## Benchmark Simulink Model on AM13x

---

Nilabh Anand, Arun Munuswamy, Val Singh

### ABSTRACT

Model-Based Design workflows increasingly require algorithm validation not only in simulation but directly on target embedded hardware, under real processor execution conditions. Benchmarking a Simulink algorithm model on target hardware provides quantitative execution time and resource utilization data that simulation alone cannot supply information that is essential for platform selection, scheduling decisions, multi-rate system design. This application note presents a structured methodology for benchmarking Simulink algorithm models on the Texas Instruments AM13x microcontroller using Processor-in-the-Loop (PIL) simulation.

## 1 Introduction

Embedded control algorithms developed in Simulink are frequently first validated in simulation or prototyped on an initial target platform before a production hardware decision is finalized. In motor control, power conversion, and signal processing applications, it is common for an algorithm such as Field-Oriented Control (FOC) to have an established simulation history verified numerically in Simulink, and potentially already deployed and profiled on a prior embedded target such as the TI C28x real-time microcontroller or the TI AM261x or from a non-TI platform entirely, represented as a self-contained Simulink subsystem with no target-specific dependencies.

## 2 Processor-in-the-Loop (PIL)

A fundamental engineering question arises when the AM13x is introduced as a candidate platform: *how does this algorithm perform on this processor?* Simulation cannot answer this question. Execution time, instruction cache behavior, pipeline utilization, and the impact of hardware-accelerated math operations (Accelerator in case of AM13x is Trigonometric Math Unit – TMU) are properties of the physical processor and are only observable through execution on target hardware.

[Processor-in-the-Loop \(PIL\)](#) provides precisely this capability. PIL executes the Simulink algorithm model directly on the connected AM13x hardware while maintaining the simulation environment as the test harness, supplying test vectors, collecting outputs, and verifying numerical correctness against the reference simulation. Execution profiling data is returned automatically at the conclusion of each PIL run, reporting the measured processor cycles and execution time consumed by the algorithm on the physical device.

## 3 Prerequisites

- [AM13x Support Package](#)
- [C2000 Microcontroller Blockset](#)
- [Motor Control Blockset](#)

## 4 Benchmarking the Current Control Algorithm on AM13x

### 4.1 Reference C28x Example Simulation Model

The starting point for this workflow is the MathWorks shipping example [Code Verification and Profiling Using PIL Testing](#). This example ships with a complete FOC motor control model demonstrating PIL on the TI C28x platform. The same model is used for retargeting to the AM13x, to benchmark the current control algorithm using identical model.

### 4.2 Simulation Model Configured for F28379D

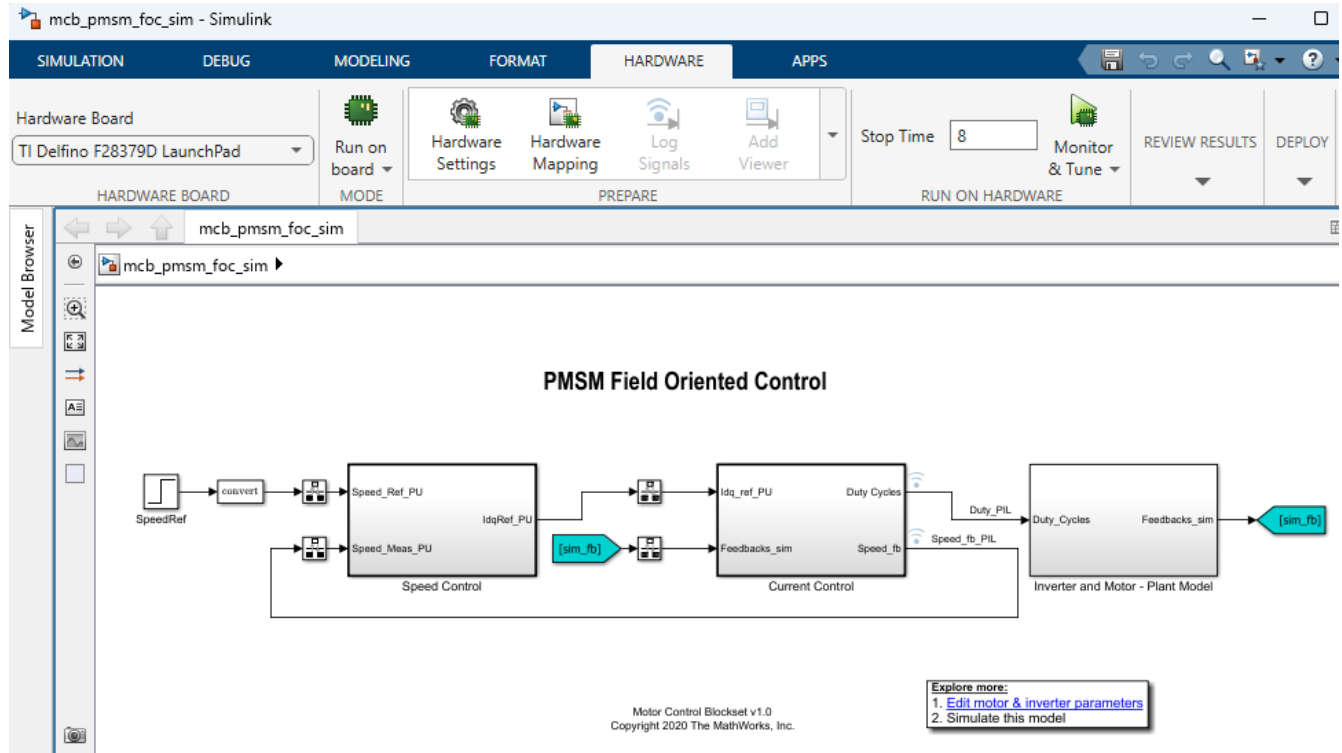

Figure 4-1. PMSM Blockset

#### Before Proceeding to PIL, Verify Baseline Simulation Correctness

- Open the example model and run the simulation to completion
- Observe the speed reference and speed feedback signals in the Simulation Data Inspector, the feedback trajectory must track the reference correctly, confirming that the algorithm is numerically sound prior to any target deployment
- This simulation result serves as the numerical reference against which PIL outputs are compared

### 4.3 Simulation Results

Figure 4-2.

## 5 Isolating the Algorithm: Converting the Subsystem to a Model Reference

PIL at the model block level requires the algorithm under test to be encapsulated as a Model Reference block. This establishes a clean input/output boundary around the current control algorithm and allows the surrounding system model to continue executing on the Simulink host while only the referenced model is deployed to the AM13x target.

### 5.1 Conversion Procedure

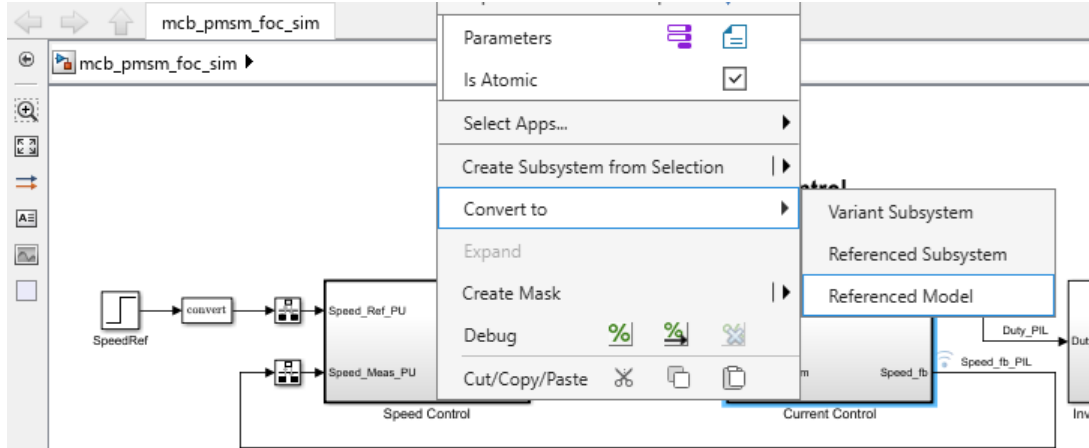

Figure 5-1. Reference Model

1. In the top-level model, right-click the current control subsystem block
2. Select *Subsystem* → *Convert to* → *Referenced Model*
  - a. Click convert the model, Model Advisor shows a successful conversion message

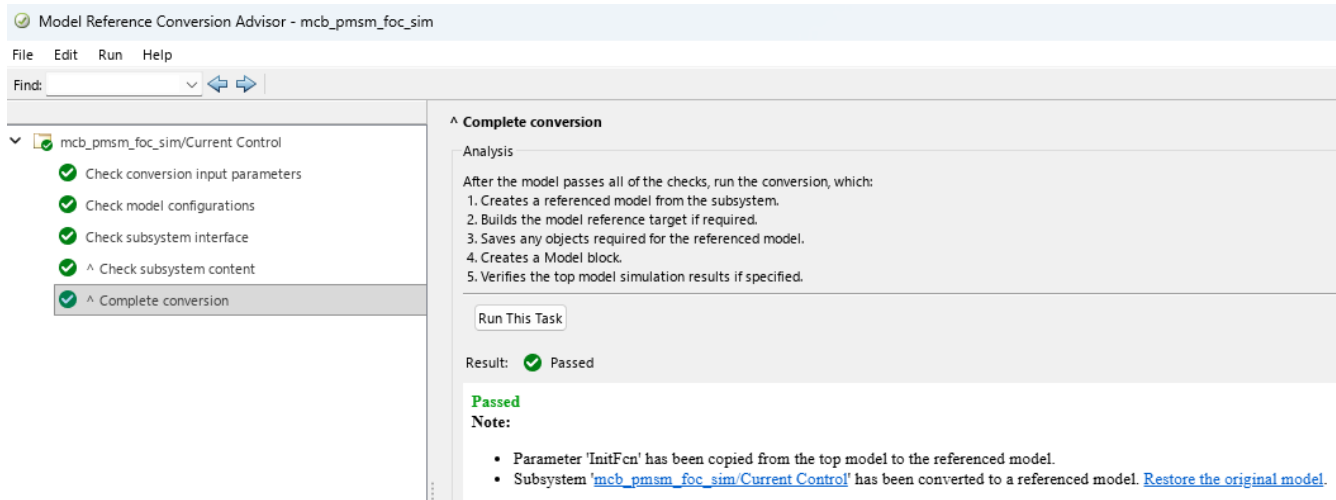

Figure 5-2. Conversion Step

3. Simulink creates a new, separate model file containing exclusively the current control algorithm contents
4. The original subsystem in the top-level model is automatically replaced by a model reference block pointing to the newly created model. Rename the top model to avoid conflict with reference example model.
5. Verify that the top-level model simulates correctly after conversion, the numerical results must remain identical to the pre-conversion baseline

The top-level FOC system continues to run entirely on the Simulink host. Only the current control Model Reference block is deployed to the AM13x during PIL execution.

## 5.2 Converted Model Reference Block Configured for Processor in the Loop

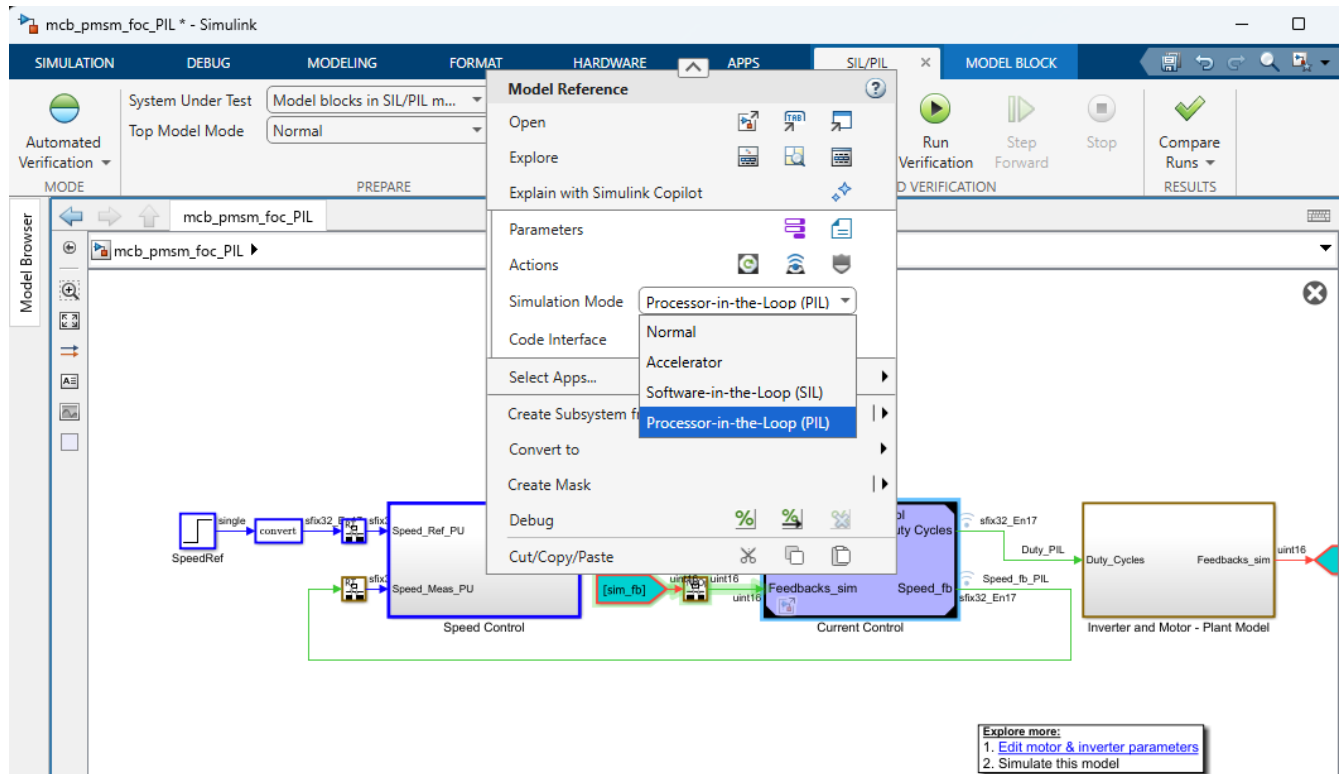

Figure 5-3. PIL

## 6 Configuring the Model Reference for AM13x PIL

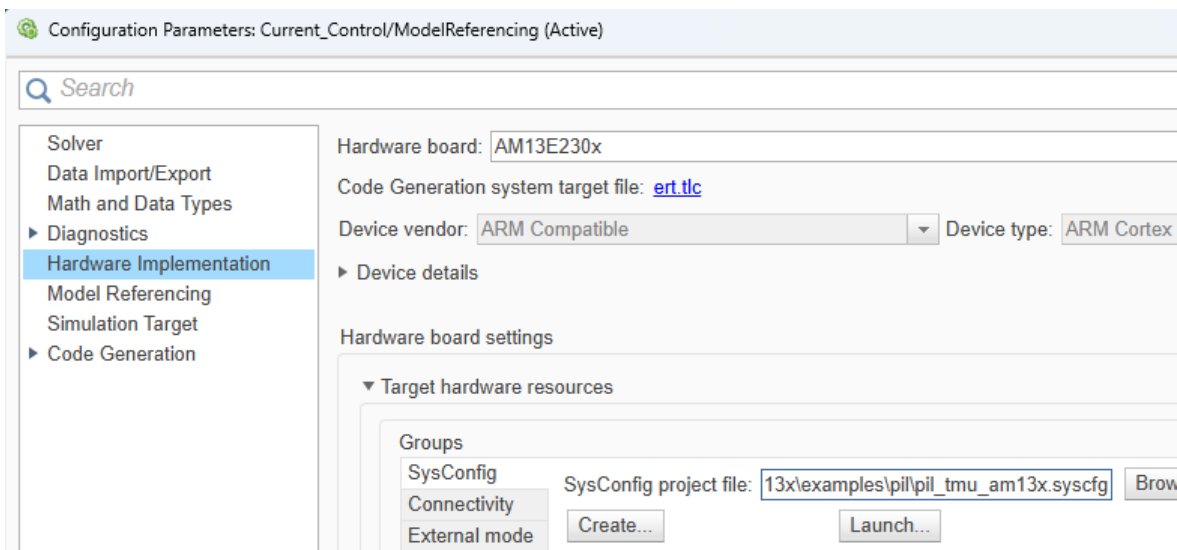

With the model reference established, the following configuration steps prepare the current control model for PIL execution on the AM13x Launchpad.

### 6.1 Target Hardware Selection

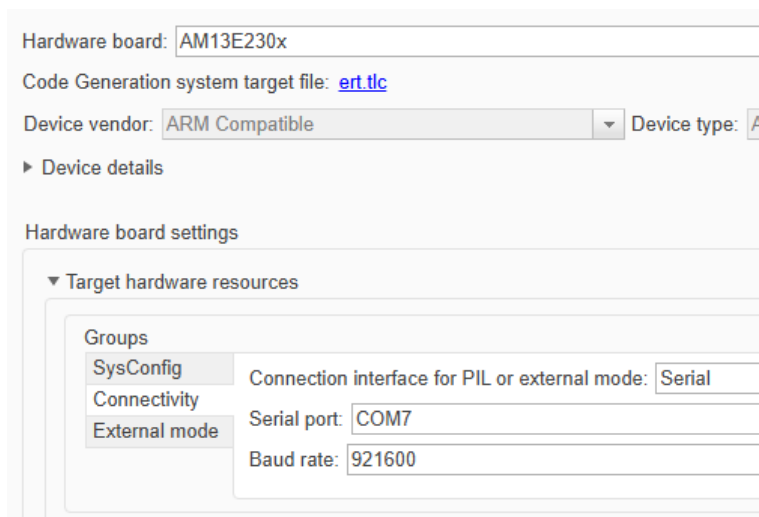

1. Open the current control referenced model (not the top-level model).
2. Navigate to *Model Configuration Parameters* → *Hardware Implementation*.
3. Set *hardware board* to AM13E230x.
4. Upon selection, the *TMU (Trigonometric Math Unit) Code Replacement Library* is activated automatically, no manual intervention is required.

### 6.2 SysConfig Configuration

1. Navigate to *Target Hardware Resources* → *SysConfig*
2. For PIL, *select the SysConfig file shipped with the AM13x PIL example*, this file is pre-configured with the communication peripheral settings required for PIL data exchange between the host and the target
3. Use a *relative path* when specifying the SysConfig file location

**Figure 6-1. Deployment Target Selection**

**Figure 6-2. UART Serial Connection**

## 7 SIL/PIL Manager

### 7.1 Launching the SIL/PIL Manager and Running PIL

1. Open the *SIL/PIL Manager* application (*Apps* → *SIL/PIL Manager* from the Simulink toolstrip)
2. The app manages PIL execution, profiling data collection, and numerical comparison automatically
3. Enable *Task Profiling* option from the Settings, as shown in the image below

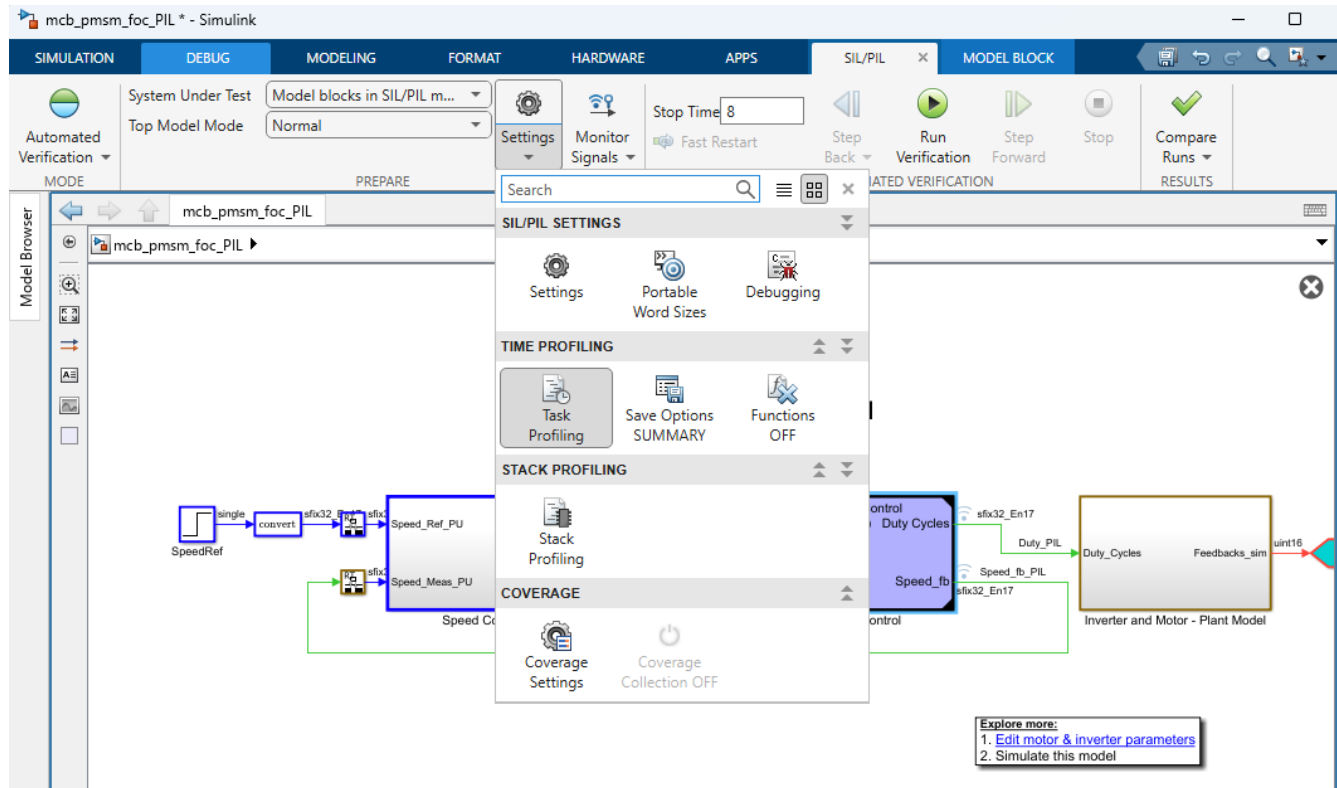

Figure 7-1. Simulink Task Profiling

#### 7.1.1 Simulation Time Consideration

PIL simulation is non-real time. Every time step requires data to travel from the Simulink host to the AM13x target and back over the serial communication link. For a motor control model with a fast base sample time, running the full simulation duration results in an impractically long PIL session. *Set the simulation stop time to 100 milliseconds (0.1)*, sufficient to capture meaningful profiling data and observe algorithm behavior without excessive run time.

1. Click *Run* in the SIL/PIL Manager to initiate PIL execution.
2. Simulink compiles and deploys the current control model to the AM13x, establishes the communication link, and begins exchanging data step by step.

### 7.1.2 PIL Results: Showing Numerical Verification

Figure 7-2. Results

### 7.1.3 PIL Results: Execution Profiling

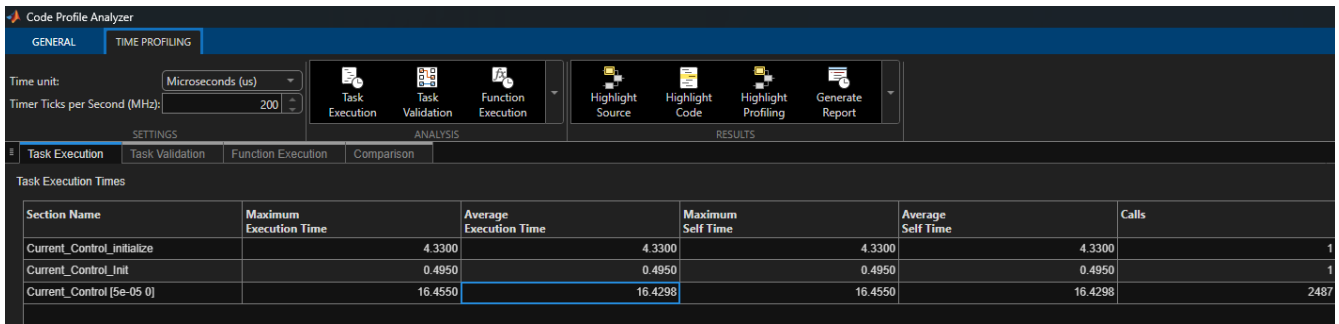

Figure 7-3. Benchmark

## 8 Optimization and Re-Profiling

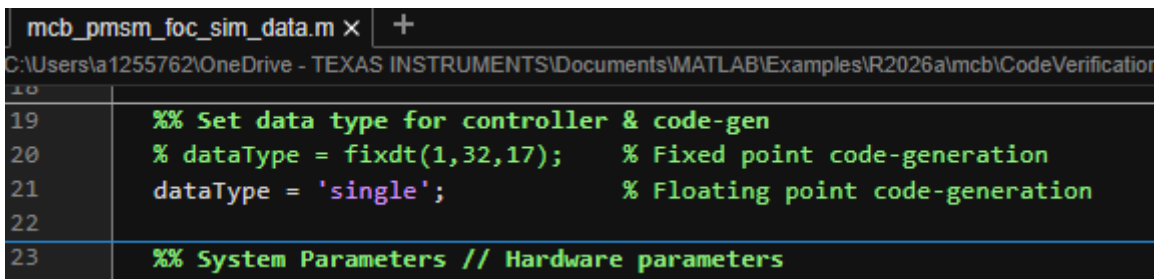

The PIL benchmarking workflow is inherently iterative. Once a baseline profiling result is established, the engineer can apply code generation and algorithm optimizations and re-run PIL to measure the precise impact of each change.

Known optimization levers for the AM13x include:

- **TMU Code Replacement Library:** automatically enabled upon AM13x target selection; replaces standard trigonometric function calls with TMU hardware-accelerated equivalents, reducing execution time for FOC algorithms significantly.
- **Compiler Optimization Level:** adjustable in *Model Configuration Parameters* → *Code Generation* → *Build configuration*
- **Data Type Refinement:** reducing unnecessary double-precision operations to single-precision where algorithm accuracy permits
- **Lookup Table Approximations:** replacing transcendental function calls with table-based approximations where TMU is not applicable
- **Additional Simulink Code Generation Optimizations** as documented in [Optimization Strategies for Generated Code](#)
- For each optimization applied, repeat the PIL run and record the updated profiling results. Comparing baseline and optimized profiling numbers provides a quantitative, hardware-validated measure of optimization effectiveness on the AM13x target.

### 8.1 PIL Results: With Single Datatype and Sine/Cosine TMU

- Change the datatype to **single** from Fixed-point from `mcb_pmsm_foc_sim_data.m`

```

mcb_pmsm_foc_sim_data.m x +
C:\Users\la1255762\OneDrive - TEXAS INSTRUMENTS\Documents\MATLAB\Examples\R2026a\mcb\CodeVerification
19      %% Set data type for controller & code-gen
20      % dataType = fixdt(1,32,17);    % Fixed point code-generation
21      dataType = 'single';          % Floating point code-generation
22
23      %% System Parameters // Hardware parameters
    
```

Figure 8-1. Datatype change

- Change the approximation method from Lookup to none to generate sine/cosine functions

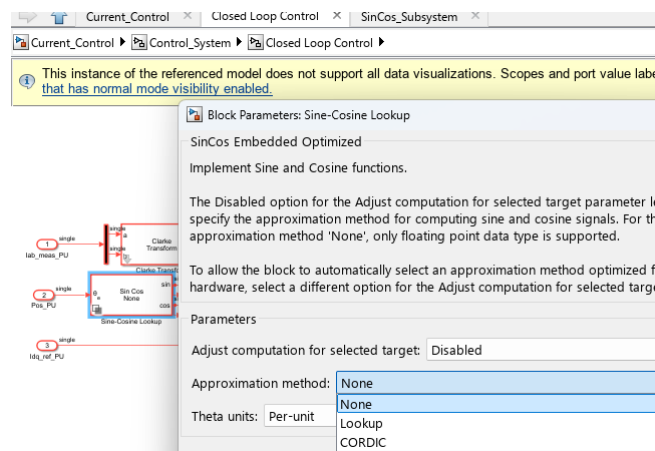

Figure 8-2. Approximation method

- Now the code generation replaces the sine/cosine with TMU functions `sinf_tmu/cosf_tmu`

## 8.2 Codegen Report Showing TMU Functions

The screenshot shows a Simulink model of a 'Closed Loop Control' system. The model includes blocks for 'Clarke Transform', 'Clarke to Park', and 'Park Transform'. A 'sinTheta' block is highlighted in green. To the right, the codegen report for 'Current\_Control.c' shows the following code:

```

531 rtb_Switch = (rtb_Switch - (real32_T)flo
532   rtb_Switch) * Current_Control_P.Multip
533   Current_Control_P.thetaUnit_Gain;
534
535 /* Trigonometry: '<S142>/SinCos' */
536 rtb_SinCos_o1 = sinf_tmu(rtb_Switch);
537 rtb_SinCos_o2 = cosf_tmu(rtb_Switch);
538
539 /* Gain: '<S198>/Get ADC Voltage' */
540 rtb_Switch = (real32_T)Current_Control_P
541
542 /* Gain: '<S171>/Inverting // Non-invert
  
```

Figure 8-3. TMU intrinsic replacement

## 8.3 Enable Code View from Compare Runs Option

The screenshot shows the 'Compare Runs' dialog box in the MATLAB/Simulink environment. The 'Code View' option is selected, and the 'Highlight Profiling' option is also selected. The background shows the same codegen report as in Figure 8-3.

Figure 8-4. Profiling

## 8.4 PIL Results: Execution Profiling with Single Datatype and Sine/Cosine TMU

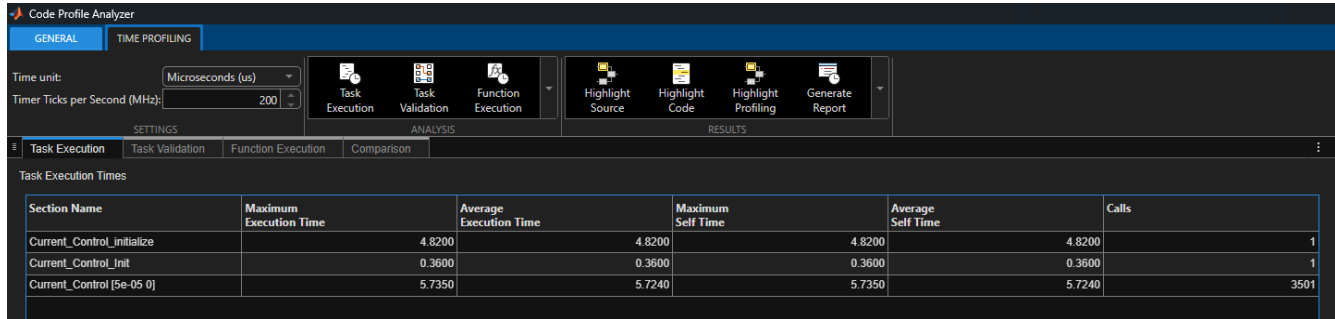

Figure 8-5. Results with TMU

## 9 Summary

This application note has presented a structured benchmarking workflow portable across algorithm model sources (C28x, other MCUs) to AM13x device. This will enable transition to AM13x smoother and faster.
