The entire PVU can be enabled or disabled via the PVU\_ENABLE register.

#### 8.3.2.3.2 PVU Channels

The module supports a number of channels (see [Section 8.3.2.1.2](#)), each having its own independent TLB and translation entries. This allows a single PVU to handle the translations for many masters, as well as keep their translations from interfering with each other.

The mapping of transactions to TLBs is made using mapping registers (PVU\_VIRTID\_MAP1 and PVU\_VIRTID\_MAP2). Each channel can be mapped to a virtID, or as a sub range of a DMA virtID. This allows the software to decide how the transactions are mapped to TLBs. It can be purely based on virtID, so that each virtual space has its own TLB. Or, it can be partly based on a highly channelized master, such as a DMA, can have 4 TLBs dedicated for channels where the sub-class on the upper chanid bits determine which of the 4 TLBs to use. This DMA mode allows for different classes of DMA traffic, such as descriptors or buffers, to be in their own TLBs and not interfere with each other. Since the TLB mapping is relatively simple, it is software's responsibility to control the definition of virtIDs in peripherals and DMAs so that they map to TLBs as required.

#### 8.3.2.3.3 TLB

Each PVU channel contains a single traditional TLB. The TLB contains a number of entries that store the translation recipes, and these entries are used only for this TLB. Any activity for other TLBs or PVU channels will not impact this TLB.

#### 8.3.2.3.4 TLB Entry

A TLB entry consists of the virtual address base and LPAE (Large Physical Address Extension) fields defined by Arm® architecture, stored in TLB Entry registers. This entry then includes the translated base address, size of the page, and other attributes of the page. When written by software, these fields must be written in the same way for correct operation.

The base addresses must be aligned to the defined page size.

#### 8.3.2.3.5 TLB Selection

The first step of the module is to map the transaction to a specific TLB by comparing the virtID, chanID upper bits, and those programmed in PVU\_VIRTID\_MAP1 and PVU\_VIRTID\_MAP2. This mapping determines which TLB to select from the virtID. That TLB is used for the remainder of the pipeline. If there is no match then the PVU automatically misses.

#### 8.3.2.3.6 DMA Classes

The first N virtIDs can be reserved for DMA class usage in the PVU\_VIRTID\_MAP1 register. These virtIDs map to TLBs along with classes that are defined in the chanID bits 10 to 11 on the bus. This creates four classes per virtID, that can select from four TLBs, allowing the transaction to restrict its translations to smaller sets from known distinct memory segments (such as the DMA accessing descriptors or buffers). A set of bitfields define the class mapping, which defines the final class value to use for an input class, and can be used to restrict the number of classes if all four are not used (by mapping 2 to 0 and 3 to 1 for example to limit to two classes). Then the final TLB selection is calculated as:

$$\text{virtID} \times 4 + \text{final class value}$$

The unused classes cause unused TLBs as entry points, but they can be used in chaining.

#### 8.3.2.3.7 General virtIDs

After the first N virtIDs for DMA class usage, the remaining virtIDs up to the maximum allowed (as set in PVU\_VIRTID\_MAP2) are for general usage. Each of these map one to one to a TLB, where the calculation is:

$$\text{dma\_cnt} \times 4 + (\text{virtID} - \text{dma\_cnt})$$

There are no classes used for this range of virtIDs. An input virtID that is beyond the MAX\_CNT bitfield value will produce an error.

#### 8.3.2.3.8 TLB Lookup

The next step of the module is to check the input address, which uses the bits just above the 4-kB size, bits 12 and up, as the virtual address base. This is compared against all the TLB entries for that TLB, given the size in each entry. The size affects which address bits need comparing for an entry. The minimum size of 4 kB, so address bits 12 and up are compared. But if the size is 64 kB, then bits 16 and up are compared, as the lower bits fall into the size of the page. In addition to the address, the psecure bit is used to match against the secure level of the transaction. Only secure transaction are allowed to match an entry with psecure set, while only non-secure transactions are allowed to match an entry with psecure clear. If the entry is valid and the base compare matches and the secure level matches then the entry is used for the translation and checks.

#### 8.3.2.3.9 TLB Miss

If the TLB lookup results in no matches and there is no chaining to another TLB (described later), then this is called a TLB miss. If the TLB misses, since there is no back-fill (such as from an MMU), the result is that the translation fails and will fault (a fault is when there is no physical address available). The transaction will be marked as in error with the flush signal, and a later slave will perform the flush that will return a bus error and read data as zeros. The PVU will record the fault as an interrupt and log the fault in the exception logging read-only registers.

#### 8.3.2.3.10 Multiple Matching Entries

The PVU does not support multiple entries in a TLB that match the same virtual address. This is an illegal condition for software to program, as there is no mechanism to select one over the other. The PVU will have unpredictable results if this occurs, with the one requirement that the input transactions will never transition from a non-secure attribute to a secure attribute even in this illegal condition. This means that there is no support for background and foreground translating entries in the same TLB (which would be the result if a real MMU were used also). If software user wants to use a foreground and background method (that is not MMU compliant), he can place the foreground entries in earlier TLBs that are chained together, and the background entries are in the later TLBs, so that no single TLB has overlapping entries. The background entry would only be hit when the address falls within the background range but not any of the foreground ranges.

#### 8.3.2.3.11 TLB Disable

A special case is when a TLB should go through a lookup but is disabled through the PVU\_CHAIN\_j[31] EN bit, or the entire PVU is disabled through the PVU\_ENABLE[0] EN bit. If a lookup is requested when the TLB or PVU is disabled, then the transaction will pass and no translation will occur (output address is the same as the input address). Also, if the atype=1 then it will change to atype=0 on the output so that the resulting bypass transaction does not get routed right back to the PVU. Any other atype value will be maintained on the output. Any entries set in the disabled TLB are ignored as well as the chaining setting (described in [Section 8.3.2.3.12](#)) is also ignored, so once a disabled TLB is used then the chain is ended. Software must take care to not include any disabled TLBs in chains that must be fully searched – if a TLB must be disabled then the chain must be updated first to skip over that TLB and any virtIDs that directly map to that TLB initially must not be used.

#### 8.3.2.3.12 TLB Chaining

If the TLB has a chain enabled by writing a non-zero chain value, then the TLB lookup will continue for the transaction using the chained TLB number. There is a latency penalty to resume the lookup at the chained TLB,

but it allows more TLB resources to be used for virtIDs that might need more translations. If a TLB misses and has a chain value of zero then the overall result is a miss. Any TLB logs are always applied to the original TLB of the chain, and not the chained TLB.

TLB chaining can be defined in the PVU\_CHAIN\_j[11:0] CHAIN register bitfield.

### 8.3.2.3.13 TLB Permissions

The TLB entry contains permissions for the page that must be checked before the translation can be used. These include if the page has *supervisor* access for read, write, or execute, and has *user* access for read, write, or execute. The supervisor or user is based on the transaction priv[0] signal (0 = user, 1 = supervisor). The access type is based on the transaction dtype[0] and dir signals (dtype[0] = 0 and dir = 1 is a read, dtype[0] = 0 and dir = 0 is a write, dtype[0] = 1 and dir = 1 is an execute). The transaction signals are checked against these permissions. If they are allowed then the translation continues. If the page does not allow this transaction then the check fails and flush signal set is on the bus, like for a firewall, indicating that the transaction is no longer valid and must return an error. PVU does not perform the error signaling, so a later module must support it. A fault interrupt is produced.

The pperm entry bits define four additional checks. If pperm[0] is clear then user privilege access is not allowed, and a matching transaction with the CBA bus priv signal set to 0 (indicating user access) will result in an error. If pperm[1] is set then write access is not allowed, and a matching transaction that is a write will result in an error. If pperm[2] is set then instruction execute is not allowed, and a matching transaction that has the CBA bus dtype signal set to 1 (instruction fetch) will result in an error. If pperm[3] is set then supervisor instruction execute is not allowed, and a matching transaction that has the CBA bus priv signal non-zero (above user) and the CBA bus dtype signal set 1 (instruction fetch) will result in an error. If all these checks pass then the translation is allowed.

The pprefetch entry bit determines whether the translation allows prefetch transactions. If set, then any transaction with the pfable signal set are allowed. But if pprefetch=0 then those transactions with pfable set will fault as prefetch is defined as not supported.

### 8.3.2.3.14 Translation

If all the checks pass, then the translated address is replaced and the transaction can proceed to the output. Only the address bits above the page size are replaced, and all the lower bits are copied from the transaction. The memory attributes are also replaced on the transaction. These attributes include the memory type, shareability, and allocation policies. In addition, the prefetchable request is only copied if the page allows prefetch, and otherwise it is forced clear, but the transaction is still allowed to continue (just the prefetch will not occur).

### 8.3.2.3.15 Memory Attributes

Table 8-38 shows the mapping of page attributes to the bus memory attributes.

**Table 8-38. Page Attributes to Bus Memory Attributes Mapping**

Bus Signal	Page Attribute	Translated Bus Signal
cinner	piallocpol	cinner = piallocpol
couter	poallocpol	couter = poallocpol
memtype	pmemtype	memtype = pmemtype
sdomain	posable, pisable	sdomain[1] = posable, sdomain[0] = pisable
pable	pprefetch	pable = pable AND pprefetch

### 8.3.2.3.16 Faulted Transactions

A faulted transaction will have the flush bit set on the outgoing transaction so that it will return errors by the interconnect. The atype will be set to 0 since the memory attributes have not been replaced. And the outgoing transaction address will have the upper bits set to the fault\_addr parameter value (see Section 8.3.2.1.2), which defines an interconnect address that will always return errors and not interfere with any valid slave traffic (such as to memory).

#### **8.3.2.3.17 Non-Virtual Transactions**

The module must not receive a transaction that does not have the atype set to an intermediate address, but if it does, there is no translation performed for that transaction. The transaction is simply copied to the output without modification.

#### **8.3.2.3.18 Allowed virtIDs**

Software can control the limit of usable virtIDs in the PVU by PVU\_VIRTID\_MAP2[11:0] MAX\_CNT register. This sets the maximum virtID allowed value. If the PVU receives a transaction with a higher virtID signal, then the transaction will be treated as a fault and error, and no TLB lookup will be performed.

#### **8.3.2.3.19 Software Control**

The software can control all the TLB entries directly. The TLB can be programmed at any time by software, and writes to the TLB take precedence over lookups. This allows the update to be reflected as soon as possible in the translations. But there is no guarantee about the timing of the update against any bus transactions, so the only way to guarantee an endpoint uses the updated table is to stall the endpoint until the update has been completed (using the write status). This allows software to directly populate TLB entries for known translation as well as locking entries down so that they cannot be replaced.

#### **8.3.2.3.20 Fault Logging**

The module will log faults into exception logging registers. It will capture that type of fault, the address that faulted, and the attributes of the transaction that faulted. It will also set an interrupt. The module can only store one fault. When the software clears the interrupt status then the fault is also cleared and another can be captured. If another fault occurs while one is pending then that fault log is lost.

There is a logging Enable/Disable bit per TLB and if disabled then faults from that TLB will not be logged. PVU\_EXCEPTION\_LOGGING\_DISABLE register allows to disable types of faults, and when disabled that type of fault will not be logged. There are additional fault status fields per TLB that capture fault status that would have been logged but could not because another fault was already logged. These status bits stay set until cleared by software.

A TLB fault that occurs after chaining will set the fault status of the original TLB, and not of the last TLB in the chain.

#### **8.3.2.3.21 Alignment Restrictions**

All accesses through the module must not cross 4-kB page boundaries. The module does not perform any checks for this requirement.

### 8.3.3 Page Based Address Translation Unit (PAT)

This chapter describes the PAT module, part of the main NAVSS.

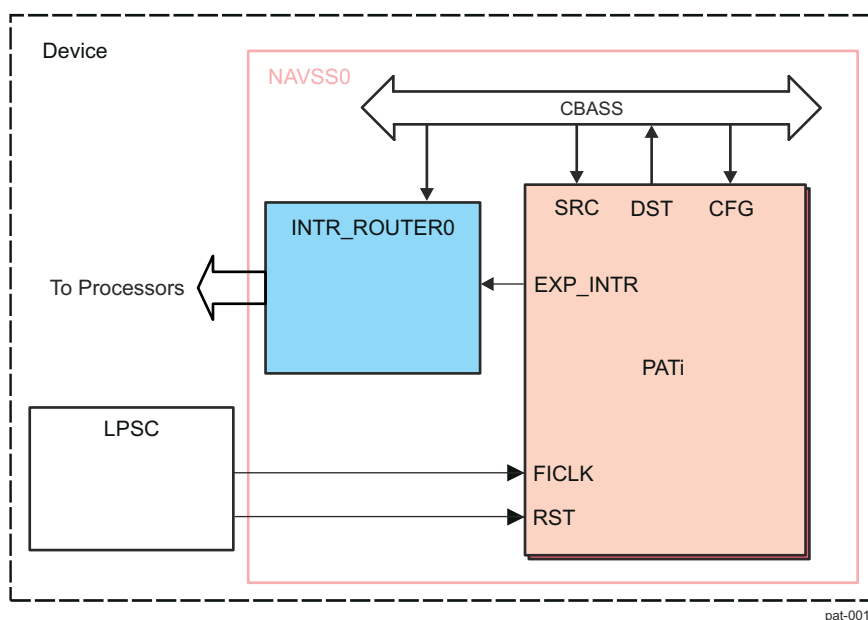

#### 8.3.3.1 PAT Overview

PAT performs a page-based address translation on a CBA VBUSM bus. [Table 8-39](#) lists PAT instances in the device.

**Table 8-39. PAT Allocation Within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_PAT0	-	-	✓ (NAVSS)
NAVSS0_PAT1	-	-	✓ (NAVSS)
NAVSS0_PAT2	-	-	✓ (NAVSS)
NAVSS0_PAT3	-	-	✓ (NAVSS)
NAVSS0_PAT4	-	-	✓ (NAVSS)

[Figure 8-21](#) shows a top-level overview of the PAT module.

**Figure 8-21. PAT Overview**

#### 8.3.3.1.1 PAT Features

Each PAT supports the following features:

- Implements a VBUSM retiming bridge with page based address translation
- Supports a number of pages (see [Table 8-40](#)), each occupying a programmable 4-KB, 16-KB, 64-KB, or 1-MB of address space
- Supports a 48-bit output address size
- Allows fast programming of the table, or fast generic SRAM access when the table is disabled
- Supports *transaction id* reassignment
- Supports isolation of registers by placing every 256 pages worth of control registers in their own 4-KB MMU page.

### 8.3.3.1.2 PAT Parameters

Table 8-40 shows the PAT configuration parameters set during SoC design.

**Table 8-40. PAT Configuration Parameters**

Module Instance	Parameters				
	Number of Pages <sup>(1)</sup>	Large	Source ID	Config FW	RouteID
NAVSS0_PAT0	16384	0	0	0x0000:6:3:4736	224
NAVSS0_PAT1	16384	0	0	0x0400:6:3:4737	225
NAVSS0_PAT2	16384	0	0	0x0800:6:3:4738	226
NAVSS0_PAT3	2048	1	1	0x0c00:6:3:4739	227
NAVSS0_PAT4	2048	1	1	0x1000:6:3:4740	228

(1) Can be read off from the PAT\_CONFIG read-only register.

### 8.3.3.1.3 PAT Not Supported Features

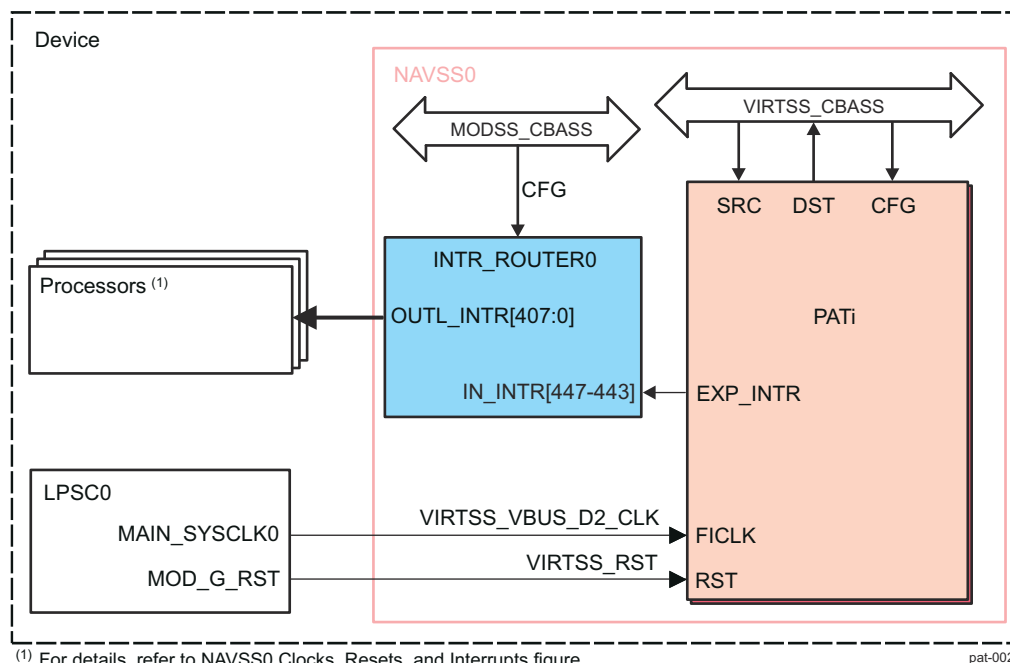

The following features are not supported by the module:

- Does not support transactions that cross a 4-KB page boundary

### 8.3.3.2 PAT Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 8-22 shows the PAT integration in the device.

**Figure 8-22. PAT Integration**

i = 0 to 4

Table 8-41 and Table 8-42 summarize the integration of the module in the device.

**Table 8-41. PAT Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
NAVSS0_PAT0	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_PAT1	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_PAT2	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_PAT3	PSC0	GP	LPSC0	VIRTSS_CBASS
NAVSS0_PAT4	PSC0	GP	LPSC0	VIRTSS_CBASS

NAVSS0_PAT2	-	-	-	No PDMA channels to external DMA engines	-
NAVSS0_PAT3	-	-	-	No PDMA channels to external DMA engines	-
NAVSS0_PAT4	-	-	-	No PDMA channels to external DMA engines	-

### Note

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

For more information on the power, reset, and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

### 8.3.3.3 PAT Functional Description

#### 8.3.3.3.1 Functional Operation Overview

PAT performs a page-based address translation on a CBA VBUSM bus. The module acts as a VBUSM retiming bridge that also performs the address translation.

The entire PAT can be enabled or disabled via the PAT\_CONTROL register.

#### 8.3.3.3.2 Page Table

The table consists of a programmed translated base address per page. Each page is a programmable 4 KB, 16 KB, 64 KB, or 1 MB in size and each translated base is 36 bits. The input address uses the bits just above the page size, shown in [Table 8-44](#), to define the index within the table. A lookup is performed using that index to find the associated translated base. Then, that translated base replaces the upper bits of the final output address. The lower bits of the output address are copied from the input address, all shown in [Table 8-44](#). If the table is disabled or the index is beyond the non-power-of-2 size of the table, then the address is not translated, and the output address is copied from the input address and zero extended. Table sizes that are an exact power-of-2 cannot detect a beyond index and the index will just wrap and alias.

The table itself is built using an SRAM.

**Table 8-44. Index Bits and Final Address vs Page Size**

Page Size	Index Bits (N depends on table size)	Final Address
4 KB	address[N:12]	trans_address[47:12], address[11:0]
16 KB	address[N:14]	trans_address[47:14], address[13:0]
64 KB	address[N:16]	trans_address[47:16], address[15:0]
1 MB	address[N:20]	trans_address[47:20], address[19:0]

#### 8.3.3.3.3 Alignment

All accesses through the PAT must not cross 4-KB page boundaries. The module does check for this condition. If a transaction crosses a 4-KB boundary, the entire transaction will set the bus *cflush* signal to return an error. The error is also logged in the PAT\_EXCEPTION\_LOGGING registers and an interrupt can be generated.

#### 8.3.3.3.4 Page Enables

There is an overall PAT enable bit PAT\_CONTROL register, and each page entry has an enable bit - PAT\_BASE\_REG\_H\_j\_k (where j = block, k = page). If the transaction is to the PAT and the PAT\_CONTROL[0] ENABLE bit is clear, then no pages are enabled and all lookups to the table will result in an error. Similarly, if the page entry bit is clear the page is not enabled and any lookups to that page will result in an error. The transaction will be flushed and the error logged in the PAT\_EXCEPTION\_LOGGING registers. If this bit is set, then the page is enabled and the translation will be performed. When changing a page entry, the safest approach is to clear the ENABLE bit first, then write the lower address value, and finally the upper address value along with setting the ENABLE bit. This will guarantee that a lookup cannot use the entry while it is in the middle of the update.

#### 8.3.3.3.5 Table Arbitration

Access to the table can follow two arbitration methods.

- The first is to always prioritize table updates before lookups. In this method, the updates will always be allowed and the lookups will be stalled until there is no update.
- If the table is being updated frequently, there is a second method that performs round robin between the accesses. This will alternate between the two access types if both are pending, and give a balanced bandwidth to each. If only one is pending then it is given access regardless of the round robin state.

#### 8.3.3.3.6 Programming

The table can be programmed at any time. There is no guarantee about the timing of the update against any bus transactions, so the only way to guarantee an endpoint uses the updated table is to stall the endpoint until the table update has been completed. Or the page update can first disable that page, and then write the updated

page entry. If a transaction arrives while the page is disabled it will result in an error. All table accesses must be for full 32-bit words, as byte access is not supported for the table registers, that is, PAT\_BASE\_REG\_L\_j\_k and PAT\_BASE\_REG\_H\_j\_k.

#### **8.3.3.3.7 Scratch RAM**

When the PAT table is disabled, the table RAM can be used as a scratch RAM. Software simply needs to access the PAT scratch (PAT\_MEM\_y) locations. The module supports bursts on the config VBUSP port to keep bandwidth as high as the burst can support. A DMA, for instance, could probably achieve full bandwidth on the 32-bit bus. Since the PAT table is disabled, the SRAM accesses will not stall any transactions through the VBUSM bridge datapath. It is illegal to access the scratch RAM when the PAT table is enabled, and unexpected behavior for translations may occur.

#### **8.3.3.3.8 Error Reporting**

The PAT will capture details of any transaction that causes an error. There are two types of errors:

- The first type is when an incoming transaction crosses a 4-KB boundary, which is illegal on the CBA bus anyway
- The second error type is when the entire PAT or requested page entry is disabled, or the translation is not valid.

If an error occurs, the transaction will be flushed and the error details logged into the PAT\_EXCEPTION\_LOGGING registers. The error logging can generate an interrupt, and can be automatically cleared by reading the bottom error logging register - PAT\_EXCEPTION\_LOGGING\_DATA3.

Only one error can be captured until the interrupt is cleared, and any further errors are lost.

## 8.4 Region-based Address Translation (RAT) Module

This section describes the RAT functionality.

### 8.4.1 RAT Functional Description

#### 8.4.1.1 RAT Availability

Table 8-45 lists the device modules and subsystems which have RAT module.

**Table 8-45. Device Modules and Subsystems with RAT Module**

RAT_INTR	RAT Interrupt Output	Level

#### 8.4.1.2 RAT Operation

The RAT module performs a region based address translation. It translates a 32-bit input address into a 48-bit output address. Any input transaction that starts inside of a programmed region will have its address translated, if the region is enabled. Any disabled region is ignored from the translation lookup.

RAT has 16 regions, with each region having dedicated registers that define its attributes:

- Base address of the region, via the RAT\_BASE\_k register.
- Size of the region, via the RAT\_CTRL\_k register.

- Translated base address (48-bit). It is defined by 32-bit lower address via the RAT\_TRANS\_L\_k register, and 16-bit upper address via the RAT\_TRANS\_U\_k register.

The input addresses are compared against all the enabled regions in parallel. The region size defines how many of the lowest address bits are included in the region space, starting from a 1B space to a 4GB space. Then the upper bits not part of the region are used for the lookup and comparison, matching those bits of the input addresses against the region base address. The region matches when it is enabled and the compare matches. The first region that matches has the output address set with the region translated base address upper bits. The lower bits that are part of the region size are copied from the input address to the output address. If there are no region matches then the input address is copied to the output address entirely.

RAT does not automatically correct transactions that cross region boundaries, that is, start inside of a region and end outside of it, or start outside of a region and end inside of it. If a boundary crossing transaction is detected, then RAT annuls the transaction as illegal, generates an interrupt and logs an error, as explained in *RAT Error Logging*.

#### Note

The region base address and translated base address must be aligned to the defined region size. For example, if the defined region size is 64KB, then the two addresses must be 64KB aligned. This is software responsibility as RAT does not perform such alignment check. Regions that are not aligned have unpredictable results.

Moreover, multiple region definitions must not overlap in their covered address space. RAT does not check for this, so it is software responsibility to take care of it. Overlapping regions may lead to unpredictable results.

#### 8.4.1.3 RAT Error Logging

The error log consists of a series of registers that capture the details of the transaction, including the input address that caused the error. These registers are the following:

- RAT\_EXCEPTION\_LOGGING\_HEADER0 and RAT\_EXCEPTION\_LOGGING\_HEADER1
- RAT\_EXCEPTION\_LOGGING\_DATA0 through RAT\_EXCEPTION\_LOGGING\_DATA3

The RAT module can capture one error before it is cleared by software. The error logging is enabled by default, but can be disabled via the RAT\_EXCEPTION\_LOGGING\_CONTROL[0] DISABLE\_F bit. Upon error logging an interrupt is also generated. To clear the log, software must either read the final error logging register, or manually clear the RAT\_EXCEPTION\_PEND\_CLEAR[0] PEND\_CLR bit by setting it to 0x1. This will clear the error status, and not the actual log registers, but it does allow the next error to be captured into the log registers. If the status is not cleared and additional errors are detected, they are not logged.

After an error occurs and is cleared (whether by reading the final error logging register or by clearing the status bit), the RAT\_EOI\_REG register must be written to guarantee the next interrupt pulse will be produced.

Table 8-48 shows the RAT source ID mapping which is associated with the RAT\_EXCEPTION\_LOGGING\_HEADER0[23-8] SRC\_ID field.

**Table 8-48. RAT Source ID Mapping**

Module Instance	Source ID Value (Decimal)
WKUP_DMSC0	0
MCU_R5FSS0_CORE0	2
MCU_R5FSS0_CORE1	3

## 9.1 Interrupt Architecture

The SoC has many peripherals and a large number of event sources (interrupt, time sync or DMA). The use of events is completely dependent on a user's specific application, which drives a need for maximum flexibility in which event sources are used in the system. It is also completely up to software control as to how the events are serviced.

The SoC includes the following interrupt servicing modules (hosts):

- Device management and security controller (WKUP\_DMSC0):
  - Single Arm Cortex-M3 core
  - Nested vectored interrupt controller (NVIC)
- Compute cluster:
  - Two processor subsystems:
    - Dual-core Arm Cortex-A72 microprocessor unit (A72SS0)
    - Single-core C71x DSP subsystem (C71SS0)
  - Two interrupt controllers, both integrated inside the MSMC wrapper:
    - Arm generic interrupt controller (GIC-500) supports both cores in the dual-A72 cluster
    - Cluster level event controller (CLEC) supports the C71x DSP
- C66x DSP subsystems (C66SS0, C66SS1), each implementing:
  - Single C66x CPU core
  - Local interrupt controller
- Microcontroller units (R5FSS0, R5FSS1, MCU\_R5FSS0), each implementing:
  - Two Arm Cortex-R5F cores
  - Vectored interrupt manager (VIM)
- Industrial communications subsystems (PRU\_ICSSG0, PRU\_ICSSG1), each implementing:
  - Two programmable real-time units (PRUs)
  - Local interrupt controller (PRU\_ICSSGn\_INTC0)

Most of the system events are routed directly to the various processing elements but in some cases it is impractical to route all events of a certain group (for example, GPIO events) to each processing element. For this purpose, the SoC integrates several interrupt router (INTRTR) instances. Each interrupt router aggregates a number of system events and can route each event to a given processing element by using simple combinational logic (a set of multiplexors). Event selection is controlled through the associated registers within each interrupt router.

The following interrupt router instances are part of the SoC interrupt architecture:

- WKUP domain GPIO interrupt router (WKUP\_GPIOMUX\_INTRTR0):
  - Provides selection of active module interrupts for the WKUP\_GPIO0 module
- MAIN domain GPIO interrupt router (GPIOMUX\_INTRTR0):
  - Provides selection of active module interrupts for the MAIN domain GPIO0 and GPIO1 modules
- MAIN-to-MCU domain level interrupt router (MAIN2MCU\_LVL\_INTRTR0):
  - Provides selection of active MAIN domain module *level* interrupts for routing to MCU domain processing elements
  - Reduces the number of event voltage domain crossings
- MAIN-to-MCU domain pulse interrupt router (MAIN2MCU\_PLS\_INTRTR0):
  - Provides selection of active MAIN domain module *pulse* interrupts for routing to MCU domain processing elements
  - Reduces the number of event voltage domain crossings
- R5FSS0 interrupt router (R5FSS0\_INTRTR0):
  - Provides selection of active module interrupts for the R5FSS0 module
- R5FSS1 interrupt router (R5FSS1\_INTRTR0):
  - Provides selection of active module interrupts for the R5FSS1 module
- C66SS0 interrupt router (C66SS0\_INTRTR0):

- Provides selection of active module interrupts for the C66SS0 module
- C66SS1 interrupt router (C66SS1\_INTRTR0):
  - Provides selection of active module interrupts for the C66SS1 module

In addition, the following interrupt router instances are part of the SoC time sync architecture:

- Time sync event router (TIMESYNC\_INTRTR0):
  - Provides selection of active common platform time synchronization (CPTS) events for routing to CPTS capable modules
- Compare event router (CMPEVT\_INTRTR0):
  - Provides selection of active CPTS counter compare events for routing as processor interrupts or DMA events

For more details on time sync routers, see [Section 11.3.2, Time Sync Routers](#).

## 9.2 Interrupt Controllers

### 9.2.1 Generic Interrupt Controller (GIC)

This section describes the Generic Interrupt Controller (GIC) module in the device.

#### 9.2.1.1 GIC Overview

The device GIC is a TI module that is based on the Arm GIC-500 interrupt controller. The Arm GIC-500 is a high-performance, area-optimized, built-time configurable interrupt controller which detects, manages, and distributes system interrupts to the Arm® Cortex®-A72 processors in the Compute Cluster.

The Arm GIC-500 is compliant to the Arm GICv3 standard. It only supports cores that implement the Armv8 architecture and the GIC CPU interface with the standard GIC Stream Protocol Interface (such as A72).

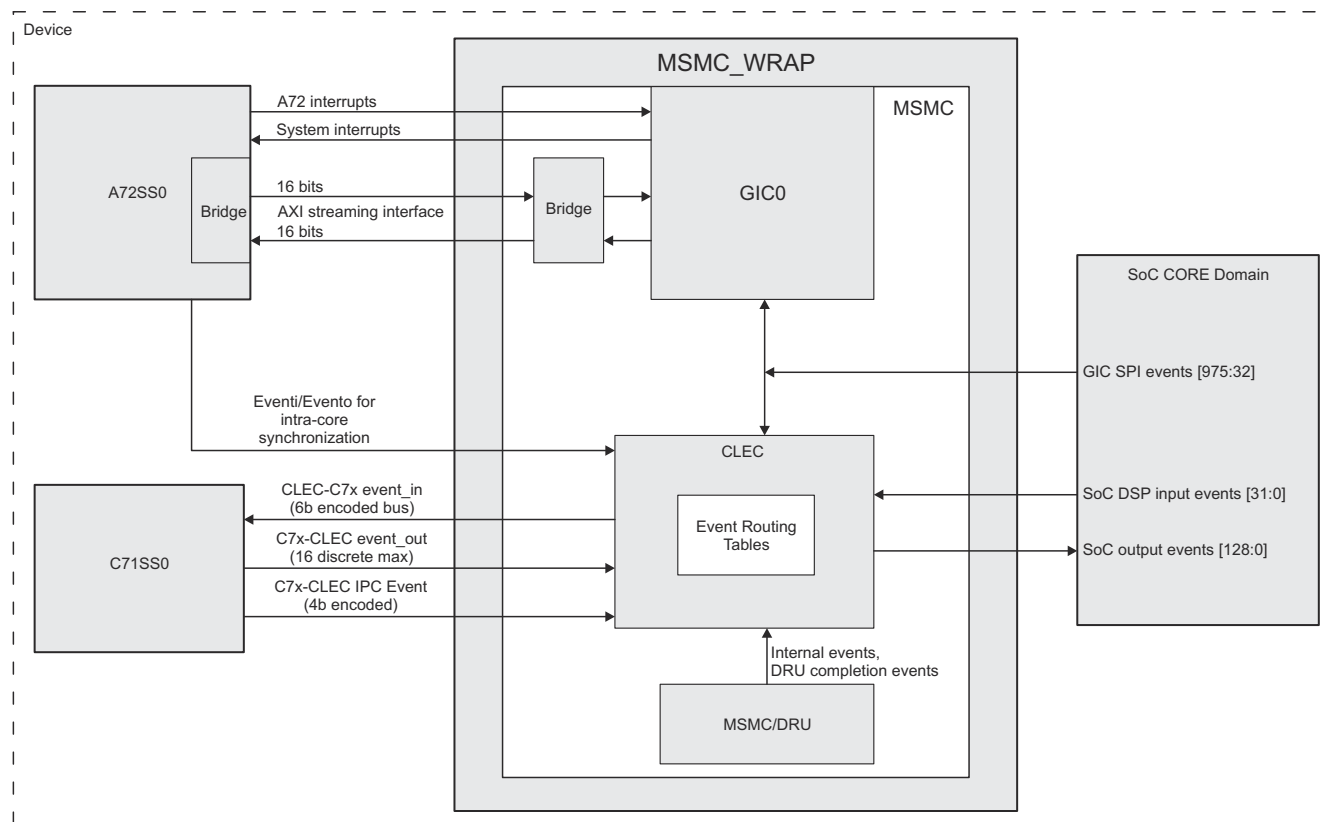

The GIC includes additional logic (TI wrapper) to fully integrate the Arm GIC-500 into the SoC.

The device includes one GIC instance named GIC0. [Table 9-1](#) shows GIC module allocation within device domains.

**Table 9-1. GIC Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
GIC0	–	–	✓

The GIC module is located inside the MSMC\_WRAP logical block in the Compute Cluster, along with the cluster level interrupt controller (CLEC), which serves the C71x DSP. [Figure 9-1](#) shows an overview of the Compute Cluster interrupt architecture.

**Figure 9-1. Compute Cluster Interrupt Architecture**

### 9.2.1.1.1 GIC Features

#### Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm®CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

The Arm GIC-500 supports the following features in the device:

- Module revision: r1p1
- Supports both cores in the dual-A72 MPU cluster
- 16 software generated interrupts (SGIs) per core
- 16 private peripheral interrupts (PPIs) per core
- 960 shared peripheral interrupts (SPIs)
- Locality-specific peripheral interrupts (LPIs), used for message-based interrupts
- Interrupt translation service (ITS)
  - Device isolation
  - ID translation for message-based interrupts
  - This allows virtual machines to program devices directly
- Interrupt masking and prioritization
- Programmable, affinity-based interrupt routing
- 32 priorities for each interrupt
- Three different interrupt groups
  - Group 0
  - Non-secure group 1
  - Secure group 1

Additionally, the GIC wrapper logic provides the following features:

- Synchronizes interrupt inputs to GIC clock
- Implements AXI2VBUSM and VBUSM2AXI bridges
  - Used for bus protocol conversion (AXI-to-VBUSM and VBUSM-to-AXI, respectively)
- Implements an integrated ECC aggregator
  - Only used to inject errors (for testing purposes)

### 9.2.1.1.2 GIC Not Supported Features

The GIC does not support the following features:

- GICv2 backwards compatibility
- AWID-based LPI mapping

### 9.2.1.1.3 GIC Configuration Summary

[Table 9-2](#) summarizes the GIC configuration for this device.

**Table 9-2. GIC Configuration Summary**

Parameter	SoC Value
Number of affinity-level 1 CPU Clusters (Corepacs)	1
Number of CPUs in cluster 0	2
Number of SPIs	960
ITS/LPI support <ul style="list-style-type: none"> <li>• TRUE: ITS is present. LPIs are supported</li> <li>• FALSE: ITS is not present. LPIs are not supported</li> </ul>	TRUE
Device ID width	20
Number of LPI cache entries	64

**Table 9-2. GIC Configuration Summary (continued)**

Parameter	SoC Value
Width of AXI4 <b>awid_s</b> and <b>bid_s</b> signals	4
Width of AXI4 <b>arid_s</b> and <b>rid_s</b> signals	4
GICv2 backwards compatibility support <ul style="list-style-type: none"> <li>TRUE: No support for GICv2 backward compatibility</li> <li>FALSE: Software-programmable GICv2 backward compatibility</li> </ul>	TRUE
Security support <ul style="list-style-type: none"> <li>TRUE: No concept of security</li> <li>FALSE: Security enabled. At least one processor must be able to make secure accesses. (Secure access requirement can be disabled by secure software at boot)</li> </ul>	FALSE

### 9.2.1.2 GIC Integration

This section describes the GIC module integration in the device, including information about clocks, resets, and hardware requests.

Figure 9-2 shows the GIC module integration.

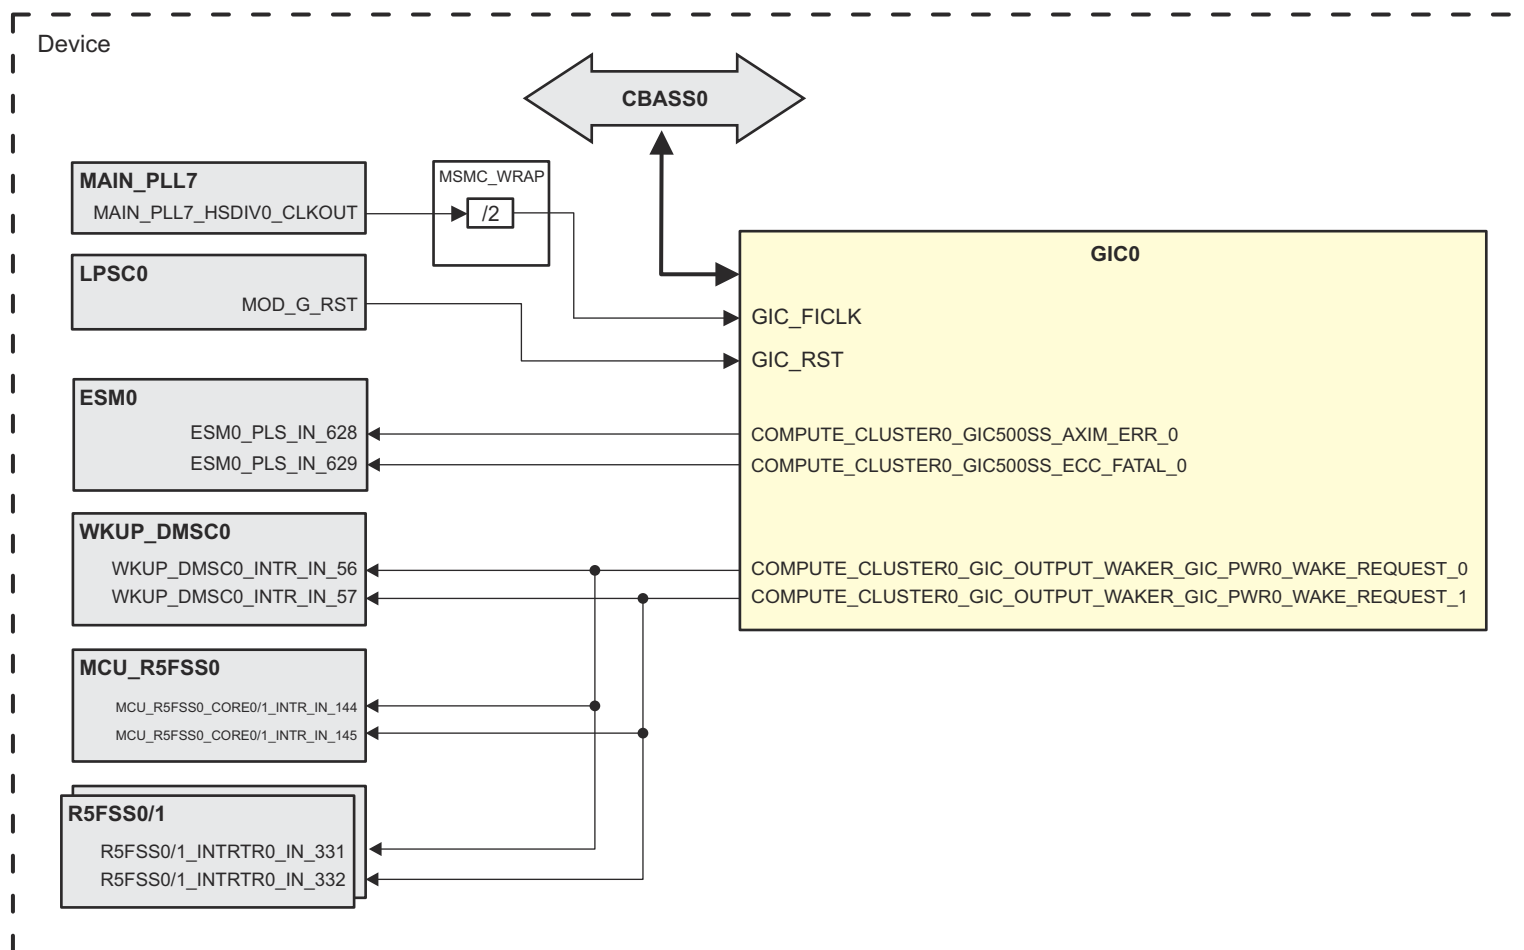

Figure 9-2. GIC Integration

Table 9-3 through Table 9-5 summarize the GIC integration.

**Table 9-3. GIC Integration Attributes**

Module Instance	Attributes

### Note

Table 9-5 lists only the GIC interrupt outputs. These GIC interrupts are further described in [Section 9.2.1.3.5, GIC Interrupt Outputs](#).

The mapping of system interrupts to GIC interrupt inputs is presented in [Section 9.4.3.1](#).

### 9.2.1.3 GIC Functional Description

#### Note

This chapter provides only a brief description of the GIC functionality and features. For more details on this module, refer to the *Arm® CoreLink™ GIC-500 Generic Interrupt Controller Technical Reference Manual*.

#### 9.2.1.3.1 GIC Block Diagram

Figure 9-3 shows the GIC block diagram.

**Figure 9-3. GIC Block Diagram**

#### 9.2.1.3.2 Arm GIC-500

The Arm GIC-500 is responsible for detecting, managing and communicating system interrupts to the two dual-core A72 clusters implemented on the SoC. The main difference between the Arm GIC-500 and previous Arm GIC versions is the direct communication with the CPU(s). Previously, an interrupt controller would set a pending bit to a CPU and that CPU would then have to query an interrupt controller MMR to find out what to do. Now, the Arm GIC-500 sends interrupts to a CPU via a dedicated message interface and the CPU communicates back about interrupts through the same interface. The CPU now uses writes and reads to system registers instead of over the memory interface. This leads to reduced latency and the ability to route interrupts to different CPUs based on a set of rules.

The Arm GIC-500 is divided into three main sections:

- **Distributor:** The Distributor receives interrupts from the wire interrupts and the programming interface. It is responsible for prioritizing these interrupts and sending them to the CPU interface via the GIC Stream Protocol Interface.
- **Redistributor:** There is one Redistributor per core. Each Redistributor holds the state that is individual to a particular core (such as the settings for PPIs and SGIs). It also stores the LPIs for that core after they have been generated using the ITS.
- **ITS:** The ITS is responsible for translating message-based interrupts from device peripherals into LPIs. The user can also use the ITS to manage existing LPIs. Note that the ITS is not used for other types of interrupt

#### 9.2.1.3.3 GIC Interrupt Types

The GIC supports four types of interrupts:

- **Software Generated Interrupts (SGIs):** There are 16 SGIs (ID0-ID15). These are inter-processor interrupts. SGIs can be sent using either Arm system registers or by writing to the Software Generated Interrupt Register (GICD\_SGIR).

- **Private Peripheral Interrupts (PPIs):** There are 16 PPIs (ID16-ID31). These are wired interrupts dedicated to a specific CPU. Many are reserved to specific functions via convention. These can be either active-low levels (by default), or rising edge triggered (software programmable).
- **Shared Peripheral Interrupts (SPIs):** There are 960 SPIs (ID32-ID991). These are wired interrupts that can be routed to any core or cluster, based on the programming of that interrupt in the GIC. These are active-high levels (by default), or rising edge triggered (software programmable).
- **Locality-Specific Peripheral Interrupts (LPIs):** There are 57,344 of these. These interrupts are used for message-based interrupts from a peripheral. They are generated through writes to the GIC slave interface. The information associated with these is located in memory. The GIC keeps a small 64-entries cache on-board in order to reduce latency either for specific interrupts or for most-recently-used. LPIs can be routed to different CPUs based on programmed rules.

The mapping of PPIs and SPIs can be found in section .

#### 9.2.1.3.4 GIC Interfaces

The GIC has the following main interfaces:

- A pair of 64-bit VBUSM write-only and read-only master interfaces
  - AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into this pair of interfaces
  - The AXI4 master interface allows the GIC ITS and redistributors to access main memory
- 32-bit VBUSM slave interface
  - Provides access to Arm GIC-500 internal resources
  - Handles all message-based interrupts. Message-based interrupts can generate SPIs or LPIs, depending on the register that is written
  - VBUSM2AXI bridge converts this interface into an 32-bit AXI4 slave interface
- 32-bit VBUSP slave interface
  - Provides access to internal ECC aggregator
- Physical interrupt and power signals
  - Inputs: CPU active signals, SPIs and PPIs (can be programmed as either level-sensitive, or edge-triggered)
  - Outputs: Error signals and wake-up requests
- GIC Stream Protocol Interface
  - Consists of a pair of AXI4-Stream interfaces (one upstream and one downstream 16-bit AXI4-Stream interface) that the GIC uses to send interrupts to the core and receive notifications when the core activates interrupts
  - There is a pair of physical interfaces, one in each direction, for each cluster

#### 9.2.1.3.5 GIC Interrupt Outputs

Table 9-6 lists the interrupts that are generated by the GIC.

**Table 9-6. GIC Interrupt Outputs**

Interrupt Name	Description
COMPUTE_CLUSTER0_GIC500SS_AXIM_ERR_0	GIC bus error interrupt. This interrupt is triggered if the GIC receives an error on a bus transaction, such as a decode or protection error. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
COMPUTE_CLUSTER0_GIC500SS_ECC_FATAL_0	GIC uncorrectable ECC error interrupt. Indicates an uncorrectable 2-bit error detected in one of the ITS cache memories. This is a pulse-high interrupt. If this interrupt occurs, the GIC might lose interrupts and must be reset. If it is not reset, behavior becomes unpredictable.
COMPUTE_CLUSTER0_GIC_OUTPUT_WAKER_GIC_PWR0_WAKE_REQUEST_0 <sup>(1)</sup>	GIC wake requests for A72 cores. Asserted state indicates that an interrupt is pending for a processor that has set the PROCESSORSLEEP bit in the GICR_WAKER register. This bit indicates that the SoC should wake up the indicated CPU so that it can process the interrupt.
COMPUTE_CLUSTER0_GIC_OUTPUT_WAKER_GIC_PWR0_WAKE_REQUEST_1 <sup>(2)</sup>	

(1) Applies to A72SS0\_CORE0

(2) Applies to A72SS0\_CORE1

#### **9.2.1.3.6 GIC ECC Support**

The Arm GIC-500 has built-in SECDED ECC on its memories to protect against errors. The syndrome generation and checking is done internally.

Additionally, the TI GIC wrapper integrates an ECC aggregator (GIC\_ECC\_AGGR) in order to allow errors to be injected for testing purposes. The generic ECC aggregator functionality is described in [Section 12.11.4, ECC Aggregator](#). Note that the GIC\_ECC\_AGGR supports only a subset of this functionality.

#### **9.2.1.3.7 GIC Interrupt Edge Detection**

All interrupt inputs are put through a standard edge-detection logic. This logic can either synchronize levels, or capture the rising edge of pulses. In this way, the GIC is agnostic to the clock frequency of the source, or pulse widths.

#### **9.2.1.3.8 GIC AXI2VBUSM and VBUSM2AXI Bridges**

The GIC uses the AXI4 master interface to allow the ITS and redistributors to access main memory. It is expected that the main memory (attached to a CBASS VBUSM port) holds the following:

- ITS translation tables
- ITS command queue, which is written by software in order to program the ITS
- LPI configuration table, which holds the priorities and enable bits for LPIs
- LPI pending tables, which can hold information on whether each LPI is pending on each core

The AXI2VBUSM bridge converts the standard 64-bit AXI4 master interface into a pair of 64-bit VBUSM write-only and read-only master interfaces. AXI4 has a separate command channel for read and write, and the AXI2VBUSM bridge keeps them separate, so that the system may prioritize or arbitrate the traffic between them as appropriate.

The GIC uses the AXI4 slave interface to provide access to the programming interfaces of all its parts (distributor, redistributors, ITS). The VBUSM2AXI bridge converts the standard 32-bit VBUSM master interface into an 32-bit AXI4 slave interface.

---

#### **Note**

The AXI2VBUSM and VBUSM2AXI bridges do not implement any MMRs.

---

## 9.2.2 Cluster Level Event Controller (CLEC)

### 9.2.2.1 CLEC Overview

The CLEC supports the following features:

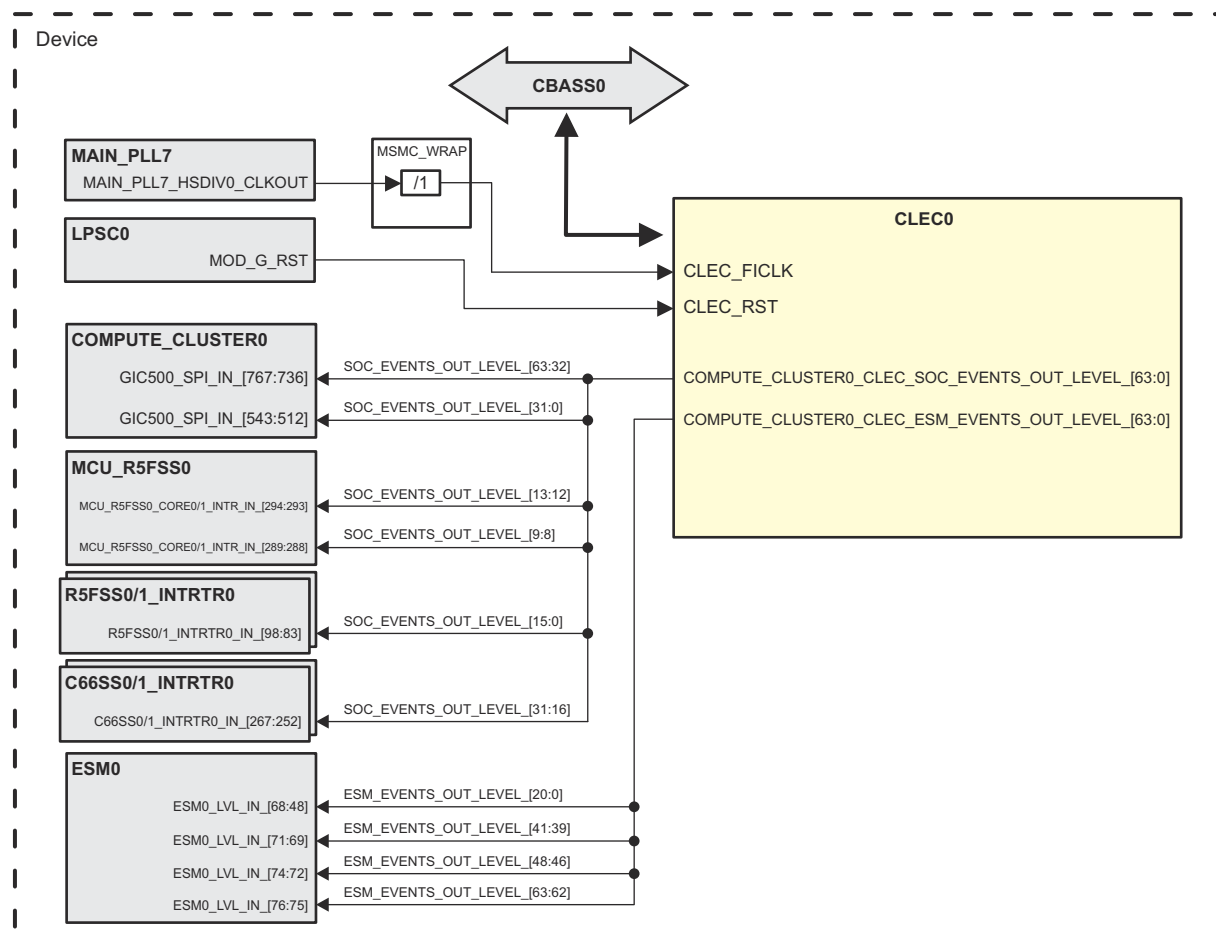

- Supports software scalable event routing mechanism
  - RAM-based interrupt event routing table
- Supports aggregation of incoming interrupt events from:
  - SoC peripherals
  - MSMC
  - DRU
  - C71SS
- Supports distribution of each aggregated interrupt event to one or more of the following:
  - SoC (could be routed to the GIC externally)
  - DRU
  - A72SS
  - C71SS
- Supports originating interrupt events through the following mechanisms:
  - MMR writes to trigger new events
  - Reporting errors detected by the CLEC
- 2048 input events
- 128 output events
- Can handle both level and pulse input interrupts
- Can be used for inter-processor communication (IPC) between A72 and C71x
- Shares SPI (shared peripheral interrupt) input events with GIC

See [Figure 9-1](#) for an overview of CLEC interrupt architecture.

### 9.2.2.2 CLEC Integration

This section describes the CLEC integration in the device, including information about clocks, resets, and hardware requests.

Figure 9-4 shows the CLEC integration.

**Figure 9-4. CLEC Integration**

Table 9-7 through Table 9-9 summarize the CLEC integration.

**Table 9-7. CLEC Integration Attributes**

**Note**

The COMPUTE\_CLUSTER0\_CLEC\_SOC\_EVENTS\_OUT\_LEVEL\_[128:64] outputs are not used in this device.

---

**Note**

[Table 9-9](#) lists only the CLEC interrupt outputs. The mapping of interrupt sources to CLEC interrupt inputs is presented in [Section 9.2.2.3.6.2](#).

---

### 9.2.2.3 CLEC Functional Description

#### 9.2.2.3.1 CLEC Interrupt Event Routing

The CLEC routes events according to a RAM-based interrupt event routing table. This table holds one entry for each supported external interrupt/event number, plus some additional entries for CLEC internal events. External in this context means "external to the CLEC", and corresponds to all interrupt events arriving at the CLEC from other sources. Internal refers to events that the CLEC generates internally, or in response to an MMR write that triggers the event.

The routing table memory has 2048 entries in size. Each routing table entry contains the following details:

- Outgoing event number: Each incoming event can be mapped to any outgoing event number
- Secure / Non-secure: Each incoming event can be claimed as a secure event
- Destination port configuration: This configuration allows for both single-cast and broadcast events

For each incoming interrupt event, the CLEC does the following processing:

- Validates the interrupt event number. For out-of-range event numbers, the CLEC triggers an "invalid event number" event
- Non-secure read/write to registers associated with a secure event will generate a privilege error
- Looks up the event in the routing table
- For each port in the destination bitmap that has a bit set, it queues the event to that destination
  - Queuing to multiple destinations happens in parallel, not sequentially, to minimize latency
  - If no bits are set, the event is dropped silently, but an interrupt dropped event is asserted. This event gets routed as determined by the routing table

#### Note

For events mapped to DRU and ARM, only event mapping number is looked at and they are not qualified by CLEC\_MRR\_j[21-16] RTMAP. Hence, this bit field is "don't care" for events that have CLEC\_MRR\_j[15-8] EXT\_EVNUM set to 128 or higher.

Since the routing table is a shared resource, the CLEC only routes one new event per cycle. The routing state machine arbitrates among all incoming event sources round-robin, with the exception that internally generated error events have priority over all other event sources.

The CLEC routes events to their destinations and also maintains pending interrupt information in an CLEC\_EFR\_k register. Firmware needs to clear this pending interrupt bit in an interrupt service routine (ISR).

#### 9.2.2.3.2 CLEC Virtualization, Isolation and Access Control

The CLEC provides direct support for virtual-machine isolation via a hypervisor. Each event's register window is deliberately spaced 64KB apart. This enables allocating individual event numbers to virtual machines via stage-2 translation. The 64KB spacing allows this to work even with the largest translation granule supported by ARM (64KB).

Individual functions associated with an event within each event's window are spaced 4KB apart. This allows a standard operating system to open up, for instance, write access to an CLEC\_ESR\_j register for a single task, while blocking access to the event routing details in CLEC\_MRR\_j register.

The CLEC implements event lock registers (CLEC\_GELRS / CLEC\_GELRNS) that allow hypervisor to lock down the configuration of events, while still permitting write access to the event send register (CLEC\_ESR\_j) for that event.

In current implementation, the CLEC provides basic support for isolating virtual machines by partitioning incoming events in the address map. However, it does not provide any support for limiting event numbers assigned for outgoing events in CLEC\_MRR\_j[15-8] EXT\_EVNUM. If such isolation is necessary, software can implement it in the hypervisor via para-virtualization calls, via trap-and-emulate for full virtualization.

### 9.2.2.3.3 CLEC Memory Protection

The CLEC implements minimal memory protection checks. It relies on protection mechanisms outside to control accesses from various masters. Chip-level firewalls control which masters may access the CLEC. MMUs provide finer-grain control for programmable processors that access the CLEC.

Specifically, the CLEC returns the following errors:

- Address error on a read or write to unimplemented space
- Address error on a read to a write-only register
- Address error on a write to a read-only register
- Privilege error on a non-secure read or write to registers associated with a secure event (CLEC\_MRR\_j[31] S = 1 for that event)
- Privilege error on a write to CLEC\_ESR\_j on an event whose CLEC\_MRR\_j[30] ESE = 0
- Privilege error on a write to CLEC\_MRR\_j on an event when CLEC\_GELRS[0] LOCK = 1

Any further access control must be implemented with firewalls and/or MMU configuration outside the CLEC.

### 9.2.2.3.4 CLEC ECC Support

Standard ECC aggregator strategy is used to implement ECC protection on the SRAM used to implement the CLEC routing table. The CLEC has two ports connected to the ECC\_AGGR at the MSMC\_WRAP level. For RAM\_ID values of CLEC ECC-protected memories, see [Section 6.1.2.3, Compute Cluster ECC Aggregators](#). For details on the generic ECC\_AGGR functionality, see [Section 12.11.4, ECC Aggregator](#).

### 9.2.2.3.5 CLEC Intra-Core Communication

In order to support intra-core synchronization inside Compute Cluster, associated C71/A72 events are routed through the CLEC.

### 9.2.2.3.6 CLEC Event Maps

#### 9.2.2.3.6.1 CLEC Output Event Routing

CLEC output events can be routed to SoC, DRU or C71/A72 corepacs. For Soc, DRU, and ARM events, the exact event number mapping is controlled by the CLEC\_MRR\_j[15-8] EXT\_EVNUM bit field. For C71 events, the exact event number mapping is controlled by the CLEC\_MRR\_j[5-0] C7X\_EVNUM bit field.

[Table 9-10](#) shows the CLEC output event map.

**Table 9-10. CLEC Output Event Map**

Destination	Event Number	Register Setting	Triggered Event
SoC	127-0	CLEC_MRR_j[15-8] EXT_EVNUM	SoC output events
DRU	159-128	CLEC_MRR_j[15-8] EXT_EVNUM	DRU local input trigger events
Reserved	191-160	Reserved	Reserved
A72 corepac	192	CLEC_MRR_j[15-8] EXT_EVNUM	A72 event for intra-core synchronization with C71
Reserved	255-193	Reserved	Reserved
C71 corepac	63-0	CLEC_MRR_j[5-0] C7x_EVNUM	C71SS events

#### 9.2.2.3.6.2 CLEC Input Event Map

[Table 9-11](#) shows the events that are mapped to CLEC event inputs. Any of these events can be routed to any of the CLEC event outputs.

**Table 9-11. CLEC Input Event Map**

Interrupt Input Line	Interrupt Name	Description
CLEC_INTR_IN_0	Reserved	Reserved
CLEC_INTR_IN_1	CLEC_ADDR_ERR	CLEC address error
CLEC_INTR_IN_2	CLEC_PRIV_ERR	CLEC privilege error
CLEC_INTR_IN_3	CLEC_INVALID_EVT	CLEC invalid event

**Table 9-11. CLEC Input Event Map (continued)**

Interrupt Input Line	Interrupt Name	Description
CLEC_INTR_IN_4	CLEC_DROPPED_EVT	CLEC dropped event
CLEC_INTR_IN_5 - CLEC_INTR_IN_7	Reserved	Reserved
CLEC_INTR_IN_8	ARM0_DFT_PBIST_CPU_ERROR_INTR	A72 DFT PBIST CPU error interrupt
CLEC_INTR_IN_9 - CLEC_INTR_IN_11	Reserved	Reserved
CLEC_INTR_IN_12	C7X_DFT_PBIST_CPU_ERROR_INTR	C71x DFT PBIST CPU error interrupt
CLEC_INTR_IN_13 - CLEC_INTR_IN_15	Reserved	Reserved
CLEC_INTR_IN_16	MSMC_CTSET_INTR	MSMC CT-SET (debug) interrupt
CLEC_INTR_IN_17	DRU_PROTOCOL_ERROR	DRU protocol error
CLEC_INTR_IN_18 - CLEC_INTR_IN_23	Reserved	Reserved
CLEC_INTR_IN_24	MSMC_NULL_SLAVE_ERROR	MSMC null slave error
CLEC_INTR_IN_25 - CLEC_INTR_IN_63	Reserved	Reserved
CLEC_INTR_IN_64 - CLEC_INTR_IN_127	DRU_COMPLETE_EVENT_IN_0 - DRU_COMPLETE_EVENT_IN_63	DRU complete events 0-63
CLEC_INTR_IN_128 - CLEC_INTR_IN_191	DRU_ERROR_EVENT_IN_0 - DRU_ERROR_EVENT_IN_63	DRU error events 0-63
CLEC_INTR_IN_192 - CLEC_INTR_IN_255	DRU_LOCALOUT_EVENT_IN_0 - DRU_LOCALOUT_EVENT_IN_63	DRU local events 0-63
CLEC_INTR_IN_256 - CLEC_INTR_IN_383	Reserved	Reserved
CLEC_INTR_IN_384 - CLEC_INTR_IN_415	C7X_DISCRETE_EVENT_0 - C7X_DISCRETE_EVENT_31	C71x discrete events 0-31
CLEC_INTR_IN_416 - CLEC_INTR_IN_511	Reserved	Reserved
CLEC_INTR_IN_512	ARM0_EVENTO	A72 intra-core (IPC) event
CLEC_INTR_IN_513 - CLEC_INTR_IN_567	Reserved	Reserved
CLEC_INTR_IN_568 - CLEC_INTR_IN_599	SOC_EVENT_IN_0 - SOC_EVENT_IN_31	SoC DSP input events 0-31
CLEC_INTR_IN_600 - CLEC_INTR_IN_1023	Reserved	Reserved
CLEC_INTR_IN_1024 - CLEC_INTR_IN_1983	GIC_SPI_IN_32 - GIC_SPI_IN_975	SoC GIC SPI events 32-975
CLEC_INTR_IN_1984 - CLEC_INTR_IN_2047	Reserved	Reserved

### 9.2.2.3.6.3 CLEC ESM Event Routing

Table 9-12 shows the CLEC ESM event output map.

**Table 9-12. CLEC ESM Event Output Map**

Destination	Source Interrupt	Description
ESM_EVENTS_OUT_LEVEL_0	MSMC_ECCAGGR0_UNCORR_LEVEL_INTR	MSMC ECC_AGGR0 uncorrectable error
ESM_EVENTS_OUT_LEVEL_1	MSMC_ECCAGGR0_CORR_LEVEL_INTR	MSMC ECC_AGGR0 correctable error
ESM_EVENTS_OUT_LEVEL_2	MSMC_ECCAGGR1_UNCORR_LEVEL_INTR	MSMC ECC_AGGR1 uncorrectable error
ESM_EVENTS_OUT_LEVEL_3	MSMC_ECCAGGR1_CORR_LEVEL_INTR	MSMC ECC_AGGR1 correctable error
ESM_EVENTS_OUT_LEVEL_4	MSMC_ECCAGGR2_UNCORR_LEVEL_INTR	MSMC ECC_AGGR2 uncorrectable error
ESM_EVENTS_OUT_LEVEL_5	MSMC_ECCAGGR2_CORR_LEVEL_INTR	MSMC ECC_AGGR2 correctable error

**Table 9-12. CLEC ESM Event Output Map (continued)**

Destination	Source Interrupt	Description
ESM_EVENTS_OUT_LEVEL_6	MSMC_DFT_PBIST_SAFETY_ERROR_INTR	MSMC DFT PBIST internal diagnostic error
ESM_EVENTS_OUT_LEVEL_7	ARM0_ECCAGGR0_UNCORR_LEVEL_INTR	A72 ECC_AGGR0 uncorrectable error
ESM_EVENTS_OUT_LEVEL_8	ARM0_ECCAGGR0_CORR_LEVEL_INTR	A72 ECC_AGGR0 correctable error
ESM_EVENTS_OUT_LEVEL_9	ARM0_ECCAGGR1_UNCORR_LEVEL_INTR	A72 ECC_AGGR1 uncorrectable error
ESM_EVENTS_OUT_LEVEL_10	ARM0_ECCAGGR1_CORR_LEVEL_INTR	A72 ECC_AGGR1 correctable error
ESM_EVENTS_OUT_LEVEL_11	ARM0_ECCAGGR2_UNCORR_LEVEL_INTR	A72 ECC_AGGR2 uncorrectable error
ESM_EVENTS_OUT_LEVEL_12	ARM0_ECCAGGR2_CORR_LEVEL_INTR	A72 ECC_AGGR2 correctable error
ESM_EVENTS_OUT_LEVEL_13	ARM0_DFT_PBIST_SAFETY_ERROR_INTR	A72 DFT PBIST internal diagnostic error
ESM_EVENTS_OUT_LEVEL_14 - ESM_EVENTS_OUT_LEVEL_38	Reserved	Reserved
ESM_EVENTS_OUT_LEVEL_39	C7X_ECCAGGR_UNCORR_LEVEL_INTR	C7x ECC_AGGR uncorrectable error
ESM_EVENTS_OUT_LEVEL_40	C7X_ECCAGGR_CORR_LEVEL_INTR	C7x ECC_AGGR correctable error
ESM_EVENTS_OUT_LEVEL_41	C7X_DFT_PBIST_SAFETY_ERROR_INTR	C7x DFT PBIST internal diagnostic error
ESM_EVENTS_OUT_LEVEL_42 - ESM_EVENTS_OUT_LEVEL_48	Reserved	Reserved
ESM_EVENTS_OUT_LEVEL_49	DDRSS0_CFG_ECCAGGR_UNCORR_LVL_INTR	DDRSS0 cfg ECC_AGGR uncorrectable error
ESM_EVENTS_OUT_LEVEL_50	DDRSS0_CFG_ECCAGGR_CORR_LVL_INTR	DDRSS0 cfg ECC_AGGR correctable error
ESM_EVENTS_OUT_LEVEL_51	DDRSS0_CTL_ECCAGGR_UNCORR_LVL_INTR	DDRSS0 ctl ECC_AGGR uncorrectable error
ESM_EVENTS_OUT_LEVEL_52	DDRSS0_CTL_ECCAGGR_CORR_LVL_INTR	DDRSS0 ctl ECC_AGGR correctable error
ESM_EVENTS_OUT_LEVEL_53	DDRSS0_VBUS_ECC_GGR_UNCORR_LVL_INTR	DDRSS0 vbus ECC_AGGR uncorrectable error
ESM_EVENTS_OUT_LEVEL_54	DDRSS0_VBUS_ECCAGGR_CORR_LVL_INTR	DDRSS0 vbus ECC_AGGR correctable error
ESM_EVENTS_OUT_LEVEL_55 - ESM_EVENTS_OUT_LEVEL_61	Reserved	Reserved
ESM_EVENTS_OUT_LEVEL_62	GIC0_ECCAGGR_UNCORR_LEVEL_INTR	GIC0 ECC_AGGR uncorrectable error
ESM_EVENTS_OUT_LEVEL_63	GIC0_ECCAGGR_CORR_LEVEL_INTR	GIC0 ECC_AGGR correctable error

#### 9.2.2.3.6.4 CLEC C7x DSP Input Event Map

Table 9-13 shows the mapping of C7x discrete events (including IPC) to associated CLEC inputs.

**Table 9-13. CLEC C7x DSP Input Event Map**

Interrupt Line	Interrupt Name	Description
C7X_DISCRETE_EVENT_0	C7X_IPC_DROP_EVT	C7x IPC dropped event
C7X_DISCRETE_EVENT_1	C7X_MEMSYS_INTR	C7x memsys interrupt
C7X_DISCRETE_EVENT_2	C7X_DBG_CTM_INTR	C7x CTM (debug) interrupt
C7X_DISCRETE_EVENT_3	C7X_DBG_AET_INTR	C7x AET (debug) interrupt
C7X_DISCRETE_EVENT_4 - C7X_DISCRETE_EVENT_15	Reserved	Reserved
C7X_DISCRETE_EVENT_16 - C7X_DISCRETE_EVENT_31	C7X_IPC_EVENT_0 - C7X_IPC_EVENT_15	C7x IPC events 0-15

### 9.2.3 Other Interrupt Controllers

For details on R5FSS vectored interrupt manager (VIM), see [Section 6.3.3.6](#), *R5FSS Vectored Interrupt Manager (VIM)*.

For details on DMSC nested vectored interrupt controller (NVIC), see *TI Device Management Security Controller and Power Management Addendum*, and *Arm Cortex-M3 Technical Reference Manual*.

For details on PRU-ICSSG local interrupt controller (INTC), see *PRU\_ICSSG Local INTC*.

## 9.3 Interrupt Routers

### 9.3.1 INTRTR Overview

The interrupt router (INTRTR) module provides a mechanism to mux  $M$  interrupt inputs to  $N$  interrupt outputs, where all  $M$  inputs are selectable to be driven per  $N$  output. There is one register per output (MUXCNTL\_N) that controls the selection.

There are several INTRTR modules in the device. Their purpose is described in [Section 9.1, Interrupt Architecture](#). [Table 9-14](#) summarizes the configuration details for the various interrupt routers.

**Table 9-14. INTRTR Modules Configuration**

Module	Number of Inputs	Number of Outputs	Input Interrupt Type
WKUP_GPIOMUX_INTRTR0	120	32	Pulse
GPIOMUX_INTRTR0	304	64	Pulse
MAIN2MCU_LVL_INTRTR0	320	64	Level
MAIN2MCU_PLS_INTRTR0	104	48	Pulse
R5FSS0_INTRTR0	432	256	Level
R5FSS1_INTRTR0	432	256	Level
C66SS0_INTRTR0	400	97	Level
C66SS1_INTRTR0	400	97	Level

The user should take the following into account when programming the MUXCNTL\_N register:

- Avoid programming this register when input interrupts are active. This could lead to spurious asynchronous output toggles which may lead to unpredictable behavior.

The recommended general programming sequence is as follows:

1. Disable interrupt by writing '0' to the INT\_ENABLE bit field. Do not change mux control configuration settings (ENABLE bit field) at this time.
2. Change the mux control configuration settings. INT\_ENABLE needs to remain '0' at this time.
3. Enable interrupt by writing '1' to INT\_ENABLE. Do not change mux control configuration settings at this time.

### **9.3.2 INTRTR Integration**

This section describes the INTRTR integration in the device, including information about clocks, resets, and hardware requests.

### 9.3.2.1 WKUP\_GPIOMUX\_INTRTR0 Integration

Figure 9-5 shows the WKUP\_GPIOMUX\_INTRTR0 integration.

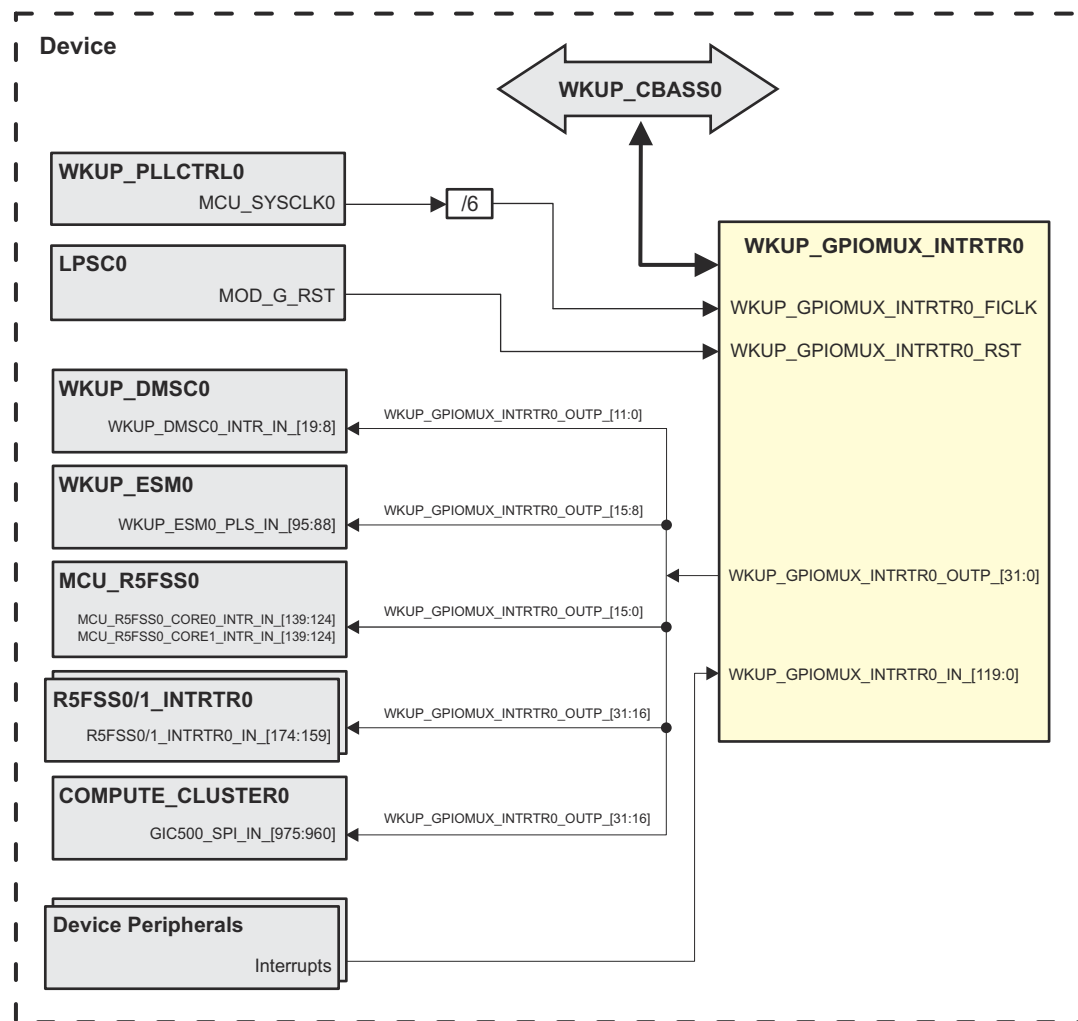

Figure 9-5. WKUP\_GPIOMUX\_INTRTR0 Integration

Table 9-15 through Table 9-17 summarize the WKUP\_GPIOMUX\_INTRTR0 integration.

**Table 9-15. WKUP\_GPIOMUX\_INTRTR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
WKUP_GPIOMUX_INTRTR0	WKUP_PSC0	PD0	LPSC0	WKUP_CBASS0

**Table 9-16. WKUP\_GPIOMUX\_INTRTR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
WKUP_GPIOMUX_INTRTR0	WKUP_GPIOMUX_INTRTR0_FICLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	Module functional and interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
WKUP_GPIOMUX_INTRTR0	WKUP_GPIOMUX_INTRTR0_RST	MOD_G_RST	LPSC0	Module hardware reset

**Table 9-17. WKUP\_GPIOMUX\_INTRTR0 Hardware Requests**

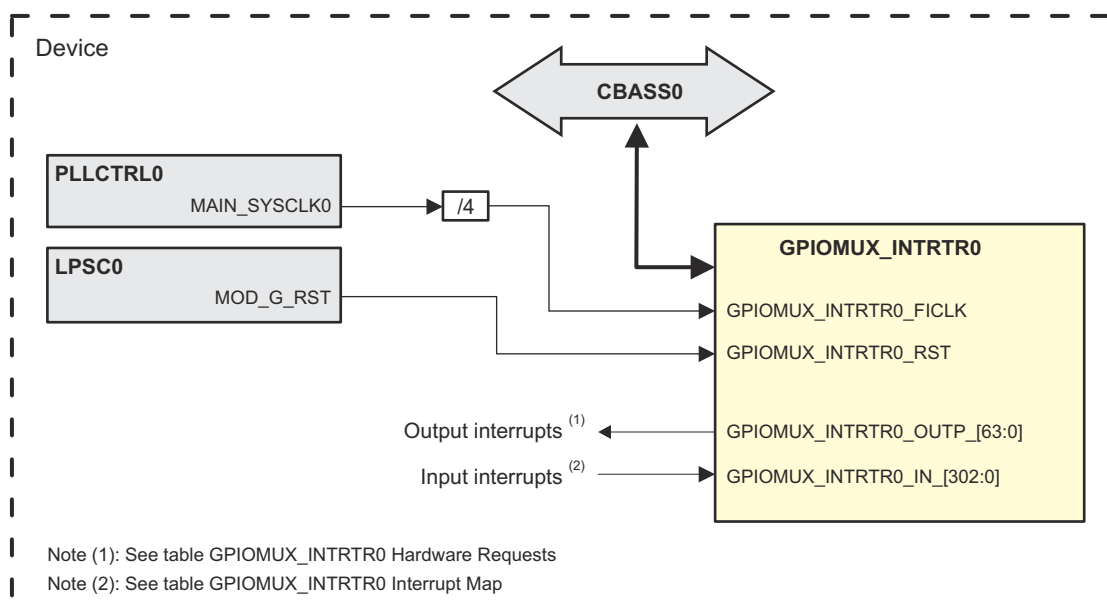

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
WKUP_GPIOMUX_INTRTR0	WKUP_GPIOMUX_INTRTR0_OUTP_[31:16]	GIC500_SPI_IN_[975:960] R5FSS0_INTRTR0_IN_[174:159] R5FSS1_INTRTR0_IN_[174:159]	COMPUTE_CLUSTER0 R5FSS0_INTRTR0 R5FSS1_INTRTR0	Module interrupt outputs [31:0]	Pulse
	WKUP_GPIOMUX_INTRTR0_OUTP_[15:8]	WKUP_ESM0_PLS_IN_[95:88]	WKUP_ESM0		
	WKUP_GPIOMUX_INTRTR0_OUTP_[15:0]	MCU_R5FSS0_CORE0_INTR_IN_[139:124] MCU_R5FSS0_CORE1_INTR_IN_[139:124]	MCU_R5FSS0_CORE0 MCU_R5FSS0_CORE1		
	WKUP_GPIOMUX_INTRTR0_OUTP_[11:0]	WKUP_DMSC0_INTR_IN_[19:8]	WKUP_DMSC0		

### Note

Table 9-17 lists only the WKUP\_GPIOMUX\_INTRTR0 interrupt outputs. The mapping of interrupt sources to WKUP\_GPIOMUX\_INTRTR0 interrupt inputs is presented in [Section 9.4.1.2](#).

### 9.3.2.2 GPIOMUX\_INTRTR0 Integration

Figure 9-6 shows the GPIOMUX\_INTRTR0 integration.

**Figure 9-6. GPIOMUX\_INTRTR0 Integration**

Table 9-18 through Table 9-20 summarize the GPIOMUX\_INTRTR0 integration.

**Table 9-18. GPIOMUX\_INTRTR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
GPIOMUX_INTRTR0	PSC0	PD0	LPSC0	CBASS0

**Table 9-19. GPIOMUX\_INTRTR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

R5FSS0_INTRTR0	R5FSS0_INTRTR0_RST	MOD_G_RST	LPSC0	Module hardware reset

**Table 9-35. R5FSS0\_INTRTR0 Hardware Requests**

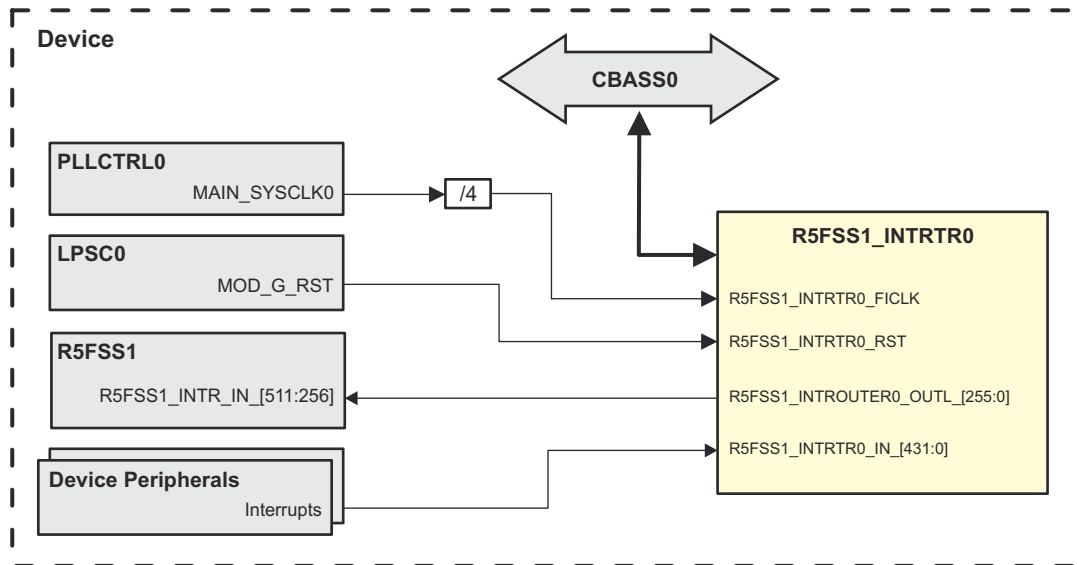

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
R5FSS0_INTRTR0	R5FSS0_INTROUTER0_OUTL_[255:0]	R5FSS0_INTR_IN_[511:256]	R5FSS0	Module interrupt outputs [255:0]	Pulse

#### Note

Table 9-26 lists only the R5FSS0\_INTRTR0 interrupt outputs. The mapping of interrupt sources to R5FSS0\_INTRTR0 interrupt inputs is presented in .

### 9.3.2.8 R5FSS1\_INTRTR0 Integration

Figure 9-12 shows the R5FSS1\_INTRTR0 integration.

**Figure 9-12. R5FSS1\_INTRTR0 Integration**

Table 9-36 through Table 9-38 summarize the R5FSS1\_INTRTR0 integration.

**Table 9-36. R5FSS1\_INTRTR0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
R5FSS1_INTRTR0	PSC0	PD0	LPSC0	CBASS0

**Table 9-37. R5FSS1\_INTRTR0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
R5FSS1_INTRTR0	R5FSS1_INTRTR0_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	Module functional and interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
R5FSS1_INTRTR0	R5FSS1_INTRTR0_RST	MOD_G_RST	LPSC0	Module hardware reset

**Table 9-38. R5FSS1\_INTRTR0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
R5FSS1_INTRTR0	R5FSS1_INTROUTER0_OUTL_[255:0]	R5FSS1_INTR_IN_[511:256]	R5FSS1	Module interrupt outputs [255:0]	Pulse

#### Note

Table 9-26 lists only the R5FSS1\_INTRTR0 interrupt outputs. The mapping of interrupt sources to R5FSS1\_INTRTR0 interrupt inputs is presented in .

## 9.4 Interrupt Sources

### 9.4.1 WKUP Domain Interrupt Maps

#### 9.4.1.1 WKUP\_DMSC0 Interrupt Map

Table 9-39 shows the mapping of events to the WKUP\_DMSC0 external interrupt inputs. Note that the WKUP\_DMSC0 interrupt controller (NVIC) includes WKUP\_DMSC0 internal inputs as well, so external interrupt input 0 actually represents NVIC event 176.

**Table 9-39. WKUP\_DMSC0 Interrupt Map**

Interrupt Input Line	Interrupt ID	Interrupt Name
WKUP_DMSC0_INTR_IN_0	176	WKUP_PORZ_SYNC0_MAIN_PORZ_LATCHED_0

### 9.4.1.2 WKUP\_GPIOMUX\_INTRTR0 Interrupt Map

Table 9-40 lists all the interrupts that are mapped to the WKUP\_GPIOMUX\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any WKUP\_GPIOMUX\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-40. WKUP\_GPIOMUX\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	WKUP_GPIOMUX_INTRTR0_MUXCNTL_n [6-0] ENABLE Field Value (DEC)
WKUP_GPIOMUX_INTRTR0_IN_0	WKUP_GPIO_VIRT_OUT0_0	0

#### 9.4.1.3 WKUP\_ESM0 Interrupt Map

Table 9-41 shows the mapping of events to the WKUP\_ESM0. Note that pulse event inputs are triple redundant so that there are three separate inputs for each pulse event (all to the same source signal) but only one connection is shown here.

**Table 9-41. WKUP\_ESM0 Interrupt Map**

Interrupt Input Line	Interrupt ID	Interrupt Name
WKUP_ESM0_LVL_IN_0	0	WKUP_DMSC0_DMTIMER_0_INTR_PEND_0

## 9.4.2 MCU Domain Interrupt Maps

### 9.4.2.1 MCU\_R5FSS0\_CORE0 Interrupt Map

[Table 9-42](#) shows the mapping of events to the MCU\_R5FSS0\_CORE0. The MCU\_R5FSS0 VIM supports both R5 cores.

The MCU\_R5FSS0\_CORE0 events are the events used by both processors when operating in lockstep mode.

**Table 9-42. MCU\_R5FSS0\_CORE0 Interrupt Map**

#### 9.4.2.2 MCU\_R5FSS0\_CORE1 Interrupt Map

Table 9-43 shows the mapping of events to the MCU\_R5FSS0\_CORE1. The MCU\_R5FSS0 VIM supports both R5 cores.

The MCU\_R5FSS0\_CORE1 events are not used when operating in lockstep mode.

**Table 9-43. MCU\_R5FSS0\_CORE1 Interrupt Map**

### 9.4.2.3 MCU\_ESM0 Interrupt Map

Table 9-44 shows the mapping of events to the MCU\_ESM0. Note that pulse event inputs are triple redundant so that there are three separate inputs for each pulse event (all to the same source signal) but only one connection is shown here.

**Table 9-44. MCU\_ESM0 Interrupt Map**

Interrupt Input Line	Interrupt ID	Interrupt Name

### 9.4.3 MAIN Domain Interrupt Maps

#### 9.4.3.1 COMPUTE\_CLUSTER0 Interrupt Map

##### 9.4.3.1.1 GIC500 PPI Interrupt Map

[Table 9-45](#) shows the mapping of events to the GIC500 PPI inputs. There are 16 PPI events per A72 core.

PPI events can be configured for either low-level (default) or high-pulse operation.

PPI events represent events 16-31 of each A72 core.

**Table 9-45. GIC500 PPI Interrupt Map**

Interrupt Input Line	Interrupt ID	Interrupt Name
<b>PPI events for A72SS0_CORE0</b>

### 9.4.3.1.2 GIC500 SPI Interrupt Map

Table 9-46 shows the mapping of events to the GIC500 SPI inputs. SPI events may be mapped by the GIC500 to signal any (or both) of the A72 cores integrated in the Compute Cluster.

SPI events may be configured by software for either level (default) or pulse operation.

SPI events represent events 32-991 of each A72 core.

### 9.4.3.2 R5FSS0\_CORE0 Interrupt Map

Table 9-47 shows the mapping of events to the R5FSS0\_CORE0. The R5FSS0 VIM supports both R5FSS0 cores.

The R5FSS0\_CORE0 events are the events used by both processors when operating in lockstep mode.

**Table 9-47. R5FSS0\_CORE0 Interrupt Map**

#### 9.4.3.3 R5FSS0\_CORE1 Interrupt Map

Table 9-48 shows the mapping of events to the R5FSS0\_CORE1. The R5FSS0 VIM supports both R5FSS0 cores.

The R5FSS0\_CORE1 events are not used when operating in lockstep mode.

**Table 9-48. R5FSS0\_CORE1 Interrupt Map**

Interrupt Input Line	Interrupt ID	Interrupt Name

#### 9.4.3.4 R5FSS1\_CORE0 Interrupt Map

Table 9-47 shows the mapping of events to the R5FSS1\_CORE0. The R5FSS1 VIM supports both R5FSS1 cores.

The R5FSS1\_CORE0 events are the events used by both processors when operating in lockstep mode.

**Table 9-49. R5FSS1\_CORE0 Interrupt Map**

#### 9.4.3.5 R5FSS1\_CORE1 Interrupt Map

Table 9-48 shows the mapping of events to the R5FSS1\_CORE1. The R5FSS1 VIM supports both R5FSS1 cores.

The R5FSS1\_CORE1 events are not used when operating in lockstep mode.

**Table 9-50. R5FSS1\_CORE1 Interrupt Map**

#### 9.4.3.6 R5FSS0\_INTRTR0 Interrupt Map

Table 9-51 lists all the interrupts that are mapped to the R5FSS0\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any R5FSS0\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-51. R5FSS0\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	R5FSS0_INTRTR0_MUXCNTL_n [8-0] ENABLE Field Value (DEC)

- (1) Do not use that setting. As it is the default one, it is strongly recommended to set the field to another value before enabling interrupt router operation.

#### 9.4.3.7 R5FSS1\_INTRTR0 Interrupt Map

Table 9-52 lists all the interrupts that are mapped to the R5FSS1\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any R5FSS1\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-52. R5FSS1\_INTRTR0 Interrupt Map**

#### 9.4.3.10 C66SS0\_INTRTR0 Interrupt Map

Table 9-55 lists all the interrupts that are mapped to the C66SS0\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any C66SS0\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-55. C66SS0\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	C66SS0_INTRTR0_MUXCNTL_n [8-0] ENABLE Field Value (DEC)
RESERVED	RESERVED	0 <sup>(1)</sup>
C66SS0_INTRTR0_IN_0	TIMER0_INTR_PEND_0	1

- (1) Do not use that setting. As it is the default one, it is strongly recommended to set the field to another value before enabling interrupt router operation.

### 9.4.3.11 C66SS1\_INTRTR0 Interrupt Map

Table 9-56 lists all the interrupts that are mapped to the C66SS1\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any C66SS1\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-56. C66SS1\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	C66SS1_INTRTR0_MUXCNTL_n [8-0] ENABLE Field Value (DEC)
RESERVED	RESERVED	0 <sup>(1)</sup>
C66SS1_INTRTR0_IN_0	TIMER0_INTR_PEND_0	1

#### 9.4.3.14 MAIN2MCU\_LVL\_INTRTR0 Interrupt Map

Table 9-59 lists all the interrupts that are mapped to the MAIN2MCU\_LVL\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any MAIN2MCU\_LVL\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-59. MAIN2MCU\_LVL\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	MAIN2MCU_LVL_INTRTR0_M UXCNTL_n[8-0] ENABLE Field Value (DEC)

#### 9.4.3.15 MAIN2MCU\_PLS\_INTRTR0 Interrupt Map

Table 9-60 lists all the interrupts that are mapped to the MAIN2MCU\_PLS\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any MAIN2MCU\_PLS\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-60. MAIN2MCU\_PLS\_INTRTR0 Interrupt Map**

- (1) Do not use that setting. As it is the default one, it is strongly recommended to set the field to another value before enabling interrupt router operation.

### 9.4.3.16 GPIOMUX\_INTRTR0 Interrupt Map

Table 9-61 lists all the interrupts that are mapped to the GPIOMUX\_INTRTR0 inputs, along with the corresponding register programming values used for mux control. Any GPIOMUX\_INTRTR0 interrupt input that is not listed in this table should be considered as unused.

**Table 9-61. GPIOMUX\_INTRTR0 Interrupt Map**

Interrupt Input Line	Peripheral Interrupt	GPIOMUX_INTRTR0_MUXCNTL_n [8-0] ENABLE Field Value (DEC)
GPIOMUX_INTRTR0_IN_0	MAIN_GPIO0_VIRT_OUT0_0	0
GPIOMUX_INTRTR0_IN_1	MAIN_GPIO0_VIRT_OUT0_1_0	1
GPIOMUX_INTRTR0_IN_2	MAIN_GPIO0_VIRT_OUT0_2_0	2

Chapter 10

**Data Movement Architecture (DMA)**

---

10.1 DMA Architecture.....	1120
10.2 Navigator Subsystem (NAVSS).....	1186
10.3 Peripheral DMA (PDMA).....	1276
10.4 Data Routing Unit (DRU).....	1307

## 10.1 DMA Architecture

This section describes the DMA (data movement) architecture in the device.

### 10.1.1 Overview

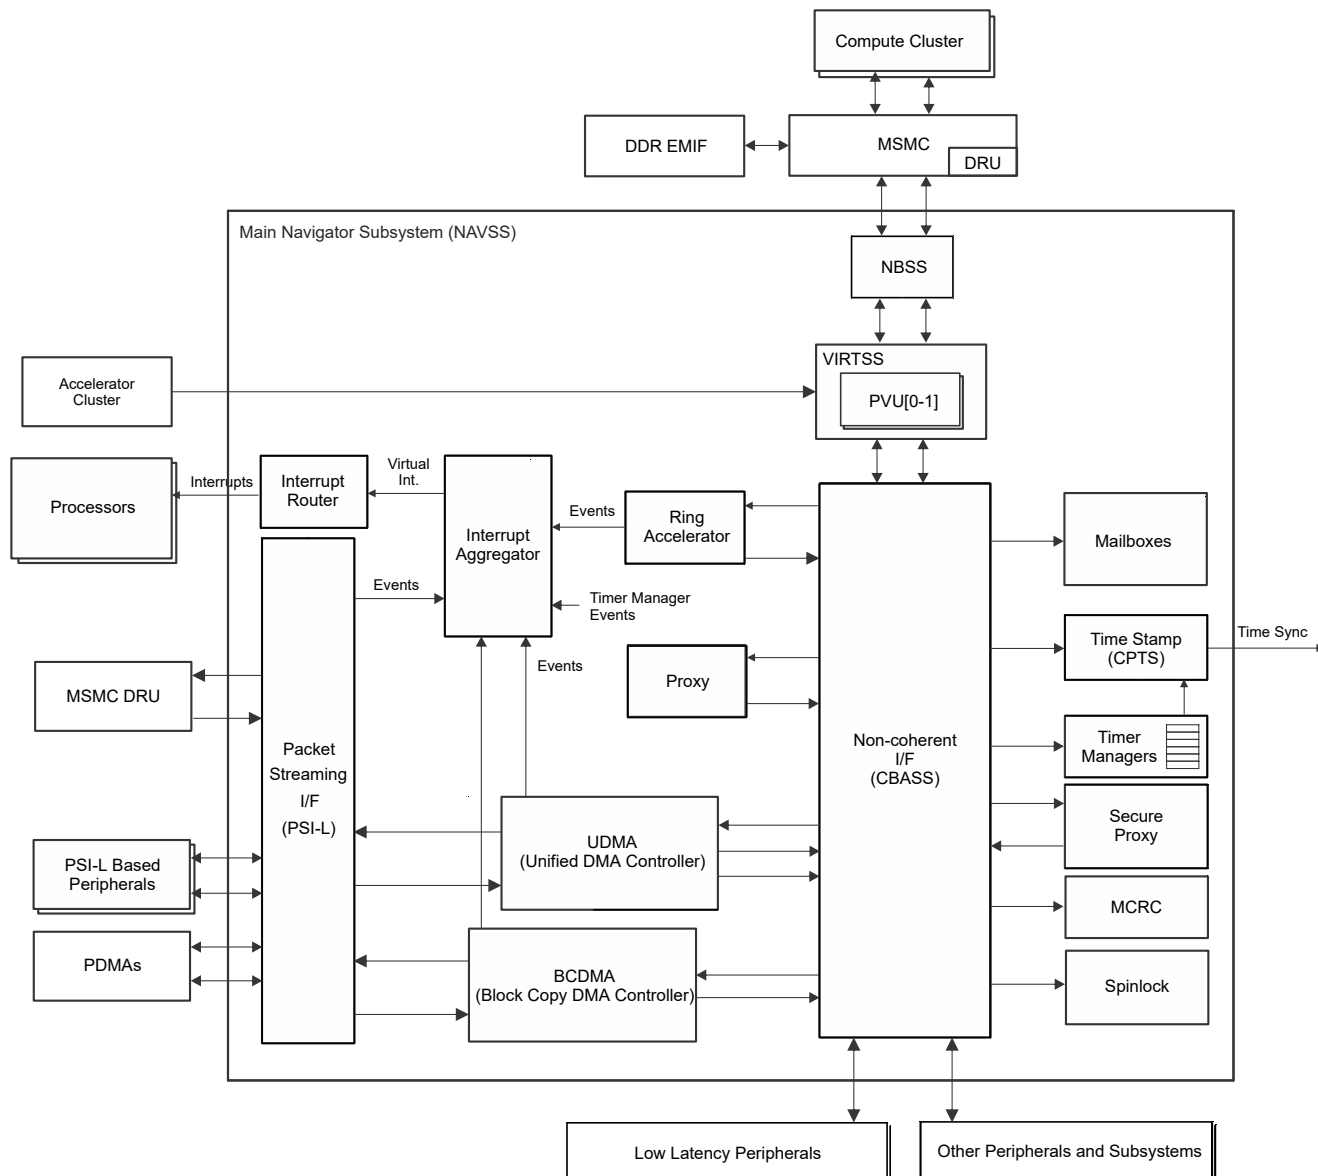

The DMA architecture specifies the data structures used by Texas Instruments standard communications modules to facilitate direct memory access (DMA) and to provide a consistent application programming interface (API) to the host software in multi-core devices. The data structures and the API used to manipulate them will be jointly referred to as NAVSS.

Frequent tasks are commonly offloaded from the host processor to peripheral hardware to increase system performance. Significant performance gains may result from careful design of the host software and communication module interface. In networking systems, packet transmission and reception are critical tasks. Texas Instruments has developed the NAVSS standard, which is aimed at maximizing the efficiency of interaction between the host software and communications modules.

The design goals for NAVSS are as follows:

- Minimize host interaction
- Maximize memory use efficiency
- Maximize bus burst efficiency
- Maximize symmetry between transmit/receive operations
- Maximize scalability for number of connections, buffer sizes, queue sizes, and protocols supported
- Minimize protocol specific features
- Minimize complexity

NAVSS architecture is shown on [Figure 10-1](#).

**Figure 10-1. NAVSS Overview**

#### 10.1.1.1 Navigator Subsystem

The Navigator Subsystem (NAVSS hardware) is a container which groups together as much as possible the components which provide the Hardware to Software boundary for data movement control in the system. All of the components which control work handoff (queuing, interrupts, monitoring and debugging) are included in the NAVSS which in turn is located as close as possible to the various host processors to which services are provided. Other DMA components such as DRUs, UTC, and PDMAs exist outside the NAVSS but all are controlled by the root complexes provided in NAVSS.

The SoC has two NAVSSes: one in main and one in MCU domain.

#### 10.1.1.2 Ring Accelerator (RA)

The ring accelerator (RINGACC or RA) is a hardware module that is responsible for accelerating management of various types of queues in the system. The RA accelerates passing of packets between a producer and

consumer in normal system memory (including cached memory). The RA is capable of accelerating the read/write pointer maintenance and occupancy tracking operations.

The ring accelerator operates like a bus infrastructure bridge in that it passes transactions through it between a source and destination interface. As transactions are passed, the RA modifies the address, byte count, and transaction identifiers and internally updates the occupancies/pointers.

Each queue that the RA provides can operate in either exposed-ring-mode or private-queue-mode.

- The exposed ring mode allows software to directly access the underlying ring structure to add or remove items from the tail or head of the ring respectively. Whenever items are added or removed from a ring, the host software is required to write to a corresponding doorbell register to increment or decrement the ring occupancy. When using the exposed ring mode, no proxy is required between the software and the RA but all queue add operations require a memory fence to be performed to ensure that the data has landed in a snooperable cache before the doorbell register is written.
- The private queue mode provides an abstract view of the ring so that the host software does not need to know the actual physical address location or current read or write indexes of the ring. The private queue mode provides a memory window for each ring which when written redirects the write to the address pointed to by the write pointer and when read redirects the read to the address pointed to by the read pointer. The same address range is always used to push or pop elements from a given queue.

Rings are an implementation of a logical queue with the following limitations:

- Each ring has a finite size. When rings are used in exposed ring mode the following conditions apply:
  - A separate operation is required to write/read the contents of a ring and to update the occupancy of the ring
  - It is not straightforward to allow multiple producers to write to a ring or multiple consumers to read from a ring. Additional synchronization and pointer passing is required since rings require software to manage one of the pointers for the queue.
  - An exposed ring cannot be used when software or hardware needs to both read and write the same queue (such as for a DMA RX free queue where errors can have the DMA write the element back onto the same RX free queue). Since software owns one side of the pointers and hardware owns the other, they cannot be kept coherent if either side needs to update either at any time.

The RA allows each ring to be configured to a different primary element size. Element sized chunks of data are placed onto and retrieved from rings when queuing or de-queuing occurs. Element sizes can be as small as 4 bytes or as large as 256 bytes.

#### 10.1.1.3 Proxy

The proxy provides a mechanism for software to access the RA coherently when the processor does not support large bursts. The RA requires a single burst for each operation so that it maintains atomicity and coherence by relying on the atomicity of the bursts on the bus interconnect fabric, since it only delivers a single burst to the RA before the next. Since processors are usually limited in the size of a burst they can deliver natively, such as 32 to 128 bits, they cannot be used directly with the data access region of the RA for larger element sizes. The proxy solves this gap by providing a temporary space for the software to form a larger burst of data before it is sent to the RA. The proxy allows smaller processor accesses to the data and only forwards to the RA when the entire data burst is complete, as directed by the software. Each proxy hardware can support multiple threads of software (whether on the same or different processors) operating on bursts at the same time, and they do not interfere with each other, as long as each thread of software only operates on its thread in the proxy. Each proxy thread also supports access to any RA queue via different offsets similar to how the RA provides access to the queues via different offsets.

For writing data to the RA, the software will write the data in native sized writes to the proxy thread it has been assigned. The proxy simply accepts the writes into a buffer reserved for that thread. Only when the software writes to the completion byte offset (last byte of the burst) then will the proxy take the entire burst of data written (including the final write data) and send it to the RA as a single write burst. After the completion write, the software can begin building a new data burst. For reading data from the RA, the software will read the data in

native sized reads to the proxy thread. For the first read, the proxy will read the entire burst from the RA, so that it atomically gets the next element off the queue. This entire data is stored in the proxy thread buffer, and the requested portion is returned to software. Then software can read any location within the burst and the proxy will read it from the buffer. When software is done reading the data, it must read the completion byte offset so that the proxy 'knows' that the read burst is completed, and that for the next read it must read a burst from the RA queue again. A single proxy thread can only be used for a single data burst at a time, so once starting a write it should complete before starting another write or a read, and similarly once starting a read, it should complete before starting another read or a write. If software needs to read and write at the same time, it should use two proxy threads. Similarly if there are multiple threads of software that need to access RA at the same time, they should use separate proxy threads.

#### 10.1.1.4 Secure Proxy

A special version of a proxy is the secure proxy that provides secured access to RA queues for communication to the security master of the system. The secure proxy provides basically the same function as a normal proxy. The data burst size is fixed for message sizes to the security master, so there is no support for all the element sizes of the RA. The security master locks down the RA queue to access and direction for each proxy thread so that the software cannot access anything they shouldn't, so the software only sees a single queue (unlike the normal proxy), and any attempts to access another queue or access it in violation of how the security master defined and an error will be flagged. This allows for a much more controlled setup for passing messages to the security master.

#### 10.1.1.5 Interrupt Aggregator (INTA)

The interrupt aggregator (INTR\_AGGR or INTA) is a hardware module which provides a persistent view of the real time status of various DMA components within the overall SoC DMA system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

The INTA block provides the following functions:

- Conversion of local event signal lines into global events
- Performing an 'Y-split' operation of global events
- Counting global events
- Steering and aggregation of global events into specified bit positions in one of N interrupt cause registers
- SoC interrupt-architecture-compliant set/clear and mask set/clear functionality to cover interrupt cause registers
- Output of virtual interrupt sources to the Interrupt Router module

#### 10.1.1.6 Interrupt Router (IR)

The interrupt router (INTR\_ROUTER or IR) is a hardware module which allows for virtual interrupt sources which were output from the INTA block to be crossbar switched onto physical interrupts which are connected to the system level Interrupt Controller (ARM GIC or other interrupt controller).

#### 10.1.1.7 Unified DMA – Third Party Channel Controller (UDMA-C)

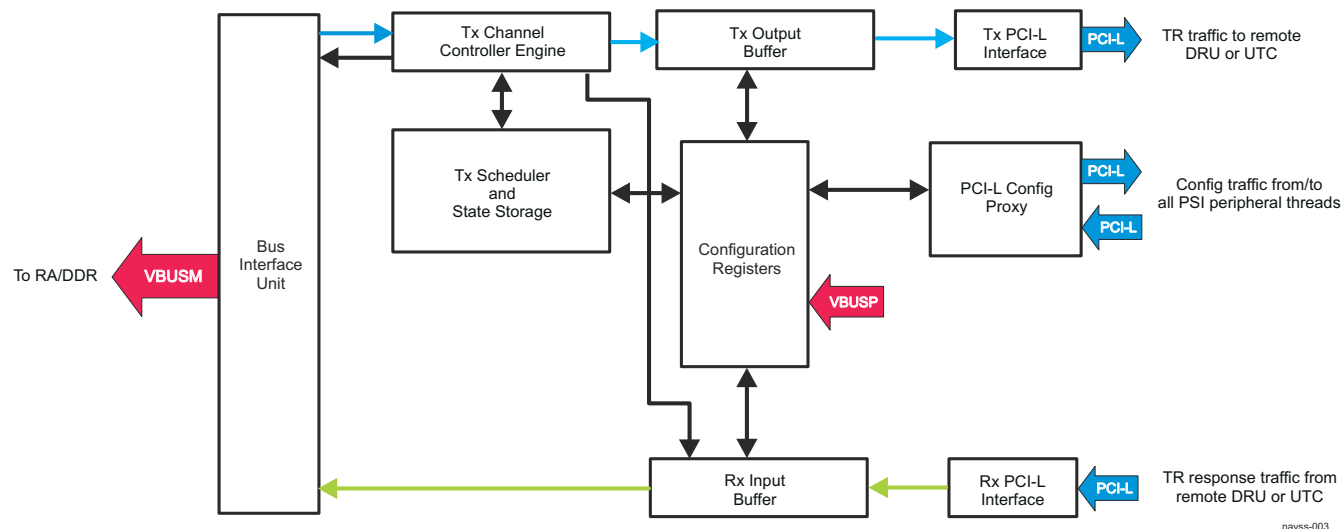

##### Note

In this SoC, UDMA-P (see [Section 10.1.1.10](#)) serves UDMA-C functions. That is, there is no discrete UDMA-C controller in this SoC device.

The Unified DMA 3<sup>rd</sup>-Party Channel Controller is intended to perform similar (but significantly upgraded) functions to the EDMA Channel Controller engine on previous SoC devices. The UDMA-C module supports the transmission of Transfer Request packets from memory mapped data structures to data channels within UTCs in the system and reception of Transfer Response packets from data channels in UTCs in the system into memory mapped data structures. Up to 512 (configuration specific) third-party DMA control channels are provided within the UDMA-C. Each control channel corresponds to a single third party DMA data channel in a separate UTC.

Transfer Request messages provide transfer parameters which are to be used by the UTC channels to move data in the system (previously implemented as PARAM entries). Transfer Response messages are sent back from the UTC in a one to one relationship with Transfer Request packets and provide an indication of both completion of a data transfer and whether or not any exception or error occurred during the data transfer.

The UDMA-C controller maintains state information for each of its channels which allows Transfer Request packet transmission and Transfer Response packet reception operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for the transmission of Transfer Request packets. The ordering and rate of Transfer Response receive operations is directly controlled by the order in which those packets are received on the Rx PSI-L interface. A block diagram of a UDMA-C module is shown Figure 10-2.

**Figure 10-2. UDMA-C Block Diagram**

#### 10.1.1.8 Unified Transfer Controller (UTC)

The Unified Transfer Controller is intended to perform similar functions to the EDMA Transfer Controller engine used on previous devices. The UTC engine is generally classified as a third-party DMA. This designation comes from the fact that the engine is not actually the source or sink of the data which is being moved but is instead an intermediary 3<sup>rd</sup>-party that performs the data move on behalf of the source and sink.

The UTC engine accepts Transfer Response messages from the UDMA-P via a PSI-L interface which provide instructions to copy data between a source read interface and a destination write interface. The sequence of operations that can be instructed includes up to 4-dimensional nested loops. Multiple types of Transfer Request messages are specified and each UTC instance in the system may support all types or any specified subset. The TR formats are specified in detail in a later section. When a Transfer Request has been completed, the UTC returns a Transfer Response message back to the originating UDMA-P. The UTC has the ability to generate events at specified completion points when processing a Transfer Request. These events are sent back to the Interrupt Aggregator block.

An UTC instance may be configured to only support VBUSM to VBUSM block copies or they may also optionally support 'split' operations where a read engine is instructed by a TR to read data from a VBUSM interface and send the data to the Packet Streaming fabric via a PSI-L master interface. A similar split operation is supported for writes where data is received into a PSI-L slave interface and is then routed to a write engine which has been instructed by a TR to move the data into a set of memory locations.

#### 10.1.1.9 Data Routing Unit (DRU)

The DRU is a special version of a UTC that also includes support for advanced operations which are critical to cache maintenance and data IO to the C7x DSP cores.

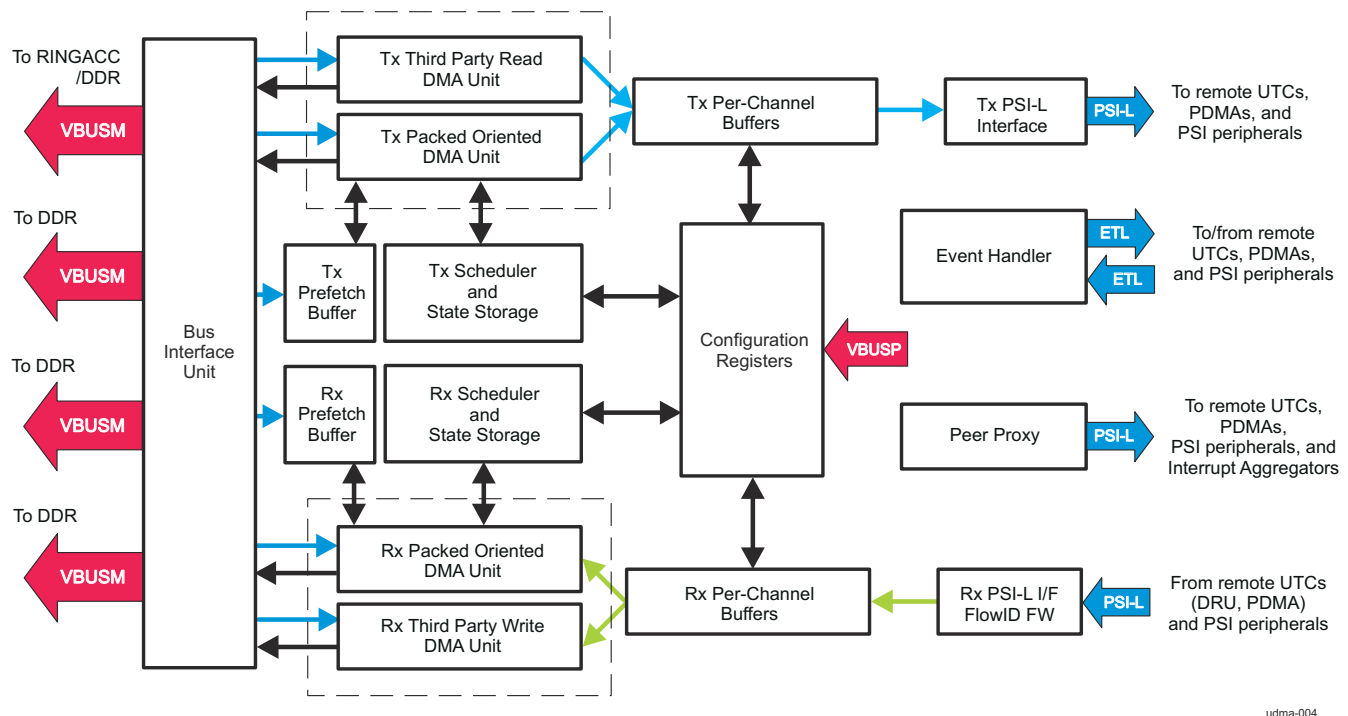

For purposes of the K3 Data Movement architecture, the DRU is essentially a UTC which supports only the block copy mode subset of the Transfer Request message formats. The DRU typically will provide the highest performance block copy data movement capability of any DMA engine within the SoC. The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CC\_ARMSS frequency.

#### 10.1.1.10 Unified DMA – Peripheral Root Complex (UDMA-P)

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices. The UDMA-P module supports the transmission and reception of various packet types. The UDMA-P is architected to facilitate the segmentation and reassembly of SoC DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. An external DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA-P also supports acting as both a UTC and UDMA-C for its internal channels. Channels in the UDMA-P can be configured to be either Packet-Based or Third-Party channels on a channel by channel basis.

A block diagram of the UDMA-P Controller is shown in [Figure 10-3](#).

**Figure 10-3. UDMA-P Block Diagram**

##### 10.1.1.10.1 Channel Classes

Not all channels within a DMA controller require the same performance capabilities. Raw bandwidth and latency tolerance requirements will vary greatly between data transfers at various points in the system. Several different classes of DMA channels are provided in the UDMA-P and are described in [Table 10-1](#)

**Table 10-1. Channel Classes**

Class Name	Description
Normal Capacity	Provides baseline amount of descriptor and TR prefetch and Tx/Rx control and data buffering. Suitable for most peripheral transfers which are communicating with on-chip memories and DDR
High Capacity	Provides an elevated amount of descriptor and TR prefetch and custom Tx/Rx control and data buffering. Suitable for applications which require moderate per-channel bandwidth with significantly increased latency (for example Transferring data to/from PCIe)
Ultra-high Capacity	Provides identical descriptor and TR prefetch as High Capacity but with increased Tx data buffering to allow for more read data in flight. Suitable for applications requiring high per-channel bandwidth with significantly increased latency (for example 16+ Gbps transfers to/from PCIe).

#### 10.1.1.11 Peripheral DMA (PDMA)

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals which perform data transfers using memory mapped registers accessed via a standard non-coherent bus fabric. The PDMA module is intended to be located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request operations. The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The Peripheral DMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

#### 10.1.1.12 Embedded DMA

Embedded DMA refers to a DMA-capable master module which either follows an industry standard hardware/software Application Programming Interface (API) or is a module which does not natively comply with the TI DMA architecture requirements. It is assumed that modules which include Embedded DMA will provide their own dedicated software drivers and interoperability with other DMA entities in the system will be accomplished with software bridging code. None of the remainder of this chapter has any effect on the operation or architecture of Embedded DMA functions.

### 10.1.1.13 Definition of Terms

<b>Host</b>	The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.
<b>Channel</b>	A channel refers to the sub-division of information (flows) that is transported across a DMA engine. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (for example, CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). Information flow within a channel is a stream of strongly ordered information.
<b>Data Buffer</b>	A data buffer is a single data structure that contains payload information for transmission to or reception from a channel.
<b>Buffer Descriptor</b>	A buffer descriptor is a single data structure that contains information about one or more data buffers.
<b>Packet Descriptor</b>	A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. All Monolithic type descriptors are packet descriptors (and are also a Data Buffer).
<b>Queue</b>	A queue is a list of strongly ordered entries which is typically used to pass work between a producer and a consumer. Queue entries in most cases are references to a work payload which is being passed but in some cases (Transfer Request Packets for example) queue entries may actually contain data which is being transferred. Queues are used throughout UDMA whenever communication is required between entities. Queues can have multiple different implementations and UDMA uses two of the most common: linked lists and rings.
<b>Linked list</b>	A linked list is a data structure in which each entry stores not only the entry data but also a chaining pointer to the next entry in the list. The last entry in each list has its chaining pointer set to NULL (typically encoded as 0x0). The list manager maintains a pointer to the head element on the list and to the tail element on the list. Since the chaining pointer is stored with the entry data, linked lists have a length which is dynamically changeable and limited only by the ability to allocate additional entries which are to be queued/de-queued. Linked lists are present in Host Descriptors to chain multiple descriptors to form a packet
<b>Ring</b>	A ring is a data structure in which a contiguous memory block defined by M N-byte entries (total size is M × N bytes) is statically allocated and sequentially written/read in order to pass data or data references. Rings are also referred to as circular buffers because when the last element in the contiguous memory array is written, the pointers wrap back to the beginning address for the ring and start the process all over again. The Ring Accelerator component uses rings in order to implement logical queues
<b>Free Descriptor/Buffer Queue</b>	A free descriptor/buffer queue is a list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Ring Accelerator.
<b>Free Descriptor Queue</b>	A free descriptor queue is a list of available descriptors that are not yet linked with buffers that are to be used by the receive ports for monolithic type descriptors. Free Descriptor Queues are implemented by the Ring Accelerator.
<b>Packet Queue</b>	A packet queue is a list of valid (that is, populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes. Packet Queues are implemented by the Ring Accelerator.
<b>Memory</b>	Memory is an area of data storage managed by the host. This area is visible to the port as a 64-bit addressable area.
<b>Device Driver</b>	A device driver is application independent software that runs on the host for purposes abstracting the low level hardware so that upper level software can use the hardware without

knowing every bit field location or initialization sequence.. General device driver functions include port initialization, transmit packet queuing, and receive packet processing.

**SOP** Start of Packet. This refers to the descriptor/buffer that is the first buffer in a packet.

**MOP** Middle of Packet. This refers to the descriptors/buffers that are neither the first or last buffers in a packet.

**EOP** End of Packet. This refers to the descriptor/buffer that is the last buffer in a packet.

### 10.1.2 DMA Hardware/Software Interface

The intent of the TI Data Movement (DMA) architecture is to provide a uniform hardware/software interface which includes a rich set of mechanisms that software can make use of to transfer data with low overhead and reasonable complexity. To this goal, the number of components which software is required to interact with on an ongoing real time basis has been kept to a minimum and is as follows (in order of anticipated frequency of access):

- Interrupt Aggregator
- Ring Accelerator
- UDMA-P/C (for managed flow control and error/exception handling only)

When interrupts are used, the interrupt aggregator will provide the vast majority of interrupt sources from all DMA components in the system. All non-exception/non-debug packet and TR completion signaling originates from the Interrupt Aggregator and the INTA provides a uniform set of registers that can be queried to quickly determine the cause of a specific interrupt. Events from PSI-L/ETL components are all routed to the host via the Interrupt Aggregator.

The Ring Accelerator provides the primary means by which work is sent to or received from the UDMA-P DMA engines (and the UTC/DRU, and PDMA engines whose control operations are proxied by the UDMA-P).

The UDMA-P are primarily fronted by the RA and the INTA but for real time operations like software controlled flow control (via pause) some registers in the UDMA-P blocks may be directly manipulated.

Data structures are used to pass anytime information between components in the system. These components may be hardware or software. The following sections describe the data structures which are used within a UDMA based system for passing information. These data structures include data buffers, packet descriptors, buffer descriptors, queues (including transmit queues, transmit completion queues, and receive queues) and the configuration registers that are provided in the various components. The following sections provide a detailed description of these data structures.

#### 10.1.2.1 Data Buffers

A data buffer is a byte aligned contiguous block of memory used to store packet payload data. Each buffer is described in an entry in either a packet descriptor or in a buffer descriptor. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 64-bit memory space.

The Buffer Length field of the packet/buffer descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

#### 10.1.2.2 Descriptors

Descriptors are so named because their primary function is to describe other data structures.

The UDMA architecture provides 4 basic types of descriptors each of which has specific characteristics intended to address different requirements. [Table 10-2](#) shows the different types of descriptors and their characteristics.

**Table 10-2. UDMA Descriptor Types and Attributes**

Descriptor Type	Includes Valid Packet Info	Provides Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Packet Descriptor	✓	1		✓	✓	Used to describe packet and SOP buffer in applications that require Host OS compatible data structures (i.e. applications where the descriptors and buffers cannot be managed independently but must instead be pre-linked by the Host software). These applications inherently require a separate descriptor for each buffer.

**Table 10-2. UDMA Descriptor Types and Attributes (continued)**

Descriptor Type	Includes Valid Packet Info	Provides Number of Slots to Link In External Data Buffers	Provides Local Packet Data Storage	Provides Local Protocol Specific Storage	Provides Slot to Link Additional Descriptors Within Same Packet	Description
Host Buffer Descriptor		1			✓	Used to describe non-SOP buffers in applications that require Host OS compatible data structures
Monolithic Packet Descriptor	✓	0	✓	✓		Used to provide descriptor and data information in one contiguous data structure.
Transfer Request Packet Descriptor		0				Used to feed transfer request sequences to the UDMA third party channel controller

As [Table 10-2](#) shows, two of the four different descriptor types (the Host Packet Descriptor and Monolithic Packet Descriptor) provide packet level information that is useful to both the ports and the Host in order to properly process the packet. These descriptors are referred to as Packet Descriptors and will always appear as the first descriptor (or only descriptor in the case of Monolithic types) within a packet.

Software must allocate descriptors on 16-byte address boundaries. 16-byte is the minimum granularity that UDMA supports. This is intended for better memory utilization by allowing on-chip descriptors which are not a power of 2 in length to be packed into arrays with little wasted memory space.

Even though descriptors and buffers may be allocated on any 16-byte alignment, careful consideration of the alignment effects should be made based on the storage location and any cache related affects that may exist. If data structures are placed in off-chip SDRAM the burst size and alignment restrictions of the memory devices must be considered in order to avoid performance issues related to continually fetching mis-aligned blocks. In this case, the memory efficiency can be reduced to 50% because two memory bank lines are read for every line sized data fetch. Similarly, placing more than one descriptor or buffer object within a single cache line can cause the adjacent object to become corrupted during cache line writeback operations.

Software/application specific control information may be added to the end of any of the packet descriptor types using as many extra words as necessary but the above alignment rules still apply.

#### 10.1.2.2.1 Host Packet Descriptor

Host Packet Descriptors are designed to be used when the application requires support for true, unlimited fragment count scatter/gather type operations. The Host Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Host Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Protocol Specific Region Size
- Protocol Specific Control/Status Bits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the packet
- Software specific information

Host Packet Descriptors always contain 48 bytes of required information and may also contain optional software specific information and protocol specific information. How much optional information (and therefore the allocated size of the descriptors) is required is application dependent.

The Host Packet descriptor layout is shown below.

Packet Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)
Extended Packet Info Block (Optional) Includes Timestamp and Software Data (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Other Software Data (Optional and User Defined)

Host Packet Descriptors may be linked with zero or more additional Host Buffer Descriptors in a singly linked list fashion to form packets. Each Host Packet consists of a single Host Packet Descriptor followed by a chain of zero or more Host Buffer Descriptors linked together using the Next Descriptor Pointer fields in the descriptors. The last descriptor in a Host packet has a zero Next Descriptor Pointer.

The 'Other Software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store completely private data. This region is not used in any way by hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Host Packet Descriptor words are detailed in [Table 10-3](#) through [Table 10-19](#).

**Table 10-3. Host Packet Descriptor Packet Information Word 0 (PD Word 0)**

Bits	Name	Description	Rx Overwrite
31:30	2'd1	64-bit Host Packet Descriptor Type Identifier	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	Protocol Specific Region Location	This field indicates the location of the Protocol Specific Words: 0 = PS Words are located in the descriptor 1 = PS Words are located in the SOP Buffer immediately prior to the data.	Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes ... 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is an error unless the packet length is set to 0x3FFFFFF. If the packet length is set to all 1s (0x3FFFFFF) the Tx port will disable truncation and will transmit as much data as is specified in the Buffer Length fields. On Rx, if the received data exceeds 4M-1 bytes, the packet length field will saturate to a value of 0x3FFFFFF. The valid range for an exact packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

**Table 10-4. Host Packet Descriptor Packet Information Word 1 (PD Word 1)**

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

**Table 10-5. Host Packet Descriptor Packet Information Word 2 (PD Word 2)**

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = Application specific	Yes
26:19	RESERVED	Reserved	No
18	Return Policy	This field indicates the return policy for this packet. 0 = Entire packet (still linked together) should be returned to queue specified in bits 15:0. 1 = Each buffer should be returned to queue specified in bits 15:0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.	No
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Packet descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Packet descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit or Receive DMA should return the descriptor pointers to the free queues This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. The Rx DMA will only use this field when an error occurs during reception and the DMA must return descriptors back to the free queue from which they came. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue/ Ring Num	This field indicates the ring number in the RA that the descriptor is to be returned to after transmission is complete. The value 0xFFFF is reserved.	No

**Table 10-6. Host Packet Descriptor Packet Information Word 3 (PD Word 3)**

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable

**Table 10-6. Host Packet Descriptor Packet Information Word 3 (PD Word 3) (continued)**

Bits	Name	Description	Rx Overwrite
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

**Table 10-7. Host Packet Descriptor Linking Word 0 (PD Word 4)**

Bits	Name	Description	Rx Overwrite
31:0	Next Descriptor Pointer LSB	The 32 LSBs of the 48-bit, 16-byte aligned (min), memory address of the next buffer descriptor in the packet. If the value of this pointer is zero then the current buffer is the last buffer in the packet. The host sets the Next Descriptor Pointer.	Yes

**Table 10-8. Host Packet Descriptor Linking Word 1 (PD Word 5)**

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Next Descriptor Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Next Descriptor Pointer MSB	The 16 MSBs of the 48-bit next descriptor pointer	Yes

**Table 10-9. Host Packet Descriptor Buffer 0 Info Word 0 (PD Word 6)**

Bits	Name	Description	Rx Overwrite
31:0	Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will be written during reception. If the protocol specific words are placed at the beginning of the SOP buffer, this pointer will point to the PS words. The offset to the data in that case must be calculated by the consumer using the Protocol Specific Valid Count from Word 2. These are the 32 LSBs of the 48-bit buffer pointer.	Yes

**Table 10-10. Host Packet Descriptor Buffer 0 Info Word 1 (PD Word 7)**

Bits	Name	Description	Rx Overwrite
31:20	RESERVED	Reserved	Yes
19:16	Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit buffer pointer	Yes

**Table 10-11. Host Packet Descriptor Buffer 0 Info Word 2 (PD Word 8)**

Bits	Name	Description	Rx Overwrite
31:22	RESERVED	Written to 0	Yes
21:0	Buffer 0 Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	Yes

**Table 10-12. Host Packet Descriptor Original Buffer Info Word 0 (PD Word 9)**

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		No

**Table 10-12. Host Packet Descriptor Original Buffer Info Word 0 (PD Word 9) (continued)**

Bits	Name	Description	Rx Overwrite
21:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in PD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

**Table 10-13. Host Packet Descriptor Original Buffer Info Word 1 (PD Word 10)**

Bits	Name	Description	Rx Overwrite
31:0	Original Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Since the buffer pointer in PD Words 6/7 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. This field contains the 32 LSBs of the 48-bit original buffer pointer	No

**Table 10-14. Host Packet Descriptor Original Buffer Info Word 2 (PD Word 11)**

#### 10.1.2.2.2 Host Buffer Descriptor

The Host Buffer Descriptor is identical in size and organization to a Host Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. Host Buffer Descriptors are designed to be linked onto a Host Packet Descriptor or another Host Buffer Descriptor to provide support for unlimited scatter/gather type operations. Host Buffer Descriptors provide information about a single corresponding data buffer.

Every Host buffer descriptor stores the following information:

1. Pointer to the first valid byte in the data buffer
2. Length of the data buffer
3. Pointer to the next buffer descriptor in the packet

Host Buffer Descriptors always contain 48 bytes of required information. Since it is a requirement that it is possible to convert a Host descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Host Buffer Descriptors will be allocated using the same sizes as Host Packet Descriptors.

The Host Buffer Descriptor layout is shown below.

Buffer Reclamation Info (16 bytes)
Linking Info (8 bytes)
Buffer Info (12 bytes)
Original Buffer Info (12 bytes)

A Host Packet Descriptor and zero or more Host Buffer Descriptors may be linked together using the Next Descriptor Pointer fields to form packets. The last descriptor in a packet has a zero Next Descriptor Pointer. Each Host Buffer descriptor also points to a single data buffer.

The contents of the Host Buffer Descriptor words are detailed in [Table 10-20](#) through [Table 10-31](#).

**Table 10-20. Host Buffer Descriptor Reserved Word 0 (BD Word 0)**

Bits	Name	Description	Rx Overwrite
31:0	RESERVED	Reserved	No

**Table 10-28. Host Buffer Descriptor Buffer N Info Word 2 (BD Word 8)**

Bits	Name	Description	Rx Overwrite
31:22	RESERVED		Yes
21:0	Buffer N Length	The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. This value will be overwritten during reception.	Yes

**Table 10-29. Host Buffer Descriptor Original Buffer Info Word 0 (BD Word 9)**

Bits	Name	Description	Rx Overwrite
31:28	RESERVED		No
27:0	Original Buffer 0 Length	The Buffer Length field indicates the original size of the buffer in bytes. Data bytes are in the buffer. This value will not be overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the host at initialization. Since the buffer length in BD Word 8 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.	No

**Table 10-30. Host Buffer Descriptor Original Buffer Info Word 1 (BD Word 10)**

Bits	Name	Description	Rx Overwrite
31:0	Original Buffer 0 Pointer LSB	The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. This value will not be overwritten during reception. This value is read by the RX DMA to determine the actual buffer location as allocated by the host at initialization. Since the buffer pointer in BD Words 6/7 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information. This field contains the 32 LSBs of the 48-bit original buffer pointer	No

**Table 10-31. Host Buffer Descriptor Original Buffer Info Word 2 (BD Word 11)**

Bits	Name	Description	Rx Overwrite
31:20	RESERVED		Yes
19:16	Original Buffer 0 Pointer Address Space Select	Effectively bits 51:48 of the address – treated special by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.	Yes
15:0	Original Buffer 0 Pointer MSB	The 16 MSBs of the 48-bit original buffer pointer	No

#### 10.1.2.2.3 Monolithic Packet Descriptor

The Monolithic Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a Monolithic Packet Descriptor
- Source and Destination Tags
- Packet Type
- Packet Length
- Packet Error Indicator
- Packet Return Information
- Protocol Specific Region Size
- Protocol Specific Region Offset

- Protocol Specific Control/Status Bits
- Packet Data

The maximum size of a Monolithic Packet Descriptor is 4 MB. Of this, Monolithic Packet Descriptors always contain 16 bytes of required information and may also contain 16 bytes of software specific tagging information and up to 128 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent.

The Monolithic Packet descriptor layout is shown below.

Packet Info (16 bytes)
Extended Packet Info Block (Optional) Includes Timestamp, and software Data Words (16 bytes)
Protocol Specific Data (Optional) (0 to M bytes where M is a multiple of 4)
Null Region (0 to 511 bytes)
Packet Data (0 to 4M – 1)
Other software Data (Optional and User Defined)

The 'Other software Data' portion of the descriptor exists after all of the defined words and is reserved for use by the host software to store private data. This region is not used in any way by the hardware components in a UDMA system and these modules will not modify any bytes within this region.

The contents of the Monolithic Packet Descriptor words are detailed in [Table 10-32](#) through [Table 10-41](#)

**Table 10-32. Monolithic Packet Descriptor Word 0**

Bits	Name	Description	Rx Overwrite
31:30	2'd2	Monolithic Packet Descriptor type.	Yes
29	Extended Packet Info Block Present	This field indicates the presence of the Extended Packet Info Block in the descriptor. 0 = EPIB is not present 1 = 16 byte EPIB is present	Yes
28	RESERVED		Yes
27:22	Protocol Specific Valid Word Count	This field indicates the valid number of 32-bit words in the protocol specific region. This is encoded in increments of 4 bytes as follows: 0 = 0 bytes 1 = 4 bytes ... 16 = 64 bytes ... 32 = 128 bytes 33-63 = RESERVED	Yes
21:0	Packet Length	The length of the packet in bytes. The valid range for the packet length is 0 to 4M-1 bytes. If the packet length is set to 0, the port will not actually transmit any information. Instead, the port will perform buffer/descriptor reclamation as instructed in the return information in word 2.	Yes

**Table 10-33. Monolithic Packet Descriptor Word 1**

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27:24	Protocol Specific Flags	This field contains protocol specific flags/information that can be assigned based on the packet type.	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes

**Table 10-33. Monolithic Packet Descriptor Word 1 (continued)**

Bits	Name	Description	Rx Overwrite
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

**Table 10-34. Monolithic Packet Descriptor Word 2**

Bits	Name	Description	Rx Overwrite
31:27	Packet Type	This field indicates the type of this packet and is encoded as follows: 0-31 = To Be Assigned	Yes
26:18	Data Offset	This field indicates the byte offset from byte 0 of this descriptor to the location where the valid data begins. On Rx, this value is set equal to the value for the SOP offset given in the Rx DMA channel's Monolithic control register. When a monolithic packet is processed, this value may be modified in order to add or remove bytes to from the beginning of the packet. The value for this field can range from 0-511 bytes. Note that the value of this field must always be greater than or equal to 4 times the value given in the Protocol Specific Valid Word Count field.	Yes
17	Early Return	This field indicates that each buffer pointer should be immediately returned to the specified queue when data transfer is started from the packet instead of waiting for the entire buffer to be emptied. This flag is used to enable in-place reception of packets on a Receive Channel while the source packet is in the process of being transferred on a Transmit Channel. 0 = Buffer/Package descriptor pointers should only be returned after all reads have been completed 1 = Buffer/Package descriptor pointers should be returned immediately upon fetching the descriptor and beginning to transfer data.	No
16	Return Push Policy	This field indicates how a Transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator.	No
15:0	Packet Return Queue Num	This field indicates the queue number that the descriptor is to be returned to after transmission is complete.	No

**Table 10-35. Monolithic Packet Descriptor Word 3**

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

**Table 10-36. Monolithic Extended Packet Info Word 0 (Optional)**

Bits	Name	Description	Rx Overwrite
31:0	Timestamp Info	This field contains an application specific timestamp which can be used for traffic shaping in a QoS enabled system.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

**Table 10-37. Monolithic Extended Packet Info Word 1 (Optional)**

Bits	Name	Description	Rx Overwrite
31:0	Software Info 0	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

**Table 10-38. Monolithic Extended Packet Info Word 2 (Optional)**

Bits	Name	Description	Rx Overwrite
31:0	Software Info 1	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

This word is only present if the Extended Packet Info Block present bit is set in Word 0.

**Table 10-39. Monolithic Extended Packet Info Word 3 (Optional)**

Bits	Name	Description	Rx Overwrite
31:0	Software Info 2	This field stores software centric information that needs to travel with the packet through the stack. This information will be copied from the source descriptor to the destination descriptor whenever a prefetch operation is performed or when transferring through an infrastructure DMA node.	Configurable

These words if present immediately follow the Software Data Block Information.

**Table 10-40. Monolithic Packet Descriptor Protocol Specific Word M (Optional)**

Bits	Name	Description	Rx Overwrite
31:0	Protocol Specific Data N	This field stores information which varies depending on the packet type.	Configurable

The payload data follows the protocol specific words at an offset specified in the data offset field of Word 0.

**Table 10-41. Monolithic Packet Descriptor Payload Data Words 0-N**

Bits	Name	Description	Rx Overwrite
31:0	Packet Data N	These words store the packet payload data.	Yes

This field is endian specific. In other words, this is the only field in the descriptor which changes based on the endianness of the system.

#### 10.1.2.2.4 Transfer Request Descriptor

The Transfer Request Descriptor contains the following information:

- Indicator which identifies the descriptor as a TR Descriptor
- Source and Destination Tags
- Packet Error Indicator
- Packet Return Information
- Set of one or more Transfer Request Records
- Set of one or more Transfer Response Records

Transfer Request Packet Descriptors always contain 16 bytes of required information and a variable number of Transfer Request/Transfer Response Records (request and response counts match).

The Transfer Request descriptor layout is shown below.

Packet Info (16 bytes)
Null (0-102 bytes to bring start of TR request array into natural alignment for memory fetch efficiency)
Array of Transfer Request Records (M bytes)
Array of Transfer Response Records (4 bytes per)

**Table 10-42. Transfer Request Packet Descriptor Word 0**

Bits	Name	Description	Rx Overwrite
31:30	2'd3	TR Packet Descriptor type.	Yes
29	RESERVED		Yes
28:20	Reload Count	Specifies what to do when the last entry is processed in this packet. This field specifies how many times to return to the Reload Index upon reaching the Last Entry. When an internal count is incremented to this value and the TR indicated by the Last Entry has been processed, this packet will be considered complete and the descriptor will be placed back on the return queue specified in Word 2.  A value of 0x1FF indicates that a perpetual loop is desired. In this case, the loop count is considered infinite and the internal count will not be incremented. A teardown operation on the channel will cause the loop to be broken at the nearest iteration boundary.	
19:14	Reload Index	Specifies the value to set the current processing index to when the last entry is processed and the Reload Enable is set to 1. This is basically an absolute index to jump to on the 2 <sup>nd</sup> and following passes through the TR packet.	
13:0	Last Entry	Specifies the index of the last valid entry in this packet	Yes

**Table 10-43. Transfer Request Packet Descriptor Word 1**

Bits	Name	Description	Rx Overwrite
31:28	Error Flags	This field contains error flags that can be assigned based on the packet type	Yes
27	RESERVED		Yes

**Table 10-43. Transfer Request Packet Descriptor Word 1 (continued)**

Bits	Name	Description	Rx Overwrite
26:24	Transfer Request Nominal Element Size	Specifies the stride between TR entries. The value in this field must be set large enough that any TR in the buffer will fit within the given dimension. TRs are expected to be placed on boundaries as given in this dimension. This field is also used to calculate the location where the Transfer Responses will be written back. This field is encoded as follows: 0 = 16 byte Transfer Request record size 1 = 32-byte Transfer Request record size 2 = 64-byte Transfer Request record size 3 = 128-byte Transfer Request record size 4-7 = RESERVED	Yes
23:14	Packet ID	Unique Packet ID for packet within FlowID	Yes
13:0	Flow ID	Flow ID within which this packet is being transported. The FlowID is used by downstream blocks to make decisions about packet steering and resource allocations. FlowIDs are also used to allow specific packets to be received into specific sets of buffers.	Yes

**Table 10-44. Transfer Request Packet Descriptor Word 2**

Bits	Name	Description	Rx Overwrite
31:17	RESERVED		No
16	Return Push Policy	This field indicates how a Transmit DMA should return the descriptor pointers to the free queues. This field is encoded as follows: 0 = Descriptor must be returned to tail of queue 1 = Descriptor must be returned to head of queue This bit is only used when the Return Policy bit is set to 1. This field must be set to 0 for descriptors which will be placed on queues managed by the Ring Accelerator	No
15:0	Packet Return Queue Num	This field indicates the queue number that the descriptor is to be returned to after transmission is complete.	No

**Table 10-45. Transfer Request Packet Descriptor Word 3**

Bits	Name	Description	Rx Overwrite
31:24	Source Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_hi_sel field in the flow configuration table entry.	Configurable
23:16	Source Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_src_tag_lo_sel field in the flow configuration table entry.	Configurable
15:8	Dest Tag – Hi	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_hi_sel field in the flow configuration table entry.	Configurable

**Table 10-45. Transfer Request Packet Descriptor Word 3 (continued)**

Bits	Name	Description	Rx Overwrite
15:0	Dest Tag – Lo	This field is application specific. During Packet reception, the DMA controller in the port will overwrite this field as specified in the rx_dest_tag_lo_sel field in the flow configuration table entry.	Configurable

**Table 10-46. Transfer Request Packet Descriptor Payload Words 0-N**

Bits	Name	Description	Rx Overwrite
31:0	Transfer Control Record Array	Transfer Control Records. This is an array of records which encapsulate the Transfer Request and Transfer Response messages which are used by the UTC	Yes (partial)

### 10.1.2.3 Transfer Request Record

#### 10.1.2.3.1 Overview

This section describes the standard transfer request (TR) format to initiate a DMA transfer. The TRs can support both half and full duplex with multiple dimensions as well as cache wars. The UTC (Universal Transfer Controller) does not have to support all types of TRs. Each TR will also generate a TR response. A TR can be sent to the UTC either through a PSI-L interface or an optionally supported Direct TR submission (previously QDMA) which will have Memory Mapped TR submission registers that can be written. The Memory Mapped TR submission registers further be classified by submission type either a single burst (atomic write) or multiple burst (non-atomic). The non-atomic TR will be sent when the submission register with word 0 is written.

**Table 10-47. Terms and Definitions**

Term	Definition
TR	A transfer request to move data.
CR	A cache operation request. A request to send messages to a specified cache controller to prepare the cache for a future operation.
UTC	Universal Transfer Controller the module in the UDMA architecture that handled the actual movement of data requested in the TR.

#### 10.1.2.3.2 Addressing Algorithm

For a basic TR request the same algorithm is used. The innermost loop always consumes physically contiguous elements from memory. Its implicit dimension is 1 byte, this can be changed if the TR contains the formatting flags field and it is supported by the UTC. The pointer itself moves from fetch to fetch on the maximum byte alignments specified for the UTC, in increasing order. In each level outside the inner loop, the loop moves the pointer to a new location based on the size of that loop level's dimension.

##### 10.1.2.3.2.1 Linear Addressing (Forward)

The following code illustrates the basic algorithm for a 4-level loop nest block move. This model assumes that it transfers data 1 byte at a time and the input and output block are the same size in all dimensions.

```
// sptr is a byte pointer.
// dptr is a byte pointer.
// Source address is indirect
if (TR_ISA) {
    sptr = *sptr;
}
// Destination address is indirect
if (TR_IDA) {
    dptr = *dptr;
}
// TR_TRIGX can be selected to come from Global events, Local event, or none.
// Check for trigger of TYPE0
if (TR_TRIG0_TYPE == TYPE0) while(!TR_TRIG0);
if (TR_TRIG1_TYPE == TYPE0) while(!TR_TRIG1);
```

```

for (i3 = 0; i3 < ICNT3; i3++)
{
    sptr3 = sptr; // save current position before entering next level
    dptr3 = dptr; // save current position before entering next level
    // Check for trigger of TYPE1
    if (TR_TRIG0_TYPE == TYPE1) while(!TR_TRIG0);
    if (TR_TRIG1_TYPE == TYPE1) while(!TR_TRIG1);
    for (i2 = 0; i2 < ICNT2; i2++) {
        sptr2 = sptr; // save current position before entering next level
        dptr2 = dptr; // save current position before entering next level
        // Check for trigger of TYPE2
        if (TR_TRIG0_TYPE == TYPE2) while(!TR_TRIG0);
        if (TR_TRIG1_TYPE == TYPE2) while(!TR_TRIG1);
        for (i1 = 0; i1 < ICNT1; i1++) {
            sptr1 = sptr; // save current position before entering next level
            dptr1 = dptr; // save current position before entering next level
            // Check for trigger of TYPE3
            if (TR_TRIG0_TYPE == TYPE3) while(!TR_TRIG0);
            if (TR_TRIG1_TYPE == TYPE3) while(!TR_TRIG1);
            for (i0 = 0; i0 < ICNT0; i0++) {
                // UTC can combine these in optimized burst aligned accesses.
                *dptr = *sptr;
                sptr = sptr++;
                dptr = dptr++;
            }
            // Update based on saved pointer for this level
            sptr = sptr1 + SDIM1;
            dptr = dptr1 + DDIM1;
        }
        // Update based on saved pointer for this level
        sptr = sptr2 + SDIM2;
        dptr = dptr1 + DDIM2;
    }
    // Update based on saved pointer for this level
    sptr = sptr3 + SDIM3;
    dptr = dptr1 + DDIM3;
}

```

This form of addressing allows programs to specify regular paths through memory in a small number of parameters. Additionally, it allows for various stall points through the loop to allow for hardware or software induced pausing of the transfer. The following table defines these parameters more explicitly.

**Table 10-48. Addressing Parameters for a Basic Stream**

Parameter	Definition
ICNT0	Number of iterations for the innermost loop dimension, loop level 0. That is, DIM0 = BYTES.
ICNT1	Number of iterations for the first level above the innermost loop, loop level 1.
SDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the source.
DDIM1	Number of bytes between the starting points for consecutive iterations of loop level 1 for the destination.
ICNT2	Number of iterations for loop level 2.
SDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the source.
DDIM2	Number of bytes between the starting points for consecutive iterations of loop level 2 for the destination.
ICNT3	Number of iterations for loop level 3.
SDIM3	Number of bytes between starting points for consecutive iterations of loop level 3 for the source.
DDIM3	Number of bytes between the starting points for consecutive iterations of loop level 3 for the destination.

### 10.1.2.3.3 Transfer Request Formats

The Transfer Request format builds on the same structure adding fields to the TR to give more configuration options. The structure in [Table 10-49](#) shows the 512-bit data structure that makes up the maximum sized UTC Transfer request.

**Table 10-49. Transfer Request Template**

word 15		word 14		word 13		word 12	
DICNT3	DICNT2	DICNT1	DICNT0	DDIM3		DDIM2	
word 11		word 10		word 9		word 8	
DADDR				DDIM1		FMTFLAGS	
word 7		word 6		word 5		word 4	
DIM3		DIM2		ICNT3	ICNT2	DIM1	
word3		word 2		word 1		word0	
ADDR				ICNT1	ICNT0	FLAGS	

The UTC defines a four-level loop nest for addressing elements within the TR, using the algorithms described in the Addressing algorithm. Most of the fields in the TR template map directly to the parameters in those algorithms.

**Table 10-50. Transfer Request Fields**

Field Name	Description	Size (bits)
FLAGS	TR flags that specify type of TR and how the TR should be handled. It also supports the TR triggering and output events.	32
ICNT0	Total loop iteration count for level 0 (innermost)	16
ICNT1	Total loop iteration count for level 1	16
ADDR	Starting address for the source data or destination data if it is a half-duplex write	64
DIM1	Signed dimension for loop level 1 for the source data	32
ICNT2	Total loop iteration count for level 2	16
ICNT3	Total loop iteration count for level 3 (outermost)	16
DIM2	Signed dimension for loop level 2	32
DIM3	Signed dimension for loop level 3	32
FMTFLAGS	Flags that tell how the data is formatted either between the input and the output or if the data should use different addressing schemes or sizes. These flags are OPTIONAL and only specific features may be supported by a given DMA implementation. The UDMA/UTC capabilities register specifies which features are supported.	32
DDIM1	Signed dimension for loop level 1 for the destination data	32
DADDR	Starting address for the destination of the data	64
DDIM2	Signed dimension for loop level 2 for the destination data	32
DDIM3	Signed dimension for loop level 3 for the destination data	32
DICNT0	Total loop iteration count for level 0 (innermost) used for destination	16
DICNT1	Total loop iteration count for level 1 used for destination	16
DICNT2	Total loop iteration count for level 2 used for destination	16
DICNT3	Total loop iteration count for level 3 used for destination	16

The TR assumes all iteration counts as unsigned integers, and all dimensions as signed integers representing byte offsets.

The template above fully specifies the type of elements, length, and dimensions of the transfer.

Since all transfers will not require all the fields the TRs have the type field which allow the number of words required to be sent for the TR to be reduced.

#### 10.1.2.3.4 Flags Field Definition

[Table 10-51](#) expands the 32-bit FLAGS field. The numbers above each field here indicate bit numbers within the field.

**Table 10-51. Transfer Request Template FLAGS Field**

31								24								23								16																																							
CONFIGURATION SPECIFIC FLAGS																CMD ID																																															
15				14				13				12				11				10				9				8				7				6				5				4				3				0											
TRIGGER1_TY PE								TRIGGER1								TRIGGER0_TY PE								TRIGGER0								EVENT_SIZE								WAIT								STATI C								TYPE							

The flags field fills in the remaining details about the stream, as follows:

**Table 10-52. FLAGS Field Descriptions**

Bit	Field	Description
0-3	TYPE	The TYPE of TR that is being sent 0: One dimensional data move 1: Two dimensional data move 2: Three dimensional data move 3: Four dimensional data move 4: Four dimensional data move with data formatting 5: Four dimensional Cache Warm 6-7: Reserved 8: Four Dimensional Block Move 9: Four Dimensional Block Move with Repacking 10: Two Dimensional Block Move 11: Two Dimensional Block Move with Repacking 12-14: Reserved 15: Four Dimensional Block Move with Repacking and Indirection
4	STATIC	This field is only valid on Type 8 and type 9 TRs The TR is static and will continually reload into the channel upon completion of the TR until a channel tear down.
5	WAIT	This field is only valid on Type 15 TRs. This field indicates whether or not this TR should ensure it completes before allowing the next TR to start on this channel. The encoding is as follows: 0 = Allow next TR to start immediately 1 = Wait for this TR to complete before allowing next TR to start When set, the next TR will not be considered triggered (regardless of any other trigger conditions) until all write status responses for the current TR have landed.

**Table 10-52. FLAGS Field Descriptions (continued)**

Bit	Field	Description
6-7	EVENT_SIZE	This is how often the TR will generate an output event. 0: Event is only generated with the TR is complete 1: Event is generated when the second inner most loop (ICNT1) is decremented by 1. 2: Event is generated when the third inner most loop (ICNT2) is decremented by 1. 3: Event is generated when the outer most loop (ICNT3) is decremented by 1.
8-9	TRIGGER0	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER0_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel
10-11	TRIGGER0_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
12-13	TRIGGER1	This is one of two selectable triggers. The receipt of this trigger will enable the TR to be active for enough data transfer as specified by the TRIGGER1_TYPE Field. 0: No Trigger 1: Global Trigger 0 for the channel 2: Global Trigger 1 for the channel 3: Local Event for the channel This field is reserved for a Direct TR.
14-15	TRIGGER1_TYPE	This is the type of data transfer that will be enabled by receiving a trigger. 0: The second inner most loop (ICNT1) will be decremented by 1. 1: The third inner most loop (ICNT2) will be decremented by 1. 2: The outer most loop (ICNT3) will be decremented by 1. 3: The entire TR will be allowed to complete.
16-23	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR. For a Direct TR this is the event number that will be generated based on the event trigger.
24-31	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC implementation.

The following sections expand on each of these fields.

#### 10.1.2.3.4.1 Type: TR Type Field

The TR Type field gives the size of the TR and which fields are expected in the TR. Based on the type the number of words required to be sent to complete the TR can be decreased. The tables below show the minimum size for each TR as well if any fields will be treated as reserved.

**Table 10-53. Transfer Request Minimum Size Type 0 One Dimensional Transfer**

w 0	w 1	w 2	w 3	w 4	w 5	w 6	w 7	w 8	w 9	w 10	w 11	w 12	w 13	w 14	w 15

#### 10.1.2.3.4.2 STATIC: Static Field Definition

The static field is used to allow for a single TR to be reused repeatedly. If the static bit is set then the UTC upon completing the specified TR will restart the TR with the same values as were in the initial TR. This TR will stay active until the channel is torn down. The initiating of a tear down of the channel will clear the STATIC field in the active TR and it will be removed from the channel FIFO after the TR completion.

#### Note

If a TR is submitted to a channel FIFO with the STATIC field set then any TRs placed in the FIFO after that will NOT be run until the teardown has been initiated.

#### 10.1.2.3.4.3 EVENT\_SIZE: Event Generation Definition

The UTC allows for an event to be generated at specified intervals for each TR. As the TR passes through the various loops in the addressing algorithm it will generate an event that then can be routed to other event receivers, such as other channels or interrupts to processors.

**Table 10-64. Event Size Encoding**

Value	Event Type	When it Fires
0	Completion Event	When the TR is complete and all status for the TR has been received.
1	ICNT1 Decrement	Type 0: When the last data transaction is sent for the TR. Type 1-11: When ICNT1 is decremented
2	ICNT2 Decrement	Type 0 – 1,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT2 is decremented
3	ICNT3 Decrement	Type 0 – 2,10-11: When the last transaction is sent for the TR. All Other Types: When ICNT3 is decremented

#### 10.1.2.3.4.4 TRIGGER INFO: TR Triggers

The TR allows for two different triggers to be set to allow for the data transfer to be prevented or halted through the process of transferring the data. The triggers are specified by selecting a type of trigger and the size of the transfer that can be allowed for the receipt of a given trigger. The triggers themselves in the UTC are collected on a per channel basis and for each of three sources. Anytime the trigger event is received the internal counter is incremented. The trigger event will not be cleared until the specified block has started its transfer and it will **only** clear the triggers that are active.

### CAUTION

This does allow for one TR in the channel to use global event 0 and the next TR to use global event 1. If while the first TR is running global event 0 can increment and will decrement each time the TR reaches the specified level. At the same time global event 1 will be incremented whenever it is received but it will not decrement until the next TR runs. If the global event 1 counter reaches overflows then an error event will NOT be generated but the event will be lost.

#### 10.1.2.3.4.5 TRIGGERX\_TYPE: Trigger Type

The trigger type sets the value of TR\_TRIGX as shown in the addressing algorithm description. The TR\_TRIGX value allows for the temporary halting of the TR until the expected event has been received. After the given loop has been entered the selected trigger will be decremented.

#### 10.1.2.3.4.6 TRIGGERX: Trigger Selection

The TR is able to select up to 2 of 3 trigger sources for a given TR. The events can come from the dedicated local event on the UTC itself or from two assigned global events that come from the PSI-L interface on the UTC. The trigger counters are always enabled so that events can be received prior to the TR getting loaded. The trigger counters are only decremented when the trigger is active and the TR has scheduled the first transfer of the transaction.

#### 10.1.2.3.4.7 CMD ID: Command ID Field Definition

The command ID is used as a unique identifier for the TR. The value is not used during the data transfer but is only used by the TR Completion Response to allow for hardware and software to identify the specific TR.

#### 10.1.2.3.4.8 Configuration Specific Flags Definition

The configuration specific flags are specific to a given TR type. If a TR type does not require additional flags the field should be filled with 0's. Currently only Types 0-4 and Type 15 support the following configuration specific flags:

**Table 10-65. Configuration Specific Flags**

Bit	Field	Description
0	ISA	Indirect Source Address 0: Source address in TR is a directly usable pointer to the data 1: Source address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
1	IDA	Indirect Destination Address 0: Destination address in TR is a directly usable pointer to the data 1: Destination address in TR is a pointer to a 64-bit location that contains the actual pointer to the data
2	SUPR_EVT	Suppress Event Output: 0 = Output events will be generated according to FLAGS.EVENT_SIZE field 1 = No output events will be generated for the duration of this TR execution This field is only valid on split and type 15 TRs (Type 0-3,15)
3	Reserved	Reserved for Future use.

**Table 10-65. Configuration Specific Flags (continued)**

Bit	Field	Description
6:4	EOL	<p>This field is only valid on split TRs (Type 0-3).</p> <p>On source (Read) split TRs, this field specifies whether or not the EOL delimiters should be produced on the Tx PSI-L bus. The encodings of this field for source split TRs is as follows:</p> <ul style="list-style-type: none"> <li>0 = SOL/EOL match SOP/EOP</li> <li>1 = SOL/EOL boundaries are each ICNT0 bytes</li> <li>2 = SOL/EOL boundaries are each ICNT0×ICNT1 bytes</li> <li>3 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2 bytes</li> <li>4 = SOL/EOL boundaries are each ICNT0×ICNT1×ICNT2×ICNT3 bytes</li> </ul> <p>On destination (Write) split TRs, this field specifies how to handle EOL delimiters when they are encountered on the Rx (write) side of a TR. EOL delimiters can be produced from the Tx (read) side of a block copy operation or from a remotely paired peripheral when operating in split TR mode. The encodings of this field are as follows:</p> <ul style="list-style-type: none"> <li>0: Ignore EOL</li> <li>1: Line length is icnt0 bytes. Clear any remaining ICNT0 bytes and increment ICNT1 by 1</li> <li>2: Line length is icnt0×icnt1 bytes. Clear any remaining ICNT0/1 bytes and increment ICNT2 by 1</li> <li>3: Line length is icnt0×icnt1×icnt2 bytes. Clear any remaining ICNT0/1/2 bytes and increment ICNT3 by 1</li> <li>4: Line length is ICNT0×ICNT1×ICNT2×ICNT3 bytes. Move on to next TR</li> <li>5-7: RESERVED</li> </ul>
7	EOP	<p>This TR should generate an EOP on the streaming interface for any downstream packet oriented consumers to denote that a 'packet' of data is complete</p> <ul style="list-style-type: none"> <li>0: No EOP flag will accompany the last PSI-L data phase associated with transfers from this TR</li> <li>1: On egress the DMA will set the EOP flag coincident with transferring the last of the data for this TR. If the TR data does not complete an entire PSI-L data phase then the remaining bytes in the data phase will be skipped and the internal FIFO pointer will be updated to begin packing new data on a new data phase boundary.</li> </ul>

#### 10.1.2.3.5 TR Address and Size Attributes

The fields described below all describe the data transfer that needs to be made as described in the Linear Memory Addressing Block Move Algorithm.

##### 10.1.2.3.5.1 ICNT0

The ICNT0 is the number of elements to transfer in the inner loop of the TR. If the TR type does not contain a FMTFLAGS field then this count is assumed to be the number of bytes to transfer. If the FMTFLAGS field is included in the types then the number of bytes to be transferred will be ICNT0 times the Element size rounded up to the nearest byte.

##### 10.1.2.3.5.2 ICNT1

The ICNT1 field is the loop count for the second innermost loop count as defined in the Addressing algorithm.

##### 10.1.2.3.5.3 ADDR

The address location is the initial address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register.

While the ADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4-bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the ADDR field is given in [Table 10-66](#).

**Table 10-66. ADDR Field Format**

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.
47:0	Address	The 48-bit source or source/destination starting address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype or rx_atype field in the DMA Tx/Rx channel's Configuration Register.

#### 10.1.2.3.5.4 DIM1

This is the offset of the address from the initial address for the first access of the second loop. This will be added to the address from the loop before. This is a signed value so that the address can be both above and below the initial address.

#### 10.1.2.3.5.5 ICNT2

This is the count for the third innermost loop in the addressing algorithm.

#### 10.1.2.3.5.6 ICNT3

This is the count for the outermost loop in the addressing.

#### 10.1.2.3.5.7 DIM2

This is the offset of the address from the initial address to the next address in the third innermost loop. This is a signed vales so that the address can be both above and below the previous address.

#### 10.1.2.3.5.8 DIM3

This is the offset of the address from the initial address to the next address in the outermost loop. This is a signed values so that the address can be both above and below the previous address.

#### 10.1.2.3.5.9 DDIM1

This is the offset of the destination address from the initial destination address for the first access of the second loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 10.1.2.3.5.10 DADDR

The destination address location is the initial destination address that will be accessed at the start of the transfer. All of the dimensions will also be based off of this value. This address can either physical or virtual based upon settings in the DMA channel Configuration register

While the DADDR field is 64 bits wide, the usable extent of the address on a K3 system is 48 bits of absolute offset plus a 4 bit address space selector which indicates 1 of 16 different orthogonal address spaces that the pointer is referencing within. The format of the DADDR field is given as follows:

**Table 10-67. DADDR Field Format**

Bits	Subfield	Description
63:52	Reserved	Reserved
51:48	Address Space Select	Effectively bits 51:48 of the address. The value given in this field will be output by the DMA masters on the casel pin which is used by the infrastructure as an identifier for which address space this particular memory region is located within. Address space 0 is the default unified address space for a given device. Address spaces 1-15 are used for alternate address maps which may be external to the device (PCIe/Hyperlink) or in other 'tiles' on large devices.

**Table 10-67. DADDR Field Format (continued)**

Bits	Subfield	Description
47:0	Address	The 48-bit starting destination address for the transfer. This address will be interpreted to be either physical, virtual, or intermediate physical based on the tx_atype field in the DMA Tx channel's Configuration Register.

#### 10.1.2.3.5.11 DDIM2

This is the offset of the destination address from the initial destination address for the first access of the third loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 10.1.2.3.5.12 DDIM3

This is the offset of the destination address from the initial destination address for the first access of the outer loop. This will be added to the destination address from the loop before. This is a signed value so that the destination address can be both above and below the initial destination address.

#### 10.1.2.3.5.13 DICNT0

This is the number of elements to use in the destination if the TR is repacking the data. This number reflects the number of elements to be transferred.

#### 10.1.2.3.5.14 DICNT1

This is the number of times to execute the second loop to use in the destination transfer.

#### 10.1.2.3.5.15 DICNT2

This is the number of times to execute the third loop to use in the destination transfer.

#### 10.1.2.3.5.16 DICNT3

This is the number of times to execute the fourth loop to use in the destination transfer. The value of DICNT0 × DICNT1 × DICNT2 × DICNT3 must equal ICNT0 × ICNT1 × ICNT2 × ICNT3. If any of the values are zero they are NOT included in the multiplication.

#### 10.1.2.3.6 FMTFLAGS

The format flags are used to specify special formatting of the transfer. [Table 10-68](#) shows the definition of the sub-fields in the FMTFLAGS field.

**Table 10-68. Transfer Request Template FMTFLAGS Field**

31										16
AMODE SPECIFIC										
15	14	13	12	11	8	7	4	3	2	0
RESERVED		SECTR		DFMT		ELTYPE		DIR		AMODE

The flags field fills in the remaining details about the stream, as follows:

**Table 10-69. FMTFLAGS Field Descriptions**

Bit	Field	Description
16-31	AMODE SPECIFIC	This 16-bit field is defined based on the addressing mode used as selected in the AMODE field.
14-15	Reserved	Reserved for Future use
12-13	SECTR	A secondary TR is required and the format of the secondary TR.
8-11	DFMT	The data reformatting function to apply in the middle of the TR
4-7	ELTYPE	The type of element and its size and potential output size for the innermost loop. If this is not specified in the TR then a byte is the assumed element.

**Table 10-69. FMTFLAGS Field Descriptions (continued)**

Bit	Field	Description
3	DIR	For a block type transfer does the addressing mode apply for source or destination. The other one will use linear. If it is a non-block type TR then this field is ignored
0-2	AMODE	The Addressing Mode of TR that is being sent 0: Linear Addressing 1: Circular Addressing 2-7: Reserved for future use

#### 10.1.2.3.6.1 AMODE: Addressing Mode Definition

The addressing mode field allows for different algorithms to be used other than the default linear addressing mode described in the Addressing algorithm.

##### 10.1.2.3.6.1.1 Linear Addressing

This is the addressing that is used if there is no FMTFLAGS field in the TR.

##### 10.1.2.3.6.1.2 Circular Addressing

Circular addressing modifies how the UTC performs address arithmetic so that addresses remain within a power-of-2 sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default—linear addressing—which allows all of the address bits to vary.

The UTC TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

Conceptually, selectable addressing mode support replaces all address arithmetic with a function similar to the following.

```
enum addr_mode_t
{
    LINEAR, // Linear addressing mode
    CIRC0, // Circular addressing with block size 0
    CIRC1, // Circular addressing with block size 1
};
uint64_t circ_mask_0; // Circular addressing mask for block size 0
uint64_t circ_mask_1; // Circular addressing mask for block size 1
uint64_t address_add( uint64_t base, int32_t offset, addr_mode_t mode )
{
    uint64_t new_addr = base + offset;
    if ( mode == LINEAR )
        return new_addr;
    // Look up address mask based on selected circular buffer size.
    // Mask contains 1s for bits that remain fixed, and 0s elsewhere.
    uint64_t addr_mask = mode == CIRC0 ? circ_mask_0 : circ_mask_1;
    return ( base & addr_mask ) | ( new_addr & ~addr_mask );
}
```

The address\_add primitive then takes the place of plain addition for all TR address computations in this mode. The following example illustrates address\_add.

```
for (i3 = 0; i3 < ICNT3; i3++)
{
    ptr3 = ptr; // save current position before entering next level
    for (i2 = 0; i2 < ICNT2; i2++)
    {
        ptr2 = ptr; // save current position before entering next level
        for (i1 = 0; i1 < ICNT1; i1++)
        {
            ptr1 = ptr; // save current position before entering next level
            for (i0 = 0; i0 < ICNT0; i0++)
            {
```

```

fetch( ptr, ELEM_BYTES );
ptr = address_add( ptr, ELEM_BYTES, addr_mode_0 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr1, DIM1, addr_mode_1 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr2, DIM2, addr_mode_2 );
}
// Update based on saved pointer for this level
ptr = address_add( ptr3, DIM3, addr_mode_3 );
}

```

The values for the circular addressing can be selected by using the 16 bits of the AMODE specific Field as described in the AMODE SPECIFIC Addressing Mode Field.

#### 10.1.2.3.6.2 DIR: Addressing Mode Direction Definition

This field is used if the TR TYPE specifies the TR is for a block move if the addressing mode specified in the AMODE field applies to the source addressing or the destination addressing. A value of 0 means the source addressing will use the method selected in the AMODE field and the destination address will use the default linear addressing. A value of 1 means that the destination addressing will use the method selected in the AMODE field and the source addressing will use the default linear addressing. If the TR TYPE is not a block transfer then this field will be ignored.

#### 10.1.2.3.6.3 ELTYPE: Element Type Definition

The Element Type field allows the user to specify the basic unit that is used for the innermost loop. If the FMTFLAGS field is not present then the UTC will assume a value of 0 which is a byte size element. The element type also allows for the some expansion or contraction of the element size from the source to the destination.

**Table 10-70. ELTYPE Encoding**

Encoding	Definition
0	1 Byte per element
1	1.5 Bytes(12 bits) per element
2	2 Bytes per element
3	3 Bytes per element
4	4 Bytes per element
5	8 Bytes per element
6	16 Bytes per element
7	32 Bytes per Element
8	1 Byte per Input Element 2 Bytes per Output Element
9	1.5 Bytes per Input Element 2 Bytes per Output Element
10	2 Bytes per Input Element 1 Byte per Output Element
11	2 Bytes per Input Element 1.5 Bytes per Output Element
12-15	Reserved for Future Use

#### 10.1.2.3.6.4 DFMT: Data Formatting Algorithm Definition

The Data Formatting Algorithm is a method to specify a manipulation of the data between how it is read and how it is sent. If the TR Type is not a block operation TR then this field will be ignored. Otherwise [Table 10-71](#) specifies what the encodings meaning.

**Table 10-71. DFMT Encoding**

Encoding	Definition
0	No Change. The input and output block will remain identical
1	Constant Copy. The input block is not an address but the address is up to a 64-bit constant

**Table 10-71. DFMT Encoding (continued)**

Encoding	Definition
2	Transpose. The inner and second most inner loops are swapped so that rows become columns and columns become rows.
3	Reverse. The data in the row will be accessed in the reverse of the order that it is read. So the largest address read in a row will be the first address written.
4	Reverse Transpose. The data will be written in the reverse of the order that is read as well as transposed. So the largest address read in a row will be the address in the first line being written out.
5-15	Reserved for Future Use

#### 10.1.2.3.6.5 SECTR: Secondary Transfer Request Definition

The Secondary Transfer Request field allows the user to specify if the TR requires an additional TR located in memory. If this is used then the address given in the TR is the pointer to the Secondary TR and the secondary TR will have a pointer to the actual final TR.

**Table 10-72. Secondary Transfer Request Format**

Encoding	Size	Definition
0	0	The TR does not require a secondary TR
1	64 bytes	The TR will fetch a 64-byte Secondary TR prior to the initial read.
2	128 bytes	The TR will fetch a 128-byte Secondary TR prior to the initial read.
3	TBD	Reserved for future use

#### 10.1.2.3.6.5.1 Secondary TR Formats

The secondary TR format is a TR that is fetched by the UTC when it is executing a TR to fill in additional information that does not fit in the original TR. It is not included in the standard TR as the information required in it is not required until execution time and is kept separate so the Channel FIFO space can be minimized. The first four words of the Secondary TR are always the real start address of the transfer followed by a Secondary TR Flags field. The remaining words in the secondary TR are defined by the Secondary TR TYPE from the Secondary TR Flags field.

**Table 10-73. Secondary Transfer Request Template for 64-Byte Secondary TR**

Type Specific	SECONDARY TR FLAGS		ADDR

#### 10.1.2.3.6.5.2 Secondary TR FLAGS

The next diagram expands the generic 32-bit Secondary TR FLAGS field. The numbers above each field here indicate bit numbers within the field.

**Table 10-74. SECONDARY TR FLAGS Field Definition**

Table 16.14. SECONDARY TR TYPE Specific Field Definition				
31				16
SEC_TR_TYPE_SPECIFIC				
15	4	3	0	
SEC TR TYPE SPECIFIC		SEC TR TYPE		

The flags field fills in the remaining details about the stream, as follows:

**Table 10-75. FLAGS Field Descriptions**

Bit	Field	Description
31-4	SEC_TR_TYPE_SPECIFIC	Reserved for the SEC_TR_TYPE to define based on its requirements
3-0	SEC_TR_TYPE	The TYPE of SEC_TR 0: Multiple Buffer Interleave 1-15: Reserved

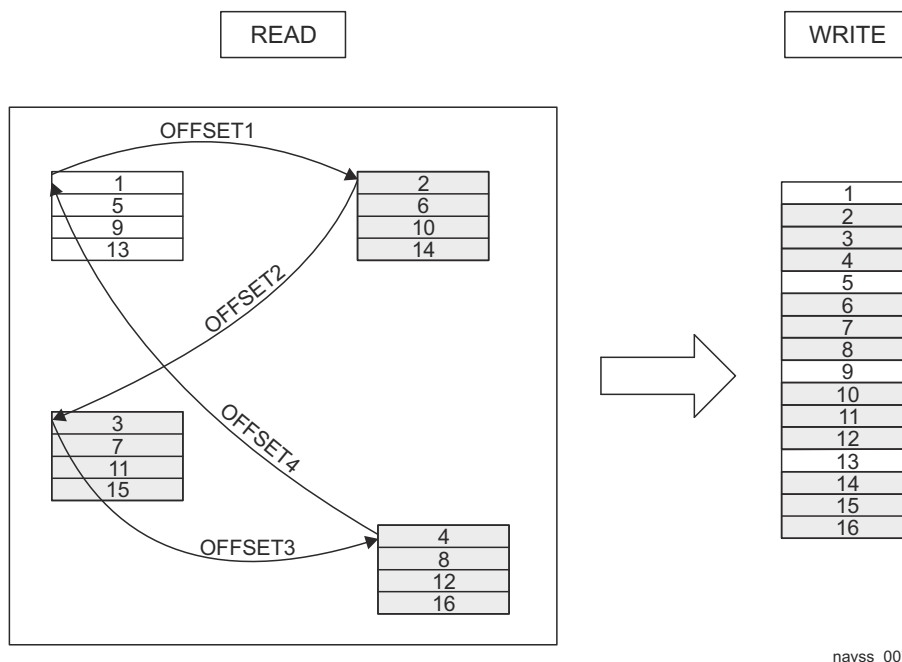

The following sections expand on each of these fields.

#### 10.1.2.3.6.5.2.1 SEC\_TR\_TYPE: Secondary TR Type Field

The Secondary TR Type field is used to state the purpose of the secondary TR. This can be defined

#### 10.1.2.3.6.5.2.2 Multiple Buffer Interleave

The multiple buffer interleave is used to have a single TR plus Secondary TR that can define a fetch where a single line is selected from multiple buffers and then sent as a single buffer. This can be used along with transpose of the data to present data in slices optimal for processing the same algorithm on different data sets at the same time. An example of this can be seen in [Figure 10-4](#).

**Figure 10-4. Example of Multiple Buffer Interleaving Read with 4 Offsets**

The case above provides the ability to minimize the number of TRs submitted to make the transfer but the interleaved Read main advantage comes when used with the transpose mode enabled. [Figure 10-5](#) shows the advantage of the interleaved mode along with the transpose mode to allow for maximum size transfer on both read and write transactions.

navss\_008

**Figure 10-5. Example of Interleaved Read with 4 Offsets and Transpose Enabled**

As the figure shows the data that is written out now contains one element from each block of memory and can be read in directly to processing units.

**Table 10-76. SECONDARY TR FLAGS Field Definition**

Table 16-16: SECONDARY TRF/ECF Field Definition															
31															16
SEC_TR_TYPE_SPECIFIC															
15						6		5		4		3		0	
SEC_TR_TYPE_SPECIFIC								NUMOFFSET				0 (Multiple Interleave Type)			

The flags field fills in the remaining details about the stream, as follows:

**Table 10-77. Multiple Buffer Interleave FLAGS Field Descriptions**

Bit	Field	Description
6-31	Reserved	Reserved for Future Use
4-5	NUMOFFSET	The encoded value for the number of offsets. 0: 4, 1: 8, 2: 16
0-3	SEC_TR_TYPE	0: Multiple Buffer Interleave

Secondary TR TYPE from the Secondary TR Flags field.

**Table 10-78. Multiple Buffer Interleave Secondary Transfer Request Template 128 Byte Secondary TR**

word 7	word 6	word 5	word 4
OFFSET3	OFFSET2	OFFSET1	OFFSET0
word3	word 2	word 1	word0
RESERVED	SECONDARY TR FLAGS	ADDR	

Multiple Buffer Interleave will work by setting the SECTR field in the TR presented to the channel to be either 64 or 128 bytes depending on the number of offsets required. An offset number of 4 or 8 will require 64 bytes while 16 offsets will require 128 bytes. When the channel becomes active it will see that the SECTR field is nonzero and fetch the SECTR of the size specified. The first access from the channel will be a read of the secondary TR as specified in the address field of the TR. Upon receiving the Secondary TR the channel will parse the type field and seeing that it is a Multiple Buffer interleave will load the offset index fields for the channel. Additionally it will load the ADDRESS field from the secondary TR into the Address of the actual TR to allow it to process as normal.

The first address fetch will then be to this SEC\_TR\_ADDRESS. After finishing the inner loop the next address will be SEC\_TR\_ADDRESS + OFFSET0.

#### Note

ICNT1 should be equal to the height of the transfer blocks times the number of offsets.

#### 10.1.2.3.6.6 AMODE SPECIFIC: Addressing Mode Field

The AMODE Specific Fields are defined based upon the Addressing Mode being used as specified in AMODE: Addressing Mode Definition.

##### 10.1.2.3.6.6.1 Circular Address Mode Specific Flags

If the circular addressing mode is selected in AMODE the definition of the upper 16 bits of the FMTFLAGS field are used to select the type of addressing for each entry in the loop and to define 2 unique masks that can be used for the circular buffering.

The following example code shows the method used to compute the masks referred to by the address\_add function described in the 'Address Arithmetic with Selectable Linear/Circular Addressing Modes' section.

```
// Circular addressing masks.
// 1 bits in the mask indicate address bits that remain fixed.
// 0 bits in the mask indicate address bits that are allowed to vary.
uint64_t circ_mask_0; // mask for circular addressing block 0
uint64_t circ_mask_1; // mask for circular addressing block 1
void compute_circular_address_masks( int cbk0, int cbk1 )
{
    int block_size_0 = cbk0 + 9; // power-of-2 of block size in bytes
    int block_size_1 = cbk0 + cbk1 + 10;
    if ( block_size_1 > 31 ) block_size_1 = 32; // clamp to 4GB maximum size
    circ_mask_0 = (~0ULL) << block_size_0;
    circ_mask_1 = (~0ULL) << block_size_1;
}
```

#### Example 3-4 Circular Address Mask Computation

**Table 10-79. Transfer Request Template FMTFLAGS AMODE SPECIFIC Circular Addressing Field**

31	30	29	28	27	26	25	24	23	20	19	16
AM3		AM2		AM1		AM0		CBK1		CBK0	

**Table 10-80. Circular Address Mode Specific Flags Field Descriptions**

Bit	Field	Description
16-19	CBK0	Specifies the circular block 0 value as used in Circular Address Mask Computation
20-23	CBK1	Specifies the circular block 1 value as used in Circular Address Mask Computation
24-25	AM0	The address mode to use with ICNT0 loop
26-27	AM1	The address mode to use with ICNT1 loop
28-29	AM2	The address mode to use with ICNT2 loop
30-31	AM3	The address mode to use with ICNT3 loop

#### 10.1.2.3.6.6.1.1 CBK0 and CBK1: Circular Block Size Selection

The CBK0 and CBK1 fields set the circular block sizes for circular addressing. CBK0 directly determines the circular block size for block 0. CBK1 combines with CBK0 to determine the circular block size for block 1. Specifically, the streaming engine sets block 1's size according to  $CBK0 + CBK1 + 1$ . Therefore, circular block 1 is always larger than circular block 0.

The following table illustrates the resulting valid block sizes for circular block 0 and 1. For circular block 0, the use the value of CBK0 directly. Circular block 0 supports block sizes ranging from 512 bytes to 16M bytes. For circular block 1, use the value of  $CBK0 + CBK1 + 1$ . Circular block 1 supports sizes ranging from 1K bytes to 4G bytes.

**Table 10-81. Circular Block Size Decoding**

Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size	Encoded Block Size	Decoded Block Size
0	512	8	128K	16	32M	24	Reserved
1	1K	9	256K	17	64M	25	Reserved
2	2K	10	512K	18	128M	26	Reserved
3	4K	11	1M	19	1M	27	Reserved
4	8K	12	1M	20	1M	28	Reserved
5	16K	13	1M	21	1M	29	Reserved
6	32K	14	1M	22	1M	30	Reserved
7	64K	15	1M	23	1M	31	Reserved

#### 10.1.2.3.6.6.1.2 Amx: Addressing Mode Selection

The fields AM0 through AM3 control the addressing modes for each of the 4 dimensions. The UTC supports the following addressing modes:

**Table 10-82. AMX Address Mode Selection Encoding**

AMX	Meaning
00b	Linear addressing
01b	CKB0 (Circular Buffer 0 is used)
10b	CKB1 (Circular Buffer 1 is used)
11b	Reserved

Each dimension has its own addressing mode, independent of the other dimensions. This permits any mixture of linear and circular addressing among the 4 dimensions.

When a given dimension selects linear addressing, the UTC uses unmodified two's complement arithmetic to update addresses for that loop level.

When a given dimension selects circular addressing via CBK0 or CBK1, the UTC uses the circular address arithmetic described above in the Address Arithmetic with Selectable Linear/Circular Addressing Modes section.

### 10.1.2.3.6.7 Cache Flags

If the TR type is a cache warm the format flags field is replaced with a Cache Flags field.

Table 10-83 shows the breakdown of the 32 bit Cache Flags field.

**Table 10-83. Transfer Request Template CACHEFLAGS Field**

31	24	23	16
CACHE OPERATION		RESERVED	
15	8	7	0
RESERVED		CACHE ID	

The flags field fills in the remaining details about the stream, as follows:

**Table 10-84. FMTFLAGS Field Descriptions**

Bit	Field	Description
24-31	Cache Operation	0: Prewarm the Cache 1: Prewarm MMU 2-255: Reserved for future use
8-23	Reserved	Reserved for future use
0-7	Cache ID	The Cache number to perform the operation on. 0-254: Cores. 255: L3 Cache

### 10.1.2.4 Transfer Response Record

Upon completing a TR the UTC will send back a TR Response to the UDMA-C. The UTC TR response format is a single 32-bit word as shown in Table 10-85.

**Table 10-85. Transfer Request Response Template STATUS FLAGS Field**

31	24	23	16
CONFIGURATION SPECIFIC STATUS		CMD ID	
15	8	7	0
RESERVED		STATUS_FIELD	STATUS_TYPE

**Table 10-86. STATUS FLAGS Field Descriptions**

Bit	Field	Description
31:24	Configuration Specific Flags	These are flag bits that can be specified by the specific UTC configuration. These bits will remain undefined in the global TR format to allow for customization requirements that might be required in the specific UTC implementation. For UDMA channels which are capable of interfacing to endpoint peripherals (or via a PDMA) the format of these flags are as follows: 31:28 error_flags – the error_flags field as is provided across PSI-L 27:24 ps_flags – the ps_flags field as is provided across PSI-L
23:16	CMD ID	The Command ID for the TR. This will be sent back with the response for the Channel controller to identify the specific TR.
15:8	Reserved	Reserved for Future use
7:4	STATUS_INFO	Information that is unique based on the STATUS_TYPE returned
3:0	STATUS_TYPE	The completion status of the TR.

#### 10.1.2.4.1 STATUS Field Definition

The Status field is made up of two sub-fields STATUS\_TYPE and STATUS\_INFO. A value of 0 means it completed as requested any other value means an error has occurred. Table 10-87 states the legal STATUS\_TYPES and the use of the STATUS\_INFO in each case.

#### 10.1.2.4.1.1 STATUS\_TYPE Definition

The STATUS\_TYPE field is used to determine what type of status is being returned. Depending on the type of Status it might additionally have information in the STATUS\_FIELD to give more details about the specific reason why the status was returned.

**Table 10-87. STATUS\_TYPE Encoded Values**

Value	Error Type	Completion	STATUS FIELD Definition
0	None	Complete	None
1	Transfer Error	None to Partial	CBA Non-Complete Status Received
2	Aborted Error	None to Partial	None
3	Submission Error	None	Submission Error Type
4	Unsupported Feature	None	Feature Type
5	Transfer Exception	Partial	Exception Type
6	Teardown Flush	None	None
7-15	Reserved	Unknown	Reserved

##### 10.1.2.4.1.1.1 Transfer Error

A transfer ERROR occurs anytime that one of the CBA transactions performed by the UTC returns a status other than complete. The UTC may continue the transfer or may abort the transfer and return back to an IDLE state. Once the transfer is finished (aborted or complete) the UTC will send back the TR Response with the STATUS TYPE of Transfer Error. The STATUS FIELD will contain the 3 bit CBA Status field the upper bit specifies if it was a read status (1) or a write status (0).

##### 10.1.2.4.1.1.2 Aborted Error

An aborted error occurs if the PSI-L interface asserts the drop signal prior to the completion of the TR. The UTC will return back to an IDLE state and send back the TR Response with the STATUS TYPE. If the UTC receives a transfer error after receiving the abort the transfer error should be reported instead of the Abort Error.

##### 10.1.2.4.1.1.3 Submission Error

A submission error is returned for a TR that is received that cannot be run. The STATUS\_INFO field specifies the type of submission errors.

**Table 10-88. Submission Error STATUS\_INFO Encodings**

Value	Submission Error Type
0	ICNT0 was 0
1	Channel FIFO was full when TR received
2	Channel is not owned by the submitter. Either CC submitting to Direct or Direct submitting to a CC channel
3-15	Reserved

##### 10.1.2.4.1.1.4 Unsupported Feature

An unsupported feature error is returned for a TR that is received that cannot be run because it specifies a feature that is optional and not supported by the UTC that received the TR. The STATUS FIELD specifies the feature that was not supported. If it specifies multiple features that were not supported the UTC implementation can determine which type it wants to return

**Table 10-89. Unsupported Feature STATUS\_INFO Encodings**

Value	Submission Error Type
0	TR Type not supported
1	STATIC not supported
2	EOL not supported
3	CONFIGURATION SPECIFIC not supported

**Table 10-89. Unsupported Feature STATUS\_INFO Encodings (continued)**

Value	Submission Error Type
4	AMODE not supported
5	ELTYPE not supported
6	DFMT not supported
7	SECTR not supported
8	AMODE SPECIFIC Field not supported
9-15	Reserved

#### 10.1.2.4.1.1.5 Transfer Exception

A transfer exception is returned for a TR that completed but experienced a known exception during reception. The STATUS\_INFO field specifies the type of transfer exception that was encountered.

**Table 10-90. Transfer Exception STATUS\_INFO Encodings**

Value	Transfer Exception Type
0	EOP on incoming data stream was encountered prematurely (short packet)
1	EOP on incoming data stream was encountered late (long packet)
2-15	Reserved

#### 10.1.2.4.1.1.6 Teardown Flush

Split mode UTC Rx channels (write channels) can respond with a teardown flush in the case that they have received a teardown message, all data has been transferred, and TRs have been prefetched (in anticipation of more data being received). In this case, the UTC will simply return the prefetched TR to the completion queue with the status type set to teardown flush.

### 10.1.2.5 Queues

Queues are used to hold either values or references that need to be passed between components in the system. These components could be software or hardware. Queues are implemented by the Ring Accelerator module.

#### 10.1.2.5.1 Queue Types

##### 10.1.2.5.1.1 Transmit Queues (Pass By Reference)

Tx channels use packet queues referred to as “transmit queues” to store the packets that are waiting to be transmitted. Tx channels require one or more packet queues dedicated to each transmit channel for this purpose. Multiple queues per channel may facilitate Quality of Service (QoS) in some applications. Pass by reference Tx Queues only pass a pointer to a descriptor (and optional information like the packet length). Pass by reference Tx Queues can contain pointers to Host, Monolithic, or TR packet descriptors (depending on Tx channel mode configuration).

##### 10.1.2.5.1.2 Transmit Queues (Pass By Value)

Pass by value Tx Queues are used for direct Transfer Request submission on Tx channels which are configured for 3<sup>rd</sup> party pass by value mode. Entries on a pass by value Tx Queue include the entire Transfer Request message and optional protocol specific information. Pass by value queues are only supported by the Ring Accelerator.

##### 10.1.2.5.1.3 Transmit Completion Queues (Pass By Reference)

Tx channels also use packet queues referred to as “transmit completion queues” to return packets to the host after they are transmitted. The number of queues required by the channel or system for this purpose is driven by the requirements of the garbage collection software within the driver. Tx completion queues are only used when the packet descriptor indicates that the packet should be returned to a queue instead of directly recycling the descriptors to their queues of origin. Pass by reference Tx Completion Queues only pass a pointer to a descriptor.

#### 10.1.2.5.1.4 Transmit Completion Queues (Pass By Value)

Pass by value Tx Completion Queues are used to pass the Transfer Response messages that are returned when a channel is configured in 3<sup>rd</sup> Party pass by value mode. Entries on a pass by value Tx Completion Queue include the Transfer Response message. Pass by value queues are only supported by the Ring Accelerator.

#### 10.1.2.5.1.5 Receive Queues

Rx ports use packet queues referred to as “receive queues” to forward completed received packets to the host or another peer port entity. Rx ports may be configured in various ways to forward the received packets onto any number of receive queues. Rx ports may choose to queue their receive packets based strictly on Rx channel, protocol type, priority, direct forwarding requirements (i.e. to another ports Tx queue) or any combination of these and this is application specific. In many cases the receive queue is in fact also a transmit queue for another peer entity. It is just a matter of semantics with respect to which port is referenced in the system.

#### 10.1.2.5.1.6 Free Descriptor Queues

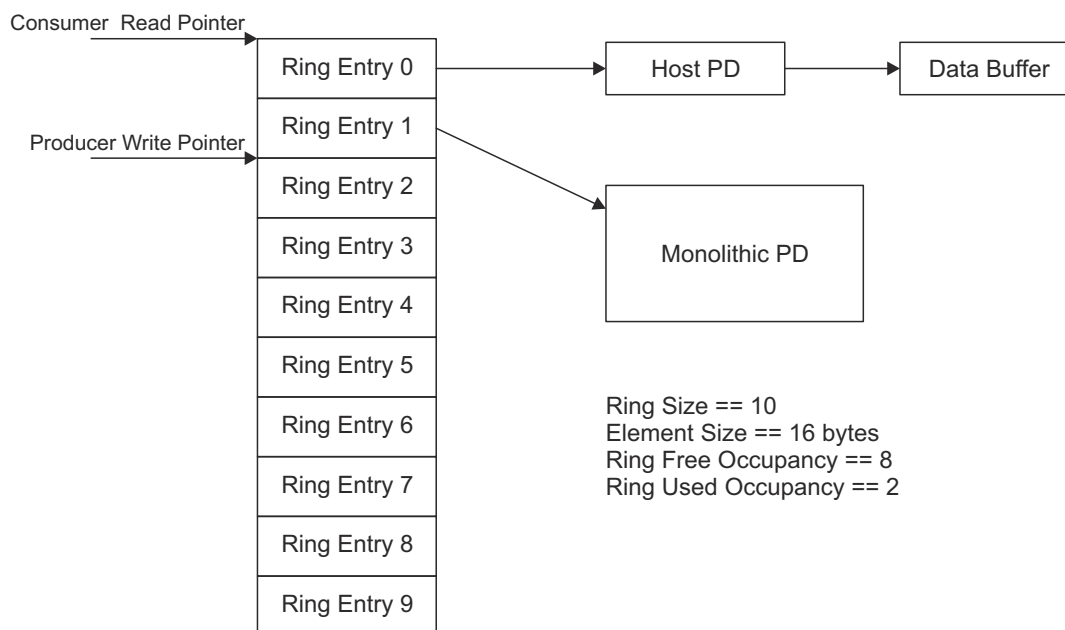

Rx ports use queues referred to as “free descriptor queues” to allocate empty monolithic descriptors. The entries on the Free Descriptor Queues do not have any buffers attached as buffers are allocated as part of the descriptor for monolithic type packets.

#### 10.1.2.5.1.7 Free Descriptor/Buffer Queues

Rx ports use queues referred to as “free descriptor/buffer queues” to allocated empty host type descriptors. The entries on the Free Descriptor/Buffer Queues have pre-attached empty buffers whose size and location are described in the “original buffer information” fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding a descriptor to a free descriptor/buffer queue.

#### 10.1.2.5.2 Ring Accelerator Queues Implementation

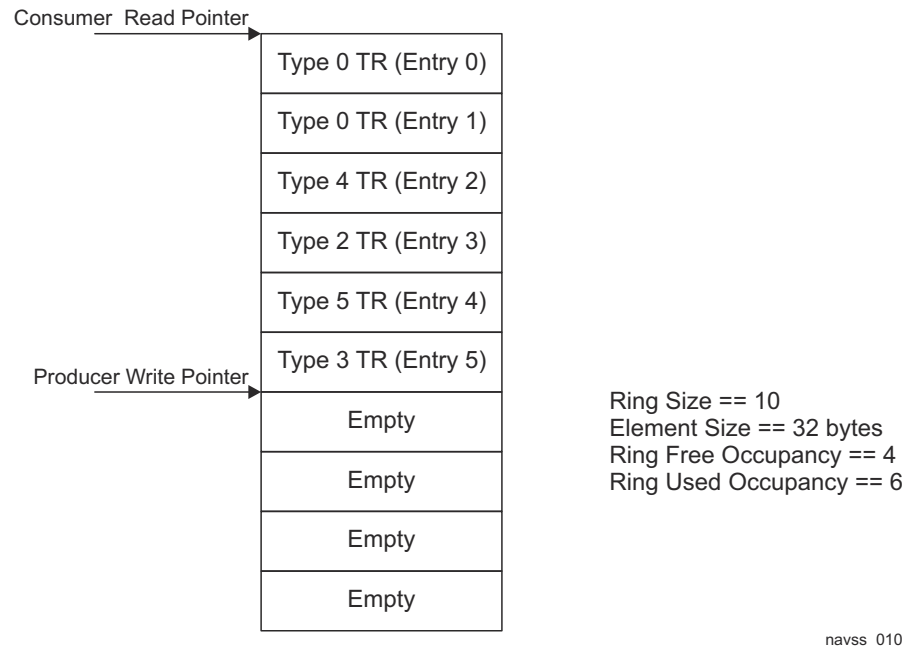

Work packets which are stored in a pass by reference queue managed by the Ring Accelerator are shown in [Figure 10-6](#).

navss\_009

**Figure 10-6. Ring Accelerator Based Queue Structure**

Work packets stored in a pass by value queue managed by the Ring Accelerator are shown in [Figure 10-7](#).

**Figure 10-7. Ring Accelerator Based Direct Transfer Request Queue Structure**

### 10.1.3 Operational Description

#### 10.1.3.1 Resource Allocation

Queues, rings, memory, interrupts, DMA channels, and flow table entries are shared resources within the data movement architecture and their ownership and use must be managed in order to provide stable, safe, and secure operation. The K3 platform provides channelized firewalls which can be used to protect arrayed resources (like queues, rings, channel control registers, etc.) from unwanted/unauthorized use as well as restricted access to the firewall configurations themselves. It is outside the scope of this document to define how the resource management system functions but it is assumed that all of these resources are isolate-able and secure-able.

#### 10.1.3.2 Ring Accelerator Operation

##### 10.1.3.2.1 Queue Initialization

The base address, size and element size for each ring must be initialized via the provided registers prior to using the ring. Ring initialization is typically done only on channel setup as once initialized the rings can be used indefinitely. Optionally, an internal initialization machine may be provided to set default values for the ring address, size, and element sizes. This capability enables the rings to be used during boot without configuration. Not all rings will necessarily support this feature and if required must be configured at design time. Whether or not this machine is present, all rings are able to be re-configured at run time through the provided registers.

##### 10.1.3.2.2 Queuing packets (Exposed Ring Mode)

Queuing of packets onto a packet queue using the Ring Accelerator is logically equivalent but requires a different set of transactions from queuing packets in queue mode. The producer (entity which is going to queue an entry onto the ring) maintains a current write pointer and a free entry occupancy count for each ring it controls. To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the memory location pointed to by the current write pointer and will decrement its free entry occupancy. After the producer has confirmed that the data has actually landed in memory, it will then write to the doorbell register for the ring to increment the used occupancy count for the ring.

More than one entry can be queued with a single doorbell write as the entry count in the doorbell write indicates how many entries have been queued.

### 10.1.3.2.3 De-queuing packets (Exposed Ring Mode)

The consumer (entity which is going to de-queue an entry from the ring) maintains a current read pointer and a used entry occupancy count for each ring it controls. To de-queue an entry the consumer will read the entry contents from the memory location pointed to by the current read pointer and will decrement its used entry occupancy. The consumer will then write to the doorbell register for the ring to increment the free occupancy count for the ring.

### 10.1.3.2.4 Queuing packets (Queue Mode)

To queue an entry the producer will write the entry contents (typically a pointer to the Packet Descriptor along with optional sideband information) to the Proxy thread location allocated by the system, with the queue offset for the queue to access. The write within the queue offset to the completion offset (final byte of the data) will cause the entire data to be written to the RA queue.

### 10.1.3.2.5 De-queuing packets (Queue Mode)

To de-queue an entry the consumer will read the entry contents from the Proxy thread location allocated by the system, with the queue offset for the queue to access. The proxy will read the entry from the RA queue. The consumer can then read the entire contents of the entry. The completion offset (final byte of the data) will cause the proxy to flush that entry (so that it can fetch a new one from the RA upon the next read).

### 10.1.3.3 UDMA Internal Transmit Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before queuing packets to a channel the host must initialize the channel's Tx Port DMA State. The host initializes the channel Tx Port DMA State by writing to the Tx Channel Configuration Register A. The Host may choose to write the enable bit in the Tx Channel Configuration Register A at the same time or after it has written all of the channel parameters but note that every write to the Tx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

It should be noted that very little configuration information is required for a UDMA Tx channel compared to previous versions of UDMA. This is because UDMA has transitioned to a full modeless model for channel operation where each packet descriptor specifies the descriptor type, packet type, and the packet return parameters. Packet queues in UDMA may include combinations of host and monolithic descriptors in any order.

After a Transmit channel has been set up, packets can be added to the Queues for the channel to begin the transmit operation. The following sections describe how the transmit operations are performed for the various descriptor types.

### 10.1.3.4

### 10.1.3.5 UDMA Internal Transmit Channel Teardown (All Packet Types)

An Tx channel teardown is initiated by the host by writing the TX\_TEARDOWN bit in the Tx Channel N Realtime Control Register. When the host initiates teardown, it can choose to perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the TX\_FORCED\_TEARDOWN bit in the Tx Channel N Realtime Control Register.

If the TX\_FORCED\_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel.
2. Completes any packets normally for which a pointer/descriptor/TR prefetch has already been performed
3. Sets the tdown bit on the EOP data phase of the last packet to be sent (if any traffic was pending when teardown was initiated) or sends a zero byte packet with the tdown, sop, and eop bits asserted. This signals the destination thread that all of the data has been sent.
4. Clears the channel enable in the Tx Channel N Realtime Control Register.
5. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
6. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

If the TX\_FORCED\_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which have been prefetched with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation).
3. Clears the channel enable in the Tx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Tx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not.

The host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

#### 10.1.3.6 UDMA External Transmit Channel Setup

External UTC/DRU channels which are managed by the UDMA follow a modified setup sequence which is as follows:

**Table 10-91. External Transmit Channel Setup Sequence**

Step	Description	module.mregion.register.field
1	Configure the UTC-DRU starting thread number	udma.gcfcg.utc_ctrl.utc_chan_start
2	Configure the UTC-DRU to accept TR's over PSIL	UTC-DRU specific
3	Enable the UDMA-C external TX channel	udma.tchanrt.tchanrt[chan]_trt_ctl.tx_enable = 1
4	Enable the UTC-DRU thread	psil.gcfcg.enable.enable(bit 31) = 1 (via psilcfc proxy)

#### 10.1.3.7 UDMA Transmit External Channel Teardown

External UTC/DRU channels which are managed by the UDMA follow a modified teardown sequence which is as follows:

**Table 10-92. External Transmit Channel Teardown Sequence**

Step	Description	module.mregion.register.field
1	Initiate UDMA-C external TX channel teardown	udma.tchanrt.tchanrt[chan]_trt_ctl.tx_tx_teardown = 1
2	Initiate UTC-DRU thread teardown	psil.gcfcg.enable.tdown(bit 30) = 1 (via psilcfc proxy)
3	Wait for UDMA-C external TX channel enable to be 0	udma.tchanrt.tchanrt[chan]_trt_ctl.tx_enable == 0

### 10.1.3.8 UDMA-P Transmit Channel Pause

Setting the TX\_PAUSE bit in the Tx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overrun conditions from a downstream data sink or upstream data source).

### 10.1.3.9

### 10.1.3.10 UDMA-P Transmit Operation (Host Packet Type)

After a channel has been set up it can begin to be used to transmit packets. Packet transmission in Host mode involves the following steps:

1. The Host is made aware of one or more chunks of data in memory that need to be transmitted as a packet. This may involve directly sourcing data from the Host or it may involve data which has been forwarded from another data source in the system.
2. The Host allocates and populates a host packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to Host)
  - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. Buffer Pointer with the byte aligned address of the first chunk of buffer data
  - h. Buffer Length with the number of bytes in the first chunk of buffer data
  - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
  - j. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
  - k. Any protocol specific descriptor sections that are required for the given packet type or system configuration
3. The Host allocates and populates host buffer descriptors as necessary to point to any remaining chunks of data that belong to this packet. The host will initialize the following fields within the host buffer descriptor:
  - a. Buffer Descriptor reclamation policy fields (if the intention is to have the DMA automatically recycle the buffer descriptors as they are transmitted).
  - b. Buffer Pointer with the byte aligned address of the given chunk of buffer data
  - c. Buffer Length with the number of bytes in the given chunk of buffer data
  - d. The Next Descriptor Pointer with the address of the next descriptor in this packet. If this is the last chunk of data in the packet, this field must be set to zero
4. The Host writes queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
5. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
6. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
7. The DMA controller reads the packet descriptor pointer from the Ring Accelerator
8. The DMA controller reads the packet descriptor from memory
9. Step 9:
  - If the return policy bit (PD Word 2, bit 15) is cleared, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves. As each buffer is emptied, the DMA will

read the next buffer descriptor to obtain the pointer and size of the data buffer as well as the pointer to the next descriptor in the chain.

- If the return policy bit is set, the DMA controller empties each buffer in sequence by transmitting the contents in one or more block data moves.

10. Step 10:

- If the return policy bit (PD Word 2, bit 15) is cleared, when all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
- If the return policy bit is set, as each buffer is emptied the DMA will write the buffer descriptor pointer to the queue specified in the return queue number field of the buffer descriptor. The DMA will also read the next buffer descriptor to obtain the pointer and size of the data buffer, the return queue information for the descriptor, as well as the pointer to the next descriptor in the chain.

11. Step 11:

- If the return policy bit (PD Word 2, bit 15) is cleared, after the Packet Descriptor pointer has been written, the Ring Accelerator will indicate the status of the Tx Completion Queue by sending an up event .
- If the return policy bit is set, when all data for the packet has been transmitted as specified in the packet size field, if the current buffer is not marked as end of packet (via a null next descriptor pointer), the DMA will continue to walk the list returning buffer descriptors to the appropriate queues as described in step 10.

12. Step 12:

- If the return policy bit (PD Word 2, bit 15) is cleared, the Interrupt Aggregator receives the up event and sets the corresponding bit in the interrupt status register as programmed in the interrupt mapping registers. This in turn causes an interrupt to the Host to be generated.
- If the return policy bit is set, when all buffers have been returned, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.

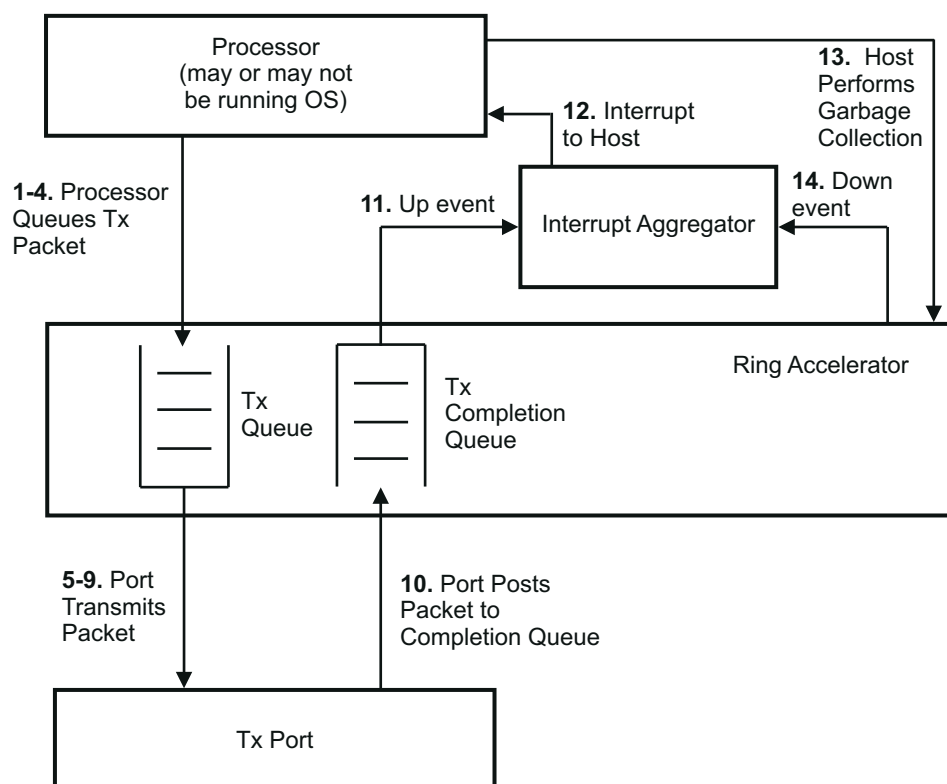

13. If the return policy bit (PD Word 2, bit 15) is cleared, host responds to status change from the Ring Accelerator (via the Interrupt Aggregator) and performs garbage collection as necessary for the packet.

14. If the return policy bit (PD Word 2, bit 15) is cleared, once the garbage collection causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator which will clear the corresponding bit in the Interrupt Status Register and potentially de-assert the interrupt line.

If the return policy bit (PD Word 2, bit 15) is cleared, the complete process is illustrated on [Figure 10-8](#).

If the return policy bit is set, the complete process is illustrated on [Figure 10-9](#).

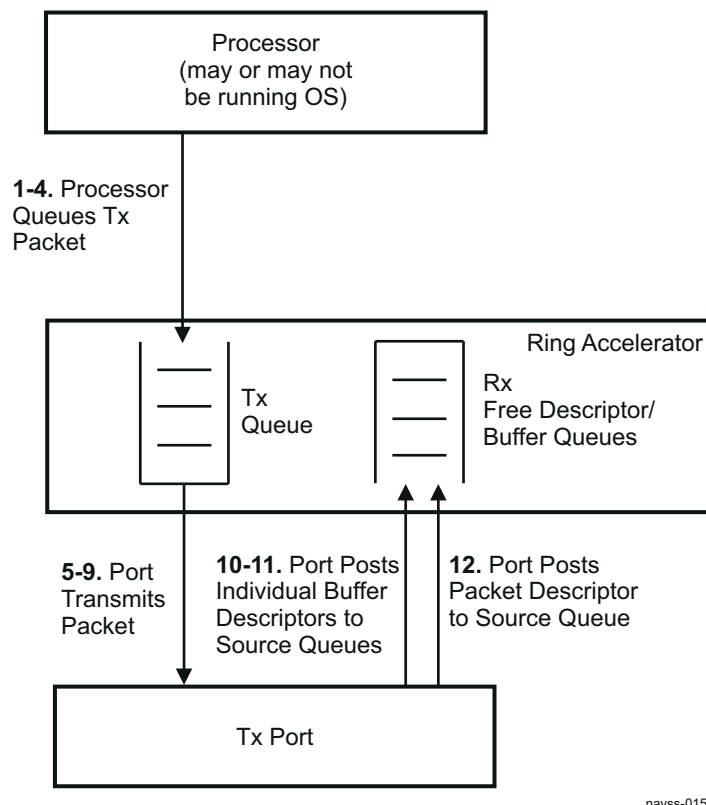

[Figure 10-8](#) shows a diagram of the host packet transmit operation – complete packet return.

navss-014

**Figure 10-8. Host Packet Tx Operation – Complete Packet Return**

Figure 10-9 shows a diagram of the host packet transmit operation – automatic buffer recycling packet return.

navss-015

**Figure 10-9. Host Packet Tx Operation – Automatic Buffer Recycling Packet Return**

#### 10.1.3.11 UDMA-P Transmit Operation (Monolithic Packet)

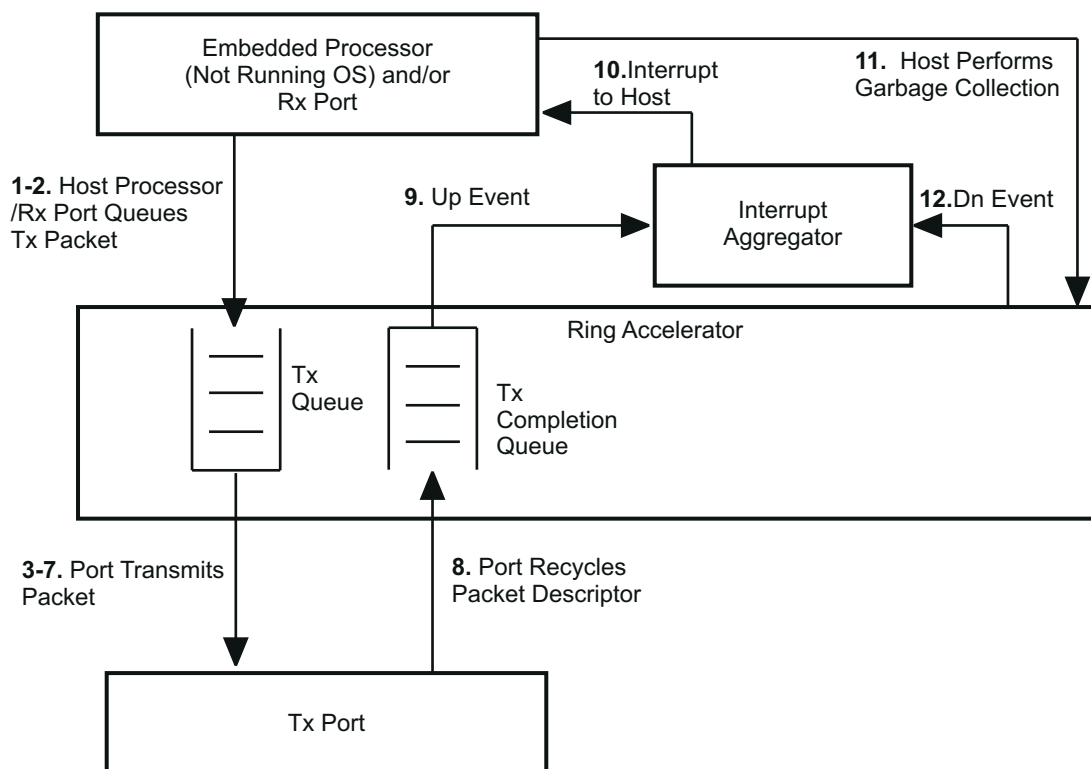

Packet transmission in Monolithic mode involves the following steps:

1. The Host allocates and populates a monolithic packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to Monolithic)
  - b. Packet Length indicating the total number of bytes in the packet
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. Offset to payload data
  - h. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
  - i. Networking Stack Information (application specific and optional)
  - j. Any protocol specific words that are required for the given packet type
2. The Host queues the packet onto one of the Transmit Queues for the desired DMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the Ring Accelerator.
6. The DMA controller reads the packet descriptor from memory

7. The DMA controller empties the data region in the descriptor by transmitting the contents in one or more block data moves. The size of these blocks is application specific. The DMA controller module specification is intended to document the block size used by a given implementation.
8. When all data for the packet has been transmitted as specified in the packet size field, the DMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
9. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

Whether or not any further processing is required on the packet at this point depends on the nature of the queue that the packet was returned to. The most common case is that the monolithic descriptor will be returned to the Rx Free Descriptor queue that it was allocated from originally. If this is the case, the Tx processing is complete at this point. Alternatively, the queue may also be a Tx Completion Queue in which case, the following optional steps may also be performed:

10. While most types of peer entities and embedded processors are able to directly and efficiently use these level sensitive status lines, cached processors may require a hardware block to convert the level status into pulsed interrupts and to perform some level of aggregation of the descriptor pointers from the completion queues into lists.
11. Host responds to status change from Ring Accelerator and performs garbage collection as necessary for packet.
12. Ring Accelerator sends down event when ring is empty

navss\_011

**Figure 10-10. Monolithic Packet Tx Operation**

#### 10.1.3.12 UDMA Transmit Operation (TR Packet)

Packet transmission in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:

- a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
  - f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
  - g. Source Tag
  - h. Destination Tag (application specific)
  - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
  - j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Transmit Queues for the desired UDMA channel. Channels may provide more than one Tx Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
  3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
  4. The DMA controller is eventually brought into context for the corresponding Tx channel and begins to process the packet.
  5. The DMA controller reads the packet descriptor pointer from the RA.
  6. The DMA controller reads the packet descriptor from memory
  7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).
  8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
  9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
  10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
  11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

#### 10.1.3.13 UDMA Transmit Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Tx Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted either to an internal UTC (in the case of a UDMA-P) or via PSI-L to a remote UTC (in the case of a UDMA-C).

5. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of reads (for single ended transfers) or reads and corresponding writes (for block copy transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Tx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

#### 10.1.3.14 UDMA Transmit Error/Exception Handling

There are 3 specific errors which may be encountered during Tx operation and which are trapped by the UDMA. The following table lists the errors and how the UDMA will process them:

**Table 10-93. UDMA Tx Error/Exception Handling**

Condition	Channel Mode	Pauses Channel	Error Flag Set in Channel	Data Transfer	TR Flush	Outputs Transfer Events
TR null icnt0	All UTC	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Unsupported TR Type	All UTC	Selectable <sup>(1)</sup>	Yes	No	Just that TR	No
Bus Errors	All	Selectable <sup>(1)</sup>	Yes	Yes	No	Yes

(1) If PAUSE\_ON\_ERROR bit is set in channel configuration

##### 10.1.3.14.1 Null Icnt0 Error

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and is unproductive wrt completion of any useful work. The Tx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### 10.1.3.14.2 Unsupported TR Type

If a TR is provided to a channel which is of a type which is not supported by the channel, the Tx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### 10.1.3.14.3 Bus Errors

If a bus error is encountered during transmit the DMA will log the error by asserting the TX\_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

#### 10.1.3.15 UDMA Receive Channel Setup (All Packet Types)

After a reset or a previous teardown operation but before receiving packets on a channel the host must initialize the channel's Rx Port DMA State. The host initializes the channel Rx Port DMA State by writing to the Rx Channel Configuration Registers. The Host may choose to write the enable bit in the Rx Global Channel Configuration Register at the same time or after it has written all of the channel parameters but note that every write to the Rx Channel Configuration Registers will overwrite the channel state for all bytes that are enabled for the write transaction.

#### 10.1.3.16 UDMA Receive Channel Teardown

A Rx channel teardown is intended to be initiated at the data source (the source thread). Initiation is commanded by the host by writing the teardown bit in the PSI-L source thread register 0x408. This will cause the source of the data to gracefully terminate any packet that is in flight and send a PSI-L data phase with the tdown signal asserted. When the UDMA receives a data phase with the tdown attribute asserted it will immediately set the internal RX\_TEARDOWN bit in the Rx Channel N Realtime Control Register.

Upon seeing the RX\_TEARDOWN bit asserted the port can perform either a graceful (no data loss) or forced teardown of the channel depending on the setting of the RX\_FORCED\_TEARDOWN bit in the Rx Channel N Realtime Control Register.

If the RX\_FORCED\_TEARDOWN bit is clear, a normal teardown has been initiated. In this case, the UDMA will do the following:

1. Stops performing any additional prefetches for the channel (TR mode channels)
2. Completes any packets normally which may be pending in the ingress port buffers (what the port considers as pending packets is application specific).
3. Clears the channel enable in the Rx Channel Global Configuration Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	0	Indicates that the teardown was graceful and data was not lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

If the RX\_FORCED\_TEARDOWN bit is set, a destructive teardown has been initiated. In this case, the UDMA will do the following:

1. Suspends any triggers to allow the channel to operate even if the trigger source is no longer functioning.
2. Completes any packets which may be pending in the ingress port buffers with or without transferring any data or generating events (the implementation has the option of doing whichever is simplest for that implementation) . Packets will be drained from the Rx FIFO either using 'null' write transfers or real transfers and the Packet Descriptors will be returned with an accurate accounting of actual bytes transferred.
3. Clears the channel enable in the Rx Channel N Realtime Control Register.
4. Resets the channel state (including scoreboards, FIFOs, counters, statistics, etc.) to their after reset values.
5. Sends a single, 4-byte, teardown complete message to the queue specified in the Rx Channel Completion Queue register for the channel. The format of this message is as follows:

Bits	Field	Value	Description
31	Forced	1	Indicates that the teardown was not graceful. Data was potentially lost.
30:14	-	0	RESERVED
13:4	Channel ID	channel number	Indicates which channel the teardown completed on
3:0	Teardown Indicator	0x1	Indicates that a teardown has completed – normal pointers must be 16 byte aligned so this value indicates this is a teardown

The host may issue a teardown on any channel at any time, regardless of whether the channel is actively receiving a packet or not. The normally intended method of issuing a teardown on a packet mode or single ended TR mode channel is to initiate the teardown at the remote PSI-L data source and allow it to flow into the UDMA. If that is not possible, the host may write the RX\_TEARDOWN bit directly to a 1.

The Host determines that a teardown is complete by periodically polling the teardown and enable bits for the channel or by waiting to receive the teardown record on the queue specified in the Tx Channel Completion Queue register for the channel.

### 10.1.3.17 UDMA-P Receive Channel Pause

Setting the RX\_PAUSE bit in the Rx Channel N Realtime Control Register will suspend the channel from arbitration resulting in a halting of the flow of data. Clearing this bit will cause the channel to be added back into the arbitration list. Pausing a channel has no other destructive side effects (other than potential underrun/overflow conditions from a downstream data sink or upstream data source).

### 10.1.3.18 UDMA-P Receive Free Descriptor/Buffer Queue Setup (Host Packets)

The Host is ultimately responsible for providing all of the free descriptors and buffers that the port uses as it receives packets. For Rx Free Descriptor/Buffer queues, descriptors are allocated in a large block by the Host and then initialized and linked with buffers before being given matched pairs where the Host initializes the descriptor to point to its corresponding buffer before being pushed onto a Receive Free Descriptor/Buffer queue. Once the host has allocated both a descriptor and a buffer, it adds them to an Rx Free Descriptor/Buffer Queue by writing the pointer to the descriptor to the Rx Free Descriptor/Buffer Queue register D for the desired queue.

Before the Host adds each Rx buffer descriptor to the queue, it must first initialize the Rx buffer descriptor values as follows:

- Write the Original Buffer Pointer with the byte aligned address of the buffer data
- Write the Original Buffer Size
- Write the Return Queue Number field in the descriptor to appropriate values (required if auto-recycling is intended)
- Write the On Chip/ Off Chip indicator in the descriptor

Depending on the software architecture, the Host may also desire to write the return policy bit in the descriptor at this point as well. The DMA will not overwrite any of these listed fields (including return policy) during reception.

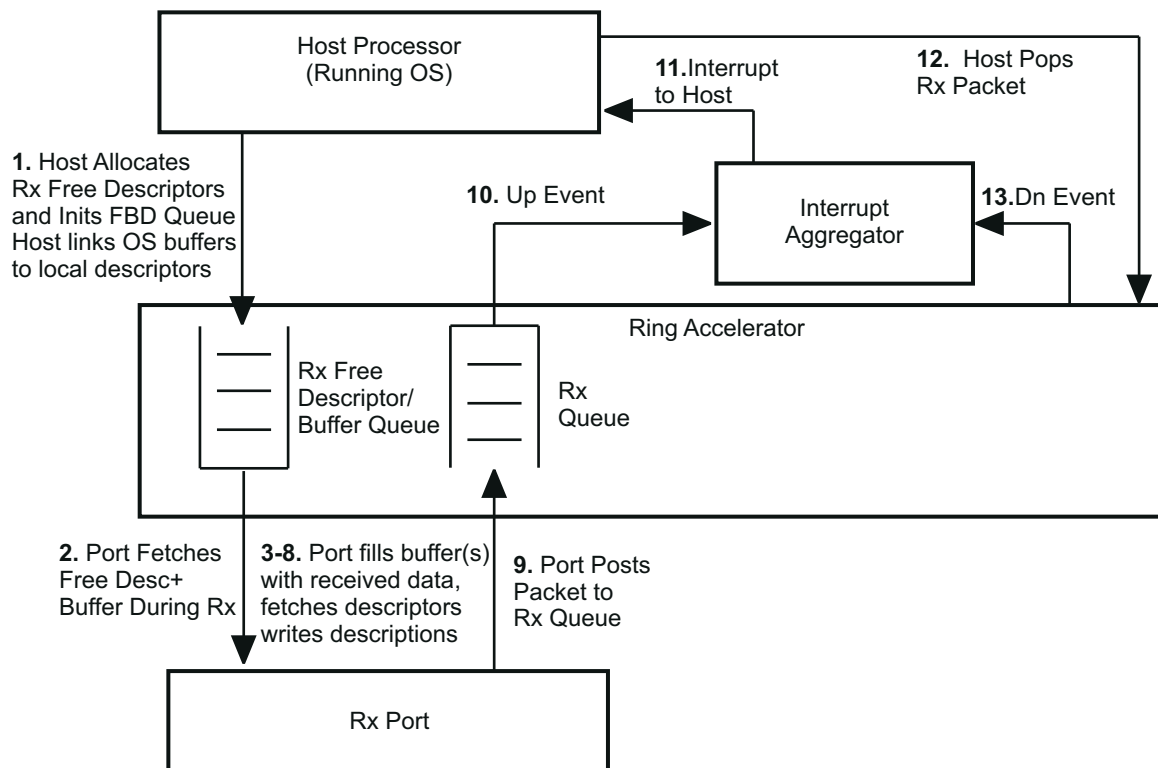

All other fields in the Descriptor do not need to be initialized as they will be overwritten by the Port on reception.

### 10.1.3.19 UDMA-P Receive FlowID Firewall Operation

Each incoming packet that enters the UDMA-P will either include an explicitly specified FlowID contained in the info words or it will have an implicitly specified default FlowID which is the same as the channel number. The Rx FlowID firewall checks the incoming FlowID on the received packet to verify that it is either the corresponding default FlowID for the channel or that the FlowID falls within the range specified in the Rx Channel Flow Range register. If the received flowID is not the channel number and it does not fall within the legal range as specified then the packet is dropped, the error is trapped in the Rx Flow ID Firewall Status register, and an optional output event is generated as specified in the Rx Flow ID Firewall Output Event Steering Register.

### 10.1.3.20 UDMA-P Receive Operation (Host Packet)

[Figure 10-11](#) shows a diagram of the overall Receive operation for Host flow mode.

navss\_012

**Figure 10-11. Host Packet Receive Operation**

When packet reception begins on a given channel, the port will begin by fetching the first descriptor + buffer from the Ring Accelerator using the Free Descriptor/Buffer Queue 0 Index that was initialized in the Rx Flow Table for the flow which is being used by the channel. If the SOP Buffer Offset in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port will then continue filling that buffer and will fetch additional descriptors + buffers as needed using the Free Descriptor/Buffer Queue 1, 2, and 3 indexes for the 2<sup>nd</sup>, 3<sup>rd</sup>, and remaining buffers in the packet.

A detailed summary is as follows:

1. Host allocates, populates, and places pointers to free descriptor/buffer structures onto Rx Free Descriptor/Buffer Queues
2. UDMA-P fetches packet descriptor pointer from RA
3. UDMA-P reads the packet descriptor to obtain the packet info, buffer pointer, and size
4. UDMA-P fills the buffer with received data
5. If packet is not complete, UDMA-P fetches next buffer descriptor pointer from RA
6. UDMA-P fills the buffer with received data

If the RX\_DESC\_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the RX\_DESC\_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine will proceed to step 8 skipping step 7.

7. UDMA-P writes previous buffer descriptor to memory. This includes the following fields:
  - a. Buffer information
  - b. Buffer Pointer with the byte aligned address of the chunk of buffer data
  - c. Buffer Length with the number of bytes in the chunk of buffer data
  - d. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.

If the RX\_DESC\_TYPE field in the Rx Flow Register A is set to 0 (Normal Rx Host Mode), Steps 5-7 continue until all packet data is received at which point the Rx engine proceeds to step 8. If the

RX\_DESC\_TYPE is set to 1 (Single Buffer Packet Host Mode) the Rx engine proceeds to step 8 as soon as the first buffer is full. Any remaining data in the packet from the line is then received into one or more additional packets each exactly one Host buffer long.

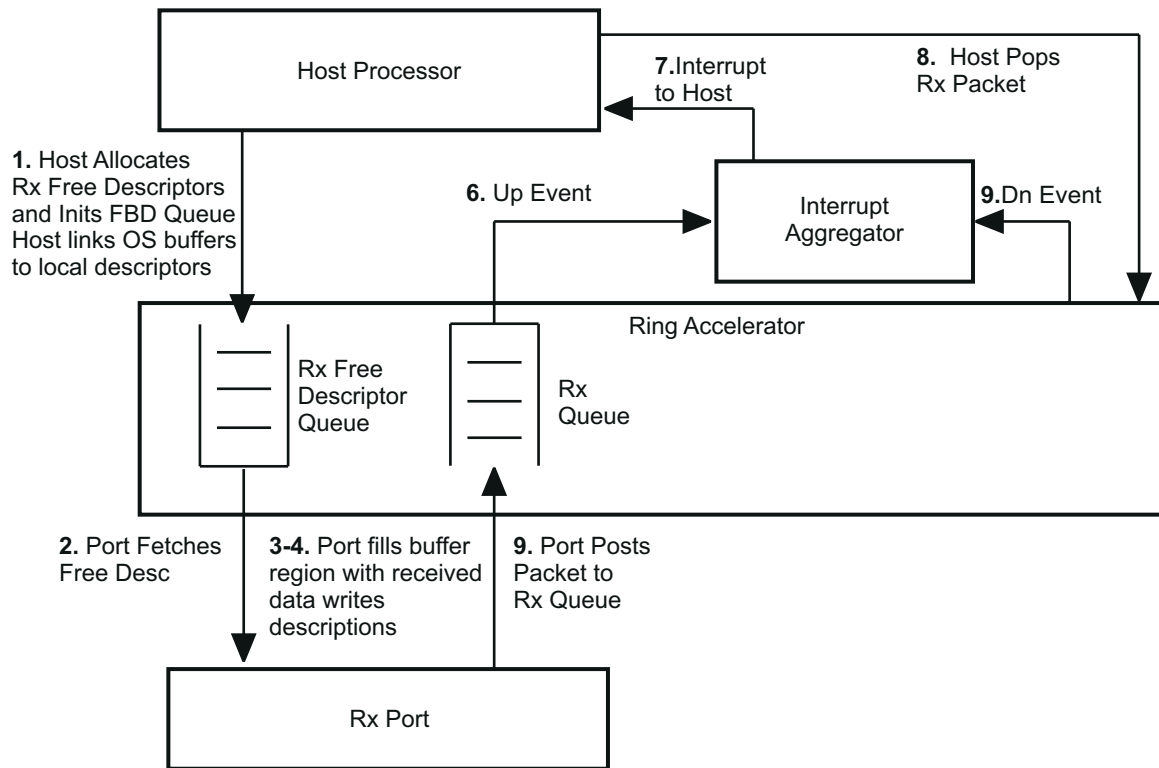

The UDMA-P performs the following operations when the entire packet has been received:

8. UDMA-P writes the packet descriptor to memory. This includes the following fields:
  - a. Descriptor Type (set to Host)
  - b. Packet Length indicating the total number of bytes that are to be read from all of the buffers for this packet.
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. SOP buffer information
    - i. Buffer Pointer with the byte aligned address of the chunk of buffer data
    - ii. Buffer Length with the number of bytes in the chunk of buffer data
  - h. Any protocol specific words that are required for the given packet type
  - i. Networking Stack Information (application specific and optional)
  - j. Pointer to next buffer descriptor in packet or 0 if this is the EOP buffer.
9. UDMA-P writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx\_dest\_qnum field in the Rx Flow Table entry or will be a queue which was provided via the PSI-L destination queue number override field.
10. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
11. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
12. The Host will pop the packet pointer from the Rx Queue
13. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/embedded processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

#### 10.1.3.21 UDMA-P Receive Operation (Monolithic Packet)

Figure 10-12 shows a diagram of the overall Receive operation for a monolithic descriptor type.

navss\_013

**Figure 10-12. Monolithic Packet Receive Operation**

The following sequence is a detailed summary of the Monolithic Packet Reception process:

1. The Host initializes free Descriptors and places them on an Rx Free Descriptor Queue
2. The UDMA-P fetches a single descriptor for the packet from the Ring Accelerator using the Monolithic Type Free Descriptor Queue Index that was initialized in the Rx Flow Table entry that is being used for the packet.
3. If the RX\_SOP\_OFFSET field in the Rx Flow Table entry is nonzero, then the port will begin writing data after the offset number of bytes in the payload portion of the monolithic descriptor. The port will then continue filling the payload portion of the descriptor until the entire packet has been received.  
The port performs the following operations when the entire packet has been received:
4. Writes the packet descriptor to memory. This includes the following fields:
  - a. Descriptor Type (set to Monolithic)
  - b. Packet Length indicating the total number of bytes in this packet.
  - c. Source Tag
  - d. Destination Tag (application specific)
  - e. Packet Type
  - f. Any protocol specific flags for the given packet type
  - g. Networking Stack Information (application specific and optional)
  - h. Any protocol specific words that are required for the given packet type
5. Writes the packet descriptor pointer to the appropriate Rx Queue. The absolute Queue that each packet to be forwarded to on completion of reception will either be the Queue which that was specified in the rx\_dest\_qnum fields in the Rx Flow Entry or can be overridden by the value in the PSI-L destination queue override field.
6. Once the packet pointer is written to the Ring Accelerator it will send an up event to the Interrupt Aggregator
7. The Interrupt Aggregator upon receiving the up event will set the appropriate bit in the Interrupt Status Register indicated by the interrupt mapping table which will cause an interrupt to be asserted to the Host
8. The Host will pop the packet pointer from the Rx Queue

9. If the pop causes the queue to become empty, the Ring Accelerator will send a down event to the Interrupt Aggregator thus causing the associated bit to be cleared and also potentially clearing the interrupt to the Host.

The Ring Accelerator is responsible for indicating the status of the Receive Queues to other ports/processors using out-of-band level sensitive status lines. These status lines are set anytime a queue is non-empty.

#### 10.1.3.22 UDMA Receive Operation (TR Packet)

Packet reception in TR Packet mode involves the following steps:

1. The Host allocates and populates a TR packet descriptor. The host will initialize the following fields within the packet descriptor:
  - a. Descriptor Type (set to TR)
  - b. Reload Enable to 1 if looping is required, otherwise 0
  - c. Reload Index to an appropriate offset if Reload Enable set, otherwise 0
  - d. Last Entry to TR count minus 1
  - e. TR Nominal Element Size to a value that is as large as required for any given TR in the buffer
  - f. Packet ID to a value that can be used to correlate the packet when it is placed back on the Tx completion queue
  - g. Source Tag
  - h. Destination Tag (application specific)
  - i. Descriptor reclamation policy fields indicating the mode and queue number for recycling the packet after transmission is complete.
  - j. A set of one or more valid Transfer Request records whose quantity matches the last index specified previously.
2. The Host queues the packet onto one of the Rx TR Queues for the desired UDMA channel. Channels may provide more than one Rx TR Queue and may provide a particular prioritization policy between the queues. This behavior is application specific and is controlled by the DMA controller/scheduler implementation.
3. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
4. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
5. The DMA controller reads the packet descriptor pointer from the RA.
6. The DMA controller reads the packet descriptor from memory
7. The DMA controller empties the data region in the descriptor by reading the contents in one or more nominal TR sized block data moves. These contents are then transmitted to an internal UTC.
8. If the UDMA includes an internal UTC, all of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
9. The UDMA will wait until Transfer Responses have been returned for each Transfer Request that it issued. As each Transfer Response is returned, the UDMA will write the response into the TR buffer in the Transfer Response records array. Each response is written into an array index which directly matches the index of the request record to which it corresponds.
10. When all Transfer Requests in the packet have been processed and all Transfer Responses have been written back and confirmed to have landed in memory, the UDMA will write the pointer to the packet descriptor to the queue specified in the return queue number fields of the packet descriptor.
11. After the Packet Descriptor pointer has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

#### 10.1.3.23 UDMA Receive Operation (Direct TR)

If the rings are configured in pass by value mode individual Transfer Request and Response records can be passed between software and hardware without any higher level data structures. This mode allows for

the UDMA to be prompted to do a transfer by just writing memory mapped locations with a source address, destination address and byte count (in the simplest case). Direct TR is accomplished as follows:

1. The Host writes a valid Transfer Request record to the Rx TR Queue of the desired UDMA channel.
2. The Ring Accelerator provides a level sensitive status signal for the queue which indicates if any packets are currently pending. This level sensitive status line is sent to the hardware block which is responsible for scheduling DMA operations.
3. The DMA controller is eventually brought into context for the corresponding channel and begins to process the packet.
4. The DMA controller reads the Transfer Request record from the ring via the RA in a single nominal TR sized block data move. These contents are then transmitted to an internal UTC (in the case of a UDMA-P).
5. All of the data transfers specified in a TR will be completed as a series of writes (for single ended transfers) and a Transfer Response will be returned indicating the completion and status of the transfer.
6. When a Transfer Response is returned for the Transfer Request record the UDMA will write the response into the next entry in the Transmit Completion Ring. Since the Transfer Responses come back from the UTC strongly ordered each response will be written into the ring strongly ordered as well.
7. After the Transfer Response has been written, the Ring Accelerator indicates the status of the Rx Completion Queues to other ports/processors/prefetcher blocks using events sent to the Interrupt Aggregator. These events are then converted into standard K3 interrupts.

#### 10.1.3.24 UDMA Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

**Table 10-94. UDMA Rx Error/Exception Handling**

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Descriptor Starvation	All Packet	Exception	No	No	Option	Option	-	No
Protocol Errors	All Packet	Info	No	No	Normal	No	-	No
Drop	Host – normal	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	-	No
	Host – single buffer	Error	Selectable <sup>(1)</sup>	Yes	Partial <sup>(2)</sup>	Until EOP <sup>(3)</sup>	-	No
	Mono	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	-	No
	UTC–single ended	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	Until EOP <sup>(4)</sup>	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	All Packet	Error	Selectable <sup>(1)</sup>	Yes	No	Yes	-	No
	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP <sup>(4)</sup>	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No

(1) If PAUSE\_ON\_ERROR bit is set in channel configuration

(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

- (3) EOP will only occur when in single buffer mode when teardown is initiated. The data is a (never ending) stream. Drop is never supposed to be asserted during this mode of operation.
- (4) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

#### **10.1.3.24.1 Error Conditions**

The following sections describe items which fall under an error severity when encountered by the UDMA on Rx:

##### **10.1.3.24.1.1 Bus Errors**

If a bus error is encountered during receive the DMA will log the error by asserting the RX\_ERROR bit for the channel (and optionally sending an error event if enabled) but the DMA will continue to attempt to complete the transfer using the returned (and potentially incorrect) data.

##### **10.1.3.24.1.2 Null Icnt0 Error**

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

##### **10.1.3.24.1.3 Unsupported TR Type**

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.24.2 Exception Conditions Exception Conditions**

There are a few cases which can occur when processing incoming packets which are not considered errors but which will require handling in order to avoid locking up the UDMA packet or TR mode write engines.

Packet mode channel exceptions include:

- Descriptor Starvation
- Protocol Errors
- Dropped Packets

Since the TR mode engine performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following sections outline these scenarios.

TR mode channel exceptions include:

- Reception of EOL delimiter
- Short Packets
- Long Packets

##### **10.1.3.24.2.1 Descriptor Starvation**

Descriptor starvation occurs when the Port attempts to fetch a free descriptor from an Rx Free Descriptor Queue or Rx Free Descriptor/Buffer Queue and none are available. When no descriptor is available, the Ring Accelerator will return a value of 0x0 for the descriptor pointer (Optionally, some ports may contain internal counters for the free queues which indicate how many elements are currently queued. In this case, no access to the RA is required and starvation is directly detected via a zero element count). When the port detects that descriptor starvation has occurred it will react based on the value of the RX\_ERROR\_HANDLING bit which was programmed into the Rx Flow N Configuration Register A.

- If the RX\_ERROR\_HANDLING bit is cleared:

The Port will assert a descriptor starvation indicator and will then return any descriptors that it has already used in the reception of the current packet back to the appropriate Free Descriptor or Free Descriptor/Buffer queue that they were fetched from. This is performed by writing the pointers for each descriptor to the Rx Free

Descriptor Queue N Register in sequence using the queue indexes in the Rx DMA state. The port may choose to implement a counter that counts the number of packets that were dropped due to descriptor starvation and may also desire to distinguish between whether the starvation occurred on the packet descriptor (SOP) or on a buffer starvation.

- If the `RX_ERROR_HANDLING` bit is set:

The Port will assert a descriptor starvation indicator (which may cause an interrupt to the Host) and will then behave as if it had not performed the current data block transfer which caused the starvation. The Port is required to pause its current processing saving the state of the transfer. The next time that the channel comes into context it will again try to allocate a descriptor with the intention being that if buffers/descriptors have been added that the operation will complete successfully on a subsequent retry.

#### **10.1.3.24.2.2 Protocol Errors**

Protocol errors occur when the port logic detects that the received packet did not pass protocol specific criteria that was checked during reception of the packet. Examples of protocol errors include packet length errors, CRC errors, or alignment errors.

When protocol errors are detected, the port may choose whether or not it will drop the packet. The mechanism that is used to determine which packets to drop and which to forward is application specific. If the port determines that it needs to forward the packet to the Host, it will set the Packet Error bit in the Descriptor indicating that this is a packet which experienced a protocol related error. The type of protocol related error is generally indicated in either the Protocol Specific bits in the Host or Monolithic descriptor or in the Protocol Specific bytes region. The packet length information and certain portions of the Protocol Specific region may not be correct for packets which encounter errors.

#### **10.1.3.24.2.3 Dropped Packets**

Packets can be dropped within an Rx Port for any number of reasons which with the exception of the starvation case which was covered above are application specific.

If a split TR mode channel receives instruction to drop a packet on the PSI-L interface, the UDMA/UTC will continue executing the TRs but without data transfer up until a TR is completed for which the EOP condition was set. Events will be generated as normal although data may not be actually transferred.

#### **10.1.3.24.2.4 Reception of EOL Delimiter**

If an end of line delimiter is received by the Rx (write) side of the UTC the `EOL_ADV` field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

#### **10.1.3.24.2.5 EOP Asserted Prematurely (Short Packet)**

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and then to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

#### **10.1.3.24.2.6 EOP Asserted Late (Long Packets)**

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

### 10.1.3.25 UTC Operation

A UTC accepts Transfer Request records from the UDMA-C and performs a sequence of transactions as specified in the TR record in accordance with the address generation algorithm that is specified in the Transfer Request format specification. The UTC will wait until an optional triggering event has occurred to load the channel state into one of its read or write engines so that the data movement operations can be completed. The UTC will complete the specified transactions until it either has transferred a pre-set number of bytes or until it has reached a point in the sequence where the TR indicates that a trigger is required to continue execution. When either of these two conditions is met, the UTC will save off the current state of the channel and will wait until the channel is re-triggered at which point the TR execution will continue. Once the entire Transfer Request specified sequence of data transfers has completed, the UTC will wait to ensure that all outstanding writes have landed at their respective destination endpoints and will then return a Transfer Response message back to the UDMA-C indicating the success or failure of the Transfer Request. The UTC processes Transfer Request operations on a given channel with strong ordering such that all Transfer Response operations will be returned in an order corresponding to the exact order that Transfer Request operations were issued.

### 10.1.3.26 UTC Receive Error/Exception Handling

Several types of errors/exceptions may be encountered during reception of data. The following table outlines the various errors and exceptions that can occur:

**Table 10-95. UTC Rx Error/Exception Handling**

Condition	Channel Type	Severity	Pauses Channel	Error Flag Set	Data Transfer	Data Flush	TR Flush	Event Output
Drop	UTC—single ended	Exception	No	No	Partial <sup>(2)</sup>	Until EOP	Until EOP <sup>(3)</sup>	Yes
	UTC- block copy	Illegal	-	-	-	-	-	-
EOL Asserted Prematurely	UTC – single ended	Exception	No	No	Normal	No	No	Yes
	UTC – block copy	Illegal	-	-	-	-	-	-
EOP Asserted Prematurely (Short Packet)	UTC – single ended	Exception	No	No	Normal	No	Until EOP <sup>(3)</sup>	Yes
EOP Asserted Late (Long Packet)	UTC – single ended	Exception	No	No	Partial	Excess	No	Yes
TR null icnt0	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No
Unsupported TR Type	All UTC	Error	Selectable <sup>(1)</sup>	Yes	No	No	Just that TR	No

(1) If pause\_on\_error bit is set in channel configuration

(2) Data will not be transferred after drop is detected. All data after that point is guaranteed to be flushed and some data prior to the exact data phase on PSI-L where drop was asserted may also be flushed since data is constantly accumulated so it can be transferred in chunks.

(3) EOP on TR is true for all PBV TRs, the final TR in a PBR, or if the user specified EOP in the TR flags

#### 10.1.3.26.1 Error Handling

If an error occurs during the processing of a Transfer Request, the UTC will discontinue any further operations on the TR and will wait for all outstanding transactions to complete. At that point, the Transfer Response record will be returned to the UDMA-C with the appropriate codes indicating the type of failure as specified in the Transfer Response Format specification.

Depending on the value of the PAUSE\_ON\_ERROR bit in the UTC configuration register, the UTC will next do one of the following:

If the PAUSE\_ON\_ERROR bit is clear the channel will move on to the next Transfer Request record that it received from the UDMA-C.

If the PAUSE\_ON\_ERROR bit is set the channel will halt from processing any new Transfer Request records in order to allow the Host to examine the current channel state in order to determine the potential cause of the failure. The UTC is required to preserve as much of the channel state as possible as soon as a failure is determined. Note that the state will not necessarily provide exact details or a 'smoking gun' as the UTC implementation allows for large scale transaction pipelining and error status returns from the bus can occur well after the machine has moved on to other channel tasks.

#### **10.1.3.26.1.1 Null Icnt0 Error**

The icnt0 parameter in a TR is never allowed to be 0 as this would cause zero byte count transactions to be issued on the bus and it unproductive towards completion of any useful work. The Rx UTC engine in the UDMA will trap any TR for which the icnt0 is zero and will immediately return a transfer response with the TR icnt0 error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.26.1.2 Unsupported TR Type**

If a TR is provided to a channel which is of a type which is not supported by the channel, the Rx UTC engine in the UDMA-P will trap that TR and immediately return a transfer response with the Unsupported TR error conditions set without performing any data transfer and without outputting any events (including end of TR event).

#### **10.1.3.26.2 Exception Conditions**

There are a few cases which can occur when processing TRs which are not considered errors but which will require handling in order to avoid locking up the UTC read or write engines. Since the UTC performs transfer sequencing using a count based mechanism it is susceptible to becoming out of synchronization if the source of the data and the destination for the data do not exactly match in their expectations for how much data will be transferred. The following outline these scenarios.

##### **10.1.3.26.2.1 Reception of EOL Delimiter**

If an end of line delimiter is received by the Rx (write) side of the UTC the EOL\_ADV field in the TR application specific flags field is used to advance the appropriate indices of the TR to the next level. Each EOL that is received will cause the TR to advance to the next specified loop iteration breaking as many intermediate loops as are required.

##### **10.1.3.26.2.2 EOP Asserted Prematurely (Short Packet)**

Split TR mode channels can experience an incoming packet whose length is shorter than what was expected based on one or more TRs which form the control description for the expected packet. If an EOP is received for a TR and the TR has not been completely executed, the port is required to receive as much data as is actually provided in the incoming data placing it in accordance with the instructions in the TR and the to continue executing any remaining TR(s) such that the required events are produced to keep downstream consumers in sync. In this case, no data will be transferred to the buffers described by the TR beyond what was provided in the incoming packet.

##### **10.1.3.26.2.3 EOP Asserted Late (Long Packets)**

Split TR mode channels can experience an incoming packet whose length is longer than what was expected based on one or more TRs which form the control description for the expected packet. If a TR completes and is marked as EOP but the incoming packet is not finished, then the port must throw away any additional received data until the incoming packet reaches an EOP condition. At this point, reception will start with a new TR and a new incoming packet.

## 10.2 Navigator Subsystem (NAVSS)

This chapter describes the features and functions of the Navigator Subsystem (NAVSS) hardware modules in the device.

The SoC device contains two NAVSSes:

- Main NAVSS (NAVSS0) – See [Section 10.2.1](#), *Main Navigator Subsystem (NAVSS)*
- MCU NAVSS (MCU\_NAVSS0) – See [Section 10.2.2](#), *MCU Navigator Subsystem (MCU NAVSS)*.

## 10.2.1 Main Navigator Subsystem (NAVSS)

This section describes the top-level integration of the main Navigator Subsystem (NAVSS) in the device.

### 10.2.1.1 NAVSS Overview

Main SoC Navigator Subsystem (NAVSS0) consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), Peripherals (Module subsystem [MODSS]), Virtualization translation (VirtSS), and a North Bridge (NBSS).

**UDMASS** – UDMASS is the essential part of the *TI Data Movement Architecture* (see [Section 10.1](#)). UDMASS consists of:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)

**MODSS** – Module subsystem is a collection of peripherals with different system-level functions, for example, interprocessor communication and time sync, among others. NAVSS0 contains the following modules:

- Mailbox – [Section 7.1](#)
- Spinlock – [Section 7.2](#)
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS) – [Section 11.1](#)
- Infrastructure components such as:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#), [Section 10.2.6](#)
  - Interrupt aggregators – [Section 10.2.7](#)
  - Interrupt router – *NAVSS Interrupt Router Configuration*

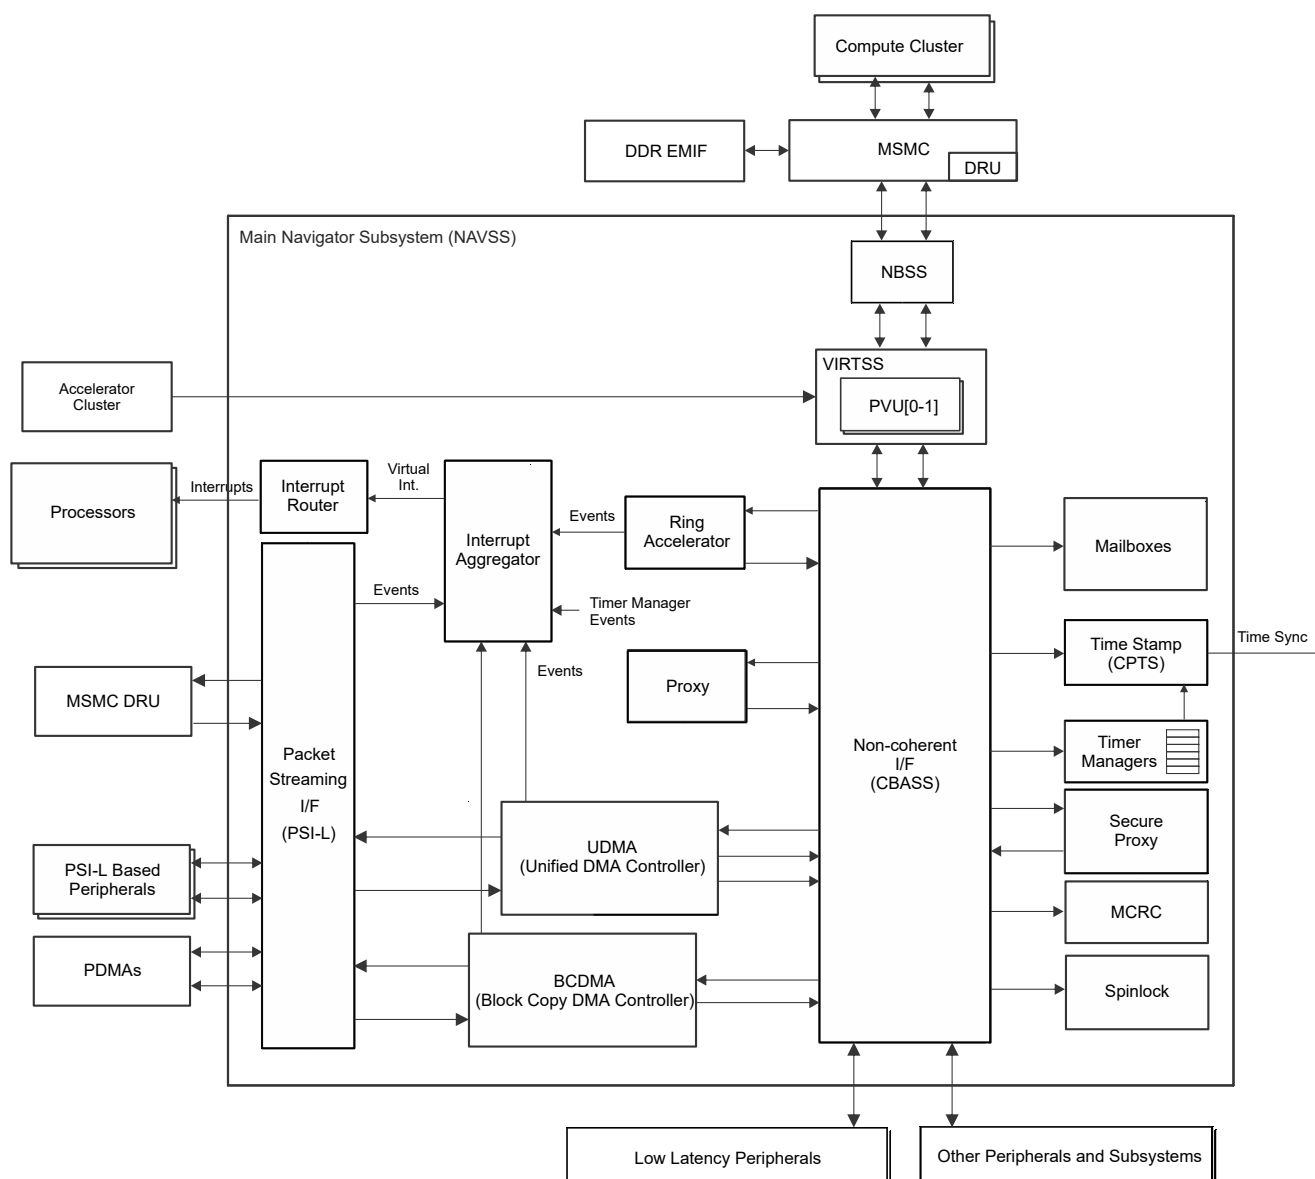

**NBSS** – North bridge – [Section 10.2.10](#)

**VirtSS** – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Page-based Address Translator (PAT) –
- Peripheral Virtualization Units (PVU) – [Section 8.3.2](#)
- Translation look-aside Buffer Unit (TBU) –
- Translation Controller Unit (TCU) –

**ECC aggregators** – [Section 12.11.4](#)

NAVSS0 hardware components and their integration are shown on [Figure 10-13](#).

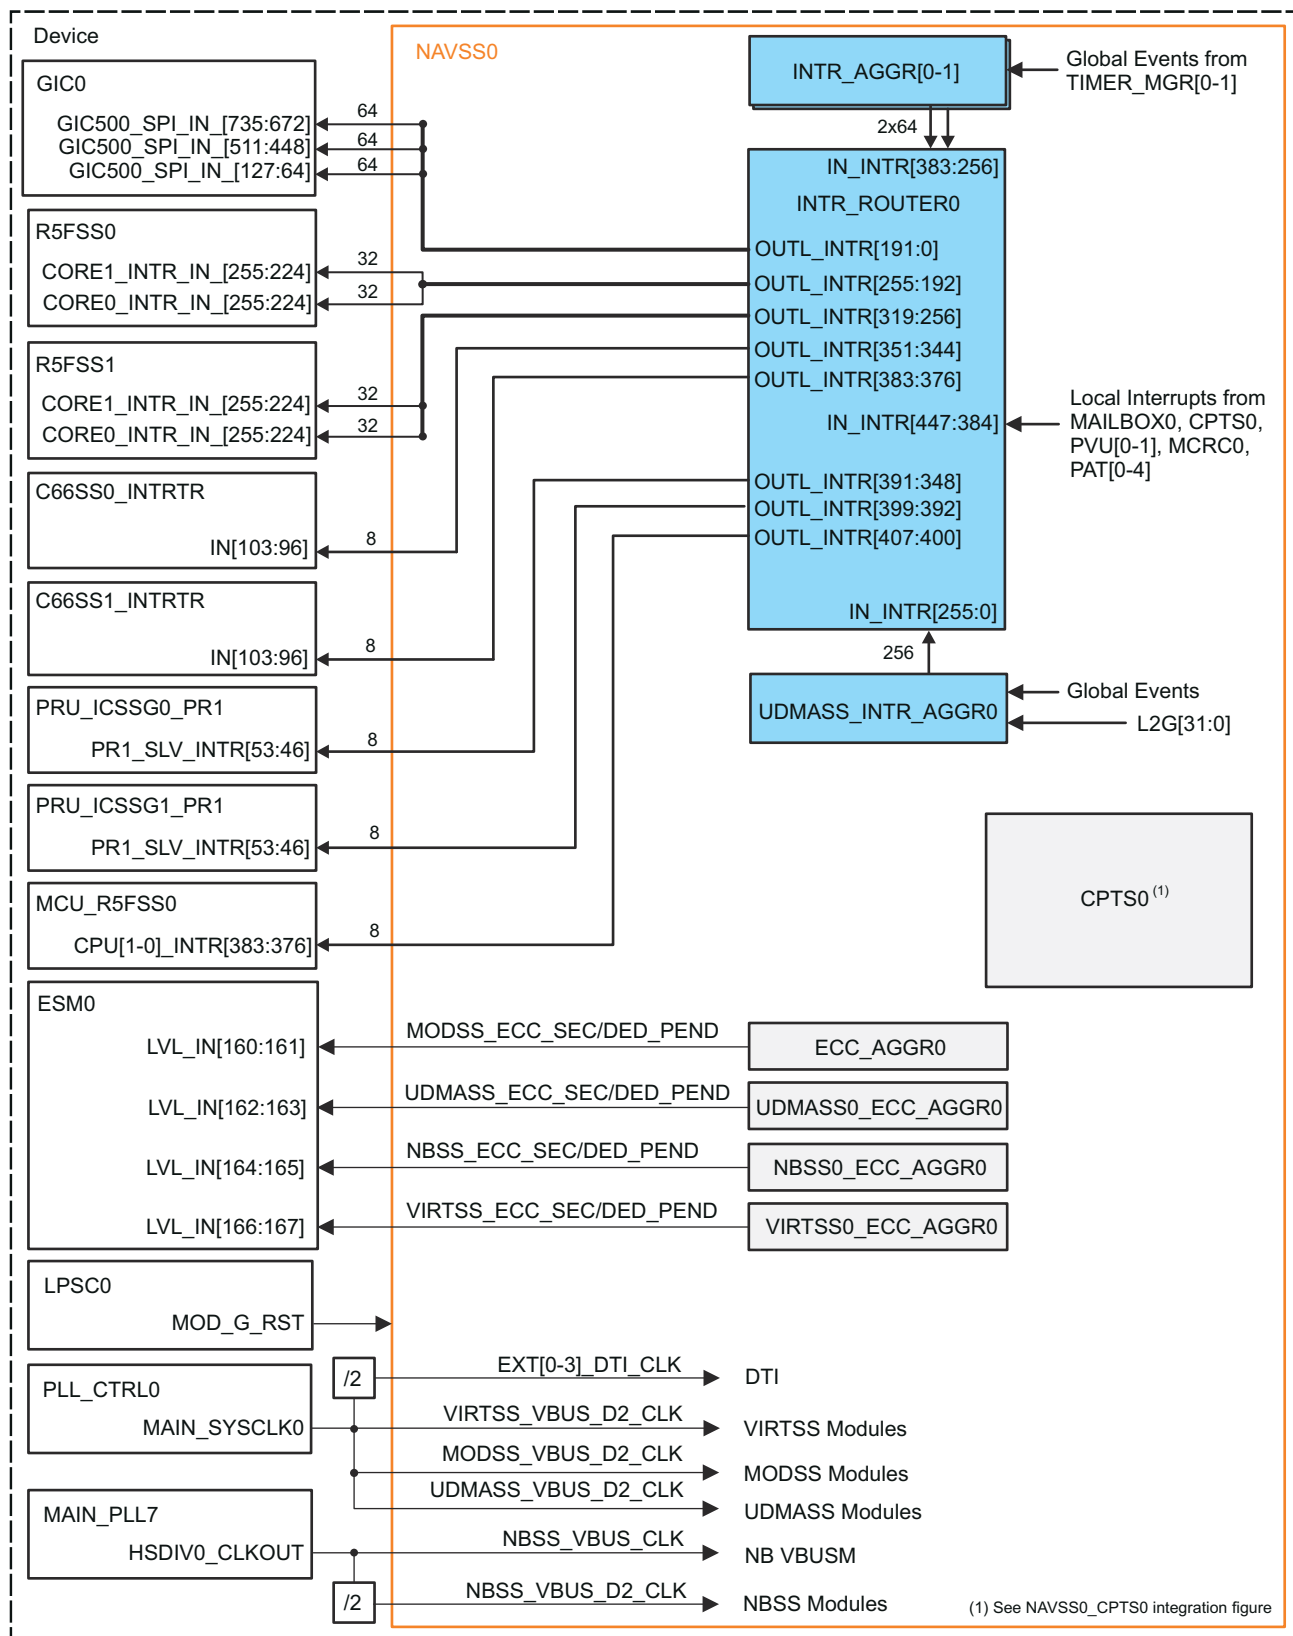

**Figure 10-13. NAVSS0 Top-Level Block Diagram**

### Note

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth.

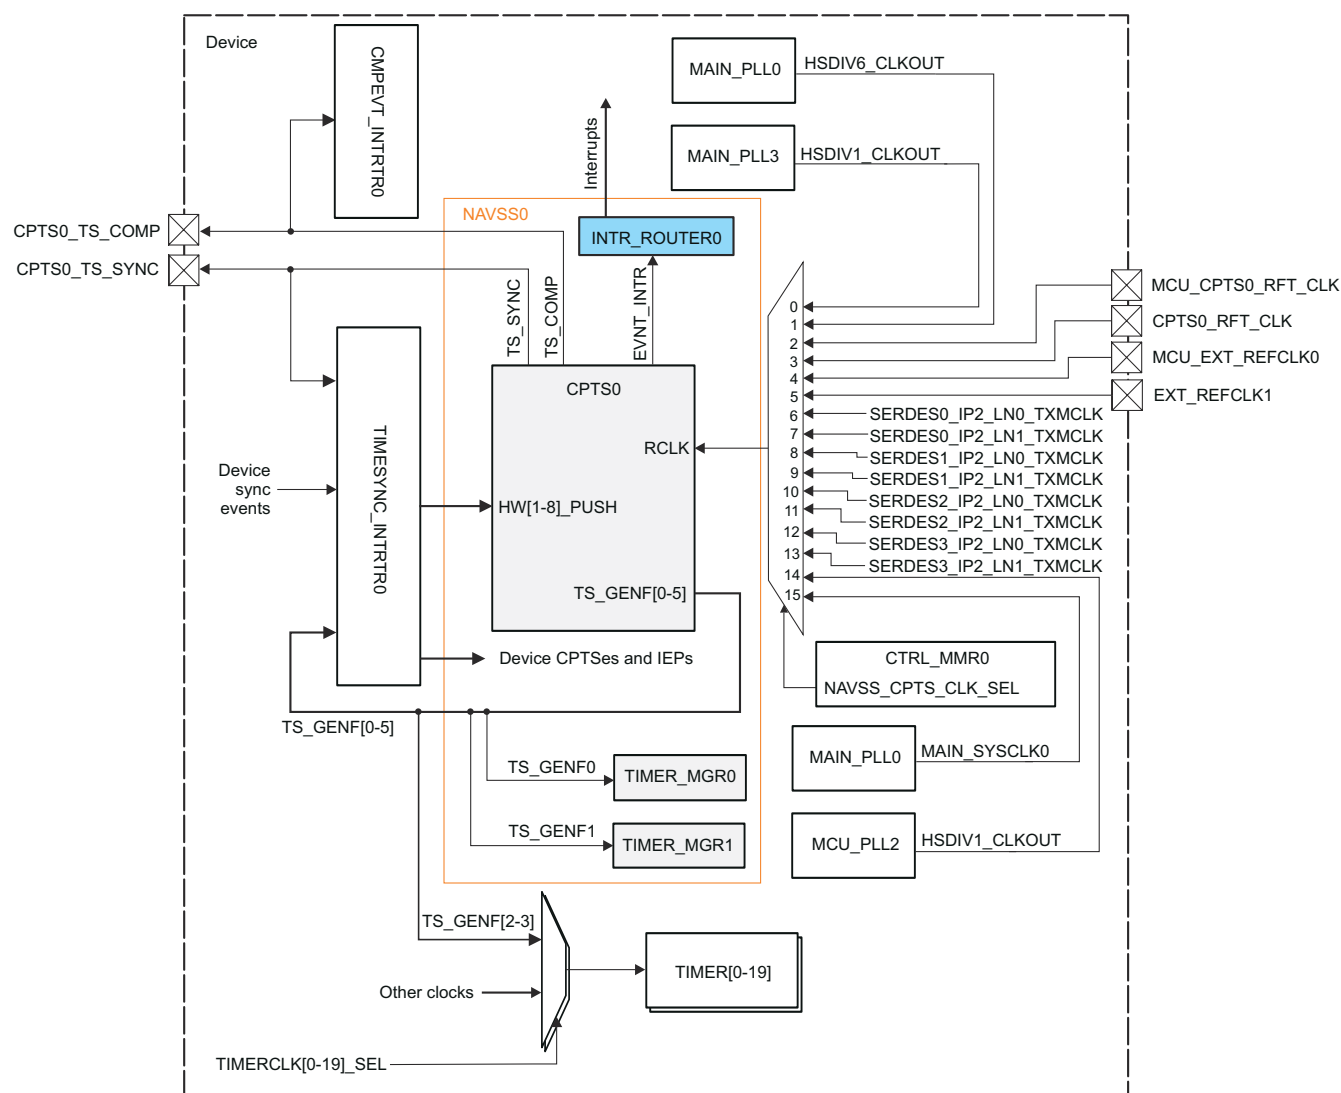

### 10.2.1.2 NAVSS Integration

Figure 10-14 to Figure 10-16 show the integration of the NAVSS0 in the device.

navss-005

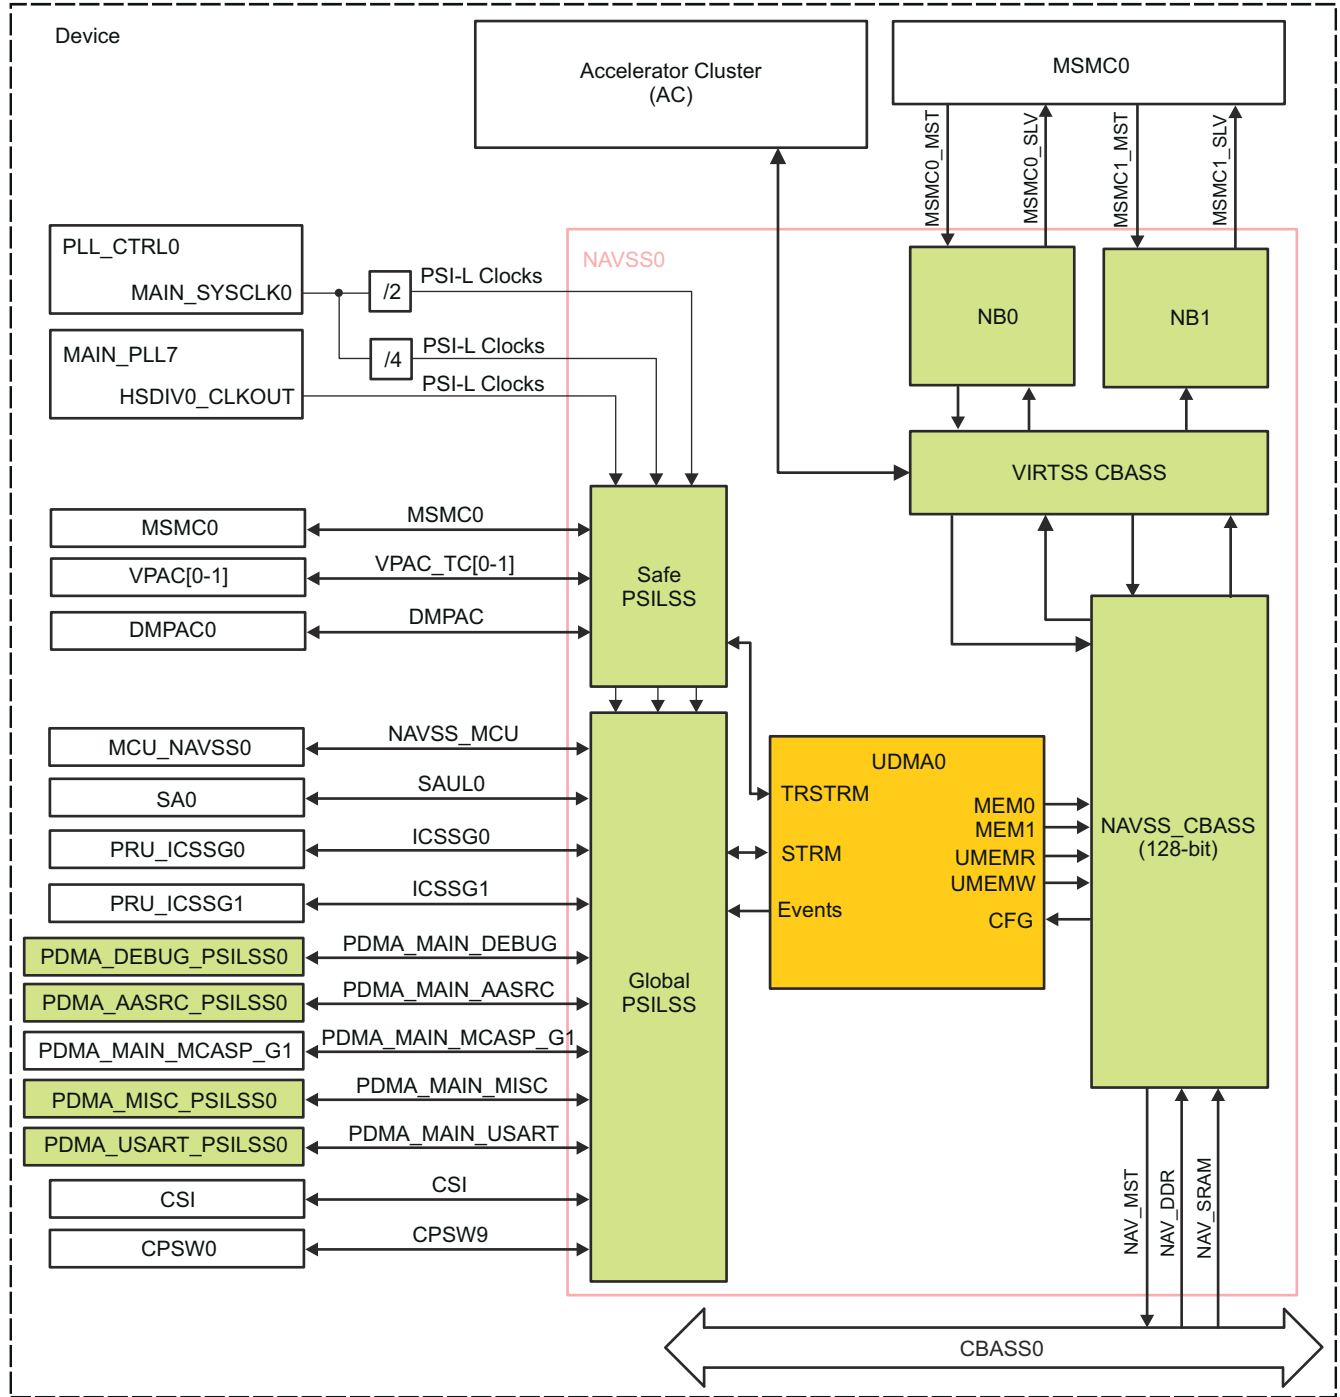

**Figure 10-14. NAVSS0 Clocks, Resets, and Interrupts**

cpts-002

navss-006

**Figure 10-16. NAVSS0 Interconnects**

Table 10-96 and Table 10-97 summarize the integration of the module in the device.

**Table 10-96. NAVSS0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

**Table 10-96. NAVSS0 Integration Attributes (continued)**

NAVSS0	PSC0	GP	LPSC0	PSI-L CBASS0 VBUSP VBUSM.C CBASS0 VBUSM
--------	------	----	-------	--

**Table 10-97. NAVSS0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
NAVSS0_MODSS	MODSS_VBUS_D2_CLK	MAIN_SYSCLK0	PLL_CTRL0	MODSS config interface clock. This clock is used for most of the NAVSS modules (MODSS).
NAVSS0_UDMASS	UDMASS_VBUS_D2_CLK	MAIN_SYSCLK0	PLL_CTRL0	UDMASS config interface clock. This clock is used for UDMASS modules.
	MSMC0_CLK	MAIN_PLL7_HSDIV0_CLKOUT	MAIN_PLL7	MSMC0 PSI-L interface clock
	PDMA_MAIN_MISC_CLK	MAIN_SYSCLK0/4	PLL_CTRL0	PDMA_MAIN_MISC PSI-L interface clock
	PDMA_MAIN_USART_CLK	MAIN_SYSCLK0/4	PLL_CTRL0	PDMA_MAIN_USART PSI-L interface clock
	PDMA_MAIN_AASRC_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	PDMA_MAIN_AASRC PSI-L interface clock
	PDMA_MAIN_DEBUG_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	PDMA_MAIN_DEBUG PSI-L interface clock
	PDMA_MAIN_MCASP_G1_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	PDMA_MAIN_MCASP_G1 PSI-L interface clock
	ICSS_G0_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	ICSS_G0 PSI-L interface clock
	ICSS_G1_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	ICSS_G1 PSI-L interface clock
NAVSS0_NBSS	NAVSS_MCU_CLK	MAIN_SYSCLK0	PLL_CTRL0	MCU_NAVSS PSI-L interface clock
	NBSS_VBUS_D2_CLK	MAIN_PLL7_HSDIV0_CLKOUT/2	MAIN_PLL7	NBSS config interface clock. This clock is used for NBSS modules (NB0-1, ECC_AGGRO).
NAVSS0_VIRTSS	NBSS_VBUS_CLK	MAIN_PLL7_HSDIV0_CLKOUT	MAIN_PLL7	NBSS VBUSM. This clock is used for NB0
	VIRTSS_VBUS_D2_CLK	MAIN_SYSCLK0	PLL_CTRL0	VIRTSS config interface clock.
	EXT[0-3]_DTI_CLK	MAIN_SYSCLK0/2	PLL_CTRL0	DTI clocks
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
NAVSS0_MODSS	MODSS_RST	MOD_G_RST	LPSC0	MODSS hardware reset
NAVSS0_UDMASS	UDMASS_RST	MOD_G_RST	LPSC0	UDMASS hardware reset
NAVSS0_NBSS	NBSS_RST	MOD_G_RST	LPSC0	NBSS hardware reset
NAVSS0_VIRTSS	VIRTSS_RST	MOD_G_RST	LPSC0	VIRTSS hardware reset

**Table 10-98. NAVSS0 Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
NAVSS0_MODSS and NAVSS0_UDMASS	INTR_ROUTER0_OUTL_IN TR[63:0]	GIC500_SPI_IN [127:64]	GIC0	INTR_PEND[191:0] interrupts to GIC SPI	Level
	INTR_ROUTER0_OUTL_IN TR[127:64]	GIC500_SPI_IN [511:448]			
	INTR_ROUTER0_OUTL_IN TR[191:128]	GIC500_SPI_IN [735:672]			

**Table 10-98. NAVSS0 Hardware Requests (continued)**

	INTR_ROUTER0_OUTL_IN TR[223:192]	CORE0_INTR_IN [255:224]	R5FSS0_CORE0	INTR_PEND[255:192] interrupts to main R5FSS0	Level
	INTR_ROUTER0_OUTL_IN TR[255:224]	CORE1_INTR_IN [255:224]	R5FSS0_CORE1		
	INTR_ROUTER0_OUTL_IN TR[287:256]	CORE0_INTR_IN [255:224]	R5FSS1_CORE0	INTR_PEND[319:256] interrupts to main R5FSS1	Level
	INTR_ROUTER0_OUTL_IN TR[319:288]	CORE1_INTR_IN [255:224]	R5FSS1_CORE1		
	INTR_ROUTER0_OUTL_IN TR[351:344]	C66SS0_INTRTR0_IN[103:9 6]	C66SS0_INTRTR 0	INTR_PEND[351:344] interrupts to C66SS0	Level
	INTR_ROUTER0_OUTL_IN TR[383:376]	C66SS0_INTRTR1_IN[103:9 6]	C66SS1_INTRTR 0	INTR_PEND[383:376] interrupts to C66SS1	Level
	INTR_ROUTER0_OUTL_IN TR[391:348]	PR1_SLV_INTR[53:46]	PRU_ICSSG0_PR 1	INTR_PEND[391:348] interrupts to PRU_ICSSG0 PR1	Level
	INTR_ROUTER0_OUTL_IN TR[399:392]	PR1_SLV_INTR[53:46]	PRU_ICSSG1_PR 1	INTR_PEND[399:392] interrupts to PRU_ICSSG1 PR1	Level
	INTR_ROUTER0_OUTL_IN TR[407:400]	CORE0_INTR_IN [383:376]  CORE1_INTR_IN [383:376]	MCU_R5FSS0	INTR_PEND[407:400] interrupts to MCU R5FSS0 CPU0 and CPU1	Level
	MODSS_ECC_SEC_PEND	ESM0_LVL_IN[160]	ESM0	SEC interrupt from MODSS ECC_AGGR0	Level
	MODSS_ECC_DED_PEND	ESM0_LVL_IN[161]	ESM0	DED interrupt from MODSS ECC_AGGR0	Level
	UDMASS_ECC_SEC_PEN D	ESM0_LVL_IN[162]	ESM0	SEC interrupt from UDMASS ECC_AGGR0	Level
	UDMASS_ECC_DED_PEN D	ESM0_LVL_IN[163]	ESM0	DED interrupt from UDMASS ECC_AGGR0	Level
NAVSS0_NBSS	NBSS_ECC_SEC_PEND	ESM0_LVL_IN[164]	ESM0	SEC interrupt from NBSS ECC_AGGR0	Level
	NBSS_ECC_DED_PEND	ESM0_LVL_IN[165]	ESM0	DED interrupt from NBSS ECC_AGGR0	Level
NAVSS0_VIRTSS	VIRTSS_ECC_SEC_PEND	ESM0_LVL_IN[166]	ESM0	SEC interrupt from VIRTSS ECC_AGGR0	Level
	VIRTSS_ECC_DED_PEND	ESM0_LVL_IN[167]	ESM0	DED interrupt from VIRTSS ECC_AGGR0	Level

**L2G Interrupt Request Inputs**

Module Instance	Module Interrupt Signal	Source Interrupt Input	Source	Description	Type
NAVSS0_UDMAS S	L2G_EVENT_PEND[7:0]	TIMESYNC_INTRTR0_OUT L [47:40]	TIMESYNC_INTR TR0	L2G interrupts from TIMESYNC_INTRTR0	Level
	L2G_EVENT_PEND[15:8]	CMPEVT_INTRTR0_OUTP [31:24]	CMPEVT_INTRTR 0	L2G interrupts from CMPEVT_INTRTR0	Level
	L2G_EVENT_PEND[31:16]	GPIOMUX_INTRTR0_OUTP [31:16]	GPIOMUX_INTRT R0	L2G interrupts from GPIOMUX_INTRTR0	Level

**DMA Events**

Module Instance	Module DMA Event	Destination DMA Event Input	Destination	Description	Type
NAVSS0	-	-	-	No PDMA channels to external DMA engines. See global event map in <a href="#">Table 10-100</a> .	-

**Time Sync Event Inputs**

Module Instance	Module Sync Input	Sync Source Signal	Source	Description	Type
-----------------	-------------------	--------------------	--------	-------------	------

**Table 10-98. NAVSS0 Hardware Requests (continued)**

NAVSS0_CPTS0	CPTS0_HW1_PUSH	TIMESYNC_INTRTR0_OUT L_0	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 1 push input	Pulse
	CPTS0_HW2_PUSH	TIMESYNC_INTRTR0_OUT L_1	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 2 push input	Pulse
	CPTS0_HW3_PUSH	TIMESYNC_INTRTR0_OUT L_2	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 3 push input	Pulse
	CPTS0_HW4_PUSH	TIMESYNC_INTRTR0_OUT L_3	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 4 push input	Pulse
	CPTS0_HW5_PUSH	TIMESYNC_INTRTR0_OUT L_4	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 5 push input	Pulse
	CPTS0_HW6_PUSH	TIMESYNC_INTRTR0_OUT L_5	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 6 push input	Pulse
	CPTS0_HW7_PUSH	TIMESYNC_INTRTR0_OUT L_6	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 7 push input	Pulse
	CPTS0_HW8_PUSH	TIMESYNC_INTRTR0_OUT L_7	TIMESYNC_INTR TR0	CPTS Asynchronous hardware timestamp 8 push input	Pulse

**Time Sync Event Outputs**

Module Instance	Module Sync Output	Destination Sync Input	Destination	Description	Type
NAVSS0_CPTS0	CPTS0_TS_GENF0	TIMESYNC_INTRTR0_IN4	TIMESYNC_INTR TR0	CPTS Generation Function Output 0	Edge
		EON_TICK_EVT	TIMER_MGR0		
	CPTS0_TS_GENF1	TIMESYNC_INTRTR0_IN5	TIMESYNC_INTR TR0	CPTS Generation Function Output 1	Edge
		EON_TICK_EVT	TIMER_MGR1		
	CPTS0_TS_GENF2	TIMESYNC_INTRTR0_IN6	TIMESYNC_INTR TR0	CPTS Generation Function Output 2	Edge
		0xC	TIMER[0:19]_CLK MUX		
	CPTS0_TS_GENF3	TIMESYNC_INTRTR0_IN7	TIMESYNC_INTR TR0	CPTS Generation Function Output 3	Edge
		0xD	TIMER[0:19]_CLK MUX

	CPTS0_TS_GENF5	TIMESYNC_INTRTR0_IN9	TIMESYNC_INTR TR0	CPTS Generation Function Output 5	Edge
	CPTS0_TS_SYNC	TIMESYNC_INTRTR0_IN36	TIMESYNC_INTR TR0	CPTS Sync Output	Edge
		CPTS0_TS_SYNC	Pin		

**Compare Event Outputs**

Module Instance	Module Compare Output	Destination Compare Input	Destination	Description	Type
NAVSS0_CPTS0	CPTS0_TS_COMP	IN8	CMPEVT_INTRTR 0	CPTS Comparison Output	Edge
		CPTS0_TS_COMP	Pin		

#### 10.2.1.2.1 NAVSS Interrupt Router Configuration

The interrupt router is configured without an INTD (no\_intd = 1), it performs only interrupt muxing.

Table 10-99 shows the interrupt inputs listed from the higher order bits to the lower order bits.

**Table 10-99. NAVSS Interrupt Router Input Mapping**

NAVSS0_INTR_ROUTER0 Input(s)	Interrupt Mapping (MSB to LSB)
INRTR_IN[447]	PAT0_EXP_INTR
INRTR_IN[446]	PAT1_EXP_INTR
INRTR_IN[445]	PAT2_EXP_INTR
INRTR_IN[444]	PAT3_EXP_INTR
INRTR_IN[443]	PAT4_EXP_INTR
INRTR_IN[442]	IO_PVU0_EXP_INTR
INRTR_IN[441]	IO_PVU1_EXP_INTR
INRTR_IN[440]	DMA_PVU1_EXP_INTR

- (1) SEVI – Mappable source input
- (2) MEVI – Multicast event input
- (3) GEVI – Global counting event input
- (4) LEVI – Local event input

### 10.2.1.2.3 PSI-L System Thread Map (All NAVSS)

Endpoints in MCU\_NAVSS0 can be paired with NAVSS0 and vice versa as shown in [Table 10-101](#) (source/destination pairs). The configuration proxy in each subsystem can configure any endpoint in the map on either subsystem without restriction.

**Table 10-101. System Thread Map for All PSI-L Threads**

Thread Number	NAVSS Instance	Endpoint
0x0000	NAVSS0	Configuration Proxy
0x0001	MCU_NAVSS0	Configuration Proxy
0x0002-0x0007	-	Reserved
0x0008	NAVSS0	UDMAP0 TRSTRM
0x0009-0x001F	NAVSS0	Reserved for future UDMA TRSTRM instances
0x0020	NAVSS0	UDMAP0 CFGSTRM
0x0021-0x003F	-	Reserved for future UDMA CFGSTRM instances
0x0040-0x0FFF	-	Reserved
0x1000-0x3FFF	NAVSS0	UDMAP0 Threads
0x4000-0x40FF	NAVSS0	SAUL0 (SA0)
0x4100-0x41FF	NAVSS0	PRU_ICSSG0
0x4200-0x42FF	NAVSS0	PRU_ICSSG1
0x4300-0x43FF	NAVSS0	MAIN_PDMA_DEBUG (to PDMA_DEBUG_PSILSS0)
0x4400-0x44FF	NAVSS0	MAIN_PDMA_AASRC (to PDMA_AASRC_PSILSS0)
0x4500-0x45FF	NAVSS0	MAIN_PDMA_MCASP_G1 (to PDMA_MAIN_MCASP_G1 directly, not through a PSILSS)
0x4600-0x46FF	NAVSS0	MAIN_PDMA_MISC (to PDMA_MISC_PSILSS0)
0x4700-0x47FF	NAVSS0	MAIN_PDMA_USART (to PDMA_USART_PSILSS0)
0x4800-0x48FF	NAVSS0	MSMC0
0x4820-0x483F	NAVSS0	VPAC TC0
0x4840-0x487F	NAVSS0	VPAC TC1
0x4880-0x48FF	NAVSS0	DMPAC
0x4900-0x49FF	NAVSS0	CSI
0x4A00-0x4AFF	NAVSS0	CPSW9 (9-port CPSW0)
0x4B00-0x5FFF	-	Reserved
0x6000-0x6FFF	MCU_NAVSS0	UDMAP0 Threads
0x7000-0x70FF	MCU_NAVSS0	CPSW0 (2-port MCU_CPSW0)
0x7100-0x71FF	MCU_NAVSS0	MCU_PDMA0
0x7200-0x72FF	MCU_NAVSS0	MCU_PDMA1
0x7300-0x73FF	MCU_NAVSS0	MCU_PDMA2
0x7400-0x74FF	MCU_NAVSS0	MCU_PDMA_ADC
0x7500-0x75FF	MCU_NAVSS0	SAUL0 (SA0)
0x7600-0x7FFF	-	Reserved

### 10.2.1.2.4 NAVSS VBUSM Route ID Table

The VBUSM Master routelds are listed in [Table 10-102](#).

**Table 10-102. VBUSM Route IDs**

VBUSM Interface	Routeld(s)	OrderId(s)
MSMC0_MST	0-127	8-15
MSMC1_MST	255	0-15
NAV_DDR0		

**Table 10-102. VBUSM Route IDs (continued)**

VBUSM Interface	RouteId(s)	OrderId(s)
NAV_DDR1		
NAV_SRAM0		
NAV_SRAM1		
PROXY0	160	0-15
SEC_PROXY0	216	0-15
RINGACC0.DST	200	0-15
UDMA0.MEM0	168	0-15
UDMA0.MEM1	169	0-15
UDMA0.UMEMW	170	0-15
UDMA0.UMEMR	171	0-15

#### 10.2.1.2.5

#### Note

For more information on the interconnects, see [Chapter 3](#), *System Interconnect*.

For more information on the power, reset, and clock management, see the corresponding sections within [Chapter 5](#), *Device Configuration*.

### 10.2.1.3 NAVSS Functional Description

See [Section 10.1](#), *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)

MODSS:

- Mailbox – [Section 7.1](#)
- Spinlock – [Section 7.2](#)
- Two Timer Managers (Timer banks) – [Section 11.2](#)
- Time Stamp Module (CPTS) – [Section 11.1](#)
- Infrastructure components:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#)
  - Interrupt aggregators – [Section 10.2.7](#)
  - Interrupt router – *NAVSS Interrupt Router Configuration*

NBSS – North bridge – [Section 10.2.10](#)

ECC aggregators – [Section 12.11.4](#)

**VirtSS** – Virtualization sub-system provides all the translation components supported in K3 for virtualization:

- Page-based Address Translator (PAT) –
- Peripheral Virtualization Units (PVU) – [Section 8.3.2](#)
- Translation look-aside Buffer Unit (TBU) –
- Translation Controller Unit (TCU) –

### 10.2.1.4 NAVSS Interrupt Configuration

This section describes the actions needed to configure interrupts within the NAVSS. The information provided is applicable to either the NAVSS or MCU\_NAVSS subsystems.

Table 10-103 are module-specific hardcoded parameters required to properly configure the NAVSS interrupt support.

**Table 10-103. NAVSS Parameters**

Parameter	Value NAVSS0	Value MCU_NAVSS0	Description
RA_RING_CNT	1024	286	Number of total rings supported
IA_SEVI	4608	1536	UDMA Interrupt Aggregator Source Event Input (SEVI) count
IA_VINTR	256	256	UDMA Interrupt Aggregator Virtual Interrupt (VINTR) count
IR_IBASE	See NAVSS Interrupt Router Input Mapping	See Interrupt Router Input Mapping	Interrupt Router input interrupt base number for given module (hardcoded values in interrupt router)
EO	See Global Event Map	See Global Event Map	Event offset (hardcoded offsets in NAVSS)

Table 10-104 lists software-configurable variables used in the examples and descriptions.

**Table 10-104. NAVSS Software Variables**

Variable	Valid Range	Description
R#	0 – RA_RING_CNT-1	Ring number
E#	0 – (destination module specific)	Event number
GE#	= EO + E#	Global event number
SB#	0 – IA_SEVI-1	Interrupt aggregator status bit number
VI#	0 – IA_VINTR-1	Virtual interrupt number
OI#	0 – 407	Interrupt router output CPU interrupt number. See NAVSS Hardware Requests

#### 10.2.1.4.1 NAVSS Event and Interrupt Flow

Figure 10-17 illustrates the event and interrupt flow within the NAVSS and output interrupts to a CPU. Information that flows between NAVSS modules is also indicated (in this case, Global Event (GE) information flows between ring accelerator and the PSILSS).

**Figure 10-17. NAVSS Interrupt Flow**

#### 10.2.1.4.1.1 NAVSS Interrupts Description

This section describes the interrupt-related information that flows within NAVSS and how this information is configured or generated.

##### 1. Ring Number (R#)

- Data is read from and written to a specific Ring Accelerator ring using direct ring-mode, proxy, or secure proxy accesses
- The Ring Accelerator has specific ring number ranges for specific purposes. The R# must match the intended purpose of the ring (see *RINGACC Ring Mapping*)

## 2. Global Event and Event Numbers (GE# and E#)

- $GE\# = EO + E\#$
- EO determines the destination module for the event. The PSILSS will route the GE# to the destination module per the NAVSS event mapping, removing EO in the process. The destination module sees only E#. See *Global event Map* for details. Examples:
  - GE# in the range 0x0000 – 0x1FFF (EO = 0x0000, E# = 0x0000 – 0x1FFF) would go to NAVSS0\_UDMASS\_INTR\_AGGR0. The INTR\_AGGR sees E#.
  - GE# in the range 0x4000 – 0x47FF (EO = 0x4000, E# = 0x0000 – 0x07FF) would go to MCU\_NAVSS0\_UDMASS\_INTR\_AGGR0. The INTR\_AGGR sees E#.
- For the INTR\_AGGR module, E# ranges from 0 to (IA\_SEVI - 1)

## 3. Virtual Interrupt (VI#)

- The INTR\_AGGR maps E# (via software configuration) to any SB#
- SB# ranges from 0 to (IA\_SEVI - 1)
- Each VI# (0 – (IA\_VINTR-1)) is driven by a group of 64 contiguous SB# numbers (VI# driven by SB#'s  $VI\# \times 64 - (VI\# \times 64) + 63$ )

## 4. Output Interrupt (OI#)

- The Interrupt Router has a hardwired set of interrupt inputs from various modules (see *NAVSS Interrupt Router Input Mapping*). Examples:
  - In the NAVSS, 256 interrupt inputs from the NAVSS0\_UDMASS\_INTR\_AGGR0 are hardwired to interrupt inputs 0 – 255. The VI# is zero-relative to this range.
  - In the MCU\_NAVSS, 4 event interrupt inputs from the MCRC0 are hardwired to interrupt inputs 256 – 259. The VI# is zero-relative to this range.
- Software configures an interrupt input (based on  $VI\# + IR\_IBASE$ ) to an OI#

### 10.2.1.4.1.2 Application Example

This section uses the following example to illustrate how to configure the NAVSS interrupt support for a specific use-case:

Using NAVSS0, use A72 MPU interrupt 7 for UDMA0 receive ring 16 (assumptions: use up/down event 10, NAVSS0\_UDMASS\_INTR\_AGGR0 for interrupt aggregation, and virtual interrupt 3).

Table 10-105 lists the modules' hardcoded parameters used for this example:

**Table 10-105. NAVSS Parameters for the Application Example**

Parameter	Value NAVSS0	From Table	Description
RA_UDMAP0_RX	300	<i>RINGACC Ring Mapping</i>	Starting ring number for UDMA0 receive channels
RA_RING_CNT	1024	<i>NAVSS0_RINGACC0 Configuration Parameters</i>	Number of total rings supported
IA_SEVI	4608	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Steerable Event Input (SEVI) count
IA_VINTR	256	<i>Interrupt Aggregators Parameters</i>	NAVSS0_UDMASS_INTR_AGGR0 Virtual Interrupt (VINTR) count
IR_IBASE	0	<i>NAVSS Interrupt Router Input Mapping</i>	Interrupt-Router-input-interrupt base for NAVSS0_UDMASS_INTR_AGGR0
EO	0	<i>Global event Map</i>	Event offset. Destination is NAVSS0_UDMASS_INTR_AGGR0
CC_IBASE	0	<i>NAVSS0 Hardware Requests</i>	Interrupt-requests-to-CC base

Table 10-106 the variables and their respective calculations for this example.

**Table 10-106. NAVSS Software Variables for the Application Example**

Variable	Calculations/Value	Description
R#	$= (RA\_UDMAP0\_RX + 16)$ $= (300 + 16)$ $= 316$	Receive ring 16 translates to ring number
E#	10	Zero-relative event number from PSILSS to NAVSS0_UDMASS_INTR_AGGR0
GE#	$= (EO + E\#)$ $= (0 + 10)$ $= 10$	Global event number (event 10 to be sent to NAVSS0_UDMASS_INTR_AGGR0)
VI#	= 3	VI# = 3 is per example assumptions. VI# could get any value 0 – IA_VINTR-1.
SB#	= 200	Must be in the range $(VI\# \times 64) - ((VI\# \times 64) + 63) = 192 - 255$ in order to drive VI# 3. We will use 200 for this example.
OI#	$= (A72\_IBASE + 7)$ $= (0 + 7)$ $= 7$	OI# = 7 is per example assumptions. OI# could get any value 0 – 119 to drive an A72 interrupt.

Table 10-107 shows software register writes that will configure the NAVSS to produce the desired interrupt per the example description.

**Table 10-107. NAVSS Register Writes for the Application Example**

Module	Register	Value to Write	Description
RINGACC0	RING[R#]_EVT (EVENT_j)	RING[316]_EVT $= GE\#$ $= 10$	Ring event number must be specified as a global event number
INTR_AGGR0	ENTRY[E#]_INTMAP (IMAP_j)	ENTRY[10]_INTMAP $= (((SB\#/64) \& 0x1FF) < 8)   (SB\ \% 64)$ $= (3 < 8)   8$ $= 0x308$	regnum = SB# / 64 bitnum = SB# % 64
INTR_AGGR0	VINT[SB#/ 64]_ENABLE_SET (ENABLE_SET_j)	VINT[3]_ENABLE_SET $= 1 < (SB\ \% 64)$ $= 1 < 8$ $= 0x100$	Enable interrupt
INTR_ROUTER0	INTERRUPT_CONTR OL[OI#] (MUXCNTL_y)	INTERRUPT_CONTROL[7] $= IR\_IBASE + VI\#$ $= 0 + 3$ $= 3$	Route interrupt

## 10.2.2 MCU Navigator Subsystem (MCU NAVSS)

This chapter describes the integration of the MCU Navigator Subsystem (MCU NAVSS) in the device and internal module parameters.

### 10.2.2.1 MCU NAVSS Overview

MCU Navigator Subsystem (MCU NAVSS) has a subset of the modules of the main NAVSS and is instantiated in the MCU domain.

MCU Navigator Subsystem consists of DMA/Queue Management components – UDMA and Ring Accelerator (UDMASS), and Peripherals (Module subsystem [MODSS]).

**UDMASS** – UDMASS is the essential part of the TI Data Movement Architecture. UDMASS consists of:

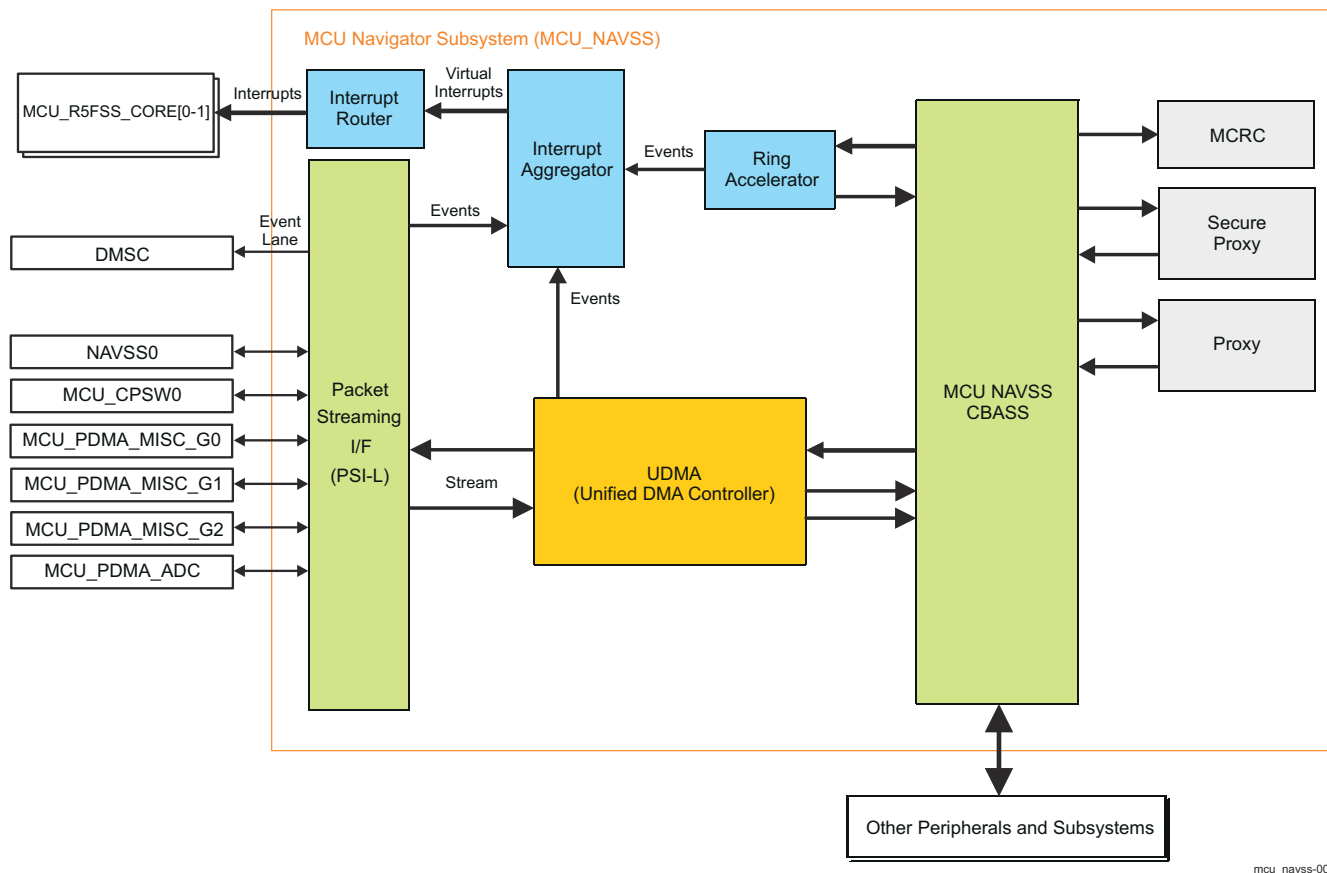

- Unified DMA Controller
- Ring Accelerator
- Packet Streaming Interface (PSILSS)

**MODSS** – MODSS is a collection of peripherals with different system-level functions. NAVSS0 contains the following modules:

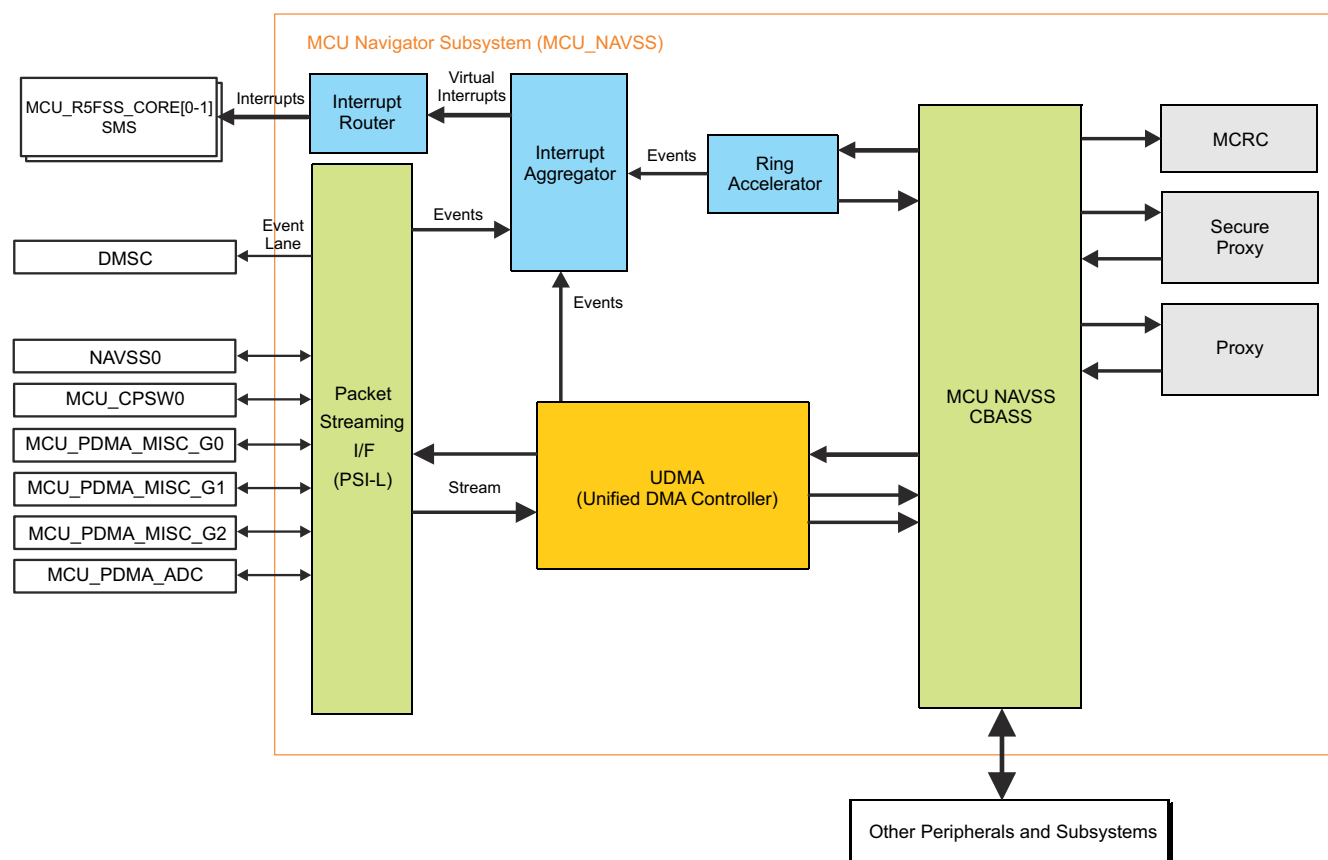

- Memory CRC module
- Infrastructure components such as CBASS, proxies, interrupt aggregators, and an interrupt router

**ECC aggregators** – for SEC/DED memory protection.

Figure 10-18 shows the MCU\_NAVSS0 top-level block diagram.

mcu\_navss-001

mcu\_navss-001

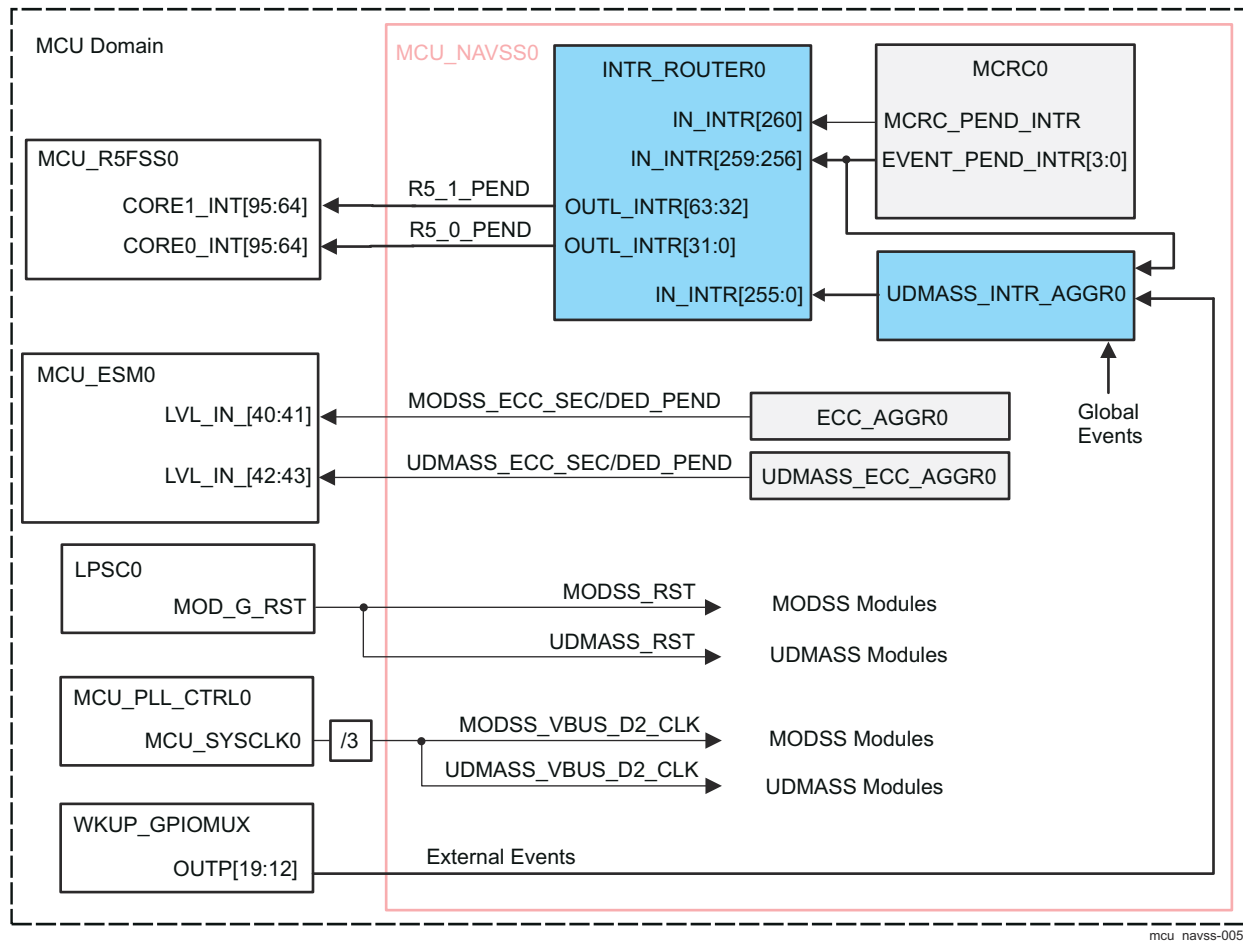

**Figure 10-18. MCU NAVSS Top-Level Block Diagram**

### Note

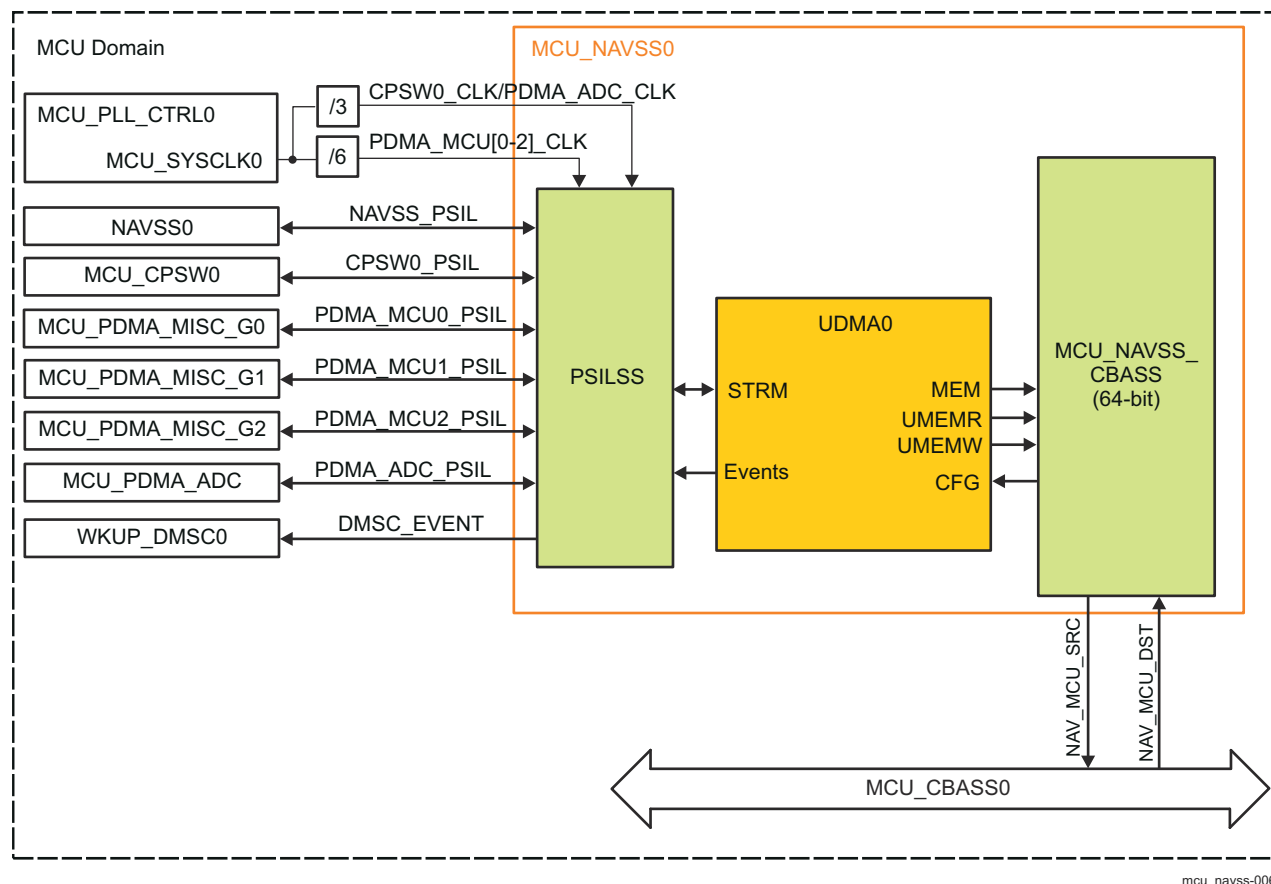

MCU NAVSS functionality is similar to that of main NAVSS, however it is composed of fewer peripherals and has reduced bandwidth. This chapter describes the integration and parameters specific for MCU NAVSS.

### 10.2.2.2 MCU NAVSS Integration

Figure 10-19 and Figure 10-20 show the top-level integration of MCU\_NAVSS0 in the device.

**Figure 10-19. MCU NAVSS Clocks, Resets, and Interrupts**

**Figure 10-20. MCU NAVSS Interconnects**

Table 10-108 and Table 10-109 summarize the integration of the module in the device.

**Table 10-108. MCU NAVSS Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_NAVSS0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0 PSI-L

**Table 10-109. MCU NAVSS Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_NAVSS0	MODSS_VBUS_D2_CLK	MCU_SYCLK0/3	MCU_PLL_CTRL0	MODSS config interface clock. This clock is used for MCU_NAVSS modules (MODSS).
	UDMASS_VBUS_D2_CLK	MCU_SYCLK0/3	MCU_PLL_CTRL0	UDMASS config interface clock. This clock is used for UDMASS modules.
	CPSW0_CLK	MCU_SYCLK0/3	MCU_PLL_CTRL0	CPSW0 PSI-L interface clock
	PDMA_MCU0_CLK	MCU_SYCLK0/6	MCU_PLL_CTRL0	PDMA_MCU0 PSI-L interface clock
	PDMA_MCU1_CLK	MCU_SYCLK0/6	MCU_PLL_CTRL0	PDMA_MCU1 PSI-L interface clock
	PDMA_MCU2_CLK	MCU_SYCLK0/6	MCU_PLL_CTRL0	PDMA_MCU2 PSI-L interface clock
	PDMA_ADC_CLK	MCU_SYCLK0/3	MCU_PLL_CTRL0	PDMA_ADC PSI-L interface clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description

**Table 10-109. MCU NAVSS Clocks and Resets (continued)**

MCU_NAVSS0_MO DSS	MODSS_RST	MOD_G_RST	WKUP_LPSC0	MODSS hardware reset
MCU_NAVSS0_UD MASS	UDMASS_RST	MOD_G_RST	WKUP_LPSC0	UDMASS hardware reset. Same as MODSS reset.

**Table 10-110. MCU NAVSS Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
MCU_NAVSS0	INTR_ROUTER0_OUTL_I NT[31:0]	CORE0_INT[95:64]	MCU_R5FSS_COR E0	Interrupts to MCU R5FSS Core 0	Level
	INTR_ROUTER0_OUTL_I NT[64:32]	CORE1_INT[95:64]	MCU_R5FSS_COR E1	Interrupts to MCU R5FSS Core 1	Level
	MODSS_ECC_SEC_PEN D	LVL_IN[40]	MCU_ESM0	SEC interrupt from MODSS ECC_AGGRO	Level
	MODSS_ECC_DED_PEN D	LVL_IN[41]	MCU_ESM0	DED interrupt from MODSS ECC_AGGRO	Level
	UDMASS_ECC_SEC_PE ND	LVL_IN[42]	MCU_ESM0	SEC interrupt from UDMASS ECC_AGGRO	Level
	UDMASS_ECC_DED_PE ND	LVL_IN[43]	MCU_ESM0	DED interrupt from UDMASS ECC_AGGRO	Level
Inbound Events					
Module Instance	DMA Event	DMA Event Input	Destination	Description	Type
MCU_NAVSS0	WKUP_GPIOMUX_OUTP[ 19:12]	L2G_EVENT_PEND 0[11:4]	MCU_INTR_AGGRO	External L2G inputs into INTR_AGGRO. 4 MCRC events + 8 external.	Level
	EVENT_PEND_INTR[3:0]	L2G_EVENT_PEND 0[3:0]			

#### 10.2.2.2.1 MCU NAVSS Interrupt Router Configuration

The interrupt router has the below interrupt inputs listed from the higher order bits to the lower order bits. The interrupt router is configured without an INTD (no\_intd = 1).

**Table 10-111. Interrupt Router Input Mapping**

MCU_NAVSS0_UDMASS_INTR_ROUTER0 Inputs	Interrupt Mapping (MSB to LSB)
INRTR_IN[260]	MCRC0_MCRC_PEND_INTR
INRTR_IN[259:256]	MCRC0_EVENT_PEND_INTR[3:0]
INRTR_IN[255:0]	UDMASS_INTA0_VINTR_PEND[255:0]

#### Note

Interrupt router outputs are described in [Table 10-110](#), first two rows.

Interrupt router registers are described in *INTR0\_INTR\_ROUTER\_CFG Registers*.

#### 10.2.2.2.2 MCU NAVSS UDMASS Interrupt Aggregator Configuration

[Table 10-112](#) shows the UDMASS Interrupt Aggregator 0 parameters set during design time.

**Table 10-112. Interrupt Aggregator Parameters**

Module Instance	Parameters				
	VINTR <sup>(1)</sup>	SEVI <sup>(2)</sup>	GEVI <sup>(3)</sup>	LEVI <sup>(4)</sup>	MEVI <sup>(5)</sup>
MCU_NAVSS0_UDMASS_INTR_AGGRO	256	1536	256	12 (4 + 8 external)	128

(1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs.

- (2) SEVI – Number of Main (Steerable) Events
- (3) GEVI – Number of Countable Global Events
- (4) LEVI – Number of Local Event inputs
- (5) MEVI – Number of Multicast Events

#### Note

4 local (LEVI) pulse interrupts are from the MCRC0 module.

If EVENT\_PEND\_INTR[3:0] needs to be converted to level interrupts, then UDMASS\_INTR\_AGGR0 can be used to generate events to the PSILSS. PSILSS would route events back to the interrupt aggregator to be turned into level output interrupts.

#### Note

For Interrupt Aggregator functional description, see [Section 10.2.7, Interrupt Aggregator](#).

### 10.2.2.2.3 MCU NAVSS UDMA Configuration

[Table 10-113](#) shows the UDMA configuration parameters set during SoC design.

**Table 10-113. UDMA Configuration Parameters**

Module Instance	Parameters <sup>(1)</sup>				
	tchan_cnt	rchan_cnt	echan_cnt <sup>(2)</sup>	hchan_cnt	rflow_cnt <sup>(3)</sup>
MCU_NAVSS0_UDMASS_UDMAP0	48	48	0	2	96

(1) Parameter values can be read from the capabilities registers. See CAP2 and CAP3 registers.

(2) External UTC channel count - specifies how many Tx channels are external UTC channels.

(3) Rx flow table entry count

#### Note

For UDMA functional description, see [Section 10.2.3, Unified DMA Controller](#).

### 10.2.2.2.4 MCU NAVSS Ring Accelerator Configuration

Each UDMA-P has an associated dedicated Ring Accelerator that is accessible by it alone (not accessible by other subsystems). The UDMA-P configuration is listed in [Table 10-114](#).

**Table 10-114. RINGACC Configuration Parameters**

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

[Table 10-115](#) shows the RINGACC ring mapping.

**Table 10-115. RINGACC Ring Mapping**

Mapping	Rings	Description
MCU_NAVSS0_UDMASS_UDMAP0 Transmit	ring[47:0]	48 UDMA0 transmit channels
MCU_NAVSS0_UDMASS_UDMAP0 Receive	ring[95:48]	48 UDMA0 receive channels
General purpose	ring[255:96]	General-purpose rings
MCU_NAVSS0_SEC_PROXY0	ring[285:256]	SEC_PROXY0 rings

#### Note

For Ring Accelerator functional description, see [Section 10.2.4, Ring Accelerator](#).

Table 10-116 shows the MSRAM configuration parameters set during SoC design. MSRAM is accessible only from the ring accelerator (DST port).

**Table 10-116. MSRAM Configuration Parameters**

Module Instance	Parameters		
	Depth	Width	Base Address
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

#### 10.2.2.2.5 MCU NAVSS Proxy Configuration

Table 10-117 shows the Proxy configuration parameters set during SoC design.

**Table 10-117. Proxy Configuration Parameters**

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Buffer Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
MCU_NAVSS0_PROXY0	64	256	MCU_NAVSS0_RIN GACC0	286	4096

- (1) Number of proxy threads supported. Can be read off from the CONFIG read-only register
- (2) Number of bytes per proxy buffer
- (3) Number of channels for the target
- (4) Number of bytes per channel supported for the target

#### Note

For Proxy functional description, see [Section 10.2.5, Proxy](#).

#### 10.2.2.2.6 MCU NAVSS Secure Proxy Configuration

Table 10-118 shows the Secure Proxy configuration parameters set during SoC design.

**Table 10-118. Secure Proxy Configuration Parameters**

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Message Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
MCU_NAVSS0_SEC_ PROXY0	90	64	MCU_NAVSS0_RING ACC0	30	4096

- (1) Number of proxy threads supported. Can be read off from the CONFIG read-only register
- (2) Number of bytes per message. Can be read off from the CONFIG read-only register
- (3) Number of channels for the target
- (4) Number of bytes per channel supported for the target

#### Note

For Secure Proxy functional description, see [Section 10.2.6, Secure Proxy](#).

#### 10.2.2.2.7 Global Event Map

The global event map for all navigator events is shown in [Table 10-100, Global Event Map](#).

#### 10.2.2.2.8 PSI-L System Thread Map (All NAVSS)

Endpoints in MCU\_NAVSS0 can be paired with NAVSS0 and visa versa as shown in [Table 10-101, System Thread Map for All PSI-L Threads](#) (source/destination pairs). The configuration proxy in each subsystem can configure any endpoint in the map on either subsystem without restriction.

#### 10.2.2.2.9 MCU NAVSS VBUSM Route ID Table

The VBUSM Master routelds are listed in [Table 10-119](#).

**Table 10-119. MCU NAVSS VBUSM Route IDs**

VBUSM Interface	RouteId(s)	OrderId(s)
MSMC0_MST	0-127	8-15
MSMC1_MST	255	0-15
NAV_MCU_DST0		
PROXY0	3616	0-15
RINGACC0.DST	3624	0-15
SEC_PROXY0	3640	0-15
UDMAP0.MEM0	3584	0-15
UDMAP0.MEM1	3585	0-15
UDMAP0.UMEMW	3586	0-15
UDMAP0.UMEMR	3587	0-15

#### 10.2.2.2.10

#### Note

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

For more information on the power, reset, and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

### 10.2.2.3 MCU NAVSS Functional Description

See *DMA Architecture*, for the *TI K3 Data Movement (DMA) Architecture* specification.

See the following sections for the respective module description:

UDMASS:

- Unified DMA Controller – [Section 10.2.3](#)
- Ring Accelerator – [Section 10.2.4](#)
- Packet Streaming Interface (PSI-L) – [Section 10.2.8](#)

MODSS:

- Infrastructure components:
  - CBASS – *System Interconnect*
  - Proxies – [Section 10.2.5](#) and [Section 10.2.6](#)
  - Interrupt aggregator – [Section 10.2.7](#)
  - Interrupt router – *MCU NAVSS Interrupt Router Configuration*

ECC aggregators – [Section 12.11.4](#)

## 10.2.3 Unified DMA Controller (UDMA)

This chapter describes the UDMA controller module, part of NAVSS.

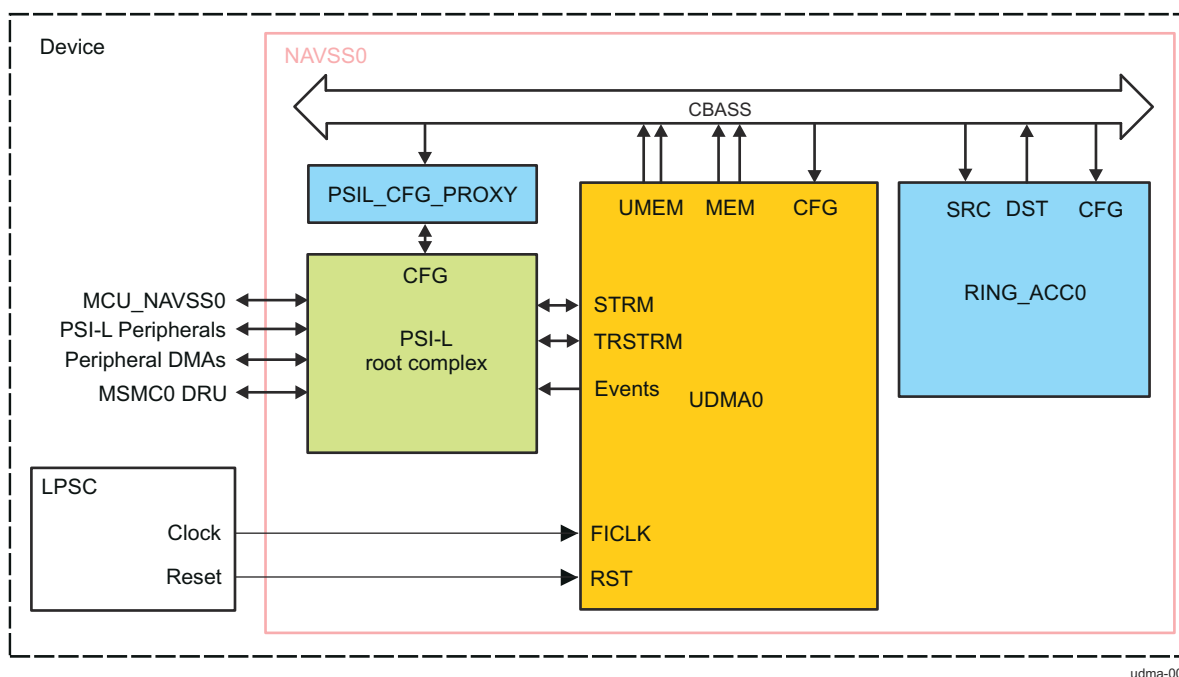

### 10.2.3.1 UDMA Overview

The UDMA-P is intended to perform similar (but significantly upgraded) functions as the packet-oriented DMA used on previous SoC devices.

**Table 10-120. UDMA Allocation Across Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_UDMAP0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMAP0	-	✓ (MCU NAVSS)	-

Figure 10-21 shows a top-level overview of the UDMA module.

**Figure 10-21. UDMA Overview**

#### 10.2.3.1.1 UDMA Features

NAVSS0\_UDMAP0 controller module supports the following modes and features:

- *TI K3 DMA Architecture* compliant Tx/Rx port implementation (see [Section 10.1, DMA Architecture](#))
- Implements *TI DMA Architecture*-compliant Packet-Oriented DMA Functionality (UDMA-P)
  - Provides internal Tx Packet Oriented DMA processing unit
  - Provides internal Rx Packet Oriented DMA processing unit
  - Supports *rflow\_cnt* unique Rx flow table entries
  - Supports 1 transmit queue per data connection
  - Supports 1 receive queue per data connection
  - Supports physical separation of buffer control and payload information
  - Supports host and monolithic descriptor formats
  - Supports unlimited buffer scatter/gather for packets using host descriptor type
  - Supports data buffer sizes up to 4 Mbytes
  - Supports variable first valid byte offset within data buffers

- Supports packet truncation on transmit
- Provides per-channel buffering:
  - Provides 16 word deep × 128-bit Packet FIFO for each Tx channel
  - Provides 4 word deep Packet Info FIFO for each Rx channel
  - Provides 8 word deep × 128-bit Packet Data FIFO for each Rx channel
  - Supports up to 32 Protocol Specific words for Tx packets
  - Supports up to 32 Protocol Specific words for Rx packets
- Implements *TI DMA Architecture* compliant Third Party Channel Controller
  - Channel controller is built as a prefetcher engine
  - Provides the same functionality as a discrete UDMA-C/UTC combination
    - Provides a fully integrated *TI DMA Architecture* Third Party DMA compliant solution
  - Can also fetch TRs and writeback TR responses for up to *echan\_cnt* external channels which are transported via the TR PSI-L interface
- Implements *TI DMA Architecture* compliant Unified Transfer Controller
  - Provides a memory read access unit
    - Supports read bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Provides a memory write access unit
    - Supports write bursts up to 128 bytes (limited by Tx Per Channel FIFO depth for the channel)
  - Supports Type 0-4, and Type 15 Transfer Request types
- Provides a set of *TI DMA Architecture* compliant Unified DMA channels which all share the execution hardware using time division multiplexing
  - Supports *tchan\_cnt* concurrent Tx channels
    - Each Tx channel can be configured at runtime to be:
      - Packet oriented Tx data channel
      - Third party combination source control and data channel (Third Party channel mode)
  - Supports *rchan\_cnt* simultaneous Rx (destination) channels
    - Each Rx channel can be configured at runtime to be:
      - Packet oriented Rx data channel
      - Third party combination destination control and data channel (Third Party channel mode)
  - Provides support for three different groups of internal channels:
    - Ultra-high capacity (UHC) channels
      - Quantity specified by: *uchan\_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - UHC channels are the first *uchan\_cnt* channels within the Tx and Rx arrays (starting with channel 0 and extending up to channel *uchan\_cnt*-1)
      - Tx and Rx UHC channels are specified as a matched pair
        - Still usable as split channels but design must have same number of Tx/Rx UHC channels
    - High-capacity (HC) channels:
      - Quantity specified by: *hchan\_cnt* - *uchan\_cnt*
      - Provide deeper Tx Per Channel FIFOs
      - Provide 16 deep descriptor/TR prefetch buffers
      - HC channels are the next *hchan\_cnt* channels (after any UHC channels) within the Tx and Rx channel arrays (starting with channel *uchan\_cnt* and extending up to *uchan\_cnt* + *hchan\_cnt*-1).
    - Normal capacity (NC) channels:
      - Quantity on Tx specified by: *tchan\_cnt* - *uchan\_cnt* - *hchan\_cnt*
      - Quantity on Rx specified by: *rchan\_cnt* - *uchan\_cnt* - *hchan\_cnt*
      - Provide standard depth Tx/Rx per channel FIFOs
      - Provide 1 deep descriptor/TR prefetch buffers

---

**Note**

User can still use ultra-high capacity and high-capacity channels as general normal-capacity channels though may not be taking advantage of the potential DMA throughput advantages.

---

- Provides per-channel buffering:
  - Provides 16 word deep data FIFO for each NC Tx (source) channel
  - Provides 8 word deep data FIFO for each NC Rx (destination) channel
- Provides single 128-bit read/write VBUSM master interface for prefetcher accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read/write VBUSM master interface for packet DMA and coherency unit accesses to RINGACC and memory.
  - Supports up to 16 outstanding reads.
  - Supports up to 16 outstanding writes.
- Provides single 128-bit read only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding reads.
- Provides single 128-bit write only VBUSM master interface for payload transfers.
  - Supports up to 16 outstanding writes.
- Provides 128-bit wide PSI-L compliant source interface for sending data to remote UTCs and remote peripherals
  - Includes 1 outgoing event transport lane
- Provides 128-bit wide PSI-L compliant destination interface for receiving data from remote UTCs and remote peripherals
  - Includes 1 incoming event transport lane
- Provides PSI-L interface for sending Transfer Requests to remote UTC channels and receiving back Transfer Responses
  - Provides 32 entry deep unified Transfer Response FIFO for external channels
- Provides 0 local event input buses

### 10.2.3.1.2 UDMA Parameters

Table 10-121 shows the UDMA configuration parameters in this SoC.

**Table 10-121. UDMA Configuration Parameters**

Module Instance	Parameters <sup>(1)</sup>					
	tchan_cnt <sup>(2)</sup>	rchan_cnt <sup>(3)</sup>	echan_cnt <sup>(4)</sup>	hchan_cnt <sup>(6)</sup>	uchan_cnt <sup>(7)</sup>	rflow_cnt <sup>(5)</sup>
NAVSS0_UDMAP0	140	140	160	16	4	300
MCU_NAVSS0_UDMAP0	48	48	0	2	0	96

(1) Parameter values can be read from the capabilities registers. See UDMA\_CAP2 and UDMA\_CAP3 registers.

(2) Total internal Tx channel count (Normal- + High- + Ultra-high capacities)

(3) Total internal Rx channel count (Normal- + High- + Ultra-high capacities)

(4) External UTC channel count

(5) Rx flow table entry count

(6) High-capacity + Ultra-high capacity channel count

(7) Ultra-high capacity channel count

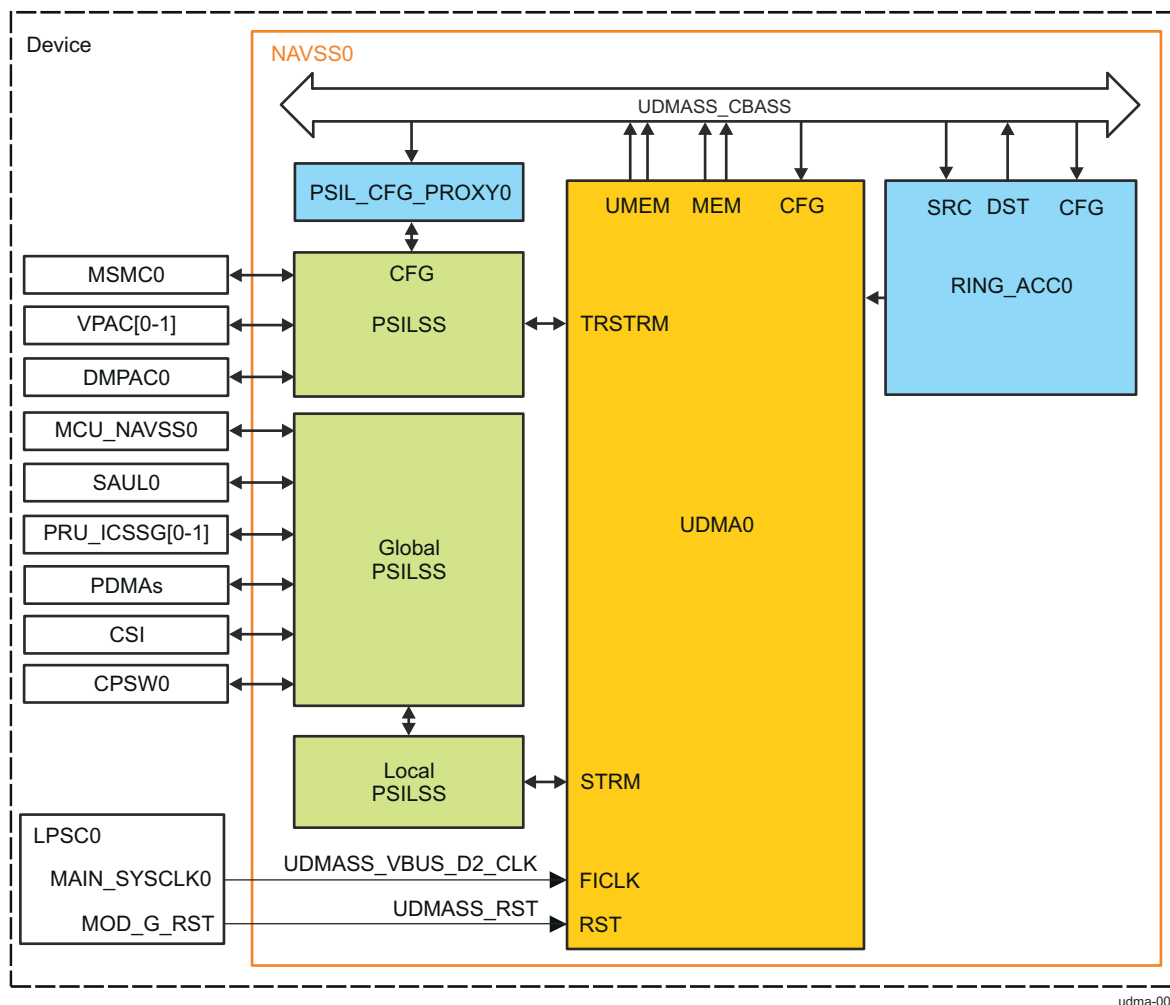

### 10.2.3.2 UDMA Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the UDMA integration in the main Navigator subsystem (NAVSS0). For MCU\_NAVSS0\_UDMA0 integration, please see *MCU Navigator Subsystem (MCU\_NAVSS)*.

Figure 10-22 shows the UDMA integration in the device.

**Figure 10-22. UDMA Integration**

Table 10-122 and Table 10-123 summarize the integration of the module in the device.

**Table 10-122. UDMA Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
NAVSS0_UDMA0	PSC0	GP	LPSC0	UDMASS_CBASS PSI-L

**Table 10-123. UDMA Clocks and Resets**

Clocks
--------

**Table 10-123. UDMA Clocks and Resets (continued)**

Module Instance	Module Clock Input	Source Clock Signal	Source	Description
NAVSS0_UDMAP0	UDMAP0_FICLK	UDMASS_VBUS_D2_CLK	MAIN_SYSCLK0	UDMA clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
NAVSS0_UDMAP0	UDMAP0_RST	UDMASS_RST	LPSC0	UDMA hardware reset

**Table 10-124. UDMA Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
NAVSS0_UDMAP0	-	-	-	The module does not generate traditional (local) interrupts	-
Outbound Events					
Module Instance	Module Event	Destination Event Number	Destination	Description	Type
NAVSS0_UDMAP0	TX Complete	Programmable	See (1)	To other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes.	ETL Push
	RX Complete	Programmable	See (1)	To other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes.	ETL Push
	Error	Programmable	See (1)		ETL Push
Inbound Events					
Module Instance	Module Event	Module Event Number	Source	Description	Type
NAVSS0_UDMAP0	TXCH0_TRG0	0	(1)	Tx Channel 0 Trigger 0 in third party mode	ETL Push
	TXCH0_TRG1	1	See (1)	Tx Channel 0 Trigger 1 in third party mode	ETL Push
	...	...	See (1)	...	ETL Push
	TXCH139_TRG0	278	See (1)	Tx Channel 139 Trigger 0 in third party mode	ETL Push
	TXCH139_TRG1	279	See (1)	Tx Channel 139 Trigger 1 in third party mode	ETL Push
	RXCH0_TRG0	280	See (1)	Rx Channel 0 Trigger 0 in third party mode	ETL Push
	RXCH0_TRG1	281	See (1)	Rx Channel 0 Trigger 1 in third party mode	ETL Push
	...	...	See (1)	...	ETL Push
	RXCH139_TRG0	558	See (1)	Rx Channel 139 Trigger 0 in third party mode	ETL Push
	RXCH139_TRG1	559	See (1)	Rx Channel 139 Trigger 1 in third party mode	ETL Push

(1) See [Section 10.2.1.2.2, Global Event Map](#).

### 10.2.3.3 UDMA Functional Description

The UDMA module supports the transmission and reception of various packet types. The UDMA is architected to facilitate the segmentation and reassembly of K3 DMA data structure compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each connected peripheral. Multiple Tx and Rx channels are provided within the DMA which allow multiple segmentation or reassembly operations to be ongoing. The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware.

An internal DMA scheduler is used to control the ordering and rate at which this multiplexing occurs for Transmit operations. The ordering and rate of Receive operations is indirectly controlled by the order in which blocks are pushed into the DMA on the Rx PSI-L interface.

The UDMA also supports acting as a Unified Channel Controller (UDMA-C)/Unified Transfer Controller (UTC) combined unit which accepts Transfer Request packets from Ring Accelerator and then performs the transfers which the Transfer Request (TR) specifies.

Channels in the UDMA can be configured to be either Packet-based or TR-based Third Party channels on a channel by channel basis.

#### 10.2.3.3.1 Block Diagram

Figure 10-23 shows UDMA main internal components.

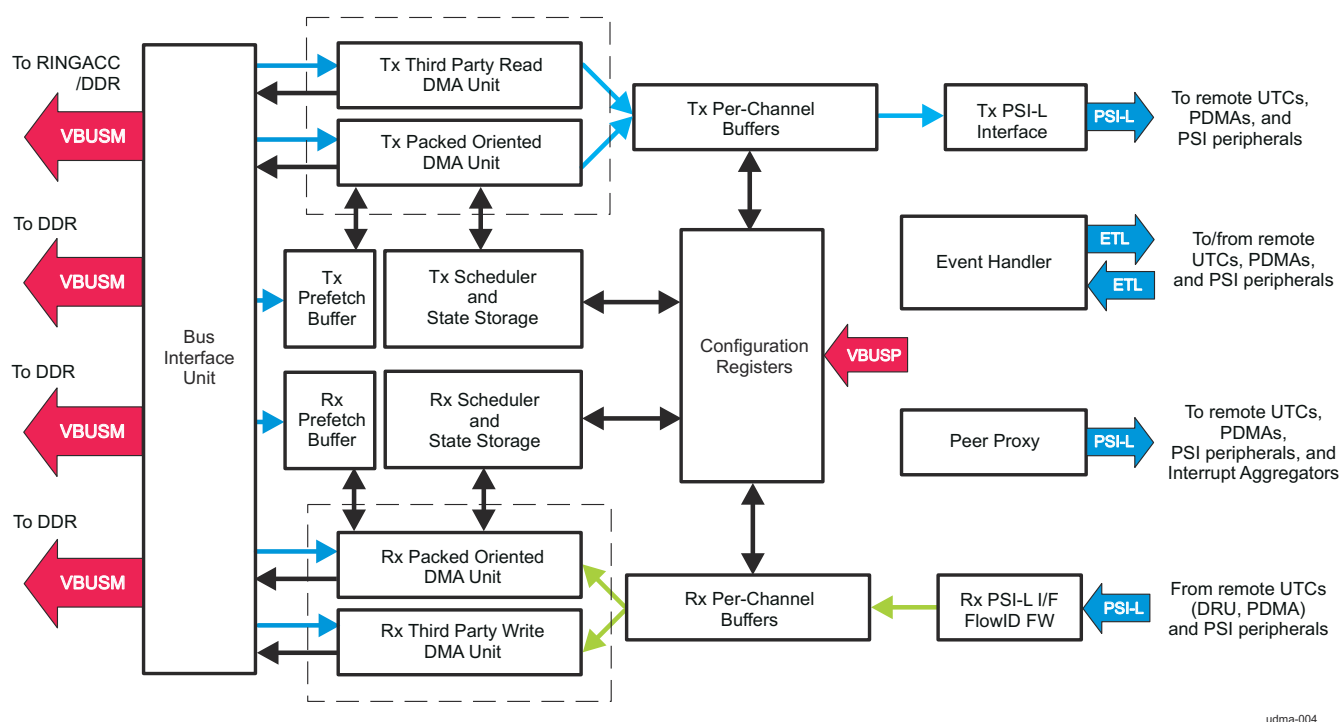

Figure 10-23. UDMA Block-Diagram

#### Bus Interface Unit

The Bus Interface Unit (BIU) is responsible for merging and buffering all of the transactions that originate from the various master blocks inside the DMA controller into the 4 separate VBUSM master interfaces. Arbitration between the blocks to a given VBUSM interface is round robin within a single priority level. A two word deep retiming buffer is provided on each sub interface of each provided VBUSM bus.

#### Tx Prefetcher Configuration Registers

The Tx Prefetcher Configuration Registers block is responsible for providing memory mapped registers for configuration of the Tx DMA function, monitoring the fullness level of the Tx prefetch buffers, maintaining Tx prefetch state information, arbitrating which channel will be allowed to perform prefetch work next, issuing scheduler commands to the Tx Prefetch Units, and writing back the updated state returned from those same prefetch units.

### **Tx Prefetch Unit(s)**

The Tx Prefetch Unit block is responsible for performing a fetch of either a Packet Descriptor (packet mode) or a TR to feed the downstream Tx DMA/Tx Read Units.

### **Tx Configuration Registers**

The Tx Configuration Registers block (*UDMASS\_UDMAP0\_CFG\_TCHAN Registers*) is responsible for monitoring the fullness level of the Tx Per Channel FIFOs, monitoring data transfer work which is pending, maintaining data movement thread state information, arbitrating which channel will be allowed to perform work next, issuing scheduler commands to the Tx Packet and TR based DMA core blocks, and writing back the updated state returned from those same DMA core blocks.

### **Tx Packet DMA Unit**

The Tx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Host and Monolithic Tx protocol. The Tx Packet DMA unit initiates VBUSM transactions in order to read and write descriptor pointers from the Ring Accelerator, read descriptors from memory, and read data from buffers in memory.

### **Tx Packet Coherency Unit**

The Tx Packet Coherency Unit is responsible for ensuring that all control structures and data have been read (and updated if applicable) by the Tx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Tx queue. This unit is only used on channels which are in Pass-By-Reference mode.

### **Tx TR Coherency Unit**

The Tx TR Coherency Unit is responsible for ensuring that all control structures and data have been read prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

### **Tx External Channel TR Coherency Unit**

The Tx External Channel TR Coherency Unit is responsible for ensuring that TRs received back from remote UTCs are written in strong order to either the Packet Descriptor or a Pass-by-Value queue in the Ring Accelerator. This unit is only used on external UTC channels.

### **Tx Event Coherency Unit**

The Tx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing Event Transport Lane (ETL). This unit is only used on channels which are in TR mode.

### **Tx Per Channel Buffers**

The Tx Per Channel Buffers implement a FIFO for each Tx DMA channel that is used for buffering packet control and payload data that has been fetched by the Tx Packet DMA units or Tx Third Party Read unit modules. The buffers are byte oriented on write so that the data from the DMA units which may not be full words can be packed properly. The buffers are block oriented on read in accordance with the transport mechanism outlined in the PSI-L Interface specification. Each Tx (source) channel in the UDMA controller maps directly onto a thread in the Tx PSI-L interface. The Tx Per Channel Buffer block outputs queue fullness information to the Tx Scheduler.

block which it then uses to determine when it must initiate DMA opportunities to backfill the buffers. The Tx Per Channel Buffer will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round robin arbitration between the different threads for the use of the Transmit PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

### **Rx FlowID Firewall**

The Rx FlowID firewall checks the incoming flowID on the received packet from the Rx PSI-L interface to verify that it is either the corresponding flowID for the channel (that is, the default flow ID for the channel which is the same as the channel number) or that the flowID falls within a programmed range that is considered legal for the channel. If the received flowID does not fall within the legal range then the packet is dropped and the error is trapped.

### **Rx Per Channel Buffers**

The Rx Per Channel Buffers implement a FIFO for each Rx DMA channel that is used for buffering packet control and payload data that has been pushed into the DMA from the Rx PSI-L interface. The Rx Per Channel Buffers also includes an arbitration unit which determines which Rx DMA channel must be serviced next

### **Rx Configuration Registers**

The Rx Configuration Registers block (*UDMASS\_UDMAP0\_CFG\_RCHAN Registers*) is responsible for providing memory mapped registers for configuration of the Rx DMA functions including the default settings for the free descriptor and destination queues. For modularity and high speed pipelining reasons, the Rx traffic is looped through the Rx Configuration Registers block where the original stream information is merged with information from the configuration registers on its way to the Rx DMA unit module. This prevents the Rx DMA Core from having to spend cycles accessing the channel configuration information for the channel.

### **Rx Packet DMA Unit**

The Rx Packet DMA Unit block implements all of the state machine functionality necessary to implement the K3 DMA Rx protocol for Host and Monolithic descriptor types. The Rx Packet DMA Unit initiates VBUSM transactions in order to read descriptor pointers from the Ring Accelerator, read buffer descriptor information, write descriptors to memory, and write data to buffers in memory.

### **Rx Packet Coherency Unit**

The Rx Packet Coherency Unit is responsible for ensuring that all control structures and data have been written by the Rx DMA unit(s) prior to returning the packet descriptor pointer to the appropriate return queue in the Ring Accelerator. This unit ensures that the ordering of the Packet Descriptor pointer writes to the return queue directly matches the ordering in which those packets were fetched from the Rx free queues. Writes are not considered complete by this unit until the entire write status has been returned for all outstanding transactions for a given packet ID. This unit is only used on channels which are in Pass By Reference mode

### **Rx TR Coherency Unit**

The Rx TR Coherency Unit is responsible for ensuring that all control structures have been read and all data has been written prior to allowing the TR response to be written to either the Packet Descriptor or a Pass by Value queue in the Ring Accelerator. This unit ensures that the ordering of TR response writes also directly matches the ordering of Transfer Requests that were processed by the channel. This unit is only used on channels which are in TR mode.

### **Rx Event Coherency Unit**

The Rx Event Coherency Unit is responsible for ensuring that all data transfers have completed before a completion event is issued through the outgoing ETL. This unit is only used on channels which are in TR mode.

### **Third Party Read Unit**

The Third Party Read Unit(s) are responsible for sequencing all of the Tx side channel control and data transfers. The Third Party Read Unit is responsible for performing the actual data read operations including sequential address generation and nested loop control. Like the Tx Packet DMA Unit, the Third Party Read Unit receives state information from the Tx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Read Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred, the transfer is completed, or the transfer has reached a point which requires an input trigger event to proceed.

### Third Party Write Unit

The Third Party Write Unit(s) are responsible for sequencing all of the Rx side channel data transfers. The Third Party Write Unit is responsible for performing the actual data write operations including sequential address generation and nested loop control. Like the Rx Packet DMA Unit, the Third Party Write Unit receives state information from the Rx Configuration Registers and returns that state when a transfer opportunity is complete. The Third Party Write Unit will perform as much data transfer as is specified in the Transfer Request up until either a fixed number of bytes have been transferred or the transfer is completed or the transfer has reached a point which requires an input trigger event to proceed.

### Event Handler

The Event Handler block is responsible for accepting and logging channel triggering events and for generating channel completion and error events.

### PSI-L Real Time Proxy

The PSI-L Real Time Proxy block is responsible for allowing tunneled VBUSP transactions to the Real Time Remote Peer registers to generate PSI-L configuration transactions to the paired remote peer for each Tx and Rx channel.

#### 10.2.3.3.2 General Functionality

This section is applicable to all UDMA modes.

##### 10.2.3.3.2.1 Operational States

At any given time the UDMA can be in one of three different states as described in [Table 10-125](#).

**Table 10-125. Operational States**

Operational State	Description
Init	This is the initial state of UDMA during and immediately after reset. During this state, all of the RAMs inside the UDMA will be initialized to known values including the ECC redundant parity bits. While in the Init state, the DMA will de-assert all ready signals on all applicable slave interfaces and will de-assert all request signals on all applicable master interfaces. The UDMA will automatically transition out of the Init state into the Idle state when all of the RAM initialization has been completed.
Idle	Once the UDMA leaves the Init state, it enters the Idle state whenever no outstanding transactions are pending on any of the UDMA interfaces (master or slave). The Idle state is generally a transient state and is used by the UDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the UDMA transitions to the Active state. When no more work is pending, or when the host pauses/disables active channels, or when the SoC power management desires to shut down the UDMA, the UDMA will account for any outstanding transactions and will re-enter the Idle state. The UDMA leaves the Idle state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
Active	The UDMA enters the Active state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent) the UDMA transitions to the Idle state.

##### 10.2.3.3.2.2 Tx Channel Allocation

In NAVSS0, a total of 140 Packet Tx channels are provided within the DMA for concurrent data transfers between memory mapped space and the Tx Per Channel Buffers. Each of these channels can be configured to operate as a packet oriented channel (uses queues/rings/descriptors/buffer) or as a Third Party DMA source

channel (uses Transfer Request packets to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to a Tx Packet DMA Unit or a Third Party Read Unit respectively.

A total of 160 external UTC channels are also provided. These channels only perform fetches and transfers of Transfer Requests to remote UTC channels and writeback of returned Transfer Responses to TR descriptors (pass by reference) or RINGACC rings (pass by value). The external channels are at channel numbers immediately above the internal channels. The Tx channels are allocated as shown in [Table 10-126](#).

**Table 10-126. Internal Tx Channel Allocation**

DMA Channel	Function	Tx Queue (Ring)
0	Tx Channel	0 (Starting queue number in RINGACC for Tx channel 0 )
...	...	...
139	Tx Channel	139

#### 10.2.3.3.2.3 Rx Channel Allocation

In NAVSS0, a total of 140 Rx channels are provided within the DMA for concurrent transfers between the Rx Per Channel Buffers and memory mapped space. Each of these channels can be configured to operate as a packet oriented channel (uses rings/descriptors/buffer) or as a Third Party DMA destination channel (uses rings/Transfer Request packets or TR standalone records to control read operations). Depending on which channel mode is selected, when a Tx channel comes into context the work for that channel will either be dispatched to an Rx Packet DMA Unit or a Third Party Write Unit respectively. The Rx channels are allocated as shown in [Table 10-127](#).

**Table 10-127. Rx Channel Allocation**

DMA Channel	Function	Src Tag
0	Rx Channel	0
...	...	...
139	Rx Channel	139

#### 10.2.3.3.2.4 Tx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates a Tx DMA channel teardown operation by writing to the TDOWN bit in the TCHANRT UDMA\_TRT\_CTL\_j register. Once a channel teardown is requested, the appropriate Tx DMA unit will complete any packet/TRs that the channel has prefetched or is currently in the process of transferring and will then clear the EN bit, will send a Teardown packet out the outbound Payload Data PSI-L interface, and will push a Teardown Completion Record onto the Tx Default Queue for the channel. If the Tx DMA engine is not currently in a packet/TR for the channel, it will immediately clear the EN, send the Teardown packet, and push the Teardown Completion Record. Once the teardown is complete, no further packet processing will occur until the host software re-enables the channel.

#### 10.2.3.3.2.5 Rx Teardown

As is specified in the *TI DMA Architecture* specification, the host initiates an optimal Rx DMA channel teardown operation by shutting down the incoming payload stream at its source (a remote peer peripheral or the Tx side of a block copy channel). Once teardown is initiated at the source, data will eventually drain from the incoming PSI-L stream and when all data is complete, the remote peer entity will send a Teardown packet (either a standalone packet or tdown asserted with eop on the last data phase of the last packet). When the UDMA receives a teardown message, the TDOWN bit will be set in RCHANRT UDMA\_RRT\_CTL\_j. In the case where a remote peer cannot generate a teardown message, the host must ensure that all data has stopped flowing from the remote peer and will then directly set the TDOWN bit. Once the UDMA sees the TDOWN asserted it will wait for any existing packets which are currently held in the Rx Per Channel FIFO to be completed and will then de-assert the EN bit in RCHANRT UDMA\_RRT\_CTL\_j. If the back end application continues to allow new

packets to be pushed into the Rx PC FIFO, the DMA will continue to delay marking the channel as torn down as long as the Rx PC FIFO never reaches an empty state

#### 10.2.3.3.2.6 Tx Clock Stop

The Tx clock stop interface allows the Tx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the `tcs_clkstop_req` input is asserted, the Tx portion of the UDMA will stop processing transmit packets/TRs for each channel at the next packet/TR boundary. Once all of the Tx channels have gracefully stopped transmission, the UDMA will assert the `tcs_clkstop_ack` output. Once the UDMA Tx engine has entered the IDLE state, it will remain there until the `tx_clockstop_req` is de-asserted.

#### 10.2.3.3.2.7 Rx Clock Stop

The Rx clock stop interface allows the Rx portion of the UDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock (FICLK) can be stopped. When the `rcs_clkstop_req` input is asserted, the Rx portion of the UDMA will stop processing receive packets for each channel at the next packet boundary. Once all of the Rx channels have gracefully stopped reception, the UDMA will assert the `rcs_clkstop_ack` output. Once the UDMA Rx engine has entered the IDLE state, it will remain there until the `rx_clockstop_req` is de-asserted.

#### 10.2.3.3.2.8 Rx Thread Enables

PSI-L threads must first be enabled in order to transfer commands or data. Threads are enabled or disabled by setting or clearing the enable bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

#### 10.2.3.3.2.9 Events

Events are used in the *TI DMA Architecture* for triggering hardware or software (by being turned into interrupts) processes. Physical (or local) events in the *TI DMA Architecture* are implemented as active-high, single-cycle, long, synchronous pulses which are strobed to communicate that a particular condition has occurred. Virtual (or global) events are implemented as a value which is passed across a shared bus (ETL) - one value per cycle. Physical (local) events can be used by the UDMA to communicate with some local peripherals. Virtual (global) events are used by the UDMA to communicate with remote peripherals, the interrupt aggregator, and other DMA instances in the system.

##### 10.2.3.3.2.9.1 Local Event Inputs

There are no local events routed to the UDMA local event inputs in the current NAVSS implementation.

##### 10.2.3.3.2.9.2 Inbound Tx PSI-L Events

The Tx PSI-L interface includes a single inbound event transport lane (ETL) which allow events to be received from other UDMA/UTC/PDMA instances for synchronization and triggering purposes. Events passed in from this event transport lane will already have been decoded as destined for some event destination index for this particular UDMA. The appropriate LSBs of each event number are extracted and the specified event is asserted.

The event map for inbound events to the UDMA is shown in [Table 10-128](#).

**Table 10-128. Inbound Event Map**

Event Number	Target
0	Tx Channel 0 Global Trigger 0
1	Tx Channel 0 Global Trigger 1
2	Tx Channel 1 Global Trigger 0
3	Tx Channel 1 Global Trigger 1
...	...
279	Tx Channel 139 Global Trigger 1
280	Rx Channel 0 Global Trigger 0
281	Rx Channel 0 Global Trigger 1

**Table 10-128. Inbound Event Map (continued)**

Event Number	Target
282	Rx Channel 1 Global Trigger 0
283	Rx Channel 1 Global Trigger 1
...	...
559	Rx Channel 139 Global Trigger 1

#### 10.2.3.3.2.9.3 Outbound Rx PSI-L Events

The Rx PSI-L interface includes a single outbound event transport lane (ETL) which allows internal events to be sent to other UDMA/UTC/PDMA instances on the device for synchronization and triggering purposes. The destination event number is programmed for each event source within the UDMA. See registers:

- TCHAN UDMA\_TOES\_j
- TCHAN UDMA\_TEOES\_j
- RCHAN UDMA\_ROES\_j
- RCHAN UDMA\_REOES\_j

#### 10.2.3.3.2.10 Emulation Control

The emulation control input and register bits (SOFT and FREE in the UDMA\_EMU\_CTRL register) allow DMA operation to be suspended. When the emulation suspend state is entered, the DMA will stop processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or transmission will be completed normally without suspension. Emulation control is implemented for compatibility with other peripherals. [Table 10-129](#) shows the operations of the emulation control input and register bits.

**Table 10-129. Emulation Behavior Control**

Emulation Control Input	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 10.2.3.3.3 Packet Oriented Transmit Operation

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interfaces onto the Transmit Packet Data PSI-L Interface. This movement of data is performed in blocks whose size is specified by the Tx DMA scheduler.

##### 10.2.3.3.3.1 Packet Mode VBUSM Master Interface Command ID Selection

The UDMA keeps a transaction command scoreboard for each specific direction for the Packet Mode VBUSM Master interface. The scoreboard tracks which command indexes are currently outstanding from the DMA on that interface. When a read or write is requested by one of the internal master agents in the UDMA, the scoreboard corresponding to the specified interface and for the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*). The index values for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

#### 10.2.3.3.4 Packet Oriented Receive Operation

Packet reception is accomplished within the UDMA by moving data from the Receive PSI-L Interface to data structures that are located in memory accessible via the VBUSM Memory Interface(s).

#### 10.2.3.3.4.1 Rx Packet Drop

The Rx PSI-L Interface master may assert the `rstrmp_drop` signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Rx Packet DMA unit will be notified that the packet is to be flushed and recycled rather than passed to the host. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops a packet on a channel configured for Packet mode there is no notification to the host.

#### 10.2.3.3.4.2 Rx Starvation and the Starvation Timer

As described in the *TI DMA Architecture* specification, whenever the Rx DMA engine needs to read a Free Descriptor Pointer from the Ring Accelerator, it is possible that the queue may be empty. When this occurs it is referred to as buffer starvation. The Ring Accelerator provides a message interface to the UDMA which provides increment and decrement information so that the UDMA can keep a local occupancy counter for each ring that it can access from the RINGACC. When the Rx engine requires a free descriptor it will first check to see if the local occupancy for that ring is non-zero. If the occupancy is zero, starvation has occurred. When starvation occurs the Rx DMA will respond in one of two ways depending on the value of the `rx_error_handling` bit in Rx Flow Table entry that is currently being used for that particular packet reception opportunity. If the `rx_error_handling` bit is 0, the Rx DMA will drop the packet and will return any descriptors which it may have previously allocated for that packet to the respective queues from which they were allocated. If the `rx_error_handling` bit is set, the Rx DMA is required to retry checking to see if a Free Descriptor is available at a later time.

A timer is provided in order to control the rate at which the retry attempts will occur. All channels share the same timer and the period of the timer is set using the `TIMEOUT_CNT` field in the `UDMA_PERF_CTRL` register. The `TIMEOUT_CNT` field specifies in clock cycles the minimum delay between subsequent attempts to check if a Free Descriptor is available on each individual channel.

*Example:* If the `TIMEOUT_CNT` is set to 256 and channel 1 finds its Free Descriptor queue empty on cycle 10, it will be required to wait until at least cycle 266 before it can make another attempt check the queue again. The actual number of cycles which will be waited by the DMA will typically be larger than the `TIMEOUT_CNT` value and this is not intended to be a highly precise operation. The critical requirement is that the DMA will not attempt to bring a channel into context to check if a buffer is available at a more frequent rate than is allowed.

#### 10.2.3.3.5 Third Party Mode Operation

##### 10.2.3.3.5.1 Events and Flow Control

The following sections describe the mechanisms that are provided for supporting flexible flow control between peripherals, the UDMA and other DMA instances.

##### 10.2.3.3.5.1.1 Channel Triggering

Channels which are configured in Third Party mode must be triggered in order for them to perform work. Triggering can be configured to be immediate, one-shot, or periodic at different levels of TR completion and is specified in the TR itself. Each channel in the UDMA is capable of being triggered by two separate events which are mapped at specific offsets in a global event target map (just like an address map for memory mapped slaves). The UDMA maps its channel triggers with Tx side channels first followed by Rx side channels as described in [Table 10-128, Inbound Event Map](#).

##### 10.2.3.3.5.1.2 Internal TR Completion Events

Each TR which is processed, provides the ability to assert 1 of 4 possible output events at specific completion levels for the TR. Since the output event is specified directly in the TR and the TRs are written by potentially untrusted software processes, channels are only able to assert *virtual events* when they complete various portions of the TR. These virtual events are then mapped to actual destination events in the global event map by the `TCHAN_UDMA_TOES_j` or `RCHAN_UDMA_ROES_j` event steering registers. These registers are programmed statically by a trusted software process that has determined the channels that should have access to the specified event destination slots.

### **10.2.3.3.5.2 Transmit Operation**

#### **10.2.3.3.5.2.1 Transfer Request**

After reset, all channels that are configured in Third Party transfer mode will be idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the host software places work in the form of either a Transfer Request Descriptor or an individual Transfer Request record onto the Tx Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

#### **10.2.3.3.5.2.2 Transfer Response**

At the completion of each set of operations which fulfill a Transfer Request record, the UDMA will return a Transfer Response record to either the original Transfer Request Descriptor or the Tx Completion Queue, depending on the mechanism which was used to provide the Transfer Request record. If the Transfer Request record originated in a Transfer Request Descriptor then a corresponding slot in the Transfer Request Descriptor will be overwritten with the response status. If the Transfer Request record originated in a pass by value Tx Ring, the Transfer Response record will be placed in a pass by value Tx Completion Ring. The Transfer Response record will only contain a completion code which indicates if the transfer was a success or if a particular type of failure occurred. The exact mechanisms which are used and the contents of the Transfer Response Record are given in the *TI DMA Architecture* specification.

#### **10.2.3.3.5.2.3 Data Transfer**

Packet transmission is accomplished within the UDMA by moving data from structures that are located in memory via the VBUSM Memory Interface(s) onto the Transmit PSI-L Interface. On the Tx side of the UDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx Per Channel Buffer for that channel. At a later time, the data is moved from the Tx Per Channel FIFO to a remote peer DMA entity via the Tx PSI-L interface.

#### **10.2.3.3.5.2.4 Memory Interface Transactions**

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Read Only VBUSM interface during transmit can be described as a sequence of piecewise linear read transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

#### **10.2.3.3.5.2.5 Error Handling**

In the case that an error occurs during any Tx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE\_ON\_ERR bit in the TCHAN UDMA\_TCFG\_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE\_ON\_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE\_ON\_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

### **10.2.3.3.5.3 Receive Operation**

#### **10.2.3.3.5.3.1 Transfer Request**

After reset, all channels that are configured in Third Party mode will be Idle and waiting for work to be assigned to them. In order to initiate Third Party channel operation, the Host places work in the form of either a Transfer

Request Descriptor or an individual Transfer Request record onto the Rx TR Queue of the channel. The exact mechanisms which are used and the contents of both the Transfer Request Descriptor and the Transfer Request record are given in the *TI DMA Architecture* specification.

#### **10.2.3.3.5.3.2 Transfer Response**

At the completion of each set of operations which fulfill a Transfer Request, the UDMA will send a Transfer Response message back to either the Packet Descriptor (pass by reference channel mode) or to the completion queue in the Ring Accelerator (pass by value channel mode). The contents of this message are described in detail in the *TI DMA Architecture*.

#### **10.2.3.3.5.3.3 Error Handling**

In the case that an error occurs during any Rx operation, the UDMA will stop processing the TR at that point and will return an appropriate error code in the Transfer Response message as specified in the *TI DMA Architecture* specification. The PAUSE\_ON\_ERR bit in the RCHAN\_UDMA\_RCFG\_j registers controls whether or not the DMA will pause operation on that channel if an error or exception occurs. If the PAUSE\_ON\_ERR bit is set to 1 the channel will be paused so that the host can optionally read the channel state to determine where in the transfer the channel execution was. If the PAUSE\_ON\_ERR bit is 0 the DMA will flush the current Transfer Request record for channels in pass by value mode and will flush the current Transfer Request Descriptor for channels in pass by reference mode.

#### **10.2.3.3.5.4 Data Transfer**

Third Party mode packet reception is accomplished within the UDMA by unpacking and moving data from the Rx Per Channel FIFOs which were filled via the Rx PSI-L Interface to specified memory mapped address ranges via the write only VBUSM master interface. On the Rx side of the UDMA, these transfers are always writes. Each write transfer which is performed by the Third Party Write Unit is to a destination address and of a size as calculated from parameters specified in the Transfer Request packet which was previously received to control the channel behavior.

##### **10.2.3.3.5.4.1 Memory Interface Transactions**

The sequence of control transactions that are performed by the UDMA on the Read/Write VBUSM interface during transmit is to read a Transfer Request record from a logical work queue and to then return a corresponding Transfer Response record to a separate logical work queue when all the transfers in the request have been completed. This sequence repeats for as long as Transfer Request records are provided on the work queue. The exact details of the operations that are involved are covered in the *TI DMA Architecture* specification (see [Section 10.1](#)).

The sequences of data transactions that are performed by the UDMA on the Write Only Memory interface during receive can be described as a sequence of piecewise linear write transfers whose starting addresses are each sequentially calculated based on loops and offsets given in the Transfer Request record. A TR can have up to 4 levels of nested transfer sets where each set can have a different element count and stride between elements. TR record formats are described in detail in the Transfer Request format specification.

##### **10.2.3.3.5.4.2 Rx Packet Drop**

The Rx PSI-L Interface master may assert the rstmr\_drop signal co-incident with the transfer of any data phase of a packet. When this signal is sampled asserted by the UDMA, the drop condition will be latched into a flag for that thread and the Third Party write unit will be notified that the packet is to be flushed and no further writes are to be performed. The drop signal is only required to be asserted with a single data phase and will only cause the current packet to be dropped from packet stream. The UDMA will drop all data given to it until the EOP is found on the thread and then the internal drop flag will be cleared. When the UDMA drops the packet on a channel that is in Third Party mode, a 'dropped by source' error code will be placed in the Transfer Response packet which is returned to the Packet Descriptor or completion queue.

## 10.2.4 Ring Accelerator (RINGACC)

This chapter describes the RINGACC module, part of the NAVSS.

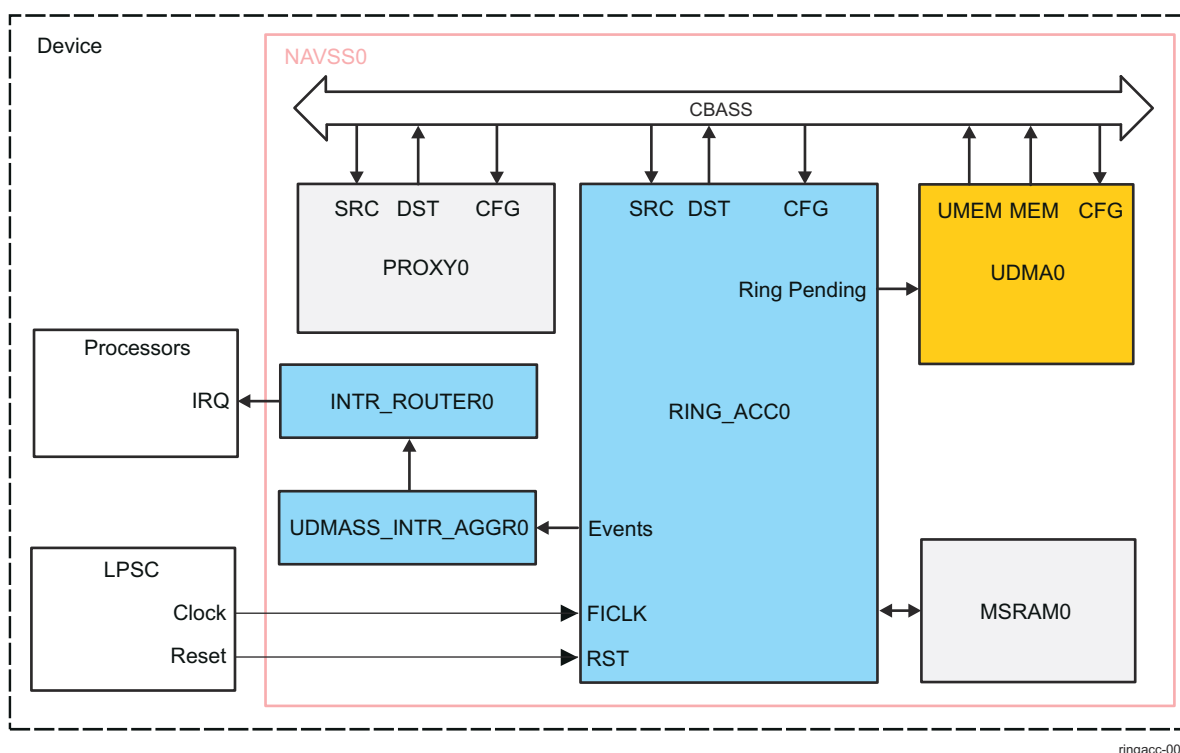

### 10.2.4.1 RINGACC Overview

The Ring Accelerator (RINGACC or RA) provides hardware acceleration to enable straightforward passing of work between a producer and a consumer. There is one RINGACC module per NAVSS.

**Table 10-130. RINGACC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_RINGACC0	-	-	✓ (NAVSS)
MCU_NAVSS0_RINGACC0	-	✓ (MCU NAVSS)	-

Figure 10-24 shows a top-level overview of the RINGACC module.

**Figure 10-24. RINGACC Overview**

#### 10.2.4.1.1 RINGACC Features

NAVSS0\_RINGACC0 supports the following features:

- Supports independent memory-mapped ring structures. See ring count in [Table 10-131, RINGACC Configuration Parameters](#).
- Supports various modes for each ring based on usage and compatibility
- Provides single-word deep shared incoming Transfer Response FIFO
- Provides bit-wide source VBUSM read/write slave interface for accesses from DMA controller entities.
  - Provides 2 word deep command FIFO
  - Provides 2 word deep write data FIFO
  - Provides 2 word deep read data FIFO
  - Provides 2 word deep write status FIFO
- Provides bit-wide destination VBUSM read/write master interface for accesses to ring structures in memory

- Supports up to 16 outstanding writes
- Supports up to 16 outstanding reads
- Source interface provides an array of 1024 × 512-byte long address windows (four for each ring) which are packed into a single contiguous address range
  - Read and write addresses which target a specific window are translated, in order to redirect the read or write transaction, to an effective address calculated from the base address for the ring plus current ring offset
  - Each read or write access presented on VBUSM slave interface is modified and bridged onto the VBUSM master interface

#### 10.2.4.1.2 RINGACC Not Supported Features

- Queue manager mode, which makes the queue act like a traditional queue-manager (QM) queue, is not supported.
- Peeks from tail

#### 10.2.4.1.3 RINGACC Parameters

Table 10-131 shows the RINGACC configuration parameters in this SoC.

**Table 10-131. RINGACC Configuration Parameters**

Module Instance	Parameters		
	Ring Count	Number of Monitors	Proxy Target Base
NAVSS0_RINGACC0	1024	32	0x000038000000
MCU_NAVSS0_UDMASS_RINGACC0	286	32	0x00002B000000

Table 10-132 shows the MSRAM configuration parameters set during SoC design. MSRAM0 is accessible only from the ring accelerator (DST port).

**Table 10-132. MSRAM Configuration Parameters**

Module Instance	Parameters		
	Depth	Width	Base Address
NAVSS0_MSRAM0	4096	128	0x000030000000
MCU_NAVSS0_UDMASS_MSRAM0	3594	64	0x000028000000
MCU_NAVSS0_UDMASS_MSRAM1	4096	64	0x000028010000

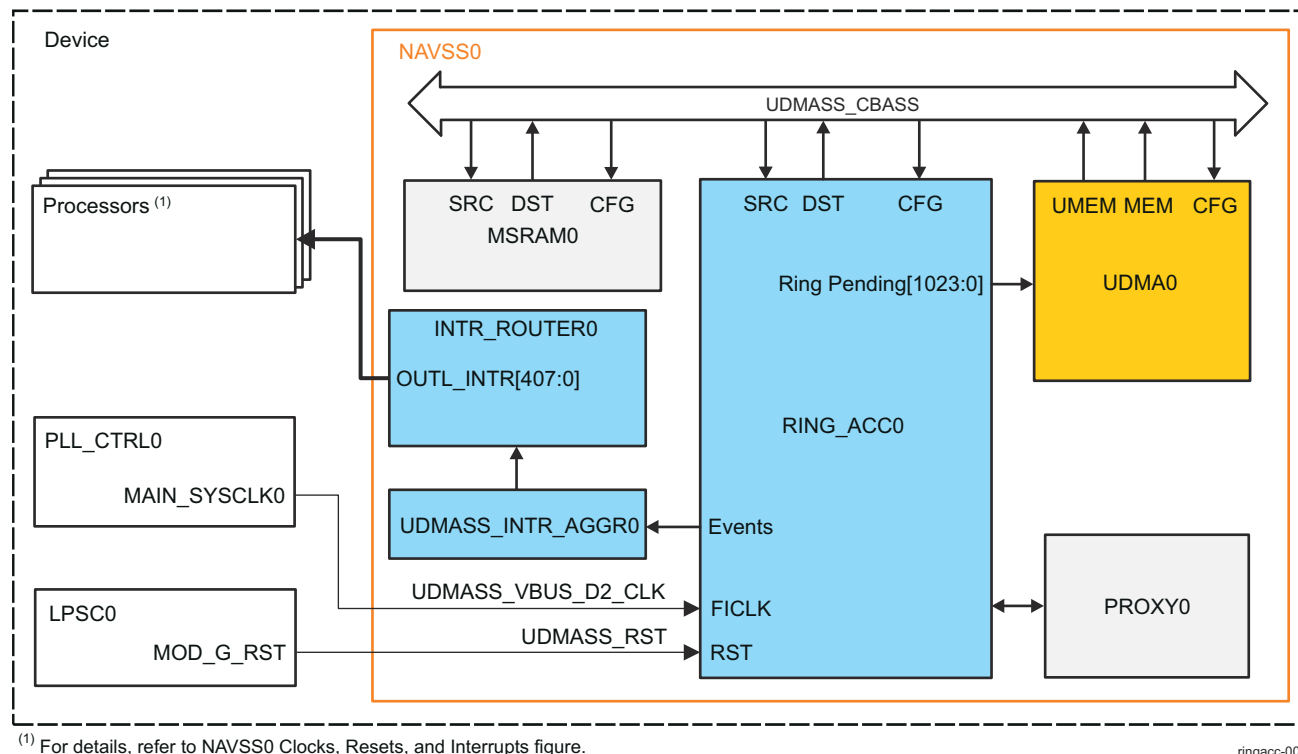

### 10.2.4.2 RINGACC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the RINGACC integration in the main Navigator subsystem (NAVSS0). For MCU\_NAVSS0\_RINGACC0 integration, please see *MCU Navigator Subsystem (MCU\_NAVSS)*.

Figure 10-25 shows the RINGACC integration in the device.

**Figure 10-25. NAVSS0\_RINGACC0 Integration**

Table 10-133 and Table 10-135 summarize the integration of the module in the device.

**Table 10-133. RINGACC Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
NAVSS0_RINGACC0	PSC0	GP	LPSC0	CBASS_NAVSS

**Table 10-134. RINGACC Ring Mapping**

Module Instance	Rings	Mapping	Description
NAVSS0_RINGACC0	ring[299:0]	UDMAP0 Transmit	300 UDMA0 transmit channels
	ring[439:300]	UDMAP0 Receive	140 UDMA0 receive channels
	ring[973:440]	General purpose	General-purpose rings
	ring[1023:974]	NAVSS0_SEC_PROXY0	SEC_PROXY0 rings

**Table 10-135. RINGACC Clocks and Resets**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
NAVSS0_RINGAC C0	-	-	-	The module does not generate traditional interrupts	-
Outbound Events					
Module Instance	Module Event	Destination Event Input	Destination	Description	Type
NAVSS0_RINGAC C0	RING[0:1023]_EVT	SEVI	UDMASS_INTR_AGGR0	Ring events. Can be used by an external host for statistics or interrupts.	ETL Push
	MON[0:31]_EVT	SEVI	UDMASS_INTR_AGGR0	Monitor events. Can be used by an external host for statistics or interrupts.	ETL Push
	RINGACC_ERROR_EVT	SEVI	UDMASS_INTR_AGGR0	Bus error event for host interrupts	ETL Push

### 10.2.4.3 RINGACC Functional Description

The Ring Accelerator (RINGACC) converts constant-address read and write accesses to equivalent read or write accesses to a circular data structure in memory. The RINGACC eliminates the need for each DMA controller which needs to access ring elements from having to know the current state of the ring (base address, current offset). The DMA controller performs a read or write access to a specific address range (which maps to the source interface on the RINGACC) and the RINGACC replaces the address for the transaction with a new address which corresponds to the head or tail element of the ring (head for reads, tail for writes). Since the RINGACC maintains the state, multiple DMA controllers or channels are allowed to coherently share the same rings as applicable. The RINGACC serves a very similar function to the Queue Manager in the earlier SoCs. The RINGACC uses less memory and is able to place data which is destined towards software into cached memory directly.

#### 10.2.4.3.1 Block Diagram

Figure 10-26 shows ring accelerator's main internal components.

**Figure 10-26. Ring Accelerator Block-Diagram**

#### 10.2.4.3.1.1 Configuration Registers

The Configuration Registers block is responsible for providing memory mapped registers for configuration of the RINGACC functions. The configuration registers are divided into:

- Static configuration fields (NAVSS0\_UDMASS\_RINGACC0\_CFG Registers), which are typically initialized and then left at specified values for long time periods (or until a reset occurs)
- Real-time (RT) registers (NAVSS0\_UDMASS\_RINGACC0\_CFG\_RT Registers), which are modified frequently during runtime.

Configuration registers are listed and described in *RINGACC Register Manual*.

#### 10.2.4.3.1.2 Source Command FIFO

The Source Command FIFO buffers VBUSM command phases which are accepted from the VBUSM source interface.

#### 10.2.4.3.1.3 Source Write Data FIFO

The Source Write Data FIFO buffers VBUSM write data phases which are accepted from the VBUSM source interface.

#### **10.2.4.3.1.4 Source Read Data FIFO**

The Source Read Data FIFO buffers VBUSM read data phases which have been returned from the VBUSM destination interface (via the main state machine) and which are to be output on the VBUSM source interface.

#### **10.2.4.3.1.5 Source Write Status FIFO**

The Source Write Status FIFO buffers VBUSM write status data phases which have been returned from the VBUSM destination interface and which are to be output on the VBUSM source interface.

#### **10.2.4.3.1.6 Main State Machine**

The Main State Machine (MSM) block implements all of the control logic which is necessary to accept a command from the source interface, perform a lookup into the ring state RAM, determine the effective address for the destination interface transaction, modify the address (and byte count for reads) for the transaction, and place that modified transaction into the outgoing destination FIFOs. The MSM block is also responsible for updating the ring index and occupancy values and for producing output status to indicate changes to the ring state. The MSM also modifies the ring state whenever the read data or write status for a previous ring transaction return and forwards those responses back to the originating master.

#### **10.2.4.3.1.7 Destination Command FIFO**

The Destination Command FIFO stores VBUSM transaction commands which are output from the MSM as modified versions of transactions that were popped from the Source Command FIFO. The Destination command FIFO allocates a new command ID for each read or write command that is pushed to the FIFO. Read IDs are allocated from a scoreboard maintained in the Destination Read Data FIFO. Write IDs are allocated from a scoreboard maintained in the Destination Write Status FIFO. When a new command is allocated, the Destination Command FIFO also pushes the original *cid* and *crouteid* values from the source side transaction into a scoreboard in either the Destination Read Data or Destination Write Status FIFOs depending on the applicable transaction direction. The read interface of the Destination Command FIFO directly drives commands onto the destination VBUSM command interface.

#### **10.2.4.3.1.8 Destination Write Data FIFO**

The Destination Write Data FIFO stores write data phases for write commands that are passing through the RINGACC towards memory. The write interface of the Destination Write Data FIFO is directly connected to the read interface of the Source Write Data FIFO and the read interface directly drives write data onto the destination VBUSM write data interface.

#### **10.2.4.3.1.9 Destination Read Data FIFO**

The Destination Read Data FIFO provides a read command translation scoreboard and also stores read data phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Read Data FIFO is directly connected to the destination VBUSM read data interface. As read data passes through the Destination Read Data FIFO, the *rid* and *rrouteid* are changed back to their original values using information which was stored in read command translation scoreboard.

#### **10.2.4.3.1.10 Destination Write Status FIFO**

The Destination Write Status FIFO provides a write command translation scoreboard and also stores write status phases that are passing through the RINGACC towards the originating DMA controller. The write interface of the Destination Writes Status FIFO is directly connected to the destination VBUSM write status interface. As write status words pass through the Destination Write Status FIFO, the *sid* and *srouteid* are changed back to their original values using information which was stored in the write command translation scoreboard.

### **10.2.4.3.2 RINGACC Functional Operation**

#### **10.2.4.3.2.1 Queue Modes**

Each ring or queue can be in one of four modes that determines how it must be accessed and the compatibility it has with hardware and software.

#### 10.2.4.3.2.1.1 Ring Mode

Ring mode is used when software owns one side of the ring, and hardware or another software owns the other side. This mode allows the software that owns a side of the ring to control that side including accessing the memory directly rather than going through hardware, and software updates the hardware on any changes through the Doorbell registers. These doorbell accesses indicate when software has pushed or popped entries, allowing the entity on the other side of the ring to know when there are elements ready. The ring mode has limitations that the exposed side of the ring is completely under software control, and any atomicity needed must also be performed by software, which is why the exposed side of a ring is usually owned by a single thread of software. This limitation also means that any hardware configuration that would normally access the same ring for both pushes and pops cannot use ring mode as hardware cannot access the exposed side of the ring, such as free queues that are normally read by hardware but could also be pushed by hardware on an error.

When software is popping from the ring, it must guarantee that it never pops more elements through the Doorbell register (RINGACC\_DB\_j) than what is valid in the Ring Occupancy (RINGACC\_OCC\_j) register, which holds how many elements are ready for software consumption. There could be some elements which have data written to memory but have not received status back from memory and those are not considered ready to pop yet as the ring status has not fully updated. Therefore, just reading from memory to determine the number of elements to pop is not sufficient. If software attempts to pop more than the RINGACC\_OCC\_j register value, then the occupancies could go negative resulting in missed down events and spurious interrupts. An optimization for software is to read the RINGACC\_OCC\_j register less frequently and keep a local copy which guarantees the maximum number of allowed pops. When the software copy of RINGACC\_OCC\_j reaches 0, or periodically, the software can read the register to refresh the value. This must reduce the frequency of register reads instead of reading the register for every software pop.

#### 10.2.4.3.2.1.2 Messaging Mode

Messaging mode requires that all accesses to the queue must go through RINGACC so that all accesses to the memory are controlled and ordered. RINGACC then controls the entire state of the queue, and software has no direct control, such as through doorbells and cannot access the storage memory directly. This is particularly useful when more than one software or hardware entity can be the producer and/or consumer at the same time. Software must access the data through bus accesses to the RINGACC. As with the earlier example, if there are free queues that need the hardware to both push and pop, then they must be configured as at least messaging mode (or a later mode) and not ring mode.

#### 10.2.4.3.2.1.3 Credentials Mode

Credentials mode adds per element credentials storage to messaging mode. This allows multiple producers with their own credentials to have those credentials stored with the element. This allows the consumer to inherit the credentials of each element rather than a single set for the entire queue, such as for DMA TR credential inheritance. This mode requires each operation to use two elements of storage since the credentials are stored in the second element, so the element count must be scaled appropriately. The credentials field is located in the same location as all modes, the word just before the first word of the message.

#### 10.2.4.3.2.1.4 Queue Manager Mode

Queue manager mode makes the queue act like a traditional queue-manager (QM) queue in previous devices.

---

#### Note

Queue Manager mode is no longer supported in this device. This section was left for completeness only.

---

#### 10.2.4.3.2.1.5 Peek Support

All modes except ring mode allow the peek operations so that software can view the next element without actually popping it from the queue. This is done by reading from a different offset from the normal pop operation. All the same fields are read but the element is not actually popped off of the queue. This is useful for algorithms

that need to know about the overall queue and head element to make decisions but have not yet decided to pop from the queue.

#### 10.2.4.3.2.1.6 Index Register Operation

In ring mode, the Index (RINGACC\_IND<sub>X</sub>\_j) register follows the software control of the ring through the doorbell registers, while the hardware index (RINGACC\_HWIND<sub>X</sub>\_j) register follows the hardware access of the ring through bus transactions. It works for a ring in either direction as the doorbell register update indicates whether elements were produced or consumed. But in the other queue modes, there is no simple manner to determine which index is for software or hardware since they both use bus transactions which the module cannot differentiate. So for these other queue modes, the index register is always the read index, and the hardware index register is the write index.

#### 10.2.4.3.2.2 VBUSM Slave Ring Operations

Each ring contains four memory spaces on the VBUSM slave bus for access, each of which is 512 bytes long, with a total of 4 kB per ring. Each ring space starts immediately after the preceding ring. The allocation per ring is as in [Table 10-137](#).

**Table 10-137. Ring Memory Partition**

Offset	Operation	Supported Ring Modes
0x0 - 0x1FF	Reads pop from head. Writes push to head.	Read supported in all modes, write supported in all modes except Ring mode
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.	Write supported in all modes, read supported in all modes except Ring mode
0x400 - 0x5FF	Reads peek from head. Writes ignored.	All modes except for Ring mode.
0x600 - 0x7FF	Reserved	Peeks from tail are not supported in this device
0x800 - 0xFFF	Reserved	Reserved

Within each 512-byte (0x200) space, the message data is right justified so that the last byte is always the 511-th byte. The element size of the ring defines which words are valid. The word just before the first valid message word is the credentials field. Access must not be made before the credentials register .

#### 10.2.4.3.2.3 VBUSM Master Interface Command ID Selection

The RINGACC keeps a transaction command scoreboard for reads and writes. Each scoreboard tracks which command indexes are currently outstanding from the RINGACC and which are free to use. When a read or write is requested by the Main State Machine, the scoreboard corresponding to the specified direction (read/write) is queried starting at index 0 and extending up to the maximum index for that scoreboard. The lowest index that is found and which is not currently allocated is selected and is directly used as the command ID (*cid*) for the outgoing transaction on the destination interface. 15 is the maximum index value for each scoreboard. Entries are freed for re-use in a write scoreboard when write status responses are received which account for all of the outstanding write data. Entries are freed for re-use in the read scoreboard only when all data has been returned for the read.

#### 10.2.4.3.2.4 Ring Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using *ring base + ring\_index*
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments hardware index and hardware occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *routeid*, *cid*, and *ring number* into scoreboard
7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and *ring number* from scoreboard
2. RINGACC increments software index and occupancy for ring
3. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 10.2.4.3.2.5 Ring Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using ring base + ring\_index
4. RINGACC increments hardware index and decrements hardware occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data
7. RINGACC pushes altered *address*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC increments software index and decrements software occupancy for ring
3. RINGACC pushes restored *routeid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 10.2.4.3.2.6 Host Doorbell Access

The following sequence will occur for each VBUSP write to the doorbell register (RINGACC\_DB\_j) for a ring:

1. RINGACC extracts ring number from config address
2. RINGACC looks up ring state using ring number
3. RINGACC adds doorbell ring value to both hardware and software occupancies for ring
4. RINGACC re-evaluates pending bit for ring

#### 10.2.4.3.2.7 Queue Push Operation (VBUSM Write to Source Interface)

The following sequence will occur for each VBUSM write which is sent to the source interface:

1. RINGACC extracts ring number from incoming write transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective write address using ring base + ring\_index
4. RINGACC re-evaluates pending bit for ring
5. RINGACC increments WR index and RD- and WR-occupancy for ring
6. RINGACC allocates *cid* from scoreboard and places original *crouteid*, *cid*, and ring number into scoreboard
7. RINGACC pushes altered *address*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when write status returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *srouteid*, *sid*, and unaltered write status to output write status FIFO

#### 10.2.4.3.2.8 Queue Pop Operation (VBUSM Read from Source Interface)

The following sequence will occur for each VBUSM read which is sent to the source interface:

1. RINGACC extracts ring number from incoming read transaction address
2. RINGACC looks up ring state using ring number
3. RINGACC calculates effective read address using *ring base + ring\_index*
4. RINGACC increments RD index and decrements RD- and WR-occupancy for ring
5. RINGACC re-evaluates pending bit for ring
6. RINGACC munges *cid* to add indicator in 4 MSBs to reconstitute *routeid* for returning read data

7. RINGACC pushes altered *caddress*, *cid* and unaltered remainder of command attributes to output FIFO (note *routeid* is not included)

At a later time when read data returns:

1. RINGACC recovers original *cid*, *crouteid*, and ring number from scoreboard
2. RINGACC pushes restored *rrouteid*, *rid*, and unaltered read data, status, and other control signals to output read FIFO

#### 10.2.4.3.2.9 Mismatched Element Size Handling

When less data is written than defined by the element size for the ring for RING or MESSAGE modes, only the written data is stored in the memory and any remaining bytes maintain their old values. The index and *occ* are still incremented normally, and any special fields that are unwritten are assumed to be 0 .

Writing less data for CREDENTIALS mode is illegal, as those types need the full data to append the additional words to the correct offsets in memory.

When more data is written than defined by the element size for the ring, it will be an error and the write will be ignored and no index or *occ* increments occur. The only exception is for writes to an 8-byte element size ring, where the additional fields up to another 8 bytes are allowed but not written (for old Queue Manager compatability).

When less data is read than defined by the element size for the ring, only the read data is fetched from memory, and any remaining bytes are lost. The index and *occ* are still incremented normally.

When more data is read than defined by the element size for the ring, it will be an error and the read will not affect the ring, the read data will be 0s, and no index or *occ* decrements occur. Access beyond the credentials word must not be attempted and can result in unpredictable behavior.

All accesses must be for multiples of 32-bit words, and partial bytes are not supported for all ring modes.

#### 10.2.4.3.3 Events

The module outputs events about queue levels that can be used by an external module for statistics or interrupts.

Each queue has

- an up event when the queue goes from 0 elements to 1 or more elements
- and a down event when the queue goes from 1 or more elements to 0 elements.

The event number is programmable per queue in the RINGACC\_EVENT\_j register. This event occurs when the state machine updates the final occupancy for the queue. In ring mode this is when the response from the memory access returns, while in other queue modes this is when the operation is processed.

An event number programmed to 0xFFFF indicates to not produce an event for that ring when an event is not necessary. The register event number fields reset to 0xFFFF, so they must be programmed to a valid value before events will be generated. This applies to the monitor event number fields as well.

#### 10.2.4.3.4 Bus Error Handling

If a bus error is detected on a response to a ring memory transaction, an error event is triggered to alert software. Since the ring contents may be corrupted as the push or pop was not completed correctly, software should consider resetting the ring and any software or hardware elements using the ring. A log register (RINGACC\_ERROR\_LOG) captures the ring that had the error and whether it was from a push or pop, and an error up event is sent to the programmed event number. After an error is logged, another will not be captured until the first is read out. When read, if an error is pending an error down event is sent to clear any interrupt, and then the next bus error log can be captured. A read of the RINGACC\_ERROR\_LOG register when there is no error log pending will not produce any down events. The event that is triggered is also programmable. Only legal push and pop operations will capture this error, and not for any peek, emudbg read, flush command, or any operations that is illegal and causes the resulting memory access to be flushed.

#### 10.2.4.3.5 Monitors

Monitors can be configured that allow various functions to be tracked of programmed queues. Each monitor is programmed to monitor a particular queue, the function to provide, and the data source to operate on. The supported functions are: to check the queue against programmed thresholds, to keep track of watermarks of the queue, to keep track of starvation occurrences (a read of an empty queue), or statistics capture. The supported data sources are: the queue element count, the head element size value, or the accumulated size value. Each monitor can also be programmed to produce an event should it have a triggering condition.

##### 10.2.4.3.5.1 Threshold Monitor

A threshold monitor uses a programmed low threshold value and a programmed high threshold value to track the data source in the queue and cause an interrupt or status when a threshold is broken, either below the low value or above the high value. This is useful for software to replenish empty buffers when a queue has too few, or for a queue to accumulate enough elements so that software must start processing them, or for debug. The threshold being broken will cause the up or down event.

##### 10.2.4.3.5.2 Watermark Monitor

A watermark monitor tracks the low and high values of the data source since the last read of the monitor. After initial setup or clearing, the watermark values will load the current value of the data source as the low and high. Then for successive operations if the resulting data source of the queue is below the low watermark, or above the high watermark, the associated watermark will be updated. When the monitor value registers are read, the value is cleared and starts tracking again using the current data source value. This can be useful for tracking low and high values of queue element counts or sizes for data tracking, debug or future optimizations, such as allocating items to a queue or buffer sizes based on counts.

##### 10.2.4.3.5.3 Starvation Monitor

A starvation monitor tracks the number of starvation events (a read to an empty queue) that occurred on the queue. The data source is ignored, and the starvation count is always incremented whenever there is a read to the queue and the queue is empty. The count is cleared when the monitor value is read. This can be useful to trigger if any starvation event occurs, or to track how many of these events occur in a timeframe, and can be used for future optimizations or debug.

##### 10.2.4.3.5.4 Statistics Monitor

The statistics monitor can track some simple statistics on the queue operations. The data source is ignored. The first value is the count of the number of writes to the queue, and the second value is the count of the number of reads from the queue. The counts are cleared when the monitor values are read. This can be useful to track the activity on a queue, and can be used for future optimizations or debug.

##### 10.2.4.3.5.5 Overflow

RINGACC provides an overflow function where a push to a full ring will result in a push to a special overflow ring, rather than just losing the pushed data. The overflow ring is defined through the RINGACC\_OVRFLOW register, and that ring must be defined with a large enough element size to cover the element size of any other ring, as well as enough elements to hold enough overflow data (as an overflow to the overflow ring will be lost). When there is a push to a full ring, there will be two elements written to the overflow ring, first the push data, and then the ring number that was full. A supervisor entity can own the overflow ring and perform what actions are needed from the overflow data. The size of the overflow ring must be an even number since two elements will be pushed for each overflow event. The overflow ring must be configured in *ring* or *message* modes.

An overflow queue value of 0xFFFF will disable the overflow function and will not record queue overflows.

##### 10.2.4.3.5.6 Ring Update Port

To enhance performance for DMAs, the RINGACC provides a bus that indicates when ring updates occur, allowing the DMA to track their own rings and detect updates before the responses arrive. The bus will go valid whenever there is an update to the state of a ring, which can be from a push, pop, or doorbell write. It will not go valid for a peek, a emudbg pop, a push to a full ring, as those do not update the ring state. When the bus is

valid, the other signals are valid and indicate whether the operation was a push or a pop, whether the resulting state of the ring is empty, the ring number, and the number of elements updated to the ring (the push determines whether it is subtracted or added to the current count). One special case is a pop from an empty ring, which indicates an update but the element count is 0 since no items were actually popped, but a DMA using the cnt to add or subtract must handle this correctly by default. The bus will go valid once the operation command has been completed, and not after the response has been received, even for ring mode rings, allowing the DMA to see the update as soon as it is known by the RINGACC even before it is known to software.

#### 10.2.4.3.5.7 Tracing

This module provides a trace output of all operations so that the traffic can be viewed at a later time. The trace uses a simple write-only 32-bit VBUSP bus, with a defined packet header. The *msgtype* field defines the type of operation, and the message data is simply the data involved in the operation. It is likely the trace output will be read slower than new operations could provide data, so there will be a trace buffer able to hold two complete messages plus trace headers. If a new operation starts while the trace buffer does not have enough space, then that trace message will not be sent. And RINGACC\_TRACE\_CTL register controls whether to enable the trace output, whether to trace a single queue or all queues, and whether to include the message data in the trace output.

Table 10-138 shows the trace message for a push.

**Table 10-138. Trace Message for a Push**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x1	Msgtype for push
1	8:0	0x009	Standard Trace Header
2	31	push_to_head	Push to head flag, 0 = to tail, 1 = to head
2	30:16	0x0	Unused
2	15:0	queue	Queue for push
3-N	31:0	message data	Optional message data for push, length dependent on message size

Table 10-139 shows the trace message for a pop.

**Table 10-139. Trace Message for a Pop**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x2	Msgtype for pop
1	8:0	0x009	Standard Trace Header
2	31	empty	empty pop, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for pop
3-N	31:0	message data	Optional message Data for pop, length dependent on message size

Table 10-140 shows the trace message for a peek.

**Table 10-140. Trace Message for a Peek**

Word	Bits	Data	Comment
1	31:16	0x0	Time to be replaced by trace hardware
1	15:9	0x3	Msgtype for peek
1	8:0	0x009	Standard Trace Header
2	31	empty	empty peek, 0 = valid message, 1 = empty
2	30:16	0x0	unused
2	15:0	queue	queue for peek

**Table 10-140. Trace Message for a Peek (continued)**

Word	Bits	Data	Comment
3-N	31:0	message data	Optional message Data for peek, length dependent on message size

## 10.2.5 Proxy

This chapter describes the Proxy module in a NAVSS.

### 10.2.5.1 Proxy Overview

The Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses.

Figure 10-27 shows a top-level overview of the Proxy module.

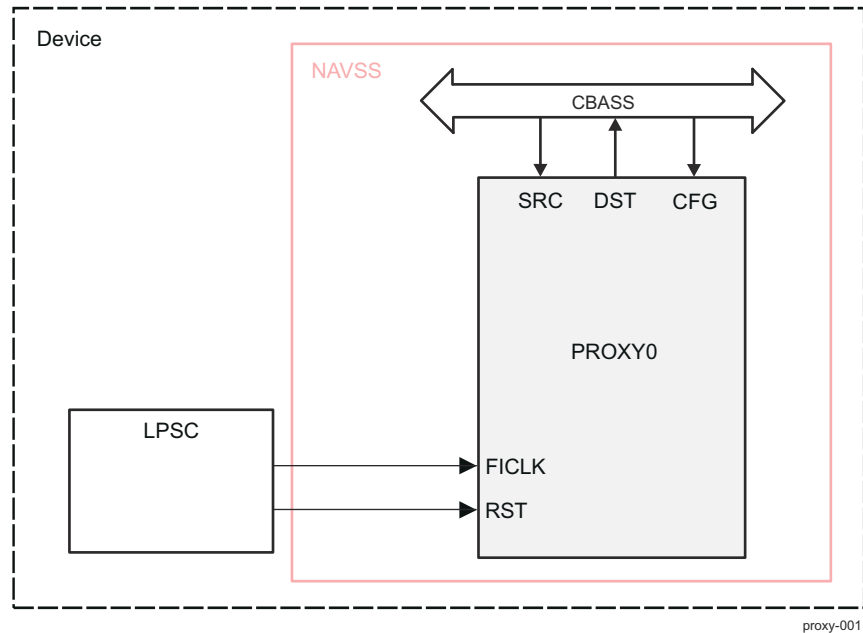

Figure 10-27. Proxy Overview

Table 10-141. Proxy Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_PROXY0	-	✓ (MCU NAVSS)	-

#### 10.2.5.1.1 Proxy Features

Each Proxy supports the following features:

- Provides proxy buffers to store large data bursts that a host can only access in smaller amounts.
- Keeps the large data coherent until the complete data has been accessed.
- Allows for interleaved access between multiple hosts using multiple proxies.
- Each target has pre-configured number of channels, size of each channel, and address offset. See [Table 10-142](#).

#### 10.2.5.1.2 Proxy Parameters

Table 10-142 shows the Proxy configuration parameters set during SoC design.

Table 10-142. Proxy Configuration Parameters

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Buffer Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
NAVSS0_PROXY0	64	256	NAVSS0_RINGACC0	1024	4096

**Table 10-142. Proxy Configuration Parameters (continued)**

MCU_NAVSS0_PROXY0	64	256	MCU_NAVSS0_RING ACC0	286	4096
-------------------	----	-----	-------------------------	-----	------

- (1) Number of proxy threads supported. Can be read off from the PROXY\_CONFIG read-only register
- (2) Number of bytes per proxy buffer
- (3) Number of channels for the target
- (4) Number of bytes per channel supported for the target

#### **10.2.5.1.3 Proxy Not Supported Features**

The following features are not supported by the module:

- Does not support proxy sharing. Each host must use its own proxy within the module.

### 10.2.5.2 Proxy Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the Proxy integration in the main Navigator subsystem (NAVSS0). For MCU\_NAVSS0\_PROXY0 integration, please see *MCU Navigator Subsystem (MCU\_NAVSS)*.

Figure 10-28 shows the Proxy integration in the NAVSS

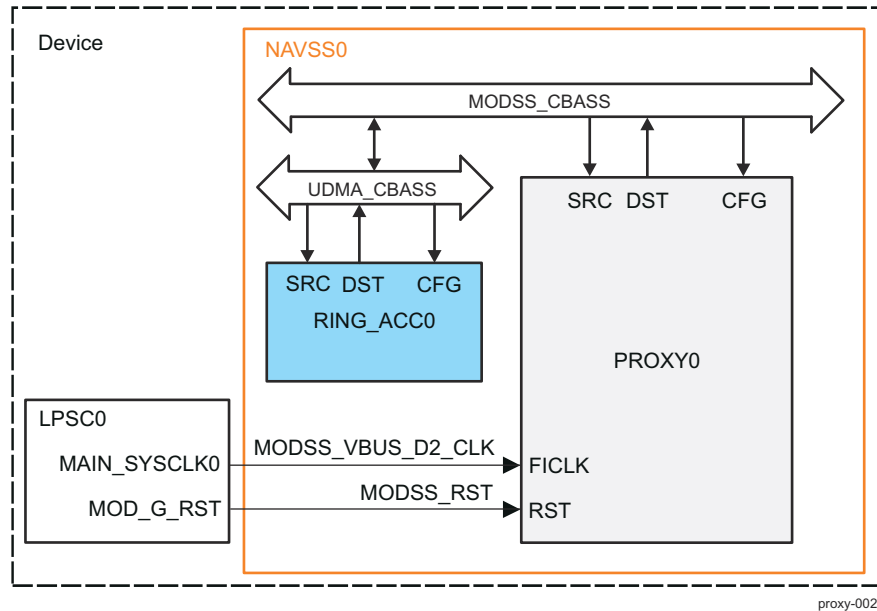

Figure 10-28. Proxy Integration

Table 10-143 and Table 10-144 summarize the integration of the module in the device.

### 10.2.5.3 Proxy Functional Description

This module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are for large Message Manager messages, Queue Manager data that is more than a pointer, or DMA Transfer Requests Messages. All of these require larger data sets, from 12 to 128 bytes, and the modules require the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as hardware registers, and the largest CPU access is typically 8 bytes. So the proxy provides the ability to access the module with a single burst, and at the same time allows the CPU to access the same data in smaller accesses. The proxy itself does not contain the resources, but it stays in front of other module (target module) that does contain the resources. The proxy will access the target module with the entire data in a single burst, once the host has completed the data.

#### 10.2.5.3.1 Targets

##### 10.2.5.3.1.1 Ring Accelerator

The RINGACC provides four distinct offsets to use per ring/queue shown in [Table 10-146](#), totaling 4 kB space per ring/queue. Each channel has access modes (enabled via PROXY\_CTL\_j[17-16] MODE field):

- head access
- tail access
- peeks from head

**Table 10-146. RINGACC Offsets per Ring/Queue**

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored.
0x600 - 0x7FF	Reads peek from tail. Writes ignored. This mode is not supported in this device.
0x800 - 0xFFFF	Reserved

#### 10.2.5.3.2 Proxy Sizes

The number of proxies in the module is configured during SoC design. See [Table 10-142](#). Each proxy has its own address space to the module and determining which proxy is being accessed is simply based on the address bits above the final size of each proxy space. The size of the proxy space is always 4 KB. This is enough to contain the data message, along with controls for which channel, access mode, and element size for the access.

#### 10.2.5.3.3 Proxy Interleaving

Each proxy must have a single owner, as each proxy only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy. Then they will have their own buffer and each can access a different resource at the same time. Each proxy is completely independent and kept coherent regardless of accesses to other proxies or regardless of the order of accesses. So the proxies support interleaving of multiple hosts' accesses.

#### 10.2.5.3.4 Proxy Host States

Each individual proxy per host uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy is in use or not, but also for error detection. The proxy always stays in

idle state, when there is no activity. There is a write state for when the proxy has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy has read data from a resource and that entire data has not been fully read by the host. When a proxy access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

#### 10.2.5.3.5 Proxy Host Channel Selection

The host must program the PROXY\_CTL\_j (where j = 0h to 3Fh) prior to accessing the PROXY\_DATA\_j\_y (where j = 0h to 3Fh, y = 0h to 7Fh) unless the previous values are to be reused. This sets the channel within the target, the access mode (head, tail, peek), and the element size. These values will be used when writing the full message to the target, or reading a new message from the target. The target address used will be based on the target base address, the programmed channel, the programmed access mode (for the offset within the 4 kB of the target channel), and the element size (for the offset within the 512 Bytes max size message).

$$\text{target address} = \text{target base} + (\text{channel} \times 4\text{KB}) + (\text{mode} \times 512\text{B}) + (512 - \text{element size in bytes})$$

, for element size in bytes length.

The proxy will detect an error if these fields are changed while in the middle of a message.

#### 10.2.5.3.6 Proxy Host Access

A proxy begins in an idle state, where there is no data in the buffer. In this state the proxy will accept any access to a new resource. If the proxy is in another state, representing a resource is in progress, and the host attempts to access another target or resource, or switches from read to write, then the proxy will detect that as an error and flush the buffer with no final target access and the data is lost and the proxy goes back to idle state.

##### 10.2.5.3.6.1 Proxy Host Writes

The first write to an idle proxy puts the proxy into write mode for the selected target and channel. Further legal writes are stored in the buffer for the enabled bytes and position within the buffer. A write to a previously written location will overwrite the previous data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy is then put back into idle state.

##### 10.2.5.3.6.2 Proxy Host Reads

When in idle state, the first read to the proxy will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy is put back into idle state.

#### 10.2.5.3.7 Permission Inheritance

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target. This will copy the secure, debug, priv, privid, and virtid signals so that they can be firewalled during the target access for the resource.

#### 10.2.5.3.8 Buffer Size

Buffer size is shown in [Table 10-142](#). An attempt to access a larger message will result in the proxy going into error mode. Software must only create messages up to the supported target size.

#### 10.2.5.3.9 Error Events

Each proxy can produce an event when it has detected an error. This error occurs when the host changes the target, resource, or access direction before completing the previous data. An error can also occur for an access to an illegal target, illegal offset within a target, such as beyond the target size or buffer size, or if the

access spans multiple channels. This error does not include accessing reserved register locations within the proxy thread, as that results in normal reserved register behavior of ignoring write data and reading 0s. There is a separate status bit per proxy for these errors. The event number is programmed via `PROXY_EVT_REG_j` (where `j = 0h to 3Fh`) for each proxy. The event will not be sent if the event is programmed to `0xFFFF`.

#### **10.2.5.3.10 Debug Reads**

Since debug reads with `emudbg=1` must not cause any side effects or bus errors, any debug read will just read the buffer and never cause a target read. It will also not return any bus errors.

## 10.2.6 Secure Proxy

This chapter describes the Secure Proxy module in NAVSS.

### 10.2.6.1 Secure Proxy Overview

The Secure Proxy module provides proxy buffers for hosts that need to create large data bursts but can only perform small accesses. Secure Proxy is a modified version of the Proxy module in NAVSS.

**Table 10-147. Secure Proxy Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_SEC_PROXY0	-	-	✓ (NAVSS)
MCU_NAVSS0_SEC_PROXY0	-	✓ (MCU NAVSS)	-

#### 10.2.6.1.1 Secure Proxy Features

Secure Proxy supports the following features:

- Provides proxy function to store large data bursts that a host can only access in smaller amounts
- Supports a number of threads, where each has their own independent proxy function
- Keeps the large data burst coherent until the complete data has been accessed
- Allows for interleaved access between multiple hosts or tasks using multiple proxy threads
- Supports a programmable fixed queue for each proxy thread
- Supports multiple producers all writing to the same queue
- Supports a max message count for outbound proxy threads limiting the number of messages a thread can produce
- Supports programmable thresholds for when to generate events.

#### 10.2.6.1.2 Secure Proxy Parameters

Table 10-148 shows the Secure Proxy configuration parameters set during SoC design.

**Table 10-148. Secure Proxy Configuration Parameters**

Module Instance	Parameters				
	Proxies <sup>(1)</sup>	Message Size <sup>(2)</sup>	Target	Channels <sup>(3)</sup>	Sizes <sup>(4)</sup>
NAVSS0_SEC_PROXY0	160	64	NAVSS0_RINGACC0	50	4096
MCU_NAVSS0_SEC_PROXY0	90	64	MCU_NAVSS0_RINGACC0	30	4096

(1) Number of proxy threads supported. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(2) Number of bytes for message. Can be read off from the SEC\_PROXY\_CONFIG read-only register

(3) Number of channels for the target

(4) Number of bytes per channel supported for the target

#### 10.2.6.1.3 Secure Proxy Not Supported Features

The following features are not supported by the module:

- Does not support proxy thread sharing. Each host or task must use its own proxy thread within the module if they can access simultaneously or independently. This includes when the task can be interrupted by another task that also uses the proxy
- In the system, a proxy must be the only method to access messages that use the same set of queues (to keep credits local), which means all hosts using the same set of message queues must also use the same proxy for access and not local proxys
- Does not support multiple proxy threads reading from the same queue. For tracking purposes, there can be only 1 consumer proxy thread per queue.

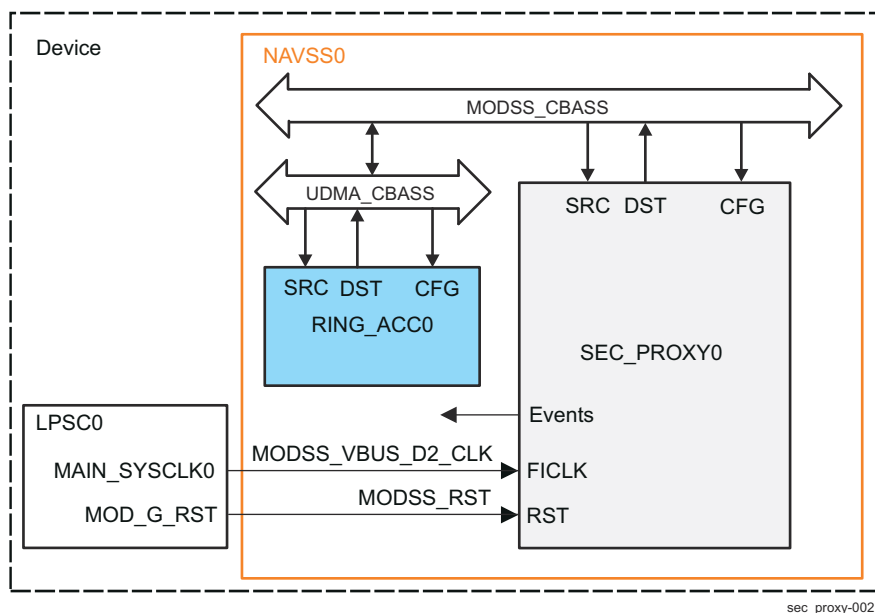

### 10.2.6.2 Secure Proxy Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the Secure Proxy integration in the main Navigator subsystem (NAVSS0). For MCU\_NAVSS0\_SEC\_PROXY0 integration, please see *MCU Navigator Subsystem (MCU\_NAVSS)*.

Figure 10-29 shows the Secure Proxy integration in the NAVSS

**Figure 10-29. Secure Proxy Integration**

Table 10-149 and Table 10-150 summarize the integration of the module in the device.

**Table 10-149. Secure Proxy Integration Attributes**

NAVSS0_SEC_PR - OXY0	-	-	-	No PDMA channels to external DMA engines	-

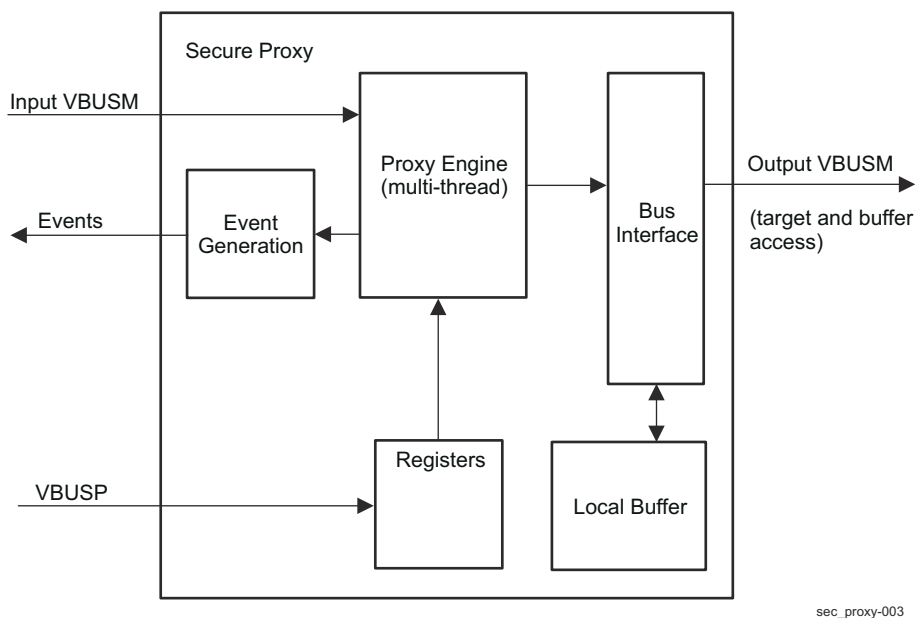

### 10.2.6.3 Secure Proxy Functional Description

This module provides proxy functions for hosts that need to create large data bursts but can only perform small accesses. Examples of this need are:

- large messages (for power control, security control, or IPC)
- data descriptors that are more than a pointer
- DMA Transfer Requests (TR)

All of these require larger data sets, from 12 to 128 bytes, and the storage hardware requires the entire data on the bus in a single burst. Unfortunately, many CPUs cannot produce bursts to device memory, such as registers, and the largest CPU access is typically 8 bytes. Therefore the proxy provides the ability to access the hardware with a single burst, and at the same time allows the CPU to access the same data in smaller accesses.

Figure 10-30 describes Secure Proxy major building blocks.

**Figure 10-30. Secure Proxy Block Diagram**

#### 10.2.6.3.1 Targets

##### 10.2.6.3.1.1 Ring Accelerator

The RING\_ACC provides four distinct offsets to use per ring/queue shown in Table 10-152, totaling 4 KB space per ring/queue.

Secure Proxy always writes to tail, which is the offsets from 0x200 to 0x3FF. Secure Proxy always reads from the head, which is the offsets from 0x000 to 0x1FF. The latter two offsets in RING\_ACC are not used by this proxy. And if the proxy message size is less than 512 bytes, then it always access the upper bytes of those regions, so that the message always ends on the last byte of each region, byte 511.

**Table 10-152. RING\_ACC Offsets per Ring/Queue**

Offset	Operation
0x0 - 0x1FF	Reads pop from head. Writes push to head.
0x200 - 0x3FF	Writes push to tail. Reads pop from tail.
0x400 - 0x5FF	Reads peek from head. Writes ignored. Not used by Secure Proxy
0x600 - 0x7FF	Reads peek from tail. Writes ignored. Not used by Secure Proxy
0x800 - 0xFFFF	Reserved

This means that target writes will use the following calculation:

$$\text{target base address} + (\text{queue} \times 4\text{KB}) + 0x400 - \text{msg\_size} \quad (17)$$

,and burst until offset 0x3FF.

And target reads will use the following calculation:

$$\text{target base address} + (\text{queue} \times 4\text{KB}) + 0x200 - \text{msg\_size} \quad (18)$$

,and burst until offset 0x1FF.

### 10.2.6.3.2 Buffers

The proxy does not store all the buffers internally. It is programmed with a buffer base address (SEC\_PROXY\_BUFFER\_L, SEC\_PROXY\_BUFFER\_H), and all accesses to the buffer are made through the output VBUSM port using that base. The external buffer must be enough to store one *msg\_size* per proxy thread. The proxy only includes a small temporary buffer to save one entire message when accessing the target. Otherwise all host accesses are made to the external buffer. This buffer storage must be considered private for the proxy hardware, so any other access can cause unpredictable results.

#### 10.2.6.3.2.1 Proxy Credits

To support outbound proxy limits, the proxy will use internal credits for tracking resource usage. SEC\_PROXY\_CTL\_j register sets the max credits each outbound proxy thread contains. When a proxy thread sends a message, the current credit count (SEC\_PROXY\_STATUS\_j) decrements by 1. If the current credit count is 0, then the proxy thread is not allowed to send any more messages, and they just remain inside the proxy (so that the host can come back later when a credit has become available and quickly send the same message). When a message that was send by this proxy thread is read by an inbound proxy thread then the credit is returned to this proxy thread and the current credit count increments by 1.

For inbound proxy threads, the credits are used to track pending messages. When an outbound proxy thread sends a message that is read by this proxy thread, then the current credit count of this proxy thread is incremented by 1. A current credit count that is non zero indicates a message is pending and can be read. When the proxy thread completes the read of a message the current credit count is decremented by 1. If the current credit count is zero, then the proxy thread will read an empty message where all the data is 0s. The credit count saturates at 255, so if there can be more messages in the system for that proxy thread than 255 then multiple proxy threads should be used, or the count can become mismatched after a saturate.

#### 10.2.6.3.2.2 Proxy Private Word

To support tracking of credits from each proxy thread, the proxy will extract the first word from the total message size for private tracking usage. This will include saving the proxy thread ID used within the proxy. This is necessary so that when a proxy reads a new message from the target it can inspect this word and return the credit to the source proxy thread. This allows the outbound proxy threads to have a set number of message credits, which decrement when a new message is written, and increment when a message from that proxy thread is read, thus keeping the credits in the system coherent. Any data written to this first word of the message will be ignored, so software should not write to the first word of messages through the proxy. Consumer software can use the first word to identify the source proxy thread of the message (SEC\_PROXY\_DATA\_j).

#### **10.2.6.3.2.3 Completion Byte**

The proxy completes a message when the completion byte is accessed. This completion byte is the final byte in the full size of the message. This byte can be written by any size access, whether byte, 32-bit, or 64-bit word. The write of a message is not complete until this final byte of the message is written, and only then will the message be sent to the target. The read of a message is not complete until this final byte of the message is read by the host, and only then will reading a new message be allowed. Even if the final byte of the message is not needed, it must be accessed to complete the message inside the proxy hardware.

#### **10.2.6.3.3 Proxy Thread Sizes**

There are a configurable number of proxy threads in the module. Each thread has its own address space to the module and determining which proxy thread is being accessed is simply based on the address bits above the final size of each proxy thread space. Since each proxy thread will be programmed to a single resource, the only space requirement is that for using 4 KB to match typically used MMU page sizes. Only the first N bytes, matching the target channel size, is usable.

#### **10.2.6.3.4 Proxy Thread Interleaving**

Each proxy thread must have a single owner, as each proxy thread only has a single buffer to work on the current data. If there are multiple owners in the system, they must each use their own proxy thread. Then they will have their own buffer and each can access a different resource at the same time. Each proxy thread is completely independent and kept coherent regardless of accesses to other proxy threads or regardless of the order of accesses. So the proxy support interleaving of multiple hosts' accesses.

#### **10.2.6.3.5 Proxy States**

Each proxy thread uses a simple state machine to track the currently usage by that host. This state machine is used to track when a proxy thread is in use or not, but also for error detection. The proxy thread always starts in idle state, when there is no currently activity. There is a write state for when the proxy thread has been written and contains data that has yet to be written to a resource. There is a read state for when the proxy thread has read data from a resource and that entire data has not been fully read by the host. When a proxy thread access completes, final write or final read, then the state will go back to idle. The following sections show the utilization of these states.

#### **10.2.6.3.6 Proxy Host Access**

A proxy thread begins in an idle state, where there is no data in the buffer. In this state the proxy thread will accept an access to the resource.

##### **10.2.6.3.6.1 Proxy Host Writes**

The first write to an idle proxy thread puts the proxy thread into write mode for the selected channel. Further legal writes are stored in the buffer for the enabled bytes and offset within the buffer. A write to a previously written location will overwrite the previous data. The buffer is not cleared initially, so if a byte is not written, the message will include previous buffer data. When there is a legal write to the last byte of the resource, then the entire data is written by the proxy to the target and channel as a single write burst. The proxy will wait for the write status from the target write before it sends the write status for this final byte host write. This allows the host to use the write status to guarantee the entire write data from the proxy has landed at the target. The proxy thread is then put back into idle state. A write completion when there are no credits available results in the message not being written to the resource and the proxy thread remains in write mode (so that the message can be quickly completed when a credit becomes available).

##### **10.2.6.3.6.2 Proxy Host Reads**

When in idle state, the first read to the proxy thread will put the proxy into read state, and the proxy will read the target and channel requested in a single burst of the target's channel size. When the data is returned it is stored in the buffer and the accessed part is returned to the host. Further legal reads are allowed and return the accessed data in the buffer. When there is a legal read to the last byte of the resource, the accessed data is returned, and the proxy thread is put back into idle state. If an initial read is made and there are no pending messages, the proxy thread will return an empty message, where the data is all 0s.

#### **10.2.6.3.6.3 Buffer Accesses**

Each read or write will actually trigger a read or write to the external buffer space allocated for that proxy thread, where the real message data is stored. In addition, when a write message completes, the external buffer will be read for the entire message for that proxy thread so that it can then be written to the target. Similarly, after a read causes a read from the target to get a new message, the entire message is written to the external buffer to store the message to the buffer.

#### **10.2.6.3.6.4 Target Access**

After the write has completed and the external buffer read for the entire message, the entire message is then written to the target as a single burst. Similarly, for a read that needs a new message, the target is read for a full message as a single burst.

#### **10.2.6.3.6.5 Error State**

If an error is detected in a proxy thread, the proxy will put that proxy thread into error state, and the current buffer will be lost. A status bit will be set that indicates the proxy thread is in error. All accesses to that proxy thread will be ignored until the status bit is cleared. Once cleared the proxy thread is put back into idle state. Errors are: an access to an offset beyond the length of the message, or a mismatch in the direction of access against what was programmed such as reading an outbound thread or writing an inbound thread.

#### **10.2.6.3.7 Permission Inheritance**

The proxy will automatically inherit the permissions from the access and pass these to the target upon the target burst access. The exact transactions that are inherited from are the final byte write or the first read, and these exact permissions are used on the output bus transaction that accesses the target.

#### **10.2.6.3.8 Resource Association**

Each proxy thread has a register (SEC\_PROXY\_CTL\_j) to define the resource within the target that the proxy thread is mapped to. The host has no ability to access any other resource in the target. This allows the setup of the proxy to determine the resources that all the hosts use.

#### **10.2.6.3.9 Direction**

Each proxy thread has a register (SEC\_PROXY\_CTL\_j) to define the direction for access. It can either be an outbound proxy thread for writing messages to resources. Or it can be an inbound proxy thread for reading messages from resources. The host must match the direction programmed or it will result in a proxy thread error.

#### **10.2.6.3.10 Threshold Events**

Each proxy thread can produce events based on the state of the resource it uses. For outbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to write. For inbound proxy threads, a threshold can be set so that an event is produced when there are now at least N messages available to read. These threshold values are programmed in SEC\_PROXY\_EVT\_MAP\_j, allowing the host to determine how often it gets events. Programming the count values while the threshold is set to 0 will not trigger events, but if the threshold is not 0 then programming the counts will trigger events based on whether the threshold is reached or not. No event is generated if the event is programmed to 0xFFFF.

#### **10.2.6.3.11 Error Events**

Each proxy thread can produce an event when it has detected an error. This error occurs when the host violates the programmed setup of the proxy thread or accesses beyond the message size. There is a separate status bit per proxy thread for these errors. No event is generated if the event is programmed to 0xFFFF.

#### **10.2.6.3.12 Bus Errors and Credits**

If a target read for a message returns a bus error, this indicates the read was bad and the data is corrupt and usually 0s. Because the private word is contained in the message, if the private word is corrupted then the source proxy thread is not valid and the credit return will not be correct. Since the data is usually 0, this means the credit would be returned to proxy thread 0 incorrectly most of the time. And the credit will be lost for the actual source proxy thread of the message that was not read correctly. The hardware has no way to correct for

this, as the message from the target is corrupt so it does not know the correct owner of the credit. If software detects that a read message is corrupt, it can attempt to correct the situation by resetting the affected proxy threads using that queue, to restore their credit counts back to the default. Software may also want to reset proxy thread 0 since it may be getting extra credits.

#### **10.2.6.3.13 Debug**

When the transaction has the *emudbg* set for a read, all side effects will not occur. This means that the read will not cause a target read since that would affect the target, and instead current buffer will be read even if the previous message has completed.

## 10.2.7 Interrupt Aggregator (INTR\_AGGR)

This chapter describes the INTR\_AGGR module, part of NAVSS.

### 10.2.7.1 INTR\_AGGR Overview

The Interrupt Aggregator (INTR\_AGGR or INTA) provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. The main function of the module is to convert between 'global events' (assertion and de-assertion events transmitted on the event-transport-lane (ETL) bus) and 'local events' (level sensitive signals on output, and level or edge sensitive signals on input).

**Table 10-153. INTR\_AGGR Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_INTR_AGGR0	-	-	✓ (NAVSS)
NAVSS0_INTR_AGGR1	-	-	✓ (NAVSS)
NAVSS0_UDMASS_INTR_AGGR0	-	-	✓ (NAVSS)
MCU_NAVSS0_UDMASS_INTR_AGGR0	-	✓ (MCU NAVSS)	-

#### 10.2.7.1.1 INTR\_AGGR Features

NAVSS0\_INTR\_AGGR0 supports the following features:

- 64-bit VBUSP slave using 64-bit registers
- Provides a set of *TI Interrupt Architecture* compliant interrupt status and mask registers which are used to pass specific event status to one or more host blocks.
  - Maps a collection of "DMA Messaged Events" which are input through an Event Transport Lane (ETL) into specific bit locations in one or more interrupt cause registers
  - Mapping is performed based on a programmable table which provides a single location for each ordinal input event number (0 through sevt\_cnt-1)
    - Table specifies a specific bit in a specific cause register that the event should set or clear depending on the type of event (up vs down)
    - Tracks a single 'event up'/'event down' condition. There is no event counting. (The 'cnt' field of the ETL is ignored)
  - Tracked status interrupts are presented to the user through a standard interrupt register interface
    - Provides separate 'enable set' and 'enable clear' registers
    - Provides both masked and unmasked interrupt status
    - Interrupt status bits can be manually cleared using 'write 1 to clear'
- Provides a set of Global Event Input (GEVI) counters which can count events which were delivered via an ingress Event Transport Lane (ETL)
  - Each counted event provides an register by which the count can be read and an register by which a specified amount can be decremented by the host
  - Each counted event generates a egress Global event on a zero to non-zero and non-zero to zero transition, controllable through a mapping register
- Provides a set of Local Event Input (LEVI) to Global event registers which can be used to convert pulsed discrete interrupt inputs or clock synchronous rising edge events into Global events on an egress ETL
  - Each ingress event index provides a configurable 'pulse' or 'rising edge' bit, plus the configurable index of the generated Global event
- Provides a set of Global Event Input (GEVI) 'Multicast' registers which can take a Global event from an ingress ETL and generate two egress Global events on two egress ETL interfaces.

### 10.2.7.1.2 INTR\_AGGR Parameters

Table 10-154 shows the MODSS Interrupt Aggregators 0 and 1, and UDMASS Interrupt Aggregator 0 parameters set during design time. 4 local (LEVI) interrupts are from the MCRC0 module. 48 LEVI interrupts are from the MAILBOX0 module. See INTR\_AGGR Integration.

**Table 10-154. Interrupt Aggregators Parameters**

Module Instance	Parameters				
	VINTR <sup>(1)</sup>	SEVI <sup>(2)</sup>	GEVI <sup>(3)</sup>	LEVI <sup>(4)</sup>	MEVI <sup>(5)</sup>
NAVSS0_INTR_AGGR0	64	1024	0	0	0
NAVSS0_INTR_AGGR1	64	1024	0	0	0
NAVSS0_UDMASS_INTR_AGGR0	256	4608	512	84	512
MCU_NAVSS0_UDMASS_INTR_AGGR0	256	1536	256	12	128

- (1) VINTR – Number of Virtual Interrupt outputs. These are connected to the interrupt router inputs. Value can be read from INTA\_INTCAP/UDMA\_INTA\_INTCAP register.
- (2) SEVI – Number of Main (Steerable) Events. Value can be read from INTA\_INTCAP/UDMA\_INTA\_INTCAP register.
- (3) GEVI – Number of Countable Events. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.
- (4) LEVI – Number of Local Event inputs. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.
- (5) MEVI – Number of Multicast Events. Value can be read from INTA\_AUXCAP/UDMA\_INTA\_AUXCAP register.

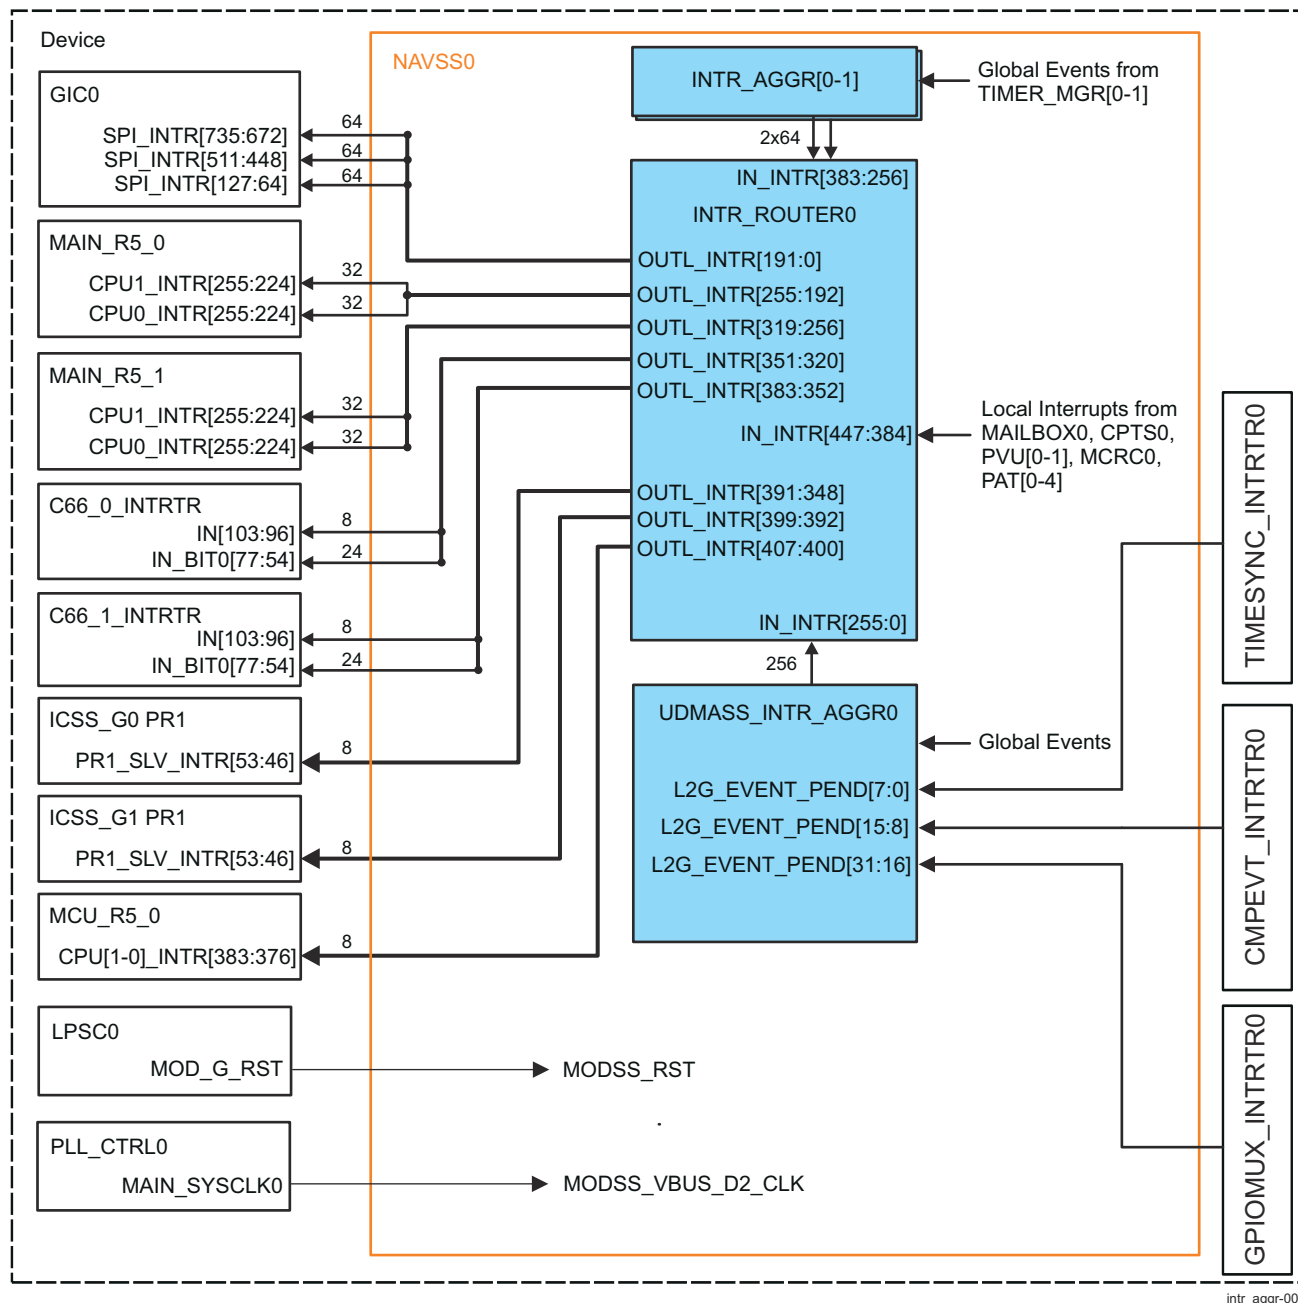

### 10.2.7.2 INTR\_AGGR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the INTR\_AGGR integration in the main Navigator subsystem (NAVSS0). For MCU\_NAVSS0\_INTR\_AGGR0 integration, please see *MCU Navigator Subsystem (MCU\_NAVSS)*.

Figure 10-31 shows the INTR\_AGGR integration in the device.

intr\_aggr-002

### 10.2.7.3 INTR\_AGGR Functional Description

The Interrupt Aggregator provides a centralized machine which handles the termination of system events to that they can be coherently processed by the host(s) in the system. Both the signaling and content of K3 system events are incompatible with standard interrupt controllers. The INTR\_AGGR provides mechanisms which convert the TI proprietary system events to standard level sensitive pending bits which can be used by the Interrupt Router and all downstream interrupt infrastructure. Events can be presented to the INTR\_AGGR in two different forms:

- Events may be active high pulses, or clock synchronous rising edges, which are input on separate orthogonal pins. These are called 'Local Events'.
  - Local event signals that are used in pulse counting mode must be sourced by the same clock as the interrupt aggregator.
  - Local event signals that are used in edge counting mode must be sourced by pseudo-synchronous sources (and be a slower clock multiple) to the interrupt aggregator clock, and they must remain high for at least 1 'slow' clock cycle.
- Events may be messages which are input in time division multiplexed sequential order from an Event Transport Lane. These are called 'Global Events'.

In both cases, these events need to be conditioned to transition them from a transient indicator that something occurred to a persistent and reliable indication of the current state of the system. The INTR\_AGGR is architected to perform this conversion in an efficient and cost effective manner.

#### 10.2.7.3.1 Submodule Descriptions

##### 10.2.7.3.1.1 Status/Mask Registers

The Status and Mask Registers block is responsible for providing persistent storage for the interrupt status and mask bits and for formatting those in a way that is compliant to the *TI Interrupt Architecture* requirements. These requirements include the ability to set and clear bits orthogonally and to provide a masked version of the status register that corresponds to the supplied bit mask for each register.

##### 10.2.7.3.1.2 Interrupt Mapping Block

The Interrupt Mapping Block accepts ordinally numbered events (0-N) and converts those ordinal event numbers into a status register number and bit number pair that is then used to manipulate the specified bit in the Status Registers block.

##### 10.2.7.3.1.3 Global Event Input (GEVI) Counters

The GEVI Counters block is responsible for accepting an Event Transport Lane events and summing the total message counts for each received event index. The module creates global egress events for zero to non-zero count up' events and non-zero to zero 'count down' events. The egress global event index is configured via GEVI UDMA\_INTA\_MCMAP\_j register, so count status egress events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

##### 10.2.7.3.1.4 Local Event Input (LEVI) to Global Event Conversion

The Local to Global event block is responsible for accepting an array of input pins and independently counting the number of cycles for which those pins are asserted high, or by counting individual clock synchronous rising edge events. The counting mode is configurable on a 'per pin' basis. The events are converted to egress Global events on an egress ETL. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

##### 10.2.7.3.1.5 Global Event Multicast

The Global event multicast block takes an ingress global event from an ingress ETL, and maps it into two egress Global events on two egress ETL interfaces. Global events can optionally be fed back into the INT\_AGGR, via the ETL switch fabric.

### 10.2.7.3.2 General Functionality

#### 10.2.7.3.2.1 Event to Interrupt Bit Steering

Each time an event message is received on the Main Event Transport Lane interface, the interrupt mapping block performs a direct lookup into an SRAM using the event number as the address. The SRAM stores a corresponding raw interrupt status register and bit number within that register which are to be manipulated anytime a message is received indicating something occurred on that specific event. When an *up* event is received, the specified bit in the *j* Status register will be set. When a *down* event is received, that same bit will be cleared. This block is what allows flexible aggregation of various system events into an array of bits in the interrupt status registers. It is intended that this mapping is essentially static - set up when a resource is allocated and left untouched until the resource is no longer needed. Note that the 'cnt' field of the ETL is ignored and no interrupt counting is performed here. When 'UpDn=1', the interrupt flag bit is set, and when 'UpDn=0', the flag bit is cleared.

#### 10.2.7.3.2.2 Interrupt Status

The event messages which are generated from the event to interrupt bit steering logic are input to the Interrupt Status registers. Each time an event is received, the interrupt status registers machine will assert or de-assert the specified bit in the specified register. The assertion and de-assertion in the interrupt status register is unaffected by the interrupt enable state. When an up event is received, the corresponding bit is set and when a down event is received, the corresponding bit is cleared. Some sources of input events will not include the ability to send a down event. In these cases, the interrupt router provides the ability to clear the status bits through the Interrupt Source Clear register. The host will write a one to the specific bit in the register which is to be cleared and the interrupt status machine will clear the bit internally. It is not intended that the Host directly clear bits which are automatically cleared via down events from the source itself.

#### 10.2.7.3.2.3 Interrupt Masked Status

Interrupt enable bits are used in conjunction with the interrupt status bits to create the interrupt masked status register values. The interrupt masked status register (INTA\_STATUSM\_j) contains the value of the interrupt status ANDed with the value of the interrupt enable register. Each time a new event message is received from the event to interrupt bit steering logic or the interrupt enable register is modified, the interrupt masked status register is re-evaluated.

#### 10.2.7.3.2.4 Enabling/Disabling Individual Interrupt Source Bits

Separate (INTA\_ENABLE\_SET\_j and INTA\_ENABLE\_CLEAR\_j) registers are provided to allow individual enable bits to be enabled or disabled without the need for a read-modify-write operation. When the INTA\_ENABLE\_SET\_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be set. When the INTA\_ENABLE\_CLEAR\_j register is written, all bits within written bytes which are 1 will cause corresponding bits in the internal enable register to be cleared.

#### 10.2.7.3.2.5 Interrupt Output Generation

Each interrupt masked status register (INTA\_STATUSM\_j) is accompanied by a single pending bit which indicates if any enabled interrupt source within the corresponding interrupt status register is currently asserted. These pending bits from the interrupt masked status registers are collectively output from the INTR\_AGGR as the VINTR\_PEND bus. The interrupt status outputs will always be updated to reflect the current values of the INTA\_STATUSM\_j register. This is accomplished by triggering output updates on write operations to the internal RAM that holds the current raw status and enable masks.

#### 10.2.7.3.2.6 Global Event Counting

When enabled, the INTR\_AGGR will provide a set of counters which will track how many outstanding messages have been observed for each ingress event index from the ingress Counted Global Event Transport Lane (ETL) interface. For each message received where the 'UpDn' flag is set, the corresponding counter will be incremented by value of the 'cnt' field of ingress message. Events where the 'UpDn' flag is cleared are ignored. The counter is made visible to software in the UDMA\_INTA\_COUNT\_j register. When software has read the count, it can acknowledge that count has been seen and processed by writing back an integer value specifying the amount by which the counter should be decremented, and the counter will subtract that value from the

current count (which may have updated since it was read). The count will saturate at a value of 0xFFFFFFFF. Writing a count 'ack' value higher than the one read is not supported and will produce non-deterministic results.

When a count transitions from zero to a non-zero value, a Global Up 'UpDn=1' event is sent out an egress ETL interface. When a count transitions from a non-zero value to zero, a down 'UpDn=0' event will be sent. The index of the Global event is mappable on a 'per-counter' basis, using the UDMA\_INTA\_MAP\_j register. The event may be mapped such that it then re-enters INTR\_AGGR's 'Event to Interrupt Bit Steering Block' to generate an interrupt to the host. The event routing is handled by an external event switch fabric. Note that writing a new egress event index via the UDMA\_INTA\_MAP\_j register does not alter the stored event count for the ingress event register index.

#### **10.2.7.3.2.7 Local Event to Global Event Conversion**

When enabled, the INTR\_AGGR will provide a set of Local to Global event conversion registers. Local events may be discrete clock synchronous pulses or clock synchronous rising edges. The counting mode is configurable on a 'per pin' basis. In pulsed mode, the module will track how many outstanding clock cycle long pulses have been observed on each of the provided LEVI interface pins. For each cycle in which a LEVI input pending bit is asserted the corresponding counter will be incremented by 1. In 'rising edge' mode, the number of rising edge transitions on the pin is counted.

The module will generate egress Global events on its egress ETL, with a different global index configured for each ingress LEVI pin. The LEVI pins numbers (1-N) are converted to arbitrary global event indices via the global event mapping UDMA\_INTA\_MAP\_j registers. The egress Global events can themselves be mapped to re-enter the INTR\_AGGR's Global Event Counting block, so that the counts can then be made visible to software in the GEVI count registers as described in [Section 10.2.7.3.1.3](#). The event routing is handled by an external event switch fabric.

#### **10.2.7.3.2.8 Global Event Multicast**

In UDMASS\_INTR\_AGGR0, the INTR\_AGGR will provide a set of Global event multicast (UDMA\_INTA\_MCMAP\_j) registers. These registers allow an ingress Global event on its ingress ETL interface to be mapped into two egress Global events on two separate egress ETL interfaces. A set of registers map the ingress Global event index (1-N) into two arbitrary egress event indices.

## 10.2.8 Packet Streaming Interface Link (PSI-L)

This section describes the Packet Streaming Interface Link (PSI-L) for the device.

### 10.2.8.1 PSI-L Overview

PSI-L is a packet based protocol used to transfer data between several device modules. Each transaction is routed based on thread ID value instead of physical address. All PSI-L interfaces are point to point direct connections to NAVSS0 or MCU\_NAVSS0. All switching functions among the PSI-L based interfaces are done inside NAVSS0 and MCU\_NAVSS0.

The PSI-L also has an event interface referred to as ETL, which is purely used to transfer event information. Only MCU\_NAVSS0 has such event interface. It is connected to WKUP\_DMSC0 and allows MCU\_NAVSS0 to send event information to the interrupt aggregator inside WKUP\_DMSC0.

[Figure 10-32](#) shows an overview of all PSI-L connections within the device.

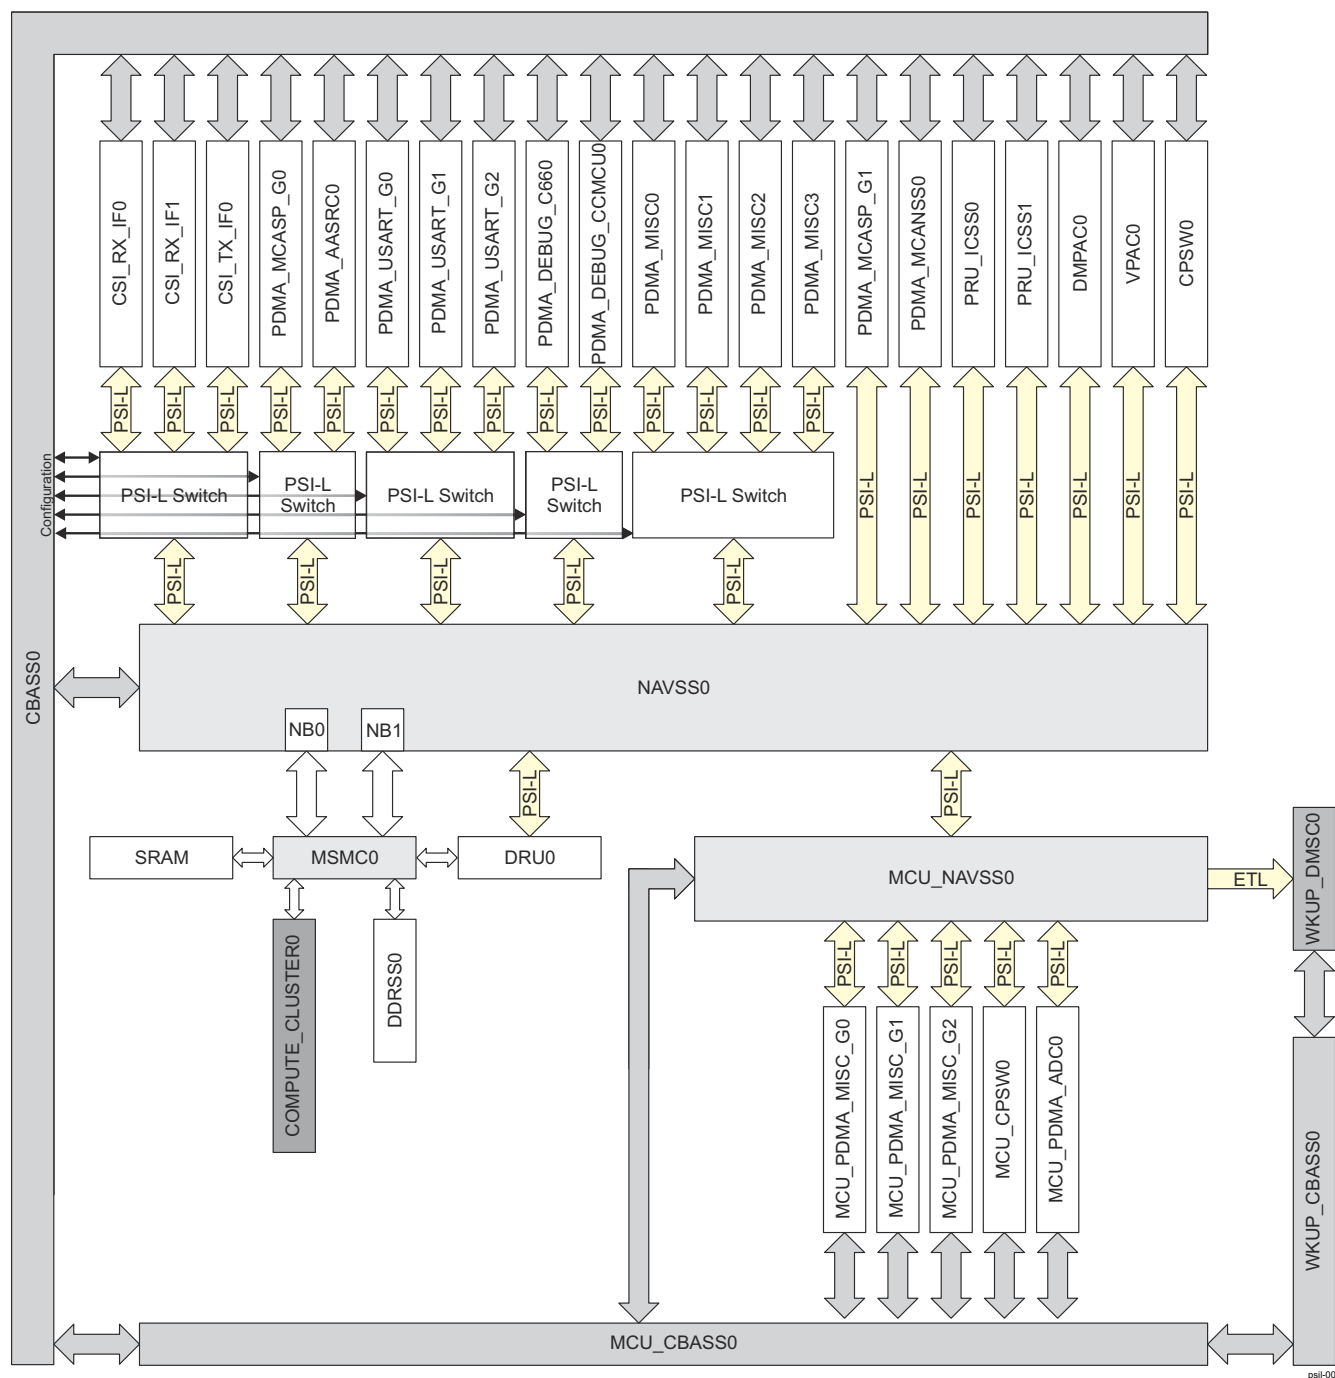

---

#### Note

For more information about the PSI-L switch (PSILSS), see *PSIL Subsystem (PSILSS)*.

---

### Figure 10-32. PSI-L Overview

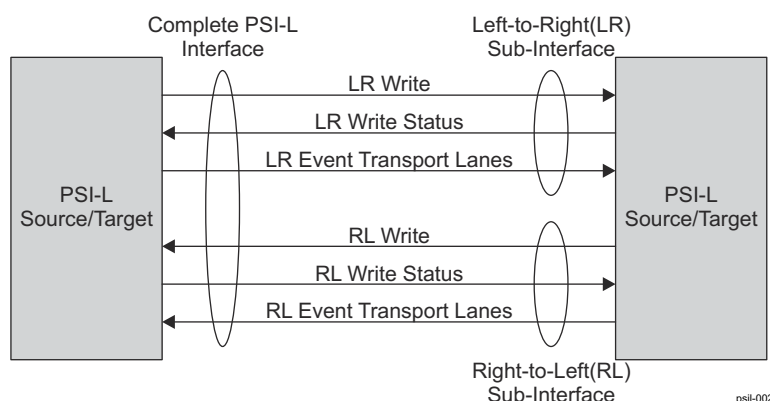

## 10.2.8.2 PSI-L Functional Description

### 10.2.8.2.1 PSI-L Introduction

The PSI-L is used to transfer words of packet data and control information between two peer entities via direct connection. There are credits used for flow control to guarantee that blocking does not occur between threads. Multiple packet transfers can be ongoing simultaneously across a PSI-L interface each on a separate logical thread but all sharing a single datapath through time division multiplexing. Each packet which is transferred is accompanied by a destination thread ID which indicates the logical destination thread to which the packet is being sent.

There is low level hardware handshake between PSI-L master and slave used for transferring data. As it is blocking by nature, a higher level protocol is also used in which credits are maintained for each thread connection. Moments of non-readiness are allowed on the interface but there is no possibility that one thread can block another for an indefinite time since a thread must have credit for the destination before it is allowed to use the interface.

Figure 10-33 illustrates the point to point PSI-L connection.

**Figure 10-33. PSI-L Connection**

PSI-L is intended to be a versatile interface which can carry various types of communications. Table 10-159 describes several types of threads which have been defined.

**Table 10-159. Types of PSI-L Threads**

Type	Description	Example Endpoints
Queue Management (QM) Messaging	Provides transport for queue push, pop, and divert messages to support distributed queue based work passing	Centralized queue manager or message manager and distributed DMA clients
Direct IO	Allows for tunneling CBASS compatible bus transactions through a PSI interconnect	Module which has no CBASS master to a remote proxy block
DMA Control Transport	Provides transport for DMA transfer descriptions from a source thread to a destination thread	DMA channel controller to DMA transfer controller
DMA Data Transport	Provides transport for packed data from a source thread to a destination thread	Packet oriented module like networking adapters to or from centralized DMA

Each thread on PSI-L is established between a single thread master and a single thread slave using a connection oriented transfer mechanism. A thread master and a thread slave are "paired" to create a logical connection between them referred to as a thread. Pairing is accomplished using a Pair Configuration Message which is valid in all thread types. Pairing can only occur between a thread master and a thread slave of the same type.

#### 10.2.8.2.2 PSI-L Operation

The PSI-L allows multiple independent streams of packet data (threads) to share a single interface using data phase granularity time division multiplexing. This time division multiplexing is accomplished by dividing each stream into single data transfers. In this way a stream is comprised of a sequence of strongly ordered data transfers but packet transfers between different streams are allowed to be interleaved. Each data phase is qualified with a type identifier which indicates whether the data is packet info, direct IO write or read info, timestamp, software info, control data, payload data, or status.

##### 10.2.8.2.2.1 Event Transport

PSI-L provides a mechanism by which events can be transported within one or more optional sub-interfaces on a link. These sub-interfaces are referred to as event transport lanes (ETLs) and are independent of any PSI-L packet or message transfers which may be ongoing on the other interfaces within the PSI-L. A maximum of one event can be transferred on each event transport lane in each clock cycle. The event transport protocol is a simple request-ready type of hardware handshake.

##### 10.2.8.2.2.2 Threads

A thread is a complete flow-controlled stream of communication. The PSI-L thread space is divided into a 32K contiguous region representing all of the source threads (0x0000 - 0x7FFF) and a 32K contiguous region representing all of the destination threads (0x8000 - 0xFFFF).

Source threads are responsible for sending request transactions, accepting response transactions, and sending data transfer transactions. Destination threads are responsible for accepting request transactions, sending response transactions, and accepting data transfer transactions. A given thread generally performs only a single class of transactions (see [Table 10-159](#)). Both source and destination threads may act as masters for transfers on one of the PSI-L write sub-interfaces but in this case source threads are actually initiating data transfers while destination threads are only responding to a previous request issued by a source request. Source threads only transfer to destination threads and destination threads only transfer to source threads. Transfers between same thread types do not occur.

The following types of message transfers always originate from source threads and terminate in destination threads:

- Configuration write message
- Configuration read message
- QM push message
- QM pop message
- QM divert message
- Direct read operation message
- Direct write operation message
- DMA transfer request message
- DMA data message

The following types of message transfers always originate in destination threads and terminate in source threads:

- Configuration write response message
- Configuration read response message
- QM push response message
- QM pop response message
- QM divert response message
- DMA transfer response message

##### 10.2.8.2.2.3 Arbitration Protocol

On each cycle, an arbiter built into the master side of each interface decides on which thread to transfer data in the next clock cycle. Both forward (from source threads) and reverse (from destination threads) direction transfers can occur across the same physical interface so the arbiter must ensure that sustained blocking of any thread can occur.

The decision about which thread to allow using the interface is based on the following factors:

1. Whether data is ready at the source to be sent
2. Whether credit exists for the thread such that it is guaranteed there is a place for the data to land in the destination endpoint. For reverse direction transfers (response messages), it is assumed that credit always exists.
3. The relative priority of the traffic that the thread is carrying for the given packet duration
4. Whether the transfer is for a forward or reverse direction thread (requests versus responses).

No thread can be considered for inclusion in arbitration unless both data is available and credit exists in the destination endpoint. For each thread which can be considered in the current arbitration cycle, the arbiter should then pick the thread with the highest priority. Reverse transfers should be considered higher priority than forward transfers.

#### **10.2.8.2.2.4 Thread Configuration**

Each source thread has programmable registers for configuring the pairing with a corresponding destination thread and for enabling data flow. Each destination thread has programmable registers for reporting the buffering capability of the thread and for enabling data flow. These registers are accessed using configuration read and write messages from a configuration host.

Each configuration write message sent from a configuration host is acknowledged with a configuration write response message from the addressed endpoint. Each configuration read message sent from a configuration host is acknowledged with a configuration read response message from the addressed endpoint.

##### **10.2.8.2.2.4.1 Thread Pairing**

Depending on the type of traffic that each source thread carries it may or may not have a fixed pairing with a destination thread.

##### **10.2.8.2.2.4.1.1 Configuration Transaction Pairing**

Configuration write and read transactions are only initiated by a special module called configuration proxy (CFG\_PROXY). Each configuration proxy in the system uses a single source thread which can initiate configuration write and read transactions to the configuration registers of every other source and destination thread in the PSI-L system. The CFG\_PROXY registers are described in *PSI-L CFG\_PROXY Registers*.

Each source thread routes to a single target thread and this pairing is specified by programming a required pairing register set for each thread. A source has no ability to change what target thread it talks to. If a source must be able to talk to different targets (or target threads), then it can either have multiple threads or a streaming switch that can be programmed to route the transfers appropriately based on specific packet fields.

##### **10.2.8.2.2.4.2 Configuration Registers Region**

The configuration registers region contains static configuration information including the settings for linking a thread source to a thread destination. These registers are described in *PSI-L Configuration Registers*. The thread ID mapping is shown in *Navigator Subsystem (NAVSS)*.

## 10.2.9 PSIL Subsystem (PSILSS)

This chapter describes the PSIL subsystem (PSILSS) in the device.

### 10.2.9.1 PSILSS Overview

The PSILSS is a PSI-L compliant hardware switch that makes the connection between PSI-L master and slave endpoints. The SoC implements the following PSILSS instances:

- PDMA\_USART\_PSILSS0
  - [3:1] switch
  - Master endpoint: NAVSS0

#### 10.2.9.1.1 PSILSS Features

Each PSILSS module supports the following features:

- Implements a PSI-L 1.2 compliant interconnect
- Integrates the configured endpoints, either master or slave, and applies clock, data width or protocol conversion when necessary
- Integrates a single level CBASS for switching traffic between multiple masters and slaves using VBUSP
  - It uses the configured data width, clock and reset for the main SCR
- Provides full connectivity between all master and all slave endpoints
- Transactions are routed based on the configured thread map to the defined slave endpoint
- Events are routed based on the configured event map to the defined slave endpoints, or the default event output for an event aggregator
- Support event endpoints that are not PSI-L but still connect to the event interconnect

## 10.2.9.2 PSILSS Functional Description

### 10.2.9.2.1 PSILSS Basic Operation

The PSILSS implements a PSI-L 1.2 interconnect between endpoints. Each endpoint connects to a CBASS that provides a CBA 4.0 VBUSP transport which is used to transport the PSI-L streams. The CBASS can implement any bridging needed for clock conversion, but any data width conversion is handled in the PSILSS as data width conversion in PSI-L requires special bridges for packing and unpacking data. In this context, a master endpoint is one that creates streams that go into the PSILSS, and a slave endpoint is one that consumes streams from the PSILSS and returns status.

The PSILSS converts the PSI-L signals to VBUSP signals in order to use the CBASS to perform the routing based on the thread maps and the requested destination thread. The CBASS performs the routing and switching of the traffic from a number of masters to a number of slaves. The masters send transactions to the CBASS. The CBASS decodes which slave is being accessed based on the signals and the map. The CBASS routes that transaction to the slave. The CBASS also arbitrates for a slave when there are multiple transactions being requested simultaneously, which can be based on transaction priority. Once a transaction is selected, the CBASS sends the transaction to the slave.

### 10.2.9.2.2 PSILSS Event Routing

The PSIL events are also routed based on the event number. An event map defines which event number range maps to the destination ETL events of that endpoint. All source events from endpoints will be routed to a destination endpoint based on this event map. When the event number does not map to any endpoint, then it is routed to a default output event interface that connects to an event aggregator to map them to interrupts.

In addition to PSI-L endpoints, event endpoints are supported. These events connect to the same event interconnect as the PSI-L endpoints and pass events in the same way. An event endpoint can be a producer or consumer of events, and the same event mapping can apply to an event or PSI-L endpoint.

### 10.2.9.2.3 PSILSS Link Down Detection

The PSILSS provides MMRs that show the current link status of all the PSIL endpoints. It also tracks and provides status MMRs of any links that went down, from being active and running to a down state when the PSILSS is not in reset. This detection can generate an event so that software can remedy the situation. The hardware does not cleanup the traffic, so software must take care to idle any traffic before an endpoint is reset, which causes the link to go down, as well as to cleanup any connections after an endpoint has gone down. Software must guarantee the endpoint link is up again before setting up new connections.

### 10.2.9.2.4 PSILSS Configuration

Table 10-161 shows the thread numbers for the PSILSS slave endpoints.

**Table 10-161. PSILSS Endpoint Thread Map**

PSILSS Instance	Endpoint	Thread Number
PDMA_DEBUG_PSILSS0	PDMA_DEBUG_CCMCU	0x4300
	PDMA_DEBUG_C66	0x4304
PDMA_AASRC_PSILSS0	PDMA_MCASP_G0	0x4400
	PDMA_AASRC	0x4404
PDMA_MISC_PSILSS0	PDMA_MISC_G0	0x4600
	PDMA_MISC_G1	0x460C
	PDMA_MISC_G2	0x4618
	PDMA_MISC_G3	0x4624
PDMA_USART_PSILSS0	PDMA_USART_G0	0x4700
	PDMA_USART_G1	0x4702
	PDMA_USART_G2	0x4704
	PDMA_MCAN	0x470C

**Table 10-161. PSILSS Endpoint Thread Map (continued)**

PSILSS Instance	Endpoint	Thread Number
CSI_PSILSS0	CSI_TX_IF0	0x4900
	CSI_RX_IF0	0x4940
	CSI_RX_IF1	0x4960

Table 10-162 through Table 10-166 provide further details about the source (src) and destination (dst) configuration parameters for the various PSILSS instances, including number of threads per endpoint. Note that the last two columns in each table present the associated source and destination thread numbers in decimal value.

**Table 10-162. PDMA\_USART\_PSILSS0 Configuration Parameters**

Endpoint	Data Width (Src / Dst)	ETL Count (Src / Dst)	Thread Count (Src / Dst)	Source Thread Map	Destination Thread Map
PDMA_STRM	128-bit / 128-bit	1 / 1	32704 / 32704	0 through 18175; 18240 through 32767	32K + 0 through 18175; 32K + 18240 through 32767
USART_G0_STRM	128-bit / 128-bit	1 / 1	2 / 2	18176 through 18177	32K + 18176 through 18177
USART_G1_STRM	128-bit / 128-bit	1 / 1	2 / 2	18178 through 18179	32K + 18178 through 18179
USART_G2_STRM	128-bit / 128-bit	1 / 1	6 / 6	18180 through 18185	32K + 18180 through 18185
MCAN_STRM	128-bit / 128-bit	1 / 1	30 / 30	18188 through 18217	32K + 18188 through 18217

## 10.2.10 NAVSS North Bridge (NB)

This section describes the North Bridge (NB) in the main Navigator Subsystem.

### 10.2.10.1 NB Overview

The North bridge bridges between CBA 4.0 compliant VBUSM interfaces and a three-threaded CBA 4.0 compliant VBUSM.C interface.

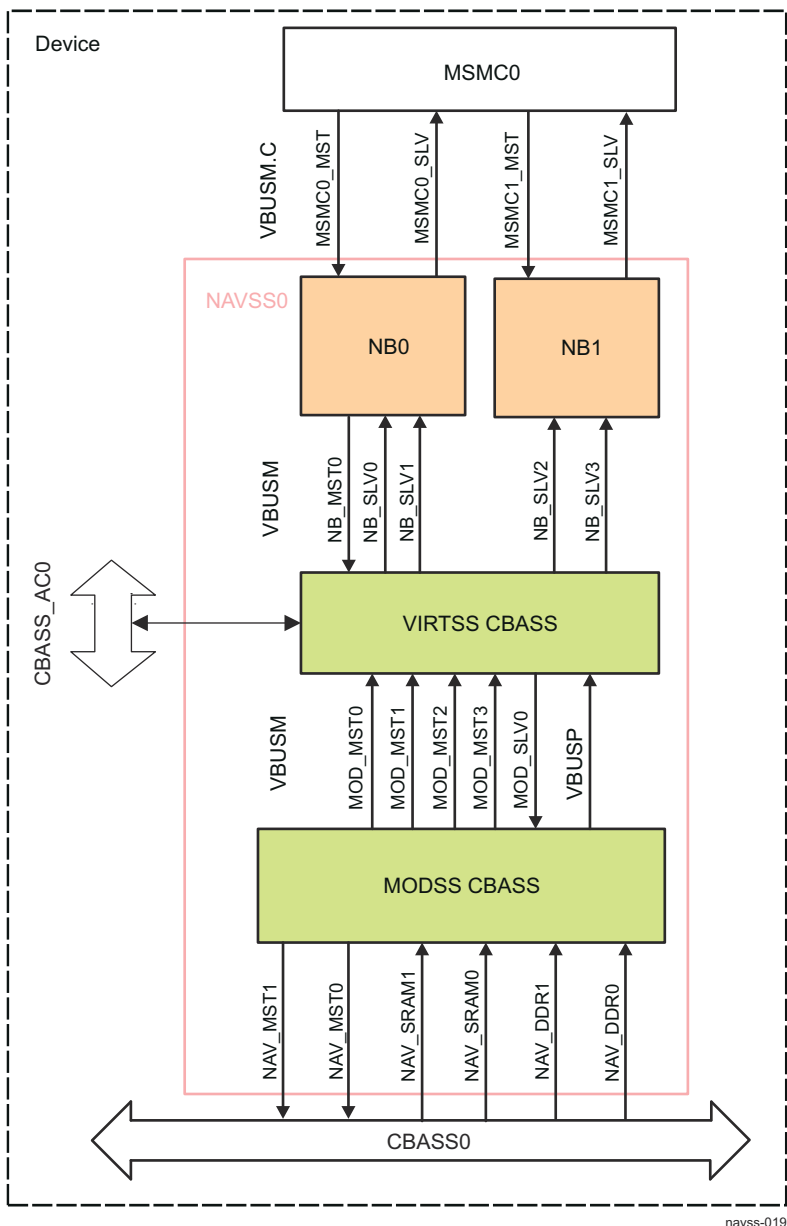

Figure 10-34. NB Overview

#### 10.2.10.1.1 Features Supported

- Implements a CBA 4.0 VBUSM to/from VBUSM.C compliant bridge
- Implements CBA 4.0 VBUSM compliant slave interface(s) to receive traffic from a VBUSM source
- Implements a CBA 4.0 VBUSM compliant master interface to create traffic to a VBUSM destination

- Implements a CBA 4.0 VBUSM.C compliant interface to receive and create traffic to and from a VBUSM.C endpoint using 3 threads
- Can optionally support fragmentation of VBUSM write commands into defined burst aligned sizes
- Can optionally support fragmentation and reassembly of VBUSM read commands into defined burst aligned sizes
- Can optionally support synchronous or asynchronous clock conversion
- Can optionally support data width conversion
- Can optionally support using the CBA 4.0 VBUSM credit interface for the VBUSM interfaces
- Allows for priority escalation through the bridge, either for higher priority pending commands inside the bridge or requesting into the bridge
- Supports the K3 clkstop idle signal
- Can optionally support a maximum outstanding read byte count to limit the total read data
- Can optionally insert memory attributes for commands
- Can optionally maintain VBUSM order based on orderid
- Allows programming the mapping of the VBUSM source interfaces to VBUSM.C threads

#### 10.2.10.1.2 NB Parameters

North Bridges are implemented in the SoC with the parameters shown in [Table 10-167](#) and [Table 10-168](#).

**Table 10-167. NB0 Configuration**

Parameter	Value	Description
Number of sources	2	The number of VBUSM source interfaces
Source 0	CBASS MSMC_SLV0 to MSMC0	Source 0
Source 1	CBASS MSMC_SLV1 to MSMC0	Source 1
source_oidmap[0]	0-7	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	8-15	
start64k	0x0060000000	This defines the starting address of the memory in VBUSM.C that uses the 64-KB table.
num64k	8192	This defines the number of entries in the 64-KB table.

**Table 10-168. NB1 Configuration**

Parameter	Value	Description
Number of sources	2	The number of VBUSM source interfaces
Source 0	CBASS MSMC_DDR_0 to MSMC1	Source 0
Source 1	CBASS MSMC_DDR_1 to MSMC1	Source 1
source_oidmap[0]	0-7	This defines the orderid mapping to the VBUSM sources. The index represents the source number. The values are integer.
source_oidmap[1]	8-15	
start16m[0]	0x0080000000	This defines the starting address of the memory in VBUSM.C that uses the 16-MB table. The index is for each of the 16-MB regions.
start16m[1]	0x0800000000	
num16m[0]	128	This defines the number of entries in the 16-MB table. The index is for each 16-MB region.
num16m[1]	8192	

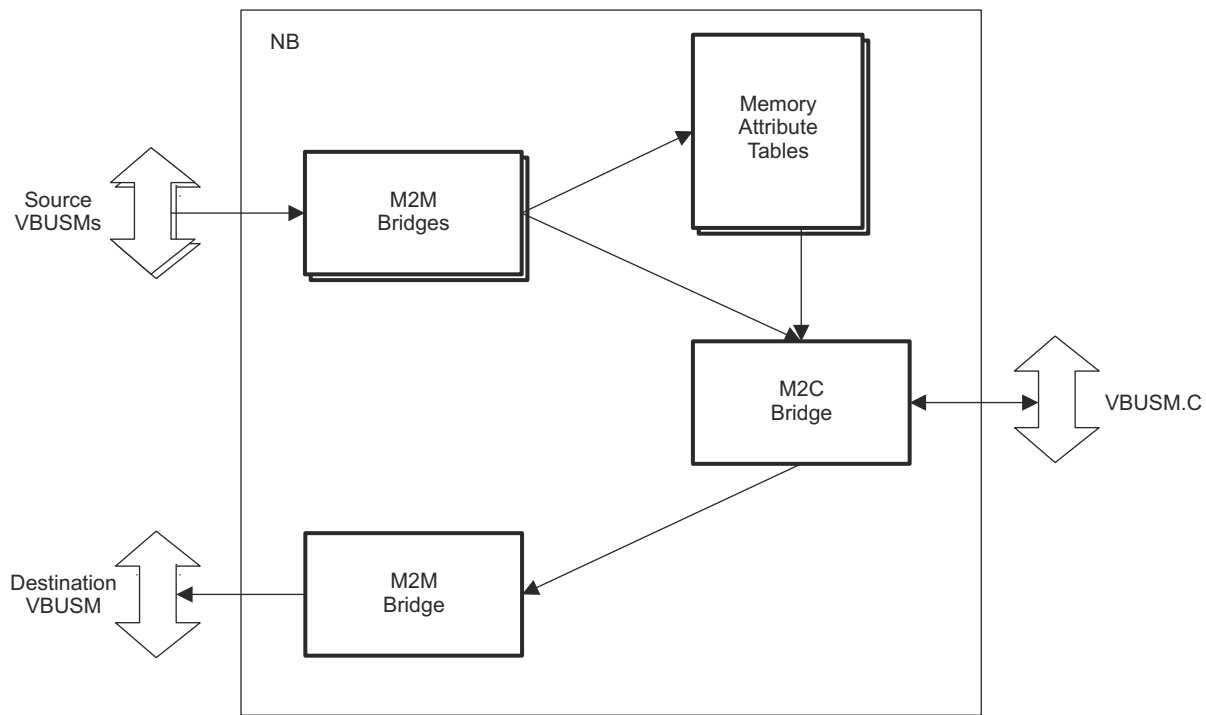

#### 10.2.10.1.2.1 Compliance to Standards

The module is compliant to the CBA 4.0 VBUSM specification and VBUSM.C annex.

#### 10.2.10.1.2.2 Features Not Supported

- Does not support fragmentation of VBUSM.C commands
- Does not support VBUSM.C coherence traffic

### 10.2.10.2 NB Functional Description

**Figure 10-35. NB Block Diagram**

The CBA 4.0 North bridge, NB, bridges between CBA 4.0 compliant VBUSM interfaces and a three threaded CBA 4.0 compliant VBUSM.C interface. This is achieved by using M2M bridges to support all the M2M features and then an M2C bridge to convert the VBUSM interfaces to a VBUSM.C interface, which support duplex traffic. The M2M bridges allow for clock frequency conversion, data width conversion and fragmentation for the Source M2M bridge(s). This allows the M2C bridge to remain simple and operate at the VBUSM.C clock frequency and data width, as well as assume all required burst limitations have already been handled. Some additional features needed for the north bridge are implemented, including: adding memory attributes to source VBUSM transactions, and forcing a maximum outstanding read data limit.

#### 10.2.10.2.1 VBUSM Slave Interfaces

The slave interfaces on the bridge is the source VBUSM port to receive commands and return data and status. These ports have the defined prefix, smX (SoC Master, input to bridge), to identify them, where the X is the number to identify each port starting from zero. The number of these interfaces and bridges is shown in [Table 10-167](#) and [Table 10-168](#).

#### 10.2.10.2.2 VBUSM Master Interface

The master interface on the bridge is the destination VBUSM port to send commands and receive data and status. These ports have the defined prefix, ss (SoC Slave, output of bridge), to identify them.

It is important to note that any feature not supported in the optional signals for this bus that is supported on the VBUSM.C interface will not be corrected inside the bridge. Examples are excluding the emudbg pin on this bus but expecting VBUSM.C transactions with emudbg set to not create bus status errors on this VBUSM bus outside the bridge (as the bridge will just pass the returned status which could be an error if it does not support the emudbg pin).

#### 10.2.10.2.3 VBUSM.C Interfaces

The pair of interfaces on the bridge is the VBUSM.C port to send and receive commands and send and receive data and status. These ports will have the defined prefix, mm (Memory Master, output of bridge) and

ms (Memory Slave, input to bridge), to identify them. These interfaces support three threads for sending and receiving traffic.

#### **10.2.10.2.3.1 Multi-Threading**

The VBUSM.C interfaces use multi-threading to support both input and output traffic on the same data signals. The threads are used to separate that traffic. Thread 0 is used for commands to VBUSM.C, thread 1 is used for commands from VBUSM.C, and thread 2 is used for realtime commands to VBUSM.C. Any responses due to commands must use the same thread when returned.

#### **10.2.10.2.3.2 Write Command Crediting**

VBUSM.C interfaces use credits for sending data phases. For writes and read responses to the MSMC (VBUSM.C consumer), there is a requirement that all credits for the write, including the command and all data phases, should be available before sending the command. Since the VBUSM.C data width is always half the max burst size on VBUSM.C, the write command must wait for a TAC credit available and 1 or 2 TDC credits available before the write can be sent.

#### **10.2.10.2.3.3 Early Credit Response**

The VBUSM.C interfaces use the credit mechanism available. They do not check for full burst available credits before sending any piece of the burst (command or data). To prevent deadlocks, the connected VBUSM.C device must support sending early credit responses, before the entire burst is received.

#### **10.2.10.2.3.4 Priority Escalation**

The VBUSM.C interface does not natively define a mechanism for priority escalation, since the cepriority signal is only valid when a command is sent, and can otherwise be ignored. To support this feature this bridge supports updating the cepriority output even if there is no valid command, so identify the highest priority of any pending commands when the bridge cannot sent a command, such as due to a lack of credits. The VBUSM.C consumer can assume the cepriority output from this bridge is always valid every cycle, and use the cepriority along with the priorities of all pending commands. When there are no pending commands, the cepriority output will be the lowest priority, 7.

#### **10.2.10.2.4 Source M2M Bridges**

The source M2M bridges perform all the usual bridging functions from the source VBUSM interface to an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface. It also performs the fragmentation to sizes the VBUSM.C interface requires. It additionally performs full read data reassembly, orderid based ordering, and read data cacheline conversion.

#### **10.2.10.2.5 Destination M2M Bridge**

The destination M2M bridge performs all the usual bridging functions to the destination VBUSM interface from an internal VBUSM interface running at the same clock frequency and data width of the VBUSM.C interface.

#### **10.2.10.2.6 M2C Bridge**

The M2C bridge performs the protocol conversion and multi-threading of the VBUSM.C interface from the internal VBUSM interfaces. It also handles the cacheline conversion of the write data.

A VBUSM.C write with a dtype of 1 (CPU instruction) will be converted to a VBUSM write with a dtype of 0 (CPU data), as this condition is allowed in VBUSM.C but not in VBUSM.

#### **10.2.10.2.7 Memory Attribute Tables**

The bridge can optionally include a memory attribute lookup table to add the coherence memory attributes required for VBUSM.C for VBUSM commands missing them. It is implemented using up to 4 tables, a table of 64-KB regions and 1 to 3 tables of 16-MB regions. The first table is meant to cover an internal memory with smaller granularity, while the second to fourth tables are meant to cover the external memory with a much larger size and larger granularity. The external memory has one to three regions as its address space might be fragmented in the SoC memory map. Starting address and number of table entries for each region are shown in [Table 10-167](#) and [Table 10-168](#).

When a command without memory attributes, an `atype = 0`, is input to the M2C bridge, this table performs the lookup in parallel and returns the memory attributes to the M2C bridge in the next cycle. If the `atype` is another value, it is assumed the memory attributes on the VBUSM interface are valid. The lookup is performed by matching the address against the starting addresses, assuming the successive regions always starts at later address, including that the up to three 16-MB regions are given in increasing order. Then the offset from the starting address of the region and the region size, 64-KB or 16-MB, is used to calculate the entry of attributes for that address. Then a memory is read to retrieve the attributes and return them to the M2C bridge. An output FIFO is implemented to capture the attributes if they are not accepted immediately.

There is a memory attribute table module for each VBUSM slave interface. If the MAT is enabled, at least one of the 64-KB region and/or the first 16-MB region must be populated, or both. The second and third 16-MB regions are optional.

#### **10.2.10.2.8 Outstanding Read Data Limiter**

If a param defines a maximum outstanding read data byte count, then this function will track the requested read bytes against the limit. If a read command does not violate the total read bytes outstanding limit then the read is allowed to the VBUSM.C, otherwise it is stalled. When read data arrives from the VBUSM.C the outstanding count is reduced, allowing more read commands to be sent.

#### **10.2.10.2.9 Ordering**

Ordering becomes a concern due to the fact that the VBUSM commands are fragmented and not guaranteed to be returned in order by the VBUSM.C interface. This violates the CBA ordering rules for a single slave endpoint. So the bridge will force read data ordering based on the `orderid` signal across all masters, as a balance between cost and performance. This means that each read command received from the VBUSM interface with a particular `orderid` value will have their read data returned in exactly the same order. This means that even if the reads are from different masters, the data will still be returned in order, to reduce the amount of tracking the bridge has to perform. But, if the reads use different `orderid` values then that read data can be returned in any order, whichever is received first on the VBUSM.C interface.

#### **10.2.10.2.10 Quality of Service**

To support quality of service, QoS, the north bridge allows for configuring multiple VBUSM source interfaces. This not only allows defining particular sources to be realtime to achieve better qos, but also to load balance and effectively utilize any extra bandwidth provided by the VBUSM.C interface. There are registers (`NB_THREADMAP`) allowing programming of which source interfaces map to which of the two VBUSM.C threads, normal or realtime traffic. All traffic on the source will always map to the defined thread.

Any sources mapped to the realtime thread will be arbitrated first, before any sources mapped to the normal thread, to provide the QoS. If there are multiple sources mapped to the same thread then they are arbitrated based on priority and if they are the same priority then by round robin.

To route return traffic from the VBUSM.C back to the correct VBUSM source, the `orderid` is used. As such, each source mapped to each thread must use a different `orderid` value in the SoC. This would mean that if there are 8 sources total, with 4 mapped to each thread, then each group of 4 should not share the same `orderid` for any traffic routed to it in the SoC to keep their `pathid` values unique. The bridge is configured to identify which VBUSM source uses which `orderid` value(s).

#### **10.2.10.2.11 IDLE Behavior**

The north bridge IDLE output is a combination of all the IDLE outputs from the components. These are combined and registered as the NB IDLE on the Destination VBUSM bus clock.

#### **10.2.10.2.12 Clock Power Management**

The north bridge provides internal clock power management for all major components: bridges and register modules. Each component will track its own activity and shut off the clock tree when there has been no activity for 12 cycles. There is a 1 cycle latency for starting up the clock once off, so bus transactions may be initially stalled. The bus early wakeup signals can be used to wakeup the clocks before the transactions arrives to remove some of the latency impact.

## 10.3 Peripheral DMA (PDMA)

This chapter describes the PDMA architecture in the device.

### 10.3.1 PDMA Controller

#### 10.3.1.1 PDMA Overview

The Peripheral DMA is a simple DMA which has been architected to specifically meet the data transfer needs of peripherals, which perform data transfers using memory mapped registers (MMRs) accessed via a standard non-coherent bus fabric. The PDMA module is located close to one or more peripherals which require an external DMA for data movement and is architected to reduce cost by using VBUSP interfaces and supporting only statically configured Transfer Request (TR) operations.

The PDMA is only responsible for performing the data movement transactions which interact with the peripherals themselves. Data which is read from a given peripheral is packed by a PDMA source channel into a PSI-L data stream which is then sent to a remote peer UDMA-P destination channel which then performs the movement of the data into memory. Likewise, a remote UDMA-P source channel fetches data from memory and transfers it to a peer PDMA destination channel over PSI-L which then performs the writes to the peripheral.

The PDMA architecture is intentionally heterogeneous (UDMA-P + PDMA) to right size the data transfer complexity at each point in the system to match the requirements of whatever is being transferred to or from. Peripherals are typically FIFO based and do not require multi-dimensional transfers beyond their FIFO dimensioning requirements, so the PDMA transfer engines are kept simple with only a few dimensions (typically for sample size and FIFO depth), hardcoded address maps, and simple triggering capabilities.

Multiple source and destination channels are provided within the PDMA which allow multiple simultaneous transfer operations to be ongoing. The DMA controller maintains state information for each of the channels and employs round-robin scheduling between channels in order to share the underlying DMA hardware.

There are several PDMA modules in the device. [Table 10-169](#) shows PDMA allocation across device domains.

**Table 10-169. PDMA Allocation Across Device Domains**

PDMA Instance	Serviced Peripherals	Domain		
		WKUP	MCU	MAIN

PDMA13 (PDMA_USART_G0)	UART0, UART1	–	–	✓
PDMA14 (PDMA_USART_G1)	UART2, UART3	–	–	✓
PDMA15 (PDMA_USART_G2)	UART4 to UART9	–	–	✓

The PDMA is linked to the UDMA-P (NAVSS) either through a direct PSI-L connection, or through a PSI-L switch (PSILSS). For more details, refer to:

- [Section 10.2, Navigator Subsystem \(NAVSS\)](#)
- [Section 10.2.8, Packet Streaming Interface Link \(PSI-L\)](#)
- [Section 10.2.9, PSIL Subsystem \(PSILSS\)](#)

#### **10.3.1.1.1 PDMA Features**

##### **10.3.1.1.1.1 MCU\_PDMA0 (MCU\_PDMA\_MISC\_G0) Features**

The MCU domain PDMA0 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access units (write unit 0)
  - Provides a 32-bit wide VBUSP write only master interface for peripheral accesses
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0):
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 7 simultaneous destination (Tx) channels
- Supports up to 7 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

##### **10.3.1.1.1.2 MCU\_PDMA1 (MCU\_PDMA\_MISC\_G1) Features**

The MCU domain PDMA1 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 8 simultaneous destination (Tx) channels
- Supports up to 8 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

##### **10.3.1.1.1.3 MCU\_PDMA2 (MCU\_PDMA\_MISC\_G2) Features**

The MCU domain PDMA2 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)

- Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
- Supports read burst up to 64 bytes (on selected channel types)
- Supports 1 outstanding read
- Supports up to 4 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.1.4 MCU\_PDMA3 (MCU\_PDMA\_ADC) Features

The MCU domain PDMA3 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 4 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.1.5 PDMA0 (PDMA\_AASRC) Features

The MAIN domain PDMA0 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 8 simultaneous destination (Tx) channels
- Supports up to 8 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports AASRC transfer mode only (does not support X-Y and MCAN)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.1.6 PDMA2 (PDMA\_DEBUG\_CCMCU) Features

The MAIN domain PDMA2 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 3 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.7 PDMA3 (PDMA\_DEBUG\_C66) Features

The MAIN domain PDMA3 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 0 memory write access units
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 0 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.8 PDMA5 (PDMA\_MCAN) Features

The MAIN domain PDMA5 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 30 simultaneous destination (Tx) channels
- Supports up to 30 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports MCAN transfer mode only (does not support X-Y and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

- Provides ECC support

#### **10.3.1.1.1.9 PDMA6 (PDMA\_MCASP\_G0) Features**

The MAIN domain PDMA6 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 3 simultaneous destination (Tx) channels
- Supports up to 3 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.10 PDMA7 (PDMA\_MCASP\_G1) Features**

The MAIN domain PDMA7 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 9 simultaneous destination (Tx) channels
- Supports up to 9 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.11 PDMA8 (PDMA\_MISC\_G0) Features**

The MAIN domain PDMA8 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read

- Supports up to 11 simultaneous destination (Tx) channels
- Supports up to 11 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.12 PDMA9 (PDMA\_MISC\_G1) Features**

The MAIN domain PDMA9 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 11 simultaneous destination (Tx) channels
- Supports up to 11 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.13 PDMA10 (PDMA\_MISC\_G2) Features**

The MAIN domain PDMA10 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 11 simultaneous destination (Tx) channels
- Supports up to 11 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.14 PDMA11 (PDMA\_MISC\_G3) Features**

The MAIN domain PDMA11 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 11 simultaneous destination (Tx) channels
- Supports up to 11 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y and MCAN transfer modes (does not support AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.15 PDMA13 (PDMA\_USART\_G0) Features

The MAIN domain PDMA13 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### 10.3.1.1.16 PDMA14 (PDMA\_USART\_G1) Features

The MAIN domain PDMA14 supports the following features:

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 2 simultaneous destination (Tx) channels
- Supports up to 2 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:

- Provides 8×128-bit word deep data FIFO for each destination channel
- Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

#### **10.3.1.1.1.17 PDMA15 (PDMA\_USART\_G2) Features**

The MAIN domain PDMA15 supports the following features:

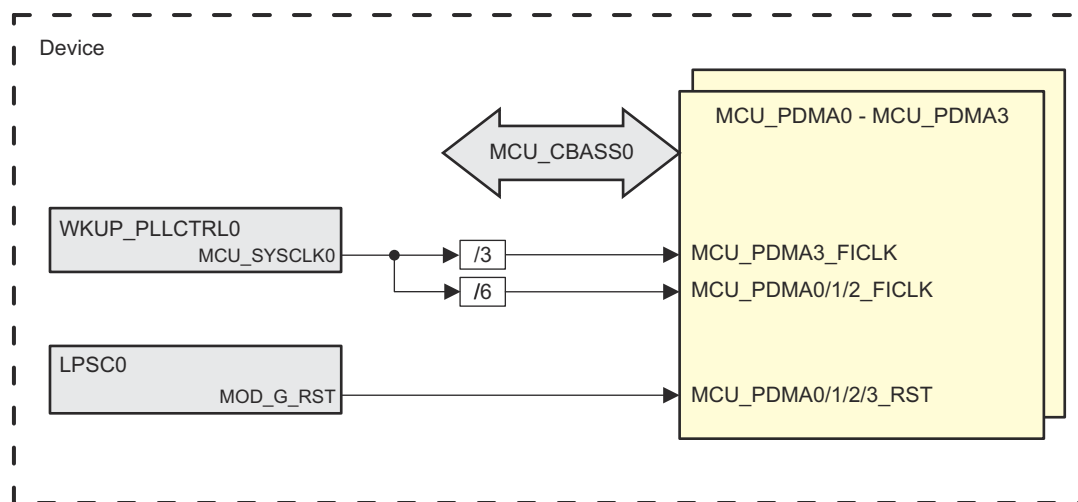

- Implements CPPI 5.0 compliant third-party Unified Transfer Controller (UTC)
- Provides 1 memory write access unit (write unit 0):
  - Provides a 32-bit wide VBUSP write-only master interface for peripheral accesses.
  - Supports write bursts up to 64 bytes (on selected channel types)
- Provides 1 memory read access unit (read unit 0)
  - Provides a 32-bit wide VBUSP read-only master interface for peripheral accesses
  - Supports read burst up to 64 bytes (on selected channel types)
  - Supports 1 outstanding read
- Supports up to 6 simultaneous destination (Tx) channels
- Supports up to 6 simultaneous source (Rx) channels
- Supports static transfer requests (TR) only
- Supports X-Y transfer mode only (does not support MCAN and AASRC)
- Provides per-channel buffering:
  - Provides 8×128-bit word deep data FIFO for each destination channel
  - Provides 8×128-bit word deep data FIFO for each source channel
- Provides 128-bit wide PSI-L compliant data interface to remote UDMA-P and remote peripherals
- Provides 128-bit wide PSI-L compliant data interface from remote UDMA-P and remote peripherals

### 10.3.1.2 PDMA Integration

This section describes the PDMA integration in the device, including information about clocks, resets, and hardware requests.

#### 10.3.1.2.1 PDMA Integration in MCU Domain

Figure 10-36 shows the integration of the PDMA modules in the device MCU domain.

**Figure 10-36. MCU Domain PDMA Integration**

Table 10-170 through summarize the integration of PDMA modules in the device MCU domain.

**Table 10-170. MCU Domain PDMA Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_PDMA0 (MCU_PDMA_MISC_G0)	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_PDMA1 (MCU_PDMA_MISC_G1)	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_PDMA2 (MCU_PDMA_MISC_G2)	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_PDMA3 (MCU_PDMA_ADC)	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

**Table 10-171. MCU Domain PDMA Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_PDMA0	MCU_PDMA0_FICLK	MCU_SYSCCLK0/3	WKUP_PLLCTRL0	MCU_PDMA0 functional and interface clock
MCU_PDMA1	MCU_PDMA1_FICLK	MCU_SYSCCLK0/3	WKUP_PLLCTRL0	MCU_PDMA1 functional and interface clock
MCU_PDMA2	MCU_PDMA2_FICLK	MCU_SYSCCLK0/3	WKUP_PLLCTRL0	MCU_PDMA2 functional and interface clock
MCU_PDMA3	MCU_PDMA3_FICLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	MCU_PDMA3 functional and interface clock

Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
MCU_PDMA0	MCU_PDMA0_RST	MOD_G_RST	LPSC0	MCU_PDMA0 hardware reset
MCU_PDMA1	MCU_PDMA1_RST	MOD_G_RST	LPSC0	MCU_PDMA1 hardware reset

**Table 10-171. MCU Domain PDMA Clocks and Resets (continued)**

MCU_PDMA2	MCU_PDMA2_RST	MOD_G_RST	LPSC0	MCU_PDMA2 hardware reset
MCU_PDMA3	MCU_PDMA3_RST	MOD_G_RST	LPSC0	MCU_PDMA3 hardware reset

### 10.3.1.2.2 PDMA Integration in MAIN Domain

Figure 10-37 shows the integration of the PDMA modules in the device MAIN domain.

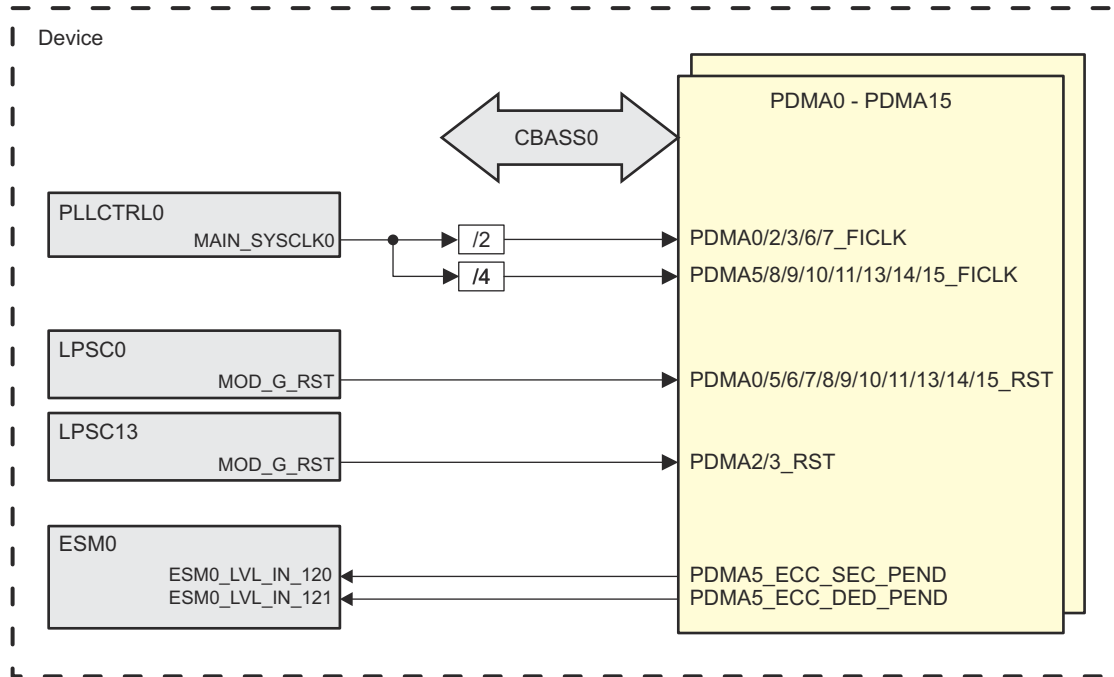

**Figure 10-37. MAIN Domain PDMA Integration**

Table 10-172 through Table 10-174 summarize the integration of the PDMA modules in the device MAIN domain.

**Table 10-172. MAIN Domain PDMA Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
PDMA0 (PDMA_AASRC)	PSC0	PD0	LPSC0	CBASS0
PDMA2 (PDMA_DEBUG_CCMCU)	PSC0	PD0	LPSC13	CBASS0
PDMA3 (PDMA_DEBUG_C66)	PSC0	PD0	LPSC13	CBASS0
PDMA5 (PDMA_MCAN)	PSC0	PD0	LPSC0	CBASS0
PDMA6 (PDMA_MCASP_G0)	PSC0	PD0	LPSC0	CBASS0
PDMA7 (PDMA_MCASP_G1)	PSC0	PD0	LPSC0	CBASS0
PDMA8 (PDMA_MISC_G0)	PSC0	PD0	LPSC0	CBASS0
PDMA9 (PDMA_MISC_G1)	PSC0	PD0	LPSC0	CBASS0
PDMA10 (PDMA_MISC_G2)	PSC0	PD0	LPSC0	CBASS0
PDMA11 (PDMA_MISC_G3)	PSC0	PD0	LPSC0	CBASS0
PDMA13 (PDMA_USART_G0)	PSC0	PD0	LPSC0	CBASS0
PDMA14 (PDMA_USART_G1)	PSC0	PD0	LPSC0	CBASS0
PDMA15 (PDMA_USART_G2)	PSC0	PD0	LPSC0	CBASS0

**Table 10-173. MAIN Domain PDMA Clocks and Resets**

Clocks
--------

**Table 10-173. MAIN Domain PDMA Clocks and Resets (continued)**

Module Instance	Module Clock Input	Source Clock Signal	Source	Description
PDMA0	PDMA0_FICLK	MAIN_SYSCLK0/2	PLLCTRL0	PDMA0 functional and interface clock
PDMA2	PDMA2_FICLK	MAIN_SYSCLK0/2	PLLCTRL0	PDMA2 functional and interface clock
PDMA3	PDMA3_FICLK	MAIN_SYSCLK0/2	PLLCTRL0	PDMA3 functional and interface clock
PDMA5	PDMA5_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	PDMA5 functional and interface clock
PDMA6	PDMA6_FICLK	MAIN_SYSCLK0/2	PLLCTRL0	PDMA6 functional and interface clock
PDMA7	PDMA7_FICLK	MAIN_SYSCLK0/2	PLLCTRL0	PDMA7 functional and interface clock
PDMA8	PDMA8_FICLK	MAIN_SYSCLK0/4	PLLCTRL0	PDMA8 functional and interface clock

### 10.3.1.3 PDMA Functional Description

#### 10.3.1.3.1 PDMA Functional Blocks

Figure 10-38 shows the PDMA block diagram.

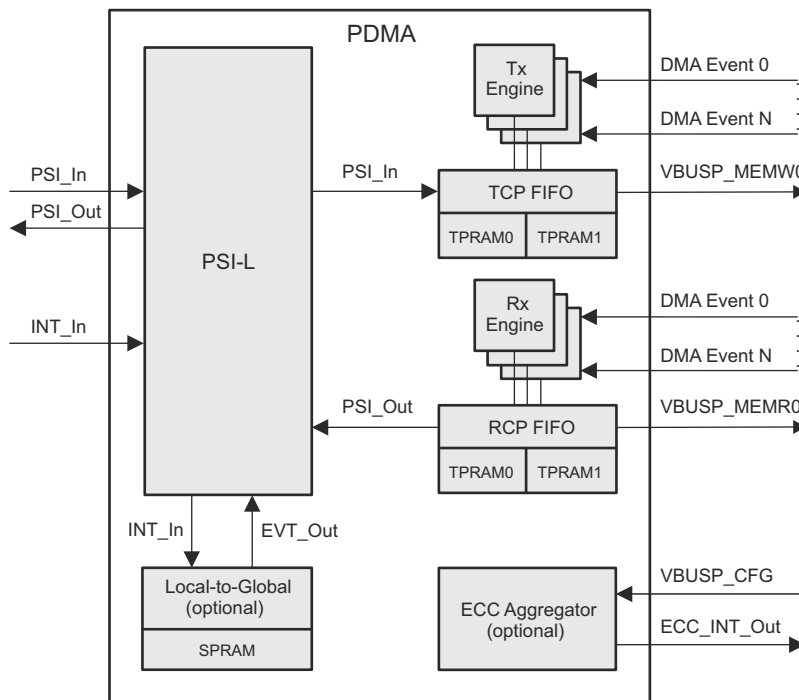

Figure 10-38. PDMA Block Diagram

#### Note

For detailed description of the PSI-L interface, see [Section 10.2.8, Packet Streaming Interface Link \(PSI-L\)](#).

##### 10.3.1.3.1.1 Scheduler

The scheduler block is responsible for monitoring the fullness level of the various FIFOs, monitoring input DMA triggering events, maintaining channel state information, and issuing credits to the Tx and Rx DMA units when it is time to perform each low-level read or write operation.

##### 10.3.1.3.1.2 Tx Per-Channel Buffers (TCP FIFO)

The Tx per-channel buffers implement channelized FIFOs for each DMA channel. A single logical data FIFO is provided for each destination DMA channel that is used for buffering payload data that has been pushed into the PDMA from the Tx PSI-L interface. The Tx per-channel buffers are always written with full Tx PSI-L wide words (except for EOL/EOP data phases) but are read on byte granularity from the Tx DMA units.

##### 10.3.1.3.1.3 Tx DMA Unit (Tx Engine)

The Tx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC destination channels. The Tx DMA unit waits until it is triggered by an incoming DMA event and then writes data from the Tx per-channel data FIFO associated with the channel to an external memory mapped target via a VBUSP master interface. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

#### 10.3.1.3.1.4 Rx Per-Channel Buffers (RCP FIFO)

The Rx per-channel buffers implement a logical FIFO for each source DMA channel that is used for buffering payload data that has been fetched by the Rx DMA units. The buffers are byte-oriented on write so that the data from the Rx DMA units, which may not be full words, can be packed properly. The buffers are word-oriented on read in accordance with the transport mechanism outlined in the PSI-L interface specification. Each channel in the Rx DMA controller maps directly onto a thread in the Rx PSI-L interface.

The Rx per-channel buffers block outputs queue fullness information to the scheduler block, which it then uses to determine when it should initiate DMA opportunities to backfill the buffers. The Rx per-channel buffers will initiate transfers to the remote paired thread whenever any data is available in each channel buffer and credits are available in the corresponding thread. The block will simultaneously monitor the status of all of the threads and will perform a round-robin arbitration between the different threads for the use of the Rx PSI-L interface. Each thread for which the target is indicating it can accept data and which currently has data available in the channel buffer will be included in the arbitration.

#### 10.3.1.3.1.5 Rx DMA Unit (Rx Engine)

The Rx DMA unit block implements all of the state machine functionality necessary to implement static TR type UTC source channels. The Rx DMA unit waits until it is triggered by an incoming DMA event and then reads data from an external memory mapped source via a VBUSP master read interface into the Rx per-channel data FIFO associated with the channel. The number and width of the writes that are performed is in accordance with the parameters, which have been programmed via PSI-L into the static TR for the channel.

#### 10.3.1.3.2 PDMA General Functionality

##### 10.3.1.3.2.1 Operational States

At any given time the PDMA can be in one of three different states as follows:

- **INIT:** This is the initial state of the machine during and immediately after reset. During this state, all of the RAMs inside the PDMA will be initialized to known values including the ECC redundant parity bits. While in the INIT state, the DMA will de-assert all 'ready' signals on all applicable slave interfaces and will de-assert all 'request' signals on all applicable master interfaces. The PDMA will automatically transition out of the INIT state into the IDLE state when all of the RAM initialization has been completed.
- **IDLE:** Once the PDMA leaves the INIT state, it enters the IDLE state whenever no outstanding transactions are pending on any of the PDMA interfaces (master or slave). The IDLE state is generally a transient state and is used by the PDMA to determine when it is appropriate to allow the SoC power management complex to turn off the clock. As channels have work queued on them and transactions begin flowing into the system, the PDMA transitions to the ACTIVE state. When no more work is pending, or when the host pauses/disables active channels, or when the power management complex on the SoC desires to shut down the PDMA and asserts 'clock stop request', the PDMA will account for any outstanding transactions and will re-enter the IDLE state. The PDMA leaves the IDLE state anytime it generates or receives a transactions that requires a return response as those protocols dictate that the clock must remain running to avoid faulting the handshaking protocol.
- **ACTIVE:** The PDMA enters the ACTIVE state as soon as it issues a transaction or receives a transaction on any interface that uses a split protocol (expects a later response for a request). When all transactions have been accounted for (responses have all been either received or sent), the PDMA transitions to the IDLE state.

##### 10.3.1.3.2.2 Clock Stop

The clock stop interface allows the PDMA to be gracefully commanded to shut down its operations and enter into an IDLE state so that the main clock can be stopped. When the 'clock stop request' input is asserted, the PDMA will stop processing TRs for each channel at the next TR boundary. Once all of the channels have gracefully reached the end of their current TRs, the PDMA will assert the 'clock stop acknowledge' output. Once the PDMA has entered the IDLE state, it will remain there until the 'clock stop request' is de-asserted.

### 10.3.1.3.2.3 Emulation Control

The emulation control input (EMUSUSP) and the per-channel emulation control FREE bit allow PDMA operation to be suspended on a per-channel basis. When the emulation suspend state is entered, the PDMA will stop processing receive and transmit TRs for each channel at the next TR boundary. Any TR currently in reception or transmission will be halted at its next FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR.

Emulation control is implemented for compatibility with other peripherals. Each source and destination channel can be configured to either honor the suspend signal, or to 'free run' without regard to suspend. This is controlled via the PDMA\_PSILCFG\_TX\_RT\_ENABLE / PDMA\_PSILCFG\_RX\_RT\_ENABLE[0] FREE bit.

### 10.3.1.3.3 PDMA Events and Flow Control

The following sections describe the simplified mechanism that is provided on the PDMA for triggering and completion event generation.

#### 10.3.1.3.3.1 Channel Types

Each channel in the PDMA is configured at design time (and cannot be changed by software) to be either standard X-Y FIFO mode or MCAN channel or AASRC channel. Either of these two sections provide information about the channel type support in the device:

- [Section 10.3.1.1.1, PDMA Features](#)
- [Section 10.3.2, PDMA Sources](#)

When reading the sections below, ignore any information that concerns unsupported channel type.

#### 10.3.1.3.3.1.1 X-Y FIFO Mode

Most peripherals which are serviced by the PDMA follow the pattern of transferring 'X' bytes from a fixed, non-changing address in a burst 'Y' times for each triggering event that is received. The 'X' parameter is typically 1-16 bytes and the 'Y' parameter can be any integer up to 2048.

#### 10.3.1.3.3.1.2 MCAN Mode

The MCAN module is found to require a few minor differences than standard X-Y mode. First, buffer ownership on transmit is different in that the PDMA will start out owning the TX buffer space (instead of waiting for an initial DMA event from the MCAN). There is also a requirement to perform a write of a fixed value to a fixed address after each DMA event is serviced to pass ownership of a buffer back to the MCAN. Finally, there is an MCAN packet fragmentation requirement to place an 8-byte header on each 64-byte chunk that is transmitted and to remove the header from each 64-byte chunk (other than the first block) that is received.

#### 10.3.1.3.3.1.3 AASRC Mode

The AASRC mode of the PDMA is similar to the X-Y mode in that X specifies the sample width, any Y specifies the number of FIFO samples to transfer per DMA request, but in addition to this, a programmable FIFO list is supplied that allows a single PDMA channel to transfer data to multiple FIFOs. The FIFO list specifies which FIFOs to access, and in which order to access them. Both AASRC 'stream' and 'group' modes are supported in terms of DMA signalling and the FIFO memory map. When in AASRC mode, the entire PDMA operates exclusively in this mode. AASRC channels do not share the same PDMA as do XY and MCAN channels.

The following additional details apply to the PDMA in AASRC mode:

- Main features:
  - Up to 16 independent RX channels and 16 TX channels
    - Each channel represents a different data stream to either the UDMA-P or a McASP PDMA
  - Each channel can be configured to read or write any of the AASRC FIFOs in any order
  - Packing support for 1, 2, 3, and 4 byte samples
    - Can directly talk to a McASP using any McASP data format
    - Packing sample size is fixed for a given channel

- Supports both 'group' and 'stream' AASRC signaling and FIFO memory maps
  - There is a single stream/group mode setting for each PDMA channel
- Additional details:
  - Each channel has a 'mask' of which DMA requests must fire to activate the channel
    - In stream mode, the mask specifies the all the FIFO DMA requests that must fire
    - In group mode, the mask specifies the one group DMA request that must fire
  - Each channel specifies an ordered list of how FIFOs should be accessed
    - All channels use a common list, specifying a range of entry indices within that list
      - This allow each channel to use a varying number of list elements
    - The order list can be processed multiple times per DMA request
      - The number of samples to be transferred per request must match the configured threshold for the DMA request in the AASRC
  - All FIFOs are specified by index only
    - In the TX ordering table, the indices are assumed to be TX FIFOs
    - In the RX ordering table, the indices are assumed to be RX FIFOs
    - If a DMA channel is in group mode, the PDMA assumes the indices referenced by that channel represent group mode FIFOs; otherwise, it assumes stream mode FIFOs
  - The PDMA has configured base addressed and inter-FIFO spans such that is can always convert from a FIFO index to the proper Stream or Group mode FIFO address

#### 10.3.1.3.3.1.4

#### 10.3.1.3.3.2 Channel Triggering

Channels must be triggered in order for them to perform work. A local event input bus is provided on the PDMA and each bit in the input bus corresponds to the trigger for the channel with the same channel index as the bit index in the bus (bit 0 triggers channel 0, bit 1 triggers channel 1, etc.).

The PDMA provides a 2-bit counter per event input to accommodate startup latency in the channel.

#### 10.3.1.3.3.3 Completion Events

All transfers on PDMA are split TRs in that they have a UDMA-P half and a (static) PDMA half. Completion events are designed to be triggered from the UDMA-P half of the split TR.

#### 10.3.1.3.4 PDMA Transmit Operation

##### 10.3.1.3.4.1 Destination (Tx) Channel Allocation

A total of  $N$  destination channels are provided within the PDMA for concurrent transfers from Tx per-channel buffers to the various attached peripherals, where  $N$  is a design-time configurable paramater. Each Tx channel requires a single PSI-L thread. See [Section 10.3.2](#) for Tx channel allocation for each PDMA.

##### 10.3.1.3.4.2 Destination (Tx) Channel Out-of-Band Signals

[Table 10-175](#) shows how PSIL signals are handled for destination channels.

**Table 10-175. Tx Channel Out-of-Band Signals**

PSI-L Signal	XY/AASRC Mode	MCAN Mode
SOP	Ignored	Ignored
EOP	Ignored	Closes current MCAN packet
SOL	Ignored	Ignored
EOL	Ignored	Ignored
DROP	Ignored	Ignored
PKT_ERROR	Ignored	Ignored
PAUSE	Ignored	Ignored
TDOWN	Reflect in status; teardown when data marker reached	Reflect in status; teardown when data marker reached

#### 10.3.1.3.4.3 Destination Channel Initialization

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a UDMA-P channel), setup the static TR for the channel, and enable the thread.

##### 10.3.1.3.4.3.1 PSI-L Destination Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each destination PDMA channel with (typically) a corresponding source channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the UDMA-P will send all their data to the destination channel in the PDMA and the destination channel in the PDMA will never see any data other than data from the source channel in the UDMA-P.

The following PSI-L registers are related to destination thread pairing:

- PDMA\_PSILCFG\_TX\_ENABLE
- PDMA\_PSILCFG\_TX\_CAPABILITIES
- PDMA\_PSILCFG\_TX\_BYTE\_COUNT
- PDMA\_PSILCFG\_TX\_RT\_ENABLE

Refer to their descriptions for further details.

##### 10.3.1.3.4.3.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will send configuration transactions across PSI-L and will setup the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X' and 'Y' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

##### 10.3.1.3.4.3.3

- PDMA\_PSILCFG\_TX\_STATIC\_TR[26-24] X
- PDMA\_PSILCFG\_TX\_STATIC\_TR[11-0] Y

Refer to their descriptions for further details.

##### 10.3.1.3.4.3.4 PSI-L Destination Thread Enables

PSI-L destination threads must first be enabled in order to accept data. Threads are enabled or disabled by setting or clearing the ENABLE bit in the PSI-L pairing registers for the thread. When a thread is disabled, it must drop any data phases which are sent but properly return the credits for the data phases which are dropped.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of write transactions.

##### 10.3.1.3.4.4 Data Transfer

Packet transmission is accomplished within the PDMA by unpacking and moving data from the Tx per-channel FIFOs which were filled via the transmit PSI-L interface to specified memory mapped address ranges via the VBUSP master interfaces. On the Tx side of the PDMA, these transfers are always writes. Each write transfer which is performed by the Tx DMA unit is to a destination address that is hardcoded in the channel at design time and of a size as specified in the static transfer request.

The sequences of logical transactions that are performed by the PDMA on the memory interface during transmit is dependent on the channel type. The following sections describe what will happen for the two different channel types.

##### 10.3.1.3.4.4.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter writes of 'X' parameter bytes to the data FIFO address specified for the channel. Each write that the DMA performs will be a single

'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the Tx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 10.3.1.3.4.4.1.1 X-Y FIFO Burst Mode

The burst mode for XY is designed to allow the PDMA to burst across a FIFO region, while extracting out the 'sample size' from each data phase. So for example, it can read a "burst" of multiple 32-bit words from a McASP, and grab only 24-bits from each data phase.

It uses the same registers as standard XY mode, where X is the encoded sample size, and Y is the number of samples to read/write per DMA request. Setting the PDMA\_PSILCFG\_TX\_STATIC\_TR[31] BURST bit enables burst.

The following are the rules for enabling burst mode. Incompatible peripherals do not need to enable burst, or can enable it on RX without enabling it on TX.

- The VBUSP address will increment throughout the burst
- Bursts will be sub-divided to fit into a 64 byte transfer window
- One sample is transferred for every bus data phase
  - Cannot burst one byte samples from a 16-bit peripheral on a 32-bit bus
  - Cannot burst 64-bit samples on a 32-bit bus (configure for 2×32-bit samples instead)
- PDMA will 'gap' the byte enables on writes as needed

#### 10.3.1.3.4.4.2 MCAN Mode Channel

The PDMA channel will remain idle until data is received from the UDMA-P over the PSIL interface. At this time, the PDMA will immediately start copying packet bytes into the MCAN TX buffer corresponding the PDMA/MCAN channel. The number of bytes copied is smaller of the remaining bytes in the packet or the value of the 'Y' parameter. Once a TX buffer has been filled, the PDMA will transfer ownership of the buffer to MCAN by performing an MCAN register write. The PDMA will then wait to regain ownership of the TX buffer by waiting for the corresponding MCAN TX event. At this time, the PDMA will continue with refilling the TX buffer for the next packet fragment. On subsequent fills (until the end of packet is reached), the PDMA will skip over the 8-byte MCAN header, leaving the original contents from the initial fragment copy in place.

#### 10.3.1.3.4.4.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

#### 10.3.1.3.4.4.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA\_PSILCFG\_TX\_AASRC\_TX\_FIFO\_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from TX order table (PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE0, PDMA\_PSILCFG\_TX\_AASRC\_TX\_ORDER\_TABLE1), starting at the configured FIRSTSLOT and ending with the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs written for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width written to the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The write transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### **10.3.1.3.4.5 Tx Pause**

The host initiates a channel pause by setting the PDMA\_PSILCFG\_TX\_RT\_ENABLE[9] PAUSE bit. The paused channel can be resumed by clearing the register bit.

#### **10.3.1.3.4.6 Tx Teardown**

The host initiates a channel teardown by setting the TDOWN bit in the UDMA-P channel that is paired with the PDMA. The UDMA-P communicates the teardown state through the PSI-L data channel, to ensure that the teardown is not seen by the PDMA until all the previous UDMA-P data for the channel has been flushed. At this time, the teardown state will be reflected in the PDMA\_PSILCFG\_TX\_RT\_ENABLE[30] TDOWN bit. Note that a non-synchronized teardown can also be initiated by directly clearing the PDMA\_PSILCFG\_TX\_RT\_ENABLE[31] ENABLE.

Once all data has been flushed from the PDMA to the peripheral, the enable state of the PDMA channel will be cleared in the PDMA\_PSILCFG\_TX\_RT\_ENABLE register, but the teardown bit will remain high. Upon completion, no further packet processing will occur until the host re-configures the channel. If the channel fails to teardown because the peripheral has stopped responding, or if the UDMA-P transmission stops on a data boundary that is not compatible with the static TR configuration, the PDMA\_PSILCFG\_TX\_RT\_ENABLE[28] FLUSH bit can be set to guarantee that all data can be properly flushed from the internal pipe.

#### **10.3.1.3.4.7 Tx Channel Reset**

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully, even with flush enabled. If this occurs, the channel may be reset by clearing the PDMA\_PSILCFG\_TX\_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

#### **10.3.1.3.4.8 Tx Debug/State Registers**

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For transmit, they are defined as follows:

- PDMA\_PSILCFG\_TX\_DEBUG\_1
- PDMA\_PSILCFG\_TX\_DEBUG\_2

Refer to their descriptions for further details.

#### **10.3.1.3.5 PDMA Receive Operation**

##### **10.3.1.3.5.1 Source (Rx) Channel Allocation**

A total of  $M$  destination channels are provided within the PDMA for concurrent transfers from the various attached peripherals into the Rx per-channel buffers and on to the PSI-L Rx Interface, where  $M$  is a design-time configurable parameter. Each Rx channel requires a single PSI-L thread. See [Section 10.3.2](#) for Rx channel allocation for each PDMA.

##### **10.3.1.3.5.2 Source Channel Initialization**

After reset, all threads/channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the host will need to first pair the channel with a remote data source (normally a UDMA-P channel), setup the static TR for the channel, and enable the thread.

### 10.3.1.3.5.2.1 PSI-L Source Thread Pairing

After reset, all threads on PSI-L are uninitialized and unpaired. The host will pair each source PDMA channel with (typically) a corresponding destination channel in the UDMA-P. The PDMA thread is configured to point to the UDMA-P thread and the UDMA-P thread is configured to point to the PDMA thread. Once paired, the source channels in the PDMA will send all their data to the source channel in the UDMA-P and the destination channel in the UDMA-P will never see any data other than data from the source channel in the PDMA.

The following PSI-L registers are related to source thread pairing:

- PDMA\_PSILCFG\_RX\_PEER\_THREAD\_ID
- PDMA\_PSILCFG\_RX\_PEER\_CREDIT
- PDMA\_PSILCFG\_RX\_ENABLE
- PDMA\_PSILCFG\_RX\_BYTE\_COUNT
- PDMA\_PSILCFG\_RX\_RT\_ENABLE

Refer to their descriptions for further details.

### 10.3.1.3.5.2.2 Static Transfer Request Setup

After reset, all channels in the PDMA will be idle and waiting for work to be assigned to them. In order to initiate PDMA operation, the Host will send configuration transactions across PSI-L and will set up the static TR for each destination channel. The format of the TR is identical for each DMA mode, consisting of 'X', 'Y', and 'Z' parameters, but the field interpretation varies somewhat. The following PSI-L register bit fields are used to setup the static TR:

- PDMA\_PSILCFG\_RX\_STATIC\_TR[26-24] X
- PDMA\_PSILCFG\_RX\_STATIC\_TR[11-0] Y
- PDMA\_PSILCFG\_RX\_STATIC\_TR\_Z[11-0] Z

Refer to their descriptions for further details.

### 10.3.1.3.5.2.3 PSI-L Source Thread Enables

PSI-L source threads must be enabled in order to process peripheral DMA requests and send data. When disabled, DMA requests are ignored.

Once a thread is paired, the TR has been set up and the enable is asserted, the channel is armed and ready to be triggered to perform the specified set of read transactions.

### 10.3.1.3.5.3 Data Transfer

Packet reception is accomplished within the PDMA by moving data from structures that are located in memory accessible via the VBUSP Memory Interface(s) onto the receive PSI-L interface. On the Rx side of the PDMA, these transfers are always reads. Data is read from an attached memory mapped space and packed into the Rx per-channel buffer for that channel. At a later time, the data is moved from the Rx per-channel FIFO to a remote peer DMA entity via the Rx PSI-L interface.

The sequences of logical transactions that are performed by the PDMA on the memory interface during receive is dependent on the channel type. The following sections describe what will happen for the two different channel types.

#### 10.3.1.3.5.3.1 X-Y FIFO Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. Once the pulse is detected, the DMA will sequentially issue a total of 'Y' parameter reads of 'X' parameter bytes from the data FIFO address specified for the channel. Each read that the DMA performs will be a single 'X' element in size (no large bursts). Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the Rx channelized FIFO and given the arbitration that may occur as a result of other channels also using the same read unit.

### 10.3.1.3.5.3.2 MCAN Mode Channel

The PDMA channel will remain idle until a pulse is detected on the associated input DMA request event pin. The DMA event pins are mapped from the CAN filter event bits. The event bits determine the channel and one of two CAN buffers to use for the RX operation. This allows the RX buffers on the CAN to be configured in a ping/pong fashion, preventing the loss of CAN packet data. When an event is received, the PDMA will start copying bytes out of the corresponding CAN buffer. The number of bytes copied is equal to the value of the 'Y' parameter in the channel configuration. Once all data has been copied from the buffer, the PDMA transfers ownership of the buffer back to the CAN by writing a CAN register. It then waits for another RX DMA event. The PDMA can copy multiple CAN RX buffers to the same CPPI packet. It will not close out the CPPI packet until it has copied out a number of RX buffers equal to the 'Z' parameter in the channel configuration. On subsequent RX buffer copies, the MCAN will skip the first 8 bytes of the RX buffer, which is the MCAN packet header.

The mapping of MCAN filter events to MCAN channels and buffer is important for properly configuring the DMA. The mapping is defined as shown in [Table 10-176](#).

**Table 10-176. Mapping of MCAN Filter Events to MCAN Channels**

CAN FE2	CAN FE1	CAN FE0	Description
0	0	0	Not used
0	0	1	Not used
0	1	0	PDMA CAN channel offset 0, RX buffer 0
0	1	1	PDMA CAN channel offset 0, RX buffer 1
1	0	0	PDMA CAN channel offset 1, RX buffer 2
1	0	1	PDMA CAN channel offset 1, RX buffer 3
1	1	0	PDMA CAN channel offset 2, RX buffer 4
1	1	1	PDMA CAN channel offset 2, RX buffer 5

By using two filter entries in the CAN, software can setup a ping-pong buffer for a particular RX packet ID. For example, the following two filter entries will setup a ping-pong using RX buffers 0 and 1 for packet ID = 5 on CAN RX channel 0 ([Table 10-177](#)).

**Table 10-177. Ping-Pong Buffer Example in MCAN Mode**

Filter Entry	Packet Match ID	Filter Event Bits
0	5	0x2
1	5	0x3

### 10.3.1.3.5.3.2.1 MCAN Burst Mode

Since MCAN buffers are stored in linear memory, the burst mode for MCAN is a simple linear burst across the transfer window. The max burst size is set to the 72 byte size of the MCAN buffer. This will allow a full MCAN packet to be read out as a single burst.

### 10.3.1.3.5.3.3 AASRC Mode Channel

The AASRC channel is controlled primarily via the PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG register for the channel. This register holds three basic pieces of information:

- Whether the channel uses AASRC stream mode or group mode
- The slot range in the order table used (from designated first slot to designated last slot)
- The AASRC DMA request event(s) that must fire before the channel becomes active

The channel will remain idle until a pulse is detected on ALL associated input DMA request event pins required by the PDMA\_PSILCFG\_RX\_AASRC\_RX\_FIFO\_CONFIG setting. The pulses for the individual events are latched and held by the PDMA until they all arrive. Once the channel activates, it will start reading FIFO index values from RX order table (PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE0, PDMA\_PSILCFG\_RX\_AASRC\_RX\_ORDER\_TABLE1), starting at the configured FIRSTSLOT and ending with

the LASTSLOT. The actual FIFO indices used are obtained from the ordering table. For example, say FIRSTSLOT=3 and LASTSLOT=5. If the first 6 slots of the ordering table were: 0, 2, 4, 6, 8, 10, the FIFOs read for the event would be 6, 8, and 10, because 'slot 3' of the table contains 6, and it would proceed through 'slot 5' of the table which contains 10.

The X and Y registers are still used as they are in a normal X-Y mode. When accessing each FIFO, the setting of X determines the sample byte width read from the FIFO. The value of 'Y' determines how many times the entire FIFO list is processed for each activation of the channel. Once the total specified number of transactions has been completed the channel will return to an idle state and wait until it is triggered again. The read transfers that are performed will be accomplished as quickly as possible given availability of data in the TX channelized FIFO and given the arbitration that may occur as a result of other channels also using the same write unit.

#### 10.3.1.3.5.4 Rx Pause

The host initiates a channel pause by setting the PDMA\_PSILCFG\_RX\_RT\_ENABLE[29] PAUSE bit. The paused channel can be resumed by clearing the register bit.

#### 10.3.1.3.5.5 Rx Teardown

The host initiates a RX channel teardown by setting the PDMA\_PSILCFG\_RX\_RT\_ENABLE[30] TDOWN bit for the target RX channel. The PDMA communicates the teardown state to the UDMA-P through the PSI-L data channel, to ensure that the teardown is not seen by the UDMA-P until all the previous PDMA data for the channel has been flushed.

The PDMA will not stop reading peripheral data until it reaches a FIFO boundary as configured through the 'X' and 'Y' parameters in the static TR. It will always attempt to complete the 'Y' count for the current event being processed. Upon reaching a stopping point, the PDMA will then clear the ENABLE bit in the pairing register, however the TDOWN bit will remain set. No further packet processing will occur until the host re-configures the channel. The teardown process will propagate to the UDMA-P and its final status can be checked there.

#### 10.3.1.3.5.6 Rx Channel Reset

In the unlikely event that channel synchronization is corrupted, a channel may fail to teardown gracefully. If this occurs, the channel may be reset by clearing the PDMA\_PSILCFG\_RX\_ENABLE[31] ENABLE bit. This will cause a local reset of the entire channel, including TR and pairing registers. Note that it does not reset the UDMA-P peer. Resetting the UDMA-P peer is also required before re-initializing and re-pairing the channel.

#### 10.3.1.3.5.7 Rx Debug/State Register

The debug/state registers are supplied to give software applications additional information about the PDMA than they would need in regular operation, but which may be useful in debug situations. These registers appear on the PSI-L bus, near the static TR registers. For receive, they are defined as follows:

- PDMA\_PSILCFG\_RX\_DEBUG\_1
- PDMA\_PSILCFG\_RX\_DEBUG\_2
- PDMA\_PSILCFG\_RX\_DEBUG\_3

Refer to their descriptions for further details.

#### 10.3.1.3.6 PDMA ECC Support

The PDMA optionally integrates an ECC aggregator module that consolidates the ECC configuration and status bits for all the ECC-supported memories within the PDMA. The ECC aggregator provides a single end-of-interrupt (EOI) handshake based interrupt to the host (for both single and double error detections), and a standard 32-bit VBUSP interface for configuring and querying the various ECC wrappers via their respective register set.

In this device, only PDMA5 includes an ECC aggregator.

For detailed description of the generic ECC aggregator functionality, see *ECC Aggregator*. For register descriptions of PDMA ECC aggregators, see *PDMA Registers*.

## 10.4 Data Routing Unit (DRU)

This section describes the SoC level Data Routing Unit (DRU) for the device.

### Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section. For the differences between all DRUs, see [Section 10.4.3.6](#).

### 10.4.1 DRU Overview

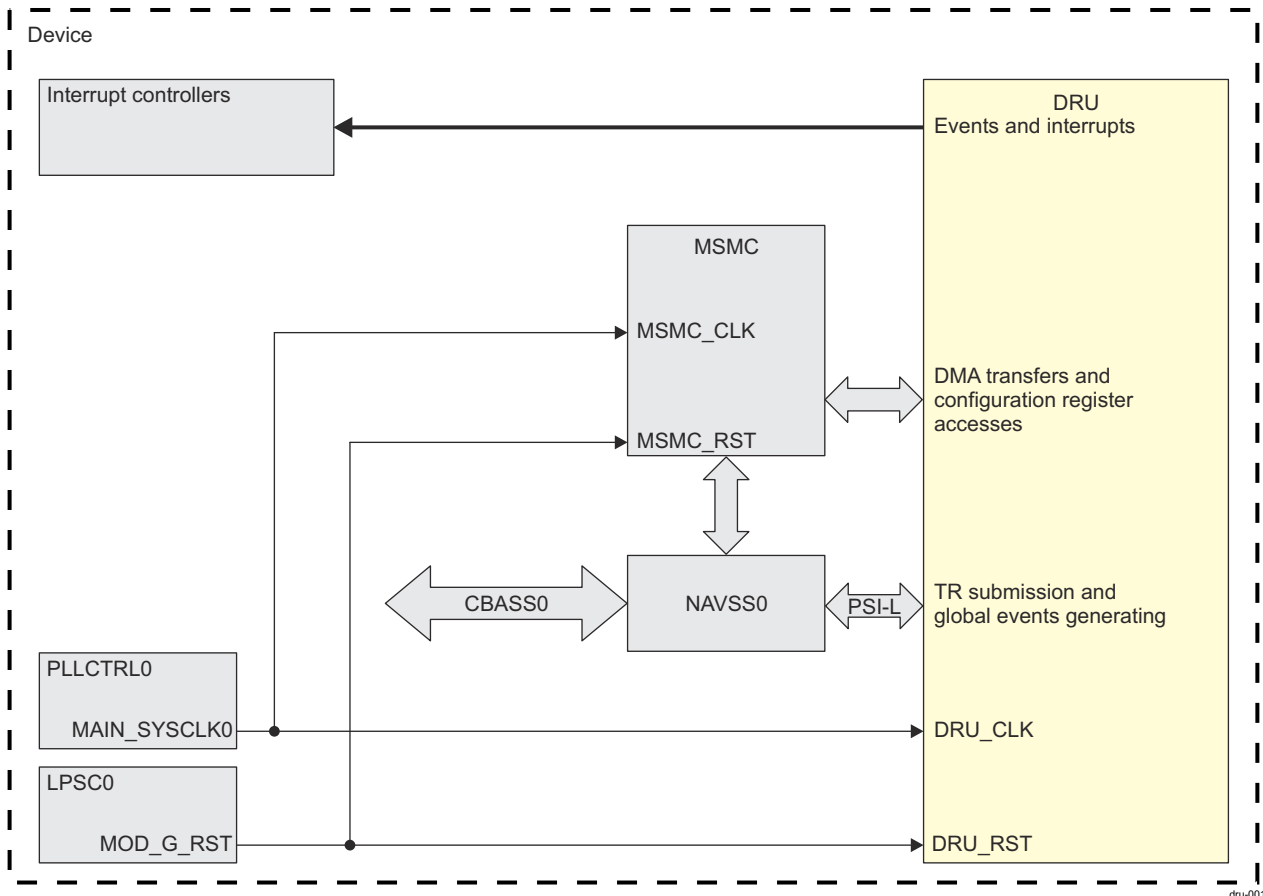

The data routing unit (DRU) is a high bandwidth, flexible routing engine with programmable DMA transfer requests. It enables user to perform high speed data transfers between memory mapped slave endpoints, processor caches and shared caches. DRU behaves like a DMA transfer controller, moving data at CPU frequency.

[Table 10-211](#) shows DRU modules allocation within device domains.

**Table 10-211. DRU Modules Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
DRU	-	-	✓

[Figure 10-39](#) shows an overview of the DRU and its surrounding modules.

**Figure 10-39. DRU Overview**

The DRU supports the following features:

- Programmable configuration registers for direct transfer request submission
  - A dedicated atomic register set that requires entire TR sent in a single burst
  - Three nonatomic register sets that allow TR to be written in separate burst and a write to the SUBMIT\_WORD0 register triggers the TR
- Read and write command queues
  - Five different queues with a split arbitration between fixed priority and round robin arbitration
  - Each channel can be configured to go to one of these queues
- Programmable priority for each queue
  - Allows setting priority for commands relative to other masters in the system
- One dedicated read port and one dedicated write port to generate independent read and write commands
  - Generates one read command every cycle
  - Generates one write data phase every cycle
  - Moves the data at CPU frequency
  - Optimizes transfers up to 128 byte boundaries
- Support for triggers to gate levels of the DMA loop
  - Supports one dedicated local trigger
  - Supports two dedicated external global triggers from the PSI-L
  - All triggers can be overwritten and controlled by software instead of hardware based event
- Support for region based and channelized firewall
  - Region based firewall intended to protect DRU configuration registers within a programmatically specified range
  - Channelized firewall that protects:
    - The real time configuration registers for each channel
    - The TR submission registers for each channel
    - The data transfers for each channel
- Data formatting networks
  - Transpose data between source and destination memory to memory transfers
  - Circular addressing support for one side of the transfer
- Independent 48-bit address fields for source and destinations
- Up to four dimensional data transfers
  - Has independent source and destination index for up to four dimensional transfers
- Error Handling
  - Debug support through memory mapped registers
  - Data transfer error reports
- Error detection and Correction
  - Full SEC/DED support for the incoming data
  - Full SEC/DED protection each entry in the TR queues
  - Single bit parity support for each 32-bit word in the data buffer
  - Parity protection for the address
- PSI-L Interface
  - Receive requests for pre-warm of L2 or L3 Cache
  - Receive TR requests from the UDMA
  - Send response TRs
  - Receive data from a remote UTC
  - Send data to a remote UTC
  - Maintains 2D formatting across PSI-L if requested in TR

### 10.4.2 DRU Integration

This section describes the SoC level DRU integration in the device, including information about clocks, resets, and hardware requests.

---

#### Note

There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as the SoC level DRU. For the differences between all DRUs, see [Section 10.4.3.6](#). For integration details about the VPAC0 and DMPAC0 DRUs, see [Section 6.9 Vision Pre-processing Accelerator \(VPAC\)](#) and [Section 6.10 Depth and Motion Perception Accelerator \(DMPAC\)](#).

---

#### 10.4.2.1 DRU Integration in MAIN Domain

A single DRU module is integrated in the device MAIN domain. [Figure 10-40](#) shows the integration of DRU.

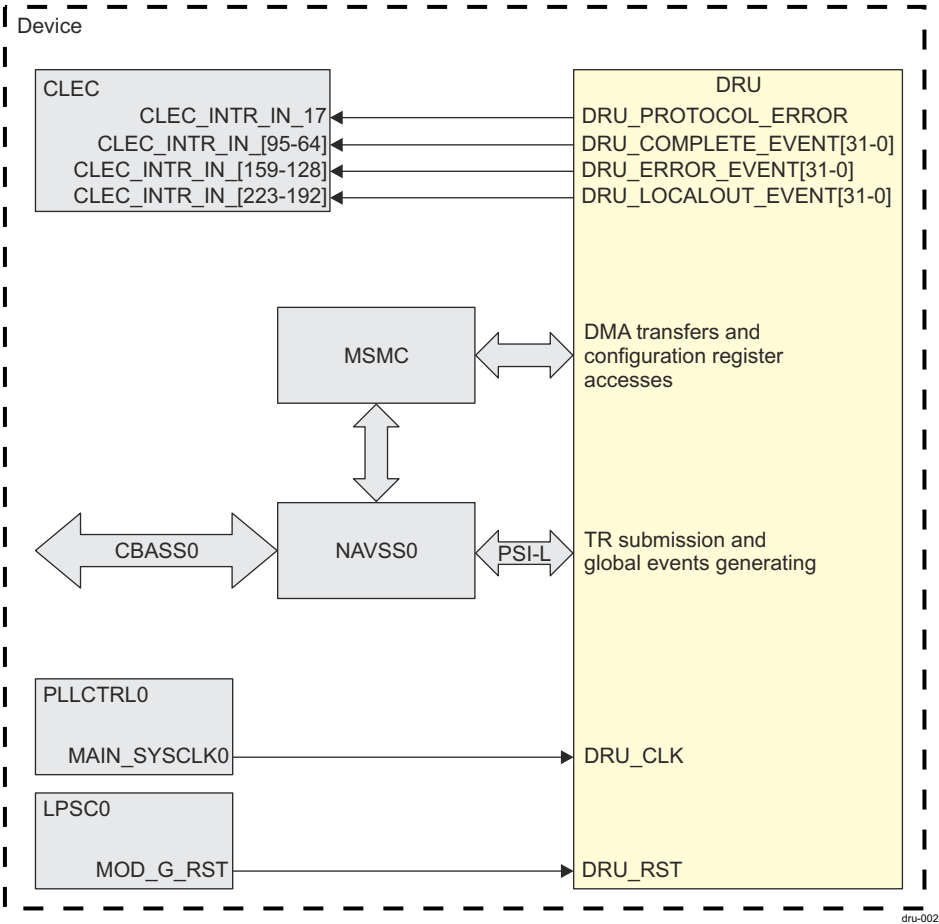

Figure 10-40. DRU Integration

Table 10-212 through Table 10-214 summarize the integration of DRU in device MAIN domain.

Table 10-212. DRU Integration Attributes

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect

**Table 10-212. DRU Integration Attributes (continued)**

DRU	PSC0	PD0	LPSC0	CBASS0 (Accessed through NAVSS0 and then through MSMC) PSI-L
-----	------	-----	-------	---

**Table 10-213. DRU Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
DRU	DRU_CLK	MAIN_SYSCLK0	PLLCTRL0	DRU clock
Resets				
Module Instance	Module Reset Input	Source Reset Signal	Source	Description
DRU	DRU_RST	MOD_G_RST	LPSC0	DRU reset

**Table 10-214. DRU Hardware Requests**

Interrupt Requests					
Module Instance	Module Interrupt Signal	Destination Interrupt Input	Destination	Description	Type
DRU	DRU_PROTOCOL_ERROR	CLEC_INTR_IN_17	CLEC	DRU protocol violation event	Level
	DRU_COMPLETE_EVENT[31-0]	CLEC_INTR_IN_[95-64]	CLEC	DRU completion events	Level
	DRU_ERROR_EVENT[31-0]	CLEC_INTR_IN_[159-128]	CLEC	DRU error completion events	Level

### Note

For more information on the DRU events, see [Section 10.4.3.2](#).

For more information on the interconnects, see [Chapter 3, System Interconnect](#).

For more information on the power, reset and clock management, see the corresponding sections within [Chapter 5, Device Configuration](#).

For more information on the device interrupt controllers, see [Section 9.2, Interrupt Controllers](#).

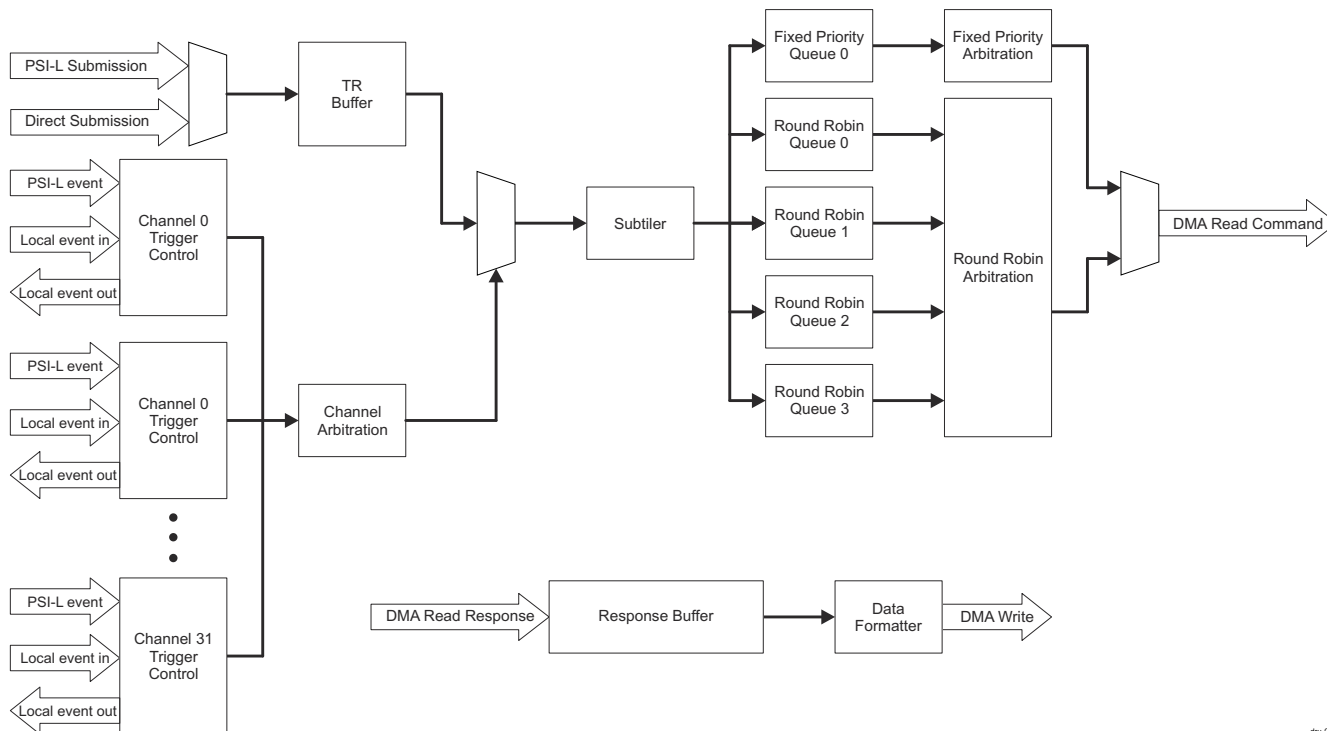

### 10.4.3 DRU Functional Description

#### Note

This section describes the SoC level Data Routing Unit (DRU) for the device. There are also DRUs in VPAC0 and DMPAC0. Their functionality is almost same as described in this section and its subsections. For the differences between all DRUs, see [Section 10.4.3.6](#).

#### 10.4.3.1 DRU Basic Functionality

Figure 10-40 shows the DRU functional diagram.

**Figure 10-41. DRU Functional Diagram**

The DRU receives commands to transfer data from one location to another called Transfer Requests (TRs) or to send messages to CPUs or MMUs to pre-warm logic called Cache Requests (CRs). The DRU can receive these commands through the following mechanisms:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The previously described mechanisms of receiving TRs and CRs are also referred to as TR submission (see, [Section 10.4.3.1.3](#)). In other words, the DRU memory-to-memory transfers work by receiving TR or CR through TR submission. Then the corresponding request (TR or CR) is placed in a queue to be processed.

Once the TR has been received the Channel Trigger Control block detects if the triggers specified in the TR have been received. If the trigger is not specified (value of 0x0 in the TRIGGER0 or TRIGGER1 fields of the TR FLAGS field), the treatment is as it is always received. Once received the channel is considered active. All active channels are involved in arbitration process for using the subtiler. The channel arbitration is based on the channel queue. There are queues using a fixed priority arbitration - the lowest channel has the highest priority. There are also round robin queues that use the same algorithm as in the fixed priority queue arbitration (lowest channel - highest priority) but on a round robin basis.

The subtiler takes the winning channel (that is, channel with highest priority) and generates the next 1D or 2D transfer (called also sub-TR) based on the trigger size, transfer type and event size specified in the TR. Then the subtiler places that sub-TR into the queue specified for the channel. Once the sub-TR is generated an event control is notified and any active triggers are cleared if the sub-TR crosses the boundary of one of the triggers. For example, if a TR has a trigger size for a 3D block and the ICNT2 value is 16, then the active triggers are cleared after 16 sub-TRs are sent to the queue. ICNT2 can be specified through one of the following:

- DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD4\_5\_j[47-32] ICNT2 field
- DRU\_SUBMIT\_WORD4\_5\_j\_k[47-32] ICNT2 field
- ICNT2 field of the UDMA-C TR received over PSI-L

Upon reaching the top of the queue the TR is processed. Based on the information in the TR a read of the specified location and size is performed followed by writing the data to the specified destination. Upon sending the last write of the entire TR loop a completion event is generated. The completion event output also places a TR response in the PSI-L response FIFO in case of UDMA-C TR. For information about the TR response format, see *Transfer Response Record* in *DMA Architecture*.

---

#### Note

The channel is an independent data flow that can be given requests for data movement. Each channel operates independently of the others but they all share common resources.

The queue is a shared unit between several channels. It holds the order of the channel data movement requests until the shared data engine can perform the actual data move. A channel is assigned a queue where its data movement requests are placed.

---

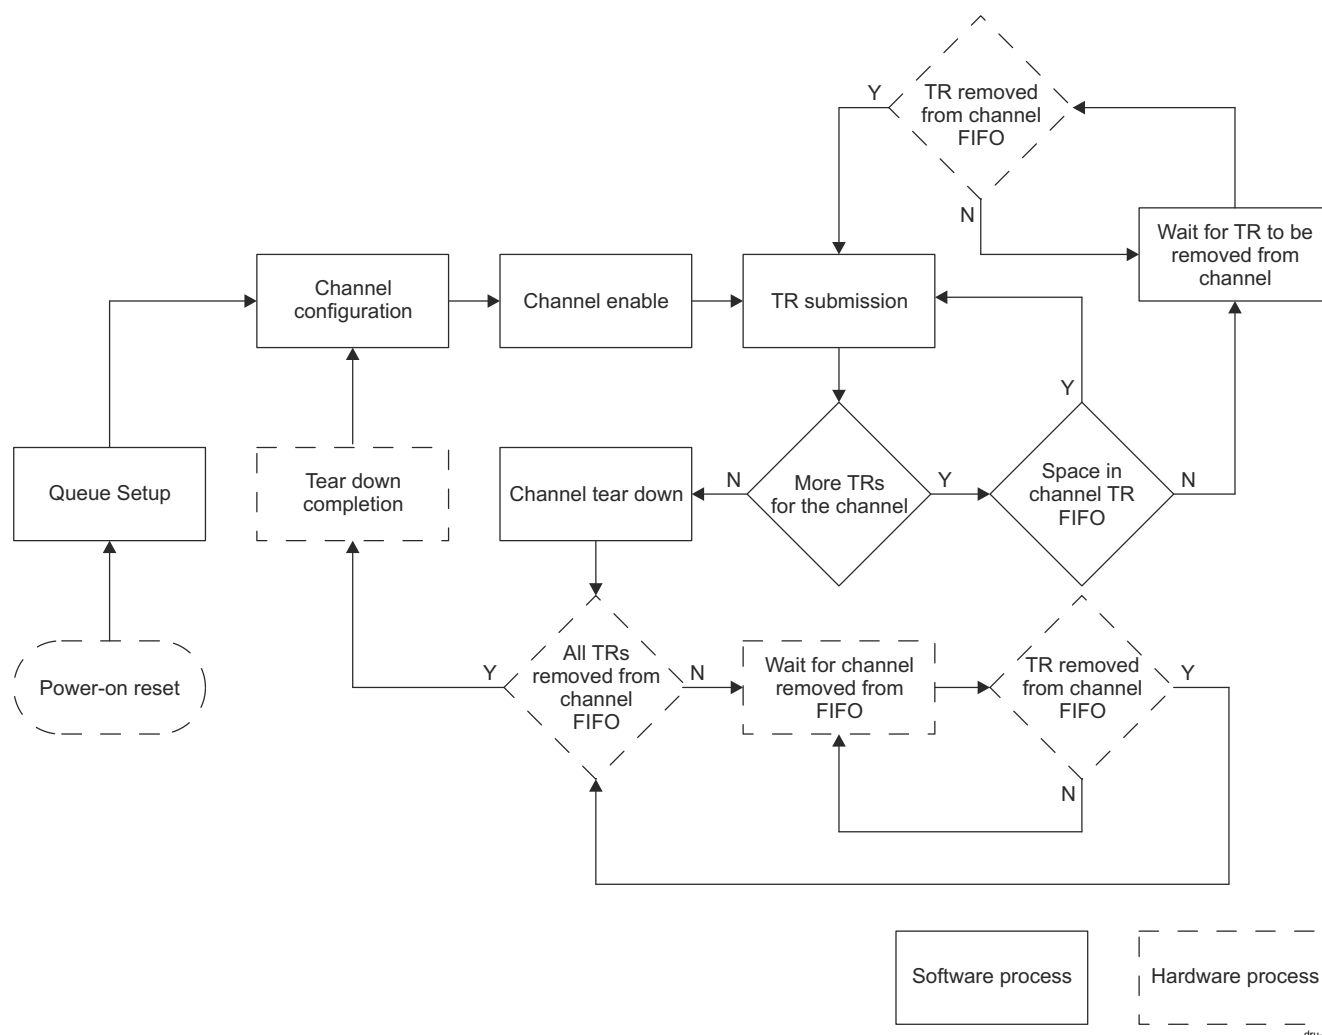

---

#### Note

The CHRT\_SWTRIG register can only be accessed directly through the DRU configuration interface and is used if software wants to control the triggers for the TR.

---

Figure 10-42 shows the interaction between software and hardware to setup DRU, submit TRs and then release the channel to be used by a different resource. Section 10.4.3.1.1 through Section 10.4.3.1.5 explain in more detail what occurs in each process or decision.

**Figure 10-42. DRU Software Managed Flow Diagram**

#### 10.4.3.1.1 Queues

Every TR that is active is placed in one of the DRU queues. Each queue operates independently of the others. In a given queue the TRs complete in the order they are placed by the subtiler. Only one read and one write queue may exist at a time. The queues use same resources and need arbitration which is performed based on fixed priority or round robin scheme. In both cases the highest priority queue is the one with the lowest number. The queue priority is specified through the DRU\_CFG\_y[2-0] PRI field.

Whenever arbitration occurs if there is a TR in a fixed priority queue that TR always goes and the round robin queues are held off. If the fixed priority queues are empty then the round robin queues are arbitrated on a round robin basis, that is, each queue sends its specified number of transactions and then arbitration starts again. On the write side an arbitration ends if the read response has not been received for the next command when the current one completes.

The arbitration happens the last phase of a transfer chunk. A transfer chunk is defined as sending the number of read transactions specified by the DRU\_CFG\_y[23-16] CONSECUTIVE\_TRANS field. After CONSECUTIVE\_TRANS number of commands elapse the queue releases the bus and waits for the number of commands specified by the DRU\_CFG\_y[31-24] REARB\_WAIT field before trying to request the bus and involve in arbitration again. Thus software can tune the data flow from each queue to prevent starvation.

If a queue is running and no other queues have a TR then the running one starts its next chunk without stopping. Each time arbitration is performed for round robin queues the queue with the next priority becomes the highest priority and the current one the lowest priority queue. If a fixed priority queue is active then the current round robin queue remains the highest priority one until the CONSECUTIVE\_TRANS count expires or queue is empty.

The DMA bus QoS and order ID attributes for each queue can also be configured through the DRU\_CFG\_y[10-8] QOS and DRU\_CFG\_y[7-4] ORDERID fields.

---

#### Note

Queue configuration must be done before setting up any channel as queue changes while channels are active can cause unknown behavior.

---

#### 10.4.3.1.2 Channel Configuration

The DRU operates on having multiple channels that can run in parallel on the shared hardware but are independently triggered by events as needed. Each channel must be configured before it is used. The channel configuration has the following parts:

- Non-realtime configuration intended to be controlled by a single master in the system for all software processes and processors
- Real time configuration controlled by the software process that owns the channel

##### 10.4.3.1.2.1 Non-realtime Channel Configuration

The non-realtime configuration consists of the following:

- Assigning the channel to a submission mechanism via the DRU\_CFG\_j[19] CHAN\_TYPE\_OWNER bit
- Assigning the channel via the DRU\_CHST\_SCHED\_j[2-0] QUEUE field to a hardware queue to be used for channel transactions
- Assigning the channel via the DRU\_CHOES0\_j[15-0] EVT\_NUM field to an event to be used for channel notifications

The DRU\_CFG\_j[31] PAUSE\_ON\_ERR bit can be used to control the channel behavior in case of error or exception.

The DRU\_CFG\_j registers must be written to before the channel is enabled via the DRU\_CHRT\_CTL\_j[31] ENABLE bit as once a channel is enabled any write to the DRU\_CFG\_j, DRU\_CHST\_SCHED\_j and DRU\_CHOES0\_j registers will result in write failure and an address error. If a channel does not exist an address error is generated upon write too.

##### 10.4.3.1.2.2 Realtime Channel Configuration

Once the non-realtime channel configuration has been done the DRU\_CHRT\_CTL\_j[31] ENABLE bit should be written. It must be written before any TRs can be written. The mechanism to write this bit is based on the ownership of the channel as specified via the DRU\_CFG\_j[19] CHAN\_TYPE\_OWNER bit. If the owner is a CPU, than this bit must be written directly through the DRU configuration interface. If the owner is UDMA, than the PSI-L interface must be used to write the ENABLE bit through the PSI-L register configuration write process as described in *PSI-L*.

---

#### Note

Once a channel has been enabled the channel configuration registers cannot be modified. The channel can only be disabled through writing 0x1 to the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit.

---

#### 10.4.3.1.3 TR Submission

The DRU supports the following TR methods:

- A direct write to the DRU submission registers
- TR submission over PSI-L from external UDMA-C

The TR submission checks the following:

- If a legal TR has been submitted
- If the correct submission method has been used
- If there is space in the channel TR FIFO for the new TR

#### 10.4.3.1.3.1 Direct TR Submission

The direct TR submission can be atomic or nonatomic. There is one atomic register set that allows for a TR to be submitted with a single burst write. There are also three nonatomic register sets for nonatomic direct TR submission. Each of these three sets allows direct TR submission without requiring submission in a single burst.

The direct atomic TR submission is handled through DRU register writes to the DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD0\_1\_j to DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD14\_15\_j registers which require write in a single 64-byte burst. Any write other than this size returns an address error. All burst values are checked if they are legal values and space in the channel FIFO is checked too. Then the TR is pushed into the FIFO and the write status is returned with success. If any of the legal TR format checks or FIFO space check fails or if the channel is not owned and enabled the result is an address error returned.

The direct nonatomic TR submission is handled through DRU register writes to the DRU\_SUBMIT\_WORD0\_1\_j\_k to DRU\_SUBMIT\_WORD14\_15\_j\_k registers which are intended to be used for cores not being able to perform a large burst write in a single cycle. There is a single set for each core regardless of the channel number. A write to the DRU\_SUBMIT\_WORD0\_1\_j\_k register triggers the TR.

#### Note

The following should be taken into account:

- If a channel is full any write to the DRU\_SUBMIT\_WORD0\_1\_j\_k register results in an address error.
- The DRU does not check anything to ensure that the same core writes to the same nonatomic register set. Software should perform the check procedure.

#### 10.4.3.1.3.2 PSI-L TR Submission

The DRU PSI-L TR submission is used for TR submissions from an external UDMA-C. The DRU has a single submission thread for each channel. The channel must be configured as UDMA-C type channel before PSI-L pairing.

The PSI-L pairing, TR submission and response follow the mechanisms as described in *PSI-L*. For every TR a TR response is sent. If the TR fails a legal check or channel ownership or FIFO fullness check, an immediate TR response is sent back with the cause of the submission error provided in the response.

#### 10.4.3.1.4 TR Removal from Channel

After all requested write responses are received from a TR the DRU sends completion event for the channel that completed the TR. Software can use this event to determine when a TR can be added to a channel FIFO. Each channel has a small FIFO allowing multiple TRs to be preloaded into a channel thus maximizing the channel throughput. The completion event signifies that an entry has become available in the FIFO.

#### 10.4.3.1.5 Channel Tear Down

A channel must be torn down through setting the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit to 0x1. This allows for channel reconfiguration. Setting the TEARDOWN bit to 0x1 forces the channel to stop sending any new requests not already in the pipeline and when all outstanding requests have been received all other bits in the DRU\_CHRT\_CTL\_j register are cleared. If the DRU\_CFG\_j[31] PAUSE\_ON\_ERR bit is set and an error occurs the tear down mechanism can be used to restart the channel. The TEARDOWN bit being set to 0x1 also makes the TR STATIC field in any future reads from the TR memory to be set to 0x0 no matter the value when the TR was submitted. This is the mechanism used to stop a static TR.

#### 10.4.3.1.5.1 Tear Down Completion

The tear down completion process is when software has set the DRU\_CHRT\_CTL\_j[30] TEARDOWN bit to 0x1 so no new TRs can be added to the channel but when previous TRs that had been added to the channel are still running. Once the TR FIFO for the channel is empty hardware clears the DRU\_CHRT\_CTL\_j[30] TEARDOWN and DRU\_CHRT\_CTL\_j[31] ENABLE bits. The channel is now back at the channel configuration process as described in [Section 10.4.3.1.2.1](#) and can be reused as needed by the system.

#### 10.4.3.2 DRU Output Events

The DRU generates the following events:

- Local output events
- PSI-L global events
- Protocol violation event
- Completion events
- Error completion events

The EVENT\_SIZE field of each TR specifies how often a TR generates an output event. That event is provided on the local output event interface as shown in [Figure 10-41](#) and as global event on the PSI-L interface. There is one event per channel. The global event number used by a PSI-L event transport lane can be configured for each channel through the DRU\_CHOES0\_j[15-0] EVT\_NUM field.

As shown in [Table 10-215](#), if the EVENT\_SIZE value is in range from 1 to 3, then the output event is generated when the write command for the given loop level (ICNT1, ICNT2 or ICNT3 decremented) has been sent. If EVENT\_SIZE = 0, then the output event is generated when all responses have been received.

**Table 10-215. EVENT\_SIZE Encoding**

EVENT_SIZE Value	Event Encoding	Description
0	TR complete	The TR has completed and all responses have been received
1	ICNT1 loop is decremented	The last write command of a row has been sent
2	ICNT2 loop is decremented	The last write command of an array has been sent
3	ICNT3 loop is decremented	The last write command of an array of an array has been sent

For more information about PSI-L interface and its event transport lane, see *PSI-L*.

For more information about the TR EVENT\_SIZE field, see *Transfer Request Record* of *DMA Architecture*.

The protocol violation event is not channel associated.

The completion events are defined for each channel. The completion event fires whenever a channel completes a TR successfully. It is only generated when all responses are received from the write portion of the block copy. A single write completion event can occur in a given cycle since it is based on the write responses being received to generate the response.

The error completion events are defined for each channel. The error completion event fires whenever a channel completes a TR with an error and it has flushed out all data related to that TR in the response buffer. Upon determining that a TR is not able to complete successfully, the DRU enters a flush mode to remove all read data received after the error is determined as well as make sure all write responses are received. Once all of this criteria has been matched the write engine fires a completion event. If multiple error completions occur at the same time the DRU will still send them out one at a time using an arbitration scheme used for the original arbitration for the queue, either fixed priority or round robin based on the queue that has the error.

#### 10.4.3.3 DRU Address Fetch Algorithm, TR and CR Formats

The address fetch algorithm, TR and CR formats are defined in *Transfer Request Record* in *DMA Architecture*. It documents all features that can be supported by a Universal Transfer Controller (UTC) like the DRU but it may not support all of them. The DRU\_CAPABILITIES register must be read to check what features of the TR are supported by the DRU.

The TR format allows to perform some kinds of data reformatting or to alter from the standard addressing formats. The DRU supports the transpose data reformatting function and the circular buffering alternate addressing algorithm.

#### 10.4.3.3.1 Transpose

Linear streams work for large classes of algorithms, but not all. In some cases it is desired to transpose rows to columns and columns to rows in the data structure. To help in these cases the DRU supports a transpose function.

The transpose type works on element sizes of 32, 64 or 128 bits by sending sub-TRs in the size of 32 elements by 32 lines for 32-bit, 16 elements by 16 lines for 64-bit and 8 elements by 8 lines for 128-bit element. The sub-TR that is being sent always results in the maximum transfer size. For the write requests the data in the response buffer always looks as a buffer aligned to the zeroth offset in the address.

#### 10.4.3.3.2 Circular Buffering

Circular addressing modifies how the DRU performs address arithmetic so that addresses remain within a power-of-two sized window. Circular addressing works by holding upper address bits constant during an address update, while allowing the lower address bits to vary. This contrasts with the default linear addressing which allows all of the address bits to vary.

The TR provides address mode selection for each level of loop nest. Each level can select between linear addressing or circular addressing with one of two circular block sizes.

If circular addressing mode is selected in the AMODE field of the TR, the definition of the upper 16 bits of the FMTFLAGS field of the TR select the type of addressing for each entry in the loop and define two unique masks that can be used for the circular buffering. Additionally, the DIR field in the TR determines if the circular addressing flags apply for the source or the destination of the block move. The other direction always follows the standard linear addressing that is used if AMODE is not set.

For more information about circular buffering and the associated TR fields, see *Circular Address Mode Specific Flags* of *DMA Architecture*.

#### 10.4.3.4 DRU Firewalls

Unlike most of the device modules whose associated firewalls reside on system interconnect (CBASS) level the DRU has its own embedded firewalls. They are the following:

- Region based firewall intended to protect DRU configuration registers within a programmatically specified range.
- Channelized firewall that protects:
  - The real time configuration registers for each channel:
    - DRU\_CHRT\_CTL\_j
    - DRU\_CHRT\_SWTRIG\_j
  - The TR submission registers for each channel:
    - DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD0\_1\_j to DRU\_ATOMIC\_SUBMIT\_CURR\_TR\_WORD14\_15\_j
    - DRU\_SUBMIT\_WORD0\_1\_j\_k to DRU\_SUBMIT\_WORD14\_15\_j\_k
  - The data transfers for each channel

The region based firewall should be configured to cover the range from 0x6D00 4000 to 0x6D0C FFFF. This allows for a single master to control the memory attribute channels and channel ownership. If the region based firewall is configured to overlap the channelized firewall then both firewall checks have to pass for the register update to occur. If the firewall check fails the DRU returns protection error status to the requestor.

#### Note

Protection error takes precedence over address error. If the address falls into the firewall protected range then a protection error is returned.

The DRU region based and channelized firewalls are same as the other device firewalls. For more information about their functionality, see [Section 3.3.4 Interconnect Firewalls](#) in *System Interconnect*. The DRU firewall associated registers are described in the following sections:

- *DRU\_FW Registers*
- *DRU\_FW\_GLB Registers*
- *DRU\_MMR\_FW Registers*
- *DRU\_MMR\_FW\_GLB Registers*

#### 10.4.3.5 DRU Errors

In all error cases the DRU reports the error to the system, ensures that all outstanding commands for the TR have completed and proceeds with the next TR in the queue as if the previous one has finished normally. In most error cases the read transaction completes as normal but the responses are flushed. This ensures that both the read and the write start fresh on the next TR. The error details are logged in the DRU\_CHRT\_STATUS\_DET\_j and DRU\_CHRT\_STATUS\_CNT\_j registers. The DRU\_CAUSE\_y registers can be read to check if an error for the corresponding channel has occurred.

#### 10.4.3.6 DRU Configurations

[Table 10-216](#) shows the differences between the SoC level DRU and the rest DRUs in the device. The rest of the features and functionality is same as described in [Section 10.4.1](#) and [Section 10.4.3](#).

**Table 10-216. Differences between DRU Configurations**

Feature	SoC Level DRU	DMPAC.UTC_DRU	VPAC.UTC0_RT_DRU, VPAC.UTC1_NRT_DRU
Cache warm support	Y	Y	N
Atomic direct TR submission	Y	N	N
Nonatomic TR submission register sets	3	0	0
Data reformat functions	Transpose	None	None
Minimum transpose size	32 bits	N/A	N/A
Embedded firewall	Y	Y	N
Event generation	Encoded	Bit vector	Bit vector

This chapter describes the time sync modules in the device.

11.1 Time Sync Module (CPTS).....	1321
11.2 Timer Manager.....	1332
11.3 Time Sync and Compare Events.....	1340

## 11.1 Time Sync Module (CPTS)

This chapter describes the Time Synchronization (CPTS) module.

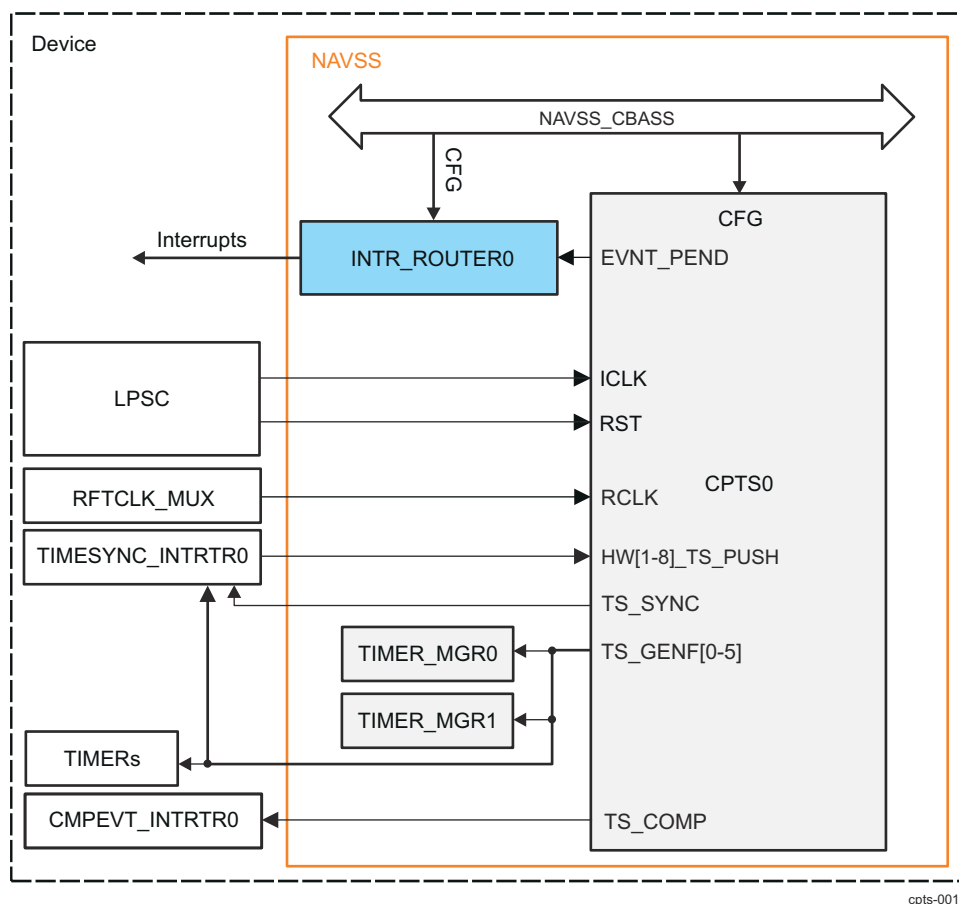

### 11.1.1 CPTS Overview

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations.

### Table 11-1. CPTS Allocation Across Device Domains

Instance	Domain		
	WKUP	MCU	MAIN
NAVSS0_CPTS0	-	-	✓ (NAVSS)
PCIE0_CPTS0	-	-	✓ (PCIE0)
PCIE1_CPTS0	-	-	✓ (PCIE1)
PCIE2_CPTS0	-	-	✓ (PCIE2)
PCIE3_CPTS0	-	-	✓ (PCIE3)
MCU_CPSW0_CPTS0	-	✓ (CPSW)	-

Figure 11-1 shows an overview of the NAVSS0 CPTS0 module.

### Figure 11-1. NAVSS0\_CPTS0 Overview

#### 11.1.1.1 CPTS Features

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling

- Supports 8 hardware timestamp push inputs
- Supports timestamp counter compare output (TS\_COMP)
- Supports timestamp counter bit output (TS\_SYNC)
- Supports 6 timestamp Generator function outputs (TS\_GENF0 to TS\_GENF5)
- 32-bit and 64-bit timestamp modes.

#### **11.1.1.2 CPTS Not Supported Features**

The following features are not supported by the module:

- Oscillator adjustment by module

### 11.1.2 CPTS Integration

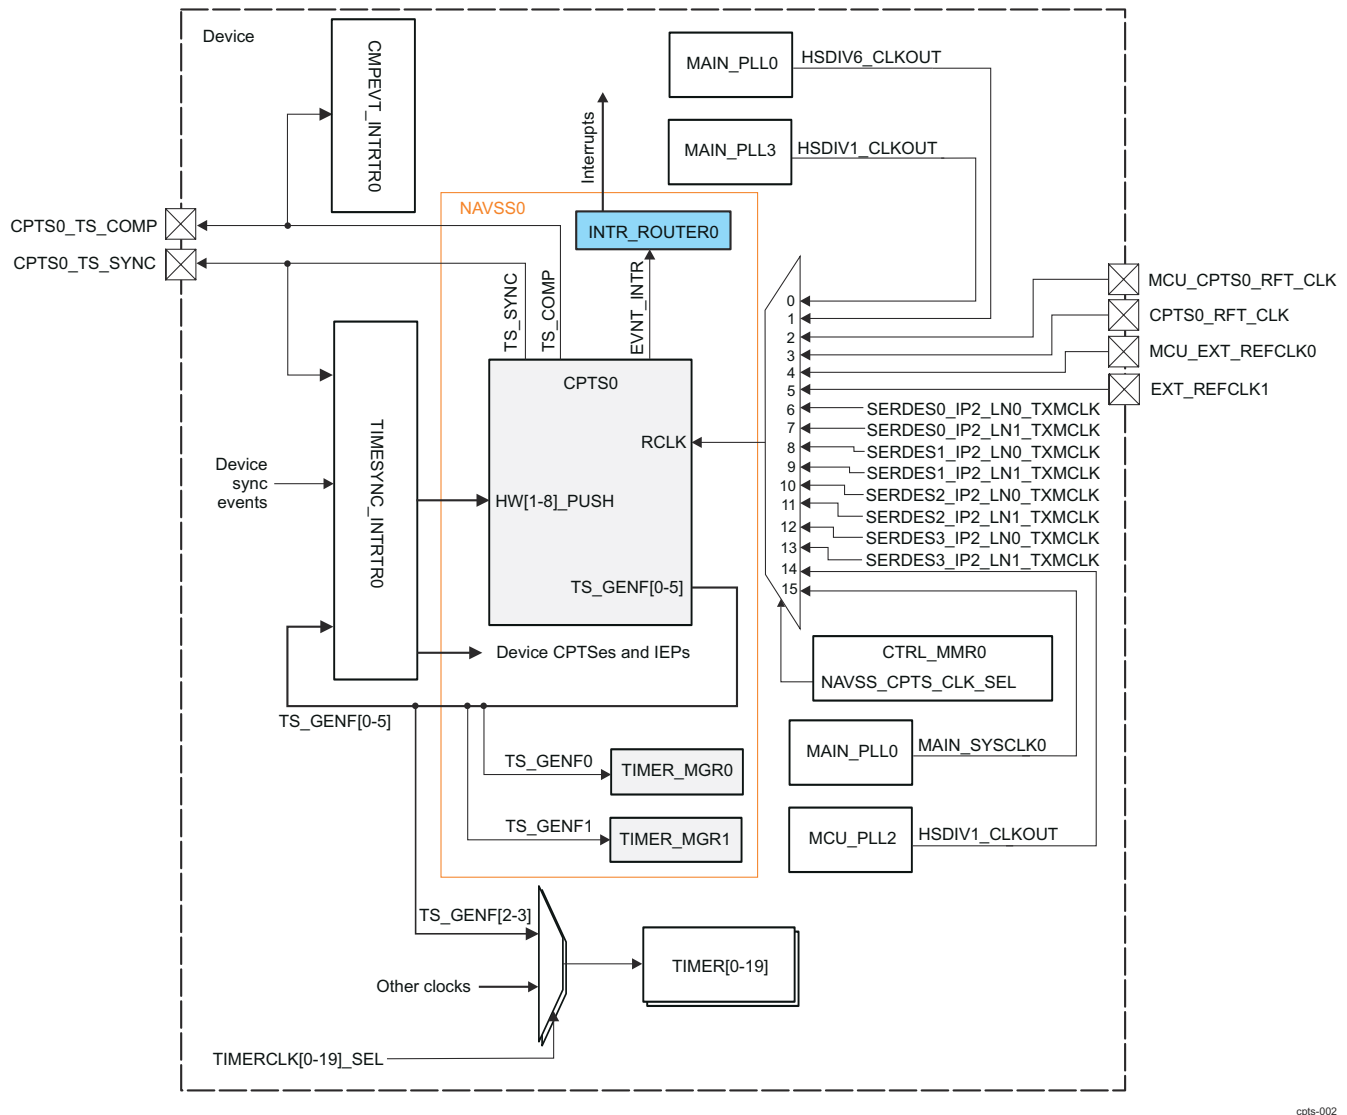

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

#### Note

This section describes the CPTS in the main Navigator subsystem (NAVSS0). For CPTS in PCIe integration, please see *PCIe Subsystem Precision Time Measurement (PTM) in Peripheral Component Interconnect Express (PCIe) Subsystem*.

For CPTS in CPSW integration, please refer to *Gigabit Ethernet Switch (CPSW)*.

Figure 11-2 shows the NAVSS0\_CPTS0 integration.

**Figure 11-2. NAVSS0\_CPTS0 Integration**

Table 11-2 and Table 11-3 summarize the integration of the module in the device.

**Table 11-2. CPTS Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
NAVSS0_CPTS0	PSC0	GP	LPSC0	NAVSS_CBASS

### 11.1.3 CPTS Functional Description

#### 11.1.3.1 CPTS Architecture

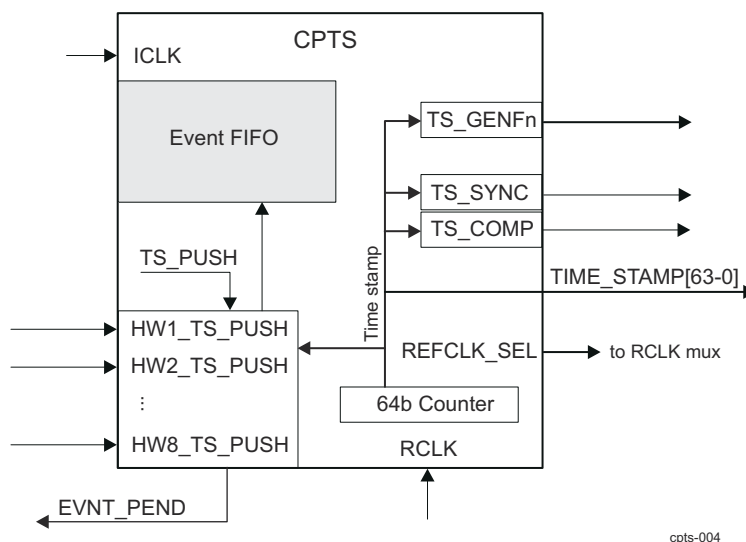

Figure 11-3 shows the architecture of the CPTS module.

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. The types of time sync events are as follows:

- Host Transmit Event (CPSW0\_CPTS0)

- Ethernet receive event (CPSW0\_CPTS0)
- Ethernet transmit event (CPSW0\_CPTS0)
- Time stamp push event
- Time stamp counter rollover event (32-bit mode only)
- Time stamp counter half-rollover event (32-bit mode only)
- Hardware Time Stamp Push Event
- Time Stamp Compare Event

The reference clock used for the time stamp (RCLK) can be derived from several sources.

**Figure 11-3. CPTS Block Diagram**

#### Note

See *CPTS Integration* for CPTS integration in the NAVSS0.

#### Note

This section describes the CPTS in the main Navigator subsystem (NAVSS0). For CPTS in PCIe integration, please see *PCIe Subsystem Precision Time Measurement (PTM) in Peripheral Component Interconnect Express (PCIe) Subsystem*.

For CPTS in CPSW integration, please refer to in *Gigabit Ethernet Switch (CPSW)*.

#### 11.1.3.2 CPTS Initialization

The CPTS module must be configured as follows:

1. Reset the CPTS module
2. Clear the CPTS\_EN bit in the CPTS\_CONTROL\_REG
3. Write the RFTCLK\_SEL value in the CPTS\_RFTCLK\_SEL\_REG with the desired reference clock selection
4. Set the CPTS\_EN bit in the CPTS\_CONTROL\_REG
5. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the CPTS\_INT\_ENABLE\_REG

#### 11.1.3.3 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS\_EN is set to 1. When CPTS\_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS\_TS\_LOAD\_VAL\_REG and CPTS\_TS\_LOAD\_EN\_REG).

The TS\_INC\_VAL[2:0] value must be zero in 32-bit mode. Nudge and PPM adjustments are not supported in 32-bit mode.

#### 11.1.3.4 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each RCLK rising edge when CPTS\_EN is set to 1. When CPTS\_EN is cleared to 0, the time stamp value is reset to 0.

64-bit mode is selected via CPTS\_CONTROL\_REG[5] MODE\_64BIT bit set to 1.

For test purposes, the time stamp can be written via the time stamp load function (CPTS\_TS\_LOAD\_VAL\_REG, CPTS\_TS\_LOAD\_HIGH\_VAL\_REG, and CPTS\_TS\_LOAD\_EN\_REG).

The TS\_ADD\_VAL feature is included to allow 1-ns timestamp operations with an RCLK rate less than 1 GHz. Table 11-5 shows the RCLK and TS\_ADD\_VAL values for 1-ns operations. The highest RCLK frequency possible should be used as allowed by the silicon technology.

**Table 11-5. TS\_ADD\_VAL**

RCLK (MHz)	TS_ADD_VAL
1000	0
500	1
333.33	2
250	3
200	4
166.66	5
142.85714	6
125	7

##### 11.1.3.4.1 64-Bit Timestamp Nudge

The 64-bit TIME\_STAMP value can be adjusted by writing the CPTS\_TS\_NUDGE\_VAL\_REG[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the next incremented TIME\_STAMP[63:0] value. A nudge value of 0x01 will add one RCLK clock to the next incremented TIME\_STAMP[63:0] value. For example, if the current TIME\_STAMP value is 0x0F06, and TS\_ADD\_VAL[2:0]=3, the next incremented timestamp value would be 0x0F0A without a nudge and 0x0F0A +/- TS\_NUDGE[7:0] with a nudge. The TS\_NUDGE value is cleared to zero when the nudge has occurred.

##### 11.1.3.4.2 64-bit Timestamp PPM

The 64-bit TIME\_STAMP can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero value to the TS\_PPM[41:0] value enables PPM operations. The adjustment is up or down depending on the TS\_PPM\_DIR bit. The TIME\_STAMP value is increased by the PPM value when TS\_PPM\_DIR is cleared and decreased by the PPM value when TS\_PPM\_DIR is set.

- To adjust for 100 parts per million the configured value for TS\_PPM[41:0] is:  
 $1\,000\,000/100 = 10\,000$  (DEC)
- To adjust for 1 part per hour at 1 GHz RCLK, the configured value for TS\_PPM[41:0] is:  
 $(1\,000\,000\,000\text{Hz}/1\text{pph}) \times (3600\text{ seconds}/\text{hour}) = 366\,30B8\,A000$  (HEX)

### 11.1.3.5 Event FIFO

All time sync events are push onto the Event FIFO. No overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

### 11.1.3.6 Timestamp Compare Output

CPTS features one Time Stamp Compare (TS\_COMP) output.

---

#### Note

64-bit mode operation is identical to 32-bit mode except that all 64 bits of the TIME\_STAMP[63-0] are used instead of only the lower 32 bits.

---

#### 11.1.3.6.1 Non-Toggle Mode

The TS\_COMP output is asserted for CPTS\_TS\_COMP\_LEN\_REG[31-0] RCLK periods when the TIME\_STAMP[31-0] value compares with the CPTS\_TS\_COMP\_VAL\_REG[31-0] and the length value is non-zero. The TS\_COMP rising edge occurs three RCLK periods after the values compare. A timestamp compare event is pushed into the event FIFO when TS\_COMP is asserted. The polarity of the TS\_COMP output is determined by the CPTS\_CONTROL\_REG[2] TS\_POLARITY bit. The output is asserted low when the polarity bit is 0.

#### 11.1.3.6.2 Toggle Mode

The TS\_COMP output is asserted for CPTS\_TS\_COMP\_LEN\_REG RCLK periods when the TIME\_STAMP[31-0] value compares with the CPTS\_TS\_COMP\_VAL\_REG[31-0] and the length value is non-zero. The TS\_COMP toggles thereafter on CPTS\_TS\_COMP\_LEN\_REG[31-0] RCLK periods. The length high or low can be adjusted by writing the CPTS\_TS\_COMP\_NUDGE\_REG[7-0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK from the CPTS\_TS\_COMP\_LEN\_REG value. A value of 0x01 will add one RCLK to the CPTS\_TS\_COMP\_LEN\_REG value. Only a single high or low time is adjusted (nudged) and the CPTS\_TS\_COMP\_NUDGE\_REG value is cleared to zero when the nudge has occurred. The TS\_COMP output is asserted low when the CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit is 0.

No compare events and no CPTS\_EVNT interrupts are generated in toggle mode.

The CPTS\_CONTROL\_REG[6] TS\_COMP\_TOG bit must be set for toggle mode, and must be set before writing a non-zero value to CPTS\_TS\_COMP\_LEN\_REG.

### 11.1.3.7 Timestamp Sync Output

The TS\_SYNC output is a selected bit of the TIME\_STAMP counter value. One of the counter bits 17-31 can be selected in CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL. The TS\_SYNC output is disabled when CPTS\_CONTROL\_REG[31-28] TS\_SYNC\_SEL is zero.

If the selected counter bit is 1 at the time when TS\_SYNC\_SEL value is written then a rising edge will not occur on the TS\_SYNC output. A rising edge will occur on the TS\_SYNC output upon the next transition-to-1 of the selected counter bit. The TS\_SYNC\_SEL value must be written to zero before changing to a different non-zero value. No events are generated due to the TS\_SYNC operation. The TS\_SYNC output is two RCLK periods after the actual count value.

### 11.1.3.8 Timestamp GENF Output

There are six TS Generate Function (TS\_GENFn) outputs (n = 0 to 5). The TS\_GENFn outputs have a programmable cycle (frequency) with a PPM feature and a software nudge feature. The TS\_GENFn output cycle is CPTS\_LENGTH\_REG\_j[31:0] RCLK periods (which is different than TS\_COMP operation).

The TS\_GENFn output cycle is CPTS\_LENGTH\_REG\_j[31:0] RCLK periods beginning when the TIME\_STAMP[63:0] value compares with the CPTS\_COMP\_LOW\_REG\_j[63:0] and the length value is non-zero. The TS\_GENFn output cycle repeats thereafter every CPTS\_LENGTH\_REG\_j[31:0] RCLK periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison

value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the TS\_GENFn\_POLARITY bit is low. No compare events and no CPTS\_EVNT interrupts are generated.

#### 11.1.3.8.1 GENFn Nudge

The cycle length can be adjusted by writing the CPTS\_NUDGE\_REG\_j[7:0] register value which is a two's complement value. A value of 0xFF will subtract one RCLK clock from the CPTS\_LENGTH\_REG\_j[31:0] value. A value of 0x01 will add one RCLK clock to the CPTS\_LENGTH\_REG\_j value. The CPTS\_NUDGE\_REG\_j value is cleared to zero when the nudge has occurred.

#### 11.1.3.8.2 GENFn PPM

The TS\_GENFn output cycle can be adjusted by parts per million (PPM) or by parts per hour (PPH). Writing a non-zero CPTS\_PPM\_LOW\_REG\_j/CPTS\_PPM\_HIGH\_REG\_j value enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single RCLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPTS\_CONTROL\_REG\_j[0] PPM\_DIR bit. When PPM\_DIR is set a single RCLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM\_DIR is clear a single RCLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

- To adjust for 100 parts per million the configured value for TS\_GENFn\_PPM[41:0] is:  
 $1\ 000\ 000/100 = 10\ 000\ (DEC)$
- To adjust for 1 part per hour at 1 GHz RCLK the configured value for TS\_GENFn\_PPM[41:0] is:  
 $(1\ 000\ 000\ 000\text{Hz}/1\text{pph}) \times (3600\ \text{seconds}/\text{hour}) = 346\ 30B8\ A000\ (HEX)$

#### 11.1.3.9 Time Sync Events

Time Sync events are 96-bit or 128-bit (for 32-bit and 64-bit time stamp respectively) values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG hold the data of a time sync event.

##### 11.1.3.9.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS\_PUSH bit of the CPTS\_TS\_PUSH\_REG. The time stamp value is returned in the event, along with a time stamp push event code.

##### 11.1.3.9.2 Time Stamp Counter Rollover Event (32-bit mode only)

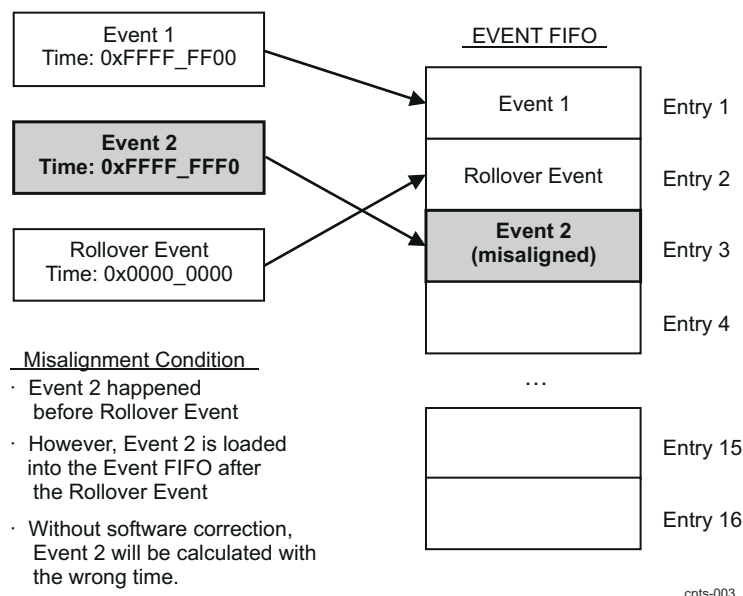

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented.

##### 11.1.3.9.3 Time Stamp Counter Half-rollover Event (32-bit mode only)

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 11-4](#) shows a misalignment condition.

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event.

The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

**Figure 11-4. Event FIFO Misalignment Condition**

#### 11.1.3.9.4 Hardware Time Stamp Push Event

There are eight hardware time stamp inputs (HW[1-8]\_TS\_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPTS Integration*.

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the CPTS\_EVENT\_1\_REG register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS\_CONTROL\_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 11.1.3.10 Timestamp Compare Event

##### Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode. The TS\_COMP output is also asserted when the event is generated. The event is generated when the TIME\_STAMP value compares with the CPTS\_TS\_COMP\_VAL\_REG/CPTS\_TS\_COMP\_HIGH\_VAL\_REG and the CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPTS\_TS\_COMP\_VAL\_REG/CPTS\_TS\_COMP\_HIGH\_VAL\_REG is written and should be zero when the comparison value is written.

#### 11.1.3.11 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE\_REG.
2. Upon interrupt, read the CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG register values.

3. Set the CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1 to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_ENABLE\_REG.
2. Upon interrupt, read the CPTS\_EVENT\_0\_REG through CPTS\_EVENT\_3\_REG register values.
3. Set the CPTS\_EVENT\_POP\_REG[0] bit to 1 to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four RCLK periods plus four ICLK periods.
5. Read the TS\_PEND\_RAW bit in the CPTS\_INTSTAT\_RAW\_REG register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, proceed to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the CPTS\_INTSTAT\_RAW\_REG to determine if a valid event is on the event FIFO.

## 11.2 Timer Manager

This chapter describes the Timer Manager module of the device.

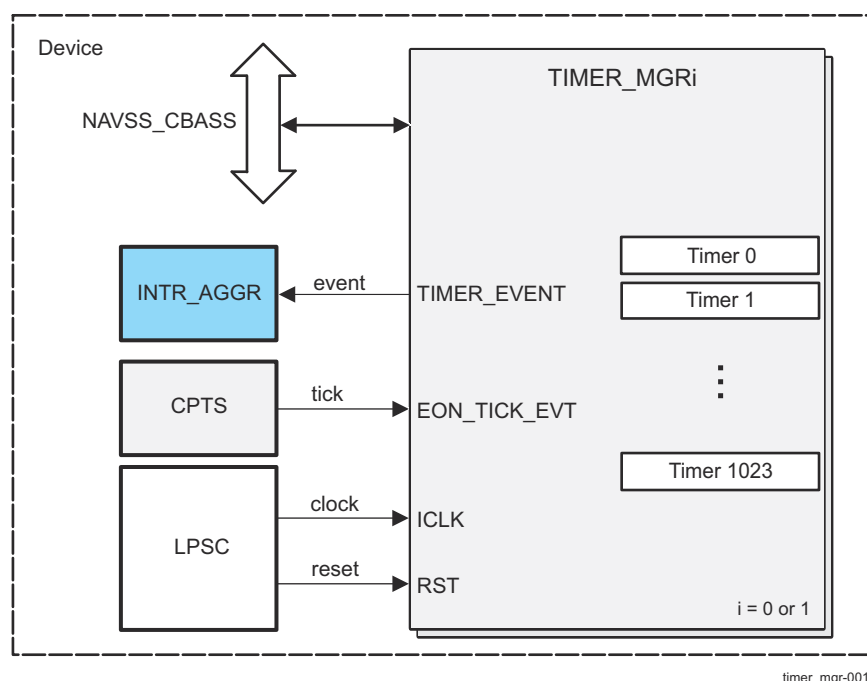

### 11.2.1 Timer Manager Overview

The Timer Manager module provides timers for timing operations for the processes running on multiple processors in the device. NAVSS supports two instances of Timer Manager.

**Table 11-6. TIMER\_MGR Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
TIMER_MGR0	-	-	✓ (NAVSS)
TIMER_MGR1	-	-	✓ (NAVSS)

Figure 11-5 shows an overview of the Timer Manager module.

**Figure 11-5. Timer Manager Overview**

#### 11.2.1.1 Timer Manager Features

Timer Manager has the following features:

- 1024 × 32-bit RAM-based independent timers (2048 in total for the two Timer Managers)
- Event interface to an interrupt aggregation module in the main NAVSS subsystem
  - Events are triggered when a timer expires or when an expired timer is reset or deactivated
- Host access to determine which timer(s) expired
- 32 registers with individual timeout status (one bit per timer)
- A pair of quick-read registers with the number of timers that have expired and the ids of the first timers to expire
- A bank timeout register with the banks that have expired timers – to avoid having to read all timeout status registers when only a few timers have expired
- Groups of 16 timers separated into pages of 4-K address space
- Timer bits within each page to read expiration status for each timer when software only has access to that page

- 10  $\mu$ s time to cycle through all of the timers
- Host access to reset individual timers
  - Reset values are preprogrammed for each timer
  - Timers may all be programmed before the timer manager is enabled, or programmed after enabled.
- Periodic hardware timers – a timer may be set to automatically reprogram itself without software intervention, so that it expires and reprograms itself endlessly.

#### **11.2.1.2 Timer Manager Not Supported Features**

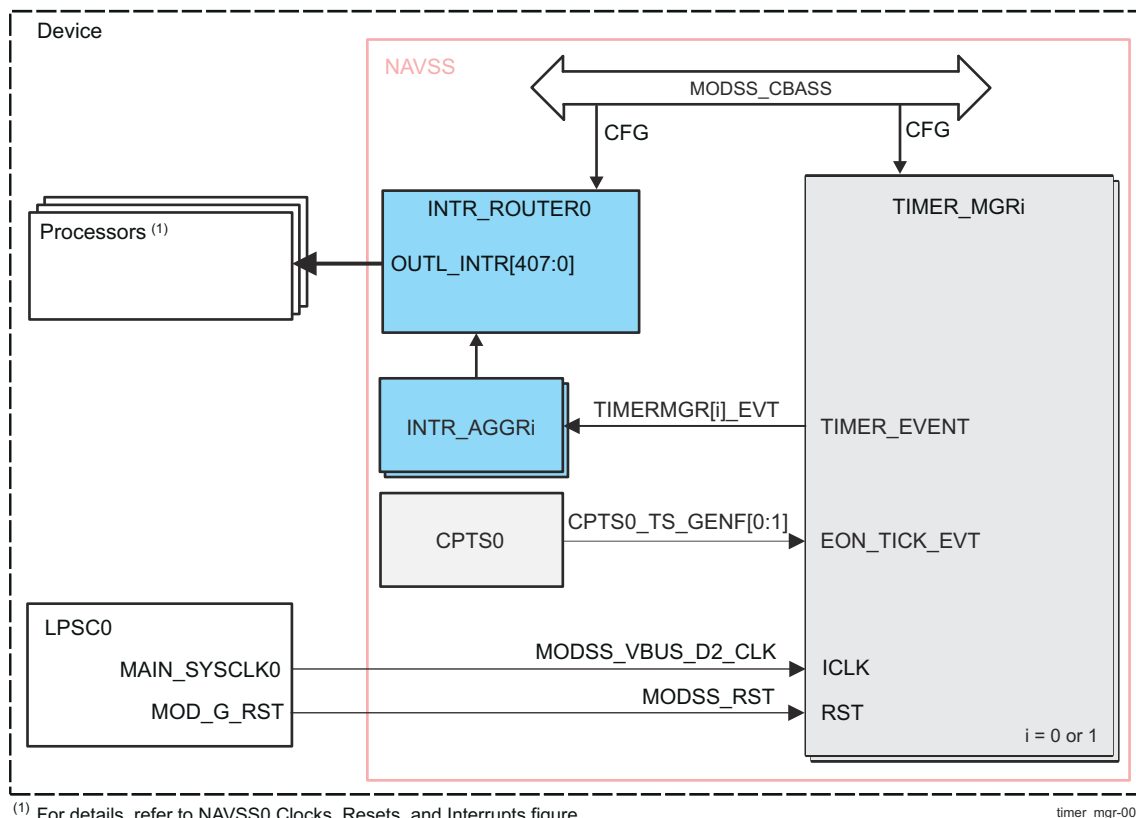

The following features are not supported by the module:

- Tunable GENF CPTS output is an input to this module. The timer bank doesn't manage the divider or the rate/offset compensation. It takes the output of a tuner module as a single input EON\_TICK event.

## 11.2.2 Timer Manager Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-6 shows the Timer Manager integration.

**Figure 11-6. Timer Manager Integration**

Table 11-7 and Table 11-8 summarize the integration of the module in the device.

**Table 11-7. Timer Manager Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
TIMER_MGR0	PSC0	GP	LPSC0	MODSS_CBASS
TIMER_MGR1	PSC0	GP	LPSC0	MODSS_CBASS

**Table 11-8. Timer Manager Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
TIMER_MGR0	TIMER_MGR0_ICLK	MODSS_VBUS_D2_CLK	MAIN_SYSCCLK0	Timer Manager0 interface clock
	EON_TICK_EVT	CPTS0_TS_GENF0	CPTS0	Timer Manager0 asynchronous tick event
TIMER_MGR1	TIMER_MGR1_ICLK	MODSS_VBUS_D2_CLK	MAIN_SYSCCLK0	Timer Manager1 interface clock
	EON_TICK_EVT	CPTS0_TS_GENF1	CPTS0	Timer Manager1 asynchronous tick event
Resets

### 11.2.3 Timer Manager Functional Description

#### 11.2.3.1 Timer Manager Function Overview

Figure 11-7 shows the Timer Manager diagram.

timer\_mgr-004

**Figure 11-7. Timer Manager Block Diagram**

The 1024 timers in the timer manager are organized as the Timer RAM in Figure 11-7. When the timer manager is enabled, the timer counter will increment with the input timer tick, and the control module continuously loops over the Timer RAM, comparing the values against this timer count. When the timer count is greater than a timer value, the timer control module will generate a timer expiration event.

Based on software writes, the timer control module will update the values in the Timer RAM to setup or cancel active timers. Whenever a new value is written to a `TIMERMGR_SETUP_j_k` memory address, the corresponding timer is touched/setup with the current sum of the timer count and the written value; written values are relative to the current timer count. These values are stored in the Timer Reprogramming RAM, so the software may also write to the `TIMERMGR_CONTROL_j_k` registers to flag a timer for reprogramming, using the previously stored reprogramming value. The latter method is preferred when the timer setup value is not changing, as it does not interrupt the RAM state machine.

### 11.2.3.2 Timer Counter

The Timer Manager takes an input timer tick to control the timer rate. All timers share a time base. On each rising edge of this tick event, the timer counter increments. The value of the timer counter may be read by software via the `TIMERMGR_COUNTER` register.

#### 11.2.3.2.1 Timer Counter Rollover

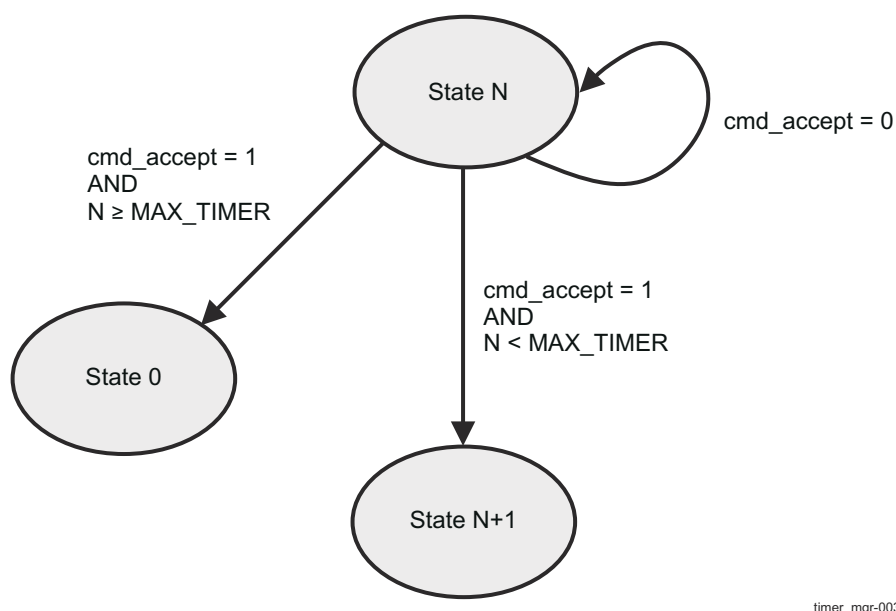

A rollover bit is maintained for each timer, such that when reprogrammed, it is the carry bit from the sum of the current time (counter) and the relative reprogramming value for that timer. This has the effect that any timer whose rollover bit is currently set to a 1 will not expire in the current epoch.

When the counter transitions from `0xFFFF FFFF` to `0x0000 0000`, the timer control module changes the rollover bit for all timers from a 1 to a 0. All timers that previously did not have the rollover bit set, will expire when they are next visited by the state machine, as their timeout value was for the previous epoch.

The overall effect is that the timers continue to expire as expected, regardless of when the counter rollover occurs relative to the state machine.

### 11.2.3.3 Timer Control Module (FSM)

The timer control module controls the RAM accesses for reading and writing. It controls the loops over the timer RAM, checks the values in the RAM to observe expiring timers, flagging timeouts so that events may be triggered and reported. It also takes as input any software-written updates to setup, clear, and touch the timers.

**Figure 11-8. Timer State Machine**

The timer states are sequential, that is, Timer 0 is checked, then Timer 1 is checked, then Timer 2, and so on. The Timer Control FSM will stall in a given state if the `cmd_accept` signal from the `ksdw_spram_ecc` module goes low, and will remain there until the ECC RAM will accept a command.

The timer state always transitions from N to N+1, unless N meets or exceeds the programmed `MAX_TIMER` value, in which case the system will start over at state 0.

#### 11.2.3.4 Timer Reprogramming

There is a reprogramming module that runs in lock step with the FSM, always one state ahead – the FSM exports its `next_state` for use by the reprogramming RAM.

This RAM keeps track of the setup values for the timers as programmed by the `TIMERMGR_SETUP_j_k` memory mapped locations. There is a SET flag for each timer outside of the RAM – if this SET flag is true for the `next_state` timer, the VBUS ready signals are deasserted; if there is a pending timer setup, there cannot be a read or write to the memory, as this would interrupt the Timer FSM state machine and, with enough accesses, potentially cause the system to exceed the 10- $\mu$ s window for timer accuracy.

##### 11.2.3.4.1 Periodic Hardware Timers

By default, timers remain expired until they are either disabled or reset by software. However, by setting the `TIMERMGR_CONTROL_j_k[8]` `AUTORESET` bit for a timer, it will be treated as a periodic hardware timer by the timer manager.

A periodic hardware timer automatically resets itself after expiration. When a periodic hardware timer expires, it is flagged so that on the next pass of the timer control loop, the timer is reprogrammed with the stored `TIMERMGR_SETUP_j_k` value, allowing a timer to repeatedly timeout at intervals equal to the setup value. No software writes are required to clear a periodic hardware timer after it is expired.

There are no *down* events for a periodic hardware timer. A periodic hardware timer pushes an *up* event to the event FIFO when it expires and then resets itself, but does not push any *down* events.

#### 11.2.3.5 Event FIFO

As the subsystem event aggregator requires more than one cycle to process events, there is an internal FIFO to store the generated events. Events may be generated by expiring timers or by activity on the CBA interface, as disabled timers or reset timers must send an event deactivation if the timer was previously expired.

This has an impact on performance, as if there are too many timer expirations in a given window, it potentially violates the 10- $\mu$ s requirement (this is true without the event FIFO as well, given that the system cannot keep up with a timer expiring every cycle, in the worst case).

#### 11.2.3.6 Output Event Lookup (OES RAM)

The expiring timers must be assigned corresponding event numbers for use in the instantiating system. These lookup values correspond to the 16-bit event number that is output on the event interface when a given timer expires.

The lookup table for timer to event number mapping defaults all timers to the invalid event number (0xFFFF), and any invalid event numbers observed upon lookup for an expiring timer will result in no events being generated by the timer manager – invalid (0xFFFF) events are suppressed and will not result in an event on the event interface.

It is expected that the output event assignments will be programmed once per module reset, and that they are static during operation of the timer manager.

## 11.2.4 Timer Manager Programming Guide

### 11.2.4.1 Timer Manager Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

#### 11.2.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Timer Manager module is used for the first time after a device reset.

**Table 11-10. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC	Timer Manager interface clock is enabled with the NAVSS0 MODSS enabled. For more information, see <i>Clocking</i>
CPTS	CPTS0 configuration must be performed as NAVSS0_CPTS0 is the tick source for Timer manager timers. See <i>CPTS</i>

#### 11.2.4.1.2 Initialization Sequence

Initialization of the Timer Manager must include the following steps:

- Set the number of timers to be used. `TIMERMGR_CNTL[10-1] MAX_TIMER`
  - This controls the loop over the timer RAM and is the highest ID timer that will be used in the operation of the Timer Manager (`MAX_TIMER + 1` is the total number of timers in use)
  - This number must not change during the course of operation; it can only be changed when `TIMERMGR_CNTL[0] ENABLE = 0`. It is assumed that the user will set the `MAX_TIMER` value as required.
  - This step can be skipped if using all timers. `MAX_TIMER` defaults to 1024 (that is, all timers in use).
- Write output event mapping for all timers to the OES output event lookup table. This must be done before enabling timer manager and must not be done again once the timer manager has been enabled.
- Write initial setup values to the `TIMERMGR_SETUP_j_k` registers. All timers that will be used initially must have a setup value before the Timer Manager is enabled.
- Enable individual timers. There are two ways to do this.
  - To enable all timers, use the `TIMERMGR_CNTL[12] MASS_ENABLE` bit. This will enable all timers from 0 to `MAX_TIMER`.
    - Note that `MAX_TIMER` and `MASS_ENABLE` should be set in successive writes, or the previous value of `MAX_TIMER` will be used for `MASS_ENABLE`
    - `MASS_ENABLE` must only be used during initialization.
  - Alternately, individual timers can be enabled or disabled with `TIMERMGR_CONTROL_j_k`
    - It is therefore faster to set the individual `TIMERMGR_CONTROL_j_k` bits if more than half of the in-use timers are to be enabled initially. If more than half of the in-use timers are to be enabled initially, it is faster to use `MASS_ENABLE` and then disable specific timers with the `TIMERMGR_CONTROL_j_k` bits.
- Enable the timer manager. Set `TIMERMGR_CNTL[0] ENABLE` to 1.

#### 11.2.4.1.3 Real-time Operating Requirements

While running, a CPU can take the following actions to enable, disable, or touch the timers:

##### 11.2.4.1.3.1 Timer Touch

When a timer needs to be updated – indicating that an interface or function is still alive and timeout should be delayed – there are two means of touching a timer:

- If the timer's respective `TIMERMGR_SETUP_j_k` has the appropriate value for its function, the timer can be set again by writing a 1 to the SET bit of the `TIMERMGR_CONTROL_j_k` register.
  - As the timer should remain enabled, this effectively means writing a 3 to the `TIMERMGR_CONTROL_j_k` register for the timer to be touched

- If the timer's respective `TIMERMGR_SETUP_j_k` needs a new value, writing this value has the side effect of also setting the timer – there is no need to also write to the SET bit of `TIMERMGR_CONTROL_j_k`. This should be relatively infrequent during operation, as the setup values for all timers must be written during initialization.

The preferred method for touching timers is using the SET bit of `TIMERMGR_CONTROL_j_k`. It is considerably more efficient. The reprogramming RAM is a single port RAM, and repeated writes to the `TIMERMGR_SETUP_j_k` registers will impact overall timer performance and may result in longer periods before a valid timeout is observed.

#### 11.2.4.1.3.2 Timer Disable

When a timer is no longer in use, the timer should be disabled with the respective `TIMERMGR_CONTROL_j_k` enable bit.

A disabled timer does not stop the time for that timer relative to the counter, and its current value is considered invalid once disabled. A timer should not be disabled and then subsequently re-enabled without reprogramming/re-setting, as it may timeout unexpectedly.

#### 11.2.4.1.3.3 Timer Enable

To enable a timer while the Timer Manager is running, the timer must first be setup again.

- If the current `TIMERMGR_SETUP_j_k` is appropriate for the timer's intended use, the timer can be re-enabled by writing a 3 to the `TIMERMGR_CONTROL_j_k` register. (ENABLE = 1, SET = 1)
- If the current `TIMERMGR_SETUP_j_k` needs to be changed, write to the `TIMERMGR_SETUP_j_k` before re-enabling the timer. After this value is changed, the timer can be re-enabled by writing 0x3 to the `TIMERMGR_CONTROL_j_k` register (ENABLE = 1, SET = 1)
  - While `TIMERMGR_SETUP_j_k` implies SET, it must still be set as the timer is enabled.

#### 11.2.4.1.4 Power Up/Power Down Sequence

The timer manager must be disabled (clear `TIMERMGR_CNTL[0]` ENABLE to 0) before the timer manager is powered down. The timer manager will only be idle if it is not enabled and the event FIFO is empty – an enabled Timer Manager means the state machine is running and the timer manager is waiting for expired timers.

To power up the Timer Manager if it has been powered down but not reset, the timer values in the timer RAM must be assumed to be invalid. Any timers must either be reprogrammed (`TIMER_SET`) before the timer is re-enabled. If this is not done, the Timer Manager may report timeouts as soon as it is enabled.

Additionally, all timers that have expired must be cleared before disabling the Timer Manager, otherwise there will be no Event Down generated on the event interface to clear the expired timers from the interrupt aggregator. This effectively means that software must disable all timers before writing a 0 to `TIMERMGR_CNTL[0]` ENABLE.

The event FIFO will continue to drive pending events even if the Timer Manager is disabled, so the remaining Event Down actions will still occur – software only needs to disable the timers to ensure that the Event Down commands are pushed into the event FIFO but does not need to wait for the event FIFO to flush before disabling the timer manager.

## 11.3 Time Sync and Compare Events

### 11.3.1 Time Sync Architecture

This section provides a high-level overview of the SoC time synchronization architecture.

#### 11.3.1.1 Time Sync Architecture Overview

[Table 11-11](#) shows the network time synchronization functions supported by the device.

**Table 11-11. Network Time Synchronization Functions in the SoC**

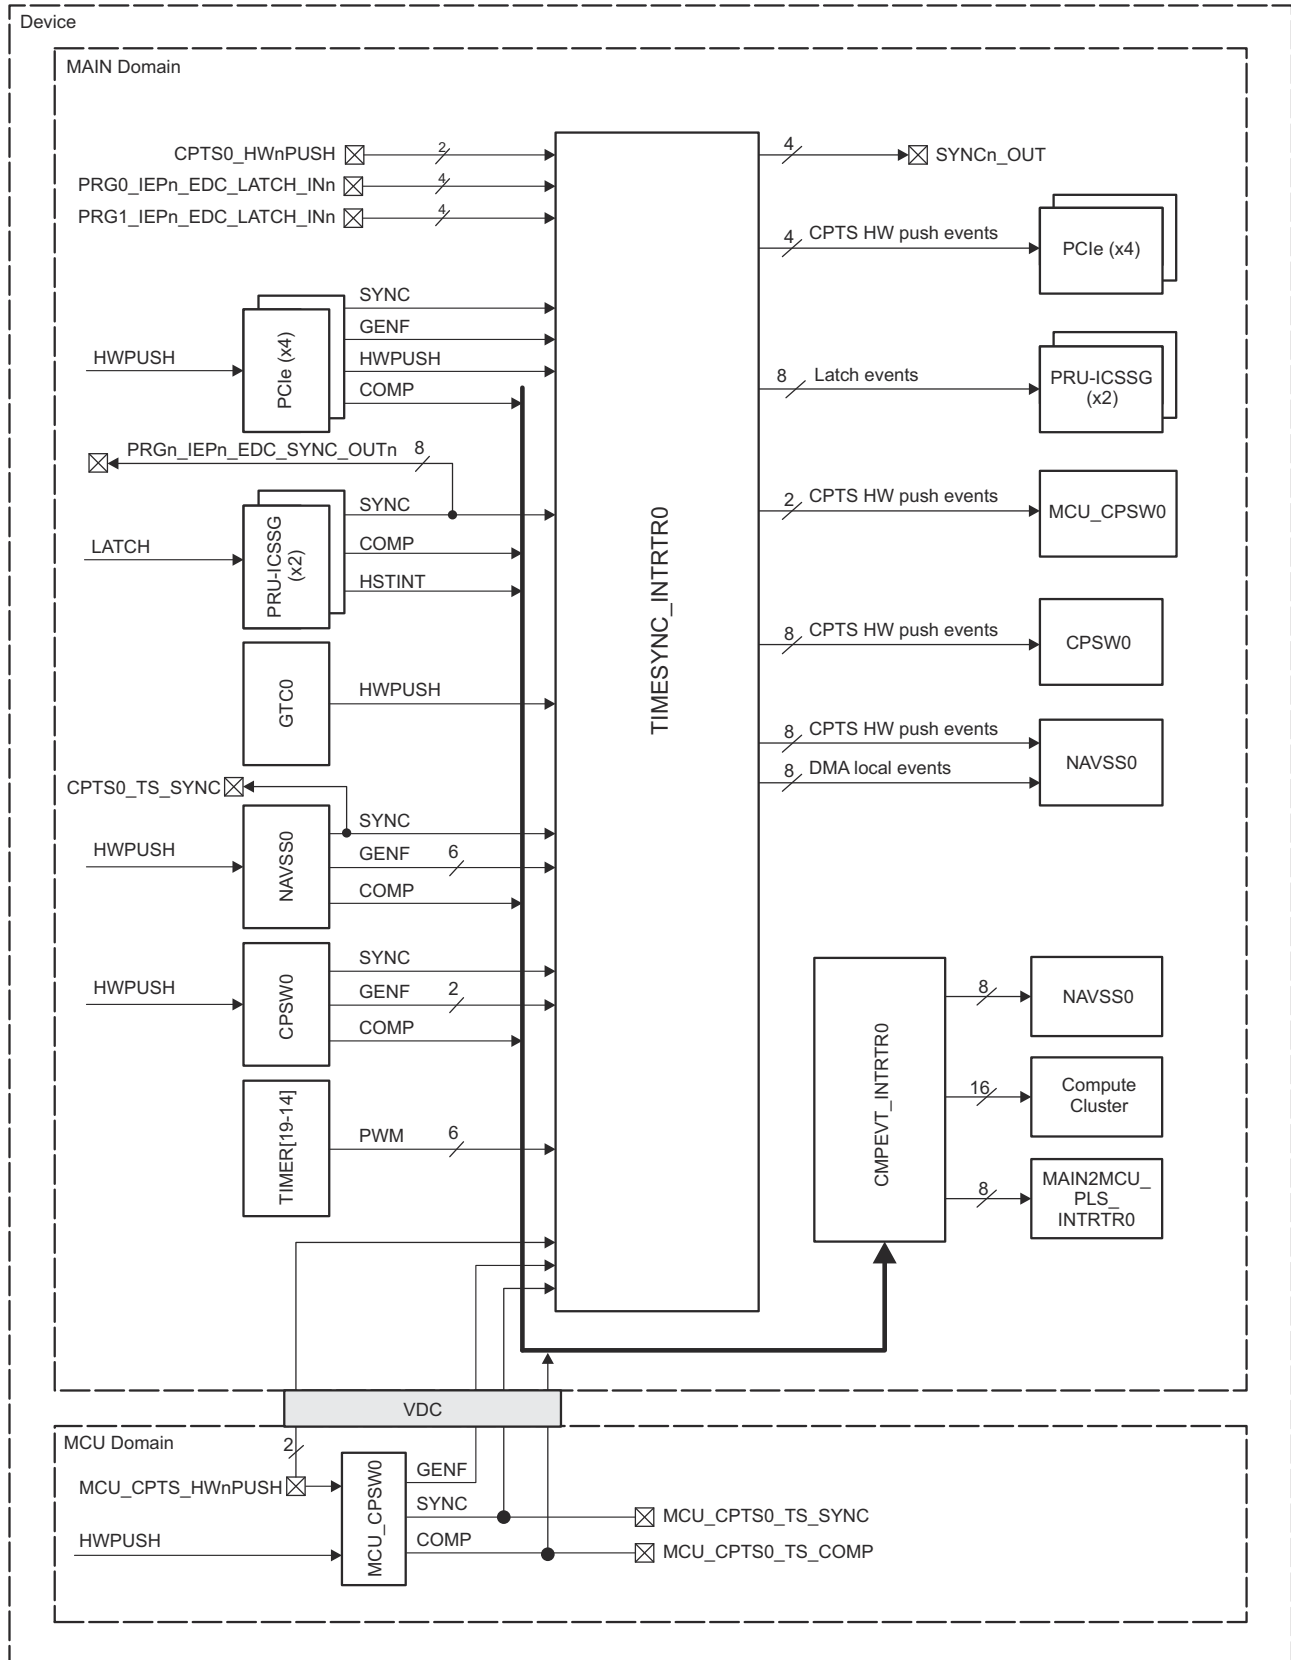

Interface	Time Sync Functions	Supported by
2×PRU-ICSSG	IEEE 1588-2008 (1/2-step), 802.1AS, TSN	PRU-ICSSG firmware
4×PCIE	Precision time measurement (PTM)	PCle controller hardware
2×CPSW	IEEE 1588-2008 (2-step), 802.1AS	CPTS in CPSW
External input reference clock	External time/clock reference	CPTS

#### Note

These time sync functions are described in detail in their respective chapters.

Any of these functions can be a time sync master in the system. A sync router (TIMESYNC\_INTRTR0) provides flexibility for each time domain to choose its synch master independently. In addition, there is also a router (CMPEVT\_INTRTR0) that provides selection of active counter compare events for routing as CPU or DMA events.

[Figure 11-9](#) shows a high-level overview of the SoC time sync architecture.

**Figure 11-9. SoC Time Sync Architecture**

## 11.3.2 Time Sync Routers

### 11.3.2.1 Time Sync Routers Overview

The timesync event router (TIMESYNC\_INTRTR0) and compare event router (CMPEVT\_INTRTR0) are instantiations of the generic interrupt router module in the device.

The TIMESYNC\_INTRTR0 implements a set of multiplexers to provide selection of active CPTS time sync events for routing to CPTS capable modules. There is one register per output that controls the selection (TIMESYNC\_INTRTR0\_MUXCNTL\_y).

The CMPEVT\_INTRTR0 implements a set of multiplexers to provide selection of active CPTS counter compare events for routing as CPU or DMA events. There is one register per output that controls the selection (CMPEVT\_INTRTR0\_MUXCNTL\_y).

[Table 11-12](#) summarizes the configuration details for TIMESYNC\_INTRTR0 and CMPEVT\_INTRTR0.

**Table 11-12. TIMESYNC\_INTRTR0 and CMPEVT\_INTRTR0 Configuration**

Module	Number of Inputs	Number of Outputs	Input Interrupt Type
TIMESYNC_INTRTR0	56	48	Level
CMPEVT_INTRTR0	96	32	Pulse

Refer to [Section 9.3.1, INTRTR Overview](#), for the general programming sequence that is recommended to be followed for all interrupt routers in the device.

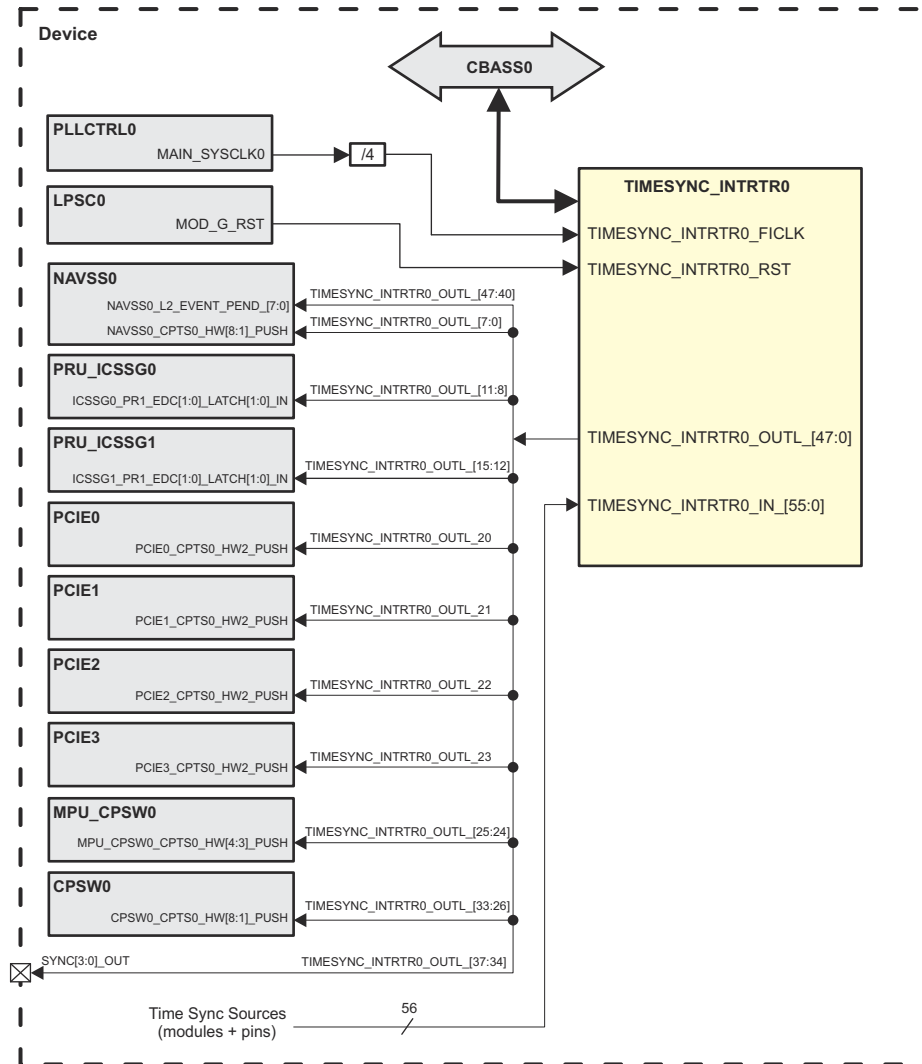

### 11.3.2.2 Time Sync Routers Integration

This section describes the Time Sync Routers integration in the device, including information about clocks, resets, and hardware requests.

### 11.3.2.3 TIMESYNC\_INTRTR0 Integration

Figure 11-10 shows the TIMESYNC\_INTRTR0 integration.

**Figure 11-10. TIMESYNC\_INTRTR0 Integration**

Table 11-13 through Table 11-15 summarize the TIMESYNC\_INTRTR0 integration.

**Table 11-13. TIMESYNC\_INTRTR0 Integration Attributes**

16	INT_ENABLE	R/W	0h	Enable for event output N 0h = Disabled 1h = Enabled
15-7	RESERVED	R	0h	Reserved
6-0	ENABLE	R/W	0h	Mux control for event output N 0h = Select event input 0 (IN0) 1h = Select event input 1 (IN1) ... and so on. Note: Avoid programming this register when input events are active. This could lead to spurious asynchronous output toggles which may lead to unpredictable behavior.

### 11.3.2.9 CMPEVT\_INTRTR0 Registers

Table 11-26 lists the memory-mapped registers for the CMPEVT\_INTRTR0. All register offset addresses not listed in Table 11-26 should be considered as reserved locations and the register contents should not be modified.

**Table 11-25. CMPEVT\_INTRTR0 Instances**

Instance	Base Address
CMPEVENT_INTRTR0_INTR_ROUTER_CFG	00A3 0000h

**Table 11-26. CMPEVT\_INTRTR0 Registers**

Offset	Acronym	Register Name	CMPEVENT_INTRTR0_INTR_ROUTER_CFG Physical Address
0h	<a href="#">CMPEVT_INTRTR0_PID</a>	Peripheral identification register	00A3 0000h
4h + formula	<a href="#">CMPEVT_INTRTR0_MUXCNTL_y</a>	Event mux control register	00A3 0004h + formula

### 11.3.2.10 CMPEVT\_INTRTR0\_PID Register (Offset = 0h) [reset = 66947900h]

CMPEVT\_INTRTR0\_PID is shown in [Figure 11-14](#) and described in [Table 11-28](#).

Description: Peripheral identification register. Uniquely identifies the module and its specific revision.

Return to [Summary Table](#).

**Table 11-27. CMPEVT\_INTRTR0\_PID Instances**

Instance	Physical Address
CMPEVENT_INTRTR0_INTR_ROUTER_CFG	00A3 0000h

**Table 11-28. CMPEVT\_INTRTR0\_PID Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	REV	R	66947900h	TI internal data. Identifies revision of peripheral.

### 11.3.2.11 CMPEVT\_INTRTR0\_MUXCNTL\_y Register (Offset = 4h + formula) [reset = X]

CMPEVT\_INTRTR0\_MUXCNTL\_y is shown in [Figure 11-15](#) and described in [Table 11-30](#).

Description: Event mux control register.

Offset = 4h + (y \* 4h); where y = 0h to 1Fh.

Return to [Summary Table](#).

**Table 11-29. CMPEVT\_INTRTR0\_MUXCNTL\_y  
Instances**

Instance	Physical Address

## 12.1 General Connectivity Peripherals

This section describes the general connectivity peripherals in the device.

### 12.1.1 Analog-to-Digital Converter (ADC)

This chapter describes the Analog-to-Digital Converter (ADC) in the device.

#### 12.1.1.1 ADC Overview

The Analog-to-Digital Converter (ADC) module contains a single 12-bit ADC which can be multiplexed to any 1 of 8 analog inputs (channels).

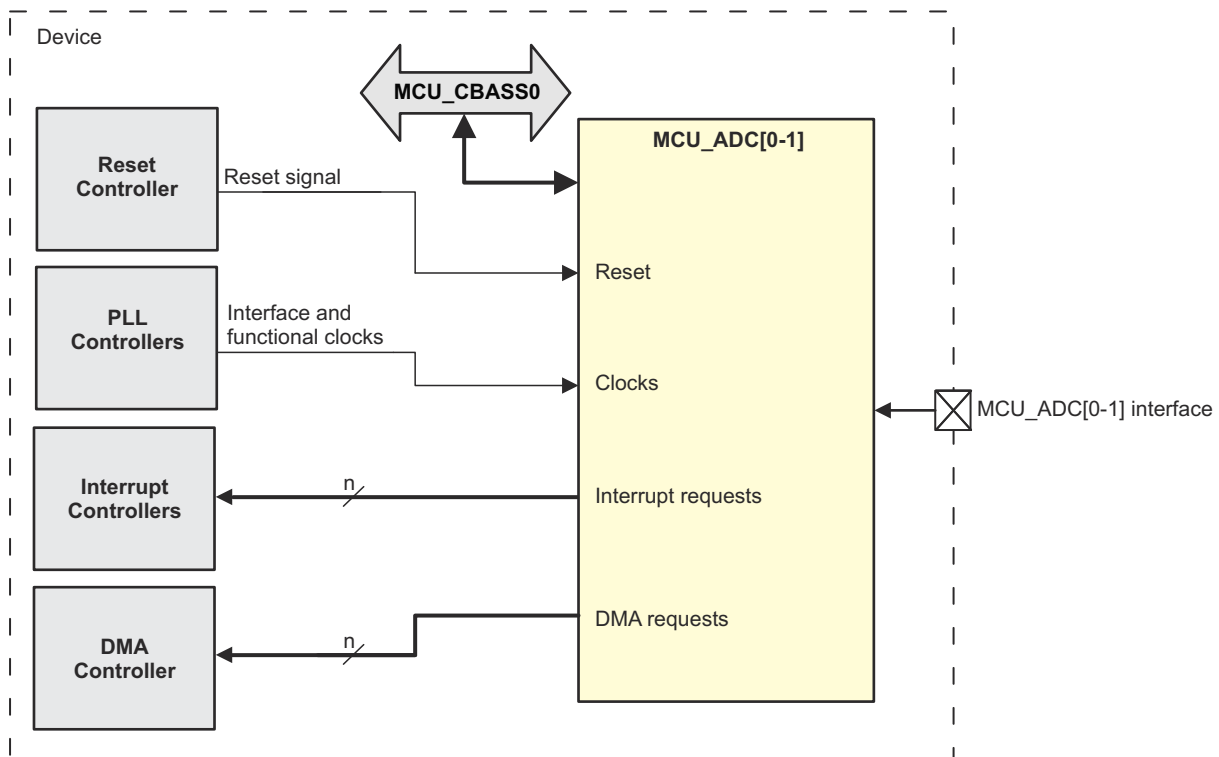

There are two ADC modules in the device.

Table 12-1 shows ADC modules allocation across device domains.

**Table 12-1. ADC Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_ADC0	-	✓	-
MCU_ADC1	-	✓	-

Figure 12-1 presents an overview of the ADC modules.

adc-001

**Figure 12-1. ADC Modules Overview**

#### 12.1.1.1.1 ADC Features

Each ADC module has the following features:

- 4 MSPS rate with a 60 MHz SMPL\_CLK

- Functional Internal Diagnostic Debug Mode
- Single-ended or differential input options
- Each ADC module can be configured and transformed into a digital test inputs
- Programmable Finite State Machine (FSM) sequencer that supports the following:
  - Software initiated start of conversion
  - Optional hardware start of conversion (SOC), synchronized to external hardware event
  - Single conversion (one-shot mode)
  - Continuous conversions (continuous mode)
  - Sequence through all enabled steps based on a mask
  - Programmable open delay before executing each step
  - Programmable sampling delay for each step
  - Programmable averaging (16, 8, 4, 2, or 1) of input samples for each step
  - Store data in either of two FIFOs – 256-word × 16-bit
  - Option to encode input (channel) number with data
  - Support for servicing FIFOs via DMA or processor
  - Programmable DMA request event (for each FIFO)
- Support for the following interrupts and status, with masking:
  - Interrupt if AFE fails to return end of conversion (EOC)
  - Interrupt after a sequence of conversions (all non-masked steps)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

#### **12.1.1.1.2 ADC Not Supported Features**

- No packing of 16-bit FIFO data onto 32-bit DMA bus
- Big endian
- Support only 32-bit aligned read/write accesses on the MCU\_CBASS0/DMA ports
- Simultaneous sampling

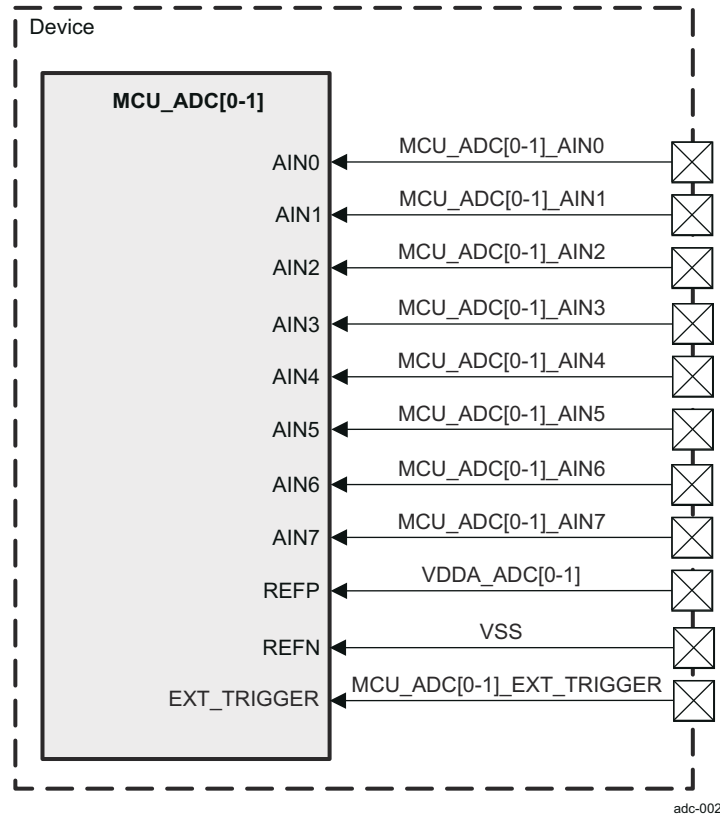

### 12.1.1.2 ADC Environment

The MCU\_ADC[0-1] modules are hereinafter referred to as ADC module.

This section describes the ADC external connections (environment).

#### 12.1.1.2.1 ADC Interface Signals

Figure 12-2 shows the ADC signals.

**Figure 12-2. ADC Signals**

Table 12-2 describes the ADC I/O signals.

**Table 12-2. ADC I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCU_ADC[0-1]</b>				
AIN0	MCU_ADC[0-1]_AIN0	A/I	Analog input 0	HiZ
AIN1	MCU_ADC[0-1]_AIN1	A/I	Analog input 1	HiZ

<b>MCU_ADC[0-1]</b>				
EXT_TRIGGER	MCU_ADC[0-1]_EXT_TRIGGER	I	External trigger for ADC	HiZ

(1) I = Input; A = Analog

(2) HiZ = High Impedance

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.1.3 ADC Integration

This section describes ADC integration in the device, including information about clocks, resets, and hardware requests.

#### 12.1.1.3.1 ADC Integration in MCU Domain

There are two ADC modules integrated in the device MCU domain - MCU\_ADC0 and MCU\_ADC1. [Figure 12-3](#) shows the integration of MCU\_ADC0 and MCU\_ADC1.

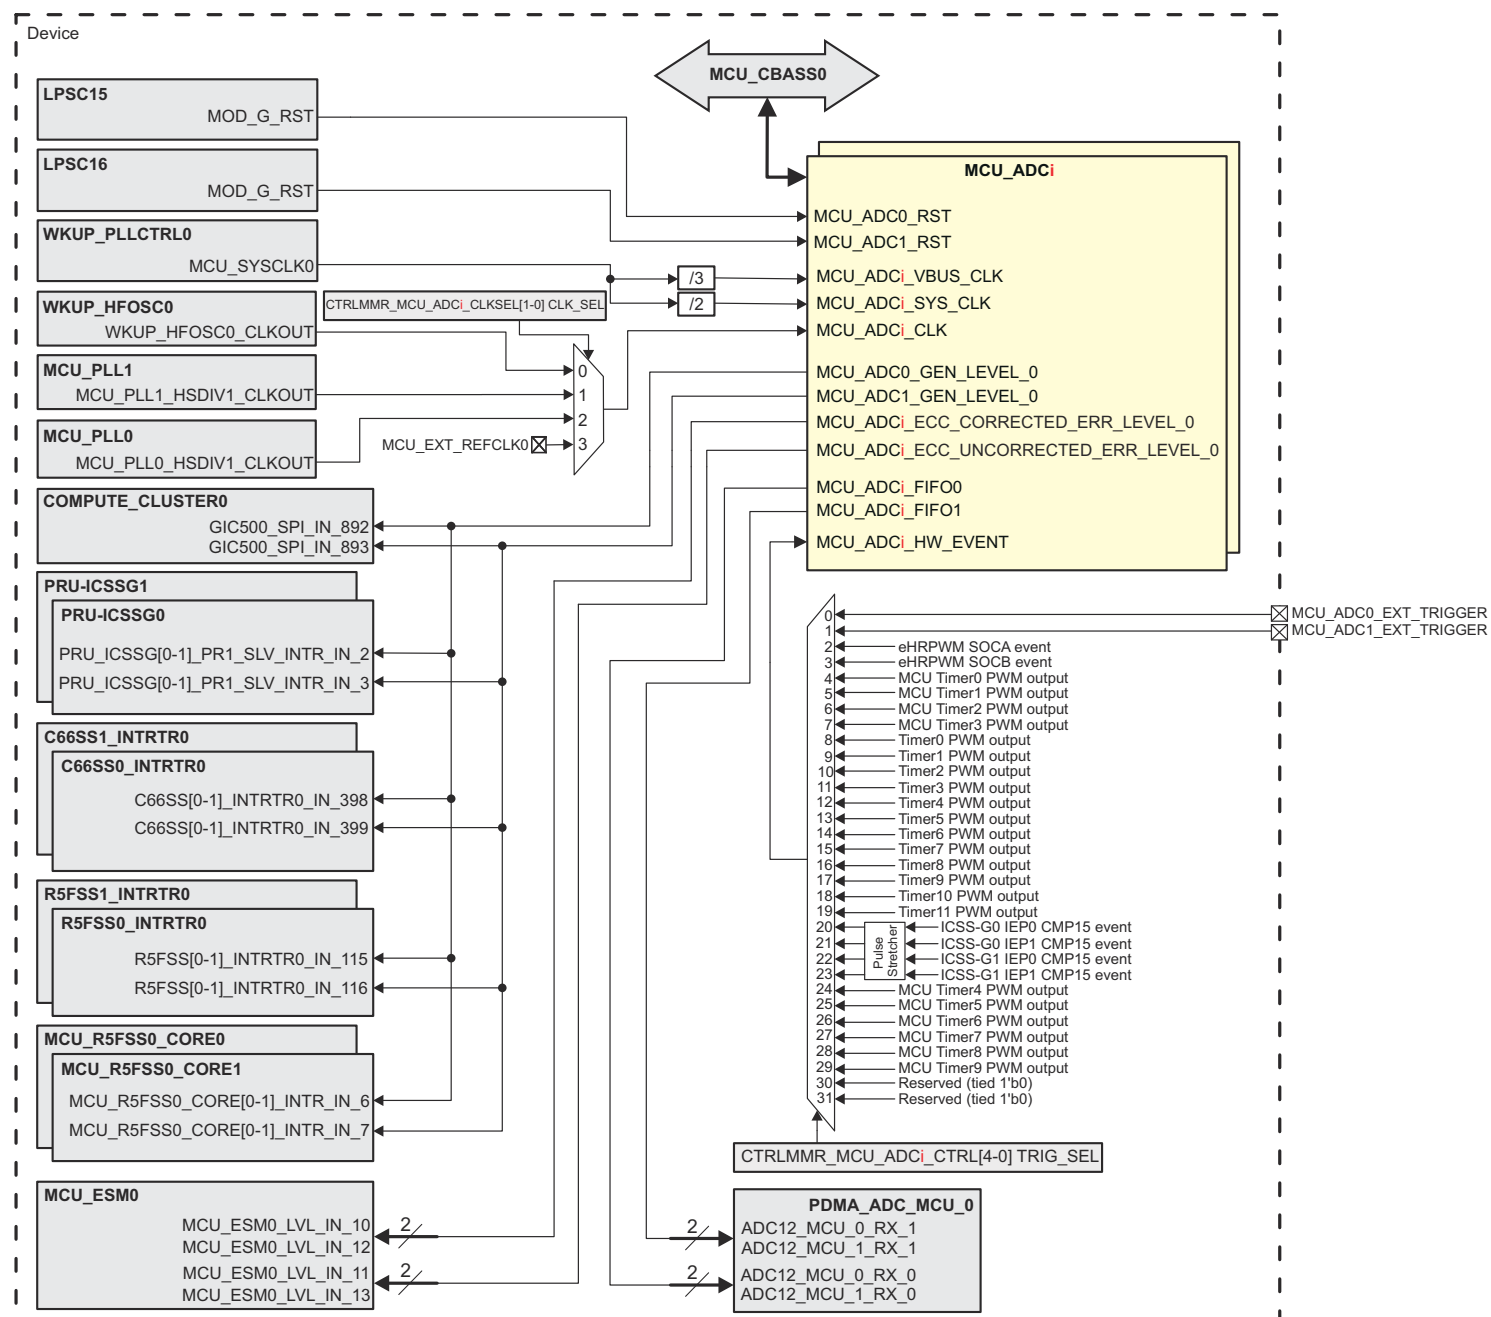

Table 12-3 through Table 12-5 summarize the integration of MCU\_ADC0 and MCU\_ADC1 in device MCU domain.

**Table 12-3. MCU\_ADC[0-1] Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_ADC0	WKUP_PSC0	PD0	LPSC15	MCU_CBASS0
MCU_ADC1	WKUP_PSC0	PD0	LPSC16	MCU_CBASS0

### 12.1.1.4 ADC Functional Description

#### 12.1.1.4.1 ADC FSM Sequencer Functional Description

The FSM sequencer supports up to 16 steps that can be configured to perform analog-to-digital conversions. Each of the 16 steps can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each step has its own programmable step configuration (ADC\_CONFIG\_j) and step delay (ADC\_DELAY\_j) registers that allow users to configure the ADC operation on a per-step basis.

The FSM sequencer enters Idle immediately after the ADC is enabled and remains in Idle while waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to Idle or immediately begin repeating steps configured for continuous mode.

An ENDOSEQUENCE interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

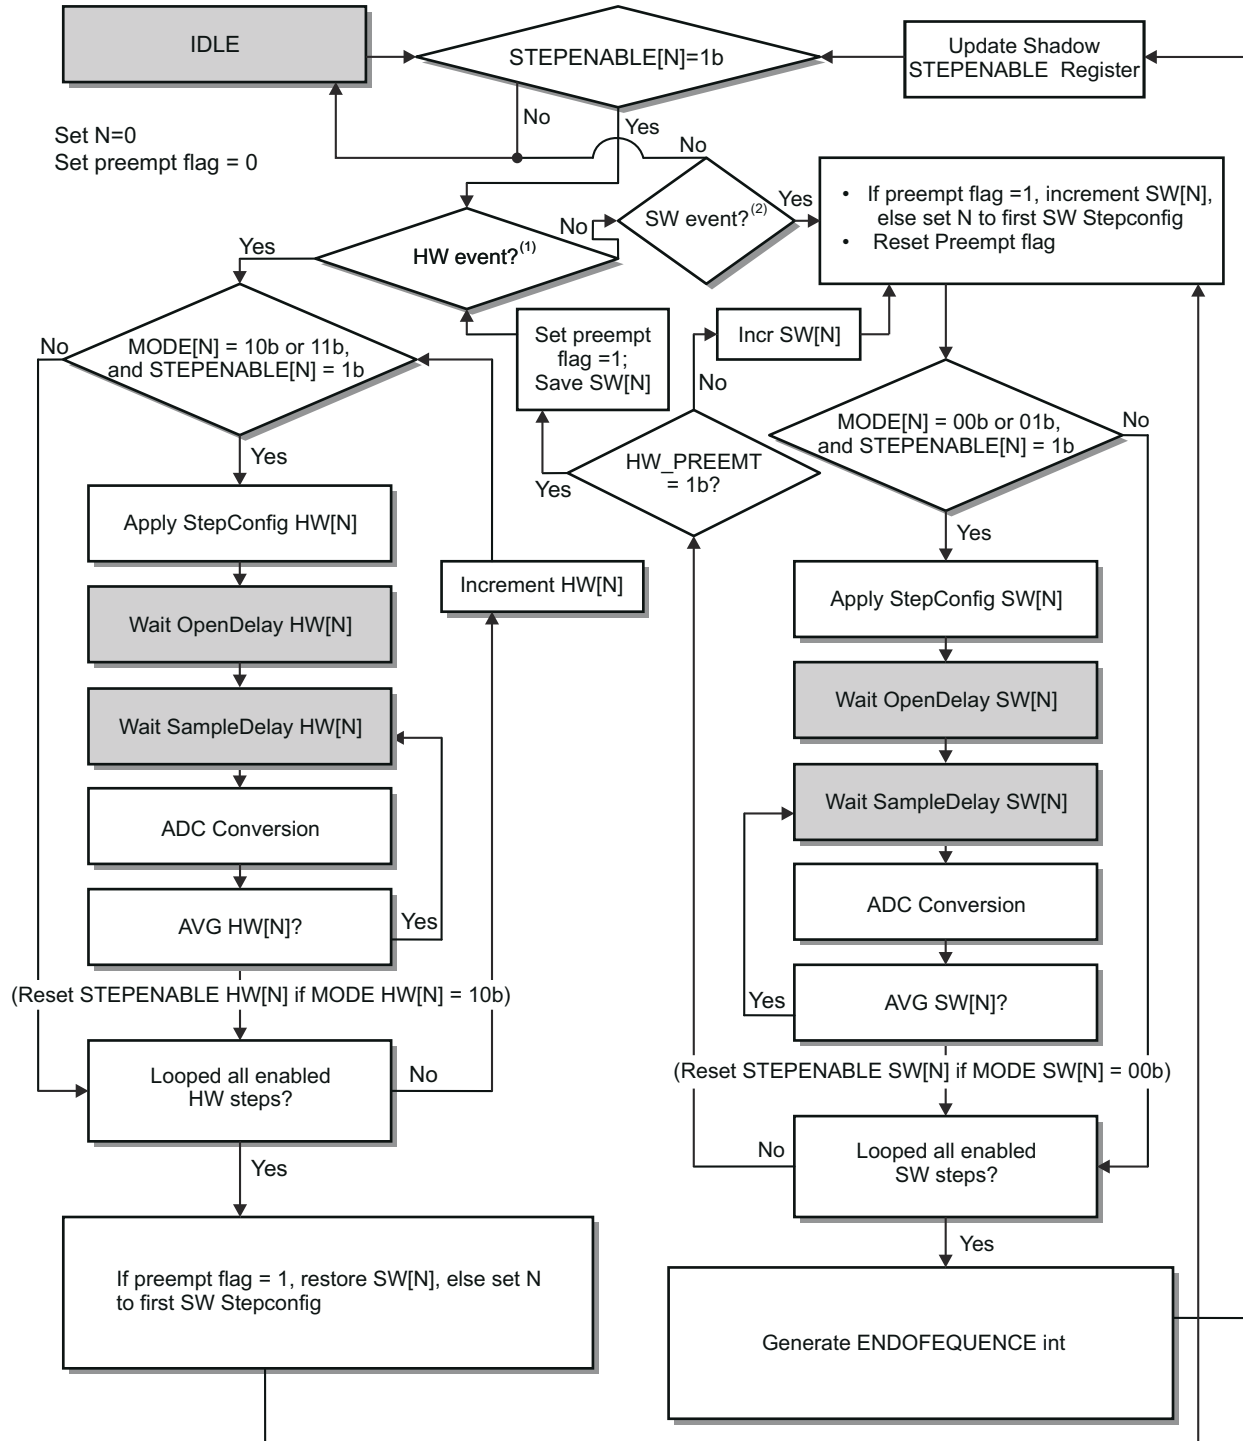

Figure 12-4 illustrates how the FSM sequencer works. Each shaded box represents a FSM state.

---

#### Note

Figure 12-4 does not represent the number of SMPL\_CLK cycles required by each state since some states implement user programmable delays that may require more than one SMPL\_CLK cycle to complete.

---

(1) MODE[N] = 10b or 11b, STEPENABLE[N] = 1b, and HW Event = 1

(2) MODE[N] = 00b or 01b and STEPENABLE[N] = 1b

adc-005

**Figure 12-4. Sequencer FSM**

#### 12.1.1.4.1.1 Step Enable

A step is enabled or disabled via the ADC\_STEPENABLE register. The system software should only write to the ADC\_STEPENABLE register when the ADC is disabled or the FSM sequencer is idle. Therefore, it may

be necessary to disable the ADC before updating the ADC\_STEPPABLE register if the FSM sequencer is executing back-to-back steps where it never enters idle.

#### **12.1.1.4.1.2 Step Configuration**

##### **12.1.1.4.1.2.1 One-Shot (Single) or Continuous Mode**

Each step can be configured to operate in one-shot or continuous mode via the least significant bit of the MODE bit-field of the respective ADC\_CONFIG\_j register. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

##### **12.1.1.4.1.2.2 Software- or Hardware-Enabled Steps**

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective ADC\_CONFIG\_j register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the ADC\_CONTROL register.

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled).

The EXT\_TRIGGER input signal is used by HW Enabled steps. The trigger input has the option of being sourced from a device input pin or several on-device peripherals via a multiplexer controlled by TRIG\_SEL of the respective CTRLMMR\_MCU\_ADC0\_CTRL or CTRLMMR\_MCU\_ADC1\_CTRL register. When this option is selected, the hardware event will be triggered after the EXT\_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of SYS\_CLK. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

SW Enabled steps can be preempted by HW Enabled steps when the HW\_PREEMPT bit in the ADC\_CONTROL register is set.

##### **12.1.1.4.1.2.3 Averaging of Samples**

Each step can be configured, via the respective ADC\_CONFIG\_j register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, open delay is only applied to the first sample while sample delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO.

##### **12.1.1.4.1.2.4 Analog Multiplexer Input Select**

The AFE contains two 9-to-1 analog multiplexers which are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. Each step can be configured, via the respective ADC\_CONFIG\_j register, to select the appropriate input sources. For more information, refer to [Figure 12-6](#) and the ADC\_CONFIG\_j register field descriptions.

##### **12.1.1.4.1.2.5 Differential Control**

The ADC supports differential inputs and each step can be configured, via the respective ADC\_CONFIG\_j register, to select single-ended input mode or differential input mode.

---

#### **Note**

The ADC INM input must be sourced from REFN for any steps configured to operate in single-ended mode.

---

##### **12.1.1.4.1.2.6 FIFO Select**

The ADC contains two FIFOs and each step can be configured, via the respective ADC\_CONFIG\_j register, to store its ADC data into either FIFO.

#### 12.1.1.4.1.2.7 Range Check Interrupt Enable

Each step can be configured, via the respective ADC\_CONFIG\_j register, to compare the value of ADC data to high and low limits programmed in the ADC\_RANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of HIRANGE or less than the value of LOWRANGE. Refer to the ADC\_RANGE register field descriptions for information related to setting the high and low limits that trigger an out-of-range interrupt.

#### 12.1.1.4.1.3 Open Delay and Sample Delay

The FSM sequencer provides two programmable delays for each step. The value of OPENDELAY is used to control when the acquisition begins after the step starts and the value of SAMPLEDELAY is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective ADC\_DELAY\_j register.

##### 12.1.1.4.1.3.1 Open Delay

OPENDELAY defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one SMPL\_CLK clock period for each incremental value of OPENDELAY.

##### 12.1.1.4.1.3.2 Sample Delay

SAMPLEDELAY defaults to a value of zero which causes the acquisition period to be equal to two SMPL\_CLK clock periods. The acquisition period can be extended one SMPL\_CLK clock for each incremental value of SAMPLEDELAY.

The value of SAMPLEDELAY should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

#### 12.1.1.4.1.4 Interrupts

The ADC has 9 internal events that can trigger an interrupt to the processor. These events are logically or'ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the ADC\_ENABLE\_SET and ADC\_ENABLE\_CLR registers. Once an interrupt is generated, the ADC\_STATUS register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a '1' to the corresponding bit of the ADC\_STATUS register.

The following interrupts are supported by the device ADC:

- An ENDOSEQUENCE interrupt is generated after the FSM sequencer completes the last enabled step.
- FIFO0UNFL/FIFO1UNFL or FIFO0OVFL/FIFO1OVFL interrupts. Each FIFO also has the ability to generate overrun and underflow interrupts. The ADC does not recover from overrun or underflow conditions automatically. Therefore, software will need to disable and re-enable the ADC after this occurs. The FSM sequencer must be Idle before turning the ADC module back on. This can be confirmed by reading the ADC\_SEQUENCER\_STAT register, when FSM\_BUSY = 0x0 and STEP\_IDLE = 0x10000.
- FIFO0THRS and FIFO1THRS interrupts. Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The FIFO0THRS and FIFO1THRS interrupt is generated when the value of NUMWDS in the respective ADC\_FIFO0WC or ADC\_FIFO1WC register equals the word count threshold value programmed in THRESHOLD of the respective ADC\_FIFO0THRESHOLD or ADC\_FIFO1THRESHOLD register.
- OUTOFRANGE interrupt. This interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global ADC\_RANGE register. The OUTOFRANGE interrupt is generated if the ADC data value is greater than the value programmed in HIRANGE or less than the value programmed in LOWRANGE.
- AFE\_EOC\_MISSING interrupt. This interrupt is generated when the FSM sequencer does not receive an expected EOC from the AFE.

#### 12.1.1.4.1.5 Power Management

The software also has the option to turn off the AFE power by writing to the ADC\_CONTROL[4] PD bit. By default, after the initial power on the AFE is powered down and software is responsible for turning it on. Software

must wait minimum 4  $\mu$ s after a AFE power up and before starting a conversion (must be followed every time the AFE is powered up). It is the software's responsibility to empty the FIFO before requesting the ADC to enter sleep state.

#### 12.1.1.4.1.6 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the ADC\_DMAENABLE\_SET and ADC\_DMAENABLE\_CLR registers.

#### 12.1.1.4.2 ADC AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of SMPL\_CLK after the falling edge of SOC. The SOC pulse width will be the value of SAMPLEDELAY plus one SMPL\_CLK periods, so the total ADC acquisition time will be the value of SAMPLEDELAY plus two SMPL\_CLK periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen SMPL\_CLK periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

The ADC output is positive binary weighted data ranging from 0 to  $(2^{12} - 1)$ . When configured for single-ended mode, ADC output data values 0 to  $(2^{12} - 1)$  represents a corresponding input voltage that ranges from the ADC negative reference (REFN) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to  $((2^{12}/2) - 1)$  represents a corresponding negative differential input voltage that ranges from the REFP voltage to the REFN voltage and output data values  $(2^{12}/2)$  to  $(2^{12} - 1)$  represents a corresponding positive differential input voltage that ranges from the REFN voltage to the REFP voltage.

Using the minimum values of OPENDELAY and SAMPLEDELAY, the ADC can sample an analog input every 15 SMPL\_CLK periods.

[Figure 12-5](#) illustrates the operation of the FSM sequencer and ADC AFE, with indicators showing when the hardware configuration defined by ADC\_CONFIG\_j and ADC\_DELAY\_j registers are applied.

#### Note

[Figure 12-5](#) assumes both steps shown are software enabled with averaging turned off, an OPENDELAY value of 1, and SAMPLEDELAY value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the SMPL\_CLK. If the value of OPENDELAY were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

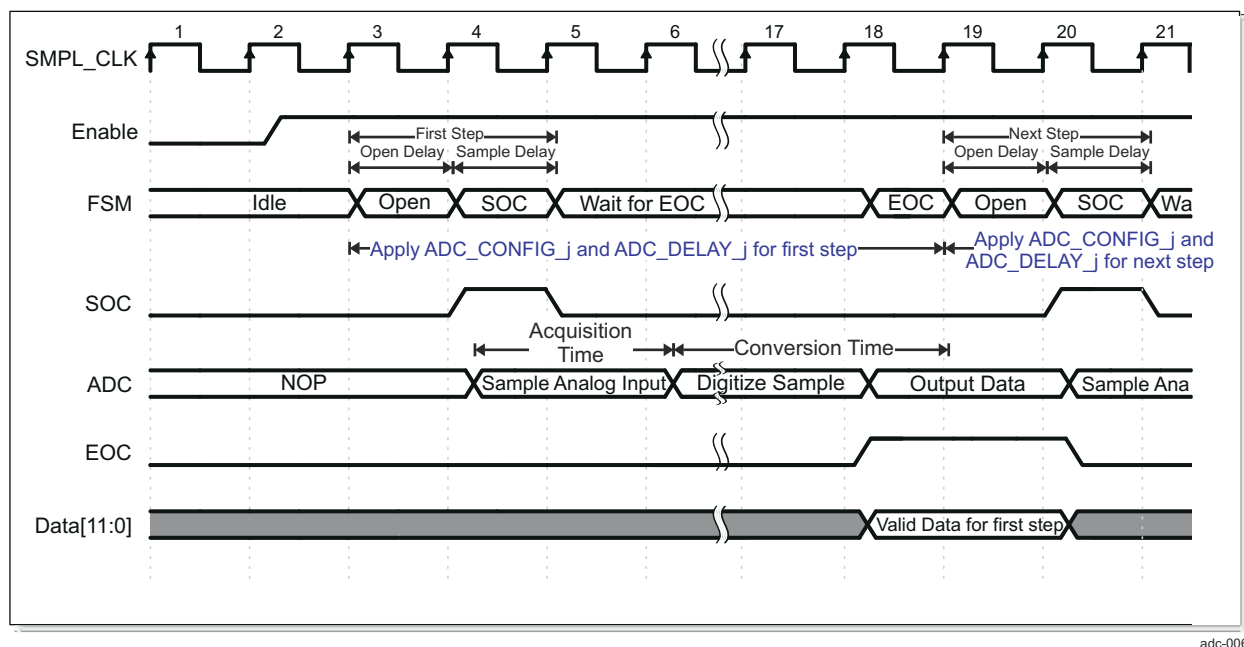

Figure 12-5. Example Timing Diagram for Sequencer

#### 12.1.1.4.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. The user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. For more information, refer to [Figure 12-6](#) and the ADC\_CONFIG\_j register field descriptions.

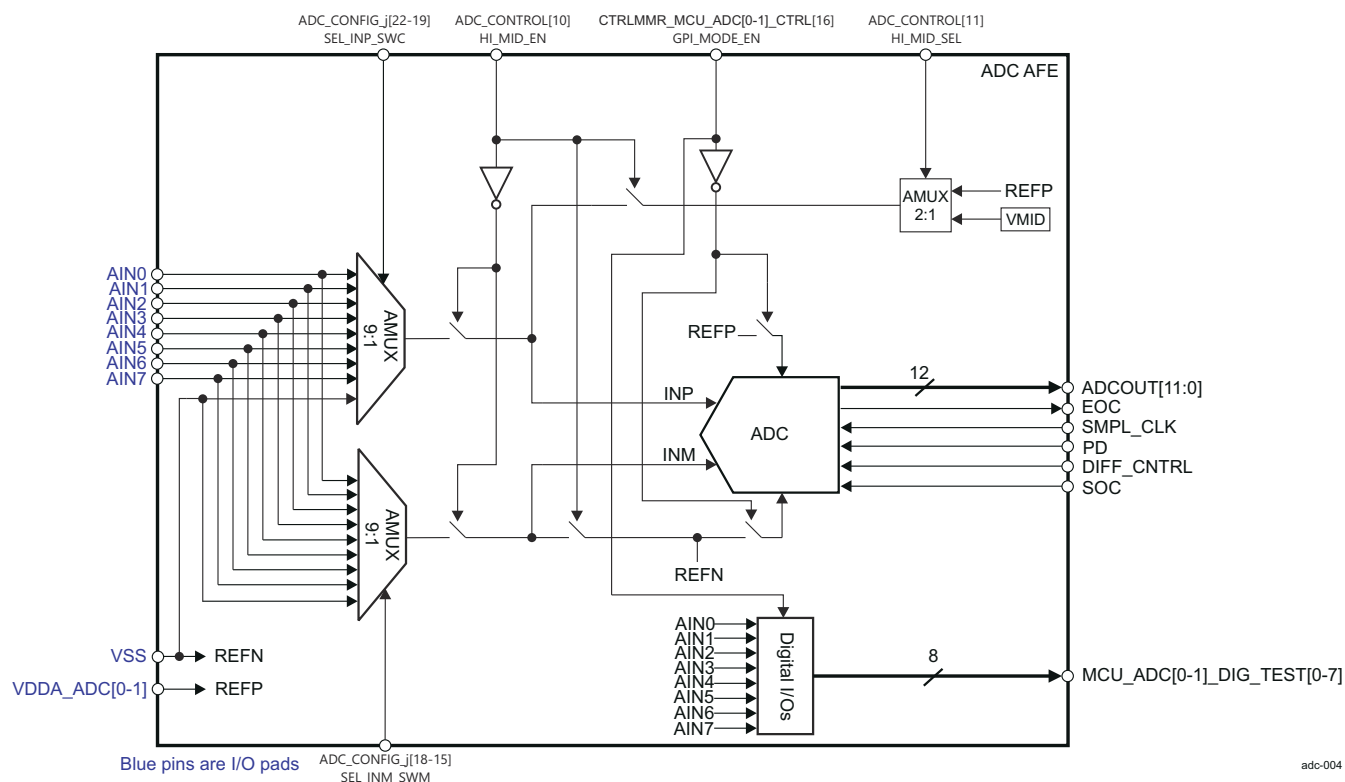

Figure 12-6. Functional Block Diagram

#### 12.1.1.4.2.2 ADC GPI Integration

The ADC module can be configured to be used as a general digital test block which can generate 8 VDDA domain digital signals MCU\_ADC[0-1]\_DIG\_TEST[0-7]. These digital outputs are made available to the device PinMux, where are used as general purpose digital inputs with some restrictions. The CTRLMMR\_MCU\_ADC[0-1]\_CTRL[16] GPI\_MODE\_EN is the enable bit.

When GPI\_MODE\_EN bit is '0', the ADC is in normal operation.

When GPI\_MODE\_EN bit is '1', the ADC multiplexes the 8 analog inputs to 8 VDDA domain digital I/O block and outputs the signals to DIG\_TEST[7-0] pins.

Restrictions on this usage are:

- The GPI\_MODE\_EN bit is not switched dynamically.
- ADC supports only 1.8V logic level.
- All ADC inputs on each ADC function either can be configured as digital or analog inputs.
- These are GPI only, not GPIO (no output buffer).

#### 12.1.1.4.3 ADC FIFOs and DMA

##### 12.1.1.4.3.1 FIFOs

There are two sample FIFOs (ADC\_FIFO0 and ADC\_FIFO1), which store sample data from the AFE. Can be configured, via the respective ADC\_CONFIG\_j register.

The processor can read ADC data directly from the FIFO by using the respective ADC\_FIFO0DATA or ADC\_FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after the ADC is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling the ADC.

##### 12.1.1.4.3.2 DMA

The ADC has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the ADC\_DMAENABLE\_SET register and disabled via the ADC\_DMAENABLE\_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in DMAREQLEVEL of the respective ADC\_FIFO0DMAREQ or ADC\_FIFO1DMAREQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

#### 12.1.1.4.4 ADC Error Correcting Code (ECC)

The Error Correcting Code (ECC) is a mechanism for providing increased system reliability (via reduction of memory soft errors) by allowing single bit errors to be detected and corrected and double bit errors to be detected.

The ECC Aggregator provides a single EOI-handshake based interrupt to the host (for both single and double error detections).

The ECC Aggregator will write 0's to all of memory after reset is released. The ADC\_SEQUENCER\_STAT[6] MEM\_INIT\_DONE bit will be 0 during this period and will be set to 1 upon completion.

For more information about the ECC Aggregator, see *ECC Aggregator* and *ADC ECC Registers*.

See also *Testing ECC Error Injection* and *ADC ECC Registers*.

##### 12.1.1.4.4.1 Testing ECC Error Injection

The read enable (REN) input to the RAMs instantiated in this module are constantly tied to 1'b1. As a result, read is continuously in progress.

In order to test ECC single error injection on a particular RAM row, the following conditions have to be maintained before setting the ADC\_ECC\_CTRL[3] FORCE\_SEC bit:

- ADC\_ECC\_CTRL[5] FORCE\_N\_ROW bit has to be clear. This is required in order to configure required row in
- ADC\_ECC\_CTRL[6] ERROR\_ONCE bit has to be clear. If this bit is set, the ECC error occurs immediately after setting ADC\_ECC\_CTRL[3] FORCE\_SEC bit since REN is always set
- ADC\_ECC\_ERR\_CTRL1[31:0] ECC\_ROW bit field has to be point to the required row address

#### **12.1.1.4.5 ADC Functional Internal Diagnostic Debug Mode**

The ADC function can be validated by measuring known reference voltage sources. This feature provides register control that connects the AFE to known reference voltage sources. However, it does not automatically configure the FSM to perform conversions to measure these sources. Software will need to configure the FSM to perform a measurement after selecting this mode of operation.

ADC\_CONTROL[10] HI\_MID\_EN is used to disconnect the AFE from all analog inputs and connect it to one of two known reference voltage sources. ADC\_CONTROL[11] HI\_MID\_SEL is used to select REFP or VMID as the known reference voltage source.

The conversion results is expected to produce a full scale value when the AFE is connected to REFP and approximate half scale value when the AFE is connected to VMID.

The steps are:

- Disable the ADC if previously enabled and wait until the FSM is not busy.
- Put the AFE in a functional internal diagnostic debug mode by setting the ADC\_CONTROL[10] HI\_MID\_EN bit to 1.
- Select one of the two reference voltage sources by setting the ADC\_CONTROL[11] HI\_MID\_SEL bit.
  - 0 selects VMID
  - 1 selects REFP
- Configure the FSM to measure the selected reference voltage source.
- Enable the ADC and evaluate the results.
- When debug is complete, disable the ADC and wait until the FSM is not busy, re-program the FSM for functional operation, then re-enable the ADC.

### 12.1.1.5 ADC Programming Guide

#### 12.1.1.5.1 ADC Low-Level Programming Models

##### 12.1.1.5.1.1 Global Initialization

##### 12.1.1.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module is to be used for the first time after a device reset.

**Table 12-6. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC15	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
LPSC16	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
WKUP_PLLCTRL0	WKUP_PLLCTRL0 configuration must be done to enable the clocks to the ADC modules, see <i>Clocking</i> .
WKUP_HFOSC0	WKUP_HFOSC0 configuration must be done to enable the clocks to the ADC modules, see <i>Clocking</i> .
MCU_PLL0	MCU_PLL0 configuration must be done to enable the clocks to the ADC modules, see <i>Clocking</i> .
MCU_PLL1	MCU_PLL1 configuration must be done to enable the clocks to the ADC modules, see <i>Clocking</i> .
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
PRU-ICSSG0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling PRU-ICSSG0/1 interrupts, see <i>Interrupts</i> .
C66SS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling C66SS0/1_INTRTR0 interrupts, see <i>Interrupts</i> .
R5FSS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0/1_INTRTR0 interrupts, see <i>Interrupts</i> .
MCU_R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_R5FSS0_CORE0/1 interrupts, see <i>Interrupts</i> .
MCU_ESM0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_ESM0 interrupts, see <i>Interrupts</i> .
PDMA_ADC_MCU_0	PDMA_ADC_MCU_0 controllers configuration must be done to enable the module PDMA_ADC_MCU_0 input request, see <i>Data Movement Architecture (DMA)</i> .
Interconnect	For information about the MCU_CBASS0 interconnect configuration, see <i>System Interconnect</i> .

##### 12.1.1.5.1.1.2 General Programming Model

**Table 12-7. General Programming Model**

Step	Register/Bit Field/Programming Model	Value
Power up the AFE	ADC_CONTROL[4] PD	0
If using DMA, set the DMA threshold and enable the appropriate DMA request(s); or set the processor threshold and enable the appropriate threshold interrupt(s) as part of the next step.	ADC_DMAENABLE_SET/ADC_FIFO0DMAREQ/ ADC_FIFO1DMAREQ/ ADC_FIFO0THRESHOLD/ ADC_FIFO1THRESHOLD	0x-
Setup or mask the appropriate interrupts.	ADC_ENABLE_SET	0x-
Configure each step being used to perform an ADC conversion.	ADC_CONFIG_j	0x-
Configure the delays for each step being used to perform an ADC conversion.	ADC_DELAY_j	0x-
Enable each step being used to perform an ADC conversion.	ADC_STEPENABLE	0x-
Wait minimum 4 $\mu$ s before starting a conversion to provide time for the AFE to power-up. (referenced from POWER_DOWN write to 0)		
Enable the ADC module	ADC_CONTROL[0] MODULE_ENABLE	1

**Table 12-8. Turn-Off**

Step	Register/Bit Field/Programming Model	Value
Turn off ADC module enable bit when finished. This will stop the ADC after the current step is complete.	ADC_CONTROL[0] MODULE_ENABLE	0

**Table 12-9. Turn-On After Turn-Off**

Step	Register/Bit Field/Programming Model	Value
Enable the ADC module enable bit	ADC_CONTROL[0] MODULE_ENABLE	1

## 12.1.2 General-Purpose Interface (GPIO)

This chapter describes the General-Purpose Input/Output (GPIO) for the device.

### 12.1.2.1 GPIO Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, the user can write to an internal register to control the state driven on the output pin. When configured as an input, user can obtain the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce host CPU interrupts and DMA synchronization events in different interrupt/event generation modes.

The device has ten instances of GPIO modules. The GPIO modules are integrated in three groups.

- Group one: WKUP\_GPIO0 and WKUP\_GPIO1. On I/O pins this group is named WKUP\_GPIO0.
- Group two: GPIO0, GPIO2, GPIO4, and GPIO6. On I/O pins this group is named GPIO0.
- Group three: GPIO1, GPIO3, GPIO5, and GPIO7. On I/O pins this group is named GPIO1.

The corresponding groups I/O pins are multiplexed within each group modules.

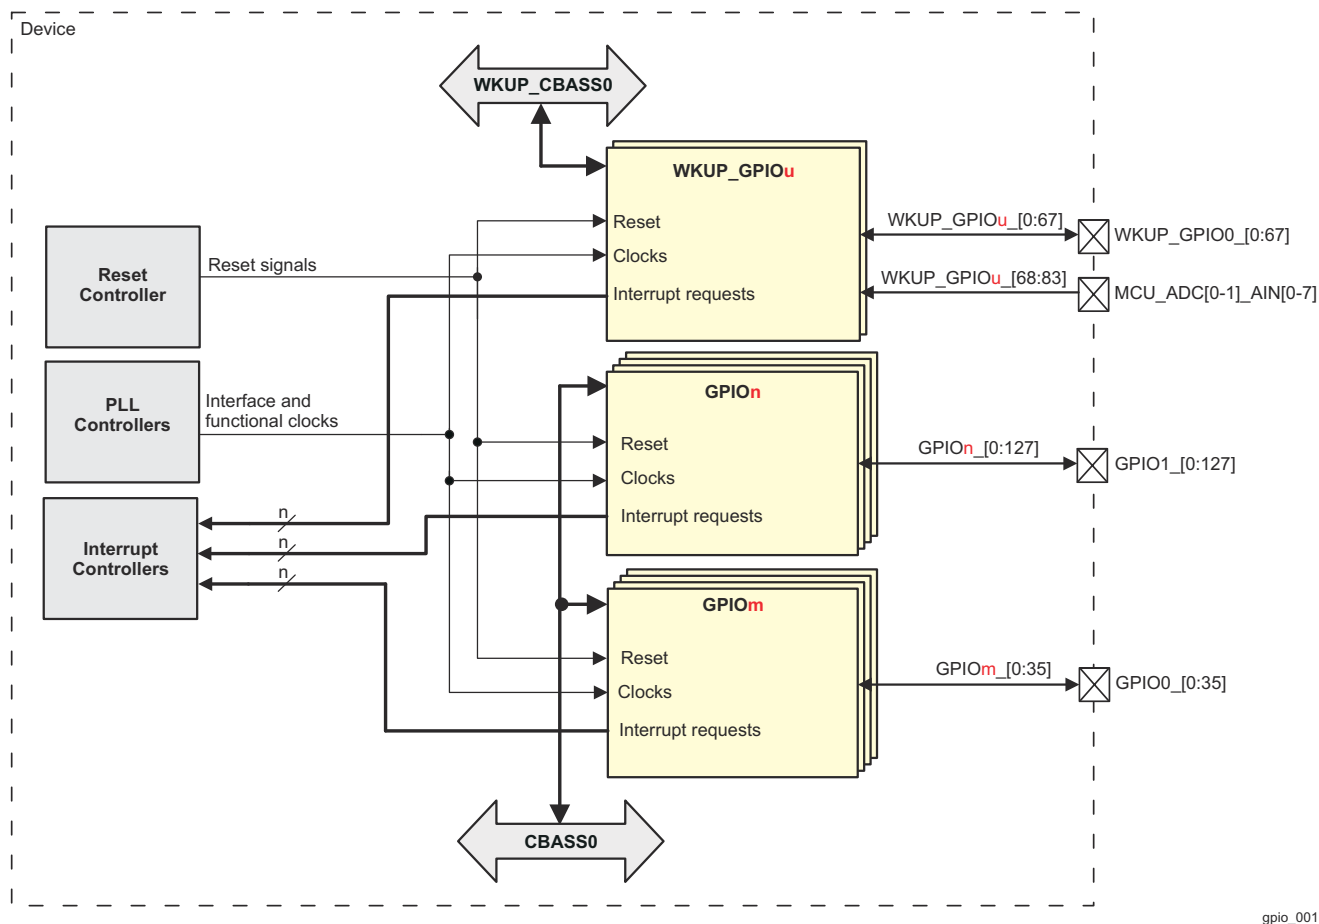

The GPIO pins are grouped into banks (16 pins per bank and 9 banks per module), which means that each GPIO module provides up to 144 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 432 (3 group instances  $\times$  (9 banks  $\times$  16 pins)) I/O pins. Since WKUP\_GPIOu\_[84:143] ( $u = 0, 1$ ), GPIOu\_[128:143] ( $n = 0, 2, 4, 6$ ), and GPIOm\_[36:143] ( $m = 1, 3, 5, 7$ ) are reserved in this device, general purpose interface supports up to 248 I/O pins.

Table 12-10 shows GPIO modules allocation across device domains.

**Table 12-10. GPIO Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
WKUP_GPIO0	✓	-	-
WKUP_GPIO1	✓	-	-
GPIO0	-	-	✓
GPIO1	-	-	✓
GPIO2	-	-	✓

 C.  $m = 1, 3, 5, 7$

**Figure 12-7. GPIO Modules Overview**

#### 12.1.2.1.1 GPIO Features

Each channel in the GPIO modules has the following features:

- Supports 9 banks of 16 GPIO signals
- Supports up to 9 banks of interrupt capable GPIOs
- Interrupts:
  - Can enable interrupts for each bank of 16 GPIO signals
  - Interrupts can be triggered by rising and/or falling edge, specified for each interrupt capable GPIO signal
- Set/clear functionality:
  - Firmware writes 1 to corresponding bit position(s) to set or to clear GPIO signal(s). This allows multiple firmware processes to toggle GPIO output signals without critical section protection (disable interrupts, program GPIO, re-enable interrupts, to prevent context switching to another process during GPIO programming).
- Separate Input/Output registers:
  - If preferred by firmware, some GPIO output signals can be toggled by direct write to the output register(s) in addition to set/clear.
  - Output register, when read in, reflects output drive status. This, in addition to the input register reflecting pin status this allows wired logic to be implemented.

**12.1.2.1.2 GPIO Not Supported Features**

- The following apply to WKUP\_GPIOu (u = 0, 1):
  - WKUP\_GPIOu\_[84:143] are not pinned out.
  - Interrupts [84:143] are not pinned out.
  - Bank Interrupts [8:6] are not pinned out.
  - From WKUP\_GPO[68] to WKUP\_GPO[83] buffer is output only.
- The following apply to GPIO<sub>n</sub> (n = 0, 2, 4, 6):
  - GPIO<sub>n</sub>\_[128:143] are not pinned out.
  - Interrupts [128:143] are not pinned out.
  - Bank Interrupt 8 is not pinned out.
- The following apply to GPIO<sub>m</sub> (m = 1, 3, 5, 7):
  - GPIO<sub>m</sub>\_[36:143] are not pinned out.
  - Interrupts [36:143] are not pinned out.
  - Bank Interrupts [8:2] are not pinned out.

### 12.1.2.2 GPIO Environment

The WKUP\_GPIOu (u = 0, 1), GPIO<sub>n</sub> (n = 0, 2, 4, 6), and GPIO<sub>m</sub> (m = 1, 3, 5, 7) modules are hereinafter referred to as GPIO module.

This section describes the GPIO external connections (environment).

The general-purpose interface combines ten GPIO modules in three groups for a flexible, user-programmable, general-purpose input/output (I/O) controller, and to allow protection between two different processor virtual worlds. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

Figure 12-8 shows a typical application using the general-purpose interface configured to operate with WKUP\_GPIO0, GPIO0, and GPIO1 on I/O pins.

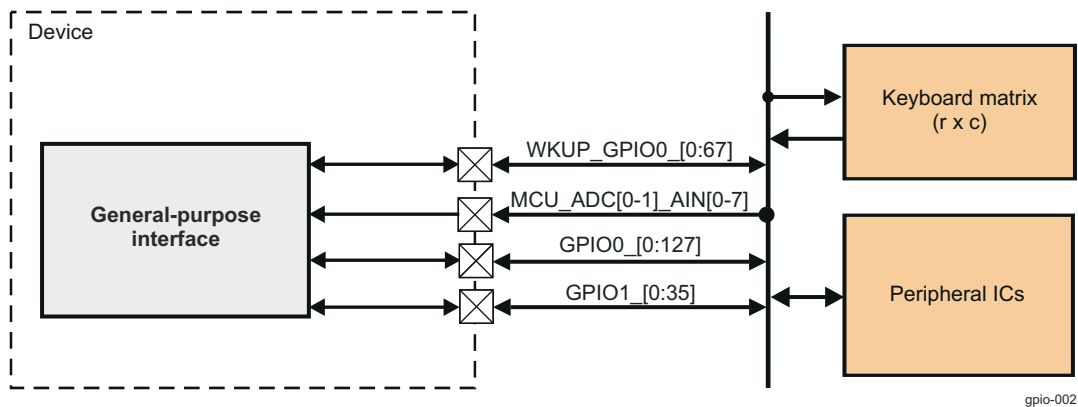

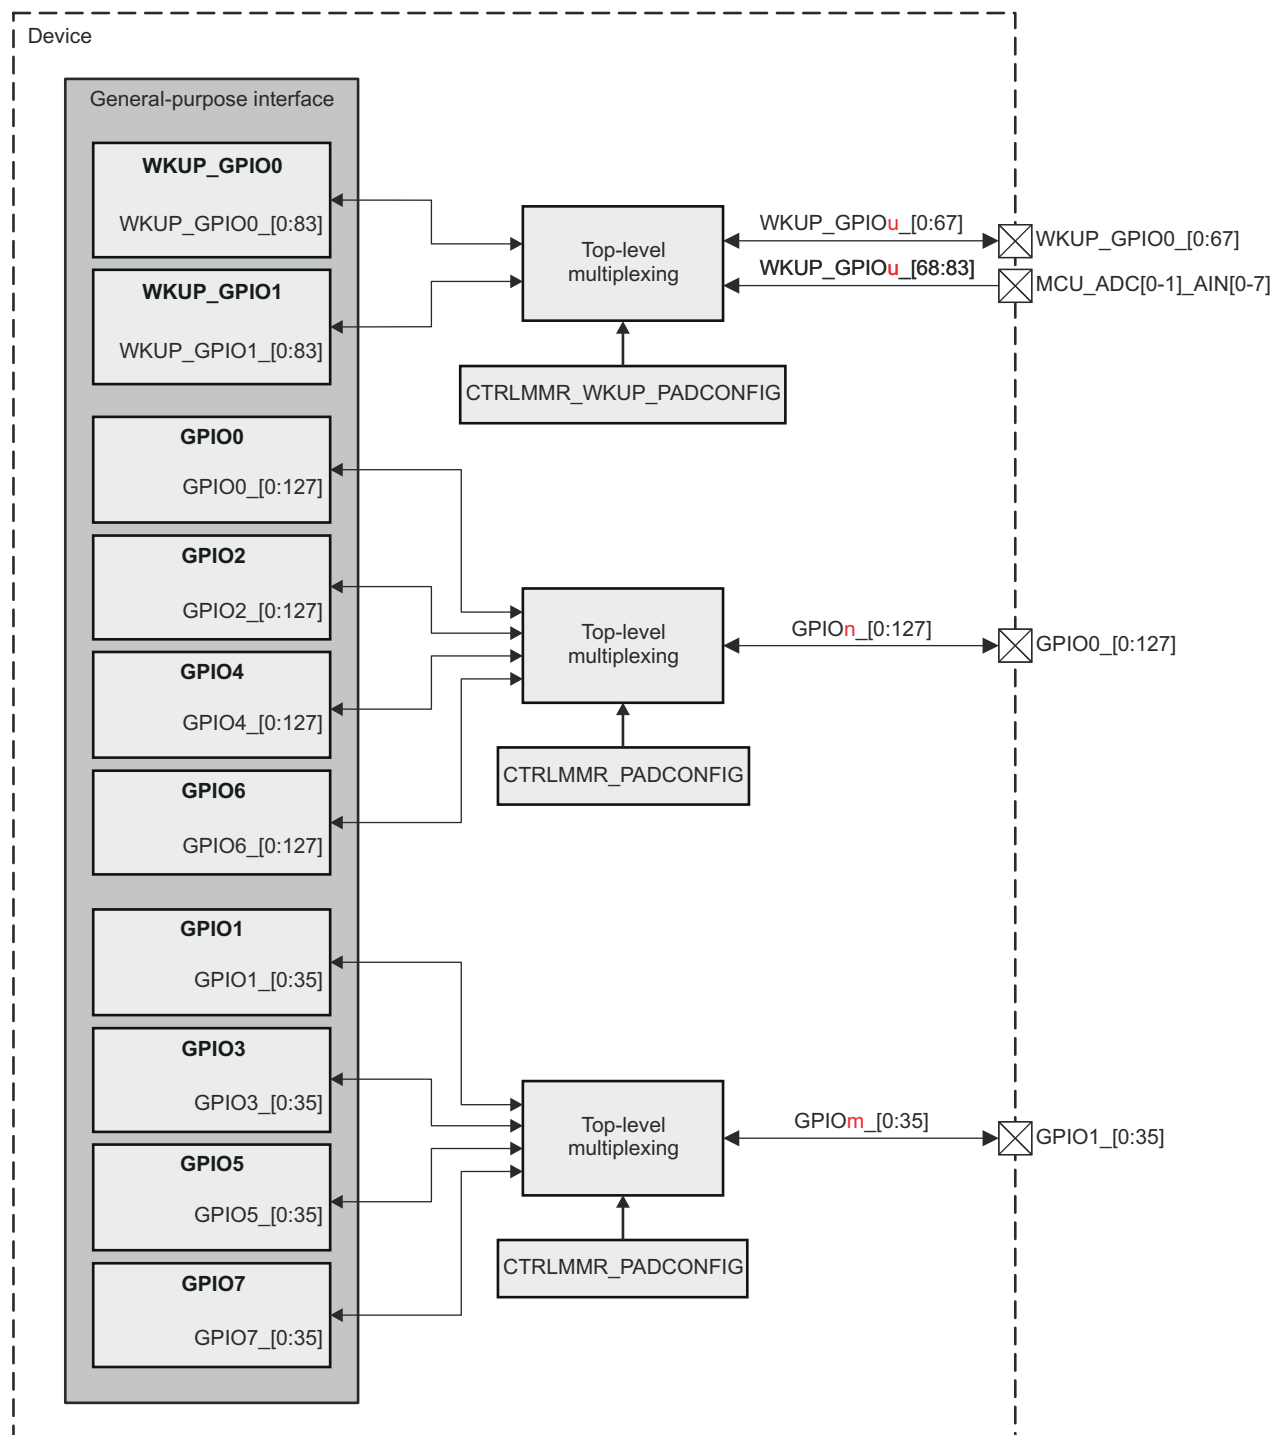

Figure 12-8. GPIO Typical Application

#### 12.1.2.2.1 GPIO Interface Signals

Figure 12-9 shows all of the GPIO interface signals.

gpio-003

- A.  $u = 0, 1$
- B.  $n = 0, 2, 4, 6$
- C.  $m = 1, 3, 5, 7$

**Figure 12-9. GPIO Interface Signals**

The active GPIO module can be selected using CTRLMMR\_WKUP\_PADCONFIG or CTRLMMR\_PADCONFIG registers. Doing so will also allow the individual per channel interrupts to be multiplexed based on the same

muxmode. At any time, only one GPIO module may control a given pin/ interrupt channel, as shown in Table [Table 12-11](#), Figure [Figure 12-9](#), and Figure [Section 12.1.2.4.4](#).

**Table 12-11. GPIO Instance Multiplexing**

PADCONFIG[3:0] MUXMODE	PADCONFIG[5:4] VGPI0_SEL	Selected Pin/Interrupt on WKUP_GPIO0	Selected Pin/Interrupt on GPIO0	Selected Pin/Interrupt on GPIO1
7h	0h	GPIO0	GPIO0	GPIO1
7h	1h	GPIO1	GPIO2	GPIO3
7h	2h	RESERVED	GPIO4	GPIO5
7h	3h	RESERVED	GPIO6	GPIO7

- 1. PADCONFIG[5:4] VGPI0\_SEL must be left at 0h for all non 7h muxmodes

Table 12-12 describes the GPIO I/O signals.

(8) m = 1, 3, 5, 7

### Note

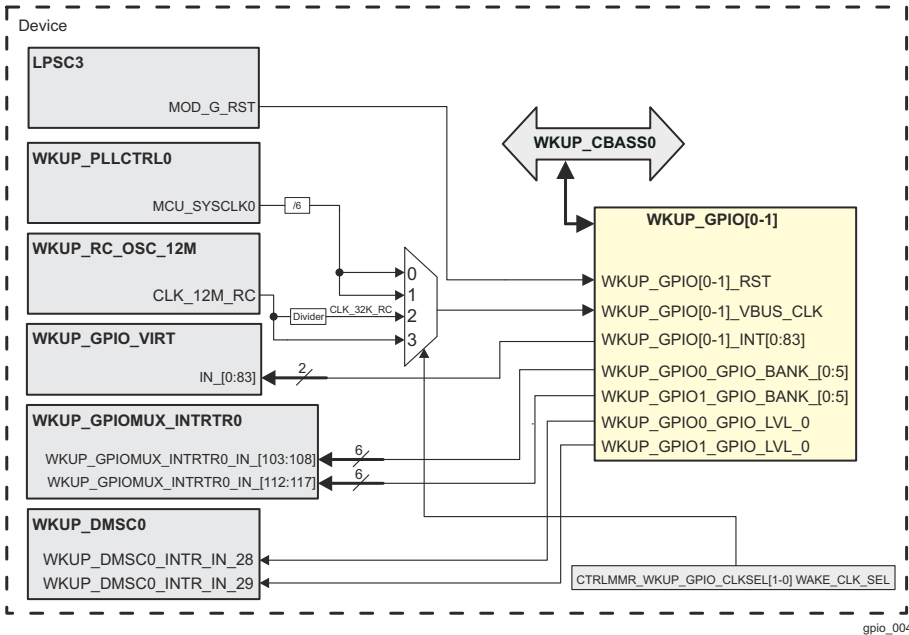

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.2.3 GPIO Integration

This section describes modules integration in the device, including information about clocks, resets, and hardware requests.

#### 12.1.2.3.1 GPIO Integration in WKUP Domain

There are two WKUP\_GPIO modules integrated in the device WKUP domain - WKUP\_GPIO0 and WKUP\_GPIO1. [Figure 12-10](#) shows the integration of WKUP\_GPIO[0-1].

**Figure 12-10. WKUP\_GPIO[0-1] Integration**

[Table 12-13](#) through [Table 12-15](#) summarize the integration of WKUP\_GPIO[0-1] in the device WKUP domain.

**Table 12-13. WKUP\_GPIO[0-1] Integration Attributes**

## 12.1.2.4 GPIO Functional Description

### 12.1.2.4.1 GPIO Block Diagram

Figure 12-13 shows the general-purpose interface block diagram.

gpio\_005

- A. Some of the GPj pins are muxed with other device signals. For details, see the device-specific Datasheet.
- B. All GPINTj can be used as host CPU interrupts and synchronization events to the DMA.
- C. The RIS\_TRIG and FAL\_TRIG registers are internal to the GPIO module and are not visible to the host CPU.

#### Note

The synchronization logic and tristate buffer are present in the SoC pinmux logic.

**Figure 12-13. GPIO Block Diagram**

### 12.1.2.4.2 GPIO Function

Each GPIO pin (GPj) can be independently configured as either an input or an output using the GPIO direction registers. The GPIO direction register (DIR) specifies the direction of each GPIO signal. Logic 0 indicates the GPIO pin is configured as output, and logic 1 indicates input.

When configured as output, writing a 0x1 to a bit in the set data register drives the corresponding GPj to a logic-high state. Writing a 0x1 to a bit in the clear data register drives the corresponding GPj to a logic-low state. The output state of each GPj can also be directly controlled by writing to the output data register.

For example, to set GP8 to a logic-high state, the software can perform one of the following:

- Write 100h to the GPIO\_SET\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x1, and write the new value back to GPIO\_OUT\_DATA01.

To set GP8 to a logic-low state, the software can perform one of the following:

- Write 100h to the GPIO\_CLR\_DATA01 register.
- Write 0h to the GPIO\_DIR01 register to configure as output pin.
- Read in GPIO\_OUT\_DATA01 register, change bit 8 to 0x0, and write the new value back to GPIO\_OUT\_DATA01.

Note that writing a 0x0 to bits in the set data and clear data registers does not affect the GPIO pin state.

Also, for GPIO pins configured as input, writing to the set data, clear data, or output data registers does not affect the pin state.

For a GPIO pin configured as input, reading the input data register (IN\_DATA) will return the pin state. Reading the SET\_DATA register or the CLR\_DATA data register will return the value in OUT\_DATA, not the actual pin state. The pin state is available by reading the input data register. Note that when the direction is configured as input, the output state is determined by software's programming set/clear/output registers, and may not agree with the pin state, which is driven by an external device.

#### **12.1.2.4.3 GPIO Interrupt and Event Generation**

Each GPIO pin (GPj) can be configured to generate a host CPU interrupt (GPINTj) or a synchronization event to the DMA (GPINTj). Configuration is on per-bank basis. Each bit of the BINTEN parameter dictates YES/NO option for each bank. Bit 0 controls bank 0, bit 1 controls bank 1, and so on.

The interrupt can be generated on the rising-edge, falling-edge, or on both edges of the GPIO signal. The edge detection logic is synchronized to the GPIO peripheral clock.

The direction of the GPIO pin does not need to be input when using the pin to generate the interrupt or DMA event. When the GPIO pin is configured as input, transitions on the pin trigger interrupts or DMA events. When the GPIO pin is configured as output, software can toggle the GPIO output register to change the pin state and in turn trigger the interrupt or DMA event.

Note that the direction of the pin need not be input for interrupt generation to work. When the GPIO pin is configured as input, transitions on the pin trigger interrupts. When the GPIO pin is configured as output, firmware can toggle the GPIO output register to change the pin state, and in turn trigger interrupts.

Each interrupt output of GPIO signal are available at the module boundary. Each group of 16 GPIO\_INTR\_INTj signals also has their masked interrupt outputs ORed together to generate a per bank interrupt, available at the module boundary. The idea is to either connect individual interrupts or per bank interrupts to the system interrupt controller.

##### **12.1.2.4.3.1 Interrupt Enable (per Bank)**

The GPIO\_BINTEN register provides interrupt enable/disable feature for each bank of 16 GPINT signals.

##### **12.1.2.4.3.2 Trigger Configuration (per Bit)**

Two internal registers, RIS\_TRIG and FAL\_TRIG, specify which edge of the GPj signal generates an interrupt or DMA event. Each bit in these two registers corresponds to a GPj pin. [Table 12-19](#) describes the host CPU interrupt and DMA event generation of GPj pin based on the bit settings of the RIS\_TRIG and FAL\_TRIG registers.

**Table 12-19. GPIO Interrupt and DMA Event Configuration Options**

RIS_TRIG Bit n	FAL_TRIG Bit n	Host CPU Interrupt and DMA Event Generation
0	0	GPINTj interrupt and DMA event is disabled
0	1	GPINTj interrupt and DMA event is triggered on falling edge of GPj signal
1	0	GPINTj interrupt and DMA event is triggered on rising edge of GPj signal
1	1	GPINTj interrupt and DMA event is triggered on both rising and falling edge of GPj signal

The RIS\_TRIG and FAL\_TRIG registers are not directly accessible or visible to the host CPU. These registers are accessed indirectly through four registers: SET\_RIS\_TRIG, CLR\_RIS\_TRIG, SET\_FAL\_TRIG, and CLR\_FAL\_TRIG. Writing 1 to a bit on the SET\_RIS\_TRIG register sets the corresponding bit on the RIS\_TRIG register. Writing 1 to a bit of the CLR\_RIS\_TRIG register clears the corresponding bit on the RIS\_TRIG register. Writing to the SET\_FAL\_TRIG and CLR\_FAL\_TRIG registers works the same way on the FAL\_TRIG register.

Reading the SET\_RIS\_TRIG or CLR\_RIS\_TRIG register returns the value of the RIS\_TRIG register. Reading from the SET\_FAL\_TRIG or CLR\_FAL\_TRIG register returns the value of the FAL\_TRIG register.

To use the GPIO pins as sources for host CPU interrupts and DMA events, the associated bank interrupt enable register bit in GPIO\_BINTEN must also be set to 1. For example, to enable GPIO0\_19 (which is in bank 1), GPIO\_BINTEN[1] = 1 should be set to enable interrupts for bank 1.

#### 12.1.2.4.3.3 Interrupt Status and Clear (per Bit)

The INTSTAT registers provide interrupt status upon reading, and interrupt clear feature upon writing 1 to the corresponding bit position(s). Upon receiving an interrupt, the ISR can examine the interrupt status and clear the processed interrupts.

#### Note

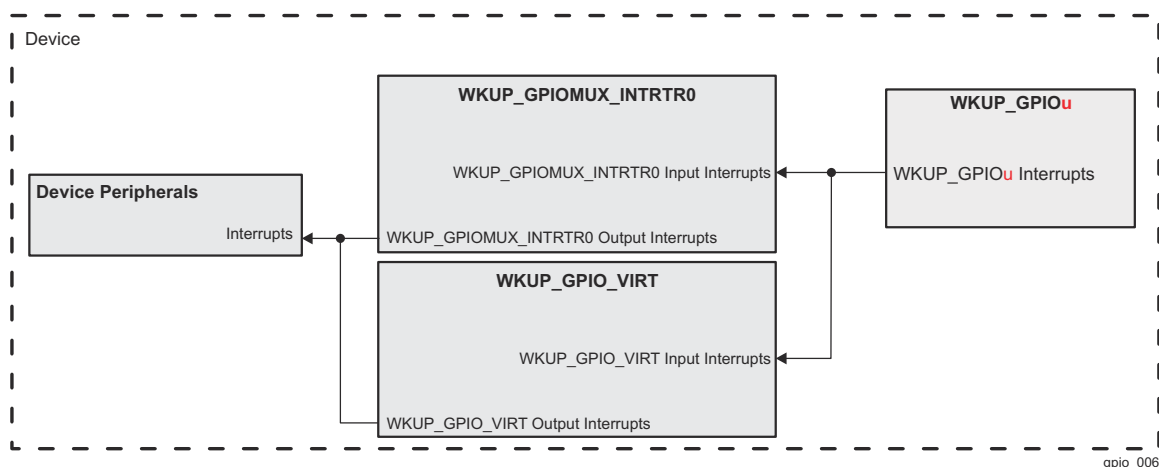

The GPIO module generates an interrupt pulse on the individual GPINT interrupt in response to each occurrence of the specified edge condition. Therefore, for GPINT signals having their interrupts routed directly to the interrupt controller, it is not necessary to clear the status bits in this module. The interrupt status and clear register is a facility for the per-bank interrupt connection.

#### 12.1.2.4.4 GPIO Interrupt Connectivity

Because this device muxes GPIO signals with other functional signals, the availability of any particular GPIO and hence the usability of its associated interrupt will change based on the use case pin muxing. The large number of possible GPIO interrupt sources makes it impractical to route all interrupt events to each processing element. Since most applications do not typically require a large number of GPIO interrupts, the interrupt uncertainty is resolved by mapping all GPIO interrupts to a series of event muxes implemented using Interrupt Router (IntRouter) modules. These muxes allow any one of the available GPIO interrupts to be selected and passed on as an event to the various processor interrupt controllers and DMA controllers. Event selection is controlled through associated registers within each IntRouter.

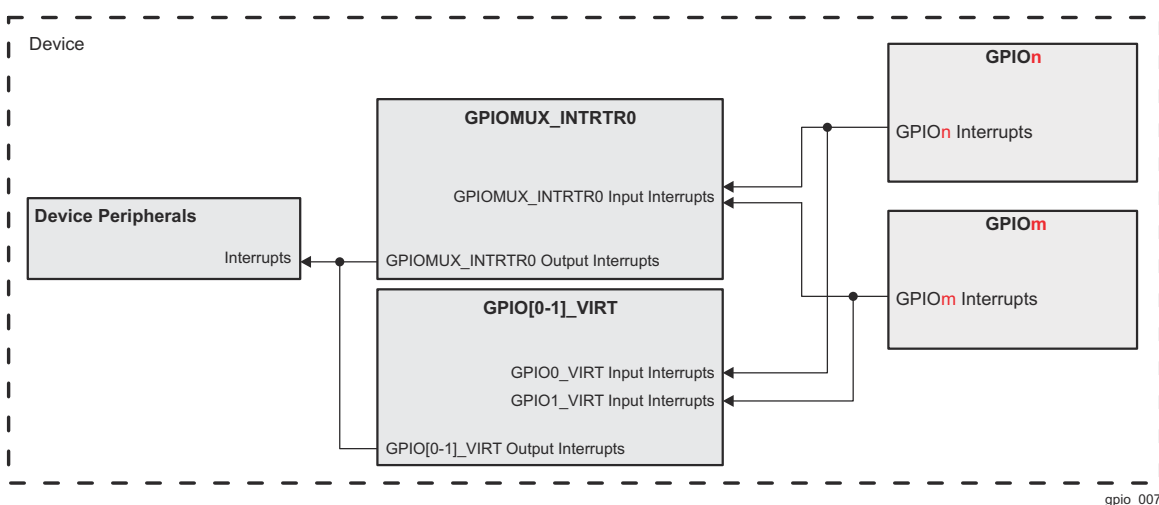

The GPIO bank interrupts already represent a consolidation of the 16 GPIO interrupts associated with each bank and are routed directly to various interrupt controllers rather than through the GPIO IntRouters.

[Figure 12-14](#) and [Figure 12-15](#) shows the GPIO Interrupt Routers connectivity. Refer to *Interrupt Routers*, for more details on the GPIO Interrupt Routers connectivity.

A.  $u = 0, 1$

**Figure 12-14. WKUP\_GPIO Interrupt Router Connectivity**

A.  $n = 0, 2, 4, 6$

B.  $m = 1, 3, 5, 7$

**Figure 12-15. GPIO Interrupt Router Connectivity**

#### 12.1.2.4.5 GPIO DeepSleep Mode

During DeepSleep power saving mode, the GPIO functional clock is powered down. This would the WKUP\_GPIOu ( $u = 0, 1$ ) modules from detecting transitions on GPIO pins to be used as wakeup from DeepSleep events. In order to correct this issue, special clocking and controls are implemented as part of the WKUP\_GPIOu ( $u = 0, 1$ ) integration to allow GPIO transition to remain detectable.

A clock MUX is provided to allow the GPIO clock to be switched to an on-chip clock source prior to gating of the standard clock source (MCU\_SYSCLOCK0/6) and power-down of the off-chip WKUP\_HFOSC0 oscillator. This clock MUX is controlled by the WKUP\_CTRL\_MMR0 register bits.

Because there is no asynchronous bridge between the WKUP\_GPIOu ( $u = 0, 1$ ) modules and the WKUP\_CBASS0, the module register may only be accessed when it is clocked using the synchronous MCU\_SYSCLOCK0/6 clock source. Prior to switching the clock source to prepare for DeepSleep, all clock accesses to the WKUP\_GPIOu ( $u = 0, 1$ ) modules must be blocked through the dedicated LPSC5 using a clock stop request. Note that when wakeup functionality for the WKUP\_GPIOu ( $u = 0, 1$ ) is enabled, (through a WKUP\_CTRL\_MMR0 registers), this clock stop request is not actually propagate to the WKUP\_GPIOu ( $u = 0,$

1) module (or stop its clock). Instead, it will be fed back to the LPSC3 as a clock stop acknowledged. This will cause the associated WKUP\_CBASS0 to route all future WKUP\_GPIO register accesses to a null endpoint. The WKUP\_GPIOu (u = 0, 1) LPSC3 must be maintained in clock stop mode until MCU\_SYSClk0/6 is fully restored upon wakeup from DeepSleep and the WKUP\_GPIOu (u = 0, 1) clock MUX has finished switching back the normal clock source.

The following are the steps required (expected to be performed by the DMSC) to enable WKUP\_GPIOu (u = 0, 1) wakeup events prior to DeepSleep:

- Determine which events are to be used for DeepSleep wakeup and enable the interrupts through the corresponding GPIO\_SET\_RIS\_TRIG and GPIO\_SET\_FALL\_TRIG registers. Disable non-wakeup interrupts through the corresponding GPIO\_CLR\_RIS\_TRIG and GPIO\_CLR\_FALL\_TRIG registers
- Set the CTRLMMR\_WKUP\_GPIO\_CTRL[0] WAKEN bit to enable DeepSleep LPSC3 operation.
- Disable further access to the WKUP\_GPIOu (u = 0, 1) through the LPSC3 clock stop request.
- Change the WKUP\_GPIOu (u = 0, 1) clock source to CLK\_32K\_RC or CLK\_12M\_RC as desired by setting the CTRLMMR\_WKUP\_GPIO\_CLKSEL[1-0] WAKE\_CLK\_SEL bit field in the WKUP\_CTRL\_MMR0. (Wait at least one clock cycle of the new clock to ensure switch has occurred.)
- Perform normal DeepSleep entry routine (enable DMSC wakeup events, clock gate MCU clocks, powerdown oscillators, etc.)

Once in DeepSleep mode, any GPIO transition (low to high or high to low) intended to cause a wakeup must be maintained at its new value for at least 0x2 of the selected functional clock (CLK\_32K\_RC or CLK\_12M\_RC) maximum periods to ensure proper detection. (Note that process variance of the RC clocks must be taken into account). The detected event will be latched in the GPIO\_INTSTAT register and the WKUP\_GPIOMUX\_INTRTR0 wakeup event sent to the DMSC to trigger the wakeup FSM.

After wakeup, the DMSC must restore the MCU\_SYSClk0/6 operation to allow the wakeup source event to be latched within the DMSC. Once this is done the DMSC may restore access to the WKUP\_GPIOu (u = 0, 1) module by reversing the steps above:

- Change the WKUP\_GPIOu (u = 0, 1) clock source back to MCU\_SYSClk0/6 using the CTRLMMR\_WKUP\_GPIO\_CLKSEL[1-0] WAKE\_CLK\_SEL bit field in the WKUP\_CTRL\_MMR0. (Wait at least 1 of the previously selected clock cycles to ensure glitch-free switch is complete.)
- Re-enable access to the WKUP\_GPIOu (u = 0, 1) through the LPSC3 clock stop request.

The specific GPIO source of the wakeup event may now be determined by reading the GPIO\_INTSTAT register and cleared by writing 0x1 to the set bits of the same register.

#### **12.1.2.4.6 GPIO Emulation Halt Operation**

The GPIO peripheral is not affected by emulation halts.

## 12.1.2.5 GPIO Programming Guide

### 12.1.2.5.1 GPIO Low-Level Programming Models

#### 12.1.2.5.1.1 Global Initialization

##### 12.1.2.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see *GPIO Environment*, and *GPIO Integration*.

**Table 12-20. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC0	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
LPSC3	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
PLLCTRL0	Interface and functional clocks must be enabled. For more information about the module configuration, see <i>Clocking</i> .
WKUP_PLLCTRL0	Interface and functional clocks must be enabled. For more information about the module configuration, see <i>Clocking</i> .
WKUP_RC_OSC_12M	Interface and functional clocks must be enabled. For more information about the module configuration, see <i>Clocking</i> .
GIOMUX_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling GIOMUX_INTRTR0 interrupts, see <i>Interrupts</i> .
WKUP_GIOMUX_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling WKUP_GIOMUX_INTRTR0 interrupts, see <i>Interrupts</i> .
WKUP_GPIO_VIRT	Device INTCs must be configured to enable the interrupt request generation. For information about enabling WKUP_GPIO_VIRT interrupts, see <i>Interrupts</i> .
GPIO0_VIRT	Device INTCs must be configured to enable the interrupt request generation. For information about enabling GPIO0_VIRT interrupts, see <i>Interrupts</i> .
GPIO1_VIRT	Device INTCs must be configured to enable the interrupt request generation. For information about enabling GPIO1_VIRT interrupts, see <i>Interrupts</i> .
DMSC_WKUP_0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling DMSC_WKUP_0 interrupts, see <i>Interrupts</i> .
Interconnects	For information about the WKUP_CBASS0, and CBASS0 interconnects configuration, see <i>System Interconnect</i> .

##### 12.1.2.5.1.1.2 GPIO Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

**Table 12-21. GPIO Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Configure GPIO channels as input or output of the corresponding bank	DIR	-h
<b>Interrupt requests configuration</b>		
Configure detection events	SET_RIS_TRIG and/or SET_FAL_TRIG	-h
Clear interrupt status	INTSTAT	FFFFh
Enable interrupts for desired banks [0:8]	GPIO_BINTEN[8-0]	-h

Write 1h to clear desired bit(s) in CLR_DATA register.	CLR_DATA	-h

### 12.1.3 Inter-Integrated Circuit (I2C) Interface

This section describes the Inter-Integrated Circuit (I2C) module in the device.

#### 12.1.3.1 I2C Overview

The device contains ten multimaster Inter-Integrated Circuit (I2C) controllers each of which provides an interface between a local host (LH), such as an Arm or a Digital Signal Processor (DSP), and any I<sup>2</sup>C-bus-compatible device that connects via the I<sup>2</sup>C serial bus. External components attached to the I<sup>2</sup>C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I<sup>2</sup>C interface.

Each multimaster I2C module can be configured to act like a slave or master I<sup>2</sup>C-compatible device.

The WKUP\_I2C0, MCU\_I2C0, I2C0, and I2C1 controllers have dedicated I<sup>2</sup>C compliant open drain buffers and support high speed mode (up to 3.4 Mbps in 1.8 V mode and up to 400 Kbps in 3.3 V mode). The MCU\_I2C1, I2C2, I2C3, I2C4, I2C5, and I2C6 controllers are multiplexed with standard LVCMOS I/O, connected to emulate open drain, and support fast mode (up to 400 Kbps in 1.8 V/3.3 V mode). The I<sup>2</sup>C emulation is achieved by configuring the LVCMOS buffers to output Hi-Z instead of driving high when transmitting logic 1.

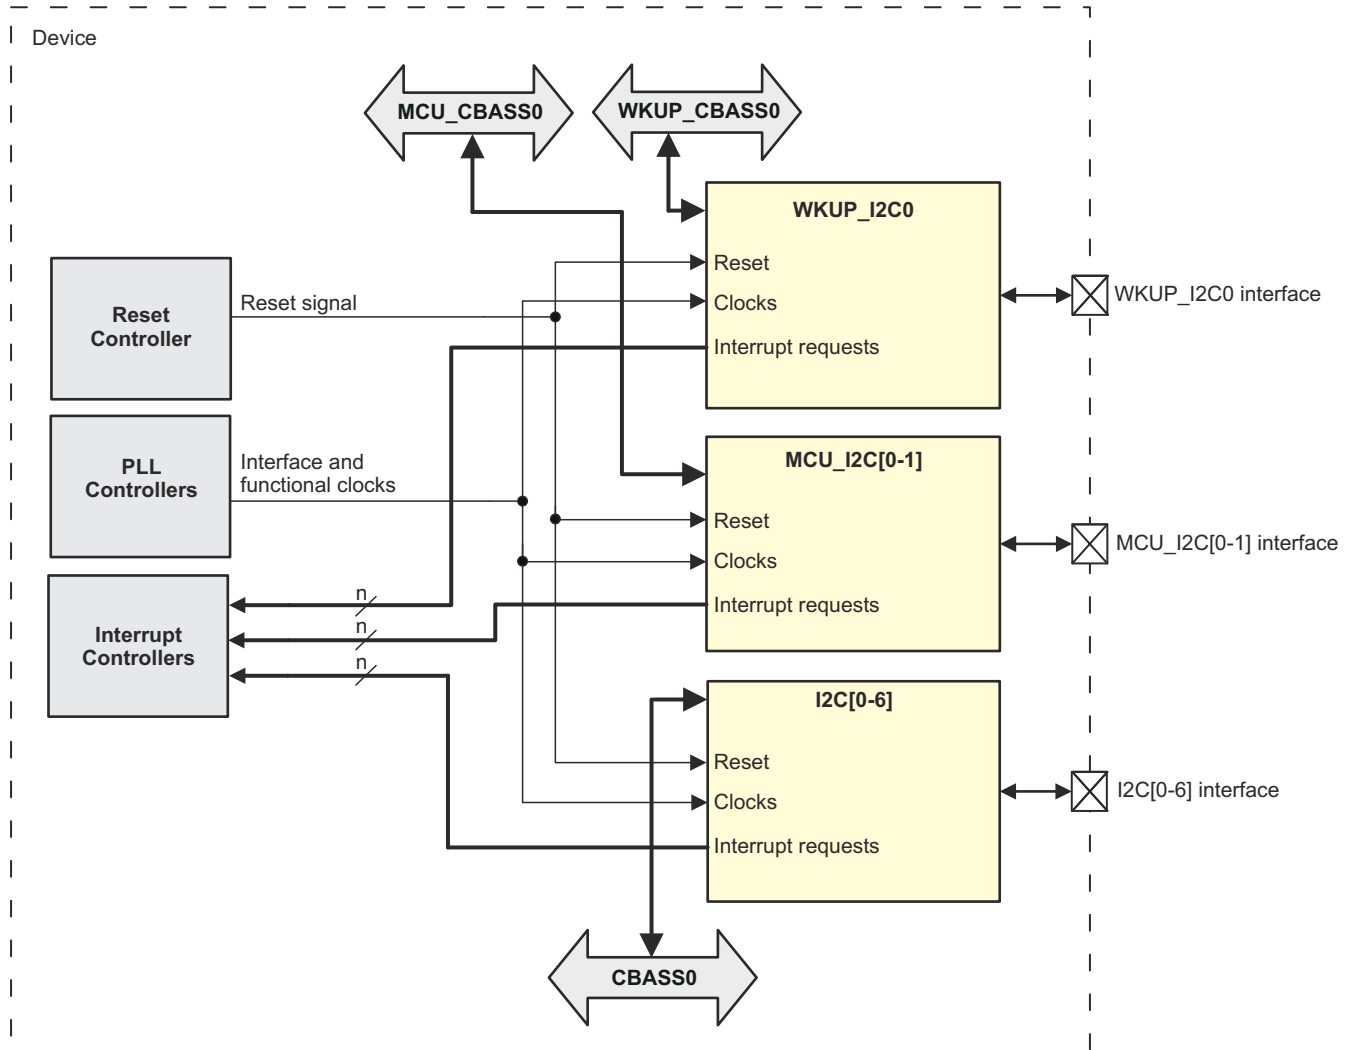

For the specific I/O timing characteristics of the different I2C instances, see the device-specific Datasheet.

[Table 12-25](#) shows I2C modules allocation across device domains.

**Table 12-25. I2C Allocation Across Device Domains**

Instance	Domain

[Figure 12-16](#) shows the I2C modules overview.

i2c\_001

**Figure 12-16. I2C Modules Overview**

#### 12.1.3.1.1 I2C Features

Each multicontroller I2C module has the following features:

- Compliant with Philips I<sup>2</sup>C-bus specification version 2.1
- Supports a standard mode (up to 100 Kbps) and fast mode (up to 400 Kbps)
- Supports HS mode (up to 3.4 Mbps) on some instances. See the the device-specific Data Manual for details.
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multicontroller transmitter/target receiver mode
- Multicontroller receiver/target transmitter mode
- Combined controller transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read
- Module enable/disable capability
- Programmable multitarget channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Low power consumption

- Support Auto Idle mechanism
- Support Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Wide interrupt capability

**12.1.3.1.2 I2C Not Supported Features**

- Serial Camera Control Bus (SCCB) Protocol
- DMA Mode
- Full I<sup>2</sup>C electrical compliance (only for MAIN and MCU domain I2C modules)
- Local power management of clock activity
- Debug suspend mode
- Clockstop wakeup interrupt (only for MCU domain I2C modules)

### 12.1.3.2 I2C Environment

The WKUP\_I2C0, MCU\_I2C[0-1], and I2C[0-6] modules are hereinafter referred to as I2C module.

This section describes the I2C external connections (environment).

#### 12.1.3.2.1 I2C Typical Application

Figure 12-17 shows the multicontroller I2C controller and their related connections with I<sup>2</sup>C-compliant devices.

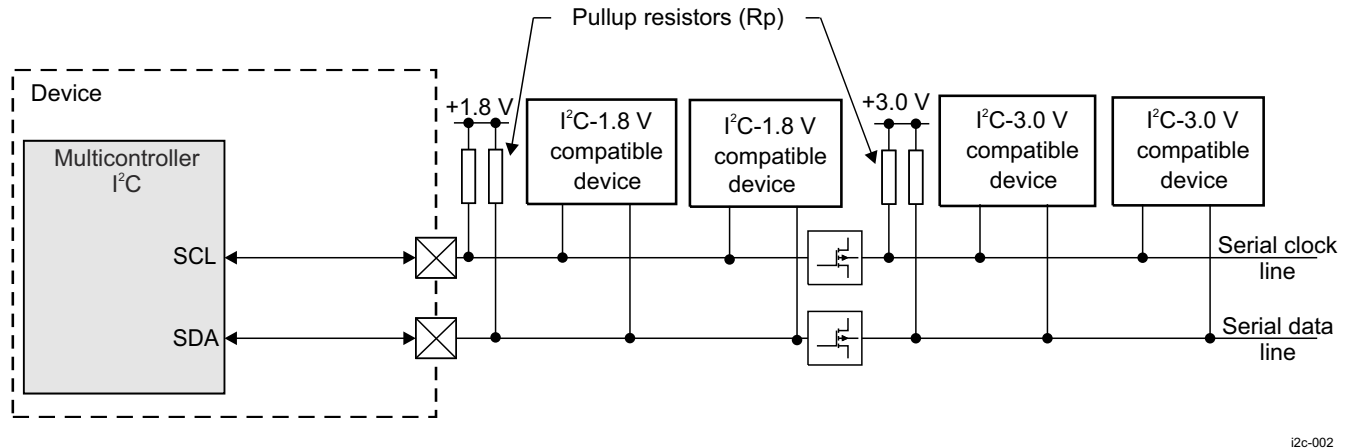

Figure 12-17. I2C and Typical Connections to I2C Devices

#### 12.1.3.2.1.1 I2C Pins for Typical Connections in I2C Mode

Figure 12-18 shows the multicontroller I2C controller pins used for typical connections with I<sup>2</sup>C devices.

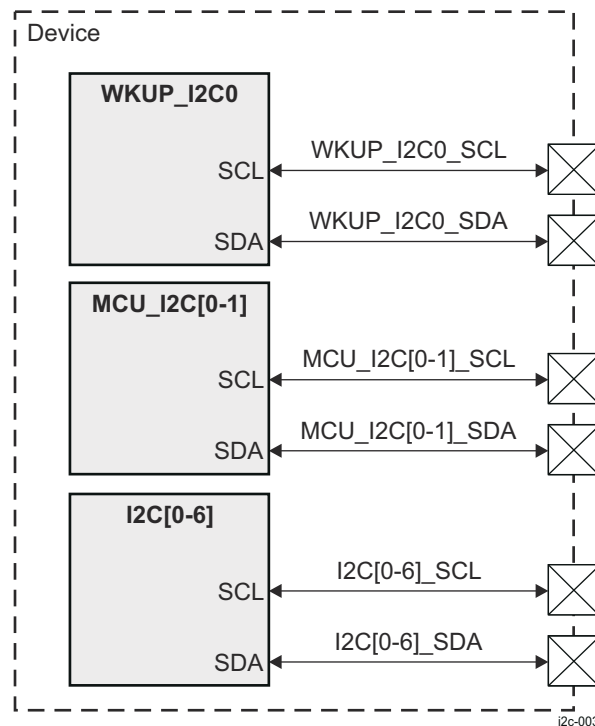

Figure 12-18. I2C Interface Signals

#### 12.1.3.2.1.2 I2C Interface Typical Connections

Table 12-26 describes the I2C I/O signals.

**Table 12-26. I2C I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
<b>WKUP_I2C0</b>				
SCL	WKUP_I2C0_SCL	I/O	I <sup>2</sup> C serial clock line. Open-drain output buffer.	1
SDA	WKUP_I2C0_SDA	I/O	I <sup>2</sup> C serial data line. Open-drain output buffer.	1
<b>MCU_I2C[0-1]</b>				
SCL	MCU_I2C0_SCL	I/O	I <sup>2</sup> C serial clock line. Open-drain output buffer.	1
SDA	MCU_I2C0_SDA	I/O	I <sup>2</sup> C serial data line. Open-drain output buffer.	1
SCL	MCU_I2C1_SCL	I/O	I <sup>2</sup> C serial clock line. Emulated open-drain output buffer.	1
SDA	MCU_I2C1_SDA	I/O	I <sup>2</sup> C serial data line. Emulated open-drain output buffer.	1
<b>I2C[0-6]</b>				
SCL	I2C[0-1]_SCL	I/O	I <sup>2</sup> C serial clock line. Open-drain output buffer.	1
SDA	I2C[0-1]_SDA	I/O	I <sup>2</sup> C serial data line. Open-drain output buffer.	1
SCL	I2C[2-6]_SCL	I/O	I <sup>2</sup> C serial clock line. Emulated open-drain output buffer.	1
SDA	I2C[2-6]_SDA	I/O	I <sup>2</sup> C serial data line. Emulated open-drain output buffer.	1

(1) I = Input; O = Output; I/O = Bidirectional

### 12.1.3.2.1.3

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.3.2.2 I2C Typical Connection Protocol and Data Format

#### 12.1.3.2.2.1 I2C Serial Data Format

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I2C module.

Figure 12-19 shows a typical I<sup>2</sup>C communication format.

**Figure 12-19. I2C Data Transfer**

#### 12.1.3.2.2.2 I2C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 12-20 is an example of data validity requirements.

**Figure 12-20. I2C Bit Transfer on the I2C Bus**

#### 12.1.3.2.2.3 I2C Start and Stop Conditions

The I2C module generates start (S) and stop (P) conditions when it is configured as a controller.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C\_IRQSTATUS\_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 12-21 shows the waveforms that occur during an S and a P condition.

**Figure 12-21. I2C S and P Condition Events**

#### Note

I2C controller does not support messages non-compliant with I<sup>2</sup>C standard. Void messages are non-standard I<sup>2</sup>C messages and will lockup the controller. A void message is a START condition followed by a STOP condition, in other words, while the bus is free the SDA line is pulled low (START) and then released (STOP). This would result in a timeout (software) of the next controller transfer which would never complete. A soft reset of the controller is recommended for recovery.

#### 12.1.3.2.2.4 I2C Addressing

The I2C module supports two data formats in fast/standard (F/S) mode:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

##### 12.1.3.2.2.4.1 Data Transfer Formats in F/S Mode

Figure 12-22 shows the I2C data transfer formats in F/S mode.

(a) 7-bit addressing format

(b) 10-bit addressing format

(c) Addressing format with repeated start condition

i2c-007

**Figure 12-22. I2C Data Transfer Formats in F/S Mode**

The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB target address bits and 1 least-significant bit (LSB) R/W\_ bit.

The LSB R/W\_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W\_ is 0, the controller writes data to the selected target; if it is 1, the controller reads data from the target.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W\_ bit. If the R/W\_ bit is 0, the next byte contains the last 8 bits of the target address. If the R/W\_ bit is 1, the next byte contains data transmitted from the target to the controller.

#### 12.1.3.2.2.4.2 Data Transfer Format in HS Mode

Figure 12-23 shows the I2C data transfer format in HS mode.

i2c-008

**Figure 12-23. HS I2C Data Transfer in HS Mode**

Each multicontroller I2C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the controller code address (0x00001XXX, where XXX is the variable portion of the controller code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the target address and the data, as shown in Figure 12-23.

#### 12.1.3.2.2.5 I2C Controller Transmitter

In controller transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

#### 12.1.3.2.2.6 I2C Controller Receiver

Controller receiver mode can be entered only from controller transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 12-22), if R/W\_ is high, the module enters controller receiver mode after the target address byte and bit R/W\_ are transmitted. Serial data bits received on bus line SDA are shifted in synchronization with the self-generated clock pulses on SCL.

#### 12.1.3.2.2.7 I2C Target Transmitter

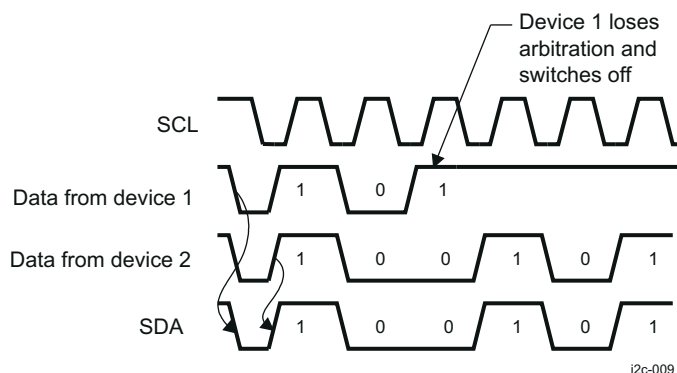

Target transmitter mode can be entered only from target receiver mode. With any of the address formats (a), (b), or (c) (see Figure 12-22), the target transmitter is entered if the target address byte is the same as its own address and bit R/W\_ is transmitted, if R/W\_ is high. The target transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

#### 12.1.3.2.2.8 I2C Target Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the controller device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

#### 12.1.3.2.2.9 I2C Bus Arbitration

If two or more controller transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the target receiver mode, sets the arbitration lost (I2C\_IRQSTATUS\_RAW[0] AL) flag, and generates the arbitration lost interrupt. Figure 12-24 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

**Figure 12-24. I2C Arbitration Between Controller Transmitters**

#### 12.1.3.2.2.10 I2C Clock Generation and Synchronization

Under normal conditions, only one controller device generates the clock signal - SCL. However, there are two or more controller devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be

released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a target can slow down a fast controller and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

### Note

In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if the I<sup>2</sup>C devices have hardware reset inputs. If the I<sup>2</sup>C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the controller should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 12-25 shows clock synchronization.

**Figure 12-25. I2C Clock Generators Synchronization**

### 12.1.3.3 I2C Integration

This section describes I2C integration in the device, including information about clocks, resets, and hardware requests.

#### 12.1.3.3.1 I2C Integration in WKUP Domain

A single WKUP\_I2C0 module is integrated in the device WKUP domain. Figure 12-26 shows the integration of WKUP\_I2C0.

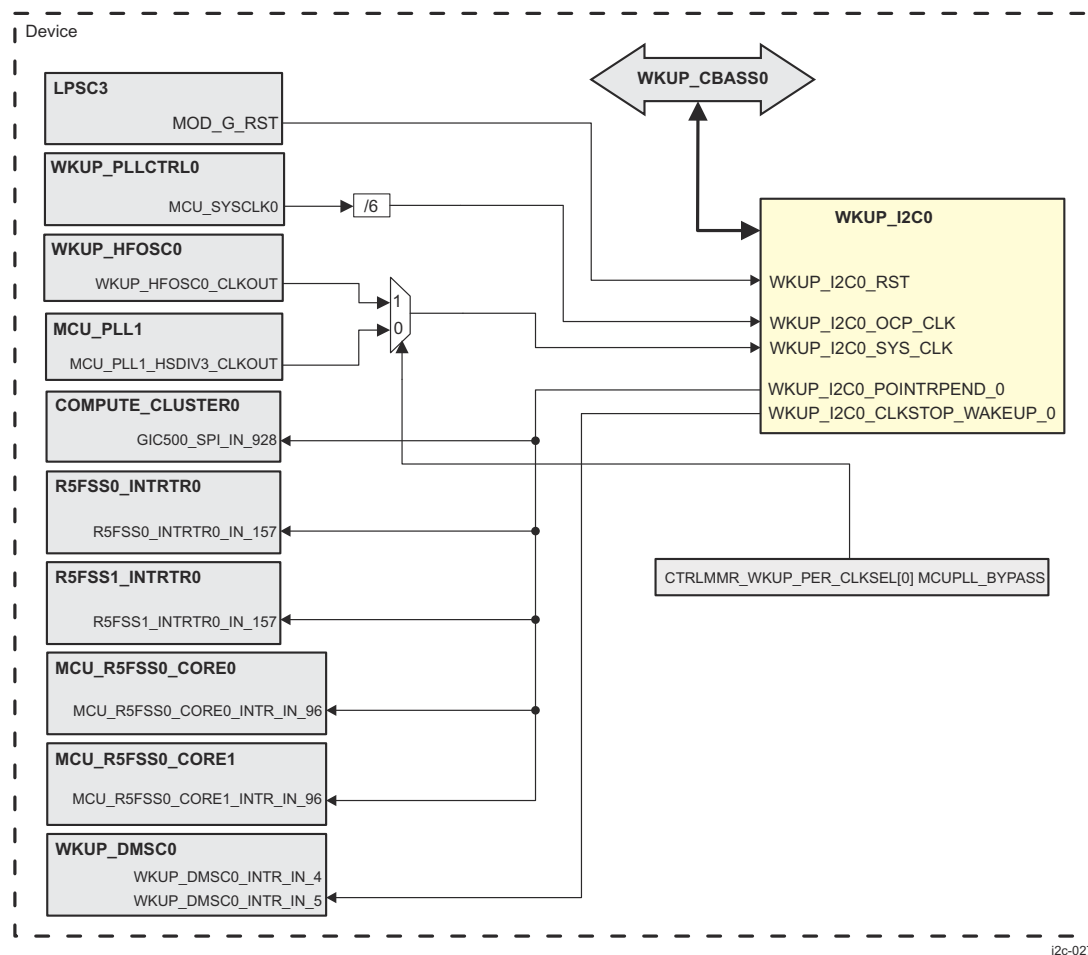

Figure 12-26. WKUP\_I2C0 Integration

Table 12-27 through Table 12-29 summarize the integration of WKUP\_I2C0 in device WKUP domain.

**Table 12-27. WKUP\_I2C0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
WKUP_I2C0	WKUP_PSC0	PD0	LPSC3	WKUP_CBASS0

**Table 12-28. WKUP\_I2C0 Clocks and Resets <sup>(1)</sup>**

Clocks

### 12.1.3.4 I2C Functional Description

#### 12.1.3.4.1 I2C Block Diagram

#### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

Figure 12-29 presents the multimaster I2C controller block diagram.

**Figure 12-29. I2C Block Diagram**

The ten multimaster I2C controllers can be configured in F/S I2C mode or HS I2C mode. The operation mode is selected by configuring the I2C\_CON[13-12] OPMODE bit field.

Table 12-36 lists the available operation modes.

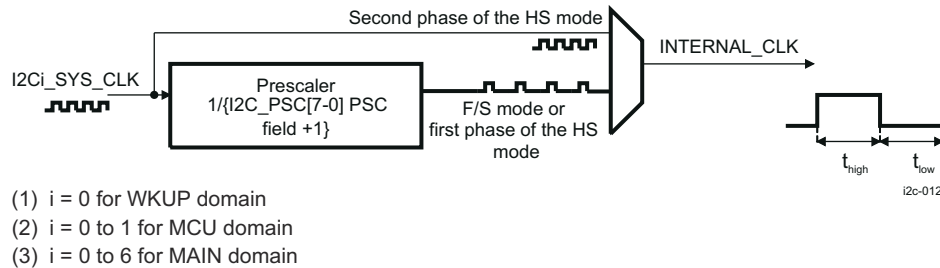

**Table 12-36. I2C Operation Mode Selection**

Operation Mode	Value of I2C_CON[13-12] OPMODE
F/S I2C	0x0
HS I2C	0x1
SCCB	0x2
Reserved (not used)	0x3

#### 12.1.3.4.2 I2C Clocks

##### 12.1.3.4.2.1 I2C Clocking

Figure 12-30 shows the I2C clock generation of the I2C controllers.

**Figure 12-30. I2C Clock Generation**

Each multimaster I2C controller uses the SYS\_CLK functional clock in the Device Configuration section. The internal sampling clock INTERNAL\_CLK is generated by dividing the functional clock by the I2C\_PSC[7-0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the SCLL signal is determined by the I2C\_SCLL[7-0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLL[15-8] HSSCLL bit field in the second phase of HS mode.

The high time of the SCLH signal is determined by the I2C\_SCLH[7-0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C\_SCLH[15-8] HSSCLH bit field in the second phase of HS mode.

Table 12-37 lists the  $t_{LOW}$  and  $t_{high}$  values in master mode only (in slave mode, the I2C controller does not generate the I2C clock).

**Table 12-37. I2C  $t_{LOW}$  and  $t_{high}$  Values of the I2C Clock**

Mode	Clock	$t_{LOW}$	$t_{high}$
F/S or HS first phase	$INTERNAL\_CLK = SYS\_CLK / (I2C\_PSC[7-0] \text{ PSC bit field} + 1)$	$(I2C\_SCLL[7-0] \text{ SCLL bit field value} + 7) \times INTERNAL\_CLK \text{ period}$	$(I2C\_SCLH[7-0] \text{ SCLH bit field value} + 5) \times I2Ci\_INTERNAL\_CLK \text{ period}$
HS second phase	SYS_CLK	$(I2C\_SCLL[15-8] \text{ HSSCLL bit field value} + 7) \times SYS\_CLK \text{ period}$	$(I2C\_SCLH[15-8] \text{ HSSCLH bit field value} + 5) \times I2Ci\_SYS\_CLK \text{ period}$

**Note**

For HS mode, the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLL[7-0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C\_SCLH[15-8] HSSCLH and I2C\_SCLH[7-0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

**Note**

The equations in Table 12-37 give the SCLL timing values for SCLL/SCLH/HSSCLL/HSSCLH at I2C controller outputs. Actual  $t_{low}$  and  $t_{high}$  periods may vary depending on the board (the load capacitance on the SCLL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

**CAUTION**

During active mode (the I2C\_CON[15] I2C\_EN bit is set to 1), make no changes to the I2C\_SCLL and I2C\_SCLH registers. Changes may result in unpredictable behavior.

Table 12-38 lists the register values for obtaining the maximum I<sup>2</sup>C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

**Table 12-38. I2C Register Values for Maximum I2C Bit Rates in I2C F/S, I2C HS Modes**

	I <sup>2</sup> C Mode for			Description
	Standard Mode	Fast Mode	High-Speed Mode	
SYS_CLK frequency (MHz)	96			
OCP_CLK frequency (MHz)	133			
<b>I2C_PSC[7-0] PSC</b>	<b>23</b>	<b>9</b>	<b>1</b>	Prescaler value for F/S and HS modes
INTERNAL_CLK frequency (MHz)	4	9.6	96	
<b>I2C_SCLL[7-0] SCLL</b>	<b>13</b>	<b>7</b>	<b>115</b>	Value for F/S mode and first phase of HS mode
<b>I2C_SCLH[7-0] SCLH</b>	<b>15</b>	<b>5</b>	<b>113</b>	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10	
<b>I2C_SCLL[15-8] HSSCLL</b>			<b>12</b>	Values for second phase of HS mode
<b>I2C_SCLH[15-8] HSSCLH</b>			<b>5</b>	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate
Maximum filter period (ns)			10	

#### Note

This table presents informative values only for the configuration parameters and the I<sup>2</sup>C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.

#### Note

For WKUP\_I2C0

For MCU\_I2C[0-1]

For I2C[0-6]

$I2Ci\_INTERNAL\_CLK \text{ freq} = I2Ci\_SYS\_CLK / (PSC + 1)$

$F/S \text{ filter period} = 1 / I2Ci\_INTERNAL\_CLK$

$HS \text{ filter period} = 1 / I2Ci\_SYS\_CLK \text{ freq}$

$HS \text{ bit rate} = I2Ci\_SYS\_CLK \text{ freq} / (HSSCLL + 7 + HSSCLH + 5)$

$FS \text{ bit rate} = I2Ci\_INTERNAL\_CLK / (SCLL + 7 + SCLH + 5)$

#### 12.1.3.4.2.2 I2C Automatic Blocking of the I2C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I<sup>2</sup>C clock after the target addressing phase, when the I2C controller is addressed by an external controller device using a certain Own Address.

The release of the I<sup>2</sup>C clock can be performed independently for each Own Address (I2C\_OA, and I2C\_OAx registers, where x = 1, 2, 3) by deasserting the corresponding bit in the I2C\_SBLOCK register.

#### 12.1.3.4.3 I2C Software Reset

Each multicontroller I2C supports the software reset by accessing the I2C\_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C\_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C\_CON[15] I2C\_EN bit to 0).
2. Set the I2C\_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C\_CON[15] I2C\_EN bit to 1.
4. Check the I2C\_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

#### Note

The I2C\_CON[15] I2C\_EN bit can hold the functional clock domain of the multicontroller I2C in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I2C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C\_CON[15] I2C\_EN bit must be set to 1 to enable the functional part of the I2C controller.

The I2C\_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C\_CON[15] I2C\_EN bit to 1.

#### 12.1.3.4.4 I2C Power Management

[Table 12-39](#) describes power-management features available for the multimaster I2C controllers.

#### Note

For information about source clock gating, see *Power*, in the *Device Configuration*.

#### Note

Some of the I2C features described in this section may not be supported on this family of devices. For more information, see *I2C Not Supported Features*.

**Table 12-39. I2C Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C_SYSC[4-3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C_SYSC[9-8] CLOCKACTIVITY	For configuration details, see <a href="#">Table 12-40</a> .
Global wake-up enable	I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

**Table 12-40. I2C Clock Activity Settings**

I2C_SYSC[9-8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	OCP_CLK	SYS_CLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; Functional clock is enabled
01	ON	OFF	Functional clock is disabled; Interface clock is enabled
11	ON	ON	Both clocks are enabled.

### 12.1.3.4.5 I2C Interrupt Requests

The I2C controller must allocate a minimum of five registers for interrupts.

- Interrupt Raw Status (I2C\_IRQSTATUS\_RAW)
- Interrupt Enabled Status (I2C\_IRQSTATUS)
- Interrupt Enable Set (I2C\_IRQENABLE\_SET)
- Interrupt enable Clear (I2C\_IRQENABLE\_CLR)
- End of interrupt (I2C\_EOI)

End of Interrupt (I2C\_EOI) is used by software to trigger an interrupt service completion.

Table 12-41 lists the event flags, and their mask, that can cause module interrupts.

**Table 12-41. I2C Events**

Event Flag	Event Unmask	Event Mask	Description
I2C_IRQSTATUS[0] AL	I2C_IRQENABLE_SET[0] AL_IE	I2C_IRQENABLE_CLR[0] AL_IE	Arbitration lost. This bit is automatically set by the hardware when it loses the arbitration in controller transmit mode, an interrupt is signaled to the host.
I2C_IRQSTATUS[1] NACK	I2C_IRQENABLE_SET[1] NACK_IE	I2C_IRQENABLE_CLR[1] NACK_IE	No acknowledgement. Bit is set when No Acknowledge is received, an interrupt is signaled to the host.
I2C_IRQSTATUS[2] ARDY	I2C_IRQENABLE_SET[2] ARDY_IE	I2C_IRQENABLE_CLR[2] ARDY_IE	Register access ready. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the host.
I2C_IRQSTATUS[3] RRDY	I2C_IRQENABLE_SET[3] RRDY_IE	I2C_IRQENABLE_CLR[3] RRDY_IE	Receive data ready. Set to 1 by core when in receiver mode, a new data can be read. An interrupt is signaled to the host.
I2C_IRQSTATUS[4] XRDY	I2C_IRQENABLE_SET[4] XRDY_IE	I2C_IRQENABLE_CLR[4] XRDY_IE	Transmit data ready. Set to 1 by core when transmitter is ready for new data. An interrupt is signaled to the host.
I2C_IRQSTATUS[5] GC	I2C_IRQENABLE_SET[5] GC_IE	I2C_IRQENABLE_CLR[5] GC_IE	General call. Set to 1 by core when General Call address was detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[6] STC	I2C_IRQENABLE_SET[6] STC_IE	I2C_IRQENABLE_CLR[6] STC_IE	Start condition detected. An interrupt is signaled to the host.
I2C_IRQSTATUS[7] AERR	I2C_IRQENABLE_SET[7] AERR_IE	I2C_IRQENABLE_CLR[7] AERR_IE	Bus Access Error. An interrupt is signaled to the host.
I2C_IRQSTATUS[8] BF	I2C_IRQENABLE_SET[8] BF_IE	I2C_IRQENABLE_CLR[8] BF_IE	Bus free. An interrupt is signaled to the host.
I2C_IRQSTATUS[9] AAS	I2C_IRQENABLE_SET[9] AAS_IE	I2C_IRQENABLE_CLR[9] AAS_IE	Address recognized as target. An interrupt is signaled to the host.
I2C_IRQSTATUS[10] XUDF	I2C_IRQENABLE_SET [10] XUDF_IE	I2C_IRQENABLE_CLR[10] XUDF_IE	Transmit underflow. An interrupt is signaled to the host.
I2C_IRQSTATUS[11] ROVR	I2C_IRQENABLE_SET [11] ROVR_IE	I2C_IRQENABLE_CLR[11] ROVR_IE	Receive overrun. An interrupt is signaled to the host.
I2C_IRQSTATUS[12] BB	N/A	N/A	Bus busy indicator
I2C_IRQSTATUS[13] RDR	I2C_IRQENABLE_SET [13] RDR_IE	I2C_IRQENABLE_CLR[13] RDR_IE	Receive draining. An interrupt is signaled to the host.
I2C_IRQSTATUS[14] XDR	I2C_IRQENABLE_SET [14] XDR_IE	I2C_IRQENABLE_CLR[14] XDR_IE	Transmit draining. An interrupt is signaled to the host.

#### 12.1.3.4.6 I2C Programmable Multitarget Channel Feature

This feature allows each multicontroller I2C to be addressed using four separate Own Addresses configured in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3). An additional register (I2C\_ACTOA) is used to indicate to the LH which address is used by the external controller to communicate with the I2C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C\_CON[7] XOA0, I2C\_CON[6] XOA1, I2C\_CON[5] XOA2, or I2C\_CON[4] XOA3).

#### 12.1.3.4.7 I2C FIFO Management

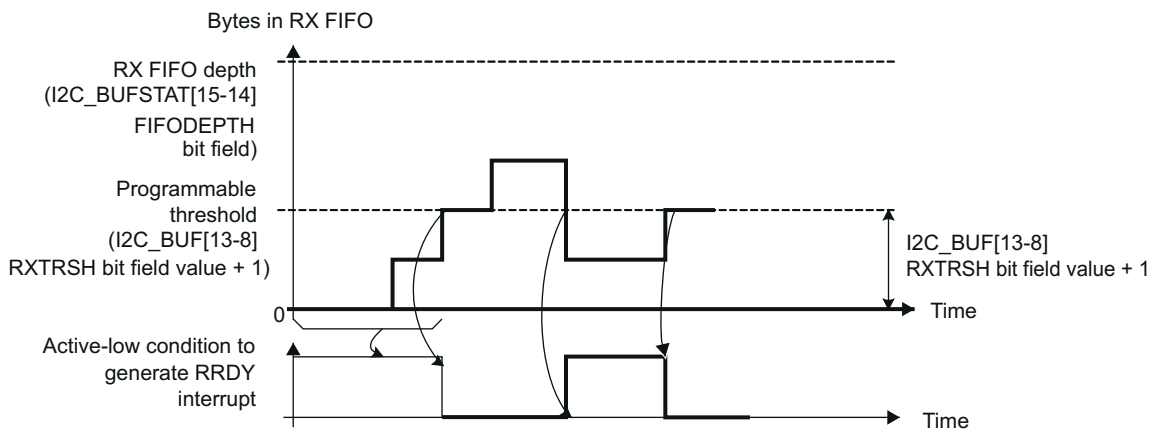

Each multicontroller I2C implements two internal 8-bit FIFOs, the RX and TX FIFOs.

The depth of the RX and TX FIFOs can be checked by reading the I2C\_BUFSTAT[15-14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

##### 12.1.3.4.7.1 I2C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C\_IRQENABLE\_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX FIFO or the I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I2C controller in receive mode and/or from any source to the I2C controller FIFO in transmit mode).

Figure 12-31 and Figure 12-32 show receive and transmit operations, respectively, from a FIFO management point of view.

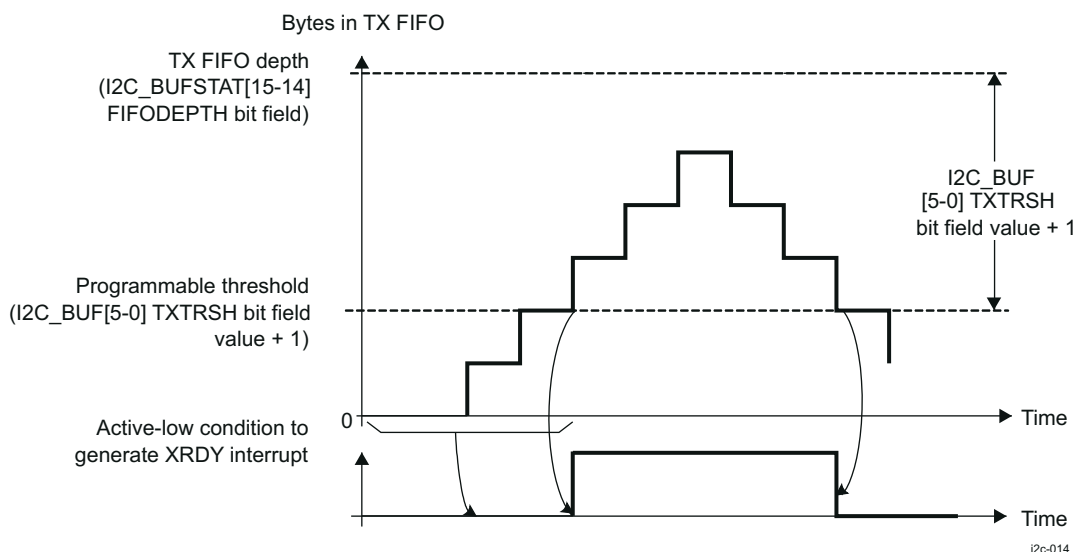

i2c-013

**Figure 12-31. I2C Receive FIFO Interrupt Request Generation**

In Figure 12-31, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C\_BUF[13-8] RXTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

**Figure 12-32. I2C Transmit FIFO Interrupt Request Generation**

In [Figure 12-32](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C\_IRQENABLE\_CLR [4] XRDY\_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C\_BUF[5-0] TXTRSH + 1 or I2C\_BUF[5-0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see [Section 12.1.3.4.7.3, Draining Feature \[I2C Mode Only\]](#)).

#### Note

In target transmit mode (the I2C\_CON[10] MST bit is cleared and the I2C\_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external controller can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in target transmit mode, data can remain in the TX FIFO without being transmitted over the I<sup>2</sup>C bus. In this case, the TX FIFO must be cleared by setting the I2C\_BUF[6] TXFIFO\_CLR bit.

#### 12.1.3.4.7.2 I2C FIFO Polling Mode

In FIFO polling mode (the I2C\_IRQENABLE\_SET[4] XRDY\_IE and I2C\_IRQENABLE\_SET[3] RRDY\_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C\_IRQSTATUS\_RAW[4] XRDY and the I2C\_IRQSTATUS\_RAW[3] RRDY bits (the I2C\_IRQSTATUS\_RAW[13] RDR and I2C\_IRQSTATUS\_RAW[14] XDR bits can also be polled if the draining feature is enabled). The I2C\_IRQSTATUS\_RAW[4] XRDY and I2C\_IRQSTATUS\_RAW[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

### 12.1.3.4.7.3 I2C Draining Feature

#### Note

DMA mode and SCCB Protocol are not supported on this family of devices.

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold and the I2C\_BUF[5-0] TXTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the DMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C\_IRQSTATUS\_RAW[7] AERR bit.

The draining mechanism generates an interrupt using the I2C\_IRQSTATUS\_RAW[13] RDR or I2C\_IRQSTATUS\_RAW[14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C\_BUFSTAT[13-8] RXSTAT or I2C\_BUFSTAT[5-0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (controller or target), if the RX FIFO threshold (the I2C\_BUF[13-8] RXTRSH bit field value + 1) is not reached, but the transfer ends on the I<sup>2</sup>C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C\_IRQSTATUS\_RAW[13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C\_BUFSTAT[13-8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C\_BUFSTAT[13-8] RXSTAT bit field (interrupt or polling mode), or reconfigures the DMA controller with the required value to drain the FIFO.

In controller transmit mode, if the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C\_IRQSTATUS\_RAW[14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C\_BUFSTAT[5-0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C\_BUFSTAT[5-0] TXSTAT bit field value or reconfigure the DMA controller with the value required to transfer the last bytes to the FIFO.

In controller mode, the LH can alternately not check the values of the I2C\_BUFSTAT[5-0] TXSTAT and I2C\_BUFSTAT[13-8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C\_CNT[15-0] DATACOUNT bit field value modulo I2C\_BUF[13-8] RXTRSH or I2C\_BUF[5-0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C\_IRQENABLE\_SET[14] XDR\_IE or I2C\_IRQENABLE\_SET[13] RDR\_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C\_BUF[5-0] TXTRSH bit field value + 1 for the TX threshold or the I2C\_BUF[13-8] RXTRSH bit field value + 1 for the RX threshold).

### 12.1.3.4.8 I2C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the INTERNAL\_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C\_PSC[7-0] PSC bit field = 4), the maximum width of suppressed spikes is 46.1 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C\_PSC[7-0] PSC bit field.

### 12.1.3.4.9 I2C System Test Mode

A system test mode is available for multicontroller I2C module testing. This mode is enabled by setting the I2C\_SYSTEST[15] ST\_EN bit to 1. When this bit is cleared to 0, the I2C controller is configured in normal operation mode.

In system test mode, the I2C\_SYSTEST[13-12] TMODE bit field selects the type of test. [Table 12-42](#) lists the tests available for the multicontroller HS I2C controllers.

**Table 12-42. I2C List of Tests**

I2C_SYSTEST[13-12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of SCL serial clock line	The SCL line is driven with a permanent clock as if controlled with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers.
11	Loop-back mode + SCL/SDA I/O	In controller transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register through an internal path through the FIFO buffers. The interrupt request is normally generated if it is enabled. Moreover, the SCL and SDA are controlled with the I2C_SYSTEST[3-0] bits.

#### Note

When the I2C\_SYSTEST[13-12] TMODE bit field is set to 11, the I2C controller must be configured in I<sup>2</sup>C F/S (I2C\_CON[13-12] OPMODE set to 00) or I<sup>2</sup>C HS mode (I2C\_CON[13-12] OPMODE set to 01).

#### Note

In normal operation mode (the I2C\_SYSTEST[15] ST\_EN bit cleared to 0), the I2C\_SYSTEST[3-0] bits that control the SCL, SDA lines in system test mode are read-only bits.

In system test mode (the I2C\_SYSTEST[15] ST\_EN bit set to 1), the I2C\_IRQSTATUS\_RAW[4] XRDY, I2C\_IRQSTATUS\_RAW[3] RRDY, I2C\_IRQSTATUS\_RAW[10] XUDF, I2C\_IRQSTATUS\_RAW[11] ROVR, I2C\_IRQSTATUS\_RAW[2] ARDY and I2C\_IRQSTATUS\_RAW[1] NACK status bits can be set to 1 when the I2C\_SYSTEST[11] SSB bit is set to 1. Clearing the I2C\_SYSTEST[11] SSB bit to 0 does not clear the I2C\_IRQSTATUS\_RAW bits to 0. The I2C\_IRQSTATUS\_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

### 12.1.3.5 I2C Programming Guide

#### 12.1.3.5.1 I2C Low-Level Programming Models

##### 12.1.3.5.1.1 I2C Programming Model

This section describes the programming model of the multimaster I2C controllers configured in I<sup>2</sup>C mode.

##### 12.1.3.5.1.1.1 Main Program

###### 12.1.3.5.1.1.1.1 Configure the Module Before Enabling the I2C Controller

Before enabling the I2C controller, perform the following steps:

1. Enable the functional and interface clocks (see *WKUP I2C Clocks and Resets*, *MCU\_I2C Clocks and Resets*, and *I2C Clocks and Resets*).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C\_PSC[7-0] PSC bit field. This value depends on the frequency of the functional clock (SYS\_CLK).
3. Program the I2C\_SCLL[7-0] SCLL and I2C\_SCLH[7-0] SCLH bit fields to obtain a bit rate of 100 Kbps or 400 Kbps. These values depend on the internal sampling clock frequency (see [Table 12-37](#)).
4. (Optional) Program the I2C\_SCLL[15-8] HSSCLL and I2C\_SCLH[15-8] HSSCLH bit fields to obtain a bit rate of 400 Kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 12-37](#)).
5. Configure the Own Address of the I2C controller by storing it in the I2C\_OA register. Up to four Own Addresses can be programmed in the I2C\_OA and I2C\_OAx registers (where x = 1, 2, 3) for each I2C controller.

---

#### Note

For a 10-bit address, set the corresponding expand Own Address bit in the I2C\_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C\_BUF[5-0] TXTRSH bit field to (TX threshold – 1) and the I2C\_BUF[13-8] RXTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I2C controller out of reset by setting the I2C\_CON[15] I2C\_EN bit to 1.

##### 12.1.3.5.1.1.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2C\_CON register:
  - For controller or target mode, set the I2C\_CON[10] MST bit (0: target; 1: controller).
  - For transmitter or receiver mode, set the I2C\_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C\_IRQENABLE\_SET register to 1 (the I2C\_IRQENABLE\_SET [4] XRDY\_IE bit for the transmit interrupt, the I2C\_IRQENABLE\_SET [3] RRDY bit for the receive interrupt).

##### 12.1.3.5.1.1.1.3 Configure Target Address and the Data Control Register

In controller mode, configure the target address register by programming the I2C\_SA[9-0] SA bit field and the number of data bytes (I<sup>2</sup>C data payload) associated with the transfer by programming the I2C\_CNT[15-0] DCOUNT bit field.

---

#### Note

For a 10-bit address, set the I2C\_CON[8] XSA bit to 1.

##### 12.1.3.5.1.1.1.4 Initiate a Transfer

Poll the I2C\_IRQSTATUS\_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C\_CON[0] STT and I2C\_CON[1] STP bits. To initiate a transfer, the I2C\_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C\_CON[1] STP bit to 1.

#### 12.1.3.5.1.1.5 Receive Data

Poll the I2C\_IRQSTATUS\_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C\_IRQENABLE\_SET [3] RRDY\_IE bit must be set to 1) to read the receive data in the I2C\_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C\_BUF[13-8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C\_IRQENABLE\_SET [13] RDR\_IE bit to 1).

#### Note

In receive mode only, the I2C\_IRQSTATUS\_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I2C controller simply holds SCL to low to prevent other bytes from being received.

The I2C\_IRQSTATUS\_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C\_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

#### 12.1.3.5.1.1.6 Transmit Data

Poll the I2C\_IRQSTATUS\_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C\_IRQENABLE\_SET [4] XRDY\_IE bit must be set to 1) to write data to the I2C\_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C\_BUF[5-0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C\_IRQENABLE\_SET [14] XDR\_IE bit to 1).

#### Note

In transmit mode only, the I2C\_IRQSTATUS\_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In controller transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C\_CNT[15-0] DCOUNT bit field is not 0).

In target transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I<sup>2</sup>C controller device still requests data bytes to be read.

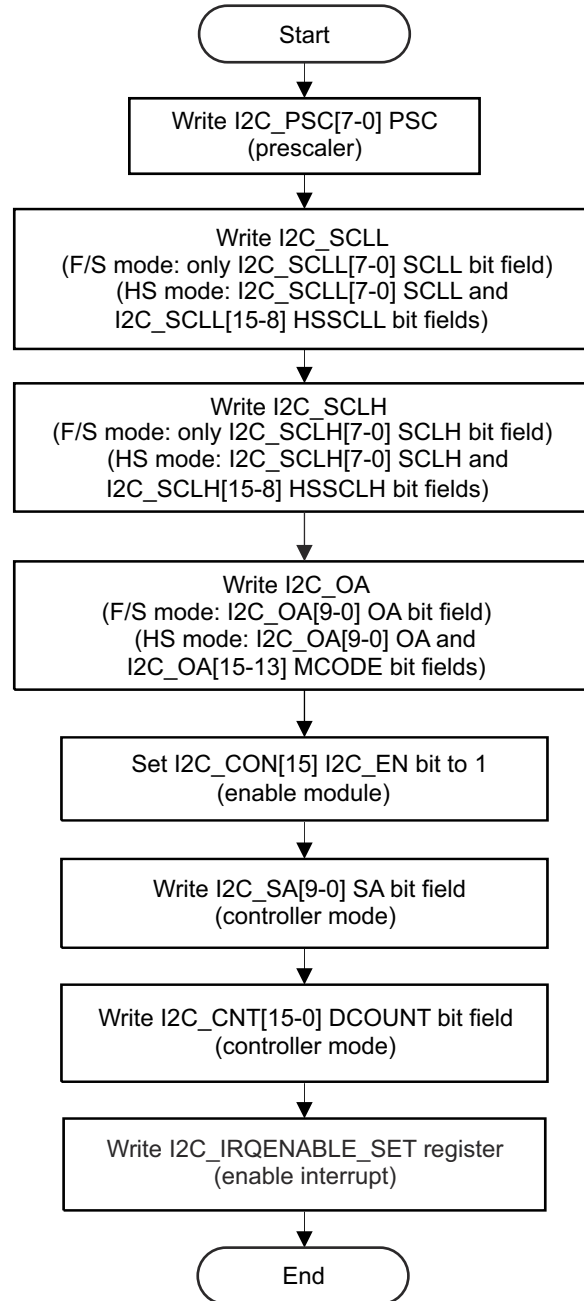

The I2C\_IRQSTATUS\_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C\_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C\_IRQENABLE\_SET [7] AERR\_IE bit to 1.

#### 12.1.3.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C\_IRQSTATUS\_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C\_IRQSTATUS\_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C\_IRQSTATUS\_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C\_IRQSTATUS\_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C\_IRQSTATUS\_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C\_IRQSTATUS\_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C\_IRQSTATUS\_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C\_IRQSTATUS\_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C\_IRQSTATUS\_RAW [8] BF bit) and resolve accordingly.

#### 12.1.3.5.1.1.3 Programming Flow-Diagrams

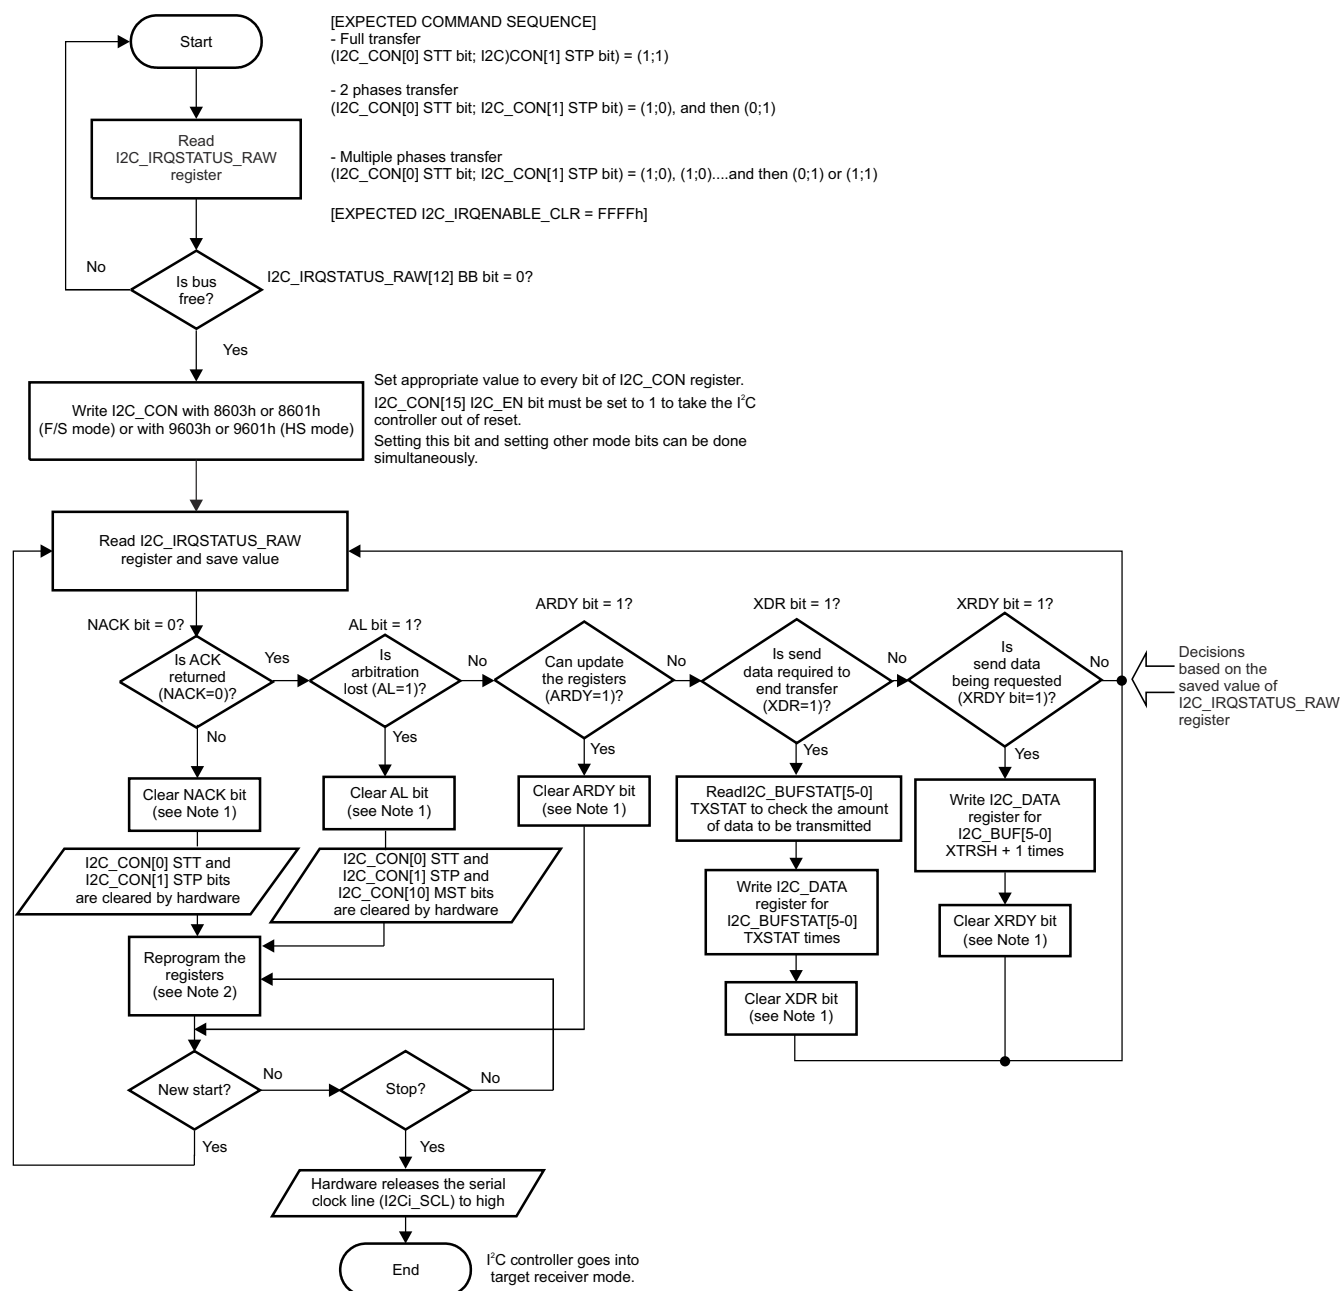

Figure 12-33 through Figure 12-39 are procedure flow charts for programming the F/S and HS I<sup>2</sup>C modes.

i2c-018

**Figure 12-33. I2C Setup Procedure**

I2C-019

- The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram the registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-34. I2C Controller Transmitter Mode, Polling Method, in F/S and HS Modes**

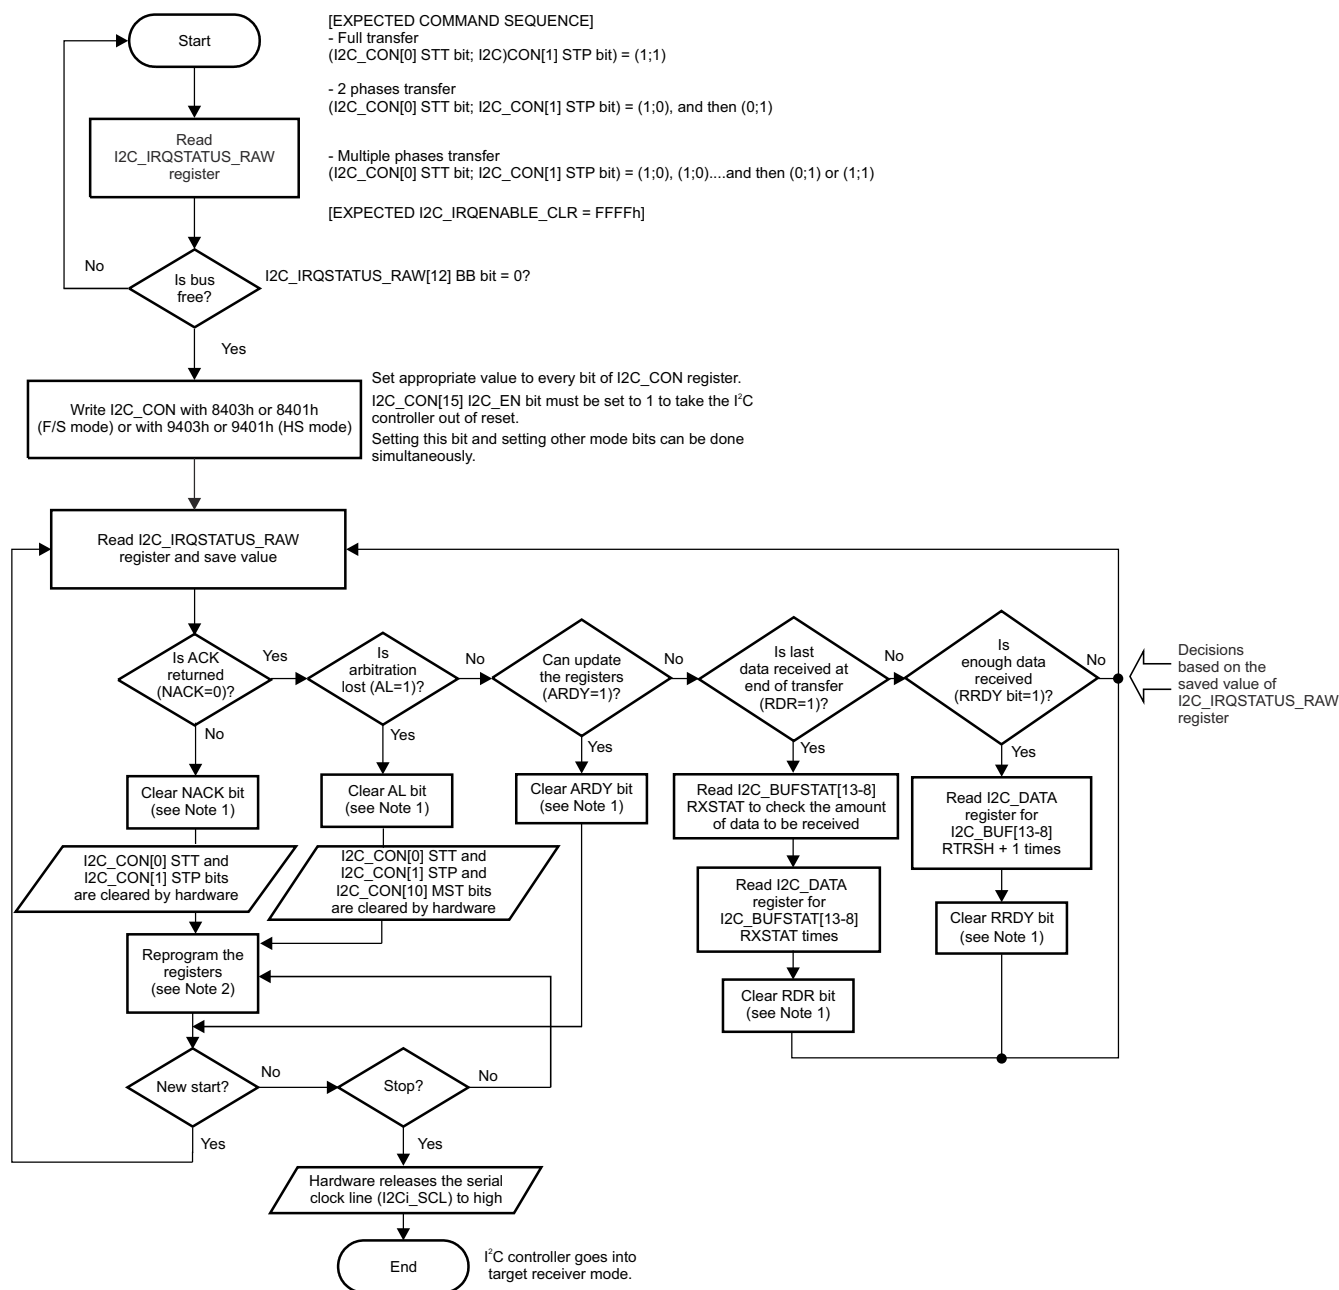

### Note

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

## Note

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

i2c-020

- The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-35. I2C Controller Receiver Mode, Polling Method, in F/S and HS Modes**

I2C-021

- The NACK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-36. I2C Controller Transmitter Mode, Interrupt Method, in F/S and HS Modes**

---

**Note**

The FIFO clearing can be made when the module is configured as transmitter, the receiver send a NACK in the middle of the transfer, and there is still data in the FIFO.

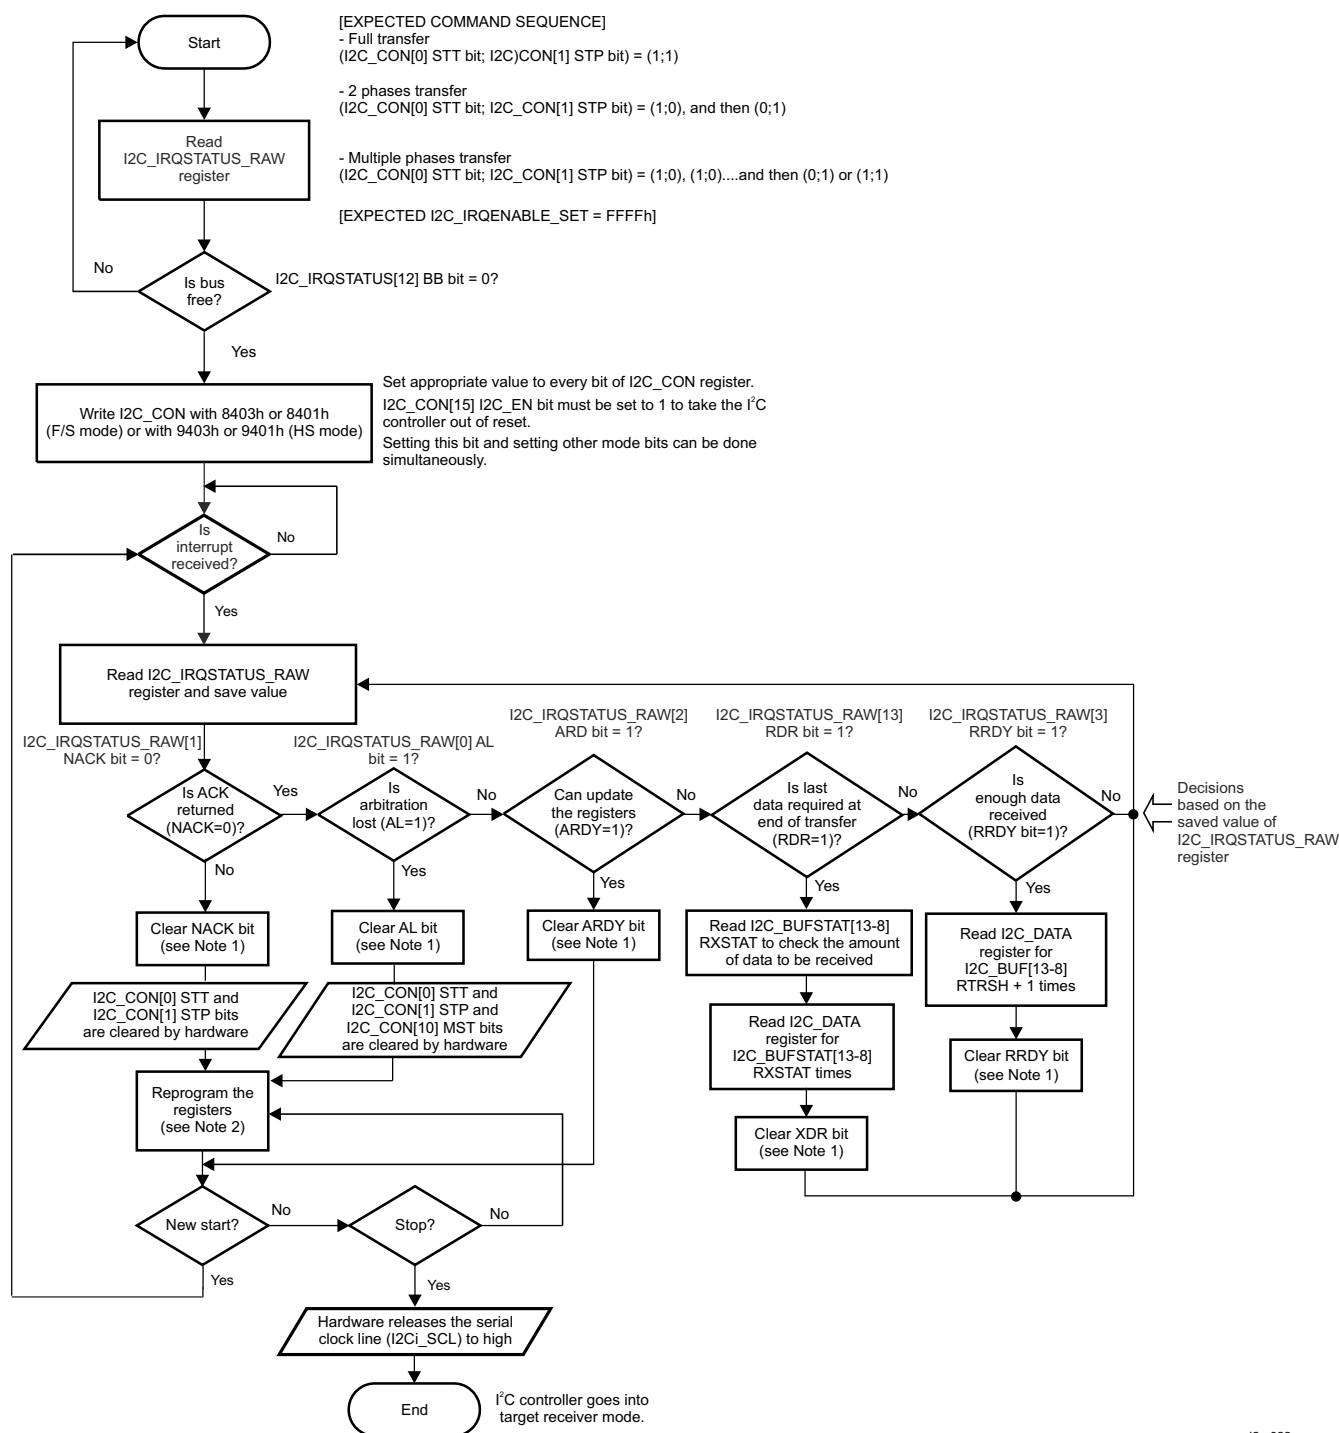

---

---

**Note**

In HS mode, the Sr condition and clock frequency switching are automatically generated by the multicontroller I2C.

---

i2c-022

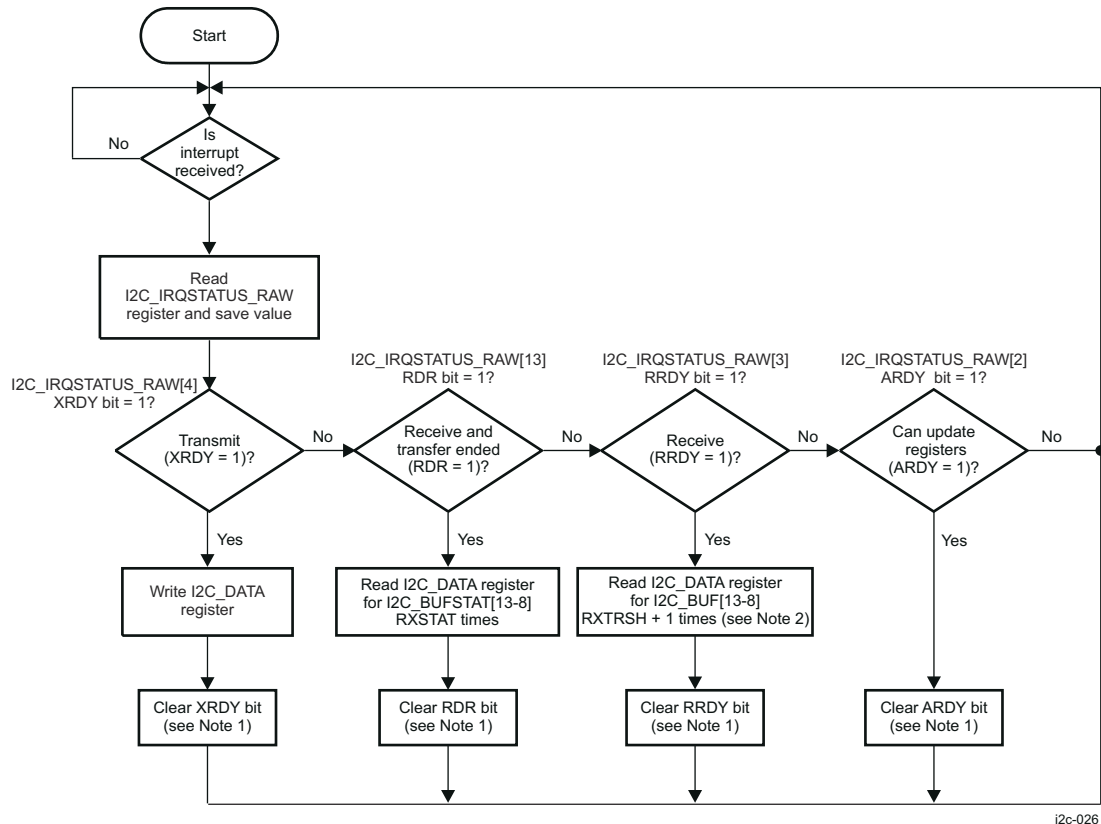

- The NACK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- Reprogram registers means: I2C\_CON[11] STB and/or I2C\_CON[10] MST bit and/or I2C\_SA[9-0] SA register and/or I2C\_CNT[15-0] DCOUNT register and/or I2C\_CON[0] STT bit and/or I2C\_CON[1] STP bit.

**Figure 12-37. I2C Controller Receiver Mode, Interrupt Method, in F/S and HS Modes**

- A. The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.
- B. In target transmitter mode, the amount of data requested by the external controller I<sup>2</sup>C device is unknown; thus, the I2C\_BUF[5-0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

**Figure 12-38. I2C Target Transmitter/Receiver Mode, Polling**

- A. The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C\_IRQSTATUS register.

- B. In target transmitter mode, the amount of data requested by the external controller I<sup>2</sup>C device is unknown; thus, the I2C\_BUF[5-0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

**Figure 12-39. I2C Target Transmitter/Receiver Mode, Interrupt**

## 12.1.4 Improved Inter-Integrated Circuit (I3C) Interface

This section describes the Improved Inter-Integrated Circuit (I3C) module in the device.

### 12.1.4.1 I3C Overview

The device contains three Improved Inter-Integrated Circuit (I3C) controllers each of which provides an interface between a local host (LH), such as an Arm, and any I3C-bus-compatible device that connects via the I3C serial bus.

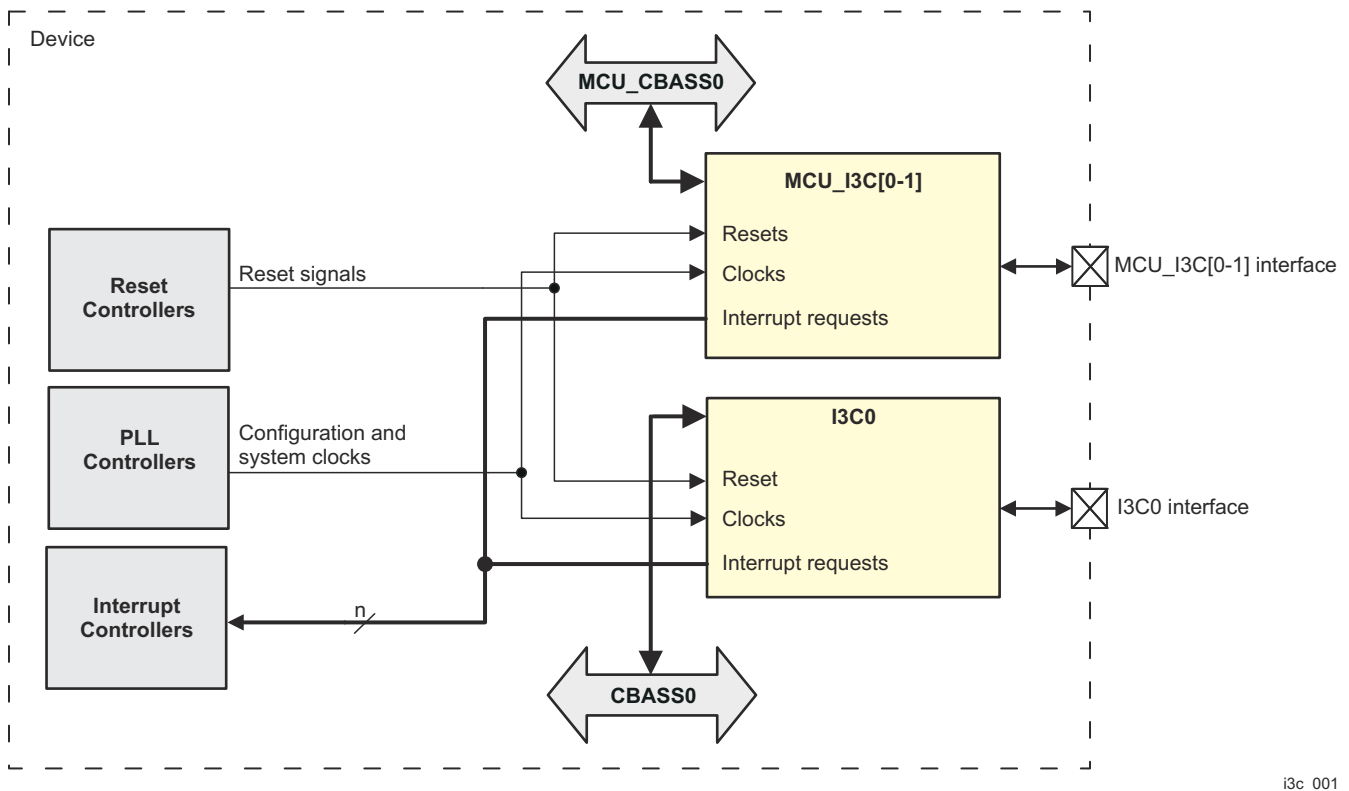

For the specific I/O timing characteristics of the I3C instances, see the device-specific Datasheet.

Table 12-43 shows I3C modules allocation across device domains.

**Table 12-43. I3C Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_I3C0	-	✓	-
MCU_I3C1	-	✓	-
I3C0	-	-	✓

Figure 12-40 shows the I3C modules overview.

i3c\_001

**Figure 12-40. I3C Modules Overview**

#### 12.1.4.1.1 I3C Features

Each I3C module has the following features:

- Communication Modes:
  - Single Data Rate (SDR) mode
  - High Data Rate – Dual Data Rate (HD-DDR) mode

- Bus Modes:
  - Pure Bus Mode (supports only I3C devices). Maximum supported frequency is 10.375 MHz
- Master and Multi-Master modes
- Common Command Codes (CCC)
- Bus Enumeration and Discovery:
  - Slaves implement standardized characteristics registers that can be queried by the master after power up to enumerate the devices attached to the bus.
- Hot-Join capability:
  - A slave device can be powered on and join the bus after initial enumeration.
- In Band Interrupts (IBI):
  - Slave devices request interrupts through the I3C bus rather than with separate side-band signals. This reduces the total IO count of the SoC as well as PCB routing.
- Dynamic Address Assignment (DAA):
  - The master can assign each slave device an address during configuration. This supports IBI because interrupt priority among slaves is arbitrated with the same address arbitration scheme that is used for all communication.
- Static Addressing (SA)
- FIFO Buffers:
  - CMD Queueing out going commands:
    - CMD0\_FIFO stores the least significant half-word of the command
    - CMD1\_FIFO stores the most significant half-word of the command
  - TXFIFO stores data transmitted with each command
  - RXFIFO stores data received as command response
  - IBI\_DATA\_FIFO stores data received as part of the in-band-interrupt transfer (IBI can transfer 0, 1, or N bytes of data payload depending on the slave)
- Immediate high priority command queue
- Registers to store the parameters for the response to an IBI interrupt from a number of slaves:
  - Each register holds the slave address and appropriate response type and payload length information for two different slaves, so that the controller can process in band interrupts without CPU intervention.

#### 12.1.4.1.2 I3C Not Supported Features

- High Data Rate – Ternary Symbol Legacy (HDR-TSL) mode
- High Data Rate – Ternary Symbol Pure (HDR-TSP) mode
- Mixed Bus (I3C devices and Legacy I2C devices with open drain or emulated open drain I/O)
- Secondary master modes
- Slave mode
- Master takeovers
- Secondary Master Hot-Join
- DMA service of I3C FIFOs
- Stamping interface (for DMA FIFO levels)
- GPIO Interface
- Optional CCCs:
  - GETMXDS

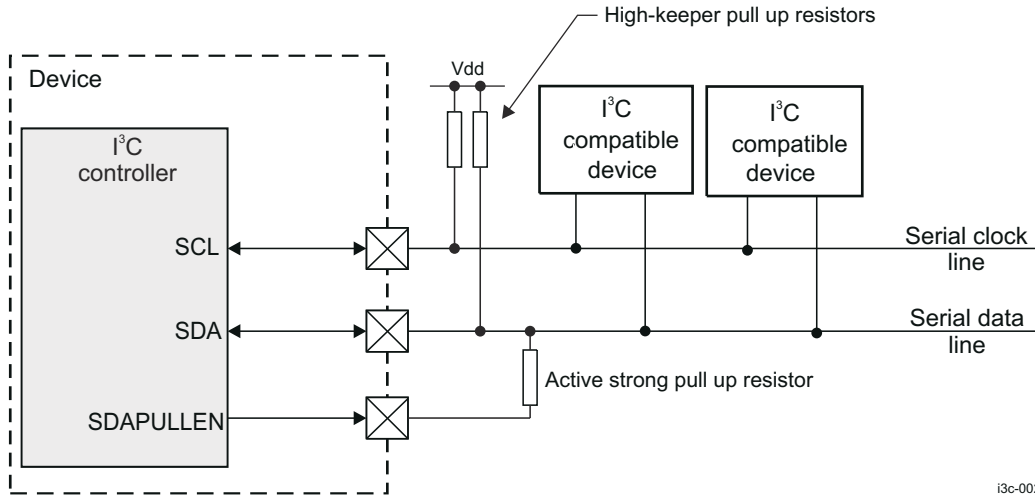

### 12.1.4.2 I3C Environment

The MCU\_I3C0, MCU\_I3C1 and I3C0 modules are hereinafter referred to as I3C module.

This section describes the I3C external connections (environment).

#### 12.1.4.2.1 I3C Typical Application

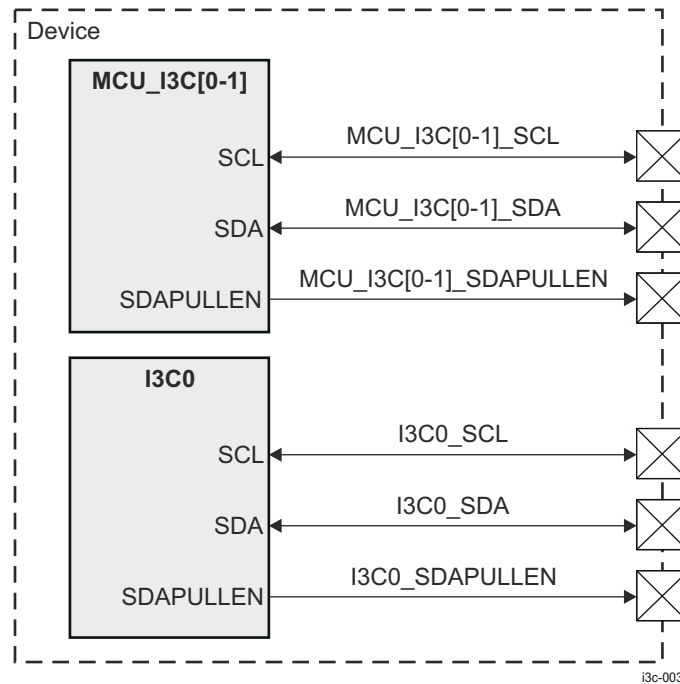

Figure 12-41 shows the I3C controllers and their related connections with I<sup>3</sup>C-compliant devices.

**Figure 12-41. I3C and Typical Connections to I3C Devices**

#### 12.1.4.2.1.1 I3C Pins for Typical Connections

Figure 12-42 shows the I3C controller pins used for typical connections with I<sup>3</sup>C devices.

**Figure 12-42. I3C Interface Signals**

#### 12.1.4.2.1.2 I3C Interface Typical Connections

Table 12-44 describes the I3C I/O signals.

**Table 12-44. I3C I/O Signals**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value
<b>MCU_I3C[0-1]</b>				
SCL	MCU_I3C[0-1]_SCL	I/O	I <sup>3</sup> C serial clock line. Emulated open-drain output buffer.	
SDA	MCU_I3C[0-1]_SDA	I/O	I <sup>3</sup> C serial data line. Emulated open-drain output buffer.	
SDAPULLEN	MCU_I3C[0-1]_SDAPULLEN	O	I <sup>3</sup> C data pull enable. <sup>(2)</sup>	
<b>I3C0</b>				
SCL	I3C0_SCL	I/O	I <sup>3</sup> C serial clock line. Emulated open-drain output buffer.	
SDA	I3C0_SDA	I/O	I <sup>3</sup> C serial data line. Emulated open-drain output buffer.	
SDAPULLEN	I3C0_SDAPULLEN	O	I <sup>3</sup> C data pull enable. <sup>(2)</sup>	

(1) I = Input; O = Output; I/O = Bidirectional

(2) Enable buffer/switch for open drain class pull-up, enabled during open drain mode.

### 12.1.4.2.1.3

#### Note

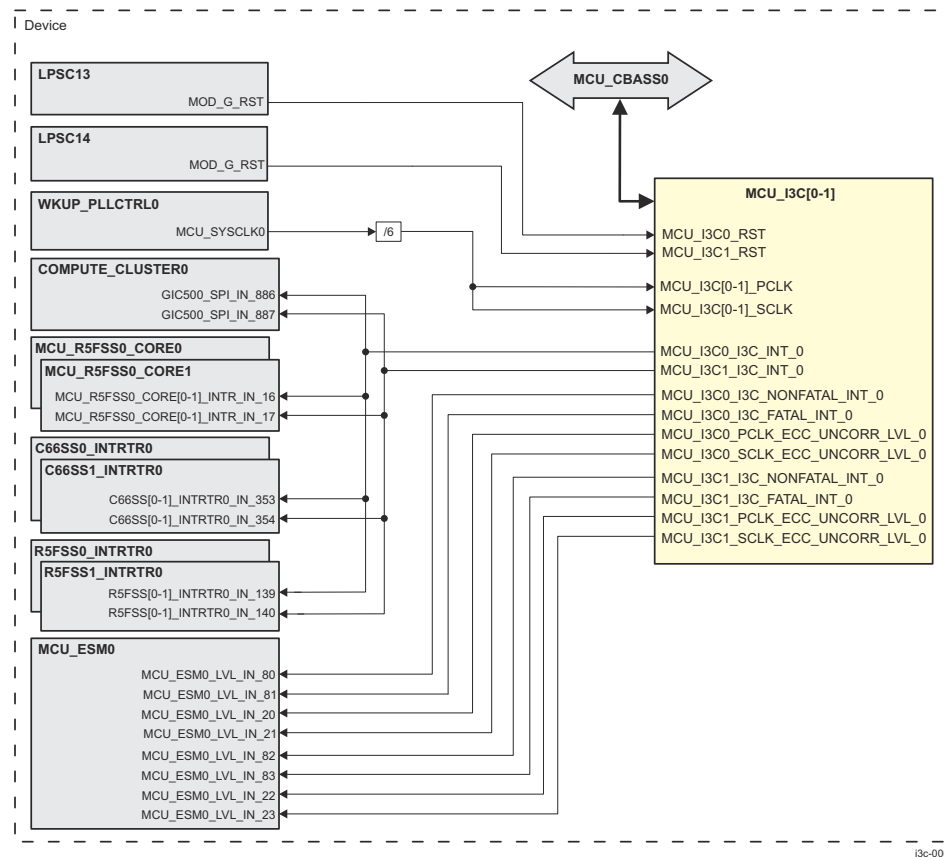

For more information about device level signals (buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.4.3 I3C Integration

This section describes I3C integration in the device, including information about clocks, resets, and hardware requests.

#### 12.1.4.3.1 I3C Integration in MCU Domain

There are two I3C modules integrated in the device MCU domain - MCU\_I3C0, MCU\_I3C1. [Figure 12-43](#) shows the integration of MCU\_I3C0, MCU\_I3C1.

**Figure 12-43. MCU\_I3C[0-1] Integration**

[Table 12-45](#) through [Table 12-47](#) summarize the integration of MCU\_I3C[0-1] in device MCU domain.

**Table 12-45. MCU\_I3C[0-1] Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_I3C0	WKUP_PSC0	PD0	LPSC13	MCU_CBASS0
MCU_I3C1	WKUP_PSC0	PD0	LPSC14	MCU_CBASS0

**Table 12-46. MCU\_I3C[0-1] Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_I3C0	MCU_I3C0_PCLK	MCU_SYSCLK0/6	WKUP_PLLCTRL0	MCU_I3C0 configuration clock

$$I3C\_PRESCL\_CTRL0[9-0] \text{ I3C} = \frac{I3C0\_SCL / MCU\_I3C[0-1]\_SCL}{(I3C\_FREQ \times 4)} - 1$$

i3c\_009

**Figure 12-46. I3C Base Frequency**

Programming the prescalers must be performed prior to enabling I3C Master controller with I3C\_CTRL[31] DEV\_EN bit in the control register.

In all timing schemes, the base frequency resulting from prescalers corresponds directly to the duration of the high level of the SCL line which takes always 50% of the base period. Depending on various conditions, the duration of low level is extended beyond the base period as necessary.

There is a specific relationship between SCL frequency and system clock frequency, which requires system clock to have a multiple of four cycles per each SCL period. Thus the selection of system clock frequency must be done with caution, since only specific frequencies will allow configuring SCL to fit into desired bandwidth.

Table 12-52 presents achievable SCL frequencies for exemplary set of system clock frequency values.

**Table 12-52. Achievable SCL Frequencies**

I3C0_SCLK / MCU_I3C[0-1]_SCLK frequency	I3C_PRESCL_CTRL0[9-0] I3C	Actual frequencies
100 MHz	0x2	8.33 MHz
133 MHz	0x3	8.313 MHz
166 MHz	0x3	10.375 MHz
200 MHz	0x4	10 MHz

#### 12.1.4.4.2.2 Asymmetric Push-Pull SCL Timing

In case of I<sup>3</sup>C messaging, asymmetric generation pattern for driving SCL can be enabled. The main purpose for this feature is supporting I3C slaves that are not capable to use maximal SCL frequency during private read/write data transfers. Host can recognize limited speed device by examining value of I3C\_DEV\_IDn\_RR2[15-8] bit-field for n = 0 to 11. Maximum frequency supported by slave can be retrieved by GETMSCL command. The low period of SCL is extended by the value programmed in I3C\_PRESCL\_CTRL1[15-8] PP\_LOW bit-field, which can be calculated using the following equation:

$$I3C\_PRESCL\_CTRL1[15-8] \text{ PP\_LOW} = \frac{I3C0\_SCL / MCU\_I3C[0-1]_SCL}{SCL\_FREQ \times (I3C\_PRESCL\_CTRL0[9-0] \text{ I3C} + 1)} - 4$$

i3c\_013

Where:

SCL\_FREQ: Maximum frequency supported by slave.

**Figure 12-47. SCL Asymmetric Push-Pull**

The I3C\_PRESCL\_CTRL1[15-8] PP\_LOW resolution is set to ¼ of SCL period. The high period of the SCL remains unchanged and is equal to half period of I<sup>3</sup>C frequency.

The low period used in push-pull mode for slaves with limited SCL capability results from following equation:

$$SCL\_LOW = I3C\_PRESCL\_CTRL1[15-8] \text{ PP\_LOW} \times \frac{T}{4}$$

i3c\_014

Where:

SCL\_LOW: SCL low period.

T: base SCL period.

**Figure 12-48. SCL Asymmetric Push-Pull Actual Low Period**

#### 12.1.4.4.2.3 Open-Drain SCL Timing

In open-drain mode, due to protocol requirement, low period cannot be shorter than 160ns to support slowly rising SDA line. To fulfill this constrain in I<sup>3</sup>C SDR mode, the low period must be always extended beyond the value resulting from the base I<sup>3</sup>C frequency. The low period of SCL is extended by the value programmed in I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW bit-field, which can be calculated using the following equation:

$$\text{I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW} = \frac{T\_LOW \times \text{I3C0\_SCL} / \text{MCU\_I3C[0-1]\_SCL}}{\text{I3C\_PRESCAL\_CTRL0[9-0] I3C} + 1} - 2$$

i3c\_010

Where:

T\_LOW: Required SCL low period.

#### Figure 12-49. SCL Open-Drain Low Period

The I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW bit-field resolution is set to ¼ of SCL period. The high period remains unchanged and is equal to half-period of I<sup>3</sup>C frequency.

The actual SCL low period used in open drain mode results from the following equation:

$$\text{SCL\_LOW} = \text{I3C\_PRESCAL\_CTRL1[7-0] OD\_LOW} \times \frac{T}{4}$$

i3c\_015

Where:

SCL\_LOW: SCL low period.

T: base SCL period.

#### Figure 12-50. SCL Open-Drain Actual Low Period

#### 12.1.4.4.2.4 Changing Programmed Frequencies

Since SCL clock is derived, in order to change the SCL timing for any mode or to keep current I<sup>3</sup>C bus timing, the following procedure should be used:

1. Disable the I3C controller by setting the I3C\_CTRL[31] DEV\_EN bit to 0.
2. Adjust I3C0\_SCLK / MCU\_I3C[0-1]\_SCLK to the new frequency if necessary, avoiding any glitches during change.
3. Reprogram the prescaler registers to achieve desired I<sup>3</sup>C timing.
4. Enable the core by setting the I3C\_CTRL[31] DEV\_EN bit to 1.

#### 12.1.4.4.3 I3C Interrupt Requests

The I3C controller has two sets of five interrupt registers:

- Interrupt Enable Register (I3C\_MST\_IER)
- Interrupt Disable Register (I3C\_MST\_IDR)
- Interrupt Mask Register (I3C\_MST\_IMR)
- Interrupt Clear Register (I3C\_MST\_ICR)
- Interrupt Status Register (I3C\_MST\_ISR)

After reset, status (I3C\_MST\_ISR) and mask (I3C\_MST\_IMR) registers both read zeroes, so all interrupts are disabled. CPU handles interrupts by several typical operations:

- To activate an interrupt, interrupt enable register (I3C\_MST\_IER) should be programmed with 0x1 on bit positions corresponding to interrupts sources which should be signaled to CPU. This interrupt mask is written to I3C\_MST\_IMR and defines which sources will be propagated.
- After receiving interrupt, I3C\_MST\_ISR should be read to identify the interrupt source. Since I3C\_MST\_ISR is always updated by all interrupt sources regardless of I3C\_MST\_IMR, the I3C\_MST\_ISR value should be compared to the programmed mask (stored in software or read from I3C\_MST\_IMR) as it can contain other flags which were not propagated. Interrupt handler should clear flag which triggered interrupt in I3C\_MST\_ISR by writing 0x1 to corresponding bits of I3C\_MST\_ICR. It is crucial for correct interrupt source identification to read status, apply mask and clear current interrupt flag before another (from the same or

different source) interrupt can occur, so these actions should be executed at the beginning of the interrupt handler routine.

- If during operation additional interrupt sources need to be enabled, clearing their flags prior to enabling is necessary to avoid false signaling of events which occurred earlier.
- To disable interrupt source anytime during operation, corresponding bit in interrupt disable register (I3C\_MST\_IDR) should be programmed with 0x1, which in turn clears corresponding bit in I3C\_MST\_IMR, disabling interrupt source.

#### 12.1.4.4.4 I3C Power Configuration

Before I3C controller is put into operation, several settings need to be adjusted after cycling the power on. The general settings collected in I3C\_CTRL register. For most common usage scheme, two fields are the most important:

1. I3C\_CTRL[31] DEV\_EN bit allows enabling and disabling the I3C bus controller. It must be enabled before any I3C bus message is initiated, however following settings need to be programmed prior to enabling controller:
  - a. Bus Mode (Only Pure Bus Mode is supported)
  - b. SCL Divider prescalers (See *I3C Clock Configuration*)
  - c. Devices Retaining Registers (See *I3C Retaining Registers Space*)

During normal operation the controller should stay enabled. Before disabling, the I3C\_MST\_STATUS0[18] IDLE should be examined to confirm that no bus operation is pending.

2. I3C\_CTRL[1-0] BUS\_MODE bit-field is set to Pure Bus Mode by default. The I3C controller supports only I3C compatible devices on I3C bus and if changed bit-field has no effect. For more information see *I3C Not Supported Features*.

#### 12.1.4.4.5 I3C Dynamic Address Management

Enumeration of I3C devices involves Dynamic Address Assignment procedure. At power up of the I3C bus, the I3C Master should provide dynamic address for all I3C devices under the following conditions:

- If I3C Slave devices with Static Address are available (not supported for this device), firmware may choose to assign Dynamic Address using SETDASA CCC to shorten bus initialization time; such devices are called Static I3C Devices.
- For the devices that are enumerated using SETDASA CCC command the Provisional ID, BCR and DCR information should be manually acquired, using GETPID / GETBCR / GETDCR CCC commands. This step is not mandatory if the values are known prior to bus initialization and programmed into I3C Master by host application.
- Devices with no Static Address and these with Static Address not enumerated receive Dynamic Address using the DAA procedure initiated by issuing the ENTDAAC CCC command.
- For the devices that are enumerated using ENTDAAC CCC command the Provisional ID, BCR and DCR information are automatically received during DAA procedure.

During I3C bus operation, current master can disable one or all I3C devices by sending Direct or Broadcast RSTDAA CCC command. In such case, corresponding \*\_CLR bits in I3C\_DEVS\_CTRL should be set by firmware to clean retaining registers. In order to re-enable these devices, DAA procedure must be performed (initiated by master or by Hot-Join requests sent by slave devices).

Depending on I3C slave implementation, the slave that received RSTDAA CCC command may restore its static address. In order to perform private transfers to such slave or assign dynamic address using SETDASA CCC command rather than DAA procedure, the corresponding I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit field (n = 0 to 11) should be updated with static address. Clearing Retaining Registers by setting corresponding I3C\_DEVS\_CTRL register is not mandatory in this scenario.

Current master can also assign new Dynamic Address to device which already has one by sending SETNEWDA command. After sending this command with new Dynamic Address in the data field, the I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit field (n = 0 to 11) must be also updated with this address in order to perform subsequent transaction to this device.

#### 12.1.4.4.6 I3C Retaining Registers Space

The information on configuration, Provisional ID, BCR and DCR of each device connected to the I<sup>3</sup>C bus is stored by the I<sup>3</sup>C master in a set of retaining registers divided into Device ID sections associated with each device. Application host take any action to guarantee maintaining this information anytime the bus topology changes.

The retaining register space is divided to up to 12 sections (depending on selected configuration), from I3C\_DEV\_ID0 to I3C\_DEV\_ID11. Each containing three 32-bit registers to hold whole necessary information on I3C devices connected to the bus (e.g. hot-join device is attached, some of DA are reset to new value, etc.).

The AMBA APB interface address space for retaining registers starts at 0x080 and is divided into 12 quadruplets.

The map organization is presented in [Table 12-53](#) below.

**Table 12-53. Retaining Registers Map Organization**

Register	Address	Contents
I3C_DEV_ID0_RR0	0x080	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID0_RR1	0x084	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID0_RR2	0x088	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>
I3C_DEV_ID1_RR0	0x090	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID1_RR1	0x094	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID1_RR2	0x098	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>
I3C_DEV_ID2_RR0	0x0A0	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID2_RR1	0x0A4	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID2_RR2	0x0A8	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>
...	...	...
I3C_DEV_ID11_RR0	0x130	Configuration register which stores settings for device that needs to be programmed by application host.
I3C_DEV_ID11_RR1	0x134	Register stores MSB of Provisional ID <sup>(1)</sup>
I3C_DEV_ID11_RR2	0x138	Register stores LSB of Provisional ID, DCR, BCR <sup>(1)</sup>

(1) The information is relevant only for I<sup>3</sup>C devices and is automatically filled by hardware during DAA procedure. Application host needs to fill the information for all devices with Dynamic Addresses Assignment with SETDASA CCC command.

A special device control register (I3C\_DEVS\_CTRL) is provided to store information on devices currently connected to the bus. Each DeviceID section contains configuration register and two registers holding Provisional ID, BCR and DCR of the corresponding device. The active state bit is set automatically by hardware after Dynamic Address is assigned to given device. Firmware shall set it for devices enumerated with SETDASA CCC command after their Retaining Registers are configured and before any transaction to these devices is initiated.

The clearing bits need to be set by firmware every time RSTDAA CCC is send to corresponding devices (firmware should clear all of them for broadcast RSTDAA) or controller constantly receives NACK response and application recognizes device as no longer connected to the bus.

#### 12.1.4.4.7 I3C Dynamic Address Assignment Procedure

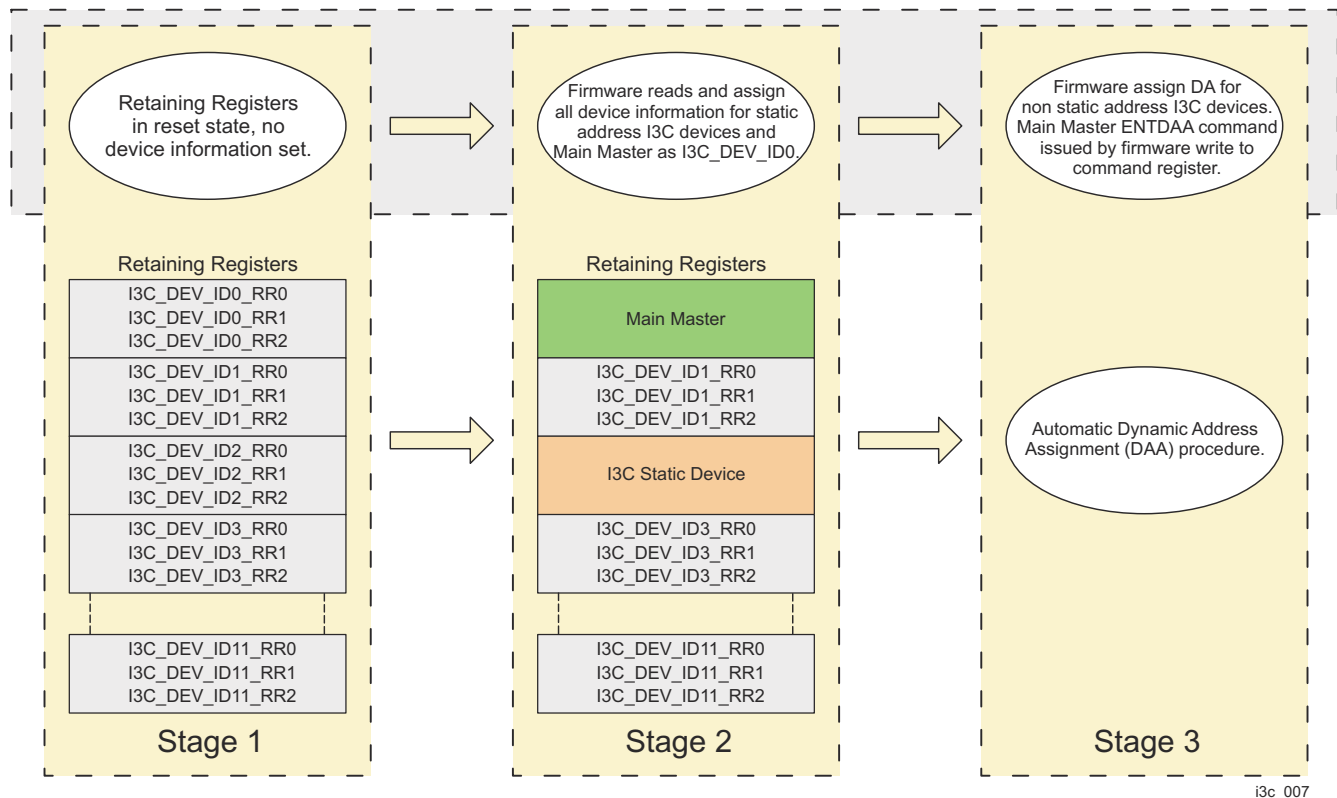

The I3C bus initialization procedure can be decomposed into three main stages, described below:

- **Stage 1:** On startup, the I3C master does not have any information about I<sup>3</sup>C slave devices and all Retaining Registers are set to the default reset vector table;

- **Stage 2:** Is fully maintained by application host. The first register section (Device ID0) is reserved for I3C master self-description. The following registers starting from Device ID1 will be filled by DAA procedure in Stage 3. This implies rules firmware should follow:
  - I<sup>3</sup>C devices with Static Address which firmware assume to enumerate with SETDASA CCC command shall be localized in Retaining Registers table (see [Figure 12-51](#)) after address space that reserved for I<sup>3</sup>C devices intended to be enumerated with ENTDAAs;
  - Corresponding I3C\_DEVS\_CTRL bits for active should be set;
- **Stage 3:** Before attempting DAA procedure, firmware should take following actions:
  - For Static I3C Devices intended to be enumerated with SETDASA CCC command:
    - Configuration registers should be programmed with Static Addresses and other settings relevant for I3C device;
    - Corresponding I3C\_DEVS\_CTRL bits for active should be set;
    - Dynamic Addresses should be assigned using SETDASA CCC command;
    - Configuration registers should be programmed with just assigned Dynamic Addresses;
    - Provisional ID / BCR / DCR Registers (I3C\_DEV\_IDn\_RR1 and I3C\_DEV\_IDn\_RR1, n = 0 to 11) should be programmed with data either predefined by application or obtained by reading PID / BCR / DCR with related CCC;
  - For I<sup>3</sup>C Devices intended to be enumerated with ENTDAAs CCC command:
    - Configuration registers should be programmed with Dynamic Addresses and other settings relevant for I3C Device;

Once all above conditions are satisfied the firmware can issue the ENTDAAs CCC command, which is considered as start condition for Stage 3.

[Figure 12-51](#) presents the I3C bus initialization for DAA procedure.

**Figure 12-51. Power-up I3C Bus Initialization**

i3c\_007

Figure 12-52 presents the I<sup>3</sup>C flow diagram for DAA procedure.

**Figure 12-52. Flow Diagram for DAA Procedure**

Static  $^{13}\text{C}$  devices have already assigned Dynamic Address with SETDASA CCC command and stay quiet during DAA procedure.

Although arbitration continues over BCR and DCR values, it is not guaranteed to be resolved in this phase, if not resolved during Provisional ID period.

- I3C\_CMD0\_FIFO[30] IS\_CCC – should be set to 1;
- I3C\_CMD0\_FIFO[7-0] CCC – specifies the Common Command Code to be sent;
- I3C\_CMD0\_FIFO[7-1] DEV\_ADDR – should address slave device in case of Direct CCC command;
- I3C\_CMD0\_FIFO[23-12] PL\_LEN – specifies the length of the Data field for commands (the number of bytes to be sent for particular CCC);
- I3C\_CMD0\_FIFO[0] RNW – defines the direction of the Data field: 0 for writing data to slave(s) and 1 for reading data from slaves;
- I3C\_CMD0\_FIFO[29] BCH – when two sequential directed CCC messages of the same type are sent; this bit determines whether the broadcast address and message code should be issued before the second address and command code;
- I3C\_CMD0\_FIFO[25] RSBC – use in conjunction with BCH when issuing short CCC messages;

The payload for CCC commands writing data to the slaves needs to be written to the TX FIFO prior to sending the two Command Words. The payload received by reading CCC commands can be read after receiving the COMP interrupt corresponding to the command. Note that ENTDAAC command uses payload of 0, since the data it receives is not stored in RX FIFO; the amount of data depends on the number of slave responding to the command.

When sending a sequence of two identical directed CCC messages to different slaves, the I3C\_CMD0\_FIFO[29] BCH and I3C\_CMD0\_FIFO[25] RSBC Command Word fields can be used to send the second message as short CCC. I3C\_CMD0\_FIFO[29] BCH should be set to 0 for the second CCC message. Instead of sending the broadcast address, waiting for it to be acknowledged and then sending the message code, this will issue restart pattern and immediately transfer the address and payload afterwards. If I3C\_CMD0\_FIFO[29] BCH is set to 1 the second CCC message is sent with broadcast address and command code in the beginning. In all other CCC message cases the I3C\_CMD0\_FIFO[29] BCH field is disregarded. Because the short CCC is preceded by restart pattern in order for this to work the I3C\_CMD0\_FIFO[25] RSBC field for the first command should also be set to 1.

Table 12-54 below summarizes available CCC set along with their payload layout in data FIFOs and Command Word settings.

**Table 12-54. CCC Commands**

CCC <sup>(1)</sup>	Description	Payload Layout <sup>(2)</sup>	PL	RNW
ENEC_BC (0x00) ENEC_DC (0x80)	Enables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
DISEC_BC (0x01) DISEC_DC (0x81)	Disables slave event driven interrupts	TX FIFO: {28'b0, 1'bHJ, 1'b0, 1'bMR, 1'bINT} (HJ – Hot-Join, MR – Mastership Request IBI, INT – regular IBI)	1	0
ENTAS0_BC (0x02) ENTAS0_DC (0x82)	Set activity to State 0 (normal operation)	No payload	0	0
RSTDAA_BC (0x06) RSTDAA_DC (0x86)	Forget current Dynamic Address and wait for new one	No payload	0	0
ENTDAA_BC (0x07)	Enter DAA procedure to assign Dynamic Addresses to unassigned devices	See Section 12.1.4.5.3, <i>Initiate DAA Procedure</i>	0	0
SETMWL_BC (0x09) SETMWL_DC (0x89)	Set maximum write length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
SETMRL_BC (0x0A) SETMRL_DC (0x8A)	Set maximum read length of a single private transfer	TX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	0
DEFSLVS_BC (0x08)	Broadcast triples of DA, DCR and SA (or 0) for each slave	No payload	0	0
ENTHDR_BC (0x20)	Switch to HD-DDR mode	No payload	0	0
SETDASA_DC (0x87)	Set Dynamic Address to slave with Static Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
SETNEWDA_DC (0x88)	Assign new Dynamic Address	TX FIFO: {24'b0, 7'bDA, 1'bP} (DA – new Dynamic Address, P – XNOR of DA bits)	1	0
GETMWL_DC (0x8B)	Get maximum write length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Write Length value)	2	1
GETMRL_DC (0x8C)	Get maximum read length of a single private transfer	RX FIFO: {16'b0, LSB, MSB} (LSB and MSB of 16-bit Max Read Length value)	2	1

**Table 12-54. CCC Commands (continued)**

CCC <sup>(1)</sup>	Description	Payload Layout <sup>(2)</sup>	PL	RNW
GETPID_DC (0x8D)	Get Slave's Provisional ID value	RX FIFO[n+1]: {16'b0, <b>PID0</b> , <b>PID1</b> } RX FIFO[n]: { <b>PID2</b> , <b>PID3</b> , <b>PID4</b> , <b>PID5</b> }	6	1
GETBCR_DC (0x8E)	Get Device's Bus Characteristic Register value	RX FIFO: {24'b0, <b>BCR</b> }	1	1
GETDCR_DC (0x8F)	Get Device's Characteristic Register value	RX FIFO: {24'b0, <b>DCR</b> }	1	1
GETSTATUS_DC (0x90)	Read Device's operating status	RX FIFO: {16'b0, 2'b <b>AM</b> , 1'b <b>PE</b> , 1'b0, 4'b <b>INT</b> , 8'b0} ( <b>AM</b> – Activity Mode, <b>PE</b> – Protocol Error, <b>INT</b> – Pending Interrupt number)		
GETACCMST_DC (0x91)	Get accept mastership	RX FIFO: {24'b0, <b>SlaveAddr</b> }	1	1
GETMXDS_DC (0x94)	Read Maximum SCL Frequency of the slave	RX FIFO: {16'b0, <b>MaxRd</b> , <b>MaxWr</b> } ( <b>MaxRd</b> – Clock to Data Turnaround Time and Maximum Sustained Read Data Rate, <b>MaxWr</b> – Maximum Sustained Write Data Rate)	1	1
GETHRCAP (0x96)	Ask slave for HDR modes it supports (can be sent only if BCR identifies HDR support)	RX FIFO: {24'b0, <b>HDRCAP</b> } ( <b>HDRCAP</b> – HDR capability modes)	1	1

(1) CCC column displays:

- The name of the Common Command Code, suffixed with **\_BC** for Broadcast CCC and **\_DC** for Direct CCC;
- In parentheses is value of CCC field to be used in Command Word 1;

(2) Payload Layout column displays:

- {<...>, <field1>, <field0>} - concatenation of 8-bit CCC data fields within 32-bit FIFO cell;
- <width>'b<field\_name> - field <field\_name> takes <width> bits (8 bits if not specified);
- The payload fields are denoted in bold;

#### 12.1.4.4.9 I3C In-Band Interrupt

In order to handle an incoming In-Band Interrupt from particular slave device, the address and configuration of IBI handling for this device needs to be stored in the I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. This register map holds information on device address, length of payload, device role and response. The map organization is presented in the [Table 12-55](#) below.

**Table 12-55. SIR Map Organization**

Register	[31-16] bit fields	[15-0] bit fields
I3C_SIR_MAP0	Device 1	Device 0
I3C_SIR_MAP1	Device 3	Device 2
I3C_SIR_MAP2	Device 5	Device 4
I3C_SIR_MAP3	Device 7	Device 6
I3C_SIR_MAP4	Device 9	Device 8
I3C_SIR_MAP5	Reserved	Device 10

All devices requesting IBI, but not added to the SIR Map, will receive the NACK response from I3C master device.

Example for IBI Map configuration looks as follows:

- Write 0x80470445 which is translated to the following configurations for first two devices:
  - Regular slave with DA = 0x22 to be ACKed and receive 4 bytes of payload (Device 0)
  - Secondary master with DA = 0x23 to be ACKed and receive no payload (Device 1)
- Write 0x004A0749 which is translated to the following configurations for the third and fourth device:
  - Regular slave with DA = 0x24 to be ACKed and receive 7 bytes of payload (Device 2)

- b. Regular slave with DA = 0x25 to be NACKed (Device 3)
3. Write 0x0000034D which configures the last fifth device as follows:
  - a. Regular slave with DA = 0x26 to be ACKed and receive 3 bytes of payload (Device 4)

After receiving regular or mastership request IBI interrupt, firmware needs to read the I3C\_IBIR register to determine which device requested IBI. The ordering of bits in the I3C\_IBIR register corresponds to ordering of devices stored in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. Note that the IBI capable devices are enumerated and ordered independently from device ordering in the retaining registers used during DAA procedure.

#### **12.1.4.4.9.1 Regular I3C Slave In-Band Interrupt**

When regular IBI request appears on the I<sup>3</sup>C bus, I<sup>3</sup>C master hardware automatically handles whole IBI procedure based on settings in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. As the IBI procedure acknowledged by I3C master finishes (including payload reception), host is informed by the IBI interrupt that such event occurred and was successfully processed. At this point, firmware should:

1. Read I3C\_IBIR register to determine requesting device
2. Read related payload from IBI RX FIFO
3. Execute related action (application/system dependent), if any designed for particular IBI/device.

#### **12.1.4.4.9.2 Current Master Takeover In-Band Interrupt**

When mastership takeover IBI request appears on the I<sup>3</sup>C bus, I<sup>3</sup>C master hardware automatically sends the response based on settings in I3C\_SIR\_MAP0 through I3C\_SIR\_MAP5 registers. After this host is informed by the I3C\_MST\_ISR interrupt that handoff procedure should be executed. At this point, firmware should:

1. Read I3C\_IBIR register to determine requesting device (optionally, if such information is useful for application host)
2. Send the GETACCMST CCC to confirm mastership handover
3. Wait for the completion of pending I3C master command signaled by I3C\_MST\_ISR interrupt – at this moment I3C master switches to the slave mode
4. Write 0x001FXXXX to FLUSH\_CTRL register to flush the FIFOs as the slave mode reuses TX and RX FIFOs (bits marked X hold RX\_FIFO threshold so should be set/maintained as needed)
5. Depending on application/system, prepare for slave operation

Note that it is firmware and/or system responsibility to provide bus information to Secondary Masters before mastership handover is granted. It can be achieved in several ways:

- Secondary Masters listen to the bus during DAA and store necessary data
- Main Master sends DEFSLVS CCC after each ENTDA / RSTDA / SETNEWD / SETDASA sequence that modifies bus

#### **12.1.4.4.10 I3C Hot-Join Request**

In order to accept any Hot-Join (HJ) request from slave device, application needs to set the I3C\_CTRL[6] HJ\_ACK and I3C\_CTRL[8] HJ\_DISEC control bits that define its response for Hot-Join request. Based on I3C\_CTRL[6] HJ\_ACK value the I3C master accepts or refuses the Hot-Join request by providing respectively ACK or NACK bit right after I3C\_CMD0\_FIFO[0] RNW bit. I3C\_CTRL[8] HJ\_DISEC bit controls whether master starts DAA procedure or sends broadcast DISEC command to disable HJ requests.

If Hot-Join request occurs, the application processor is notified by the I3C\_MST\_ISR interrupt. The application processor is aware how this particular Hot-Join request should be handled by checking current setting (can read the control bits or the stored previously used setting). In case of acknowledged request with subsequent DAA, the application processor is notified of automatically completed enumeration of hot-joined device by subsequent I3C\_MST\_ISR interrupt and simultaneously set I3C\_MST\_STATUS0 flag. In case of DISEC command, only I3C\_MST\_ISR interrupt will be set.

It is recommended to keep the I3C\_CTRL[6] HJ\_ACK bit disabled until the bus initialization procedure is completed in order to prevent slaves from indirect DAA enforcement.

#### 12.1.4.4.11 I3C Immediate Commands

Immediate Command Register is implemented in order to allow the application processor to issue immediate command which has a higher priority over the ordinary command. The immediate commands are supposed to be used in exceptional cases and only CCC commands are applicable. The I3C supports only one immediate command at a time and it is accessed by the host through two APB registers: I3C\_IMD\_CMD0 and I3C\_IMD\_CMD1. If a normal command is currently being executed and new immediate command is loaded, then controller waits to finish the current command and after that starts executing the higher priority command regardless of the content of the ordinary command FIFO. Immediate command can be used only for CCC commands and the corresponding payload must not exceed 4 bytes. As a result the GETPID and DEVSLVS CCC commands cannot be executed using immediate commands. The format for the immediate command words is the same as for the ordinary commands, although some fields are reserved since not used or fixed for CCC commands (writing to these fields has no effect).

#### 12.1.4.4.12 I3C Host Commands

The normal operation of the controller allows the firmware to build a message and then issue the transaction to the I3C controller. The command queue is provided in order to allow the host to load a request for multiple messages. Single message consists of two 32-bit words (Command Word0 and Command Word1). In order to issue the transaction the following procedure should be followed:

- Write the payload to the TX FIFO (applicable for write transfers only);
- Write Command Word1;
- Write Command Word0;

If controller is enabled (I3C\_CTRL[31] DEV\_EN bit is set to 0x01), writing Command Word0 triggers the execution of the command, resulting in start condition on the I3C bus.

#### 12.1.4.4.13 I3C Sending Private Data in SDR Messages

The I3C controller supports private data transfers in Single Data Rate with SCL frequencies up to 10.375 MHz. It supports all types of SDR transfers and provides hardware built-in features for transfers to I3C slave devices with limited maximum SCL frequency. Before any private transfer to the slave devices occurs, bus mode and SCL prescalers shall be programmed properly. Controller also provides vendor extension to the basic transfers which simplifies addressing internal registers of slave devices. To take advantage of this extension, the I3C controller must communicate with the slave devices supporting such transmission scheme.

The extension, called XMIT modes, combines standard private write and read frames to pass the slave register sub-address in addition to the actual payload. Four transmit modes are designed for specific usage:

- XMIT00 – burst (byte-by-byte) transfer with static register sub-address. Sends static sub-address followed by data bytes only. Expecting slave will make self-increment of the address for each data byte or will have payload buffer implemented.
- XMIT01 – single transfer with incremented register sub-address. Each data byte followed by repeated start condition and the slave's internal register address are incremented explicitly.
- XMIT10 – single transfer with static register sub-address. Each data byte followed by repeated start condition, register sub-address remains intact.
- XMIT11 – burst (byte-by-byte) transfer without register sub-address (first data byte after the slave address is a payload byte).

In addition to the multiple transmit modes, I3C controller has an option to provide 16-bit address of the internal register in slave device to support slaves with more than 256 internal addresses.

For arbitration priorities management, private SDR commands may use Broadcast Command Header or not. This is controlled by BCH field of command descriptor.

##### 12.1.4.4.13.1 SDR Private Write Message

The Private Write message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-53, Master Write Transaction for Single and Multi Address Sequences](#). The provided transmit modes use additional I3C write frame that utilizes the data field to pass slave register address ahead of payload byte(s).

As writing command word triggers start condition immediately, it shall be guaranteed by firmware that the data payload is written to the Tx FIFO in advance before it is going to be transmitted.

The completion of the message frame on the I3C bus is signaled by the I3C\_MST\_ISR[16] IMM\_COMP interrupt.

In case of transfers with data payload greater than the TX FIFO size, firmware can use I3C\_MST\_ISR[15] TX\_THR interrupt to fill the FIFO on time. The system design should prevent the TX FIFO from underflow. During the time elapsed between reading the last four bytes from almost empty TX FIFO and reading the subsequent one, firmware is required to refill the TX FIFO.

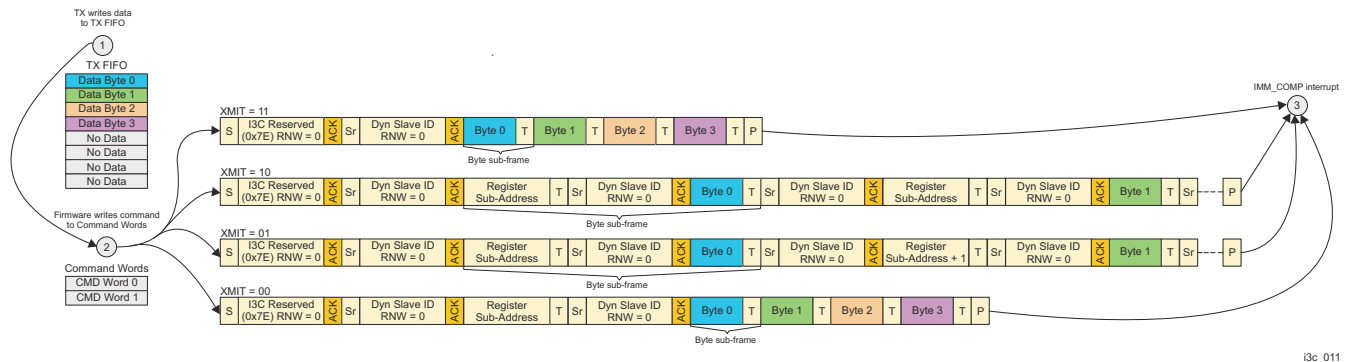

Figure 12-53. Master Write Transaction for Single and Multi Address Sequences

#### 12.1.4.4.13.2 SDR Private Read Message

The Private Read message transmitted over I3C bus in all supported transmit modes is presented in [Figure 12-54](#), *Master Read Transaction for Single and Multi Address Sequences*

Similarly to Private Write message, each I3C read frame is preceded by I3C write frame which sends slave register address to be read. After sending the command, firmware should wait for I3C\_MST\_ISR[16] IMM\_COMP interrupt which signals the end of message and RX FIFO content ready to read.

In case of payload lengths exceeding RX FIFO size, firmware should utilize I3C\_MST\_ISR[7] TX\_THR interrupt to read RX FIFO before it gets filled and prevent from data corruption. For easier management of long FIFO and/or long host read intervals, the amount of data available in FIFO that triggers the interrupt can be programmed according to actual conditions in given system.

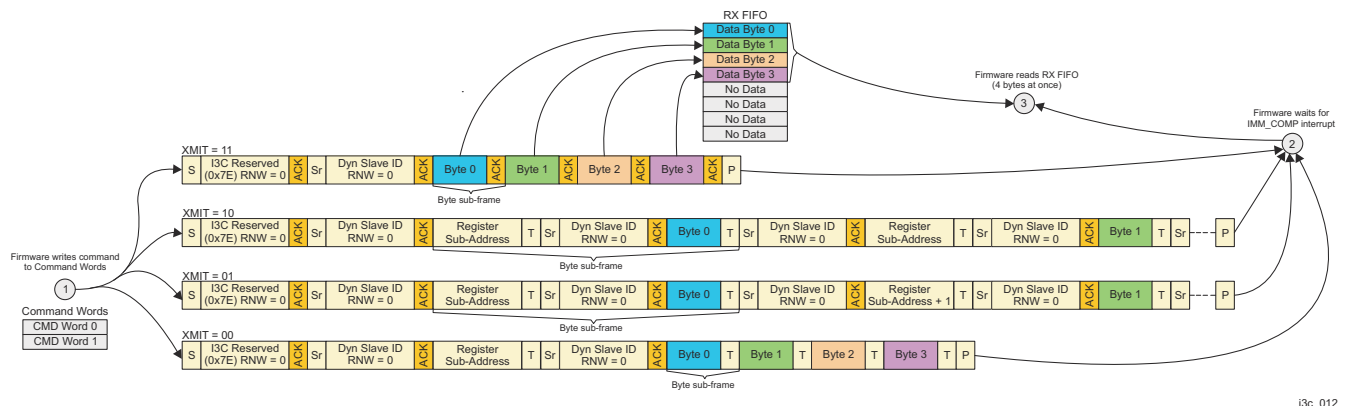

Figure 12-54. Master Read Transaction for Single and Multi Address Sequences

#### 12.1.4.4.13.3 SDR Payload Length Adjustment

In case of Private Write SDR commands, the payload length that needs to be specified is always equal to the number of data bytes sent to slave in Private Write transmission. If the payload specified is greater than slave's capability, the data are simply ignored by slave.

In case of Private Read SDR commands slave is the device which normally decides how many bytes it is able to send and when the read transfer is terminated. This can also result from hardware architecture or from SETMRL CCC command sent earlier to the slave.

For simplified handling I3C design triggers the read abort procedure after receiving specified number of payload bytes. This matters in these transfer modes which send data bytes after one another. If one of these modes is used, the I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field is interpreted as payload size that should not be reached during transfer rather than the actual number of bytes to be received. This applies only to read transfer from I3C devices.

**Table 12-56. Payload Setting in SDR Mode**

Transmission	I3C_CMD0_FIFO[28-27] XMIT_MODE	I3C_DEV_IDn_RR0[9] IS_I3C (n = 0 to 11)	I3C_CMD0_FIFO[23-12] PL_LEN
I3C, NCA	11	1	Abort limit <sup>(1)</sup>
I3C, Single	00	1	Abort limit <sup>(1)</sup>
I3C, Multi-Static	10	1	Number of bytes to receive
I3C, Multi-Incremental	01	1	Number of bytes to receive

- (1) If payload size is known, it can be set to one more than the known size; otherwise it should be set to MRL+1 where MRL is value programmed with SETMRL CCC in particular slave or its hardware payload size limit, if known.

### 12.1.4.5 I3C Programming Guide

#### 12.1.4.5.1 I3C Power-On Programming Model

Typical power-on programming sequence is as follows:

1. Program bus description into Retaining Registers according [Section 12.1.4.4.6](#) and I3C\_DEVS\_CTRL.
2. If default values of SCL prescalers do not fit applied clock frequencies, program PRESCL\_CTRL0 and PRESCL\_CTRL1 according [Section 12.1.4.4.2](#).
3. If any of following applies:
  - a. Address Header Optimization is to be enabled.
  - b. Halt mechanism should be enabled.

then alter values of I3C\_CTRL[1-0] BUS\_MODE, I3C\_CTRL[3] AHDR\_OPT and I3C\_CTRL[30] HALT\_EN fields, respectively:

- a. Program I3C\_CTRL register with value 0x80000000 to enable the controller.

#### 12.1.4.5.2 I3C Static Devices Programming

I3C devices shipped with Static Address can be enumerated prior to DAA procedure using SETDASA CCC command. In order to enumerate I3C device firmware needs to follow procedure:

1. Prepare device's retaining register:
  - a. Write corresponding I3C\_DEV\_IDn\_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11:
    - i. I3C\_DEV\_IDn\_RR0[9] IS\_I3C (n = 0 to 11): 0x01
    - ii. I3C\_DEV\_IDn\_RR0[7-0] DEV\_ADDR bit-field (n = 0 to 11): set to device's Static Address for [7-1] bits and set to Static Address parity for bit 0
2. Issue SETDASA CCC:
  - a. Make sure that controller is enabled.
  - b. Write new Dynamic Address to TX FIFO.
  - c. Write Command Word1 with SETDASA CCC value:
    - i. I3C\_CMD1[7-0] CCC bit-field: 0x87
  - d. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Static Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x00
3. Enable at least COMP, NACK and INVALID\_DA interrupts by writing 0h to IER register.
4. Wait for COMP interrupt (read I3C\_MST\_ISR).
5. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation.
6. Fill Dynamic Address into device configuration register:
  - a. Modify I3C\_DEV\_IDn\_RR0 (offset 0x080 + (n × 0x010)) for n = 0 to 11 register by writing Dynamic Address to DEV\_ADDR field and its parity to ADDR\_PAR field (keep values of other fields)
7. If not already known to application host, retrieve BCR with GETBCR CCC:
  - a. Write Command Word1 with GETBCR CCC value:
    - i. I3C\_CMD1[7-0] CCC bit-field: 0x8E
  - b. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
  - c. Wait for COMP interrupt
  - d. Read RX FIFO register - BCR is stored in bits [7:0]
8. Optionally retrieve Provisional ID and DCR with corresponding CCCs:
  - a. Write Command Word1 with GETDCR CCC value:

- i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x8F
- b. Write Command Word0 with following field values:
  - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
  - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x01
  - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
  - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
- c. Wait for COMP interrupt
- d. Read RX FIFO register - DCR is stored in bits [7:0]
- e. Write Command Word1 with GETPID CCC value:
  - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x8D
- f. Write Command Word0 with following field values:
  - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
  - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x06
  - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: Dynamic Address
  - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x01
- g. Wait for COMP interrupt
- h. Read RX FIFO register twice – PID bytes are stored in two FIFO locations. See [Table 12-54](#)
9. Write retrieved device configuration data to retaining registers:
  - a. Write four MSB of obtained PID value into I3C\_DEV\_IDn\_RR1 (offset 0x084 + (n × 0x010)) for n = 0 to 11:
  - b. Write two LSB of obtained PID value as well as BCR and DCR values into I3C\_DEV\_IDn\_RR2 (offset 0x088 + (n × 0x010)) for n = 0 to 11:

#### Note

SETDASA CCC command has advantage over DAA in shorter time spent on device configuration as retrieving PID and DCR (6 + 1 bytes transmitted over I3C bus) is optional and can be skipped if not used.

#### 12.1.4.5.3 I3C DAA Procedure Initiation

To initiate the DAA procedure I3C needs to issue ENTDAACCC command following the below procedure:

1. Enable at least COMP and NACK interrupts.
2. Issue ENTDAACCC command:
  - a. Make sure controller is enabled.
  - b. Write Command Word1 with ENTDAACCC command value:
    - i. I3C\_IMD\_CMD1[7-0] CCC bit-field: 0x07
  - c. Write Command Word0 with following field values:
    - i. I3C\_CMD0\_FIFO[30] IS\_CCC bit: 0x01
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN bit-field: 0x00
    - iii. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR bit-field: 0x00
    - iv. I3C\_CMD0\_FIFO[0] RNW bit: 0x00
3. Wait for COMP interrupt (read I3C\_MST\_ISR)
4. If COMP and no other interrupt occurs, continue. Otherwise, handle the error situation. NACK interrupt indicates no slave devices available on bus.
5. Read I3C\_MST\_STATUS0[25] DAA\_COMP bit. It is asserted simultaneously with I3C\_MST\_ISR interrupt flag.

#### Note

DAA procedure takes significant amount of time since there are always 9 bytes of data transmitted for each device (PID, BCR, DCR from device and DA to device), so for maximum bus size it will take 99 bytes.

#### 12.1.4.5.4 I3C SDR Write Message Programming Model

To accomplish the SDR write transfer, the host must perform the following steps:

1. Write all payload data bytes into TX FIFO buffer:
  - a. Write first four or less bytes to be sent, with first byte stored at LSB position.
  - b. Repeat writes until whole payload is written.
2. Write Private Write command to command queue:
  - a. Write the Command Word 1 (I3C\_CMD1\_FIFO) with slave CSR address:
    - i. CSR (bits [15:0] or [7:0]): Slave register address
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x0
    - iii. I3C\_CMD0\_FIFO[28-27] XMIT\_MODE: Transmit Mode
    - iv. I3C\_CMD0\_FIFO[26] SB\_CA: 0x1 for 16-bit CSR address, 0x0 otherwise
    - v. I3C\_CMD0\_FIFO[23-12] PL\_LEN: Number of bytes to send
    - vi. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR: Slave Address
    - vii. I3C\_CMD0\_FIFO[0] RNW: 0x0
3. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

#### 12.1.4.5.5 I3C SDR Read Message Programming Model

To accomplish the SDR read transfer, the host must perform the following steps:

1. Write Private Write command to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO) with slave CSR address:
    - i. CSR (bits [15:0] or [7:0]): Slave register address
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x0
    - iii. I3C\_CMD0\_FIFO[28-27] XMIT\_MODE: Transmit Mode
    - iv. I3C\_CMD0\_FIFO[23-12] PL\_LEN: See [Section 12.1.4.4.13.3](#)
    - v. I3C\_CMD0\_FIFO[7-1] DEV\_ADDR: Slave Address
    - vi. I3C\_CMD0\_FIFO[0] RNW: 0x1
2. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
3. Read all payload data bytes from RX FIFO buffer:
  - a. Read first four or less received bytes, with first received byte stored at LSB position.
  - b. Repeat reads until whole payload is read.

#### 12.1.4.5.6 I3C DDR Write Message Programming Model

To accomplish the DDR write transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB aligned in TX FIFO cell; set bits unspecified below to 0):
  - a. Write command word for write HDR-DDR command to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x01
    - ii. CMD (bits[17:10]): Write Command Code (from 0x00 to 0x7F)
    - iii. DA (bits[9:3]): Slave Dynamic Address
    - iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
  - b. Write first data word to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x10
    - ii. Data (bits[17:2]): 16-bit data

- iii. Parity (bits[1:0]): Parity
  - c. Write zero or more subsequent data words to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 0x11
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - d. Write CRC word to TX FIFO:
    - i. Preamble (bits [19:18]): 0x01
    - ii. Token (bits[17:14]): Ch
    - iii. CRC (bits[13:9]): CRC5
  - e. Repeat steps 1(a) to 1(d) as many write commands are to be sent.
2. Write ENTHDR CCC command to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO) of ENTHDR CCC.
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) of ENTHDR CCC with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x1
    - iii. I3C\_CMD0\_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO).
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x1
    - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN: Number of TX FIFO words
  - c. Repeat steps 2(a) and 2(b) as many write commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit, which indicates that all data of particular command are successfully transmitted to the slave.

If I3C\_MST\_ISR[16] IMM\_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C\_MST\_ISR[5] CMDD\_EMP interrupt may be utilized instead. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C\_MST\_ISR[5] CMDD\_EMP interrupt corresponding to the last command in the queue.

#### 12.1.4.5.7 I3C DDR Read Message Programming Model

To accomplish the DDR read transfer, the host must perform the following steps:

1. Prepare HDR-DDR message words (each 20-bit word is LSB-aligned in TX FIFO cell, set bits unspecified below to 0):
  - a. Write Command Word for Read HDR-DDR command to TX FIFO using following field values:
    - i. Preamble (bits [19:18]): 2'b01
    - ii. CMD (bits[17:10]): Read Command Code (0x80..0xBF)
    - iii. DA (bits[9:3]): Slave Dynamic Address
    - iv. Parity (bits[1:0]): Parity (XOR of odd and even bits of 16-bit payload)
  - b. Repeat step 1(a) as many read commands are to be sent.
2. Write ENTHDR CCC command to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO) of ENTHDR CCC.
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) of ENTHDR CCC with following data fields:
    - i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x0
    - ii. I3C\_CMD0\_FIFO[30] IS\_CCC: 0x1
    - iii. I3C\_CMD0\_FIFO[0] RNW: 0x0
3. Write HDR-DDR command(s) to command queue:
  - a. Write the Command Word1 (I3C\_CMD1\_FIFO)
  - b. Write the Command Word0 (I3C\_CMD0\_FIFO) with following data fields:

- i. I3C\_CMD0\_FIFO[31] IS\_DDR: 0x1
  - ii. I3C\_CMD0\_FIFO[23-12] PL\_LEN: 0x1
- c. Repeat steps 2(a) and 2(b) as many read commands are prepared in TX FIFO in step 1.
4. Wait for transfer completion notified by I3C\_MST\_ISR[16] IMM\_COMP bit in interrupt status register, which indicates that all data of particular command are successfully sent by the slave device and received data are ready to be read by the host.
5. Read received payload:
  - a. Read first data word from RX FIFO extracting field values:
    - i. Preamble (bits [19:18]): 0x10
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - b. Read zero or more subsequent data words from RX FIFO extracting field values as long as the read preamble matches following value:
    - i. Preamble (bits [19:18]): 0x11
    - ii. Data (bits[17:2]): 16-bit data
    - iii. Parity (bits[1:0]): Parity
  - c. As read preamble changes, read CRC Word:
    - i. Preamble (bits [19:18]): 0x01
    - ii. Token (bits[17:14]): Ch
    - iii. CRC (bits[13:9]): CRC5
  - d. Confirm (by firmware) that CRC5 value matches data payload received.

If I3C\_MST\_ISR[16] IMM\_COMP interrupt is utilized, the controller allows the application processor to perform other tasks or sleep while message is being sent.

In case of multiple command issued to command queue, I3C\_MST\_ISR[5] CMDD\_EMP interrupt may be utilized instead of I3C\_MST\_ISR[16] IMM\_COMP. It indicates completion of all commands in command queue and allows yet more efficient application processor resources management. It is issued simultaneously with the I3C\_MST\_ISR[16] IMM\_COMP interrupt corresponding to the last command in the queue.

## 12.1.5 Multichannel Serial Peripheral Interface (MCSPi)

This section describes the Multichannel Serial Peripheral Interface (MCSPi) modules for the device.

### 12.1.5.1 MCSPi Overview

The MCSPi module is a multichannel transmit/receive, master/slave synchronous serial bus.

There are eleven MCSPi modules in the device. [Table 12-57](#) shows the MCSPi allocation across device domains.

**Table 12-57. MCSPi Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
MCU_MCSPi0	-	✓	-
MCU_MCSPi1	-	✓	-
MCU_MCSPi2	-	✓	-
MCSPi0	-	-	✓
MCSPi1	-	-	✓
MCSPi2	-	-	✓
MCSPi3	-	-	✓
MCSPi4	-	-	✓
MCSPi5	-	-	✓
MCSPi6	-	-	✓
MCSPi7	-	-	✓

MCSPi3 and MCSPi4 include internal connectivity to MCSPi modules in the MCU domain, as follows:

- MCSPi3 is connected as a master to MCU\_MCSPi1 by default at power-up. MCU\_MCSPi1 and MCSPi3 may be optionally mapped to external device pads.
- MCSPi4 is directly connected as a slave to MCU\_MCSPi2 by default at power-up. MCSPi4 and MCU\_MCSPi2 are not pinned out externally.

[Figure 12-55](#) shows the MCSPi overview.

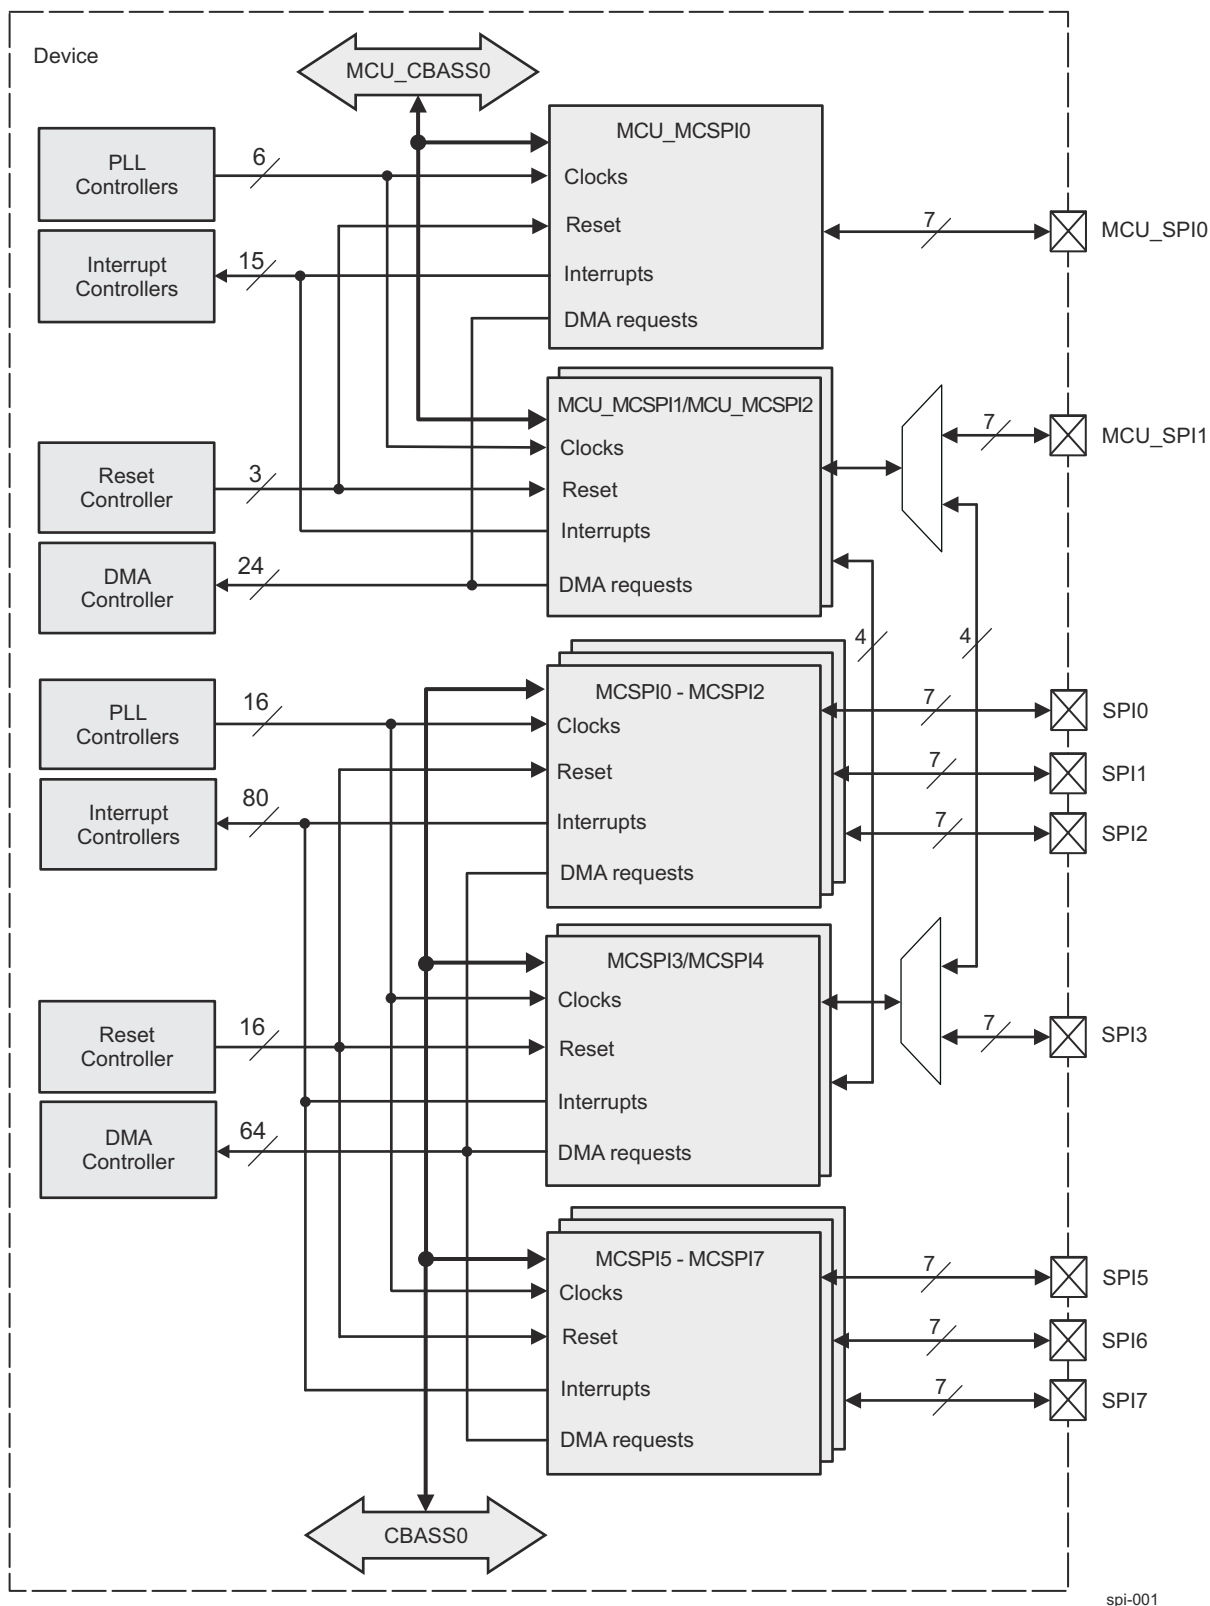

Figure 12-55. MCSPI Overview

#### **12.1.5.1.1 SPI Features**

The SPI module includes the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to channels in controller mode, or single channel in receive mode
- Controller multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible input/output (I/O) port controls per channel
  - Programmable clock granularity
  - Per channel configuration for clock definition, polarity enabling, and word width
- Single interrupt line for multiple interrupt source events
- Enable the addition of a programmable start-bit for MCSPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Programmable timing control between chip select and external clock generation
- Built-in FIFO available for a single channel

#### **12.1.5.1.2 MCSPI Not Supported Features**

The following features are not supported on this family of devices:

- Slave mode wake-up
- Retention during power down
- MCU\_MCSPI2 and MCSPI4 are not pinned out
- MCSPI4 master mode is not supported
- In slave mode only channel 0 is used
- Local power management of clock activity.

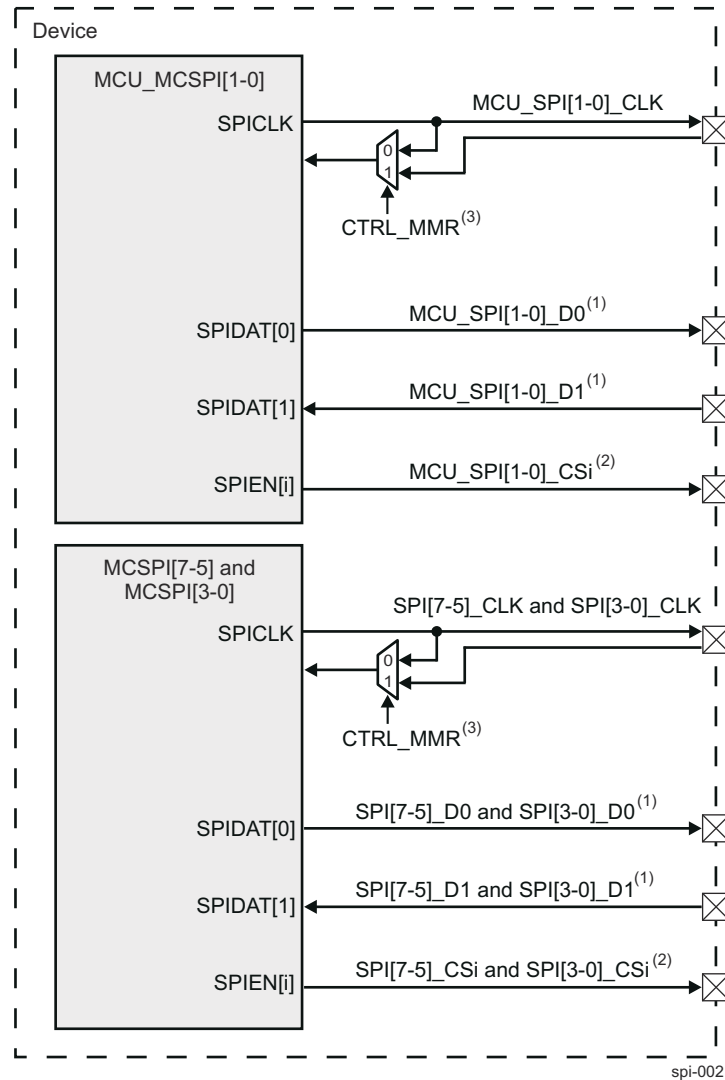

### 12.1.5.2 MCSPI Environment

The MCU\_MCSPI[2-0] and MCSPI[7-0] modules are hereinafter referred to as MCSPI module.

This section describes the MCSPI external connections (environment).

#### 12.1.5.2.1 Basic MCSPI Pins for Master Mode

Figure 12-56 shows all of the MCSPI interface signals in master mode.

- A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits
- B.  $i = 0$  to 3
- C. The source of the loopback clock is defined by CTRLMMR\_WKUP\_MCU\_SPI0\_CLKSELCTRLMMR\_WKUP\_MCU\_SPI0\_CLKSEL[16] MSTR\_LB\_CLKSEL bit (and the respective register for MCU\_MCSPI1) and CTRLMMR\_SPI0\_CLKSELCTRLMMR\_SPI0\_CLKSEL[16] MSTR\_LB\_CLKSEL bit (and the respective for MCSPI[3-0] and MCSPI[7-5]) in *Control Module (CTRL\_MMR)*.
- D. MCU\_MCSPI2 and MCSPI4 are not pinned out

**Figure 12-56. MCSPI Interface Signals in Master Mode<sup>(4)</sup>**

Table 12-58 describes the MCSPI I/O signals in master mode.

**Table 12-58. MCSPI I/O Signals (Master Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>MCU_MCSPI[1-0]</b>				
SPICLK	MCU_SPI[1-0]_CLK	O	MCSPI Serial clock output for master mode.	HiZ
SPIDAT[0]	MCU_SPI[1-0]_D0	O <sup>(3)</sup>	MCSPI Data I/O for master mode.	HiZ
SPIDAT[1]	MCU_SPI[1-0]_D1	I <sup>(4)</sup>	MCSPI Data I/O for master mode.	HiZ
SPIEN[i]	MCU_SPI[1-0]_CSi	O	MCSPI Chip-select i output for master mode	HiZ
<b>MCSPi[7-5] and MCSPi[3-0]</b>				
SPICLK	SPI[7-5]_CLK and SPI[3-0]_CLK	O	MCSPI Serial clock output for master mode.	HiZ
SPIDAT[0]	SPI[7-5]_D0 and SPI[3-0]_D0	O <sup>(3)</sup>	MCSPI Data I/O for master mode.	HiZ
SPIDAT[1]	SPI[7-5]_D1 and SPI[3-0]_D1	I <sup>(4)</sup>	MCSPI Data I/O for master mode.	HiZ
SPIEN[i]	SPI[7-5]_CSi and SPI[3-0]_CSi	O	MCSPI Chip-select i output for master mode	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[16] DPE0.

(4) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[17] DPE1.

#### Note

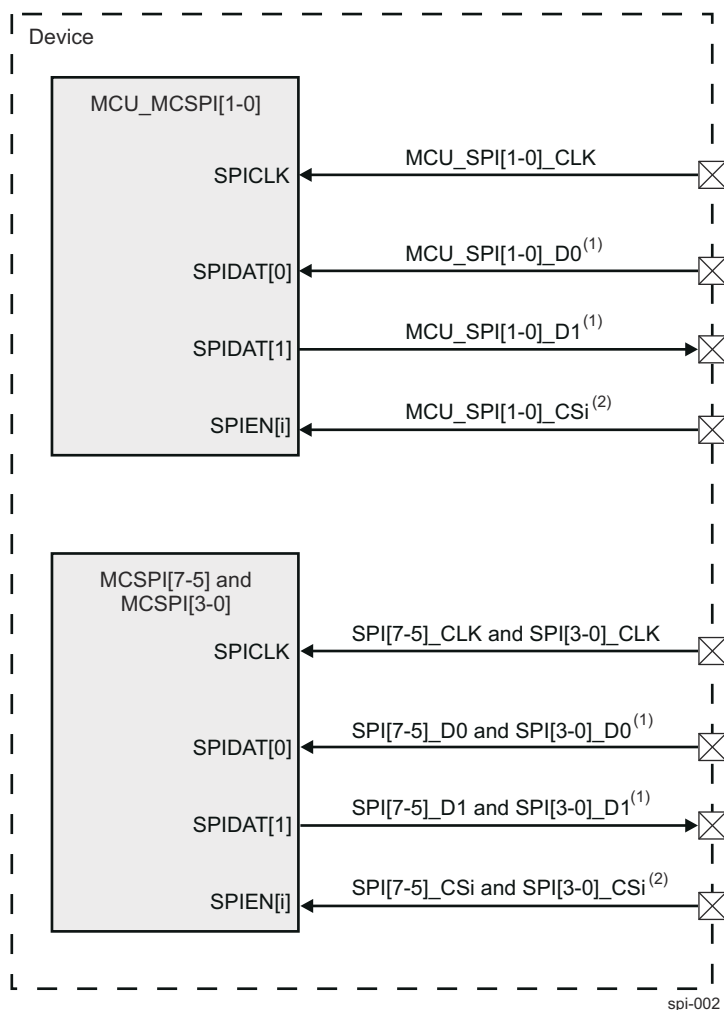

For SPI[7-5]\_CLK, SPI[3-0]\_CLK, and MCU\_SPI[1-0]\_CLK signals to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_WKUP\_PADCONFIGx/ CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.5.2.2 Basic MCSPI Pins for Slave Mode

Figure 12-57 shows all of the MCSPI interface signals in slave mode.

- A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits
- B.  $i = 0$  to 3
- C. MCU\_MCSPI2 and MCSPI4 are not pinned out

**Figure 12-57. MCSPI Interface Signals in Slave Mode<sup>(3)</sup>**

Table 12-59 describes the MCSPI I/O signals in slave mode.

**Table 12-59. MCSPI I/O Signals (Slave Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
<b>MCU_MCSPI[1-0]</b>				
SPICLK	MCU_SPI[1-0]_CLK	I	MCSPI serial clock input for slave mode.	HiZ
SPIDAT[0]	MCU_SPI[1-0]_D0	I <sup>(2)</sup>	MCSPI Data I/O for slave mode.	HiZ
SPIDAT[1]	MCU_SPI[1-0]_D1	O <sup>(3)</sup>	MCSPI Data I/O for slave mode.	HiZ
SPIEN[i]	MCU_SPI[1-0]_CSi	I <sup>(4)</sup>	MCSPI chip-select i input for slave mode.	HiZ
<b>MCSPI[7-5] and MCSPI[3-0]</b>				
SPICLK	SPI[7-5]_CLK and SPI[3-0]_CLK	I	MCSPI serial clock input for slave mode.	HiZ
SPIDAT[0]	SPI[7-5]_D0 and SPI[3-0]_D0	I <sup>(2)</sup>	MCSPI Data I/O for slave mode.	HiZ

**Table 12-59. MCSPI I/O Signals (Slave Mode) (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(1)</sup>
SPIDAT[1]	SPI[7-5]_D1 and SPI[3-0]_D1	O <sup>(3)</sup>	MCSPI Data I/O for slave mode.	HiZ
SPIEN[i]	SPI[7-5]_CSi and SPI[3-0]_CSi	I <sup>(4)</sup>	MCSPI chip-select i input for slave mode.	HiZ

(1) HiZ = High Impedance

(2) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[16] DPE0.

(3) Example configuration only. Can be configured either as input or as output depending on MCSPI\_CHCONF\_0/1/2/3[18] IS and MCSPI\_CHCONF\_0/1/2/3[17] DPE1.

(4) The chip-select input in slave mode can be selected through the MCSPI\_CHCONF\_0/1/2/3[22-21] SPIENSLV bit field.

#### Note

For SPI[7-5]\_CLK, SPI[3-0]\_CLK, and MCU\_SPI[1-0]\_CLK signals to work properly, the RXACTIVE bit of the appropriate CTRLMMR\_WKUP\_PADCONFIGx/ CTRLMMR\_PADCONFIGy registers should be set to 0x1 because of retiming purposes.

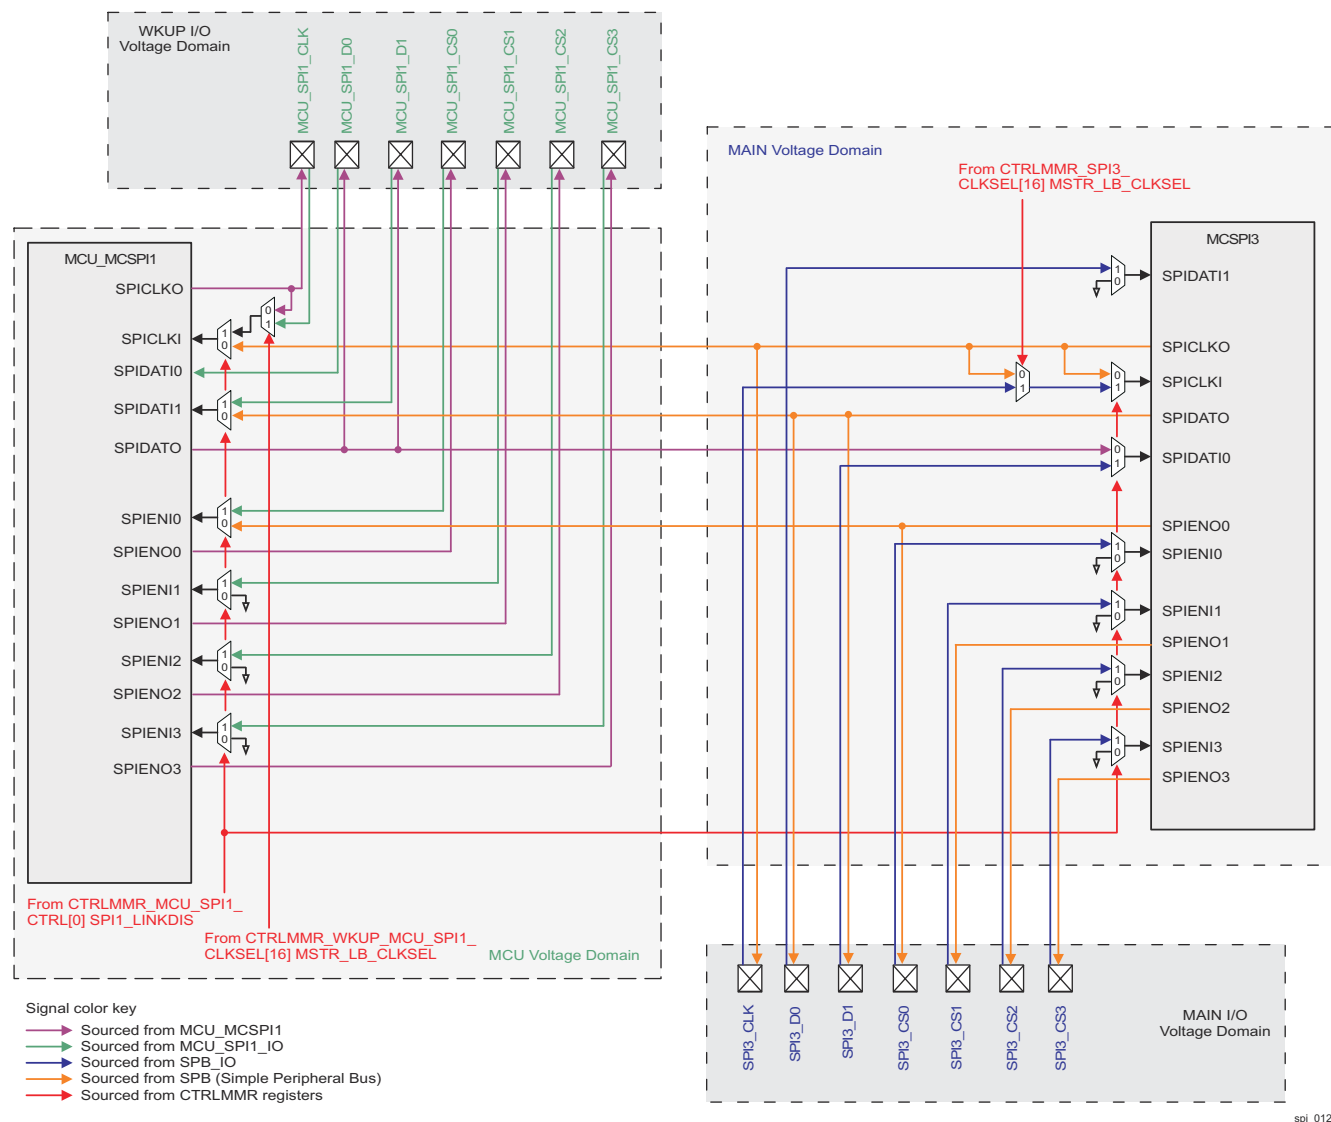

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.5.2.3 MCSPI Internal Connectivity

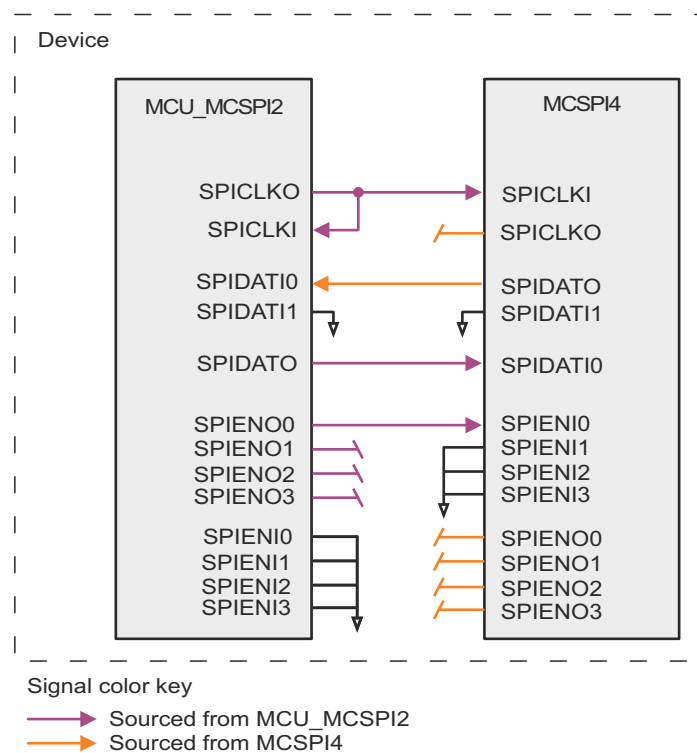

Figure 12-58 shows the MCSPI3 connected as a master to MCU\_MCSPI1 internally in the device. These MCSPIs also support external connectivity when configured in CTRL\_MMR.

**Figure 12-58. MCSPi3 and MCU\_MCSPi1 Connectivity Details**

Figure 12-59 shows the MCSPi4 connected as a slave to MCU\_MCSPi2 internally in the device. MCSPi4 and MCU\_MCSPi2 are not pinned out externally.

spi\_0122

**Figure 12-59. MCU\_MCSPi2 to MCSPI4 Internal Connectivity**

#### 12.1.5.2.4 MCSPI Protocol and Data Format

The synchronous MCSPI protocol allows a controller device to initiate serial data transfers to a peripheral device. A peripheral select line (SPIEN[i]) allows selection of an individual peripheral MCSPI device. Peripheral devices that are not selected do not interfere with MCSPI bus activities.

MCSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

MCSPI supports any MCSPI word ranging from 4 bits to 32 bits long (the MCSPI\_CHCONF\_0/1/2/3[11-7] WL bit field).

MCSPI word length can be changed between transmissions to allow the controller device to communicate with peripheral peripherals that have different requirements.

- MCSPI enable (SPIEN[i], for channel i)

The polarity of the MCSPI enable signals is programmable (the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit). SPIEN[i] signals can be active high or low.

Assertion of the SPIEN[i] signals is programmable and can be done manually or automatically. The manual assertion mode is available in single controller mode only. SPIEN[i] can be kept active between words with the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit.

Two consecutive words for two different peripheral devices can go along with active SPIEN[i] signals with different polarity.

- Programmable start-bit

In start-bit mode a start-bit is added before the MCSPI word length to indicate how the next MCSPI word must be handled. The start-bit is enabled by setting the MCSPI\_CHCONF\_0/1/2/3[23] SBE bit to 1. The MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit defines the polarity of the start-bit.

- Programmable MCSPI clock

- Bit rate

In controller mode, the baud rate of the MCSPI serial clock is programmable using the 50-MHz reference clock (from the device clock management module). [Table 12-60](#) lists the SPICLK bit rates obtained for data transfer when programming the clock divider (the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field). This is valid when MCSPI\_CHCONF\_0/1/2/3[29] CLKD bit field is 0.

**Table 12-60. MCSPI Controller Clock Rates**

Divider	Clock Rate
1	50 MHz <sup>(1)</sup>
2	25 MHz <sup>(1)</sup>
4	12.5 MHz
8	6.25 MHz
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	390.625 kHz
256	~195 kHz
512	~97.7 kHz
1024	~48.8 kHz
2048	~24.4 kHz
4096	~12.2 kHz

(1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Datasheet.

– Polarity and phase

The polarity (the MCSPI\_CHCONF\_0/1/2/3[1] POL bit) and the phase (the MCSPI\_CHCONF\_0/1/2/3[0] PHA bit) of the MCSPI serial clock (SPICLK) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 12-61](#) and [Figure 12-60](#).

**Table 12-61. Phase and Polarity Combinations**

Polarity (POL)	Phase (PHA)	MCSPI Mode	Description
0	0	Mode 0	SPICLK is inactive low and sampling occurs at the rising edge.
0	1	Mode 1	SPICLK is inactive low and sampling occurs at the falling edge.
1	0	Mode 2	SPICLK is inactive high and sampling occurs at the falling edge.
1	1	Mode 3	SPICLK is inactive high and sampling occurs at the rising edge.

**Figure 12-60. Phase and Polarity Combinations**

#### 12.1.5.2.4.1 Transfer Format

In controller and peripheral modes, the MCSPI drives the data lines when SPIEN[i] is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

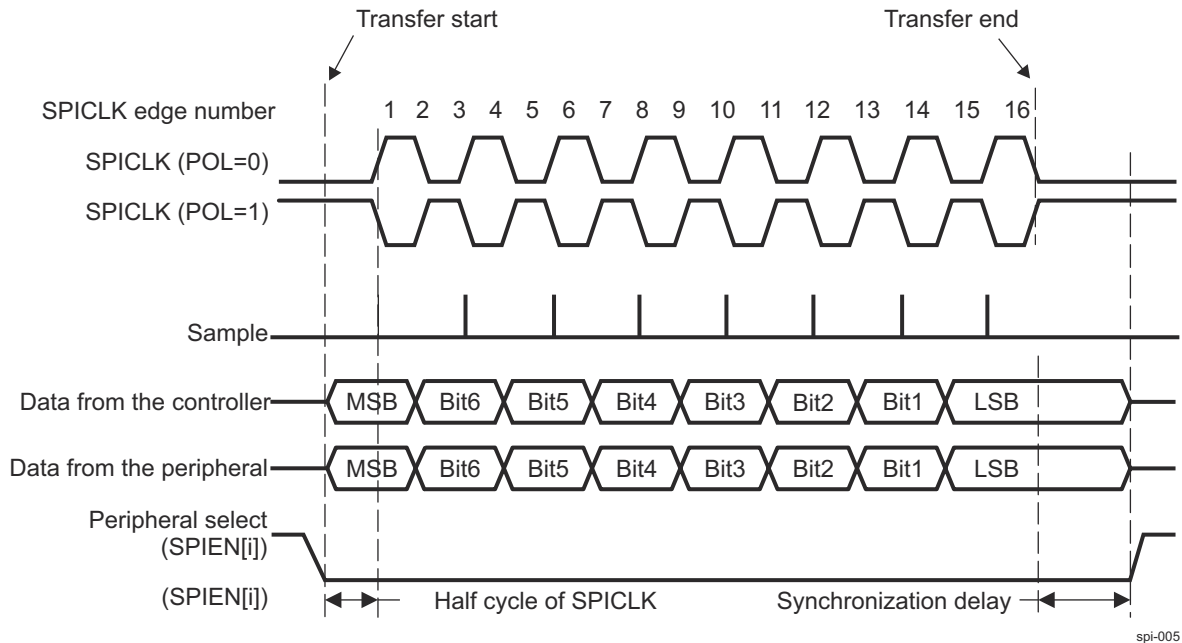

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the MCSPI word to transmit (on the controller or the peripheral data output pin) is valid one-half cycle of SPICLK after the assertion of SPIEN[i].

Therefore, the first edge of the SPICLK line is used by the controller to sample the first data bit sent by the peripheral. On the same edge, the first data bit sent by the controller is sampled by the peripheral.

On the next SPICLK edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the SPICLK line defined by the MCSPI word length programmed in the controller device, with data being latched on odd-numbered edges and shifted on even-numbered edges, see [Figure 12-61](#).

**Figure 12-61. Full-Duplex Transfer Format With PHA = 0**

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the MCSPI word to transmit (on the controller or the peripheral data output pin) is valid on the following SPICLK edge (one-half cycle later). This is the sampling edge for the controller and peripheral. A synchronization delay is added between the activation of SPIEN[i] and the first SPICLK edge.

The received data bit is shifted into the shift register on the third SPICLK edge.

This process continues for a number of pulses on the SPICLK line defined by the MCSPI word length programmed in the controller device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

#### Note

The minimum synchronization delay is one cycle of SPICLK, if the frequency of SPICLK equals the frequency of MCSPI\_FCLK (MCSPI functional clock) in controller mode. The minimum synchronization delay is one-half cycle of SPICLK, if the frequency of SPICLK is lower than the frequency of MCSPI\_FCLK in the controller and peripheral modes.

- Transmission with a start-bit (SBE = 1)

When the MCSPI\_CHCONF\_0/1/2/3[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next MCSPI word must be handled as a command or as data.

Figure 12-62 shows an example of a data transfer with an extra start-bit.

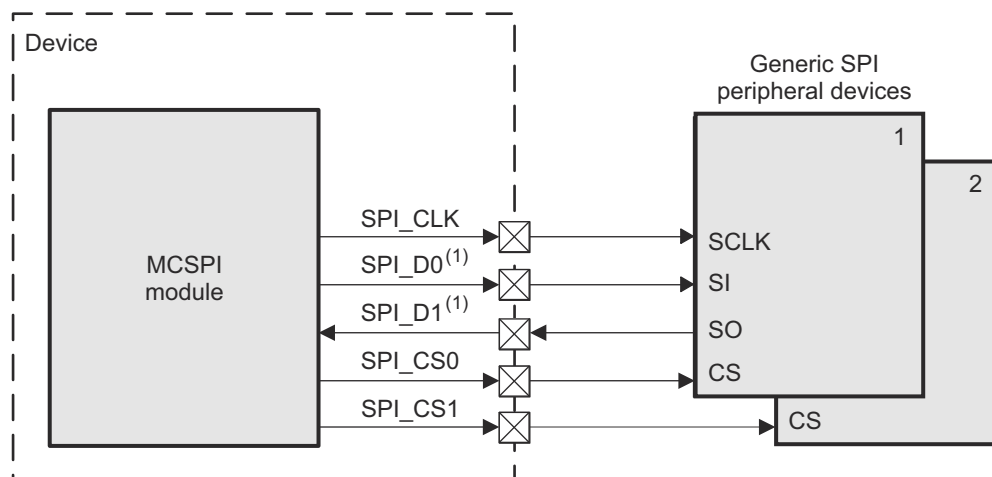

spl-006

**Figure 12-62. Extended MCSPI Transfer With a Start-Bit (SBE = 1)**

#### 12.1.5.2.5 MCSPI in Controller Mode

Figure 12-63 shows a case in controller mode (full-duplex) where the MCSPI module is connected with two peripheral devices.

spl-007

- A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-63. MCSPI Controller Mode (Full Duplex)**

Figure 12-64 shows the controller single mode, which can also be configured in receive-only mode.

spl-008

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

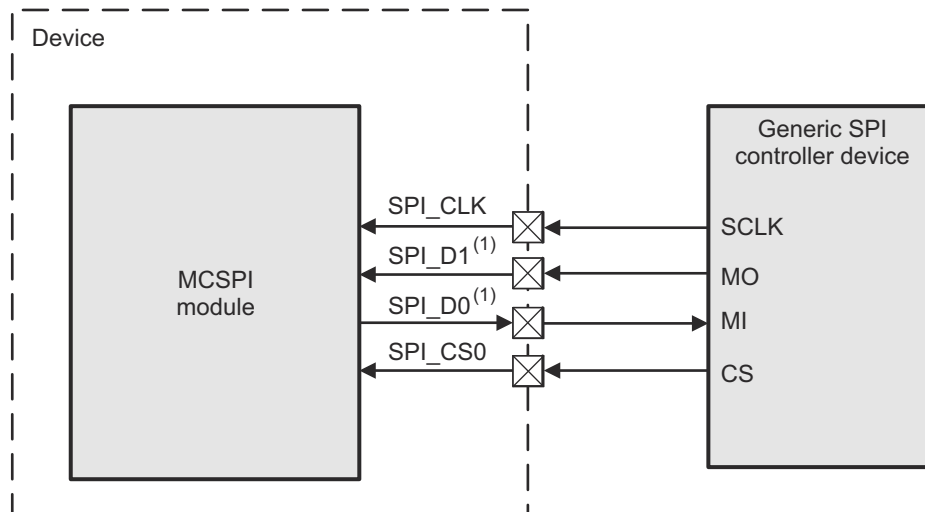

**Figure 12-64. MCSPI Controller Single Mode (Receive Only)**

#### 12.1.5.2.6 MCSPI in Peripheral Mode

Figure 12-65 shows a case in peripheral mode (full-duplex).

#### Note

Only channel 0 can be configured as peripheral, but the chip-enable signal can be connected to any SPIEN[i] pin and then rerouted internally to channel 0 (the MCSPI\_CHCONF\_0[22-21] SPIENSLV bit field). For more information, see [Section 12.1.5.4.4, MCSPI Peripheral Mode](#).

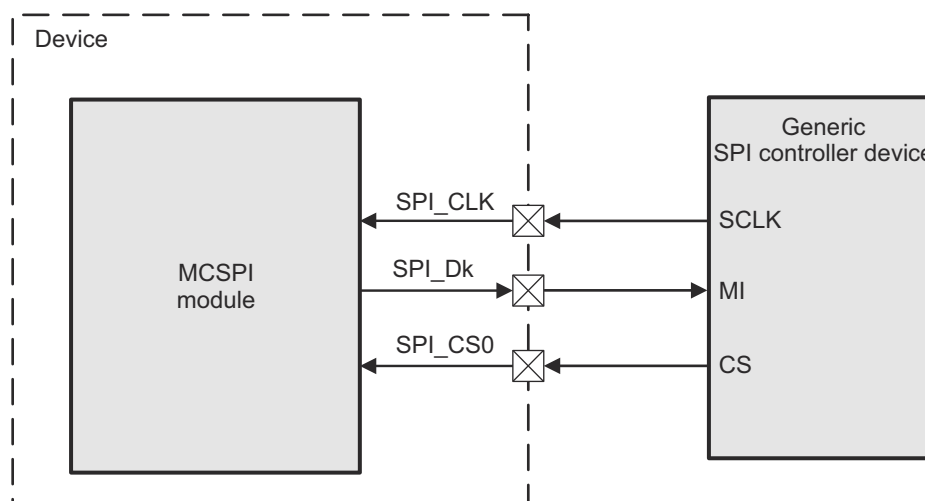

spl-009

A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-65. MCSPI Peripheral Mode (Full Duplex)**

Figure 12-66 shows the peripheral single mode, which can also be configured in transmit-only mode.

spl-010

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-66. MCSPI Peripheral Single Mode (Transmit Only)**

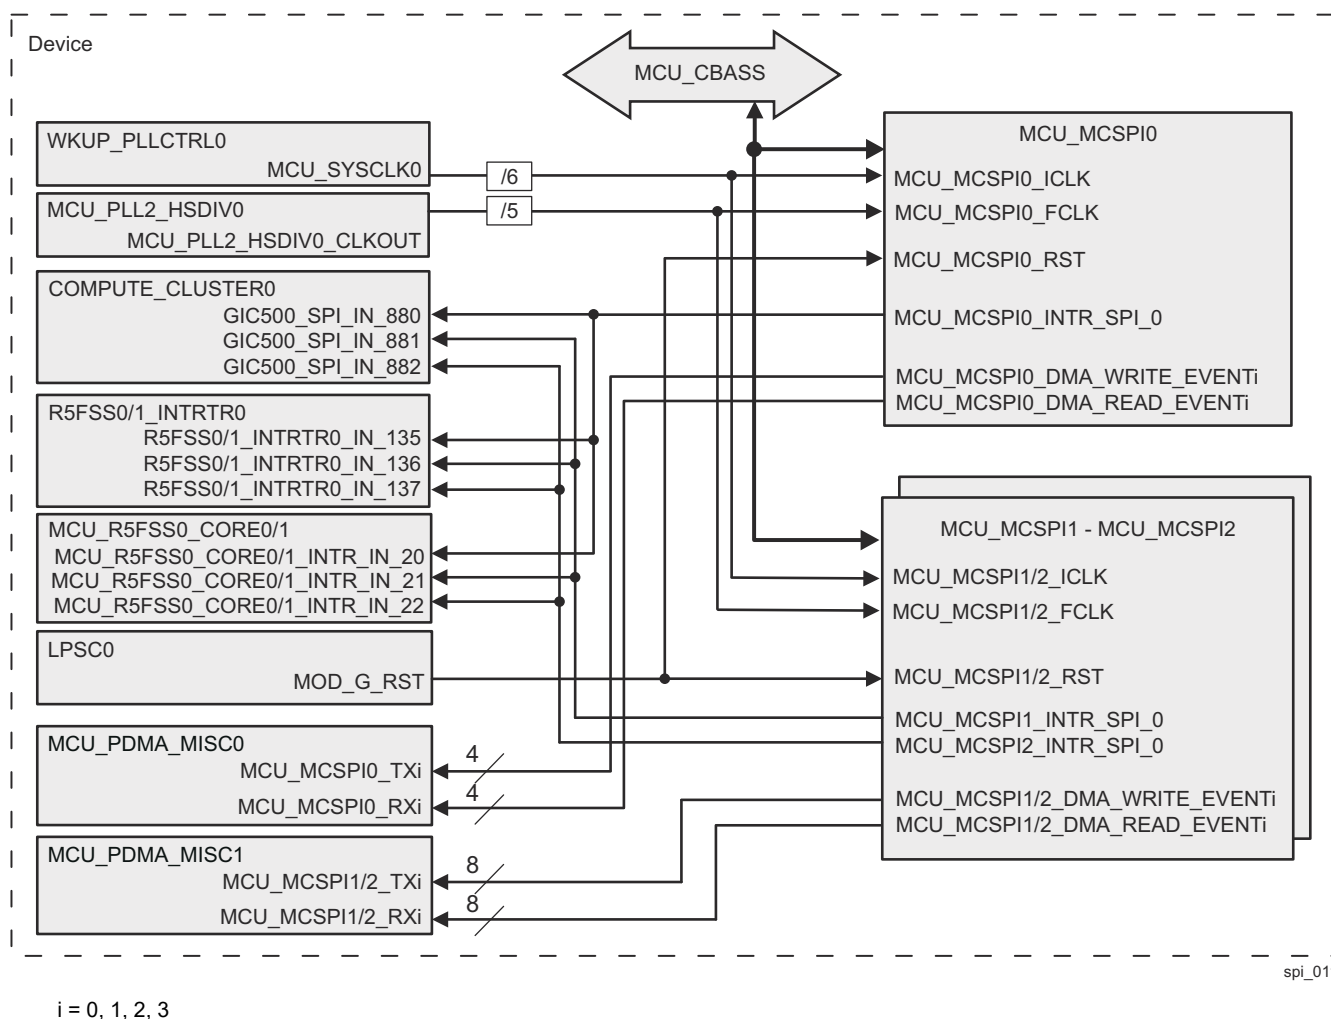

### 12.1.5.3 MCSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

### 12.1.5.3.1 MCSPI Integration in MCU Domain

There are three MCSPI modules integrated in the device MCU domain - MCU\_MCSPi0, MCU\_MCSPi1, and MCU\_MCSPi2. Figure 12-67 shows their integration in the device.

**Figure 12-67. MCU\_MCSPi Integration**

Table 12-62 through Table 12-64 summarize the integration of MCU\_MCSPi0, MCU\_MCSPi1, and MCU\_MCSPi2 in device MCU domain.

**Table 12-62. MCU\_MCSPi Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_MCSPi0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_MCSPi1	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0
MCU_MCSPi2	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

**Table 12-63. MCU\_MCSPi Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_MCSPi0	MCU_MCSPi0_ICLK	MCU_SYSClk0/6	WKUP_PLLCTRL0	MCU_MCSPi0 Interface Clock

### 12.1.5.3.2 MCSPI Integration in MAIN Domain

There are eight MCSPI modules integrated in the device MAIN domain - MCSPI0 through MCSPI7. Figure 12-68 shows their integration in the device.

**Figure 12-68. MCSPI Integration**

Table 12-65 through Table 12-67 summarize the integration of MCSPI0 through MCSPI7 in device MAIN domain.

**Table 12-65. MCSPI Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCSPi0	PSC0	PD0	LPSC7	CBASS0
MCSPi1	PSC0	PD0	LPSC7	CBASS0
MCSPi2	PSC0	PD0	LPSC7	CBASS0
MCSPi3	PSC0	PD0	LPSC7	CBASS0
MCSPi4	PSC0	PD0	LPSC7	CBASS0
MCSPi5	PSC0	PD0	LPSC7	CBASS0
MCSPi6	PSC0	PD0	LPSC7	CBASS0
MCSPi7	PSC0	PD0	LPSC7	CBASS0

**Table 12-66. MCSPI Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

### 12.1.5.4 MCSPI Functional Description

#### 12.1.5.4.1 SPI Block Diagram

Figure 12-69 shows the SPI module.

#### Note

For single channel operation ( $i=0$  or  $i=1$ ), MCSPI\_CHiCON[20]FORCE is asserted over the SPIENi and SPIENOi lines.

**Figure 12-69. SPI Block Diagram**

#### 12.1.5.4.2 MCSPI Reset

The MCSPI module can be reset either by hardware or by software reset. All configuration registers and all state machines are reset by the hardware reset signal (MCSPI\_RST). MCSPI can be reset by software through the MCSPI\_SYSCONFIG[1] SOFTRESET bit. This bit has the same impact on the module as the hardware reset signal. The only exception is that the MCSPI\_SYSCONFIG register is not affected by that software reset.

### 12.1.5.4.3 MCSPI Controller Mode

#### 12.1.5.4.3.1 Controller Mode Features

The MCSPI controller mode supports multichannel communication with up to four independent MCSPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) and generates clock (SPICLK) and control (SPIEN[i]) signals.

Connected to multiple external devices, the MCSPI exchanges data with one MCSPI device at a time through two main modes (available in peripheral mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

---

#### Note

There is a fixed chip select line allocation in multichannel controller mode. Channel *i* is mapped to SPIEN[i].

---

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in controller mode (for more information about interrupts, see [Section 13.1.3.4.7.1, Interrupt Events in Controller Mode](#)).

#### 12.1.5.4.3.2 Controller Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on SPIDAT[0]) and received (shifted in serially on SPIDAT[1]) simultaneously on separate data lines.

The controller transmit-and-receive mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI\_TX\_0/1/2/3 transmitter register state, the MCSPI\_RX\_0/1/2/3 receiver register state, and round-robin arbitration.

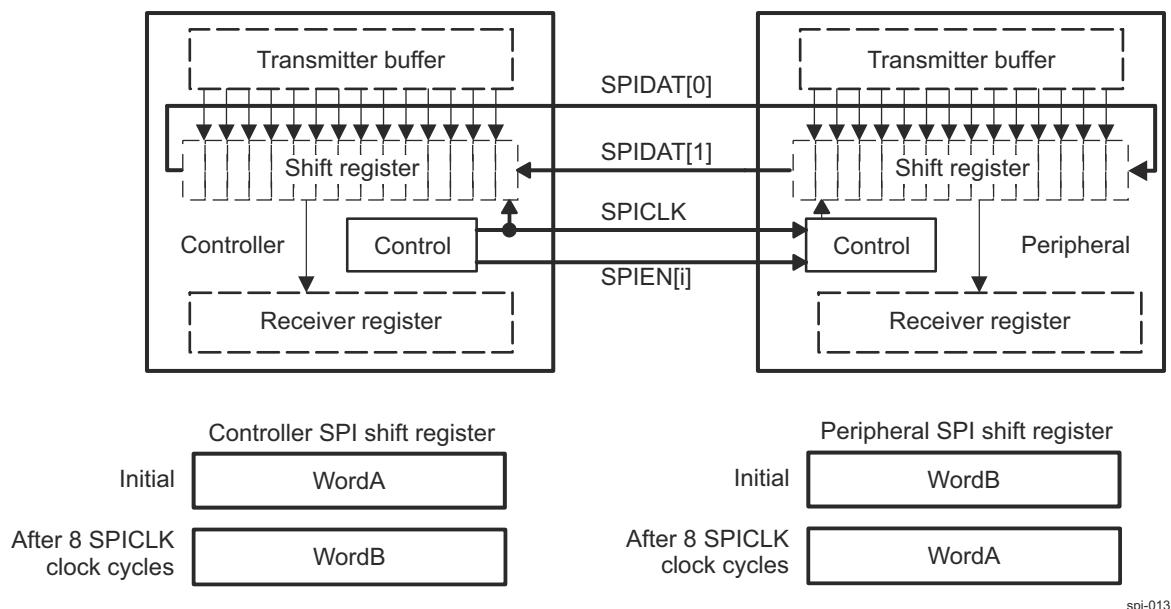

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

- Rule 1: Only enabled channels (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI\_TX\_0/1/2/3 transmitter register is not empty (the MCSPI\_CHSTAT\_0/1/2/3[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI\_TX\_0/1/2/3 register is empty when the shift register is assigned, the TXx\_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the MCSPI\_CHSTAT\_0/1/2/3[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI\_RX\_0/1/2/3 register cannot be overwritten. The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set to this mode.

When MCSPI word transfer completes (the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit is set), the updated MCSPI\_TX\_0/1/2/3 register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT[0] and SPIDAT[1]). Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral.

[Figure 12-70](#) shows an example of a full-duplex system with a controller device on the left and a peripheral device on the right. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral. At the same time, WordB transfers from the peripheral to the controller.

**Figure 12-70. MCSPI Full-Duplex Transmission (Example)**

#### 12.1.5.4.3.3 Controller Transmit-Only Mode (Half Duplex)

The controller transmit-only mode prevents the processor from reading the MCSPI\_RX\_0/1/2/3 register (minimizing data movement) when only transmission is meaningful.

The controller transmit-only mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field). Transmission starts only after data is loaded into the MCSPI\_TX\_0/1/2/3 register.

Rule 1 and Rule 2, defined in [Section 12.1.5.4.3.2](#), apply in this mode.

Rule 3, defined in [Section 12.1.5.4.3.2](#), does not apply.

In controller transmit-only mode, the MCSPI\_RX\_0/1/2/3 register state FULL does not prevent transmission and the MCSPI\_RX\_0/1/2/3 register is always overwritten with the new MCSPI word. This event is not significant when only transmission is meaningful. Thus, the RX0\_OVERFLOW bit in the MCSPI\_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX\_FULL interrupt and the DMA read requests.

The transfer status is given by the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit.

#### 12.1.5.4.3.4 Controller Receive-Only Mode (Half Duplex)

The controller receive mode prevents the processor from refilling the MCSPI\_TX\_0/1/2/3 register (minimizing data movement) when only reception is meaningful.

The controller receive mode is programmable per channel (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field).

The controller receive-only mode enables channel scheduling only on the empty state of the MCSPI\_RX\_0/1/2/3 register.

Rule 1 and Rule 3, defined in [Section 12.1.5.4.3.2](#), apply in this mode.

Rule 2, defined in [Section 12.1.5.4.3.2](#), does not apply.

In the controller receive-only mode, software must write dummy data to the MCSPI\_TX\_0/1/2/3 register. Only one dummy write is enough to receive any number of words from the peripheral. Software must ensure that the MCSPI\_TX\_0/1/2/3 register is always full (the TXx\_EMPTY bits of MCSPI\_IRQSTATUS) when receiving. The content of the MCSPI\_TX\_0/1/2/3 register is always loaded into the shift register when the shift

register is assigned. After writing the dummy data to the MCSPI\_TX\_0/1/2/3 register, the TXx\_EMPTY and TXx\_UNDERFLOW bits in the MCSPI\_IRQSTATUS register are never set in receive-only mode.

The MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit gives the status of serialization. The RXx\_FULL bits of the MCSPI\_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI\_RX\_0/1/2/3 register. The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.5.4.3.5 Single-Channel Controller Mode

When the MCSPI is configured as a controller device with a single enabled channel (MCSPI\_MODULCTRL[2] MS = 0 and MCSPI\_MODULCTRL[0] SINGLE = 1), the assertion of the SPIEN[i] signal is optional depending on device connected to the controller. In 3-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 1) the controller starts transmitting data when a write to the MCSPI\_TX\_0/1/2/3 register or the FIFO is performed. In 4-pin mode (MCSPI\_MODULCTRL[1] PIN34 = 0) the assertion and de-assertion of SPIEN[i] is controlled by software using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit.

##### 12.1.5.4.3.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the MCSPI word transfer to complete (wait until the MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

##### 12.1.5.4.3.5.2 Force SPIEN[i] Mode

Continuous transfers are allowed manually by keeping the SPIEN[i] signal active for successive MCSPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN[i] line. This mode is supported by all channels and any controller sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN[i] active mode is supported when:

- A single channel is used (with the MCSPI\_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (MCSPI\_CHCONF\_0/1/2/3).

The state of the SPIEN[i] signal is programmable:

- Writing 1 to the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit drives the SPIEN[i] line high when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven low when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 1.
- Writing 0 to the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit drives the SPIEN[i] line low when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 0. SPIEN[i] is driven high when the MCSPI\_CHCONF\_0/1/2/3[6] EPOL bit is set to 1.
- A single channel is enabled (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit is set to 1). The first enabled channel activates the SPIEN[i] line.

When the channel is enabled, the SPIEN[i] signal activates with the programmed polarity. As in the multichannel controller mode, the transfer start depends on the status of the MCSPI\_TX\_0/1/2/3 register (the MCSPI\_CHSTAT\_0/1/2/3[1] TXS bit), the status of the MCSPI\_RX\_0/1/2/3 register (the MCSPI\_CHSTAT\_0/1/2/3[1] RXS bit), and the defined mode (the MCSPI\_CHCONF\_0/1/2/3[13-12] TRM bit field) of the channel enabled.

The MCSPI\_CHSTAT\_0/1/2/3[2] EOT bit gives the transfer status of each MCSPI word. The RXx\_FULL bit in the MCSPI\_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI\_RX\_0/1/2/3 register.

A change in the configuration parameters is propagated directly on the MCSPI interface. If the SPIEN[i] signal is activated, ensure that the configuration is changed only between MCSPI words to avoid corrupting the current transfer.

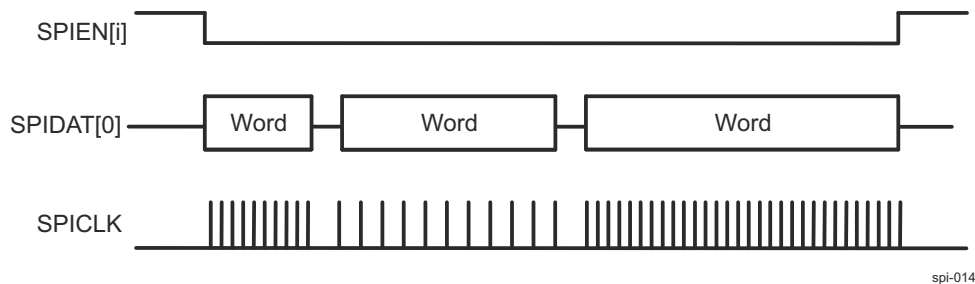

### Note

To avoid data corruption, SPIEN[i] polarity and SPICLK phase and SPICLK polarity must not be modified when the SPIEN[i] signal is activated.

A delay between MCSPI words that requires the connected MCSPI peripheral device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last MCSPI word, the channel must be deactivated (the MCSPI\_CHCTRL\_0/1/2/3[0] EN bit set to 0) and SPIEN[i] can be forced to its INACTIVE state using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit.

Figure 12-71 and Figure 12-72 show successive transfers with SPIEN[i] maintained active low with a different configuration for each MCSPI word in single-data-pin and dual-data-pin interface modes, respectively.

**Figure 12-71. Continuous Transfers With SPIEN[i] Maintained Active (Single-Data-Pin Interface Mode)**

**Figure 12-72. Continuous Transfers With SPIEN[i] Maintained Active (Dual-Data-Pin Interface Mode)**

### Note

The SPIEN[i] signal can be maintained active via software using the MCSPI\_CHCONF\_0/1/2/3[20] FORCE bit only when the MCSPI\_MODULCTRL[0] SINGLE bit is set to 0x1.

#### 12.1.5.4.3.5.3 Turbo Mode

Turbo mode improves the throughput of the MCSPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI\_RX\_0/1/2/3 register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the MCSPI\_CHCONF\_0/1/2/3[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see [Section 12.1.5.4.3.2, Controller Transmit-and-Receive Mode \(Full Duplex\)](#)). An enabled channel can be scheduled if its receive register is full (the MCSPI\_CHSTAT\_0/1/2/3[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI\_RX\_0/1/2/3 register cannot be overwritten in turbo mode. Consequently, the MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW bit is never set in this mode.

#### 12.1.5.4.3.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the MCSPI word to indicate whether the next MCSPI word must be handled as a command or as data. This feature is available only in controller mode. Start-bit mode cannot be used at the same time as turbo mode and/or force SPIEN[i] mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the MCSPI\_CHCONF\_0/1/2/3[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit is set to 0, the MCSPI word must be handled as a command. When the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit is set to 1, the MCSPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the MCSPI\_CHCONF\_0/1/2/3[24] SBPOL bit before writing the MCSPI word to be transmitted to the TX register.

#### 12.1.5.4.3.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in controller mode with automatic CS generation (the MCSPI\_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge. This option is available only in 4-pin mode when MCSPI\_MODULCTRL[1] PIN34 set to 0.

This mode is programmable per channel through the MCSPI\_CHCONF\_0/1/2/3[26-25] TCS0 bit field.

Figure 12-73 shows the CS SPIEN timing controls.

**Figure 12-73. CS SPIEN Timing Controls**

#### Note

Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

#### 12.1.5.4.3.8 Programmable MCSPI Clock (SPICLK)

In controller mode, the baud rate of the MCSPI serial clock is programmable.

An internal reference clock, SPICLKREF, is used as input of a programmable divider (the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field) to generate the bit rate of the serial output clock SPICLK. [Table 12-68](#) summarizes the supported divisor values.

**Table 12-68. MCSPI Controller Clock Rates**

Divider	Clock Rate
1	50 MHz <sup>(1)</sup>
2	25 MHz <sup>(1)</sup>
4	12.5 MHz
8	6.25 MHz
16	3.125 MHz
32	1.5625 MHz
64	781.25 kHz
128	390 kHz <sup>(2)</sup>
256	195 kHz <sup>(2)</sup>
512	97.7 kHz <sup>(2)</sup>
1024	48.8 kHz <sup>(2)</sup>
2048	24.4 kHz <sup>(2)</sup>
4096	12.2 kHz <sup>(2)</sup>
8192 and higher: Division not supported	—

- (1) These frequencies are not necessarily supported by all MCSPI modules. For more information, see the *Timing Requirements and Switching Characteristics* chapter in the device-specific Data sheet.
- (2) Approximate Frequency

#### 12.1.5.4.3.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the MCSPI\_CHCONF\_0/1/2/3[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the MCSPI\_CHCTRL\_0/1/2/3[15-8] EXTCLK bit field is concatenated with the MCSPI\_CHCONF\_0/1/2/3[5-2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the MCSPI\_CHCONF\_0/1/2/3[1] POL and MCSPI\_CHCONF\_0/1/2/3[0] PHA bits (see [Table 12-69](#)).

**Table 12-69. CLKSPPIO High/Low Time Computation**

Clock Ratio $F_{RATIO}$	CLKSPPIO High Time	CLKSPPIO Low Time
1	$T_{HIGH\_REF}$	$T_{LOW\_REF}$
Even $\geq 2$	$T_{ref} * (F_{RATIO}/2)$	$T_{ref} * (F_{RATIO}/2)$
Odd $\geq (POL = PHA)$	$T_{ref} * (F_{RATIO} - 1)/2$	$T_{ref} * (F_{RATIO} + 1)/2$
Odd $\geq (POL \neq PHA)$	$T_{ref} * (F_{RATIO} + 1)/2$	$T_{ref} * (F_{RATIO} - 1)/2$

#### Note

$F_{RATIO}$  = SPICLK frequency ( $F_{OUT}$ ) division ratio  
 $T_{HIGH}$  = SPICLK high time period  
 $T_{LOW}$  = SPICLK low time period  
 $T_{ref}$  = MCSPI\_FCLK period  
 $T_{HIGH\_REF}$  = MCSPI\_FCLK high time period  
 $T_{LOW\_REF}$  = MCSPI\_FCLK low time period

If the CLKG bit is set to 1;  $F_{RATIO}$  = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

$$\text{Duty\_cycle} = (1 - 1/F_{\text{RATIO}})/2$$

Table 12-70 shows examples of clock granularity with a clock source frequency of 50 MHz.

**Table 12-70. Clock Granularity Examples**

EXTCLK	CLKD	CLKG	F <sub>RATIO</sub>	PHA	POL	T <sub>HIGH</sub> (ns)	T <sub>LOW</sub> (ns)	T <sub>PERIOD</sub> (ns)	Duty Cycle	F <sub>OUT</sub> (MHz)
X	0	0	1	X	X	10.0	10.0	20.0	50–50	50
X	1	0	2	X	X	20.0	20.0	40.0	50–50	25
X	2	0	4	X	X	40.0	40.0	80.0	50–50	12.5
X	3	0	8	X	X	80.0	80.0	160.0	50–50	6.2
0	0	1	1	X	X	10.0	10.0	20.0	50–50	50
0	1	1	2	X	X	20.0	20.0	40.0	50–50	25
0	2	1	3	1	0	40.0	20.0	60.0	66–33	16.6
0	2	1	3	1	1	20.0	40.0	60.0	33–66	16.6
0	3	1	4	X	X	40.0	40.0	80.0	50–50	12.5
5	0	1	81	1	0	820.0	800.0	1620.0	50.6–49.4	0.617
5	7	1	88	X	X	880.0	880.0	1760.0	50–50	0.568

#### 12.1.5.4.4 MCSPI Peripheral Mode

To select the MCSPI peripheral mode, set the MCSPI\_MODULCTRL[2] MS bit.

A MCSPI peripheral device can be connected to up to four external MCSPI controller devices but handles transactions with one MCSPI controller device at a time.

In peripheral mode, the MCSPI initiates data transfer on the data lines (SPIDAT[0] and SPIDAT[1]) when it is selected by an active control signal (SPIEN[i]) and receives an MCSPI clock (SPICLK) from the external MCSPI controller device. Only channel 0 can be configured as a peripheral but through the MCSPI\_CHCONF\_0[22-21] SPIENSLV bit field any of the SPIEN[i] signals can be used to select the MCSPI module. In peripheral mode and when the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0 (default behaviour), the MCSPI uses the edge of SPIEN[i] to detect word length. For this reason, SPIEN[i] must become inactive between each word.

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x0, the MCSPI does not support SPIEN[i] active between MCSPI words. In this case, the MCSPI uses the edge to detect word length.

When the MCSPI\_MODULCTRL[1] PIN34 is set to 0x1, a multiword transfer can be performed without needing the external MCSPI controller to deactivate SPIEN[i] between each word as in this case the MCSPI module works in 3-pin peripheral mode and SPIEN[i] is not needed.

##### 12.1.5.4.4.1 Dedicated Resources

Only channel 0 can be enabled in peripheral mode.

Figure 12-74 shows an example of four peripherals wired on a single controller device.

spi-017

- A. Direction depends on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-74. Example of MCSPI Peripheral With One Controller and Multiple Peripheral Devices on Channel 0**

Channel 0 in peripheral mode has the following resources:

- Its own channel enable, programmable with the MCSPI\_CHCTRL\_0[0] EN bit. This channel must be enabled before transmission and reception.
- For this mode, the peripheral-select signal can be detected on any of the SPIEN[i] ports. This is programmable with the MCSPI\_CHCONF\_0[22-21] SPIENSLV bit field.
- Its own transmitter register, MCSPI\_TX\_0, on top of the common transmit shift register. If the MCSPI\_TX\_0 register is empty, the MCSPI\_CHSTAT\_0[1] TXS bit is set. If MCSPI is selected by an external controller (the active signal on the SPIEN[i] port assigned to channel 0), the MCSPI\_TX\_0 register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI\_TX\_0 register must be loaded before MCSPI is selected by a controller.
- Its own receiver register, MCSPI\_RX\_0, on top of the common receive shift register. If the MCSPI\_RX\_0 register is full, the MCSPI\_CHSTAT\_0[0] RXS bit is set.

### Note

The MCSPI\_TX\_1/2/3 and MCSPI\_RX\_1/2/3 registers are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the MCSPI\_CHCONF\_0:
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The MCSPI modules are in peripheral mode after reset and must be properly configured for the modules to act in controller mode.)
  - MCSPI word length, programmable with the WL bit
  - SPIEN[i] polarity, programmable with the EPOL bit
  - SPICLK polarity, programmable with the POL bit
  - SPICLK phase, programmable with the PHA bit

The SPICLK frequency of a transfer is controlled by the external MCSPI controller connected to the MCSPI peripheral device. The MCSPI\_CHCONF\_0[5-2] CLKD bit field is not used in peripheral mode.

### Note

The configuration of the channel can be loaded in the MCSPI\_CHCONF\_0 only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the MCSPI\_CHCONF\_0[15] DMAR bit for reading and the MCSPI\_CHCONF\_0[14] DMAW bit for writing.
- Four interrupt events (see [Section 12.1.5.4.7.2, Interrupt Events in Peripheral Mode](#)).

#### 12.1.5.4.4.2 Peripheral Transmit-and-Receive Mode

The peripheral receive mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x0).

In peripheral transmit-and-receive mode, the MCSPI\_TX\_0 register must be loaded before MCSPI is selected by an external MCSPI controller device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI\_TX\_0 register content is always loaded in the shift register whether it is updated or not. The event TX0\_UNDERFLOW is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI\_CHSTAT\_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX\_0 register (see [Section 12.1.5.4.7.2, Interrupt Events in Peripheral Mode](#)).

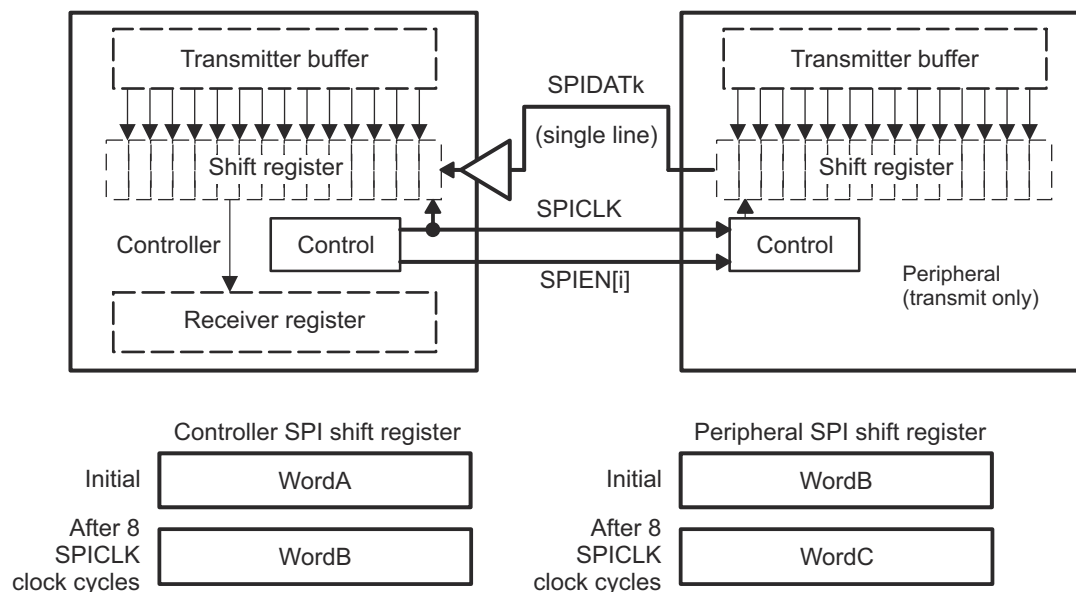

#### 12.1.5.4.4.3 Peripheral Transmit-Only Mode

The peripheral transmit-only mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x2) and avoids the requirement for the processor to read the MCSPI\_RX\_0 register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a peripheral transmit-only device, the RX0\_FULL and RX0\_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI\_RX\_0 register.

When the MCSPI word transfer completes, the MCSPI\_CHSTAT\_0[2] EOT bit is set.

[Figure 12-75](#) shows a half-duplex system with a controller device on the left and a transmit-only peripheral device on the right. Each time a bit transfers out from the peripheral, 1 bit transfers in the controller. After eight cycles of the serial clock SPICLK, WordB transfers from the peripheral to the controller.

spi-018

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-75. MCSPI Half-Duplex Transmission (Transmit-Only peripheral)**

#### 12.1.5.4.4.4 Peripheral Receive-Only Mode

The peripheral receive mode is programmable (set the MCSPI\_CHCONF\_0[13-12] TRM bit field to 0x1).

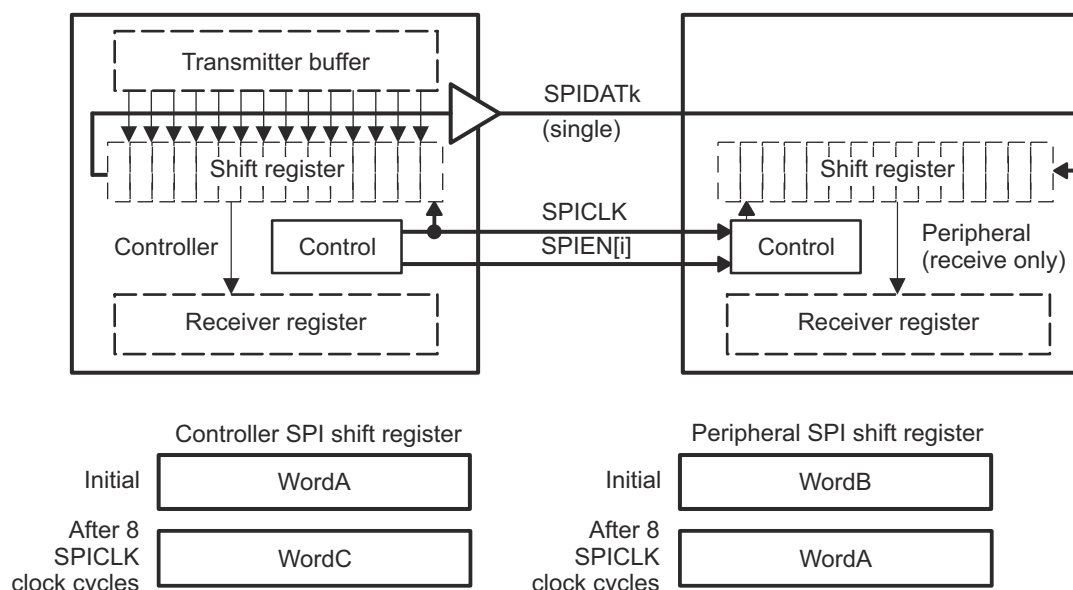

In receive-only mode, the MCSPI\_TX\_0 register must be loaded before the MCSPI is selected by an external MCSPI controller device. The MCSPI\_TX\_0 register content is always loaded into the shift register whether it is updated or not. The TX0\_UNDERFLOW event is activated accordingly and does not prevent transmission.

When the MCSPI word transfer completes (the MCSPI\_CHSTAT\_0[2] EOT bit is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a peripheral receive-only device, the TX0\_EMPTY and TX0\_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI\_TX\_0 register.

For a full-duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines. If SPICLK synchronizes on a single serial data line, the data line should be half-duplex.

Figure 12-76 shows a half-duplex system with a controller device on the left and a receive-only peripheral device on the right. Each time a bit transfers out from the controller, 1 bit transfers in from the peripheral. After eight cycles of the serial clock SPICLK, WordA transfers from the controller to the peripheral.

spi-019

k = 0 or 1 depending on MCSPI\_CHCONF\_0/1/2/3[16] DPE0, MCSPI\_CHCONF\_0/1/2/3[17] DPE1 and MCSPI\_CHCONF\_0/1/2/3[18] IS bits

**Figure 12-76. MCSPI Half-Duplex Transmission (Receive-Only Peripheral)**

#### 12.1.5.4.5 MCSPI 3-Pin or 4-Pin Mode

Depending on targeted application the MCSPI interface can be configured to use 3 or 4 pins through the MCSPI\_MODULCTRL[1] PIN34 bit. If this bit is set to 0, MCSPI is in 4-pin mode using the SPICLK, SPIDAT[0], SPIDAT[1] and SPIEN[i] signals. If PIN34 is set to 1 the controller is in 3-pin mode and SPIEN[i] is not used. In this mode all options related to chip select management are useless (EPOL, FORCE and TCS0 bits of MCSPI\_CHCONF\_0/1/2/3). 3-pin and 4-pin operation applies to both controller and peripheral modes.

#### 12.1.5.4.6 MCSPI FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the MCSPI\_CHCONF\_0/1/2/3[28] FFER or MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Controller or peripheral mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (MCSPI\_CHCONF\_0/1/2/3[11-7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see [Figure 12-77](#)) or receive (see [Figure 12-78](#)) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two halves, one for each direction (see [Figure 12-79](#)).

spi-020

**Figure 12-77. Buffer Used in Transmit Direction Only**

spi-021

**Figure 12-78. Buffer Used in Receive Direction Only**

spi-022

**Figure 12-79. Buffer Used for Transmit and Receive Directions**

Two levels (MCSPi\_XFERLEVEL[5-0] AEL and MCSPi\_XFERLEVEL[13-8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the MCSPi word length. The driver must set these values as a multiple of the MCSPi word length defined in WL. [Table 12-71](#) lists the number of bytes written in the FIFO, depending on the word length.

**Table 12-71. FIFO Writes, Word Length Relationship**

	MCSPi Word Length (WL)		
	$3 \leq WL \leq 7$	$8 \leq WL \leq 15$	$16 \leq WL \leq 31$
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

#### 12.1.5.4.6.1 Buffer Almost Full

The MCSPI\_XFERLEVEL[15-8] AFL bit field is needed when the buffer is used to receive an MCSPI word from a peripheral (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit must be set to 1). It defines the almost-full buffer status. See [Figure 12-80](#).

When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the processor to enable the system to read AFL + 1 bytes from the receive register.

#### Note

AFL + 1 must correspond to a multiple value of the MCSPI\_CHCONF\_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

**Figure 12-80. Buffer Almost Full Level (AFL)**

#### Note

The MCSPI\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the MCSPI\_DMA\_READ\_EVENTi request is asserted on the same conditions as the MCSPI\_IRQSTATUS RXx\_FULL flag.

#### 12.1.5.4.6.2 Buffer Almost Empty

The MCSPI\_XFERLEVEL[7-0] AEL bit field is needed when the buffer is used to transmit an MCSPI word to a peripheral (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See [Figure 12-81](#).

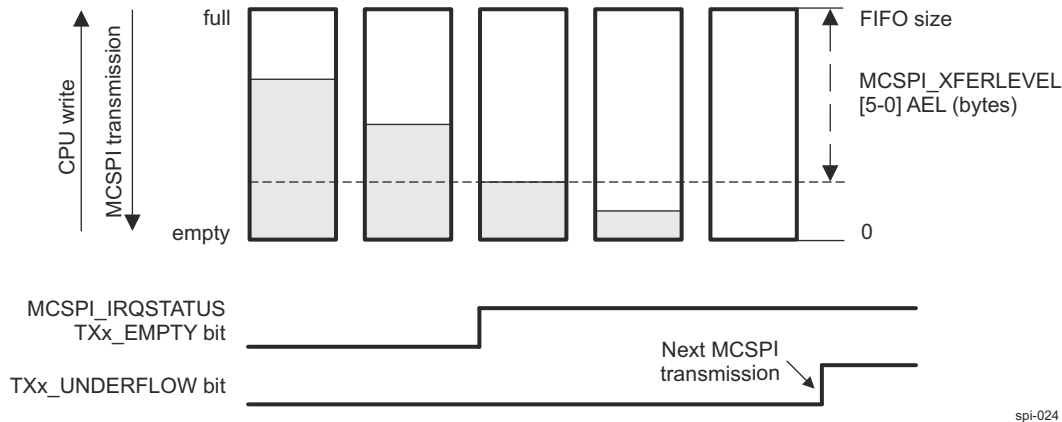

When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the processor to enable the system to write AEL + 1 bytes to the transmit register.

#### Note

AEL + 1 must correspond to a multiple value of the MCSPI\_CHCONF\_0/1/2/3[11-7] WL bit field.

When DMA is used, the request is de-asserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

**Figure 12-81. Buffer Almost Empty Level (AEL)**

#### Note

The MCSPI\_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the MCSPI\_DMA\_WRITE\_EVENTi request is asserted on the same conditions as the MCSPI\_IRQSTATUS TXx\_EMPTY flag.

#### 12.1.5.4.6.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI\_XFERLEVEL register the AEL and AFL levels and especially the MCSPI\_XFERLEVEL[31-16] WCNT bit field to define the number of MCSPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of MCSPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many MCSPI transfers have been done. For received words, software must poll the MCSPI\_CHSTAT\_i[5] RXFFE bit and read the MCSPI\_RX\_0/1/2/3 receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI\_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI\_CHSTAT\_0/1/2/3[5] RXFFE bit to know the last MCSPI words in the FIFO buffer and read them.

#### 12.1.5.4.6.4 Multiple MCSPI Word Access

The processor has the ability to perform multiple MCSPI word access to the receive or transmit registers within a single 32-bit interface access by setting the MCSPI\_MODULCTRL[7] MOA to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- MCSPI\_MODULCTRL[7] MOA is set to 1.
- Only 32-bit interface access and data width can be performed to receive or transmit registers, for other kind of access the processor must de-assert MCSPI\_MODULCTRL[7] MOA bit.
- The level MCSPI\_XFERLEVEL[7-0] AEL and MCSPI\_XFERLEVEL[15-8] AFL must be 32-bit aligned, it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI\_XFERLEVEL[31-16] WCNT is used it must be configured according to MCSPI word length.
- The word length of MCSPI words allows to perform multiple MCSPI access, that means that MCSPI\_CHCONF\_0/1/2/3[11-7] WL is <16.

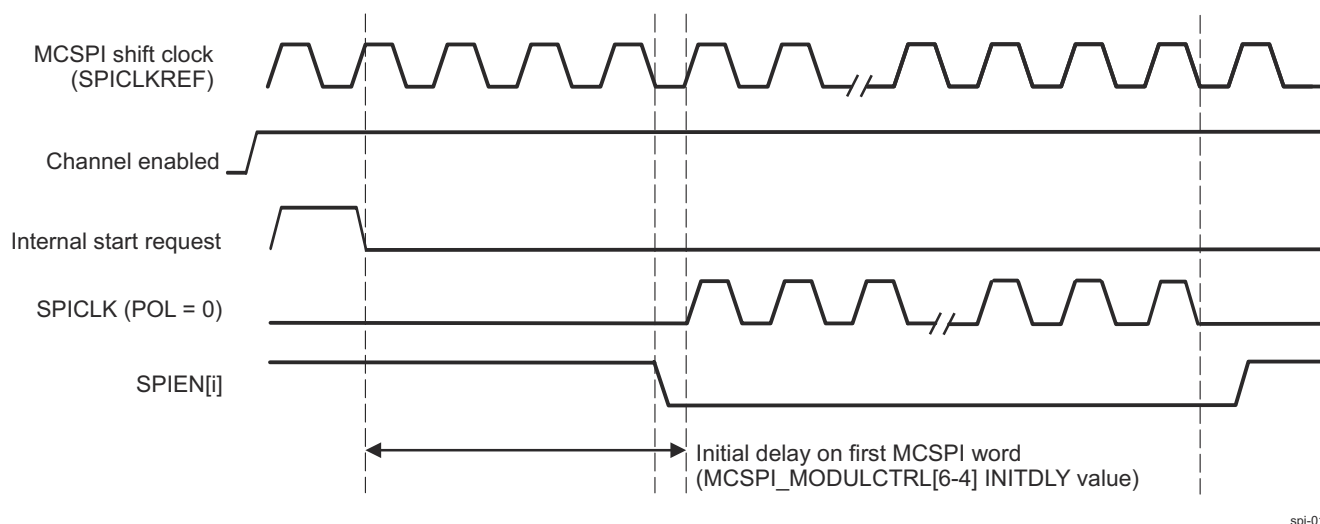

The number of MCSPI word access depends on MCSPI word length:

- $3 \leq WL \leq 7$ , MCSPI word length smaller or equal to byte length, 4 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = WCNT[1] = 0.
- $8 \leq WL \leq 15$ , MCSPI word length greater than byte or equal to 16-bit length, 2 MCSPI words accessed per 32-bit interface read/write. If word count is used (MCSPI\_XFERLEVEL[31-16] WCNT), set the bit field to WCNT[0] = 0.
- $16 \leq WL$  Multiple MCSPI word access is not applicable.

#### 12.1.5.4.6.5 First MCSPI Word Delay

Figure 12-82 shows the MCSPI controller ability to delay the first MCSPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first MCSPI word after MCSPI channel enabled and first write in transmit register. It is based on output clock frequency.

This option is meaningful in controller mode and single channel mode asserted through MCSPI\_MODULCTRL[0] SINGLE.

**Figure 12-82. Controller Single Channel Initial Delay**

Few delay values are available: No delay, 4/8/16/32 MCSPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

#### 12.1.5.4.7 MCSPI Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the MCSPI\_IRQSTATUS register (RXx\_FULL, TXx\_UNDERFLOW, TXx\_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the MCSPI\_IRQENABLE register (RXx\_FULL\_ENABLE, TXx\_UNDERFLOW\_ENABLE, TXx\_EMPTY\_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

##### 12.1.5.4.7.1 Interrupt Events in Controller Mode

In controller mode, the interrupt events related to the state of the MCSPI\_TX\_0/1/2/3 register are TXx\_EMPTY and TXx\_UNDERFLOW. The interrupt event related to the state of the MCSPI\_RX\_0/1/2/3 register is RXx\_FULL.

#### 12.1.5.4.7.1.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TX\_0/1/2/3 register is empty (transient event). Enabling a channel automatically triggers this event, except in controller receive-only mode (see [Section 12.1.5.4.3.4, Controller Receive-Only Mode](#)). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit is set to 1), the MCSPI\_IRQSTATUS TXx\_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TX\_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TX\_0/1/2/3 register defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### 12.1.5.4.7.1.2 TXx\_UNDERFLOW

The event TXx\_UNDERFLOW is activated when the channel is enabled and if the MCSPI\_TX\_0/1/2/3 register or the FIFO is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

The TXx\_UNDERFLOW is a harmless warning in controller mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TX\_0/1/2/3 register, because the channel is enabled. To avoid having a TXx\_UNDERFLOW event, the MCSPI\_TX\_0/1/2/3 register must seldom be loaded.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.4.7.1.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI\_XFERLEVEL[13-8] AFL threshold.

The MCSPI\_RX\_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RX\_0/1/2/3. The processor must perform the correct number of reads.

#### 12.1.5.4.7.1.4 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI\_XFERLEVEL[31-16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.4.7.2 Interrupt Events in Peripheral Mode

In peripheral mode, the interrupt events related to the state of the MCSPI\_TX\_0/1/2/3 register are TX0\_EMPTY and TX0\_UNDERFLOW. The interrupt events related to the state of the MCSPI\_RX\_0/1/2/3 are RX0\_FULL

and RX0\_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI\_IRQSTATUS register.

#### 12.1.5.4.7.2.1 TXx\_EMPTY

The TXx\_EMPTY event is activated when a channel is enabled and its MCSPI\_TX\_0/1/2/3 register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[27] FFEW bit is set to 1), the TXx\_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI\_XFERLEVEL[5-0] AEL bit field.

The MCSPI\_TX\_0/1/2/3 register must be loaded with data to remove the source of the interrupt; the MCSPI\_IRQSTATUS TXx\_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx\_EMPTY event is asserted as long as the processor has not performed the number of writes into the MCSPI\_TX\_0/1/2/3 register defined by MCSPI\_XFERLEVEL[5-0] AEL bit field. The processor must perform the correct number of writes.

#### 12.1.5.4.7.2.2 TXx\_UNDERFLOW

The TXx\_UNDERFLOW event is activated when a channel is enabled and if the MCSPI\_TX\_0/1/2/3 register is empty (not updated with new data) when an external controller device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the old data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx\_UNDERFLOW indicates an error (data loss) in peripheral mode.

To avoid having a TXx\_UNDERFLOW event at the beginning of a transmission, the TXx\_UNDERFLOW event is not activated when no data has been loaded into the MCSPI\_TX\_0/1/2/3 register because the channel is enabled.

The MCSPI\_IRQSTATUS TXx\_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.4.7.2.3 RXx\_FULL

The RXx\_FULL event is activated when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI\_CHCONF\_0/1/2/3[28] FFER bit is set to 1), RXx\_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI\_XFERLEVEL[13-8] AFL bit field.

The MCSPI\_RX\_0/1/2/3 register must be read to remove the source of the interrupt; the MCSPI\_IRQSTATUS RXx\_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx\_FULL event is asserted as long as the processor has not performed AFL + 1 reads into MCSPI\_RX\_0/1/2/3. The processor must perform the correct number of reads.

#### 12.1.5.4.7.2.4 RX0\_OVERFLOW

The RX0\_OVERFLOW event is activated in peripheral mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI\_RX\_0/1/2/3 register or FIFO is full when a new MCSPI word is received. The MCSPI\_RX\_0/1/2/3 register is always overwritten with the new MCSPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0\_OVERFLOW event should not appear in peripheral mode using the FIFO.

The RX0\_OVERFLOW event indicates an error (data loss) in peripheral mode.

The MCSPI\_IRQSTATUS[3] RX0\_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.4.7.2.5 End Of Word Count

The MCSPI\_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI\_XFERLEVEL[31-16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the MCSPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI\_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

#### 12.1.5.4.7.3 Interrupt-Driven Operation

An interrupt enable bit in the MCSPI\_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the processor must:

1. Read the MCSPI\_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI\_RX\_0/1/2/3 register that corresponds to the event to remove the source of an RXx\_FULL event or write into the MCSPI\_TX\_0/1/2/3 register that corresponds to the event to remove the source of a TXx\_EMPTY event. No action is required to remove the source of the TXx\_UNDERFLOW and RX0\_OVERFLOW events.
3. Set the corresponding bit of the MCSPI\_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

#### 12.1.5.4.7.4 Polling

When the interrupt capability of an event is disabled in the MCSPI\_IRQENABLE register, the interrupt line is not asserted, but the status bits in the MCSPI\_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx\_FULL: To remove the source of the event, the processor must read the corresponding MCSPI\_RX\_0/1/2/3 register.
- TXx\_EMPTY: To remove the source of the event, the processor must write into the corresponding MCSPI\_TX\_0/1/2/3 register.
- TXx\_UNDERFLOW and RX0\_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the MCSPI\_IRQSTATUS register to 1. This does not affect the interrupt line state.

#### 12.1.5.4.8 MCSPI DMA Requests

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the MCSPI\_CHCONF\_0/1/2/3[15] DMAR bit. The DMA read request line is de-asserted when reading of the MCSPI\_RX\_0/1/2/3 register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI\_TX\_0/1/2/3 register of the MCSPI channel is empty. A DMA write request can be individually masked with the MCSPI\_CHCONF\_0/1/2/3[14] DMAW bit. The DMA write request line is de-asserted when loading of the MCSPI\_TX\_0/1/2/3 register of the channel completes.

#### 12.1.5.4.9 MCSPI Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity.

##### 12.1.5.4.9.1 Normal Mode

In normal mode, internal MCSPI module clocks are automatically switched off (autogated) when there is no activity in peripheral or controller mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The MCSPI\_SYSCONFIG[0] AUTOIDLE bit is set.
- In controller mode, there is no data to transmit or receive in all channels.
- In peripheral mode, the MCSPI is not selected by the external controller and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In controller mode, an internal access occurs.
- In peripheral mode, an internal access occurs or the MCSPI is selected by the external controller.

##### 12.1.5.4.9.2 Idle Mode

#### Note

Some of the MCSPI features described in this section may not be supported on this family of devices. For more information, see *MCSPI Not Supported Features*.

At the power management level, when all conditions to shut off the MCSPI\_FCLK or MCSPI\_ICLK clocks are met, the corresponding LPSC asserts a clock stop request to the MCSPI. Although this procedure is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the clock stop request can be configured through the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgement modes are:

- Force-idle mode (the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the clock stop request, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges the clock stop request and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow shut off of MCSPI\_FCLK and MCSPI\_ICLK.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the clock stop request, depending on its internal activity. MCSPI acknowledges the shut off of MCSPI\_FCLK and MCSPI\_ICLK only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional feature to control gating of MCSPI\_FCLK or MCSPI\_ICLK. The MCSPI\_SYSCONFIG[9-8] CLOCKACTIVITY bit field determines which clock shuts down (MCSPI\_FCLK, MCSPI\_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the clock stop request are tested. For example, if MCSPI\_FCLK is not shut off on clock stop request, the MCSPI considers only MCSPI\_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with MCSPI\_ICLK and others with MCSPI\_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if MCSPI acknowledges the clock stop request.

##### 12.1.5.4.9.2.1 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the MCSPI\_SYSCONFIG[4-3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the clock stop request by de-asserting unconditionally the interrupt and DMA request lines, if asserted.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI\_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely de-asserted. The interface clock and MCSPI clock provided to the MCSPI can be switched off.
  - A clock stop request during an MCSPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.

### 12.1.5.5 MCSPI Programming Guide

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

#### 12.1.5.5.1 MCSPI Global Initialization

##### 12.1.5.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MCSPI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MCSPI. For further information, see *MCSPI Integration* and *MCSPI Environment*.

[Table 12-72](#) lists the information on the global initialization of the surrounding modules.

**Table 12-72. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
R5FSS0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0 and R5FSS1 interrupts, see <i>Interrupts</i> .
R5FSS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_INTRTR0 and R5FSS1_INTRTR0 interrupts, see <i>Interrupts</i> .
MCU_R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_R5FSS0_CORE0 and MCU_R5FSS0_CORE1 interrupts, see <i>Interrupts</i> .
C66SS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling C66SS0_INTRTR0 and C66SS1_INTRTR0 interrupts, see <i>Interrupts</i> .
PRU-ICSSG0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling PRU-ICSSG0 and PRU-ICSSG1 interrupts, see <i>Interrupts</i> .
MAIN2MCU_LVL_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MAIN2MCU_LVL_INTRTR0 interrupts, see <i>Interrupts</i> .
MCU_PDMA_MISC0 and MCU_PDMA_MISC1; PDMA1_MISC0, PDMA1_MISC1, PDMA1_MISC2, and PDMA1_MISC3	Device INTCs must be configured to enable the interrupt request generation.
WKUP_PLLCTRL0 and MCU_PLL2; PLLCTRL0 and MAIN_PLL0_HSDIV5	PLL controller's configuration must be done to enable the module clocks. For more information, see <i>Clocking</i> .

#### 12.1.5.5.1.2 MCSPI Global Initialization

##### 12.1.5.5.1.2.1 Main Sequence – MCSPI Global Initialization

The procedure in [Table 12-73](#) can be used to initialize MCSPI when performing software reset.

**Table 12-73. MCSPI Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	MCSPI_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	MCSPI_SYSSTATUS[0] RESETDONE	=1
Configure static settings (such as SPI controller or peripheral) as required.	MCSPI_MODULCTRL[8-0]	0x-
Write MCSPI_SYSCONFIG	MCSPI_SYSCONFIG	0x-

#### 12.1.5.5.2 MCSPI Operational Mode Configuration

##### 12.1.5.5.2.1 MCSPI Operational Modes

The selection of the working mode is done with the MCSPI\_CHCONF\_0/1/2/3 register.

**Table 12-74. MCSPI Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set receive mode for the channel.	MCSPI_CHCONF_0/1/2/3[13-12] TRM	0x1

**Table 12-74. MCSPI Receive Mode Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

**Table 12-75. MCSPI Transmit Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit mode for the channel.	MCSPi_CHCONF_0/1/2/3[13-12] TRM	0x2
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

**Table 12-76. MCSPI Transmit-and-Receive Mode Initialization**

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode for the channel.	MCSPi_CHCONF_0/1/2/3[13-12] TRM	0x0
Configure SPI clock polarity/phase, clock divider, word length, and others for the channel.	MCSPi_CHCONF_0/1/2/3	0x-
Reset the status bits.	MCSPi_IRQSTATUS	0x0

#### 12.1.5.5.2.1.1 Common Transfer Sequence

MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT-RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN[i] lines assertion/deassertion: automatic, manual

For all these sequences, the host process contains the main process and the interrupt routines.

The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

[Table 12-77](#) represents the main sequence which is common to all transfers.

In multi-channel controller mode, the sequences of different channels can be run simultaneously.

**Table 12-77. Common Transfer Sequence (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	0x-
Write MCSPi_CHCONF_0/1/2/3 to configure the channel	MCSPi_CHCONF_0/1/2/3	0x-
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait for the first write request (TX empty or DMA write)		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.5.2.1.2 End of Transfer Sequences

The end of transfer depends on the transfer mode. [Table 12-78](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-78. End of Transfer Sequences**

		TRANSMIT-AND-RECEIVE		TRANSMIT-ONLY		RECEIVE-ONLY	
		INTERRUPT	DMA	INTERRUPT	DMA	INTERRUPT	DMA
<b>CONTROL LER Normal</b>	End of transfer sequence	See <a href="#">Section 12.1.5.5.2.1.3</a>		See <a href="#">Section 12.1.5.5.2.1.4.1</a>	See <a href="#">Section 12.1.5.5.2.1.4.2</a>	See <a href="#">Section 12.1.5.5.2.1.5.1</a>	See <a href="#">Section 12.1.5.5.2.1.5.2</a>
	Minimum number of word	1	1	1	1	1	2
	DMA transfer size		N		N		N-1
<b>CONTROL LER Turbo</b>	End of transfer sequence	See <a href="#">Section 12.1.5.5.2.1.3</a>		See <a href="#">Section 12.1.5.5.2.1.4.1</a>	See <a href="#">Section 12.1.5.5.2.1.4.2</a>	See <a href="#">Section 12.1.5.5.2.1.6.1</a>	See <a href="#">Section 12.1.5.5.2.1.6.2</a>
	Minimum number of word	1	1	1	1	2	3
	DMA transfer size		N		N		N-2
<b>PERIPHER AL</b>	End of transfer sequence	See <a href="#">Section 12.1.5.5.2.1.3</a>		See <a href="#">Section 12.1.5.5.2.1.4.1</a>	See <a href="#">Section 12.1.5.5.2.1.4.2</a>	See <a href="#">Section 12.1.5.5.2.1.7</a>	
	Minimum number of word	1	1	1	1	1	1
	DMA transfer size		N		N	N	N

The transfer to execute has a size of N words.

The different sequences can be merged in one process to manage transfers of several types. The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = 0
- read\_count = 0
- channel\_enable = FALSE
- last\_transfer = FALSE
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.5.5.2.1.3 Transmit-and-Receive (Controller and Peripheral)

If the requests are configured in DMA, write\_count and read\_count are assigned with 'N' when the DMA handlers have completed their 'N' CBASS0 accesses.

**Table 12-79. Transmit-and-Receive (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait for write_count = N <b>AND</b> read_count = N		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-80. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY</b>		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
<b>IF: RXx_FULL</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	

**Table 12-80. Transmit-and-Receive (Controller and Peripheral) (Interrupt Routine) (continued)**

Step	Register/Bit Field/Programming Model	Value
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.5.5.2.1.4 Transmit-Only (Controller and Peripheral)

##### 12.1.5.5.2.1.4.1 Based on Interrupt Requests

**Table 12-81. Transmit-Only With Interrupts (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-82. Transmit-Only With Interrupts (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY AND write_count &lt; N</b>		
Write the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
Increment write_count +1		
<b>ELSEIF: write_count ≥ N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

##### 12.1.5.5.2.1.4.2 Based on DMA Write Requests

When the DMA handler has completed its 'N' CBASS0 accesses, write\_count is assigned with 'N'.

**Table 12-83. Transmit-Only With DMA (Controller and Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until write_count = N		
Disable DMA write request	MCSPi_CHCONF_0/1/2/3[14] DMAW	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-84. Transmit-Only With DMA (Controller and Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: TXx_EMPTY AND write_count = N</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

### 12.1.5.5.2.1.5 Controller Normal Receive-Only

#### 12.1.5.5.2.1.5.1 Based on Interrupt Requests

**Table 12-85. Receive-Only With Interrupt (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until last_request = TRUE		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		

**Table 12-86. Receive-Only With Interrupt (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL AND read_count = N - 1</b>		
last_request = TRUE		
<b>ELSEIF: read_count ≠ N - 1</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
<b>ENDIF</b>		

#### 12.1.5.5.2.1.5.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-1' CBASS0 accesses, read\_count is assigned with 'N-1'.

**Table 12-87. Receive-Only With DMA (Controller Normal) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until read_count = N - 1		
Disable DMA read request	MCSPi_CHCONF_0/1/2/3[15] DMAR	0
Wait until last_transfer = TRUE		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		

**Table 12-88. Receive-Only With DMA (Controller Normal) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL AND read_count = N-1</b>		
last_transfer = TRUE		
<b>ENDIF</b>		

### 12.1.5.5.2.1.6 Controller Turbo Receive-Only

#### 12.1.5.5.2.1.6.1 Based on Interrupt Requests

**Table 12-89. Receive-Only With Interrupt (Controller Turbo) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until channel_enable = TRUE		

**Table 12-89. Receive-Only With Interrupt (Controller Turbo) (Main Process) (continued)**

Step	Register/Bit Field/Programming Model	Value
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Wait until channel_enable = FALSE		

**Table 12-90. Receive-Only With Interrupt (Controller Turbo) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL</b>		
<b>IF: read_count = N - 2</b>		
last_transfer = TRUE		
channel_enable = FALSE		
<b>ENDIF</b>		
<b>IF: read_count &lt; N</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
<b>ENDIF</b>		
<b>ENDIF</b>		

#### 12.1.5.5.2.1.6.2 Based on DMA Read Requests

When the DMA handler has completed its 'N-2' CBASS0 accesses read\_count is assigned with 'N-2'.

**Table 12-91. Receive-Only With DMA (Controller Turbo) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until channel_enable = TRUE		
Wait until read_count = N-2		
Disable DMA read request	MCSPi_CHCONF_0/1/2/3[15] DMAR	0
Wait until last_transfer = TRUE		
Wait for end of transfer	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Wait until channel_enable = FALSE		

**Table 12-92. Receive-Only With DMA (Controller Turbo) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL</b>		
<b>IF: read_count = N - 2</b>		
last_transfer = TRUE		
channel_enable = FALSE		
<b>ENDIF</b>		
<b>IF: read_count &lt; N</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count +1		
<b>ENDIF</b>		

**Table 12-92. Receive-Only With DMA (Controller Turbo) (Interrupt Routine) (continued)**

Step	Register/Bit Field/Programming Model	Value
<b>ENDIF</b>		

**12.1.5.5.2.1.7 Peripheral Receive-Only**

If the requests are configured in DMA, read\_count is assigned with 'N' when the DMA handler has completed its 'N' CBASS0 accesses.

**Table 12-93. Receive-Only (Peripheral) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Wait until read_count = N		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

**Table 12-94. Receive-Only (Peripheral) (Interrupt Routine)**

Step	Register/Bit Field/Programming Model	Value
Read MCSPi_IRQSTATUS	MCSPi_IRQSTATUS	0x-
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS[channel i bits]	0b1111
<b>IF: RXx_FULL</b>		
Read the receiver register	MCSPi_RX_0/1/2/3	0x-
Increment read_count + 1		
<b>ENDIF</b>		

**12.1.5.5.2.1.8 Transfer Procedures With FIFO**

These flows describe the transfer with FIFO.

The MCSPi module allows the transfer of one or several words, according to different modes:

- CONTROLLER Normal, CONTROLLER Turbo, PERIPHERAL
- TRANSMIT–RECEIVE, TRANSMIT-ONLY, RECEIVE-ONLY
- Write and Read requests: IRQ, DMA

For all these flows, the host process contains the main process and the interrupt routine. This routine is called on the IRQ signals or by an internal call if the module is used in polling mode.

For more information, see [Section 12.1.5.4.6, MCSPi FIFO Buffer Management](#).

**Table 12-95. FIFO Mode Common Sequence (Controller) (Main Process)**

Step	Register/Bit Field/Programming Model	Value
Write MCSPi_IRQSTATUS to reset channel status bits	MCSPi_IRQSTATUS	1
Write MCSPi_IRQENABLE to enable interrupts	MCSPi_IRQENABLE	1
Write MCSPi_CHCONF_0/1/2/3 to configure the channel	MCSPi_CHCONF_0/1/2/3	0x-
Write MCSPi_XFERLEVEL	MCSPi_XFERLEVEL	0x-
Start the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	1
<b>IF: Receive only</b>		
Wait for the write request (TX empty or DMA write)		
Write for the transmitter register with data	MCSPi_TX_0/1/2/3	0x-
<b>ENDIF</b>		
Wait for the host event for end of transfer		
Stop the channel	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.5.2.1.8.1 Common Transfer Sequence in FIFO Mode

This flow describes the host sequence for a transfer of any type defined in [Section 12.1.5.5.2.1.8, Transfer Procedures With FIFO](#).

In multi-channel, only one channel can use the FIFO.

Before enabling the FIFO for a channel (MCSPI\_CHCONF\_0/1/2/3[28] FFER and MCSPI\_CHCONF\_0/1/2/3[27] FFEW bits), the host must check that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit-and-receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In Peripheral mode, the channel 0 only can be activated. The correct SPIEN line is chosen in MCSPI\_CHCONF\_0[22-21] SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request has been released by writing the MCSPI\_TX\_0/1/2/3 register, even in receive-only mode (only one write request occurs in this case).

#### 12.1.5.5.2.1.8.2 End of Transfer Sequences in FIFO Mode

[Table 12-96](#) summarizes the type of end of transfer per transfer mode and gives a reference to the appropriate section for details.

**Table 12-96. End of Transfer Sequences in FIFO Mode**

Word count	TRANSMIT AND RECEIVE	TRANSMIT-ONLY	RECEIVE-ONLY
Yes	See <a href="#">Figure 12-83</a>	See <a href="#">Figure 12-85</a>	See <a href="#">Figure 12-86</a>
No	See <a href="#">Figure 12-84</a>	See <a href="#">Figure 12-85</a>	See <a href="#">Figure 12-87</a>

The end of transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

- write\_count = N
- read\_count = N
- last\_request = FALSE

They are initialized before starting the channel.

#### 12.1.5.5.2.1.8.3 Transmit-and-Receive With Word Count

[Figure 12-83](#) shows the flow of a transfer in transmit-and-receive mode, with word count.

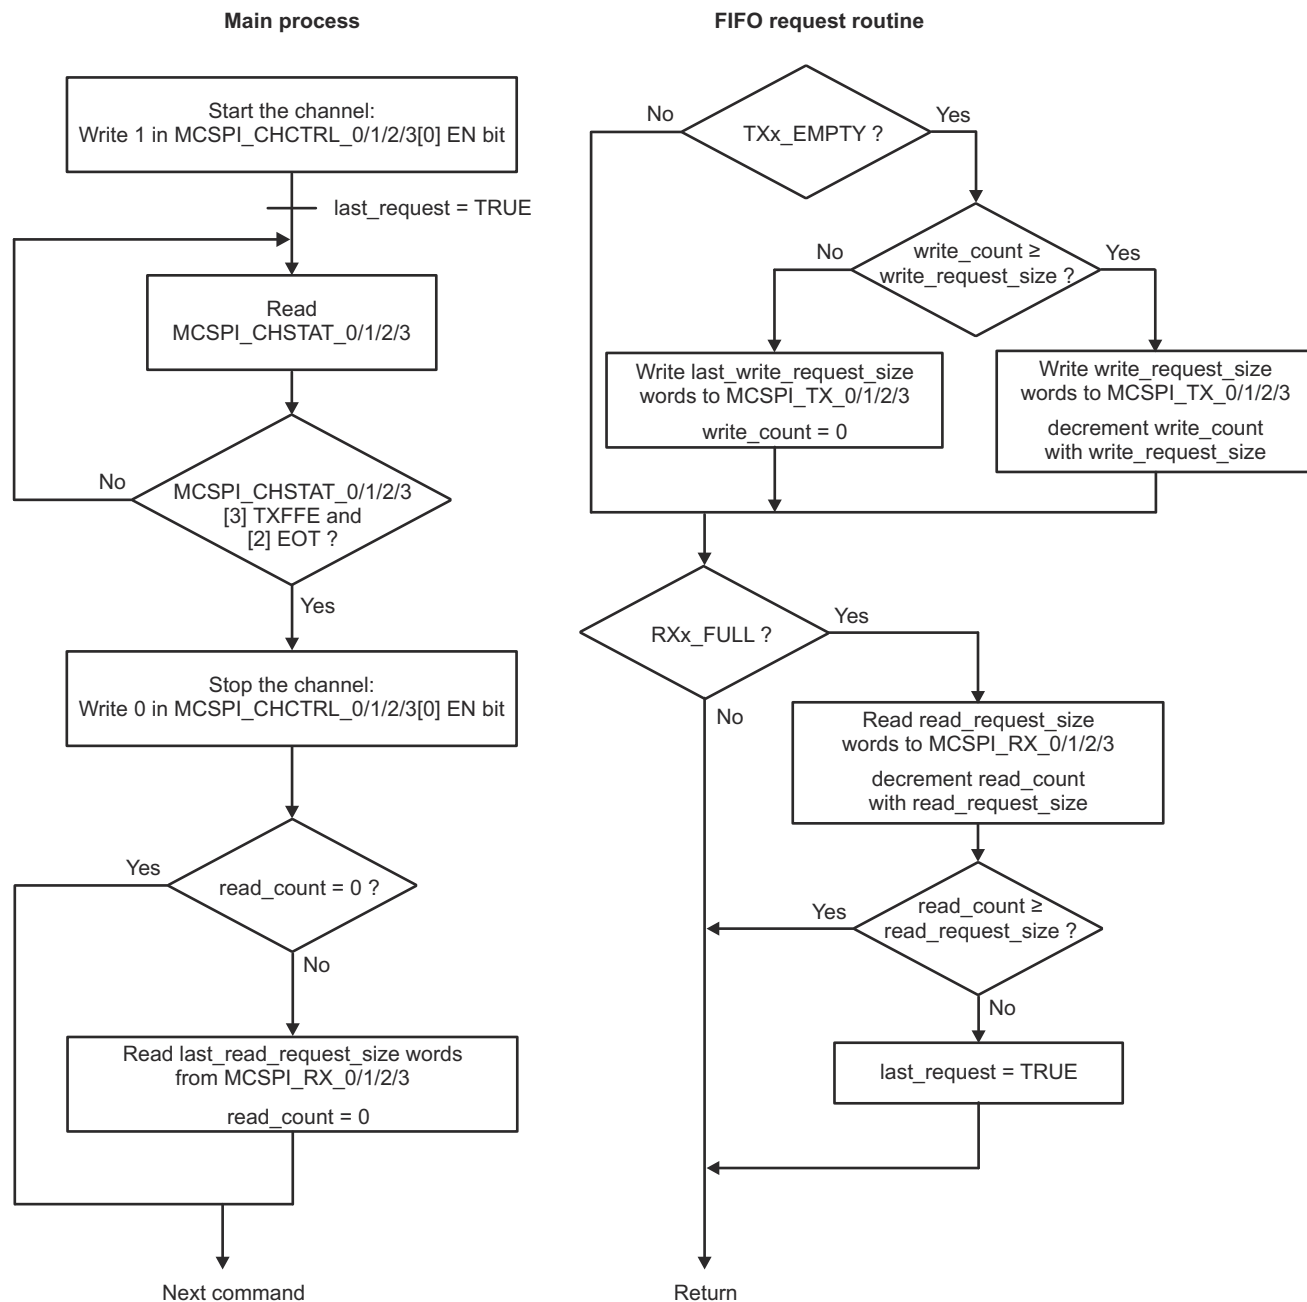

mcspi\_025

**Figure 12-83. FIFO Mode Transmit-and-Receive With Word Count (Controller)**

#### 12.1.5.5.2.1.8.4 Transmit-and-Receive Without Word Count

Figure 12-84 shows the flow of a transfer in transmit-and-receive mode, without word count.

mcspi\_026

**Figure 12-84. FIFO Mode Transmit-and-Receive Without Word Count (Controller)**

#### 12.1.5.5.2.1.8.5 Transmit-Only

Figure 12-85 shows the flow of a transfer in transmit-only mode, with or without word count. The difference between word count enabled or not is just on the condition after starting the channel:

- word count enable: wait for EOW interrupt
- word count disable: wait for write\_count = 0

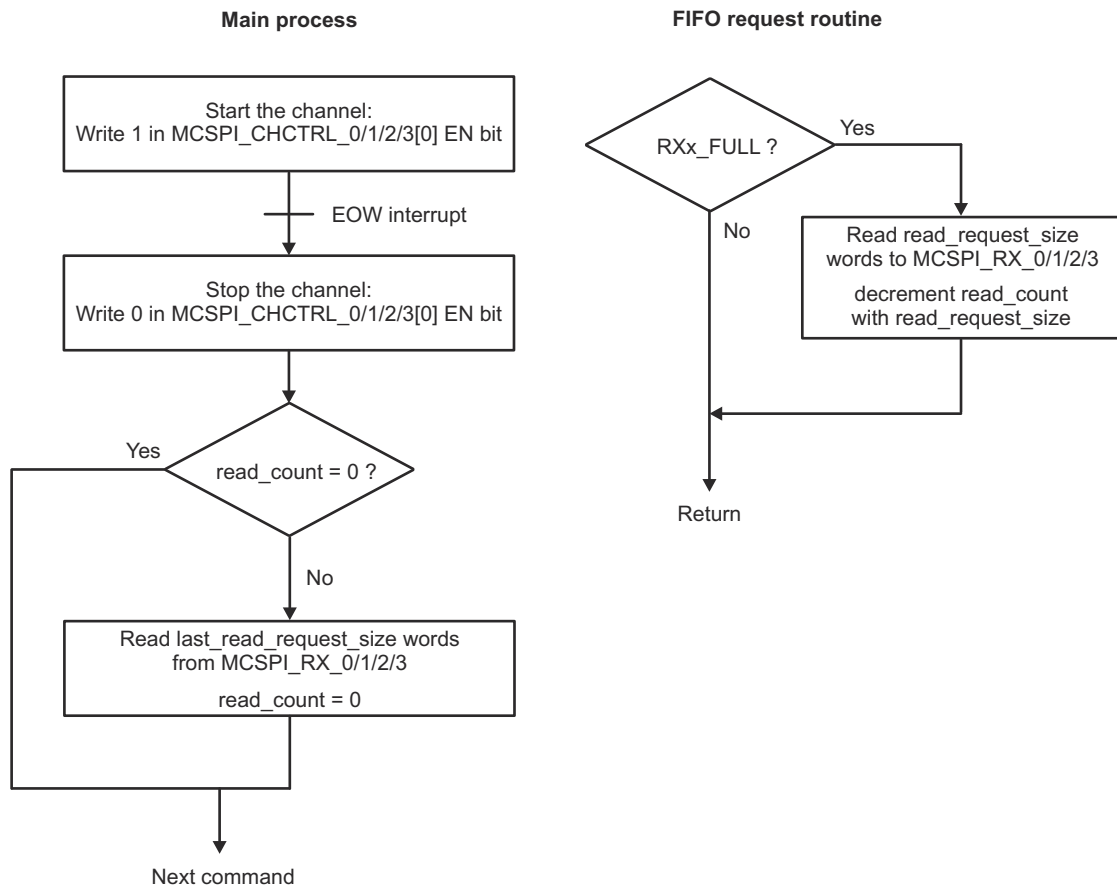

mcspi\_027

**Figure 12-85. FIFO Mode Transmit-Only (Controller)**

#### 12.1.5.5.2.1.8.6 Receive-Only With Word Count

Figure 12-86 shows the flow of a transfer in receive-only mode, with word count.

Table 12-98 lists the receive-only procedure using the interrupt method.

**Table 12-98. Receive-Only Procedure – Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-74.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Enable the interrupt for the receiver register.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	1
Wait for interrupt.		
Read the status register.	MCSPi_IRQSTATUS[2] RX_FULL	1
Disable the interrupt if no more data is expected.	MCSPi_IRQENABLE[2] RX_FULL_ENABLE	0
Stop the channel if no more data is expected.	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register.	MCSPi_RX_0/1/2/3	0x-

#### 12.1.5.5.2.1.9.3 Transmit-Only Procedure – Polling Method

Table 12-99 lists the transmit-only procedure using the polling method.

**Table 12-99. Transmit-Only Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-75.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Write the transmitter register with data.	MCSPi_TX_0/1/2/3	0x-
Wait until end of transfer?	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	0

#### 12.1.5.5.2.1.9.4 Transmit-and-Receive Procedure – Polling Method

Table 12-100 lists the transmit-and-receive procedure using the polling method.

**Table 12-100. Transmit-and-Receive Procedure – Polling Method**

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 12-76.	
Start the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	1
Write the transmitter register with data.	MCSPi_TX_0/1/2/3	0x-
Wait until transmit/receive word?	MCSPi_CHSTAT_0/1/2/3[2] EOT	=1
Stop the channel.	MCSPi_CHCTRL_0/1/2/3[0] EN	0
Read the receiver register.	MCSPi_RX_0/1/2/3	0x-

## 12.1.6 Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the function, operation, and configuration of the Universal Asynchronous Receiver/Transmitter (UART)/RS-485/Infrared Data Association (IrDA)/Consumer Infrared (CIR)/ISO 7816 module in the device.

### Note

UART and USART acronyms are used interchangeably in this section.

### 12.1.6.1 UART Overview

The UART is a peripheral that utilizes the DMA for data transfer or interrupt polling via host CPU. There are twelve UART modules in the device. All UART modules support IrDA and CIR modes when 48 MHz function clock is used. Each UART can be used for configuration and data exchange with a number of external peripheral devices or interprocessor communication between devices.

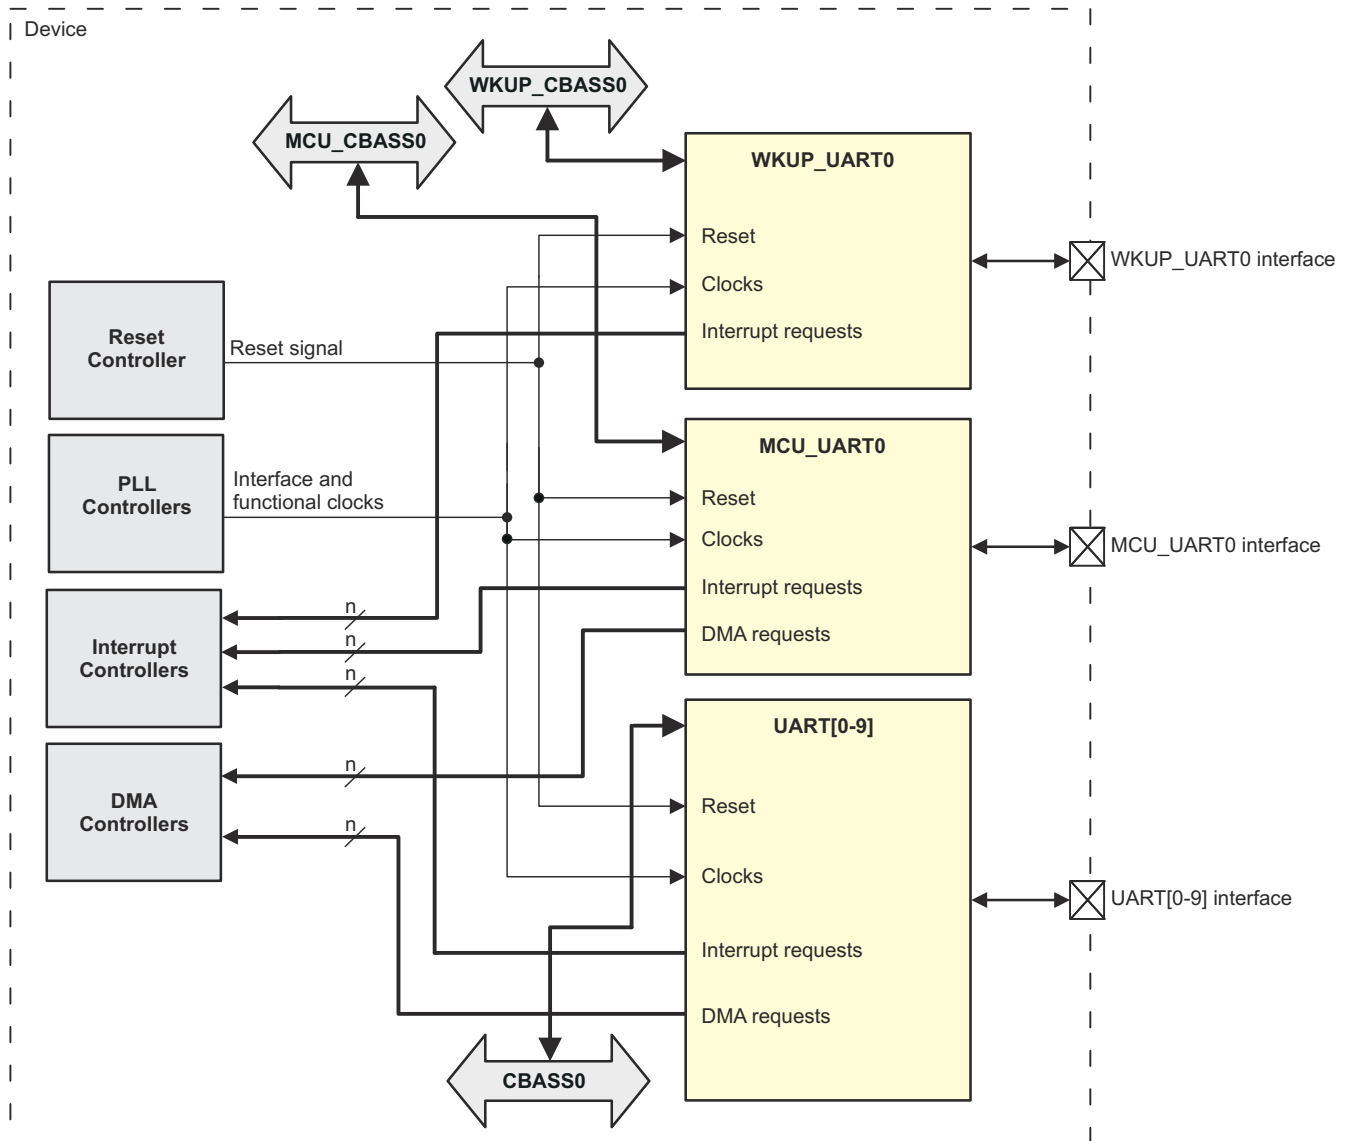

[Table 12-101](#) shows UART modules allocation across device domains.

**Table 12-101. UART Allocation Across Device Domains**

Instance	Domain		
	WKUP	MCU	MAIN
WKUP_UART0	✓	-	-
MCU_UART0	-	✓	-
UART0	-	-	✓
UART1	-	-	✓
UART2	-	-	✓
UART3	-	-	✓
UART4	-	-	✓
UART5	-	-	✓
UART6	-	-	✓
UART7	-	-	✓
UART8	-	-	✓
UART9	-	-	✓

[Figure 12-88](#) shows the UART modules overview.

uart\_001

**Figure 12-88. UART Modules Overview**

#### 12.1.6.1.1 UART Features

The UART includes the following features:

- 16C750-compatible
- RS-485 external transceiver auto flow control support
- 64-byte FIFO buffer for receiver and 64-byte FIFO buffer for transmitter
- Programmable interrupt trigger levels for FIFOs
- Programmable sleep mode
- The 48 MHz functional clock is default option and allows baud rates up to 3.6 Mbps
- Auto-baud between 1200 bits/s and 115.2 Kbits/s (only when 48 MHz function clock is used)
- Optional multi-drop transmission
- Configurable time-guard feature
- Configurable data format:
  - Data bit: 5, 6, 7, 8, or 9 bit
  - Parity bit: Even, Odd, None

- Stop-bit: 1, 1.5, 2 bit
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions (CTS, RTS)
- Only module instance in MAIN domain has extended modem control signals (DCD, RI, DTR, DSR)

#### **12.1.6.1.2 IrDA Features**

The IrDA includes the following features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
  - Frame formatting: addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - 
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection
- IrDA mode when 48 MHz function clock is used

#### **12.1.6.1.3 CIR Features**

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following features to provide CIR support for remote-control applications:

- Transmit and receive mode
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle
- CIR mode when 48 MHz function clock is used

#### **12.1.6.1.4 UART Not Supported Features**

- Synchronous mode
- ISO7816 mode
- DMA mode 2
- Full modem handshaking is not available on all instances - see device datasheet for details
- Multi-drop transmission
- 9-bit mode
- 12 Mbps operation

### 12.1.6.2 UART Environment

The WKUP\_UART0, MCU\_UART0, UART[0-9] modules are hereinafter referred to as UART module.

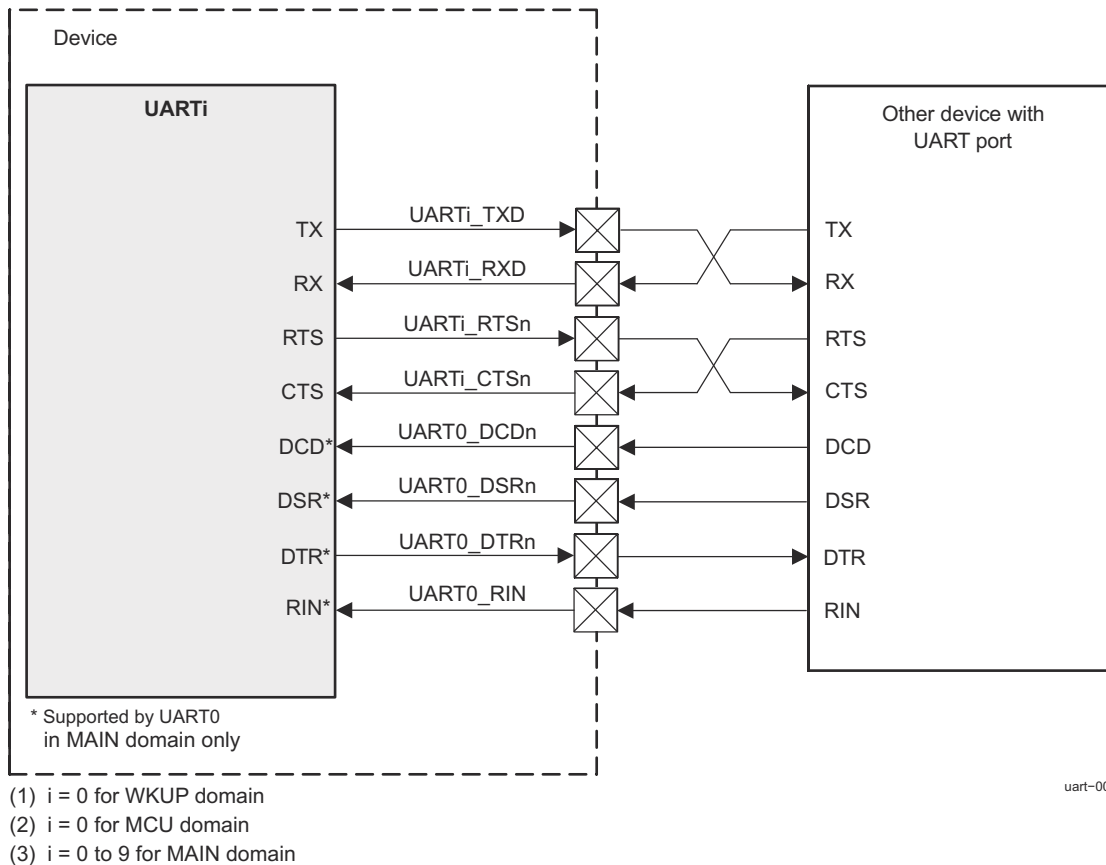

This section describes the UART/RS-485/IrDA/CIR external connections (environment).

- The UART interface is described in [Section 12.1.6.2.1, UART Functional Interfaces](#).
- The RS-485 interface is described in [Section 12.1.6.2.2, RS-485 Functional Interfaces](#).
- The IrDA interface is described in [Section 12.1.6.2.3, IrDA Functional Interfaces](#).
- The CIR interface is described in [Section 12.1.6.2.4, CIR Functional Interfaces](#).

#### 12.1.6.2.1 UART Functional Interfaces

##### 12.1.6.2.1.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see [Figure 12-89](#) ).

**Figure 12-89. UART Mode Interface Signals**

### 12.1.6.2.1.2 UART Interface Description

Table 12-102 lists the UART interface input/output (I/O) signals.

**Table 12-102. UART I/O Signals**

Module Pin Name	Device Level Signal Name	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UART0</b>				
RX	WKUP_UART0_RXD	I	Serial data input	HiZ
TX	WKUP_UART0_TXD	O	Serial data output <sup>(3)</sup>	1
CTS	WKUP_UART0_CTS	I	Clear to send <sup>(4)</sup>	HiZ
RTS	WKUP_UART0_RTS	O	Request to send <sup>(5)</sup>	1
<b>UART[0-9]</b>				
RX	UART[0-9]_RXD	I	Serial data input	HiZ
TX	UART[0-9]_TXD	O	Serial data output <sup>(3)</sup>	1
CTS	UART[0-9]_CTS <sub>n</sub>	I	Clear to send <sup>(4)</sup>	HiZ
RTS	UART[0-9]_RTS <sub>n</sub>	O	Request to send <sup>(5)</sup>	1
DCD		I	Data Carrier Detect <sup>(6)</sup>	HiZ
DSR		I	Data Set Ready <sup>(7)</sup>	HiZ
DTR		O	Data Terminal Ready <sup>(8)</sup>	1
RIN		I	Ring Indicator <sup>(9)</sup>	HiZ

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UART\_MDR1[2-0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UART\_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).

(4) Active-low modem status signal. Reading the UART\_MSR[4] NCTS\_STS bit checks the condition of CTS. Reading the UART\_MSR[0] CTS\_STS bit checks a change of state of CTS since the last read of the modem status register. The auto-CTS mode uses CTS to control the transmitter.

(5) When active (low), the module is ready to receive data. Setting the UART\_MCR[1] RTS bit activates RTS signal, which becomes inactive as the result of a module reset, loopback mode, or clearing the UART\_MCR[1] RTS bit. In auto-RTS mode, RTS signal becomes inactive as a result of the receiver threshold logic.

(6) Active-low modem status signal. The condition of DCD can be checked by reading the UART\_MSR[7] NCD\_STS bit. Any change in its state can be detected by reading the UART\_MSR[3] DCD\_STS bit.

(7) Active-low modem status signal. Reading the UART\_MSR[5] NDSR\_STS bit checks the condition of DSR. Reading the UART\_MSR[1] DSR\_STS bit checks a change of state of DSR since the last read of the UART\_MSR register.

(8) When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting the UART\_MCR[0] DTR bit.

(9) Active-low modem status signal. The condition of RIN can be checked by reading the UART\_MSR[6] NRI\_STS bit. Any change in its state can be detected by reading the UART\_MSR[2] RI\_STS bit.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.6.2.1.3 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16× (<= 230.4 kbps)
- UART 16× with autobauding (>= 1200 bps and <= 115.2 kbps)
- UART 13× (>= 460.8 kbps)

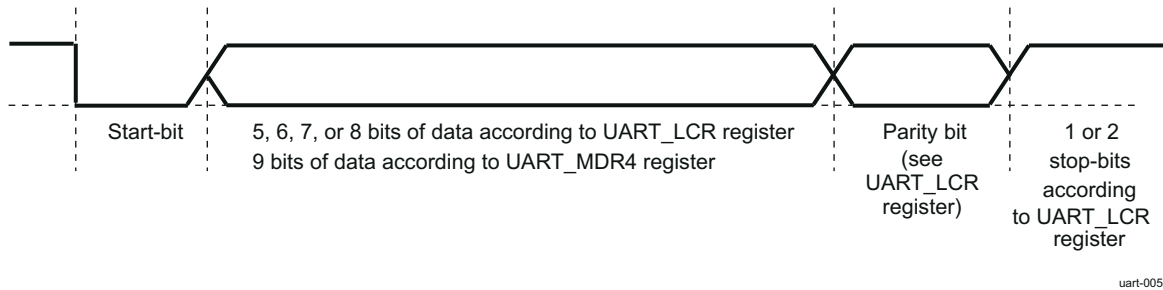

### CAUTION

To be used as a UART, the operating mode must be programmed appropriately in the UART\_MDR1[2-0] MODE\_SELECT bit field to select UART, IrDA, or CIR mode, and the UART\_MDR3[4] DIR\_EN bit field to select RS-485 mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 12-90 shows the UART frame data format.

**Figure 12-90. UART Frame Data Format**

### Note

Not all operating modes are described in the diagram. The UART module is capable of supporting a 9-bit mode that is not shown in the diagram.

#### 12.1.6.2.1.4 UART 9-bit Mode Data Format

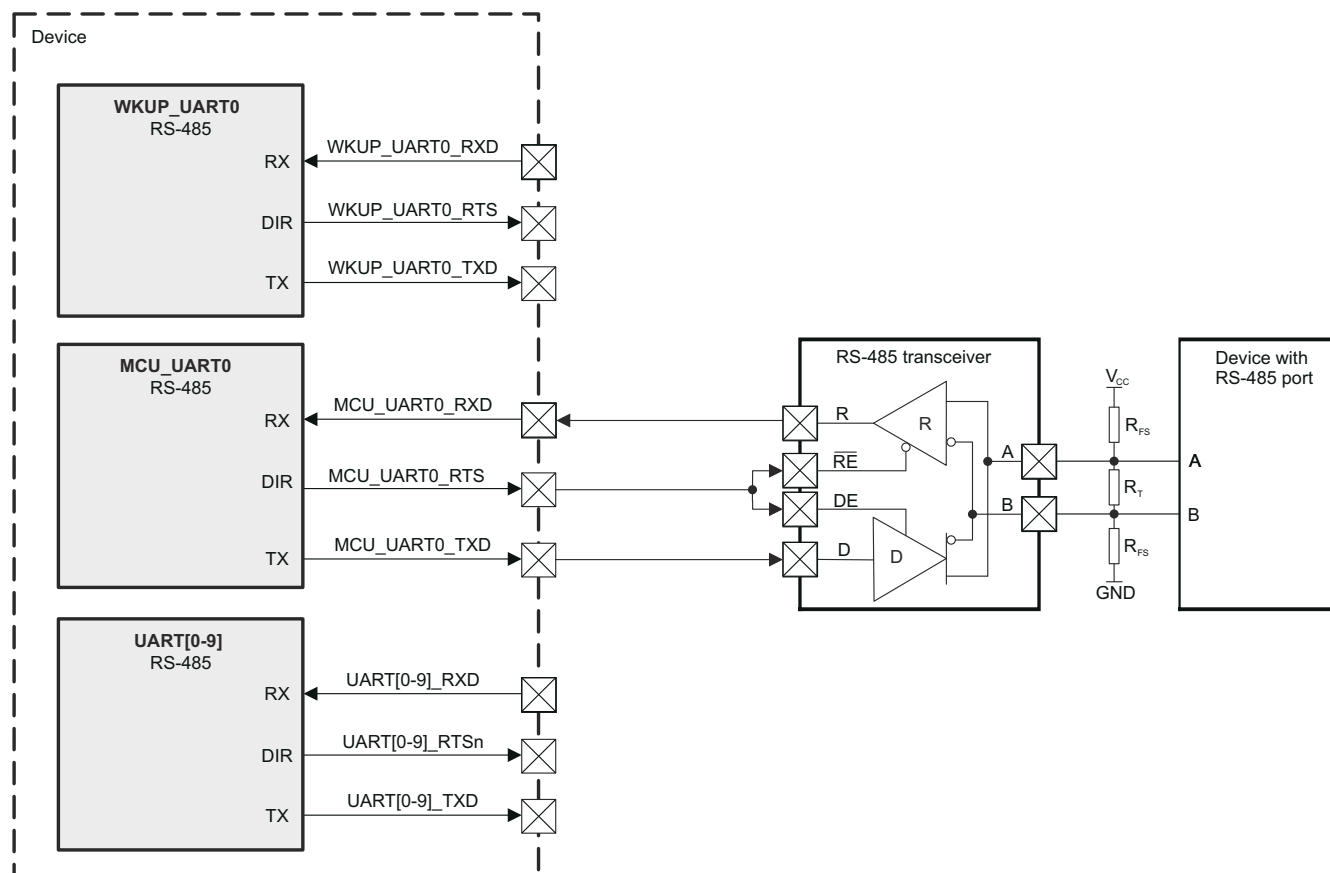

The UART is capable of full 9-bit operation when configured so in UART\_MDR4[6] MODE9 bit. The full 9-bit data can only be written and read through the UART\_ETHR / UART\_ERHR registers. The data can be accessed either with a single or two accesses using appropriate OCP byte enables. In case two accesses are used, make sure to read/write the higher byte first, as reading/writing the lower one will advance the FIFO.

The UART\_RHR / UART\_ERHR and UART\_THR / UART\_ETHR registers point to the same location and either can be used as preferred, in regards to the lower 8 bits.

#### 12.1.6.2.2 RS-485 Functional Interfaces

##### 12.1.6.2.2.1 System Using RS-485 Communication

The RS-485 network physical layer consists of two-wire differential bus, usually twisted pair. External RS-485 transceiver IC is needed to access a RS-485 bus by the RS-485 mode. Figure 12-91 shows an example connection of UART in RS-485 mode.

uart-037

**Figure 12-91. RS-485 Mode Interface Signals**

#### 12.1.6.2.2.2 RS-485 Interface Description

Table 12-103 lists the RS-485 interface input/output (I/O) signals.

**Table 12-103. UART I/O Signals (RS-485 Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UART0</b>				
RX	WKUP_UART0_RXD	I	Serial data input	HiZ
TX	WKUP_UART0_TXD	O	Serial data output	1
DIR	WKUP_UART0_RTS	O	RS-485 Direction	1
<b>MCU_UART0</b>				
RX	MCU_UART0_RXD	I	Serial data input	HiZ
TX	MCU_UART0_TXD	O	Serial data output	1
DIR	MCU_UART0_RTS	O	RS-485 Direction	1
<b>UART[0-9]</b>				
RX	UART[0-9]_RXD	I	Serial data input	HiZ
TX	UART[0-9]_TXD	O	Serial data output	1
DIR	UART[0-9]_TXD	O	RS-485 Direction	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

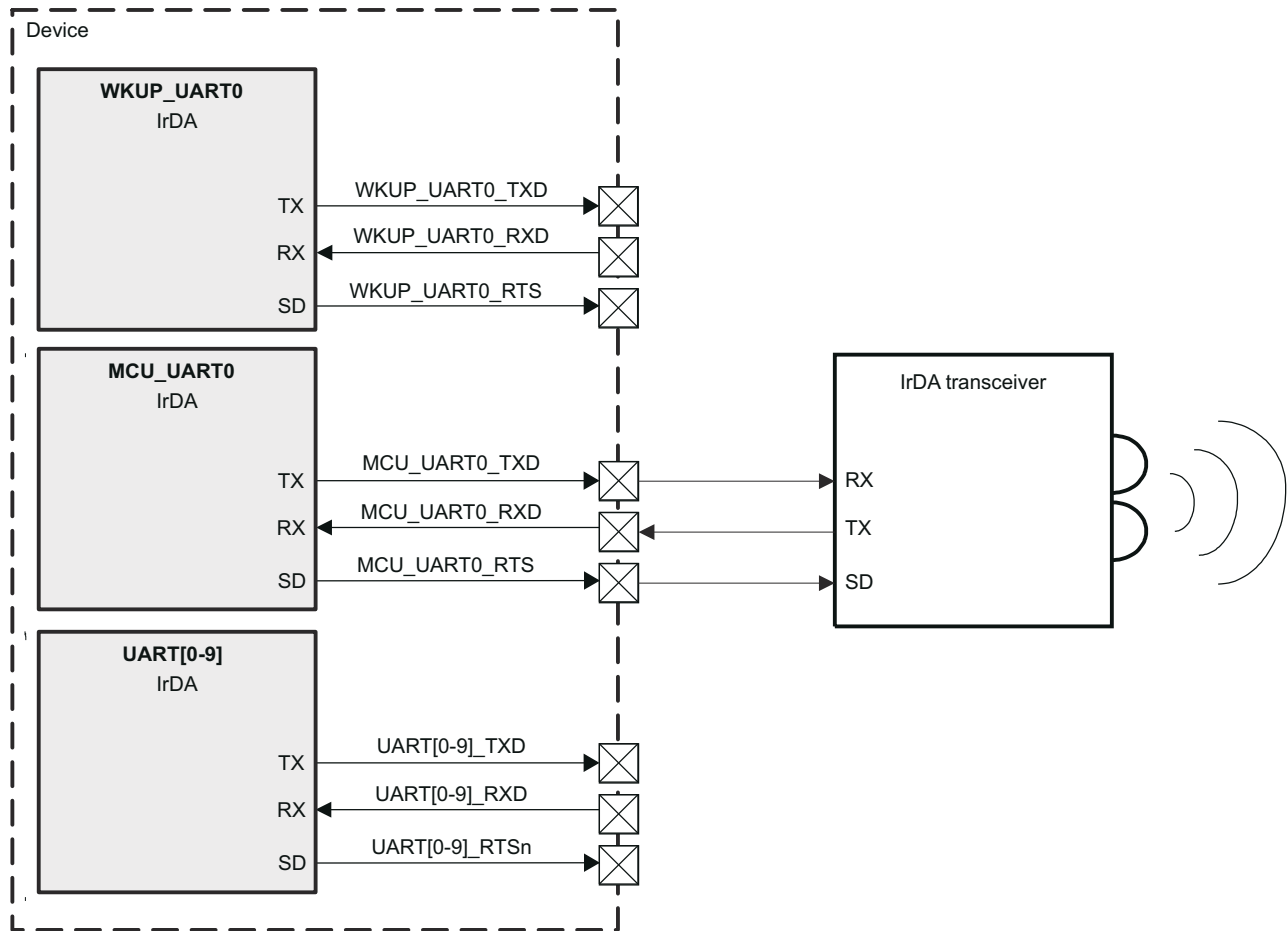

### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.6.2.3 IrDA Functional Interfaces

##### 12.1.6.2.3.1 System Using IrDA Communication Protocol

Figure 12-92 shows an example connection of MCU\_UART0 to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

uart-003

Figure 12-92. IrDA Mode Interface Signals

### 12.1.6.2.3.2 IrDA Interface Description

Table 12-104 lists the IrDA interface I/O signals.

**Table 12-104. UART I/O Signals (IrDA Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UART0</b>				
RX	WKUP_UART0_RXD	I	Serial data input	HiZ
TX	WKUP_UART0_TXD	O	Serial data output in IrDA modes (SIR, MIR, and FIR). <sup>(3)</sup>	0
SD	WKUP_UART0_RTS	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
<b>MCU_UART0</b>				
RX	MCU_UART0_RXD	I	Serial data input	HiZ
TX	MCU_UART0_TXD	O	Serial data output in IrDA modes (SIR, MIR, and FIR). <sup>(3)</sup>	0
SD	MCU_UART0_RTS	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
<b>UART[0-9]</b>				
RX	UART[0-9]_RXD	I	Serial data input	HiZ
TX	UART[0-9]_TXD	O	Serial data output in IrDA modes (SIR, MIR, and FIR). <sup>(3)</sup>	0
SD	UART[0-9]_RTSn	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) In other modes, this pin is set to the reset value (inactive state).

(4) The SD pinout (see UART\_ACREG[6] SD\_MOD bit).

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

### 12.1.6.2.3.3 IrDA Protocol and Data Format

#### 12.1.6.2.3.3.1 SIR Mode

In SIR mode, data is transferred between the Host CPU and peripheral devices at speeds of up to 115200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART\_LCR register.

The UART\_BLR[6] XBOF\_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

The SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine sends an escape character (0x7D), inverts the fifth bit of the real data to be sent, and then sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to find possible errors of the received frame.

### Note

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART\_ACREG[5] DIS\_IR\_RX bit. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be 1.6-μs or 3/16 encoding, selected by the UART\_ACREG[7] PULSE\_TYPE bit. In 1.6-μs encoding, the infrared pulse width is 1.6 μs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

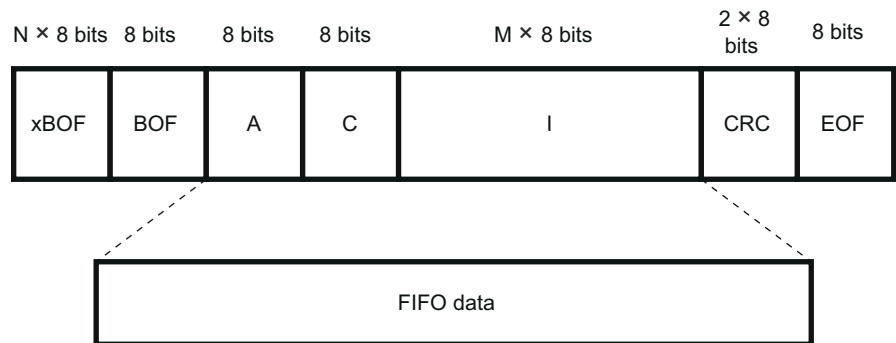

For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

### Note

Reception supports variable-length stop-bits.

#### 12.1.6.2.3.3.1.1 Frame Format

Figure 12-93 shows the IrDA SIR frame format.

uart-006

**Figure 12-93. IrDA SIR Frame Format**

The CRC is applied on the address (A), control (C), and information (I) bytes.

### Note

The two words of CRC are written to the FIFO in reception.

#### 12.1.6.2.3.3.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

- In reception:

For the A, C, I, and CRC fields:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
- If the byte is equal to the CE byte, discards the CE byte

- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

#### 12.1.6.2.3.3.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

#### 12.1.6.2.3.3.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6-μs pulse duration methods. The UART\_ACREG[7] PULSE\_TYPE bit selects the pulse-width method in transmit mode.

#### 12.1.6.2.3.3.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the TX line is always low, and the counter used to form a pulse on TX is cleared continuously.

After the TX FIFO output resets to 0, TX rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, TX falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh clock to the tenth clock of each 16-clock bit cycle.

Figure 12-94 shows the IrDA SIR encoding mechanism.

**Figure 12-94. IrDA SIR Encoding Mechanism**

#### 12.1.6.2.3.3.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 12-95 shows the IrDA SIR decoding mechanism.

**Figure 12-95. IrDA SIR Decoding Mechanism**

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the RX input can be disabled using the UART\_ACREG[5] DIS\_IR\_RX bit. The UART\_MDR2[6] IRRXINVERT bit can invert the signal from the transceiver (RX) pin to the IR RX logic in the UART. This inversion is performed by default.

#### 12.1.6.2.3.3.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART\_EFR[1-0] bit field (see [Table 12-105](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UARTi receives in IrDA mode, use the UART\_XON1\_ADDR1[7-0] and UART\_XON2\_ADDR2[7-0] bit fields.

**Table 12-105. UART\_EFR[1-0] IR Address Checking Options**

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

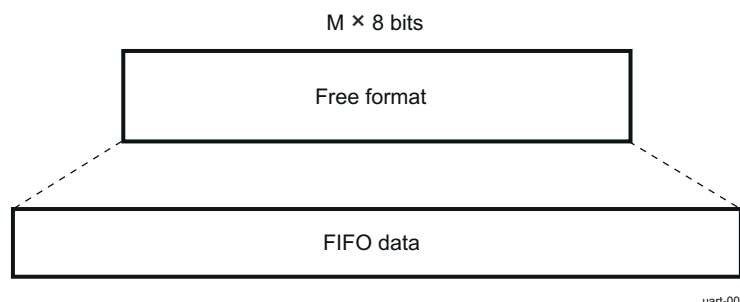

#### 12.1.6.2.3.3.2 SIR Free-Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 12-96](#) shows SIR FF mode.

uart-009

**Figure 12-96. SIR FF Mode**

In SIR FF mode, the Host CPU software must construct (that is, encode and decode) the entire FIFO data packet.

The SIR Free Format mode is selected by setting the module in UART mode (MDR1[2:0] = 000) and the MDR2[3] register bit to one to allow the pulse shaping. As the bit format is to remain the same, some UART mode configuration registers need to be set at specific value:

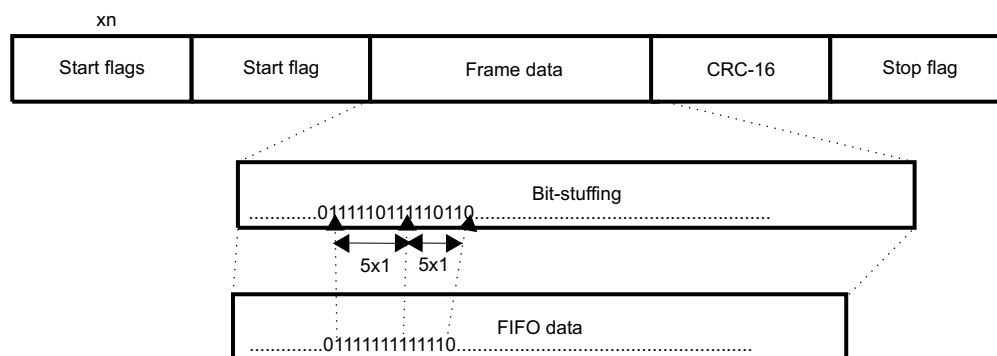

- LCR[1:0] = "11" (8 data bits)
- LCR[2] = 0 (2 stop bit)
- LCR[3] = 0 (no parity)
- ACREG[7] = 0 (3/16 of baud-rate pulse width)

The features defined through MDR2[6] and ACREG[5] are also supported, however:

- All other configuration registers need to be at the reset value
- The same UART mode interrupts used for the SIR FF mode are not necessarily relevant (XOFF, RTS, CETS, Modem Status Register)

#### 12.1.6.2.3.3.3 MIR Mode

In MIR mode, data is transferred between the Host CPU and the peripheral devices at 0.576 Mbps or 1.152 Mbps. A MIR transmit frame starts with at least two start flags, followed by a frame data and a CRC-16, and ends with a stop flag (see [Figure 12-97](#)).

uart-010

**Figure 12-97. MIR Transmit Frame Format**

On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).

- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

#### 12.1.6.2.3.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 12-98 shows the MIR baud rate adjustment mechanism.

Figure 12-98. MIR Baud Rate Adjustment Mechanism

#### 12.1.6.2.3.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 12-99 shows the SIP.

**Figure 12-99. SIP**

When the SIP\_MODE bit of the Mode Definition Register 1 is equal to 1 (MDR1[6]), the TX state machine will always send one SIP at the end of the transmission frame. When MDR1[6] is equal to 0, the transmission of the SIP depends on the SEND\_SIP bit of the Auxiliary Control Register (ACREG[3]). The system (Host CPU) can set ACREG[3] at least once every 500ms. The advantage of this approach over the default approach is that the TX state machine does not need to send the SIP at the end of each frame, which may reduce the overhead required.

#### 12.1.6.2.3.3.4 FIR Mode

In FIR mode, data is transferred between the Host CPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 12-100 shows the FIR transmit frame format.

**Figure 12-100. FIR Transmit Frame Format**

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag
----------------	------------	------------	--------	-----------

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 12-106) and generates the SIP (see Section 12.1.6.2.3.3.3.2, *SIP Generation*).

**Table 12-106. 4-PPM Format**

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 12-106 are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 12-107).

**Table 12-107. FIR Preamble, Start Flag, and Stop Flag**

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted LSBs of each byte first (see Table 12-108).

**Table 12-108. FIR Data Byte Transmission Order Example**

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

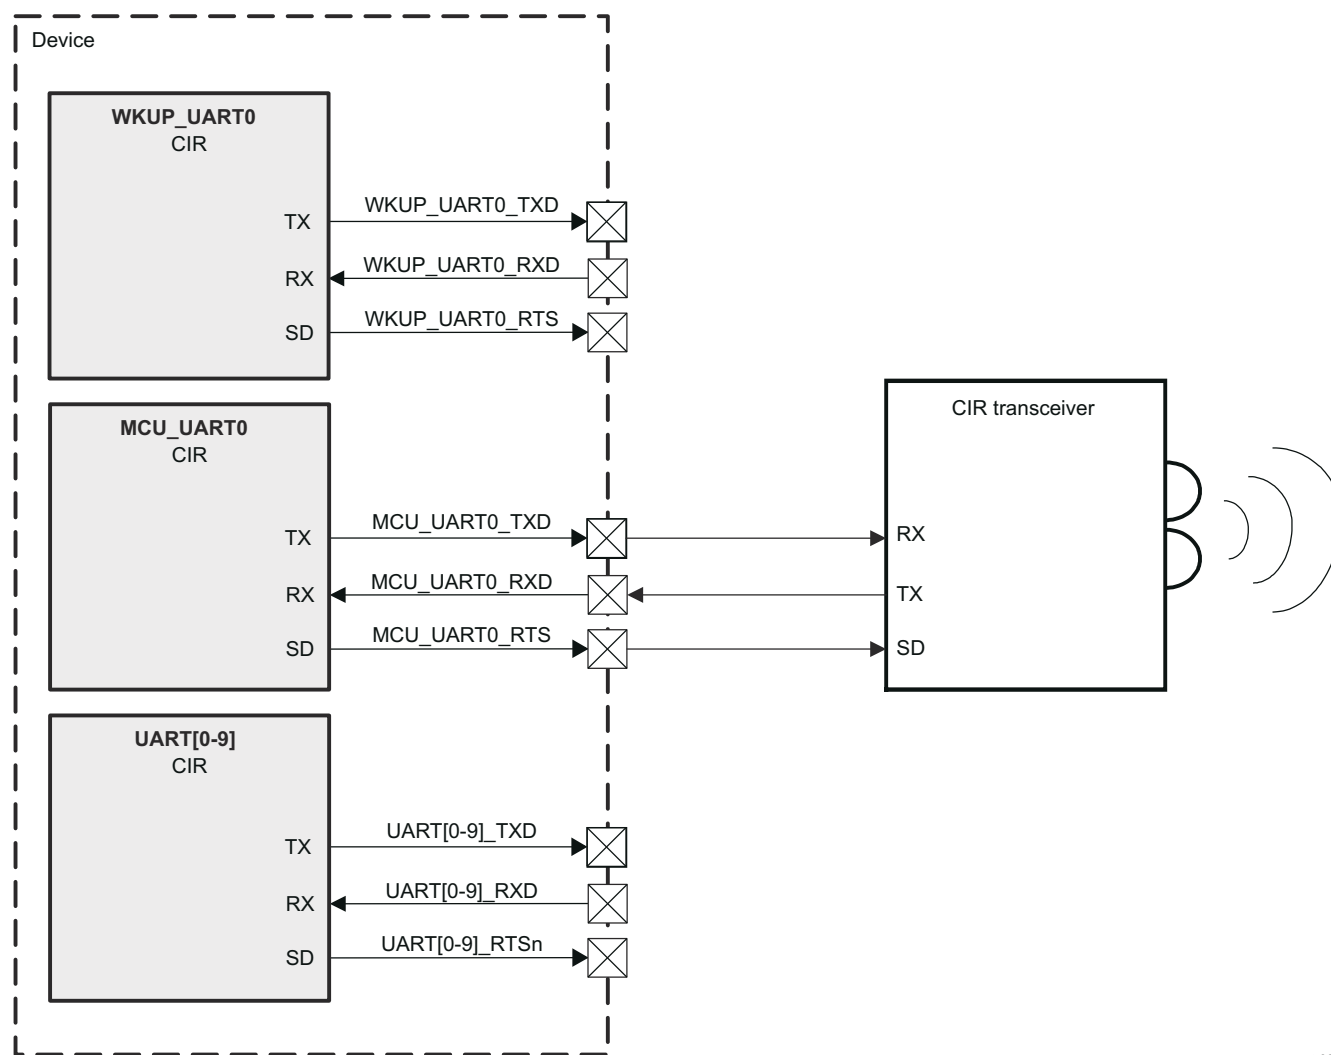

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the Host CPU reads the line status register (UART\_LSR\_IRDA) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

#### 12.1.6.2.4 CIR Functional Interfaces

##### 12.1.6.2.4.1 System Using CIR Communication Protocol With Remote Control

All UART modules can be connected to an external infrared transceiver in CIR mode. [Figure 12-101](#) shows an example connection of MCU\_UART0 in CIR mode.

uart-004

**Figure 12-101. CIR Mode Interface Signals**

#### 12.1.6.2.4.2 CIR Interface Description

Table 12-109 lists the CIR interface I/O signals.

**Table 12-109. UART I/O Signals (CIR Mode)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
<b>WKUP_UART0</b>				
RX	WKUP_UART0_RXD	I	Serial data input	HiZ
TX	WKUP_UART0_TXD	O	Serial data output in CIR mode. <sup>(3)</sup>	0
SD	WKUP_UART0_RTS	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
<b>MCU_UART0</b>				
RX	MCU_UART0_RXD	I	Serial data input	HiZ
TX	MCU_UART0_TXD	O	Serial data output in CIR mode. <sup>(3)</sup>	0
SD	MCU_UART0_RTS	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1
<b>UART[0-9]</b>				
RX	UART[0-9]_RXD	I	Serial data input	HiZ

**Table 12-109. UART I/O Signals (CIR Mode) (continued)**

Module Pin	Device Level Signal	I/O <sup>(1)</sup>	Description	Module Pin Reset Value <sup>(2)</sup>
TX	UART[0-9]_TXD	O	Serial data output in CIR mode. <sup>(3)</sup>	0
SD	UART[0-9]_RTSn	O	SD mode is used to configure the transceivers. <sup>(4)</sup>	1

(1) I = Input; O = Output

(2) HiZ = High Impedance

(3) In other modes, this pin is set to the reset value (inactive state).

(4) The SD pinout is an inverted value of the UART\_ACREG[6] SD\_MOD bit.

#### Note

For more information about device level signals (pull-up/down resistors, buffer type, multiplexing and others), see tables *Pin Attributes* and *Pin Multiplexing* in the device-specific Datasheet.

#### 12.1.6.2.4.3 CIR Protocol and Data Format

In CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable  $t$  period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

##### 12.1.6.2.4.3.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see [Figure 12-102](#)).

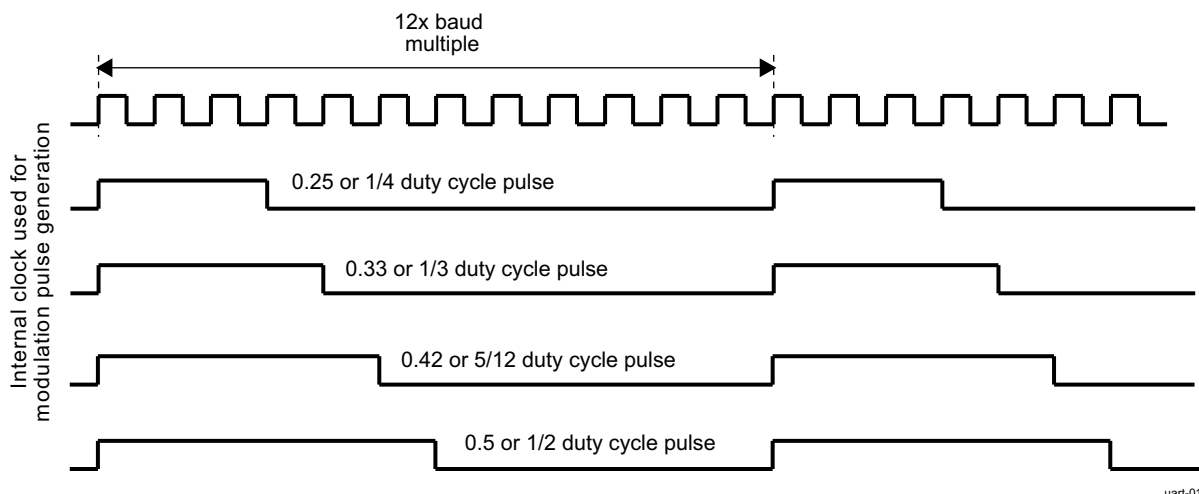

**Figure 12-102. CIR Pulse Modulation**

### 12.1.6.2.4.3.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART\_MDR2[5-4] CIR\_PULSE\_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 12-103 shows the CIR modulation duty cycles.

**Figure 12-103. CIR Modulation Duty Cycle**

The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

### 12.1.6.2.4.3.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration  $t$ .

Similarly, 0 is transmitted as a blank duration  $T$ . The Host CPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 12-104).

**Figure 12-104. UART RC-5 Bit Encoding**

Because CIR mode logic does not impose a fixed format for infrared packets of data, the Host CPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the Host CPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of  $t$ ) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 12-105 shows SIRC bit encoding.

**Figure 12-105. UART SIRC Bit Encoding**

To construct comprehensive packets constituting remote-control commands, the Host CPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 12-106 shows a standard RC-5 frame as detected by UART in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two  $t$  pulses (digital bits) from the TX FIFO.

uart-018

**Figure 12-106. UART RC-5 Standard Packet Format**

Where:

S1, S2: Start-bits (always 1)  
T: Toggle bit  
A4..A0: Address (or system) bits  
C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the Host CPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

The SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 12-107 shows the packet format and bit encoding. As Figure 12-108 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

uart-019

**Figure 12-107. UART SIRC Packet Format**

### Note

The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

uart-020

**Figure 12-108. UART SIRC Bit Transmission Example**

---

**Note**

This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

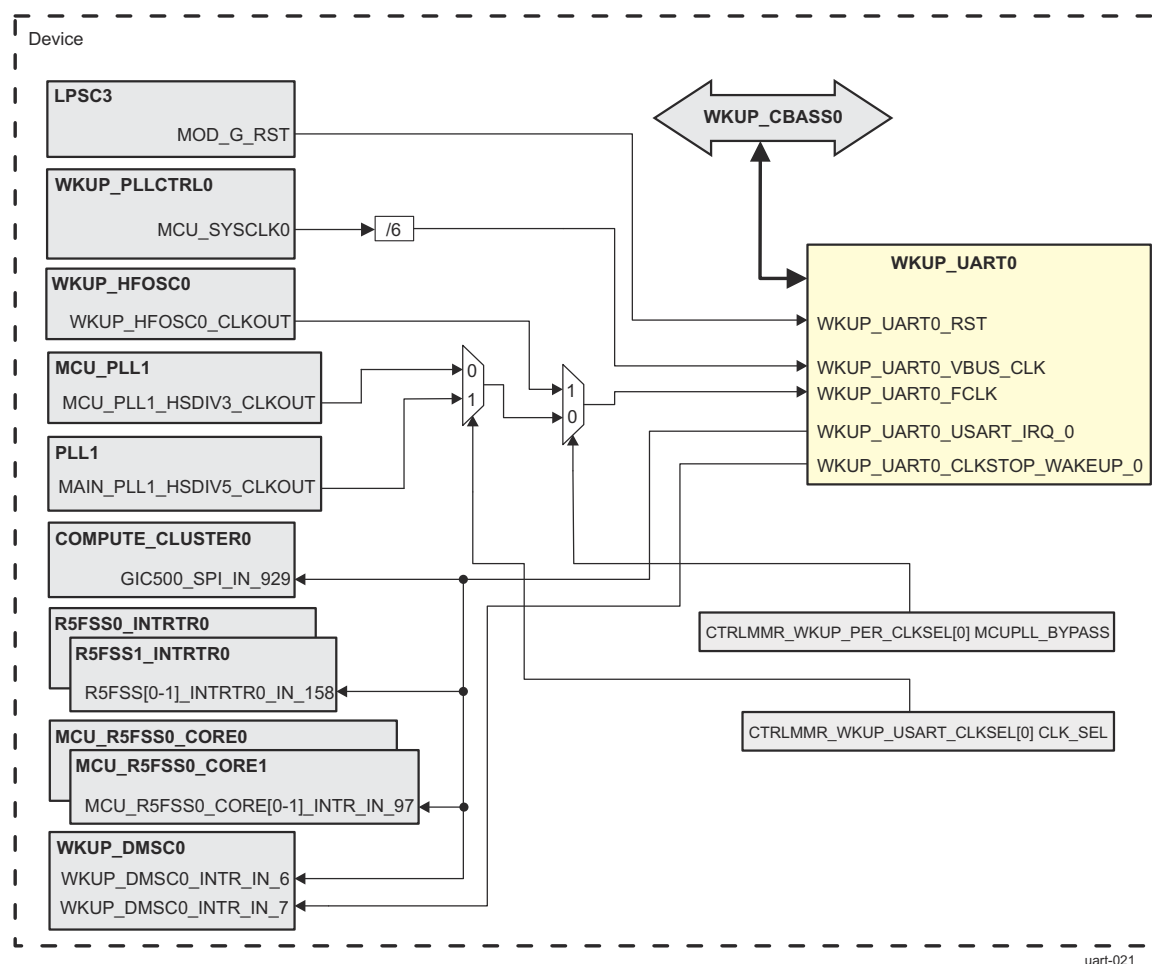

---

### 12.1.6.3 UART Integration

This section describes UART integration in the device, including information about clocks, resets, and hardware requests.

#### 12.1.6.3.1 UART Integration in WKUP Domain

A single WKUP\_UART0 module is integrated in the device WKUP domain. [Figure 12-109](#) shows the integration of WKUP\_UART0.

**Figure 12-109. WKUP\_UART0 Integration**

[Table 12-110](#) through [Table 12-112](#) summarize the integration of WKUP\_UART0 in the device WKUP domain.

**Table 12-110. WKUP\_UART0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
WKUP_UART0	WKUP_PSC0	PD0	LPSC3	WKUP_CBASS0

**Table 12-111. WKUP\_UART0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
WKUP_UART0	WKUP_UART0_CLK	MCU_SYSCCLK0/6	WKUP_PLLCTRL0	WKUP_UART0 interface clock
	WKUP_UART0_FCLK	MCU_PLL1_HSDIV3_CLKOUT	MCU_PLL1	WKUP_UART0 functional clock. Output of multiplexer, see <a href="#">Figure 12-109</a> , <i>WKUP_UART0 Integration</i> . Multiplexers control is provided via CTRLMMR_WKUP_USART_CLKSEL[0] CLK_SEL and CTRLMMR_WKUP_PER_CLKSEL[0] MCUPLL_BYPASS bit fields.
		MAIN_PLL1_HSDIV5_CLKOUT	PLL1

---

**Note**

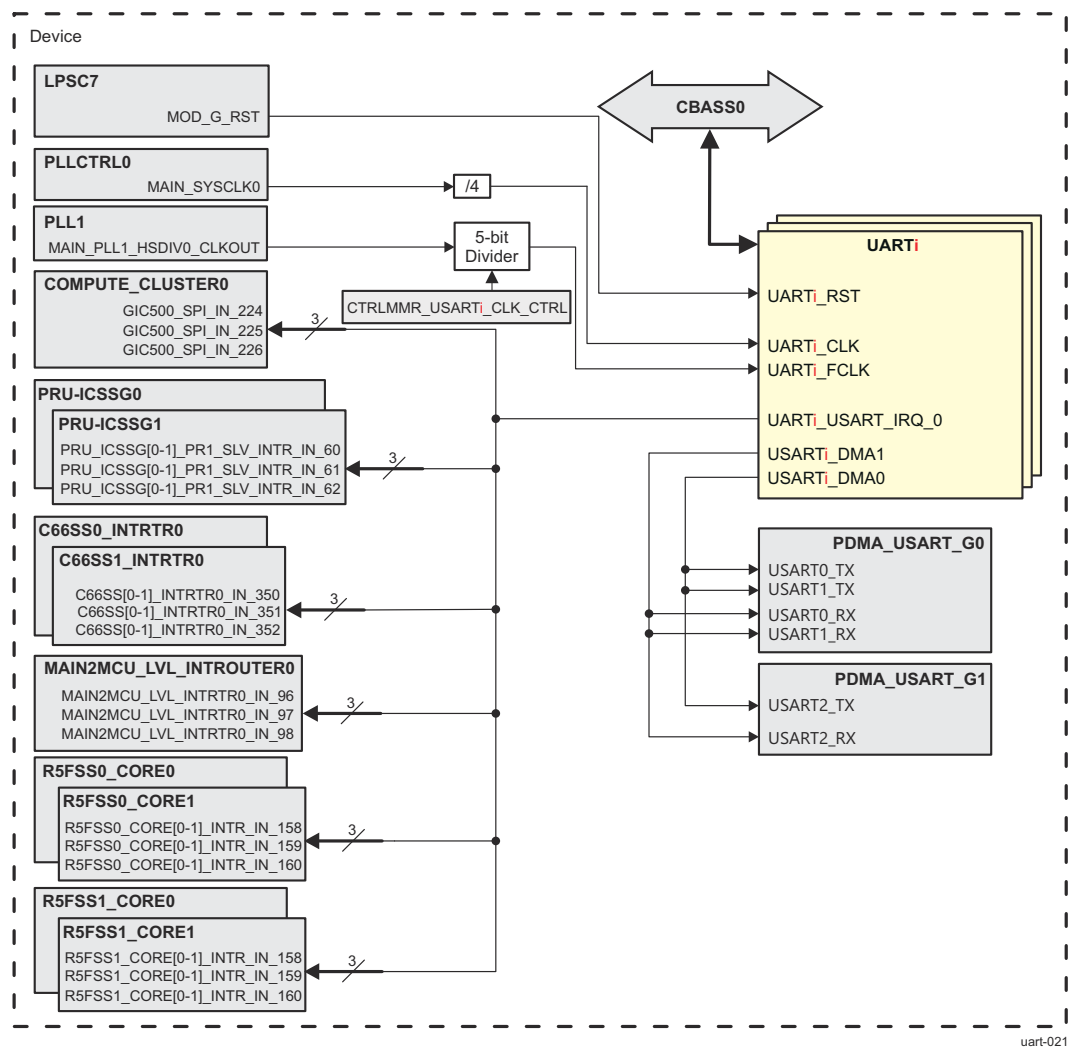

UART interrupts are further described in [Section 12.1.6.4.5](#), *UART Interrupt Requests*.

UART DMA events are further described in [Section 12.1.6.4.6.4](#), *FIFO DMA Mode Operation*.

---

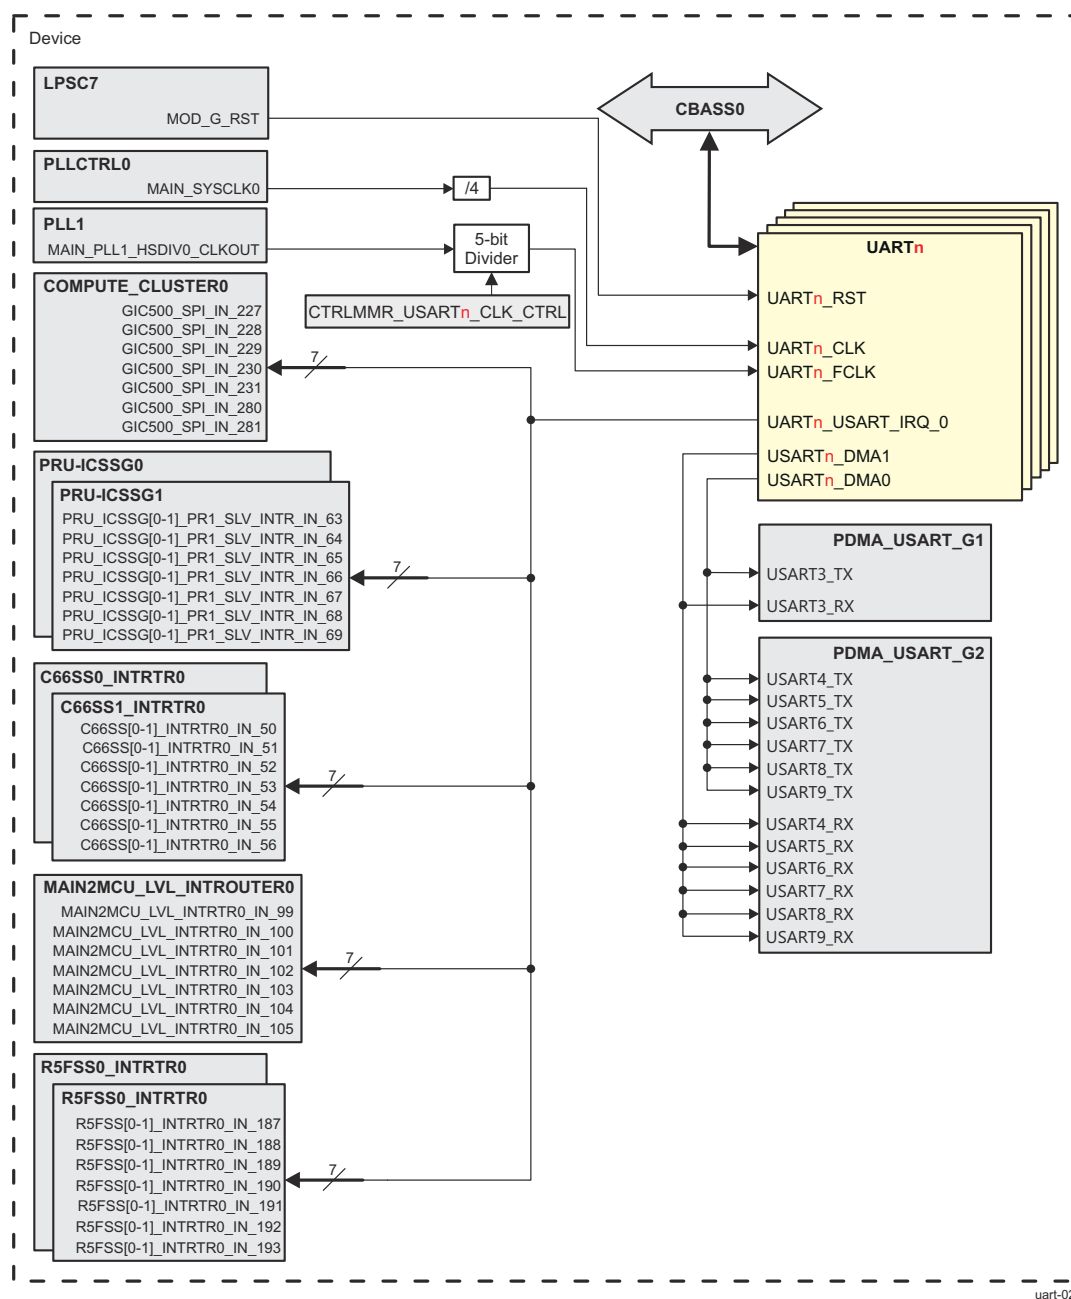

**12.1.6.3.3 UART Integration in MAIN Domain**

There are ten UART modules integrated in the device MAIN domain - UART0, UART1, UART2, UART3, UART4, UART5, UART6, UART7, UART8, and UART9. [Figure 12-111](#) shows the integration of UART[0-2]. [Figure 12-112](#) shows the integration of UART[3-9].

A.  $i = 0$  to 2

Figure 12-111. UART[0-2] Integration

A n = 3 to 9

Table 12-116 through Table 12-118 summarize the integration of UART[0-9] in the device MAIN domain.

**Table 12-116. UART Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
UART0	PSC0	PD0	LPSC7	CBASS0
UART1	PSC0	PD0	LPSC7	CBASS0
UART2	PSC0	PD0	LPSC7	CBASS0
UART3	PSC0	PD0	LPSC7	CBASS0
UART4	PSC0	PD0	LPSC7	CBASS0
UART5	PSC0	PD0	LPSC7	CBASS0
UART6	PSC0	PD0	LPSC7	CBASS0
UART7	PSC0	PD0	LPSC7	CBASS0
UART8	PSC0	PD0	LPSC7	CBASS0
UART9	PSC0	PD0	LPSC7	CBASS0

**Table 12-117. UART Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description

## 12.1.6.4 UART Functional Description

### 12.1.6.4.1 UART Block Diagram

The UART module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, RS-485, IrDA, or CIR) and enables the mechanism corresponding to the chosen function.
- Register mode: Enables conditional access to registers.

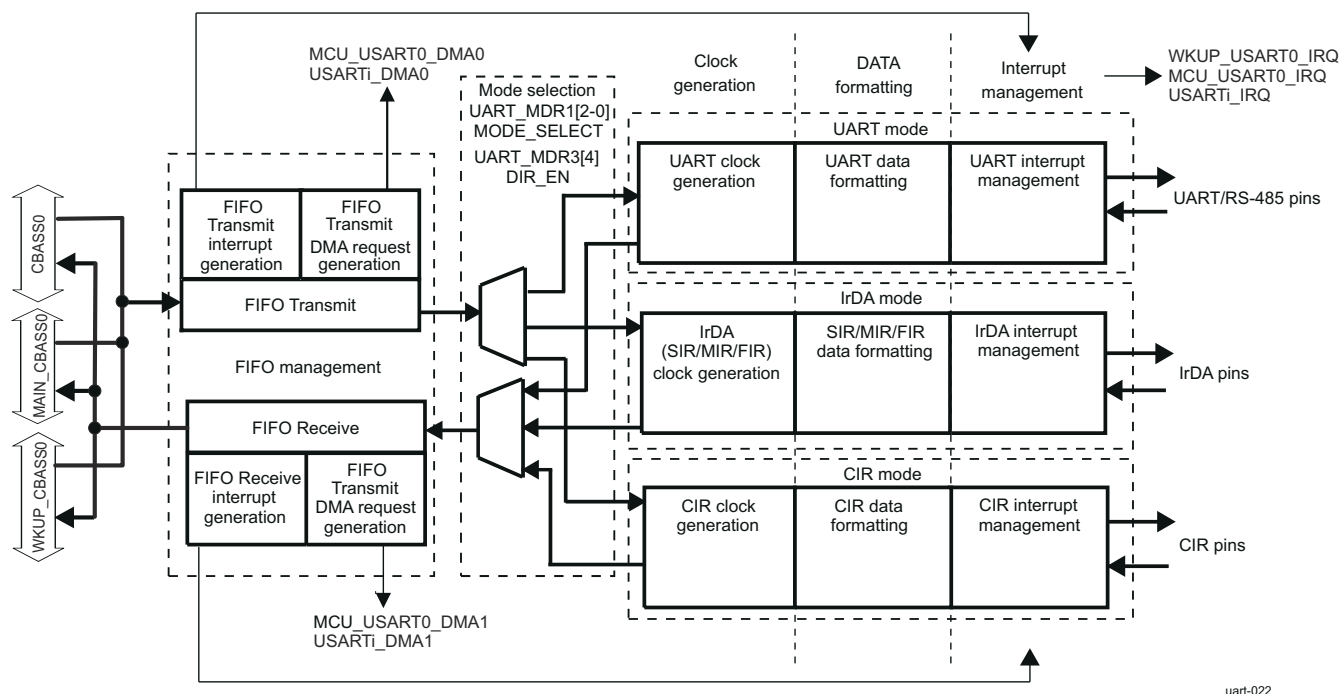

For more information about mode configuration, see *Mode Selection*.

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses a dedicated state-machine that is responsible for the transition between FIFO data and the associated frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function. In each mode, when an interrupt is generated, the UART\_IIR\_UART register indicates the interrupt type.
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

In parallel with these functional blocks, a power-saving strategy exists for each function.

The UART block diagram is shown below.

**Figure 12-113. UART Functional Block Diagram**

#### 12.1.6.4.2 UART Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses.

#### 12.1.6.4.3 UART Software Reset

The UART\_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

##### 12.1.6.4.3.1 Independent TX/RX

The receiver and transmitter are enabled by default after reset. Software can choose to disable, re-enable or to reset either the RX or the TX side independently of the other through the UART\_ECR register.

#### 12.1.6.4.4 UART Power Management

##### 12.1.6.4.4.1 UART Mode Power Management

##### 12.1.6.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UART\_IER\_UART[4] SLEEP\_MODE bit to 1 (when the UART\_EFR[4] ENHANCED\_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RX, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the RX line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UART\_SCR[4] RX\_CTS\_WU\_EN bit to 1. To understand how to manage the interrupt, see [Section 12.1.6.4.5.1.2, Wake-Up Interrupt](#).

---

#### Note

There must be no writing to the divisor latches, UART\_DLL and UART\_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UART\_IER\_UART[4] SLEEP\_MODE bit before writing to the UART\_DLL or UART\_DLH register.

---

##### 12.1.6.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

For more information, see *Power*, in the *Device Configuration*.

##### 12.1.6.4.4.2 IrDA Mode Power Management

##### 12.1.6.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART\_MDR1[3] IR\_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, RXD, is idle.
- The TX FIFO and TX shift register are empty.

- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the RXD line or when data is written to the TX FIFO.

#### 12.1.6.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see [Section 12.1.6.4.4.1.2, System Power Saving](#)).

#### 12.1.6.4.4.3 CIR Mode Power Management

##### 12.1.6.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see [Section 12.1.6.4.4.2.1, Module Power Saving](#)).

##### 12.1.6.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see [Section 12.1.6.4.4.1.2, System Power Saving](#)).

#### 12.1.6.4.4.4 Local Power Management

[Table 12-119](#) describes power-management features available for the UART.

#### Note

For information about source clock gating and the sleep/wake-up transitions description, see *Power*, in the *Device Configuration*.

**Table 12-119. UART Local Power-Management Features**

Feature	Registers	Description
Clock autogating		
Peripheral idle modes		
Clock activity	N/A	Feature not available
Controller standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

#### 12.1.6.4.5 UART Interrupt Requests

##### 12.1.6.4.5.1 UART Mode Interrupt Management

##### 12.1.6.4.5.1.1 UART Interrupts

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UART\_IIR\_UART) sets the UART\_IIR\_UART[0] IT\_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UART\_IIR\_UART[5-1] bit field. [Table 12-120](#) summarizes the interrupt control functions.

**Table 12-120. UART Mode Interrupts**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	N/A	No Interrupt	N/A	N/A
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR_UART register.

**Table 12-120. UART Mode Interrupts (continued)**

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register if using the default timeout behavior: EFR2[6]=0 Cleared by reading its value (IIR) if using the periodic timeout behavior: EFR2[6]=1
000100	2	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears
000010	3	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears
000000	4	Modem status	See the UART_MSR register.	Read the MSR register
010000	5	XOFF interrupt/ special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR_UART register, if special character interrupt
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high)	Read the UART_IIR_UART register

For the receiver-line status interrupt, the UART\_LSR\_UART[7] RX\_FIFO\_STS bit generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UART\_IIR\_UART register.

#### 12.1.6.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the RX\_CTS\_DSR\_WAKE\_UP\_ENABLE bit of the Supplementary Control Register (SCR[4]) is set to 1. The IIR register is not modified when it occurs, SSR[1] must be checked to detect a wake-up event. When a wake-up event occurs, the only way to clear it is to reset SCR[4] to 0. Wake-up can also occur if the WER[7] TX\_WAKEUP\_EN is set to 1 and one of the following events occurs:

1. THR interrupt is enabled and occurs (omitted if TX DMA request is enabled)
2. TX DMA request is enabled and occurs
3. TX\_STATUS\_IT is enabled and occurs (only IrDA and CIR modes). Cannot be used with THR Interrupt.

#### 12.1.6.4.5.2 IrDA Mode Interrupt Management

##### 12.1.6.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_IRDA). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_IRDA).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_IRDA and UART\_IIR\_IRDA mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 12-121](#)). The interrupt line is activated when any interrupt is generated (there is no priority).

**Table 12-121. IrDA Mode Interrupts**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disabled) RX FIFO above trigger level (FIFO enabled)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR until the interrupt condition disappears.

**Table 12-121. IrDA Mode Interrupts (continued)**

IIR_IRDA Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the UART_RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error OR Transmission of the last bit of the IrDA frame completed successfully.	Read the UART_RESUME register OR Read the UART_IIR_IRDA register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR_IRDA register.

**12.1.6.4.5.2.2 Wake-Up Interrupts**

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see [Section 12.1.6.4.5.1.2, Wake-Up Interrupt](#)).

**12.1.6.4.5.3 CIR Mode Interrupt Management****12.1.6.4.5.3.1 CIR Interrupts**

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART\_IER\_CIR). The interrupt status of the device can be checked by reading the interrupt identification register (UART\_IIR\_CIR).

The UART, IrDA, and CIR modes have different interrupts in the UART module and, therefore, different UART\_IER\_CIR and UART\_IIR\_CIR mappings, depending on the selected mode.

[Table 12-122](#) lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART\_IIR\_CIR[5] TX\_STATUS\_IT bit is to indicate that the last bit of infrared data was passed to the TX pin.

**Table 12-122. CIR Mode Interrupts**

IIR_CIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0			
1	THR interrupt	TFE (THR empty) (FIFO disabled) TX FIFO below trigger level (FIFO enabled)	Write to the UART_THR register until the interrupt condition disappears
2			
3			
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully	Read the UART_IIR_CIR register
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

**12.1.6.4.5.3.2 Wake-Up Interrupts**

The wake-up interrupt for CIR mode has the same function as that for UART mode (see [Section 12.1.6.4.5.1.2, Wake-Up Interrupt](#)).

**12.1.6.4.6 UART FIFO Management**

The FIFO is accessed by reading and writing the UART\_RHR and UART\_THR registers. Parameters are controlled using the FIFO control register (UART\_FCR) and supplementary control register (UART\_SCR). Reading the UART\_SSR[0] TX\_FIFO\_FULL bit at 1 means the FIFO is full.

The UART\_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. [Figure 12-114](#) shows the FIFO management registers.

---

**Note**

Data in the UART\_RHR register is not overwritten when an overflow occurs.

---

---

**Note**

The UART\_SFLSR, UART\_SFREGL, and UART\_SFREGH status registers are used in IrDA mode only. For information about their use, see [Section 12.1.6.4.8.3.3, IrDA Data Formatting](#).

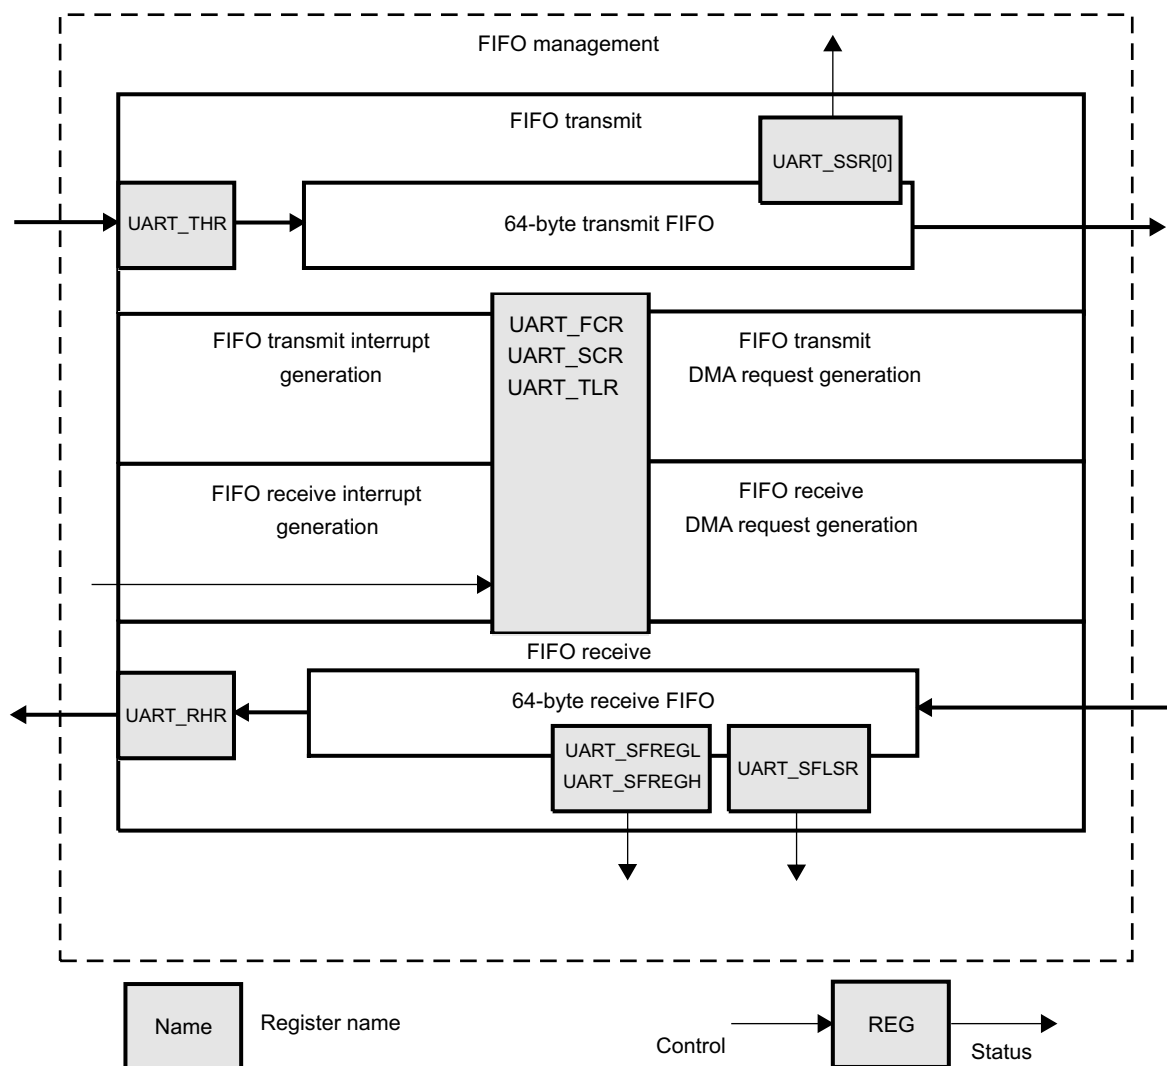

---

---

**Note**

Bits UART\_FCR[2] TX\_FIFO\_CLEAR and UART\_FCR[1] RX\_FIFO\_CLEAR are automatically cleared by hardware after  $4 \times \text{UARTi\_CLK} + 5 \times \text{UARTi\_FCLK}$  clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

---

uart-023

**Figure 12-114. UART FIFO Management Registers**

#### 12.1.6.4.6.1 FIFO Trigger

##### 12.1.6.4.6.1.1 Transmit FIFO Trigger

Table 12-123 lists the TX FIFO trigger level settings.

**Table 12-123. UART TX FIFO Trigger Level Setting Summary**

SCR[6]	TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[5-4] TX_FIFO_TRIG bit field (8, 16, 32, or 56 spaces)
0	!= 0x0	Defined by the UART_TLR[3-0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TLR[3:0] (higher bits) and FCR[5:4] (lower bits) from 1 to 63 spaces with a granularity of 1 space.

**Note:** The combination of TLR[3:0]=0000 and FCR[5:4]=00 (all zeros) is not supported (min 1 space required). All zeros will result in unsupported behavior.

##### 12.1.6.4.6.1.2 Receive FIFO Trigger

Table 12-124 lists the RX FIFO trigger-level settings.

**Table 12-124. UART RX FIFO Trigger-Level Setting Summary**

SCR[7]	TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UART_FCR[7:6] RX_FIFO_TRIG bit field (8, 16, 56, or 60 characters)
0	!= 0x0	Defined by the UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] from 1 to 63 characters with a granularity of one character.  <b>Note:</b> The combination of TLR[7:4]=0000 and FCR[7:6]=00 (all zeros) is not supported (min 1 character required). All zeros will result in unsupported behavior.

The receive threshold is programmed using the UART\_TCR[7:4] RX\_FIFO\_TRIG\_START and UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX\_FIFO\_TRIG\_HALT > RX\_FIFO\_TRIG when auto-RTS is enabled.

$$\text{Delay} = [4 + 16 \times (1 + \text{CHAR\_LENGTH} + \text{Parity} + \text{Stop} - 0.5)] \times \text{Baud\_rate} + 4 \times \text{FCLK}$$

#### Note

The RTS signal is deasserted after the UART module receives the data over RX\_FIFO\_TRIG\_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX\_FIFO\_TRIG\_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UART\_TCR[7:4] RX\_FIFO\_TRIG\_START bit field or the UART\_FCR[7:6] RX\_FIFO\_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

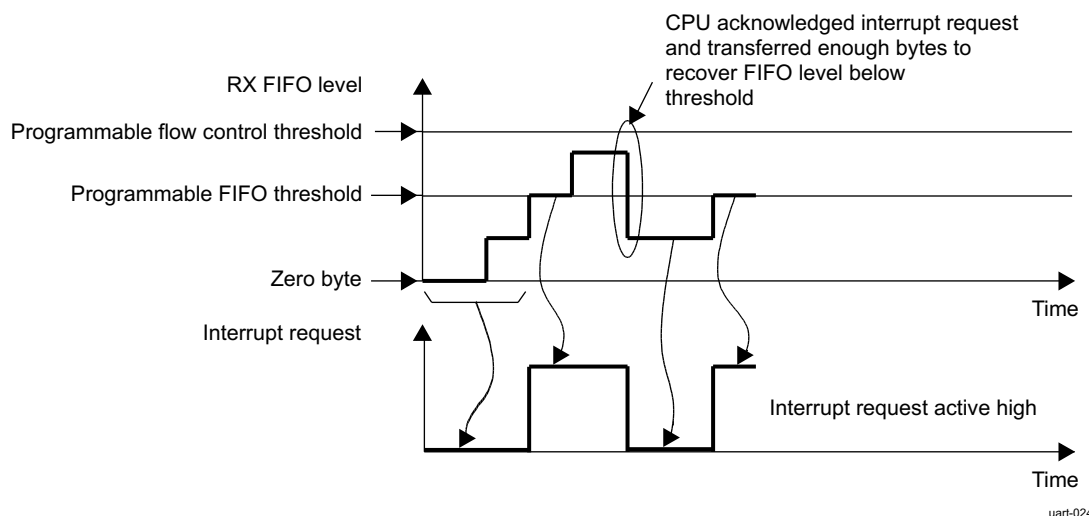

#### 12.1.6.4.6.2 FIFO Interrupt Mode

In FIFO interrupt mode (the FIFO control register UART\_FCR[0] FIFO\_EN bit is set to 1 and relevant interrupts are enabled by the UART\_IER\_UART register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UART\_TLR[7:4] RX\_FIFO\_TRIG\_DMA and UART\_TLR[3:0] TX\_FIFO\_TRIG\_DMA bit fields or the UART\_FCR[7:6] RX\_FIFO\_TRIG and UART\_FCR[5:4] TX\_FIFO\_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the Host CPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UART\_TCR[3:0] RX\_FIFO\_TRIG\_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 12-115 shows the generation of the RX FIFO interrupt request.

**Figure 12-115. UART RX FIFO Interrupt Request Generation**

In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the Host CPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 12-116 shows the generation of the TX FIFO interrupt request.

**Figure 12-116. UART TX FIFO Interrupt Request Generation**

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

#### 12.1.6.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UART\_FCR[0] FIFO\_EN bit is set to 0 and the relevant interrupts are disabled by the UART\_IER\_UART register), the status of the receiver and transmitter can be checked by polling the line status register (UART\_LSR\_UART).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the Host CPU.

#### 12.1.6.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in *UART Hardware Requests*, assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the USARTi\_DMA0, and MCU\_USART0\_DMA0 signals (where i = 0 to 9).

The USARTi\_DMA1 (where i = 0 to 9), and MCU\_USART0\_DMA1 signals are not used by the module in mode 2 and mode 3:

The DMA mode and signals usage can be selected as follows:

- When SCR[0]=0:
  - Setting FCR[3] to 0 enables DMA mode 0
  - Setting FCR[3] to 1 enables DMA mode 1
- When SCR[0]=1:
  - SCR[2:1] determines DMA mode 0 to 3 according to the Supplementary Control Register (SCR) description.

For example:

- If no DMA operation is desired: set SCR[0] to 1 and SCR[2:1] to 00 (FCR[3] is discarded)
- If DMA mode 1 is desired: either set SCR[0] to 0 and FCR[3] to 1 or set SCR[0] to 1 and SCR[2:1] to 01 (FCR[3] is discarded)

If the FIFOs are disabled (FCR[0]=0), DMA operations occur in single character transfers.

Note that when DMA Mode 0 has been programmed, the signals associated with DMA operation are not active.

Depending on UART\_MDR3[2] SET\_DMA\_TX\_THRESHOLD, the threshold can be programmed different ways:

- SET\_TX\_DMA\_THRESHOLD = 1:
 

The threshold value will be the value of the UART\_TX\_DMA\_THRESHOLD register. If SET\_TX\_DMA\_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET\_TX\_DMA\_THRESHOLD = 0:
 

The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

##### 12.1.6.4.6.4.1 DMA sequence to disable TX DMA

In order to disable TX DMA if it is not needed anymore (e.g. all transfers are done and UART idle mode is desired), the following sequence must be use

1. DMA mode 1 is set (both TX/RX DMA) by registers UART\_SCR[0] DMA\_MODE\_CTL = 0 and UART\_FCR[3] DMA\_MODE = 1:
  - a. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit fields to 01 (DMA mode 1)
  - b. Set the UART\_SCR[0] DMA\_MODE\_CTL bit to 1 (this setting of UART\_SCR[0] DMA\_MODE-CTL will ignores UART\_FCR[3] DMA\_MODE\_CTL bit)

#### Note

It is strongly suggested to do steps 'a' and 'b' in two separate write in order to avoid malfunction of the device.

- c. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read

out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- f. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- g. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
2. DMA mode 1 is set (both TX/RX DMA) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 01. It is almost the same as above, but steps 'a', and 'b' can be skipped:
  - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.
3. DMA mode 3 is set (TX DMA only) by registers UART\_FCR[3] DMA\_MODE = 0 and UART\_SCR[0] DMA\_MODE\_CTL = 1, UART\_SCR[2-1] DMA\_MODE\_2 = 11. It is the same as above:
  - a. Set the UART\_FCR[3] DMA\_MODE bit to 0. It is not necessary but suggested to avoid restore of DMA mode 1 during accidental reset of UART\_SCR[0] DMA\_MODE\_CTL bit. Be sure that all data was read out from RX FIFO and if it possible disable the RX side. In UART mode the RTS/CTS or XOFF/XON protocol can be used. In IrDA modes RX can be forcibly disabled by setting UART\_ACREG[5] DIS\_IR\_RX bit

---

#### Note

There can be RX DATA loss during the next steps if all DATA was not read out or there was an ongoing reception!

- b. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO).
- c. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 10 (DMA mode 2, RX only).
- d. Set the UART\_FCR[2-1] DMA\_MODE bit field to 11 (clear TX and RX FIFO and the DMA request again).
- e. Set the UART\_SCR[2-1] DMA\_MODE\_2 bit field to 00 (no DMA) or keep 10 if RX DMA is needed.

#### 12.1.6.4.6.4.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 12-117 through Figure 12-120 show the supported DMA operations.

**Figure 12-117. UART Receive FIFO DMA Request Generation (32 Characters)**

In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UART\_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the device DMA controllers.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UART\_TLR register is written by the device DMA controllers. If an insufficient number of characters is written, the DMA request stays active.

**Figure 12-118. UART Transmit FIFO DMA Request Generation (56 Spaces)**

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UART\_TLR register.

The threshold can be programmed in a number of ways. [Figure 12-118](#) shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UART\_FCR[5-4] TX\_FIFO\_TRIG bit field or the UART\_TLR[3-0] TX\_FIFO\_TRIG\_DMA bit field concatenated with the TX\_FIFO\_TRIG bit field.

The setting of 56 spaces in the UART module must correlate with the settings of the device DMA controllers, so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART module).

[Figure 12-119](#) shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART module.

**Figure 12-119. UART Transmit FIFO DMA Request Generation (8 Spaces)**

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see [Figure 12-120](#)). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART\_DLL and UART\_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

**Figure 12-120. UART Transmit FIFO DMA Request Generation (1 Space)**

The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART\_MDR3[1] NONDEFAULT\_FREQ bit and UART\_TX\_DMA\_THRESHOLD register (see [Figure 12-121](#)). In the example, the UART\_TX\_DMA\_THRESHOLD[5-0] TX\_DMA\_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART\_DLL and UART\_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART\_MDR3[1] NONDEFAULT\_FREQ value.

The DMA settings should correspond to the system Local Host DMA controller settings in order to ensure the correct operation of this logic.

uart-036

**Figure 12-121. UART Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)**

#### 12.1.6.4.6.4.3 DMA Transmission

Figure 12-122 shows DMA transmission.

uart-030

**Figure 12-122. DMA Transmission**

1. Data to be transmitted are put in the device memory reserved for UART transmission by the DMA:
  - a. Until the TX FIFO trigger level is not reached, a DMA request is generated
  - b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UART\_THR empty (TX FIFO empty).

#### Note

In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UART\_THR register empties.

#### 12.1.6.4.6.4.4 DMA Reception

Figure 12-123 shows DMA reception.

**Figure 12-123. DMA Reception**

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
  - a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
  - b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

#### 12.1.6.4.7 UART Mode Selection

##### 12.1.6.4.7.1 Register Access Modes

##### 12.1.6.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UART\_LCR register determines the register access mode (see [Table 12-125](#)).

**Table 12-125. UART Register Access Mode Programming (Using UART\_LCR)**

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7-0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7-0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

#### 12.1.6.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR\_SPR, TCR\_TLR, and XOFF). These registers are identified in [Table 12-149](#), *UART Load FIFO Triggers Defined by the Concatenated Value*.

[Table 12-126](#) through [Table 12-128](#) summarize the register access submodes.

**Table 12-126. UART Subconfiguration Mode A Summary**

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

**Table 12-127. UART Subconfiguration Mode B Summary**

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

**Table 12-128. UART Suboperational Mode Summary**

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

#### 12.1.6.4.7.1.3 Registers Available for the Register Access Modes

[Table 12-129](#) lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

**Table 12-129. UART Register Access Mode Overview**

Address Offset	Registers

#### 12.1.6.4.7.2 UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UART\_MDR1[2:0] MODE\_SELECT bit field (see [Table 12-130](#)).

**Table 12-130. UART Mode Selection**

Value	Mode
0x0:	UART 16× mode
0x1:	SIR mode
0x2:	UART 16× auto-baud
0x3:	UART 13× mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode
0x7:	Disable (default state)

MODE\_SELECT is effective when the module is in operational mode (see [Section 12.1.6.4.7.1, Register Access Modes](#)).

To select a RS-485 mode, set the UART\_MDR3[4] DIR\_EN bit field to 0x1.

#### 12.1.6.4.7.2.1 Registers Available for the UART Function

Only the registers listed in [Table 12-131](#) are used for the UART function.

**Table 12-131. UART Mode Register Overview**

Address Offset	Registers <sup>(1) (2)</sup>					
	Configuration Mode A		Configuration Mode B		Operational Mode

(1) REGISTER\_NAME(UART) notation indicates that the register exists for other functions (IrDA or CIR), but fields have different meanings for other functions (described separately in *UART Registers*).

(2) REGISTER\_NAME[m:n] notation indicates that only register bits numbered m to n apply to the UART function.

#### 12.1.6.4.7.2.2 Registers Available for the IrDA Function

Only the registers listed in [Table 12-132](#) are used for the IrDA function.

**Table 12-132. IrDA Mode Register Overview**

Address Offset	Registers <sup>(1) (2)</sup>

### 12.1.6.4.8 UART Protocol Formatting

#### 12.1.6.4.8.1 UART Mode

##### 12.1.6.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-124 shows the baud rate generator and associated controls.

**Figure 12-124. UART Baud Rate Generation**

#### CAUTION

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), UART\_MDR1[2-0] MODE\_SELECT = DISABLE must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

##### 12.1.6.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16× mode: Divisor value = Operating frequency / (16× baud rate)
- UART 13× mode: Divisor value = Operating frequency / (13× baud rate)

Table 12-134 describe the UART baud rate settings.

**Table 12-134. UART Baud Rate Settings (48-MHz Clock)**

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
0.3 kbps	16x	10000	0x27, 0x10	0.3 kbps	0

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
1.843 Mbps	13x	2	0x00, 0x02	1.846 Mbps	+0.16
3.6884 Mbps	13x	1	0x00, 0x01	3.6923 Mbps	+0.16

#### 12.1.6.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

##### 12.1.6.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UART\_LCR register.

Character length is specified using the UART\_LCR[1-0] CHAR\_LENGTH bit field.

The number of stop-bits is specified using the UART\_LCR[2] NB\_STOP bit.

The parity bit is programmed using the UART\_LCR[5-3] PARITY\_EN, UART\_LCR[5-3] PARITY\_TYPE\_1, and UART\_LCR[5-3] PARITY\_TYPE\_2 bit fields (see [Table 12-135](#)).

**Table 12-135. UART Parity Bit Encoding**

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

##### 12.1.6.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UART\_EFR[7] AUTO\_CTS\_EN and UART\_EFR[6] AUTO\_RTS\_EN bit fields, respectively.

With auto-CTS, CTS signal must be active before the module can transmit data.

Auto-RTS activates the RTS output only when there is enough room in the RX FIFO to receive data. It deactivates the RTS output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UART\_TCR register determine the levels at which RTS is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UART\_TCR register. RTS is active if the RX FIFO level is below the HALT trigger level in the UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT bit field. When the RX FIFO HALT trigger level is reached, RTS is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

RTS is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UART\_TCR[7-4] RX\_FIFO\_TRIG\_START bit field. This reassertion requests the sending device to resume transmission.

In this case, RTS is an active-low signal.

- Auto-CTS:

The transmitter circuitry checks CTS before sending the next data byte. When CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, CTS must be deasserted before the middle of the last stop-bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the CTS state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, CTS is an active-low signal.

#### 12.1.6.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UART\_EFR) and the modem control register (UART\_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UART\_EFR[3-0] bit field (see [Table 12-136](#)).

Two other enhanced features relate to software flow control:

- XON-any function (UART\_MCR[5] XON\_EN): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

#### Note

The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UART\_EFR[5] SPECIAL\_CHAR\_DETECT): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UART\_IIR\_UART) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UART\_IIR\_UART. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

**Table 12-136. UART\_EFR[3:0] Software Flow Control Options**

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 <sup>(1)</sup>

- (1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.  
XON1 is defined in the UART\_XON1\_ADDR1[7-0] XON\_WORD1 bit field. XON2 is defined in the UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit field.  
XOFF1 is defined in the UART\_XOFF1[7-0] XOFF\_WORD1 bit field. XOFF2 is defined in the UART\_XOFF2[7-0] XOFF\_WORD2 bit field.

#### 12.1.6.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of

XOFF also sets the UART\_IIR\_UART[4] bit (if enabled by UART\_IER\_UART[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UART\_IIR\_UART[4] bit is cleared and the XOFF interrupt disappears.

---

#### Note

When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

---

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UART\_EFR[1-0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UART\_EFR[1-0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

#### 12.1.6.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UART\_TCR[3-0] RX\_FIFO\_TRIG\_HALT. As soon as the RX FIFO reaches the trigger level programmed by UART\_TCR[7-4] RX\_FIFO\_TRIG\_START, two XON1 characters are sent, so the data transfer recovers.

---

#### Note

If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

---

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

#### 12.1.6.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UART\_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

---

#### Note

The combination of 7-bit character plus space parity is not supported.

---

Autobauding mode is selected when the UART\_MDR1[2-0] MODE\_SELECT bit field is set to 0x2. In UART autobauding mode, UART\_DLL, UART\_DLH, and UART\_LCR[5-0] bit field settings are not used; instead, the UART\_UASR register is updated with the configuration detected by the autobauding logic.

#### UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UART\_LCR, UART\_DLL, and UART\_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UART\_MDR1[2-0] MODE\_SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115.2 bps (10 possibilities)

#### 12.1.6.4.8.1.3.5 Error Detection

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UART\_LSR\_UART register and then reading the UART\_RHR register identifies errors in a character.

Reading the UART\_RHR register updates the BI, FE, and PE bits (see [Table 12-120](#) for the UART mode interrupts).

The UART\_LSR\_UART[7] RX\_FIFO\_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

### Note

Reading the UART\_LSR\_UART register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UART\_RHR register.

Reading the UART\_LSR\_UART register clears the OE bit if it is set (see [Table 12-120](#) for the UART mode interrupts).

#### 12.1.6.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the Host CPU with the UART\_IIR\_UART[5-1] IT\_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the Host CPU must:

- Reset the RX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

#### 12.1.6.4.8.1.3.7 Time-Out and Break Conditions

##### 12.1.6.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (RX) is high for a time that equals 4x the programmed word length + 12 bits or manually configured amount of baud clocks, if a value other zero is set in the timeout register. RX is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on RX.

There are two modes of operation:

- In default operation on the UART\_EFR2[6] TIMEOUT\_BEHAVE is set to 0. For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on RX or when the UART\_RHR register is read.
- Optionally, for choose to enable the timeout counter even if no character has been received by setting UART\_EFR2[6] TIMEOUT\_BEHAVE bit. This will generate periodic interrupts if the RX line remains idle. In this mode the counter will auto-reset when a timeout has been reached. Reading the UART\_IIR\_UART will clear the interrupt, but not the counter.

##### 12.1.6.4.8.1.3.7.2 Break Condition

When a break condition occurs, TX is pulled low. A break condition is activated by setting the UART\_LCR[6] BREAK\_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UART\_LSR\_UART[6] TX\_SR\_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK\_EN bit to 1.

The break condition is asserted while the BREAK\_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

#### 12.1.6.4.8.2 RS-485 Mode

##### 12.1.6.4.8.2.1 RS-485 External Transceiver Direction Control

The UART\_MDR3[4] DIR\_EN bit enables hardware control over an external transceiver to support RS-485. The direction signal comes across the DIR port. The direction polarity is controlled by the UART\_MDR3[3] DIR\_POL bit. The direction is determined by the hardware monitoring the TX FIFO and the TX shift register. When both are empty the transceiver is set to RX. There is a guard band delay counter of 3 bit clock cycles after the TX

shift register is going empty to allow time for the stop bit to transition through the transceiver before a direction change to receive might be applied.

Figure 12-125 shows the direction control.

**Figure 12-125. RS-485 External Transceiver Direction Control**

#### 12.1.6.4.8.3 IrDA Mode

##### 12.1.6.4.8.3.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 12-126 shows the baud rate generator and associated controls.

uart-033

**Figure 12-126. IrDA Baud Rate Generator**

**CAUTION**

Before initializing or modifying clock parameter controls (UART\_DLH, UART\_DLL), MODE\_SELECT=DISABLE (UART\_MDR1[2-0] MODE\_SELECT) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

**12.1.6.4.8.3.2 Choosing the Appropriate Divisor Value**

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16× baud rate)
- MIR mode: Divisor value = Operating frequency/(41×/42× baud rate)
- FIR mode: Divisor value = None

Table 12-137 lists the IrDA baud rate settings.

**Table 12-137. IrDA Baud Rate Settings**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 μs

**Table 12-137. IrDA Baud Rate Settings (continued)**

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
0.576 Mbps	MIR	41×/42×	1/4	2	0.5756 Mbps <sup>(1)</sup>	0	+1.63/-0.80	416 ns
1.152 Mbps	MIR	41×/42×	1/4	1	1.1511 Mbps <sup>(1)</sup>	0	+1.63/-0.80	208 ns
4 Mbps	FIR	6×	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

#### Note

Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

#### 12.1.6.4.8.3.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

##### 12.1.6.4.8.3.3.1 IR RX Polarity Control

The UART\_MDR2[6] IRRXINVERT bit provides the flexibility to invert the RX pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.

##### 12.1.6.4.8.3.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the RX input can be disabled by the UART\_ACREG[5] DIS\_IR\_RX bit.

##### 12.1.6.4.8.3.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART\_XON1\_ADDR1[7-0] XON\_WORD1 and UART\_XON2\_ADDR2[7-0] XON\_WORD2 bit fields.

Setting the UART\_EFR[0] bit to 1 selects address1 checking. Setting the UART\_EFR[1] bit to 1 selects address2 checking. Setting the UART\_EFR[1-0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

##### 12.1.6.4.8.3.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 0. The Host CPU writes the value of the frame length to the UART\_TXFLH and UART\_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the UART\_MDR1[7] FRAME\_END\_MODE bit to 1. The Host CPU writes 1 to the UART\_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the Host CPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

##### 12.1.6.4.8.3.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the Host CPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the Host CPU writes 1 to the UART\_ACREG[2] SCTX\_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART\_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

#### **12.1.6.4.8.3.3.6 Error Detection**

When the UART\_LSR\_UART register is read, the UART\_LSR\_UART[4-2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see [Table 12-121](#)). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

#### **12.1.6.4.8.3.3.7 Underrun During Transmission**

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the Host CPU must:

- Reset the TX FIFO.
- Read the UART\_RESUME register, which clears the internal flag.

This function can be disabled by the UART\_ACREG[4] DIS\_TX\_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

#### **12.1.6.4.8.3.3.8 Overrun During Receive**

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see [Section 12.1.6.4.8.1.3.6, Overrun During Receive](#)).

#### **12.1.6.4.8.3.3.9 Status FIFO**

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART\_SFREGH[3-0] MSB and UART\_SFREGL[3-0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART\_SFLSR register. Reading the UART\_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The Host CPU uses the frame-length information to locate the frame boundary in the received frame data. The Host CPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the Host CPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

#### **12.1.6.4.8.3.3.10 Multi-drop Parity Mode with Address Match**

Multi-drop mode is enabled in the UART\_EFR2 register.

Address matching mode is only available with 8 bit character length setting. UART\_LCR[1-0] CHAR\_LENGTH bit fields should always be set to 0x11 (8 bits) prior to enabling the feature.

This mode allows the transmitter to send data on a line where multiple receivers are connected, when supported. In this mode, a set parity bit is used to mark an address, and a parity of 0 denotes data.

This setting affects how the parity is generated. Writing a 0x1 into the UART\_ECR[0] A\_MULTIDROP bit will set the parity bit for the next byte to be sent, which will then be considered an address, for sending a data frame, the UART\_ECR[0] A\_MULTIDROP bit has to be cleared.

On reception if the feature is enabled by setting the UART\_EFR2[2] MULTIDROP bit to 0x1 incoming frames with parity set to 0x1 are treated as address frames and with parity set to 0x0 as data frames. The receiver will drop all data frames until a matching address frame was found.

The matching address is determined by the values set in UART\_MAR, UART\_MMR and UART\_MBR registers and the value set in UART\_EFR2[7] BROADCAST bit.

Table 12-138 summarizes the operation of address matching based on the mentioned values.

**Table 12-138. Details of address matching**

Received frame	Received parity	Frame type	UART_MAR	UART_MMR	UART_MBR	UART_EFR2[7] BROADCAST	Operation of receiver	Address matching
0xXX <sup>(2)</sup>	0	DATA	X <sup>(1)</sup>	X <sup>(1)</sup>	0xXX <sup>(2)</sup>	X <sup>(1)</sup>	Drops data until matching address found	N/A
0xXX <sup>(2)</sup>	1	ADDRESS	0xXX <sup>(2)</sup>	0x00	0xXX <sup>(2)</sup>	0	Matches any address	Yes
0xEF	1	ADDRESS	0xXX <sup>(2)</sup>	0xXX <sup>(2)</sup>	0xEF	1	Matches broadcast address	Yes
0x1A	1	ADDRESS	0x1A	0xFF	0xXX <sup>(2)</sup>	0	Single address match	Yes
0xF5	1	ADDRESS	0xF3	0xF9	0xXX <sup>(2)</sup>	0	Group address match	Yes

(1) X indicates a do not care bit value

(2) 0xXX indicates a do not care 8 bit hexadecimal value

The possible values for matching address can be calculated in the following way:

- Single and Group addresses can be formed by masking the UART\_MAR registers value with the value set in the UART\_MMR register, bits set to 0x0 in the UART\_MMR register result in do not care values.
- Broadcast addresses can be set in the UART\_MBR register if broadcast address is enabled in the UART\_EFR2[7] BROADCAST bit, the module will match on received address frames containing the broadcast address.
- For more details, see example below:
  - UART\_MAR: 0xF3, UART\_MMR: 0xF9, UART\_MBR: 0xFF
  - Single and Group addresses: 0xF1, 0xF3, 0xF5, 0xF7
  - Broadcast addresses: 0xFF

If an address match occurred the matching address value can be obtained from the UART\_RHR register in the following way:

- If the FIFO is disabled or the threshold is set to 0x1, the matching address can be directly read from UART\_RHR as the FIFO will not be overwritten.
- If the FIFO is enabled or the threshold is greater than 0x1, the matching address will be the latest frame in the FIFO with a parity error bit set.

For received data, the parity error bit in the UART\_LSR\_UART register is set when a bit with a parity of 0x1 is received indicating an address frame and the received address matches based on the values of UART\_MAR, UART\_MMR, UART\_MBR and UART\_EFR2[2] MULTIDROP bit.

In Multi-drop mode no parity is used, as the parity bit is used to differentiate address and data frames. The parity error bit is used for indicating an address match.

For enabling the interrupt generation for address matching UART\_IER\_UART[2] LINE\_STS\_IT bit has to be set to 0x1.

An interrupt for the matching address can be identified by reading the UART\_IIR\_UART[5-1] IT\_TYPE bit fields, a value of 0x00011 indicates a receiver line status error. After the UART\_LSR\_UART[2] RX\_PE bit has to be read, a value of 0x1 indicates that an address match occurred. The reception of a frame is indicated with a value

of 0x1 in the UART\_LSR\_UART[0] RX\_FIFO\_E bit as the matching value is written into the FIFO regardless of the frame type (data or address). UART\_LSR\_UART[7] RX\_FIFO\_STS bit will also be set to 0x1 as the parity error bit is used to indicate a matching address.

Note that the operation of the UART\_LSR\_UART[2] RX\_PE bit depends on the value set in UART\_EFR2[2] MULTIDROP bit. If UART\_EFR2[2] MULTIDROP bit is set to 0x0, UART\_LSR\_UART[2] RX\_PE bit is used to indicate a received parity error. If UART\_EFR2[2] MULTIDROP bit is set to 0x1, the receiver is in Multi-drop Address Match mode, thus the value in UART\_LSR\_UART[2] RX\_PE bit is used to indicate an address match.

The interrupt is cleared the same way in both operation modes: reading the UART\_LSR\_UART register updates the values.

This feature is available in UART and synchronous modes. The ISO7816 has not defined Multidrop Parity Mode, so the feature should be left off.

#### **12.1.6.4.8.3.3.11 Time-guard**

The time-guard feature enables the UART interface to operate with slow remote devices.

When set, it will insert a number of idle states between transmitting two characters, the length of which can be set in the UART\_TIMEGUARD register. The value in the register defines the number of baud clocks of idle period to insert.

This idle state essentially acts like a long stop bit. In UART and synchronous modes, a Timeguard is added in addition to the stop bit. In ISO7816 there is a waiting period rather than an actual stop bit. Software should set 1-2 or more Timeguard cycles according to the protocol used and the card requirements.

#### **12.1.6.4.8.3.4 SIR Mode Data Formatting**

This section provides specific instructions for SIR mode programming.

##### **12.1.6.4.8.3.4.1 Abort Sequence**

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART\_ACREG[1] ABORT\_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

#### **CAUTION**

When the TX FIFO is not empty and the UART\_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

##### **12.1.6.4.8.3.4.2 Pulse Shaping**

SIR mode supports the 3/16 or the 1.6-μs pulse duration methods. The UART\_ACREG[7] PULSE\_TYPE bit selects the pulse width method in the transmit mode.

##### **12.1.6.4.8.3.4.3 SIR Free Format Programming**

The SIR FF mode is selected by setting the module in the UART mode (UART\_MDR1[2-0] MODE\_SELECT = 0x0) and the UART\_MDR2[3] PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART\_LCR[1-0] CHAR\_LENGTH bit field = 0x3 (8 data bits)
- UART\_LCR[2] NB\_STOP bit = 0x0 (1 stop-bit)
- UART\_LCR[3] PARITY\_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

#### **12.1.6.4.8.3.5 MIR and FIR Mode Data Formatting**

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the CPU reads the line status register (UART\_LSR\_UART) to detect errors in the received frame.

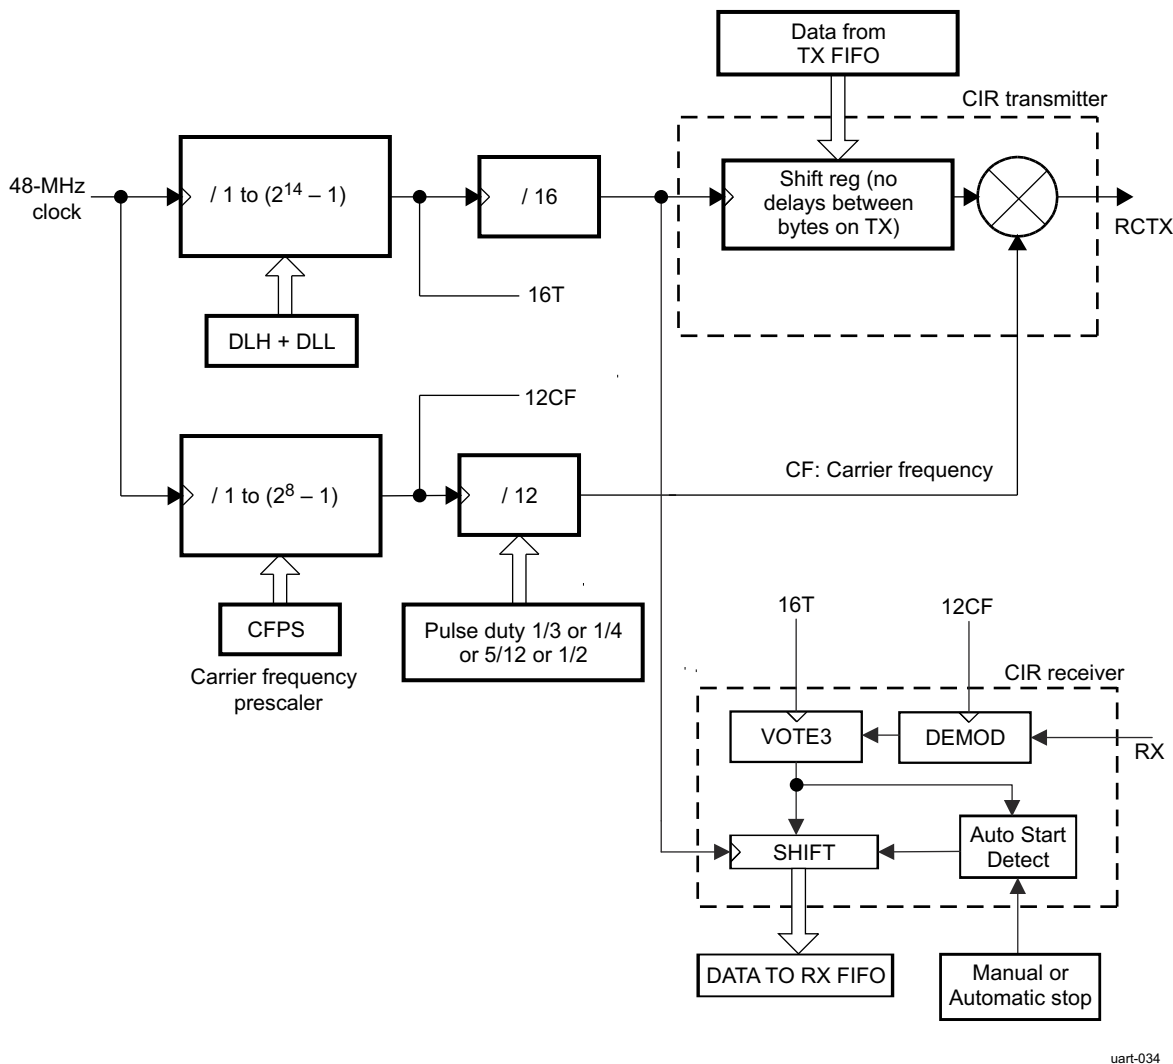

When the UART\_MDR1[6] SIP\_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP\_MODE bit is set to 0, SIP transmission depends on the UART\_ACREG[3] SEND\_SIP bit.

The CPU can set the SEND\_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

#### **12.1.6.4.8.4 CIR Mode**

##### **12.1.6.4.8.4.1 CIR Mode Clock Generation**

Depending on the encoding method (variable pulse distance/biphase), the Host CPU must develop a data structure that combines 1 and 0 with a  $t$  period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 12-127](#).

uart-034

**Figure 12-127. CIR Mode Block Components**

Based on the requested modulation frequency, the UART\_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK} / 12) / \text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

#### Note

The UART\_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART\_MDR2 register. [Table 12-139](#) shows the duty cycle.

**Table 12-139. CIR Duty Cycle**

UART_MDR2[5-4] CIR_PULSE_MODE	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

#### 12.1.6.4.8.4.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

##### 12.1.6.4.8.4.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see [Section 12.1.6.4.8.3.3.1, IR RX Polarity Control](#)).

##### 12.1.6.4.8.4.2.2 CIR Transmission

In transmission, the Host CPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a  $t$  period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART\_MDR1[5] SCT bit and the UART\_ACREG[2] SCTX\_EN bit, depending on the timer status
  - Using the UART\_IIR\_UART[5] TX\_STATUS\_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

##### 12.1.6.4.8.4.2.3 CIR Reception

There are 2 ways to stop a CIR reception:

- The Host CPU can disable the reception by setting the UART\_ACREG[5] DIS\_IR\_RX bit to 1. When it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the UART\_ACREG[5] DIS\_IR\_RX bit must be set to 0.
- An automatic stop mechanism can be configured by setting a value in the BOF length register (UART\_EBLR). If the value set in the UART\_EBLR register is different than 0, this feature is enabled and the number of bits received will begin counting from 0. When the counter reaches the value defined in the UART\_EBLR register, reception is automatically disabled and UART\_IIR\_CIR[2] RX\_STOP\_IT bit is set. When a 1 is detected on the RX pin, reception is automatically re-enabled.

There is a limitation when receiving data in UART CIR mode. Certain IrDA transceivers on the market have a characteristic that causes shrinking of the received modulation pulse hold-time. The UART receive filtering schema is based on the same encoding mechanism used for transmission.

For the following scenario:

- Shift register period: 0.9μs
- Modulation frequency: 36kHz
- Duty cycle: 1/4 of a modulation frequency period

Data sent with these conditions would contain 7µs pulses within a 28µs period. The UART expects to receive similar incoming data on receive, but various transceiver timing characteristics typically only send 2µs modulated pulses. These 2µs pulses will be filtered out and RX FIFO will not receive data. This does not affect UART CIR mode in transmission.

CIR RX demodulation can be bypassed by setting the UART\_MDR3[0] DISABLE\_CIR\_RX\_DEMOD bit.

### 12.1.6.5 UART Programming Guide

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

#### Note

Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 12.1.6.4.7.1, Register Access Modes](#).

#### 12.1.6.5.1 UART Global Initialization

##### 12.1.6.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the UART module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the UART.

For more information, see [Table 12-140](#).

**Table 12-140. UART Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
LPSC0	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
LPSC3	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
LPSC7	Module reset must be enabled. For more information about the module configuration, see <i>Reset</i> .
PLLCTRL0	PLLCTRL0 configuration must be done to enable the clocks to the UART modules, see <i>Clocking</i> .
WKUP_PLLCTRL0	WKUP_PLLCTRL0 configuration must be done to enable the clocks to the UART modules, see <i>Clocking</i> .
WKUP_HFOSC0	WKUP_HFOSC0 configuration must be done to enable the clocks to the UART modules, see <i>Clocking</i> .
PLL1	PLL1 configuration must be done to enable the clocks to the UART modules, see <i>Clocking</i> .
MCU_PLL1	MCU_PLL1 configuration must be done to enable the clocks to the UART modules, see <i>Clocking</i> .
COMPUTE_CLUSTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling COMPUTE_CLUSTER0 interrupts, see <i>Interrupts</i> .
R5FSS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0/1_INTRTR0 interrupts, see <i>Interrupts</i> .
MCU_R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MCU_R5FSS0_CORE0/1 interrupts, see <i>Interrupts</i> .
WKUP_DMSC0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling WKUP_DMSC0 interrupts, see <i>Interrupts</i> .
PRU-ICSSG0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling PRU_ICSSG0/1 interrupts, see <i>Interrupts</i> .
C66SS0/1_INTRTR0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling C66SS0/1_INTRTR0 interrupts, see <i>Interrupts</i> .
MAIN2MCU_LVL_INTROUTER0	Device INTCs must be configured to enable the interrupt request generation. For information about enabling MAIN2MCU_LVL_INTROUTER0 interrupts, see <i>Interrupts</i> .
R5FSS0_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS0_CORE0/1 interrupts, see <i>Interrupts</i> .

**Table 12-140. UART Global Initialization of Surrounding Modules (continued)**

Surrounding Modules	Comments
R5FSS1_CORE0/1	Device INTCs must be configured to enable the interrupt request generation. For information about enabling R5FSS1_CORE0/1 interrupts, see <i>Interrupts</i> .
MCU_PDMA0	MCU_PDMA0 controllers configuration must be done to enable the module MCU_PDMA0 channel request, see <i>Data Movement Architecture (DMA)</i> .
PDMA_UART_G0	PDMA_UART_G0 controllers configuration must be done to enable the module PDMA_UART_G0 channel request, see <i>Data Movement Architecture (DMA)</i> .
PDMA_UART_G1	PDMA_UART_G1 controllers configuration must be done to enable the module PDMA_UART_G1 channel request, see <i>Data Movement Architecture (DMA)</i> .
PDMA_UART_G2	PDMA_UART_G2 controllers configuration must be done to enable the module PDMA_UART_G2 channel request, see <i>Data Movement Architecture (DMA)</i> .
Interconnects	For information about the WKUP_CBASS0, MCU_CBASS0, and CBASS0 interconnects configuration, see <i>System Interconnect</i> .

#### 12.1.6.5.1.2 UART Module Global Initialization

The procedure in [Table 12-141](#) can be used to initialize UART when performing software reset.

**Table 12-141. UART Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	UART_SYSC[1] SOFTRESET	1
Wait until reset is finished.	UART_SYSS[0] RESETDONE	=1

#### 12.1.6.5.2 UART Mode selection

[Table 12-142](#) describes how to set different register access mode.

**Table 12-142. UART Configure Register Access Mode**

Step	Register/Bit Field/Programming Model	Value
Set the register access mode A	UART_LCR[7] DIV_EN	1
	UART_LCR[7-0]	≠0xBF
Set the register access mode B	UART_LCR[7-0]	0xBF
Set the operational mode	UART_LCR[7] DIV_EN	0

#### 12.1.6.5.3 UART Submode selection

This section describes how to set different register access submode.

**Table 12-143. UART Configure Register Access Submode TCR\_TLR**

Step	Register/Bit Field/Programming Model	Value
Configure the submode TCR_TLR		
Configure mode B	see <a href="#">Table 12-142</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1
Configure mode A	see <a href="#">Table 12-142</a>	0x1
Set the submode TCR_TLR	UART_MCR[6] TCR_TLR	1

**Table 12-144. UART Configure Register Access Submode MSR\_SPR**

Step	Register/Bit Field/Programming Model	Value
First option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-142</a>	
Set the submode MSR_SPR	UART_EFR[4] ENHANCED_EN	0
Second option: configure the submode MSR_SPR		
Configure mode B	see <a href="#">Table 12-142</a>	
Enable writing to register bits UART_MCR[7-5]	UART_EFR[4] ENHANCED_EN	1

**Table 12-144. UART Configure Register Access Submode MSR\_SPR (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the submode MSR_SPR	UART_MCR[6] TCR_TLR	0

**Table 12-145. UART Configure Register Access Submode XOFF**

Step	Register/Bit Field/Programming Model	Value
Configure of the XOFF		
Configure B	see <a href="#">Table 12-142</a>	
Set the submode XOFF	UART_EFR[4] ENHANCED_EN	0

**12.1.6.5.4 UART Load FIFO trigger and DMA mode settings****12.1.6.5.4.1 DMA mode Settings**

To enable and configure program the DMA mode, perform the following steps:

**Table 12-146. DMA Mode Settings**

Step	Register/Bit Field/Programming Model	Value
Set the option of DMA mode configuration	UART_SCR[0] DMA_MODE_CTL	-
IF Configure DMA mode 0 and 1	UART_SCR[0] DMA_MODE_CTL	=0
Select the DMA mode, for more information see <a href="#">Section 12.1.6.4.6.4</a>	UART_FCR[3] DMA_MODE	-
IF Configure DMA mode from 0 to 3	UART_SCR[0] DMA_MODE_CTL	=1
Select the DMA mode, for more information see <a href="#">Section 12.1.6.4.6.4</a>	UART_SCR[2-1] DMA_MODE_2	-

**12.1.6.5.4.2 FIFO Trigger Settings**

In this section is described configuration and settings of FIFO trigger level, which enable DMA and interrupt generation.

**Table 12-147. Load FIFO Triggers Defined by the FCR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-143</a>	0x-
Set the desire RX FIFO trigger level	UART_FCR[5-4] TX_FIFO_TRIG	0x-
Set the desire TX FIFO trigger level	UART_FCR[7-6] RX_FIFO_TRIG	0x-

**Table 12-148. Load FIFO Triggers Defined by the TLR**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-143</a>	0x-
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA	0x-
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA	0x-

**Table 12-149. Load FIFO Triggers Defined by the Concatenated Value**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-143</a>	0x-
Set the register bit	UART_SCR[7] RX_TRIG_GRANU1	1
Set the desire RX FIFO trigger level	UART_TLR[7-4] RX_FIFO_TRIG_DMA UART_FCR[7-6] RX_FIFO_TRIG	0x-
Set the register bit	UART_SCR[6] TX_TRIG_GRANU1	1
Set the desire TX FIFO trigger level	UART_TLR[3-0] TX_FIFO_TRIG_DMA UART_FCR[5-4] TX_FIFO_TRIG	0x-

### 12.1.6.5.5 UART Protocol, Baud rate and interrupt settings

#### 12.1.6.5.5.1 Baud rate settings

**Table 12-150. UART Baud Rate Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Switch to register configuration mode B	see <a href="#">Table 12-142</a>	
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-142</a>	
Disable sleep mode	UART_IER_UART[4] SLEEP_MODE	0
Switch to register configuration mode A or B	see <a href="#">Table 12-142</a>	
Set the appropriate divisor value	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x-

#### 12.1.6.5.5.2 Interrupt settings

**Table 12-151. UART Interrupt Settings**

Step	Register/Bit Field/Programming Model	Value
Switch to register configuration mode B	see <a href="#">Table 12-142</a>	0x7
Enable access to UART_IER_UART[7-4]	UART_EFR[4] ENHANCED_EN	1
Switch register operational mode	see <a href="#">Table 12-142</a>	
Set the desired interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt)	UART_IER_UART[7] CTS_IT UART_IER_UART[6] RTS_IT UART_IER_UART[5] XOFF_IT UART_IER_UART[4] SLEEP_MODE UART_IER_UART[3] MODEM_STS_IT UART_IER_UART[2] LINE_STS_IT UART_IER_UART[1] THR_IT UART_IER_UART[0] RHR_IT	0x-

#### 12.1.6.5.5.3 Protocol settings

Load the desired protocol formatting (parity, stop-bit, character length) and switch to register operational mode.

**Table 12-152. UART Protocol Settings**

Step	Register/Bit Field/Programming Model	Value
Load desired protocol formatting, see <a href="#">Section 12.1.6.4.8.1.3.1</a> , <i>Frame Formatting</i>	UART_LCR[5] PARITY_TYPE_2 UART_LCR[4] PARITY_TYPE_1 UART_LCR[3] PARITY_EN UART_LCR[2] NB_STOP UART_LCR[1-0] PARITY_LENGTH	0x-
Switch to register operational mode	UART_LCR[7] DIV_EN UART_LCR[6] BREAK_EN	0

#### 12.1.6.5.5.4 UART/RS-485/IrDA(SIR/MIR/FIR)/CIR

**Table 12-153. UART Mode Selection**

Step	Register/Bit Field/Programming Model	Value
Load the desired UART/IrDA (SIR, MIR, FIR)/CIR modes, see <a href="#">Section 12.1.6.4.7.2</a> , <i>UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</i>	UART_MDR1[2-0] MODE_SELECT	0x-

**Table 12-153. UART Mode Selection (continued)**

Step	Register/Bit Field/Programming Model	Value
Load the desired RS-485 mode, see <a href="#">Section 12.1.6.4.7.2, UART/RS-485/IrDA (SIR, MIR, FIR)/CIR Mode Selection</a>	UART_MDR3[4] DIR_EN	0x1

**12.1.6.5.5.5 UART Multi-drop Parity Address Match Mode Configuration****Table 12-154. UART Multi-drop Parity Address Match Mode Configuration**

Step	Register/Bit Field/Programming Model	Value
Disable receive mode	UART_ECR[3] RX_EN	0
Enable Multi-drop parity Address match mode	UART_EFR2[2] MULTIDROP	1
Set the matching device address	UART_MAR[7-0] ADDRESS	0x-
Set the address match masking	UART_MMR[7-0] MASK	0x-
Set the broadcast address match	UART_MBR[7-0] BROADCAST_ADDRESS	0x-
Enable broadcast address matching if needed	UART_EFR2[7] BROADCAST	1
Enable receive mode	UART_ECR[3] RX_EN	1

**12.1.6.5.6 UART Hardware and Software Flow Control Configuration**

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

**12.1.6.5.6.1 Hardware Flow Control Configuration****Table 12-155. UART Hardware Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure register submode TCR_TLR	see <a href="#">Table 12-143</a>	0x7
Load the start and halt trigger value.	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable receive and transmit hardware flow control mode.	UART_EFR[7] AUTO_CTS_EN UART_EFR[6] AUTO_RTS_EN	0x-

**12.1.6.5.6.2 Software Flow Control Configuration****Table 12-156. UART Software Flow Control Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the register access submode XOFF	see <a href="#">Table 12-145</a>	
Load the software control characters	UART_XON1_ADDR1[7-0] XON_WORD1 UART_XON2_ADDR2[7-0] XON_WORD2 UART_XOFF1[7-0] XOFF_WORD1 UART_XOFF2[7-0] XOFF_WORD2	0x-
Set the register access submode TCR_TLR	see <a href="#">Table 12-143</a>	
Enable or disable XON any function (0: Disable; 1: Enable).	UART_MCR[5] XON_EN	--
Load start and halt trigger value for software flow control	UART_TCR[7-4] AUTO_RTS_START UART_TCR[3-0] AUTO_RTS_HALT	0x-
Enable or disable special character function (0: Disable; 1: Enable)	UART_EFR[5] SPEC_CHAR	0x-
Set the software flow control mode	UART_EFR[3-0] SW_FLOW_CONTROL	0x-

### 12.1.6.5.7 IrDA Programming Model

#### 12.1.6.5.7.1 SIR mode

##### 12.1.6.5.7.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 115.2 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

**Table 12-157. SIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate(115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB	0x1A
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

##### 12.1.6.5.7.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 115.2 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

**Table 12-158. SIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 Kbps)	UART_DLL[7-0] CLOCK_LSB	0x1A
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 6 bytes	UART_TXFLL[7-0] TXFLL	0x06
Set the seven starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
Set SIR pulse width to be 1.6 $\mu$ s	UART_ACREG[7] PULSE_TYPE	1

#### 12.1.6.5.7.2 MIR mode

##### 12.1.6.5.7.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-159. MIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (1.152 bps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set MIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00

**Table 12-159. MIR Mode Receive Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Force outputs DTR and RTS to active	UART_MCR[1-0]	0x3
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

#### 12.1.6.5.7.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mbps, and FIFOs disabled.

**Table 12-160. MIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Load the baud rate (115.2 kbps)	UART_DLL[7-0] CLOCK_LSB	0x01
	UART_DLH[5-0] CLOCK_MSB	0x00
Set SIR mode	UART_MDR1[2-0] MODE_SELECT	0x4
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	0x1
Set transmit frame length to 60 bytes	UART_TXFLL[7-0] TXFLL	0x3C
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

#### 12.1.6.5.7.3 FIR mode

##### 12.1.6.5.7.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

**Table 12-161. FIR Mode Receive Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB	0x0
	UART_DLH[7-0] CLOCK_MSB	
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.6.5.4</a> , <i>Load FIFO trigger and DMA mode settings</i>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x5
Set frame length	UART_RXFLL[7-0] RXFLL	0xA
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Enable the UART_RHR interrupt	UART_IER_IRDA[0] RHR_IT	1

##### 12.1.6.5.7.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

**Table 12-162. FIR Mode Transmit Settings**

Step	Register/Bit Field/Programming Model	Value
Disable UART mode	UART_MDR1[2-0] MODE_SELECT	0x7

**Table 12-162. FIR Mode Transmit Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Grant access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x80
Enable access to change UART_FCR[0]	UART_DLL[7-0] CLOCK_LSB UART_DLH[5-0] CLOCK_MSB	0x0
FIFO clear and enable	UART_FCR[2-0]	0x7
Set the FIFO trigger level	see <a href="#">Section 12.1.6.5.4, Load FIFO trigger and DMA mode settings</a>	
Set FIR mode	UART_MDR1[2-0] MODE_SELECT	0x1
Disable access to the UART_DLL and UART_DLH registers	UART_LCR[7-0]	0x00
Set FIR mode and enable auto-SIP mode	UART_MDR1[7-0]	0x45
Set frame length	UART_TXFLL[7-0] TXFLL UART_TXFLH[7-0] TXFLH	0x4 0x0
Force output DTR to active	UART_MCR[0] DTR	1
Enable the UART_THR interrupt	UART_IER_IRDA[1] THR_IT	1
Set the eight additional starts of frame transmission	UART_EBLR[7-0] EBLR	0x08
SIP is sent at the end of transmission	UART_ACREG[3] SEND_SIP	1

## 12.2 High-speed Serial Interfaces

This section describes the high-speed serial interfaces in the device.

## 12.2.1 Gigabit Ethernet MAC (MCU\_CPSW0)

This chapter describes the Gigabit Ethernet MAC (Media Access Controller). For conceptual purposes the below documentation refers to this MAC as being a two port CPSW with port 0 being the CPPI DMA host port and port 1 being the Ethernet port.

### 12.2.1.1 MCU\_CPSW0 Overview

The two-port Gigabit Ethernet MAC (MCU\_CPSW0) subsystem provides Ethernet packet communication for the device and is configured in a similar manner as an Ethernet switch.

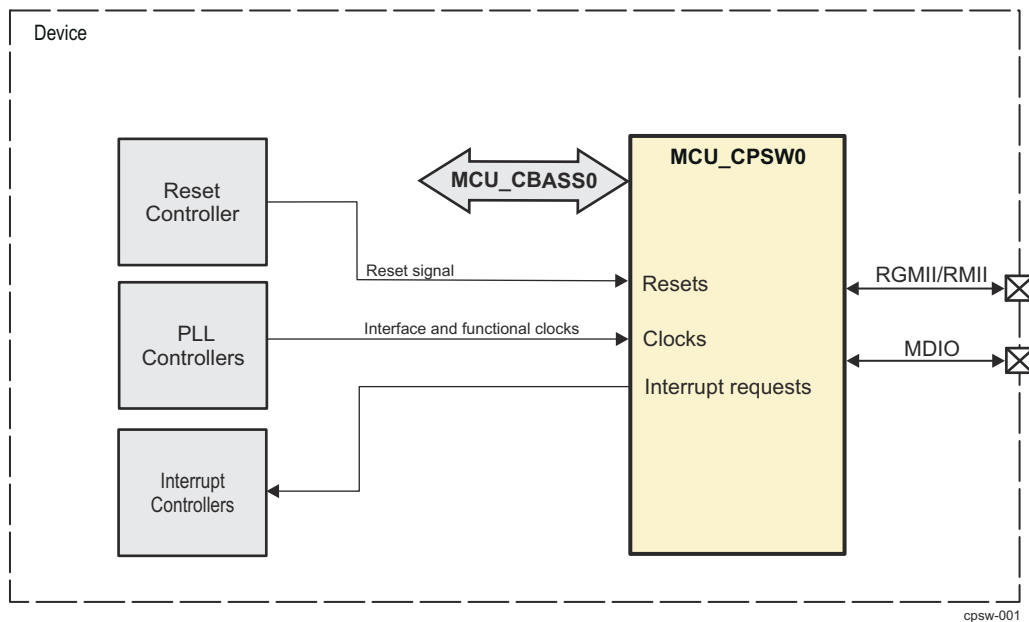

MCU\_CPSW0 features the Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII), and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

The device has integrated two-port Gigabit Ethernet Switch subsystem into device MCU domain named MCU\_CPSW0. [Table 12-163](#) shows the MCU\_CPSW0 module allocation within device domains.

**Table 12-163. MCU\_CPSW0 Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
MCU_CPSW0	-	✓	-

[Figure 12-128](#) shows the MCU\_CPSW0 module overview.

**Figure 12-128. MCU\_CPSW0 Overview**

#### 12.2.1.1.1 MCU\_CPSW0 Features

The 2-port MCU\_CPSW0 subsystem provides the following features:

- One Ethernet port (port 1) with selectable RGMII and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0)
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)

- Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
- CPTS module that supports time stamping for IEEE1588 with support for 4 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Wire rate switching (802.1d)
- Non-Blocking switch fabric
- Time Sensitive Network Support
  - IEEE P802.3br/D2.0 Interspersing Express Traffic
  - IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
  - 64 ALE table entries
  - Configurable number of addresses plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging and/or auto-aging
  - Spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based Multicast and Broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Configurable number of classifier/policers (8)
  - VLAN support
    - 802.1Q compliant
      - Auto add port VLAN for untagged frames on ingress
      - Auto VLAN removal on egress and auto pad to minimum frame size
- EtherStats and 802.3Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Ethernet Mac transmit to Ethernet Mac receive Loopback mode (digital loopback) supported
- CPSGMII Loopback Modes (transmit to receive)
- Maximum frame size of 2024 bytes
- Management Data Input/Output (MDIO) module for PHY Management with Clause 45 support
- Programmable interrupt control with selected interrupt pacing
- Host port CPPI Streaming Packet Interface (CPPI\_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

#### 12.2.1.1.2 MCU\_CPSW0 Not Supported Features

The following features are not supported for 2-port MCU\_CPSW0 switch:

- Maximum frame size of 9600 bytes
- MII and GMII Mode
- SGMII Mode
- MACSEC
- Synchronous Ethernet
- InterVLAN routing
- RGMII Internal Delay Mode disabled

#### 12.2.1.1.3 Terminology

**Terminology:**

<b>AVB</b>	Audio Video Bridging
<b>AVBTP</b>	Audio Video Bridging Transport Protocol
<b>BMCA</b>	Best Master Clock Algorithm
<b>CFI</b>	Canonical Format Indicator
<b>CPPI</b>	Communications Port Programming Interface
<b>CPSW</b>	Common Platform Switch
<b>DLR</b>	Device Level Ring
<b>DSCP</b>	Differentiated Services Code Point
<b>EEE</b>	Energy Efficient Ethernet
<b>EMAC</b>	Ethernet Media Access Control
<b>EOP</b>	End of Packet
<b>EOQ</b>	End of Queue
<b>IPG</b>	Inter-Packet Gap
<b>LPI</b>	Low Power Indicator
<b>MDIO</b>	Management Data Input/Output
<b>MOF</b>	Middle of Frame
<b>OUI</b>	Organizationally Unique Identifier
<b>PFC</b>	Priority based Flow Control
<b>PTP</b>	Precision Time Protocol
<b>RMON</b>	Remote Monitoring
<b>RTCP</b>	RTP Control Protocol
<b>RTP</b>	Real-time Transport Protocol
<b>SCR</b>	Switched Central Resource
<b>SRP</b>	Stream Reservation Protocol
<b>TOS</b>	Type of Service
<b>VLAN</b>	Virtual Local Area Network

### 12.2.1.2 MCU\_CPSW0 Environment

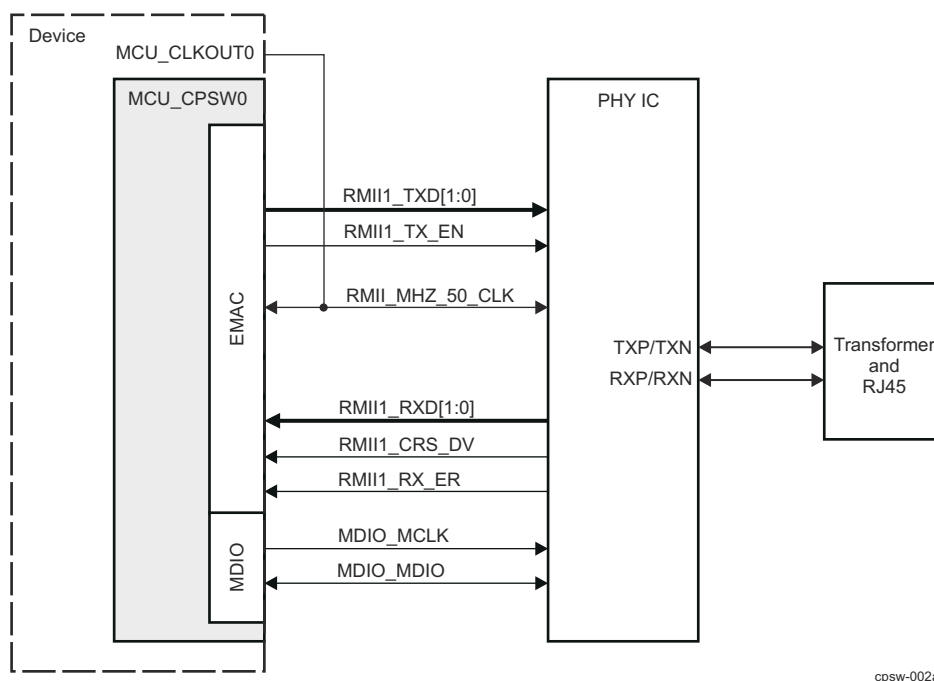

This section describes the MCU\_CPSW0 external connections (environment).

#### 12.2.1.2.1 MCU\_CPSW0 RMII Interface

Figure 12-129 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system. The individual MCU\_CPSW0 and MDIO signals for the RMII interface are summarized in Table 12-164.

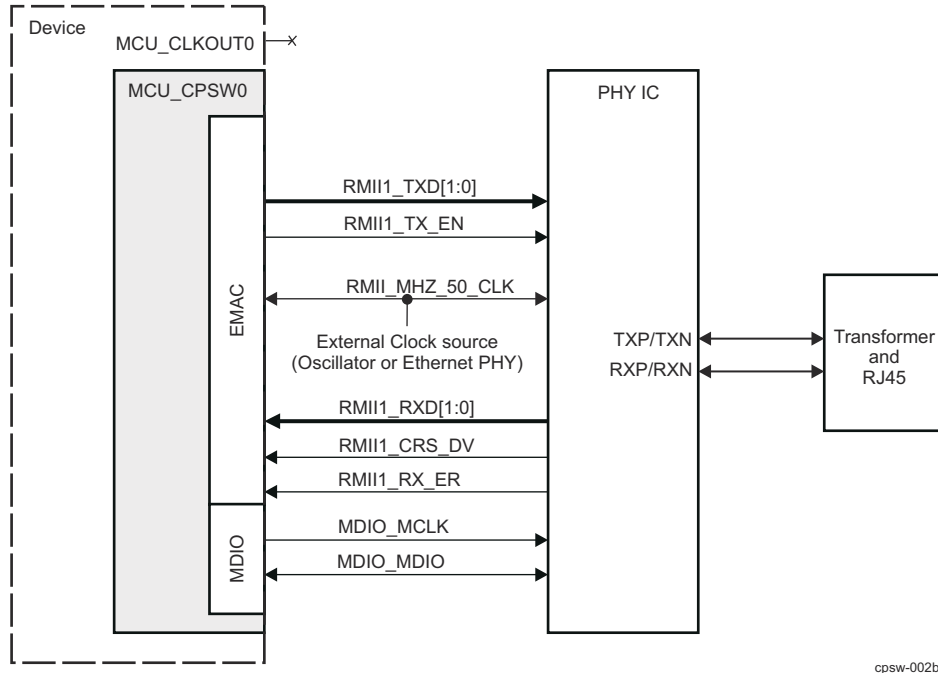

The MCU\_CPSW0 module integrated in the device supports internal and external clock sources in RMII mode. Figure 12-129 shows the internal clock source for RMII\_MHZ\_50\_CLK clock. It is 50 MHz clock source that is provided on the MCU\_CLKOUT0 device pin. This clock has to be routed on the PCB to the MCU\_RMII1\_REF\_CLK device pin and the external PHY, RMII clock input.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 12-129. RMII Interface Typical Application (Internal Clock Source)**

Figure 12-130 shows the external clock source for RMII\_MHZ\_50\_CLK clock. In this case a 50 MHz clock is available on the PCB and it can be sourced from an oscillator or from the Ethernet PHY. This externally generated clock should be routed to both MCU\_RMII1\_REF\_CLK device pin and the external PHY, RMII clock input.

cpsw-002b

**Figure 12-130. RMI1 Interface Typical Application (External Clock Source)**

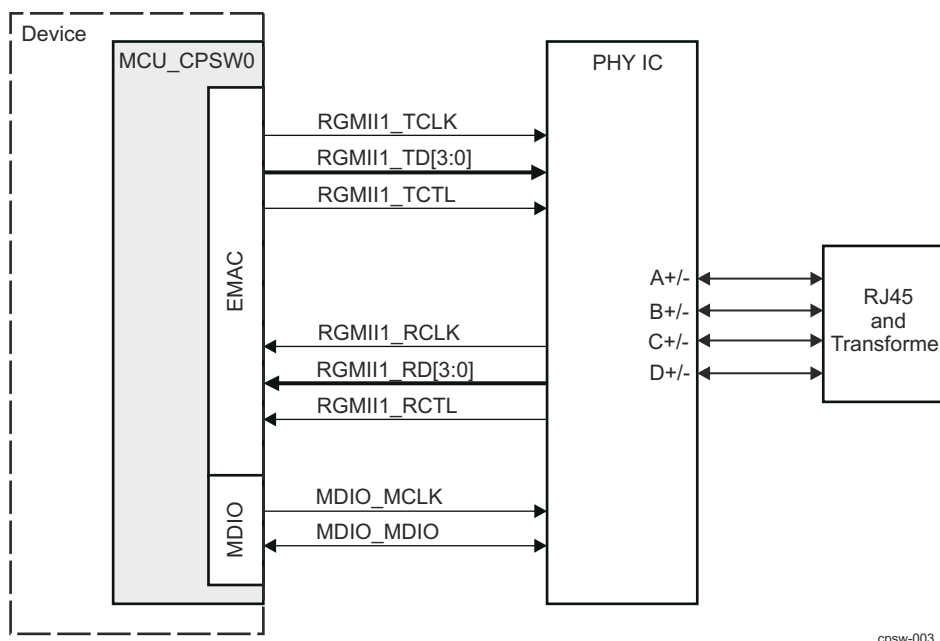

**Table 12-164. RMI1 I/O Description**

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
RMI1_TXD[1:0]	MCU_RMI1_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when RMI1_TX_EN is asserted.
RMI1_TX_EN	MCU_RMI1_TX_EN	O	RMI1 transmit enable. The transmit enable signal indicates that the MCU_RMI1_TXD[1:0] pins are generating data for use by the PHY. RMI1_TX_EN is synchronous to RMI1_MHZ_50_CLK.
RMI1_MHZ_50_CLK	MCU_RMI1_REF_CLK	I	RMI1 50MHz reference clock.  The reference clock is used to synchronize all RMI1 signals. RMI1_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMI1_RXD[1:0]	MCU_RMI1_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMI1_MHZ_50_CLK and valid only when RMI1_CRD_DV is asserted and RMI1_RX_ER is de-asserted.
RMI1_CRD_DV	MCU_RMI1_CRD_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMI1_RX_ER	MCU_RMI1_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MCLK	MCU_MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_MDIO pin.
MDIO_MDIO	MCU_MDIO0_MDIO	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

### 12.2.1.2.2 MCU\_CPSW0 RGMII Interface

Figure 12-131 shows a device with integrated EMAC and MDIO interfaced via a RGMII connection in a typical system. The individual MCU\_CPSW0 and MDIO signals for the RGMII interface are summarized in Table 12-165.

cpsw-003

**Figure 12-131. RGMII Interface Typical Application**

**Table 12-165. RGMII I/O Description**

Signal	Device Pin(s)	I/O <sup>(1)</sup>	Description
RGMII1_TD[3:0]	MCU_RGMII1_TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII1_TCTL is asserted.
RGMII1_TCTL	MCU_RGMII1_TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII1_TCLK	MCU_RGMII1_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RGMII1_RD[3:0]	MCU_RGMII1_RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII1_RCTL is asserted
RGMII1_RCTL	MCU_RGMII1_RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII1_RCLK	MCU_RGMII1_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MCLK	MCU_MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MCU_MDIO0_MDIO pin.
MDIO_MDIO	MCU_MDIO0_MDIO	I/O	The MCU_MDIO0_MDIO pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MCU_MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

---

**Note**

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see *Pad Configuration Registers* in *Control Module (CTRL\_MMR)* and the device-specific Datasheet.

---

Figure 12-132 shows the integration of the MCU CPSW0 module in the device.

The following MCU\_CPSW0 control registers are located in MCU\_CTRL\_MMR0 module: CTRLMMR\_MCU\_ENET\_CTRL, CTRLMMR\_MCU\_ENET\_CLKSEL, CTRLMMR\_MCU\_MAC\_ID0, CTRLMMR\_MCU\_MAC\_ID1.

Table 12-166 through Table 12-168 summarize the integration of the MCU\_CPSW0 module in the device.

**Table 12-166. MCU\_CPSW0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
MCU_CPSW0	WKUP_PSC0	PD0	LPSC0	MCU_CBASS0

**Table 12-167. MCU\_CPSW0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
MCU_CPSW0	CPPI_ICLK	MCU_SYSCCLK0/3	MCU_PLLCTRL	CPPI packet streaming interface clock (333-MHz). Main clock for MCU_CPSW0.
	GMII_RFT_CLK	MCU_PLL2_HSDIV0_CLK OUT/2	MCU_PLL2 (HSDIV0 of MCU_CPSW0 PLL)	125-MHz GMII Gigabit mode clock.
	RGMII_MHZ_5_CLK	MCU_PLL2_HSDIV0_CLK OUT/50	MCU_PLL2 (HSDIV0 of MCU_CPSW0 PLL)	5-MHz RGMII reference clock.
	RGMII_MHZ_50_CLK	MCU_PLL2_HSDIV0_CLK OUT/5	MCU_PLL2 (HSDIV0 of MCU_CPSW0 PLL)	50-MHz RGMII reference clock.
	RGMII_MHZ_250_CLK	MCU_PLL2_HSDIV0_CLK OUT	MCU_PLL2 (HSDIV0 of MCU_CPSW0 PLL)	250-MHz RGMII reference clock.
	RMII_MHZ_50_CLK	MCU_RMII1_REF_CLK	MCU_RMII1_REF_CLK pad	50-MHz RMII reference clock. This clock is derived from the MCU_RMII1_REF_CLK pad.
	CPTS_RFT_CLK	MAIN_PLL3_HSDIV1_CLK KOUT	HSDIV1 of CPSW0 PLL Controller, selected through CPTS Multiplexer (200 or 250-MHz clock)	CPTS IEEE 1588 clock. Selected through the CTRLMMR_MCU_ENET_CLKSEL register.
		MAIN_PLL0_HSDIV6_CLK KOUT	HSDIV6 of MAIN PLL0 Controller, selected through CPTS Multiplexer (200 or 250-MHz clock)	
		MCU_CPTS_RFT_CLK pad	MCU_CPTS_RFT_CLK pad, selected through CPTS Multiplexer (200-MHz clock)	
		CPTS_RFT_CLK pad	CPTS_RFT_CLK pad, selected through CPTS Multiplexer (200-MHz clock)	
		MCU_EXT_REFCLK0 pad	MCU_EXT_REFCLK0 pad, selected through CPTS Multiplexer (100-MHz clock)	
		EXT_REFCLK1 pad	EXT_REFCLK1 pad, selected through CPTS Multiplexer (100-MHz clock)	
		SERDES0_IP2_LN0_TXM_CLK	SERDES0 Lane0 (500-MHz clock)	
		SERDES0_IP2_LN1_TXM_CLK	SERDES0 Lane1 (500-MHz clock)	

**Table 12-167. MCU\_CPSW0 Clocks and Resets (continued)**

	SERDES1_IP2_LN0_TXM_CLK	SERDES1 Lane0 (500-MHz clock)
	SERDES1_IP2_LN1_TXM_CLK	SERDES1 Lane1 (500-MHz clock)
	SERDES2_IP2_LN0_TXM_CLK	SERDES2 Lane0 (500-MHz clock)
	SERDES2_IP2_LN1_TXM_CLK	SERDES2 Lane1 (500-MHz clock)
	SERDES3_IP2_LN0_TXM_CLK	SERDES3 Lane0 (500-MHz clock)
	SERDES3_IP2_LN1_TXM_CLK	SERDES3 Lane1 (500-MHz clock)
	MCU_PLL2_HSDIV1_CLK_OUT	HSDIV1 of MCU_CPSW0 PLL Controller, selected through CPTS Multiplexer (500-MHz clock)
	MCU_SYSCLOCK/2	MCU_PLLCTRL (500-MHz clock)
GMII1_MT_CLK	RGMII_MHZ_250_CLK/10	RGMII_MHZ_250_CLK
		<i>Note: GMII mode is not supported on this device. GMII1_MT_CLK transmit reference clock is needed to enable clock-stop protocol on this module.</i>
GMII1_MR_CLK	RGMII_MHZ_250_CLK/10	RGMII_MHZ_250_CLK
		<i>Note: GMII mode is not supported on this device. GMII1_MR_CLK receive reference clock is needed to enable clock-stop protocol on this module.</i>
RGMII1_RXC_I	RGMII1_RXC	MCU_RGMII1_RXC pad
		RGMII reference clock that provides the timing reference for receive operations.
RGMII1_TXC_O	RGMII1_TXC	MCU_RGMII1_TXC pad
		RGMII transmit reference clock.
MDIO_MCLK	MDIO_MCLK	MCU_MDIO0_MDC pad
		Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.

#### 12.2.1.4 MCU\_CPSW0 Functional Description

The two-port switch Ethernet subsystem module (CPSW) is compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in [Figure 12-133](#).

##### 12.2.1.4.1 Functional Block Diagram

The two-port Ethernet subsystem consists of:

- CPSW\_2G
- One RGMII interface module
- One RMII interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

**Figure 12-133. CPSW Top Level Block Diagram**

##### 12.2.1.4.2 CPSW Ports

The Ethernet Subsystem has two ports. Port 0 is the Host port (internal to the Subsystem). Port 1 is the external port connected to RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI Host Port
- Port1 is referred to the interfaces RGMII/RMII

##### 12.2.1.4.2.1 Interface Mode Selection

The two-port switch (CPSW) Ethernet Subsystem has one 10/100/1000 Ethernet port with selectable RMII, and RGMII interfaces.

The interface mode is selected by configuring the Ethernet interface mode selection bitfield (MODE\_SEL) in the CTRLMMR\_MCU\_ENET\_CTRL register.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

### **12.2.1.4.3 Clocking**

#### **12.2.1.4.3.1 Subsystem Clocking**

CPSW clocking summary is shown in *CPSW Integration*.

#### **12.2.1.4.3.2 Interface Clocking**

Data is transmitted and received with respect to the reference clocks of the interface pins.

##### **12.2.1.4.3.2.1 RGMII Interface Clocking**

RGMII\_RXC, RGMII\_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

##### **12.2.1.4.3.2.2 RMII Interface Clocking**

RMII interface clock RMII\_50MHZ\_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

MCU\_RMII1\_REF\_CLK device pin or internal RGMII\_MHZ\_50\_CLK clock (default clock) can be selected through CTRLMMR\_MCU\_ENET\_CLKSEL[0] RMII\_CLK\_SEL and one of these clocks can be used as the clock source for RMII interface. For more details on RMII clocking, please see *MCU\_CPSW0 Integration*

CTRLMMR\_MCU\_CLKOUT0\_CTRL[4] CLK\_EN and CTRLMMR\_MCU\_CLKOUT0\_CTRL[0] CLK\_SEL bits are used to enable and select the clock source for MCU\_CLKOUT0 device pin.

##### **12.2.1.4.3.2.3 MDIO Clocking**

The MDIO clock is based on a divide-down of the interface (CPPI\_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW\_MDIO\_CONTROL\_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

#### **12.2.1.4.4 Software IDLE**

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW\_2G is in the idle state when all two submodules are in the idle state. The CPSW\_SOFT\_IDLE\_REG[0] SOFT\_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT\_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

#### **12.2.1.4.5 Interrupt Functionality**

CPSW Ethernet Subsystem has six interrupt outputs:

- EVNT\_PEND - CPTS Event Pending Interrupt
- STAT\_PEND0 – Statistics Pending Interrupts
- ECC\_DED\_INT - ECC DED Level Interrupt
- ECC\_SEC\_INT - ECC SEC Level Interrupt
- MDIO\_INTR - MDIO Pending Interrupt (combined MDIO\_LINKINT and MDIO\_USERINT events)

#### 12.2.1.4.5.1 EVNT\_PEND Interrupt

See *Common Platform Time Sync (CPTS)* for more details on this interrupt.

#### 12.2.1.4.5.2 Statistics Interrupt (STAT\_PEND0)

The statistics level interrupt (STAT\_PEND0) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement any statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The statistics are mapped into internal memory space and are 32-bits wide. The raw and masked statistics interrupt status may be read by reading the CPSW\_CPTS\_INTSTAT\_RAW\_REG and CPSW\_CPTS\_INTSTAT\_MASKED\_REG registers, respectively.

The statistics interrupt is enabled by setting to 1h the TS\_PEND\_EN bit in the CPSW\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.1.4.5.3 ECC DED Level Interrupt (ECC\_DED\_INT)

Level interrupt (ECC\_DED\_INT) indicating an ECC double error has been detected.

#### 12.2.1.4.5.4 ECC SEC Level Interrupt (ECC\_SEC\_INT)

Level interrupt (ECC\_SEC\_INT) indicating an ECC single error has been detected and corrected.

#### 12.2.1.4.5.5 MDIO Interrupts

**Normal Mode:** (CPSW\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 0h)

MDIO\_LINKINT event is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR\_MON field of the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register and the corresponding LINKINT\_ENABLE bit is set. The MDIO\_LINKINT event is also captured in the MDIO CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register. When the GO bit in the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG register is set, the MDIO\_USERINT signal is asserted. The MDIO\_USERINT event is also captured in the CPSW\_MDIO\_USER\_INT\_MASKED\_REG register.

**State Change Mode:** (CPSW\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 1h)

In State Change Mode, the MDIO will assert MDIO\_LINKINT[0] when any bit in the MDIO CPSW\_MDIO\_ALIVE\_REG or CPSW\_MDIO\_LINK\_REG registers changes due to MDIO operations. The MDIO\_LINKINT event is also captured in the CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register. MDIO\_LINKINT[1] output is unused in State Change Mode. The CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k registers are unused in state change mode.

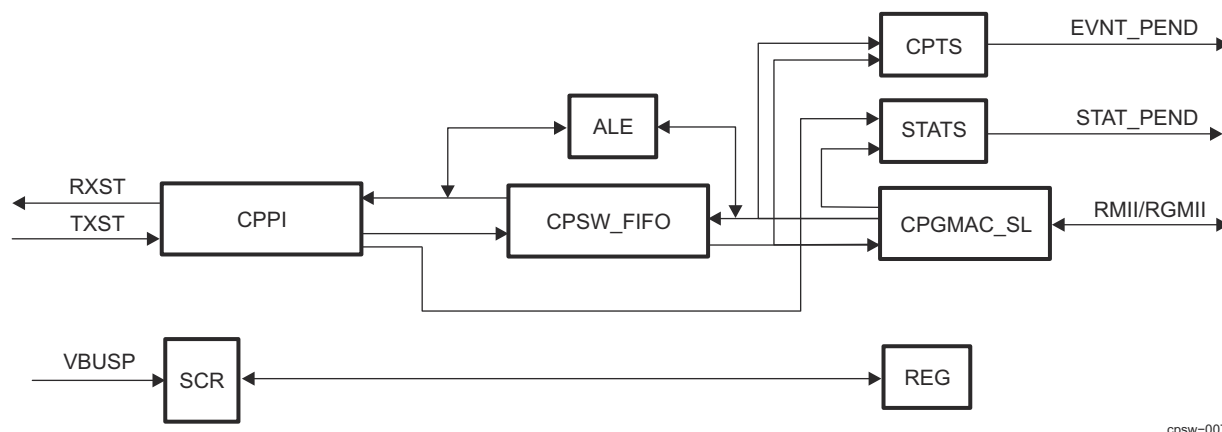

**Manual Mode:** (CPSW\_MDIO\_POLL\_REG[31] MANUALMODE = 1h)

Manual Mode allows software to directly control the MDIO serial clock output (CPSW\_MDIO\_MANUAL\_IF\_REG[2] MDIO\_MDCLK\_O) and the MDIO serial data output enable (CPSW\_MDIO\_MANUAL\_IF\_REG[1] MDIO\_OE). Manual Interface Mode is enabled when the MANUALMODE bit is set in the CPSW\_MDIO\_POLL\_REG register. Manual Mode is intended to be used by software for slow speed general purpose IO operations and not for MDIO PHY operations.

#### 12.2.1.4.6 CPSW\_2G

The CPSW\_2G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW\_2G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW\_2G is shown in [Figure 12-134](#).

**Figure 12-134. CPSW\_2G Block Diagram**

#### 12.2.1.4.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines to which port(s) the packet should be forwarded. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE\_ALE bit in the CPSW\_ALE\_CONTROL register is set. All packets are dropped when the ENABLE bit is cleared to 0.

##### 12.2.1.4.6.1.1 Error Handling

In normal operation, the Ethernet port modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the CPSW\_PN\_MAC\_CONTROL\_REG configuration bit(s) RX\_CEF\_EN, RX\_CSF\_EN, or RX\_CMF\_EN are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

##### 12.2.1.4.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the ENABLE\_BYPASS bit in the CPSW\_ALE\_CONTROL register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

##### 12.2.1.4.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the ENABLE\_OUI\_DENY bit in the CPSW\_ALE\_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the SUPER bit set. When ENABLE\_OUI\_DENY bit is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

#### 12.2.1.4.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. There are many reasons to drop frames the below drop events are individually counted in CPSW per port statistics counters. For more information on ALE statistics please refer to the *CPSW Network Statistics* section.

#### 12.2.1.4.6.1.5 Automotive Security Features

The ALE has many automotive security features that most enterprise switches do not require.

- VLANs can be configured to not allow fragmented IPv4 frames. That is a VLAN can be configured to not allow fragmented IPv4 traffic.
- VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6. Next Header values, for example a VLAN can be configured to only allow TCP traffic in both IPv4 and IPv6 packets.
- Drop invalid Source Addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
- IEEE802.3 Length Check, drop frames that the IEEE802.3 Length is not contained within the frame. (Ether Types 0-1500)
- Any Source Address can be secured to a port dropping any attempts from other ports to masquerade as a service.
- Any source or destination address can be blocked.
- Per Port or Per VLAN ingress checking, dropping traffic from non-member ports.
- Classification, Policing on L2 and L3 information.

#### 12.2.1.4.6.1.6 CPSW Switching Solutions

The host port can operate in many different modes as well depending on the functionality of the host. It is important to understand the modes and configure them properly.

The ALE Table is designed to maximize the modes without compromise of the system functionality as well.

##### 12.2.1.4.6.1.6.1 Basics of 2-port Switch Type

The 2-port switch has a host port, and that port can operate in two fundamental modes. Bridge mode allows the host to extend the switched domain to another network like Wi-Fi or another multi-port switch. In this case the host must be able to see unknown unicast addresses so they can be broadcast to the other network. In Port mode the host need not see any unknown unicast traffic. The CPSW\_ALE\_CONTROL[8] EN\_HOST\_UNI\_FLOOD bit determines the host mode for unknown unicast traffic. This bit should only be set if you are bridging two or more networks together.

Essentially the two port switch is a MAC with all the switching features like VLAN insertion, removal, update, etc.

The 2-port switch would normally have a very small ALE table. Its primary use is for the Host filtering features. For example you would not ever need to auto learn or add addresses of external nodes to the ALE table, the table's primary purpose is to host unicast addresses, multicast addresses, VLANs, IP addresses etc.

#### 12.2.1.4.6.1.7 VLAN Routing and OAM Operations

##### 12.2.1.4.6.1.7.1 InterVLAN Routing

The CPSW module supports wire rate InterVLAN routing for a small number of routes, that is the host will setup an ALE classifier with an associated egress operation that will cause the CPSW to perform particular egress operations. The ALE can optionally check time to live validity as well.

The ALE uses the classifier along with an egress opcode, destination port mask and TTL check field to tell the CPSW to manipulate the packet on the egress. The CPSW will use the opcode along with a per port operation table to process the packet. By setting up the CPSW egress operation table you can replace the DA, SA and VLAN along with optionally updating the time to live IP header field. This allows the CPSW to perform the routing function for a small set of routes without getting the local host/CPU involved.

The Egress opcode will only be used for a classifier match and the packet would normally be sent only to the host. That is the host would have routed the packet but the CPSW has been configured to do the work instead. In the event that the time-to-live check feature is enabled and the time-to-live is either 0 or 1, the packet will not get

the egress opcode and instead be sent to the host as if the route is not setup. This allows the host to deal with invalid TTL fields.

#### 12.2.1.4.6.1.7.2 OAM Operations

The ALE supports OAM loopback on ports so that a remote link can be tested. That is a port placed in OAM loopback will echo packets received on a port back to the port with an egress op of 0xFF which will swap the SA and DA on egress in the CPSW.

Any supervisory packet will not be affected, so the spanning tree and other bridging functions are not affected.

Packets will only be echoed if the port is in OAM loopback mode, the received packet is not a supervisor packet. The port is in a forwarding state and the packet received DA!=SA and there are no errors in the packet.

When a port is in OAM loopback the port will not egress traffic from other ports, no address for loop backed traffic will be learned if enabled. Any packet received on the OAM loopback port with an error will be process as if the port is not in OAM. That is if the host has enabled copy errored frames the errored frames will be sent to the host instead.

#### 12.2.1.4.6.1.8 Supervisory packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise blocked to be forwarded for special purposes.

#### 12.2.1.4.6.1.9 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 12-169. Learned Address Control Bits**

Bit(s)	Value
Ageable	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

#### Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### 12.2.1.4.6.1.9.1 Free Table Entry

**Table 12-170. Free (Unused) Address Table Entry Bit Values**

70:62	61:60	59:0
Reserved	ENTRY_TYPE (00)	Reserved

#### 12.2.1.4.6.1.9.2 Multicast Address Table Entry

**Table 12-171. Multicast Address Table Entry Bit Values**

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (01)	Reserved	MULTICAST_ADDRESS

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(1:0) (PORT\_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Multicast Forward State (MCAST\_FWD\_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT\_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 12.2.1.4.6.1.9.3 VLAN/Multicast Address Table Entry

**Table 12-172. VLAN/Multicast Address Table Entry Bit Values**

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_MASK	SUPER	Reserved	MCAST_FWD_STATE	ENTRY_TYPE (11)	VLAN_ID	MULTICAST_ADDRESS

### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

### Port Mask(1:0) (PORT\_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

### Multicast Forward State (MCAST\_FWD\_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT\_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 12.2.1.4.6.1.9.4 Unicast Address Table Entry

**Table 12-173. Unicast Address Table Entry Bit Values**

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (01)	Reserved	UNICAST_ADDR ESS

### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 12.2.1.4.6.1.9.5 OUI Unicast Address Table Entry

**Table 12-174. OUI Unicast Address Table Entry Bit Values**

70:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE (10)	ENTRY_TYPE (01)	Reserved	UNICAST_OUI	Reserved

### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

### 12.2.1.4.6.1.9.6 VLAN/Unicast Address Table Entry

**Table 12-175. Unicast Address Table Entry Bit Values**

70:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE (11)	VLAN_ID	UNICAST_ADDRESS

#### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

#### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

#### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT\_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

#### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

#### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

### 12.2.1.4.6.1.9.7 VLAN Table Entry

**Table 12-176. VLAN Table Entry**

70:68	67	66	65	64:62	61:60	59:48	47:46	45:44
Reserved	NO_LEARN_MASK	Reserved	VLAN_FORCE_INGRESS_CHECK	Reserved (000)	ENTRY_TYPE (10)	VLAN_ID	Reserved	REG_MCAST_FLOOD_INDEX
43:26	25:24	23:22	21:20	19:2	1:0			
Reserved	FORCE_UNTAGGED_EGRESS	Reserved	UNREG_MCAST_FLOOD_INDEX	Reserved	VLAN_MEMBER_LIST			

#### No Learn Mask (NO\_LEARN\_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

#### VLAN Force Ingress Check (VLAN\_FORCE\_INGRESS\_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the `ly_REG_Py_VID_INGRESS_CHECK` bit in the `CPSW_ly_ALE_PORTCTL0_y` registers except this check is for this VLAN only (not all VLANs).

#### Table Entry Type (ENTRY\_TYPE)

10: VLAN entry

#### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### Registered Multicast Flood Index (REG\_MCAST\_FLOOD\_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the registered multicast flood mask.

#### Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

#### Unregistered Multicast Flood Mask (UNREG\_MCAST\_FLOOD\_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the unregistered multicast flood mask.

#### VLAN Member List (VLAN\_MEMBER\_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

### 12.2.1.4.6.1.10 ALE Policing and Classification

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate limiting functions. A policer is a hardware engine that is used for policing. The `POLCNTDIV8` field in the `CPSW_ALE_STATUS` register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- VLANID

- Ether Type
- IP Source Address - IPSA with full CIDR masking
- IP Destination Address - IPSA with full CIDR masking
- Support Host Thread/Flow ID mapping based on any packet classification above

#### 12.2.1.4.6.1.10.1 ALE Classification

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

##### 12.2.1.4.6.1.10.1.1 Classifier to CPPI Transmit Flow ID Mapping

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST\_THREAD\_MREADY) but there are 6-bits of FLOW\_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW\_P0\_FLOW\_ID\_OFFSET\_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW\_ALE\_THREADMAPDEF, CPSW\_ALE\_THREADMAPCTL and CPSW\_ALE\_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW\_ALE\_THREADMAPCTL register allows the CPSW\_ALE\_THREADMAPVAL register contents to be written to the selected classifier. There is a single CPSW\_ALE\_THREADMAPDEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

##### 12.2.1.4.6.1.11 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW\_P0\_RX\_DSCP\_MAP\_REG\_y and CPSW\_PN\_RX\_DSCP\_MAP\_REG\_y registers in the Register Manual section for DSCP mapping.

##### 12.2.1.4.6.1.12 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN\_Aware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST\_FWD\_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet

is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port, if the port has the RX\_CMF\_EN, RX\_CEF\_EN, or RX\_CSF\_EN bit(s) set in the CPSW\_PN\_MAC\_CONTROL\_REG register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW\_PN\_MAC\_CONTROL\_REG register:

- [22] RX\_CEF\_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX\_CSF\_EN - enables short frames to be forwarded
- [24] RX\_CMF\_EN - enables MAC control frames to be forwarded.

#### 12.2.1.4.6.1.12.1 Ingress Filtering Process

Condition and action
If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process
if (directed packet) then use directed port number and go to Egress process
If (Rx Iy_REG_Py_PORTSTATE is Disabled) then discard the packet
if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet
if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not BCAST_MCAST_CTL)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> <li>• Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.</li> </ul>
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet

<p>If (VLAN_Unaware)</p> <p>CPSW_ALE_UVLAN_UNTAG = "000"</p> <p>CPSW_ALE_UVLAN_RMCAST = "111"</p> <p>CPSW_ALE_UVLAN_URCAST = "111"</p> <p>CPSW_ALE_UVLAN_MEMBER = "111"</p> <p>else if (VLAN not found)</p> <p>CPSW_ALE_UVLAN_UNTAG = CPSW_ALE_UVLAN_UNTAG</p> <p>CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST</p> <p>CPSW_ALE_UVLAN_URCAST = CPSW_ALE_UVLAN_URCAST</p> <p>CPSW_ALE_UVLAN_MEMBER = CPSW_ALE_UVLAN_MEMBER</p> <p>else</p> <p>CPSW_ALE_UVLAN_UNTAG = found CPSW_ALE_UVLAN_UNTAG</p> <p>CPSW_ALE_UVLAN_URCAST = found CPSW_ALE_UVLAN_URCAST</p> <p>CPSW_ALE_UVLAN_RMCAST = found CPSW_ALE_UVLAN_RMCAST</p> <p>CPSW_ALE_UVLAN_MEMBER = found CPSW_ALE_UVLAN_MEMBER</p>
<p>if ((not SUPER) and (ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member))</p> <p>then discard the packet</p>
<p>if ((ENABLE_AUTH_MODE) and (source address not found) and not(destination address found and (SUPER)))</p> <p>then discard the packet</p>
<p>if (destination address equals source address)</p> <p>then discard the packet</p>
<p>if (VLAN_AWARE) goto VLAN_Aware_Lookup process</p> <p>else goto VLAN_Unaware_Lookup process</p>

#### 12.2.1.4.6.1.12.2 VLAN\_Aware Lookup Process

Condition and action
<p>if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER))</p> <p>then portmask is the logical "AND" of the PORT_NUMBER and UVLAN_MEMBER_LIST less the host port</p> <p>and goto Egress process</p>
<p>if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER))</p> <p>then portmask is the logical "AND" of the PORT_NUMBER and the UVLAN_MEMBER_LIST and goto Egress process</p>
<p>if ((unicast packet) and (destination address found with or without VLAN) and (SUPER))</p> <p>then portmask is the PORT_NUMBER and goto Egress process</p>
<p>if (Unicast packet) # destination address not found</p> <p>then portmask is VLAN member LIST less host port and goto Egress process</p>
<p>if ((Multicast packet) and (destination address found with or without VLAN) and (not SUPER))</p> <p>then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and found destination address/VLAN portmask (PORT_MASK) and UVLAN_MEMBER_LIST and goto Egress process</p>
<p>if ((Multicast packet) and (destination address found with or without VLAN) and (SUPER))</p> <p>then portmask is the PORT_MASK and goto Egress process</p>

if (Multicast packet) # destination address not found then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and UVLAN_MEMBER_LIST then goto Egress process
if (Broadcast packet) then use found UVLAN_MEMBER_LIST and goto Egress process

### Note

The UVLAN\_MEMBER\_LIST, UVLAN\_UNREG\_MCAST\_FLOOD\_MASK, UVLAN\_REG\_MCAST\_FLOOD\_MASK and UVLAN\_FORCE\_UNTAGGED\_EGRESS are set in the [Section 12.2.1.4.6.1.12.1 Ingress Filtering Process](#), based on VLAN\_Unaware, Unknown\_VLAN rules and VLAN table entries.

#### 12.2.1.4.6.1.12.3 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and ((not mcast destination address) and (SUPER))) then Clear host port from portmask
if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER))) then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (BCAST_MCAST_CTL)) then if (not SUPER) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

#### 12.2.1.4.6.1.12.4 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

##### 12.2.1.4.6.1.12.4.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not learn address

if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not learn address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VLANID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VLANID))) then learn address without VLAN

#### 12.2.1.4.6.1.12.4.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not update address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not update address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

#### 12.2.1.4.6.1.12.4.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched
---

#### 12.2.1.4.6.1.13 VLAN Aware Mode

The CPSW is in VLAN aware mode when the VLAN\_AWARE bit is set in the CPSW\_CONTROL\_REG register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT\_TYPE), packet priority (PKT\_PRI), and VLAN information.

The VLAN\_LTYPE\_SEL value is selected by the S\_CN\_SWITCH bit in the CPSW\_CONTROL\_REG register and is either the VLAN\_LTYPE\_INNER (8100h default) or VLAN\_LTYPE\_OUTER (88A8h default) value.

#### 12.2.1.4.6.1.14 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is cleared to 0h. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

#### 12.2.1.4.6.2 Packet Priority Handling

Packets are received on two ports, one Ethernet port and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority.

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register (CPSW\_PN\_RX\_PRI\_MAP\_REG) to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

The header packet priority is mapped at each destination FIFO through the CPSW\_PN\_TX\_PRI\_MAP\_REG register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

##### 12.2.1.4.6.2.1 Priority Mapping and Transmit VLAN Priority

There are three priorities that are used inside the Gigabit Ethernet Switch: **packet priority**, **header packet priority**, and **switch priority**. The **header packet priority** is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The **switch priority** determines which of the 8 FIFO priority queues the packet uses during egress.

[Figure 12-135](#) below, as well as the corresponding explanation that follows, explains each of the priorities, how they are determined, and how they are used. A number in parentheses in the figure indicates a process (Ethernet port ingress, host port egress, etc.). Each bullet in the text following the diagram explains one of the 5 processes pointed out in the figure.

**Figure 12-135. Gigabit Ethernet Switch Priority Mapping and Transmit VLAN Processing**

From [Figure 12-135](#) above:

- (1) is the ingress process that occurs at the external Ethernet ports
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the ingress port's priority. This **packet priority** is then mapped to a **header packet priority** using the CPSW\_PN\_RX\_PRI\_MAP\_REG register where N is the port where the packet entered the switch. This process is explained in further detail in [Section 12.2.1.4.6.2](#).
- (2) is the egress process that occurs at the external Ethernet ports
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1) or (5). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.4.6.4.1](#).
- (3) is the process by which it is decided which priority TX queue to place the packet on in the Port N TX FIFO during egress
  - Each Port's TX FIFO has 8 queues that each correspond to a priority that is used when determining which packet will egress from the switch next at that port. The **header packet priority** (Ethernet port ingress, process (1)) or the receive packet thread (host port 0 ingress, process (5)) gets mapped through the CPSW\_PN\_RX\_PRI\_MAP\_REG register (where N is the egress port number) to determine the **switch priority** of the packet. The **switch priority** determines which TX FIFO queue to place the packet in. The FIFO architecture is described in [Section 12.2.1.4.6.10.5](#). The header packet priority to switch priority mapping is discussed in [Section 12.2.1.4.6.2](#).
- (4) is the egress process that occurs at Host Port 0 toward the transmit streaming interface (TXST)
  - The TXST has 8 egress threads for each external Ethernet port (32 threads in a 5-port switch and 64 threads in a 9-port switch). The TX thread that is selected for a packet is determined by the Ethernet port of ingress and the **switch priority** of the packet that was determined in process (3).
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.1.4.6.4.1](#).
- (5) is the ingress process that occurs at Host Port 0
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the host port's priority. This packet priority is then mapped to a **header packet priority** using the CPSW\_PN\_RX\_PRI\_MAP\_REG register.
  - Host port 0 also has a received packet thread. The receive packet thread is based on either the packet's VLAN priority, IPv4 or IPv6 DSCP value, or the streaming interface (RXST) thread that the packet entered host port 0 on.

#### 12.2.1.4.6.3 CPPI Port Ingress

Packets received on the CPPI host port have a received packet priority (0 to 7 with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG register, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG register, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

For CPPI ingress packets, the destination port hardware switch priority is the below selected value remapped through CPSW\_PN\_RX\_PRI\_MAP\_REG:

1. If the ingress packet is priority tagged or vlan tagged:
  - If RX\_REMAP\_VLAN in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_VLAN in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (CPSW\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPv4 packet). Port 1 transmit remapping (CPSW\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
3. Else if the ingress packet has the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (CPSW\_PN\_TX\_PRI\_MAP\_REG should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI receive thread number.

#### 12.2.1.4.6.4 Packet CRC Handling

The P0\_TX\_CRC\_REMOVE bit in the CPSW\_CONTROL\_REG register determines if host port egress packets have CRC included or not. If P0\_TX\_CRC\_REMOVE is set to 1h then all packets that are transmitted from port 0 do not contain CRC. If P0\_TX\_CRC\_REMOVE bit is cleared to 0h then all packets that are transmitted from port 0 contain CRC. The CRC type, if present, is determined by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register. If the CRC\_TYPE bit is cleared to 0h then the CRC present in each packet after host port egress is Ethernet CRC. If the CRC\_TYPE bit is set to 1h then the CRC present in each packet after host port egress is Castagnoli CRC.

#### Note

The CRC type present in the packet after host port egress is determined solely by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register regardless of the CRC type present in the packet during Ethernet port ingress.

#### 12.2.1.4.6.4.1 Transmit VLAN Processing

Transmit packets are NOT modified during switch egress when the VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is cleared to 0h. This means that the switch is not in VLAN-aware mode.

The next three sections cover transmit processing when the switch is in VLAN-aware mode for different packet types. The Gigabit Ethernet switch is in VLAN-aware mode when the VLAN\_AWARE bit is set in the CPSW\_CONTROL\_REG register. While in VLAN-aware mode, VLAN is added, removed, or replaced according to the type of packet as well as the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header as explained below.

##### 12.2.1.4.6.4.1.1 Untagged Packets (No VLAN or Priority Tag Header)

Untagged packets are all packets that are not a VLAN packet or a priority tagged packet. According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header the packet may exit the switch with a VLAN tag inserted or the packet may leave the switch unchanged. The two cases are discussed below.

- Insert VLAN Case:

Untagged input packets have the header packet VLAN inserted when the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the transmit packet header is de-asserted. For untagged packets, the VLAN EtherType = 0x8100 is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the header packet priority along with the PORT\_CFI and PORT\_VID values from the CPSW\_PN\_PORT\_VLAN\_REG register (where N is the port that the untagged packet entered the switch) through. The packet length/type field is output four bytes later than it is input and is not removed or replaced. If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a hardware generated CRC.

- No Change Case:

Untagged input packets are output unchanged when the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS transmit packet header bit is asserted.

##### 12.2.1.4.6.4.1.2 Priority Tagged Packets (VLAN VID == 0 && EN\_VID0\_MODE == 0h)

Priority tagged packets are packets that contain a VLAN header with VID = 0. According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, priority tagged packets may exit the switch with their VLAN ID and priority replaced or they may have their priority tag completely removed. The two cases are discussed below.

#### Note

In order for a priority tagged packet to fall into this category the ENABLE\_VID0\_MODE bit in the CPSW\_ALE\_CONTROL register must also be set to 0h. If the ENABLE\_VID0\_MODE bit in the CPSW\_ALE\_CONTROL register is set to 1h, then packets with a VLAN VID of 0 will fall into the VLAN Tagged Packets category in [Section 12.2.1.4.6.4.1.3](#) below.

- Replace Priority and VLAN ID Case:

Priority tagged input packets have the packet VLAN ID and the packet priority replaced with the header packet VLAN ID and the header packet priority when the transmit packet header CPSW\_FORCE\_UNTAGGED\_EGRESS\_REG[1-0] MASK bit is de-asserted. The header packet VLAN ID comes from the PORT\_VID bits in the CPSW\_PN\_PORT\_VLAN\_REG register (where N is the port where the packet entered the switch). The header packet priority is based on the packet priority to header packet priority mapping in the CPSW\_PN\_RX\_PRI\_MAP\_REG register (where N is the port where the packet entered the switch).

- Remove VLAN Header Case:

Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority-tagged packets use all four input CRC bytes as pad, input 65-byte priority-tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority-tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### **12.2.1.4.6.4.1.3 VLAN Tagged Packets (VLAN VID != 0 || (EN\_VID0\_MODE == 1h && VLAN VID == 0))**

VLAN tagged packets are packets that contain a VLAN header specifying the VLAN the packet belongs to (VID), the packet priority (PRI), and the drop eligibility indicator (CFI). According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, VLAN tagged packets may exit the switch with their VLAN priority replaced or they may have their VLAN header completely removed. The two cases are discussed below.

- Replace Priority Case:

VLAN tagged input packets are output with the packet priority replaced with the header packet priority when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is deasserted. The header packet priority is based on the packet priority to header packet priority mapping in the CPSW\_PN\_RX\_PRI\_MAP\_REG register (where N is the port where the packet entered the switch). If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a generated CRC.

- Remove VLAN Header Case:

VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### **12.2.1.4.6.4.2 Ethernet Port Ingress Packet CRC**

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register.

#### **12.2.1.4.6.4.3 Ethernet Port Egress Packet CRC**

Ethernet ports transmit each egress packet with the CRC selected by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

#### **12.2.1.4.6.4.4 CPPI Port Ingress Packet CRC**

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for

correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the INFO0 PASSED\_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED\_CRC bit is set then the packet is received and forwarded unchanged. The CRC type is input in the INFO0 word CRC\_TYPE bit and must be Ethernet CRC.

#### 12.2.1.4.6.4.5 CPPI Port Egress Packet CRC

The P0\_TX\_CRC\_REMOVE bit in the CPSW\_CONTROL\_REG register determines if CPPI egress packet have an Ethernet CRC included or not.

#### 12.2.1.4.6.5 FIFO Memory Control

Each of the two CPSW\_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX\_MAX\_BLKs field in the FIFOs associated CPSW\_PN\_MAX\_BLKs\_REG register determines the maximum number of 1k FIFO memory blocks to be allocated to the eight logical transmit queues (transmit total). The RX\_MAX\_BLKs field in the FIFO's associated CPSW\_PN\_MAX\_BLKs\_REG register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX\_MAX\_BLKs value plus the RX\_MAX\_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports is Port1.

Each transmit FIFO contains a configurable number of blocks (20 max) that are either 1k or 4k byte blocks that can be allocated to any priority.

#### 12.2.1.4.6.6 FIFO Transmit Queue Control

There are eight transmit queues in the Ethernet port transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues).

##### 12.2.1.4.6.6.1 CPPI Port Receive Rate Limiting

Port 0 receive operations can be configured to rate limit the host ingress data for each receive thread (priority). CPPI Receive has 8 threads for QOS. There is a committed information rate (CPSW\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each thread (CPSW\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a thread when the committed information rate for the thread is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. No bulk thread will be enabled to send unless there are CPSW\_PN\_PRI\_CTL\_REG[15-12] TX\_HOST\_BLKs\_REM number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The "blocks remaining check" ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then threads 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the priority type must be fixed for receive. Round-robin priority type is not allowed when rate-limiting is configured for any thread. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to receive is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate [Mbit/s] = (((Frequency in MHz) \* CPSW\_P0\_PRI\_CIR\_REG\_y) / 32768) + (((Frequency in MHz) \* CPSW\_P0\_PRI\_EIR\_REG\_y) / 32768))

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

For example, 10Mbps on priority 7 would give the below:

10Mbps =  $\sim ((350 * 936) / 32768)$ , at 350Mhz and CPSW\_P0\_PRI\_CIR\_REG\_y[27-0] PRI\_CIR value = 936 (no excess information rate)

#### 12.2.1.4.6.6.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (CPSW\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each priority (CPSW\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

Priority Transfer rate [Mbit/s] =  $(((((\text{Frequency in MHZ}) * \text{CPSW\_P0\_PRI\_CIR\_REG\_y}) / 32768) + (((\text{Frequency in MHZ}) * \text{CPSW\_P0\_PRI\_EIR\_REG\_y}) / 32768)))$

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

#### 12.2.1.4.6.7 Intersperced Express Traffic (IET – P802.3br/D2.0)

When IET is enabled through CPSW\_CONTROL\_REG[17] IET\_ENABLE = 1h and configured, IET allows preemptable traffic on selected transmit priorities to be preempted by express traffic on selected express priorities. Received traffic is separated onto express and preempt receive queues. When IET is disabled (IET\_ENABLE = 0h), all Ethernet traffic is express traffic and switch operation is as if IET does not exist. Traffic is only intended to be moved to the preempt queue after preemption is verified and enabled.

##### 12.2.1.4.6.7.1 IET Configuration

- Using the preempt receive queue requires more blocks to be allocated to the ports receive FIFO. Write a value of decimal 7 to the CPSW\_PN\_MAX\_BLKES\_REG[7-0] RX\_MAX\_BLKES bit field, and a value of decimal 13 to the CPSW\_PN\_MAX\_BLKES\_REG[15-8] TX\_MAX\_BLKES register for every port to be enabled for IET.
- Write the [23-0]MAC\_VERIFY\_CNT bit field in the Ethernet port CPSW\_PN\_IET\_VERIFY\_REG register to set the verify/response timeout count. The default is 10ms for Gigabit mode. For other time values or link speeds the verify count should be updated. If CPSW\_PN\_IET\_CONTROL\_REG[2] MAC\_DISABLEVERIFY bit is to be set (this is forced mode) then this step is unneeded.
- The receive FIFO block allocation is insufficient if CPSW\_STAT0\_RX\_BOTTOM\_OF\_FIFO\_DROP/ CPSW\_STAT1\_RX\_BOTTOM\_OF\_FIFO\_DROP[31-0] COUNT is nonzero, indicating that receive packets are being dropped due to FIFO block allocation.
- Write the CPSW\_PN\_IET\_CONTROL\_REG register in the Ethernet port as below:
  - Set the CPSW\_PN\_CONTROL\_REG[16] IET\_PORT\_EN bit. The port will not actually be enabled until bit IET\_ENABLE is set in the CPSW\_CONTROL\_REG.
  - The CPSW\_PN\_IET\_CONTROL\_REG[0] MAC\_PENABLE bit can be set as desired. No effect will occur until IET\_ENABLE is set. This bit enables preemptable packets to be preempted by express traffic but does not preclude packets from being sent to the preempt queue.
  - If verify/response is desired then CPSW\_PN\_IET\_CONTROL\_REG[3] MAC\_LINKFAIL should be cleared by software to enable verify and response packets. Otherwise, MAC\_DISABLEVERIFY bit should be set for forced mode. Verification and response will occur immediately after clearing this bit.
  - Configure the remaining CPSW\_PN\_IET\_CONTROL\_REG register bits as desired.
- Set the IET\_ENABLE bit in the CPSW\_CONTROL\_REG register to enable IET operations.

6. After preemption has been verified, the CPSW\_PN\_IET\_CONTROL\_REG[23-16] MAC\_PREMPT field is written to configure the FIFO priorities to be sent to the preempt queue (the other priorities with cleared bits go to the express queue). The hardware switch for each queue from express to preempt happens only when there are no packets queued on the priority.

#### **12.2.1.4.6.8 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)**

##### **12.2.1.4.6.8.1 Enhanced Scheduled Traffic Overview**

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 MSB's) and an 8-bit priority fetch allow (8 LSB's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (zero allow).
- EST can be used with or without preemption. The CPSW\_PN\_IET\_CONTROL\_REG[23-16] MAC\_PREMPT value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

##### **12.2.1.4.6.8.2 Enhanced Scheduled Traffic Fetch RAM**

- The EST fetch RAM is read/writable in the CPSW configuration address space.
- The Ethernet transmit port has 128 locations in the global EST fetch RAM.
  - Ethernet port 1 has EST fetch RAM addresses 0x000-0x07F.
- **One buffer operation:** When CPSW\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF is set to 1h, the 128 port locations operate as one buffer. The EST\_BUFACT bit in CPSW\_PN\_FIFO\_STATUS\_REG register is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- **Two buffer operation:** When CPSW\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF is cleared there are two 64-location buffers with CPSW\_PN\_EST\_CONTROL\_REG[1] EST\_BUFSEL selecting the buffer to be used. When the buffer is switched by changing the CPSW\_PN\_EST\_CONTROL\_REG[1] EST\_BUFSEL value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the EST\_BUFACT bit in CPSW\_PN\_FIFO\_STATUS\_REG. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port address zero is then read again at the beginning of the next cycle repeating the time interval packet operations.

##### **12.2.1.4.6.8.3 Enhanced Scheduled Traffic Time Interval**

- Each Ethernet port has an Enhanced Scheduled Traffic Function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS\_RFT\_CLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.

- The first fetch allowed value is at the port base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock cycle delay allows the first fetch value time to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when CPSW\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF = 0h, and 128 maximum fetch values when CPSW\_PN\_EST\_CONTROL\_REG[0] EST\_ONEBUF = 1h.
- The next cycle start then causes the fetch to once again start at the port address zero.

#### 12.2.1.4.6.8.4 Enhanced Scheduled Traffic Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in Gigabit mode (CPSW\_PN\_MAC\_CONTROL\_REG[7] GIG = 1h) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. The actual packet transmission on the wire may carry over into the next fetch count and is the reason for the wire clear time in the fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks.
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch. The fetch allow previous to a zero allow should have only preempt priorities enabled or only express priorities enabled but not both.
- The number of clocks required to clear the wire varies depending Ethernet wire speed and on whether express or preempt priorities were allowed in the previous fetch command.

#### 12.2.1.4.6.8.5 Enhanced Scheduled Traffic Packet Fill

Packet fill can be enabled (CPSW\_PN\_EST\_CONTROL\_REG[8] EST\_FILL\_EN = 1h) to occur in the fetch count time associated with a fetched zero allow. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill is intended to be used with either only express priorities in the previous non-zero fetched allow, or only preempt priorities in the previous non-zero fetched allow but not both. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch.

- **Express fill:**
  1. CPSW\_PN\_EST\_CONTROL\_REG[8] EST\_FILL\_EN is set and
  2. A fetch contains a non-zero fetch count with a zero fetch allow, and
  3. The previous allow contained only express priorities.
  4. The fetch count loaded should be at least TBD clocks and the CPSW\_PN\_EST\_CONTROL\_REG[25-16] EST\_FILL\_MARGIN should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  5. The fetch count loaded should be at least TBD clocks and the CPSW\_PN\_EST\_CONTROL\_REG[25-16] EST\_FILL\_MARGIN should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
- **Preempt fill:**
  1. CPSW\_PN\_EST\_CONTROL\_REG[8] EST\_FILL\_EN is set and

2. A fetch contains a non-zero fetch count with a zero fetch allow, and
  3. The previous allow contained only preempt priorities
  4. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  5. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
- **Express non-fill:**
    1. CPSW\_PN\_EST\_CONTROL\_REG[8] EST\_FILL\_EN is clear and
    2. The previous allow contained only express priorities.
    3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
    4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  - **Preempt non-fill:**
    1. CPSW\_PN\_EST\_CONTROL\_REG[8] EST\_FILL\_EN is clear and
    2. The previous allow contained only preempt priorities.
    3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
    4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

#### 12.2.1.4.6.8.6 Enhanced Scheduled Traffic Time Stamp

The EST can be configured to generate CPTS timestamp events for selected express traffic. The EST timestamp events use the CPTS host event type (CPSW\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE = 7 decimal). The EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.

- EST Events (host events) contain the below information:
  - Time Stamp of the selected express packet.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[28-24] PORT\_NUMBER indicates the transmit port number.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE is decimal 7 (host event).
  - The event CPSW\_CPTS\_EVENT\_1\_REG[23-20] MESSAGE\_TYPE indicates the packet transmit hardware switch priority.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID upper nibble indicates the packet receive port number.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence ID rolls over to zero after 0xFF (8-bits).
  - The event domain is the value from the CPSW\_EST\_TS\_DOMAIN\_REG[7-0] EST\_TS\_DOMAIN register.
- When CPSW\_PN\_EST\_CONTROL\_REG[2] EST\_TS\_EN is set, timestamp events will be generated on selected express traffic.
- When CPSW\_PN\_EST\_CONTROL\_REG[3] EST\_TS\_FIRST is also set, events will be generated only on the first express packet in each time interval. If CPSW\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is also set then the event will only be on the first CPSW\_PN\_EST\_CONTROL\_REG[7-5] EST\_TS\_PRI express packet in the time interval. If CPSW\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is clear then the event will be generated on the first express packet in the time interval on any priority.
- When CPSW\_PN\_EST\_CONTROL\_REG[3] EST\_TS\_FIRST is clear, events will be generated on every express packet. If CPSW\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is set then the event will be generated on every CPSW\_PN\_EST\_CONTROL\_REG[7-5] EST\_TS\_PRI express packet. If CPSW\_PN\_EST\_CONTROL\_REG[4] EST\_TS\_ONEPRI is clear then event will be generated on every express packet on any priority.

### 12.2.1.4.6.8.7 Enhanced Scheduled Traffic Packets Per Priority

The number of packets allowed in a transmit FIFO priority can be selected by writing a non-zero value to CPSW\_P0\_RX\_PKTS\_PRI\_REG register (packet priority 0 to 7). Then port 0 receive gap should then be enabled by setting the corresponding priority through CPSW\_P0\_RX\_GAP\_REG[7-0] RX\_GAP\_EN bit field. The receive gap allows a packet to land in the transmit FIFO before another packet is allowed in which guarantees that only the selected number (max) of packets is allowed in on the specified priority. If the receive gap is not enabled, then there might be one or two more packets allowed in on the priority/thread than the packets per priority value has selected (through CPSW\_P0\_RX\_PKTS\_PRI\_REG register).

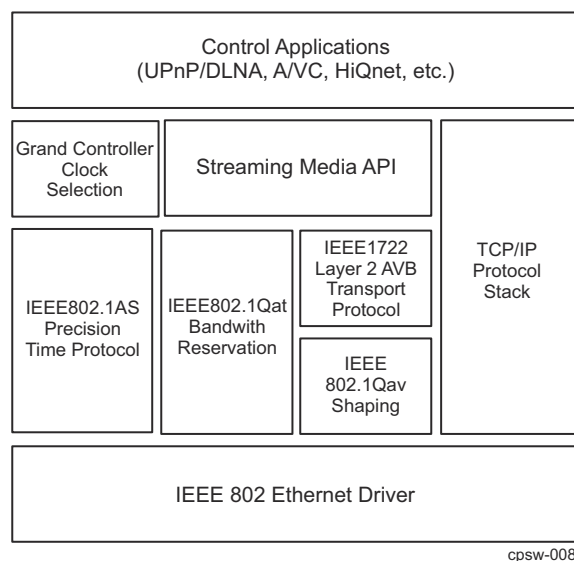

### 12.2.1.4.6.9 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*." a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

**Figure 12-136. The Network Static with AVB**

The following sections describe the media transport protocols that work within the AVB framework.

**12.2.1.4.6.9.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))**

The protocol defined by 802.1AS automatically selects a device to be the controller clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

---

**Note**

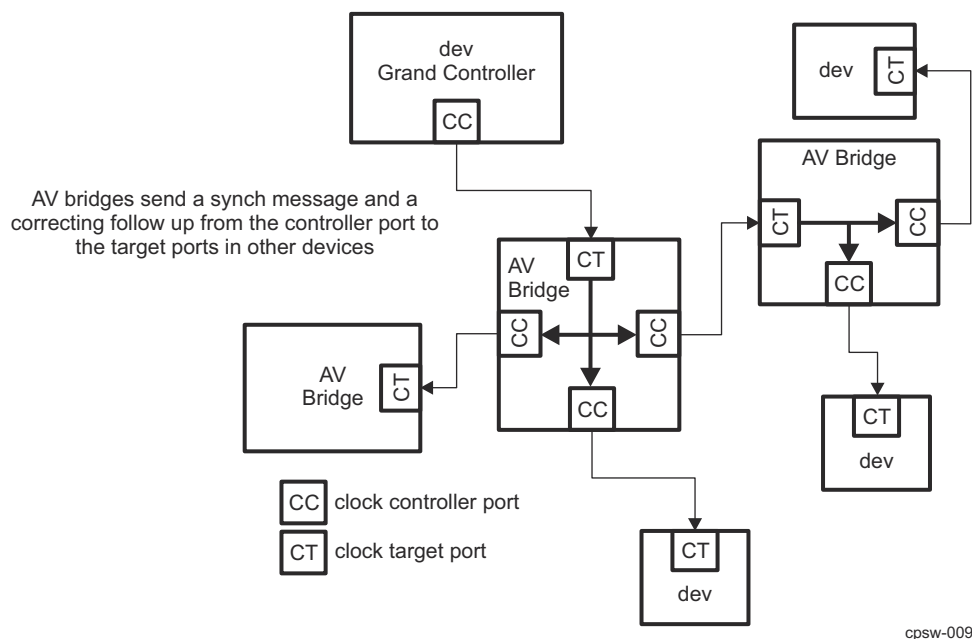

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

---

Based on IEEE 1588:2002, A PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock controller selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2-in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock controller, the Best Controller Clock Algorithm (BCCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandcontroller. Once a Grandcontroller has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Target nodes compare the value of their RTC against the PTP Grandcontroller and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW\_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- $\mu$ s accuracy over seven network hops.

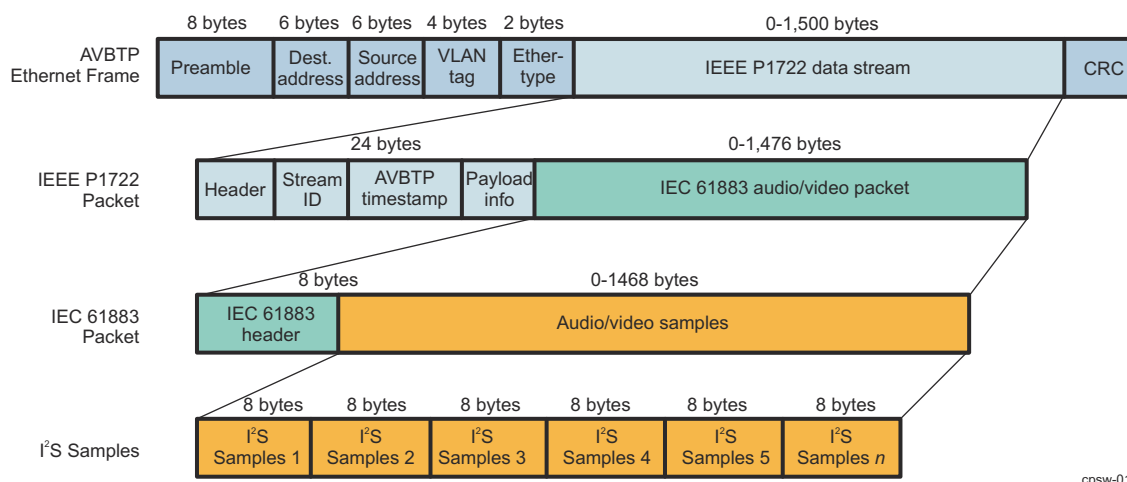

**Figure 12-137. AVB Network & PTP Clock Entities**

The media transport protocols that work within the AVB framework are:

#### 12.2.1.4.6.9.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 12-138 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

#### IEEE 1722 Packet Construction

**Figure 12-138. IEEE 1722 Packets**

1722 or AVBTP Presentation Time and Synchronization:

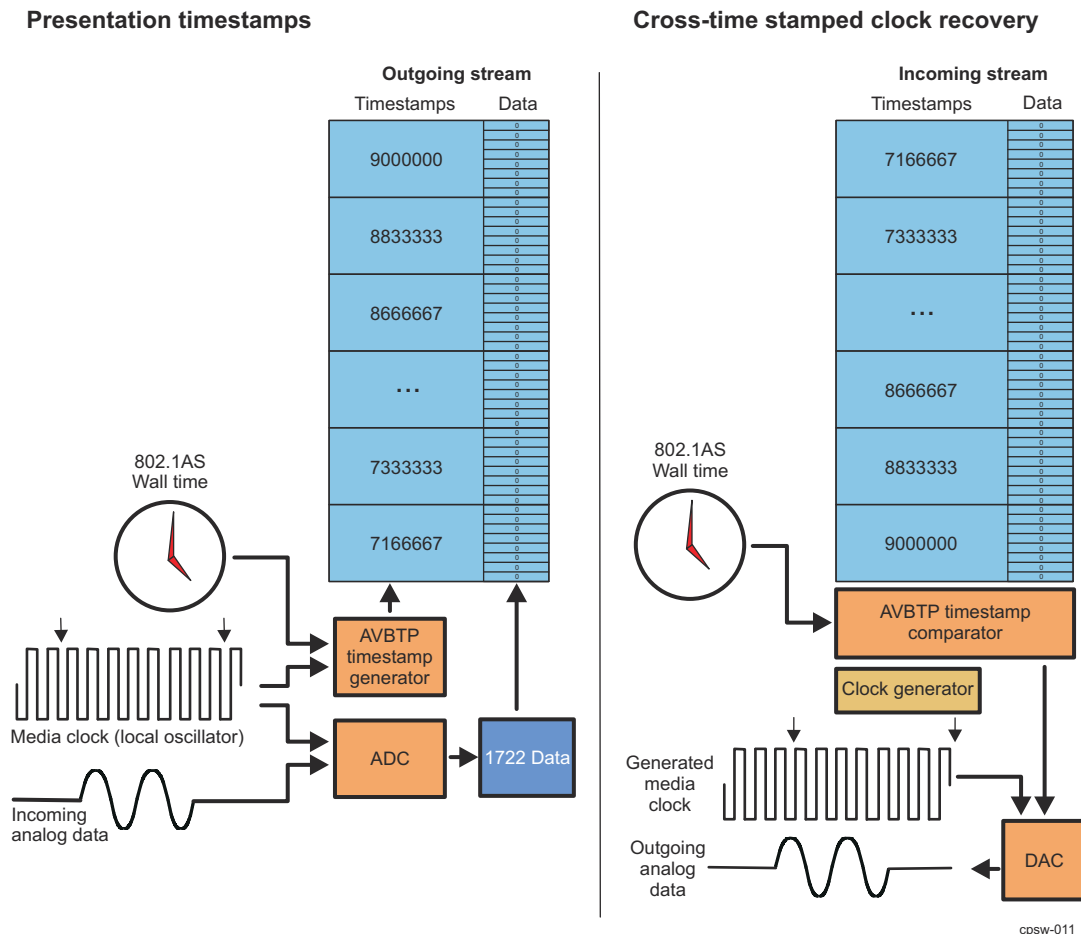

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for

synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

#### 12.2.1.4.6.9.1.1 Cross-timestamping and Presentation Timestamps

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandcontroller. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. [Figure 12-139](#) illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

**Figure 12-139. Cross Time Stamping and Presentation Timestamps**

#### 12.2.1.4.6.9.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

#### 12.2.1.4.6.9.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress

metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing
  - Transmit rate control.

### End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

### Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

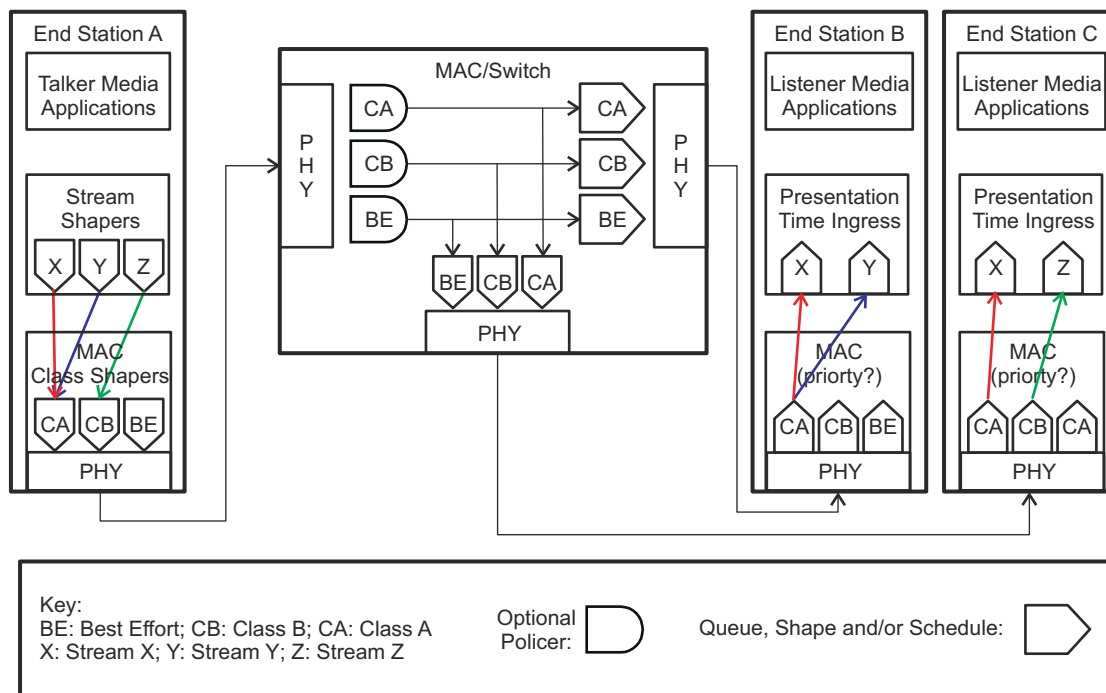

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 12-140](#).

### Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

cpsw-012

**Figure 12-140. AV Stream Queuing/Policing**

#### 12.2.1.4.6.9.2.1 Configuring the Device for 802.1Qav Operation

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

**Table 12-177. Example of TX Configuration**

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

**Table 12-178. Example of RX Configuration**

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

#### 12.2.1.4.6.10 Ethernet MAC Sliver

The Ethernet port peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

## Features:

- Synchronous 10/100/1000 Mbit operation
- RMII/RGMII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

**12.2.1.4.6.10.1****12.2.1.4.6.10.1.1****12.2.1.4.6.10.1.1.1 CRC Insertion**

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS\_CRC bit is 0h. For the Ethernet port generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS\_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS\_CRC bit is set.

**12.2.1.4.6.10.1.1.2 MTXER**

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

**12.2.1.4.6.10.1.1.3 Adaptive Performance Optimization (APO)**

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX\_PACE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

**12.2.1.4.6.10.1.1.4 Inter-Packet-Gap Enforcement**

The measurement reference for the IPG of 96-bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48-bit times of MTXEN being de-asserted, then 96-bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48-bit times after MTXEN is de-asserted, then 96-bit times (approximately, but not less) is measured from MCRS.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the [10] TX\_SHORT\_GAP\_ENABLE bit in the CPSW\_PN\_MAC\_CONTROL\_REG register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value

determines if the gap is shortened, and so on. The CPSW\_GAP\_THRESH\_REG register value determines the short gap threshold. If the FIFO blocks used is greater than or equal to the GAP\_THRESH value then short gap is triggered.

#### **12.2.1.4.6.10.1.1.5 Back Off**

The Gigabit Ethernet Mac Sliver implements the 802.3 binary exponential back-off algorithm.

#### **12.2.1.4.6.10.1.1.6 Programmable Transmit Inter-Packet Gap**

The transmit inter-packet gap (IPG) is programmable through the CPSW\_PN\_MAC\_CONTROL\_REG register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### **12.2.1.4.6.10.1.1.7 Speed, Duplex and Pause Frame Support Negotiation**

The Ethernet port can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

#### **12.2.1.4.6.10.2 RMII Interface**

The CPRMII peripheral is compliant to the RMII specification document.

##### **12.2.1.4.6.10.2.1 Features**

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

##### **12.2.1.4.6.10.2.2 RMII Receive (RX)**

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII\_RXER on any di-bit in the received packet will cause an MII\_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII\_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII\_CRS\_DV toggle will issue an MII\_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII\_CRS\_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

##### **12.2.1.4.6.10.2.3 RMII Transmit (TX)**

The CPRMII transmit (TX) interface converts the CPGMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The CPGMAC does not source the transmit error (MII\_TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII\_TXD[1:0] for each clock that RMII\_TXEN is de-asserted.

#### **12.2.1.4.6.10.3 RGMII Interface**

The CPRGMII peripheral is compliant to the RGMII specification document.

##### **12.2.1.4.6.10.3.1 Features**

- Supports 1000/100/10 Mbps speed

- Full and Half Duplex support (CPGMAC supports only Full duplex in Gigabit mode).
- MII mode support
- Energy Efficient Ethernet Support

#### 12.2.1.4.6.10.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

#### 12.2.1.4.6.10.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII\_RX\_INBAND input is asserted. RGMII\_RX\_INPUT is asserted by configuring the EXT\_EN bit to 1h of the CPSW\_PN\_MAC\_CONTROL\_REG register. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX\_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 12-179](#).

**Table 12-179. In-Band Data**

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0h: half-duplex	0h: 10-Mbps mode	2.5 MHz	0h: Link is down
1h: full-duplex	1h: 100-Mbps mode	25 MHz	1h: Link is up
	2h: 1000-Mbps mode	125 MHz	
	3h: Reserved	Reserved	

#### 12.2.1.4.6.10.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII\_RX\_INBAND input is deasserted by setting to 0h bit EXT\_EN of the CPSW\_PN\_MAC\_CONTROL\_REG register. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the CPSW\_PN\_MAC\_CONTROL\_REG[0] FULLDUPLEX and CPSW\_PN\_MAC\_CONTROL\_REG[7] GIG bits. If bit [7] GIG = 1h, then CPRGMII is operating in Gigabit mode. If bit [7] GIG is cleared (0h), then CPRGMII is operating in 100 Mbps mode.

#### 12.2.1.4.6.10.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 Mbps mode, the TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 Mbps mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII\_LINK. Packet transmission will begin on the first TX\_CTL rising edge after the 4096 transmit clock count has expired.

#### 12.2.1.4.6.10.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and CPSW\_P0\_RX\_MAXLEN\_REG[13:0] RX\_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW\_P0\_RX\_MAXLEN\_REG/ CPSW\_PN\_RX\_MAXLEN\_REG register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames. If RX\_CSF\_EN bit in CPSW\_PN\_MAC\_CONTROL\_REG is set to 1h, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If RX\_CSF\_EN and RX\_CEF\_EN in CPSW\_PN\_MAC\_CONTROL\_REG are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain RX\_MAXLEN number of bytes transferred to memory (if CPSW\_PN\_MAC\_CONTROL\_REG[22]RX\_CEF\_EN = 1h). An example with RX\_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

#### 12.2.1.4.6.10.5 Receive FIFO Architecture

This section describes the architecture of the Ethernet port's receive FIFOs. Internal to the Gigabit Ethernet switch, all Ethernet ports have an identical associated packet FIFO. Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each transmit FIFO memory contains 81,920 bytes total organized as 2560 by 256-bit words. Each FIFO also contains a single memory for the receive queue. Each receive FIFO memory contains a total of 32768 bytes total organized as 1024 by 256-bit words.

#### 12.2.1.4.6.11 Embedded Memories

**Table 12-180. Embedded Memories**

Memory Type Description	Number of Instances	
Single-port 3072-word × 64 RAM	1	(Combined FIFO RAM)
Single-port 128-word × 28-bit RAM	1	1 (EST)

#### 12.2.1.4.6.12 Memory Error Detection and Correction

The CPSW error detection and correction logic uses the ECC Aggregator Module.

The ECC CPSW\_ECC\_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in [Table 12-181](#). The CPSW FIFO RAMs implement ECC only on packet headers. The packet data is protected by Ethernet CRC. The ALE and EST RAMs have complete ECC as normal.

**Table 12-181. ECC RAM to CPSW RAM Mapping**

ECC RAM Number	CPSW RAM
0	ALE RAM
1	Port 0 FIFO RAM

##### 12.2.1.4.6.12.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC\_ERR\_CTRL1[31-0] ECC\_ROW bit is used to activate a row address where force single-bit error or force double-bit error needs to be applied. ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC\_CRC\_MODE bit is cleared in the CPSW\_CONTROL\_REG register. The ECC status registers return the RAM row address where the single or double-bit error has occurred (ECC\_ERR\_STAT2[31-0] ECC\_ROW) along with the bit position in the RAM data that is in error (ECC\_ERR\_STAT1[31-16] ECC\_BIT1 value). Forcing double-bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single-bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC\_CRC\_MODE is set to 1h. Either the RX\_ECC\_ERR\_EN (enable receive ECC error operations) or the TX\_ECC\_ERR\_EN (enable transmit ECC error operations) bits must be set in the CPSW\_P0\_CONTROL\_REG register to test ECC header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse interrupt (ECC\_PULSE\_INTR) as does an ALE RAM ECC error.

##### 12.2.1.4.6.12.2 Packet Protect CRC

Each packet received without error is passed through the CPSW\_3G memories with a generated Ethernet protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST\_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC\_PULSE\_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT\_PEND\_INTR if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC\_CRC\_MODE bit in the CPSW\_CONTROL\_REG register is set, the ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 bit field will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC\_CRC\_MODE is set. Either the RX\_ECC\_ERR\_EN or the TX\_ECC\_ERR\_EN bits must be set in the CPSW\_P0\_CONTROL\_REG register to test packet CRC errors.

##### 12.2.1.4.6.12.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word.

The header data bits and ECC code bits are shown in [Table 12-182](#). The [15-0] ECC\_BIT1 value returned on error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC\_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is,  $(26 \times 3) + 8$ ).

**Table 12-182. ECC Submodule Header Data Bit to Encoder/Decoder Mapping**

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:78	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

#### 12.2.1.4.6.13 Ethernet Port Flow Control

The Ethernet port have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The Ethernet port have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an Ethernet port can be sent to the CPPI port. The destination port can trigger the receive Ethernet port flow control. An Ethernet destination port triggers another Ethernet receive flow control when the destination port is full.

When a packet is received on an Ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the Ethernet port will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX\_BLK\_CNT = 0h). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX\_FLOW\_EN bit in CPSW\_PN\_MAC\_CONTROL\_REG be set to 1h. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit.

### 12.2.1.4.6.13.1 Ethernet Receive Flow Control

For every Ethernet port to be configured for full-duplex receive flow control, write a value of decimal 7 to the CPSW\_PN\_MAX\_BLKs\_REG[7-0] RX\_MAX\_BLKs bit field, and a value of decimal 13 to the CPSW\_PN\_MAX\_BLKs\_REG[15-8] TX\_MAX\_BLKs register. This re-allocation allows for flow control runout on the receive FIFO at the expense of FIFO memory on the Ethernet transmit side. 10/100Mbps half-duplex collision based receive flow control does not need this re-allocation. Receive flow control is enabled by the RX\_FLOW\_EN bit in the CPSW\_PN\_MAC\_CONTROL\_REG register.

#### 12.2.1.4.6.13.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW\_PN\_MAC\_CONTROL\_REG). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

#### 12.2.1.4.6.13.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit is set in the CPSW\_PN\_MAC\_CONTROL\_REG register). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full at which time the receive FIFO will overrun and CPSW\_STAT0\_RX\_BOTTOM\_OF\_FIFO\_DROP/ CPSW\_STAT1\_RX\_BOTTOM\_OF\_FIFO\_DROP[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL\_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If CPSW\_PN\_MAC\_CONTROL\_REG[3] RX\_FLOW\_EN is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to 0h and a 0 count pause frame will be sent.

#### 12.2.1.4.6.13.2 Flow Control Trigger

Receive flow control is triggered (when enabled), when the number of words in the receive FIFO is greater than or equal to the value written in the CPSW\_PN\_RX\_FLOW\_THRESH\_REG[8-0] COUNT bit field. The flow control packet runout is then contained in the remainder of the receive FIFO.

#### 12.2.1.4.6.13.3 Ethernet Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Ethernet port from transmitting any further frames. Incoming pause frames are only acted upon when the [0] FULLDUPLEX and [4] TX\_FLOW\_EN bits in the CPSW\_PN\_MAC\_CONTROL\_REG register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the [24] RX\_CMF\_EN (RX Copy MAC Control Frames Enable) bit in the CPSW\_PN\_MAC\_CONTROL\_REG register is set. The [4] TX\_FLOW\_EN and [0] FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- [4] TX\_FLOW\_EN is set in CPSW\_PN\_MAC\_CONTROL\_REG register, and
- the RX maximum frame length is 64 bytes inclusive (CPSW\_PN\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN), and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If [4] TX\_FLOW\_EN in CPSW\_PN\_MAC\_CONTROL\_REG register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01, or the Ethernet port SL\_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit CPSW\_PN\_MAC\_TX\_PAUSETIMER\_REG[15-0] TX\_PAUSETIMER. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 Bytes. The standard allows pause frames longer than 64 Bytes to be discarded or interpreted as valid pause frames. The Ethernet port will recognize any pause frame between 64 Bytes and CPSW\_PN\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN bytes in length.

#### 12.2.1.4.6.14 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the LPSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW\_EEE\_PRESCALE\_REG register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (CPSW\_PN\_IDLE2LPI\_REG[23-0] COUNT) are written with the desired values
3. The port LPI to Wake count values (CPSW\_PN\_LPI2WAKE\_REG[23-0] COUNT) are written with the desired values
4. The [0] EEE\_EN bit is set in the switch CPSW\_SS\_CONTROL\_REG register

EEE operation can begin after configuration. The host allows (through LPSC) the CPSW to enter a low power state by asserting the EEE\_CLKSTOP\_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE\_CLKSTOP\_REQ to the CPSW.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the CPSW\_PN\_IDLE2LPI\_REG value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPPI (port 0) LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive have both been idle for the Idle to LPI time (CPSW\_P0\_IDLE2LPI\_REG). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

#### Note

External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX\_CTL at the rising and the falling TXC edges, respectively. RXDV and RXER are the sampled values of RX\_CTL at the rising and the falling RXC clock edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE\_CLKSTOP\_ACK signal is asserted, and the LPSC is allowed to stop the module clock. When EEE\_CLKSTOP\_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform target read/write operations to the CPSW memory address space, and then turn off the clock again while EEE\_CLKSTOP\_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE\_CLKSTOP\_REQ. There must be at least one rising edge of the clock before EEE\_CLKSTOP\_REQ is de-asserted. The module EEE\_CLKSTOP\_ACK output signal will be deasserted on the clock after the de-assertion of EEE\_CLKSTOP\_REQ. The host may queue CPPI receive packets at any time without regard to the CPSW module LPI state. The Host must deassert EEE\_CLKSTOP\_REQ on wakeup for a minimum of two clock periods. If EEE\_CLKSTOP\_REQ is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet port to awaken.

The external Ethernet PHY's can also wakeup the LPSC by removing the Ethernet receive LPI indication. If the CPSW module is in Idle state with `EEE_CLKSTOP_ACK` asserted and the receive LPI indication is removed, the `EEE_CLKSTOP_WAKEUP` signal will be asynchronously asserted. On wakeup, the LPSC restarts the clock and de-assert the `EEE_CLKSTOP_REQ` signal. The `EEE_CLKSTOP_WAKEUP` signal will be synchronously deasserted with `EEE_CLKSTOP_ACK`. Upon the deassertion of `EEE_CLKSTOP_REQ`, the Ethernet ports will count the `CPSW_PN_LPI2WAKE_REG` time for each port at which time the port is available for transmit.

#### 12.2.1.4.6.15 Ethernet Switch Latency

When CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

The store and forward latency is shown in [Table 12-183](#):

**Table 12-183. Switch Latency**

Mode	Latency
Gig (1000)	880 ns
100	1.3 $\mu$ s
10	6.5 $\mu$ s

#### 12.2.1.4.6.16 MAC Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW operation to be completely or partially suspended. Each Ethernet port has associated emulation control registers (`CPSW_EM_CONTROL_REG` and `CPSW_PN_MAC_EMCONTROL_REG`). The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

#### Ethernet port Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the `CPSW_PN_MAC_EMCONTROL_REG` register) allow Ethernet port operation to be suspended. When the emulation suspend state is entered, the Ethernet port will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the Ethernet port after the suspend state is entered are ignored.

[Table 12-184](#) shows the operations of the emulation control input and register bits.

**Table 12-184. Emulation Control Input**

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 12.2.1.4.6.17 MAC Command IDLE

The `CMD_IDLE` bit in the `CPSW_PN_MAC_CONTROL_REG` register allows MAC operation to be suspended. When the idle state is commanded, the MAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

### 12.2.1.4.6.18 CPSW Network Statistics

The CPSW has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of MCU\_CPSW0\_RST. When one or more port enable (Pn\_STAT\_EN) bits in the CPSW\_STAT\_PORT\_EN\_REG register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT\_PEND0) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

[Section 12.2.1.4.6.18.1](#) and [Section 12.2.1.4.6.18.8](#) summarize network statistics.

#### 12.2.1.4.6.18.1 Rx-only Statistics Descriptions

##### 12.2.1.4.6.18.1.1 Good Rx Frames (Offset = 3A000h - Port 0 or Offset = 3A200h - Port 1)

#### All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the *Rx Align/Code Errors* and *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.1.4.6.18.1.2 Broadcast Rx Frames (Offset = 3A004h - Port 0 or Offset = 3A204h - Port 1)

#### All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the *Rx Align/Code Errors* and *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.1.4.6.18.1.3 Multicast Rx Frames (Offset = 3A008h - Port 0 or Offset = 3A208h - Port 1)

#### All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6](#), *Rx Align/Code Errors* and [Section 12.2.1.4.6.18.1.5](#), *Rx CRC errors* statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.1.4.6.18.1.4 Pause Rx Frames (Offset = 3A20Ch - Port 1)

##### Ethernet port 1

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX\_FLOW\_EN = 1h).

The port could have been in either half or full-duplex mode.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.1.4.6.18.1.5 Rx CRC Errors (Offset = 3A010h - Port 0 or Offset = 3A210h - Port 1)

##### All ports

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

#### 12.2.1.4.6.18.1.6 Rx Align/Code Errors (Offset = 3A214h - Port 1)

##### Ethernet port 1

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

#### Note

RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

**12.2.1.4.6.18.1.7 Oversize Rx Frames (Offset = 3A018h - Port 0 or Offset = 3A218h - Port 1)****All ports**

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.8 Rx Jabbers (Offset = 3A21Ch - Port 1)****All ports**

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.9 Undersize (Short) Rx Frames (Offset = 3A020h - Port 0 or Offset = 3A220h - Port 1)****All ports**

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

**12.2.1.4.6.18.1.10 Rx Fragments (Offset = 3A024h - Port 0 or Offset = 3A224h - Port 1)****Ethernet port 1**

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.1.4.6.18.1.11 RX IPG Error (Offset = 3A25Ch - Port 1)

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

#### 12.2.1.4.6.18.1.12 ALE Drop (Offset = 3A028h - Port 0 or Offset = 3A228h - Port 1)

##### All ports

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT\_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT\_MASK

#### 12.2.1.4.6.18.1.13 ALE Overrun Drop (Offset = 3A02Ch - Port 0 or Offset = 3A22Ch - Port 1)

##### All ports

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX\_CSF\_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

#### 12.2.1.4.6.18.1.14 Rx Octets (Offset = 3A030h - Port 0 or Offset = 3A230h - Port 1)

##### All ports

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.1.4.6.18.1.6, Rx Align/Code Errors](#) and [Section 12.2.1.4.6.18.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.1.4.6.18.1.15 Rx Bottom of FIFO Drop (Offset = 3A084h - Port 0 or Offset = 3A284h - Port 1)

##### Ethernet port 1

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)

- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

---

**Note**

This statistic should be zero if proper flow control is being followed.

---

**Host port 0**

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 33 bytes.

**12.2.1.4.6.18.1.16 Portmask Drop (Offset = 3A088h - Port 0 or Offset = 3A288h - Port 1)**
**All ports**

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT\_MASK=0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

---

**Note**

This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT\_MASK.

---

**12.2.1.4.6.18.1.17 Rx Top of FIFO Drop (Offset = 3A08Ch - Port 0 or Offset = 3A28Ch - Port 1)**
**All ports**

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

**12.2.1.4.6.18.1.18 ALE Rate Limit Drop (Offset = 3A090h - Port 0 or Offset = 3A290h - Port 1)**
**All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

#### **12.2.1.4.6.18.1.19 ALE VLAN Ingress Check Drop (Offset = 3A094h - Port 0 or Offset = 3A294h - Port 1)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

#### **12.2.1.4.6.18.1.19.1 ALE DA=SA Drop (Offset = 3A098h - Port 0 or Offset = 3A298h - Port 1)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

#### **12.2.1.4.6.18.1.19.2 Block Address Drop (Offset = 3A09Ch - Port 0 or Offset = 3A29Ch - Port 1)**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source or destination address matched a table entry with the block bit set.

#### **12.2.1.4.6.18.1.19.3 ALE Secure Drop (Offset = 3A0A0h - Port 0 or Offset = 3A2A0h - Port 1)**

The total number of frames received on a port that were dropped (zero port\_mask) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source address is an entry in the table with the SECURE bit set and a port number for a different receive port.

#### **12.2.1.4.6.18.1.19.4 ALE Authentication Drop (Offset = 3A0A4h - Port 0 or Offset = 3A2A4h - Port 1)**

The total number of frames received on a port that were dropped (zero port\_mask) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- CPSW\_ALE\_CONTROL[1] ENABLE\_AUTH\_MODE is set to 1h, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the SUPER bit set.

#### **12.2.1.4.6.18.1.19.5 ALE Unknown Unicast (Offset = 3A0A8h - Port 0 or Offset = 3A2A8h - Port 1)**

##### **All ports**

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

Note: The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

#### **12.2.1.4.6.18.1.19.6 ALE Unknown Unicast Bytecount (Offset = 3A0ACh - Port 0 or Offset = 3A2ACh - Port 1)**

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.7 ALE Unknown Multicast (Offset = 3A0B0h - Port 0 or Offset = 3A2B0h - Port 1)**

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

#### **12.2.1.4.6.18.1.19.8 ALE Unknown Multicast Bytecount (Offset = 3A0B4h - Port 0 or Offset = 3A2B4h - Port 1)**

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.9 ALE Unknown Broadcast (Offset = 3A0B8h - Port 0 or Offset = 3A2B8h - Port 1)**

The total number of frames received on a port that had a broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

#### **12.2.1.4.6.18.1.19.10 ALE Unknown Broadcast Bytecount (Offset = 3A0BCh - Port 0 or Offset = 3A2BCh - Port 1)**

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

#### **12.2.1.4.6.18.1.19.11 ALE Policier/Classifier Match (Offset = 3A0C0h - Port 0 or Offset = 3A2C0h - Port 1)**

##### **All ports**

The total number of frames received on a port that matched a policier. The frame is defined to be:

- was any data frame
- matched a condition on a policier,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.2 ALE Policer Match Red (Offset = 3A0C4h - Port 0 or Offset = 3A2C4h - Port 1)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.3 ALE Policer Match Yellow (Offset = 3A0C8h - Port 0 or Offset = 3A2C8h - Port 1)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.1.4.6.18.4 IET Receive Assembly Error (Offset = 3A140h - Port 0 or Offset = 3A340h - Port 1)**

The total number of preemptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine)

#### **12.2.1.4.6.18.5 IET Receive Assembly OK (Offset = 3A144h - Port 0 or Offset = 3A344h - Port 1)**

The total number of correctly received and re-assembled preemptable frames.

- any preemptable frame received
- was any size, and
- was correctly received and re-assembled without error

#### **12.2.1.4.6.18.6 IET Receive SMD Error (Offset = 3A148h - Port 0 or Offset = 3A348h - Port 1)**

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note: If IET\_ENABLE is not set, this statistic counts any received frame with any non express SMD.

#### **12.2.1.4.6.18.7 IET Receive Merge Fragment Count (Offset = 3A14Ch - Port 0 or Offset = 3A34Ch - Port 1)**

The total number of received non-initial fragments that did not have an assembly error. The IET stat CPSW\_STAT0\_RXFRAGMENTS/ CPSW\_STAT1\_RXFRAGMENTS is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error

#### **12.2.1.4.6.18.8 Tx-only Statistics Descriptions**

The maximum and minimum transmit frame size is software controllable.

#### **12.2.1.4.6.18.8.1 Good Tx Frames (Offset = 3A034h - Port 0 or Offset = 3A234h - Port 1)**

**All ports**

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **12.2.1.4.6.18.8.2 Broadcast Tx Frames (Offset = 3A038h - Port 0 or Offset = 3A238h - Port 1)**

##### **All ports**

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **12.2.1.4.6.18.8.3 Multicast Tx Frames (Offset = 3A03Ch - Port 0 or Offset = 3A23Ch - Port 1)**

##### **All ports**

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **12.2.1.4.6.18.8.4 Pause Tx Frames (Offset = 3A240h - Port 1)**

##### **Ethernet port 1**

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

#### **12.2.1.4.6.18.8.5 Deferred Tx Frames (Offset = 3A244h - Port 1)**

##### **Ethernet port 1**

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.6 Collisions (Offset = 3A248h - Port 1)**

##### **Ethernet port 1**

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
  - Was destined for any unicast, broadcast or multicast address
  - Was any size

- Had no carrier loss and no underrun
- Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

#### **12.2.1.4.6.18.8.7 Single Collision Tx Frames (Offset = 3A24Ch - Port 1)**

##### **Ethernet port 1**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.8 Multiple Collision Tx Frames (Offset = 3A250h - Port 1)**

##### **Ethernet port 1**

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.9 Excessive Collisions (Offset = 3A254h - Port 1)**

##### **Ethernet port 1**

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.10 Late Collisions (Offset = 3A258h - Port 1)**

##### **Ethernet port 1**

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple-, and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.11 Carrier Sense Errors (Offset = 3A260h - Port 1)**

##### **Ethernet port 1**

The total number of frames on the port that experienced carrier loss. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

#### **12.2.1.4.6.18.8.12 Tx Octets (Offset = 3A064h - Port 0 or Offset = 3A264h - Port 1)**

##### **All ports**

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

#### **12.2.1.4.6.18.8.13 Transmit Priority 0-7 (Offset = 3A380h to 3A3A8h - Port 1)**

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- Any frame transmitted from priority 0-7, and
- Was less than or equal to CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG
- Collision retries are not counted in this statistic.
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note: The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

#### **12.2.1.4.6.18.8.14 Transmit Priority 0-7 Drop (Offset = 3A3C0h to 3A3E8h - Port 1)**

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG.

- Any frame destined to be transmitted from priority 0-7, and
- Was any size, and
- Was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG.

Note: The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

#### **12.2.1.4.6.18.8.15 Tx Memory Protect Errors (Offset = 3A17Ch - Port 0 or Offset = 3A37Ch - Port 1)**

##### **All ports**

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

### Note

1. Frames to the host with memory protect errors are dropped via TXST\_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
2. This statistic is 8-bits wide only and will not rollover but will limit at 0xFF.
3. A non-zero value in this statistic will issue a STAT\_PEND0 interrupt for the associated port.

#### 12.2.1.4.6.18.8.16 IET Transmit Merge Hold Count (Offset = 3A350h - Port 1)

The total number of preemptable frames that were preempted and reassembled by the assertion of MAC\_HOLD in the CPSW\_PN\_IET\_CONTROL\_REG register or were preempted by Enhanced Scheduled Traffic (EST). The IET statistic can be derived and maintained by software.

- Any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was preempted by the assertion of MAC\_HOLD.
- was preempted by Enhanced Scheduled Traffic (EST).

#### 12.2.1.4.6.18.8.17 IET Transmit Merge Fragment Count (Offset = 3A154h - Port 0 or Offset = 3A354h - Port 1)

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- Any frame destined to be transmitted on the preemptable port, and
- Was any size, and
- was a non-initial fragment.

#### 12.2.1.4.6.18.9 Rx- and Tx (Shared) Statistics Descriptions

**Table 12-185. Rx Statistics Summary**

Rx Statistic	Frame/ Oct	Rx/ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024- rx_max len	>rx_max len	Flow Coll. (8)	CRC Error	Align/ Code	Overrun	Add. Disc.
			Pause frame	Non-pause <sup>(4)</sup>	Multicast	Broadcast	Unicast													
Good Rx Frames	F	Rx	(y  <sup>(1)</sup>	y	y	y	y	n	(y	y	y	y	y	y)	n	.(2)	n	n	-	n
Broadcast Rx Frames	F	Rx	(%  (6)	%	n	y)	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Multicast Rx Frames	F	Rx	(%	%	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	(y	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y	y	y)	y <sup>(7)</sup>	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns <sup>(9)</sup>	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	y	n
64octet Frames	F	Rx+ Tx <sup>(3)</sup>	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n

**Table 12-185. Rx Statistics Summary (continued)**

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)										Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. <sup>(8)</sup>	CRC Error	Align/ Code	Overrun	Add. Disc.		
			Pause frame	Non-pause <sup>(4)</sup>	Multicast	Broadcast	Unicast															
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n		
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	n	-	-	-	-	n		
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n		
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n		
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n		
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n		
Net Octets	O	Rx+Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	y)	-	-	-	-		

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx\_overruns stat is for RX\_MOF\_OVERRUNS and RX\_SOF\_OVERRUNS added together.

**Table 12-186. Tx Statistics Summary**

Tx Statistic <sup>(9)</sup>	Fra me/ Oct	Tx/ Rx +Tx	Frame Type					Frame Size (bytes)							Event

Net Octets	O	Rx+ Tx	(y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	\$ <sup>(7)</sup>	\$	\$	\$	\$	-	-	-			

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See Rx Statistics Summary.)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

#### 12.2.1.4.6.18.9.1 Rx + Tx 64 Octet Frames (Offset = 3A068h - Port 0 or Offset = 3A268h - Port 1)

#### All ports

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.9.2 Rx + Tx 65–127 Octet Frames (Offset = 3A06Ch - Port 0 or Offset = 3A26Ch - Port 1)**

##### **All ports**

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.9.3 Rx + Tx 128–255 Octet Frames (Offset = 3A070h - Port 0 or Offset = 3A270h - Port 1)**

##### **All ports**

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.9.4 Rx + Tx 256–511 Octet Frames (Offset = 3A074h - Port 0 or Offset = 3A274h - Port 1)**

##### **All ports**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.9.5 Rx + Tx 512–1023 Octet Frames (Offset = 3A078h - Port 0 or Offset = 3A278h - Port 1)**

##### **All ports**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.1.4.6.18.9.6 Rx + Tx 1024\_Up Octet Frames (Offset = 3A07Ch - Port 0 or Offset = 3A27Ch - Port 1)**

##### **All ports**

The total number of frames of size 1024 to RX\_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX\_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 12.2.1.4.6.18.9.7 Net Octets (Offset = 3A080h - Port 0 or Offset = 3A280h - Port 1)

#### All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 12-187](#).)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

### 12.2.1.4.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

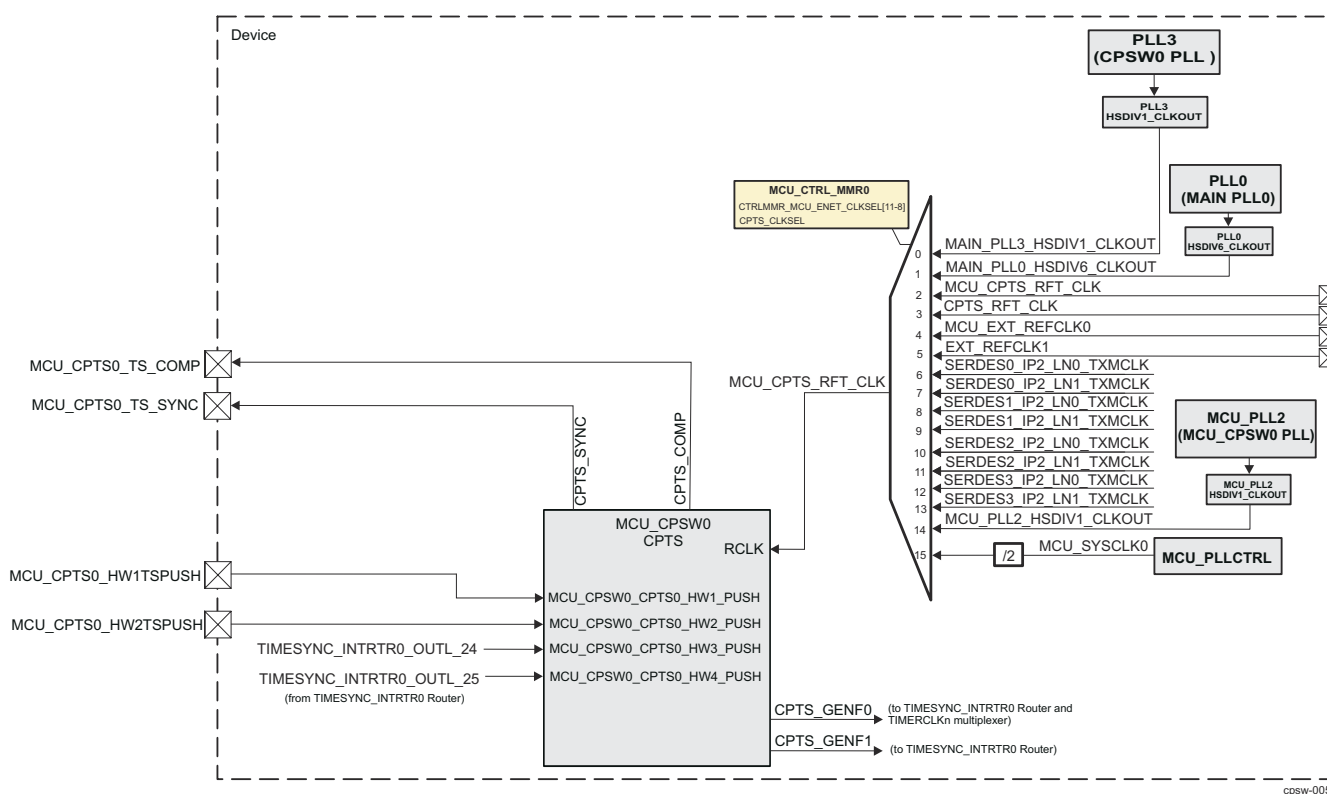

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports up to 4 hardware timestamp push inputs
- Supports timestamp counter compare output (CPTS\_COMP)
- Supports timestamp counter bit output (CPTS\_SYNC)
- Supports a configurable number of timestamp Generator bit outputs (CPTS\_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (CPTS\_ESTFn).
- 32-bit and 64-bit timestamp modes with PPM and nudge adjustment.

#### 12.2.1.4.7.1 MCU\_CPSW0 CPTS Integration

This section describes CPTS module integration in the MCU\_CPSW0 module, including information about clocks, resets, and hardware requests.

Figure 12-141 shows CPTS integration in the device MCU\_CPSW0 module.

**Figure 12-141. MCU\_CPSW0 CPTS Integration**

CPTS IEEE 1588 clock (RCLK) is selected through the CTRLMMR\_MCU\_ENET\_CLKSEL register.

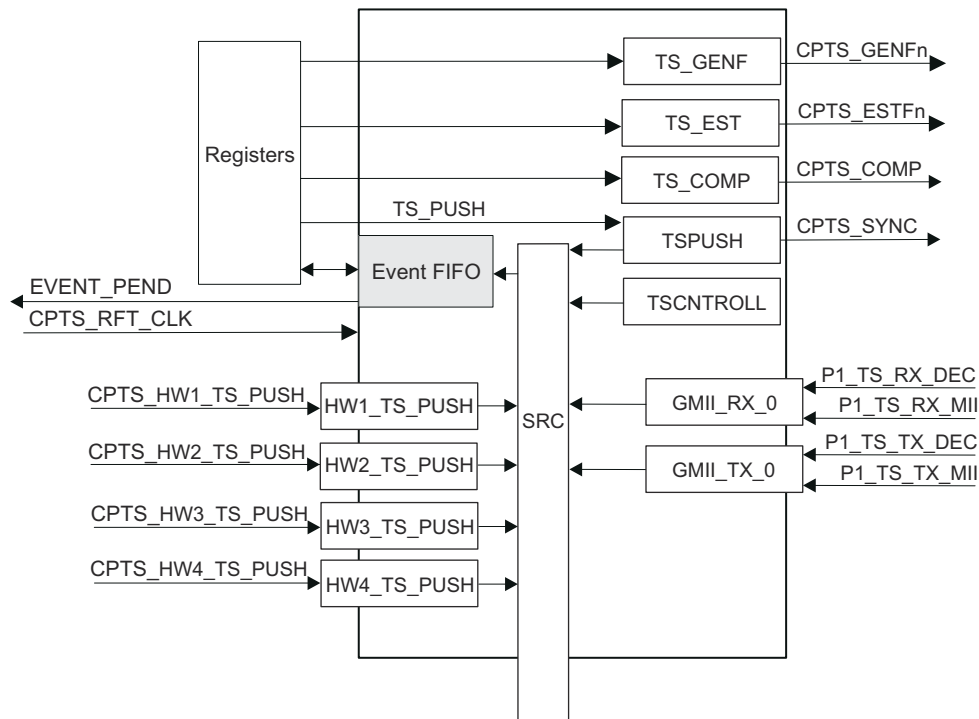

#### Note

For more information about CPTS clocks and resets, see *MCU\_CPSW0 Integration*.

#### 12.2.1.4.7.2 CPTS Architecture

Figure 12-142 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on external port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWN\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS\_RFT\_CLK) can be derived from several sources.

Note: CPTS\_HW1\_TS\_PUSH to CPTS\_HW4\_TS\_PUSH events are used for CPTS implemented in MCU\_CPSW0 module.

cpsw-013

**Figure 12-142. CPTS Block Diagram**

#### Note

See *MCU\_CPSW0 CPTS Integration* for CPTS integration in the device MCU\_CPSW0 module.

#### 12.2.1.4.7.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the CPTS\_CLKSEL value in the CTRLMMR\_MCU\_ENET\_CLKSEL register with the desired reference clock selection. This value is allowed to be written only when the CPTS\_EN bit in the CPSW\_CPTS\_CONTROL\_REG register is cleared to zero.
3. Set the CPTS\_EN bit in the CPSW\_CPTS\_CONTROL\_REG register.
4. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the CPSW\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.1.4.7.4 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPSW\_CPTS\_TS\_LOAD\_VAL\_REG / CPSW\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG and CPSW\_CPTS\_TS\_LOAD\_EN\_REG registers).

#### 12.2.1.4.7.5 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

64-bit mode is selected when CPSW\_CPTS\_CONTROL\_REG[5] MODE bit set to 1h.

For test purposes, the time stamp value can be written via the time stamp load function (CPSW\_CPTS\_TS\_LOAD\_EN\_REG, CPSW\_CPTS\_TS\_LOAD\_VAL\_REG, and CPSW\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG registers). The CPSW\_CPTS\_TS\_ADD\_VAL\_REG feature is included to allow 1ns timestamp operations with an CPTS\_RFT\_CLK rate less than 1Ghz. [Table 12-189](#) shows the CPTS\_RFT\_CLK and CPSW\_CPTS\_TS\_ADD\_VAL\_REG values for 1ns operations.

**Table 12-189. ADD\_VAL feature**

CPTS_RFT_CLK (MHz)	CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL
1 GHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

#### 12.2.1.4.7.6 64-Bit Timestamp Nudge

The 64-bit TIME\_STAMP value can be adjusted by writing the CPSW\_CPTS\_TS\_NUDGE\_VAL\_REG[7-0] TS\_NUDGE\_VAL bit field value which is a two's complement value. A value of FFh will subtract 1 clock cycle from the next incremented 64-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP and CPSW\_CPTS\_EVENT\_3\_REG[31-0] TIME\_STAMP value). A nudge value of 1h will add 1 clock cycle to the next incremented TIME\_STAMP[63-0] value. For example, if the current TIME\_STAMP value is F06h, and CPSW\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL = 3h, the next incremented timestamp value would be F0Ah without a nudge and F0Ah +/- [7-0] TS\_NUDGE\_VAL with a nudge. The [7-0] TS\_NUDGE\_VAL value is cleared to zero when the nudge has occurred.

#### 12.2.1.4.7.7 64-bit Timestamp PPM

The 64-bit TIME\_STAMP can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL (Time stamp PPM Low value) and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL (Time stamp PPM High value) enables PPM operations. The adjustment is up or down depending on the [7] TS\_PPM\_DIR bit in the CPSW\_CPTS\_CONTROL\_REG register. The TIME\_STAMP value is increased by the PPM value when [7] TS\_PPM\_DIR bit is cleared. The TIME\_STAMP value is decreased by the PPM value when [7] TS\_PPM\_DIR bit is set.

#### Parts Per Million example:

To adjust for 100 parts per million the configured value for TS\_PPM[41-0] (through CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $1,000,000/100 = 10,000(\text{decimal})$

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for TS\_PPM[41-0] (through CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

#### 12.2.1.4.7.8 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 32 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 12.2.1.4.7.9 Timestamp Compare Output

CPTS features one Time Stamp Compare (CPTS\_COMP) output. The CPTS\_COMP function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. CPTS\_COMP is not compatible with timestamp PPM or a non-zero CPSW\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL value.

##### 12.2.1.4.7.9.1 Non-Toggle Mode: 32-bit

The CPTS\_COMP output is asserted for CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH periods when the CPSW\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP value (lower 32-bits) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_VAL and the length value is non-zero. The CPTS\_COMP rising edge occurs three CPTS\_RFT\_CLK clock periods after the values compare. A timestamp compare event is pushed into the event FIFO when CPTS\_COMP is asserted. The polarity of the CPTS\_COMP output is determined by the CPSW\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit. The output is asserted low when the polarity bit is 0h.

##### 12.2.1.4.7.9.2 Non-Toggle Mode: 64-bit

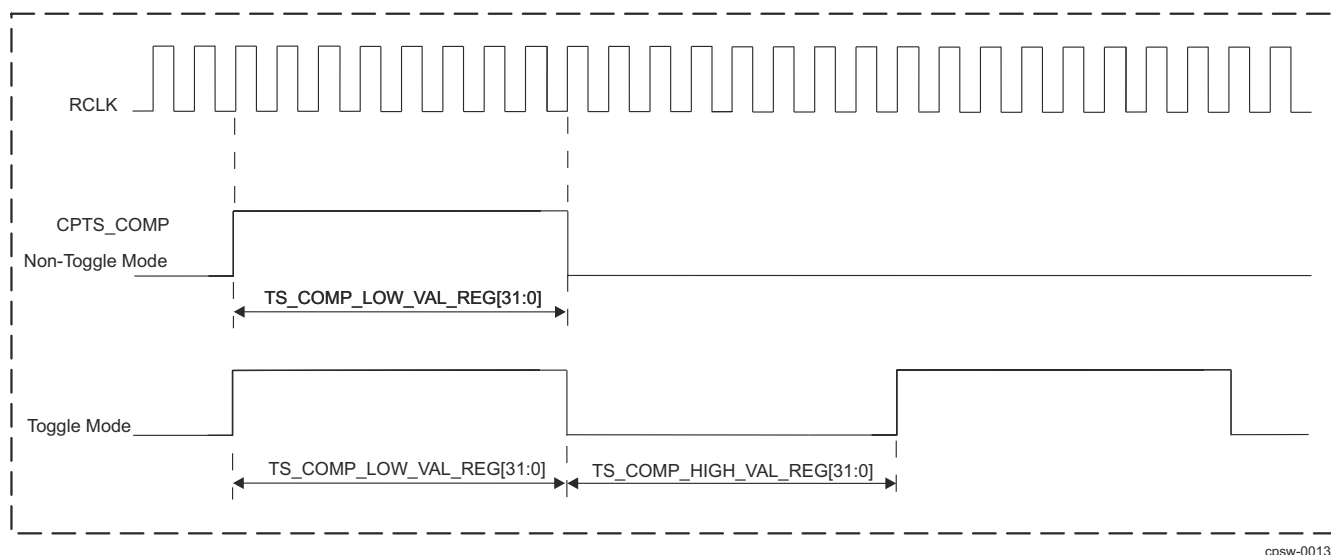

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME\_STAMP are used (CPSW\_CPTS\_EVENT\_0\_REG and CPSW\_CPTS\_EVENT\_3\_REG). In 32-bit mode only the lower 32-bits (CPSW\_CPTS\_EVENT\_0\_REG) are used.

##### 12.2.1.4.7.9.3 Toggle Mode: 32-bit

The CPTS\_COMP output is asserted (CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH) for CPTS\_RFT\_CLK clock periods when the TIME\_STAMP[31:0] value compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG and the length value is non-zero. The CPTS\_COMP toggles thereafter on CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH for CPTS\_RFT\_CLK periods. The length high or low can be adjusted by writing the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE bit field value which is a two's complement value. A value of FFh will subtract one CPTS\_RFT\_CLK period from the CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH value. A value of 0x01h will add one CPTS\_RFT\_CLK period to the CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH value. Only a single high or low time is adjusted (nudged) and the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred. The CPTS\_COMP output is asserted low when the CPSW\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit is 0h. No compare events and no CPTS\_EVNT interrupts are generated in toggle mode. The CPSW\_CPTS\_CONTROL\_REG[6] TS\_COMP\_TOG bit must be set for toggle mode (value 1h). Note this bit must be set before writing a non-zero value to CPSW\_CPTS\_TS\_COMP\_VAL\_REG register.

#### 12.2.1.4.7.9.4 Toggle Mode: 64-bit

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the **TIME\_STAMP** are used (**CPSW\_CPTS\_EVENT\_0\_REG** and **CPSW\_CPTS\_EVENT\_3\_REG**). In 32-bit mode only the lower 32-bits (**CPSW\_CPTS\_EVENT\_0\_REG**) are used.

**Figure 12-143. CPTS\_COMP Output in Toggle and Non-Toggle Mode**

#### 12.2.1.4.7.10 Timestamp Sync Output

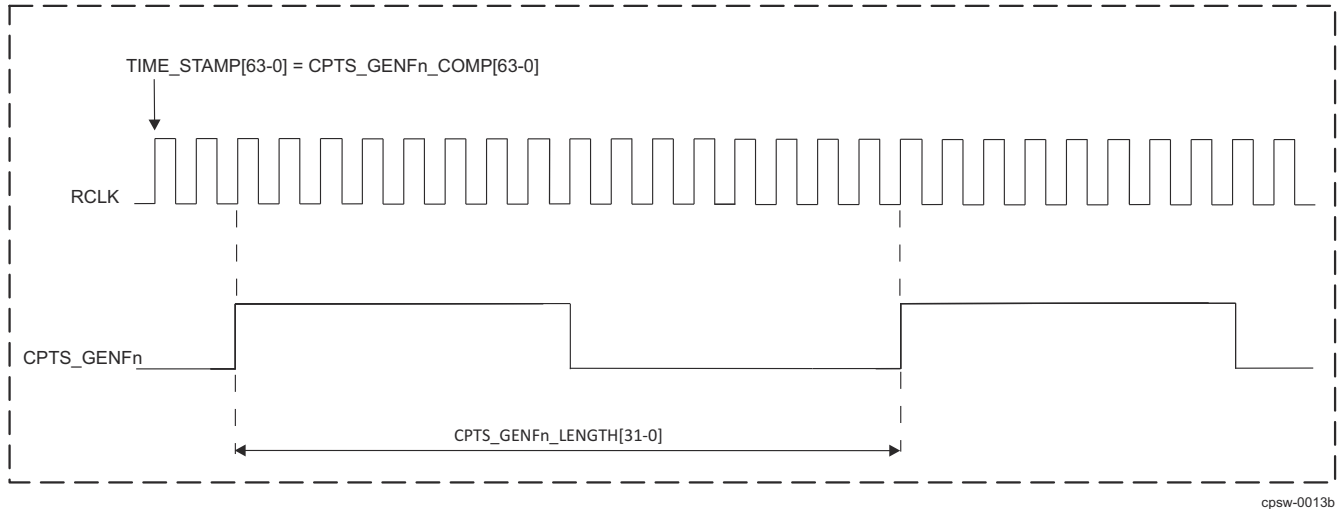

The **CPTS\_SYNC** output is a selected bit of the [31:0]**TIME\_STAMP** counter value. One of bits 17-31 can be selected in **CPSW\_CPTS\_CONTROL\_REG[31:28]** **TS\_SYNC\_SEL**. The **CPTS\_SYNC** output is disabled when **CPSW\_CPTS\_CONTROL\_REG[31:28]** **TS\_SYNC\_SEL** is zero.

If the selected counter bit is 1 at the time when **TS\_SYNC\_SEL** value is written then a rising edge will not occur on the **CPTS\_SYNC** output. A rising edge will occur on the **CPTS\_SYNC** output upon the next transition to 1 of the selected counter bit. The **TS\_SYNC\_SEL** value must be written to zero before changing to a different non-zero value. No events are generated due to the **CPTS\_SYNC** operation. The **CPTS\_SYNC** output is two **CPTS\_RFT\_CLK** periods after the actual count value.

#### 12.2.1.4.7.11 Timestamp GENFn Output

The **CPTS\_GENFn** outputs have a programmable cycle (frequency) with a PPM feature and software nudge feature. The **CPTS\_GENFn** output cycle is **CPSW\_GENF0\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods (which is different than **CPTS\_COMP** operation). [Figure 12-144](#) represents the **CPTS\_GENFn** output signal.

The **CPTS\_GENFn** output cycle is **CPSW\_GENF0\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods beginning when the 64-bit **TIME\_STAMP** value compares with the 64-bit **GENFn\_COMP** value (**CPSW\_GENF0\_COMP\_LOW\_REG\_L** and **CPSW\_GENF0\_COMP\_HIGH\_REG\_L** registers) and the length value is non-zero. The **CPTS\_GENFn** output cycle repeats thereafter every **CPSW\_GENF0\_LENGTH\_REG\_L[31:0]** **CPTS\_RFT\_CLK** periods. The upper 32-bit word should be written first for 64-bit values. The length should be zero while the comparison value and other configuration parameters are being configured. The length should be written non-zero to enable operations last. The first cycle after comparison is active high when the **CPSW\_CPTS\_CONTROL\_REG[2]** **TS\_COMP\_POLARITY** bit is low. No compare events and no **CPTS\_EVT** interrupts are generated.

**Figure 12-144. CPTS\_GENFn Output Signal Diagram**

#### 12.2.1.4.7.11.1 GENFn Nudge

The cycle length can be adjusted by writing the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE register value which is a two's complement value. A value of FFh will subtract 1 CPTS\_RFT\_CLK from the CPSW\_GENF0\_LENGTH\_REG\_L[31-0] value. A value of 1h will add 1 CPTS\_RFT\_CLK to the CPSW\_GENF0\_LENGTH\_REG\_L[31-0] value. The CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred.

#### 12.2.1.4.7.11.2 GENFn PPM

The CPTS\_GENFn output cycle can be adjusted by parts per million or by parts per hour. Writing a non-zero value to CPSW\_GENF0\_PPM\_LOW\_REG\_L/ CPSW\_GENF0\_PPM\_HIGH\_REG\_L enables PPM operations. The PPM counter continually loads and decrements to zero and then loads again. A single CPTS\_RFT\_CLK adjustment is made when the PPM counter decrements to zero. The adjustment is up or down depending on the CPSW\_GENF0\_TS\_GENF\_CONTROL\_REG[0] PPM\_DIR bit. When PPM\_DIR bit is set a single CPTS\_RFT\_CLK time is subtracted from the generate function counter which has the effect of increasing the generate function frequency by the PPM amount. When PPM\_DIR bit is cleared a single CPTS\_RFT\_CLK time is added to the generate function counter which has the effect of decreasing the generate function frequency by the PPM amount.

#### Parts Per Million example:

To adjust for 100 parts per million the configured value for GENF\_PPM[41-0] (through CPSW\_GENF0\_PPM\_LOW\_REG\_L and CPSW\_GENF0\_PPM\_HIGH\_REG\_L) is:  
 $1,000,000/100 = 10,000$ (decimal)

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for GENF\_PPM[41-0] (through CPSW\_GENF0\_PPM\_LOW\_REG\_L and CPSW\_GENF0\_PPM\_HIGH\_REG\_L) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000}$  (hex)

#### 12.2.1.4.7.12 Timestamp ESTFn

Each Ethernet port has a dedicated ESTFn generator which operates identically to the GENFn function.

#### 12.2.1.4.7.13 Time Sync Events

Time Sync events are 96-bit values that are pushed onto the event FIFO and read by software in 32-bit reads. Four 32-bit registers, CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG hold the data of a time sync event. There are eight types of sync events:

- Time Stamp Push Event

- Time Stamp Counter Rollover Event (32-bit mode only)
- Time Stamp Counter Half-rollover Event (32-bit mode only)
- Hardware Time Stamp Push Event
- Ethernet Receive Event
- Ethernet Transmit Event
- Time Stamp Compare Event
- Host Transmit Event

#### **12.2.1.4.7.13.1 Time Stamp Push Event**

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the [0]TS\_PUSH bit of the CPSW\_CPTS\_TS\_PUSH\_REG register. The time stamp value is returned in the event, along with a time stamp push event code. The upper 32-bits (CPSW\_CPTS\_EVENT\_3\_REG register) of the timestamp are zero in 32-bit mode.

#### **12.2.1.4.7.13.2 Time Stamp Counter Rollover Event (32-bit mode only)**

The CPTS module contains a 32-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG). The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF FFFF to 0x0000 0000 and the software-maintained upper count value should be incremented. This event occurs only in 32-bit mode.

#### **12.2.1.4.7.13.3 Time Stamp Counter Half-rollover Event (32-bit mode only)**

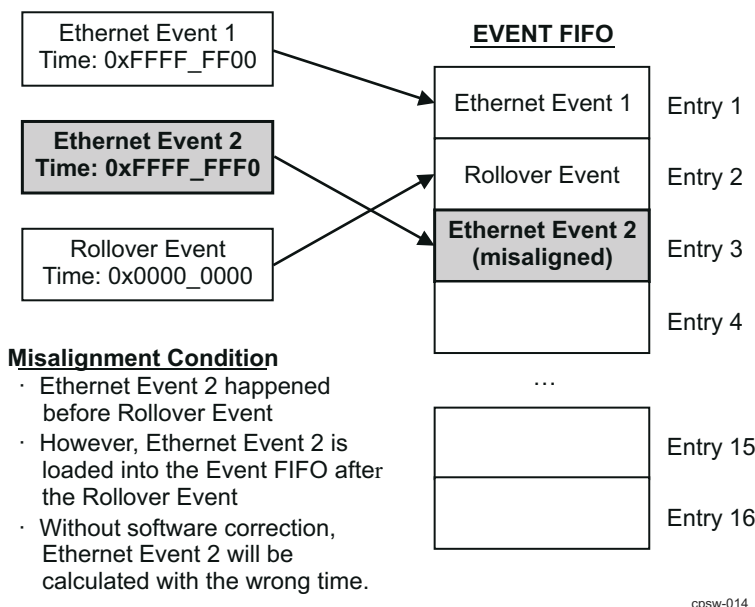

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value (CPSW\_CPTS\_EVENT\_0\_REG[31:0] TIME\_STAMP) has incremented from 0x7FFF FFFF to 0x8000 0000. The half-rollover event is included to enable software to correct a misaligned event condition. This event occurs only in 32-bit mode.

The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. [Figure 12-145](#) shows a misalignment condition. This misaligned event condition arises because an Ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Host software must detect and correct for misaligned event conditions. For every event time stamp after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000 0000 through 0x7FFF FFFF), then the event time stamp was taken after the rollover and no correction is required. If the value is high (0x8000 0000 through 0xFFFF FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

When a rollover occurs, software increments the software time stamp upper value. The misaligned case indicates to software that the misaligned event time stamp has a valid upper value that is pre-increment, so one must be subtracted from the upper value to allow software to calculate the correct time for the misaligned event.

**Figure 12-145. Event FIFO Misalignment Condition**

#### 12.2.1.4.7.13.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs ( CPTS\_HW[1:4]\_TS\_PUSH events) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each time stamp input is mapped in the device as shown in *CPSW0 CPTS Integration*. The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the CPSW\_CPTS\_EVENT\_1\_REG register indicates the hardware push input that caused the event (encoded).

The hardware time stamp inputs are asynchronous and are low frequency signals. The CPTS logic synchronizes and performs a rising edge detect on the incoming asynchronous input.

Each hardware time stamp input must be asserted for at least 10 periods of the selected CPTS\_RFT\_CLK clock. Each input can be enabled or disabled by setting the respective bits in the CPSW\_CPTS\_CONTROL\_REG register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 12.2.1.4.7.13.5 Ethernet Port Events

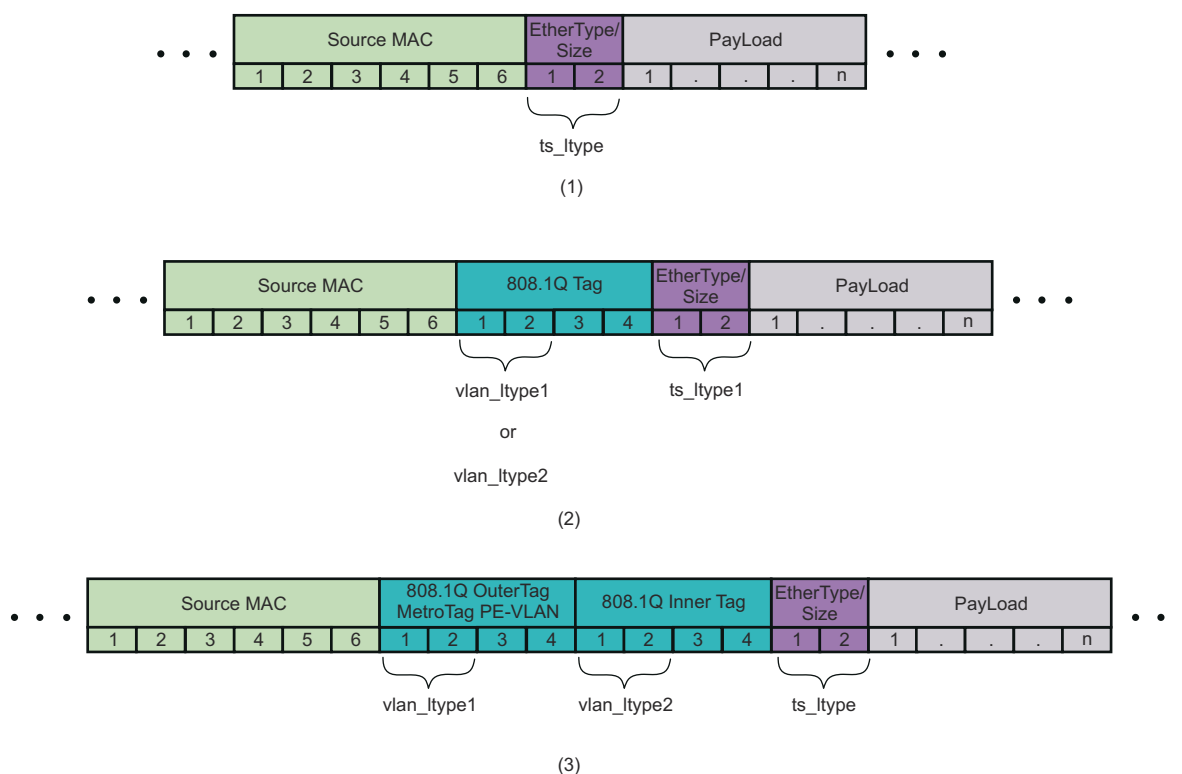

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in [Figure 12-146](#). For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS\_LTYPE1 field in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG or the TS\_LTYPE2 field in CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register (depending on which enable bit was set) , which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in [Figure 12-146](#). To indicate to the CPTS hardware that a virtual LAN is in use, the TS\_TX\_VLAN\_LTYPE1\_EN (or TS\_TX\_VLAN\_LTYPE2\_EN) enable bit must be set in the

CPSW\_PN\_TS\_CTL\_REG register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the TS\_VLAN\_LTYPE1 (or TS\_VLAN\_LTYPE2 depending on which enable bit was set) field in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 12-146. In this case, both TS\_VLAN\_LTYPE1 and TS\_VLAN\_LTYPE2 must be enabled. The outer tag must match the value of the TS\_VLAN\_LTYPE1 field, and the inner tag must match the value of the TS\_VLAN\_LTYPE2 field.

cpsw-015

**Figure 12-146. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)**

#### 12.2.1.4.7.13.5.1 Ethernet Port Receive Event

This section describes Ethernet port receive events. Ethernet port generates time synchronization events for valid received time sync packets. For every packet received on the Ethernet port, a timestamp will be captured by the receive module inside the CPTS for the corresponding port. The time stamp will be captured by the receive module regardless of whether or not the packet is a time synchronization packet to make sure that the time stamp is captured as soon as possible. The packet is sampled on both the rising and falling edges of the CPTS\_RFT\_CLK, and the time stamp will be captured once the start of frame delimiter for the receive packet is detected.

After the time stamp has been captured, the receive interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPSW decoder determines if the packet is a valid Ethernet receive time synchronization event. The receive interface for the port will use the following criteria to determine if the packet is a valid Annex D, Annex E, or Annex F time synchronization Ethernet receive event:

#### Annex D (IPv4)

1. Receive annex D time sync is enabled (TS\_RX\_ANNEX\_D\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register).

2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

#### Note

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 22 contains any value if CPSW\_PN\_TS\_CTL\_LTYPE2\_REG is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h and Bytes 30 through 33 contain:
  - a. Decimal 224.0.1.129 and the TS\_129 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 224.0.1.130 and the TS\_130 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. Decimal 224.0.1.131 and the TS\_131 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - d. Decimal 224.0.1.132 and the TS\_132 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - e. Decimal 224.0.0.107 and the TS\_107 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set
- OR-
- The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set -OR-
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG register.
11. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

#### Annex E (IPv6)

1. Receive annex E time sync is enabled (TS\_RX\_ANNEX\_E\_EN bit is set in the switch CPSW\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x86dd.
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd

- LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register.
- e. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG register.
  - f. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register.
  - g. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE1 in the CPSW\_PN\_TS\_SEQ\_LTYPE\_REG register.
  - h. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_RX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches TS\_LTYPE2 in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register and TS\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register
3. The PTP message begins in the byte after the LTYPE.
  4. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG register.
  5. The packet was received without error (not long/short/mac\_ctl/CRC/code/align).

If all of the criteria described above are met for either Annex D, Annex E, or Annex F, and the packet is determined to be a valid time synchronization packet, then the RX interface will push an Ethernet receive event into the event FIFO.

#### 12.2.1.4.7.13.5.2 Ethernet Port Transmit Event

This section describes Ethernet port transmit events. For every packet transmitted on the Ethernet ports, the port transmit interface will begin parsing the packet to determine if it is a valid Ethernet time synchronization packet. The CPTS transmit interface for the port will use the following criteria to determine if the packet is a valid time synchronization Ethernet transmit event. The CPSW decoder determines if the packet is a valid ethernet receive time synchronization event. To be a valid Ethernet transmit time synchronization event, the conditions listed below must be true for either Annex D, Annex E, or Annex F:

##### **Annex D (IPv4)**

1. Transmit time sync is enabled (TS\_TX\_ANNEX\_D\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x0800
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x0800
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x0800
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IPv4).

The byte numbering assumes that there are no VLANs. The byte number is intended to show the relative order of the bytes.

4. Byte 20 contains 0bXXX00000 (5 lower bits zero) and Byte 21 contains 0x00 (fragment offset zero)
5. Byte 22 contains 0x01 (HOP Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 22 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 22 is the TTL/HOP field.
6. Byte 23 contains 0x11 (Next Header UDP Fixed).
7. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h and Bytes 30 through 33 contain:
  - a. Decimal 224.0.1.129 and the TS\_129 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 224.0.1.130 and the TS\_130 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. Decimal 224.0.1.131 and the TS\_131 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - d. Decimal 224.0.1.132 and the TS\_132 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - e. Decimal 224.0.0.107 and the TS\_107 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - f. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set and Bytes 30 through 33 contain any values.
8. Bytes 36 and 37 contain:
  - a. Decimal 0x01 and 0x3F respectively and the TS\_319 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. Decimal 0x01 and 0x40 respectively and the TS\_320 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set.
9. The PTP message begins in byte 42.
10. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG register.
11. The packet was sent by host port 0.

1. Transmit annex E time sync is enabled (TS\_TX\_ANNEX\_E\_EN bit is set in the switch CPSW\_PN\_TS\_CTL\_REG register).
2. One of the sequences below is true.
  - a. The first packet LTYPE matches 0x86dd.
  - b. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
  - c. The first packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches 0x86dd
  - d. The first packet LTYPE matches TS\_VLAN\_LTYPE1 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE1\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the second packet LTYPE matches TS\_VLAN\_LTYPE2 in the CPSW\_PN\_TS\_VLAN\_LTYPE\_REG register and TS\_TX\_VLAN\_LTYPE2\_EN is set in the CPSW\_PN\_TS\_CTL\_REG register and the third packet LTYPE matches 0x86dd
3. Byte 14 (the byte after the LTYPE) contains 0x6X (IPv6).
4. Byte 20 contains 0x11 (UDP Fixed Next Header).
5. Byte 21 contains 0x01 (Hop Limit = 1) if the TS\_TTL\_NONZERO bit in the switch CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0h, or byte 21 contains any value if TS\_TTL\_NONZERO is set to 1h. Byte 21 is the TTL/HOP field..
6. The TS\_UNI\_EN bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is cleared to 0 and Bytes 38 through 53 contain:
  - a. FF0M:0:0:0:0:0:0:0181 and the TS\_129 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - b. FF0M:0:0:0:0:0:0:0182 and the TS\_130 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or
  - c. FF0M:0:0:0:0:0:0:0183 and the TS\_131 bit in the CPSW\_PN\_TS\_CTL\_LTYPE2\_REG register is set, or

3. The packet message type is enabled in the TS\_MSG\_TYPE\_EN field in the CPSW\_PN\_TS\_CTL\_REG register.
4. The packet was sent by host port 0.

If all of the criteria described above are met, and the packet is determined to be a valid time synchronization packet, then the time stamp for the transmit event will not be generated until the start of frame delimiter of the packet is actually transmitted. The start of frame delimiter will be sampled on every rising and falling edge of the CPTS\_RFT\_CLK. Once the packet is transmitted, then the TX interface will push an Ethernet transmit event into the event FIFO.

**Table 12-190. Values of Message Type Field**

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW\_CPTS\_EVENT\_1\_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW\_CPTS\_EVENT\_0\_REG (and CPSW\_CPTS\_EVENT\_3\_REG) register contains the time stamp value when the packet arrived at the corresponding port.

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO.

The CPSW\_CPTS\_EVENT\_1\_REG register contains the Message Type and Sequence ID values from the original time sync packet. The CPSW\_CPTS\_EVENT\_0\_REG (and CPSW\_CPTS\_EVENT\_3\_REG) register contains the time stamp value when the packet arrived at the corresponding port.

#### 12.2.1.4.7.14 Timestamp Compare Event

##### Note

Timestamp compare events are generated for non-toggle mode only.

The CPTS can generate an event for a time stamp comparison in 32-bit or 64-bit mode.

##### 12.2.1.4.7.14.1 32-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 32-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register and the CPSW\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

##### 12.2.1.4.7.14.2 64-Bit Mode

The CPTS\_COMP output is also asserted when the event is generated. The event is generated when the 64-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG and CPSW\_CPTS\_EVENT\_3\_REG) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG and CPSW\_CPTS\_TS\_COMP\_HIGH\_VAL\_REG registers and the CPSW\_CPTS\_TS\_COMP\_LEN\_REG value is non-zero. The CPSW\_CPTS\_TS\_COMP\_LEN\_REG value should be written by software after the CPSW\_CPTS\_TS\_COMP\_VAL\_REG register is written and should be zero when the comparison value is written.

#### 12.2.1.4.7.15 Host Transmit Event

The host can send a packet to be transmitted on an Ethernet port that will generate a time synchronization event. The host sets the TSTAMP\_EN bit and sends the DOMAIN, MESSAGE\_TYPE, and SEQUENCE\_ID in the additional control information that resides in the protocol specific section of the descriptor that is transmitted to the CPSW\_3G. An event is then generated and placed on the event FIFO once the packet is transmitted. Host events allow the user to timestamp exactly when a software generated packet exits the device.

#### 12.2.1.4.7.16 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW\_CPTS\_INT\_ENABLE\_REG register.
2. Upon interrupt, read the CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG registers values.
3. Set the CPSW\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPSW\_CPTS\_INT\_ENABLE\_REG
2. Upon interrupt, enter the CPTS service routine.
3. Read the CPSW\_CPTS\_EVENT\_0\_REG through CPSW\_CPTS\_EVENT\_3\_REG registers values.
4. Set the CPSW\_CPTS\_EVENT\_POP\_REG[0] EVENT\_POP bit to 1h to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than four CPTS\_RFT\_CLK periods plus four CPPI\_ICLK periods.
6. Read the TS\_PEND\_RAW bit in the CPSW\_CPTS\_INTSTAT\_RAW\_REG register to determine if another valid event is in the event FIFO. If bit TS\_PEND\_RAW is asserted, go to step 3. If bit TS\_PEND\_RAW is not asserted proceed with step 7.
7. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS\_PEND\_RAW bit of the CPSW\_CPTS\_INTSTAT\_RAW\_REG register to determine if a valid event is on the event FIFO.

#### 12.2.1.4.8 CPPI Streaming Packet Interface

The receive streaming interface on port 0 of the CPSW is responsible for receiving packet for Ethernet egress data from the packet streaming switch in the NAVSS. The CPPI receive port is equivalent to an Ethernet port with the difference being that the data is provided to the CPSW in the 128-bit streaming interface data format instead RGMII data format.

In addition to the packet data, the receive streaming interface also can provide additional control information that resides in the information words of the descriptor that was transmitted to the CPSW.

The tables below show the information that may be passed along with which descriptor information word to put it in.

##### 12.2.1.4.8.1 Port 0 CPPI Transmit Packet Streaming Interface (CPSW\_2G Egress)

The CPSW2G has a single transmit packet streaming interface. All Ethernet packet data destined for the host (Port 0) is transferred on the transmit packet streaming interface. The transmit packet streaming interface is equivalent to an Ethernet MAC output with the difference being that 128-bit streaming interface data is output. Egress packet data is packed on the 128-bit data bus with all words having 16-bytes except possibly the last packet data word which is the word previous to the EOP word. INFO Word 0–3 is transferred on SOP. The EOP word contains the packet status 0–3 (data type 24) which includes the timestamp and checksum data. Packets are not dropped on the transmit streaming interface due to pushback, but packets may be dropped in the associated priority FIFO.

INFO Word 0–3 and Status Data Word 0–3 (on EOP) are the only non-payload data word types that are transferred. Long packets are truncated at the CPSW\_PN\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN byte value of the ingress port (only the CPSW\_PN\_RX\_MAXLEN\_REG number of bytes are kept if long packets are transferred due to CPSW\_PN\_MAC\_CONTROL\_REG register copy error frames set - RX\_CEF\_EN). MAC control frames are only transferred if the receiving Ethernet port has the CPSW\_PN\_MAC\_CONTROL\_REG[24] RX\_CMF\_EN bit set.

The error encoding on the TXST\_PKT\_ERR[3:0] output is shown in [Table 12-193](#).

**Table 12-193. Error Encoding on the TXST\_PKT\_ERR[3:0] Output**

TXST_PKT_ERR[3:0]	Description
0000	No Error
0001	CRC Error
0010	Code or alignment error
0011	Short (no code/align/crc error)
0100	FragCRC (short with crc error)
0101	Frag Code/Align (short with code/align error)
0110	Long
0111	Jabber CRC (long with crc error)
1000	Jabber Code/Align (long with code/align error)
1001	Mac ontl packet (CPSW_PN_MAC_CONTROL_REG[24] RX_CMF_EN set on ingress Ethernet port)
1010	Mac control CRC
1011	Mac control Code/Align
1100	Mac control short/frag (short MAC control frame with CRC/Code/Align)
1101	Mac control long/jabber (long MAC control frame with CRC/Code/Align)
1110	Reserved
1111	Reserved

The CPPI Port 0 transmit packet streaming interface has a single output thread. If a packet transmission has begun then the entire packet will be transmitted before the next packet is sent (packet data from multiple packets are not interleaved on the transmit streaming interface). The default egress flow is the port number minus 1, concatenated with the 3-bit Port 0 transmit FIFO hardware switch priority. For example, a packet that was received on port 4 with a Port 0 transmit FIFO hardware switch priority of 5 would be sent on flow 29 (decimal) or flow 0b0011101 (binary). Priority remapping on ingress and Port 0 transmit egress effects the output flow.

INFO Words () are a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 12-147. TX INFO Word 0 Format**

Bit	Field	Description
31-27	PKT_TYPE	Always set to 0b00111. Host PD (Packet Descriptor) Word 2. Packet Type: bits[31-27].
26-24	RESERVED	Reserved.

Bit	Field	Description
23	PASS_CRC	This bit is cleared to zero (no CRC passed) when the P0_TX_CRC_REMOVE bit in the CPSW_CONTROL_REG register is set (and the egress packet has no errors). When the remove bit is cleared to zero then this bit is cleared and no CRC is passed with the output packet. The packet length includes the CRC if it is present.
22	CRC_TYPE	The packet CRC type. The type of CRC passed is determined by CRC_TYPE field in the CPSW_PN_MAC_CONTROL_REG register (not by the type of CRC the packet had on Ethernet port ingress). Host PD Word 1. Protocol Specific Flags: bits[27-24]. 0h: Ethernet CRC 1h: Castagnoli CRC
21-8	RESERVED	Reserved.
7-0	FLOW_ID	This is the packet output transmit streaming interface flow. The default flow ID can be overridden by ALE classification (Thread mapping). The switch default flow is the 3-bit "From Port" value concatenated with the 3-bit "Switch Priority" {From_Port[2:0], Switch_Priority[2:0]} as shown below: Host PD (Packet Descriptor) Word 1. Flow ID: bits[13-0]. 0h: The packet was received on Ethernet port 1 Switch Priority – The actual hardware switch priority that the packet was stored in on the CPPI transmit FIFO.

#### 12.2.1.4.8.2 Port 0 CPPI Receive Packet Streaming Interface (CPSW\_2G Ingress)

Info Word 0/1/2/3 (INFO1 and INFO3 are ignored) are transferred on SOP. If a timestamp word (Extended Packet Info Word 0/1/2/3) is to be transferred it must be after SOP and before any packet data is transferred. Any following non-data type words will be dropped. The EOP word must be payload data.

Input receive packets cannot be aborted by the host. The INFO Word bit descriptions and Extended Packet INFO Word bit descriptions are shown below. The PASS\_CRC bit indicates that the CRC is passed with the packet data. Packets that have a passed CRC that is an error CRC will be output on the Ethernet port with at least one CRC byte inverted to indicate the error if P0\_RX\_PASS\_CRC\_ERR bit is set, otherwise they are dropped. The packet is a directed packet when any of the TO\_PORT bits are nonzero. A packet may be directed only to a single port. The packet will be sent to the port number indicated. For directed packets the lookup process is skipped to determine the destination. However, in vlan aware mode (when VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is set to 1h) the lookup is performed to determine untagged egress. Packets longer than the value in CPSW\_P0\_RX\_MAXLEN\_REG[13-0] RX\_MAXLEN bit field are dropped. Packets shorter than 60-Bytes are padded to 64-Bytes (after adding pad and CRC) if P0\_RX\_PAD bit in the CPSW\_CONTROL\_REG register is set and if PASS\_CRC is clear, otherwise they are dropped. This means that packets shorter than 64-Bytes are dropped if the PASS\_CRC info bit is set regardless of P0\_RX\_PAD bit (packets are padded only if they are short and do not have CRC).

A RX INFO word () is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

#### Note

RX Control Data Words [0..2] are mapped to Host Packet Descriptor Protocol Specific Words if (TCHAN[a]\_TCFG.tx\_filt\_pswords = 0) and (Host PD Word 1.Protocol Specific Region Location.bit[28] = 0h) and (Host PD Word 1.Protocol Specific Valid Word Count.bits[22-27] = 4h)

31-21	RESERVED	Reserved.
20-16 (Host PD (Packet Descriptor) Word 3. Dest Tag Low bits[8-0])	TO_PORT	Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode. 0h: Not directed 1h: Send the packet to port 1.
15-0	RESERVED	Reserved.

**Figure 12-157. RX Control Data Word 1 Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEQUENCE_ID															

Bit	Field	Description
31	TIMESTAMP_EN	When set, this bit indicates that the packet will generate a timesync event on Ethernet egress (if the CPTS is configured properly) with the associated DOMAIN, MSG_TYPE, and SEQUENCE_ID.
30-28	RESERVED	Reserved.
27-20	DOMAIN	Timesync domain.
19-16	MSG_TYPE	Timesync message type.
15-0	SEQUENCE_ID	Timesync sequence ID.

**Figure 12-158. RX Control Data Word 2 Format**

CHECKSUM_RESULT								CHECKSUM_START_BYTE							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CHECKSUM_INV	RESERVED	CHECKSUM_BYTECOUNT													

Bit	Field	Description
31-24	CHECKSUM_RESULT	This is the packet byte number where the checksum result will be placed in the egress packet. The first packet byte which is the first byte of the destination address is Byte 1 (not byte zero).
23-16	CHECKSUM_START_BYTE	This is the packet byte number to start the checksum calculation on. The first packet byte is Byte 1.
15	CHECKSUM_INV	When set, a zero checksum value will be inverted and sent as FFFFh.
14	RESERVED	Reserved.
13-0	CHECKSUM_BYTECOUNT	This is the number of bytes to calculate the checksum on. The outgoing Ethernet packet will have a checksum inserted when this value is non-zero.

Other INFO words are not taken into account.

#### 12.2.1.4.8.3 CPPI Checksum Offload

The CPPI host port can be enabled to perform checksum offload on host port packet ingress and egress. UDP (User Datagram Protocol) and TCP (Transmission Control Protocol) over IPV4 and IPV6 are supported. For the purposes of checksum description, the first packet byte (the first byte of the destination address) is byte 1 (not byte 0). That is, a 64 byte packet goes from byte 1 to byte 64. For all packet types, the S\_CN\_SWITCH bit in the CPSW\_CONTROL\_REG register must be set for the Outer VLAN L type to be supported.

##### 12.2.1.4.8.3.1 CPPI Transmit Checksum Offload

IPV4 and IPV6 UDP and TCP packets that are received on any Ethernet port and destined for port 0 egress are checked for correct checksum as described below. The byte counts below are shown for packets with no VLAN's. The byte counts vary with one or two packet VLAN's. Packets received on an Ethernet port with errors are not checked for a correct checksum if they are passed to the host.

##### 12.2.1.4.8.3.1.1 IPV4 UDP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no UDP header).
- Byte 24 = 0x11 for UDP protocol.
- Received packet UDP checksum of zero means that there is no IPV4 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

##### 12.2.1.4.8.3.1.2 IPV4 TCP

- Byte 15 Upper Nibble = 4 for IPV4
- Byte 15 Lower Nibble = IHL - Nibble with number of 32-bit words in IPV4 header (5 to 15 supported).
- Bytes 20-21 = fragment[15-0] – Bit 13 is the MF bit and bits [12-0] are the Fragment offset. A packet is a fragment if the MF bit is set or if the fragment offset is non-zero. The first packet fragment has MF=1 with a

zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets have MF=0 and a zero offset. A count is output for packet fragments but no errors are reported. First fragments have the UDP header included in the count. Middle and last fragments have only data included in the count (there is no TCP header).

- Byte 24 = 0x06 for TCP protocol.

#### **12.2.1.4.8.3.1.3 IPV6 UDP**

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x11 for UDP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x11). Middle and last fragments have a fragment extension header followed by data only (no UDP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.
- Received packet UDP checksum of zero means that there is no IPV6 checksum sent with the packet so no error will be issued.
- Received packet UDP checksum of 0xFFFF means that the checksum was calculated to be 0xFFFF or 0x0000 but was sent in the transmitted packet as 0xFFFF by the sending originating entity.

#### **12.2.1.4.8.3.1.4 IPV6 TCP**

- Byte 15 upper nibble = 6 for IPV6.
- Byte 21 = 0x06 for TCP protocol as next header.
- Fragment extension headers are supported. First fragments have a fragment extension header (byte 21 = 0x2C) followed by a UDP header (byte 55 = 0x06). Middle and last fragments have a fragment extension header followed by data only (no TCP header). The first packet fragment has MF=1 with a zero offset. Middle fragments have MF=1 with a nonzero offset. The last packet fragment has MF=0 with a nonzero offset. Non-fragmented packets do not have a fragment extension header. A count is output for packet fragments but no errors are reported.

#### **12.2.1.4.8.4 CPPI Receive Checksum Offload**

Packets sent from host port 0 (switch ingress) to any Ethernet port can have a checksum calculated and inserted into the Ethernet egress packet. The RX\_CHECKSUM\_EN bit in the CPSW\_P0\_CONTROL\_REG register must be set for receive checksum operation to be enabled. When bit RX\_CHECKSUM\_EN is enabled, Control Data Word 2 input on CPPI receive PSI interface determines how the checksum is calculated. The CHECKSUM\_RESULT field in Control Data Word 2 determines where the checksum is inserted. The checksum result location is adjusted by the egress port if a VLAN is to be inserted or removed on Ethernet port egress.

#### **12.2.1.4.8.5 Egress Packet Operations**

Each CPSW egress port (Ethernet and Host) is capable of performing egress packet processing operations (CPSW\_ALE\_EGRESSOP). IntraVLAN processing either adds, removes, or replaces VLAN information or does nothing. InterVLAN routing allows hardware routing between a limited number of VLANs - thereby allowing high-bandwidth or other routing operations to be offloaded from software to the CPSW (hardware). IntraVLAN processing and InterVLAN routing operations are mutually exclusive. In addition, the packet source and destination addresses can be swapped on egress to facilitate OAM or generic testing operations.

#### 12.2.1.4.9 MII Management Interface (MDIO)

The MII Management interface module implements the 802.3 serial management interface to interrogate and control external Ethernet PHY using a two-wire bus.

##### 12.2.1.4.9.1 MDIO Frame Formats

[Table 12-194](#) shows the address, [Table 12-195](#) shows the read format and [Table 12-196](#) shows the write format of the supported Clause 45 MII Management interface frames. Post-increment accesses are not supported.

**Table 12-194. MDIO Clause 45 Address Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	00	AAAAA	RRRRR	10	AAAA.AAAA.AAAA.AAAA

**Table 12-195. MDIO Clause 45 Read Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	11	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

**Table 12-196. MDIO Clause 45 Write Frame Format**

Pre-amble	Start Delimiter	Operation Code	PHY Address	MMD Number	Turnaround	Data
FFFF FFFFh	00	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction. The MDIO CPSW\_MDIO\_USER\_ADDR0\_REG register must be written before a read or write operation is performed to set the address used in the operation. Each read or write operation has a preceeding address frame.

#### Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization. The preamble is required in clause 45 operation.

#### Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 00 pattern.

#### Operation Code

The operation code for an address transaction is 00. The operation code for a read is 11, while the operation code for a write is a 01.

#### PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

#### MMD Number

The MMD number is the 5 bits allowing 32 unique values. The first bit transmitted is the MSB.

#### Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall

drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

### Address

The address field is 16 bits on address operations. The first bit transmitted is the MSB of the address word. Each read/write operation initiated has an automatic address operation initiated first that uses the MDIO CPSW\_MDIO\_USER\_ADDR0\_REG/ CPSW\_MDIO\_USER\_ADDR1\_REG register values as the 16-bit address.

### Data

The Data field is 16 bits on read and write operations. The first bit transmitted and received is the MSB of the data word.

#### 12.2.1.4.9.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the CPSW\_MDIO\_CONTROL\_REG register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO CPSW\_MDIO\_LINK\_REG register. Individual PHY's can be enabled or disabled for polling the associated bit in the CPSW\_MDIO\_POLL\_EN\_REG register. The CPSW\_MDIO\_LINK\_REG and CPSW\_MDIO\_ALIVE\_REG register bit values are updated on the poll of each PHY. The LINKSEL bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO CPSW\_MDIO\_LINK\_INT\_RAW\_REG register and the MDIO CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register, if enabled by the LINKINT\_ENABLE bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register.

The MDIO CPSW\_MDIO\_ALIVE\_REG register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO CPSW\_MDIO\_ALIVE\_REG register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a CPSW\_MDIO\_USER\_ACCESS\_REG\_k register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW field in the CPSW\_MDIO\_USER\_INT\_RAW\_REG register corresponding to the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register being used. The corresponding bit in the CPSW\_MDIO\_USER\_INT\_MASKED\_REG register may also be set depending on the mask setting in the MDIO CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG and CPSW\_MDIO\_USER\_INT\_MASK\_CLEAR\_REG registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different CPSW\_MDIO\_USER\_ACCESS\_REG\_k registers. The host should check the status of the GO bit in the MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the CPSW\_PN\_MAC\_CONTROL\_REG register in the corresponding MAC.

#### 12.2.1.5 MCU\_CPSW0 Programming Guide

##### 12.2.1.5.1 Initialization and Configuration of CPSW Subsystem

To configure the CPSW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (RMII, or RGMII ) Mode. See the CTRLMMR\_MCU\_ENET\_CTRL[1-0] MODE\_SEL register.
2. Configure pads (pin muxing), as per the interface selected. Refer to *Pad Configuration Registers* and the device-specific Datasheet.
3. Enable the CPSW Ethernet Subsystem clocks. See *CPSW Integration*
4. Ensure that at least 2000 CPPI\_ICLK periods are run after reset is de-asserted.

5. Configure the CPSW\_CONTROL\_REG register
6. Configure the Ethernet Port Source Address registers (CPSW\_PN\_SA\_L\_REG and CPSW\_PN\_SA\_H\_REG)
7. Configure the CPSW statistic port enable register CPSW\_STAT\_PORT\_EN\_REG
8. Configure the ALE (*Address Lookup Engine*)
9. Configure the MDIO (*Initializing the MDIO Module*)
10. Configure Ethernet port, as per the desired mode of operations

#### 12.2.1.5.2 CPSW Reset

To reset the Ethernet port, the host must perform the following:

1. Set CMD\_IDLE bit to 1h in the Ethernet port control register: CPSW\_PN\_MAC\_CONTROL\_REG.
2. Wait for IDLE bit to be set to 1h, which is indicated in the Ethernet port status register: CPSW\_PN\_MAC\_STATUS\_REG.
3. Set SOFT\_RESET bit to 1h in the Ethernet port software reset register: CPSW\_PN\_MAC\_SOFT\_RESET\_REG.
4. Wait for SOFT\_RESET bit in the CPSW\_PN\_MAC\_SOFT\_RESET\_REG registers to be cleared to confirm reset completion.
5. Configure the Ethernet ports.
6. Re-configure registers reset to default value by CPSW\_PN\_MAC\_SOFT\_RESET\_REG.

#### 12.2.1.5.3 MDIO Software Interface

##### 12.2.1.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (CPSW\_MDIO\_CONTROL\_REG).
2. Enable the MDIO module by setting the ENABLE bit in CPSW\_MDIO\_CONTROL\_REG.
3. The MDIO PHY alive status register (MDIO CPSW\_MDIO\_ALIVE\_REG) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO CPSW\_MDIO\_LINK\_REG) can determine whether this PHY already has a link.
4. Set the appropriate PHY addresses in the MDIO user PHY select register (CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k, where k = 0 or 1), and set the LINKINT\_ENABLE bit to enable a link change event interrupt if desirable.
5. Set the appropriate LINKSEL bit in the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register (where k = 0 or 1).
6. Set the appropriate USERINTMASKSET bit field in the CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG register.
7. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG) to use the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1).

##### 12.2.1.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k corresponding to the PHY and PHY register SW wants to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

#### 12.2.1.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (CPSW\_MDIO\_USER\_ACCESS\_REG\_k, where k = 0 or 1) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register corresponding to the PHY and PHY register SW wants to read.
3. The read data value is available in the DATA bit field in MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k register after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in CPSW\_MDIO\_USER\_ACCESS\_REG\_k register. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_RAW\_REG) corresponding to MDIO CPSW\_MDIO\_USER\_ACCESS\_REG\_k used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG), then the bit is also set in the MDIO user command complete interrupt register (CPSW\_MDIO\_USER\_INT\_MASKED\_REG) and an interrupt is triggered on the host processor.

## 12.2.2 Gigabit Ethernet Switch (CPSW0)

This chapter describes the Gigabit Ethernet Switch (CPSW0) subsystem in the device.

### 12.2.2.1 CPSW0 Overview

The 9-port Gigabit Ethernet Switch (CPSW0) subsystem provides Ethernet packet communication for the device and can be configured as an Ethernet switch.

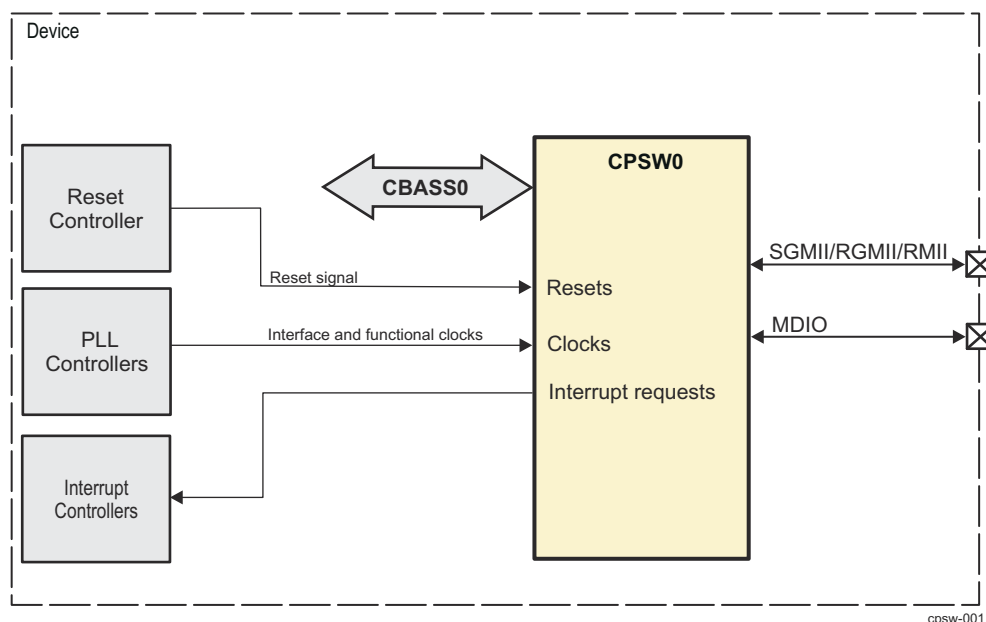

CPSW0 features the Serial Gigabit Media Independent Interface (SGMII), Reduced Gigabit Media Independent Interface (RGMII), Reduced Media Independent Interface (RMII) and the Management Data Input/Output (MDIO) interface for physical layer device (PHY) management.

The device has integrated one 9-port Gigabit Ethernet Switch subsystem into device MAIN domain named CPSW0. [Table 12-197](#) shows the CPSW0 module allocation within device domains.

**Table 12-197. CPSW0 Module Allocation within Device Domains**

Module Instance	Domain		
	WKUP	MCU	MAIN
CPSW0	-	-	✓

[Figure 12-159](#) shows the CPSW0 module overview.

**Figure 12-159. CPSW0 Overview**

#### 12.2.2.1.1 CPSW0 Features

The 9-port CPSW0 subsystem provides the following features:

- Eight Ethernet ports with selectable SGMII, RGMII, and RMII interfaces and an internal Communications Port Programming Interface (CPPI) port (port 0)
- Synchronous 10/100/1000 Mbit operation
- Flexible logical FIFO-based packet buffer structure
- Eight priority level Quality Of Service (QOS) support (802.1p)
- Support for Audio/Video Bridging (P802.1Qav/D6.0 and 802.1Qaz)
- Ethernet port reset isolation
- Support for IEEE 1588 Clock Synchronization (2008 Annex D, Annex E and Annex F)

- Timestamp module capable of time stamping external timesync events like Pulse-Per-Second and also generating Pulse-Per-Second outputs
- CPTS module that supports time stamping for IEEE1588 with support for 8 hardware push events and generation of compare output pulses
- DSCP Priority Mapping (IPv4 and IPv6)
- IPV4/IPV6 UDP/TCP checksum offload
- Priority Based Flow Control (802.1QBB) and Flow Control (802.3x) Support
- Wire rate switching (802.1d)
- Store and Forward Switching
- Non-Blocking switch fabric
- Time Sensitive Network Support
  - IEEE P802.3br/D2.0 Interspersing Express Traffic
  - IEEE 802.1Qbv/D2.2 Enhancements for Scheduled Traffic
- Address Lookup Engine (ALE)
  - 1024 ALE table entries
  - Parameterized number of addresses plus VLANs (total)
  - Wire rate lookup
  - LAN support
  - Host controlled time-based aging and/or auto-aging
  - Spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based Multicast and Broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Configurable number of classifier/policers (96)
  - Port and VLAN, OUI, or address traffic mirroring
  - Port trunking for up to four trunks across any port combination
  - Policing of ingress data flows
  - Castagnoli or Ethernet CRC selectable per port
- EtherStats and 802.3 Stats Remote Network Monitoring (RMON) statistics gathering (per port statistics)
- Maximum frame size of 2020 bytes
- Management Data Input/Output (MDIO) module for PHY Management
- Host port CPPI Streaming Packet Interface (CPPI\_GCLK)
- Digital loopback and FIFO loopback modes supported
- Emulation support
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps modes only.
- RAM Error Detection and Correction (SECCDED)

#### **12.2.2.1.2 CPSW0 Not Supported Features**

The following features are not supported for 9-port CPSW0 switch:

- MII and GMII Mode
- Gigabit half-duplex in 1Gbit or 10Gbit modes.
- Software reset on CPRGMII, CPRMII, PCSR submodules
- Interspersed Express Traffic (IET) in RMII mode
- Jumbo sized packets (9600 bytes)
- Rate limiting in half-duplex mode
- Dual VLAN switch operations
- MACSEC
- Synchronous Ethernet
- Cut Through Switching
- RGMII Internal Delay Mode disabled

### 12.2.2.1.3 Terminology

**Terminology:**

<b>AVB</b>	Audio Video Bridging
<b>AVBTP</b>	Audio Video Bridging Transport Protocol
<b>BMCA</b>	Best Master Clock Algorithm
<b>CFI</b>	Canonical Format Indicator
<b>CPPI</b>	Communications Port Programming Interface
<b>CPSW</b>	Common Platform Switch
<b>DLR</b>	Device Level Ring
<b>DSCP</b>	Differentiated Services Code Point
<b>EEE</b>	Energy Efficient Ethernet
<b>EMAC</b>	Ethernet Media Access Control
<b>EOP</b>	End of Packet
<b>EOQ</b>	End of Queue
<b>IPG</b>	Inter-Packet Gap
<b>LPI</b>	Low Power Indicator
<b>MDIO</b>	Management Data Input/Output
<b>MOF</b>	Middle of Frame
<b>OUI</b>	Organizationally Unique Identifier
<b>PFC</b>	Priority based Flow Control
<b>PTP</b>	Precision Time Protocol
<b>RMON</b>	Remote Monitoring
<b>RTCP</b>	RTP Control Protocol
<b>RTP</b>	Real-time Transport Protocol
<b>SCR</b>	Switched Central Resource
<b>SRP</b>	Stream Reservation Protocol
<b>TOS</b>	Type of Service
<b>VLAN</b>	Virtual Local Area Network

### 12.2.2.2 CPSW0 Environment

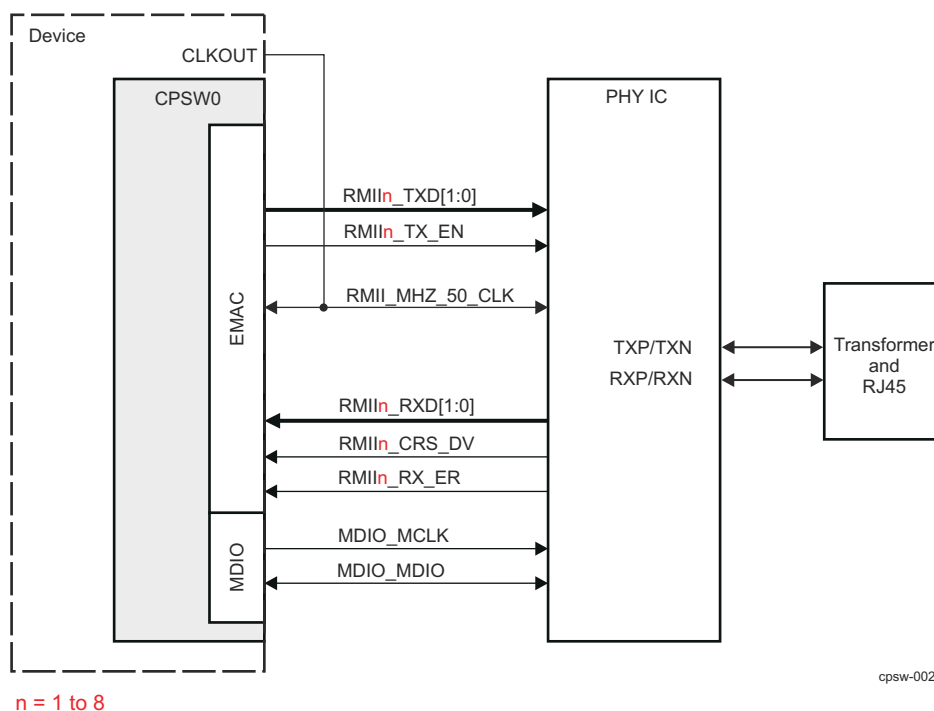

This section describes the CPSW0 external connections (environment).

#### 12.2.2.2.1 CPSW0 RMII Interface

Figure 12-160 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system. The individual CPSW0 and MDIO signals for the RMII interface are summarized in Table 12-198.

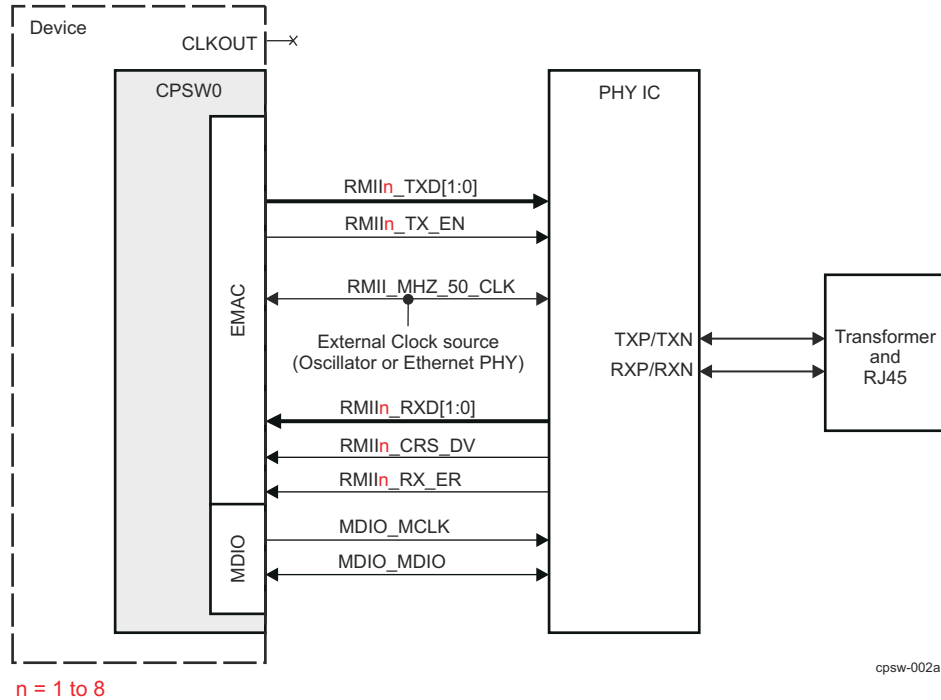

The CPSW0 module integrated in the device supports internal and external clock sources in RMII mode. Figure 12-160 shows the internal clock source for RMII\_MHZ\_50\_CLK clock. It is 50 MHz clock source that is provided on the CLKOUT device pin. For more details see *CPSW0 Integration*. This clock has to be routed on the PCB to the RMII\_REF\_CLK device pin and the external PHY, RMII clock input (shared by all RMII ports).

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 12-160. RMII Interface Typical Application (Internal Clock Source)**

Figure 12-161 shows the external clock source for RMII\_MHZ\_50\_CLK clock. In this case a 50 MHz clock is available on the PCB and it can be sourced from an oscillator or from the Ethernet PHY. This externally generated clock has to be routed to both RMII\_REF\_CLK device pin and the external PHY, RMII clock input.

**Figure 12-161. RMII Interface Typical Application (External Clock Source)**

**Table 12-198. RMII I/O Description**

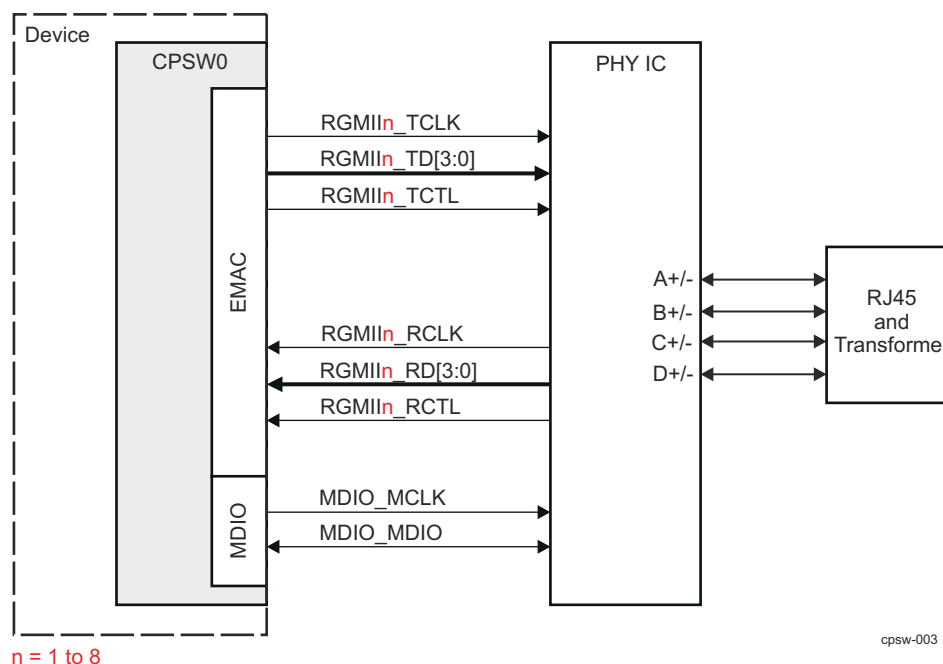

Signal <sup>(2)</sup>	Device Pin(s)	I/O <sup>(1)</sup>	Description
RMIIIn_TXD[1:0]	RMIIIn_TXD[1:0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMIIIn_TX_EN is asserted.
RMIIIn_TX_EN	RMIIIn_TX_EN	O	RMII transmit enable. The transmit enable signal indicates that the RMIIIn_TXD[1:0] pins are generating data for use by the PHY. RMIIIn_TX_EN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	RMII_REF_CLK	I	RMII 50MHz reference clock.  The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMIIIn_RXD[1:0]	RMIIIn_RXD[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMIIIn_CRS_DV is asserted and RMIIIn_RX_ER is de-asserted.
RMIIIn_CRS_DV	RMIIIn_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMIIIn_RX_ER	RMIIIn_RX_ER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MCLK	MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO data pin.
MDIO_MDIO	MDIO0_MDIO	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n 1 to 8

### 12.2.2.2.2 CPSW0 RGMII Interface

Figure 12-162 shows a device with integrated EMAC and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW0 and MDIO signals for the RGMII interface are summarized in Table 12-199.

**Figure 12-162. RGMII Interface Typical Application**

**Table 12-199. RGMII I/O Description**

Signal <sup>(2)</sup>	Device Pin(s)	I/O <sup>(1)</sup>	Description
RGMII_n_TD[3:0]	RGMII_n_TD[3:0]	O	The transmit data pins are a collection of 4 bits of data. TD0 is the least-significant bit (LSB). The signals are valid only when RGMII_n_TCTL is asserted.
RGMII_n_TCTL	RGMII_n_TX_CTL	O	Transmit Control/enable. The transmit enable signal indicates that the TD pins are generating data for use by the PHY.
RGMII_n_TCLK	RGMII_n_TXC	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RGMII_n_RD[3:0]	RGMII_n_RD[3:0]	I	The receive data pins are a collection of 4 bits of data. RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_n_RX_CTL is asserted
RGMII_n_RCTL	RGMII_n_RX_CTL	I	The receive data valid/control signal indicates that the RD pins are nibble data for use by the EMAC.
RGMII_n_RCLK	RGMII_n_RXC	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MCLK	MDIO0_MDC	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO0_MDIO pin.
MDIO_MDIO	MDIO0_MDIO	I/O	The MDIO0_MDIO pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO0_MDIO pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

(2) n 1 to 8

---

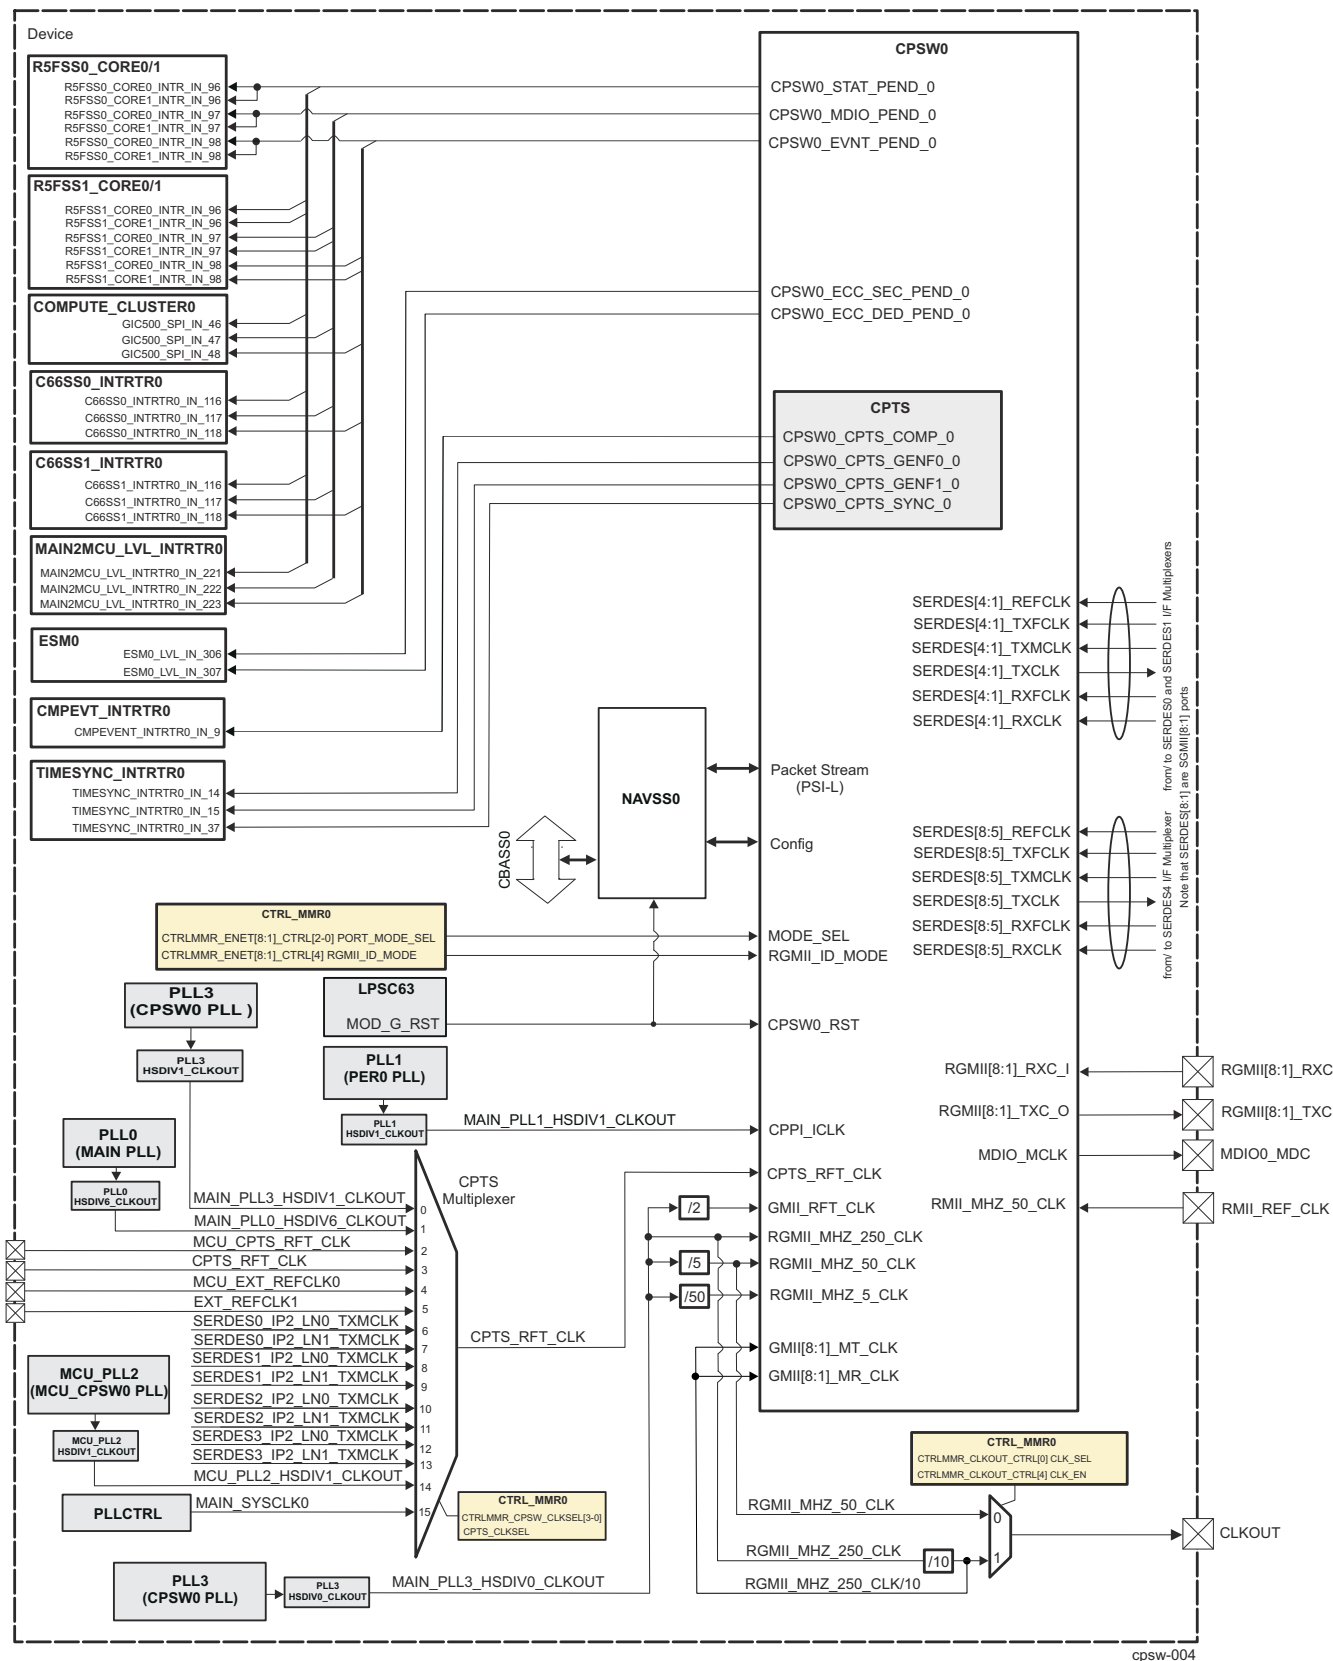

**Note**

The Control Module registers assign the specific function to the device pads. For more information on Control Module settings, see Pad Configuration Registers in *Control Module (CTRL\_MMR)* and the device-specific Datasheet.

---

### 12.2.2.3 CPSW0 Integration

[Figure 12-163](#) shows the integration of the CPSW0 module in the device.

### Figure 12-163. CPSW0 Integration

The following CPSW0 control registers are located in CTRL\_MMR0 module: CTRLMMR\_ENET1\_CTRL to CTRLMMR\_ENET8\_CTRL, CTRLMMR\_CPSW\_CLKSEL.

Table 12-200 through Table 12-202 summarize the integration of the CPSW0 module in the device.

**Table 12-200. CPSW0 Integration Attributes**

Module Instance	Attributes			
	Power Sleep Controller	Power Domain	Module Domain	Interconnect
CPSW0	PSC0	PD4	LPSC63	CBASS0

**Table 12-201. CPSW0 Clocks and Resets**

Clocks				
Module Instance	Module Clock Input	Source Clock Signal	Source	Description
CPSW0	CPPI_ICLK	MAIN_PLL1_HSDIV1_CL KOUT	PLL1 (HSDIV1 of PER0 PLL)	CPPI packet streaming interface clock (320-MHz). Main clock for CPSW0.
	GMII_RFT_CLK	MAIN_PLL3_HSDIV0_CL KOUT/2	PLL3 (HSDIV0 of CPSW0 PLL)	125-MHz GMII Gigabit mode clock.
	RGMII_MHZ_5_CLK	MAIN_PLL3_HSDIV0_CL KOUT/50	PLL3 (HSDIV0 of CPSW0 PLL)	5-MHz RGMII reference clock.
	RGMII_MHZ_50_CLK	MAIN_PLL3_HSDIV0_CL KOUT/5	PLL3 (HSDIV0 of CPSW0 PLL)	50-MHz RGMII reference clock.
	RGMII_MHZ_250_CLK	MAIN_PLL3_HSDIV0_CL KOUT	PLL3 (HSDIV0 of CPSW0 PLL)	250-MHz RGMII reference clock.
	RMII_MHZ_50_CLK	RMII_REF_CLK	RMII_REF_CLK pad	50-MHz RMII reference clock. This clock is derived from the RMII_REF_CLK pad.
	CPTS_RFT_CLK	MAIN_PLL3_HSDIV1_CL KOUT	HSDIV1 of CPSW0 PLL Controller, selected through CPTS Multiplexer (200 or 250-MHz clock)	CPTS IEEE 1588 clock. Selected through the CTRLMMR_CPSW_CLKSEL register.
		MAIN_PLL0_HSDIV6_CL KOUT	HSDIV6 of MAIN PLL Controller, selected through CPTS Multiplexer (200 or 250-MHz clock)	
		MCU_CPTS_RFT_CLK pad	MCU_CPTS_RFT_CLK pad, selected through CPTS Multiplexer (200-MHz clock)	
		CPTS_RFT_CLK pad	CPTS_RFT_CLK pad, selected through CPTS Multiplexer (200-MHz clock)	
		MCU_EXT_REFCLK0 pad	MCU_EXT_REFCLK0 pad, selected through CPTS Multiplexer (100-MHz clock)	
		EXT_REFCLK1 pad	EXT_REFCLK1 pad, selected through CPTS Multiplexer (100-MHz clock)	
		SERDES0_IP2_LN0_TXM_CLK	SERDES0 Lane0 (500-MHz clock)	
		SERDES0_IP2_LN1_TXM_CLK	SERDES0 Lane1 (500-MHz clock)	
		SERDES1_IP2_LN0_TXM_CLK	SERDES1 Lane0 (500-MHz clock)	

**Table 12-201. CPSW0 Clocks and Resets (continued)**

	SERDES1_IP2_LN1_TXM_CLK	SERDES1 Lane1 (500-MHz clock)

### 12.2.2.4 CPSW0 Functional Description

The 9-port switch Ethernet subsystem module (CPSW) is compliant to the IEEE Std 802.3 Specification. CPSW top level functional block diagram is shown in [Figure 12-164](#).

#### 12.2.2.4.1 Functional Block Diagram

The 9-port Ethernet subsystem consists of:

- CPSW\_9G
- One RGMII<sub>n</sub> (where n = 1 to 8) interface module
- One SGMII<sub>n</sub> (where n = 1 to 8) interface modules
- One RMII<sub>n</sub> (where n = 1 to 8) interface module
- One Host Port 0 CPPI Packet Streaming Interface
- CPSW subsystem control registers (REG)
- One MDIO interface module
- One Interrupt Controller module

**Figure 12-164. CPSW Top Level Block Diagram**

#### 12.2.2.4.2 CPSW Ports

The Ethernet Subsystem has 9 ports. Port 0 is the Host port (internal to the Subsystem). Port 1 to Port 8 are the external ports connected to RGMII, SGMII or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the CPPI Host Port
- Port1 to Port8 is referred to the interfaces RGMII/SGMII/RMII

##### 12.2.2.4.2.1 Interface Mode Selection

The 9-port switch (CPSW) Ethernet Subsystem has eight 10/100/1000 Ethernet ports with selectable RMII, RGMII and SGMII interfaces.

The interface modes for all 8 Ethernet ports are selected by configuring the Ethernet interface mode selection bitfield (PORT\_MODE\_SEL) in the CTRLMMR\_ENET1\_CTRL to CTRLMMR\_ENET8\_CTRL registers.

See the device-specific Datasheet for configuring the pin mux mode as per the interface selected.

#### **12.2.2.4.3 Clocking**

##### **12.2.2.4.3.1 Subsystem Clocking**

CPSW clocking summary is shown in *CPSW0 Integration*.

##### **12.2.2.4.3.2 Interface Clocking**

Data is transmitted and received with respect to the reference clocks of the interface pins.

##### **12.2.2.4.3.2.1 RGMII Interface Clocking**

RGMII\_RXC, RGMII\_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

##### **12.2.2.4.3.2.2 RMII Interface Clocking**

RMII interface clock RMII\_50MHZ\_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

RMII\_REF\_CLK from device pin or internal RGMII\_MHZ\_50\_CLK clock (default clock) can be used as the clock source for RMII interface. For more details on RMII clocking, please see *CPSW0 Integration*

CTRLMMR\_CLKOUT\_CTRL[4]CLK\_EN and CTRLMMR\_CLKOUT\_CTRL[0]CLK\_SEL bits are used to enable and select the clock source for CLKOUT device pin.

##### **12.2.2.4.3.2.3 MDIO Clocking**

The MDIO clock is based on a divide-down of the interface (CPPI\_ICLK) clock. The application software or driver must control the divide-down value.

See the CPSW\_MDIO\_CONTROL\_REG register for configuring the Clock Divider ([15-0]CLKDIV) value.

##### **12.2.2.4.4 Software IDLE**

The submodule software idle register bits enable CPSW operation to be completely or partially suspended by software control. There are two CPSW submodules that contain software idle register bits. Each of the two submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW module enters the idle state when all two submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the two submodule idle bits. The CPSW\_9G is in the idle state when all two submodules are in the idle state. The CPSW\_SOFT\_IDLE\_REG[0] SOFT\_IDLE bit may be set if desired after the submodules are in the idle state. The SOFT\_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

##### **12.2.2.4.5 Interrupt Functionality**

CPSW Ethernet Subsystem has six interrupt outputs:

- EVNT\_PEND - CPTS Event Pending Interrupt
- STAT\_PEND0 – Statistics Pending Interrupts
- ECC\_DED\_INT - ECC DED Level Interrupt
- ECC\_SEC\_INT - ECC SEC Level Interrupt
- MDIO\_INTR - MDIO Pending Interrupt (combined MDIO\_LINKINT and MDIO\_USERINT events)

#### 12.2.2.4.5.1 EVNT\_PEND Interrupt

See [Section 12.2.2.4.7](#), *Common Platform Time Sync (CPTS)* for more details on this interrupt.

#### 12.2.2.4.5.2 Statistics Interrupt (STAT\_PEND0)

The statistics level interrupt (STAT\_PEND0) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement any statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The statistics are mapped into internal memory space and are 32-bits wide. The raw and masked statistics interrupt status may be read by reading the CPSW\_CPTS\_INTSTAT\_RAW\_REG and CPSW\_CPTS\_INTSTAT\_MASKED\_REG registers, respectively.

The statistics interrupt is enabled by setting to 1h the TS\_PEND\_EN bit in the CPSW\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.2.4.5.3 ECC DED Level Interrupt (ECC\_DED\_INT)

Level interrupt (ECC\_DED\_INT) indicating an ECC double error has been detected.

#### 12.2.2.4.5.4 ECC SEC Level Interrupt (ECC\_SEC\_INT)

Level interrupt (ECC\_SEC\_INT) indicating an ECC single error has been detected and corrected.

#### 12.2.2.4.5.5 MDIO Interrupts

**Normal Mode:** (CPSW\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 0h)

MDIO\_LINKINT event is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR\_MON field of the CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k register and the corresponding LINKINT\_ENABLE bit is set. The MDIO\_LINKINT event is also captured in the MDIO CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register. When the GO bit in the CPSW\_MDIO\_USER\_ACCESS\_REG\_k register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the CPSW\_MDIO\_USER\_INT\_MASK\_SET\_REG register is set, the MDIO\_USERINT signal is asserted. The MDIO\_USERINT event is also captured in the CPSW\_MDIO\_USER\_INT\_MASKED\_REG register.

**State Change Mode:** (CPSW\_MDIO\_POLL\_REG[30] STATECHANGEMODE = 1h)

In State Change Mode, the MDIO will assert MDIO\_LINKINT[0] when any bit in the MDIO CPSW\_MDIO\_ALIVE\_REG or CPSW\_MDIO\_LINK\_REG registers changes due to MDIO operations. The MDIO\_LINKINT event is also captured in the CPSW\_MDIO\_LINK\_INT\_MASKED\_REG register. MDIO\_LINKINT[1] output is unused in State Change Mode. The CPSW\_MDIO\_USER\_PHY\_SEL\_REG\_k registers are unused in state change mode.

**Manual Mode:** (CPSW\_MDIO\_POLL\_REG[31] MANUALMODE = 1h)

Manual Mode allows software to directly control the MDIO serial clock output (CPSW\_MDIO\_MANUAL\_IF\_REG[2] MDIO\_MDCLK\_O) and the MDIO serial data output enable (CPSW\_MDIO\_MANUAL\_IF\_REG[1] MDIO\_OE). Manual Interface Mode is enabled when the MANUALMODE bit is set in the CPSW\_MDIO\_POLL\_REG register. Manual Mode is intended to be used by software for slow speed general purpose IO operations and not for MDIO PHY operations.

#### 12.2.2.4.6 CPSW\_9G

The CPSW\_9G RMII/ RGMII interface is compliant to the IEEE Std 802.3 Specification.

The CPSW\_9G contains one Ethernet port interface (Ethernet port 1), one CPPI packet streaming interface host port (port 0), Common Platform Time Sync (CPTS), ALE Engine and Statistics (STATS). A top-level block diagram of the CPSW\_9G is shown in [Figure 12-165](#).

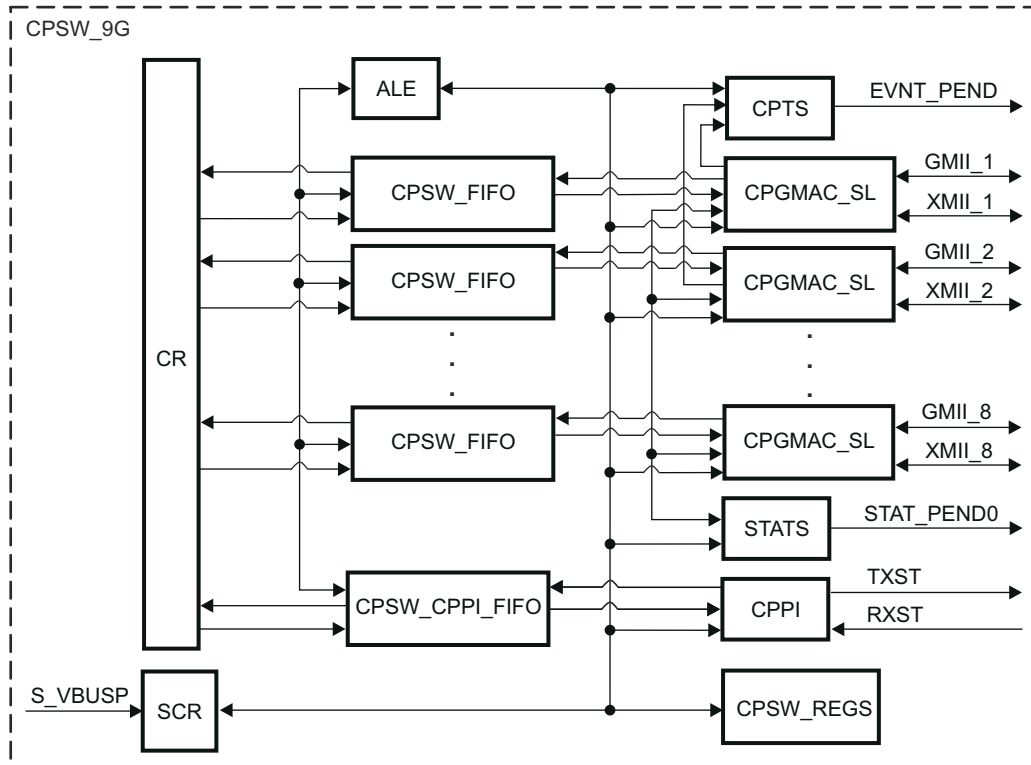

Figure 12-165. CPSW\_9G Block Diagram

#### 12.2.2.4.6.1 Address Lookup Engine (ALE)

The Address Lookup Engine (ALE) is a sub-block of the CPSW Switch and it processes all received packets and determines the packet destination port(s). The ALE uses the incoming packet data: received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the `ENABLE_ALE` bit in the `CPSW_ALE_CONTROL` register is set. All packets are dropped when the `ENABLE_ALE` bit is cleared to 0h.

##### 12.2.2.4.6.1.1 Error Handling

In normal operation, the Ethernet port modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a MAC control packet. However, when the `CPSW_PN_MAC_CONTROL_REG_k` configuration bit(s) `RX_CEF_EN`, `RX_CSF_EN`, or `RX_CMF_EN` are set, error frames, short frames or MAC control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a MAC control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). Packets with errors that are forwarded to the host have no VLAN untagging or drop due to rate limiting. No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address. Directed packets from the host are not learned, updated, or touched.

##### 12.2.2.4.6.1.2 Bypass Operations

The ALE may be configured to operate in bypass mode by setting the `ENABLE_BYPASS` bit in the `CPSW_ALE_CONTROL` register. When in bypass mode, all Ethernet port received packets are forwarded only to the host port (port 0). In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

### 12.2.2.4.6.1.3 OUI Deny or Accept

The ALE may be configured to operate in OUI deny mode by setting the ENABLE\_OUI\_DENY bit in the CPSW\_ALE\_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the SUPER bit set. When ENABLE\_OUI\_DENY bit is cleared, any packet source address matching an OUI address table entry will be dropped to the host unless the destination address matches with a supervisory address table entry. Broadcast packets will be dropped unless the broadcast address is entered into the table with the SUPER bit set. Unicast packets will be dropped unless the unicast address is in the table with BLOCK and SECURE both set (supervisory unicast packet).

### 12.2.2.4.6.1.4 Statistics Counting

ALE sends many statistics along with the frame routing so the CPSW can count them on a per port basis. There are many reasons to drop frames the below drop events are individually counted in CPSW per port statistics counters.

**Table 12-203. Learned Address Control Bits**

Abbreviation	Description
vddc	Dual VLAN or Double VLAN drop counter.
frdc	IPv4 fragmented drop counter.
nldc	IPv4 Protocol or IPv6 Next Header drops due to next header limit drop counter.
etdc	Ether Type field is <= 1500 and the frame size is too small drop counter.
smdc	The Source Address has bit 40 set drop counter.
badc	The Source or Destination Address blocked drop counter.
svdc	The Source Address is locked to a different port drop counter.
des	The Source and Destination are equal and the Source Address is not in the table drop counter.
adc	The Source Address is not in the table in authentication mode drop counter.
vicdc	The VLAN ingress check failed drop counter.
rlcd	Rate Limit Drop Counter.
over	Lookup Overflow, the rate of the ALE clock is not sufficient to handle the incoming frame rate (Should never happen).
drop	Packet is dropped and not forwarded.

### 12.2.2.4.6.1.5 Automotive Security Features

The ALE has many automotive security features that most enterprise switches do not require.

- VLANs can be configured to not allow fragmented IPv4 frames. That is a VLAN can be configured to not allow fragmented IPv4 traffic.
- VLANs can be configured to only allow up to four different IPv4 Protocols or IPv6. Next Header values, for example a VLAN can be configured to only allow TCP traffic in both IPv4 and IPv6 packets.
- Drop invalid Source Addresses, that is drop Source Addresses with bit 40 set (Multicast/Broadcast indicator on Destination Addresses)
- IEEE802.3 Length Check, drop frames that the IEEE802.3 Length is not contained within the frame. (Ether Types 0-1500)
- Any Source Address can be secured to a port dropping any attempts from other ports to masquerade as a service.

- Any source or destination address can be blocked.
- Per Port or Per VLAN ingress checking, dropping traffic from non-member ports.
- Classification, Policing on L2 and L3 information.

#### **12.2.2.4.6.1.6 CPSW Switching Solutions**

The host port can operate in many different modes as well depending on the functionality of the host. It is important to understand the modes and configure them properly.

The ALE Table is designed to maximize the modes without compromise of the system functionality as well.

##### **12.2.2.4.6.1.6.1 Basics of 5-port Switch Type**

The 5-port switch has a host port, and that port can operate in two fundamental modes. Bridge mode allows the host to extend the switched domain to another network like Wi-Fi or another multi-port switch. In this case the host must be able to see unknown unicast addresses so they can be broadcast to the other network. In Port mode the host need not see any unknown unicast traffic. The CPSW\_ALE\_CONTROL[8] EN\_HOST\_UNI\_FLOOD bit determines the host mode for unknown unicast traffic. This bit should only be set if you are bridging two or more networks together.

In 5-port switch, the ALE table is shared between the host port and the network.

##### **12.2.2.4.6.1.7 VLAN Routing and OAM Operations**

###### **12.2.2.4.6.1.7.1 InterVLAN Routing**

The CPSW module supports wire rate InterVLAN routing for a small number of routes, that is the host will setup an ALE classifier with and associated egress operation that will cause the CPSW to perform particular egress operations. The ALE can optionally check time to live validity as well.

The ALE uses the classifier along with an egress opcode, destination port mask and TTL check field to tell the CPSW to manipulate the packet on the egress. The CPSW will use the opcode along with a per port operation table to process the packet. By setting up the CPSW egress operation table you can replace the DA, SA and VLAN along with optionally updating the time to live IP header field. This allows the CPSW to perform the routing function for a small set of routes without getting the local host/CPU involved.

The Egress opcode will only be use for a classifier match and the packet would normally be sent only to the host. That is the host would have routed the packet but the CPSW has been configured to do the work instead. In the event that the time-to-live check feature is enabled and the time-to-live is either 0 or 1, the packet will not get the egress opcode and instead be sent to the host as if the route is not setup. This allows the host to deal with invalid TTL fields.

###### **12.2.2.4.6.1.7.2 OAM Operations**

The ALE supports OAM loopback on ports so that a remote link can be tested. That is a port placed in OAM loopback will echo packets received on a port back to the port with an egress op of 0xFF which will swap the SA and DA on egress in the CPSW.

Any supervisory packet will not be affected, so the spanning tree and other bridging functions are not affected.

Packets will only be echoed if the port is in OAM loopback mode, the received packet is not a supervisor packet. The port is in a forwarding state and the packet received DA!=SA and there are no errors in the packet.

When a port is in OAM loopback the port will not egress traffic from other ports, no address for loop backed traffic will be learned if enabled. Any packet received on the OAM loopback port with an error will be process as if the port is not in OAM. That is if the host has enabled copy errored frames the errored frames will be sent to the host instead.

###### **12.2.2.4.6.1.8 Supervisory packets**

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise

blocked to be forwarded for special purposes. For example the BPDU packets that sent during link start up must also be seen on ports in a blocking state. This allows the bridge software to remove loops in the fabric.

#### 12.2.2.4.6.1.9 Address Table Entry

The ALE table contains multiple table entry types. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 12-204. Learned Address Control Bits**

Bit(s)	Value
AGEABLE	1
Touch	1
BLOCK	0
SECURE	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

#### Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40**.

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### 12.2.2.4.6.1.9.1 Free Table Entry

**Table 12-205. Free (Unused) Address Table Entry Bit Values**

74:62	61:60	59:0
RESERVED	ENTRY_TYPE (00)	RESERVED

#### 12.2.2.4.6.1.9.2 Multicast Address Table Entry (Bit 40 == 0)

**Table 12-206. Multicast Address Table Entry Bit Values**

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUMBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_T YPE (01)	RESERVE D	MULTICA ST_ADDR ESS

#### Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk numbe

#### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Touch Indicator (TOUCH)

Only valid when AGEABLE it a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

### Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 12.2.2.4.6.1.9.3 Multicast Address Table Entry (Bit 40 == 1)

**Table 12-207. VLAN/Multicast Address Table Entry Bit Values**

74:66	65	64	63:62	61:60	59:48	47:0
PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYP E (1h)	RESERVED	MULTICAST_AD DRESS

### Port Mask(1:0) (PORT\_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0h = Non-supervisory packet

1h = Supervisory packet

### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

### Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

3h = VLAN address entry. Unicast or multicast determined by address bit 40.

### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 12.2.2.4.6.1.9.4 VLAN Unicast Address Table Entry (Bit 40 == 0)

**Table 12-208. Unicast Address Table Entry Bit Values**

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUM BER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TY PE (11)	VLAN_ID	UNICAST_A DDRESS

### Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk numbe

### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

### Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

1h = Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 12.2.2.4.6.1.9.5 OUI Unicast Address Table Entry

**Table 12-209. OUI Unicast Address Table Entry Bit Values**

74:64	63:62	61:60	59:48	47:24	23:0
RESERVED	UNICAST_TYPE (2h)	ENTRY_TYPE (1h)	RESERVED	UNICAST_OUI	RESERVED

### Unicast Type (UNICAST\_TYPE)

This field indicates the type of unicast address the table entry contains.

0h = Unicast address that is not ageable.

1h = Ageable unicast address that has not been touched.

2h = OUI address - lower 24-bits are don't cares (not ageable).

3h = Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

1h: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

#### 12.2.2.4.6.1.9.6 VLAN/Unicast Address Table Entry (Bit 40 == 0)

**Table 12-210. Unicast Address Table Entry Bit Values**

74	73:70	69:66	65	64	63	62	61:60	59:48	47:0
TRUNK	RESERVED	PORT_NUMBER	BLOCK	SECURE	TOUCH	AGEABLE	ENTRY_TYPE (3h)	VLAN_ID	UNICAST_ADDRESS

### Trunk Indicator (TRUNK)

0h = The port bits in the entry are the port number

1h = The port bits in the entry are the trunk number

### Port Number (PORT\_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

### Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0h = Address is not blocked.

1h = Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT\_NUMBER.

0h = Received port number is a don't care.

1h = Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Touch Indicator (TOUCH)

Only valid when AGEABLE is a 1h.

0h = Ageable unicast address has not been touched

1h = Ageable unicast address that has been touched

### Ageable (AGEABLE)

This bit indicates that the address is ageable.

0h = Unicast address that is not ageable

1h = Unicast address that is ageable

#### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

3h: VLAN address entry. Unicast or multicast determined by address bit 40.

#### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 12.2.2.4.6.1.9.7 VLAN/ Multicast Address Table Entry (Bit 40 == 1)

**Table 12-211. Multicast Address Table Entry Bit Values**

74:66	65	64	63:62	61:60	59:48	47:0
PORT_MASK	SUPER	IGNMBITS	FWDSTLVL	ENTRY_TYPE (3h)	VLAN_ID	UNICAST_ADD RESS

#### Port Mask(1:0) (PORT\_MASK)

This 2-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0h = Non-supervisory packet

1h = Supervisory packet

#### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

#### Forward State Level (FWDSTLVL)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s).

A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

0h = Forwarding

1h = Blocking/Forwarding/Learning

2h = Forwarding/Learning

3h = Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

3h = VLAN address entry. Unicast or multicast determined by address bit 40.

## VLAN ID (VLAN\_ID)

The VLAN ID associated with the Address entry.

## Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 12.2.2.4.6.1.9.8 Inner VLAN Table Entry

**Table 12-212. Inner VLAN Table Entry**

74:66	65	64:62	61:60	59:48	47	46:45	44:36
NO_LEARN_MASK	VLAN_FORCE_INGRESS_CHECK	RESERVED	ENTRY_TYPE (1h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_FLOOD_INDEX
35:33	32:24	23	22:21	20:12	11:9	8:0	
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST	

## No Learn Mask (NO\_LEARN\_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

## VLAN Force Ingress Check (VLAN\_FORCE\_INGRESS\_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the `ly_REG_Py_VID_INGRESS_CHECK` bit in the `CPSW_ly_ALE_PORTCTL0_y` registers except this check is for this VLAN only (not all VLANs).

## Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

## VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

## (NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

## Registered Multicast Flood Index (REG\_MCAST\_FLOOD\_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the registered multicast flood mask.

## Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

## VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the `CPSW_ALE_NXT_HDR` register values.

## VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

## VLAN Member List (VLAN\_MEMBER\_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

### 12.2.2.4.6.1.9.9 Outer VLAN Table Entry

**Table 12-213. Outer VLAN Table Entry**

74:66	65	64:62	61:60	59:48	47	46:45	44:36
NO_LEARN_MASK	VLAN_FORCE_INGRESS_CHECK	RESERVED	ENTRY_TYPE (2h)	VLAN_ID	NOFRAG	RESERVED	REG_MCAST_FLOOD_INDEX
35:33	32:24	23	22:21	20:12	11:9	8:0	
RESERVED	FORCE_UNTAGGED_EGRESS	LMTNXTHDR	RESERVED	UREGMSK	RESERVED	VLAN_MEMBER_LIST	

#### No Learn Mask (NO\_LEARN\_MASK)

When a bit is set in this mask, a packet with an unknown source address received on the associated port will not be learned (i.e. When a VLAN packet is received and the source address is not in the table, the source address will not be added to the table).

#### VLAN Force Ingress Check (VLAN\_FORCE\_INGRESS\_CHECK)

If the receive port is not a member of this VLAN then the packet is dropped. This is similar to the `ly_REG_Py_VID_INGRESS_CHECK` bit in the `CPSW_ly_ALE_PORTCTL0_y` registers except this check is for this VLAN only (not all VLANs).

#### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

#### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

#### (NOFRAG)

VLAN No IPv4 Fragmented frames Control - Causes IPv4 fragmented IP frames to be dropped.

#### Registered Multicast Flood Index (REG\_MCAST\_FLOOD\_INDEX)

Index into `CPSW_ALE_MSK_MUX0` to `CPSW_lx_ALE_MSK_MUXx` register array that is used to create the registered multicast flood mask.

#### Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress for the specified port(s) (except on port 0).

#### VLAN Limit Next Header Control (LMTNXTHDR)

This bit causes frames to be dropped if the Protocol/Nxt Header does not match the `CPSW_ALE_NXT_HDR` register values.

#### VLAN Unregister Multicast Mask (UREGMSK)

This field indicates which port(s) are the unregistered multicast flood mask.

#### VLAN Member List (VLAN\_MEMBER\_LIST)

This field indicates which port(s) are members of the associated VLAN. One bit per port.

### 12.2.2.4.6.1.9.10 EtherType Table Entry

**Table 12-214. EtherType Table Entry**

74:65	64:62	61:60	59:16	15:0
RESERVED	RESERVED	ENTRY_TYPE (1h)	RESERVED	ETHERTYPE

#### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### Ether Type (ETHERTYPE)

16-bits Ether Type field.

#### 12.2.2.4.6.1.9.11 IPv4 Table Entry

**Table 12-215. IPv4 Table Entry**

74:70	69:65	64:62	61:60	59:32	31:0
RESERVED	IGNMBITS	RESERVED	ENTRY_TYPE (2h)	RESERVED	IPv4ADR

### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv4 Address (IPv4ADR)

32-bit IPv4 Address. Any ignored bits must be zero value in the table entry.

#### 12.2.2.4.6.1.9.12 IPv6 Table Entry High

**Table 12-216. IPv6 Table Entry High**

74:71	70:64	63	62	61:60	59:0
RESERVED	IGNMBITS	RESERVED	(1h)	ENTRY_TYPE (2h)	IPv6ADR[127:68]

### Ignore Multicast Bits (IGNMBITS)

Indication that the Multicast Address has ignored bits.

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv6 Address - upper 64 bits (IPv6ADR[127:68])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

#### 12.2.2.4.6.1.9.13 IPv6 Table Entry Low

**Table 12-217. IPv6 Table Entry Low**

74:71	70:63	62	61:60	59:0
RESERVED	IPv6ADR[67:60]	RESERVED	ENTRY_TYPE (2h)	IPv6ADR[59:0]

### Table Entry Type (ENTRY\_TYPE)

2h: VLAN entry

### IPv6 Address - upper 8 bits (IPv6ADR[67:60])

### IPv6 Address - upper 60 bits (IPv6ADR[59:0])

This address is split into three fields in the IPv6 High and IPv6 Low table entry. Any ignored bits must be zero in the table entry(s).

Note: IPv6 table address entries operate differently than all other table entry types. IPv6 table entries have a high entry concatenated with a low entry. The high entry must have an entry\_pointer value of the low entry\_pointer plus 0x40. Bit six of the entry\_pointer must be set for the high entry and must be zero for the low entry.

#### 12.2.2.4.6.1.10 Multicast Address

Multicast addresses are addresses with bit 40 set. Only destination addresses can be Multicast addresses. The group bit (bit 40) of the source address is reserved in the IEEE standard.

A multicast address of all ones is the broadcast address which can be added to the lookup table if forwarding of broadcast packets need be modified.

##### 12.2.2.4.6.1.10.1 Multicast Ranges

Added IgnMbits to indicate at least one bit of the multicast address is ignored. Up to 10 bits of the multicast address can be ignored to provide the ability to create multiple multicast address ranges.

```
if ((IgnMbits)&(MultiCastAddress[0] == 0x000)) { MultiCastAddress[0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[1:0] == 0x001)) { MultiCastAddress[1:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[2:0] == 0x003)) { MultiCastAddress[2:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[3:0] == 0x007)) { MultiCastAddress[3:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[4:0] == 0x00F)) { MultiCastAddress[4:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[5:0] == 0x01F)) { MultiCastAddress[5:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[6:0] == 0x03F)) { MultiCastAddress[6:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[7:0] == 0x07F)) { MultiCastAddress[7:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[8:0] == 0x0FF)) { MultiCastAddress[8:0] is ignored in compare}
if ((IgnMbits)&(MultiCastAddress[9:0] == 0x1FF)) { MultiCastAddress[9:0] is ignored in compare}
```

Below is 'C' code to modify ALE MultiCastAddress and IgnMbits when iNumOfBitsToIgnore is greater than zero. Where fGenMask(iOffset,iBitsToMask) creates a Mask for the value provided. For example fGenMask(0,5) will return 0x1F.

```
if(iNumOfBitsToIgnore)
{
    int iIgnClrMsk,iIgnSetMsk;
    iIgnClrMsk=fGenMask(0, iNumOfBitsToIgnore);
    iIgnSetMsk=fGenMask(0, iNumOfBitsToIgnore -1);
    MultiCastAddress &= ~iIgnClrMsk;
    MultiCastAddress |= iIgnSetMsk;
    IgnMbits = 1;
}
else
{
    IgnMbits = 0;
}
```

Multicast Addresses or Ranges can overlap, in the event of an overlap; the higher ALE index will be used.

##### 12.2.2.4.6.1.11 Supervisory Packets

Multicast supervisory packets are designated by the SUPER bit in the table entry. Unicast supervisory packets are indicated when BLOCK and SECURE are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing. The purpose of supervisory packets is to allow packets that would be otherwise

blocked to be forwarded for special purposes. For example the BPDU packets that sent during link start up must also be seen on ports in a blocking state. This allows the bridge software to remove loops in the fabric.

#### **12.2.2.4.6.1.12 Aging and Auto Aging**

The ALE supports software control or automatic aging of agable addresses.

Any time an agable address is seen as a source address entering from a port the source address entry will be marked as touched.

If the aging timer expires or the software sets the [29] AGE\_OUT\_NOW bit in the CPSW\_ALE\_CONTROL, the aging process will be started.

The aging process will read each ALE entry and for all entries that are an address with or without VLAN that is also agable, the touch check process will be done.

The touch check process will test the TOUCH bit and if clear, the entry will be marked as free, else the TOUCH bit will be cleared.

What this means is that if the aging interval was programmed as one second, any unused entry could stay in the ALE table for 1.000001 to 1.999999 seconds

#### **12.2.2.4.6.1.13 ALE Policing and Classification**

The ALE has a number of configurable classifier engines (policers) that can be used for classification. Classification is a subset of the policing function and uses a policer without the color marking or rate limiting functions. A policer is a hardware engine that is used for policing. The POLCNTDIV8 field in the CPSW\_ALE\_STATUS register indicates the number of policers available to be used for classification. Each policer can be enabled to match on one or more of any of the below packet fields for classification. All but Port and Priority are index references to the ALE table entries.

- Port Number
- Priority extracted from VLAN, mapped from DSCP if enabled, or Default Port Priority
- Organization Network Unique identifier - ONU
- Destination Address - DA
- Source Address - SA
- Outer VLANID -S-VLANID
- Inner VLANID -C-VLANID
- Ether Type
- IP Source Address - IPSA with full CIDR masking for IPv4 and IPv6
- IP Destination Address - IPSA with full CIDR masking for IPv4 and IPv6
- Support Host Thread/Flow ID mapping based on any packet classification above

##### **12.2.2.4.6.1.13.1 ALE Policing**

The policing function on each policer engine is implemented as dual-counter three-color marking engine as described in the IETF RFC2698. The first counter is the Committed Information Rate (CIR) counter and the second counter is the Peak Information Rate (PIR) counter. The policing function can use either or both counters. Based on the counter values the packet color is determined. The color is used to determine whether the packet is dropped or forwarded. The ALE has a local feature that can drop packets regardless of queue state.

The policing rates are determined by the below equations:

CIR policing rate in Mbit/s = ((ALE frequency in Mhz) \* CPSW\_ALE\_POLICECFG7[31-0] CIR\_IDLE\_INC\_VAL) / 32768

PIR policing rate in Mbit/s = ((ALE frequency in Mhz) \* CPSW\_ALE\_POLICECFG6[31-0] PIR\_IDLE\_INC\_VAL) / 32768

Each policer has 10 different match operations (see [Section 12.2.2.4.6.1.13](#)). Since multiple policing entries can be hit on a single packet this provides the ability to create precise traffic stream control.

Packets are colored at ALE lookup time. Packets can be colored RED, YELLOW, or GREEN. If multiple policers are configured for a packet stream then the packet color is merged from all matching (hit) policers. If any policer is RED then the packet is marked RED. Else if any policer is YELLOW then the packet is marked YELLOW. Otherwise the packet is marked GREEN.

The Policing engine supports several modes such that packets that don't hit a policing/classifier match can be treated as RED, YELLOW, GREEN or policer 0 color. Using policer 0 allows for a system to regulate unregulated traffic.

#### **12.2.2.4.6.1.13.2 Classifier to Host Thread Mapping**

The ALE module allows Host Thread mapping based on any packet classification. That is the ALE can generate a thread ID used by the host based on ALE classifier matches.

When enabled the highest classifier match can map to a particular thread ID value.

The ALE also supports an optional default Thread ID value in the event that no classifier match.

Each Thread ID including the default thread ID has an enable such that if no matches occur with the enable bit set are seen the default is used, if the default is not enabled, the switch will use the {port,priority} value instead. If multiple classifier matches occur, the highest matching entry with a thread enable bit set will be used.

Three registers are used for ALE classification thread mapping configuration (CPSW\_ALE\_THREADMAPDEF, CPSW\_ALE\_THREADMAPCTL and CPSW\_ALE\_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW\_ALE\_THREADMAPCTL register allows the CPSW\_ALE\_THREADMAPVAL register contents to be written to the selected classifier. There is a CPSW\_ALE\_THREADMAPDEF register that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

#### **12.2.2.4.6.1.13.3 ALE Classification**

When the policers are configured as classifiers, the color marking and policing functions of the policing/classifier engines are not used. One or multiple classifiers can be configured to match on a single packet. For example, a classifier can be enabled to match on priority while another classifier could match IP address.

##### **12.2.2.4.6.1.13.3.1 Classifier to CPPI Transmit Flow ID Mapping**

The ALE can generate a 6-bit transmit CPPI Flow ID based on classifier matches that can be used instead of the switch default transmit Flow ID mapping. The switch default flow ID is the remapped received packet priority (0 to 7). Thread and flow ID are used interchangeably for this since there is a single hardware thread (TXST\_THREAD\_MREADY) but there are 6-bits of FLOW\_ID in the transmit CPPI INFO word 0. When enabled, the highest classifier match can map to a particular 6-bit flow ID value that is associated with the classifier. The ALE also supports an optional ALE default thread/flow ID value in the event that no classifiers match. Each thread/flow ID, including the ALE default thread/flow ID, has an enable such that the ALE default thread/Flow ID is used if enabled and if no matches occur (instead of the remapped received packet priority). If the ALE default is not enabled and no matches occur then the switch default value will be used. If multiple classifier matches occur, the highest match with a thread enable bit set will be used. The resultant flow ID has the CPSW\_P0\_FLOW\_ID\_OFFSET\_REG register value added to it to determine the actual value in the INFO 0 Flow ID field.

Three registers are used for ALE classification thread/flow ID mapping configuration (CPSW\_ALE\_THREADMAPDEF, CPSW\_ALE\_THREADMAPCTL and CPSW\_ALE\_THREADMAPVAL). The three thread mapping registers are used independently and are separate from the other ALE policing registers. The CPSW\_ALE\_THREADMAPCTL register allows the CPSW\_ALE\_THREADMAPVAL register contents to be written to the selected classifier. There is a single CPSW\_ALE\_THREADMAPDEF that is used for all classifiers. The thread mapping registers can be written or changed at any time but any packets that are already processed will not have their thread altered.

#### 12.2.2.4.6.1.14 Mirroring

The ALE supports three mirroring modes: destination port, source port and or table entry.

**Destination port mirroring** allows packets from any ingress port or trunk which ends up switching to a particular egress destination port or trunk to be mirrored to yet another egress destination port or trunk. For example any traffic from any port that is switched to port 'A' can be also mirrored to port 'B'. (MIRROR\_DP=A, MIRROR\_DEN=1h, MIRROR\_TOP=B in the CPSW\_ALE\_CONTROL register).

**Source port mirroring** allows packets received on any enabled ingress source port or trunk to be switched to the mirror egress port as well as the actual egress destination ports. For example traffic received on ingress port 'A' can be switched to egress port 'B' as well as the intended egress destination port. (ly\_REG\_Py\_MIRROR\_SP=1h in the CPSW\_ly\_ALE\_PORTCTL0\_y register, MIRROR\_SEN=1h, MIRROR\_TOP=B in the CPSW\_ALE\_CONTROL register).

**Table entry mirroring** allows for any MAC Address, MAC Address with VLAN, ONU Address or VLAN entry that matches on ingress to be switched to the egress destination as well as the actual egress destination. For example all traffic for VLAN ID of 35 can be mirrored to port 'B'. That is any traffic switched on VLAN ID of 35 will be mirrored. ({VLAN ID of 35 in ALE Table entry index=C}, MIRROR\_MIDX=C, MIRROR\_MEN=1h, MIRROR\_TOP=B)

In the event that mirrored packets are mirrored to or from a port that is also the mirror port the packet will not be duplicated or marked as a mirror packet since the packet has already been on the port as ingress or egress. The packet sent to the mirror port may have modified VLAN info based on the port and VLAN lookup table entries. The mirror port need not be a member of the VLAN ID it is mirroring, the ALE will forward traffic to the mirror port after ingress and egress filters are applied.

The switch may decide to drop any mirror traffic based on switch buffer thresholds as to prevent required traffic from becoming congested.

Port mirroring is controlled by register fields in CPSW\_ALE\_CONTROL, CPSW\_ALE\_CTRL2 and the port control registers.

- MIRROR\_DP - The destination port that will have its traffic mirrored (CPSW\_ALE\_CONTROL register).
- MIRROR\_TOP - The port to which mirrored traffic is sent (CPSW\_ALE\_CONTROL register).
- MIRROR\_MEN - The enable for mirroring traffic that matches a supported lookup table entry (CPSW\_ALE\_CONTROL register).
- MIRROR\_DEN - The Enable for destination port mirroring (CPSW\_ALE\_CONTROL register).
- MIRROR\_SEN - The Enable for source port mirroring (CPSW\_ALE\_CONTROL register).
- MIRROR\_MIDX - The index of a lookup table entry that will be mirrored CPSW\_ALE\_CTRL2 register).
- ly\_REG\_Py\_MIRROR\_SP - The enable for the Source port to be mirrored. Although multiple source ports can be mirrored concurrently, a mirror traffic bandwidth issue may occur on the mirror egress port (CPSW\_ly\_ALE\_PORTCTL0\_y register).

#### 12.2.2.4.6.1.15 Trunking

The ALE supports port trunking of any port in any of four trunk groups. That is, four trunk groups can be supported with up to eight ports in each trunk group. There are no port adjacency rules for trunk groups. When ports are a member of a trunk group, addresses added and used in the lookup table will refer to the trunk group rather than port as indicated in the lookup table entries. If ports are removed from a trunk group, the ALE will redistribute the traffic based on the crc polynomial of enabled fields and the remaining ports within the trunk group. A trunk group may contain only one port. Packet priority, DA, SA, C-VLAN ID, IPv4SA, IPv4DA, IPv6SA, and/or IPv6DA can be used in the hash to generate destination port within the trunk group. If all hash enables are disabled, the packet can be directed to a particular port within the trunk group which allows for testing paths etc. A host directed frame is directed to the directed port regardless of trunk group settings.

Trunking is controlled through fields in the CPSW\_ALE\_CTRL2 register and in each ALE CPSW\_ly\_ALE\_PORTCTL0\_y register:

- TRK\_EN\_DST - Enable destination address hashing for trunk port calculation.

- TRK\_EN\_SRC - Enable source address hashing for trunk port calculation.
- TRK\_EN\_PRI - Enable priority hashing for trunk port calculation.
- TRK\_EN\_IVLAN - Enable inner C-VLAN ID hashing for trunk port calculation.
- TRK\_EN\_SIP - Enable source IP address hashing for trunk port calculation.
- TRK\_EN\_DIP - Enable destination IP address hashing for trunk port calculation.
- TRK\_BASE - Hashing formula starting value and test port offset.
- ly\_REG\_Py\_TRUNKEN - Enable this port as a trunk group
- ly\_REG\_Py\_TRUNKNUM - Trunk group number defines this port as a member of a particular trunk group.

#### 12.2.2.4.6.1.16 DSCP

The ALE can map DSCP field to priority prior to classification matching. When enabled the DSCP is mapped via 64 priority entries such that any DSCP value can be mapped to any of the eight priorities. When a packet is received without a VLAN priority this remapped priority can be used instead of the default Port VLAN priority field. See CPSW\_P0\_RX\_DSCP\_MAP\_REG\_y and CPSW\_PN\_RX\_DSCP\_MAP\_REG\_k\_y registers in the Register Manual section for DSCP mapping.

#### 12.2.2.4.6.1.17 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are *Ingress Filtering*, *VLAN\_Aware Lookup*, and *Egress*.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The MCAST\_FWD\_STATE indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The BLOCK and SECURE bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the Ethernet port to the ALE. Packets with errors may be passed to the host (not aborted) by a Ethernet port port, if the port has the RX\_CMF\_EN, RX\_CEF\_EN, or RX\_CSF\_EN bit(s) set in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. Error packets that are passed to the host by the Ethernet port are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with long or short errors received by the host are dropped. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register:

- [22] RX\_CEF\_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX\_CSF\_EN - enables short frames to be forwarded
- [24] RX\_CMF\_EN - enables MAC control frames to be forwarded.

#### 12.2.2.4.6.1.17.1 Ingress Filtering Process

##### Condition and action

<p>If ((ALE BYPASS) and (host port is not the receive port)) then use host portmask and go to Egress process</p>
<p>if (directed packet) then use directed port number and go to Egress process</p>
<p>If (Rx ly_REG_Py_PORTSTATE is Disabled) then discard the packet</p>
<p>if ((ALE BYPASS or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process</p>
<p>if (((BLOCK) and (unicast source address found)) or ((BLOCK) and (unicast destination address found))) then discard the packet</p>
<p>if ((ENABLE_RATE_LIMIT) and (rate limit exceeded) and (not BCAST_MCAST_CTL)) then if (((Multicast/Broadcast destination address found) and (not SUPER)) or (Multicast/Broadcast destination address not found)) then discard the packet</p>
<p>if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements</p> <ul style="list-style-type: none"> <li>Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.</li> </ul>
<p>if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements</p>
<p>if (source address found) and (secure) and (not block) and (receive port number != port_number)) then discard the packet</p>
<p>if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet</p>
<p>If (VLAN_Unaware)</p> <p>CPSW_ALE_UVLAN_UNTAG = "000000"</p> <p>CPSW_ALE_UVLAN_URCAST = "111111"</p> <p>CPSW_ALE_UVLAN_URCAST = "111111"</p> <p>UVLAN_MEMBER_LIST = "111111"</p> <p>else if (VLAN not found)</p> <p>CPSW_ALE_UVLAN_UNTAG = CPSW_ALE_UVLAN_UNTAG</p> <p>CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST</p> <p>CPSW_ALE_UVLAN_RMCAST = CPSW_ALE_UVLAN_RMCAST</p> <p>CPSW_ALE_UVLAN_MEMBER = CPSW_ALE_UVLAN_MEMBER</p> <p>else</p> <p>CPSW_ALE_UVLAN_UNTAG = found CPSW_ALE_UVLAN_UNTAG</p> <p>CPSW_ALE_UVLAN_URCAST = found CPSW_ALE_UVLAN_URCAST</p> <p>CPSW_ALE_UVLAN_RMCAST = found CPSW_ALE_UVLAN_RMCAST</p> <p>UVLAN_MEMBER_LIST = found UVLAN_MEMBER_LIST</p>
<p>if ((not SUPER) and (ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member)) then discard the packet</p>
<p>if ((ENABLE_AUTH_MODE) and (source address not found) and not(destination address found and (SUPER))) then discard the packet</p>

if (destination address equals source address) then discard the packet
if (VLAN_AWARE) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

#### 12.2.2.4.6.1.17.2 VLAN\_Aware Lookup Process

Condition and action
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and UVLAN_MEMBER_LIST less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of the PORT_NUMBER and the UVLAN_MEMBER_LIST and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_NUMBER and goto Egress process
if (Unicast packet) # destination address not found then portmask is VLAN member LIST less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not SUPER)) then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and found destination address/VLAN portmask (PORT_MASK) and UVLAN_MEMBER_LIST and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (SUPER)) then portmask is the PORT_MASK and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of CPSW_ALE_UVLAN_URCAST and UVLAN_MEMBER_LIST then goto Egress process
if (Broadcast packet) then use found UVLAN_MEMBER_LIST and goto Egress process

#### Note

The UVLAN\_MEMBER\_LIST, UVLAN\_UNREG\_MCAST\_FLOOD\_MASK, UVLAN\_REG\_MCAST\_FLOOD\_MASK and UVLAN\_FORCE\_UNTAGGED\_EGRESS are set in the [Section 12.2.2.4.6.1.17.1 Ingress Filtering Process](#), based on VLAN\_Unaware, Unknown\_VLAN rules and VLAN table entries.

#### 12.2.2.4.6.1.17.3 Egress Process

Condition and action
Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((ENABLE_OUI_DENY) and (OUI source address not found) and (not ALE BYPASS) and (not error packet) and ((not mcast destination address) and (SUPER))) then Clear host port from portmask

if ((not ENABLE_OUI_DENY) and (OUI source address found) and (not ALE BYPASS) and (not error packet) and not ((mcast destination address) and (SUPER)))
then Clear host port from portmask
if ((ENABLE_RATE_LIMIT) and (BCAST_MCAST_CTL))
then if (not SUPER) and (rate limit exceeded on any tx port)
then clear rate limited tx port from portmask
If address not found then SUPER cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

#### 12.2.2.4.6.1.17.4 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

##### 12.2.2.4.6.1.17.4.1 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Condition and action
If (directed) then do not learn, update, or set touched else continue
If (not (Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_LEARN)) then do not learn address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not learn address
if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not learn address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address found) and (receive port_number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address else continue
if ((source address found) and (receive port number != PORT_NUMBER)) then update address else continue
if ((source address not found) and (VLAN_AWARE) and not (LEARN_NO_VLANID)) then learn address with VLAN
if ((source address not found) and ((not VLAN_AWARE) or (VLAN_AWARE and LEARN_NO_VLANID))) then learn address without VLAN

##### 12.2.2.4.6.1.17.4.2 Updating Process

Condition and action
if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (ENABLE_AUTH_MODE) or (packet error) or (ly_REG_Py_NO_SA_UPDATE)) then do not update address
if ((Non-tagged packet) and (ly_REG_Py_DROP_UN_TAGGED)) then do not update address

if ((VLAN_AWARE) and (VLAN not found) and (unknown UVLAN_MEMBER_LIST = "000")) then do not update address
if ((ly_REG_Py_VID_INGRESS_CHECK) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER) and (SECURE or BLOCK)) then do not update address
if ((source address found) and (receive port number != PORT_NUMBER)) then update address

#### 12.2.2.4.6.1.17.4.3 Touching Process

if ((source address found) and (ageable) and (not touched)) then set touched
---

#### 12.2.2.4.6.1.18 VLAN Aware Mode

The CPSW is in VLAN aware mode when the VLAN\_AWARE bit is set in the CPSW\_CONTROL\_REG register.

In VLAN aware mode, transmitted packet data is changed depending on the packet type (PKT\_TYPE), packet priority (PKT\_PRI), and VLAN information.

The VLAN\_LTYPE\_SEL value is selected by the S\_CN\_SWITCH bit in the CPSW\_CONTROL\_REG register and is either the VLAN\_LTYPE\_INNER (8100h default) or VLAN\_LTYPE\_OUTER (88A8h default) value.

#### 12.2.2.4.6.1.19 VLAN Unaware Mode

An egress port is operating in the VLAN unaware mode when the VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is cleared to 0h. In VLAN unaware mode, transmit (egress) packets are not modified on egress.

#### 12.2.2.4.6.2 Packet Priority Handling

Packets are received on 9 ports, eight Ethernet ports and one CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG\_k, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG\_k, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority.

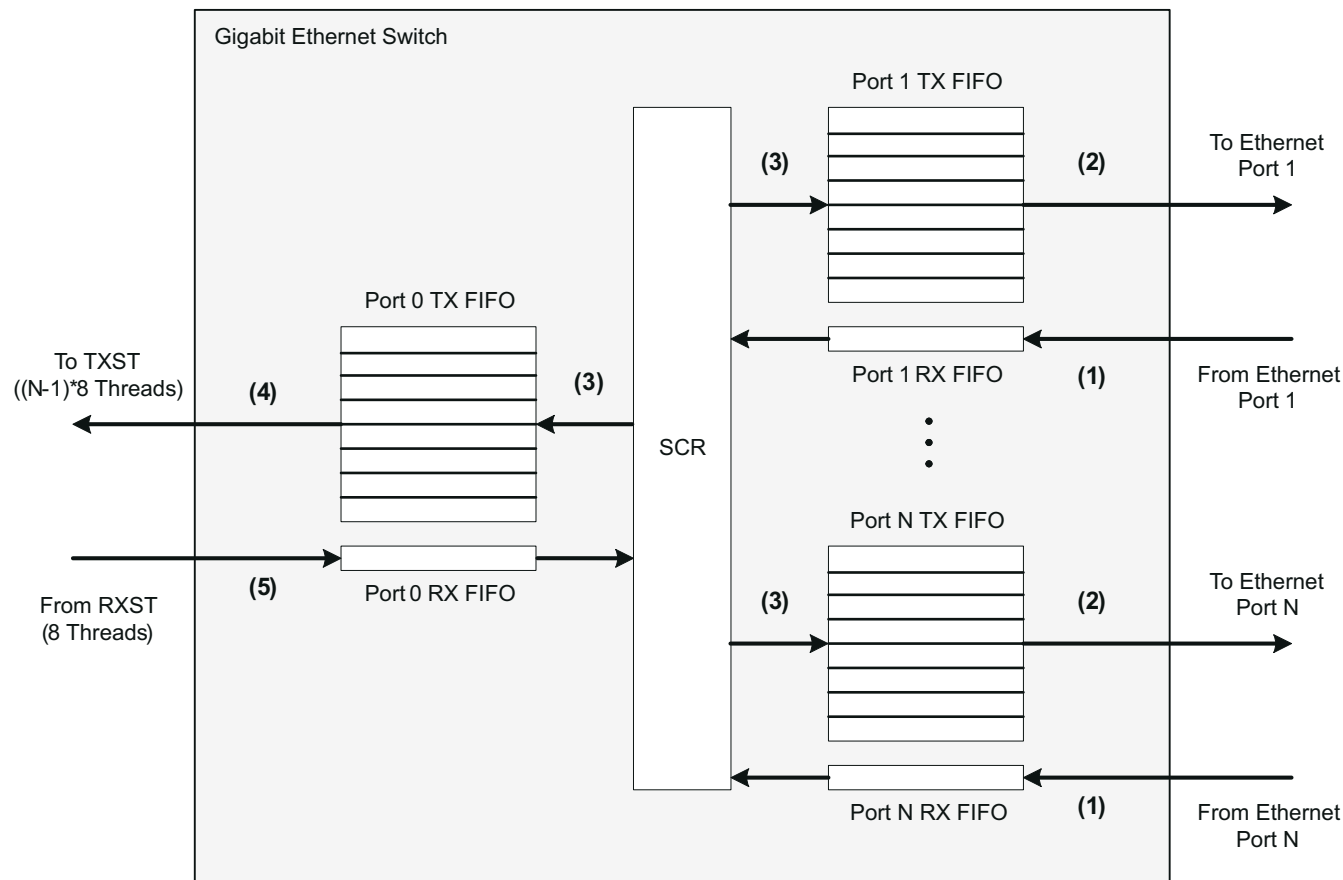

The received packet priority is mapped through the receive ports associated packet-priority-to-header-packet-priority-mapping register (CPSW\_PN\_RX\_PRI\_MAP\_REG\_k) to obtain the header packet priority. The header packet priority is the hardware switch priority. The header packet priority is also used as the actual transmit packet priority if the VLAN information is to be sent on egress.

The header packet priority is mapped at each destination FIFO through the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register (header priority to switch priority mapping register) to obtain the hardware switch priority (hardware queue 0 through 7).

### 12.2.2.4.6.2.1 Priority Mapping and Transmit VLAN Priority

There are three priorities that are used inside the Gigabit Ethernet Switch: **packet priority**, **header packet priority**, and **switch priority**. The **header packet priority** is used as the outgoing VLAN priority if the packet is egressing from the switch with a VLAN tag. The **switch priority** determines which of the 8 FIFO priority queues the packet uses during egress.

Figure 12-166 below, as well as the corresponding explanation that follows, explains each of the priorities, how they are determined, and how they are used. A number in parentheses in the figure indicates a process (Ethernet port ingress, host port egress, etc.). Each bullet in the text following the diagram explains one of the 5 processes pointed out in the figure.

**Figure 12-166. Gigabit Ethernet Switch Priority Mapping and Transmit VLAN Processing**

From [Figure 12-166](#) above:

- (1) is the ingress process that occurs at the external Ethernet ports
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the ingress port's priority. This **packet priority** is then mapped to a **header packet priority** using the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register where N is the port where the packet entered the switch. This process is explained in further detail in [Section 12.2.2.4.6.2](#).
- (2) is the egress process that occurs at the external Ethernet ports
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1) or (5). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.2.4.6.4.1](#).
- (3) is the process by which it is decided which priority TX queue to place the packet on in the Port N TX FIFO during egress
  - Each Port's TX FIFO has 8 queues that each correspond to a priority that is used when determining which packet will egress from the switch next at that port. The **header packet priority** (Ethernet port ingress, process (1)) or the receive packet thread (host port 0 ingress, process (5)) gets mapped through the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register (where N is the egress port number) to determine the **switch priority** of the packet. The **switch priority** determines which TX FIFO queue to place the packet in. The FIFO architecture is described in [Section 12.2.2.4.6.10.11](#). The header packet priority to switch priority mapping is discussed in [Section 12.2.2.4.6.2](#).
- (4) is the egress process that occurs at Host Port 0 toward the transmit streaming interface (TXST)
  - The TXST has 8 egress threads for each external Ethernet port (32 threads in a 5-port switch and 64 threads in a 9-port switch). The TX thread that is selected for a packet is determined by the Ethernet port of ingress and the **switch priority** of the packet that was determined in process (3).
  - If the switch is in VLAN Aware mode then the VLAN header may be added, replaced, or removed during the egress process. If the VLAN header is to be added or replaced, the VLAN priority will come from the **header packet priority** that was determined in process (1). Transmit VLAN processing is the same for both the host port and the external Ethernet ports and is described in [Section 12.2.2.4.6.4.1](#).
- (5) is the ingress process that occurs at Host Port 0
  - The incoming packet is assigned a **packet priority** based on either its VLAN priority, IPv4 or IPv6 DSCP value, or the host port's priority. This packet priority is then mapped to a **header packet priority** using the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register.
  - Host port 0 also has a received packet thread. The receive packet thread is based on either the packet's VLAN priority, IPv4 or IPv6 DSCP value, or the streaming interface (RXST) thread that the packet entered host port 0 on.

### 12.2.2.4.6.3 CPPI Port Ingress

Packets received on the CPPI host port have a received packet priority (0 to 7 with 7 being the highest priority).

The received packet priority is determined as follows:

1. If the first packet LTYPE = VLAN\_LTYPE\_SEL then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. Else if the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG\_k register, then the received packet priority is the 6-bit TOS field in byte 15 (upper 6 bits) mapped through the port's DSCP priority mapping registers (IPv4 packet).
3. Else if the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW\_P0\_CONTROL\_REG or CPSW\_PN\_CONTROL\_REG\_k register, then the received packet priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet).
4. Else the received packet priority is the source (ingress) port priority

The CPPI Port (port 0) also has a received packet thread. The received packet thread is determined exactly as the received packet priority except for untagged packets. For untagged packets, the received packet thread is the packet streaming interface thread that the packet was received on (instead of the port VLAN priority or DSCP priority). The received packet thread is the hardware switch priority. The received packet thread only determines which hardware switch priority the packet should be sent to, the egress VLAN rules are identical to packets that were received on Ethernet ports (as determined by the header packet priority).

For CPPI ingress packets, the destination port hardware switch priority is the below selected value remapped through CPSW\_PN\_RX\_PRI\_MAP\_REG\_k:

1. If the ingress packet is priority tagged or vlan tagged:
  - If RX\_REMAP\_VLAN in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_VLAN in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the packet priority value. Port transmit remapping (CPSW\_PN\_RX\_PRI\_MAP\_REG\_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
2. Else if the ingress packet has the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x4X, and DSCP\_IPV4\_EN is set in CPSW\_P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V4 bit in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping registers (IPv4 packet). Port 1 transmit remapping (CPSW\_PN\_RX\_PRI\_MAP\_REG\_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
3. Else if the ingress packet has the first packet LTYPE = 0x86DD and the most significant nibble of byte 14 (following the LTYPE) is equal to 0x6, and DSCP\_IPV6\_EN is set in CPSW\_P0\_CONTROL\_REG register:
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW\_P0\_CONTROL\_REG register is clear then the destination hardware switch priority is the CPPI receive thread number.
  - If RX\_REMAP\_DSCP\_V6 bit in CPSW\_P0\_CONTROL\_REG register is set then the destination hardware switch priority is the 6-bit priority (in the 6-bits following the upper nibble 0x6) mapped through the port's DSCP priority mapping registers (IPv6 packet). Port 1 transmit remapping (CPSW\_PN\_RX\_PRI\_MAP\_REG\_k should remain the default value) is not compatible with this bit being set, but remapping can be configured on port 0 receive.
4. Else the ingress packet is non-tagged and the destination hardware switch priority is the CPPI receive thread number.

#### 12.2.2.4.6.4 Packet CRC Handling

The P0\_TX\_CRC\_REMOVE bit in the CPSW\_CONTROL\_REG register determines if host port egress packets have CRC included or not. If P0\_TX\_CRC\_REMOVE is set to 1h then all packets that are transmitted from port 0 do not contain CRC. If P0\_TX\_CRC\_REMOVE bit is cleared to 0h then all packets that are transmitted from port 0 contain CRC. The CRC type, if present, is determined by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. If the CRC\_TYPE bit is cleared to 0h then the CRC present in each packet after host port egress is Ethernet CRC. If the CRC\_TYPE bit is set to 1h then the CRC present in each packet after host port egress is Castagnoli CRC.

#### Note

The CRC type present in the packet after host port egress is determined solely by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register regardless of the CRC type present in the packet during Ethernet port ingress.

#### 12.2.2.4.6.4.1 Transmit VLAN Processing

Transmit packets are NOT modified during switch egress when the VLAN\_AWARE bit in the CPSW\_CONTROL\_REG register is cleared to 0h. This means that the switch is not in VLAN-aware mode.

The next three sections cover transmit processing when the switch is in VLAN-aware mode for different packet types. The Gigabit Ethernet switch is in VLAN-aware mode when the VLAN\_AWARE bit is set in the CPSW\_CONTROL\_REG register. While in VLAN-aware mode, VLAN is added, removed, or replaced according to the type of packet as well as the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header as explained below.

##### 12.2.2.4.6.4.1.1 Untagged Packets (No VLAN or Priority Tag Header)

Untagged packets are all packets that are not a VLAN packet or a priority tagged packet. According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header the packet may exit the switch with a VLAN tag inserted or the packet may leave the switch unchanged. The two cases are discussed below.

- Insert VLAN Case:

Untagged input packets have the header packet VLAN inserted when the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the transmit packet header is de-asserted. For untagged packets, the VLAN EtherType = 0x8100 is inserted after the source address followed by the two byte header packet VLAN. The header packet VLAN is composed of the header packet priority along with the PORT\_CFI and PORT\_VID values from the CPSW\_PN\_PORT\_VLAN\_REG\_k register (where N is the port that the untagged packet entered the switch) through. The packet length/type field is output four bytes later than it is input and is not removed or replaced. If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a hardware generated CRC.

- No Change Case:

Untagged input packets are output unchanged when the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS transmit packet header bit is asserted.

##### 12.2.2.4.6.4.1.2 Priority Tagged Packets (VLAN VID == 0 && EN\_VID0\_MODE == 0h)

Priority tagged packets are packets that contain a VLAN header with VID = 0. According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, priority tagged packets may exit the switch with their VLAN ID and priority replaced or they may have their priority tag completely removed. The two cases are discussed below.

#### Note

In order for a priority tagged packet to fall into this category the ENABLE\_VID0\_MODE bit in the CPSW\_ALE\_CONTROL register must also be set to 0h. If the ENABLE\_VID0\_MODE bit in the CPSW\_ALE\_CONTROL register is set to 1h, then packets with a VLAN VID of 0 will fall into the VLAN Tagged Packets category in [Section 12.2.2.4.6.4.1.3](#) below.

- Replace Priority and VLAN ID Case:

Priority tagged input packets have the packet VLAN ID and the packet priority replaced with the header packet VLAN ID and the header packet priority when the transmit packet header CPSW\_FORCE\_UNTAGGED\_EGRESS\_REG[1-0] MASK bit is de-asserted. The header packet VLAN ID comes from the PORT\_VID bits in the CPSW\_PN\_PORT\_VLAN\_REG\_k register (where N is the port where the packet entered the switch). The header packet priority is based on the packet priority to header packet priority mapping in the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register (where N is the port where the packet entered the switch).

- Remove VLAN Header Case:

Priority tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority-tagged packets use all four input CRC bytes as pad, input 65-byte priority-tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority-tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### **12.2.2.4.6.4.1.3 VLAN Tagged Packets (VLAN VID != 0 || (EN\_VID0\_MODE == 1h && VLAN VID == 0))**

VLAN tagged packets are packets that contain a VLAN header specifying the VLAN the packet belongs to (VID), the packet priority (PRI), and the drop eligibility indicator (CFI). According to the CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit in the packet header, VLAN tagged packets may exit the switch with their VLAN priority replaced or they may have their VLAN header completely removed. The two cases are discussed below.

- Replace Priority Case:

VLAN tagged input packets are output with the packet priority replaced with the header packet priority when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is deasserted. The header packet priority is based on the packet priority to header packet priority mapping in the CPSW\_PN\_RX\_PRI\_MAP\_REG\_k register (where N is the port where the packet entered the switch). If the CRC is present in the packet data (PASS\_CRC is asserted), then the packet CRC is replaced with a generated CRC.

- Remove VLAN Header Case:

VLAN tagged input packets have the 4-byte packet VLAN information removed when the transmit packet header CPSW\_ALE\_UVLAN\_UNTAG[1-0] UVLAN\_FORCE\_UNTAGGED\_EGRESS bit is asserted. The 0x8100 EtherType is removed as is the two byte packet VLAN. Input 64-67 byte priority tagged packets go out with the VLAN removed and padded to 64-bytes if the PASS\_CRC input bit is asserted. The input CRC bytes are used as the pad data. Input 64-byte priority tagged packets use all four input CRC bytes as pad, input 65-byte priority tagged packets use three of the input CRC bytes as pad, and so on. No pad is performed if the PASS\_CRC input bit is not asserted - input 64-67 byte (on the wire) priority tagged packets go out as 60-63 byte packets. The output CRC is replaced with a generated CRC when the VLAN is removed.

#### **12.2.2.4.6.4.2 Ethernet Port Ingress Packet CRC**

All Ethernet ports check the ingress packet CRC in all modes/speeds. The receive port can check either Ethernet CRC or Castagnoli CRC as determined by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register.

#### **12.2.2.4.6.4.3 Ethernet Port Egress Packet CRC**

Ethernet ports transmit each egress packet with the CRC selected by the CRC\_TYPE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register, regardless of the type of CRC that the packet had on ingress to the switch. At the egress port after passing through the switch, the packet CRC is checked for correctness and if the CRC is correct then the packet is output with the generated selected output CRC. If the packet CRC is incorrect, due either to a bit flip in a memory or an error CRC passed in on host ingress, then the generated egress CRC type is used with at least a single byte of the CRC inverted to indicate the error. If the packet length including CRC is divisible by 4 then all 4 CRC bytes will be inverted on error. If there are three bytes remainder after dividing the packet length by 4 then three bytes will be inverted (and so on down to one byte remainder).

#### **12.2.2.4.6.4.4 CPPI Port Ingress Packet CRC**

CPPI port ingress packets can be passed in with or without a CRC. The host port is Ethernet CRC only. CPPI ingress packets are not checked for CRC correctness on CPPI ingress, however they are checked for

correctness on Ethernet egress and are output with a CRC error if they came in with a CRC error. If a CPPI ingress packet does not have the INFO0 PASSED\_CRC bit set then a CRC will be generated for the packet on CPPI ingress. If the PASSED\_CRC bit is set then the packet is received and forwarded unchanged. The CRC type is input in the INFO0 word CRC\_TYPE bit and must be Ethernet CRC.

#### 12.2.2.4.6.4.5 CPPI Port Egress Packet CRC

The P0\_TX\_CRC\_REMOVE bit in the CPSW\_CONTROL\_REG register determines if CPPI egress packet have an Ethernet CRC included or not.

#### 12.2.2.4.6.5 FIFO Memory Control

Each of the two CPSW\_9G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX\_MAX\_BLKs field in the FIFOs associated CPSW\_PN\_MAX\_BLKs\_REG register determines the maximum number of 1k FIFO memory blocks to be allocated to the eight logical transmit queues (transmit total). The RX\_MAX\_BLKs field in the FIFO's associated CPSW\_PN\_MAX\_BLKs\_REG register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX\_MAX\_BLKs value plus the RX\_MAX\_BLKs value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports is Port1.

Each transmit FIFO contains a configurable number of blocks (20 max) that are either 1k or 4k byte blocks that can be allocated to any priority.

#### 12.2.2.4.6.6 FIFO Transmit Queue Control

There are eight transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPPI receive (also switch egress). The CPPI nomenclature is reversed from the Ethernet port nomenclature due to legacy reasons.

##### 12.2.2.4.6.6.1 CPPI Port Receive Rate Limiting

Port 0 receive operations can be configured to rate limit the host ingress data for each receive thread (priority). CPPI Receive has 8 threads for QOS. There is a committed information rate (CPSW\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each thread (CPSW\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a thread when the committed information rate for the thread is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. No bulk thread will be enabled to send unless there are CPSW\_PN\_PRI\_CTL\_REG\_k[15-12] TX\_HOST\_BLKs\_REM number of unused blocks remaining in each of the Ethernet port transmit FIFOs. The "blocks remaining check" ensures that bulk traffic from the host will not block rate-limited traffic from the host. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then threads 7 and 6 should be configured for committed information (and excess information if desired). When any channels are configured to be rate-limited, the priority type must be fixed for receive. Round-robin priority type is not allowed when rate-limiting is configured for any thread. The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to receive is controlled by the below equation. If the configured excess information rate is zero, then only the committed information rate is transferred:

Priority Transfer rate [Mbit/s] = (((Frequency in MHZ) \* CPSW\_P0\_PRI\_CIR\_REG\_y) / 32768) + (((Frequency in MHZ) \* CPSW\_P0\_PRI\_EIR\_REG\_y) / 32768))

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

For example, 10Mbps on priority 7 would give the below:

10Mbps =  $\sim ((350 * 936) / 32768)$ , at 350Mhz and CPSW\_P0\_PRI\_CIR\_REG\_y[27-0] PRI\_CIR value = 936 (no excess information rate)

#### 12.2.2.4.6.2 Ethernet Port Transmit Rate Limiting

Ethernet port transmit operations can be configured to rate limit egress data for each egress priority. There is a committed information rate (CPSW\_P0\_PRI\_CIR\_REG\_y, where y = 0 to 7) and an excess information rate for each priority (CPSW\_P0\_PRI\_EIR\_REG\_y, where y = 0 to 7). Rate limiting is enabled for a priority when the committed information rate for the priority is non-zero. The excess information rate for a priority is enabled when the excess information rate for the priority is non-zero. The committed information rate must be non-zero if the excess information rate is configured to be non-zero. That is, there must be a configured non-zero committed information rate for there to be a configured non-zero excess information rate. Bulk traffic on other non-rate limited priorities does not impact the committed information traffic on a priority. However, bulk traffic on other non-rate limited threads does impact the excess information rates. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then priorities 7 and 6 should be configured for committed information (and excess information if desired). The configured transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is configured to send is controlled by the below equation. If the excess information rate is disabled then the committed information rate only is transferred:

Priority Transfer rate [Mbit/s] =  $(((((\text{Frequency in MHz}) * \text{CPSW\_P0\_PRI\_CIR\_REG\_y}) / 32768) + (((\text{Frequency in MHz}) * \text{CPSW\_P0\_PRI\_EIR\_REG\_y}) / 32768)))$

Where the *frequency* is the CPPI\_ICLK frequency (in MHz) and priority 0 to 7.

#### 12.2.2.4.6.7 Interspersed Express Traffic (IET – P802.3br/D2.0)

When IET is enabled through CPSW\_CONTROL\_REG[17] IET\_ENABLE = 1h and configured, IET allows preemptable traffic on selected transmit priorities to be preempted by express traffic on selected express priorities. Received traffic is separated onto express and preempt receive queues. When IET is disabled (IET\_ENABLE = 0h), all Ethernet traffic is express traffic and switch operation is as if IET does not exist. Traffic is only intended to be moved to the preempt queue after preemption is verified and enabled.

##### 12.2.2.4.6.7.1 IET Configuration

- Using the preempt receive queue requires more blocks to be allocated to the ports receive FIFO. Write a value of decimal 7 to the CPSW\_PN\_MAX\_BLKs\_REG[7-0] RX\_MAX\_BLKs bit field, and a value of decimal 13 to the CPSW\_PN\_MAX\_BLKs\_REG[15-8] TX\_MAX\_BLKs register for every port to be enabled for IET.
- Write the [23-0]MAC\_VERIFY\_CNT bit field in the Ethernet port CPSW\_PN\_IET\_VERIFY\_REG\_k register to set the verify/response timeout count. The default is 10ms for Gigabit mode. For other time values or link speeds the verify count should be updated. If CPSW\_PN\_IET\_CONTROL\_REG\_k[2] MAC\_DISABLEVERIFY bit is to be set (this is forced mode) then this step is unneeded.
- The receive FIFO block allocation is insufficient if CPSW\_STAT\_RX\_BOTTOM\_OF\_FIFO\_DROP\_k[31-0] COUNT is nonzero, indicating that receive packets are being dropped due to FIFO block allocation.
- Write the CPSW\_PN\_IET\_CONTROL\_REG\_k register in the Ethernet port as below:
  - Set the CPSW\_PN\_CONTROL\_REG\_k[16] IET\_PORT\_EN bit. The port will not actually be enabled until bit IET\_ENABLE is set in the CPSW\_CONTROL\_REG.
  - The CPSW\_PN\_IET\_CONTROL\_REG\_k[0] MAC\_PENABLE bit can be set as desired. No effect will occur until IET\_ENABLE is set. This bit enables preemptable packets to be preempted by express traffic but does not preclude packets from being sent to the preempt queue.
  - If verify/response is desired then CPSW\_PN\_IET\_CONTROL\_REG\_k[3] MAC\_LINKFAIL should be cleared by software to enable verify and response packets. Otherwise, MAC\_DISABLEVERIFY bit should be set for forced mode. Verification and response will occur immediately after clearing this bit.
  - Configure the remaining CPSW\_PN\_IET\_CONTROL\_REG\_k register bits as desired.

5. Set the IET\_ENABLE bit in the CPSW\_CONTROL\_REG register to enable IET operations.
6. After preemption has been verified, the CPSW\_PN\_IET\_CONTROL\_REG\_k[23-16] MAC\_PREMPT field is written to configure the FIFO priorities to be sent to the preempt queue (the other priorities with cleared bits go to the express queue). The hardware switch for each queue from express to preempt happens only when there are no packets queued on the priority.

#### **12.2.2.4.6.8 Enhanced Scheduled Traffic (EST – P802.1Qbv/D2.2)**

##### **12.2.2.4.6.8.1 Enhanced Scheduled Traffic Overview**

- When enabled and configured, EST allows express queue traffic to be scheduled (placed) on the wire at specific repeatable time intervals.
- EST operates on a repeating time interval generated by the CPTS EST function generator. For example, a 125us repeating time interval can be configured.
- Each Ethernet port has 128 EST fetch commands maximum in the global EST fetch RAM.
- Each 22-bit fetch command consists of a 14-bit fetch count (14 MSB's) and an 8-bit priority fetch allow (8 LSB's) that will be applied for the fetch count time in wireside clocks.
- The configured port fetch commands are executed in sequence, beginning at port address zero each time through the time interval beginning at cycle start.
- EST allows non-scheduled express and preempt queue traffic to be cleared from the wire to ensure that the scheduled traffic is transmitted at the proper time (zero allow).
- EST can be used with or without preemption. The CPSW\_PN\_IET\_CONTROL\_REG\_k[23-16] MAC\_PREMPT value determines whether the priority is enabled on the express or preempt queue. Whether a priority is on the express or preempt queue only effects the wire clear time from an EST operation perspective.
- Software should not move priorities to the preempt queue unless preemption is configured, enabled, and verified allowing preemption to occur.
- Express packet time stamp events can be enabled to assist software in configuring and timing EST operations.

##### **12.2.2.4.6.8.2 Enhanced Scheduled Traffic Fetch RAM**

- The EST fetch RAM is read/writable in the CPSW configuration address space.
- Each Ethernet transmit port has 128 locations in the global EST fetch RAM.
  - Ethernet port 1 has EST fetch RAM addresses 0x080-0x0FF, and so on.
- **One buffer operation:** When CPSW\_PN\_EST\_CONTROL\_REG\_k[0] EST\_ONEBUF is set to 1h, the 128 port locations operate as one buffer. The EST\_BUFFACT bit in CPSW\_PN\_FIFO\_STATUS\_REG\_k register is the upper address bit of the port's fetch RAM address indicating whether operation is currently in the upper or lower 64 locations of the port's fetch RAM.
- **Two buffer operation:** When CPSW\_PN\_EST\_CONTROL\_REG\_k[0] EST\_ONEBUF is cleared there are two 64-location buffers with CPSW\_PN\_EST\_CONTROL\_REG\_k[1] EST\_BUFSEL selecting the buffer to be used. When the buffer is switched by changing the CPSW\_PN\_EST\_CONTROL\_REG\_k[1] EST\_BUFSEL value, the actual switch occurs on cycle start. The actual buffer being used is indicated by the EST\_BUFFACT bit in CPSW\_PN\_FIFO\_STATUS\_REG\_k. Software should avoid writing the switched out buffer fetch RAM locations until it detects that the actual switch has occurred.
- The first address location in the port's fetch RAM space (location zero) is read at the beginning of each EST time interval (cycle start). Addresses are then read in ascending order for the duration of the interval. The port address zero is then read again at the beginning of the next cycle repeating the time interval packet operations.

##### **12.2.2.4.6.8.3 Enhanced Scheduled Traffic Time Interval**

- Each Ethernet port has an Enhanced Scheduled Traffic Function (ESTF) generator in the CPTS submodule.
- The EST function generator generates the EST time interval as a configured number of CPTS reference clocks (CPTS\_RFT\_CLK).
- The EST function generator rising edge is the cycle start time and the cycle repeats (cycle start occurs) after every time interval.

- The first fetch allowed value is at the port base address zero in the EST fetch RAM and is actually applied 16 wireside clocks after cycle start. The 16 clock cycle delay allows the first fetch value time to be fetched from the EST fetch RAM (prefetch time at cycle start).
- Each successive fetch allow is applied for the associated fetch count thereafter. The minimum non-zero fetch count is 16. The minimum value of 16 guarantees that the next fetch value has time to be fetched before the current fetch count is over. There are 64 maximum fetch values when CPSW\_PN\_EST\_CONTROL\_REG\_k[0] EST\_ONEBUF = 0h, and 128 maximum fetch values when CPSW\_PN\_EST\_CONTROL\_REG\_k[0] EST\_ONEBUF = 1h.
- The next cycle start then causes the fetch to once again start at the port address zero.

#### 12.2.2.4.6.8.4 Enhanced Scheduled Traffic Fetch Values

- The 22-bit fetch value is made up of the 14-bit fetch count and the 8-bit fetch allow.
- The fetch time indicates the number of wireside clocks that the fetch allow will be active.
- The fetch count is in Ethernet wireside clocks which is bytes in Gigabit mode (CPSW\_PN\_MAC\_CONTROL\_REG\_k[7] GIG = 1h) and nibbles in 10/100Mbps mode.
- When a fetch allow bit is set, the corresponding priority is enabled to begin packet transmission on an allowed priority subject to rate limiting. The actual packet transmission on the wire may carry over into the next fetch count and is the reason for the wire clear time in the fetch zero allow.
- When a fetch allow bit is cleared, the corresponding priority is not enabled to transmit for the fetch count time.
- A non-zero fetch allow value with a non-zero fetch count causes the fetch allow value to be applied for the fetch count number of wireside clocks.
- A zero fetch count causes the associated fetch allow to be held for the duration of the cycle (until the next cycle start).
- A zero fetch allow with a non-zero fetch count is intended to clear the wire for a scheduled (timed) express packet in the next fetch. A zero fetch allow indicates that no packet can be started for transmission for the associated fetch count. The associated fetch count must be sufficient to guarantee that the wire is cleared given that a packet on an allowed priority in the previous fetch could have been started on the previous clock and that there is hardware latency in the clear time. The timed packet should be sent on a priority that is enabled in the next fetch but disabled in the current zero allow fetch. The fetch allow previous to a zero allow should have only preempt priorities enabled or only express priorities enabled but not both.
- The number of clocks required to clear the wire varies depending Ethernet wire speed and on whether express or preempt priorities were allowed in the previous fetch command.

#### 12.2.2.4.6.8.5 Enhanced Scheduled Traffic Packet Fill

Packet fill can be enabled (CPSW\_PN\_EST\_CONTROL\_REG\_k[8] EST\_FILL\_EN = 1h) to occur in the fetch count time associated with a fetched zero allow. The intention with fill is that a smaller packet on a non-timed priority might be able to be inserted on the wire during the wire clear time which would increase wire utilization. Fill is intended to be used with either only express priorities in the previous non-zero fetched allow, or only preempt priorities in the previous non-zero fetched allow but not both. Fill must be configured to ensure that any fill packet does not conflict with the timed express packet allowed in the next fetch.

- **Express fill:**
  1. CPSW\_PN\_EST\_CONTROL\_REG\_k[8] EST\_FILL\_EN is set and
  2. A fetch contains a non-zero fetch count with a zero fetch allow, and
  3. The previous allow contained only express priorities.
  4. The fetch count loaded should be at least TBD clocks and the CPSW\_PN\_EST\_CONTROL\_REG\_k[25-16] EST\_FILL\_MARGIN should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  5. The fetch count loaded should be at least TBD clocks and the CPSW\_PN\_EST\_CONTROL\_REG\_k[25-16] EST\_FILL\_MARGIN should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
- **Preempt fill:**

1. CPSW\_PN\_EST\_CONTROL\_REG\_k[8] EST\_FILL\_EN is set and
  2. A fetch contains a non-zero fetch count with a zero fetch allow, and
  3. The previous allow contained only preempt priorities
  4. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  5. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
- **Express non-fill:**
    1. CPSW\_PN\_EST\_CONTROL\_REG\_k[8] EST\_FILL\_EN is clear and
    2. The previous allow contained only express priorities.
    3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
    4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
  - **Preempt non-fill:**
    1. CPSW\_PN\_EST\_CONTROL\_REG\_k[8] EST\_FILL\_EN is clear and
    2. The previous allow contained only preempt priorities.
    3. The fetch count loaded should be at least TBD clocks in Gigabit mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.
    4. The fetch count loaded should be at least TBD clocks in 10/100Mbps mode to ensure that the wire is cleared for the timed express packet allowed in the next fetch.

#### 12.2.2.4.6.8.6 Enhanced Scheduled Traffic Time Stamp

The EST can be configured to generate CPTS timestamp events for selected express traffic. The EST timestamp events use the CPTS host event type (CPSW\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE = 7 decimal). The EST timestamps will not override host sent timestamps for packets that were sent from the host with an enabled host timestamp.

- EST Events (host events) contain the below information:
  - Time Stamp of the selected express packet.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[28-24] PORT\_NUMBER indicates the transmit port number.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[23-20] EVENT\_TYPE is decimal 7 (host event).
  - The event CPSW\_CPTS\_EVENT\_1\_REG[23-20] MESSAGE\_TYPE indicates the packet transmit hardware switch priority.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID upper nibble indicates the packet receive port number.
  - The event CPSW\_CPTS\_EVENT\_1\_REG[15-0] SEQUENCE\_ID lower byte indicates the sequence number of the express packet in numerical order. The first event is event one, the second is event two and so on. The sequence ID rolls over to zero after 0xFF (8-bits).
  - The event domain is the value from the CPSW\_EST\_TS\_DOMAIN\_REG[7-0] EST\_TS\_DOMAIN register.
- When CPSW\_PN\_EST\_CONTROL\_REG\_k[2] EST\_TS\_EN is set, timestamp events will be generated on selected express traffic.
- When CPSW\_PN\_EST\_CONTROL\_REG\_k[3] EST\_TS\_FIRST is also set, events will be generated only on the first express packet in each time interval. If CPSW\_PN\_EST\_CONTROL\_REG\_k[4] EST\_TS\_ONEPRI is also set then the event will only be on the first CPSW\_PN\_EST\_CONTROL\_REG\_k[7-5] EST\_TS\_PRI express packet in the time interval. If CPSW\_PN\_EST\_CONTROL\_REG\_k[4] EST\_TS\_ONEPRI is clear then the event will be generated on the first express packet in the time interval on any priority.
- When CPSW\_PN\_EST\_CONTROL\_REG\_k[3] EST\_TS\_FIRST is clear, events will be generated on every express packet. If CPSW\_PN\_EST\_CONTROL\_REG\_k[4] EST\_TS\_ONEPRI is set then the event will be generated on every CPSW\_PN\_EST\_CONTROL\_REG\_k[7-5] EST\_TS\_PRI express packet. If CPSW\_PN\_EST\_CONTROL\_REG\_k[4] EST\_TS\_ONEPRI is clear then event will be generated on every express packet on any priority.

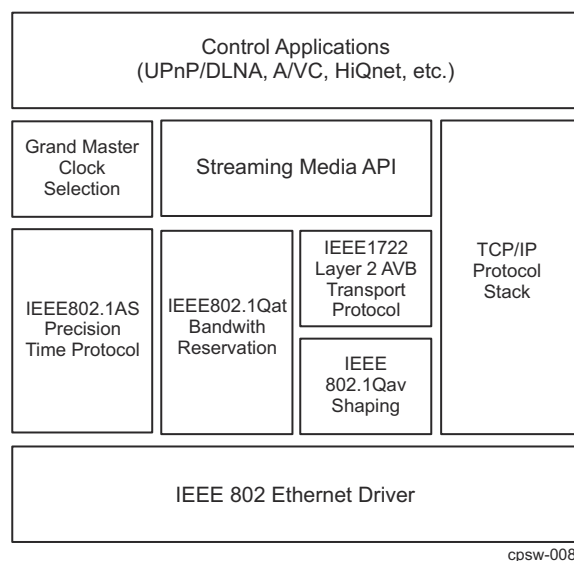

### 12.2.2.4.6.9 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks*. "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams*."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)*."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

**Figure 12-167. The Network Static with AVB**

The following sections describe the media transport protocols that work within the AVB framework.

#### 12.2.2.4.6.9.1 IEEE 802.1AS: *Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))*

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

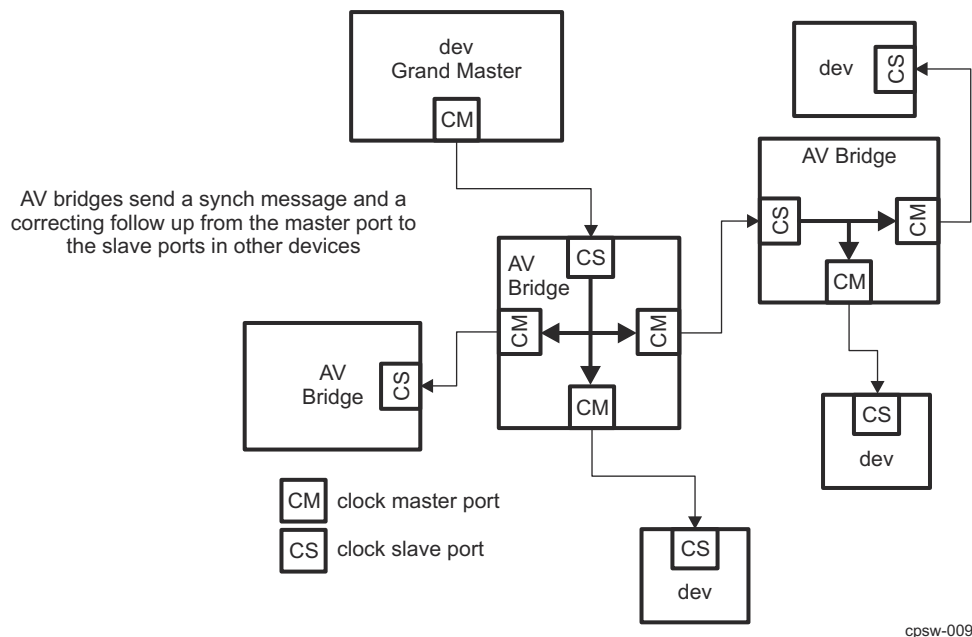

### Note

The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

Based on IEEE 1588:2002, PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2-in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW\_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1- $\mu$ s accuracy over seven network hops.

**Figure 12-168. AVB Network & PTP Clock Entities**

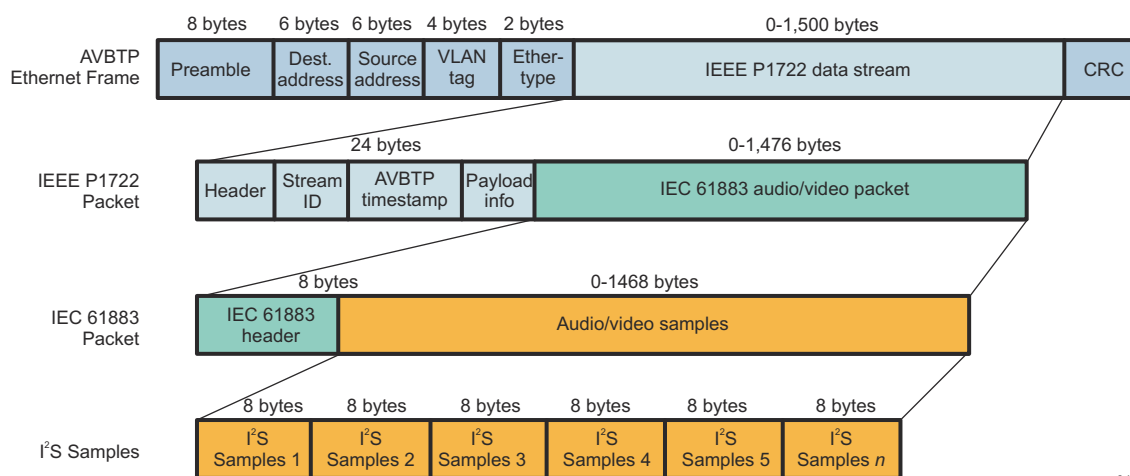

The media transport protocols that work within the AVB framework are:

#### 12.2.2.4.6.9.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks.

A complete AVBTP Ethernet packet is shown in [Figure 12-169](#) and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

### IEEE 1722 Packet Construction

cpsw-010

**Figure 12-169. IEEE 1722 Packets**

1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

#### 12.2.2.4.6.9.1.1.1 Cross-timestamping and Presentation Timestamps

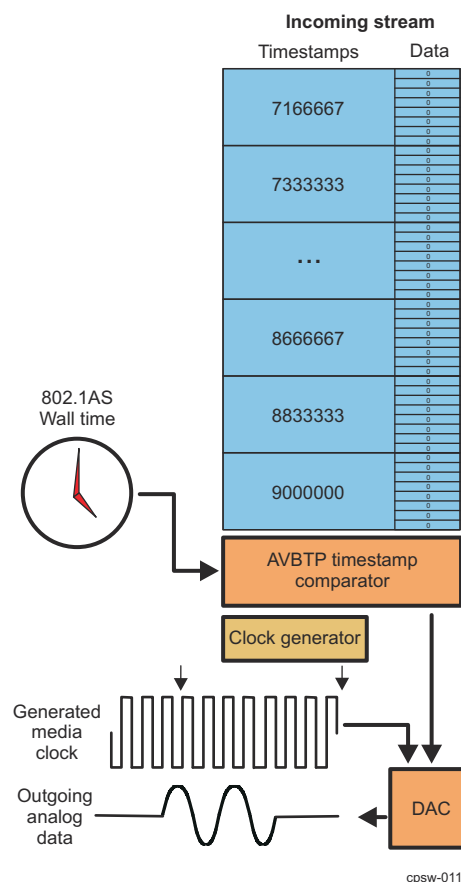

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. [Figure 12-170](#) illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

### Presentation timestamps

### Cross-time stamped clock recovery

**Figure 12-170. Cross Time Stamping and Presentation Timestamps**

#### 12.2.2.4.6.9.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

#### 12.2.2.4.6.9.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing
  - Transmit rate control.

## End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

## Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

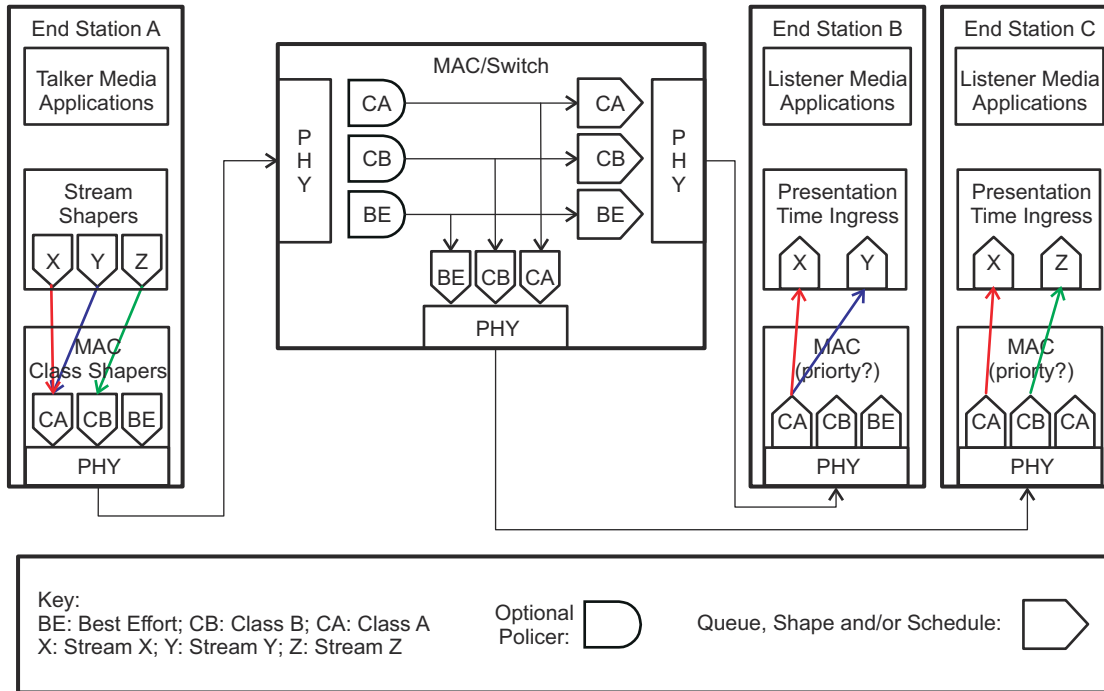

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like [Figure 12-171](#).

## Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

cpsw-012

**Figure 12-171. AV Stream Queuing/Policing**

#### 12.2.2.4.6.9.2.1 Configuring the Device for 802.1Qav Operation

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW\_9G that will have to be configured are:

- DESCRIPTORS and CHANNEL CONFIGURATIONS:
  - CPPI TX and RX descriptors
  - VLAN and Priority tags

**Table 12-218. Example of TX Configuration**

TX DMA CHANNEL	Packet Priority	Switch Queue Priority
7	7	3
6	5	2
5	3	1
4	1	0

**Table 12-219. Example of RX Configuration**

RX DMA CHANNEL	Packet Priority	Switch Queue Priority
0	7	0
0	5	0
0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

#### 12.2.2.4.6.10 Ethernet MAC Sliver

The Ethernet port peripheral is compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

## Features:

- Synchronous 10/100/1000 Mbit operation
- RMII/RGMII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control
- Programmable Inter Packet Gap (IPG).

**12.2.2.4.6.10.1 CRC Insertion**

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS\_CRC bit is 0h. For the Ethernet port generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS\_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS\_CRC bit is set.

**12.2.2.4.6.10.2 MTXER**

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

**12.2.2.4.6.10.3 Adaptive Performance Optimization (APO)**

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX\_PACE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

**12.2.2.4.6.10.4 Inter-Packet-Gap Enforcement**

The measurement reference for the IPG of 96-bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRC is de-asserted within approximately 48-bit times of MTXEN being de-asserted, then 96-bit times is measured from MTXEN. If the frame suffered a collision, or if MCRC is not de-asserted until more than approximately 48-bit times after MTXEN is de-asserted, then 96-bit times (approximately, but not less) is measured from MCRC.

The Ethernet port transmit inter-packet gap (IPG) may be shortened by eight bit times when short gap is enabled and triggered. Setting the [10] TX\_SHORT\_GAP\_ENABLE bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register enables the gap to be shortened when triggered. The condition is triggered when the ports associated transmit packet FIFO has a user defined number of FIFO blocks used. The associated transmit FIFO blocks used value determines if the gap is shortened, and so on. The CPSW\_GAP\_THRESH\_REG register value

determines the short gap threshold. If the FIFO blocks used is greater than or equal to the GAP\_THRESH value then short gap is triggered.

#### **12.2.2.4.6.10.5 Back Off**

The Gigabit Ethernet Mac Sliver implements the 802.3 binary exponential back-off algorithm.

#### **12.2.2.4.6.10.6 Programmable Transmit Inter-Packet Gap**

The transmit inter-packet gap (IPG) is programmable through the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

#### **12.2.2.4.6.10.7 Speed, Duplex and Pause Frame Support Negotiation**

The Ethernet port can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

#### **12.2.2.4.6.10.8 RMII Interface**

The CPRMII peripheral is compliant to the RMII specification document.

##### **12.2.2.4.6.10.8.1 Features**

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

##### **12.2.2.4.6.10.8.2 RMII Receive (RX)**

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII\_RXER on any di-bit in the received packet will cause an MII\_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII\_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII\_CRS\_DV toggle will issue an MII\_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII\_CRS\_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

##### **12.2.2.4.6.10.8.3 RMII Transmit (TX)**

The CPRMII transmit (TX) interface converts the CPGMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The CPGMAC does not source the transmit error (MII\_TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII\_TXD[1:0] for each clock that RMII\_TXEN is de-asserted.

#### **12.2.2.4.6.10.9 RGMII Interface**

The CPRGMII peripheral is compliant to the RGMII specification document.

##### **12.2.2.4.6.10.9.1 Features**

- Supports 1000/100/10 Mbps speed
- Full and Half Duplex support (CPGMAC supports only Full duplex in Gigabit mode).

- MII mode support
- Energy Efficient Ethernet Support

#### 12.2.2.4.6.10.9.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

#### 12.2.2.4.6.10.9.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the RGMII\_RX\_INBAND input is asserted. RGMII\_RX\_INPUT is asserted by configuring the CTL\_EN bit to 1h of the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX\_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in [Table 12-220](#).

**Table 12-220. In-Band Data**

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0h: half-duplex	0h: 10-Mbps mode	2.5 MHz	0h: Link is down
1h: full-duplex	1h: 100-Mbps mode	25 MHz	1h: Link is up
	2h: 1000-Mbps mode	125 MHz	
	3h: Reserved	Reserved	

#### 12.2.2.4.6.10.9.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the RGMII\_RX\_INBAND input is deasserted by setting to 0h bit CTL\_EN of the CPSW\_PN\_MAC\_CONTROL\_REG\_k register. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the CPSW\_PN\_MAC\_CONTROL\_REG\_k[0] FULLDUPLEX and CPSW\_PN\_MAC\_CONTROL\_REG\_k[7] GIG bits. If bit [7] GIG = 1h, then CPRGMII is operating in Gigabit mode. If bit [7] GIG is cleared (0h), then CPRGMII is operating in 100 Mbps mode.

#### 12.2.2.4.6.10.9.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

In 10/100 Mbps mode, the TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 Mbps mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII\_LINK. Packet transmission will begin on the first TX\_CTL rising edge after the 4096 transmit clock count has expired.

#### 12.2.2.4.6.10.10 Frame Classification

Received frames are proper (good) frames if they are between 64 and CPSW\_P0\_RX\_MAXLEN\_REG[13:0] RX\_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the CPSW\_P0\_RX\_MAXLEN\_REG/ CPSW\_PN\_RX\_MAXLEN\_REG\_k register. The register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames. If RX\_CSF\_EN

bit in CPSW\_PN\_MAC\_CONTROL\_REG\_k is set to 1h, undersized frames from 33 to 63 bytes will be forwarded only to the host on a best effort basis (meaning that the ALE may or may not be able to keep up with the packet rate and the short packet may be dropped due to bandwidth limitations). If RX\_CSF\_EN and RX\_CEF\_EN in CPSW\_PN\_MAC\_CONTROL\_REG\_k are set, fragment frames from 33 to 63 bytes will also be forwarded only to the host on a best effort basis. Ethernet port received frames shorter than 33 bytes are dropped in all cases.

A received long packet will always contain RX\_MAXLEN number of bytes transferred to memory (if CPSW\_PN\_MAC\_CONTROL\_REG\_k[22]RX\_CEF\_EN = 1h). An example with RX\_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

#### 12.2.2.4.6.10.11 Receive FIFO Architecture

This section describes the architecture of the Ethernet port's receive FIFOs. Internal to the Gigabit Ethernet switch, all Ethernet ports have an identical associated packet FIFO. Each transmit packet FIFO contains eight logical transmit queues (priority 0 through 7 with 7 the highest priority). Each transmit FIFO memory contains 81,920 bytes total organized as 2560 by 256-bit words. Each FIFO also contains a single memory for the receive queue. Each receive FIFO memory contains a total of 32768 bytes total organized as 1024 by 256-bit words.

#### 12.2.2.4.6.11 Embedded Memories

**Table 12-221. Embedded Memories**

Memory Type Description	Number of Instances	
Single-port 3072-word × 64 RAM	1	(Combined FIFO RAM)
Single-port 128-word × 28-bit RAM	1	1 (EST)

#### 12.2.2.4.6.12 Memory Error Detection and Correction

The CPSW\_9G error detection and correction logic uses the ECC Aggregator Module.

The ECC CPSW\_ECC\_VECTOR register is used to select which ECC RAM's status and control registers are currently being read or written as shown in [Table 12-222](#). The CPSW FIFO RAMs implement ECC only on packet headers. The packet data is protected by Ethernet CRC. The ALE and EST RAMs have complete ECC as normal.

**Table 12-222. ECC RAM to CPSW RAM Mapping**

ECC RAM Number	CPSW RAM
0	ALE RAM
1	Port 0 FIFO RAM

##### 12.2.2.4.6.12.1 Packet Header ECC

Only packet headers bits are protected by ECC in the FIFO RAMs. The ECC\_ERR\_CTRL1[31-0] ECC\_ROW bit is used to activate a row address where force single-bit error or force double-bit error needs to be applied. ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 is implemented to determine which bit of the header is flipped for an SEC error when the ECC\_CRC\_MODE bit is cleared in the CPSW\_CONTROL\_REG register. The ECC status registers return the RAM row address where the single or double-bit error has occurred (ECC\_ERR\_STAT2[31-0] ECC\_ROW) along with the bit position in the RAM data that is in error (ECC\_ERR\_STAT1[31-16] ECC\_BIT1 value). Forcing double-bit errors in testing can cause indeterminate operation if multiple used packet header bits are flipped given that only single-bit errors are fixed by the ECC logic. Header bits 207 down to 200 are not currently used in the CPSW and may be used to test double bit errors without the possibility of requiring a reset for the switch to recover from the double bit error. No header bits are flipped when ECC\_CRC\_MODE is set to 1h. Either the RX\_ECC\_ERR\_EN (enable receive ECC error operations) or the TX\_ECC\_ERR\_EN (enable transmit ECC error operations) bits must be set in the CPSW\_P0\_CONTROL\_REG register to test ECC header errors.

The header ECC code is stored in bits 255 down to 208. If any bit is flipped in the ECC code, the flipped bit will be corrected, but the index of the flipped bit will be reported as bit zero. This implies that when the aggregator reports that there is a SEC on bit 0, it can mean two things: either SEC on data bit 0 or SEC somewhere inside the ECC code. Any packet header with ECC error issues a pulse interrupt (ECC\_PULSE\_INTR) as does an ALE RAM ECC error.

##### 12.2.2.4.6.12.2 Packet Protect CRC

Each packet received without error is passed through the CPSW\_9G memories with a generated Ethernet protect CRC. The protect CRC is checked on egress for correctness and removed. If the CRC is correct (no RAM bit errors), then the packet is output with the selected port CRC type. If a protect CRC error is detected on host egress then the TXST\_DROP signal will be asserted so that the packet is dropped to the host. If a protect CRC error is detected on Ethernet egress then the egress CRC will be generated on the packet and at least one byte of the CRC will be inverted on output. CRC memory protect errors do not assert the ECC\_PULSE\_INTR signal. CRC memory protect errors are counted in the associated port statistics registers and issue an interrupt on STAT\_PEND\_INTR if any CRC memory protect error occurs (and the statistics for that port are enabled). When the ECC\_CRC\_MODE bit in the CPSW\_CONTROL\_REG register is set, the ECC\_ERR\_CTRL2 [15-0] ECC\_BIT1 bit field will flip the associated column bit in any FIFO memory read operation, inducing a CRC protect error when the protect CRC is checked. No header bits are flipped when ECC\_CRC\_MODE is set. Either the RX\_ECC\_ERR\_EN or the TX\_ECC\_ERR\_EN bits must be set in the CPSW\_P0\_CONTROL\_REG register to test packet CRC errors.

##### 12.2.2.4.6.12.3 Aggregator RAM Control

The ECC logic for each FIFO RAM (receive and transmit) is divided into eight separate ECC encoders/decoders that encode/decode 26-bits of data each. Each of the 8 encoders (0 to 7) generates 6-bits of ECC code (48 code bits total), and each of the eight decoders (0 to 7) checks 6-bits of ECC code across the 26-bits of data (208 data bits total). The 48-bits of ECC code are passed through the RAM in the upper 48 unused bits in the header word.

The header data bits and ECC code bits are shown in [Table 12-223](#). The [15-0] ECC\_BIT1 value returned on error is a 16-bit value that is the concatenation of 5 bits of zero, 3 bits of the encoder/decoder number (0 to 7), 3 bits of zero, and 5 bits of index into the indicated 26-bit encoder/decoder.

For example, an ECC\_BIT1 value of 0x0308 is bit 8 of encoder/decoder 3, which is header bit 86 (that is,  $(26 \times 3) + 8$ ).

**Table 12-223. ECC Submodule Header Data Bit to Encoder/Decoder Mapping**

Header Data Bits	Encoder/Decoder
25:0	Encoder/Decoder 0 Data
51:26	Encoder/Decoder 1 Data
77:52	Encoder/Decoder 2 Data
103:52	Encoder/Decoder 3 Data
129:104	Encoder/Decoder 4 Data
155:130	Encoder/Decoder 5 Data
181:156	Encoder/Decoder 6 Data
207:182	Encoder/Decoder 7 Data
213:208	Encoder/Decoder 0 ECC
219:214	Encoder/Decoder 1 ECC
225:220	Encoder/Decoder 2 ECC
231:226	Encoder/Decoder 3 ECC
237:232	Encoder/Decoder 4 ECC
243:238	Encoder/Decoder 5 ECC
249:244	Encoder/Decoder 6 ECC
255:250	Encoder/Decoder 7 ECC

#### 12.2.2.4.6.13 Ethernet Port Flow Control

The Ethernet port have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The Ethernet port have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an Ethernet port can be sent to the CPPI port. The destination port can trigger the receive Ethernet port flow control. An Ethernet destination port triggers another Ethernet receive flow control when the destination port is full.

When a packet is received on an Ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the Ethernet port will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX\_BLK\_CNT = 0h). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX\_FLOW\_EN bit in CPSW\_PN\_MAC\_CONTROL\_REG\_k be set to 1h. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit.

### 12.2.2.4.6.13.1 Ethernet Receive Flow Control

For every Ethernet port to be configured for full-duplex receive flow control, write a value of decimal 7 to the CPSW\_PN\_MAX\_BLKs\_REG[7-0] RX\_MAX\_BLKs bit field, and a value of decimal 13 to the CPSW\_PN\_MAX\_BLKs\_REG[15-8] TX\_MAX\_BLKs register. This re-allocation allows for flow control runout on the receive FIFO at the expense of FIFO memory on the Ethernet transmit side. 10/100Mbps half-duplex collision based receive flow control does not need this re-allocation. Receive flow control is enabled by the RX\_FLOW\_EN bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register.

#### 12.2.2.4.6.13.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in CPSW\_PN\_MAC\_CONTROL\_REG\_k). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

#### 12.2.2.4.6.13.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit is set in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full at which time the receive FIFO will overrun and CPSW\_STAT\_RX\_BOTTOM\_OF\_FIFO\_DROP\_k[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL\_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If CPSW\_PN\_MAC\_CONTROL\_REG\_k[3] RX\_FLOW\_EN is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to 0h and a 0 count pause frame will be sent.

#### 12.2.2.4.6.13.2 Qbb (10/100/1G/10G) Receive Priority Based Flow Control (PFC)

IEEE 802.1Qbb based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX bit must be set in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register). When receive PFC (Priority based Flow Control) flow control is enabled and triggered for a priority, the port will transmit a PFC pause frame to request that the sending station stop transmitting on that priority (and perhaps others) for the period indicated within the transmitted pause frame (FFFFh pause time). When the triggering condition is removed, or when PFC flow control is disabled, the port will transmit a pause frame to cancel the pause request (00.00 pause time). Priority based pause frames can have one to eight priorities enabled as determined by the priority enable vector in the pause frame. Pause frames can give some priorities pause on and others pause off in the same frame. An enabled priority will have either a pause on value (FFFFh) or a pause off value (00.00). Priorities with a zero enable bit in the pause frame priority enable vector are unchanged by the pause frame on the sending station side. The [23-16] RX\_FLOW\_PRI value in the CPSW\_PN\_PRI\_CTL\_REG\_k register indicates which port receive priorities are enabled for PFC. The priority enable vector in the pause frame only refers to the priorities that have a valid pause on or pause off sent in the sent pause frame.

The Ethernet port will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh) on each priority to be paused along with a set priority enable vector bit. The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control trigger is removed for a specific priority, the MAC will transmit a pause frame with a set priority enable vector bit and a zero pause time on that priority to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full at which time the receive FIFO will overrun and CPSW\_STAT\_RX\_TOP\_OF\_FIFO\_DROP\_k[31-0] COUNT value will increment).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame on the priority to be paused or not.

The Ethernet port will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL\_SA[47-0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 01.01
- The 16-bit priority enable vector. The lower 8-bits are used for priorities 7 down to 0.
- A 16-bit pause time value for each priority. The pause on value is FFFFh and the pause off value is 00.00. A pause-quantum is 512 bit-times.
- Zero padding to 64-byte data length (The Ethernet port will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX\_FLOW\_EN bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k is cleared to 0h while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent. For any priority that has flow control enabled then associated priority in the CPSW\_PN\_TX\_BLKs\_PRI\_REG\_k register should be written with zero.

#### 12.2.2.4.6.13.3 Ethernet Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the Ethernet port from transmitting any further frames. Incoming pause frames are only acted upon when the [0] FULLDUPLEX and [4] TX\_FLOW\_EN bits in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred

to memory. MAC control frames will be transferred to memory if the [24] RX\_CMF\_EN (RX Copy MAC Control Frames Enable) bit in the CPSW\_PN\_MAC\_CONTROL\_REG\_k register is set. The [4] TX\_FLOW\_EN and [0] FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

- [4] TX\_FLOW\_EN is set in CPSW\_PN\_MAC\_CONTROL\_REG\_k register, and
- the RX maximum frame length is 64 bytes inclusive (CPSW\_PN\_RX\_MAXLEN\_REG\_k[13-0] RX\_MAXLEN), and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If [4] TX\_FLOW\_EN in CPSW\_PN\_MAC\_CONTROL\_REG\_k register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01, or the Ethernet port SL\_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit CPSW\_PN\_MAC\_TX\_PAUSETIMER\_REG\_k[15-0] TX\_PAUSETIMER. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 Bytes. The standard allows pause frames longer than 64 Bytes to be discarded or interpreted as valid pause frames. The Ethernet port will recognize any pause frame between 64 Bytes and CPSW\_PN\_RX\_MAXLEN\_REG\_k[13-0] RX\_MAXLEN bytes in length.

#### 12.2.2.4.6.14 PFC Trigger Rules

There are five rules that can each set and clear a PFC (Priority based Flow Control) trigger condition for each enabled priority. The five rules are the destination based rule, the sum of outflows rule, the sum of blocks per port rule, the sum of blocks total rule, and the top of receive FIFO rule. Ethernet ports issue transmit PFC pause frames when any priority is triggered for any rule. Port 0 issues flow control on the associated receive thread when any priority is triggered for any rule. There are no pause frames sent on port 0 transmit (no port 0 outflow). Receive priority remapping is taken into account for all rules on all ports. Transmit priority remapping is taken into account for the sum of outflows rule, the sum of blocks per port rule, and the destination based rule.

Transmit priority remapping is not taken into account for the sum of blocks total rule or the top of receive FIFO rule. The intent of PFC is to shutdown lower priorities as traffic congestion increases so that the higher priorities can continue to operate. Systems with only 1518 byte packets may only need to configure the destination based rule.

#### 12.2.2.4.6.14.1 Destination Based Rule

The destination based rule is the primary rule for PFC and should be configured when PFC is enabled. The rule is evaluated for PFC trigger when the destination ports are determined on address lookup at packet reception (bottom of receive FIFO). The conditions of all packet destination port transmit FIFO's at packet reception determine whether or not one or more receive port priorities will be triggered. Each packet destination port is evaluated for each priority and the results are combined to produce the priority flow control trigger(s) on the receive port. A priority trigger is cleared at any time the clear condition is satisfied for that priority on all destination port FIFO's (all transmit FIFO's that set the trigger). The intent of the rule is to progressively trigger receive PFC with decreasing priority as the FIFO allocated blocks (CPSW\_PN\_BLK\_CNT\_REG\_k[12-8] TX\_BLK\_CNT) increases, and have the effect of priority outflow increase with decreasing priority. The add amount for outflow is zero if the outflow is not set and CPSW\_PN\_TX\_D\_OFLOW\_ADDVAL\_L\_REG\_k/ CPSW\_PN\_TX\_D\_OFLOW\_ADDVAL\_H\_REG\_k if the outflow is set for a particular priority.

A PFC priority is triggered by conditions in any destination transmit FIFO by the below equation at packet reception:

$$\text{priX\_trig\_set} = ((\text{addvalX}[4:0] \& \{5\{\text{tx\_d\_trig\_setX}\}\}) + \text{pn\_tx\_blk\_cnt}[4:0]) \geq \text{tx\_d\_thresh\_setX}[4:0]$$

A PFC priority is cleared by conditions in all destination transmit FIFO's by the below equation at any time after the set has occurred:

$$\text{priX\_trig\_clr} = ((\text{addvalX}[4:0] \& \{5\{\text{tx\_d\_trig\_setX}\}\}) + \text{pn\_tx\_blk\_cnt}[4:0]) \leq \text{tx\_d\_thresh\_clrX}[4:0]$$

Where,

- **X** is the priority
- **addvalX** is from CPSW\_PN\_TX\_D\_OFLOW\_ADDVAL\_L\_REG\_k and CPSW\_PN\_TX\_D\_OFLOW\_ADDVAL\_H\_REG\_k registers and has a maximum value of 11 decimal
- **tx\_d\_trig\_setX** is set when transmit flow control (outflow) is triggered on the destination TX FIFO priority (by receiving a pause frame with the associated priority paused).
- **pn\_tx\_blk\_cnt** is the total number of blocks allocated on all priorities in the destination transmit FIFO (0 to 20).
- **tx\_d\_thresh\_setX** is from CPSW\_PN\_TX\_D\_THRESH\_SET\_L\_REG\_k and CPSW\_PN\_TX\_D\_THRESH\_SET\_H\_REG\_k registers
- **tx\_d\_thresh\_clrX** is from CPSW\_PN\_TX\_D\_THRESH\_CLR\_L\_REG\_k and CPSW\_PN\_TX\_D\_THRESH\_CLR\_H\_REG\_k registers
- **tx\_d\_thresh\_setX** must be greater than **tx\_d\_thresh\_clrX**

#### 12.2.2.4.6.14.2 Sum of Outflows Rule

The Sum of Outflows rule is a global control that sets and clears PFC triggers on a receive port due to conditions in all other Ethernet port transmit FIFOs regardless of receive traffic. An outflow is set for a transmit FIFO priority when a PFC pause frame is received on the port with a non-zero pause quanta for that priority indicating that the port should not transmit on that priority. An outflow is clear for a priority when the transmit pause condition is removed either due to receiving a pause frame with a zero pause quanta or by the pause timer expiring for the priority. Port 0 does not have transmit flow control. The sum of outflows rule is intended to be used in some systems to pass along outflow on lower priorities with larger packet sizes. Triggering PFC on priorities due to this rule also prevents packet transmission from Ethernet ports to the host for the duration of the pause time on the triggered priorities. When configured to trigger due to this rule, pause frames will be sent on Ethernet ports regardless of receive traffic.

A PFC priority is triggered by conditions in all other Ethernet transmit FIFOs by the below equation at any time:

$$\text{priX\_trig\_set} = \text{sum of all other Ethernet port priX\_outflows} \geq \text{tx\_g\_oflow\_thresh\_setX}[4:0]$$

A PFC priority is cleared by conditions in all other Ethernet transmit FIFO's by the below equation at any time:

**priX\_trig\_clr = sum of all other Ethernet port priX\_outflows <= tx\_g\_oflow\_thresh\_clrX[4:0]**

Where,

- **X** is the priority
- **tx\_g\_oflow\_thresh\_setX** is from CPSW\_TX\_G\_OFLOW\_THRESH\_SET\_REG
- **tx\_g\_oflow\_thresh\_clrX** is from CPSW\_TX\_G\_OFLOW\_THRESH\_CLR\_REG
- **tx\_g\_oflow\_thresh\_setX** must be greater than **tx\_g\_oflow\_thresh\_clrX**.

#### 12.2.2.4.6.14.3 Sum of Blocks Per Port Rule

The Sum of Blocks Per Port rule is an aggressive global control that sets and clears PFC triggers on receive ports due to conditions in any other port transmit FIFO regardless of receive traffic. When any transmit FIFO has a trigger condition set, all other receive ports will trigger PFC for that priority. This rule is intended to be configured in systems with high traffic rate jumbo packets on lower priorities.

A PFC priority is triggered by conditions in any other transmit FIFO by the below equation at any time:

**priX\_trig\_set when the sum of all Tx FIFO blocks allocated on the port >= thresh\_setX[4:0]**

A PFC priority is cleared when conditions in all other Ethernet transmit FIFO's satisfy the below equation at any time:

**priX\_trig\_clr when the sum of all tx FIFO blocks allocated on the port <= thresh\_clrX[4:0]**

Where,

- **X** is the priority
- **thresh\_setX** is from CPSW\_PN\_TX\_G\_BUF\_THRESH\_SET\_L\_REG\_k/  
CPSW\_PN\_TX\_G\_BUF\_THRESH\_SET\_H\_REG\_k (or CPPI port0  
CPSW\_P0\_TX\_G\_BUF\_THRESH\_SET\_L\_REG/CPSW\_P0\_TX\_G\_BUF\_THRESH\_SET\_H\_REG)
- **thresh\_clrX** is from CPSW\_PN\_TX\_G\_BUF\_THRESH\_CLR\_L\_REG\_k/  
CPSW\_PN\_TX\_G\_BUF\_THRESH\_CLR\_H\_REG\_k (or CPPI port0  
CPSW\_P0\_TX\_G\_BUF\_THRESH\_CLR\_L\_REG/CPSW\_P0\_TX\_G\_BUF\_THRESH\_CLR\_H\_REG)
- **thresh\_setX** must be greater than **thresh\_clrX** for each priority.

#### 12.2.2.4.6.14.4 Sum of Blocks Total Rule

The Sum of Blocks Total rule is an extremely aggressive global control that sets and clears PFC triggers on receive ports due to conditions in all transmit FIFOs regardless of receive traffic. When any priority has a trigger condition set, all receive ports will trigger PFC for that priority. The intent of this rule is to shutdown lower priorities with jumbo packets as the total switch congestion increases.

A PFC priority is triggered by conditions in all transmit FIFO by the below equation at any time:

**priX\_trig\_set = sum of all tx FIFO blocks allocated in all ports >= thresh\_setX[4:0]**

A PFC priority is cleared when conditions in all transmit FIFO's satisfy the below equation at any time:

**priX\_trig\_clr = sum of all tx FIFO blocks allocated in all ports <= thresh\_clrX[4:0]**

Where,

- **X** is the priority
- **thresh\_setX** is from CPSW\_TX\_G\_BUF\_THRESH\_SET\_L\_REG/  
CPSW\_TX\_G\_BUF\_THRESH\_SET\_H\_REG
- **thresh\_clrX** is from CPSW\_TX\_G\_BUF\_THRESH\_CLR\_L\_REG/  
CPSW\_TX\_G\_BUF\_THRESH\_CLR\_H\_REG
- **thresh\_setX** must be greater than **thresh\_clrX** for each priority.

#### 12.2.2.4.6.14.5 Top of Receive FIFO Rule

The Top of Receive FIFO Rule sets PFC triggers on the associated receive port for all priorities. This rule requires no configuration and is enabled when PFC flow control is enabled. The Top of Receive FIFO rule triggers when a received packet cannot be transferred to an intended destination port due to insufficient space in that destination port transmit FIFO. The receive FIFO exists to accept flow control runout (especially for 802.3 flow control). The trigger condition for this rule is cleared when the receive FIFO is emptied after runout.

Preferable PFC configurations preclude this rule from triggering. If a lower priority packet triggers this rule then higher priority packets could be in the runout after the lower priority packet(s), which would increase the switch latency of the higher priority packets. This rule ensures that there is no packet loss on any priority in any configuration. However, PFC configuration should ensure that this rule is triggered only by high priority packets or preferably not at all. The [27] TORF bit in the CPSW\_PN\_MAC\_STATUS\_REG\_k register indicates that this rule has triggered. The CPSW\_PN\_MAC\_STATUS\_REG\_k[26-24] TORF\_PRI field indicates the lowest priority that has triggered this rule since the last clearing of the status register fields. More aggressive shutdown of lower priorities in the other rules is preferable to having this rule trigger.

#### 12.2.2.4.6.15 Energy Efficient Ethernet Support (802.3az)

Energy Efficient Ethernet (EEE) allows the LPSC to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. The module EEE clock stop interface is used by the external controller to control module EEE operations. EEE operations are configured as shown below:

1. The 12-bit EEE clock pre-scale value is written to the CPSW\_EEE\_PRESCALE\_REG register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (CPSW\_PN\_IDLE2LPI\_REG\_k[23-0] COUNT) are written with the desired values
3. The port LPI to Wake count values (CPSW\_PN\_LPI2WAKE\_REG\_k[23-0] COUNT) are written with the desired values
4. The [0] EEE\_EN bit is set in the switch CPSW\_SS\_CONTROL\_REG register

EEE operation can begin after configuration. The host allows (through LPSC) the CPSW to enter a low power state by asserting the EEE\_CLKSTOP\_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert EEE\_CLKSTOP\_REQ to the CPSW.

Each Ethernet port has a transmit and a receive LPI (low power indicate) state. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the CPSW\_PN\_IDLE2LPI\_REG\_k value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPPI (port 0) LPI state includes transmit and receive. The CPPI LPI state is entered when the CPPI transmit and receive have both been idle for the Idle to LPI time (CPSW\_P0\_IDLE2LPI\_REG). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

#### Note

External PHY signaling has the following conditions:

- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX\_CTL at the rising and the falling TXC edges, respectively. RXDV and RXER are the sampled values of RX\_CTL at the rising and the falling RXC clock edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the EEE\_CLKSTOP\_ACK signal is asserted, and the LPSC is allowed to stop the module clock. When EEE\_CLKSTOP\_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW memory address space, and then turn off the clock again while EEE\_CLKSTOP\_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting EEE\_CLKSTOP\_REQ. There must be at least one rising edge of the clock before EEE\_CLKSTOP\_REQ is de-asserted. The module EEE\_CLKSTOP\_ACK output signal will be deasserted on the clock after the de-assertion of EEE\_CLKSTOP\_REQ. The host may queue CPPI receive packets at any time

without regard to the CPSW module LPI state. The Host must deassert `EEE_CLKSTOP_REQ` on wakeup for a minimum of two clock periods. If `EEE_CLKSTOP_REQ` is deasserted for less than 5 clock periods for a wakeup event from the host to a particular Ethernet port (or visa versa), then the wakeup event will not cause the other Ethernet port port to awaken.

The external Ethernet PHY's can also wakeup the LPSC by removing the Ethernet receive LPI indication. If the CPSW module is in Idle state with `EEE_CLKSTOP_ACK` asserted and the receive LPI indication is removed, the `EEE_CLKSTOP_WAKEUP` signal will be asynchronously asserted. On wakeup, the LPSC restarts the clock and de-assert the `EEE_CLKSTOP_REQ` signal. The `EEE_CLKSTOP_WAKEUP` signal will be synchronously deasserted with `EEE_CLKSTOP_ACK`. Upon the deassertion of `EEE_CLKSTOP_REQ`, the Ethernet ports will count the `CPSW_PN_LPI2WAKE_REG_k` time for each port at which time the port is available for transmit.

#### 12.2.2.4.6.16 Ethernet Switch Latency

When CPSW is configured as a store and forward switch, the switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

The store and forward latency is shown in [Table 12-224](#):

**Table 12-224. Switch Latency**

Mode	Latency
Gig (1000)	880 ns
100	1.3 $\mu$ s
10	6.5 $\mu$ s

#### 12.2.2.4.6.17 MAC Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW operation to be completely or partially suspended. Each Ethernet port has associated emulation control registers (`CPSW_EM_CONTROL_REG` and `CPSW_PN_MAC_EMCONTROL_REG_k`). The submodule emulation control registers must be accessed to facilitate CPSW emulation control. The CPSW module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

#### Ethernet port Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the `CPSW_PN_MAC_EMCONTROL_REG_k` register) allow Ethernet port operation to be suspended. When the emulation suspend state is entered, the Ethernet port will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the Ethernet port after the suspend state is entered are ignored.

[Table 12-225](#) shows the operations of the emulation control input and register bits.

**Table 12-225. Emulation Control Input**

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### 12.2.2.4.6.18 MAC Command IDLE

The `CMD_IDLE` bit in the `CPSW_PN_MAC_CONTROL_REG_k` register allows MAC operation to be suspended. When the idle state is commanded, the MAC will stop processing receive and transmit frames

at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the MAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

#### 12.2.2.4.6.19 CPSW Network Statistics

The CPSW has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of CPSW0\_RST. When one or more port enable (Pn\_STAT\_EN) bits in the CPSW\_STAT\_PORT\_EN\_REG register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STAT\_PEND0) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

[Table 12-226](#) and [Table 12-227](#) summarize network statistics.

#### 12.2.2.4.6.19.1 Rx-only Statistics Descriptions

##### 12.2.2.4.6.19.1.1 Good Rx Frames (Offset = 3A000h)

#### All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.2.4.6.19.1.2 Broadcast Rx Frames (Offset = 3A004h)

#### All ports

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for address FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error.

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

##### 12.2.2.4.6.19.1.3 Multicast Rx Frames (Offset = 3A008h)

#### All ports

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Had a length of 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.2.4.6.19.1.4 Pause Rx Frames (Offset = 3A00Ch)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (TX\_FLOW\_EN = 1h).

The port could have been in either half or full-duplex mode.

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.2.4.6.19.1.5 Rx CRC Errors (Offset = 3A010h)**

##### **All ports**

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had no code/align error
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles, and
- Failing the Frame Check Sequence test.

#### **12.2.2.4.6.19.1.6 Rx Align/Code Errors (Offset = 3A014h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to RX\_MAXLEN bytes inclusive
- Had either an alignment error, or a code error.

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

### Note

RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

#### 12.2.2.4.6.19.1.7 Oversize Rx Frames (Offset = 3A018h)

##### All ports

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error, or code error.

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.2.4.6.19.1.8 Rx Jabbers (Offset = 3A01Ch)

##### All ports

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than RX\_MAXLEN in bytes
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.2.4.6.19.1.9 Undersize (Short) Rx Frames (Offset = 3A020h)

##### All ports

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes
- Had no CRC error, alignment error, or code error

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### 12.2.2.4.6.19.1.10 Rx Fragments (Offset = 3A024h)

##### Ethernet port N (where N = 1 to 8)

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half-duplex, collision-based flow control

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.2.4.6.19.1.11 RX IPG Error**

The total number of 10G frames received on a port that had a correct preamble but did not have at least five bytes of IDLE preceding the frame. This does not indicate if the frame with the IPG error was kept or ignored.

#### **12.2.2.4.6.19.1.12 ALE Drop (Offset = 3A028h)**

##### **All ports**

The total number of frames received on a port such that the destination address was not equal to the source address and the packet was not destined to the port it was received on, but the frame was not forwarded to any port (the PORT\_MASK was zero).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was not equal to the source address
- the packet was not destined for the port it was receive on
- had a zero PORT\_MASK

#### **12.2.2.4.6.19.1.13 ALE Overrun Drop (Offset = 3A02Ch)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to exceeding the maximum ALE lookup rate (Port 0 should not have ALE Overrun Drops because the ingress rate is controlled to prevent it). This statistic should be zero and when non-zero indicates a system clock issue or indicates that short packets were sent with RX\_CSF\_EN at a rate that exceeded the maximum lookup rate.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- the maximum ALE lookup rate was exceeded so the lookup was aborted and the packet was dropped.

#### **12.2.2.4.6.19.1.14 Rx Octets (Offset = 3A030h)**

##### **All ports**

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to RX\_MAXLEN bytes inclusive
- Had no CRC error, alignment error or code error

See the [Section 12.2.2.4.6.19.1.6, Rx Align/Code Errors](#) and [Section 12.2.2.4.6.19.1.5, Rx CRC errors](#) statistic descriptions for definitions of alignment, code and CRC errors.

Overruns have no effect upon this statistic.

#### **12.2.2.4.6.19.1.15 Rx Bottom of FIFO Drop (Offset = 3A084h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames received on a port that overran the port's receive FIFO and were dropped (bottom of receive FIFO). Port 0 (CPPI receive port) should not drop packets on receive because port 0 receive flow control should be enabled. The Ethernet ports will only drop packets in the receive FIFO when receive flow control is

enabled and the sending port ignores sent pause frame and then overruns the receive FIFO. An overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- Was dropped on port 0 due to a lack of memory space in the receive FIFO.

---

#### Note

This statistic should be zero if proper flow control is being followed.

---

### Host port 0

This statistic also counts frames dropped on port 0 that were 17 to 63 bytes (only for port 0). For Ethernet ports, the drop count for frames shorter than 33 bytes is included in the undersized or fragment count. Port 0 simply gives an indication that a packet was dropped. No other statistics are counted for frames shorter than 33 bytes.

#### 12.2.2.4.6.19.1.16 Portmask Drop (Offset = 3A088h)

##### All ports

The total number of frames received on a port that were dropped by the ALE (the ALE did not forward the packet to any port). Port mask drop frame is defined to be:

- Any data or MAC control frame
- Any length greater than 32 bytes
- Was dropped by the ALE due to PORT\_MASK=0 (was not sent to any destination port)
- The frame could have been dropped due to error or other counted reason, so it could be counted elsewhere also.

---

#### Note

This statistic does not count in the overall total as it includes every packet received greater than 32 bytes that had a zero PORT\_MASK.

---

#### 12.2.2.4.6.19.1.17 Rx Top of FIFO Drop (Offset = 3A08Ch)

##### All ports

The total number of frames received on a port that had a start-of-frame (SOF) overrun on any destination port egress (when attempting to load the packet from the top of the ingress port receive FIFO into any other port's transmit FIFO). If a multicast/broadcast packet is dropped by multiple destination ports then this statistic will increment by the number of ports that dropped the packet. Rx Top Of FIFO Drop is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error or code error
- had a SOF of frame overrun on another port egress.

#### 12.2.2.4.6.19.1.18 ALE Rate Limit Drop (Offset = 3A090h)

##### All ports

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to receive rate limiting on this port or due to transmit rate limiting on any destination port (not sent to all expected destination ports if transmit rate limiting).

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)

- had no CRC error, alignment error, or code error
- the receive rate was exceeded and the packet was dropped, or the transmit rate was exceeded to any destination port and the packet was dropped to one or more expected destination ports (indicates that the destinations were reduced due to rate limiting).

#### **12.2.2.4.6.19.1.19 ALE VLAN Ingress Check Drop (Offset = 3A094h)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to VLAN ingress check failure.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the VLAN ID ingress check failed (the receive port was not in the group)
- The address lookup did not return a match with the SUPER bit set.

#### **12.2.2.4.6.19.1.19.1 ALE DA=SA Drop (Offset = 3A098h)**

##### **All ports**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to destination address equal to source address.

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error
- the destination address was equal to the source address
- the source address was not an entry in the table.

#### **12.2.2.4.6.19.1.19.2 Block Address Drop (Offset = 3A09Ch)**

The total number of frames received on a port that were dropped (zero PORT\_MASK) due to the destination or source address being blocked.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source or destination address matched a table entry with the block bit set.

#### **12.2.2.4.6.19.1.19.3 ALE Secure Drop (Offset = 3A0A0h)**

The total number of frames received on a port that were dropped (zero port\_mask) due to a secure violation (the source address is owned by a different receive port).

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and
- the source address is an entry in the table with the SECURE bit set and a port number for a different receive port.

#### **12.2.2.4.6.19.1.19.4 ALE Authentication Drop (Offset = 3A0A4h)**

The total number of frames received on a port that were dropped (zero port\_mask) due to authentication failure.

- was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode, and
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)
- had no CRC error, alignment error, or code error, and

- CPSW\_ALE\_CONTROL[1] ENABLE\_AUTH\_MODE is set to 1h, and
- the source address is not equal to the destination address, and
- the source address is not a table entry, and
- the destination address is not a table entry with the SUPER bit set.

#### **12.2.2.4.6.19.1.19.5 ALE Unknown Unicast (Offset = 3A0A8h)**

##### **All ports**

The total number of frames received on a port that had a unicast destination address with an unknown source address.

- was any data frame with a unicast destination address
- the source address was not a table entry
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

Note: The ALE Unknown Unicast Bytecount statistic is the number of bytes contained in the ALE Unknown Unicast frames.

#### **12.2.2.4.6.19.1.19.6 ALE Unknown Unicast Bytecount (Offset = 3A0ACh)**

The total number of bytes received on a port that had a unicast destination address with an unknown source address.

#### **12.2.2.4.6.19.1.19.7 ALE Unknown Multicast (Offset = 3A0B0h)**

The total number of frames received on a port that had a multicast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Multicast Bytecount statistic is the number of bytes contained in the ALE Unknown Multicast frames.

#### **12.2.2.4.6.19.1.19.8 ALE Unknown Multicast Bytecount (Offset = 3A0B4h)**

The total number of bytes received on a port that had a multicast destination address with an unknown source address.

#### **12.2.2.4.6.19.1.19.9 ALE Unknown Broadcast (Offset = 3A0B8h)**

The total number of frames received on a port that had a broadcast destination address with an unknown source address. The frame is defined to be:

- was any data frame with a unicast destination address
- the source address was not a table entry, and
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error or code error

Note: The ALE Unknown Broadcast Bytecount statistic is the number of bytes contained in the ALE Unknown Broadcast frames.

#### **12.2.2.4.6.19.1.19.10 ALE Unknown Broadcast Bytecount (Offset = 3A0BCh)**

The total number of bytes received on a port that had a broadcast destination address with an unknown source address.

#### **12.2.2.4.6.19.1.19.11 ALE Policier/Classifier Match (Offset = 3A0C0h)**

##### **All ports**

The total number of frames received on a port that matched a policier. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.2.4.6.19.2 ALE Policer Match Red (Offset = 3A0C4h)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.2.4.6.19.3 ALE Policer Match Yellow (Offset = 3A0C8h)**

The total number of frames received on a port that had matched a policer and the condition was red. The frame is defined to be:

- was any data frame
- matched a condition on a policer,
- was of length 64 to RX\_MAXLEN bytes inclusive
- had no CRC error, alignment error, or code error

#### **12.2.2.4.6.19.4 IET Receive Assembly Error (Offset = 3A140h)**

The total number of preemptable received frames with IET assembly errors.

- any frame received
- was any size, and
- was a non-initial fragment that mismatched the frame count or fragment count (went to the assembly error state in the IET receive state machine)

#### **12.2.2.4.6.19.5 IET Receive Assembly OK (Offset = 3A144h)**

The total number of correctly received and re-assembled preemptable frames.

- any preemptable frame received
- was any size, and
- was correctly received and re-assembled without error

#### **12.2.2.4.6.19.6 IET Receive SMD Error (Offset = 3A148h)**

The total number of received frames rejected due to an unknown SMD value or received frames rejected with an SMD-C when no frame is in progress.

- any frame received
- was any size, and
- was rejected because of an unknown SMD value or SMD-C with no frame in progress.

Note: If IET\_ENABLE is not set, this statistic counts any received frame with any non express SMD.

#### **12.2.2.4.6.19.7 IET Receive Merge Fragment Count (Offset = 3A14Ch)**

The total number of received non-initial fragments that did not have an assembly error. The IET stat CPSW\_STAT\_RXFRAGMENTS\_k is derived by adding the Receive Assembly Error count to this value.

- any frame received
- was any size, and
- was a non-initial fragment that did not contain an assembly error

#### **12.2.2.4.6.19.8 Tx-only Statistics Descriptions**

The maximum and minimum transmit frame size is software controllable.

#### 12.2.2.4.6.19.8.1 Good Tx Frames (Offset = 3A034h)

##### All ports

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 12.2.2.4.6.19.8.2 Broadcast Tx Frames (Offset = 3A038h)

##### All ports

The total number of good broadcast frames transmitted on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 12.2.2.4.6.19.8.3 Multicast Tx Frames (Offset = 3A03Ch)

##### All ports

The total number of good multicast frames transmitted on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than FF.FF.FF.FF.FF.FF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### 12.2.2.4.6.19.8.4 Pause Tx Frames (Offset = 3A040h)

##### Ethernet port N (where N = 1 to 8)

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex, carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64-byte multicast frames so will appear in the *Tx Multicast Frames* and *64octet Frames* statistics.

#### 12.2.2.4.6.19.8.5 Deferred Tx Frames (Offset = 3A044h)

##### Ethernet port N (where N = 1 to 8)

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

#### 12.2.2.4.6.19.8.6 Collisions (Offset = 3A048h)

##### Ethernet port N (where N = 1 to 8)

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:

- Was destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

#### **12.2.2.4.6.19.8.7 Single Collision Tx Frames (Offset = 3A04Ch)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

#### **12.2.2.4.6.19.8.8 Multiple Collision Tx Frames (Offset = 3A050h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.2.4.6.19.8.9 Excessive Collisions (Offset = 3A054h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

#### **12.2.2.4.6.19.8.10 Late Collisions (Offset = 3A058h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The *Late Collisions* statistic dominates over the single-, multiple-, and excessive- collision statistics. If a late collision occurs, the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

#### **12.2.2.4.6.19.8.11 Carrier Sense Errors (Offset = 3A060h)**

##### **Ethernet port N (where N = 1 to 8)**

The total number of frames on the port that experienced carrier loss. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

#### **12.2.2.4.6.19.8.12 Tx Octets (Offset = 3A064h)**

##### **All ports**

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

#### **12.2.2.4.6.19.8.13 Transmit Priority 0-7 (Offset = 3A180h to 3A1A8h)**

The total number of frames transmitted on the port from transmit FIFO priority 0-7. Collision retries do not affect this statistic. Pause frames do not affect this statistic.

- Any frame transmitted from priority 0-7, and
- Was less than or equal to CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG
- Collision retries are not counted in this statistic.
- Pause frames are not counted in this statistic.
- Carrier sense errors do not affect this statistic.

Note: The Transmit Priority 0-7 Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 statistic.

#### **12.2.2.4.6.19.8.14 Transmit Priority 0-7 Drop (Offset = 3A1C0h to 3A1E8h)**

The total number of transmit frames on the port that overran the transmit FIFO priority 0-7 and were dropped. This count includes frames dropped due to CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG.

- Any frame destined to be transmitted from priority 0-7, and
- Was any size, and
- Was dropped due to priority 0-7 FIFO overrun (Start of packet overrun).
- Was dropped due to frame size larger than CPSW\_TX\_PRI0\_MAXLEN\_REG to CPSW\_TX\_PRI7\_MAXLEN\_REG.

Note: The Transmit Priority 0-7 Drop Bytecount statistic is the number of bytes contained in the frames of the Transmit Priority 0-7 Drop statistic.

#### **12.2.2.4.6.19.8.15 Tx Memory Protect Errors (Offset = 3A17Ch)**

##### **All ports**

The total number of transmit frames on the port that had a memory protect CRC error on egress:

- Any frame destined to be transmitted,
- Was any size
- Had a memory protect CRC error on egress.

### Note

1. Frames to the host with memory protect errors are dropped via TXST\_DROP. Ethernet frames will have at least one byte of the generated port type CRC inverted on egress.
2. This statistic is 8-bits wide only and will not rollover but will limit at 0xFF.
3. A non-zero value in this statistic will issue a STAT\_PEND0 interrupt for the associated port.

#### 12.2.2.4.6.19.8.16 IET Transmit Merge Fragment Count (Offset = 3A14Ch)

The total number of non-initial preemptable transmit fragments on preemptable transmit.

- Any frame destined to be transmitted on the preemptable port, and
- Was any size, and
- was a non-initial fragment.

#### 12.2.2.4.6.19.8.17 IET Transmit Merge Hold Count (Offset = 3A150h)

The total number of preemptable frames that were preempted and reassembled by the assertion of MAC\_HOLD in the CPSW\_PN\_IET\_CONTROL\_REG\_k register or were preempted by Enhanced Scheduled Traffic (EST). The IET statistic can be derived and maintained by software.

- Any frame destined to be transmitted on the preemptable port, and
- was any size, and
- was preempted by the assertion of MAC\_HOLD.
- was preempted by Enhanced Scheduled Traffic (EST).

#### 12.2.2.4.6.19.9 Rx- and Tx (Shared) Statistics Descriptions

**Table 12-226. Rx Statistics Summary**

Rx Statistic	Frame/ Oct	Rx/ Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024- rx_max len	>rx_max len	Flow Coll. (8)	CRC Error	Align/ Code	Overrun	Add. Disc.

Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y	y	y)	y <sup>(7)</sup>	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns <sup>(9)</sup>	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	y	n
64octet Frames	F	Rx+ Tx <sup>(3)</sup>	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n

**Table 12-226. Rx Statistics Summary (continued)**

Rx Statistic	Frame/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)										Event				
			MAC control		Data <sup>(5)</sup>			<64	64	65-127	128-255	256-511	512-1023	1024-rx_max len	>rx_max len	Flow Coll. <sup>(8)</sup>	CRC Error	Alignment/ Code	Overrun	Add. Disc.		
			Pause frame	Non-pause <sup>(4)</sup>	Multicast	Broadcast	Unicast															
65-127octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n		
128-255octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	n	-	-	-	-	n		
256-511octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n		
512-1023octet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n		
1024-UPoctet Frames	F	Rx+Tx	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n		
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n		
Net Octets	O	Rx+Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y	y)	y)	-	-	-	-		

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx\_overruns stat is for RX\_MOF\_OVERRUNS and RX\_SOF\_OVERRUNS added together.

**Table 12-227. Tx Statistics Summary**

Tx Statistic <sup>(9)</sup>	Fra me/ Oct	Tx/ Rx +Tx	Frame Type					Frame Size (bytes)							Event

Tx Octets	O	Tx	(y	y	y	y	y)	(y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n			
Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y)	-	-	<sup>(7)</sup> \$	\$	\$	\$	\$	-	-	-			

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See Rx Statistics Summary.)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

#### 12.2.2.4.6.19.9.1 Rx + Tx 64 Octet Frames (Offset = 3A068h)

#### All ports

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### **12.2.2.4.6.19.9.2 Rx + Tx 65–127 Octet Frames (Offset = 3A06Ch)**

##### **All ports**

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.2.4.6.19.9.3 Rx + Tx 128–255 Octet Frames (Offset = 3A070h)**

##### **All ports**

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.2.4.6.19.9.4 Rx + Tx 256–511 Octet Frames (Offset = 3A074h)**

##### **All ports**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.2.4.6.19.9.5 Rx + Tx 512–1023 Octet Frames (Offset = 3A078h)**

##### **All ports**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **12.2.2.4.6.19.9.6 Rx + Tx 1024\_Up Octet Frames (Offset = 3A07Ch)**

##### **All ports**

The total number of frames of size 1024 to RX\_MAXLEN bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to RX\_MAXLEN bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### 12.2.2.4.6.19.9.7 Net Octets (Offset = 3A080h)

#### All ports

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than RX\_MAXLEN bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (that is, multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of Ethernet utilization.

#### 12.2.2.4.6.19.10

**Table 12-228. Rx Statistics Summary**

Rx Statistic	Fra me/ Oct	Rx/ Rx+ Tx	Frame Type					Frame Size (bytes)								Event

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
- (5) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).
- (6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (7) "y^" Frame fragments are not counted if less than 8 bytes.
- (8) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
- (9) The rx\_overruns stat is for RX\_MOF\_OVERRUNS and RX\_SOF\_OVERRUNS added together.

**Table 12-229. Tx Statistics Summary**

Tx Statistic <sup>(9)</sup>	Fra me/ Oct	Tx/ Rx +Tx	Frame Type					Frame Size (bytes)							Event

65-127octet Frames	F	Rx+ Tx	(y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-			
128-255octet Frames	F	Rx+ Tx	(y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-			
256-511octet Frames	F	Rx+ Tx	(y	y	y	y)	n	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-			
512-1023octet Frames	F	Rx+ Tx	(y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-			
1024-UPoctet Frames	F	Rx+ Tx	(y	y	y	y)	n	n	n	n	n	y	y	y	-	-	-	-	n	n	n	-	-	-			
Tx Octets	O	Tx	(y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n			
Net Octets	O	Rx+ Tx	(y	y	y	y)	(y	y	y	y	y	y	y	y)	-	-	\$ <sup>(7)</sup>	\$	\$	\$	\$	-	-	-			

- (1) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
- (2) "-" indicates conditions which are ignored in the formations of the statistic.
- (3) Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
- (4) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
- (5) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
- (6) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
- (7) "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
- (8) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 12-228](#).)
- (9) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

#### 12.2.2.4.7 Common Platform Time Sync (CPTS)

The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

Main features of CPTS module are:

- Supports the selection of multiple external clock sources
- Software control of time sync events via interrupt or polling
- Supports up to 4 hardware timestamp push inputs
- Supports timestamp counter compare output (CPTS\_COMP)
- Supports timestamp counter bit output (CPTS\_SYNC)
- Supports a configurable number of timestamp Generator bit outputs (CPTS\_GENFn).
- Supports Ethernet Enhanced Scheduled Traffic Operations (CPTS\_ESTFn).
- 32-bit and 64-bit timestamp modes with PPM and nudge adjustment.

##### 12.2.2.4.7.1 CPSW0 CPTS Integration

This section describes CPTS module integration in the CPSW0 module, including information about clocks, resets, and hardware requests.

Figure 12-172 shows CPTS integration in the device CPSW0 module.

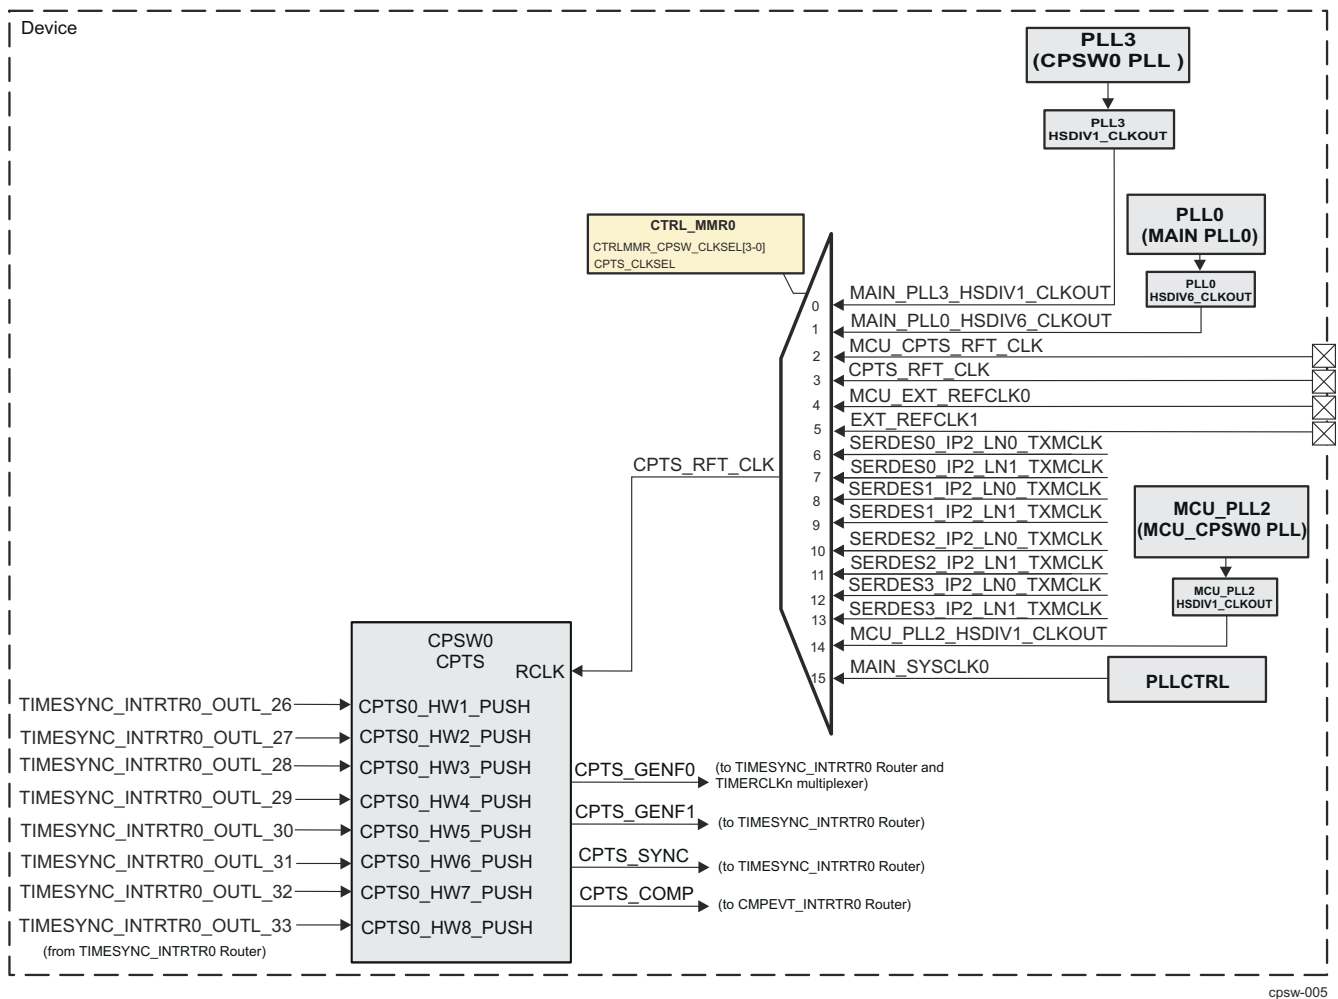

Figure 12-172. CPSW0 CPTS Integration

CPTS IEEE 1588 clock (RCLK) is selected through the CTRLMMR\_MCU\_ENET\_CLKSEL register.

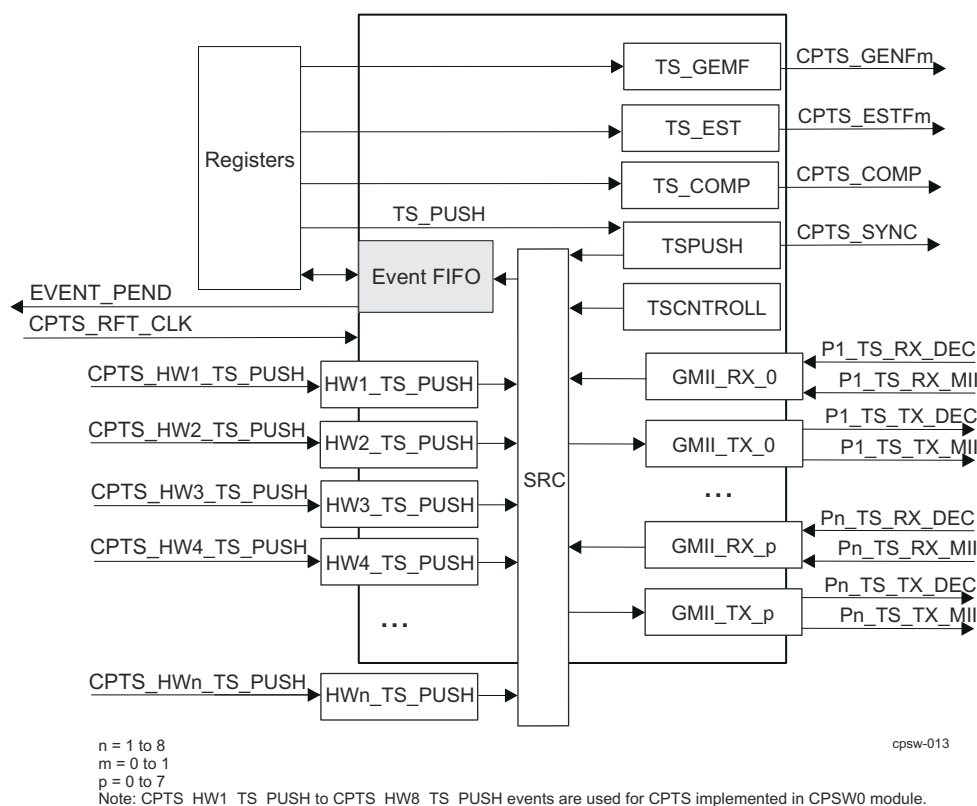

### Note

For more information about CPTS clocks and resets, see *MCU\_CPSW0 Clocks and Resets* in *CPSW0 Integration*.

#### 12.2.2.4.7.2 CPTS Architecture

Figure 12-173 shows the architecture of the CPTS module inside the CPSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the CPSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWN\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO. The reference clock used for the time stamp (CPTS\_RFT\_CLK) can be derived from several sources.

**Figure 12-173. CPTS Block Diagram**

### Note

See [Section 12.2.2.4.7.1](#), *CPSW0 CPTS Integration* for CPTS integration in the device CPSW0 module.

#### 12.2.2.4.7.3 CPTS Initialization

The CPTS module should be configured as follows:

1. Reset the CPTS module.
2. Write the CPTS\_CLKSEL value in the CTRLMMR\_CPSW\_CLKSEL register with the desired reference clock selection. This value is allowed to be written only when the CPTS\_EN bit in the CPSW\_CPTS\_CONTROL\_REG register is cleared to zero.
3. Set the CPTS\_EN bit in the CPSW\_CPTS\_CONTROL\_REG register.

4. If using interrupts and not polling, enable the interrupt by setting the TS\_PEND\_EN bit in the CPSW\_CPTS\_INT\_ENABLE\_REG register.

#### 12.2.2.4.7.4 32-bit Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPSW\_CPTS\_TS\_LOAD\_VAL\_REG / CPSW\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG and CPSW\_CPTS\_TS\_LOAD\_EN\_REG registers).

#### 12.2.2.4.7.5 64-bit Time Stamp Value

The time stamp value is a 64-bit value that increments on each CPTS\_RFT\_CLK rising edge when CPTS\_EN bit is set to 1h. When CPTS\_EN bit is cleared to 0h, the time stamp value is reset to 0h.

64-bit mode is selected when CPSW\_CPTS\_CONTROL\_REG[5] MODE bit set to 1h.

For test purposes, the time stamp value can be written via the time stamp load function (CPSW\_CPTS\_TS\_LOAD\_EN\_REG, CPSW\_CPTS\_TS\_LOAD\_VAL\_REG, and CPSW\_CPTS\_TS\_LOAD\_HIGH\_VAL\_REG registers). The CPSW\_CPTS\_TS\_ADD\_VAL\_REG feature is included to allow 1ns timestamp operations with an CPTS\_RFT\_CLK rate less than 1Ghz. [Table 12-230](#) shows the CPTS\_RFT\_CLK and CPSW\_CPTS\_TS\_ADD\_VAL\_REG values for 1ns operations.

**Table 12-230. ADD\_VAL feature**

CPTS_RFT_CLK (MHz)	CPSW_CPTS_TS_ADD_VAL_REG[2-0] ADD_VAL
1000 MHz	0
500 MHz	1
333.33 MHz	2
250 MHz	3
200 MHz	4
166.66 MHz	5
142.85714 MHz	6
125 MHz	7

#### 12.2.2.4.7.6 64-Bit Timestamp Nudge

The 64-bit TIME\_STAMP value can be adjusted by writing the CPSW\_CPTS\_TS\_NUDGE\_VAL\_REG[7-0] TS\_NUDGE\_VAL bit field value which is a two's complement value. A value of FFh will subtract 1 clock cycle from the next incremented 64-bit time stamp value (CPSW\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP and CPSW\_CPTS\_EVENT\_3\_REG[31-0] TIME\_STAMP value). A nudge value of 1h will add 1 clock cycle to the next incremented TIME\_STAMP[63-0] value. For example, if the current TIME\_STAMP value is F06h, and CPSW\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL = 3h, the next incremented timestamp value would be F0Ah without a nudge and F0Ah +/- [7-0] TS\_NUDGE\_VAL with a nudge. The [7-0] TS\_NUDGE\_VAL value is cleared to zero when the nudge has occurred.

#### 12.2.2.4.7.7 64-bit Timestamp PPM

The 64-bit TIME\_STAMP can be adjusted by parts per million or by parts per hour. Writing a non-zero value to the CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL (Time stamp PPM Low value) and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL (Time stamp PPM High value) enables PPM operations. The adjustment is up or down depending on the [7] TS\_PPM\_DIR bit in the CPSW\_CPTS\_CONTROL\_REG register. The TIME\_STAMP value is increased by the PPM value when [7]

TS\_PPM\_DIR bit is cleared. The TIME\_STAMP value is decreased by the PPM value when [7] TS\_PPM\_DIR bit is set.

#### Parts Per Million example:

To adjust for 100 parts per million the configured value for TS\_PPM[41-0] (through CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $1,000,000/100 = 10,000(\text{decimal})$

#### Parts Per Hour example:

To adjust for 1 part per hour at 1 GHz CPTS\_RFT\_CLK the configured value for TS\_PPM[41-0] (through CPSW\_CPTS\_TS\_PPM\_LOW\_VAL\_REG[31-0] TS\_PPM\_LOW\_VAL and CPSW\_CPTS\_TS\_PPM\_HIGH\_VAL\_REG[9-0] TS\_PPM\_HIGH\_VAL) is:  
 $(1,000,000,000\text{Hz}/1\text{pph}) * (3600 \text{ seconds/hour}) = 34630\text{B8A000} (\text{hex})$

#### 12.2.2.4.7.8 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 10 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 12.2.2.4.7.9 Timestamp Compare Output

CPTS features one Time Stamp Compare (CPTS\_COMP) output. The CPTS\_COMP function is a software oriented feature that is intended to be replaced going forward by the hardware oriented GENF function. CPTS\_COMP is not compatible with timestamp PPM or a non-zero CPSW\_CPTS\_TS\_ADD\_VAL\_REG[2-0] ADD\_VAL value.

##### 12.2.2.4.7.9.1 Non-Toggle Mode: 32-bit

The CPTS\_COMP output is asserted for CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH periods when the CPSW\_CPTS\_EVENT\_0\_REG[31-0] TIME\_STAMP value (lower 32-bits) compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_VAL and the length value is non-zero. The CPTS\_COMP rising edge occurs three CPTS\_RFT\_CLK clock periods after the values compare. A timestamp compare event is pushed into the event FIFO when CPTS\_COMP is asserted. The polarity of the CPTS\_COMP output is determined by the CPSW\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit. The output is asserted low when the polarity bit is 0h.

##### 12.2.2.4.7.9.2 Non-Toggle Mode: 64-bit

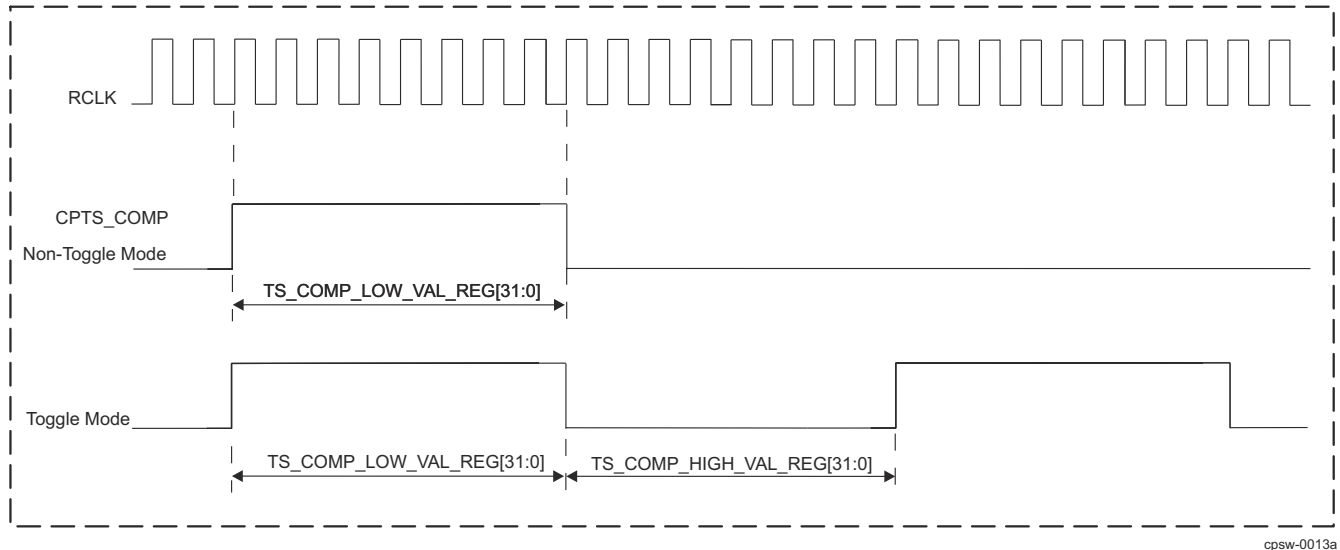

64-bit mode operation is identical to 32-bit mode except that all 64-bits of the TIME\_STAMP are used (CPSW\_CPTS\_EVENT\_0\_REG and CPSW\_CPTS\_EVENT\_3\_REG). In 32-bit mode only the lower 32-bits (CPSW\_CPTS\_EVENT\_0\_REG) are used.

##### 12.2.2.4.7.9.3 Toggle Mode: 32-bit

The CPTS\_COMP output is asserted (CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH) for CPTS\_RFT\_CLK clock periods when the TIME\_STAMP[31:0] value compares with the CPSW\_CPTS\_TS\_COMP\_VAL\_REG and the length value is non-zero. The CPTS\_COMP toggles thereafter on CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH for CPTS\_RFT\_CLK periods. The length high or low can be adjusted by writing the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE bit field value which is a two's complement value. A value of FFh will subtract one CPTS\_RFT\_CLK period from the CPSW\_CPTS\_TS\_COMP\_VAL\_REG[31-0] TS\_COMP\_LENGTH value. A value of 0x01h will add one CPTS\_RFT\_CLK period to the CPSW\_CPTS\_TS\_COMP\_LEN\_REG[31-0] TS\_COMP\_LENGTH value. Only a single high or low time is adjusted (nudged) and the CPSW\_CPTS\_TS\_COMP\_NUDGE\_REG[7-0] NUDGE value is cleared to zero when the nudge has occurred. The CPTS\_COMP output is asserted low when the CPSW\_CPTS\_CONTROL\_REG[2] TS\_COMP\_POLARITY bit is 0h. No compare events and no CPTS\_EVNT interrupts are generated in toggle mode. The CPSW\_CPTS\_CONTROL\_REG[6] TS\_COMP\_TOG bit must be set for toggle mode (value 1h). Note this bit must be set before writing a non-zero value to CPSW\_CPTS\_TS\_COMP\_VAL\_REG register.

#### 12.2.2.4.7.9.4 Toggle Mode: 64-bit
