

# ISO164x 拡張 EMC および GPIO 付きホット・スワップ可能な双方向 I2C アイソレータ

## 1 特長

- 信頼性の高い絶縁型双方向、I<sup>2</sup>C 互換、通信
  - ISO1640: 双方向の絶縁型 SDA および SCL 通信
  - ISO1641: 双方向 SDA と単方向 SCL 通信
  - ホットスワップ可能な SDA と SCL
- 最大 1.7MHz の双方向データ転送動作
- EMC を強化した堅牢な絶縁バリア
  - 450V<sub>RMS</sub> の動作電圧 (D-8) と 1500V<sub>RMS</sub> の動作電圧 (DW-16) では、100 年を超える予測寿命を提供
  - 最大 5000V<sub>RMS</sub> の絶縁定格
  - 最大 10kV まで再強化可能なのサージ能力
  - CMT1: ±100kV/μs (標準値)
  - 絶縁バリアの両側で ±8kV の IEC-ESD 61000-4-2 接触放電保護
  - SCL2 および SDA2 (サイド 2) で同じ側の ±8kV IEC-ESD 電源非接続接触放電
- 電源電圧範囲: 3V~5.5V (サイド 1)、2.25V~5.5V (サイド 2)
- オープン・ドレイン出力 3.5mA (サイド 1)、50mA (サイド 2) のシンク電流能力
- 最大容量性負荷 80pF (サイド 1) と 400pF (サイド 2)
- 16-SOIC (DW-16) および 8-SOIC (D-8) パッケージオプション
- 40°C~+125°C の動作温度
- 安全性関連の認定 (予定)
  - UL 1577 部品認定プログラム
  - DIN VDE V 0884-11
  - IEC 62368-1、IEC 61010-1、IEC 60601-1、GB4943.1-2011 認証

## 2 アプリケーション

- 絶縁 I<sup>2</sup>C バス
- SMBus および PMBus インターフェイス
- PoE (Power Over Ethernet)
- モータ制御システム
- バッテリー管理

## 3 概要

ISO1640、ISO1641 (ISO164x) デバイスは、I<sup>2</sup>C インターフェイスと互換性のある、ホットスワップ可能、低消費電力の双方向アイソレータです。ISO164x は 16-DW パッケージで 5000V<sub>RMS</sub>、8-D パッケージで 3000V<sub>RMS</sub> の UL 1577 絶縁定格をサポートしています。この低排出デバイスの各絶縁チャンネルは、二酸化ケイ素 (SiO<sub>2</sub>) の二重の容量性絶縁バリアで分離されたロジック入力およびオープン・ドレイン出力を備えています。このファミリには、VDE、UL、CSA、TUV、CQC 認定済みの基本絶縁型と強化絶縁型の定格デバイスが含まれます。ISO1640 にはクロックおよびデータ・ライン用の 2 つの絶縁型双方向チャンネルがあり、ISO1641 には双方向のデータ・チャンネルと、単方向のクロック・チャンネルがあります。ISO164x ファミリには、双方向チャンネルをサポートするために必要なロジックが組み込まれており、フォトカプラ・ベースのソリューションに比べて設計の大幅な簡素化とフットプリントの小型化を実現します。

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup> <sup>(2)</sup>

		MIN	MAX	UNIT
Supply Voltage	$V_{CC1}, V_{CC2}$	-0.5	6	V
Input/Output Voltage	SDA1, SCL1	-0.5	$V_{CCX} + 0.5^{(3)}$	V
	SDA2, SCL2	-0.5	$V_{CCX} + 0.5^{(3)}$	
	INx (ISO1644 only)	-0.5	$V_{CCX} + 0.5$	
Input/Output Current	SDA1, SCL1	0	20	mA
	SDA2, SCL2	0	100	
	$I_{IO}$ (ISO1644 only)	-15	15	
Temperature	Maximum junction temperature, $T_J$		150	°C
	Storage temperature, $T_{stg}$	-65	150	°C

- Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- All voltage values are with respect to the local ground pin (GND1 or GND2) and are peak voltage values.
- During powered off hotswap, the bus pins can go  $0\text{ V} < \text{SDAx}, \text{SCLx} < 6\text{ V}$ . Maximum voltage for INx must not exceed 6 V.

### 6.2 ESD Ratings

			VALUE	UNIT	
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	All pins	±6000	V
			ISO1640/1: Bus pins (SDA1, SCL1)	±10000	V
			ISO1640/1: Bus pins (SDA2, SCL2)	±14000	V
			ISO1644: Bus pins (SDA1, SCL1)	±8000	V
			ISO1644: Bus pins (SDA2, SCL2)	±8000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±1500	V	
		Contact discharge per IEC 61000-4-2; Isolation barrier withstand test <sup>(3)</sup> <sup>(4)</sup>	±8000	V	
Same side unpowered IEC ESD contact discharge per IEC 61000-4-2; Side 2	ISO1640/1: SCL2, SDA2	±8000	V		

- JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.
- IEC ESD strike is applied across the barrier with all pins on each side tied together creating a two-terminal device.
- Testing is carried out in air or oil to determine the intrinsic contact discharge capability of the device.

- (1) Creepage and clearance requirements should be applied according to the specific equipment isolation standards of an application. Care should be taken to maintain the creepage and clearance distance of a board design to ensure that the mounting pads of the isolator on the printed-circuit board do not reduce this distance. Creepage and clearance on a printed-circuit board become equal in certain cases. Techniques such as inserting grooves, ribs, or both on a printed circuit board are used to help increase these specifications.
- (2) ISO164xDW is suitable for *safe electrical insulation* and ISO164xBD is suitable for *basic electrical insulation* only within the safety ratings. Compliance with the safety ratings shall be ensured by means of suitable protective circuits.
- (3) Testing is carried out in air or oil to determine the intrinsic surge immunity of the isolation barrier.

- (4) Apparent charge is electrical discharge caused by a partial discharge (pd).
- (5) All pins on each side of the barrier tied together creating a two-pin device.

T <sub>S</sub>	Safety temperature <sup>(1)</sup>				150	°C
<b>ISO1644 DW-16 Package</b>						
I <sub>S</sub>	Safety input, output, or supply current <sup>(1)</sup>	R <sub>θJA</sub> = 137.5 °C/W, V <sub>I</sub> = 5.5 V, T <sub>J</sub> = 150°C, T <sub>A</sub> = 25°C			166	mA
		R <sub>θJA</sub> = 137.5 °C/W, V <sub>I</sub> = 3.6 V, T <sub>J</sub> = 150°C, T <sub>A</sub> = 25°C			253	
P <sub>S</sub>	Safety input, output, or total power <sup>(1)</sup>	R <sub>θJA</sub> = 137.5 °C/W, T <sub>J</sub> = 150°C, T <sub>A</sub> = 25°C			910	mW
T <sub>S</sub>	Safety temperature <sup>(1)</sup>				150	°C

- (1) The maximum safety temperature, T<sub>S</sub>, has the same value as the maximum junction temperature, T<sub>J</sub>, specified for the device. The I<sub>S</sub> and P<sub>S</sub> parameters represent the safety current and safety power respectively. The maximum limits of I<sub>S</sub> and P<sub>S</sub> should not be exceeded. These limits vary with the ambient temperature, T<sub>A</sub>.

The junction-to-air thermal resistance, R<sub>θJA</sub>, in the table is that of a device installed on a high-K test board for leaded surface-mount packages. Use these equations to calculate the value for each parameter:

$$T_J = T_A + R_{\theta JA} \times P, \text{ where } P \text{ is the power dissipated in the device.}$$

$$T_{J(max)} = T_S = T_A + R_{\theta JA} \times P_S, \text{ where } T_{J(max)} \text{ is the maximum allowed junction temperature.}$$

$$P_S = I_S \times V_I, \text{ where } V_I \text{ is the maximum input voltage.}$$

(1) This parameter does not apply to the SCL1 line of the ISO1641 device because it is unidirectional.

(2)  $\Delta V_{OIT1} = V_{OL1} - V_{IHT1}$ . This value represents the minimum difference between a threshold for the low-level output voltage and a threshold for the high-level input voltage to prevent a permanent latch condition that would otherwise occur with bidirectional communication.

(3) Any supply voltages on either side that are less than the minimum value make sure that the device does a lockout. Both supply voltages that are greater than the maximum value keep the device from a lockout.

## 8 Detailed Description

### 8.1 Overview

The I<sup>2</sup>C bus consists of a two-wire communication bus that supports bidirectional data transfer between a master device and several slave devices. The master, or processor, controls the bus, specifically the serial clock (SCL) line. Data is transferred between the master and slave through a serial data (SDA) line. This data can be transferred in four speeds: standard mode (0 to 100 kbps), fast mode (0 to 400 kbps), fast-mode plus (0 to 1 Mbps), and high-speed mode (0 to 3.4 Mbps).

The I<sup>2</sup>C bus operates in bidirectional, half-duplex mode, using open collector outputs to allow for multiple devices to share the bus. When a specific device is ready to communicate on the bus, it can take control pulling the lines low accordingly in order to transmit data. A standard digital isolator or optocoupler is designed to transfer data in a single direction. In order to support an I<sup>2</sup>C bus, external circuitry is required to separate the bidirectional bus into two unidirectional signal paths. The ISO164x devices internally handle the separation and partitioning of the transmit and receive signals, integrating the external circuitry needed and provide the open-collector signals. They provide high electromagnetic immunity and low emissions at low power consumption. Each isolation channel has a logic input and output buffer separated by TI's double capacitive silicon dioxide (SiO<sub>2</sub>) insulation barrier. When used in conjunction with isolated power supplies, these devices block high voltages, isolate grounds, and prevent noise currents from entering the local ground and interfering with or damaging sensitive circuitry.

### 8.3 Feature Description

The device enables a complete isolated I<sup>2</sup>C interface to be implemented within a small form factor having the features listed in 表 8-1.

表 8-1. Features List

ISO1640	Bidirectional SCL Bidirectional SDA	5000 V <sub>RMS</sub> (16DW) 7071 V <sub>PK</sub> (16DW) 3000 V <sub>RMS</sub> (8D) 4242 V <sub>PK</sub> (8D)	1.7 MHz
ISO1641	Unidirectional (SCL) Bidirectional (SDA)	3000 V <sub>RMS</sub> (8D) 4242 V <sub>PK</sub> (8D)	

(1) See for detailed Isolation specifications.

#### 8.3.1 Hot Swap

The ISO164x includes Hot Swap circuitry on Side 2 of the isolator to prevent loading on the I<sup>2</sup>C bus lines while VCC2 is either unpowered or in the process of being powered on. While VCC2 is below the UVLO threshold, the ISO164x bus lines will not load the bus to avoid disrupting or corrupting an active I<sup>2</sup>C bus. If the isolator is plugged into a live backplane using a staggered connector, where VCC2 and GND2 make connection first followed by the bus lines, the SDA and SCL lines are pre-charged to VCC2 / 2 to minimize the current required to charge the parasitic capacitance of the device. Once the device is fully powered on, the device bus pins become active providing bidirectional, isolated, SCL and SDA lines.

#### 8.3.2 Protection Features

Features are integrated in the ISO164x to help protect the device from high current events. Enhanced ESD protection cells are designed on the I<sup>2</sup>C bus pins to support 10 kV HBM ESD on side 1 and 14 kV HBM ESD on side 2. The I<sup>2</sup>C bus pins on side 2 are designed to withstand an unpowered IEC ESD strike of 8kV, improving robustness and system reliability in hot swap applications. In addition to the improved ESD performance, a short circuit protection circuit is included on side 2 to protect the bus pins (SDA2 and SCL2) against strong short circuits of 5 ohms or less to VCC2.

Thermal shutdown is integrated in the ISO164x to protect the device from high current events. If the junction temperature of the device exceeds the thermal shutdown threshold of 190C (typical), the device turns off, disabling the I<sup>2</sup>C circuits and releasing the bus. The shutdown condition is cleared when the junction temperature drops at least the thermal shutdown hysteresis temperature of 10C (typical) below the thermal shutdown temperature of the device.

### 8.3.3 GPIO Channels

TBD

## 8.4 Isolator Functional Principle

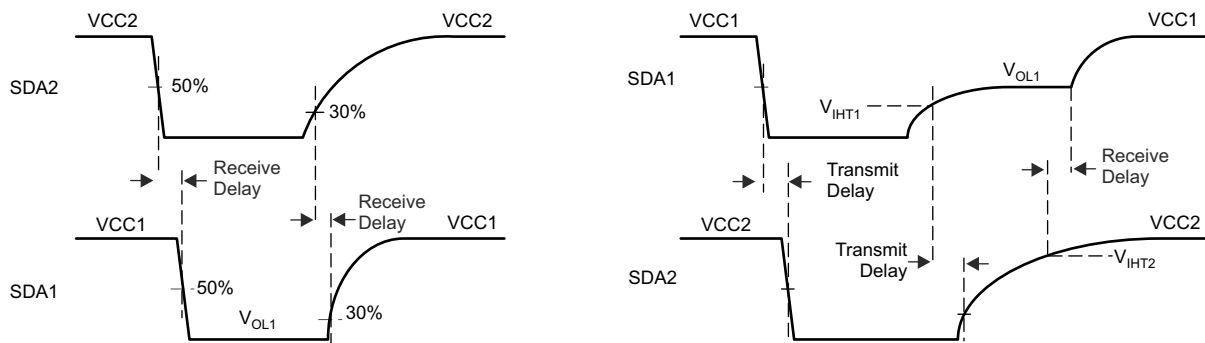

To isolate a bidirectional signal path (SDA or SCL), the ISO1640 internally splits a bidirectional line into two unidirectional signal lines, each of which is isolated through a single-channel digital isolator. Each channel output is made open-drain to comply with the open-drain technology of I<sup>2</sup>C. Side 1 of the ISO1640 connects to a low-capacitance I<sup>2</sup>C node (up to 80 pF), while side 2 is designed for connecting to a fully loaded I<sup>2</sup>C bus with up to 400 pF of capacitance.

**Figure 8-3. SDA Channel Design and Voltage Levels at SDA1**

At first sight, the arrangement of the internal buffers suggests a closed signal loop that is prone to latch-up. However, this loop is broken by implementing an output buffer (B) whose output low-level is raised by a diode drop to approximately 0.65 V, and the input buffer (C) that consists of a comparator with defined hysteresis. The comparator's upper and lower input thresholds then distinguish between the proper low-potential of 0.4 V (maximum) driven directly by SDA1 and the buffered output low-level of B.

**Figure 8-4** demonstrate the switching behavior of the I<sup>2</sup>C isolator, ISO164x, between a master node at SDA1 and a heavy loaded bus at SDA2.

**Figure 8-4. SDA Channel Timing in Receive and Transmit Directions**

### 8.4.1 Receive Direction (Left Diagram of **Figure 8-4**)

When the I<sup>2</sup>C bus drives SDA2 low, SDA1 follows after a certain delay in the receive path. The output low is the buffered output of  $V_{OL1} = 0.65$  V, which is sufficiently low to be detected by Schmitt-trigger inputs with a minimum input-low voltage of  $V_{IL} = 0.9$  V at 3 V supply levels.

When SDA2 is released, its voltage potential increases towards VCC2 following the time-constant formed by  $R_{PU2}$  and  $C_{bus}$ . After the receive delay, SDA1 is released and also rises towards VCC1, following the time-constant  $R_{PU1} \times C_{node}$ . Because of the significant lower time-constant, SDA1 may reach VCC1 before SDA2 reaches VCC2 potential.

### 8.4.2 Transmit Direction (Right Diagram of )

When a master drives SDA1 low, SDA2 follows after a certain delay in the transmit direction. When SDA2 turns low it also causes the output of buffer B to turn low but at a higher 0.65 V level. This level cannot be observed immediately as it is overwritten by the lower low-level of the master.

However, when the master releases SDA1, the voltage potential increases and first must pass the upper input threshold of the comparator,  $V_{IHT1}$ , to release SDA2. SDA1 then increases further until it reaches the buffered output level of  $V_{OL1} = 0.65$  V, maintained by the receive path. When comparator C turns high, SDA2 is released after the delay in transmit direction. It takes another receive delay until B's output turns high and fully releases SDA1 to move toward VCC1 potential.

### 8.5 Device Functional Modes

表 8-2 lists the ISO164x functional modes.

表 8-2. Function Table<sup>(1)</sup>

POWER STATE	INPUT	OUTPUT
VCC1 < 2.3 V or VCC2 < 1.7 V	X	Z

(1) H = High Level; L = Low Level; Z = High Impedance or Float; X = Irrelevant

(2) Invalid input condition as an I<sup>2</sup>C system requires that a pullup resistor to VCC is connected.

## 9 Application and Implementation

### Note

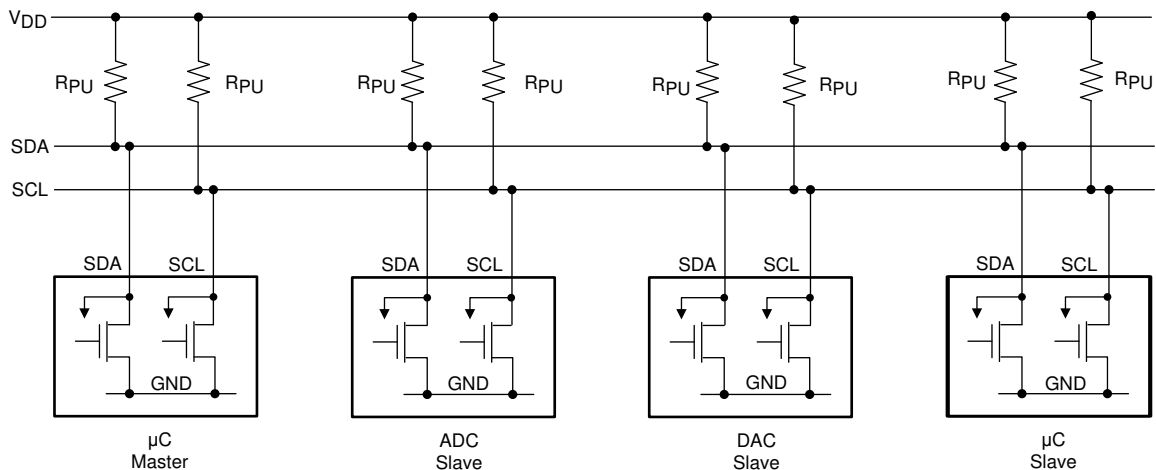

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

#### 9.1.1 I<sup>2</sup>C Bus Overview

The inter-integrated circuit (I<sup>2</sup>C) bus is a single-ended, multi-master, 2-wire bus for efficient inter-IC communication in half-duplex mode.

I<sup>2</sup>C uses open-drain technology, requiring two lines, serial data (SDA) and serial clock (SCL), to be connected to VDD by resistors (see [Figure 9-1](#)). Pulling the line to ground is considered a logic zero while letting the line float is a logic one. This logic is used as a channel access method. Transitions of logic states must occur while the SCL pin is low. Transitions while the SCL pin is high indicate START and STOP conditions. Typical supply voltages are 3.3 V and 5 V, although systems with higher or lower voltages are allowed.

**Figure 9-1. I<sup>2</sup>C Bus**

I<sup>2</sup>C communication uses a 7-bit address space with 16 reserved addresses, so a theoretical maximum of 112 nodes can communicate on the same bus. In practice, however, the number of nodes is limited by the specified, total bus capacitance of 400 pF, which also restricts communication distances to a few meters.

The specified signaling rates for the ISO164x devices are 100 kbps (standard mode), 400 kbps (fast mode), 1.7 Mbps (fast mode plus).

The bus has two roles for nodes: master and slave. A master node issues the clock and slave addresses, and also initiates and ends data transactions. A slave node receives the clock and addresses and responds to requests from the master. [Figure 9-2](#) shows a typical data transfer between master and slave.

**Figure 9-2. Timing Diagram of a Complete Data Transfer**

The master initiates a transaction by creating a START condition, following by the 7-bit address of the slave it wishes to communicate with. This is followed by a single read and write (R/W) bit, representing whether the master wishes to write to (0), or to read from (1) the slave. The master then releases the SDA line to allow the slave to acknowledge the receipt of data.

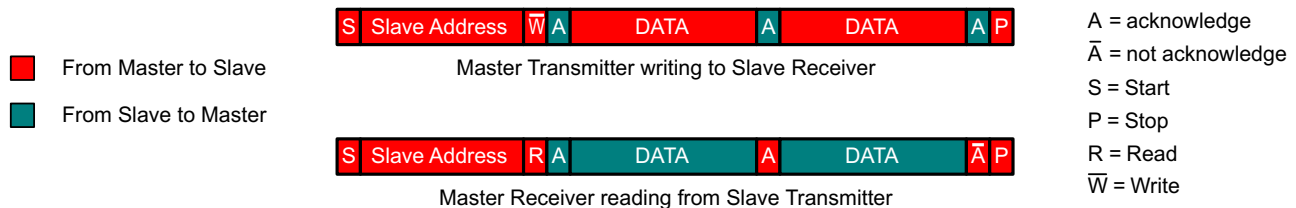

The slave responds with an acknowledge bit (ACK) by pulling the SDA pin low during the entire high time of the 9th clock pulse on the SCL signal, after which the master continues in either transmit or receive mode (according to the R/W bit sent), while the slave continues in the complementary mode (receive or transmit, respectively).

The address and the 8-bit data bytes are sent most significant bit (MSB) first. The START bit is indicated by a high-to-low transition of SDA while SCL is high. The STOP condition is created by a low-to-high transition of SDA while SCL is high.

If the master writes to a slave, it repeatedly sends a byte with the slave sending an ACK bit. In this case, the master is in master-transmit mode and the slave is in slave-receive mode.

If the master reads from a slave, it repeatedly receives a byte from the slave, while acknowledging (ACK) the receipt of every byte but the last one (see Figure 9-3). In this situation, the master is in master-receive mode and the slave is in slave-transmit mode.

The master ends the transmission with a STOP bit, or may send another START bit to maintain bus control for further transfers.

**Figure 9-3. Transmit or Receive Mode Changes During a Data Transfer**

When writing to a slave, a master mainly operates in transmit-mode and only changes to receive-mode when receiving acknowledgment from the slave.

When reading from a slave, the master starts in transmit-mode and then changes to receive-mode after sending a READ request (R/W bit = 1) to the slave. The slave continues in the complementary mode until the end of a transaction.

**Note**

The master ends a reading sequence by not acknowledging (NACK) the last byte received. This procedure resets the slave state machine and allows the master to send the STOP command.

**9.2 Typical Application**

In Figure 9-4, the ultra low-power microcontroller, MSP430G2132, controls the I<sup>2</sup>C data traffic of configuration data and conversion results for the analog inputs and outputs. Low-power data converters build the analog interface

to sensors and actuators. The ISO164x device provides the required isolation between different ground potentials of the system controller, remote sensor, and actuator circuitry to prevent ground loop currents that otherwise may falsify the acquired data.

The entire circuit operates from a single 3.3-V supply. A low-power push-pull converter, SN6501, drives a center-tapped transformer with an output that is rectified and linearly regulated to provide a stable 5-V supply for the data converter.

FIG 9-4. Isolated I<sup>2</sup>C Data Acquisition System

### 9.2.1 Design Requirements

The recommended power supply voltages must be from 3 V to 5.5 V for VCC1 and 2.25 V to 5.5 V for VCC2. A recommended decoupling capacitor with a value of 0.1 µF is required between both the VCC1 and GND1 pins, and the VCC2 and GND2 pins to support of power supply voltages transient and to ensure reliable operation at all data rates.

### 9.2.2 Detailed Design Procedure

Although the ISO1640 features bidirectional data channels, the device performs optimally when side 1 (SDA1 and SCL1) is connected to a single controller or node of an I2C network while side 2 (SDA2 and SCL2) is connected to the I2C bus.

The power-supply capacitor with a value of 0.1-µF must be placed as close to the power supply pins as possible. The recommended placement of the capacitors must be 2-mm maximum from input and output power supply pins (VCC1 and VCC2).

The maximum load permissible on the input lines, SDA1 and SCL1, is ≤ 80 pF and on the output lines, SDA2 and SCL2, is ≤ 400 pF.

The minimum pullup resistors on the input lines, SDA1 and SCL1 to VCC1 must be selected in such a way that input current drawn is ≤ 3.5 mA. The minimum pullup resistors on the input lines, SDA2 and SCL2, to VCC2 must be selected in such a way that output current drawn is ≤ 50 mA. The maximum pullup resistors on the bus lines (SDA1 and SCL1) to VCC1 and on bus lines (SDA2 and SCL2) to VCC2, depends on the load and rise time requirements on the respective lines to comply with I2C protocols. For more information, see .

The output waveforms for SDA1 and SCL1 are captured on the oscilloscope focusing on the low  $V_{OL1}$  voltage offset offered with the ISO164x. This voltage offset is due to the high output low level on side 1 designed to prevent a latch-up state mentioned in [セクション 8.4](#).

### 9.3 Insulation Lifetime

Insulation lifetime projection data is collected by using industry-standard Time Dependent Dielectric Breakdown (TDDB) test method. In this test, all pins on each side of the barrier are tied together creating a two-terminal device and high voltage is applied between the two sides; see [Figure 9-8](#) for TDDB test setup. The insulation breakdown data is collected at various high voltages switching at 60 Hz over temperature. For basic insulation, VDE standard requires the use of a TDDB projection line with failure rate of less than 1000 part per million (ppm). For reinforced insulation, VDE standard requires the use of a TDDB projection line with failure rate of less than 1 part per million (ppm).

Even though the expected minimum insulation lifetime is 20 years, at the specified working isolation voltage, VDE basic and reinforced certifications require additional safety margin of 20% for working voltage. For basic certification, device lifetime requires a safety margin of 30% translating to a minimum required insulation lifetime of 26 years at a working voltage that is 20% higher than the specified value. For reinforced insulation, device lifetime requires a safety margin of 87.5% translating to a minimum required insulation lifetime of 37.5 years at a working voltage that is 20% higher than the specified value.

[Insulation Lifetime Projection Data for ISO164x in 8-D Package](#) and [Insulation Lifetime Projection Data for ISO164x in 16-DW Package](#) show the intrinsic capability of the isolation barrier to withstand high voltage stress over its lifetime. Based on the TDDB data, the intrinsic capability of the insulation is 450 V<sub>RMS</sub> with a lifetime in excess of 100 years in the 8-D package and 1500 V<sub>RMS</sub> with a lifetime in excess of 135 years in the 16-DW package. Other factors, such as package size, pollution degree, material group, etc. can further limit the working voltage of the component. At the lower working voltages, the corresponding insulation lifetime is much longer than 100 years in the 8-D package and 135 years in the 16-DW package.

## 10 Power Supply Recommendations

To help ensure reliable operation at data rates and supply voltages, TI recommends connecting a 1- $\mu$ F bypass capacitor at the input and output supply pins (VCC1 and VCC2). The capacitors should be placed as close to the supply pins as possible. If only a single, primary-side power supply is available in an application, isolated power can be generated for the secondary-side with the help of a transformer driver such as TI's [SN6501](#) device. For such applications, detailed power supply design and transformer selection recommendations are available in [SN6501 Transformer Driver for Isolated Power Supplies](#). (SLLSEA0).

## 11 Layout

### 11.1 Layout Guidelines

A minimum of four layers is required to accomplish a low EMI PCB design (see [Figure 11-1](#)). Layer stacking should be in the following order (top-to-bottom): high-speed signal layer, ground plane, power plane and low-frequency signal layer.

- Routing the high-speed traces on the top layer avoids the use of vias (and the introduction of their inductances) and allows for clean interconnects between the isolator and the transmitter and receiver circuits of the data link.
- Placing a solid ground plane next to the high-speed signal layer establishes controlled impedance for transmission line interconnects and provides an excellent low-inductance path for the return current flow.
- Placing the power plane next to the ground plane creates additional high-frequency bypass capacitance of approximately 100 pF/in<sup>2</sup>.
- Routing the slower speed control signals on the bottom layer allows for greater flexibility as these signal links usually have margin to tolerate discontinuities such as vias.

If an additional supply voltage plane or signal layer is needed, add a second power or ground plane system to the stack to keep it symmetrical. This makes the stack mechanically stable and prevents it from warping. Also the power and ground plane of each power system can be placed closer together, thus increasing the high-frequency bypass capacitance significantly.

For detailed layout recommendations, see the [Digital Isolator Design Guide](#) (SLLA284)

#### 11.1.1 PCB Material

For digital circuit boards operating at less than 150 Mbps, (or rise and fall times greater than 1 ns), and trace lengths of up to 10 inches, use standard FR-4 UL94V-0 printed circuit board. This PCB is preferred over cheaper alternatives because of lower dielectric losses at high frequencies, less moisture absorption, greater strength and stiffness, and the self-extinguishing flammability-characteristics.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

### NOTES:

1. All linear dimensions are in millimeters. Dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. This dimension does not include mold flash, protrusions, or gate burrs. Mold flash, protrusions, or gate burrs shall not exceed 0.15 mm, per side.
4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.25 mm, per side.
5. Reference JEDEC registration MS-013.
