

# TPS7A10 300mA、低 $V_{IN}$ 、低 $V_{OUT}$ 、超低ドロップアウト・レギュレータ

## 1 特長

- 非常に低い入力電圧範囲: 0.75V~3.3V
- 非常に低いドロップアウトで最小限の電力損失
  - 300mA ( $V_{OUT} > 1.0V$ )で70mV (最大値)、YKAパッケージ
- 低い静止電流
  - $V_{IN} I_Q = 1.6\mu A$  (標準値)
  - $V_{BIAS} I_Q = 6\mu A$  (標準値)
- すべての負荷、ライン、温度範囲での精度: 1.5%
- 高いPSRR: 1kHzにおいて60dB
- 固定出力電圧で利用可能
  - 0.5V~3.0V (50mV刻み)
- $V_{BIAS}$  範囲: 1.7V~5.5V
- パッケージ
  - 0.74mm×1.09mm WCSP-5
  - 1.50mm×1.50mm WSON-6
- $V_{OUT}$  が単調増加するソフトスタートを内蔵
- アクティブ出力放電

## 2 アプリケーション

- スマートウォッチ、フィットネス・トラッカー
- ワイヤレス・ヘッドホン/イヤホン
- カメラ・モジュール
- スマートフォンおよびタブレット
- ポータブル医療機器

## 3 概要

TPS7A10は超小型で静止電流が低い、低ドロップアウト・レギュレータ(LDO)であり、300mAを供給可能で、AC特性(負荷、ライン過渡応答)が非常に優れています。入力範囲は0.75V~3.3V、出力範囲は0.5V~3.0Vで、全負荷/ライン/温度範囲で1.5%という非常に高い精度を実現しています。この性能は、最新のMCUやアナログ・センサの低いコア電圧を供給するには理想的です。

主電源路は $V_{IN}$ を経由し、出力電圧+70mVという低い電源に接続できます。 $V_{BIAS}$ レールを追加してLDOの内部回路に電力を供給することで、極めて低い入力電圧に対応します。 $V_{IN}$ と $V_{BIAS}$ で消費される静止電流は非常に低く、それぞれ1.6 $\mu A$ 、6 $\mu A$ です。 $I_Q$ が低く、超低ドロップアウトであることから、消費電力が重視される用途でソリューションの効率を高めることができます。例えば、 $V_{IN}$ を高効率のDC/DC降圧レギュレータの出力とし、 $V_{BIAS}$ ピンを充電式バッテリーに接続できます。

また、オフ時に出力を高速放電するアクティブ・プルダウン回路を内蔵しており、既知の起動状態を確保できます。

TPS7A10は超小型の5ピンDSBGA (YKA)パッケージで供給されるため、スペースの制約が厳しいアプリケーションに適しています。TPS7A10は6ピンWSON (DSE)パッケージでも供給されます。

### 製品情報<sup>(1)</sup>

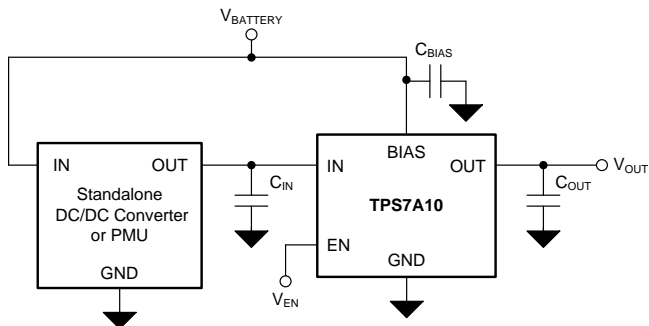

型番	パッケージ	本体サイズ(公称)
TPS7A10	WSON (6)	1.50mm×1.50mm
	DSBGA (5)	0.74mm×1.09mm (0.35mmピッチ)

(1) 利用可能なすべてのパッケージについては、このデータシートの末尾にあるパッケージ・オプションについての付録を参照してください。

## 5 Pin Configuration and Functions

### Pin Functions

NAME	PIN		I/O	DESCRIPTION
	DSE	YKA		
IN	6	A1	I	Input pin. For best transient response and to minimize input impedance, use the recommended or larger value ceramic capacitor from IN to ground, as listed in the <a href="#">Recommended Operation Conditions</a> . Place the input capacitor as close as possible to input of the device.
OUT	1	A3	O	Regulated output pin. A capacitor is required from OUT to ground for stability. For best transient response, use larger than the minimum recommended value ceramic capacitor. Follow the recommended capacitor value as listed in the <a href="#">Recommended Operation Conditions</a> . Place the output capacitor as close as possible to output of the device.
GND	5	B2	—	Ground pin. This pin must be connected to ground.
BIAS	4	C1	I	BIAS pin. This pin enables the use of low-input voltage, low-output voltage conditions, (LILO). For best response, use the recommended or larger value ceramic capacitor from BIAS to ground as listed in the <a href="#">Recommended Operation Conditions</a> . Place the bias capacitor as close as possible to input of the device.
EN	3	C3	I	Enable pin. Driving this pin to logic high enables the device. Driving this pin to logic low disables the device. If enable functionality is not required, this pin must be connected to IN or BIAS; however, connecting EN to IN is only acceptable if the $V_{IN}$ voltage is greater than 0.9 V.

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range unless otherwise noted.<sup>(1)</sup>

		MIN	MAX	UNIT
Voltage	Supply, $V_{IN}$	-0.3	3.6	V
	Enable, $V_{EN}$	-0.3	6.0	
	Bias, $V_{BIAS}$	-0.3	6.0	
	Output, $V_{OUT}$	-0.3	$V_{IN} + 0.3$ <sup>(2)</sup>	
Current	Maximum output current	Internally limited		A
Temperature	Operating junction temperature, $T_J$	-40	150	°C
	Storage temperature, $T_{stg}$	-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) The absolute maximum rating is 3.6 or ( $V_{IN} + 0.3$ ), whichever is less.

### 6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±1000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating junction temperature range (unless otherwise noted).

		MIN	NOM	MAX	UNIT
$V_{IN}$	Input voltage	0.75		3.3	V
$V_{BIAS}$	Bias voltage	1.7		5.5	V
$V_{OUT}$	Output voltage	0.5		3.0	V
$I_{OUT}$	Peak output current	0		300	mA
$C_{IN}$	Input capacitor	2.2			µF
$C_{BIAS}$	Bias capacitor		0.1		µF
$C_{OUT}$ <sup>(1)</sup>	Output capacitor	2.2		22	µF
$T_J$	Operating junction temperature	-40		125	°C

- (1) Maximum ESR must be lower than 250 mΩ

### 6.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		TPS7A10		UNIT
		DSE (WSON)	YKA (WSCP)	
		6 PINS	5 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	188.8	169.4	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	82.9	1.1	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	101.0	55.4	°C/W
$\Psi_{JT}$	Junction-to-top characterization parameter	6.6	1.7	°C/W
$\Psi_{JB}$	Junction-to-board characterization parameter	100.4	55.6	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	N/A	N/A	°C/W

- (1) For more information about traditional and new thermal metrics, see [Semiconductor and IC Package Thermal Metrics](#).

## 6.5 Electrical Characteristics

over  $T_J = -40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$ ,  $V_{IN} = V_{OUT(NOM)} + 0.5\text{ V}$ ,  $V_{BIAS} = V_{OUT(NOM)} + 1.4\text{ V}$ ,  $I_{OUT} = 1\text{ mA}$ ,  $V_{EN} = 1.0\text{ V}$ ,  $C_{IN} = 2.2\text{ }\mu\text{F}$ ,  $C_{OUT} = 2.2\text{ }\mu\text{F}$ , and  $C_{BIAS} = 0.1\text{ }\mu\text{F}$  ( unless otherwise noted); all typical values are at  $T_J = 25^{\circ}\text{C}$  .

## 7 Detailed Description

### 7.1 Overview

The TPS7A10 is a low input, ultra-low dropout, and low quiescent current linear regulator that is optimized for excellent transient performance. These characteristics make the device ideal for most battery-powered applications. The implementation of the BIAS pin on the TPS7A10 vastly improves efficiency of low-voltage output applications by allowing the use of a preregulated, low-voltage input supply that offers sub-band-gap output voltages. The high power-supply rejection ratio (PSRR), low noise, low ground pin current, and ultra-small packaging make this device suitable for ultra-portable applications. This device also offers high output voltage accuracy of 1.5% over the recommended junction temperature range.

### 7.2 Functional Block Diagram

## 7.3 Feature Description

### 7.3.1 Excellent Transient Response

The TPS7A10 responds quickly to a transient on the input supply (line transient) or the output current (load transient) that results from the device high input impedance and low output impedance across frequency. This same capability also means that the device has a high power-supply rejection ratio (PSRR) and low internal noise floor ( $e_n$ ). The low-dropout regulator (LDO) approximates an ideal power supply in ac (small-signal) and dc (large-signal) conditions.

The choice of external component values optimizes the small- and large-signal response; see the [Input and Output Capacitor Requirements](#) section for proper selection.

### 7.3.2 Global Undervoltage Lockout (UVLO)

The TPS7A10 uses two undervoltage lockout (UVLO) circuits: one on the BIAS pin and one on the IN pin to prevent the device from turning on before both  $V_{BIAS}$  and  $V_{IN}$  rise above their lockout voltages. The two UVLO signals are connected internally through an AND gate, as shown in [Figure 38](#). This internal connection allows the device to be turned off when either rail is below its lockout voltage.

**Figure 38. Global UVLO circuit**

### 7.3.3 Active Discharge

The active discharge option (P version only) have internal pulldown MOSFET that connects a 120- $\Omega$  resistor to ground when the device is disabled in order to actively discharge the output voltage. The active discharge circuit is activated by driving the enable pin to logic low to disable the device, or when the device is in thermal shutdown.

The discharge time after disabling the device depends on the output capacitance ( $C_{OUT}$ ) and the load resistance ( $R_L$ ) in parallel with the 120- $\Omega$  pulldown resistor. [Equation 1](#) calculates the discharge time constant:

$$\tau = \frac{120 \cdot R_L}{120 + R_L} \cdot C_{OUT} \quad (1)$$

Do not rely on the active discharge circuit for discharging a large amount of output capacitance after the input supply collapses because reverse current can possibly flow from the output to the input. This reverse current flow can cause damage to the device. Limit reverse current to no more than 5% of the device-rated current.

### 7.3.4 Enable

The enable pin for this device is active high. The output of the device is turned on when the enable pin voltage is greater than the EN pin logic high voltage, and the output of the device is turned off when the enable pin voltage is less than the EN pin voltage logic low .

The EN pin can be tied to the IN pin, the BIAS pin, or can be driven separately to enable and disable the device; however, connecting the EN pin to the IN pin is only acceptable if the  $V_{IN}$  voltage is greater than 0.9 V.

## Feature Description (continued)

### 7.3.5 Sequencing Requirement

The  $V_{IN}$ ,  $V_{BIAS}$ , and  $V_{EN}$  voltages can be sequenced in any order without causing damage to the device. The start up is always monotonic regardless of the sequencing order or the ramp rates of IN, BIAS, and EN pins. For optimum device performance, have  $V_{BIAS}$  present before enabling the device in any sequence order between  $V_{IN}$  and  $V_{EN}$  because the device internal circuitry is powered off the  $V_{BIAS}$ , refer to [Recommended Operating Conditions](#) for proper voltage ranges of  $V_{IN}$ ,  $V_{BIAS}$ , and  $V_{EN}$ .

### 7.3.6 Internal Foldback Current Limit

The internal foldback current limit circuit is used to protect the LDO against high-load current faults or shorting events. The foldback mechanism lowers the current limit as the output voltage decreases, and limits power dissipation during short-circuit events while still allowing for the device to operate at the rated output current; see [Figure 15](#).

For example, when  $V_{OUT}$  is 90% of  $V_{OUT(nom)}$ , the current limit is  $I_{CL}$  (typical); however, if  $V_{OUT}$  is forced to 0 V, the current limit is  $I_{SC}$  (typical).

In many LDOs, the foldback current limit can prevent start up into a constant-current load or a negatively-biased output. A *brick-wall* current limit is when there is an abrupt current stop after the current limit is reached. The foldback mechanism for this device goes into a *brick-wall* current limit when  $V_{OUT} > 500$  mV (typical), thus limiting current to  $I_{CL}$  (typical). When  $V_{OUT}$  is approximately 0 V, current is limited to  $I_{SC}$  (typical) in order to provide normal start up into a variety of loads.

Thermal shutdown can activate during a current-limit event because of the high power dissipation typically found in these conditions. To provide proper operation of the current limit, minimize the inductances to the input and load. Continuous operation in current limit is not recommended.

### 7.3.7 Thermal Shutdown

The device contains a thermal shutdown protection circuit to disable the device when the thermal junction temperature ( $T_J$ ) of the main pass-FET rises to the thermal shutdown temperature ( $T_{SD}$ ) for shutdown listed in the [Electrical Characteristics](#). Thermal shutdown hysteresis makes sure that the LDO resets again (turns on) when the temperature falls to the  $T_{SD}$  for reset.

The thermal time constant of the semiconductor die is fairly short, and thus the device may cycle on and off when thermal shutdown is reached until the power dissipation is reduced.

For reliable operation, limit the junction temperature to a maximum of 125°C. Operation above 125°C causes the device to exceed the operational specifications. Although the internal protection circuitry of the device is designed to protect against thermal overload conditions, this circuitry is not intended to replace proper heat sinking. Continuously running the device into thermal shutdown or above a junction temperature of 125°C reduces long-term reliability.

A fast start up when  $T_J > T_{SD}$  for reset causes the device thermal shutdown to assert at  $T_{SD}$  for reset, and prevents the device from turning on until the junction temperature is reduced below  $T_{SD}$  for reset.

## 7.4 Device Functional Modes

The device has the following modes of operation:

- Normal operation: The device regulates to the nominal output voltage.
- Dropout operation: The pass element operates as a resistor and the output voltage is set as  $V_{IN} - V_{DO}$ .
- Disabled: The output of the device is disabled and the discharge circuit is activated.

表 1 shows the conditions that lead to the different modes of operation.

**表 1. Device Functional Mode Comparison**

OPERATING MODE	PARAMETER				
	$V_{IN}$	$V_{BIAS}$	$V_{EN}$	$I_{OUT}$	$T_J$
Normal mode	$V_{IN} > V_{OUT(nom)} + V_{DO}$ and $V_{IN} > V_{IN(min)}$	$V_{BIAS} > V_{OUT} + 1.05\text{ V}$	$V_{EN} > V_{HI(EN)}$	$I_{OUT} < I_{CL}$	$T_J < T_{SD}$ for shutdown
Dropout mode	$V_{IN(min)} < V_{IN} < V_{OUT(nom)} + V_{DO}$	$V_{BIAS} < V_{OUT} + 1.05\text{ V}$	$V_{EN} > V_{HI(EN)}$	$I_{OUT} < I_{CL}$	$T_J < T_{SD}$ for shutdown
Disabled mode (any true condition disables the device)	$V_{IN} < V_{UVLO(IN)}$	$V_{BIAS} < V_{BIAS(UVLO)}$	$V_{EN} < V_{LO(EN)}$	—	$T_J > T_{SD}$ for shutdown

### 7.4.1 Normal Mode

The device regulates the output to the nominal output voltage when all normal mode conditions in 表 1 are met.

### 7.4.2 Dropout Mode

The device is not in regulation, and the output voltage tracks the input voltage minus the voltage drop across the pass element of the device. In this mode, PSRR and the noise performance of the device are significantly degraded.

### 7.4.3 Disable Mode

In this mode, the pass element is turned off, the internal circuits are shut down, and the output voltage is actively discharged to ground by an internal resistor.

## 8 Application and Implementation

---

### 注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

---

### 8.1 Application Information

Successfully implementing an LDO in an application depends on the application requirements. This section discusses key device features and the best implementation to achieve a reliable design.

#### 8.1.1 Recommended Capacitor Types

The device is designed to be stable using low equivalent series resistance (ESR) ceramic capacitors at the input, output, and BIAS pins. Multilayer ceramic capacitors are the industry standard for these types of applications, but must be used with good judgment. Ceramic capacitors that use X7R-, X5R-, and COG-rated dielectric materials provide relatively good capacitive stability across temperature. Avoid Y5V-rated capacitors because of large variations in capacitance.

Regardless of the ceramic capacitor type selected, ceramic capacitance varies with operating voltage and temperature. As a rule of thumb, assume that effective capacitance decreases by as much as 50%. The input, output, and bias capacitors recommended in the [Recommended Operating Conditions](#) table account for an effective capacitance of approximately 50% of the nominal value.

#### 8.1.2 Input and Output Capacitor Requirements

A minimum 2.2- $\mu$ F ceramic capacitor at the input is required for stability. A minimum 2.2- $\mu$ F ceramic capacitor with a maximum ESR value of less than 250 m $\Omega$  at the output is also required for stability. The input capacitor counteracts reactive input sources and improves transient response, input ripple, and PSRR. A higher-value input capacitor may be necessary if large, fast rise-time load or line transients are anticipated, or if the device is located several inches from the input power source. Dynamic performance of the device is improved with the use of an output capacitor larger than the minimum value specified in the [Recommended Operating Conditions](#) table.

Although a bias capacitor is not required, connect a 0.1- $\mu$ F ceramic capacitor from BIAS to GND for best analog design practice. This capacitor counteracts reactive bias sources if the source impedance is not sufficiently low.

Place the input, output, and bias capacitors as close as possible to the device to minimize traces parasitics.

## Application Information (continued)

### 8.1.3 Load Transient Response

The load-step transient response is the output voltage response by the LDO to a step in load current while output voltage regulation is maintained. See [Figure 9](#), [Figure 10](#), [Figure 11](#), and [Figure 12](#) for typical load transient response. There are two key transitions during a load transient response: the transition from a light to a heavy load, and the transition from a heavy to a light load. The regions in [Figure 39](#) are broken down as described in this section. Regions A, E, and H are where the output voltage is in steady-state operation.

**Figure 39. Load Transient Waveform**

During transitions from a light load to a heavy load:

- The initial voltage dip is a result of the depletion of the output capacitor charge and parasitic impedance to the output capacitor (region B)
- Recovery from the dip results from the LDO increasing the sourcing current, and leads to output voltage regulation (region C)

During transitions from a heavy load to a light load:

- The initial voltage rise results from the LDO sourcing a large current, and leads to the output capacitor charge to increase (region F)
- Recovery from the rise results from the LDO decreasing the sourcing current in combination with the load discharging the output capacitor (region G)

A larger output capacitance reduces the peaks during a load transient, but slows down the response time of the device. A larger dc load also reduces the peaks because the amplitude of the transition is lowered, and a higher current discharge path is provided for the output capacitor.

### 8.1.4 Dropout Voltage

Generally, dropout voltage refers to the minimum voltage difference between the input and output voltage ( $V_{DO} = V_{IN} - V_{OUT}$ ) that is required for regulation. When  $V_{IN} - V_{OUT}$  drops below the required  $V_{DO}$  for the given load current, the device functions as a resistive switch and does not regulate output voltage. Dropout voltage is proportional to the output current because the device is operating as a resistive switch.

Dropout voltage is affected by the drive strength of the pass-element gate. This drive strength is nonlinear with respect to  $V_{IN}$  on this device.

### 8.1.5 Behavior During Transition From Dropout Into Regulation

Some applications may have transients that place this device into dropout, especially when this device can be powered from a battery with relatively high ESR. The load transient saturates the output stage of the error amplifier when the pass element is driven fully on, making the pass element function like a resistor from  $V_{IN}$  to  $V_{OUT}$ . The error amplifier response time to this load transient is limited because the error amplifier must first recover from saturation and then place the pass element back into active mode. During this time,  $V_{OUT}$  overshoots because the pass element is functioning as a resistor from  $V_{IN}$  to  $V_{OUT}$ .

When  $V_{IN}$  ramps up slowly for start-up, the slow ramp-up voltage may place the device in dropout. As with many other LDOs, the output can overshoot on recovery from this condition. However, this condition is easily avoided through the use of the enable signal.

If operating under these conditions, apply a higher dc load or increase the output capacitance to reduce the overshoot. These solutions provide a path to dissipate the excess charge.

## Application Information (continued)

### 8.1.6 Undervoltage Lockout Circuit Operation

The  $V_{IN}$  UVLO circuit makes sure that the device remains disabled before the input supply reaches the minimum operational voltage range. The  $V_{IN}$  UVLO circuit also makes sure that the device shuts down when the input supply collapses. Similarly, the  $V_{BIAS}$  UVLO circuit makes sure that the device stays disabled before the bias supply reaches the minimum operational voltage range. The  $V_{BIAS}$  UVLO circuit also makes sure that the device shuts down when the bias supply collapses.

Figure 40 depicts the UVLO circuit response to various input or bias voltage events. This figure can be separated into the following parts:

- Region A: The device does not start until the input or bias voltage reaches the UVLO rising threshold.
- Region B: Normal operation, regulating device
- Region C: Brownout event above the UVLO falling threshold (UVLO rising threshold – UVLO hysteresis). The output may fall out of regulation, but the device is still enabled.
- Region D: Normal operation, regulating device
- Region E: Brownout event below the UVLO falling threshold. The device is disabled in most cases, and the output falls as a result of the load and active discharge circuit. The device is re-enabled when the UVLO rising threshold is reached, and a normal start-up follows.
- Region F: Normal operation followed by the input or bias falling to the UVLO falling threshold
- Region G: The device is disabled as the input or bias voltages fall below the UVLO falling threshold to 0 V. The output falls as a result of the load and active discharge circuit.

Figure 40. Typical  $V_{IN}$  or  $V_{BIAS}$  UVLO Circuit Operation

### 8.1.7 Power Dissipation ( $P_D$ )

Circuit reliability demands that proper consideration be given to device power dissipation, location of the circuit on the printed circuit board (PCB), and correct sizing of the thermal plane. The PCB area around the regulator must be as free as possible of other heat-generating devices that cause added thermal stresses.

Equation 2 calculates the maximum allowable power dissipation for the device in a given package:

$$P_{D-MAX} = [(T_J - T_A) / R_{\theta JA}] \quad (2)$$

Equation 3 represents the actual power being dissipated in the device:

$$P_D = (I_{GND} + I_{OUT}) \times (V_{IN} - V_{OUT}) \quad (3)$$

Power dissipation can be minimized, and thus greater efficiency achieved, by proper selection of the system voltage rails. Proper selection allows the minimum input-to-output voltage differential to be obtained. The low dropout of the TPS7A10 allows for maximum efficiency across a wide range of output voltages.

The main heat conduction path for the device depends on the ambient temperature and the thermal resistance across the various interfaces between the die junction and ambient air.

## Application Information (continued)

The maximum power dissipation determines the maximum allowable junction temperature ( $T_J$ ) for the device. According to 式 4, maximum power dissipation and junction temperature are most often related by the junction-to-ambient thermal resistance ( $R_{\theta JA}$ ) of the combined PCB and device package and the temperature of the ambient air ( $T_A$ ). The equation is rearranged in 式 5 for output current.

$$T_J = T_A + (R_{\theta JA} \times P_D) \tag{4}$$

$$I_{OUT} = (T_J - T_A) / [R_{\theta JA} \times (V_{IN} - V_{OUT})] \tag{5}$$

Unfortunately, this thermal resistance ( $R_{\theta JA}$ ) is highly dependent on the heat-spreading capability built into the particular PCB design, and therefore varies according to the total copper area, copper weight, and location of the planes. The  $R_{\theta JA}$  recorded in the *Thermal Information* table is determined by the JEDEC standard, PCB, and copper-spreading area, and is only used as a relative measure of package thermal performance.

### 8.1.7.1 Estimating Junction Temperature

The JEDEC standard recommends the use of psi ( $\Psi$ ) thermal metrics to estimate the junction temperatures of the LDO when in-circuit on a typical PCB board application. These metrics are not strictly speaking thermal resistances, but rather offer practical and relative means of estimating junction temperatures. These psi metrics are determined to be significantly independent of the copper-spreading area. The key thermal metrics ( $\Psi_{JT}$  and  $\Psi_{JB}$ ) are used in accordance with 式 6 and are given in the *Thermal Information* table.

$$\Psi_{JT} : T_J = T_T + \Psi_{JT} \times P_D \text{ and } \Psi_{JB} : T_J = T_B + \Psi_{JB} \times P_D$$

where:

- $P_D$  is the power dissipated as explained in 式 3
  - $T_T$  is the temperature at the center-top of the device package
  - $T_B$  is the PCB surface temperature measured 1 mm from the device package and centered on the package edge
- (6)

### 8.1.7.2 Recommended Area for Continuous Operation

The operational area of an LDO is limited by the dropout voltage, output current, junction temperature, and input voltage. The recommended area for continuous operation for a linear regulator is shown in 图 41, and can be separated into the following regions:

- Dropout voltage limits the minimum differential voltage between the input and the output ( $V_{IN} - V_{OUT}$ ) at a given output current level.
- The rated output currents limits the maximum recommended output current level. Exceeding this rating causes the device to fall out of specification.
- The rated junction temperature limits the maximum junction temperature of the device. Exceeding this rating causes the device to fall out of specification and reduces long-term reliability.
  - 式 5 provides the shape of the slope. The slope is nonlinear because the maximum rated junction temperature of the LDO is controlled by the power dissipation across the LDO, thus when  $V_{IN} - V_{OUT}$  increases, the output current must decrease.
- The rated input voltage range governs both the minimum and maximum of  $V_{IN} - V_{OUT}$ .

图 41. Region Description of Continuous Operation Regime

## 8.2 Typical Application

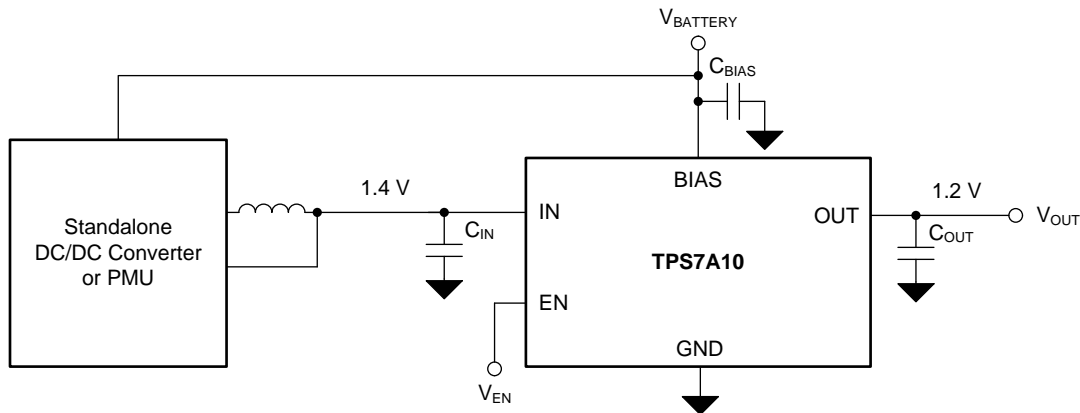

图 42. Supplying a Clean DC Voltage

### 8.2.1 Design Requirements

表 2 summarizes the design requirements for 图 42.

表 2. Design Parameters

DESIGN PARAMETER	EXAMPLE VALUE
$V_{IN}$	1.4 V
$V_{BIAS}$	2.7 V
$V_{OUT}$	1.2 V
$I_{OUT}$	10-mA typical, 300-mA peak
Maximum ambient temperature	65°C

### 8.2.2 Detailed Design Procedure

For this design example, the 1.2-V, fixed-version TPS7A1012 device is selected. Use a 4.7- $\mu$ F input capacitor to minimize transient currents drawn from the DC/DC converter. Use a 4.7- $\mu$ F output capacitor for optimized load transient response. The dropout voltage ( $V_{DO}$ ) is kept within the TPS7A10 dropout voltage specification for the 1.2-V output voltage option in order to keep the device in regulation under all load and temperature conditions for this design. The high-PSRR and low-noise measurements for this design example are given in the [Thermal Dissipation](#) section.

#### 8.2.2.1 Input Current

During normal operation, the input current to the LDO is approximately equal to the output current of the LDO. During startup, the input current is higher as a result of the inrush current charging the output capacitor. Use 式 7 to calculate the current through the input.

$$I_{OUT(t)} = \left[ \frac{C_{OUT} \times dV_{OUT}(t)}{dt} \right] + \left[ \frac{V_{OUT}(t)}{R_{LOAD}} \right]$$

where:

- $V_{OUT}(t)$  is the instantaneous output voltage of the turnon ramp
- $dV_{OUT}(t) / dt$  is the slope of the  $V_{OUT}$  ramp
- $R_{LOAD}$  is the resistive load impedance

(7)

### 8.2.2.2 Thermal Dissipation

The junction temperature can be determined using the junction-to-ambient thermal resistance ( $R_{\theta JA}$ ) and the total power dissipation ( $P_D$ ). Use 式 8 to calculate the power dissipation. As 式 9 shows, multiply  $P_D$  by  $R_{\theta JA}$  and add the ambient temperature ( $T_A$ ) to calculate the junction temperature ( $T_J$ ).

$$P_D = (I_{GND} + I_{OUT}) \times (V_{IN} - V_{OUT}) \tag{8}$$

$$T_J = R_{\theta JA} \times P_D + T_A \tag{9}$$

If the ( $T_{J(MAX)}$ ) value does not exceed 125°C, use 式 10 to calculate the maximum ambient temperature. 式 11 calculates the maximum ambient temperature with a value of 99.59°C.

$$T_{A(MAX)} = T_{J(MAX)} - R_{\theta JA} \times P_D \tag{10}$$

$$T_{A(MAX)} = 125^\circ\text{C} - 169.4 \times (1.4\text{ V} - 1.2\text{ V}) \times (0.3\text{ A}) = 114.84^\circ\text{C} \tag{11}$$

### 8.2.3 Application Curve

$$V_{IN} = 1.4\text{ V}, V_{OUT} = 1.2\text{ V}, V_{BIAS} = 2.7\text{ V},$$

$$C_{IN} = 4.7\ \mu\text{F}, C_{OUT} = 4.7\ \mu\text{F}, C_{BIAS} = 0.1\ \mu\text{F}$$

图 43. PSRR vs Frequency and  $I_{OUT}$

## 9 Power Supply Recommendations

This device is designed to operate from an input supply voltage range of 0.75 V to 3.3 V, and a bias supply voltage range of 1.7 V to 5.5 V. The input and bias supplies must be well regulated and free of spurious noise. To make sure that the output voltage is well regulated and dynamic performance is optimum, the input supply must be at least  $V_{OUT(nom)} + 0.5\text{ V}$  and  $V_{BIAS} = V_{OUT(nom)} + 1.05\text{ V}$ .

## 10 Layout

### 10.1 Layout Guidelines

For correct printed circuit board (PCB) layout, follow these guidelines:

- Place input, output, and bias capacitors as close to the device as possible.
- Use copper planes for device connections to optimize thermal performance.
- Place thermal vias around the device to distribute heat.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
