

# TCAN843-Q1 Automotive CAN FD Transceiver With Sleep Mode

## 1 Features

- AEC Q100 Qualified for automotive applications
- **Functional Safety-Capable** 
  - Documentation available to aid in functional safety system design
- Meets the requirements of ISO 11898-2:2024
- Wide input operational voltage range
- Supports classic CAN and CAN FD up to 5Mbps
- V<sub>IO</sub> level shifting supports: 3.3V to 5.5V
- Operating modes:
  - Normal mode
  - Silent mode
  - Standby mode
  - Low-power sleep mode
- High-voltage INH output for system power control
- Local wake-up support using the WAKE pin
- Defined behavior when unpowered
  - Bus and IO terminals are high impedance (no load to operating bus or application)
- Protection features:
  - ±40V CAN bus fault tolerant
  - Load dump support on V<sub>SUP</sub>
  - IEC ESD protection
  - Under-voltage protection
  - Thermal shutdown protection
  - TXD dominant state timeout (TXD DTO)
- Available in 14-pin leaded (SOT and SOIC) packages and leadless (VSON) package with wettable flanks for improved automated optical inspection (AOI) capability

## 2 Applications

- Body electronics and lighting
- Automotive gateway
- Advanced driver assistance systems (ADAS)
- Infotainment and cluster
- Hybrid, electric & powertrain systems
- Personal transport vehicles electric bike
- Industrial transportation

## 3 Description

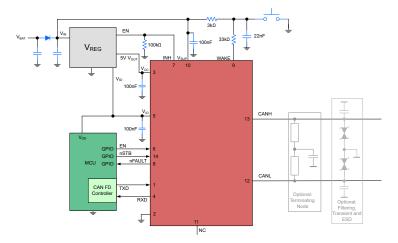

The TCAN843-Q1 is a high-speed Controller Area Network (CAN) transceiver that meets the physical layer requirements of the ISO 11898-2:2024 highspeed CAN specification. The device supports both classical CAN and CAN FD data rates up to 5 megabits per second (Mbps).

The TCAN843-Q1 allows for system-level reductions in battery current consumption by selectively enabling the various power supplies that can be present on a system via the INH output pin. This allows a low-current sleep state in which power is gated to all system components except for the TCAN843-Q1, while monitoring the CAN bus. When a wake-up event is detected, the TCAN843-Q1 initiates system start-up by driving INH high.

#### **Package Information**

PART NUMBER	PACKAGE <sup>(1)</sup>	PACKAGE SIZE <sup>(2)</sup>			
	DYY (SOT, 14)	4.2mm × 2mm			
TCAN843-Q1	D (SOIC, 14)	8.65mm × 6mm			
	DMT (VSON, 14)	4.5mm × 3mm			

- For more information, see Section 11.
- The package size (length × width) is a nominal value and includes pins, where applicable.

**Simplified Schematic**

# **4 Pin Configuration and Functions**

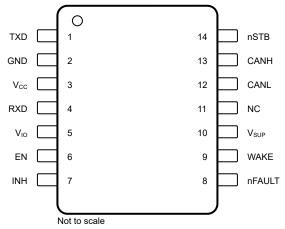

Figure 4-1. D and DYY Packages, 14 Pin (SOIC) and (SOT) (Top View)

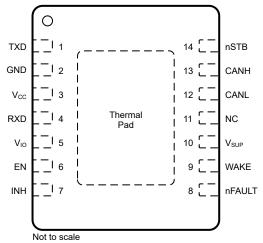

Figure 4-2. DMT Package, 14 Pin (VSON) (Top View)

PINS		TYPE (1)	DECORPTION
NAME	NO.	I TYPE (1)	DESCRIPTION
TXD	1	I	CAN transmit data input, integrated pull-up
GND	2	GND	Ground connection
V <sub>CC</sub>	3	Р	5V transceiver supply
RXD	4	0	CAN receive data output, tri-state when V <sub>IO</sub> < UV <sub>IO</sub>
V <sub>IO</sub>	5	Р	I/O supply voltage
EN	6	I	Enable input for mode control, integrated pull-down
INH	7	0	Inhibit pin to control system voltage regulators and supplies, high-voltage
nFAULT	8	0	Fault output, inverted logic
WAKE	9	I	Local WAKE input terminal, high voltage
V <sub>SUP</sub>	10	Р	High-voltage supply from battery
NC	11	NC	No connect, internally not connected
CANL	12	I/O	Low-level CAN bus input/output line
CANH	13	I/O	High-level CAN bus input/output line
nSTB	14	I	Standby mode control input, integrated pull-down
Thermal Pad		<u> </u>	Connect the thermal pad to the printed circuit board (PCB) ground plane for thermal relief

(1) I = input, O = output, P = power, GND = ground, NC = not connected

# **5 Specifications**

## 5.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)(1)

		MIN	MAX	UNIT
V <sub>SUP</sub>	Supply voltage	-0.3	40	V
V <sub>CC</sub>	Supply voltage	-0.3	6	V
V <sub>IO</sub>	Supply voltage I/O level shifter	-0.3	6	V
V <sub>BUS</sub>	CAN bus I/O voltage (CANH, CANL)	-40	40	V
V <sub>DIFF</sub>	CAN bus differential voltage (V <sub>DIFF</sub> = V <sub>CANH</sub> - V <sub>CANL</sub> )	-40	40	V
V <sub>WAKE</sub>	WAKE input voltage	-40	40 and V <sub>I</sub> ≤ V <sub>SUP</sub> +0.3	V
V <sub>INH</sub>	INH pin voltage	-0.3	40 and V <sub>O</sub> ≤ V <sub>SUP</sub> +0.3	V
V <sub>LOGIC</sub>	Logic pin voltage	-0.3	6	V
I <sub>O(LOGIC)</sub>	Logic pin output current		8	mA
I <sub>O(INH)</sub>	Inhibit pin output current		6	mA
I <sub>O(WAKE)</sub>	WAKE pin output current		3	mA
TJ	Junction temperature	-40	165	°C
T <sub>STG</sub>	Storage temperature	-65	150	°C

<sup>(1)</sup> Operation outside the Absolute Maximum Ratings may cause permanent device damage. Absolute maximum ratings do not imply functional operation of the device at these or any other conditions beyond those listed under Recommended Operating Conditions. If briefly operating outside the Recommended Operating Conditions but within the Absolute Maximum Ratings, the device may not sustain damage, but it may not be fully functional. Operating the device in this manner may affect device reliability, functionality, performance, and shorten the device lifetime.

# 5.2 ESD Ratings

				VALUE	UNIT
V <sub>ESD</sub> Electrostatic discharge	Human body model (HBM), per AEC	CANH and CANL with respect to GND	±8000	V	
	Q100-002 <sup>(1)</sup>	All pins except CANH and CANL with respect to GND	±2000	V	
		Charged device model (CDM), per AEC Q100-011	All pins	±500	V

<sup>(1)</sup> AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

## 5.3 ESD Ratings - IEC Specifications

					VALUE	UNIT
	,	System level electro-static	CANH, CANL, and V <sub>SUP</sub> to GND	IEC 62228-3: Unpowered contact	±8000	V
'	ESD	discharge (ESD)	WAKE pin to GND	discharge <sup>(1)</sup>	±6000	V

<sup>(1)</sup> According to IEC 62228-3 Integrated circuits - EMC evaluation of transceivers - Part 3: CAN transceivers.

## **5.4 Recommended Operating Conditions**

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM MAX	UNIT
V <sub>SUP</sub>	Supply voltage	4.5	28	V
V <sub>IO</sub>	I/O supply voltage	2.9	5.5	V
V <sub>CC</sub>	CAN transceiver supply voltage	4.5	5.5	V
I <sub>OH(DO)</sub>	Digital output high-level current	-2		mA
I <sub>OL(DO)</sub>	Digital output low-level current		2	mA
I <sub>O(INH)</sub>	Inhibit output current		2	mA

Submit Document Feedback

<sup>(2)</sup> The WAKE pin automatically configures itself based on the applied voltage to either an internal pull-up to 5V or pull-down to GND. A high-level input results in an internal pull-up to 5V and a low-level input results in an internal pull-down to GND. Current consumption is minimized overall when WAKE is connected to V<sub>CC</sub> or GND.

# 7 Detailed Description

## 7.1 Overview

The TCAN843-Q1 is a high-speed Controller Area Network (CAN) transceiver that meets the physical layer requirements of the ISO 11898-2:2024 high-speed CAN specification. The TCAN843-Q1 supports both classical CAN and CAN FD networks up to 5 megabits per second (Mbps).

The TCAN843-Q1 supports at least the following CAN and CAN FD standards:

- · Physical layer:
  - ISO 11898-2:2024 High-speed physical medium attachment (PMA) sublayer
  - SAE J2284-1 High Speed CAN (HSC) for Vehicle Applications at 125kbps
  - SAE J2284-2 High Speed CAN (HSC) for Vehicle Applications at 250kbps
  - SAE J2284-3 High Speed CAN (HSC) for Vehicle Applications at 500kbps
  - SAE J2284-4 High Speed CAN (HSC) for Vehicle Applications at 500kbps with CAN FD Data at 2Mbps
  - SAE J2284-5 High Speed CAN (HSC) for Vehicle Applications at 500kbps with CAN FD Data at 5Mbps
- Conformance test requirements
  - ISO 16845-2:2018 High-speed medium access unit Conformance test plan
  - IOPT.CAN Interoperability test specification for high-speed CAN transceiver or equivalent devices

The transceiver has three separate supply inputs,  $V_{SUP}$ ,  $V_{CC}$ , and  $V_{IO}$ . By using  $V_{IO}$ , the TCAN843-Q1 can interface directly to a 3.3V, or 5V controller without the need for a level shifter. The TCAN843-Q1 allows for system-level reductions in battery current consumption by selectively enabling the various power supplies that can be present in the system via the INH output pin. This enables a low-current sleep state in which power is gated to all system components except for the TCAN843-Q1, which remains in a low-power state while monitoring the CAN bus. When a wake-up pattern is detected on the bus or when a local wake up is requested via the WAKE input, the device initiates node start-up by driving INH high.

The TCAN843-Q1 includes many protection and diagnostic features including undervoltage detection, CAN bus fault detection, battery connection detection, thermal shutdown (TSD), driver dominant timeout (TXD DTO), and bus fault protection up to ±40V.

# 7.2 Functional Block Diagram

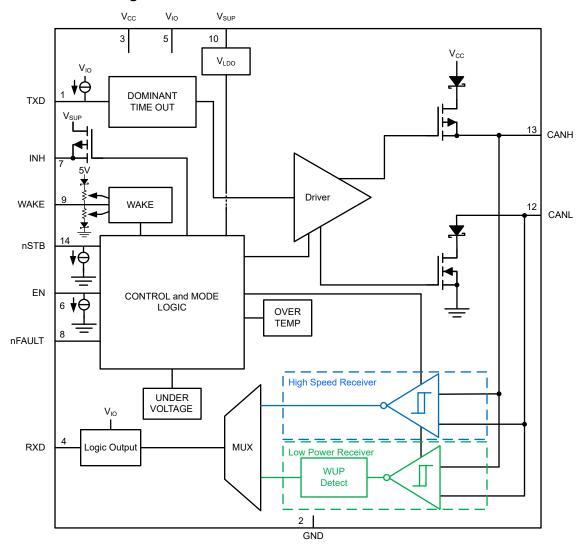

Figure 7-1. TCAN843-Q1 Functional Block Diagram

## 7.3 Feature Description

## 7.3.1 Supply Pins

The TCAN843-Q1 implements three independent supply inputs for regulating different portions of the device.

#### 7.3.1.1 V<sub>SUP</sub> Pin

This pin is connected to the battery supply. The pin provides the supply to the internal regulators that support the digital core and the low power CAN receiver.

#### 7.3.1.2 V<sub>CC</sub> Pin

This pin provides the 5V supply voltage for the CAN transceiver.

#### 7.3.1.3 V<sub>IO</sub> Pin

This pin provides the digital I/O voltage to match the CAN FD controller's I/O voltage. The pin supports I/O voltages from 2.9V to 5.5V providing a wide range of controller support.

## 7.3.2 Digital Inputs and Outputs

#### 7.3.2.1 TXD Pin

TXD is a logic-level input signal, referenced to  $V_{IO}$ , from a CAN FD controller to the TCAN843-Q1. TXD is biased to the  $V_{IO}$  level to force a recessive input in case the pin floats.

#### 7.3.2.2 RXD Pin

RXD is a logic-level signal output, referenced to  $V_{IO}$ , from the TCAN843-Q1 to a CAN FD controller. The RXD pin is driven to the  $V_{IO}$  level as logic-high outputs once a valid  $V_{IO}$  is present.

When a power-on or wake-up event takes place, the RXD pin is pulled low.

#### 7.3.2.3 nFAULT Pin

nFAULT is a logic-level output signal, referenced to  $V_{IO}$ , from the TCAN843-Q1 to a CAN FD controller. The nFAULT output is driven to the  $V_{IO}$  level as logic-high output.

The nFAULT output is used to transmit the TCAN843-Q1 status indicator flags to the CAN FD controller. Please see Table 7-1 for the specific fault scenarios that are indicated externally via the nFAULT pin. The TCAN843-Q1 drives the nFAULT pin high when  $V_{IO}$  is present and in the Sleep mode to conserve power because there are no fault scenarios that are indicated externally in Sleep mode.

#### 7.3.2.4 EN Pin

EN is a logic-level input signal, referenced to  $V_{IO}$ , from a CAN FD controller to the TCAN843-Q1. The EN input pin is for mode selection in conjunction with the nSTB pin. EN is internally pulled low to prevent excessive system power and false wake-up events.

#### 7.3.2.5 nSTB Pin

nSTB is a logic-level input signal, referenced to  $V_{IO}$ , from a CAN FD controller to the TCAN843-Q1. The nSTB input pin is for mode selection in conjunction with the EN pin. nSTB is internally pulled low to prevent excessive system power and false wake-up events.

## 7.3.2.6 NC Pin

NC pin is not connected internally, leave this pin floating or connect the pin to GND

#### 7.3.3 GND

GND is the ground pin of the transceiver, the pin must be connected to the PCB ground.

## 7.3.4 INH Pin

The INH pin is a high-voltage output. The pin can be used to control external regulators. These regulators are typically used to support the microprocessor and  $V_{IO}$  pin. The INH function is on in all modes except for sleep mod. In sleep mode, the INH pin is turned off, going into a high-impedance state. This allows the node to be

placed into the lowest power state while in sleep mode. A  $100k\Omega$  load can be added to the INH output for a fast transition time from the driven high state to the low state and to force the pin low when left floating.

This terminal must be considered a high-voltage logic terminal, not a power output. The INH pin must be used to drive the EN terminal of the system power management device, and must not be used as a switch for the power management supply. This terminal is not reverse-battery protected; thus, must not be connected outside the system module.

#### 7.3.5 WAKE Pin

The WAKE pin is a high-voltage reverse-blocked input used for the local wake-up (LWU) function. The WAKE pin is bi-directional edge-triggered and recognizes a local wake-up (LWU) on either a rising or falling edge of WAKE pin transition. The LWU function is explained further in the Local Wake-Up (LWU) via WAKE Input Terminal section.

#### 7.3.6 CAN Bus Pins

These are the CAN high and CAN low, CANH and CANL, differential bus pins. These pins are internally connected to the CAN transceiver and the low-voltage wake receiver.

#### 7.3.7 Faults

#### 7.3.7.1 Internal and External Fault Indicators

The following device status indicator flags are implemented to allow for the MCU to determine the status of the device and the system. In addition to faults, the nFAULT terminal also signals wake-up requests and a "cold" power-up sequence on the  $V_{SUP}$  battery terminal so the system can do any diagnostics or cold booting sequence necessary. The RXD terminal indicates wake-up request and the faults are multiplexed (ORed) to the nFAULT output.

Submit Document Feedback

## Table 7-1. TCAN843-Q1 Transceiver Status Indicator

EVENT	FLAG NAME	CAUSE	INDICATORS(1)	FLAG IS CLEARED	COMMENT
Power-up	PWRON	Power up on $V_{SUP}$ and any return of $V_{SUP}$ after the battery supply has been below $UV_{SUP}$	nFAULT = low upon entering silent mode from standby or sleep mode	After a transition to normal mode	A cold start condition generates a local wake-up WAKERQ, WAKESR and a PWRON flag.
Wake-up Request	WAKERQ <sup>(2)</sup>		nFAULT = RXD = low after wake-up upon entering standby mode	After a transition to normal mode or $V_{CC} < UV_{CC(F)}$ or $V_{IO} < UV_{IO(F)}$ for $t \ge t_{UV}$	Wake-up request can only be set from standby, go-to-sleep, or sleep mode. Resets expired timers for UV <sub>VCC</sub> or UV <sub>VIO</sub> in sleep mode.
Wake-up Source Recognition <sup>(3)</sup>	WAKESR	Wake-up event on CAN bus, state transition on WAKE pin, or initial power up	Available upon entering normal mode <sup>(4)</sup> nFAULT = low indicates a local wake-up event from the WAKE pin nFAULT = high indicates a remote wake-up event from the CAN bus	After four recessive-to-dominant edges on TXD in normal mode, (5) leaving normal mode, or $V_{CC} < UV_{CC(F)}$ or $V_{IO} < UV_{IO(F)}$ for $t \ge t_{UV}$	A cold start condition generates a local wake-up WAKERQ, WAKESR and a PWRON flag.
	UV <sub>CC</sub>	V <sub>CC</sub> < UV <sub>CC(F)</sub>	Not externally indicated	V <sub>CC</sub> > UV <sub>CC(R),</sub> or a wake-up request occurs	
Undervoltage	UV <sub>IO</sub>	V <sub>IO</sub> < UV <sub>IO(F)</sub>	Not externally indicated	V <sub>IO</sub> > UV <sub>IO(R),</sub> or a wake-up request occurs	
	UV <sub>SUP</sub>	V <sub>SUP</sub> < UV <sub>SUP(F)</sub>	Not externally indicated	V <sub>SUP</sub> > UV <sub>SUP(R)</sub>	A V <sub>SUP</sub> undervoltage event generates a cold start condition once V <sub>SUP</sub> > UV <sub>SUP(R)</sub> .
Local Faults	TXDDTO	TXD dominant time out, dominant (low) signal for t ≥ t <sub>TXDDTO</sub>	nFAULT = low upon entering silent mode from normal mode	RXD = low and TXD = high for 4µs, or a mode transition into normal, standby, go-to-sleep,	CAN driver remains disabled until the <i>TXDDTO</i> is cleared. CAN receiver remains active during the <i>TXDDTO</i> fault.
	TXDRXD	TXD and RXD pins are shorted together for t ≥ t <sub>TXDDTO</sub>		or sleep modes	CAN driver remains disabled until the <i>TXDRXD</i> is cleared. CAN receiver remains active during the <i>TXDRXD</i> fault. <i>TXDRXD</i> is detected while TXD = RXD = low.
	CANDOM	CAN bus dominant fault, when dominant bus signal received for t ≥ t <sub>BUSDOM</sub>		RXD = high, or a transition into normal, standby, go-to-sleep, or sleep modes	CAN driver remains enabled during <i>CANDOM</i> fault.
	TSD	Thermal shutdown, T <sub>J</sub> ≥ T <sub>SDR</sub>		$T_J$ < $T_{SDF}$ and RXD = low and TXD = high for $4\mu s$ , or transition into normal, standby, go-to-sleep, or sleep modes	CAN driver remains disabled until the <i>TSD</i> event is cleared. CAN receiver remains active during the <i>TSD</i> fault.

- (1) V<sub>IO</sub> and V<sub>SUP</sub> are present
- (2) Transitions to go-to-sleep mode is blocked until WAKERQ flag is cleared
- (3) Wake-up source recognition reflects the first wake up source. If additional wake-up events occur the source still indicates the original wake-up source
- (4) Indicator is only available in normal mode until the flag is cleared
- (5) A minimum of 4µs between recessive-to-dominant edges is required to clear the WAKESR flag

## 7.3.7.1.1 Power-Up (PWRON Flag)

This is an internal and external flag that can be used to control the power-up sequence of the system. When a new battery connection to the transceiver is made the PWRON flag is set signifying a cold start condition. The TCAN843-Q1 treats any undervoltage conditions on the  $V_{SUP}$ ,  $V_{SUP} < UV_{SUP(F)}$ , as a cold start. Therefore, when the  $V_{SUP} > UV_{SUP(R)}$  condition is met the TCAN843-Q1 sets the PWRON flag which can be used by the system to enter a routine that is only called upon in cold start situations. The PWRON flag is indicated by nFAULT driven low after entering silent mode from either standby mode or sleep mode. This flag is cleared after a transition to normal mode.

Copyright © 2025 Texas Instruments Incorporated

Submit Document Feedback

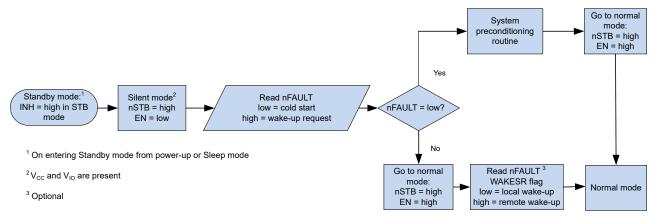

Figure 7-2. Distinguishing between PWRON and Wake Request by Entering Silent Mode

#### 7.3.7.1.2 Wake-Up Request (WAKERQ Flag)

This is an internal and external flag that can be set in standby, go-to-sleep, or sleep mode. This flag is set when either a valid local wake-up (LWU) request occurs, or a valid remote wake request occurs, or on power up on  $V_{SUP}$ . The setting of this flag clears the  $t_{UV}$  timer for the  $UV_{CC}$  or  $UV_{IO}$  fault detection. This flag is cleared upon entering normal mode or during an undervoltage event on  $V_{CC}$  or  $V_{IO}$ .

## 7.3.7.1.3 Undervoltage Faults

The TCAN843-Q1 device implements undervoltage detection circuits on all supply terminals:  $V_{SUP}$ ,  $V_{CC}$ , and  $V_{IO}$ . The undervoltage flags are internal indicator flags and are not indicated on the nFAULT output pin.

#### 7.3.7.1.3.1 Undervoltage on V<sub>SUP</sub>

 $UV_{SUP}$  is set when the voltage on  $V_{SUP}$  drops below the undervoltage detection voltage threshold,  $UV_{SUP}$ . The PWRON, WAKERQ, and WAKESR flags are set once  $V_{SUP} > UV_{SUP(R)}$ .

#### 7.3.7.1.3.2 Undervoltage on V<sub>CC</sub>

 $UV_{CC}$  is set when the voltage on  $V_{CC}$  drops below the undervoltage detection voltage threshold,  $UV_{CC}$ , for longer than the  $t_{LIV}$  undervoltage filter time.

#### 7.3.7.1.3.3 Undervoltage on V<sub>IO</sub>

 $UV_{IO}$  is set when the voltage on  $V_{IO}$  drops below the undervoltage detection voltage threshold,  $UV_{IO}$ , for longer than the  $t_{LIV}$  undervoltage filter time.

#### 7.3.7.1.4 TXD Dominant State Timeout (TXDDTO Flag)

TXDDTO is an external flag that is set if the TXD pin is held dominant for  $t > t_{TXDDTO}$ . If a TXD DTO condition exists, the nFAULT pin is driven low upon entering silent mode from normal mode. The TXDDTO flag is cleared when TXD = H and RXD = L in normal mode or upon a transition into normal, standby, go-to-sleep, or sleep modes.

#### 7.3.7.1.5 TXD Shorted to RXD Fault (TXDRXD Flag)

TXDRXD is an external flag that is set if the transceiver detects that the TXD and RXD lines have been shorted together. The device requires a dominant signal for  $t \ge t_{TXDDTO}$  for this fault to be detected. If a TXDRXD condition exists, the nFAULT pin is driven low upon entering silent mode from normal mode and the CAN bus driver is disabled until the TXDRXD fault is cleared. The TXDRXD flag is cleared on the next dominant-to-recessive transition with TXD high and RXD low or upon a transition into normal, standby, go-to-sleep, or sleep modes.

## 7.3.7.1.6 CAN Bus Dominant Fault (CANDOM Flag)

CANDOM is an external flag that is set if the CAN bus is stuck dominant state for  $t > t_{BUSDOM}$ . If a CANDOM condition exists, the nFAULT pin is driven low upon entering silent mode from normal mode. The CANDOM

flag is cleared on the next dominant-to-recessive transition on RXD or upon a transition into normal, standby, go-to-sleep, or sleep modes.

#### 7.3.8 Local Faults

Local faults are detected in both normal mode and silent mode, but are only indicated via the nFAULT pin when the TCAN843-Q1 transitions from normal mode to silent mode. All other mode transitions clear the local fault flag indicators.

#### 7.3.8.1 TXD Dominant Timeout (TXD DTO)

While the CAN driver is in active mode a TXD dominant state timeout circuit prevents the local node from blocking network communication in event of a hardware or software failure where TXD is held dominant longer than the timeout period,  $t > t_{TXDDTO}$ . The TXD dominant state timeout circuit is triggered by a falling edge on the TXD pin. If no rising edge is seen before on TXD before  $t > t_{TXDDTO}$  than the CAN driver is disabled releasing the bus lines to the recessive level. This keeps the bus free for communication between other nodes on the network.

The CAN driver is activated again once there is a mode transition, or once TXD is high while RXD is low. During a *TXDDTO* fault the high-speed receiver remains active and the RXD output pin mirrors the CAN bus.

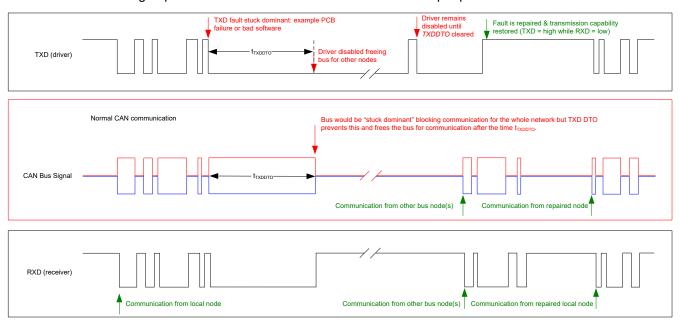

Figure 7-3. Timing Diagram for TXD DTO

The minimum dominant TXD time allowed by the dominant state timeout circuit limits the minimum possible transmitted data rate of the transceiver. The CAN protocol allows a maximum of eleven successive dominant bits to be transmitted in the worst case, where five successive dominant bits are followed immediately by an error frame. The minimum transmitted data rate is calculated using the minimum  $t_{TXDDTO}$  time in Equation 1.

Minimum Data Rate = 11 bits / 
$$t_{TXDDTO}$$
 = 11 bits / 1.2ms = 9.2kbps (1)

#### 7.3.8.2 Thermal Shutdown (TSD)

If the junction temperature of the TCAN843-Q1 exceeds the thermal shutdown threshold the device turns off the CAN driver circuits thus blocking the TXD to bus transmission path. The CAN bus terminals are biased to recessive level during a TSD fault and the receiver to RXD path remains operational. The TSD fault condition is cleared when the junction temperature,  $T_J$ , of the device drops below the thermal shutdown release temperature,  $T_{SDF}$ , of the device and either a mode change into Normal, Standby, or Sleep mode occurs or TXD = H while TXD = L. If the fault condition that caused the TSD fault is still present, the temperature can rise again, and the device enters thermal shutdown again. Prolonged operation with TSD fault conditions can affect device reliability.

The TSD circuit includes hysteresis to avoid any oscillation of the driver output. During the fault the *TSD* fault condition is indicated to the CAN FD controller via the nFAULT terminal in Silent mode.

#### 7.3.8.3 Undervoltage Lockout (UVLO)

The supply terminals,  $V_{SUP}$ ,  $V_{IO}$  and  $V_{CC}$ , are monitored for undervoltage events. If an undervoltage event occurs the TCAN843-Q1 enters a protected state where the bus pins present no load to the CAN bus. This protects the CAN bus and system from unwanted glitches and excessive current draw that can impact communication between other CAN nodes on the CAN bus.

If an undervoltage event occurs on  $V_{\text{SUP}}$  in any mode, the TCAN843-Q1 CAN transceiver enters the CAN off state.

If an undervoltage event occurs on  $V_{CC,}$  the TCAN843-Q1 remains in normal or silent mode but the CAN transceiver changes to the CAN passive state. During a  $UV_{CC}$  event, RXD remains high as long as  $V_{IO}$  is present and there is no wake-up event being signaled on RXD. The CAN bus is weakly biased to GND. If the undervoltage event persists longer than  $t_{IJV}$ , the TCAN843-Q1 transitions to sleep mode.

If an undervoltage event occurs on the  $V_{IO}$ , the TCAN843-Q1 transitions to standby mode. If the undervoltage event persists longer than  $t_{UV}$ , the TCAN843-Q1 transitions to sleep mode.

Once an undervoltage condition is cleared and the supplies have returned to valid levels, the device typically needs  $t_{MODE1}$  to transition to normal operation.

#### 7.3.8.4 Unpowered Devices

The device is designed to be high-impedance to the CAN bus if the device is unpowered. The CANH and CANL pins have low leakage currents when the device is unpowered, so no load is present on the bus. This is critical if some nodes of the network are unpowered while the rest of the of network remains in operation.

The logic terminals also have low leakage currents when the device is unpowered, so there is not a load down other circuits which can remain powered.

## 7.3.8.5 Floating Terminals

The TCAN843-Q1 has internal pull-ups and pull-downs on critical pins to make sure a known operating behavior if the pins are left floating. See Table 7-2 for the pin fail-safe biasing protection description.

PIN	FAIL-SAFE PROTECTION	VALUE	COMMENT	
TXD	Recessive level		Weak pull-up to V <sub>IO</sub>	
EN	Low-power mode	60kΩ	Weak pull-down to GND	
nSTB	Low-power mode		Weak pull-down to GND	

Table 7-2. Pin Fail-safe Biasing

This internal bias must not be relied upon by design but rather a fail-safe option. Special care needs to be taken when the transceiver is used with a CAN FD controller that has open-drain outputs. The TCAN843-Q1 implements a weak internal pull-up resistor on the TXD pin. The bit timing requirements for CAN FD data rates require special consideration and the pull-up strength must be considered carefully when using open-drain outputs. An adequate external pull-up resistor must be used to make sure the TXD output of the CAN FD controller maintains proper bit timing input to the CAN device.

#### 7.3.8.6 CAN Bus Short-Circuit Current Limiting

The TCAN843-Q1 has several protection features that limit the short-circuit current when a CAN bus line is shorted. These include CAN driver current limiting in the dominant and recessive states and TXD dominant state timeout which prevents permanently having the higher short-circuit current of a dominant state in case of a system fault.

During CAN communication the bus switches between the dominant and recessive states, thus the short-circuit current can be viewed either as the current during each bus state or as an average current. The average short-circuit current must be used when considering system power for the termination resistors and common-mode

Product Folder Links: TCAN843-Q1

22

choke. The percentage of time that the driver can be dominant is limited by the TXD dominant state timeout and the CAN protocol which has forced state changes and recessive bits such as bit stuffing, control fields, and interframe spacing. These makes sure there is a minimum recessive time on the bus even if the data field contains a high percentage of dominant bits.

The short-circuit current of the bus depends on the ratio of recessive to dominant bits and the respective short-circuit currents. The average short-circuit current can be calculated using Equation 2.

$$I_{OS(AVG)}$$
 = %Transmit × [(%REC\_Bits ×  $I_{OS(SS)}$  REC) + (%DOM\_Bits ×  $I_{OS(SS)}$  DOM)] + [%Receive ×  $I_{OS(SS)}$  REC] (2)

#### Where:

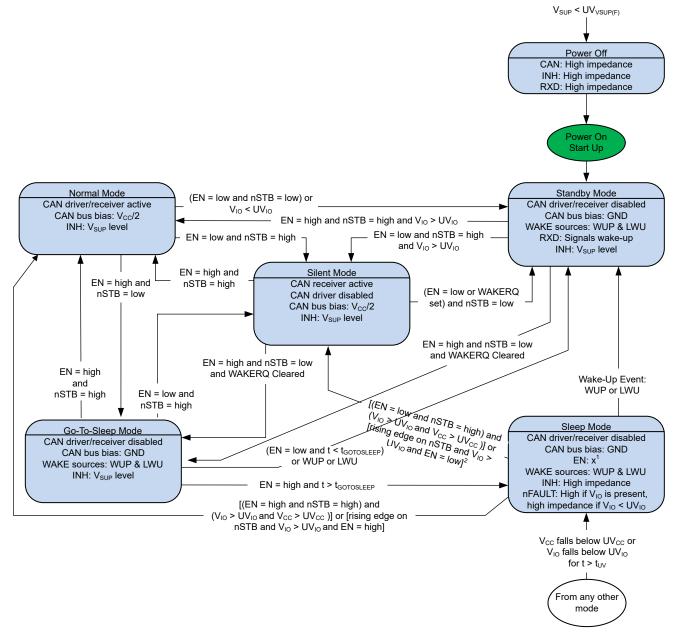

- I<sub>OS(AVG)</sub> is the average short-circuit current
- %Transmit is the percentage the node is transmitting CAN messages
- %Receive is the percentage the node is receiving CAN messages
- %REC Bits is the percentage of recessive bits in the transmitted CAN messages
- %DOM\_Bits is the percentage of dominant bits in the transmitted CAN messages
- I<sub>OS(SS)</sub> REC is the recessive steady state short-circuit current
- I<sub>OS(SS)</sub> DOM is the dominant steady state short-circuit current

The short-circuit current and possible fault cases of the network must be taken into consideration when sizing the power ratings of the termination resistance and other network components.

## 7.4 Device Functional Modes

The TCAN843-Q1 has six operating modes: normal, standby, silent, go-to-sleep, sleep, and off mode. Operating mode selection is controlled using the nSTB pin and EN pin in conjunction with supply conditions, temperature conditions, and wake events.

- 1. The enable pin can be in a logical high or low state while in sleep mode but since the pin has an internal pull-down, the lowest possible power consumption occurs when the pin is left either floating or pulled low externally.
- 2. First set EN = low at least 0.5µs before setting nSTB = high to produce a transition directly from Sleep mode to Silent mode without first passing through Normal mode (and thus inadvertently clearing fault flags).

Figure 7-4. TCAN843-Q1 State Machine

Table 7-3. TCAN843-Q1 Mode Overview

MODE	V <sub>CC</sub> and V <sub>IO</sub>	V <sub>SUP</sub>	EN	nSTB	WAKERQ FLAG	DRIVER	RECEIVER	RXD	INH

## Table 7-3. TCAN843-Q1 Mode Overview (continued)

MODE	V <sub>CC</sub> and V <sub>IO</sub>	V <sub>SUP</sub>	EN	nSTB	WAKERQ FLAG	DRIVER	RECEIVER	RXD	INH
	> UV <sub>CC</sub> and > UV <sub>IO</sub>	> UV <sub>SUP</sub>	High	Low	Set	Disabled	Low power bus monitor enabled	Low signals wake-up	On
Standby	> UV <sub>CC</sub> and > UV <sub>IO</sub>	> UV <sub>SUP</sub>	Low	Low	Х	Disabled	Low power bus monitor enabled	Low signals wake-up	On
	> UV <sub>CC</sub> and < UV <sub>IO</sub>	> UV <sub>SUP</sub>	Low	Low	Х	Disabled	Low power bus monitor enabled	High impedance	On
Go-to-sleep <sup>(1)</sup>	> UV <sub>CC</sub> and > UV <sub>IO</sub>	> UV <sub>SUP</sub>	High	Low	Cleared	Disabled	Low power bus monitor enabled	High or high impedance (no V <sub>IO</sub> )	On <sup>(2)</sup>
Sleep <sup>(3)</sup>	> UV <sub>CC</sub> and > UV <sub>IO</sub>	> UV <sub>SUP</sub>	High	Low	Cleared	Disabled	Low power bus monitor enabled	High or high impedance (no V <sub>IO</sub> )	High Impedance
·	< UV <sub>CC</sub> or < UV <sub>IO</sub>	> UV <sub>SUP</sub>	х	х	Х	Disabled	Low power bus monitor enabled	High or high impedance (no V <sub>IO</sub> )	High impedance
Passive <sup>(4)</sup>	< UV <sub>CC</sub> and > UV <sub>IO</sub>	> UV <sub>SUP</sub>	Х	High	×	Disabled	Disabled	High	On
Protected	х	< UV <sub>SUP</sub>	х	Х	Х	Disabled	Disabled	High impedance	High impedance

- (1) Go-to-sleep: Transitional mode for EN = H, nSTB = L until t<sub>GOTOSLEEP</sub> timer has expired. The low-power bus monitor becomes/remains enabled in this state.
- The INH pin transitions to high impedance once the t<sub>GOTOSLEEP</sub> timer has expired and the device transitions to Sleep mode.
- Mode change from Go-to-Sleep mode to Sleep mode once  $t_{\mbox{\scriptsize GOTOSLEEP}}$  timer has expired.
- Passive mode is entered from Normal mode or Silent mode when a UV<sub>CC</sub> event occurs for t > t<sub>UV\_det</sub>. The device transitions from Passive mode to Sleep mode once the t<sub>UV</sub> timer has expired.

## 7.4.1 Operating Mode Description

#### 7.4.1.1 Normal Mode

This is the normal operating mode of the device. The CAN driver and receiver are fully operational and CAN communication is bi-directional. The driver is translating a digital input on TXD to a differential output on CANH and CANL. The receiver is translating the differential signal from CANH and CANL to a digital output on RXD.

Entering normal mode clears both the WAKERQ and the PWRON flags. If Normal mode is entered while TXD is low, the driver is not enabled until TXD becomes high, preventing glitches during state transitions or bus interruptions due to TXD faults.

#### 7.4.1.2 Silent Mode

Silent mode is commonly referred to as listen only and receive only mode. In this mode, the CAN driver is disabled but the receiver is fully operational and CAN communication is unidirectional into the device. The receiver is translating the differential signal from CANH and CANL to a digital output on the RXD terminal.

In silent mode, PWRON and Local Failure flags are indicated on the nFAULT pin.

#### 7.4.1.3 Standby Mode

Standby mode is a low-power mode where the driver and receiver are disabled, reducing current consumption. However, this is not the lowest power mode of the device since the INH terminal is on, allowing the rest of the system to resume normal operation.

During standby mode, a wake-up request (WAKERQ) is indicated by the RXD terminal being low. The wake-up source is identified via the nFAULT pin after the device is returned to normal mode.

## 7.4.1.4 Go-To-Sleep Mode

Go-to-sleep mode is the transitional mode of the device from any state to sleep. In this state, the driver and receiver are disabled, reducing the current consumption. The INH pin is active to supply an enable to the V<sub>IO</sub> controller which allows the rest of the system to operate normally. In this mode, the low-power bus monitor activates or remains active to monitor for bus wake-up events. If the device is held in this state for t ≥ t<sub>GOTOSLEEP</sub>, the device transitions to sleep mode and the INH turns off transitioning to the high impedance state.

If any wake-up events persist, the TCAN843-Q1 remains in standby mode until the device is switched into normal mode to clear the pending wake-up events.

#### **7.4.1.5 Sleep Mode**

Sleep mode is the lowest power mode of the TCAN843-Q1. In sleep mode, the CAN transmitter and the main receiver are switched off, and the transceiver cannot send or receive data. The low power receiver is able to monitor the bus for any activity that validates the wake-up pattern (WUP) requirements, and the WAKE monitoring circuit monitors for state changes on the WAKE terminal for a local wake-up (LWU) event. The INH pin is switched off in sleep mode causing any system power supplies controlled by INH to be switched off thus reducing system power consumption.

Sleep mode is exited if:

- a valid wake-up pattern (WUP) is received via the CAN bus pins
- a local WAKE (LWU) event occurs
- nSTB becomes high while VIO > UV<sub>IO</sub> (the device enters Normal or Silent mode depending upon the logic level on the EN pin)

## 7.4.1.5.1 Remote Wake Request via Wake-Up Pattern (WUP)

The TCAN843-Q1 implements a low-power wake receiver in the standby and sleep mode that uses the multiple filtered dominant wake-up pattern (WUP) defined in the ISO11898-2:2016 standard.

The wake-up pattern (WUP) consists of a filtered dominant bus, then a filtered recessive bus time followed by a second filtered dominant bus time. The first filtered dominant initiates the WUP and the bus monitor is now waiting on a filtered recessive. Other bus traffic does not reset the bus monitor. Once a filtered recessive is received, the bus monitor is now waiting on a filtered dominant. Other bus traffic does not reset the bus monitor. Immediately upon receiving of the second filtered dominant, the bus monitor recognizes the WUP and drives the RXD terminal low, if a valid  $V_{IO}$  is present signaling to the controller the wake-up request. If a valid,  $V_{IO}$  is not present when the wake-up pattern is received, the transceiver drives the RXD output pin low once  $V_{IO} > UV_{IO(R)}$  after  $t_{UV(RE-ENABLE)}$ .

The WUP consists of:

- A filtered dominant bus of at least t<sub>WK(FILTER)</sub> followed by
- A filtered recessive bus time of at least t<sub>WK(FILTER)</sub> followed by
- A second filtered dominant bus time of at least t<sub>WK(FILTER)</sub>

For a dominant or recessive to be considered "filtered," the bus must be in that state for more than  $t_{WK(FILTER)}$  time. Due to variability in the  $t_{WK(FILTER)}$  the following scenarios are applicable. Bus state times less than the  $t_{WK(FILTER)}$  minimum are never detected as part of a WUP, and thus, no wake request is generated. Bus state times between  $t_{WK(FILTER)}$  minimum and  $t_{WK(FILTER)}$  maximum can be detected as part of a WUP and a wake request can be generated. Bus state times more than  $t_{WK(FILTER)}$  maximum is always detected as part of a WUP, and thus, a wake request is always generated. See Figure 7-5 for the timing diagram of the WUP.

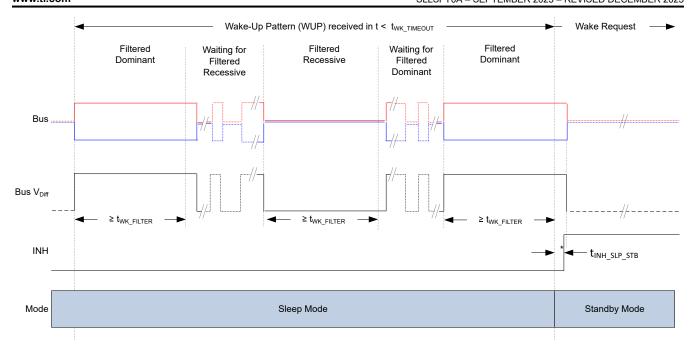

The pattern and  $t_{WK(FILTER)}$  time used for the WUP and wake request prevents noise and bus stuck dominant faults from causing false wake requests while allowing any CAN or CAN FD message to initiate a wake request.

ISO11898-2:2024 has two sets of times for a short and long wake-up filter times. The  $t_{WK(FILTER)}$  timing for the TCAN843-Q1 has been picked to be within the min and max values of both filter ranges. This timing has been chosen such that a single bit time at 500kbps, or two back to back bit times at 1Mbps trigger the filter in either bus state.

For an additional layer of robustness and to prevent false wake-ups, the transceiver implements the  $t_{WK(TIMEOUT)}$  timer. For a remote wake-up event to successfully occur, the entire wake-up pattern must be received within the timeout value. If the full wake-up pattern is not received before the  $t_{WK(TIMEOUT)}$  expires then the internal logic is reset and the transceiver remains in sleep mode without waking up. The full pattern must then be transmitted again within the  $t_{WK(TIMEOUT)}$  window. See Figure 7-5.

A recessive bus of at least  $t_{WK(FILTER)}$  must separate the next WUP pattern if the CAN bus is dominant when the  $t_{WK(TIMEOUT)}$  expires.

Product Folder Links: TCAN843-Q1

<sup>\*</sup>The RXD pin is only driven once  $V_{\text{IO}}$  is present.

Figure 7-5. Wake-Up Pattern (WUP)

## 7.4.1.5.2 Local Wake-Up (LWU) by WAKE Input Terminal

The WAKE terminal is a bi-directional high-voltage reverse-battery protected input which can be used for local wake-up (LWU) requests through a voltage transition. A LWU event is triggered on either a low-to-high or high-to-low transition due to the bi-directional input thresholds. The WAKE pin can be used with a switch to  $V_{SUP}$ , to  $V_{CC}$ , to  $V_{IO}$ , or to ground. If the terminal is unused, the terminal must be pulled to supply or to ground to avoid unwanted parasitic wake-up events. Current consumption is minimized when WAKE is connected to 5V or to ground.

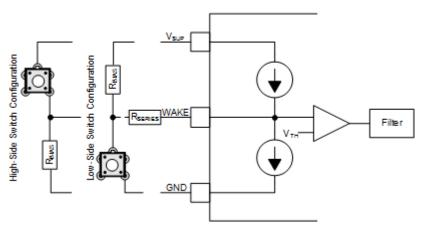

Figure 7-6. WAKE Circuit Example

Figure 7-6 shows two possible configurations for the WAKE pin, a low-side and high-side switch configuration. The objective of the series resistor,  $R_{SERIES}$ , is to protect the WAKE input of the device from over current conditions that can occur in the event of a ground shift or ground loss. The minimum value of  $R_{SERIES}$  can be calculated using the maximum supply voltage,  $V_{SUPMAX}$ , and the maximum allowable current of the WAKE pin,  $I_{IO(WAKE)}$ .  $R_{SERIES}$  is calculated using:

$$R_{SERIES} = V_{SUPMAX} / I_{IO(WAKE)}$$

(3)

With absolute maximum voltage,  $V_{SUPMAX}$ , of 40V and maximum allowable  $I_{IO(WAKE)}$  of 3mA, the minimum required  $R_{SERIES}$  value is 13.3k $\Omega$ .

The LWU circuitry is active in Sleep mode and Standby mode.

The WAKE circuitry is switched off in Normal mode and Silent mode.

## 7.4.2 CAN Transceiver

## 7.4.2.1 CAN Transceiver Operation

The TCAN843-Q1 supports the ISO 11898-2:2024 CAN physical layer standard normal bus biasing scheme. Normal bus biasing means that the CAN bus is biased when the transceiver is in Normal mode or Silent mode. In other modes, the CAN pins are either high-impedance or weakly biased to GND.

## 7.4.2.1.1 Driver and Receiver Function Tables

**Table 7-4. Driver Function Table** 

DEVICE MODE	TVD INDUTE(1)	BUS OL	JTPUTS	DRIVEN BUS STATE(2)
DEVICE MODE	TAD INPUTS	CANH	CANL	DRIVEN BUS STATE
Normal	Low	High	Low	Dominant
Nomiai	High or Open	High impedance	High impedance	V <sub>CC</sub> /2
Silent	x	High impedance	High impedance	V <sub>CC</sub> /2
Standby	х	High impedance	High impedance	Weak bias to GND
Sleep	х	High impedance	High impedance	Weak bias to GND

- (1) x = irrelevant
- (2) For bus states and typical bus voltages see Figure 7-9

## **Table 7-5. Receiver Function Table**

DEVICE MODE	CAN DIFFERENTIAL INPUTS VID = VCANH - VCANL	BUS STATE	RXD TERMINAL
	V <sub>ID</sub> ≥ 0.9V	Dominant	Low
Normal / Silent	0.5V < V <sub>ID</sub> < 0.9V	Indeterminate	Indeterminate
Normal / Silent	V <sub>ID</sub> ≤ 0.5V	Recessive	High
	Open (V <sub>ID</sub> ≈ 0V)	Open	High
	V <sub>ID</sub> ≥ 1.15V	Dominant	
Ctandby	0.4V < V <sub>ID</sub> < 1.15V	Indeterminate	High
Standby	V <sub>ID</sub> ≤ 0.4	Recessive	Low if wake-up event persists
	Open (V <sub>ID</sub> ≈ 0V)	Open	
	V <sub>ID</sub> ≥ 1.15V	Dominant	
Sleep / Go-to-	0.4V < V <sub>ID</sub> < 1.15V	Indeterminate	High
sleep <sup>(1)</sup>	V <sub>ID</sub> ≤ 0.4V	Recessive	Tri-state if V <sub>IO</sub> or V <sub>SUP</sub> are not present
	Open (V <sub>ID</sub> ≈ 0V)	Open	

(1) Low power wake-up receiver is active

#### 7.4.2.1.2 CAN Bus States

The CAN bus has two logical states during operation: recessive and dominant. See Figure 7-9.

A dominant bus state occurs when the bus is driven differentially and corresponds to a logic low on the TXD and RXD pins. A recessive bus state occurs when the bus is biased to one half of the CAN transceiver supply voltage via the high resistance internal input resistors ( $R_{IN}$ ) of the receiver and corresponds to a logic high on the TXD and RXD pins.

A dominant state overwrites the recessive state during arbitration. Multiple CAN nodes can be transmitting a dominant bit at the same time during arbitration, and in this case the differential voltage of the CAN bus is greater than the differential voltage of a single CAN driver. The TCAN843-Q1 CAN transceiver implements low-power standby modes which enable a third bus state where the bus pins are biased to ground via the high-resistance internal resistors of the receiver.

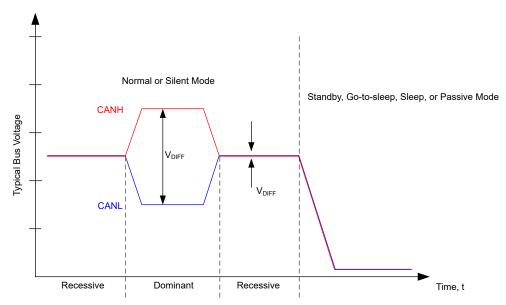

Figure 7-9. Bus States

# 8 Application Information Disclaimer

#### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

## 8.1 Application Information

The TCAN843-Q1 transceiver is typically used in applications with a host microprocessor or FPGA that includes the data link layer portion of the CAN protocol. These types of applications typically also include power management technology that allows for power to be gated to the application using an enable (EN) or inhibit (INH) pin. A single 5V regulator can be used to drive both  $V_{CC}$  and  $V_{IO}$ , or independent 5V and 3.3V regulators can be used to drive V<sub>CC</sub> and V<sub>IO</sub> separately as shown in Figure 8-1. The bus termination is shown for illustrative purposes.

# 8.1.1 Typical Application

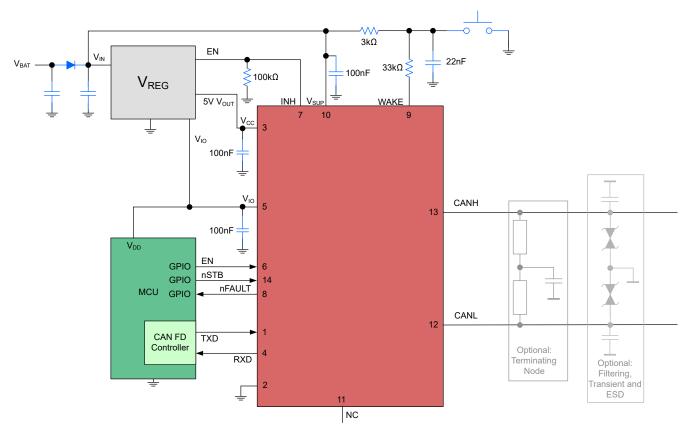

Figure 8-1. Typical Application

#### 8.1.2 Design Requirements

#### 8.1.2.1 Bus Loading, Length and Number of Nodes

A typical CAN application can have a maximum bus length of 40 meters and maximum stub length of 0.3m. However, with careful design, users can have longer cables, longer stub lengths, and many more nodes to a bus. A high number of nodes requires a transceiver with high input impedance such as the TCAN843-Q1.

Product Folder Links: TCAN843-Q1

Many CAN organizations and standards have scaled the use of CAN for applications outside the original ISO11898-2:2024 standard. These organization and standards made system level trade off decisions for data rate, cable length, and parasitic loading of the bus. Examples of these CAN systems level specifications are ARINC825, CANopen, DeviceNet, SAEJ2284, SAEJ1939, and NMEA200.

A CAN network system design is a series of tradeoffs. In the ISO 11898-2:2024 specification the differential output driver is specified with a bus load that can range from  $50\Omega$  to  $65\Omega$  where the differential output must be greater than 1.5V. The TCAN843-Q1 is specified to meet the 1.5V requirement down to  $50\Omega$  and is specified to meet 1.4V differential output at  $45\Omega$  bus load. The differential input resistance,  $R_{ID}$ , of the TCAN843-Q1 is a minimum of  $50k\Omega$ . If 100 TCAN843-Q1 transceivers are in parallel on a bus, this is equivalent to a  $500\Omega$  differential load in parallel with the nominal  $60\Omega$  bus termination which gives a total bus load of approximately  $54\Omega$ . Therefore, the TCAN843-Q1 theoretically supports over 100 transceivers on a single bus segment. However, for CAN network design margin must be given for signal loss across the system and cabling, parasitic loadings, timing, network imbalances, ground offsets and signal integrity thus a practical maximum number of nodes is often lower. Bus length can also be extended beyond 40 meters by careful system design and data rate tradeoffs. For example, CANopen network design guidelines allow the network to be up to 1km with changes in the termination resistance, cabling, less than 64 nodes and significantly lowered data rate.

This flexibility in CAN network design is one of the key strengths allowing for these system level network extensions and additional standards to build on the original ISO11898-2 CAN standard. However, when using this flexibility, the CAN network system designer must take the responsibility of good network design for a robust network operation.

## 8.1.3 Detailed Design Procedure

#### 8.1.3.1 CAN Termination

Termination can be a single  $120\Omega$  resistor at each end of the bus, either on the cable or in a terminating node. If filtering and stabilization of the common-mode voltage of the bus is desired then split termination can be used, see Figure 8-2. Split termination improves the electromagnetic emissions behavior of the network by filtering higher-frequency common-mode noise that can be present on the differential signal lines.

Submit Document Feedback

## 8.2 Power Supply Recommendations

The TCAN843-Q1 is designed to operate off of three supply rails;  $V_{SUP}$ ,  $V_{CC}$ , and  $V_{IO}$ .  $V_{SUP}$  is a high-voltage supply pin designed to connect to the  $V_{BAT}$  rail,  $V_{CC}$  is a low-voltage supply pin with an input voltage range from 4.5V to 5.5V that supports the CAN transceiver and  $V_{IO}$  is a low-voltage supply pin with an input voltage range from 2.95V to 5.5V that provides the I/O voltage to match the system controller. For a reliable operation, a 100nF decoupling capacitor must be placed as close to the supply pins as possible. This helps to reduce supply voltage ripple present on the output of switched-mode power supplies, and also helps to compensate for the resistance and inductance of the PCB power planes.

## 8.3 Layout

Robust and reliable CAN node design can require special layout techniques depending on the application and automotive design requirements. Since transient disturbances have high frequency content and a wide bandwidth, high-frequency layout techniques must be applied during PCB design.

## 8.3.1 Layout Guidelines

The layout example provides information on components around the device. Place the protection and filtering circuitry as close to the bus connector, J1, to prevent transients, ESD and noise from propagating onto the board. Transient voltage suppression (TVS) device can be added for extra protection, shown as D1. The production solution can be either a bi-directional TVS diode or varistor with ratings matching the application requirements. This example also shows optional bus filter capacitors C6 and C7. A series common-mode choke (CMC) is placed on the CANH and CANL lines between the device and connector J1.

Design the bus protection components in the direction of the signal path. Do not force the transient current to divert from the signal path to reach the protection device. Use supply and ground planes to provide low inductance. Note that high-frequency currents follow the path of least impedance and not the path of least resistance. Use at least two vias for supply and ground connections of bypass capacitors and protection devices to minimize trace and via inductance.

- Bypass and bulk capacitors must be placed as close as possible to the supply terminals of transceiver, examples are C1 on V<sub>CC</sub>, C2 on V<sub>IO</sub>, and C3 and C4 on the V<sub>SUP</sub> supply.
- V<sub>IO</sub> pin of the transceiver is connected to the microcontroller IO supply voltage (μC V).
- Bus termination: this layout example shows split termination. This is where the termination is split into two
  resistors, R3 and R4, with the center or split tap of the termination connected to ground via capacitor C5. Split
  termination provides common-mode filtering for the bus. When bus termination is placed on the board instead
  of directly on the bus, additional care must be taken to make sure the terminating node is not removed from
  the bus; thus, also removing the termination.
- INH, pin 7, can have a 100kΩ resistor (R1) to ground.
- WAKE, pin 9, can recognize either a rising or a falling edge of a wake signal and is typically connected to an external switch. The pin must be configured as shown with C8 which is a 22nF capacitor to GND where R5 is  $33k\Omega$  and R6 is  $3k\Omega$ .

<sup>(1)</sup> Status: For more details on status, see our product life cycle.

Multiple part markings will be inside parentheses. Only one part marking contained in parentheses and separated by a "~" will appear on a part. If a line is indented then it is a continuation of the previous line and the two combined represent the entire part marking for that device.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

<sup>(2)</sup> Material type: When designated, preproduction parts are prototypes/experimental devices, and are not yet approved or released for full production. Testing and final process, including without limitation quality assurance, reliability performance testing, and/or process qualification, may not yet be complete, and this item is subject to further changes or possible discontinuation. If available for ordering, purchases will be subject to an additional waiver at checkout, and are intended for early internal evaluation purposes only. These items are sold without warranties of any kind.

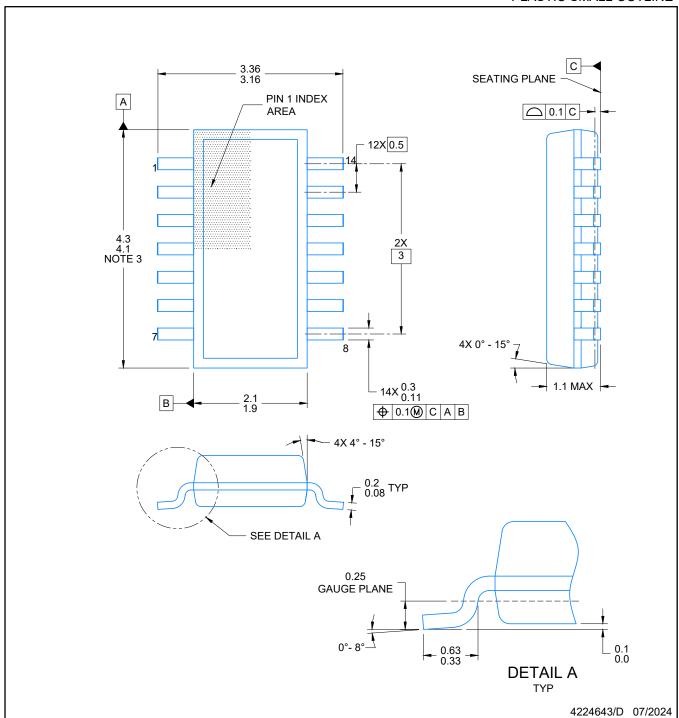

<sup>(3)</sup> RoHS values: Yes, No, RoHS Exempt. See the TI RoHS Statement for additional information and value definition.

<sup>(4)</sup> Lead finish/Ball material: Parts may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

<sup>(5)</sup> MSL rating/Peak reflow: The moisture sensitivity level ratings and peak solder (reflow) temperatures. In the event that a part has multiple moisture sensitivity ratings, only the lowest level per JEDEC standards is shown. Refer to the shipping label for the actual reflow temperature that will be used to mount the part to the printed circuit board.

<sup>(6)</sup> Part marking: There may be an additional marking, which relates to the logo, the lot trace code information, or the environmental category of the part.

- 4. This dimension does not include interlead flash. Interlead flash shall not exceed 0.43 mm, per side.
- 5. Reference JEDEC registration MS-012, variation AB.

SMALL OUTLINE INTEGRATED CIRCUIT

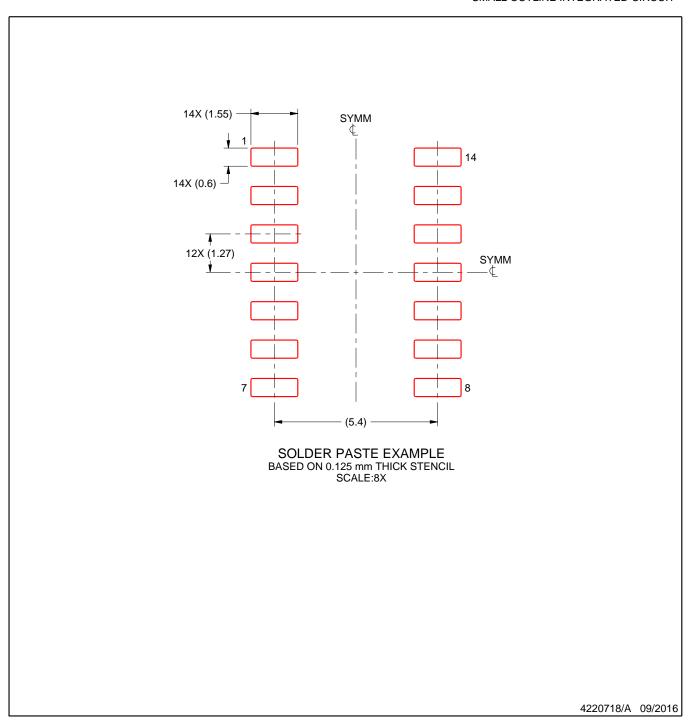

NOTES: (continued)

6. Publication IPC-7351 may have alternate designs.

7. Solder mask tolerances between and around signal pads can vary based on board fabrication site.

SMALL OUTLINE INTEGRATED CIRCUIT

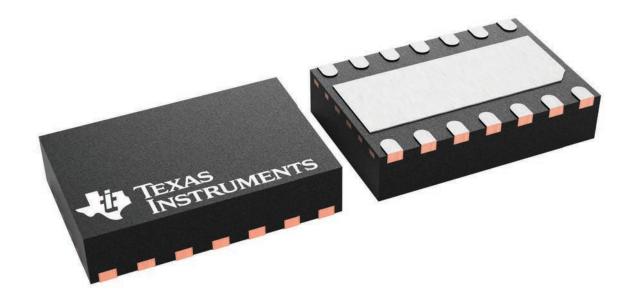

- 8. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.
- 9. Board assembly site may have different recommendations for stencil design.

3 x 4.5, 0.65 mm pitch

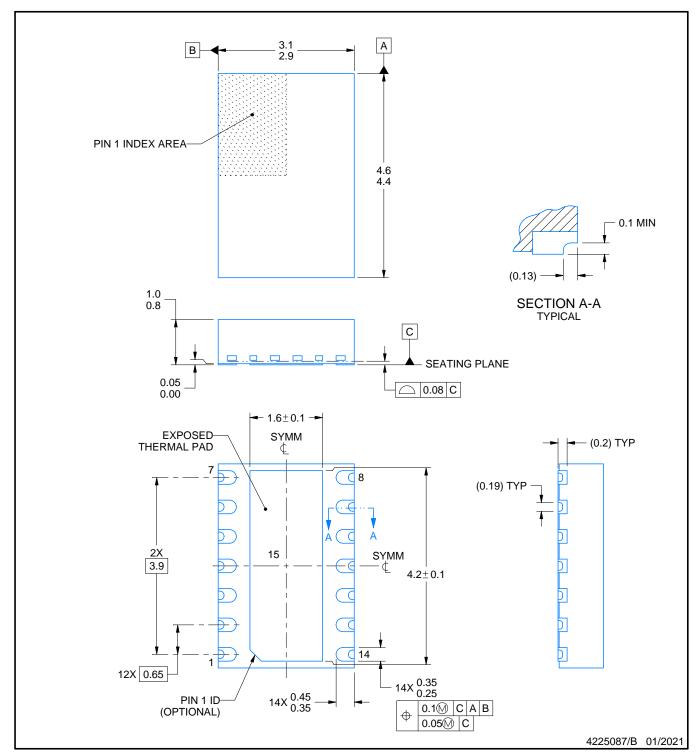

PLASTIC SMALL OUTLINE - NO LEAD

This image is a representation of the package family, actual package may vary. Refer to the product data sheet for package details.

PLASTIC SMALL OUTLINE - NO LEAD

#### NOTES:

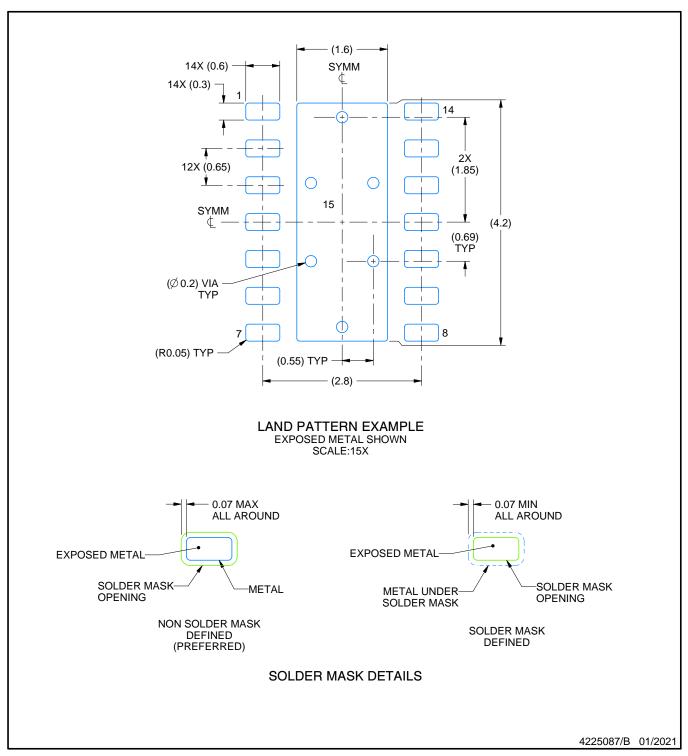

- 1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.

  2. This drawing is subject to change without notice.

  3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

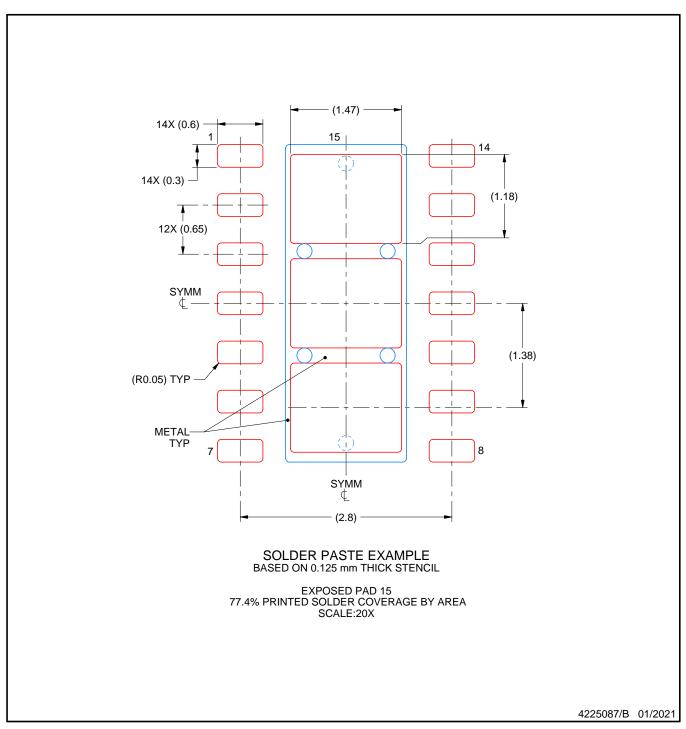

PLASTIC SMALL OUTLINE - NO LEAD

- 4. This package is designed to be soldered to a thermal pad on the board. For more information, see Texas Instruments literature number SLUA271 (www.ti.com/lit/slua271).
- 5. Vias are optional depending on application, refer to device data sheet. If any vias are implemented, refer to their locations shown on this view. It is recommended that vias under paste be filled, plugged or tented.

PLASTIC SMALL OUTLINE - NO LEAD

NOTES: (continued)

6. Laser cutting apertures with trapezoidal walls and rounded corners may offer better paste release. IPC-7525 may have alternate design recommendations.

#### IMPORTANT NOTICE AND DISCLAIMER

TI PROVIDES TECHNICAL AND RELIABILITY DATA (INCLUDING DATASHEETS), DESIGN RESOURCES (INCLUDING REFERENCE DESIGNS), APPLICATION OR OTHER DESIGN ADVICE, WEB TOOLS, SAFETY INFORMATION, AND OTHER RESOURCES "AS IS" AND WITH ALL FAULTS, AND DISCLAIMS ALL WARRANTIES, EXPRESS AND IMPLIED, INCLUDING WITHOUT LIMITATION ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT OF THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

These resources are intended for skilled developers designing with TI products. You are solely responsible for (1) selecting the appropriate TI products for your application, (2) designing, validating and testing your application, and (3) ensuring your application meets applicable standards, and any other safety, security, regulatory or other requirements.

These resources are subject to change without notice. TI grants you permission to use these resources only for development of an application that uses the TI products described in the resource. Other reproduction and display of these resources is prohibited. No license is granted to any other TI intellectual property right or to any third party intellectual property right. TI disclaims responsibility for, and you fully indemnify TI and its representatives against any claims, damages, costs, losses, and liabilities arising out of your use of these resources.

TI's products are provided subject to TI's Terms of Sale, TI's General Quality Guidelines, or other applicable terms available either on ti.com or provided in conjunction with such TI products. TI's provision of these resources does not expand or otherwise alter TI's applicable warranties or warranty disclaimers for TI products. Unless TI explicitly designates a product as custom or customer-specified, TI products are standard, catalog, general purpose devices.

TI objects to and rejects any additional or different terms you may propose.
