

TPS61175 ソフトスタート搭載、スイッチング周波数をプログラム可能な 3A、高電圧昇圧コンバータ

1 特長

- 入力電圧範囲: 2.9V~18V
- 3A、40V の内部スイッチ
- 高効率の電力変換: 最大 93%
- 外付け抵抗により周波数を設定: 200kHz~2.2MHz
- 外部同期スイッチング周波数
- 最大負荷までのソフトスタートをユーザー定義
- スキップ・スイッチング・サイクルによる軽負荷時の出力レギュレーション
- 14ピンHTSSOPパッケージ: PowerPAD™
- [WEBENCH Power Designer](#) で、TPS61175 を使用するカスタム設計を作成

2 アプリケーション

- 5Vから12V、24V の電力変換
- SEPIC およびフライバックのトポロジをサポート
- ADSL モデム
- TV チューナー

3 概要

TPS61175 はモノリシックなスイッチング・レギュレータで、3A、40V の電力スイッチが内蔵されています。このデバイスは、昇圧、SEPIC、フライバックなど、複数の標準的なスイッチング・レギュレータのトポロジに構成できます。このデバイスは広い入力電圧範囲に対応しているため、複数のセルによるバッテリーや、レギュレートされた 5V または 12V 電力レールからの入力電圧を使用するアプリケーションをサポートできます。

TPS61175 は、電流モードのパルス幅変調 (PWM) 制御を使用して、出力電圧をレギュレートします。PWM のスイッチング周波数は、外付け抵抗、または外部クロック信号により設定されます。ユーザーは、スイッチング周波数を 200kHz~2.2MHz の範囲でプログラムできます。

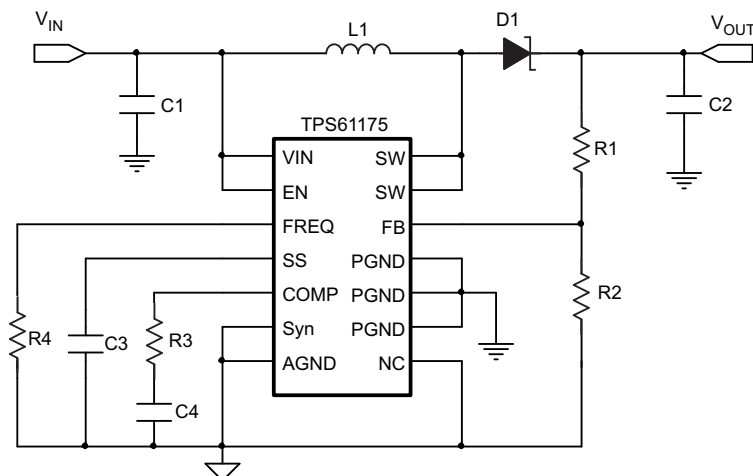

デバイスは、プログラム可能なソフト・スタート機能によって、スタートアップ時の突入電流を制限し、パルス単位の過電流制限やサーマル・シャットダウンなど他の保護機能も内蔵しています。TPS61175 は、PowerPAD 付きの 14 ピン HTSSOP パッケージで供給されます。

5 Pin Configuration and Functions

Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
AGND	7	I	Signal ground of the IC
COMP	8	O	Output of the internal transconductance error amplifier. An external RC network is connected to this pin to compensate the regulator.
EN	4	I	Enable pin. When the voltage of this pin falls below the enable threshold for more than 10ms, the IC turns off.
FB	9	I	Feedback pin for positive voltage regulation. Connect to the center tap of a resistor divider to program the output voltage.
FREQ	10	O	Switch frequency program pin. An external resistor is connected to this pin to set switch frequency. See application section for information on how to size the FREQ resistor.
NC	11	I	Reserved pin. Must connect this pin to ground.
PGND	12,13,14	I	Power ground of the IC. It is connected to the source of the PWM switch.
SS	5	O	Soft start programming pin. A capacitor between the SS pin and GND pin programs soft start timing. See Application and Implementation for information on how to size the SS capacitor.
SW	1,2	I	This is the switching node of the IC. Connect SW to the switched side of the inductor.
SYNC	6	I	Switch frequency synchronous pin. Customers can use an external signal to set the IC switch frequency between 200-kHz and 2.2-MHz. If not used, this pin should be tied to AGND as short as possible to avoid noise coupling.
Thermal Pad			The thermal pad should be soldered to the analog ground. If possible, use thermal via to connect to top and internal ground plane layers for ideal power dissipation.
VIN	3	I	The input supply pin for the IC. Connect VIN to a supply voltage between 2.9 V and 18 V. It is acceptable for the voltage on the pin to be different from the boost power stage input for applications requiring voltage beyond VIN range.

6 Specifications

6.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted)⁽¹⁾

	MIN	MAX	UNIT
Supply voltages on pin VIN ⁽²⁾	-0.3	20	V
Voltages on pins EN ⁽²⁾	-0.3	20	V
Voltage on pin FB, FREQ and COMP ⁽²⁾	-0.3	3	V
Voltage on pin SYNC, SS ⁽²⁾	-0.3	7	V
Voltage on pin SW ⁽²⁾	-0.3	40	V
Continuous power dissipation	See Thermal Information		
Operating junction temperature range	-40	150	°C
Storage temperature, T _{stg}	-65	150	°C

- (1) Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) All voltage values are with respect to network ground terminal.

6.2 ESD Ratings

			VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V _{IN}	Input voltage	2.9		18	V
V _O	Output voltage	V _{IN}		38	V
L	Inductor ⁽¹⁾	4.7		47	μH
f _{SW}	Switching frequency	200		2200	kHz
C _I	Input capacitor	4.7			μF
C _O	Output capacitor	4.7			μF
V _{SYN}	External switching frequency logic			5	V
T _A	Operating ambient temperature	-40		85	°C
T _J	Operating junction temperature	-40		125	°C

- (1) The inductance value depends on the switching frequency and end application. While larger values may be used, values between 4.7-μH and 47-μH have been successfully tested in various applications. Refer to [Selecting the Inductor](#) for detail.

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		TPS61175	UNIT
		PWP (HTSSOP)	
		14 PINS	
$R_{\theta JA}$	Junction-to-ambient thermal resistance	45.2	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	34.9	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	30.1	°C/W
ψ_{JT}	Junction-to-top characterization parameter	1.5	°C/W
ψ_{JB}	Junction-to-board characterization parameter	29.9	°C/W
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	5.8	°C/W

7 Detailed Description

7.1 Overview

The TPS61175 integrates a 40-V low-side switch FET for up to 38-V output. The device regulates the output with current mode pulse width modulation (PWM) control. The PWM control circuitry turns on the switch at the beginning of each switching cycle. The input voltage is applied across the inductor and stores the energy as inductor current ramps up. During this portion of the switching cycle, the load current is provided by the output capacitor. When the inductor current rises to the threshold set by the error amplifier output, the power switch turns off and the external Schottky diode is forward biased. The inductor transfers stored energy to replenish the output capacitor and supply the load current. This operation repeats each every switching cycle. As shown in [Functional Block Diagram](#), the duty cycle of the converter is determined by the PWM control comparator which compares the error amplifier output and the current signal. The switching frequency is programmed by the external resistor or synchronized to an external clock signal.

A ramp signal from the oscillator is added to the current ramp to provide slope compensation. Slope compensation is necessary to avoid subharmonic oscillation that is intrinsic to the current mode control at duty cycle higher than 50%. If the inductor value is lower than 4.7 μH , the slope compensation may not be adequate.

The feedback loop regulates the FB pin to a reference voltage through a transconductance error amplifier. The output of the error amplifier is connected to the COMP pin. An external RC compensation network is connected to the COMP pin to optimize the feedback loop for stability and transient response.

7.3 Feature Description

7.3.1 Switching Frequency

The switch frequency is set by a resistor (R4) connected to the FREQ pin of the TPS61175. Do not leave this pin open. A resistor must always be connected for proper operation. See 表 2 and 图 7 for resistor values and corresponding frequencies.

表 2. Switching Frequency vs External Resistor

R4 (kΩ)	f _{sw} (kHz)
443	240
256	400
176	600
80	1200
51	2000

图 7. Switching Frequency vs External Resistor

Alternatively, the TPS61175 switching frequency will synchronize to an external clock signal that is applied to the SYNC pin. The logic level of the external clock is shown in the specification table. The duty cycle of the clock is recommended in the range of 10% to 90%. The resistor also must be connected to the FREQ pin when IC is switching by the external clock. The external clock frequency must be within $\pm 20\%$ of the corresponding frequency set by the resistor. For example, if the corresponding frequency as set by a resistor on the FREQ pin is 1.2-MHz, the external clock signal should be in the range of 0.96 MHz to 1.44 MHz.

If the external clock signal is higher than the frequency per the resistor on the FREQ pin, the maximum duty cycle specification (D_{MAX}) should be lowered by 2%. For instance, if the resistor set value is 2.5 MHz, and the external clock is 3 MHz, D_{MAX} is 87% instead of 89%.

7.3.2 Soft Start

The TPS61175 has a built-in soft start circuit which significantly reduces the start-up current spike and output voltage overshoot. When the IC is enabled, an internal bias current (6 μ A typically) charges a capacitor (C3) on the SS pin. The voltage at the capacitor clamps the output of the internal error amplifier that determines the duty cycle of PWM control, thereby the input inrush current is eliminated. Once the capacitor reaches 1.8 V, the soft start cycle is completed and the soft-start voltage no longer clamps the error amplifier output. Refer to 图 16 for the soft start waveform. See 表 3 for C3 and corresponding soft start time. A 47-nF capacitor eliminates the output overshoot and reduces the peak inductor current for most applications.

表 3. Soft-Start Time vs C3

V _{IN} (V)	V _{OUT} (V)	LOAD (A)	C _{OUT} (μF)	f _{sw} (MHz)	C3 (nF)	t _{ss} (ms)	OVERSHOT (mV)
5	24	0.4	10	1.2	47	4	none
					10	0.8	210
12	35	0.6	10	2	100	6.5	none
					10	0.4	300

When the EN is pulled low for 10 ms, the IC enters shutdown and the SS capacitor discharges through a 5-kΩ resistor for the next soft start.

7.3.3 Overcurrent Protection

The TPS61175 has a cycle-by-cycle overcurrent limit protection that turns off the power switch once the inductor current reaches the overcurrent limit threshold. The PWM circuitry resets itself at the beginning of the next switch cycle. During an overcurrent event, the output voltage begins to droop as a function of the load on the output. When the FB voltage drops lower than 0.9 V, the switching frequency is automatically reduced to 1/4 of the set value. The switching frequency does not reset until the overcurrent condition is removed. This feature is disabled during soft start.

7.3.4 Enable and Thermal Shutdown

The TPS61175 enters shutdown when the EN voltage is less than 0.4 V for more than 10 ms. In shutdown, the input supply current for the device is less than 1.5 μA (maximum). The EN pin has an internal 800-kΩ pulldown resistor to disable the device when it is floating.

An internal thermal shutdown turns off the device when the typical junction temperature of 160°C is exceeded. The IC restarts when the junction temperature drops by 15°C.

7.3.5 Undervoltage Lockout (UVLO)

An undervoltage lockout circuit prevents mis-operation of the device at input voltages below 2.5-V (typical). When the input voltage is below the undervoltage threshold, the device remains off, and the internal switch FET is turned off. The UVLO threshold is set below minimum operating voltage of 2.9 V to avoid any transient VIN dip triggering the UVLO and causing the device to reset. For the input voltages between UVLO threshold and 2.9 V, the device attempts to operate, but the specifications are not ensured.

7.4 Device Functional Modes

7.4.1 Minimum ON Time and Pulse Skipping

Once the PWM switch is turned on, the TPS61175 has minimum ON pulse width of 60 ns. This sets the limit of the minimum duty cycle of the PWM switch, and it is independent of the set switching frequency. When operating conditions result in the TPS61175 having a minimum ON pulse width less than 60 ns, the IC enters pulse-skipping mode. In this mode, the device keeps the power switch off for several switching cycles to keep the output voltage from rising above the regulated voltage. This operation typically occurs in light load condition when the PWM operates in discontinuous mode. Pulse skipping increases the output voltage ripple, see [Figure 15](#).

When setting switching frequency higher than 1.2 MHz, TI recommends using an external synchronous clock as switching frequency to ensure pulse-skipping function works at light load. When using the internal switching frequency above 1.2 MHz, the pulse-skipping operation may not function. When the pulse-skipping function does not work at light load, the TPS61175 always runs in PWM mode with minimum ON pulse width. To keep the output voltage in regulation, a minimum load is required. The minimum load is related to the input voltage, output voltage, switching frequency, external inductor value and the maximum value of the minimum ON pulse width. Use [Equation 1](#) and [Equation 2](#) to calculate the required minimum load at the worst case. The maximum t_{\min_ON} could be estimated to 80 ns. C_{SW} is the total parasite capacitance at the switching node SW pin. It could be estimated to 100 pF.

$$I_{(\min_load)} = \frac{1}{2} \times \frac{\left(V_{IN} \times t_{\min_ON} + (V_{OUT} + V_D - V_{IN}) \times \sqrt{L \times C_{SW}} \right)^2 \times f_{SW}}{L \times (V_{OUT} + V_D - V_{IN})} \quad \text{When } V_{OUT} + V_D - V_{IN} < V_{IN} \quad (1)$$

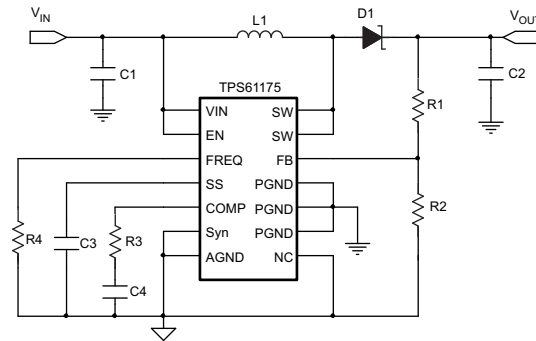

$$I_{(\min_load)} = \frac{1}{2} \times \frac{\left(V_{IN} \times t_{\min_ON} + V_{IN} \times \sqrt{L \times C_{SW}} \right)^2 \times f_{SW}}{L \times (V_{OUT} + V_D - V_{IN})} \quad \text{When } V_{OUT} + V_D - V_{IN} > V_{IN} \quad (2)$$

8 Application and Implementation

8.1 Application Information

The following section provides a step-by-step design approach for configuring the TPS61175 as a voltage regulating boost converter, as shown in [Figure 8](#). When configured as SEPIC or flyback converter, a different design approach is required.

8.2 Typical Application

PARAMETERS	VALUES
Input voltage	5 V
Output voltage	24 V
Operating frequency	1.2 MHz

8.2.2 Detailed Design Procedure

8.2.2.1 Custom Design with WEBENCH Tools

[Click here](#) to create a custom design using the TPS61175 device with the WEBENCH® Power Designer.

1. Start by entering your V_{IN} , V_{OUT} and I_{OUT} requirements.
2. Optimize your design for key parameters like efficiency, footprint and cost using the optimizer dial and compare this design with other possible solutions from Texas Instruments.
3. WEBENCH Power Designer provides you with a customized schematic along with a list of materials with real time pricing and component availability.
4. In most cases, you will also be able to:
 - Run electrical simulations to see important waveforms and circuit performance,
 - Run thermal simulations to understand the thermal performance of your board,
 - Export your customized schematic and layout into popular CAD formats,
 - Print PDF reports for the design, and share your design with colleagues.
5. Get more information about WEBENCH tools at www.ti.com/webench.

8.2.2.2 Determining the Duty Cycle

The TPS61175 has a maximum worst case duty cycle of 89% and a minimum on time of 60 ns. These two constraints place limitations on the operating frequency that can be used for a given input to output conversion ratio. The duty cycle at which the converter operates is dependent on the mode in which the converter is running. If the converter is running in discontinuous conduction mode (DCM), where the inductor current ramps to zero at the end of each cycle, the duty cycle varies with changes to the load much more than it does when running in continuous conduction mode (CCM). In continuous conduction mode, where the inductor maintains a dc current, the duty cycle is related primarily to the input and output voltages as computed in 式 3:

$$D = \frac{V_{OUT} + V_D - V_{IN}}{V_{OUT} + V_D} \quad (3)$$

In discontinuous mode the duty cycle is a function of the load, input and output voltages, inductance and switching frequency as computed in 式 4:

$$D = \frac{2 \times (V_{OUT} + V_D) \times I_{OUT} \times L \times f_{SW}}{V_{IN}^2} \quad (4)$$

All converters using a diode as the freewheeling or catch component have a load current level at which they transition from discontinuous conduction to continuous conduction. This is the point where the inductor current just falls to zero. At higher load currents, the inductor current does not fall to zero but remains flowing in a positive direction and assumes a trapezoidal wave shape as opposed to a triangular wave shape. This load boundary between discontinuous conduction and continuous conduction can be found for a set of converter parameters in 式 5:

$$I_{OUT(crit)} = \frac{(V_{OUT} + V_D - V_{IN}) \times V_{IN}^2}{2 \times (V_{OUT} + V_D)^2 \times f_{SW} \times L} \quad (5)$$

For loads higher than the result of 式 5, the duty cycle is given by 式 3 and for loads less than the results of 式 4, the duty cycle is given 式 5. For 式 3 through 式 5, the variable definitions are as follows:

- V_{OUT} is the output voltage of the converter in V
- V_D is the forward conduction voltage drop across the rectifier or catch diode in V
- V_{IN} is the input voltage to the converter in V
- I_{OUT} is the output current of the converter in A
- L is the inductor value in H
- f_{SW} is the switching frequency in Hz

Unless otherwise stated, the design equations that follow assume that the converter is running in continuous mode.

8.2.2.3 Selecting the Inductor

The selection of the inductor affects steady state operation as well as transient behavior and loop stability. These factors make it the most important component in power regulator design. There are three important inductor specifications, inductor value, DC resistance and saturation current. Considering inductor value alone is not enough.

Inductor values can have $\pm 20\%$ tolerance with no current bias. When the inductor current approaches saturation level, its inductance can fall to some percentage of its 0-A value depending on how the inductor vendor defines saturation current. For CCM operation, the rule of thumb is to choose the inductor so that its inductor ripple current (ΔI_L) is no more than a certain percentage (RPL% = 20–40%) of its average DC value ($I_{IN(AVG)} = I_{L(AVG)}$).

$$\Delta I_L = \frac{V_{IN} \times D}{L \times f_{SW}} = \frac{(V_{OUT} + V_D - V_{IN}) \times (1 - D)}{L \times f_{SW}} = \frac{1}{L \times f_{SW} \times \left(\frac{1}{V_{OUT} + V_D - V_{IN}} + \frac{1}{V_{IN}} \right)}$$

$$\leq \text{RPL}\% \times \frac{P_{OUT}}{V_{IN} \times \eta_{est}} \quad (6)$$

Rearranging and solving for L gives:

$$L \geq \frac{\eta_{\text{est}} \times V_{\text{IN}}}{f_{\text{SW}} \left(\frac{1}{V_{\text{OUT}} + V_{\text{D}}} - \frac{1}{V_{\text{IN}}} \right)} \times \text{RPL} \% P_{\text{OUT}} \quad (7)$$

Choosing the inductor ripple current to closer to 20% of the average inductor current results in a larger inductance value, maximizes the converter's potential output current and minimizes EMI. Choosing the inductor ripple current closer to 40% of $I_{\text{L(AVG)}}$ results in a smaller inductance value, and a physically smaller inductor, improves transient response but results in potentially higher EMI and lower efficiency if the DCR of the smaller packaged inductor is significantly higher. Using an inductor with a smaller inductance value than computed above may result in the converter operating in DCM. This reduces the maximum output current of the boost converter, causes larger input voltage and output ripple, and typically reduces efficiency. 表 5 lists the recommended inductor for the TPS61175.

表 5. Recommended Inductors for TPS61175

PART NUMBER	L (μH)	DCR MAX (m Ω)	SATURATION CURRENT (A)	SIZE (L x W x H mm)	VENDOR
D104C2	10	44	3.6	10.4 x 10.4 x 4.8	TOKO
VLF10040	15	42	3.1	10 x 9.7 x 4	TDK
CDRH105RNP	22	61	2.9	10.5 x 10.3 x 5.1	Sumida
MSS1038	15	50	3.8	10 x 10.2 x 3.8	Coilcraft

The device has built-in slope compensation to avoid subharmonic oscillation associated with current mode control. If the inductor value is lower than 4.7 μH , the slope compensation may not be adequate, and the loop can be unstable. Applications requiring inductors above 47 μH have not been evaluated. Therefore, the user is responsible for verifying operation if they select an inductor that is outside the 4.7- μH to 47- μH recommended range.

8.2.2.4 Computing the Maximum Output Current

The over-current limit for the integrated power FET limits the maximum input current and thus the maximum input power for a given input voltage. Maximum output power is less than maximum input power due to power conversion losses. Therefore, the current limit setting, input voltage, output voltage and efficiency can all change the maximum current output ($I_{\text{OUT(MAX)}}$). The current limit clamps the peak inductor current, therefore the ripple has to be subtracted to derive maximum DC current.

$$I_{\text{OUT(max)}} = \frac{V_{\text{IN(max)}} \times I_{\text{IN(max)}} \times \eta_{\text{est}}}{V_{\text{OUT}}} = \frac{V_{\text{IN(max)}} \times I_{\text{LIM}} \times (1 - \% \text{RPL} / 2) \times \eta_{\text{est}}}{V_{\text{OUT}}}$$

where

- I_{LIM} = overcurrent limit
 - η_{est} = efficiency estimate based on similar applications or computed above
- (8)

For instance, when $V_{\text{IN}} = 12 \text{ V}$ is boosted to $V_{\text{OUT}} = 24 \text{ V}$, the inductor is 10 μH , the Schottky forward voltage is 0.4 V, and the switching frequency is 1.2 MHz; then the maximum output current is 1.2 A in typical condition, assuming 90% efficiency and a %RPL = 20%.

8.2.2.5 Setting Output Voltage

To set the output voltage in either DCM or CCM, select the values of R1 and R2 according to 式 9:

$$V_{\text{out}} = 1.229 \text{ V} \times \left(\frac{R1}{R2} + 1 \right)$$

$$R1 = R2 \times \left(\frac{V_{\text{out}}}{1.229 \text{ V}} - 1 \right) \quad (9)$$

Considering the leakage current through the resistor divider and noise decoupling into FB pin, an optimum value for R2 is around 10 k. The output voltage tolerance depends on the V_{FB} accuracy and the tolerance of R1 and R2.

8.2.2.6 Setting the Switching Frequency

Choose the appropriate resistor from the resistance versus frequency table 表 2 or graph 图 7. A resistor must be placed from the FREQ pin to ground, even if an external oscillation is applied for synchronization.

Increasing switching frequency reduces the value of external capacitors and inductors, but also reduces the power conversion efficiency. The user should set the frequency for the minimum tolerable efficiency.

8.2.2.7 Setting the Soft-Start Time

Choose the appropriate capacitor from the soft-start table, 表 3. Increasing the soft-start time reduces the overshoot during start-up.

8.2.2.8 Selecting the Schottky Diode

The high switching frequency of the TPS61175 demands a high-speed rectification for optimum efficiency. Ensure that the diode's average and peak current rating exceed the average output current and peak inductor current. In addition, the diode's reverse breakdown voltage must exceed the switch FET rating voltage of 40 V. So, the VISHAY SS3P6L-E3/86A is recommended for TPS61175. The power dissipation of the diode's package must be larger than $I_{OUT(max)} \times V_D$.

8.2.2.9 Selecting the Input and Output Capacitors

The output capacitor is mainly selected to meet the requirements for the output ripple and load transient. Then the loop is compensated for the output capacitor selected. The output ripple voltage is related to the capacitor's capacitance and its equivalent series resistance (ESR). Assuming a capacitor with zero ESR, the minimum capacitance needed for a given ripple can be calculated using 式 10:

$$C_{out} = \frac{(V_{OUT} - V_{IN})I_{out}}{V_{OUT} \times F_s \times V_{ripple}} \quad (10)$$

where V_{ripple} = peak to peak output ripple. The additional output ripple component caused by ESR is calculated using:

$$V_{ripple_ESR} = I \times R_{ESR}$$

Due to its low ESR, V_{ripple_ESR} can be neglected for ceramic capacitors, but must be considered if tantalum or electrolytic capacitors are used.

The minimum ceramic output capacitance needed to meet a load transient requirement can be estimated using 式 11:

$$C_{OUT} = \frac{\Delta I_{TRAN}}{2 \times \pi \times f_{LOOP-BW} \times \Delta V_{TRAN}}$$

where

- ΔI_{TRAN} is the transient load current step
- ΔV_{TRAN} is the allowed voltage dip for the load current step
- $f_{LOOP-BW}$ is the control loop bandwidth (that is, the frequency where the control loop gain crosses zero). (11)

Care must be taken when evaluating a ceramic capacitor's derating under DC bias, aging and AC signal. For example, larger form factor capacitors (in 1206 size) have their self resonant frequencies in the range of the switching frequency. So the effective capacitance is significantly lower. The DC bias can also significantly reduce capacitance. Ceramic capacitors can lose as much as 50% of its capacitance at its rated voltage. Therefore, one must add margin on the voltage rating to ensure adequate capacitance at the required output voltage.

For a typical boost converter implementation, at least 4.7 μ F of ceramic input and output capacitance is recommended. Additional input and output capacitance may be required to meet ripple and/or transient requirements.

The popular vendors for high value ceramic capacitors are:

TDK (<http://www.component.tdk.com/components.php>)

Murata (<http://www.murata.com/cap/index.html>)

8.2.2.10 Compensating the Small Signal Control Loop

All continuous mode boost converters have a right half plane zero (f_{RHPZ}) due to the inductor being removed from the output during charging. In a traditional voltage mode controlled boost converter, the inductor and output capacitor form a small signal double pole. For a negative feedback system to be stable, the fed back signal must have a gain less than 1 before having 180 degrees of phase shift. With its double pole and RHPZ all providing phase shift, voltage mode boost converters are a challenge to compensate. In a converter with current mode control, there are essentially two loops, an inner current feedback loop created by the inductor current information sensed across R_{SENSE} (40mΩ) and the output voltage feedback loop. The inner current loop allows the switch, inductor and modulator to be lumped together into a small signal variable current source controlled by the error amplifier, as shown in [Figure 9](#).

Figure 9. Small Signal Model of a Current Mode Boost in CCM

The new power stage, including the slope compensation, small signal model becomes:

$$G_{PS}(s) = \frac{R_{OUT} \times (1-D)}{2 \times R_{SENSE}} \times \frac{\left(1 + \frac{s}{2 \times \pi \times f_{ESR}}\right) \left(1 - \frac{s}{2 \times \pi \times f_{RHPZ}}\right)}{1 + \frac{s}{2 \times \pi \times f_P}} \times He(s) \quad (12)$$

Where

$$f_P = \frac{2}{2 \pi \times R_O \times C_2} \quad (13)$$

$$f_{ESR} \approx \frac{1}{2 \pi \times R_{ESR} \times C_2} \quad (14)$$

$$f_{RHPZ} = \frac{R_O}{2 \pi \times L} \times \left(\frac{V_{IN}}{V_{OUT}}\right)^2 \quad (15)$$

And

$$He(s) = \frac{1}{1 + \frac{s \times \left[\left(1 + \frac{S_e}{S_n}\right) \times (1-D) - 0.5\right]}{f_{SW}} + \frac{s^2}{(\pi \times f_{SW})^2}} \quad (16)$$

$He(s)$ models the inductor current sampling effect as well as the slope compensation effect on the small signal response. Note that if $S_n > S_e$, for example, when L is smaller than recommended, the converter operates as a voltage mode converter and the above model no longer holds.

The slope compensation in TPS61175 is shown as follows:

$$S_n = \frac{V_{OUT} + V_D - V_{IN}}{L} \times R_{SENSE} \quad (17)$$

$$S_e = \frac{0.32 \text{ V} / R_4}{16 \times (1-D) \times 6 \text{ pF}} + \frac{0.5 \text{ } \mu\text{A}}{6 \text{ pF}}$$

Where R4 is the frequency setting resistor (18)

Figure 10 shows a Bode plot of a typical CCM boost converter power stage.

Figure 10. Bode Plot of Power Stage Gain and Phase

The TPS61175 COMP pin is the output of the internal trans-conductance amplifier. Equation 19 shows the equation for feedback resistor network and the error amplifier.

$$H_{EA} = G_{EA} \times R_{EA} \times \frac{R_2}{R_2 + R_1} \times \frac{1 + \frac{s}{2 \times \pi \times f_Z}}{\left(1 + \frac{s}{2 \times \pi \times f_{P1}}\right) \times \left(1 + \frac{s}{2 \times \pi \times f_{P2}}\right)}$$

where

- G_{EA} and R_{EA} are the amplifier's trans-conductance and output resistance located in the *Electrical Characteristics* table. (19)

$$f_{P1} = \frac{1}{2 \pi \times R_{EA} \times C_4} \quad (20)$$

$$f_{P2} = \frac{1}{2 \pi \times R_3 \times C_5} \text{ (optional)}$$

C_5 is optional and can be modeled as 10 pF stray capacitance. (21)

and

$$f_Z = \frac{1}{2 \pi \times R_3 \times C_4} \quad (22)$$

Figure 11 shows a typical bode plot for transfer function H(s).

Figure 11. Bode Plot of Feedback Resistors and Compensated Amplifier Gain and Phase

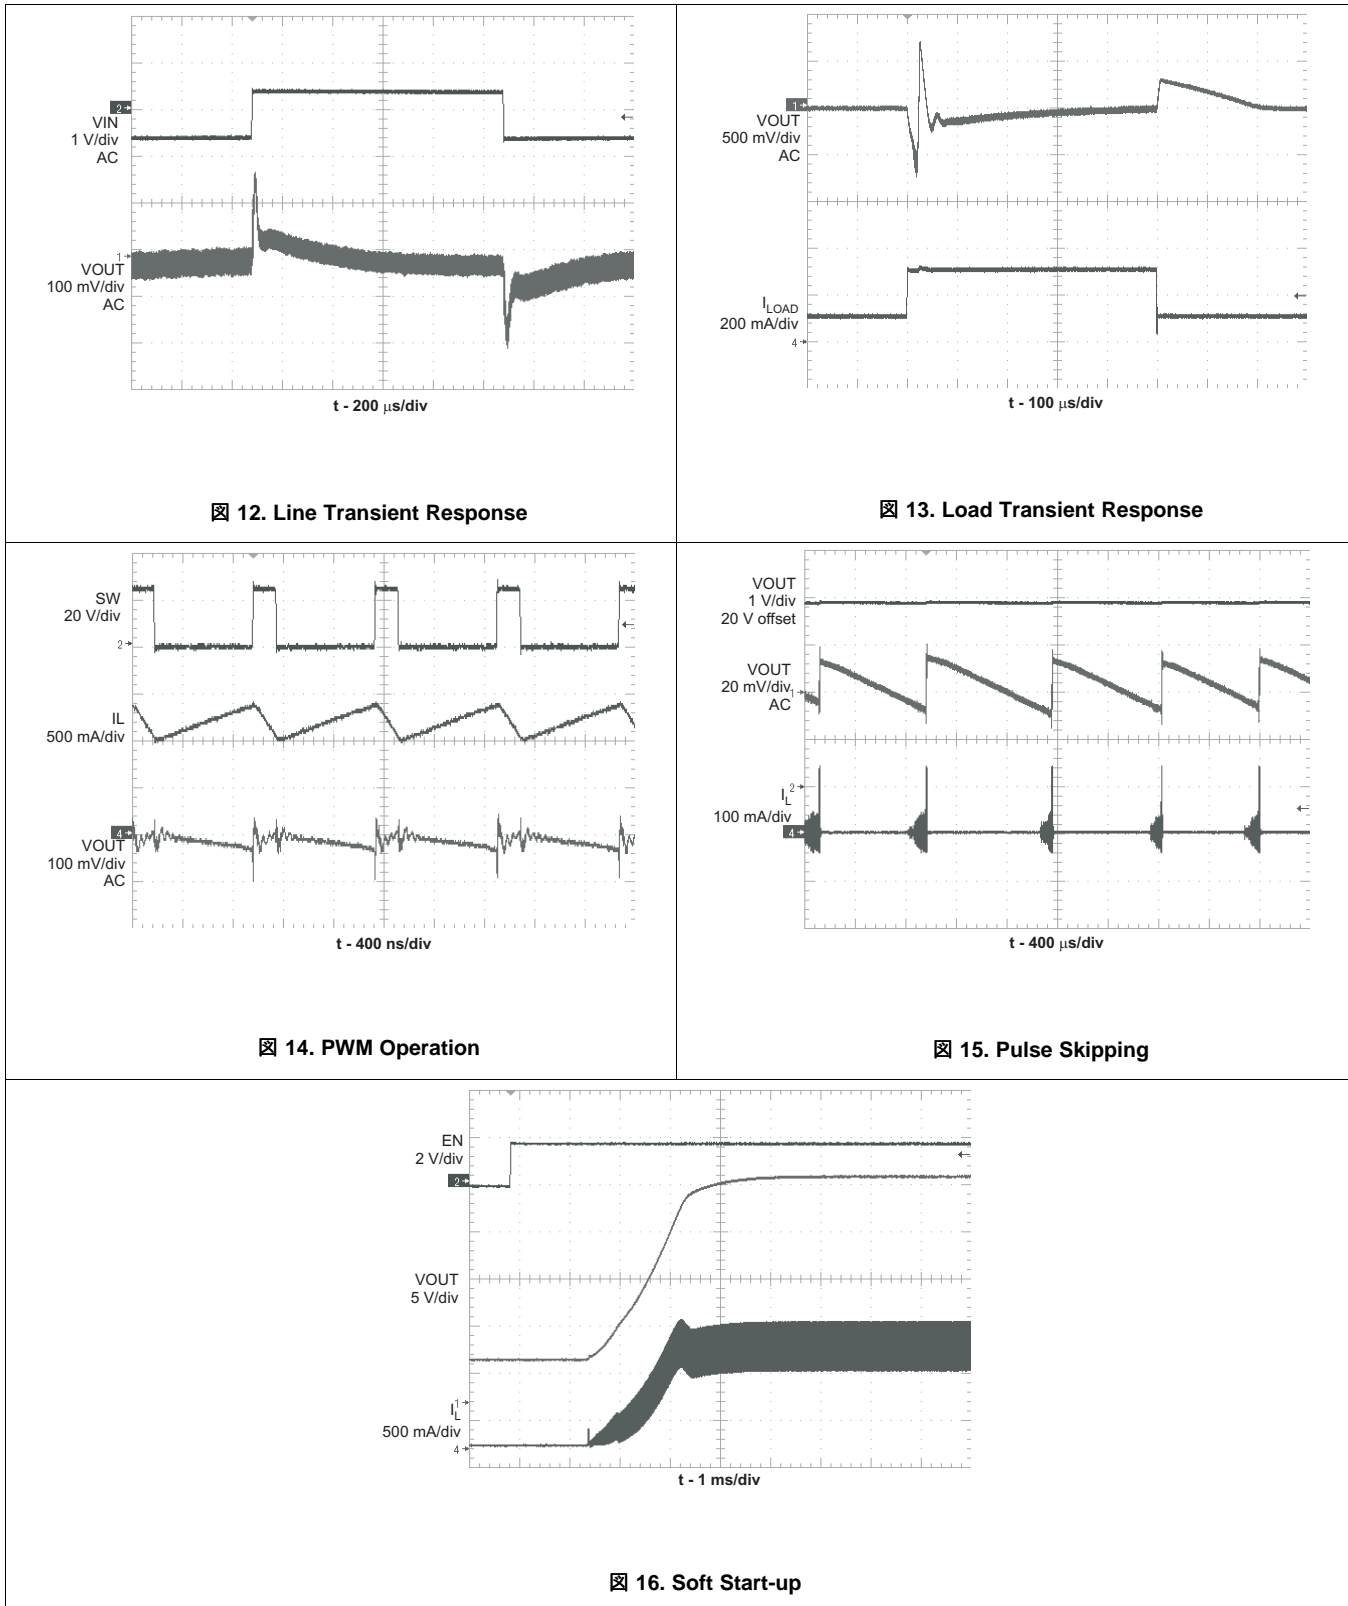

The next step is to choose the loop crossover frequency, f_c . The higher in frequency that the loop gain stays above zero before crossing over, the faster the loop response will be and therefore the lower the output voltage will droop during a step load. It is generally accepted that the loop gain cross over no higher than the lower of either 1/5 of the switching frequency, f_{SW} , or 1/3 of the RHPZ frequency, f_{RHPZ} . To approximate a single pole roll-off up to f_{p2} , select R3 so that the compensation gain, K_{COMP} , at f_c on Figure 11 is the reciprocal of the gain, K_{PW} , read at frequency f_c from the Figure 10 bode plot, or more simply:

$$K_{COMP}(f_c) = 20 \times \log(G_{EA} \times R3 \times R2 / (R2 + R1)) = 1 / K_{PW}(f_c)$$

This makes the total loop gain, $T(s) = G_{PS}(s) \times H_{EA}(s)$, zero at the f_c . Then, select C4 so that $f_z \cong f_c / 10$ and optional $f_{p2} > f_c \times 10$. Following this method should lead to a loop with a phase margin near 45 degrees. Lowering R3 while keeping $f_z \cong f_c / 10$ increases the phase margin and therefore increases the time it takes for the output voltage to settle following a step load.

In the TPS61175, if the FB pin voltage changes suddenly due to a load step on the output voltage, the error amplifier increases its transconductance for 8-ms in an effort to speed up the IC's transient response and reduce output voltage droop due to the load step. For example, if the FB voltage decreases 10 mV due to load change, the error amplifier increases its source current through COMP by 5 times; if FB voltage increases 11 mV, the sink current through COMP is increased to 3.5 times normal value. This feature often results in saw tooth ringing on the output voltage, shown as Figure 13. Designing the loop for greater than 45 degrees of phase margin and greater than 10-db gain margin minimizes the amplitude of this ringing. This feature is disabled during soft start.

8.2.3 Application Curves

9 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 2.9 V and 18 V. The input power supply's output current must be rated according to the supply voltage, output voltage and output current of the TPS61175.

10 Layout

10.1 Layout Guidelines

- As for all switching power supplies, especially those running at high switching frequency and high currents, layout is an important design step. If layout is not carefully done, the regulator could suffer from instability as well as noise problems. To maximize efficiency, switch rise and fall times are very fast. To prevent radiation of high frequency noise (for example, EMI), proper layout of the high frequency switching path is essential.
- Minimize the length and area of all traces connected to the SW pin and always use a ground plane under the switching regulator to minimize interplane coupling.
- The high current path including the switch, Schottky diode, and output capacitor, contains nanosecond rise and fall times and must be kept as short as possible.
- The input capacitor must not only be close to the VIN pin, but also to the GND pin in order to reduce the input supply ripple.

10.2 Layout Example

17. TPS61175 Layout

10.3 Thermal Considerations

Restrict the maximum IC junction temperature to 125°C under normal operating conditions. This restriction limits the power dissipation of the TPS61175. Calculate the maximum allowable dissipation, $P_{D(\text{maximum})}$, and keep the actual dissipation less than or equal to $P_{D(\text{maximum})}$. The maximum-power-dissipation limit is determined using [式 23](#):

$$P_{D(\text{max})} = \frac{125^{\circ}\text{C} - T_A}{R_{\theta JA}}$$

where

- T_A is the maximum ambient temperature for the application
- $R_{\theta JA}$ is the thermal resistance junction-to-ambient given in [Thermal Information](#). (23)

The TPS61175 comes in a thermally enhanced TSSOP package. This package includes a thermal pad that improves the thermal capabilities of the package. The $R_{\theta JA}$ of the TSSOP package greatly depends on the PCB layout and thermal pad connection. The thermal pad must be soldered to the analog ground on the PCB. Using thermal vias underneath the thermal pad.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TPS61175PWP	ACTIVE	HTSSOP	PWP	14	90	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 125	61175	Samples
TPS61175PWPR	ACTIVE	HTSSOP	PWP	14	2000	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 125	61175	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
