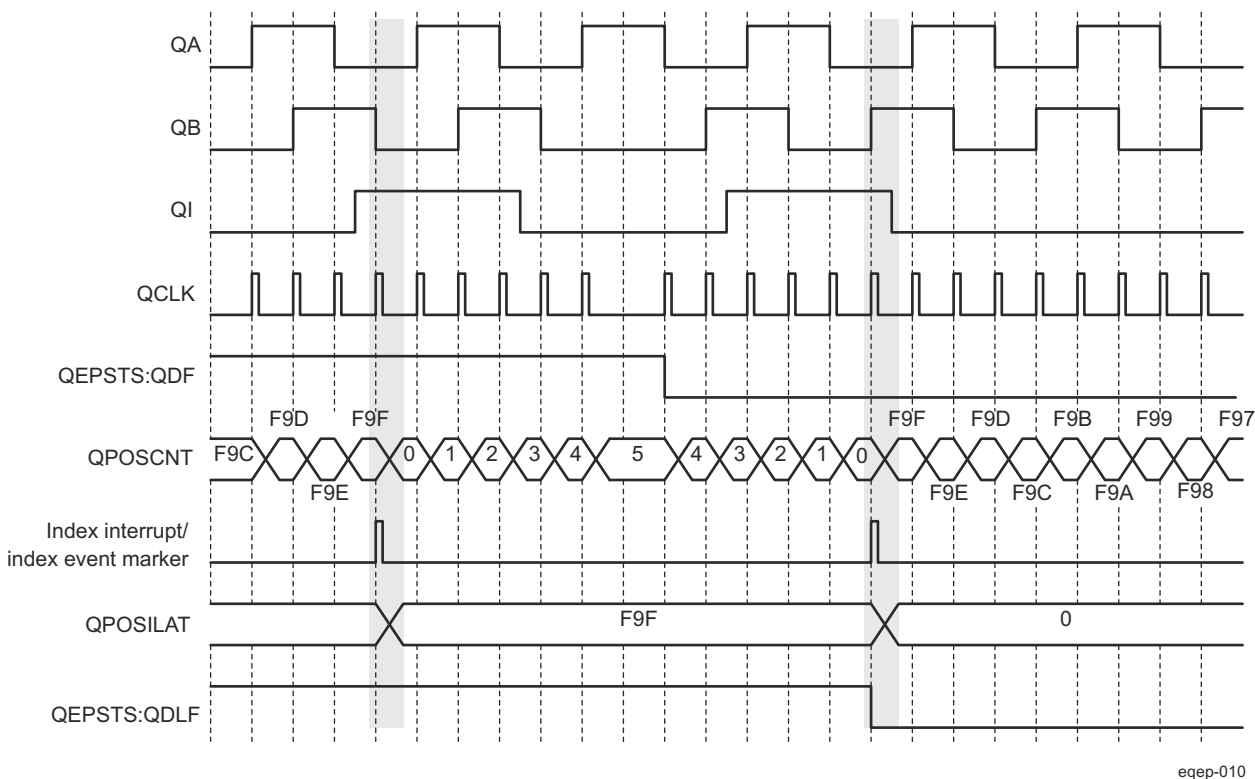

If the index event occurs during the forward movement, then position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOS MAX register on the next EQEP clock.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of EQEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of EQEPB for the forward rotation and on the rising edge of EQEPB for the reverse rotation as shown in Figure 12-448.

The position-counter value is latched to the EQEP\_QPOSILAT register and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) and error interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) are set if the latched value is not equal to 0 or QPOS MAX. The position-counter error flag (EQEP\_QEP\_STS\_CT[0] PCEF) is updated on every index event marker and an interrupt flag (EQEP\_QINT\_EN\_FLG[17] PCEI\_FLG) will be set on error that can be cleared only through software.

The index event latch configuration EQEP\_QDEC\_QEP\_CTL[21-20] IEL bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

eqep-010

**Figure 12-448. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOS MAX = 3999 or F9Fh)**

#### 12.4.3.4.3.1.2 EQEP Position Counter Reset on Maximum Position (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM=0b01)

If the position counter is equal to QPOSMAX (in EQEP\_QPOSMAX register), then the position counter is reset to 0 on the next EQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to 0, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 12-449 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF); it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL= 0b11).

**Figure 12-449. Position Counter Underflow/Overflow (QPOSMAX = 4)**

eqep-011

#### 12.4.3.4.3.1.3 Position Counter Reset on the First Index Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next EQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the EQEP\_QPOSMAX register on the next EQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in [Section 12.4.3.4.3.1.2](#).

First index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and direction on the first index event marker (EQEP\_QEP\_STS\_CT[6] FIDF) in EQEP\_QEP\_STS\_CT registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11).

#### 12.4.3.4.3.1.4 Position Counter Reset on Unit Time out Event (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b11)

In this mode, the QPOSCNT value is latched to the EQEP\_QPOSILAT register and then the QPOSCNT field is reset (to 0 or the QPOSMAX value in the EQEP\_QPOSMAX register, depending on the direction mode selected by EQEP\_QDEC\_QEP\_CTL[15-14] QSRC bits on a unit time event). This is useful for frequency measurement.

#### 12.4.3.4.3.2 EQEP Position Counter Latch

The EQEP index and strobe input can be configured to latch the position counter QPOSCNT (EQEP\_QPOSCNT) into QPOSILAT (EQEP\_QPOSILAT register) and QPOSSLAT (EQEP\_QPOSSLAT register) bitfields, respectively, on occurrence of a definite event on these pins.

##### 12.4.3.4.3.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b01 and EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b10 modes).

In such cases, the EQEP position counter can be configured to latch on the following events and direction information is recorded in the EQEP\_QEP\_STS\_CT[4] QDLF bit on every index event marker.

- Latch on Rising edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)
- Latch on Falling edge (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)
- Latch on Index Event Marker (EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (EQEP\_QINT\_EN\_FLG[26] IELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSILAT register. The index event latch configuration bits are ignored when EQEP\_QDEC\_QEP\_CTL[29-28] PCRM = 0b00.

When Position counter reset on an index event mode is selected through EQEP\_QDEC\_QEP\_CTL[29-28] PCRM bit field (value: 0h), EQEP\_QDEC\_QEP\_CTL[21-20] IEL bit field must be configured to 0h and position counter value is latched into the EQEP\_QPOSILAT[31-0] QPOSILAT register for every index marker.

##### Latch on Rising Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b01)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every rising edge of an index input.

##### Latch on Falling Edge

(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b10)

The position counter value (QPOSCNT) is latched to the EQEP\_QPOSILAT register on every falling edge of index input.

##### Latch on Index Event

Marker/Software Index Marker  
(EQEP\_QDEC\_QEP\_CTL[21-20] IEL = 0b11)

The first index marker is defined as the quadrature edge following the first index edge. The EQEP peripheral records the occurrence of the first index marker (EQEP\_QEP\_STS\_CT[1] FIMF) and

Figure 12-450 shows the position counter latch using an index event marker.

Instruments Families of Products

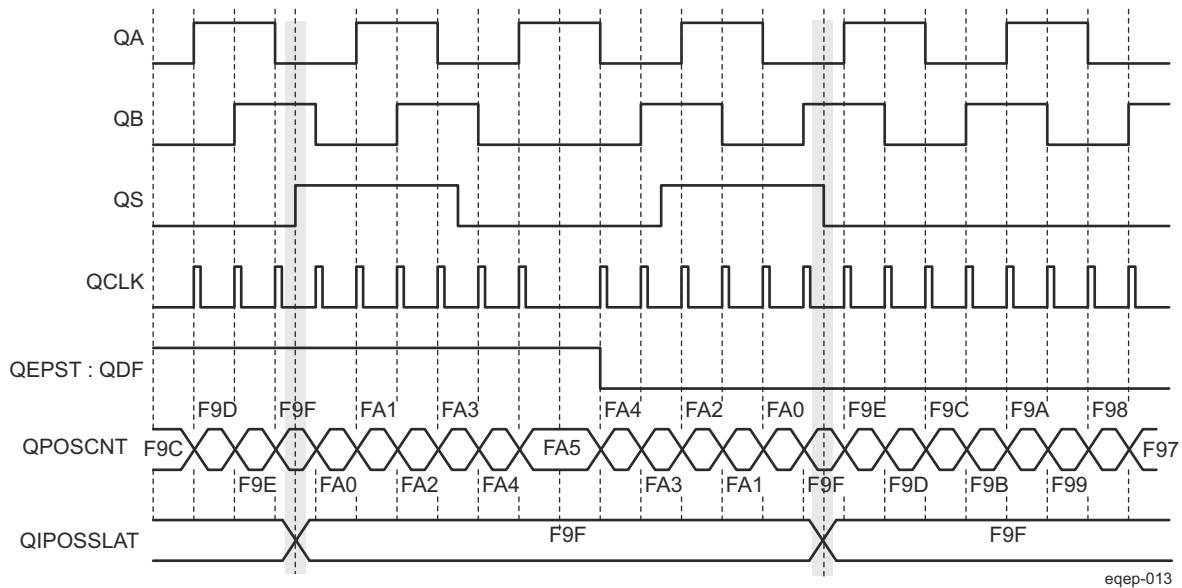

#### 12.4.3.4.3.2.2 EQEP Strobe Event Latch

The position-counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input (QCLK) by clearing the EQEP\_QDEC\_QEP\_CTL[22] SEL bit. Latching on the falling edge of the strobe input (QCLK) can be done by inverting the strobe input using the EQEP\_QDEC\_QEP\_CTL[5] QSP bit.

If the EQEP\_QDEC\_QEP\_CTL[22] SEL bit is set, then the position counter value is latched to the EQEP\_QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in [Figure 12-451](#).

The strobe event latch interrupt flag (EQEP\_QINT\_EN\_FLG[25] SELI\_FLG) is set when the position counter is latched to the EQEP\_QPOSSLAT register.

**Figure 12-451. EQEP Strobe Event Latch (EQEP\_QDEC\_QEP\_CTL[22] SEL = 0b1)**

### 12.4.3.4.3.3 EQEP Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization.

#### Note

When all of the above events occur simultaneously, the sequence of priority is as follows: 1) Software Initialization, 2) strobe event initialization, 3) Index Event Initialization.

#### Index Event Initialization (IEI)

The EQEPx\_I index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the EQEP\_QDEC\_QEP\_CTL[25-24] IEI bits are 2h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[25-24] IEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 0h (default) or 1h, the index event initialization of position counter is disabled.

If EQEP\_QDEC\_QEP\_CTL[25-24] IEI bit field is configured with value 3h, then the the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the falling edge of strobe input signal.

#### Strobe Event Initialization (SEI)

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 2h, then the position counter is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input.

If the EQEP\_QDEC\_QEP\_CTL[27-26] SEI bits are 3h, then the position counter (EQEP\_QPOSCNT) is initialized with a value in the EQEP\_QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The strobe event initialization interrupt flag (EQEP\_QDEC\_QEP\_CTL[27-26] SEI) is set when the position counter is initialized with a value in the EQEP\_QPOSINIT register.

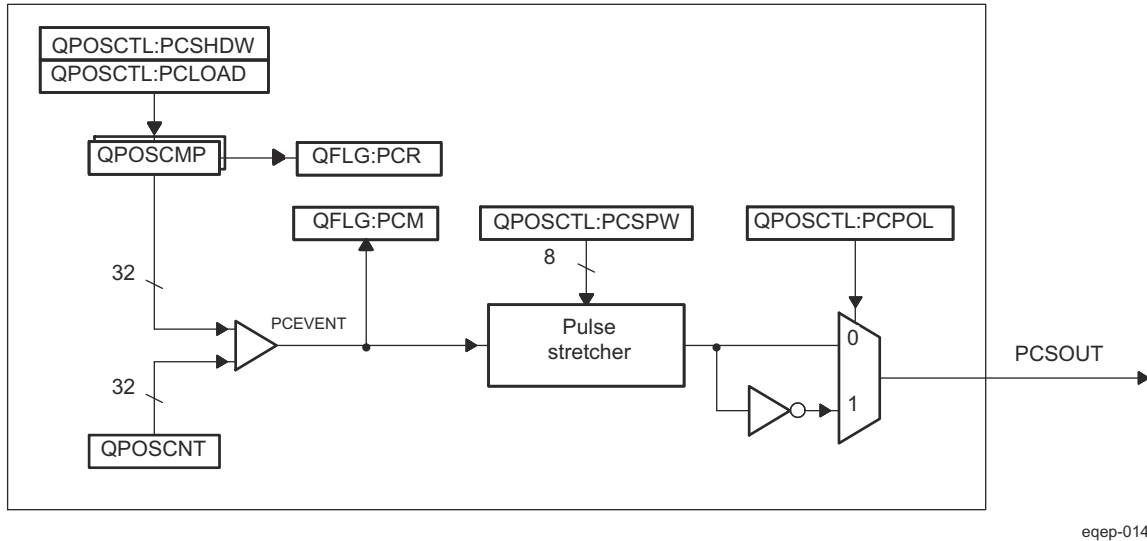

If EQEP\_QDEC\_QEP\_CTL[27-26] SEI bit field is configured with value 0h (default) or 1h, the strobe event initialization of position counter is disabled.

#### Software Initialization (SWI)

The position counter can be initialized in software by writing a 1h to the EQEP\_QDEC\_QEP\_CTL[23] SWI bit, which will automatically be cleared after initialization.

### 12.4.3.4.3.4 EQEP Position-Compare Unit

The EQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. [Figure 12-452](#) shows a diagram. The position-compare (EQEP\_QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the EQEP\_QCAP\_QPOS\_CTL[31] PCSHDW bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

**Figure 12-452. EQEP Position-compare Unit**

In shadow mode, SW can configure the position-compare unit (EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD) to load the shadow register value into the active register on the following events and to generate the position-compare ready (EQEP\_QINT\_EN\_FLG[23] PCRI\_FLG) interrupt after loading.

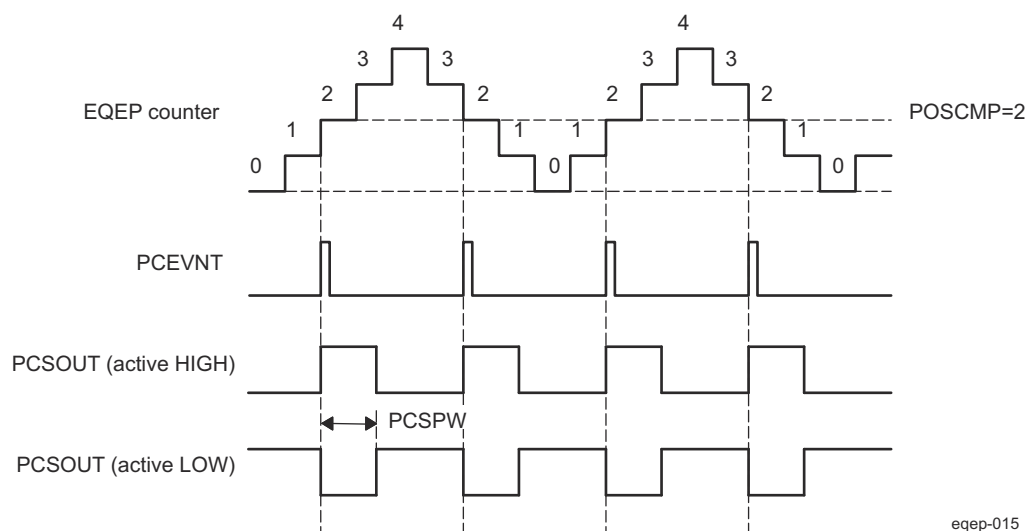

- Load on compare match
- Load on position-counter zero event.

The position-compare match (EQEP\_QINT\_EN\_FLG[24] PCMI\_FLG) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (EQEP\_QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if EQEP\_QPOSCMP bitfield POSCMP = 0x2, the position-compare unit generates a position-compare event on the transition from 1 to 2 of the EQEP position counter for forward counting direction and on the transition from 3 to 2 of the EQEP position counter for reverse counting direction (see [Figure 12-453](#)).

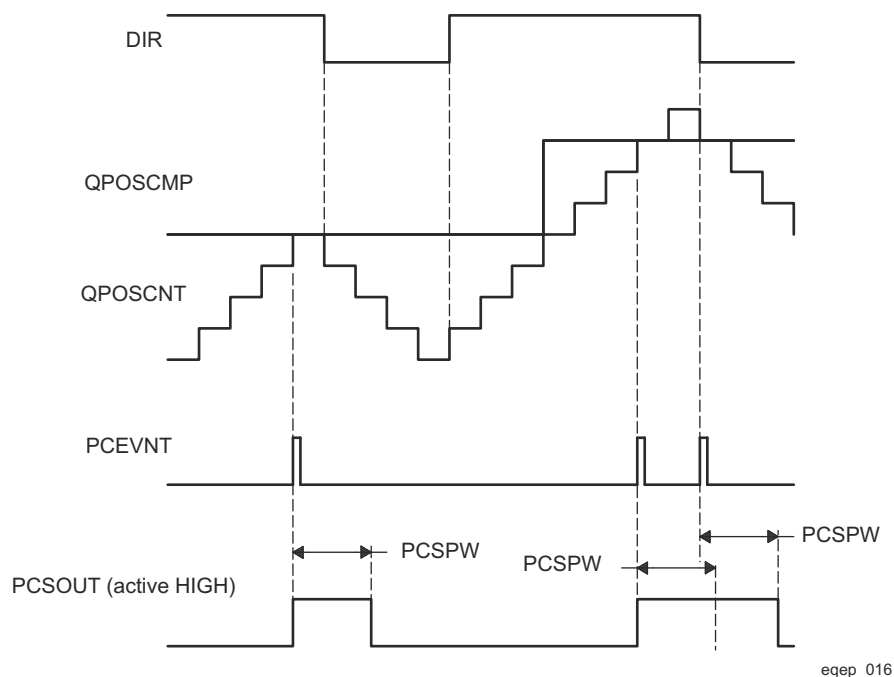

#### Note

When EQEP\_QCAP\_QPOS\_CTL[30] PCLOAD=0h, the shadow register is loaded into the active register as soon as POSCNT becomes zero, and it should not generate another shadow load if the POSCNT continues to stay at zero

**Figure 12-453. EQEP Position-compare Event Generation Points**

The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 12-454.

**Figure 12-454. EQEP Position-compare Sync Output Pulse Stretcher**

#### 12.4.3.4.4 EQEP Edge Capture Unit

The EQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 12-455. This feature is typically used for low speed measurement using the following equation:

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \quad \text{eqep-017} \quad (21)$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see [Figure 12-456](#))
- $\Delta T$  - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The EQEP capture timer (QCTMR bitfield in EQEP\_QCTMR register) runs from prescaled SYSCLKOUT and the prescaler is programmed by the EQEP\_QCAP\_QPOS\_CTL[6-4] CCPS bits. The capture timer QCTMR value is latched into the capture period register (EQEP\_QC\_PRD\_TLAT) on every unit position event and then the capture timer is reset.

Time measurement ( $\Delta T$ ) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the EQEP overflow error flag (EQEP\_QEP\_STS\_CT[3] COEF) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (EQEP\_QEP\_STS\_CT[2] CDEF).

Capture Timer (EQEP\_QCTMR register) and Capture period register (EQEP\_QC\_PRD\_TLAT) can be configured to latch on following events.

- CPU read of EQEP\_QPOSCNT register
- Unit time-out event

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is cleared, then the capture timer and capture period values are latched into the EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, when the CPU reads the position counter in EQEP\_QPOSCNT.

---

#### Note

Capture timer and capture period values are not latched for an emulation read.

---

If the EQEP\_QDEC\_QEP\_CTL[18] QCLM bit is set, then the position counter, capture timer, and capture period values are latched into the EQEP\_QPOSLAT, EQEP\_QC\_PRD\_TLAT and EQEP\_QCPRDLAT registers, respectively, on unit time out.

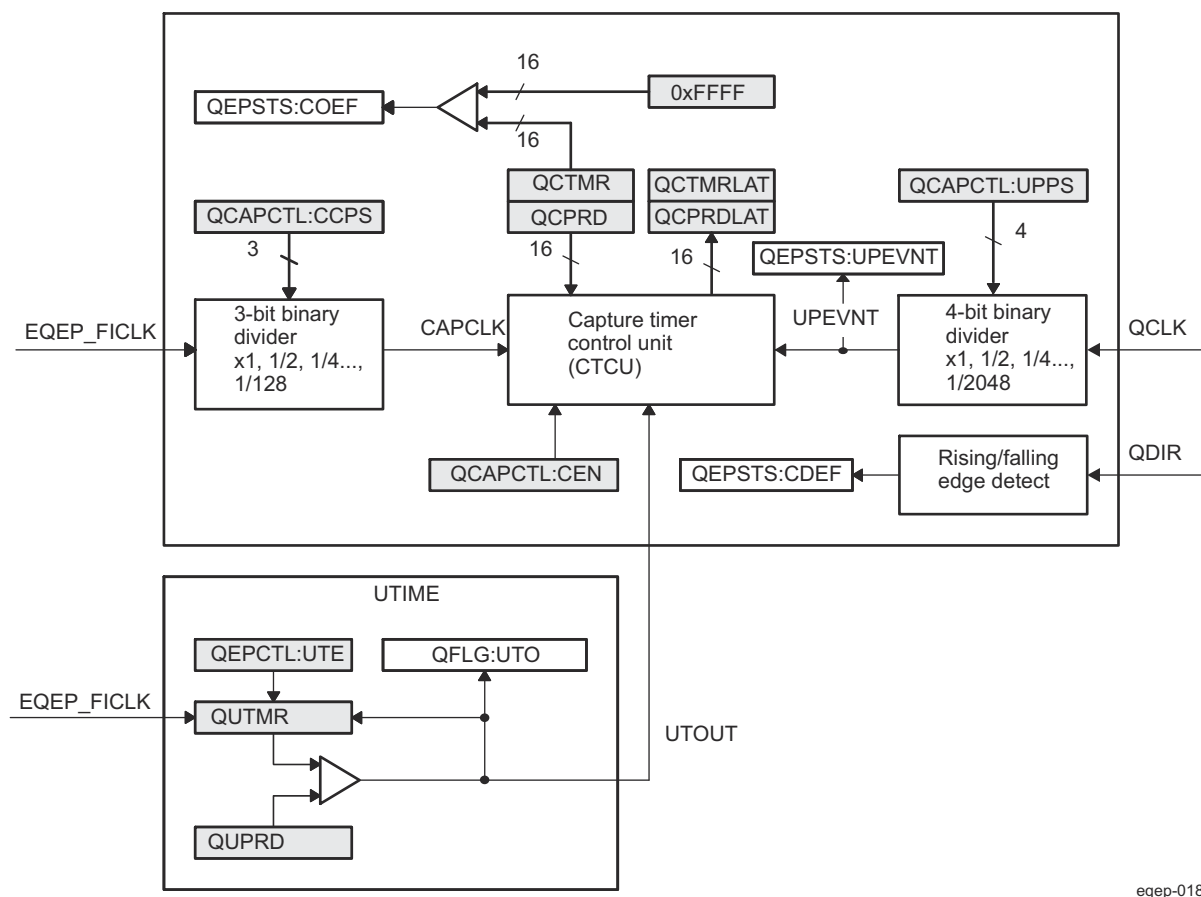

[Figure 12-457](#) shows the capture unit operation along with the position counter.

---

#### Note

The EQEP\_QCAP\_QPOS\_CTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from SYSCLKOUT/4 to SYSCLKOUT/8, where SYSCLKOUT is equivalent to EQEPx\_FICLK). The capture unit must be disabled before changing the prescaler.

---

eqep-018

Figure 12-455. EQEP Edge Capture Unit

eqep-019

N - Number of quadrature periods selected using EQEP\_QCAP\_QPOS\_CTL[3-0] UPPS bits

Figure 12-456. Unit Position Event for Low Speed Measurement (EQEP\_QCAP\_QPOS\_CTL[UPPS] = 0010)

**Figure 12-457. EQEP Edge Capture Unit - Timing Details**

Velocity Calculation Equations:

$$V(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \quad \text{or}$$

$$V(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T}$$

eqep\_021

(22)

where

$v(k)$ : Velocity at time instant  $k$

$x(k)$ : Position at time instant  $k$

$x(k-1)$ : Position at time instant  $k - 1$

$T$ : Fixed unit time or inverse of velocity calculation rate

$\Delta X$ : Incremental position movement in unit time

$X$ : Fixed unit position

$\Delta T$ : Incremental time elapsed for unit position movement

$t(k)$ : Time instant " $k$ "

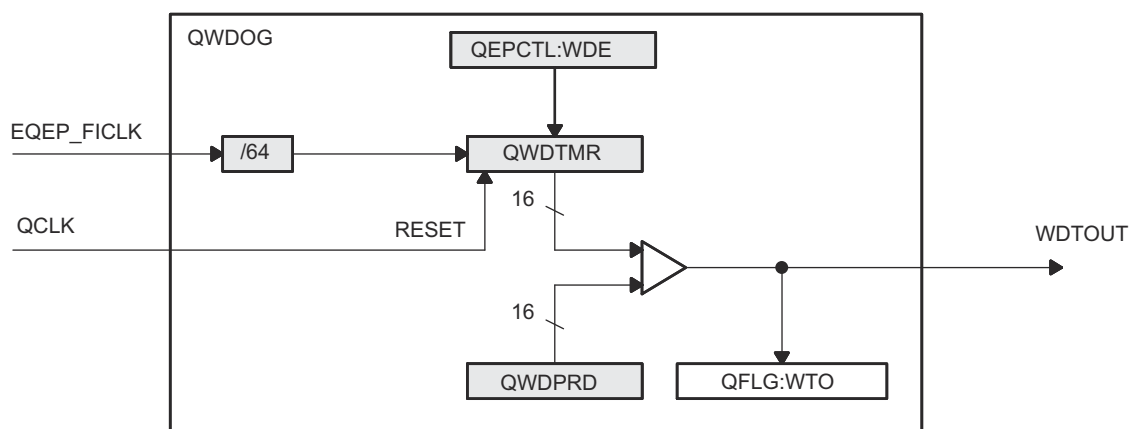

$t(k-1)$ : Time instant " $k - 1$ "

Unit time (T) and unit period (X) are configured using the EQEP\_QUPRD and EQEP\_QCAP\_QPOS\_CTL[3-0] UPPS registers. Incremental position output and incremental time output is available in the EQEP\_QOSLAT and EQEP\_QCPRLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (EQEP_QUPRD)
$\Delta X$	Incremental Position = QOSLAT(k) - QOSLAT(k - 1)
X	Fixed unit position defined by sensor resolution and QCAPCTL[3-0] UPPS bits
$\Delta T$	Capture Period Latch (QCPRLAT)

#### 12.4.3.4.5 EQEP Watchdog

The EQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The EQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrature clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (EQEP\_QINT\_EN\_FLG[20] WDOI\_FLG). The time-out value is programmable through the watchdog period bit field (EQEP\_QWD\_TMR\_PRD[31-16] QWDPRD).

eqep-022

**Figure 12-458. EQEP Watchdog Timer**

#### 12.4.3.4.8 Summary of EQEP Functional Registers

Table 12-468 lists the registers with their memory locations, sizes, and reset values.

**Table 12-468. EQEP Control and Status Functional Registers**

Offset	Acronym	Register Description	Size (×16)/ #shadow
0h	EQEP_QPOSCNT	EQEP Position Counter Register	2/0
4h	EQEP_QPOSINIT	EQEP Position Counter Initialization Register	2/0
8h	EQEP_QPOSMAX	EQEP Maximum Position Count Register	2/0

## 12.4.4 Controller Area Network (MCAN)

This section describes the Controller Area Network (MCAN) modules in the device.

### 12.4.4.1 MCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time control. CAN has high immunity to electrical interference. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The MCAN module supports both classic CAN and CAN FD (CAN with Flexible Data-Rate) specifications. CAN FD feature allows high throughput and increased payload per data frame. The classic CAN and CAN FD devices can coexist on the same network without any conflict.

The device supports 16 MCAN modules:

- 2 in the device MCU domain
- 14 in the device MAIN domain

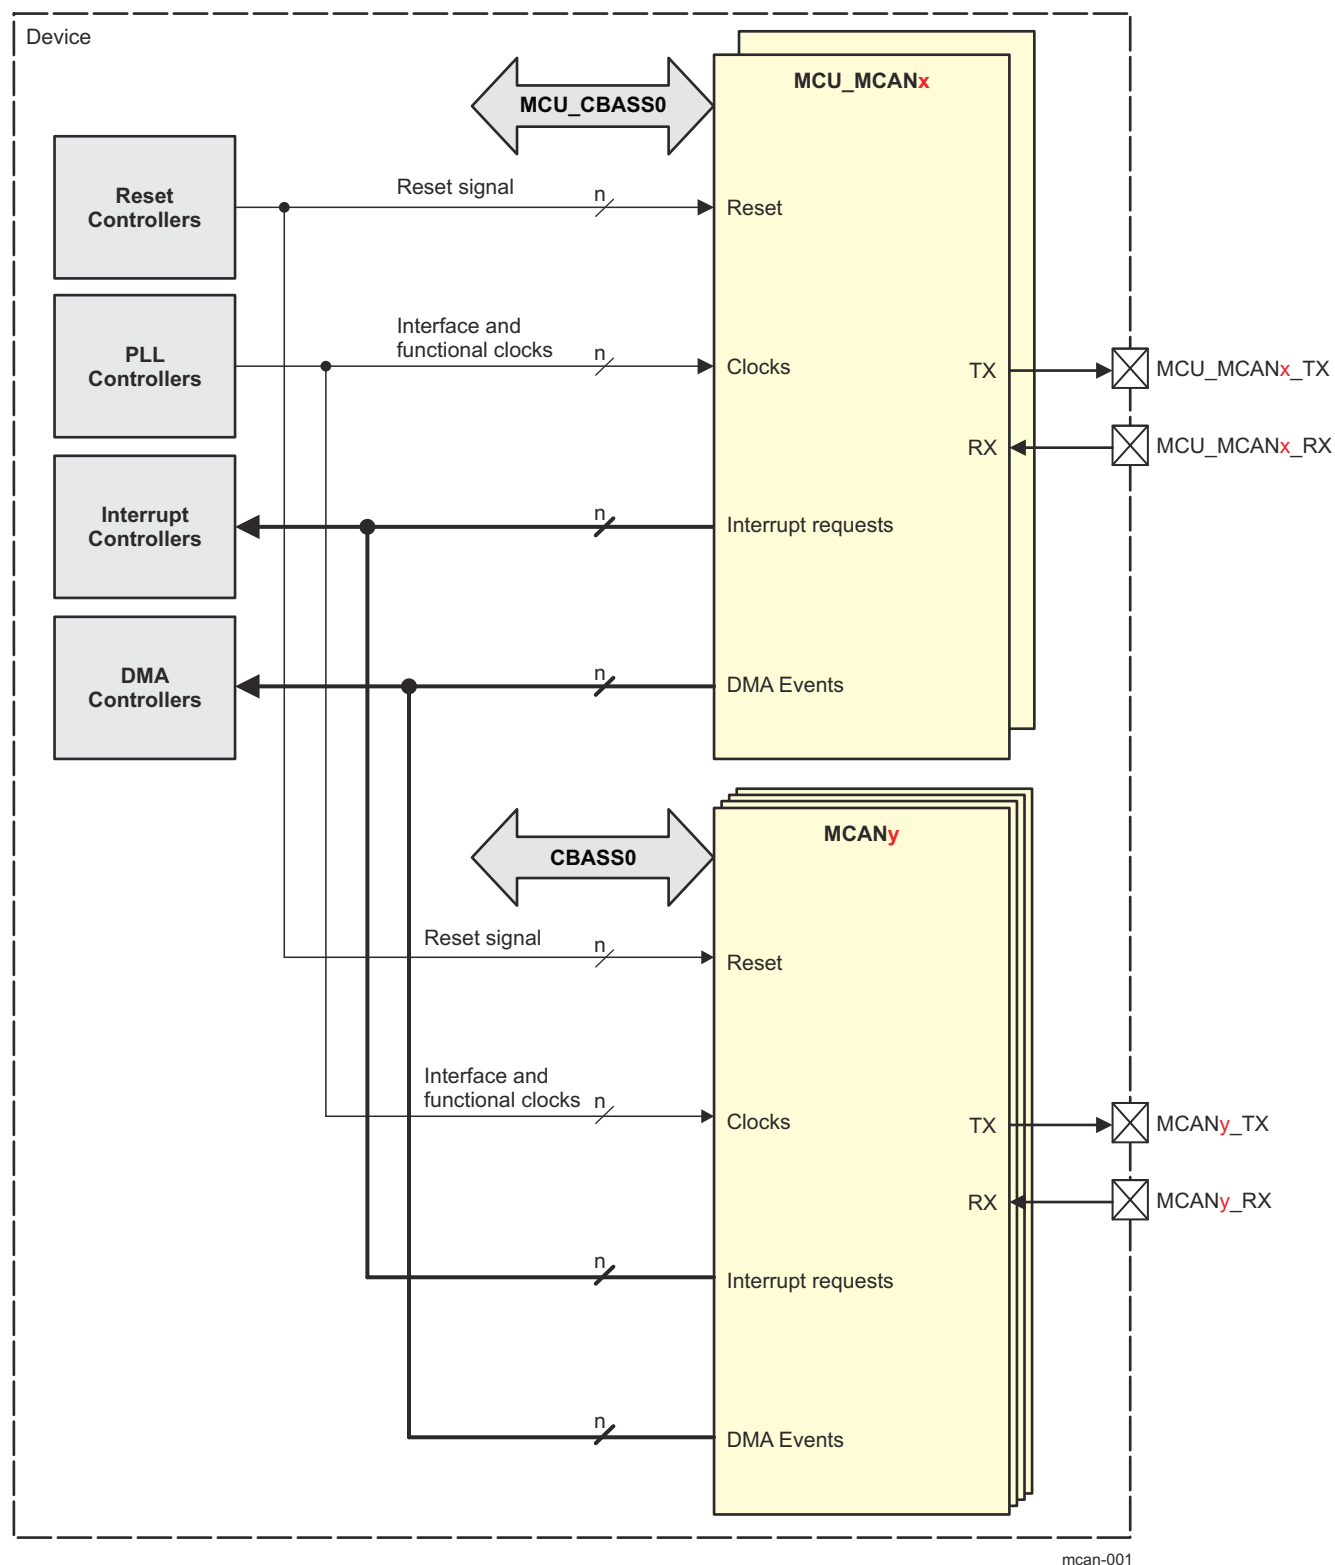

They connect to the physical layer of the CAN network through external (for the device) transceivers. Each MCAN module supports flexible bit rates greater than 1 Mbps and is compliant to ISO 11898-1:2015.

[Table 12-469](#) shows MCAN allocation across device domains.

**Table 12-469. MCAN Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_MCAN0	-	✓	-
MCU_MCAN1	-	✓	-
MCAN0	-	-	✓
MCAN1	-	-	✓
MCAN2	-	-	✓
MCAN3	-	-	✓
MCAN4	-	-	✓
MCAN5	-	-	✓
MCAN6	-	-	✓
MCAN7	-	-	✓
MCAN8	-	-	✓
MCAN9	-	-	✓
MCAN10	-	-	✓
MCAN11	-	-	✓
MCAN12	-	-	✓
MCAN13	-	-	✓

[Figure 12-461](#) shows the MCAN modules overview.

- A.  $x = 0 - 1$   
B.  $y = 0 - 13$

Figure 12-461. MCAN Modules Overview

#### **12.4.4.1.1 MCAN Features**

Each MCAN module implements the following features:

- Conforms with CAN Protocol 2.0 A, B and ISO 11898-1:2015
- Full CAN FD support (up to 64 data bytes)
- SAE J1939 support
- AUTOSAR support (only on DRA829 and TDA4VM family of devices)
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO, up to 32 elements
- Configurable Transmit Queue, up to 32 elements
- Configurable Transmit Event FIFO, up to 32 elements
- Up to 64 dedicated Receive Buffers
- Two configurable Receive FIFOs, up to 64 elements each
- Up to 128 filter elements
- Internal Loopback mode for self-test
- Maskable interrupts, two interrupt lines
- Two clock domains (CAN clock/Host clock)
- Parity/ECC support - Message RAM single error correction and double error detection (SECDED) mechanism
- Local power-down and wakeup support
- Timestamp Counter

#### **12.4.4.1.2 MCAN Not Supported Features**

- Host bus firewall
- GPIO mode
- Clock calibration
- External (IO) Loopback mode
- Debug DMA (see [Section 12.4.4.4.7.4](#))
- TX DMA channels [31:3]

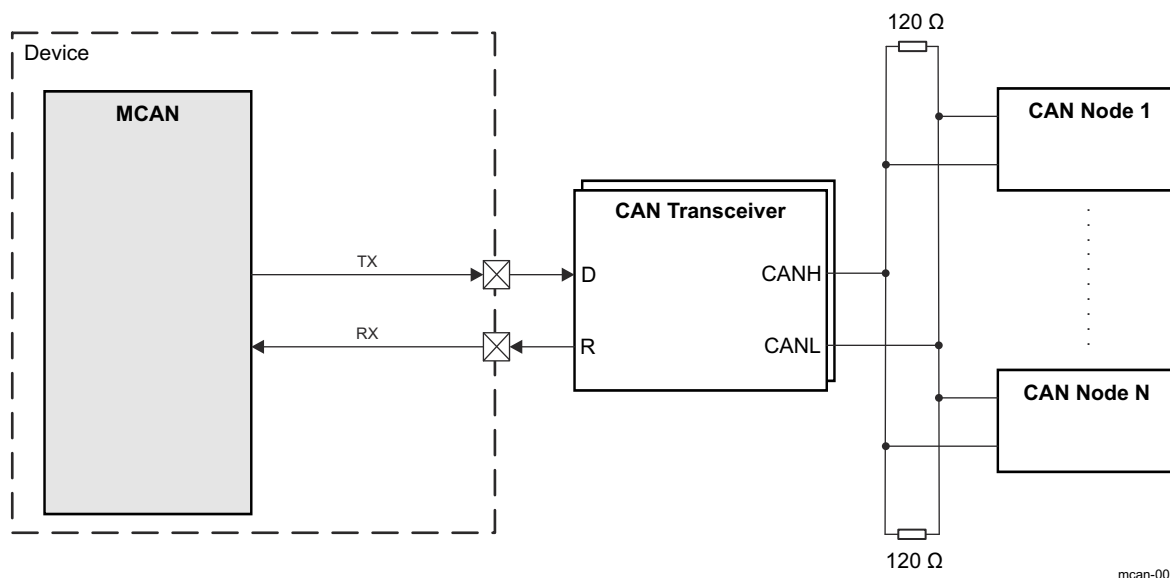

### 12.4.4.2 MCAN Environment

The MCU\_MCAN[0-1] and MCAN[0-13] modules are hereinafter referred to as MCAN module.

This section describes the MCAN external connections (environment).

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the MCAN.

Figure 12-462 shows the MCAN typical application.

**Figure 12-462. MCAN Typical Application**

Table 12-470 describes the MCAN I/O signals.

**Table 12-470. MCAN I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
<b>MCU_MCAN[0-1]</b>				
RX	MCU_MCAN0_RX	I	Serial data input from external CAN transceiver	HiZ

RX	MCAN12_RX	I	Serial data input from external CAN transceiver	HiZ
TX	MCAN13_TX	O	Serial data output to external CAN transceiver	1
RX	MCAN13_RX	I	Serial data input from external CAN transceiver	HiZ

(1) I = Input; O = Output; HiZ = High Impedance

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables Pin Attributes and Pin Multiplexing in the device-specific Datasheet.

#### 12.4.4.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using Non-Return-to-Zero (NRZ) encoding and has two states:
  - Recessive state (logical 1)
  - Dominant state (logical 0)
- The network is multimaster. When two or more nodes (ECUs) attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost.
- The message transmission is multicast. Data messages transmitted are identifier based, not address based.
- Content of message is labeled by the identifier that is unique throughout the network (for example: rpm, temperature, position, pressure, and so forth).
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored.
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is).
- Data is transmitted and received using message frames, consisting of the following basic fields:
  - Arbitration field
  - Control field
  - Data field (up to 8 bytes for Classical CAN and up to 64 bytes for CAN FD)
  - CRC field
  - ACK field

For more information, see *ISO 11898-1:2015: CAN data link layer and physical signaling*.

### 12.4.4.3 MCAN Integration

This section describes the MCAN integration in the device, including information about clocks, resets, and hardware requests.

#### 12.4.4.3.1 MCAN Integration in MCU Domain

There are two MCAN modules integrated in the device MCU domain - MCU\_MCAN0 and MCU\_MCAN1.

Figure 12-463 shows the integration of MCU\_MCAN0.

Figure 12-464 shows the integration of MCU\_MCAN1.

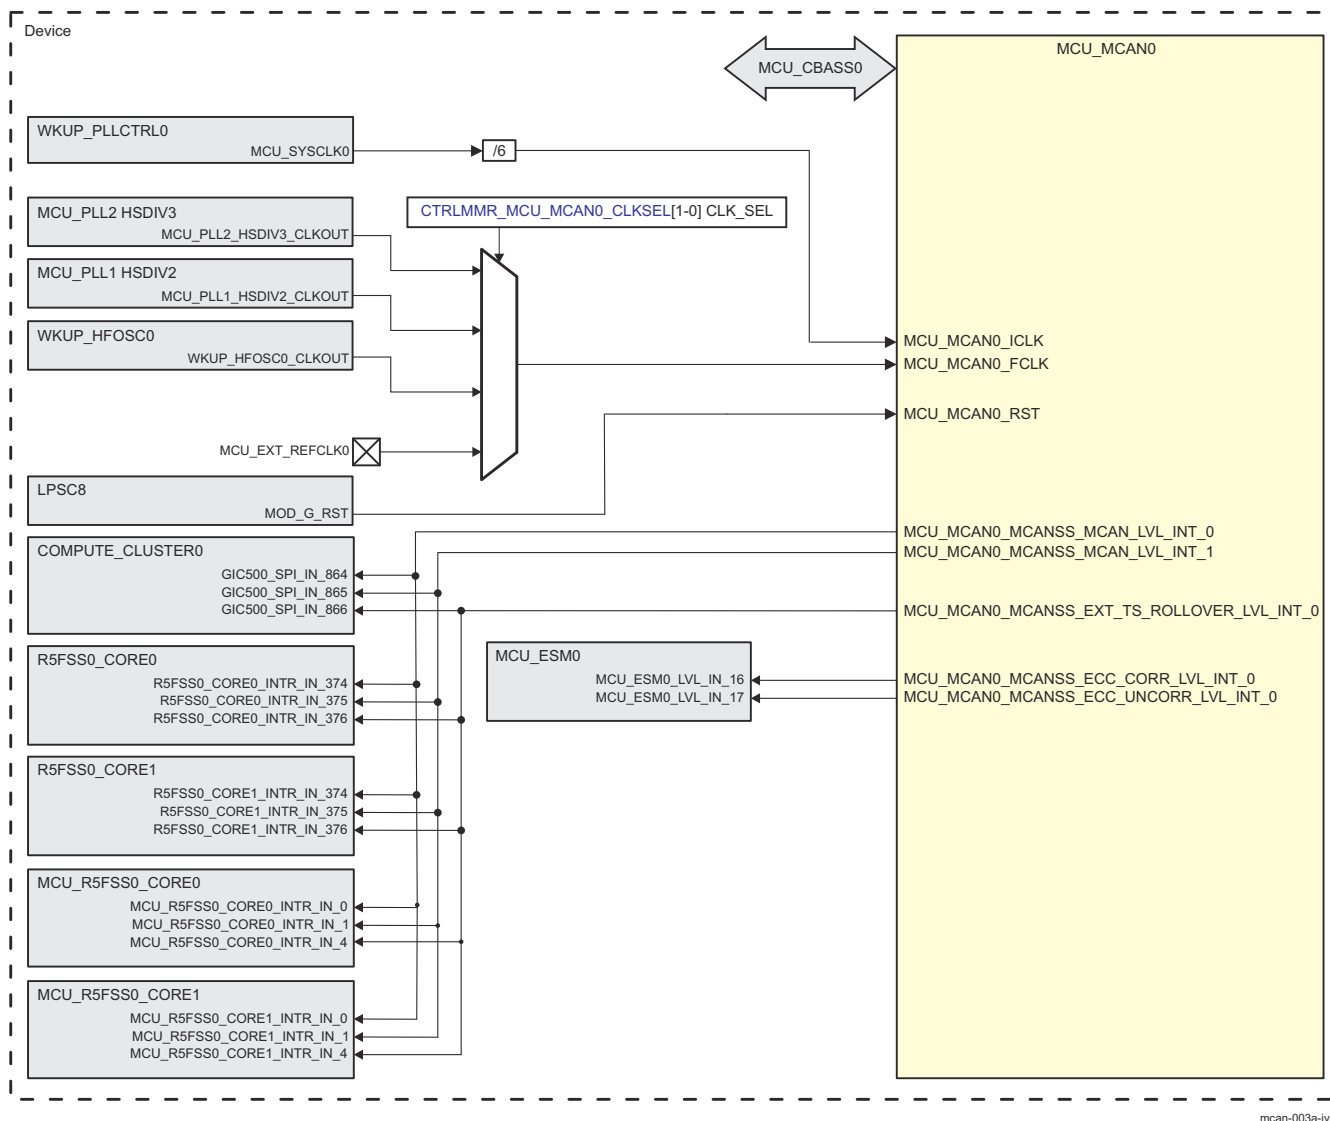

Figure 12-463. MCU\_MCAN0 Integration

mcan-003a-jvcl

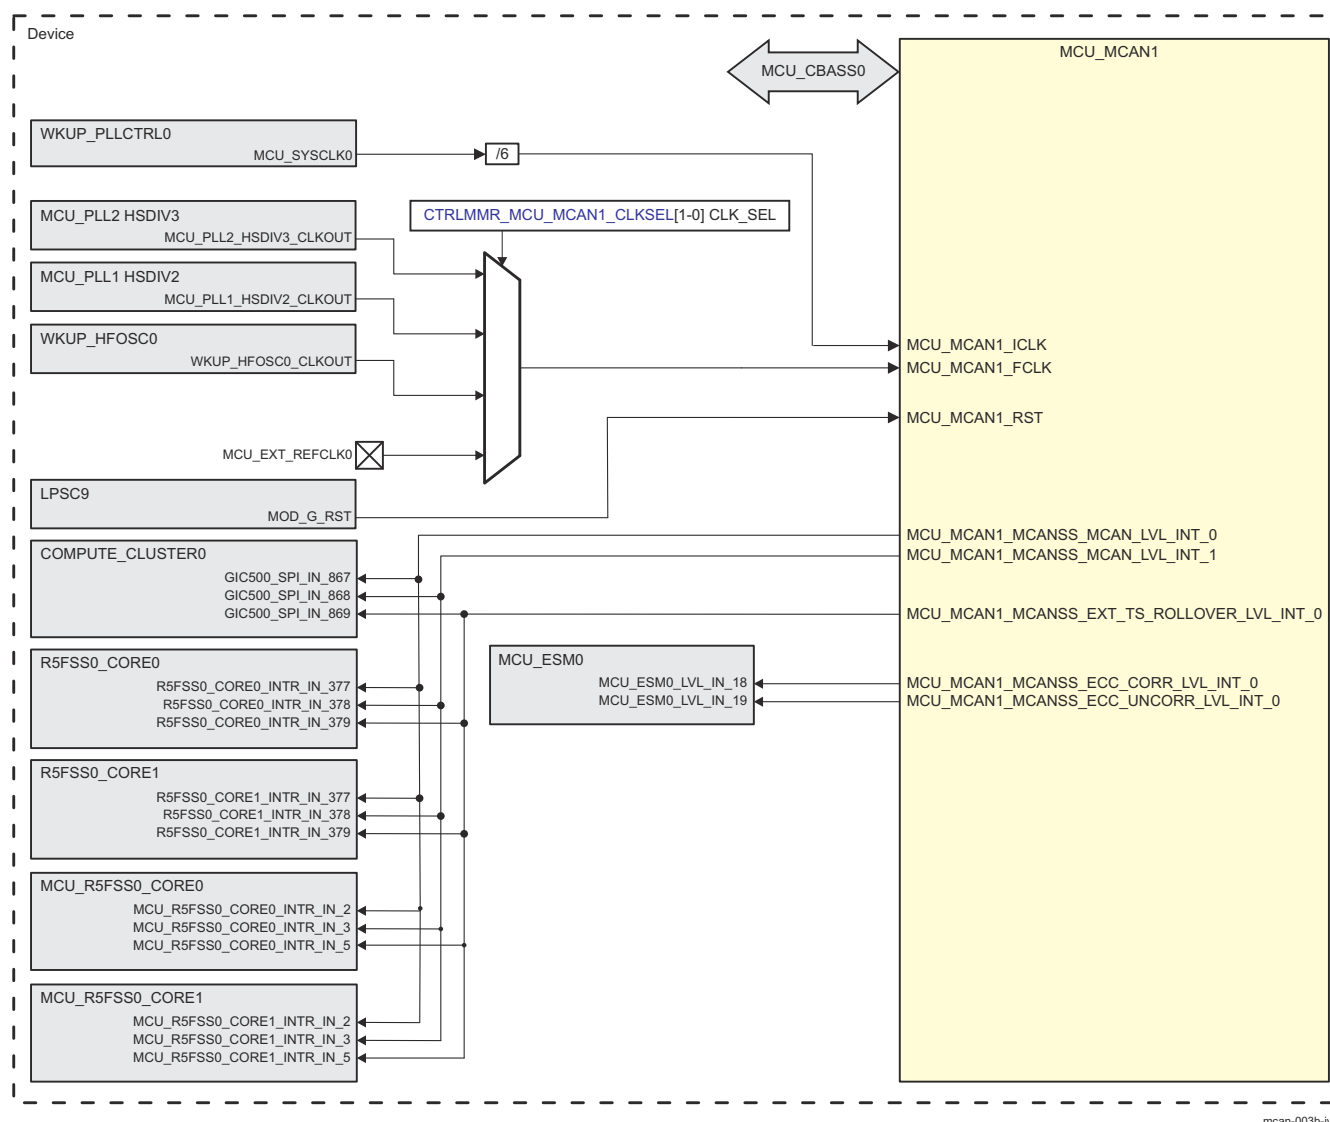

**Figure 12-464. MCU\_MCAN1 Integration**

Table 12-471 through Table 12-473 summarize the integration of MCU\_MCAN0 and MCU\_MCAN1 in the device MCU domain.

**Table 12-471. MCU\_MCAN Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

### 12.4.4.3.2 MCAN Integration in MAIN Domain

There are fourteen MCAN modules integrated in the device MAIN domain - MCAN[0-13].

Figure 12-465 shows the integration of MCAN[0-13].

A.  $i = 0 - 13$

**Figure 12-465. MCAN[0-13] Integration**

Table 12-474 through Table 12-476 summarize the integration of MCAN[0-13] in the device MAIN domain.

**Table 12-474. MCAN Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCAN0	PSC0	PD1	LPSC34	CBASS0
MCAN1	PSC0	PD1	LPSC35	CBASS0
MCAN2	PSC0	PD1	LPSC36	CBASS0
MCAN3	PSC0	PD1	LPSC37	CBASS0
MCAN4	PSC0	PD1	LPSC38	CBASS0
MCAN5	PSC0	PD1	LPSC39	CBASS0
MCAN6	PSC0	PD1	LPSC40	CBASS0
MCAN7	PSC0	PD1	LPSC41	CBASS0
MCAN8	PSC0	PD1	LPSC42	CBASS0
MCAN9	PSC0	PD1	LPSC43	CBASS0
MCAN10	PSC0	PD1	LPSC44	CBASS0
MCAN11	PSC0	PD1	LPSC45	CBASS0
MCAN12	PSC0	PD1	LPSC46	CBASS0
MCAN13	PSC0	PD1	LPSC47	CBASS0

**Table 12-475. MCAN Clocks and Resets**

Module Instance	Clocks			
	Module Clock Input	Source Clock Signal	Source	Description
MCAN0	MCAN0_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN0_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN0_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN0_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN1	MCAN1_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN1_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN1_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN1_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN2	MCAN2_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN2_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN2_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN2_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	

**Table 12-475. MCAN Clocks and Resets (continued)**

MCAN3	MCAN3_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN3_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN3_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN3_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN4	MCAN4_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN4_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN4_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN4_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN5	MCAN5_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN5_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN5_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN5_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN6	MCAN6_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN6_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN6_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN6_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0	
MCAN7	MCAN7_ICLK	MCU_SYSCLK0/4	WKUP_PLLCTRL0	Interface Clock
	MCAN7_FCLK	MAIN_PLL0_HSDIV4_CLKOUT (default)	PLL0_HSDIV4	Functional Clock (for more information about clock multiplexing, see CTRLMMR_MCAN7_CLKSEL[1-0] CLK_SEL bit field in <i>Control Module (CTRL_MMR)</i> . Default: CTRLMMR_MCAN7_CLKSEL[1-0] CLK_SEL = 0h, MAIN_PLL0_HSDIV4_CLKOUT is selected)
		MCU_EXT_REFCLK0	I/O pin	
		HFOSC1_CLKOUT	HFOSC1	
		HFOSC0_CLKOUT	WKUP_HFOSC0

#### 12.4.4.4 MCAN Functional Description

The MCAN module performs CAN protocol communication according to ISO 11898-1:2015. The bit rate can be programmed to values greater than 1 Mbps. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

For communication on a CAN network, individual message frames can be configured. The message frames and identifier masks are stored in the Message RAM.

All functions concerning the handling of messages are implemented in the Message Handler.

The register set of the MCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the Message Handler, and to access the Message RAM.

Figure 12-466 shows the MCAN module block diagram.

**Figure 12-466. MCAN Block Diagram**

The MCAN module blocks description:

- **CAN Core:** the CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1:2015 protocol functions and supports 11-bit and 29-bit identifiers.
- **Message Handler:** the Message Handler (Rx Handler and Tx Handler) is a state machine that controls the data transfer between the single-ported Message RAM and the CAN core's Rx/Tx shift register. It also handles the acceptance filtering and the Interrupt/DMA request generation as programmed in the control registers.
- **Message RAM:** the main purpose of the Message RAM is to store Rx/Tx messages, Tx Event elements, and Message ID Filter elements (for more information, see *Message RAM*).
- **Message RAM Interface:** enables connection between the Message RAM and the other blocks in the MCAN module.
- **Registers and Message Object Access:** data consistency is ensured by indirect accesses to the message objects. The interface registers have the same word-length as the Message RAM.

- **Module Interface:** provides connection to the Registers and Message Object Access block and Message RAM Interface block
- **Clocking:** two clocks are provided to the MCAN module: the peripheral synchronous clock (interface clock ICLK) and the peripheral asynchronous clock (functional clock - FCLK). For more information, see *MCU\_MCAN Clocks and Resets* and *MCAN Clocks and Resets*.
- **Extension Interface:** this interface is used for DMA requests signaling (see *DMA Requests*).

#### 12.4.4.4.1 Module Clocking Requirements

Two clocks are provided to the MCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

Within the MCAN module there is a synchronization mechanism implemented to ensure safe data transfer between the two clock domains. There is synchronization between the signals from the Host clock domain to the CAN clock domain and vice versa and between the reset signal to the Host clock domain and to the CAN clock domain.

#### Note

ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the MCAN module. Here, also the frequency shift of the modulated ICLK has to be considered:

$$f_{0,ICLK} \pm \Delta f_{FM,ICLK} \geq f_{FCLK}$$

For more information on how to configure the relevant clock source registers, see *Clocking* and the device-specific Datasheet.

#### 12.4.4.4.2 Interrupt and DMA Requests

The MCAN module provides interrupt and DMA requests. They are configured via the Host CPU. The Suspend Mode is requesting or forcing (based on MCANSS\_CTRL[3] DBGSUSP\_FREE bit) the MCAN module to go into initialization mode (see MCAN\_CCCR[0] INIT bit) in which new interrupts and DMA requests will not be issued, that is to prevent the interrupt and DMA requests from propagating to the Host CPU (for more information, see [Section 12.4.4.4.3.8.2, Suspend Mode](#)).

##### 12.4.4.4.2.1 Interrupt Requests

The MCAN module has two interrupt lines. There are 30 internal interrupt sources. Each source can be configured to drive one of the two interrupt lines. The interrupts are 'level high' interrupts.

The MCAN core provides two interrupt requests (for Line 0 and Line 1).

For more information, see the following registers:

- Interrupt Register (MCAN\_IR)
- Interrupt Enable (MCAN\_IE)
- Interrupt Line Select (MCAN\_ILS)
- Interrupt Line Enable (MCAN\_ILE)

The MCAN module is capable of issuing ECC interrupts. After clearing the ECC interrupt source, the application software must also write 1 to EOI register (MCANSS\_ECC\_SEC\_EOI\_REG/MCANSS\_ECC\_DED\_EOI\_REG). For more information, see *ECC Aggregator*.

The MCAN module supports External Timestamp Counter. When the External Timestamp Counter rolls over it produces an interrupt (see *External Timestamp Counter*).

For more information, see the following registers:

- Interrupt Clear Shadow Register (MCANSS\_ICS)
- Interrupt Raw Status Register (MCANSS\_IRS)
- Interrupt Enable Clear Shadow Register (MCANSS\_IECS)

- Interrupt Enable Register (MCANSS\_IE)
- Interrupt Enable Status Register (MCANSS\_IES)
- End Of Interrupt Register (MCANSS\_EOI)
- External Timestamp Prescaler Register (MCANSS\_EXT\_TS\_PRESCALER)
- External Timestamp Unserved Interrupts Counter Register (MCANSS\_EXT\_TS\_UNSERVICED\_INTR\_CNTR)

For more information about available Interrupt Requests, see *MCU\_MCAN Hardware Requests* and *MCAN Hardware Requests*.

#### 12.4.4.4.2.2 DMA Requests

Functional transmit and Filter DMA requests are generated by the MCAN module based on the signaling in the Extension Interface. The DMA signaling uses a simple DMA request active high pulse.

The active high pulse indicates a pending message is transmitted (see MCAN\_TXBRP). This pulse can be used to transfer another message to the Tx Buffer, which would need to be followed by writing 1 to the corresponding MCAN\_TXBAR[0] AR bit to mark a new Tx message pending transmission.

The Parity on Tx DMA Events is available using an EDC Controller which can be accessed through the ECC Aggregator.

Standard and Extended message filters can be set to issue a pulse when a filter match occurs. These 'Filter Events' can be used to DMA messages from the Rx FIFO. The events are high level single clock cycle pulses (ICLK).

#### 12.4.4.4.2.3

For more information about available DMA Requests, see [Table 12-473](#) and [Table 12-476](#).

#### 12.4.4.4.3 Operating Modes

##### 12.4.4.4.3.1 Software Initialization

Setting the MCAN\_CCCR[0] INIT bit to 1 starts a software initialization. This is done either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus\_Off state. While the MCAN\_CCCR[0] INIT bit is set, the message transfer is stopped and the status of the output TX pin is recessive (high). The counters of the Error Management Logic (EML) are unchanged. Setting the MCAN\_CCCR[0] INIT bit does not change any configuration register. Resetting the MCAN\_CCCR[0] INIT bit finishes the software initialization. After waiting for the occurrence of a sequence of 11 consecutive recessive bits (indication for Bus\_Idle state) the message transfer starts.

Access to the MCAN configuration registers is only enabled when both MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are set (write protection).

The MCAN\_CCCR[1] CCE bit can only be set/reset while the MCAN\_CCCR[0] INIT = 1. The MCAN\_CCCR[1] CCE bit is automatically reset when the MCAN\_CCCR[0] INIT bit is reset.

The following registers are reset when the MCAN\_CCCR[1] CCE bit is set:

- MCAN\_HPMS - High Priority Message Status
- MCAN\_RXF0S - Rx FIFO 0 Status
- MCAN\_RXF1S - Rx FIFO 1 Status
- MCAN\_TXFQS - Tx FIFO/Queue Status
- MCAN\_TXBRP - Tx Buffer Request Pending
- MCAN\_TXBTO - Tx Buffer Transmission Occurred
- MCAN\_TXBCF - Tx Buffer Cancellation Finished
- MCAN\_TXEFS - Tx Event FIFO Status

The Timeout Counter value MCAN\_TOCV[15:0] TOC field is preset to the value configured by the MCAN\_TOCC[31:16] TOP field when the MCAN\_CCCR[1] CCE bit is set.

In addition the Tx Handler and Rx Handler are held in idle state while MCAN\_CCCR[1] CCE = 1.

The following registers are only writeable while MCAN\_CCCR[1] CCE = 0

- MCAN\_TXBAR - Tx Buffer Add Request
- MCAN\_TXBCR - Tx Buffer Cancellation Request

MCAN\_CCCR[7] TEST and MCAN\_CCCR[5] MON bits can only be set by the Host CPU while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1. Both bits may be reset at any time. The MCAN\_CCCR[6] DAR bit can only be set/reset while MCAN\_CCCR[0] INIT = 1 and MCAN\_CCCR[1] CCE = 1.

Table 12-477 shows the steps to configure the MCAN module.

**Table 12-477. Steps to Configure MCAN Module**

Step	Operation	Description	Pseudo Code
1	Initialize MCAN_CCCR	Set MCAN_CCCR[0] INIT bit and check that it has been set	INIT = 1; If INIT ≠ 1, wait until it is
2	Unlock protected registers	Set MCAN_CCCR[1] CCE bit	CCE = 1;
3	Configure CAN mode	Set MCAN_CCCR[8] FDOE bit to CAN FD	FDOE = 1 for CAN FD FDOE = 0 for CAN
4	Configure Bit Rate Switching	Set MCAN_CCCR[9] BRSE bit	BRSE = 1 with bit rate switching BRSE = 0 without bit rate switching
5	Set bit timing	Set MCAN_NBTP register	
6	Lock protected registers	Clear MCAN_CCCR[1] CCE bit	CCE = 0;
7	Return MCAN module to normal operation	Clear MCAN_CCCR[0] INIT bit and check it has been cleared	INIT = 0; If INIT ≠ 0, wait until it is

#### 12.4.4.4.3.2 Normal Operation

Once the MCAN module is initialized and the MCAN\_CCCR[0] INIT bit is reset to zero, the MCAN module synchronizes itself to the CAN bus and is ready for communication. After passing the acceptance filtering, received messages including Message Identifier (ID) and Data Length Code (DLC) are stored into a dedicated Rx Buffer or into Rx FIFO 0/Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated.

#### Note

Automated transmission on reception of remote frames is not supported.

#### 12.4.4.4.3.3 CAN FD Operation

The CAN FD standard allows extended frames to be sent, up to 64 data bytes in a single frame at a higher bit rate for the data phase of a frame, up to 8 Mbps. The CAN FD standard introduces the ability to switch from one bit rate to another. Extended Data Length (EDL), as shown in Figure 12-467, sets a data length of up to 8 or up to 64 data bytes. Bit Rate Switching (BRS) indicates whether two bit rates (the data phase is transmitted at a different bit rate to the arbitration phase) are enabled.

\* 17 bit CRC for data fields with up to 16 bytes

mcan-004a

**Figure 12-467. CAN FD Frame**

### Note

Figure 12-467 presents CAN FD frame according to the Non-ISO CAN FD (legacy) protocol. In the new ISO CAN FD protocol the CRC Field includes additional 5 bits (three stuff bit counter (SBC) bits and two parity bits). With these additional bits, a weakness identified in the error detection scheme chosen by the original protocol is removed. By setting MCAN\_CCCR[15] NISO bit, the ISO or Non-ISO CAN FD format can be chosen. In CAN network ISO CAN FD and non-ISO CAN FD devices should never mix.

There are two variants of CAN FD frame transmission:

- CAN FD frame transmission without bit rate switching
- CAN FD frame transmission where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

In the CAN frames FDF = recessive (logical 1) signifies a CAN FD frame, FDF = dominant (logical 0) signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF - res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. Note that the coding of res = recessive is reserved for future expansion of the protocol.

In case the MCAN module receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting the MCAN\_PSR[14] EXE bit. When Protocol Exception Handling is enabled (MCAN\_CCCR[12] PXHD = 0), this causes the operation state to change from Receiver (MCAN\_PSR[4-3] ACT = 10) to Integrating (MCAN\_PSR[4-3] ACT = 00) at the next sample point. In case Protocol Exception Handling is disabled (MCAN\_CCCR[12] PXHD = 1), the MCAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming the MCAN\_CCCR[8] FDOE bit. In case MCAN\_CCCR[8] FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via the FDF bit in the respective Tx Buffer element.

With MCAN\_CCCR[8] FDOE = 0, received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if the FDF bit of a Tx Buffer element is set. The MCAN\_CCCR[8] FDOE and MCAN\_CCCR[9] BRSE bits can only be changed while the MCAN\_CCCR[0] INIT and MCAN\_CCCR[1] CCE bits are both set. With MCAN\_CCCR[8] FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.

With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 0, only FDF bit of a Tx Buffer element is evaluated. With MCAN\_CCCR[8] FDOE = 1 and MCAN\_CCCR[9] BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wakeup messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the DLC coding differs from the standard CAN format (see [Table 12-478](#)).

**Table 12-478. DLC Coding**

DLC	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Number of Data Bytes in Standard CAN	0	1	2	3	4	5	6	7	8	8	8	8	8	8	8	8
Number of Data Bytes in CAN FD	0	1	2	3	4	5	6	7	8	12	16	20	24	32	48	64

For CAN FD frames, the bit timing will be switched inside the frame after the BRS (Bit Rate Switch) bit in case this bit is recessive. In the CAN FD arbitration phase, before the BRS bit, the nominal CAN bit timing (see [Figure 12-468](#)) is used as configured by the Nominal Bit Timing and Prescaler Register MCAN\_NBTP. In the following CAN FD data phase, the data phase bit timing is used as configured by the Data Bit Timing and Prescaler Register MCAN\_DBTP. The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

**Figure 12-468. CAN Bit Timing**

The maximum configurable data phase bit timing depends on the CAN clock frequency (FCLK). Example: with FCLK = 20 MHz and the shortest configurable bit time of 4  $t_q$  (time quanta), the bit rate in the data phase is 5 Mbps.

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the ESI (Error Status Indicator) bit depends on transmitter's error state (see MCAN\_PSR[11] RESI bit) monitored at the start of the transmission. If the transmitter has error passive flag the ESI bit is transmitted recessive, else it is transmitted dominant.

#### 12.4.4.4.3.4 Transmitter Delay Compensation

##### 12.4.4.4.3.4.1 Description

When only one CAN FD node is transmitting and all others are receivers the length of the bus line has no impact. When transmitting via the TX pin the MCAN module receives the transmitted data from its local CAN transceiver via the RX pin. The received data is delayed. If the transmitter delay is greater than TSEG1 (time segment before sample point), a bit error is detected.

The MCAN module provides a delay compensation mechanism to compensate the transmitter delay. The compensation mechanism enables transmission with higher bit rates during the CAN FD data phase

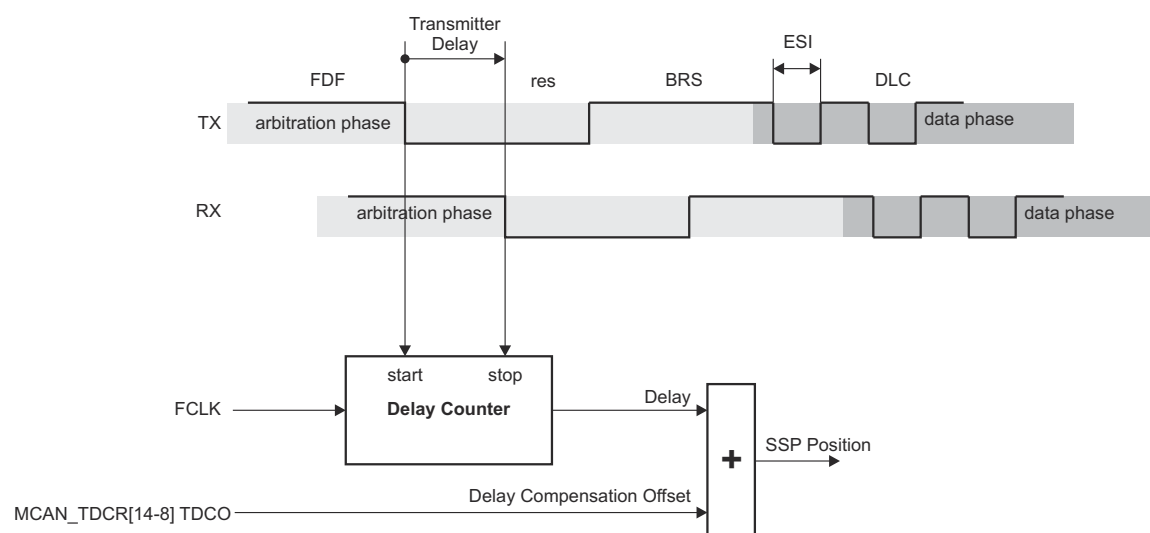

independent of the delay of a specific CAN transceiver. Without transmitter delay compensation the bit rate in the data phase is limited by the transmitter delay.

The mechanism enables configurations where the data bit time is shorter than the transmitter delay (it is described in detail in ISO 11898-1:2015). The transmitter delay compensation is enabled by setting the MCAN\_DBTP[23] TDC bit to 1.

The delayed transmit data is compared against the received data at the Secondary Sample Point (SSP) in order to check for bit errors during the data phase of transmitting nodes. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the MCAN's transmit output TX pin through the transceiver to the receive input RX pin plus the transmitter delay compensation offset configured by the MCAN\_TDCR[14-8] TDCO field (see Figure 12-469). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (example: half of the bit time in the data phase). The position of the SSP is rounded down to the next integer number of mtq.

The actual transmitter delay compensation value can be checked by reading the MCAN\_PSR[22-16] TDCV field. This field is cleared when the MCAN\_CCCR[0] INIT bit is set and is updated at each transmission of CAN FD frame while the MCAN\_DBTP[23] TDC bit is set.

mcan-005

**Figure 12-469. Transmitter Delay Measurement**

#### 12.4.4.3.4.2 Transmitter Delay Compensation Measurement

When transmitter delay compensation is enabled (by programming MCAN\_DBTP[23] TDC = 1), the measurement is started within each transmitted CAN FD frame at the falling edge of FDF bit to bit res. The measurement is stopped when this edge is seen at the receive input RX pin of the transmitter. The resolution of this measurement is one mtq (see Figure 12-469). The mtq (minimum time quantum) dimension is equal to the CAN clock period (FCLK).

The use of a transmitter delay compensation filter window can be enabled by programming MCAN\_TDCR[6-0] TDCF field. This filter feature defines a minimum value for the SSP position to avoid the case in which a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in an early taken SSP position. Dominant edges on the RX pin, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least MCAN\_TDCR[6-0] TDCF field and the RX pin is low.

#### 12.4.4.4.3.7 Disabled Automatic Retransmission (DAR) Mode

According to the CAN Specification (see ISO11898-1:2015, *Recovery Management* section), the MCAN module provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled (see the MCAN\_CCCR[6] DAR bit).

##### 12.4.4.4.3.7.1 Frame Transmission in DAR Mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending MCAN\_TXBRP[xx] TRPx bit is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

Successful transmission:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is not set

Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

Arbitration lost or frame transmission disturbed:

- Corresponding Tx Buffer Transmission Occurred MCAN\_TXBTO[xx] TOx bit is not set
- Corresponding Tx Buffer Cancellation Finished MCAN\_TXBCF[xx] CFx bit is set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

#### 12.4.4.4.3.8 Power Down (Sleep Mode)

The entering in Power Down mode is controlled via two sources:

- PSC (via clock stop request signal)
- Software (by writing to the MCAN\_CCCR[4] CSR bit)

As long as the clock stop request signal is active, the MCAN\_CCCR[4] CSR bit is read as 1.

When all pending transmission requests have completed, the MCAN module waits until bus idle state is detected. Then the MCAN module sets the MCAN\_CCCR[0] INIT bit to 1 to prevent any further CAN transfers.

The MCAN module acknowledges that it is ready for power down:

- By asserting clock stop acknowledge signal to the PSC (in case of PSC source).
- By setting the MCAN\_CCCR[3] CSA flag bit to 1 (in case of Software source).

In this state, before the clocks are switched off, further register accesses can be made. Now the module clock inputs ICLK and FCLK may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting the input clock stop request signal respectively the MCAN\_CCCR[4] CSR flag bit. The MCAN will acknowledge this by resetting the output clock stop acknowledge signal respectively the MCAN\_CCCR[3] CSA flag bit. Afterwards, the application can restart CAN communication by resetting the MCAN\_CCCR[0] INIT bit.

Restoring the clocks from clock stop mode, needs to be done according to how the clock stop was initiated:

- If Software asserts the MCAN\_CCCR[3] CSA flag bit, once the MCAN module goes idle, the MCAN\_CCCR[0] INIT bit is set. To get it started again, Software needs to write 0 to the MCAN\_CCCR[0] INIT bit.
- If PSC is issuing a clock stop request, than there are two options for waking up:
  - After removing clock stop request signal, Software would need to write 0 to the MCAN\_CCCR[0] INIT bit, or
  - If the MCANSS\_CTRL[5] AUTOWAKEUP bit is set, than after removing clock stop request signal, an FSM inside the MCAN module will reset the MCAN\_CCCR[0] INIT bit (without Software).

#### 12.4.4.4.3.8.1 External Clock Stop Mode

The MCAN module supports two external clock stop modes:

- Immediate
- Graceful

In a graceful clock stop mode, when the clock stop request is asserted, the MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. The MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.4.3.8.3, Wakeup request](#)). When external clock stop request is removed and no suspend request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

#### 12.4.4.4.3.8.2 Suspend Mode

The MCAN module supports two suspend modes:

- Immediate
- Graceful

In a graceful suspend mode (see the MCANSS\_CTRL[3] DBGSUSP\_FREE bit), when the suspend request is asserted, a clock stop request to the MCAN core is performed. The MCAN core will respond with clock stop acknowledge when all pending Tx messages have been processed and an Idle line had been detected. At that point the MCAN\_CCCR[0] INIT bit will be set, the MCAN core will go and stay Idle. The suspend state can be verified by reading MCAN\_CCCR[0] INIT bit.

The automatic wakeup feature is enabled by setting the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits to 1 (for more information, see [Section 12.4.4.4.3.8.3, Wakeup request](#)). When suspend request is removed, if no external clock stop request is active, a read-modify-write to the MCAN\_CCCR[0] INIT bit is performed to clear it.

During suspend mode the auto-clear feature is disabled. The following register fields have an auto-clear feature:

- MCAN\_ECR[23-16] CEL
- MCAN\_PSR[2-0] LEC
- MCAN\_PSR[10-8] DLEC
- MCAN\_PSR[11] RESI
- MCAN\_PSR[12] RBRS
- MCAN\_PSR[13] RFDF
- MCAN\_PSR[14] PXE

#### 12.4.4.4.3.8.3 Wakeup request

Issuing a clock stop request puts the MCAN module into Power Down mode (Sleep Mode). During transition from IDLE to ACTIVE, if the MCANSS\_CTRL[5] AUTOWAKEUP and MCANSS\_CTRL[4] WAKEUPREQEN bits are enabled, after the MCAN Core respond to the removal of the clock stop request with removing the clock stop acknowledge, a read-modify-write will be issued to clear the MCAN\_CCCR[0] INIT bit and the MCAN core will resume operation.

If the MCANSS\_CTRL[4] WAKEUPREQEN bit is set, the MCAN module provides a wakeup request on the following wakeup event:

- The receive RX pin is dominant (logical 0)

The wakeup request is de-asserted when any of the following conditions occur:

- Clock stop request is removed and clock stop acknowledge is de-asserted
- A reset is applied to the MCAN module

#### 12.4.4.4.3.9 Test Modes

The MCAN\_TEST register write access is enabled by setting the test mode enable MCAN\_CCCR[7] TEST bit to 1. The MCAN\_TEST register allows the configuration of the test modes and test functions.

The CAN transmit TX pin has four output functions. One of those functions can be selected by programming the MCAN\_TEST[6-5] TX field. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the MCAN's bit timing and it can drive constant dominant or recessive values.

The actual value of the CAN receive RX pin can be monitored from MCAN\_TEST[7] RX bit. Both functions can be used to check the CAN bus physical layer. Due to the synchronization mechanism between CAN clock (FCLK) and Host clock (ICLK) domain, there may be a delay of several Host clock periods between writing to the MCAN\_TEST[6-5] TX field until the new configuration is visible at the output TX pin. This applies also when reading input RX pin via the MCAN\_TEST[7] RX bit.

### Note

Test modes should be used for self test only. The software control for TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

#### 12.4.4.4.3.9.1 Internal Loopback Mode

The MCAN module can be set into Internal Loopback Mode by programming MCAN\_TEST[4] LBCK and MCAN\_CCCR[5] MON bits to 1. The Internal Loopback Mode is used for a 'Hot Selftest'. The 'Hot Selftest' allows the MCAN module to be tested without affecting a running CAN system connected to the TX and RX pins. In this mode RX pin is disconnected from the MCAN module and TX pin is held recessive. [Figure 12-471](#) shows the connection of the TX and RX pins to the MCAN module in case of Internal Loopback Mode.

**Figure 12-471. Internal Loopback Mode**

#### 12.4.4.4.4 Timestamp Generation

The MCAN module has integrated a 16-bit wrap-around counter for timestamp generation. The timestamp counter prescaler MCAN\_TSCC[19-16] TCP field can be configured to clock the counter in multiples of CAN bit times (1-16). The counter is readable via the MCAN\_TSCV[15-0] TSC field. A write access to the MCAN\_TSCV register resets the counter to zero. When the timestamp counter wraps around the interrupt MCAN\_IR[16] TSW flag is set. On start of a frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15-0]) or Tx Event FIFO (TXTS[15-0]) element. For more information, see [Section 12.4.4.4.10, Message RAM](#).

#### 12.4.4.4.1 External Timestamp Counter

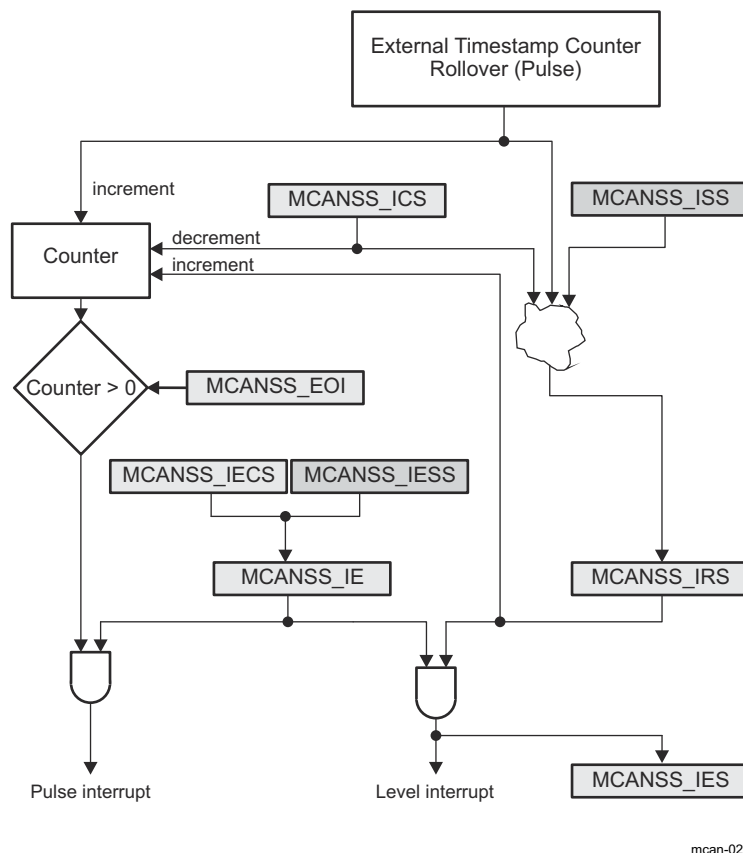

For CAN FD operation mode the MCAN core requires an External Timestamp Counter. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter (internal timestamp counter) for receive

and transmit timestamp generation. An external 16-bit timestamp counter can be used by programming the MCAN\_TSCC[1-0] TSS field.

The External Timestamp Counter uses the interface clock (ICLK) as a reference clock. The MCAN Core accepts a 16-bit timestamp. A 24-bit prescaler provides a programmable resolution for the timestamp (see MCANSS\_EXT\_TS\_PRESCALER[23-0] PRESCALER bit field). The External Timestamp Counter counter can be enabled or disabled through the MCANSS\_CTRL[6] EXT\_TS\_CNTR\_EN bit. When disabled the counter is reset back to zero. While enabled the counter keeps incrementing. When the timestamp rolls over the MCAN timestamp interrupt is generated.

When the timestamp rolls over the MCANSS\_IRS register is set (see Figure 12-472). The MCANSS\_IE register can be affected by writing to the MCANSS\_IESS register to set or to the MCANSS\_IECS register to clear. The MCANSS\_IESS register is a shadow register mapped to the same address as the MCANSS\_IE register. The level interrupt is a reflection of both MCANSS\_IRS and MCANSS\_IE being set. The MCANSS\_IES register reflects the level interrupt. When an rollover event occurs the interrupt counter is incremented. Writing to the MCANSS\_ICS register to clear the MCANSS\_IRS register will also decrement the interrupt counter. Writing to the MCANSS\_EOI register will issue another pulse if the interrupt counter is not zero.

The rollover event can be artificially simulated by software through writing to the Interrupt Set Shadow register (MCANSS\_ISS). The MCANSS\_ISS register is a shadow register mapped to the same address as the MCANSS\_IRS register.

**Figure 12-472. External Timestamp Counter Interrupt**

#### 12.4.4.4.5 Timeout Counter

The MCAN module has integrated a 16-bit Timeout Counter. It is used to signal timeout conditions for the Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO Message RAM elements. The Timeout Counter is configured via the MCAN\_TOCC register. It is enabled via the MCAN\_TOCC[0] ETOC bit. The Timeout Counter operates

as down-counter and uses the same prescaler programmed by the MCAN\_TSCC[19-16] TCP field as the Timestamp Counter. The actual counter value can be monitored from the MCAN\_TOCV[15-0] TOC field. The Timeout Counter can be started only when MCAN\_CCCR[0] INIT = 0 and stopped when MCAN\_CCCR[0] INIT = 1 (example: when the MCAN enters Bus\_Off state). The operation mode is selected by the MCAN\_TOCC[2-1] TOS field. When Continuous Mode is selected, the counter starts when MCAN\_CCCR[0] INIT = 0, a write to the MCAN\_TOCV register presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field and continues down-counting.

In case the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by the MCAN\_TOCC[31-16] TOP field. Down-counting is started when the first FIFO element is stored. Writing to the MCAN\_TOCV register has no effect. When the counter reaches zero, the interrupt MCAN\_IR[18] TOO flag is set.

In Continuous Mode, the counter is immediately restarted at the value configured by the MCAN\_TOCC[31-16] TOP field.

#### 12.4.4.4.6 ECC Support

The Message Memory is wrapped in an ECC wrapper providing SECDED parity functionality. The ECC wrapper is controlled by an ECC Aggregator.

##### 12.4.4.4.6.1 ECC Wrapper

The ECC wrapper provides Single Error Correction (SEC) and Double Error Detection (DED) parity to the Message Memory content. It has side band signals for error notification. The ECC Wrapper implements an error injection test mode.

The error correction is done using a lazy write back. When an error is detected, it is noted in a FIFO Queue which waits for an access gap to write the data back and refresh the memory. If a transaction writes new data to the compromised entry before the lazy write back completes, the write back is discarded.

##### 12.4.4.4.6.2 ECC Aggregator

---

#### Note

For more information about ECC Aggregator, refer to [Section 12.11.4, ECC Aggregator](#).

---

#### 12.4.4.4.7 Rx Handling

The Rx Handler controls the following operations:

- Acceptance filtering
- The transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1)
- Rx FIFO Put and Get Index operations

##### 12.4.4.4.7.1 Acceptance Filtering

The MCAN module is capable to configure two sets of acceptance filters - one set for standard and one set for extended identifiers. These filters can be assigned to an Rx Buffer or to one of the two Rx FIFOs.

The main features of the filter elements are:

- Each filter element can be configured as:
  - Range Filter (from - to)
  - Filter for specific IDs (for one or two dedicated IDs)
  - Classic Bit Mask Filter
- Each filter element can be enabled/disabled individually
- Each filter element can be configured for acceptance or rejection filtering
- Filters are checked sequentially and execution (acceptance filtering procedure) stops at the first matching filter element or when the end of the filter list is reached

Related configuration registers are:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register
- Extended ID AND Mask (MCAN\_XIDAM) register

Depending on the configuration of the filter element (see SFEC/EFEC in [Section 12.4.4.4.10, Message RAM](#)) if filter matches, one of the following actions is performed:

- Received frame is stored in FIFO 0 or FIFO 1
- Received frame is stored in Rx Buffer
- Received frame is stored in Rx Buffer and generation of pulse at filter event pin is performed. This is high level single ICLK pulse. For more information, see [Section 12.4.4.4.2.1, DMA Requests](#).
- Received frame is rejected
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM
- Set High Priority Message interrupt flag MCAN\_IR[8] HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering starts when complete Message ID is received. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If a filter element matches - the Rx Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If an error condition occurs (for example: CRC error), this message is rejected with the following impact on the affected Rx Buffer or Rx FIFO:

- Rx Buffer:  
New Data flag (MCAN\_NDAT1/MCAN\_NDAT2) of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields).
- Rx FIFO:  
Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data (for error type see MCAN\_PSR[2-0] LEC respectively MCAN\_PSR[10-8] DLEC fields). If matching Rx FIFO is configured to operate in overwrite mode, the boundary conditions described in [Section 12.4.4.4.7.2.2](#) have to be considered.

#### 12.4.4.4.7.1.1 Range Filter

Each filter element can be configured to operate as Range Filter (Standard Filter Type SFT = 00/Extended Filter Type EFT = 00). The filter matches for all received message frames with IDs in the range from SFID1 to SFID2 (SFID2 ≥ SFID1) respectively in the range from EFID1 to EFID2 (EFID2 ≥ EFID1). For more information see [Section 12.4.4.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.4.10.6, Extended Message ID Filter Element](#).

There are two options for range filtering of extended frames:

- Extended Filter Type EFT = 00: The Extended ID AND Mask (MCAN\_XIDAM) is used for Range Filtering. The Message ID of received frames is ANDed with the Extended ID AND Mask (MCAN\_XIDAM) before the range filter is applied.
- Extended Filter Type EFT = 11: The Extended ID AND Mask (MCAN\_XIDAM) is not used for Range Filtering.

#### 12.4.4.4.7.1.2 Filter for specific IDs

Each filter element can be configured to filter one or two dedicated Message IDs (Standard Filter Type SFT = 01/Extended Filter Type EFT = 01). To filter only one specific Message ID, the filter element has to be configured with SFID1 = SFID2 respectively EFID1 = EFID2. For more information see [Section 12.4.4.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.4.10.6, Extended Message ID Filter Element](#).

#### **12.4.4.4.7.1.3 Classic Bit Mask Filter**

Classic bit mask filtering can filter groups of Message IDs (Standard Filter Type SFT =10/Extended Filter Type EFT =10). This is done by masking single bits of a received Message ID. In this case SFID1/EFID1 element is used as Message ID filter, while SFID2/EFID2 element is used as filter mask.

A 0 bit at the filter mask (SFID2/EFID2) will mask out the corresponding bit position of the configured Message ID filter (SFID1/EFID1) and the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are 1 are relevant for acceptance filtering.

There are two interesting cases:

- All mask bits are 1: a match occurs only when the received Message ID and the configured Message ID filter are identical.
- All mask bits are 0: all Message IDs match.

#### **12.4.4.4.7.1.4 Standard Message ID Filtering**

The standard Message ID (11-bit ID) filtering flow is shown in [Figure 12-473](#). [Section 12.4.4.4.10.5](#), *Standard Message ID Filter Element* describes the standard Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Standard ID Filter Configuration (MCAN\_SIDFC) register

mcan-009

**Figure 12-473. Standard Message ID Filter Path**

#### 12.4.4.4.7.1.5 Extended Message ID Filtering

The extended Message ID (29-bit ID) filtering flow is shown in [Figure 12-474](#). [Section 12.4.4.4.10.6](#), *Extended Message ID Filter Element* describes the extended Message ID filter element.

The Remote Transmission Request (RTR) and Extended Identifier (XTD) bits of the received frames are compared against the list of configured filter elements. This is controlled by the following registers:

- Global Filter Configuration (MCAN\_GFC) register
- Extended ID Filter Configuration (MCAN\_XIDFC) register

Note that before the filter list is executed the received identifier is ANDed with the Extended ID AND Mask (MCAN\_XIDAM).

mcan-010

**Figure 12-474. Extended Message ID Filter Path**

#### 12.4.4.4.7.2 Rx FIFOs

The configuration of the Rx FIFOs (Rx FIFO 0 and Rx FIFO 1) can be done via the MCAN\_RXF0C and MCAN\_RXF1C registers. Each Rx FIFO can be configured to store up to 64 received messages.

After acceptance filtering the received messages that passed are transferred to the Rx FIFO. The filter mechanisms available for the Rx FIFO 0 and Rx FIFO 1 is described in [Section 12.4.4.4.7.1, Acceptance Filtering](#). [Section 12.4.4.4.10.2, Rx Buffer and FIFO Element](#) describes the Rx FIFO element.

The Rx FIFO watermark can be used to prevent an Rx FIFO overflow. If the Rx FIFO fill level reaches the Rx FIFO watermark configured by the MCAN\_RXFnC[30-24] FnWM field (where: n = 0 or 1) an interrupt flag MCAN\_IR[1] RF0W/MCAN\_IR[5] RF1W is set.

When the Rx FIFO Put Index reaches the Rx FIFO Get Index (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) an Rx FIFO Full condition is signalled by the MCAN\_RXFnS[24] FnF status bit and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set. [Figure 12-475](#) shows Rx FIFO Status. The FIFOs fill level is presented in the MCAN\_RXFnS[6-0] FnFL field (the number of elements stored in Rx FIFO).

**Figure 12-475. Rx FIFO Status**

Rx FIFOs start address in the Message RAM (MCAN\_RXFnC[15-2] FnSA field) have to be configured when reading from an Rx FIFO (Rx FIFO Get Index - MCAN\_RXFnS[13-8] FnGI). [Table 12-479](#) presents Rx Buffer/Rx FIFO Element Size for different Rx Buffer/Rx FIFO Data Field Size which is configured via the MCAN\_RXESC register.

**Table 12-479. Rx Buffer/Rx FIFO Element Size**

MCAN_RXESC[10-8] RBDS MCAN_RXESC[2-0] F0DS/ MCAN_RXESC[6-4] F1DS	Data Field [bytes]	FIFO Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.4.4.7.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is the default operation mode for the Rx FIFOs. It is configured by the MCAN\_RXFnC[31] FnOM = 0.

If an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by the MCAN\_RXFnS[24] FnF = 1 and interrupt flag MCAN\_IR[2] RF0F/MCAN\_IR[6] RF1F is set.

In case a message is received while the corresponding Rx FIFO is full, this message is rejected and the message lost condition is signalled by MCAN\_RXFnS[25] RFnL = 1 and interrupt flag MCAN\_IR[3] RFnL/MCAN\_IR[25] RFnL is set.

#### 12.4.4.4.7.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by the MCAN\_RXFnC[31] FnOM = 1. When an Rx FIFO full condition is reached (MCAN\_RXFnS[21-16] FnPI = MCAN\_RXFnS[13-8] FnGI) signalled by MCAN\_RXFnS[24] FnF = 1, the next accepted message for the FIFO will overwrite the oldest FIFO message. Put index/Get index are both incremented by one.

In overwrite mode if an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (Put index) while the Host CPU is reading from the Message RAM (Get index). In this case inconsistent data may be read from the respective Rx FIFO element. The problem is solved by adding an offset to the Get index when reading from the Rx FIFO. The offset depends on how fast the Host CPU accesses the Rx FIFO. [Figure 12-476](#) shows an offset of two with respect to the Get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

**Figure 12-476. Rx FIFO Overflow Handling**

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index MCAN\_RXFnA[5-0] FnAI. This increments the get index to that element number. In case the Put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (MCAN\_RXFnS[24] FnF = 0).

#### 12.4.4.4.7.3 Dedicated Rx Buffers

The MCAN supports up to 64 dedicated Rx Buffers. The start address of the Rx Buffers section in the Message RAM is configured via MCAN\_RXBC[15-2] RBSA field. To store in an Rx Buffer a Standard or Extended Message ID Filter Element with SFEC/EFEC = 111 and SFID2/EFID2[10-9] = 00 has to be configured (see [Section 12.4.4.4.10.5, Standard Message ID Filter Element](#) and [Section 12.4.4.4.10.6, Extended Message ID Filter Element](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element (the format is the same as for an Rx FIFO element). In addition the flag MCAN\_IR[19] DRX (Message stored in Dedicated Rx Buffer) is set.

[Table 12-480](#) shows Example Filter Configuration for Rx Buffers.

**Table 12-480. Example Filter Configuration for Rx Buffers**

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
0	ID message 1	00	00 0000

**Table 12-480. Example Filter Configuration for Rx Buffers (continued)**

Filter Element	SFID1[10-0] EFID1[28-0]	SFID2[10-9] EFID2[10-9]	SFID2[5-0] EFID2[5-0]
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register MCAN\_NDAT1/MCAN\_NDAT2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host CPU by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

#### 12.4.4.7.3.1 Rx Buffer Handling

Rx Buffer Handling include the following steps:

- Reset interrupt flag MCAN\_IR[19] DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

#### 12.4.4.7.4 Debug on CAN Support

Debug DMA is not supported feature. Debug messages can be traced through the RX FIFO (see [Section 12.4.4.7.2](#)).

#### 12.4.4.8 Tx Handling

The Tx Handler is used to handle the Tx requests. It controls the transfer of transmit messages from the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue to the CAN Core, the Tx Event FIFO, and the Put and Get Index operations. The MCAN module supports up to 32 Tx Buffers. These Tx Buffers can be configured as dedicated Tx Buffers, Tx FIFO, or Tx Queue and as combination of dedicated Tx Buffers/Tx FIFO or dedicated Tx Buffers/Tx Queue. For each Tx Buffer element Classical CAN or CAN FD transmission mode can be configured. [Section 12.4.4.10.3](#) describes the Tx Buffer Element. [Table 12-481](#) shows the possible configurations for message transmission.

**Table 12-481. Possible Configurations for Message Transmission**

MCAN_CCCR		Tx Buffer Element		Frame Transmission
MCAN_CCCR[9] BRSE	MCAN_CCCR[8] FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	CAN FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	CAN FD without bit rate switching
1	1	1	1	CAN FD with bit rate switching

When the Tx Buffer Request Pending MCAN\_TXBRP register is updated, or when a transmission has been started the Tx Handler starts scanning to check for the highest priority pending Tx request. The Tx Buffer with lowest Message ID has highest priority.

### Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

#### 12.4.4.4.8.1 Transmit Pause

The transmit pause feature is intended for use in CAN networks where the CAN Message IDs are specific and cannot easily be changed. These Message IDs may have a higher priority than other defined Message IDs, while in a specific application their relative priority should be inverse. This allows for a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed (paused).

The transmit pause feature is enabled by the MCAN\_CCCR[14] TXP bit. By default this bit is disabled (MCAN\_CCCR[14] TXP = 0). Each time after successfully transmitted message, a pause for two CAN bit times occurs before the start of the next transmission. This allows the other CAN nodes in the network to transmit messages even if their Message IDs have lower priority.

#### 12.4.4.4.8.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU.

There are two options:

- Each dedicated Tx Buffer is configured with a specific Message ID.
- Two or more dedicated Tx Buffers are configured with the same Message ID. In this case the Tx Buffer with the lowest buffer number is transmitted first.

After the data section has been updated, a transmission is requested by an Add Request. This is done via the MCAN\_TXBAR[x]ARn bit (where x = 0 - 31). The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Table 12-482 shows Tx Buffer/Tx FIFO/Tx Queue Element Size. A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM. The start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index from 0 to 31 (MCAN\_TXFQS[20-16] TFQPI) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

**Table 12-482. Tx Buffer/Tx FIFO/Tx Queue Element Size**

MCAN_TXESC[2-0] TBDS	Data Field [bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

#### 12.4.4.4.8.3 Tx FIFO

Tx FIFO mode is configured by setting bit MCAN\_TXBC[30] TFQM = 0. The stored in the Tx FIFO messages are transmitted starting with the message referenced by the Get Index MCAN\_TXFQS[12-8] TFGI field. After each transmission the Get Index is incremented until the Tx FIFO is empty. The Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field indicates the number of the available free Tx FIFO elements. The Tx FIFO allows transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. After each Add Request (MCAN\_TXBAR[x] ARn = 1) the

Put Index is incremented to the next free Tx FIFO element. When the Put Index reaches the Get Index (MCAN\_TXFQS[20-16] TFQPI = MCAN\_TXFQS[12-8] TFGI), Tx FIFO Full condition is signalled by bit MCAN\_TXFQS[21] TFQF = 1. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field.

In case a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level MCAN\_TXFQS[5-0] TFFL field is recalculated. In case transmission cancellation is applied to any other Tx Buffer - the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see [Table 12-482](#)). The start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS[20-16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.4.4.8.4 Tx Queue

Tx Queue mode is configured by setting bit MCAN\_TXBC[30] TFQM = 1. The stored in the Tx Queue messages are transmitted starting with the highest priority message (lowest Message ID). In case two or more Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index MCAN\_TXFQS[20-16] TFQPI field. Each Add Request cyclically increments the Put Index to the next free Tx Buffer. In case of Tx Queue Full condition (MCAN\_TXFQS[21] TFQF = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the MCAN\_TXBRP register instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 12-482](#)). The start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index MCAN\_TXFQS[20-16] TFQPI (from 0 to 31) × Element Size to the Tx Buffer Start Address MCAN\_TXBC[15-2] TBSA field.

#### 12.4.4.4.8.5 Mixed Dedicated Tx Buffers/Tx FIFO

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx FIFO: the number of Tx Buffers assigned to the Tx FIFO is configured by the MCAN\_TXBC[29-24] TFQS field

If the MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the MCAN\_TXFQS[12-8] TFGI field)
- Buffer with lowest Message ID gets highest priority and is transmitted next

[Figure 12-477](#) shows Mixed Dedicated Tx Buffers/Tx FIFO example.

**Figure 12-477. Mixed Dedicated Tx Buffers/Tx FIFO (example)**

#### 12.4.4.4.8.6 Mixed Dedicated Tx Buffers/Tx Queue

For this combination the Tx Buffers section in the Message RAM is separated in two parts:

- Dedicated Tx Buffers: the number of Dedicated Tx Buffers is configured by the MCAN\_TXBC[21-16] NDTB field
- Tx Queue: the number of Tx Buffers assigned to the Tx Queue is configured by the MCAN\_TXBC[29-24] TFQS field

If MCAN\_TXBC[29-24] TFQS field is empty (zero) - only Dedicated Tx Buffers are used.

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

Figure 12-478 shows Mixed Dedicated Tx Buffers/Tx Queue example.

**Figure 12-478. Mixed Dedicated Tx Buffers/Tx Queue (example)**

#### 12.4.4.4.8.7 Transmit Cancellation

This feature is especially intended for gateway and AUTOSAR based applications. The Host CPU can cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer by setting bit MCAN\_TXBCR[n] CRn = 1 (where n = 0 - 31). The corresponding bit position n is equivalent to the number of the Tx Buffer.

Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the MCAN\_TXBCF register (MCAN\_TXBCF[n] CFn = 1).

If transmission from a Tx Buffer is already ongoing and a transmit cancellation is requested, the corresponding MCAN\_TXBRP[n] TRPn bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding MCAN\_TXBTO[n] TOn and MCAN\_TXBCF[n] CFn bits are set. If the transmission was not successful, only the corresponding bit MCAN\_TXBCF[n] CFn = 1.

---

**Note**

If pending transmission is cancelled immediately before this transmission could have been started, a short time window occurs where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

---

**12.4.4.4.8 Tx Event Handling**

To support Tx Event Handling the Message RAM has implemented a Tx Event FIFO section. Up to 32 Tx Event FIFO elements can be configured. [Section 12.4.4.4.10.4](#) describes the Tx Event FIFO element. After message transmission on the CAN bus, Message ID and Timestamp are stored in a Tx Event FIFO element. To link a Tx Event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

A Tx Event FIFO full condition is signalled by the MCAN\_IR[14] TEFF bit. In this case no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented (MCAN\_TXEFS[12-8] EFGI). In case a Tx Event occurs while the Tx Event FIFO is full, this event is rejected and interrupt flag MCAN\_IR[15] TEFL bit is set.

The Tx Event FIFO watermark can be configured to avoid a Tx Event FIFO overflow. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by the MCAN\_TXEFC[29-24] EFWM field, interrupt flag MCAN\_IR[13] TEFW is set. When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index MCAN\_TXEFS[12-8] EFGI field has to be added to the Tx Event FIFO start address MCAN\_TXEFC[15-2] EFSA field.

**12.4.4.4.9 FIFO Acknowledge Handling**

The Get Indices of the two Rx FIFOs (Rx FIFO 0 or Rx FIFO 1) and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see MCAN\_RXF0A, MCAN\_RXF1A, and MCAN\_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level.

There are two use cases:

- A single element has been read from the FIFO: the Get Index value is written to the FIFO Acknowledge Index.
- A sequence of elements has been read from the FIFO: the Get Index value (Index of the last element read) is written to the FIFO Acknowledge Index at the end of that read sequence.

The Host CPU has free access to the Message RAM. The special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This can be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also changes the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

---

**Note**

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The MCAN module does not check for erroneous values.

---

#### 12.4.4.4.10 Message RAM

The MCAN module has implemented Message RAM. The main purpose of the Message RAM is to store:

- Receive Messages
- Transmit Messages
- Tx Event Elements
- Message ID Filter Elements

##### 12.4.4.4.10.1 Message RAM Configuration

The MCAN module is configured to allocate 4352 words in the Message RAM. The Message RAM has a width of 32 bits.

[Table 12-483](#) presents the Message RAM Address Range for all device MCAN instances.

**Table 12-483. Message RAM Address Range**

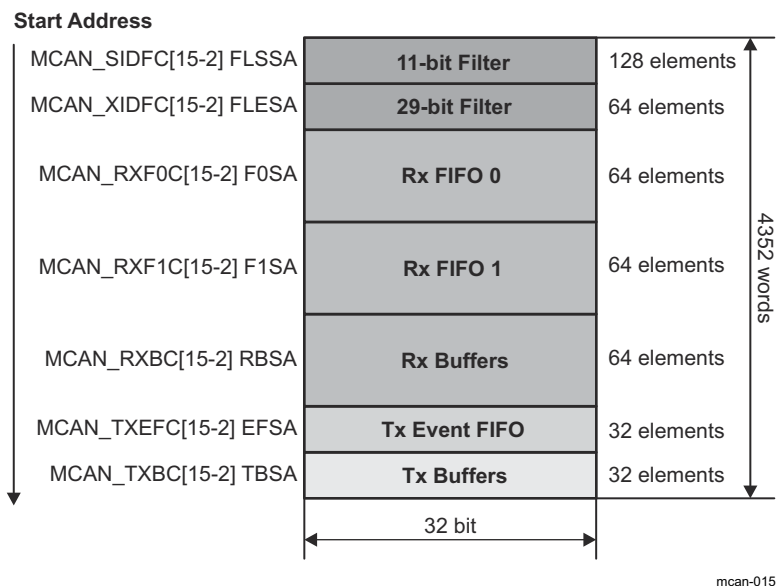

Module Instance	Region Name	Address Range		Size
		Start	End	
MCU_MCAN0	MCU_MCAN0_MSGMEM_RAM	4050 0000h	4050 7FFFh	32 KB
MCU_MCAN1	MCU_MCAN1_MSGMEM_RAM	4054 0000h	4054 7FFFh	32 KB
MCAN0	MCAN0_MSGMEM_RAM	0270 8000h	0270 FFFFh	32 KB
MCAN1	MCAN1_MSGMEM_RAM	0271 8000h	0271 FFFFh	32 KB
MCAN2	MCAN2_MSGMEM_RAM	0272 8000h	0272 FFFFh	32 KB
MCAN3	MCAN3_MSGMEM_RAM	0273 8000h	0273 FFFFh	32 KB
MCAN4	MCAN4_MSGMEM_RAM	0274 8000h	0274 FFFFh	32 KB
MCAN5	MCAN5_MSGMEM_RAM	0275 8000h	0275 FFFFh	32 KB
MCAN6	MCAN6_MSGMEM_RAM	0276 8000h	0276 FFFFh	32 KB
MCAN7	MCAN7_MSGMEM_RAM	0277 8000h	0277 FFFFh	32 KB
MCAN8	MCAN8_MSGMEM_RAM	0278 8000h	0278 FFFFh	32 KB
MCAN9	MCAN9_MSGMEM_RAM	0279 8000h	0279 FFFFh	32 KB
MCAN10	MCAN10_MSGMEM_RAM	027A 8000h	027A FFFFh	32 KB
MCAN11	MCAN11_MSGMEM_RAM	027B 8000h	027B FFFFh	32 KB
MCAN12	MCAN12_MSGMEM_RAM	027C 8000h	027C FFFFh	32 KB
MCAN13	MCAN13_MSGMEM_RAM	027D 8000h	027D FFFFh	32 KB

The Message RAM is capable to include each of the sections listed in [Figure 12-479](#). It is not necessary to configure each of the sections (a section in the Message RAM may be 0) and there is not restriction with respect to the sequence of the sections. For parity checking or ECC a respective number of bits has to be added to each word.

When the MCAN module addresses the Message RAM it addresses 32-bit words. The start addresses are configurable and they are 32-bit word addresses.

The element size can be configured for:

- Rx FIFO 0 via the MCAN\_RXESC[2-0] F0DS field
- Rx FIFO 1 via the MCAN\_RXESC[6-4] F1DS field
- Rx Buffers via the MCAN\_RXESC[10-8] RBDS field
- Tx Buffers via the MCAN\_TXESC[2-0] TBDS field

**Figure 12-479. Message RAM Configuration**

The Host CPU configures the following information in the Message RAM:

- Start addresses of the memory sections
- Number of elements in each section
- The size of the elements in some sections

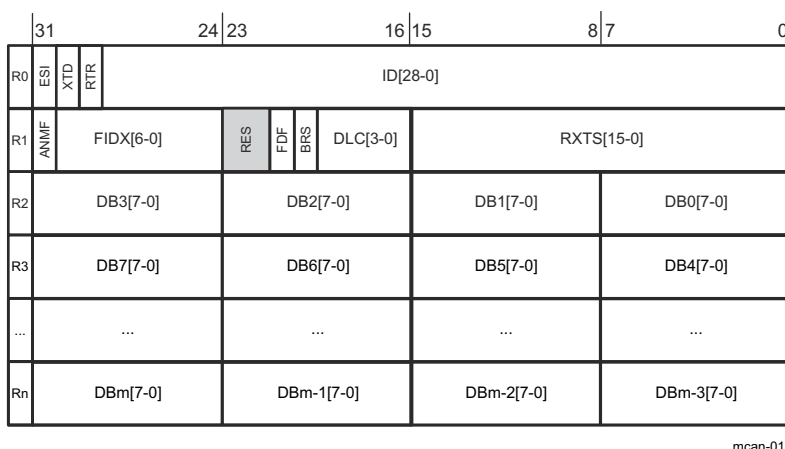

**Note**

The MCAN module does not check for errors in the Message RAM configuration. The configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully. This will prevent falsification or loss of data.

**12.4.4.4.10.2 Rx Buffer and FIFO Element**

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_RXESC register.

Figure 12-480 shows Rx Buffer/Rx FIFO element structure.

**Figure 12-480. Rx Buffer/Rx FIFO Element Structure**

Table 12-484 shows Rx Buffer/Rx FIFO element field descriptions.

**Table 12-484. Rx Buffer/Rx FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
R0	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>0h = Transmitting node is error active</li> <li>1h = Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier Signals to the Host CPU whether the received frame has a standard or extended identifier. <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request Signals to the Host CPU whether the received frame is a data frame or a remote frame. <ul style="list-style-type: none"> <li>0h = Received frame is a data frame</li> <li>1h = Received frame is a remote frame</li> </ul> <p><b>Note:</b> There are no remote frames in CAN FD format. In case a CAN FD frame was received (FDF = 1), RTR bit reflects the state of the reserved r1 bit (RES[23]).</p>
	28-0	ID[28-0]	Identifier Standard or extended identifier depending on XTD bit. A standard identifier is stored into ID[28-18].

**Table 12-484. Rx Buffer/Rx FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
R1	31	ANMF	Accepted Non-matching Frame Acceptance of non-matching frames may be enabled via the MCAN_GFC[5-4] ANFS and MCAN_GFC[3-2] ANFE fields. <ul style="list-style-type: none"> <li>0h = Received frame matching filter index FIDX field</li> <li>1h = Received frame did not match any Rx filter element</li> </ul>
	30-24	FIDX[6-0]	Filter Index 0h-7Fh (0-127): Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to MCAN_SIDFC[23-16] LSS - 1 respectively MCAN_XIDFC[22-16] LSE - 1.
	23-22	RES	Reserved
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0h = Frame received without bit rate switching</li> <li>1h = Frame received with bit rate switching</li> </ul>
	19-16	DLC[3-0]	Data Length Code <ul style="list-style-type: none"> <li>0h-8h (0-8) = CAN + CAN FD: received frame has 0-8 data bytes</li> <li>9h-Fh (9-15) = CAN: received frame has 8 data bytes</li> <li>9h-Fh (9-15) = CAN FD: received frame has 12/16/20/24/32/48/64 data bytes</li> </ul>
R2	15-0	RXTS[15-0]	Rx Timestamp Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19-16] TCP.
	31-24	DB3[7-0]	Data Byte 3
	23-16	DB2[7-0]	Data Byte 2
	15-8	DB1[7-0]	Data Byte 1
R3	7-0	DB0[7-0]	Data Byte 0
	31-24	DB7[7-0]	Data Byte 7
	23-16	DB6[7-0]	Data Byte 6
	15-8	DB5[7-0]	Data Byte 5
Rn	7-0	DB4[7-0]	Data Byte 4
	...	...	...
	31-24	DBm[7-0]	Data Byte m
	23-16	DBm-1[7-0]	Data Byte m-1
Rn	15-8	DBm-2[7-0]	Data Byte m-2
	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_RXESC), between two and sixteen 32-bit words (Rn = 3-17) are used for storage of a CAN message's data field.

### 12.4.4.4.10.3 Tx Buffer Element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler makes difference between dedicated Tx Buffers and Tx FIFO/Tx Queue via the MCAN\_TXBC[29-24] TFQS and MCAN\_TXBC[21-16] NDTB fields. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via the MCAN\_TXESC register.

Figure 12-481 shows Tx Buffer element structure.

mcan-018

**Figure 12-481. Tx Buffer Element Structure**

Table 12-485 shows Tx Buffer element field descriptions.

**Table 12-485. Tx Buffer Element Field Descriptions**

Word	Bits	Field Name	Description
T0	31	ESI	<p>Error State Indicator</p> <ul style="list-style-type: none"> <li>0h = ESI bit in CAN FD format depends only on error passive flag</li> <li>1h = ESI bit in CAN FD format transmitted recessive</li> </ul> <p><b>Note:</b> The ESI bit of the transmit buffer is or'ed with the error passive flag to decide the value of the ESI bit in the transmitted CAN FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.</p>
	30	XTD	<p>Extended Identifier</p> <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>

	7-0	DBm-3[7-0]	Data Byte m-3

**Note:** Depending on the configuration of the element size (MCAN\_TXESC), between two and sixteen 32-bit words (Tn = 3-17) are used for storage of a CAN message's data field.

#### 12.4.4.4.10.4 Tx Event FIFO Element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from the MCAN\_TXEFS register.

Figure 12-482 shows Tx Event FIFO element structure.

**Figure 12-482. Tx Event FIFO Element Structure**

Table 12-486 shows Tx Event FIFO element field descriptions.

**Table 12-486. Tx Event FIFO Element Field Descriptions**

Word	Bits	Field Name	Description
E0	31	ESI	Error State Indicator <ul style="list-style-type: none"> <li>0h = Transmitting node is error active</li> <li>1h = Transmitting node is error passive</li> </ul>
	30	XTD	Extended Identifier <ul style="list-style-type: none"> <li>0h = 11-bit standard identifier</li> <li>1h = 29-bit extended identifier</li> </ul>
	29	RTR	Remote Transmission Request <ul style="list-style-type: none"> <li>0h = Data frame transmitted</li> <li>1h = Remote frame transmitted</li> </ul>
	28-0	ID[28-0]	Identifier <p>Standard or extended identifier depending on XTD bit. A standard identifier has to be written to ID[28-18].</p>

**Table 12-486. Tx Event FIFO Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
E1	31-24	MM[7-0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status (see also MM[7-0] field in <a href="#">Table 12-485</a> ).
	23-22	ET[1-0]	Event Type <ul style="list-style-type: none"> <li>0h = Reserved</li> <li>1h = Tx event</li> <li>2h = Transmission in spite of cancellation (always set for transmissions in DAR mode)</li> <li>3h = Reserved</li> </ul>
	21	FDF	FD Format <ul style="list-style-type: none"> <li>0h = Standard frame format</li> <li>1h = CAN FD frame format (new DLC-coding and CRC)</li> </ul>
	20	BRS	Bit Rate Switch <ul style="list-style-type: none"> <li>0h = Frame transmitted without bit rate switching</li> <li>1h = Frame transmitted with bit rate switching</li> </ul>
	19-16	DLC[3-0]	Data Length Code <ul style="list-style-type: none"> <li>0h-8h (0-8) = CAN + CAN FD: frame with 0-8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN: frame with 8 data bytes transmitted</li> <li>9h-Fh (9-15) = CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted</li> </ul>
	15-0	TXTS[15-0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler MCAN_TSCC[19-16] TCP field.

#### 12.4.4.4.10.5 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address MCAN\_SIDFC[15-2] FLSSA field plus the index of the filter element (0-127).

[Figure 12-483](#) shows Standard Message ID Filter element structure.

**Figure 12-483. Standard Message ID Filter Element Structure**

[Table 12-487](#) shows Standard Message ID Filter element field descriptions.

**Table 12-487. Standard Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
S0	31-30	SFT[1-0]	<p>Standard Filter Type</p> <ul style="list-style-type: none"> <li>0h = Range filter from SFID1 to SFID2 (SFID2 ≥ SFID1)</li> <li>1h = Dual ID filter for SFID1 or SFID2</li> <li>2h = Classic filter: SFID1 = filter; SFID2 = mask</li> <li>3h = Filter element disabled</li> </ul> <p><b>Note:</b> With SFT = 11 the filter element is disabled and the acceptance filtering continues (same behaviour as with SFEC = 000)</p>
	29-27	SFEC[2-0]	<p>Standard Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer , configuration of SFT[1-0] ignored</li> </ul>
	26-16	SFID1[10-0]	<p>Standard Filter ID 1</p> <p>When filtering for Rx Buffers this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.</p>
	15-11	RES	Reserved
		SFID2[10-0]	<p>Standard Filter ID 2</p> <p>This bit field has a different meaning depending on the configuration of SFEC:</p> <ul style="list-style-type: none"> <li>1) SFEC = 001 - 110 Second ID of standard ID filter element</li> <li>2) SFEC = 111 Filter for Rx Buffers</li> </ul>
	10-0	SFID2[10-9]	<p>This field is decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence.</p> <ul style="list-style-type: none"> <li>0h = Store message into an Rx Buffer</li> <li>1h = Debug Message A</li> <li>2h = Debug Message B</li> <li>3h = Debug Message C</li> </ul> <p><b>Note:</b> Debug feature is not supported.</p>
		SFID2[8-6]	<p>This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches.</p> <p><b>Note:</b> Only three filter event pins are supported.</p>
		SFID2[5-0]	<p>This field defines the offset to the Rx Buffer Start Address</p>

#### 12.4.4.4.10.6 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address MCAN\_XIDFC[15-2] FLESA field plus two times the index of the filter element (0-63).

Figure 12-484 shows Extended Message ID Filter element structure.

**Figure 12-484. Extended Message ID Filter Element Structure**

Table 12-488 shows Extended Message ID Filter element field descriptions.

**Table 12-488. Extended Message ID Filter Element Field Descriptions**

Word	Bits	Field Name	Description
F0	31-29	EFEC[2-0]	<p>Extended Filter Element Configuration</p> <p>All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = 100, 101, or 110 a match sets interrupt flag MCAN_IR[8]HPM and, if enabled, an interrupt is generated. In this case the MCAN_HPMS register is updated with the status of the priority match.</p> <ul style="list-style-type: none"> <li>0h = Disable filter element</li> <li>1h = Store in Rx FIFO 0 if filter matches</li> <li>2h = Store in Rx FIFO 1 if filter matches</li> <li>3h = Reject ID if filter matches</li> <li>4h = Set priority if filter matches</li> <li>5h = Set priority and store in FIFO 0 if filter matches</li> <li>6h = Set priority and store in FIFO 1 if filter matches</li> <li>7h = Store into Rx Buffer or as debug message, configuration of EFT[1-0] ignored</li> </ul>
	28-0	EFID1[28-0]	<p>Extended Filter ID 1</p> <p>First ID of extended ID filter element.</p> <p>When filtering for Rx Buffers this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see <a href="#">Section 12.4.4.4.7.1.5, Extended Message ID Filtering</a>) is used.</p>

**Table 12-488. Extended Message ID Filter Element Field Descriptions (continued)**

Word	Bits	Field Name	Description
F1	31-30	EFT[1-0]	Extended Filter Type <ul style="list-style-type: none"> <li>0h = Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1)</li> <li>1h = Dual ID filter for EFID1 or EFID2</li> <li>2h = Classic filter: EFID1 = filter, EFID2 = mask</li> <li>3h = Range filter from EFID1 to EFID2 (EFID2 ≥ EFID1), XIDAM mask not applied</li> </ul>
	29	RES	Reserved
		EFID2[28-0]	Extended Filter ID 2 This bit field has a different meaning depending on the configuration of EFEC: <ul style="list-style-type: none"> <li>1) EFEC = 001 - 110 Second ID of extended ID filter element</li> <li>2) EFEC = 111 Filter for Rx Buffers</li> </ul>
	28-0	EFID2[10-9]	This field decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. <ul style="list-style-type: none"> <li>0h = Store message into an Rx Buffer</li> <li>1h = Debug Message A</li> <li>2h = Debug Message B</li> <li>3h = Debug Message C</li> </ul> <b>Note:</b> Debug feature is not supported.
		EFID2[8-6]	This field is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one MCAN_ICKL period in case the filter matches. <b>Note:</b> Only three filter event pins are supported.
		EFID2[5-0]	This field defines the offset to the Rx Buffer Start Address MCAN_RXBC[15-2] RBSA field for storage of a matching message.

## 12.5 Audio Interfaces

## 12.5.1 Audio Tracking Logic (ATL)

This chapter describes the integration of the Audio Tracking Logic (ATL) subsystem in the device.

### 12.5.1.1 ATL Overview

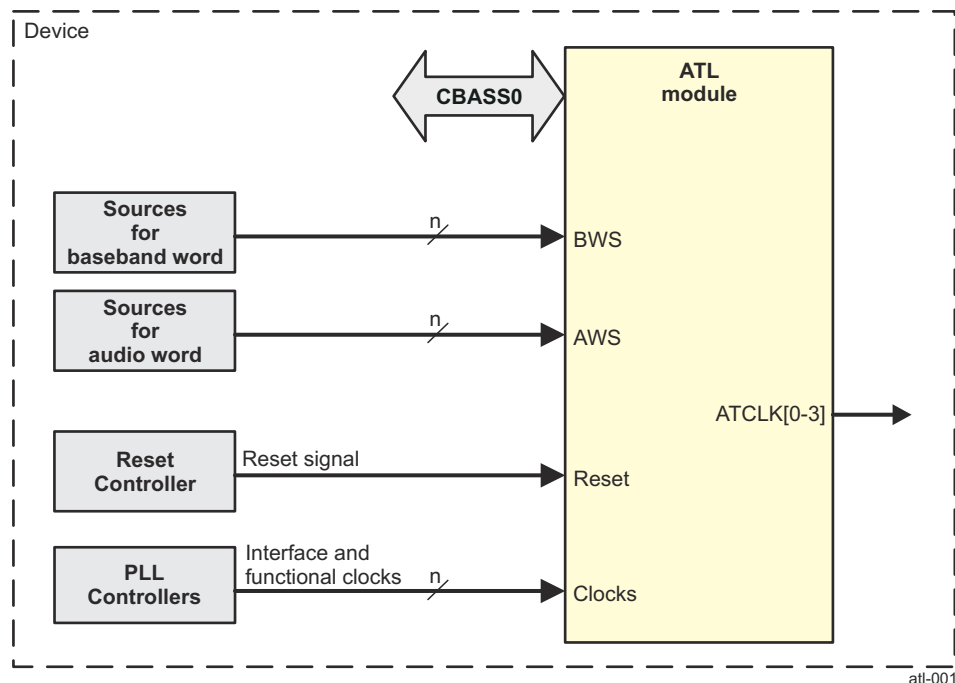

The Audio Tracking Logic (ATL) is used by HD Radio™ applications to synchronize the digital audio output to the baseband clock. This same IP can also be used generically to track errors between two reference signals (such as frame syncs) and generate a modulated clock output (using software-controlled cycle stealing) which averages to some desired frequency. This process can be used as a hardware assist for asynchronous sample rate conversion algorithms.

Table 12-489 shows ATL module allocation across device domains.

**Table 12-489. ATL Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
ATL	-	-	✓

Figure 12-485 shows the ATL module overview.

**Figure 12-485. ATL Module Overview**

#### 12.5.1.1.1 ATL Features Overview

The ATL module supports the following features:

- One ATL module, containing four ATL instances, for HD Radio support and asynchronous sample rate conversion assistance
- Each instance tracks the time error between two syncs (local audio word select [AWS] and baseband word select [BWS])
- Each instance selects between 28 mux choices for BWS and 30 mux choices for AWS.
- Each instance generates modulated ATCLK clock signals with software-initiated pulse stealing.

The intention is to use these clocks to derive audio output bit clock on MCASP

- Selection between ATL\_VCLK clock or functional ATL\_PCLK to run error counting timers and to derive modulated ATCLK clock outputs.
- Clock and reset management: Receives clock and reset signals from the device PSC module. The ATL module receives hardware reset.
- Power management: The ATL belongs to the PD0 power domain.
- Local software reset

#### **12.5.1.1.2 ATL Not Supported Features**

The ATL module not supports the following features:

- Smart ATL\_CLK\_STOP
- ATL\_MOD\_OUT[3-0] clock outputs

## 12.5.2 Multichannel Audio Serial Port (MCASP)

This section describes the Multichannel Audio Serial Port (MCASP).

### 12.5.2.1 MCASP Overview

This section introduces the Multichannel Audio Serial Port (MCASP) module and describes its main functions and connections in the device.

The MCASP functions as a general-purpose audio serial port are optimized to the requirements of various audio applications. The MCASP module can operate in both transmit and receive modes. The MCASP is useful for time-division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an inter-component digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component.

Although inter-component digital audio interface reception (DIR) mode (this is, S/PDIF stream receiving) is not natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

shows MCASP modules allocation across device domains.

[Figure 12-486](#) shows the MCASP modules overview.

**Figure 12-486. MCASP Modules Overview**

#### 12.5.2.1.1 MCASP Features

Each MCASP module includes the following main features:

- Independent serializer for each AXRx channel of each MCASP module
- Clock stop request/acknowledge protocol
- A single 32-bit buffer per serializer for transmit and receive operations
- Interconnect interface port for CBASS0
- Two independent clock generator modules for transmit and receive (clocking flexibility allows the MCASP to receive and transmit at different rates. For example, the MCASP can receive data at 48 kHz, but output up-sampled data at 96 kHz or 192 kHz)
- Each MCASP module functional clock can be generated:
  - Internally (master mode)
  - Supplied over MCASP serial interface (slave mode)
  - Has a controllable functional clock divide ratio
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator
  - TDM streams from 2 to 32, and 384 time slots
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits
  - Data formatter for bit manipulation
- Glueless connection to audio Analog-to-Digital Converters (ADC), Digital-to-Analog Converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components
- Wide variety of I2S and similar bit-stream format
- Integrated digital audio interface transmitter (DIT):
  - S/PDIF, IEC60958-1, AES-3 formats
  - Enhanced channel status/user data RAM
- 384-slot TDM with external digital audio interface receiver (DIR) device
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the MCASP receive section
- Support for 2 × DMA requests (one per direction):
  - 1 level-sensitive transmit direct memory access (DMA) request common for all of the MCASP serializers
  - 1 level-sensitive receive direct memory access (DMA) request common for all of the MCASP serializers
  - All transmit DMA requests are mapped to the device DMA controllers
- One transmit interrupt request common for all serializers

- One receive interrupt request common for all serializers
- Each of the Rx and Tx interrupts is propagated to different host processors via the device Interrupts

---

**Note**

Because a serializer receive and transmit channels data is shared on the same MCASP data pin, user can choose to have either Tx or Rx function from a serializer, not both at the same time.

---

**12.5.2.1.2 MCASP Not Supported Features**

Each MCASP module does not support the following features:

- Muting output (AMUTE)
- Muting input (AMUTEIN)

### 12.5.2.2 MCASP Environment

This section describes the MCASP application fields from an environment point of view (external connections). This section also lists the possible interfaces and describes the protocol and data format used in each case.

#### 12.5.2.2.1 MCASP Signals

Figure 12-487 shows all of the MCASP interface signals.

**Figure 12-487. MCASP Interface Signals**

Table 12-490 describes the MCASP I/O signals.

**Table 12-490. MCASP I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCASP0 module</b>				
AXR0	MCASP0_AXR0	I/O	Audio transmit/receive data - channel 0	HiZ

ACLKX	MCASP2_ACLKX	I/O	Transmit bit clock	HiZ
AFSX	MCASP2_AFSX	I/O	Transmit frame synchronization	HiZ
ACLKR	MCASP2_ACLKR	I/O	Receive bit clock	HiZ
AFSR	MCASP2_AFSR	I/O	Receive frame synchronization	HiZ
MCASP2_AHCLKX_I/O	AUDIO_EXT_REFCLK[0-1]	I/O	Transmit high-frequency master clock. See <a href="#">Figure 12-496</a>	HiZ
MCASP2_AHCLKR_I/O	AUDIO_EXT_REFCLK[0-1]	I/O	Receive high-frequency master clock. See <a href="#">Figure 12-496</a>	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

(2) HiZ = High Impedance

#### Note

signals are multiplexed to AUDIO\_EXT\_REFCLK[0-1] device pins.

#### Note

For signals to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### Note

A serializer AXR data pin is shared between the transmit and receive logic of that serializer. The direction of data is determined in the MCASP\_PDIR register and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP\_SRCTLn (n = 0 to 15).

### 12.5.2.2.2 MCASP Protocols and Data Formats

#### 12.5.2.2.2.1 Protocols Supported

The MCASP supports a wide variety of protocols:

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats
  - TDM streams from 2 to 32 time slots
  - S/PDIF, IEC60958-1, AES-3 formats
- Receive section supports:

- Wide variety of I2S and similar bit-stream formats
- TDM streams from 2 to 32 time slots
- TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to MCASP using the I2S protocol (one time slot for each DIR subframe)

The transmit and receive sections of the module may be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AFSSR/X and AHCLKR/X\_I/O
- Slot length (number of bits per time slot): 2, 4, 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 2, 4, 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0, 1, 2 bit clocks
- Left/right alignment of word inside slot
- Bit order: MSB first or LSB first
- Bit mask/pad/rotate function
  - Automatically aligns data internally in either Q31 or integer formats
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

---

#### Note

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

---

In DIT mode for MCASP, additional features of the transmitters are:

- Transmit-only mode 384 time slots (subframe) per frame
- Biphase encoded 3.3 V Output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Support for consumer and professional applications
- Separate valid bit (V) for subframe A, B
- Stereo Support Only (Mono means send data 2 × via software)

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

---

#### Note

The MCASP does NOT natively support DIR-mode reception (this is, receiving in the S/PDIF format). To allow this, the MCASP can use a DIR-input to I2S-output converter implemented by an external device (this is, external DIR component). To facilitate reception in this case, the TDM mode of MCASP receivers logic is extended to support a non-standard 384-slot TDM stream.

---

---

#### Note

An external transceiver must be connected to the MCASP port in the device to translate the electrical signals delivered by the MCASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

---

#### 12.5.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a MCASP serializer is a long sequence of 1s and 0s on an audio transmit/receive pins AXRn. However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 12-488](#) shows two of the three basic components: the clock signal (ACLKX/ACLKR) and the data signals AXRn. [Figure 12-488](#) does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the MCASP are configured to operate synchronously.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.

- Word:

A word is a group of bits that make up the data being transferred between the MCASP and the external device. [Figure 12-488](#) shows an 8-bit word.

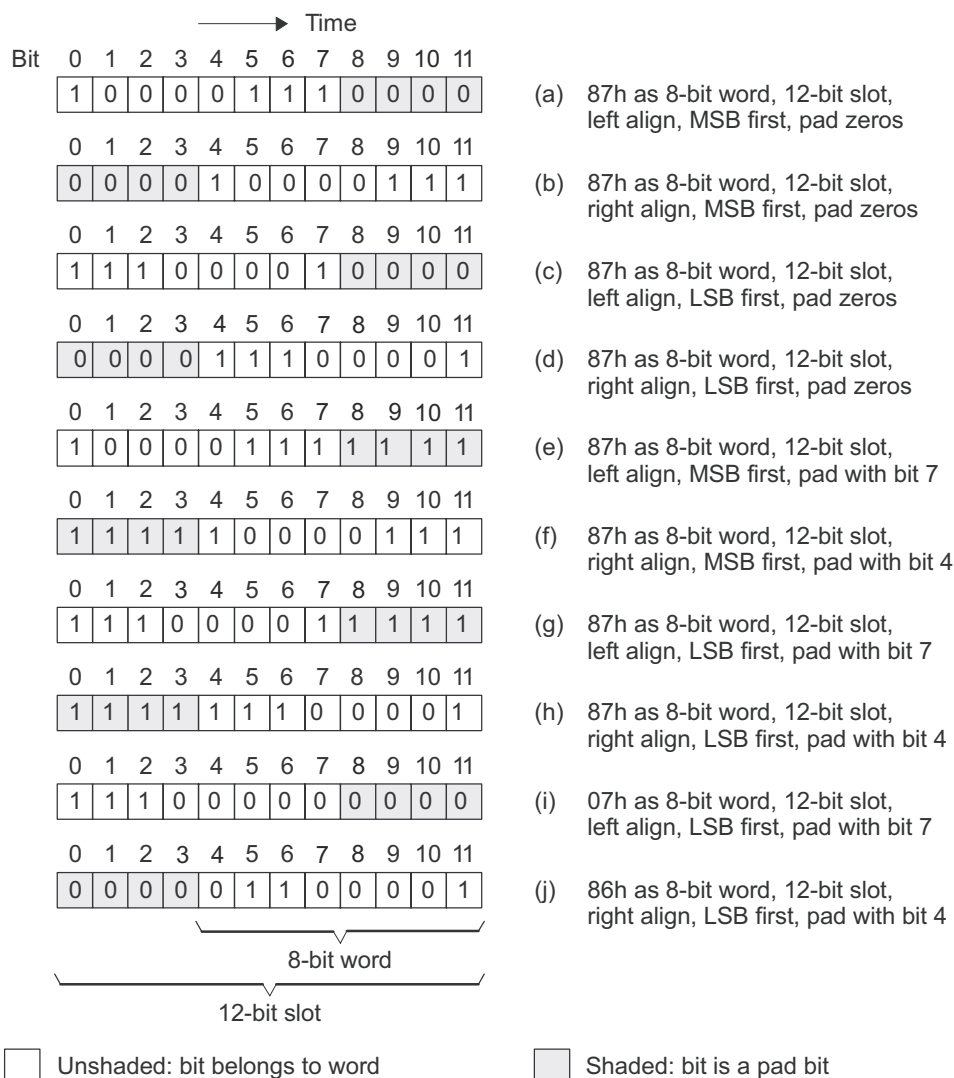

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the MCASP and the external device. In [Figure 12-488](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the MCASP on an AXRn pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, this is, left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. [Figure 12-489](#) shows these options.

**Figure 12-488. Definition of Bit, Word, and Slot**

**Figure 12-489. Bit Order and Word Alignment Within a Slot Examples**

- Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 12-490](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses AFSX, and the receiver - AFSR signal. [Figure 12-490](#) does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter/receiver uses AFSX/AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the MCASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see [Section 12.5.2.2.2.3, TDM Format](#) and [Section 12.5.2.2.2.5, S/PDIF-Coding Format](#).

### Note

All of the MCASP serializers share the same, device pad accessible, clock and frame signals, as follows:

- AHCLKX\_I/O, ACLKX and AFSX for the transmitting section
- AHCLKR\_I/O, ACLKR and AFSR for the receiving section

**Figure 12-490. Definition of Frame and Frame-Sync Width**

The following terms are used throughout this chapter:

- TDM: Time-division multiplexed. See [Section 12.5.2.2.2.3, TDM Format](#) for details on the TDM protocol.
- I2S: Inter-Integrated Sound protocol, commonly used on audio interfaces. The MCASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
- DIT: Digital audio interface transmit. The MCASP supports transmitting in S/PDIF format on each AXRn data pin.
- DIR: Digital audio interface receive. The MCASP does NOT natively support receiving in S/PDIF format on AXRn data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT/DIR format, a MCASP time slot corresponds to a DIT/DIR subframe.

#### 12.5.2.2.2.3 TDM Format

The TDM format is used to transfer data between the host CPU and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one MCASP data pin - AXRn is illustrated on [Figure 12-491](#).

- (1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported
- (2) - Slot 0 of AXRn stream is being offset with 0-, 1-, and 2- clock cycle delay from the frame sync, respectively.

mcasp-006

**Figure 12-491. TDM Format - 6 channel example**

The TDM format uses three signals in a basic synchronous serial interface: data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also [Section 12.5.2.2.2](#)), the latter being also referred to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For MCASP, there is an option to offset the first bit of the first slot with a 0-, 1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does not determine the boundaries of a slot, there is a requirement for a connected transmitter and receiver to agree on the number of transferred bits per slot.

In a typical audio system involving MCASP module, a single TDM data frame is transferred during each sample period  $T_s$  of a data converter. The user has following choices to implement multiple channels:

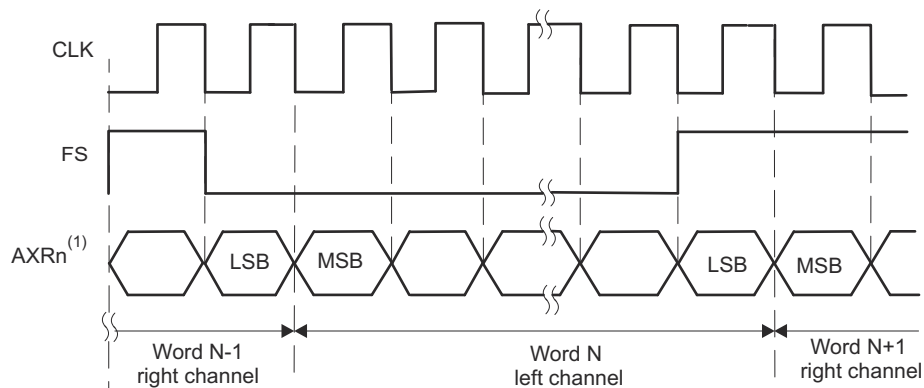

- Use more data slots (on a price of higher speed serial clock) per frame transmitted/received on just one of the available MCASP data pins AXRn.
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the MCASP pins AXRn.

#### 12.5.2.2.4 I2S Format

The TDM transfer mode of the MCASP supports the I2S format when frame is configured to have 2 slots. The I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. The "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on [Figure 12-492](#).

(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-007

**Figure 12-492. I2S Format Overview**

#### 12.5.2.2.2.5 S/PDIF Coding Format

The MCASP transmitter supports the S/PDIF format with 3.3 V biphase-mark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the MCASP. This section briefly discusses the S/PDIF coding format.

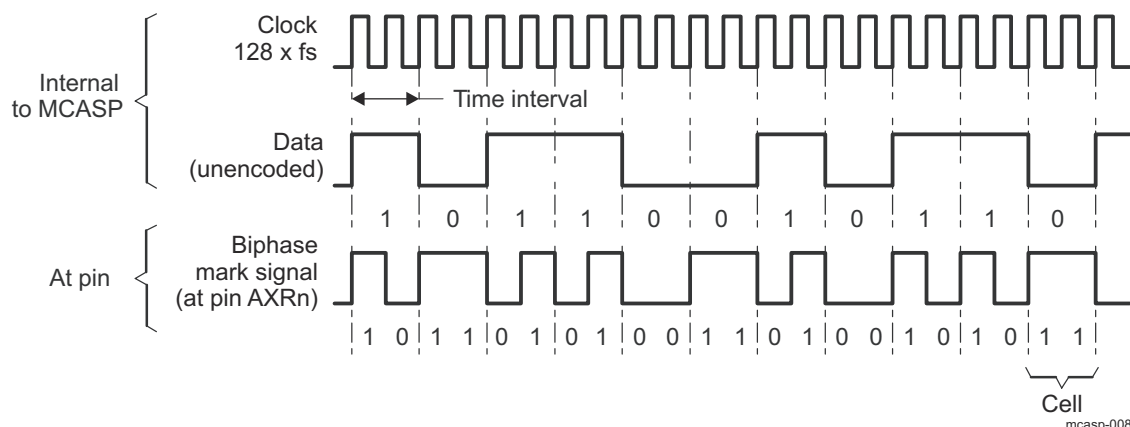

#### Note

The DIR- reception of S/PDIF format frames is NOT natively supported from the device MCASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the MCASP TDM-only compatible receiver input.

#### 12.5.2.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter  $n$ , the clock, frame, and data are embedded in only one signal - the data signal AXR $n$ . In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 12-493](#) and [Table 12-491](#) show how data is encoded to the BMC format.

As shown in [Figure 12-493](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see [Section 12.5.2.2.2.5.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

**Figure 12-493. Biphase-Mark Code**

**Table 12-491. Biphase-Mark Encoder**

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

#### 12.5.2.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. [Figure 12-494](#) shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 12-492](#).
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in [Table 12-492](#), the preambles (time intervals 0–3) are also defined with even parity.

**Figure 12-494. S/PDIF Subframe Format**

As listed in [Table 12-492](#), the MCASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the MCASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

**Table 12-492. Preamble Codes**

Preamble Code <sup>(1)</sup>	Previous Logical State	Logical States on pin AXRn <sup>(2)</sup>	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

- (1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.
- (2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

#### 12.5.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 12-495](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32$  cells per subframe  $\times 2$  clocks per cell  $\times 2$  subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is  $128 \times 192$  kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

**Figure 12-495. S/PDIF Frame Format**

### 12.5.2.3 MCASP Integration

This section describes MCASP integration in the device, including information about clocks, resets, and hardware requests.

#### 12.5.2.3.1 MCASP Integration in MAIN Domain

There are MCASP modules integrated in the device MAIN domain - . [Figure 12-496](#) shows the integration of MCASP[0-].

**Figure 12-496. MCASP Integration**

[Table 12-493](#) through [Table 12-495](#) summarize the integration of MCASP[0-] in the device MAIN domain.

**Table 12-493. MCASP Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCASP0	PSC0	PD0	LPSC3	CBASS0
MCASP1	PSC0	PD0	LPSC3	CBASS0
MCASP2	PSC0	PD0	LPSC3	CBASS0

**Table 12-494. MCASP Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCASPi	MCASPi_ICLK	MAIN_SYSCLK0/2	PLLCTRL0	MCASPi interface clock
	MCASPi_AUX_CLK	MAIN_PLL4_HSDIV0_CLKOUT	PLL4	MCASPi functional clock (Master Mode). Output of multiplexer, see <i>MCASP Integration</i> . <sup>(1)</sup>
		MAIN_PLL2_HSDIV2_CLKOUT	PLL2	
		ATCLK0	ATL	
		ATCLK1	ATL	
		ATCLK2	ATL	
		ATCLK3	ATL	
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MCASPi	MCASPi_RST	MOD_G_RST	LPSC3	MCASPi reset

(1) Multiplexers control is provided via CTRLMMR\_MCASPi\_CLKSEL[2-0] AUXCLK\_SEL bit-field for module MCASPi (). For more information, see *Control Module (CTRL\_MMR)* of the chapter *Device Configuration*.

### 12.5.2.4 MCASP Functional Description

In the text throughout this section a single instance of MCASP is described assuming that all modules are functionally identical. For module availability and integration differences, see *MCASP Environment* and *MCASP Integration*.

#### 12.5.2.4.1 MCASP Block Diagram

Figure 12-497 shows the major blocks of the MCASP module.

mcasp-012

A. i represents a valid instance of MCASP in a domain. See the device datasheet for valid instances.

- B. All signals might not be valid for an instance. See the device datasheet for specifics.

**Figure 12-497. MCASP Module Block Diagram**

### Note

The internal and external clocks mentioned in this section are with respect to clock and frame-sync generator modules.

#### 12.5.2.4.2 MCASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the MCASP serializers. The first three scenarios are identical between the Tx and Rx part of the MCASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx/Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part and pin ACLKR for the Rx part, respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- /Tx- high-speed clock logic is bypassed for the XCLK/RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) pin, which is configured as input. In this case the AHCLKX clock frequency can be divided down via programming the ACLKX associated divider to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for MCASP receivers - RCLK is derived from the bit rate clock of the MCASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

##### 12.5.2.4.2.1 MCASP Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP\_ACLKXCTL
- MCASP\_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP\_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP\_ACLKXCTL[4-0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in [Section 12.5.2.4.2](#), the MCASP\_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP\_AHCLKXCTL[11-0] HCLKXDIV bit field) from the MCASP internal clock source AUXCLK.

Internally, the MCASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see [Figure 12-498](#)). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP\_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the

MCASP shifts transmit data at the rising edge of ACLKX. If MCASP\_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the MCASP shifts transmit data at the falling edge of ACLKX.

It can be seen in [Figure 12-498](#) that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between MCASP transmitters and receivers. This is used for example in the MCASP loopback mode.

#### Note

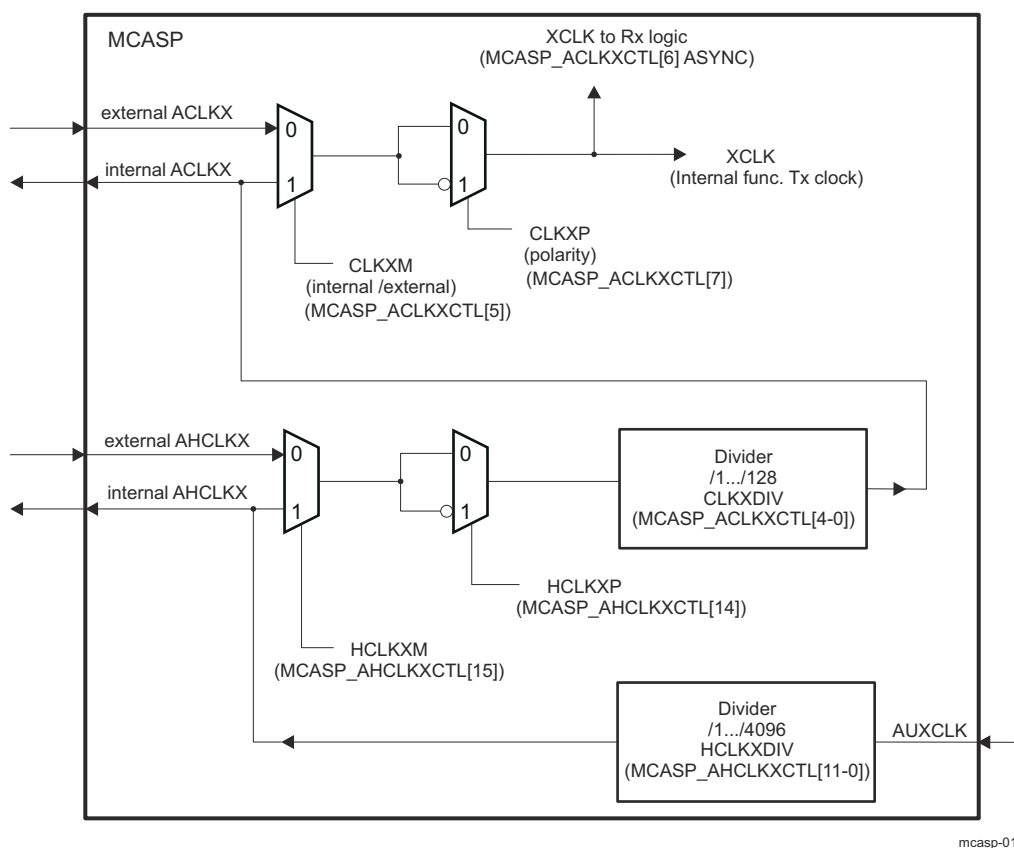

The polarity of ACLKX can be controlled in the MCASP\_ACLKXCTL[7] CLKXP bit, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP\_AHCLKXCTL[14] HCLKXP bit.

#### Note

In a similar way, the polarity of AHCLKX clock can be controlled in the MCASP\_AHCLKXCTL[14] HCLKXP bit, regardless of the AHCLKX signal being internally or externally sourced.

[Figure 12-498](#) presents the block diagram of the transmit clock generator.

**Figure 12-498. Transmit Clock Generator Block Diagram**

---

### Note

In this device:

- ACLKX is mapped on the device ball ACLKX
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKX is mapped on MCASPi\_AHCLKX clock from the Device Configuration

For more information about MCASP integration, see *MCASP Environment* and *MCASP Integration*.

---

#### 12.5.2.4.2.2 MCASP Receive Clock

The MCASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP\_ACLKRCTL
- MCASP\_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP\_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP\_ACLKRCTL[4-0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is, first scenario described in [Section 12.5.2.4.2](#)) and the MCASP\_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP\_AHCLKRCTL[11-0] HCLKRDIV bit field) from the MCASP internal clock source AUXCLK.

---

### Note

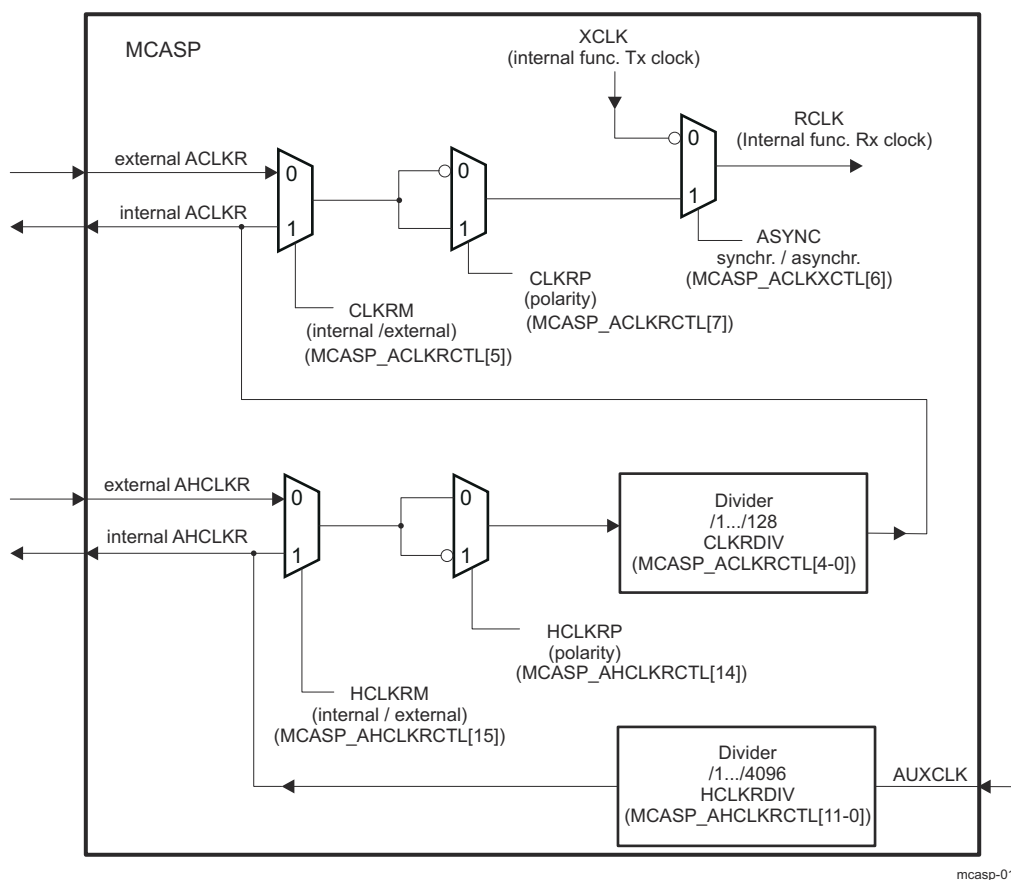

The polarity of ACLKR can be controlled in the MCASP\_ACLKRCTL[7] CLKRP bit, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in the MCASP\_AHCLKRCTL[14] HCLKRP bit, regardless of the AHCLKR signal being internally or externally sourced.

---

There is an option for the MCASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see [Figure 12-498](#) and [Figure 12-499](#)) becomes source of the receive clock (RCLK output), when the MCASP\_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to [Section 12.5.2.4.2.4](#).

[Figure 12-499](#) presents the block diagram of the receive clock generator.

**Figure 12-499. Receive Clock Generator Block Diagram**

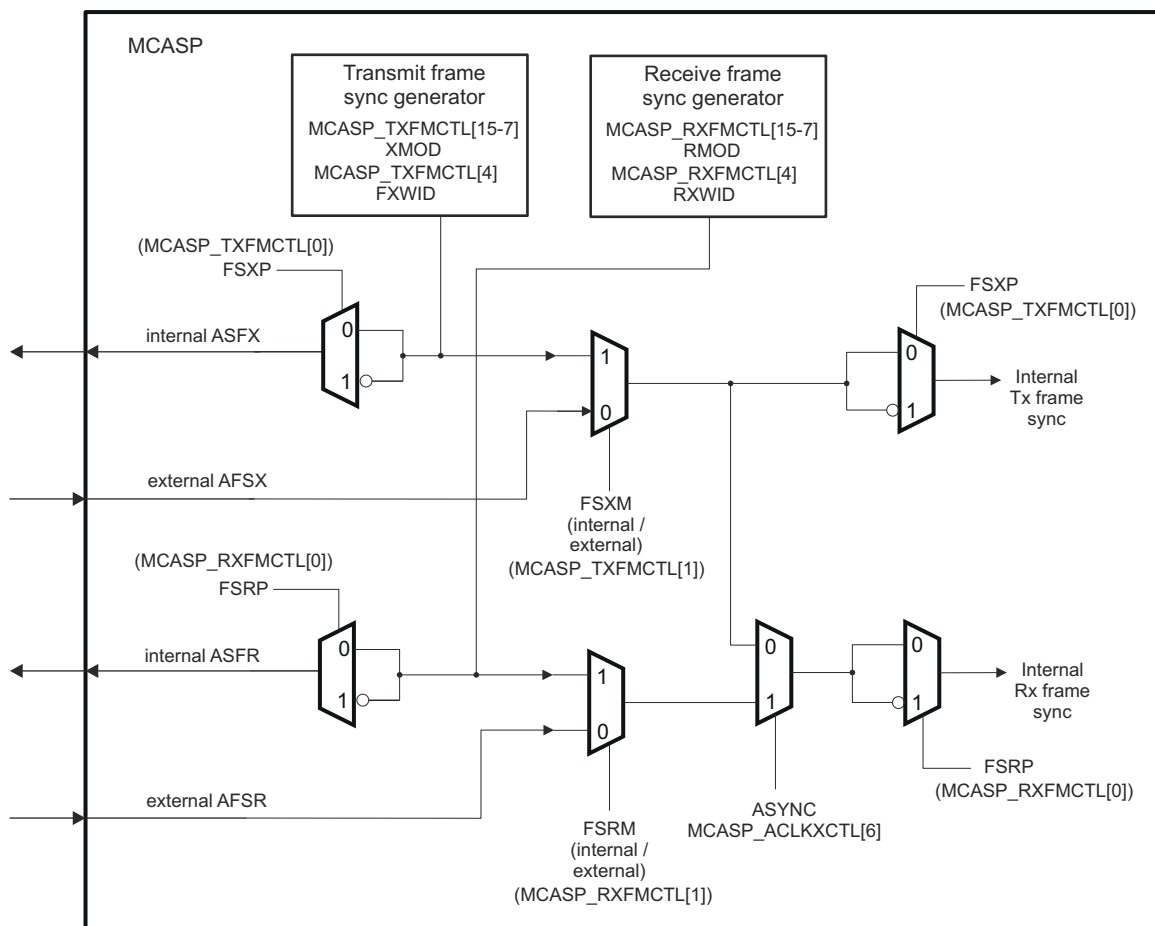

### Note

In this device:

- ACLKR is mapped on the device ball ACLKR
- internal AHCLKX is mapped on the device balls AUDIO\_EXT\_REFCLK[0-1]
- external AHCLKR is mapped on Device Configuration MCASPi\_AHCLKR from Device Configuration

#### 12.5.2.4.2.3 Frame-Sync Generator

There are two different modes for frame sync: burst and TDM. The MCASP frame sync generator logic is illustrated in [Figure 12-500](#). The I/O buffers are not part of the MCASP module, and are not shown in the figure.

mcasep-015

**Figure 12-500. Frame Sync Generator Block Diagram**

**For the transmit logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSXCTL[1] FSXM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSXCTL[0] FSXP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSXCTL[4] FXWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSXCTL[15-7] XMOD bit field, as follows:
  - For DIT mode (384 slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSXCTL[15-7] XMOD bit field set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP\_XFMT[17-16] XDADLY bit field

**For the receive logic**, following frame-sync generator configurations can be selected:

- Internally/externally generated frame-sync via configuring MCASP\_AFSRCTL[1] FSRM bit
- Frame-sync polarity: Rising edge or falling edge via configuring MCASP\_AFSRCTL[0] FSRP bit
- Frame-sync width: "single bit" or "single word" via configuring MCASP\_AFSRCTL[4] FRWID bit
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the MCASP\_AFSRCTL[15-7] RMOD bit field, as follows:
  - For I2S mode (2 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP\_AFSRCTL[15-7] RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - MCASP\_AFSRCTL[15-7] RMOD = 0x180

- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in the MCASP\_RFMT[17-16] RDATA bit field
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP\_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to [Section 12.5.2.4.2.4, Synchronous and Asynchronous Transmit and Receive Operations](#).

Regardless of the AFSX/AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

#### Note

Certain restrictions apply to the receive and transmit logic settings, when the MCASP\_ACLKXCTL[6] ASYNC bit is set to 0b0. They are described in [Section 12.5.2.4.2.4](#).

#### 12.5.2.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

##### Synchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC bit is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format, it has to be configured to have the same slot size than the transmit section one. As shown on the [Figure 12-499](#), with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When the MCASP\_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP\_DITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ \* RMOD product value must equal XSSZ \* XMOD product value)
- The settings in the MCASP\_ACLKRCTL register are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

##### Asynchronous Transmit and Receive Operations -

When the MCASP\_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

#### Note

Synchronous transmit and receive operations are allowed only in the MCASP TDM (I2S) mode (this is, when MCASP\_DITCTL[0] DITEN = 0b0).

#### 12.5.2.4.3 MCASP Frame Sync Feedback for Cross Synchronization

The device level requirement is to align frame syncs across McASP that may be feeding DACs with different formats but the same frequency.

The intent of is to provide a mechanism to check for the alignment of frame syncs. This works by feeding the frame sync of McASP into the a receive data pin of McASP. If this serializer is enabled as a receiver, then the frame sync of McASP will appear as receive data for McASP.

To adjust the McASP transmit bit clock, the MCASP\_ACLKXCTL[17-16] CLKXADJ register bit field can be used to lengthen (write 0x2) or reduce (write 0x1) the McASP bit clock period in a one-shot fashion. After each adjustment the frame sync should be checked again and the process repeated until the two frame syncs are aligned.

This process is expected to be carried out once, before any audio transfers occur. It is not intended to be used for sample rate conversion but rather initial phase alignment of transmit data across MCASP.

#### 12.5.2.4.4 MCASP Serializers

The MCASP serializers shift serial data in (Rx) and out (Tx) of the MCASP. A given serializer  $n$  consists of a shift register (XRSR $n$ ) with a single-entry data buffer XRBUFF $n$  used either for transmitting (write accessible in the MCASP\_XBUFF $n$  register) or for receiving (read accessible in the MCASP\_RBUFF $n$  register) data. In addition, each serializer has a dedicated control register (MCASP\_SRCTL $n$ ) and a serial bidirectional data pin - AXR $n$ . The register MCASP\_SRCTL $n$  allows  $n$ -th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the MCASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSR $n$  shifter configured as a receiver in the MCASP\_SRCTL $n$  register, shifts in data through MCASP corresponding device level bidirectional data pad AXR $n$ . A given serializer XRSR $n$  shifter configured as a transmitter in the MCASP\_SRCTL $n$  register, shifts out data on MCASP corresponding device level bidirectional data pad AXR $n$  ( $n = 0$  to  $15$ ).

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for MCASP there are at most a couple of zones, one for transmit and one for receive.

Figure 12-501 shows the serializer block diagram.

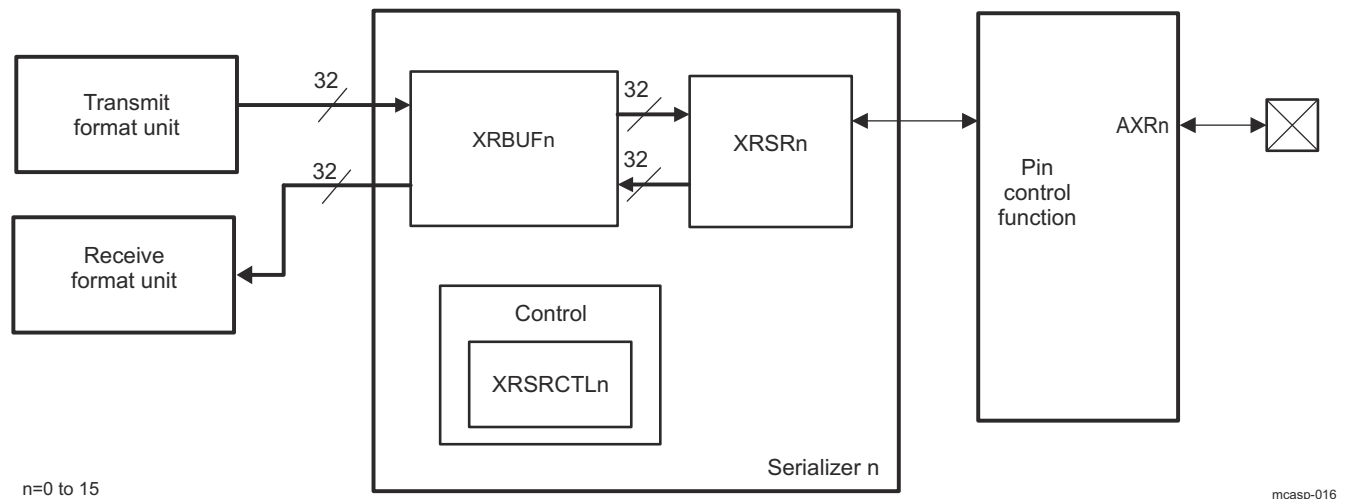

Figure 12-501. Individual Serializer and Connections Within MCASP

#### Transmission on the $n$ -th serializer is performed as follows:

The MCASP is serviced by writing data into the MCASP\_XBUFF $n$  register, which is an alias of the serializer data buffer - XRBUFF $n$  for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFF $n$  register in the serializer. The data is then copied from the XRBUFF $n$  to XRSR $n$  and shifted out from AXR $n$  synchronously to the serial clock.

#### Reception from the $n$ -th serializer is performed as follows:

The data is shifted into the MCASP XRSR $n$  serializer register through the AXR $n$  pin, bit by bit. Once the entire slot becomes available within the XRSR $n$  shift register, the data is copied into the serializer data buffer - XRBUFF $n$ , and can be accessed in the MCASP\_RBUFF $n$  register, which is an alias of the serializer data buffer - XRBUFF $n$  for receive function. When software reads the data from this register, the MCASP passes the data through the receive format unit, hence it returns the formatted data.

#### Serializer controls:

A serializer  $n$  is configured as inactive via setting MCASP\_SRCTL $n$ [1-0] SRMOD bit field to 0x0.

For a transmitting serializer, the MCASP\_SRCTL $n$ [3-2] DISMOD bitfield, defines the AXR $n$  pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the  $n$ -th serializer is selected via setting MCASP\_SRCTL $n$ [1-0] SRMOD bit field to 0x1.

Receive function for the  $n$ -th serializer is selected via setting MCASP\_SRCTL $n$ [1-0] SRMOD bit field to 0x2 ( $n = 0$  to 15).

In the DIT-transmission mode (that is S/PDIF format data transmission): in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see *S/PDIF Coding Format*.

#### 12.5.2.4.5 MCASP Format Units

The MCASP has one transmit data formatting unit and one receive data formatting unit, shared between the device MCASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the device processors (for example, a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the MCASP only supports one transmit format at a time. For example, the MCASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the MCASP only supports one data format at a time, and this format applies to all receiving serializers.

#### Note

The MCASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP\_RFMT/MCASP\_XFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the MCASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY/XDATDLY bits in the MCASP\_RFMT/MCASP\_XFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY/XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in the MCASP\_RFMT/MCASP\_XFMT register means that the MCASP supports a wide variety of data formats, both on the serial data lines, and in the device CPU data representation.

##### 12.5.2.4.5.1 Transmit Format Unit

The MCASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 12-502 shows the transmit formatting unit.

The MCASP transmitter supports serial formats of:

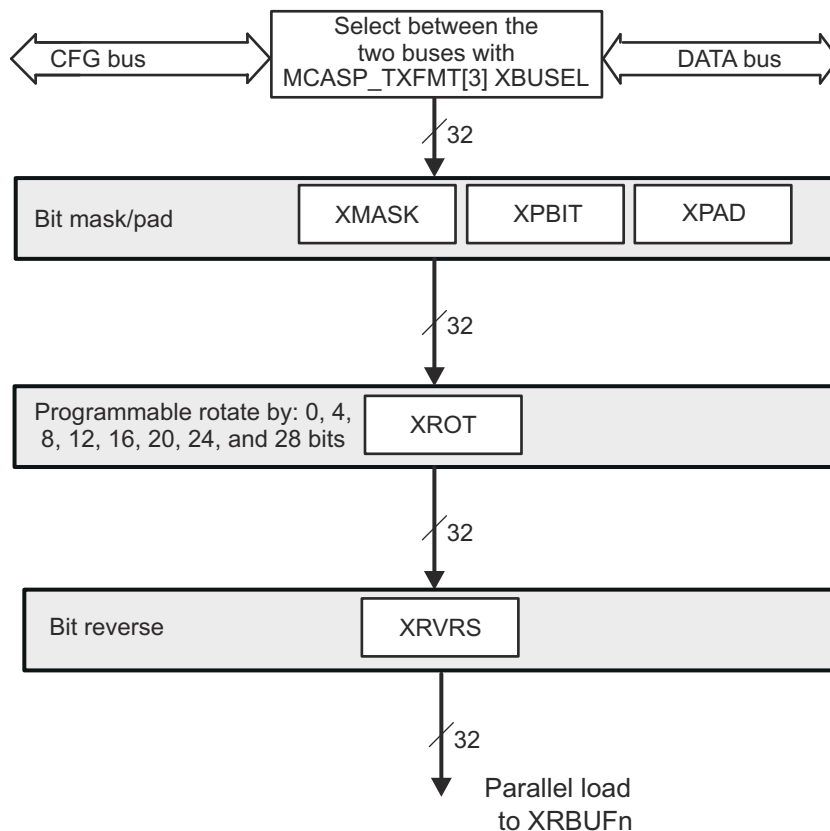

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size  $\leq$  Slot size

- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register

- MCASP\_XFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits

mcasp-017

**Figure 12-502. Transmit Format Unit**

As shown in [Figure 12-502](#), the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_XFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.4.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.4.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP\_XMASK[31-0] XMASK contents. The masked data is then right-rotated to the MCASP\_XFMT[2-0] XROT bit field positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

### 12.5.2.4.5.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots. XSSZ should always be programmed to match the slot size of the serial stream.

#### Note

Note that, TDM word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the XROT field.

The [Table 12-496](#) show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The [Table 12-496](#) assumes that all slot size (SLOT in [Table 12-496](#)) and word size (WORD in [Table 12-496](#)) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter (typically Q31 or integer).

**Table 12-496. MCASP TFU TDM Mode Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_XFMT bits	
			XROT <sup>(1)</sup>	XRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first <sup>(2)</sup>	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

### 12.5.2.4.5.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP\_XFMT[17-16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP\_XFMT[2-0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP\_XMASK[32] XMASK = 0xFFFFFFFF00 – 0xFFFF0000
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP\_XFMT[2-0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP\_XFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP\_XMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF
- MCASP\_XFMT[14-13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 12-497](#) should be applied to MCASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the MCASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 CPU data:

**Table 12-497. MCASP TFU DIT-Mode Example Settings**

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFF000	0x3
LEFT	24	8	0xFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated on the MCASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the [Table 12-497](#), the user must set XMASK = 0xFFFF000, and to select a right-rotation to 12 positions (XROT = 0x3).

- After applying 0-s (XPAD = 0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is: 0x000FA5AF. Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by software on the MCASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table MCASP TFU Example Settings, user is supposed to set XMASK = 0x0000FFFF, and to select right-rotation to 0 positions (XROT = 0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

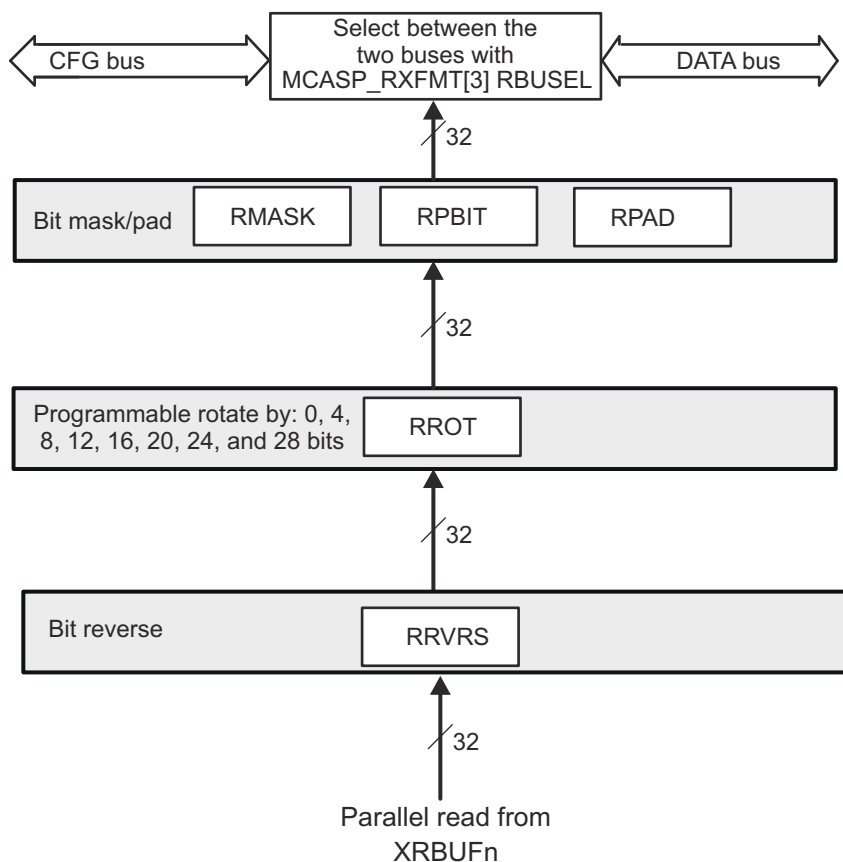

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 12.5.2.4.5.2 Receive Format Unit

The MCASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

[Figure 12-503](#) shows the receive format unit (RFU).

mcasp-018

**Figure 12-503. Receive Format Unit**

The MCASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP\_RFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on [Figure 12-503](#), the data processed in the RFU can be output to host CPU through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP\_RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the [Section 12.5.2.4.11.1.3, Transfers Through the DATA Port](#), and [Section 12.5.2.4.11.1.4, Transfers Through the Configuration \(CFG\) Bus](#).

#### 12.5.2.4.5.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream.

### Note

Note that the word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the RROT field.

Table 12-498 shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

**Table 12-498. MCASP RFU Settings**

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RFMT bits	
			RROT <sup>(1)</sup>	RRVRS
MSB first <sup>(2)</sup>	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	$(32 - (\text{SLOT} - \text{WORD})) \% 32$	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first <sup>(2)</sup>	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 12-498 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be received in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 12-503), and the data is aligned in the same representation as it is read from the receiver (typically Q31 or integer).

#### 12.5.2.4.6 MCASP State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the MCASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX/TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP\_XFMT) and it reports the MCASP status and error conditions in the transmitter status register (MCASP\_XSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP\_RFMT) and it reports the MCASP status and error conditions in the receiver status register (MCASP\_RSTAT).

#### 12.5.2.4.7 MCASP TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of the MCASP\_RTDM/MCASP\_XTDM register and determines if the MCASP should receive/transmit in that time slot.

There are two possibilities for a slot: The MCASP either performs Rx/Tx operations during the time slot (transmit/receive bit is active), or the MCASP skips Rx/Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUFF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control MCASP\_SRCTLn[3-2] DISMOD register. Refer also to [Section 12.5.2.4.10.2.1, TDM Time Slots Generation and Processing](#), for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

**In case of a DIT-transmission (S/PDIF transfers):** the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP\_XBUFn register during the current time slot (slot 1) is actually shifted out on the next time slot (n = 0 to 15).

The transmit TDM sequencer is controlled by the MCASP\_XTDM register and reports the current transmit slot to the MCASP\_XTDMSLOT[9-0] XSLOT CNT bit field.

#### 12.5.2.4.8 MCASP Software Reset

The MCASP can be put into reset through the global transmit and receive control register (MCASP\_GBLCTL). A valid serial clock must be supplied to the MCASP to assert the software reset bits in the MCASP\_GBLCTL register.

#### 12.5.2.4.9 MCASP Power Management

[Table 12-499](#) describes power-management features available to the MCASP.

**Table 12-499. Local Power-Management Features**

Feature	Registers	Description
Slave clock stop modes	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	Force-clock stop, no-clock stop, and smart-clock stop modes are available.

#### CAUTION

No wakeup schema is supported for the MCASP. To ensure a correct behavior after enabling MCASP at device Device Configuration level, the user software is strongly recommended to choose *No Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x1. Before disabling MCASP at device Device Configuration level, user software is strongly recommended to choose a *Smart-Idle* mode, setting MCASP\_PWRIDLESYSCONFIG[1-0] IDLE\_MODE bit field to 0x2.

#### 12.5.2.4.10 MCASP Transfer Modes

##### 12.5.2.4.10.1 Burst Transfer Mode

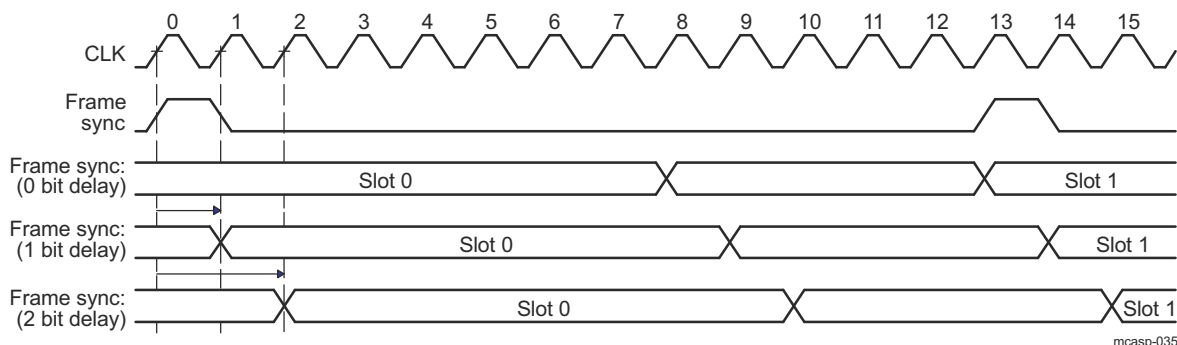

The MCASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

When operating in burst frame sync mode (see [Figure 12-504](#)), as specified for transmit (MCASP\_AFSXCTL[15-7] = 0) and receive (MCASP\_AFSRCTL[15-7] RMOD = 0), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (MCASP\_AFSRCTL[4] FRWID = 0, MCASP\_AFSXCTL[4] FXWID = 0).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF<sub>n</sub> (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF<sub>n</sub> (for every serializer set to operate as a receiver) has been read.

**Figure 12-504. Burst Frame Sync Mode**

The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- MCASP\_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP\_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP\_PDOUT, MCASP\_PDIN, MCASP\_PDCLR: Not applicable. Leave at default.
- MCASP\_GBLCTL: Follow the initialization sequence in *MCASP Global Initialization*, to configure this register.
- MCASP\_AMUTE: Not applicable. Leave at default.
- MCASP\_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.4.15, MCASP Loopback Modes](#), otherwise leave this register at default.
- MCASP\_DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- MCASP\_RMASK/MCASP\_XMASK: Mask desired bits according to [Section 12.5.2.4.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Program all fields according to data format desired. See [Section 12.5.2.4.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Clear RMOD/XMOD bits to 0 to indicate burst mode. Clear FRWID/FXWID bits to 0 for single bit frame sync duration. Configure other fields as desired.
- MCASP\_ACLKRCTL/MCASP\_ACLKXCTL: Program all fields according to bit clock desired. See [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL: Program all fields according to high-frequency clock desired. See [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_RTDM/MCASP\_XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- MCASP\_RINTCTL/MCASP\_XINTCTL: Program all fields according to interrupts desired.
- MCASP\_RCLKCHK/MCASP\_XCLKCHK: Not applicable. Leave at default.
- MCASP\_SRCTL<sub>n</sub>: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default (n = 0 to 15).
- MCASP\_DITCSR<sub>Ai</sub>, MCASP\_DITCSR<sub>Bi</sub>, MCASP\_DITUDR<sub>Ai</sub>, MCASP\_DITUDR<sub>Bi</sub>: Not applicable. Leave at default (i = 0 to 5).

#### 12.5.2.4.10.2 Time-Division Multiplexed (TDM) Transfer Mode

The MCASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in *TDM Format*.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock

- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to transmit

For more details on MCASP transmitting serializers clock and frame sync options, refer to the [Section 12.5.2.4.2.1, Transmit Clock](#), and [Section 12.5.2.4.2.3, Frame-Sync Generator](#).

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn, whose serializers are configured to receive

For more details on MCASP receiving serializers clock and frame sync options, refer to [Section 12.5.2.4.2.2, Receive Clock](#), and [Section 12.5.2.4.2.3, Frame-Sync Generator](#).

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold:

- MCASP\_PFUNC: The clock, frame, data pins must be configured for MCASP function.
- MCASP\_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP\_PDOUT, MCASP\_PDIN, MCASP\_PDCLR: Not applicable. Leave at default.
- MCASP\_GBLCTL: Follow the initialization sequence is described in the [Section 12.5.2.5.2, MCASP Operational Modes Configuration](#).
- MCASP\_AMUTE: Leave this register at default state.
- MCASP\_DLBCTL: If loopback mode is desired, configure this register according to [Section 12.5.2.4.15](#), otherwise leave this register at default.
- MCASP\_DITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP\_RMASK/MCASP\_XMASK: Mask desired bits according to [Section 12.5.2.4.5, MCASP Format Units](#).
- MCASP\_RFMT/MCASP\_XFMT: Program all fields according to data format desired. See the [Section 12.5.2.4.5, MCASP Format Units](#).
- MCASP\_AFSRCTL/MCASP\_AFSXCTL: Set RMOD/XMOD bits to (0x2 - 0x20) for Rx/Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by MCASP. Configure other fields as desired.
- MCASP\_ACLKRCTL/MCASP\_ACLKXCTL: Program all fields according to bit clock desired. For more information, refer to [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_AHCLKRCTL/MCASP\_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to [Section 12.5.2.4.2, MCASP Clock and Frame-Sync Configurations](#).
- MCASP\_RTDM/MCASP\_XTDM: Program all fields according to the time slot characteristics desired.
- MCASP\_XINTCTL: Program all fields according to transmit interrupts desired.
- MCASP\_RCLKCHK/MCASP\_XCLKCHK: Program all fields according to clock checking desired.
- MCASP\_SRCTLn: Program all fields according to serializer operation desired (n = 0 to 15).

#### Note

The MCASP\_DITCSRAi, MCASP\_DITCSRBi, MCASP\_DITUDRAi, MCASP\_DITUDRBi (i = 0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

#### 12.5.2.4.10.2.1 TDM Time Slots Generation and Processing

TDM mode on the MCASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the MCASP may be configured to participate or to be inactive by configuring MCASP\_XTDM and/or MCASP\_RTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP\_XTDM or MCASP\_RTDM register to determine if the MCASP transmits/receives in that time slot.

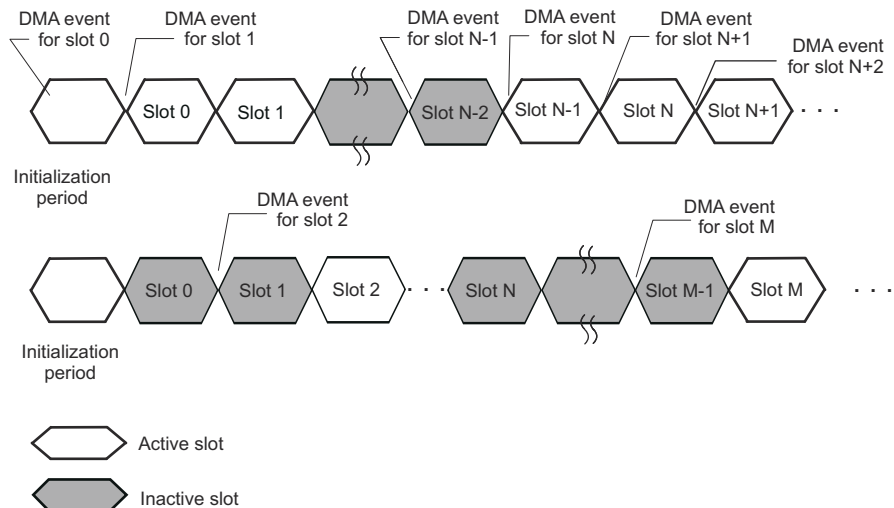

### Note

If a MCASP\_XTDM/MCASP\_RTDM bit defines an active slot (number of slot matches the bit position), the MCASP functions normally during that time slot; otherwise, the MCASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. MCASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP\_SRCTLn[3-2] DISMOD (n = 0 to 15).

Figure 12-505 shows when the transmit DMA event - XINT is generated. See Section 12.5.2.4.11.1, *Data Ready Status and Event/Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

mcasp-019

**Figure 12-505. Transmit DMA Event (XINT) Generation in TDM Time Slots**

#### 12.5.2.4.10.2.2 Special 384-Slot TDM Mode for Connection to External DIR

The MCASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to MCASP frame) size is 384 samples. The receive TDM time slot register (MCASP\_RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block). To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set MCASP\_AFSRCTL[15-7] RMOD bit field to 384 (0x180) to receive 384 time slots

### 12.5.2.4.10.3 DIT Transfer Mode

The DIT transfer mode of the MCASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not as receiver. For a description of the S/PDIF format, see *S/PDIF Coding Format*.

#### 12.5.2.4.10.3.1 Transmit DIT Encoding

When the MCASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the MCASP. The MCASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

#### Note

The transmit TDM time slot register (MCASP\_XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

For DIT Mode Transmission Data Alignment Settings see [Section 12.5.2.4.5.1.2, DIT Mode Transmission Data Alignment Settings](#).

If the MCASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

#### 12.5.2.4.10.3.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP\_AFSXCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP\_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP\_XFMT), XSSZ = 1111 (32-bit slot size)

All combinations of AHCLKX and ACLKX are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP\_PFUNC: The data pin - AXRn must be configured for MCASP function. If AHCLKX is used, it must also be configured for MCASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP\_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the AHCLKX device level signal by configuring AHCLKX pin as an output.
- MCASP\_GBLCTL: Global initialization
- MCASP\_AMUTE: Leave this register at default state.
- MCASP\_DITCTL: The DITEN bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- MCASP\_XMASK: Mask the desired bits, depending upon left-aligned or right-aligned internal data.

- MCASP\_XFMT: XDATDLY = 0. XRVRS = 0. XPAD = 0. XSSZ = Fh (32-bit slot). XBUSEL = configured as desired. The XROT bit is configured, as described in the [Section 12.5.2.4.5.1.2](#).
- MCASP\_AFSXCTL: Configure the bits according to former discussions.
- MCASP\_ACLKXCTL: ASYNC = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- MCASP\_AHCLKXCTL: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- MCASP\_XTDM: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP\_XINTCTL: Program all fields according to the interrupts desired.
- MCASP\_XCLKCHK: Program all fields according to the clock checking desired.
- MCASP\_SRCTLn: Set SRMOD = 1 (transmitter) for the DIT pins (n = 0 to 15).
- MCASP\_DITCSRAi and MCASP\_DITCSRBi: Program the channel status bits as desired (i = 0 to 5).
- MCASP\_DITUDRAi and MCASP\_DITUDRBi: Program the user data bits as desired (i = 0 to 5).

### Note

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see *Biphase-Mark Code*).

#### 12.5.2.4.10.3.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP\_DITCSRAi and MCASP\_DITCSRBi) and user data registers (MCASP\_DITUDRAi and MCASP\_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the software reads the transmit TDM slot counter to determine which word of the register is being used (i = 0 to 5).

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP\_DITCSRA0 to MCASP\_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP\_DITCSR0 to MCASP\_DITCSR5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP\_DITUDRA0 to MCASP\_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP\_DITUDRB0 to MCASP\_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in *S/PDIF Frame Format*. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 12-500](#).

**Table 12-500. Channel Status and User Data for Each DIT Block**

#### 12.5.2.4.11 MCASP Data Transmission and Reception

The MCASP is serviced by writing data to the MCASP\_XBUF<sub>n</sub> registers for transmit operations, and by reading data from the MCASP\_RBUF<sub>n</sub> registers for receive operations. The MCASP sets status flags and notifies the software whenever data is ready to be serviced. The [Section 12.5.2.4.11.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in details (n = 0 to 15).

The MCASP transmit/receive XRBUF<sub>n</sub> buffer can be accessed through one of the two peripheral ports of the device:

- **DATA port:** This port is dedicated to DMA initiated data transfers on the device for MCASP transmit (Tx) purposes.
- **Configuration bus (CFG):** The configuration bus- CFG port is used for peripheral configuration control and receive/transmit data transfers initiated by the host CPU in the device.

[Section 12.5.2.4.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.4.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

A device CPU and DMA usages are discussed in [Section 12.5.2.4.11.1.5, Using the device CPUs for MCASP Servicing](#), and [Section 12.5.2.4.11.1.6, Using the DMA for MCASP Servicing](#), respectively.

MCASP DATA port allows DMAs to access the MCASP transmit buffer more efficiently on the CBASS0, using burst transfers. The physical addresses to access these registers are listed in *DMA Registers*.

#### **12.5.2.4.11.1 Data Ready Status and Event/Interrupt Generation**

##### **12.5.2.4.11.1.1 Transmit Data Ready**

The transmit data ready flag - XDATA in the MCASP\_XSTAT register reflects the data ready status of XRBUF<sub>n</sub> buffers for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUF<sub>n</sub> to its corresponding XRSR<sub>n</sub> shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUF<sub>n</sub> is emptied and ready to accept new data from the host (CPU or DMA). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP\_SRCTL<sub>n</sub>[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP\_XBUF<sub>n</sub> is written to by the host, the MCASP\_SRCTL<sub>n</sub>[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_XBUF<sub>n</sub> register has to be currently written. Once all requested MCASP\_XBUF<sub>n</sub> are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP\_XSTAT[5] XDATA bit is written to 0b1, or once MCASP\_XBUF<sub>n</sub> registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the XINT event is automatically generated on MCASP[0-2]\_XMIT\_DMA\_EVT line (if enabled in the MCASP\_XEVTCTL register) to notify the DMA of the MCASP\_XBUF<sub>n</sub> empty status. An interrupt - MCASP[0-2]\_XMIT\_INTR\_PEND can be also generated if the XDATA interrupt is enabled in the MCASP\_XINTCTL register (for details, see [Section 12.5.2.4.13.1, Transmit Data Ready Interrupt](#)).

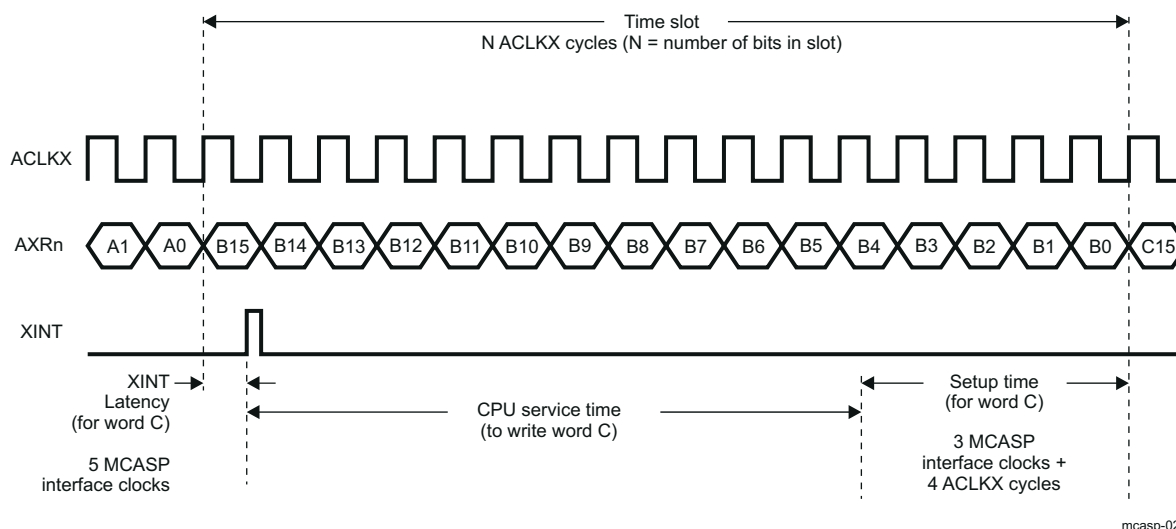

For DMA requests, the MCASP does not require that MCASP\_XSTAT register be read between DMA events. This means that, even if MCASP\_XSTAT register already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

[Figure 12-506](#) shows the timing details of when XINT is generated at the MCASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the MCASP sets the XDATA flag and generates an XINT event. However, it takes up to five MCASP interface clocks (XINT latency) before XINT is active at the MCASP boundary. Upon XINT, the CPU can begin servicing the MCASP by writing word C into the MCASP\_XBUF<sub>n</sub> (service time). The CPU must write word C into the MCASP\_XBUF<sub>n</sub> within the setup time required by the MCASP (setup time) (n = 0 to 15).

The maximum service time (see [Figure 12-506](#)) can be calculated as:

*Service Time = Time Slot – XINT Latency – Setup Time*

**Figure 12-506. Service Time Upon Transmit DMA Event (XINT)**

#### 12.5.2.4.11.1.2 Receive Data Ready

Similarly, the receive data ready flag - RDATA in the MCASP\_RSTAT register reflects the data ready status of XRBUFFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFFn already contains received data (this is, a buffer is full) and is ready to transfer it to the host. The receive data ready event is individually indicated per serializer in its corresponding control register MCASP\_SRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP\_RBUFFn register is read from the host, the MCASP\_SRCTLn [5] RRDY bit is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP\_RBUFFn register has to be currently read. Once all requested MCASP\_RBUFFn registers are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP\_RSTAT[5] RDATA bit is written to 0b1, or once MCASP\_RBUFFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Whenever RDATA flag is set, the RINT event is automatically generated on MCASP[0-2]\_REC\_DMA\_EVT line (if enabled in the MCASP\_PIDTCTL register) to notify the DMA of the MCASP\_RBUFFn full status. An interrupt - MCASP[0-2]\_REC\_INTR\_PEND can be also generated if the RDATA interrupt is enabled in the MCASP\_RINTCTL register (for details, see [Section 12.5.2.4.13.1, Receive Data Ready Interrupt](#)).

[Figure 12-507](#) shows the timing details of when RINT event is generated at the MCASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the MCASP sets the RDATA flag and generates an RINT event. However, it takes up to five MCASP interface clocks (RINT Latency) before RINT is active at the MCASP boundary. Upon RINT, the CPU can begin servicing the MCASP by reading Word A from the MCASP\_RBUFFn (service time). The CPU must read Word A from the MCASP\_RBUFFn register no later than the setup time required by the MCASP (Setup Time) (n = 0 to 15).

The maximum service time (see [Figure 12-507](#)) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{RINT Latency} - \text{Setup Time}$$

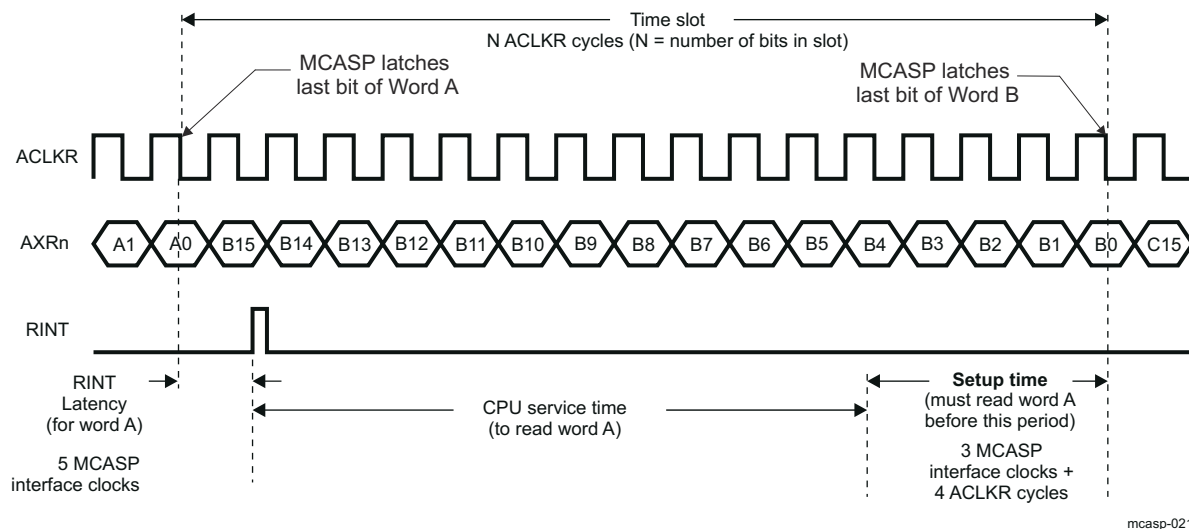

Figure 12-507. CPU Service Time Upon Receive Event (RINT)

#### 12.5.2.4.11.3 Transfers Through the Data Port (DATA)

##### CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL/RBUSEL bit to 0b0 in the MCASP\_XFMT/MCASP\_RFMT register, respectively. Failure to do so may result in software malfunction.

In a typical MCASP transfer scenario, the DMA Controller write accesses the XRBUFn transmit buffer through the MCASP data port (DATA) on CBASS0 Interconnect. CPU hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address via DATA port corresponding address. To perform transfers through the DATA port, simply have the DMA Controller write the MCASP Tx buffer through Interconnect DATA port location. Refer to *DMA Registers*. Although the transfer is passed through an integrated AFIFO transmit/receive buffer, the host (DMA or CPU) must follow the described below procedure to access the data buffers of each serializer, regardless the AFIFO is enabled or disabled. The AFIFO operation is described in [Section 12.5.2.4.12](#).

For accesses through the DATA port, the DMA/CPU services all the serializers through accessing only a single address. In addition, as can be seen in *DMA Registers*, the same physical DATA port address is used regardless of a read or write access is performed. The MCASP automatically cycles through the active slot transmitting/receiving serializers, internally generating the appropriate offsets.

##### Note

DATA port allows the DMA/CPU to automatically access only the data buffers. There is no way for DMA/CPU to access the MCASP configuration registers addressing their corresponding MCASP DATA port.

For transmit operations through the DATA port, the host must always write to the same transmit buffer DATA port address (which is same than the receive buffer DATA port address) to service all of the active slot transmitting serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the destination address to match the DATA port location of TXBUF buffer (See *DMA Registers*).

In addition, the DMA/CPU must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3

upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

#### Note

For write transfers through MCASP DATA port it is preferable to use DMA on corresponding Interconnect. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, the DMA/CPU must always read from the same receive buffer DATA port address (which is same than the transmit buffer DATA port address) to service all of the active slot receiving serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the DMA/CPU source address to match the DATA port location of RXBUF buffer (See *DMA Registers*).

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the CPU should read from the same receive buffer DATA port address three times to obtain data for serializers 0, 1 and 3 in this exact order, upon each receive data ready event.

#### Note

To service a serializer for a transmit or receive operation through the MCASP DATA port, the initiator always writes (preferably DMA) and reads from the same address (refer to *DMA Registers*), respectively.

#### Note

When transmitting through the DATA port, the DMA/CPU must write data (at the same address) to each serializer configured as *active* (active slot selected in MCASP\_XTDM) and *transmit* (Tx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see [Section 12.5.2.4.16.1, Buffer Underrun Error - Transmitter](#)). Similarly, when DMA/CPU receives, data must be read from each serializer configured as *active* (active slot selected in MCASP\_RTDM) and *receive* (Rx enabled in MCASP\_SRCTLn) within each time slot. Failure to do so results in a buffer overrun condition (see [Section 12.5.2.4.16.2, Buffer Overrun Error - Receiver](#)) (n = 0 to 15).

#### 12.5.2.4.11.1.4 Transfers Through the Configuration Bus (CFG)

#### CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL/RBUSEL bit to 1 in the MCASP\_XFMT/MCASP\_RFMT registers, respectively. Failure to do so may result in software malfunction.

#### Note

MCASP[0-2] whose data ports are accessible directly via CBASS0 do not support FIFO/constant addressing modes. Incrementing transfers must be used instead.

In this method, the CPU accesses the XRBUFn transmit or receive buffer through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit/receive buffer physical address for any particular serializer is determined by adding the transmit/receive buffer alias register offset for that particular serializer to the base address of MCASP CFG port actual for CBASS0 accesses. The XRBUFn buffer of the n-th serializer configured as a transmitter is aliased

- MCASP\_XBUF<sub>n</sub> in the CFG port address space. For example, the XBUF2 transmit buffer is mapped as the MCASP\_XBUF2 register. Similarly, the XBUF<sub>n</sub> buffer of the n-th serializer configured as a receiver is aliased - MCASP\_RBUF<sub>n</sub> in the CFG port address space. For example, the XBUF3 receive buffer is mapped as the MCASP\_RBUF3 register.

Accessing the XBUF through the DATA port (see [Section 12.5.2.4.11.1.3](#)) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index, while accessing through the peripheral configuration port - CFG, the CPU must provide the exact MCASP\_XBUF<sub>n</sub> or MCASP\_RBUF<sub>n</sub> address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP\_XBUF<sub>n</sub> and MCASP\_RBUF<sub>n</sub> addresses corresponding to MCASP CFG port, see *CFG Registers* (n = 0 to 15).

#### 12.5.2.4.11.1.5 Using a Device CPU for MCASP Servicing

The device CPUs can be used to service the MCASP transmit channels through interrupts (upon MCASP[0-2]\_XMIT\_INTR\_PEND and MCASP[0-2]\_REC\_INTR\_PEND interrupts). Because these interrupt events are connected to device COMPUTE\_CLUSTER0, PRU\_ICSSG0/1, MAIN2MCU\_LVL\_INTRTR0, R5FSS0/1\_INTRTR0, C66SS0/1\_INTRTR0, R5FSS0/1 modules, they could be software mapped to input interrupt lines of any device CPU. Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP\_XSTAT register and RDATA bit in the MCASP\_RSTAT register can be performed by device CPUs, respectively. As discussed in [Section 12.5.2.4.11.1.3, Transfers Through the Data Port \(DATA\)](#), and [Section 12.5.2.4.11.1.4, Transfers Through the Configuration Bus \(CFG\)](#), the device CPUs can access MCASP XBUF serializer buffer through their corresponding DATA and CFG port locations.

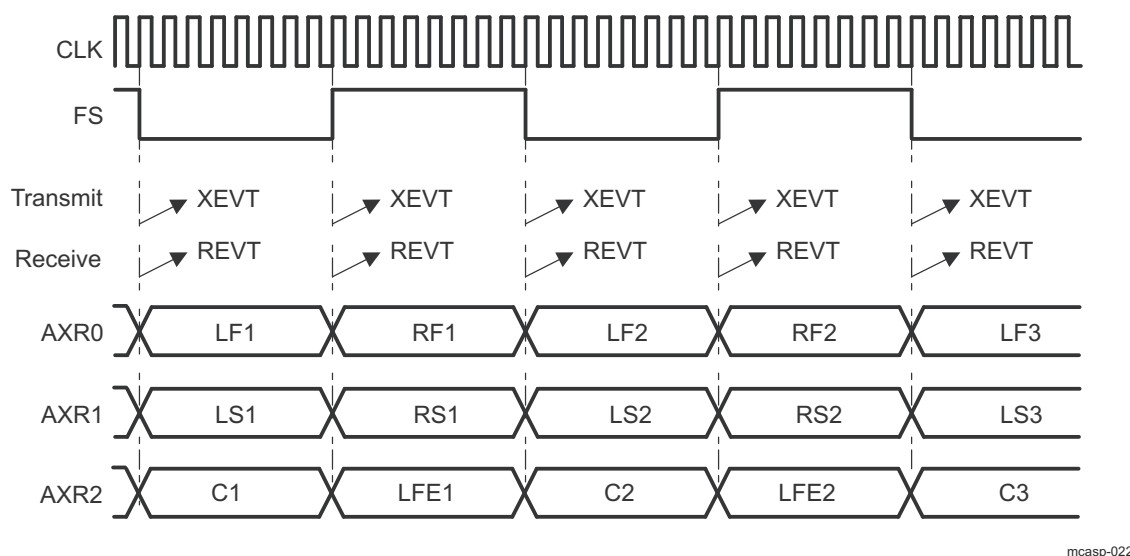

To use the device CPUs to service the MCASP through interrupts, the XDATA/RDATA bit must be enabled in the respective MCASP\_XINTCTL/MCASP\_RINTCTL registers, to generate interrupts MCASP[0-2]\_XMIT\_INTR\_PEND/MCASP[0-2]\_REC\_INTR\_PEND to the device CPUs upon data ready

#### 12.5.2.4.11.1.6 Using the DMA for MCASP Servicing

##### Note

The associated static Transfer Request (TR) operations of PDMA0, located in front of MCASP, must be configured to match the MCASP configuration. For more information, refer to *DMA Controllers*.

The typical scenario is to use the DMA to service the MCASP transmit and receive logic through the DATA port. The transfer passes through integrated AFIFO transmit/receive buffer. If AFIFO is enabled, DMA requests are collected and fed to a device DMA controller (see [Figure 12-497](#)). The data transfer is managed by the AFIFO according to generated transmit and receive events in the MCASP and data is fed to transmit buffers and fetched from receive buffers as described in [Section 12.5.2.4.12, MCASP Audio FIFO \(AFIFO\)](#). The generation of transmit and receive request is described below. After generation of transmit/receive DMA events from MCASP module, these events are collected in AFIFO and on specific AFIFO conditions described in [Section 12.5.2.4.12, MCASP Audio FIFO \(AFIFO\)](#) the requests (transmit or receive) are forwarded to a DMA controller via MCASP[0-2]\_XMIT\_DMA\_EVT and MCASP[0-2]\_REC\_DMA\_EVT outputs. If the AFIFO is disabled (default state) it is transparent for the MCASP module and all request are directly sent to the DMA controller.

**Figure 12-508. DMA Transmit and Receive Event in an Audio Example – One Event**

In transmit mode, the DMA event - XINT (MCASP[0-2]\_XMIT\_DMA\_EVT output), which is triggered upon each XDATA transition from 0 to 1, is used to service the MCASP TXBUF<sub>n</sub> transmit buffers. In receive mode, the DMA event RINT (MCASP[0-2]\_REC\_DMA\_EVT output) which is triggered upon each RDATA transition from 0 to 1, is used to service the MCASP RXBUF<sub>n</sub> receive buffers.

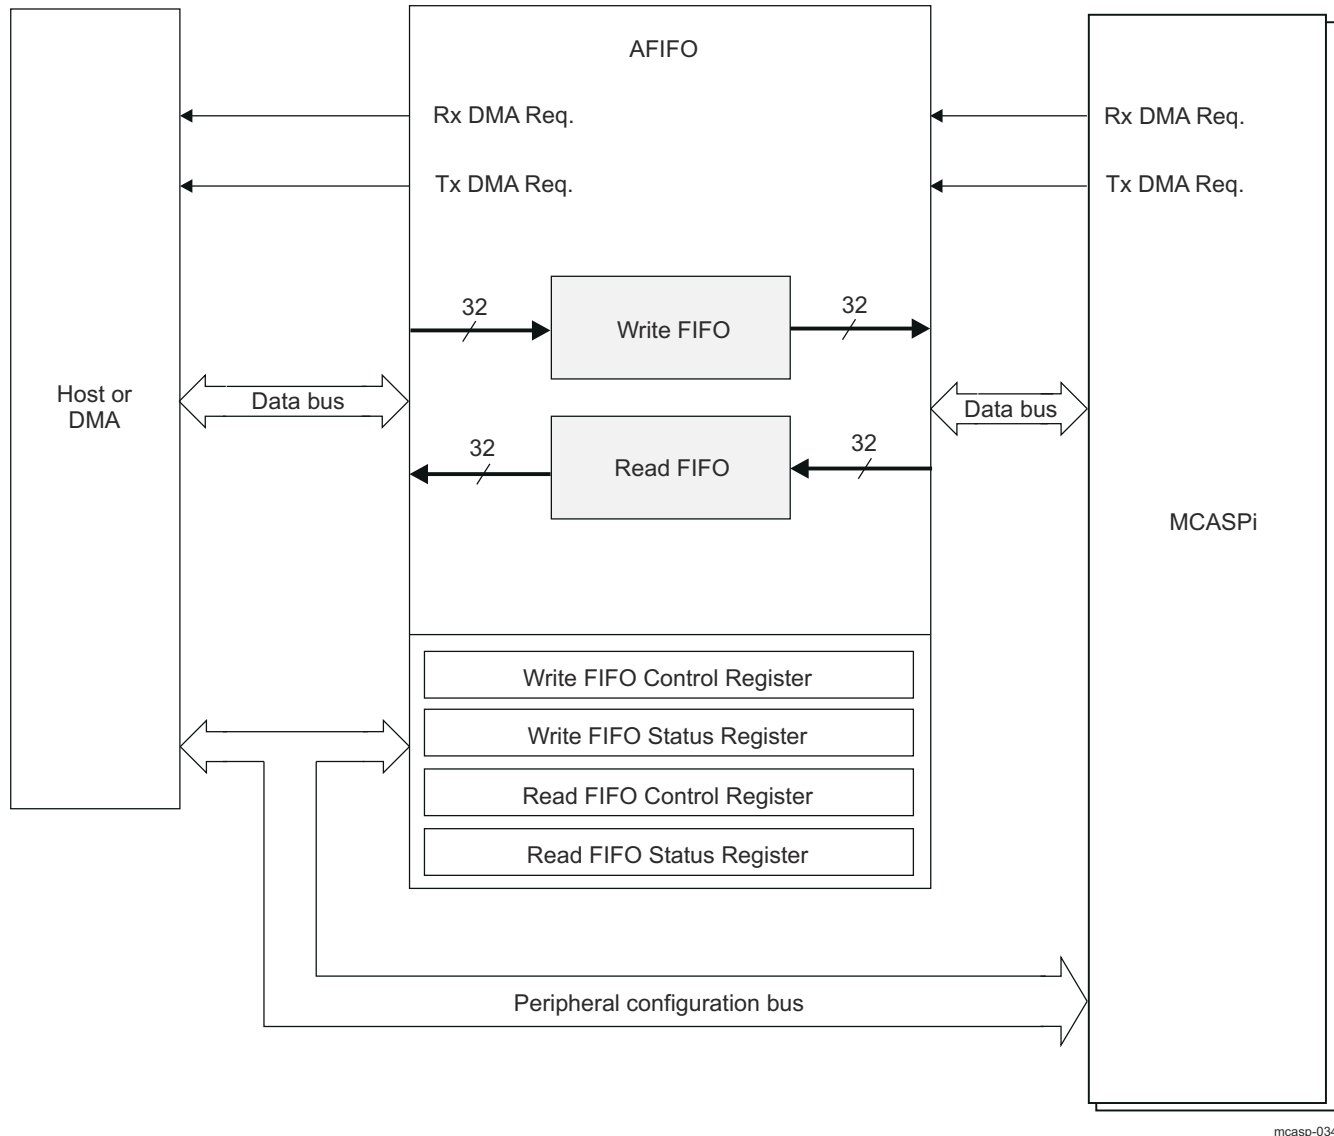

Figure 12-508 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted or received through the MCASP signals - AXR0, AXR1 and AXR2. It shows the points at which events XINT/RINT are triggered.

In Figure 12-508, a Tx DMA event XINT is triggered on each time slot. In the example, XINT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, provided that DMA TX requests generation is enabled in the MCASP\_XEVTCTL register. Similarly, Rx DMA event RINT is triggered for each of the receive audio channel time slot. Receive DMA events are generated automatically upon receive data ready, provided that DMA RX requests generation is enabled in the MCASP\_PIDTCTL register.

#### 12.5.2.4.12 MCASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). The RFIFO and the WFIFO are the same size: 64 32-bit Words. To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 12-509 for a high-level block diagram of the AFIFO. The AFIFO may be enabled/disabled and configured via the MCASP\_WFIFOCTL and MCASP\_RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the MCASP.

**Figure 12-509. MCASP Audio FIFO (AFIFO) Block Diagram**

#### 12.5.2.4.12.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the MCASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the MCASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Write FIFO is enabled, transmit DMA requests from the MCASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller. If the Write FIFO is enabled, upon a transmit DMA request from the MCASP, the WFIFO writes WNUMDMA 32-bit words to the MCASP if and when there are at least WNUMDMA words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes WNUMDMA words to the MCASP (see description for the MCASP\_WFIFOCTL[7-0] WNUMDMA). If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded. Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

##### 12.5.2.4.12.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the

host or DMA controller is reduced. If the Write FIFO has space to accept WNUMEVT 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once WNUMEVT words have been written to the FIFO, it checks again to see if there is space for WNUMEVT 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled. Note that if transmit DMA event pacing is desired, MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field. If transmit DMA event pacing is not desired, then the value in MCASP\_WFIFOCTL[15-8] WNUMEVT bit field should be set equal to the value in MCASP\_WFIFOCTL[7-0] WNUMDMA bit field.

#### 12.5.2.4.12.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from MCASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the MCASP generates receive DMA requests as needed; the AFIFO is “invisible” to the MCASP. When the Read FIFO is enabled, receive DMA requests from the MCASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller. If the Read FIFO is enabled and the MCASP makes a receive DMA request, the RFIFO reads RNUMDMA 32-bit words from the MCASP, if and when the RFIFO has space for RNUMDMA words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads RNUMDMA words from the MCASP (see description for the MCASP\_RFIFOCTL[7-0] RNUMDMA). If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than RNUMEVT words, those words will be read correctly, emptying the FIFO.

#### 12.5.2.4.12.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced. If the Read FIFO contains at least RNUMEVT 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once RNUMEVT 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another RNUMEVT words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty. Note that if receive DMA event pacing is desired, MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set to a non-zero integer multiple of the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field. If receive DMA event pacing is not desired, then the value in MCASP\_RFIFOCTL[15-8] RNUMEVT bit field should be set equal to the value in MCASP\_RFIFOCTL[7-0] RNUMDMA bit field.

#### 12.5.2.4.12.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete. If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

#### 12.5.2.4.13 MCASP Events and Interrupt Requests

[Table 12-501](#) lists all the transmit event flags. [Table 12-502](#) lists all the Receive event flags. Source of each of these TX/RX events can be a TX/RX channel from any MCASP serializer configured as transmitter or receiver respectively.

**Table 12-501. TX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[0] XUNDRN	MCASP_XSTAT[0] XUNDRN	MCASP[0-2]_XMIT_INTR_PEND	Transmit buffer underrun
MCASP_XINTCTL[1] XSYNCERR	MCASP_XSTAT[1] XSYNCERR	MCASP[0-2]_XMIT_INTR_PEND	Unexpected transmit frame sync
MCASP_XINTCTL[2] XCKFAIL	MCASP_XSTAT[2] XCKFAIL	MCASP[0-2]_XMIT_INTR_PEND	Transmit clock failure

**Table 12-501. TX Events (continued)**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_XINTCTL[3] XDMAERR	MCASP_XSTAT[7] XDMAERR	MCASP[0-2]_XMIT_INTR_PEND	DATA port transmit error
MCASP_XINTCTL[4] XLAST	MCASP_XSTAT[4] XLAST	MCASP[0-2]_XMIT_INTR_PEND	Transmit last slot interrupt
MCASP_XINTCTL[5] XDATA	MCASP_XSTAT[5] XDATA	MCASP[0-2]_XMIT_INTR_PEND	Transmit data-ready interrupt
MCASP_XINTCTL[7] XSTAFRM	MCASP_XSTAT[6] XSTAFRM	MCASP[0-2]_XMIT_INTR_PEND	Transmit start of frame interrupt
n.a.	MCASP_XSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR   XCKFAIL   XUNDRN   XSYNCERR ). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_XSTAT[3] XTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

**Table 12-502. RX Events**

Event Mask <sup>(1)</sup>	Event Flag	Map to <sup>(1)</sup>	Description
MCASP_RINTCTL[0] ROVRN	MCASP_RSTAT[0] ROVRN	MCASP[0-2]_REC_INTR_PEND	Receive buffer overrun
MCASP_RINTCTL[1] RSYNCERR	MCASP_RSTAT[1] RSYNCERR	MCASP[0-2]_REC_INTR_PEND	Unexpected receive frame sync
MCASP_RINTCTL[2] RCKFAIL	MCASP_RSTAT[2] RCKFAIL	MCASP[0-2]_REC_INTR_PEND	Receive clock failure
MCASP_RINTCTL[3] RDMAERR	MCASP_RSTAT[7] RDMAERR	MCASP[0-2]_REC_INTR_PEND	DATA port receive error
MCASP_RINTCTL[4] RLAST	MCASP_RSTAT[4] RLAST	MCASP[0-2]_REC_INTR_PEND	Receive last slot
MCASP_RINTCTL[5] RDATA	MCASP_RSTAT[5] RDATA	MCASP[0-2]_REC_INTR_PEND	Receive data-ready
MCASP_RINTCTL[7] RSTAFRM	MCASP_RSTAT[6] RSTAFRM	MCASP[0-2]_REC_INTR_PEND	Receive start of frame
n.a.	MCASP_RSTAT[8] RERR	n.a.	OR-event of all Rx-error events: (RDMAERR   RCKFAIL   ROVRN   RSYNCERR ). RERR event is cleared once all error flags are cleared.
n.a.	MCASP_RSTAT[3] RTDM SLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Every MCASP module generates separate interrupt event.

Software has to read the MCASP\_XSTAT/MCASP\_RSTAT register to determine which event occurs at a global level for MCASP Tx/Rx logic. In addition user software has to scan the XRDY/RRDY read-only flags in the MCASP\_SRCTLn registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASP[0-2]\_XMIT\_INTR\_PEND) is asserted (active high) when one of the MCASP\_XSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_XINTCTL bit. Similarly, a Rx interrupt line (MCASP[0-2]\_REC\_INTR\_PEND) is asserted (active high) when one of MCASP\_RSTAT notified events occurs, provided that it is enabled in its corresponding MCASP\_RINTCTL bit. See also [Section 12.5.2.4.13.4, Multiple Interrupts](#) and the [Section 12.5.2.4.11.1, Data Ready Status and Event/Interrupt Generation](#) (n = 0 to 15).

#### 12.5.2.4.13.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if the MCASP\_XSTAT[5] XDATA bit is 1 and MCASP\_XINTCTL[5] XDATA bit is enabled. The [Section 12.5.2.4.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when XDATA is set in the MCASP\_XSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### 12.5.2.4.13.2 Receive Data Ready Event and Interrupt

The receive data-ready interrupt (RDATA) is generated if the MCASP\_RSTAT[5] RDATA bit is 1 and MCASP\_RINTCTL[5] RDATA bit is enabled. The [Section 12.5.2.4.11.1, Data Ready Status and Event/Interrupt Generation](#), provides details on when the MCASP\_RSTAT[5] RDATA bit is set.

A receiver start of frame (RSTAFRM) interrupt is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) interrupt is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

#### 12.5.2.4.13.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP\_XSTAT):

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP\_XINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP\_RSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (MCASP\_RINTCTL). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP\_RSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### 12.5.2.4.13.4 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP\_XSTAT is set and the interrupt is enabled in MCASP\_XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the MCASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP\_XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the serializer with the interrupt flag set in MCASP\_XSTAT/MCASP\_RSTAT and the interrupt enabled in MCASP\_XINTCTL/MCASP\_RINTCTL generates a request on the MCASP transmit or receive interrupt port.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the MCASP transmit or receive interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the MCASP transmit or receive interrupt port.

The interrupt is serviced with the CPU writing to MCASP\_XSTAT/MCASP\_RSTAT. If any interrupt requests are active after the write, a new request is generated on the MCASP transmit or receive interrupt port.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

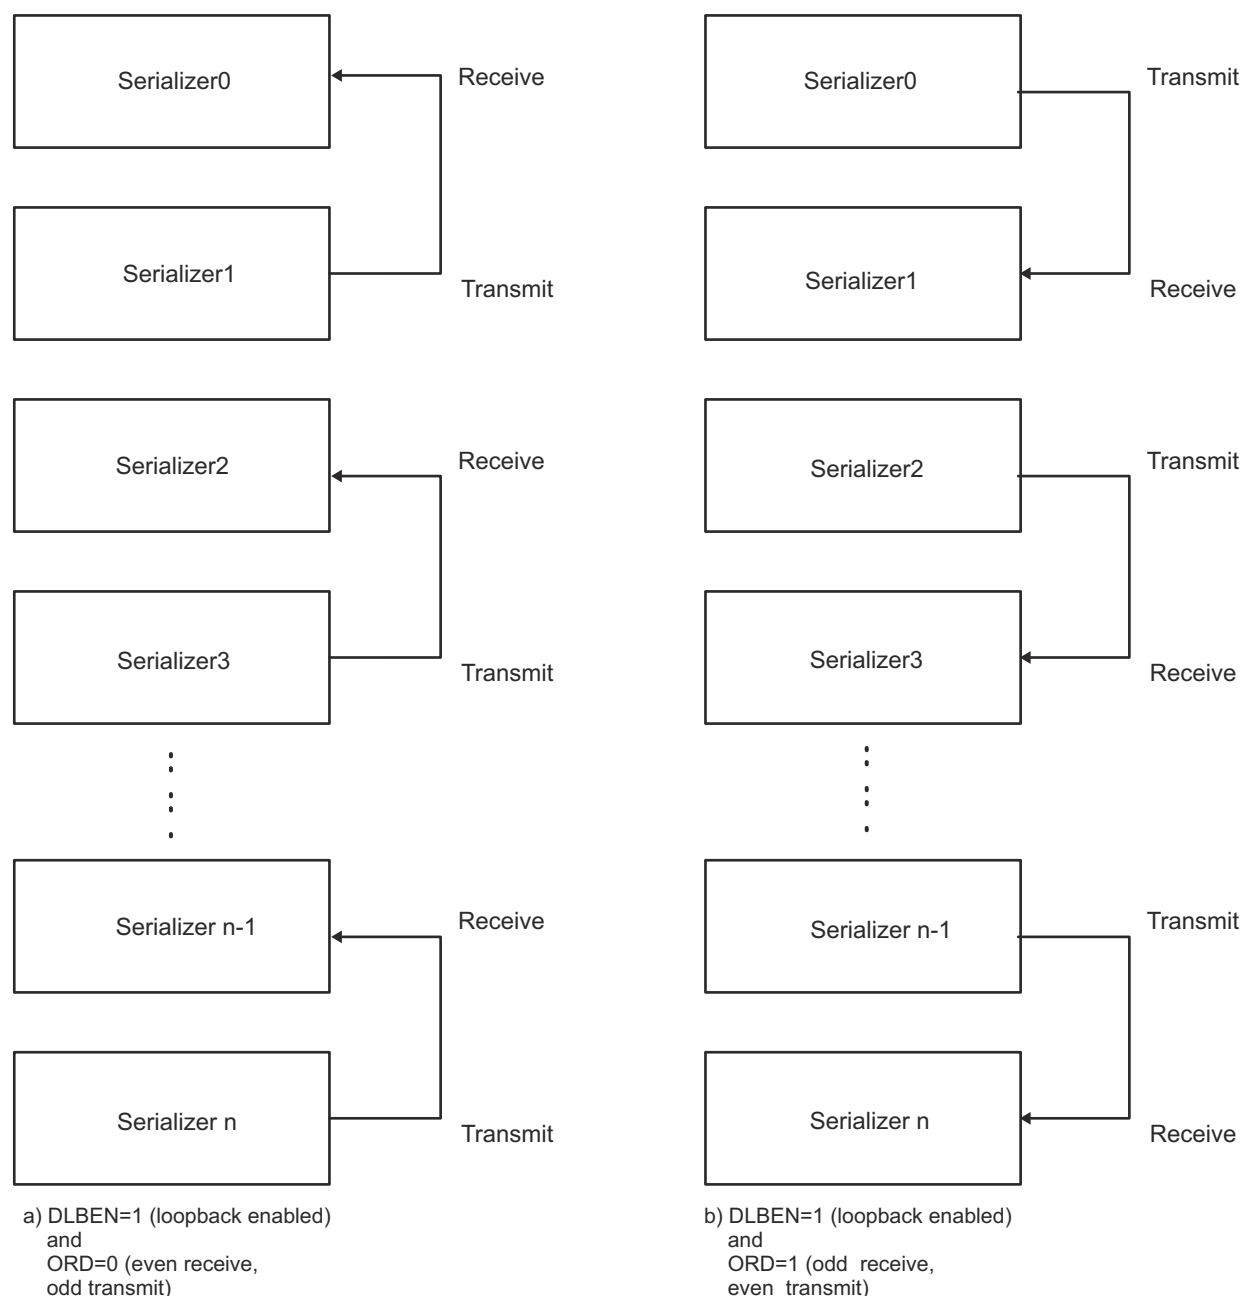

#### **12.5.2.4.14 MCASP DMA Requests**

The MCASP can generate one DMA request to the DMA controller to transmit (MCASP[0-2]\_XMIT\_DMA\_EVT) or receive (MCASP[0-2]\_REC\_DMA\_EVT) data. A DMA request to transmit data is generated if the MCASP\_XEVTCTL[0] XDATDMA bit is cleared. A DMA request to receive data is generated if the MCASP\_PIDTCTL[0] RDATDMA bit is cleared.

#### **12.5.2.4.15 MCASP Loopback Modes**

The MCASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between MCASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the MCASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180) or burst mode (XMOD = 0).

[Figure 12-510](#) shows the basic logical connection of the serializers in loopback mode.

mcasp-023

**Figure 12-510. MCASP Serializers Operation in Loopback Mode**

Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP\_DLBCCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (the MCASP\_DLBCCTL[4] IOLBEN bit) between a MCASP module internal loopback and a device I/O level loopback.

When a **MCASP internal loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b0 ), it is NOT necessary to configure MCASP\_PFUNC and MCASP\_PDIR registers for MCASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a MCASP output pin by setting the corresponding MCASP\_PFUNC bit to 0 (this is, to function as MCASP, not GPIO) and MCASP\_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP\_DLBCTL[4] IOLBEN = 0b1 ), the MCASP\_PFUNC and MCASP\_PDIR registers must be configured with the appropriate settings for all AXRn pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (this is, reaching device I/O buffers ).

When in loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the MCASP. The transmit and receive sections operate synchronously. This is achieved by setting the MCASP\_DLBCTL[3-2] MODE bit field to 0x1 and the MCASP\_ACLKXCTL[6] ASYNC bit to 0b0.

#### 12.5.2.4.15.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The MCASP\_DLBCTL[0] DLBEN bit must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal MCASP operation.
- The MCASP\_DLBCTL[4] IOLBEN bit must be set to select between internal (MCASP local) loopback mode or device I/O level loopback mode.
- The MCASP\_DLBCTL[3-2] MODE bit field must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP\_DLBCTL[1] ORD bit must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The MCASP\_ACLKXCTL[6] ASYNC bit must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The MCASP\_AFSRCTL[15-7] RMOD bit field and MCASP\_AFSXCTL[15-7] XMOD bit field must be set within range (0x2 - 0x20) to indicate TDM mode.

#### Note

Loopback mode does not apply to DIT or burst mode, because MCASP receivers do NOT natively support DIR - reception.

#### 12.5.2.4.16 MCASP Error Reporting

The MCASP includes error-checking capability for the serial protocol and data underrun. In addition, the MCASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected, an interrupt can be generated if desired, based on one or more error sources.

##### 12.5.2.4.16.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer is instructed by the transmit state-machine to transfer data from XRBUFFn buffer to XRSRn shift register, but the corresponding (MCASP\_XBUFFn ) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP\_XSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it (n = 0 to 15).

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the MCASP and restart with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the MCASP and start again with the proper initialization.

#### 12.5.2.4.16.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP\_RBUFn register has not yet been read since the last time the transfer occurred. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting (n = 0 to 15).

An overrun is checked only once per time slot. The MCASP\_RSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

#### 12.5.2.4.16.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the MCASP\_XSTAT[7] XDMAERR bit, occurs when the DMA or device CPU writes more words to the DATA port of the MCASP than it should.

The MCASP\_XSTAT[7] XDMAERR = 0b1 indicates that the DMA or device CPU wrote too many words to the MCASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting the MCASP\_XSTAT[0] XUNDRN bit.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP transmitter and the DMA must be reinitialized to resynchronize them.

#### 12.5.2.4.16.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the MCASP\_RSTAT[7] RDMAERR bit, occurs when the DMA or device CPU reads more words from the DATA port of the MCASP than it should.

The MCASP\_RSTAT[7] RDMAERR bit indicates that the DMA or device CPU read too many words from the MCASP DATA port for a given receive RINT event. Reading too few words results in a receiver overrun error setting the MCASP\_RSTAT[0] ROVRN bit.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA or device CPU. The MCASP receiver and the DMA must be reinitialized to resynchronize them.

#### 12.5.2.4.16.5 Unexpected Frame Sync Error

An unexpected frame sync occurs in when:

- in burst mode and TDM mode, the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- in TDM mode, an unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the MCASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
  - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).

- Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
- 2. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
  - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
  - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in burst mode and TDM mode. However, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

#### 12.5.2.4.16.6 Clock Failure Detection

##### 12.5.2.4.16.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP\_XCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP\_XSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  - a. The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP\_XINTCTL)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP\_RCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP\_RSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
  - a. the receive clock failure (RCKFAIL) interrupt enable bit in the receive interrupt control register (MCASP\_RINTCTL)

##### 12.5.2.4.16.6.2 Transmit Clock Failure Check and Recovery

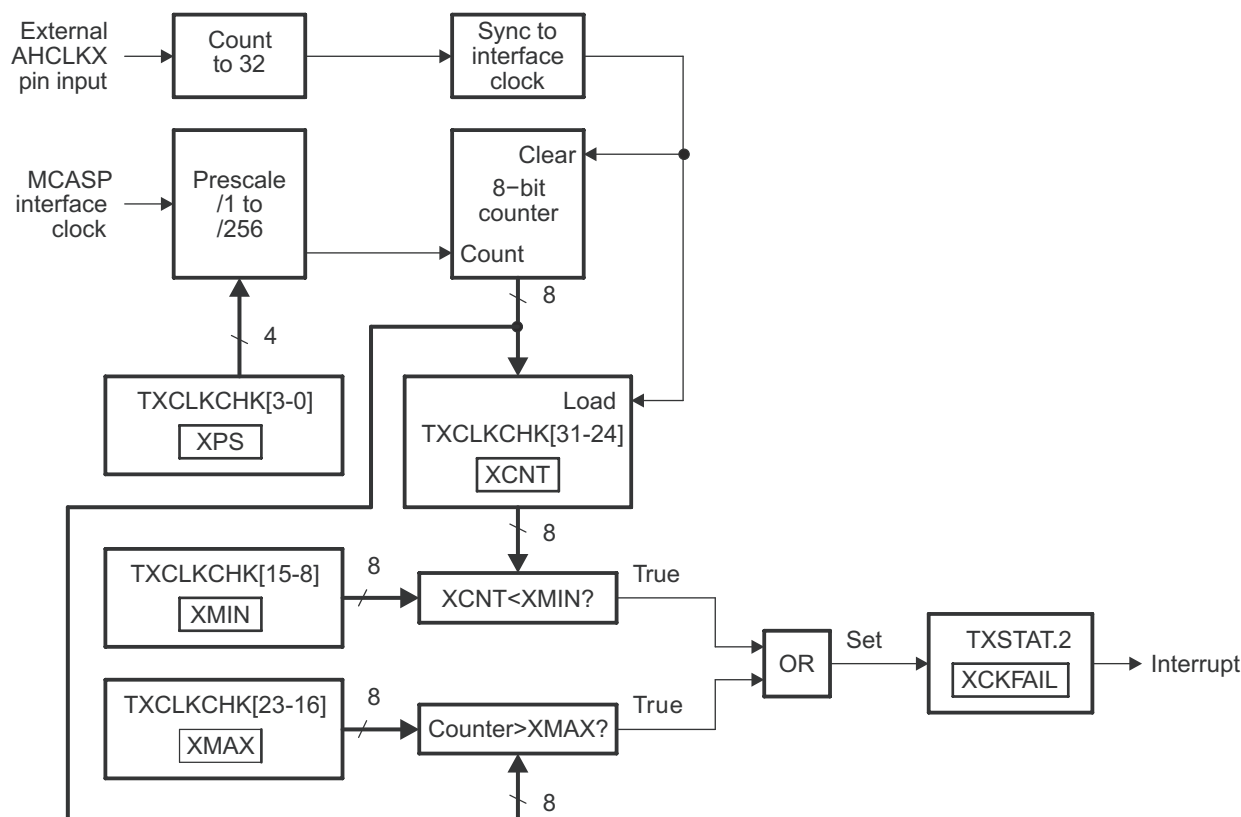

The transmit clock failure check circuit (see [Figure 12-511](#)) works off the internal MCASP interface clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of interface clocks for every 32 high-rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (MCASP\_XCLKCHK) every 32 high-rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (the MCASP\_XSTAT[2] XCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running interface clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the MCASP\_XSTAT[2] XCKFAIL transmit clock failure flag is set. This causes an interrupt if the MCASP\_XINTCTL[2] XCKFAIL transmit clock failure interrupt enable bit is set.

mcasps-024

**Figure 12-511. Transmit Clock Failure Detection Circuit Block Diagram**

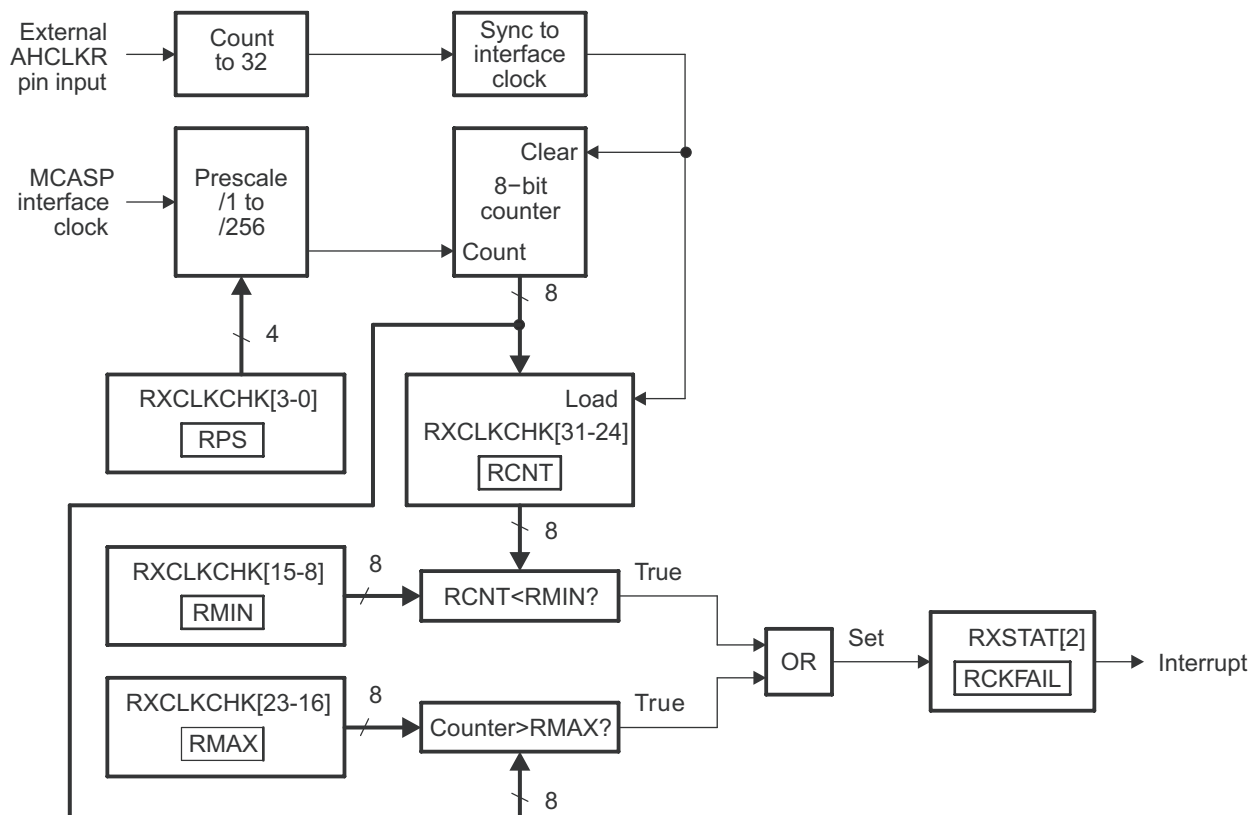

#### 12.5.2.4.16.6.3 Receive Clock Failure Check and Recovery

The receive clock failure check circuit (see [Figure 12-512](#)) works off both the internal MCASP interface clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of interface clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP\_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (the MCASP\_RSTAT[2] RCKFAIL bit) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running interface clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

**Figure 12-512. Receive Clock Failure Detection Circuit Block Diagram**

## 12.5.2.5 MCASP Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCASP module.

### 12.5.2.5.1 MCASP Global Initialization

#### 12.5.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MCASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MCASP (for more information, see *MCASP Integration*, and *MCASP Environment* ).

[Table 12-503](#) describes the global initialization of surrounding modules.

**Table 12-503. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC3	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
PLLCTRL0	PLLCTRL0 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
PLL4	PLL4 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
PLL2	PLL2 configuration must be done to enable the clocks to the MCASP modules, see <i>Clocking</i> .
ATL	ATL configuration must be done to enable the clocks to the MCASP modules, see <i>Audio Tracking Logic (ATL)</i> .
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
MAIN2MCU_LVL_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MAIN2MCU_LVL_INTRTR0 interrupts, see <i>Interrupts</i> .
R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_CORE0/1 interrupts, see <i>Interrupts</i> .
PDMA0_MCASP_G0	PDMA0_MCASP_G0 controllers configuration must be done to enable the module PDMA0_MCASP_G0 channel request, see <i>PDMA Controller</i> .
Interconnects	For information about the CBASS0 interconnects configuration, see <i>System Interconnect</i> .

#### Note

NAVSS configuration (UMDA channel set-up) must be done in order to move data from/to MCASP via the PDMA Controller. For more information, see *Navigator Subsystem (NAVSS)*.

#### Note

The COMPUTE\_CLUSTER0, MAIN2MCU\_LVL\_INTRTR0, R5FSS0\_CORE0/1, and the PDMA0\_MCASP\_G0 configurations are required when the interrupt and DMA-based communication modes are used. Further initialization of the selected interrupt and DMA controllers of the host CPU must be done for full functionality of the MCASP DMA and interrupt lines.

### 12.5.2.5.1.2 MCASP Global Initialization

#### 12.5.2.5.1.2.1 Main Sequence – MCASP Global Initialization for DIT-Transmission

The procedure in [Table 12-504](#) initializes the MCASP serializers transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

#### CAUTION

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP\_GBLCTL register.

**Table 12-504. MCASP Transmitters Global Initialization for DIT-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP components.	MCASP_GBLCTL[12-8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12-8]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See <a href="#">Section 12.5.2.5.1.2.1.1</a> .	
5. Configure the transmit frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.1.2</a> .	
6. Configure the transmit clock generator.	See <a href="#">Section 12.5.2.5.1.2.1.3</a> .	
7. Configure the TDM sequencer—set all slots active.	MCASP_XTDM[31-0] XTDMs	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. <sup>(3)</sup>	MCASP_SRCTLn [1-0] SRMOD; n = 0 to 15	0x1
9. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.1.4</a> .	
10. Enable the MCASP DIT - transmission mode.	MCASP_DITCTL[0] DITEN	0x1 <sup>(2)</sup>
11. Configure DIT-specific subframe fields.	See <a href="#">Table 12-509</a> .	
12. Release from reset state the divider that outputs the AHCLKX clock. <sup>(1)</sup>	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKX clock. <sup>(1)</sup>	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKXCTL and MCASP\_ACLKXCTL registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

(2) This globally configures all active transmitters to operate in DIT-mode.

(3) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).

#### 12.5.2.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in [Table 12-505](#) configures the transmit frame format unit of the MCASP module for a DIT-transmission.

#### Note

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

**Table 12-505. Transmit Format Unit Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_XFMT[7-4] XSSZ	0xF
<b>IF:</b> the data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_XMASK[31-0] XMASK	0x- <sup>(1)</sup>
Rotate data right by a multiple-of-4- bit positions.	MCASP_XFMT[2-0] XROT	0x- <sup>(1)</sup>
<b>ELSE</b>		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_XMASK[31-0] XMASK	0x- <sup>(1)</sup>
Rotate data right by 0-bit positions.	MCASP_XFMT[2-0] XROT	0x0
<b>ENDIF</b>		

**Table 12-505. Transmit Format Unit Configuration for DIT-Transmission (continued)**

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_XFMT[3] XBUSEL	0x-

(1) Refer to [Section 12.5.2.4.5.1](#), *Transmit Format Unit* and [Section 12.5.2.4.5.1.2](#), *DIT-Mode Transmission Data Alignment Settings*.

#### 12.5.2.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in [Table 12-506](#) configures the transmit frame synchronization generator of the MCASP module.

#### Note

The frame synchronization signal is always rising-edge active and always has a single-bit width.

**Table 12-506. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_AFSXCTL[15-7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_AFSXCTL[1] FSXM	0x1

#### 12.5.2.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

#### Note

By default, the ACLKX and AHCLKX clocks are generated only from the MCASP internal clock source.

The procedure in [Table 12-507](#) configures the transmit clock generator of the MCASP module.

**Table 12-507. Transmit Clock Generator Configuration in DIT-Mode**

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11-0] HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4-0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.16.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.1.4 Subsequence - MCASP Pins Functional Configuration

The procedure in [Table 12-508](#) configures the MCASP pins for MCASP functionality.

**Table 12-508. MCASP Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31-0]	0x0
Configure the MCASP pins as outputs:		
AFSX	MCASP_PDIR[28] AFSX;	0x1
AHCLKX	MCASP_PDIR[27] AHCLKX;	0x1
ACLKX	MCASP_PDIR[26] ACLKX;	0x1
Desired i-th MCASP data pin AXRi is configured as an output for DIT-transmission.	MCASP_PDIR [i] AXRi	0x1

#### 12.5.2.5.1.2.1.5 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in [Table 12-509](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

**Table 12-509. DIT-Specific Subframe Fields Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_DITCTL[3] VB	0x-

**Table 12-509. DIT-Specific Subframe Fields Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for even time slots.	MCASP_DITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31-0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31-0] DITUDRBi, where i = 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRai[31-0], where i = 0 to 5 MCASP_DITCSRBi[31-0], where i = 0 to 5	0x- 0x-

#### 12.5.2.5.1.2.2 Main Sequence – MCASP Global Initialization for TDM-Reception

The procedure in [Table 12-510](#) initializes a MCASP serializer n receiver(s) to operate in TDM-mode (the only mode supported by MCASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

#### CAUTION

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP\_GBLCTL register.

#### Note

The MCASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (this is, S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device MCASP receiver input (TDM-only compatible).

**Table 12-510. MCASP Receivers Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP receive components.	MCASP_GBLCTL[4-0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4-0]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the receive format unit.	See <a href="#">Section 12.5.2.5.1.2.2.1</a> .	
5. Configure the receive frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.2.2</a> .	
6. Configure the receive clock generator.	See <a href="#">Section 12.5.2.5.1.2.2.3</a> .	
7. Program all bits - RTDMSk (where k = 0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RTDM[k] RTDMSk, where k = 0 to 31	0x-
8. Configure the desired n-th serializer for receive mode operation. <sup>(4)</sup>	MCASP_SRCTLn [1-0] SRMOD; n = 0 to 15	0x2
9. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.2.4</a> .	
10. Optional: Configure a MCASP Rx channel for a loopback operation (TDM mode only) in MCASP_DLBCTL [31-0].	See <a href="#">Section 12.5.2.4.15.1</a> , <i>Loopback Mode Configurations</i> .	0x- <sup>(5)</sup>
11. Release from reset state the divider that outputs the AHCLKR clock. <sup>(1)</sup> See also <sup>(2)</sup> .	MCASP_GBLCTL[1] RHCLKRST	0x1
12. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(2)</sup> .	MCASP_GBLCTL[1] RHCLKRST	=0x1
13. Release from reset state the divider that outputs the ACLKR clock. <sup>(1)</sup> See also <sup>(3)</sup> .	MCASP_GBLCTL[0] RCLKRST	0x1

**Table 12-510. MCASP Receivers Global Initialization for TDM-Mode Operation (continued)**

Step	Register/Bit Field/Programming Model	Value
14. Poll the bit to ensure that it is successfully latched in the register. See also <sup>(3)</sup> .	MCASP_GBLCTL[0] RCLKRST	=0x1

- (1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKRCTL and MCASP\_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.
- (2) This step is necessary even if external high-frequency serial clocks are used.
- (3) This step can be skipped if external serial clocks are used and they are running.
- (4) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).
- (5) In this case the receiver clock and frame sync are derived from the MCASP transmitter logic, so MCASP\_ACLKXCTL[6] ASYNC must be set to 0b0. Neither MCASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

#### 12.5.2.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in [Table 12-511](#) configures the receive frame format unit of the MCASP module for TDM slots reception.

**Table 12-511. Receive Format Unit Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RFMT[7-4] RSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RMASK[31-0] RMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	MCASP_RFMT[14-13] RPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RBUF <sub>n</sub> which value to be used as a pad value in case MCASP_RFMT[14-13] RPAD = 0x2. (n = 0 to 15)	MCASP_RFMT[12-8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RFMT[2-0] RROT	0x- <sup>(3)</sup>
Received stream bit order (LSB- or MSB-first ). Must be set to 0x1 for an I2S stream reception (MSB-first).	MCASP_RFMT[15] RRVRS	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream reception.	MCASP_RFMT[17-16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RFMT[3] RBUSEL	0x-

- (1) Refer to [Section 12.5.2.4.5.2, Receive Format Unit](#), regarding options for received TDM-slot sizes.
- (2) For more details on Rx masking value, refer to [Section 12.5.2.4.5.2.1, TDM - Mode Reception Data Alignment Settings](#)
- (3) For more details on rotation and received TDM stream bit order, refer to [Section 12.5.2.4.5.2.1, TDM - Mode Reception Data Alignment Settings](#) and [Table 12-498, MCASP RFU Settings](#).

#### 12.5.2.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 12-512](#) configures the transmit frame synchronization generator of the MCASP module.

#### Note

The same bit - MCASP\_ACLKXCTL[6] ASYNC which is used to determine if MCASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either internally or externally sourced). Hence, the settings in below table [Table 12-512](#) have no effect, if MCASP\_ACLKXCTL[6] ASYNC = 0.

**Table 12-512. Receive Frame-Synchronization Generator Configuration for TDM-Reception**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2, in case of an I2S-reception. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[15-7] RMOD	0x- <sup>(1)</sup>

**Table 12-512. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)**

Step	Register/Bit Field/Programming Model	Value
Choose the receive frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[0] FSRP	0x-
<b>IF</b> receive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[1] FSRM	0b1
If MCASP receiver is required to output internally generated frame, AFSR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 12-510</a> . This must not be done in current step because the frame control register - MCASP_AFSXCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
<b>ELSE</b>		
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3</a> .	MCASP_AFSRCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: MCASPi_AFSR)	MCASP_PDIR[31] AFSR	0b0
<b>ENDIF</b>		
To generate MCASP receive frame sync in receiver logic, select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

(1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to *MCASP Integration*.

#### 12.5.2.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in [Table 12-513](#) configures the receive clock generator of the MCASP module.

#### Note

The settings in below table [Table 12-513](#) have no effect, if MCASP\_ACLKXCTL[6] ASYNC = 0 (this is, receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when MCASP loopback mode is used.

**Table 12-513. Receive Clock Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
To use the MCASP receive clock generator, select an asynchronous receiver clock schema (ASYNC = 1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
<b>IF</b> receive clock - RCLK is internally generated	Software test condition	
The high-speed receive clock - AHCLKR is internally generated based on AUXCLK		
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity: non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11-0] HCLKRDIV	0x-

**Table 12-513. Receive Clock Generator Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4-0] CLKRDIV	0x-
Optional: If MCASP receiver is required to output internally generated clock, ACLKR pin must be set as an output in step 9 of the sequence documented in the <a href="#">Table 12-510</a> . This must not be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
<b>ELSE</b>		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising/falling edge. Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input direction for the ACLKR pin	MCASP_PDIR[29] ACLKR	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.16.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.2.4 Subsequence—MCASP Receiver Pins Functional Configuration

The procedure in [Table 12-514](#) configures the MCASP pins for MCASP functionality.

**Table 12-514. MCASP Receiver Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31-0]	0x0
Configure the MCASP pins direction:	MCASP_PDIR[31] AFSR;	0x-(1)
AFSR	MCASP_PDIR[29] ACLKR;	0x-(2)
ACLRK	MCASP_PDIR[n] AXRn;	0x0
Desired n-th MCASP data pin AXRn is configured as an input for receiving.		

(1) See [Table 12-512](#).

(2) For more details on MCASP clock configurations, refer to [Table 12-513](#).

#### 12.5.2.5.1.2.3 Main Sequence – MCASP Global Initialization for TDM -Transmission

The procedure in [Table 12-515](#) initializes a MCASP serializer n transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

#### CAUTION

Before performing MCASP global initialization, If external clock ACLKR is used, it must be running already for proper synchronization of the MCASP\_GBLCTL register.

**Table 12-515. MCASP Transmitters Global Initialization for TDM-Mode Operation**

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP transmit components.	MCASP_GBLCTL[12-8]	0x00

**Table 12-515. MCASP Transmitters Global Initialization for TDM-Mode Operation (continued)**

Step	Register/Bit Field/Programming Model	Value
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12-8]	=0x00
3. Configure the local power management.	MCASP_PWRIDLESYSCONFIG[1-0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See <a href="#">Section 12.5.2.5.1.2.3.1</a> .	
5. Configure the transmit frame sync generator.	See <a href="#">Section 12.5.2.5.1.2.3.2</a> .	
6. Configure the transmit clock generator.	See <a href="#">Section 12.5.2.5.1.2.3.3</a> .	
7. Program all bits - XTDMSk, where k = 0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_XTDM[k] XTDMSk, where k = 0 to 31 <sup>(4)</sup>	0x-
8. Configure the desired n-th serializer for transmit mode operation. <sup>(3)</sup>	MCASP_SRCTLn[1-0] SRMOD; n = 0 to 15	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_DITCTL[0] DITEN	0x0 <sup>(2)</sup>
10. Configure the MCASP pins functionality.	See <a href="#">Section 12.5.2.5.1.2.3.4</a> .	
11. Optional: Configure a MCASP Tx channel for loopback operation (TDM mode only) in MCASP_DLBCTL [31-0].	See <a href="#">Section 12.5.2.4.15.1</a> , <i>Loopback Mode Configurations</i> .	0x-
12. Release from reset state the divider that outputs the AHCLKR clock. See <sup>(1)</sup>	MCASP_GBLCTL[9] XHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. See <sup>(1)</sup>	MCASP_GBLCTL[8] XCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

- (1) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP\_AHCLKXCTL and MCASP\_ACLKXCTL registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.
- (2) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.
- (3) For an unused serializer n, write MCASP\_SRCTLn [1-0] SRMOD = 0x0 to disable it (n = 0 to 15).
- (4) Appropriately program in the MCASP\_SRCTLn[3-2] DISMOD bit field, the desired level (high-impedance state, 0, or 1) at AXRn output, during time of inactive slots. Note, that this setting does NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode) (n = 0 to 15).

#### 12.5.2.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in [Table 12-516](#) configures the transmit frame format unit of the MCASP module for TDM slots transmission.

**Table 12-516. Transmit Format Unit Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_XFMT[7-4] XSSZ	0x- <sup>(1)</sup>
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_XMASK[31-0] XMASK	0x- <sup>(2)</sup>
Select a padding value for masked-out bits.	MCASP_XFMT[14-13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_XBUFn which value to be used as a pad value in case MCASP_XFMT[14-13] XPAD = 0x2 (n = 0 to 15).	MCASP_XFMT[12-8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_XFMT[2-0] XROT	0x- <sup>(3)</sup>
transmitted stream bit order (LSB- or MSB-first). Must be set to 0x1 for an I2S stream transmission (MSB-first).	MCASP_XFMT[15] XRVRS	0x- <sup>(3)</sup>
Specify a delay between frame sync and first bit of data in number of bits. Must be set to 0x1 for an I2S stream transmission.	MCASP_XFMT[17-16] XDATDLY	0x-

**Table 12-516. Transmit Format Unit Configuration for TDM-Transmission (continued)**

Step	Register/Bit Field/Programming Model	Value
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_XFMT[3] XBUSEL	0x-

- (1) Refer to [Section 12.5.2.4.5.1, Transmit Format Unit](#), regarding options for transmitted TDM-slot sizes.
- (2) For more details on Tx masking value, refer to [Section 12.5.2.4.5.1.1, TDM - Mode Transmission Data Alignment Settings](#)
- (3) For more details on rotation and transmitd TDM stream bit order, refer to [Section 12.5.2.4.5.1.1, TDM - Mode Transmission Data Alignment Settings](#) and [Table 12-496, MCASP TFU TDM Mode Settings](#).

#### 12.5.2.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in [Table 12-517](#) configures the transmit frame synchronization generator of the MCASP module.

**Table 12-517. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission**

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2, in case of an I2S-transmission. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[15-7] XMOD	0x-
Choose the transmit frame sync width -single bit/single word. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[4] FXWID	0x-
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[0] FSXP	0x-
<b>IF</b> transmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[1] FSXM	0b1
If MCASP transmitter is required to output internally generated frame, AFSX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-515</a> . This must NOT be done in current step because the frame control register - MCASP_AFSXCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
<b>ELSE</b>		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to <a href="#">Section 12.5.2.4.2.3, Frame-Sync Generator</a> .	MCASP_AFSXCTL[1] FSXM	0b0
Setup the AFSX pin as input	MCASP_PDIR[28] AFSX	0b0

#### 12.5.2.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in [Table 12-518](#) configures the transmit clock generator of the MCASP module.

**Table 12-518. Transmit Clock Generator Configuration for TDM Cases**

Step	Register/Bit Field/Programming Model	Value
<b>IF</b> transmit clock - XCLK is internally generated	Software test condition	
<b>IF</b> high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11-0] HCLKXDIV	0x-

**Table 12-518. Transmit Clock Generator Configuration for TDM Cases (continued)**

Step	Register/Bit Field/Programming Model	Value
Optional: If MCASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-515</a> . This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1
<b>ELSE</b>		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity: non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input direction for the AHCLKX pin	MCASP_PDIR[27] AHCLKX	0b0
<b>ENDIF</b>		
Select an internally-generated transmit clock.	MCASP_AHCLKXCTL[5] CLKXM	0b1
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_AHCLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_AHCLKXCTL[4-0] CLKXDIV	0x-
Optional: If MCASP transmitter is required to output internally generated clock, ACLKX pin) must be set as an output in step 10 of the sequence documented in the <a href="#">Table 12-515</a> . This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
<b>ELSE</b>		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_AHCLKXCTL[5] CLKXM	0b0
Transmitter samples on rising/falling edge. Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.	MCASP_AHCLKXCTL[7] CLKXP	0x-
Setup an input direction for the ACLKX pin	MCASP_PDIR[26] ACLKX	0b0
<b>ENDIF</b>		
Configure the transmit clock failure detect logic.	See <a href="#">Section 12.5.2.4.16.6.1</a> , <i>Clock Failure Check Startup</i> .	

#### 12.5.2.5.1.2.3.4 Subsequence—MCASP Transmit Pins Functional Configuration

The procedure in [Table 12-519](#) configures the MCASP pins for MCASP functionality.

**Table 12-519. MCASP Transmit Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31-0]	0x0
Configure the MCASP pins direction:	MCASP_PDIR[28] AFSR;	0x-(1)
AFSX	MCASP_PDIR[27] AHCLKR;	0x-(2)
AHCLKX	MCASP_PDIR[26] ACLKR;	0x-(2)
ACLKX	MCASP_PDIR[n] AXRn	0x1
Desired n-th MCASP data pin AXRn is configured as an output for transmission.		

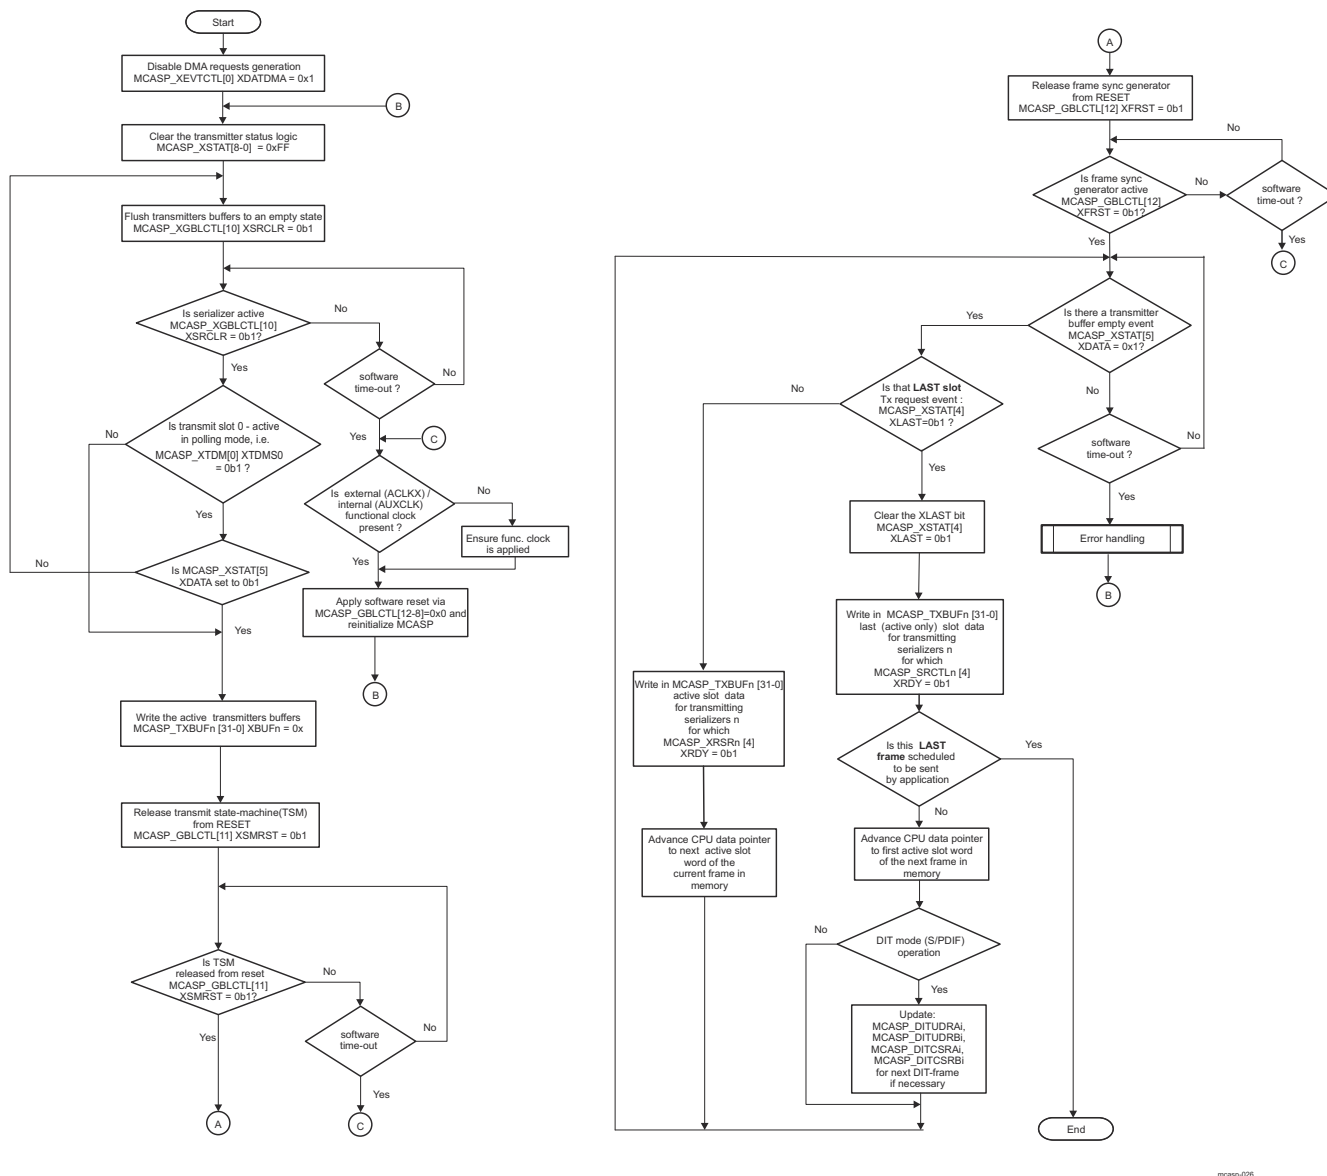

(1) See [Table 12-517](#).

### 12.5.2.5.2 MCASP Operational Modes Configuration

#### 12.5.2.5.2.1 MCASP Transmission Modes

##### 12.5.2.5.2.1.1 Main Sequence – MCASP DIT-/TDM- Polling Transmission Method

Figure 12-513 shows the MCASP DIT-/TDM- polling method.

**Figure 12-513. MCASP DIT-/TDM- Transmission Polling Method**

These registers are for MCASP DIT-/TDM- transmission polling method: MCASP\_XEVTCTL, MCASP\_XSTAT, MCASP\_GBLCTL, MCASP\_XTDM, MCASP\_XBUFn, MCASP\_SRCTLn, MCASP\_DITUDRAi, MCASP\_DITUDRbi, MCASP\_DITCSRai, MCASP\_DITCSRbi (n = 0 to 15 and i = 0 to 5).

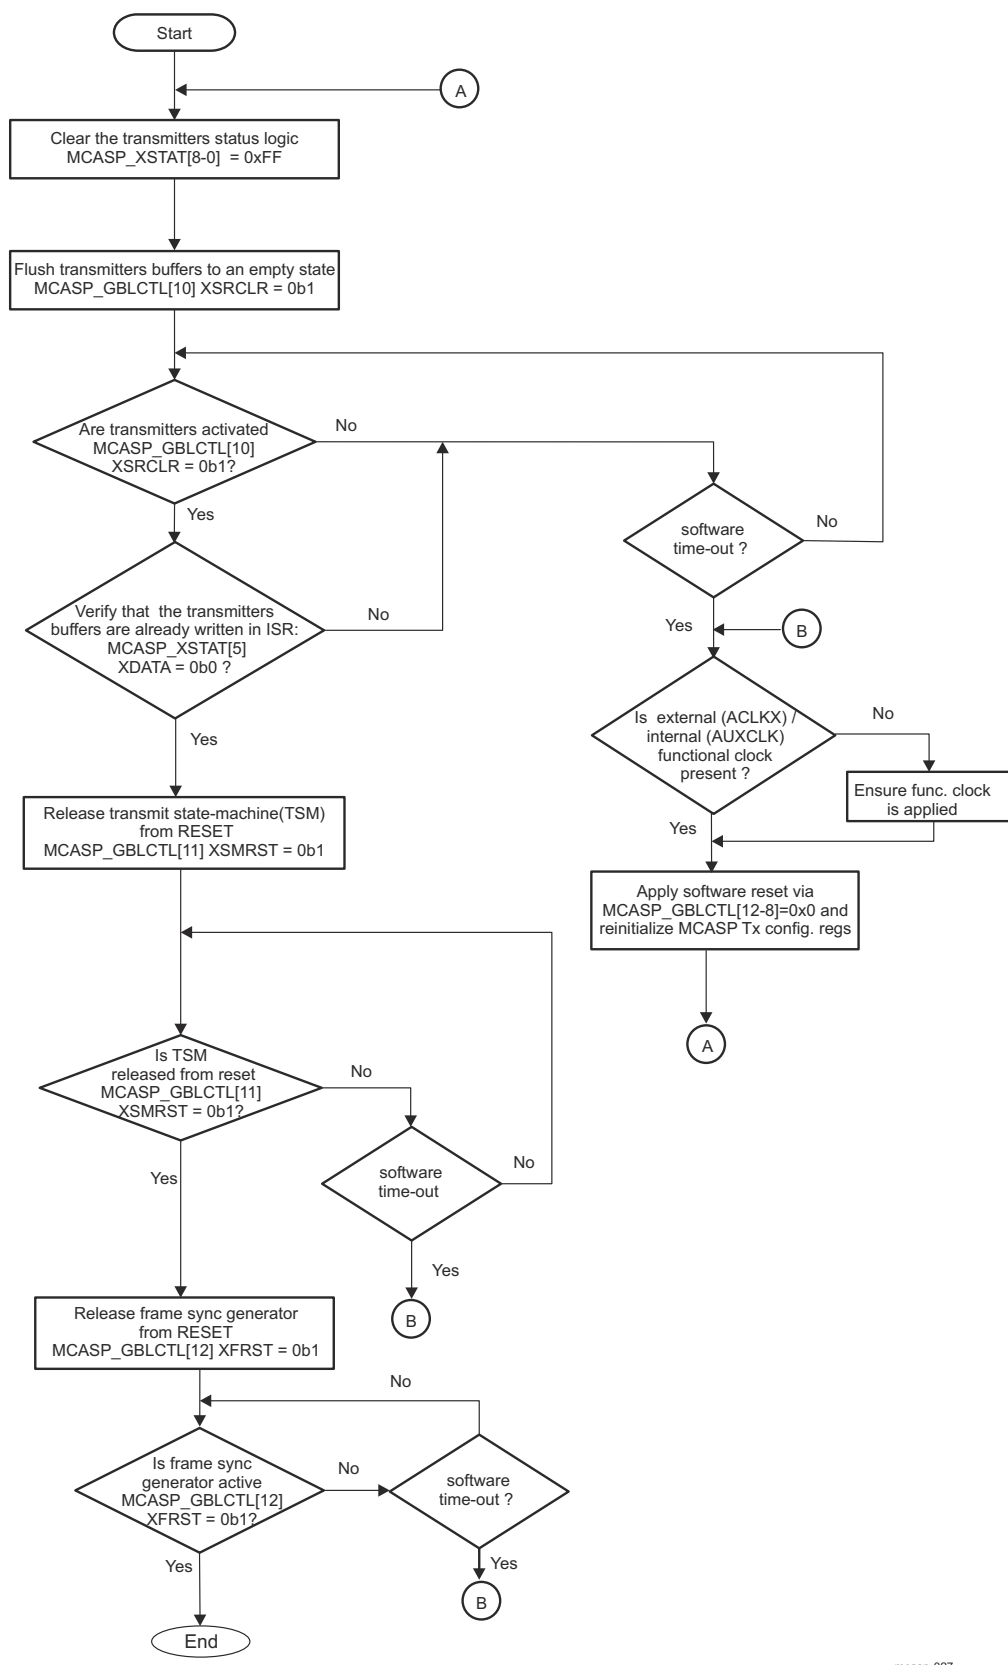

Table 12-520 summarizes the subprocess call for the DIT-/TDM- transmission polling mode.

**Table 12-520. Subprocess Call Summary for Main Sequence – MCASP DIT-/TDM- Transmission Polling Method**

Subprocess Name	Cross-Reference
Error handling	Figure 12-519

**12.5.2.5.2.1.2 Main Sequence – MCASP DIT- /TDM - Interrupt Transmission Method**

Figure 12-514 shows the initial setup for interrupt-based transmission.

mcasep-027

**Figure 12-514. Subsequence – DIT-/TDM- Transmission Startup Procedure**

Table 12-521 shows the configuration of the MCASP using an interrupt method for DIT-/TDM- transmission.

**Table 12-521. MCASP DIT-/TDM- Interrupt Transmission Model**

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_XINTCTL[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update).	MCASP_XINTCTL[4] XLAST	0x1
IF write transfer is through the MCASP DATA port (MCASP_XFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the MCASP Transmitters Global Initialization - see MCASP Transmitters Global Initialization for DIT-Mode Operation)	
Enable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_XINTCTL[3] XDMAERR	0x0
<b>ENDIF</b>		
DIT/TDM - Transmission Startup Procedure	See Figure 12-514.	

These registers are for MCASP DIT-/TDM- transmission startup procedure: MCASP\_GBLCTL, MCASP\_XSTAT.

#### 12.5.2.5.2.1.3 Main Sequence –MCASP DIT- /TDM - Mode DMA Transmission Method

Table 12-522 shows the configuration of the ↓ using the DMA method for transmission. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

**Table 12-522. MCASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_XFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_XEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of MCASP DATA port usage.	MCASP_XINTCTL[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_XINTCTL[2] XCKFAIL	0x1
	MCASP_XINTCTL[1] XSYNCERR	0x1
	MCASP_XINTCTL[0] XUNDRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_XINTCTL[7] XSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_XINTCTL[4] XLAST	0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_XINTCTL[5] XDATA	0x0
DMA startup transmission procedure. This procedure is identical than the one shown in Figure 12-514. The only difference is that DMA automatically services all the XINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 12-517.	See Figure 12-514.	

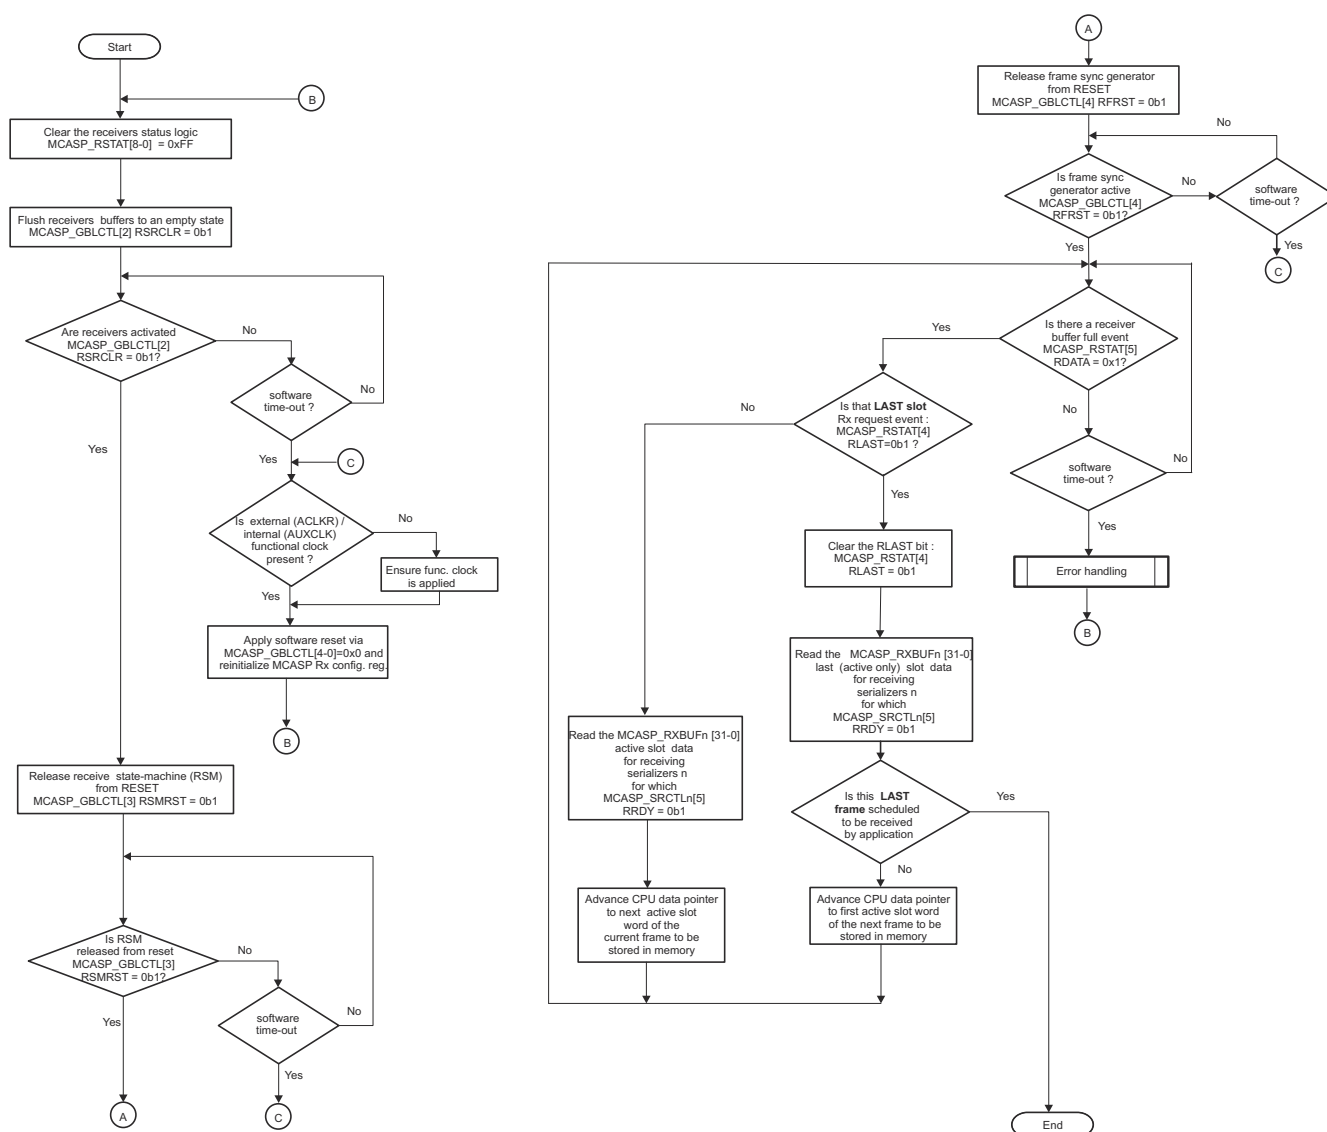

### 12.5.2.5.2.2 MCASP Reception Modes

#### 12.5.2.5.2.2.1 Main Sequence – MCASP Polling Reception Method

Figure 12-515 shows the MCASP polling reception method.

#### Note

The MCASP polling reception model considers the device CPUs as the accessor of audio data from the MCASP receive buffers.

mcaspp-028

**Figure 12-515. MCASP Polling Reception Method**

These registers are for MCASP reception polling method: MCASP\_RSTAT, MCASP\_XGBLCTL, MCASP\_RBUFn, MCASP\_SRCTLn (n = 0 to 15).

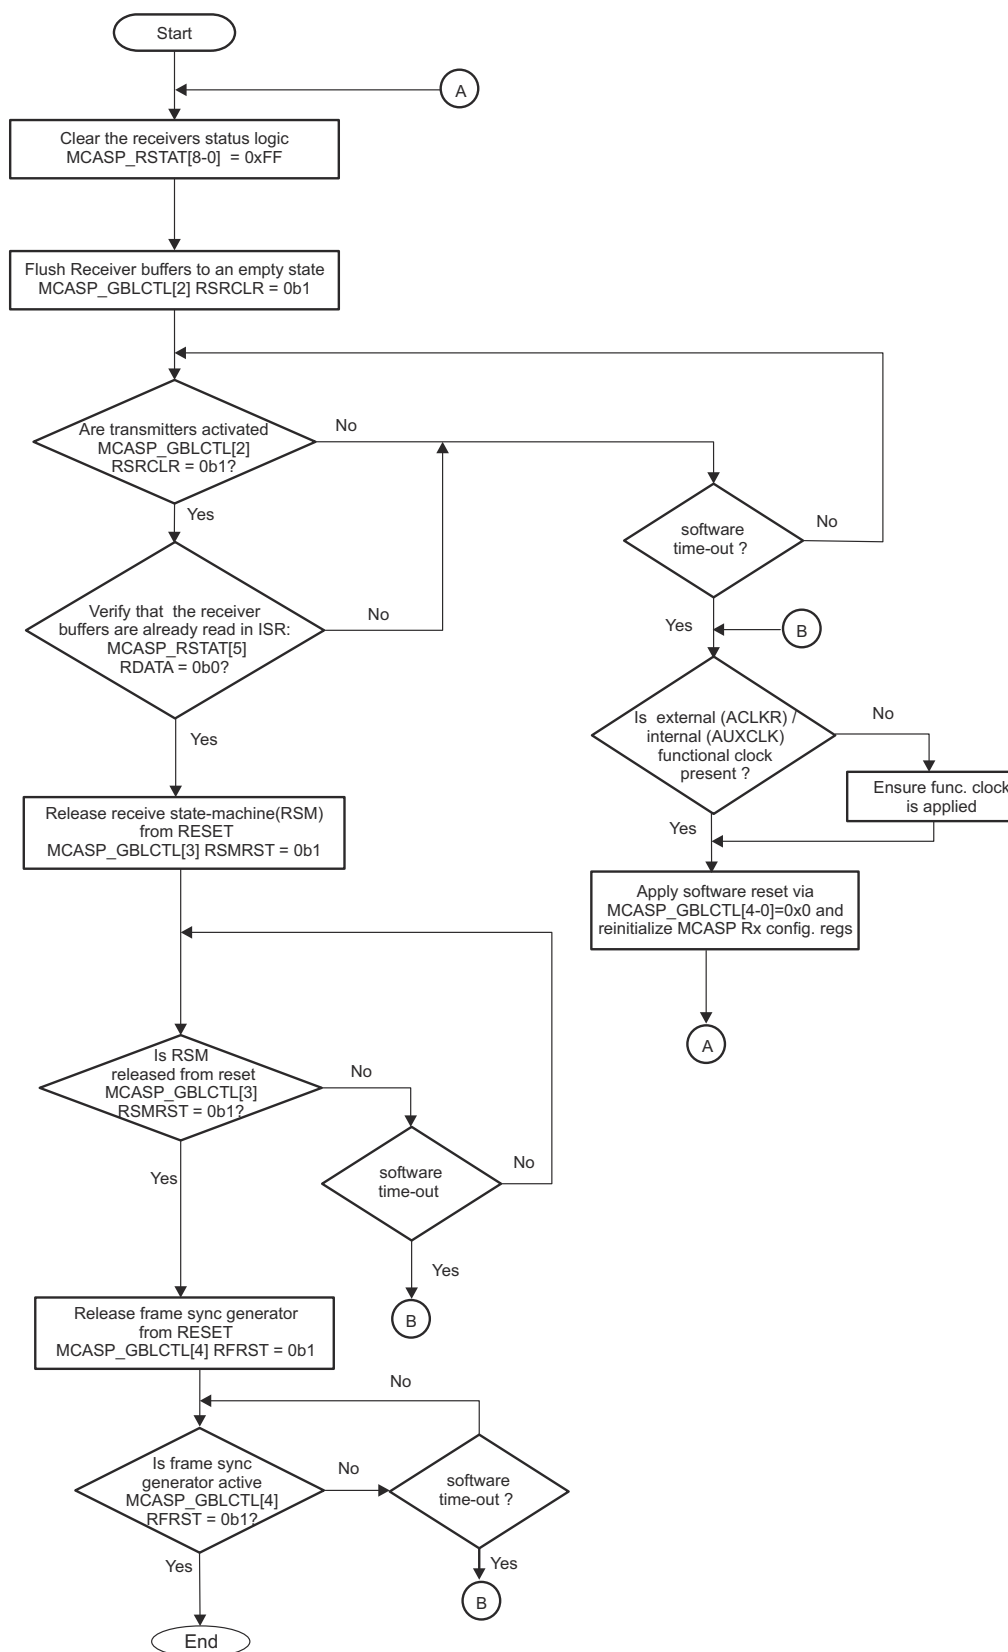

[Table 12-523](#) summarizes the subprocess call for the polling mode.

**Table 12-523. Subprocess Call Summary for Main Sequence – MCASP Reception Polling Method**

Subprocess Name	Cross-Reference
Error handling	<a href="#">Figure 12-520</a>

#### **12.5.2.5.2.2 Main Sequence – MCASP TDM - Interrupt Reception Method**

[Figure 12-516](#) shows the initial setup for interrupt-based reception.

mcasp-032

**Figure 12-516. Subsequence – TDM - Reception Startup Procedure**

Table 12-524 shows the configuration of the MCASP using an interrupt method for TDM- reception.

**Table 12-524. MCASP TDM- Interrupt Reception Model**

Step	Register/Bit Field/Programming Model	Value
Disable Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x1
Enable the data ready event receive interrupt.	MCASP_RINTCTL[5] RDATA	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt	MCASP_RINTCTL[4] RLAST	0x1
<b>IF</b> read transfer is through the MCASP DATA port (MCASP_RFMT[3] RBUSEL is set to 0b0).		
Software test condition (setting is done in step4 of the <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> - see <i>MCASP Receivers Global Initialization for TDM-Mode Operation</i> )		
Enable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x1
<b>ELSE</b>		
Disable the DATA port error based interrupt.	MCASP_RINTCTL[3] RDMAERR	0x0
<b>ENDIF</b>		
TDM - Transmission Startup Procedure	See <a href="#">Figure 12-516</a> .	

These registers are for MCASP TDM- interrupt reception model: MCASP\_XGBLCTL, MCASP\_RSTAT.

#### 12.5.2.5.2.2.3 Main Sequence – MCASP TDM - Mode DMA Reception Method

Table 12-525 shows the configuration of the MCASP using the DMA method for reception. Possible interrupt error event servicing is also considered. shows the initial setup for DMA - based transmission.

#### Note

Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

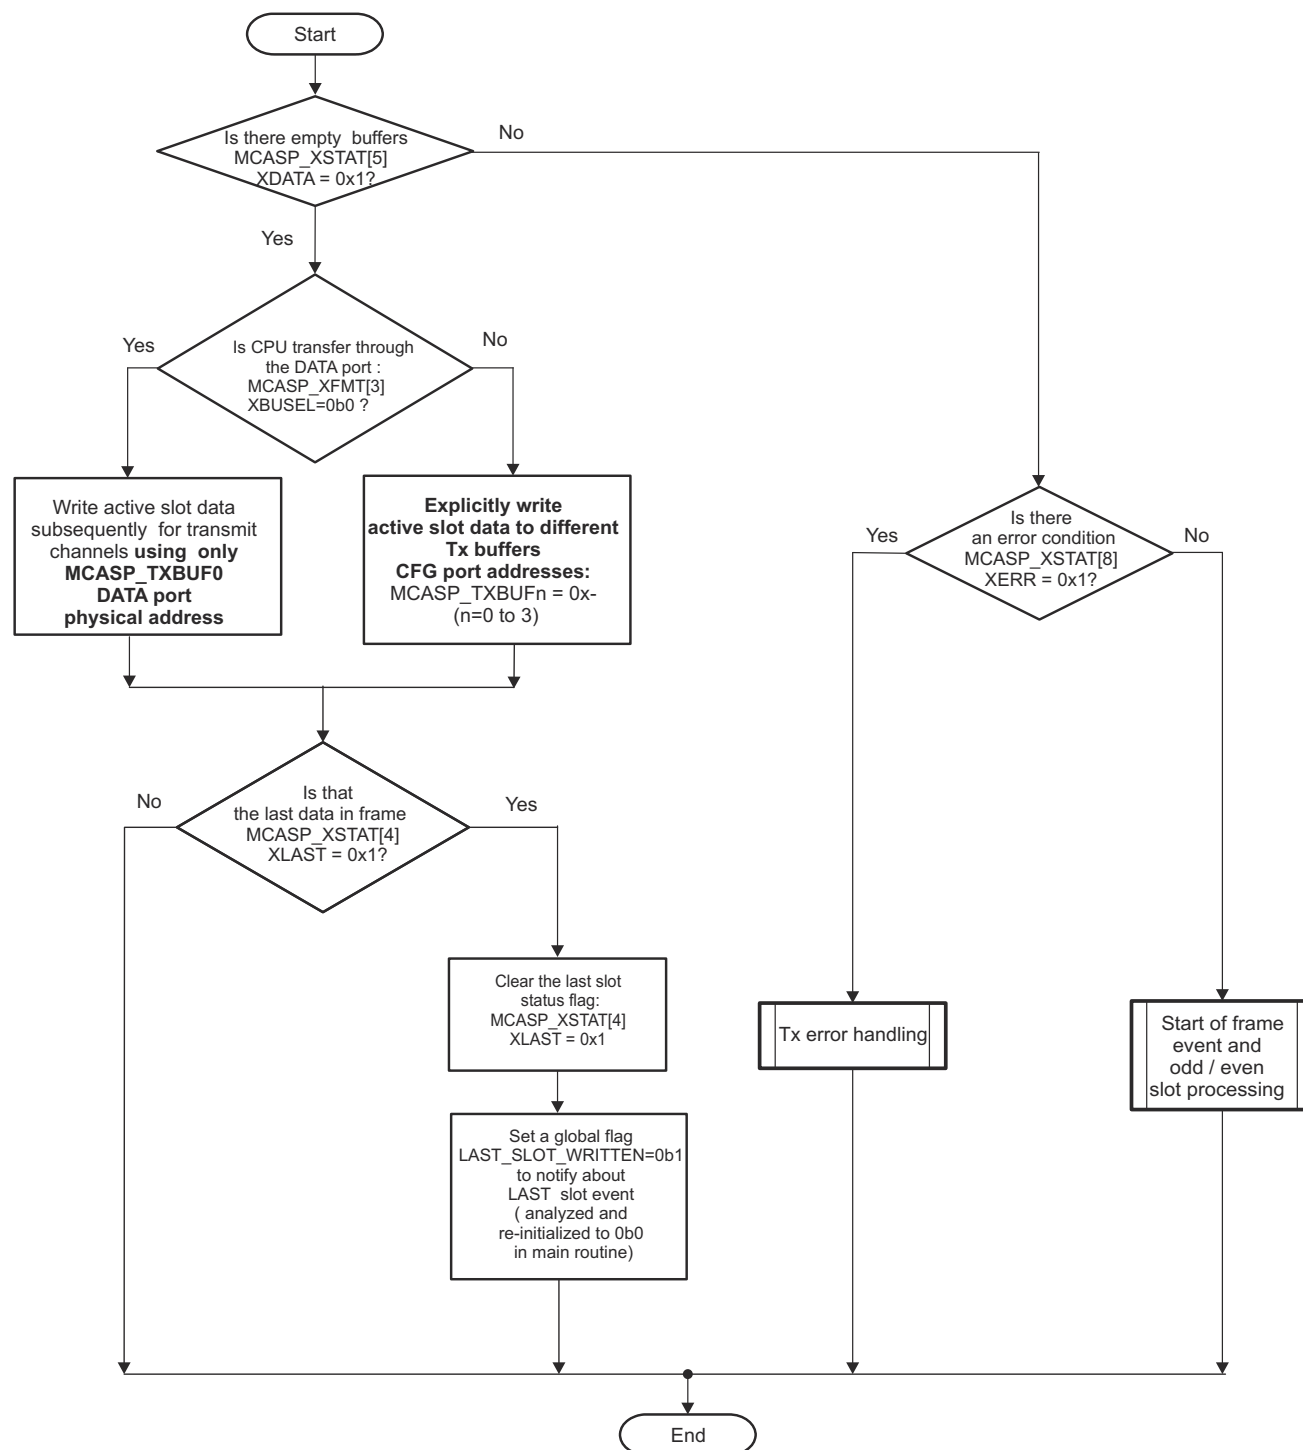

**Table 12-525. MCASP DMA Reception Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
<b>Recommended:</b> Select DATA port to access the transmit buffers.	MCASP_RFMT[3] RBUSEL	0x0
Enable the Rx DMA requests generation.	MCASP_PIDTCTL[0] RDATDMA	0x0
Enable the Rx DMA error event, because of MCASP DATA port usage.	MCASP_RINTCTL[3] RDMAERR	0x1
Optional: Enable the receive error event interrupts.	MCASP_RINTCTL[2] RCKFAIL	0x1
	MCASP_RINTCTL[1] RSYNCERR	0x1
	MCASP_RINTCTL[0] ROVRN	0x1
Optional: Enable the start of frame interrupt.	MCASP_RINTCTL[7] RSTAFRM	0x1
Optional: Enable the last slot data interrupt.	MCASP_RINTCTL[4] RLAST	0x1
Disable the data ready event receive interrupt, as DMA is used to service this request.	MCASP_RINTCTL[5] RDATA	0x0
DMA startup reception procedure. This procedure is identical than the one shown in <a href="#">Figure 12-516</a> . The only difference is that DMA automatically services all the RINT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in <a href="#">Figure 12-518</a> .	See <a href="#">Figure 12-516</a> .	

### 12.5.2.5.2.3 MCASP Event Servicing

#### 12.5.2.5.2.3.1 MCASP DIT-/TDM- Transmit Interrupt Events Servicing

Figure 12-517 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

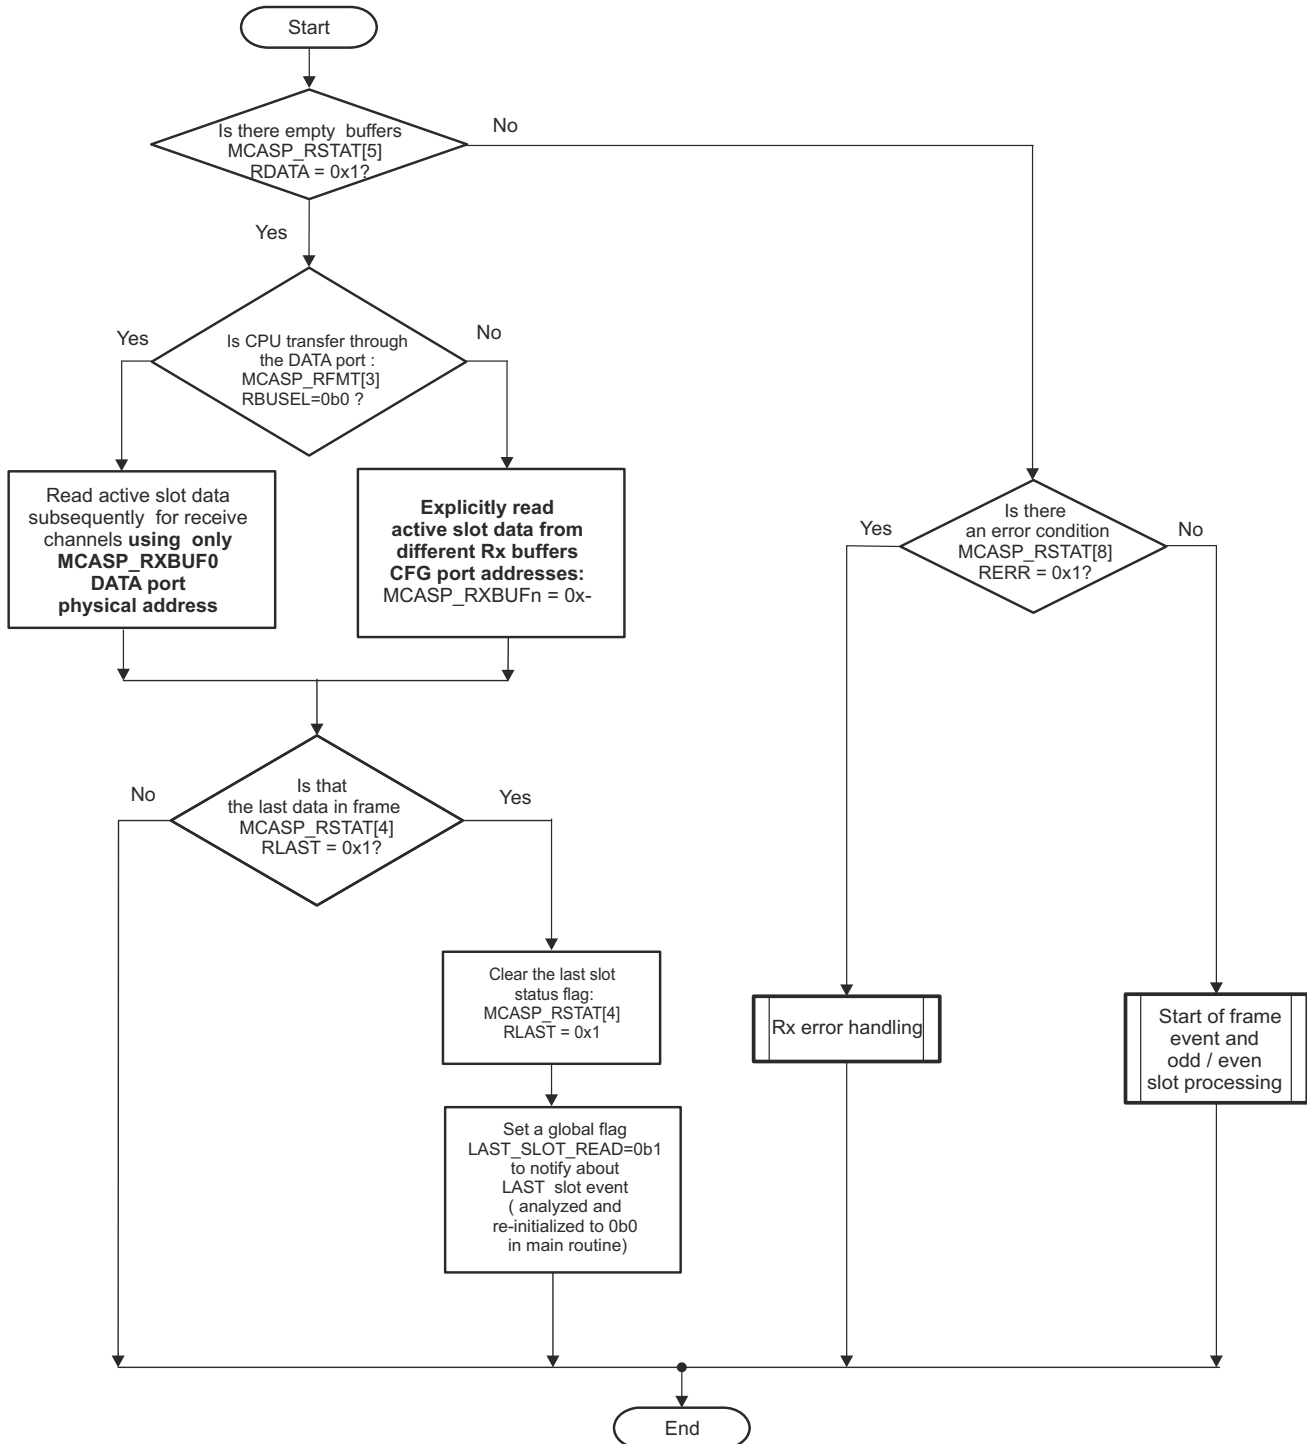

mcasp-029

**Figure 12-517. MCASP Transmit Interrupt Events Servicing**

### 12.5.2.5.2.3.2 MCASP TDM- Receive Interrupt Events Servicing

Figure 12-518 shows the flow of DIT-/TDM- mode transmit interrupt events servicing for the MCASP module.

mcasp-033

**Figure 12-518. MCASP Receive Interrupt Events Servicing**

These registers are for MCASP receive interrupt events servicing: MCASP\_RSTAT, MCASP\_RBUF<sub>n</sub>, MCASP\_RFMT (n = 0 to 15).

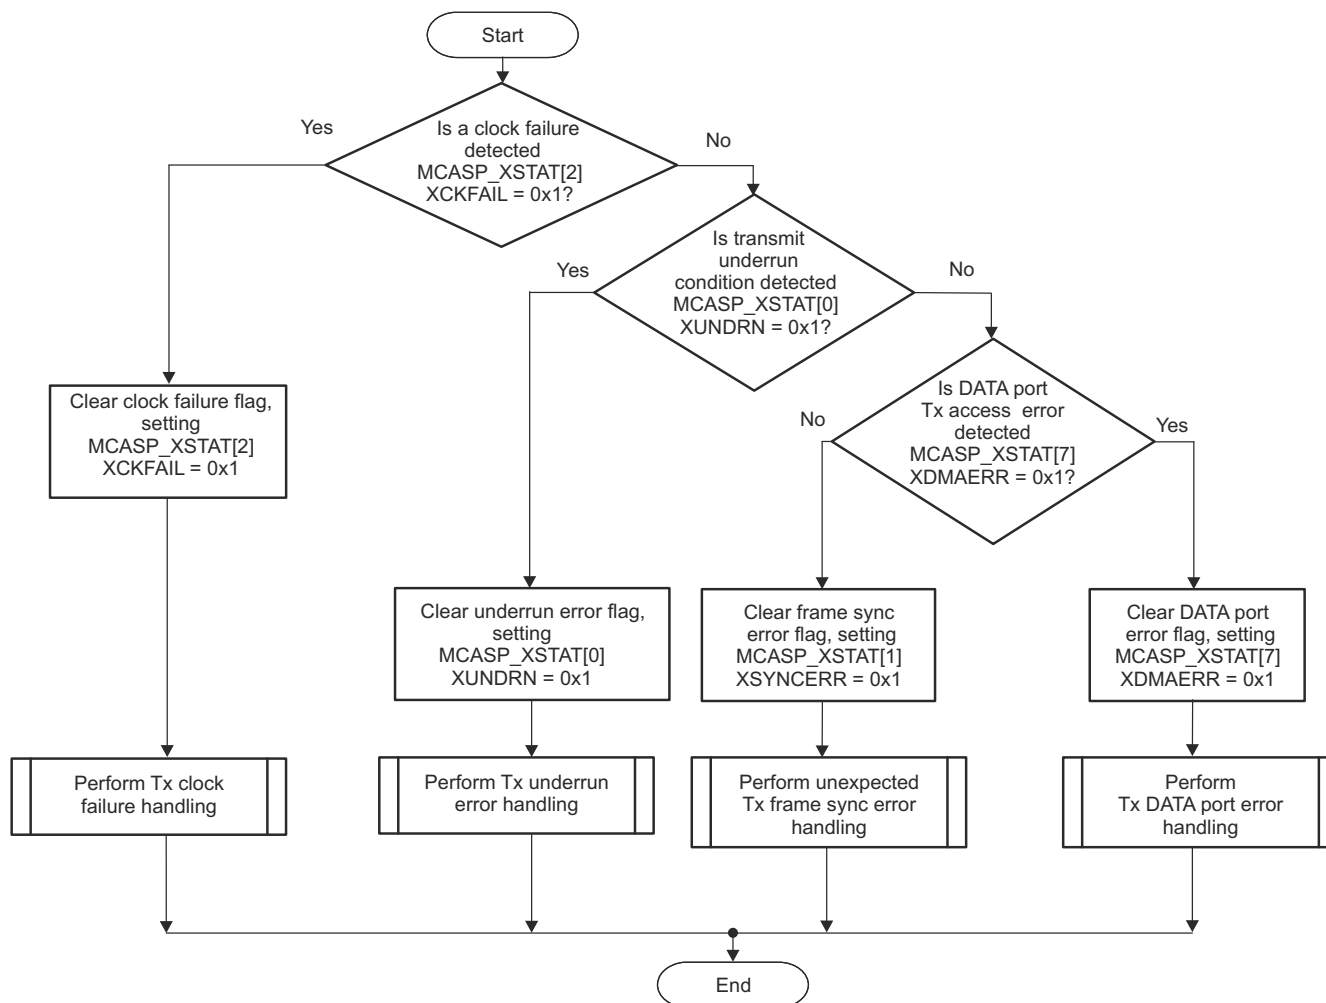

Table 12-526 lists the subprocess call summary for receive interrupt events servicing.

**Table 12-526. Subprocess Call Summary for Receive Interrupt Events Servicing**

Subprocess Name	Cross-Reference
MCASP receive error handling	Figure 12-520
Start of frame handling	Section 12.5.2.4.13.2, <i>Receive Data Ready Event and Interrupt</i>

### 12.5.2.5.2.3.3 Subsequence – MCASP DIT-/TDM -Modes Transmit Error Handling

Figure 12-519 shows the transmit error handling schema for the MCASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

mcasp-030

**Figure 12-519. MCASP Transmit Error Handling**

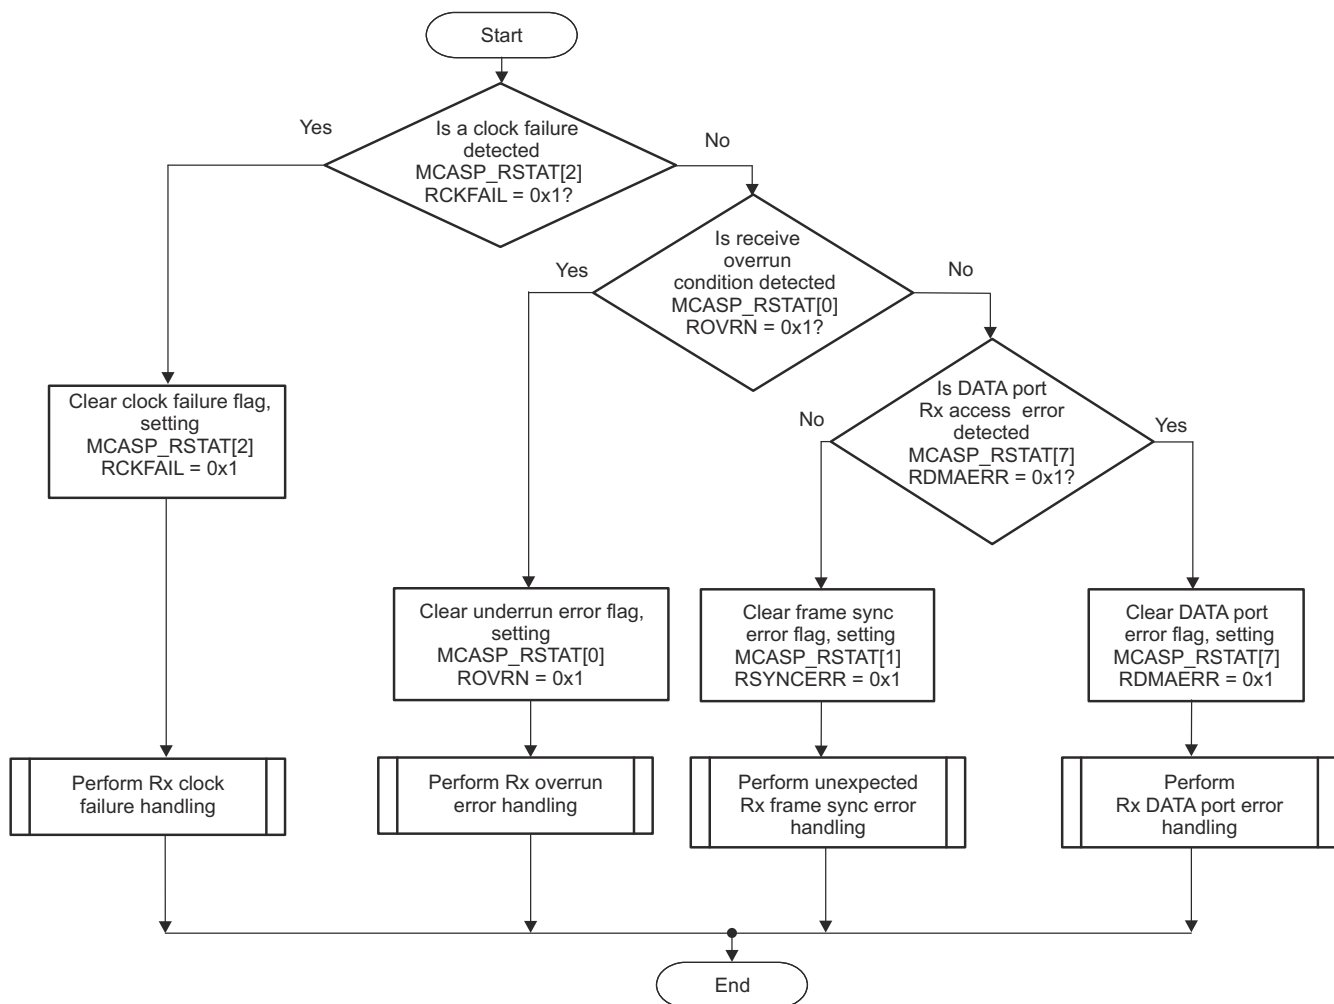

### Note

- For more information about transmit clock failure handling, see [Section 12.5.2.4.16.6.2, Transmit Clock Failure Check and Recovery](#).
- For more information about transmit buffer underrun handling, see [Section 12.5.2.4.16.1, Buffer Underrun Error - Transmitter](#).
- For more information about DATA port Tx error handling, see [Section 12.5.2.4.16.3, DATA Port Error - Transmitter](#).
- For more information about unexpected Tx frame sync error handling, see [Section 12.5.2.4.16.5, Unexpected Frame Sync Error](#).

#### 12.5.2.5.2.3.4 Subsequence – MCASP Receive Error Handling

Figure 12-520 shows the receive error handling schema for the MCASP, which can ONLY be implemented as part of the Rx polling sequence.

mcasp-031

**Figure 12-520. MCASP Receive Error Handling**

This register is for MCASP receive error handling: MCASP\_RSTAT.

---

**Note**

- For more information about receive clock failure handling, see [Section 12.5.2.4.16.6.3](#), *Receive Clock Failure Check and Recovery*.
  - For more information about receive buffer overrun handling, see [Section 12.5.2.4.16.2](#), *Buffer Overrun Error - Receiver*.
  - For more information about DATA port Rx error handling, see [Section 12.5.2.4.16.4](#), *DATA Port Error - Receiver*.
  - For more information about unexpected Rx frame sync error handling, see [Section 12.5.2.4.16.5](#), *Unexpected Frame Sync Error*.

## 12.6 Display Subsystem (DSS) and Peripherals

This section describes the Display Subsystem (DSS) in the device, integrated together with display peripherals, such as the MIPI Display Serial Interface (DSI) transmitter host controller with associated MIPI DSI (Physical Layer) D-PHY module (DPHY\_TX), and the Embedded Display Port (eDP) transmitter with associated SerDes and auxiliary complex I/O (eDP AUXPHY) modules.

### 12.6.1 DSS Overview

The DSS is a flexible composition-enabled display subsystem, that supports multiple high resolution display outputs. It consists of a Display Controller (DISPC) and a Frame Buffer Decompression Core (FBDC). The DISPC supports a multi-layer blending and transparency for each of its display outputs. The DISPC also supports a write-back pipeline with scaling to enable memory-to-memory composition and/or to capture a display output for Ethernet video encoding. The DISPC supports gamma correction and programmable color control in both source and destination pipelines for enhanced color space control and video output quality. The DISPC video outputs connect to various display interface controllers, integrated at the SoC level, to drive specific displays in the end application. The DSS also includes freeze frame detection and data signature check capabilities for each display output path.

The MIPI DSI v1.3.1 Controller (DSITX) implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI 1.3 standard. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes). The accompanying DSI (Physical Layer) D-PHY module (DPHY\_TX) provides the video output interfacing by implementing a four-lane MIPI D-PHY transmitter.

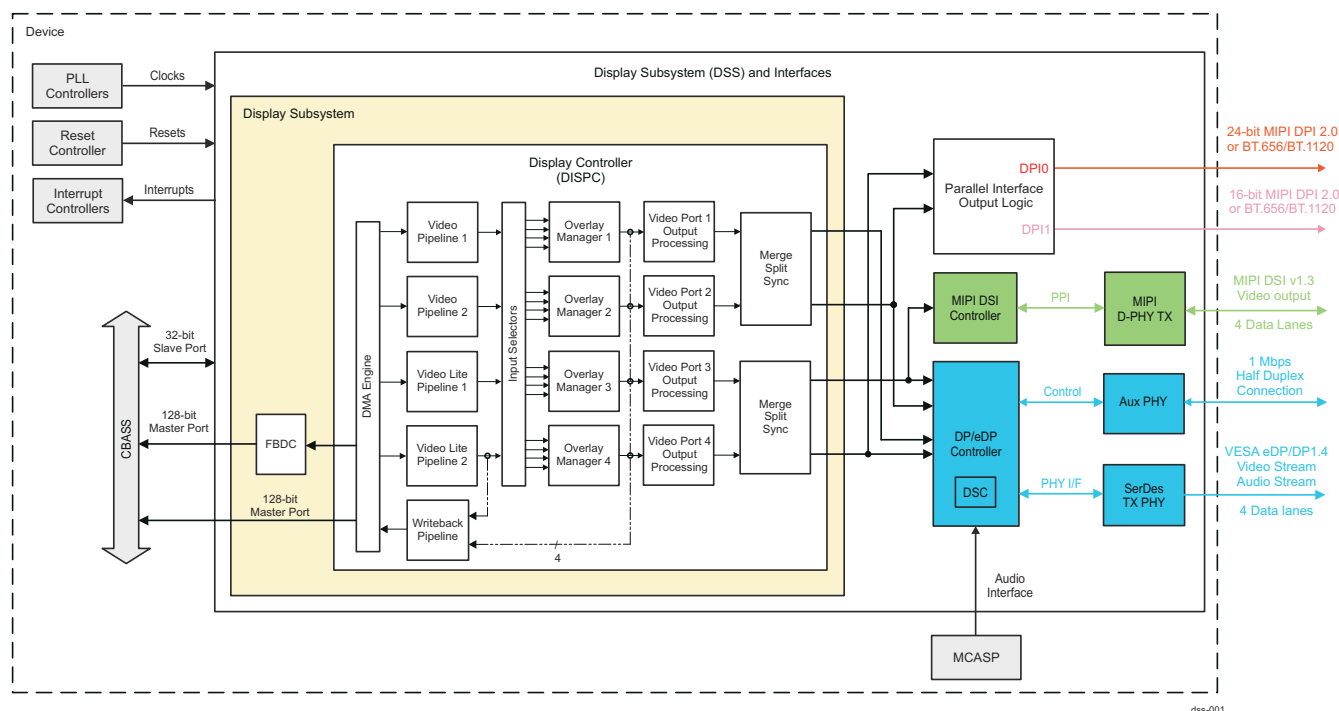

The VESA DP1.4/eDP1.4 Compliant Transmitter Host Controller (EDP) can output up to 4 video streams (through Multiple Stream Transport / MST) and one audio stream through the 4-lane accompanying SerDes module. It provides up to 25.92 Gbps of application bandwidth. An additional auxiliary PHY (AUXPHY) module implements a doubly-terminated differential pair required for 1 Mbps data rates over a long (15m) cable. This is a half duplex, Manchester II encoded connection, used by the EDP to configure the link. The AUX channel is used to access the Display Port Configuration Data (DPCD) memory area in the sink device and to implement VESA Enhanced Extended Display Identification Data (EDID) function.

[Table 12-527](#) shows the DSS and display peripherals allocation across device domains.

**Table 12-527. DSS and Display Peripherals Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DSS0 (DISPC0 and FBDC)	-	-	✓
DSI0 with shared DPHY_TX0	-	-	✓
EDP0 with AUXPHY0	-	-	✓

[Figure 12-521](#) shows an overview of the DSS module and connections to the display peripherals.

**Figure 12-521. DSS and Display Peripherals Overview**

### 12.6.1.1 DSS Features

The Display Controller (DISPC) supports:

- An embedded DMA Controller with the following features:
  - Support for 1D-only DMA transfers
  - Support for 48b addressable memory space
  - Support for memory fragmentation through external PAT (Page Address Translation) table at SoC level
  - Integrated shared buffer management for pipelines within the same DMA controller group
    - Support for up to 8K-pixels wide frame buffer for 8/16/32/64 bits per pixel (total buffer space requirement not exceeding the total DMA buffer size of the DISPC)
  - Programmable DMA request management
    - Programmable buffer thresholds for request priority
    - Bandwidth limiter on write requests (insertion on idle cycles between requests)
    - Self-refresh using the DMA buffers
    - Arbitration between normal/low priority pipelines
  - Support for source image flip along X and Y-axis
  - Support for secure access to firewall protected frame buffer in DDR memory
- Two input display processing Video Pipelines, each supporting:
  - Input RGB source pixel formats:
    - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB16-565/BGR16-565 with a separate A8 plane
    - RGB24-888, BGR24-888
    - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
    - ARGB64-16161616, RGBA64-16161616

- Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
- Pre-multiplied ARGB/RGBA formats
- Input YUV source pixel formats:
  - Packed: YUV422-UYYVY, YUV422-YUV2
  - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
  - 8-bit per component support for all YUV formats
  - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
  - 16-bit unpacked source format (internally processed as 10-bit component data)
- Programmable poly-phase filter (scaler):
  - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25)
  - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
  - Alpha blending factor is re-scaled like the R, G and B color components
  - Implementation with 16 phases with symmetrical coefficients
- Programmable color space conversion from YUV422/YUV420 (chroma upsampled to YUV444 using the scaler) into ARGB48-12121212
- Programmable VC1 range mapping
- Programmable Brightness/Contrast/Hue/Saturation
- Programmable Gamma Correction LUT
- Luma Key generation
- 10-bit processing pipeline
- Two input display processing Video Lite Pipelines, each supporting:
  - Input RGB source pixel formats:
    - Bitmap-1, Bitmap-2, Bitmap-4, Bitmap-8
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB16-565/BGR16-565 with a separate A8 plane
    - RGB24-888, BGR24-888
    - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
    - ARGB64-16161616, RGBA64-16161616
    - Additionally, equivalent RGBx, xRGB, xBGR, and BGRx pixel formats defined, considering that A component of RGBA, ARGB, ABGR, BGRA pixel formats is ignored by HW (for example, ARGB → xRGB); ("A" can be ignored by not selecting Alpha pixel)
    - Pre-multiplied ARGB/RGBA formats
  - Input YUV source pixel formats:
    - Packed: YUV422-UYYVY, YUV422-YUV2
    - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
    - 8-bit per component support for all YUV formats
    - 10-bit IMG pack-format and 12-bit TI fully packed format support for 420/422 (internally processed as 10-bit component data)
    - 16-bit unpacked source format (internally processed as 10-bit component data)
  - YUV420 to YUV422 chroma upsampling using an average filter
  - YUV422 to YUV444 chroma upsampling using a 4-tap filter based on Catmull-Rom algorithm
  - Programmable color space conversion from YUV422/YUV420 into ARGB48-12121212
  - Programmable VC1 range mapping
  - Programmable Brightness/Contrast/Hue/Saturation
  - Programmable Gamma Correction LUT
  - Luma Key generation

- 10-bit processing pipeline
- One Write-back (WB) pipeline, supporting:
  - Destination RGB pixel formats:
    - ARGB16-4444, ABGR16-4444, RGBA16-4444, RGB16-565, BGR16-565, ARGB16-1555, ABGR16-1555
    - RGB24-888 (no support for BGR24-888)
    - RGB16-565/BGR16-565 with a separate A8 plane
    - ARGB32-8888, ABGR32-8888, BGRA32-8888, RGBA32-8888, ARGB32-2101010, ABGR32-2101010
    - ARGB64-16161616, RGBA64-16161616
  - Destination YUV pixel formats:
    - Packed: YUV422-UYVY, YUV422-YUV2
    - 2-plane: YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21
    - Only 8-bit output support for YUV formats
  - Programmable poly-phase filter (scaler):
    - Independent horizontal and vertical re-sampling: up-sampling (up to x16) and down-sampling (down to x0.25). When the output format of the WB pipeline includes a format change RGB/YUV422 → YUV420, the maximum downscaling provided by the WB scaler is x0.5.
    - Maximum input width of 2048 pixels using ARGB pixels and 5-tap, 4096 pixels using YUV pixels and 5-tap, and 4096 pixels using ARGB pixels and 3-tap. No limitation on the input height.
    - Alpha blending factor is re-scaled like the R, G and B color components
    - Implementation with 16 phases with symmetrical coefficients
  - Operation modes:
    - Output capture mode (to save one of the display outputs)
    - Memory-to-memory (M2M) mode (to save a M2M composition/conversion operation result)
- Four Overlay Managers (OVR), each supporting:
  - Input pixel format: ARGB48-12121212
  - Output pixel format: ARGB48-12121212 ("A" component data is only used for the Write-back path)
  - Overlay of the input pipelines (fully mapped to all input pipelines)
  - Up to 4 input layers blending, plus background layer
  - Transparency color key (source and destination)
  - Alpha blending support: Embedded pixel alpha (ARGB and RGBA), global pixel, and combination of global pixel and pixel alpha
  - Z-order programmable (full flexibility)
  - Color bar test pattern insertion
  - Any overlay output can be selected to drive the Write-back pipeline
- Four Video Port (VP) display outputs, each supporting:
  - 36-bit per pixel on the RGB output interface (12-bits per component)
  - Independent programmable timing generator, supporting up to 600 MHz pixel clock video formats (actual support limited by the maximum pixel clock provided to DSS at SoC level)
  - Independent programmable 10-bit gamma correction
  - Independent programmable multiple cycles output format on 8/9/12/16-bit interface (TDM)
  - Selection between RGB and YUV422 output pixel format (YUV422 only available when BT.656/BT.1120 output is enabled)
  - Configurable VP output mode: progressive mode only on RGB output, or progressive/interlaced mode on BT.656/BT.1120 output
- Internal data check diagnostic features:
  - Supports up to 4 programmable (position/size) check regions on the DISPC video port display outputs
  - Support for 1 check region on each input video pipeline output
  - MISR (Multiple Input Signature Register) used on each check region to perform data correctness check and/or freeze frame detection
- Local power management features:

- Low power saving modes
- Capability to associate all buffers with a single pipeline for a display self-refresh
- System interconnect ports:
  - Two 128-bit VBUSM master interfaces for data read/write
  - One 32-bit VBUSP slave interfaces for configuration

The MIPI Display Serial Interface (DSI) transmitter host controller supports:

- Compliance with MIPI DSI v1.3.1 protocol specification and previous specifications
- Compliance with MIPI Stereoscopic Display Formats (MIPI SDF v1.0) specification
- Video and command operational modes
- Both burst and non-burst modes for video mode data transmission (with either sync pulses or sync events)
- Up to 4 virtual channels via command mode
  - Supports data interleaving support for one synchronous stream (video mode) from the display controller, and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  - Supports data interleaving for up to four interleaved asynchronous streams (virtual channels in command mode) from the interconnect
- Bi-directional communication and escape mode (only on Lane-0)
- Pixel clock rate range 25-330 MHz (10-bit/component, 4MPix @60fps performance). Actual performance is limited by the maximum pixel clock provided to the DSI controller at SoC level.
- Programmable display resolutions with maximum clock rate not exceeding the total available bandwidth over 4MPix @60fps (10-bit/component RGB)
- 16/18/24/30/36-bit RGB input data formats for video mode
- RGB16, RGB18 packed, and RGB24 input data formats for command mode
- All generic data types defined by MIPI
- Display Command Set (DCS): transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral
- ECC on the APB interface
- Data splitter for 2-, 3-, or 4-data lane configuration
- Connection to a single MIPI D-PHY complex I/O through an 8-bit Protocol Peripheral Interface (PPI)
- Bus contention recovery
- Video mode pattern generator: color bar pattern image and D-PHY BET testing pattern
- APB slave interface with 32-bit data and address for configuration

The MIPI DSI (Physical Layer) D-PHY module supports:

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features
- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane
- Protocol Peripheral Interface (PPI)
- HS continuous and burst mode
- LP (Low-Power), ULPM (Ultra-Lower Power Mode), and Shutdown modes
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- DSI D-PHY IO pad signals work at/with electrical specification specified by requested standards
- Single 32-bit VBUSP slave interface

The Embedded Display Port (eDP) transmitter host controller supports:

- Compliance with VESA Display Port (DP) 1.3 (with 1.4 DSC/FEC support) specification
- Compliance with VESA embedded Display Port (eDP) 1.4 specification
- Static configuration of either DP or eDP mode
- Link rates up to HBR3 (maximum application bandwidth up to 25.92Gbps)
- Pixel clock rate range 25-600 MHz (10-bit/component, 8MPix@60fps performance).
- Transceiver AUX CH (1 MHz Manchester II coding mode) for access of DPCD and EDID
- 8, 10, and 12 bpc (bits per component), in RGB/YCbCr444 colorimetry formats (CEA-861 compliant) and YCbCr422 (via simple decimation)

- Data splitter for 1-, 2-, or 4-data lane configuration
- SST (Single Stream Transport)
- MST (Multiple Stream Transport):
  - Up to 4 video and up to 1 audio sources
  - Support for up to 25 Gbps throughput (equivalent to approximately 4K + 2xFHD streams) use case
  - HDCP support on one video source
  - DSC (Display Stream Compression) support on one 4K or 2x2.5K streams
- HDCP 1.4 and HDCP 2.2 with True Random Number Generator (TRNG with 8 FRO)
- DSC (Display Stream Compression) encoded stream data transport via an embedded DSC core:
  - Supports VESA DSC 1.1 compliant video compression at 2x~3x compression ratios
  - Supports all DSC 1.1 mandatory encoding mechanisms (MMAP, BP, MPP and ICH)
  - Supports configurable maximum display resolution up to 8Mpix @60fps including (but not limited to) 4K@60 (4096x2160), and up to 8K wide-aspect-ratio resolution displays
  - Supports two hard encoder slices (peak pixel ratio <= 340MP/s on each slice)
  - Supports 8 and 10 bits per video component
  - Supports RGB/YCbCr4:4:4 video input format (Native Encoding) only
  - Supports Dual pixel streams or Split panel input streams
  - Supports dual or single transport link
- Forward Error Correction (FEC) encoder with/without DSC enabled in DP mode
- Various eDP specific features:
  - eDP DPCD registers
  - Full and Fast Link Training
  - (Regional) backlights and multi-touch command over AUX channel
  - Alternate Scrambler Reset
- Audio transport features:
  - I2S (LPCM/IEC60948/619376) audio input stream
  - Audio transport of uncompressed multichannel (up to eight channels) via SDP (Secondary-data Packet)
- Metadata transport via MSA (Main Stream Attribute) packet or via SDP
- Display Port transmitter functionalities:
  - Scrambler
  - 8/10-bit Encoder (in the DPTX core)
  - Inter Lane Skew Insertion
  - Training Pattern Generation – TPS1,2,3,4 PRBS7 and 80-bit custom training pattern generation (bypassing the scrambler and encoder)
- PAPB Interface:
  - The primary APB slave port controls the HD Display controller from the host processor
  - During the boot, the primary APB slave port enables access to the I-MEM and D-MEM, and to the full address space for debugging purposes
  - After the boot, the primary APB slave port enables direct register access to designated HW modules and enables communication with uCPU through a mailbox channel
- SAPB Interface
  - For configuring the embedded HDCP, this bus is considered as a secured APB to carry secured commands over the mailbox channel
- Internal diagnostic features:
  - ECC on the critical memories
  - Parity check on the configuration interface
  - Encoder self-check diagnostics support in the DSC core
  - Corrected/Uncorrected error interrupt generation
  - Injection of ECC and parity errors

The DP (Physical Layer) SERDES and Aux PHY modules support:

- DP1.3 HBR3 and eDP1.4a HBR3 throughput

- 1, 2, or 4 lanes at 1.62 Gbps, 2.7 Gbps, 5.4 Gbps, and 8.1 Gbps per lane
- Additional link rates (2.16, 2.43, 3.24, 4.32 Gbps) per lane in eDP mode
- Reduced differential voltage swing (0.2/0.25/0.30/0.35/0.40/0.45) in eDP mode
- Hot Plug Detect (HPD) for connection detection and interrupt from sink
- Integrated Low Jitter, Fixed Bandwidth PLL
- 1 Mbps AUX PHY for link training, DPCD register access, HDCP authentication and EDID access.

#### 12.6.1.2 DSS Not Supported Features

The DISPC does not support the following features:

- 2D tiled buffer access
- On the fly rotation (90/270-degree)
- Sending ancillary data on the video port outputs during VBLANK period
- YUV422 planar formats (8-bit and 10-bit) for video pipelines and write-back (encoder/decoder compatibility)

The DSI controller does not support the following features:

- Audio data transmission
- Optional sub-link
- VESA DSC (Display Stream Compression)
- 12-bit wide input component width
- SDI video mode

The eDP transmitter does not support the following features:

- Multi-SST Operation (MSO) for segmented display panel support in eDP mode
- Type-C DP Alt Mode
- FAUX (Fast AUX)(720MBps AUX)
- SPDIF Audio Interface
- Advanced Low Power Management (ALPM)(Pending proposal in VESA to remove the requirement of ALPM in eDP)
- MCCS Support (other mode available to access needed registers in Sink device)
- PSR-1 mode (Full Panel Refresh Mode)
- Specific DP 1.4 standard features:
  - SDP splitting and chaining (DP 1.4 specification, chapter 2.2.5.12)
  - New SDP formats introduced in DP 1.4 specification
  - Video Stream Configuration Extension (VESA SDP), (DP 1.4 specification, chapter 2.2.5.10)
  - CEA SDP (DP 1.4 specification, chapter 2.2.5.11)
  - New DP 1.4 audio formats:
    - 3D LPCM audio (up to 32 audio channels) (DP 1.4 specification, chapter A.4.5, A.4.6)
    - 1-bit audio (DP 1.4 specification, chapter A.4.3)
    - Direct Stream Transfer (DST) audio (DP 1.4 specification, chapter A.4.7)
    - HBR 8-channel audio up to 1536 kHz
    - Changes to the Audio\_Stream SDP header (DP 1.4 specification, chapter 2.2.5.3.2)
  - New 3DChannelCount, OneBit\_DST\_Double\_Rate fields
  - New supported values for the Coding Type field
  - 16-bit data format
- Specific DSC core features:
  - VESA DSC 1.2 updated requirements (no support for YCbCr 422 or 420 native coding)
  - De-rasterization buffer
  - 12-bit wide input component width

## 12.6.2 DSS Environment

This section describes the interfaces handled by the Display Subsystem.

The DSS is capable of driving multiple displays in parallel, through a combination of interfaces:

- Two DPI parallel interfaces, directly delivered on SoC pads from DISPC Video Port (VP) outputs
- One MIPI Display Serial Interface (DSI)
- One Embedded DisplayPort (DP/eDP) interface

The pixel format mapping between the DISPC VP outputs and DPI, eDP, and DSI display peripherals varies depending on the interface used. The pixel bit color mapping for the DISPC VP outputs is as shown in [Figure 12-522](#).

Color Format	Pixel Width	Pixel Interface Mapping																																			
		35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RGB565	16-bit																																				
RGB666	18-bit																																				
RGB888	24-bit																																				
RGB101010	30-bit																																				
RGB121212	36-bit																																				

dss-007

**Figure 12-522. DSS Pixel Mapping on the DISPC Video Port Outputs**

The pixel format support at a DISPC VP output when connected to each of the DPI, eDP, and DSI peripherals is as listed in [Table 12-528](#).

**Table 12-528. DSS Pixel Format Interoperability between DISPC VP Output and DPI, eDP, and DSI**

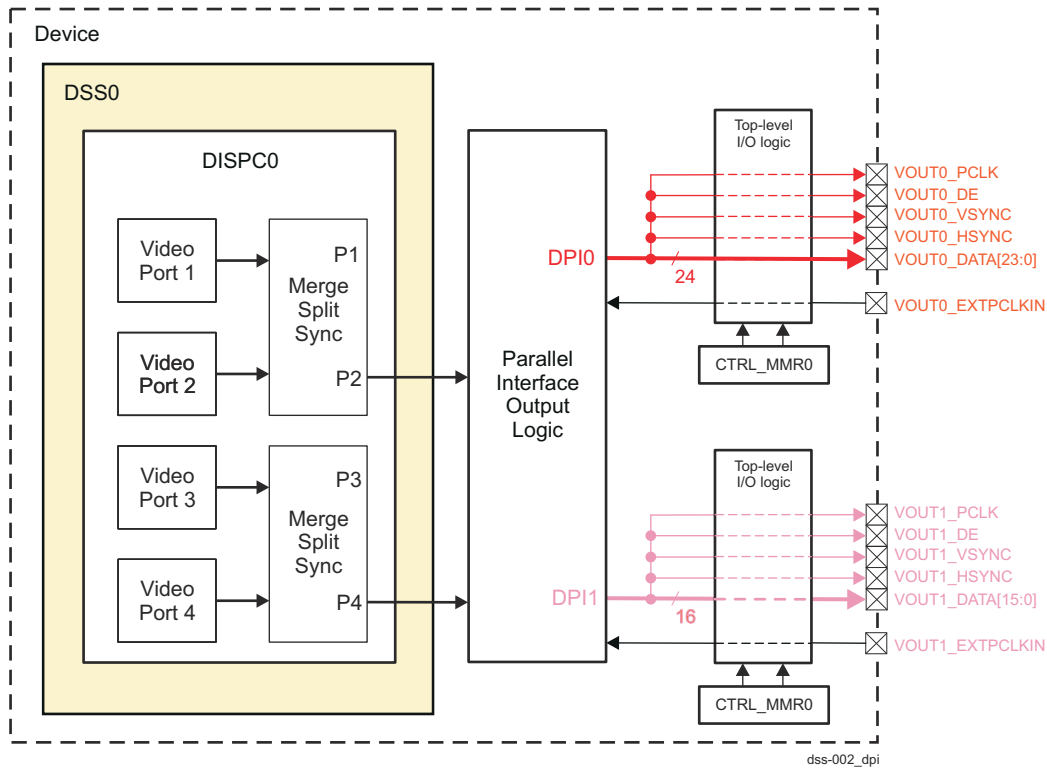

Pixel Format	DISPC VP Output Pixel Format	DPI Parallel Out	DSI		eDP
	DSS0_VP_CONTROL [10-8] DATALINES Register Field Value		DSI-DPI Interface	DSI-SDI Interface	
RGB565	0x1	Supported	Supported	Supported	Not supported
RGB666	0x2	Supported	Supported	Supported	Not supported
RGB888	0x3	Supported	Supported	Supported	Not supported
RGB101010	0x4	Not supported	Supported	Not supported	Supported
RGB121212	0x5	Not supported	Supported	Not supported	Supported

### Note

The DISPC VP outputs are connected to the display peripherals through the Merge-Split-Sync (MSS) block. For more details, see [Section 12.6.4.11.9, DISPC VP Merge-Split-Sync \(MSS\) Module](#).

### 12.6.2.1 DISPC Environment

[Figure 12-523](#) shows the DSS DPI parallel interface signals. The output data bus of the DISPC video ports is 36 bits wide. The DSS DPI parallel interface uses up to the 24 LSB bits [23:0] of the data bus.

**Figure 12-523. DSS DPI Parallel Interface Signals**

Each DISPC video port in [Figure 12-523](#) can be connected to any DPI output via the parallel interface output logic.

The [3-0] DPI\_0\_CONN and [7-4] DPI\_1\_CONN fields in the [DSS0\\_COMMON\\_DISPC\\_CONNECTIONS](#) register define the DISPC VP connections to DPI0 and DPI1 outputs, respectively.

The DISPC video ports output the required data and control signals to device pads to support one of the following display interface modes:

- Parallel MIPI DPI 2.0 (Digital Pixel Interface): RGB 16/18/24-bit output with separate sync signals.
- BT.656/BT.1120 interface: YUV422 output (8/10-bit modes) with embedded syncs.
- BT.601 interface: YUV422 output with discrete syncs. For more details, see [Section 12.6.2.1.4, VSYNC/HSYNC/DE Signal Export to SoC Boundary](#).

[Table 12-529](#) describes the DSS DPI parallel interface I/O signals.

**Table 12-529. DSS DPI Parallel Interface I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description
<b>DPI0 Interface</b>			
DSS_DPI0_DATA[23:0]	VOUT0_DATA[23:0]	O	Pixel data output. RGB data for MIPI DPI 2.0 interface. YUV data for BT.656/BT.1120 interfaces.
DSS_DPI0_VSYNC	VOUT0_VSYNC	O	Vertical synchronization. The frame synchronization pulse (vsync) toggles after all the lines in a frame are transmitted and a programmable number of line clock cycles has elapsed at the beginning and the end of each frame.
DSS_DPI0_HSYNC	VOUT0_HSYNC	O	Horizontal synchronization. The line synchronization pulse (hsync) toggles after all pixels in a line are transmitted and a programmable number of pixel clock wait-states has elapsed at the beginning and the end of each line.

**Table 12-529. DSS DPI Parallel Interface I/O Signals (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description
DSS_DPI0_PCLK	VOUT0_PCLK	O	Pixel clock output.
DSS_DPI0_DE	VOUT0_DE	O	Pixel data output-enable signal to indicate when data must be latched using the pixel clock.
DSS_DPI0_EXTPCLKIN	VOUT0_EXTPCLKIN	I	Pixel clock input from external source.
-	VOUT0_VP0_DE	O	Alternative pixel data output-enable signal from DISPC VP1. <sup>(2)</sup>
-	VOUT0_VP0_HSYNC	O	Alternative horizontal synchronization signal from DISPC VP1. <sup>(2)</sup>
-	VOUT0_VP0_VSYNC	O	Alternative vertical synchronization signal from DISPC VP1. <sup>(2)</sup>
-	VOUT0_VP2_DE	O	Alternative pixel data output-enable signal from DISPC VP3. <sup>(2)</sup>
-	VOUT0_VP2_HSYNC	O	Alternative horizontal synchronization signal from DISPC VP3. <sup>(2)</sup>
-	VOUT0_VP2_VSYNC	O	Alternative vertical synchronization signal from DISPC VP3. <sup>(2)</sup>
<b>DPI1 Interface</b>			
DSS_DPI1_DATA[15:0]	VOUT1_DATA[15:0]	O	Pixel data output. RGB data for MIPI DPI 2.0 interface. YUV data for BT.656/BT.1120 interfaces.
DSS_DPI1_VSYNC	VOUT1_VSYNC	O	Vertical synchronization. Vertical synchronization. The frame synchronization pulse (vsync) toggles after all the lines in a frame are transmitted and a programmable number of line clock cycles has elapsed at the beginning and the end of each frame.
DSS_DPI1_HSYNC	VOUT1_HSYNC	O	Horizontal synchronization. Horizontal synchronization. The line synchronization pulse (hsync) toggles after all pixels in a line are transmitted and a programmable number of pixel clock wait-states has elapsed at the beginning and the end of each line.
DSS_DPI1_PCLK	VOUT1_PCLK	O	Pixel clock output.
DSS_DPI1_DE	VOUT1_DE	O	Pixel data output-enable signal to indicate when data must be latched using the pixel clock.
DSS_DPI1_EXTPCLKIN	VOUT1_EXTPCLKIN	I	Pixel clock input from external source.
-	VOUT1_VP0_DE	O	Alternative pixel data output-enable signal from DISPC VP1. <sup>(2)</sup>
-	VOUT1_VP0_HSYNC	O	Alternative horizontal synchronization signal from DISPC VP1. <sup>(2)</sup>
-	VOUT1_VP0_VSYNC	O	Alternative vertical synchronization signal from DISPC VP1. <sup>(2)</sup>
<b>FSYNC Interface<sup>(2)</sup></b>			
-	DSS_FSYNC0	O	Video Output Frame Sync 0 (from DISPC VP1 VSYNC).
-	DSS_FSYNC1	O	Video Output Frame Sync 1 (from DISPC VP2 VSYNC).
-	DSS_FSYNC2	O	Video Output Frame Sync 2 (from DISPC VP3 VSYNC).
-	DSS_FSYNC3	O	Video Output Frame Sync 3 (from DISPC VP4 VSYNC).

(1) I = Input; O = Output

(2) For more details on the usage of the alternative sync signals, see [Section 12.6.2.1.4, VSYNC/HSYNC/DE Signal Export to SoC Boundary](#).

### Note

For more information about device level signals, see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Data Manual.

The effective output pixel clock rate for interleaved data formats (that is, BT.656 output mode or TDM (Time Division Multiplexed) output mode) will be either 1/2 or 1/3 of the maximum pixel clock rate, respectively, depending on the interleaving ratio.

#### 12.6.2.1.1 RGB Data Output

This section describes the pixel data bus for RGB formats and shows timing diagrams of transactions and synchronizations.

For the active matrix display type, one pixel per pixel clock is displayed. The diagrams represent the configuration of assertion of the data on the rising edge of the pixel clock. It is possible to program the interface timings to output the data on the falling edge of the pixel clock.

Figure 12-524 through Figure 12-527 show the interface to 12-, 16-, 18-, and 24-bit RGB active matrix displays. Each vertical line represents one output pixel. The width of the data bus can be configured through DSS0\_VP\_CONTROL[10-8] DATALINES register bitfield.

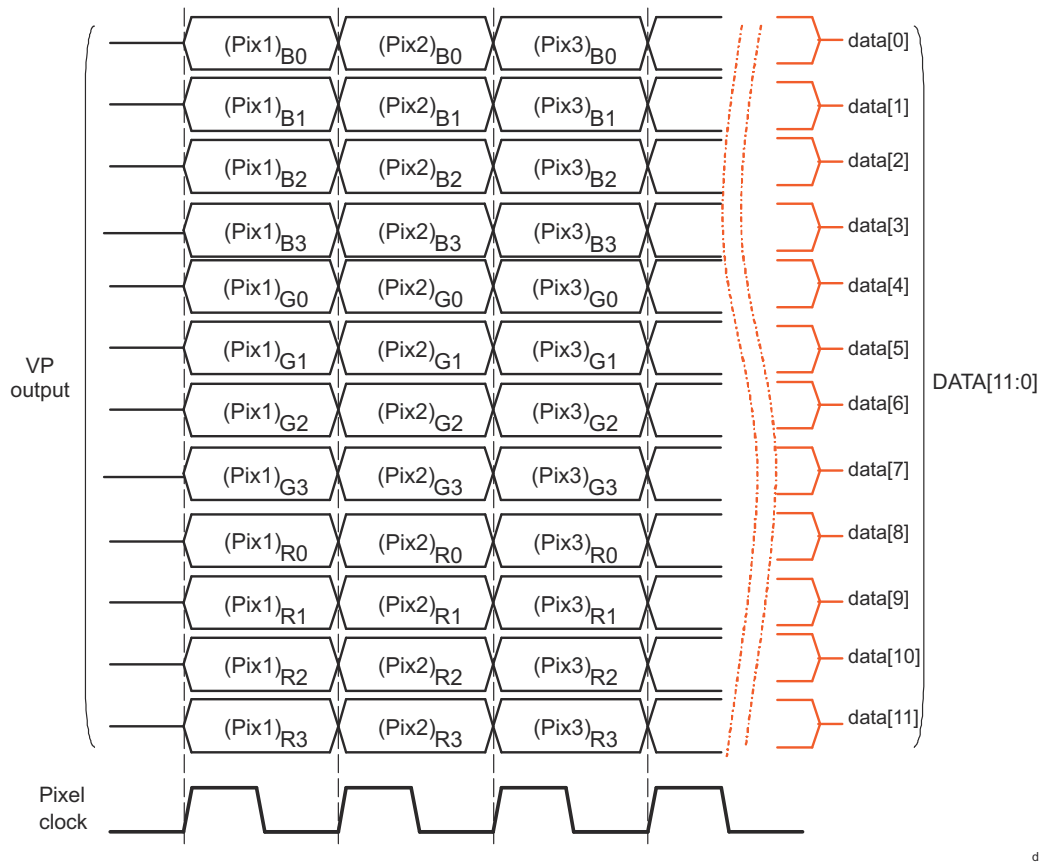

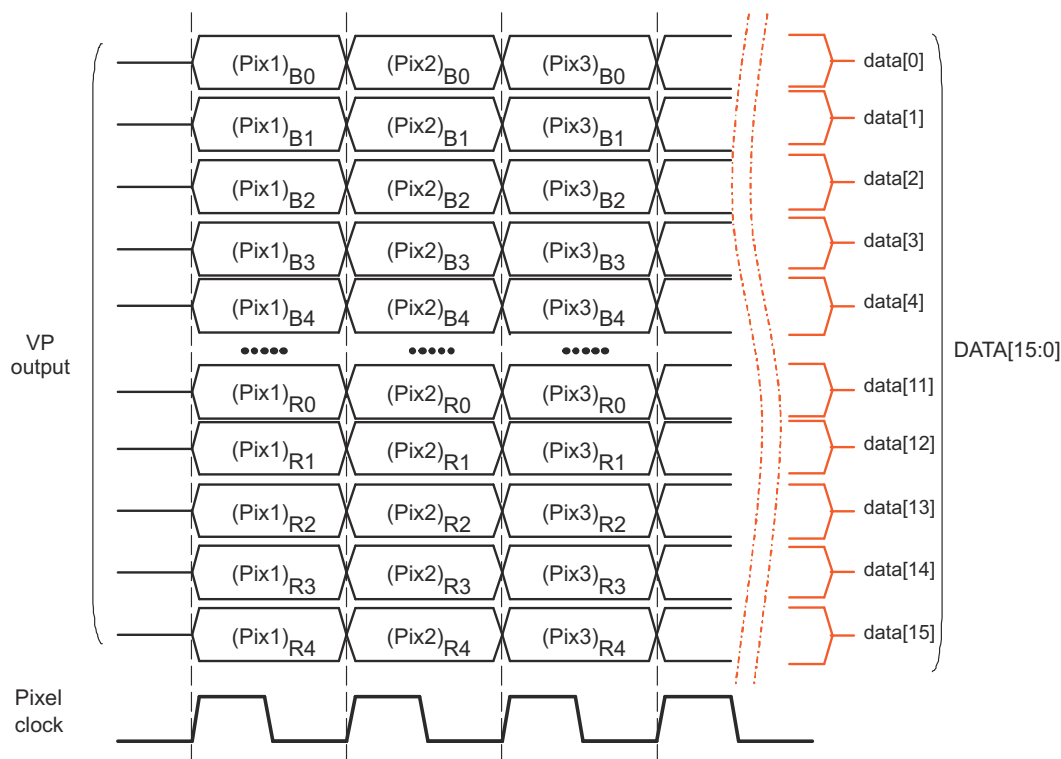

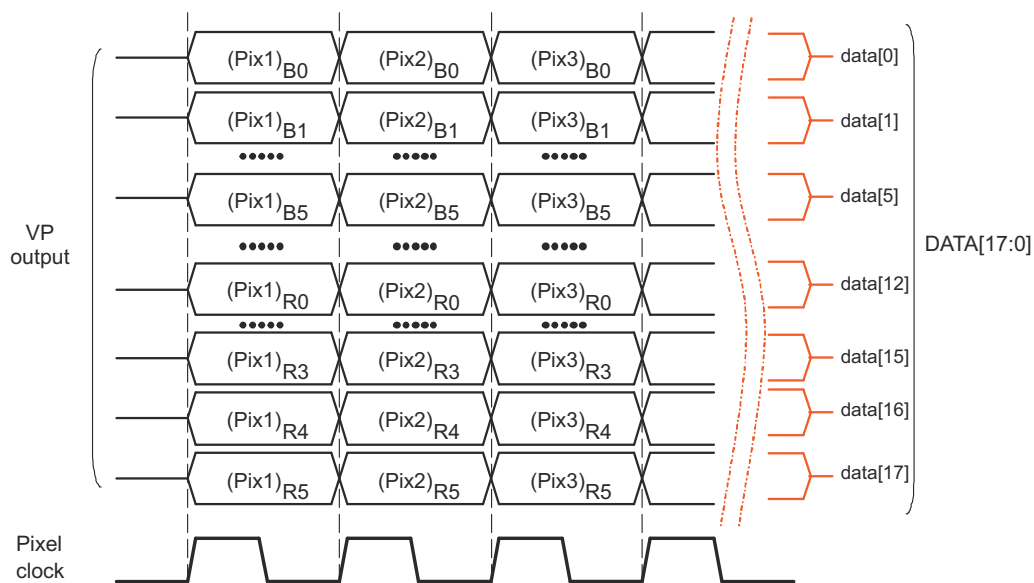

Figure 12-524. DISPC Video Port Pixel Data - 12-bit RGB Active Matrix

dispc-051

**Figure 12-525. DISPC Video Port Pixel Data - 16-bit RGB Active Matrix**

dispc-052

**Figure 12-526. DISPC Video Port Pixel Data - 18-bit RGB Active Matrix**

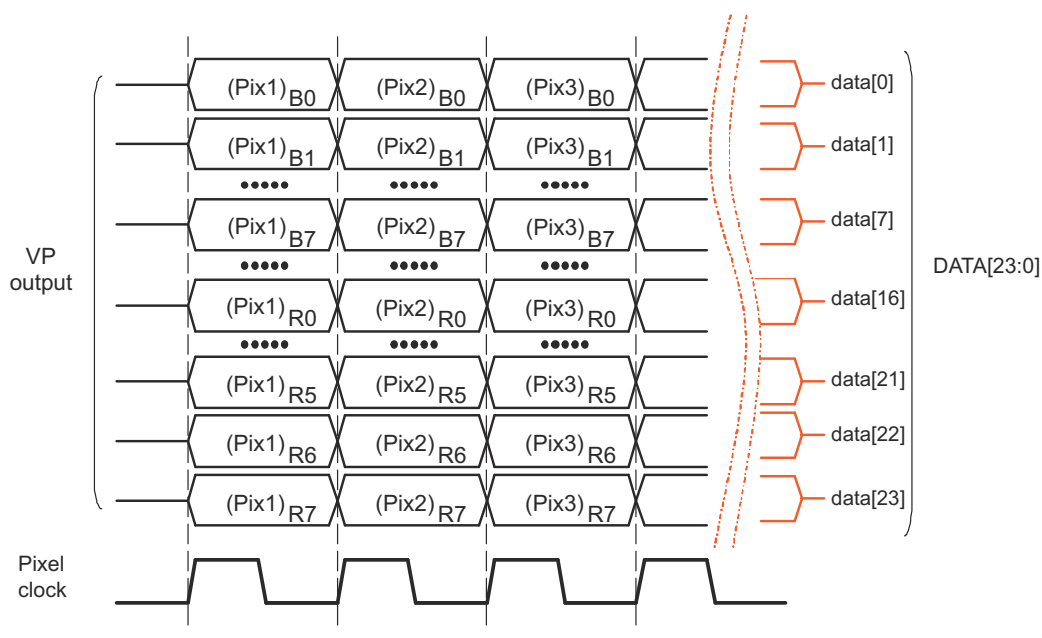

Figure 12-527. DISPC Video Port Pixel Data - 24-bit RGB Active Matrix

#### 12.6.2.1.2 YUV Data Output (BT.656/BT.1120)

Figure 12-528 shows the signal mapping on the DATA[23:0] output data bus for the BT.656 mode. Bits [9-0] are dedicated for BT.656 mode (10-bit). In BT.656 mode however, for compatibility with existing 8-bit interfaces, the two LSBs are ignored and only bits [9-2] are effectively used.

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused														BT.656									

Figure 12-528. DISPC Video Port Data Mapping for BT.656 Mode

Figure 12-529 shows the signal mapping on a DATA[23:0] output data bus for the BT.1120 mode. Bits [19-10] (CbCr) and [9-0] (Y) are used in 20-bit mode. Bits [19-12] (CbCr) and [9-2] (Y) are used in 16-bit mode (YCbCr422).

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused				BT.1120 (CbCr, 20-bit mode)										BT.1120 (Y, 20-bit mode)									

Figure 12-529. DISPC Video Port Data Mapping for BT.1120 Mode

The DISPC VP outputs support both interlace and progressive content in BT.656/BT.1120 modes. For more information on timings configuration, see [Section 12.6.4.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

#### Note

In progressive BT.656/BT.1120 mode the maximum output resolution will be limited, as it requires two pixel clock cycles to send out one pixel.

### 12.6.2.1.3 Display Timing Diagrams

Figure 12-530 through Figure 12-533 show examples with timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC video ports directly drive these signals, which are related to the programmable fields listed in Table 12-530. For more information, see also Section 12.6.4.11.8, *DISPC VP Timing Generator and Display Panel Settings*.

**Table 12-530. DISPC Video Port Register Fields for Active Matrix Display**

Name	Register	Description
PPL	DSS0_VP_SIZE_SCREEN[13-0] PPL value + 1	Pixels per line
LPP	DSS0_VP_SIZE_SCREEN[29-16] LPP value + 1	Lines per panel
HBP	DSS0_VP_TIMING_H[31-20] HBP value + 1	Horizontal back porch
HFP	DSS0_VP_TIMING_H[19-8] HFP value + 1	Horizontal front porch
HSW	DSS0_VP_TIMING_H[7-0] HSW value + 1	Horizontal synchronization pulse width
VBP	DSS0_VP_TIMING_V[31-20] VBP value	Vertical back porch
VFP	DSS0_VP_TIMING_V[19-8] VFP value	Vertical front porch
VSW	DSS0_VP_TIMING_V[7-0] VSW value + 1	Vertical synchronization pulse width
ALIGN	DSS0_VP_POL_FREQ[18] ALIGN	Alignment between HSYNC and VSYNC assertion
ONOFF	DSS0_VP_POL_FREQ[17] ONOFF	HSYNC and VSYNC pixel clock control
RF	DSS0_VP_POL_FREQ[16] RF	HSYNC and VSYNC pixel clock edge control
IEO	DSS0_VP_POL_FREQ[15] IEO	Invert output enable
IPC	DSS0_VP_POL_FREQ[14] IPC	Invert PCLK
IHS	DSS0_VP_POL_FREQ[13] IHS	Invert HSYNC
IVS	DSS0_VP_POL_FREQ[12] IVS	Invert VSYNC

- Active matrix timing configuration 1:
  - DSS0\_VP\_POL\_FREQ[17] ONOFF = 0
  - DSS0\_VP\_POL\_FREQ[16] RF = 0
  - The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.
  - DSS0\_VP\_POL\_FREQ[15] IEO = 0
  - The DE signal is active high.
  - DSS0\_VP\_POL\_FREQ[14] IPC = 0
  - The pixel data are driven on the rising edge of PCLK.
  - DSS0\_VP\_POL\_FREQ[13] IHS = 0
  - The HSYNC signal is active high.
  - DSS0\_VP\_POL\_FREQ[12] IVS = 0
  - The VSYNC signal is active high.
  - DSS0\_VP\_POL\_FREQ[18] ALIGN = 0
  - The VSYNC and HSYNC assertion is not aligned.

**Figure 12-530. DISPC Display Timing Diagram of Configuration 1 (Start of Frame)**

**Figure 12-531. DISPC Display Timing Diagram of Configuration 1 (Between Lines)**

**Figure 12-532. DISPC Display Timing Diagram of Configuration 1 (Between Frames)**

**Figure 12-533. DISPC Display Timing Diagram of Configuration 1 (End of Frame)**

- Active matrix timing configuration 2:
  - DSS0\_VP\_POL\_FREQ[17] ONOFF = 1
  - DSS0\_VP\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[15] IEO = 1

The DE signal is active low.

- DSS0\_VP\_POL\_FREQ[14] IPC = 1

The pixel data is driven on the falling edge of PCLK.

- DSS0\_VP\_POL\_FREQ[13] IHS = 1

The HSYNC signal is active low.

- DSS0\_VP\_POL\_FREQ[12] IVS = 1

The VSYNC signal is active low.

- DSS0\_VP\_POL\_FREQ[18] ALIGN = 0

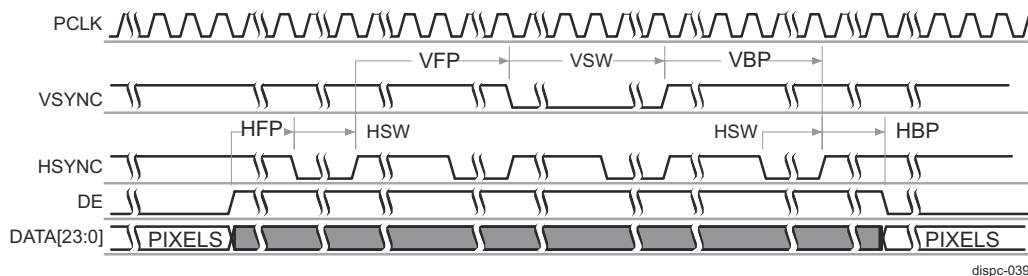

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-534. DISPC Display Timing Diagram of Configuration 2 (Start of Frame)**

**Figure 12-535. DISPC Display Timing Diagram of Configuration 2 (Between Lines)**

**Figure 12-536. DISPC Display Timing Diagram of Configuration 2 (Between Frames)**

**Figure 12-537. DISPC Display Timing Diagram of Configuration 2 (End of Frame)**

- Active matrix timing configuration 3:
  - DSS0\_VP\_POL\_FREQ[17] ONOFF = 1
  - DSS0\_VP\_POL\_FREQ[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[15] IEO = 0

The DE signal is active high.

- DSS0\_VP\_POL\_FREQ[14] IPC = 0

The pixel data are driven on the rising edge of PCLK.

- DSS0\_VP\_POL\_FREQ[13] IHS = 0

The HSYNC signal is active high.

- DSS0\_VP\_POL\_FREQ[12] IVS = 0  
The VSYNC signal is active high.
- DSS0\_VP\_POL\_FREQ[18] ALIGN = 0  
The VSYNC and HSYNC assertion is not aligned.

The VSYNC and HSYNC assertion is not aligned.

**Figure 12-538. DISPC Display Timing Diagram of Configuration 3 (Start of Frame)**

**Figure 12-539. DISPC Display Timing Diagram of Configuration 3 (Between Lines)**

**Figure 12-540. DISPC Display Timing Diagram of Configuration 3 (Between Frames)**

**Figure 12-541. DISPC Display Timing Diagram of Configuration 3 (End of Frame)**

#### 12.6.2.1.4 VSYNC/HSYNC/DE Signal Export to SoC Boundary

The DSS exports the VSYNC, HSYNC and DE signals of all DISPC video port outputs to the SoC boundary. This feature is supplementary to the signals already exported out on the parallel DPI interfaces (DPI0/DPI1). This allows the support of the following use cases:

- BT.601 interface (YUV output with discrete syncs)
- FSYNC support for external camera sensor

The necessary singnal muxing is achieved at SoC level (via I/O pin multiplexing).

#### BT.601 Standard Support

The DSS only supports YUV output with embedded syncs (BT.656 and BT.1120 standards). YUV output with discrete sync (BT.601 standard) is not supported natively on the DISPC VP outputs.

At SoC level, it is possible to achieve BT.601 operation on a DPI parallel out (DPI0/DPI1) by combining two DISPC VP outputs as follows:

- Enable one DISPC VP to output YUV422 data in BT.656 mode on either DPI0 or DPI1 output.
- Use an alternative DISPC VP, that is synchronized and programmed (in RGB TDM mode), to output the discrete sync signals on the same DPI output. This can be achieved by configuring the I/O pin multiplexing at SoC level.
- The following restrictions apply:
  - If DPI0 is used to output YUV422 data, then the VSYNC/HSYNC/DE signals of either VP1 or VP3 can be output on DPI0.
  - If DPI1 is used to output YUV422 data, then the VSYNC/HSYNC/DE signals of only VP1 can be output on DPI1.

#### FSYNC Support for External Camera Sensor

An external camera sensors can use the VSYNC output from DSS as a synchronization input (FSYNC input). To make this connection, the VSYNC signals of all DISPC video ports are made available at SoC boundary.

Generally, in the cases where the DISPC VP is connected to DSI or eDP, the VSYNC information is "lost" as a separate signal at SoC boundary, although this VSYNC is still available at DISPC module boundary. For such cases, the VSYNCs are exported to SoC level in parallel to the DSI/eDP connection.

#### 12.6.2.2 DSI Environment

[Figure 12-542](#) shows the DSI interface signals.

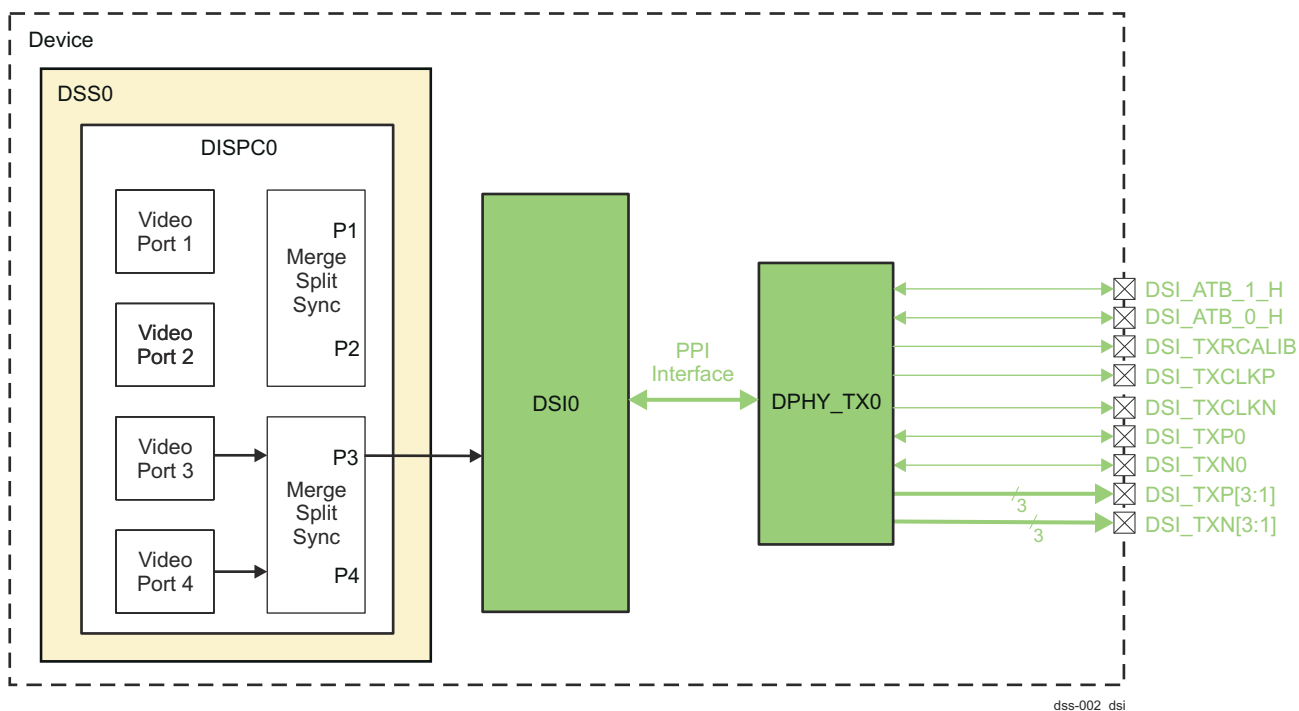

**Figure 12-542. DSI Interface Signals**

Table 12-531 describes the DSI I/O signals.

**Table 12-531. DSI Interface I/O Signals**

Device Level Signal	I/O <sup>(1)</sup>	Description
DSI_TXN0	I/O	External differential I/O Lane 0
DSI_TXP0	I/O	
DSI_TXN1	O	External differential output Lane 1
DSI_TXP1	O	
DSI_TXN2	O	External differential output Lane 2
DSI_TXP2	O	
DSI_TXN3	O	External differential output Lane 3
DSI_TXP3	O	
DSI_TXCLKN	O	External differential clock Lane
DSI_TXCLKP	O	
DSI_TXRCALIB	A	Pin for external calibration resistor
DSI_ATB_0_H	I/O	Analog test bus
DSI_ATB_1_H	I/O	

(1) I = Input; O = Output; I/O = Bidirectional; A = Analog

#### Note

For more information about device level signals, see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Data Manual.

### 12.6.2.3 EDP Environment

Figure 12-543 shows the EDP interface signals.

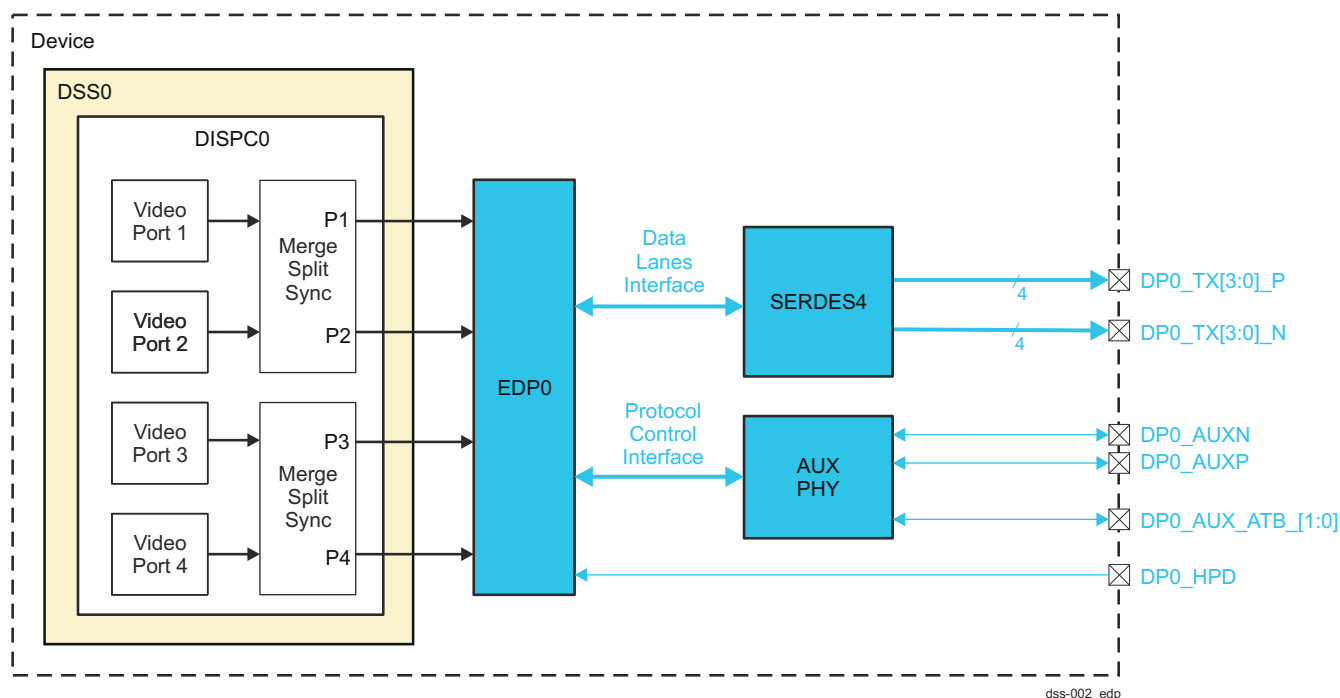

**Figure 12-543. DP/eDP Interface Signals**

Table 12-532 describes the EDP I/O signals.

**Table 12-532. DP/eDP I/O Signals**

Device Level Signal	I/O <sup>(1)</sup>	Description
<b>EDP TX PHY (SERDES)</b>		
DP0_TX0_N	O	External differential output Lane 0
DP0_TX0_P	O	
DP0_TX1_N	O	External differential output Lane 1
DP0_TX1_P	O	
DP0_TX2_N	O	External differential output Lane 2
DP0_TX2_P	O	
DP0_TX3_N	O	External differential output Lane 3
DP0_TX3_P	O	
<b>EDP AUX PHY</b>		
DP0_AUXN	I/O	Auxiliary channel differential transceiver
DP0_AUXP	I/O	
DP0_AUX_ATB_0	I/O	Analog test bus
DP0_AUX_ATB_1	I/O	
<b>EDP</b>		
DP0_HPD	I	Hot plug detect input

(1) I = Input; O = Output; I/O = Bidirectional

### Note

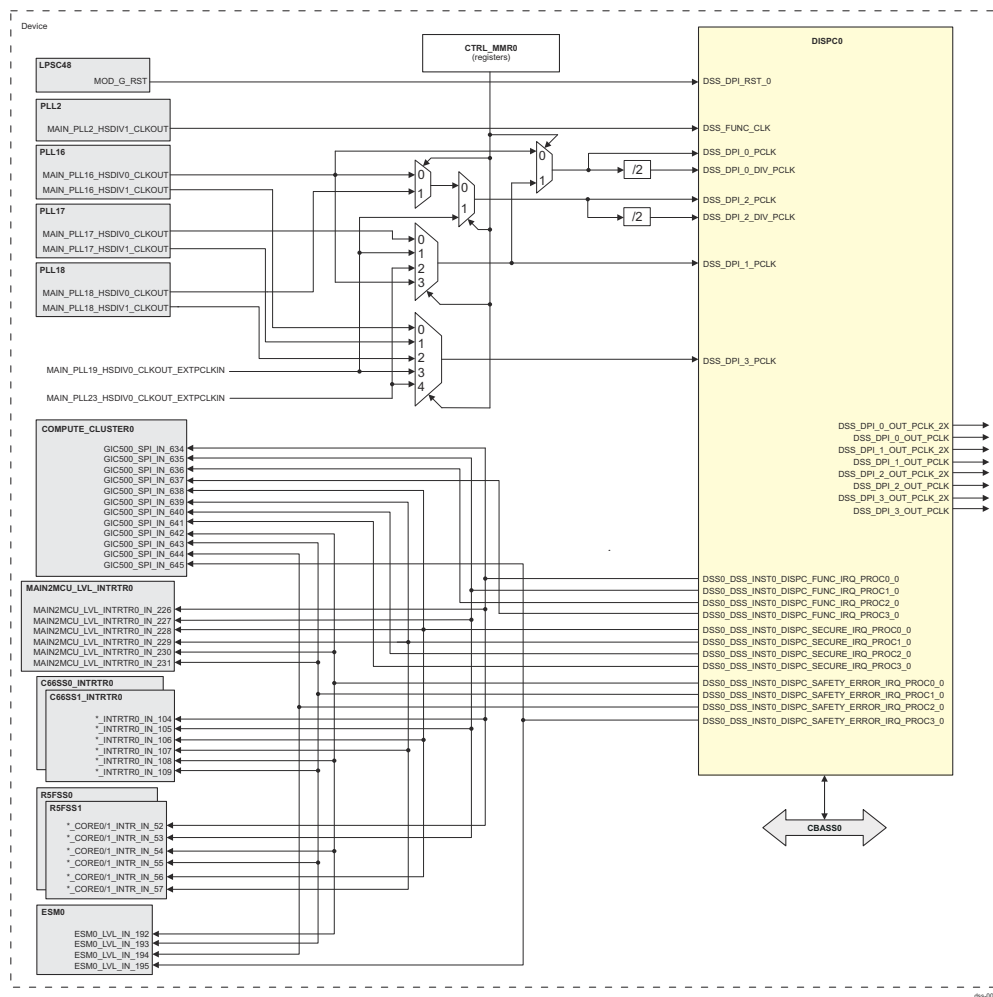

For more information about device level signals, see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Data Manual.

## 12.6.3 DSS Integration

This section describes the DSS integration in the device, including information about clocks, resets, and hardware requests.

### 12.6.3.1 DISPC Integration

There is one DISPC module integrated in the device MAIN domain. [Figure 12-544](#) shows the integration of DISPC0.

**Figure 12-544. DISPC Integration**

Table 12-533 through Table 12-535 summarize the integration of DISPC in the device MAIN domain.

**Table 12-533. DISPC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DISPC0	PSC0	PD2	LPSC48	CBASS0

**Table 12-534. DISPC Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DISPC0	DSS_FUNC_CLK	MAIN_PLL2_HSDIV1_CLKOUT	PLL2	DISPC0 functional clock.
	DSS_DPI_0_PCLK	MAIN_PLL16_HSDIV0_CLKOUT or DSS_DPI_1_PCLK source clock	PLL16 or the selected DSS_DPI_1_PCLK source clock	DISPC0 peripheral pixel clocks for VP1. The selection of the source signal (see <a href="#">Figure 12-544, DISPC Integration</a> ) can be done via the CTRLMMR_DSS_DISPC0_CLKSEL3[2:0] DPI3_PCLK register field in device Control Module.
	DSS_DPI_0_DIV_PCLK	MAIN_PLL16_HSDIV0_CLKOUT / 2 or DSS_DPI_1_PCLK source clock / 2		
	DSS_DPI_1_PCLK	MAIN_PLL16_HSDIV0_CLKOUT	PLL16	DISPC0 peripheral pixel clock for VP2.
		MAIN_PLL19_HSDIV0_CLKOUT_EXTCLKIN	See (1)	The selection of the source signal (see <a href="#">Figure 12-544, DISPC Integration</a> ) can be done via the CTRLMMR_DSS_DISPC0_CLKSEL1[1:0] DPI1_PCLK register field in device Control Module.
		MAIN_PLL23_HSDIV0_CLKOUT_EXTCLKIN	See (1)	
		MAIN_PLL17_HSDIV0_CLKOUT	PLL17	
	DSS_DPI_2_PCLK	MAIN_PLL16_HSDIV0_CLKOUT	PLL16	DISPC0 peripheral pixel clocks for VP3.
		MAIN_PLL18_HSDIV0_CLKOUT	PLL18	The selection of the source signal (see <a href="#">Figure 12-544, DISPC Integration</a> ) can be done via the CTRLMMR_DSS_DISPC0_CLKSEL3[2:0] DPI3_PCLK and
		MAIN_PLL19_HSDIV0_CLKOUT_EXTCLKIN	See (1)	CTRLMMR_DSS_DISPC0_CLKSEL2[0] DPI2_PCLK register fields in device Control Module.
	DSS_DPI_2_DIV_PCLK	MAIN_PLL16_HSDIV0_CLKOUT / 2	PLL16	
		MAIN_PLL18_HSDIV0_CLKOUT / 2	PLL18	
	DSS_DPI_3_PCLK	MAIN_PLL19_HSDIV0_CLKOUT_EXTCLKIN / 2	See (1)	
		MAIN_PLL16_HSDIV1_CLKOUT	PLL16	DISPC0 peripheral pixel clock for VP4.
		MAIN_PLL17_HSDIV1_CLKOUT	PLL17	The selection of the source signal (see <a href="#">Figure 12-544, DISPC Integration</a> ) can be done via the CTRLMMR_DSS_DISPC0_CLKSEL3[2:0] DPI3_PCLK register field in device Control Module.
		MAIN_PLL18_HSDIV1_CLKOUT	PLL18	
		MAIN_PLL19_HSDIV0_CLKOUT_EXTCLKIN	See (1)	
		MAIN_PLL23_HSDIV0_CLKOUT_EXTCLKIN	See (1)	
Module Instance	Module Clock Output	Destination Clock Signal	Destination	Description

**Table 12-534. DISPC Clocks and Resets (continued)**

### 12.6.3.2 DSI Integration

There is one DSI module integrated in the device MAIN domain. [Figure 12-545](#) shows the integration of DSI0.

**Figure 12-545. DSI Integration**

Table 12-536 through summarize the integration of DSI in the device MAIN domain.

**Table 12-536. DSI Integration Attributes**

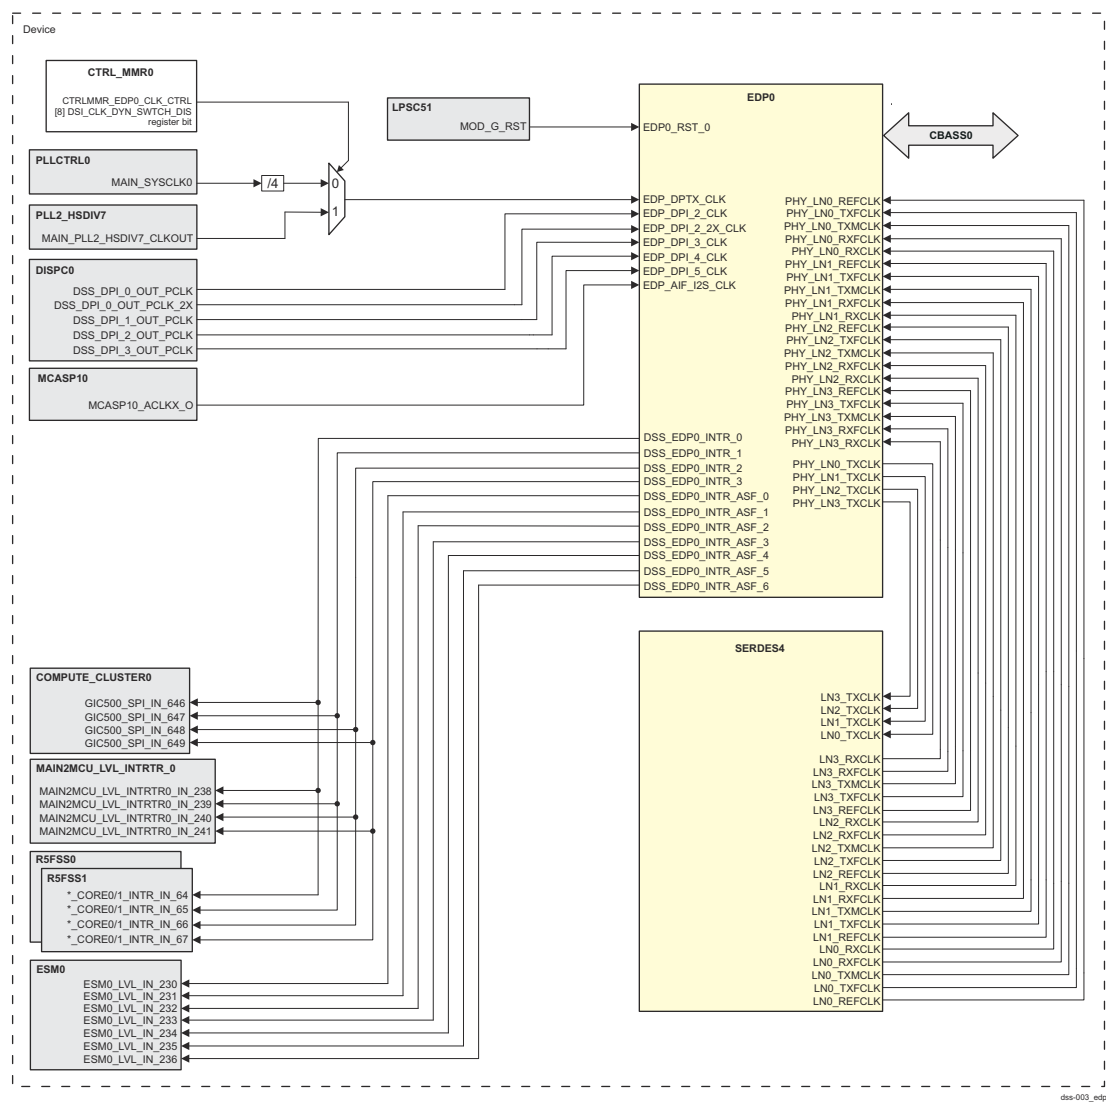

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DSI0	PSC0	PD2	LPSC50	CBASS0

**Table 12-537. DSI Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DSI0	DSI_SYS_CLK	MAIN_SYSCLK0/2	PLLCTRL0	DSI0 system clock.
	DSI_DPI_0_CLK	DSS_DPI_2_OUT_PCLK	DISPC0	DSI0 DPI clock.
	DSI_DPHY_0_TX_ESC_CLK	DPHY_PPI_K_LN0_M_TXCLKESC_DL	DSI0_DPHY_TX0	DSI0 DPHY clock.
		MAIN_PLL1_HSDIV8_CLKOUT	PLL1	DSI0 clock.
	DSI_DPHY_0_RX_ESC_CLK	DPHY_PPI_K_LN0_M_RXCLKESC_DL	DSI0_DPHY_TX0	DSI0 DPHY clock.
	DSI_PPI_0_TXBYTECLKHS_CL_CLK	DPHY_PPI_C_TXBYTECLKHS_CL_L	DSI0_DPHY_TX0	
DPHY_TX0	DPHY_CLK	MAIN_SYSCLK0/4	PLLCTRL0	DPHY_TX0 clocks.
	DPHY_PSM_CLK	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
	DPHY_PPI_K_M_TXCLKESCCLK_CL	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
	DPHY_PPI_K_LN0_M_TXCLKESC_DL	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
		DSI_DPHY_0_TX_ESC_CLK	DSI0	
	DPHY_PPI_K_LN1_M_TXCLKESC_DL	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
	DPHY_PPI_K_LN2_M_TXCLKESC_DL	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
	DPHY_PPI_K_LN3_M_TXCLKESC_DL	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	
	DPHY_REF_CLK	HFOSC0_CLKOUT	HFOSC0	DPHY_TX0 reference clock.
		HFOSC1_CLKOUT	HFOSC1	The selection of the source clock (see <i>DSI0 Integration</i> ) is done via the
		MAIN_PLL3_HSDIV4_CLKOUT	PLL3	CTRLMMR_DPHY0_CLKSEL[1-0] REF_CLK_SEL register field
		MAIN_PLL2_HSDIV4_CLKOUT	PLL2	the device Control Module.
	DPHY_TX_P_CL_L	DSI0_TXCLKP	I/O pin	DSI0_DPHY_TX0 input pin clock.
	DPHY_TX_M_CL_L	DSI0_TXCLKN	I/O pin	DSI0_DPHY_TX0 input pin clock.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
DSI0	DSI_RST_0	MOD_G_RST	LPSC50	DSI0 reset.

### 12.6.3.3 EDP Integration

There is one EDP module integrated in the device MAIN domain. [Figure 12-546](#) shows the integration of EDP0.

**Figure 12-546. EDP Integration**

Table 12-538 through Table 12-540 summarize the integration of EDP0 in the device MAIN domain.

**Table 12-538. EDP Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
EDP0 (with AUXPHY0)	PSC0	PD2	LPSC51	CBASS0

**Table 12-539. EDP Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
EDP0	EDP_DPTX_CLK	MAIN_SYSCCLK0 / 4	PLLCTRL0	EDP0 main clock.
		MAIN_PLL2_HSDIV7_CLKOUT	PLL2_HSDV17	To enable a reset isolation clock selection for the EDP0, the source clock can be dynamically switched to the MAIN_PLL2_HSDIV7_CLKOUT on a warm reset event, by configuring the CTRLMMR_EDP0_CLK_CTRL[8] DSI_CLK_DYN_SWITCH_DIS register bit in the device Control Module.
	EDP_DPI_2_CLK	DSS_DPI_0_OUT_PCLK	DISPC0	EDP0 video stream pixel clocks.
	EDP_DPI_2_2X_CLK	DSS_DPI_0_OUT_PCLK_2X		
	EDP_DPI_3_CLK	DSS_DPI_1_OUT_PCLK		
	EDP_DPI_4_CLK	DSS_DPI_2_OUT_PCLK		
	EDP_DPI_5_CLK	DSS_DPI_3_OUT_PCLK		
	EDP_AIF_I2S_CLK	MCASP10_ACLKX_O	MCASP10	EDP0 audio stream clock.
	PHY_LN0_REFCLK	IP1_LN0_REFCLK	SERDES4	EDP0 lane input clocks.
	PHY_LN0_TXFCLK	IP1_LN0_TXFCLK

## 12.6.4 Display Subsystem Controller (DISPC) with Frame Buffer Decompression Core (FBDC)

### 12.6.4.1 DISPC Overview

Figure 12-547 is a simplified block diagram of DISPC.

**Figure 12-547. DISPC Architecture Overview**

The DISPC integrated within DSS is capable of fetching pixel data from the device system memory through its dual master ports, performing various pixel processing, and then providing the processed pixels to an external display panel. The internal DMA engine tightly coupled to the DISPC is used for the pixel data transfer from system memory (frame buffer). The DISPC DMA engine is in charge of scheduling the memory requests. Several processes are configurable in order to manage the video pipeline features (color space conversion, up-sampling, down-sampling) and overlay features. The internal timing generator logic generates the video port output signals based on VESA DMT and CEA-861 standards. The DISPC video port outputs can be connected to display panels either directly (for MIPI DPI 2.0 or BT.656/BT.1120 support), or through either MIPI DSI or DisplayPort (DP/eDP) interfaces.

#### Note

The DISPC does not support any tiled frame buffer. The DISPC has no internal capability to support rotation of the frame buffer. The support for a compressed frame buffer is provided via the Frame Buffer Decompression (FBDC) module connected to the DISPC secondary master port.

### Note

The display resolution is programmable and can be any width in the range [1:4096] pixels. The following limitations apply, related to the type of display or the processing done:

- Active Matrix screen + dithering forces a width multiple of 2 pixels
- Active Matrix + TDM may force a width multiple of 2 pixels

The display buffers in the system memory must consist of contiguous pixels.

#### 12.6.4.2 DISPC Clocks

The DISPC has one clock domain for its internal logic and separate domains for each video port output.

The DISPC functional clock (DSS\_FUNC\_CLK) serves as the internal logic clock and also acts as the interface clock for the DISPC master and slave ports to system interconnect. There is no internal divider on this clock.

The DISPC pixel clocks (DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK, where  $p = 0$  to 3) serve as the clocks for the output display interface. The DSS\_DPI\_p\_PCLK clock is the 2x version of the DSS\_DPI\_p\_DIV\_PCLK clock. There are no internal dividers on the pixel clocks.

The relationship between the outgoing pixel clock and the input pixel clocks is as shown in [Section 12.6.4.11.9.1, MSS Clocking Scheme](#).

The frequency of the display controller logic clock (DSS\_FUNC\_CLK) has to be greater than the frequency of the DSS\_DPI\_p\_PCLK clocks, in order to get the DISPC internal logic to function properly. The frequency of the DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks depend on the required output display resolution and frame rate. For information on the maximum supported frequency ratings, see the device-specific Datasheet.

The DSS\_FUNC\_CLK is asynchronous to DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks. They can be generated by different sources.

The DSS\_DPI\_p\_PCLK and DSS\_DPI\_p\_DIV\_PCLK clocks are synchronous to one another (for the same value of  $p$ ).

The DSS0\_COMMON\_DSS\_SYSCONFIG[0] AUTOCLKGATING register bit is set by default to allow the auto-gating of the interface and functional clocks. The AUTOCLKGATING bit can be reset to disable the auto-gating of the clocks, if required.

The DISPC provides also a clock-gating control on sub-module level, via configuration of the appropriate DSS0\_COMMON\_DISPC\_CLKGATING\_DISABLE register fields.

#### 12.6.4.3 DISPC Resets

DISPC receives a single hardware reset signal. For more information, see *DSS Integration*.

To perform a software reset on the DISPC, set the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit to 0x1. The DSS0\_COMMON\_DSS\_SYSSTATUS[0] DISPC\_FUNC\_RESETDONE bit indicates that the software reset is complete (for the DISPC internal logic) when its value is 0x1. When the software reset completes, the DSS0\_COMMON\_DSS\_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

The completion of the software reset for the video ports logic is indicated in the DSS0\_COMMON\_DSS\_SYSSTATUS[3-1] DISPC\_VP\_RESETDONE register bit-field.

#### 12.6.4.4 DISPC Power Management

DISPC supports a power management protocol with the device Power Sleep Controller (PSC).

The (software) sequence, while performing a *clkstop\_req* to DISPC, is as follows:

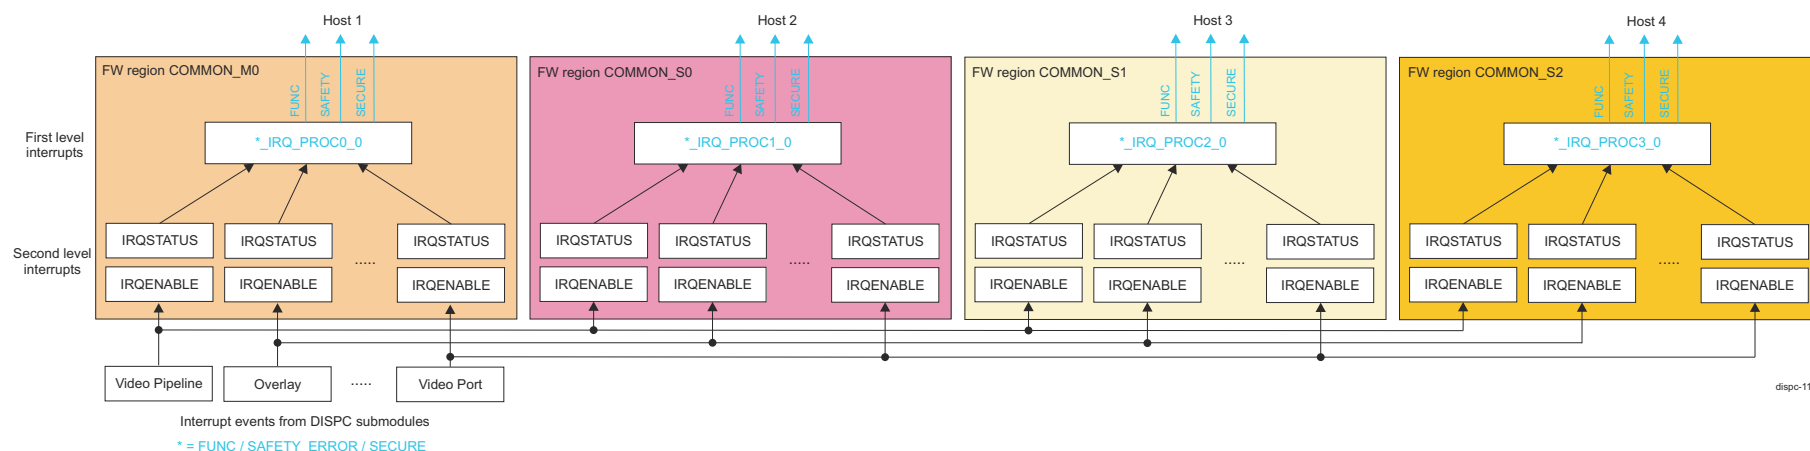

1. Disable DISPC by programming the [0] ENABLE bit of DSS0\_VP\_CONTROL register to 0.
2. DISPC hardware completes the output of the current frame. Then hardware sets the DSS0\_COMMON\_DSS\_SYSSTATUS[9] DISPC\_IDLE\_STATUS register bit to 1.

3. Poll the DSS\_IDLE\_STATUS bit to ensure that DISPC is in idle mode.
4. PSC initiates *clkstop\_req* to DISPC.
5. DISPC hardware acknowledges with *clkstop\_ack* immediately.

### 12.6.4.5 DISPC Interrupt Requests

The DISPC supports twelve interrupt output lines. The DISPC interrupt events are classified into functional, internal diagnostic error, and secure interrupt sub-categories, and then mapped to the respective sub-category interrupt line. Multiple sets of IRQ aggregation registers and IRQ generators enable fully independent monitoring and control of the interrupt events by up to 4 processor hosts at SoC level, as shown in [Figure 12-548](#). For more details on the mapping of the interrupt lines to SoC-level resources, see *DISPC Integration*.

- The 4 functional interrupt (FUNC\_IRQ) lines are DISPC\_FUNC\_IRQ\_PROC0\_0 through DISPC\_FUNC\_IRQ\_PROC3\_0.
- The 4 internal diagnostic error interrupt (SAFETY\_ERROR\_IRQ) lines are DISPC\_SAFETY\_ERROR\_IRQ\_PROC0\_0 through DISPC\_SAFETY\_ERROR\_IRQ\_PROC3\_0.
- The 4 secure interrupt (SECURE\_IRQ) lines are DISPC\_SECURE\_IRQ\_PROC0\_0 through DISPC\_SECURE\_IRQ\_PROC3\_0.

**Figure 12-548. DISPC Interrupts Generation**

Each of the interrupt signals indicates that one or more interrupt events are detected by the hardware. Each event is independently maskable for each interrupt output.

There are two level of interrupt events, as shown in [Figure 12-548](#). The first level is used to indicate common events and is also source for the second level of interrupts. The second level of interrupt events consists of status and enable interrupt registers for each video pipeline and each video port.

[Table 12-541](#) describes the first level of interrupt events with associated mask and status register fields. Each interrupt event is captured in an interrupt status register. Equivalent DSS0\_COMMON\_DISPC\_IRQSTATUS\_RAW register exist, which is updated even if interrupts are not enabled. This allows software to get access to updated status for all interrupt events.

**Table 12-541. DISPC Interrupts - First Level**

Interrupt Name	Set Interrupt Enable Register DSS0_COMMON_DISPC_IRQENABLE_SET	Clear Interrupt Enable Register DSS0_COMMON_DISPC_IRQENABLE_CLR	Interrupt Status Register DSS0_COMMON_DISPC_IRQSTATUS	Description
VID1_IRQ	[4] SET_VID_IRQ	[4] CLR_VID_IRQ	[4] VID_IRQ	At least one event of the VID1 pipeline interrupt events has occurred. See <a href="#">Table 12-542</a> for more details.
VIDL1_IRQ	[5] SET_VID_IRQ	[5] CLR_VID_IRQ	[5] VID_IRQ	At least one event of the VIDL1 pipeline interrupt events has occurred. See <a href="#">Table 12-543</a> for more details.
VID2_IRQ	[6] SET_VID_IRQ	[6] CLR_VID_IRQ	[6] VID_IRQ	At least one event of the VID2 pipeline interrupt events has occurred.
VIDL2_IRQ	[7] SET_VID_IRQ	[7] CLR_VID_IRQ	[7] VID_IRQ	At least one event of the VIDL2 pipeline interrupt events has occurred.
VP1_IRQ	[0] SET_VP_IRQ	[0] CLR_VP_IRQ	[0] VP_IRQ	At least one event of the VP1 interrupt events has occurred. See <a href="#">Table 12-545</a> for more details.
VP2_IRQ	[1] SET_VP_IRQ	[1] CLR_VP_IRQ	[1] VP_IRQ	At least one event of the VP2 interrupt events has occurred. See <a href="#">Table 12-546</a> for more details.
VP3_IRQ	[2] SET_VP_IRQ	[2] CLR_VP_IRQ	[2] VP_IRQ	At least one event of the VP3 interrupt events has occurred.
VP4_IRQ	[3] SET_VP_IRQ	[3] CLR_VP_IRQ	[3] VP_IRQ	At least one event of the VP4 interrupt events has occurred.
WB_IRQ	[14] SET_WB_IRQ	[14] CLR_WB_IRQ	[14] WB_IRQ	At least one event of the WB pipeline interrupt events has occurred.

[Table 12-542](#) describes the second level of interrupts for VID1 and VID2 pipelines with associated mask and status register bits.

**Table 12-542. DISPC Interrupts - Second Level - VID1 and VID2 Pipeline**

Interrupt Name	VID1 Interrupt Mask DSS0_COMMON_VID_IRQENABLE_0	VID1 Interrupt Status DSS0_COMMON_VID_IRQSTATUS_0	VID2 Interrupt Mask DSS0_COMMON_VID_IRQENABLE_2	VID2 Interrupt Status DSS0_COMMON_VID_IRQSTATUS_2	Description
VIDBUFFERUNDERFLOW_IRQ	[0] VIDBUFFERUNDERFLOW_EN	[0] VIDBUFFERUNDERFLOW_IRQ	[0] VIDBUFFERUNDERFLOW_EN	[0] VIDBUFFERUNDERFLOW_IRQ	Video DMA buffer underflow (FUNC_IRQ): The input video DMA buffer goes underflow. This does not necessarily mean that the buffer is empty (out of order refill), but simply that the required pixel is not in yet.

**Table 12-542. DISPC Interrupts - Second Level - VID1 and VID2 Pipeline (continued)**

VIDENDWINDOW_IRQ	[1] VIDENDWINDOW_EN	[1] VIDENDWINDOW_IRQ	[1] VIDENDWINDOW_EN	[1] VIDENDWINDOW_IRQ	End of the video window (FUNC_IRQ): The DMA engine has fetched all the data from memory for the video for the current frame.
VIDSAFETYREGION_IRQ	[2] SAFETYREGION_EN	[2] SAFETYREGION_IRQ	[2] SAFETYREGION_EN	[2] SAFETYREGION_IRQ	Video output MISR signature mismatch OR Video output freeze frame detect (SAFETY_ERROR_IRQ). The MISR signature generated does not match the expected signature OR the Video output frame freeze detection has triggered.
FBDC_CORRUPTTILE_IRQ	[3] FBDC_CORRUPTTILE_EN	[3] FBDC_CORRUPTTILE_IRQ	[3] FBDC_CORRUPTTILE_EN	[3] FBDC_CORRUPTTILE_IRQ	Corrupt tile is detected (FUNC_IRQ).
FBDC_ILLEGALTILEREQ_IRQ	[4] FBDC_ILLEGALTILEREQ_EN	[4] FBDC_ILLEGALTILEREQ_IRQ	[4] FBDC_ILLEGALTILEREQ_EN	[4] FBDC_ILLEGALTILEREQ_IRQ	Illegal tile request is detected (FUNC_IRQ).

Table 12-544 describes the second level of interrupts for the WB pipeline with associated mask and status register bits.

**Table 12-544. DISPC Interrupts - Second Level - WB Pipeline**

Interrupt Name	WB Interrupt Mask DSS0_COMMON_WB_IRQENABLE	WB Interrupt Status DSS0_COMMON_WB_IRQSTATUS	Description
BUFFEROVERFLOW_IRQ	[0] WBBUFFEROVERFLOW_EN	[0] WBBUFFEROVERFLOW_IRQ	Write-back DMA buffer Overflow (FUNC_IRQ): The output Write-back DMA buffer goes overflow. It cannot occur when write-back channel is used in memory to memory transfer mode but only in capture mode. In capture mode the timings are defined by the timer associated with the output. In memory-to-memory mode, there is a timing constraint.

**Table 12-544. DISPC Interrupts - Second Level - WB Pipeline (continued)**

Interrupt Name	WB Interrupt Mask DSS0_COMMON_WB_IRQENABLE	WB Interrupt Status DSS0_COMMON_WB_IRQSTATUS	Description
UNCOMPLETEERROR_IRQ	[1] WBUNCOMPLETEERROR_EN	[1] WBUNCOMPLETEERROR_IRQ	Write-back un-complete error (FUNC_IRQ): The WB pipeline is reset before all data of the frame currently written back are output to the interconnect interface.
FRAMEDONE_IRQ	[2] WBFRAMEDONE_EN	[2] WBFRAMEDONE_IRQ	Write-back Frame Done (FUNC_IRQ): The WB frame done in memory-to-memory mode of operation.
SECURITYVIOLATION_IRQ	[3] SECURITYVIOLATION_EN	[3] SECURITYVIOLATION_IRQ	Security Violation for WB output (SECURE_IRQ): A security violation (for example, a secure VID pipeline connected to a non-secure WB channel) has occurred.
SYNC_IRQ	[4] WBSYNC_EN	[4] WBSYNC_IRQ	Write-back sync (FUNC_IRQ): A configuration is copied from shadow registers to work for WB for next frame.

Table 12-545 describes the second level of interrupts for VP1 and VP2 outputs with associated mask and status register bits.

**Table 12-545. DISPC Interrupts - Second Level - VP1 and VP2 Outputs**

Interrupt Name	VP1 Interrupt Mask DSS0_COMMON_VP_IRQENABLE_0	VP1 Interrupt Status DSS0_COMMON_VP_IRQSTATUS_0	VP2 Interrupt Mask DSS0_COMMON_VP_IRQENABLE_1	VP2 Interrupt Status DSS0_COMMON_VP_IRQSTATUS_1	Description
FRAMEDONE_IRQ	[0] VPFRAMEDONE_EN	[0] VPFRAMEDONE_IRQ	[0] VPFRAMEDONE_EN	[0] VPFRAMEDONE_IRQ	Frame done for VP output (FUNC_IRQ). After disabling the VP output of the DISPC, the interrupt is set when the active frame related to the VP has completed.
VSYSNCR_IRQ	[1] VPVSYSNCR_EN	[1] VPVSYSNCR_IRQ	[1] VPVSYSNCR_EN	[1] VPVSYSNCR_IRQ	VSYSNCR for VP output (FUNC_IRQ): VSYSNCR interrupt for the VP has occurred at the end of the frame.

**Table 12-545. DISPC Interrupts - Second Level - VP1 and VP2 Outputs (continued)**

The MISR signature generated does not match the expected signature, or the VP output frame freeze detection has triggered.

#### 12.6.4.6 DISPC DMA Controller

The DISPC DMA controller is based on a 5-channel DMA engine that:

- Requests and supplies data from system memory to the VID and VIDL pipelines (up to 4 input layers) through the SoC system interconnect, based on the configuration of the pipeline settings.
- Stores the composed frames back into system memory by using the WB pipeline.
- Is fully programmable and fetches pixel data via 128-bit requests using 1D burst.

The DISPC DMA engine has an additional (secondary) 128-bit master port. By default, all transactions from every channel go through the primary 128-bit master port. If compression is enabled for a particular channel (by using the FBDC module), then all the transactions of that channel go through the secondary master port. It is also possible to force transactions from a particular channel to the secondary master port (even without compression) by setting the DSS0\_VID\_ATTRIBUTES2[25] MPORTSEL register bit to 0x1. This is possible only when compression through the FBDC is completely disabled (that is, none of the read channels are fetching compressed data).

Each pipeline has a dedicated DMA buffer and channel with independent settings. If a pipeline is disabled (that is, not used), then its DMA buffer can be assigned to another pipeline by configuring the DSS0\_COMMON\_DISPC\_GLOBAL\_BUFFER register. For example, unused buffers for a VIDL pipeline can be used by a VID pipeline.

Each DMA channel supports a total of 8 line buffers, each of which can store 2048 32-bit pixels.

- The size of each DMA buffer associated to the VID, VIDL and WB pipelines is 8x512x128-bit.

The DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration has been programmed for the video layer), that is, when the video window is present and the video pipeline is active.

##### 12.6.4.6.1 DISPC DMA Addressing and Bursts

For each line to be fetched, the DMA engine address generator:

- Calculates the pixel address
- Aligns the address
- Determines byte enable pattern
- Determines 1D burst length

The meaning of the address bits is as follows:

- Bits [31-0]: system (DDR) memory address (pixel address)
- Bits [47-32]: 32 bits + address extension

The address extension bits are defined by the programmable parameter DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 and DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers, optionally used to extend the BA memory addressing to 48-bit addressed external memory space (that is, to extend DISPC address space into 4GB+ space).

The DDR scan pixel addresses are generated by the DMA engine in order to read data from the system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The DSS0\_VID\_ROW\_INC register allow the access to a frame using 1D bursts (but as a two-dimensional block) by adding a fixed address offset at the end of a line. The ROW\_INC can also be used to skip lines from the input frame.

The byte address of each pixel in the frame buffer located in the system memory is determined by:

Pixel address = base\_address + x × (bpp/8) + y × (width × (bpp/8) + increment), where:

- "base\_address" corresponds to the base address defined by:
  - DSS0\_VID\_BA\_0/DSS0\_VID\_BA\_1[31-0] BA register bit-fields for all formats, and Y frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_EXT\_0/DSS0\_VID\_BA\_EXT\_1 registers.

- DSS0\_VID\_BA\_UV\_0/DSS0\_VID\_BA\_UV\_1[31-0] BA register bit-fields for UV frame buffer in case of YUV-NV12 format. Optional extension bits in DSS0\_VID\_BA\_UV\_EXT\_0/DSS0\_VID\_BA\_UV\_EXT\_1 registers.
- "bpp" corresponds to the number of bits per pixel defined by the DSS0\_VID\_ATTRIBUTES[6-1] FORMAT register bit-field.
- "width" corresponds to the number of pixels per line defined by the DSS0\_VID\_PICTURE\_SIZE[11-0] MEMSIZEX + 1 register bit-field.
- "increment" corresponds to the number of bytes to skip between two contiguous lines defined by the DSS0\_VID\_ROW\_INC [31-0] ROWINC – 1 register bit-field.
- "x" corresponds to the pixel position on the x-axis.
- "y" corresponds to the pixel position on the y-axis.

In cases where the DMA controller is doing a flip/mirror (see [Section 12.6.4.6.4, DISPC Flip/Mirror Support](#)) or fetching a compressed frame buffer (see [DISPC Compressed Data Format Support](#)), the above equation for pixel byte address needs to be modified according to those features.

### Note

Since the base address is aligned on pixel size boundary the horizontal resolution is one pixel. In case of YUV422 formats, the resolution is 4 bytes (2 pixels). In case of RGB24 packed format the resolution is 4 pixels. In case of Y frame buffer (YUV-NV12 format) the resolution is one byte. The vertical resolution is one line.

In case of YUV422 non-planar format, the number of pixels per line shall be a multiple of 2 pixels and the size of a pixel shall be considered as 2 bytes. In case of YUV planar format (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21), the Y buffer shall be considered as an 8-bit frame buffer, and the CbCr shall be considered as a 16-bit frame buffer. The pixel size is 1 byte and 2 bytes respectively for Y and CbCr.

For two-plane pixel formats (YUV420-NV12, YUV420-NV21, YUV422-NV12, YUV422-NV21, RGB565-A8), the pixel values are defined in two separate buffers (Y and UV buffers). The first buffer consists of Y values (8 bits for each Y sample) or 16-bit RGB value. The second buffer consists of CbCr values (16 bits for each pair of CbCr samples) or 8-bit Alpha value. The base address, the number of bytes to skip between pixels and between lines of each buffer are defined by separate registers:

- The DSS0\_VID\_BA\_0/DSS0\_VID\_BA\_1, DSS0\_VID\_PIXEL\_INC and DSS0\_VID\_ROW\_INC registers define the values to use for the first buffer
- The DSS0\_VID\_BA\_UV\_0/DSS0\_VID\_BA\_UV\_1 and DSS0\_VID\_ROW\_INC\_UV define the values to use for the second buffer
- Internal to the DMA controller, the two planes use the same shared memory space, which is allocated to the relevant pipeline which has the two-plane pixel format set

In case of interlaced mode, DSS0\_VID\_BA\_0 and DSS0\_VID\_BA\_UV\_0 registers define the base address of the even field, and DSS0\_VID\_BA\_1 and DSS0\_VID\_BA\_UV\_1 registers define the base address of the odd field.

[Table 12-547](#) summarizes the register settings for a simple access of a picture in the system memory.

**Table 12-547. DISPC Register Settings for Accessing Image in Internal Memory**

Pipeline Registers	Value
DSS0_VID_BA_0 <sup>(1)</sup> and DSS0_VID_BA_1 <sup>(2)</sup> / DSS0_WB_BA_0 and DSS0_WB_BA_1	The physical base address (PBA) of image in the memory for all formats and Y buffer.
DSS0_VID_BA_EXT_0 and DSS0_VID_BA_EXT_1 / DSS0_WB_BA_EXT_0 and DSS0_WB_BA_EXT_1	Address extension bits of PBA for all formats and Y buffer.
DSS0_VID_BA_UV_0 <sup>(1)</sup> and DSS0_VID_BA_UV_1 <sup>(2)</sup> / DSS0_WB_BA_UV_0 and DSS0_WB_BA_UV_1	The physical base address (PBA) of UV buffers image in the memory.

**Table 12-547. DISPC Register Settings for Accessing Image in Internal Memory (continued)**

Pipeline Registers	Value
DSS0_VID_BA_UV_EXT_0 and DSS0_VID_BA_UV_EXT_1 / DSS0_WB_BA_UV_EXT_0 and DSS0_WB_BA_UV_EXT_1	Address extension bits of PBA for UV buffers.
DSS0_VID_PIXEL_INC / DSS0_WB_PIXEL_INC	1 or other in pixel incremental value.
DSS0_VID_ROW_INC / DSS0_WB_ROW_INC	1 or other in row incremental value. Used for Y buffer.
DSS0_VID_ROW_INC_UV / DSS0_WB_ROW_INC_UV	1 or other in row incremental value. Used for UV buffer.

(1) The BA\_0 and BA\_UV\_0 registers define the base address of even field, in case of interlaced mode.

(2) The BA\_1 and BA\_UV\_1 registers define the base address of odd field, in case of interlaced mode.

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports only 1D burst. 1D burst is used, if the fetch data is linear in memory. The size of the burst can be one of the following values:

- 1x128-bit, 2x128-bit, 4x128-bit: Only during start of the row and end of the row, if there is a misaligned address
- 8x128-bit: Steady state burst size
- 16x128-bit: Only while accessing a compressed frame buffer

The DMA controller supports the start address of a row of pixels to be aligned to any arbitrary boundary in memory (with the restriction that a 32-bit format is aligned to 32-bit boundary, a 16-bit format is aligned to a 16-bit boundary, a 8-bit format is aligned to a 8-bit boundary, etc.). However, it operates most efficiently when the start address of a row is aligned to the max burst boundary of 8x128-bit. For all other cases of unaligned rows the DMA will need to go through non-optimal transactions at the start and end of each row, till it can issue a max burst of 8x128.

While accessing a compressed frame buffer (through the FBDC module), the base-address needs to be aligned to 256 bytes. In this case, the DMA will always issue a burst of 16x128-bit.

#### 12.6.4.6.2 DISPC Read DMA Buffers

The read DMA buffers are used by the VID and VIDL pipelines.

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line, the DMA buffers are flushed according to the video port output associated with the particular video pipeline. The DMA engine restarts fetching new frame data from the memory through the DISPC master port. Enabling or disabling the DISPC also flushes the DMA buffers.

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data through the master port.

- When low threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [15:0] BUFLOWTHRESHOLD register bit-field) is reached, the DMA engine starts a request on the device interconnect to fill the DMA buffer.
- When high threshold (set in the DSS0\_VID\_BUF\_THRESHOLD [31:16] BUFHIGHTHRESHOLD register bit-field) is reached, the DMA engine stops requesting encoded pixels.

### Note

The configuration of thresholds for optimal performance can be defined using the DSS0\_VID\_BUF\_SIZE\_STATUS[15-0] BUFSIZE register field value, as follows:

- For high threshold: BUFSIZE (in number of 128-bit words) – 1
- For low threshold: BUFSIZE (in number of 128-bit words) – burst size (in number of 128-bit words)

The following limitations for BUFLOWTHRESHOLD values must be also considered:

- If the scaler in VID pipeline is disabled, BUFLOWTHRESHOLD can be programmed as low as interconnect latency and pixel output rate allow it.
- If the scaler in VID pipeline is enabled, BUFLOWTHRESHOLD must be programmed to guarantee that at least four full lines can be stored.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes and the high threshold value. When the preload value is reached, the associated channel will start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DSS0\_VID\_PRELOAD[11-0] PRELOAD register bit-field, the DSS0\_VID\_ATTRIBUTES[19] BUFPRELOAD register bit must be set to 0x0.

The vertical blanking between two frames must be long enough to allow fetching the number of pixels defined by the DSS0\_VID\_PRELOAD register and preloading the whole video pipeline. If the value set in the preload register is greater than some overflow conditions detected by the hardware, then data will start to be read from the video DMA buffer before the preload value is reached. If SYNCLOST\_IRQ event occurs the video buffer needs to be increased (buffer merge). Preload value must be greater or equal to low threshold, and smaller or equal to high threshold value.

### Note

When self-refresh mode is selected (which means that the data in the DMA buffer are used for multiple frames) the DMA buffers are not flushed at the end of each frame. Each DMA buffer has an independent control for selecting the self-refresh mode. For more information, see [Section 12.6.4.6.10, DISPC DMA Ultra-Low Power Mode](#).

#### 12.6.4.6.3 DISPC Write DMA Buffer

The write DMA buffer is used by the WB pipeline.

Two modes for filling the DMA buffer are supported by the WB channel, selectable through the DSS0\_WB\_ATTRIBUTES[19] WRITEBACKMODE bit:

- Capture mode, WRITEBACKMODE bit set to 0: One of the overlay outputs connected to an external interface is captured at the same time the data are sent on the output. The WB timings are controlled by the VP timings.
- Memory-to-memory mode, WRITEBACKMODE bit set to 1: One of the overlay outputs or one of the pipelines is captured to perform a memory-to-memory transfer, with some processing by the DISPC (rescaling, overlaying, color space conversion, etc.).

**In capture mode:** Transfer is synchronous (that is, tightly coupled) to one of the display outputs. In this mode, the write back buffer starts receiving data after DSS0\_WB\_ATTRIBUTES[0] ENABLE register bit has been set and the associated output vertical sync has triggered the start of the transfer (VFP). In addition, the WB ENABLE bit shall be set prior to the enable of the captured channel output in order to capture the first frame.

**In memory-to-memory mode:** The data transfer is not synchronous to any of the display outputs. In this mode, the write back buffer starts receiving data after the DSS0\_WB\_ATTRIBUTES[0] ENABLE has been set. The WB ENABLE bit also is triggering the update of the shadow register in the WB pipeline.

Programmable high and low thresholds are used by the DMA engine to start and stop sending data to the system interconnect.

- When high threshold (set in the DSS0\_WB\_BUF\_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, and there are enough data for at least one burst of pixels in the DMA buffer ready for transfer, the DMA engine generates a request to the arbitration logic. The size of the burst is defined by the user.
- When low threshold (set in the DSS0\_WB\_BUF\_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine stops sending encoded pixels.

At the end of the frame, to completely drain the DMA buffer, some smaller bursts (even single requests) may have to be issued. To limit the number of interconnect requests from the DISPC (that is, to limit the throughput of the write-back channel to the memory), a number of IDLE cycles between requests can be inserted. IDLE cycles can be inserted only when WB is used in memory-to-memory mode. It is ignored when WB is in capture mode.

The number of IDLE cycles between requests can be activated and determined by:

- Setting the DSS0\_WB\_ATTRIBUTES[27] IDLESIZE bit to 0x0 (default value) and entering the number of idles between requests in the DSS0\_WB\_ATTRIBUTES[31:28] IDLENUMBER bit field. Idle numbers vary from 0 to 15.
- Setting the DSS0\_WB\_ATTRIBUTES[27] IDLESIZE bit to 0x1, which considers the size of the burst (the DSS0\_WB\_ATTRIBUTES[15:14] BURSTSIZE bit field) to determine the number of IDLE cycles.
  - If BURSTSIZE = 0x0, then the number of IDLE cycles equals IDLENUMBER (0 to 15).
  - If BURSTSIZE = 0x1, then the number of IDLE cycles equals IDLENUMBER × 4 (0 to 60).
  - If BURSTSIZE = 0x2, then the number of IDLE cycles equals IDLENUMBER × 8 (0 to 120).

#### 12.6.4.6.4 DISPC Flip/Mirror Support

The DISPC supports on-the-fly source image flip along the x/y-axis for 8-bit/component formats (ARGB or YUV) to create a mirror effect on the source data. The DMA engine reads the source frame from right to left by requesting burst transfers for each line in negative address increments while performing each burst transfer as a linear incremental burst. The read data is repacked and stored in the line buffer incrementally - effectively storing the frame as a flipped image for the processing pipeline. The configuration of the flip/mirror operation is explained in [Table 12-548](#).

**Table 12-548. DISPC Flip/Mirror Configuration**

Flip Direction	FLIP Bit	Base Address	Byte Increment
Along Y-axis (vertical mirror)	1	Start of window	1
Along X-axis (horizontal mirror)	0	Start of last line of the window	-(2*(width of the line in bytes))
Along both X-axis and Y-axis (horizontal and vertical mirror)	1	Start of last line of the window	-(2*(width of the line in bytes))

In [Table 12-548](#):

- The FLIP bit is located in DSS0\_VID\_ATTRIBUTES register.
- The base address of the video buffer must be configured as explained in [Section 12.6.4.6.1, DISPC DMA Addressing and Bursts](#).
- The the number of bytes to increment at the end of the row in the video buffer can be configured through DSS0\_VID\_ROW\_INC and DSS0\_VID\_ROW\_INC\_UV registers. For more information, see [Section 12.6.4.6.1, DISPC DMA Addressing and Bursts](#), and [Section 12.6.4.6.5, DISPC DMA Predecimation](#).

The flip/mirror feature is not supported for compressed data formats (when the DMA engine receives data from the FBDC module).

#### 12.6.4.6.5 DISPC DMA Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels out of the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1D

burst. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the ROW\_INC and ROW\_INC\_UV registers (see [Section 12.6.4.6.1, DISPC DMA Addressing and Bursts](#)).

- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 out of 2 pixels, up to 1 of out 2047 pixels, by setting the PIXEL\_INC register (see [Section 12.6.4.6.1, DISPC DMA Addressing and Bursts](#)) to the number of pixels to skip (n), multiplied by the size of a pixel (in bytes), +1. The condition to generate a burst is that there is at least one useful pixel per 128-bit OCP request. Therefore, when the pixels are 16/32-bit, the maximum number of pixels that can be skipped is 8/4. If  $\text{PixelWidthInBytes} + \text{BytesToSkip}$  is greater than 16, then the programmed burst is changed into single request.

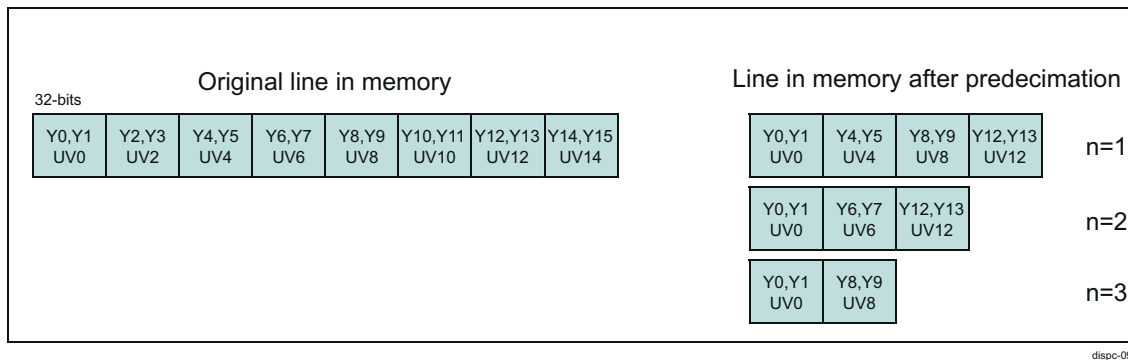

No decimation is supported when the input format is 1, 2, 4, or 8-bit BITMAP.

For RGB and YUV420 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXEL\_INC register, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV422 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see [Figure 12-549](#)). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV422 format, caution must be taken because n equals the number of pixel data containers to skip, and not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

**Figure 12-549. DISPC YUV422 Predecimation**

#### 12.6.4.6.6 DISPC DMA Buffer Sharing

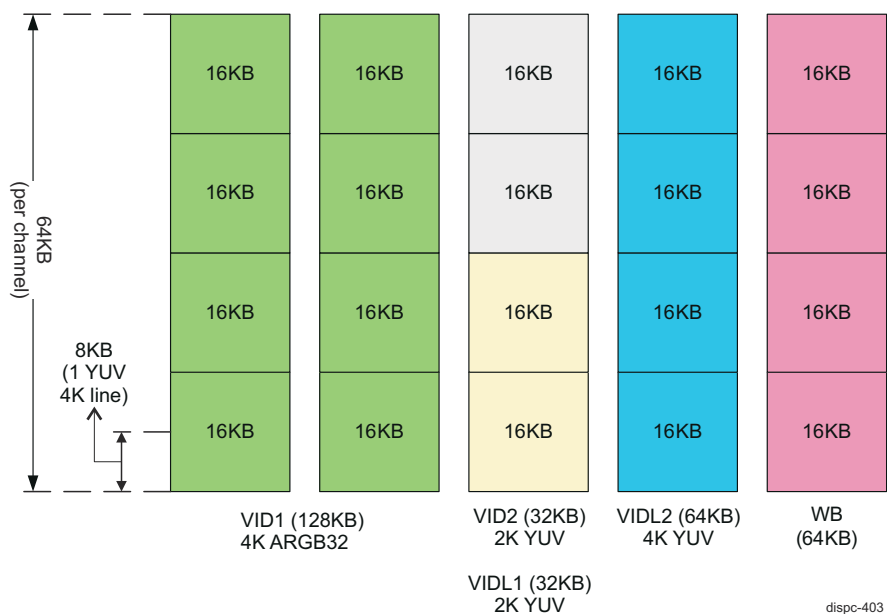

The DISPC DMA controller supports dynamic re-partition of the memory among the different channels.

At reset, each channel in DMA is allocated a uniform buffer size of 64KB. This 64KB is further partitioned into four 16KB blocks as shown in [Figure 12-550](#). A 64KB buffer is enough to support ping-pong mode for resolutions up to 4K for YUV420/YUV422 formats and up to 2K for ARGB32 formats.

**Figure 12-550. DISPC DMA Channel Memory Allocation at Reset**

To support resolutions larger than 4K YUV or 2K ARGB (with ping-pong configuration), the default buffer size of 64KB per read channel is not sufficient. In such cases, the DISPC allows dynamic repartition of the allocated buffers across the different read channels. In this way each read channel can have a variable buffer size allocated to it, starting from a minimum of 16KB to a maximum of 256KB, in 16KB increments. The WB channel buffers cannot be re-allocated and remain fixed. This is the case even when WB channel is disabled. A particular configuration (for a specific example use-case) is as shown in [Figure 12-551](#).

**Figure 12-551. DISPC Dynamic Buffer Repartition between DMA Read Channels**

When the size of the buffer is changed, the thresholds shall be re-programmed by the user to reflect the new DMA buffer configuration.

The activity on a read channel is controlled by the timing of the Overlay/VP to which the channel is connected (or to the WB, if the channel is connected to WB in M2M mode). Due to this, the DISPC HW ensures that any

change in a channel buffer setting is synchronized with regard to the Overlay/VP or WB (M2M mode) to which the channel is connected. In addition, the software also must follow the following programming sequences:

- Initialization sequence (before enabling any pipe or VP or WB):
  1. Allocate the total available memory among the different threads (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZE[19-0] VP#nTHREADSIZESIZE and [24-20] WBTHREADSIZESIZE register bit-fields).
  2. Wait for the DISPC HW to sync to the programmed THREADSIZESIZE (read the value from DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZESTATUS[19-0] VP#nTHREADSIZESIZE and [24-20] WBTHREADSIZESIZE register bit-fields).
  3. Allocate a buffer for each of the (active) read channels (configurable through the DSS0\_VID\_DMA\_BUFSIZE[4-0] BUFSIZE register field). Software needs to ensure that the total size allocated to all the channels in a thread does not surpass the total size allocated to the thread.
  4. Enable the read channels as well as the VP output.
- Intra thread re-allocation sequence. Within the thread the re-allocation always happens at the next VSYNC. There is no handshake needed on the part of software.
  1. Allocate the new buffer size (configurable through the DSS0\_VID\_DMA\_BUFSIZE[4-0] BUFSIZE register field).
- Inter thread re-allocation sequence. The synchronization events (VSYNC) between two threads will be different. Therefore, any re-allocation between two threads needs to go through a software managed handshake sequence as follows:
  1. Free the required amount of memory from Thread-#n (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZE register).
  2. Wait till the synchronization event of Thread-#n (achieved by looking at the status reflected in the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZESTATUS register).
  3. Allocate the freed buffer space to a different thread, Thread-#m (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZE register).
  4. Further allocate this space to the different read channels of Thread-#m (configurable through the DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESIZESTATUS register).
  5. Further allocate the new buffer size to the read channels in Thread-#m (configurable through DSS0\_VID\_DMA\_BUFSIZE register).

#### Note

In a case where a channel is connected to multiple Overlay/VP (multi-cast use-case), then the channel belongs to the thread corresponding to the first (lowest numbered) Overlay/VP to which it is connected.

#### 12.6.4.6.7 DISPC DMA MFLAG Mechanism

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read buffers.

The MFLAG mechanism is used when fullness of the DMA buffers is critical (close to underflow). The mechanism is implemented for all DMA buffers of the video pipelines.

Programmable buffer thresholds (forming hysteresis) are used to configure when a local MFLAG signal is generated. The 1-bit MFLAG signal is generated on DISPC master port in order to inform the system that the outstanding requests from DISPC shall be considered with higher priority in order to get faster interconnect responses. The MFLAG signal is asynchronous to any ongoing interconnect transaction.

Each pipeline maintains its own MFLAG bit. The MFLAG bit is asserted depending on the fullness of the DMA buffers associated with the pipeline and depending on the thresholds programmed by software. All MFLAG signals are OR-ed together to generate the single 1-bit MFLAG for the master port connected to the DISPC DMA engine.

The threshold for video pipelines corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT\_MFLAG: High threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [31-16] HT\_MFLAG register field.
- LT\_MFLAG: Low threshold.
  - For read access from video pipelines, when the pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the DSS0\_VID\_MFLAG\_THRESHOLD [15-0] LT\_MFLAG register field.

Summary of the MFLAG value, based on DMA read buffer fullness:

- If DMA read buffer fullness < LT\_MFLAG, then MFLAG signal = 1
- If LT\_MFLAG < DMA read buffer fullness < HT\_MFLAG, then MFLAG signal = 1
- If DMA read buffer fullness > HT\_MFLAG, then MFLAG signal = 0

Similarly, the MFLAG is set based on fullness and the transition history on the out bound writeback pipeline. There is no pre-fetch state for out bound DMA controller. The MFLAG is set when the buffer fullness rises above the HT\_MFLAG bit-field value. The MFLAG is cleared only when the buffer fullness falls back below the LT\_MFLAG bit-field value. In between these two fullness states, the MFLAG bit keeps the previous value.

By default, the MFLAG mechanism is disabled (DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field = 0x0), and the MFLAG signal is low (de-asserted). The arbitration scheme for the pipelines is the same as described in [Section 12.6.4.6.9, DISPC DMA Arbitration](#). That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the MFLAG\_CTRL register field is set to 0x2, the MFLAG mechanism is enabled, and the MFLAG signal is dynamically set to 0 or 1, depending on DMA buffer fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for the pipelines is round-robin between those high-priority pipelines, which have asserted their local MFLAG signals. If there are no high-priority pipelines with their local MFLAG signals asserted, then the arbitration scheme is the same as described in [Section 12.6.4.6.9, DISPC DMA Arbitration](#).

The DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[6] MFLAG\_START bit defines the following additional rules for the MFLAG mechanism:

- If the MFLAG\_START bit is set to 0x0 (default value), then when the DMA buffer is empty at the beginning of the frame, the MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see [Section 12.6.4.6.2, DISPC Read DMA Buffers](#)). Then, based on the setting of the DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field, the MFLAG signal is generated and DISPC internal logic is arbitrating between pipeline requests.
- If the MFLAG\_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the configuration of DSS0\_COMMON\_DISPC\_GLOBAL\_MFLAG\_ATTRIBUTE[1-0] MFLAG\_CTRL register field determines the generation of the MFLAG signal.

#### 12.6.4.6.8 DISPC DMA Priority Requests Control

The DSS0\_COMMON\_DSS\_CBA\_CFG register controls the priority level for DMA requests going out to the memory through the system interconnect.

As explained in [Section 12.6.4.6.7, DISPC DMA MFLAG Mechanism](#), the DISPC master port generates a 1-bit MFLAG output signal to raise the priority of all requests made on that port, if any of its DMA buffers runs critically low (determined by a set of user programmable threshold values for each buffer).

DSS uses the MFLAG signal from DISPC to set a 3-bit priority level output (*Mpriority*) for the master port to either a low or high value (configurable in DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields with optional values of 0~7) as follows:

- When MFLAG = 0, the PRI\_LO register field determines the value of the Mpriority output for the normal transactions.
- When MFLAG = 1, the PRI\_HI register field determines the value of the Mpriority output for the high-priority transactions.

This Mpriority output directly drives the respective input of the system interconnect port, which corresponds to the DISPC DMA master port.

#### CAUTION

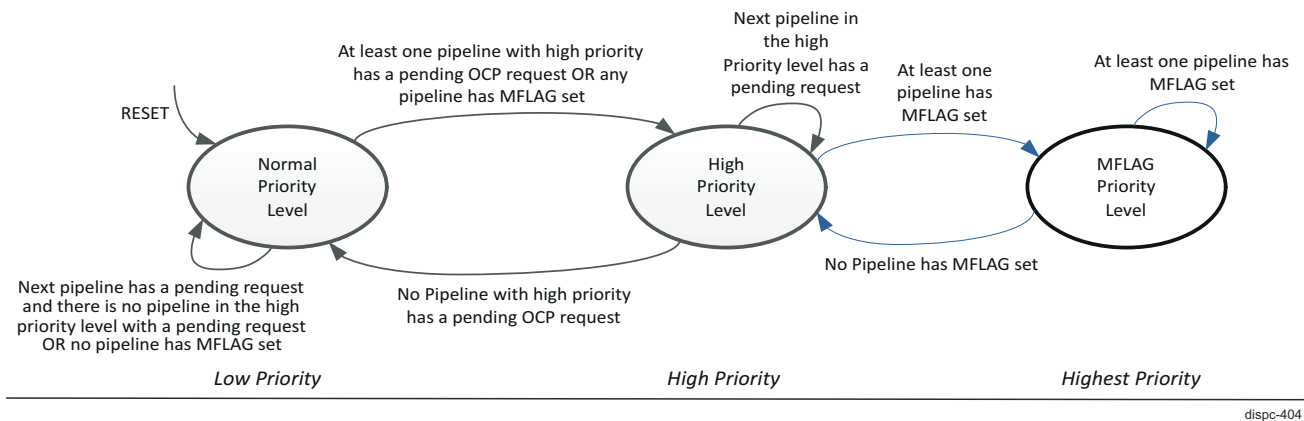

Upon a hardware reset, DSS0\_COMMON\_DSS\_CBA\_CFG[2-0] PRI\_LO and [5-3] PRI\_HI register fields are set by default to 4 and 1, respectively. Afterwards, these priority level register fields can only be modified by a secure host.

#### 12.6.4.6.9 DISPC DMA Arbitration

The read requests sent to the system interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme can be modified by setting the priority attribute of each pipeline as defined in the DSS0\_VID\_ATTRIBUTES[23] ARBITRATION register bit.

By default, all pipelines have the same priority (normal priority), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the system interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, then the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

In addition to the priority bit-field, the MFLAG mechanism can also result in a higher priority for a pipeline. An MFLAG priority level is set, for all pipelines for which MFLAG bit is set, which is defined as the highest priority level for arbitration. For more details on MFLAG mechanism, see [Section 12.6.4.6.7, DISPC DMA MFLAG Mechanism](#). [Figure 12-552](#) shows the transition between the different priority levels.

**Figure 12-552. DISPC DMA High/Low Priority Arbitration**

#### 12.6.4.6.10 DISPC DMA Ultra-Low Power Mode

In ultra-low power mode, the system interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. Then, the system interconnect is not used anymore to fetch new pixels for the consequent frames. The data are fetched once into the DMA buffer and then the following frames re-use the DMA buffer to display on the screen.

The programming of the ultra-low power mode is independent for each pipeline and is achieved via the DSS0\_VID\_ATTRIBUTES[24] SELFREFRESH register bit. One pipeline may have all frame pixels into the DMA

buffer and other pipeline may have to refill the DMA buffers along the display scan, because the frame buffer is too big to be stored in the DMA buffer.

The DMA buffers can be merged in order to optimize the system interconnect OFF time. Each DMA buffer dedicated to one pipeline can be split into two buffers. The merge of the DMA buffers into a single one can be used at the same time to improve the Ultra-Low Power mode.

Two ultra-low power modes can be entered, manual or automatic mode:

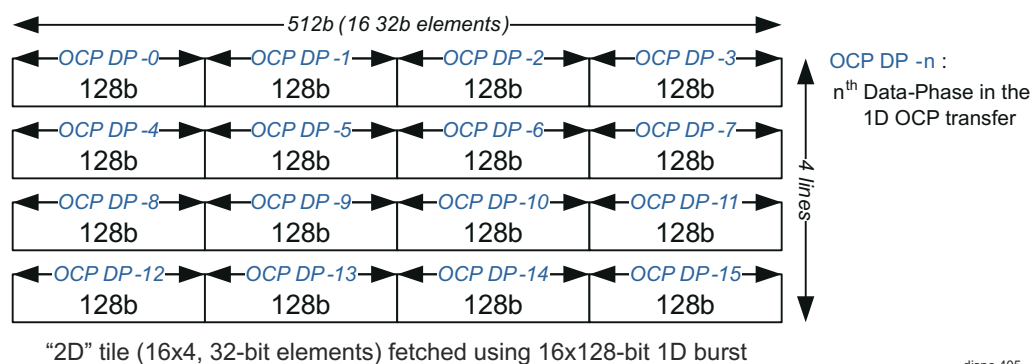

- **Manual self-refresh mode:** Starting self-refresh mode is done manually by setting the SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0. Software must first disable the SELFREFRESH bit during at least one frame in order to capture the data (by setting the GOBIT register bit of the video port the pipeline is associated with). Once the DSS0\_VP\_CONTROL[5] GOBIT bit has been set, the software must read the GOBIT bit to ensure that the frame has been loaded into the buffer, then it can set the SELFREFRESH bit to 1. Once SELFREFRESH is enabled, the fetch of data from the system memory is stopped for the following frames. The software needs to reset the SELFREFRESH bit in order to restart fetching data from system memory.
- **Automatic self-refresh mode:** By setting the DSS0\_VID\_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from disabled to enabled for self-refresh mode is controlled by hardware. This allows the software to reset the SELFREFRESH bit to "disabled", and then automatically after the fetch of the first frame the hardware switches back SELFREFRESH bit to "enabled". The SELFREFRESH must be disabled during at least one frame in order to capture the data, so software must reset the bit to 0 every time the data in the DMA buffer needs to be updated. The hardware reads the data inside the DMA buffer without accessing the interconnect and system memory during the frame, then modifies the SELFREFRESH bit to reflect the current state of the self-refresh mode by setting the bit to 0x1.

#### 12.6.4.6.11 DISPC Compressed Data Format Support

The DISPC is capable of reading a compressed frame buffer through the FBDC block. The FBDC is a Frame Buffer Decompression module that is compatible with the lossless compression module (FBC) in the GPU in the SoC. The FBDC performs the lossless decompression of the compressed images on a tile-by-tile basis. The size of the tiles is 16 pixels by 4 lines or 32 pixels by 2 lines. The FBDC is enabled by setting the DSS0\_VID\_FBDC\_ATTRIBUTES[0] ENABLE register bit.

##### 12.6.4.6.11.1 FBDC Tile Request

Since the compression/decompression is tile based, the DMA engine generates a 256-byte (16x128-bit) 1D burst request for each tile (a tile is a 16x4 or 32x2 2D structure of 32-bit elements) to FBDC which handles the DMA transfer and decompression of the requested tile. The de-compression phases are transparent to the DISPC hardware. Only ordering of the pixels from a returned tile is taken care by the DISPC DMA engine using 1D burst. The data returned from the FBDC, for a single tile over different OCP data-phases (DP), is as shown in Figure 12-553.

**Figure 12-553. DISPC FBDC Tile Request (16x4 Tile)**

---

**Note**

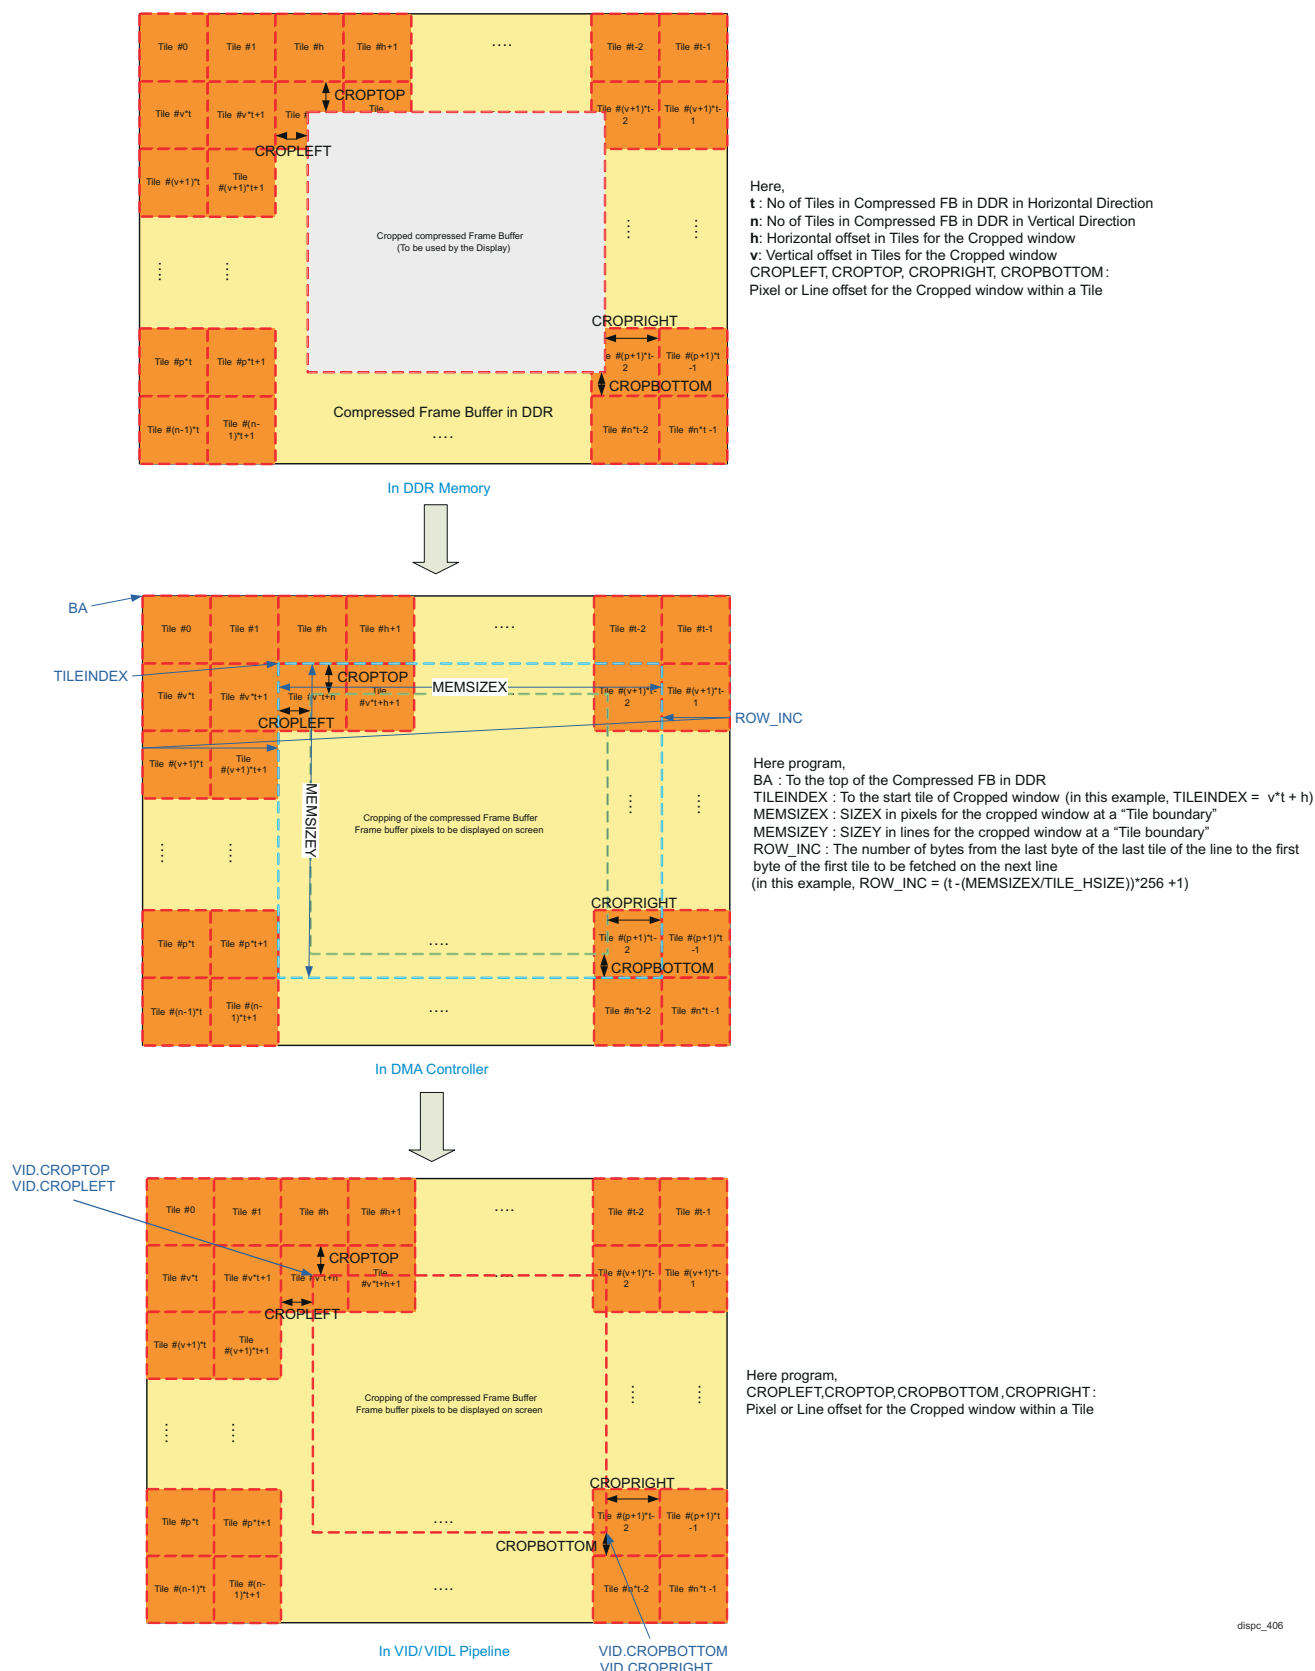

Due to the tile nature of the data, the following DMA features are not available with compressed data formats:

- Flip/Mirror support
  - ROW\_INC on a line basis (that is, ROW\_INC cannot be used to skip lines). It can only be specified in such a way as to skip entire tile rows.
- 

**12.6.4.6.11.2 FBDC Source Cropping**

The FBDC supports a source cropping of the compressed frame buffer. The source cropping is achieved as a two-step process.

- Cropping at a tile boundary is achieved by the DMA controller.
- Cropping within a tile (to a pixel or a line) is achieved by the VID/VIDL pipeline. That is a regular crop feature in the VID/VIDL pipeline which is useful for non-compressed frames as well.

dispc\_406

Figure 12-554. DISPC FBDC Example of a Frame Buffer Source Cropping (Decompression)

The necessary programming for cropping at a tile boundary within the DMA Controller (based on [Figure 12-554](#)) is as follows:

- BA must be programmed to the top of the compressed frame buffer in DDR.
- TILEINDEX must be programmed to the start tile of the cropped window in the DSS0\_VID\_TILE[22-0] TILEINDEX register field. In this example,  $TILEINDEX = v \cdot t + h$ .
- MEMSIZE\_X is the SIZE\_X in pixels for the cropped window at a "Tile boundary".
- MEMSIZE\_Y is the SIZE\_Y in lines for the cropped window at a "Tile boundary".
- ROW\_INC is the number of bytes from the last byte of the last tile of the line to the first byte of the first tile to be fetched on the next line. In this example,  $ROW\_INC = (t - (MEMSIZE\_X / TILE\_H\_SIZE)) \cdot 256 + 1$ , where  $TILE\_H\_SIZE = 16$  or  $32$  depending on whether 16x4 tile-type is used or a 32x2 tile-type is used. The tile type must be programmed in the DSS0\_VID\_FBDC\_ATTRIBUTES[9-8] TILETYPE register field.

For details on the register programming for the crop feature in the VID/VIDL pipeline, see [Section 12.6.4.8.9, DISPC VID Cropping Support](#).

#### 12.6.4.7 DISPC Pixel Data Formats

The DISPC pipelines support various types of memory formats, as listed in [Table 12-549](#).

For BITMAP formats the nibble mode (pixels in each byte are packed in reverse order) can be enabled by setting the DSS0\_VID\_ATTRIBUTES[10] NIBBLEMODE register bit to 0x1. The nibble mode is supported only for the VID/VIDL pipelines, but not for the WB pipeline.

The pixel data format can be selected by loading the corresponding value from [Table 12-549](#) in the DSS0\_VID\_ATTRIBUTES/DSS0\_WB\_ATTRIBUTES[6-1] FORMAT register bit-field.

**Table 12-549. DISPC Supported Pixel Data Formats**

- (1) The video and writeback pipelines support an optional 8-bit Alpha plane (separate buffer), if the pixel format of the source/destination buffer is either RGB16-565 or BGR16-565.
- (2) NV21 formats for YUV420/YUV422 are indirectly supported through chroma swapping during the color space conversion.
- (3) The 10-bit/12-bit versions of these YUV formats are also supported in both packed and unpacked (in 16-bit container) formats. For unpacked formats, both LSB or MSB alignments are supported. These configurations are set using a separate configuration registers: DSS0\_VID\_ATTRIBUTES2 and DSS0\_WB\_ATTRIBUTES2. The default is an 8-bit packed format support.
- (4) All RGB formats with alpha component include both pre/non-pre-multiplied data support. Also, alpha can be disabled to work as X (can be replaced with global alpha value).
- (5) The writeback path supports only 8-bit and 10-bit YUV data formats.

Figure 12-555 shows the pixel data memory organization for the bitmap pixel formats.

**Figure 12-569. DISPC YUV 10-bit/12-bit Unpacked Pixel Formats 3**

### 12.6.4.8 DISPC Video Pipeline

The DISPC includes two types of input video pipelines:

- Video pipeline (VID1 and VID2)
- Video lite pipeline (VIDL1 and VIDL2)

The video pipeline (VID) consists of:

- VC-1 range mapping unit for YUV422/YUV420 input formats;
- Replication logic for ARGB input formats;
- One 256 x 24-bit entries Color Look-up Table (CLUT);
- Polyphase-filter based resizer unit (scaler) supporting chroma upsampling;
- Luma-key support;
- Color Space Conversion (CSC) unit (YUV to RGB), which can be used also for programmable BCHS (Brightness/Contrast/Hue/Saturation) control;

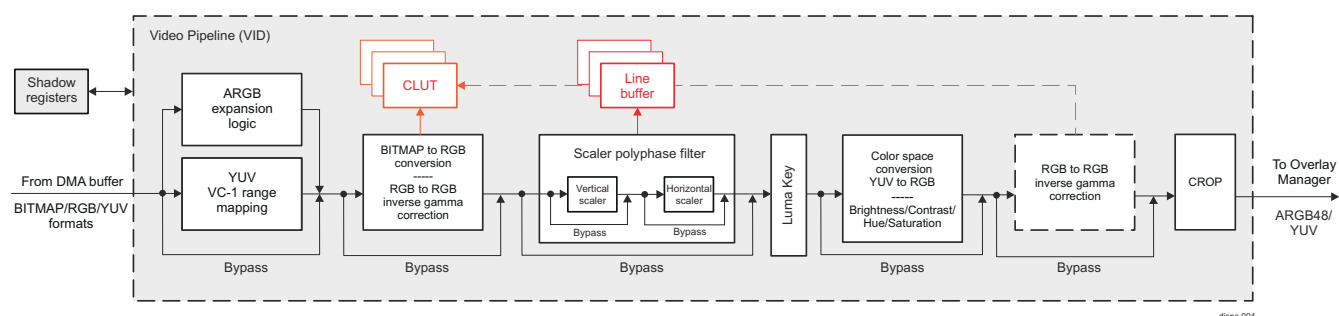

The video lite pipeline (VIDL) is identical to the video pipeline (VID), except for:

- Polyphase-filter based resizer (scaler) is not included;
- Chroma upsampling is done using dedicated YUV420-to-422 and YUV422-to-444 upsamplers (instead of using the scaler);

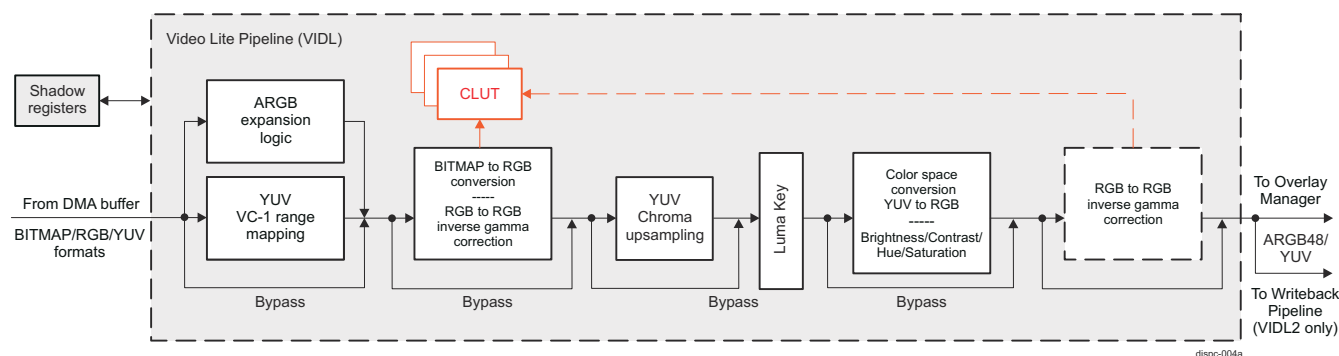

Each pipeline processing block can be independently bypassed.

#### Note

The DISPC input video pipelines, VID and VID1L, will be commonly referred to as *video pipeline (VID)* in the following sections. Any differences in their functionality will be highlighted.

**Figure 12-570. DISPC Video Pipeline Configuration**

**Figure 12-571. DISPC Video Lite Pipeline Configuration**

The input of the VID pipeline is connected to the video DMA buffer controller. The pixel output of the VID pipeline is connected to the overlay managers. The VID pipeline configuration supports various BITMAP, RGB (ARGB and RGBA), and YUV formats, as listed in [Table 12-549, DISPC Pixel Data Formats](#).

The 256-entry CLUT is either used to convert BITMAP (1, 2, 4, or 8-bit indexed formats) into RGB format, or for RGB to RGB inverse gamma correction. For a BITMAP format data, scaling is not supported. Scaling and color look-up table features are mutually exclusive. If the color look-up feature is enabled, then the video pipeline scaler has to be disabled.

For chroma sub-sampled YUV formats (YUV422 and YUV420-NV12/NV21):

- VID pipeline: the scaler unit upsamples the chrominance data using both vertical and horizontal polyphase filters;
- VIDL pipeline: dedicated YUV420 to YUV422 and YUV422 to YUV444 chroma upsamplers are used;

For ARGB source data with less than/equal to 10-bit component data size the replication logic (ARGB expansion) converts the data to ARGB48 by replicating the MSBs into the LSBs:

- When scaling is disabled (or no scaler supported), the resulting ARGB48 data is directly provided to the pipeline output;
- When vertical scaling is engaged, the resulting ARGB48 data is first truncated to ARGB8888, and then converted to ARGB10101010 (by MSBs replication into LSBs), before being fed to the vertical scaler input;
- When vertical scaling is disabled, but horizontal scaling is engaged, the resulting ARGB48 data is directly provided to the horizontal scaler input;

#### Note

There are limitations on using the inverse gamma (InvGamma) operation along with scaling. If the scaler is enabled, the InvGamma operation must always take place after the scaler in the data-path (as shown in [Figure 12-570](#)). This position of the InvGamma operation is controllable through the DSS0\_VID\_ATTRIBUTES2[29] GAMMAINVERSIONPOS register field.

All the memories (line buffers attached to the scaler, LUT and chroma upsamplers) are sized to support 10-bit per color component. This allows full 10-bit support inside the video pipeline.

The VID pipeline can be enabled by setting the DSS0\_VID\_ATTRIBUTES[0] ENABLE register bit. If the video pipeline is disabled, the video window does not exist on the screen and the whole video pipeline and its DMA are inactive. Prior to enabling the video layer a valid configuration has to be set by the user.

#### 12.6.4.8.1 DISPC VID Replication Logic

The replication logic (ARGB expansion) converts ARGB pixel formats into ARGB48 format by replicating the MSBs into the LSBs. The logic is always enabled.

[Table 12-550](#) shows how some of the ARGB formats supported by VID are remapped into ARGB48 by default.

**Table 12-550. DISPC VID Replication: ARGB Pixel Formats Remapping into ARGB48-12121212**

ARGB32-8888	A[7:0]A[7:4]	R[7:0]R[7:4]	G[7:0]G[7:4]	B[7:0]B[7:4]

#### 12.6.4.8.2 DISPC VID VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components to the full range (from the reduced data range) before

displaying. The unit is used primarily for YUV420-NV12 (NV21) pixel format, but also can be applied to YUV422 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DSS0\_VID\_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The VC-1 range mapping must be enabled only for 8 bits/component YUV input data.

The DSS0\_VID\_ATTRIBUTES2[3:1] VC1\_RANGE\_Y and [6:4]VC1\_RANGE\_CBCR register bitfields are two 3-bit values programmed by the user.

The equations for the mapping process are:

$$Y_{out} = \text{CLIP}((((Y_{int} - 128) \times (\text{VC1\_RANGE\_Y} + 9) + 4) / 8) + 128)$$

$$C_b = \text{CLIP}((((C_b - 128) \times (\text{VC1\_RANGE\_CBCR} + 9) + 4) / 8) + 128)$$

$$C_r = \text{CLIP}((((C_r - 128) \times (\text{VC1\_RANGE\_CBCR} + 9) + 4) / 8) + 128)$$

#### Note

The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP() clips to 0 or 255 when minimum or maximum, respectively, is reached. Otherwise, the resulting output remains identical.

#### 12.6.4.8.3 DISPC VID Color Look-Up Table (CLUT)

The video pipeline supports a look up table to perform either of the following operations:

- Conversions of BITMAP formats (1, 2, 4, or 8-bit indexed) into RGB format (CLUT mode), or
- Inverse gamma correction on non-linear RGB source data (gamma mode)

The look-up table consists of 3 separate 1024 x 10-bit memories and is indexed either by the source BITMAP data or by R/G/B component data. The table is loaded through direct register access by writing to the CLUT registers.

The sequence to load the table is:

1. SW writes (only writes are supported) 32-bit values for both color and monochrome mode using single access, or burst access in linear increment burst mode, into the DSS0\_VID\_CLUT\_0 through DSS0\_VID\_CLUT\_15 registers. The LSB 30 bits [29:0] are used for the value and the MSB 1 bit [31] is used to reset the index of the table for the color mode, while the LSB 8 bits are used for the value and the MSB 1 bit to reset the index of the table for monochrome mode. [Figure 12-572](#) describes the format of one of the palette value in the memory.
2. Loop to Step 1, if there is a new access to the CLUT registers. Software can access other registers between two accesses to the CLUT registers.

SW needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the look-up table in CLUT mode is activated when a BITMAP format is selected in the DSS0\_VID\_ATTRIBUTES[6:1] FORMAT register bit-field.

The usage of the look-up table for RGB inverse gamma correction can be enabled by setting DSS0\_VID\_ATTRIBUTES[30] GAMMAINVERSION register bit.

**Figure 12-572. DISPC VID CLUT/Gamma Data Memory Organization**

### Note

Scaling and color look-up table features are mutually exclusive. If color look-up feature is enabled, then video pipeline scaler has to be disabled.

#### 12.6.4.8.4 DISPC VID Chrominance Resampling

##### 12.6.4.8.4.1 Chrominance Resampling for VID Pipeline

The chrominance resampling from 8-bpc or 10-bpc to 12-bit color components is always performed using filtering (the scaler unit filter). Chrominance resampling and rescaling can be combined to support native rescaling of YUV formats.

The usage of the scaler unit for resampling the chrominance of YUV420 and YUV422 is shown in [Figure 12-573](#) and [Figure 12-574](#), respectively. The settings of the scaler unit to perform chrominance resampling are described in [Section 12.6.4.8.5, DISPC VID Scaler Unit](#).

**Figure 12-573. DISPC VID YUV420 to ARGB48 Using Scaler Unit for Resampling Chrominance**

**Figure 12-574. DISPC VID YUV422 to ARGB48 Using Scaler Unit for Resampling Chrominance**

The vertical scaler is not a mandatory block for resampling the chrominance of YUV422 data, as shown in [Figure 12-574](#).

Using the filter it is possible to re-sample the chrominance from either MPEG1 or MPEG2 sub-sampled chroma source.

##### 12.6.4.8.4.2 Chrominance Resampling for VIDL Pipeline

The VIDL pipeline does not include a scaler unit. Chroma upsampling is done using dedicated YUV420 to YUV422, and YUV422 to YUV444 chroma upsamplers.

The VIDL pipeline converts YUV420 (Chroma) data to YUV422 (Chroma) using a simple vertical average filter (average of two adjacent chroma lines to generate a missing line except for the very bottom line which is generated by repeating the previous chroma line). If the video image is a sub-image of a larger video frame data, then the vertical Luma line offset from the top should be an even number.

The VIDL pipeline converts YUV422 data to YUV444 format using a 4-tap filter (implementing the Catmull-Rom algorithm) to generate missing chroma data as follows:

$$\text{Cout}[2*i] = \text{Cin}[i]$$

$$\text{Cout}[2*i+1] = \text{CLIP} \left( -\frac{1}{16} * \text{Cin}[i-1] + \frac{9}{16} * \text{Cin}[i] + \frac{9}{16} * \text{Cin}[i+1] - \frac{1}{16} * \text{Cin}[i+2] \right)$$

The missing chroma data is generated as a simple weighted average of the surrounding 4 chroma values, which is equivalent to a 4x1 filter kernel with values:  $[-1/16, 9/16, 9/16, -1/16]$ . In this algorithm, edge effects are treated by repeating the first and last pixel.

### 12.6.4.8.5 DISPC VID Scaler Unit

#### Note

Only VID pipeline includes a resizer unit (scaler). The VIDL pipeline does not include a scaler.

The programmable scaler filter works with all supported video formats, including formats with alpha channel. The alpha channel is scaled with the same parameters as the RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. A RGB 64-bit source (16 bits per component) is truncated to 8-bit/component, if the scaler is enabled. Otherwise, it will be truncated to ARGB48 format in the scaler bypass mode. A 10-bit/12-bit YUV source is also truncated to 8-bit, since the scaler is enabled to either upsample the chroma component and/or resize the YUV frame data directly (for memory-to-memory operation with YUV format as the memory destination type).

The filter is based on a finite impulse response (FIR) filter with 16 phases. The filter is a 5-tap for horizontal filtering, and can be configured for 3 or 5 taps for vertical filtering. The filtering can be used for various processing:

- Up-sampling of the picture
- Down-sampling of the picture
- Anti-aliasing reduction
- Chrominance resampling in case of YUV data formats

The following limitations must be considered:

- The up-sampling ratio is up to x16.
- The down-sampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The down-sampling ratio using 5-tap configuration is down to x0.25 for RGB format.

#### Note

The user must set the correct size and position of the original video before resize in order for the up-sampled/down-sampled video to be displayed inside the screen boundaries.

Figure 12-575 shows an example of video up-sampling, with corresponding video window attributes.

**Figure 12-575. DISPC Video Window Attributes**

The video window attributes can be configured in the following register bit-fields:

- Source data format (input to the scaler unit) in DSS0\_VID\_ATTRIBUTES[6-1] FORMAT bit-field
- Video picture width in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE[13-0] MEMSIZE\_X bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed except for YUV422 formats. In case of YUV422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Video picture height in system memory (frame buffer) in DSS0\_VID\_PICTURE\_SIZE[29-16] MEMSIZE\_Y bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed.
- Video window width at pipeline output (after resizing) in DSS0\_VID\_SIZE[13-0] SIZE\_X bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen width minus the horizontal start location of the window on the screen.
- Video window height at pipeline output (after resizing) in DSS0\_VID\_SIZE[29-16] SIZE\_Y bit-field. The window height is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed up to the screen height minus the vertical start location of the window on the screen.
- Video window overlay X-position in DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4[13-0] POS\_X bit-field. See [Section 12.6.4.10, DISPC Overlay Managers](#).
- Video window overlay Y-position in DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4[29-16] POS\_Y bit-field. See [Section 12.6.4.10, DISPC Overlay Managers](#).
- For configuration of LPP and PPL video port output display parameters, see [Section 12.6.4.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

For vertical up-sampling and down-sampling in a 3-tap configuration, the equations are:

For RGB formats

$$Aout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Rout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Gout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Bout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

For YUV formats

$$Yout(n) = \left( \sum_{i=-1}^{i=1} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Cbout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Crout(n) = \left( \sum_{i=-1}^{i=1} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-013

(23)

For vertical and horizontal up-sampling and down-sampling in a 5-tap configuration, the equations are:

For RGB formats

$$Aout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Ain(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Rout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Gout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Gin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Bout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Bin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

For YUV formats

$$Yout(n) = \left( \sum_{i=-2}^{i=2} Cyi(\Phi_y) \times Yin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Cbout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Cbin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

$$Crout(n) = \left( \sum_{i=-2}^{i=2} Cci(\Phi_c) \times Crin(n+i) \right) \gg (Cwidth - (OutWidth - InWidth) - 1)$$

Component	Vertical	Horizontal
Cwidth (Coefficient Width)	10 bits	10 bits
InWidth (Input Width)	10 bits	12 bits
OutWidth (Output Width)	12 bits	12 bits

dispc-012

(24)

### Note

The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients  $C_i()$  depend on the phase between input and output pixels.

The coefficients are different for Y and Cr/Cb filtering because the calculations are independent due to the chrominance resampling for YUV422 and YUV420.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of:

- Six lines of 2048 × 32 bits for 5-tap configuration
- Three lines of 4096 × 32 bits for 3-tap configuration

Table 12-551 lists some of the scaler supported configurations.

**Table 12-551. DISPC VID Line Buffer Width for Scaler Unit**

Pixel Format	Maximum Input Width (Pixels) for 5-tap	Maximum Input Width (Pixels) for 3-tap
32 bits per pixel (ARGB32-8888, ARGB-2101010, etc.)	2048 pixels wide <sup>(1)</sup>	4096 pixels wide
YUV420, YUV422	4096 pixels wide	4096 pixels wide

- (1) For the 5-tap configuration, the 6th video line is used on the output of the horizontal scaler in order to start the next output line generation while the video pipeline output is being stalled by the overlay manager (either due to display in blanking period and/or in background pixel period). The 6th line buffer is actually 48-bit wide to allow storage of ARGB48 format pixel data.

At the beginning of frame scaling processing, the first line may be duplicated multiple times depending on the initial vertical phase programmed for the poly-phase filter.

At the end of frame scaling processing the last line is duplicated, if the scaling logic requires loading more lines and the last line has been reached.

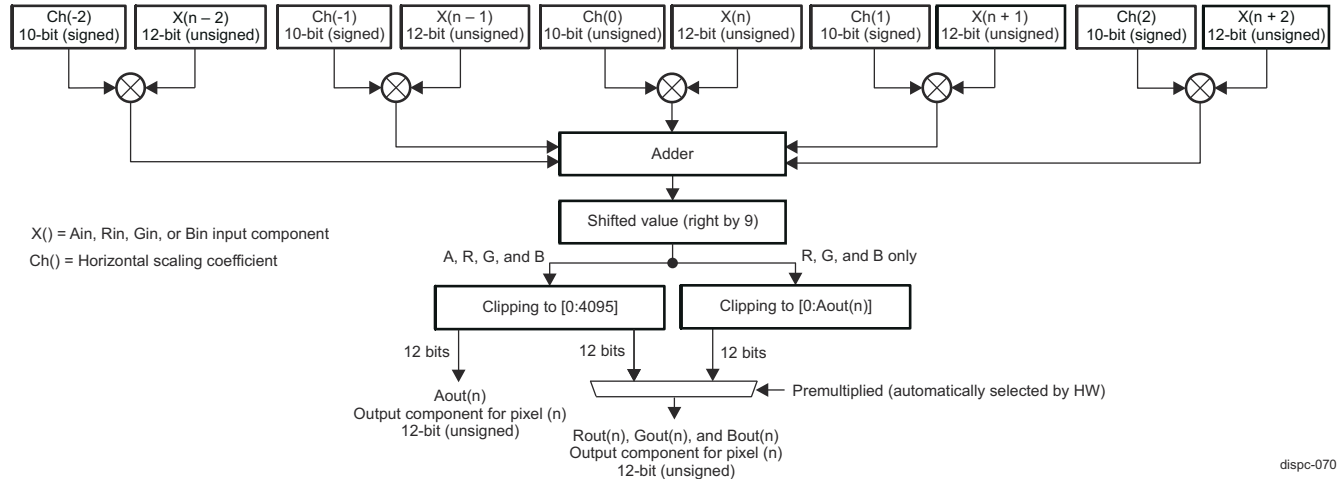

Similarly, the first pixel may be duplicated multiple times depending on the initial horizontal phase programmed for the poly-phase filter. The last pixel is duplicated, if the scaling logic requires loading more pixels and the last pixel has been reached.

The programmable coefficients of the polyphase filters are signed 10-bit values (except for the central coefficient, which is unsigned). The vertical video scaler has an 10-bit input and a 12-bit output. The horizontal scaling stage takes the resulting 12-bit input and produces 12-bit output.

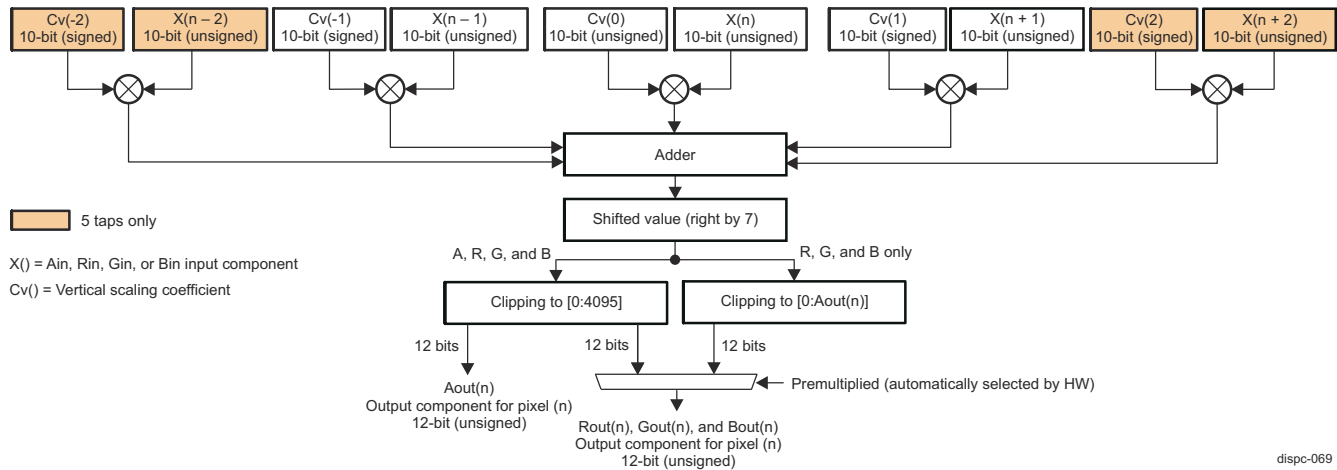

Figure 12-576 and Figure 12-577 show the scaler macro-architecture for components A, R, G, and B. Figure 12-578 and Figure 12-579 show the scaler macro-architecture for components Y, Cr, and Cb.

### Note

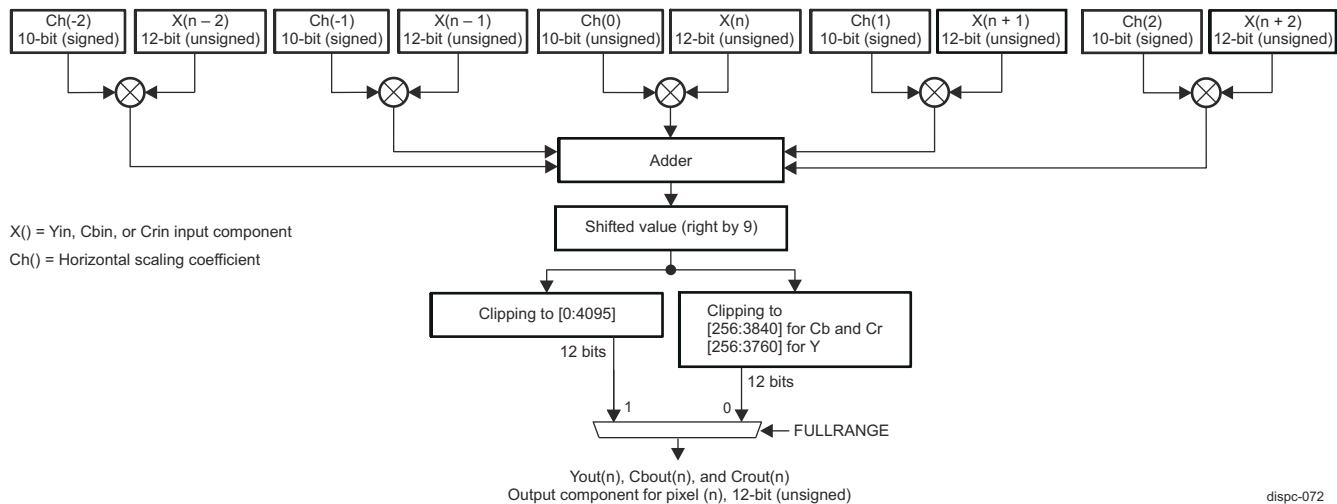

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

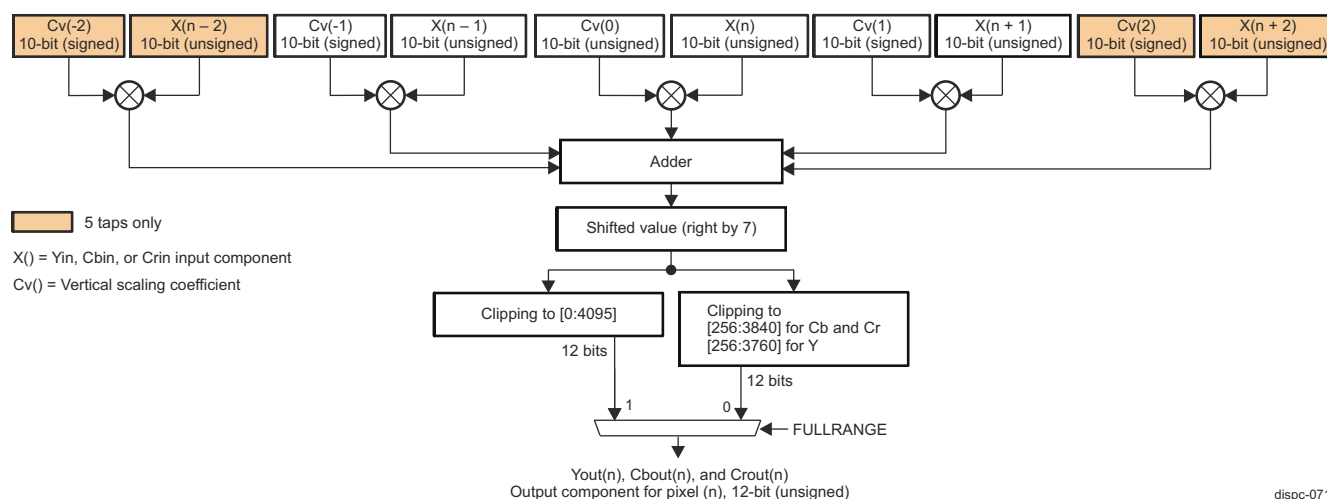

**Figure 12-576. DISPC VID Macro-Architecture of the Horizontal Scaling for A, R, G, and B Components (5-tap Restriction)**

**Figure 12-577. DISPC VID Macro-Architecture of the Vertical Scaling for A, R, G, and B Components (5 and 3 taps)**

**Figure 12-578. DISPC VID Macro-Architecture of the Horizontal Scaling for Y, Cr, and Cb Components (5-tap Restriction)**

**Figure 12-579. DISPC VID Macro-Architecture of the Vertical Scaling for Y, Cr, and Cb Components (5 and 3 taps)**

Table 12-552 list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8, and DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers.

**Table 12-552. DISPC Register Fields Associated to Coefficients for ARGB and Y Configuration in VID Horizontal Scaler**

Phases	Ch(2)	Ch(1)	Ch(0)	Ch(-1)	Ch(-2)

#### Note

In [Table 12-552](#), the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8, and DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8, and DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15, and DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 and DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 are used) .

The VID scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0\_VID\_ATTRIBUTES[8-7] RESIZEENABLE bit field.

Prior to enabling the video up/down-sampling block a valid configuration has to be set by the user. After configuring the required VID registers change the DSS0\_VP\_CONTROL[5] GOBIT register bit of the video port the video pipeline is associated with. The software has to wait before setting the GO bit that the hardware has reset the bit. The software reset is not recommended since the application cannot guarantee to be able to reset it before the HW.

The following fields define the configuration of the video up-sampling/down-sampling block in the VID pipeline for ARGB and YUV formats:

- Vertical upsampling and downsampling increment value in the [23-0] FIRVINC bit field of DSS0\_VID\_FIRV (for ARGB and Y) and DSS0\_VID\_FIRV2 (for CbCr) registers. The unsigned integer value range is  $2^{23}$ . Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{MEMSIZEY+1}{SIZEY+1} \right)$$

dispc-066

- Horizontal upsampling and downsampling increment value in the [23-0] FIRHINC bit field of the DSS0\_VID\_FIRH (for ARGB and Y) and DSS0\_VID\_FIRH2 (for CbCr) registers. The unsigned integer value range is [1:16384]. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{MEMSIZEH+1}{SIZEH+1} \right)$$

dispc-067

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 (for ARGB and Y), and DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts. The DSS0\_VID\_ACCUV\_0 register is used for progressive output, while for interlace output both DSS0\_VID\_ACCUV\_0 and DSS0\_VID\_ACCUV\_1 registers are used. The DSS0\_VID\_ACCUV2\_0 and DSS0\_VID\_ACCUV2\_1 registers are used in the same manner for progressive or interlace output.

- Vertical upsampling and downsampling line buffer configuration via the DSS0\_VID\_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 (for ARGB and Y), and DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts. The register DSS0\_VID\_ACCUH\_0 is used for progressive output, while for interlace output both DSS0\_VID\_ACCUH\_0 and DSS0\_VID\_ACCUH\_1 registers are used. The DSS0\_VID\_ACCUH2\_0 and DSS0\_VID\_ACCUH2\_1 are used in the same manner for progressive or interlace output.

Table 12-553 lists the scaler vertical and horizontal accumulator values and phases.

**Table 12-553. DISPC VID Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V0\_0 to DSS0\_VID\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_V0\_C\_0 to DSS0\_VID\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_V12\_0 to DSS0\_VID\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_V12\_C\_0 to DSS0\_VID\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H0\_0 to DSS0\_VID\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).

- Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0\_VID\_FIR\_COEF\_H0\_C\_0 to DSS0\_VID\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0\_VID\_FIR\_COEF\_H12\_0 to DSS0\_VID\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0\_VID\_FIR\_COEF\_H12\_C\_0 to DSS0\_VID\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0\_VID\_FIRH2 and DSS0\_VID\_FIRV2, and DSS0\_VID\_ACCUV2\_0/DSS0\_VID\_ACCUV2\_1 and DSS0\_VID\_ACCUH2\_0/DSS0\_VID\_ACCUH2\_1 registers need to be configured differently than DSS0\_VID\_FIRH and DSS0\_VID\_FIRV, and DSS0\_VID\_ACCUH\_0/DSS0\_VID\_ACCUH\_1 and DSS0\_VID\_ACCUV\_0/DSS0\_VID\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

#### 12.6.4.8.6 DISPC VID Color Space Conversion YUV to RGB

The Color Space Conversion (CSC) unit converts the video-encoded pixel values from YUV444 format into ARGB48 format (12-bit value per component A, R, G, and B, with A fixed at 0xFFFF).

In case of YUV420 or YUV422 formats, a chrominance resampling to YUV444 is performed before converting the YUV into RGB values (see [Section 12.6.4.8.4, DISPC VID Chrominance Resampling](#)). The YUV422/YUV420 to YUV444 chrominance resampling is a pre-processing to the color space conversion.

[Figure 12-580](#) and [Figure 12-581](#) show the 3 × 3 11-bit coefficients used to convert from YUV444 into ARGB48. The value of A component is fixed at 0xFFFF in the output. The coefficients are set according to the standard used to encode the pixel data in YUV color space. [Table 12-554](#) summarizes the coefficients with their respective register bit fields.

**Table 12-554. DISPC VID CSC - YUV to RGB Register Settings**

Coefficients	Register Fields
R <sub>Y</sub>	DSS0_VID_CSC_COEF0[10-0] C00
R <sub>Cr</sub>	DSS0_VID_CSC_COEF0[26-16] C01
R <sub>Cb</sub>	DSS0_VID_CSC_COEF1[10-0] C02
G <sub>Y</sub>	DSS0_VID_CSC_COEF1[26-16] C10
G <sub>Cr</sub>	DSS0_VID_CSC_COEF2[10-0] C11
G <sub>Cb</sub>	DSS0_VID_CSC_COEF2[26-16] C12
B <sub>Y</sub>	DSS0_VID_CSC_COEF3[10-0] C20
B <sub>Cr</sub>	DSS0_VID_CSC_COEF3[26-16] C21
B <sub>Cb</sub>	DSS0_VID_CSC_COEF4[10-0] C22
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3

- Limited data range conversion (video data range)

If the active range for the luminance samples (Y) is [256:3760] and for the chrominance samples (Cb and Cr) is [256:3840], the following equation in [Figure 12-580](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 256 \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-005

**Figure 12-580. DISPC VID CSC YCbCr to RGB Equation (Limited Data Range), 12-Bit Outputs**

In [Figure 12-580](#), the offset values (-256, -2048, -2048) are also programmed via corresponding register bit-fields shown in [Table 12-554, DISPC VID CSC - YUV to RGB Register Settings](#).

- Full data range conversion (graphics data range)

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], the following equation in [Figure 12-581](#) (based on 11-bit coefficients) must be used to convert the YUV to RGB. To clip the values of R, G, and B output components to the full output data range [0:4095], set the DSS0\_VID\_ATTRIBUTES[11] FULLRANGE bit to 0x1.

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{Cr} & R_{Cb} \\ G_Y & G_{Cr} & G_{Cb} \\ B_Y & B_{Cr} & B_{Cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 2048 \\ Cb_{IN} - 2048 \end{bmatrix}$$

dispc-006

**Figure 12-581. DISPC VID CSC YCbCr to RGB Equation (Full Data Range), 12-Bit Outputs**

In [Figure 12-580](#) and [Figure 12-581](#), the offset values (0, -256, -2048) can be programmed via the corresponding register bit-fields shown in [Table 12-554, DISPC VID CSC - YUV to RGB Register Settings](#).

### Note

In case of YUV420/YUV422-NV21 data, the coefficients for Cr and Cb must be swapped in order to correctly support YUV420/YUV422-NV21 format.

The scaling and CSC clipping is set by the same bit, DSS0\_VID\_ATTRIBUTES[11] FULLRANGE.

## Output Clipping

It is possible for the output results to be larger (overflow) than the maximum or smaller (underflow) than the minimum value the output representation supports. The Color Space Conversion module clips the overflow/underflow result to the maximum/minimum value as follows:

- FULLRANGE = 1 (Graphics range)
  - Maximum: 4095
  - Minimum : 0
- FULLRANGE = 0 (Video range)
  - Maximum: 3760 for Luma, 3840 for Chroma
  - Minimum: 256 for both Luma and Chroma

The FULLRANGE = 0 setting should only be used when the CSC logic is used to convert RGB to YCrCb and the output needs to be in the video data range.

For YCrCb to RGB conversion and other RGB to RGB processing, the FULLRANGE bit should be set to 1 to enable full data range in the output.

#### 12.6.4.8.7 DISPC VID Brightness/Contrast/Saturation/Hue Control

The brightness/contrast/saturation controls are implemented in the same Color Space Conversion (CSC) block by making adjustments to the conversion coefficients and input/output offset values as shown in [Figure 12-582](#):

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * B0 & m * k * C0 \\ m * A1 & m * k * B1 & m * k * C1 \\ m * A2 & m * k * B2 & m * k * C2 \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-101

**Figure 12-582. DISPC VID Brightness/Contrast/Saturation Equation for YUV to RGB**

In [Figure 12-582](#) the following terminology is used:

- A/B/C coefficients and the offset parameters are for YUV to RGB conversion. See [Table 12-555](#) below for coefficients and offsets mapping to register fields.
- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness offset (b) is added to  $Y\_offset\_adj$ . The allowed range (for 8-bit example) is:  $-128 \leq b \leq +127$  (where  $b=0$  means brightness bypass).

The hue adjustment can also be built into the above equation ([Figure 12-582](#)) to comprehend the following Cb/Cr hue angle adjustments:

$$Cb\_hue\_adj = (Cb * \cos \emptyset + Cr * \sin \emptyset)$$

$$Cr\_hue\_adj = (Cr * \cos \emptyset - Cb * \sin \emptyset), \text{ where } \emptyset \text{ is the desired hue angle (with } \emptyset=0 \text{ meaning hue adjustment bypass)}$$

The final combined matrix equation for controlling brightness/contrast/saturation/hue (BCSH) during YUV to RGB conversion is shown in [Figure 12-583](#)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} Y + Y\_offset\_adj \\ Cr + Cr\_offset \\ Cb + Cb\_offset \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

dispc-102

**Figure 12-583. DISPC VID Brightness/Contrast/Saturation/Hue Equation for YUV to RGB**

Gain and offset terms in the above equation ([Figure 12-583](#)) are programmed in the hardware registers as adjusted CSC coefficients (11-bit signed) and offset values (13-bit signed) to control the brightness, contrast, saturation and hue. Mapping of the coefficients and offsets to register fields is provided in [Table 12-555](#). Outputs are clipped to keep the output values in the proper range.

**Table 12-555. DISPC VID BCSH Register Settings for YUV to RGB**

Coefficients	Register Fields
A0	DSS0_VID_CSC_COEF0[10-0] C00
B0	DSS0_VID_CSC_COEF0[26-16] C01
C0	DSS0_VID_CSC_COEF1[10-0] C02
A1	DSS0_VID_CSC_COEF1[26-16] C10
B1	DSS0_VID_CSC_COEF2[10-0] C11
C1	DSS0_VID_CSC_COEF2[26-16] C12
A2	DSS0_VID_CSC_COEF3[10-0] C20
B2	DSS0_VID_CSC_COEF3[26-16] C21
C2	DSS0_VID_CSC_COEF4[10-0] C22

**Table 12-555. DISPC VID BCSH Register Settings for YUV to RGB (continued)**

Coefficients	Register Fields
Y offset	DSS0_VID_CSC_COEF5[15-3] PREOFFSET1
Cr offset	DSS0_VID_CSC_COEF5[31-19] PREOFFSET2
Cb offset	DSS0_VID_CSC_COEF6[15-3] PREOFFSET3
R offset	DSS0_VID_CSC_COEF6[31-19] POSTOFFSET1
G offset	DSS0_VID_CSC_COEF7[15-3] POSTOFFSET2
B offset	DSS0_VID_CSC_COEF7[31-19] POSTOFFSET3

For RGB input formats, the same CSC block can be used to adjust contrast, brightness, saturation, and hue using the matrix equation from [Figure 12-584](#).

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} m * A0 & m * k * [B0 * \cos(Hue) + C0 * \sin(Hue)] & m * k * [C0 * \cos(Hue) - B0 * \sin(Hue)] \\ m * A1 & m * k * [B1 * \cos(Hue) + C1 * \sin(Hue)] & m * k * [C1 * \cos(Hue) - B1 * \sin(Hue)] \\ m * A2 & m * k * [B2 * \cos(Hue) + C2 * \sin(Hue)] & m * k * [C2 * \cos(Hue) - B2 * \sin(Hue)] \end{bmatrix} \begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} R\_offset \\ G\_offset \\ B\_offset \end{bmatrix}$$

Coefficients a/b/c are related to A/B/C (for RGB to YUV and YUV to RGB conversions) as follows:

$$\begin{bmatrix} a0 & b0 & c0 \\ a1 & b1 & c1 \\ a2 & b2 & c2 \end{bmatrix} = \begin{bmatrix} A0 & B0 & C0 \\ A1 & B1 & C1 \\ A2 & B2 & C2 \end{bmatrix}^{-1}$$

dispc-103

**Figure 12-584. DISPC VID Brightness/Contrast/Saturation/Hue Equation for RGB Input**

In [Figure 12-584](#) the following specifics apply:

- A/B/C coefficients and the RGB offset parameters mapping to register fields is provided in [Table 12-555](#).
- The gain term (m) is used for contrast control. The allowed range is:  $0 < m \leq 2.0$  (where  $m=1$  means contrast bypass).
- The gain term (k) is used for saturation control. The allowed range is:  $0 < k \leq 2.0$  (where  $k=1$  means saturation bypass).
- The brightness is controlled by the RGB offset values.
- The Hue angle is used to adjust hue. Hue  $\emptyset=0$  means hue adjustment bypass.

Outputs are clipped to keep the output values in the proper range.

#### 12.6.4.8.8 DISPC VID Luma Key Support

The video pipeline supports Luma key transparency for Blue-ray video layer composition. When enabled, Y value of each pixel will be checked against luma key range values. The range values are defined in DSS0\_VID\_LUMAKEY register fields, as follows: [11-0] LUMAKEYMIN < Y < [27-16] LUMAKEYMAX. If this condition is true, then the pixel alpha value will be forced to zero (transparent) to make the pixel transparent during the blending process in the overlay manager.

#### 12.6.4.8.9 DISPC VID Cropping Support

At the output of the video pipeline a final crop stage is added which allows further cropping of the video window to the required dimensions. The crop feature is enabled by DSS0\_VID\_ATTRIBUTES[13] CROP register field and the cropping dimensions are further set by DSS0\_VID\_CROP[...] CROPLEFT/CROPTOP/CROPBOTTOM/CROPRIGHT register fields. Cropping of up to 31 pixels/lines is supported in every direction.

The crop feature is especially useful while dealing with the compressed frame buffer using the FBDC module, as explained in [Section 12.6.4.6.11, DISPC Compressed Data Format Support](#).

#### 12.6.4.9 DISPC Write-Back Pipeline

The write-back (WB) pipeline is used to store in the system memory the capture of the overlay output or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. The format from the overlay managers is always ARGB48. The format from the output of the VID pipeline

can be YUV422, YUV420 or ARGB48. Because the overlay works on ARGB48 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

The write-back pipeline can be connected either to the VID pipeline output or to the output of one of the overlay managers, either in M2M (memory-to-memory) or Capture mode (see [Section 12.6.4.6.3, DISPC Write DMA Buffer](#)), by configuring the DSS0\_COMMON\_DISPC\_CONNECTIONS[20-16] WB\_CONN register field.

- In M2M mode, the pipeline or overlay manager connected to WB must not be connected to any VP.
- In Capture mode, the pipeline or overlay manager connected to WB must be connected to at least one VP.

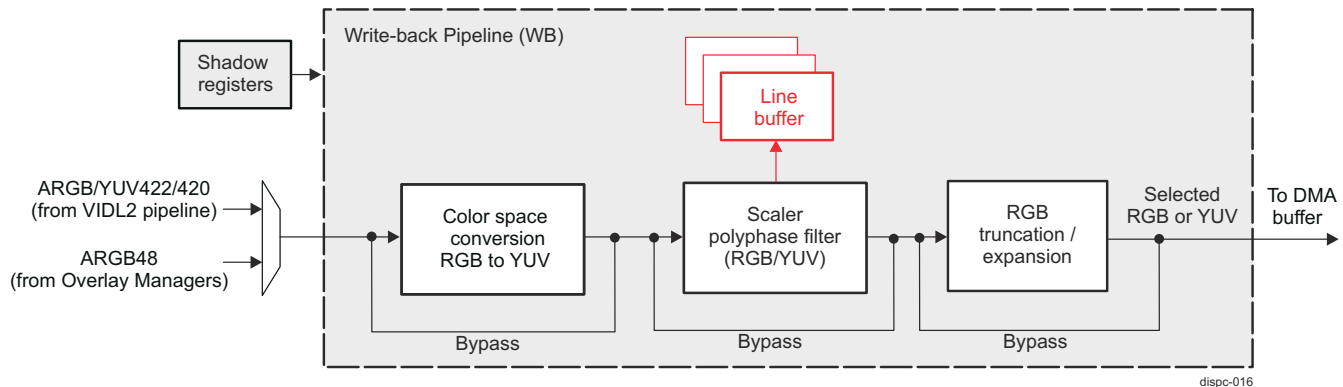

The capture frame rate can be set in the DSS0\_WB\_ATTRIBUTES[26:24] CAPTUREMODE bit field.

The write-back pipeline also supports input source cropping to allow a sub-frame capture.

The ARGB48 format is truncated (LSB drop) or expanded to match the output color depth formats. No dithering on the output is supported. When there is no alpha field mentioned by x in the pixel format description, 0's shall be used. For example, for RGB12 pixel format the upper 4 bits are 0's since RGB value is only 12 bits inside a 16-bit container.

The WB pipeline is enabled by setting the DSS0\_WB\_ATTRIBUTES[0] ENABLE bit to 0x1.

[Figure 12-585](#) shows the WB pipeline.

**Figure 12-585. DISPC Write-Back Pipeline**

#### 12.6.4.9.1 DISPC WB Color Space Conversion RGB to YUV

The WB CSC unit converts the encoded pixel values from RGB48 into YUV444 format. For YUV420 or YUV422 as output formats, a chrominance subsampling (YUV444 to YUV422, and YUV422 to YUV420) is performed in the WB scaler block after the CSC operation.

[Figure 12-586](#) and [Figure 12-587](#) show the  $3 \times 3$  11-bit coefficients used for the CSC operation. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. [Table 12-556](#) lists the coefficients with their respective bit fields, together with the post offsets (that are 13-bit signed integer numbers).

**Table 12-556. DISPC WB CSC - RGB to YUV Register Settings**

Coefficients	Register Bit Fields
$Y_R$	DSS0_WB_CSC_COEF0[10:0] C00
$Y_G$	DSS0_WB_CSC_COEF0[26:16] C01
$Y_B$	DSS0_WB_CSC_COEF1[10:0] C02
$Cr_R$	DSS0_WB_CSC_COEF1[26:16] C10
$Cr_G$	DSS0_WB_CSC_COEF2[10:0] C11
$Cr_B$	DSS0_WB_CSC_COEF2[26:16] C12
$Cb_R$	DSS0_WB_CSC_COEF3[10:0] C20

**Table 12-556. DISPC WB CSC - RGB to YUV Register Settings (continued)**

Coefficients	Register Bit Fields
Cb <sub>G</sub>	DSS0_WB_CSC_COEF3[26:16] C21
Cb <sub>B</sub>	DSS0_WB_CSC_COEF4[10:0] C22
R <sub>POSTOFFSET</sub>	DSS0_WB_CSC_COEF6[31-19] POSTOFFSET1
G <sub>POSTOFFSET</sub>	DSS0_WB_CSC_COEF7[15-3] POSTOFFSET2
B <sub>POSTOFFSET</sub>	DSS0_WB_CSC_COEF7[31-19] POSTOFFSET3

**Limited data range conversion (video data range)**

If the active range for the 12-bit output luminance samples (Y) is to be [256:3760] and for the output chrominance samples (Cb and Cr) is to be [256:3840], then [Figure 12-586](#) gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The range selection is done by setting the DSS0\_WB\_ATTRIBUTES[11] FULLRANGE bit to 0x0. The [256, 2048, 2048] offset values are programmable through the registers from [Table 12-556](#).

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-017

**Figure 12-586. DISPC WB CSC RGB to YCbCr Equation (Limited Data Range), 12-bit Outputs****Full data range conversion (graphics data range)**

If the active range for the output luminance samples (Y) and or the chrominance samples (Cb and Cr) is [0:4095], then [Figure 12-587](#) gives the equation (based on 11-bit coefficients) to convert the RGB to YUV. The [0, 2048, 2048] offset values are programmable through the registers from [Table 12-556](#).

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-018

**Figure 12-587. DISPC WB CSC RGB to YCbCr Equation (Full Data Range), 12-bit Outputs****12.6.4.9.2 DISPC WB Scaler Unit**

The functional aspect of the WB pipeline scaler unit is identical to the VID pipeline scaler unit (see [Section 12.6.4.8.5, DISPC VID Scaler Unit](#)), except that the WB scaler is 8-bit only and takes only the 8 most significant bits of the data fed through. The WB scaler, similarly to the one in the video pipeline, can perform scaling in the native ARGB, YUV422, or YUV420 formats. The support for scaling in YUV formats allows a YUV source to be scaled through video and write-back scalers without chroma up and downsampling, if the output is to remain in the same format. In addition, the scaling capability of VID and WB pipelines can be combined to double the maximum rescaling factor (applicable for memory-to-memory operations only).

The downscaling capability is further reduced, if the pipeline is doing a format conversion where downsampling is inherent. When doing RGB/YUV422-to-YUV420 conversion in WB pipeline, the downsampling capability of WB scaler is reduced to:

- If 5 taps is selected, then the downsampling is limited to 0.5 in RGB
- If 3 taps is selected, then no down-scaling is available

The write-back window attributes of the WB pipeline can be configured in the following register bit-fields:

- Source data format for write-back (input to the scaler unit) in DSS0\_WB\_ATTRIBUTES[6-1] FORMAT bit-field

- Start position (offset) of the window on the overlay which WB will capture in DSS0\_WB\_POSITION[29-16] POSY and [13-0] POSX register field. Only applicable when the WB pipeline is operating in capture\_mode.
- Write-back picture width in system memory (frame buffer) in DSS0\_WB\_PICTURE\_SIZE[13-0] MEMSIZEX bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed in the case of RGB16 and RGB24 video data. In the case of YUV422 and UYVY422 formats the width has to be a multiple of 2 pixels.
- Write-back picture height in system memory (frame buffer) in DSS0\_WB\_PICTURE\_SIZE[29-16] MEMSIZEY bit-field. The window width is from 1 up to 4096 pixels. All the integer values in the range [1:4096] are allowed. In the case of YUV420 the height has to be a multiple of 2 lines.
- Write-back window width at pipeline input (before resizing) in DSS0\_WB\_SIZE[13-0] SIZEX bit-field. The window width is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 pixels, if its format (input) is YUV420/YUV422.
- Write-back window height at pipeline input (before resizing) in DSS0\_WB\_SIZE[29-16] SIZEY bit-field. The window height is from 1 up to 4096 pixels. The width of the image sent to the write back pipe has to be a multiple of 2 lines, if its format (input) is YUV420.

### Note

The WB pipeline supports input source cropping to allow a sub-frame capture by specifying the offset position and the size of the sub-frame. With the offset position parameters (POSY, POSX) set to (0,0) and the size parameters (SIZEY, SIZEX) set to the full size, no clipping should be applied. The software must make sure that the clipping parameters are set up correctly to avoid going over the WB input frame boundaries. Otherwise, the pipeline may lock up.

**Table 12-557** list the register fields in the function of the coefficients for the VID horizontal scaler in the DSS0\_WB\_FIR\_COEF\_H0\_0 to DSS0\_WB\_FIR\_COEF\_H0\_8, and DSS0\_WB\_FIR\_COEF\_H12\_0 to DSS0\_WB\_FIR\_COEF\_H12\_15 registers.

**Table 12-557. DISPC Register Fields Associated to Coefficients for ARGB and Y Configuration in WB Horizontal Scaler**

### Note

In [Table 12-557](#), the cells without color are duplicated from the grey cells.

Similar table approach applies to the vertical scaler (registers DSS0\_WB\_FIR\_COEF\_V0\_0 to DSS0\_WB\_FIR\_COEF\_V0\_8, and DSS0\_WB\_FIR\_COEF\_V12\_0 to DSS0\_WB\_FIR\_COEF\_V12\_15 are used).

Similar table approach applies to the coefficients for Cb/Cr filtering in case of YUV format (registers DSS0\_WB\_FIR\_COEF\_H0\_C\_0 to DSS0\_WB\_FIR\_COEF\_H0\_C\_8, and DSS0\_WB\_FIR\_COEF\_H12\_C\_0 to DSS0\_WB\_FIR\_COEF\_H12\_C\_15, and DSS0\_WB\_FIR\_COEF\_V0\_C\_0 to DSS0\_WB\_FIR\_COEF\_V0\_C\_8 and DSS0\_WB\_FIR\_COEF\_V12\_C\_0 to DSS0\_WB\_FIR\_COEF\_V12\_C\_15 are used).

The WB scaler unit vertical and/or horizontal sampling is selected by configuring the DSS0\_WB\_ATTRIBUTES[8-7] RESIZEENABLE register bit field.

Prior to enabling the WB scaler a valid configuration has to be set by the user.

In case of capturing data of one of the output channels, the corresponding DSS0\_VP\_CONTROL[5] GOBIT bit has to be set to update the configuration depending to which VP output the write-back pipeline is associated with. Refers also to [Section 12.6.4.11.12, DISPC Shadow Mechanism for Registers](#) when write back channel is active. The SW has to wait before setting the GOBIT bit that the HW has reset the same bit. The DSS0\_WB\_ATTRIBUTES[0] ENABLE bit can be set to update those registers, if it has been previously disabled.

The following register fields define the configuration of the video up/downsampling block in the WB pipeline:

- Vertical up/downsampling increment value in the[23-0] FIRVINC bit field of DSS0\_WB\_FIRV (for ARGB and Y) and DSS0\_WB\_FIRV2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRVINC = 2^{21} * \left( \frac{SIZEY+1}{MEMSIZEY+1} \right) \quad \text{dispc-066} \quad (25)$$

- Horizontal up/downsampling increment value in the [23-0] FIRHINC bit field of the DSS0\_WB\_FIRH (for ARGB and Y) and DSS0\_WB\_FIRH2 (for CbCr) registers. Software calculates the value using the following equation:

$$FIRHINC = 2^{21} * \left( \frac{SIZEX+1}{MEMSIZEX+1} \right) \quad \text{dispc-067} \quad (26)$$

- Vertical up/downsampling accumulator value in the [23-0] VERTICALACCU bit field of the DSS0\_WB\_ACCUV\_0 and DSS0\_WB\_ACCUV\_1 (for ARGB and Y), and DSS0\_WB\_ACCUV2\_0 and DSS0\_WB\_ACCUV2\_1 (for CbCr) registers. The accumulator value indicates on which phase the vertical filtering starts.
- Vertical upsampling and downsampling line buffer configuration via the DSS0\_WB\_ATTRIBUTES[21] VERTICALTAPS bit. The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value in the [23-0] HORIZONTALACCU bit field of the DSS0\_WB\_ACCUH\_0 and DSS0\_WB\_ACCUH\_1 (for ARGB and Y), and DSS0\_WB\_ACCUH2\_0 and DSS0\_WB\_ACCUH2\_1 (for CbCr) registers. The accumulator value indicates on which phase the horizontal filtering starts.

Table 12-558 lists the DISPC vertical and horizontal accumulator values and phases. Other accumulator values are also supported. The HW determines the nearest phase value in order to load the corresponding one.

**Table 12-558. DISPC WB Scaler Vertical and Horizontal Accumulator Phases**

Accumulator Value (MSB bits)	Phases f
0	0
256 or -3840	1
512 or -3584	2
768 or -3328	3
1024 or -3072	4
1280 or -2816	5
1536 or -2560	6
1792 or -2304	7
2048 or -2048	8
2304 or -1792	9
2560 or -1536	10
2816 or -1280	11
3072 or -1024	12
3328 or -768	13
3584 or -512	14
3840 or -256	15

- Vertical upsampling and downsampling central coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling central coefficients are defined in the DSS0\_WB\_FIR\_COEF\_V0\_0 to DSS0\_WB\_FIR\_COEF\_V0\_8 registers. There are 9 registers for the 16 phases with 1 coefficient for each of them. Symetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).
  - Four CbCr, the vertical upsampling and downsampling central coefficients are set in DSS0\_WB\_FIR\_COEF\_V0\_C\_0 to DSS0\_WB\_FIR\_COEF\_V0\_C\_8 registers.
- Vertical upsampling and downsampling coefficients:
  - For ARGB and Y, the vertical upsampling and downsampling coefficients are defined in the DSS0\_WB\_FIR\_COEF\_V12\_0 to DSS0\_WB\_FIR\_COEF\_V12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the vertical up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the vertical upsampling and downsampling coefficients are set in DSS0\_WB\_FIR\_COEF\_V12\_C\_0 to DSS0\_WB\_FIR\_COEF\_V12\_C\_15 registers.
- Horizontal upsampling and downsampling central coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling central coefficients are defined in the DSS0\_WB\_FIR\_COEF\_H0\_0 to DSS0\_WB\_FIR\_COEF\_H0\_8 registers. There are 9 registers for the 16

phases with 1 coefficient for each of them. Symmetrical implementation is used, so only 9 coefficients are used. Each register contains one 10-bit unsigned coefficient (the central one).

- Four CbCr, the horizontal upsampling and downsampling central coefficients are set in DSS0\_WB\_FIR\_COEF\_H0\_C\_0 to DSS0\_WB\_FIR\_COEF\_H0\_C\_8 registers.
- Horizontal upsampling and downsampling coefficients:
  - For ARGB and Y, the horizontal upsampling and downsampling coefficients are defined in the DSS0\_WB\_FIR\_COEF\_H12\_0 to DSS0\_WB\_FIR\_COEF\_H12\_15 registers. There are 16 registers for the 16 phases with 2 coefficient for each of them, so a total of 32 programmable coefficients for the horizontal up/down-sampling block. Each register contains two 10-bit signed coefficients.
  - Four CbCr, the horizontal upsampling and downsampling coefficients are set in DSS0\_WB\_FIR\_COEF\_H12\_C\_0 to DSS0\_WB\_FIR\_COEF\_H12\_C\_15 registers.

The YUV filtering is based on the equations of the ARGB filtering. In addition to the registers used for ARGB filtering configuration, a second set of registers for filtering is used. The first set of registers is used for Y configuration (instead of ARGB configuration) and the second set of registers is used for CbCr filtering configuration. The two sets of registers can be the same when the YUV format is not converted to RGB after filtering. When the RGB conversion is required after filtering, then the chrominance needs to be re-sampled with a different filtering configuration because:

- Chrominance samples are offset to the luminance samples. That is, DSS0\_WB\_FIRH2 and DSS0\_WB\_FIRV2, and DSS0\_WB\_ACCUV2\_0/DSS0\_WB\_ACCUV2\_1 and DSS0\_WB\_ACCUH2\_0/DSS0\_WB\_ACCUH2\_1 registers need to be configured differently than DSS0\_WB\_FIRH and DSS0\_WB\_FIRV, and DSS0\_WB\_ACCUH\_0/DSS0\_WB\_ACCUH\_1 and DSS0\_WB\_ACCUV\_0/DSS0\_WB\_ACCUV\_1 registers used for the luminance filtering.
- Chrominance is sub-sampled by two horizontally only in case of YUV422, and horizontally and vertically in case of YUV420. The coefficients for the vertical chrominance re-sampling are identical to the coefficients for vertical luminance filtering in case of YUV422. The coefficients for the horizontal and vertical chrominance re-sampling are different than the ones for luminance filtering in case of YUV420.

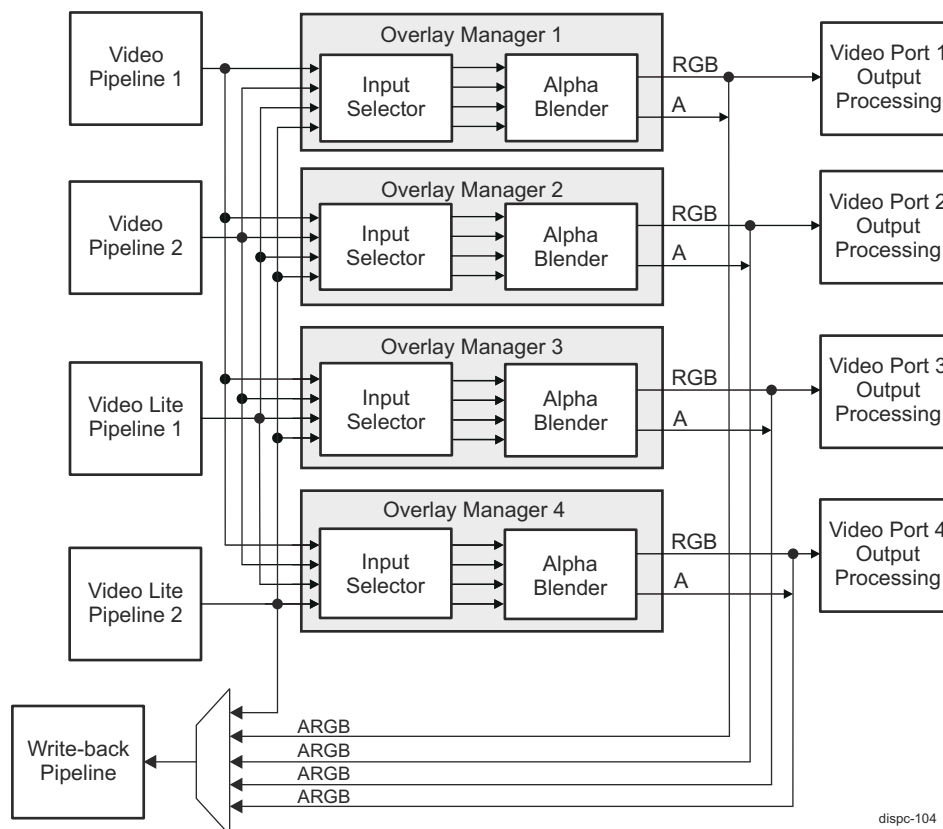

#### 12.6.4.10 DISPC Overlay Manager

The overlay manager (OVR) is responsible for compositing selected input layers together to generate the final display output frame. The DISPC implements four identical overlay managers, one for each display output (see [Figure 12-547, DISPC Architecture Overview](#)). Any of these overlay managers can be used to source also the Write-back pipeline.

- OVR1 is connected to Video Port 1 (VP1).
- OVR2 is connected to Video Port 2 (VP2).
- OVR3 is connected to Video Port 3 (VP3).
- OVR4 is connected to Video Port 4 (VP4).

Each OVR is preceded by a programmable input pipeline selector which re-maps the output of the selected input pipelines according to the overlay manager Z-order configuration.

**Figure 12-588. DISPC Overlay Manager and Input Selector**

#### Note

The DISPC overlay managers, OVR1 through OVR4, will be commonly referred to as *overlay manager* (OVR) in the following sections.

#### 12.6.4.10.1 DISPC Overlay Input Selector

The overlay input selector before the overlay manager is a n-input to n-output crossbar switch. As such, any input can be connected to any output in the selector. The selection is based on the Z-order layer selection in the overlay configuration through the following register fields:

- DSS0\_OVR\_ATTRIBUTES\_0[4-1] CHANNELIN field for layer 0, Z-order 0
- DSS0\_OVR\_ATTRIBUTES\_1[4-1] CHANNELIN field for layer 1, Z-order 1
- DSS0\_OVR\_ATTRIBUTES\_2[4-1] CHANNELIN field for layer 2, Z-order 2
- DSS0\_OVR\_ATTRIBUTES\_3[4-1] CHANNELIN field for layer 3, Z-order 3
- DSS0\_OVR\_ATTRIBUTES\_4[4-1] CHANNELIN field for layer 4, Z-order 4

The z-order determines the order in which the selected layers are blended together to generate the final output by the overlay manager:

- The lowest enabled order input is the bottom-most layer, just above the background color
- The highest enabled order input is the top-most layer

The OVR input selector also passes the following attributes from the selected input pipeline to the corresponding selector output port (*zsel*):

- Source pipeline size attributes:
  - Number of pixels per line (from DSS0\_VID\_SIZE[13-0] SIZEX register field)
  - Number of lines (from DSS0\_VID\_SIZE[29-16] SIZEY register field)

- Source pipeline global blending level (from DSS0\_VID\_GLOBAL\_ALPHA register)

Then, the overlay manager uses the above listed attributes as input layer attributes along with POSX and POSY overlay manager configuration parameters. The POSX and POSY can be configured in the [13-0] POSX and [29-16] POSY fields of the following registers:

- For layer 0, Z-order 0, in DSS0\_OVR\_ATTRIBUTES2\_0 register
- For layer 1, Z-order 1, in DSS0\_OVR\_ATTRIBUTES2\_1 register
- For layer 2, Z-order 2, in DSS0\_OVR\_ATTRIBUTES2\_2 register
- For layer 3, Z-order 3, in DSS0\_OVR\_ATTRIBUTES2\_3 register
- For layer 4, Z-order 4, in DSS0\_OVR\_ATTRIBUTES2\_4 register

#### Note

The output of an input pipeline can be mapped to more than one overlay manager simultaneously, if and only if the following conditions are true:

- All video port timing generators controlling the overlay managers are identically programmed (same frame width/height with same blanking parameters running at same frame rate) and clocked by the same pixel clock source, AND ...
- The pipeline output is positioned on each display output at the same frame position, OR ...
- One of the overlay managers is connected to the write-back path only.

The software is responsible for managing the pipeline assignment and setting up the video port timing generators properly in order to avoid any resource conflicts that may cause the DISPC to lock up (sync loss).

#### 12.6.4.10.2 DISPC Overlay Mechanism

The overlay mechanism consists of displaying more than one input layer (graphics and/or video layers) using:

- A priority rule based on the display Z-order (selected by configuring the overlay input selector, as described in [Section 12.6.4.10.1](#))
- Transparency color keys configuration (destination and source transparency)
- Alpha blending values (using the alpha component of each pixel or a global alpha value set by the user)
- Size and position attributes of the source window data, as described in [Section 12.6.4.10.1](#)

The overlay manager is configured by using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order of the window on the screen. If the Z-order value of window A is lower than the Z-order of layer B, then layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see [Section 12.6.4.10.2.1](#), *Overlay Alpha Blender*, and [Section 12.6.4.10.2.2](#), *Overlay Transparency Color Keys*).

[Figure 12-589](#) gives an simplified example of how two input pipeline frame outputs are merged together to generate the final display output.

**Figure 12-589. DISPC Overlay Example and Display Attributes**

As shown in [Figure 12-589](#), each input pipeline generates one rectangular sub-frame output in ARGB48 format. The overlay is responsible for positioning the sub-frame in the display output frame (specified by DSS0\_VP\_SIZE\_SCREEN[13-0] PPL and [29-16] LPP video port register fields), using the overlay window position parameters (specified by the [13-0] POSX and [29-16] POSY overlay fields in the DSS0\_OVR\_ATTRIBUTES2\_0 through DSS0\_OVR\_ATTRIBUTES2\_4 registers), and the window size parameters (specified by the [13-0] SIZEX and [29-16] SIZEY input pipeline fields in the DSS0\_VID\_SIZE registers). When the overlay manager does not require the input pipeline data (either because it is currently outputting the background color pixel or it is being stalled by the VP output module), the overlay manager stalls the input pipeline.

When there are no video-encoded pixels at a specific position, the programmable solid background color appears. The solid background color can be set in the DSS0\_OVR\_DEFAULT\_COLOR and DSS0\_OVR\_DEFAULT\_COLOR2 registers.

The entire pixels of the video window have to be inside the display screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width must be adjusted by software to limit the right edge of the window inside the display screen. The same is also true for the video layer height in the input pipe line configuration.

#### 12.6.4.10.2.1 Overlay Alpha Blender

The overlay manager can blend as many as four input pipelines using three cascaded stages of basically the same alpha-blending logic. Alpha output generation is supported only for the write-back path.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format (alpha in the source pixel data is converted to 8-bit alpha value in the input pipeline logic):
  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see [Table 12-559](#)).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see [Table 12-559](#)).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF, and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value can be set in the DSS0\_VID\_GLOBAL\_ALPHA register of the input pipeline, and is updated in synch with the selected output channel.
- The modulated alpha blending value (that is, a total alpha blending value, when a combination of the pixel alpha blending value A and a global alpha blending ia present) is determined as: Alpha = (Pixel\_Alpha × Global\_Alpha) / 256.

[Table 12-559](#) shows the remapping and the percentage of alpha blending achieved.

**Table 12-559. DISPC Overlay Alpha Blending – ARGB**

Alpha Blending 1-Bit Value (ARGB16-1555)	Alpha Blending 4-Bit Value (ARGB16-4444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x0	0x00	100% (transparent)
N/A	0x1	0x11	93.33%
N/A	0x2	0x22	86.6%
N/A	...	...	...
N/A	0xE	0xEE	6.6%
0x1	0xF	0xFF	0% (opaque)

## Premultiplied Alpha and Alpha Output Generation

The source image in ARGB format may have its RGB component already premultiplied with the alpha (AR'G'B') where:

- $R' = A * R$
- $G' = A * G$
- $B' = A * B$

In that case, the processing is as follows:

- Color components of premultiplied layers are multiplied with the global alpha, if Global\_Alpha is not equal to 0.
- Color components of the composed underlying layer are multiplied with  $(1 - A * \text{Global\_Alpha})$ .

The premultiplied alpha option is accessible through the DSS0\_VID\_ATTRIBUTES[28] PREMULIPLYALPHA register bit of the input pipeline. The following settings are available:

- PREMULIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the overlay manager.
- PREMULIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

When the write-back channel copies back to memory the premultiplied color component, the the alpha value is computed as follows:

$$A(\text{dst}) = A(\text{src}) + (1 - A(\text{src}))A(\text{dst})$$

When the DSS0\_WB\_ATTRIBUTES[9] ALPHAENABLE register bit is cleared or when the overlay channel is not selected for write-back, the computation of the A(dst) is disabled.

### Note

There is no alpha blending between the background and the next layer (layer-0) above it.

Layer-0 cannot be pre-multiplied, if the overlay output is driving the display, since that layer (or the background color) defines the bottom most layer. In this case, layer-0 alpha is 1 always.

Layer-0 can have an alpha value other than 1 when the overlay output is only used to generate an intermediate layer composition result in a memory-to-memory operation (through the WB pipeline). But, if alpha is not 1, the resulting data will be "pre-multiplied". If a non-premultiplied data is required, the resulting overlay output must be fed through a Porter-Duff compositing engine to have the result divided by the overlay alpha output.

#### 12.6.4.10.2.2 Overlay Transparency Color Keys

The overlay manager supports two color transparency modes - source and destination. These modes cannot be active at the same time.

The source transparency is tied to the top most layer, so the layer to have this transparency applied to has to be mapped to the highest Z-ordered input (layer-4) of the overlay manager. The destination transparency is tied to the bottom most layer, so the layer to have this transparency applied to has to be mapped to the lowest Z-ordered input (layer-0) of the overlay manager.

The source and destination transparencies are defined as following:

- Source color transparency: Top layer pixel that meets the source transparency color check is made transparent.
- Destination color transparency: Top layer pixel is made transparent, only if the bottom layer pixel does not meet the destination transparency color check.

The transparency color key is enabled via the DSS0\_OVR\_CONFIG[10] TCKLCDENABLE register bit.

The minimum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MIN and DSS0\_OVR\_TRANS\_COLOR\_MIN2 registers.

The maximum transparency color values are specified in the TRANSCOLORKEY field of the DSS0\_OVR\_TRANS\_COLOR\_MAX and DSS0\_OVR\_TRANS\_COLOR\_MAX2 registers.

The transparency color key values defined in the registers are compared with the pixel values. If each color component (R, G, and B) is in the range defined by MIN and MAX, then there is a match. If at least one of the color component is not in the range, then there is no match.

#### • Source transparency color key

The values of the source transparency color key define the range of encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value inside the valid range are not visible, and the encoded pixel values of the under layers or solid background color are visible.

The source transparency color key can be used with YUV and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care, since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison, in case the original format is YUV.

The scaler can be enabled as a preprocessor in the video pipelines. The pixel scaling processing can be considered in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x1.

Figure 12-590 shows an example of source transparency color key usage. The pixels with the transparency color key are not displayed. Instead, pixels of the resulting layer underneath are shown.

**Figure 12-590. DISPC Overlay Source Transparency Color Key Example**

- **Destination transparency color key**

The destination transparency color key values define the range of the encoded pixels in layer-0 (bottom layer), which are not going to be displayed. That is, the encoded pixel values matching the destination color key value range are pixels not visible on the screen. Pixels at the same position in the layers above layer-0 are visible. The destination transparency color key is applicable in the layer in the background only when there is an overlap between the layer in background position and the layer just above it, otherwise, the destination transparency color key is ignored. See [Section 12.6.4.10.2, DISPC Overlay Mechanism](#), for details on layer position depending on the Z-order parameter.

The destination transparency color key can be used only with RGB formats (ARGB, RGB, xRGB, RGBA, and RGBx). In that case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care since the comparison is between the input pixel value of the overlay manager from pipeline and the color key value. The YUV data is converted to RGB format. The user must consider the color space conversion processing in order to define the RGB color key value used for the comparison in case the original format is YUV.

The scaler can be enabled as a preprocessor in the pipelines. The pixel scaling processing must be considered in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the DSS0\_OVR\_CONFIG[11] TCKLCDSELECTION register bit to 0x0.

Figure 12-591 shows an example of the destination color key usage. The pixels from layer-0 (bottom layer) equal to the transparency color key are not displayed and are replaced by the pixels from layer-1 (top layer). All other layer-0 pixels, different from the transparency color key, are displayed over layer-1.

**Figure 12-591. DISPC Overlay Destination Transparency Color Key Example**

#### 12.6.4.10.3 Overlay 3D Support

In order to support S3D (Stereoscopic 3D) by combining in hardware left and right frames into the same output frame, the following configurations (defined by HDMI 1.4b standard specification) can be used:

- Separate pipeline mode: Left/Right or Top/Bottom. One layer is used for left/top and another layer is used for right/bottom.

#### 12.6.4.10.4 Overlay Color Bar Insertion

Each overlay manager supports a simple internal color bar insertion in each display output path to enable testing of display output interface without using the frame buffer data from the memory.

The colors are: White, Yellow, Cyan, Green, Magenta, Red, Blue, Black, as shown in below. These make three primary colors, three secondary colors, white, and black.

**Figure 12-592. DISPC Overlay Internal Color Bar**

When the DSS0\_OVR\_CONFIG[1] COLORBAREN register bit is set to 1, the overlay output data is replaced by the predefined ARGB48 color bar data.

When color bar mode is used, the color space conversion matrix should be appropriately programmed, so that it can convert the full-range RGB to the desired color format.

**Table 12-560. DISPC Overlay Color Bar Table**

Color	G	B	R
White	0xFFFF	0xFFFF	0xFFFF
Yellow	0xFFFF	0	0xFFFF
Cyan	0xFFFF	0xFFFF	0
Green	0xFFFF	0	0
Magenta	0	0xFFFF	0xFFFF
Red	0	0	0xFFFF
Blue	0	0xFFFF	0
Black	0	0	0

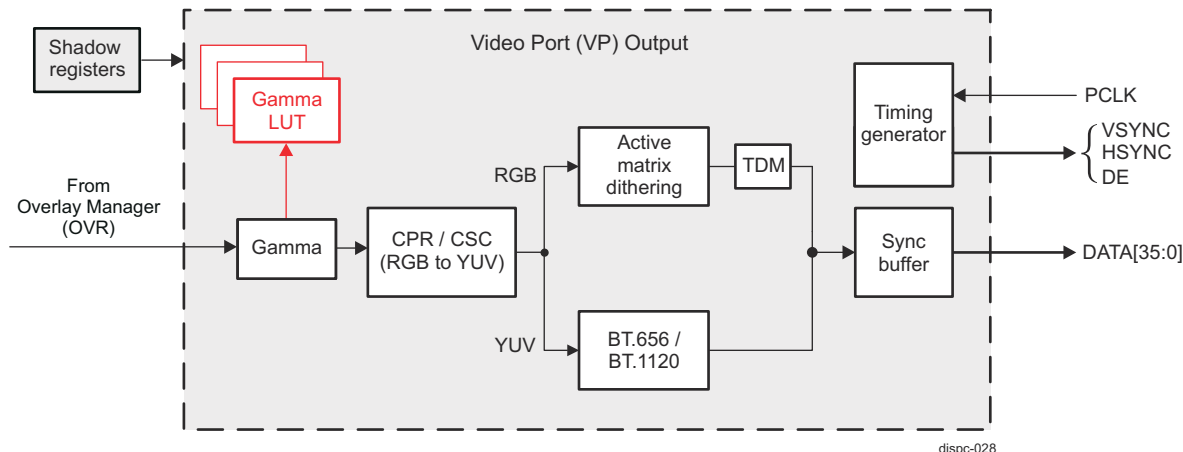

#### 12.6.4.11 DISPC Video Port Output

The DISPC implements four identical Video Port (VP) outputs:

- VP1 processes data received from Overlay Manager 1 (OVR1)
- VP2 processes data received from Overlay Manager 2 (OVR2)
- VP3 processes data received from Overlay Manager 3 (OVR3)
- VP4 processes data received from Overlay Manager 4 (OVR4)

The VP output path consists of several processing blocks (see [Figure 12-593](#)):

- Gamma correction unit
- Color phase rotation (CPR) unit, also used for RGB to YUV color space conversion (CSC)
- Active matrix dithering with TDM (multiple cycle output format)
- BT.656/BT.1120 block
- Timing generator
- Async buffer

**Figure 12-593. DISPC VP Output Architecture**

The CSC processing can be configured to occur either before or after the gamma correction in the VP output module via the DSS0\_VP\_CONFIG[26] COLORCONVPOS register bit. For RGB to YUV color space conversion, the conversion must be done after the gamma correction. For other RGB output applications, the conversion must be done before the final gamma correction.

#### Note

The DISPC video port (VP) outputs, VP1 through VP4, will be commonly referred to as *video port (VP)* in the following sections.

#### 12.6.4.11.1 DISPC VP Gamma Correction Unit

The VP supports a look up table to perform the gamma correction on the display output. The look up table consists of 3 separate 1024x10-bit memories, which are indexed by the R/G/B component data.

When performing gamma correction, the selected encoded pixel values from the video pipeline path are sent by the overlay manager to the gamma curve table. Each R/G/B component of the encoded pixel value is used as a pointer to index 1 out of 1024x30-bit gamma curve entries in the table. Each 10-bit component is replaced with the 10-bit table value corresponding to R, G, or B component. The table is loaded by software via the DSS0\_VP\_GAMMA\_TABLE\_0 through DSS0\_VP\_GAMMA\_TABLE\_15 registers. It is possible to load only part of the table.

The sequence to load the gamma table is:

1. SW writes (only writes are supported) 32-bit gamma correction values using single access, or burst access in linear increment burst mode, into the 64-byte region strating at DSS0\_VP\_GAMMA\_TABLE\_0 register address. The LSB 30 bits [29:0] are used for the value, and the MSB 1 bit [31] is used for resetting the index into the table at the end.
2. Loop to step #1, if there is a new access to the gamma table register. The software can access other registers between two accesses to the gamma table register.

Software needs to ensure that there is no visible effect when modifying the table, since it is not under hardware control.

The usage of the gamma table is activated by setting DSS0\_VP\_CONFIG[2] GAMMAENABLE register bit.

Figure 12-594 describes the format of one of the gamma curve values in the memory.

Figure 12-594. DISPC VP Output Gamma Table Write Data Format

#### 12.6.4.11.2 DISPC VP Color Phase Rotation Unit

If required, a color phase rotation (CPR) processing can be applied on the "gamma" data before the spatial/temporal dithering.

The CPR can be selected to correct the non-pure white backlight of the display panel by using a programmable matrix to convert the 36-bit RGB pixel value into a new 36-bit RGB pixel value. The matrix is programmed through a set of nine 11-bit signed coefficients. The output of the calculation is clipped to [0:4095]. The CPR is enabled by setting the DSS0\_VP\_CONFIG[15] CPR bit to 0x1.

The CPR processing is expressed by the equation shown in Figure 12-595. Table 12-561 lists all coefficients with their respective register bitfields for configuration.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_r & R_g & R_b \\ G_r & G_g & G_b \\ B_r & B_g & B_b \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dispc-023

DSS0_VP_CSC_COEF7[31-19] POSTOFFSET3	-	B offset

### 12.6.4.11.3 DISPC VP Color Space Conversion - RGB to YUV

The RGB to YUV color space conversion (CSC) in the video port is done by using the same programmable logic used for CPR. If CPR is also required, then the process can be combined with the CSC processing by adjusting matrix coefficients. [Table 12-561](#) lists the associated coefficients with their respective register bit-fields. The CSC processing is enabled by setting the DSS0\_VP\_CONFIG[24] COLORCONVENABLE register bit.

The color space conversion can be selected in order to convert from 36-bit RGB to YUV444. The conversion matrix is programmed through a set of nine 11-bit signed coefficients. The result is clipped to [256:3760] for the luminance and [256:3840] for the chrominance, when a full-range YUV output is not desired (equivalent to clipping to [16..235] and [16..240] in 8-bit video). In this case the DSS0\_VP\_CONFIG[25] FULLRANGE register bit must be set to 0x0.

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 256 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-098

**Figure 12-596. DISPC VP CSC RGB to YUV Equation (FULLRANGE=0)**

If the programmed active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:4095], then the values Y, Cb, and Cr are clipped to the range [0:4095]. The following equation gives the 11-bit coefficients of the RGB to YUV color space conversion, for full range (when DSS0\_VP\_CONFIG[25] FULLRANGE = 0x1).

$$\begin{bmatrix} Y_{OUT} \\ Cr_{OUT} \\ Cb_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cr_R & Cr_G & Cr_B \\ Cb_R & Cb_G & Cb_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 2048 \\ 2048 \end{bmatrix}$$

dispc-099

**Figure 12-597. DISPC VP CSC RGB to YUV Equation (FULLRANGE=1)**

In order to provide YUV422 data to the BT.656 / BT.1120 block, the YUV444 format is further converted to YUV422 by sub-sampling the chrominance values. The hardware does this by averaging two-by-two the

chrominance samples. The conversion from YUV444 to YUV422 is performed when the color space conversion in the VP is enabled.

#### 12.6.4.11.4 DISPC VP BT.656 and BT.1120 Modes

Each VP output can be configured in BT.656 or BT.1120 mode. The following standards are not supported in BT.656 mode:

- BT.470 (Support for conventional Analog TV Systems)
- BT.803 (The avoidance of interference generated by digital television studio equipment)
- BT.1364 (Format of ancillary data signals carried in digital component studio interfaces)
- BT.601 (Studio encoding parameters for digital TV standards for standard 4:3 and wide 16:9 aspect ratios)

Unsupported formats when BT.1120 mode is used:

- BT.1364 (Support for Ancillary Data during blanking period)
- BT.709 (Square pixel support)

BT.656/BT.1120 modes use embedded EAV/SAV syncs.

Enabling BT.656 or BT.1120 format for a VP output is done by setting DSS0\_VP\_CONFIG[20] BT656ENABLE or [21] BT1120ENABLE register bit, respectively

---

#### Note

It is not possible to enable BT.656 and BT.1120 modes simultaneously on the same VP output.

---

##### 12.6.4.11.4.1 DISPC BT Mode Blanking

During the transmission of the video signal, the portion of the stream in-between active video data segments is known as the horizontal blanking interval.

Strictly speaking this entire region is the blanking interval, but this interval also includes the EAV and SAV codes. The remaining bytes of information in a digital blanking interval are filled with values corresponding to the blanking levels of the Cb, Y and Cr signals respectively, and in accordance with the standard multiplex sequence for the stream (CbYCrY..). The blanking levels are as follows:

- Cb = 80h
- Y = 10h
- Cr = 80h.

The sequence in the BLANKING region of the data stream is therefore: 80h, 10h, 80h, 10h.....80h, 10h

For more details on setting the blanking timing values for BT.1120 and/or BT.656 mode, see [Section 12.6.4.11.8, DISPC VP Timing Generator and Display Panel Settings](#).

##### 12.6.4.11.4.2 DISPC BT Mode EAV and SAV

The End of Active Video (EAV) and Start of Active Video (SAV) parts of the stream are timing codes. Their function can be summarized as follows:

- EAV – marks the end of the active video data within the current line and therefore also the start of the subsequent line.
- SAV – heralds the start of the active video data within the current line.

These codes are embedded within the BT.656 video data stream, thereby eliminating the need for additional timing signals (HSYNC, VSYNC) to be included as part of the interface.

Both EAV and SAV codes are comprised of a sequence of four bytes ( FFh – 00h – 00h - XY). The first three bytes in the sequence constitute a fixed preamble. The fourth byte, contains information about the field being transmitted (Field 1 or Field 2 in an interlaced video signal), the state of field blanking (Vertical) and the state of line blanking (Horizontal). The bit assignment for this byte of the code is shown in [Figure 12-598](#), with the function of each bit described in [Table 12-562](#).

MSB							LSB
1	F	V	H	P3	P2	P1	P0

**Figure 12-598. DISPC BT Mode Bit-Assignment for the Fourth Byte of EAV/SAV Codes**
**Table 12-562. DISPC BT Mode Bit Function**

Bit	Symbol	Function
7	1	Always set to '1'.
6	F	Field bit. 0 – Field 1 1 – Field 2
5	V	Vertical Blanking Status bit. This bit goes High during a vertical field blanking interval, otherwise it remains Low.
4	H	Horizontal Blanking Status bit. 0 – byte is part of SAV code (i.e. stream is entering an active video data region for the current line) 1 – byte is part of EAV code (i.e. stream has entered a horizontal blanking interval - start of a new line)
3	P3	Protection bit 3
2	P2	Protection bit 2
1	P1	Protection bit 1
0	P0	Protection bit 0

The protection bits allow for detection and correction of 1-bit errors and the detection of 2-bit errors. The status of P3, P2, P1 and P0 depend on the states of bits F, V, and H. This dependency is shown in [Table 12-563](#).

**Table 12-563. DISPC BT Mode Status of Protection Bits in Function of F, V, and H**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

#### 12.6.4.11.5 DISPC VP Spatial/Temporal Dithering

The active spatial/temporal dithering logic can be enabled to minimize the color banding when displaying the data on a LCD panel with color depth lower than 24-bit. The dithering logic is integrated after the color/gamma conversion blocks and before the TDM (Time Division Multiplexing) block. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control (the value of removed bits and the frame number). The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DSS0\_VP\_CONTROL[31-30] SPATIALTEMPORALDITHERINGFRAMES register field. In the case of a single frame, only spatial processing is applied. In case of multiple frames, both spatial and temporal processing are applied to the pixels. The number of frame is initialized before enabling the spatial/temporal dithering logic. It must be never changed by the software while the spatial/temporal logic is enabled. The spatial/temporal dithering logic is enabled by setting the DSS0\_VP\_CONTROL[7] STDITHERENABLE bit to 0x1.

### Note

- If the interface data bus is smaller than the pixel format size and the spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, then by programming the pixel components replication active/inactive the MSB is replicated to the LSB of the interface data bus.

#### 12.6.4.11.6 DISPC VP Multiple Cycle Output Format (TDM)

The pixels (only RGB components) after the active matrix dithering unit are formatted on one or multiple cycles (from 1 to 3 cycles). On three cycles, two pixels can concatenate and send to the panel. The cycle format is selected through the DSS0\_VP\_CONTROL[24-23] TDMCYCLEFORMAT bit field. The number of bits for each cycle is set in the DSS0\_VP\_DATA\_CYCLE\_0 register for the first cycle, the DSS0\_VP\_DATA\_CYCLE1 register for the second cycle, and the DSS0\_VP\_DATA\_CYCLE2 register for the third cycle. The output interface data bus width, when TDM mode is enabled (DSS0\_VP\_CONTROL[20] TDMENABLE register bit = 1), can be 8, 9, 12, or 16 bits, configurable through the DSS0\_VP\_CONTROL[22-21] TDMPARALLELMODE register field.

When the TDM is disabled (DSS0\_VP\_CONTROL[20] TDMENABLE = 0), the video port output interface data bus width is configured through the DSS0\_VP\_CONTROL[10-8] DATALINES register field.

When using TDM mode, only up to 24 bits per pixel can be output on the interface. For higher color depth, only the upper bits are kept before converting each pixel into TDM output.

[Figure 12-599](#) through [Figure 12-602](#) show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

**Figure 12-602. DISPC VP TDM 16-Bit Interface Settings**

#### 12.6.4.11.7 DISPC VP Stall Mode

The VP output can be programmed to operate in Stall Mode, where there is a stall handshake mechanism (back-pressure) with the display peripheral to which the VP is connected. No sync signals (HS, VS) are generated in Stall Mode of operation. Data and Enable (DE) signals are provided only when the stall signal is de-asserted (1'b0) by the peripheral. The Stall Mode can be enabled via the DSS0\_VP\_CONTROL[11] STALLMODE register bit.

### Note

In this SoC, the Stall Mode of operation is supported only on the VP outputs connected to the DSI peripheral module.

There are two types of data transfer, if Stall Mode is enabled, that can be selected by the DSS0\_VP\_CONTROL[12] STALLMODETYPE register bit:

- In DSI Video Mode, multiple frames are sent out on VP until the VP is disabled. A FRAMEDONE\_IRQ interrupt is generated at the end of each frame. No VSYNC\_IRQ interrupt is generated.
- In DSI Command Mode, a single frame is sent out on VP and the VP is auto disabled. A FRAMEDONE\_IRQ interrupt is generated at the end of frame. To transfer another frame in Command Mode, the user needs to re-enable the VP. No VSYNC\_IRQ interrupt is generated.

#### 12.6.4.11.8 DISPC VP Timing Generator and Display Panel Settings

Each video port output has a dedicated timing generator supporting progressive and interlaced modes. It is clocked using the pixel clock and is configured to generate the video data and sync signals to match the desired video display standard timings.

Two-level configuration for enabling the video ports exists:

- Via the individual DSS0\_VP\_CONTROL[0] ENABLE register bit for each VP. It allows each VP to be independently controlled by two different hosts.
- Via the common DSS0\_COMMON\_DISPC\_GLOBAL\_OUTPUT\_ENABLE[2-0] VP\_ENABLE register field. It allows two or more VP timing generators to be in sync by enabling them simultaneously with a single register write.

Both ENABLE and VP\_ENABLE register fields must be set in order for a VP (timing generator) to start.

Figure 12-603 shows the timing generator display parameters.

**Figure 12-603. DISPC VP Display Timing Parameters**

The width of VP output data bus is configured in the DSS0\_VP\_CONTROL[10-8] DATALINES register field, when TDM feature is disabled. When TDM is enabled, the width of the output data bus is defined according to [Section 12.6.4.11.6, DISPC VP Multiple Cycle Output Format \(TDM\)](#).

The size of the display panel is defined by:

- Number of lines per frame, DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field
- Number of pixels per line, DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field

Standard HSYNC/VSYNC timing generation is programmable as follows:

- Horizontal front porch is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
- Horizontal back porch is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
- Horizontal synchronization pulse width is set in the DSS0\_VP\_TIMING\_H[7-0] HSW bit field.
- Vertical front porch is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
- Vertical back porch is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
- Vertical synchronization pulse width is set in the DSS0\_VP\_TIMING\_V[7-0] VSW bit field.

When the output is in BT.1120 or BT.656 mode, the following timing constants are mapped onto the DSS0\_VP\_TIMING\_H and DSS0\_VP\_TIMING\_V registers:

- Progressive mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical frame blanking No 1 is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
  - Vertical frame blanking No 2 is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
  - Number of lines per frame is set in the DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field.
  - Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field.
- Interlaced mode:
  - Horizontal blanking (12 bits) is set in the {DSS0\_VP\_TIMING\_V[3-0] VSW, DSS0\_VP\_TIMING\_H[7-0] HSW} register fields (up to 2048 bytes of horizontal blanking supported).
  - Vertical field blanking No.1 for Even Field is set in the DSS0\_VP\_TIMING\_H[19-8] HFP bit field.
  - Vertical field blanking No.2 for Even Field is set in the DSS0\_VP\_TIMING\_H[31-20] HBP bit field.
  - Vertical field blanking No.1 for Odd Field is set in the DSS0\_VP\_TIMING\_V[19-8] VFP bit field.
  - Vertical field blanking No.2 for Odd Field is set in the DSS0\_VP\_TIMING\_V[31-20] VBP bit field.
  - Number of lines per field (even) is set in the DSS0\_VP\_SIZE\_SCREEN[29-16] LPP bit field.
  - Delta number of odd field compared to even field (in a single line) is set in the DSS0\_VP\_SIZE\_SCREEN[15-14] DELTA\_LPP bit field. The DELTA\_LPP field only controls the output channel and not the size of the field fetched from the frame buffer in memory. This field must be set to zero for YUV420 format.
  - Number of pixels per line is set in the DSS0\_VP\_SIZE\_SCREEN[13-0] PPL bit field.

Horizontal/vertical synchronization and output enable signals polarity are programmable by setting the DSS0\_VP\_POL\_FREQ[12] IVS, [13] IHS, and [15] IEO register bits. These signals can be gated by setting the DSS0\_VP\_CONFIG[7] VSYNCGATED and [6] HSYNCGATED register bits. In addition, the alignment between VSYNC and HSYNC signals can be programmed via the DSS0\_VP\_POL\_FREQ[18] ALIGN register bit.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DSS0\_VP\_POL\_FREQ[14] IPC register bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DSS0\_VP\_POL\_FREQ[16] RF bit.

Each VP output can be configured in progressive output mode or interlaced output mode. The selection is done by writing into the bit-field DSS0\_VP\_CONFIG[22] OUTPUTMODEENABLE register bit. The default setting is for progressive mode. The selection can be changed only when the corresponding VP output is disabled. The configuration is independent for each VP output. It is possible to change the configuration of one of the VP outputs while the other VP is enabled.

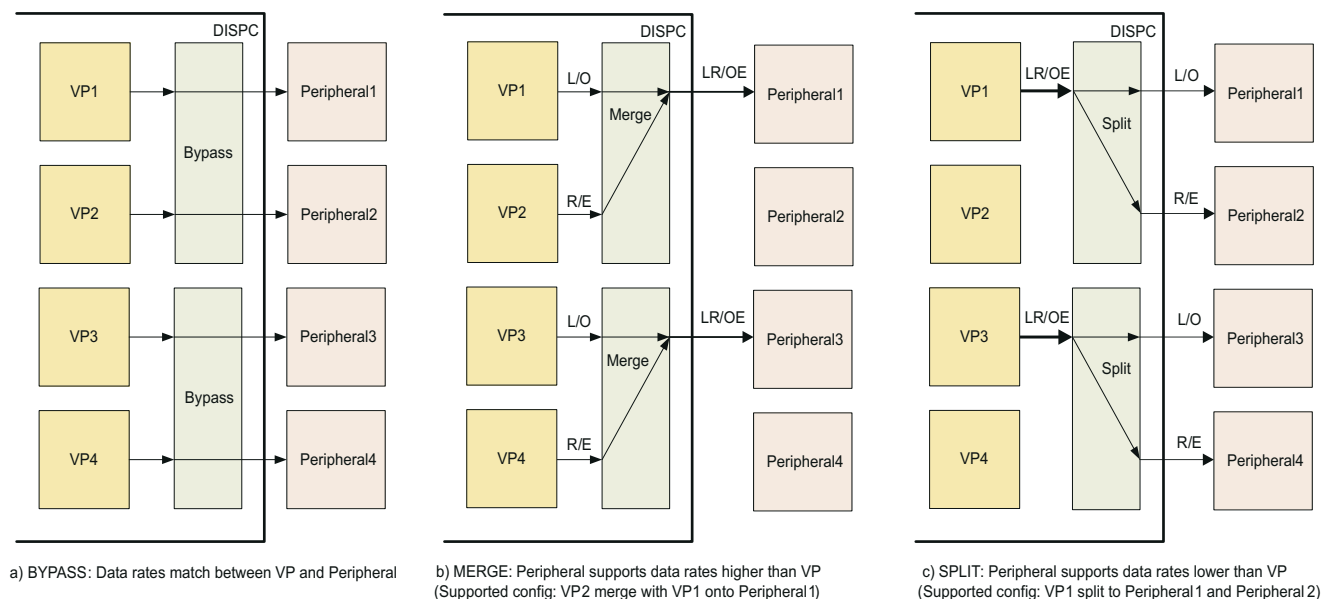

The pixel clock for each VP output can be gated by setting the DSS0\_VP\_CONFIG[5] PIXELCLOCKGATED register bit.

The hold time of the pixels on the data bus is determined in clock cycles by the DSS0\_VP\_CONTROL[16-14] HT register field.

### 12.6.4.11.9 DISPC VP Merge-Split-Sync (MSS) Module

In order to interface with peripherals which can support a different data rate than the VP output, a Merge-Split-Sync (MSS) module is introduced between the VP outputs and DISPC final output. When interfacing with a peripheral which can support a higher data rate than the VP, two VP outputs can be merged to generate one high data rate stream on the DISPC output (MERGE mode). When interfacing with a peripheral which requires dual physical links to support a high resolution video, one VP output can be split into two half data rate pixel streams on two separate DISPC outputs (SPLIT mode).

Both left/right (L/R) or odd/even (O/E) pixel selection types are supported.

**Figure 12-604. DISPC VP Merge-Split Scheme**

Additionally, the MSS module can also operate in a SYNC mode where two VP outputs get the same source pixel clock. The SYNC mode only affects the clock muxing and does not manipulate the data going out of each VP output.

Only the following configurations, as shown in [Figure 12-604](#), are supported:

- MERGE Mode
  - VP2 (Right/Even stream) merged with VP1 (Left/Odd stream) output onto Peripheral #1 (P1)
  - VP4 (Right/Even stream) merged with VP3 (Left/Odd stream) output onto Peripheral #3 (P3)
- SPLIT Mode
  - VP1 split into Peripheral #1 (P1)(Left/Odd stream) and Peripheral #2 (P2)(Right/Even stream)
  - VP3 split into Peripheral #3 (P3)(Left/Odd stream) and Peripheral #4 (P4)(Right/Even stream)
- SYNC Mode
  - VP1 and VP2 in sync and get the same pixel clock
  - VP3 and VP4 in sync and get the same pixel clock

The DSS0\_COMMON\_DISPC\_MSS\_VP1 and DSS0\_COMMON\_DISPC\_MSS\_VP3 registers control the MSS operation.

The MSS line buffers are sized to support up to 6K RGB30 video data. Therefore, in MERGE use-case, two 3K VP outputs can be merged to create a 6K output at DISPC. In SPLIT use-case, one 6K output can be split into two 3K outputs.

In both, MERGE and SPLIT use-cases, all the control signals (VS, HS, DE) are re-generated so as to match with the timing of the new merged frame or split frames.

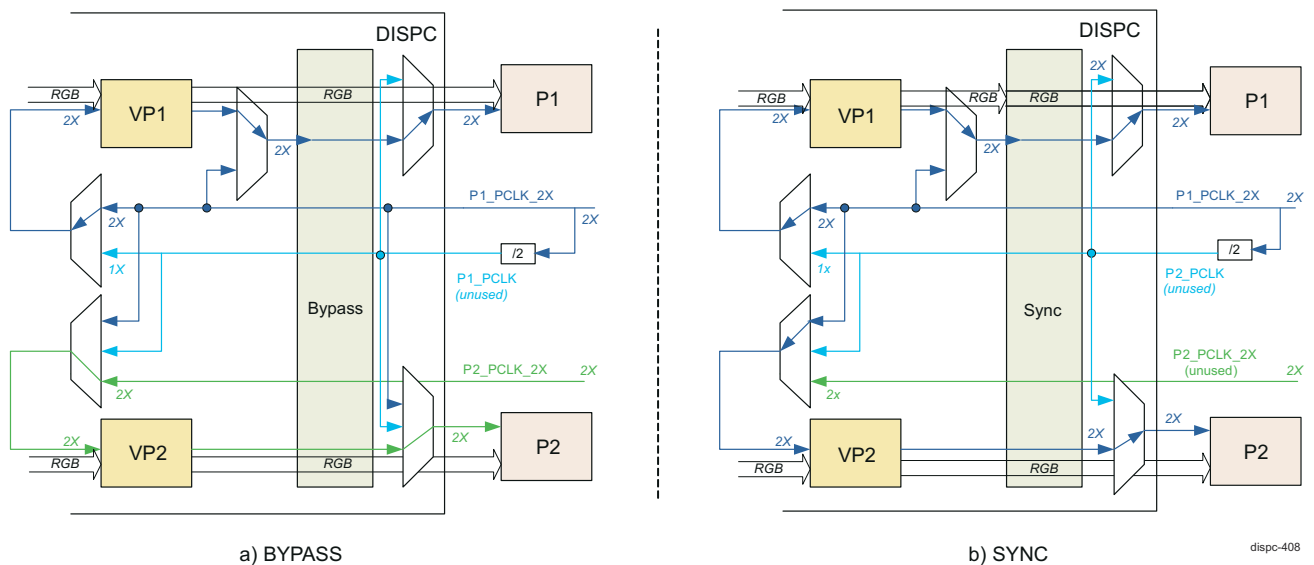

### Note

For Merge-Split-Sync mode of operation, the VP outputs need to be programmed to be active-high for the different signals (DE, VS, HS). For SPLIT mode of operation, it is required that the total number of pixels in a line is a multiple of 2. For both SPLIT mode and SYNC mode of operation, both the VP blocks need to be enabled at the same cycle. This is achieved by making a single write to the global enable register (DSS0\_COMMON\_DISPC\_GLOBAL\_OUTPUT\_ENABLE[3-0] VP\_ENABLE field).

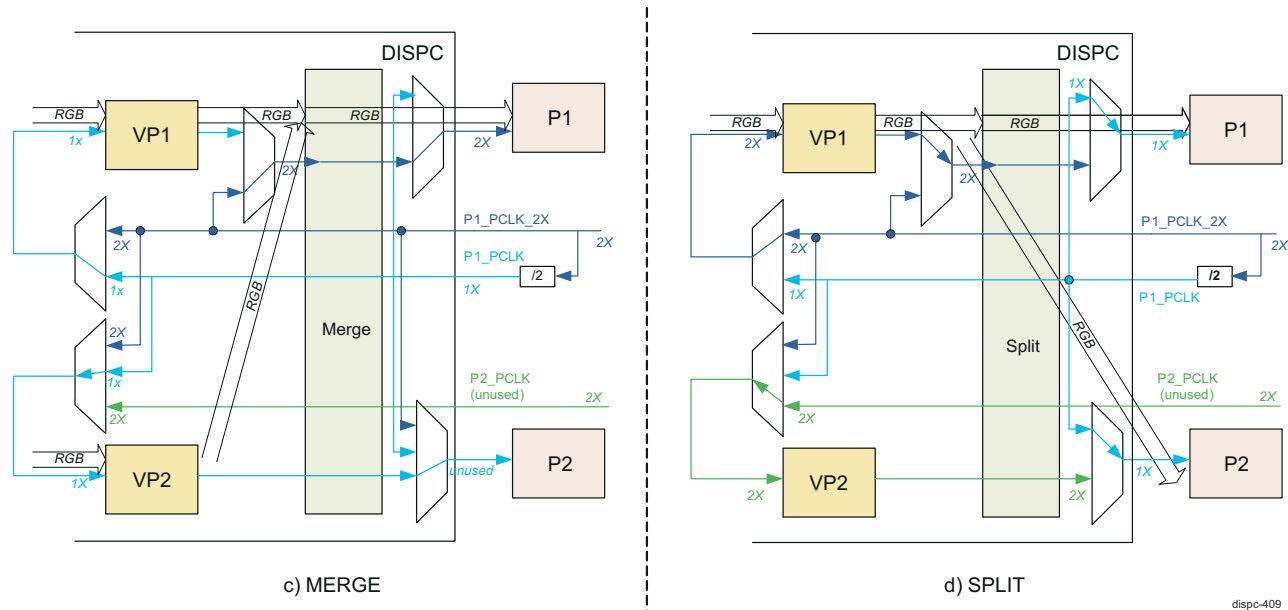

When the DISPC is interfaced with the DP/eDP peripheral, the SPLIT mode corresponds to the Split (single stream transport) mode of operation of the DSC (Digital Stream Compression) sub-module within the EDP module. In this case, the two streams at half the pixel clock rate are first provided to DSC\_ENC0 and DSC\_ENC1 within the EDP. Then, the combined encoded stream is provided to the EDP MHDPTX Controller VIF0 port. The SYNC mode corresponds to the Dual (multi stream transport) mode of operation of the EDP module. In this case, the two streams at full pixel clock rate are provided to the EDP VIF0 and VIF1 ports (the EDP DSC has to be bypassed in this mode). For more details, see the EDP [Section 12.6.6.2.1, Video Stream Clock/Data Muxing](#).

#### 12.6.4.11.9.1 MSS Clocking Scheme

The pixel clocks going to the VPn as well as the pixel clocks going to the peripherals (Pn) will be different under different cases, depending on whether the output is in BYPASS, SYNC, MERGE or SPLIT mode. The different combinations of the clocks are as shown in [Figure 12-605](#) and [Figure 12-606](#).

**Figure 12-605. DISPC VP Clocking Scheme for MSS BYPASS and SYNC Modes**

**Figure 12-606. DISPC VP Clocking Scheme for MSS MERGE and SPLIT Modes**

Figure 12-606 show VP1 and VP2. Same clock scheme is applicable to VP3 and VP4.

For all cases in Figure 12-605 and Figure 12-606 there is no async interaction between P1\_PCLKs and P2\_PCLKs.

#### 12.6.4.11.9.2 MSS Merge with Scaling

Merge operation with scaling enabled in the VID pipelines can result in visual artifacts at the merged boundary. The artifacts can be avoided by scaling each half to a larger window size and then using the crop feature of the VID pipelines to get to the required size for each half.

#### 12.6.4.11.10 DISPC Internal Diagnostic Features

The DSS supports the following internal diagnostic features in DISPC hardware:

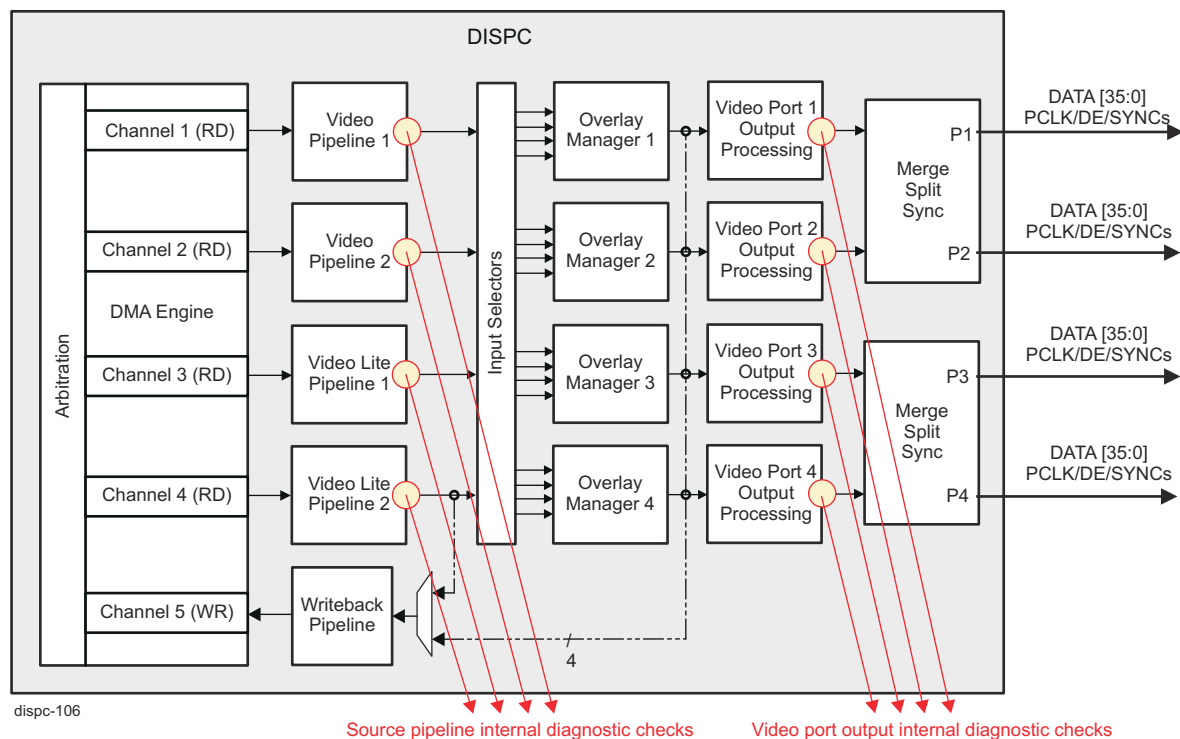

- Data correctness check: To verify intended data is shown correctly on the display.
- Freeze frame detection: To notify a possible frame freeze, when there is no change in the display frame over a multiple frame periods.

These features are implemented by collecting signatures from user-defined regions within each pipeline output frame and the final display output frame, and comparing them to reference signatures provided by the user (software) and/or to previously saved signatures. The signature from each region is generated by using a MISR (Multiple Input Signature Register) module.

#### 12.6.4.11.10.1 Internal Diagnostic Check Regions

The DSS supports the following internal diagnostic check regions:

- Video pipelines: One internal diagnostic check region at the output of each video pipeline.
- Video port outputs: Up to eight internal diagnostic sub-regions within the active video output area of the final display output of each video port.

**Figure 12-607. DISPC Internal Diagnostic Check Regions**

Table 12-564 lists the parameters supported by each of the internal diagnostic check regions, together with the associated register control fields.

**Table 12-564. DISPC Internal Diagnostic Check Regions Parameters**

Internal Diagnostic Region Parameter	Video Pipeline Control Register	Video Port Sub-region m (m = 0 to 7) Control Register

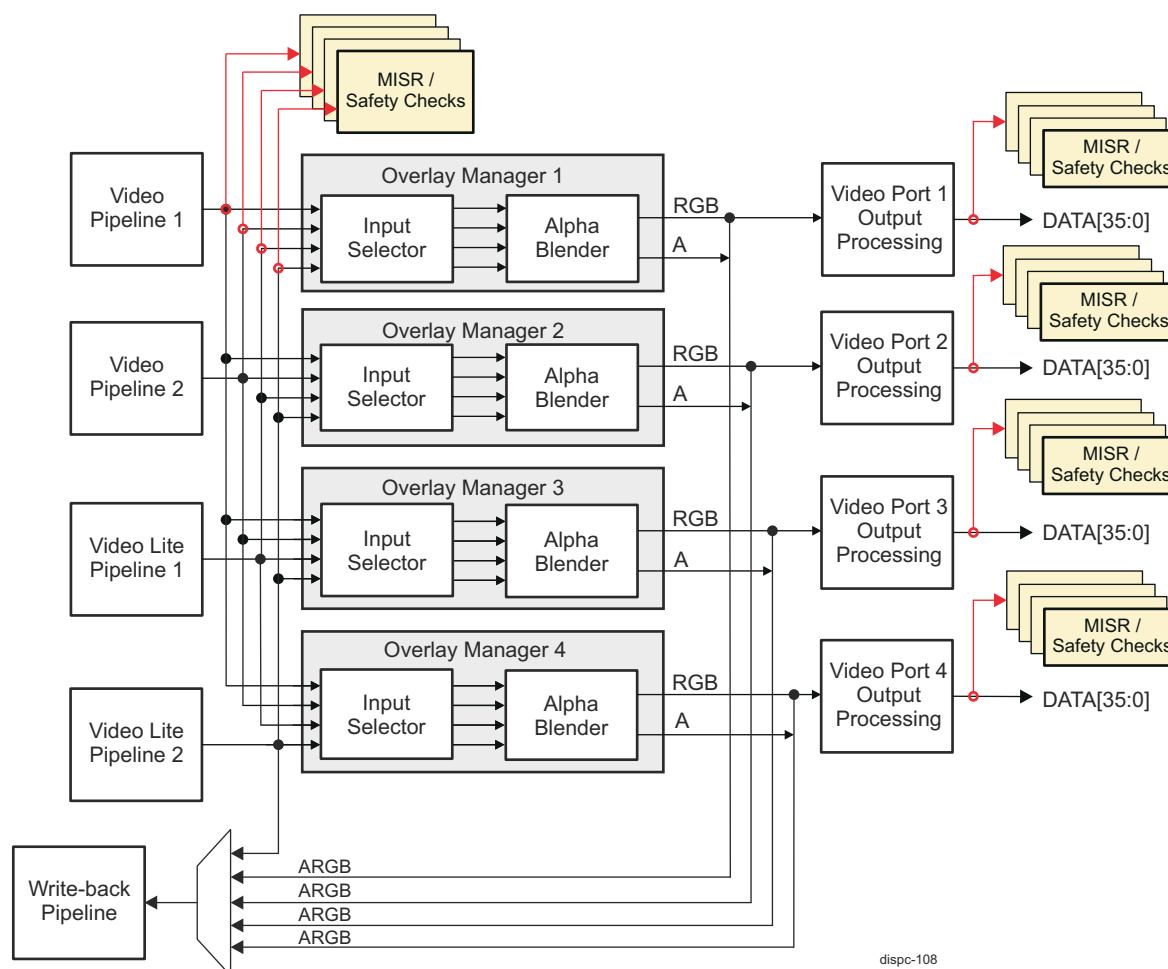

Figure 12-608 shows examples of one internal diagnostic region in the video pipeline output stage and up to 8 possible regions in the final video port output stage.

**Figure 12-608. DISPC Internal Diagnostic Check Region Examples**

The internal diagnostic region in the video pipeline captures data, only if the embedded alpha data is not equal to 0 (that is, non-transparent pixels). The internal diagnostic regions in the display video port output captures all active video pixels within the region boundary. The regions (up to eight) in the display output should be typically non-overlapping areas of the screen, but the hardware does not restrict them to be non-overlapping.

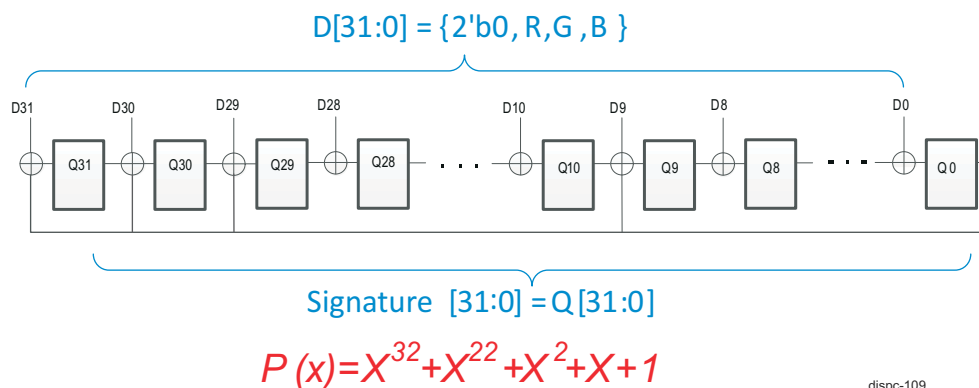

Figure 12-609 shows the locations within DISPC data path where the data is analyzed.

**Figure 12-609. DISPC Internal Diagnostic Check Locations**

### 12.6.4.11.10.2 Internal Diagnostic Signature Generator Using MISR

A 32-bit multiple input signature register (MISR) with 32-bit Galois LFSR polynomial,  $P(x)=X^{32}+X^{22}+X^2+X+1$ , is used to capture a signature of active video pixel data (the 10 MSB bits of each color component) for each internal diagnostic region, as shown in Figure 12-610 and the algorithm below it.

**Figure 12-610. DISPC Internal Diagnostic 32-bit MISR Implementation**

The MISR (32-bit Galois LFSR based) signature generation algorithm is as follows:

```
Tap_polynomial = 32'hE000_0200
```

```
lfsr_q = seed // initial LFSR value - any non zero value should work
```

```
For each (pixel data in the internal diagnostic region) {
```

```
data_in[31:0] = { 2'b0, r,g,b } // 10 MSB bits of R,G,B components
```

```
lfsr_d = (data_in(lfsr_q >> 1))
```

```
If (lfsr_q[0]) lfsr_d = lfsr_d ^ Tap_polynomial
```

```
lfsr_q = lfsr_d
```

```
}
```

```
signature = lfsr_q
```

All MISRs are initialized at the beginning of each frame with a non-zero "seed" value either with the default constant value (0xFFFF\_FFFF) or with the programmable seed configuration value in SAFETY\_LFSR\_SEED register for each group of regions (refer to Table 12-564, *DISPC Internal Diagnostic Check Regions Parameters*). Note that a same seed must be used to compare signatures between two frames. If different than the default seed value is desired, then a SEEDSELECT parameter must be set before the corresponding SAFETY\_LFSR\_SEED register is configured with the customer seed value.

All captured signatures from the internal diagnostic regions are memory mapped to read-only SAFETY\_CAPT\_SIGNATURE registers for each video port (refer to Table 12-564, *DISPC Internal Diagnostic Check Regions Parameters*). A SAFETY\_CAPT\_SIGNATURE register is updated with the signature from each sub-region at the end of every frame. This register returns the signature of the last frame data when the MISR is enabled. When MISR is disabled, this register is cleared.

The MISR aliasing (faulty signature matches fault-free signature) probability is:

$$(2^{(L-n)} - 1) / (2^L - 1) \approx 2^{(L-n)} / 2^L = 2^{-n} \text{ for large } L, \text{ where}$$

$n$  = length of signature register

$L$  = length of input sequence

Using the above approximation, the result is:

n=4, aliasing probability = 6.25%

n=16, aliasing probability = 0.0015%

...

n=32 (as in DISPC MISR), aliasing probability is  $\sim 2^{-32}$  (negligible)

#### 12.6.4.11.10.3 Internal Diagnostic Checks

If the data correctness check is enabled (see [Table 12-564](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is compared against the reference signature provided by the software. A SAFETY\_REF\_SIGNATURE register must be configured with a reference signature data, see [Table 12-564](#), *DISPC Internal Diagnostic Check Regions Parameters*.
- If signatures do not match, an interrupt event is generated to indicate data mismatch.

If the freeze frame detection is enabled (see [Table 12-564](#), *DISPC Internal Diagnostic Check Regions Parameters*):

- When a new signature is generated, it is first compared against the saved signature (from previous frame).
  - There exists a capability within the frame freeze detection logic to skip alternate frames during comparison. This feature is useful while handling ping-pong buffers or interlaced input video. This feature is controlled via the [12-11] FRAMESKIP field within a SAFETY\_ATTRIBUTES register.
- If signatures match, an internal counter used to keep track of the number of frames with no data change (for the region) is incremented.
- If signatures do not match, the counter is cleared.
- If the counter value is greater than the user programmed freeze frame detection threshold value (see [Table 12-564](#), *DISPC Internal Diagnostic Check Regions Parameters*), an interrupt event (VIDSAFETYREGION\_IRQ or VPSAFETYREGION\_IRQ, see [Section 12.6.4.5](#), *DISPC Interrupt Requests*) is generated to indicate a possible freeze frame detection. The threshold value must be configured with the maximum number of identical successive frames allowed before an interrupt is generated.
- After the comparison, the signature is saved as the previous signature.
- The counter is cleared when the interrupt event is generated or when freeze frame detection check is disabled.

This frame freeze is different from the display getting frozen due to pipeline lock up. In that case, the DISPC will generate an SYNCLOST\_IRQ and/or DMA VIDBUFFERUNDERFLOW\_IRQ interrupt. The freeze frame detection is for source data getting frozen while the DSS is working normally.

The two internal diagnostic checks are continuously performed over multiple frames as long as their mode enable register bits are set.

#### 12.6.4.11.10.4 Internal Diagnostic Check Limitations

The internal diagnostic check is only be available when the DISPC is outputting RGB/YUV component data with separate sync signals. The internal diagnostic functions are not available for the following output modes:

- YUV422 embedded sync modes (BT.656 and BT.1120)
- RGB TDM (Time Division Multiplex) mode

#### 12.6.4.11.11 DISPC Security Management

##### 12.6.4.11.11.1 Security Implementation

DSS supports the following security features:

- Secure mode configuration
- Illegal connection prevention

#### Secure Mode

The DISPC supports secure mode configuration registers (DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE) which defines the "secure mode" attribute of each pipeline,

overlay manager, and video port instance in DISPC. These registers can only be modified by a host with an appropriate secure privilege (MReqSecure=1). When the SECURE bit corresponding to an instance is set by a secure host, the instance is deemed to be in "secure mode" and the DISPC hardware prevents the output of the instance getting connected to a non-secure downstream module. Also, any DMA transfer initiated by a secure pipeline will have its OCP in-band signal MReqSecure set to HIGH to indicate that is a secure mode transaction request.

By default, all pipelines, overlay managers, and video ports are in a "non-secure mode". The corresponding SECURE bits in the DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE registers are active, only when the DSS0\_COMMON\_DISPC\_SECURE\_DISABLE[0] SECURE\_DISABLE register bit is configured properly to 0x0. When the SECURE\_DISABLE bit is set to 0x1, the SECURE register bits are non-active and DISPC will behave as non-secure module.

### Illegal Connection Prevention

The DISPC hardware enforces the following rules to prevent an illegal connection:

- Secure input pipeline can only connect to a secure overlay manager: If any host (secure or non-secure) configures an overlay manager input selection to connect a secure input pipeline to a non-secure overlay manager, then the DISPC hardware will block the connection and issue a "security violation" interrupt (SECURITYVIOLATION\_IRQ) to alert the host.
- Non-Secure WB pipeline can take its input only from a non-secure input pipeline or a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data transfer through WB and issue a "security violation" interrupt to alert the host.
- Non-Secure video port can only display data from a non-secure overlay manager output. Otherwise, the DISPC hardware will block the data display on the video port and issue a "security violation" interrupt to alert the host.

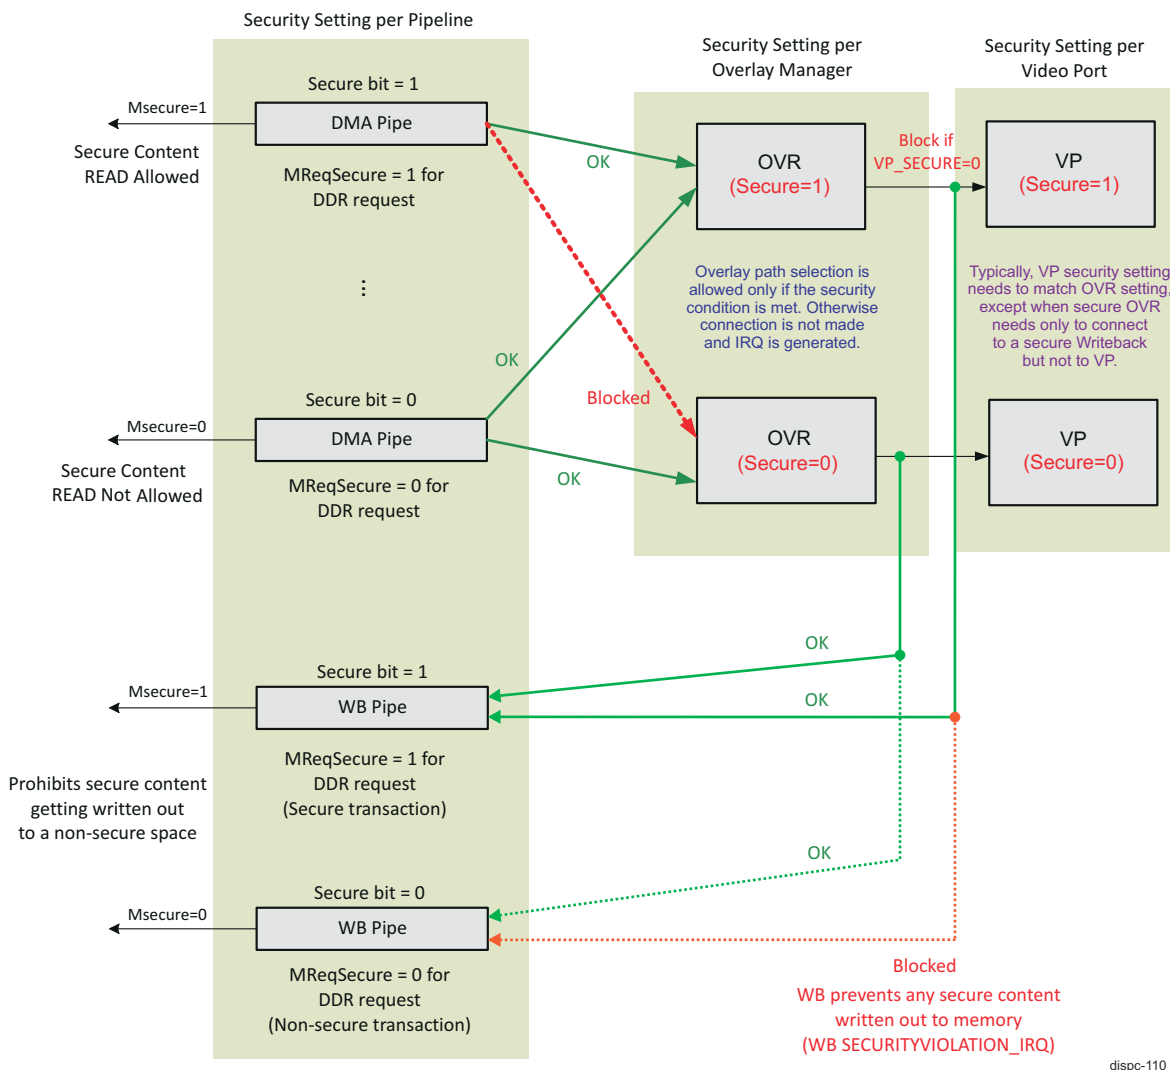

Figure 12-611. DISPC Secure Bit Setting and Illegal Connection Block

#### 12.6.4.11.11.2 Secure Mode Configuration

The SECURE bit in DSS0\_VID\_SECURE, DSS0\_WB\_SECURE, DSS0\_OVR\_SECURE and DSS0\_VP\_SECURE registers is set/reset by a secure transaction. When the SECURE bit has been set, the software in "secure mode" is responsible for checking the DISPC configuration. The SECURE bit is propagated by DISPC to the system Interconnect in order to qualify all DISPC requests as secure or non-secure requests, based on the secure bits defined in the control register.

When DISPC accesses the frame buffer, in the case the SECURE bit has been reset and the frame buffer has been set secure, the DISPC will receive an "error" in response of non-secure requests.

#### 12.6.4.11.12 DISPC Shadow Mechanism for Registers

Some DISPC registers are termed *shadow registers*. The shadow registers allow the software to modify them at any time, without direct effect on the DISPC hardware configuration. When all the values for a given configuration are written into the shadow registers, software must set only one register bit to validate the configuration. When the hardware reaches the end of the current frame and sees that the bit has been set by software, the new configuration is now the configuration used by the hardware.

The DSS0\_VP\_CONTROL[5] GOBIT bit enables the hardware to use the new configuration, for all shadow registers associated with each VP output.

The registers are statically associated to a particular output (for example, timing registers) or dynamically associated to one output at a time (for example, video registers).

#### 12.6.4.11.13 DISPC Registers

This section describes the DISPC registers.

##### 12.6.4.11.13.1 DSS\_COMMON Registers

Table 12-566 lists the memory-mapped registers for the DSS\_COMMON. All register offset addresses not listed in Table 12-566 should be considered as reserved locations and the register contents should not be modified.

DSS COMMON Registers

**Table 12-565. DSS\_COMMON Instances**

### 12.6.4.11.13.1.26 DSS0\_COMMON\_DISPC\_IRQ\_EOI\_FUNC Register (Offset = 80h) [reset = 0h]

DSS0\_COMMON\_DISPC\_IRQ\_EOI\_FUNC is shown in [Figure 12-637](#) and described in [Table 12-618](#).

Return to [Summary Table](#).

End-Of-Interrupt register for FUNC interrupts, to be used if pulse interrupts are used

The EOI register is used to re-trigger the pulse interrupt signal to ensure that any nested interrupt events are serviced. The software interrupt handler must write to the EOI register at the end of the current interrupt processing routine, so that new events can re-trigger the pulse interrupt signal again. For level interrupt signals the EOI register is not functional and must not be used.

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 12-664. DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	Reserved
24-20	WBTHREADSIZE	R/W	0h	Total DMA buffer size for all the pipelines connected to WB THREAD4.If the value programmed is n, then the allocated buffer size is 16KB*n. Default:0KB
19-15	VP3THREADSIZE	R/W	0h	Total DMA buffer size for all the pipelines connected to VP3 THREAD3.If the value programmed is n, then the allocated buffer size is 16KB*n. Default:0KB
14-10	VP2THREADSIZE	R/W	0h	Total DMA buffer size for all the pipelines connected to VP2 THREAD2.If the value programmed is n, then the allocated buffer size is 16KB*n. Default:0KB
9-5	VP1THREADSIZE	R/W	0h	Total DMA buffer size for all the pipelines connected to VP1 THREAD1.If the value programmed is n, then the allocated buffer size is 16KB*n. Default:0KB
4-0	VP0THREADSIZE	R/W	10h	Total DMA buffer size for all the pipelines connected to VP0 THREAD0.If the value programmed is n, then the allocated buffer size is 16KB*n. Default:256KB

### 12.6.4.11.13.1.50 DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESTATUS Register (Offset = F4h) [reset = 10h]

DSS0\_COMMON\_GLOBAL\_DMA\_THREADSIZESTATUS is shown in [Figure 12-661](#) and described in [Table 12-666](#).

Return to [Summary Table](#).

This register read the synchronized value of DMA buffer size allocated to the different threads - Shared memory feature

**Table 12-665.**

### 12.6.4.11.13.2 DSS\_VID Registers

Table 12-670 lists the memory-mapped registers for the DSS\_VID. All register offset addresses not listed in Table 12-670 should be considered as reserved locations and the register contents should not be modified.

VID and VIDL Registers

**Table 12-669. DSS\_VID Instances**

Instance	Base Address
DSS0_VIDL1	04A2 0000h
DSS0_VIDL2	04A3 0000h
DSS0_VID1	04A5 0000h
DSS0_VID2	04A6 0000h

### 12.6.4.11.13.2.1 DSS0\_VID\_ACCUH\_0 Register (Offset = 0h) [reset = 0h]

DSS0\_VID\_ACCUH\_0 is shown in [Figure 12-663](#) and described in [Table 12-672](#).

Return to [Summary Table](#).

The register configures the resize accumulator init values for horizontal up/down-sampling of the video window. DISPC\_VIDx\_ACCU\_\_0 & DISPC\_VIDx\_ACCU\_\_1 for ping-pong mechanism with external trigger, based on the field polarity. This register is used for ARGB and Y in YUV420/YUV422. Shadow register

### 12.6.4.11.13.2.3 DSS0\_VID\_ACCUH2\_0 Register (Offset = 8h) [reset = 0h]

DSS0\_VID\_ACCUH2\_0 is shown in [Figure 12-665](#) and described in [Table 12-676](#).

Return to [Summary Table](#).

The register configures the resize accumulator init value for horizontal up/down-sampling of the video window. DISPC\_VID n\_ACCU2\_\_0 & DISPC\_VID n\_ACCU2\_\_1 for ping-pong mechanism with external trigger, based on the field polarity. This register is used for U/V components in YUV420/YUV422. It is not used when the input format is any RGB format. Shadow register

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 12-688. DSS0\_VID\_ATTRIBUTES Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	LUMAKEYENABLE	R/W	0h	Enable Luma Key transparency matching 0h = Luma Key operation is disabled 1h = Luma Key operation is enabled
30	GAMMAINVERSION	R/W	0h	Inverse Gamma support [using the CLUT table] 0h = Gamma inversion is disabled 1h = Gamma inversion is enabled
29	GAMMAINVERSIONPOS	R/W	0h	Position of Inverse Gamma operation 0h = GAMMAINVERSION is before Scaler. Only Horizontal Resize is possible in this mode 1h = GAMMAINVERSION is after Scaler. No restrictions on resizing

**Table 12-688. DSS0\_VID\_ATTRIBUTES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
28	PREMULTIPLYALPHA	R/W	0h	The field configures the DISPC VID to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data  0h = Non premultiplied alpha data color component 1h = Premultiplied alpha data color component
27-25	RESERVED	R	0h	Reserved
24	SELFREFRESH	R/W	0h	Enables the self refresh of the video window, from its own DMA buffer only  0h = The video pipeline accesses the interconnect to fetch data from the system memory 1h = The video pipeline does not need any more to fetch data from memory. Only the DMA buffer associated with the video1 is used. It takes effect after the frame has been loaded in the DMA buffer
23	ARBITRATION	R/W	0h	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipelines. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there are only normal priority pipelines sending requests, the round-robin applies between the normal priority pipelines  0h = The video pipeline is one of the normal priority pipelines 1h = The video pipeline is one of the high priority pipelines
22	RESERVED	R	0h	Reserved
21	VERTICALTAPS	R/W	0h	Video Vertical Resize Tap Number. The vertical poly-phase filter can be configured in 3-tap or 5-tap configuration. According to the number of taps, the maximum input picture width is double while using 3-tap compared to 5-tap  0h = 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit-fields for the 2 other taps coefficients do not need to be initialized 1h = 5 taps are used for the vertical filtering logic
20	RESERVED	R	0h	Reserved
19	BUFPRELOAD	R/W	0h	Video DSS0_VID_PRELOAD Value  0h = H/W prefetches pixels up to the DSS0_VID_PRELOAD value defined in the DSS0_VID_PRELOAD register 1h = H/W prefetches pixels up to high threshold value
18	RESERVED	R	0h	Write 0's for future compatibility. Reads return 0

**Table 12-688. DSS0\_VID\_ATTRIBUTES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	SELFREFRESHAUTO	R/W	0h	Automatic self refresh mode  0h = The transition from SELFREFRESH disabled to enabled is controlled SW  1h = The transition from SELFREFRESH disabled to enabled is controlled only by HW
16-14	RESERVED	R	0h	Reserved
13	CROP	R/W	0h	Enables cropping operation at the output of Video Pipeline  0h = DSS0_VID_CROP feature is disabled  1h = DSS0_VID_CROP feature is enabled
12	FLIP	R/W	0h	Describes the frame buffer flip operation  0h = No Flip  1h = Frame Buffer is flipped
11	FULLRANGE	R/W	0h	Color Space Conversion full range setting  0h = Limited Range Selected  1h = Full Range Selected
10	NIBBLEMODE	R/W	0h	Video Nibble mode [only for 1-, 2- and 4-bpp]  0h = Nibble Mode Disabled  1h = Nibble Mode Enabled
9	COLORCONVENABLE	R/W	0h	Enable the color space conversion. The HW does not enable/disable the conversion based on the pixel format  0h = Color Space Conversion Disabled  1h = Color Space Conversion Enabled
8-7	RESIZEENABLE	R/W	0h	Video Resize Enable  0h = Disable both horizontal and vertical resizing  1h = Enable horizontal resizing  2h = Enable vertical resizing  3h = Enable both horizontal and vertical resizing

**Table 12-688. DSS0\_VID\_ATTRIBUTES Register Field Descriptions (continued)**

**Table 12-690. DSS0\_VID\_ATTRIBUTES2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	Reserved
30-26	TAGS	R/W	Fh	Number of OCP TAGS to be used for the pipeline [from 0x0 to 0xF]. A value of 0x0 means only a single tag will be used. A value of 0xF means all 16 tags can be used
25	MPORTSEL	R/W	0h	Master-Port Selection. By default, use primary master port only 0h = Use Primary Master Port 1h = Use Secondary Master Port
24-20	RESERVED	R	0h	Reserved
19-16	RESERVED	R/W	X	
15-11	RESERVED	R	0h	Reserved
10	YUV_ALIGN	R/W	0h	Alignment [MSB or LSB align] for unpacked 10b/12b YUV data 0h = lsb aligned - unused msb 1h = msb aligned - unused lsb

**Table 12-690. DSS0\_VID\_ATTRIBUTES2 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9	YUV_MODE	R/W	0h	<p>Mode of packing for YUV data [only for 10b/12b formats]</p> <p>0h = YUV 10-bit formats have the same component packing order as 8-bit formats except that the packing is done across a multiple 32-bit word with 2 MSB in each 32-bit word not used. YUV 12-bit formats have the same component packing order as 8-bit formats except that the packing is done across a multiple 64-bit word with 4 MSB in each 64-bit word not used</p> <p>1h = YUV 10-bit/12-bit unpacked formats have the same component packing order as 8-bit formats except that each component is stored in a 16-bit container - with MSB or LSB bits within the 16-bit container not used depending on the MSB/LSB alignment</p>
8-7	YUV_SIZE	R/W	0h	<p>DSS0_VID_SIZE of YUV data 8b/10b/12b</p> <p>0h = 8b per component-default</p> <p>1h = 10b per component</p> <p>2h = 12b per component</p>
6-4	VC1_RANGE_CBCR	R/W	0h	Defines the VC1 range value for the CbCr component from 0 to 7
3-1	VC1_RANGE_Y	R/W	0h	Defines the VC1 range value for the Y component from 0 to 7
0	VC1ENABLE	R/W	0h	<p>Enable/disable the VC1 range mapping processing.</p> <p>The bit-field is ignored if the format is not one of the supported YUV formats</p> <p>0h = VC1 range mapping disabled</p> <p>1h = VC1 range mapping enabled</p>

#### 12.6.4.11.13.2.11 DSS0\_VID\_BA\_0 Register (Offset = 28h) [reset = 0h]

DSS0\_VID\_BA\_0 is shown in [Figure 12-673](#) and described in [Table 12-692](#).

Return to [Summary Table](#).

The register configures the base address of the single video buffer. In case of single plane ARGB or YUV, this is the BA. In case of two plane YUV, this is the BA\_Y. In case of two plane RGB565-A8, this is the BA\_Alpha. BA\_\_0 & BA\_\_1 for ping-pong mechanism with external trigger, based on the field polarity otherwise only BA\_\_0 is used. Shadow register

**Table 12-691. DSS0\_VID\_BA\_0 Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0028h

### 12.6.4.11.13.2.73 DSS0\_VID\_FIR\_COEF\_H12\_C\_11 Register (Offset = 120h) [reset = 0h]

DSS0\_VID\_FIR\_COEF\_H12\_C\_11 is shown in [Figure 12-735](#) and described in [Table 12-816](#).

Return to [Summary Table](#).

The bank of registers configures the up/down-scaling coefficients for the horizontal resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

### 12.6.4.11.13.2.124 DSS0\_VID\_FIR\_COEF\_V12\_C\_12 Register (Offset = 1ECh) [reset = 0h]

DSS0\_VID\_FIR\_COEF\_V12\_C\_12 is shown in [Figure 12-786](#) and described in [Table 12-918](#).

Return to [Summary Table](#).

The bank of registers configures the up/down-scaling coefficients for the vertical resize of the video picture associated with the video window for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

DSS0\_VID\_BA\_UV\_EXT\_0 is shown in [Figure 12-799](#) and described in [Table 12-944](#).

Return to [Summary Table](#).

The register configures the 16-bit base address extension of the UV buffer for two plane YUV or the RGB buffer for two plane RGB565-A8. 0 & 1 : For ping-pong mechanism with external trigger, based on the field polarity. Shadow register

**Table 12-943. DSS0\_VID\_BA\_UV\_EXT\_0 Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0234h
DSS0_VIDL2	04A3 0234h

#### 12.6.4.11.13.2.140 DSS0\_VID\_ROW\_INC\_UV Register (Offset = 248h) [reset = 1h]

DSS0\_VID\_ROW\_INC\_UV is shown in [Figure 12-802](#) and described in [Table 12-950](#).

Return to [Summary Table](#).

The register configures the number of bytes to increment at the end of the row for the UV buffer associated with the video window for YUV420 formats. For non-YUV420 formats this register is unused. Shadow register

**Table 12-949. DSS0\_VID\_ROW\_INC\_UV Instances**

ROWINC																															
R/W-1h																															

LEGEND: R/W = Read/Write; -n = value after reset

**Table 12-950. DSS0\_VID\_ROW\_INC\_UV Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ROWINC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value [from $-2^{31}-1$ to $2^{31}$ ] to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid The value 1 means next pixel. The value $1+n* bpp$ means increment of n pixels. The value $1- [n+1]* bpp$ means decrement of n pixels

### 12.6.4.11.13.2.141 DSS0\_VID\_TILE Register (Offset = 24Ch) [reset = X]

DSS0\_VID\_TILE is shown in [Figure 12-803](#) and described in [Table 12-952](#).

Return to [Summary Table](#).

Defines the characteristics of the position of the first pixel inside the compressed frame buffer. In case of non-compressed frame buffer, the register is not used.

**Table 12-951. DSS0\_VID\_TILE Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 024Ch
DSS0_VIDL2	04A3 024Ch
DSS0_VID1	04A5 024Ch
DSS0_VID2	04A6 024Ch

**Figure 12-803. DSS0\_VID\_TILE Register**

RESERVED										TILEINDEX																					
R/W-X										R/W-0h																					

LEGEND: R/W = Read/Write; -n = value after reset

**Table 12-952. DSS0\_VID\_TILE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-23	RESERVED	R/W	X	
22-0	TILEINDEX	R/W	0h	Defines the DSS0_VID_TILE number for the first DSS0_VID_TILE of the frame buffer: -0 means that the first DSS0_VID_TILE is accessed otherwise some tiles are skipped to support cropping of the frame buffer

### 12.6.4.11.13.2.142 DSS0\_VID\_TILE2 Register (Offset = 250h) [reset = 0h]

DSS0\_VID\_TILE2 is shown in [Figure 12-804](#) and described in [Table 12-954](#).

Return to [Summary Table](#).

Defines the number of tiles in the frame buffer. In case of non-compressed frame buffer, the register is not used.

**Table 12-953. DSS0\_VID\_TILE2 Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0250h
DSS0_VIDL2	04A3 0250h

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	0h	Reserved
22-0	NUM_TILES	R/W	0h	Defines the total number of tiles in the compressed frame buffer

### 12.6.4.11.13.2.143 DSS0\_VID\_FBDC\_ATTRIBUTES Register (Offset = 254h) [reset = X]

DSS0\_VID\_FBDC\_ATTRIBUTES is shown in [Figure 12-805](#) and described in [Table 12-956](#).

Return to [Summary Table](#).

Defines the DSS0\_VID\_ATTRIBUTES for the compression engine -FBDC

**Table 12-955. DSS0\_VID\_FBDC\_ATTRIBUTES  
Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0254h

0	ENABLE	R/W	0h	Frame Buffer Compression is Enabled. Transactions shall use secondary master port

### 12.6.4.11.13.2.144 DSS0\_VID\_FBDC\_CLEAR\_COLOR Register (Offset = 258h) [reset = 0h]

DSS0\_VID\_FBDC\_CLEAR\_COLOR is shown in [Figure 12-806](#) and described in [Table 12-958](#).

Return to [Summary Table](#).

Defines the Clear Color value to be used for the channel in FBDC

**Table 12-957. DSS0\_VID\_FBDC\_CLEAR\_COLOR Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0258h

**Table 12-958. DSS0\_VID\_FBDC\_CLEAR\_COLOR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	CLEARCOLOR	R/W	0h	Defines the Clear Color value to be used for the channel in FBDC

### 12.6.4.11.13.2.145 DSS0\_VID\_CLUT\_0 Register (Offset = 260h) [reset = X]

DSS0\_VID\_CLUT\_0 is shown in [Figure 12-807](#) and described in [Table 12-960](#).

Return to [Summary Table](#).

The register configures the Color Look Up Table CLUT for VID pipeline. CLUT is used in conjunction with bitmap formats

**Table 12-959. DSS0\_VID\_CLUT\_0 Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 0260h

LEGEND: R = Read Only; R/W = Read/Write; -n = value after reset

**Table 12-992. DSS0\_VID\_SAFETY\_ATTRIBUTES Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	Reserved
12-11	FRAMESKIP	R/W	0h	Indicates which frames to be skipped while doing FRAMEFREEZE or DATACHECK [Useful for interlaced displays]. 0x 0: No frames are skipped, 0x 1: Even Frames are skipped starting from second frame after ENABLE, 0x 2: Odd Frames are skipped starting from first frame after ENABLE, 0x 3: Reserved  0h = No frames are skipped 1h = Even Frames are skipped starting from second frame after ENABLE 2h = Odd Frames are skipped starting from first frame after ENABLE 3h = Reserved

**Table 12-992. DSS0\_VID\_SAFETY\_ATTRIBUTES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10-3	THRESHOLD	R/W	0h	Allowed maximum number of frames with the same frame signature. When the freeze frame counter reaches 1 over this value [freeze_frame_thold+1], a freeze frame detection will occur. Note: The freeze frame counter is cleared on reset -OR- MISR not enabled -OR- terminal count reached -OR- compare == no match
2	SEEDSELECT	R/W	0h	Initial seed selection control  0h = Initial seed is always 0xFFFF_FFFF 1h = Initial seed is defined by SAFETY_LFSR_START.SEED
1	CAPTUREMODE	R/W	0h	Mode of operation of the safety check module  0h = Frame freeze detect enabled 1h = Data correctness check enabled
0	ENABLE	R/W	0h	Safety check Enable for the region. Note: Transition from 0 to 1 clears the signature register

### 12.6.4.11.13.2.162 DSS0\_VID\_SAFETY\_CAPT\_SIGNATURE Register (Offset = 2A4h) [reset = 0h]

DSS0\_VID\_SAFETY\_CAPT\_SIGNATURE is shown in [Figure 12-824](#) and described in [Table 12-994](#).

Return to [Summary Table](#).

The register captures the signature from the MISR of the safety sub-region. Shadow register

**Table 12-993.**

**DSS0\_VID\_SAFETY\_CAPT\_SIGNATURE Instances**

Instance	Physical Address
DSS0_VIDL1	04A2 02A4h

#### 12.6.4.11.3.4.1 DSS0\_VP\_CONFIG Register (Offset = 0h) [reset = 0h]

DSS0\_VP\_CONFIG is shown in [Figure 12-853](#) and described in [Table 12-1056](#).

Return to [Summary Table](#).

The DSS0\_VP\_CONTROL register configures the Display Controller module for the VP output. Shadow register.

Bit	Field	Type	Reset	Description
10-8	DATALINES	R/W	0h	Width of the data bus on VP output Shadow bit-field 0h = 12-bit output aligned on the LSB of the pixel data interface 1h = 16-bit output aligned on the LSB of the pixel data interface 2h = 18-bit output aligned on the LSB of the pixel data interface 3h = 24-bit output aligned on the LSB of the pixel data interface 4h = 30-bit output aligned on the LSB of the pixel data interface 5h = 36-bit output aligned on the LSB of the pixel data interface
7	STDITHERENABLE	R/W	0h	Spatial Temporal dithering enable for the VP output Shadow bit-field 0h = Spatial/Temporal dithering logic disabled 1h = Spatial/Temporal dithering logic enabled
6	DPIENABLE	R/W	1h	Enable the DPI output. wr:immediate 0h = DPI output disabled 1h = DPI output enabled
5	GOBIT	R/W	0h	GO Command for the VP output. It is used to synchronize the pipelines associated with the VP output wr:immediate 0h = The hardware has finished the synchronization 1h = Software has requested for synchronization after register updates and the hardware has not finished the synchronization
4	M8B	R/W	0h	Deprecated. Always write 0
3	STN	R/W	0h	Deprecated. Always write 0
2	MONOCOLOR	R/W	0h	Deprecated. Always write 0
1	VPPROGLINENUMBERMODULO	R/W	0h	Enable the modulo of the line number interrupt generation 0h = Disable modulo 1h = Enable Modulo
0	ENABLE	R/W	0h	Enable the video port output. wr:immediate 0h = LCD output disabled-at the end of the frame when the bit is reset 1h = LCD output enabled

### 12.6.4.11.13.4.3 DSS0\_VP\_CSC\_COEF0 Register (Offset = 8h) [reset = 0h]

DSS0\_VP\_CSC\_COEF0 is shown in [Figure 12-855](#) and described in [Table 12-1060](#).

Return to [Summary Table](#).

The register configures the color space conversion matrix coefficients. Shadow register

**Table 12-1059. DSS0\_VP\_CSC\_COEF0 Instances**

Instance	Physical Address
DSS0_VP1	04A8 0008h

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	Write 0's for future compatibility Reads return 0
18	ALIGN	R/W	0h	Defines the alignment between HSYNC and VSYNC assertion 0h = VSYNC and HSYNC are not aligned 1h = VSYNC and HSYNC assertions are aligned.
17	ONOFF	R/W	0h	HSYNC/VSYNC Pixel clock DSS0_VP_CONTROL On/Off 0h = HSYNC and VSYNC are driven on opposite edges of pixel clock than pixel data 1h = HSYNC and VSYNC are driven according to bit 16
16	RF	R/W	0h	Program HSYNC/VSYNC Rise or Fall 0h = HSYNC and VSYNC are driven on falling edge of pixel clock -if bit 17 set to 1 1h = HSYNC and VSYNC are driven on rising edge of pixel clock -if bit 17 set to 1

**Table 12-1074. DSS0\_VP\_POL\_FREQ Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
15	IEO	R/W	0h	Invert output enable 0h = DE is active high 1h = DE is active low
14	IPC	R/W	0h	Invert pixel clock 0h = Data is driven on the LCD data lines on the rising-edge of the pixel clock 1h = Data is driven on the LCD data lines on the falling-edge of the pixel clock
13	IHS	R/W	0h	Invert HSYNC 0h = Hsync pin is active high and inactive low 1h = Hsync pin is active low and inactive high
12	IVS	R/W	0h	Invert VSYNC 0h = Vsync pin is active high and inactive low 1h = Vsync pin is active low and inactive high
11-8	ACBI	R/W	0h	AC Bias Pin transitions per interrupt Value [from 0 to 15] used to specify the number of AC Bias pin transitions
7-0	ACB	R/W	0h	AC Bias Pin Frequency Value [from 0 to 255] used to specify the number of line clocks to count before transitioning the AC Bias pin. This pin is used to periodically invert the polarity of the power supply to prevent DC charge build-up within the display

#### 12.6.4.11.13.4.11 DSS0\_VP\_SIZE\_SCREEN Register (Offset = 50h) [reset = X]

DSS0\_VP\_SIZE\_SCREEN is shown in [Figure 12-863](#) and described in [Table 12-1076](#).

Return to [Summary Table](#).

The register configures the panel size horizontal and vertical. Shadow register. A delta value is used to indicate if the odd field has same vertical size as the even field or +/- one line.

**Table 12-1075. DSS0\_VP\_SIZE\_SCREEN Instances**

Instance	Physical Address
DSS0_VP1	04A8 0050h

Bit	Field	Type	Reset	Description
10-3	THRESHOLD	R/W	0h	Allowed maximum number of frames with the same frame signature When the freeze frame counter reaches 1 over this value [freeze_frame_thold+1], a freeze frame detection will occur Note: The freeze frame counter is cleared on reset -OR- MISR not enabled -OR- terminal count reached -OR- compare == no match
2	SEEDSELECT	R/W	0h	Initial seed selection DSS0_VP_CONTROL 0h = Initial seed is always 0xFFFF_FFFF 1h = Initial seed is defined by SAFETY_LFSR_START.SEED
1	CAPTUREMODE	R/W	0h	Mode of operation of the safety check module 0h = Frame freeze detect enabled 1h = Data correctness check enabled
0	ENABLE	R/W	0h	Safety check Enable for the region Note: Transition from 0 to 1 clears the signature register

#### 12.6.4.11.13.4.25 DSS0\_VP\_SAFETY\_ATTRIBUTES\_6 Register (Offset = 88h) [reset = 0h]

DSS0\_VP\_SAFETY\_ATTRIBUTES\_6 is shown in [Figure 12-877](#) and described in [Table 12-1104](#).

Return to [Summary Table](#).

The register configures the safety sub-region n. Shadow register

**Table 12-1103. DSS0\_VP\_SAFETY\_ATTRIBUTES\_6 Instances**

### 12.6.4.11.13.5.3 DSS0\_WB\_ACCUH2\_0 Register (Offset = 8h) [reset = 0h]

DSS0\_WB\_ACCUH2\_0 is shown in [Figure 12-931](#) and described in [Table 12-1214](#).

Return to [Summary Table](#).

The register configures the resize accumulator init value for horizontal up/down-sampling of the write-back window. It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB, all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter as the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

**Table 12-1226. DSS0\_WB\_ATTRIBUTES Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	IDLENUMBER	R/W	0h	Determines the number of idles between requests on the L3 interconnect. It is only used when the write-back pipeline does data transfer from memory to memory. When the output of an overlay is stored in memory through the write-back pipeline in capture mode, the bit-field IDLENUMBER is ignored since a timing generator is used to time the transfer The number of IDLE cycles is IDLENUMBER [from 0 to 15] if IDLESIZE=0 The number of IDLE cycles is IDLENUMBERx8 [from 0 to 120] if IDLESIZE=1
27	IDLESIZE	R/W	0h	Determines if the IDLENUMBER corresponds to a number of bursts or singles  0h = The number of idles between requests is defined by IDLENUMBER as number of cycles  1h = The number of idles between requests is defined by IDLENUMBERx8 as number of cycles

**Table 12-1226. DSS0\_WB\_ATTRIBUTES Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
26-24	CAPTUREMODE	R/W	0h	<p>Defines the frame rate capture</p> <p>0h = All frames are captures until the write-back channel is disabled or there is no more data generated by the overlay or the pipeline attached to the write-back channel</p> <p>1h = Only one frame is captured</p> <p>2h = Only one out of two frames is captured. The first one is captured then the second one is skipped and so on</p> <p>3h = Only one out of three frames is captured. The first one is captured then the second one is skipped and so on</p> <p>4h = Only one out of four frames is captured. The first one is captured then the second one is skipped and so on</p> <p>5h = Only one out of five frames is captured. The first one is captured then the second one is skipped and so on</p> <p>6h = Only one out of six frames is captured. The first one is captured then the second one is skipped and so on</p> <p>7h = Only one out of seven frames is captured. The first one is captured then the second one is skipped and so on</p>
23	ARBITRATION	R/W	0h	<p>Determines the priority of the write-back pipeline.</p> <p>The write-back pipeline is one of the high priority pipelines. The arbitration gives always the priority first to the high priority pipelines using round-robin between them When there are only normal priority pipelines sending requests, the round-robin applies between them</p> <p>0h = The write-back pipeline is one of the normal priority pipelines.</p> <p>1h = The write-back pipeline is one of the high priority pipelines.</p>
22	RESERVED	R	0h	Reserved
21	VERTICALTAPS	R/W	0h	<p>Video Vertical Resize Tap Number</p> <p>0h = 3 taps are used for the vertical filtering logic. The 2 other taps are not used.</p> <p>1h = 5 taps are used for the vertical filtering logic.</p>
20	GOBIT	R/W	0h	<p>GO Command for the WB output.</p> <p>It is used to synchronize the pipelines associated with the WB output wr:immediate</p> <p>0h = The hardware has finished updating the internal shadow registers of the pipeline</p> <p>1h = The user has finished to program the shadow registers of the pipeline</p>
19	WRITEBACKMODE	R/W	0h	<p>When connected to the overlay output of a channel the write back can operate as a simple transfer from memory to memory [composition engine] or as a capture channel</p> <p>0h = Capture mode</p> <p>1h = Memory to memory mode</p>

31-0	BA	R/W	0h	Write-back base address Base address of the WB buffer [aligned on pixel DSS0_WB_SIZE boundary except in case of RGB24 packed format, where 4-pixel alignment is required. In case of YUV422, 2-pixel alignment is required, and YUV420, byte alignment is supported]] In case of YUV 4:2:0 format, it indicates the base address of the Y buffer

#### 12.6.4.11.13.5.13 DSS0\_WB\_BA\_UV\_0 Register (Offset = 30h) [reset = 0h]

DSS0\_WB\_BA\_UV\_0 is shown in [Figure 12-941](#) and described in [Table 12-1234](#).

Return to [Summary Table](#).

The register configures the base address of the UV buffer for the write-back pipeline. DISPC\_WB\_BA\_UV\_\_0 & DISPC\_WB\_BA\_UV\_\_1 for ping-pong mechanism with external trigger, based on the field polarity, otherwise only DISPC\_WB\_BA\_UV\_\_0 is used. The register is also used to configure the RGB plane BA for RGB565A8 format. Shadow register

31-0	BA	R/W	0h	WB base address aligned on 16-bit boundary. Base address of the UV WB buffer

#### 12.6.4.11.13.5.15 DSS0\_WB\_BUF\_SIZE\_STATUS Register (Offset = 38h) [reset = 1000h]

DSS0\_WB\_BUF\_SIZE\_STATUS is shown in [Figure 12-943](#) and described in [Table 12-1238](#).

Return to [Summary Table](#).

The register defines the DMA buffer DSS0\_WB\_SIZE for the write back pipeline

**Table 12-1237. DSS0\_WB\_BUF\_SIZE\_STATUS  
Instances**

Instance	Physical Address
DSS0_WB	04AF 0038h

The bank of registers configures the up/down-scaling coefficients for the horizontal resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

### 12.6.4.11.13.5.66 DSS0\_WB\_FIR\_COEF\_H12\_C\_4 Register (Offset = 104h) [reset = 0h]

DSS0\_WB\_FIR\_COEF\_H12\_C\_4 is shown in [Figure 12-994](#) and described in [Table 12-1340](#).

Return to [Summary Table](#).

The bank of registers configures the up/down-scaling coefficients for the horizontal resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

### 12.6.4.11.13.5.77 DSS0\_WB\_FIR\_COEF\_H12\_C\_15 Register (Offset = 130h) [reset = 0h]

DSS0\_WB\_FIR\_COEF\_H12\_C\_15 is shown in [Figure 12-1005](#) and described in [Table 12-1362](#).

Return to [Summary Table](#).

The bank of registers configures the up/down-scaling coefficients for the horizontal resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

#### 12.6.4.11.13.5.91 DSS0\_WB\_FIR\_COEF\_V0\_C\_4 Register (Offset = 168h) [reset = 0h]

DSS0\_WB\_FIR\_COEF\_V0\_C\_4 is shown in [Figure 12-1019](#) and described in [Table 12-1390](#).

Return to [Summary Table](#).

The bank of registers configures the down/up/down-scaling coefficients for the vertical resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter. If the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

29-20	FIRVC2	R/W	0h	Signed coefficient C2 for the vertical up/down-scaling with the phase n
19-10	FIRVC1	R/W	0h	Signed coefficient C1 for the vertical up/down-scaling with the phase n
9-0	RESERVED	R	0h	Reserved

### 12.6.4.11.13.5.117 DSS0\_WB\_FIR\_COEF\_V12\_C\_5 Register (Offset = 1D0h) [reset = 0h]

DSS0\_WB\_FIR\_COEF\_V12\_C\_5 is shown in [Figure 12-1045](#) and described in [Table 12-1442](#).

Return to [Summary Table](#).

The bank of registers configures the down/up/down-scaling coefficients for the vertical resize of the video picture associated with the write back pipeline for the phases from 0 to 15. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter. When the register is not used by the HW, any value can be used for the bit-fields. Shadow register

#### 12.6.4.11.13.5.129 DSS0\_WB\_PICTURE\_SIZE Register (Offset = 208h) [reset = X]

DSS0\_WB\_PICTURE\_SIZE is shown in [Figure 12-1057](#) and described in [Table 12-1466](#).

Return to [Summary Table](#).

The register configures the DSS0\_WB\_SIZE of the write-back picture associated with the write back pipeline after up/down-scaling DSS0\_WB\_SIZE of the image stored in DDR memory, generated by WB pipe. Shadow register

**Table 12-1465. DSS0\_WB\_PICTURE\_SIZE Instances**

Instance	Physical Address
DSS0_WB	04AF 0208h

13-0	MEMSIZEX	R/W	0h	Number of pixels of the wb picture in memory Encoded value [from 1 to 16384] to specify the number of pixels of the picture stored in memory [program to value minus one]

### 12.6.4.11.13.5.130 DSS0\_WB\_SIZE Register (Offset = 210h) [reset = X]

DSS0\_WB\_SIZE is shown in [Figure 12-1058](#) and described in [Table 12-1468](#).

Return to [Summary Table](#).

The register configures the DSS0\_WB\_SIZE of the output of overlay connected to the write-back pipeline when the overlay output is only used by the write-back pipeline. When the overlay is output on the primary LCD or secondary LCD or TV outputs, the DSS0\_WB\_SIZE of the frame is defined in the DISPC\_SIZE\_LCD1, DISPC\_SIZE\_LCD2, and DISPC\_SIZE\_TV respectively. Shadow register.

**Table 12-1467. DSS0\_WB\_SIZE Instances**

## 12.6.5 MIPI Display Serial Interface (DSI) Controller

### 12.6.5.1 DSI Block Diagram

The MIPI DSI v1.3.1 Transmitter Controller (DSITX) provides an interface that receives data and control from the host processor display system using either the DPI or SDI input bus interfaces. The DSITX will translate the incoming pixel information and control signals into an internal packed byte format, in the case of DPI, or pass in the prepacked SDI byte format, before the internal byte format data is packetized and sent to the MIPI DSI Compatible display via the MIPI D-PHY physical interface. It supports video and command mode displays and can work in multi-display mode using virtual channel identification on the packets.

The DSITX controller provides two interfaces for connection to a display panel. Normal operation for a panel supporting DCS commands can be done using either SDI interface, or using the APB (Advanced Peripheral Bus) access to DIRECT\_CMD registers. Video streaming applications can only use the SDI or DPI interface. The DSI controller supports flow control using the SDI video interface.

The DSITX implements the stream arbitration and low-level protocol layer functionalities required by MIPI DSI specification v1.3. It supports up to 4 x 2.5 Gbps D-PHY data lanes in a single-link configuration and handles the byte lane mapping per use case (1, 2, 3, or 4-lanes).

The DSITX controller block diagram is illustrated in [Figure 12-1068](#).

Figure 12-1068. DSITX Controller Block Architecture

### 12.6.5.2 DSI Clocking

The DSI receives all the clocks from DISPC or DPHY\_TX modules. There are no other dedicated PLLs. For more details on DSI clocks mapping at DSS and SoC level, see *DSI Integration*.

The DSI requires multiple clocks running asynchronously, that are shown in [Table 12-1487](#).

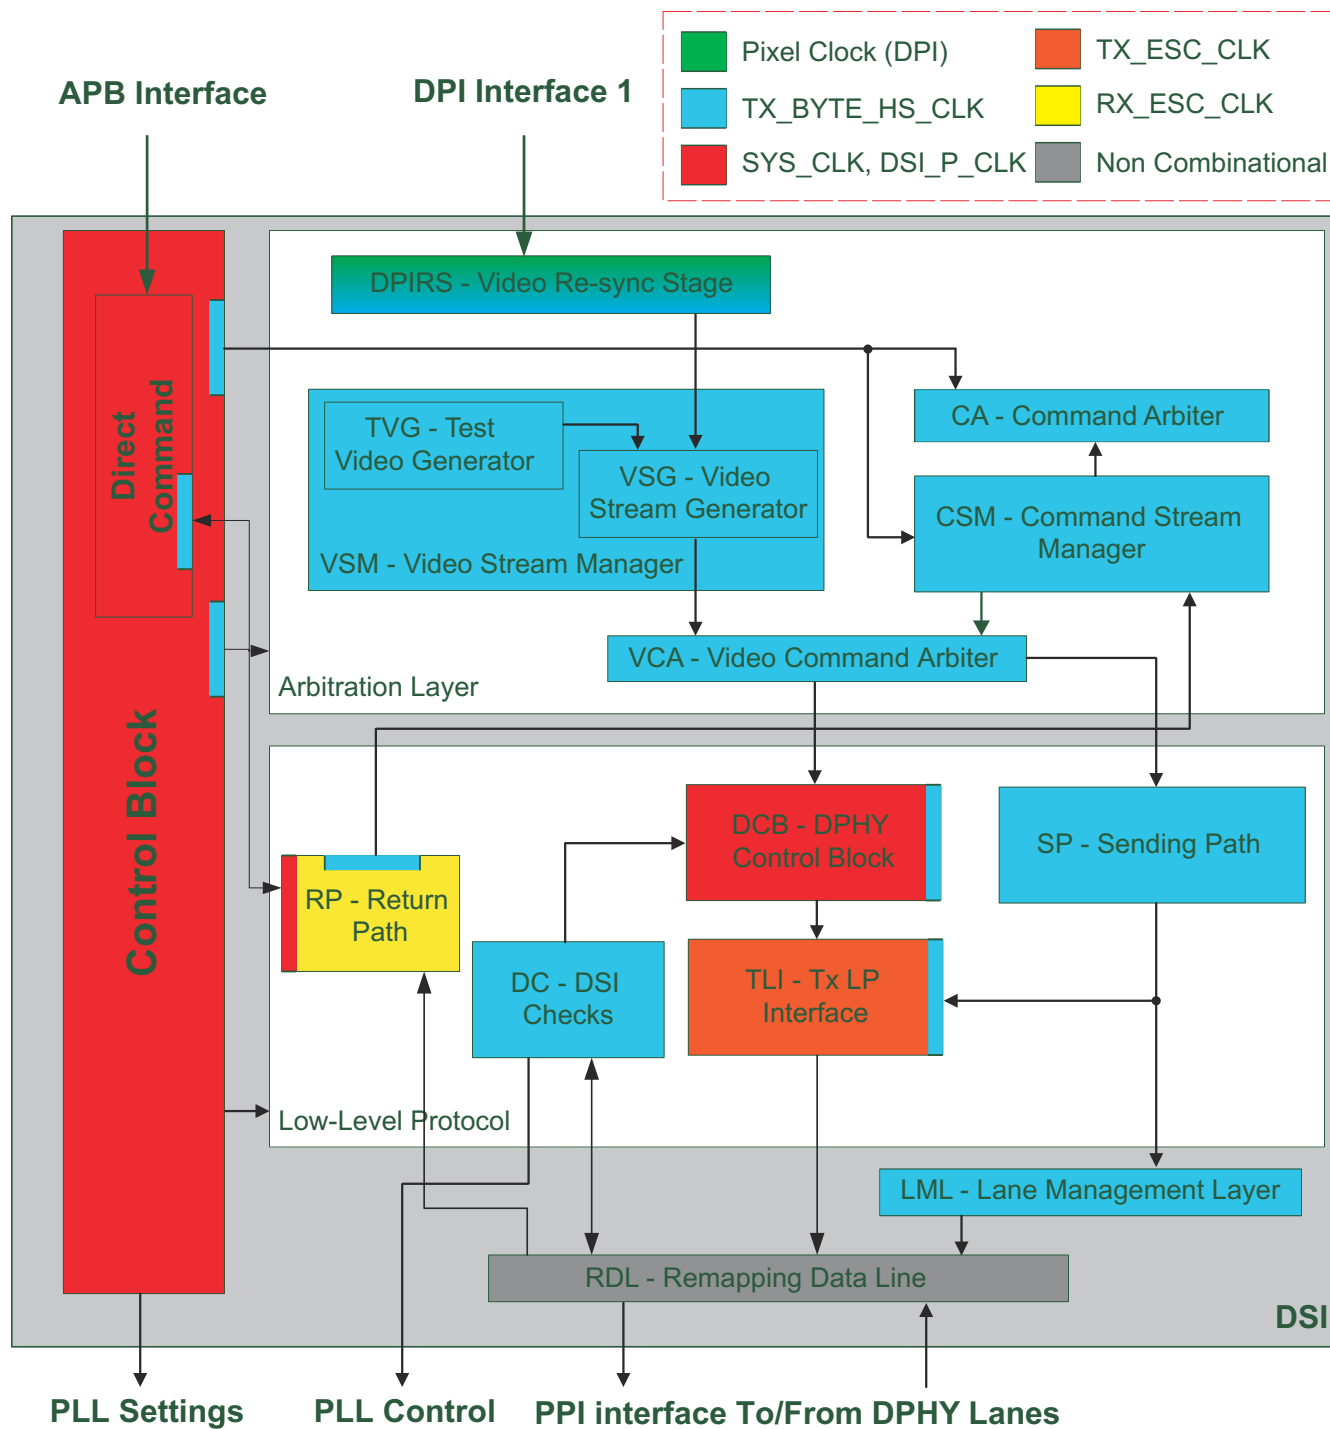

Table 12-1487. DSI Clocking

Clock	Direction	Min	Max	Constraints	Description
dpi_0_clk (Async to all other clocks)	Input	7 MHz	425 MHz	$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_hs\_clk}} \times \text{active\_lanes} \times 8 / (\text{bits\_per\_pixel})$	Used for DPI interface only. Frequency range depends on expected data rate with respect of number of data lanes, data lane frequency and frame rate

**Table 12-1487. DSI Clocking (continued)**

Clock	Direction	Min	Max	Constraints	Description
sys_clk (Async to all other clocks)	Input	7 MHz	250 MHz	1. Cannot be slower than $\text{tx\_byte\_hs\_clk} \times \text{datapath\_size} / \text{if\_datasize}$ (risk of underrun) in SDI mode. 2. Must be greater than: $\text{rx\_esc\_clk} \times 8$ . 3. Speed should be sufficient to provide enough data in SDI operation. 4. Must be faster than the $\text{tx\_byte\_hs\_clk}$ for Direct command operation.	Main functional clock Also used for the VBUS/APB interface
dphy_0_tx_byte_hs_clk (Async to all other clocks)	Input	10 MHz	312.5 MHz	The max value in SDI interface operation depends on sys_clk: can't exceed sys_clk freq x if_datasize datapath_size Otherwise 312.5 MHz to match the 2.5Gbps limit on DPHY v1.3 specification	DPHY PPI Byte Clock Frequency set by the DPHY and its High Speed input clock ( $\text{tx\_byte\_hs\_clk} = \text{dphy bit rate} / 8$ ) Maximum limit due to risk of underrun
dphy_0_tx_esc_clk (Async to all other clocks)	Input	1 MHz	20 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 20 MHz	TX Escape Clock
dphy_0_rx_esc_clk (Async to all other clocks)	Input	1 MHz	10 MHz	No minimum limit is given by the DSI itself - while regular function mode max limit is 10 MHz	RX Escape Clock

Figure 12-1069 describes the clock scheme and domains of the DSI\_TX.

dsi\_spruij7-057

Figure 12-1069. DSITX Clock Scheme and Domains

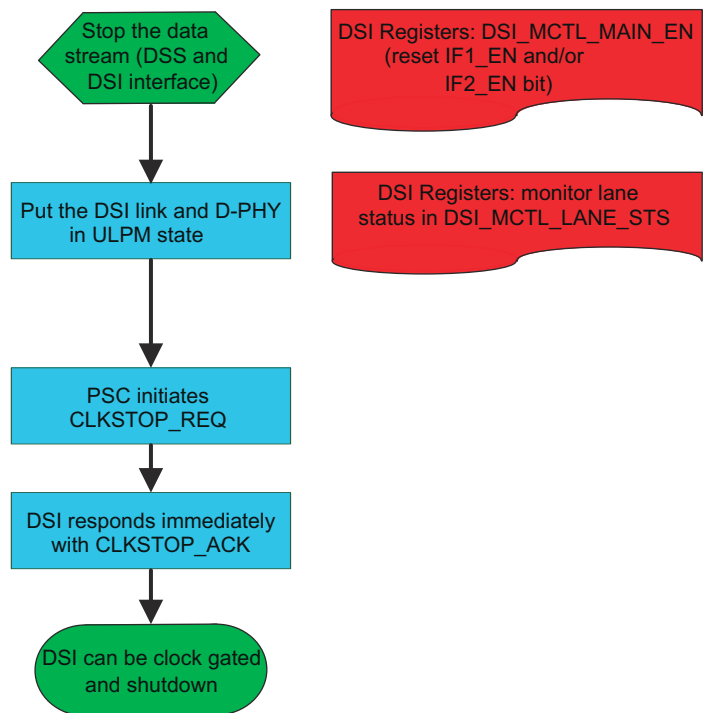

### 12.6.5.3 DSI Reset

The DSI has one active low reset input. The entire internal logic is reset by this reset. Internal resets (synchronous and asynchronous) for different clock domains are generated internally (synchronized to the respective clock domain).

### 12.6.5.4 DSI Power Management

The DSI implements a power management protocol to interface to a PSC (Power and Sleep Controller) module SoC level.

Figure 12-1070 shows the expected sequence from SW while performing a *clkstop\_req* to the DSI.

ds\_i\_spruij7-058

**Figure 12-1070. DSI Clock Gate / Power Off Procedure**

### 12.6.5.5 DSI Interrupts

Table 12-1488 shows the interrupts that are generated by the DSI module.

**Table 12-1488. DSI Interrupts**

Interrupt (n = 0)	Description	Source Module	Source Signal Name
dsi_#n_func_intr	DSI-#n Func Interrupt	DSI Controller	dsi_irq_n
dsi_#n_safety_error_fatal_intr	DSI #n Internal Diagnostic Fatal interrupt	DSI Controller	asf_int_fatal
dsi_#n_safety_error_nonfatal_intr	DSI #n Internal Diagnostic Non-fatal interrupt	DSI Controller	asf_int_nonfatal
ecc_intr_uncorr_level_sys_intr	ECC aggr uncorrectable error	-	-

### 12.6.5.6 DSI Internal Interfaces

#### 12.6.5.6.1 Video Input Interfaces

DSITX supports following video streaming interfaces:

- DPI (Uncompressed video stream)
- SDI (Serial Display Interface)

The DSI does not require DSI sub-link support. Therefore, only one video mode source is supported.

### 12.6.5.6.3 SDI (Serial Data Interface)

DSITX uses a SDI interface (32-bit) to receive active video data from an internal frame memory using a DMA or other data pull mechanism. The interface uses req/ready handshake signaling to control the data flow.

The DSITX SDI Interface supports one of the following modes:

- Command-only

SDI-DSI Interface requires following signals:

- dsi\_if\_valid
- dsi\_if\_stall
- dsi\_if\_start (Line Start)
- dsi\_if\_frame\_sync (frame\_sync)
- dsi\_if\_data

The SDI interface of DSI\_TX receives data directly from DSS VP output and is functional when the user configures the DSS to operate in COMMAND\_STALLMODE (DSS0\_VP\_CONTROL[11] STALLMODE = '1' and DSS0\_VP\_CONTROL[12] STALLMODETYPE = '0').

#### 12.6.5.6.3.1 Secure Display Support

Only secure peripherals can be connected to a secure DPI (VP) output of DSS. In order to support this requirement, the DSS exports a secure qualifier to the DSI\_TX. Inside the DSI a SECURE register is implemented (DSI\_WRAP\_DPI\_SECURE), which contains SECURE bits, [0] DPI\_0\_SECURE and [1] DPI\_0\_SECURE\_VIOLATION, corresponding to the DPI port. These SECURE bits can only be set or reset by a secure host (vbusp transactions with secure qualifier set).

The behavior of DSI module for different settings of SECURE register bit and SECURE qualifier from DSS is as shown below:

**Table 12-1490. Secure Display Support**

SECURE Register Bit (DSI)	SECURE mqualifier (DSS)	Security Violation Status	Comments
0	0	0	Data is passed (non-secure DSS data through non-secure DSI)
1	0	0	Data is passed (non-secure DSS data through secure DSI)
1	1	0	Data is passed (secure DSS data through secure DSI)
0	1	1	<b>Security Violation.</b> Data is blocked (secure DSS data through non-secure DSI)

Once a security violation is detected, it is captured in the DSI\_WRAP\_DPI\_SECURE[1] DPI\_0\_SECURE\_VIOLATION register status bit.

### 12.6.5.7 DSI Programming Guide

This section describes the programming guidelines for the DSI Controller and D-PHY.

The goal of this section is to present more in detail how the DSI link should be used at application level plus some scenarios of use of the DSI link (start-up, display switch on/off, dual-display).

#### 12.6.5.7.1 Application Guidelines

The purpose of this section is to provide guidelines on how to drive the DSI host controller, provide general sequence of operations and some typical application notes.

### 12.6.5.7.1.1 Overview of a Display Subsystem

Figure 12-1072 shows an overview of a display subsystem. It covers the point to point interfaces between the DPI/SDI and DSI blocks. Other blocks and interfaces are included to give a better understanding of the environment for this interface.

A DSI interface is made up from one DSI controller and one D-PHY block. D-PHY is the physical layer of the DSI interface. The DSI block handles protocol. The DSI interfaces support displays that comply with the MIPI DSI standard.

The displays can be of either command mode type or video mode type. Command mode displays have a frame memory that can hold the entire image. The display is refreshed from this memory and only changes of the display content are sent over the display interface. Video mode displays do not have this memory and thus all data for every refresh must be transferred in real time.

The SDI block can support one display in command mode. By using command mode displays and rerouting of connections, between display updates, more than two displays can be connected and active.

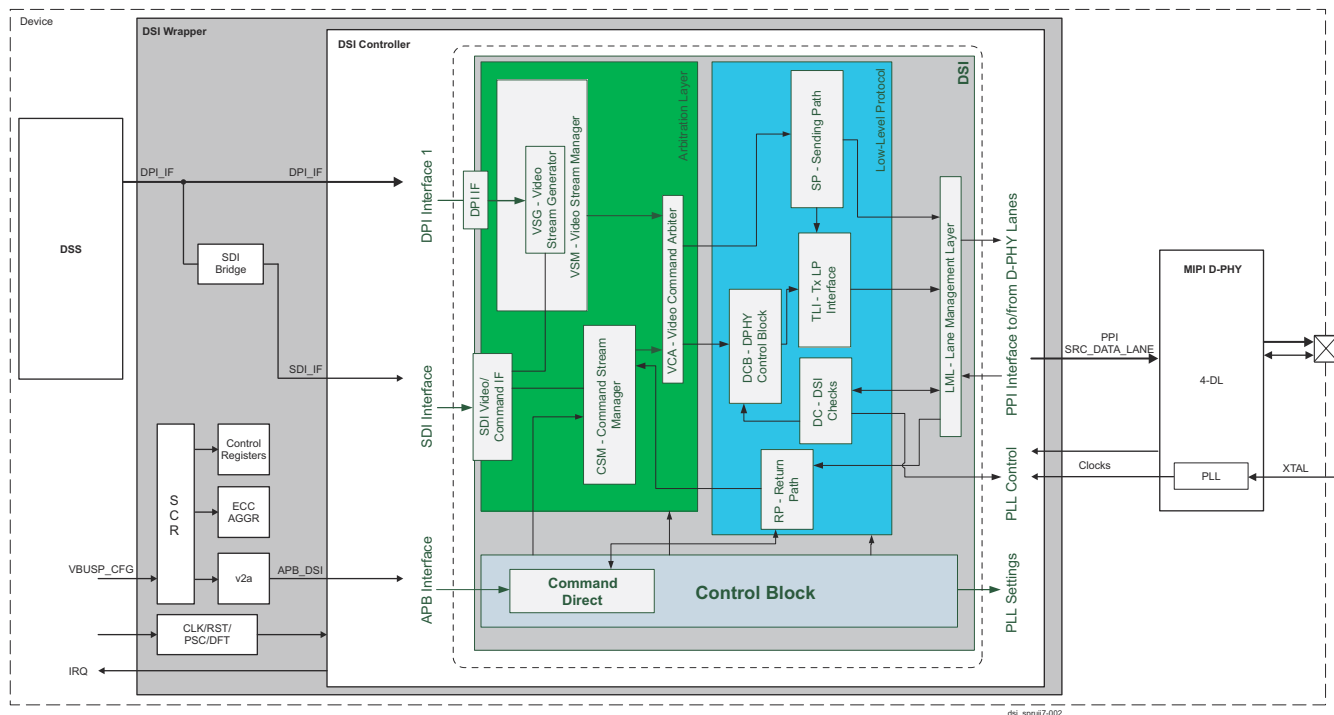

Figure 12-1072. Example Display Subsystem Showing Controller and PHY Blocks

#### 12.6.5.7.1.2 D-PHY And DSI Configuration

The DPHY and DSI controller must be configured before any panel video display can be used. All accesses to the DPHY to configure it for use with the DSI Controller should be performed through the DPHY own APB interface .

#### 12.6.5.7.1.3 DSI Controller Initialization

The DSI controller will always require the DPHY and data path configuration to be set after power up and any hard reset. The minimum sequence should define the data path lane configuration; mappings, available lanes, DPHY power, resets and lane swap. All these register values should be set before the DSI controller is enabled for functional operation.

The DSI registers are accessed through the APB interface. The programming sequence for command, video and controller configuration must follow a sequence of accesses to ensure the clock gate control updates the internal nodes before the link is enabled.

All DSI\_VID\_xxx registers must be programmed, if required, before the write to the DSI\_VID\_MAIN\_CTL register.

All DSI\_MCTL\_DPHY\_xxx registers must be programmed, if required, before the write to the DSI\_MCTL\_MAIN\_DATA\_CTL register to set the [0] LINK\_EN bit.

#### 12.6.5.7.1.4 Panel Configuration Using Command Mode

The DSI controller can provide DCS command access using either the SDI interface or through the APB interface control of the DIRECT COMMAND registers (see [Table 12-1491](#)). The panel registers will be programmed using the LP mode before the high-speed video is enabled. Commands can either be sent using the command interface or through the Command FIFO using the APB registers.

The command FIFO access is done through the APB Command mode registers by forming packets of DCS commands. The DCS commands can be found in the MIPI DCS specification or the display panel data sheet.

DCS commands are essentially register write or read transfers to panel registers. The initialization of a panel will require APB register writes to fill the FIFO with the DCS commands. The commands can be grouped into a long packet by sending the packet split into 4 bytes to fill the FIFO using a write to the DSI\_DIRECT\_CMD\_WRDAT register.

**Table 12-1491. DSI Direct Command Mode Registers**

DSI Register	Description
DSI_DIRECT_CMD_SEND	Direct Command - trigger the direct command sending - write only
DSI_DIRECT_CMD_MAIN_SETTINGS	Direct Command - main settings
DSI_DIRECT_CMD_STS	Direct Command - status - read only
DSI_DIRECT_CMD_RD_INIT	Direct Command - stop read operation
DSI_DIRECT_CMD_WRDAT	Direct Command - data to write byte 0 to 3
DSI_DIRECT_CMD_FIFO_RST	Direct Command- reset the write FIFO pointer

Each DCS command packet to be sent can be built by first selecting the packet configuration using the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS. The DCS Command data types are defined in the DSI specification based on the number of parameters that are expected to be sent. Configuration of a panel display will normally use DCS write data types.

[Table 12-1492](#) shows the DSI\_DIRECT\_CMD\_MAIN\_SETTINGS register bit description.

**Table 12-1492. DSI Main Settings Register Description**

DSI_DIRECT_CMD_MAIN_SETTINGS Register Bit	Description
[24] CMD_LP_EN	Enables LP sending for the command request.
[23:16] CMD_SIZE	Size of the command in case of write command - when written value is bigger than 0x10, the value is rounded to 0x10 for write - when size is bigger to 0x2 for read it is rounded to 0x2.
[15:14] CMD_ID	In case of read/write command, Virtual Channel of the command.
[13:8] CMD_HEAD	In case of read/write command, data type of the command:
	0x05 DCS Write 0 parameters Short Packet
	0x15 DCS Write 1 parameter Short packet
	0x39 DCS Long Write N parameters Long Packet
[3] CMD_LONGNOTSHORT	This bit must be tied to one.
[2:0] CMD_NAT	Nature of the direct command: 000: write command.

Once the packet is loaded, issue a DIRECT\_CMD\_SEND (via the DSI\_DIRECT\_CMD\_SEND register) and the data will be sent in LP mode.

#### 12.6.5.7.1.5 VIDEO Interface Configuration

The DSI video operation requires the configuration of the VSG and TVG registers to match the panel configuration. The two video interface options will also require careful selection of the clock and registers to achieve error free video streaming.

The DSITX controller supports the mechanism for initial skew calibration for D-PHY data rates greater than 1.5 Gbps.

#### DPI Video Interface Operation

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. If this is the case, then the blanking and active data periods must be matched up. The DSI controller will slave its frame timing to the incoming DPI **VSYNC**, if it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered.

The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So, programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

Program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

The timing should also be matched per line, therefore the blanking and active periods should match. DPI horizontal timing is measured in pixels, whereas the DSI controller uses bytes. If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure the FIFO depth and vsync\_delay is suitable.

The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. Additionally, the PPI short packets and packet headers that are inserted by the controller must be accounted for. HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and footer (4 + 2 bytes) and the HSE short packet (4 bytes). HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (6 bytes). HFP should be reduced by 6 bytes to account for the long packet header and footer. Finally, for lines with no active data, the BLKLINE\_PULSE\_PCK is the total size minus 20 bytes (14 for HSA, 6 for the remaining blanking which is all combined into a single packet).

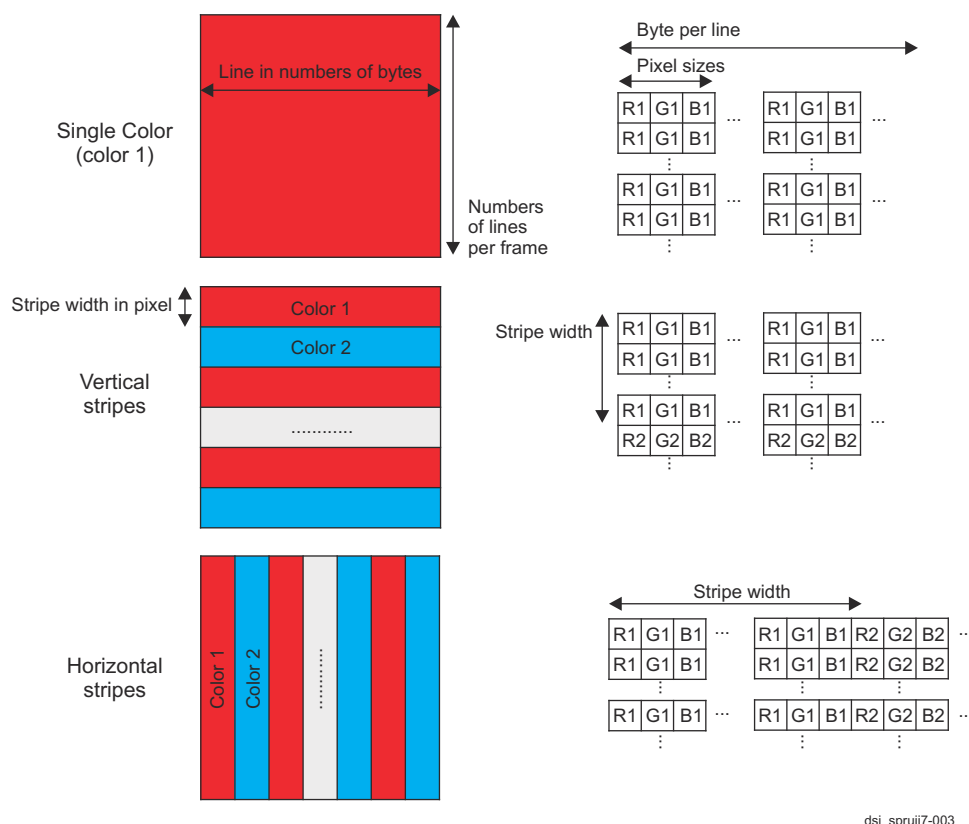

Program the DSI horizontal size registers as follows:

- HSA = (DPI\_HSA × bpp/8) - 14
- HBP = (DPI\_HBP × bpp/8) - 12
- HACT = (DPI\_HACT × bpp/8) NOTE: (DPI\_HACT × bpp/32) must be an integer.
- HFP = (DPI\_HFP × bpp/8) - 6
- BLKLINE\_PULSE\_PCK = ((DPI\_HSA + DPI\_HBP + DPI\_HACT + DPI\_HFP) × bpp/8) - 20;

#### TVG Generator

The TVG oversees generating dummy data (to display something even if there is no video stream running). It is also able to ease verification or validation of the DSI without having a complete environment (application or verification test bench). The controller has a Test Video Generator that can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-1073 presents TVG MODE patterns.

dsi\_sprui7-003

**Figure 12-1073. TVG MODE Patterns**

The TVG generates a data stream in the same format than the one specified for the normal functional video stream (as set in VSG register). The content of that flow is specified by registers. Those registers specify the following information: Image size: Number of bytes per line (see TVG\_LINE\_SIZE[14:0] register) and number of lines per frame (TVG\_NBLINE[12:0]).

Image kind: Single color, vertical stripes or horizontal stripes (see TVG\_MODE[1:0] register). Stripe width: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128 (see TVG\_STRIPE\_SIZE[2:0] register).

Pixel kind: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB (see VID\_PIXEL\_MODE[3:0] register).

Color one: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered (see COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers).

Color two: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered. (see COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers). Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

An example of the sequence is as follows:

- Select TVG for video stream generation instead of SDI 1 interface:
  - IF1\_EN bit to 0 (stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL:
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register:
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.

- Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
- Stripes size in TVG\_STRIPE\_SIZE field.
- Image size in TVG\_IMG\_SIZE register.

**Note:** The number of lines per frame and number of bytes per line. It is required that TVG settings on active area match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL:
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register. Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.6.5.7.2 Application Considerations

The following sections outline the normal operation of the DSITX controller and the programming and sequences require to operate the DSITX controller for normal video and command operation.

##### 12.6.5.7.2.1 D-PHY Timings Control

Several DPHY timing constraints must be respected by the system, which are described in this section. When a switch in ULP is requested, the application should be aware that the D-PHY needs 1 ms to leave this state (this timing is guaranteed by the DSI itself). It makes no sense to start an ULP request if the expected time in ULP is short.

When PLL power down is asserted, the system should continue to assert for a specific minimum period of time (PLL internal requirement – please refer to DPHY documentation). Please note that shutting down the PLL implies that no clock is present on tx\_byte\_hs\_clk input and thus the DSI link is stopped; even if the system-side interface clocks remain active, no more HS transfers can be done.

Force\_stop, ppi\_c\_force\_tx\_stop (clock lane) and ppi\_d\_force\_tx\_stop (1 per data lane), can be useful to resolve certain deadlock situations, for example: DSI slave does not give back control to master, or critical DPHY error. When a 'force stop mode' is issued by the application, the system should maintain this state on the bus to ensure the request is correctly considered by the D-PHY cells and the **stop\_state** is asserted and direction signal is deasserted.

reg\_wait\_burst\_time (for the LML) must be programmed to ensure that two HS bursts are separated by at least 100 ns. The value will be based on the period of the tx\_byte\_clk cycle.

VCA: When trying to interleave commands to video stream, it is assumed that only write/read commands and BTA request are sent (no TE). The reason is that such transfers are slow and difficult to predict in term of duration. They could take longer than the slots available for video. The read commands are unpredictable and may cause some break in the video stream, however, they can still be used, if an appropriate response time can be guaranteed. It is the responsibility of the system integrator and the application to plan and implement recovery procedures when the video stream is stalled due to a read that takes too long.

##### 12.6.5.7.2.2 Control Block

Most of the register contents must be resynchronized against a DSI internal clock (tx\_hs\_byte\_clk). This means there is a certain time to pass data from one clock domain to the other. If two writes in the same register are too close, the register itself is updated but the synchronization may fail.

The formula to calculate the number of system clock periods between two writes is:

$$\text{nb\_cycle}(\text{dsi\_p\_clk}) = 6 * (\text{f}_{\text{dsi\_p\_clk}} / \text{f}_{\text{tx\_byte\_hs\_clk}} + 1)$$

The application must respect a period of TX ns between two write accesses to the same register (there is no issue writing different registers back-to-back).

[Table 12-1493](#) shows an example of required time between two write accesses.

**Table 12-1493. Example of Required Time between Two Write Accesses**

$f_{\text{dsi\_p\_clk}}$	$f_{\text{tx\_byte\_hs\_clk}}$	TX minimum time between 2 writes accesses
200 MHz	106 MHz	~ 90 ns
160 MHz	10 MHz	~ 650 ns
200 MHz	10 MHz	~ 650 ns

Another place where asynchronous behaviour may interfere with programming in the CB is the direct command status register `DIRECT_CMD_STS`. Some of the bits of this register are set when a pulse (that lasts one clock period) coming from `tx_hs_byte_clk` domain is observed (after resynchronization on `dsi_p_clk`) and is reset when the clear bit is written. In use case where `tx_byte_hs_clk` is slow (10 MHz range), the bit can be read and a clear attempted before the end of the source pulse. This can result in the re-assertion of the bit immediately after it is cleared. For that reason, it is recommended to wait for a while between reading the bits of the `DIRECT_CMD_STS` register and clearing them.

### Application Issues

Some register fields cannot take all the possible values but are restricted to a certain number of combinations (mode control). The DSI controller does not check that all the fields match a valid setup so it is the responsibility of the system integrator and the application to check that the written values are amongst the permitted combinations. Amongst the register fields that fall in to this category are most of the mode settings (stop mode, recovery mode, direct command type, image sizes, etc.)

### Programming Coherency

The application level must ensure that the register configurations are valid for the system to operate correctly. There are several possible combinations are possible in the CB registers however should be avoided. A few examples:

- No HS transfer should be enabled when PLL is shut-off.
- TVG should not be run when the video interface is running.
- No access (from interface or from register) should be attempted while TBG is active.
- Prior to shut-down of the DPHY PLL, application should verify that the DSI link is in proper state. If the bit that enables BTA is not set and that any operation implying a BTA is sent, the system is stalled. Then the bit that enables BTA must be aligned with application needs. Moreover, read enable or TE enable cannot be set if `bta_en` is not set (these operations cannot be enabled when BTA is not enabled).
- TE feature must not be enabled in SDI interface.

#### 12.6.5.7.2.3 Video Coherency

In video mode, there are a lot of sizes defined for the video stream generation. This data corresponds to the payload of the various generated packets and not to their duration. However, they are closely linked. It is the responsibility of the system integrator and the application to use correct sizes to ensure the correct video timing and behaviour, because the system may use 1 to 4 active data lanes with a fixed number of bytes for the header/checksum overhead. In the same way, when programming D-PHY time (to switch from LP to HS), the application must consider D-PHY time plus overhead due to LLP and LML crossing time (see [Section 12.6.5.7.7.2, Video stream settings \(VSG\)](#)).

### VSG Control

Start and stop sequences can take a long time to be performed. If the requests are not maintained up to the time the status bit are indicating effective start or stop, they can be ignored and the VSG may not have started or stopped as expected by application. It is then up to the application to carefully manage the request and to verify that requests are being processed before changing the state of the VSG.

### Test Generator:

The DSITX provides test generator to provide a video data stream. When using TVG, all sources can be used (provided VCA permits it) however the SDI interface must not be programmed to send video data and must be restricted to command mode.

The pixel modes supported are: RGB 16-, 18-, 24-, 30- and 36-bit; YCbCr422 16-bit; and YCbCr420 12-bit (note that additional YCbCr422 20-bit and YCbCr420 24-bit may be supported using SDI interface, but are restricted to command mode only).

The supported display sizes are listed below:

- QQVGA (160 x 120) - 15/20/30/60 fps - RGB 16-18-24 (-30 and 36) bits per pixels
- QCIF (176x144), QCIF + (176x208 and 176x220) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QVGA (320x240) - 15/20/30/60 fps - RGB R16-18 and 24 bits per pixels
- CIF (352x288), CIF + (352x416 or 352x440) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- 1/2 VGA (320x480) and 2/3 VGA (640x320) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- VGA (640x480) - 15/20/30/60 fps - RGB 16-18-24(-30 and 36) bits per pixels
- WVGA (800x480 - 848x480 - 854x480 - 852x480) - RGB 15/20/30/60 fps - 16-18 and 24 bits per pixels
- SVGA (800x600) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- QHD (960x540) - 15/20/30/60 fps - RGB 16-18 and 24 bits per pixels
- XVGA (1024x768) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- Full HD (1920x1080) - 15/20/30/60 fps - 16-18 and 24 bits per pixels
- WUXGA(1920x1200) - 15/20/30/60/(120 fps – 16 bpp only) 16, 18 and 24 bits per pixels
- 4Kx4K(4096x4096) - 15/20/30 fps - 16-18 and 24 bits per pixels

### 12.6.5.7.3 Start-up Procedure

The start-up sequence described in [Figure 12-1074](#) assumes that the rest of the chip is ready (all clocks are present except tx\_byte\_hs\_clk, application it is ready...) and that the DSI is ready (reset de-asserted).

The following is the most common start up sequence:

Firstly, application layer programs and enables the PLL, then waits for a period for the PLL to lock (minimum time will be defined by the PHY documentation). At the end of the minimum wait period, the application layer should poll the PLL lock status register periodically to confirm lock status, repeating until confirmed. At the end of this step, it is assumed that a clock is present on the tx\_byte\_hs\_clk input (this step may be replaced by an interrupt-based alternative if available from the selected DPHY or provided in the system integration logic).

During the time taken by the PLL to lock, the application can program the configuration registers and prepare the DSI link. This can also be done after the PLL is locked. It should at least configure enough to be able to use LP mode to send direct commands.

Enable clock and data lane(s) per the needs. This action is only concerned with programming registers that control the D-PHY lane enable signal. The active lane configuration with the DSI\_MCTL\_MAIN\_PHY\_CTL and DSI\_MCTL\_MAIN\_EN registers must be programmed to match, i.e. for two data lanes (0 and 1).

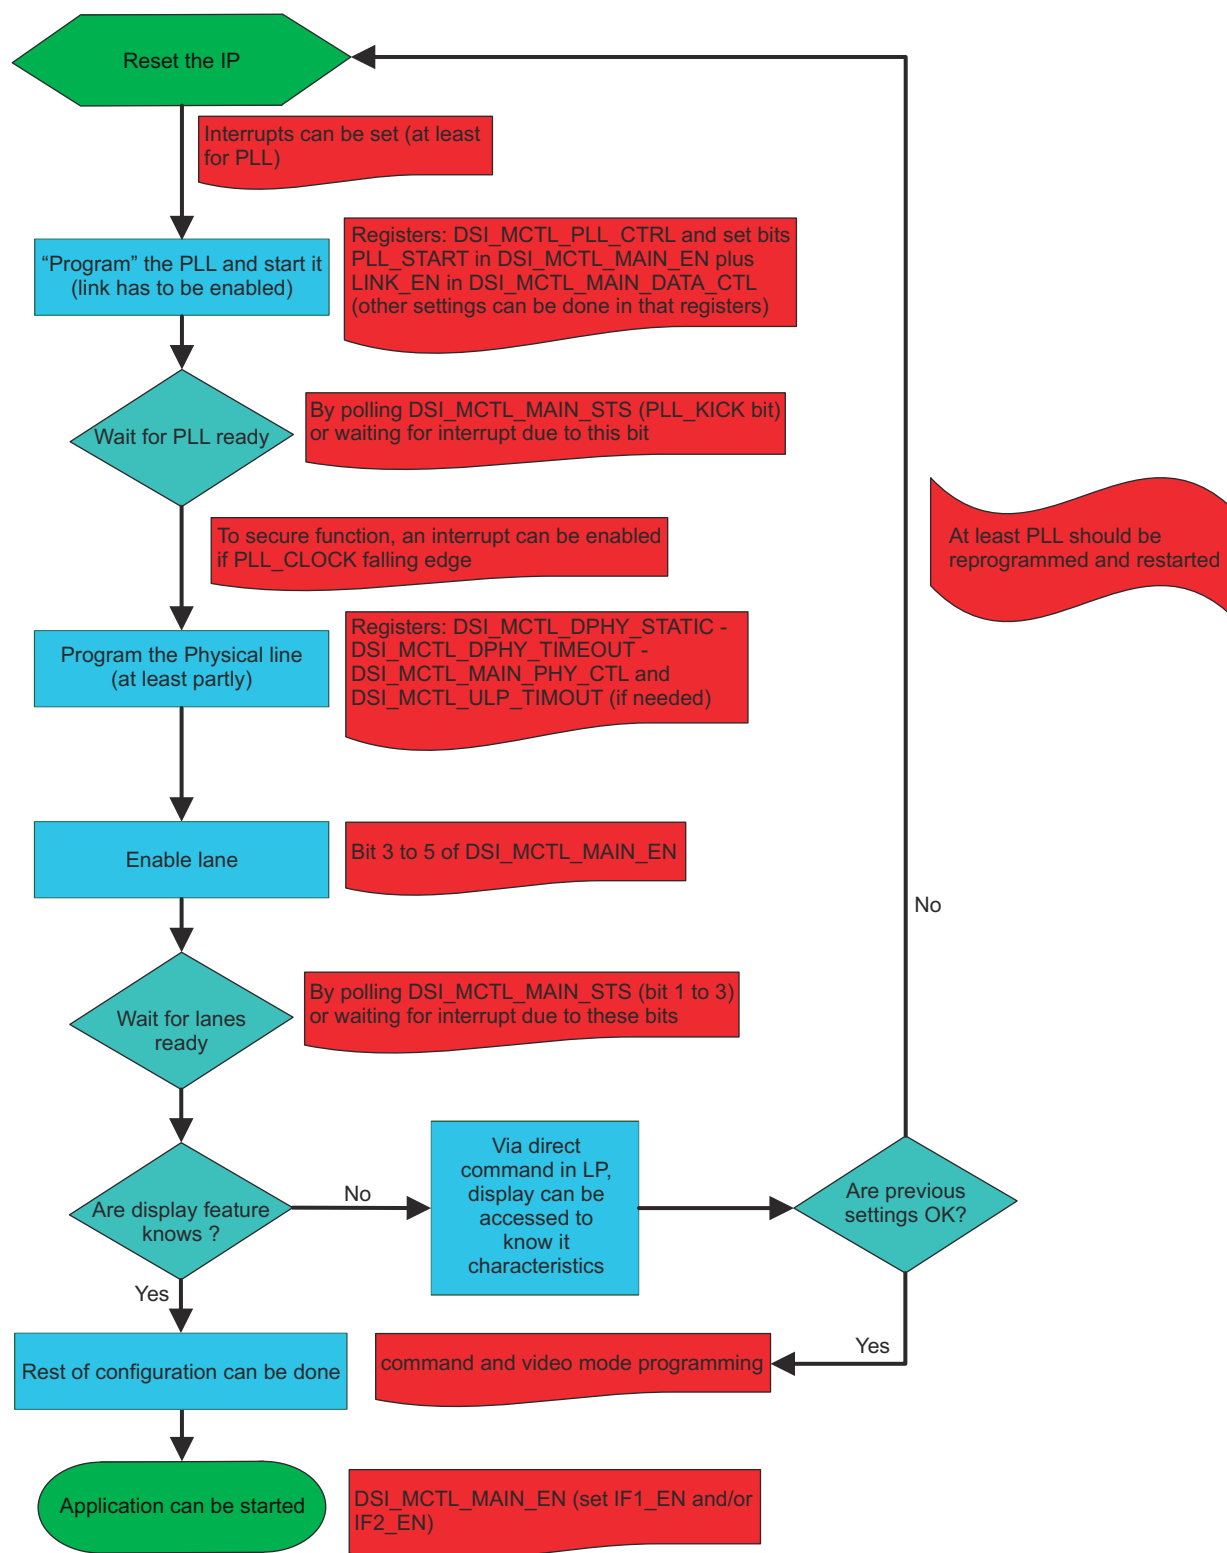

- DSI\_MCTL\_MAIN\_PHY\_CTL (0x08) register – LANE3/4\_EN - bits[2:1] set to zero to disable lanes 2/3.
- DSI\_MCTL\_MAIN\_EN (0x24) register – DAT3/4\_EN fields - bits[6:5] set to zero to disable lanes 2/3.

Start the lane in the DCB. The DCB state machine puts the lanes in the correct state to be ready.

At this step, the DSI link should be able to access to display - at least in LP mode. If the system (DSI link and display) is fully programmed, code to display image can be started. If display characteristics must be read from the display and the system is programmed in LP mode, this is time to read the displays parameters to allow correct programming of the DSI. A new round of programming can then take place to set-up the system, based on the parameters which have been read fro the display.

The DSI internal setting is now completed and it is ready to accept data. The application can now enable the interface so that the stall signal is removed and that DSI link can accept data.

When the procedure described above is terminated, it does not imply that display itself is ready. At this stage, the D-PHY and DSI link are ready to send/receive data to/from display and thus application may still need to initialize the display itself.

dsi\_spruij7-005

**Figure 12-1074. Start-up Procedure Summary**

#### 12.6.5.7.4 Interrupt Management

There are numerous error and status conditions that can be monitored via the interrupt mechanism. The edge on which these conditions are generated is programmable.

Each interrupt source has four associated registers:

1. The status register itself "<sts\_reg>"
2. a control register "<sts\_reg>\_ctl" to control corresponding interrupt behaviour
3. a flag register "<sts\_reg>\_flag" to observe when interrupt/event has been triggered
4. A clear register "<sts\_reg>\_clr" to clear the event flag register.

The decision of which status bits (<sts\_bit>) can generate interrupt is taken when the corresponding enable bit "<sts\_bit>\_en" is set in the status control register. In the same register the status bit edge "<sts\_bit>\_edge" states on which edge of the status bit the interrupt is triggered. When the selected edge is observed, the flag bit "<sts\_bit>\_flag" is set. The interrupt signal is an OR of all flag bits that are enabled. When the register "<sts\_reg>\_clr" is written with the bit "<sts\_bit>\_clr", the "<sts\_bit>\_flag" is cleared.

##### 12.6.5.7.4.1 Error and Status Registers

The error register bank handles storing all error flags that are identified. It also stores some status bits that must be observable and detectable by the application. These status and error registers can generate an interrupt on the rising or falling edge if this generation is enabled.

This mechanism is different depending on the nature of the status or error bits. For those that are generated in the DSI block (basically all status and error bits except direct command), the status bits cannot be easily controlled and toggle according to the internal status meaning only the current value is observed in the status/error register itself.

If the interrupt generation is enabled with the associated enable bit, a rising edge (associated edge bit set to 0) or a falling edge (associated edge bit set to 1) of that status bit toggles the corresponding flag bit. At the end, all the flag bits are put together with an OR to generate the interrupt signal. The flag register can be reset by writing in the clear register.

The described behavior can be summarized by the following pseudo-HDL. The signal named signal\_sts\_bit is the bit that is observable by reading status bit.

- reg\_sts\_q is the status register (accessible via APB)
- reg\_flag\_sts\_q is the flag register
- clear\_the\_flag is set when the register clear is written
- edge\_sts\_ctl is the edge bit
- enable\_sts\_ctl is the enable bit

```
reg_sts_d <= signal_sts_bit;
```

```
reg_flag_sts_d <= '0' WHEN clear_the_flag = '1' ELSE
```

- '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
- '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;

```
irq_n <= NOT (OR_OF_ALL(reg_flag_sts_q AND enable_sts_ctl));
```

The code is slightly different in cases where the observed bit is a generated condition (in the control block), as is the case for the direct command status and error flags. The status/error information is automatically generated but is cleared only when writing in the corresponding clear bit. The interrupt generation behaves similarly to the error condition cases, however, as the status falling edge is observed only when the bit is cleared, it is not possible to use the falling edge detection on flag (however the code is kept as-is to provide a standard implementation method). This leads to the following code:

- reg\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
- '1' WHEN the\_sts\_bit (Note 1) = '1' AND reg\_sts\_q = '0' ELSE -- (see Note)

- reg\_sts\_q;
- reg\_flag\_sts\_d <= '0' WHEN clear\_the\_flag = '1' ELSE
  - '1' WHEN (reg\_sts\_q = '0' AND reg\_sts\_d = '1' AND edge\_sts\_ctl = '0') ELSE – detect rising
  - '1' WHEN (reg\_sts\_q = '1' AND reg\_sts\_d = '0' AND edge\_sts\_ctl = '1') ELSE – detect falling
- reg\_flag\_sts\_q;
- int <= NOT(OR\_OF\_ALL(reg\_flag\_sts\_q AND enable\_sts\_ctl));

**Note:** In some case (pulse generated), the rising edge detection is not done and the code becomes simply '1' WHEN signal\_sts\_bit = '1' ELSE...

#### 12.6.5.7.4.2 Interrupt Management for Direct Command Registers

The following direct command status bits/registers are only set when error is generated and only cleared when the clear bit is written:

- all the status bits of the register DSI\_DIRECT\_CMD\_RD\_STS
- all the status bits of the register DSI\_DIRECT\_CMD\_STS
- all the status bits except bit 0 (cmd\_transmission) of the register DSI\_DIRECT\_CMD\_STS

As these registers are reset only when the clear register is written, it is not possible to detect the falling edge on them to generate interrupts. Only the rising edges can generate the interrupt.

**Note:** There can be issues with detection when using the bits for all the signals that are a pulse generated in the tx\_byte\_hs\_clk domain. When the speed of that clock is slower in relation to dsi\_p\_clk, it is possible to have the interrupt set, the bit read and the clear attempted before the end of the tx\_byte\_hs\_clk pulse, after the clear, the bit is set again.

#### 12.6.5.7.5 Direct Command Usage

The direct command mechanism is a way to send commands (with a maximum size of direct\_cmd\_fifodepth bytes) by writing and reading registers. It allows commands to be sent that are not allowed through the SDI-DSI interface (DSI commands, triggers), to perform read operations or to send DCS / generic write / generic read operations when the DSI link is not fully programmed and cannot use the SDI interface for commands.

Figure 12-1075 shows direct command management sequence.

Basically, the procedure to do so is as follows:

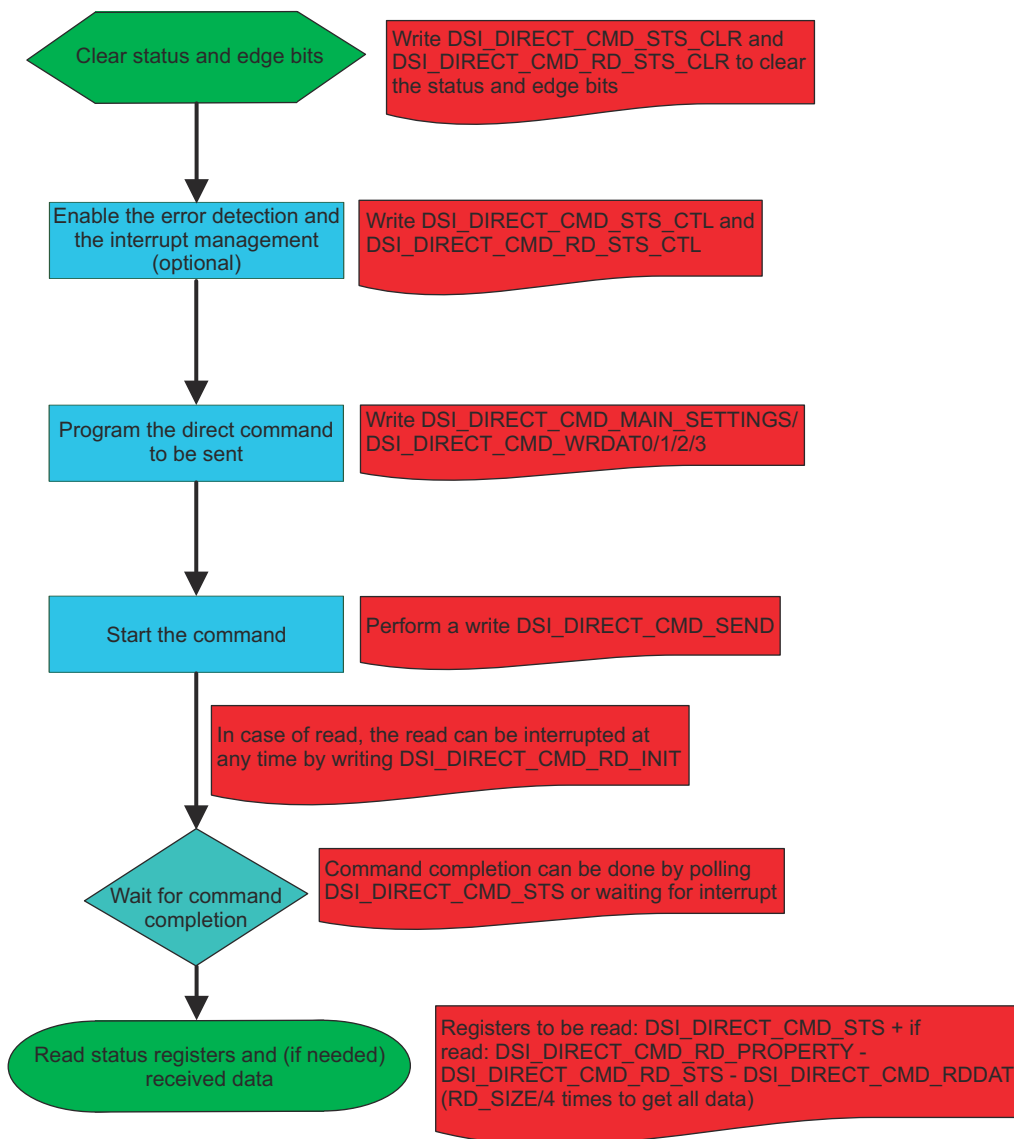

- Clear the status bits (when reading the status bits, only the DSI reads the current access status).
- Program the various registers that define the command to send.
- Write the direct\_cmd\_send register. Writing in that register (any value) triggers the command sending mechanism.

The command should be started only if the command request is amongst the defined ones for DCS or Generic Write or Read with 0, 1, or more parameters:

- DCS Write codes 0x05, 0x15, 0x39
- DCS Read codes 0x06
- Generic Write codes 0x03, 0x13, 0x23, 0x29
- Generic Read codes 0x04, 0x14, 0x24

**Note:** The direct\_cmd\_main\_settings register can use other data type values for cmd\_head to support future types and no check is performed for invalid types.

- Wait for the assertion of the command\_completed bit in the direct\_cmd\_sts register (or any of the relevant bits that indicate a specific command termination). Instead of polling the registers, it is possible to enable the corresponding interrupts and wait for its detection.
- Read the received data and (if any) the different status bits.

dsi\_spruij7-006

**Figure 12-1075. Direct Command Management**

There are several checks performed when sending a direct command to verify that requested command sizes are supported and to check that the requested command exists (otherwise the request to send the command is ignored).

- For Short packets commands the DCS and Generic Read and Write the data size is rounded to maximum of 2.
- For Long packet DCS and Generic Read and Write the data size is rounded to the maximum size of the FIFO.
- No checks are made for the write FIFO having the expected number of bytes programmed into the CMD\_SIZE in the dir\_cmd\_main register. In this case the data written out will loop back through the value in the FIFO.

At completion of a read command, registers can be read (they contain read data and/or errors detected during the communication) and trigger events are sent to the application to announce the request completion (using the status and error register bank).

When a read request is performed, the read data is put in the RP FIFO. If more bytes are sent, they are ignored and errors are set accordingly. The received read can then be accessed by reading several times the register that gives an access to the FIFO.

For every new command, several status bits are present: one signals that a command is being transmitted (cmd\_transmission). When the command is complete, several bits can be toggled to signal it (write\_completed, trigger\_completed, te\_received, read\_completed and read\_completed\_with\_err).

Some complex commands provide intermediate information. For BTA requests, there is a bit that signals when the BTA request has been sent (BTA\_completed) and another one that signals when the DSI is master of the D-PHY interface again (BTA\_finished). For commands that imply a BTA, some other bits specify whether specific data has been received (such as trigger, acknowledge with or without error).

#### 12.6.5.7.5.1 Trigger Mapping Information

Triggers are one of the groups of direct commands that can be sent and received using the DPHY in Low Power escape mode. The trigger\_val[3:0] bits (in the registers DIRECT\_CMD\_MAIN\_SETTINGS and DIRECT\_CMD\_STS) are used to define which of the four possible trigger entry codes has to be sent or has been received. The register fields described above are copied in signal ppi\_d1\_tx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_MAIN\_SETTINGS) or are a copy of ppi\_d1\_rx\_trigger\_esc[3:0] (for trigger\_val[3:0] of DIRECT\_CMD\_STS). Only one bit out of the four should be set else the D-PHY behavior is not very precisely defined. [Table 12-1494](#) gives the trigger mapping in the system.

**Table 12-1494. Trigger Mapping**

Trigger name	Trigger entry code	trigger_val	meaning in TX direction	meaning in RX direction
trigger 0 - reset	01100010	1b0001	Reset	Not affected by DSI spec
trigger 1 - unknown 3	01011101	1b0010	Not affected by DSI spec	TE response <sup>(1)</sup>
trigger 2- unknown 4	00100001	1b0100	Not affected by DSI spec	Acknowledge with no error <sup>(1)</sup>
trigger 3 - unknown 5	10100000	1b1000	Not affected by DSI spec	Not affected by DSI spec

(1) These triggers are not observed in the trigger\_val field of the direct\_cmd\_sts register because they are used by the DSI link for a specific purpose.

**Trigger Reset** – This will request from the display and expects an immediate reset of the DSI command/video mode with all pending requests in TX sending path FIFO for transfer to be discarded.

**Acknowledge** – This is a response to DSITX controller. The host processor may request a command acknowledge and error information related to any transmission by asserting Bus Turnaround with the transmission. The peripheral shall respond with ACK Trigger Message if there are no errors and with Acknowledge and Error Report packet if any errors were detected in previous transmissions. Appropriate flags shall be set to indicate what errors were detected on the preceding transmissions.

If the transmission was a Read request, the peripheral shall return READ data without issuing additional ACK Trigger Message or an Acknowledge and Error Report packet if no errors were detected. If there was an error in the Read request, the peripheral shall return the appropriate Acknowledge and Error Report unless the error was a single-bit correctable error. In that case, the peripheral shall return the requested READ data packet followed by Acknowledge and Error Report packet with appropriate error bits set.

**Tearing Effect** - The Tearing effect on the display is avoided by having synchronization information from the display. It is used only in command mode. Users are responsible for selecting the command mode for the VC using the TE feature and selecting the polling or automatic mechanism.

The user is responsible for ensuring that there is a delay after a trigger is issued by the host to the panel, before any other action, message or trigger is performed. When the host issues a reset trigger, the system will expect the controller to stop and re initialise the clock and data links. All other triggers issued by the host will be application specific and are outside the scope of this document.

#### 12.6.5.7.5.2 Command Mode Settings

The command mode is enabled on the SDI interface. This is controlled using the register `mctl_main_en`. Other settings can be set using the registers: `mctl_main_data_ctrl` (to decide about TE usage, read enable...); and `cmd_mode_ctl` (Virtual Channel of the command packets, arbitration between requests of the two interfaces, possibility to use LPDT, TE timer programming and padding value in case of an error).

When programming Direct READ commands, a BTA request is sent automatically following the read transmission, for the peripheral to respond – it is therefore not necessary to explicitly send a BTA request at that time. The system must allow the BTA request to be completed and the bus returned to the host before issuing any new read or write command. The system must either: poll the `read_completed` (and `read_completed_with_err`) status bits; or, wait for an interrupt caused by these bits before issuing any new command.

When programming Direct WRITE commands, it is advisable to ensure that each transaction can complete successfully before moving on to a subsequent command. There are two recommended methods to achieve this, either: explicitly request a BTA between write transactions while checking for the associated interrupt or polling the appropriate status flag (this method also provides the added security of an ACK response from the peripheral); or allowing a gap between commands sufficient to allow completion of the first before commencing with the second. The recommended approximate gap time required to ensure that all commands complete successfully is equivalent to 100 TX ESC byte periods. If required (for instance, to minimize the start-up time), it is also possible to calculate the minimum delay time required for each transaction, based on the TX escape clock frequency used in the application and the length of each command (no active video transmission should be enabled at the time – a typical use case would be peripheral parameter configuration). As with read operations, any write operation followed by an explicit BTA request must allow the BTA to be completed and the bus returned to the host before issuing any new read or write command.

For single parameter commands, the upper bytes of the 32-bit value written to the Direct Command write data register (`direct_cmd_wrdat`) should be masked to zero to comply with the DSI specification requirement that unused parameter locations are set to zero. For zero parameter writes, assuming there have been previous write commands sent, it is necessary to clear the sending path FIFO by writing to the `direct_cmd_fifo_rst` register to clear the data path, then write a zero value to the `direct_cmd_wrdat` register to send the zero parameter write command.

**Note:** Failure to follow these procedures may result in non-zero data in the unused parameter locations; this may or may not affect the peripheral, however it is recommended to use the process described to ensure compliance with the DSI specification in this regard.

If STOP mode is forced during a command mode read or write transaction, all outstanding transactions should be considered lost and all status and error flags should be disregarded and cleared. Similarly, if an LPDT read data operation is stopped by writing to the `STOP_READ_OPERATION` field of the `DIRECT_CMD_RD_INIT` register, the status for the aborted read operation should be disregarded and cleared before resuming normal operation.

#### 12.6.5.7.5.3 Bus Turnaround Sequence

The command operation can request a read or an acknowledge response from the panel after a long sequence of packets is sent. The Bus turnaround is also used to control the Tearing Effect control.

When a Bus Turnaround is requested from the command stream manager, the DPHY will be given a turn request. The request will make the DPHY interface perform a sequence of LP states (LP11-10-00-10-00) to indicate that it is releasing control of the DP/DN signals. The DPHY Direction signal will change once it detects the Panel side driving the LP00-10-11 states. The panel will then be able to send any response packets (see section 0) and release the bus by issuing a bus turnaround sequence to the controller DPHY. The DSITX controller DPHY will detect the sequence and change the direction signal once the pattern is sent and LP00 state is valid for 2-3 TX\_ESC\_CLK cycles.

Figure 12-1076 shows Bus turnaround timing sequence from controller to panel and panel to controller.

**Figure 12-1076. Bus Turnaround Timing Sequence from Controller to Panel and Panel to Controller**

#### 12.6.5.7.5.4 Tearing Effect Control

The DSI command control for a tearing effect request can be performed using the polling method or automatically. The enable bits for BTA and TE must be enabled for the mechanism to be performed with either the SDI or DIRCMD interface. For automatic operation, the DSI will send a first BTA, and then waits for BTA reception and if no TE has been received during the first BTA <sup>(1)</sup>, it sends another BTA and then waits for TE. There are three possible error conditions that can happen (but only the two first are detected by the DSITX controller and passed to registers):

- If the display answers to the second BTA with another BTA and thus does not sent the TE - this means that the display does not support TE generation OR that TE generation mechanism has not been enabled (reg\_err\_no\_te).
- If the TE has not arrived within a given programmable period – this means that the TE request arrived too late and that the Display Application Processor is not synchronized with the display. The error reported is reg\_err\_te\_miss but the system continues to wait until the TE is received. <sup>(2)</sup>
- If a time-out has been detected by the DSI showing that a problem happened during the BTA and that the system is forced back to idle without BTA – in this case, a BTA without TE is seen and the CSM generates a reg\_err\_no\_te (as for first case).

For the polling method to request a tearing effect (TE polling mode is enabled with te\_hw\_polling\_en = 1) the DSI sends a first BTA, waits for peripheral TE + BTA, if only BTA has been received after the first BTA, it keeps sending BTAs until peripheral responds to the BTA by a TE + BTA instead of BTA only; in this specific mode reg\_err\_no\_te will never be asserted. To stop sending BTA and waiting for TE a force stop <sup>(3)</sup> ) is needed.

**Note 1:** TE received is checked on the first BTA in case a BTA was the last command issued by the DSI link (BTA or read command sent via direct command interface).

**Note 2:** Again to support the cases where a BTA was emitted just before the TE request, the TE windows is counted on the first BTA (in case the display understands this BTA as the TE request and thus may emits too late the TE), and is restarted after the second BTA.

**Note 3:** The time to wait before forcing a stop should be around the duration of a frame. The reason is that if you miss the TE time at the end of the current frame, you've to wait till the end of the next frame before new TE can be sent by display.

The following table describes the TE timeout counter operation, Programming of the IP. The counter value should be calculated based on the tx\_byte\_clk period.

**Table 12-1495. TE Timeout Programming**

te_timeout(11)	te_timeout(10)	timeout value
0	0	$256 \times \text{te\_timeout}<9:0>$
0	1	$512 \times \text{te\_timeout}<9:0>$
1	0	$1024 \times \text{te\_timeout}<9:0>$

**Table 12-1495. TE Timeout Programming (continued)**

te_timeout(11)	te_timeout(10)	timeout value
1	1	$2048 \times te\_timeout<9:0>$

#### 12.6.5.7.5.5 Tearing Effect Control on Panels with Frame Buffer

Display panels will use command mode sequencing when an on-board frame buffer is used to store the video image rather than using the video streaming and synchronisation packets to control the update of the image information. This means that the host display driver must know when the panel is processing the image and avoid changing pixel information before it is updated. The mechanism is known as the tearing effect. The DSITX controller can support two schemes as outlined in the MIPI DSI specification.

#### TE control using the Polling Method

For polling to the display module, the host processor shall detect the current scan line information with a DCS command such as **get\_scan\_line** to avoid Tearing Effects. DSITX controller will issue a READ using this command until it gets to the expected value for the last line.

#### DCS Command - get\_scanline (45h)

##### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 1 45h

##### Parameter 1

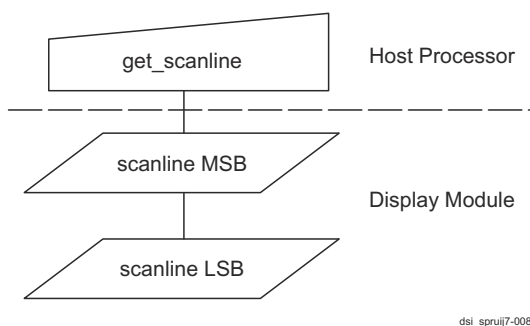

Direction D->H

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

##### Parameter 2

Direction D->H

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-1077. get\_scan\_line Command**

#### Description

The display module returns the current scanline, N, used to update the display device. The total number of scanlines on a display device is defined as VSYNC + VBP + VACT + VFP. The first scanline is defined as the first line of V Sync and is denoted as Line 0.

In Sleep Mode, the value returned by **get\_scanline** is undefined. See [MIPI-DPI] for definitions of VSYNC, VBP, VACT, and VFP.

- In 2D mode, the scanline value of the display memory and the display panel is the same.
- In 3D Mode, the scanline value of the display memory and the display panel can be different; **get\_scanline** shall return the current scanline of the display panel.

## Restrictions

None

## TE control using the Automatic Method

For TE-reporting from the display module, the TE-reporting function is enabled and disabled by three DCS commands to the display module controller: `set_tear_on`, `set_tear_scanline`, and `set_tear_off`. See [MIPI-DCS] for details.

`set_tear_on` and `set_tear_scanline` are sent to the display module as DSI Data Type 0x15 (DCS Short Write, one parameter) and DSI Data Type 0x39 (DCS Long Write/write\_LUT), respectively. The host processor ends the transmission with Bus Turn-Around asserted, giving bus possession to the display module.

Since the display module DSI Protocol layer does not interpret DCS commands, but only passes them through to the display controller, it responds with a normal Acknowledge and returns bus possession to the host processor. In this state, the display module cannot report TE events to the host processor since it does not have bus possession.

To enable TE-reporting, the host processor shall give bus possession to the display module without an accompanying DSI command transmission after TE reporting has been enabled. This is accomplished by the host processor protocol logic asserting (internal) Bus Turn-Around signal to its D-PHY functional block. The PHY layer will then initiate a Bus Turn-Around sequence in LP mode, which gives bus possession to the display module.

Since the timing of a TE event is unknown to the host processor, the host processor shall give bus possession to the display module and then wait for up to one video frame period for the TE response. During this time, the host processor cannot send new commands, or requests to the display module, because it does not have bus possession.

## DCS Command - `set_tear_on` (35h)

### Command

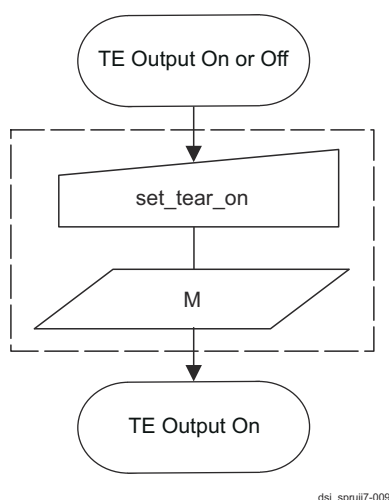

Direction H->D

Hex Code 35h

### Parameter

Direction H->D

Hex Code X X X X X X M XXh

**Figure 12-1078. `set_tear_on` Command - 1**

## Description

This command turns on the display module Tearing Effect output signal on the TE signal line. The TE signal is not affected by changing set\_address\_mode bit B4. set\_tear\_on has one parameter that describes the Tearing Effect Output Line mode.

If M = 0 (Mode 0):

The Tearing Effect Output line consists of V-Blanking information only.

**Figure 12-1079. set\_tear\_on Command - 2**

If M = 1 (Mode 1):

The Tearing Effect Output Line consists of both V-Blanking and H-Blanking information.

**Figure 12-1080. set\_tear\_on Command - 3**

The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI- DPI] for definitions of tvdl, tvdh, thdl and thdh.

## Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tearing Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

### DCS Command - set\_tear\_scanline (44h)

#### Command

Direction H->D

Hex Code 0 1 0 0 0 1 0 0 44h

#### Parameter 1

Direction H->D

Hex Code N15 N14 N13 N12 N11 N10 N9 N8 XXh

#### Parameter 2

Direction H->D

Hex Code N7 N6 N5 N4 N3 N2 N1 N0 XXh

**Figure 12-1081. set\_tear\_scanline Command - 1**

### Description

This command turns on the display module Tearing Effect output signal on the TE signal line when the display module reaches line N. The TE signal is not affected by changing set\_address\_mode bit B4.

The Tearing Effect Line On has one parameter that describes the Tearing Effect Output Line mode.

After issuing a set\_tear\_scanline command to the display module, the Tearing Effect output signal, e.g. as in DBI- 2 systems, shall be a delayed version of V-Blanking information as illustrated in [Figure 12-1082](#).

**Figure 12-1082. set\_tear\_scanline Command - 2**

Note that set\_tear\_scanline with N = 0 is equivalent to set\_tear\_on with M = 0. The Tearing Effect Output line shall be active low when the display module is in Sleep mode. See [MIPI-DBI] for definitions of tvdl and tvdh and [MIPI-DSI] for definition of display module line numbers. In 2D mode, the scanline value of the display memory and the display panel is the same.

### Restrictions

This command takes effect on the frame following the current frame. Therefore, if the Tear Effect (TE) output is already ON, the TE output shall continue to operate as programmed by the previous set\_tear\_on, or set\_tear\_scanline, command until the end of the frame.

### DCS Command - set\_tear\_off (34h)

#### Command

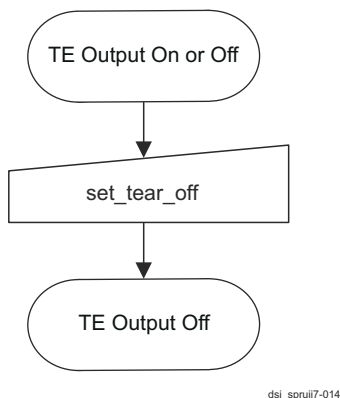

Direction H->D

Hex Code 0 0 1 1 0 1 0 0 34h

Parameters None

## Description

This command turns off the display module Tearing Effect output signal on the TE signal line.

**Figure 12-1083. set\_tear\_off Command**

## Restrictions

This command has no effect when the Tearing Effect output is already off.

### 12.6.5.7.5.6 Return Path Operation

The DSI Return Path behaves like a slave, by collecting data from the DPHY receive interface when the DPHY is configured to accept a transmission from the peripheral. The RP receives 6 signals from the DPHY (see [Table 12-1496](#)).

The data (and trigger) reception is inactive if the DPHY PPI direction signal is at low level. When it is active, data is received using the RX ESC\_CLK clock (the clock is transmitted with the data itself - see D-PHY protocol description from MIPI) and may stop if there is a pause in the data transmission but data is generated on clock falling edge. New data is available on rx\_data\_esc on a rising edge of the clock, if both rx\_lpd\_t\_esc and rx\_valid\_esc are asserted.

**Table 12-1496. Interface Between Return Path and DPHY**

Signal Name	I/O	From/To	Description
rx_lpd_t_esc	I	DPHY	Escape Low Power data receive mode This active high signal is asserted to indicate that the lane module is in low-power data receive mode. While in this mode, received data bytes are driven onto the rx_data_esc output when rx_valid_esc is active. The lane module remains in this mode with rx_lpd_t_esc asserted until a stop state is detected on the lane interconnect.
rx_trigger_esc(3:0)	I	DPHY	Escape trigger received These signals indicate that an escape trigger command has been received. Only one of these signals will be asserted at any time and the signal will remain asserted until the lane module returns to stop state.
rx_data_esc(7:0)	I	DPHY	Escape receive data For Low Power data receptions, this eight-bit value is driven by the D-PHY and is valid on rising edges of rx_clk_esc with rx_valid_esc asserted. The bit connected to rx_data_esc[0] was received first.
rx_valid_esc	I	DPHY	Escape receive data valid This signal indicates that the lane module is driving data on rx_data_esc and expects the protocol layers to take the data at the current rising edge of rx_clk_esc. There is no "ready" signal to throttle the receive data.

**Table 12-1496. Interface Between Return Path and DPHY (continued)**

Signal Name	I/O	From/To	Description
stop_state_dl1	I	DPHY	Lane is in stop state This signal indicates that the lane module is in STOP state. Note that this signal is asynchronous to any clock in the protocol interface.
direction	I	DPHY	Lane direction. When this signal is high, the lane module is in receive mode. When direction is low, the lane module is in transmit mode. (Mnemonic: 1 = Input, 0 = Output.)

The received data messages are identified as one of two possible types:

- Trigger
- Read packet

**Trigger** messages are passed almost directly to the register (reg\_req = reg\_trigger = 1 and reg\_rd\_data<3:0> equals to trigger value during one clock cycle). However, triggers are decoded to see if they are a TE trigger or an acknowledge with no error.

- The TE data is passed separately to the CSM using csm\_te\_received pin. It needs to be resynchronized with tx\_byte\_clk byte clock because of the CSM working clock domain.
- The acknowledge is only passed to register using reg\_req and reg\_ack pins. All other trigger values are passed undecoded to the registers without any processing. It is the responsibility of the application to decode and decide what to do with them.

**Read Packet:** When data is received, the system waits for the 4 bytes of the **HEADER**, and performs an ECC correction (if it is enabled) and then decodes the packets.

The following cases are considered when the system performs the ECC check:

- If the received command is not in the list of legal display opcodes, (i.e. errors in the packet header), it discards that packet and all further incoming bytes, even if they are legal packets (until the next BTA - i.e. direction change). It sends errors to the register bank (err\_undecodable and uncorrectable\_err). This may also result in an EOT error being reported as no further bytes have been decoded. But even if ECC correction shows an uncorrected error, decoding is attempted (if the errors are in the ECC byte or in the payload bytes, the opcode can be understood and data correctly recovered). In this case only err\_uncorrectable error bit is sent to register and it falls in the situation of regular commands (acknowledge with error or read).
- If "an acknowledge with error", the two status bytes are sent to the registers (reg\_req = 1 and reg\_ack\_err = 1 and reg\_rd\_data<15:0> contains the correct value).
- If the message type is a short read (either DCS or generic), data is passed to the registers (2 bytes without any specific decoding). Interface signals must be set accordingly and the two bytes are sent to registers (reg\_req = reg\_start = reg\_end = reg\_read = 1 with data and dscnotgen set accordingly). Size information is decoded in the first byte of the received packet depending on the data type information and then sent to register using reg\_size port.
- If a long read, the size is sent to the register using reg\_size. The system goes to **LONG state**. All data received are sent to register using reg\_data and are used for checksum detection. If during receive, return packet fifo (in control block) becomes full (rd\_data\_fifo\_full), the error flag err\_oversize must be set. All remaining data is used for checksum calculation but are not transferred to registers. When the number of received bytes is equal to the packet size, the system will check the **CHECKSUM**. The two checksum bytes are never transferred to register. They are used to make checksum detection and indicate err\_checksum status.
- If the transfer is shorter than the size specified in the header, the error err\_wrong\_length is issued along with any subsequent errors such as err\_missing\_eot (if needed). The case where it is longer drives to a tentative checksum decoding that generates an error and by a tentative to decode a new header (that is in fact a part of the previous packet) that drives to an error err\_undecodable and the throwing of the rest of the received bytes (with corresponding errors such as err\_missing\_eot).

- If it is an EoT packet, it is not passed to the control block. The following data is ignored (if any). If the system is waiting for **EoT**, this is the only action. If system is not waiting for EoT packet, the err\_eot\_with\_err is sent.
- If after an "acknowledge with error", the system waits for EoT packet and counts 4 bytes but is not able to decode them, it emits an err\_eot\_with\_err and err\_undecodable.
- If direction is removed at a "wrong" time (i.e before the fourth byte of a small packet, the system stops to works but emit errors to the register: err\_receive with eventually err\_missing\_eot.

The DSI is designed to support multi-peripheral integration, the virtual channel of the received packet is also stored in register using reg\_vc port.

The application FW layer is responsible of all read actions, it is assumed that once a read is requested, application reads return packets before requesting other read actions. Based on this assumption, the receive FIFO implemented in the register block is cleared each time a read action is started. All data not read before the new read command are lost.

A re-initialization of the return path is also performed using register access on reg\_init\_rp.

All errors related to short or long received data packets should be captured in the register when the direction changes (to capture all errors at the same time and not generate several errors and possibly several interrupts on the same reverse transaction). As soon as an error is detected on a packet, the error must be recorded and maintained up to the end of the packet transfer.

The maximum packet size supported by the DSI return path is 16 bytes. If a longer packet is received, only the first 16 bytes are available (by register way) for application.

#### **12.6.5.7.5.7 EoT Packet Management**

The DSI protocol states that, in the sending path, only the HS transmission requires use of EoT packet. For transfer from display to host, it is not recommended to use EoT but it is possible. The host needs to be able to detect the EoT packet and then behaves accordingly.

In case the display makes use of the EoT packet, the bit disp\_eot\_gen must be set to one. In that case, if after the ECC correction, the packet header is 0x08, we've detected an EoT packet and all bytes that may arrive between this packet and the direction change must be ignored.

If additional data is received between the EOT packet and the next BTA (end of read process), or if an unwanted EOT packet is detected, the unwanted bytes must be rejected and err\_receive is asserted.

If the EoT packet is not detected although it should be present, the error err\_missing\_eot is set. If after an "acknowledge with error", 4 bytes are received before BTA but are not identified as EoT (because of errors), it is assumed these 4 bytes are the EoT. In that case, the error err\_eot\_with\_err has to be set with err\_undecodable.

#### **12.6.5.7.5.8 ECC Correction**

The DSITX controller uses the packet header ECC information to detect and correct one error, and can detect two or more errors without correction.

#### **12.6.5.7.5.9 LP Transmission and BTA**

The DSI host may send a command sequence and then request an acknowledge message from the panel. The host will send the command and release the bus by performing a BTA sequence. The panel will then respond with an acknowledge message (or error response) followed by a BTA to return the bus to the host. This sequence is illustrated in Overview of a Display Subsystem.

Overview of a Display Subsystem.

[Figure 12-1084](#) shows LP transmission timing diagram.

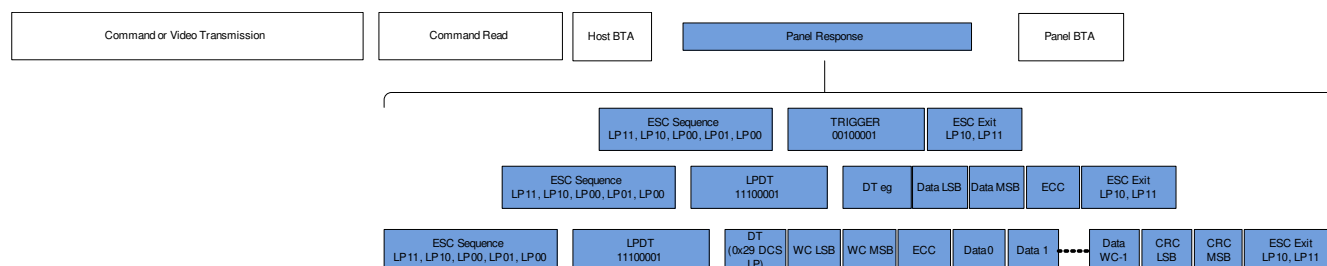

dsi\_spruij7-015

**Figure 12-1084. LP Transmission Timing Diagram for Host Read and Trigger ACK**

The Host will not be able to transmit any other packets once the BTA is sent to the panel and will expect either an ACK trigger or response LPDT message with a payload. The system must ensure there is sufficient time to send any command and issue the BTA, receive the response (Trigger, Short or long packet) and accept the BTA from the panel, if this request is made in the line blanking intervals.

Figure 12-1085 presents panel read response sequences.

**Figure 12-1085. Panel Read Response Sequences**

The panel response time will be based on the tx\_esc\_clk used inside the panel and the expected number of bytes for the payload. The expected responses are illustrated in the blocks in the MIPI DSI standard.

#### 12.6.5.7.6 Low-power Management

There are several low-power scenarios which consist of switching off various parts of the design:

1. Switch D-PHY cells in ULP mode when there are no data to be sent (bits clk\_lane\_ulpm\_en, dat1\_ulpm\_en, dat2\_ulpm\_en, dat3\_ulpm\_en and dat4\_ulpm\_en in register mctl\_main\_en set to one with ULP mode enabled in register mctl\_main\_phy\_ctl). Please, note that the time to leave ULP state is 1 ms and needs to be set in clock cycles in the register mctl\_ulpout\_time.
2. Switch the DPHY byte/bit clock PLL off (refer to DPHY documentation for control sequence). In this case, the D-PHY cell can only transmit data in LPDT thus maximum bandwidth is 10 Mb/s.
3. More drastic methods are to shut-down some parts of the design. The D-PHY and the DSI themselves can be shut down.

When D-PHY and DSI are both shut-down and the display is powered down, the restart is a normal start procedure as described in [Section 12.6.5.7.3, Start-up procedure](#).

When only the D-PHY is stopped, it is placed in either the stop or ULP state. Restarting the D-PHY is similar to the regular start-up procedure, however, after the lanes are enabled by the DSI Controller (clk\_lane\_en, dat1\_en, dat2\_en, dat3\_en and dat4\_en in register mctl\_main\_en are set), the D-PHY generates a rising edge on the stopstate signal to indicate to the DSI Controller that the enable request has been effective within the D-PHY. After that the start-up procedure may continue up to the point that the DSI link is ready to begin transmission.

Note that when setting the D-PHY into the ULP state, the application needs to wait enough time between the time it sets the ULP request in register and the time the D-PHY is disabled – this ensures that the ULP request is detected on the D-PHY interface.

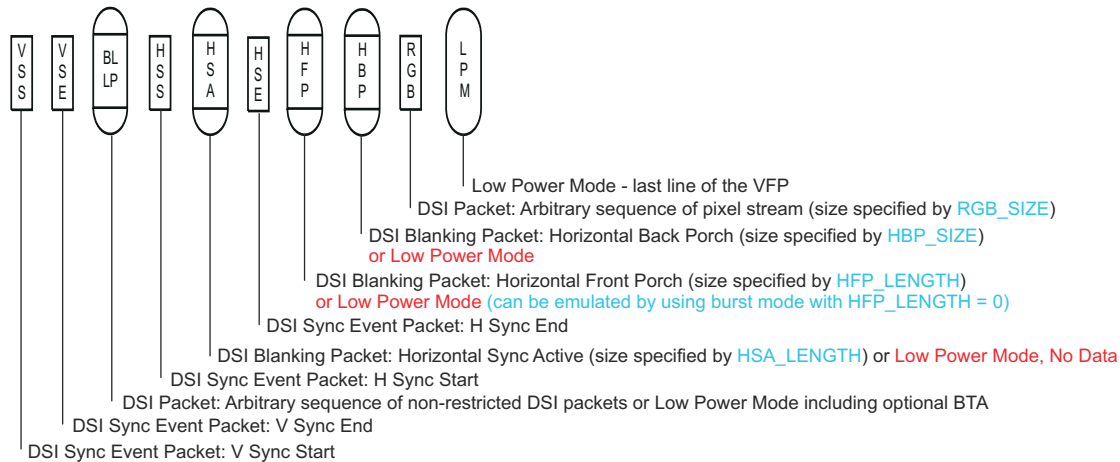

### 12.6.5.7.7 Video Mode Settings

All values contained in the Control Block (CB) registers must be set with meaningful values and are expressed with a range of different units: clock cycles, bytes, number of lines.

#### 12.6.5.7.7.1 Video Stream Presentation

In [Figure 12-1086](#), it shows the list of packets that can be part of a video stream and the associated register fields. In the four following figures ([Figure 12-1087](#), [Figure 12-1088](#), [Figure 12-1089](#), [Figure 12-1090](#)), different video streams that can be generated are presented.

ds1-017

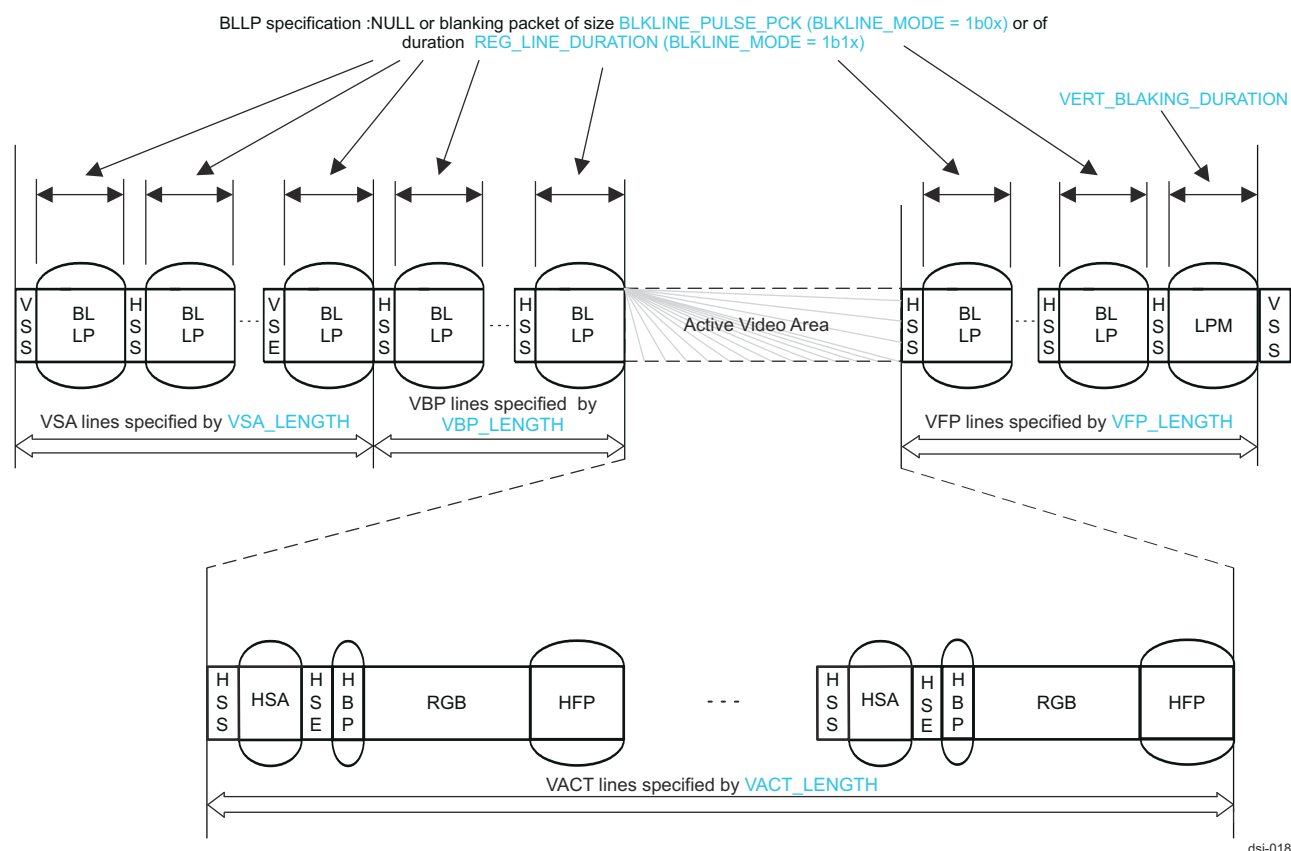

**Figure 12-1086. DSI Packet Terminology**

**Red text** - behaviour not possible.

**Blue text** - register fields used to specify the packet size.

The BLLP (Blanking – Low Power) periods allow the DPHY link to perform the following sequences:

- Host Transmit blanking packets in HS.
- Host Transmit command packets in HS or LP (Escape mode).
- Host Transmit packets using interleaving to a different virtual Channel in HS or LP (Escape mode).
- Host performs BTA and waits for response packets from the panel using Escape Mode followed by a panel BTA.

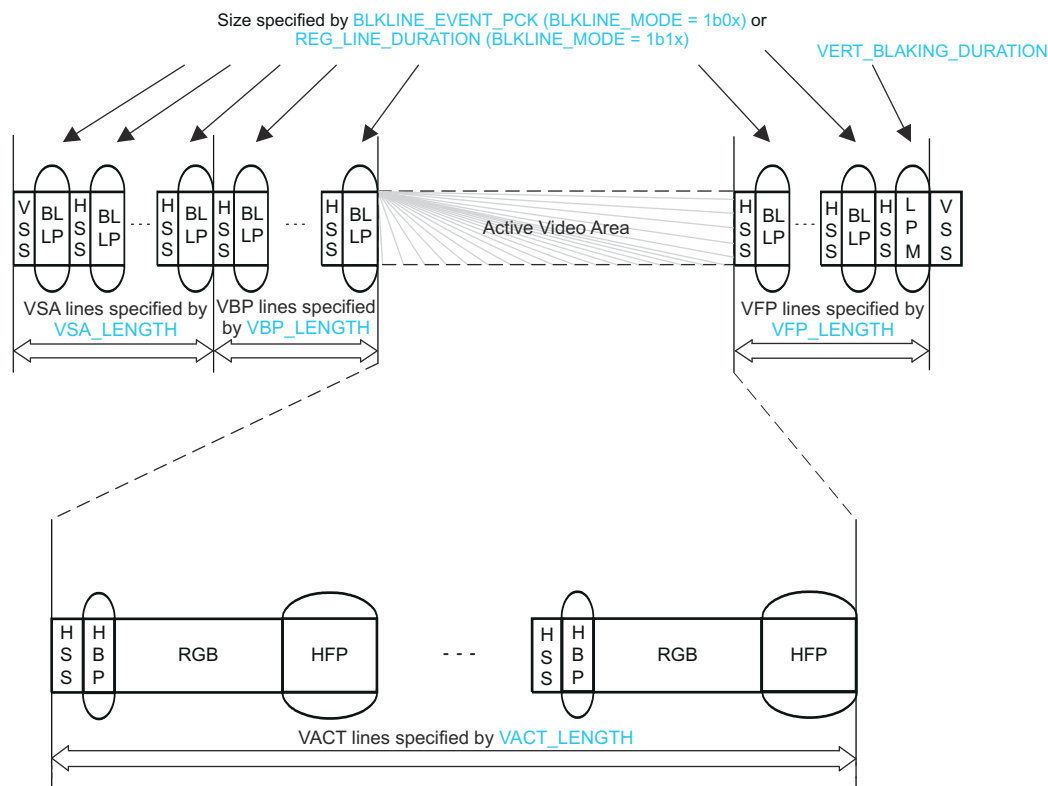

**Figure 12-1087. Video Pulse Mode (Non-Burst) Timing Diagram**

**Note**

This sequence is no longer specified in the MIPI spec Version 1.02.00 28-Jun-2010 but supported by the DSI-controller.

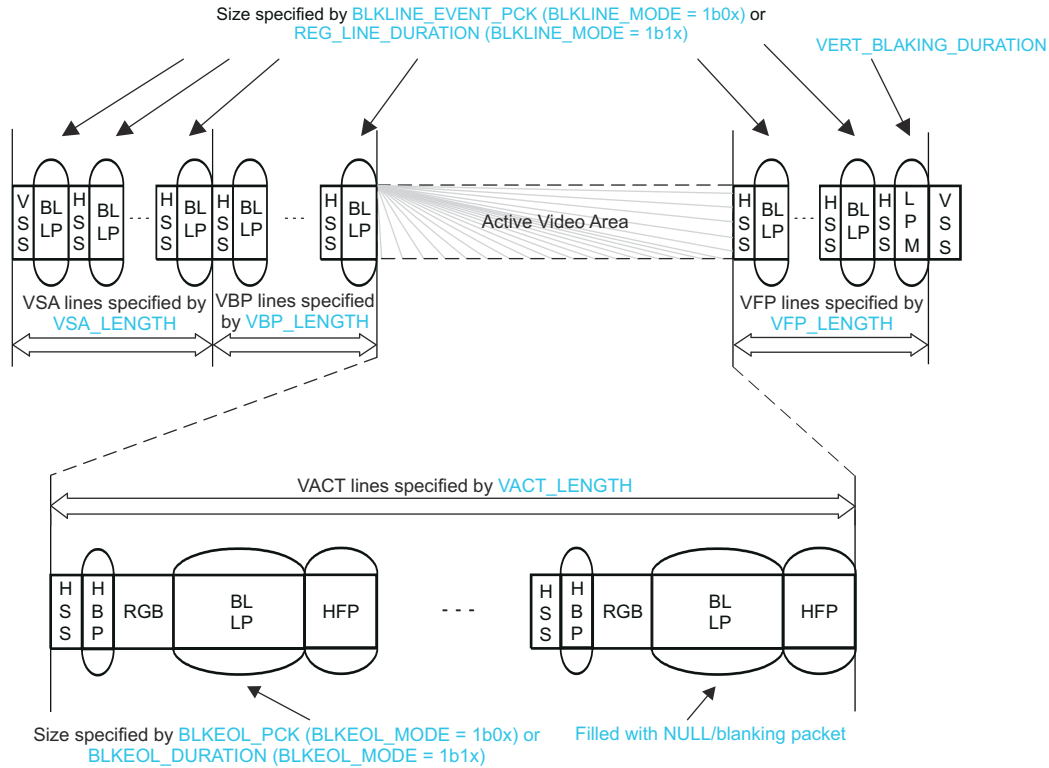

dsi-020

**Figure 12-1089. Video Event Mode (Non-Burst)**

burst\_mode = sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

dsi-021

**Figure 12-1090. Video Sync Event in Burst Mode**

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0 - all spec versions.

Burst Mode operation requires the tx\_byte\_clk to be set to double the bit rate compared to the non-burst case. The calculations for the video parameters must then be increased to match the higher rate. The DPI FIFO must also be large enough to store at least half of the active line bytes before the output transmission begins otherwise it will underrun.

#### 12.6.5.7.7.2 Video Stream Settings (VSG)

The following is all the registers that need to be set before using the video in SDI or DPI interface operation.

- vid\_vsize1, 2
- vid\_hsize1, 2
- vid\_blksize1, 2
- vid\_pck\_time
- vid\_dphy\_time
- vid\_error\_color1, 2
- vid\_vca\_setting1, 2
- vid\_main\_ctl – programmed last in sequence of vid registers to apply to DSI registers

This section addresses the dependencies between all video registers, and details how the TVG and VCA registers must be set per VSG registers.

#### vid\_main\_ctl

- header information must correspond with the vid\_pixel\_mode used to control the generation of the recovery streams. The header information is used to be enable management of future cases where the DSI link could be used to pass streams with formats that differ feom those currently supported directly.
- sync\_pulse\_horizontal can only be asserted if sync\_pulse\_active = 1.

When `sync_pulse_active` is set to one, the HSYNC pulses are emulated only during the active part of the frame. When both `sync_pulse_horizontal` and `sync_pulse_active` are set, the HSYNC pulses are present on all lines of the frame.

**vid\_vsize** - the variables are expressed in line numbers in this register.

- `vsa_length` should be at least one (in order VSG can insert at least the vertical synchronization start VSS line) and greater or equal to 2 when pulse mode (`sync_pulse_active` = 1).
- `vbp_length` 0 to 63.
- `vfp_length` must be greater than 0.
- `vact_length` must be greater than 0.
- `vid_hsize1`: - the numbers are expressed in number of bytes (the fields are specifying the payload).

**vid\_hsize1** - the numbers are expressed in number of bytes (the fields are specifying the payload of the corresponding packet).

- `hsa_length` need to be at least set to one if pulse mode is enabled. The expected normal operating range is 1 to 255, large values for the HAS length will impact on the size of the DPI FIFO required.
- `hbp_length` can have any value. However, when set to 0, a HBP packet is generated with 0 payload.

**vid\_hsize2** - again the fields are specifying the payload of the corresponding packet (in byte).

- `hfp_length` can have any value. However, when set to 0, no HFP blanking packet is generated.
- `rgb_size` must match the number of pixel per line of the display multiplied by the number of byte per pixel.

**vid\_blksize1** - still specifying size of the payload in byte.

- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.
- `blkline_event_pck` defines the payload length of the blanking or NULL packet to be inserted in blanking line (with sync event). This value is used when `reg_blkline_mode` = 0b01 or 0b00 and when `sync_pulse_active` = 0. It is also needed by the VSG when `reg_blkline_mode` = 0b1x. Its value depends on the `hbp`, `rgb`, `blkeol`, and `hfp` packet length.

-- 32767 = 0x7FFF = max value on 15 bits and -100 to take

margin `blkeol_pck` < 32767 - `hfp_length` - `hbp_length` - `hsa_length` - `rgb_size` - 100;

The `blkeol_pck` (and `blkeol_duration`) must be adapted to the `reg_wakeup_time` in case VCA is authorized to go back in LP.

**vid\_blksize2** - still specifying size of the payload in byte.

- `blkline_pulse_pck` has almost the same definition than `blk_event_pck` but it concerns blanking lines with sync pulse.

**vid\_pck\_time** - specifies duration in clock cycles.

- `blkeol_duration`: `blkeol_duration` = `div_round_up` <sup>(1)</sup> ((`blkeol_pck` + 6), `lane_nb`);
- `vert_blanking_duration` is no longer used and can always be set to 0. It remains present in the design for legacy reason.

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

**vid\_dphy\_time**: specifies duration in clock cycles. These are values that have external dependencies and thus need to be calculated first (and rest of VSG programming is calculated from these values).

**reg\_line\_duration**: depends on display type and size and of its programming (in some display, the blanking sizes can be adapted to provide a given number of frame per second with one of the D-PHY possible clock frequency (as PLL can only generate a given number of discrete frequencies).

**if (pulse mode) {**

```

line_length = (blkline_pulse_pck + 6);
}
else (event mode) {
line_length = (blkline_event_pck + 6);
if (burst_mode and burst_lp and lane_nb == 2 and
hsa_length[0:0] == 1 and hfp_length[0:0] == 1)
line_length = line_length - 1;
}
result = div_round_up(line_length, lane_nb);

```

**Note 1:** The function `div_round_up` is a function that performs a division then round the result to the first entire number superior or equal to the division result.

Additional Notes about the line duration:

- If line length (in bytes) is a multiple of the number of lanes enabled, DSI will never face any timing jitter except due to the resynchronization in SP/DCB.
- If line length (in bytes) is NOT a multiple of the number of lanes enabled For Non LP operation, there should not have any problem since the line is once longer, once shorter than the "normal" value. For example: if line length is 491 bytes, it will be 245 then 246 in clock cycles with 2 lanes for an average value of 245.5.

For LP enabled operation, the controller cannot allow underflow of the line and frame timing. With the previous example, the LP line length in clock cycles will be 246 since we cannot start the HS transmission in the middle of a clock cycle. And there is no mechanism to have one line in 245 and the next one in 246 cycles. For LP see section 0.

**reg\_wakeup\_time** must be shorter than line duration and depends on the D-PHY cell plus some pipelines delays inserted by the DSI link. This value strongly depends on the DPHY PLL programming and configuration, and is a mix of both internal and external analog and digital timing factors, therefore it is very difficult to provide an exact formula. The recommended approach to selecting a suitable value for this parameter is to characterize behaviour in at the system level environment using simulation, emulation (e.g. Palladium) or validation (e.g. FPGA).

The DPHY needs 100 ns + time for THXS-EXIT to go to Low Power mode.

The timing for the clock lane TXRequestHS going active to the TXReadyHS will be determined by the DPHY DDR bit rate clock frequency. The timing will be the total number of DDR bit clk cycles for the TXRequestHS to be detected and the clock lane to transition to High Speed, so  $TLPX + TCLK\_PREPARE + TCLK\_ZERO$ . Additional time is required between the clock lane driving HS clocks and the Data Lanes being activate,  $TCLK\_PRE$ . All of these parameters can be calculated from the DPHY datasheet.

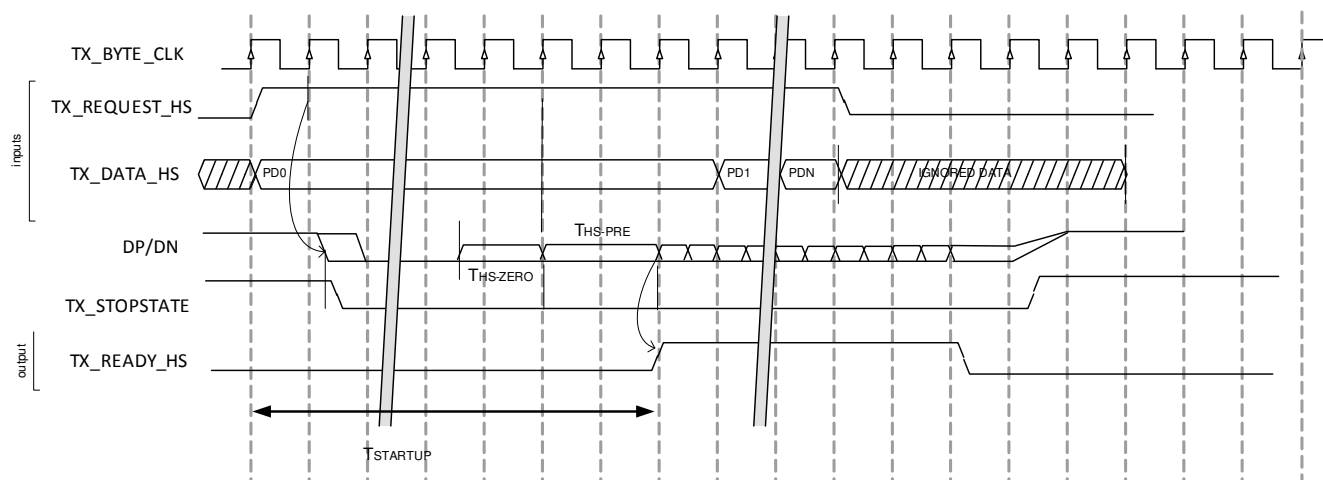

[Figure 12-1091](#) shows timing diagram for clock lane activation/deactivation.

**Figure 12-1091. Timing Diagram for Clock Lane Activation/Deactivation**

The data lane request follows a similar timing sequence from the TX\_Request\_HS to TX\_Ready\_HS, TLPX + THS-PREPARE + THS\_ZERO. The data lane requests will be activated once the clock lane is ready, i.e TX\_Ready\_HSCLK is high.

Figure 12-1092 shows timing diagram for data lane activation/deactivation.

**Figure 12-1092. Timing Diagram for Data Lane Activation/Deactivation**

**Table 12-1497. Timing Parameters**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
TLPX	Transmitted length of any Low- Power state period.	50 ns		50 ns
TCLK-PREPARE	Time that the transmitter drives the Clock Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	38 ns	95 ns	38-95 ns
TCLK-PREPARE + TCLK-ZERO	TCLK-PREPARE + time that the transmitter drives the HS-0 state prior to starting the Clock.	300 ns		300 ns
Wakeup Time CL				388-445 ns
TCLK-PRE	Time that the HS clock shall be driven by the transmitter prior to any associated Data Lane beginning the transition from LP to HS mode.	8 UI		12.3 ns

**Table 12-1497. Timing Parameters (continued)**

Parameter	Description	Min	Max	Example 650 Mbps (UI = 1.538 ns)
THS-PREPARE	Time that the transmitter drives the Data Lane LP-00 Line state immediately before the HS-0 Line state starting the HS transmission.	40 ns + 4 × UI	85 ns + 6 × UI	~ 46-95 ns
THS-PREPARE + THS-ZERO	THS-PREPARE + time that the transmitter drives the HS-0 state prior to transmitting the Sync sequence.	145 ns + 10 × UI		160 ns
Wakeup Time DL				~ 270 ns

So the wakeup time values expressed as tx\_byte\_clk (12.3ns) cycles, CL = 36 and CLKPRE + DL = 22.

Figure 12-1093 shows wakeup time timing diagram.

**Figure 12-1093. Wakeup Time Timing Diagram**

Here is the example of the calculation done for the system running at **650 MHz**.

```

if (clk_continuous == TRUE) {
wakeup_time_cl = 0x1;
} else {
wakeup_time_cl = 0x24;
};

wakeup_time_dsi = 0xA; -- from request on VSG to request HS on DL1 (+ 1 for VSG internal cycle)
wakeup_time_dl = 0x14; -- from stop state falling edge to tx_ready rising edge
reg_wakeup_time = wakeup_time_dsi + wakeup_time_cl + wakeup_time_dl + (hs_host_eot × 4 / lane_nb)

```

**Note:** It is not necessary to program all the register values every time because some of them are used only in some modes. For instance, blkline\_event\_pck and blkline\_pulse\_pck are used depending on the way SYNC is generated, and then in pulse mode, there is no need to program blkline\_event\_pck and vice-versa.

#### 12.6.5.7.7.3 VCA Configuration

The VCA setting done in two registers: vid\_vca\_setting\_1 and vid\_vca\_setting\_2. Their programming must respect the following rules:

- vid\_vca\_setting\_1:

- max\_burst\_limit specifies the size of the bigger packet that generates the following sequence RGB + packet + NULL packet + BLK packet; it must be linked with blkeol\_pck (same size minus the smaller NULL packet). It is equal to blkeol\_pck - 6.
  - burst\_lp can be set to 1'b1 if blkeol\_pck > 2 × reg\_wakeup\_time × lane\_number (reg\_wakeup\_time is only specifying the time to go from LP to HS thus need to consider the time to go from HS to LP too).
- vid\_vca\_setting\_2:
  - exact\_burst\_limit: as it specifies (in byte) the payload of the packet that generates a sequence RGB + packet + HFP, it must have the same value as of blkeol\_pck when the DSI link is in burst mode.
  - max\_line\_limit specifies the maximum size of a packet that generates HSS + (HSA + HSE) + packet + NULL packet. It then depends on line\_duration, hsa\_length regardless if the system is using pulse or event synchronizing. Its size is linked to vert\_blanking\_duration.

```

if (sync_pulse_active == 0) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = (blkline_event_pck-6);
};
if (sync_pulse_active == 1) {
-- size of the payload of the inserted packet followed by a NULL pkt
max_line_limit = gen_blkline_pulse_pck-6;

```

Another constraint to respect when using VCA is to ensure that only supported operations are sent from command side when video is active. For instance, no TE should be attempted, because it could break the video stream (TE completion time can be long). Command messages can be inserted into the LP states provided there is sufficient space for the message bytes and any associate bytes for the header and CRC, if a long packet type.

#### 12.6.5.7.7.4 TVG Configuration

The TVG has a single register: tvg\_img\_size that should complies with the following rules against VSG settings:

tvg\_line\_size: must be equal to rgb\_size set for VSG

tvg\_nblne: must be equal to vact\_length set for VSG

The TVG generates a data stream in the same format than the one specified at the output of the VRS. The content of that flow is specified by the following registers:

- Image size - TVG\_LINE\_SIZE[14:0] and TVG\_NBLINE[12:0] registers: Number of bytes per line and number of lines per frame.
- Image kind - TVG\_MODE[1:0] register: Single color, vertical stripes or horizontal stripes.
- Stripe width - TVG\_STRIPE\_SIZE[2:0] register: Significant when a stripe mode is enabled. Possible values are 1, 2, 4, 8, 16, 32, 64 and 128.
- Pixel kind VID\_PIXEL\_MODE[3:0] register: 16 bits RGB, 18 bits RGB, 18 bits loosely RGB, 24 bits RGB, 30 bits RGB or 36 bits RGB.
- Color one - COL1\_GREEN[11:0], COL1\_RED[11:0], COL1\_BLUE[11:0] registers: Color used in single color mode or first color when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant ones are the ones considered.
- Color two - COL2\_GREEN[11:0], COL2\_RED[11:0], COL2\_BLUE[11:0] registers: Color two when in stripe mode. 12 bits per component R/G/B. For formats using fewer bits than 12, the least significant are the one considered.
- Start pulse and stop handshake (+ stop mode) (see TVG\_CTL register).

The Test Video Generator can be programmed to generate a set of test colour patterns based on the display panel that will be used. The panel parameters for horizontal and vertical resolution along with the frame rate and pixel colour depth need to be set based on the datasheet information for the panel.

Figure 12-1094 presents TVG MODE patterns.

**Figure 12-1094. TVG MODE Patterns**

An example of the sequence is as follows:

- Select TVG for video stream generation instead of DPI/SDI 1 interface.
  - IF1\_EN bit to 0 (SDI stall signal at 1) in MCTL\_MAIN\_EN.
- Select video mode for interface 1 in MCTL\_MAIN\_DATA\_CTL.
  - TVG\_SEL bit to 1 in MCTL\_MAIN\_DATA\_CTL register to select stream from TVG.
- Select generated frame format in TVG\_CTL register.
  - Image format (single color, H stripes, V stripes) in TVG\_MODE field.
  - Image color selection in TVG\_COLOR1, TVG\_COLOR1\_BIS, TVG\_COLOR2, VG\_COLOR2\_BIS.
  - Stripes size in TVG\_STRIPE\_SIZE field.
  - Image size in TVG\_IMG\_SIZE register.

**Note:** The TVG settings on active area for the number of lines per frame and number of bytes per line must match VSG settings on active area. Any mismatch will create an error that is detected in the VSG and forces recovery mode in TVG, stopping test frame generation.

- Select TVG stop mode with TVG\_STOPMODE field of TVG\_CTL.
  - TVG video stream generation start/stop controlled by the TVG\_RUN bit in TVG\_CTL register.
  - Polling TVG run status from the TVG\_RUNNING bit in TVG\_STS register is useful when setting TVG\_RUN to 0. TVG video stream generation does not stop the instantaneously (depends on TVG stop mode), so this should be checked to confirm the TVG has stopped.

#### 12.6.5.7.8 DPI To DSI Programming

The DPI interface will normally be driven from a graphics driver that will be configured to match a frame geometry and refresh rate for a panel display. The DPI driver will use the expected refresh rate and geometry for the active and blanking parts of a frame to determine the pixel rate clock. The DSITX controller will then translate this to match the incoming byte information to send across the DSI DPHY link.

A system will always expect the bandwidth of the incoming pixels × BPP to match the transmission of bytes from the DSI DPHY based on the number of active lanes. The relationship of DPI clock to TX byte clock must ideally hold with the following formula:

$$F_{\text{pixel\_clk}} = F_{\text{tx\_byte\_clk}} \times \text{active\_lanes} \times 8 \div \text{bits\_per\_pixel};$$

The DSI will supply packets to the DPHY interface using the internal sequencing and counters clocked from the tx\_byte clock. The normal system operation will mean that the DSI must always have the correct number of tx\_byte clock cycles to match the number of pixel clock cycles. This means that all the events used for the packet generation will be directly impacted by the delay that exists in the DPHY High Speed request to ready.

The DSITX controller relies upon the DPHY PLL being programmed and locked before starting the DPI video. The DSITX controller can then be configured and enabled (clock lane and data lanes) before starting the video transmission.

The DSITX controller will begin data transmission with a High Speed request after it receives the falling edge of the VSYNC on the DPI interface. The controller will then begin to build the bytes for the VSYNC packets (VSS, HSA, Blanking packets) during the delay period before the ready is returned from the DPHY. This delay will add an interval effect on all the packets that follow.

The DPI FIFO size must be sufficient to buffer all the incoming pixel data during the active line stage while the DSITX controller continues to send the previous lines packet information due to this interval effect.

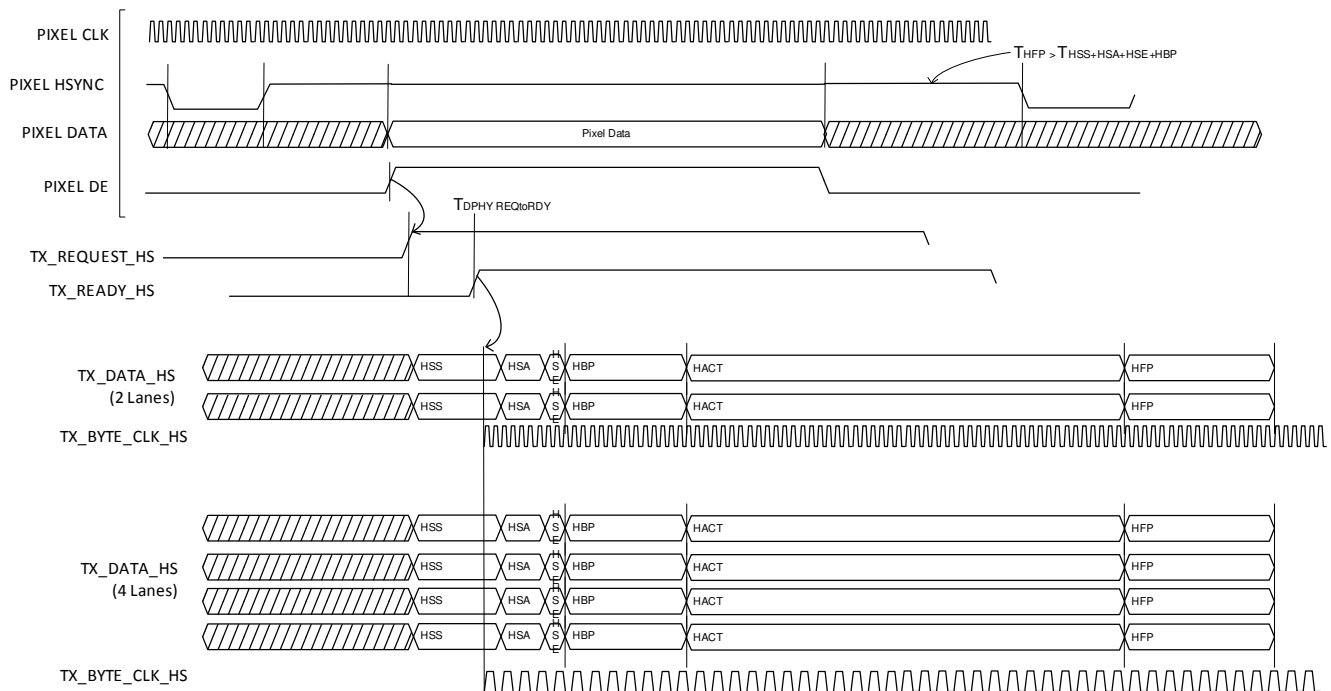

**Figure 12-1095. Timing Diagram**

The DPI and DSI system may not be able to guarantee the exact frequency on the pixel clock input or tx\_byte clock from the DPHY. The DSI configuration can be adjusted to support a small deviation in frequencies using the size of the HFP packet so that it changes the alignment of packets on the active lanes to absorb the different pixel clock cycles during the line. More details are given in section 0.

#### 12.6.5.7.8.1 DSI and DPHY Operation

The DPI FIFO is used to buffer all the active pixel data from the DPI interface during the active line. The depth of the FIFO must be selected to allow the pixel to be stored after the DPHY request to ready delay is introduced at the start of every frame. The FIFO will fill to a depth based on the tx\_byte clock cycles used from the point where VSYNC is identified to the response from the DPHY link after it has exited Low Power and entered the zeroes state on the active data lanes.

Figure 12-1096 presents DPI interface to DSI DPHY timing diagram.

**Figure 12-1096. DPI Interface to DSI DPHY Timing Diagram**

The timing diagram above illustrates how the packets are generated for a DPHY with two and with four lanes activated. The diagram shows that the tx\_byte clock changes based on the number of lanes, and that the configuration register values for the number of bytes used for HSA, HBP and HFP will remain the same.

The register values calculated for each of the line synchronization stages needs to take the number of bytes used to form the packet into account so that the timing for each stage aligns to the timing of the DPI input and most importantly that the total number of bytes exactly matches the number of byte clock cycles. The values used for the Horizontal Front porch must be larger than the combined horizontal sync and back porch to allow the DPI FIFO to empty.

The basic rule is that the values used for the DSI will be based on the  $\text{DPI} \times \text{BPP}/8$ .

The DPI graphics driver must be configured with horizontal values that can be directly translated to DSI packet payloads.

- The minimum values for the DPI HSA must convert to be greater than:
  - Non-Burst Sync Pulses – 15 bytes
  - Non-Burst Sync Events – 11 bytes
- The minimum values for the DPI HBP must convert to be greater than:
  - Non-Burst Sync Pulses – 7 bytes
  - Non-Burst Sync Events – 7 bytes

These values will then form the number of tx\_byte\_clk cycles used to send the bytes over the number of active lanes. So, for an RGB888, DSI configuration the minimum values will be:

- $\text{HSA} = \text{roundup}(15/3) = 5$
- $\text{HBP} = \text{roundup}(11/3) = 4$

The diagram below, D-PHY Timings Control (see [Figure 12-1097](#)), illustrates the byte mapping for a four lane DPHY link. In this example, the calculation for the horizontal sync stage aligns exactly across the four byte lanes.

- HSS – Four Bytes
- HSA – Blank Packet with Header (4) + HSA\_Count + CRC(2)
- HSE – Four Bytes

The next stage is the horizontal back porch:

- HBP – Blank Packet with Header (4) + HBP\_Count + CRC(2)

The value used in the HBP count can be used to account for the Header bytes used in the active data packet in next stage, although it is best to add this to the HFP stage calculation and allow time to empty the FIFO.

**Figure 12-1097. Horizontal Line Packet Timing Diagram**

The Active part of the line will be a fixed size based on the line size and BPP, and include the six bytes for the packet header and CRC. The final stage is the horizontal front porch.

- HFP – Blank Packet with Header (4) + HFP\_Count + CRC(2)

The HFP value should be adjusted to ensure that the number of tx\_byte clock cycles for the horizontal line exactly matches the pixel clock cycles for the line times the BPP.

The timing diagram below, Control Block, illustrates the byte alignment changing when the HBP calculated is two bytes shorter than the previous case. This leads to the active and front porch packet headers beginning two bytes earlier, however the HFP count is adjusted to keep the end of the line on exactly the same tx\_byte\_clk cycle count.

**Figure 12-1098. Horizontal Line Packet - Shorter HBP - Longer HFP Timing Diagram**

The recommendation is to ensure that the total bytes for each horizontal line results in an exact integer tx\_byte clock cycles (Total\_bytes MOD num\_of\_lanes = zero), except for the case where the clocks are not exactly matched.

#### 12.6.5.7.8.2 Pixel Clock to TX\_BYTE\_CLK Variation

The selection of the Pixel clock rate and DPHY Bit clock rate should ideally match based on the ratio of bpp on the pixel side compared to the tx\_byte\_clk. The timing for the horizontal sync, back and front porch will also be configured to allow the pixel data to be transferred without any over or underflow of the DPI FIFO.

The DPI FIFO fill level register (DPI\_CFG) can be used to track that the parameters are sufficient and that any clock variation can still be handled by the FIFO depth. This register will show the pixel data held in the buffer, so during the HSA and HBP packet generation stages DPI pixel data will be stored and this value will increment. Once the data packet is being generated, the DPI\_CFG level will remain constant, as the buffer is emptied at the same bandwidth as it is filled. Finally, the value will reduce to zero during the HFP stage.

The packet length of the HFP can be adjusted to help absorb small differences in the pixel\_clk to tx\_byte\_clk relationship. The DSITX controller will concatenate all of the packets during High Speed transmission, so for example adding to the byte value of the HFP will make the bytes at the end of the packet move to align on another lane.

The packets that follow will then be concatenated and aligned to the next available lane, so if the tx\_byte\_clk is faster than the expected pixel clock times bpp the extra byte will delay the start of the new line tx\_byte\_clk × extra\_byte/lanes.

Figure 12-1099, Video coherency, illustrates the impact of increasing the HFP by one byte so that the next line begins ¼ tx\_byte clock later. This allows averaging out across the line length of small differences in the pixel to tx\_byte clocks when the tx\_byte clock is not ideally matched to the expected pixel clock multiplied by bpp.

dsi\_spruij7-030

**Figure 12-1099. Packet Alignment Control Using HFP Byte Increase - tx\_byte\_clk Faster than Ideal Rate**

The DPI\_CFG register will show any clock misalignment as an increasing/decreasing value for the FIFO fill level on each line of pixels (must be read mid-line for an accurate reading of the level). When the byte count adjustment is made, the DPI\_CFG register will return to the original fill level value every four lines.

#### 12.6.5.7.8.3 LP Operation

The DSITX controller can be configured to perform a transition between LP state and HS state during the horizontal lines which have long periods of blanking. The registers controlling the timing for the DPHY wakeup time and the reg\_line\_duration must be programmed to exactly match the DPI cycles of the horizontal line to the tx\_byte\_clk cycles required for the number of active lanes selected.

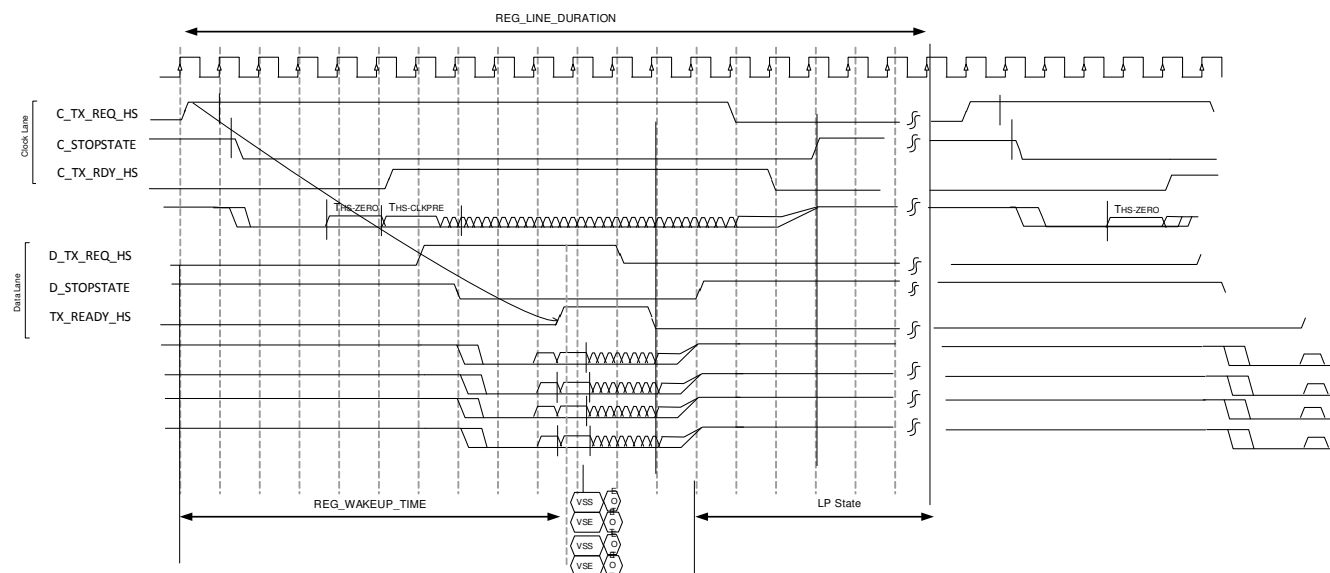

**Figure 12-1100. Low Power Operation with Four and Two Active Lanes**

The LP operation for each vertical blanking line will require the reg\_line\_duration to be configured to match the following:

- Max\_line\_length (in tx\_byte\_clk cycles see 2.2.4) minus Eot (if enabled), also minus further 10 if CLOCK lane is non-continuous.

Note REG\_WAKEUP\_TIME is used internally to adjust the cycles for each vertical LP line.

**Figure 12-1101. REG\_LINE\_DURATION Timing Example for LP Operation**

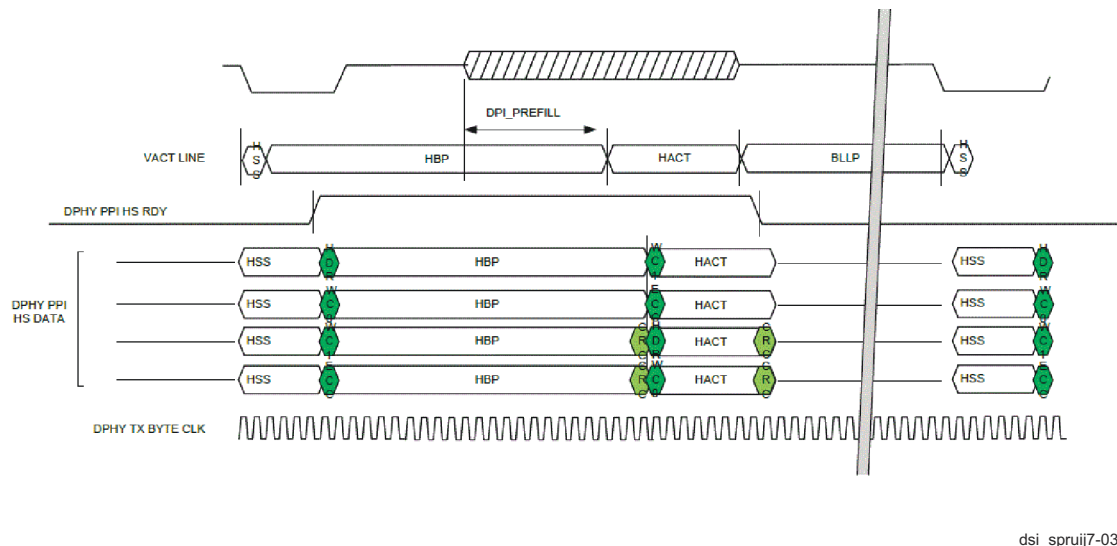

#### 12.6.5.7.8.4 DPI Interface Burst Operation

The DSITX controller can support burst operation on the DPI interface provided the DPI FIFO size is large enough to store the line pixel data with enough data to not underflow. The burst operation will use a tx\_byte\_clk that is faster than normal event based operation, so the DPI FIFO size will be impacted by the ratio of the pixel\_clk and BPP input to the tx\_byte\_clk and number of lanes on the output.

The recommended operation is to set the DSI HSA and DSI HFP registers to zero, and adjust the DSI HBP size to control the number of bytes prefilled in the DPI FIFO before the burst is sent.

Figure 12-1102 shows DPI operation with event burst mode.

**Figure 12-1102. DPI Operation with Event Burst Mode**

#### 12.6.5.7.9 Programming the DSITX Controller to Match the Incoming DPI Stream

The time taken to output a frame on the PPI needs to match what is coming in on the DPI. This is best achieved by using the recommended clock ratio between the pixel and byte clocks. Assuming that is the case, then the blanking and active data periods must be matched up.

For each frame of video the time will be:

$$(V_{\text{total}} * H_{\text{total}})_{\text{@pixel\_clk}} = (V_{\text{total}} * H_{\text{total}})_{\text{@tx\_byte\_clk}} \times \text{bits\_per\_pixel}/8;$$

So for example, the time for a full HD frame 1920x1080 with reduced blanking in RGB565 will be:

$$2200 \times 1200 \text{ pixels} = 2200 \times 1200 \text{ tx\_bytes} \times 16/8;$$

The DSITX controller will slave its frame timing to the incoming DPI vsync, as long as it is programmed to generate a frame of slightly less than the same size when the VFP blanking is considered. The controller works by transitioning to LP during the last programmed line of VFP. It will then remain in LP until the start of the next frame. So programming the controller to match the DPI, but with at least one fewer line of VFP should result in a reliable configuration.

##### 12.6.5.7.9.1 Vertical Timing

The DSITX controller will generate vertical packets for each part of the frame beginning with the VSS and VSE combined with blanking packets to fill the VSA. The blanking packets for the pulse mode program the DSI vertical size registers as follows:

- VSA = DPI\_VSI (lines, minimum of 2 → VSS and VSE)
- VBP = DPI\_VBP (lines, minimum of 0)
- VACT = DPI\_VACT (lines)
- VFP < DPI\_VFP (minimum of 1)

DPI horizontal timing is measured in pixel clocks, whereas the DSITX controller uses byte clocks. The horizontal timing should also be matched per line; therefore the blanking and active periods of each line should match. The relationship therefore depends upon the pixel format, which could be 24, 18 or 16 bpp. The timing for a horizontal line for the DPI driver side will be the number of pixel cycles for the **HLINE** = (HSA + HBP + HACT +

HFP) and this will form **HLINE** × bpp/8 bytes for the controller. These bytes will then be sent using 1, 2, 3 or 4 data lanes, so the DSITX controller will required 1, 1/2, 1/3, 1/4 this number of tx\_byte\_clk cycles respectively.

e.g a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line.

This gives the DSI horizontal lines 3936 bytes to transmit and would use 984 tx\_byte\_clks on a four lane system, or 1312 on a three lane system etc..

The horizontal configuration uses different registers depending on the Mode (Pulse or Event) and the control of the BLKLINE\_MODE register bit.

- Non-Burst Mode with Sync Pulses – enables the peripheral to accurately reconstruct original video timing, including sync pulse widths.

Note that for accurate reconstruction of timing, packet overhead including Data ID, ECC, and Checksum bytes should be taken into consideration.

- Non-Burst Mode with Sync Events – similar to above, but accurate reconstruction of sync pulse widths is not required, so a single Sync Event is substituted.
- Burst mode – RGB pixel packets (active video) portion are time-compressed, leaving more time during a scan line for LP mode (saving power) or for multiplexing other transmissions onto the DSI link.

dsi-034

**Figure 12-1103. Vertical Timing**

#### 12.6.5.7.9.2 Horizontal Timing for Non-Burst Mode with Sync Pulses

Sync Pulse Mode uses the Short packet and Long packet structures to accurately track the DPI interface timing. Figure 12-1104 illustrates the packet sequence for a single frame.

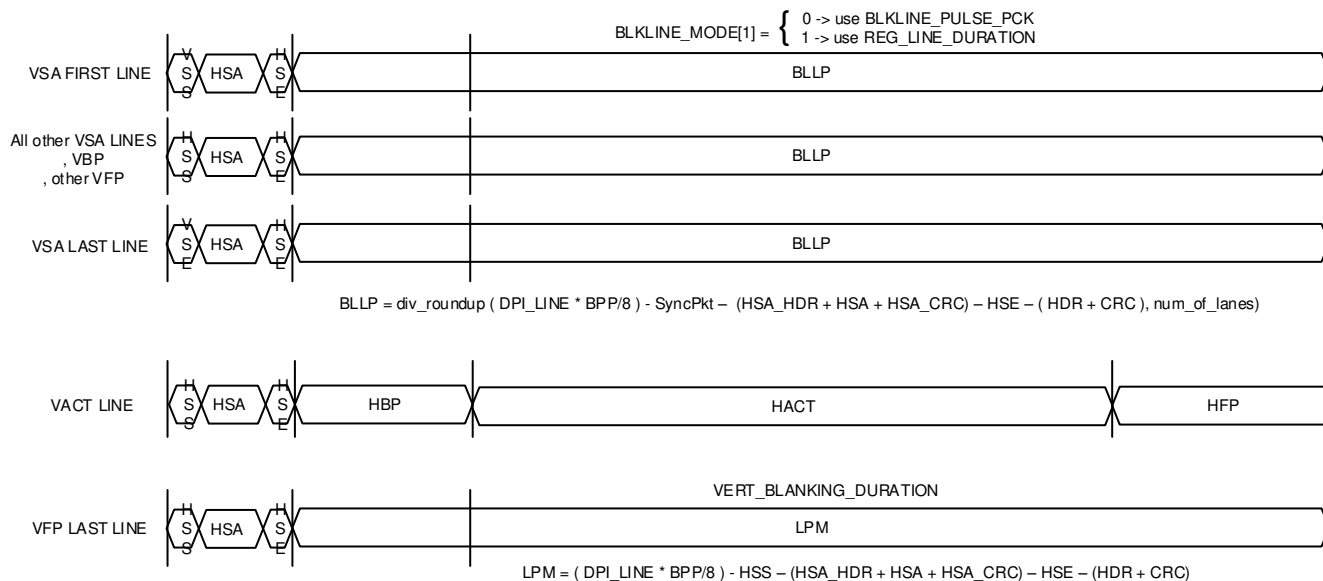

dsi-035

**Figure 12-1104. Vertical Timing**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, Trigger Mapping Information. The calculation of the total number of bytes in any horizontal line must always be  $\text{HLINE} \times \text{bpp}/8$  bytes.

**Figure 12-1105. Non-Burst Mode With Sync Pulse Line Structures**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- HSA should be reduced by 14 bytes to account for the HSS short packet (4 bytes), the long blanking packet header and CRC footer (4 + 2 bytes) and the HSE short packet (4 bytes).
- HBP should be reduced by 12 to account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes).
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.

Finally for lines with no active data, the controller will use either:

- **BLKLINE\_PULSE\_PCK**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in bytes minus the HSA 20 bytes (14 for HSA header and CRC, 6 for the remaining blanking which is all combined into a single packet).
- **REG\_LINE\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) minus the EOT packet (4 bytes) if required, divided by number of lanes). This should be aligned to the number of active lane so rounding the value so that  $REG\_LINE\_DURATION \bmod \text{Lanes}$  equals zero.
- **VERT\_BLANKING\_DURATION**: Total line size ( $H_{LINE} \times \text{bpp}/8$ ) in tx\_byte\_clk cycles minus the calculated HSA in tx\_byte\_clk cycles ( $HSA \times \text{bpp}/8$  minus 14 bytes (14 for HSA header and CRC) divided by number of lanes).

Program the DSI horizontal size registers as follows:

burst\_mode = 0 and sync\_pulse\_active = sync\_pulse\_horizontal = 1;

$HSA = (DPI\_HSA \times \text{bpp}/8) - 14$  – DPI HSA min value 5 for RGB888

$HBP = (DPI\_HBP \times \text{bpp}/8) - 12$  – DPI HBP min value 5 for RGB888

$HACT = (DPI\_HACT \times \text{bpp}/8)$

$HFP = (DPI\_HFP \times \text{bpp}/8) - 6$  – DPI HFP min value 10 for RGB888

**Note:**  $(DPI\_HACT \times \text{bpp}/32)$  must be an integer. Total Line Length =  $\text{div\_roundup}((H_{LINE} \times \text{bpp}/8), \text{num of lanes})$ ;

$(BLKLINE\_PULSE\_PCK) \text{ bytes} = (H_{LINE} \times \text{bpp}/8) - 20 - HSA$ ;

$(REG\_LINE\_DURATION)_{tx\_byte\_clks} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

$(VERT\_BLANKING\_DURATION)_{tx\_byte\_clks} = \text{Total Line Length} - \text{div\_roundup}((HSA \times \text{bpp}/8) - 14, \text{number of lanes})$ ;

For example; a DPI with  $HSA = 12$ ,  $HBP = 12$ ,  $HACT = 1920$ ,  $HFP = 24$  and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI  $H_{LINE}$  of 3936 bytes. So for 4 lanes, 984 tx\_byte\_clk cycles;

$HSA = (12 \times 16/8) - 14 = 10$

$HBP = (12 \times 16/8) - 12 = 12$

$HACT = (1920 \times 16/8) = 3840$

$HFP = (24 \times 16/8) - 6 = 42$

Total Line =  $\text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984 \text{ tx\_byte\_clk cycles} = 3936 \text{ bytes}$ ;

$BLKLINE\_PULSE\_PCK = (3936) - 20 - 10 = 3906$

$REG\_LINE\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

$VERT\_BLANKING\_DURATION = 984 - \text{div\_roundup}(12 \times 2, 4) = 978$

Confirming the calculation for each line with  $BLKLINE\_MODE = 0$ ;

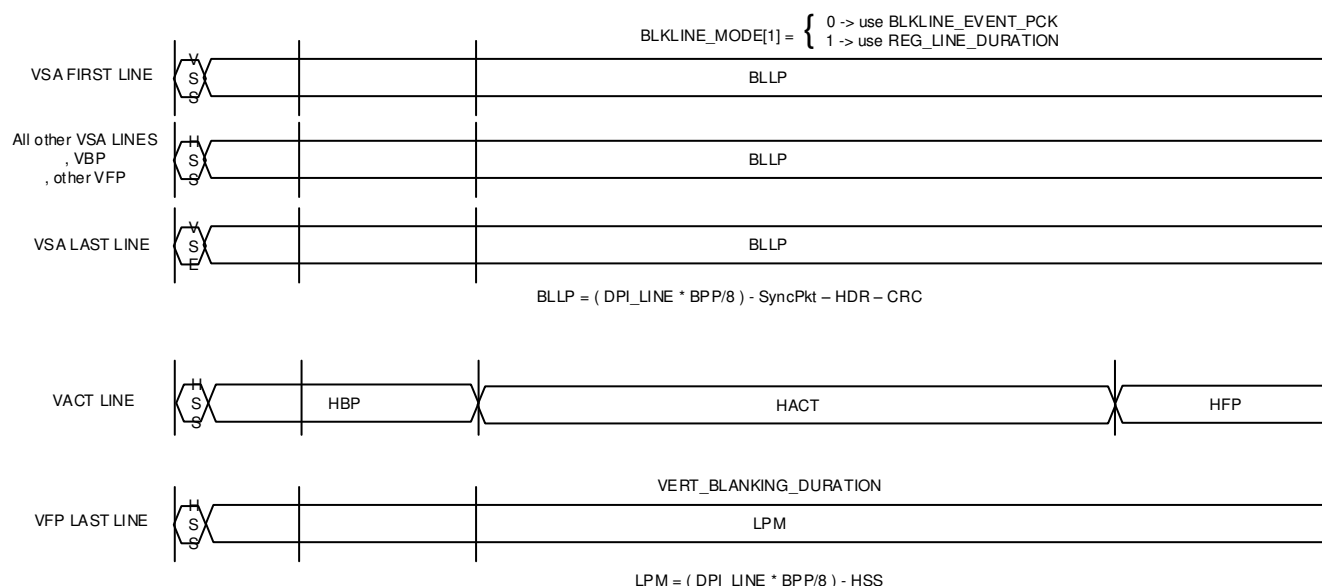

$VSS = VSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSA_{Line} = HSSPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VSE = VSEPkt + HSAPkt + HSEPkt + BLK\_LINE\_PULSE\_PCKPkt = 4 + (4 + 10 + 2) + 4 + (4 + 3906 + 2) = 3936$ ;

$VACT = HSSPkt + HSAPkt + HSEPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 10 + 2) + 4 + (4 + 12 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936$ ;

**Figure 12-1107. Horizontal Timing - 1**

The DSI short packets and packet headers that are inserted by the controller must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header on the active data packet (2 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet.
- HFP should be reduced by 6 bytes to account for the long packet header and CRC footer and footer of the active data.

Finally, for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK: Total line size (HLINE \* bpp/8) in bytes minus 10 bytes (4 for VSS/VSE/HSS, 6 for the remaining blanking header/footer which is all combined into a single packet).
- REG\_LINE\_DURATION: Total line size div\_roundup(HLINE \* bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 8 bytes (4 for VSS/VSE/HSS, and 4 for EOT). This should be aligned to the number of active lane so round the value so that REG\_LINE\_DURATION MOD Lanes equals zero.
- VERT\_BLANKING\_DURATION: Total line size div\_roundup(HLINE \* bpp/8, num\_of\_lanes) in tx\_byte\_clk cycles minus tx\_byte cycles for the 4 bytes (4 for HSS).

Program the DSI horizontal size registers as follows:

burst\_mode = 0 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = ((DPI\_HSA + DPI\_HBP) \* bpp/8) - 12 - DPI HSA + HBP min value 5 for RGB888
- HACT = (DPI\_HACT \* bpp/8)
- HFP = (DPI\_HFP \* bpp/8) - 6 - DPI HFP min value 10 for RGB888

**Note:** (DPI\_HACT \* bpp/32) must be an integer. Total Line Length = div\_roundup((HLINE \* bpp/8), num of lanes).

(BLKLINE\_EVENT\_PCK) bytes} = (HLINE \* bpp/8) - 10

(REG\_LINE\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(8, number of lanes)

(VERT\_BLANKING\_DURATION) tx\_byteclks} = Total Line Length - div\_roundup(4, number of lanes)

For example: a DPI with HSA = 12, HBP = 12, HACT = 1920, HFP = 24 and 16bpp will be 1968 pixel clocks for each horizontal line. This give each DSI HLINE of 3936 bytes.

HSA = 0

$$HBP = ((12 + 12) \times 16/8) - 12 = 24$$

$$HACT = (1920 \times 16/8) = 3840$$

$$HFP = (24 \times 16/8) - 6 = 42$$

$$\text{Total Line} = \text{div\_roundup}((12 + 12 + 1920 + 24) \times 16/8, 4) = 984$$

$$\text{BLKLINE\_EVENT\_PCK} = (\text{HLIN} \times \text{bpp}/8) - 10 = 981$$

$$\text{REG\_LINE\_DURATION} = 984 - \text{div\_roundup}(8, 4) = 982$$

$$\text{VERT\_BLANKING\_DURATION} = 984 - \text{div\_roundup}(4, 4) = 983$$

Confirming the calculation for each line:

$$VSS = VSSPkt + \text{BLK\_LINE\_EVENT\_PCK}Pkt = 4 + (4 + 3926 + 2) = 3936$$

$$VSAline = HSSPkt + \text{BLK\_LINE\_EVENT\_PCK}Pkt = 4 + (4 + 3926 + 2) = 3936$$

$$VSE = VSEPkt + \text{BLK\_LINE\_EVENT\_PCK}Pkt = 4 + (4 + 3926 + 2) = 3936$$

$$VACT = HSSPkt + HBPPkt + HACTPkt + HFPPkt = 4 + (4 + 24 + 2) + (4 + 3840 + 2) + (4 + 42 + 2) = 3936$$

$$VFP = HSSPkt + \text{BLK\_LINE\_EVENT\_PCK}Pkt = 4 + (4 + 3926 + 2) = 3936$$

$$VFPLast = HSSPkt + \text{VERT\_BLANKING\_DURATION} = 4 + (983 \times 4) = 3936$$

#### 12.6.5.7.9.4 Burst Event Mode Horizontal Timing

Burst Event Mode uses the Short packet and Long packet structures to transmit the video information in short bursts and allow the system to use the Low Power states to save active power. This can only be supported with DSITX controllers able to store a horizontal line in the DPI FIFO. The burst mode will expect the tx\_byte\_clk to be twice the rate of the non burst event mode, and the register calculation will expect the total bytes for each line to double. [Figure 12-1108](#) illustrates the packet sequence for a single frame.

**Figure 12-1108. Burst Event Mode Horizontal Timing - 1**

The DSITX controller registers for this mode are used to generate the exact number of bytes required for each horizontal line based on the DPI line configuration and the BPP for the colour pixel data.

The packet structure for each type of line during the frame is shown below, with the DSI HFP = 0 to select BLLP operation.

ds\_i\_spruij7-040

**Figure 12-1109. Burst Event Mode Horizontal Timing - 2**

The DSI short packets and packet headers that are inserted by the controller for active lines must be accounted for:

- VSS/VSE/HSS short packet (4 bytes).
- HBP should account for the header and footer on the blanking packet (6 bytes) plus the header/footer on the active data packet (6 bytes). This will match the DPI\_HSA + DPI\_HBP minus the Sync Short packet. In this case the DPI must also reduce the HSA and HFP timing.
- BLLP uses BLKEOL\_PCK or BLKEOL\_DURATION and will change depending on the HFP use case:
  - HFP can be zero to extend the BLKEOL\_x values (recommended).
  - or a non-zero value to transmit a Blanking Packet instead of LP state. The Blanking Packet HFP should be reduced by 6 bytes to account for the long packet header and CRC footer.
  - The host\_eot state will cause the BLLP to either add and EOT cycle or not. The BLKEOL\_PCK or BLKEOL\_DURATION value will need to be adjusted to include this extra cycle if host\_eot is disabled.

Finally for lines with no active data, the controller will use either:

- BLKLINE\_EVENT\_PCK in bytes, excluding the header and crc.
- REG\_LINE\_DURATION or VERT\_BLANKING\_DURATION.
- Both are the total expected tx\_byte\_clk cycle for the line minus the number of cycles required to send the header packet bytes (4 for VSS/VSE/HSS) over the active lanes.

Program the DSI horizontal size registers as follows:

burst\_mode = 1 and sync\_pulse\_active = sync\_pulse\_horizontal = 0;

- HSA = 0
- HBP = (2 \* (DPI\_HSA + DPI\_HBP) \* bpp/8) - 12 + DPI FIFO Prefill
- HACT = (DPI\_HACT \* bpp/8) NOTE: (DPI\_HACT \* bpp/32) must be an integer.
- HFP = Zero

Total Line Length = div\_roundup((HLINE \* bpp/8), num of lanes);

{BLKLINE\_EVENT\_PCK} = (HLINE \* bpp/8) \* 2 - 4

$(\text{REG\_LINE\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{VERT\_BLANKING\_DURATION})\} = \text{Total Line Length} \times 2 - \text{div\_roundup}(4, \text{number of lanes})$

$(\text{BLKEOL\_DURATION})\} = \text{Total Line Length} \times 2 - \text{TX\_BYTE\_CYCLES}$

$(\text{BLKEOL\_PCK}) \text{ bytes} = \text{Total Line Length} \times 2 - (\text{HACT} + \text{HBP} + \text{HSS})$

**Note:**  $\text{TX\_BYTE\_CYCLES} = \text{TX Byte clock cycles to send Active Line bytes on the number of active lanes} = \text{div\_roundup}(\text{HBP} + \text{HACT}, \text{number of lanes})$ .

### Burst Operation Frame Configuration

Burst mode operation can be used to save power provided the system configuration can support the higher tx\_byte clock rate. The user should consider if the power saving during LP states is more than reducing the number of active lanes and running in non-burst mode.

The burst mode can only be used if the controller configuration can support it; either using SDI video interface, of DPI interface with a buffer size large enough to prefill the data. The video driver timing from the DPI side will also need to be changed.

ds\_i\_spruij7-041

**Figure 12-1110. DSITX Controller Video Frames for Burst Mode Compared with DPI Driver Side**

For example:

The VESA configuration for a 1920x1200 frame at 60-frames per second with normal blanking would have a pixel clock at 193.25 MHz, HSA 200 pixels, HBP 336 pixels, HFP 136 pixels and total line 2592 pixels. This would need to be reconfigured to move the active area earlier in the horizontal line for the DSITX controller, so could be changed to; HSA 20 pixels, HBP 30 pixels, HFP 622 pixels. This would allow the HFP LP state to be almost  $\frac{1}{4}$  of the line ( $622/2592$ ).

#### 12.6.5.7.9.5 Burst Mode Operation

The DSI IP offers different options for behavior in the BLLP areas:

- Insertion of blanking or null packets.
- Switch to LP (power saving).
- Insertion of commands (if any) + blanking or null packet.

Figure 12-1111 shows burst mode operation.

**Figure 12-1111. Burst Mode Operation**

The user should balance the increase in the clock frequencies for transmission of the active display, against the power saving by using BLLP(Null) or LP state.

For Burst with the LP state the register fields must be programmed for `burst_lp = 1` and `reg_blkeol_mode = 2'b2`.

### Command Insertion Operation

The DSITX can use the burst operation to allow the blanking/LP stages to be used for DCS/GEN command insertion by programming the size of the space available after the sync of each line.

Only one command packet can be passed within each video line. The decision to insert a command in a video line is done at the beginning of the slot just after the previous video packet. If a command arrives in the middle of the slot, it is not processed in that line, the decision to accept the command will be taken in the next line.

If the packet does not fit in a short slot (size bigger than `reg_max_burst_limit` and not equal to `reg_exact_burst_limit`), it is delayed up to next long slot. The signal `reg_err_burstwrite` is flagged (it is only an information that can help application software control). If its length is longer than `reg_max_line_limit`, it is discarded and the error `reg_err_linewrite` is generated.

Read commands and BTA requests are only passed during long slots, as there is no way to calculate their duration exactly. In the case where their duration takes longer time than the vertical blanking period, the error `reg_err_longread` is flagged.

**Figure 12-1112. Burst Mode Command Locations During Video Frame**

### Command Insertion Registers in Burst Operation

The burst operation requires the configuraton of the registers to control the size of the packets that will fit in the space available on each type of horizontal line.

In VSA, VBP or VFP: Insertion of short and long command packets, read or BTA are allowed.

ds1-045

- In VACT: Only short packets can be inserted.
- Command, if inserted, is inserted right after the HSA or HSE or the video packet.
- Only one command can be inserted by line.

- When a command is inserted on a video line, no switch to LP but Null packet insertion.
- Trigger and TE insertion not supported.

VID\_VCA\_SETTING1 register:

[16] BURST\_LP: After an active line, in burst mode, the system can switch in LP (1) or should complete the line with NULL packet (0).

VID\_VCA\_SETTING1 register:

[15:0] MAX\_BURST\_LIMIT: Maximum length of a packet (number of bytes) that can be passed during the blanking period at the end of an active line (in burst mode) followed by a NULL packet with no data (6 bytes).

VID\_VCA\_SETTING2 register:

[15:0] EXACT\_BURST\_LIMIT: Exact maximum size of the burst packet (packet that fits after pixel data in burst mode), that is with no Null packet insertion afterwards.

VID\_VCA\_SETTING2 register:

[31:16] MAX\_LINE\_LIMIT: The "maximum" packet (number of bytes) that can be passed during the vertical blanking period.

If the packet does not fit in a short slot (size bigger than MAX\_BURST\_LIMIT and not equal to EXACT\_BURST\_LIMIT), it is delayed up to next long slot.

- If the packet length is longer than MAX\_LINE\_LIMIT, it is thrown away (an error is asserted).

[Table 12-1498](#) outlines the expected behaviour of each packet type during the video frame.

**Table 12-1498. Behavior of the DSITX Transmission when Both Video and Command are Running**

Packet type	Packet Size	Behavior	Error Flagged
VACT Active Line - Read and BTA do not pass			
No packet	-	LP mode null packet sent	
Short packet		Packet passed followed by a null packet	
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	

**Table 12-1498. Behavior of the DSITX Transmission when Both Video and Command are Running  
(continued)**

Packet type	Packet Size	Behavior	Error Flagged
Long packet	size = reg_exact_burst_limit	Packet passed	
Long packet	reg_max_burst_limit < size < reg_exact_burst_limit	Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Long packet	reg_exact_burst_limit < size <= reg_max_line_limit	packet is delayed to non-active part of frame: Packet delayed, LP mode packet delayed, null packet sent	Burstwrite Burstwrite
Packet type	Packet Size	Behavior	Error Flagged
Long packet	size > reg_max_line_limit	Packet thrown, LP mode packet thrown, null packet sent	Linewrite Linewrite
Read packet	-	Packet delayed, LP mode Packet delayed, null packet sent	-
BTA request	-	Packet delayed, LP mode Packet delayed, null packet sent	-
VSA, VBP, VFP - Long packet, read and BTA can be passed			
No packet	-	LP mode	-
Short packet	-	Packet passed followed by a null packet	-
Long packet	size < reg_max_burst_limit	Packet passed followed by a null packet	
Long packet	size > reg_exact_burst_limit	packet thrown, LP mode	Linewrite
Read packet	read completed (direction) before end of slot	Packet passed	
Read packet	read not completed (direction) before end of slot	Packet passed	Longread If operation lasts too long
BTA request	-	Packet passed	Longread If operation lasts too long

Note that for burst operation with Low Power, the command will be sent as a high-speed packet even if the request is made to send as Low Power. Also, the next active line will return to using LP during the HFP phase if no other commands are requested.

#### 12.6.5.7.9.6 Example Configurations

1. Here is an example for a VGA frame with 24bpp @60fps using non burst pulse sync mode: With blanking, total size 500 lines, each line is 800 pixels.

400000 DPI cycles/frame @ 24 MHz pixel clock <=> 300000 DSI cycles/frame @ 18 MHz byte clock;

800 DPI cycles/line @ 24 MHz <=> 600 DSI cycles/line @ 18 MHz;

**Table 12-1499. DPI and DSI Parameters - 1**

Parameter	DPI	DSI
VSA	5	5
VBP	5	5
VACT	480	480

**Table 12-1499. DPI and DSI Parameters - 1 (continued)**

Parameter	DPI	DSI
VFP	10	5
HSA	40	106 (120-14)
HBP	40	108 (120-12)
HACT	640	1920
HFP	80	234 (240-6)
HTOTAL	800 pixel cycles	2400 bytes

burst\_mode = 0

sync\_pulse\_active = 1

sync\_pulse\_horizontal = 1

BLKLINE\_PULSE\_PCK = 2380 (2400-20)

REG\_LINE\_DURATION = 2380

VERT\_BLANKING\_DURATION = 2384

**Note:** The controller will send 4 VFP lines then transition to LP for the duration equivalent to 6 lines.

2. Here are some example values for a 24fps UHD frame size with 24bpp using non-burst event mode: With blanking, total size 2250 lines, each line is 4000 pixels.

9000000 DPI cycles/frame @ 216 MHz pixel clock <-> 6750000 DSI cycles/frame @ 162 MHz byte clock

4000 DPI cycles/line @ 216 MHz <-> 3000 DSI cycles/line @ 162 MHz

**Table 12-1500. DPI and DSI Parameters - 2**

Parameter	DPI	DSI
VSA	2	2
VBP	0	0
VACT	2160	2160
VFP	40	1
HSA	40	0
HBP	40	228 (120 + 120 - 12)
HACT	3840	11520
HFP	80	234 (240 - 6)
HTOTAL	4000	12000

burst\_mode = 0

sync\_pulse\_active = 0

sync\_pulse\_horizontal = 0

BLKLINE\_EVENT\_PCK = 11990 (12000-10)

REG\_LINE\_DURATION = 11990

VERT\_BLANKING\_DURATION = 11996

**Note:** After the active data the controller will transition immediately to LP for the duration equivalent to 88 lines, giving the maximum power saving between lines.

If any of the DPI related interrupts are triggered, then this highlights that the FIFO depth and/or the vsync\_delay settings require to be tuned to the current configuration. Simulating the core operation with the expected clocks is the best way to ensure.

#### 12.6.5.7.9.7 Stereoscopic Video Support

The DSI controller can support stereoscopic display format (SDF) using both command and video modes.

- Command Mode
  - APB Direct Command 3D Commands – Use get\_3D\_control with Read
  - SDI Command Mode – DCS Writes
- Video Mode – Single Link Operation
  - VSYNC Parameter1 Definition (L/R, Mode, Format)
  - SDI Video Mode
  - DPI Video Mode – Video stream will expect to follow expected format; frame, line, pixel
    - 3DVSNC = 0 not currently supported.

The DSI must be configured to enable the 3D operation and identify the format that is being used using the register control to enable the 3D features and the configuration that matches the video stream from the system.

The SDF format requires the system to provide frame and synchronisation information using the two parameter fields within the vertical sync short packet (VSS).

Configured the DSI mctl\_3dvideo\_ctl register to match format – L/R Pixel, L/R Line, L/R Frame Drive video stream based on orientation and format.

**Note:** DSI Controller will not perform any on-the-fly pixel manipulation for L-R ordering.

#### Example Video Operation

For a 3D video stream where the DSI video is given the combined images as one continuous large frame, the VSYNC packet would identify that the left image is sent first, it is a line based format and in landscape mode (see [Table 12-1501](#)).

**Table 12-1501. Example Video Operation**

Position	D7	D6	D5	D4	D3	D2	D1	D0
Value	0	0	0	0	0	0	1	0
Description	Rsvd	Rsvd	Left First	No Sync	Line-based		Landscape	

mctl\_3dvideo\_ctl (0x20)

**Table 12-1502. VSYNC Parameter 1**

[7]	vid_vsync_3d_en	1
[5]	vid_vsync_3d_lr	0
[4]	vid_vsync_3d_second_en	1
[3:2]	vid_vsync_3dformat	00
[1:0]	vid_vsync_3dmode	10

The video stream would then be configured in the DSI to be twice the line length of the normal image.

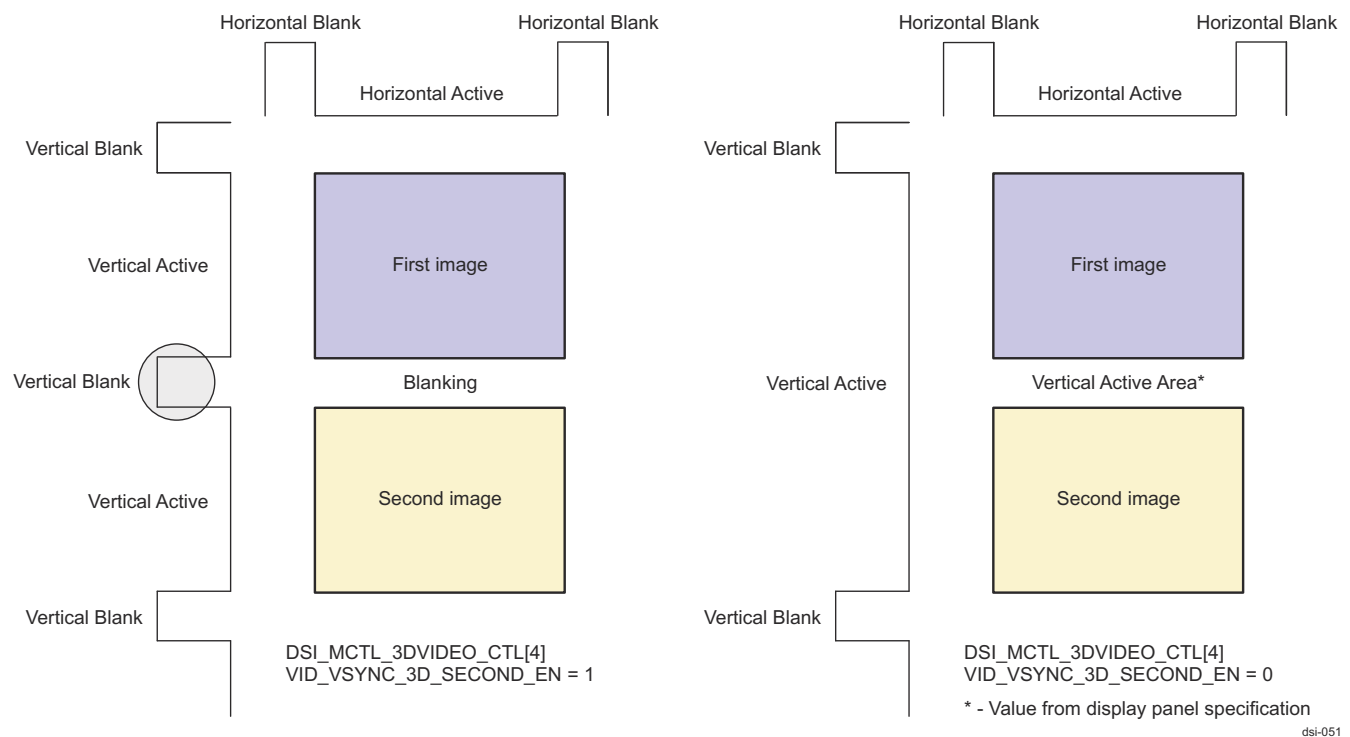

dsi\_spruij7-050

**Figure 12-1113. Example DPI Image Format for SDF Combining Left And Right Pixels**

**Note:** The vertical operation DSI controller will expect the system to provide the left and right as two individual frames with SYNC to allow the blanking to be generated. The DSI does not insert the vertical blanking area when VSYNC = 0.

dsi-051

**Figure 12-1114. 3D Image format for 3DVSYNC splitting first and second images**

#### 12.6.5.7.10 DSITX Video Stream Variable Refresh

The DSITX Controller can be programmed to allow the video stream sequence from a video source to halt between frames and enter Low Power state. The DPI video stream can halt before the new VSYNC is sent and remain in this state until the host video system wants to begin transmitting the new frame.

The DSITX will not perform the normal frame recovery mechanism when this is enabled, however it will continue to recover from line errors until the end of the frame.

**Table 12-1503. DSITX Video Stream Variable Refresh**

Variable refresh rate operation enable control	Configures how the video generation timing is controlled.0, 1 DPI mode operation supports = 1 (enabled). For SDI operation, this parameter can optionally be set to FALSE (= 0) when the system clock and tx_byte_clk are generated from the same reference clock source, or TRUE to allow variable refresh rate control.
--	--

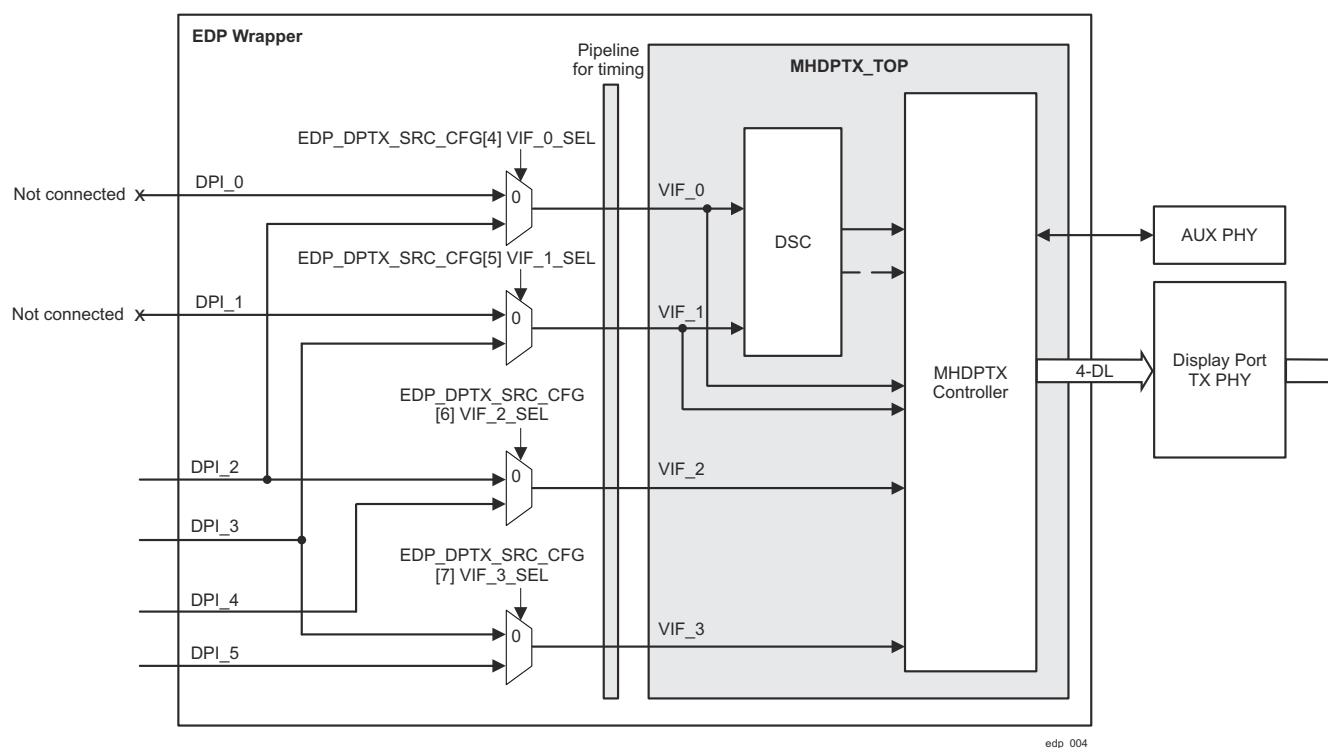

**Table 12-1504. EDP Wrapper DPI Interface Signals**

Signal Name <sup>(1)</sup>	Direction	Default Value	Description
dpi_n_data[47:0]	Input	48'd0	Pixel Data
dpi_n_m_mdata[47:0]	Input	48'd0	Master Meta Data Only bit [10] secure mode bit is used
dpi_n_de	Input	1'd0	Data Enable (active high)
dpi_n_vs	Input	1'd0	Start of frame or Vsync (active low)
dpi_n_hs	Input	1'd0	Start of line or Hsync (active low)

(1) n = 0 to 5

Figure 12-1116 shows the DPI data mapping to VIF ports via muxing in the EDP wrapper.

**Figure 12-1116. DP Wrapper DPI Data Muxing and VIF Mapping**

The following data stream transport modes are supported by the DPI data mapping to VIF ports:

**SST Mode (Single Stream Transport) – VIF0 used**

- DPI\_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI\_2/DPI\_3 - Split Panel Dual Inputs (for DSC compression only) mapped to VIF0 (via DSC) (see Note 1)

**MST Mode (Multi-Stream Transport) – All VIFs used**

- DPI\_2 - Single Panel Input (optional DSC compression) mapped to VIF0
- DPI\_3 - Single Panel Input (optional DSC compression in dual panel mode) mapped to VIF1 (see Note 2 and Note 3)
- DPI\_2/DPI\_3 - Split Panel Dual Inputs (for DSC compression only - two L/R streams compressed separately but outputs combined as one stream) with compressed output mapped to VIF0 (via DSC)
- DPI\_2 or DPI\_4 - Single Panel Input (no DSC compression) mapped to VIF2
- DPI\_3 or DPI\_5 - Single Panel Input (no DSC compression) mapped to VIF3

Notes:

1. DSC can be enabled to perform compression on a single input stream as Left and Right panel data for high resolution video (pixel clock > ~400 MHz) that cannot be compressed with a single DSC encoder. In this mode, two input streams share the same video timing (vs/hs/de) and identical input pixel clocks. This mode is referred to as **"split panel mode"**.
2. DSC can also be enabled to perform compression of two unrelated input streams of the same resolution. These streams must share the same pixel input clock since the DSC encoders require two encoder clocks to be synchronous. But, in this case, two streams can be asynchronous in terms of video timing (vs/hs/de). This mode is also referred to as **"dual panel mode"**.
3. When DSC is using only one encoder, then it is required to be on Enc0 input (meaning the stream to be compressed must be on DPI\_2). In MST mode (where this constraint is applicable), the single stream that is to be compressed must be placed on DPI\_2 and therefore the DP sink device (that receives the compressed stream) will be assigned to receive the STREAM\_0.

When DSC is in split or dual panel mode, the DSS uses a common clock to send two streams. In the EDP, two DSC input clocks are sourced from the same DPI\_2 source clock to keep these clocks to be the same (per DSC requirement) in order to minimize the skew between two DSC encoder clocks.

For detailed description of the clock diagrams, including the clock muxes per data selection, refer to [Section 12.6.6.5.1, Clock Diagram](#).

#### 12.6.6.2.2 Secure Video Content Protection

Each DPI\_n input port includes a 48-bit DPI\_n\_M\_MDATA bus from DSS (DISPC) which carries attribute sideband signals associated with the DPI interface. The EDP sets the security status (DPISECURE) of the incoming DPI interface using the DPI\_n\_M\_MDATA[10] bit as shown in [Table 12-1505](#).

**Table 12-1505. EDP Secure Video Content Protection**

Sideband bit(s)	Name	Description
DPI_n_M_MDATA[10]	DPISECURE	DPI-np secure bit 1: DPI-np is secure 0: DPI-np is not secure

The EDP performs a simple security check on the selected DPI connection by comparing the value of the selected DPISECURE bit (per EDP\_DPTX\_SRC\_CFG[7-4] VIF\_n\_SEL bits (where n = 0 to 3)) to the EDP\_DPTX\_VIF\_SECURE\_MODE\_CFG[3-0] VIF\_n bits.

If the selected DPISECURE bit is set to 1, the video content is considered to be secure and the connection (transmission via DPTX) is only made if the EDP\_DPTX\_VIF\_SECURE\_MODE\_CFG[3-0] VIF\_n bits are also set to 1 (indicating the display is also secure). Otherwise, the EDP forces the DSS\_DPI\_DATA to be 0h while leaving the sync signals alone – in effect, causing the video to go black. If the DPISECURE bit is set to 0, then the connection is also enabled.

#### 12.6.6.2.3 DPI\_DATA Input Pixel Format Supported

[Figure 12-1117](#) shows the supported by the EDP pixel packing formats in the DSS\_DPI\_DATA.

Default: **RGB121212** - 36-bit pixel data (12 bpc) LSB aligned in 48-bit data bus

Optional: **RGB101010** - 30-bit pixel data (10 bpc) LSB aligned in 48-bit data bus

EDP\_005

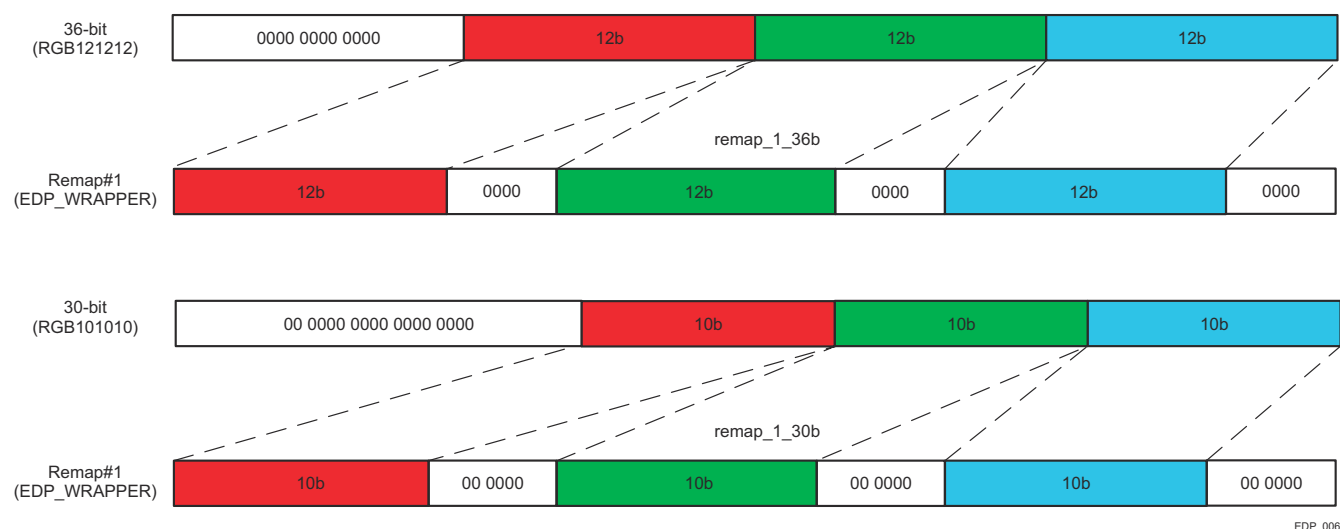

**Figure 12-1117. EDP Wrapper Supported Input DSS\_DPI\_DATA Pixel Formats**

The selection between these two formats is made per VIF\_n source by configuration EDP\_DPTX\_SRC\_CFG[11-8] VIF\_n\_IN30B parameters. The default is 36-bit format (RGB121212). Optionally,

the 30-bit format (which is the pixel format when the DPI\_data is generated from the DSS's merge/split module) can be selected to match the DSS configuration.

Internally, the EDP wrapper performs following pixel data/component realignments to match the input pixel data alignment required by the MHDPTX core (MSB alignment) and DSC (native LSB alignment).

Figure 12-1118 shows the internal mapping from the LSB packed pixel bus to MSB-aligned container packed bus: the 30 or 36-bit pixel data remapped to 48-bit (16 bpc (bits per component) MSB aligned within color component). The MHDPTX core extracts MSB 8/10/12-bits from each 16-bit color component to include in the display port video transport packet (see Table 12-1506, *EDP Video Interface Pixel Mapping (MSB Mapping)*).

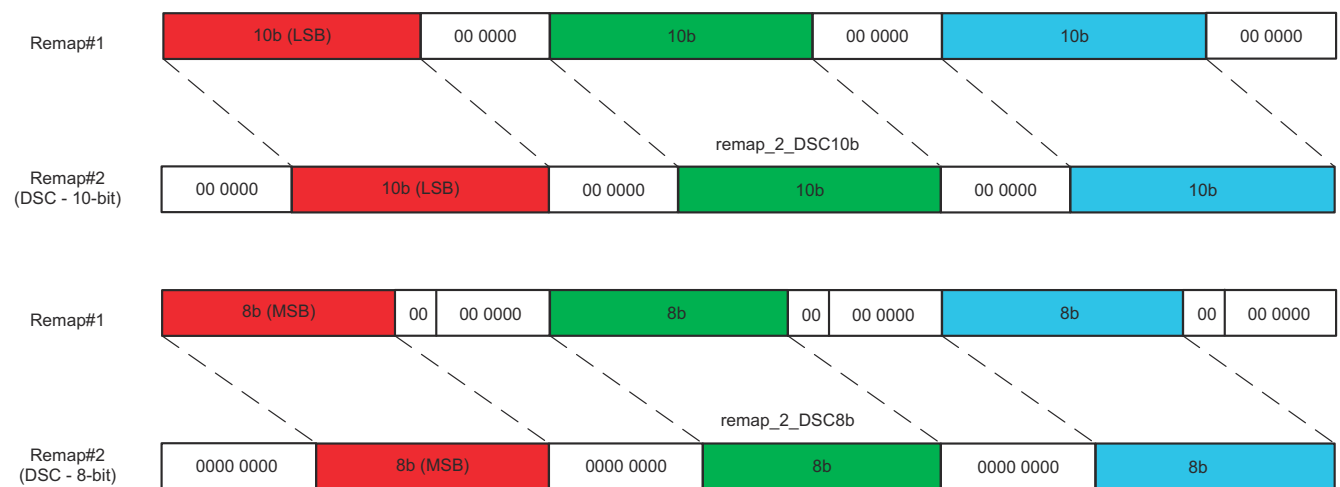

EDP\_006

**Figure 12-1118. EDP Wrapper Internal Pixel Bus Remapping (First Stage)**

DSC Input Data Re-alignment (Optional for DSC enabled VIF\_0 and VIF\_1) – From the 48-bit aligned data bus, the EDP wrapper performs additional re-alignment (LSB aligned component data per DSC requirement) and pixel data alignment per DSC input processing bit size configuration.

For this LSB alignment, EDP\_DPTX\_DSC\_CFG[6-5] DSC\_1/0\_10BPC bits must be configured to extract significant 8 or 10-bit component data from the input pixel bus, as shown on Figure 12-1119.

The parameters in these bits must match the parameters in the EDP\_CORE\_ENC0\_MAIN\_CONF\_P/EDP\_CORE\_ENC1\_MAIN\_CONF\_P[1-0] IPUT\_BPC bitfields.

EDP\_007

**Figure 12-1119. EDP Wrapper Internal Pixel Remapping (Additional for DSC Bound Pixel Data Bus)**

Pixel data alignment within the MHDPTX\_TOP should be set to be MSB always to enable the pixel mapping, as shown in [Table 12-1506](#). DSC bound pixel data bus is to be LSB aligned and requires no other MHDPTX\_TOP configuration.

**Table 12-1506. EDP Wrapper Video Interface Pixel Mapping (MSB Mapping)**

Video Bus	Source RGB/YCbCr444 (C of YCbCr422 <sup>(2)</sup> )				
	Bit Width	8-bit	10-bit	12-bit	16-bit <sup>(1)</sup>
Channel 2	[47:40]	R/Cr[15:8] / C[15:8]	R/Cr[15:6] / C[15:6]	R/Cr[15:4] / C[15:4]	R/Cr[15:0] / C[15:0]
	[39:38]				
	[37:36]				
	[35:32]				
Channel 1	[31:24]	G/Y[15:8]	G/Y[15:6]	G/Y[15:4]	G/Y[15:0]
	[23:22]				
	[21:20]				
	[19:16]				
Channel 0	[15:8]	B/Cb[15:8]	B/Cb[15:6]	B/Cb[15:4]	B/Cb[15:0]
	[7:6]				
	[5:4]				
	[3:0]				

(1) 16-bit source format is not supported. When selected, lower 4 bits are set to 0x0.

(2) YCbCr422 format is locally generated from YCbCr444 input from DSS (by a simple chroma decimation).

#### 12.6.6.2.4 Audio Input Interface

The audio input interface provides the following features:

- One I2S interface configured to support multiple physical audio channels (up to 8-channels)
- Frame Format – TDM mode
  - Multiple Physical Channels N = 1, 2, or 4
  - Variable TDM time slots M = 2 or 8
  - Time slot size: 32, 24, or 16
  - Variable word length (28, 24, 20, 16) configured as left or right justified
- I2S\_DATA - 4-bits wide
- Supports data rate up to 8-channel L-PCM @192 kHz (Buffer dependent)
- SPDIF mode is not supported

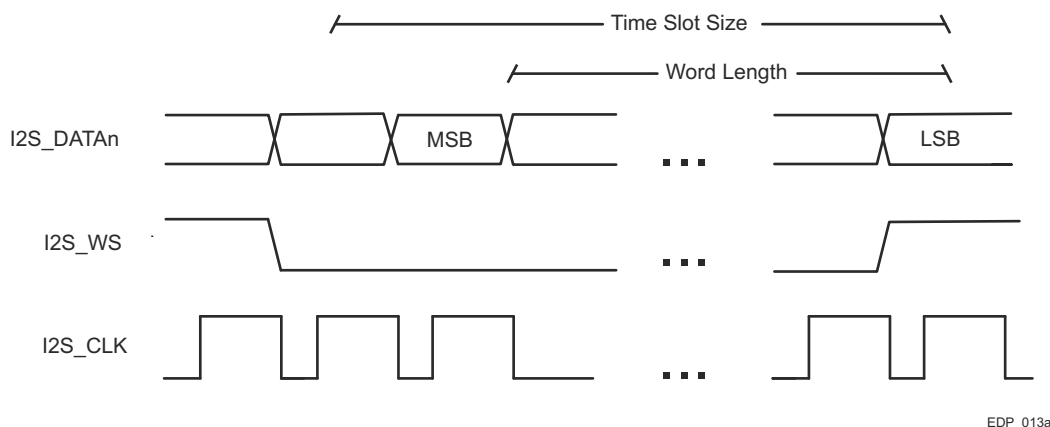

##### 12.6.6.2.4.1 Audio I2S Signals/Timing

[Table 12-1507](#) shows the I2S signals and timing.

**Table 12-1507. EDP Audio I2S Signals/Timing**

Signal Name	Direction	Default Value	Description
AIF_I2S_CLK	Input	1'd0	I2S clock
AIF_I2S_DATA[3:0]	Input	4'd0	I2S data for up to 4*M logical channels. Number of physical channels: 1, 2, or 4 M – number of time slots: 2 or 8
AIF_I2S_WS	Input	1'd0	I2S word-select indication. In TDM mode, WS = 0 indicates channel 0.

[Figure 12-1120](#) and [Figure 12-1121](#) show the I2S timing.

EDP\_013a

**Figure 12-1120. EDP Audio I2S Timing - Bit Allocation (Right Justification)**

EDP\_013b

**Figure 12-1121. EDP Audio I2S Timing - TDM Time Slot Allocation (M = 8)**

#### 12.6.6.2.4.2 Audio I2S Clock Frequency

The bit clock frequency is defined as below:

- Bit clk freq = Sampling\_rate \* Number\_of\_bits\_per\_channel \* Number\_of\_channels

For 16-bit/44.1 kHz stereo channels:

- I2S\_CLK (freq) = 44.1 kHz x 16 x 2 = 1.4112 MHz

For 24-bit/192 kHz stereo channels:

- I2S\_CLK (freq) = 192 kHz x 24 x 2 = 9.216 MHz

#### 12.6.6.3 EDP Transmitter Controller Subsystem (MHDPTX\_TOP)

The EDP Transmitter Controller Subsystem (MHDPTX\_TOP) integrates the following major components:

- Display Stream Compression (DSC) v1.1 Encoder – VESA Compression Engine
- Display Port TX Controller (MHDPTX Controller) - EDP/DP Transmitter Controller

##### 12.6.6.3.1 Display Stream Compression Encoder (DSC)

This module performs the VESA Digital Stream Compression encoding for the Display Port TX interface. The DSC contains two parallel Hard Slice Encoders, which support compression for VESA Display Port transmitter.

##### 12.6.6.3.1.1 DSC Encoder Features

The DSC Encoder supports the following main features:

- Maximum image width and height per encoder slice can be configured with up to 8K
  - Programmable slice width and height
  - All slices must be the same height, including the final slice of the picture
- 8 bits/component (24 bits/pixel)
- 10 bits/component (30 bits/pixel)

- An encoder built for 10 bits/component will be able to run in either 8 or 10 bits/component mode based on a register value
- RGB/YCbCr with 4:4:4 sampling support only on the input streams
- Single or Dual Pixel input(s)
  - Single pixel input (one encoder slice processing only)
  - Dual pixel inputs
    - Split Panel (Left/Right) streams – requires low skew between streams
- Support for all DSC 1.1 encoding mechanisms
  - MMAP, BP, MPP predictions and ICH
  - Flatness detection and signaling
- Supports CBR (Constant Bit Rate) mode only - Configurable target bpp (bits per pixel), non-integer values supported. The following modes are available:
  - 8 bpp and 12 bpp compressed bit rates for 8 bits/component - Corresponds to 3:1 and 2:1 compression
  - 10 bpp and 15 bpp compressed bit rates for 10 bits/component - Corresponds to 3:1 and 2:1 compression
  - 12 bpp and 18 bpp compressed bit rates for 12 bits/component
- Each Hard Slice encoder instance can be configured (with the parameter NB\_SS\_ENC) to support the following number of slices per line
  - Supports 1 or 2 slices (soft slices) per line
    - When configured with support for 2 slices per line, the encoder support dynamically the configuration of both 1 and 2 slices per line.
  - Thus a total of up to 4 slices per line can be supported with two Hard Slice Encoders
- Encoder data flow supported:
  - Synchronous Streaming mode – no back pressure support
- Implements the following active internal diagnostic mechanisms:
  - Self-Checking during VBLANK
  - Control output diagnostics
  - SRAM Protection
  - Configuration and Status Register (CSR) Protection
  - Fault avoidance mechanism

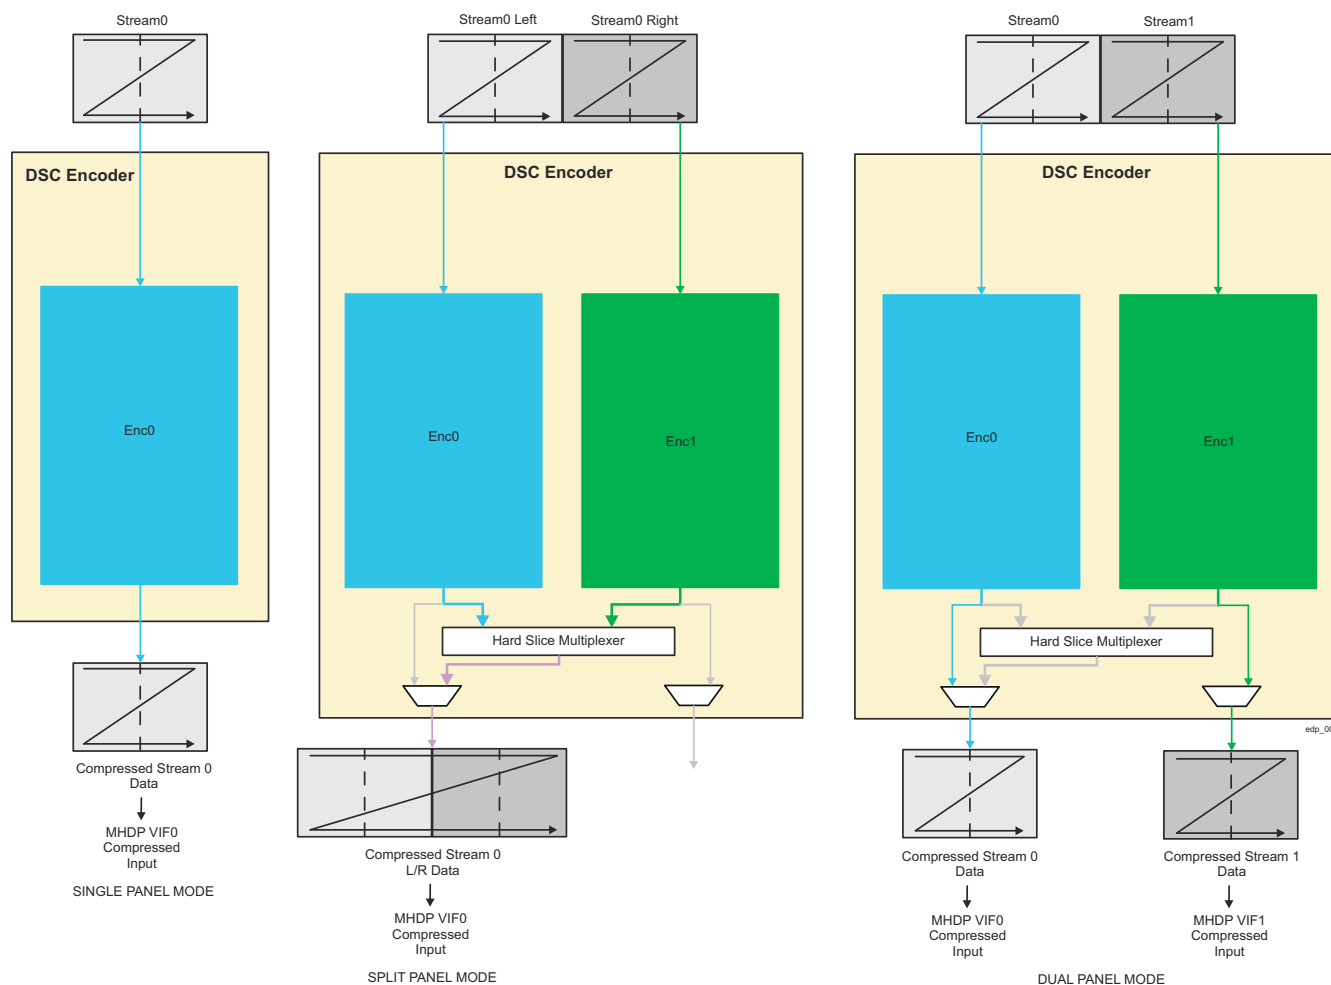

#### 12.6.6.3.1.2 Usage Models for EDP

[Table 12-1508](#) summarizes the usage models supported by DSC instantiated in the MHDPTX\_TOP subsystem.

**Table 12-1508. EDP DSC Usage Models**

Usage Models			
	Single Panel Mode (SST/MST)	Split Panel Mode (SST/MST)	Dual Panel Mode (Only in MST)
ENC0	Stream 0 Full Frame	Stream 0 Left Frame	Stream 0
ENC1	Not Used	Stream 0 Right Frame	Stream 1

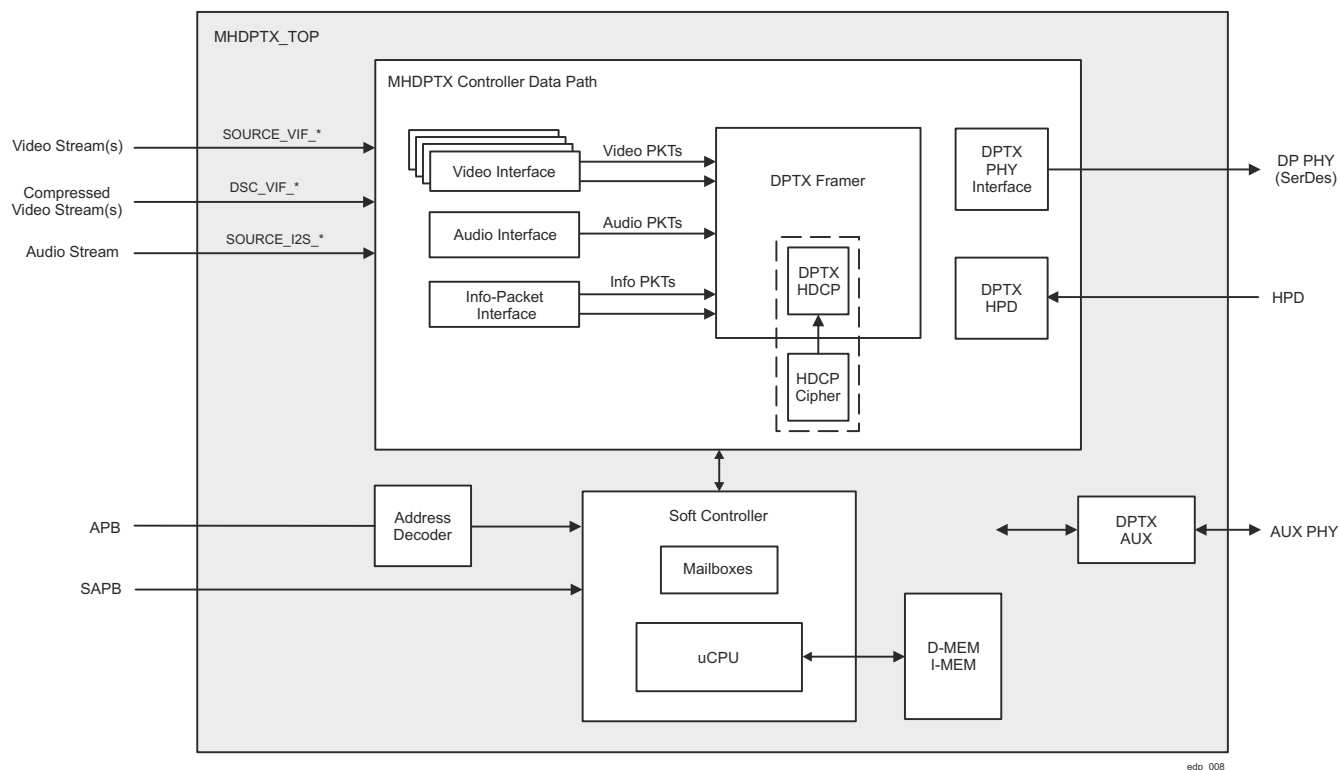

The shaded boxes in [Table 12-1508](#) indicate the encoder slice enabled for EDP usage. The active paths for these two modes are shown on [Figure 12-1122](#).

**Figure 12-1122. EDP DSC Single Input/1-Transport Link Mode and Split Panel/Dual Panel Mode**

#### 12.6.6.3.2 Display Port Transmitter Controller (MHDPTX Controller)

Figure 12-1123 shows a simplified block diagram of the EDP Display Port Transmitter Controller (MHDPTX) that is included in the EDP subsystem.

**Figure 12-1123. EDP Display Port Transmitter Controller Functional Block Diagram**

n = 0 to 3

#### 12.6.6.3.2.1 EDP Transmitter Controller Mode Configurations

This section describes the configuration mode input signals of the MHDPTX\_TOP module.

##### SOURCE\_SECURE\_MODE

This mode configuration signal sets the "source\_secure\_mode" of the MHDPTX's APB interface to provide additional security control on the host interface. The main APB interface in "debug" mode can be used to access almost all internal registers as well as IIRAM/DRAM of the internal uCPU. This signal must be set to 0 to load FW during boot time. By setting SOURCE\_SECURE\_MODE to 1, this functionality can be disabled to only allow mailbox and basic control register accesses.

In EDP, this signal is mapped to a wrapper level configuration register within the EDP\_CFG region: EDP\_DPTX\_IPCFG[0] APB\_SECURE\_REG\_BLOCK\_EN. If tempering of this register should be blocked, the EDP\_CFG region should be firewalled to grant access only to a secure host only.

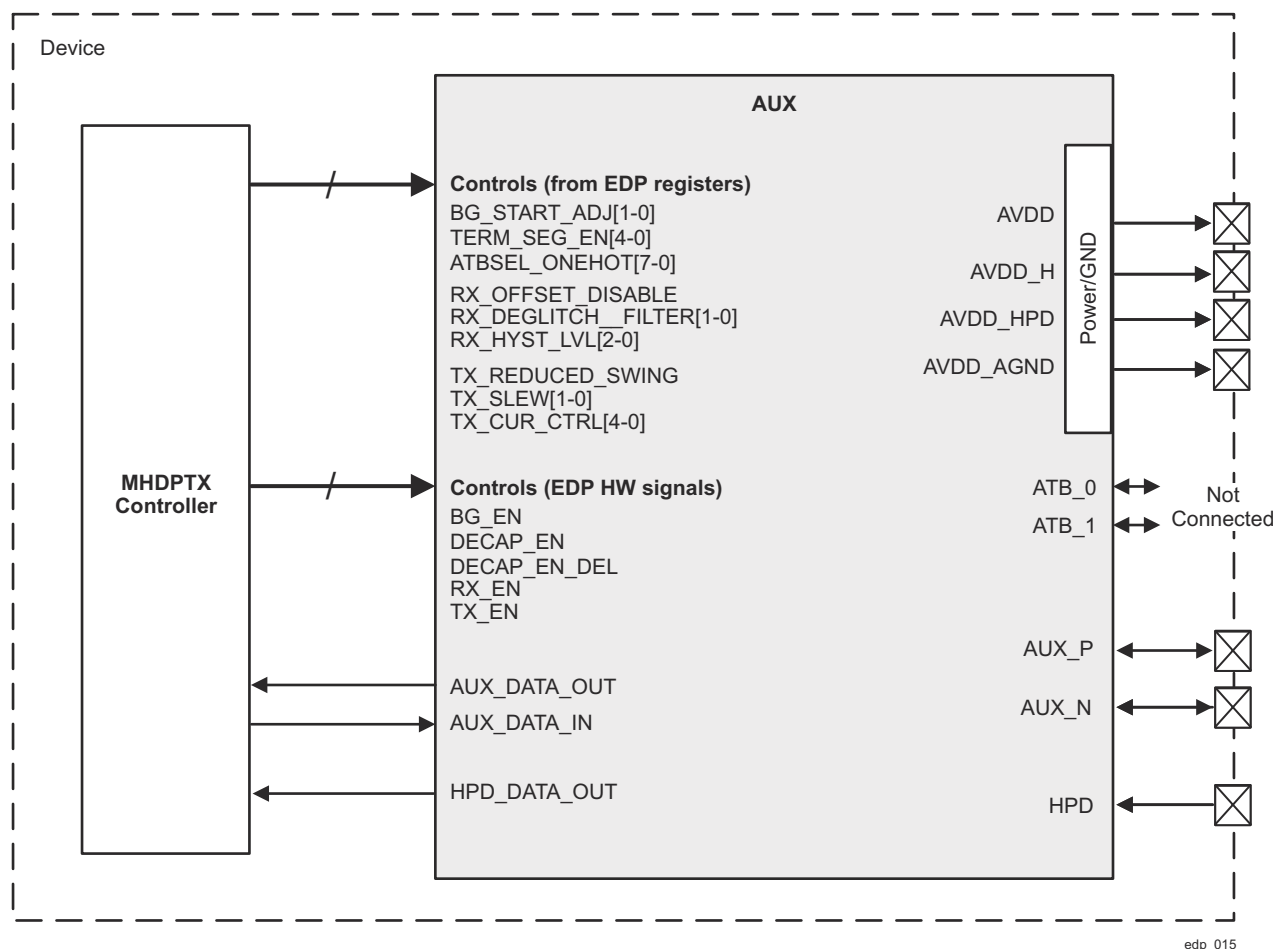

If the DP firmware regions are needed to be protected (to prevent either corruption or altering of the firmware), a secure host can change this setting to 1 after initializing the firmware memories. Then, a non-secure host can come and take the CPU out of reset and enable the DP function without an ability to alter the firmware.

##### SOURCE\_CRYPTO\_DIS

This mode configuration signal is used to completely disable HDCP functionality by disabling Crypto module (module responsible for keys encryption during authentication) . Refer to *EDP eFuse Tie-Off*, for eFuse tie-off information.

#### 12.6.6.4 EDP AUX\_PHY Interface

The AUX PHY module is required for each Display Port interface. The AUX\_PHY module is integrated with the EDP controller as shown on [Figure 12-1124](#). The AUX PHY has no configuration interface. All configuration and control signals are supplied from EDP\_CORE\_APB memory-mapped registers.

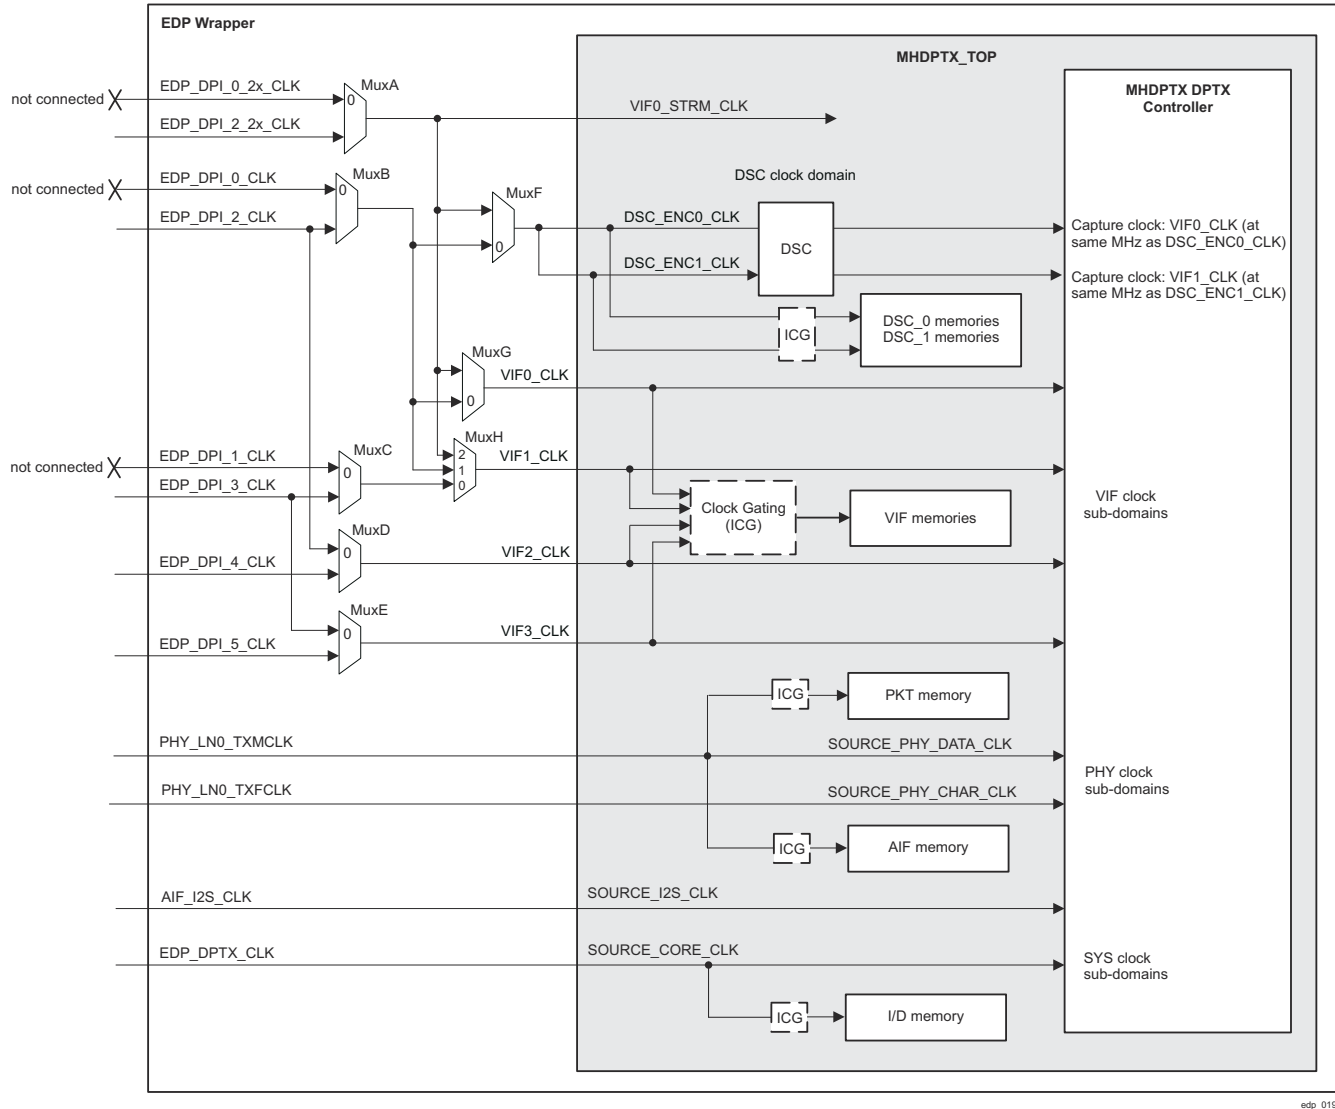

**Figure 12-1124. EDP Interface to AUX PHY**

The configurations and controls in [Figure 12-1124](#) are specified through EDP\_CORE\_AUX\_CONFIG\_P and EDP\_CORE\_AUX\_CTRL\_P registers.

#### 12.6.6.5 EDP Clocks

##### 12.6.6.5.1 Clock Diagram

[Figure 12-1125](#) shows the input clocks of eDP and muxing on the DPI input clocks to match the pixel data selection.

**Figure 12-1125. EDP Clock Diagram**

#### 12.6.6.5.1.1 DPI Interface Clock Sourcing

In default (non-DSC enabled) modes, the EDP performs the matching pixel data clock selection (MuxA - MuxE) based only on the VIF input source selection (EDP\_DTPX\_SRC\_CFG[7-4] VIF\_n\_SEL register fields) settings.

For VIF0\_CLK, the source selection in non-DSC enabled mode comes from the output of MuxA (EDP\_DPI\_0\_2x\_CLK or EDP\_DPI\_2\_2x\_CLK). These clocks are full pixel data frequency clocks.

When DSC is enabled, the DSC\_ENC0\_CLK and DSC\_ENC1\_CLK clocks are sourced (MuxF) from:

- Full pixel data frequency clock (MuxA selected clock) - when DSC is configured in a non-split panel mode (EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL != 0h AND EDP\_DPTX\_DSC\_CFG[2] SPLIT\_PANEL\_EN = 0h)
- Half pixel data frequency clock (MuxB selected clock) – when DSC is configured in the split panel mode (EDP\_DPTX\_DSC\_CFG[1-0] MODE\_SEL = 2h AND eDP\_DPTX\_DSC\_CFG[2] SPLIT\_PANEL\_EN = 1h)

VIF0\_CLK and VIF1\_CLK selection goes through additional muxing (MuxG/MuxH) to match the DSC encoder clocks.

#### 12.6.6.5.1.2 Memory Clock Gating

Memory clock gating is handled at the wrapper based on the scheme described below.

Functional mode clock enable (functional clock gating – for memory):

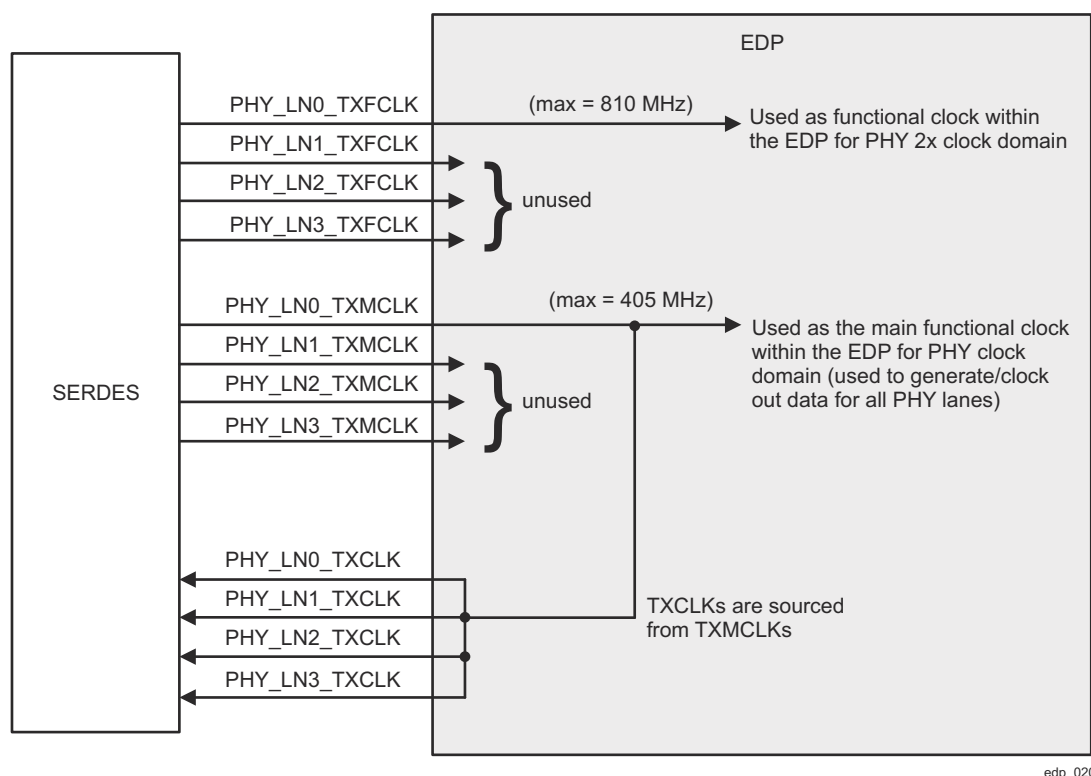

- DPTX firmware memory (I/D mem) clocks are enabled when `EDP_DPTX_IPCFG[1] FW_MEM_CLK_EN = 1`.
- Memory clocks for all DPTX data memories in the normal functional mode are only enabled when the corresponding source (video/audio/pif) is enabled per `DPTX_SRC_CFG`.
  - Clocks for the video stream memories (vif\_mem) are enabled whenever the stream is enabled (`EDP_DPTX_SRC_CFG[3-0] VIF_n_EN`).
  - Clocks for the packet memories (pkt\_mem) are enabled whenever the packet stream interface is enabled (`EDP_DPTX_SRC_CFG[3-0] VIF_n_EN`).
  - Similarly clock for the audio buffer (aif\_mem) is enabled whenever the audio stream is enabled (`EDP_DPTX_SRC_CFG[16] AIF_EN`).
- Clocks for the DSC memories (DSC\_ENC0 and DSC\_ENC1 mem) are enabled based on the ENC0/ENC1 usage (`EDP_DPTX_DSC_CFG[1-0] MODE_SEL`). When `EDP_DPTX_DSC_CFG[1-0] MODE_SEL` is not 0 (that is, at least one DSC encoder is enabled), the wrapper enables `VIF_n_MEM` clock based on the DSC usage

Functional mode clock enable override:

- Clocks for all ECC memories can be forced to turn on (that is, functional clock gating bypassed) during ECC diagnostic access mode by setting `EDP_ECC_MEM_CFG[0] CLK_EN = 1`.

#### 12.6.6.5.1.3 PHY Clock Connections

There are multiple clocks from/to the physical interface. [Figure 12-1126](#) shows clocks used for the PHY clock domain logic (TXMCLK/TXFCLK) and for the return data clock (TXCLK). Not shown in the diagram are RX mode input clocks unused by EDP (TX only mode) – `PHY_INn_RXCLK/RXFCLK/REFCLK`.

**Figure 12-1126. EDP PHY Clock Connections**

#### 12.6.6.5.2 Clock Groups

Following are the major groups of clocks in the EDP subsystem:

- System clock – This is the VBUSP configuration clock. It is used to source the clock for all internal configuration interfaces (VBUSP and PAB) and the core logic of the MHDPTX controller.
- DPI clocks - These are video stream source clocks. These can be sourced either directly from PLL or DSS (that is, DPI\_CLK outputs, DSS sourced mode).
- PHY I/O clocks - These are clocks used to transmit display port raw data to the SERDES or the clock used to receive audio data from MCASP.

Table 12-1509 describes clocks at the EDP boundary.

**Table 12-1509. EDP Clocks**

Clock	Freq Min	Freq Max	Source	Description
EDP_DPTX_CLK	125 MHz	125 MHz	System PLL	Functional clock (all VBUSP/APB/DPTX_core logics are clocked by this clock) Valid Freq: 100 – 200 MHz (125 MHz chosen to be 1/4x of CBASS 500 MHz clock)
EDP_DPI_2_2x_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_2x_CLK	DPI Streaming Clock – Typically 1x of the corresponding EDP_DPI_2_CLK. But, in DSC split-panel mode, 2x of the EDP_DPI_2_CLK
EDP_DPI_2/3/4/5_CLK	25 MHz	600 MHz	Video PLL or DSS EDP_DPI_CLK	DPI Clock – pixel clock of the EDP_DPI_DATA bus. In DSS-sourced mode, EDP_DPI_n_CLK is the pixel clock of the EDP_DPI_n_DATA bus. In PLL-sourced mode, the pixel clock needs to be internally muxed between EDP_DPI_2_2x_CLK and EDP_DPI_2_CLK depending on the EDP_DPI_DATA type (split panel data or not).
EDP_AIF_I2S_CLK	1 MHz	125 MHz	MCASP	Audio I2S Clock (192 kHz clock)
PHY_LN0_TXMCLK (SOURCE_PHY_DATA_CLK)	81 MHz	405 MHz	DP-SERDES (PHY) PLL	PHY Data clock (1/2 Char Clock)
PHY_LN0_TXFCLK (SOURCE_PHY_CHAR_CLK)	162 MHz	810 MHz	DP-SERDES (PHY) PLL	PHY Char Clock

#### 12.6.6.6 EDP Resets

The EDP subsystem has one synchronous active low reset input. The entire subsystem is reset by this reset. All resets for different clock domains (both synchronous and asynchronous) are generated internally using this reset.

All resets within the MHDPTX\_TOP are asynchronous. Each clock's sub-domain resets are synchronized with respective software reset.

#### 12.6.6.7 EDP Interrupt Requests

The interrupt signals generated by the EDP subsystem and propagated to SoC level are shown in Table 12-1510.

**Table 12-1510. EDP Subsystem Interrupts**

Interrupt	Description
EDP_INTR[3:0]	EDP Controller Interrupt Event (Functional)
EDP_INTR_ASF[6:0]	EDP Controller ASF Error Interrupt

#### 12.6.6.7.1 EDP\_INTR Interrupt Description

Table 12-1511 provides details on the EDP\_INTR[3:0] interrupt lines. Each of the interrupts listed in Table 12-1511 has a corresponding set of memory-mapped interrupt registers (status/mask/clear).

**Table 12-1511. EDP\_INTR Interrupts**

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[3]	DSC	DSC Enc1 interrupt event detected	EDP_CORE_ENC1_IN_T_STAT_P	EDP_CORE_ENC1_IN_T_MASK_P	EDP_CORE_ENC1_IN_T_CLR_P
[2]		DSC Enc0 interrupt event detected	EDP_CORE_ENC0_IN_T_STAT_P	EDP_CORE_ENC0_IN_T_MASK_P	EDP_CORE_ENC0_IN_T_CLR_P
[1]	MHDPTX Controller	DPTX SIRQ - Secure APB domain interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_STA_TUS_S	EDP_CORE_APB_INT_MASK_S	-
[0]		DPTX PIRQ - General DPTX interrupt event. Set when an interrupt in the status register is reported.	EDP_CORE_APB_INT_STATUS_P	EDP_CORE_APB_INT_MASK_P	-

### 12.6.6.7.2 EDP\_INTR\_ASF Interrupt Description

Table 12-1512 provides details on the EDP\_INTR\_ASF[6:0] interrupts lines. Each of the interrupts listed in Table 12-1512 has corresponding set of memory-mapped interrupt registers (status/mask/clear).

**Table 12-1512. EDP\_INTR\_ASF Interrupts**

Interrupt Bit	Source	Description	Status Register	Mask Register	Clear Register
[6]	ECC_AGGR_DSC	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_DSC_DED_STATUS_REG0	EDP_ECC_DSC_DED_ENABLE_SET_REG0	EDP_ECC_DSC_DED_ENABLE_CLR_REG0
[5]	ECC_AGGR_PHY	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_PHY_DED_STATUS_REG0	EDP_ECC_PHY_DED_ENABLE_SET_REG0	EDP_ECC_PHY_DED_ENABLE_CLR_REG0
[4]	ECC_AGGR_CORE	ECC Aggregator Uncorrected Error Interrupt	EDP_ECC_CORE_DED_STATUS_REG0	EDP_ECC_CORE_DED_ENABLE_SET_REG0	EDP_ECC_CORE_DED_ENABLE_CLR_REG0
[3]	DSC	ASF Corrected interrupt detected in DSC	EDP_CORE_ENC_ASF_INT_STAT_P	EDP_CORE_ENC_ASF_INT_MASK_P	EDP_CORE_ENC_ASF_INT_CLR_P
[2]		ASF Un-Corrected interrupt detected in DSC			
[1]	MHDPTX Controller	ASF Corrected (NonFatal) event detected in MHDPTX Controller. Set if non-fatal error occurs.	EDP_CORE_ASF_INT_STATUS <sup>(1)</sup>	EDP_CORE_ASF_INT_MASK <sup>(1)</sup>	-
[0]		ASF Un-corrected (Fatal) event detected in MHDPTX Controller. Set when fatal error occurs.			

(1) Each interrupt can be individually defined as fatal or non-fatal in the EDP\_CORE\_ASF\_FATAL\_NONFATAL\_SELECT register.

### 12.6.6.8 EDP Embedded Memories

#### 12.6.6.8.1 MHDPTX Controller Memories

**Table 12-1513. EDP MHDPTX Controller Memories**

Name	ECC	Description
IRAM	Yes	uCPU Instruction Memory. Contains uCPU FW, loaded by host during boot time.

**Table 12-1513. EDP MHDPTX Controller Memories (continued)**

Name	ECC	Description
DRAM	Yes	uCPU DATA Memory. Contains uCPU data-memory, mailbox for communication between uCPU and host processor and EDID segment. In DisplayPort mode, it contains DPCD registers and AUX mailbox. In HDMI mode, it contains SCDC standard registers. When HDCP is supported, it contains keys and protected information.
PKT_MEM_n (n = 0 to 3)	Yes	Source Packet Memory. Contains up to 16 info-frames. Accessed by host processor (over APB) for write and by HD Display TX Controller for read.
VIF_MEM_n (n = 0 to 3)	No (No ECC for the video buffer)	Video Memory. Elastic buffer, compensating the difference between the pixel clock and the line clock.
AIF_MEM	Yes	Audio Memory. Buffer audio samples during H active period.

#### 12.6.6.8.2 DSC Memories

**Table 12-1514. EDP DSC Memories**

Name	ECC	Description
ENC0/1_LB	Yes	Line Buffer RAM. Stores the reconstructed pixels that will be re-used for next line processing.
ENC0/1_OB0	Yes	Output Buffer RAM. Holds (as FIFO) results of encoder slices.
ENC0/1_SSM_S	Yes	Sub-stream Mux Size RAM. Holds context information required to generate the proper order of the mux words.
ENC0/1_SSM_D	Yes	Sub-stream mux balance FIFO RAM. Holds stream data for re-ordering.

#### 12.6.6.8.3 ECC Aggregation

The tasks of ECC detection/correction of 'ECC enabled' memories are handled within the MHDPTX Controller. The EDP wrapper provides 'ECC error injection' using a combination of ECC\_Wrapper (to access the memory) and ECC\_Aggregator (to allow system to access the ECC injection logic). An ECC\_Aggregator can access multiple ECC\_Wrappers of the same clock group. [Table 12-1515](#) shows how the ECC memories (and the EDC\_CTRL for Parity Inv) in the EDP are grouped to three ECC aggregators.

**Table 12-1515. EDP ECC\_Aggregator (Based on Clock Group)**

Memory / Logic	ECC Vector_ID	ECC_Aggregator
IRAM	0	ECC_AGGR_CORE
DRAM	1	
EDC_CTRL (Parity)	2	
PKT_MEM_0	0	ECC_AGGR_PHY
PKT_MEM_1	1	
PKT_MEM_2	2	
PKT_MEM_3	3	
AIF_MEM	4	
VIF_MEM_0	-	N/A (No ECC for the video buffer)
VIF_MEM_1	-	
VIF_MEM_2	-	
VIF_MEM_3	-	

**Table 12-1515. EDP ECC\_Aggregator (Based on Clock Group) (continued)**

Memory / Logic	ECC Vector_ID	ECC_Aggregator
ENC0_LB	0	ECC_AGGR_DSC
ENC0_SSM_S	1	
ENC0_SSM_D	2	
ENC0_OB0	3	
ENC1_LB	4	
ENC1_SSM_S	5	
ENC1_SSM_D	6	
ENC1_OB0	7	

Furthermore, each ECC\_Aggregator is connected to the VBUSP\_CFG via the main CBASS SCR (with asynchronous bridge). All ECC aggregator bound VBUSP\_CFG transactions are mapped to a separate RSEL (in EDP case, RSEL=3), see [Figure 12-1127](#).

Each ECC\_Aggregator and the asynchronous VBUSP interface of the aggregator are clocked using the read clocks used to read the memory, as follows:

- ECC\_AGGR\_CORE: EDP\_DPTX\_CLK
- ECC\_AGGR\_PHY: SOURCE\_PHY\_DATA\_CLK (PHY\_LN0\_TXMCLK)
- ECC\_AGGR\_DSC: EDP\_DPI\_0\_CLK or EDP\_DPI\_2\_CLK (selected by mux)

The clocks to some ECC memories may be disabled when the associated video or audio channel is not enabled. If none of the memories for an ECC aggregator is enabled (for example, DSC memory clocks are disabled, if the DSC is not enabled), then the clock for the aggregator is also disabled and the aggregator is disconnected from the CBASS (resulting in null return for any VBUSP access to the aggregator)

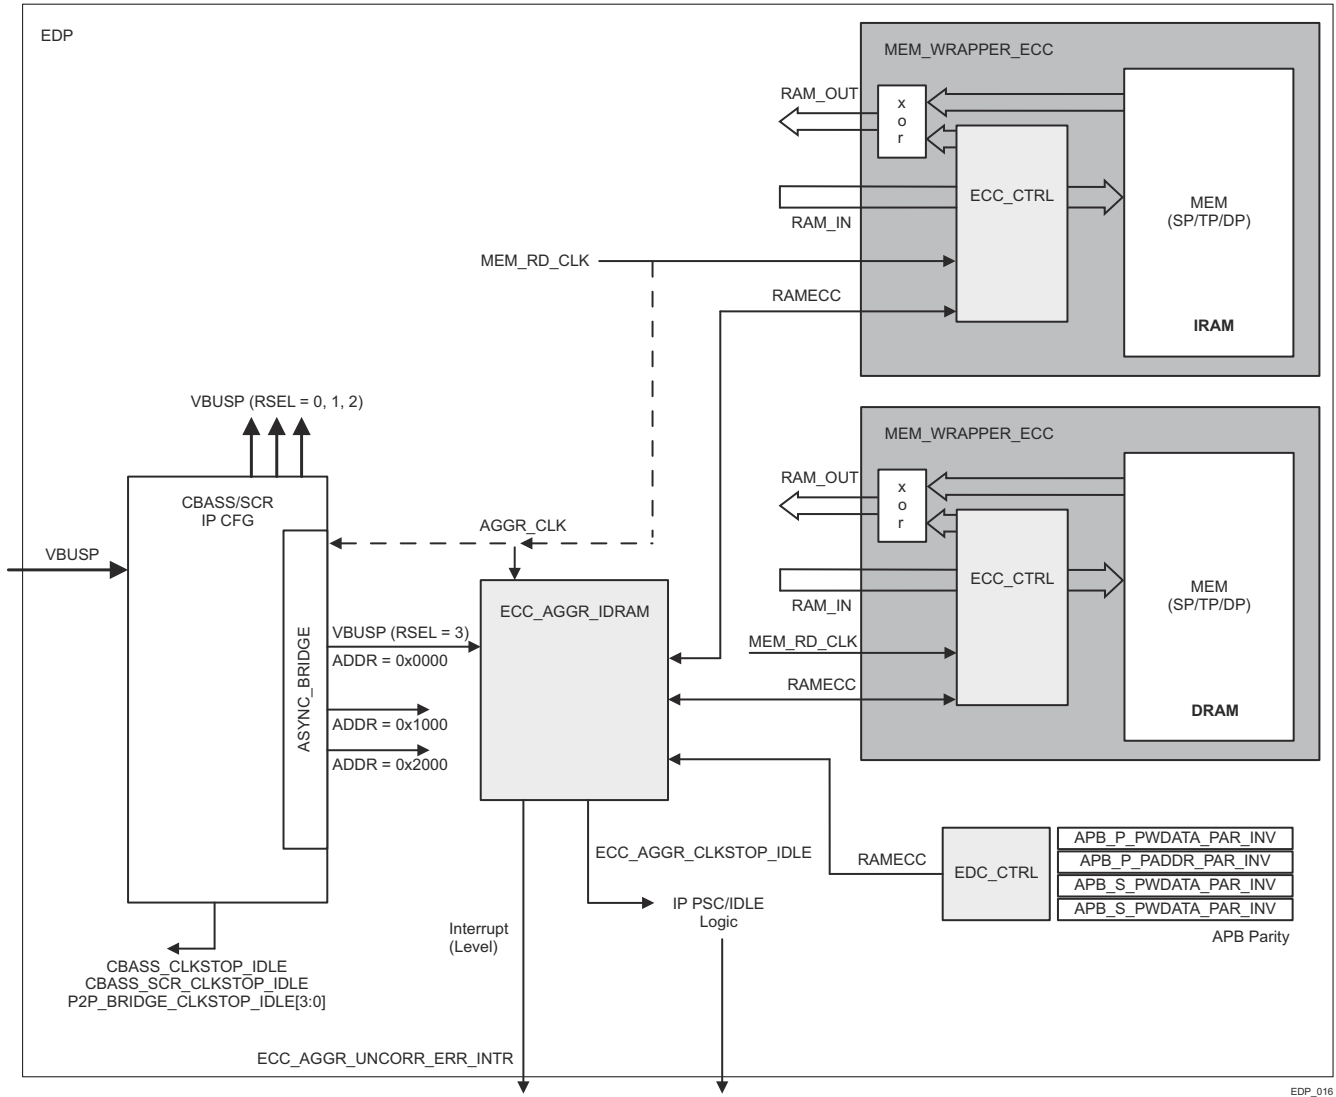

But, if any of the ECC memories connected to an ECC aggregator is enabled, the clock for the ECC aggregator must also be enabled. Any access to the ECC\_CTRL of the disabled memory will result in TIMEOUT error (interrupt generated) since the memory clock is not running.

If ECC diagnostics/access are needed for all ECC memories whether the memories are enabled or not, the ECC software can set the clock enable override configuration register - EDP\_ECC\_MEM\_CFG[0] CLK\_EN to bypass the clock gating.

Even with this bit set, the ECC\_CTRL connected to the ECC\_AGGR\_PHY aggregator may not get any clock if the PHY is not enabled and properly configured. The EDP\_PHY\_CLK\_STATUS[0] VALID status register tells whether the PHY data clock is running or not.

The DSC clock is sourced from the system video PLL and therefore it should be running. Therefore, the ECC software just need to ensure the clock gating is not active and/or set the ECC CLK\_EN override bit to get the clock to the memory.

The ECC\_CORE Aggregator clock should be running whenever the EDP is enabled. There is no clock gating to the IRAM/DRAM memories.

**Figure 12-1127. EDP ECC\_WRAP/ECC\_AGGR and PARITY\_INV Logic Connection**

#### 12.6.6.9 EDP Programmer's Guide

This chapter describes the programming guidelines for the MDPTX Controller and EDP PHY.

##### 12.6.6.9.1 EDP Controller Programming

###### 12.6.6.9.1.1 MHDPTX Register/Memory Regions

Table 12-1516 provides a summary of the bus interfaces and the MMR regions mapped to each interface in this module.

**Table 12-1516. EDP Memory Map Region - Firewall Secure Mode Settings**

Region Name	Firewall Secure Mode Settings <sup>(1) (2)</sup>
INTG_CFG_VP	Should be Secure
V2A_CORE_VP_REGS_APB	Secure (for Secure display) / Non-secure
V2A_S_CORE_VP_REGS_SAPB	Must be Secure always (HDCP configuration)
MHDPTX_WRAPPER_ECC_AGGR_CORE_CFG	Secure (for Secure display) / Non-secure
MHDPTX_WRAPPER_ECC_AGGR_PHY_CFG	Secure (for Secure display) / Non-secure

**Table 12-1516. EDP Memory Map Region - Firewall Secure Mode Settings (continued)**

Region Name	Firewall Secure Mode Settings <sup>(1) (2)</sup>
MHDPTX_WRAPPER_ECC_AGGR_DSC_CFG	Secure (for Secure display) / Non-secure

- (1) Firewall secure mode settings:
- The V2A\_S\_CORE\_VP\_REGS\_SAPB (secure APB) region must be restricted to secure host access only (for HDCP key protection)
  - The INTG\_CFG\_VP region should be set to secure host access only since this region controls the security of the DPI ports and controls the clock enables.
  - Other regions should be set to secure, if the display connected is to be secure.
- (2) Word-access only for RSEL (1 and 2) – accessing APB and SAPB regions of MHDPTX core. Any non-word access request will result in either rstatus=1 or sstatus=1.

Table 12-1517 shows the MHDPTX Controller register/memory regions that are accessible during various operational modes:

**Table 12-1517. EDP MHDPTX Controller APB/SAPB Memory Map and Access Modes**

Description	Address Base [19:0]	Register Bank	Direct access (x= APB (x= APB /SAPB)	Mailbox access (x= APB (x= APB /SAPB)	FW (uCPU) access	APB debug (Bootmode) access

SDP control stream 3	0x308c0	SOURCE_PIF	APB			x
Registers related with IPS configuration	0x30A00	IPS_REGS	APB			x
Fault reporting module	0x30B00	ASF	APB			x
DSC encoder	0x30C00 - 0x30F00	DSC	APB			x

**Access Modes:**

- APB Debug (Boot Mode) Access - After a hardware reset, MHDPTX comes up in this mode – allowing APB access to all regions including IMEM/DMEM (for FW download)
- Direct Access - Once the boot mode initialization is complete, APB\_CTRL register is cleared. This takes it out of the Boot mode and into the direct access mode in which only the mailbox control (APB\_CFG space) and regions marked as APB in the direct access column.
- Mailbox Access - While in Direct Access mode, all configurations of the DPTX for DP operation are done through the APB mailbox accesses. Secure transactions (secure refers to transactions to protect "secure" content) are done through the secure mailbox access via SAPB interface. The SAPB access is made through the secure EDP vbusp region (must be configured as such in the cfg Firewall)
- FW (uCPU) Access – This column indicates register/memory bank accessible by FW access.

**12.6.6.9.1.2 Boot Sequence**

After reset, the uCPU is disabled. The full MHDPTX Controller address space is accessible for the host processor for debugging purposes, and the I-MEM and D-MEM.

The host processor must perform the following:

- Load the FW into the memories.
- Enable the uCPU.
- Verify that FW is running as expected.

**Figure 12-1128. EDP MHDPTX Controller Boot Sequence**

#### 12.6.6.9.1.3 Setting Core Clock Frequency

The FW relies on a known core\_clock frequency for configuring time HW dividers and timeout counters.

Therefore, core\_clock frequency (SW\_CLK\_H, SW\_CLK\_I) must be configured by the host processor, prior to booting the FW.

#### 12.6.6.9.1.4 Loading Firmware

The FW binaries are provided in the hexadecimal format that is composed from two files IRAM0.DATA and DRAM0.DATA.

The IRAM0.DATA contains the instruction memory and the DRAM0.DATA contains the variables initialization.

The external host processor should load the FW into the I-MEM and D-MEM, and enable the uCPU. Accessing the I-MEM, D-MEM is enabled only after reset (after reset, the system is going into debug mode, after loading

FW and set EDP\_CORE\_APB\_CTRL\_P register to 0 system is going out from debug mode, and only reset can bring the system back to debug mode).

After loading the memories, the host processor should select the uCPU to be the master of the I-MEM and D-MEM memories, and enable the uCPU by writing 0x00 to the EDP\_CORE\_APB\_CTRL\_P register.

#### 12.6.6.9.1.5 FW Running indication

After loading the FW, the embedded FW takes approximately 2ms to complete the INIT phase and start running. The EDP\_CORE\_KEEP\_ALIVE\_P register specifies whether the FW is running.

**KEEP\_ALIVE** – The EDP\_CORE\_KEEP\_ALIVE\_P register is a counter initialized to 0 after reset and incremented by the FW on any scheduler loop.

When a valid FW is running, this register will be changed on every FW Scheduler loop (< 2ms). The host processor may use the mailbox channel immediately after reset, FW will response after the completion of INIT phase.

### Operational mode

After completion of boot sequence, the FW set the MHDPTX Controller in a standby mode. In the standby mode, it is ensured that no transaction is executed over the external interfaces (that is, AUX, PHY, Video).

Switching into active mode is done by executing the GENERAL\_MAIN\_CONTROL command.

#### 12.6.6.9.1.6 Software Events Handling

Software events are captured by the MHDPTX Controller FW, where the Event Value is stored in a designated area (in the D-MEM) and a bit is set by the FW in EDP\_CORE\_SW\_EVENTS0\_P register, see [Table 12-1518](#).

The host processor should poll the EDP\_CORE\_SW\_EVENTS0\_P register (cleared after read) and following a detection of event(s) the host processor should call the relevant command which returns the Event Value.

The Event Value holds the latest value associated with the event.

The EDP\_CORE\_SW\_EVENTS0\_P register is not cleared by the FW. Therefore, it is recommended to read this register (dummy read) to initialize the events to zero.

While any bit in EDP\_CORE\_SW\_EVENTS0\_P register is set, the MHDPTX Controller raises a hardware interrupt.

**Table 12-1518. EDP MHDPTX Controller Software Events**

Bit	Event	Description
31:8	RESERVED	-
7	HDCP_TX_IS_RECEIVER_ID_VALID	IP has an ID to check if it is valid, HDCP_TX_IS_RECEIVER_ID_VALID_REQ needs to be called.
6	HDCP2_TX_STORE_KM	IP has Km to store, HDCP2_TX_STORE_KM_REQ needs to be called.
5	HDCP2_TX_IS_KM_STORED	IP need to check if Km is stored, HDCP2_TX_IS_KM_STORED_REQ needs to be called.
4	HDCP_TX_STATUS	HDCP TX was changed, HDCP_TX_STATUS_REQ needs to be called.
3:1	RESERVED	-
0	DPTX_HPDP	HPD was changed, DPTX_READ_EVENT_REQUEST needs to be called.

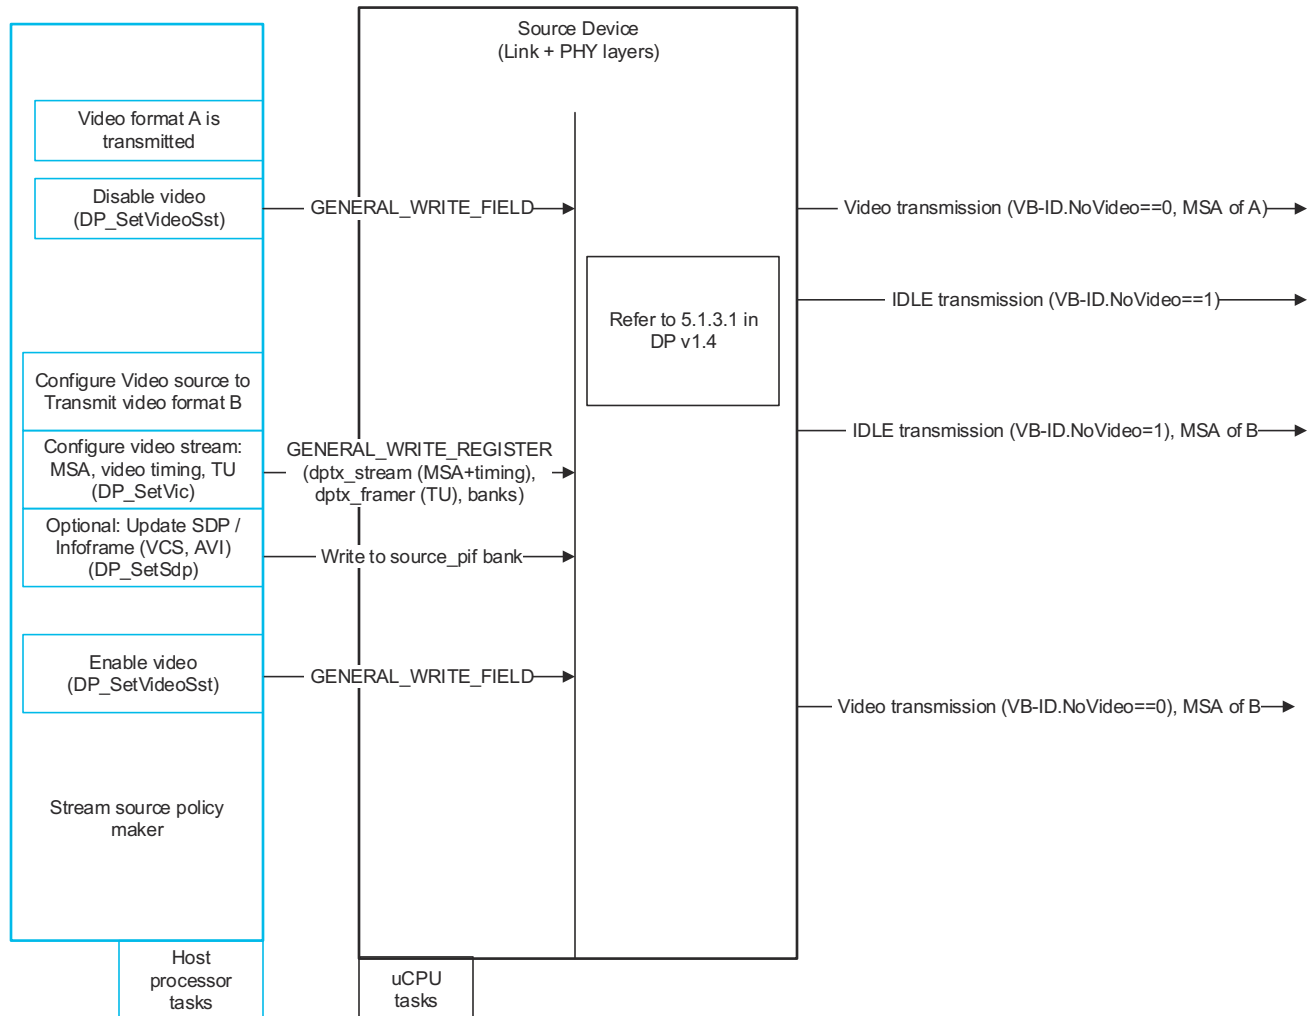

#### 12.6.6.9.1.7 DisplayPort Source (TX) Sequence

[Figure 12-1129](#) shows the expected host processor and uCPU tasks executed to start a video/audio transmission.

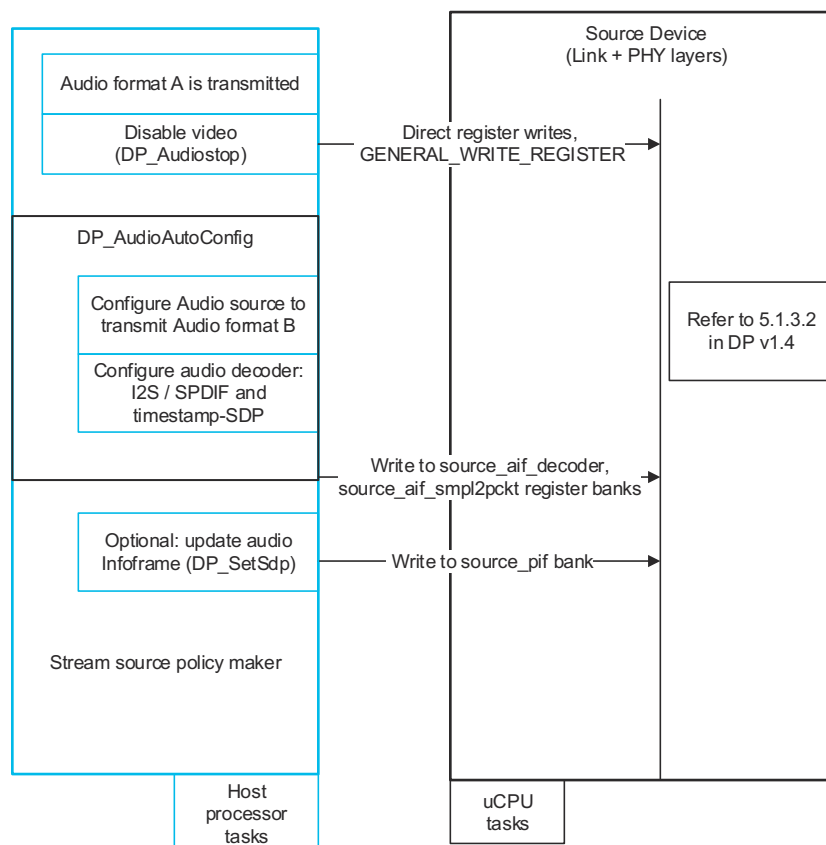

Copyright © 2024 Texas Instruments Incorporated

**Figure 12-1130. EDP Operation Sequence – DisplayPort Video Format Change**

**Figure 12-1131. EDP Operation Sequence – DisplayPort Audio Format Change**

#### 12.6.6.9.1.8 HDCP

The FW supports embedded HDCP crypto, with optional Km-key encryption.

##### 12.6.6.9.1.8.1 Embedded HDCP Crypto

In this mode, the HDCP functionality is fully supported by the MHDPTX Controller. The AKE phase and the corresponding cryptographic operations are handled by the FW.

Following the AKE phase, the FW initializes the stream cipher with the session key.

The host processor communicates with the MHDPTX Controller for:

- Configuring the capabilities
- Loading the HDCP keys (or certificate)
- Monitoring authentication status.

#### Note

Commands that carry secret information must be protected from tampering. Therefore, SAPB must be used to carry secured commands over mailbox.

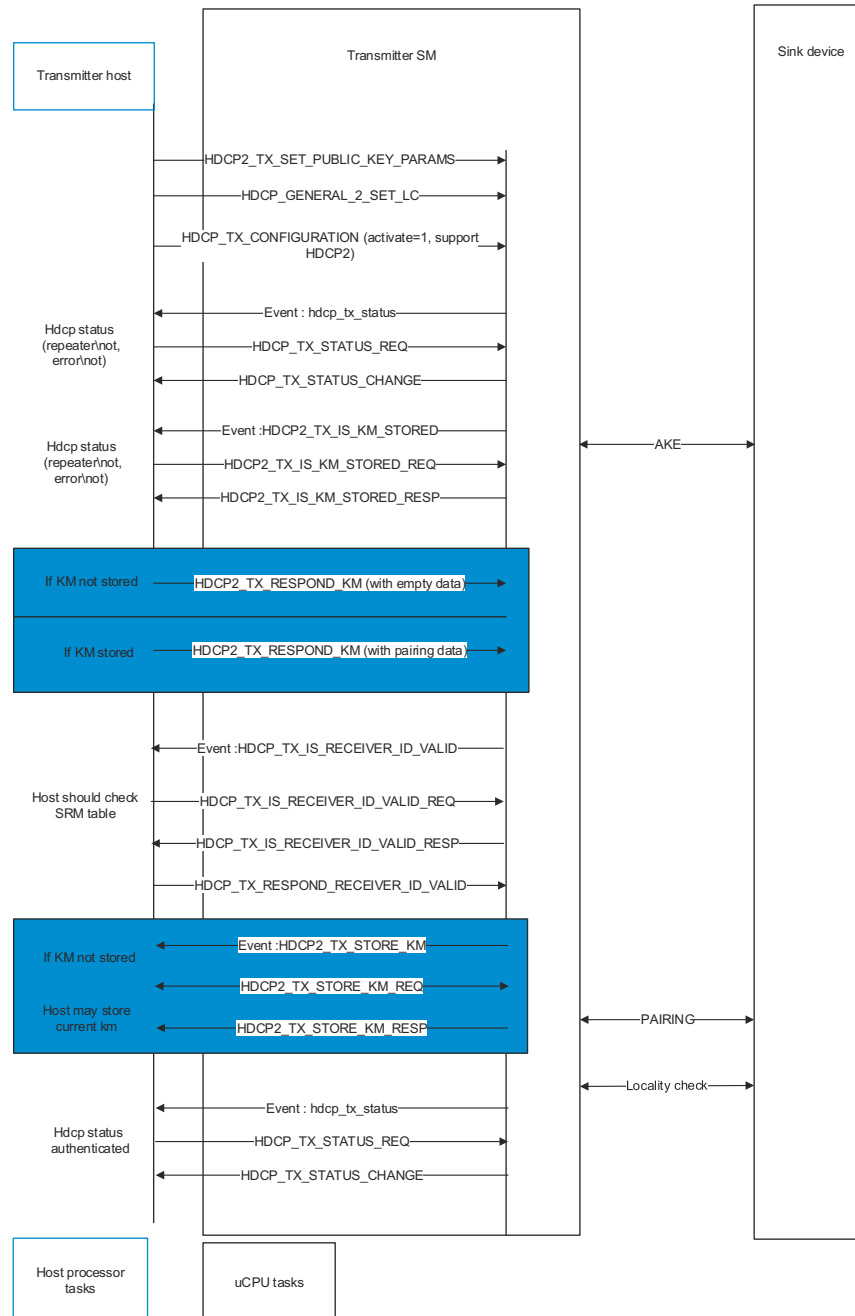

**Table 12-1519. EDP HDCP Commands With Secret Information**

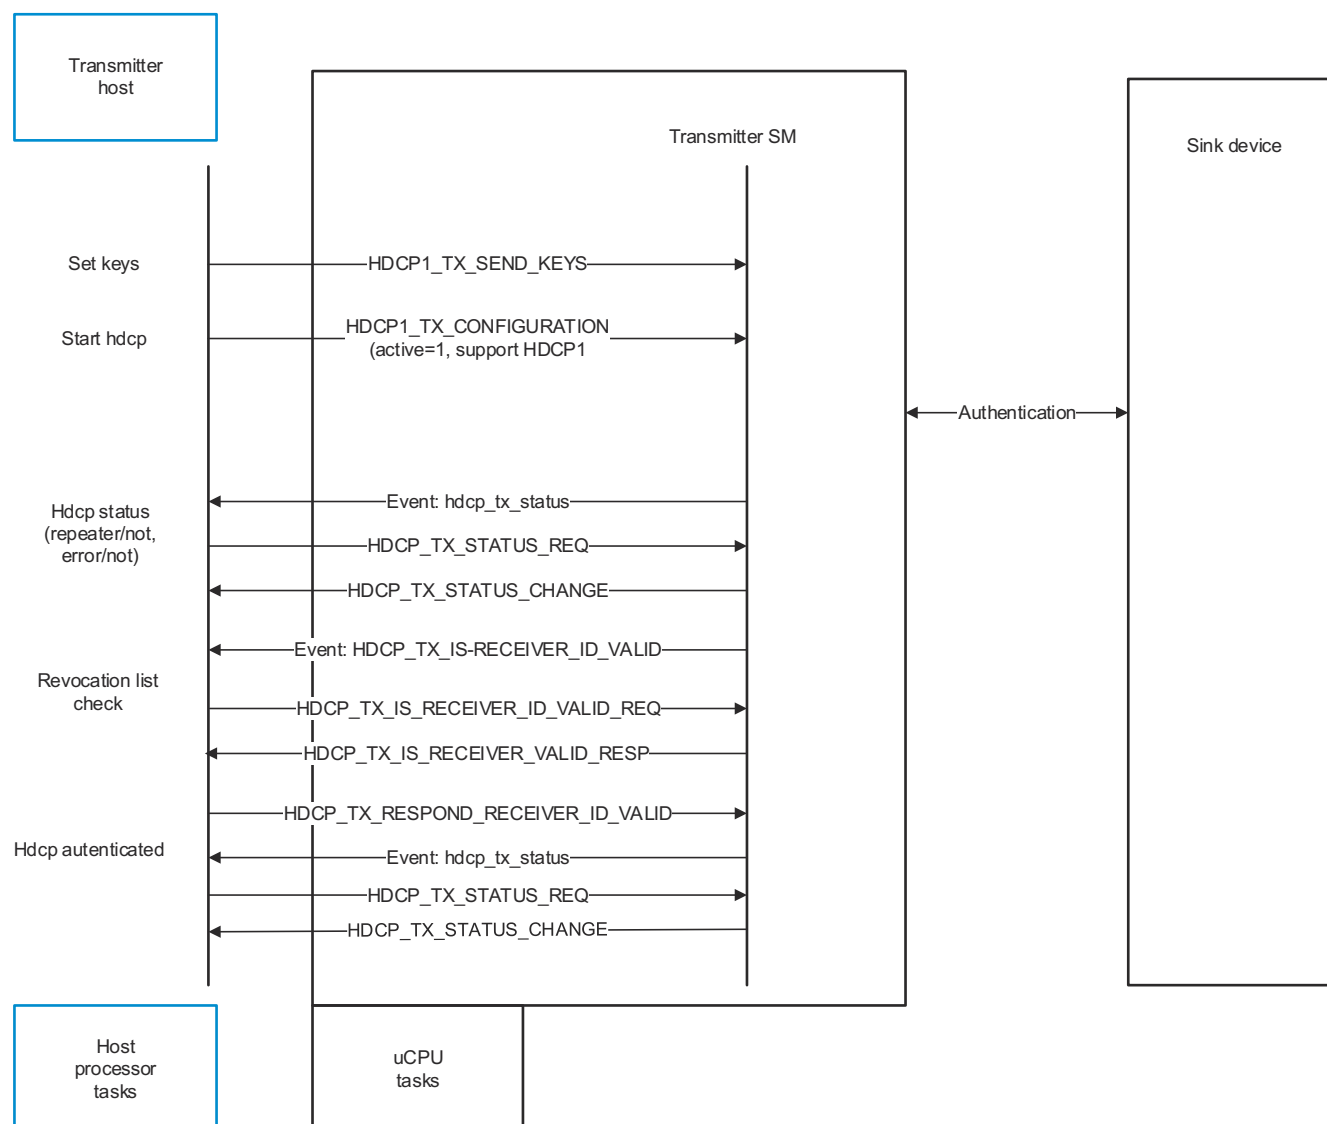

HDCP command	Description
HDCP_GENERAL_2_SET_LC	Refer to HDCP 2.2 Appendix A
HDCP_GENERAL_SET_SEED	External TRNG must be used for generating a true random seed number. Therefore, it is expected that the seed number will meet the high entropy level.
HDCP2_TX_RESPOND_KM	Refer to HDCP 2.2 Appendix A
HDCP1_TX_SEND_KEYS	Refer to HDCP 1.4 Appendix B

**Table 12-1519. EDP HDCP Commands With Secret Information (continued)**

HDCP command	Description
HDCP2_TX_STORE_KM	Refer to HDCP 2.2 Appendix A

Figure 12-1132 and Figure 12-1133 show the operation sequences for an embedded HDCP 2.2 and HDCP 1.4

**Figure 12-1132. EDP Operation Sequence – Embedded HDCP 2.2**

**Figure 12-1133. EDP Operation Sequence – Embedded HDCP 1.4**

### 12.6.6.9.1.8.2 Additional Security Features

#### 12.6.6.9.1.8.2.1 KM-Key Encryption

In order to provide higher security level an optional Km-key encryption is provided. If Km-key encryption is enabled while sending `HDCP_TX_CONFIGURATION` command, then HDCP controller will expect Master Key, 1.4 Device Keys and Global Constant. These keys will be decrypted using Km-key (loaded using `HDCP2_TX_SET_KM_KEY_PARAMS` command) by the controller's internal Firmware and used during Authentication and Key Exchange procedure. The Km-key encryption will also assure that when host reads Master Key it will receive it in encrypted form.

Enabling Km-key encryption affects the following commands or their parameters:

- `HDCP2_TX_RESPOND_KM/Km`
- `HDCP1_TX_SEND_KEYS/Transmitter Device Key`
- `HDCP2_TX_STORE_KM_RESP/Km`
- `HDCP_GENERAL_2_SET_LC`

#### **12.6.6.9.1.8.2.2 Cyphertext Stealing**

In order to use Km-key encryption for the 1.4 Device Keys and avoid changes in the API a Cyphertext Stealing technique is used. This technique allows to apply AES-ECB in Km-key encryption while 1.4 Device Key does not have size equal to multiple of 16.

#### **12.6.6.9.1.9 HD Display TX Controller**

##### **12.6.6.9.1.9.1 Info-Frame Handling**

Info-frames, which include meta-data (that is, auto type or video format), are initialized by the host processor.

The host processor directly initializes the PKT-MEM (which stores the info-frames). Initialization includes loading info-frame into PKT-MEM and updating the PKT LUT. Refer to DP\_SetSdp, DP\_RemoveSdp.

##### **12.6.6.9.1.9.1.1 EDID Handling**

The MHDPTX Controller issues command for reading EDID data from the remote side (sink). The EDID is sent to the host processor in a single block, that is, each block in one message. The MHDPTX Controller does not parse the EDID blocks. Refer to DP\_ReadEdid.

##### **12.6.6.9.1.9.1.2 Audio Control**

When changing an audio stream format, the host processor must follow a specific programming sequence by configuring the I2S decoder and audio info frame packet. Refer to DP\_AudioAutoConfig.

##### **12.6.6.9.1.9.1.3 Video Control**

The host processor need to configure the video timing before enabling the video stream over the VIF interface.

#### **12.6.6.9.1.10 DPTX TX Controller**

##### **12.6.6.9.1.10.1 Protocol over Auxiliary**

The firmware provides an interface for the AUX and I2C-over-AUX data transactions. The host processor may use it for direct DPCD (including the HDCP address range) or EDID access.

##### **12.6.6.9.1.10.2 PHY (Physical layer) Handling**

Separate PHY driver is used to initialize PHY.

DPTX PHY is handled by Core Driver, during link training (that is, Lane count, Link Rate, Pre-emphasis and Voltage Swing control).

#### **12.6.6.9.2 EDP PHY Wrapper Initialization**

EDP connects to the SERDES PHY wrapper (WIZ) using the RAW data mode. To enable this connection, the WIZ configuration registers in the SERDES PHY must be configured. For details on the SERDES PHY wrapper configuration, see Section 10-G SerDes Programming Guide.

The following is an example configuration for enabling 4-data lane RAW data mode for Display Port connection.

```
// SERDES_TOP_CTRL register bit-field settings:
```

```
// PMA_CMN_REF_CLK_MODE = 2'b10, PMA_CMN_REF_CLK_INT_MODE = 2'b10,  
PMA_CMN_REFCLK_DIV = 0, PMA_SUSPEND_OVERRIDE = 0
```

```
SERDES_TOP_CTRL register value = 32'h30000000
```

```
// SERDES_RST register bit-field settings:
```

```
// PHY_RESET_N = 0 (PHY in reset)
```

```
// PHY_EN_REFCLK = 0 (PHY reference clock output disabled)
```

```
// PLL1/0_REFCLK_SEL = 0 (for cmn_refclk_<p/m> select), 1 (for pma_cmn_refclk_int select)
```

```
// REFCLK_TERM_DIS = 1 (termination disabled)
```

```
// REFCLK_DIG_SEL = 1 (PMA common reference clock select: 0 for cmn_refclk_<p/m>, 1 –
pma_cmn_refclk_int)

// If the reference clock is sourced from internal digital input:

// PLL1_REFCLK_SEL = 1, PLL0_REFCLK_SEL = 1, REFCLK_TERM_DIS = 1, REFCLK_DIG_SEL = 1
SERDES_RST register value = 32'h39000000

// Alternatively, if the reference clock is sourced from <p/m> inputs:

// PLL1_REFCLK_SEL = 0, PLL0_REFCLK_SEL = 0, REFCLK_TERM_DIS = 0, REFCLK_DIG_SEL = 0
SERDES_RST alternative register value = 32'h00000000

// LANECTLx register bit-field settings:

// P0_ENABLE = 0, P0_FORCE_ENABLE = 1, P0_ALIGN = 1, P0_RAW_AUTO_START = 1,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL0 register value = 32'h70000000 // for lane 0

// P0_ENABLE = 1, P0_FORCE_ENABLE = 0, P0_ALIGN = 0, P0_RAW_AUTO_START = 0,
P0_STANDARD_MODE = 0, P0_FULLRT_DIV = 0
LANECTL1 register value = 32'h80000000 // for lane 1
LANECTL2 register value = 32'h80000000 // for lane 2
LANECTL3 register value = 32'h80000000 // for lane 3

// LANEDIVx register bit-field settings:

// P0_MAC_DIV_SEL0 = 7'b1, P0_MAC_DIV_SEL1 = 9'b1
LANEDIV0 register value = 32'h00010001 // for lane 0
LANEDIV1 register value = 32'h00010001 // for lane 1
LANEDIV2 register value = 32'h00010001 // for lane 2
LANEDIV3 register value = 32'h00010001 // for lane 3

// Set DIAG_REG register to 0
DIAG_TEST register value = 32'h0
```

### Note

The SERDES PHY reset is not driven by the EDP controller (that is, by writing to the EDP\_CORE\_PHY\_RESET\_P[8] PHY\_RESET register bit. Instead, the SERDES PHY reset is mapped to the SERDES\_RST[31] PHY\_RESET\_N register bit in the SERDES PHY wrapper. But, the EDP\_CORE\_PHY\_RESET[8] PHY\_RESET bit is still used in the EDP controller to disable the controller's output to the SERDES. Therefore, after reset, the EDP\_CORE\_PHY\_RESET[8] PHY\_RESET bit must be set to 1 (reset off). After this, the SERDES reset can be controlled strictly with the SERDES\_RST[31] PHY\_RESET\_N bit.

### 12.6.6.9.3 EDP PHY Programming

Table 12-1520 shows information on how to program the EDP PHY (SERDES).

**Table 12-1520. EDP PHY (SERDES) Programming Details**

General Information	
Standards / links / lanes supported	Display port and embedded display port / 2 links / 1, 2, or 4 lanes per link
Reference clock information and setup	

**Table 12-1520. EDP PHY (SERDES) Programming Details (continued)**

<b>General Information</b>	
External / internal reference clock selection	Set up external or internal reference clock.
Reference clock frequency selection	Set up the reference clock programming for the selected reference clock frequency
<b>PLL and high speed clocking information and setup</b>	
PLL 0, Mode 0	Display port link 0. Note, if only link 1 is used, PLL 0 must be programmed in the same as PLL 1.
PLL 0, Mode 1	Unused
PLL 1, Mode 0	Display port link 1. Note, if only link 0 is used, PLL 1 must be programmed in the same as PLL 0.
PMA common full rate and data rate clocks	Unused
PMA transceiver full rate and data rate clocks	Full rate and data rate clocks are used as specified in the PMA spec table Clock rates for supported standards.
<b>Top level pins</b>	
PMA: cmn_pll0_mode_sel (Driven by PHY internal logic)	1'b0
PMA: cmn_pll1_mode_sel (Driven by PHY internal logic)	1'b0
PHY: phy_ln{nn:00}_mode[1:0]	2'b11
PHY: phy_link_cfg_ln_{n:1}	1'b0 for slave lanes of each link 1'b1 for the master lane of each link
<b>PHY configuration specific registers</b>	
SERDES register PHY_AUTO_CFG_SPDUP, bit-fields [1] PHY_PLL_CFG_1 and [0] PHY_PLL_CFG_0	16'h0000 for single DP link configuration 16'h0002 for 2 DP link configuration
<b>Set PLL analog clock divider values</b>	
SERDES register CMN_PDIAG_PLL0_CLK_SEL_M0__CMN_PDIAG_PLL0_CTL_M0	Link 0: Program it as described
SERDES register CMN_PDIAG_PLL1_CLK_SEL_M0__CMN_PDIAG_PLL1_CTL_M0	Link 1: Program it as described
<b>Select analog high speed clock, and transceiver clock divider values</b>	
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [15:0] Link 0 Link 1	16'h0000 16'h0001
SERDES register XCVR_DIAG_HSCLK_DIV__XCVR_DIAG_HSCLK_SEL_j, bits [31:16]	Program it as described
<b>Select digital PLL clock and data rate divider values</b>	
SERDES register XCVR_DIAG_PLLDRC_CTRL__XCVR_DIAG_XDP_PWRI_S TAT_j Link 0 Link 1	16'h0001 16'h0009
<b>Protocol specific setup</b>	
Display port and embedded display	Program it as described

## 12.7 Camera Subsystem

This section describes the Camera Subsystem in the device.

## 12.7.1 Camera Streaming Interface Receiver (CSI\_RX\_IF)

The following sections describe the camera streaming receiver interface (CSI\_RX\_IF) modules in the device.

### 12.7.1.1 CSI\_RX\_IF Overview

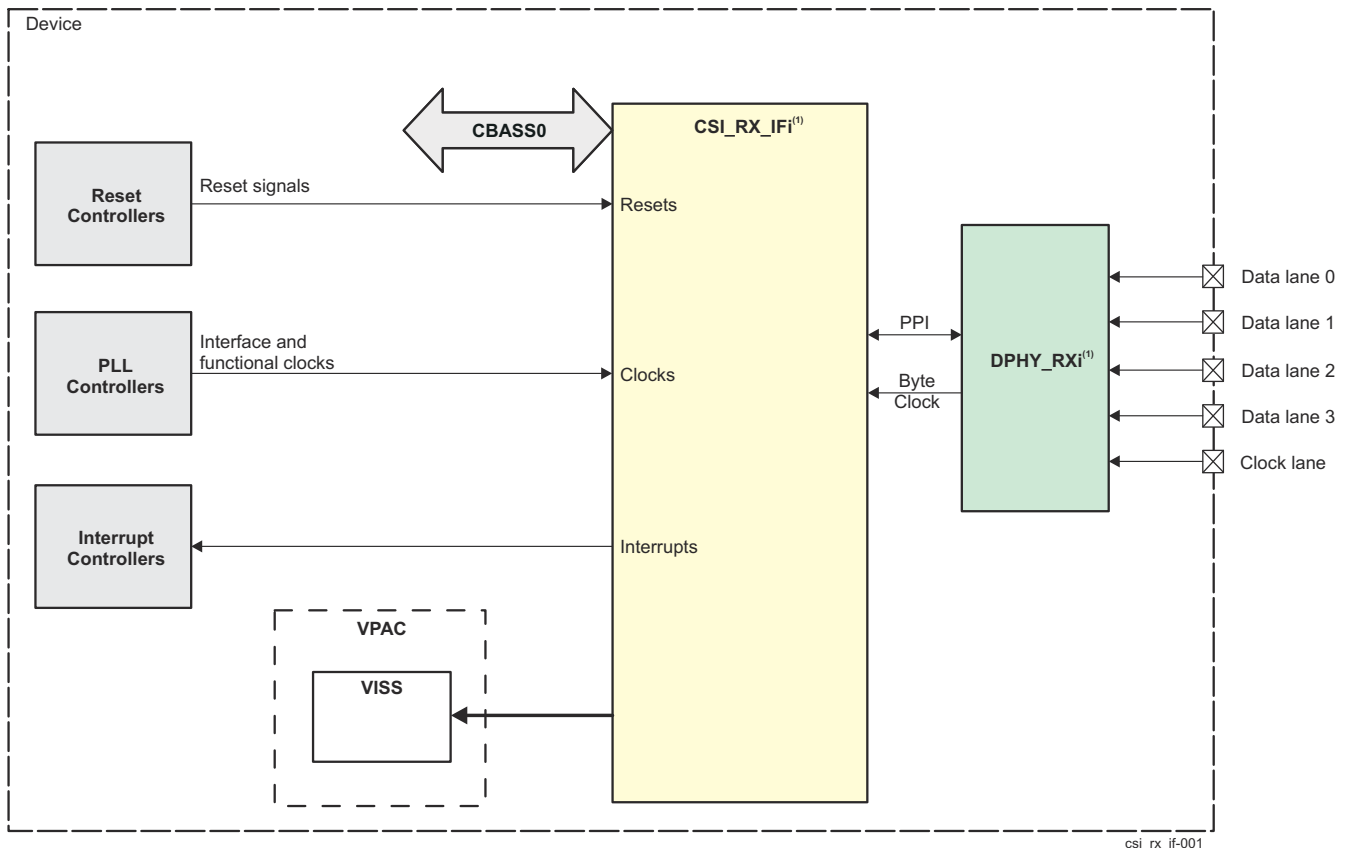

The integration of the CSI\_RX\_IF module allows the device to stream video inputs from multiple cameras to the image processing accelerator (VPAC) or to internal memory. The video input may also be retransmitted via the transmitter CSI (CSI\_TX\_IF) for debug and test purposes.

Table 12-1521 shows the CSI\_RX\_IF module allocation across device domains.

**Table 12-1521. CSI\_RX\_IF Modules Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
CSI_RX_IF0	-	-	✓
CSI_RX_IF1	-	-	✓

Figure 12-1134 shows the CSI\_RX\_IF module overview.

A. i = 0 to 1

**Figure 12-1134. CSI\_RX\_IF Module Overview**

#### 12.7.1.1.1 CSI\_RX\_IF Features

The CSI\_RX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3
- Supports up to 16 virtual channels per input (partial MIPI CSI v2.0 feature)

- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_RX
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported)
- Four independent (simultaneous) output streams:
  - Two VP 32-bit streams to VISS inputs of VPAC image processing accelerator:
    - 2x 16-bit pixels per clock cycle
    - One virtual channel and data type per port
    - Raw format only (8-16 bits)
    - 32bit, 2 pixels wide, elastic buffer mode
      - Data[15:0]: Pixel n (MSB zero padding)
      - Data[31:0]: Pixel n+1 (MSB zero padding)
      - Internal full flag (FF) based FIFO (2048x32)
      - VP clock asynchronous to CSI\_RX\_IF main clock. Crossing done internally.
  - One (up to 4 channels) PPI 16-bit pixel retransmission interface to CSI\_TX\_IF:
    - 2x 16-bit pixels per clock cycle
    - 32bit retransmission width
    - No external buffer
    - Raw format only (8-20 bits, partial MIPI CSI v2.0 feature)
    - CSI\_RX\_IF and CSI\_TX\_IF main clocks must be running at the same frequency and synchronous.
  - One (up to 32 Channels) DMA interface through a 128-bit PSI\_L connection to NAVSS for transfers to memory:
    - Byte packed (32x4) format, elastic buffer mode
    - Max rate 1 data cycle every 4 main clocks
    - ByteValid per byte in Last Data Phase (LDP)
    - 32 thread ID's supported (virtual channel & data type combinations); Flexible number of threads (32 Max)
    - Virtual channels and data types mapped via mmr to PSI\_L thread ID's
    - Internal FF based FIFO; RAM based buffer (2kx128)
- Functional and data path error interrupts
- ECC support

#### 12.7.1.1.2 CSI\_RX\_IF Not Supported Features

The CSI\_RX\_IF does not support the following features:

- MIPI CSI2 v2.0 scrambling
- MIPI CSI2 v2.0 optional no LP (low power state) between packets
- Cropping
- Pixel processing
- Virtualization
- YUV420-8 legacy not supported
- YUV420 interleave limitation. The entire frame must be sent.
- Full line buffer mode is not supported

#### 12.7.1.2 CSI\_RX\_IF Environment

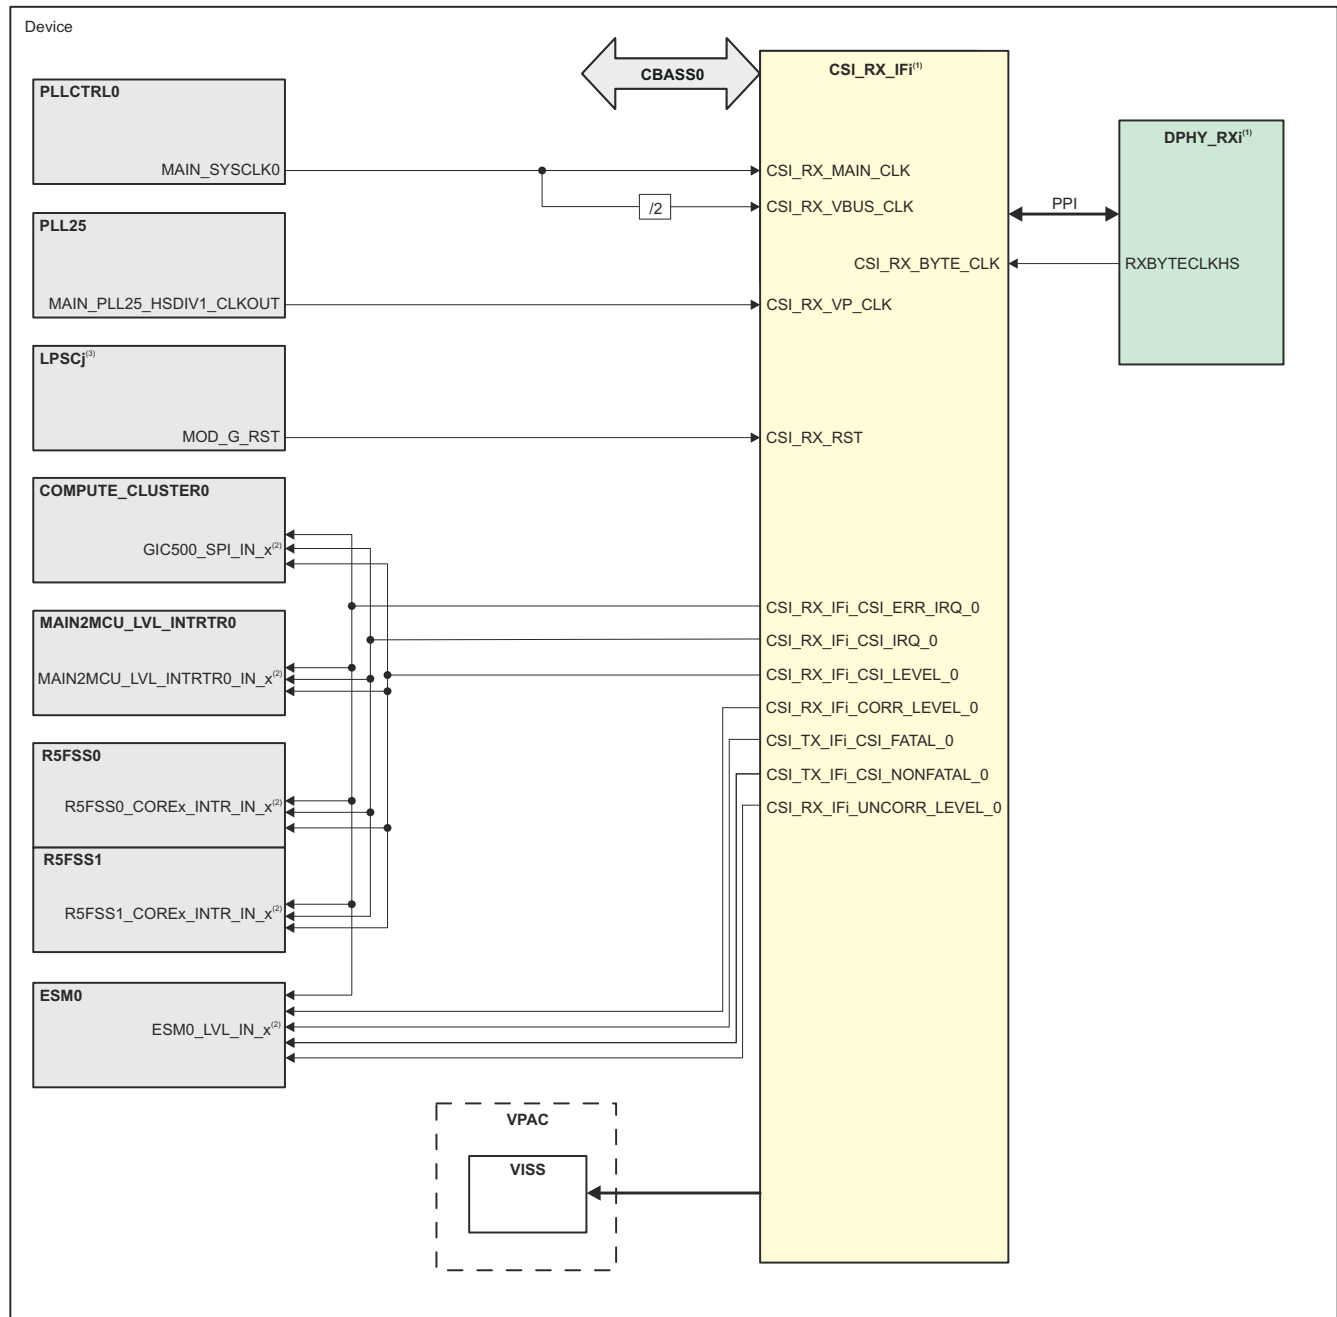

The CSI\_RX\_IF has no dedicated pins. At the device level, video inputs come from the DPHY\_RX, see [Section 12.7.2](#).

### 12.7.1.3 CSI\_RX\_IF Integration

This section describes the CSI\_RX\_IF integration in the device, including information about clocks, resets, and hardware requests.

#### 12.7.1.3.1 CSI\_RX\_IF Integration in MAIN Domain

There are several CSI\_RX\_IF modules integrated in the device MAIN domain. [Figure 12-1135](#) shows the integration of CSI\_RX\_IF modules.

csi\_rx\_if-002

- A.  $i = 0$  to  $1$
- B.  $x$  = Interrupt port index, see [Table 12-1524](#)

C. j = LPSC index, see [Table 12-1522](#)

**Figure 12-1135. CSI\_RX\_IF Integration**

[Table 12-1522](#) through [Table 12-1524](#) summarize the integration of CSI\_RX\_IF in the device MAIN domain.

**Table 12-1522. CSI\_RX\_IF Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
CSI_RX_IF0	PSC0	PD2	LPSC53	CBASS0
CSI_RX_IF1	PSC0	PD2	LPSC54	CBASS0

**Table 12-1523. CSI\_RX\_IF Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
CSI_RX_IF0	CSI_RX_MAIN_CLK	MAIN_SYSCLK0	PLLCTRL0	Main functional clock.
	CSI_RX_VBUS_CLK	MAIN_SYSCLK0 / 2	PLLCTRL0	The VBUS clock runs at always half the speed of the CSI_RX_MAIN_CLK.
	CSI_RX_VP_CLK	MAIN_PLL25_HSDIV1_CLKOUT	PLL25	Video port interface clock. It must run at the same speed or higher than the CSI_RX_MAIN_CLK. It can be async to the CSI_RX_MAIN_CLK clock. However, it must be sync to VPAC video clock.
	CSI_RX_BYTE_CLK	RXBYTECLKHS	DPHY_RX0	The byte clock is the clock supplied by the DPHY_RX.
CSI_RX_IF1	CSI_RX_MAIN_CLK	MAIN_SYSCLK0	PLLCTRL0	Main functional clock.
	CSI_RX_VBUS_CLK	MAIN_SYSCLK0 / 2	PLLCTRL0	The VBUS clock runs at always half the speed of the CSI_RX_MAIN_CLK.
	CSI_RX_VP_CLK	MAIN_PLL25_HSDIV1_CLKOUT	PLL25	Video port interface clock. It must run at the same speed or higher than the CSI_RX_MAIN_CLK. It can be async to the CSI_RX_MAIN_CLK clock. However, it must be sync to VPAC video clock.
	CSI_RX_BYTE_CLK	RXBYTECLKHS	DPHY_RX1	The byte clock is the clock supplied by the DPHY_RX.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
CSI_RX_IF0	CSI_RX_RST	MOD_G_RST	LPSC53	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.
CSI_RX_IF1	CSI_RX_RST	MOD_G_RST	LPSC54	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state

### 12.7.1.4 CSI\_RX\_IF Functional Description

#### 12.7.1.4.1 CSI\_RX\_IF Block Diagram

Figure 12-1136 depicts a simplified internal block diagram of the CSI\_RX\_IF and its surroundings.

**Figure 12-1136. CSI\_RX\_IF Block Diagram**

The CSI2 core streams 4 channels of data to the several export paths.

**Stream0** (high BW DMA up to 32 channel contexts) streams 32-bits worth of data, that is re-formatted and sent as pixel format into 128 bits as PSIL data. There are 32 sets of MMRs/Registers that map virtual channels and data type to PSIL threads. Data is sent out PSIL in FIFO order as it is received. There is no priority. Data re-formatting is done to end up with correct data organization in memory so that other ip can use the data. The data type must be configured in MMRs to ensure proper reformatting. See Section 12.7.1.4.5. The large buffer of PSIL data (2048x128) has ECC protection, see Section 12.7.1.4.7

**Stream1** (unlimited channel contexts, minimal buffering) streams an optional loopback output to CSI\_TX\_IF controller for diagnostic check.

#### 12.7.1.4.2 CSI\_RX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_RX\_IF by device LPSC. It is internally resynchronized to the functional clock domain.

A software reset is triggered by configuring the CSI\_RX\_IF\_VBUS2APB\_SOFT\_RESET bit-fields for protocol reset and/or module reset.

#### 12.7.1.4.3 CSI\_RX\_IF Clock Configuration

There are four clock domain in the CSI\_RX\_IF.

1. The CSI\_RX\_MAIN\_CLK clock runs the CSI2 core, PSIL DMA, and retransmits to CSI\_TX\_IF. The minimum clock rate for the CSI\_RX\_MAIN\_CLK is 312.5MHz when DPHY is at max data rate (slower clock permissible when DPHY is at lower data rates). When CSI\_RX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY\_RX. Said another way, CSI\_RX\_MAIN\_CLK must be at least the CSI\_RX\_BYTE\_CLK rate, else FIFOs will overflow. The maximum clock rate is 500MHz 16ffc, 650 Max  $f(\text{CSI\_RX\_BYTE\_CLK}) \times \text{nb\_lanes} / 4$ ; where  $f(\text{CSI\_RX\_BYTE\_CLK})$  is the minimum frequency of CSI\_RX\_BYTE\_CLK.
2. The CSI\_RX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_RX\_MAIN\_CLK.
3. The CSI\_RX\_VP\_CLK is the video port interface clock. It must run at the same speed or higher than CSI\_RX\_MAIN\_CLK. It can be async to CSI\_RX\_MAIN\_CLK clock. It also must be sync to VPAC video clock. Up to 720MHz max rate
4. The CSI\_RX\_BYTE\_CLK is the clock supplied by the DPHY\_RX PLL and is divided down to byte clock. The DPHY\_RX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_RX is not in HS operation.

Table 12-1525 shows the CSI\_RX\_IF and DPHY\_RX inter-clock dependencies.

**Table 12-1525. CSI\_RX\_IF Inter-clock Dependencies**

	CSI_RX_MAIN_CLK	CSI_RX_VBUS_CLK	CSI_RX_VP_CLK	CSI_RX_BYTE_CLK
<b>Min freq</b>	CSI_RX_BYTE_CLK freq	CSI_RX_MAIN_CLK / 2 freq	CSI_RX_BYTE_CLK freq	N/A
<b>Max freq</b>	500MHz	CSI_RX_MAIN_CLK / 2 freq	720MHz	312.5MHz

#### 12.7.1.4.4 CSI\_RX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_RX\_IF interrupt signals. For detailed description and mapping of the interrupt of the device interrupt processors see *CSI\_RX\_IF Integration*.

The interrupts are generally handled within the INTD module of the CSI\_RX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

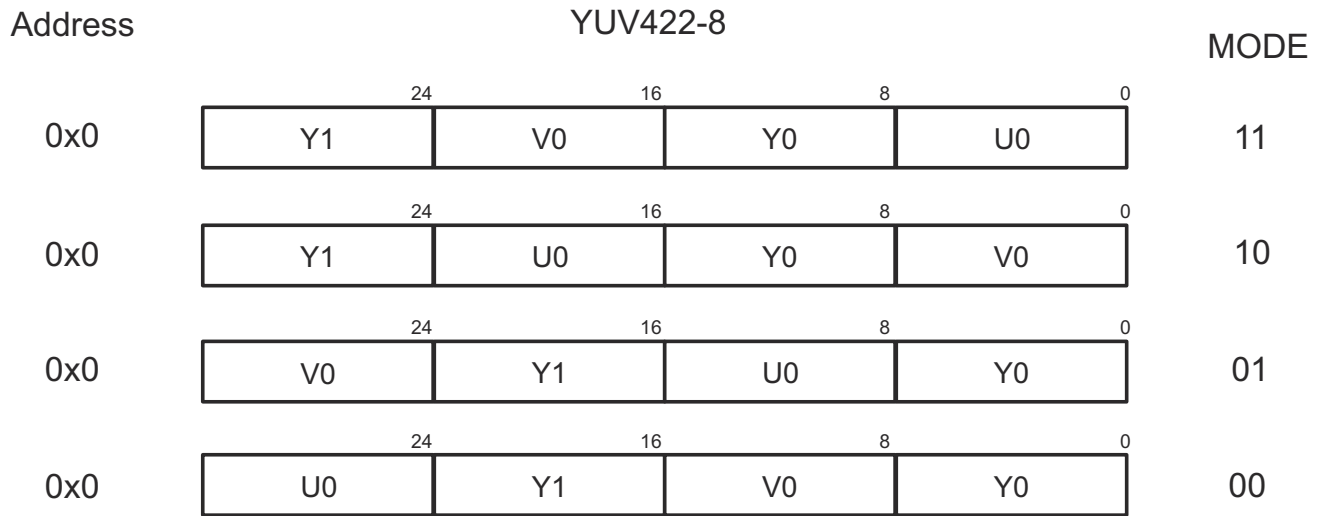

Table 12-1526 lists the event generation and corresponding registers of the CSI\_RX\_IF controller.

**Table 12-1526. CSI\_RX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_RX_CSI_ERR_IRQ	CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_ERROR_IRQS	Stream error detected. The CSI_RX_IF0 will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI_RX_CSI_ERR_IRQ. Read the status register bitfields to trace the source of the event.
CSI_RX_CSI_IRQ	CSI_RX_IF_CP_INTD_ENABLE_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS_MASK_CFG	CSI_RX_IF_CP_INTD_STATUS_REG_LEVEL_0 CSI_RX_IF_VBUS2APB_ERROR_IRQS	Global functional interrupt that various resynchronized sources converge into interrupt generation.
CSI_RX_CSI_LEVEL	CSI_RX_IF_VBUS2APB_MONITOR_IRQS_MASK_CFG	CSI_RX_IF_VBUS2APB_STREAM0_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM1_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM2_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM3_FIFO_FILL_LVL CSI_RX_IF_VBUS2APB_STREAM0_FIFO_FILL_LVL	PSI_L fifo overflow or VP0/VP1 frame/line mismatch (at the minimum an error interrupt will occur at the end of frame but may be issued within the frame as well). Read the status register bitfields to trace the source of the event.
CSI_RX_CORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.
CSI_RX_UNCORR_LEVEL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	This interrupt is for checking the interface signals of the CSI_RX_IF0 controller for parity.
CSI_RX_CSI_FATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_RX_IF_VBUS2APB_ASF_INT_MASK	CSI_RX_IF_VBUS2APB_ASF_INT_STATUS	ASF port non-fatal interrupt. Level sensitive. Set CSI_RX_IF_VBUS2APB_ASF_FATAL_NONFATAL_SELECT to whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_RX_IF_VBUS2APB_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.7.1.4.6 CSI\_RX\_IF PSI\_L (DMA) Interface

##### Note

This section describes CSI\_RX\_IF PSI\_L specific functionality related to the camera interface. The general PSI\_L functional description and registers are described in the PSI\_L specific chapter (see *PSIL Subsystem (PSILSS)*).

##### 12.7.1.4.6.1 PSI\_L DMA framing

The CSI\_RX\_IF stream interface provides the usual VSYNC/HSYNC signals. The signals are per virtual channel where the transition from 1-to-0 or 0-to-1 represents SOF/EOF or SOL/EOL. VSYNC/HSYNC transition is usually not coincident with a valid data phase, though there are use cases where it can be. Because of the nature of CSI protocol, the VSYNC and HSYNC transactions require at least a single clock cycle and can only transition sequentially (important fact in handling of VSYNC events).

There is a rarely used mode of CSI where an entire frame is passed in a single packets without line breaks. In this mode, there are no HSYNC transitions at line starts/ends.

Lastly, there is redundant information provided with each CSI packet where the packet length is supplied in bytes.

To overcome these framing restrictions, the CSI\_RX\_IF PSILSS0 passes metadata through the DMA FIFO. Anytime metadata is inserted into the FIFO, the CSI\_RX\_IF stream is stalled for a clock cycle. The forms of supported meta tags are:

- SOF for a given virtChan
- EOF for a given virtChan
- Packet length in bytes for a given dmaCntx

The PSILSS0 will disregard the HSYNC signal entirely. The long packet beginning is used as SOL and the EOL will be "counted" using the packet length provided. In the special case where packets are of FRAME length, the SOL/EOL handling is identical.

The PSILSS0 solution for VSYNC handling is to create the concept of metadata FIFO entry which is indicated by a metadata bit. The SOF or EOF VSYNC information plus the virtualChan index is fed into the FIFO. On the output of the FIFO, the SOF is saved for each context of that virtualChan type. The very next data phase of that channel context will be marked as SOF. Additionally a state bit per context is maintained indicating the channel is MOP (middle of packet). Once the EOF arrives at the FIFO output, all contexts of that type virtual channel (and currently in MOP state) will receive a PSI\_EOP with zero active bytes of data.

### CAUTION

The line and frame size is not known outside the CSI core (i.e. not passed to the DMA interface). Therefore any mismatches at system level programming will be unknown. If the DMA line/frame size does not match the CSI\_RX\_IF line/frame size, it is assumed the DMA will not result in any adverse side effects as a result of not enough data or too much data.

#### 12.7.1.4.6.2 PSI\_L DMA error handling due to FIFO overflow

The DMA error handling is also called a PSI\_L protocol enforcer. It is intended to prevent hang of the PSILSS0. Unnatural packet size should not cause hang so only SOP/SOL/EOL/EOP framing is enforced. The following list highlights the error handling mechanism:

- For context cleanup the protocol enforcer:
  - cycle through each context index checking if context is in MOL or MOP
  - close out MOP with EOP and MOL&MOP with EOL&EOP
- dropOnFloor SOP if currently in MOPstate
- dropOnFloor EOP if not currently in MOPstate
- dropOnFloor FIFO data
- EOL context if EOP and MOLstate
- After closing out all open contexts the PSILSS0 logic will then wait till end of frame per virtual channel. Once a new frame starts it will then start sending out data from that new frame

#### 12.7.1.4.7 CSI\_RX\_IF ECC Protection Support

ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_RX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregator in the CSI\_RX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. It provides a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUSP interface for configuring and querying the ECC register set, see *CSI\_RX\_IF ECC Registers*. For complete details on the features and functions of the ECC aggregator, see chapter *ECC Aggregator*.

#### 12.7.1.4.8 CSI\_RX\_IF Programming Guide

##### 12.7.1.4.8.1 Overview

This section details specific steps on how to program the CSI\_RX\_IF controller.

##### 12.7.1.4.8.2 Controller Configuration

The CSI\_RX\_IF streams will default to accept all virtual channels and all data types after reset, so the user must program the stream configuration and pixel interface to match the system use case.

### Note

The CSI\_RX\_IF controller can be configured so that the reset values can adopt the users Power\_On state. This can reduce the programming steps required by the system.

The CSI\_RX\_IF controller is designed to operate all the defined streams with all virtual channels and all data types passed to the pixel interface. Also, the connection to the front interface adopts reset values that will allow the connection of the lanes to expect no remapping.

The basic system configuration steps are then programming the number of enabled data lanes and starting the streams.

The system can also decrease the virtual channel and data type processed by the stream by configuring the data config (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG) registers.

The user must perform a read from the stream config register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CFG) at power up to identify the number of streams and pixel interface mode. The stream FIFO depth must be determined from the system configuration information defined at build time to ensure that any programmed [31-16] FIFO\_FILL level is valid for the available FIFO depth.

#### 12.7.1.4.8.3 Power on Configuration

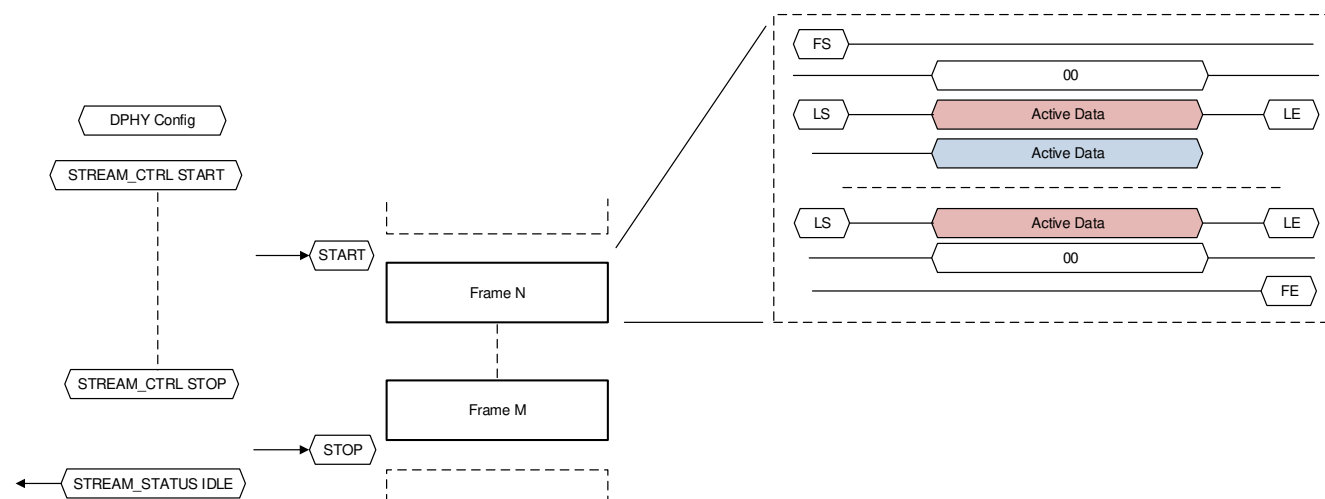

The CSI\_RX\_IF requires the system to perform the configuration of the DPHY\_RX interface before starting the streams of the controller. The default configuration of the controller and each stream can be identified by reading the device ID CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG register.

The FW must read the CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG register at power up. This will provide the FW the number of streams that will need to be configured, and all the default system information for the FIFO structures in the available streams.

**Table 12-1527. CSI\_RX\_IF\_VBUS2APB\_DEVICE\_CONFIG bitfield details**

STREAMx_NUM_PIXELS	The width of the pixel interface and the bits per pixel for the selected datatype will determine how many pixels can be output in a single cycle. Default will be 1 pixel per clock. 00 -> 1 pixel per clock 01 -> 2 pixels per clock 10 -> 4 pixels per clock
DATAPATH_SIZE	Internal Datapath width 00 - 32 bit, all other values are reserved.
NUM_STREAMS	Number of Stream interfaces (1-4) = (value+1)
MAX_LANE_NB	Max Number of Lanes (1-4) = (value+1)

Figure 12-1144 shows the minimal sequence of registers that will configure the DPHY\_RX and then start the stream; this will output all the pixel information for all virtual channels and all data types detected in the link data stream.

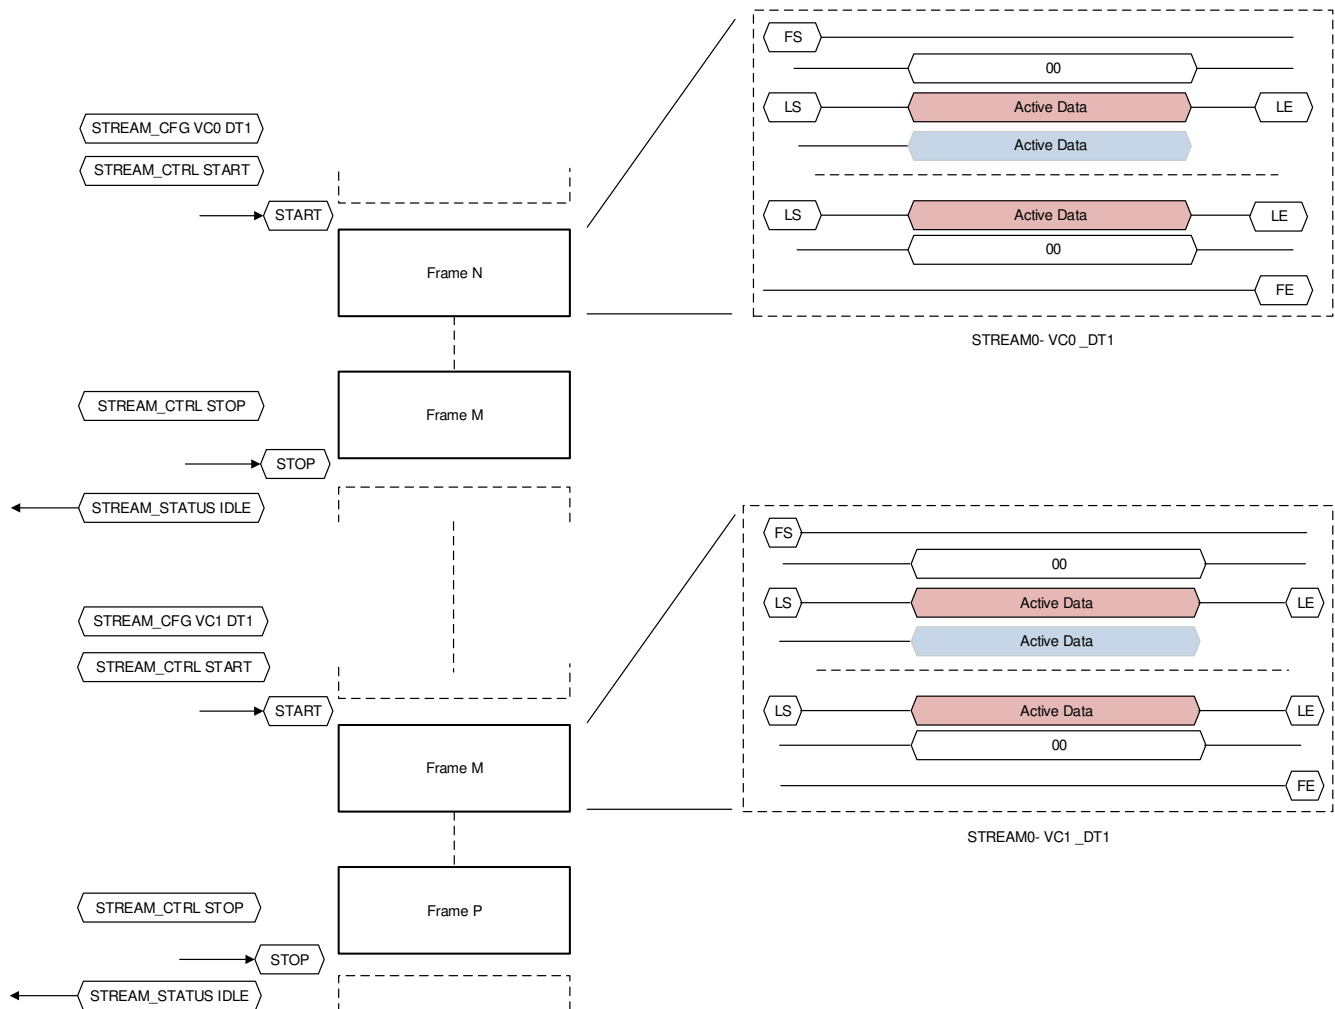

**Figure 12-1144. Minimal Stream Control - Start and Stop**

#### 12.7.1.4.8.4 Stream Start and Stop

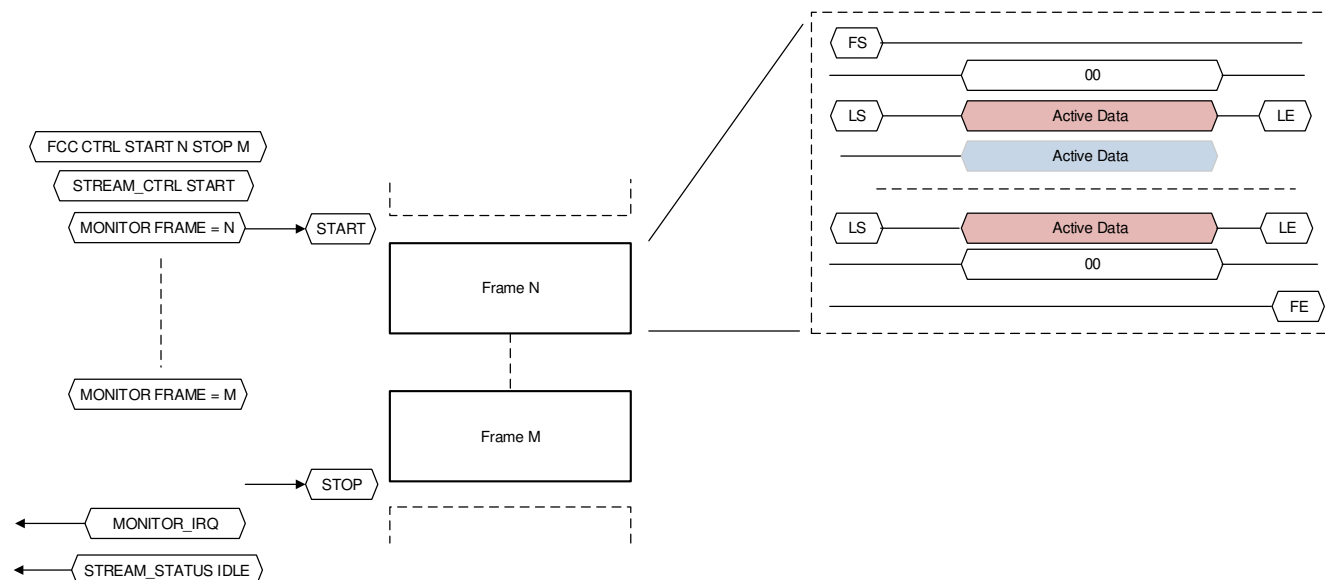

The CSI\_RX\_IF will perform management of the stop and halt control to the pixel stream during functional operation to allow any stream to change the virtual channel or data type information that the stream will process.

- The FW will use the stream control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL) to perform a stop (set bit 1) and wait for the end of any current frame, and wait for the stream to return its state to IDLE, which can be read from stream status register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_STATUS - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_STATUS)[31] RUNNING = 1.
- The FW will use the stream control register to perform an abort and wait for the end of any current line, and wait for the stream to return its state to IDLE, which can be read from register STREAM\_STATUS[31] RUNNING = 1.

**Figure 12-1145. Stream Reconfiguration Using Start Stop Start Flow**

The CSI\_RX\_IF will use the monitor control or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-1146. Stream Start and Stop Using Monitor Control**

#### 12.7.1.4.8.5 Error Control With Soft Resets

The CSI\_RX\_IF will perform control of the soft reset either for error event recovery or to clear a stream FIFO or internal state machine.

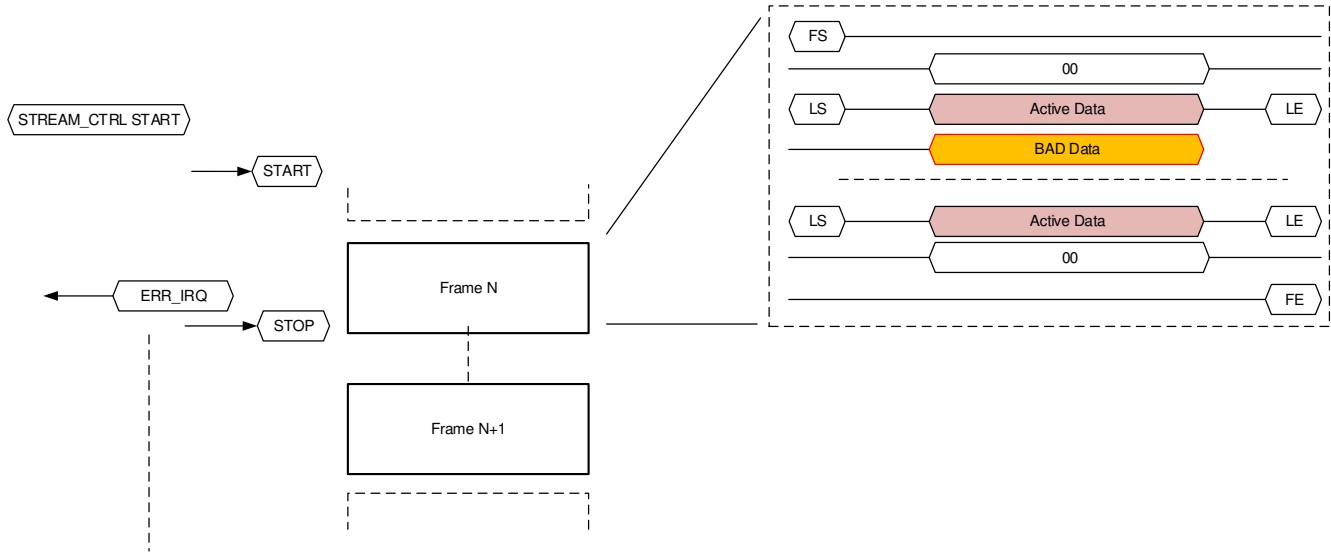

- The FRONT block can be soft reset if the DPHY\_RX becomes unresponsive and the controller wishes to maintain its configuration. In this case the DPHY\_RX resets can be applied and the DPHY\_RX enabled to begin the transfer again.
- The Protocol block can be soft reset if the FRONT soft reset is required, and the protocol is not in the IDLE state.
- The stream soft resets (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL)[4] SOFT\_RST can be used to clear the stream to the stop state and reset all the stream state machines and FIFO. If the system has a failure and wishes to clear the stream FIFO and return to a safe state on the pixel interface, the stream soft reset should be asserted.

#### 12.7.1.4.8.6 Stream Error Detected – No Error Bypass Mode

The CSI\_RX\_IF will default to stop processing the frame whenever a header Reserved DT or ECC error is detected, or when a long packet payload CRC is identified.

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS.

The CSI\_RX\_IF will stop processing the current frame and stop the stream.

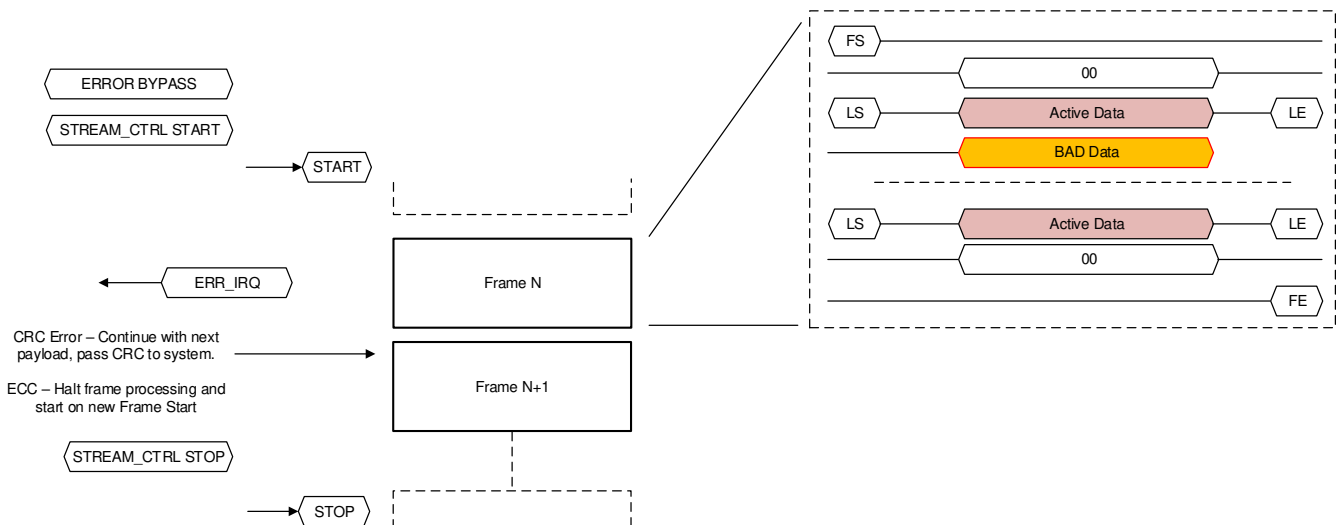

**Figure 12-1147. Stream Error Detection Causing Stop**

#### 12.7.1.4.8.7 Stream Error Detected – Error Bypass Mode

The CSI\_RX\_IF will detect the error condition and capture the associated VC, DT and WC information for the packet header before generating an error interrupt flag on CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS.

The CSI\_RX\_IF will continue processing the current frame and continue the stream when a header Reserved DT or a long packet payload CRC error is detected.

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

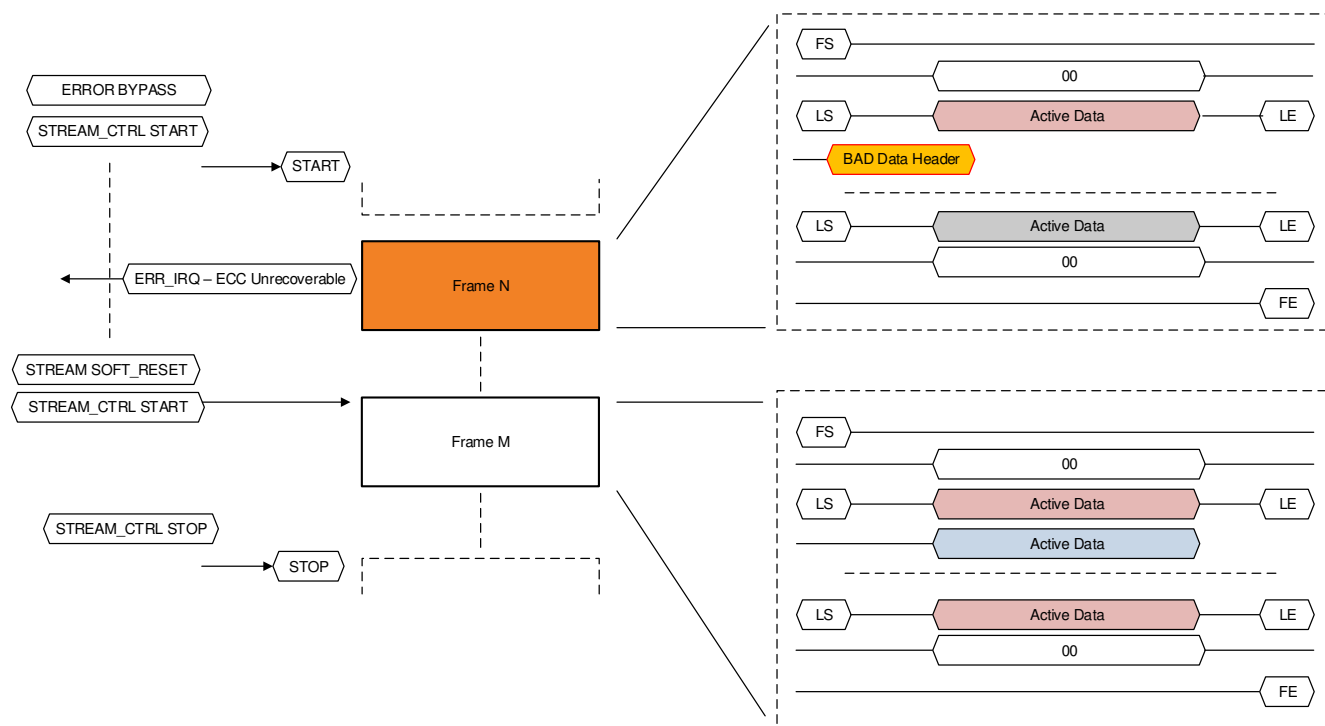

**Figure 12-1148. Stream Error Bypass - CRC Error During Payload**

#### 12.7.1.4.8.8 Stream Error Detected – Soft Reset Recovery

The CSI\_RX\_IF will stop processing the current frame and continue the stream when a packet header ECC error is detected, as the current frame synchronisation cannot be maintained.

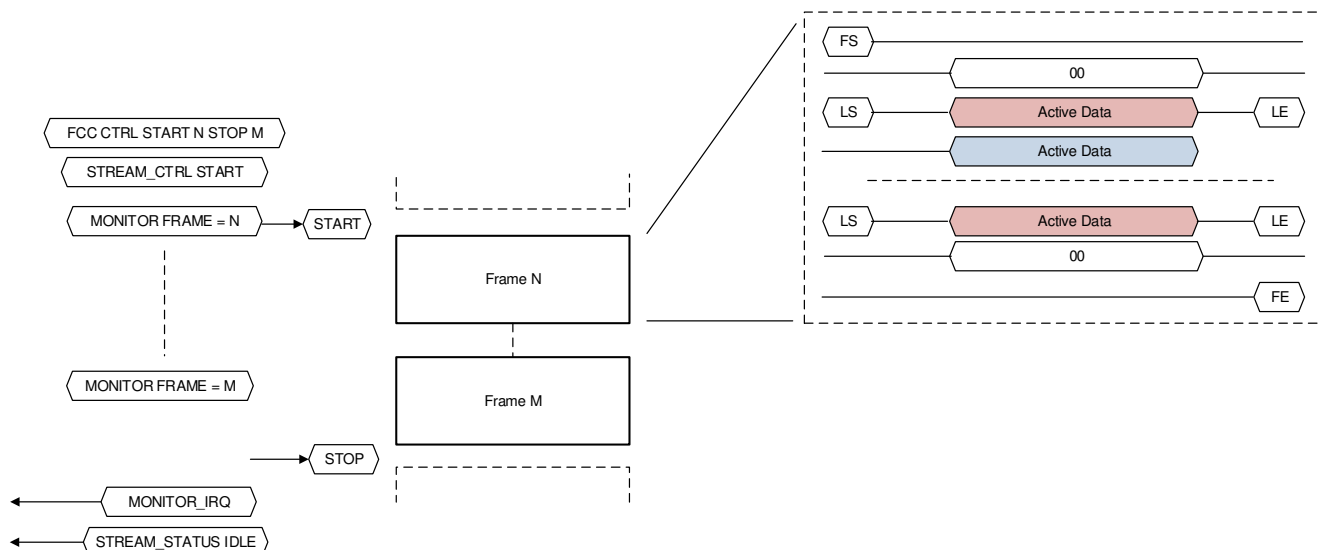

The system can perform a soft reset on the individual stream to clear the pixel interface and payload FIFO and allow the system to restart the stream from the next frame start.

**Figure 12-1149. Stream Soft Reset After ECC Non-Recoverable Error**

#### 12.7.1.4.8.9 Stream Monitor Configuration

The CSI\_RX\_IF will use the monitor control (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL) or STOP mechanism to stop the stream processing at the end of the active frame. The stream monitor, configuration and interrupt registers can be redefined and then the stream restarted. The pixel interface will begin processing at the next frame start.

**Figure 12-1150. Stream Start and Stop Using Monitor Control**

The FW will use the FCC config control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CFG) to perform a start and stop as soon as a frame count is detected. The FCC config control register will define the start and stop frame count and the

stream will identify when these values are matched. The stream output will begin when start frame is detected and then stop once the stop frame is reached. The virtual channel can be defined in CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[4:1] FCC\_VC, and must match the virtual channels that are available to the stream in the CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG register.

The frame capture is enabled when CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[0] FCC\_EN is set '1'

The FW can check the current frame counter value from the CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL[31:16] FRAME\_COUNTER

#### 12.7.1.4.8.10 Stream Monitor Frame Capture Control

To use Monitor Frame Capture Control Start and Stop operations:

1. Set Stop and Start values in config register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CFG). Set to '0' for free-running.
  - a. [31:16] FRAME\_COUNT\_STOP -> define desired value
  - b. [15:0] FRAME\_COUNT\_START -> define desired value
2. Set the Virtual Channel to the one that is enabled and the enable in register CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL.
  - a. [4:1] FCC\_VC -> define VC used
  - b. [0] FCC\_EN -> set to '1'

This will allow visual checking, by setting the Start/Stop as the following examples, this is the behaviour to be observed:

- Stop = 1 / Start = 1: Output (i.e. display) will show a Frame of the Input (i.e. camera)
- Stop = F / Start = 1: Output will show live image from the input during 14 frames and then will freeze in the last one.

Optionally software can read back the frame count value from register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL).

In order to do that, software will first need to enable the monitor control register.

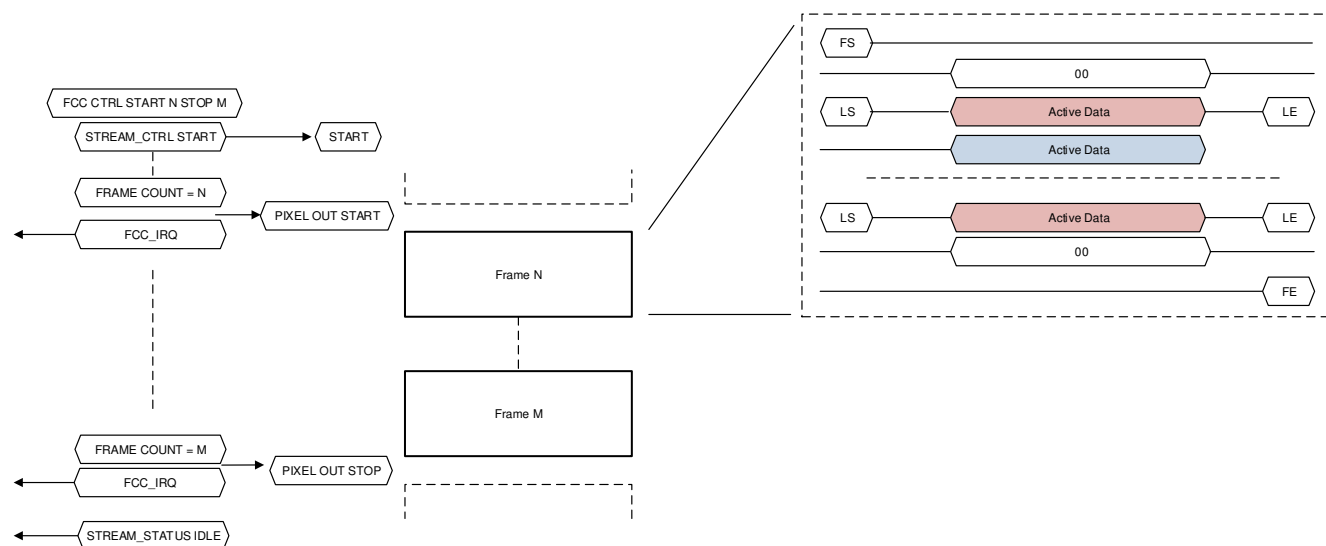

1. Define the same Virtual Channel as above and enable the monitor control register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL).
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
2. Read frame\_counter containing the current frame number being processed from CSI\_RX\_IF\_VBUS2APB\_STREAM0\_FCC\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_FCC\_CTRL (only when frame numbers are coming from the protocol, not when internal counter)
  - a. [31:16] FRAME\_COUNTER -> read frame number value

The easiest way to check that the frame number matches the Start and/or Stop values defined, is to use the interrupts in CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS register. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0's, meaning all interrupts are disabled.
  - a. [4] STREAM0\_FCC\_STOP\_IRQM -> set to '1'
  - b. [3] STREAM0\_FCC\_START\_IRQM -> set to '1'
2. Create an interrupt handler to read from CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS.
  - a. [4] STREAM0\_FCC\_STOP\_IRQ -> read, if '1', Stop interrupt triggered
  - b. [3] STREAM0\_FCC\_START\_IRQ -> read, if '1', Start interrupt triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled if software is using Frame Counter Control features.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-1151. Stream Frame Capture Control Flow Diagram**

#### 12.7.1.4.8.11 Stream Monitor Timer interrupt

To use the Stream Monitor Timer operations:

1. Set Count value in timer register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_TIMER - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_TIMER). If set to 0 won't count but interrupt will still trigger every EOF or SOF.
  - a. [24:0] COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, define timer\_eof and set enable in the monitor controll register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_CTRL).
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [10] TIMER\_EOF -> set to '1' to count from EOF, set to '0' to count from SOF
  - d. [9] TIMER\_EN -> set to '1'
  - e. [8:5] TIMER\_VC -> define VC used

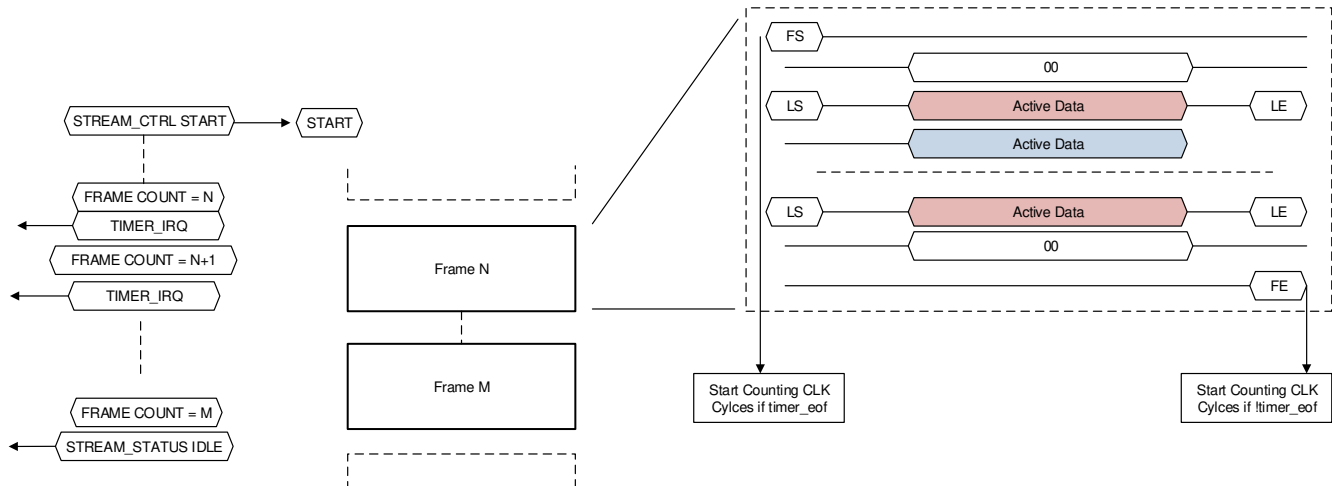

Software should now use the interrupts in register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [0] STREAM0\_TIMER\_IRQM -> set to '1'
2. Create an interrupt handler to read from monitor\_irqs.
  - a. [0] STREAM0\_TIMER\_IRQ -> read, if '1', timer interrupt is triggered

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-1152. Timer Interrupt Flow Diagram**

#### 12.7.1.4.8.12 Stream Monitor Line/Byte Counters Interrupt

To use the stream Monitor Line and Byte counters operations:

1. Set LineCount and ByteCount values in register (CSI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_LB - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_MONITOR\_LB).
  - a. [31:16] LINE\_COUNT -> define desired value
  - b. [15:0] BYTE\_COUNT -> define desired value
2. Set the Virtual Channel to the one that is enabled, and set enable in register SI\_RX\_IF\_VBUS2APB\_STREAM0\_MONITOR\_CTRL.
  - a. [15] FRAME\_MON\_EN -> set to '1'
  - b. [14:11] FRAME\_MON\_VC -> define VC used
  - c. [4] LB\_EN -> set to '1'
  - d. [3:0] LB\_VC -> set to VC used

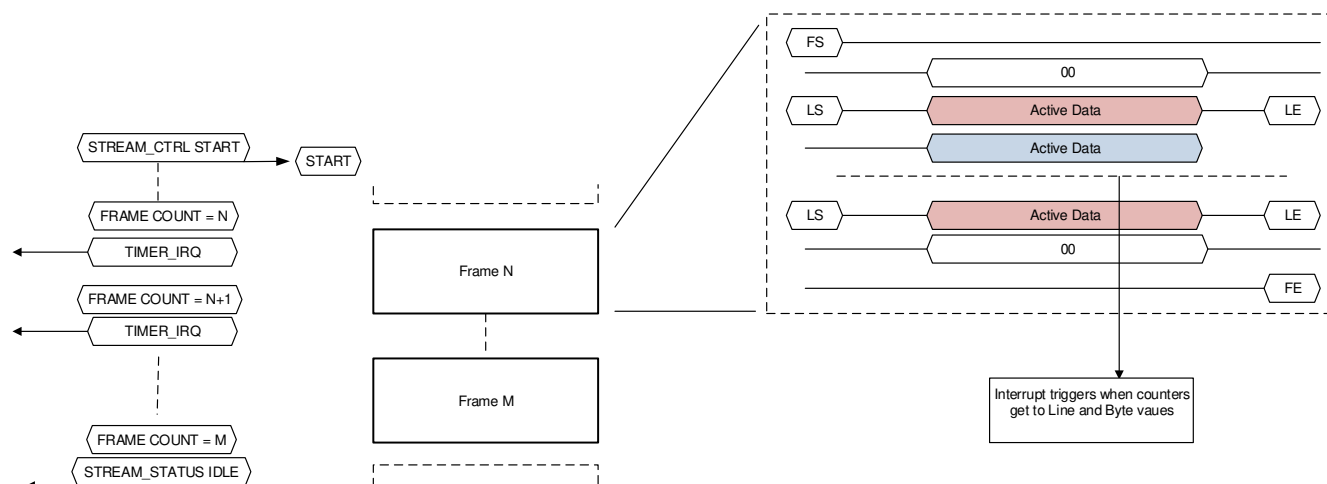

Software should now use the interrupts in register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS. To be able to do that you will need to allow those interrupts through the mask register CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG.

1. By default, the CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS\_MASK\_CFG register is set to all '0', meaning all interrupts are disabled.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQM -> set to '1'
  - b. STREAM0\_LB\_IRQM [1] -> set to '1'
2. Create an interrupt handler to read from CSI\_RX\_IF\_VBUS2APB\_MONITOR\_IRQS.
  - a. [7] STREAM0\_LINE\_CNT\_ERROR\_IRQ -> read, if '1', line count error interrupt is triggered
  - b. [1] STREAM0\_LB\_IRQ -> read, if '1', line/byte counter interrupt is triggered

Note that the interrupt will trigger on each frame when it reaches byte number BYTE\_COUNT in line number LINE\_COUNT.

To ensure correct functionality, it is highly recommended that the input device (i.e. camera) should be configured after the CSI\_RX\_IF has been configured and enabled.

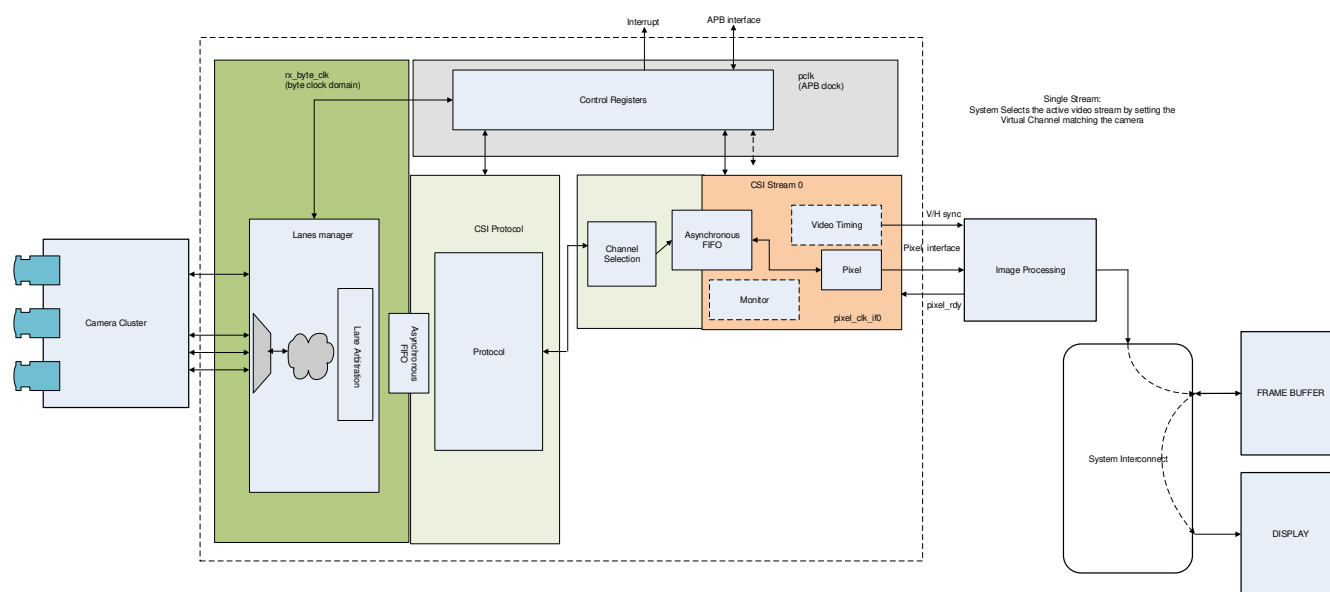

Software must make sure all the Virtual Channel fields in the registers explained above are set to the correct VC being used by the stream.

**Figure 12-1153. Line/Byte Counters Interrupt Flow Diagram**

#### 12.7.1.4.8.13 Example Controller Programming Sequence (Single Stream Operation)

The single stream operation will provide the smallest multi-lane IP configuration with the reduced registers configuration removing some control and status registers. The stream will not require a large FIFO configuration and the clock rates will be matched to simplify the implementation to single pixel transfers using all the available interface bits, (i.e. up to 32).

**Figure 12-1154. Basic Single Stream Use Case Illustration**

For single pixel stream configuration, elastic buffer, RAW8 Data type on VC2, one pixel per cycle:

1. Configure the number of DPHY\_RX lanes:
  - a. See CSI\_RX\_IF\_VBUS2APB\_STATIC\_CFG register
2. Set Error Interrupt mask:
  - a. See CSI\_RX\_IF\_VBUS2APB\_ERROR\_IRQS\_MASK\_CFG register
3. Set the Pixel Interface and FIFO configuration. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CFG.
  - a. Set [9-8] FIFO\_MODE to select the elastic buffer configuration -> '1'

- b. Set the FIFO fill level that will determines the FIFO depth that must be reached before data is output -> 0x0000
  - c. Select the number of pixels to be output on each cycle -> '0'.
  - d. Set the type of stream interface to "pixel" mode -> '0'
4. Select the virtual channel and data types to be processed. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_DATA\_CFG - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_DATA\_CFG register.
  - a. Set [31-16] VC\_SELECT and virtual channel bits if not supporting all virtual channels -> 1h, 2h
  - b. Set [7] ENABLE\_DT0 and [5-0] DATATYPE\_SELECT0 values for one or both data types (default all DT) -> 0h, 1h, 2Ah
5. Enable the stream to begin processing the incoming data from the DPHY\_RX. See CSI\_RX\_IF\_VBUS2APB\_STREAM0\_CTRL - CSI\_RX\_IF\_VBUS2APB\_STREAM3\_CTRL.
  - a. Set [0] START bit -> '1'

The stream will begin to pass pixel data matching the configuration on the next frame start.

#### 12.7.1.4.8.14 CSI\_RX\_IF Programming Restrictions

The following CSI\_RX\_IF programming restrictions apply:

- Full line buffer mode is not supported.
- LS/LE detection has a restriction to be disabled
- Only use Pixel transmit mode can be used, never packet mode
  - In pixel mode only single, dual, or quad mode can be used. It is not allowed to mix these based on data format or virtual channels.
- LSB alignment only
- In CSI\_RX\_IF to CSI\_TX\_IF loop back, the stream needs to have the same mode on both controllers(single, dual, quad). Can not mix dual on CSI\_RX\_IF and single on CSI\_TX\_IF.
- Video port(VP) stream interfaces must be programmed in the CSI\_RX\_IF to meet the following restrictions:
  - Raw 8-16 formats only
  - Dual pixel mode
  - Filtering for single virtual channel and single data type

#### Note

CSI\_RX\_IF has a limitation that any line must fully be exported on its stream interface before a new line or even end of frame is sent on the D-PHY interface. To meet this requirement, software will need to take into account export rates on stream interface(single, dual, quad modes) at 500MHz versus D-PHY 32-bits @ byte clock frequency to know when a new line or end of frame can be sent in after last line was sent over D-PHY interface.

Table 12-1528 shows the CSI\_RX\_IF programming requirements for pixel modes and data sizes.

**Table 12-1528. CSI\_RX\_IF Programming requirements for pixel modes and data sizes**

Format	Pixel transmit mode used	Size	Details
RAW(6-8), user defined 8-bit	Single	0	
RAW(6-8), user defined 8-bit	Dual	1	
RAW(6-8), user defined 8-bit	Quad	2	
RAW(10-16), user defined 16-bit	Single	1	
RAW(10-16), user defined 16-bit	Dual	2	
RAW20	Single	2	
YUV422-8	Single	0	must set dual mode=0
YUV422-8	Dual	0	must set dual mode=1
YUV422-10	Single	1	
YUV420-8	Single	0	must set dual mode=0

**Table 12-1528. CSI\_RX\_IF Programming requirements for pixel modes and data sizes (continued)**

Format	Pixel transmit mode used	Size	Details
YUV420-8	Dual	0	must set dual mode=1
YUV420-10	Single	1	

#### 12.7.1.4.8.15 CSI\_RX\_IF Real-time operating requirements

Care must be taken on blanking requirements for next line, end of frame, or start of frame. The previous packets(long or short) must be fully consumed before any new line, end of frame, or start frame can be sent over the CSI interface. Software will get various error conditions if these are not met. Below are some sample equations to determine this blanking time. Note that this is not blanking data. High level details are that the internal FIFO must be completely empty prior to sending any thing new into it. below are some sample equations to determine how much time is needed to empty the FIFO and blanking time needed. Byte clock rates, pixel data type, and export modes play into the calculation as well.

$$\text{Byte\_clock\_rate} \times 8 \times \#\text{lanes} \times \text{Tcsi} = \text{pixel\_clock\_rate} \times \text{BPP} \times \text{Tpix} = \text{total bits} \quad (27)$$

BPP = Bits Per Pixel. This number is how many bits are sent per pixel clock cycle is based on single, dual, quad modes and data type.

Tcsi = Time for csi interface to complete 1 line

Tpix = Time for pixel interface to complete 1 line

Tpix16 = Tpix+16/pixel\_clock\_rate

(Tpix16-Tcsi) = required blanking time on CSI interface

Tpix16-Tcsi <= 0 implies 0

## 12.7.2 MIPI D-PHY Receiver (DPHY\_RX)

The following sections describe the MIPI D-PHY receiver (DPHY\_RX) modules in the device.

### 12.7.2.1 DPHY\_RX Overview

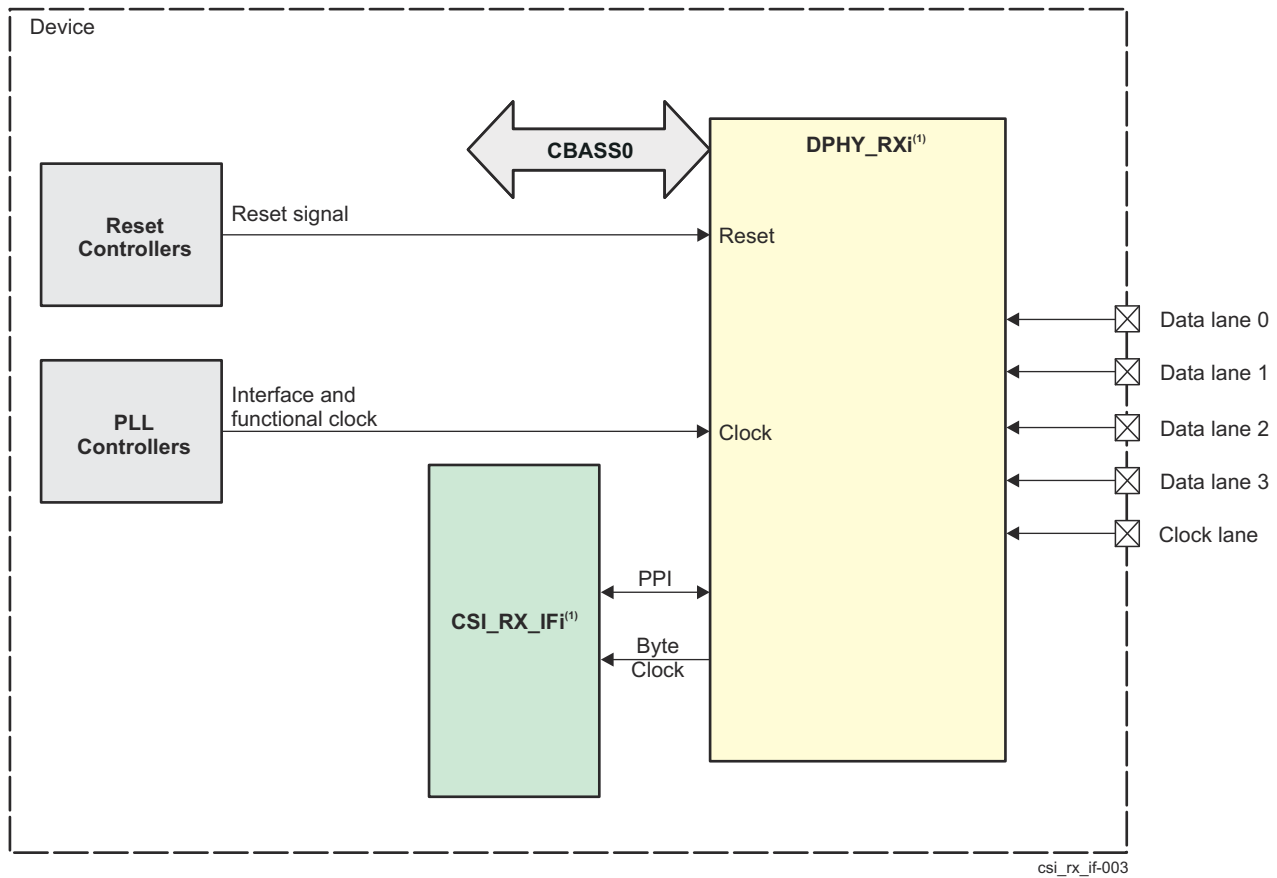

The integration of the DPHY\_RX camera physical port module allows the device to grab video streams from external sensor cameras and other CSI2 compliant sources.

Table 12-1529 shows the DPHY\_RX module allocation across device domains

**Table 12-1529. DPHY\_RX Modules Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DPHY_RX0	-	-	✓
DPHY_RX1	-	-	✓

Figure 12-1134 shows the DPHY\_RX module overview.

A.  $i = 0$  to  $1$

**Figure 12-1155. DPHY\_RX Module Overview**

#### 12.7.2.1.1 DPHY\_RX Features

The DPHY\_RX module supports the following features:

- Compliant to MIPI D-PHY standard v1.2
- Supports up to 4 data and 1 clock lanes
- Supports up to 2.5 Gbps (with deskew) and 1.5 Gbps (without deskew) per data lane
- Clock lane control / interface logic type is CIL-SCNN for HS and low power receiving:

1. **Slave**
  2. **Clock**
  3. **N/A** forward, **N/A** reverse escape mode features
- Data lane control / interface logic type is CIL-SFAN for HS and low power receiving:
    1. **Slave**
    2. **Forward** direction only for high speed mode
    3. **All** forward direction escape mode features are supported
    4. **No** reverse direction escape mode features are supported
  - Data lanes can be independently operated in HS or ULP mode
  - Swapping of DP/DN signals within each clock/data pair (Facilitated by CSI\_RX\_IF controller)

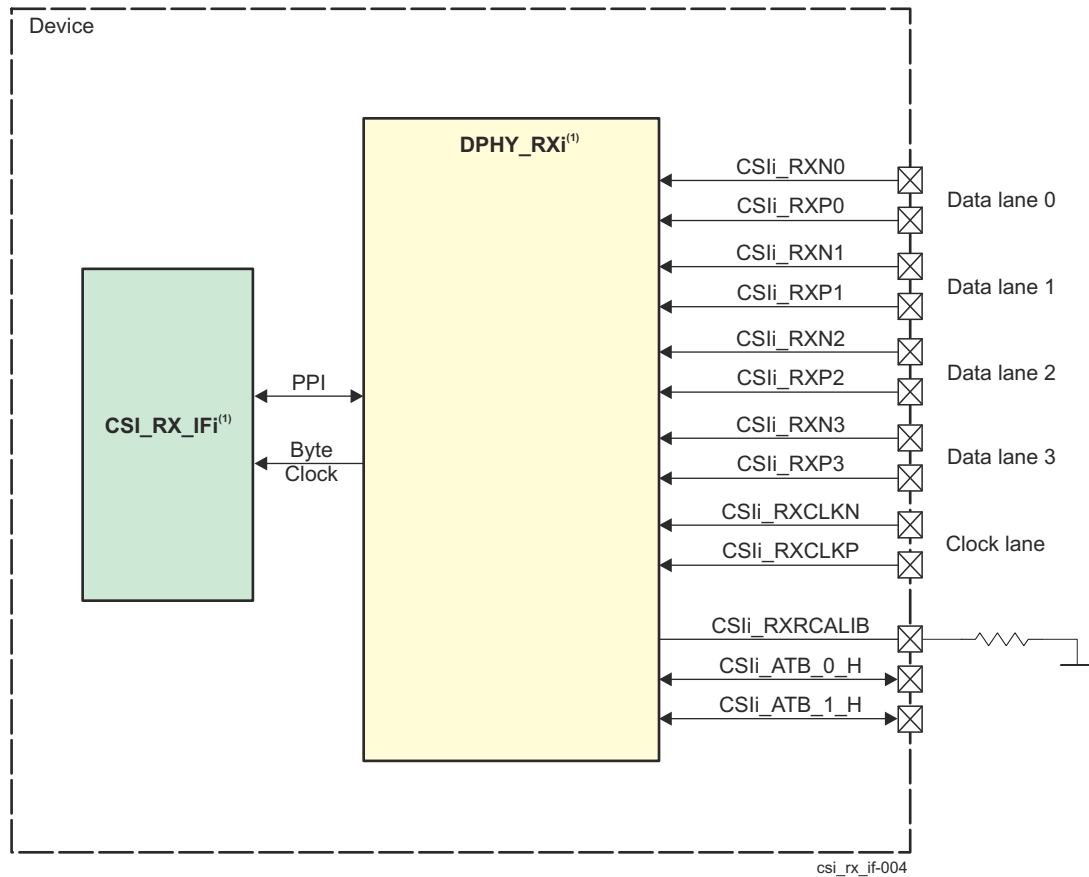

#### **12.7.2.1.2 DPHY\_RX Not Supported Features**

The DPHY\_RX does not support the following features:

- Swapping of clock & data lanes to ease PCB routing

### 12.7.2.2 DPHY\_RX Environment

This section describes the DPHY\_RX application fields from an environment point of view (external connections).

A. i = 0 to 1

**Figure 12-1156. DPHY\_RX Enviroment**

[Table 12-1530](#) describes the external signals of the DPHY\_RX.

**Table 12-1530. DPHY\_RX I/O Signals**

Device Level Signal	I/O	Description
<b>DPHY_RX0</b>		
CSI0_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI0_RXP0	I	Lane 0 Receive Differential Data (Positive)
CSI0_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI0_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI0_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI0_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI0_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI0_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI0_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI0_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI0_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.
<b>DPHY_RX1</b>		
CSI1_RXN0	I	Lane 0 Receive Differential Data (Negative)
CSI1_RXP0	I	Lane 0 Receive Differential Data (Positive)
CSI1_RXN1	I	Lane 1 Receive Differential Data (Negative)
CSI1_RXP1	I	Lane 1 Receive Differential Data (Positive)
CSI1_RXN2	I	Lane 2 Receive Differential Data (Negative)
CSI1_RXP2	I	Lane 2 Receive Differential Data (Positive)
CSI1_RXN3	I	Lane 3 Receive Differential Data (Negative)
CSI1_RXP3	I	Lane 3 Receive Differential Data (Positive)
CSI1_RXCLKN	I	Lane 3 Receive Differential Clock (Negative)
CSI1_RXCLKP	I	Lane 3 Receive Differential Clock (Positive)
CSI1_RXRCALIB	A	Pin for external calibration resistor. An external resistor must be connected between this pin and package ground. Refer to the device-specific Datasheet for a recommended resistor value.

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

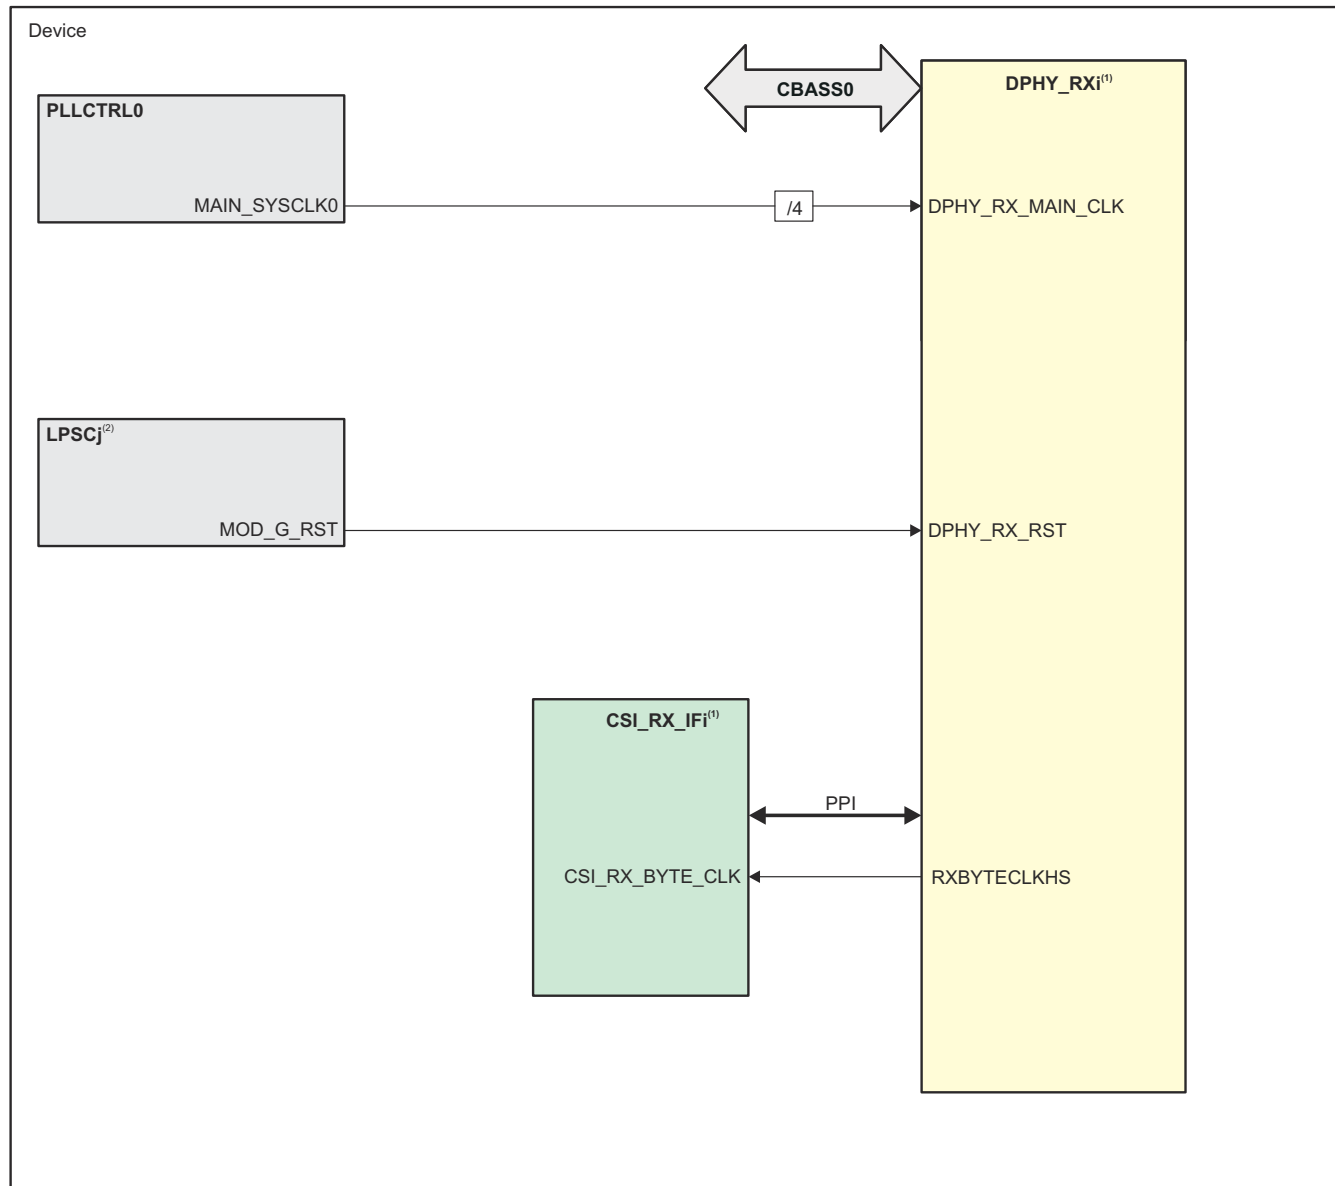

### 12.7.2.3 DPHY\_RX Integration

This section describes the DPHY\_RX integration in the device, including information about clocks, resets, and hardware requests.

#### 12.7.2.3.1 DPHY\_RX Integration in MAIN Domain

There are several DPHY\_RX modules integrated in the device MAIN domain. [Figure 12-1157](#) shows the integration of DPHY\_RX modules.

csi\_rx\_if-005

- A.  $i = 0$  to  $1$
- B.  $j$  = LPSC index, see [Table 12-1531](#)

**Figure 12-1157. DPHY\_RX Integration**

[Table 12-1531](#) through [Table 12-1532](#) summarize the integration of DPHY\_RX in the device MAIN domain.

**Table 12-1531. DPHY\_RX Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DPHY_RX0	PSC0	PD2	LPSC58	CBASS0
DPHY_RX1	PSC0	PD2	LPSC59	CBASS0

**Table 12-1532. DPHY\_RX Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DPHY_RX0	DPHY_RX_MAIN_CLK	MAIN_SYSCLK0 / 4	PLLCTRL0	Main functional clock.
	CSI_RX_BYTE_CLK	RXBYTECLKHS	DPHY_RX0	The byte clock is the clock supplied by the DPHY_RX.
DPHY_RX1	DPHY_RX_MAIN_CLK	MAIN_SYSCLK0 / 4	PLLCTRL0	Main functional clock.
	CSI_RX_BYTE_CLK	RXBYTECLKHS	DPHY_RX1	The byte clock is the clock supplied by the DPHY_RX.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
DPHY_RX0	DPHY_RX_RST	MOD_G_RST	LPSC58	Asynchronous module global reset.
DPHY_RX1	DPHY_RX_RST	MOD_G_RST	LPSC59	Asynchronous module global reset.

## 12.7.2.4 DPHY\_RX Functional Description

### 12.7.2.4.1 DPHY\_RX Programming Guide

#### 12.7.2.4.1.1 Overview

This section details specific steps on how to program the DPHY\_RX

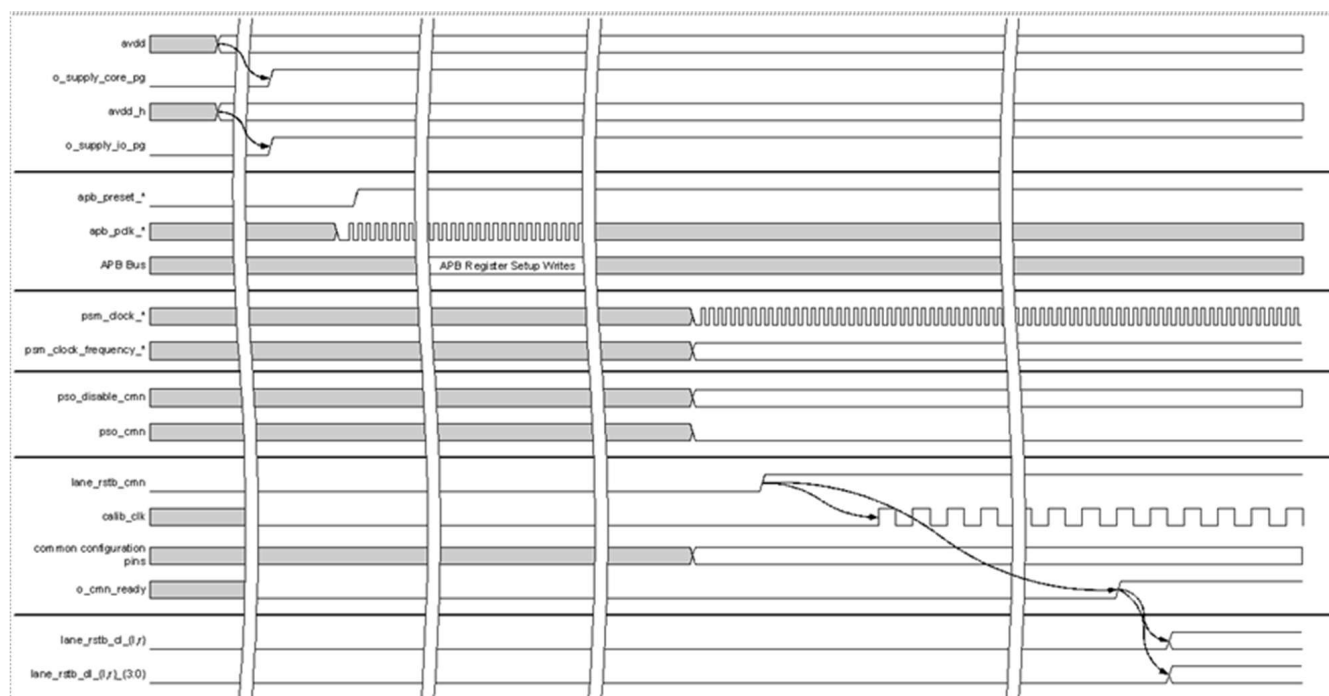

#### 12.7.2.4.1.2 Initial Configuration Programming

The DPHY\_RX operation shows the registers that are written during the startup sequence.

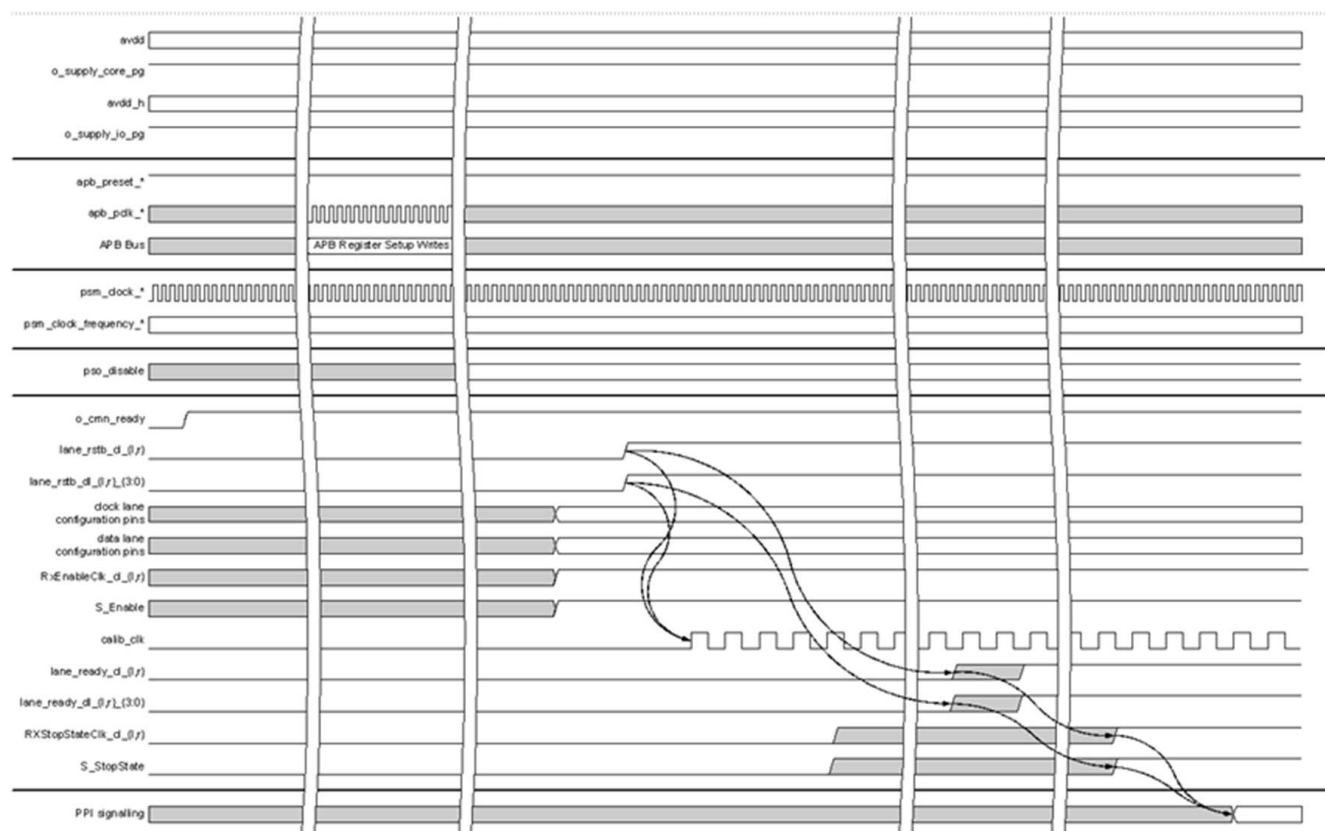

This section provides description and timing diagrams for DPHY\_RX operation. Unless otherwise described in this subsection, the DPHY\_RX PPI interface is compliant with the timing diagrams described in the MIPI D-PHY v1.2 specification.

##### 12.7.2.4.1.2.1 Start-up Sequence Timing Diagram

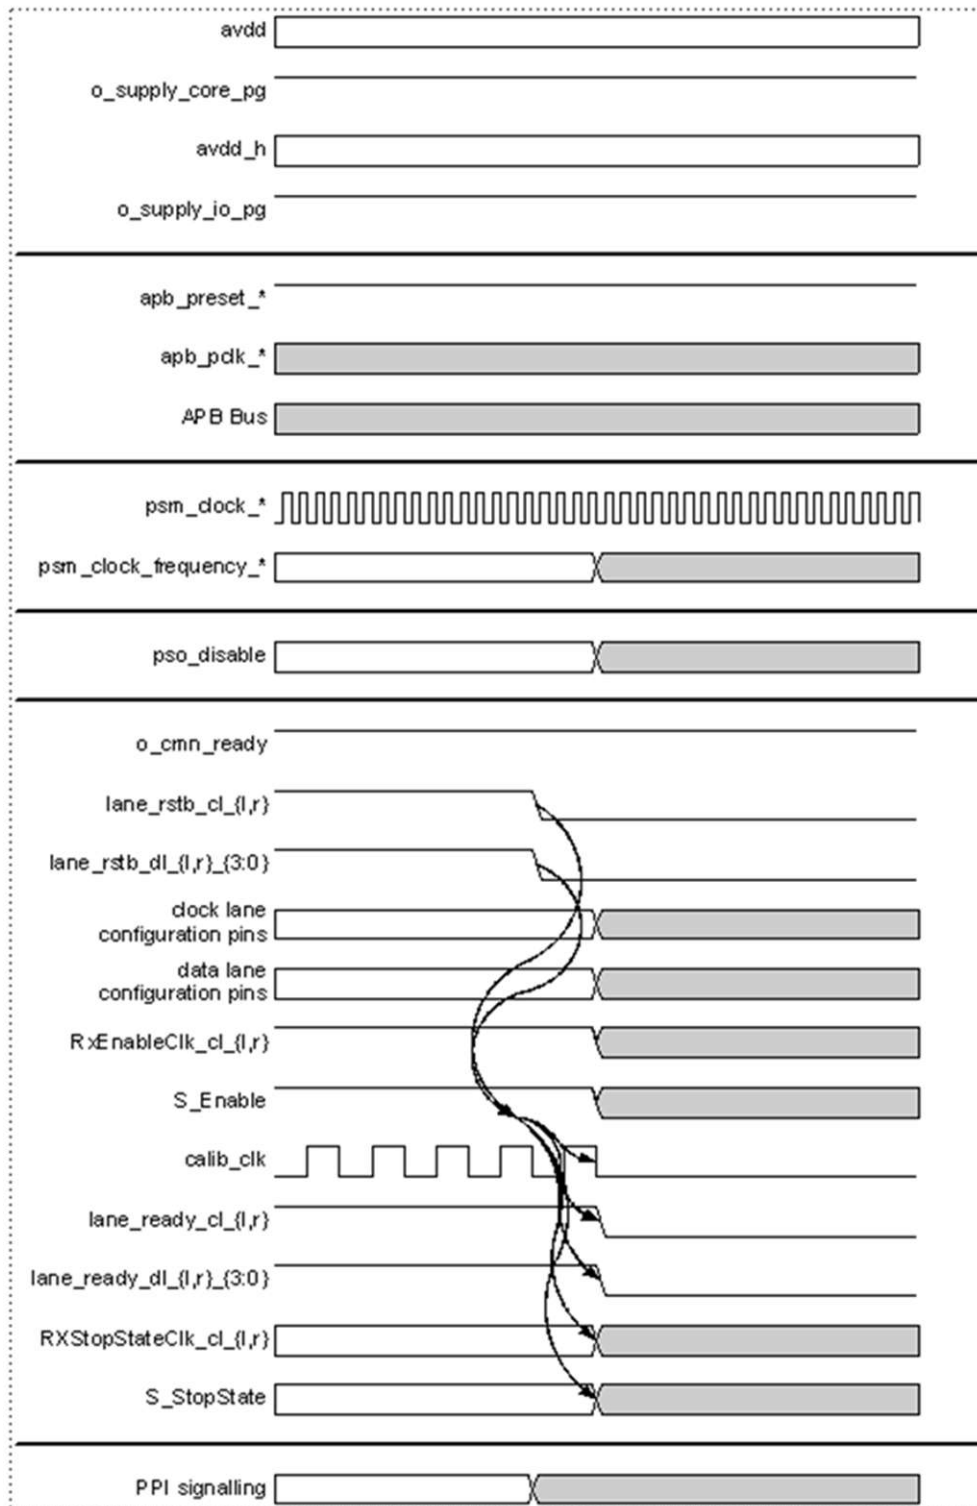

The common configuration pins noted in [Figure 12-1158](#) are ipconfig\_cmnn, pll\_ipdiv, pll\_fbdiv, pll\_opdiv, psm\_clock\_freq\_cmnn. Drive these pins as per the pin description given in PHY pin list.

**Figure 12-1158. Common Power Up and Initialization Timing Diagram**

**Figure 12-1159. Lane Power Up and Initialization Timing Diagram**

**Figure 12-1160. PHY Disable Timing Diagram**

For initial set up, the DPHY\_RX must be configured/set (registers and configuration input pins) for the common module prior to releasing it from reset, and the lane modules prior to releasing them from reset. Registers shall be configured (as required) between releasing the APB from reset and releasing the common / lanes from reset.

Note that in some cases, the option exists to configure a function using either a pin or a register. In such cases, both options will be specified and the you can select the preferred option.

### 12.7.2.4.1.3 Common Configuration

**Table 12-1533. Common Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Pin: psm_clock_freq PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 1	Set the PMA state machine clock frequency divider. Set either the pin or the register, as specified in the respective description, for the required PMA state machine clock.
PHY Pin: ipconfig_cmh PHY Register: DPHY_RX_MMR_SLV_LANE[11-9] IPCONFIG_CMN	Set the clock lane configuration. Set as specified in the description for the required clock lane configuration.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[0] O_CMN_SSM_EN, DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT2[10] O_CMN_RX_MODE_EN	Enable the startup state machines for TX mode of operation. Set both register bits to 1'b1.
PMA Register: DPHY_RX_VBUS2APB_CMN0_CMN_DIG_T BIT35	Set the RX oscillator calibration feedback clock counter start values. Set the register fields, as specified in the description for the required PMA state machine clock and oscillator clock.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 2	Set the required power island phase 2 time. Set the register to 32'hAAAAAAAA.
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[7:4] POWER_SW_2_TIME_CL_R, DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 3[3:0] POWER_SW_2_TIME_CL_L	Set the required power island phase 2 time. Set the register to 8'hAA

### 12.7.2.4.1.4 Lane Configuration

**Table 12-1534. Lane Configuration-Related Setup**

Configuration Register / Pin	Configuration Requirement
PHY Register: DPHY_RX_VBUS2APB_PCS_TX_DIG_TBIT 0	Set the lane band control value. Set the register fields, as specified in the register description for the required data rate.
PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBI T2[18:15] RXDA_FREQ_BAND_SEL1 PMA Register (clock lanes): DPHY_RX_VBUS2APB_CLK0_RX_DIG_TBI T2[13:10] RXDA_FREQ_BAND_SEL2	Set the analog frequency band selects, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[21] TM_1P5TO2P5G_MODE_EN	Set the analog data rate select, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 0 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 0[16] TM_SETTLE_COUNT_SEL and [15-9] TM_SETTLE_COUNT	Set the HS-settle counter, as specified in the register description for the required data rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 3 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 3	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

**Table 12-1534. Lane Configuration-Related Setup (continued)**

Configuration Register / Pin	Configuration Requirement
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 5 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 5	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 7 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 7	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 9 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 9	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.
PMA Register (data lanes): DPHY_RX_VBUS2APB_DL0_RX_DIG_TBIT 12 - DPHY_RX_VBUS2APB_DL3_RX_DIG_TBIT 12	Set the iteration and initialization wait timer values to create a delay of 500 nSec as a function of the PSM clock rate.

#### 12.7.2.4.1.5 Procedure: Clock Lane Low Power Analog Receiver Functions Test

##### 12.7.2.4.1.5.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

##### 12.7.2.4.1.5.2 Details of the Procedure

- Follow the procedure described in section [Section 12.7.2.4.1.2](#), but do not release the common or lanes from reset.
- Write the following registers.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[23:20] = 4'b1111, to enable the clock lane diagnostic low power override functions, and drive LP11 from common to the clock lanes.
  - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2[24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
  - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2[1:0] = 2'b11, to force the analog ULPS receiver to be enabled.
- Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
- Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.
- Poll PMA Register (CMN): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
- Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the clock lanes: 2'b01, 2'b00, 2'b10, 2'b11.
  - Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[22,20] = value.
  - Read and confirm the PMA Register (clock lanes):  
DPHY\_RX\_VBUS2APB\_CLK0\_RX\_DIG\_TBIT4[13:12] = value.
  - Read and confirm the PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_CLK0\_RX\_DIG\_TBIT4[9:8] = value.

### 12.7.2.4.1.6 Procedure: Data Lane Low Power Analog Receiver Functions Test

#### 12.7.2.4.1.6.1 Description of Procedure

This procedure describes how the low power analog receiver functions (LPRX, and ULPRX) can be tested. The process used in this test is to enable test MUXes for the low power receiver functions, then write registers in common to drive LP signaling states to the lanes, and read registers in the lanes to detect the current state of the analog functions in the lane.

#### 12.7.2.4.1.6.2 Details of the Procedure

1. Follow the procedure described in section [Section 12.7.2.4.1.2](#), but do not release the common or lanes from reset.
2. Write the following registers.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
  - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[19:16] = 4'b1111, to enable the data lane diagnostic low power override functions, and drive LP11 from common to the data lanes.
  - PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT30[1] TM\_LPRX\_BIST\_EN = 1'b1, to enable the diagnostic low power override MUXes in the analog.
  - PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT1[9:8] = 2'b11, to force the analog ULPS receiver to be enabled.
3. Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
4. Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.
5. Poll PMA Register (CMN): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
6. Repeat the following for each of the following values, to drive LP values from common and test the analog functions in the data lanes: 2'b01, 2'b00, 2'b10, 2'b11.
  - a. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT28[18,16] = value.
  - b. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT34[13:12] = value.
  - c. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT34[9:8] = value.

### 12.7.2.4.1.7 Procedure: Clock and Data Lane High Speed Receiver BIST Functions Test

#### 12.7.2.4.1.7.1 Description of Procedure

This procedure describes how to use the high speed data BIST generation and checking functions to test the high speed data receiver functions. The process used in this test is to enable test MUXes for the low power and high speed data receiver functions, then write registers to setup, run and check the results of the BIST functions.

#### 12.7.2.4.1.7.2 Details of the Procedure

1. Set up IP for BIST operations.
  - a. Follow the procedure described in section [Section 12.7.2.4.1.2](#), but do not release the common or lanes from reset.
  - b. Write the following registers.
    - PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT21[0] O\_RX\_DIG\_BIST\_EN = 1'b1, to enable the analog BIST power island in common.
    - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT2 [24] = 1'b1, to enable the diagnostic low power override MUXes in the analog.
    - PMA Register (clock lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT2 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT2 [21:20] = 2'b11, to enable the diagnostic high speed override MUXes in the analog.

- PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT30 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT30[1:0] = 2'b11, to enable the diagnostic low power and high speed override MUXes in the analog.
- c. Release the common from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[5] O\_CMN\_READY to be driven to 1'b1.
- d. Release the clock and data lanes from reset, and wait for DPHY\_RX\_VBUS2APB\_ISO\_PHY\_ISO\_CMN\_CTRL[8] LANE\_READY\_CMN to be driven to 1'b1.
- e. Poll PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT56[20-11] I\_CMN\_RX\_SSM\_STATE until it is set to 9'b100000000.
- f. When running BIST at 1.5 Gbps, do the following, otherwise skip this if running BIST at 2.5 Gbps.
  - i. Write PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT36[1] O\_RX\_TM\_SEL\_1P5G\_M\_ODE = 1'b1.
  - ii. Wait 5 uSec.
- 2. Run BIST operations.
  - a. At this point, the BIST generator and checker registers can be written to the values required to generate the desired data patterns. One should see the BIST register descriptions for information about programming the various fields for creating different data patterns. If no registers are written, the BIST default pattern will be generated and checked.
  - b. If running infinite BIST mode is desired, write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[15] BIST\_INF\_MODE = 1'b1, to enable infinite BIST mode.
- 3. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT27[0] = 1'b1, to enable the pattern checkers in the data lanes.
- 4. Write PMA Register (cmn): CMN\_DIG\_TBIT22[0] TM\_BIST\_EN = 1'b1, to enable the pattern generator in the common.
- 5. If infinite BIST mode was enabled, do the following.
  - a. Allow the BIST to run as long as required.
  - b. Write the PMA Register (cmn lanes): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[15] BIST\_INF\_MODE = 1'b0, to disable infinite BIST mode.
- 6. Wait for a minimum of 100 nSec.
- 7. Poll PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT50[1] BIST\_COMPLETE until it is set to 1'b1, indicating that the BIST pattern generation process is complete.
- 8. Wait 1 uSec.
- 9. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[0] W\_DRX\_BIST\_PASS = 1'b1, indicating the BIST checker has indicated a pass condition.
- 10. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[1] R\_PAT\_CHE\_SYNC = 1'b1, indicating the BIST checker has observed a marker symbol.
- 11. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT48 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT48[2] W\_BIST\_ERROR = 1'b0, indicating the BIST checker has not detected any errors.
- 12. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT47 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT47[15:0] W\_PAT\_CHE\_PKT\_COUNT = the generated number of packets (15 by default).
- 13. Read and confirm the PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT47 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT47[31:16] W\_PAT\_CHE\_ERROR\_COUNT = 16'h0000, indicating the BIST checker error count is 0.
- 14. Clear the internal state of the BIST pattern checkers by doing the following:
  - a. Read PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT29 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT29[28] TM\_CLEAR\_BIST.
  - b. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT29 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT29[28] TM\_CLEAR\_BIST = inverted value of what was read from this bit in the previous step.

15. Write PMA Register (data lanes): DPHY\_RX\_VBUS2APB\_DL0\_RX\_DIG\_TBIT27 - DPHY\_RX\_VBUS2APB\_DL3\_RX\_DIG\_TBIT27[0] TM\_BIST\_EN = 1'b0, to disable the pattern checkers in the data lanes.
16. Clear the internal state of the BIST pattern generator by doing the following:
  - a. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT24[6] = 1'b1,
  - b. Write the PMA Register (cmn): CMN\_DIG\_TBIT24[6] BIST\_CLEAR = 1'b0.
17. Write the PMA Register (cmn): DPHY\_RX\_VBUS2APB\_CMN0\_CMN\_DIG\_TBIT22[0] BIST\_CONTROLLER\_EN = 1'b0, to disable the BIST pattern generator.
18. If desired, the run BIST operations can be repeated without needing to run set up the IP for BIST operations again.

### 12.7.3 Camera Streaming Interface Transmitter (CSI\_TX\_IF)

The following sections describe the camera streaming transmitter interface (CSI\_TX\_IF) module in the device.

#### 12.7.3.1 CSI\_TX\_IF Overview

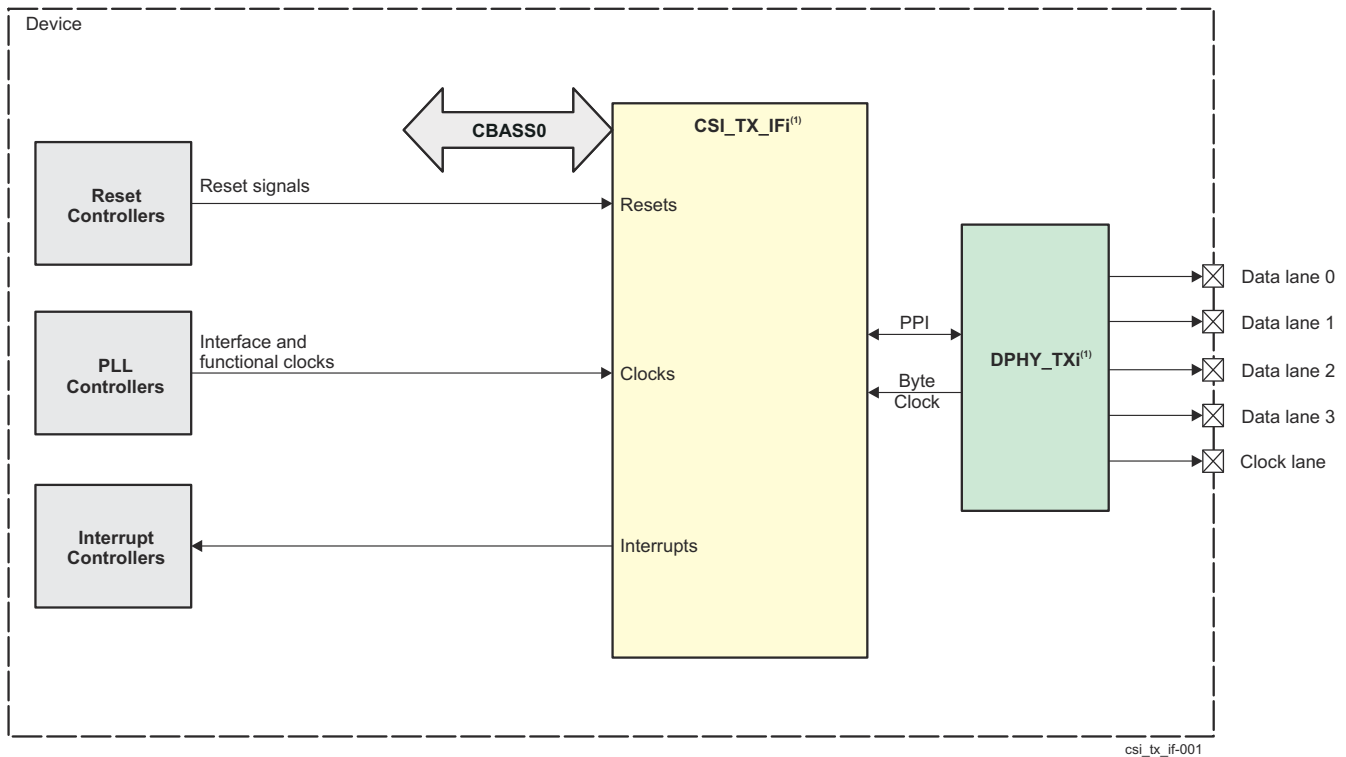

The integration of the CSI\_TX\_IF module allows the device to stream out video data from memory, or retransmit from the CSI receivers as an optional loopback output for diagnostics, debug, and test purposes.

The device has one instance of the CSI\_TX\_IF module. Table 12-1535 shows CSI\_TX\_IF module allocation within device domains.

**Table 12-1535. CSI\_TX\_IF0 Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
CSI_TX_IF0	-	-	✓

Figure 12-1161 shows the CSI\_TX\_IF module overview.

A.  $i = 0$

**Figure 12-1161. CSI\_TX\_IF Module Overview**

#### 12.7.3.1.1 CSI\_TX\_IF Features

The CSI\_TX\_IF module supports the following features:

- Compliant to MIPI CSI v1.3 and MIPI D-PHY v1.2
- Data rate up to 2.5 Gbps per lane (wire rate)
- Supports 1, 2, 3, or 4 Data Lane connection to DPHY\_TX
- Programmable formats including YUV420, YUV422, RGB, Raw, and User Defined (over 25 different formats supported); Limitations apply depending on the stream used
- 16 virtual channel support (partial MIPI CSI-2 v2.0 feature, see for limitations)
- Four configurable input streams supported:

- **Stream0:** DMA interface through a 128-bit PSI\_L connection for transfers from memory:
  - 128bit wide pixel data with bursting
  - ByteValid per byte in Last Data Phase (LDP)
  - 32 thread IDs supported (virtual channel and data type combinations); Flexible number of threads (32 Max). Arbitration to next thread is done by lowest thread ID number. Care needs to be taken by software that it does not send too many threads at any given time as that could cause delays for higher thread IDs.
  - Unpacking PSI\_L data and converting to CSI video format (see for limitations)
  - Internal FF based FIFO and external RAM based buffer
- **Stream1:** Color bar video data generator
  - 2 pixel wide
  - YUV422 8-bit format support only
  - Configurable frame/line size via registers
  - 1 programmable virtual channel
  - Internal FF based FIFO; No external buffer.
- **Stream2:** Re-transmit loopback from CSI\_RX\_IF (first VC)
  - 1 virtual channel supported only (see for limitations)
  - RAW formats support only
  - Internal based FIFO, 2k×32
  - Programmable registers for which single VC is used from CSI\_RX\_IF to retransmit
- **Stream3:** Re-transmit loopback from CSI\_RX\_IF (second VC)
  - 1 virtual channel supported only (see for limitations)
  - RAW formats support only
  - Internal based FIFO, 2k×32
  - Programmable registers for which single VC is used from CSI\_RX\_IF to retransmit
- Functional and data path error interrupts
- ECC support on external RAMs

#### 12.7.3.1.2 CSI\_TX\_IF Not Supported Features

The CSI\_TX\_IF does not support the following features:

- MIPI CSI2 v2.0 scrambling
- MIPI CSI2 v2.0 optional no LP (low power state) between packets
- Cropping
- Pixel processing
- YUV420 8-bit legacy not supported
- Limitation on interleaving virtual channels per stream. Only 1 virtual channel supported per stream. The entire frame must be sent. CSI\_TX\_IF will only allow current active thread to go through till end of frame.

#### 12.7.3.2 CSI\_TX\_IF Environment

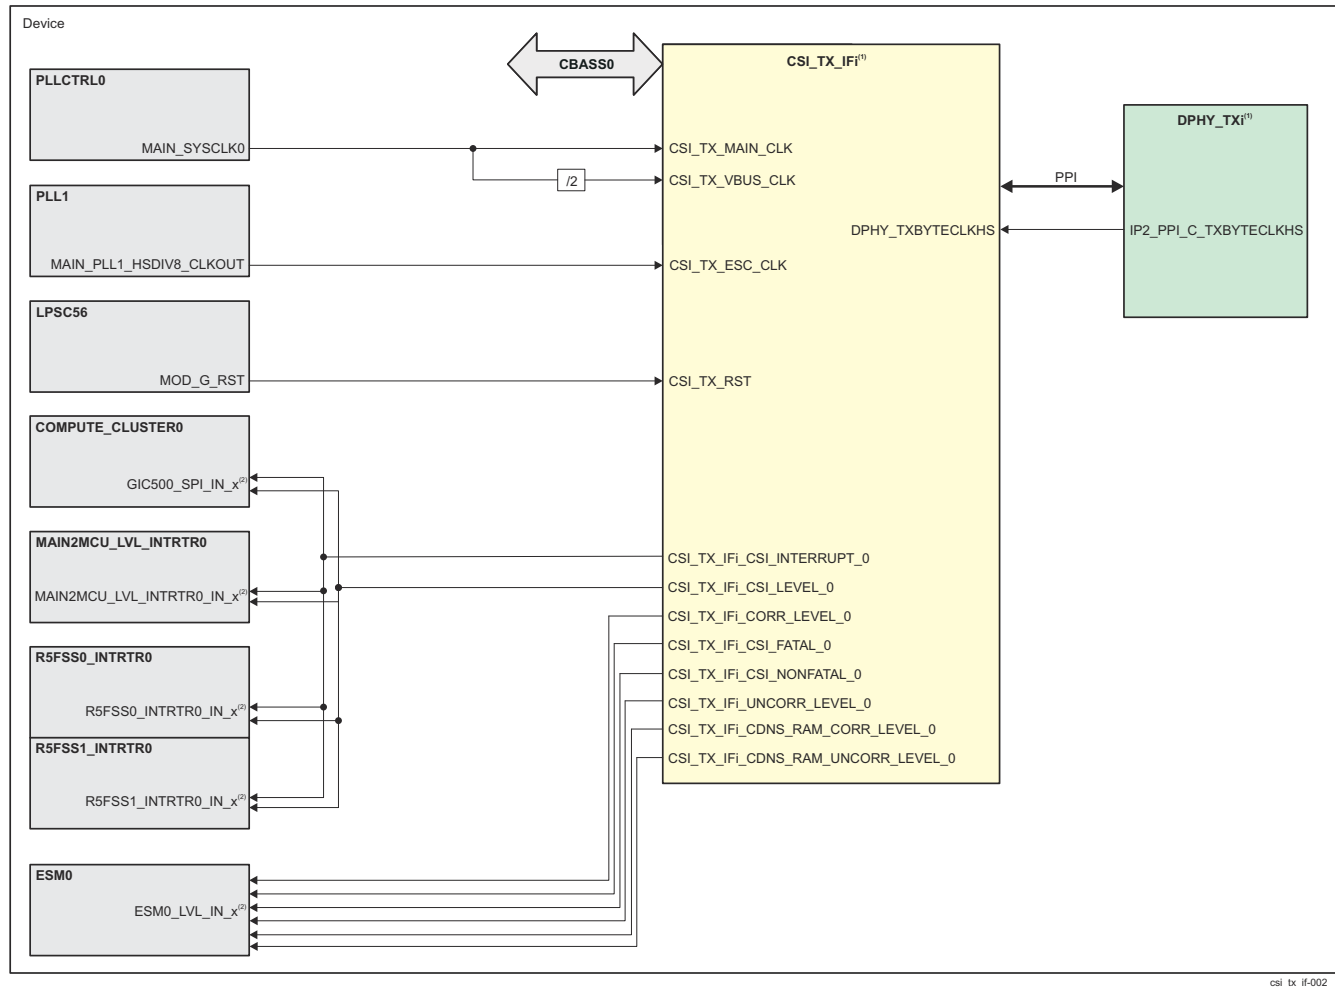

The CSI\_TX\_IF has no dedicated pins. At the device level, the CSI\_TX\_IF video output goes through the shared(with DSS\_DSI0) DPHY\_TX. See chapter [Section 12.8, Shared MIPI D-PHY Transmitter \(DPHY\\_TX\)](#).

#### 12.7.3.3 CSI\_TX\_IF Integration

This section describes the CSI\_TX\_IF integration in the device, including information about clocks, resets, and hardware requests.

#### 12.7.3.3.1 CSI\_TX\_IF Integration in MAIN Domain

There is one CSI\_TX\_IF module integrated in the device MAIN domain. Figure 12-1162 shows the integration of CSI\_TX\_IF module.

- A.  $i = 0$   
B.  $x$  = Interrupt port index, see

**Figure 12-1162. CSI\_TX\_IF Integration**

Table 12-1536 through Table 12-1538 summarize the integration of CSI\_TX\_IF in the device MAIN domain.

**Table 12-1536. CSI\_TX\_IF Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
CSI_TX_IF0	PSC0	PD2	LPSC56	CBASS0

**Table 12-1537. CSI\_TX\_IF Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

**Table 12-1537. CSI\_TX\_IF Clocks and Resets (continued)**

CSI_TX_IF0	CSI_TX_MAIN_CLK	MAIN_SYSCLK0	PLLCTRL0	Main functional(sometimes referred to as pixel clock) clock.
	CSI_TX_VBUS_CLK	MAIN_SYSCLK0 / 2	PLLCTRL0	The VBUS clock runs at always half the speed of the CSI_TX_MAIN_CLK.
	CSI_TX_ESC_CLK	MAIN_PLL1_HSDIV8_CLKOUT	PLL1	20 MHz max clock input for low speed data transmission and some control signals.
	DPHY_TXBYTECLKHS	IP2_PPI_C_TXBYTECLKHS	DPHY_TX0	The byte clock is the clock supplied by the DPHY_TX.
<b>Resets</b>				
<b>Module Instance</b>	<b>Module Reset Input</b>	<b>Source Reset Signal</b>	<b>Source</b>	<b>Description</b>
CSI_TX_IF0	CSI_TX_RST	MOD_G_RST	LPSC56	Asynchronous module global reset, driving all collateral asynchronous resets of the 4 clock domains to the low state.

#### 12.7.3.4 CSI\_TX\_IF Functional Description

##### 12.7.3.4.1 CSI\_TX\_IF Block Diagram

Figure 12-1163 depicts a simplified internal block diagram of the CSI\_TX\_IF and its surroundings.

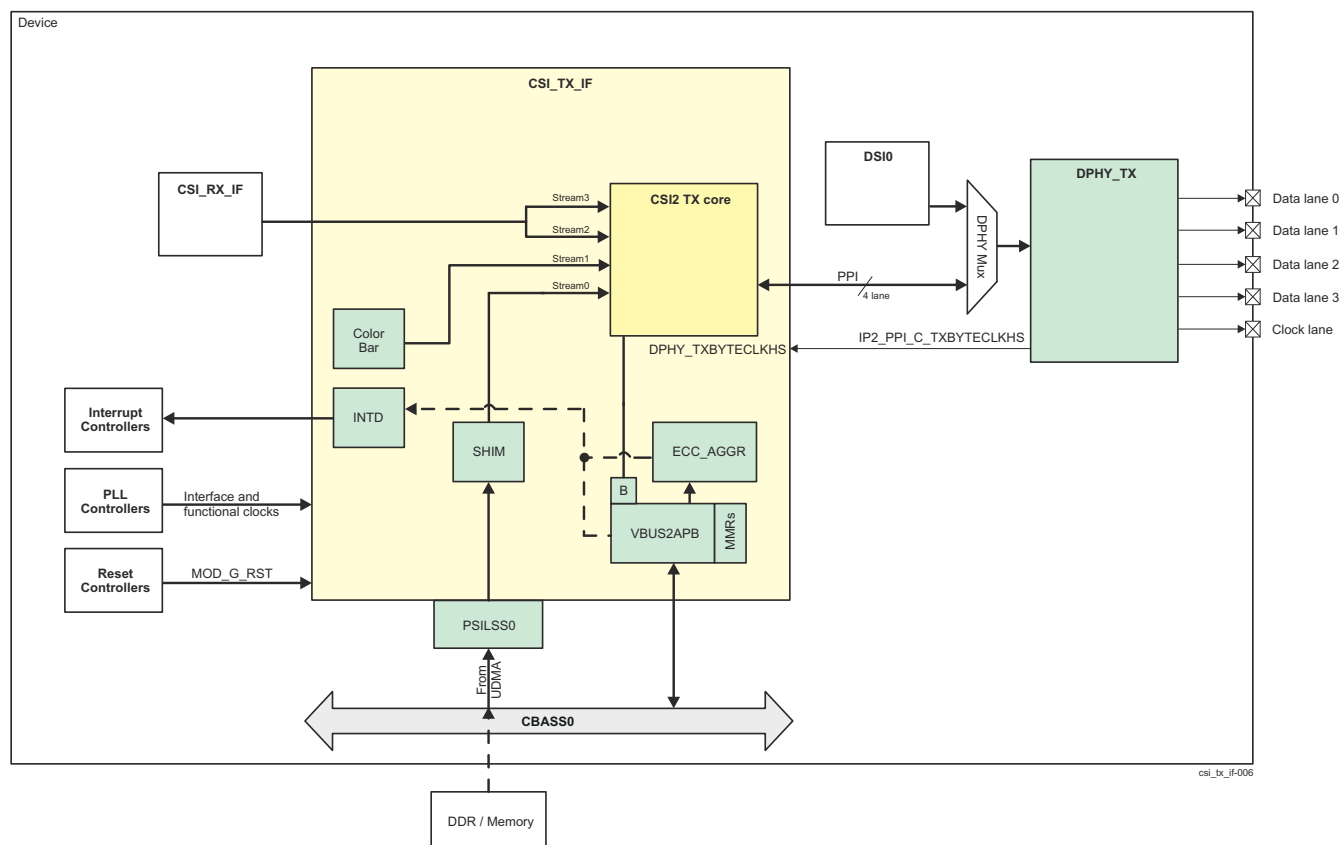

Figure 12-1163. CSI\_TX\_IF Block Diagram

The CSI2 core streams 4 channels of data to the several export paths.

**Stream0** goes through the PSI\_L that converts 128(4x32) bits pixel data and converts it to single 32-bit CSI streaming protocol of pixel data. Each 128 bit set of PSI\_L data is split into N M-bit data transfers based on the SIZE\_CFG bitfield setting in the CSI\_TX\_IF\_DMANTX<sub>j</sub> register for a given thread. See memory organization details in . Via register mapping in the CSI\_TX\_IF\_DMANTX<sub>j</sub> register the PSIL thread ID is mapped to a virtual channel and a data type. The CSI\_TX\_IF\_DMANTX<sub>j</sub> register is the thread filter. There are 32 dma context registers. Figure 12-1164 shows the stream to PSI\_L thread mapping.

Figure 12-1164. CSI\_TX\_IF PSI\_L thread mapping

Software must take the following notes in consideration

- Current CSI\_TX\_IF does not support interleaved virtual channels. Software must send the entire frame per channel before starting a new channel. CSI\_TX\_IF logic will push back on thread IDs not of the current frame till frame is complete.

- CSI\_TX\_IF logic will re-arbitrate after completion of thread to lowest available thread IDs ready for transmit, thread ID 0 goes before thread ID1. This could mean that if there are multiple pending threads the higher order ones could be delayed indefinitely.
- DATA is assumed in a specific organization for CSI\_TX\_IF to export data correctly. See memory organization details in

Registers CSI\_TX\_IF\_L2L\_DELAY\_j control the line start to next line start. Also register CSI\_TX\_IF\_F2F\_DELAY\_y control the last line of frame to next start of frame first line start of next frame. Buffering of PSI\_L data is 2k×128 RAM.

**Stream1** streams data from the Color Bar generator. It supports YUV422 8bit format only. CSI\_TX\_IF\_COLOR\_PARAM register is used to control height and width information. Width is divided by 8 for each color section. Colors are defined below. Transfers are done on the Stream1 interface in 32-bit packed 8-bit pixel format(required programming in CSI\_TX\_IF core). Virtual channel and data type is configurable in CSI\_TX\_IF\_COLOR\_CNTL register. Data selection inside CSI\_TX\_IF controller maps data type information. CSI\_TX\_IF\_COLOR\_START\_DELAY register can configure delays from enabled to start. CSI\_TX\_IF\_COLOR\_LINE\_DELAY, and CSI\_TX\_IF\_COLOR\_FRAME\_DELAY register can delay last line to first line of new frame. Once enabled, it will continuously send out frames until disabled. Once disabled, it will stop at end of current frame. [Table 12-1539](#) shows the Color Bar format.

**Table 12-1539. CSI\_TX\_IF Color Bar format details**

Color	Y	CB	CR
White	235	128	128
Yellow	162	44	142
Cyan	131	156	44
Green	112	72	58
Magenta	84	184	198
Red	65	100	212
Blue	35	212	114
Black	16	128	128

csi\_tx\_if-015

**Figure 12-1165. CSI\_TX\_IF PSI\_L Color Bar sample output**

**Stream2 and Stream3** stream data via a loopback path from the CSI\_RX\_IF.

**CAUTION**

Program limitations apply on the CSI\_RX\_IF and CSI\_TX\_IF sides. The CSI\_TX\_IF only supports single, non interleaved virtual channels. Program restriction on CSI\_RX\_IF side must limit this.

The CSI\_TX\_IF will use Stream2 and Stream3 to support 2 virtual channels of CSI\_RX\_IF data. The CSI\_RX\_IF can stream interleaved virtual channels of data. It is limited to programming the CSI\_RX\_IF so that it only sends

data on up to 2 static virtual channels. The VC0 and VC1 fields in CSI\_TX\_IF\_RETRANS\_CNTL register need to be programmed to match which virtual channels are streamed on the CSI\_RX\_IF side so that the CSI\_TX\_IF can stream them. CSI\_TX\_IF can only stream a single virtual channel at any given time. Only RAW data formats can be used for this retransmit interface due to CSI\_TX\_IF limitations.

### Note

It is a requirement that only PSI\_L/DMA, color bar, or loopback streams are not active at the same point in time. The intended use model is not to have multiple combinations active at any given time. The main issue with this is that RAMs are not sized for concurrent operation and will likely overflow resulting in data loss. The 2 loopback streams can be active at the same time just not in addition to the color or DMA streams.

#### 12.7.3.4.2 CSI\_TX\_IF Hardware and Software Reset

An active low asynchronous hardware reset is provided to CSI\_TX\_IF by device LPSC. It is internally re-synchronized to the functional clock domain.

A software reset is triggered by configuring the CSI\_TX\_IF\_TX\_CONF[1] SOFT\_RESET\_REQUEST bit-field for protocol reset and/or module reset.

#### 12.7.3.4.3 CSI\_TX\_IF Clock Configuration

There are four clock domain in the CSI\_TX\_IF.

1. The CSI\_TX\_MAIN\_CLK(or also referred to as pixel clock) runs most of the logic. It needs to be same frequency as CSI\_RX\_MAIN\_CLK main clock (500MHz). When CSI\_TX\_MAIN\_CLK is operating lower than 312.5MHz, then the clock is essentially limiting the clock rate of the DPHY\_TX. Said another way, CSI\_TX\_MAIN\_CLK must be at least the DPHY\_TXBYTECLKHS rate else FIFOs will overflow, crashing the module.
2. The CSI\_TX\_VBUS\_CLK is the interface configuration clock that runs at half the speed of the CSI\_TX\_MAIN\_CLK (250MHz).
3. The DPHY\_TXBYTECLKHS is the clock supplied by the DPHY\_TX PLL and is divided down to byte clock. The DPHY\_TX is designed for max of 10gbps. This translates to a max byte clock of 312.5MHz. The clock is inactive when DPHY\_TX is not in HS operation.
4. The CSI\_TX\_ESC\_CLK escape clock runs at 20 MHz. CSI\_TX\_ESC\_CLK is rarely used by the CSI\_TX\_IF, usually is only to clock in some low speed control signals from DPHY\_TX. The ESC interface is a low speed DPHY common link to the camera/sensor.

Table 12-1540 shows the CSI\_TX\_IF and DPHY\_TX inter-clock dependencies.

**Table 12-1540. CSI\_TX\_IF Inter-clock Dependencies**

	CSI_TX_MAIN_CLK	CSI_TX_VBUS_CLK	DPHY_TXBYTECLKHS	CSI_TX_ESC_CLK
<b>Min freq</b>	DPHY_TXBYTECLKHS freq	CSI_TX_MAIN_CLK / 2 freq	N/A	N/A
<b>Max freq</b>	500 MHz	CSI_TX_MAIN_CLK / 2 freq	312.5MHz	20 MHz

#### 12.7.3.4.4 CSI\_TX\_IF Interrupt Events

This section describes the register configuration of the interrupt events that can trigger the several CSI\_TX\_IF interrupt signals.

The interrupts are generally handled within the INTD module of the CSI\_TX\_IF, although there are several interrupt registers in the ECC\_AGGR for ECC errors and in the VBUS2APB for stream monitoring errors/flags.

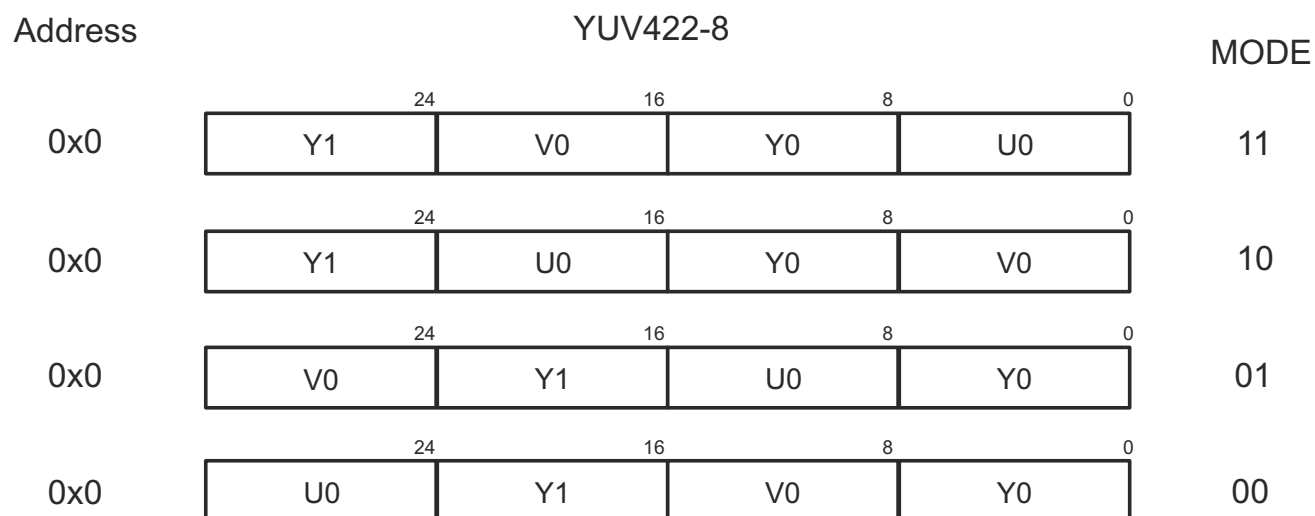

Table 12-1541 lists the event generation and corresponding registers of the CSI\_TX\_IF controller.

**Table 12-1541. CSI\_TX\_IF Interrupt Events Cross Table**

Event	Mask Register	Status Register	Description
CSI_TX_IF_MAIN_0_INTERRUPT	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Global interrupt that various re-synchronized sources converge into interrupt generation. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_LEVEL	CSI_TX_IF_IRQ_MASK CSI_TX_IF_DPHY_IRQ_MASK	CSI_TX_IF_IRQ CSI_TX_IF_DPHY_IRQ_MASK	Error interrupt that is generated under the following conditions: <ul style="list-style-type: none"> <li>Retransmit error on Stream2 (packet error on the stream interface)</li> <li>Retransmit error on Stream3 (packet error on the stream interface)</li> </ul> Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_CORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_UNCORR_LEVEL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_SRAM_UNCORR_FAULT_STATUS	Interrupt on internal FIFO RAM. Read the status register bitfields to trace the source of the event.
CSI_TX_IF_MAIN_0_CSI_FATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.
CSI_RX_CSI_NONFATAL	CSI_TX_IF_ASF_INT_MASK	CSI_TX_IF_ASF_INT_STATUS	ASF port fatal interrupt. Level sensitive. Set CSI_TX_IF_ASF_FATAL_NONFATAL_SELECT for whether fatal or non-fatal ASF interrupt is triggered. If any of the CSI_TX_IF_ASF_INT_STATUS bit is set, the CSI_RX_CSI_FATAL or CSI_RX_CSI_NONFATAL event signal is asserted.

#### 12.7.3.4.5 CSI\_TX\_IF Data Memory Organization Details

Figure 12-1166 shows the YUV422-8 data organization in memory.

csi\_tx\_if-007

**Figure 12-1166. CSI\_TX\_IF YUV422-8 Memory Data Organization**

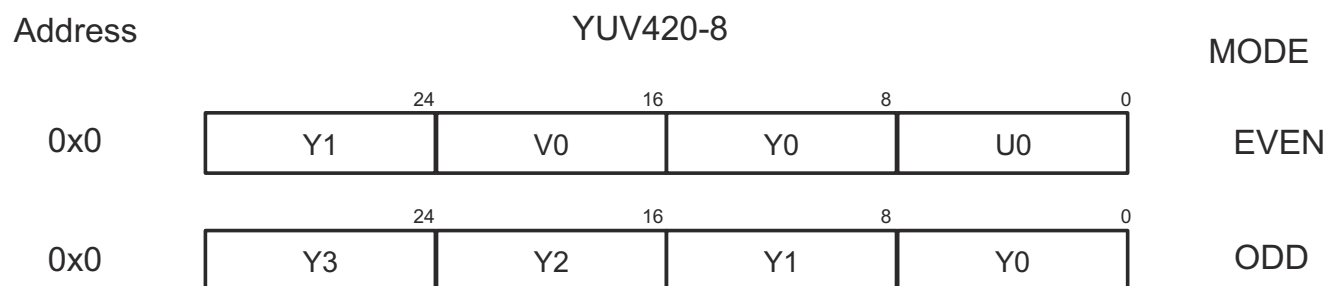

Figure 12-1167 shows the YUV422-10 data organization in memory.

Figure 12-1172 shows the RAW12 (PACKED) data organization in memory.

csi\_tx\_if-013

A. Where data does not fill out to a byte boundary it is zero extended.

**Figure 12-1172. CSI\_TX\_IF RAW12 (PACKED) memory data organization**

#### 12.7.3.4.6 CSI\_TX\_IF PSI\_L (DMA) Interface

The PSI\_L (DMA) interfaces is common for both CSI\_RX\_IF and CSI\_TX\_IF, see chapter *Camera Streaming Interface Receiver (CSI\_RX\_IF) and MIPI DPHY Receiver (DPHY\_RX)*., subsection *CSI\_RX\_IF PSI\_L (DMA) Interface*

#### 12.7.3.4.7 CSI\_TX\_IF ECC Protection Support

The CSI\_TX\_IF has two ECC aggregators, one for byte clock (DPHY\_TXBYTECLKHS) and the other one for all other clocks. The ECC is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC protection on the CSI\_TX\_IF RAM provides Single Error Correction and Double Error Detection (SEC/DED). This logic detects and corrects a single bit error (1 bit error per ECC word or per ECC data segment). For memories that contain critical and/or persistent data, automatic (immediate or delayed) write-back of the corrected data to the corresponding memory address is supported. In addition, the ECC also supports multiple options for partial word writes, such as read-modify-write or multiple ECC code segments per word.

The ECC protection also provides Double Error Detection (DED). This logic only detects (does not correct) double errors (2 bit errors per ECC word or per ECC data segment).

The ECC aggregators on the CSI\_TX\_IF subsystem level consolidates the ECC configuration and status bits for all the ECC supported memories in the subsystem. They provide a single EOI-handshake based interrupt to the interrupt processors (for both single and double error detections) and a standard 32-bit VBUS interface for configuring and querying the ECC register set, see *CSI\_RX\_IF ECC Registers*. For complete details on the features and functions of the ECC aggregator, see *ECC Aggregator*.

#### 12.7.3.5 CSI\_TX\_IF Programming Guide

##### Note

Software must keep the CSI\_TX\_IF\_CONTROL1[0] PIXEL\_RESET register in the asserted state in the control register until all CSI\_TX\_IF controller registers are programmed. Only after all CSI\_TX\_IF controller programming can software de-assert CSI\_TX\_IF\_CONTROL1 register. If software has to reprogram any CSI\_TX\_IF controller registers it MUST have the control CSI\_TX\_IF\_CONTROL1 register reset asserted.

#### 12.7.3.5.1 Programming (Configuration Mode)

Although it is always possible to read/write all control registers, it strongly recommended writing to the control registers only while configuration mode is active. To enter configuration mode, the CSI\_TX\_IF\_TX\_CONF[2]

CONFIGURATION\_REQUEST bit must be set. CSI\_TX\_IF enters configuration mode when transmission of any ongoing frame has ended and the request bit is set. Configuration mode is the default state after reset. While configuration mode is active, the CSI\_TX\_IF\_STATUS[2] CONFIGURATION\_ACTIVE bit is set. Traffic at the pixel interface is ignored during configuration mode, and it is safe to write to control registers and change configuration.

To exit configuration mode, the CONFIGURATION\_REQUEST bit in the CSI\_TX\_IF\_TX\_CONF register must be cleared. The CSI\_TX\_IF then starts normal operation, with first new frame incoming after configuration mode exit.

During configuration mode, all interrupts are disabled.

---

#### Note

A mandatory assertion of soft reset occurs following the de-assertion of CONFIGURATION\_REQUEST. This ensures the controller is in a known state and all the parameters set in the configuration registers have been loaded correctly into the internal state. The DPHY\_TXBYTECLKHS must be active before the configuration request is completed.

---

#### 12.7.3.5.2 System Initialization Programming

The power up/reset release of the system will clear all the register values to their reset conditions. Software must perform programming of the virtual channel and data type registers to match the system operation if the reset conditions do not match the required values. Software must guarantee that all the data type configuration registers are programmed with valid values for the pixel\_dt\_sel\_if[:]X parameter used.

The CSI\_TX\_IF registers for all the DPHY\_TX related control and delays must be set before starting the system. The DPHY\_TX delays must be calculated using the system clock periods associated with CSI\_TX\_ESC\_CLK and DPHY\_TXBYTECLKHS. The wait burst time must be calculated using the DPHY\_TX data sheet to ensure that all the lanes begin new requests at the same point.

Software will configure the FIFO fill level control registers if required by the system clock and payload control configurations. When all registers are programmed the configuration can be made active. The pixel streams can then start requests.

---

#### Note

The CSI\_TX\_IF is configured at design time, so that the reset values adopt a generic desired Power\_On state. This reduces the programming steps required by the system for the general use case scenario.

---

#### 12.7.3.5.3 Lane Control Programming

The CSI\_TX\_IF links to the DPHY\_TX clock and data lanes. After power up, software must identify that the DPHY\_TX is powered on and the DPHY\_TX PLL has locked. The DPHY\_TX controls for swapping the DP/DN control can be modified using the CSI\_TX\_IF\_DPHY\_CFG1 register if required.

Software must then program the enable for the clock lane and each data lane that is required. The DPHY\_TX lane signals can be checked using the CSI\_TX\_IF\_DPHY\_STATUS register to identify that the lane is in STOPSTATE and is ready for High Speed transmission. This register can also be used to identify when ULPS is active.

#### 12.7.3.5.4 Line Control

The line control block uses the DPHY\_TXBYTECLKHS from the DPHY\_TX PPI interface to take the line data from the packet interface FIFO and transfer the bytes to the active lanes of the DPHY\_TX. The block detects when the DPHY\_TX is ready to transmit high speed data and the pixel stream has packets available.

The line control block performs pixel stream arbitration using the line control arbitration block when more than one pixel stream is generated in the configuration. The block performs all the clock and data lane control required to activate the high-speed transmission and return the lane to ULPS state as required.

#### 12.7.3.5.5 Line Control Arbitration

The CSI\_TX\_IF controller uses a simple arbitration scheme for configurations with more than one pixel interface.

The arbitration has 2 levels; the first is a round-robin scheme and if no streams are granted by this a priority based scheme is used. The arbitration will select the first stream making a request if there is only one stream waiting or the first in the round robin after a stream has completed transmission. This means that there may be one cycle where the round-robin selector moves across a stream position that is not requesting to transmit.

The re-arbitration boundary is between packets except where line sync is used. In this case the line start packet, long packet and line end are grouped together.

The selected stream will pass the line data from the stream FIFO to the line control block for distribution to the active PPI lanes of the DPHY\_TX.

#### 12.7.3.5.6 Lane Manager FSM

Data distribution to the available lanes is controlled via the lane manager FSM.

The state descriptions can be found in [Table 12-1542](#).

**Table 12-1542. Lane Manager FSM State Description**

State (line_fsm_st_r)	Description
LINE_FSM_IDLE	Wait for new transmission to be ready. When start_hs_transmission_c is high then go to the transmission state per enabled lanes (lanes_enable_r)
LINE_FSM_BURST_1L	Transmit burst data over lane 0 until end of the burst. When end then go to the BURST_END state.
LINE_FSM_BURST_2L	Transmit burst data over lanes 0 and 1 until end of the burst. When end then go to the BURST_END state.
LINE_FSM_BURST_4L	Transmit burst data over all lanes until end of the burst. When end then go to the BURST_END state.
BURST_END	Wait for being ready for new burst transmission. In this state counter counts until WAIT_BURST_TIME value in the register is reached.

#### 12.7.3.5.7 Data Lane Control FSM

Data lanes control uses a simple FSM to sequence entry and exit of Ultra Low Power mode. This FSM observes inputs from the control registers and based on these inputs it generates PPI outputs for ULP mode.

The State descriptions are presented in [Table 12-1543](#).

**Table 12-1543. Data Lanes Control FSM State Description**

State (ulps_data_fsm_st_r)	Description
DATA_LN_IDLE	Idle state. In this state HS transmission can be issued if clock lane is in HS mode.
DATA_LN_ULPS_REQ	Request to enter ULP state. Waiting for activation ULP confirmed by tx_ulps_active_n input.
DATA_LN_ULPS_ACTIVE	ULPS for data lanes is active. Waiting for ulps_req_sync being low to exit ULPS.
DATA_LN_ULPS_EXIT	ULPS exiting, waiting for time defined in ULPS_DATA_WAKEUP_TIME register.

#### 12.7.3.5.8 Clock Lane Control

The clock lane of the DPHY\_TX must always be active and prepared for high speed transmission by moving from ULPS state to high speed clock active. The high speed bit clock PLL should be configured for the desired clock rate and locked before the clock lane exits from ULPS.

### 12.7.3.5.9 Clock Lane Control FSMs

The clock lane is controlled in HS and ULP modes using two simple FSMs which have been implemented in the clock control module. Separate FSMs are required as the HS and ULP signals operate in different clock domains.

A brief description of the states of the HS clock lane FSM is presented in [Table 12-1544](#).

**Table 12-1544. HS Clock Lane Control FSM State Description**

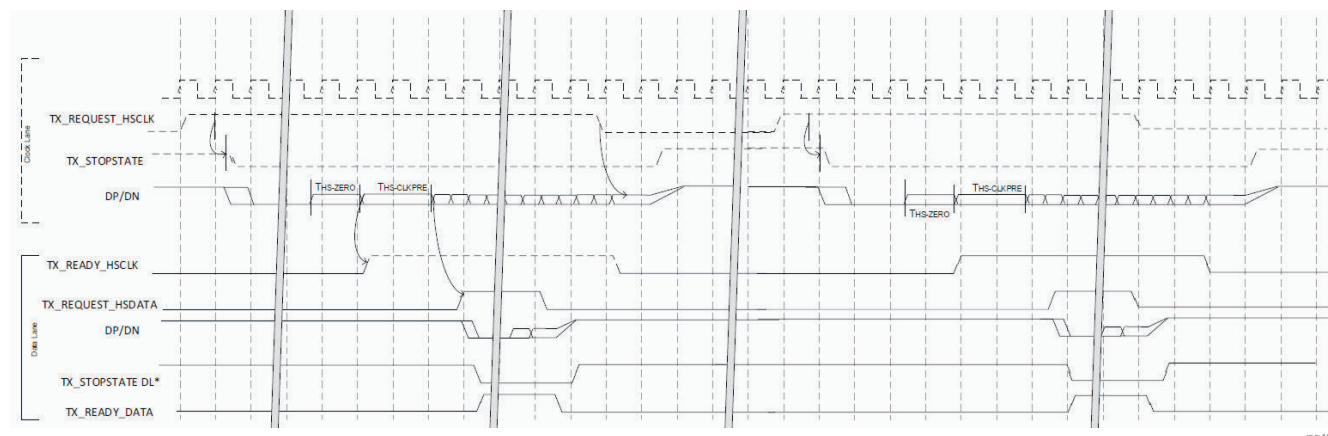

State (clk_fsm_r)	Description
CLK_IDLE	Waiting for HS request and for Clock ULPS FSM to enter IDLE
CLK_HS_REQ	HS mode request, waiting for DPHY_TX HS mode active
CLK_HS_MODE	HS mode active
CLK_HS_EXIT	Exiting HS mode

A brief description of the states of the ULP clock lane FSM is presented in [Table 12-1545](#).

**Table 12-1545. ULPS Clock Lane Control FSM State Description**

State (clk_fsm_r)	Description
ULPS_CLK_IDLE	Waiting for ULP request and for HS Clock Lane FSM to enter IDLE
ULPS_CLK_ULPS_REQ	ULP state request, waiting for DPHY_TX ULPS state active
ULPS_CLK_ULPS_ACTIVE	ULPS state is active
ULPS_CLK_ULPS_EXIT	Exiting ULPS. Waiting for time defined in DPHY_CLK_WAKEUP register

The clock lane will operate in either continuous or non-continuous clock operation based on the bit value on the CSI\_TX\_IF\_DPHY\_CFG[10] DPHY\_CLOCK\_MODE register bitfield. When the non-continuous clock mode is active the clock lane will automatically move between LP and HS modes based on the activity of the streams.

**Figure 12-1173. Clock Lane Control FSMs Timing Diagram**

In this mode of operation, after a High Speed burst, if there are no new HS requests pending, the CSI\_TX\_IF controller will deactivate the Clock Lane request, and the Clock Lane will exit High Speed mode and reach stop state. The Clock Lane will remain in LP while there are no active requests. When a new HS request is received, the Clock Lane will exit LP mode and resume High Speed operation.

The CSI\_TX\_IF controller can request that the DPHY\_TX enters ULPS when there are no active frames, and must return through LP11 when there are new requests to be processed by changing the CSI\_TX\_IF\_DPHY\_CFG[9-8] DPHY\_MODE back to High Speed.

### 12.7.3.5.10 CSI\_TX\_IF Configuration for PSI\_L

Table 12-1546 lists the settings that must be programmed before enabling CSI\_TX\_IF controller and sending PSI\_L data.

**Table 12-1546. CSI\_TX\_IF configuration table for PSI\_L**

Format	Pixel transmit mode used	Size	Details
YUV420-8	single	0	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV420-10	single	1	Must set YUV420 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	single	0	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-10	single	1	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
YUV422-8	packed	2	Must set YUV422 mode in CSI_TX_IF_DMACNTX_j
RGB888, RGB666	single	2	
RGB565, RGB555, RGB444	single	1	
RAW6-8	single	0	
RAW8	dual	1	
RAW8	quad	2	
RAW10	single	1	
RAW10	dual	2	
RAW12	single	1	No packing
RAW12	dual	2	No packing
RAW12(packed)	single	0	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW12(packed)	dual	1	Must set CSI_TX_IF_DMACNTX_j[23] PACK12_CFG = 1
RAW14	single	1	
RAW14	dual	2	
RAW16	single	1	
RAW20	single	2	
User defined 8	single	0	Same as RAW8
User defined 16	single	1	Same as RAW16

### 12.7.3.5.11 CSI\_TX\_IF Configuration for Re-transmit

The following lists the re-transmit configuration requirements:

- Software must program re-transmit related registers before enabling CSI\_RX\_IF to send data.
- In CSI\_RX\_IF to CSI\_TX\_IF loopback needs to have the same mode on both CSI\_RX\_IF and CSI\_TX\_IF controllers(single, dual, quad). Cannot mix for example dual on CSI\_RX\_IF and single on CSI\_TX\_IF.
- Update CSI\_TX\_IF\_RETRANS\_CNTL for virtual channel desired to be transmitted on Stream2/3.
- Enable CSI\_TX\_IF to send out data (Only supports RAW formats)
- Data type select(CSI\_TX\_IF\_DT0\_CFG - CSI\_TX\_IF\_DT7\_CFG) for CSI\_TX\_IF are driven by bottom 3 bits of datatype from CSI\_RX\_IF. CSI\_RX\_IF has the true data type. Software will need to program the appropriate configuration registers based on this.

**Table 12-1547. CSI\_TX\_IF configuration table for PSI\_L**

DataseI(TX)	Datatype(RX)	Description
0	0x28	RAW6
1	0x29	RAW7

**Table 12-1547. CSI\_TX\_IF configuration table for PSI\_L (continued)**

DataseI(TX)	Datatype(RX)	Description
2	0x2A	RAW8
3	0x2B	RAW10
4	0x2C	RAW12
5	0x2D	RAW14
6	0x2E	RAW16
7	0x2F	RAW20

#### 12.7.3.5.12 CSI\_TX\_IF Configuration for Color Bar

The following lists the Color Bar configuration requirements:

- Color bar must be set to packed YUV422-8 format, this is an extended datatype in CSI\_TX\_IF controller.
- Software must program CSI\_TX\_IF controller before enabling the color bar from the CSI\_TX\_IF\_COLOR\_CNTL[0] EN bit-field.
- Program CSI\_TX\_IF\_COLOR\_LINE\_DELAY, CSI\_TX\_IF\_COLOR\_FRAME\_DELAY, CSI\_TX\_IF\_COLOR\_START\_DELAY, and CSI\_TX\_IF\_COLOR\_PARAM registers with appropriate configurations. Update CSI\_TX\_IF\_COLOR\_CNTL with virtual channel and data type desired and enable it.

#### 12.7.3.5.13 CSI\_TX\_IF Error Recovery

When an underflow error occurs, software must reset the entire CSI\_TX\_IF by SoC PSC reset and restart over.

#### 12.7.3.5.14 CSI\_TX\_IF Power Up/Down Sequence

The following lists the power up/down sequence requirements:

1. Software must ensure no more PSI\_L traffic is directed toward the CSI\_TX\_IF module.
2. Software must then go through a tear down process on PSI\_L gasket inside CSI\_TX\_IF wrapper. Refer to chapter *PSI\_L* for tear down process.
3. Software must then check the stream idle values so that they are idle in the CSI\_TX\_IF\_CONTROL1 register.
4. Software must then stop all traffic inside the CSI\_TX\_IF controller and wait till it is idle.
5. After that software can then proceed to do PSC power down routine.

## 12.8 Shared MIPI D-PHY Transmitter (DPHY\_TX)

This section describes the features and functions of the shared MIPI D-PHY Transmitter (DPHY\_TX).

### 12.8.1 DPHY\_TX Subsystem Overview

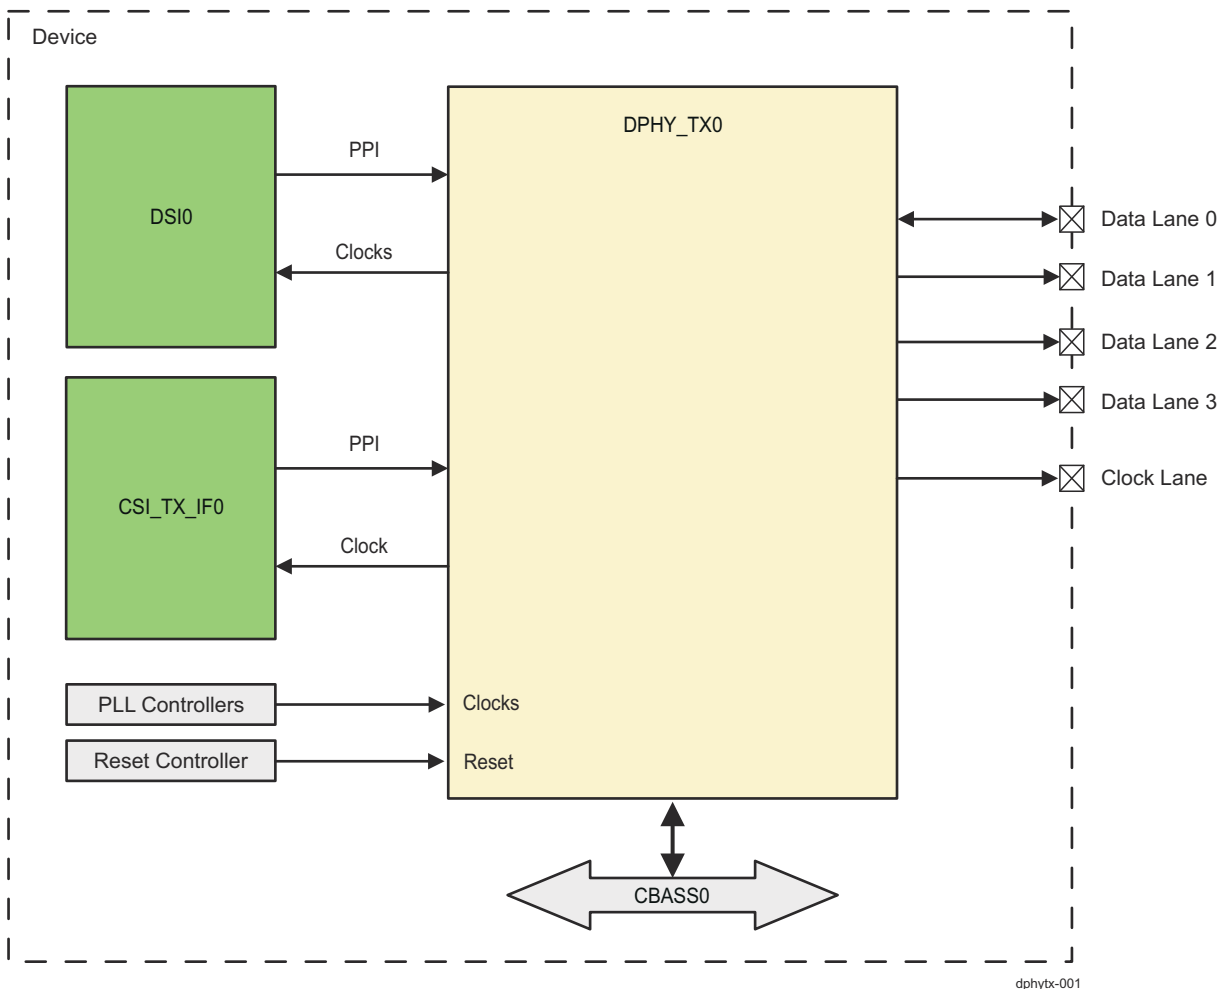

The DPHY\_TX module provides one option for video output interfacing by implementing a four-lane MIPI D-PHY Transmitter.

The device includes one instantiation of DPHY\_TX module. [Table 12-1548](#) shows the DPHY\_TX allocation within device domains:

**Table 12-1548. DPHY\_TX Allocation Accross Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DPHY_TX0	-	-	✓

[Figure 12-1174](#) provides DPHY\_TX module overview.

**Figure 12-1174. DPHY\_TX Overview**

#### 12.8.1.1 DPHY\_TX Features

The DPHY\_TX module supports the following main features:

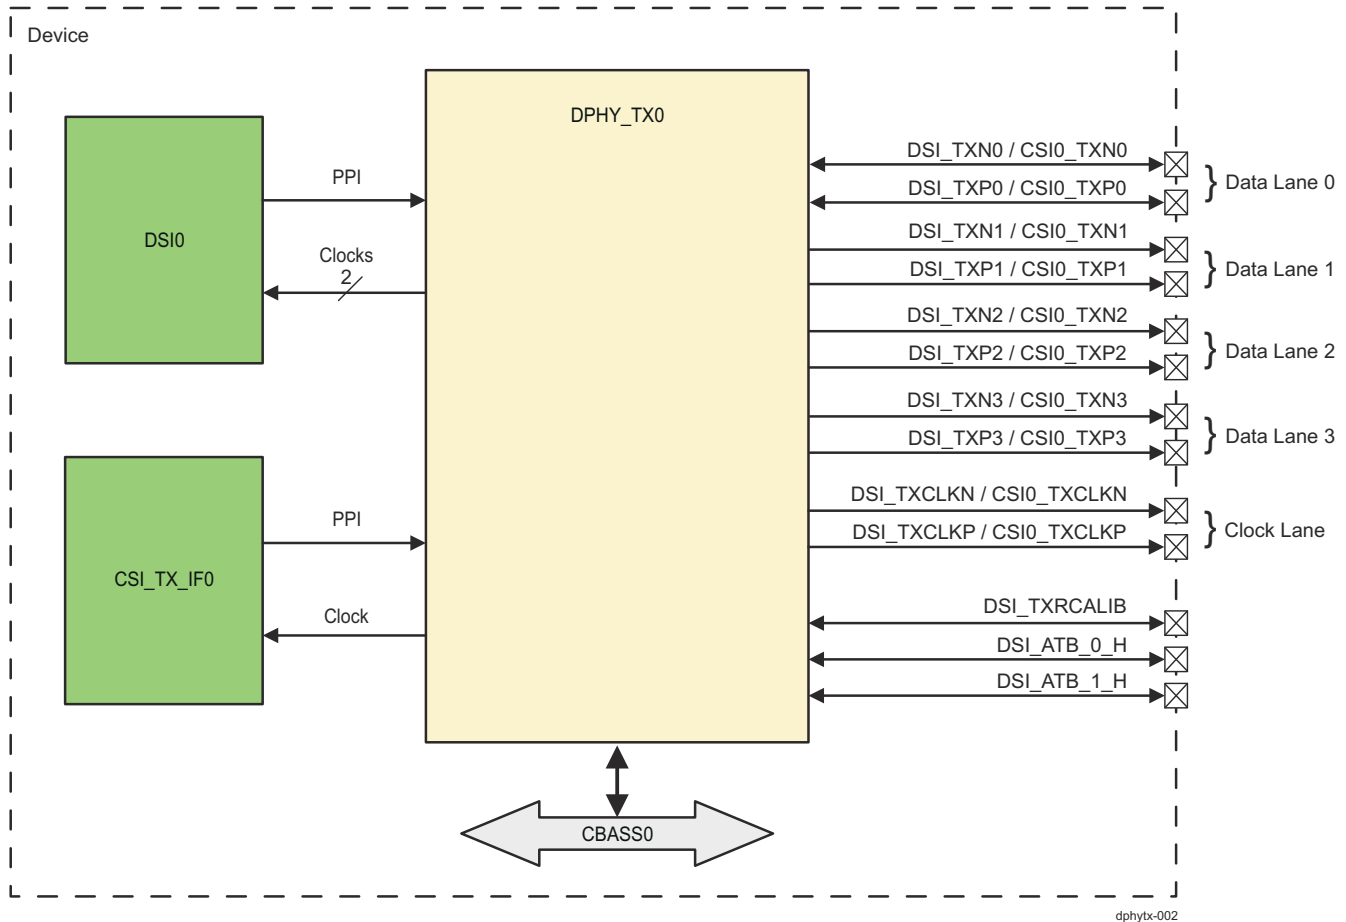

- Compliance with MIPI D-PHY 1.2 physical layer interface specification and features

- 1, 2 or 4 data lanes, in addition to clock signaling
- Maximum data rate up to 2.5 Gbps per data lane (with deskew) and 1.5 Gbps (without deskew)
- Protocol Peripheral Interface (PPI)
- HS (High-Speed) continuous and burst modes
- LP (Low-Power), ULPM (Ultra-Lower Power), and Shutdown modes
- Data lanes can be independently operated in HS or ULP mode.
- Forward direction and reverse direction escape modes (only on Lane-0)
- Automatic termination control in both high-speed and low-power modes
- Fault detection:
  - Contention detection
  - Sequence error detection (corruption on lanes)

## 12.8.2 DPHY\_TX Environment

This section describes the DPHY\_TX application fields from an environment point of view (external connections).

**Figure 12-1175. DPHY\_TX Enviroment**

[Table 12-1549](#) describes the DPHY\_TX signals when transmitting data from a DSI module, and [Table 12-1550](#) describes the DPHY\_TX signals when transmitting data from a CSI\_TX\_IF module.

The CTRLMMR\_DPHY\_TX0\_CTRL[1-0] LANE\_FUNC\_SEL register field in the device Control Module selects which module, DSI0 or CSI\_TX\_IF0, uses the DPHY\_TX0 lanes.

**Table 12-1549. DPHY\_TX I/O Signals in DSI Mode**

Device Level Signal	I/O <sup>(1)</sup>	Description
<b>DPHY_TX0</b>		
DSI_TXN0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Negative)
DSI_TXP0	I/O	DPHY_TX0 Lane 0 Transmit Differential Data (Positive)
DSI_TXN1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Negative)
DSI_TXP1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Positive)
DSI_TXN2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Negative)
DSI_TXP2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Positive)
DSI_TXN3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Negative)
DSI_TXP3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Positive)
DSI_TXCLKN	O	DPHY_TX0 Transmit Differential Clock Lane (Negative)
DSI_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)
DSI_TXRCALIB	A	DPHY_TX0 pin for external calibration resistor. Refer to the device-specific Datasheet for a recommended resistor value.
DSI_ATB_0_H	I/O	DPHY_TX0 Analog Test Bus 0
DSI_ATB_1_H	I/O	DPHY_TX0 Analog Test Bus 1

(1) I = Input; O = Output.

**Table 12-1550. DPHY\_TX I/O Signals in CSI Mode**

Device Level Signal	I/O	Description
<b>DPHY_TX0</b>		
CSI0_TXN0	O	DPHY_TX0 Lane 0 Transmit Differential Data (Negative)
CSI0_TXP0	O	DPHY_TX0 Lane 0 Transmit Differential Data (Positive)
CSI0_TXN1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Negative)
CSI0_TXP1	O	DPHY_TX0 Lane 1 Transmit Differential Data (Positive)
CSI0_TXN2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Negative)
CSI0_TXP2	O	DPHY_TX0 Lane 2 Transmit Differential Data (Positive)
CSI0_TXN3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Negative)
CSI0_TXP3	O	DPHY_TX0 Lane 3 Transmit Differential Data (Positive)
CSI0_TXCLKN	O	DPHY_TX0 Transmit Differential Clock Lane (Negative)
CSI0_TXCLKP	O	DPHY_TX0 Transmit Differential Clock Lane (Positive)

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.8.3 DPHY\_TX Integration

This section describes the DPHY\_TX integration in the device MAIN domain, including information about clocks and resets.

There is one DPHY\_TX integrated in the device MAIN domain - DPHY\_TX0. Figure 12-1176 shows the integration of DPHY\_TX.

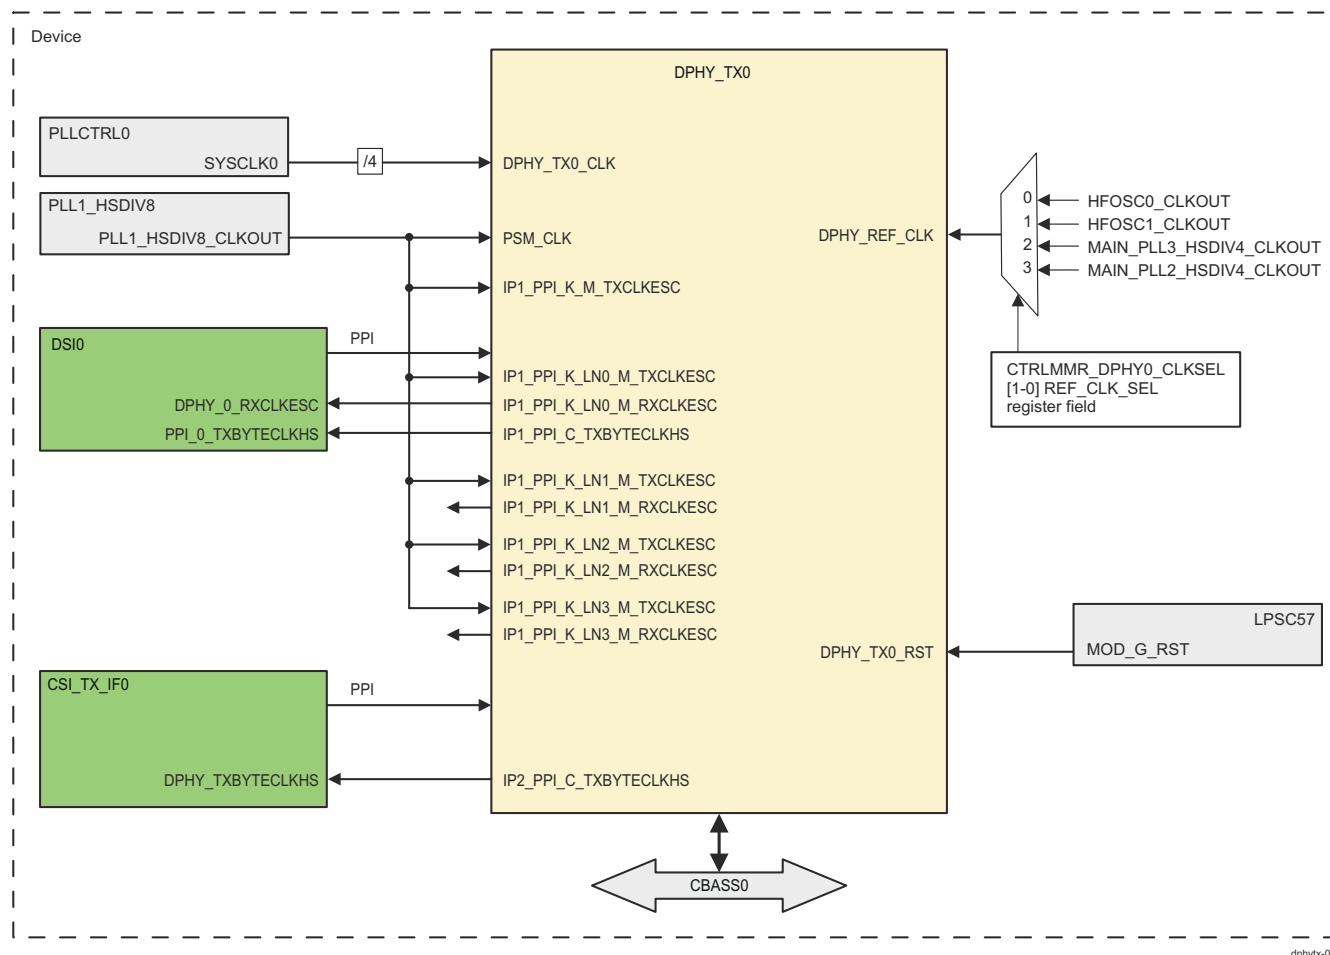

Figure 12-1176. DPHY\_TX Integration

Table 12-1551 and Table 12-1552 summarize the integration of DPHY\_TX in device MAIN domain.

Table 12-1551. DPHY\_TX Integration Attributes

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
DPHY_TX0	PSC0	PD2	LPSC57	CBASS0

Table 12-1552. DPHY\_TX Clocks and Resets

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DPHY_TX0	DPHY_TX0_CLK	SYSClk0 / 4	PLLCTRL0	DPHY_TX0 interface clock

**Table 12-1552. DPHY\_TX Clocks and Resets (continued)**

	PSM_CLK	PLL1_HSDIV8_CLKOUT	PLL1_HSDIV8	DPHY_TX0 reference clock
	IP1_PPI_K_M_TXCLKE SC			DPHY_TX0 escape mode clock
	IP1_PPI_K_LN0_M_TX CLKESC			DPHY_TX0 escape mode clock for lane 0 for IP1_PPI

### Note

For more information on the interconnects in device MAIN domain, see [Chapter 3, System Interconnect](#).

For more information on the power, reset and clock management in device MAIN domain, see the corresponding sections within [Chapter 5, Device Configuration](#).

## 12.9 Video Processing Front End (VPFE)

This section describes the Video Processing Front End (VPFE) module for the device.

### 12.9.1 VPFE Overview

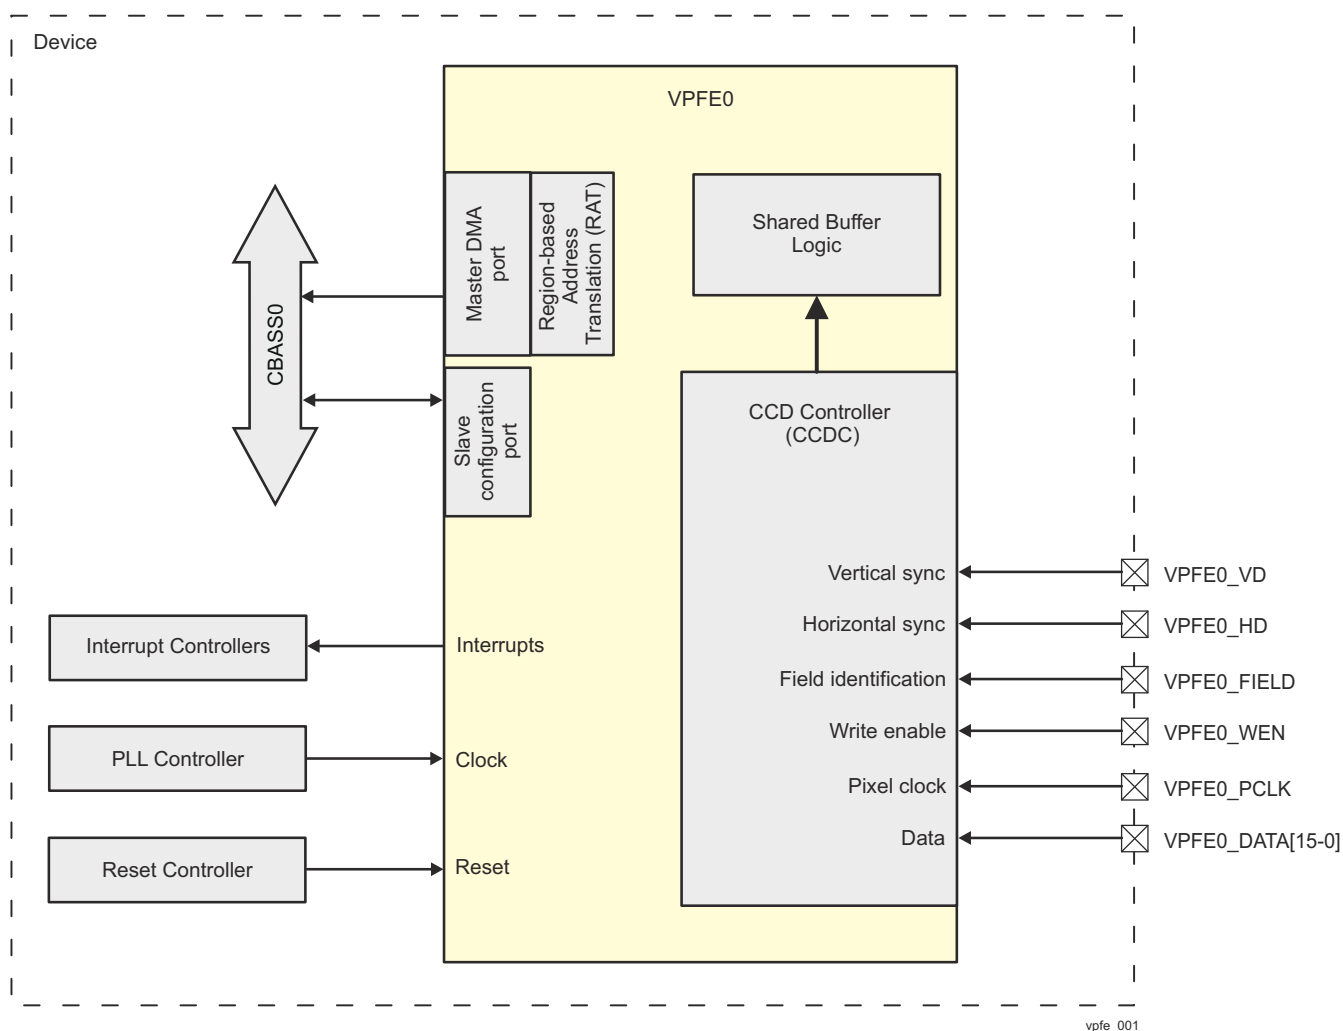

The Video Processing Front End (VPFE) is an input interface module that receives raw (unprocessed) image/video data or YUV digital video data from external imaging peripherals (such as image sensors, video decoders, etc) and performs DMA transfers to store the captured data in the system DDR memory.

Table 12-1553 shows the VPFE allocation within device domains.

**Table 12-1553. VPFE Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
VPFE0	-	-	✓

Figure 12-1177 is an overview of the VPFE.

**Figure 12-1177. VPFE Overview**

#### 12.9.1.1 VPFE Features

The VPFE module supports the following features:

- 
- Encompasses a buffer memory for interfacing to the DMA at the chip level and preventing the charge-coupled device (CCD) Controller from overflowing.
- Support for conventional Bayer pattern and Foveon sensor formats.
- Generates HD/VD timing signals and field ID to an external timing generator or can synchronize to the external timing generator
- Support for progressive (non-interlaced) and interlaced sensors (hardware support for up to 2 fields and firmware support for higher number of fields, typically 3-, 4-, and 5-field sensors).
- Support for up to 110-MHz sensor clock.
- Support for REC656/CCIR-656 standard (YCbCr 422 format, either 8- or 16-bit).
- Support for YCbCr 422 format, either 8- or 16-bit with discrete HSYNC and VSYNC signals.
- Support for up to 16-bit input.
- Generates optical black clamping signals.
- Support for digital clamping and black level compensation.
- Support for 10-bit to 8-bit A-law compression.
- Support for a low-pass filter prior to writing to DDR. If this filter is enabled, 2 pixels each in the left and right edges of each line are cropped from the output.
- Support for generating output to range from 16-bits to 8-bits wide (8-bits wide allows for 50% saving in storage area).
- Support for downsampling via programmable culling patterns.
- Ability to control output to the DDR via an external write enable signal.
- Support for up to 16K pixels (image size) in both the horizontal and vertical directions.
- Region-based Address Translation (RAT) module for converting legacy 32-bit to 48-bit addressing scheme in the write DMA path.

#### 12.9.1.2 VPFE Not Supported Features

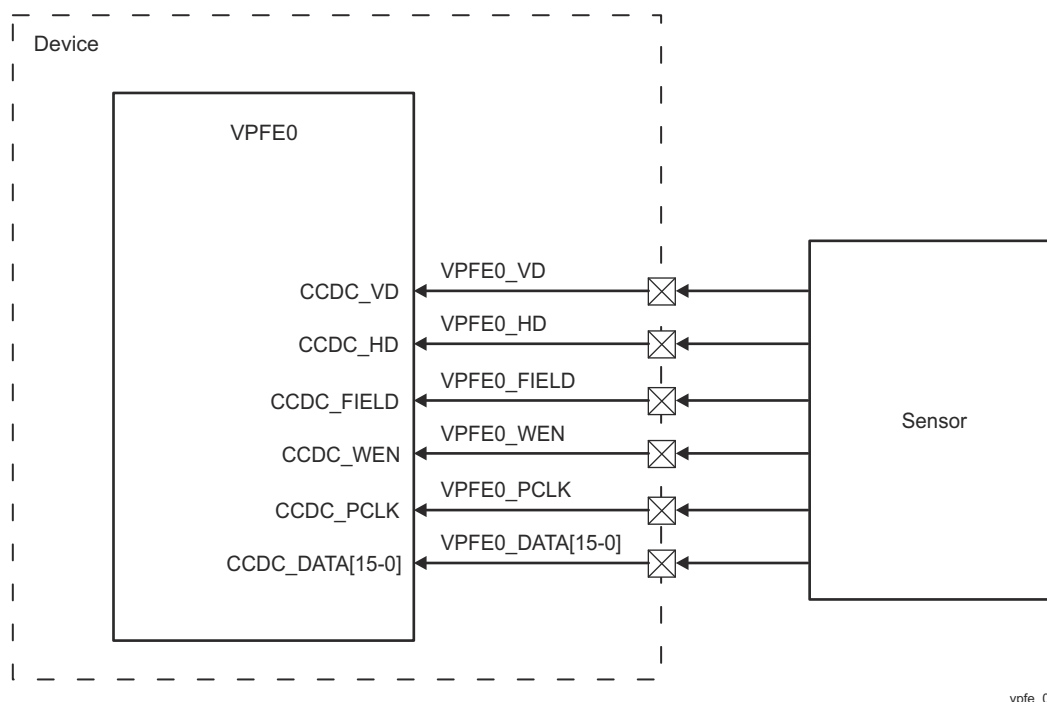

The following features are not supported on this family of devices:

- 
- Hardware de-interlace (only field identification is supported).

## 12.9.2 VPFE Environment

This section describes the VPFE external connections (environment).

### 12.9.2.1 VPFE External System Interface

vpfe\_002

**Figure 12-1178. VPFE External System Interface**

**Table 12-1554. VPFE I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value

**Table 12-1554. VPFE I/O Signals (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
CCDC_FIELD	VPFE_FIELD	I	Field identification signal	HiZ
CCDC_WEN	VPFE_WEN	I	Write enable signal	HiZ
CCDC_PCLK	VPFE_PCLK	I	Pixel clock	HiZ

(1) When configured for that function; I = Input, O = Output

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.9.3 VPFE Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.9.3.1 VPFE Integration in MAIN Domain

There is one VPFE module integrated in the device MAIN domain - VPFE0. Figure 12-1179 shows its integration in the device.

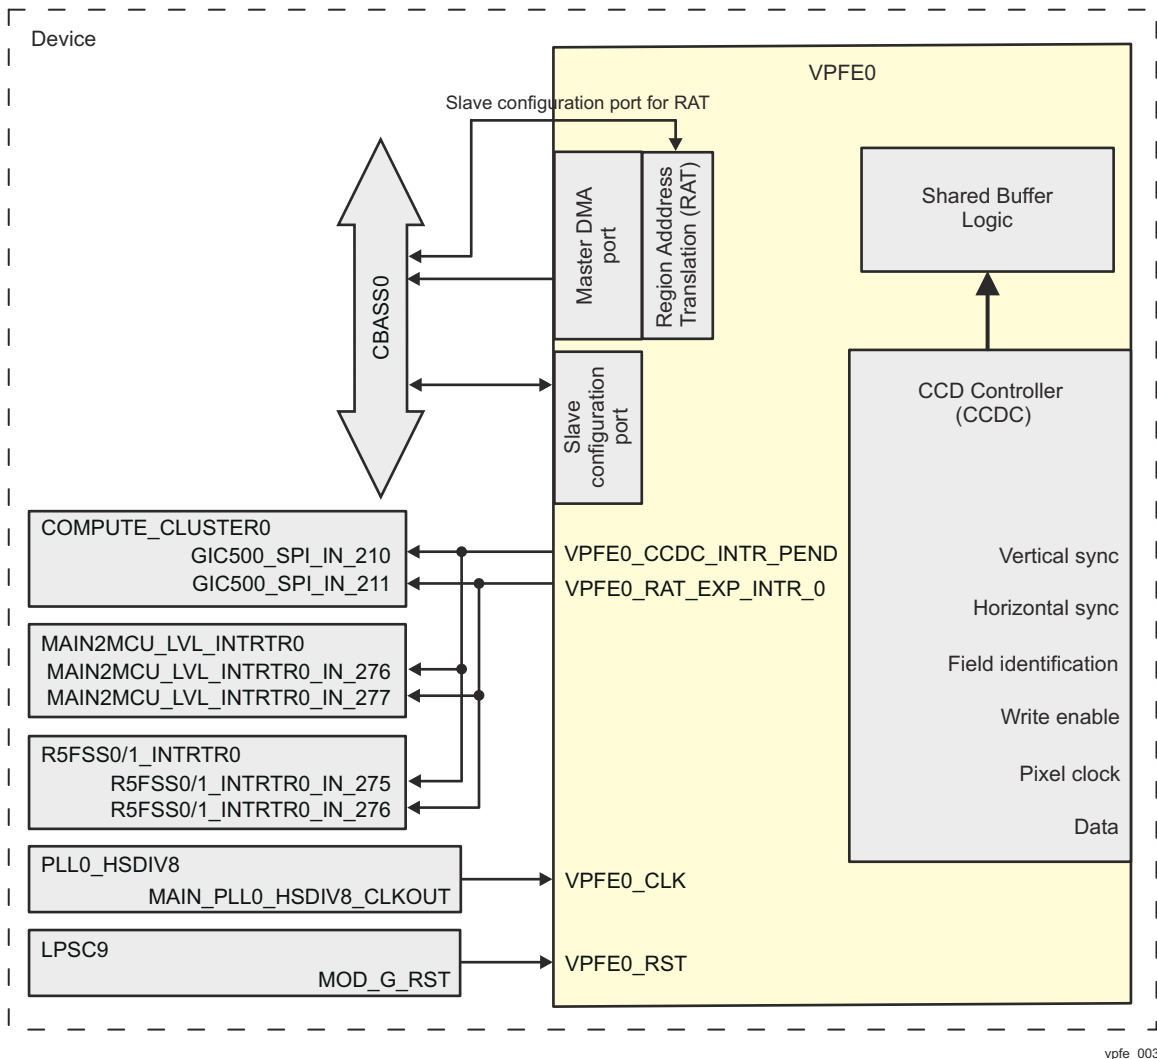

Figure 12-1179. VPFE Integration

Table 12-1555 through Table 12-1557 summarize the integration of VPFE0 in device MAIN domain.

Table 12-1555. VPFE0 Integration Attributes

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
VPFE0	PSC0	PD0	LPSC9	CBASS0

Table 12-1556. VPFE0 Clocks and Resets

		R5FSS0_INTRTR0_IN_275	R5FSS0_INTRTR0	VPFE interrupt to R5FSS0_INTRTR0	
		R5FSS1_INTRTR0_IN_275	R5FSS1_INTRTR0	VPFE interrupt to R5FSS1_INTRTR0	
	VPFE0_RAT_EXP_IN_TR_0	GIC500_SPI_IN_211	COMPUTE_CLUSTER0	VPFE RAT exception interrupt to COMPUTE_CLUSTER0	Level
		MAIN2MCU_LVL_INTRTR0_IN_277	MAIN2MCU_LVL_INTRTR0	VPFE RAT exception interrupt to MAIN2MCU_LVL_INTRTR0 router	
		R5FSS0_INTRTR0_IN_276	R5FSS0_INTRTR0	VPFE RAT exception interrupt to R5FSS0_INTRTR0	
		R5FSS1_INTRTR0_IN_276	R5FSS1_INTRTR0	VPFE RAT exception interrupt to R5FSS1_INTRTR0	

### Note

VPFE interrupts are further described in [Section 12.9.4.3, VPFE Interrupts](#).

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

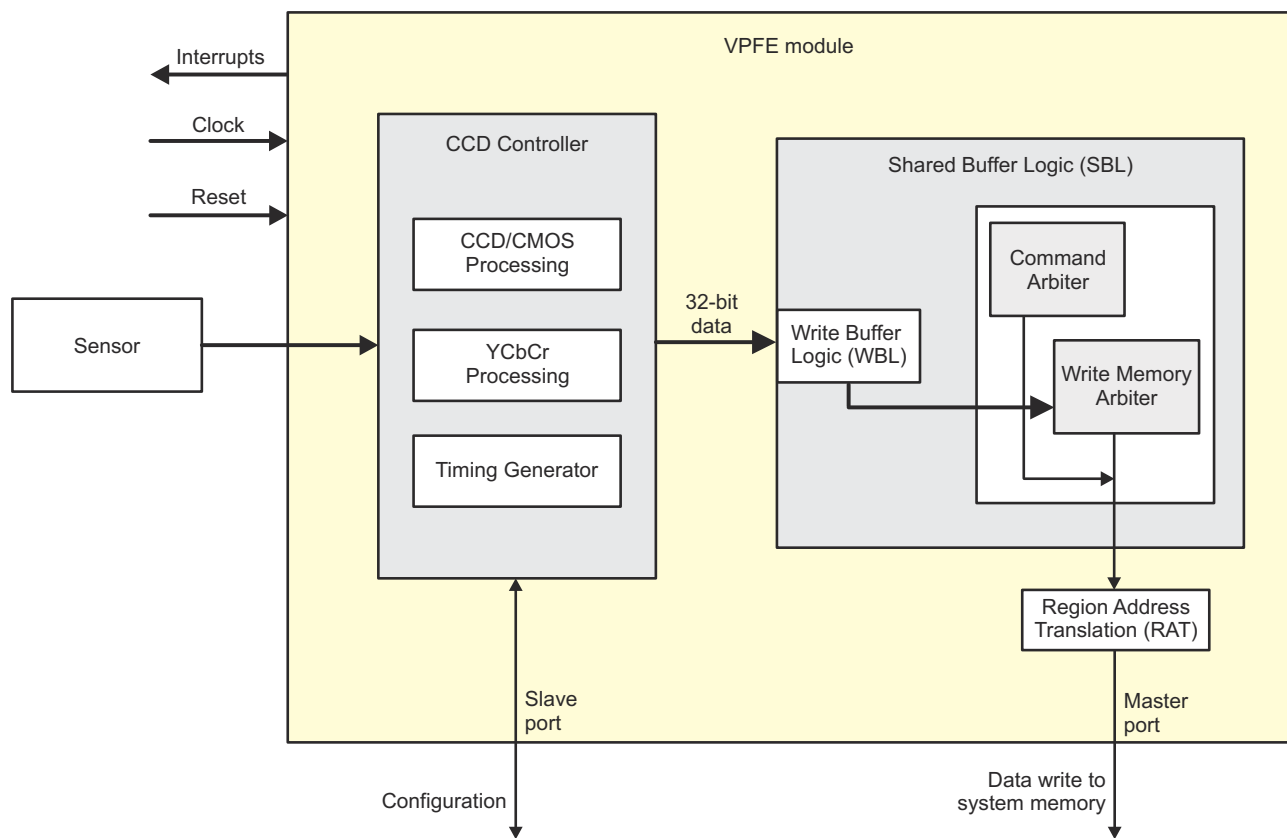

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

## 12.9.4 VPFE Functional Description

### 12.9.4.1 VPFE Block Diagram

Figure 12-1180 shows the simplified internal block diagram of VPFE.

vpfe\_004

**Figure 12-1180. VPFE Block Diagram**

The VPFE module is mainly comprised of two processing blocks:

- CCD controller (CCDC) for data capture.
- Shared Buffer Logic (SBL) for data transfer to DDR.

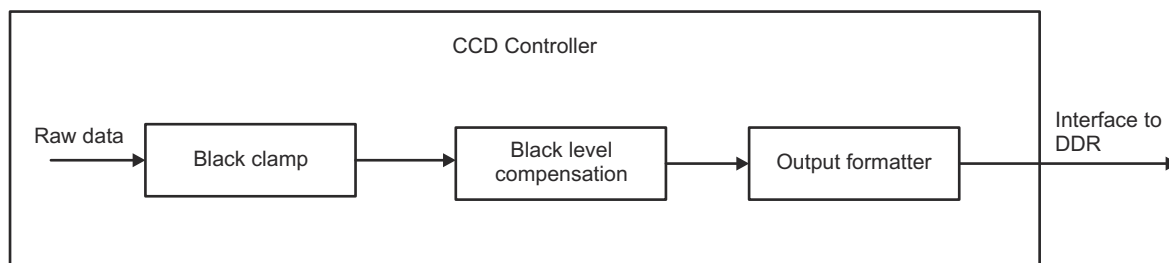

Additionally, a Region-based Address Translation (RAT) block is included to extent DMA address map space.

The VPFE module has the following two system data bus interfaces:

- Slave interface for VPFE configuration by a host processor.
- Master interface for writing data to the system memory by VPFE.

#### 12.9.4.1.1 CCD Controller (CCDC)

The CCDC accepts raw image/video data from an external CCD/CMOS sensor and performs minimal image processing before it outputs the data to DDR, see Figure 12-1181. The CCDC can also accept REC656/CCIR-656 input data.

vpfe\_005

**Figure 12-1181. CCD/CMOS Processing**

#### 12.9.4.1.2 Shared Buffer Logic (SBL)

The shared buffer logic/memory provides local buffering of the captured video data from CCDC module and performs bandwidth efficient burst DMA transfers to DDR memory via a 32-bit wide high bandwidth system data bus. The shared buffer logic/memory (divided into the write buffer and arbitration logic) is capable of performing the following functions:

- Interface to the CCDC module. Receives data from the CCDC and provides a zero latency interface.
- Write buffer logic (WBL) block to interface between the respective module/write port and the write buffer memory.
- A command arbiter to generate the larger VBUSP commands.
- Make appropriate VBUSP requests to the DMA interface to send data to the DDR. The data resides in the write buffer memory until enough data exists to make a large enough burst to be efficient.

#### 12.9.4.1.3 Region-based Address Translation

The region-based address translation works by translating a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup. For more information about RAT, see [Section 8.4, Region-based Address Translation \(RAT\) Module](#).

#### 12.9.4.2 VPFE Power Management

The following software sequence enables the controller in the VPFE module (CCDC) to receive video or image capture data.

1. Power-up the VPFE module using the device Power Sleep Controller (PSC).
2. Disable the CCDC by setting VPFE\_PCR[1] ENABLE bit to 0.
3. Configure the VPFE registers to match the system requirements, including interrupt setup.
4. Enable the CCDC by setting VPFE\_PCR[1] ENABLE bit to 1.

The CCDC should be enabled prior to data transmission from the external device to avoid data loss. Once enabled, it starts to process input data continuously. No user intervention is necessary to re-start the process. As a result, the VPFE interrupt must be set up correctly in order to operate properly. User can terminate its operation by disabling the CCDC.

#### 12.9.4.3 VPFE Interrupts

The VPFE module can generate one interrupt signal (VPFE0\_CCDC\_INTR\_PEND) to the device host interrupt controllers and one interrupt signal from the RAT in the module (VPFE0\_RAT\_EXP\_INTR\_0).

The CCDC controller can generate three interrupts: CCDC\_VD0\_INT, CCDC\_VD1\_INT, and CCDC\_VD2\_INT. These signals are passed through interrupt generator to generate the CCDC\_PEND\_INTR.

#### Note

Enable the VPFE\_SYNMODE[16] VDHEN to receive any of the VPFE controller interrupts.

The CCDC\_VD0\_INT and CCDC\_VD1\_INT interrupts occur relative to the VD pulse, as shown in [Figure 12-1182](#) and [Figure 12-1183](#). Note that VPFE\_SYNMODE[2] VDPOL bit changes the trigger timing.

- If VPFE\_SYNMODE[2] VDPOL = 1, the VDINT0 and VDINT1 counters begin counting CCDC\_HD pulses from the falling edge of the external VD.
- If VPFE\_SYNMODE[2] VDPOL = 0, the VDINT0 and VDINT1 counters begin counting CCDC\_HD pulses from the rising edge of the external VD.
- Interrupts CCDC\_VD0\_INT and CCDC\_VD1\_INT occur after receiving the number of horizontal lines (CCDC\_HD pulse signals) set in the VPFE\_VDINT[30-16] VDINT0 and VPFE\_VDINT[14-0] VDINT1 bitfields, respectively.

**Figure 12-1182. CCDC\_VD0\_INT/CCDC\_VD1\_INT Interrupt Behavior when VDPOL = 0**

**Figure 12-1183. CCDC\_VD0\_INT/CCDC\_VD1\_INT Interrupt Behavior when VDPOL = 1**

The CCDC\_VD2\_INT interrupt always occurs at the falling edge of the CCDC\_WEN signal (via an external pin), as shown in [Figure 12-1184](#). There are no registers in the VPFE module to configure this interrupt.

**Figure 12-1184. CCDC\_VD2\_INT Interrupt Behavior**

The required software behavior for handling interrupts is as follows:

- Program the interrupt mask by writing a '1' into the correct bitfields of VPFE\_IRQ\_ENABLE\_SET.
- An interrupt is detected by the interrupt controller .
- Read the VPFE\_IRQ\_STATUS register and handle the different interrupt status bits.
- Write into VPFE\_IRQ\_STATUS the value read previously to specify the bits which have been handled.
- Write into the VPFE\_IRQ\_EOI register to enable the interrupt to propagate through the interrupt controllers.

For more details on programmable configuration of the module interrupt signals mapping to the different device host interrupt controllers, see *Interrupt Controllers*.

### 12.9.4.4 VPFE Register Configuration

#### 12.9.4.4.1 General Register Setup

Table 12-1558 lists the minimum register bitfields that must be configured.

**Table 12-1558. Basic Configuration of VPFE Registers**

Register	Bit and Bitfield Name	Function
VPFE_SYNMODE	[16] VDHDEN [7] FLDMODE [6] DATAPOL [5] EXWEN [4] FLDPOL [3] HDPOL [2] VDPOL	External signal configuration (This includes signals CCDC_VD, CCDC_HD, CCDC_FIELD, and CCDC_WEN)
VPFE_CCDCFG	[15] VDLC	Latching function on VSYNC
VPFE_REC656IF	[0] R656ON	REC656 interface
VPFE_SYNMODE	[13-12] INPMOD	Input data mode
VPFE_COLPTN	All bitfields	Color pattern
VPFE_BLKCOMP	All bitfields	Black compensation
VPFE_SYNMODE	[17] WEN	Data path configuration

#### 12.9.4.4.2 Status

The status bit (VPFE\_PCR[1] BUSY) is set when the start of frame occurs (if the VPFE\_PCR[0] ENABLE bit is 1 at that time). It automatically resets to 0 at the end of a frame.

#### 12.9.4.4.3 CCDC\_VD Latched Registers

The VPFE\_CCDCFG[15] VDLC bit affects the access of the following registers and register bits.

- VPFE\_PCR register
- VPFE\_HORZ\_INFO register
- VPFE\_VERT\_START register
- VPFE\_VERT\_LINES register
- VPFE\_CULLING register
- VPFE\_HSIZE\_OFF register
- VPFE\_SDOFST register
- VPFE\_SDR\_ADDR register
- VPFE\_SYNMODE[17] WEN bit
- VPFE\_SYNMODE[14] LPF bit
- VPFE\_CLAMP[31] CLAMPEN bit
- VPFE\_CCDCFG[4] YCINSWP bit

#### Note

If the VPFE\_CCDCFG[15] VDLC is 0, changes to the above registers/register bits takes effect immediately.

If the VPFE\_CCDCFG[15] VDLC is 1, changes to the above registers/register bits takes effect at the start of a new frame (which means the changes are latched by the CCDC\_VD signal). Reads from these registers/register bits returns the most recent write value (even though these values may not take effect).

#### 12.9.4.4.3.1 Inter-Frame Operations

VPFE\_PCR and VPFE\_SDR\_ADDR registers are latched by the CCDC\_VD signal if the VPFE\_CCDCFG[15] VDLC is 0 (see *VPFE CCDC\_VD Latched Registers* for more information). This important feature provides a reliable way to enable/disable the VPFE module and/or modify the memory pointers in-between frames. For example, the VPFE interrupt service routine can program the VPFE\_SDR\_ADDR register to a new value before

the end of the current frame. By doing so, the current frame is received without any interruption and the new external memory address (VPFE\_SDR\_ADDR register) is used for receiving the next frame.

#### 12.9.4.5 VPFE Limitations

The major limitations of the VPFE module are as follows:

- The CCDC\_PCLK (pixel clock) signal shall be up to 110 MHz.
- Both VPFE\_SDR\_ADDR and VPFE\_HSIZE\_OFF registers should be programmed to values with 5 LBS bits as 0; namely, the memory space they point to should be on a 32-byte boundary.
- The VPFE\_COLPTN register should be set to 0 in YCbCr and BT.656 modes.
- The VPFE\_BLKCOMP register should be set to 0 in YCbCr and BT.656 modes.
- Low-pass filter through VPFE\_SYNMODE[14] LPF should be disabled in YCbCr and BT.656 modes.
- A-law transformation should be disabled through VPFE\_ALAW register in YCbCr and BT.656 modes.

#### 12.9.4.6 VPFE Interfaces

The following subsections explain how to connect VPFE signal pins to various input devices.

##### 12.9.4.6.1 Interfaces Summary

[Table 12-1559](#) summarizes the VPFE signal pins required by common input devices.

**Table 12-1559. Summary of VPFE Signal Pins and Common Input Devices**

Signal Name	Type <sup>(1)</sup>	Description	Raw Data Mode 16-bit	Raw Data Mode 8-bit	Raw Data Mode, no FIELD or WEN 16-bit	Raw Data Mode, no FIELD or WEN 8-bit	BT.656 Mode 16-bit	BT.656 Mode 8-bit	Digital YCbCr Mode 16-bit	Digital YCbCr Mode 8-bit

(1) I = Input, O = Output

#### 12.9.4.6.2 Timing Generator and Frame Settings

The timing generator in the CCDC either enables the use of external sync signals (HD/VD) or internal generated timing signals. The CPU controls width, polarity, position and direction of internal generated signals. [Figure 12-1185](#) shows various CCDC register settings related to the timing. The shaded area is the physical imager size and the gray area is the valid data area. The image data in this area is processed and stored to external DDR. The vertical start position for even and odd fields are configured independently.

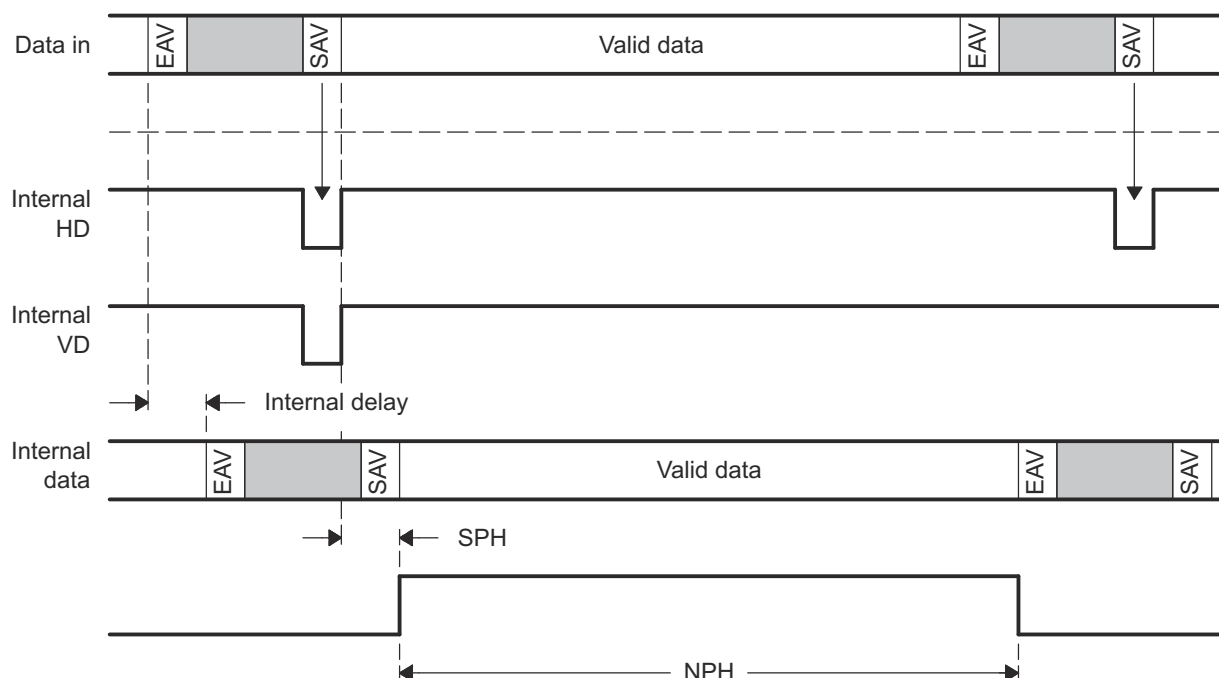

**Figure 12-1185. CCD Controller Frame Settings and Format**

#### 12.9.4.6.3 ITU-R BT.656 Interface

The ITU-R BT.656 interface supports either 8-bit or 16-bit processing of input video YCbCr data. See [Table 12-1559](#) for signals used to configure this mode.

Since the data synchronization information is carried along with the data lines, no synchronization signals (that is CCDC\_HD, CCDC\_VD, and CCDC\_FIELD) are necessary in this mode.

Two timing reference codes are transmitted as the synchronization signal. At the start and end of each video data block, two unique codes are sent, respectively. The start code is called the Start of Active Video Signal (SAV), and the end code is called the End of Active Video Signal (EAV). The SAV and EAV codes proceed and follow valid data, as shown in [Figure 12-1186](#). The controller in the VPFE internally bases on SAV and EAV codes to generate the necessary synchronization signals, that is, horizontal sync, vertical sync, and field ID.

vpfe\_007

**Figure 12-1186. BT.656 Signal Interface**

Both timing reference signals, SAV and EAV, consist of a four-word sequence in the following format: FF 00 00 XY, where FF 00 00 are a set preamble and the fourth word defines the field identification, the state of vertical field blanking, the state of horizontal line blanking, and protection (error correction) codes. The bit format of the fourth word is shown in [Table 12-1560](#) and the definitions for bits, F, V, and H, are given in [Table 12-1561](#). F, V, and H are used in place of the usual horizontal sync, vertical sync, and blank timing control signals. Bits P3, P2, P1, and P0 are protection (error correction) bits for F, V, and H. The relationship between F, V, and H and the protection (error correction) bits is given in [Table 12-1562](#). To enable error correction, set the VPFE\_REC656IF[1] ECCFVH bit. The controller in the VPFE automatically detects and applies error correction when the VPFE\_REC656IF[1] ECCFVH bit is set.

**Table 12-1560. Video Timing Reference Codes for SAV and EAV**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

**Table 12-1561. F, V, H Signal Descriptions**

Signal	Value	Command
F	0	Field 1
	1	Field 2

**Table 12-1561. F, V, H Signal Descriptions  
(continued)**

Signal	Value	Command
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

**Table 12-1562. F, H, V Protection (Error Correction)  
Bits**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

#### Note

The controller in the VPFE outputs the XY code in the SAV and EAV into the external memory. In order to eliminate this, set the VPFE\_HORZ\_INFO[30-16] SPH field to +1. Also set the VPFE\_HORZ\_INFO[14-0] NPH bitfield to accurately represent the number of active pixels.

#### 12.9.4.6.4 Digital YCbCr Interface

The digital YCbCr interface supports either 8-bit or 16-bit devices. See [Table 12-1559](#) for signals used to configure this mode.

Unlike the BT.656 mode, discrete horizontal sync (CCDC\_HD) and vertical sync (CCDC\_VD) signals are required. An NTSC/PAL decoder is an example device that can be connected to the YCbCr interface.

Data lines YIN[7-0] or CIN[7-0] are used for input in 8-bit mode. Alternately, two separate devices can be connected; however, only one can be active at any given time. Setting the VPFE\_CCDCFG[4] YCINSWP bit determines which set of 8-bit inputs are active.

Data lines YIN[7-0] and CIN[7-0] are used for input in 16-bit mode. Use the VPFE\_CCDCFG[4] YCINSWP bit to swap the Y and Cr/Cb data lines.

### 12.9.4.7 VPFE Data / Image Processing

This section describes the data / image processing of each module in the VPFE in more detail. [Section 12.9.4.7.1](#) describes the Raw Data mode and [Section 12.9.4.7.2](#) explains the YCbCr and BT.656 modes.

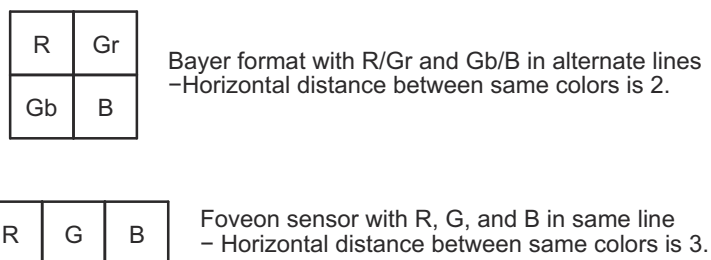

#### 12.9.4.7.1 Raw Data Mode

Raw data mode is enabled by setting VPFE\_SYNMODE[13-12] INPMOD bitfield to 0 and setting VPFE\_REC656IF[0] R656ON bit to 0. [Figure 12-1187](#) shows the corresponding data processing diagram.

**Figure 12-1187. Data Processing for Raw Data Mode**

Typically, raw sensor data is one color per pixel in a color filter array (CFA). The color filter array applied is typically a Bayer pattern, as shown in [Figure 12-1188](#) for RGB color space. Alternatively, the special Foveon X3-family sensors capture R, G, and B lights at each pixel location. Both Bayer and Foveon sensors are supported by the controller in the VPFE module.

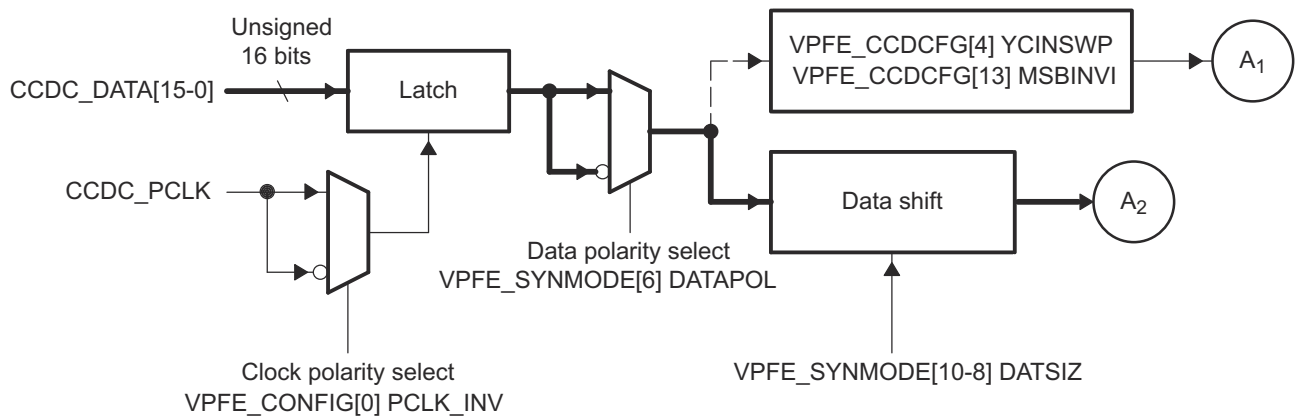

**Figure 12-1188. Color Patterns**

#### 12.9.4.7.1.1 Input Sampling and Formatting for Raw Data Mode

The data path of raw data mode is shown in the thicker lines in [Figure 12-1189](#) (that is A2). Data path A1 is applicable to YUV input mode only.

- The pixel clock (CCDC\_PCLK) latches the data.
- Pixel clock polarity can be either rising or falling edge and is set in VPFE clock control register (VPFE\_CONFIG[0] PCLK\_INV).
- VPFE\_SYNMODE[6] DATAPOL bit affects the data representation.
- Data is right-shifted to align the data in the least significant bits of the data bus and provide the maximum dynamic range for the remainder of the processing (VPFE\_SYNMODE[10-8] DATSIZ bitfield). This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment when it is written to external memory.

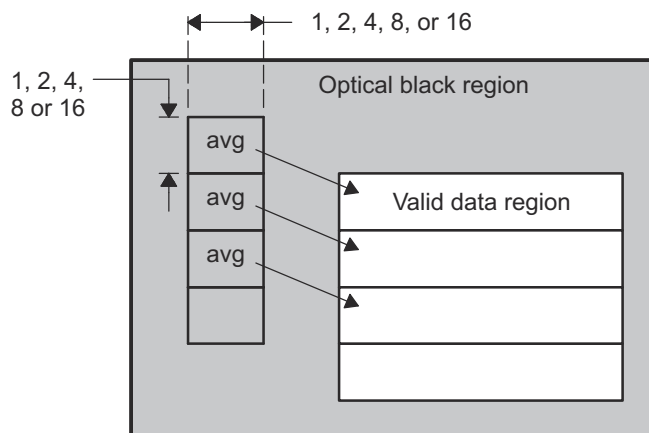

vpfe\_010

**Figure 12-1189. Input Sampling Block Diagram for Raw Data Mode**

#### 12.9.4.7.1.2 Optical Black Clamping for Raw Data Mode

Some sensors provide few optically masked pixels at the beginning/end of each line which allow user to determine the noise floor on any given frame of data. The optical black clamping function provides a means to average the optically black pixels and subtract that value from each input pixel as the first step in reducing the noise on the input pixels.

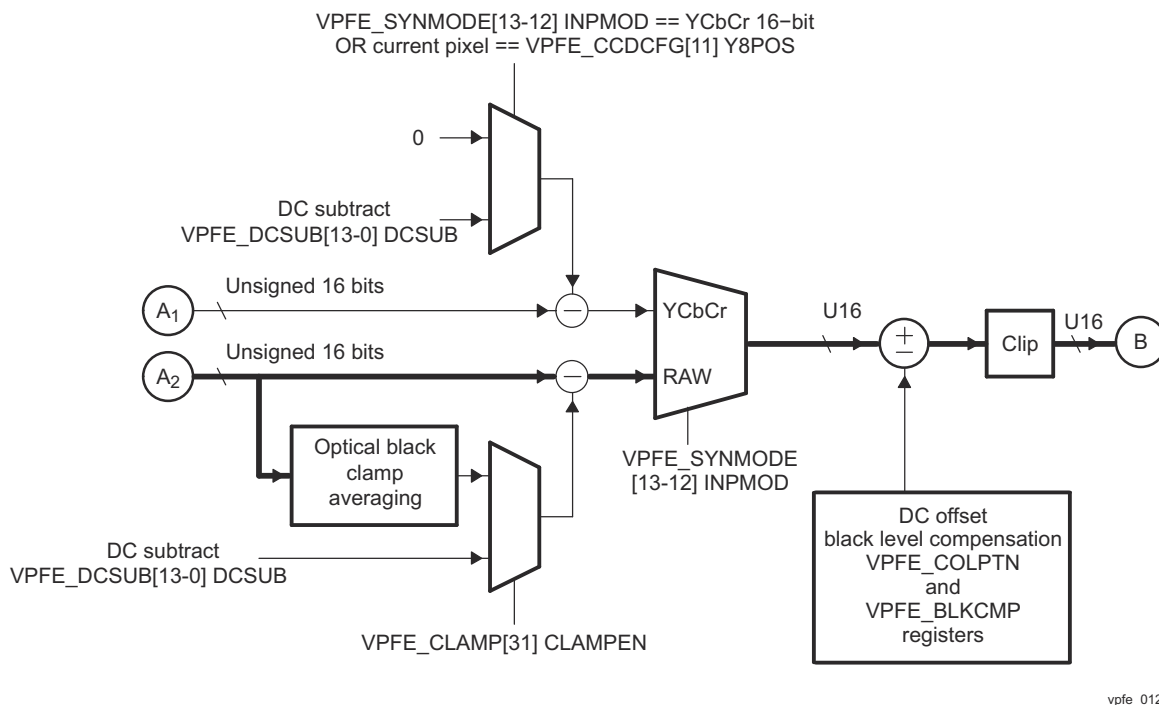

**Figure 12-1190. Optical Black Averaging and Application for Raw Data Mode**

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (in the VPFE\_CLAMP[24-10] OBST bitfield) of each line (in the VPFE\_CLAMP[30-28] OBSLEN bitfield) and for the number of indicated lines (VPFE\_CLAMP[27-25] OBSLN bitfield), plus an optional gain adjustment (VPFE\_CLAMP[4-0] OBGAIN bitfield). The resultant value is subtracted from the image data at the succeeding line. User can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line that are averaged, and the number of lines (1, 2, 4, 8, or 16) that are averaged.

Alternately, user can disable black clamp averaging (VPFE\_CLAMP[31] CLAMPEN bit) and select a constant black value for subtraction (VPFE\_DCSUB[13-0] DCSUB bit) instead of using the calculated average value.

The corresponding data path is shown in the thicker lines in [Figure 12-1191](#).

vpfe\_012

**Figure 12-1191. Black Clamping and Black Level Compensation for Raw Data Mode**

#### 12.9.4.7.1.3 Black Level Compensation

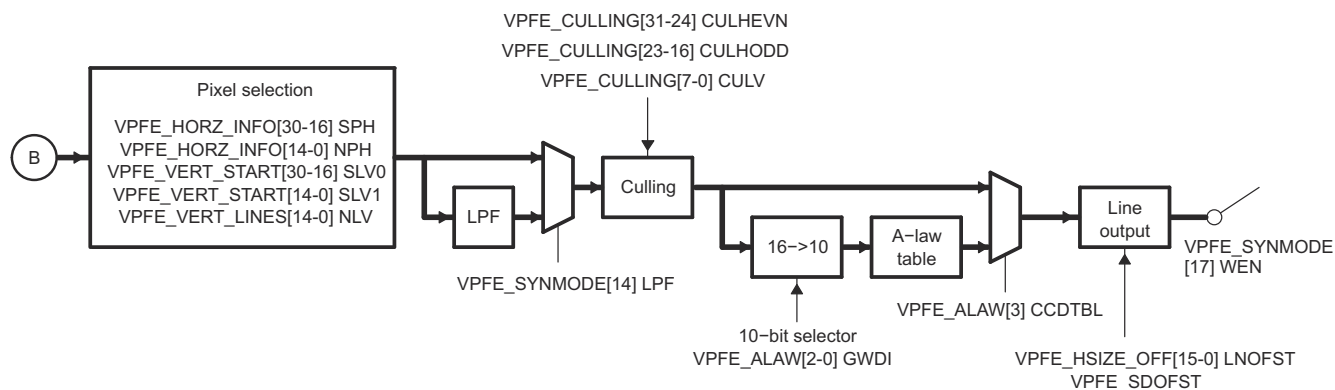

After the digital clamping is applied to the data, black level compensation is applied (see [Figure 12-1191](#)). In this operation, a fixed value is subtracted from the data depending on the color (that is R/Ye, Gr/Cy, Gb/G, and B/Mg). The offset (VPFE\_BLKCOMP register) that is applied to each data sample is selected according to the 0/1/2/3 phase and the color (0/1/2/3) specified for each phase (VPFE\_COLPTN). The color pattern definition is very flexible in order to accommodate many different capture devices, including normal Bayer CFA sampling, Foveon sensors, and VGA movie mode CCDs, whose VGA draft mode output does not follow the typical Bayer pattern.

#### 12.9.4.7.1.4 Output Formatter for Raw Data Mode

The final stage of VPFE processing is the output formatter, shown on [Figure 12-1192](#). A framing selection is applied to limit the processing area by the settings in the VPFE\_HORZ\_INFO, VPFE\_VERT\_START and VPFE\_VERT\_LINES registers.

#### Note

In addition to the framing applied at the beginning and end of the data formatter operation, user must apply a framing selection to limit the processing area. User must ensure that the settings are relative to that frame.

vpfe\_013

**Figure 12-1192. Output Formatter for Raw Data Mode**

#### 12.9.4.7.1.4.1 Low Pass Filter (LPF)

Use the VPFE\_SYNMODE[14] LPF bit to apply an optional low-pass filter after the reframing. The low-pass filter consists of a simple 3-tap ( $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{1}{4}$ ) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled.

#### 12.9.4.7.1.4.2 Culling

Use the VPFE\_CULLING[31-24] CULHVEN and VPFE\_CULLING[23-16] CULHODD bitfields (8-bit repeating mask, one per field) to enable an optional culling operation, which culls (deletes) selected pixel data from a line. Use the VPFE\_CULLING[7-0] CULV bitfield to select lines from a frame.

[Table 12-1563](#) illustrates how the register values apply the decimation pattern to the data. The pixels in white will be saved to external memory and the shaded pixels are discarded.

In this case:

- VPFE\_CULLING = 59C4 0066h, with
- VPFE\_CULLING[31-24] CULHVEN = 59h,
- VPFE\_CULLING[23-16] CULHODD = C4h, and
- VPFE\_CULLING[7-0] CULV = 66h.

**Table 12-1563. Example for Decimation Pattern**

	MSB							LSB	
CULHEVN	0	1	0	1	1	0	0	1	
CULHODD	1	1	0	0	0	1	0	0	
0th line									0
1st line									1
2nd line									1
3rd line									0
4th line									0
5th line									1
6th line									1
7th line									0
									CULV

#### 12.9.4.7.1.4.3 A-Law Transformation

Use the VPFE\_ALAW[3] CCDBTL bit to apply an optional 10-to-8-bit A-Law transformation using a fixed A-Law table (see [Figure 12-1193](#), [Table 12-1564](#) and [Table 12-1565](#)) as the final processing stage. Using this causes the data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to external memory. Since

the data resolution can be greater than 10 bits at this stage, user must select the 10 bits for input to the A-Law operation. Use the VPFE\_ALAW[2-0] GWDI register to select the 10 bits for input.

**Figure 12-1193. A-Law Table**

**Table 12-1564. A-Law Table – Part 1**

Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law	Input	A-Law

#### 12.9.4.7.1.4.4 Line Output Control

The final stage of the raw data mode is the line output control, which controls how the input sensor lines are written to external memory. The value of the bits in the VPFE\_SDR\_ADDR register defines the starting address where the frame should be written in external memory. The value of the VPFE\_HSIZE\_OFF[15-0] LNOFST bitfield defines the distance between the beginning of output lines in bytes. Both the starting address and line offset must be aligned to 32-byte boundaries (that is, either 16 or 32 pixels, depending on the VPFE\_SYNMODE[11] PACK8 bit). Use the VPFE\_SDOFST register to define additional offsets, depending on the field ID and the even/odd line numbers.

Figure 12-1194 shows example of input and output images in the two formats - non-inversed and inversed.

**Figure 12-1194. Input and Output Image in Non-Inversed vs Inversed Formats**

vpfe\_015

#### 12.9.4.7.1.4.5 Output Format in External Memory for Raw Data Mode

The pixel data format in external memory is shown in [Table 12-1567](#).

- If pixel data format is 8-bit or if the A-Law compression is applied, every 16-bit word in external memory stores two pixel data with VPFE\_SYNMODE[11] PACK8 bit set.
- If pixel data format is greater than 8-bit, every 16-bit word in external memory stores one pixel data, and the unused bits are MSB which are filled with 0.

**Table 12-1566. Storage Format in External Memory for Raw Data Mode**

Upper Word																Lower Word																			
	MSB (31)									LSB (16)									MSB (15)									LSB (0)							
16-bit									Pixel1									Pixel0																	
15-bit	0								Pixel1	0								Pixel0																	
14-bit		0							Pixel1		0							Pixel0		0															
13-bit			0						Pixel1			0						Pixel0			0														
12-bit				0					Pixel1				0					Pixel0				0													
11-bit					0				Pixel1					0				Pixel0					0												
10-bit						0			Pixel1						0			Pixel0						0											
9-bit							0		Pixel1							0		Pixel0							0										
8-bit								0	Pixel1								0	Pixel0								0									

**Table 12-1566. Storage Format in External Memory for Raw Data Mode (continued)**

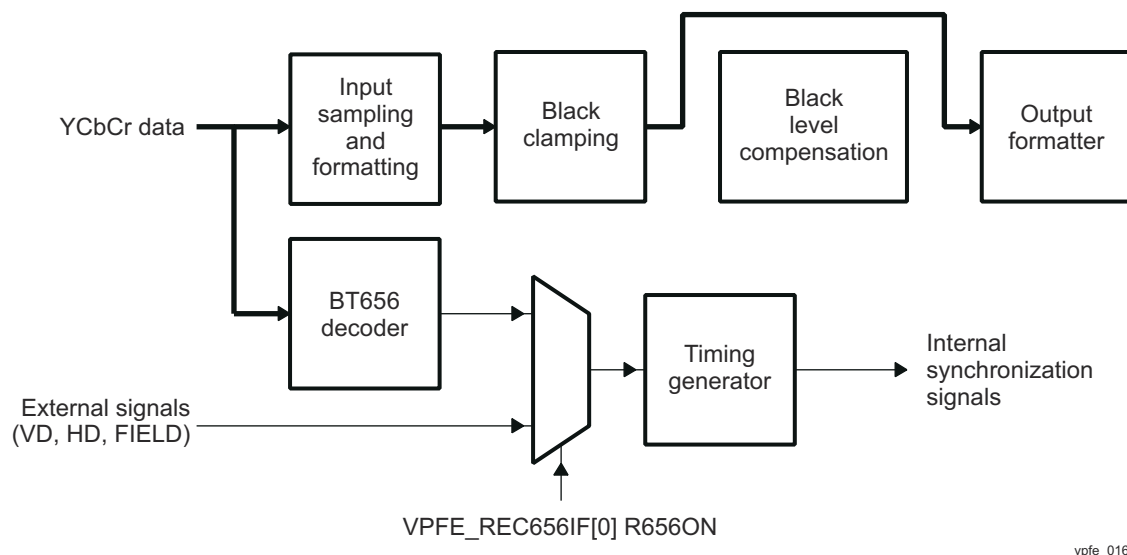

Upper Word		Lower Word	
8-bit pack	Pixel3	Pixel2	Pixel1
			Pixel0

#### 12.9.4.7.2 YCbCr and BT.656 Modes

YCbCr mode and BT.656 mode are similar in operation, as shown in [Figure 12-1195](#). The additional logic used in BT.656 mode is the CCIR-656 decoder, which extracts synchronization information from input YCbCr data and regenerates the corresponding timing for internal operation.

- YCbCr mode is enabled by setting VPFE\_SYNMODE[13-12] INPMOD bitfield to 1h or 2h and clearing VPFE\_REC656IF[0] R656ON bit.
- BT.656 mode is enabled by setting VPFE\_REC656IF[0] R656ON to 1.

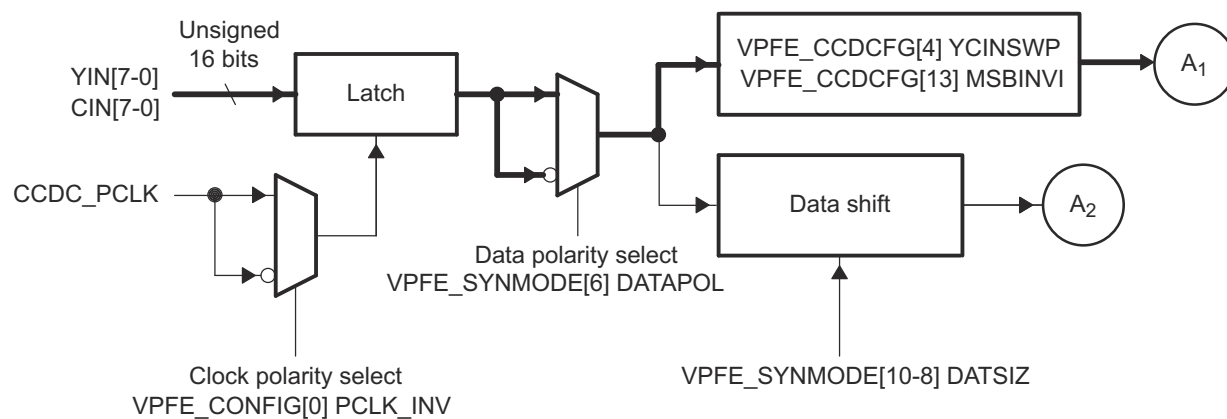

**Figure 12-1195. Data Processing for YCbCr/BT.656 Modes**

##### 12.9.4.7.2.1 Input Sampling and Formatting for YCbCr and BT.656 Modes

The data path of YCbCr/BT.656 modes is shown in the thicker lines in [Figure 12-1196](#) (that is A1). Data path A2 is applicable to raw data mode only.

- The pixel clock (CCDC\_PCLK) latches data.
- Pixel clock polarity can be either rising or falling edge and is set in VPFE clock control register (VPFE\_CONFIG[0] PCLK\_INV bit).
- The VPFE\_SYNMODE[6] DATAPOL bit affects the data representation.
- The VPFE\_CCDCFG[4] YCINSWP bit can be used to swap the upper and lower portions of the 16-bit YCbCr data bus.
  - In 16-bit YCbCr mode, this swap bit determines which part of the bus luma and chroma samples occupy respectively.
  - In 8-bit mode, this swap bit determines which part of the bus is the effective 8-bit input.
- The VPFE\_CCDCFG[13] MSBINVI bit can be used to invert the MSB of the chroma signal.

vpfe\_017

**Figure 12-1196. Input Sampling Block Diagram for YCbCr/BT.656 Modes**

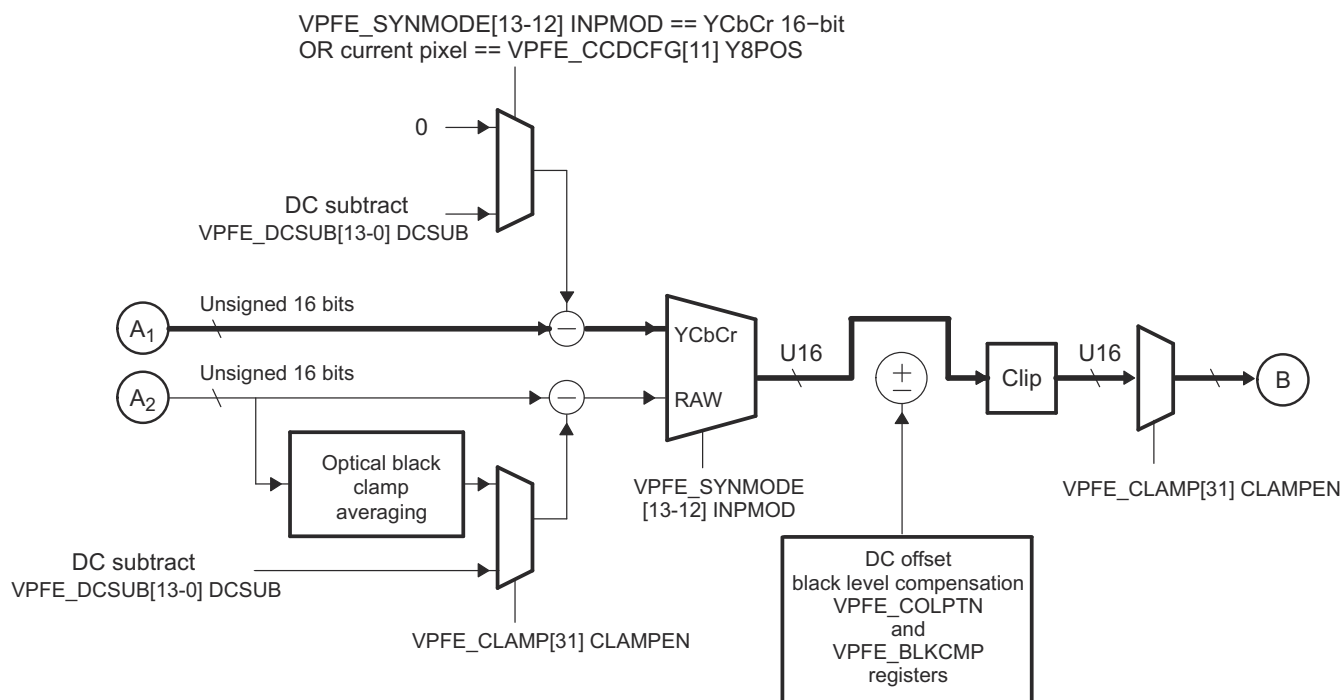

#### 12.9.4.7.2.2 Black Clamping for YCbCr and BT.656 Modes

The second step in BT.656/YCbCr processing is black clamping.

The VPFE\_DCSUB[13-0] DCSUB bitfield is used to subtract a fixed value from the luma sample for YUV data. Set the subtraction value to 0 to disable the operation. For more information, see [Figure 12-1197](#).

#### Note

Black level compensation (VPFE\_BLKCOMP register) is not used in YCbCr and BT.656 modes.

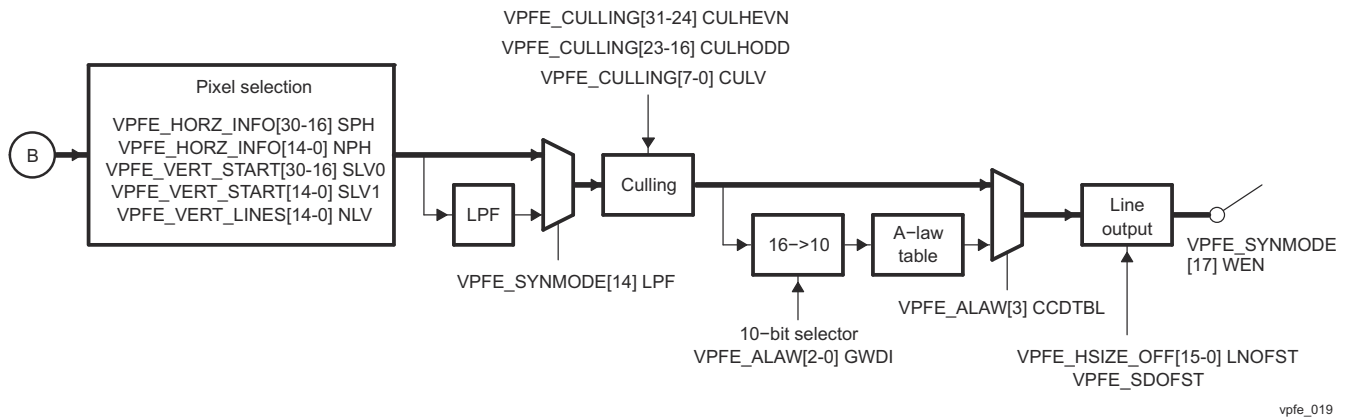

vpfe\_018

**Figure 12-1197. Black Clamping for YCbCr/BT.656 Modes**

#### 12.9.4.7.2.3 Output Formatter for YCbCr and BT.656 Modes

The final stage of VPFE processing is the output formatter, for YCbCr and BT.656 modes it is shown on [Figure 12-1198](#). A framing selection is applied to limit the processing area by the settings in the VPFE\_HORZ\_INFO, VPFE\_VERT\_START and VPFE\_VERT\_LINES registers.

**Figure 12-1198. Output Formatter for YCbCr/BT.656 Modes**

- Set the VPFE\_SYNMODE[14] LFP bit to 0 to disable the Low Pass Filter.
- Culling can be used in YCbCr and BT.656 modes, however user must take care to preserve the 422 output format.
- Set the VPFE\_ALAW[3] CCDTBL bit to 0 as A-Law transformation is not used in YCbCr or BT.656 modes.

#### 12.9.4.7.2.3.1 Output Format in External Memory for YCbCr and BT.656 Modes

The pixel data in external memory is shown in [Table 12-1567](#).

**Table 12-1567. Storage Format in External Memory for YCbCr/BT.656 Modes**

External memory	Upper word		Lower word	
Address	MSB (31)	LSB (16)	MSB (15)	LSB (0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr2	Y2	Cb2
N + 2	Y5	Cr4	Y4	Cb4

## 12.10 Timer Modules

This section describes the timer modules in the device.

### 12.10.1 Global Timebase Counter (GTC)

This section describes the Global Timebase Counter (GTC) in the device.

#### 12.10.1.1 GTC Overview

The GTC module provides a continuous running counter that can be used for time synchronization and debug trace time stamping.

The device includes one GTC instance named GTC0. [Table 12-1568](#) shows GTC module allocation within device domains.

**Table 12-1568. GTC Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
GTC0	–	–	✓

#### 12.10.1.1.1 GTC Features

The GTC supports the following features:

- 64-bit up counter
- No rollover during the lifetime of the device
- Compatible with ARMv8 system counter requirements:
  - Disabled at power-up
  - Register definition and memory map aligned to ARMv8 definition
  - Implements memory-mapped counter control and status frames
- Outputs reflected binary (Gray) encoded timer value for system timer bus distribution to other modules
- Selectable counter bit output as a push event that can be used by CPTS modules, timers or interface protocols

#### 12.10.1.1.2 GTC Not Supported Features

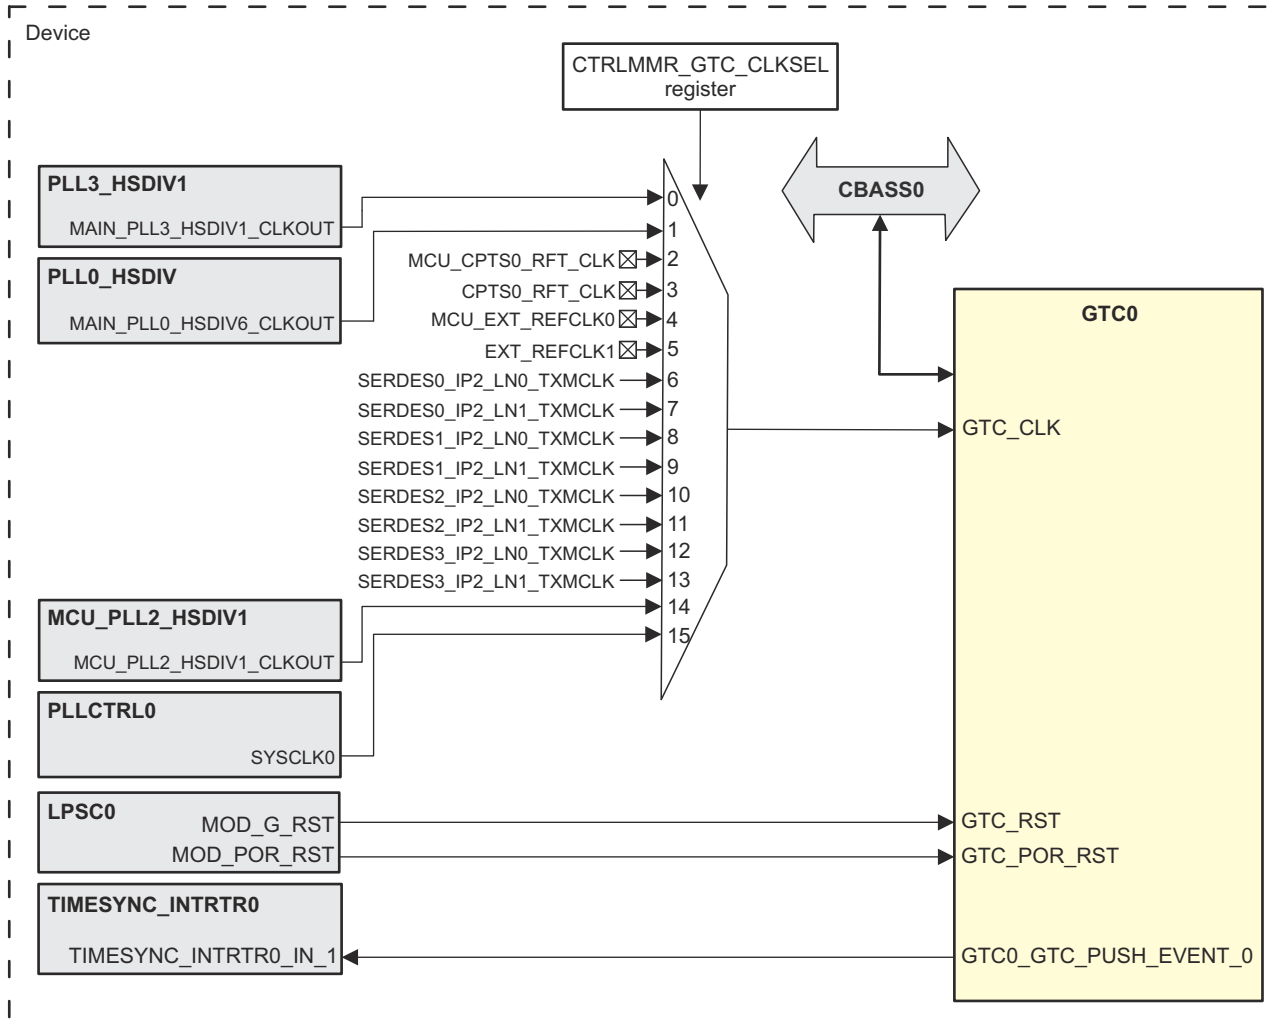

The GTC module does *not* support:

- System counter frequency change for reduced power operation
- ARMv8 memory-mapped timer
- Register write locks (MMR kick protection)

### 12.10.1.2 GTC Integration

This section describes the GTC integration in the device, including information about clocks, resets, and hardware requests.

Figure 12-1199 shows the GTC integration.

**Figure 12-1199. GTC Integration**

Table 12-1569 through Table 12-1571 summarize the GTC integration.

**Table 12-1569. GTC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
GTC0	PSC0	PD0	LPSC0	CBASS0

**Table 12-1570. GTC Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

	GTC_RST	MOD_G_RST	LPSC0	GTC0 MMR reset (affects GTC0 registers)

**Table 12-1571. GTC Hardware Requests**

Time Sync Events					
Module Instance	Module Sync Output	Destination Sync Input	Destination	Description	Type
GTC0	GTC0_GTC_PUSH_EVE NT_0	TIMESYNC_INTRTR0_IN_ 1	TIMESYNC_INTRT R0	GTC hardware push event	Pulse

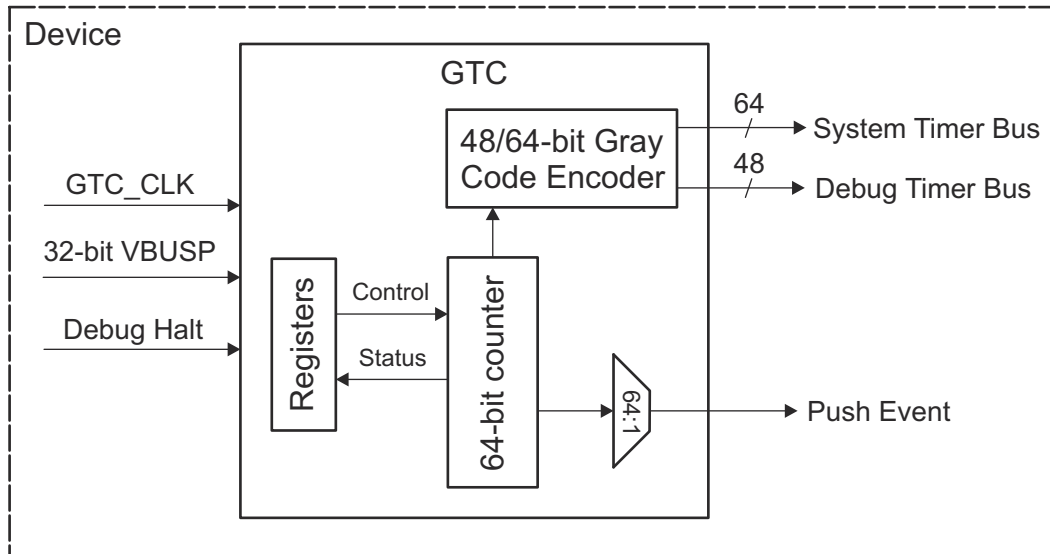

### Note

GTC hardware push event is further described in [Section 12.10.1.3.4, GTC Push Event Generation](#).

### 12.10.1.3 GTC Functional Description

#### 12.10.1.3.1 GTC Block Diagram

The GTC is essentially comprised of a 64-bit up counter, a Gray encoder, a 64-bit multiplexer, and memory-mapped control registers. [Figure 12-1200](#) shows a high-level block diagram of the GTC.

**Figure 12-1200. GTC Block Diagram**

#### 12.10.1.3.2 GTC Counter

The counter is a 64-bit binary up counter that increments on every GTC\_CLK rising edge. The source for GTC\_CLK is selected through a mux which is controlled via the CTRLMMR\_GTC\_CLKSEL[2-0] CLK\_SEL register bit field.

The counter is disabled by default (at power-on-reset) and increments only when enabled by setting the GTC\_CNTCR[0] EN bit to '1'. The current counter value is readable via the combined COUNTVALUE bit field of both GTC\_CNTCV\_HI (upper 32 bits) and GTC\_CNTCV\_LO (lower 32 bits) registers.

When counting is disabled, a new counter value can be loaded via a software write to the combined COUNTVALUE bit field. In this case, when the counter gets re-enabled, it will start counting from the last value written to this field.

The counter can be optionally configured to stop incrementing when a debug halt signal is issued, by writing a '1' to the GTC\_CNTCR[1] HDBG bit. This condition is indicated through the GTC\_CNTSR[1] DBGH status bit.

#### 12.10.1.3.3 GTC Gray Encoder

The Gray encoder performs a realtime conversion of the binary counter value into a 64-bit Gray code. This value is exported as the system timer bus for distributing the counter value to:

- A72SS global timestamp inputs
- GPU timestamp input

A second realtime conversion of the 48 LSBs of the binary counter value into a 48-bit Gray code value is also performed and exported to:

- A72SS debug timestamp inputs
- DMPAC timestamp input
- VPAC timestamp input

#### 12.10.1.3.4 GTC Push Event Generation

The GTC can generate periodic push events for global time synchronization at up to half the GTC\_CLK frequency. The frequency of the events is determined by selecting one of the counter bits through the internal [64:1] mux, which is controlled through the GTC\_PUSHEVT[5-0] EXPBIT\_SEL bit field.

#### 12.10.1.3.5 GTC Register Partitioning

The ARMv8 architecture spec requires specific system-level components, each with one or two register frames. To accommodate this, the GTC memory-mapped registers (MMRs) are divided into four separate regions (4KB each):

- Peripheral MMRs (GTC0\_GTC\_CFG0): This region includes standard peripheral identification registers and any other control registers not associated with the ARMv8 system timer functions.
- Counter Control MMRs (GTC0\_GTC\_CFG1): This region includes registers that provide control over the operation of the system timer.
- Counter Status MMRs (GTC0\_GTC\_CFG2): This region includes registers that provide a mechanism for reading the status of the system timer.
- Timer Control MMRs (GTC0\_GTC\_CFG3): This region includes registers that identify and provide a control mechanism for memory-mapped timer implementations. For this device, no memory-mapped timers are implemented and only the minimum registers required to indicate the presence of no timers are necessary.

### 12.10.2 Windowed Watchdog Timer (WWDT)

This section describes the Windowed Watchdog Timer (WWDT), implemented by using the Digital Windowed Watchdog (DWWD) function of the Real Time Interrupt (RTI) module in the device.

#### CAUTION

The RTI module shall be used to serve only as a Digital Windowed Watchdog (DWWD).

The Real Time Interrupt module provides timer functionality for operating systems and for benchmarking code. The module incorporates several counters, which define the timebases needed for scheduling in the operating system.

This module is specifically designed to fulfill the requirements for OSEK (“Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug”; “Open Systems and the Corresponding Interfaces for Automotive Electronics”) as well as OSEK/Time compliant operating systems.

The timers also provide the ability to benchmark certain areas of code by reading the counter contents at the beginning and the end of the desired code range and calculating the difference between the values.

#### 12.10.2.1 RTI Overview

There are twelve RTI modules in the device. [Table 12-1572](#) shows the RTI allocation within device domains.

**Table 12-1572. RTI Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MCU_RTI0	-	✓	-
MCU_RTI1	-	✓	-
RTI0	-	-	✓
RTI1	-	-	✓
RTI15	-	-	✓
RTI16	-	-	✓
RTI24	-	-	✓
RTI25	-	-	✓
RTI28	-	-	✓
RTI29	-	-	✓
RTI30	-	-	✓
RTI31	-	-	✓

Instances in the MCU domain:

- MCU\_RTI0 is dedicated to the MCU cluster (MCU\_R5FSS0) in lockstep and when unlocked serves as a Windowed Watchdog for the first R5F CPU core in the MCU domain (MCU\_R5FSS0\_CORE0).
- MCU\_RTI1 is dedicated to the second R5F CPU core of the MCU cluster (MCU\_R5FSS0\_CORE1) when unlocked.

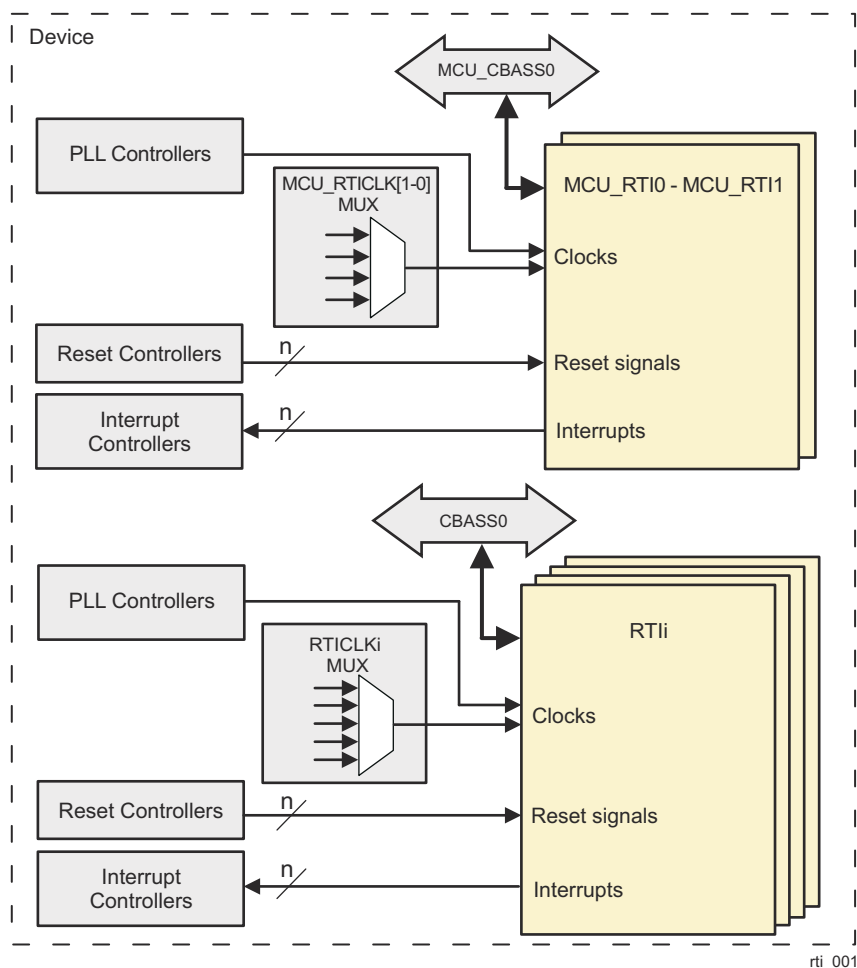

Instances in the MAIN domain: They are intended to function as a Digital Windowed Watchdog for the CPU core that they are associated with, that is:

- RTI0 is dedicated to the first A72 CPU core in the A72 cluster (A72SS0\_CORE0)
- RTI1 is dedicated to the second A72 CPU core in the A72 cluster (A72SS0\_CORE1)
- RTI15 is dedicated to the GPU
- RTI16 is dedicated to the C7x DSP
- RTI24 is dedicated to the first C66x DSP core (C66SS0\_CORE0)
- RTI25 is dedicated to the second C66x DSP core (C66SS1\_CORE0)

- RTI28 is dedicated to the first R5F CPU core in the Main domain (R5FSS0\_CORE0)
- RTI29 is dedicated to the second R5F CPU core in the Main domain (R5FSS0\_CORE1)
- RTI30 is dedicated to the third R5F CPU core in the Main domain (R5FSS1\_CORE0)
- RTI31 is dedicated to the fourth R5F CPU core in the Main domain (R5FSS1\_CORE1)

It is not intended to use an RTI that is provisioned for a particular CPU core with a different CPU core.

Figure 12-1201 shows the RTI overview.

i = 0, 1, 15, 16, 24, 25, 28, 29, 30, 31

**Figure 12-1201. RTI Overview**

#### 12.10.2.1.1 RTI Features

The RTI modules include the following main features:

- Windowed Watchdog Timer (WWDT) feature.
- Two independent 64 bit counter blocks (counter block0 or counter block1). Each block consists of
  - One 32 bit up counter
  - One 32 bit free running counter
  - Two capture registers for capturing the prescale and free running counter on a special event.
- Free running counter 0 can be incremented by either the internal prescale counter or by an external event.
- Four configurable compare registers for generating operating system ticks. Each event can be driven by either counter block0 or counter block1.
- Fast enabling/disabling of events.

- RTI clock input derived from any of the available clock sources, selectable in the System Module
- Optional capability to drive a pulse-width modulated signal out on an interrupt line.

#### **12.10.2.1.2 RTI Not Supported Features**

The following features are not supported on this family of devices:

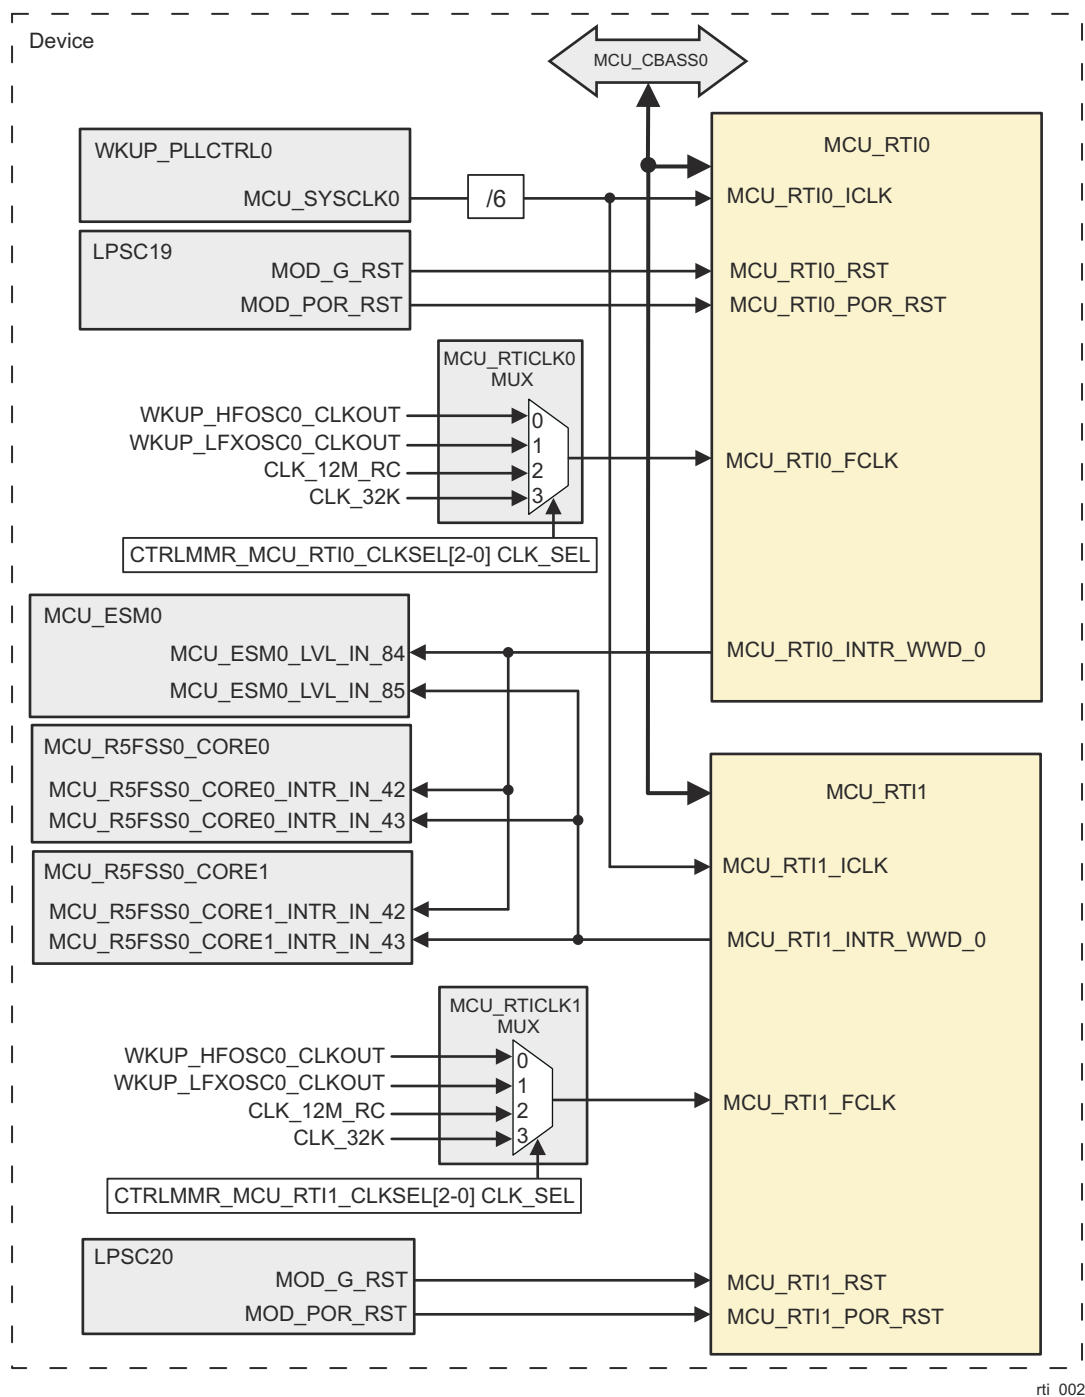

- Real time interrupt functionality
- Analog and Digital Watchdog (DWD) Timers
- Periodic interrupt / DMA events
- Capture and compare events not used
- Counter operation is not supported and counter overflow interrupts are not used.

### 12.10.2.2 RTI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.10.2.2.1 RTI Integration in MCU Domain

There are two RTI modules integrated in the device MCU domain - MCU\_RTIO and MCU\_RT11. [Figure 12-1202](#) shows their integration in the device.

**Figure 12-1202. MCU RTI Integration**

[Table 12-1573](#) through [Table 12-1575](#) summarize the integration of MCU\_RTIO and MCU\_RT11 in device MCU domain.

Each MCU\_RT1 instance is supplied by dedicated MCU\_RTICLK[1-0] clock mux.

**Table 12-1573. MCU\_RTI Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_RTI0	WKUP_PSC0	PD1	LPSC19	MCU_CBASS0

#### 12.10.2.2.2 RTI Integration in MAIN Domain

There are ten RTI modules integrated in the device MAIN domain. [Figure 12-1203](#) shows their integration in the device.

Device

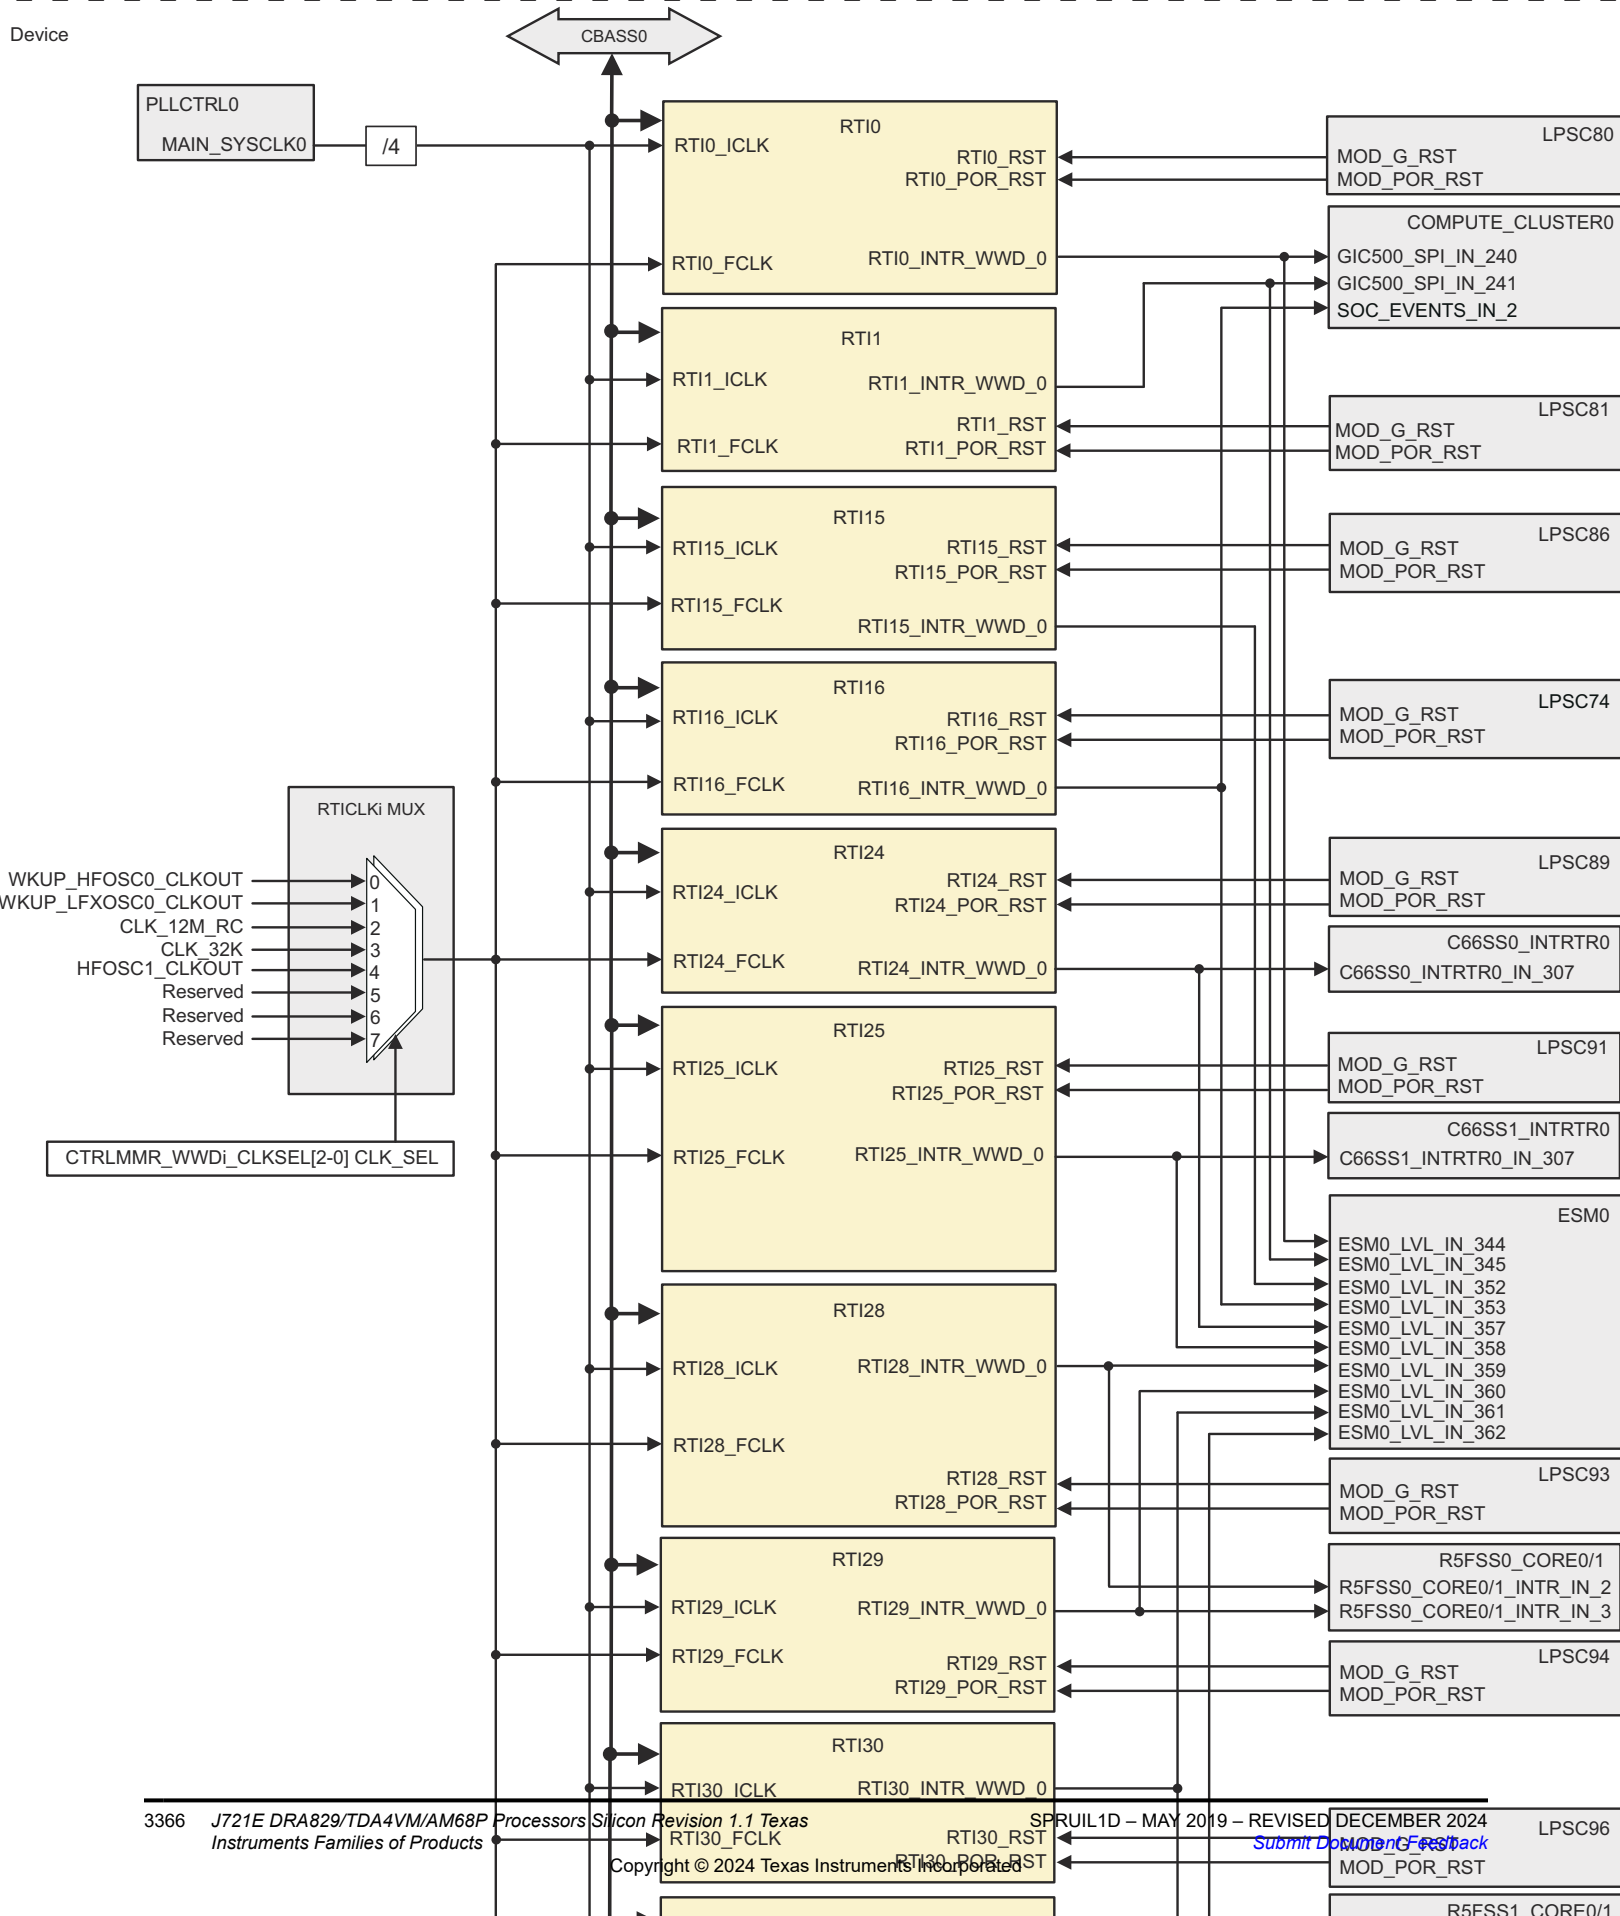

Table 12-1576 through Table 12-1578 summarize the integration of RTIi (where i = 0, 1, 15, 16, 24, 25, 28, 29, 30, 31) in device MAIN domain.

Each RTI instance is supplied by dedicated RTICLK<sub>i</sub> mux.

**Table 12-1576. RTI Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
RTI0	PSC0	PD15	LPSC80	CBASS0
RTI1	PSC0	PD16	LPSC81	CBASS0
RTI15	PSC0	PD20	LPSC86	CBASS0
RTI16	PSC0	PD12	LPSC74	CBASS0
RTI24	PSC0	PD22	LPSC89	CBASS0
RTI25	PSC0	PD23	LPSC91	CBASS0
RTI28	PSC0	PD24	LPSC93	CBASS0
RTI29	PSC0	PD24	LPSC94	CBASS0
RTI30	PSC0	PD25	LPSC96	CBASS0
RTI31	PSC0	PD25	LPSC97	CBASS0

### 12.10.2.3 RTI Functional Description

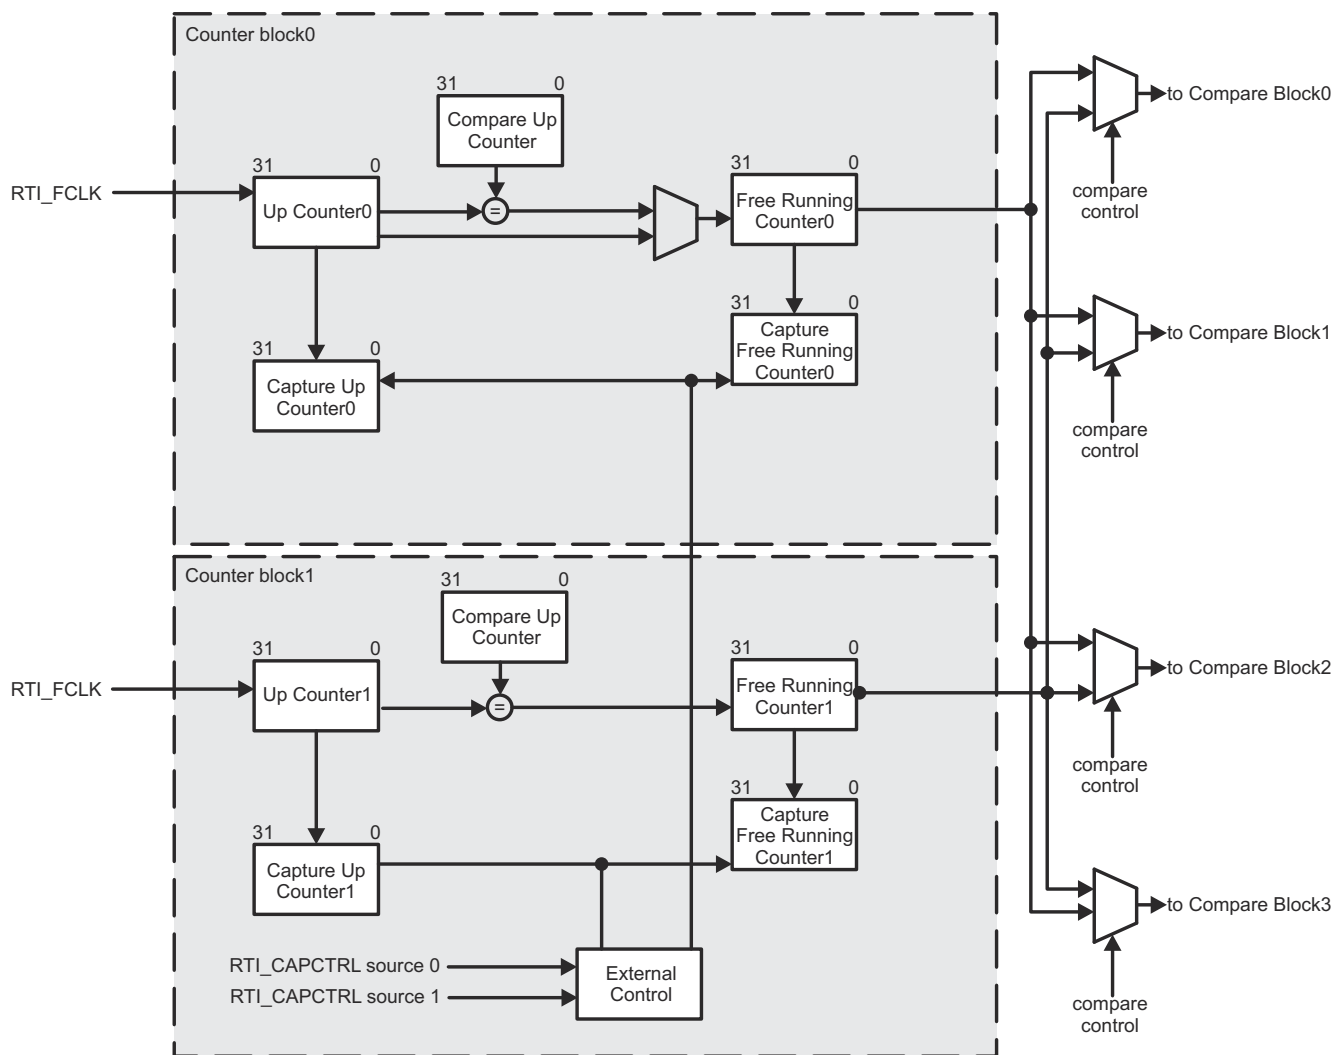

The MCU\_RTI[1-0] and RTIi (where i = 0, 1, 15, 16, 24, 25, 28, 29, 30, 31) modules are hereinafter referred to as RTI module.

#### 12.10.2.3.1 RTI Counter Operation

##### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Figure 12-1204 shows the RTI module counter blocks. The RTI module supports two counter blocks.

rti-004

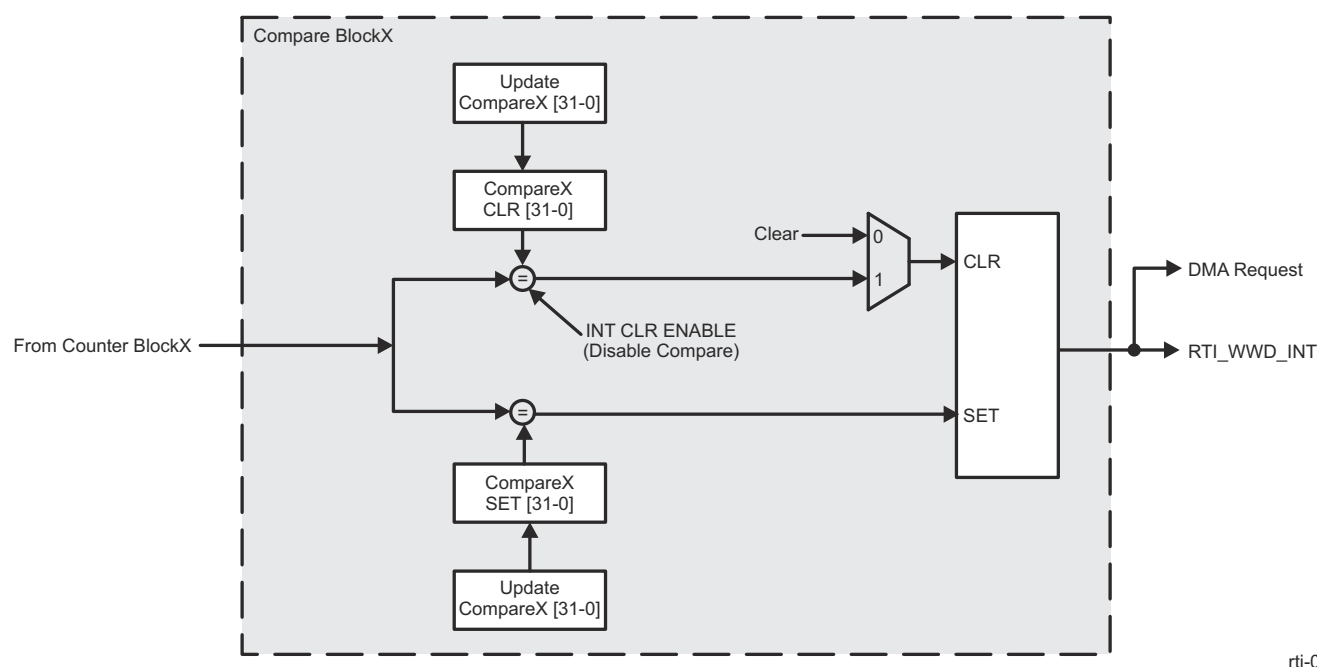

**Figure 12-1204. RTI Counters Block Diagram**

Each block consists of two 32-bit up counters: Up Counter (UC), and Free Running Counter (FRC). The Up Counter (RTI\_UC0 or RTI\_UC1 register) is driven by the RTI\_FCLK, and counts up until the compare value in the Compare Up Counter register (RTI\_CPUC0 or RTI\_CPUC1) is reached. When the compare matches, the second counter (RTI\_FRC0 or RTI\_FRC1 register), which is a free running counter, is incremented. At the same time UCx is reset to zero.

To ensure the consistency of the counters, when both counter values have to be determined, read the Free Running Counter first. This makes sure that at the time when the counter register is read, the Up Counter value has been stored into the counter register. The second read is then performed on the Up Counter register, which holds then the value of the counter cycle of the previous read on the Free Running Counter register.

Both blocks provide also a capture feature on external events. Two capture sources can trigger the capture event. Which event triggers block 0 or block 1 is configurable from the RTI\_CAPCTRL register. The event sources come from the interrupt manager, enabling the device to generate a capture event when a peripheral module generates an interrupt. The peripheral which generates an RTI capture event is configured in the interrupt manager. When the event is detected, UCx and FRCx are stored in Capture Up Counter (RTI\_CAUC0 or RTI\_CAUC1) and Capture Free Running Counter (RTI\_CAFRC0 or RTI\_CAFRC1) registers. The read order of the captured values must be in the same order as the counter register reads. So, the CAFRCx must be read first, and then the CAUCx registers are read after the CAFRCx value has been determined. While CAFRCx is read, the CAUCx value is loaded into a shadow register to maintain data consistency, in case a capture event happens during the two reads. If the application fails to read the two registers before a second capture event happens, the previous data is overwritten.

Figure 12-1205 shows the block diagram for one compare block. The RTI module supports four compare blocks.

rti-005

**Figure 12-1205. RTI Compare Block Diagram**

In order to generate interrupt requests to the interrupt manager, there are four compare registers (RTI\_COMP0, RTI\_COMP1, RTI\_COMP2, and RTI\_COMP3). Each of the compare registers can be configured to work either on FRC0 (Counter block0) or FRC1 (Counter block1). When the counter value matches the compare value, an interrupt is generated. This sets an interrupt request line to the interrupt manager. The compare value gets updated automatically with the value stored in Update Compare (RTI\_UDCP0, RTI\_UDCP1, RTI\_UDCP2, and RTI\_UDCP3) registers when the compare matches. This gives the ability to generate periodic interrupts/DMA requests without having to update the compare value by software.

An optional feature allows an application to program another compare value which is then used to clear the interrupt request line. This feature is supported by four compare clear registers (RTI\_COMP0CLR, RTI\_COMP1CLR, RTI\_COMP2CLR, and RTI\_COMP3CLR). When the counter value matches the compare clear value, the interrupt line is cleared. This clears the interrupt request line to the interrupt manager. The

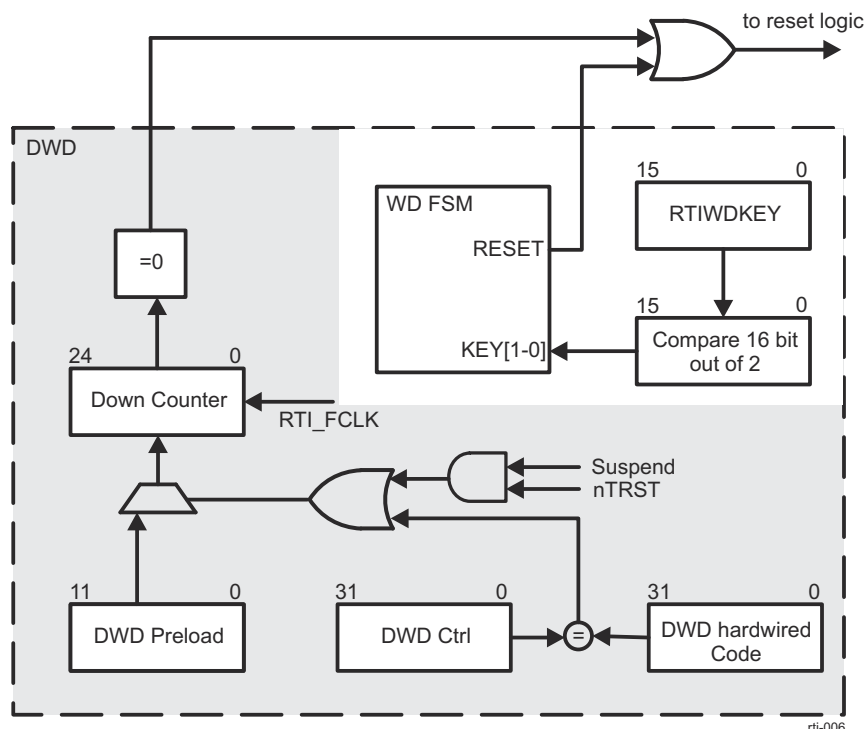

compare clear value gets updated automatically with the value stored in Update Compare (RTI\_UDCPx) registers when the compare matches.

### 12.10.2.3.2 RTI Digital Watchdog

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

Some applications might use a digital watchdog (DWD) integrated in the RTI module. The digital watchdog generates resets after a programmable period, if no correct key sequence is written to the RTI\_WDKEY register. Figure 12-1206 shows the digital watchdog functional block.

**Figure 12-1206. RTI Digital Watchdog Functional Block Diagram**

The digital watchdog functionality is implemented such that it can be enabled by software.

The DWD starts counting down from the reset value of the RTI\_DWDCNTR (DWD Counter Register). The DWD preload register can be configured at any time by the application according to the desired time-out period.

When enabled by software, the digital watchdog is disabled after system reset. If it should be used, it has to be enabled by writing A98559DAh to the RTI\_DWDCTRL register. The DWD timeout period must be configured using the DWD preload register before the DWD is enabled. The DWD cannot be disabled by the application once it is enabled.

#### Note

When the DWD is enabled by software, any system reset will disable the DWD. This reset could have been generated by the watchdog itself.

If the correct key sequence is written to the RTI\_WDKEY register (E51Ah followed by A35Ch), the 25-bit DWD Down Counter is reloaded with the 12-bit preload value stored in RTI\_DWDPRLD register. If any incorrect value

is written to the RTI\_WDKEY register, a watchdog reset will occur immediately. A reset will also be generated, when the DWD Down Counter is decremented to 0.

The user has to take into account that the write to the RTI\_WDKEY register takes 3 RTI\_ICLK cycles. This needs to be considered for the DWD expiration calculation.

The DWD Down Counter will be decremented with RTI\_FCLK frequency. If the RTI\_FCLK is switched off via the disable registers of the Clock management, the DWD counter stops decrementing. The DWD module cannot generate a reset under this condition.

**Figure 12-1207. RTI Digital Watchdog Operation**

The expiration time of the DWD Down Counter can be determined with following equation:

$$t_{exp} = (RTI\_DWDPRLD + 1) \times 2^{13} / RTI\_FCLK \quad (28)$$

where RTI\_DWDPRLD = 0...4095

### 12.10.2.3.3 RTI Digital Windowed Watchdog

#### Note

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

#### Note

Digital windowed watchdog (DWWD) timer is implemented using the digital windowed watchdog function of the RTI modules. Real time interrupt functionality is not supported. In this mode, the timer should default to disabled and user can adjust the period as desired before enabling the watchdog.

In addition to the time-out boundary configurable via the digital watchdog (DWD), some applications may also want to configure the start-time boundary of the watchdog. This is enabled by the digital windowed watchdog (DWWD) feature.

### Functional Behavior

The DWWD opens a configurable time window in which the watchdog must be serviced. Any attempt to service the watchdog outside this time window, or a failure to service the watchdog in this time window, will cause the watchdog to generate either a reset or a non-maskable interrupt to the CPU. This is controlled by configuring the RTI\_WWDRXNCTRL register. As stated earlier, when the watchdog needs to be enabled by software, the watchdog counter is disabled on a system reset. When the DWWD is configured to generate a non-maskable interrupt on a window violation, the watchdog counter continues to count down. The RTI\_INTR\_WWD interrupt handler needs to clear the watchdog violation status flag(s) and then service the watchdog by writing the correct sequence in the watchdog key RTI\_WDKEY register. This service will cause the watchdog counter to get reloaded from the preload value and start counting down. If the RTI\_INTR\_WWD handler does not service the watchdog in time, it could count down all the way to zero and wrap around. No second exception for a time out is generated in this case.

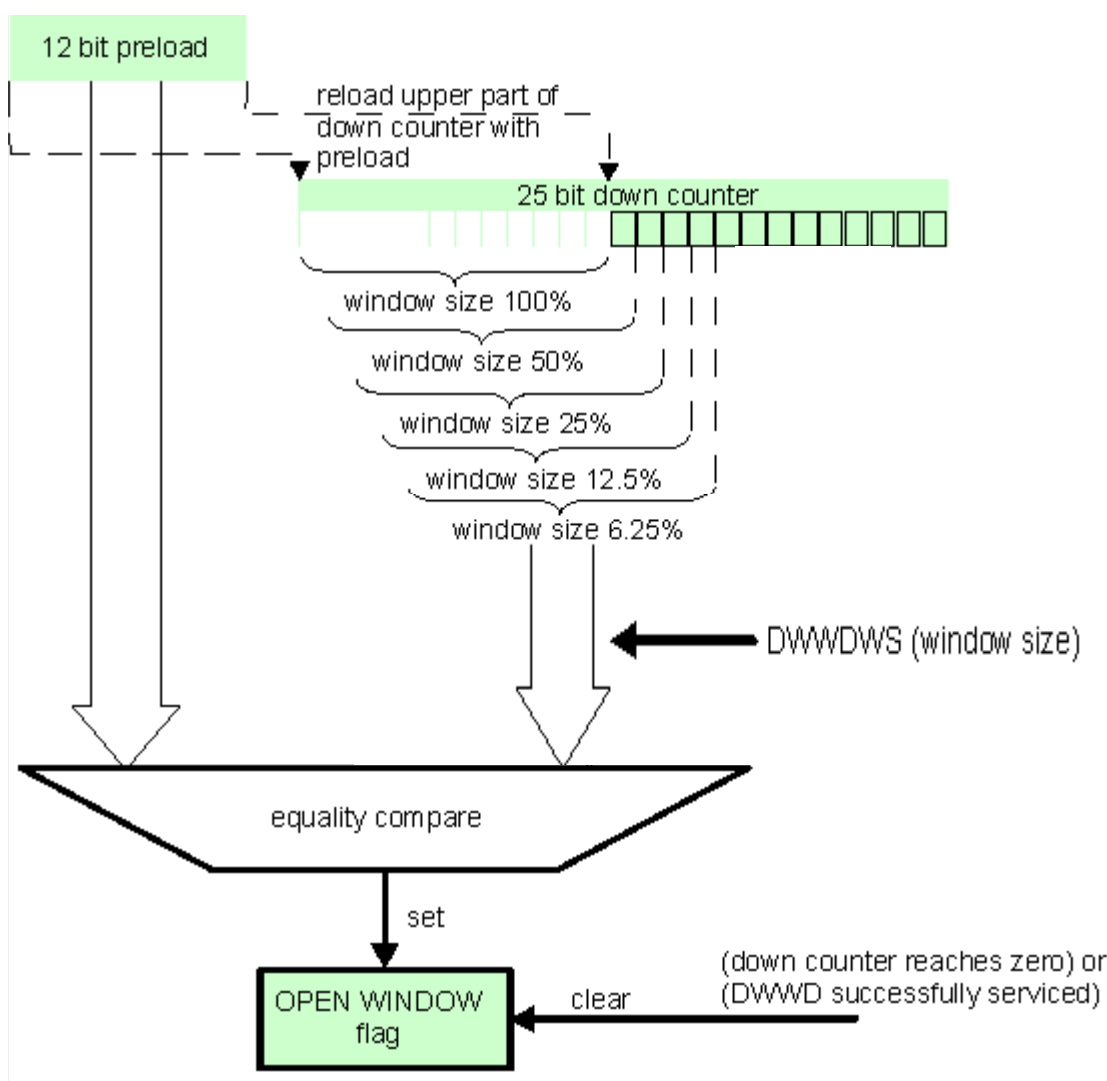

### Configuration of DWWD

The DWWD preload value (same as DWD preload) can only be configured when the DWWD counter is disabled. The window size and watchdog reaction to a violation can be configured even after the watchdog has been enabled. Any changes to the window size and watchdog reaction configurations will only take effect after the next servicing of the DWWD.

**Figure 12-1208. RTI Digital Windowed Watchdog Timing Example**

**Figure 12-1209. RTI Digital Windowed Watchdog Operation Block Diagram**

#### 12.10.2.3.4 RTI Low Power Mode Operation

The operation of the RTI module is guaranteed in run, doze and snooze mode. In sleep or hibernate mode all clocks will be switched off and the RTI module will not work.

In doze and snooze modes all parts of the RTI are active, since it has to be able to wake up the device with compare and timebases interrupts. Capturing events generated by the interrupt module is also possible since in both modes the peripheral modules are able to generate interrupts, which can trigger capture events. The RTI module will generate compare and timebases interrupts. The compare interrupts will periodically wake up the device.

#### Note

In the special case of doze mode with DPLL off, RTI\_FCLK might have a different period than with DPLL enabled, since RTI\_FCLK will be derived from the oscillator output. It has to be ensured that the RTI\_ICLK to RTI\_FCLK ratio is at least 3:1.

The DWD/DWWD remains active when the device enters low power mode as long as the RTI\_FCLK is kept active.

Whenever the LPSC that controls an RTI is in any state other than Enable (see *Module States*), the RTI cannot count or generate interrupts. For more information, see *Power Control Modules*.

During standard SoC warm reset the RTI and the rest of the SoC are reset. In this case, the RTI counters are stopped and interrupts are not issued. During reset-isolated warm reset, if an R5FSS is put in reset-isolation, then the associated RTI also becomes reset isolated. As such, the R5FSS and the RTI are not reset, but RTI stops counting and cannot generate interrupts until R5FSS is taken out of CLKSTOP (brought to Enable state).

#### **12.10.2.3.5 RTI Debug Mode Behavior**

---

##### **Note**

Some of the RTI features described in this section may not be supported on this family of devices. For more information, see *RTI Not Supported Features*.

---

Once the system enters debug mode, the behavior of the RTI depends on the RTI\_GCTRL[15] COS bit. If the bit is cleared and debug mode is active, all counters will stop operation. If the bit is set to one, all counters will be clocked normally and the RTI will work like in normal mode.

The DWD counter will not decrement in debug mode and will hold its current value, regardless of the RTI\_GCTRL[15] COS bit.

---

##### **Note**

The user must not service the watchdog while in debug mode.

---

## 12.10.3 Timers

This section describes the Timer modules for the device.

### 12.10.3.1 Timers Overview

There are thirty timer modules in the device. [Table 12-1579](#) shows the timers allocation across device domains.

**Table 12-1579. Timers Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN

TIMER19	-	-	✓

All timers include specific functions to generate accurate tick interrupts to the operating system.

Each timer can be clocked from several different independent clocks. The selection of clock source is made from registers in the MCU\_CTRL\_MMR0/CTRL\_MMR0.

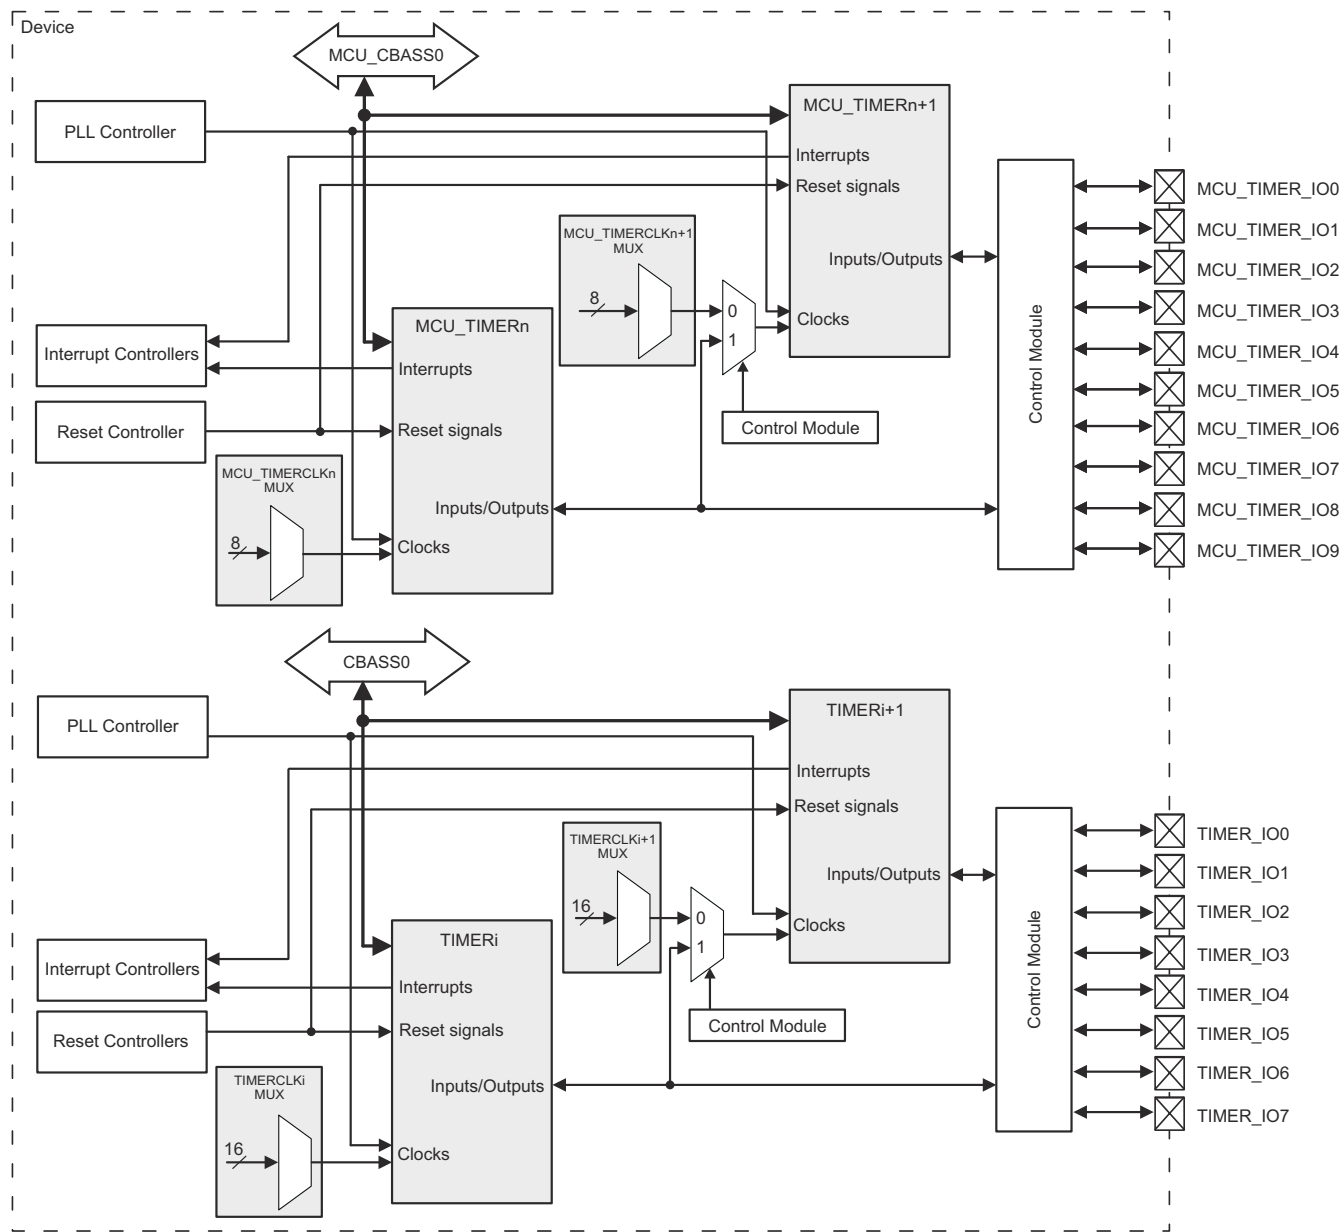

In the MCU domain the device provides 10 timer pins to be used as MCU Timer Capture inputs or as MCU Timer PWM outputs. In order to provide maximum flexibility, these 10 pins may be used with any of MCU\_TIMER0 through MCU\_TIMER9 instances. System level muxes are used to control the capture source pin for each MCU\_TIMER[9-0] and the MCU\_TIMER[9-0] source for each MCU\_TIMER\_IO[9-0] PWM output.

In the MAIN domain the device provides 8 timer pins to be used as Timer Capture inputs or as Timer PWM outputs. For maximum flexibility, these 8 pins may be used with any of TIMER0 through TIMER19 instances. System level muxes are used to control the capture source pin for each TIMER[19-0] and the TIMER[19-0] source for each TIMER\_IO[7-0] PWM output.

Each odd numbered timer instance from each of the domains may be optionally cascaded with the previous even numbered timer instance from the same domain to form up to a 64-bit timer. For example, TIMER1 may be cascaded to TIMER0, MCU\_TIMER1 may be cascaded to MCU\_TIMER0, etc.

When cascaded,  $TIMER_i$  acts as a 32-bit prescaler to  $TIMER_{i+1}$ , as well as  $MCU\_TIMER_n$  acts as a 32-bit prescaler to  $MCU\_TIMER_{n+1}$ .  $TIMER_i$  /  $MCU\_TIMER_n$  must be configured to generate a PWM output edge at the desired rate to increment the  $TIMER_{i+1}$  /  $MCU\_TIMER_{n+1}$  counter.

Figure 12-1210 is an overview of the timers.

$i = 0, 2, 4, 6, 8, 10, 12, 14, 16, 18$

timers\_001

n = 0, 2, 4, 6, 8

## Figure 12-1210. Timers Overview

### 12.10.3.1.1 Timers Features

The following are the main features of the timer controllers:

- Slave interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 10-bit address bus width
  - Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source ( $2^n$ , where  $n = [0-8]$ )
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- Generates a 1-ms tick clock when functional clock is 32.768 kHz

### 12.10.3.1.2 Timers Not Supported Features

The following features are not supported on this family of devices:

- Atomic 64-bit timer value read of cascaded timers is not supported.
- Smart-idle with wake-up mode is not supported.

### 12.10.3.2 Timers Environment

The MCU\_TIMER[9-0] and TIMER[19-0] modules are hereinafter referred to as timer module.

This section describes the timers external connections (environment).

#### 12.10.3.2.1 Timer External System Interface

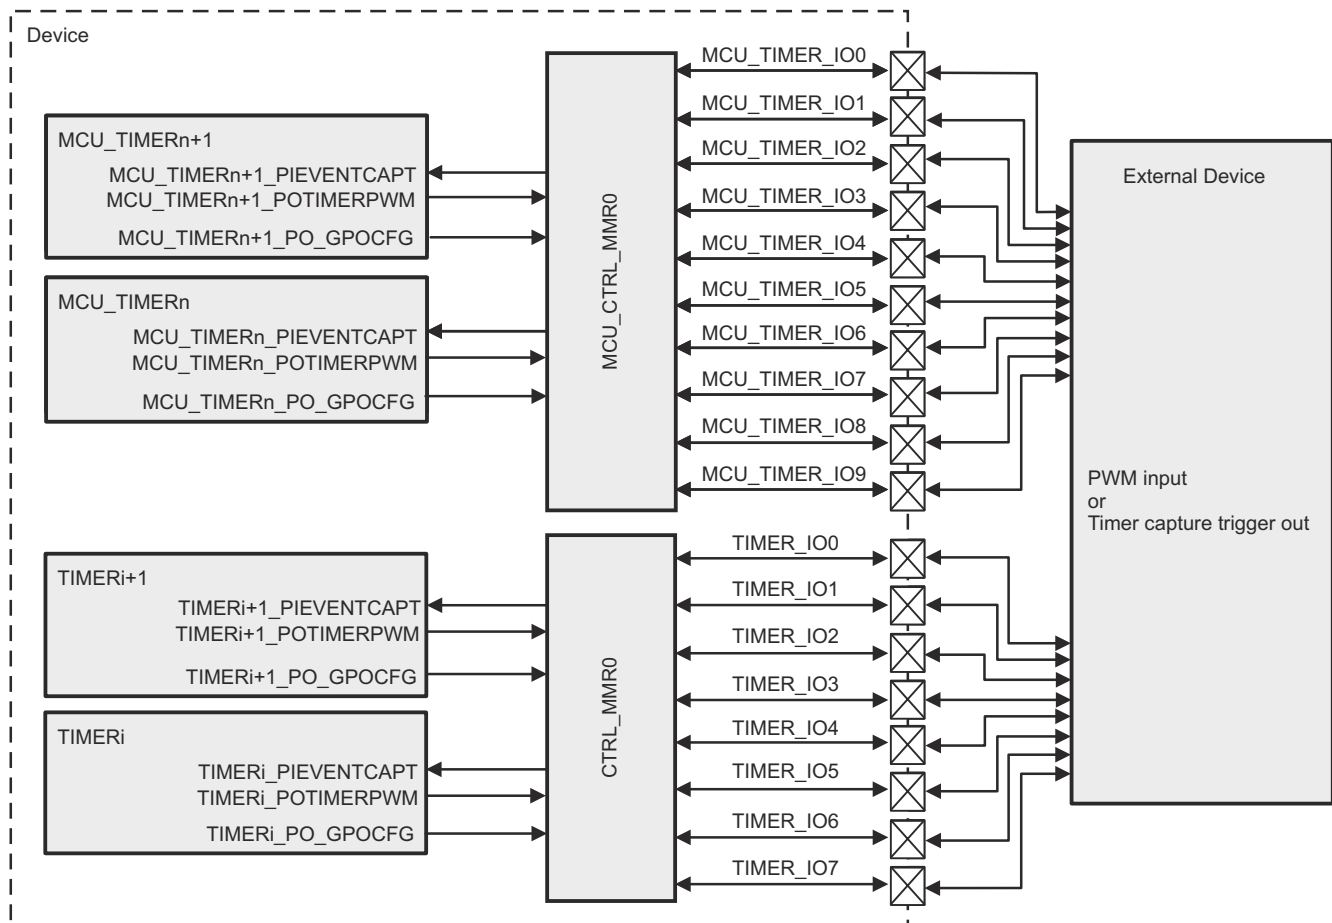

Each timer can send or receive stimulus to/from the external (off-chip) system. In the device all timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count.

Figure 12-1211 shows the external system interface for the timers, and Table 12-1580 describes the timer inputs and outputs.

#### Note

Software control (MCU\_CTRL\_MMR0 and CTRL\_MMR0) must ensure that MUX mode is configured to select the MCU\_TIMER[9-0] signals on ten different pads and to select the TIMER0 through TIMER19 signals on eight different pads. For more information about registers in MCU\_CTRL\_MMR0 and CTRL\_MMR0, see *Timer IO Muxing Control Registers* and *Timer IO Muxing Control Registers in Control Module (CTRL\_MMR)*.

For more information about the configuration of the MCU\_TIMER\_IO[9-0] and TIMER\_IO[7-0] pads, see *Pad Configuration Registers*.

(1) When configured for that function; I = Input, O = Output

---

**Note**

Each MCU\_TIMER\_PO\_GPOCFG and TIMER\_PO\_GPOCFG signals are used as an output enable to control the function of the MCU\_TIMER\_IO[9-0], and respectively TIMER\_IO[7-0], as the PWM output (PO\_GPOCFG = 0) or capture input (PO\_GPOCFG = 1).

---

---

**Note**

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

---

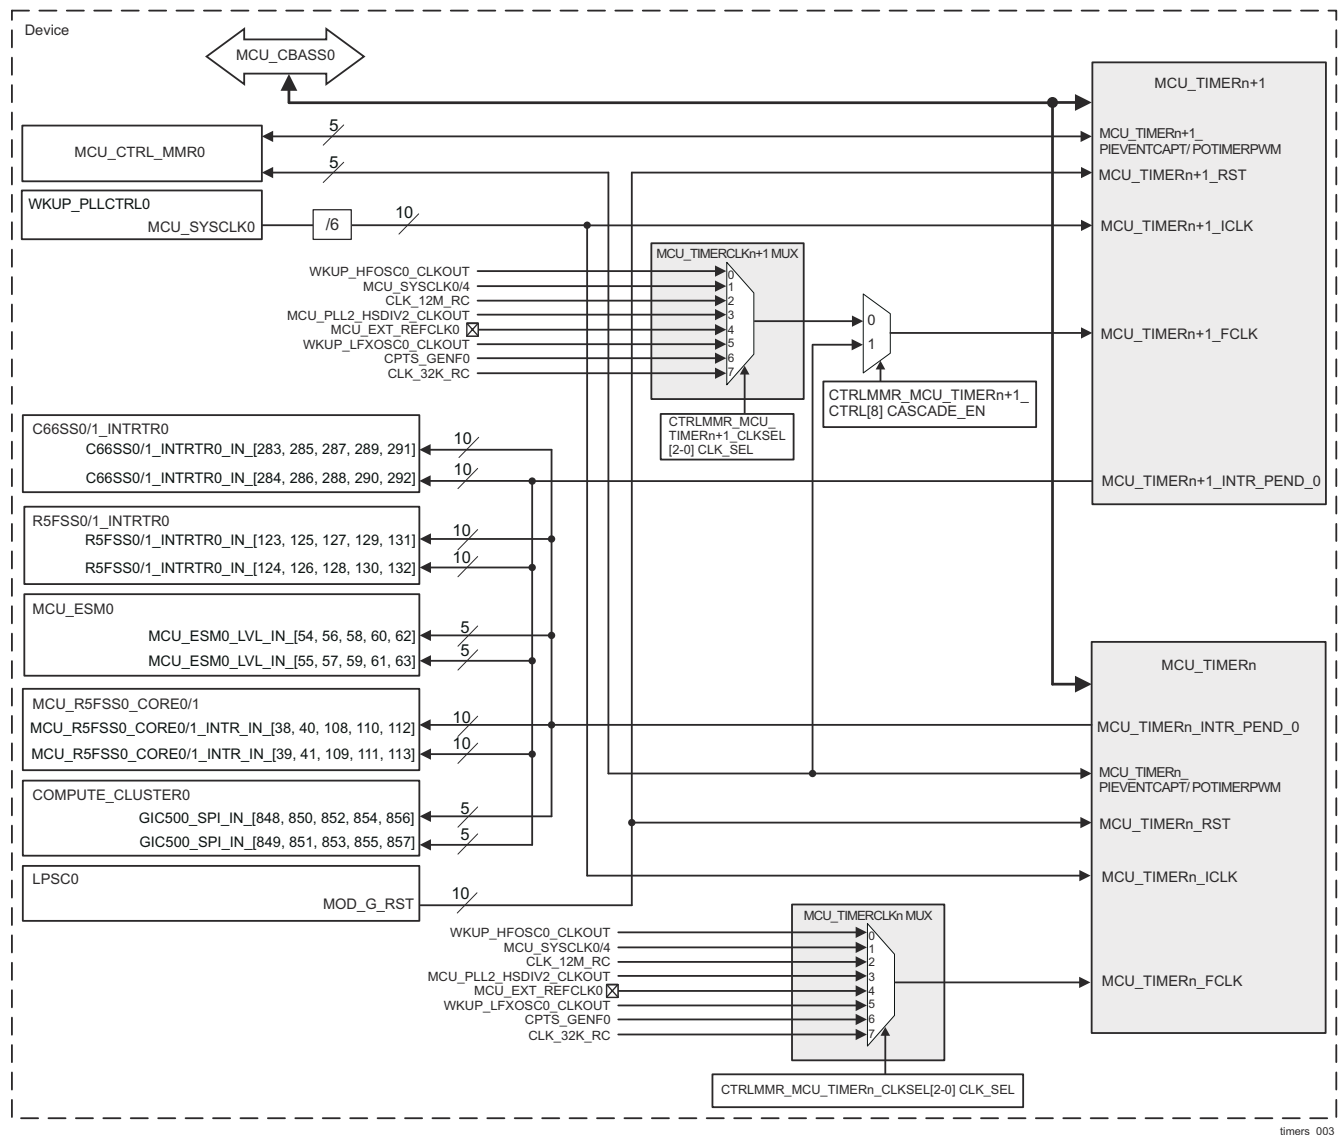

### 12.10.3.3 Timers Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.10.3.3.1 Timers Integration in MCU Domain

There are ten timer modules integrated in the device MCU domain - MCU\_TIMER0 through MCU\_TIMER9. Figure 12-1212 shows their integration in the device.

Each timer instance is supplied by dedicated TIMERCLKn clock mux. For MCU\_TIMERn+1 the TIMERCLKn output is further muxed with the TIMERn\_POTIMERPWM output.

n = 0, 2, 4, 6, 8

**Figure 12-1212. MCU\_TIMER Integration**

Table 12-1581 through Table 12-1583 summarize the integration of MCU\_TIMER0 through MCU\_TIMER9 in device MCU domain.

**Table 12-1581. MCU\_TIMER Integration Attributes**

#### 12.10.3.3.2 Timers Integration in MAIN Domain

There are twenty timer modules integrated in the device MAIN domain - TIMER0 through TIMER19. [Figure 12-1213](#) shows their integration in the device.

Each timer instance is supplied by dedicated TIMERCLKi clock mux. For TIMERi+1 the TIMERCLKi output is further muxed with the TIMERi\_POTIMERPWM output.

**Figure 12-1213. TIMER Integration**

Table 12-1584 through Table 12-1586 summarize the integration of TIMER0 through TIMER19 in device MAIN

domain.

**Table 12-1584. TIMER Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
TIMER0	PSC0	PD11	LPSC70	CBASS0
TIMER1	PSC0	PD11	LPSC71	CBASS0
TIMER2	PSC0	PD11	LPSC72	CBASS0
TIMER3	PSC0	PD11	LPSC73	CBASS0
TIMER4	PSC0	PD0	LPSC0	CBASS0
TIMER5	PSC0	PD0	LPSC0	CBASS0
TIMER6	PSC0	PD0	LPSC0	CBASS0
TIMER7	PSC0	PD0	LPSC0	CBASS0
TIMER8	PSC0	PD0	LPSC0	CBASS0
TIMER9	PSC0	PD0	LPSC0	CBASS0
TIMER10	PSC0	PD0	LPSC0	CBASS0
TIMER11	PSC0	PD0	LPSC0	CBASS0
TIMER12	PSC0	PD0	LPSC0	CBASS0
TIMER13	PSC0	PD0	LPSC0	CBASS0
TIMER14	PSC0	PD0	LPSC0	CBASS0
TIMER15	PSC0	PD0	LPSC0	CBASS0
TIMER16	PSC0	PD0	LPSC0	CBASS0
TIMER17	PSC0	PD0	LPSC0	CBASS0
TIMER18	PSC0	PD0	LPSC0	CBASS0
TIMER19	PSC0	PD0	LPSC0	CBASS0

#### 12.10.3.4 Timers Functional Description

Each timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the `TIMER_IRQSTATUS_SET` and `TIMER_IRQSTATUS_CLR` register for the interrupt features, and a dedicated bit of the `TIMER_IRQWAKEEN` register for a wake-up. In addition, timers have a mechanism implemented to generate an accurate tick interrupt.

For each timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

For more information of the selection of the input clock source, see *Clocking*.

Each timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

##### 12.10.3.4.1 Timer Block Diagram

[Figure 12-1214](#) is a block diagram of the timers.

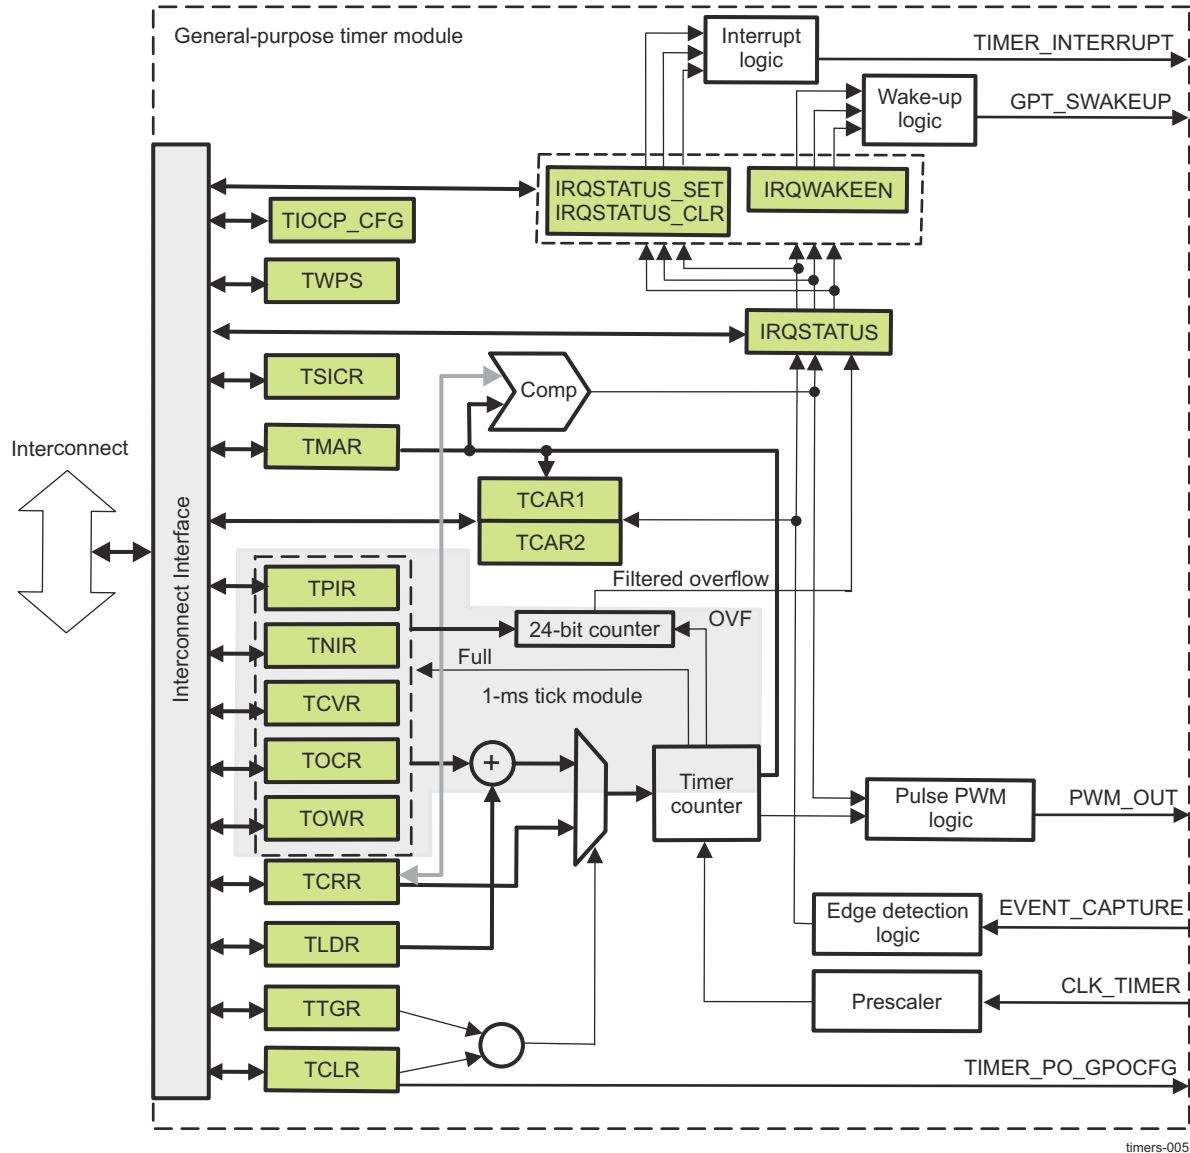

Figure 12-1214. Timer Block Diagram

#### 12.10.3.4.2 Timer Power Management

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

The way the timer acknowledges the LPSC clock stop request is configurable through the `TIMER_TIOCP_CFG[3-2] IDLEMODE` bit field.

Table 12-1587 lists the IDLEMODE settings and the related acknowledgment modes.

Table 12-1587. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The clock stop request is unconditionally acknowledged from the timer, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.

**Table 12-1587. IDLEMODE Settings (continued)**

IDLEMODE Value	Selected Mode	Description
01	No-idle	The clock stop request is never acknowledged from the timer. This mode is safe from a module point of view but is not efficient from a power-saving perspective because the clocks remain active.
10	Smart-idle	The timer acknowledges the clock stop request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and interrupt requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

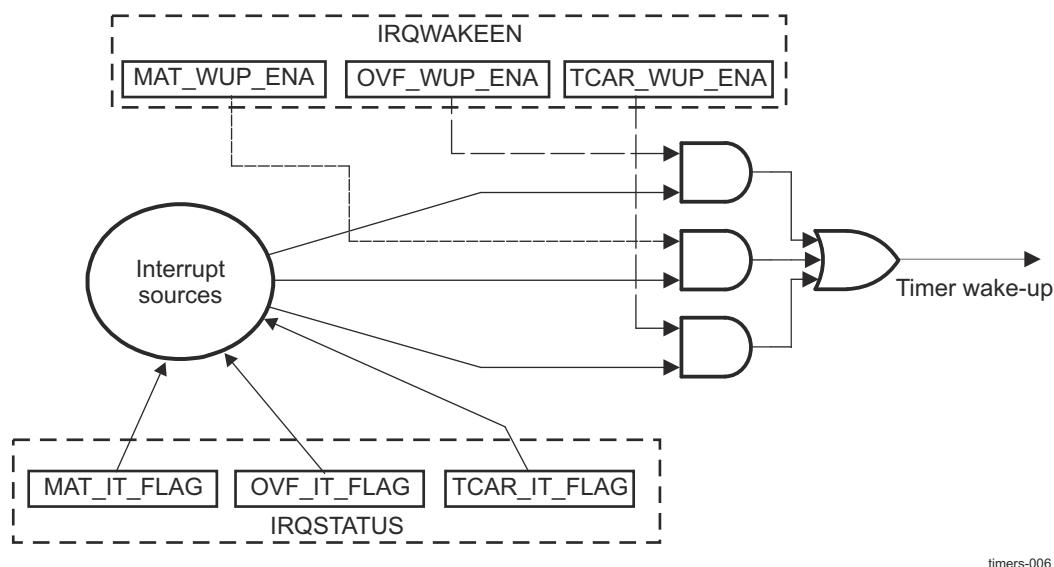

#### 12.10.3.4.2.1 Wake-Up Capability

##### Note

Some of the timers features described in this section may not be supported on this family of devices. For more information, see *Timers Not Supported Features*.

If the TIMER\_TIOCP\_CFG[3-2] IDLEMODE bit field sets the smart-idle mode or smart-idle with wake-up mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the clock stop acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request if configured in smart-idle with wake-up mode.

Figure 12-1215 shows the wake-up request generation.

timers-006

**Figure 12-1215. Wake-Up Request Generation**

The timer wake-up-enable register allows masking of the expected source of the wake-up event that generates a wake-up request. The register is synchronously programmed with the interface clock before the Clock management sends a clock stop request. The expected source of the wake-up event is an overflow (TIMER\_TCR), a timer match (the compare result of TIMER\_TCR and TIMER\_TMAR matches the counter value), and a timer capture (detection of an external pulse transition of the correct polarity on the TIMER\_PIEVENTCAPT).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (TIMER\_IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

### Note

The status bit must be reset to re-enter idle mode.

#### 12.10.3.4.3 Timer Software Reset

TIMER\_TIOCP\_CFG[0] SOFTRESET bit can initiate a software reset of the timer. This bit is autocleared to 0 when the reset is complete.

Before accessing or using the timer, the local host must ensure that internal reset is released by reading the TIMER\_TIOCP\_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

#### 12.10.3.4.4 Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (TIMER\_IRQSTATUS\_SET) and disabled in the interrupt-disable register (TIMER\_IRQSTATUS\_CLR). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (TIMER\_IRQSTATUS).

#### 12.10.3.4.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TIMER\_TCLR[0] ST bit). The timer counter register (TIMER\_TCRR) can be loaded when stopped or on-the-fly (while counting). TIMER\_TCRR can be loaded directly by a TIMER\_TCRR write access with a new timer value. TIMER\_TCRR can also be loaded with the value held in the timer load register (TIMER\_TLDR) by a trigger register (TIMER\_TTGR) write access. The loading of TIMER\_TCRR is done regardless of the written value of TIMER\_TTGR. The value of TIMER\_TCRR can be read when stopped or captured on-the-fly by a TIMER\_TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TIMER\_TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

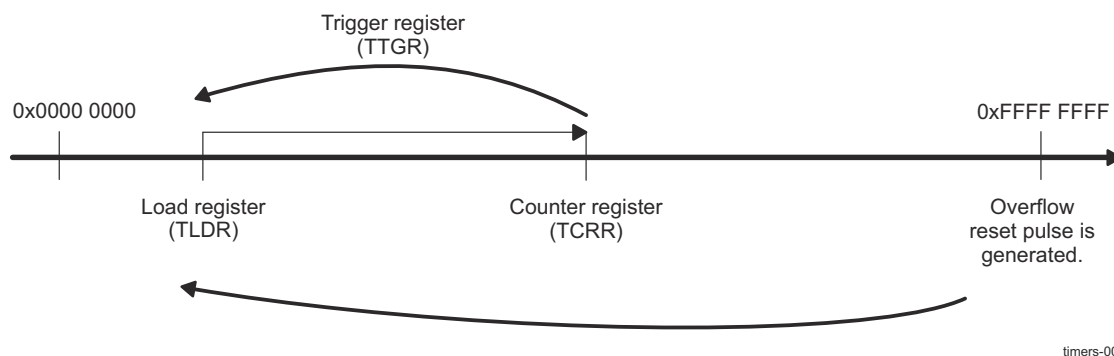

When the autoreload mode is enabled (the TIMER\_TCLR[1] AR bit is set to 1), TIMER\_TCRR is reloaded with the value of TIMER\_TLDR after a counting overflow occurs.

### CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TIMER\_TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the TIMER\_IRQSTATUS\_SET[1] OVF\_EN\_FLAG bit is set to 1). A dedicated output pin (POTIMERPWM) can be programmed in the TIMER\_TCLR[12] PT bit through the TIMER\_TCLR[11-10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TIMER\_TCLR[12] PT bit selects pulse/toggle modulation (the TIMER\_TCLR[11-10] TRG bit field selects trigger mode).

Figure 12-1216 shows the TIMER\_TCRR timing value.

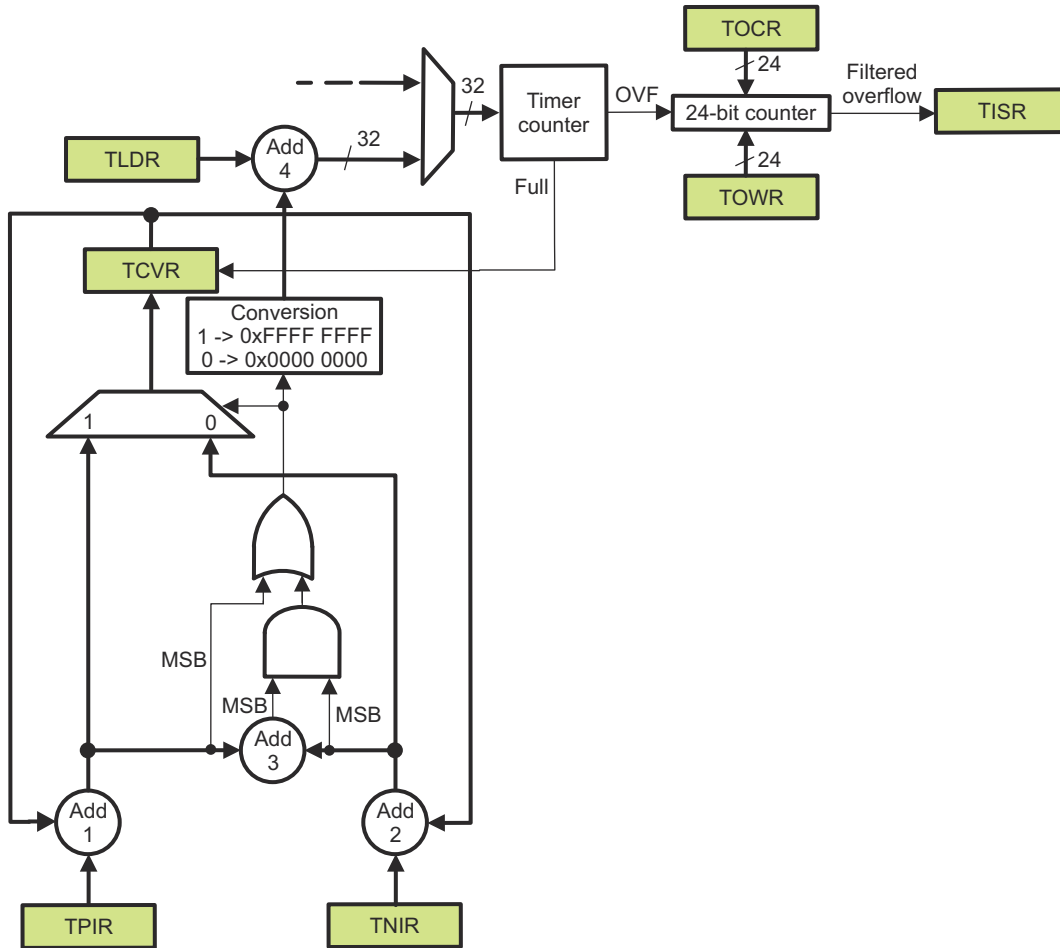

**Figure 12-1216. TIMER\_TCRR Timing Value**

#### 12.10.3.4.5.1 1-ms Tick Generation

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 kHz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-kHz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See [Figure 12-1217](#).

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the `TIMER_TPIR[31-0]` `POSITIVE_INC_VALUE` bit field) and the timer negative increment register (the `TIMER_TNIR[31-0]` `NEGATIVE_INC_VALUE` bit field). An automatic adaptation mechanism is used to simplify the programming model.

timers-009

**Figure 12-1217. Block Diagram of the 1-ms Tick Module**

The TIMER\_TPIR, TIMER\_TNIR, and TIMER\_TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the TIMER\_TCRR[31:0] TIMER\_COUNTER bit field) is the value of the TIMER\_TLDR[31:0] LOAD\_VALUE bit field (period less than 1 ms) or the value of TIMER\_TLDR[31:0] LOAD\_VALUE – 1 (period greater than 1 ms).

Table 12-1588 lists the value loaded in the TIMER\_TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

**Table 12-1588. Value Loaded in TIMER\_TCRR to Generate 1-ms Tick**

Add1 MSB	Add2 MSB	Add3 MSB	Value of TIMER_TCRR Register
0	0	0	TIMER_TLDR[31:0] LOAD_VALUE bit field
0	0	1	TIMER_TLDR[31:0] LOAD_VALUE bit field
0	1	0	TIMER_TLDR[31:0] LOAD_VALUE bit field
0	1	1	TIMER_TLDR[31:0] LOAD_VALUE – 1
1	0	0	N/A
1	0	1	N/A
1	1	0	TIMER_TLDR[31:0] LOAD_VALUE – 1
1	1	1	TIMER_TLDR[31:0] LOAD_VALUE – 1

The values of the TIMER\_TPIR and TIMER\_TNIR registers are calculated using the following formulas:

- Positive increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] + 1) \times 1\text{e}6 - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$
- Negative increment value =  $(\text{INTEGER}[F_{\text{clk}} \times T_{\text{tick}}] \times 1\text{e}6) - (F_{\text{clk}} \times T_{\text{tick}} \times 1\text{e}6)$

---

#### Note

$F_{\text{clk}}$  clock frequency (kHz)

$T_{\text{tick}}$  tick period (ms)

---

The timer overflow counter register (TIMER\_TOCR) and the timer overflow wrapping register (TIMER\_TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TIMER\_TOCR. When the values in the 24-bit TIMER\_TOCR match the values in the 24-bit TIMER\_TOWR and the timer overflow is asserted, the TIMER\_TOCR is reset and an interrupt is generated to the TIMER\_IRQSTATUS register.

---

#### Note

TIMER\_TOWR has to be set to requested value. For example, if no interrupt needs to be masked TIMER\_TOWR must be set to 0, if one interrupt needs to be masked TIMER\_TOWR must be set to 1, if two interrupts need to be masked TIMER\_TOWR must be set to 2 and so on.

It is important to have in mind that the case when FFFFFFF interrupts need to be masked is not possible.

---

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of timers remain unchanged.

For 1-ms tick with a 32.768-kHz clock:

- TIMER\_TPIR[31-0] POSITIVE\_INC\_VALUE = 232,000
- TIMER\_TNIR[31-0] NEGATIVE\_INC\_VALUE = -768,000
- TIMER\_TLDR[31-0] LOAD\_VALUE = 0xFFFF FFE0

---

#### Note

Any value of the tick period can be generated with the appropriate value of the TIMER\_TPIR, TIMER\_TNIR, and TIMER\_TLDR.

By default, the TIMER\_TPIR, TIMER\_TNIR, TIMER\_TCVR, TIMER\_TOCR, and TIMER\_TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

---

#### 12.10.3.4.6 Timer Capture Mode Functionality

When a transition is detected on the module input pin (PIEVENTCAPT), the timer value in the TIMER\_TCRR can be captured and saved in the TIMER\_TCAR1 or TIMER\_TCAR2 register function of the mode selected in the TIMER\_TCLR[13] CAPT\_MODE bit. The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

The rising edge, falling edge, or both, can be selected in the TIMER\_TCLR[9-8] TCM bit field to trigger the timer counter capture. The module sets the TIMER\_IRQSTATUS[2] TCAR\_IT\_FLAG bit when an active edge is detected, and at the same time, the counter value TIMER\_TCRR is stored in timer capture register TIMER\_TCAR1 or TIMER\_TCAR2, as follows:

- If the TIMER\_TCLR[13] CAPT\_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the TIMER\_TCAR1 register, and the next events are ignored (no update on the TIMER\_TCAR1 register and no interrupt triggering) until the detection logic is reset or the TIMER\_IRQSTATUS[2] TCAR\_IT\_FLAG is cleared by writing 1 to it.
- If the TIMER\_TCLR[13] CAPT\_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the TIMER\_TCAR1 register, and on the second enabled capture event, the value of the

counter register is saved in the `TIMER_TCAR2` register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on `TIMER_TCAR1/TIMER_TCAR2` and no interrupt triggering) until the detection logic is reset or the `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the `PIEVENTCAPT` input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The `TIMER_IRQSTATUS[2] TCAR_IT_FLAG` bit is cleared by writing 1 to it or when the edge detection mode bits (the `TIMER_TCLR[9-8] TCM` bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (`PIEVENTCAPT`). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the `TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG` bit. See the examples in [Figure 12-1218](#) and [Figure 12-1219](#).

In [Figure 12-1218](#), the value of the `TIMER_TCLR[9-8] TCM` bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 0. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` and `TIMER_TCAR2` registers, and only the `TIMER_TCAR1` register updates.

timers-010

**Figure 12-1218. Capture Wave Example for `TIMER_TCLR[13] CAPT_MODE = 0`**

In [Figure 12-1219](#), the value of the `TIMER_TCLR[9-8] TCM` bit field is 1h, and the `TIMER_TCLR[13] CAPT_MODE` bit is 1. Only the rising edge of `PIEVENTCAPT` triggers a capture in the `TIMER_TCAR1` register on the first enabled event, and the `TIMER_TCAR2` register updates on the second enabled event.

**Figure 12-1219. Capture Wave Example for TIMER\_TCLR[13] CAPT\_MODE = 1**

#### 12.10.3.4.7 Timer Compare Mode Functionality

When the compare-enable register `TIMER_TCLR[6]` CE bit is set to 1, the timer value (the `TIMER_TCRR[31-0]` `TIMER_COUNTER` bit field) is continuously compared to the value held in the timer match register (`TIMER_TMAR`). The value of the `TIMER_TMAR[31-0]` `COMPARE_VALUE` bit field can be loaded at any time (timer counting or stopped). When the `TIMER_TCRR` and the `TIMER_TMAR` values match, an interrupt is issued, if the `TIMER_IRQSTATUS_SET[0]` `MAT_EN_FLAG` bit is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the `TIMER_TMAR` before setting the `TIMER_TCLR[6]` CE bit.

The dedicated output pin (`POTIMERPWM`) can be programmed in the `TIMER_TCLR[12]` PT bit through the `TIMER_TCLR[11-10]` TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

#### 12.10.3.4.8 Timer Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the `TIMER_TCLR[5]` PRE bit is set. The `TIMER_TCLR[4-2]` PTV bit field sets the  $2^n$  division ratio (prescaler value is  $2^{(PTV + 1)}$ ). The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 12-1589 lists the prescaler/timer reload values versus contexts.

**Table 12-1589. Prescaler/Timer Reload Values Versus Contexts**

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	<code>TIMER_TLDR[31-0]</code>
<code>TIMER_TCRR</code> write	Reset	<code>TIMER_TCRR[31-0]</code>
<code>TIMER_TTGR</code> write	Reset	<code>TIMER_TLDR[31-0]</code>
Stop	Reset	Frozen

#### 12.10.3.4.9 Timer Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM (`POTIMERPWM`) output pin can be configured to toggle on an event. The `TIMER_TCLR[11-10]` TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

### Note

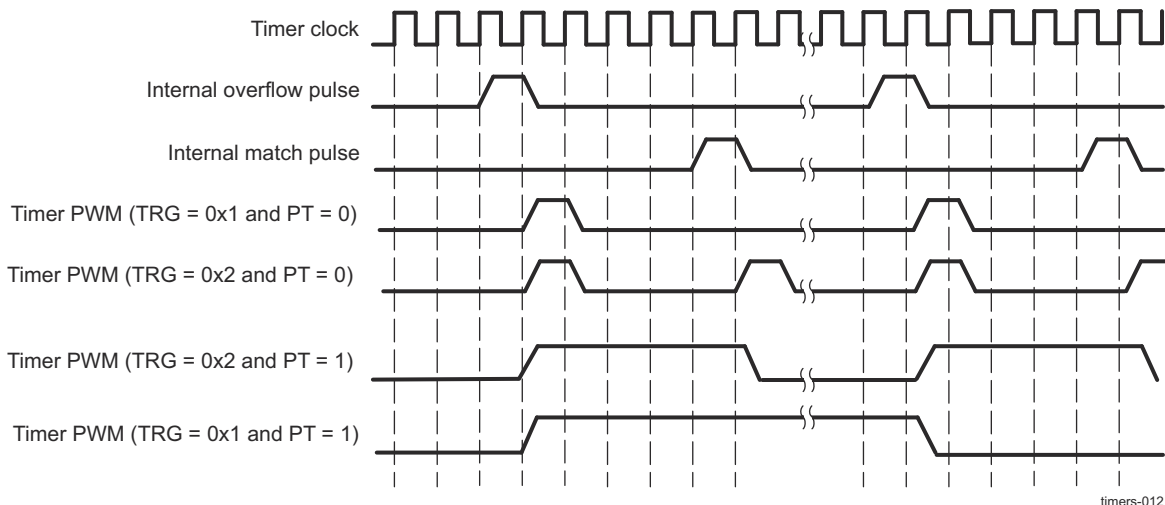

In toggle mode, when `TIMER_TCLR[11-10] TRG = 0x2` (overflow and match), the first event that toggles the PWM line is an overflow event.

The `TIMER_TCLR[7] SCPWM` bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the `TIMER_TCLR[11-10] TRG` bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

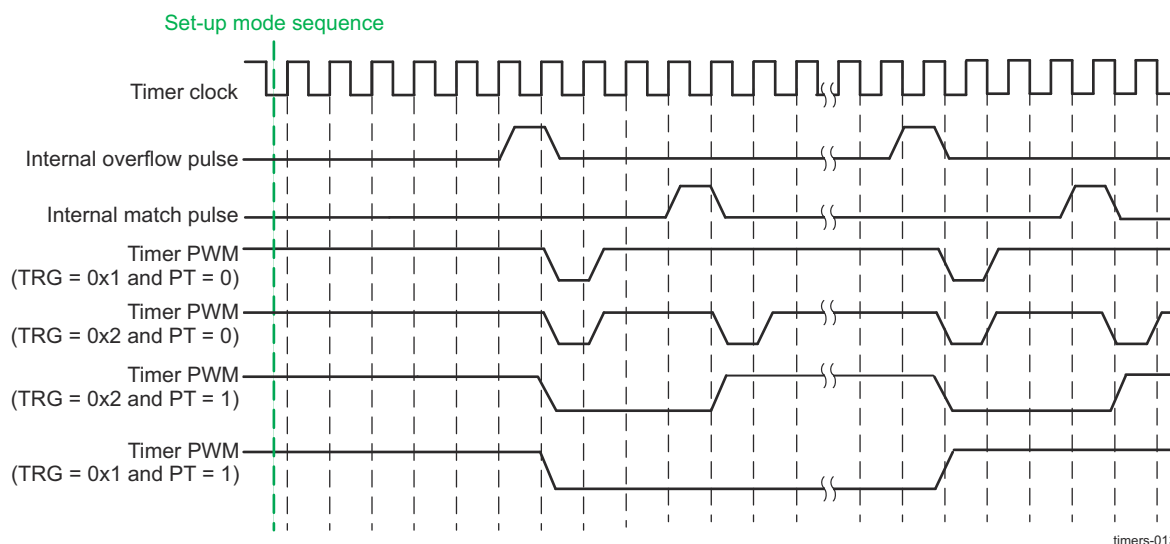

In [Figure 12-1220](#), the internal overflow pulse is set each time the  $(0xFFFF - \text{TIMER\_TLDR}[31-0] \text{ LOAD\_VALUE} + 1)$  value is reached, and the internal match pulse is set when the counter reaches the value of `TIMER_TMAR`. Depending on the value of the `TIMER_TCLR[12] PT` bit and `TIMER_TCLR[11-10] TRG` bit field, the timer provides pulse or PWM event on the output pin (`POTIMERPWM`).

The `TIMER_TLDR` and `TIMER_TMAR` must keep values below the overflow value (`0xFFFF FFFF`) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the `TIMER_TMAR` and the value in the `TIMER_TLDR` must be at least two units. When match event is used, the compare mode `TIMER_TCLR[6] CE` bit must be set.

In [Figure 12-1220](#), the `TIMER_TCLR[7] SCPWM` bit is set to 0. In [Figure 12-1221](#), the `TIMER_TCLR[7] SCPWM` bit is set to 1. To obtain the desired wave form, start the counter at `0xFFFF FFFE` value (to ensure an overflow first) or adjust the line polarity (`TIMER_TCLR[7] SCPWM` bit).

**Figure 12-1220. Timing Diagram of PWM With `TIMER_TCLR[7] SCPWM` Bit = 0**

**Figure 12-1221. Timing Diagram of PWM With TIMER\_TCLR[7] SCPWM Bit = 1**

#### 12.10.3.4.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TIMER\_TCLR[5] PRE bit and TIMER\_TCLR[4-2] PTV bit field)
- Value loaded into the TIMER\_TLDR

Table 12-1590 lists the prescaler clock ratio values.

**Table 12-1590. Prescaler Clock Ratio Values**

TIMER_TCLR[5] PRE	TIMER_TCLR[4-2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

$$\text{OVF\_Rate} = (0\text{xFFFF FFFF} - \text{TIMER\_TLDR} + 1) \times (\text{timer-functional clock period}) \times \text{PS}$$

With (timer-functional clock period) =  $1/(\text{timer-functional clock frequency})$  and PS =  $2^{(\text{PTV} + 1)}$  if prescaler is enabled, or PS = 1 if prescaler is disabled.

#### CAUTION

Internal resynchronization causes any write to the TIMER\_TCLR[1] ST bit to have some latency before the register is updated:

$2.5 \times$  functional clock cycles write\_TIMER\_TCLR\_latency  $3.5 \times$  functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TIMER\_TCLR[1] ST bit.

### CAUTION

- In non-PWM mode, TIMER\_TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TIMER\_TLDR must be maintained at less than or equal to 0xFFFF FFDD.

For example, with a timer clock input of 32 kHz and the TIMER\_TCLR[5] PRE bit set to 0, the timer output period is as listed in [Table 12-1591](#).

**Table 12-1591. Value and Corresponding Interrupt Period**

TIMER_TLDR[31-0] LOAD_VALUE	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 $\mu$ s
0xFFFF FFFE	62.5 $\mu$ s

#### 12.10.3.4.11 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the TIMER\_TIOCP\_CFG[1] EMUFREE bit.

If the TIMER\_TIOCP\_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIMER\_TIOCP\_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (MCU\_TIMER\_IO[9-0] or TIMER\_IO[7-0]) is internally synchronized on two timer-clock rising edges.

#### 12.10.3.4.12 Accessing Timer Registers

All accesses are posted mode, under the assumption that  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ , until software reconfiguration. In addition, it is not recommended to access the timer registers prior to the PLLs generating the timer and interface clocks have been configured and the clocks have stabilized. All registers are 32 bits wide, accessible through the configuration interface with 32-bit access (read/write).

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TIMER\_TCLR
- TIMER\_TCR
- TIMER\_TLDR
- TIMER\_TTGR
- TIMER\_TMAR
- TIMER\_TPIR
- TIMER\_TNIR
- TIMER\_TCV
- TIMER\_TOCR
- TIMER\_TOWR

The following registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one interface clock cycle from command assertion:

- TIMER\_TIDR
- TIMER\_TIOCP\_CFG
- TIMER\_IRQSTATUS
- TIMER\_IRQSTATUS\_RAW
- TIMER\_IRQSTATUS\_SET
- TIMER\_IRQSTATUS\_CLR
- TIMER\_IRQWAKEEN
- TIMER\_TWPS

- TIMER\_TSICR

#### 12.10.3.4.12.1 Writing to Timer Registers

The host uses the configuration interface to write to the following registers synchronously with the timer interface clock:

- TIMER\_TLDR
- TIMER\_TCRR
- TIMER\_TCLR
- TIMER\_TIOCP\_CFG
- TIMER\_IRQSTATUS
- TIMER\_IRQSTATUS\_SET
- TIMER\_IRQSTATUS\_CLR
- TIMER\_IRQWAKEEN
- TIMER\_TTGR
- TIMER\_TSICR
- TIMER\_TMAR
- TIMER\_TPIR
- TIMER\_TNIR
- TIMER\_TCVR
- TIMER\_TOCR
- TIMER\_TOWR

#### 12.10.3.4.12.1.1 Write Posting Synchronization Mode

This mode is used if the TIMER\_TSICR[2] POSTED bit is set to 1 (default value).

This mode uses a posted write scheme to update any internal register (TIMER\_TCLR, TIMER\_TCRR, TIMER\_TLDR, TIMER\_TTGR, TIMER\_TMAR, TIMER\_TPIR, TIMER\_TNIR, TIMER\_TCVR, TIMER\_TOCR, and TIMER\_TOWR). Therefore, the write transaction is immediately acknowledged on the configuration interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect, nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status (TIMER\_TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the interface clock. Consequently, any read access to TIMER\_TCRR does not add any resynchronization latency; the current value is always available.

---

#### Note

Because the overflow IRQ is generated when the value of TIMER\_TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of ( $1 \times PS \times$  timer functional clock period) before any read access to TIMER\_TCRR to ensure a correct reading of its content.

---

---

#### Note

If TIMER\_TTGR register is written during a posted write to TIMER\_TCRR, the value to be written to TIMER\_TCRR will be discarded.

If a posted write to TIMER\_TCVR is started, the user must not write to TIMER\_TPIR or TIMER\_TNIR before the TIMER\_TCVR write is finished, because the value of TIMER\_TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

---

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

Functional frequency range:  $\text{freq}(\text{timer clock}) < \text{freq}(\text{interface clock})/4$ .

#### **12.10.3.4.12.1.2 Write Nonposting Synchronization Mode**

This mode is used if the `TIMER_TSICR[2] POSTED` bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the configuration interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the configuration interface frequency and the timer clock frequency.

#### **12.10.3.4.12.2 Reading From Timer Counter Registers**

##### **Note**

LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

The `TIMER_TCRR` is a 32-bit “atomic datum” and its 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. This capture scheme is also performed for the `TIMER_TCAR1` and `TIMER_TCAR2` registers as they can be changed due to internal processes too.

##### **12.10.3.4.12.2.1 Read Posted**

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. The recommended functional frequency range is  $\text{freq}(\text{timer}) < \text{freq}(\text{interface clock})/4$ .

Read posted mode is used if `TIMER_TSICR[2] POSTED = 0x1` or `TIMER_TSICR[3] READ_MODE` is set to 0. This mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the configuration interface, prior to the value to be read has been resynchronized. With this method, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which needs resynchronization from functional to interface clock domains.

Note that in Posted mode, if the `TIMER_TCRR` is read immediately after wake-up and the interface clock is off during idle state, then it is possible to get an old value from just before going to idle state due to the fact the interface clock is needed for synchronization.

In order to avoid this situation, another synchronization mechanism is used for the first read operation after idle state. The `TIMER_TSICR[4] READ_AFTER_IDLE` bit is used to enable/disable the mechanism.

When the synchronization mechanism is disabled (`READ_AFTER_IDLE` bit is set to 1), first read transaction takes only 2 interface clock cycles, but the read value of `TIMER_TCRR` could be wrong.

When the synchronization mechanism is enabled (`READ_AFTER_IDLE` bit is set to 0), first read value of `TIMER_TCRR` is correct, but the read transaction takes more than 2 interface clock cycles.

##### **12.10.3.4.12.2.2 Read Non-Posted**

This mode is functional regardless of the ratio between the configuration interface frequency and the functional clock frequency. Recommended functional frequency range is  $\text{freq}(\text{timer}) \geq \text{freq}(\text{interface clock})/4$ .

Read non-posted mode is used if `TIMER_TSICR[2] POSTED = 0x0` and `TIMER_TSICR[3] READ_MODE = 0x1`. This mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the configuration interface until the effective read operation occurs, after the resynchronization

in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

This mode applies to `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`, which need resynchronization from functional to interface clock domains.

#### **12.10.3.4.13 Timer Posted Mode Selection**

A choice between two synchronization modes is made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain. For write operation, the registers affected by posted and non-posted selection are `TIMER_TCLR`, `TIMER_TLDR`, `TIMER_TCRR`, `TIMER_TTGR`, `TIMER_TMAR`, `TIMER_TPIR`, `TIMER_TNIR`, `TIMER_TCVR`, `TIMER_TOCR`, and `TIMER_TOWR`. For read operation, the registers affected by this selection are: `TIMER_TCRR`, `TIMER_TCAR1`, `TIMER_TCAR2`, `TIMER_TCVR`, and `TIMER_TOWR`.

The interface clock domain synchronous registers `TIMER_TIDR`, `TIMER_TIOCP_CFG`, `TIMER_IRQSTATUS`, `TIMER_IRQSTATUS_SET`, `TIMER_IRQWAKEEN`, `TIMER_TWPS`, and `TIMER_TSICR` are not affected by posted and non-posted mode selection. The operation (read or write) is effective and acknowledged after one interface clock cycle from the command assertion.

The configuration of posted or non-posted mode can be changed (overwritten) by software by writing in `TIMER_TSICR[2]` `POSTED` bit. The `TIMER_TSICR[3]` `READ_MODE` defines how the read operation is performed when the module is configured in non-posted mode (see `TIMER_TSICR`). The following cases are possible:

- `TIMER_TSICR[2]` `POSTED` = 0x1 and `TIMER_TSICR[3]` `READ_MODE` = x (don't care): read and write operations are expected in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x0: the write operation is executed in non-posted mode and read is executed in posted mode.
- `TIMER_TSICR[2]` `POSTED` = 0x0 and `TIMER_TSICR[3]` `READ_MODE` = 0x1: write is executed in non-posted mode and read is executed in non-posted mode.

### 12.10.3.5 Timers Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 12.10.3.5.1 Timer Global Initialization

##### 12.10.3.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the timer. For more information, see *Timers Integration* and *Timers Environment*. [Table 12-1592](#) summarizes the surrounding modules.

**Table 12-1592. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
C66SS0_INTRTR0 and C66SS1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling C66SS0_INTRTR0 and C66SS1_INTRTR0 interrupts, see <i>Interrupts</i> .
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
MAIN2MCU_LVL_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MAIN2MCU_LVL_INTRTR0 interrupts, see <i>Interrupts</i> .
R5FSS0_INTRTR0 and R5FSS1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_INTRTR0 and R5FSS1_INTRTR0 interrupts, see <i>Interrupts</i> .
R5FSS0_CORE0/1 and R5FSS1_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_CORE0/1 and R5FSS1_CORE0/1 interrupts, see <i>Interrupts</i> .
PLLCTRL0 and WKUP_PLLCTRL0	PLL controller's configuration must be done to enable the module clocks. For more information, see <i>Clocking</i> .
TIMERCLK0 MUX to TIMERCLK19 MUX	TIMERCLK0 MUX to TIMERCLK19 MUX configuration must be done to enable the module clocks. For more information, see <i>Control Module (CTRL_MMR)</i> .

#### 12.10.3.5.1.2 Timer Module Global Initialization

##### 12.10.3.5.1.2.1 Main Sequence – Timer Module Global Initialization

[Table 12-1593](#) identifies the main steps for initializing the timer module when the module is to be used for the first time.

**Table 12-1593. Timer Module Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIMER_TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIMER_TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIMER_TIOCP_CFG[3-2] IDLEMODE	0x-
Enable wake-up interrupt events.	TIMER_IRQWAKEEN[2-0]	0x-
Select posted mode.	TIMER_TSICR[2] POSTED	0x-

#### 12.10.3.5.2 Timer Operational Mode Configuration

##### 12.10.3.5.2.1 Timer Mode

##### 12.10.3.5.2.1.1 Main Sequence – Timer Mode Configuration

[Table 12-1594](#) lists the steps in the timer mode configuration.

**Table 12-1594. Timer Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable overflow interrupt.	TIMER_IRQSTATUS_SET[1] OVF_EN_FLAG	0x1

**Table 12-1594. Timer Mode Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Load timer counter value.	TIMER_TCRR	0x-
Load timer load value.	TIMER_TLDR	0x-
Start the timer.	TIMER_TCLR[0] ST	0x1

### 12.10.3.5.2.2 Timer Compare Mode

#### 12.10.3.5.2.2.1 Main Sequence – Timer Compare Mode Configuration

Table 12-1595 lists the steps in the timer compare mode configuration.

**Table 12-1595. Timer Compare Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Enable match interrupt.	TIMER_IRQSTATUS_SET[0] MAT_EN_FLAG	0x1
Load timer counter value.	TIMER_TCRR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare mode.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

### 12.10.3.5.2.3 Timer Capture Mode

#### 12.10.3.5.2.3.1 Main Sequence – Timer Capture Mode Configuration

Table 12-1596 lists the steps in the timer capture mode configuration.

**Table 12-1596. Timer Capture Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See <a href="#">Section 12.10.3.5.2.3.2</a> .	
Enable capture interrupt.	TIMER_IRQSTATUS_SET[2] TCAR_EN_FLAG	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1
Detect event.	See <a href="#">Section 12.10.3.5.2.3.3</a> .	

#### 12.10.3.5.2.3.2 Subsequence – Initialize Capture Mode

Table 12-1597 lists the steps to initialize capture mode.

**Table 12-1597. Initialize Capture Mode**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select TIMER[19-0] or MCU_TIMER[9-0] Capture input at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x1
Select single or second event capture.	TIMER_TCLR[13] CAPT_MODE	0x-
Select transition capture mode.	TIMER_TCLR[9-8] TCM	0x-

#### 12.10.3.5.2.3.3 Subsequence – Detect Event

Table 12-1598 lists the steps in detecting an event.

**Table 12-1598. Detect Event**

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TIMER_TCAR1 and/or TIMER_TCAR2	
Clear capture interrupt request.	TIMER_IRQSTATUS[2] TCAR_IT_FLAG	0x1

#### 12.10.3.5.2.4 Timer PWM Mode

##### 12.10.3.5.2.4.1 Main Sequence – Timer PWM Mode Configuration

[Table 12-1599](#) lists the steps in the timer PWM mode configuration.

**Table 12-1599. Timer PWM Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TIMER_TCLR[1] AR	0x-
Set prescale timer value.	TIMER_TCLR[4-2] PTV	0x-
Enable prescaler.	TIMER_TCLR[5] PRE	0x1
Select trigger output mode.	TIMER_TCLR[11-10] TRG	0x-
Select pulse or toggle modulation PWM mode.	TIMER_TCLR[12] PT	0x-
Select TIMER[19-0] or MCU_TIMER[9-0] PWM output at device pins TIMER_IO[7-0] for TIMER[19-0] or at pins MCU_TIMER_IO[9-0] for MCU_TIMER[9-0].	TIMER_TCLR[14] GPO_CFG	0x0
Configure PWM output pin default value.	TIMER_TCLR[7] SCPWM	0x-
Load timer load value.	TIMER_TLDR	0x-
Load timer compare value.	TIMER_TMAR	0x-
Enable compare.	TIMER_TCLR[6] CE	0x1
Start the timer.	TIMER_TCLR[0] ST	0x1

## 12.11 Internal Diagnostics Modules

This section describes the internal diagnostics modules in the device.

### 12.11.1 Dual Clock Comparator (DCC)

This section describes the Dual Clock Comparator (DCC) modules in the device.

#### 12.11.1.1 DCC Overview

The Dual Clock Comparator (DCC) is used to determine the accuracy of a clock signal during the time execution of an application. Specifically, the DCC is designed to detect drifts from the expected clock frequency. The desired accuracy can be programmed based on calculation for each application. The DCC measures the frequency of a selectable clock source using another input clock as a reference.

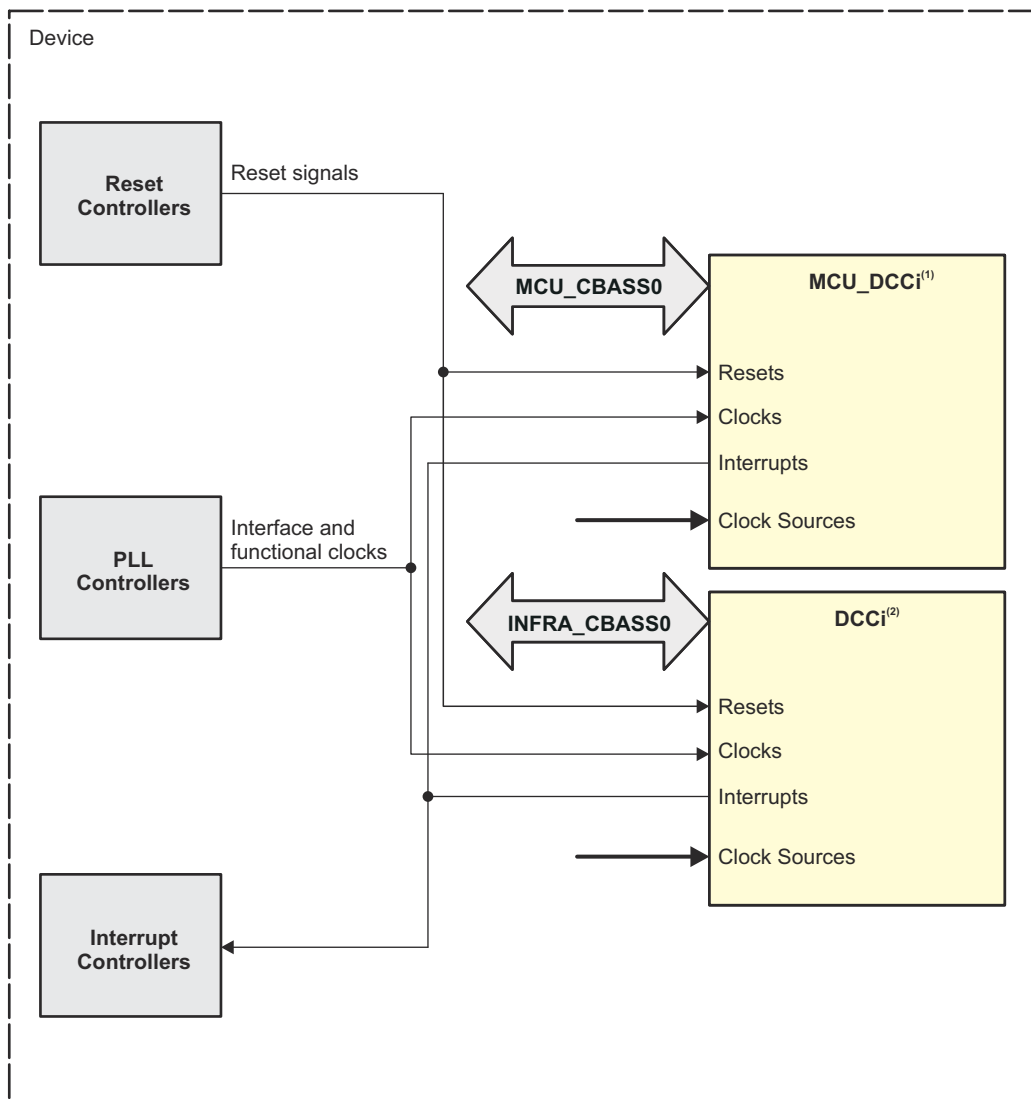

The device has sixteen instances of DCC modules. [Table 12-1600](#) shows DCC modules allocation across device domains.

**Table 12-1600. DCC Modules Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MCU_DCC0	-	✓	-
MCU_DCC1	-	✓	-
MCU_DCC2	-	✓	-
DCC0	-	-	✓
DCC1	-	-	✓
DCC2	-	-	✓
DCC3	-	-	✓
DCC4	-	-	✓
DCC5	-	-	✓
DCC6	-	-	✓
DCC7	-	-	✓
DCC8	-	-	✓
DCC9	-	-	✓
DCC10	-	-	✓
DCC11	-	-	✓
DCC12	-	-	✓

[Figure 12-1222](#) shows the DCC modules overview.

dcc-001

- A.  $i = 0$  to  $2$
- B.  $i = 0$  to  $12$

**Figure 12-1222. DCC Modules Overview**

#### 12.11.1.1.1 DCC Features

The DCC uses two independent clock sources to detect when one is out of specification. Each DCC module implements the following features:

- Two independent counter blocks count clock pulses from each clock source
- Each counter block is programmable, however, for proper operation the counters must be programmed with seed values that respect the ratio of the two clock frequencies
- Configurable timebase for error signal
- Error signal generation when one of the clocks is out of specification
- Clock frequency measurement

#### 12.11.1.1.2 DCC Not Supported Features

The DCC does not support the following features:

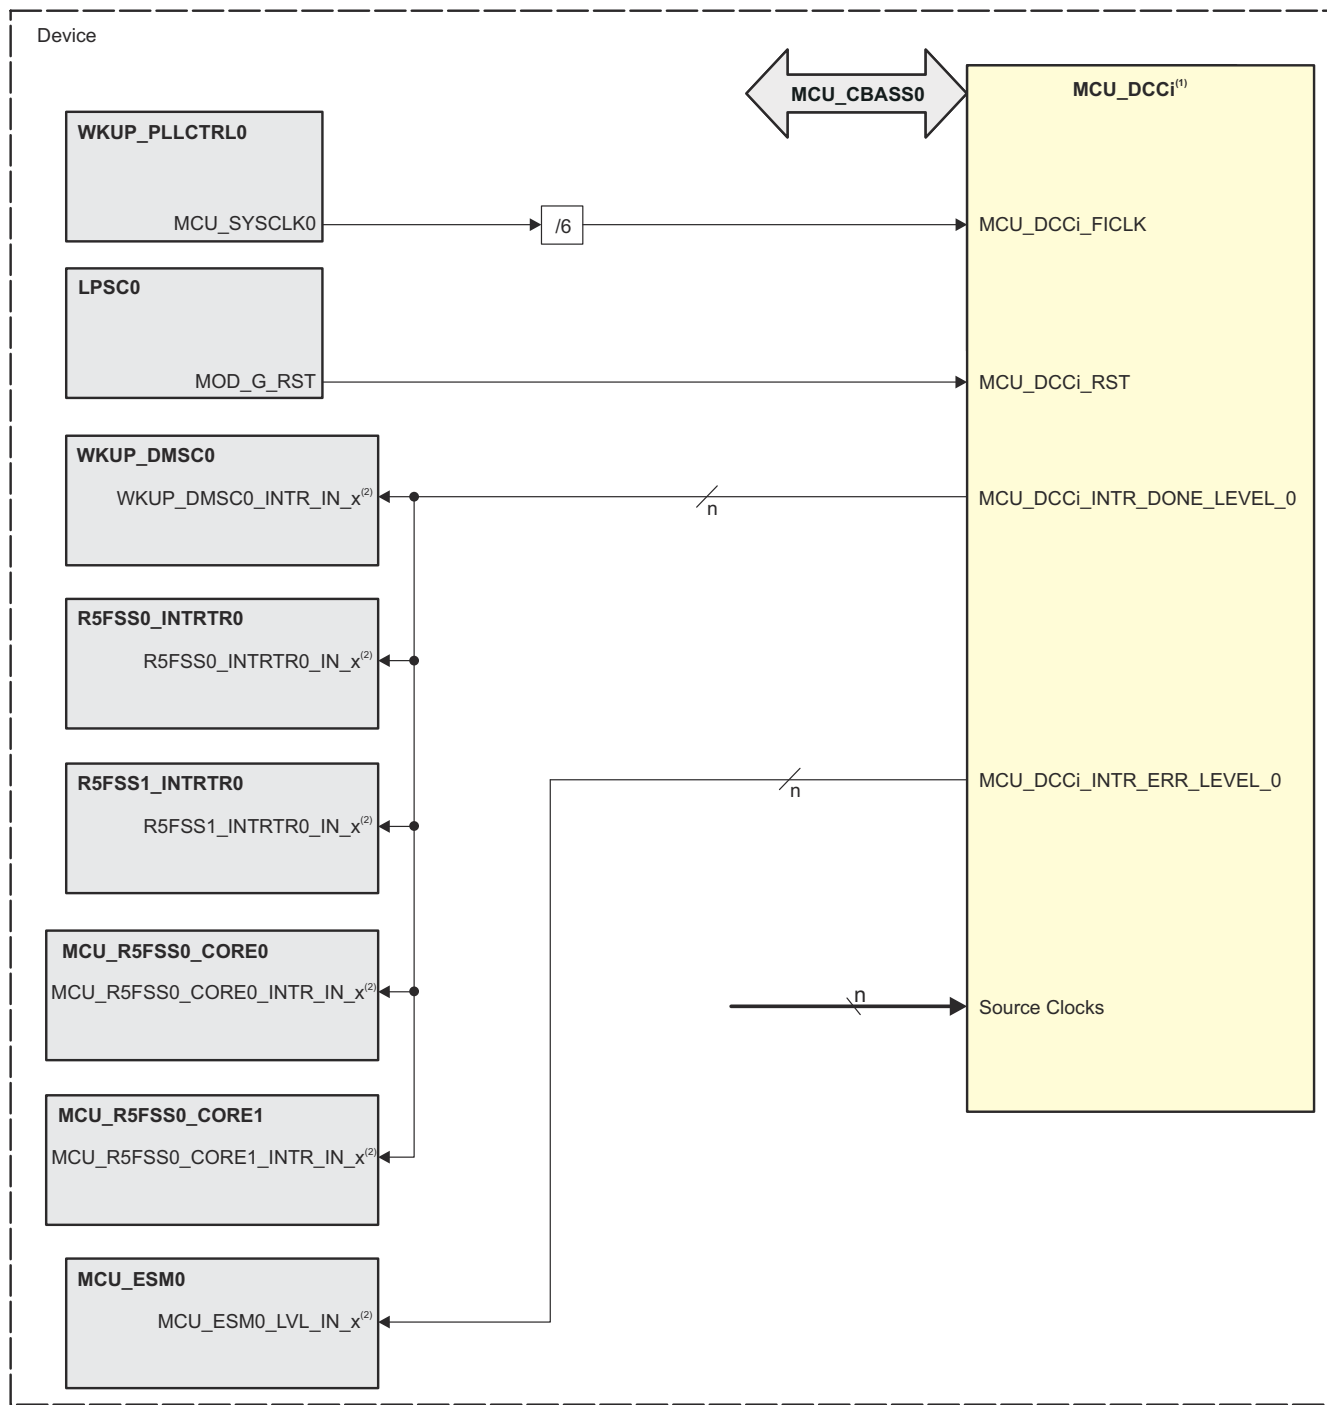

- Debug suspend functionality depreciated . Software will have to disable DCCs if it starts messing with clocks during debug.

### 12.11.1.2 DCC Integration

This section describes the DCC integration in the device, including information about clocks, resets, and hardware requests.

#### 12.11.1.2.1 DCC Integration in MCU Domain

There are three DCC modules integrated in the device MCU domain - MCU\_DCC0 through MCU\_DCC2. [Figure 12-1223](#) shows the integration of MCU\_DCC modules.

dcc-002

A.  $i = 0$  to 2

B. x = Interrupt port index, see [Table 12-1603](#)

**Figure 12-1223. MCU\_DCC Integration**

[Table 12-1601](#) through [Table 12-1603](#) summarize the integration of DCC in the device MCU domain.

**Table 12-1601. MCU\_DCC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_DCC0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_DCC1	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_DCC2	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

**Table 12-1602. MCU\_DCC Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_DCC0	MCU_DCC0_FICLK	MCU_SYSCLK0/6	WKUP_PLLCTRL0	MCU_DCC0 interface and functional clock
MCU_DCC1	MCU_DCC1_FICLK	MCU_SYSCLK0/6	WKUP_PLLCTRL0	MCU_DCC1 interface and functional clock
MCU_DCC2	MCU_DCC2_FICLK	MCU_SYSCLK0/6	WKUP_PLLCTRL0	MCU_DCC2 interface and functional clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MCU_DCC0	MCU_DCC0_RST	MOD_G_RST	LPSC0	MCU_DCC0 asynchronous module reset

### 12.11.1.3 DCC Functional Description

The DCC module supports two selectable clock sources for Counter0 and Counter1. Counter0 receives CLOCK0[2] at reset. Counter1 receives CLOCK1 at reset. Figure 12-1225 shows the DCC functional block diagram.

**Figure 12-1225. DCC Functional Block Diagram**

#### 12.11.1.3.1 DCC Counter Operation

##### Note

For detailed DCC compute calculations, refer to [Continuous Monitor of the PLL Frequency With the DCC App Note](#).

The DCC has two parallel counters that count clock pulses for two independent clock sources:

- Counter0 generates a fixed-width counting window (VALID0) after a pre-programmed number of pulses (COUNT0). The values for VALID0 and COUNT0 can be programmed in DCCVALIDSEED0 and DCC\_CNTSEED0 registers respectively.
- Counter1 generates a fixed-width pulse (1 cycle) after a pre-programmed number of pulses (COUNT1). This pulse sets an error signal if Counter1 does not reach 0 during the time when VALID0 is running. The seed value for COUNT1 can be programmed in DCC\_CNTSEED1 register.

The error signal is generated by any one of the following conditions:

- Clock1 expires before the COUNT0 reaches 0.
- Clock1 expires after both COUNT0 and VALID0 reach 0.
- Clock1 not present.
- Clock0 not present.

Any of these errors causes the counters to stop counting. An application must then read out the counter values to determine what caused the error. Once the error is detected, the counters are stopped after 3 FICLK and 2 source clock cycles due to the cross clock domain synchronisation.

Reloads or restarts occur under two conditions:

- The module is reset or restarted through software (that is, software starts the module after reset, or software checks an error condition and decides to restart the module).
- COUNT0, COUNT1, and VALID0 all reach 0 without error.

### CAUTION

The DCC module does not check jitter for Clock0 or Clock1.

As the counter preset signal is synchronized to either of the source clock domains, the counters begin downcounting after two corresponding source clock cycles.

The error signal is captured to the FICLK domain. There is 1 FICLK period uncertainty on either side of the fixed width counting window (VALID0) in generating the error signal since the counters work in different clock domains. This should be accounted for when setting the count value for VALID0.

Figure 12-1226 through Figure 12-1230 shows examples of counters relationship and error generation.

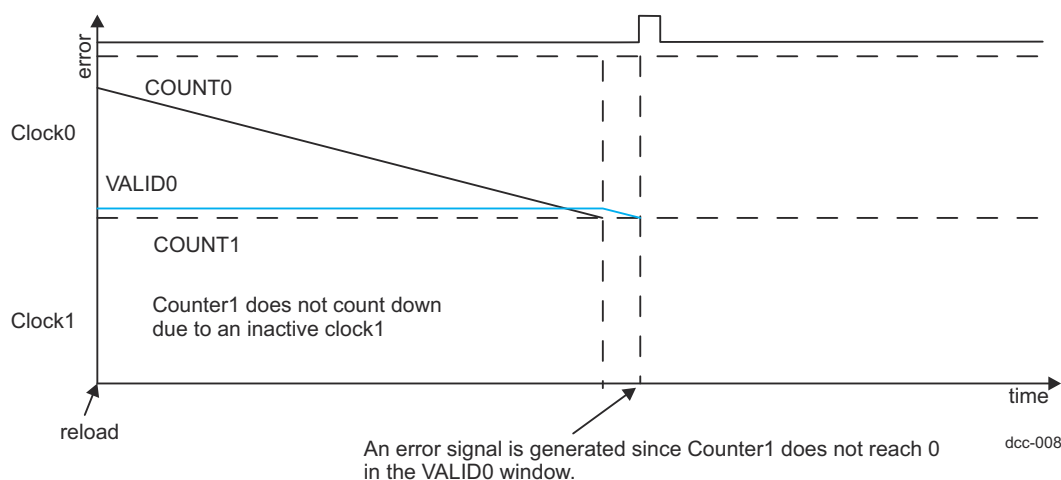

**Figure 12-1226. DCC Clock0 and Clock1 With no Error**

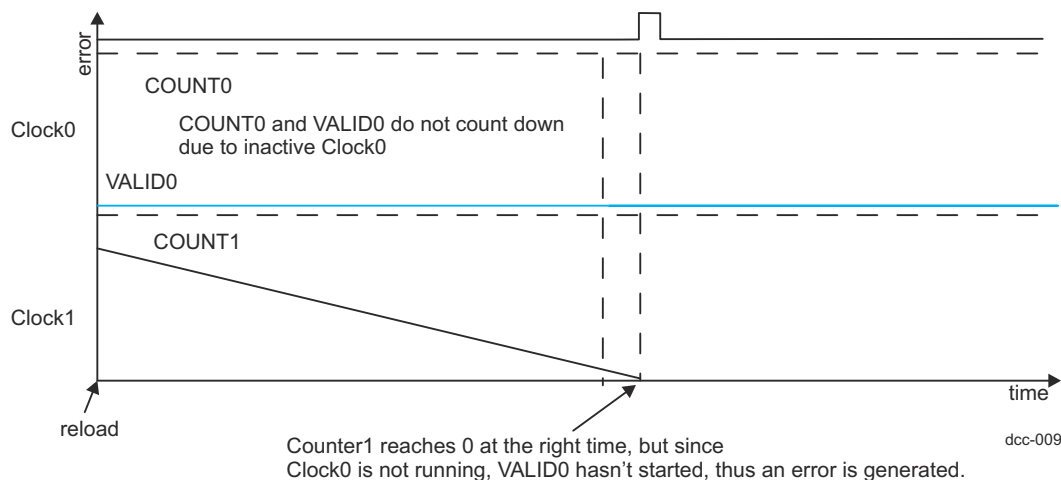

**Figure 12-1227. DCC Clock1 slower than Clock0 results in an error and stops counting**

**Figure 12-1228. DCC Clock1 faster than Clock0 results in an error and stops counting**

**Figure 12-1229. DCC Clock1 not present results in an error and stops counting**

**Figure 12-1230. DCC Clock0 not present results in an error and stops counting**

### 12.11.1.3.2 DCC Low Power Mode Operation

The DCC module does not function in Low Power Mode. It is the responsibility of software to stop the module before entering low power mode and to restart the module after exiting low power mode.

### 12.11.1.3.3 DCC Suspend Mode Behavior

The DCC module will continue running regardless of the state of emulation. All registers are readable via emulation reads.

### 12.11.1.3.4 DCC Single-Shot Mode

The DCC can be programmed to count down one time using single-shot mode. In this mode, the DCC stops operation when both COUNT0 and VALID0 reach 0.

At the end of one sequence in single-shot mode the DCC\_GCTRL[3-0] DCCENA bitfield is set to disabled, which stops further counting. Single-shot mode is enabled from the DCC\_GCTRL[11-8] SINGLESOT bitfield.

At the end of one sequence in single-shot mode, if there is no error which stops counting, then the done status bit is set in the DCC\_STAT[1] DONEFLG bitfield and a done interrupt DCCx\_INTR\_DONE\_LEVEL is generated. Software must clear the done bit before restarting the counting.

### 12.11.1.3.5 DCC Continuous mode

When DCC runs in continuous mode both the counts shall get reloaded with seed value upon completion of counts without error. If the counts end in error DCC stops the operation and counts are not reloaded.

#### 12.11.1.3.5.1 DCC Continue on Error

During debug, if there are events which are causing clocks to be anomalous over short period covering more than one evaluation window then it would be important to capture trajectory of error event and period around such event. To allow capturing the successive error events DCC can be programmed to continue after error. DCC\_GCTRL2[3-0] CONT\_ON\_ERR shall be set to value other than "0101" to enable this mode. It is recommended to write "1010" to avoid single soft errors.

#### 12.11.1.3.5.2 DCC Error Count

DCC also counts the number of error pulses generated since reset or since last time the error count is cleared. This is read/write register for CPU to clear when new trace of number of errors is required to be maintained.

### 12.11.1.3.6 DCC Control and count hand-off across clock domains

As the counters run in two different selectable clock domains and the register interface runs on the fixed bus clock domain, control signals and counter value hand-off have synchronizers implemented. These add to the margins of error while comparing the counts.

1. With all three counts synchronized to FICLK domain for comparison error detection there is delay in terms of FICLK domain.
2. Based on the error signal, the enable for the counters is synchronized back to the respective clock domains of the counters, which adds latency in terms of clock periods which are different, this would create a skew between start of count. Depending upon frequency ratios of the clocks used, the difference between two could vary.

Application needs to consider the worst case delay differences while measuring the clocks.

### 12.11.1.3.7 DCC Error Trajectory record

Once the clock errors out, the host can read the counter values to determine the extent of error to analyze type of failure. For short window comparisons this would become difficult, specially if there are back to back errors due to some transient event. Secondly, for random events which can cause an interrupt during the critical phase of application running, then event if not recorded may get overwritten and also not provide meaningful trace of error.

#### 12.11.1.3.7.1 DCC FIFO capturing for Errors

DCC provides the FIFO for capturing COUNT0, VALID0, and COUNT1 information which captures all three counts upon "Error" event. For "Done" event no results are captured by default.

#### **12.11.1.3.7.2 DCC FIFO in continuous capture mode**

To track the VALID0 counter values regardless of "Error" or not, FIFOs can be configured to capture the count for each compare window. This is useful in validation and characterization exercise. [DCC\\_GCTRL2\[11-7\]](#) FIFO\_NONERR control when set to value other than "0101" this mode is set; it is recommended to write "1010" to avoid single soft errors. Note, this capture is applicable only in continuous mode and not in single shot mode.

#### **12.11.1.3.7.3 DCC FIFO Details**

The FIFO is 4 deep for each count and updates new count information for all the non-full FIFOs. Information is updated on every configured trigger of error or cycle completion. If full, the next values are not written till at-least one entry is read. Application owns responsibility to read the FIFOs uniformly to keep synchronisation between three entries of the FIFO. Both empty and full indications for individual FIFOs is provided through the [DCC\\_STATUS2](#).

#### **12.11.1.3.7.4 DCC FIFO Debug mode behavior**

Upon debug access, the FIFO pointers should not advance hence not impacting the functional behavior. This requirement is same as other functional blocks in the device.

#### **12.11.1.3.8 DCC Count read registers**

DCC has provision to read the counts during operation. This is performed using DCC\_CNT0, DCC\_VALID0, and DCC\_CNT1 registers. Read from these registers in default mode allows reading the present value of count. This is useful when in single shot mode or mode where DCC stops upon error.

These registers can be used to read the FIFO through the DCC\_GCTRL2[7-4] FIFO\_READ configuration. Reads on the empty FIFO shall provide the contents of last pointed location. Application shall track the empty/full conditions of the FIFOs to track the count records consistently.

Regardless of FIFO\_READ configuration, the FIFO internally keeps updating records based on configured triggers till full.

#### 12.11.1.4 DCC Registers

Table 12-1614 lists the memory-mapped registers for the DCC registers. All register offset addresses not listed in Table 12-1614 through Table 12-1619 should be considered as reserved locations and the register contents should not be modified.

**Table 12-1613. DCC Instances**

Instance	Base Address
DCC0	0080 0000h
DCC1	0080 4000h
DCC2	0080 8000h
DCC3	0080 C000h
DCC4	0081 0000h
DCC5	0081 4000h
DCC6	0081 8000h
DCC7	0081 C000h
DCC8	0082 0000h
DCC9	0082 4000h
DCC10	0082 8000h
DCC11	0082 C000h
DCC12	0083 0000h
MCU_DCC0	4010 0000h
MCU_DCC1	4011 0000h
MCU_DCC2	4012 0000h

Bit	Field	Type	Reset	Description
31-30	SCHEME	R	1h	User, privilege, and debug mode (read): Returns 01. Privilege and debug mode (write): Writes have no effect.
29-28	RESERVED	R	X	

**Table 12-1623. DCC\_REV Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
27-16	FUNC	R	0h	Reflects software-compatibility. If there is no level of software compatibility, a unique func number is assigned for compatible modules, the same number is maintained. User, privilege, and debug mode (read): 0x0 Privilege and debug mode (write): Writes have no effect.
15-11	RTL	R	0h	Incremented for releases due to spec changes or post-release design changes. Reset to 0 when either MAJOR or MINOR is incremented. User, privilege, and debug mode (read): 0x0 Privilege and debug mode (write): Writes have no effect.
10-8	MAJOR	R	2h	Represents major changes to the module (e.g. entirely new features are added/changed). The major revision number for this module. User, privilege, and debug mode (read): 0x2 Privilege and debug mode (write): Writes have no effect.
7-6	CUSTOM	R	0h	Indicates a special version of the module. May not be supported by standard software. User, privilege, and debug mode (read): 0x0 Privilege and debug mode (write): Writes have no effect.
5-0	MINOR	R	4h	Represents minor changes to the module (e.g. enhancements to existing features). The minor revision number for this module. User, privilege, and debug mode (read): 0x4 Privilege and debug mode (write): Writes have no effect.

### 12.11.1.4.3 DCC\_CNTSEED0 Register (Offset = 8h) [reset = X]

DCC\_CNTSEED0 is shown in [Figure 12-1233](#) and described in [Table 12-1625](#).

Return to [Summary Table](#).

Seed value for the counter attached to clock source 0

**Table 12-1624. DCC\_CNTSEED0 Instances**

Instance	Physical Address

9-0	ERRCNT	R/W	0h	Counts the number of errors after the last write to this register or reset. If reached terminal count the count freezes. User needs to clear it.

## 12.11.2 Error Signaling Module (ESM)

This section describes the Error Signaling Module (ESM) in the device.

### 12.11.2.1 ESM Overview

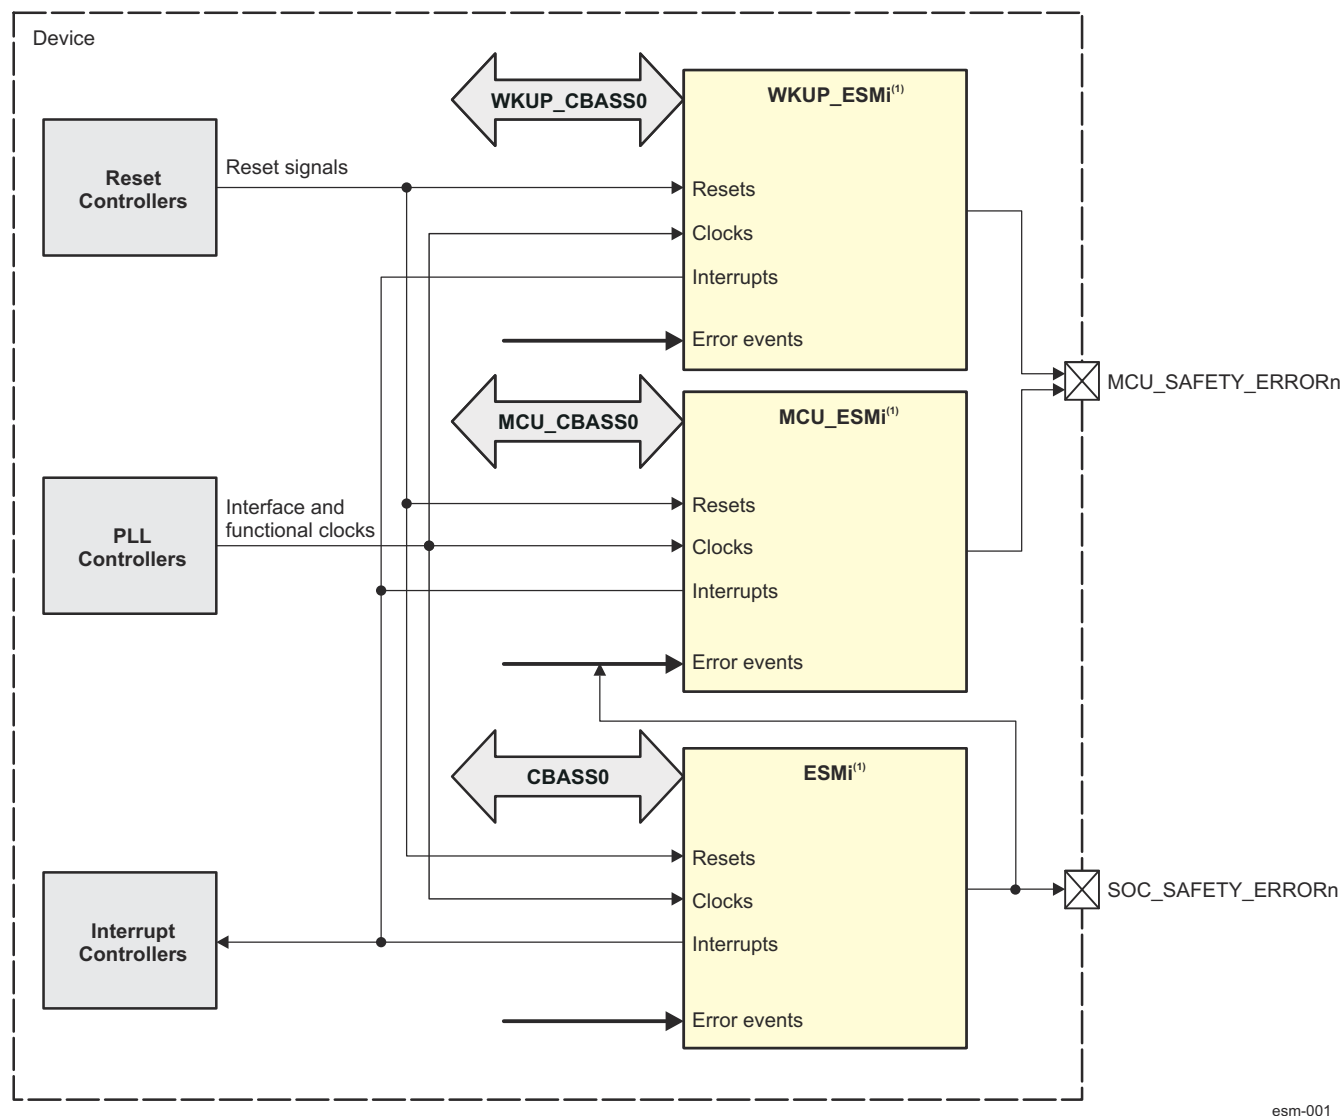

The Error Signaling Module (ESM) aggregates events and/or errors from throughout the device into one location. It can signal both low and high priority interrupts to a processor to deal with an event and/or manipulate an I/O error pin to signal an external hardware that an error has occurred. Therefore an external controller is able to reset the device or keep the system in a safe, known state.

The device has three instances of ESM modules. [Table 12-1648](#) shows ESM modules allocation within device domains.

**Table 12-1648. ESM Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
WKUP_ESM0	✓	-	-
MCU_ESM0	-	✓	-
ESM0	-	-	✓

[Figure 12-1245](#) shows the ESM modules overview.

esm-001

A.  $i = 0$ 
**Figure 12-1245. ESM Modules Overview**

### 12.11.2.1.1 ESM Features

Each ESM module implements the following features:

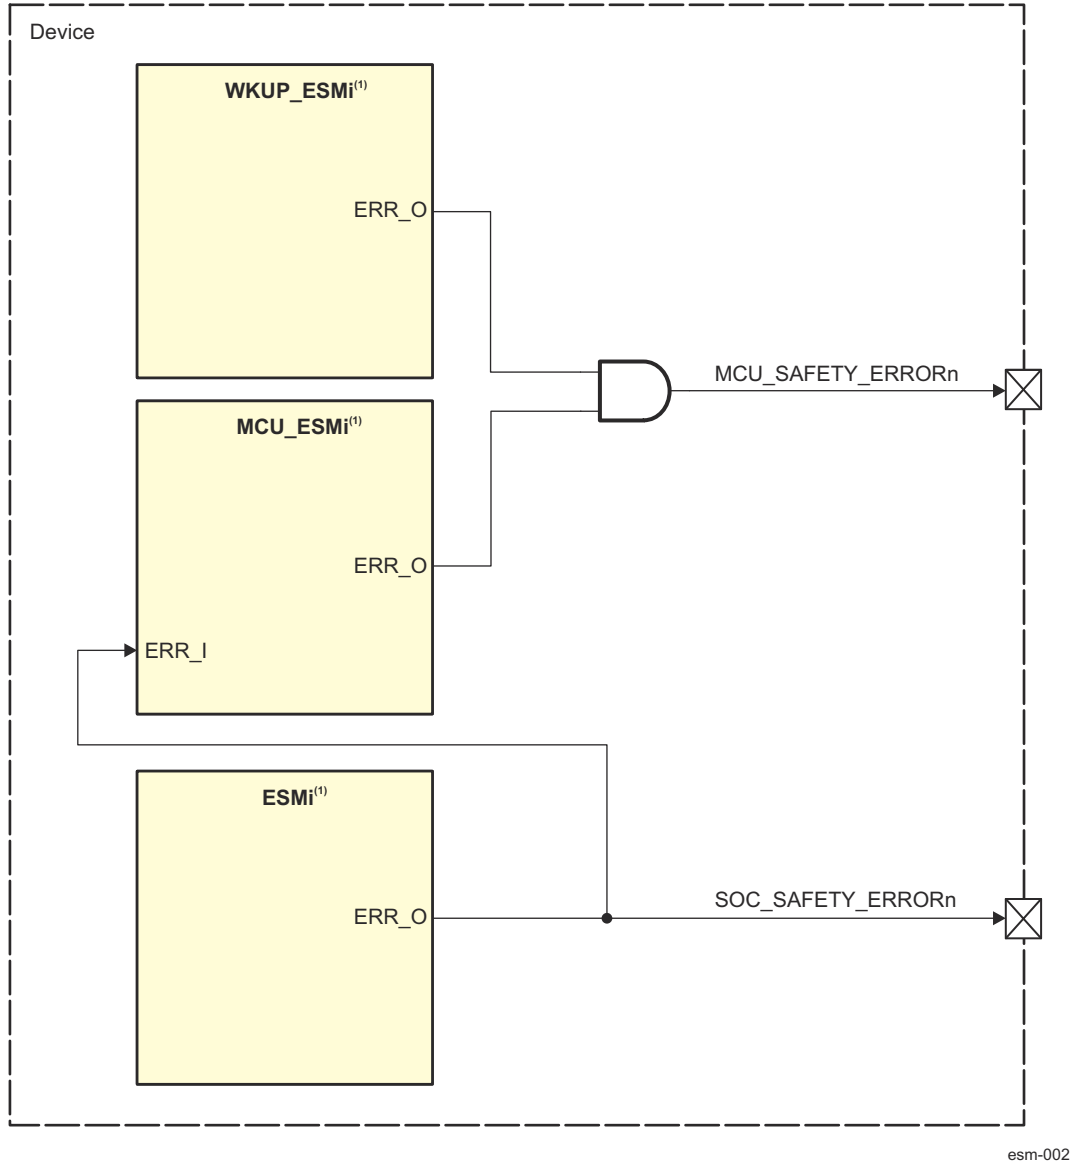

- Up to 1024 error event inputs
  - Implemented in groups of 32 events
  - Level or Pulse inputs (Pulse inputs are triple redundant)
- Selectable low and high priority interrupt error pin prioritization of each error event
- Error pin to signal severe device failure
- Configurable timebase for error signal
- Error forcing capability
- Internal redundant flops on critical fields

### 12.11.2.2 ESM Environment

The WKUP\_ESM0, MCU\_ESM0, and ESM0 modules are hereinafter referred to as ESM module.

This section describes the ESM external connections (environment).

Figure 12-1246 shows the ESM pins used for typical connections with external devices.

A.  $i = 0$

**Figure 12-1246. ESM Modules Environment**

Table 12-1649 describes the ESM I/O signals.

**Table 12-1649. ESM I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
<b>WKUP_ESM0</b>				
ERR_O	MCU_SAFETY_ERRORn	O	Active low error output signal.	0 <sup>(2)</sup>
<b>MCU_ESM0</b>				

**Table 12-1649. ESM I/O Signals (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
ERR_O	MCU_SAFETY_ERRORn	O	Active low error output signal.	0 <sup>(2)</sup>
<b>ESM0</b>				
ERR_O	SOC_SAFETY_ERRORn	O	Active low error output signal.	0 <sup>(2)</sup>

(1) O = Output;

(2) During POR, the pin state is weak pull-down and the I/O is under the control of the device. Once PORz are de-asserted, SAFETY\_ERRORn will be driven by the ESM module

### Note

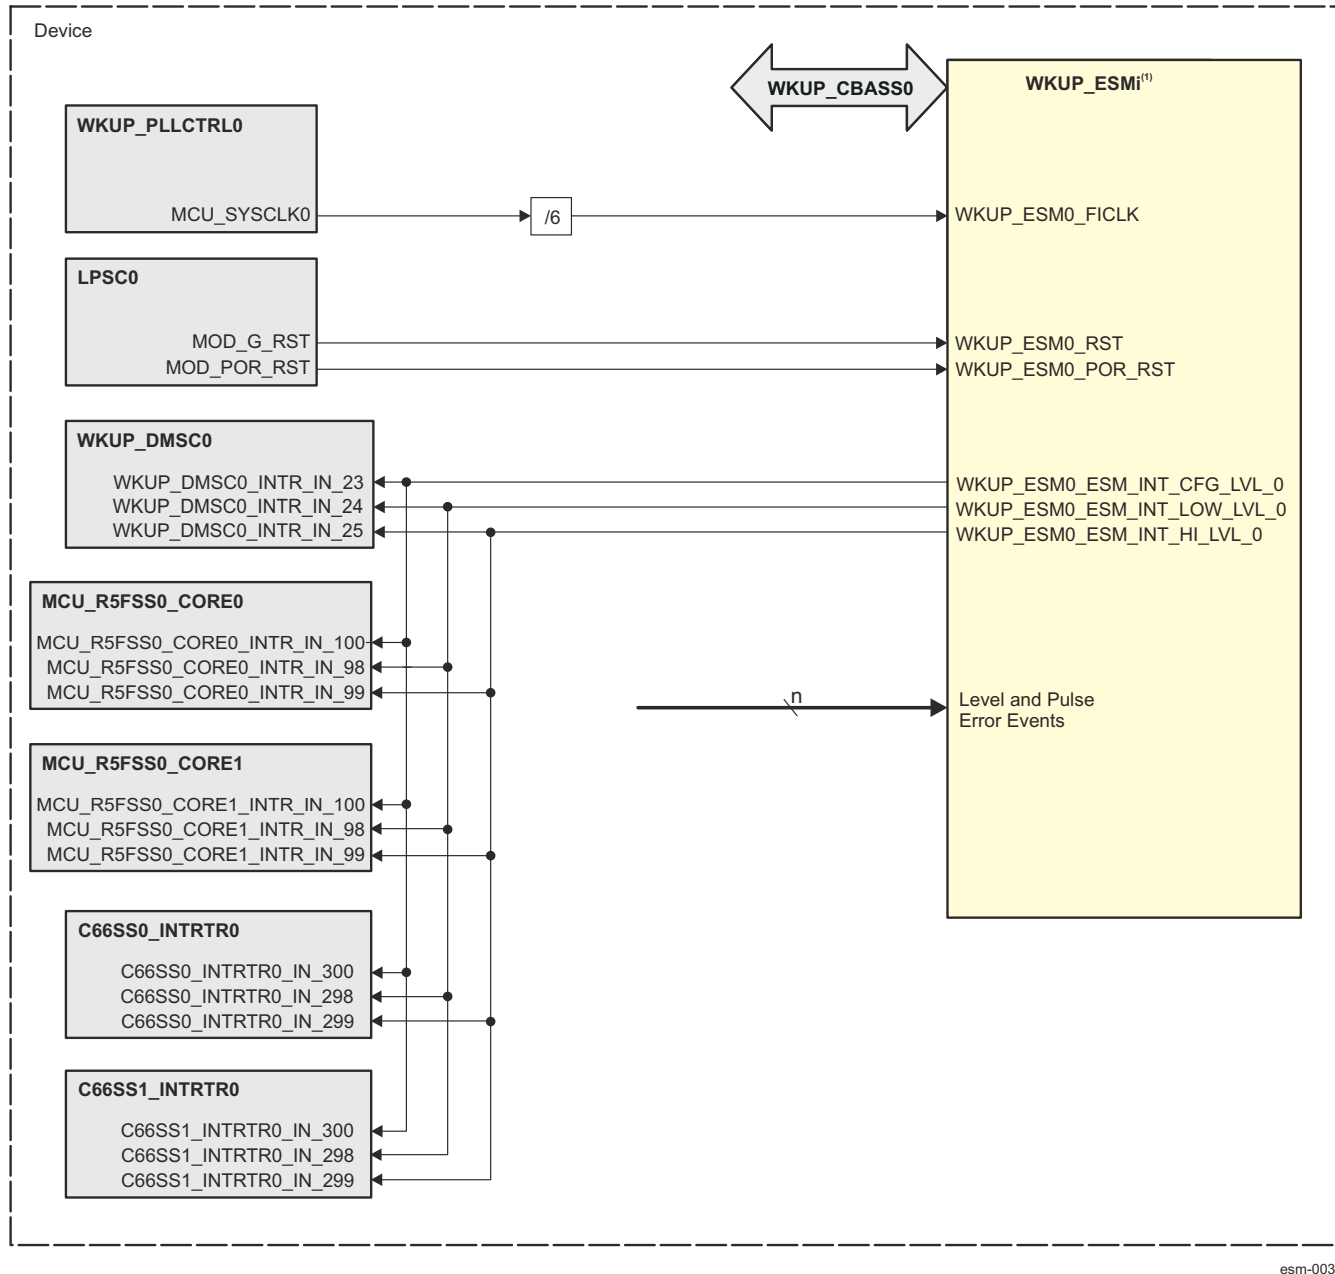

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.11.2.3 ESM Integration

This section describes the ESM integration in the device, including information about clocks, resets, and hardware requests.

#### 12.11.2.3.1 ESM Integration in WKUP Domain

There is one ESM module integrated in the device WKUP domain - WKUP\_ESM0. [Figure 12-1247](#) shows the integration of WKUP\_ESM0.

esm-003

A.  $i = 0$

**Figure 12-1247. WKUP\_ESM Integration**

[Table 12-1650](#) through [Table 12-1652](#) summarize the integration of ESM in the device WKUP domain.

### Note

[Table 12-1658](#) lists only the ESM0 interrupt outputs. For the mapping of system interrupt error events to ESM0 interrupt inputs, see *Interrupt Sources*.

#### 12.11.2.4 ESM Functional Description

The Error Signaling Module (ESM) centralizes fault reports. It provides mechanisms to classify errors by severity and to provide programmable error response. The error classification in the ESM is determined by programmed configuration for each individual error input. For each individual error input the configuration can be set to assert an output error pin, or generate an interrupt to a CPU, or both. When an individual error input is configured to generate an interrupt, the configuration will also select whether the interrupt that is generated will be one of high priority or low priority.

By reporting the faults in a central location, the system may determine what caused the fault and what action can be taken. In general, the faults can be split into two categories:

- Corrected faults
- Non-corrected faults

The ESM reports errors in two ways:

- An interrupt to a processor in the device. This allows the device to analyze and try to recover from an error.
- An external ERROR pin. This allows the system outside of the SoC to monitor for potentially fatal errors(errors that the device cannot self-recover from). Moreover, the external I/O (ERROR pin) will remain asserted (active low) for a minimum period of time. After that period of time, if the error has been cleared by an internal processor, the pin will go inactive (high). If it does not go inactive in that time, then an external agent should intervene, as there may be an unrecoverable error.

Both mechanisms can be used at the same time for the same fault, signaling both an interrupt and the external ERROR pin. This allows the device to attempt to recover, but if it fails, then the external system is still alerted. If it succeeds, then it can remove the ERROR pin assertion so that the external system knows that a potentially unsafe condition was avoided.

Lastly, the ESM does not specify any methods of intervention, only the process of alerting internal CPUs and external monitor(s) of an existing error event.

[Figure 12-1250](#) shows the ESM module block diagram.

**Figure 12-1250. ESM Block Diagram**

#### 12.11.2.4.1 ESM Interrupt Requests

The ESM module generates three output interrupts to the device interrupt controllers:

- Configuration error interrupt (see [Section 12.11.2.4.1.1](#))
- High priority error interrupt (see [Section 12.11.2.4.1.2](#))
- Low priority error interrupt (see [Section 12.11.2.4.1.3](#))

The error interrupt outputs are provided so that a processor in the device can be signaled to intervene when an error event occurs. Each error event input can be enabled, via software, to cause an error interrupt to occur (via the ESM\_INTR\_EN\_SET\_j register). Additionally, each error event input can be programmed to influence either the low priority (default) interrupt or the high priority interrupt (via the ESM\_INT\_PRIO\_j). The low priority interrupt is intended for events that are of interest, but do not require immediate intervention. For example, an indication that there was a single bit error that was corrected may signal a low priority interrupt, so that information can be collected for statistical purposes. A high priority interrupt is intended for events that need immediate attention. For example, an indication that there was an uncorrected two-bit error may be signaled as a high priority interrupt.

##### 12.11.2.4.1.1 ESM Configuration Error Interrupt

The configuration error interrupt (ESM\_INT\_CFG\_LVL\_0) indicates that there is an inconsistency in the configuration of one (or more) error group *j* registers (MMRs).

In such inconsistency in the internal copies of any of the MMRs caused by fault associated with error group *j*, the corresponding raw status will be set in the ESM\_ERR\_RAW register. If the corresponding bit is enabled in the ESM\_ERR\_EN\_SET register, a configuration error interrupt will be triggered.

When a configuration error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_ERR\_STS register to determine which group has a configuration error
2. Write the correct values to the following group registers:

---

**Note**

If there has been a configuration error, the values in the below registers cannot be guaranteed to be correct anymore. Therefore, software should maintain a copy of the correct values prior to an error to ensure that they can be re-programmed with the correct configuration.

---

- a. ESM\_INTR\_EN\_SET\_j
  - b. ESM\_INTR\_EN\_CLR\_j
  - c. ESM\_INT\_PRIO\_j
  - d. ESM\_PIN\_EN\_SET\_j
  - e. ESM\_PIN\_EN\_CLR\_j
3. Service any pending interrupts in steps 4, 5, and 6 below
- 

**Note**

The raw status of any pending interrupts may be inconsistent. Servicing the interrupt will return it to consistency via the error group ESM\_RAW\_j register.

---

4. Write 0x1 to the appropriate bits in the ESM\_ERR\_STS register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no additional errors, the level interrupt will go low
5. Write the end of interrupt vector to the ESM\_EOI register
  - a. If there are additional configuration error interrupts pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error interrupts pending, there will be no new pulse.

**12.11.2.4.1.2 ESM Low Priority Error Interrupt**

Events mapped to the low priority error interrupt (ESM\_INT\_LOW\_LVL\_0) are intended to be events of interest that should be addressed eventually, not events that require immediate attention. An example would be an event indicating a corrected error. The system may want to track this for statistical purposes, but it does not require immediate attention.

Any error event can be mapped to the low priority error interrupt. A low priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j register) and mapped to the low priority error interrupt (via ESM\_INT\_PRIO\_j register) and the raw status is set (via the ESM\_RAW\_j register).

When a low priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_LOW\_PRI register
    - a. If both [31-16]PLS and [15-0]LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
    - b. If either [31-16]PLS or [15-0]LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
      - i. First option: Record the value in [31-16]PLS and [15-0]LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority low priority error event
- 

**Note**

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

---

- ii. Second option:
  1. Read the ESM\_LOW register to determine which event group(s) have pending low priority error interrupts

2. Read the desired error group  $j$  ESM\_STS\_ $j$  register
  3. Identify which low priority interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.11.2.4.1.2.1](#)) or pulse (see [Section 12.11.2.4.1.2.2](#)) event.

#### 12.11.2.4.1.2.1 ESM Low Priority Error Level Event

When a low priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the low priority error level event at the source
2. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_ $j$  register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are low priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional low priority error level events enabled and pending, there will be no new pulse
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_ $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.11.2.4.1.2.2 ESM Low Priority Error Pulse Event

When a low priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_ $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are additional low priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional low priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_ $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.11.2.4.1.3 ESM High Priority Error Interrupt

Events mapped to the high priority error interrupt are intended to be events that require immediate intervention from the system because a potentially dangerous error has occurred. An example would be an event indicating an uncorrected error. The system will want to diagnose the issue and intervene to ensure there are no violations.

Any error event can be mapped to the high priority error interrupt. A high priority error interrupt will be generated when an event is enabled to cause an interrupt (via the ESM\_INTR\_EN\_SET\_j) register and mapped to the high priority interrupt (via the ESM\_INT\_PRIO\_j) register and the raw status is set (via the ESM\_RAW\_j).

When a high priority error interrupt is received, the acting processor must perform the following steps:

1. Read the ESM\_HI\_PRI register
  - a. If both [31-16] PLS and [15-0] LVL bit fields are equal to 0xFFFF, then interrupt is no longer asserted and the interrupt routine has ended.
  - b. If either [31-16] PLS or [15-0] LVL bit fields are not equal to 0xFFFF, software has two options for determining what event to service:
    - i. First option: Record the value in [31-16] PLS and [15-0] LVL bit fields. Determine which is higher priority. This is based on the global event map number of the highest priority high priority error event.

---

#### Note

The global event map is neither defined by nor maintain in ESM. The global event map must be defined and maintained by software using software determined memory resources. It is conceivable that the global event map will be predefined and loaded during the execution of a secondary boot loader.

- ii. Second option:
    1. Read the ESM\_HI register to determine which event group(s) have pending high priority error interrupts
    2. Read the desired error group *j* ESM\_STS\_j register
    3. Identify which high priority error interrupt to service
2. Determine, based on the global event map for the device, where the error event came from
3. Service the error event based on the IP's specification:
  - a. The system may take several actions including (but not limited to):
    - i. Fixing the error
    - ii. Resetting the errored IP peripheral
    - iii. Resetting the device
    - iv. Communicating outside the device via the error pin for outside intervention

The rest of the steps assume that the error has been handled and the system wants to clear the error event. Clearing the error event depends on whether the event is a level (see [Section 12.11.2.4.1.3.1](#)) or pulse (see [Section 12.11.2.4.1.3.2](#)) event.

#### 12.11.2.4.1.3.1 ESM High Priority Error Level Event

When a high priority error level event has to be cleared, the acting processor must perform the following steps:

1. Clear the error event at the source
2. Write 0x1 to the appropriate bit in the error group *j* of the ESM\_STS\_j register. This step will clear the raw status
  - a. If the error event is still asserted (or re-asserted) the raw status will be set back to 0x1
  - b. If there are no error events, the level will de-assert

---

#### Note

There is a possible software race condition if software manages to write to the Clear register before the de-asserted level from the source has been synchronized to the ESM clock. If this is an issue, software may perform a read-back at the source IP before writing the clear register to insure order.

3. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error level events enabled and pending, then a new pulse will be generated
  - b. If there are no additional high priority error level events enabled and pending, there will be no new pulse

4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_ $j$  register, but may be done regardless as an extra CLEAR is not harmful.

#### 12.11.2.4.1.3.2 ESM High Priority Error Pulse Event

When a high priority error pulse event has to be cleared, the acting processor must perform the following steps:

1. Write 0x1 to the appropriate bit in the error group  $j$  of the ESM\_STS\_ $j$  register. This will clear the raw status and will de-assert the level interrupt.
2. Write the end of interrupt vector to the ESM\_EOI interrupt register
  - a. If there are high priority error pulse events enabled and pending, then a new pulse will be generated and the level interrupt will remain asserted
  - b. If there are no additional high priority error pulse events enabled and pending, there will be no new pulse
3. Clear the error event at the source. The source may generate a new pulse which will show up as a new error event at the ESM
4. Write a CLEAR (0x5) to the ESM\_PIN\_CTRL register. This step is optional if the event is not enabled to influence the error pin (error group  $j$  ESM\_PIN\_EN\_SET\_ $j$  register), but may be done regardless as an extra CLEAR is not harmful.

#### 12.11.2.4.2 ESM Error Event Inputs

The ESM can have up to 1024 error event inputs, configurable by groups of 32. For the mapping of system interrupt error events to ESM interrupt inputs, see *Interrupt Sources*.

Level error events (active high) are synchronized to the ESM clock. This synchronized value is captured in to a flop.

Pulse error events use rising edge detection. Each pulse error event has 3 redundant inputs. Each input has its own edge detection logic. Multiple transmission protects against Single Event Upsets (SEUs, transient errors) causing a pulse to be lost during transmission and against failure of the edge detection logic. Once an edge has been detected on any of the three inputs, the ESM\_RAW\_ $j$  status is set. Subsequent pulses are likely to come concurrently or quickly enough that software will not have reacted yet. This logic is intentionally biased against false negatives and towards false positives. An SEU that causes an event where none actually occurred will cause software to be called in to action. Software must observe that there is no real error and clear the false status.

#### 12.11.2.4.3 ESM Error Pin Output

The error pin output (ERR\_O) is used to signal an external agent that it needs to (or may need to) intervene because of an error. Each error event input can be programmed, via software, to influence the error pin output (via the ESM\_PIN\_EN\_SET\_ $j$  register). The error pin output is active low.

During Power-On Reset (POR), the error pin is active (asserted low) and the device drives this via a weak internal pull-down. The I/O is under the control of the device. When POR is removed from the ESM, it will be driving the error pin inactive (high) so the device can hand over control to the ESM. The user may also add an external pull-down that is only active when the device is in reset.

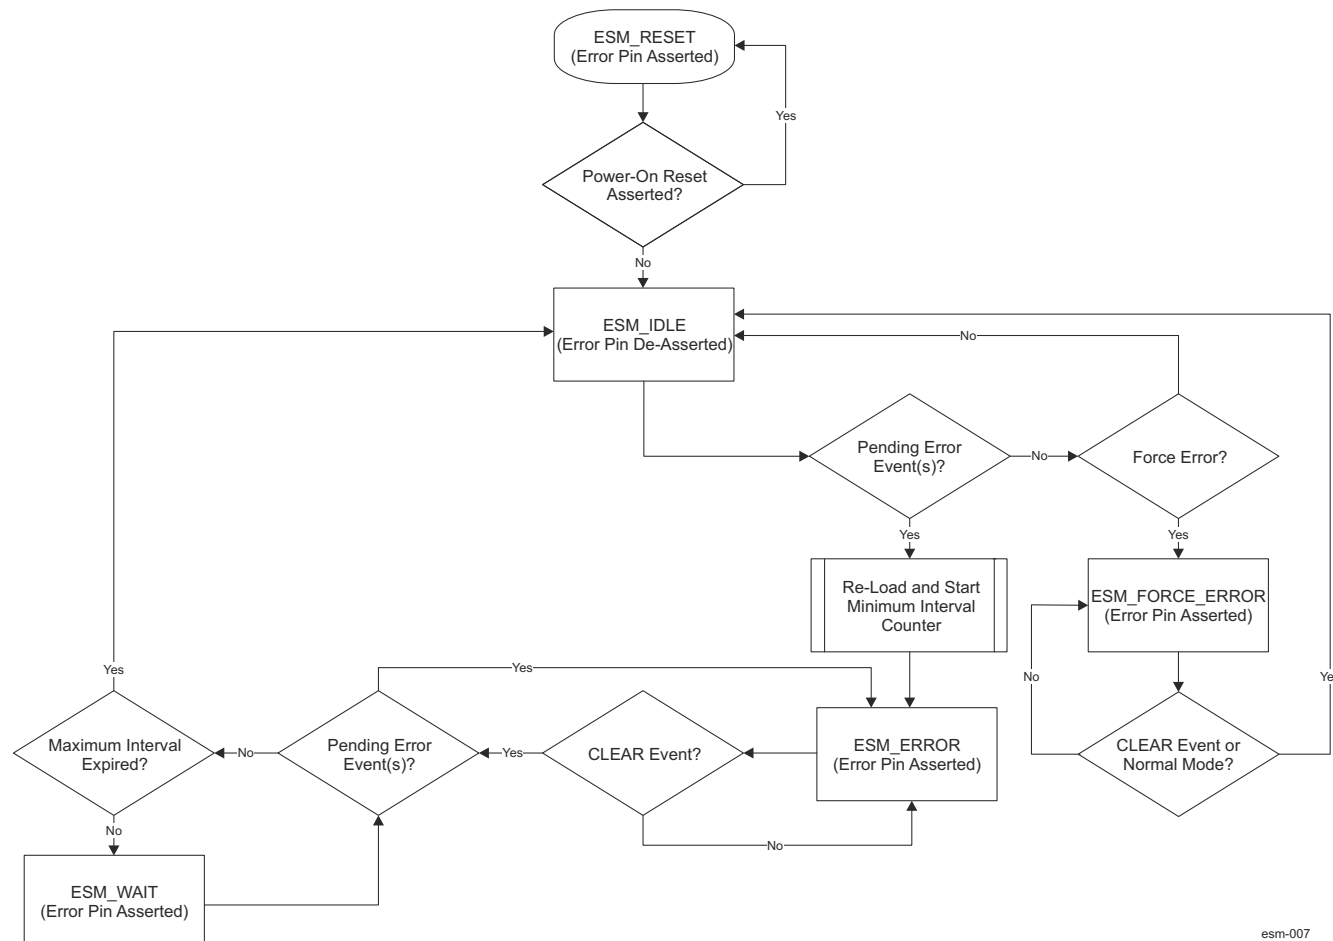

During a warm reset the state of the error pin is unchanged, that is the error pin logic is only reset by a POR. The device leaves the I/O active during a warm reset.

The ESM has also a software error forcing capability on the error pin. That is, a force error can be set via the ESM\_EN[3-0] KEY bit field.

### CAUTION

The isolation value for the ERR\_O output of ESM is active (0). This is intended and supposed to protect against an accidental transition to a low power state. If the actual low power mode transition is intended, the PMIC should be made aware by software to ignore the ESM error signal. Otherwise device resets will be asserted from companion chip.

Figure 12-1251 describes the behavior of the error pin. Not shown is that a reset (Power-On-Reset only) will immediately transition the error pin to the ESM\_RESET state and a Global Soft Reset will immediately transition the error pin to the ESM\_IDLE state. A pending error interrupt event is any error event with the raw state set and the error pin Influence enabled. There are two types of "clear" events associated with servicing the error pin. The first is to clear the status of the pending event (see Section 12.11.2.4.1 for how to clear level and pulse pending events). The second is the CLEAR event meant to de-assert the error pin.

**Figure 12-1251. ESM Error Pin State Flowchart**

If an error event happens that has been programmed to influence the error pin, the error pin will assert (active low) for a minimum time (as programmed by the ESM\_PIN\_CNTR\_PRE register). In order for the error pin to de-assert, the following 3 things must happen:

1. The minimum time interval must expire
2. The event that caused the error pin to assert must be cleared (see Section 12.11.2.4.1)
3. A CLEAR (0x5) must be written to the ESM\_PIN\_CTRL register.

#### Note

Step 3 should happen after step 2, but either (or both) of these steps may happen before or after step 1.

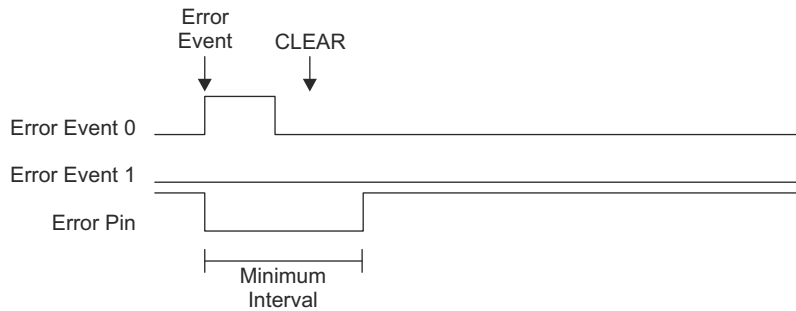

Figure 12-1252 shows a typical error pin assertion.

esm-008

**Figure 12-1252. ESM Error Pin Assertion**

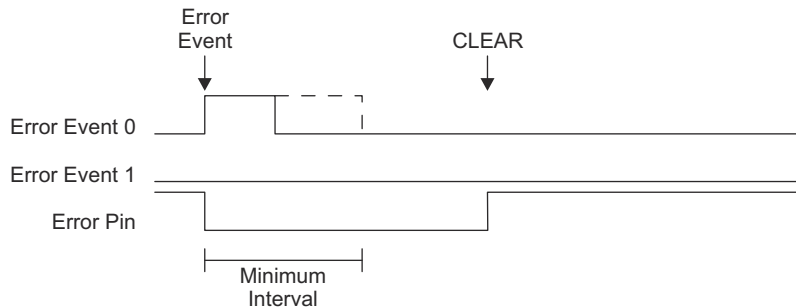

If, during the minimum time, CLEAR is written to the error key, then the error pin will de-assert after the minimum time interval, as shown in [Figure 12-1253](#).

esm-009

**Figure 12-1253. ESM Error Pin Assertion with CLEAR during Minimum Interval**

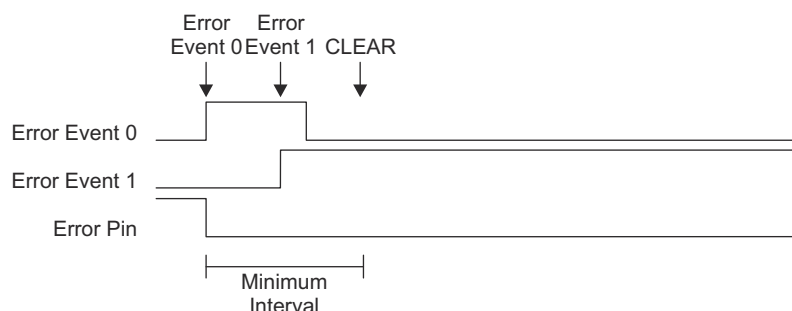

If CLEAR is not written till after the minimum time interval, the error pin will de-assert when CLEAR is written. This is regardless of whether the error interrupt event itself is removed before or after the minimum time interval, as shown by the dotted line in [Figure 12-1254](#).

esm-010

**Figure 12-1254. ESM Error Pin Asserting with CLEAR after Minimum Interval**

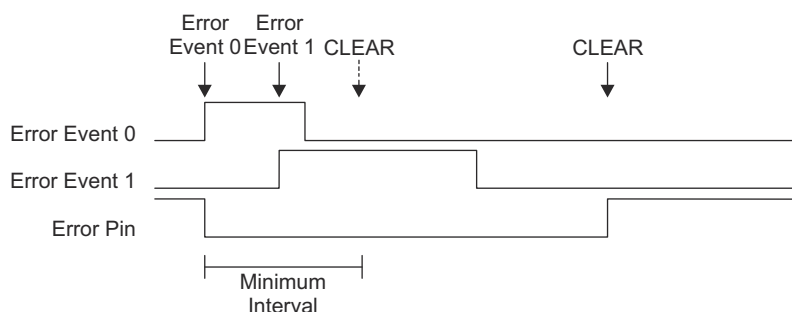

When in the ESM\_ERROR state and a CLEAR event happen, if there are still pending error events, the ESM stays in the ESM\_ERROR state with the error pin asserted. Multiple error events when in the ESM\_ERROR state do not reset the minimum time interval counter as shown in [Figure 12-1255](#).

esm-011

**Figure 12-1255. ESM Error Pin Asserting with Interval Reset by Additional Error Event(s)**

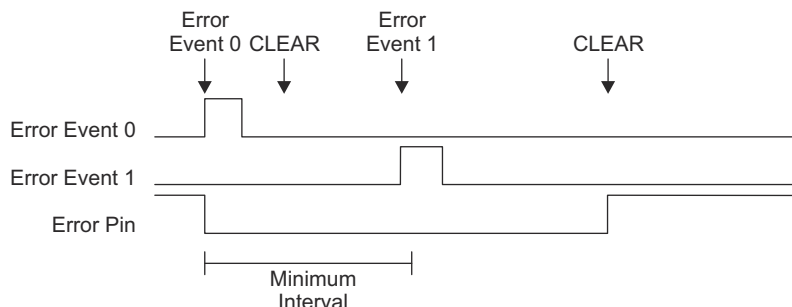

A CLEAR event causes a re-evaluation of whether there are any pending error events. As such, a single CLEAR can be used to clear the error pin after multiple error events. Multiple CLEAR events can occur (such as the one with the dotted arrow shown in Figure 12-1256), but are not necessary. No matter how many error events occur nor when (or how many) CLEAR events occur, the error pin will always be asserted for at least the minimum time interval

esm-012

**Figure 12-1256. ESM Error Pin Asserting with Single CLEAR for Multiple Events**

If all error events are cleared and the ESM is in the ESM\_WAIT state, waiting for the minimum time interval to expire, and a new error interrupt event occurs, the ESM will go back to the ESM\_ERROR state. The minimum time interval will not reset, but a new CLEAR event will be required as shown in Figure 12-1257.

esm-013

**Figure 12-1257. ESM Error Pin Asserting with New Error During Minimum Time Interval**

Table 12-1659 shows some common scenarios of how the error pin as well as the two associated registers (ESM\_PIN\_CTRL and ESM\_PIN\_STS) will be set.

**Table 12-1659. ESM Error Pin Scenarios**

Scenario	Error Pin State Value	ESM_PIN_CTRL[3-0] KEY	ESM_PIN_STS[0] VAL status value	Additional Notes
POR Asserted	0	N/A	N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
After de-assertion of POR	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was not asserted when reset asserted)	1	0x0 (Normal Mode)	0x0	-
After de-assertion of Warm Reset (error was asserted when reset asserted)	0	0x0 (Normal Mode)	0x1	-
Force error pin	0	0xA (Force Error Mode)	0x0	Forcing error on the pin via software.

#### 12.11.2.4.4 ESM Minimum Time Interval

The minimum time interval is the minimum amount of time that the error pin will be asserted (active low) when an enabled error interrupt event happens. This value is system dependent, but should be enough time so that the external monitoring agent can always see the error pin asserted, but short enough so that if all of the error events are cleared, then the error pin can be de-asserted before the external agent decides to intervene. This is highly dependent on the application and the Fault Tolerant Time Interval.

The Minimum Time Interval counter is clock cycle based, therefore the time of the interval is a combination of the value in the ESM\_PIN\_CNTR\_PRE register and the clock frequency of the ESM. Software must calculate the value accordingly. The Minimum Time Interval should be set according to the needs of the application.

#### 12.11.2.4.5 ESM Protection for Registers

The configuration for each error group *j* of registers are backed up by 3 flops in order to protect against single or double-bit errors. When written, all 3 bits are set to the same value. When read (and for functioning of the internal state machines) the value is the OR of all 3 bits. Whenever any of the bits disagree, the Configuration Error interrupt is asserted (if enabled). The registers covered by this mechanism are:

- ESM\_ERR\_RAW
- ESM\_ERR\_STS
- ESM\_ERR\_EN\_SET
- ESM\_ERR\_EN\_CLR
- ESM\_RAW<sub>j</sub>
- ESM\_STS<sub>j</sub>
- ESM\_INTR\_EN\_SET<sub>j</sub>
- ESM\_INTR\_EN\_CLR<sub>j</sub>
- ESM\_INT\_PRIO<sub>j</sub>
- ESM\_PIN\_EN\_SET<sub>j</sub>
- ESM\_PIN\_EN\_CLR<sub>j</sub>

The error pin control register ESM\_PIN\_CTRL contains a multi-bit field KEY. The key value ensures normal operation on the error pin and that an error even will be generated if one occurs. Software should periodically read check the KEY bit field value and make sure it is 0x0. If the value is not 0x0, software must re-write it to this key value (unless in test mode forcing an error on the pin) to ensure the normal operation. [Table 12-1660](#) lists the KEY values and their respective meaning.

**Table 12-1660. ESM Error Pin Control Values**

ESM_PIN_CTRL[3-0] KEY	Description
N/A	Registers are inaccessible. Device disables the I/O and pulls down internally.
0x0 (Normal)	Normal operation mode - Error pin will activate when an enabled error event occurs.

**Table 12-1660. ESM Error Pin Control Values (continued)**

ESM_PIN_CTRL[3-0] KEY	Description
0xA (Force Error)	Force error mode - Forces the error pin active. To clear the error pin (return to the ESM_IDLE state) write this field back to normal mode (writing a CLEAR event will also work). Force error mode must be set only while in IDLE. Attempting force error while in another state will have no effect.
0x5 (CLEAR)	CLEAR Event - generates a CLEAR event to the ESM state machine. KEY will return to normal mode (0x0) on the next cycle.
Other Values	All other values - Normal mode. Writing any of these values will have no effect. When reading any of these values indicates that one or more bits have experienced a single event upset, software should write the field back to 0x0. The ESM will continue to operate in normal mode.

The error pin counter pre-load register ESM\_PIN\_CNTR\_PRE should also be read and checked periodically by software.

#### 12.11.2.4.6 ESM Clock Stop

The ESM can only be put in to clock stop if all of the internal state machines are idle and the [3-0] KEY bit field for the global enable command is cleared in the ESM\_EN register.

### 12.11.3 Memory Cyclic Redundancy Check (MCRC) Controller

This chapter describes the Memory Cyclic Redundancy Check (MCRC) controller in the device.

#### 12.11.3.1 MCRC Overview

VBUSM CRC controller is a module which is used to perform CRC (Cyclic Redundancy Check) to verify the integrity of a memory system. A signature representing the contents of the memory is obtained when the contents of the memory are read into MCRC Controller. The responsibility of MCRC controller is to calculate the signature for a set of data and then compare the calculated signature value against a pre-determined good signature value. MCRC controller provides four channels to perform CRC calculation on multiple memories in parallel and can be used on any memory system.

**Table 12-1661. MCRC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_MCRC0	-	-	✓ (NAVSS)
MCU_NAVSS0_MCRC0	-	✓ (MCU NAVSS)	-

#### 12.11.3.1.1 MCRC Features

MCRC has the following features:

- Four channels to perform background signature verification on any memory subsystem
- Data compression on 8-, 16-, 32-, and 64-bit data size
- Maximum-length PSA (Parallel Signature Analysis) register constructed based on 64-bit primitive polynomial
- Each channel has a CRC Value Register which contains the pre-determined CRC value
- Use timed base event trigger from timer to initiate DMA data transfer
- Programmable 20-bit pattern counter per channel to count the number of data patterns for compression
- Three modes of operation:
  - Auto
  - Semi-CPU
  - Full-CPU
- For each channel, CRC can be performed either by MCRC Controller or by CPU
- Automatically performs signature verification without CPU intervention in AUTO mode
- Generates interrupt to CPU in Semi-CPU mode to allow CPU to perform signature verification itself
- Generates CRC fail interrupt in AUTO mode if signature verification fails
- Generates Timeout interrupt if CRC is not performed within the time limit
- Generates DMA request per channel to initiate CRC value transfer
- An 128-byte block burst address for the PSA register to DMA without constant mode bus attribute

#### 12.11.3.1.2 MCRC Not Supported Features

The following features are not supported by the module:

- Data trace capability on VBUSM, ITCM and DTCM data buses.

**Table 12-1664. MCRC Hardware Requests (continued)**

Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
NAVSS0_MCRC0	INT_MCRC_INTR	IN_INTR[388]	INTR_ROUTER0	MCRC Interrupt signal	Level
DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
NAVSS0_MCRC0	DMA_EVENT_INTR0	IN_INTR[384]	INTR_ROUTER0	MCRC DMA event for channel 1	Pulse
		INTAGGR_LEVI_PEND[0]	UDMASS_INTR_AGGR0		
	DMA_EVENT_INTR1	IN_INTR[385]	INTR_ROUTER0	MCRC DMA event for channel 2	Pulse
		INTAGGR_LEVI_PEND[1]	UDMASS_INTR_AGGR0		
	DMA_EVENT_INTR2	IN_INTR[386]	INTR_ROUTER0	MCRC DMA event for channel 3	Pulse
		INTAGGR_LEVI_PEND[2]	UDMASS_INTR_AGGR0		
	DMA_EVENT_INTR3	IN_INTR[387]	INTR_ROUTER0	MCRC DMA event for channel 4	Pulse
		INTAGGR_LEVI_PEND[3]	UDMASS_INTR_AGGR0		

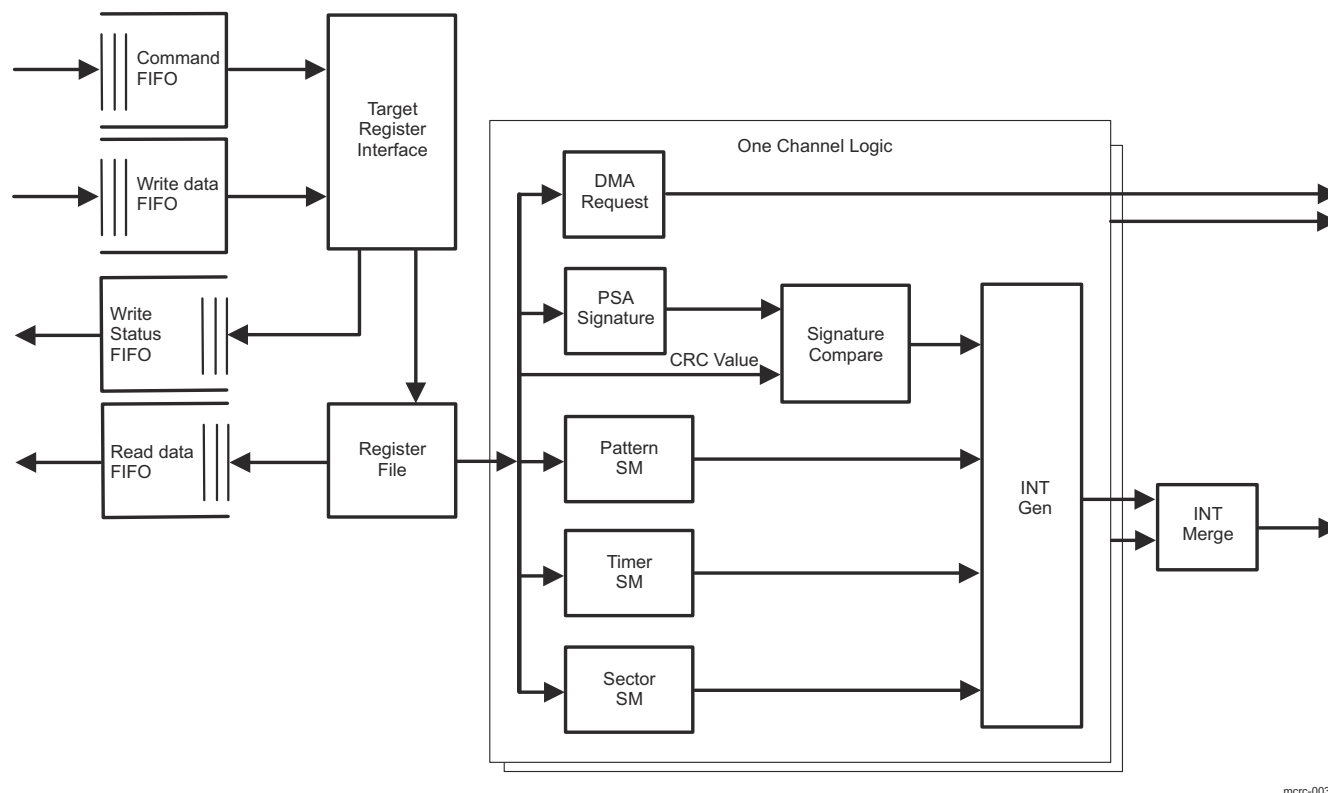

### Note

If DMA\_EVENT\_INTR[0-3] needs to be converted to level interrupts, then UDMASS\_INTR\_AGGR0 can be used to generate events to the PSILSS. PSILSS would route events back to the interrupt aggregator to be turned into level output interrupts.

### 12.11.3.3 MCRC Functional Description

#### 12.11.3.3.1 MCRC Block Diagram

Figure 12-1259 shows the MCRC internal blocks.

**Figure 12-1259. MCRC Block Diagram**

- **Command FIFO**: The Command FIFO pipelines the commands to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 4 elements deep.
- **Write FIFO**: The Write FIFO pipelines the write data to the target register interface. The Command and Write FIFOs allow the data to be coincident for processing. If there is no space for writes in the Write Status FIFO or no space in the Read Data FIFO for reads, the command processing will be halted until there is space in the appropriate FIFO. This FIFO is 2 elements deep.
- **Write Status FIFO**: The Write Status FIFO pipelines the write status back to the VBUSM. A write status will be issued on the final data phase of a write command. This FIFO is 2 elements deep.
- **Read Data FIFO**: The Read Data FIFO pipelines the read data back to the VBUSM. This FIFO is 3 elements deep.
- **Target Register Interface**: The Target Register Interface directs the written data to the register file.
- **PSA Signature**: The PSA Signature creates the signature of the data written. This data will then be compared to the CRC Value or read by software to determine goodness.
- **Pattern State Machine**: The Pattern State Machine determines when a block of data has been serviced.
- **Timer State Machine**: The Timer State Machine determines when overrun and under-run events are detected.
- **Sector State Machine**: The Sector State Machine determines when a sector error should be captured so the software can determine the errant block of data.
- **Signature Compare**: The Signature Compare block compares the current signature to the CRC Value register and sends the result to the Interrupt Generation block.

### 12.11.3.3.2 MCRC General Operation

There are four channels in MCRC controller and for each channel there is a PSA (Parallel Signature Analysis) Signature Register (MCRC\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC\_CRC\_REGL1-4).

A memory can be organized into multiple sectors with each sector consisting of multiple data patterns. A data pattern can be a 8-, 16-, 32-, or 64-bit data. MCRC module performs the signature calculation and compares the signature to a pre-determined value. The PSA Signature Register compresses an incoming data pattern into a signature when it is written. When one sector of data patterns are written into PSA Signature Register, a final signature corresponding to the sector is obtained. CRC Value Register stores the pre-determined signature corresponding to one sector of data patterns. The calculated signature and the pre-determined signature are then compared to each other for signature verification. To minimize CPU's involvement, data patterns transfer can be carried out at the background of CPU using DMA controller. DMA is setup to transfer data from memory of which the contents to be verified to the memory mapped PSA Signature Register. When DMA transfers data to the memory mapped PSA Signature Register, a signature is generated.

A programmable 20-bit data pattern counter is used for each channel to define the number of data patterns to calculate for each sector. Signature verification can be performed automatically by MCRC controller in AUTO mode or by CPU itself in Semi-CPU or Full-CPU mode. In AUTO mode, a self-sustained CRC signature calculation can be achieved without any CPU intervention.

### 12.11.3.3.3 MCRC Modes of Operation

MCRC Controller can operate in AUTO, Semi-CPU, and Full-CPU modes.

#### 12.11.3.3.3.1 AUTO Mode

In AUTO mode, MCRC Controller in conjunction with DMA controller can perform CRC without CPU intervention. A sustained transfer of data to both the PSA Signature Register (MCRC\_PSA\_SIGREGL1-4) and a CRC (Cyclic Redundancy Check) Value Register (MCRC\_CRC\_REGL1-4) are performed in the background of CPU. When a mismatch is detected, an interrupt is generated to the CPU. A 16-bit, current sector ID register (MCRC\_CRC\_CURSEC\_REG1-4) is provided to identify which sector causes a CRC failure.

#### 12.11.3.3.3.2 Semi-CPU Mode

In Semi-CPU mode, DMA controller is also utilized to perform data patterns transfer to PSA Signature Register (MCRC\_PSA\_SIGREGL1-4). Instead of performing signature verification automatically, the CRC controller generates an compression complete interrupt to CPU after each sector is compressed. Upon responding to the interrupt the CPU performs the signature verification by reading the calculated signature stored at the PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4) and compare it to a pre-determined CRC value.

#### 12.11.3.3.3.3 Full-CPU Mode

In Full-CPU mode, the CPU does the data patterns transfer and signature verification all by itself. When CPU has enough throughput, it can perform data patterns transfer by reading data from the memory system to the PSA Signature Register (MCRC\_PSA\_SIGREGL1). After certain number of data patterns are compressed, the CPU can read from the PSA Signature Register and compare the calculated signature to the pre-determined CRC signature value. In Full-CPU mode, neither interrupt nor DMA request is generated. All counters are also disabled.

### 12.11.3.3.4 PSA Signature Register

The 64-bit PSA Signature Register (MCRC\_PSA\_SIGREGL1-4 and MCRC\_PSA\_SIGREGLH1-4) is based on one of the selected CRC polynomials to produce the maximum length LFSR (Linear Feedback Shift Register).

$$\text{CRC16: } f(x) = x^{16} + x^{12} + x^5 + 1 \quad (29)$$

$$\text{CRC32: } f(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \quad (30)$$

$$\text{CRC64: } f(x) = x^{64} + x^4 + x^3 + x + 1 \quad (31)$$

$$\text{SAE J1850 CRC8: } f(x) = x^8 + x^4 + x^3 + x^2 + 1 \quad (32)$$

$$\text{H2F Autosar 4.0: } f(x) = x^5 + x^3 + x^2 + x + 1 \quad (33)$$

$$\text{CASTAGNOLI, iSCSI: } f(x) = x^{28} + x^{27} + x^{26} + x^{25} + x^{23} + x^{22} + x^{20} + x^{19} + x^{18} + x^{14} + x^{13} + x^{11} + x^{10} + x^9 + x^8 + x^6 + 1 \quad (34)$$

$$\text{E2E Profile 4: } f(x) = x^{31} + x^{30} + x^{29} + x^{28} + x^{26} + x^{23} + x^{21} + x^{19} + x^{18} + x^{15} + x^{14} + x^{13} + x^{12} + x^{11} + x^9 + x^8 + x^4 + x + 1 \quad (35)$$

- A. More details of the 64-bit primitive polynomial can be found at W. Stahnke, Primitive binary polynomials, Math. Comp. 27 (1973), 977–980.

There is one PSA Signature Register per CRC channel. PSA Signature Register can be both read and written. When it is written, it can either compress the data or just capture the data depending on the state of CHI\_MODE bits (where i = 1 to 4). If CHI\_MODE=0x0 (Data Capture), a seed value can be planted in the PSA Signature Register without compression. Other modes other than Data Capture will result with the data compressed by PSA Signature Register when it is written. Each channel can be planted with different seed value before compression starts. When PSA Signature Register is read, it gives the calculated signature.

MCRC Controller should be used in conjunction with the on-chip DMA controller to produce optimal system performance. The incoming data pattern to PSA Signature Register is typically initiated by the DMA controller. When DMA is properly setup, it would read data from the pre-determined memory system and write them to the memory mapped PSA Signature Register. Each time PSA Signature Register is written a signature is generated. CPU itself can also perform data transfer by reading from the memory system and perform write operation to PSA Signature Register if CPU has enough throughput to handle data patterns transfer.

After a system reset and when AUTO mode is enabled, MCRC Controller automatically generates a DMA request to request the pre-determined CRC value corresponding to the first sector of memory to be checked.

In AUTO mode, when one sector of data patterns is compressed, the signature stored at the PSA Signature Register is first copied to the PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4) and PSA Signature Register is then cleared out to all zeros. An automatic signature verification is then performed by comparing the signature stored at the PSA Sector Signature Register to the CRC Value Register (MCRC\_CRC\_REGL1-4). After the comparison the MCRC Controller can generate a DMA request. Upon receiving the DMA request the DMA controller will update the CRC Value Register by transferring the next pre-determined signature value associated with the next sector of memory system. If the signature verification fails then MCRC Controller can generate a CRC fail interrupt.

In Full-CPU mode, no DMA request and interrupt are generated at all. The number of data patterns to be compressed is determined by CPU itself. Full-CPU mode is useful when DMA controller is not available to perform background data patterns transfer. Software can periodically generate a software interrupt to CPU and use CPU to accomplish data transfer and signature verification.

MCRC Controller supports double word, word, half word and byte access to the PSA Signature Register. During a non-doubleword write access, all unwritten byte lanes are padded with zeros before compression. Note that comparison between PSA Sector Signature Register and CRC Value Register is always in 64 bits because a compressed value is always expressed in 64 bits.

There is a software reset per channel for PSA Signature Register. When set, the PSA Signature Register is reset to all zeros.

PSA Signature Register is reset to zero under the following conditions:

- System reset
- PSA Software reset
- One sector of data patterns is compressed

### 12.11.3.3.5 PSA Sector Signature Register

After one sector of data is compressed, the final resulting signature calculated by PSA Signature Register is transferred to the 64-bit PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4 and MCRC\_PSA\_SECSIGREGH1-4). PSA Signature Register is a read-only register. During Semi-CPU mode, the host CPU must read from the PSA Sector Signature Register instead of reading from PSA Signature Register for signature verification to avoid data coherency issue. The PSA Signature Register can be updated with new signature before the host CPU is able to retrieve it.

In Semi-CPU mode, no DMA request is generated. When one sector of data patterns is compressed, CRC controller first generates a compression complete interrupt. Responding to the interrupt, CPU will read the PSA Sector Signature Register and compare it to the known good signature or write the signature value to another memory location to build a signature file. In Semi-CPU mode, CPU must perform the signature verification in a manner to prevent any overrun condition. The overrun condition occurs when the compression complete interrupt is generated after one sector of data patterns is compressed and CPU has not read from the PSA Sector Signature Register to perform necessary signature verification before PSA Sector Signature Register is overridden with a new value. An overrun interrupt can be enabled to generate when overrun condition occurs.

### 12.11.3.3.6 CRC Value Register

Associated with each channel there is a 64-bit CRC Value Register (MCRC\_CRC\_REGL1-4 and MCRC\_CRC\_REGH1-4).

The CRC Value Register stores the pre-determined CRC value. After one sector of data patterns is compressed by PSA Signature Register, MCRC Controller can automatically compare the resulting signature stored at the PSA Sector Signature Register with the pre-determined value stored at the CRC Value Register if AUTO mode is enabled. If the signature verification fails, MCRC Controller can be enabled to generate an CRC fail interrupt. When the channel is set up for Semi-CPU mode, CRC controller first generates a compression complete interrupt to CPU. Upon servicing the interrupt, CPU will then read the PSA Sector Signature Register and then read the corresponding CRC value stored at another location and compare them. CPU must not read from the CRC Value Register during Semi-CPU or Full-CPU mode because the CRC Value Register is not updated during these two modes.

In AUTO mode, for first sector's signature, DMA request is generated when mode is programmed to AUTO. For subsequent sectors, DMA request is generated after each sector is compressed. Responding to the DMA request, DMA controller reloads the CRC Value Register for the next sector of memory system to be checked. The user software needs to configure the DMA to ensure that the DMA first writes to the MCRC\_CRC\_REGL1 followed by the MCRC\_CRC\_REGH1 register in during the AUTO Mode.

When CRC Value Register is updated with a new CRC value, an internal flag is set to indicate that CRC Value Register contains the most current value. This flag is cleared when CRC comparison is performed. Each time at the end of the final data pattern compression of a sector, MCRC Controller first checks to see if the corresponding CRC Value Register has the most current CRC value stored in it by polling the flag. If the flag is set then the CRC comparison can be performed. If the flag is not set then it means the CRC Value Register contains stale information. A CRC underrun interrupt is generated. When an underrun condition is detected, signature verification is not performed.

MCRC Controller supports double word, word, half word and byte access to the CRC Value Register. As noted before comparison between PSA Sector Signature Register and CRC Value Register during AUTO mode is carried out in 64 bits.

### 12.11.3.3.7 Raw Data Register

The raw or un-compressed data written to the PSA Signature Register is also saved in the 64-bit Raw Data Register (MCRC\_RAW\_DATAAREGL1-4 and MCRC\_RAW\_DATAAREGH1-4). This register is read only.

### 12.11.3.3.8 Example DMA Controller Setup

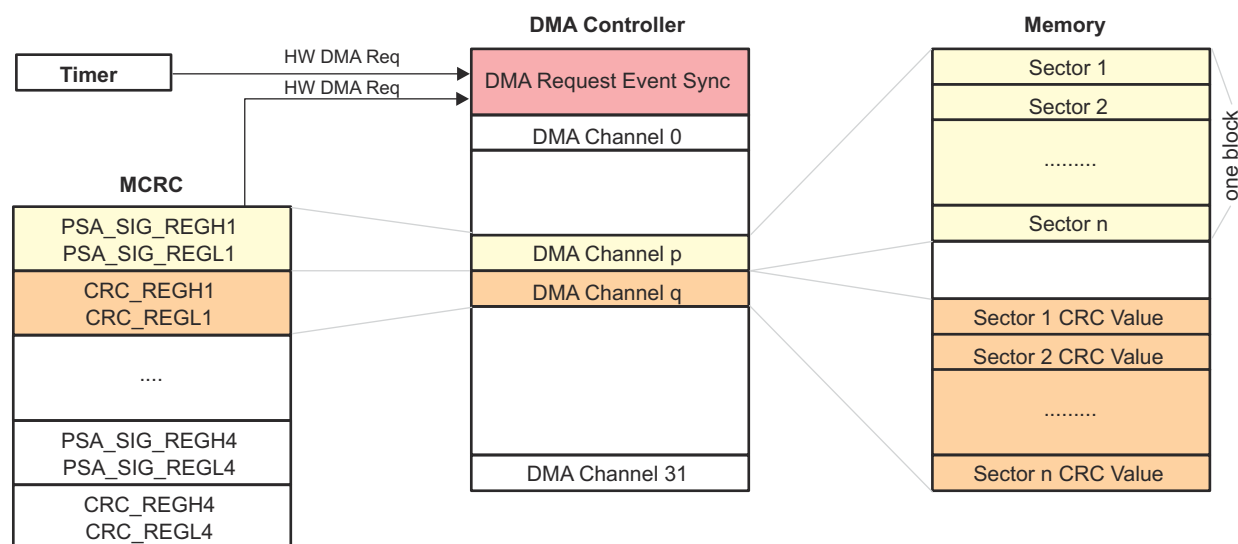

DMA controller needs to be setup properly in either AUTO or Semi-CPU mode as DMA controller is used to transfer data patterns. Hardware or a combination of hardware and software DMA triggering are supported.

### 12.11.3.3.8.1 AUTO Mode Using Hardware Timer Trigger

There are two DMA channels associated with each CRC channel when in AUTO mode. One DMA channel is setup to transfer data patterns from the source memory to the PSA Signature Register (MCRC\_PSA\_SIGREGL1-4). The second DMA channel is setup to transfer the pre-determined signature to the CRC Value Register (MCRC\_CRC\_REGL1-4). The trigger source for the first DMA channel can be either by hardware or by software. As illustrated in Figure 12-1260, a timer can be used to trigger a DMA request to initiate transfer from the source memory system to PSA Signature Register. In AUTO mode, MCRC Controller also generates DMA request after one sector of data patterns is compressed to initiate transfer of the next CRC value corresponding to the next sector of memory. Thus a new CRC value is always updated in the CRC Value Register (MCRC\_CRC\_REGL1-4) by DMA synchronized to each sector of memory.

A block of memory system is usually divided into many sectors. All sectors are the same size. The sector size is programmed in the MCRC\_CRC\_PCOUNT\_REG1-4 and the number of sectors in one block is programmed in the MCRC\_CRC\_SCOUNT\_REG1-4 of the respective channel. MCRC\_CRC\_PCOUNT\_REG1-4 multiplies MCRC\_CRC\_SCOUNT\_REG1-4 and multiplies transfer size of each data pattern should give the total block size in number of bytes.

The total size of the memory system to be examined is also programmed in the respective transfer count register inside DMA module. The DMA transfer count register is divided into two parts. They are element count and frame count. Note that a hardware DMA request can be programmed to trigger either one frame or one entire block transfer. In Figure 12-1260, a hardware DMA request from a timer is used as a trigger source to initiate DMA transfer. If all four CRC channels are active in AUTO mode then a total of four DMA requests would be generated by MCRC Controller.

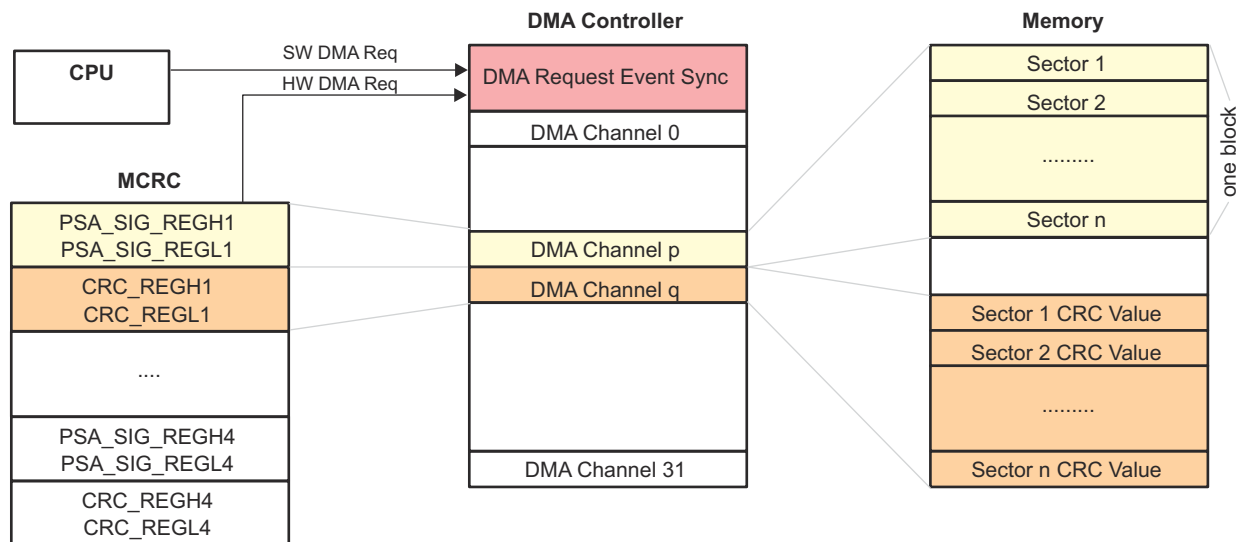

mrcr-004

**Figure 12-1260. AUTO Mode Using Hardware Timer Trigger**

### 12.11.3.3.8.2 AUTO Mode Using Software Trigger

The data patterns transfer can also be initiated by software. CPU can generate a software DMA request to activate the DMA channel to transfer data patterns from source memory system to the PSA Signature Register. To generate a software DMA request CPU needs to set the corresponding DMA channel in the DMA software trigger register. Note that just one software DMA request from CPU is enough to complete the entire data patterns transfer for all sectors. Please see [AUTO Mode With Software CPU Trigger](#) for illustration.

mcr-005

**Figure 12-1261. AUTO Mode With Software CPU Trigger**

#### 12.11.3.3.8.3 Semi-CPU Mode Using Hardware Timer Trigger

During Semi-CPU mode, no DMA request is generated by CRC controller. Therefore, no DMA channel is allocated to update CRC Value Register. CPU should not read from CRC Value Register in semi-CPU mode as it contains stale value. Note that no signature verification is performed at all during this mode. Similar to AUTO mode, either by hardware or by software DMA request can be used as a trigger for data patterns transfer. [Figure 12-1262](#) illustrates the DMA setup using semi-CPU mode with hardware timer trigger.

mcr-006

**Figure 12-1262. Semi-CPU Mode With Hardware Timer Trigger**

**Table 12-1665. DMA Request and Counter Logic Operation According to CRC Mode**

CRC Mode	DMA Request	Pattern Counter	Sector Counter	Timeout Counter
AUTO	Active	Active	Active	Active
Semi-CPU	Inactive	Active	Active	Active
Full CPU	Inactive	Inactive	Inactive	Inactive

### 12.11.3.3.9 Pattern Count Register

There is a 20-bit data pattern counter for every CRC channel. The data pattern counter is a down counter and can be pre-loaded with a programmable value stored in the Pattern Count Register (MCRC\_CRC\_PCOUNT\_REG1-4). When the data pattern counter reaches zero, a compression complete interrupt is generated in Semi-CPU mode and an automatic signature verification is performed in AUTO mode. In AUTO only, DMA request is generated to trigger the DMA controller to update the CRC Value Register.

#### Note

The data pattern count must be divisible by the total transfer count as programmed in DMA controller. The total transfer count is the product of element count and frame count.

### 12.11.3.3.10 Sector Count Register/Current Sector Register

Each channel contains a 16-bit sector counter. The sector count register stores the number of sectors. Sector counter is a free running counter and is incremented by one each time when one sector of data patterns is compressed. When the signature verification fails, the current value stored in the sector counter is saved into current sector register (MCRC\_CRC\_CURSEC\_REG1-4). If signature verification fails, CPU can read from the current sector register to identify the sector which causes the CRC mismatch. To aid and facilitate the CPU in determining the cause of a CRC failure it is advisable to use the following equation during CRC and DMA setup.

$$\text{CRC Pattern Count} \times \text{CRC Sector Count} = \text{DMA Element Count} \times \text{DMA Frame Count} \quad (36)$$

The current sector register is frozen from being updated until both the current sector register is read and CRC fail (CHi\_CRC\_FAIL) status bit is cleared by CPU. If CPU does not respond to the CRC failure in a timely manner before another sector produces a signature verification failure, the current sector register is not updated with the new sector number. An overrun interrupt is generate instead. If current sector register is already frozen with an erroneous sector and emulation is entered with SUSPEND signal goes to high then the register still remains frozen even it is read.

In Semi-CPU mode, the current sector register is used to indicate the sector for which the compression complete has last happened.

Current sector register is reset when the PSA software reset is enabled.

#### Note

Both data pattern count and sector count registers must be greater than or equal to one for the counters to count. After reset, pattern count and sector count registers default to zero and the associated counters are inactive.

### 12.11.3.3.11 Interrupts

CRC generate several types of interrupts per channel. Associated with each interrupt there is a interrupt enable bit (see MCRC\_CRC\_INTS). No interrupt is generated in Full-CPU mode.

- Compression complete interrupt
- CRC fail interrupt
- Overrun interrupt
- Underrun interrupt
- Timeout interrupt

**Table 12-1666. Interrupt Conditions Per CRC Mode**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
AUTO	No	Yes	Yes	Yes	Yes
Semi-CPU	Yes	No	Yes	No	Yes

**Table 12-1666. Interrupt Conditions Per CRC Mode (continued)**

CRC Mode	Compression Complete	CRC Fail	Overrun	Underrun	Timeout
Full-CPU	No	No	No	No	No

#### 12.11.3.3.11.1 Compression Complete Interrupt

Compression complete interrupt is generated in Semi-CPU mode only. When the data pattern counter reaches zero, the compression complete flag is set and the interrupt is generated

#### 12.11.3.3.11.2 CRC Fail Interrupt

CRC fail interrupt is generated in AUTO mode only. When the signature verification fails, the CRC fail flag is set, and CPU must take action to address the fail condition and clear the CRC fail flag after it resolves the CRC mismatch.

#### 12.11.3.3.11.3 Overrun Interrupt

Overrun Interrupt is generated in either AUTO or Semi-CPU mode. During AUTO mode, if a CRC fail is detected then the current sector number is recorded in the current sector register (MCRC\_CRC\_CURSEC\_REG1-4). If CRC fail status bit is not cleared and current sector register is not read by the host CPU before another CRC fail is detected for another sector then an overrun interrupt is generated. During Semi-CPU mode, when the data pattern counter finishes counting, it generates a compression complete interrupt. At the same time the signature is copied into the PSA Sector Signature Register (MCRC\_PSA\_SECSIGREGL1-4). If the host CPU does not read the signature from PSA Sector Signature Register before it is updated again with a new signature value then an overrun interrupt is generated.

#### 12.11.3.3.11.4 Underrun Interrupt

Underrun interrupt only occurs in AUTO mode. The interrupt is generated when the CRC Value Register is not updated with the corresponding signature when the data pattern counter finishes counting. During AUTO mode, MCRC Controller generates DMA request to update CRC Value Register in synchronization to the corresponding sector of the memory. Signature verification is also performed if underrun condition is detected. And CRC fail interrupt is generated at the same time as the underrun interrupt.

#### 12.11.3.3.11.5 Timeout Interrupt

To ensure that the memory system is examined within a pre-defined time frame and no loss of incoming data there is a 24-bit timeout counter per CRC channel. The timeout counter can be pre-loaded with two different pre-load values, watchdog timeout pre-load value (MCRC\_CRC\_WDTPOLD1-4) and block complete timeout pre-load value (MCRC\_CRC\_BCTOPLD1-4). The timeout counter is clocked by a prescaler clock which is permanently running at division 64 of FICLK clock.

Watchdog timeout pre-load register (MCRC\_CRC\_WDTPOLD1-4) is used to check if DMA does supply a block of data responding to a request in a given time frame. Block complete timeout pre-load register (MCRC\_CRC\_BCTOPLD1-4) is used to check if one complete block of data patterns are compressed within a specific time frame. The timeout counter is first pre-loaded with MCRC\_CRC\_WDTPOLD1-4 after either AUTO or Semi-CPU mode is selected and starts to down count. If the timeout counter expires before DMA transfers any data pattern to PSA Signature Register then a timeout interrupt is generated. An incoming data pattern before the timeout counter expires will automatically pre-load the timeout counter with MCRC\_CRC\_BCTOPLD1-4 the block complete timeout pre-load value.

Block complete timeout pre-load value is used to check if one block of data patterns are compressed within a given time limit. If the timeout counter pre-loaded with MCRC\_CRC\_BCTOPLD1-4 value expires before one block of data patterns are compressed a timeout interrupt is generated. When one block (pattern count × sector count) of data patterns are compressed before the counter has expired, the counter is pre-loaded with MCRC\_CRC\_WDTPOLD1-4 value again. If the timeout counter is pre-loaded with zero then the counter is disable and no timeout interrupt is generated.

### 12.11.3.3.11.6 Interrupt Offset Register

MCRC Controller only generates one interrupt request to interrupt manager. An interrupt offset register (MCRC\_CRC\_INT\_OFFSET\_REG) is provided to indicate the source of the pending interrupt with highest priority. [Table 12-1667](#) shows the offset interrupt vector address of each interrupt in an ascending order of priority.

**Table 12-1667. Interrupt Offset Mapping**

Interrupt Condition	Offset Value
Phantom	0x0
Ch1 CRC Fail	0x1
Ch2 CRC Fail	0x2
Ch3 CRC Fail	0x3
Ch4 CRC Fail	0x4
reserved	0x5-0x8
Ch1 Compression Complete	0x9
Ch2 Compression Complete	0xA
Ch3 Compression Complete	0xB
Ch4 Compression Complete	0xC
reserved	0xD-0x10
Ch1 Overrun	0x11
Ch2 Overrun	0x12
Ch3 Overrun	0x13
Ch4 Overrun	0x14
reserved	0x15-0x18
Ch1 Underrun	0x19
Ch2 Underrun	0x1A
Ch3 Underrun	0x1B
Ch4 Underrun	0x1C
reserved	0x1D-0x20
Ch1 Timeout	0x21
Ch2 Timeout	0x22
Ch3 Timeout	0x23
Ch4 Timeout	0x24

### 12.11.3.3.11.7 Error Handling

When an interrupt is generated, host CPU must take appropriate actions to identify the source of error and restart the respective channel in DMA and MCRC module. To restart a CRC channel user must perform the following steps in the ISR:

1. Write to software reset bit in MCRC\_CRC\_CTRL0 register to reset the respective PSA Signature Register
2. Reset the CHi\_MODE bits to 0 in MCRC\_CRC\_CTRL2 register as Data capture mode
3. Set the CHi\_MODE bits in MCRC\_CRC\_CTRL2 register to desired new mode again
4. Release software reset

The host CPU must use byte write to restart each individual channel.

### 12.11.3.3.12 Power Down Mode

MCRC module can be put into power down mode when the power down control bit MCRC\_CRC\_CTRL1[0] PWDN is set. The module wakes up when the PWDN bit is cleared.

#### **12.11.3.3.13 Emulation**

A read access from a register in functional mode can sometimes trigger a certain internal event to follow. For example, reading interrupt offset register triggers an event to clear the corresponding interrupt status flag. During emulation when SUSPEND signal is high, a read access from any register should only return the register contents to the bus and should not trigger or mask any event as it would have in functional mode. This is to prevent debugger from reading the interrupt offset register, that is, during refreshing screen and cause the corresponding interrupt status flag to get cleared. Timeout counters are stopped to generate timeout interrupts in emulation mode. No VBUSM bus error will be generated if reading from the unimplemented locations. .

CEMUDBG is the VBUSM suspend signal which need not explicitly indicate that whether CPU is in suspend mode or not. In data trace mode, a separate suspend signal CPU\_EMUSP, is used to indicate MCRC controller that the CPU is in suspend mode or not.

### 12.11.3.4 MCRC Programming Examples

#### 12.11.3.4.1 Example: Auto Mode Using Time Based Event Triggering

A large memory area with 2 Mbyte (256 k × 32-bit [doubleword]) is to be checked in the background of CPU. CRC is to be performed every 1 Kbyte (128 doubleword). Therefore there will be 2048 pre-recorded CRC values. For illustration purpose, we map MCRC\_CRC\_REGL1 register to DMA channel 1 and MCRC\_PSA\_SIGREGL1 register to DMA channel 2. Let's assume all DMA transfers are carried out in 64-bit transfer size.

##### 12.11.3.4.1.1 DMA Setup

- Setup DMA channel 1 with the starting address from which the pre-determined CRC values are stored. Setup the destination address to the MCRC\_CRC\_REGL1. Put the source address at post increment addressing mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1 to trigger a frame transfer.
- Setup DMA channel 2 with the source address from which the contents of memory to be verified. Setup the destination address to the MCRC\_PSA\_SIGREGL1. Program the element transfer count to 128 and the frame transfer count to 2048. Program the read and write element size to 64 bits. Put the source address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request for channel 2 to trigger an entire block transfer.

##### 12.11.3.4.1.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 2. For example, software can setup the timer to generate a DMA request every 10 ms.

##### 12.11.3.4.1.3 CRC Setup

- Program the pattern count MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the sector count MCRC\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load (MCRC\_CRC\_BCTOPLD1-4) value to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz.
- Enable AUTO mode and all interrupts.

After AUTO mode is selected MCRC Controller automatically generates a DMA request on channel 1. Around the same time the timer module also generates a DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC\_PSA\_SECSIGREGL1/H1 does not match the MCRC\_CRC\_REGL1/H1 Register. MCRC Controller generates a DMA request on DMA channel 1 when one sector of data patterns are compressed. This routine will continue until the entire 2 Mbytes are consumed. If the timeout counter reached zero before the entire 2 Mbytes are compressed, a timeout interrupt is generated. After 2Mbytes are transferred, the DMA can generate an interrupt to CPU. The entire operation will continue again when DMA responds to the DMA request from both the timer and MCRC Controller. The CRC is performed totally without any CPU intervention.

#### 12.11.3.4.2 Example: Auto Mode Without Using Time Based Triggering

A small but highly secured memory area with 1 Kbytes is to be checked in the background of CPU. CRC is to be performed every 1 Kbytes. Therefore, there is only one pre-recorded CRC value. For illustration purpose, we map channel 1 MCRC\_CRC\_REGL1/H1 to DMA channel 1 and channel 1 MCRC\_PSA\_SIGREGL1/H1 to DMA channel 2. Assume all transfers carried out by DMA are in 64-bit transfer size.

##### 12.11.3.4.2.1 DMA Setup

- Setup DMA channel 1 with the source address from which the pre-determined CRC value is stored. Setup the destination address to the MCRC\_CRC\_REGL1 Register. Put the source address at constant addressing

mode and put the destination address at constant addressing mode. Use hardware DMA request for channel 1.

- Setup DMA channel 2 with the source address from which the memory area to be verified. Setup the destination address to the MCRC\_PSA\_SIGREGL1/H1. Program the element transfer count to 128 and the frame transfer count to 1. Put the source address at post increment addressing mode and put the destination address at constant address mode. Generate a software DMA request on channel 2 after CRC has completed its setup. Enable autoinitiation for DMA channel 2.

#### 12.11.3.4.2.2 CRC Setup

- Program the MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC\_CRC\_SCOUNT\_REG1 to 1
- Leaving the timeout count MCRC\_CRC\_BCTOPLD1 register with the reset value of zero means no timeout interrupt is generated
- Enable AUTO mode and all interrupts

After AUTO mode is selected the MCRC Controller automatically generates a DMA request on channel 1. At the same time the CPU generates a software DMA request on DMA channel 2. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the MCRC Controller will compress it. After some time, the DMA controller would update the MCRC\_CRC\_REGL1/H1 with a pre-determined value matching the calculated signature for the first sector of 128 64-bit data patterns. After one sector of data patterns are compressed, the MCRC Controller generate a CRC fail interrupt if signature stored at the MCRC\_PSA\_SECSIGREGL1/H1 does not match the MCRC\_CRC\_REGL1/H1. MCRC Controller generate a DMA request on DMA channel 1 again after one sector is compressed. After 1 Kbytes are transferred, the DMA can generate an interrupt to CPU. Responding to the DMA interrupt CPU can restart the CRC routine by generating a software DMA request onto channel 2 again.

#### 12.11.3.4.3 Example: Semi-CPU Mode

If DMA controller is available in a system the CRC module can also operate in semi-CPU mode. This means that CPU can still make use of the DMA to perform data patterns transfer to CRC controller in the background. The difference between semi-CPU mode and AUTO mode is that CRC controller does not automatically perform the signature verification. CRC controllers generates a compression complete interrupt to CPU when the one sector of data patterns are compressed. CPU needs to perform the signature verification itself.

A memory area with 2 Mbytes is to be verified with the help of the CPU. CRC operation is to be performed every 1 Kbyte. Since there are 2 Mbytes (256 K doublewords) of memory to be check and we want to perform a CRC every 1 Kbytes (128 doublewords) and therefore there must be 2048 pre-recorded CRC values. In Semi-CPU mode, the MCRC\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

##### 12.11.3.4.3.1 DMA Setup

- Setup DMA channel 1 with the source address from which the memory area to be verified are mapped. Setup the destination address to the MCRC\_PSA\_SIGREGL1/H1. Put the starting address at post increment addressing mode and put the destination address at constant address mode. Use hardware DMA request to trigger an entire block transfer for channel 1. Disable autoinitiation for DMA channel 1.

##### 12.11.3.4.3.2 Timer Setup

The timer can be any general purpose timer which is capable of generating a time-based DMA request.

- Setup Timer to generate DMA request associated with DMA channel 1. For example, software can setup the timer to generate a DMA request every 10 ms.

##### 12.11.3.4.3.3 CRC Setup

- Program the MCRC\_CRC\_PCOUNT\_REG1 to 128
- Program the MCRC\_CRC\_SCOUNT\_REG1 to 2048
- For example, we want the entire 2 Mbytes to be compressed within 5 ms. We can program the block complete timeout pre-load value MCRC\_CRC\_BCTOPLD1 to 15625 (5 ms / (1 FICLK period × 64)) if CRC is operating at 200 MHz
- Enable AUTO mode and all interrupts.

The timer module first generates a DMA request on DMA channel 1 when it is enabled. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/H1, the CRC controller will compress it. After one sector of data patterns are compressed, the CRC controller generate a compression complete interrupt. Upon responding to the interrupt the CPU would read from the MCRC\_PSA\_SECSIGREGL1/H1. It is up to the CPU on how to deal with the PSA value just read. It can compare it to a known signature value or it can write it to another memory location to build a signature file or even transfer the signature out of the device via SCI or SPI. This routine will continue until the entire 2 Mbytes are consumed. The latency of the interrupt response from CPU can cause overrun condition. If CPU does not read from MCRC\_PSA\_SECSIGREGL1 before the PSA value is overridden with the signature of the next sector of memory, an overrun interrupt will be generated by CRC controller.

#### **12.11.3.4.4 Example: Full-CPU Mode**

In a system without the availability of DMA controller, the CRC routine can be operated by CPU provided the CPU has enough throughput. CPU needs to read from the memory area from which CRC is to be performed.

A memory area with 2 Mbytes is to be checked with the help of the CPU. CRC operation is to be performed every 1 Kbyte. In CPU mode, the MCRC\_CRC\_REGL1/H1 is not updated and contains indeterminate data.

##### **12.11.3.4.4.1 CRC Setup**

- All control registers can be left in their reset state. Only enable Full-CPU mode.

CPU itself reads from the memory and write the data to the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1 inside MCRC Controller. When the first incoming data pattern arrives at the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1, the MCRC Controller will compress it. After n data patterns are compressed, CPU can read from the MCRC\_PSA\_SIGREGL1/MCRC\_PSA\_SIGREGH1. It is up to the CPU on how to deal with the PSA signature value just read. It can compare it to a known signature value stored at another memory location.

## 12.11.4 ECC Aggregator

This section describes the common ECC aggregator functionality.

### 12.11.4.1 ECC Aggregator Overview

To increase functional and system reliability the memories (for example, FIFOs, queues, SRAMs and others) in many device modules and subsystems are protected by error correcting code (ECC). This is accomplished through an ECC aggregator and ECC wrapper. The ECC aggregator is connected to these memories (hereinafter ECC RAMs) and involved in the ECC process. Each memory is surrounded by an ECC wrapper which performs the ECC detection and correction. The wrapper communicates via serial interface with the aggregator which has memory mapped configuration interface.

The ECC aggregator is also connected to interconnect ECC components that protect the command, address and data buses of the system interconnect. ECC is calculated for the data bus and parity and redundancy for the command and address buses. Each interconnect ECC component has the same serial interface for communication with the aggregator as the ECC wrapper. An ECC aggregator may be connected to both endpoints - the ECC wrapper and interconnect ECC component.

The ECC aggregator, ECC wrapper and interconnect ECC component are considered as single entity and are hereinafter referred to as ECC aggregator unless otherwise explicitly specified.

[Table 12-1668](#) lists the device modules and subsystems which have ECC aggregator.

#### 12.11.4.1.1 ECC Aggregator Features

The ECC aggregator has the following features:

- Reduces memory software errors via single error correction (SEC) and double error detection (DED)
- Provides a mechanism to control and monitor the ECC protected memories in a module or subsystem
- SEC and DED over the system interconnect data bus and parity and redundancy for the system interconnect command and address buses
- Generates an interrupt for correctable error
- Generates an interrupt for non-correctable error
- Supports inject only mode for diagnostic purposes
- Supports software readable status for single and double-bit ECC errors and associated information such as row address where error has occurred and data bits that have been flipped
- Supports up to 256 ECC endpoints. An ECC endpoint can be either ECC RAM or interconnect ECC component.
- Detects single bit error via parity checking on:
  - Memory mapped configuration interface FIFO
  - Serial interface FIFO
  - Serial interface transaction
- Single bit error detection via parity checking results in a non-correctable error interrupt
- Supports timeout mechanism on transactions over the ECC serial interface. Timeout occurrence results in a non-correctable error interrupt.
- Certain control bits have redundancy and if a bit flips an interrupt is generated

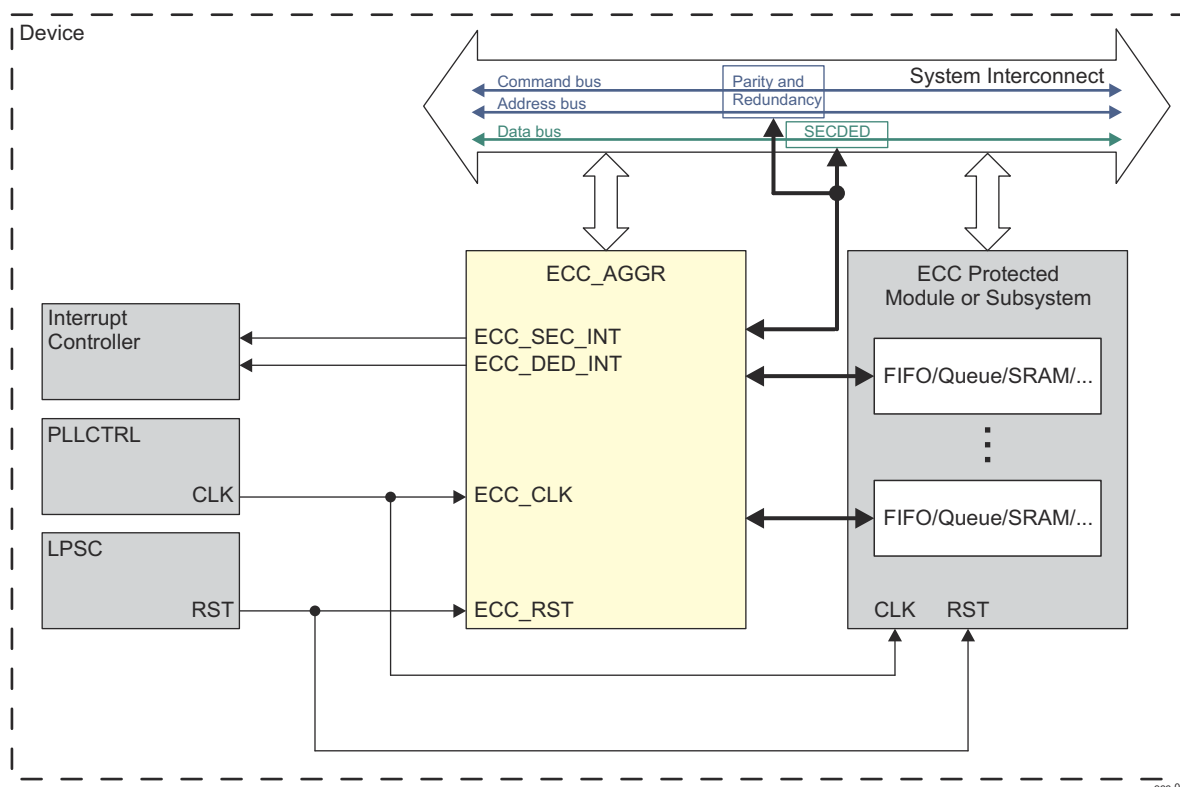

### 12.11.4.2 ECC Aggregator Integration

This section describes an ECC aggregator integration in the device, including information about clocks, resets, and hardware requests.

#### Note

For a list of the device modules and subsystems which have ECC aggregator, see .

Table 12-1669 shows the integration of an ECC aggregator module.

**Figure 12-1263. ECC Aggregator Integration**

Table 12-1669 through Table 12-1671 summarize the integration of an ECC aggregator module.

**Table 12-1669. ECC Aggregator Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
ECC_AGGR	Same PSC as the corresponding module or subsystem	Same PD as the corresponding module or subsystem	Same LPSC as the corresponding module or subsystem	Same CBASS as the corresponding module or subsystem

**Table 12-1670. ECC Aggregator Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
ECC_AGGR	ECC_CLK	Same as the corresponding module or subsystem <sup>(1)</sup>	Same as the corresponding module or subsystem <sup>(1)</sup>	ECC aggregator clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
ECC_AGGR	ECC_RST	Same as the corresponding module or subsystem <sup>(1)</sup>	Same as the corresponding module or subsystem <sup>(1)</sup>	ECC aggregator reset

(1) For information about clock and reset sources, see the respective *Clocks and Resets* table of the module or subsystem with ECC aggregator.

**Table 12-1671. ECC Aggregator Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
ECC_AGGR	ECC_SEC_INT	See <sup>(1)</sup>	See <sup>(1)</sup>	Interrupt for correctable error (SEC)	Level
	ECC_DED_INT	See <sup>(1)</sup>	See <sup>(1)</sup>	Interrupt for non-correctable error (DED, parity, redundancy, timeout)	Level
DMA Events					
Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
ECC_AGGR	-	-	-	-	-

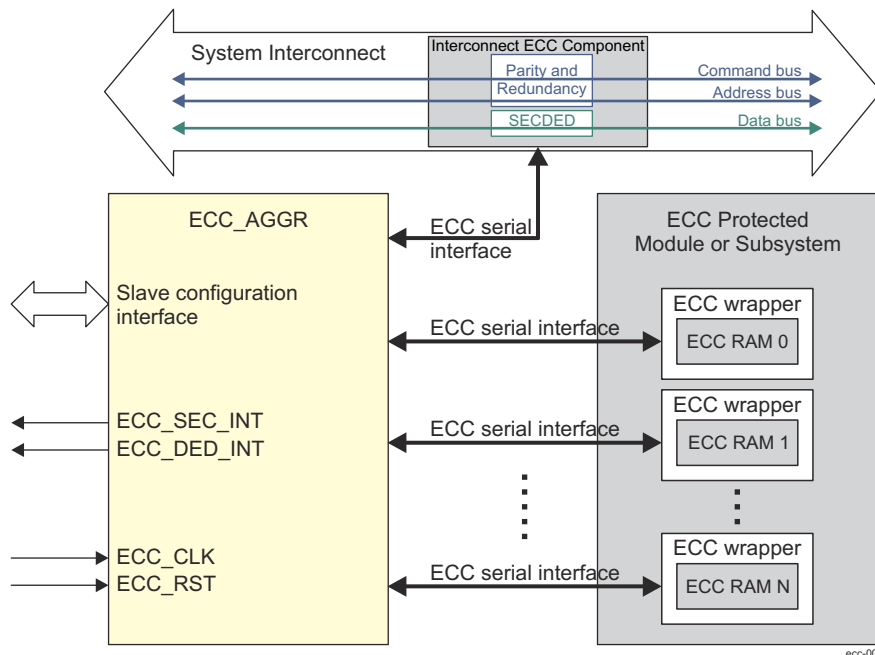

(1) See the respective *Hardware Requests* table of the module or subsystem with ECC aggregator.

### 12.11.4.3 ECC Aggregator Functional Description

This section describes the architecture and functional details of the ECC aggregator.

#### 12.11.4.3.1 ECC Aggregator Block Diagram

Figure 12-1264 shows the ECC aggregator block diagram.

**Figure 12-1264. ECC Aggregator Block Diagram**

The ECC aggregator is connected to one or more ECC endpoints each of which has assigned a unique ID used when the endpoint is accessed for status information or configuration. The ECC aggregator provides software access to all ECC related registers through its memory mapped slave configuration interface while the serial interface is used to communicate with the ECC endpoints. Upon detection of single or double-bit error the corresponding interrupt line is asserted.

#### 12.11.4.3.2 ECC Aggregator Register Groups

The ECC aggregator has ECC control, status and interrupt registers for each ECC endpoint in a module or subsystem. These registers are memory mapped and occupy 1 KB address space although part of it may contain reserved locations. The registers are split in the following types:

- **Global registers.** They are common to all ECC endpoints associated with the ECC aggregator and include the ECC\_VECTOR and ECC\_REV registers. Each ECC endpoint has assigned a unique ID. When this ID is written to the ECC\_VECTOR[10-0] ECC\_VECTOR field the corresponding endpoint is selected either for control or for status reading.
- **ECC control and status registers.** These registers are specific to each ECC endpoint and reside in the range from address offset 0x10 to 0x28, if the endpoint is ECC RAM or from 0x10 to 0x24, if the endpoint is interconnect ECC component. They are memory mapped but are accessed through the ECC serial interface. They are also selected by the ECC endpoint ID written to the ECC\_VECTOR[10-0] ECC\_VECTOR field. Because of latency on the serial interface the ECC control and status registers are read by performing special sequence as described in [Section 12.11.4.3.3](#). These registers have also different functionality for both types of endpoints - ECC RAM and interconnect ECC component.
- **Interrupt registers.** They include interrupt status, interrupt enable, interrupt disable, and EOI registers. For more information, see *Interrupts*.

#### 12.11.4.3.3 Read Access to the ECC Control and Status Registers

Read accesses to the ECC control and status registers for each ECC endpoint represent read operations over the ECC serial interface and are triggered by performing the following sequence:

- Software writes the following in the ECC\_VECTOR register:
  - The ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field to select particular ECC endpoint.
  - The register read address in the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field to select which register has to be read through the ECC serial interface.
  - A value of 0x1 in the ECC\_VECTOR[15] RD\_SVBUS bit to trigger read operation through the ECC serial interface.
- Software polls the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit to check if it is 0x1. This indicates that the read operation on the ECC serial interface has completed.
- Software reads the data from the register previously selected by the ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field.

The following is an example for serial read operation:

- Write 0x0010 8005 to the ECC\_VECTOR register. This sends read request to the ECC\_WRAP\_REV or ECC\_CBASS\_REV register (address = 0x10) associated with ECC endpoint with ID = 5.
- Poll the ECC\_VECTOR[24] RD\_SVBUS\_DONE bit until value of 0x1 is read.
- Read the ECC\_WRAP\_REV or ECC\_CBASS\_REV register to get its value.

#### 12.11.4.3.4 Serial Write Operation

Write operations over the ECC serial interface are performed as follows:

- Software specifies the ECC endpoint ID in the ECC\_VECTOR[10-0] ECC\_VECTOR field. The ECC\_VECTOR[23-16] RD\_SVBUS\_ADDRESS field is a don't care but the ECC\_VECTOR[15] RD\_SVBUS bit must be set to 0x0.
- Software performs regular write operation to the desired address. If the ECC endpoint ID has already been specified, step 1 can be skipped. Unlike serial read operations it is not necessary to always specify the endpoint ID before performing serial write operation.

The following is an example for serial write operation:

- Write 0x0000 0008 to the ECC\_VECTOR register.
- Write 0x0000 000F to the ECC\_CTRL register. This sends write request with data 0x0000 000F to the ECC\_CTRL register associated with ECC RAM with ID = 8.

#### 12.11.4.3.5 Interrupts

The ECC aggregator generates the following interrupts:

- Correctable interrupt (ECC\_SEC\_INT) where hardware can correct the error but notifies the system in case of SEC.
- Non-correctable interrupt (ECC\_DED\_INT) where hardware cannot correct the error in cases of DED, parity check, redundancy check or timeout occurrence.

The following is the sequence for servicing interrupts:

- Software enables the interrupts for an ECC endpoint by writing 0x1 to the corresponding bit of the following interrupt enable registers:
  - ECC\_SEC\_ENABLE\_SET\_REG0 through ECC\_SEC\_ENABLE\_SET\_REG7 for the correctable interrupt
  - ECC\_DED\_ENABLE\_SET\_REG0 through ECC\_DED\_ENABLE\_SET\_REG7 for the non-correctable interrupt
- On receiving an interrupt, software checks which ECC endpoint has caused the error by reading the following interrupt status registers:
  - ECC\_SEC\_STATUS\_REG0 through ECC\_SEC\_STATUS\_REG7 for the correctable interrupt
  - ECC\_DED\_STATUS\_REG0 through ECC\_DED\_STATUS\_REG7 for the non-correctable interrupt
- Software performs serial read operations as described in [Section 12.11.4.3.3](#) to read the following status registers that contain details about the error:

- If the endpoint is ECC RAM:
  - ECC\_ERR\_STAT1
  - ECC\_ERR\_STAT2
  - ECC\_ERR\_STAT3
- If the endpoint is interconnect ECC component:
  - ECC\_CBASS\_ERR\_STAT1
  - ECC\_CBASS\_ERR\_STAT2
- After the interrupt has been serviced, depending on the error type, software should clear the corresponding status bits in the ECC\_ERR\_STAT1 and ECC\_ERR\_STAT3 registers or in the ECC\_CBASS\_ERR\_STAT1 register. Software has to poll these registers to guarantee that status bits are cleared as there is no other indication for write completion over the ECC serial interface.  
The value of the \*\_PEND\_CLR fields in the ECC\_CBASS\_ERR\_STAT1 register must be read and then written back to decrement the count of each field back to 0x0. A further error capture into the ECC\_CBASS\_ERR\_STAT1 register does not occur unless all its fields are 0x0. The decrement value should not be larger than the read value. If a field in the ECC\_CBASS\_ERR\_STAT1 register should not be modified, write a value of 0x0 to that field.
- Software writes 0x1 to the corresponding end of interrupt register to clear the interrupt:
  - ECC\_SEC\_EOI\_REG for the correctable interrupt
  - ECC\_DED\_EOI\_REG for the non-correctable interrupt

#### 12.11.4.3.6 Inject Only Mode

There are modules that already perform the ECC generation and checking as part of their data path. In this case, the ECC wrapper may be configured in inject only mode, if needed. In this mode the ECC wrapper does not perform ECC detection and correction. The inject only mode allows users to inject single or double-bit errors so that the module logic can be tested for diagnostic purposes.

---

#### Note

There is no software control to enable inject only mode. It is configured via tie-off value. Inject only and ECC modes are mutually exclusive.

---

The interconnect ECC component also supports error injection mode. There is error injection logic for testing of the error checking logic (checkers). The injection logic can be configured to inject either single or double bit error and what data pattern to be used for injection (ECC\_CBASS\_CTRL[11-8] ECC\_PATTERN). The ECC\_CBASS\_ERR\_CTRL1 and ECC\_CBASS\_ERR\_CTRL2 registers should be written first to setup the injection. Then, either the ECC\_CBASS\_CTRL[3] FORCE\_SE or the ECC\_CBASS\_CTRL[4] FORCE\_DE bit must be set to 0x1 to start the injection. Both bits must not be set at the same time. If the injection should continue in incrementing mode, then the ECC\_CBASS\_CTRL[5] FORCE\_N\_BIT bit should be set to 0x1. Once the FORCE\_N\_BIT is set, then each successive injection can simply write the ECC\_CBASS\_CTRL register to set the FORCE\_SE or FORCE\_DE again. Reading 0x0 from either the FORCE\_SE or the FORCE\_DE bit indicates that the injection has completed, as these bits automatically clear when the checker indicates that it has performed the injection. The time for an injection to complete is not guaranteed, so some delay is needed between successive injections.

This chapter describes the on-chip debug support.

<b>13.1 Introduction to SoC Debug Framework.....</b>	<b>3530</b>
--	-------------

## 13.1 Introduction to SoC Debug Framework

The SoC debug capabilities are centered around the Debug Subsystem (DebugSS). The DebugSS works in conjunction with the debug capabilities integrated in the various processing units (such as CPUs and hardware accelerators) to provide a comprehensive hardware platform for a rich debug and development experience.

The SoC debug framework provides support for the following features:

- Top-level debug support
  - IEEE 1149.1 (JTAG + boundary scan) and IEEE 1149.6 (boundary scan extensions)
  - Centralized debug access gateway (DebugSS) that provides support for debug access and trace in multiple CPU core subsystems
    - JTAG can access all debug and system resources
    - Other system masters can also access all debug resources (self-hosted debug)
  - Direct debug master to system memory that bypasses any CPU datapath used for debug
  - Global execution and system level debug triggering (simultaneous run/halt)
    - ARM CoreSight cross trigger architecture
      - Channel Interface (CI)
      - Cross Trigger Interface (CTI), Cross Trigger Matrix (CTM)
    - TI legacy cross trigger architecture (for C66x only)
    - ARM/TI trigger merge at the DebugSS level
  - Trace architecture that includes various trace sources, sinks and supporting modules
    - Processor trace (A72, R5F, C66x, C71x)
    - Discrete event trace
      - Counter, Timer, and System Event Trace (CTSET) module
    - CBA4 compliant bus probing
      - CPTracer2 (CPT2) aggregators and probes
      - Three levels of bus probing (SoC, MCU domain, MSMC)
    - Software message trace
      - ARM CoreSight STM-500 module
    - Universal debug time distribution for correlating various trace sources
      - Wide Timestamp Interface (WTI)
    - Trace distribution via ARM Advanced Trace Bus (ATB) network
    - Trace storing into dedicated on-chip Trace Buffer Router (TBR) modules
    - Trace streaming off-chip
      - Export via ARM CoreSight Trace Port Interface Unit (TPIU)
      - Export via high-speed functional interfaces (Ethernet, PCIe)
        - Requires software assistance
  - Advanced debug power, clock and reset management
  - Ownership aware peripheral debug events (suspend mapping)
  - Authenticating a debug connection on device configured for high-security (HS) operations
- Compute Cluster debug support
  - A72SS
    - Invasive debug (halt mode, monitor mode)
    - Non-invasive debug (processor trace, performance monitoring)
    - CoreSight Embedded Trace Macrocell (ETM)
    - Cross triggering via CoreSight CTI and CTM
  - C71SS
    - Core debug
    - Advanced Event Triggering (AET)
    - Real-time trace
    - Physical address watchpoints

- Event analysis
- MSMC
  - Bus probing
  - Discrete event trace
  - Cross triggering via CoreSight CTI and CTM
- R5FSS debug support (applies to all three R5FSS instances)
  - Invasive debug (halt mode, monitor mode)
  - Non-invasive debug (processor trace, performance monitoring)
  - CoreSight ETM-R5
  - Cross triggering via CoreSight CTI and CTM
- C66SS debug support (applies to both C66SS instances)
  - Invasive debug (halt mode, monitor mode, real-time debug)
  - Non-invasive debug (processor trace)
  - Cross triggering
    - AET
    - TI legacy trigger channels (EMU0, EMU1)
  - Dedicated AMBA trace bus DSP Trace Formatter (ADTF) per C66x core
    - Provides the required C66x trace formatting for on-chip store or off-chip export
    - Resides outside the C66x CorePac
- DMPAC debug support
  - HWA basic debug (system visibility, run control)
  - Cross triggering
  - Discrete event trace
- VPAC debug support
  - HWA basic debug (system visibility, run control)
  - Cross triggering
  - Discrete event trace

---

**Note**

For DMSC debug support, refer to the DMSC Addendum.

---

## Revision History

### Changes from March 8, 2022 to December 31, 2024 (from Revision C (March 2022) to Revision D (December 2024))

	Page
• Updated Note in Introduction section.....	79
• Updated Device JTAG ID table.....	117
• Updated Quality of Service (QoS) section.....	221
• Updated ISC Config Registers per Region diagram.....	228
• Added xSPI Boot Configuration Fields table.....	285
• Added eMMC Flash section.....	303
• Updated X.509 Certificate information from 'Optional.'.....	315
• Updated PRU_ICSSG Control Registers table.....	356
• Power: Added Power Management Unit section with overview of the contents of the Power Management Unit.....	361
• Power: Added filtering for AM263/Px.....	361
• Power: Added further detail surrounding connections with the 1.8V LDO.....	361
• Add POK Types.....	361
• Updated POKs in POR Module Programming image.....	372
• Removed Note.....	381
• Updated VTM Features.....	381
• Updated Internal RC Oscillator section.....	480
• Updated MAIN Domain PLLs Integration - Part 1 diagram.....	484
• Updated PLLs in MAIN Domain section.....	487
• Updated Master Interfaces section.....	547
• Added R5FSS Interrupts section.....	562
• Updated Spinlock Software Reset section.....	827
• removed unnecessary text from diagram.....	827
• Added detail to main spinlock operations.....	829
• Removed unnecessary text in diagram.....	829
• Updated DDRSS Not Supported Features section.....	850
• Updated Inline ECC for SDRAM Data section.....	860
• Added Note to DDR Controller Functional Description section.....	867
• Added Note to BIST Engine section.....	869
• Updated PI Functional Description section.....	901
• Added RAT Clocks and Resets and RAT Hardware Requests tables.....	930
• Updated WKUP_DMSC0 Interrupt Map.....	966
• Updated MCU_R5FSS0_CORE0 Interrupt Map.....	973
• Updated MCU_R5FSS0_CORE1 Interrupt Map.....	981
• Updated GIC500 SPI Interrupt Map.....	992
• Updated R5FSS0_INTRTR0 Interrupt Map.....	1049
• Updated R5FSS1_INTRTR0 Interrupt Map.....	1057
• Update CPTS_TS_COMP_LEN_REG from 24 to 32 bits.....	1328
• Update CPTS_TS_COMP_LEN_REG from 24 to 32 bits.....	1328
• [Trigger Configuration (per Bit)] Clarify configuration of GPIO interrupt generation.....	1402

• [Trigger Configuration (per Bit)] updated method to return the value of the FAL_TRIG register. User can read SET_FAL_TRIG <b>or</b> CLR_FAL_TRIG registers to obtain FAL_TRIG value (rather than SET_FAL_TRIG <b>and</b> CLR_FAL_TRIG).	1402
• Added HS Mode entry to Features section.	1409
• Removed HS Mode footnote from I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes table.	1426
• Updated Figure MCSPI Overview. Moved and Renamed Figures MCSPI3/4 Connectivity Details to New Subsection MCSPI Internal Connectivity.	1472
• [MCSPI Protocol and Data Format] Added CLKG bit field information to Programmable MCSPI Clock bullet point.	1480
• [Peripheral Receive-Only Mode] Added clarification to definition of full-duplex mode (requires 2 serial data lines).	1509
• Renamed master words with "controller" and slave words with "peripheral" in complete UART chapter.	1534
• Added note to UART Frame Data Format diagram.	1538
• [SIR Free-Format Mode] Added additional information per design feedback.	1545
• [SIP Generation] add additional information for SIP_MODE registers bit setting.	1547
• [UART Interrupts] added additional register bit information for 001100 row in UART Mode Interrupts table.	1570
• [Wake-Up Interrupt] modified topic to include conditions for wake-up interrupt.	1571
• [Transmit FIFO Trigger] changed register naming to align with RA. Updated note to correct register bits.	1574
• [Receive FIFO Trigger] changed register naming to align with RA. Updated note to correct register bits.	1574
• [FIFO DMA Mode Operation] Updated register naming to match RA.	1577
• [Multi-drop Parity Mode with Address Match] added line at end of topic detailing supported and unsupported modes.	1599
• [Time-guard] added details related to other modes.	1601
• Make corrections to VLAN_Unaware.	1639
• Update bit from CTL_EN to EXT_EN.	1662
• Update bit from CTL_EN to EXT_EN.	1662
• Update Encoder/Decoder 3 Data to 103:78.	1664
• Update Event FIFO depth from 10 to 32.	1691
• Updated LTSSM State Encoding table.	1873
• Updated PMA bullets in 2-L SerDes Features section.	1894
• Updated PMA bullets in 4-L SerDes Features section.	1911
• Updated OSPI DMA bullet in FSS Not Supported Features.	1922
• Changed OTFA references to OTFE.	1927
• Remove misleading statement: Supports dual Quad-SPI mode for fast boot applications.	1934
• Added the requirement of RESET_OUT[1:0] signals when OSPI flash memory is used for Boot.	1936
• Maximum bytes supported by STIG is 16.	1952
• Added eMMC PHY BIST section.	2119
• Updated UFS Features section.	2190
• Removed UFS Encryption/Decryption Support section.	2198
• (RTI Digital Watchdog): Added note that this feature is only available for the WWDT defined modules.	3373
• (RTI Digital Windowed Watchdog): Fixed error in RTI Digital Windowed Watchdog Operation Block Diagram.	3374
• [PSA Signature Register] added CRC polynomial equations for all supported CRC polynomials.	3509
