About This Manual

FCC Warning

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

Information About Cautions and Warnings

This book may contain cautions and warnings.

CAUTION

This is an example of a caution statement.

A caution statement describes a situation that could potentially damage your software or equipment.

WARNING

This is an example of a warning statement.

A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.

Register, Field, and Bit Calls

The naming convention applied for a call consists of:

- For a register call: *<Module name>.<Register name>*; for example: UART.UASR
- For a bit field call:
  - *<Module name>.<Register name>[End:Start] <Field name> field*; for example, UART.UASR[4:0] SPEED bit field
  - *<Field name> field <Module name>.<Register name>[End:Start]*; for example, SPEED bit field UART.UASR[4:0]
- For a bit call:
  - *<Module name>.<Register name>[pos] <Bit name> bit*; for example, UART.UASR[5] BIT_BY_CHAR bit
  - *<Bit name> bit <Module name>.<Register name>[pos]*; for example, BIT_BY_CHAR bit UART.UASR[5]

To help the reader navigate the document, each register call is hyperlinked to its register description in the register manual section. After each register description, a table summarizes all hyperlinked register calls.

To navigate in the PDF documents, see Acrobat Reader Tips.

Coding Rules

The programming models or code listings follow the rules:

Type	Definition	Example
File	Starts with the module name	PRCM_test1.c MCBSP1_init.h
Variable	Global variables are prefixed by "g_" Pointers are prefixed by "p" Global pointers are prefixed by "g_p"	g_SDMA_LogicalChan pAddrCounter g_pSDMA_LogicalChan
Function	Starts with the module name	PRCM_SetupClocks() ArmIntC_MaskInterrupts()
Typedef	Ends with "_t"	PRCM_Struct_t
Definition	Starts with the module name and is followed by the register name	#define SMS_ERR_TYPE *((volatileUint32*)0x680080F4) #define MCBSP2_RCR1_REG *((volatile Uint32*)0x4807401C)
Enumeration	Starts with the module name	Typedef enum DMA_Mode_Label { INPUT_MODE OUTPUT_MODE } DMA_Mode_t;

Flow Chart Rules

Flow charts follow the following rules:

Shape	Name	Definition
	Process	Any computational steps or processing function of a program; defined operation(s) causing change in value, form, or location of information
	Decision	A decision or switching-type operation that determines which of a number of alternate paths is followed
	Predefined process or sub-process	One or more named operations or program steps specified in a subroutine or another set of flow charts
	Data or I/O	General I/O function; information available for processing (input) or recording of processed information (output)
	Terminator	Terminal point in a flow chart: start, stop, halt, delay, or interrupt; may show exit from a closed subroutine
	Annotation	Additional descriptive clarification, comment
	On page connector (reference)	Exit to, or entry from, another part of chart in the same page
	Off page connector (reference)	The flow continues on a different page.
	Summing Junction	Logical AND
	Or	Logical OR
	Parallel mode (ISO)	Beginning or end of two or more simultaneous operations
	Flow Line	Lines indicate the sequence of steps and the direction of flow.

Acrobat Reader Tips

Acrobat includes two methods to search for words in a PDF:

- The Find toolbar provides a basic set of options to locate a word in the current PDF.
- The Search window lista words or partial words that match your text in the current PDF.

These guidelines apply to Acrobat Reader 5.x, 6.0, and 7.0.

For more information on Acrobat Reader search features, see the Adobe Reader Help.

To search for words in a document using the Find dialog box:

1. Open the document.
2. To display the Find toolbar, right-click in the toolbar area and select Find.
3. In the Find box, type the word, words, or partial words for which you want to search.
4. From the Find Options menu, select options as desired.
5. To view each search result, click the Find toolbar, the Find Previous button, or the Find Next button to go backward or forward through the document.

To search for words in a document using the Search PDF window:

1. Open the document.
2. Click the Search button on the File toolbar or right-click on your document and select Search.
3. Type the word, words, or part of a word for which you want to search.
4. Click Search.
5. The results appear in page order and, if applicable, show a few words of context. Each result displays an icon to identify the type of occurrence. All other searchable areas display the Search Result icon.
6. To display the page that contains a search result, click an item in the Results list. The occurrence is highlighted.
7. To navigate to the next result, choose Edit > Search Results > Next Result (or Ctrl+G).
8. To navigate to the previous result, choose Edit > Search Results > Previous Result (or Shift+Ctrl+G).

Navigate through your previous view

To retrace your path within an Adobe PDF document:

- For the previous view: Choose View > Go To > Previous View or Alt+Left Arrow.
- For the next view: Choose View > Go To > Next View or Alt+Right Arrow. The Next View command is available only if you have chosen Previous View.

  If you view the PDF document in a browser, use options on the Navigation toolbar to move between views.

  - Right-click the toolbar area, and then choose *Navigation*.
  - Click the Go To Previous View button or the Go To Next View button.

NOTE: This navigation tip is useful to return to your previous view after clicking on a register call hyperlink.

OMAP3 Disclaimer

All programming models and use cases presented in this manual are provided for educative purposes only and may differ from or be optimized for your applications.

All OMAP peripheral devices presented in this manual are provided for illustration purposes and may be different from those in your system.

- Chapter 18: Multichannel Buffered Serial Port
- Chapter 20: Universal Serial Bus (USB)

Introduction

This chapter introduces the features, supporting subsystems, and architecture of the AM35x ARM Microprocessors.

Topic **Page**

1.1 Overview

The AM35x ARM Microprocessors are integrated on TI's advanced 65-nm process technology.

NOTE: This technical reference manual describes all available features. Some features may not be available or supported on your particular device. For more information, see your device-specific data manual and Section 1.4, *Device Family*.

These devices are designed to provide maximum flexibility for ARM based applications including, but not limited to, Industrial Automation/Control, Single Board Computers, and Human Machine Interface.

These devices also feature M-Shield™ mobile security technology to enable secure e-commerce applications and the replay of copyright-protected digital media content.

Security features integrated on these devices support applications designed for:

- Protection against malicious attacks
- M-commerce
- Content protection for recordable media (CPRM)
- Digital rights management (DRM)

High-security (HS) devices rely on a security scheme based on hardware mechanisms and secure read-only memory (ROM) code, ensuring that only trusted code can access secure resources. These resources are in specific regions of memory as well as in peripherals, hardware cryptographic accelerators, and eFuse keys.

NOTE: To determine if a high-security (HS) version of your device is available and for more information on HS devices, see your device-specific data manual and Section 1.4, *Device Family*.

The device supports high-level operating systems such as:

- Windows CE
- Linux

Multiple RTOS are also supported.

These devices also include state-of-the-art power-management techniques required for high-performance mobile products.

The following subsystems are part of the device:

- Microprocessor unit (MPU) subsystem based on the ARM® Cortex™-A8 microprocessor
- SGX subsystem for 3D graphics acceleration to support display and gaming effects

NOTE: SGX is not available on all devices. For more information see your device-specific data manual and Section 1.4, *Device Family*.

- Camera image signal processor (VPFE) that supports multiple formats and interfacing options connected to a wide variety of image sensors
- Display subsystem with a wide variety of features for multiple concurrent image manipulation, and a programmable interface supporting a wide variety of displays. The display subsystem also supports NTSC/PAL video out.
- Level 3 (L3) and level 4 (L4) interconnects that provide high-bandwidth data transfers for multiple initiators to the internal and external memory controllers and to on-chip peripherals

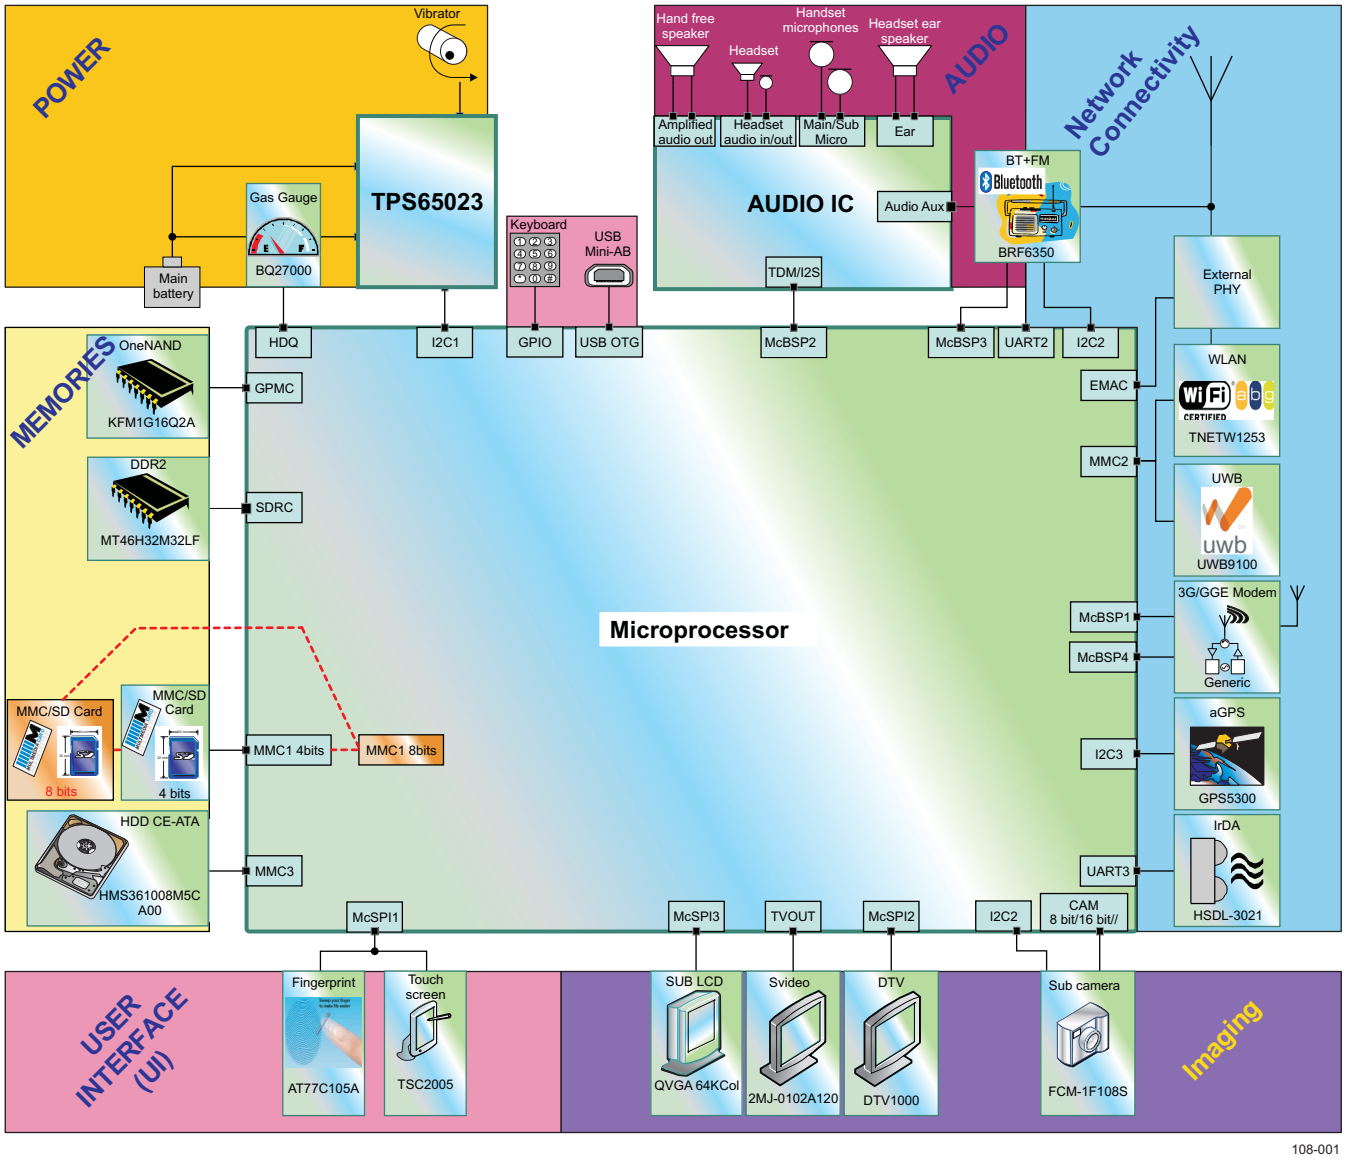
These devices also offer a comprehensive power and clock-management scheme that enables high-performance and low-power operation.

1.2 Environment

This section provides an overview of the device when integrated with the TPS65023 power integrated circuit (IC). For more information on the TPS65023 device, contact your TI representative.

Figure 1-1 provides an overview of a nonexhaustive environment for the high-tier device.

Figure 1-1. Environment Using TPS65023



108-001

NOTE: Some features are not available on all devices. For more information. see your device-specific data manual and Section 1.4, *Device Family*.

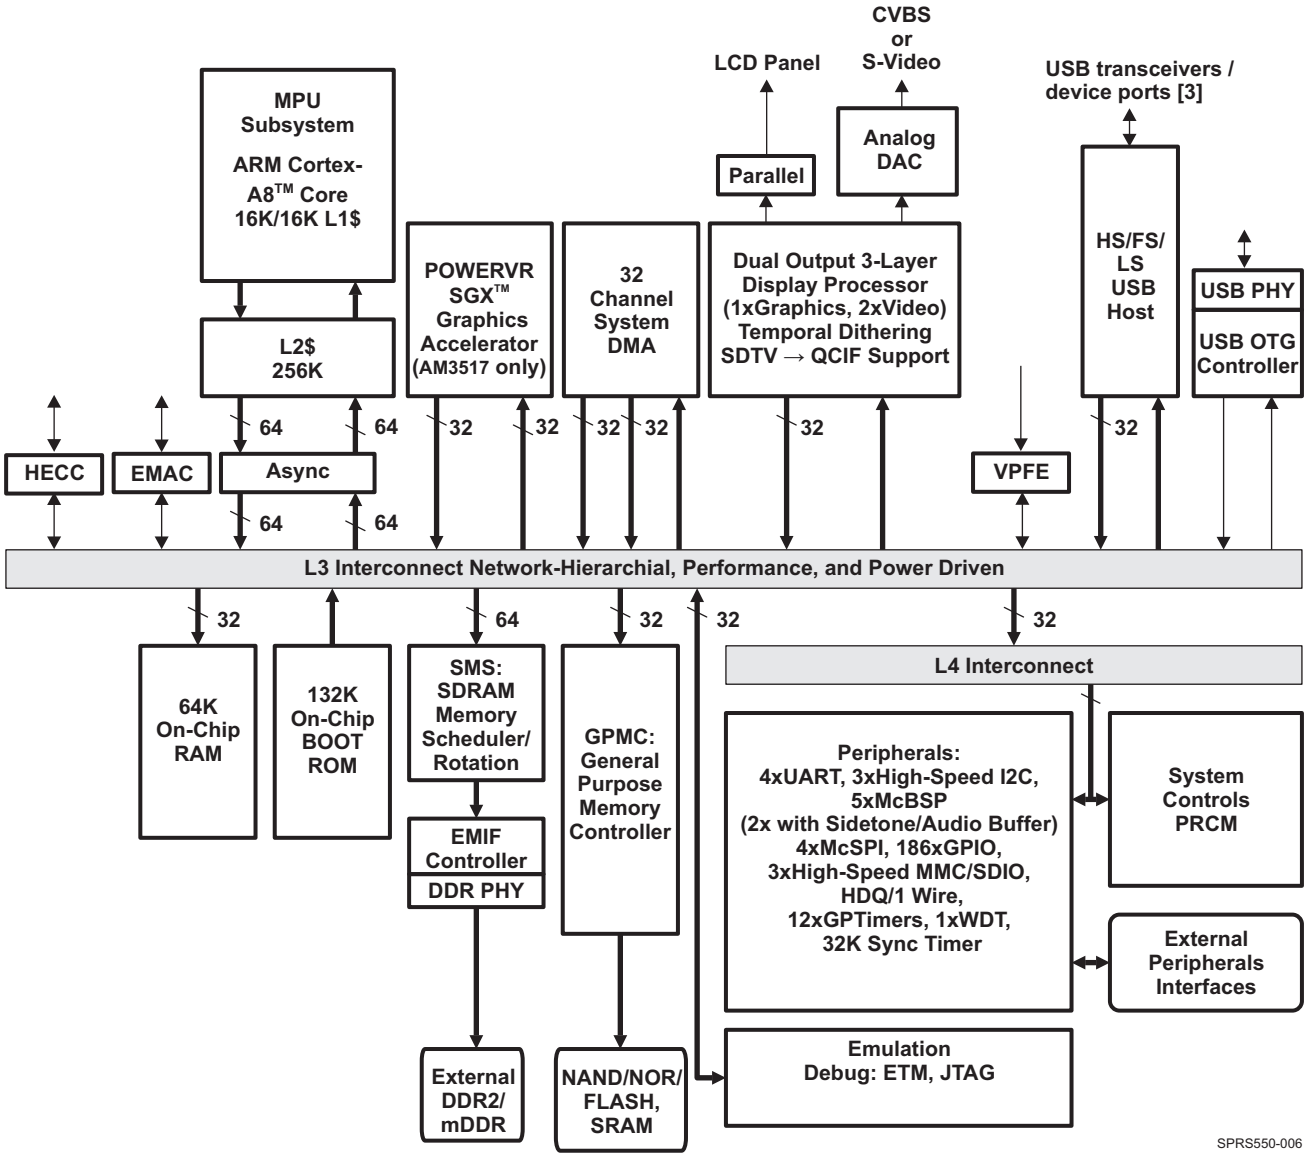
1.3 Description

These devices are offered in the following package:

- ZCN package: 491-pin BGA (17x17, 0.65mm pitch)
- ZER package: 484-pin PBGA (23x23, 1mm pitch)

Figure 1-2 shows the block diagram.

Figure 1-2. Block Diagram



NOTE: Some features are not available on all devices. For more information, see your device-specific data manual and Section 1.4, *Device Family*.

1.3.1 MPU Subsystem

The MPU subsystem integrates the following modules

- ARM subchip
  - ARM® Cortex™-A8 core
  - ARM Version 7™ ISA: Standard ARM instruction set + Thumb®-2, Jazelle® RCT Java accelerator, and media extensions
  - NEON™ SIMD coprocessor (VFP lite + media streaming instructions)
  - Cache memories
    - Level 1: 16KB instruction and 16KB data—4-way set associative cache, 64 bytes/line
    - Level 2: see Section 1.4, *Device Family*
- Interrupt controller (MPU INTC) of 96 synchronous interrupt lines
- Asynchronous interface with core logic
- Debug, trace, and emulation features: ICE-Crusher, ETM, ETB modules

1.3.2 On-Chip Memory

On-chip memory configuration offers memory resources for program and data storage:

- 112KB ROM
- 64KB single-access static random access memory (SRAM)

1.3.3 External Memory Interfaces

The device includes two external memory interfaces:

- General-purpose memory controller (GPMC)
  - NOR flash, NAND flash (with ECC Hamming code calculation), SRAM and Pseudo-SRAM asynchronous and synchronous protocols
  - Flexible asynchronous protocol control for external ASIC or peripheral interfacing
  - 16-bit data, up to 8 chip-selects (CSs)
  - 128M-byte addressable per chip-select, 1G-byte total address space
  - Nonmultiplexed device with limited address (2K bytes)
- SDRAM Controller (SDRC)
  - Double data rate (DDR2 and LPDDR) SDRAM
  - 16-bit or 32-bit data, 2 chip-selects, configurations for a maximum of 1 G-byte address space per chip-select
  - Work in conjunction with the SDRAM memory scheduler (SMS) companion module

1.3.4 DMA Controllers

The device embeds one generic DMA controller, the system DMA (sDMA) controller, used for memory-to-memory, memory-to-peripheral, and peripheral-to-memory transfers:

- One read port, one write port
- 32 prioritizable logical channels
- 96 hardware requests
- 256 x 32-bit FIFO dynamically allocable between active channels

The device also embeds two dedicated DMA controllers: display DMA and USB HS DMA.

1.3.5 Multimedia Accelerators

The device uses the following multimedia accelerators for display and gaming effects as well as high-end imaging and video applications:

- 3D graphics accelerator (SGX)
  - 3D graphics and video codecs supported on common hardware
  - Tile-based architecture
  - Universal scalable shader engine (USSE™) multithreaded engine incorporating pixel and vertex shader functionality reducing die area
  - Advanced shader feature set in excess of Microsoft VS3.0, PS3.0, and OGL2.0
  - Industry standard API supports OGL-ES 1.1 and 2.0, OpenVG 1.0, and OpenMax
  - Fine-grained task switching, load balancing, and power management
  - Programmable high-quality image anti-aliasing
  - Advanced geometry DMA driven operation for minimum CPU interaction
  - Fully virtualized memory addressing for OS operation in a unified memory architecture
  - Advanced and standard 2D operations (that is, vector graphics, BLTs, ROPs, etc.)
- Video Processing Front End (VPFE)
  - Supports most of the raw and smart image sensors available in the market
  - 16-bit parallel interface supported
  - Pixel clock up to 75 MHz

CAUTION

Clock configurations depend on the core voltage and maximum clock frequencies. Values in this document might not apply to production devices. Refer to your device-specific data manual for supported values for production devices.

- Display interface
  - Display controller
  - Color and monochrome displays up to 2048 x 2048 x 24-bpp resolution
  - 256 x 24-bit entries palette in red, green, blue (RGB)
  - 3,375 colors, 15 grayscales
  - Picture-in-picture (overlay), color-space conversion, rotation, color-phase rotation, and resizing support
  - Remote frame buffer interface
  - Liquid-crystal display (LCD) pixel interfaces (MIPI DPI 1.0) and LCD bus interfaces (MIPI DBI 1.0) supported
  - NTSC/PAL video encoder outputs with integrated digital-to-analog converters (DACs) output are supported on CVBS and S-video TV analog output signals
  - Embedded DMA controller

1.3.6 Security (HS Devices Only)

The secure firmware resides in a secure version of the ROM and includes hardware security features that enable HS devices and encryption/decryption accelerators. The following encryption/decryption accelerators are only available in HS devices:

- RNG
- 2 x DES/3DES
- SHA1/MD5
- SHA2/MD5
- 2 x AES with counter mode
- Fast PKA

The customer programmable fuse ROM (CPFROM) module is only available on high-security (HS) devices.

NOTE: To determine if a high-security (HS) version of your device is available and for more information on HS devices, see your device-specific data manual and Section 1.4, *Device Family*.

1.3.7 Comprehensive Power Management

The device includes the following power management features:

- Clock and reset generation and distribution
- Auto clock gating to save active power by gating clock when peripheral is not active

1.3.8 Peripherals

The device supports a comprehensive set of peripherals to provide flexible and high-speed interfacing and on-chip programming resources. Table 1-1 provides a list and description of the peripherals that are available.

Table 1-1. Device Peripherals

Type	Name	Number	Description
Serial Communication	Multi-channel Buffered Serial Ports (McBSPs)	5	The McBSPs provide a full-duplex direct serial interface between the device and other devices in a system such as audio and voice codecs and other application chips. McBSP1, McBSP2, and McBSP3 serve as general purpose serial ports while McBSP2 and McBSP3 include additional audio-loopback capability.
	Multi-channel Serial Port Interface (McSPI)	4	The McSPIs provide a master/slave interface to SPI devices.
	High-speed Multi-port USB Host Controller	1	High-speed USB2.0 host controller with three host ports each offering high-speed data transactions (up to 480 Mbps) or full-speed/low-speed data transactions (12 and 1.5 Mbps, respectively). In high-speed mode, the USB host controller ports interface to external USB PHYs using a 12-pin or 8-pin UTMI low pin interface (ULPI). In full-speed and low-speed mode, the ports interface to external USB PHYs using a 6-/4-/3-pin serial interface.
	High-speed USB OTG Controller	1	High-speed USB2.0 OTG controller that offers high-speed data transactions (up to 480 Mbps) on a USB port with embedded DMA controller. The high speed USB OTG controller includes integrated PHY, thus eliminating need of external PHY.
	HDQ/1-Wire®	1	The HDQ/1-Wire interface supports the Benchmark HDQ protocol and the Dallas Semiconductor 1-Wire protocol.
	Universal Asynchronous Receiver/Transmitter (UART)	4	Serial communication interfaces compatible to the industry standard TL16C550 asynchronous communications element. UART1 and UART 2 are general serial communication interfaces. UART3 provides additional support for infrared data association (IrDA) and consumer infrared (CIR) communications.
	High-speed (HS) Inter-integrated Circuit (I2C) Controllers	3	Master/slave I2C high-speed standard interfaces with support for standard mode (up to 100K bits/s), fast mode (up to 400K bits/s), and high-speed mode (up to 3.4M bits/s).
	HECC	1	Interface used to connect to vehicle bus in automotive.
Removable Media	Multimedia Card/Secure Digital/Secure Digital I/O (MMC/SDIO) Card Interface	3	MMC memory card, SD memory card, or SDIO cards interface.
Miscellaneous	GP timers	12	Twelve general-purpose timers
	Watchdog timers (WDTs)	1	Three watchdog timers
	32-kHz synchronization timer	1	32-kHz clock timer
	General-purpose input/output (GPIO)	Package-specific	General-purpose input/output pins controlled by six GPIO controllers.
	EMAC	1	10/100 Mbit Ethernet MAC operation with CPPI4.0 compliant & RMII interface. Interface used to connect to vehicle
	Control module	1	I/O multiplexing and chip-configuration control.
Security Modules (High-security Devices Only)			RNG, Fast PKA, 2xDES/3DES, SHA1/MD5, SHA2/MD5, 2xAES, and Secure Watchdog Timer.

1.4 Device Family

1.4.1 Device Features

Devices are configured with different sets of features on different devices. This technical reference manual details all available features. Some features may not be available or supported in your particular device. Features supported across different devices are shown in Table 1-2 (ZCN package). For more information on the ZCN package, refer to your device-specific data manual.

Table 1-2. Subsystem, Co-Processor, and Peripheral Support Matrixon the (ZCN Package)

Subsystem/Co-Processor/Peripheral	Chapter	AM3517	AM3505
POWERVR SGX™ 3D Graphics Accelerator	11	x	
Cortex-A8 Neon Co-Processor	3	x	x
SDRAM Controller	9	x	x
General-Purpose Memory Controller	9	x	x
VPFE	10	x	x
Display Subsystem	12	x	x
LCD DPI, LCD RFBI and TV Output Interface		x	x
LCD DSI and LCD SDI			
McBSP1/2/3/4/5	17	x	x
McSPI1/2/3/4	16	x	x
High-Speed USB OTG Controller	20	x	x
High-Speed USB Host Controller	20	x	x
HDQ/1-Wire	18	x	x
UART1/2	14	x	x
UART3/IrDA/CIR	14	x	x
I2C1/2/3	15	x	x
EMAC	22	x	x
HECC	23	x	x
MMC/SD/SDIO1/2/3	19	x	x

SHA1/MD5	1		
SHA2/MD5	1		
AES	1		
Fast PKA	1		
Secure Watchdog Timer	1		
High-security Device	1		
General-purpose Device	1	x	x

1.4.2 Device Identification

The identification registers include the CONTROL_IDCODE and CONTROL_DIE_ID data registers. These registers are accessible through the L4 interconnect port starting at physical address 0x4830 A204 and 0x4830 A218, respectively. See the Memory Mapping chapter for more information about the L4 memory space mapping. Table 1-3 describes the identification registers.

The silicon type can be read in the HAWKEYE bit field value of the CONTROL.CONTROL_IDCODE register. The silicon revision can be read in the VERSION bit field value of the CONTROL.CONTROL_IDCODE register.

Table 1-3. Device Identification Registers

Register Name	Address	Size
CONTROL.CONTROL_IDCODE[31:0]	0x4830 A204	32
CONTROL.CONTROL_DIE_ID[127:0]	0x4830 A218	128

To retrieve chip identification, see Table 1-4. This register helps software identify the chip derivative.

Table 1-4. Chip Identification

Scalable Resource	Name	Bit	Value	Description	AM3517	AM3505
SGX	SGX_scalable_control	14:13	00	Full use.	00	
			01	Core clock restricted in HW to /6 from L3.		
			10	HW not present.		10
			11	Reserved.		
Reserved	Reserved	12	0	Reserved. Not available for use.	0	0
MPU L2 Cache Size	MPU_L2_cache_size	11:10	00	0 KB.		
			01	64 KB.		
			10	128 KB.		
			11	Full use (256 KB).	11	11
MPU Frequency	ARM_MHz	9:8	00	500 MHz.	00	00
			01	400 MHz.		
			10	266 MHz.		
			11	Reserved.		
Reserved	Reserved	7:5	1	Reserved. Not available for use.	0	0
NEON & VFP	NEON_VFPLite	4	0	Full use.	0	0
			1	Not available for use.		
Reserved	Reserved	3:2	1	Reserved. Not available for use.	0	0
MMC1 Width	4_8_bit_mmc	1	0	Full use (8-bit width at 3.0v IO)	0	0
			1	Restricted use (4-bit width at 3.0v IO)		
TV Out	TO_OUT	0	0	Full use.	0	0
			1	Not available for use.		
Control Device Status Register 15:0 (Address 0x4800 244C)					0x0C00	0x4C00

Table 1-5. CONTROL_IDCODE Register Definition

Field	Bits	Value	Comment
CONTROL.CONTROL_IDCODE [31:28]	VERSION	See Table 1-6	Revision number
CONTROL.CONTROL_IDCODE [27:12]	HAWKEYE	See Table 1-7	Hawkeye number
CONTROL.CONTROL_IDCODE [11:1]	TI_IDM	0x13	Manufacturer identity (TI)
CONTROL.CONTROL_IDCODE [0]	--	0x1	Always set to 1.

The Hawkeye number is hardcoded in the design. Table 1-7 lists the Hawkeye number values, and Table 1-6 lists the silicon revision values.

Table 1-6. Revision Number Value

Silicon Type	Field	Value
ES1.0	CONTROL.CONTROL_IDCODE[31:28]	0000
ES1.1	CONTROL.CONTROL_IDCODE[31:28]	0001

Table 1-7. Hawkeye Number Value

Silicon Type	Field	Value
ES1.0	CONTROL.CONTROL_IDCODE[27:12]	0xB868
ES1.1	CONTROL.CONTROL_IDCODE[27:12]	0xB868

- The CONTROL.CONTROL_DIE_ID register is the 128 bits single identifier of the device.

Table 1-8. CONTROL_DIE_ID

Field	Bits	Value
DIE_ID[127:0]	RESERVED	Single identifier

1.4.3 General Recommendations Relative to Unavailable Features/Modules

As explained in the previous section, some features are not available in all devices. For unavailable features, use the following recommendations:

- Memory mapping: Memory area of unavailable modules and features are RESERVED, read is undefined, and write can lead to unpredictable behavior.
- Interrupt controllers: Ensure that interrupts of unavailable modules and features are masked in the MPU subsystem.
- DMA: Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.
- System Control Module (SCM): Unavailable modules and feature pins are not functional and should not be used.
- Power, Reset, and Clock Management Module (PRCM): For power management and power-saving consideration, ensure that power domains of unavailable features/modules are switched off and clocks are cut off.
- Interconnect: To flag potential interconnect outstanding commands, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Memory Mapping

This chapter describes memory mapping.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Topic **Page**

2.1 Introduction

The microprocessor unit (MPU) has a 32-bit address port, allowing it to handle a 4Gbytes space divided into several regions, depending on the target type.

The memory map is composed of a memory space (general-purpose memory controller [GPMC], external memory interface [EMIF4], etc.), register space (L3 and L4 interconnects), and dedicated spaces (SGX, etc.), all of which are shared among the initiators (for example, the MPU subsystem or the display subsystem).

The GPMC and EMIF4 are dedicated to memory connection. The GPMC is used for NOR/NAND flash and PSRAM memories. The EMIF4 is used for DDR2. For more information, see the *Memory Subsystem* chapter.

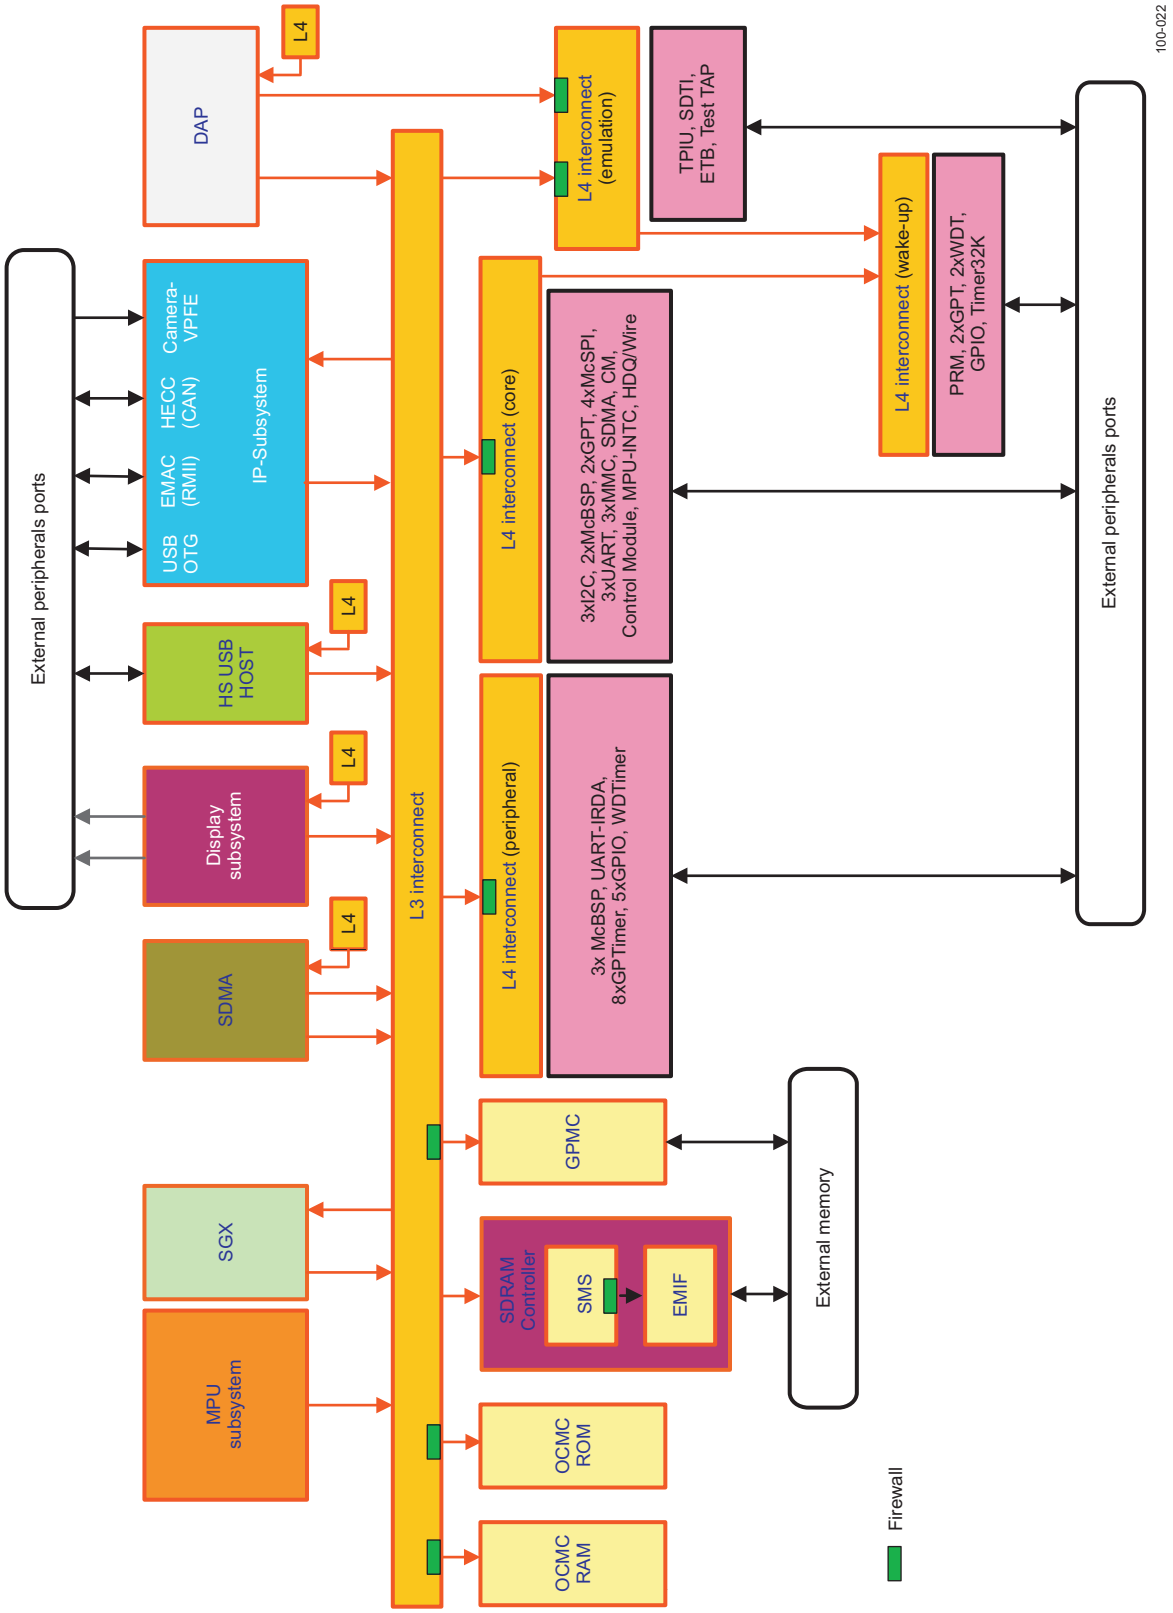
The L3 interconnect allows the sharing of resources, such as peripherals and external or on-chip memories, between all the initiators of the platform. The L4 interconnects control access to the peripherals.

Transfers between initiators and targets across the platform are physically conditioned by the chip interconnect and can be logically conditioned by firewalls. For more information about the intercommunication (L3 and L4 interconnects) and protection mechanisms implemented in the device, see the *Interconnect*.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, *Device Family*, and your device-specific data manual.

Figure 2-1 shows the interconnect of the device and the main modules and subsystems in the platform.

Figure 2-1. Interconnect Overview



2.2 Global Memory Space Mapping

This section provides a global view of the memory mapping and details the boot, GPMC, EMIF4, and virtual rotated frame buffer (VRFB) memory spaces.

The system memory mapping is flexible, with two levels of granularity for target address space allocation:

- Level 1: Four quarters are labeled Q0, Q1, Q2, and Q3. Each quarter corresponds to a 1Gbyte address space (total address space is 4Gbytes).
- Level 2: Each quarter is divided into eight blocks of 128Mbytes, with target spaces mapped inside the blocks.

This organization allows all target spaces to be decoded based on the five most significant bits (MSBs) of the 32-bit address ([31:27]).

- **Boot space**

  The system has a 1Mbyte boot space either in the on-chip boot ROM or on the GPMC memory space.

  When booting from the on-chip ROM with the appropriate external sys_boot5 pin configuration, the 1Mbyte memory space is redirected to the on-chip boot ROM memory address space [0x4000 0000 – 0x400F FFFF].

  When booting from the GPMC with the appropriate external sys_boot5 pin configuration, the memory space is part of the GPMC memory space.

  For more information on sys_boot5 pin configuration, see the *Memory Subsystem* and *Initialization* chapters.

- **GPMC space**

  Eight independent GPMC chip-selects (gpmc_ncs0 to gpmc_ncs7) are available in the first quarter (Q0) of the addressing space to access NOR/NAND flash and PSRAM memories. The chip-selects have a programmable start address and programmable size (16Mbytes, 32Mbytes, 64Mbytes, or 128Mbytes) in a total memory space of 1Gbyte.

- **EMIF4 space**

  Two EMIF4 chip-selects (emif4_ncs0 and emif4_ncs1) are available on the third quarter (Q2) of the addressing space to access SDRAM memories. The base address of EMIF4 space starts at 0x8000 0000. For more information on EMIF please refer to MemorySubsystem Chapter.

- **VRFB space**

  The EMIF4-SMS virtual memory space is a different memory space used to access a subset of the EMIF4 memory space through the rotation engine. The virtual address space size is 768Mbytes split into two parts: The first 256M-byte part is in the second quarter (Q1) of the memory; the second 512Mbytes part is in the fourth quarter (Q3) of the memory.

For more information on GPMC, EMIF4, and VRFB, see the *Memory Subsystem* chapter.

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Table 2-1 describes the global memory space mapping.

Table 2-1. Global Memory Space Mapping

2.3 L3 and L4 Memory Space Mapping

The memory space system is defined from a hierarchical view: L1, L2, L3, and L4.

L1 memory includes the MPU subsystem.

The chip-level interconnect, which is made of one L3 and four L4s, enables communication between all modules and subsystems.

L3 handles many types of data transfers and, in particular, the data exchange with system on-chip/external memories.

The four L4s that handle transfers with peripherals are: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects.

For more information about the interconnect, see the *Interconnect* chapter.

The following sections describe the register mapping of the L3 and L4 interconnects. The software configures these registers.

2.3.1 L3 Memory Space Mapping

The L3 interconnect control registers are mapped in a 16Mbytes space and allow the configuration of the L3 interconnect parameters.

The L3 default settings are fully functional and enable all possible functional data paths. However, the interconnect parameters can be changed to accommodate expectations.

Accesses to the L3 interconnect can be configured on a per-module basis using the internal L3 registers, which are grouped into five register block types:

- IA: initiator agent configuration registers
- TA: target agent configuration registers
- RT: register target (global configuration registers)
- PM: protection mechanism (firewalls) configuration registers
- SI: global sideband signal configuration registers

For more information, see the *Interconnect* chapter.

This section gives information about all modules and features in the high-tier device. to check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Table 2-2 describes the mapping of the L3 interconnect control registers.

Table 2-2. L3 Control Register Mapping

2.3.2 L4 Memory Space Mapping

The device contains four L4 interconnects: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects.

As with the L3 interconnect, the L4 interconnects can be configured to tune the access depending on the characteristics of each module.

For more information on the L4 interconnect, see the *Interconnect* chapter.

2.3.2.1 L4-Core Memory Space Mapping

The L4-Core interconnect is a 16Mbytes space composed of the L4-Core interconnect configuration registers and the module registers.

Table 2-3 describes the mapping of the registers for the L4-Core interconnect.

NOTE: All memory spaces described as modules provide direct access to module registers outside the L4-Core interconnect. All other accesses are internal to the L4-Core interconnect.

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

2.3.2.3 L4-Peripheral Memory Space Mapping

The L4-Per interconnect is a 1Mbyte space composed of the L4-Per interconnect configuration registers and the module registers.

Table 2-5 describes the mapping of the registers for the L4-Per interconnect.

NOTE: All memory spaces described as modules provide direct access to the module registers outside the L4-Per interconnect. All other accesses are internal to the L4-Per interconnect.

MPU Subsystem

This chapter describes the microprocessor unit (MPU) subsystem.

Topic **Page**

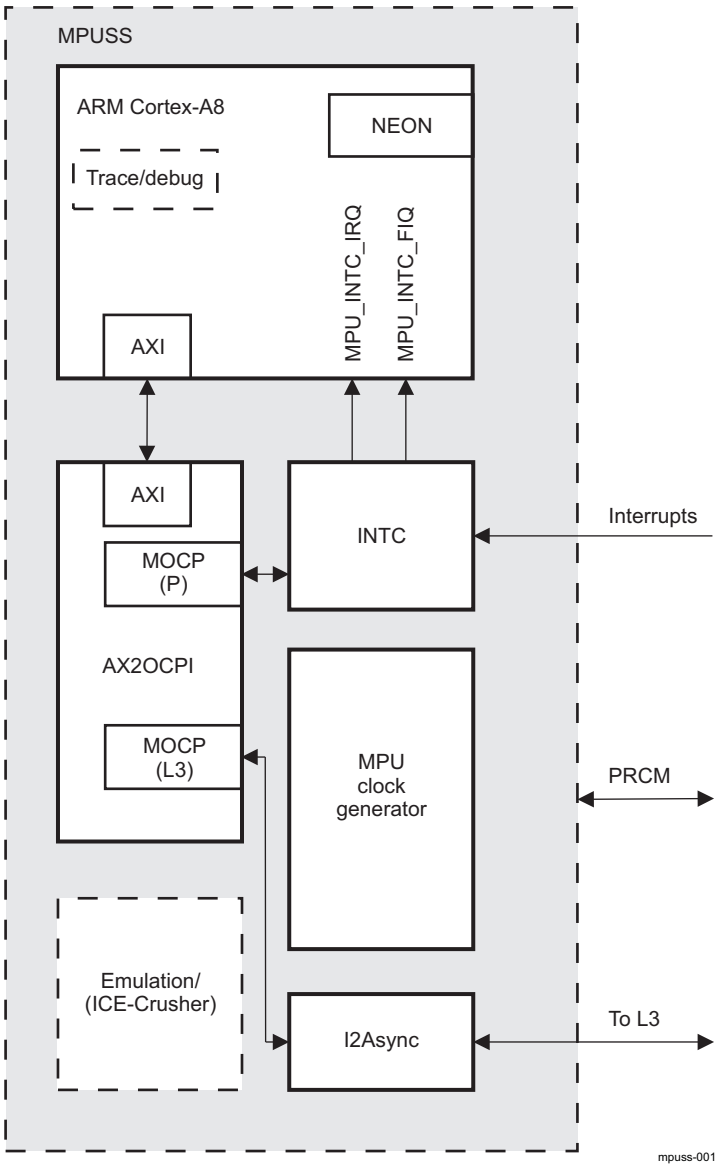
3.1 MPU Subsystem Overview

3.1.1 Introduction

The MPU subsystem of the device handles transactions among the ARM core, the L3 interconnect, and the interrupt controller (INTC).

The MPU subsystem is a hard macro that integrates the ARM subchip with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements. Figure 3-1 is a high-level block diagram of the MPU subsystem.

Figure 3-1. MPU Subsystem Overview



3.1.2 Features

The MPU subsystem integrates the following:

- ARM subchip
  - Public ARM Cortex™-A8 core
  - ARM version 7 ISA: Standard ARM instruction set + Thumb-2™, Jazelle® RCT Java accelerator, and media extensions
  - Neon single instruction, multiple data (SIMD) coprocessor (VFP light + media streaming instructions)
  - Cache memories
    - Level 1: 16-KB instruction and 16-KB data caches – 4-way associative, 64 bytes/line
    - Level 2: See Section 1.4, .
  - Emulation/debug
- INTC of 96 synchronous level-sensitive interrupt lines (For details, see Chapter 8, *Interrupt Controller*.)
- AXI2OCP bridge between ARM AXI bus, L3 master open-core protocol (OCP) bus, and INTC master OCP bus
- MPU clock generator: Clock generation module that generate clocks, power modes, and idle and active acknowledge signals
- Debug, trace, and emulation features: ICECrusher™, embedded trace macrocell (ETM), advanced peripheral bus (APB) modules. Cortex-A8 MPU implements an APB slave interface that allows access to ETM, ICECrusher, and debug registers.

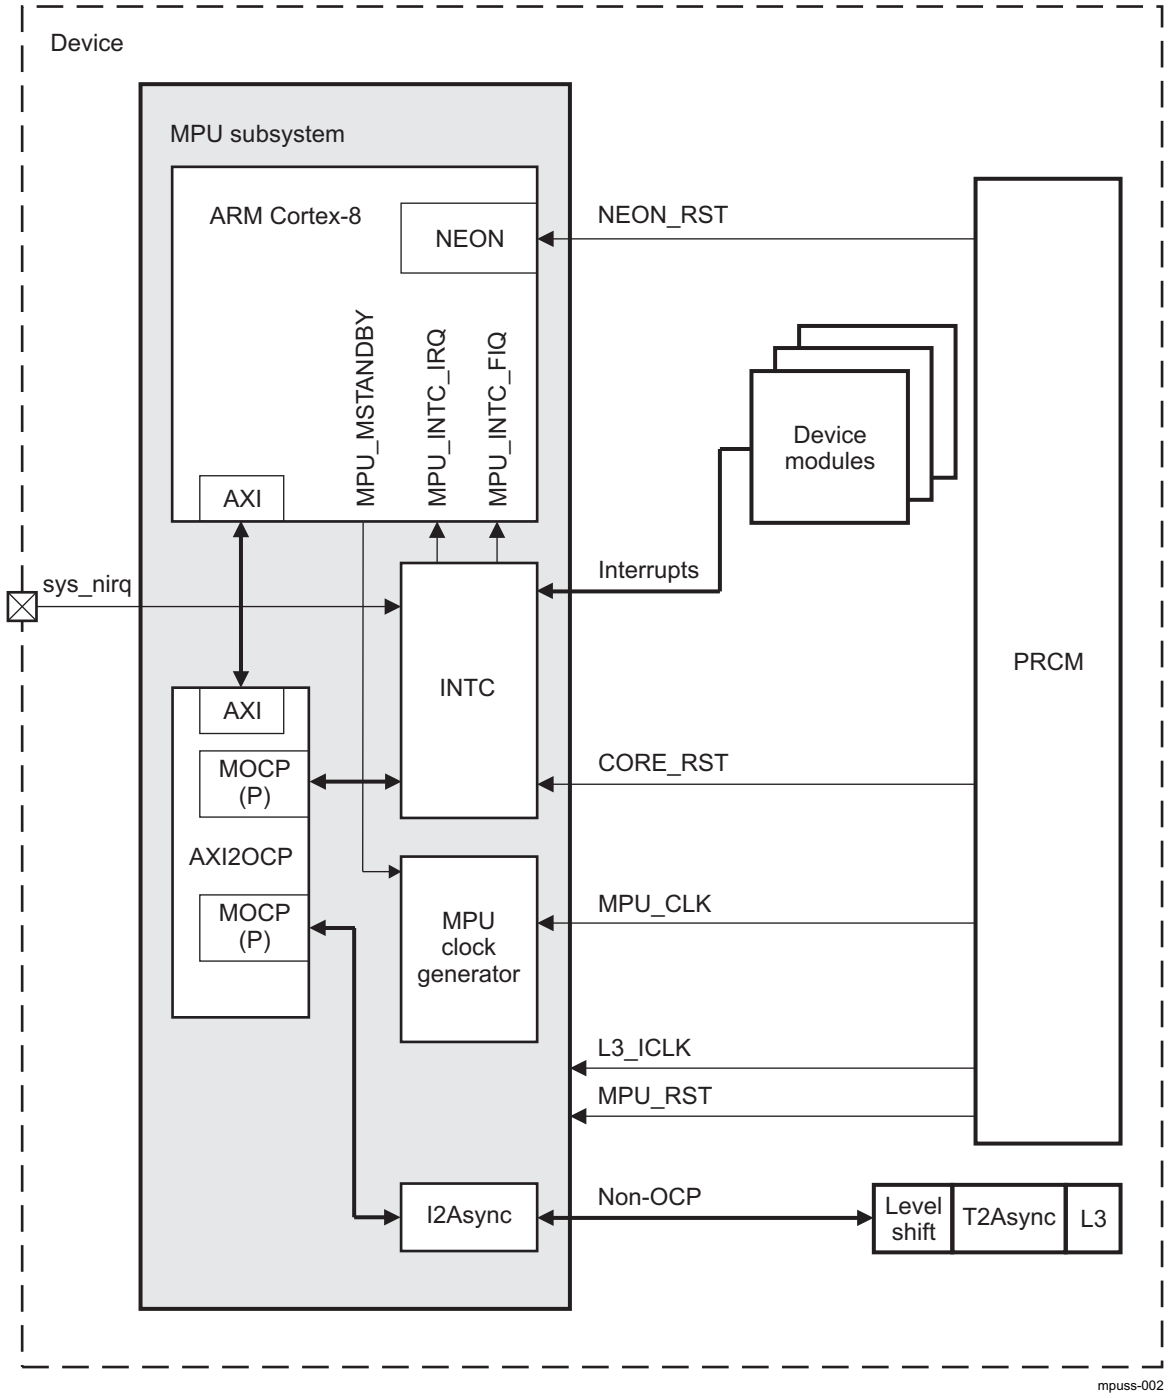
3.2 MPU Subsystem Integration

The MPU subsystem integrates the following group of submodules:

- Public ARM Cortex-A8 MPU: Provides a high processing capability, including the Neon technology for mobile multimedia acceleration. The ARM communicates through an AXI bus with the AXI2OCP bridge and receives interrupts from the MPU INTC.
- INTC: Handles module interrupts (for details, see Chapter 8, *Interrupt Controller*).
- AXI2OCP bridge: Allows communication among the ARM (AXI), the INTC (OCP), and the modules (OCP L3).
- I2Async bridge: An asynchronous bridge interface providing an asynchronous OCP-to-OCP interface. This interface is between the AXI2OCP bridge in the MPU subsystem and the T2Async bridge external to the MPU subsystem. The T2Async bridge connects to OCP L3.
- MPU clock generator: Provides clocks to internal modules of the MPU subsystem; fed by the MPU digital phase-locked loop (DPLL) of the power, reset, and clock management (PRCM) module of the device. The MPU DPLL generates the clock for the ARM Cortex-A8 CPU and the Cortex-A8 MPU subsystem logic. The power, reset, and MPU DPLL source clock are generated from the device PRCM module.

Figure 3-2 shows the signals that interface with the external modules.

Figure 3-2. MPU Subsystem Integration Overview



NOTE: Some debug, trace, and emulation features are implemented in the MPU subsystem. This chapter includes only clock/reset inputs and power-management aspects for these features.

3.2.1 MPU Subsystem Clock and Reset Distribution

3.2.1.1 Clock Distribution

The MPU subsystem includes a clock generator block that supplies clocks for the modules in the MPU subsystem. It is fed by the MPU_CLK clock from the PRCM module.

All major modules in the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV bit field; the frequency is relative to the ARM core. For details see , *Power, Reset, and Clock Management (PRCM) module* . The clock generator generates the following functional clocks:

- **ARM (ARM_FCLK):** This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including Neon, L2 cache, the ETM core (emulation), and the ARM core. It runs at one half the frequency of the MPU_CLK when DPLL1 is locked, and runs at the same frequency as the MPU_CLK when DPLL1 is bypassed.
- **AXI2OCP clock (AXI_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). The OCP interface thus performs at one half the frequency of ARM.
- **INTC functional clock (MPU_INTC_FCLK):** This clock, which is part of the INTC module, is half the frequency of the ARM clock (ARM_FCLK).
- **ICE-Crusher functional clock (ICECRUSHER_FCLK):** ICECrusher clocking operates on the APB interface, using the ARM core clocking.
- **I2Async clock (I2ASYNC_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). It matches the OCP interface of the AXI2OCP bridge.

NOTE: The second half of the asynchronous bridge (T2ASYNC) is clocked directly by the PRCM module with the core clock. T2ASYNC is not part of the MPU subsystem.

Emulation clocking: Except for the ICECrusher functional clock, which is provided by the MPU DLL, the emulation modules in the MPU subsystem are not generated by the MPU subsystem DPLL, but by an EMU DPLL. These clocks (EMU_CLOCKS) are distributed by the PRCM module, are asynchronous with the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock.

Figure 3-3 shows the MPU subsystem clocking scheme.

Figure 3-3. MPU Subsystem Clocking Scheme

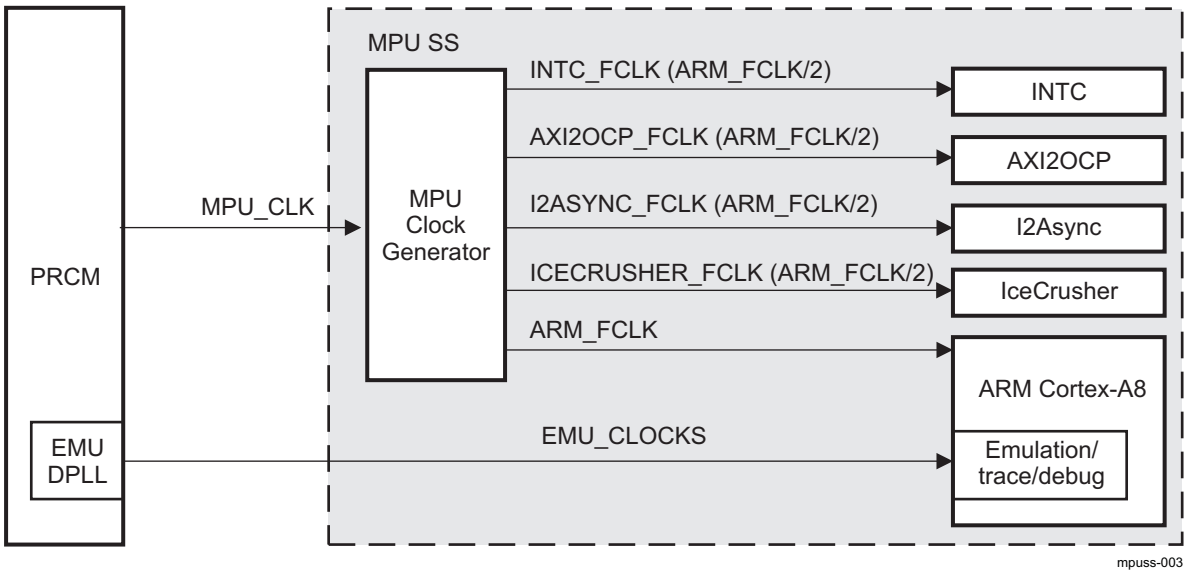


Table 3-1 lists the clocks generated in the MPU subsystem by the MPU clock generator.

Table 3-1. MPU Clock Generator Clock Signals

Signal Name	I/O	Interface	Comments
MPU_CLK	I	PRCM	MPU DPLL clock out
ARM_FCLK	O	ARM	ARM functional clock
MPU_INTC_FCLK	O	MPU INTC	MPU INTC functional clock
I2ASYNC_FCLK	O	I2Async	I2Async functional clock
AXI_FCLK	O	AXI2OCP	AXI2OCP functional clock
ICECRUSHER_FCLK	O	ICE-Crusher	ICECrusher functional clock

3.2.1.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM module and controlled by the clock generator module. There are as many reset signals as power domains. For details about power domains, see Section 3.3.2.1. Figure 3-4 shows the reset scheme of the MPU subsystem.

Figure 3-4. MPU Subsystem Reset Scheme

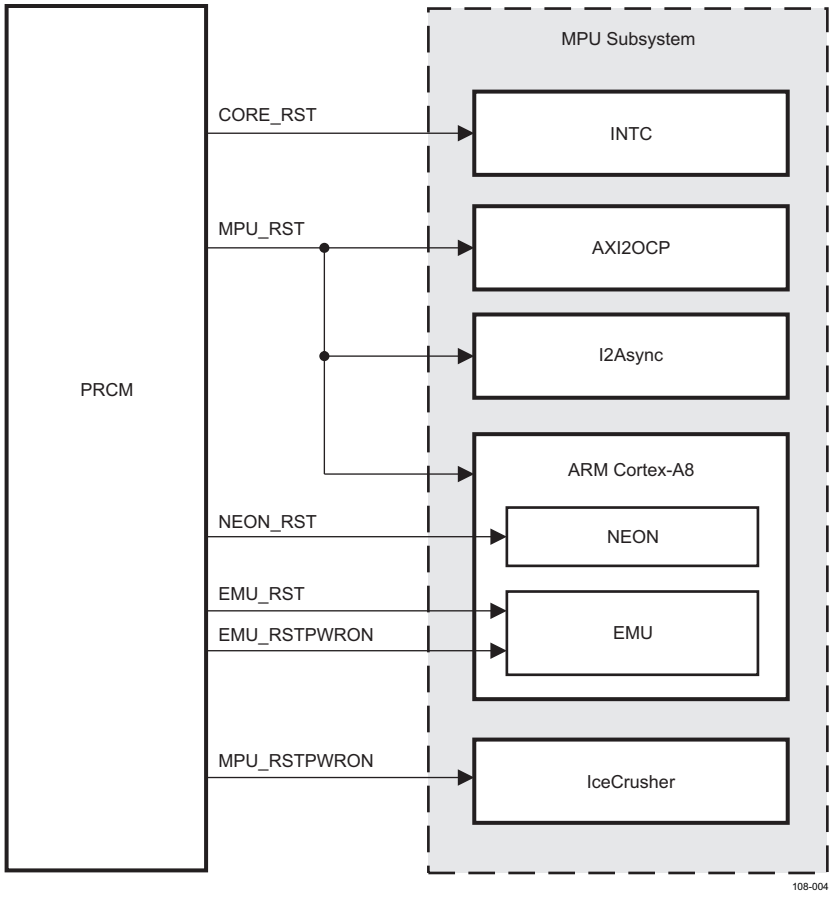

Table 3-2. MPU Subsystem Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
Neon_RST	I	PRCM	Neon power domain reset
CORE_RST	I	PRCM	CORE power domain reset
MPU_RSTPWRON	I	PRCM	ICECrusher reset. It is active only on cold reset.
EMU_RST	I	PRCM	Emulation interconnect reset
EMU_RSTPWRON	I	PRCM	Emulation modules reset

For details about clocks, resets, and power domains, see , *Power, Reset, and Clock Management*.

3.2.2 ARM Subchip

3.2.2.1 ARM Overview

The public ARM Cortex-A8 processor incorporates the technologies available in the ARM7 architecture. These technologies include Neon for media and signal processing and Jazelle RCT for acceleration of realtime compilers, Thumb-2 technology for code density and the VFPv3 floating-point architecture.

For details, see the public ARM Cortex-A8 Technical Reference Manual.

3.2.2.2 ARM Description

3.2.2.2.1 Public ARM Cortex-A8 Instruction, Data, and Private Peripheral Port

The AXI bus interface is the main interface to the ARM system bus. It performs L2 cache fills and noncacheable accesses for instructions and data. The AXI interface supports 64-bit wide input and output data buses. It supports multiple outstanding requests on the AXI bus and a wide range of bus clock-to-core clock ratios. The bus clock is synchronous with the core clock.

See the public ARM Cortex-A8 Technical Reference Manual for a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address.

3.2.2.2.2 MPU Subsystem Features

Table 3-3 is a list of main functionalities of the ARM core supported in the MPU subsystem for the device. The MPU subsystem implements the ARM7™ instruction set architecture.

Table 3-3. ARM Core Key Features

Feature	Comment
ARM version 7 ISA	Standard ARM instruction set + Thumb-2, Jazelle RCT Java accelerator, and media extensions. Backward-compatible with previous ARM ISA versions.
L1 Icache and Dcache	16KB, 4-way, 64-byte cache line, and 128-bit interface. Note: L1 memories cannot be put in retention mode.
L2 Cache	The L2 cache and cache controller are embedded in the ARM core. For size, see Section 1.4, .
TLB	Fully associative and separate ITLB with 32 entries and DTLB with 32 entries
CoreSight ETM	The CoreSight ETM is embedded in the ARM core. The 4KB buffer (ETB) exists at the device level.
Branch target address cache	512 entries
Enhanced Memory Management Unit	Mapping sizes are 4KB, 64KB, 1MB, and 16MB. ARM MMU adds extended physical address ranges.
Neon	Enhances throughput for media workloads and VFP-Lite support
Tightly coupled memory	Not present
AXI Bus	Separate 64-bit input and 64-bit output data buses. The public ARM Cortex-A8 has a single AXI bus interface. The AXI interface is shared by instruction fetches, data accesses, peripheral accesses and PLE (on-chip preload engine, previously known as DMA) accesses. DMA is available.
Low interrupt latency	Interrupt request (IRQ) and fast interrupt request (FIQ) are directly connected to ARM and INTC is before L3.
Vectored Interrupt Controller Port	Not used
JTAG based debug	Supported through debug access port (DAP)
Trace support	Supported through trace port interface unit (TPIU)
External coprocessor	Not supported

For more information, see the public *ARM Cortex-A8 Technical Reference Manual*.

3.2.2.3 Clock, Reset, and Power Management

3.2.2.3.1 Clocks

Table 3-4 shows the ARM functional clock. For configuration, see , *Power, Reset, and Clock Management*.

Table 3-4. MPU Subsystem Clock Signal

Signal Name	I/O	Interface	Comments
ARM_FCLK	I	MPU Clock Generator	Functional clock

3.2.2.3.2 Reset

Table 3-5 lists the resets for the ARM. They include the power domain reset, Neon_RST, which resets the Neon module of the ARM subchip only, and MPU_RST, which resets the rest of the ARM subchip and the AXI2OCP and I2Async bridges.

Table 3-5. ARM Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
Neon_RST	I	PRCM	Reset Neon only
EMU_RST	I	PRCM	Emulation interconnect reset
EMU_RSTPWRON	I	PRCM	Emulation modules reset

3.2.2.3.3 Power Management

For details, see Section 3.3.2.

3.2.3 AXI2OCP and I2Async Bridges

3.2.3.1 Bridges Overview

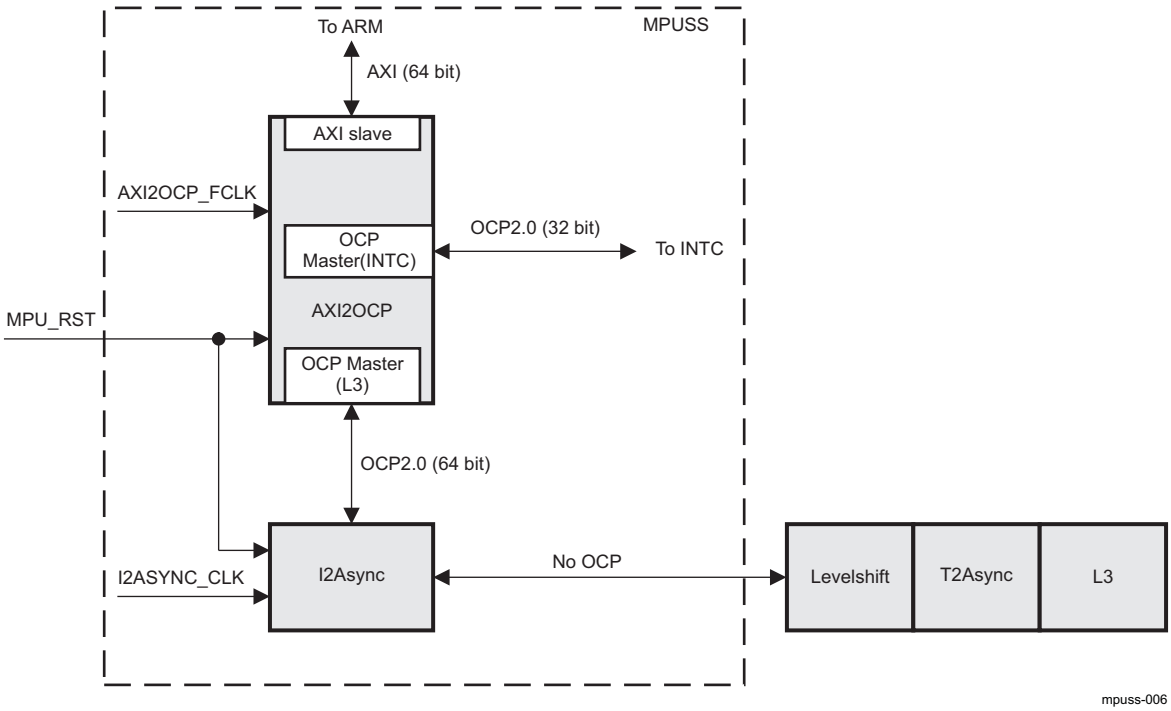
The AXI2OCP bridge connects the AXI bus on the ARM MPU to the OCP native L3 interconnect and INTC. It converts between AXI and OCP protocols and maintains a mapping of AXI tags to the OCP thread ID. This bridge is responsible for some minimal address decoding to determine where to forward requests between L3 and INTC.

Bridging to the L3 is accomplished through an asynchronous interface involving the I2Async and T2Async modules. The I2Async module in the MPU subsystem has an OCP port that is asynchronously transferred to the T2Async module and routed to the L3. T2Async is outside the MPU subsystem.

NOTE: The interface between I2Async and T2Async is not an OCP protocol.

Figure 3-5 is an overview of the AXI2OCP and the L3 bridges.

Figure 3-5. Bridges Overview



3.2.3.2 AXI2OCP Description

The AXI2OCP bridge key features are:

- Connection to the L3 interconnect through a 64-bit OCP port. Address bus is 32-bit.
- Connection to the INTC through a 32-bit OCP port (only single transactions are supported)
- Support of single-request-multiple-data (data handshaking) burst mode to pipeline requests to L3. Bursts with width less than 64 bits are converted as single requests on L3. This can affect system performance. The INTC does not support burst transfers
- Support of multiple outstanding requests
- Remapping of the AXI tags to five OCP threads:
  - Instruction fetch (Thread_IR)
  - Cacheable data read (Thread_CR)
  - Cacheable data write (Thread_CW)
  - Noncacheable data read (Thread_DR)
  - Noncacheable data write (Thread_DW)
- Interface to the L3 through the asynchronous bridge (I2Async)
- Emulation and support of boot-mode translation
- Translation of exclusive accesses to nonexclusive read/write in the bridge
- Boot mode address translation
- Force write nonposted support
- Debug related: Ready fail, force ready
- Interconnect attach neutralizer
- Narrow burst support
- Time-out counter for nonresponsive slaves on OCP

3.2.3.3 Clocks, Reset, and Power Management

3.2.3.3.1 Clocks

Table 3-6 lists the bridge functional clocks.

Table 3-6. Bridge Clock Signals

Signal Name	I/O	Interface	Comments
AXI2OCP_FCLK	I	MPU Clock Generator	AXI2OCP functional clock
I2ASYNC_FCLK	I	MPU Clock Generator	I2Async functional clock

3.2.3.3.2 Reset

Table 3-7 lists the bridge reset. It is a power domain reset that also resets the ARM.

Table 3-7. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset

3.2.3.3.3 Power Management

For details, see Section 3.3.2.

3.2.4 Interrupt Controller

For information, see Chapter 8, *Interrupt Controllers*.

3.2.4.1 Clocks

Table 3-8 lists the INTC clocks.

Table 3-8. Bridge Clock Signals

Signal Name	I/O	Interface	Comments
MPU_INTC_FCLK	I	MPU Clock Generator	INTC functional clock
MPU_INTC_ICLK	I	OCP Clock	INTC interface clock

3.2.4.2 Reset

Table 3-9 lists the reset of the INTC. It is a power domain reset that resets the entire CORE power domain. For details, see Chapter 8, *Interrupt Controller* and , *Power, Reset, and Clock Management*.

Table 3-9. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
CORE_RST	I	PRCM	CORE power domain reset

3.2.4.3 Power Management

See Chapter 8, *Interrupt Controller*, and , *Power, Reset, and Clock Management*.

3.3 MPU Subsystem Functional Description

3.3.1 Interrupts

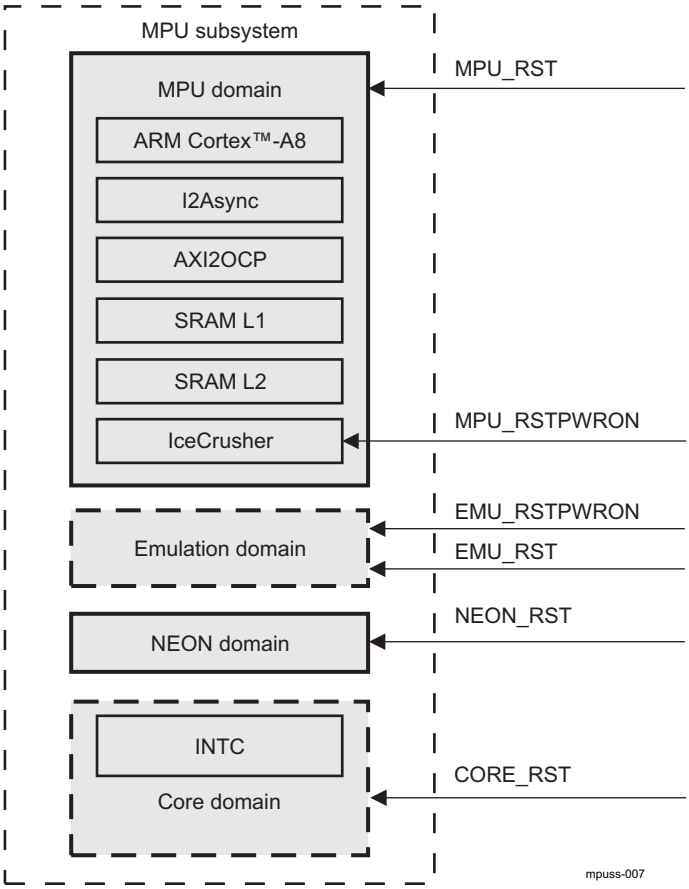
The MPU INTC is connected to the MPU through the AXI2OCP bridge. It runs at half-processor speed. The INTC prioritizes all service requests from the system peripherals and generates an IRQ or an FIQ to the MPU, depending on the INTC programming. The INTC handles only interrupts directed to the MPU subsystem. A maximum of 96 requests can be steered/prioritized as MPU FIQ or IRQ interrupt requests. For details, see Chapter 8, *Interrupt Controller*.

3.3.2 Power Management

3.3.2.1 Power Domains

The MPU subsystem is divided into five power domains controlled by the PRCM module, as shown in Figure 3-6. The EMU and CORE power domains are not fully embedded in the MPU subsystem.

Figure 3-6. MPU Subsystem Power Domain Overview



Power-management requirements at the device level govern power domains for the MPU subsystem.

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross reference to the different voltage domains. Table 3-10 shows the power domains of the MPU subsystem and the modules inside it.

Table 3-10. Overview of the MPU Subsystem Power Domain

Functional Power Domain	Physical Power Domain per System/Module
MPU subsystem domain	ARM, AXI2OCP, I2Asynch Bridge, ARM L1 and L2 periphery logic and array, ICECrusher, ETM, APB modules

Table 3-10. Overview of the MPU Subsystem Power Domain (continued)

Functional Power Domain	Physical Power Domain per System/Module
MPU Neon domain	ARM Neon accelerator
CORE domain	MPU INTC
EMU domain	EMU (ETB, DAP)

NOTE: L1 and L2 array memories have separate control signals to the MPU subsystem; thus are directly controlled by the PRCM module.

For information about the physical power domains and the voltage domains, see , *Power, Reset, and Clock Management.*

3.3.2.2 Power States

Each power domain can be driven by the PRCM module in four power states, depending on the functional mode required by the user.

Table 3-11. MPU Power States

Power State	Logic Power	Memory Power	Clocks	Memory State Retention
ACTIVE	On	On or Off	On (at least one clock)	All
INACTIVE	On	On or Off	Off	All
RETENTION	On or Off	On or Off	Off (all clocks)	All or part
OFF	Off	Off	Off (all clocks)	None

For each power domain, the PRCM module manages all transitions by controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention. The MPU DPLL internally synchronizes the internal clocks, resets, and switches.

3.3.2.3 Power Modes

MPU DPLL power modes:

The PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL bit field lets the MPU DPLL be put in an auto-idle mode when set to 0x1. In this mode, the MPU DPLL is automatically put in low power stop mode when the MPU clock is not required. It is also restarted automatically. Table 3-12 describes the power modes of the MPU DPLL in auto-idle or manual mode. The manual modes (locked and low-power bypass) can be configured by the PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL bit field. The status of the MPU DPLL clock activity can be checked with the PRCM.CM_IDLEST_PLL_MPU[0] ST_MPU_CLK bit.

Table 3-12. MPU DPLL Power Modes

Mode	System Input Clock	Clock Output	DPLL Power State	Condition
Locked	ON	ON	ON	Software request (manual) or MPU wakes up (auto)
Low-power bypass	ON	ON	ON	Software request (manual) or on global reset release (auto)
Stop low power	OFF	OFF	ON	MPU is RET or OFF (auto).
OFF	OFF	OFF	OFF	Device is OFF (auto).

The MPU DPLL power domain is switched off automatically by the PRCM module only when the device enters OFF mode.

MPU subsytem power modes:

The major part of the MPU subsystem belongs to the MPU power domain. Modules in this power domain can be off when the ARM processor is in OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block, but initiated by the PRCM module. The MPU standby status can be checked with the PRCM.CM_IDLEST_MPU[0] ST_MPU bit.

For the MPU to be on, the core (referred to here as the device core) power must be on.

Device power management does not allow INTC to go to OFF state when the MPU domain is on (active or one of the retention modes).

The Neon core is in independent power off mode when not in use. Enabling and disabling of Neon can be controlled by software.

The MPU retention modes are described in Table 3-13.

Table 3-13. MPU Retention Modes

Name	ARM Logic	L1	L2
Dormant	OFF	OFF	RET
RET	RET	RET	RET

Table 3-14 lists the supported operational power modes. All other combinations are illegal. The ARM L2, Neon, and ETM/debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

Table 3-14. MPU Subsystem Operation Power Modes

Mode	MPU and ARM Core Logic	ARM L2 RAM	Neon	OMAP Core INTC	APB/ATB ETM/Debug	Comments
1	Active	Active	Active	Active	Disabled or enabled	Functional active run mode (ETM enabled mode when emulation/debug required. Production devices should have ETM disabled).
2	Active	Active	OFF	Active	Disabled or enabled	Functional active run mode. Neon disabled through software; Neon is internally clock-gated.
3	Active	RET	Active	Active	Disabled or enabled	Do not use; see (1).
4	Active	RET	OFF	Active	Disabled or enabled	Do not use; see (1).
5	Active	OFF	Active	Active	Disabled or enabled	Active mode; L2 is off. Controlled through software to the PRCM module. L2 context save and restore required or L2 flush.
6	Active	OFF	OFF	Active	Disabled or enabled	Active mode; L2 is off. Controlled through software to the PRCM module. L2 context save and restore required or L2 flush.

(1) The L2 can be put in retention mode regardless of other voltage domain states. The combination of Cortex Logic active and L2 in retention mode (modes 3 and 4) is legal, but results in incorrect execution of instructions with referencing data from L2. This combination must not be used.

Table 3-14. MPU Subsystem Operation Power Modes (continued)

Mode	MPU and ARM Core Logic	ARM L2 RAM	Neon	OMAP Core INTC	APB/ATB ETM/Debug	Comments
7	OFF	RET	OFF	OFF	Disabled or enabled	Lowest power sleep mode (dormant mode); L2 is in retention. Controlled through software to the PRCM module. ARM core and L1 context save and restore required or L1 flush.
8	Standby	Active	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI (wait for interrupt) controlled to put into standby and wakeup through interrupt.
9	Standby	Active	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup through interrupt when Neon is off.
10	Standby	RET	Standby	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is in retention.
11	Standby	RET	OFF	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is in retention and Neon is off.
12	Standby	OFF	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is off.
13	Standby	OFF	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup through interrupt when L2 and Neon are off.
14	OFF	OFF	OFF	OFF	Disabled or enabled	Power-down mode

In any mode where the MPU or Neon power domains are active, the MPU DPLL clocks must be active (modes 1, 3, and 5 require active clocks from the DPLL, while modes 7 and 8 do not).

Thus, the MPU DPLL must be in one of the following states:

- Locked
- Low-power bypass: inclk = on, clkout = on, power = on

When the MPU DPLL is not providing clocks, the MPU subsystem must be in a power mode where the MPU power domain, Neon power domain, debug power domain, and INTC power domain are in standby, RETENTION, or OFF state. The states of the MPU DPLL can be:

- Locked
- STOP low power
- OFF

CAUTION

The L2 can be put into retention mode regardless of other voltage domain states. The combination of ARM Logic active and L2 in retention mode (modes 3 and 4) is legal, but results in incorrect execution of instructions with referencing data from L2. This combination must not be used.

3.3.2.4 Transitions

Table 3-15 describes allowable transitions from power modes described in Table 3-14. For example, a transition from mode 13 to mode 4 is allowed, but the reverse is not true, because the L2 RET to OFF is illegal.

Any mode change that requires state saving or flush must be serialized. For example, L2 RET does not require state saving, so it can happen at the same time as power-down Neon. L2 off and Neon off cannot happen at the same time, because L2 flush and Neon state saving must be serialized. Standby mode can enter from active mode only by executing the WFI instruction.

Table 3-15. Power Mode Allowable Transitions

	To Power Mode													
From	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**
1	Y	Y	Y	Y	Y			Y						Y
2	Y	Y	Y	Y		Y			Y		Y			Y
3	Y	Y	Y	Y			Y			Y				
4	Y	Y	Y	Y			Y				Y			
5	Y		Y	Y	Y	Y	Y			Y		Y		Y
6		Y	Y	Y	Y	Y	Y				Y		Y	Y
7	Y	Y	Y	Y			Y							
8	Y		Y					Y		Y				
9	Y	Y	Y	Y					Y		Y			
10	Y		Y					Y		Y				
11	Y	Y	Y	Y					Y		Y			
12	Y		Y		Y							Y		
13	Y	Y	Y	**Y**	Y	Y			Y		Y		Y	
14	Y	Y	Y	Y	Y	Y	Y							Y

For more information about clocks, reset, power management, and wake-up events for the MPU subsystem, see , *Power, Reset, and Clock Management*.

3.4 MPU Subsystem Basic Programming Model

For detailed descriptions of registers used for MPU configuration, see , *Power, Reset, and Clock Management*, and Chapter 8, *Interrupt Controller*.

3.4.1 Clock Control

For clock configuration settings, see , *Power, Reset, and Clock Management*.

3.4.2 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for the MPU power domain:

- Basic power on reset
- MPU to standby mode
- MPU out of standby mode
- MPU power on from a powered-off state

3.4.2.1 Basic Power-On Reset

The following power-on reset (POR) sequence applies to initial power-up and wakeup from device off mode:

1. Reset DPLL, supply reference clock, program the MPU DPLL in applicable DPLL mode to generate clocks for MPU subsystem modules. This is controlled solely by the PRCM module.
2. Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during MPU reset and CORE reset.

3.4.2.2 MPU to Standby Mode

The following MPU to standby mode sequence applies to initial power-up and wakeup from device off mode:

1. The ARM core initiates entering standby through software only (CP15 - WFI).
2. MPU modules requested internally by MPU subsystem to enter idle, after ARM core standby detected.
3. MPU is in standby output asserted for the PRCM module (all outputs ensured to be at reset values).
4. The PRCM module requests the INTC to enter idle mode. Acknowledge from INTC goes to the PRCM module.
5. The PRCM module starts to shut down clocks through DPLL programming.

NOTE: The INTC SWAKEUP output is a pure hardware signal to the PRCM module for the status of its IDLE request and IDLE acknowledge handshake.

NOTE: In debug mode, ICECrusher can prevent the MPU subsystem from entering IDLE mode.

3.4.2.3 MPU Out of Standby Mode

The following MPU out of standby mode sequence of operation applies to initial power-up and wakeup from device off mode:

1. PRCM must start clocks through DPLL programming.
2. Detect active clocking through status output of DPLL.
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

3.4.2.4 MPU Power-On from a Powered-Off State

1. To minimize the peaking of current during power up, DPLL power on, MPU power on, Neon power on, and Core power on (INTC) should follow the ordered sequence per power switch daisy chain.

NOTE: Before the MPU can be reset, the CORE power domain must be on, and reset, with the DPLL clocks on.

2. Follow the reset sequence as described in Section 3.4.2.1, *Basic Power-On Reset*.

3.4.3 Neon Power Mode Transition

Because of the hardware sleep dependency between Neon and the MPU domain, when the Neon power domain transition is configured to automatic hardware-supervised mode (the CM_CLKSTCTRL_Neon[1:0] CLKTRCTRL_Neon bit field is set to 0x3), it cannot transition to idle mode unless the MPU goes to standby mode. The MPU domain must also be configured in automatic hardware-supervised mode (the CM_CLKSTCTRL_MPU[1:0] CLKTRCTRL_MPU bit field must be set to 0x3) for the Neon power domain transition to occur.

3.4.4 ARM Programming Model

For the complete programming model, see the public *ARM Cortex-A8 Technical Reference Manual*.

Power, Reset, and Clock Management

This chapter describes power, reset, and clock management.

Topic **Page**

4.1 PRCM Introduction to Power Management

This introduction contains the following information:

- Requirement and goal of power management in mobile devices
- State-of-the-art power-management techniques for maximizing battery life for mobile devices
- Essential architectural building blocks for power management
- Overview of the device power-management architecture

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

4.1.1 Goal of Power Management

Power management (efficient use of the available limited battery resources of a mobile device) is one of the most important design aspects of any mobile system. It imposes strong control over limited available power resources to ensure they function for the longest possible amount of time.

The device architecture ensures maximum performance for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements.

4.1.2 Architectural Blocks for Power Management

The processor does not support Voltage and Power domains. As a result, there is one voltage supply to the device processors and peripherals. There is also no support for switching power on or off to individual power domains. Although the power domain terminology is retained, the state of power to all domains is either ON when the device is supplied with external power, or OFF when the external power source to the device is off.

The device does support dynamic clock gating for power management through clock domains. A clock domain is a group of modules or subsections of the device that share a common clock.

4.1.2.1 Clock Domain

A clock domain is a group of modules fed with the same gated clock signal (see Figure 4-1). By gating the clock to each domain, it is possible to cut a clock to a group of inactive modules to lower their active power consumption. Thus, a clock domain allows control of dynamic power consumption by the device.

Figure 4-1. Generic Clock Domain

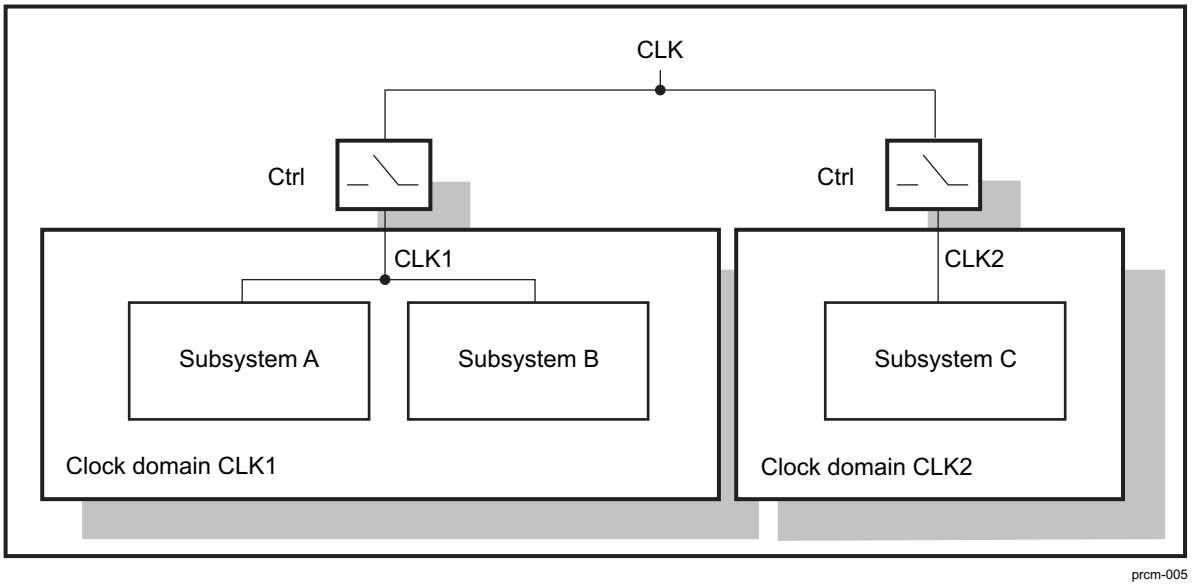


Table 4-1 lists the two possible states of the clock domain.

Table 4-1. States of a Clock Domain

State	Description
Active	The domain clock is running.
Idle	The domain clock is stopped or gated.

4.1.2.2 Power Domain

Some members of the device family support independent control of power to subsections of the device (called Power Domains) via independent power switches. While retaining some of the Power Domain terminology, this device does not support independent Power Domain control. The state of all Power Domains in the device is either ON when the device is externally supplied with power or OFF when the device is completely powered down. In effect, the entire device is a single power domain.

4.1.2.3 Voltage Domain

Whereas some members of the device family have subsystems grouped into voltage domains that can be supplied by independently scalable voltage regulators, the device has its core subsystems all in a single voltage domain. Therefore, the voltage domain concept does not apply to this device.

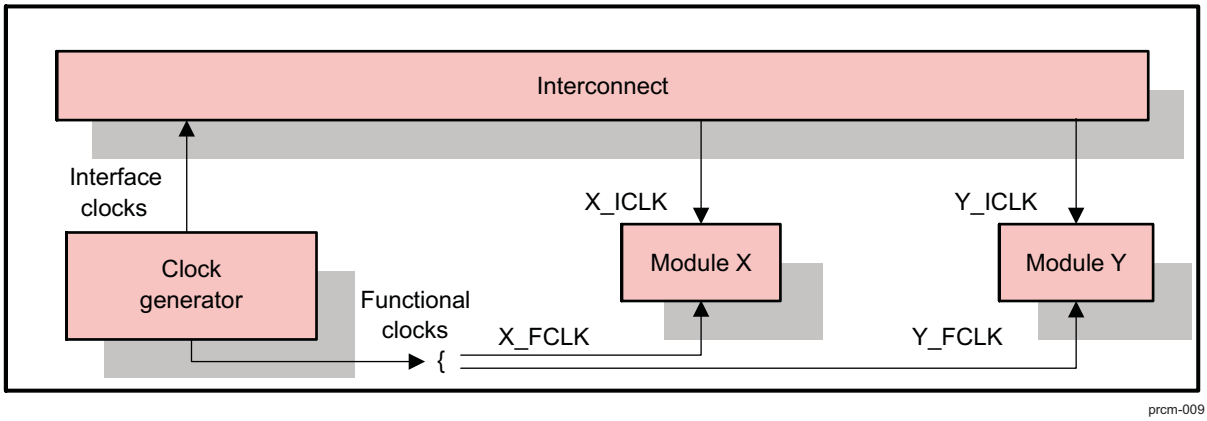
4.1.3 Device Power-Management Architecture

The device supports a clock distribution and control architecture, which is described in the following sections.

4.1.3.1 Module Interface and Functional Clocks

The clocks delivered to the modules in the device are divided into two categories: interface clocks and functional clocks (see Figure 4-2).

Figure 4-2. Functional and Interface Clocks



Interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the module interface and registers.
- A typical module has one interface clock, but it can have several.
- They are synchronous across the entire device, because the interconnect fabric is itself fully synchronous.
- Interface clock management is done at the device level.
- From the standpoint of the power, reset, and clock management (PRCM) module, an interface clock is distributed through the device interconnect and is identified with an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or a subsystem.
- Each module can have several functional clocks, or none at all. A module may or may not require its functional clocks to be active (nonidle).
- Several modules can share the same functional clock signals, but the branches of the clock tree are not balanced between the modules.
- From the PRCM standpoint, a functional clock is directly distributed to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

NOTE: At the module level, the interface clocks are always fed by the interface clock outputs of the PRCM. The functional clocks are fed either by a PRCM functional clock output or a PRCM interface clock output. In the latter case, the functional and interface clocks of the module inherit capabilities (autoidle features) from the PRCM interface clock (see Section 4.7, *Clock Manager Functional Description*).

4.1.3.2 Autoidle Clock Control

The device supports an autoidle clock control scheme for the module interface clocks. With this control scheme, PRCM can automatically activate and deactivate the interface clock of any device module, depending on its operating mode. This scheme executes under hardware control and is transparent to the software. This scheme identifies two module types in the device: the target and the initiator modules, or subsystems.

NOTE: The functional clocks do not have the autoidle clock scheme, and the software must gate the functional clock of each module when it is not needed.

Initiator

An initiator can generate bus transactions (read, write, etc.) toward targets. It is considered to be active when it generates transactions. If it enters standby mode, it stops generating transactions. Because most initiators also support a target port for configuration purposes, they are both targets and initiators. Some examples of initiators are processors, direct memory access (DMA), and memory management unit (MMU).

Target

A target is a passive module that can process bus transactions (that is, it reads/writes to memory-mapped registers). It is considered to be active when its interface clocks and some or all of its functional clocks are available so it can accept incoming transactions. A target can be put in idle mode by the PRCM, and in this mode its interface clock can be gated at any time. An idle module can still receive its functional clocks and generate interrupts and DMA requests. It can also generate asynchronous wake-up requests, if it is wakeup-capable.

Active, Idle, and Standby Modes

The PRCM module handles automatic clock control differently for initiator and target modules.

For the initiator module, the following hardware handshake scheme is employed:

1. The initiator, when switching from active to idle mode, signals its status to the PRCM.
2. The PRCM cuts off the interface clock to the initiator module.
3. When the initiator module must reactivate, it signals the PRCM, which reactivates its functional and interface clocks.

For the target module, the following hardware handshake scheme is employed:

1. When the PRCM confirms that the target module satisfies the idle conditions, it signals the target module.
2. The target module acknowledges the idle request of the PRCM, depending on its idle mode internal settings (for details about idle mode settings, see the chapter in the technical reference manual for the corresponding device module):

- If the module is set to smart-idle mode, it terminates its current operations, and then acknowledges the idle request to the PRCM.
- If the module is set to force-idle mode, it acknowledges immediately, regardless of its current state. Because pending transfers, interrupts, and DMA requests can potentially be lost, special software care must be taken.
- If the module is set to no-idle mode, it does not acknowledge the idle request. This forces the PRCM to maintain the clock active.

3. The PRCM cuts off the module clocks.
4. The target module can be wakened by the PRCM when its wake-up conditions are satisfied (wake-up event). It activates the module clocks, and then signals the wakeup.
5. The target module acknowledges the wake-up request.
6. Some target modules can support wake-up capability. They can explicitly request the PRCM to activate their clock.

This automatic clock control ensures reduced dynamic power consumption of the device without any associated software overhead.

4.2 PRCM Overview

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power saving considerations, ensure that clocks for unavailable or unused modules are gated.

4.2.1 Introduction

The power-management framework of the device significantly reduces dynamic power consumption to extend the life of the battery in the end-product. This framework incorporates support for state-of-the-art power-management techniques. It ensures optimal device operation with significantly reduced power consumption. The PRCM module, which is the enhanced power-management subsystem of the device, is the central control module for the clock, reset, and power-management signals in the device.

The device has the following features to support the different power-management techniques:

- Clock tree with selective clock-gating conditions
- Hardware-controlled reset sequencing management
- Support for hardware-controlled autogating of module clocks
- Support for low-power device standby mode

The PRCM module is the centralized management module for the power, reset, and clock control signals. It interfaces with all the components on the device for power, clock, and reset management through power-control signals. It integrates enhanced features to allow the device to adapt energy consumption dynamically according to changing application and performance requirements.

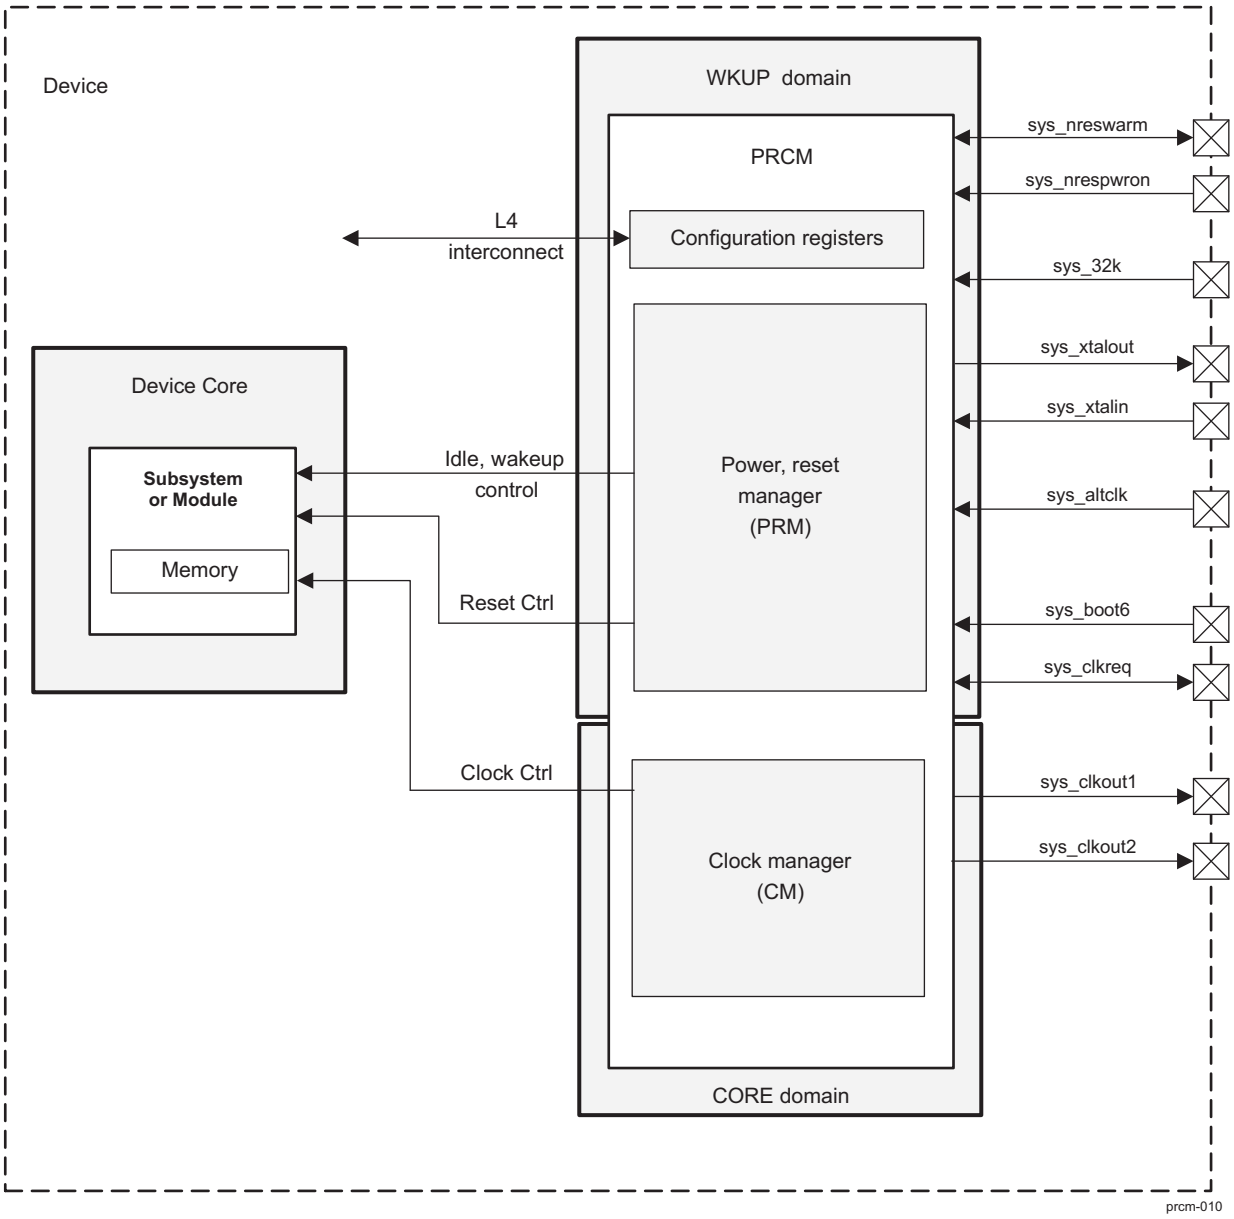
The PRCM module is composed of two main entities:

- Power reset manager (PRM): Handles the power, reset, wake-up management, and system clock source control (oscillator)
- Clock manager (CM): Handles the clock generation, distribution, and management

The PRCM is fully configurable through its L4 interface port.

Figure 4-3 is an overview of the PRCM module and its internal connections with a generic power domain (a group of modules with related functionality).

Figure 4-3. PRCM Overview



4.2.2 PRCM Features

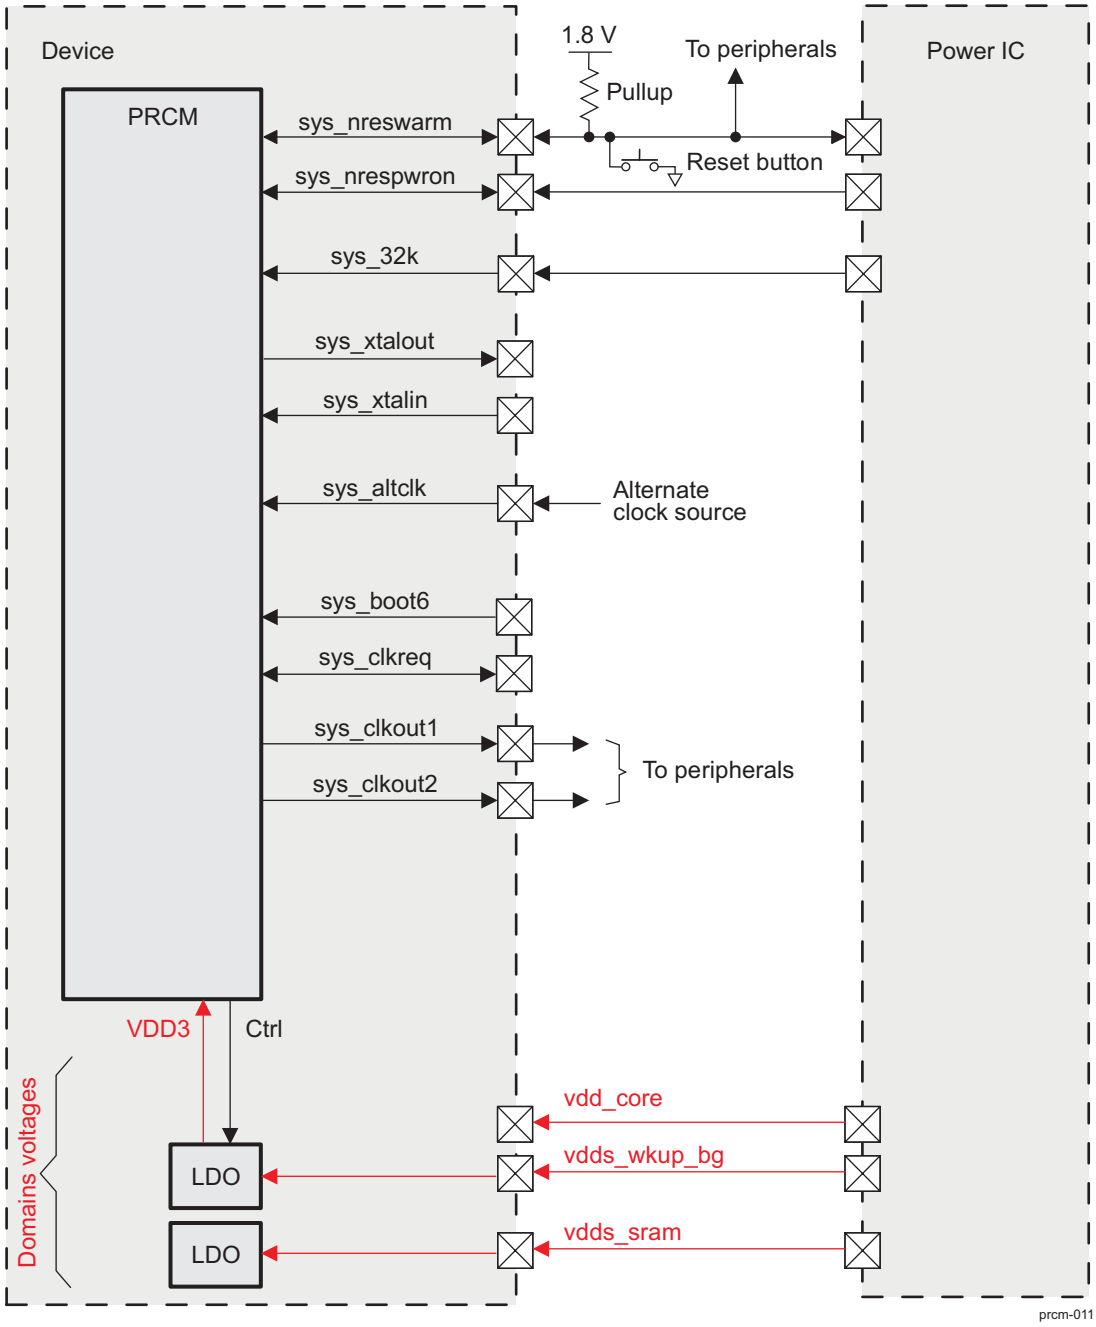
The PRCM module includes the following features:

- Handling proper idle/wake-up procedures
- Allowing both software and partial hardware control
- Monitoring and handling wake-up events
- Controlling system clock/reset input sources
- Managing and distributing clocks and resets with high granularity
- Handling power-up sequences
- Debug and emulation features

4.3 PRCM Environment

The PRCM module receives the external reset, clock, and power signals. Figure 4-4 shows the interface of the PRCM with external reset, clock, and power sources.

Figure 4-4. PRCM Functional External Interface (Detailed View)



NOTE: In the remainder of this chapter, the term "power IC" refers to a peripheral power source IC that is interfaced with the device.

The following sections describe the interfaces for the external clock, reset, and power sources.

4.3.1 External Clock Signals

The device has three external clock inputs: low frequency (sys_32k), high frequency (sys_xtalin), and an optional clock (sys_altclk). The device has two configurable clock outputs: sys_clkout1 and sys_clkout2. Figure 4-5 shows the external clock signals of the PRCM module. Table 4-2 lists the external clock signals, I/Os, and module reset values.

Figure 4-5. External Clock Interface

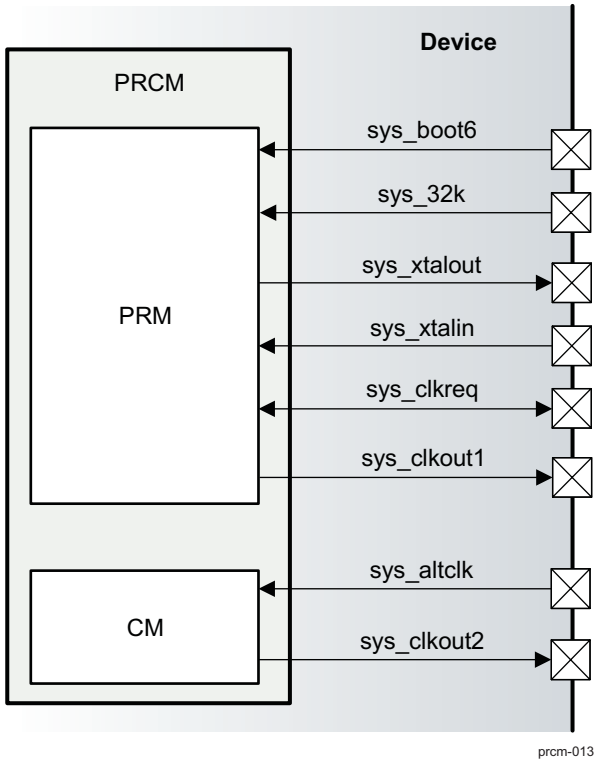


Table 4-2. External Clock Signal Descriptions

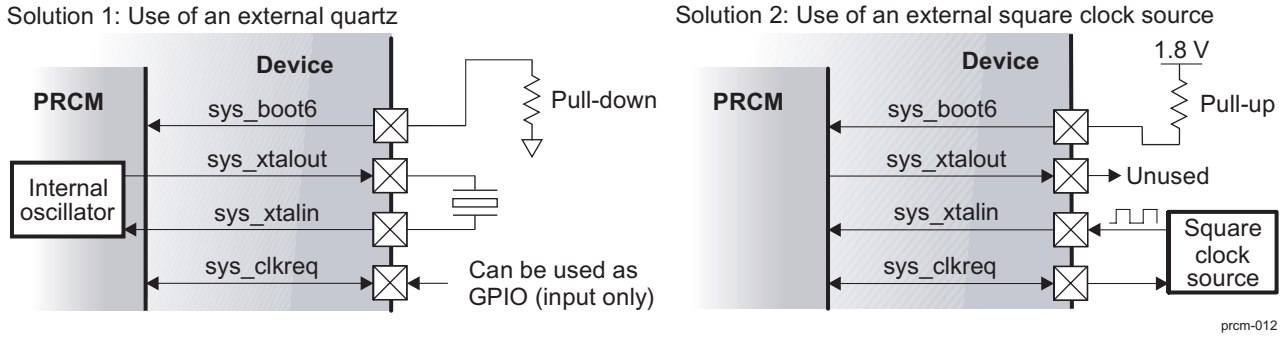
Signal Name	I/O[1]	Description	Module Reset Value
sys_boot6	I	Boot oscillator mode control	Unknown
sys_32k	I	32-kHz clock input	Unknown
sys_xtalout	O	Output of oscillator	0
sys_xtalin	I	Main input clock. Crystal oscillator clock (only at 26 MHz) or CMOS digital clock (at 26 MHz).	Unknown
sys_clkreq	I/O	Clock request to/ from device for system clock	1
sys_clkout1	O	Configurable output clock 1	0
sys_altclk	I	Alternate clock source selectable for USB (48 MHz) or NTSC/PAL (54 MHz)	Unknown
sys_clkout2	O	Configurable output clock 2	0

(1) I = Input, O = Output

Figure 4-6 shows the PRCM external clock sources.

Figure 4-6. PRCM External Clock Sources



The system clock source can be either of the following:

- Internal oscillator with crystal connected between sys_xtalin and sys_xtalout
- A CMOS digital clock that arrives at the sys_xtalin pin

In the first option, the sys_clkreq signal is used in input mode to control sys_clkout1 and the internal clock oscillator. In the second option, the signal is used in output mode to request the external system clock.

An external pulldown or pullup tied on sys_boot6 determines whether the internal oscillator is used or an external clock source is supplied, respectively.

CAUTION

Only one clock source option can be used at a time.

An alternate clock input (sys_altclk) provides a precise clock source for 54 MHz, 48 MHz, or other frequencies (for example, 59 MHz or 49.04 MHz for VDAC).

For more information about external clock signals, see Section 4.7.5 , *External Clock Controls*.

4.3.2 External Reset Signals

The device supports two reset signals: power-on (sys_nrespwron) and warm reset (sys_nreswarm).

sys_nrespwron is asserted at power up to reset the full logic in the device. sys_nreswarm can be activated at any time by an external device or an external reset push-button action (see Figure 4-4) to cause a global warm reset event.

Because sys_nreswarm is bidirectional, it can also be used to drive a reset of external devices. Any global warm reset source (for example, a push-button) causes sys_nreswarm to be driven out and maintained for a limited length of time at the boundary of the device. In this way, the device and its related peripherals are properly reset together.

The sys_nrespwron assertion also causes the sys_nreswarm assertion.

Figure 4-7 shows the external reset signals. Table 4-3 lists the external reset signals, I/Os, and module reset values.

Figure 4-7. External Reset Signals

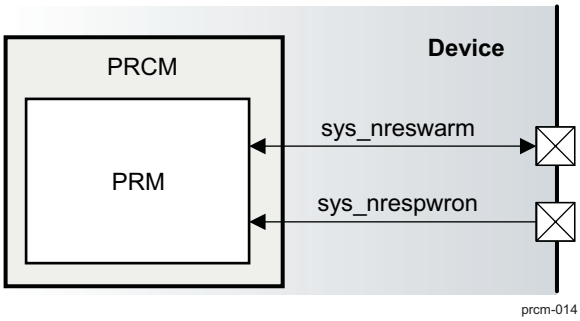


Table 4-3. External Reset Signals Description

Signal Name	I/O[1]	Description	Module Reset Value
sys_nreswarm	I/O	Warm-boot reset	1
sys_nrespwron	I	Power-on reset	Unknown

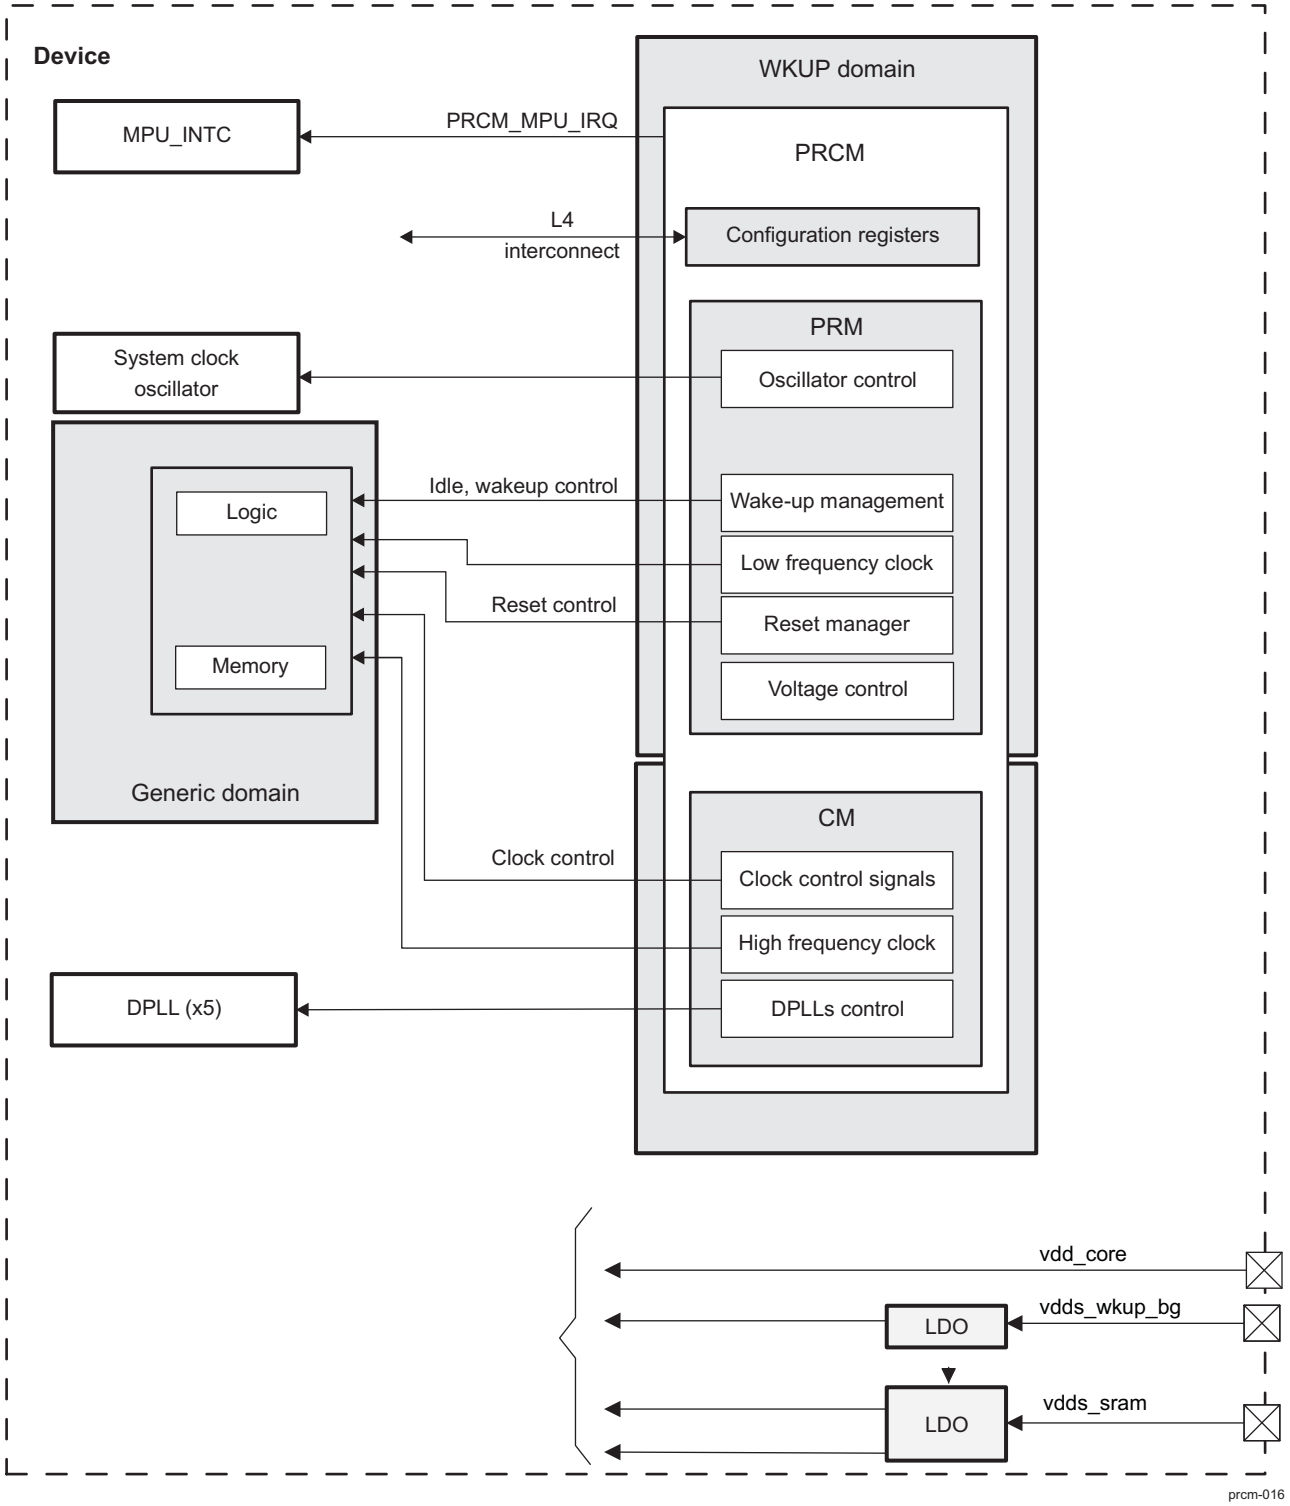
(1) I = Input, O = Output

4.4 PRCM Integration

The PRCM internal registers can be accessed for configuration and controlled through the WKUP L4 interconnect. In addition to the L4 interconnect, the PRCM internal module interface contains the following:

- A set of signals for idle/wake-up control for each module
- Clocks and reset signals
- Interrupt to the MPU subsystem interrupt controller (INTC)
- Digital phase-locked loop (DPLL) control commands for recalibration and bypass
- System clock oscillator control for device-level sleep/wake-up transitions

Figure 4-8. PRCM Integration



4.4.1 Power-Management Scheme, Reset, and Interrupt Requests

4.4.1.1 Resets

The PRM and CM modules are reset by independent reset signals (see Table 4-4).

Table 4-4. PRCM Reset Signals

PRCM Subsystem	Reset Signal
PRM	PRM_RSTPWRON
CM	CM_RSTPWRON_RET

The PRM module is reset by the cold reset signal PRM_RSTPWRON. The CM module is reset by assertion of the CM_RSTPWRON_RET signal.

The CM logic is reset on:

- Any global cold reset

The PRM logic is reset on:

- Any global cold reset

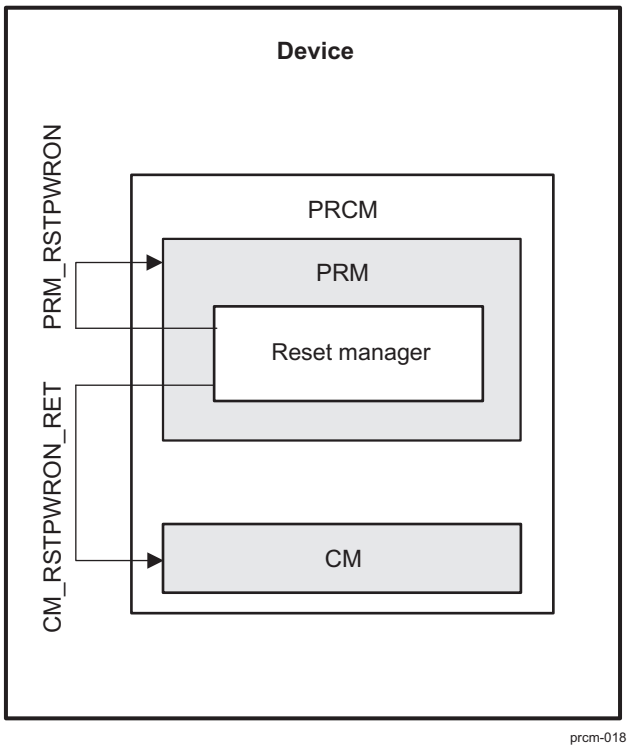
CM and PRM registers that are sensitive to a warm reset are also reset when a global warm reset occurs. However, the CM and PRM logic is not reset.

NOTE: At global cold reset:

- Only the device finite state-machine (FSM) in the PRM is operating on the 32-kHz clock, and it is released from reset on the release of the global reset.
- PRM logic operates on the system clock and is released from reset on release of the reset PRM_RSTPWRON.

Figure 4-9 shows the PRCM reset signals.

Figure 4-9. PRCM Reset Signals



4.4.1.2 Interrupt Requests

The PRCM module can generate an interrupt to the MPU interrupt controller module:

- PRCM_MPU_IRQ: Mapped to the MPU INTC module (M_IRQ_11 interrupt line)

4.5 PRCM Reset Manager Functional Description

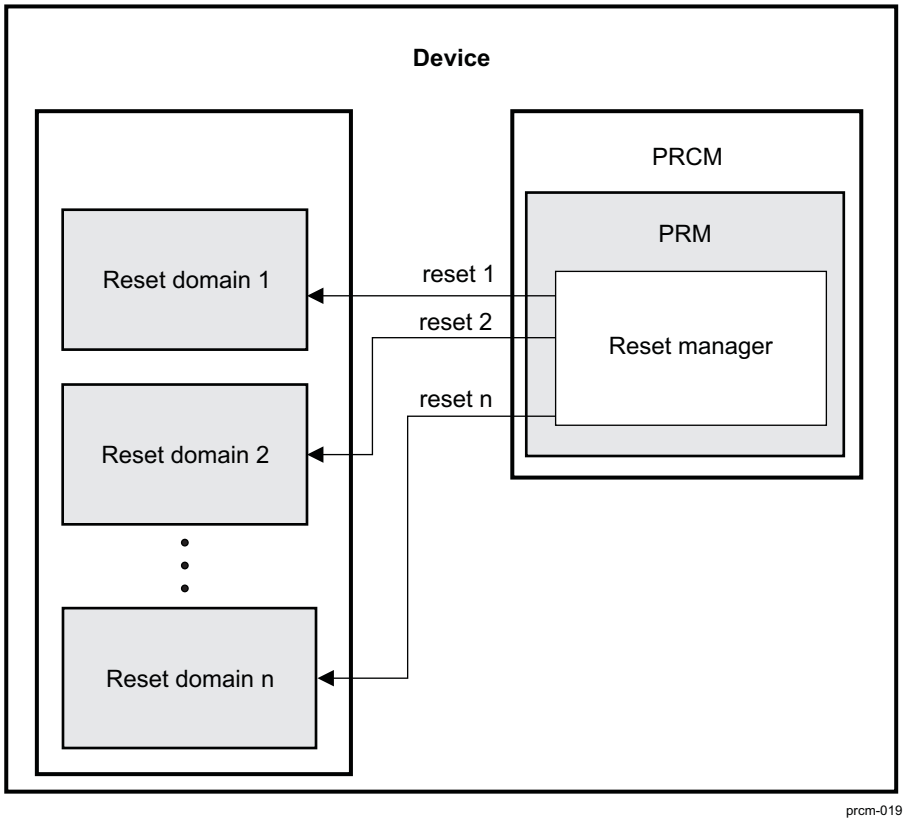
4.5.1 Overview

The PRCM manages the reset of all the modules in the device, including DPLLs.

Several reset domains are defined. A reset domain is defined by a unique reset signal that originates from the reset manager and is connected to one or multiple modules of the device. All the connected modules of the reset domain are reset simultaneously when the reset signal is asserted.

Figure 4-10 is an overview of the reset manager interface with a generic domain in the device.

Figure 4-10. Reset Manager Interface



Resets can be generated either by hardware sources or software control. For modules that can be reset by software control, a software-reset bit is implemented in their <module name>_SYSCONFIG configuration register. Software reset has the same effect on the module logic as a hardware reset.

Special reset control is available when the device operates under emulation control to reset specific reset domains.

NOTE: All reset assertion is asynchronous, and all reset signals are active low, except for the DPLL reset signals.

4.5.2 General Characteristics of Reset Signals

Reset signals can be categorized based on three criteria:

- Scope
- Occurrence
- Source type

4.5.2.1 Scope

A reset signal can be categorized according to its scope (the area of the device affected by that reset):

- Global reset: Affects the entire device; all modules are reset. Generally, when the device powers up or an abnormal operation is detected (secure watchdog timer overflows, the eFuse bad device is detected, etc.).
- Local reset: Affects one reset domain. When a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

4.5.2.2 Occurrence

A reset signal can also be categorized depending on when the reset occurs:

- Cold reset: Occurs only on device power up or in certain emulation modes. The cold reset is a global reset that affects every module on the device. It usually corresponds to the initial power-on reset.
- Warm reset: Occurs when the device is in normal operating state. The warm reset is also a global reset, but it does not affect all the modules on the device. Usually, the device does not require a complete reboot on a warm reset. Several reset sources are types of warm resets, such as the global software reset and the watchdog reset.

Modules that behave differently in cold reset and warm reset have two reset signals: RST and PWRON_RST. These reset signals reconstruct warm reset and cold reset in modules that require them.

For a global warm reset, the PRCM performs the following sequence:

1. It applies a warm reset on all the modules.
2. It drives the sys_nreswarm reset output low and holds it for a specified length of time (programmed in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).

A global warm reset does not apply to the following modules of the device:

- SDRC
- System control module (SCM) (I/O control)
- Part of PRM and CM registers (see note below)
- 32-kHz synchronization timer
- DPLL3 (refer to)
- Emulation modules
- eFuse farm

NOTE: For information on the PRCM registers affected by the global warm reset see the Registers Mapping Summary tables in Section 4.12, *PRCM Register Manual*.

4.5.2.3 Source Type

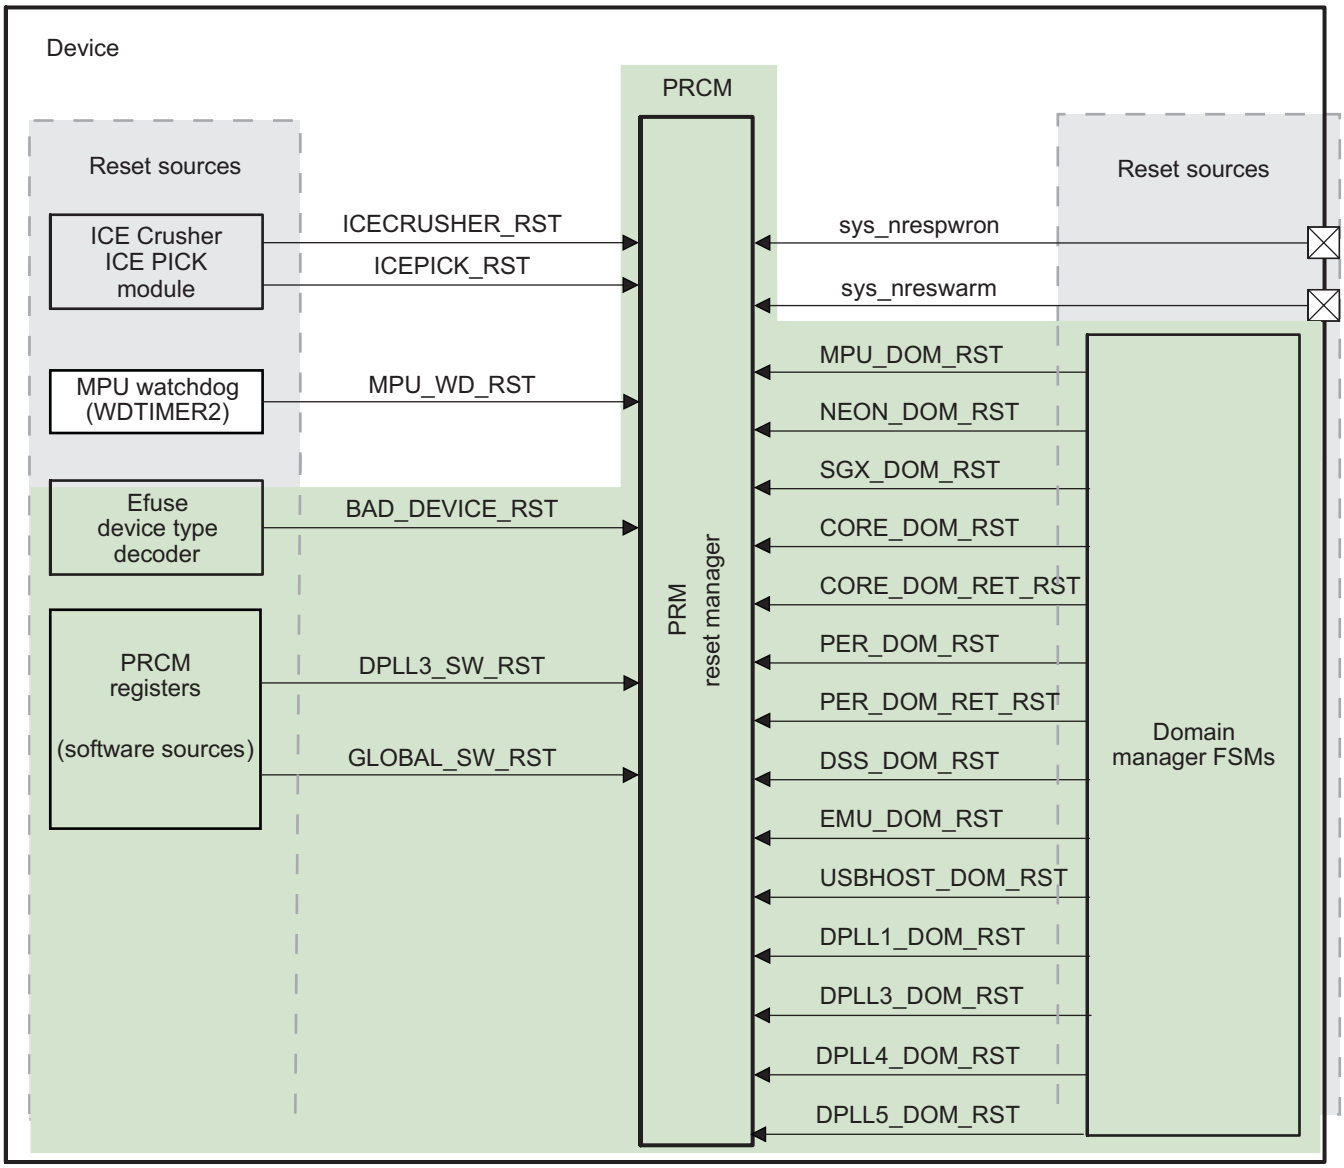
A reset can also be categorized depending on whether it is software-controlled or hardware-triggered:

- Software reset: Triggered by setting a bit in a configuration register of the PRCM module
- Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

4.5.3 Reset Sources

Figure 4-11 is an overview of the reset sources.

Figure 4-11. Reset Sources Overview



*The green region in the figure represents the boundary of the PRCM.

prcm-020

4.5.3.1 Global Reset Sources

Table 4-5 lists the global reset sources of the device. The global reset source signals received by the reset manager trigger the reset of all the device modules. For all hardware reset signals, the source of the reset is identified; for the software reset signals, the reset triggering bit is identified.

Table 4-5. Global Reset Sources

Type[1]	Name	Source/Control	Description
H/C	sys_nrespwron	Input pin	The entire device is reset on power up.
H/C	BAD_DEVICE_RST	PRCM	Asserted when during the power-up sequence the device is identified as bad, after reading eFuses.
H/W	sys_nreswarm	Bidirectional pin	External hardware warm reset

(1) H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

Table 4-5. Global Reset Sources (continued)

Type[1]	Name	Source/Control	Description
H/W	SECURE_WD_RST	WDTIMER1	Security watchdog timer overflow reset
H/W	MPU_WD_RST	WDTIMER2	MPU watchdog timer overflow reset
H/W	MPU_SEC_VIOL_RST	Processor security FSM	Security violation reset request by the processor security FSM
S/W	GLOBAL_SW_RST	PRCM.PRM_RSTCTRL[1] RST_GS	Global software reset
S/W	DPLL3_SW_RST	PRCM.PRM_RSTCTRL[2] RST_DPLL3	Local cold reset for DPLL3 and a global cold reset to the device.
H/W	ICEPICK_RST	ICEPick module	Global warm reset from ICEPick emulation module.

4.5.3.2 Local Reset Sources

Table 4-6 lists the local reset sources of the device. A local reset source signal received by the reset manager resets only some of the device modules.

Table 4-6. Local Reset Sources

Type[1]	Name	Source/Control	Description
H/C	CORE_DOM_RET_RST	PRCM	Asserted only for a domain transition from OFF to ACTIVE state as in the case of the device power-up. See note below for further clarification.
H/C	USB_DOM_RET_RST	PRCM	
H/C	PER_DOM_RET_RST	PRCM	
H/C	MPU_DOM_RST	PRCM	Asserted only for a domain transition from OFF to ACTIVE state as in the case of the device power-up. See note below for further clarification.
H/C	NEON_DOM_RST	PRCM	
H/C	SGX_DOM_RST	PRCM	
H/C	CORE_DOM_RST	PRCM	
H/C	PER_DOM_RST	PRCM	
H/C	DSS_DOM_RST	PRCM	
H/C	DPLL1_DOM_RST	PRCM	
H/C	DPLL3_DOM_RST	PRCM	
H/C	DPLL4_DOM_RST	PRCM	
H/C	DPLL5_DOM_RST	PRCM	

(1) H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

NOTE: For domains with <domain name>_DOM_RST and <domain name>_DOM_RET_RST, the reset sources are asserted together when the device transitions from OFF to ON power state, whereas only <domain name>_DOM_RET_RST is asserted on a global or local warm reset.

4.5.4 Reset Distribution

Each domain can contain one power-on reset (RSTPWRON) and one or more reset (RST) signals. These signals behave as follows:

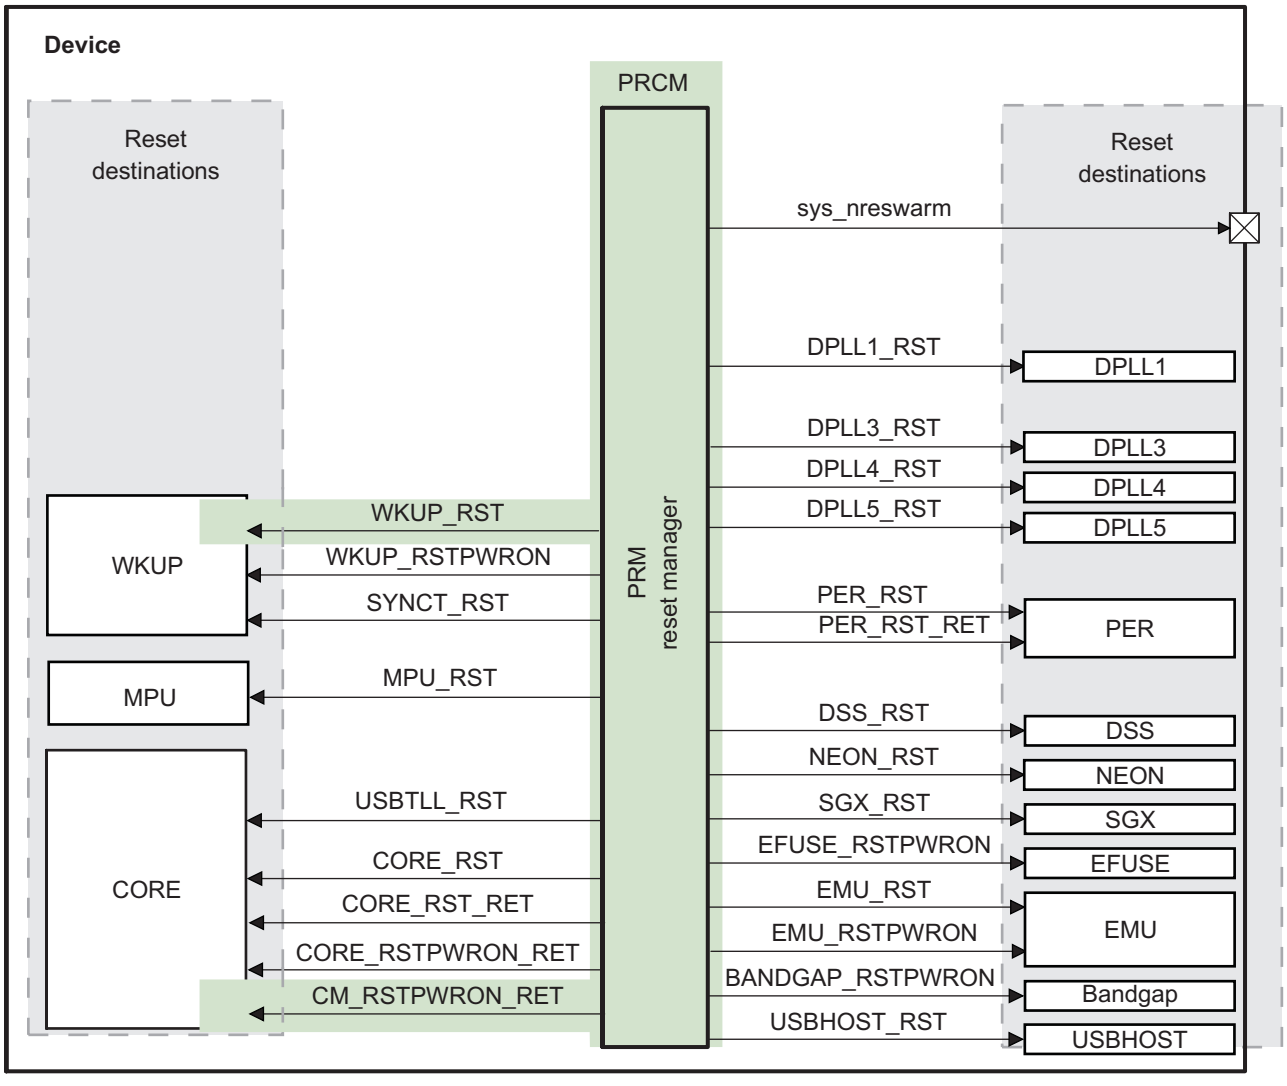
- On any global or local cold reset, both RST and RSTPWRON are asserted.
- On any global or local warm reset, only RST is asserted.

The CORE domain receives two additional legacy reset signals: retention reset (RST_RET) and power-on retention reset (RSTPWRON_RET). These signals behave as follows:

- On any global cold reset, both RST_RET and RSTPWRON_RET are asserted.
- On any global warm reset, only RST_RET is asserted.

Figure 4-12 shows the reset distribution among the domains.

Figure 4-12. Reset Destinations Overview



*The green region in the figure represents the boundary of the PRCM

prcm-021

4.5.5 Domain Reset Descriptions

4.5.5.1 MPU Domain

The MPU domain has one input and one output reset signal (see Table 4-7).

Table 4-7. MPU Domain Reset Signals

Name	I/O[1]	Source/Destination[2]	Reset Domain
MPU_RST	I	PRM	Resets the MPU processor core and the asynchronous bridge in the MPU domain.
MPU_SEC_VIOL_RST	O	PRM	Global cold reset source to reset manager. Generated by the security FSM in the MPU subsystem.

(1) I = Input, O = Output
(2) Source for an input signal and destination for an output signal.

NOTE: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

4.5.5.2 NEON Domain

The NEON domain has one reset input signal (see Table 4-8).

Table 4-8. NEON Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
NEON_RST	I	PRM	Resets the NEON coprocessor

(1) I = Input, O = Output

4.5.5.3 CORE Domain

The CORE domain has eight input reset signals. (See Table 4-9).

Table 4-9. CORE Domain Reset Signals

Name	I/O[1]	Source/Destination[2]	Reset Domain
CORE_RST	I	PRM	Resets parts of the three asynchronous bridges, MPU INTC, interconnects, GPMC, OCM, UART[1,2], HDQ and HS USB, I2C[1..3], McBSP 1 and 5, McSPI [1..3], MMC[1..3], GPTIMER[10,11], D3D[1,2], SHAM1, RNG, AES[1..2], PKA, and SHAM2
CORE_RST_RET	I	PRM	Resets part of the SDRC, SDMA, SMS, and MPU INTC
CORE_RSTPWRON_RET	I	PRM	Resets part of the SDRC and SCM
CM_RSTPWRON_RET	I	PRM	Resets the clock manager
CPEFUSE_RST	I	PRM	Reset the Customer Programmable EFUSE controller. Asserted under the same condition as that of CORE_RST. The CPEFUSE functional clock must be active to release the reset. This clock is enabled by default following a power-on reset. (For the reset sequence, see Section 4.5.9.2.)
USBTLL_RST	I	PRM	Resets the USB TLL asynchronously

(1) I = Input, O = Output
(2) Source for an input signal and destination for an output signal

The CM logic is reset on:

- Any global cold reset

Because the CM logic is not reset in this case, the CM registers that are sensitive to a warm reset must also be reset synchronously with the L4 clock when a global warm reset occurs.

4.5.5.4 DSS Domain

The DSS domain has one reset input signal (see Table 4-10).

Table 4-10. DSS Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
DSS_RST	I	PRM	Resets the entire display subsystem

(1) I = Input, O = Output

4.5.5.5 USBHOST Domain

The USBHOST domain has one reset input signal (see Table 4-11).

Table 4-11. USBHOST Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
USBHOST_RST	I	PRM	Resets the entire HS USB Host subsystem

(1) I = Input, O = Output

4.5.5.6 SGX Domain

The SGX domain has one reset input signal (see Table 4-12).

Table 4-12. SGX Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
SGX_RST	I	PRM	Resets the entire SGX subsystem

(1) I = Input, O = Output

4.5.5.7 WKUP Domain

The WKUP domain has three reset input signals and two reset output signals (see Table 4-13).

Table 4-13. WKUP Domain Reset Signals

Name	I/O[1]	Source/Destination[2]	Reset Domain
WKUP_RST	I	PRM	Resets the GPTIMER[1,12], WDTIMER2, GPIO 1 and USIMOCP
WKUP_RSTPWRON	I	PRM	Reset the wake-up control module and WDTIMER1
SYNCT_RST	I	PRM	Resets the 32-kHz sync timer. This reset is directly connected to the sys_nrespwron global reset source.
SECURE_WD_RST	O	PRM	Global warm reset for PRM. Generated by WDTIMER1.
MPU_WD_RST	O	PRM	Global warm reset for PRM. Generated by WDTIMER2.

(1) I = Input, O = Output
(2) Source for an input signal and destination for an output signal

The PRM logic is reset on any global cold reset. Because the PRM logic is not reset in this case, the PRM registers that are sensitive to a warm reset must also be reset synchronously with the system clock when a global warm reset occurs.

4.5.5.8 PER Domain

The PER domain has two reset input signals (see Table 4-14).

Table 4-14. PER Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
PER_RST	I	PRCM	Resets the UART3, McBSP[2,3,4], GPTIMER[2,..,9], WDTIMER3 modules
PER_RST_RET	I	PRCM	Resets the GPIO [2,..,6] modules

(1) I = Input, O = Output

4.5.5.9 DPLL Domains

The DPLL domains for DPLL1, DPLL3, DPLL4 and DPLL5 each have one reset input signal.

Table 4-15. DPLL Domain Reset Signals

Name	I/O[1]	Source	Reset Domain
DPLL1_RSTPWRON	I	PRCM	Resets the DPLL1 module
DPLL3_RSTPWRON	I	PRCM	Resets the DPLL3 module
DPLL4_RSTPWRON	I	PRCM	Resets the DPLL4 module
DPLL5_RSTPWRON	I	PRCM	Resets the DPLL5 module

(1) I = Input, O = Output

They are asserted for any type of global cold reset.

4.5.5.10 EFUSE Domain

The EFUSE domain has one reset input signal (see Table 4-16).

Table 4-16. EFUSE Domain Reset Signal

Name	I/O[1]	Source	Reset Domain
EFUSE_RSTPWRON	I	PRCM	Resets the eFuse controller

(1) I = Input, O = Output

This signal is asserted for any type of global cold reset.

4.5.5.11 BANDGAP Logic

The BANDGAP logic has one reset input signal (see Table 4-17).

Table 4-17. BANDGAP Logic Reset Signal

Name	I/O[1]	Source	Reset Domain
BANDGAP_RSTPWRON	I	PRCM	Resets the BANDGAP logic

(1) I = Input, O = Output

This signal is asserted for any type of global cold reset.

4.5.5.12 Other Module Resets

Both Figure 4-13 and Figure 4-14 show the reset connectivity of the remaining modules. The CBASS, USBOTG subsystem, CPGMAC subsystem, VPFE, HECC, EMIF subsystem, and VBUS-to-OCP bridges are connected to the Warm Reset output of the PRM as shown in the Figure 4-13.

Additionally, a software reset register is present the system control module to allow software to reset these modules. Note that SW Reset is not self clearing. Software needs to write '1' to put these modules in reset and write '0' to bring it out of reset. Please refer to the *System Control Module* chapter for more details on the software reset register.

Figure 4-13. Other Module Reset Distributions Overview

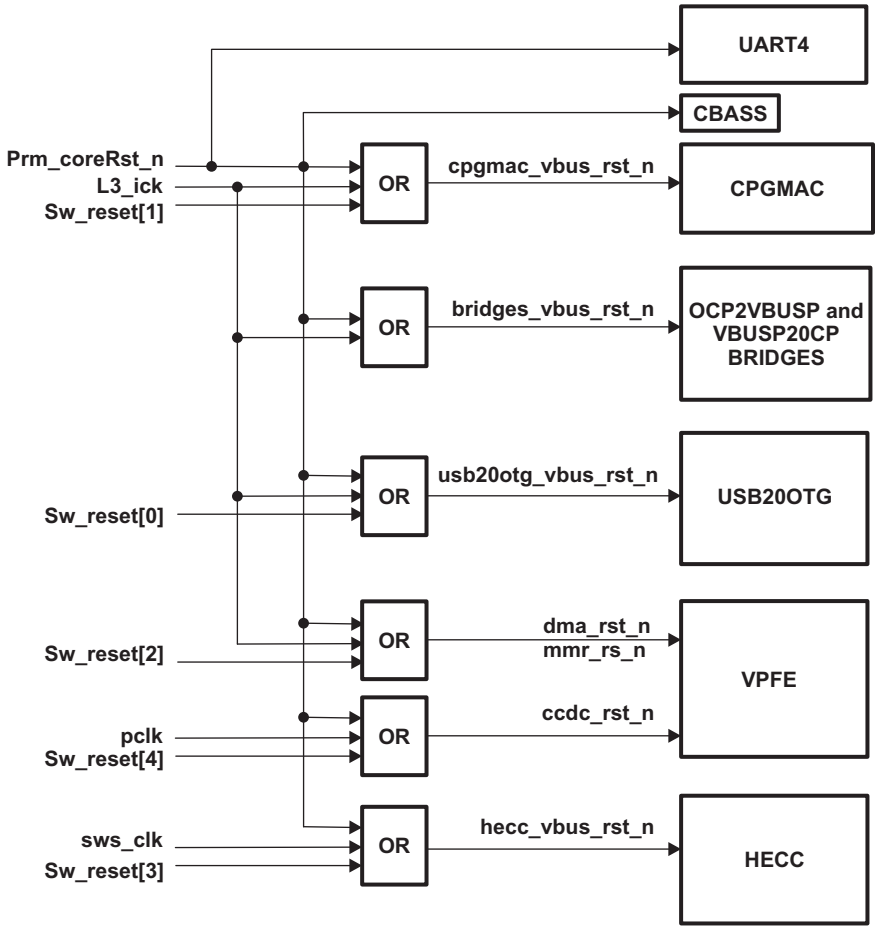


Figure 4-14. EMIF4 Reset Distributions Overview

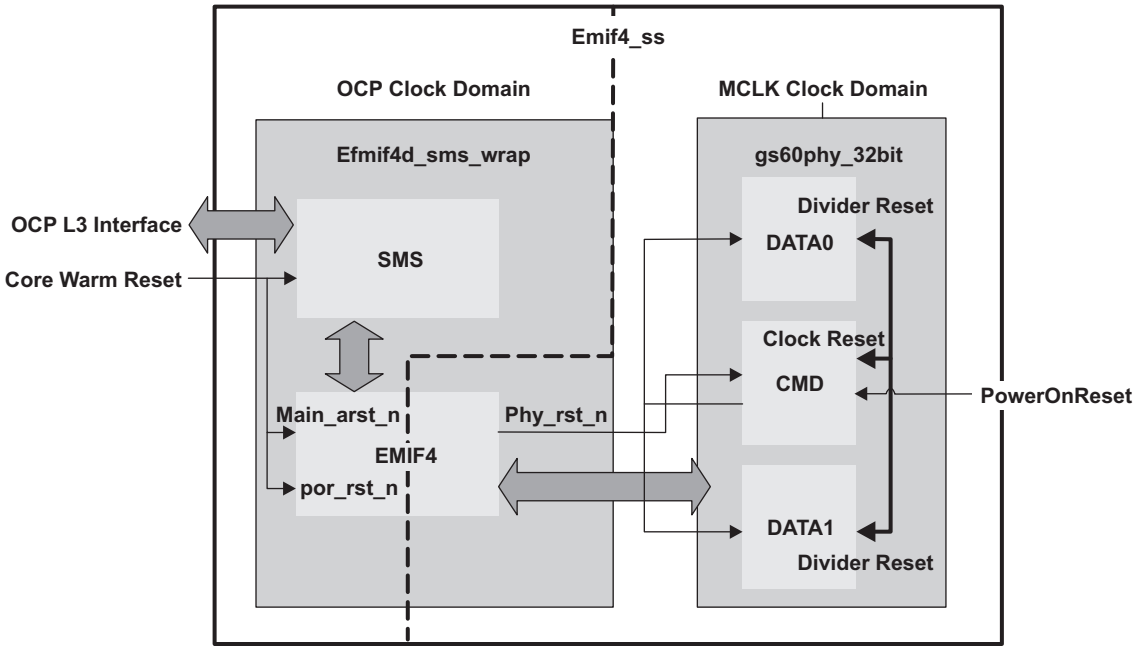
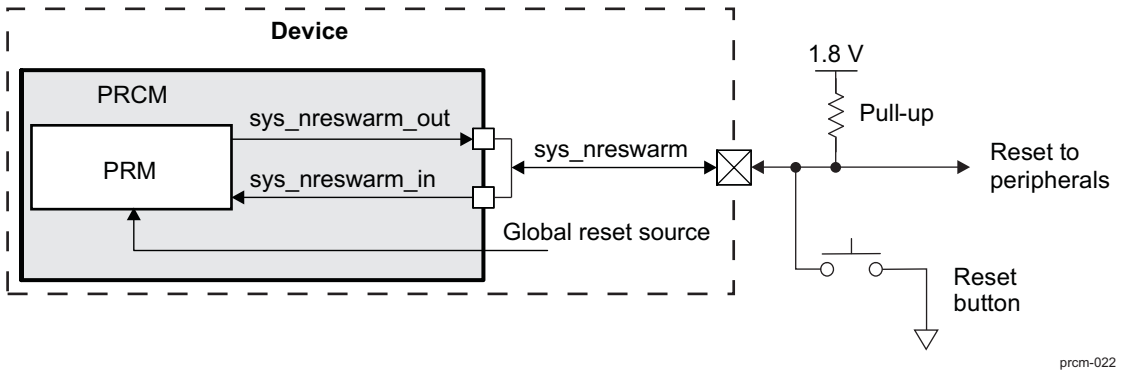


4.5.5.13 External Warm Reset Assertion

Figure 4-15 shows the external warm reset interface.

Figure 4-15. External Warm Reset Interface



Any global reset source (internal or external) causes sys_nreswarm_out to be driven and maintained at the boundary of the device for at least the amount of time configured in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field. This ensures that the device and its related peripherals are properly reset together.

NOTE: Because the system warm-reset output is implemented on a bidirectional pad, any input pulse on sys_nreswarm causes a global warm reset.

4.5.6 Reset Logging

The reset in the device is logged in two ways. First, dedicated registers in the PRCM (that is, the RM_RSTST_power domain> and PRM_RSTST registers) log the reset source. Second, the SCM also logs the device reset activity in dedicated registers, for security purposes.

4.5.6.1 PRCM Reset Logging Mechanism

The reset status registers (RM_RSTST_power domain> and PRM_RSTST) are reset asynchronously on assertion of a global cold reset. However, a reset status bit is always logged when the reset is released to the domain.

For this reason, after the assertion of a global cold reset, the reset status register is cleared to 0. When the domain reset is released, the register bit to log the global cold reset (that is, the RM_RSTST_<power domain> [0] GLOBALCOLD_RST bit) is updated to 1. For the same reason, the reset status register of domains released from reset by software is updated only when software releases the domain reset.

The assertion of a global cold reset prevents logging any other source of reset until after the release of the domain reset. This is valid in the following situations:

- A source of reset other than global cold reset is asserted before, during, or after the active period of a global cold source of reset and before the release of the domain reset signal.
- A source of reset other than global cold reset was asserted and then released, but a global cold reset source was asserted before the release of the domain reset signal.

4.5.6.2 SCM Reset Logging

The PRM exports reset the activity status signals to the SCM. For security purposes, the SCM uses these signals to log a reset status in the SCM.CONTROL_SEC_STATUS register. The reset activity status signal is asserted high when any source of reset to the domain is active.

It also provides reset status for the following global reset signals:

- Global cold reset
- Global warm reset
- Global warm secure watchdog reset (SECURE_WD_RST)
- Global warm security violation reset (MPU_SEC_VIOL_RST)

There is one reset activity status signal for each of the following domains:

- CORE
- DSS
- EMU
- SGX
- MPU
- NEON
- PER
- USBHOST

These signals are asserted high on assertion of any source of reset on the domain and logged. For information about the SCM, see the *System Control Module* chapter.

4.5.7 Reset Management Overview

The reset management structure in the device can be considered as a 2-layered structure composed of multiple instances of the reset manager. In the first layer, a top-level reset manager, called the device reset manager, handles all the sources of global reset (cold and warm). It provides reset managers for the second layer, called local reset managers, and the global reset and global power-on reset signals.

Each domain has a minimum of one local reset manager. The local reset manager also receives resets, such as the software reset and domain power transition reset, from the local reset source for the domain.

Figure 4-16 through Figure 4-19 provide an overview of reset management in the device. They do not provide reset sequencing between the reset managers.

NOTE: The domain must be ready (that is, the domain clocks must be active) before its reset is released.

Figure 4-16. Device Reset Manager Overview

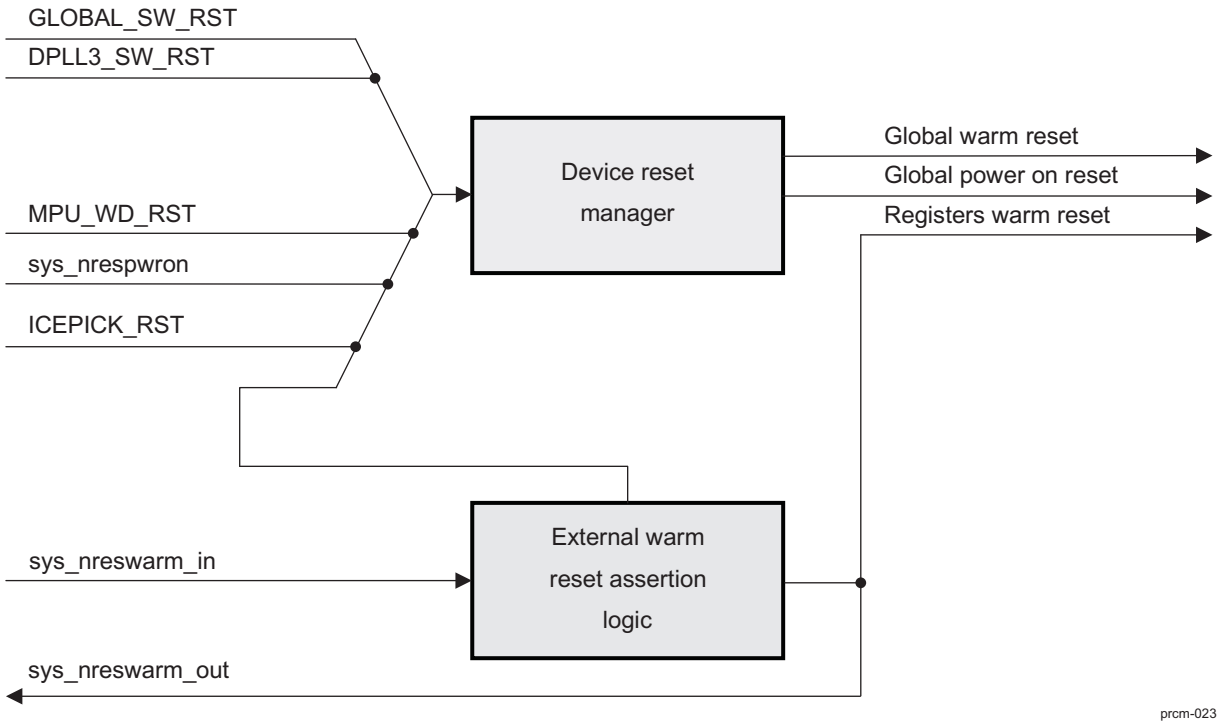


Figure 4-17. Domain Reset Management: Part 1

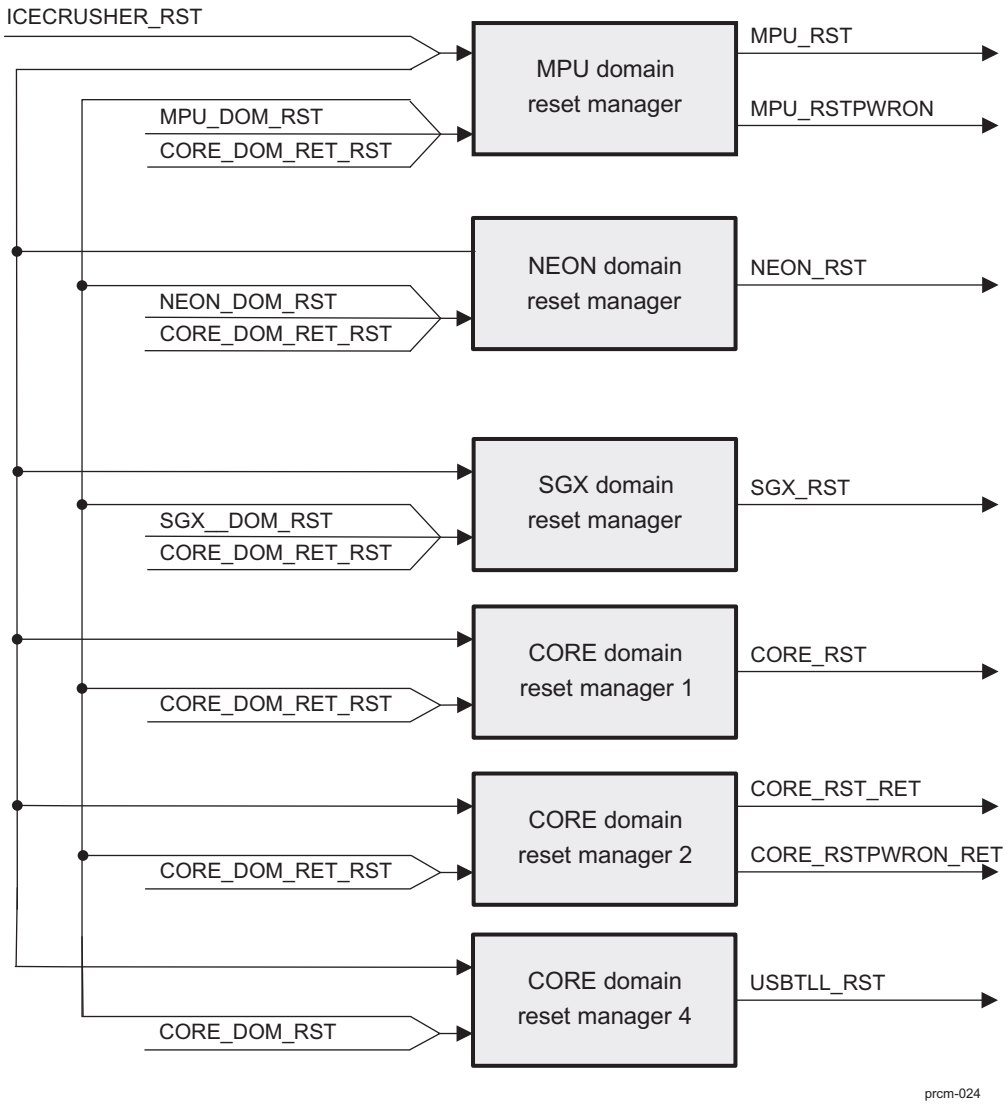

Figure 4-18. Domain Reset Management: Part 2

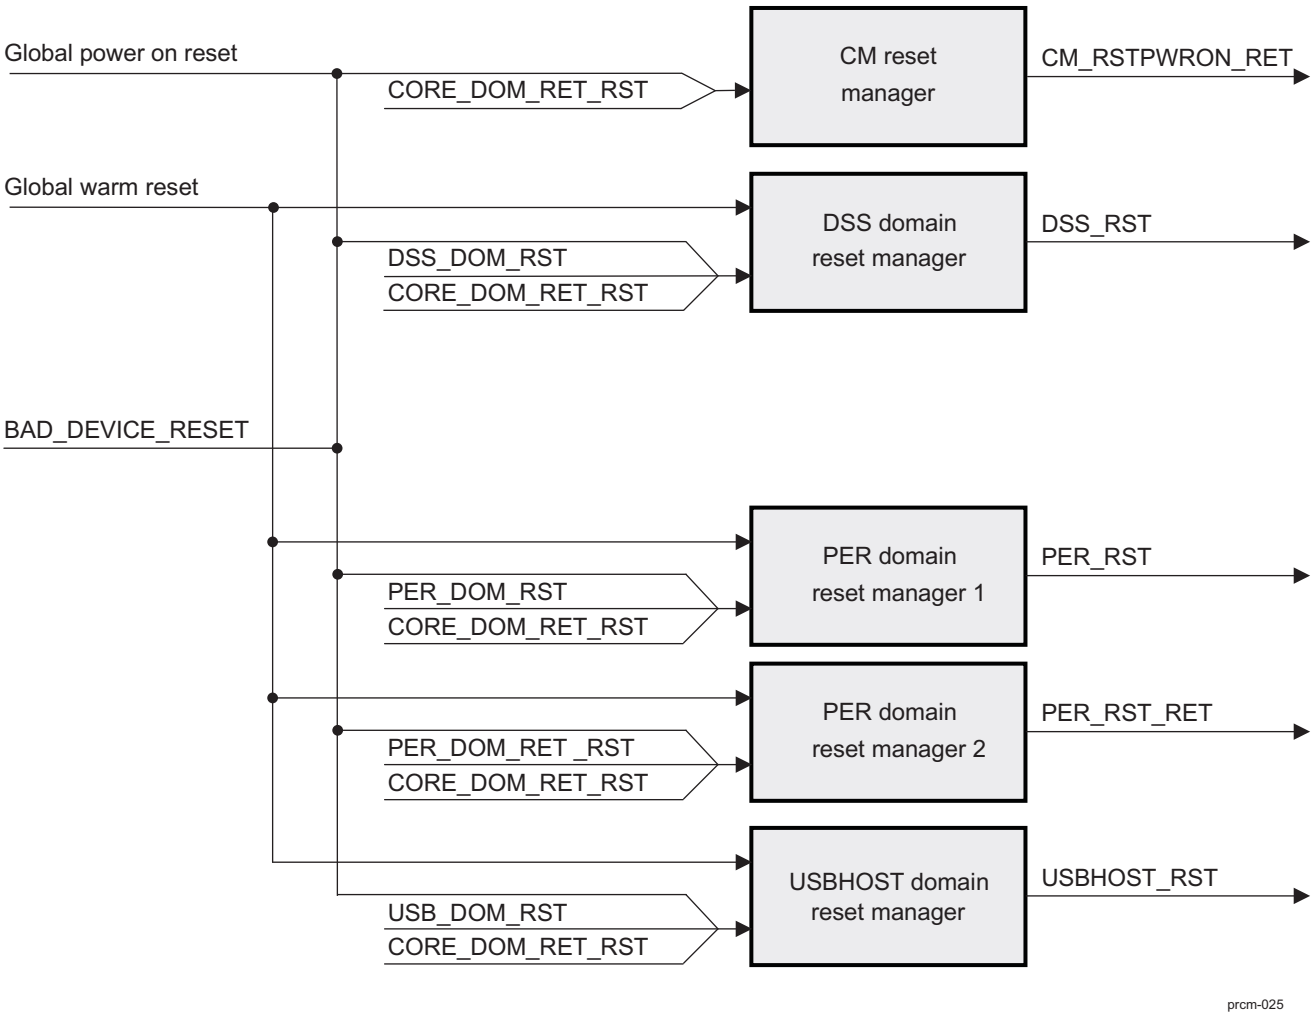

Figure 4-19. Domain Reset Management: Part 3

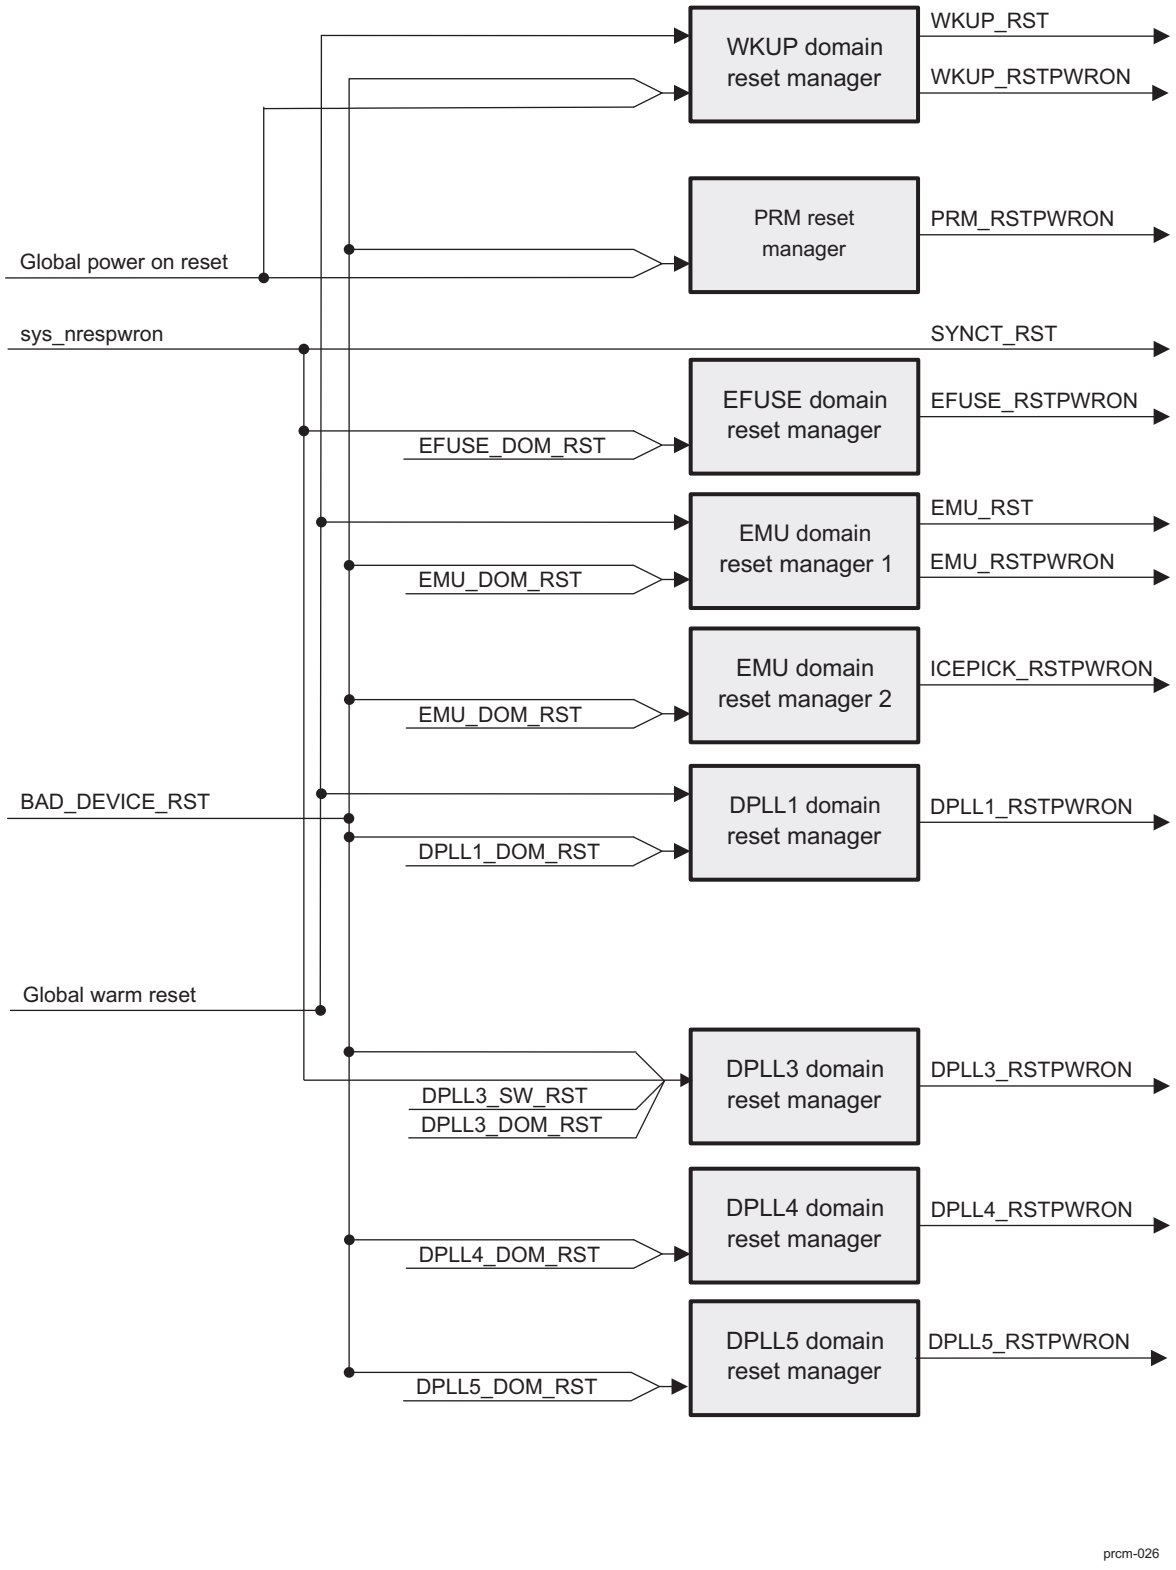

4.5.8 Reset Summary

Table 4-18 and Table 4-19 summarize the different sources of global and local resets and their actions on the reset signals.

Table 4-18. Global Reset Summary[1]

Domain Resets		Reset Sources				
Power Domain	Signal	Cold Reset		Warm Reset		
		sys_nres pweron	DPLL3_ SW_RST	sys_nres warm_in	MPU_WD_ RST	GLOBAL_ SW_RST

4.5.9 Reset Sequences

4.5.9.1 Power-Up Sequence

NOTE: Please reference the device-specific data manual for power-up sequencing.

4.5.9.2 CPEFUSE Reset Sequence

In the CPEFUSE reset sequence, Customer Programmable EFUSE is coupled with the SCM. Whenever the SCM is reset, the CPEFUSE cells are sensed. This sequence is initiated by the PRCM module and the SCM (hardware-controlled) after a device cold reset. Under these conditions, the CM part of the PRCM is released from reset, and, according to the configuration of the PRCM.CM_FCLKEN3_CORE[0] EN_CPEFUSE bit, the CPEFUSE functional clock is automatically restarted and the CPEFUSE_RST reset is released (de-asserted). The SCM completes the autoload sequence of the CPEFUSE. Software must poll the autoload completion status bit in the SCM before switching off the CPEFUSE functional clock.

Whenever the software must blow a CPEFUSE, it must ensure that the functional clock is enabled; it starts the autoload sequence by programming the SCM.

For information about the SCM, see the *System Control Module* chapter.

4.6 PRCM Power Manager Functional Description

4.6.1 Overview

4.6.1.1 Device Partitioning

Table 4-20 lists the device modules split over the domains.

Table 4-20. Domain Modules

Power Domain	Modules
MPU	MPU core
	ICE-crusher CS
	MPU async bridge (master)
	SSM
NEON	NEON coprocessor
SGX	SGX subsystem
CORE	GPMC
	GPTIMER[10, 11]
	HDQ/1-Wire
	HS USB
	I2C[1, 2, 3]
	McBSP[1, 5]
	McSPI[1, 2, 3, 4]
	MMC/SD/SDIO[1, 2, 3]
	MPU async bridge (slave)
	MPU INTC
	OCM_RAM
	OCM_ROM
	SCM
	SDRC
	SHAM[1, 2]
	SMS

Table 4-20. Domain Modules (continued)

Power Domain	Modules
	L3 Interconnect
	UART[1, 2]
	SDMA
	Temperature sensor (x2)]
	CPEfuse farm
	L4_Core interconnect
DSS	Display subsystem
	Video DAC
PER	UART3
	WDTIMER3
	McBSP[2..4]
	GPIO[2..6]
	GPTIMER[2..9]
	L4_Per interconnect
WKUP	GPIO1
	GPTIMER[1, 2]
	WDTIMER[1, 2]
	32-kHz sync timer
	L4_Wakeup interconnect
EMU	CWT
	DAP-APB
	ETB
	ICEPICK
	SDTI
	TRACEPORT
	L4_EMU interconnect
EFUSE	eFuse farm
DPLL1	MPU DPLL
DPLL3	CORE DPLL
DPLL4	Peripherals DPLL
DPLL5	Peripherals DPLL2

4.6.1.2 Domain State Transitions

For each domain, the PRM manages state transitions, controlling domain clocks and resets.

Two types of power state transitions are possible:

- Sleep: Moving from a higher consumption power state (ACTIVE) to a lower consumption power state (INACTIVE).
- Wake-up: Moving directly from a lower consumption power state (INACTIVE) to the ACTIVE power state.

4.6.1.3 Device Power Modes

A device power mode is a specific functional combination of the states of all the domains of the device.

Unlike domain states, device power modes are not hardware-defined; they are defined by software as relevant combinations of the domain states.

There are two types of device power modes:

- Active: Any valid combination of domain states in which one or several domains are still active,

regardless of whether any software is running.

- Standby: Any valid combination of domain states in which all the domains are in INACTIVE state.

4.6.2 Domain Implementation

4.6.2.1 Domain Dependencies

Besides the inner conditions to operate a state transition on a single domain, the device offers hardwired and software-programmable dependencies between the domains.

Two kinds of dependencies exist:

- Sleep dependencies: Used to start a sleep transition on a domain only if the related domains are in mute mode (not requesting any service from the linked domain)
- Wake-up dependencies: Used to initiate a wake-up transition on a domain as a consequence of a linked domain wake-up transition

Two dedicated sets of registers (PRCM.CM_SLEEPDEP_<domain> and PRCM.PM_WKDEP_<domain>) allow the setting of programmable dependencies.

Section 4.8.5, *Sleep and Wake-Up Dependencies*, summarizes the possible dependency combinations between domains.

4.6.2.2 Domain Software Controls

If all conditions are met to initiate a domain state transition (that is, all the modules are idle/standby and the related clocks are shut down), the PRCM automatically manages the transition according to the following settings:

- Dependencies setting: The PRCM.CM_SLEEPDEP_<domain> registers and PRCM.PM_WKDEP_<domain> registers are used to set/clear programmable dependencies between domains.

  Not all dependencies are programmable by software; some are hardwired and thus do not allow any control. For more information about the dependencies between domains, see Section 4.8, *Idle and Wake-Up Management*, and Section 4.11, *Basic Programming Model*.
- Event generator: Three registers (PRCM.PM_EVGENCTRL_MPU, PRCM.PM_EVGENONTIM_MPU, and PRCM.PM_EVGENOFFTIM_MPU) allow the MPU domain to be switched between on inactive mode. The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers are used to set the durations of the on and inactive modes, respectively.

  For details, see Section 4.11, *Basic Programming Model*, and Section 4.12,*PRCM Registers Manual*.

4.7 PRCM Clock Manager Functional Description

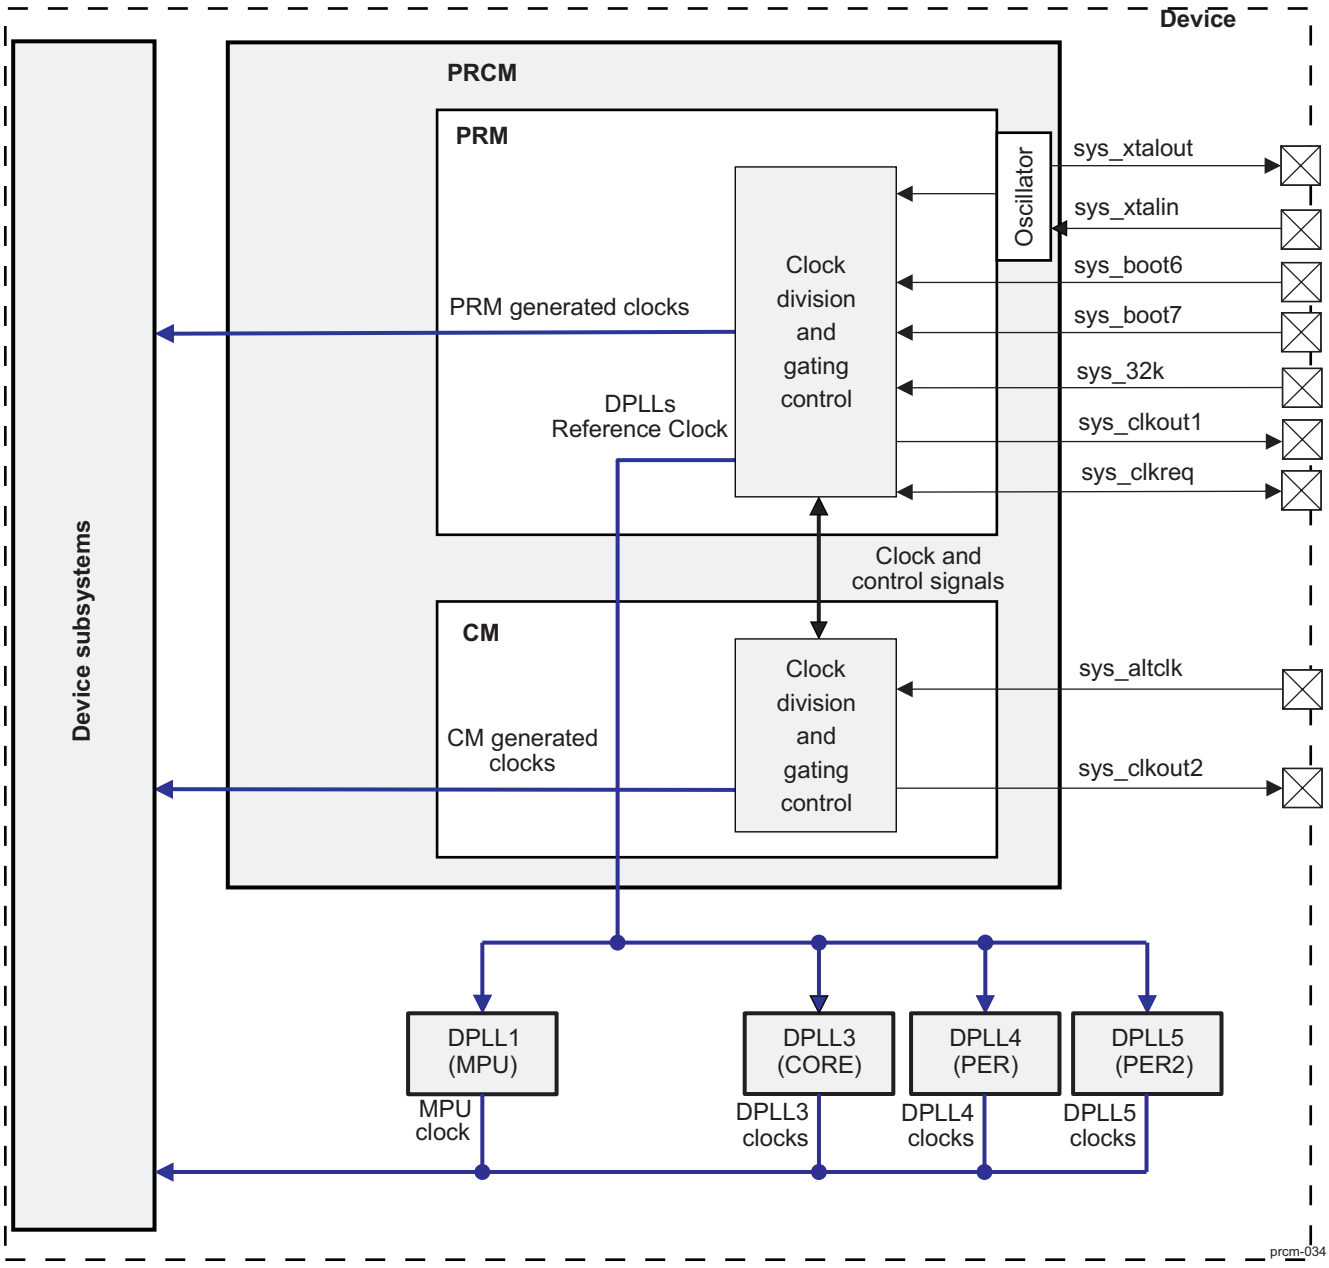
This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power saving considerations, ensure that clocks to unused domains and modules are properly gated.

4.7.1 Overview

The PRCM module provides control for clock generation, division, distribution, synchronization, and gating. It distributes the clock sources to all the modules in the device.

The device-level clock generation is handled by internal oscillators (the system clock oscillator and the 32-kHz oscillator for secure clock) and DPLLs; clock division and gating are handled by the PRM and the CM sections of the PRCM. Figure 4-20 shows the high-level clock-management scheme in the device.

Figure 4-20. PRCM Clock Manager Overview



4.7.1.1 Interface and Functional Clocks

The PRCM propagates two kinds of clocks:

- Interface clock: Ensures proper communication between any module and the system interconnects (L3 or L4). In most cases, the interface clock supplies the interface and registers of the module. For some modules, the interface clock is also used as the functional clock.
- Functional clock: Supplies the functional part of a module or subsystem. In some cases, a module or subsystem may require several functional clocks.

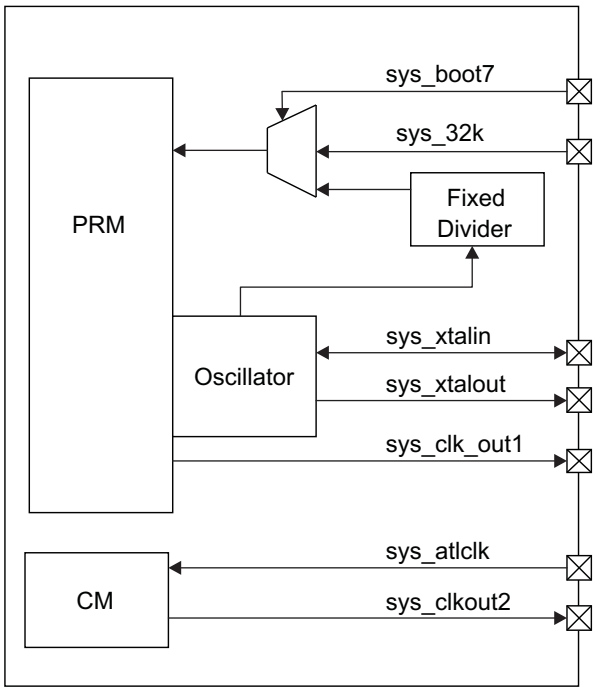
To be operational, a module requires functional clock(s); to communicate with other modules, it requires an interface clock. For example, the functional clock of a general-purpose timer (GPTIMER) must be active for it to run, but its interface clock can be turned off.

A module can use one or more optional functional clocks. Because an optional functional clock is used only for specific features of the module, it can be shut down without stopping the module activity (for example, 54 MHz for the DSS domain).

4.7.2 External Clock I/Os

Figure 4-21 shows the external clock I/Os of the device.

Figure 4-21. External Clock I/O



4.7.2.1 External Clock Inputs

4.7.2.1.1 32-kHz Always-On Clock

The 32-kHz clock is used for low-frequency operation (timers, denouncing, etc.). It also supplies the WKUP domain for operation in the lowest power standby mode. The device supports an external 32kHz clock signal or an internal 32kHz clock divided down from the external 26MHz high-frequency clock. The selection between external and internal 32kHz clock is done by sys_boot7 pin. The sys_32k input pin supplies the 32-kHz always-on clock (32K_FCLK clock) when the sys_boot7 pin is configured for external 32-kHz clock.

4.7.2.1.2 High-Frequency System Clock

The high-frequency system clock (SYS_CLK) is either supplied to the device from an external clock source through the sys_xtalin input pin or is generated internally by a local system clock crystal oscillator. In the latter case, a crystal is connected between the sys_xtalout and sys_xtalin device pins. The sys_boot[6] pin is used to set the oscillator operating mode (see Figure 4-6).

The source system clock can be 26 MHz and is internally divided by 2 to provide the standard frequencies (26 MHz becomes 13 MHz). It supplies the reference to the DPLLs and is also used by several modules. The system clock is activated in the device after the device power-on reset is released by the reset manager in the PRCM module.

The source-clock selection register (PRCM.PRM_CKSEL [2:0] SYS_CLKIN_SEL bit field) is set by the software to identify the input frequency of the system clock.

Table 4-21 provides the system clock input configurations.

Table 4-21. System Clock Input Configurations

Input Source	Device Pin Mapping	Description
Quartz	sys_xtalin and sys_xtalout	Internal oscillator is enabled.
Square clock (1.8-V CMOS signal)	sys_xtalin (sys_xtalout is not connected)	Internal oscillator is bypassed.

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the internal oscillator is used (oscillator mode) or an external clock source is supplied to the sys_xtalin input pin (bypass mode).

4.7.2.1.3 Alternate Clock

The sys_altclk pin can be used to provide an alternate 54-MHz, 48-MHz, or any other frequency clock.

4.7.2.2 External Clock Outputs

The device can output two clocks externally:

- sys_clkout1 can output an oscillator clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) at any time. The output oscillator clock can be controlled either by software or externally using sys_clkreq control.
- sys_clkout2 can output sys_clk (12, 13, 16.8, 19.2, 26, or 38.4 MHz), core_clk (CORE DPLL output), or 96-MHz or 54-MHz clocks. It can be divided by 2, 4, 8, or 16. This output is active only when the CORE domain is ACTIVE. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock.

4.7.2.3 Summary

Table 4-22 summarizes the external clock I/O.

Table 4-22. External Clock I/Os

Name	I/O[1]	Source/Destination	Description
sys_xtalin	I	Oscillator	Main input clock. Crystal oscillator clock (only at 26 MHz) or CMOS digital clock (at 26 MHz).
sys_xtalout	O	Oscillator	Output of oscillator
sys_clkout1	O	PRCM	Configurable output clock 1
sys_clkout2	O	PRCM	Configurable output clock 2
sys_32k	I	PRCM	32-kHz clock input
sys_altclk	I	PRCM	Alternate selectable clock source for UARTs or NTSC/PAL. It can be 54 MHz, 48 MHz, or any frequency.

(1) I = Input, O = Output

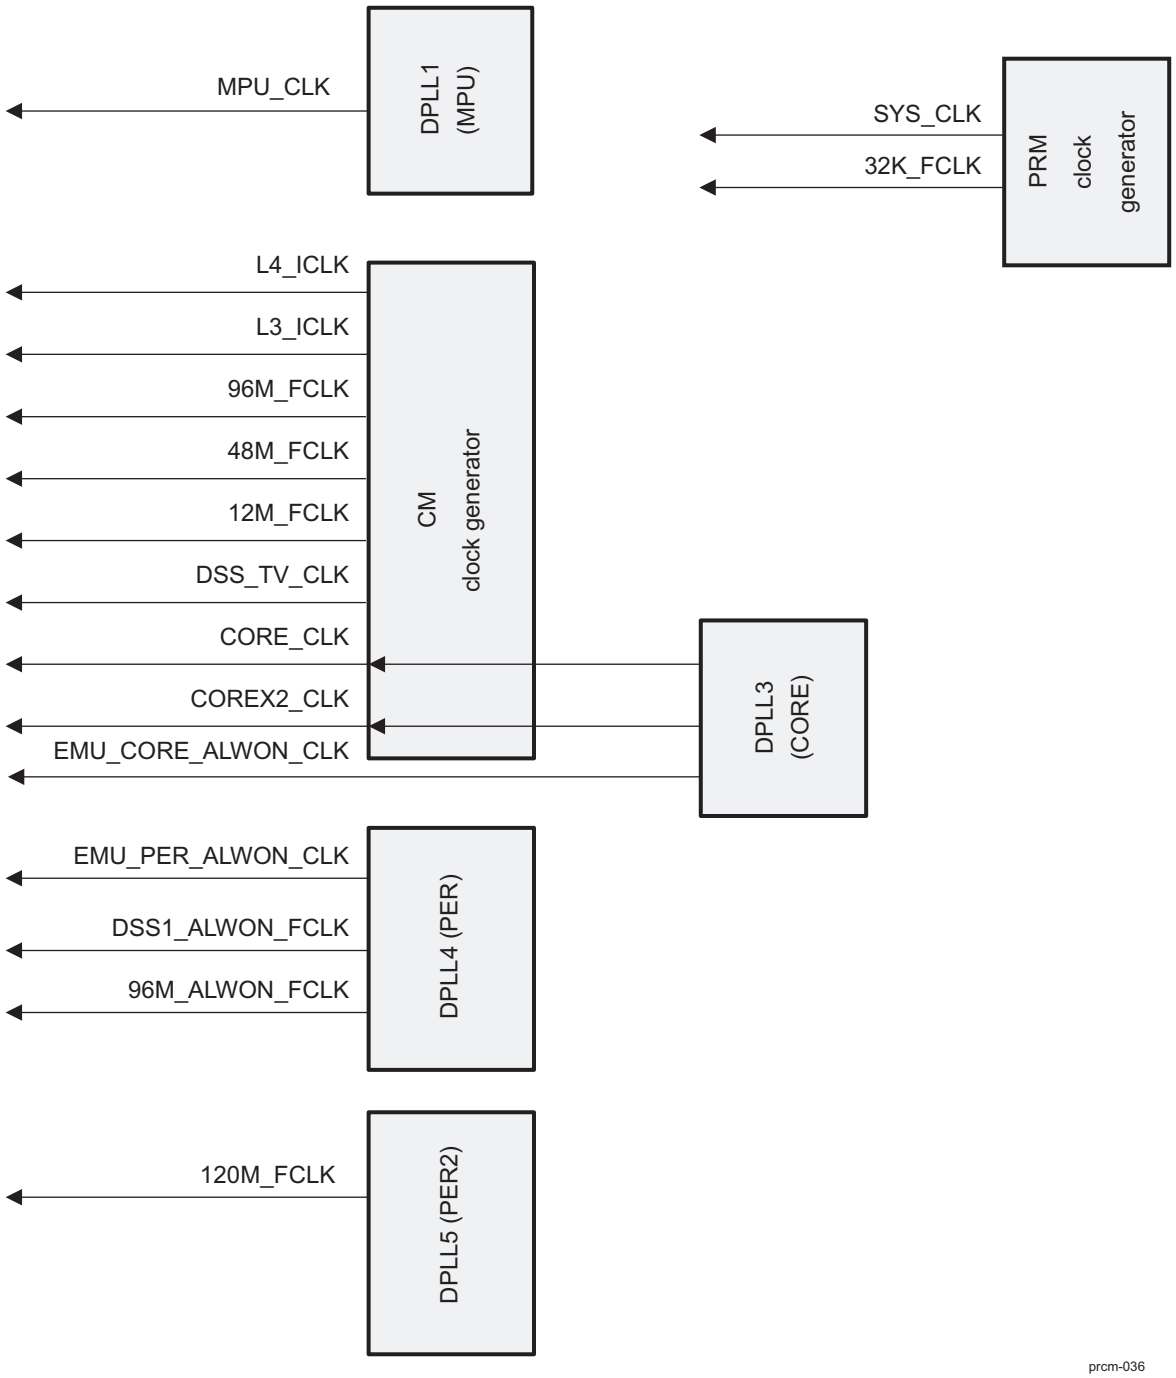
4.7.3 Internal Clock Generation

The device generates internal clocks from four sources:

- PRM
- CM
- DPLLs
- 32-kHz oscillator

Figure 4-22 shows the internal clock generation scheme of the device.

Figure 4-22. Internal Clock Sources



4.7.3.1 PRM

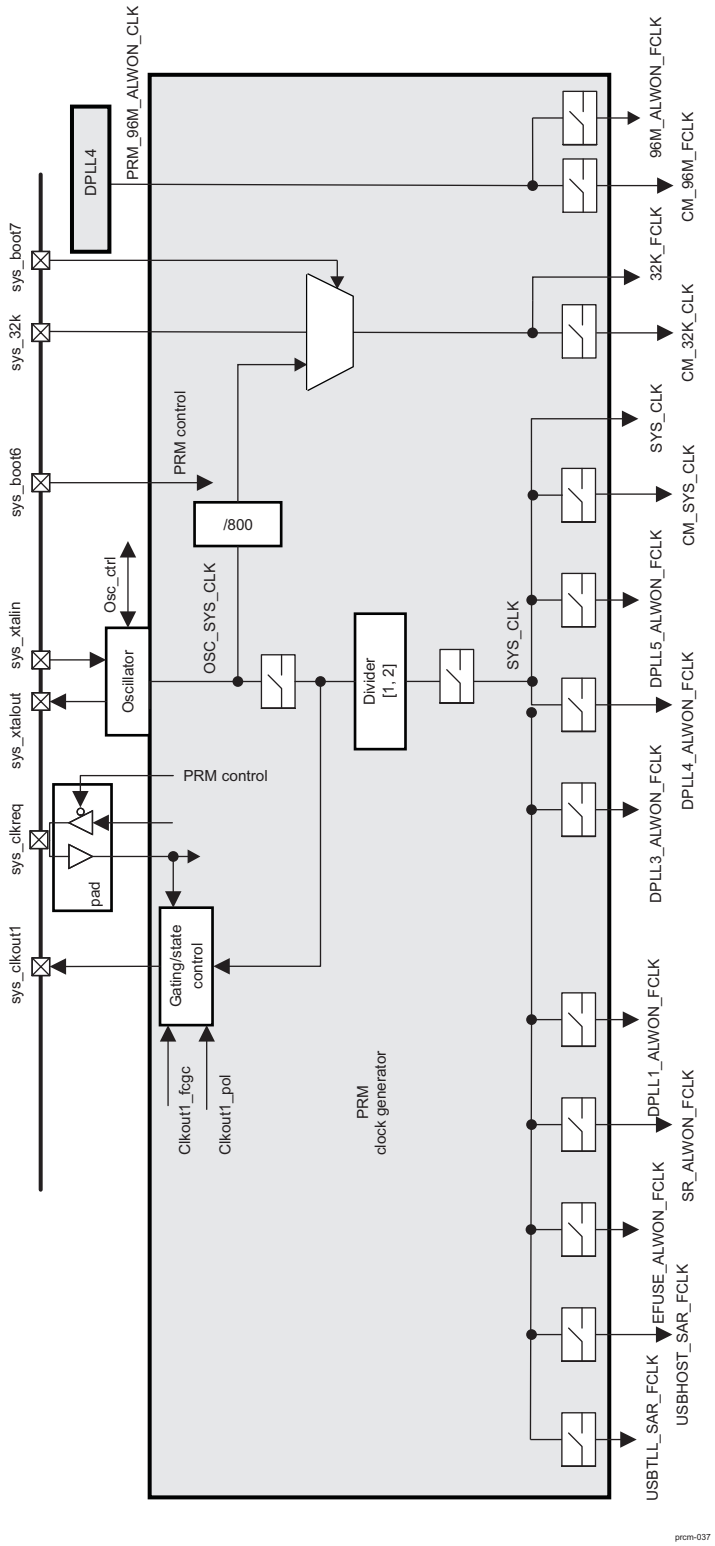
The PRM resides in the WKUP domain. It handles the generation of the 32-kHz low-frequency clocks and the high-frequency system clocks from the SYS_CLK. It also manages the clock oscillator and the external clock output sys_clkout1.

SYS_CLK is generated by the internal oscillator or supplied as the external clock signal on the sys_xtalin pin. It supplies most of the clocks in the device. SYS_CLK is also the source of the WKUP domain interface clocks.

It also handles the gating and distribution of the 96-MHz clock from DPLL4 to the CM and the PER domain modules.

Figure 4-23 is the functional overview of the PRM. The other clocks in the figure are explained in the following sections.

Figure 4-23. PRM Clock Generator



4.7.3.2 CM

The CM clock generator generates interface clocks and peripheral functional clocks for most of the modules. It also controls DPLL3, DPLL4, and the external peripheral clock output sys_clkout2 (see Figure 4-24).

The CM is in the CORE domain.

DPLL3 receives SYS_CLK from the PRM and generates CORE_CLK through the CM. CORE_CLK is the source for the interface clocks (L3 and L4) and the functional clock . The L3 and L4 interface clocks supply the device interconnects and all module interface clocks. The L4 clock is divided to supply the reset managers (PRM) in the WKUP domain. The clocks derived from CORE_CLK are fully balanced over the device.

The 96M_FCLK, 48M_FCLK, and 12M_FCLK clocks are functional unbalanced clocks for a number of modules in the CORE and PER domains.

The functional 96-MHz clock path can be bypassed with SYS_CLK to allow a peripheral such as I^2C to be functional while the DPLL4 is not yet enabled. The default configuration after initial power-on is bypassed with the system clock. Software must switch to the DPLL-generated clock after programming the proper system settings.

The 96-MHz clock input from PRM to the CM (that is, CM_96M_FCLK) is internally gated by the CM.

Figure 4-24 shows the functional overview of the CM.

Figure 4-24. CM Clock Generator Functional Overview

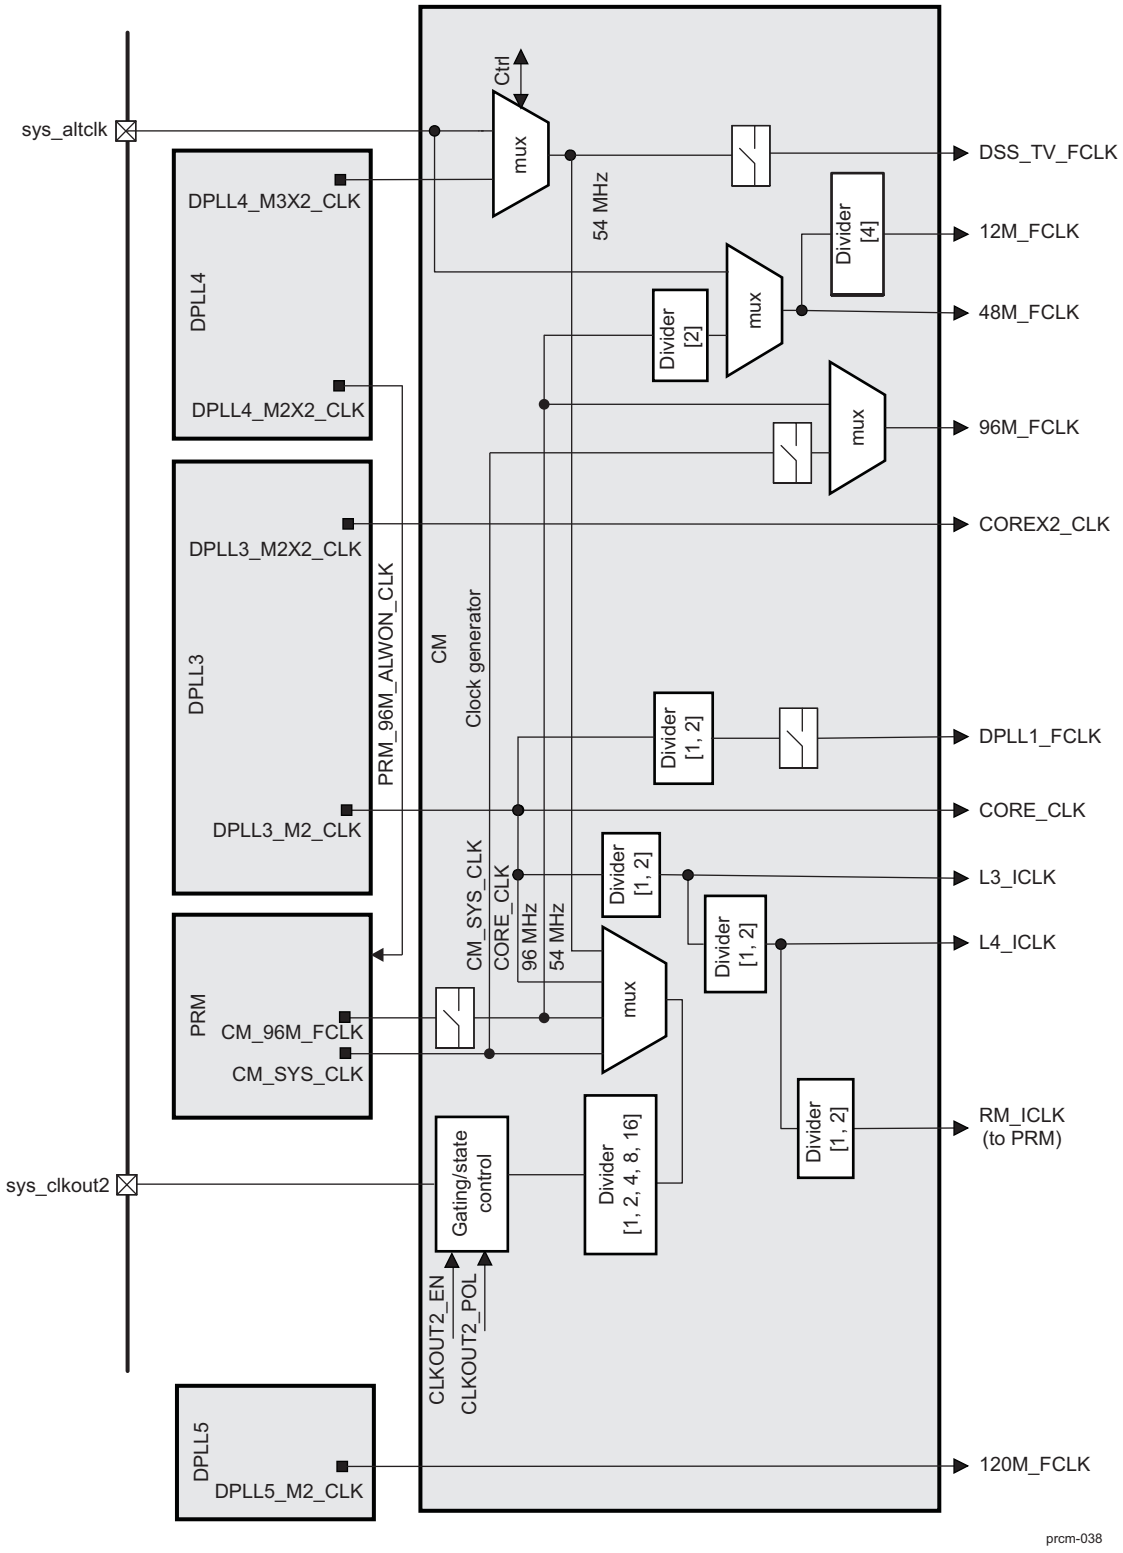


Figure 4-25 shows the functional overview of the CM for emulation clocks.

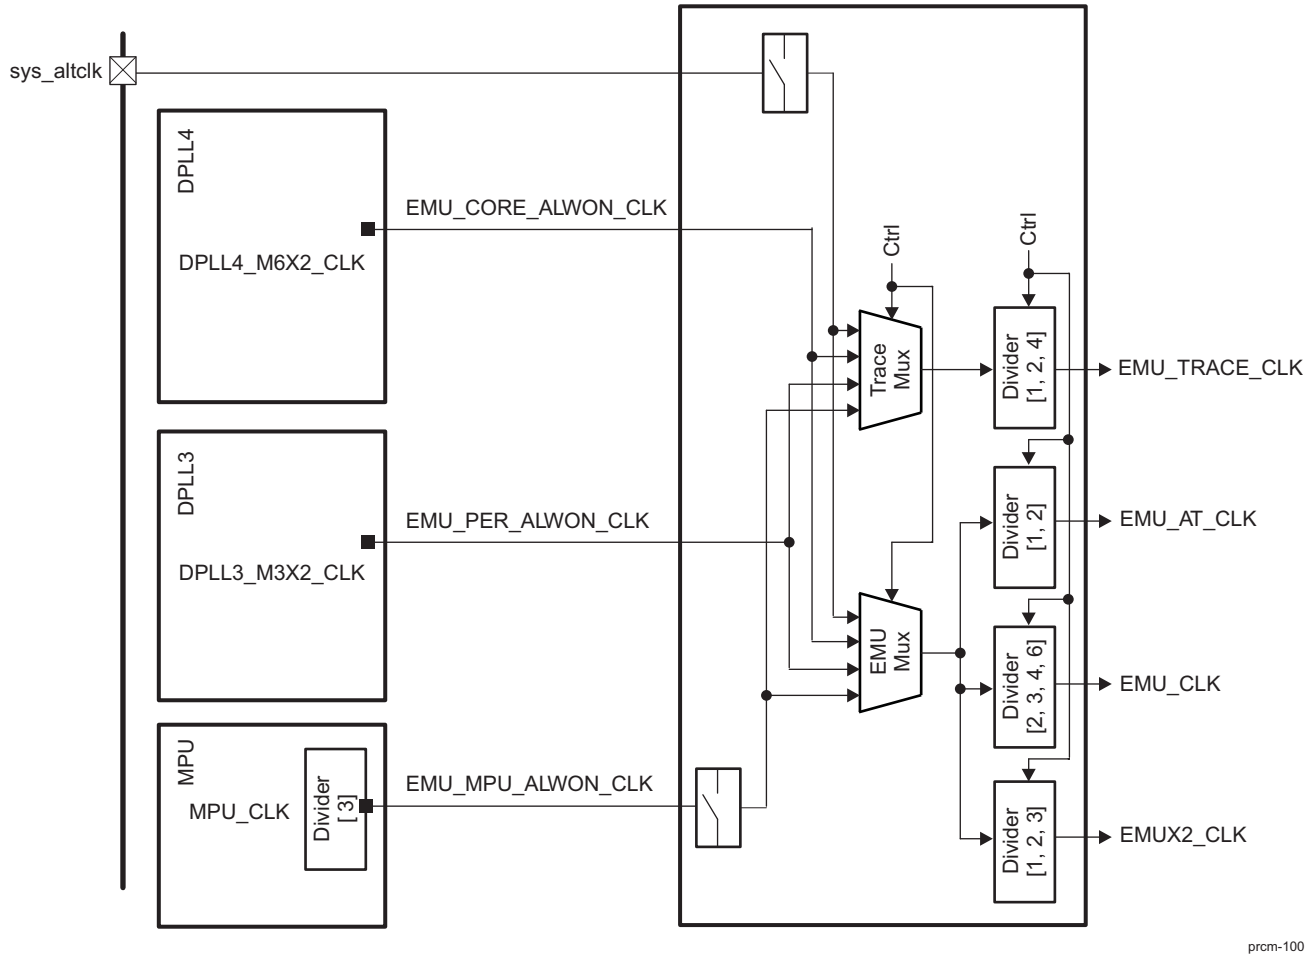
Figure 4-25. CM Emulation Clock Generator Functional Overview



4.7.3.3 DPLLs

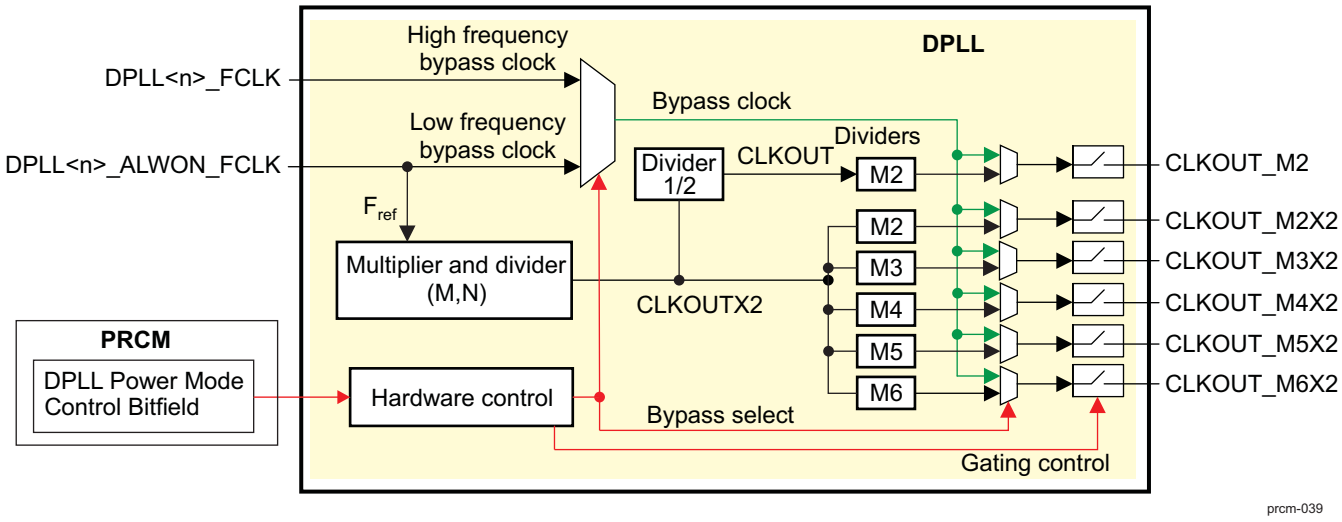
To generate high-frequency clocks, the device supports five on-chip DPLLs controlled directly by the PRCM:

- DPLL1 (MPU)
- DPLL3 (CORE)
- DPLL4 (PER)
- DPLL5 (PER2)

NOTE: This chapter discusses only DPLL1 to DPLL5, because they are directly controlled by the PRCM module. The *Display Interface Subsystem* chapter discusses the DPLLs in the DSS.

Figure 4-26 shows the functional architecture of a generic DPLL.

Figure 4-26. Generic DPLL Functional Diagram



Depending on its hardware configuration, the DPLL may receive one or two clock inputs.

When the DPLL has two clock inputs, it uses one as the reference clock (F_{ref}) to generate the high-frequency clock; the second one serves as the bypass clock when the DPLL is in bypass mode (that is, not locked and generating the high-frequency clock). For example, DPLL1 receives the high-frequency bypass clock from the DPLL3 output, and the reference clock from the PRM.

When the DPLL has only one clock input, it uses that clock input as the reference clock and bypass clock. For example, DPLL3, DPLL4, and DPLL5 receive only one input clock from PRM, and it is used as both the reference and the bypass clock.

It internally generates two main clocks according to the following equations:

- $CLKOUTX2 = (F_{ref} \times 2 \times M) / (N+1)$
- $CLKOUT = CLKOUTX2/2$

where M is an 11-bit multiplier and N is a 7-bit divider.

NOTE: When M is set to 0 or 1, the DPLL is forced into bypass mode.

The internal clocks (CLKOUT and CLKOUTX2) of the DPLL may then be used to generate six independent output clocks:

- CLKOUT_M2 = CLKOUT / M2
- CLKOUT_M2X2 = CLKOUTX2 / M2
- CLKOUT_M3X2 = CLKOUTX2 / M3

- CLKOUT_M4X2 = CLKOUTX2 / M4
- CLKOUT_M5X2 = CLKOUTX2 / M5
- CLKOUT_M6X2 = CLKOUTX2 / M6

where M2, M3, M4, M5, and M6 are additional dividers for the DPLL-synthesized clock.

The output clock frequencies defined by these equations are generated by the DPLL only when it is locked. When the DPLL is in bypass mode, however, all clock outputs run at the bypass clock frequency. The bypass clock can either be a high-frequency bypass clock (only for DPLL1) or the low-frequency reference clock.

The DPLL also provides an independent clock-gating signal for each of the six output clocks. The PRCM provides the DPLL with a clock-gating control signal, and the DPLL returns a clock activity status signal indicating whether the output clock is effectively gated or running.

For an explanation of the DPLL multiplier, divider settings, and gating controls, see Section 4.7.6, *DPLL Control.*

Each clock-generating DPLL of the device has the following features:

- Independent domain
- Control by the CM
- Fed by always-on SYS_CLK with independent gating control for the SYS_CLK
- Analog part supplied by a dedicated power supply and an embedded LDO to eliminate 1-MHz noise
- Up to six independent output dividers for simultaneous generation of multiple output clocks with different frequencies

4.7.3.3.1 DPLL1 (MPU)

DPLL1 is in the MPU subsystem. It supplies clocks to this subsystem that are used as the source clocks for internally generating all subsystem clocks.

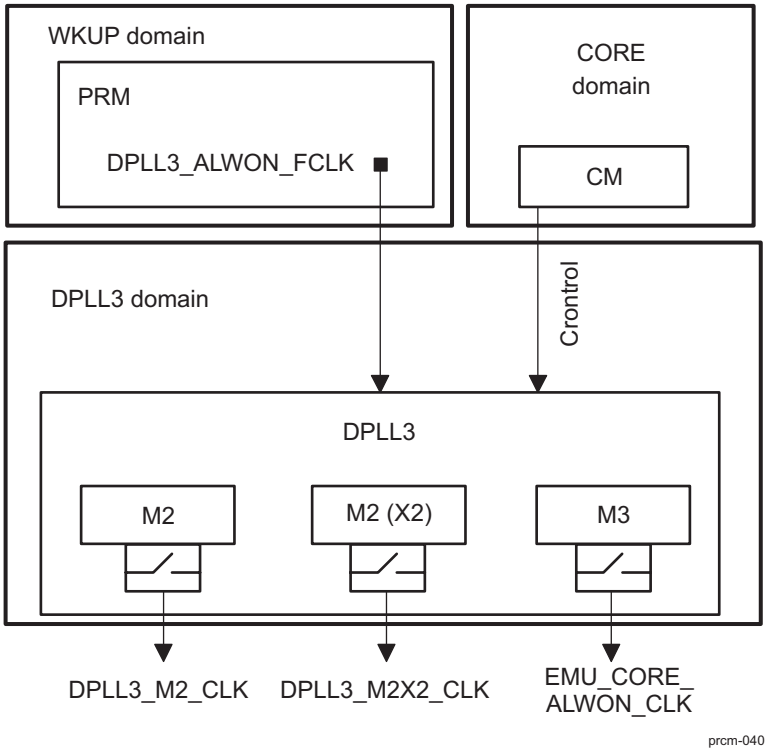
DPLL1 uses a reference clock to produce its synthesized clock. It receives the reference clock (DPLL1_ALWON_FCLK) from the PRM and its high-frequency bypass clock (DPLL1_FCLK) from the CM. The reference clock is SYS_CLK and the high-frequency bypass clock is CORE_CLK.

To save on DPLL power consumption by the processor, the high-frequency bypass input clock from DPLL3 (CORE) is used when the DPLL is set to bypass mode (either statically, or dynamically during relock time) or when the processor is not required to run faster than at L3 clock speed. This use of the high-frequency bypass input clock also optimizes the performance of the DPLLs during frequency scaling.

4.7.3.3.2 DPLL3 (CORE)

Figure 4-27 is the block diagram of DPLL3.

Figure 4-27. DPLL3 Clocks

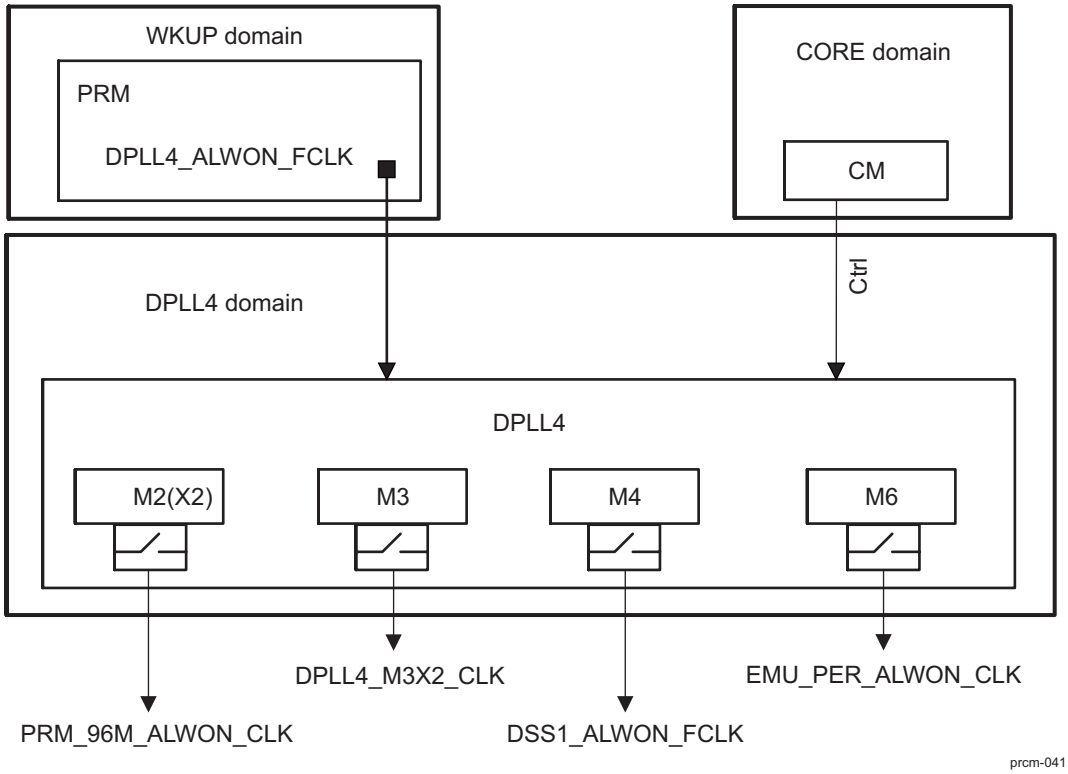


DPLL3 receives its reference clock (DPLL3_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL3 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL3 supplies the source clock for all interfaces and a few functional clocks for the device modules. It also serves as the source of the emulation trace clock. While the CORE domain is on, the output of DPLL3 can be used as HS bypass clock input to DPLL1.

4.7.3.3.3 DPLL4 (Peripherals)

Figure 4-28 is the block diagram of DPLL4.

Figure 4-28. DPLL4 Clocks



DPLL4 receives its reference clock (DPLL4_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL4 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL4 generates clocks for the peripherals, supplying five clock sources:

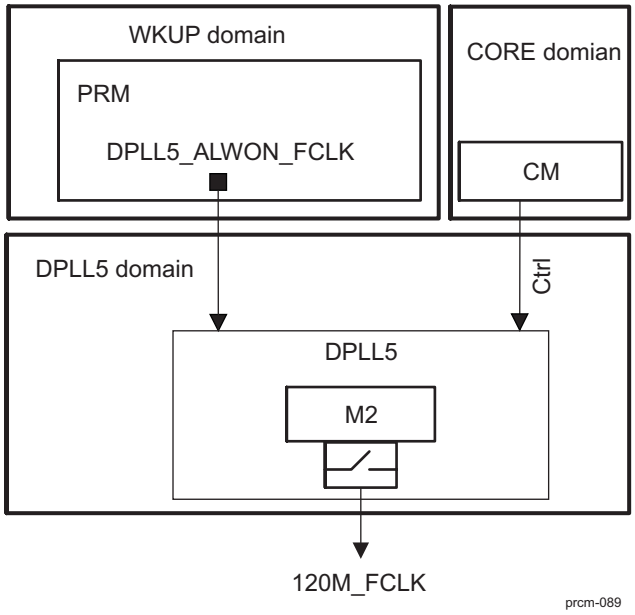
- 96-MHz always-on source clock for the PRM
- 54-MHz to TV DAC
- Display functional clock
- Emulation trace clock

The clock outputs to the DSS, PER, and EMU domains are always on.

4.7.3.3.4 DPLL5 (Peripherals)

Figure 4-29 is the block diagram of DPLL5.

Figure 4-29. DPLL5 Clocks



DPLL5 receives its reference clock (DPLL5_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL5 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL5 generates clocks for the peripherals, supplying five clock sources:

- 120-MHz functional clock to the peripheral domain modules.
- USIM source clock for the functional clock of the USIM open-core protocol (OCP) in the WKUP domain.

4.7.3.3.5 DPLL Clock Summary

Table 4-23 summarizes the use of the divided output clocks of the five DPLLs in the device.

Table 4-23. DPLL Output Clocks

	CLKOUT_M2	CLKOUT_M2X2	CLKOUT_M3X2	CLKOUT_M4X2	CLKOUT_M5X2	CLKOUT_M6X2
DPLL1		X[1]				
DPLL3	X	X	X			
DPLL4		X	X	X	X	X
DPLL5	X					

(1) X represents the DPLL clock output used.

4.7.3.4 32-kHz Oscillator

An internal 32-kHz always-on oscillator feeds the secure watchdog timer (WDTIMER1) and the secure timer (GPTIMER12). It is not software-controllable. The oscillator ensures protection for these timers against clock stoppage caused by an external attack.

4.7.3.5 Summary

Table 4-24 summarizes the source clocks in the device.

Table 4-24. Source-Clock Summary

Clock Name	External/Internal Source	Clock Generator	Description
32K_FCLK	sys_32k (input pin)	PRM	
SYS_CLK	Oscillator	PRM	System clock. Serves as primary source clock of the device. Also used as functional and interface clock for PRM.
DSS_TV_CLK	DPLL4/sys_altclk (input pin)	CM	DSS TV clock
120M_FCLK	DPLL5	CM	
96M_FCLK	DPLL4	CM	
48M_FCLK	DPLL4/sys_altclk (input pin)	CM	
12M_FCLK	DPLL4/sys_altclk (input pin)	CM	
96M_ALWON_CLK		DPLL4	Direct from DPLL4
CORE_CLK	DPLL3	CM	DPLL3 clock output frequency
COREX2_CLK	DPLL3	CM	DPLL3 clock output frequency x 2
L3_ICLK	DPLL3	CM	L3 interconnect interface clock
L4_ICLK	DPLL3	CM	L4 interconnect interface clock
MPU_CLK		DPLL1	MPU subsystem source clock
SECURE_32K_FCLK		32-kHz oscillator	Generated internally by an RC oscillator. It is always active.

4.7.4 Clock Distribution

4.7.4.1 Domain Clock Distribution

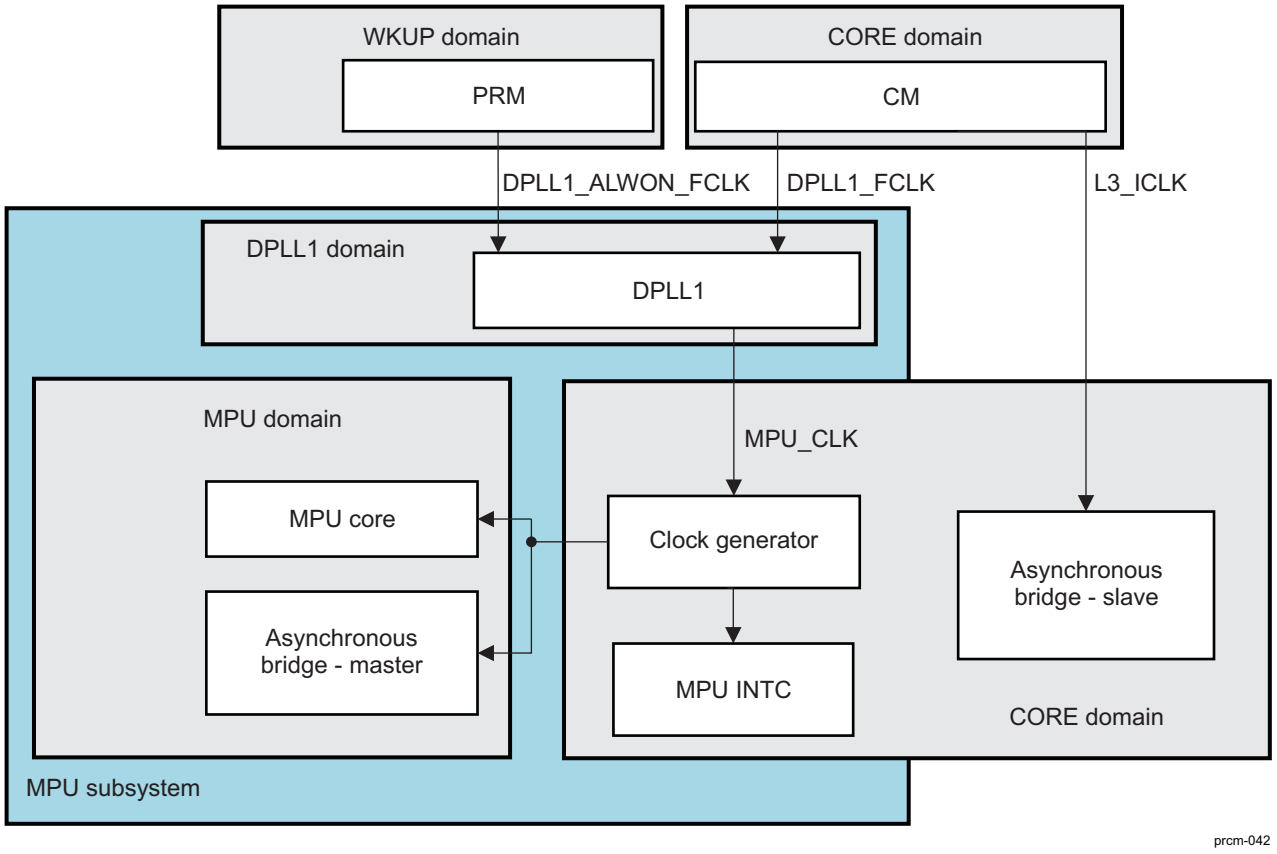
This section describes the PRCM clock distribution over device domains:

4.7.4.1.1 MPU Domain

The PRCM does not directly provide any clock to the MPU domain. It feeds only DPLL1, which generates MPU_CLK. All clocks are then locally generated by the clock generator in the MPU subsystem.

Figure 4-30 shows the clocking scheme in the MPU domain.

Figure 4-30. MPU Domain Clocking Scheme



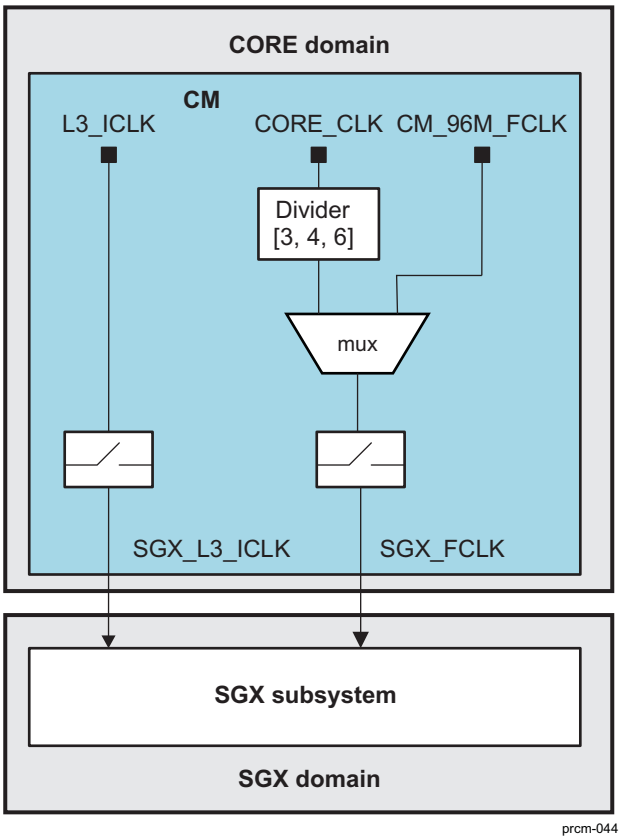
4.7.4.1.2 SGX Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are properly cut off.

The SGX subsystem interface clock is sourced by the L3 clock, whereas the functional clock source can be selected between CORE_CLK and CM_96M_FCLK. When the functional clock source is CORE_CLK, its frequency can be divided (by 3, 4, or 6).

Figure 4-31 shows the clocking scheme in the SGX domain.

Figure 4-31. SGX Domain Clocking Scheme



4.7.4.1.3 CORE Domain

The CORE domain has both L3- and L4-derived clock domains.

The CORE domain receives several functional clocks (12-, 48-, 96-MHz, system, and 32-kHz) that feed its peripherals and modules, with an exception:

- The McBSP 1 and McBSP 5 modules can be clocked either by CORE_96M_FCLK from the CM or from an external clock, MCBSP_CLKS. The SCM manages the selection between the two sources. For more information about the SCM, see *System Control Module* chapter.

Figure 4-32 through Figure 4-34 show the clock signals and their relationships in the CORE domain.

Figure 4-32. CORE Clock Signals: Part 1

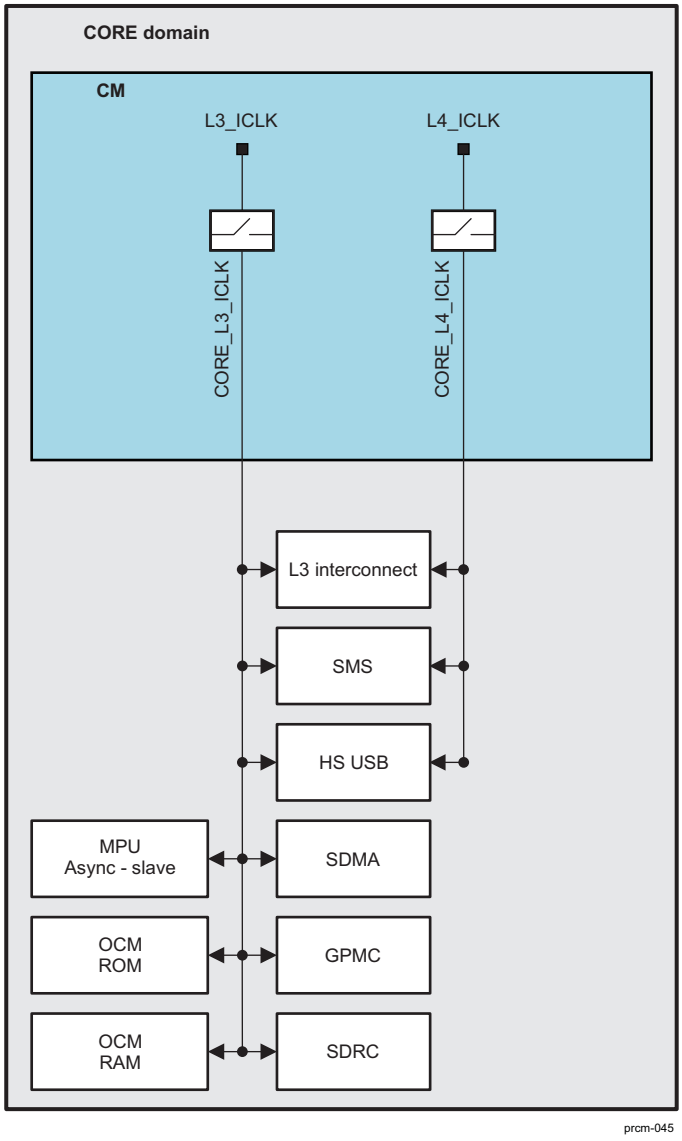


Figure 4-33. CORE Clock Signals: Part 2

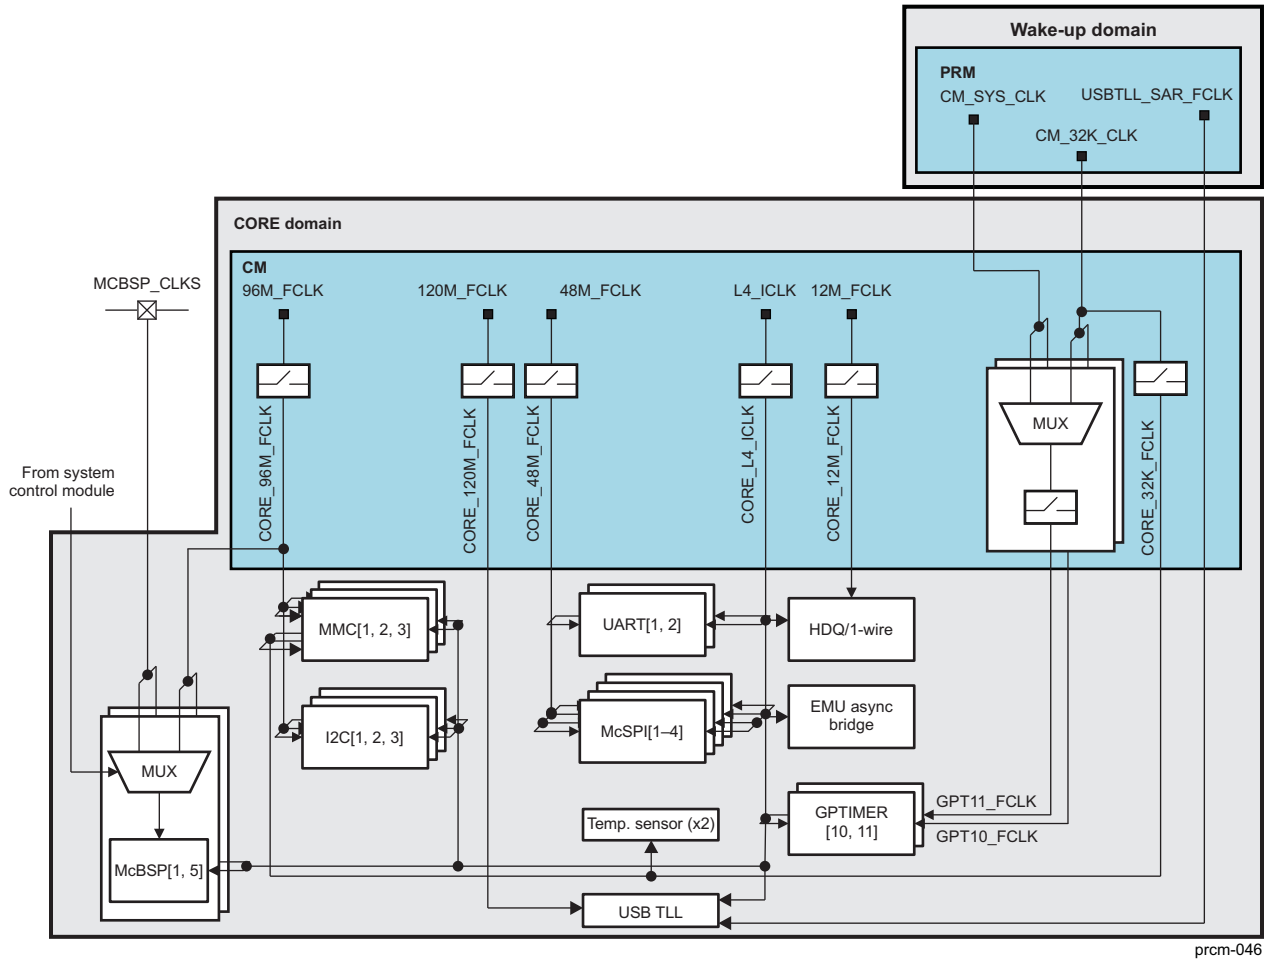

Figure 4-34. CORE Clock Signals: Part 3

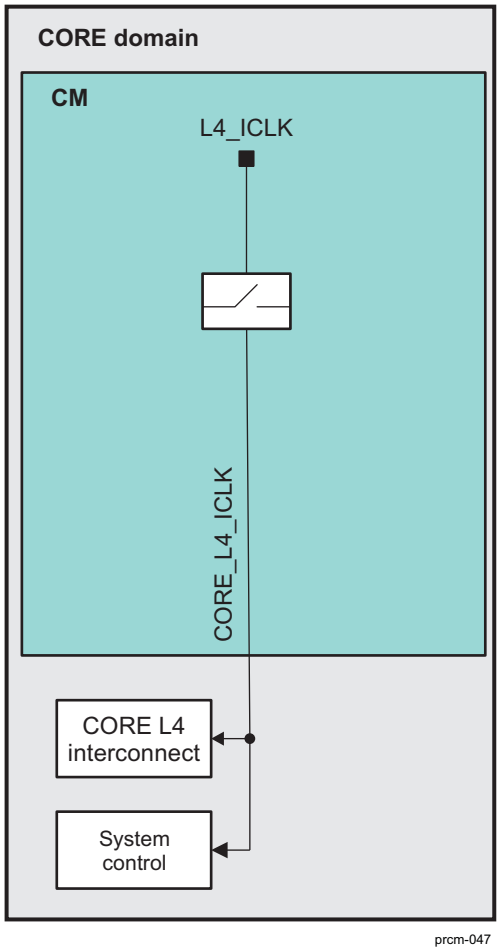


4.7.4.1.4 IPSS Domain

The IPSS domain receives following clocks from the system:

- **L3_ICLK:** interface clock that feeds VBUS, VBUS2OCP and OCP2VBUS architecture of IPSS. This clock is used as interface clock for all the IPSS modules.
- **SYS_CLK:** used as functional clock for HECC module and as source clock for USBOTG SS.

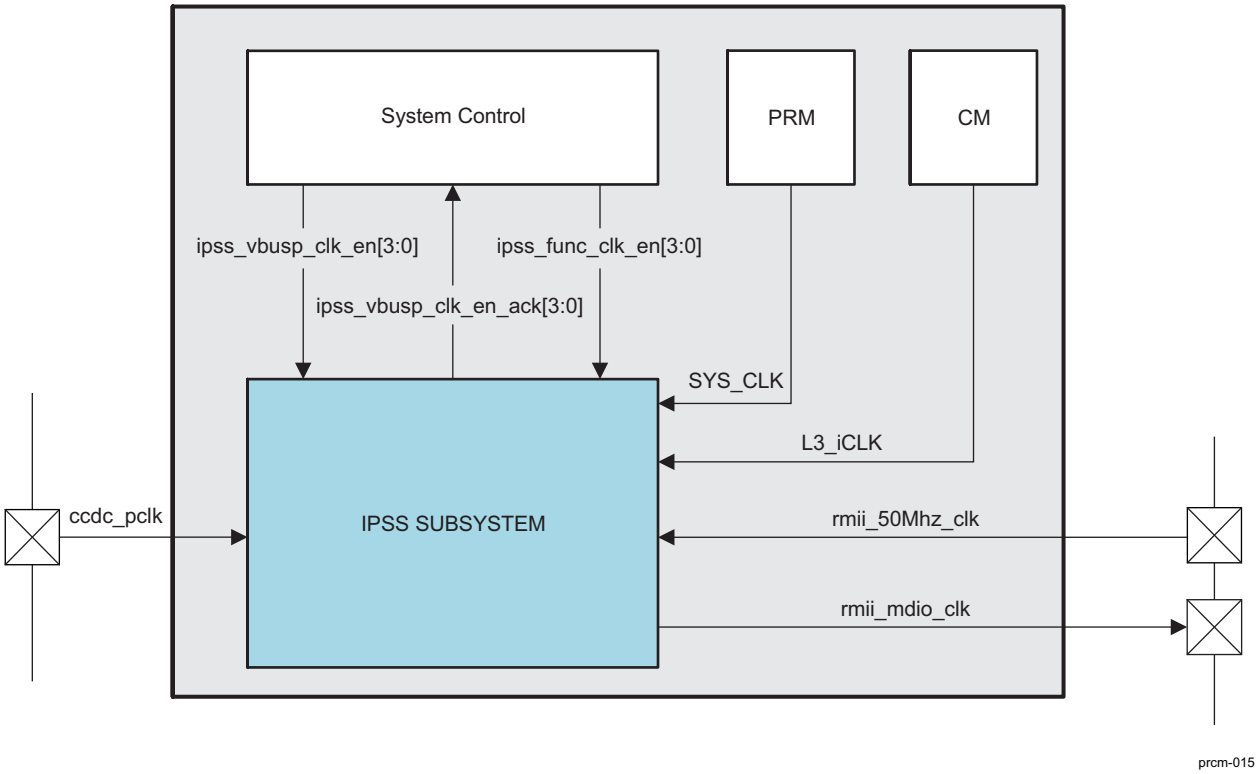
External clocks include:

- rmii_50mhz_clk: This clock feeds EMAC module for RMII functionality. (Refer to the EMAC chapter for more information on EMAC and RMII clocks.)
- rmii_mdio_clk: This is the output clock coming from EMAC which is used for external PHY.
- ccdc_pclk: This is the VPFE pixel clock input from the external sensor. (Refer to the VPFE chapter for more information on ccdc_pclk.)

The CONTROL_IPSS_CLK_CTRL register controls the clocking for IPSS. The field ipss_vbusp_clk_en has the gating control for interface clock and ipss_func_clk_en field will switch ON the functional clock for the IPSS modules (VPFE, USBOTG, HECC and EMAC). Few of the modules use their interface clock as functional clock, for more details refer to corresponding modules chapter.

Software can program ipss_vbusp_clk_en register bits to put corresponding modules in IDLE mode. It needs to read ipss_vbusp_clk_en_ack bits to make sure that these module clocks are gated. (Refer to the System Control Module chapter for more details.)

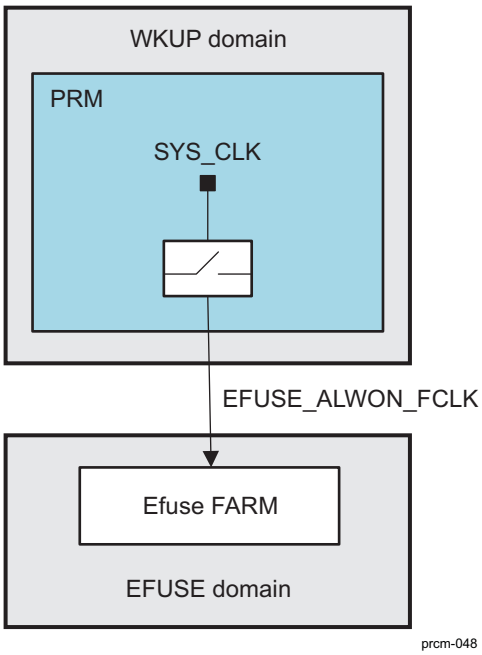
Figure 4-35. IPSS Domain



4.7.4.1.5 EFUSE Domain

Figure 4-36 shows the clock signals and their relationships in the EFUSE domain.

Figure 4-36. EFUSE Clock Signals



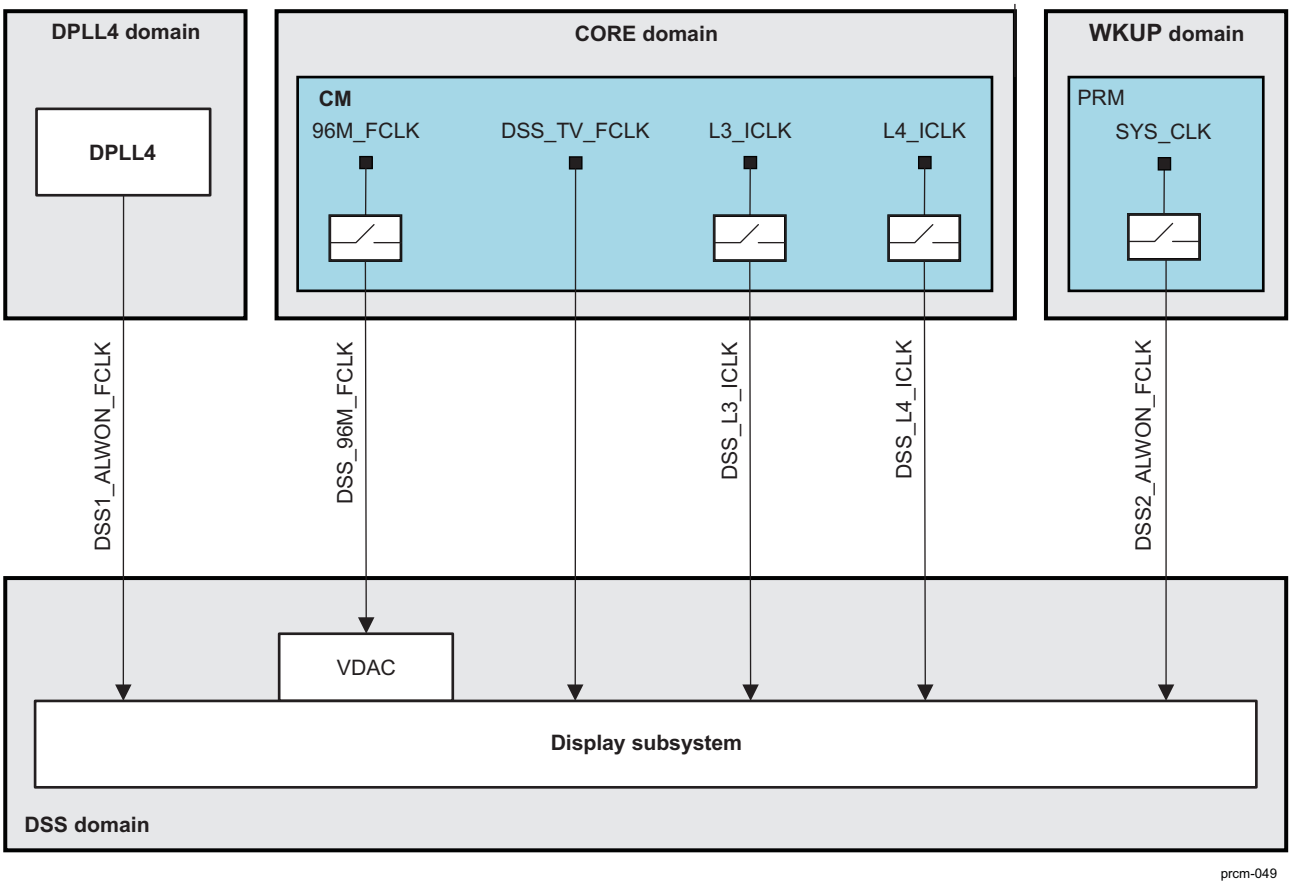
The EFUSE sense procedure is performed at device power up. During this procedure, the PRM enables the EFUSE_ALWON_FCLK clock.

4.7.4.1.6 DSS Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are properly cut off.

Figure 4-37 shows the clock signals and their relationships in the DSS domain.

Figure 4-37. DSS Clock Signals



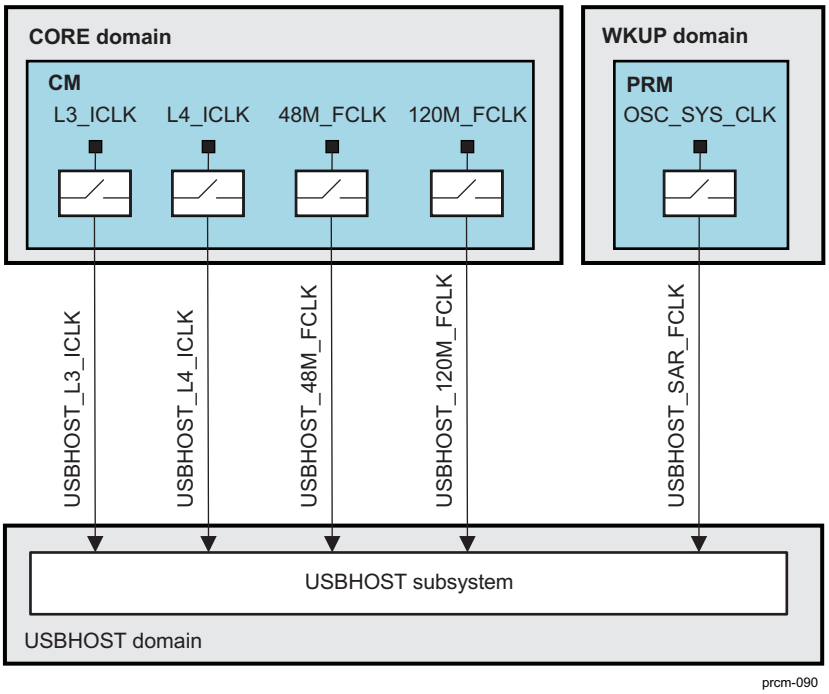
The DSS subsystem interface is clocked with the L3 and L4 clocks. It receives four functional clocks:

- DSS1_ALWON_FCLK: Issued from DPLL4. Its frequency can be a division by 1 to 16 of the frequency of the DPLL4 synthesized clock.
- DSS2_ALWON_FCLK: The gated SYS_CLK. Used mainly for display in low-power refresh modes.
- DSS_96M_FCLK: Required when TV output is activated
- DSS_TV_FCLK: Required when TV output is activated

4.7.4.1.7 USBHOST Domain

Figure 4-38 shows the clock signals and their relationships in the USBHOST domain.

Figure 4-38. USBHOST Clock Signals



The HS USB Host subsystem interface is clocked with the L3 and L4 clocks (USBHOST_L3_ICLK and USBHOST_L4_ICLK, respectively).

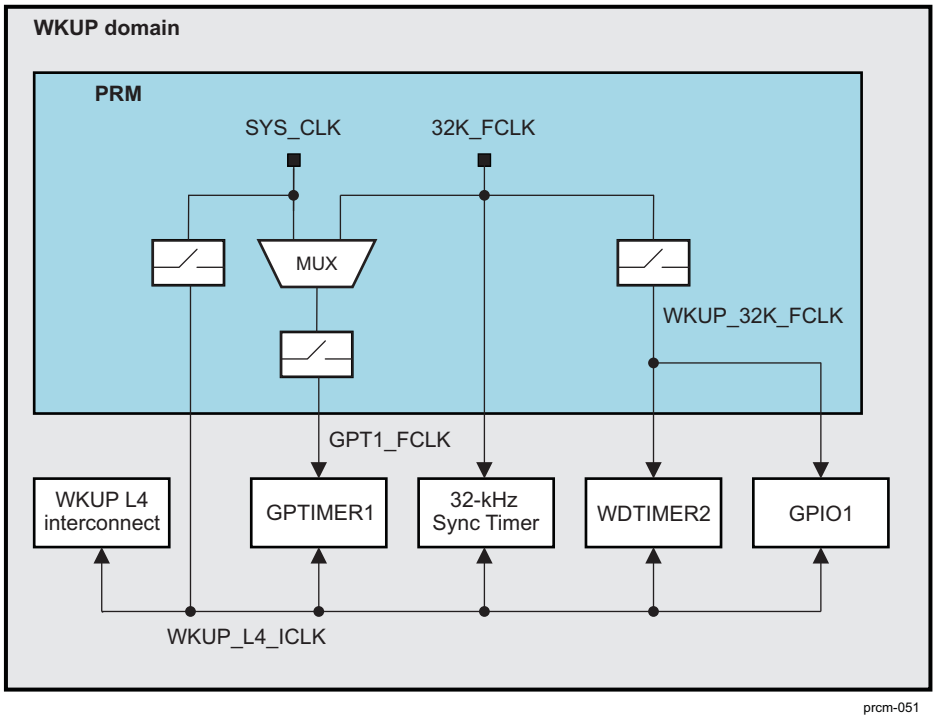
The HS USB Host subsystem requires two functional clocks (USBHOST_120M_FCLK and USBHOST_48M_FCLK) that may or may not be requested simultaneously. Therefore, they are gated independently based on the configuration of the CM_FCLKEN_USBHOST[0] EN_USBHOST1 and CM_FCLKEN_USBHOST[1] EN_USBHOST2 bits.

The HS USB Host subsystem gets an additional functional clock from the PRM (USBHOST_SAR_FCLK). It is dedicated to the save-and-restore mechanism and is automatically gated/enabled by the PRM, based on the HS USB Host save-and-restore bit configuration (that is, the PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit) and on the USBHOST domain state transitions.

4.7.4.1.8 WKUP Domain

Figure 4-39 shows the clock signals and their relationships in the WKUP domain.

Figure 4-39. WKUP Clock Signals



All clocks in the WKUP domain are generated by the PRM, except for the functional clock for the secure timers (WDTIMER1 and GPTIMER12). This clock is supplied directly by the internal 32-kHz oscillator (SECURE_32K_FCLK). The functional clock GPT1_FCLK of GPTIMER1 can be selected as either SYS_CLK or 32K_FCLK. The 32-kHz sync timer, WDTIMER2, and GPIO1 receive 32K_FCLK as their functional clock. This is the low-frequency always-on clock.

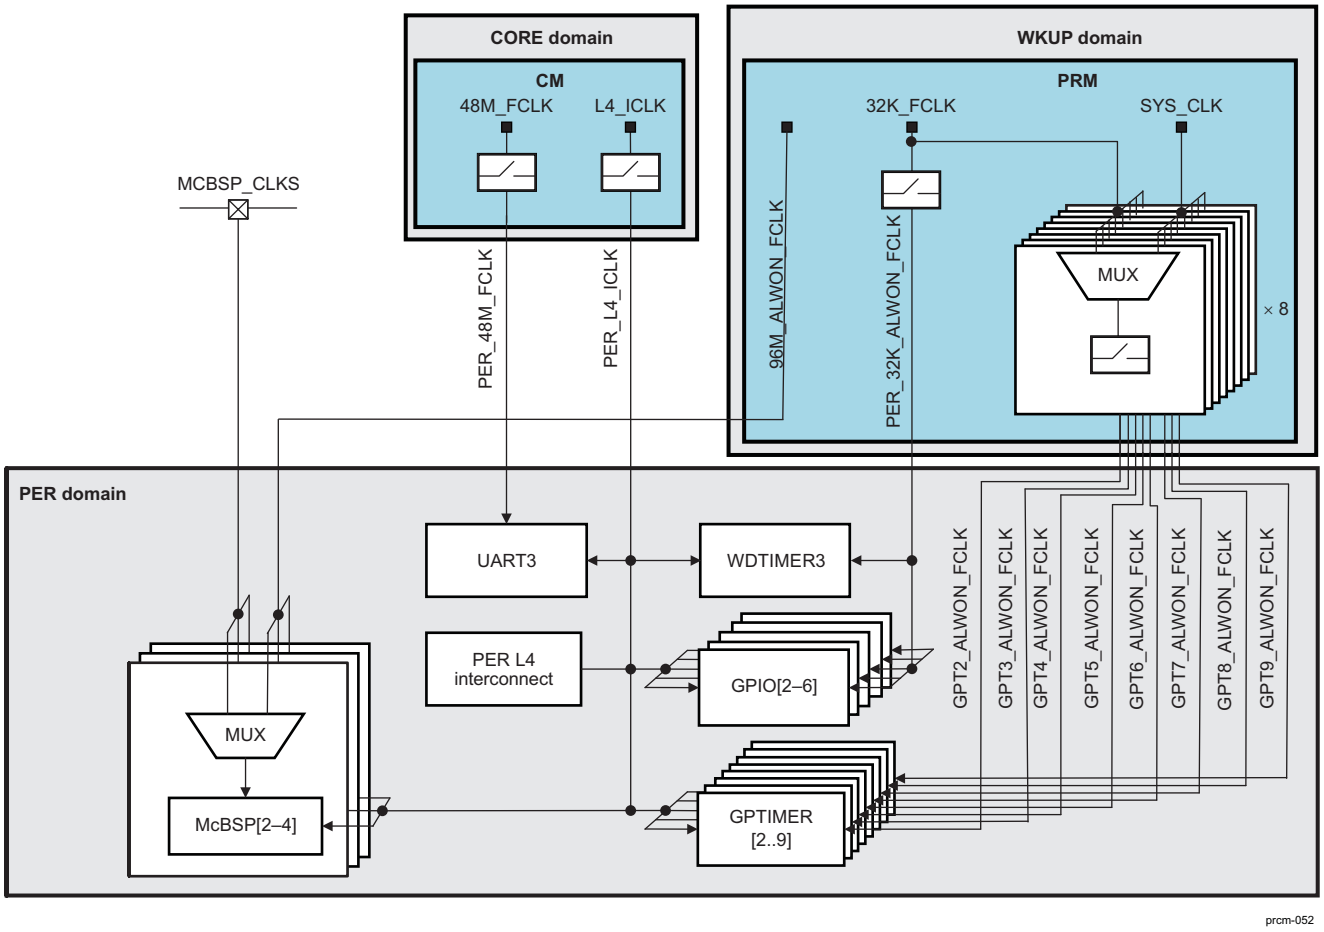
The PRM receives SYS_CLK as the L4 interface clock. For all other modules of the WKUP domain, the L4 interface clock WKUP_L4_ICLK is derived from SYS_CLK. Communication between the WKUP domain and CORE L4 interconnects is asynchronous.

The USIM OCP module receives the functional clocks (USIM_FCLK and 32K_FCLK) and the L4 interface clock (WKUP_L4_ICLK) from the PRM.

4.7.4.1.9 PER Domain

Figure 4-40 shows the clock signals and their relationships in the PER domain.

Figure 4-40. PER Clock Signals



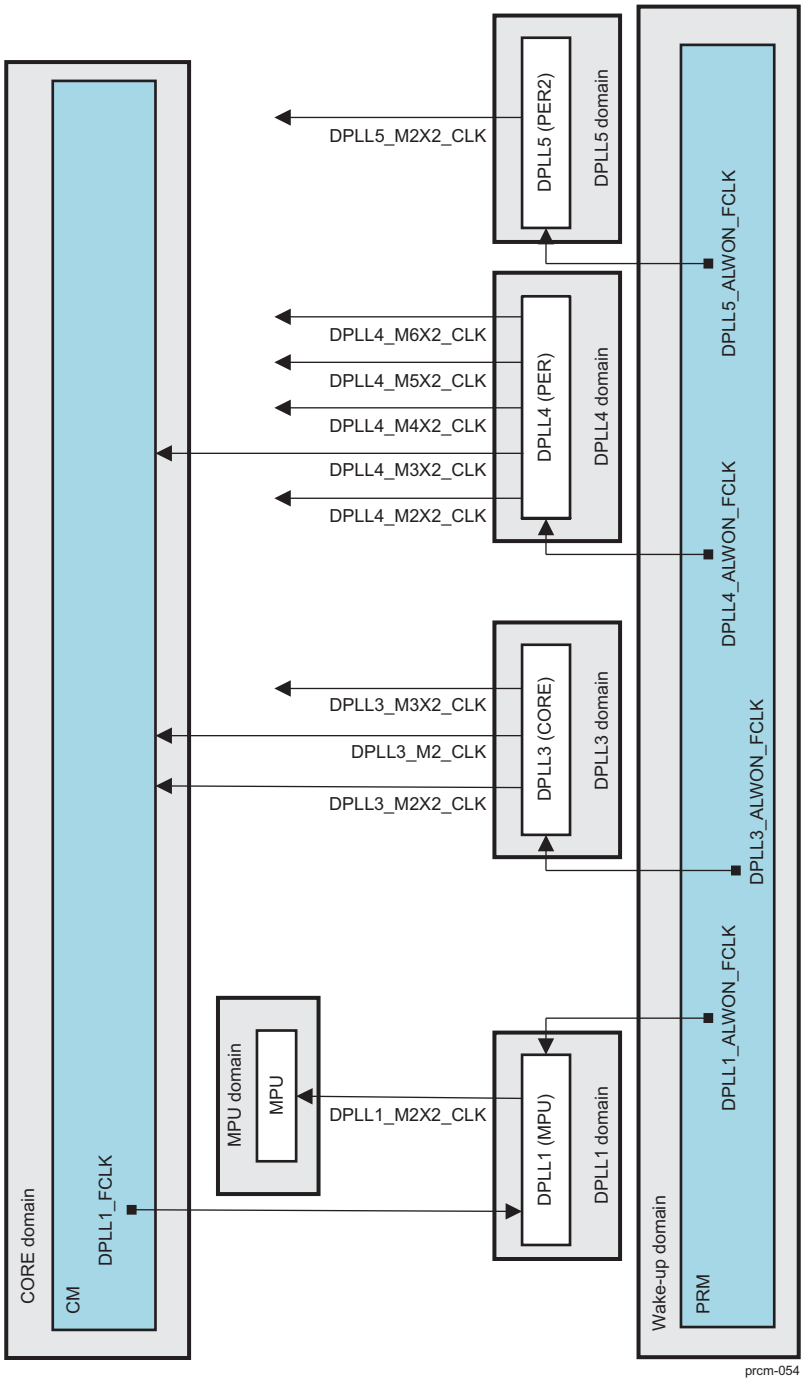
The PER domain receives several functional clocks (48M_FCLK, 96M_ALWON_FCLK, SYS_CLK, and 32K_FCLK) that feed its peripherals and modules. All the functional clocks (except 48M_FCLK) are permanently supplied so that the peripherals can be used during low-power scenarios. Figure 4-40 shows the clock distribution scheme in the PER domain.

The McBSP 2, 3, and 4 modules can be clocked either by a clock from PRM (PER_96M_FCLK) or from an external clock (MCBSP_CLKS). This clock must be permanently buffered from the pad to the PER domain. The device SCM manages the selection between the two (see *System Control Module* chapter).

4.7.4.1.10 DPLL Domains

The PRCM provides clock sources for the DPLLs, as shown in Figure 4-41

Figure 4-41. DPLL Clock Signals



The PRCM also manages clock-gating control for these DPLL outputs.

The MPU uses clock outputs locally in the subsystem. The CM uses the DPLL3 clock outputs to generate all interface clocks and some functional clocks. The CM uses two of the five clocks generated by DPLL4 and one clock output of DPLL5 to generate functional clocks for the peripheral domain modules. The remaining three clocks of DPLL4 are propagated to their corresponding modules.

4.7.4.2 Clock Distribution Summary

4.7.4.2.1 Domain Source Clocks

Table 4-25 summarizes clock distribution for each domain.

Table 4-25. Clock Distribution

Power Domain	Clock	Generator	Destination
MPU	MPU_CLK	DPLL1	MPU subsystem
NEON			NEON
SGX	SGX_FCLK	CM	SGX subsystem
	SGX_L3_ICLK	CM	
CORE	CORE_ 120M_FCLK	CM	USB TLL
	CORE_ 96M_FCLK	CM	McBSP[1,5], MMC[1,2,3], I2C[1,2,3]
	CORE_48M_FCLK	CM	UART[1,2], McSPI[1..4]
	CORE_12M_FCLK	CM	HDQ
	GPT10_FCLK	CM	GPTIMER10
	GPT11_FCLK	CM	GPTIMER11
	CPEFUSE_FCLK	CM	CPEFUSE
	USBTLL_SAR_FCLK	PRM	USB TLL
	CM_32K_CLK	PRM	Temperature sensor (x2), MMC[1,2,3]
	CORE_L3_ICLK	CM	L3 interconnect, SDMA, MPU Async Bridge(Slave), USB20OTGSS, SMS, GPMC, OCM ROM, SDRC, OCM RAM, CORE L3 interconnect
	CORE_L4_ICLK	CM	L3 interconnect, SDMA, McBSP[1,5], MMC[1,2], I2C[1..3], GPTIMER [10,11], UART[1,2], McSPI[1..4], HDQ, CORE L4 interconnect, SCM
DSS	DSS_TV_FCLK	CM	DSS, VDAC
	DSS_96M_FCLK	CM	VDAC
	DSS1_ALWON_FCLK	DPLL4	DSS
	DSS2_ALWON_FCLK	PRM	
	DSS_L3_ICLK	CM	
	DSS_L4_ICLK	CM	
PER	96M_ALWON_FCLK	PRM	McBSP[2..4]

	GPT5_ALWON_FCLK	PRM	GPTIMER5
	GPT6_ALWON_FCLK	PRM	GPTIMER6
	GPT7_ALWON_FCLK	PRM	GPTIMER7
	GPT8_ALWON_FCLK	PRM	GPTIMER8
	GPT9_ALWON_FCLK	PRM	GPTIMER9

Table 4-25. Clock Distribution (continued)

Power Domain	Clock	Generator	Destination
	PER_L4_ICLK	CM	UART3, PER L4 interconnect, WDTIMER3, GPIO[2..6], GPTIMER[2..9], McBSP[2..4]
WKUP	WKUP_32K_FCLK	PRM	WDTIMER2, GPIO1
	SECURE_32K_FCLK	32-kHz oscillator	WDTIMER1, GPTIMER12
	32K_FCLK	PRM	32-kHz sync timer, USIM OCP
	GPT1_FCLK	PRM	GPTIMER1
	USIM_FCLK	CM	USIM OCP
	WKUP_L4_ICLK	PRM	WKUP L4 interconnect, GPTIMER[1,12], 32-kHz sync timer, GPIO1, WDTIMER[1,2], USIM OCP
EFUSE	EFUSE_ALWON_FCLK	PRM	eFuse farm
DPLL1	DPLL1_ALWON_FCLK	PRM	DPLL1
	DPLL1_FCLK	CM	
DPLL3	DPLL3_ALWON_FCLK	PRM	DPLL3
DPLL4	DPLL4_ALWON_FCLK	PRM	DPLL4
DPLL5	DPLL5_ALWON_FCLK	PRM	DPLL5

NOTE:

- Modules supplied by the L3 interface clock only:
  - MPU asynchronous bridge
  - All memory controllers (OCM ROM, OCM RAM, SDRC, SMS, and GPMC)
- Modules that require both L3 and L4 clocks:
  - SDMA
  - HS USB
  - All security modules (FPKA, AES, RNG, SHAM, and D3D)
- Modules fed by the L4 clock:
  - SCM
  - All peripherals (McBSP1, McBSP5, MMC1, MMC2, I2C1, I2C2, I2C3, McSPI1, McSPI2, McSPI3, McSPI4, UART1, UART2, HDQ, GPTIMER10, and GPTIMER11)

4.7.4.2.2 Peripheral Module Clocks

Table 4-26 lists the peripherals and DSS functional clock frequency requirements.

Table 4-26. Peripheral Module Functional Clock Frequencies

Module	Functional Clock	Frequency
MMC-SDIO[1,2,3]	96M_FCLK	96 MHz
McBSP[1, 5]	96M_FCLK	96 MHz
McSPI[1..4]	CORE_48M_FCLK	48 MHz
UART[1..3]		
Display subsystem	DSS1_ALWON_FCLK	Up to 173 MHz
	DSS2_ALWON_FCLK	System clock
	DSS_96M_FCLK	96 MHz
	DSS_TV_FCLK	54 MHz
I2C[1..3]	CORE_96M_FCLK	96 MHz
HDQ	CORE_12M_FCLK	12 MHz
GPTIMER1	GPT1_FCLK	32-kHz (p) or system clock
GPTIMER[2..9]	GPTn_ALWON_FCLK	32-kHz (p) or system clock

Table 4-26. Peripheral Module Functional Clock Frequencies (continued)

Module	Functional Clock	Frequency
GPTIMER[10, 11]	GPTn_FCLK	32-kHz or system clock
GPTIMER12	SECURE_32K_FCLK	32 kHz (p) (s)
FPKA1	SECURITY_L3_ICLK	L3_ICLK
AES 1	SECURITY_L4_ICLK2	L4_ICLK
D3D 1		
SHAM 1		
RNG1		
AES 2	CORE_L4_ICLK	L4_ICLK
SHAM 2		
D3D 2		
WDTIMER1	SECURE_32K_FCLK	32 kHz (p) (s)
WDTIMER2	WKUP_32K_FCLK	32 kHz
WDTIMER3	PER_32K_ALWON_FCLK	32 kHz
GPIO1	WKUP_32K_FCLK	32 kHz
GPIO[2-6]	PER_32K_ALWON_FCLK	32 kHz
32-kHz sync timer	32K_FCLK	32 kHz (p)
Bandgap/temp sensor	32K_FCLK	32 kHz (p)
System control	CORE_L4_ICLK	L4_ICLK

4.7.5 External Clock Controls

Because the use of sys_32k and sys_altclk was discussed previously (see Section 4.7.3.1, *PRM*, and Section 4.7.3.2, *CM*), these clock signals are not discussed here. This section discusses the remaining external clock signals.

4.7.5.1 Clock Request (sys_clkreq) Control

The system clock request signal sys_clkreq is bidirectional. In bypass mode in the system clock oscillator (see Section 4.7.5.2), it is an output signal driven by the device to request an external clock. In this case, the output buffer is driven as long as the system clock is requested by the device; otherwise, it remains in high impedance. In this way, other external peripherals can share the same clock request signal with the device.

If PRM_POLCTRL.CLKREQ_POL = 1, the software must configure the SCM to select the internal pulldown on the sys_clkreq pad, or an external pulldown is connected to the pad. If PRM_POLCTRL.CLKREQ_POL = 0, the internal pull-up on the sys_clkreq pad, or an external pull-up is connected to the pad.

In master mode in the system clock oscillator (see Section 4.7.5.2), sys_clkreq is an input. If PRM_POLCTRL.CLKREQ_POL = 1, the software must configure the SCM to select the internal pulldown on the sys_clkreq pad, or an external pulldown is connected to the pad. If PRM_POLCTRL.CLKREQ_POL = 0, the internal pull-up on the sys_clkreq pad, or an external pull-up is connected to the pad.

The PRCM.PRM_POLCTRL[1] CLKREQ_POL bit allows software control over the polarity of sys_clkreq. This software setting takes effect when the clock is requested by the device and also when the clock request is driven externally. The output buffer is directly driven by this register when the clock request comes from the device.

Table 4-27 shows the bidirectional control of the sys_clkreq Pad:

Table 4-27. sys_clkreq Pad Direction Control

					Description
Oscillator Mode	Sys_boot6	Internal Clock request (always active high)	External Clock request (Note: polarity depends on CLKREQ_POL)	Sys_clkreq Direction	
Master Mode	0	0	0[1]	Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of the device in that case)	The clock is neither requested internally nor externally (external device/peripheral)
	0	0	1[1]	Input (Output buffer in Hi-Z)	The clock is requested externally
	0	1	0[1]	Output	The clock is requested internally
	0	1	1[1]	Output Note: (The pad is driven both by the device and from outside of the device in taht case.)	The clock is requested both internally and externally
Bypass Mode	1	0	0[1]	Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of the device in that case.)	The clock is neither requested internally nor externally
	1	0	1[2]	Input (output buffer in Hi-Z)	The clock is requested externally
	1	1	0[2]	Output	The clock is requested internally
	1	1	1[2]	Output Note: (Input is not driven from outside of the device in that case.)	The clock is requested both internally and externally

(1) Case when PRM_POLCTRL.CLKREQ_POL = 1 (sys_clkreq active high). These values would be inverted in the table above, in case PRM_POLCTRL.CLKREQ_POL = 0 (sys_clkreq active low).

(2) Case when PRM_POLCTRL.CLKREQ_POL = 1 (sys_clkreq active high). These values would be inverted in the table above, in case PRM_POLCTRL.CLKREQ_POL = 0 (sys_clkreq active low).

4.7.5.2 System Clock Oscillator Control

Depending on the hardware configuration, the device can receive the system clock from an external source or generate it locally using the internal system clock crystal oscillator. Thus, the device oscillator has two possible operating modes:

- Master (oscillator enable) mode: The oscillator is enabled and connected to an external quartz. It provides the system clock to the device. The oscillator is activated on a device wake-up or on an external clock request.
- Bypass (oscillator inactive) mode: The system clock is supplied by an external device and the oscillator is always set in bypass mode. The oscillator is insensitive to the external system clock request on the sys_clkreq pin.

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the oscillator is in master or bypass mode. See Section 4.3.1, *External Clock Signals*.

When operating in master mode, the device receives an external clock request (sys_clkreq) and provides the system clock to external peripherals through the sys_clkout1 pin; in bypass mode, the device generates a clock request to the external clock source to request the system clock.

The selected mode of the oscillator can be read from the PRCM.PRM_CLKSRC_CTRL[1:0] SYSCLKSEL bit field.

Whatever the oscillator mode, the oscillator can be powered down when the device enters inactive mode, unless an external system clock request is active (from the sys_clkreq pin). Note that this option can only be used if the 32kHz clock is not derived from the high frequency sysclk, as the 32kHz clock is required for autonomous wakeup capability. This setting is configured in the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field. Table 4-29 lists the four possible operation modes of the system clock.

Table 4-28. System Clock Operation Modes

AUTOEXTCLKMODE	System Clock Mode	Oscillator Mode	Description
0x0	Always-active mode	Master	The oscillator is kept active even when the clock is neither requested by the device internally (all device clocks are inactive) nor externally (that is, the sysclkreq input signal is not asserted).
		Bypass	The sys_clkreq output signal is permanently asserted by the device, regardless of its internal clocks state (active or inactive).
0x1	Off when device in INACTIVE state	Master	The oscillator is switched off when the device is in INACTIVE mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is de-asserted when the device is in idle mode.

To exit power-down mode, the oscillator requires a device wakeup or an external clock request.

The device allows configuring of the system clock stabilization time to ensure a stable system clock in the device. This delay is configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

Figure 4-42 shows the system clock oscillator controls in the device.

Figure 4-42. System Clock Oscillator Controls

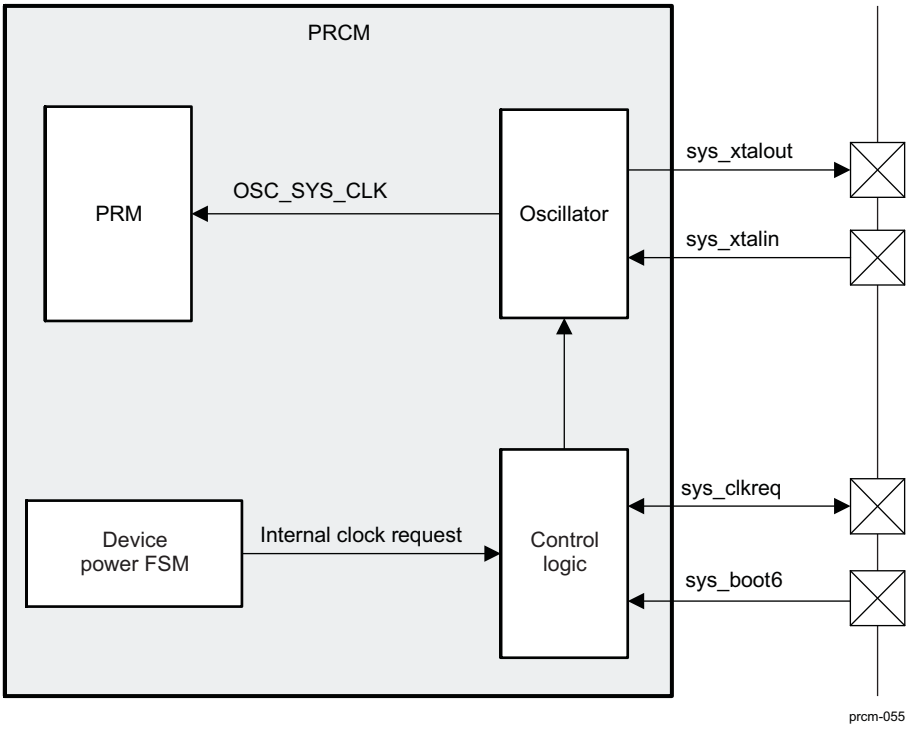

Table 4-29 lists the oscillator controls.

Table 4-29. Oscillator Controls

Oscillator Mode	Internal Clock Request[1]	External Clock Request[1]	Oscillator State	sys_clkreq Pad Direction	sys_clkreq[1]	Description
Master	Not asserted	Not asserted	Off	Both input and output	Not asserted	System clock not requested internally (within the device) and externally (by an external device or peripheral).
	Not asserted	Asserted	Active	Input	Asserted	System clock is requested externally only.
	Asserted	Not asserted	Active	Output	Asserted	System clock is requested internally only.
	Asserted	Asserted	Active	Both input and output (that is, driven internally by device and externally by peripheral)	Asserted	System clock is requested internally and externally.
Bypass	Not asserted	x[2]	Bypass	Both input and output (when external request is not asserted) or input (when external request is asserted)	External clock request state	System clock is not requested internally (sys_clkreq input has no effect).
	Asserted	x[2]	Bypass	Output (when only internal request is asserted) or both input and output (when external and internal request are asserted)	Asserted	System clock is requested internally (sys_clkreq input has no effect).

(1)
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active high (that is, 0x1), Asserted = 1, and Not asserted = 0.
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active low (that is, 0x0), Asserted = 0, and Not asserted = 1.

(2) x indicates that the signal may be asserted or not asserted.

4.7.5.3 External Output Clock1 (sys_clkout1) Control

The sys_clkout1 clock is active if the oscillator clock (OSC_SYS_CLK) is active (stable) and an external system clock request is active. It can be gated by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit. The polarity of the sys_clkout1 signal, when the clock is gated, is controllable by programming the PRCM.PRM_POLCTRL[2] CLKOUT_POL bit.

When the device is in standby mode, both SYS_CLK and sys_clkout1 are disabled. In that case, reactivation of sys_clkout1 depends on the oscillator mode:

- Oscillator in active mode (sys_boot6 is 0): The sys_clkout1 clock can be reactivated (after oscillator stabilization), provided its gating was previously enabled by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit and asserting an external clock request. This activation does not generate a device wake-up event; an external clock request activates only the internal SYS_CLK oscillator and sys_clkout1.
- Oscillator in bypass mode (sys_boot6 is 1): The sys_clkout1 clock can be reactivated only after the device wakes up (on any wake-up event) and SYS_CLK is active. When the device is active, SYS_CLK is running and sys_clkout1 is enabled as soon as requested by software.

4.7.5.4 External Output Clock2 (sys_clkout2) Control

A second output clock, sys_clkout2, is generated with a frequency that can be the source-clock frequency divided by 1, 2, 4, 8, or 16. Its source clock can be CORE_CLK, CM_SYS_CLK, 96 MHz, or 54 MHz. The selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock. The polarity of the sys_clkout2 signal, when the clock is gated, is controllable by programming the PRCM.CM_POLCTRL[0] CLKOUT2_POL bit.

4.7.6 DPLL Control

The PRCM allows the configuration of the output clock frequencies of the DPLLs by setting their respective multipliers and dividers. It also allows control of the operating mode of the DPLLs and automatic recalibration mode.

4.7.6.1 DPLL Multiplier and Divider Factors

DPLL clock outputs are set by programming the corresponding multiplier and divider factors M, N, M2, M3, M4, M5, and M6. Table 4-30 lists the register bit fields for configuration of the multiplier and divider factors for the DPLLs.

Table 4-30. DPLL Multiplier and Divider Factors

	DPLL1	DPLL3	DPLL4	DPLL5
M	PRCM.CM_CLKSEL1_ PLL_MPU[18:8] MPU_ DPLL_MULT	PRCM.CM_CLKSEL1_ PLL[26:16] CORE_DPLL_MULT	PRCM.CM_CLKSEL2_ PLL[18:8] PERIPH_ DPLL_MULT	PRCM.CM_CLKSEL4_ PLL[18:8] PERIPH2_ DPLL_MULT
N	PRCM.CM_CLKSEL1_ PLL_MPU[6:0] MPU_ DPLL_DIV	PRCM.CM_CLKSEL1_ PLL[14:8] CORE_DPLL_DIV	PRCM.CM_CLKSEL2_ PLL[6:0] PERIPH_ DPLL_DIV	PRCM.CM_CLKSEL4_ PLL[6:0] PERIPH2_ DPLL_DIV
M2	PRCM.CM_CLKSEL2_ PLL_MPU[4:0] MPU_ DPLL_CLKOUT_DIV	PRCM.CM_CLKSEL1_ PLL[31:27] CORE_DPLL_ CLKOUT_DIV	PRCM.CM_CLKSEL3_ PLL[4:0] DIV_96M	PRCM.CM_CLKSEL5_ PLL[4:0] DIV_120M
M3	Not used	PRCM.CM_CLKSEL1_ EMU[20:16] DIV_DPLL3	PRCM.CM_CLKSEL_ DSS[12:8] CLKSEL_TV	Not used
M4	Not used	Not used	PRCM.CM_CLKSEL_ DSS[4:0] CLKSEL_DSS1	Not used
M5	Not used	Not used	PRCM.CM_CLKSEL_	Not used
M6	Not used	Not used	PRCM.CM_CLKSEL1_ EMU[28:24] DIV_DPLL4	Not used

4.7.6.2 DPLL Jitter Correction

To satisfy the jitter specification of the DPLL at a specific internal clock frequency, set the corresponding CM_CLKEN_PLL_processor_name>[7:4]processor_name>_DPLL_FREQSEL, CM_CLKEN_PLL[23:20] PERIPH_DPLL_FREQSEL, CM_CLKEN_PLL[7:4] CORE_DPLL_FREQSEL, CM_CLKEN2_PLL[7:4] PERIPH2_DPLL_FREQSEL bit field. Table 4-31 lists the possible values for the bit field and the corresponding internal clock frequency ranges.

NOTE: The internal clock frequency is the frequency of the internal interface clock Fint, with Fint= (CLKINP/(N + 1).

Table 4-31. Internal Clock Frequency

Bit Field Values	Clock Frequency Ranges
0x3	0.75 MHz—1.0 MHz
0x4	1.0 MHz—1.25 MHz
0x5	1.25 MHz—1.5 MHz
0x6	1.5 MHz—1.75 MHz
0x7	1.75 MHz—2.1 MHz
0xB	7.5 MHz—10 MHz
0xC	10 MHz—12.5 MHz
0xD	12.5 MHz—15 MHz
0xE	15 MHz—17.5 MHz
0xF	17.5 MHz—21 MHz
Other cases are reserved.	

NOTE: In the DPLL programming sequence, the DPLL_FREQSEL must be programmed before the new Multiplier factor M and the Divider factor N are programmed so that the new value is taken into account during current DPLL relock.

4.7.6.3 DPLL Frequency Ramp-Up Delay

When the DPLL switches from bypass mode to lock mode, the clock output frequency changes from bypass clock frequency to normal operating frequency. The frequency ramp-up feature allows the DPLL output frequency to switch gradually (in steps) from the bypass to locked frequency. Before reaching the locked frequency, the DPLL output switches to four intermediate frequencies:

1. Fout/8
2. Fout/4
3. Fout/2
4. Fout

The time delay in passing from the bypass clock frequency to normal frequency is the ramp-up delay. The ramp-up delay is configured by setting the CM_CLKEN_PLL_processor_name>[9:8]processor_name>_DPLL_RAMPTIME, CM_CLKEN_PLL[25:24] PERIPH_DPLL_RAMPTIME, CM_CLKEN_PLL[9:8] CORE_DPLL_RAMPTIME, CM_CLKEN2_PLL[9:8] PERIPH2_DPLL_RAMPTIME bit field.

There are three possible values for the bit field and the corresponding ramp-up delays:

- 0x0: Disables the frequency ramping feature.
- 0x1: Ramp step size range is 2–40 Fint cycles.
- 0x2: Ramp step size range is 4–80 Fint cycles.
- 0x3: Ramp step size range is 12–240 Fint cycles.

NOTE: If the ramp-up time configured for the DPLL is less than the DPLL lock time, the last frequency step, Fout/2 to Fout, gets stretched to the DPLL lock time.

4.7.6.4 DPLL Modes

DPLL supports several power modes (see Table 4-32). Each mode results in a tradeoff between power savings and relock time.

Table 4-32. DPLL Power Modes

Mode	Clock Input	Clock Output	DPLL Power State	Power Consumption	Latency
Locked	On	Lock frequency	ON	Maximum	N/A
Low-power bypass	On	Bypass frequency	ON	Less than locked	Same as low-power stop
Fast-relock bypass	On	Bypass frequency	ON	Less than locked	Less than low-power bypass
Low-power stop	On	Bypass frequency	ON	Less than locked	Same as low-power bypass
MN bypass	On	Bypass frequency	ON	Less than locked	Maximum
Off	Off	Off	OFF	Minimum	Maximum

A DPLL power mode can be achieved on a software request (manual) and/or automatically (automatic), depending on the specific hardware conditions. After a device power-on reset, the DPLL can be kept in either low-power stop mode (DPLL4 and DPLL5) or MN bypass mode (DPLL1 and DPLL3).

A DPLL can switch from one mode to the other as a result of the following:

- Software-programmed transition only (manual): The software configures a dedicated register for the

next desired DPLL mode. It must ensure that the transition can be performed based on the activity on the device.

- Combined software-programmed and hardware-conditions-based transition (automatic): The PRCM triggers the transition when the software requests it (by configuring the registers) and the hardware conditions are satisfied. When the hardware conditions are no longer met, the PRCM triggers the return transition.

For automatic transition, automatic mode must be enabled by programming the PRCM.CM_AUTOIDLE_PLL or the PRCM.CM_AUTOIDLE_PLLprocessor_name> registers.

Table 4-33 describes the manual and automatic control of the DPLL power modes by the PRCM.

Table 4-33. DPLL Power Modes Support

Mode	DPLL1	DPLL3	DPLL4	DPLL5
Locked	Software request (manual) or MPU wakes up (automatic).	Software request (manual) or CORE wakes up (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).
Low-power bypass	Software request (manual)	Software request (manual) or all interface clocks are gated (automatic).	N/A	N/A
Fast-relock bypass	N/A	Software request (manual).	N/A	N/A
Low-power stop	MPU is idle (automatic).	Device is idle (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL are unused or on global reset release (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL (120-MHz clock) are unused or on global reset release (automatic).
MN bypass	Global reset (automatic)	Global reset (automatic).	N/A	N/A
Off	Device off (automatic)	Device off (automatic).	Device off (automatic)	Device off (automatic)

NOTE: DPLL1 and DPLL3 cannot be manually forced to switch to Low-Power Stop mode from any other power mode. They must be in Locked state with automatic transition to Low-Power Stop mode configured and the hardware condition for the transition (identified in Table 4-33) must be satisfied, in order to switch to the Low-Power Stop mode.

Table 4-34 lists the bit fields that must be programmed for manual and automatic mode control of the four DPLLs.

Table 4-34. DPLL Power Mode Control

Mode	Manual Control	Auto Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL
DPLL3	PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL
DPLL4	PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL
DPLL5	PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL

NOTE: The DPLL automatically enters locked mode on a domain wakeup only if the DPLL is locked before the sleep transition and one of the automatic modes is enabled.

4.7.6.5 DPLL Low-Power Mode

The DPLL can operate in a low-power mode by reducing the operating frequency range. This in turn reduces the power consumption of the DPLL. In this mode, however, there is a period and phase jitter effect.

The DPLL can enter this mode only if the targeted lock frequency of the DPLL is less than 600 MHz. This implies locking or relocking the DPLL to a new targeted locked-frequency when entering or exiting low-power mode. Software must ensure that the DPLL lock-frequency does not exceed 600 MHz in low-power mode.

Software can enable/disable automatic switching of the DPLL between normal mode and low-power mode. The new mode is effective only after the DPLL is relocked. Low-power mode control is considered only during the following transitions:

- From bypass mode to lock
- From stop mode to lock
- From lock to relock

Table 4-35 lists the bit fields that must be programmed for manual control of the four DPLLs.

Table 4-35. LP Mode Control

Mode	Manual Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[10] EN_MPU_DPLL_LPMODE
DPLL3	PRCM.CM_CLKEN_PLL[10] EN_CORE_DPLL_LPMODE
DPLL4	PRCM.CM_CLKEN_PLL[26] EN_PERIPH_DPLL_LPMODE
DPLL5	PRCM.CM_CLKEN2_PLL[10] EN_PERIPH2_DPLL_LPMODE

4.7.6.6 DPLL Clock Path Power Down

DPLL3 and DPLL4 can power down the CLKOUTX2 path. A small section of logic is powered down as the M2 post divider is also shared with the CLKOUT path, which remains functional.

The HSDIVIDER can power down each CLKOUTn path (with n in the range of 3 to 6) independently, therefore allowing further power savings. The clock output path is also powered down when the DPLL is in stop mode, regardless of the software setting.

Software must ensure the proper sequencing of the control. To avoid a glitch at the output, activate this control when the clock is no longer required, and when the output clock is gated. Conversely, ensure a delay between deactivation and reactivation of the clock by using the power-down control.

Table 4-36 lists the bit fields and the corresponding clock outputs of the DPLLs.

Table 4-36. Clock Path Power-Down Control

DPLL	Control Bit Field	Clock Path
DPLL4	PRCM.CM_CLKEN_PLL[27] PWRDN_96M	96-MHz clock output (DPLL4 output M2X2)
	PRCM.CM_CLKEN_PLL[28] PWRDN_TV	DSS TV clock output (DPLL4 output M3X2)
	PRCM.CM_CLKEN_PLL[29] PWRDN_DSS1	DSS1 clock output (DPLL4 output M4X2)
	PRCM.CM_CLKEN_PLL[31] PWRDN_EMU_PERIPH	EMU_PERIPH clock output (DPLL4 output M6X2)
DPLL3	PRCM.CM_CLKEN_PLL[12] PWRDN_EMU_CORE	EMU_CORE clock output (DPLL3 output M3X2)

4.7.6.7 Latencies

Lock mode for the DPLL is frequency lock.

Lock latencies depend on the internal reference frequency (F_{INT}) of the DPLL, calculated as:

$F_{INT} = F_{ref} / (N+1)$

where F_{ref} is the reference clock input to DPLL.

Table 4-37 lists the operating modes of the DPLL and the output clock frequency and associated lock latency.

FREQSEL[3] = 0 refers to the following bits:

- CM_CLKEN_PLL_MPU[7]
- CM_CLKEN_PLL[7]
- CM_CLKEN_PLL[23]
- CM_CLKEN2_PLL[7]

Table 4-37. DPLL Operating Mode and Latency

Mode	CLKOUTX2	Lock Time in FINT cycles (FREQSEL[3] = 0)	Lock Time in Fint Cycles (FREQSEL[3]= 1)
OFF	Off	150	780
M, N reprogramming	bypass clock	150	780
Low-power stop mode	Off	40	400
Low-power bypass	bypass clock	40	400
Fast-relock bypass	bypass clock	10	100
Active (locked)	CLKINP x M/(N+1)/M2 x 2	N/A	N/A

The post-divider M2 supports change on the fly. The time required to switch from the clock with the old period to the clock with the new period depends on the old value of M2 (see Table 4-38).

Table 4-38. Time Required to Switch Clocks

Old Value of M2	Time for Switching
1	4 REFCLKs + 8 CLKOUTX2s
Even	4 REFCLKs + 2 CLKOUTX2s
Odd & > 1	4 REFCLKs + 4 CLKOUTX2s

4.7.6.8 Recalibration

A lock sequence occurs during an initial lock or during a relock following a new multiplier or divider value. Each time the DPLL is reset or performs a lock sequence, it performs a recalibration of the output frequency, based on the voltage and temperature conditions. By compensating for voltage and temperature changes within a certain range, the calibration allows the lock frequency to remain steady. If the voltage or temperature drifts outside the acceptable range, the DPLL asserts a recalibration flag.

For example, a large temperature drift can cause the DPLL to lose its lock and require recalibration. When the DPLL locks at a temperature within the 080 degrees Celsius range, the maximum temperature drift is approximately 55 degrees Celsius. When DPLL starts at a negative temperature, the maximum temperature drift is higher.

If the DPLL locks at 30 degrees Celsius, the temperature can change by 60 degrees Celsius (from 30 to +90 degrees Celsius) and the DPLL will not lose the lock. However, for temperatures above the 60 degrees Celsius range, the DPLL may need to be relocked. A new relock sequence reinitializes the starting temperature.

This compensation mechanism is active only while the DPLL is locked. When the DPLL is in off or bypass mode (low-power or fast-relock), it does not assert the recalibration flag. If the voltage or temperature exceeds the drift limits while the DPLL is not locked, and then the DPLL tries to relock, the DPLL fails to lock within the normal delay and recalibrates automatically before eventually locking. The only difference from a standard relock is the delay.

The DPLL can automatically start recalibration when the recalibration flag is asserted, or recalibration can be managed by the software. The mode of operation is selected by configuring the corresponding registers in the PRCM (see Table 4-39). The software or manual control mode is selected by default.

NOTE: Automatic recalibration of the DPLL can start at any time. While relocking, the DPLL switches to bypass mode. For modules that are sensitive to frequency change while operating, this can introduce operational instability. For example, the SDRC is sensitive to a frequency change on DPLL3 because its embedded DLL relocks on a frequency change. Any access during this DLL relock period can be corrupted. It is important, therefore, to stall SDRC access during DPLL recalibration.

To allow the software to recalibrate the DPLL at the correct time depending on the device activity, the PRCM can generate a wake-up event on the MPU domain, followed by an interrupt on the MPU when the DPLL recalibration flag is asserted.

Table 4-39 summarizes the software programming control over the DPLL recalibration feature.

Table 4-39. DPLL Recalibration Controls

DPLL	Software Control	Description
DPLL1 (MPU)	PRCM.CM_CLKEN_PLL_MPU[3] MPU_DPLL_DRIFTGUARD	Enable/disable the MPU DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN	Enable/disable the MPU DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST	Status of the MPU DPLL recalibration interrupt
DPLL3 (CORE)	PRCM.CM_CLKEN_PLL[3] EN_CORE_DPLL_DRIFTGUARD	Enable/disable the CORE DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL	Enable/disable the CORE DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST	Status of the CORE DPLL recalibration interrupt
DPLL4 (PER)	PRCM.CM_CLKEN_PLL[19] EN_PERIPH_DPLL_DRIFTGUARD	Enable/disable the PER DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL	Enable/disable the PER DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST	Status of the PER DPLL recalibration interrupt
DPLL5 (PER2)	PRCM.CM_CLKEN2_PLL[3] EN_PERIPH2_DPLL_DRIFTGUARD	Enable/disable the PER DPLL2 automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN	Enable/disable the PER DPLL2 recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_ST	Status of the PER DPLL2 recalibration interrupt

NOTE: DPLL recalibration is not necessary in real use (specified operating voltage and temperature range).

4.7.6.9 DPLL Programming Sequence

The DPLL programming sequence follows:

1. Set the multiplier (M) and divider (N) values for the desired CLKOUT frequency (see Section 4.7.6.1).
2. Set the corresponding output dividers (M2, M3, M4, M5, and M6) (see Section 4.7.6.1).
3. Set the corresponding FREQSEL bit field to satisfy the jitter specification (see Section 4.7.6.2).

4. Set the corresponding ramp-up delay (see Section 4.7.6.3).
5. Enable/disable the auto-recalibration feature (see Section 4.7.6.8).
6. Enable/disable the autoidle feature (see Section 4.7.6.4).
7. Mask/unmask the interrupt to the MPU (see Section 4.7.6.8).
8. Enable the DPLL lock mode (see Section 4.7.6.4).

4.7.7 Internal Clock Controls

This section describes the software and hardware controls of the internal source clocks. Figure 4-43 through list the clock controls. The *Source selection/division* column lists the PRCM register bits used to select or divide the clocks. The *Software control* column lists the PRCM register bits used to enable/disable the clocks. The *Hardware control* column lists the hardware conditions required to effectively gate the clocks.

In the *Hardware control* column, the boxes labeled CL, GS, GC, and HC indicate specific information about the hardware clock controls:

- CL (combinational logic): The functional or interface clock is required by more than one module across more than one domain. The gating control is the OR combination of all the domain clock requests. If any module of this clock domain requests the clock, the clock is not gated.
- GS (gating selection): The clock is selectable among several possible source clocks for a module. The gating control depends on the software programming of the CM_CLKSEL_<domain_name> type of register. The clock request of the module or domain must be set by the CM_CLKSEL bit.
- GC (gating control): The functional/interface clock is required by a single module across the domain. The gating control depends only on the software programming of the FCLKEN/ICLKEN bit. For the interface clock, the enable bit is effective only if autoidle mode is not used. If autoidle mode is used, the gating control also depends on the state of the domain.
- HC (hardware control): A specific rule not covered by CL, GS, or GC.

NOTE: Because the PRCM must receive hardware acknowledgement from the different modules before it can gate the clock, the clock is not gated immediately after the software requests clock-gating conditions.

4.7.7.1 PRM Source-Clock Controls

Figure 4-43 shows the common source-clock controls for the PRM.

Figure 4-43. Common PRM Source-Clock Controls

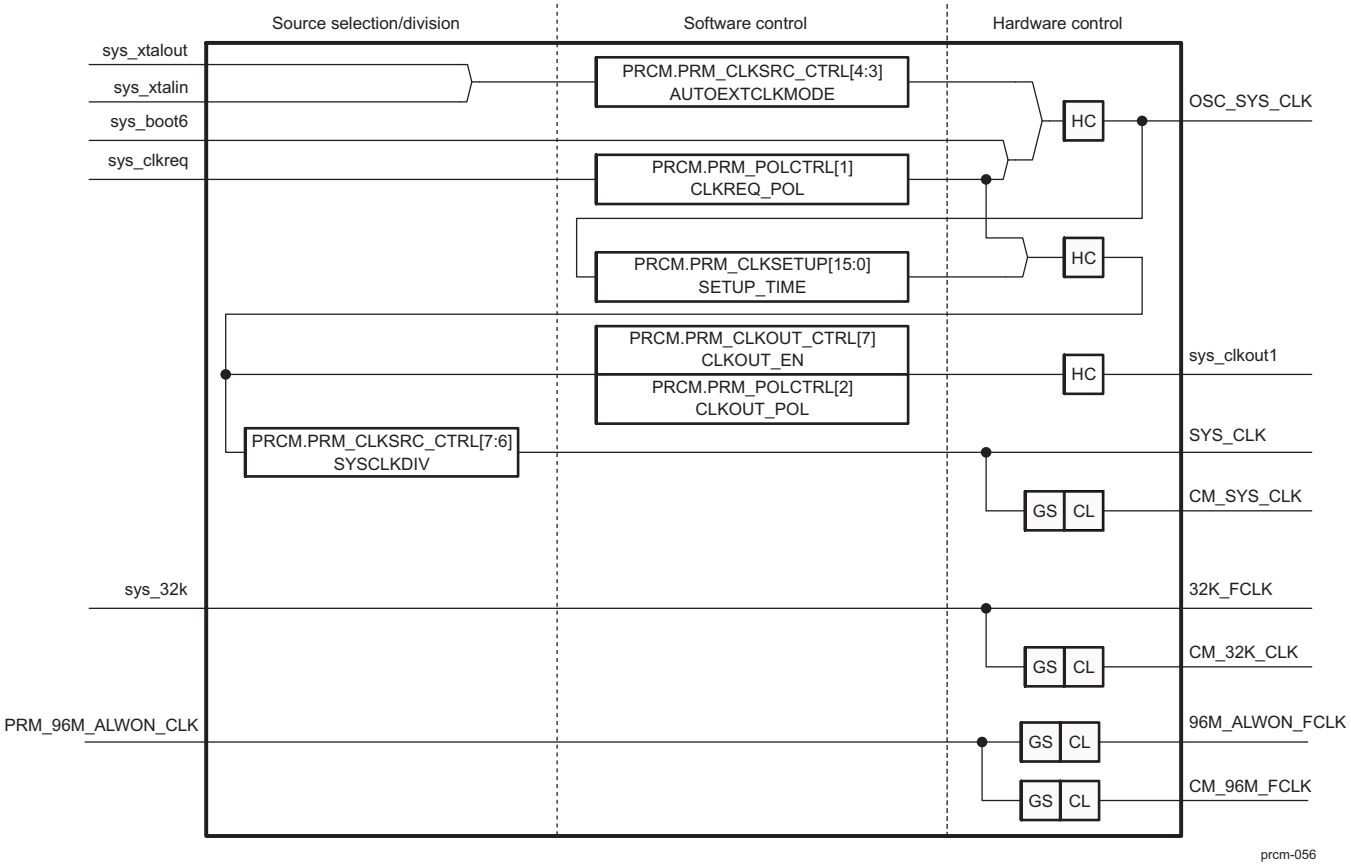

Table 4-40 shows the common source-clock gating controls for the PRM.

Table 4-40. Common PRM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
OSC_SYS_CLK	Running	PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE and device power state and sys_clkreq	Gated when the oscillator is programmed to power down with the device sleep/retention/off transition.
sys_clkout1	Running	PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN and PRCM.PRM_POLCTRL[2] CLKOUT_POL and sys_clkreq	Active when OSC_SYS_CLK is active, sys_clkout1 is enabled, and sys_clkreq is asserted.
SYS_CLK	Running	Activated after clksetup_count_overflow	Active when OSC_SYS_CLK is active and the SYS_CLK setup time is up.
CM_SYS_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active.
32K_FCLK	Running	None	Always-active clock from sys_32k input pin
CM_32K_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active.
CM_96M_FCLK	Gated	CM_CLKSEL1_PLL[3] SOURCE_48M bit cleared, and depends on the clock-gating condition of 96M_FCLK, 48M_FCLK, and 12M_FCLK	Active if the derived clocks (96M_FCLK, 48M_FCLK, and 12M_FCLK) are active.
96M_ALWON_FCLK	Gated	CM_FCLKEN_PER[0] EN_MCBSP2, CM_FCLKEN_PER[1] EN_MCBSP3, and CM_FCLKEN_PER[2] EN_MCBSP4	Gated when none of the three McBSPs [2..4] have their functional clock enable requested.

The oscillator output clock (OSC_SYS_CLK) is gated whenever the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field is programmed to power down the oscillator when the device enters retention. In this condition, all the clock trees in the device must be gated, and the four DPLLs (DPLL1, DPLL3, and DPLL4) must enter stop mode before this transition can occur.

SYS_CLK is gated under the same conditions as the oscillator output clock, but it is enabled only after the oscillator stabilizes. Oscillator stabilization is determined by a counter overflow configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

The sys_clkreq active condition is described in Section 4.7.5, *External Clock Control*.

4.7.7.2 CM Source-Clock Controls

Figure 4-44 shows the common source-clock controls for the CM.

Figure 4-44. Common CM Source-Clock Controls

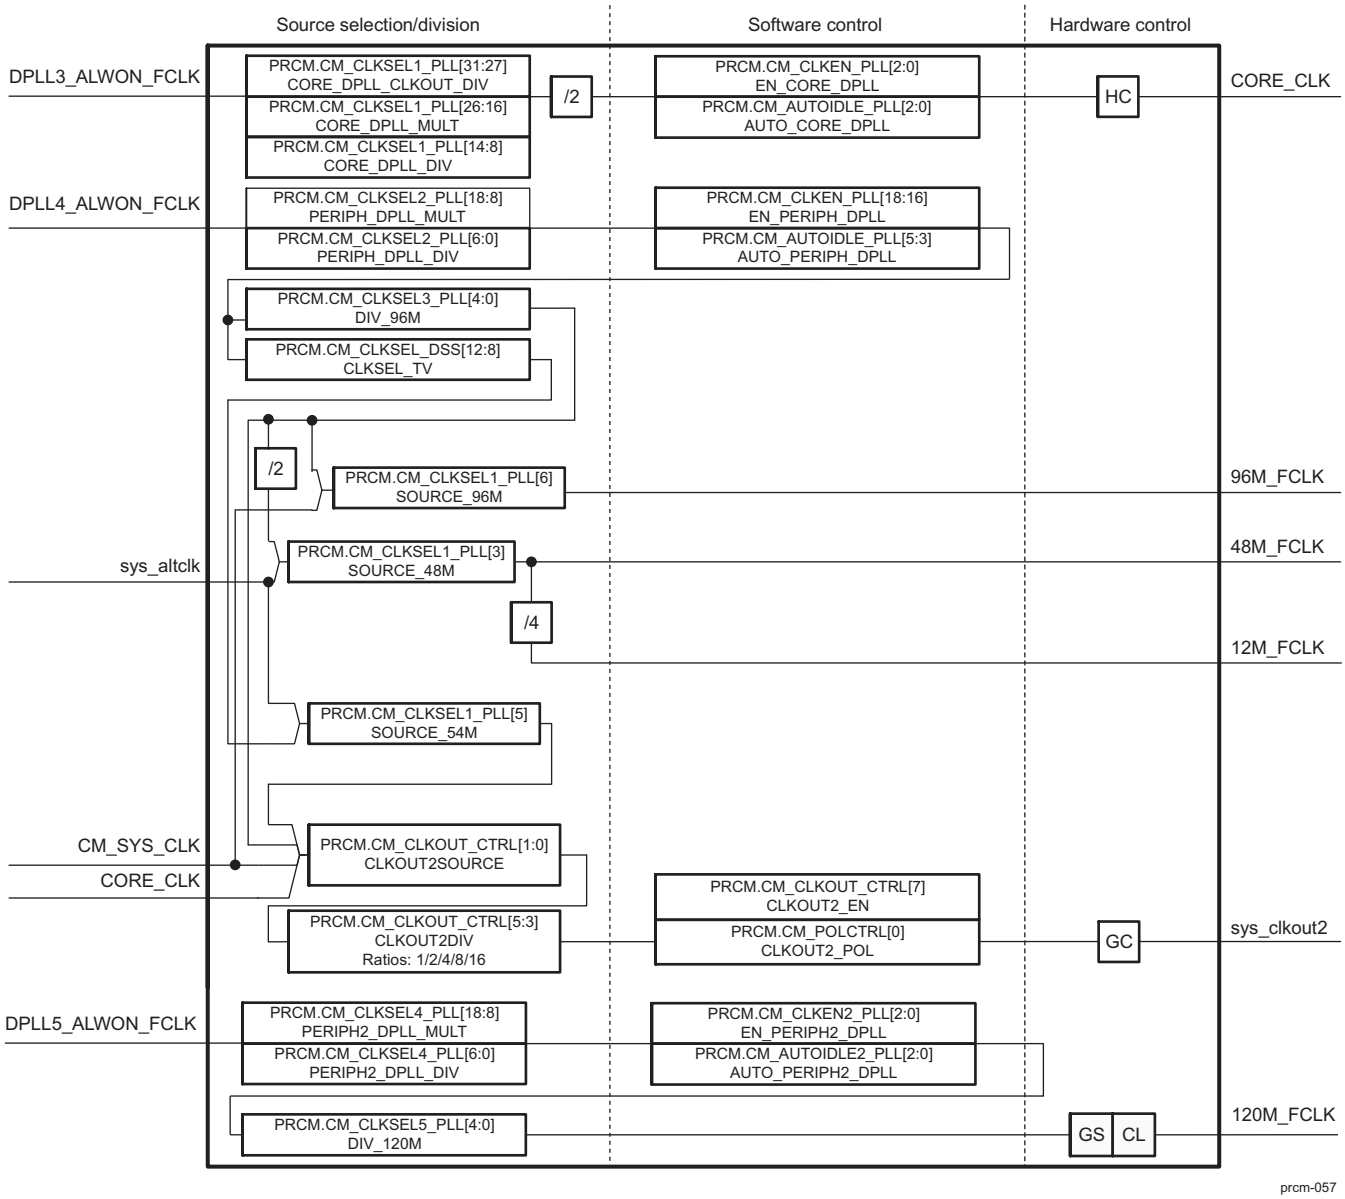

Table 4-41 shows the common source-clock gating controls for the CM.

Table 4-41. Common CM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
CORE_CLK	Running	Depends on the clock-gating conditions of: L3_ICLK and L4_ICLK	Gated when all interface clocks of the different modules of the device are gated
96M_FCLK	Stopped	Depends on the clock-gating conditions of: CORE_96M_FCLK and DSS_96M_FCLK	If the dependent clocks are active, the clock is active.
48M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK, PER_48M_FCLK and USBHOST_48M_FCLK	If the dependent clocks are active, the clock is active.
12M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK	If the dependent clock is active, the clock is active.
sys_clkout2	Stopped	PRCM.CM_CLKOUT_CTRL[7] CLKOUT2_EN	Active if enabled
DPLL4_M2_CLK	Stopped	Depends on the clock-gating conditions of: 96M_FCLK	If the dependent clocks are active, the clock is active.
DPLL4_M3_CLK	Stopped	CM_CLKSEL1_PLL.SOURCE_54M and depends on the clock-gating conditions of: DPLL4_M2_CLK and DSS_TV_CLK	If the dependent clocks are active, the clock is active. DSS_TV_CLK is a dependent clock if set by the register configuration.
120M_FCLK	Stopped	CM_FCLKEN_USBHOST[1] EN_USBHOST2, CM_FCLKEN3_CORE[2] EN_USBTLL, CM_FCLKEN_WKUP[9] EN_USIMOCP, CM_CLKSEL_WKUP[6:3] CLKSEL_USIMOCP	If any of the dependent clocks (that is, USIM_FCLK, CORE_120M_FCLK, or USBHOST_12M_FCLK) is active, the clock is active. The USIM_FCLK is a dependent clock if set by the register configuration.

4.7.7.3 Common Interface Clock Controls

Figure 4-45 shows the clock controls for the common interface.

Figure 4-45. Common Interface Clock Controls

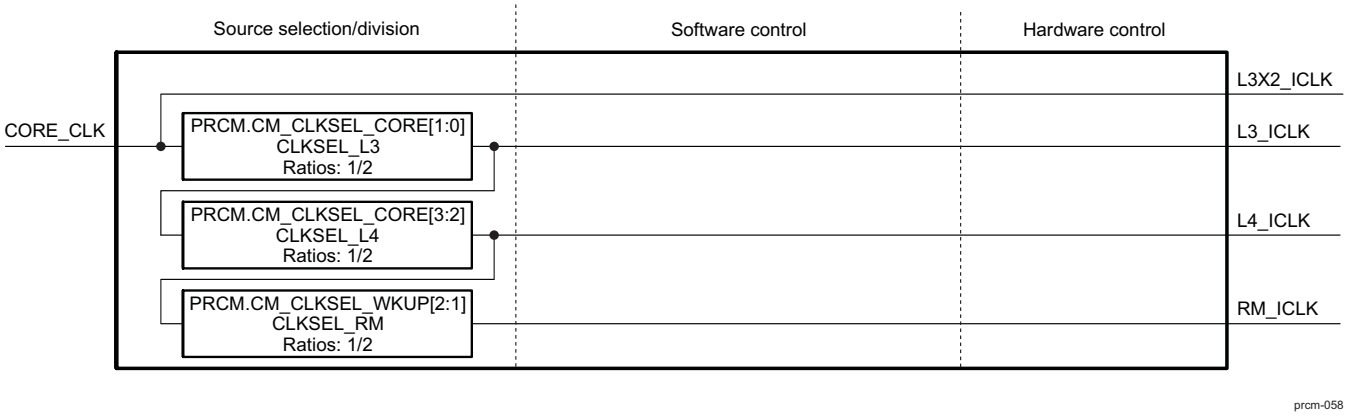

Table 4-42 shows the clock-gating controls for the common interface.

Table 4-42. Common Interface Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
L3X2_ICLK	Running	CORE_CLK gating conditions	Depends on the gating conditions of the CORE_CLK
L3_ICLK	Running	Depends on the clock-gating conditions of: SGX_L3_ICLK, CORE_L3_ICLK, SECURITY_L3_ICLK	Gated when all L3 interface clocks of the different modules of the device are gated
L4_ICLK	Running	Depends on the clock-gating conditions of CORE_L4_ICLK, SECURITY_L4_ICLK, DSS_L4_ICLK, PER_L4_ICLK, SR_L4_ICLK, and WKUP_L4_ICLK	Gated when all L4 interface clocks of the different modules of the device are gated
RM_ICLK	Running	None	Gated with source clock (CORE_CLK)

4.7.7.4 DPLL Source-Clock Controls

Figure 4-46 shows the clock controls for the DPLL domain.

Figure 4-46. DPLL Domain Clock Controls

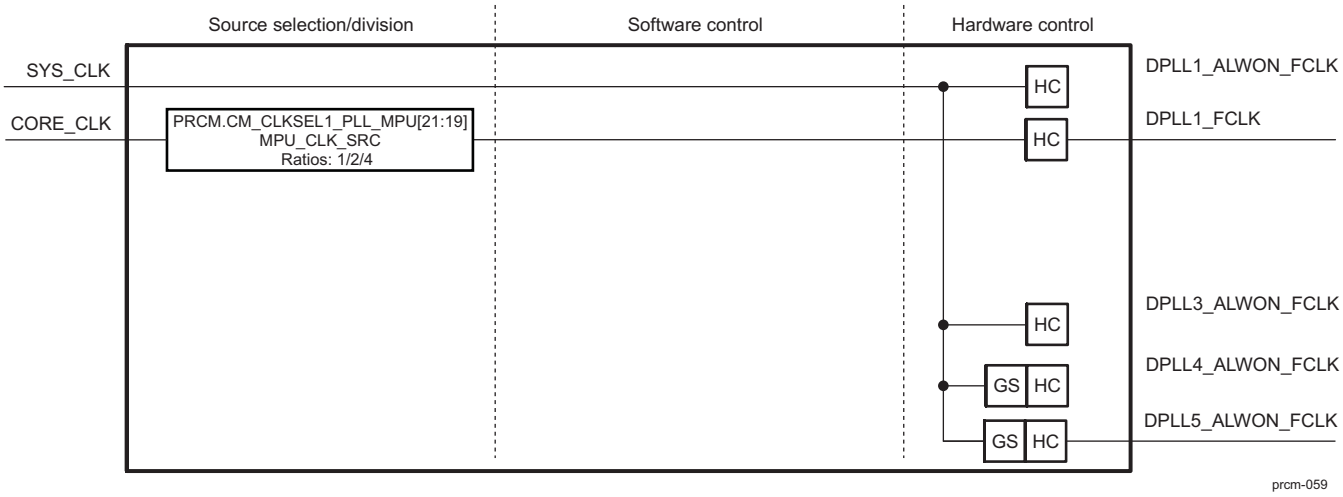

Table 4-43 shows the clock-gating controls for the DPLL domain.

Table 4-43. DPLL Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DPLL1_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL, PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL, and MPU domain power state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the MPU domain goes into retention or off mode. It is also gated if DPLL is set to low-power bypass mode.
DPLL1_FCLK	Stopped		
DPLL3_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL, PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL, and CORE domain power clocks state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the CORE domain is idle. It is also gated if DPLL is set to low-power or fast-relock bypass mode.
DPLL4_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL, PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL, and depends on the clock-gating conditions of DPLL4_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode.
DPLL5_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL, PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL, and depends on the clock-gating conditions of DPLL5_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode.

4.7.7.5 SGX Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are cut off.

Figure 4-47 shows the clock controls for the SGX domain.

Figure 4-47. SGX Domain Clock Controls

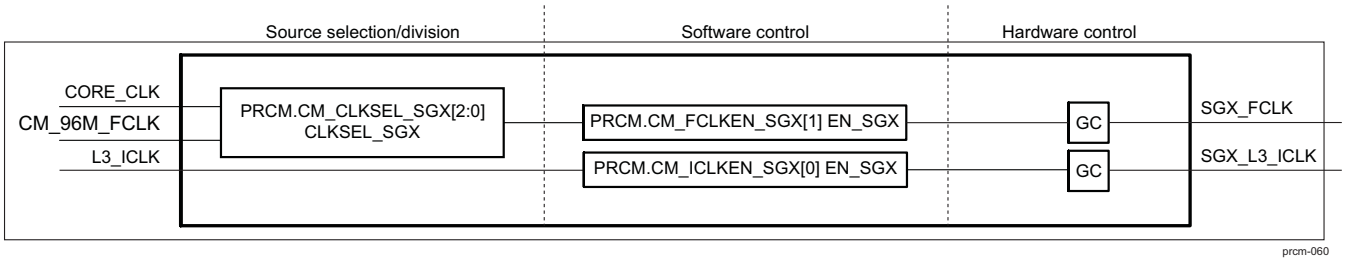

Table 4-44 lists the clock-gating controls for the SGX domain.

Table 4-44. SGX Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
SGX_FCLK	Stopped	PRCM.CM_FCLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0
SGX_ICLK	Stopped	PRCM.CM_ICLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0

4.7.7.6 CORE Domain Clock Controls

Figure 4-48 through Figure 4-50 show the clock controls for the CORE domain.

Figure 4-48. CORE Domain Clock Controls: Part 1

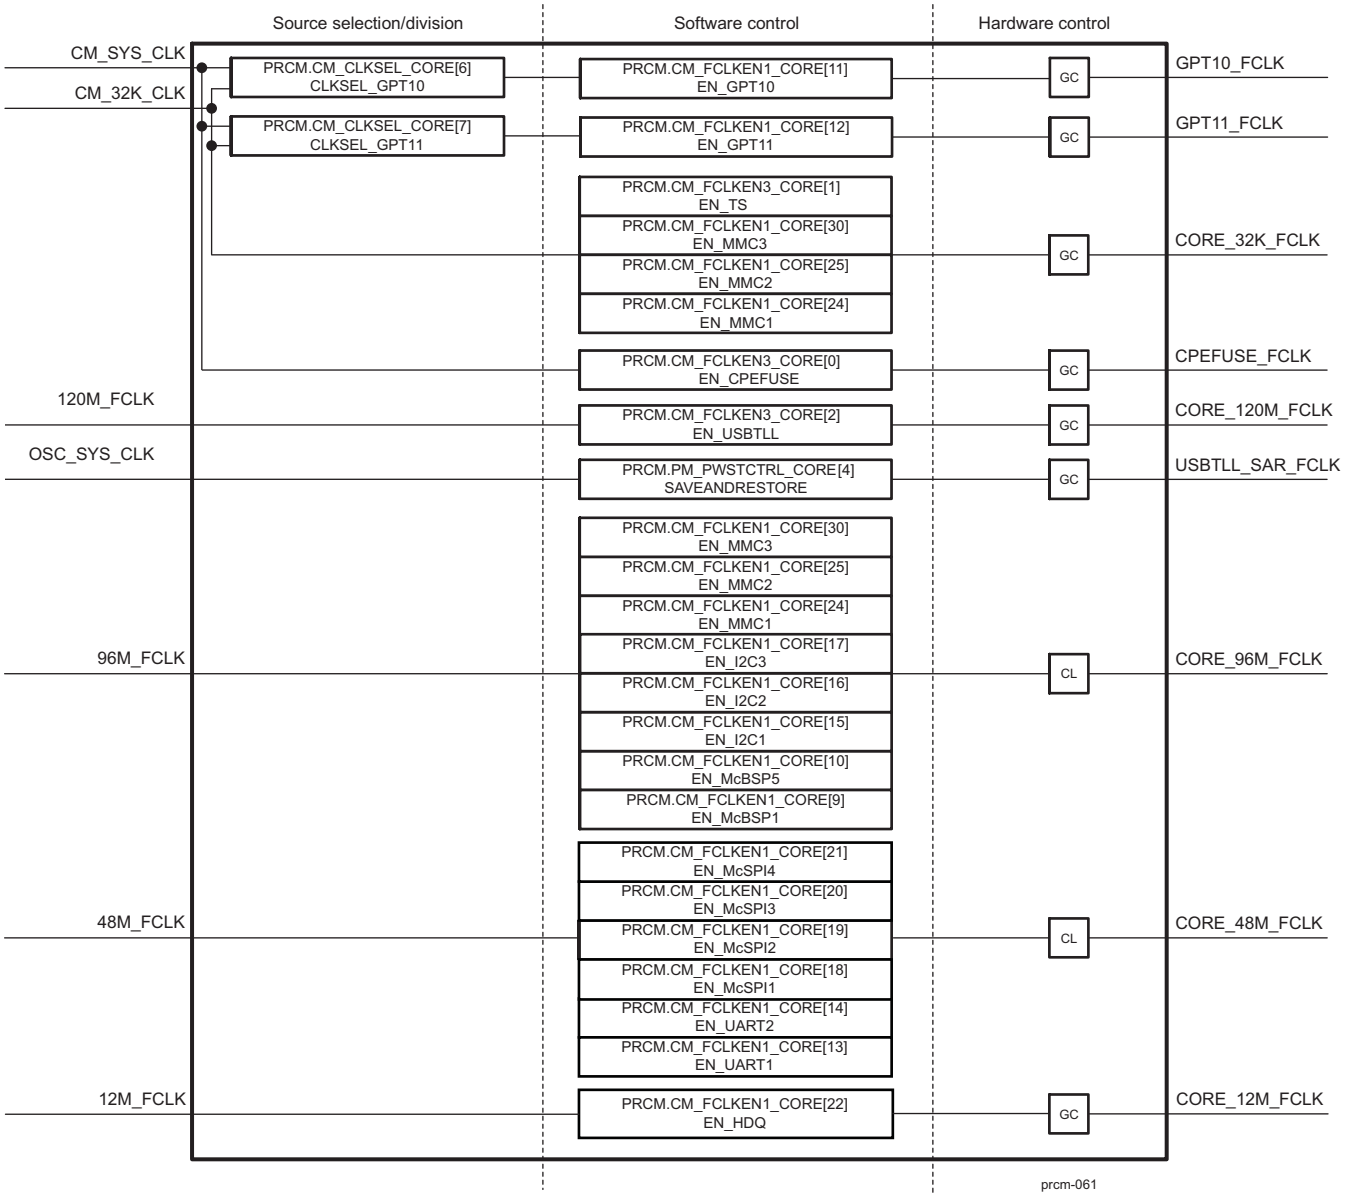

Figure 4-49. CORE Domain Clock Controls: Part 2

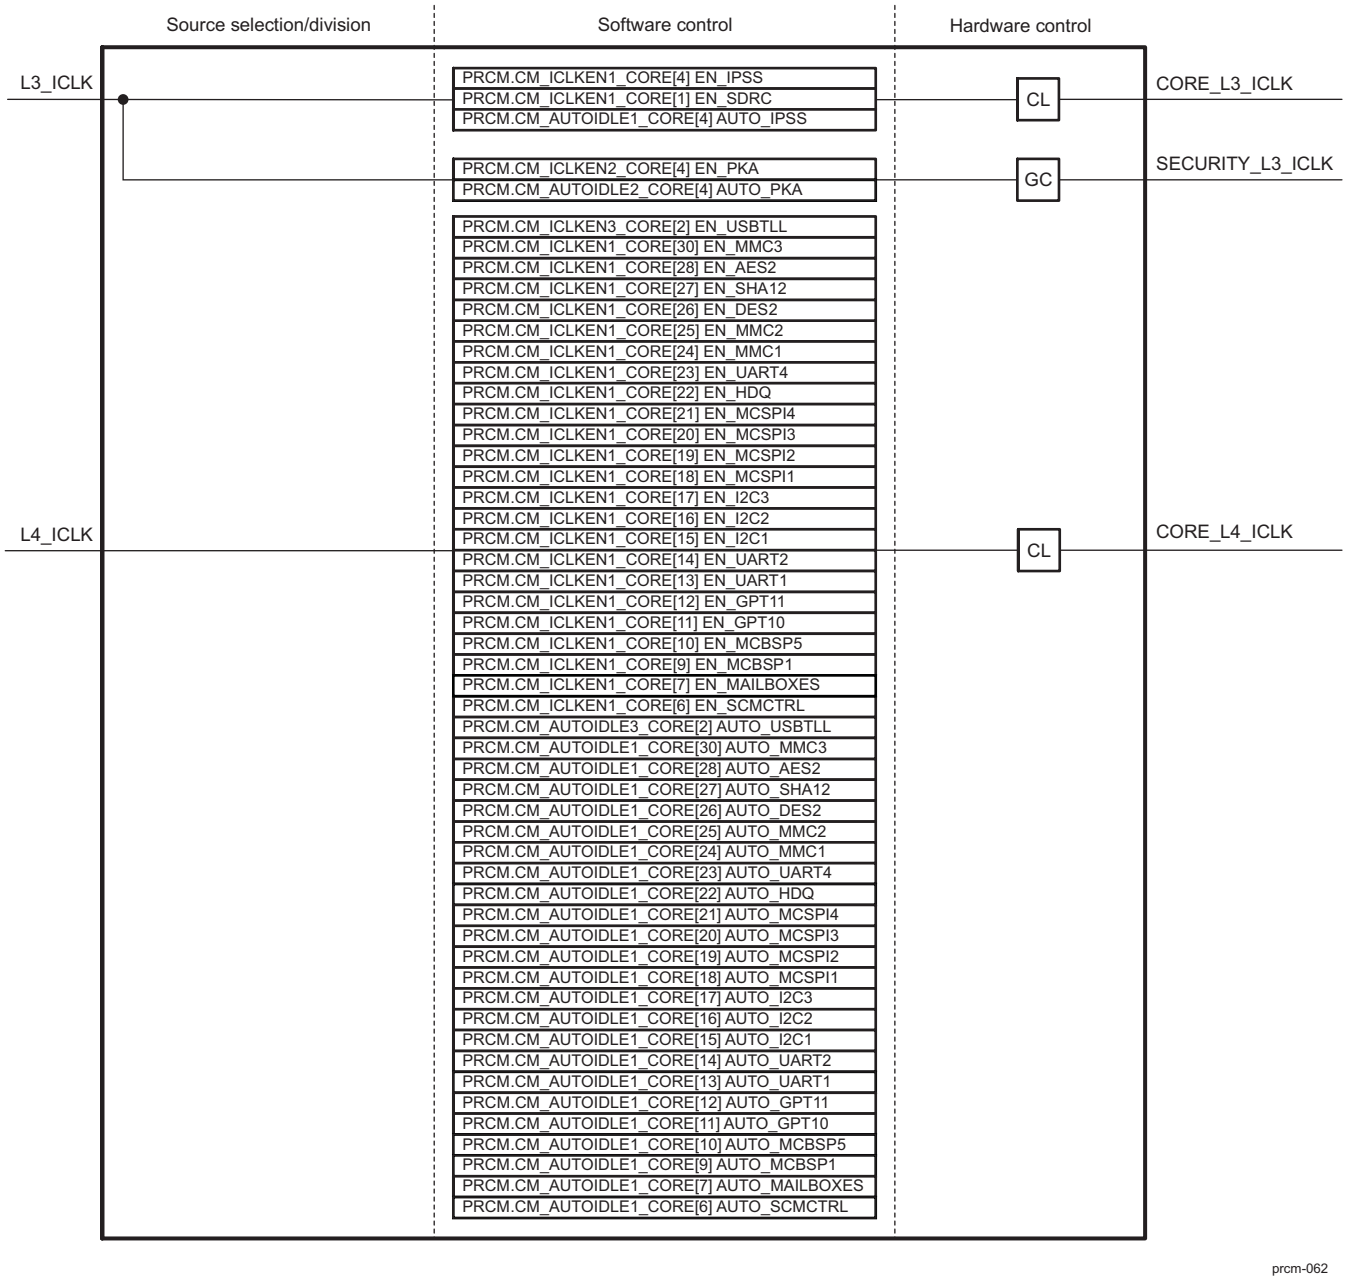

Figure 4-50. CORE Domain Clock Controls: Part 3

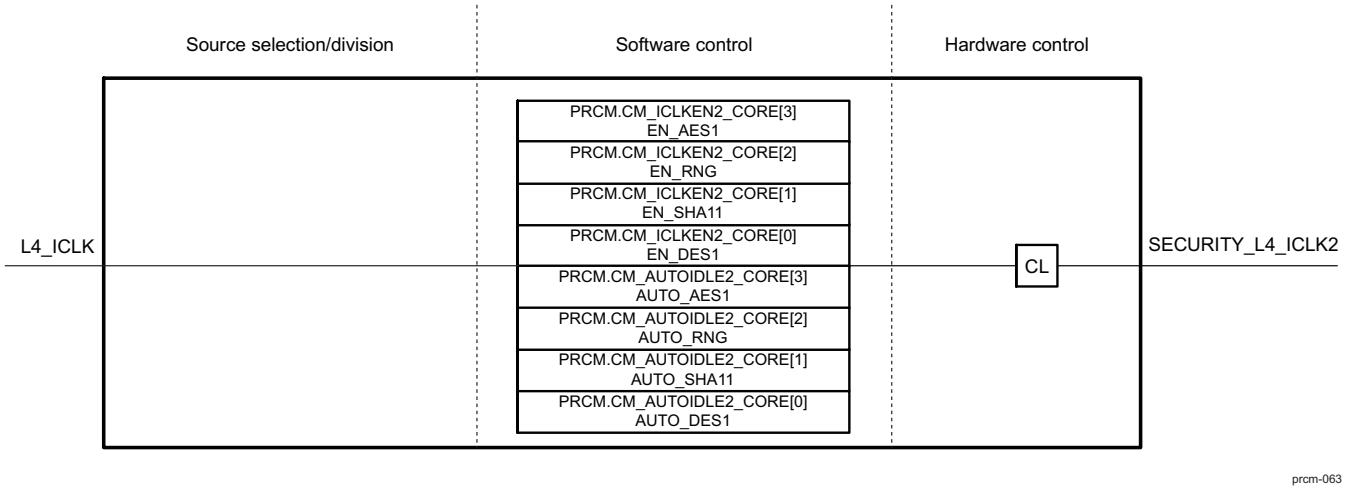

Table 4-45 lists the clock-gating controls for the CORE domain.

Table 4-45. CORE Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
GPT10_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[11] EN_GPT10	Gated when the enable bit is set to 0
GPT11_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[12] EN_GPT11	Gated when the enable bit is set to 0
CORE_96M_FCLK	Stopped	McBSP[1..5] input clock source select (in SCM) and PRCM.CM_FCLKEN1_CORE (MMC[1-2], McBSP[1, 5], I2C[1-3])	Gated when the enable bits of the module functional clock are set to 0. (The McBSPs can have MCBSP_CLKS as an alternate functional clock.)
CORE_48M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE (UART[1-2], McSPI[1-4])	Gated when the functional clock enable bits of the module are set to 0
CORE_12M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[22] EN_HDQ	Gated when the enable bit is set to 0
CORE_L3_ICLK	Running	PRCM.CM_ICLKEN1_CORE EN_(SDRC, IPSS), PRCM.CM_AUTOIDLE1_CORE4] AUTO_IPSS	Gated when: 1. All enable bits are set to 0. 2. The enable-autoidle bit pair is set to 1, the remaining enable bits are set to 0, and the clock is not requested by any module.
CORE_L4_ICLK	Running	PRCM.CM_ICLKEN1_CORE (AES2, SHAM2, D3D2, MMC[1..2], HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], SCMCTRL) and PRCM.CM_AUTOIDLE1_CORE (AES2, SHAM2, D3D2, MMC[1..2], HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], SCMCTRL)	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
CORE_32K_FCLK	Stopped	CM_FCLKEN1_CORE[24] EN_MMC1, CM_FCLKEN1_CORE[25] EN_MMC2, CM_FCLKEN1_CORE[30] EN_MMC3, CM_FCLKEN3_CORE[1] EN_TS	Gated when: 1. All enable bits are set to 0.
CPEFUSE_FCLK	Stopped	CM_FCLKEN3_CORE[0] EN_CPEFUSE	Gated when CPEFUSE autoload sequence is performed, and the enable bit is set to 0
CM_USIM_CLK	Stopped	CM_FCLKEN_WKUP[9] EN_USIMOCP	Gated when the enable bit is set to 0
USBTLL_SAR_FCLK	Stopped	CORE domain power state and PM_PWSTCTRL_CORE[4] SAVEANDRESTORE	Gated when the save-restore bit is set to 0 after the restore operation completes.
CORE_120M_FCLK	Stopped	CM_FCLKEN3_CORE[0] EN_USBTLL and DPLL5 operating mode	Gated when the enable bit is set to 0, or the DPLL5 is in stop or bypass mode

4.7.7.7 EFUSE Domain Clock Controls

Figure 4-51 shows the clock controls for the EFUSE domain. Table 4-46 lists the clock-gating control for the EFUSE domain.

Figure 4-51. EFUSE Domain Clock Controls

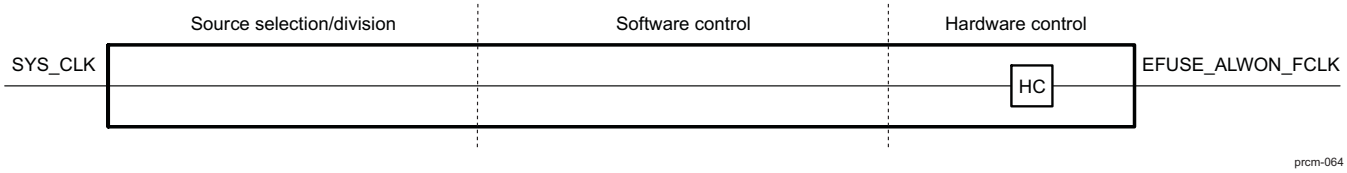

Table 4-46. EFUSE Domain Clock-Gating Control

Clock Name	Reset	Clock-Gating Control	Gating Description
EFUSE_ALWON_FCLK	Running	None	Active when VDD_CORE is ramped up to power on the device and the eFuse-ready hardware signal is released.

4.7.7.8 DSS Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are cut off.

Figure 4-52 shows the clock controls for the DSS domain. Table 4-47 lists the clock-gating controls for the DSS domain.

Figure 4-52. DSS Domain Clock Controls

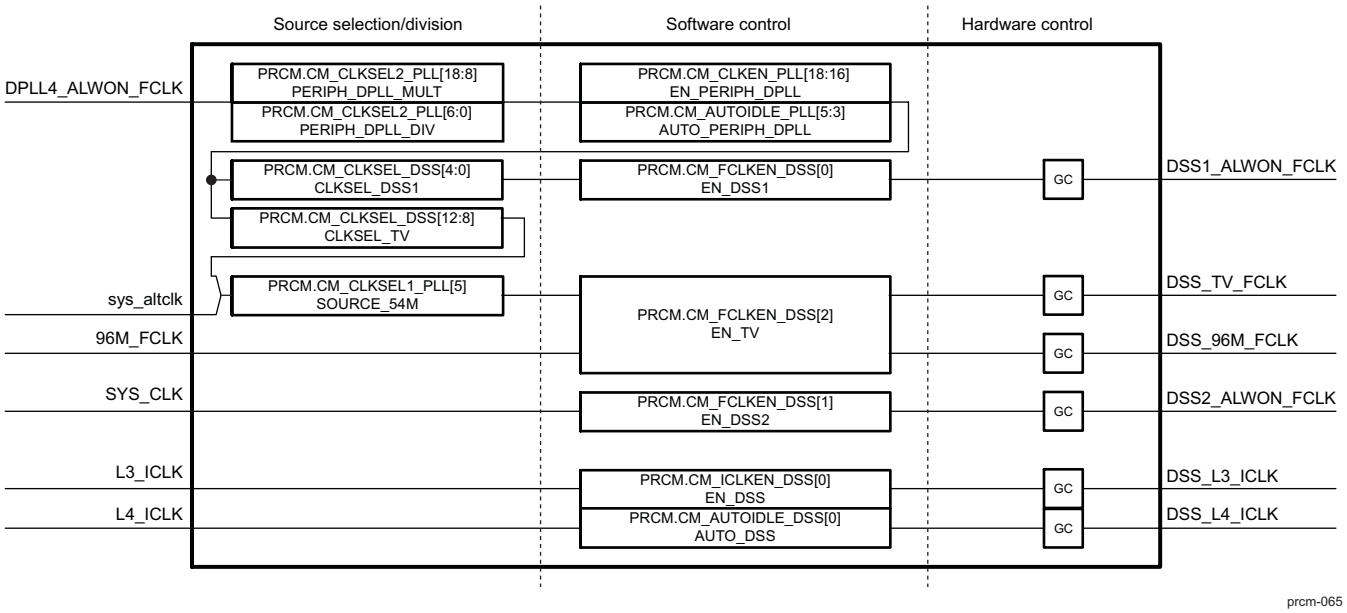

Table 4-47. DSS Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DSS1_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[0] EN_DSS1	Gated when the enable bit is set to 0
DSS2_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[1] EN_DSS2	Gated when the enable bit is set to 0
DSS_TV_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[2] EN_TV	Gated when the enable bit is set to 0
DSS_96M_FCLK	Stopped		

Table 4-47. DSS Domain Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
DSS_L3_ICLK	Stopped	PRCM. CM_ICLKEN_DSS[0] EN_DSS, PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS	Gated when: 1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by any module.
DSS_L4_ICLK	Stopped		

4.7.7.9 USBHOST Domain Clock Controls

Figure 4-53 shows the clock controls for the USBHOST domain. Table 4-48 lists the clock-gating controls for the USBHOST domain.

Figure 4-53. USBHOST Domain Clock Controls

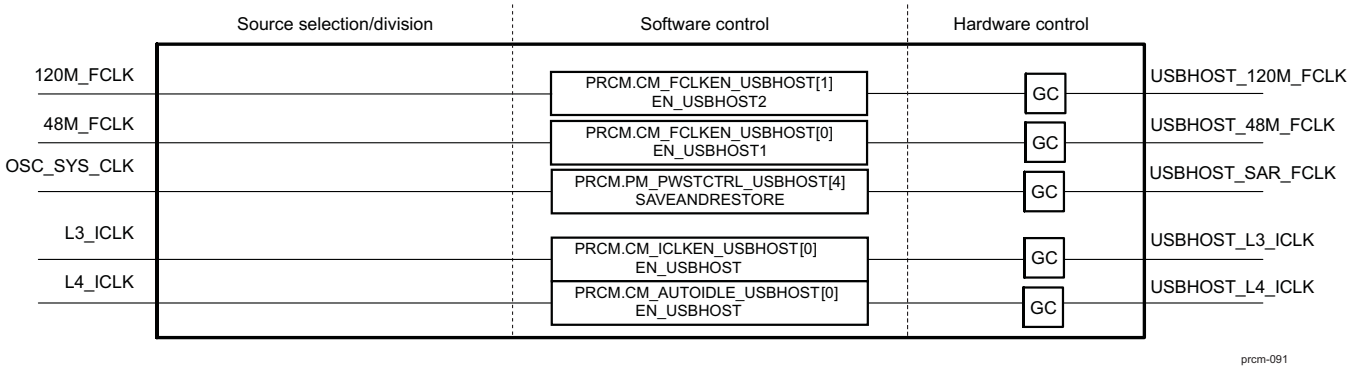

Table 4-48. USBHOST Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
USBHOST_48M_FCLK	Stopped	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1	Gated when the enable bit is set to 0
USBHOST_120M_FCLK	Stopped	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2	Gated when the enable bit is set to 0
USBHOST_L3_ICLK	Stopped	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST, PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST	Gated when: 1. Enable bit is set to 0.
USBHOST_L4_ICLK	Stopped		2. Enable-autoidle bit pair is set to 1, and the clock is not requested by subsystem.
USBHOST_SAR_FCLK	Stopped	PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE	Gated when the save-restore bit is set to 0, or when the domain is in OFF state after the save operation completes or in ON state after the restore operation completes.

4.7.7.10 WKUP Domain Clock Controls

Figure 4-54 shows the clock controls for the WKUP domain. Table 4-49 lists the clock-gating controls for the WKUP domain.

Figure 4-54. WKUP Domain Clock Controls

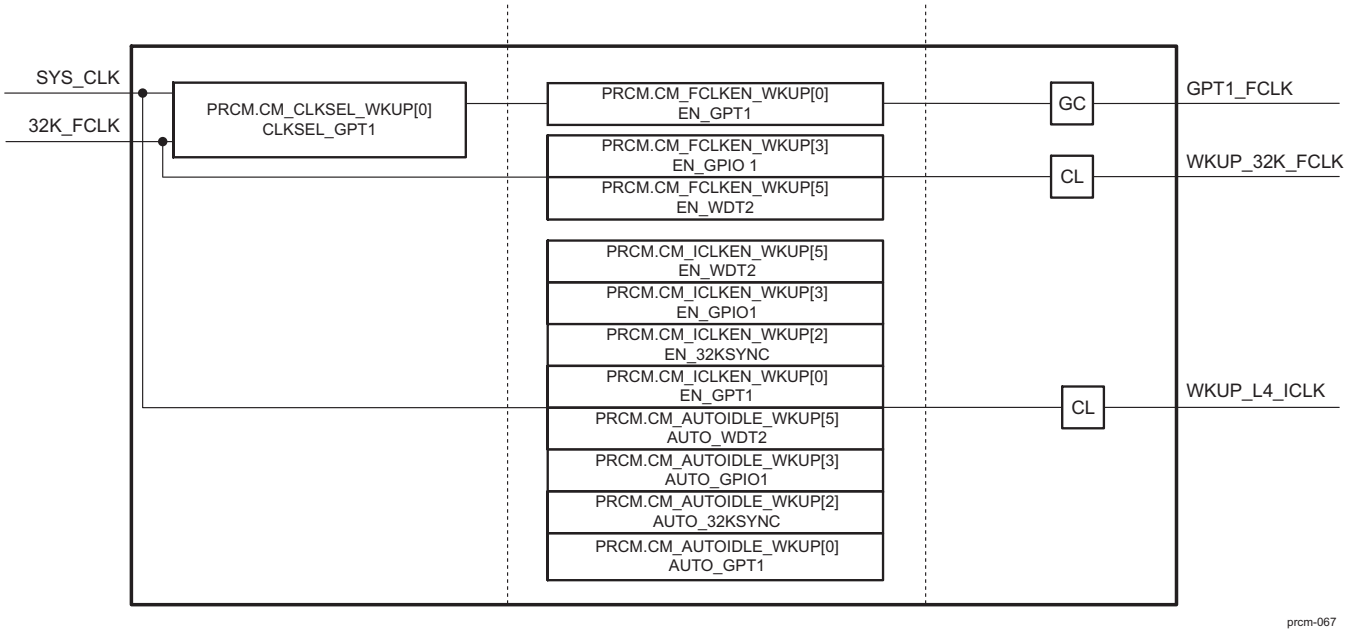

Table 4-49. WKUP Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
GPT1_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1	Gated when the enable bit is set to 0
WKUP_32K_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[3] GPIO1 and PRCM.CM_FCLKEN_WKUP[5] WDT2	Gated when the enable bits are set to 0
SECURE_32K_FCLK	Running	None	
WKUP_L4_ICLK	Running	PRCM.CM_ICLKEN_WKUP EN_(WDT[1,2], GPIO1, 32KSYNC, GPTIMER[1,12]), PRCM.CM_AUTOIDLE_WKUP AUTO_ (WDT[1,2], GPIO1, 32KSYNC, and GPTIMER[1,12])	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
USIM_FCLK	Running	PRCM.CM_FCLKEN_WKUP[9] EN_USIMOCP	Gated when the enable bit is set to 0

4.7.7.11 PER Domain Clock Controls

Figure 4-55 and Figure 4-56 show the clock controls for the PER domain.

Figure 4-55. PER Domain Clock Controls: Part 1

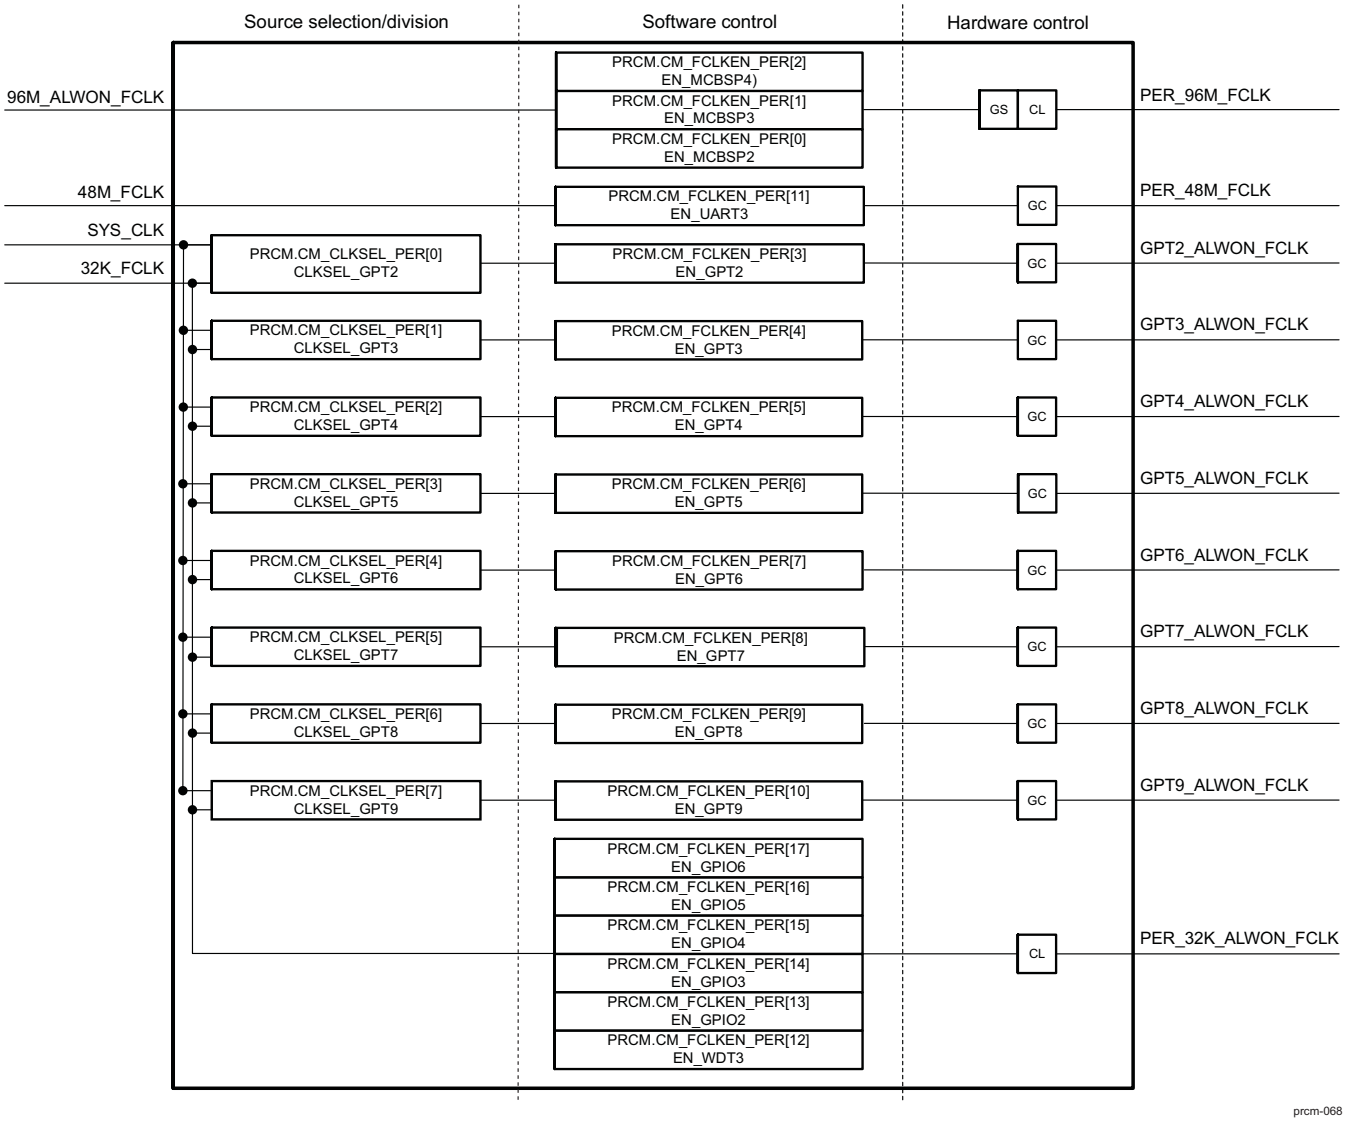

Figure 4-56. PER Domain Clock Controls: Part 2

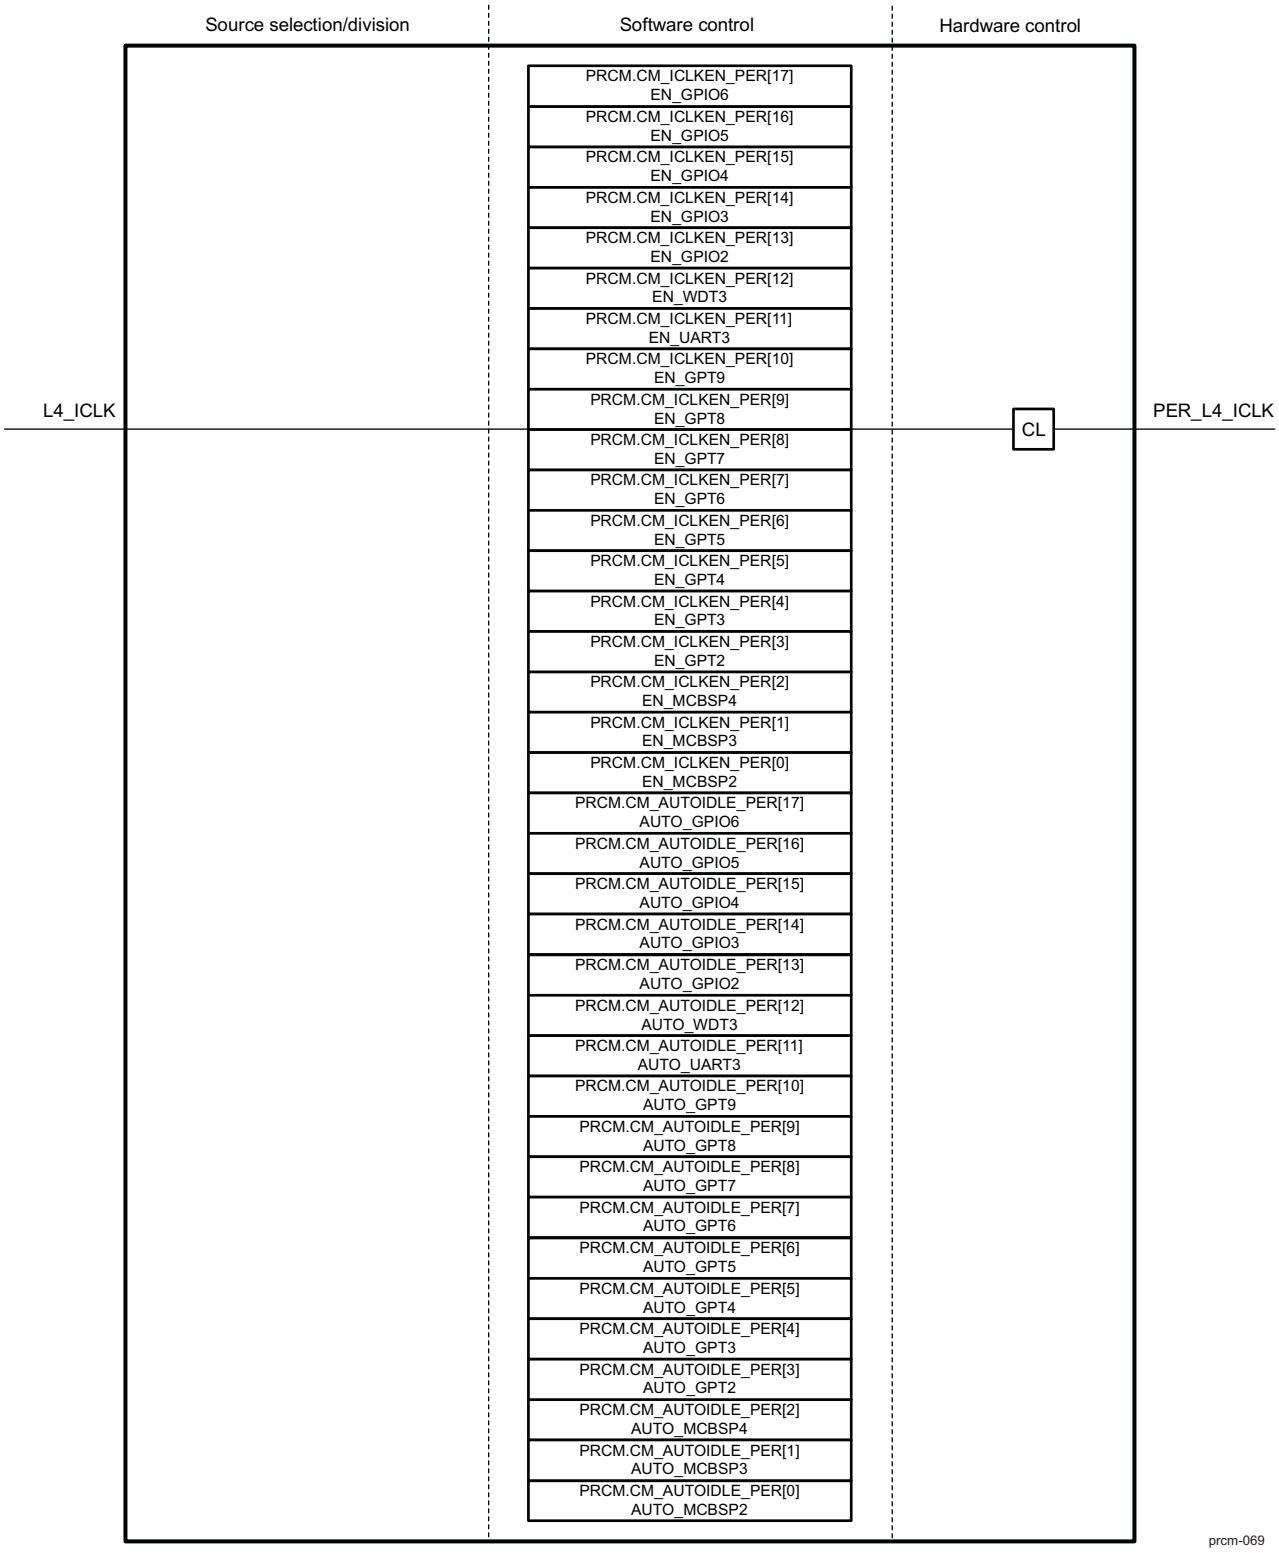

Table 4-50 lists the clock-gating controls for the PER domain.

Table 4-50. PER Domain Clock-Gating Controls

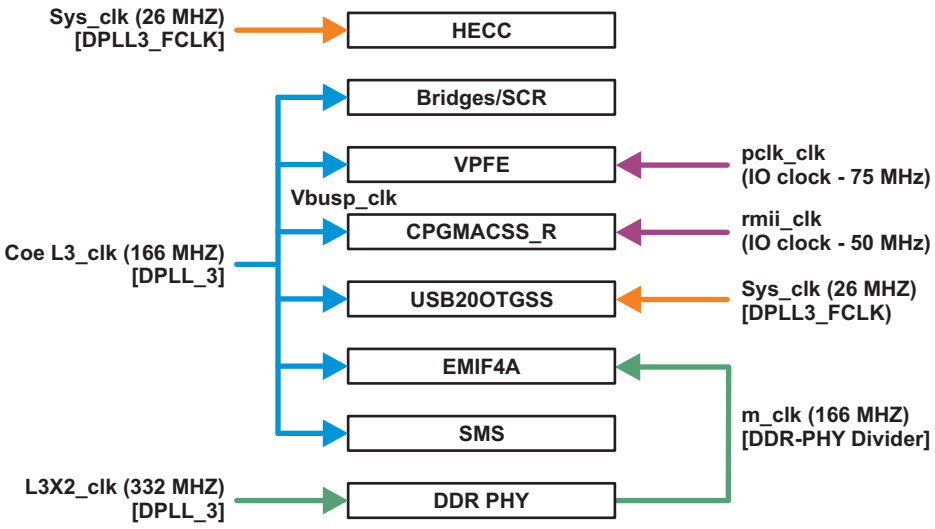
Clock Name	Reset	Clock-Gating Control	Gating Description
PER_48M_FCLK	Stopped	PRCM.CM_FCLKEN_PER[11] EN_UART3	Gated when the enable bit is set to 0
PER_96M_FCLK	Stopped	McBSP[2..4] input clock source select (in SCM) and PRCM.CM_FCLKEN_PER EN_MCBSP[2-4] and the DPLL4 operating mode	Gated when the enable bits of the module functional clock are set to 0 (the McBSPs can have MCBSP_CLKS as an alternate functional clock) or DPLL4 is in stop or bypass mode
MCBSP_CLKS	Stopped	See the *System Control Module* chapter.	
PER_32K_ALWON_ FCLK	Stopped	PRCM.CM_FCLKEN_PER EN_GPIO[2-6] and PRCM.CM_FCLKEN_PER[12] EN_WDT3	Gated when all the enable bits are set to 0
GPT2_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[3] EN_GPT2	Gated when the enable bit is set to 0
GPT3_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[4] EN_GPT3	Gated when the enable bit is set to 0
GPT4_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[5] EN_GPT4	Gated when the enable bit is set to 0
GPT5_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[6] EN_GPT5	Gated when the enable bit is set to 0
GPT6_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[7] EN_GPT6	Gated when the enable bit is set to 0
GPT7_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[8] EN_GPT7	Gated when the enable bit is set to 0
GPT8_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[9] EN_GPT8	Gated when the enable bit is set to 0
GPT9_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[10] EN_GPT9	Gated when the enable bit is set to 0
PER_L4_ICLK	Stopped	PRCM.CM_ICLKEN_PER EN_(GPIO[2..6], WDT3, UART3, GPT[2..9], MCBSP[2..4]) and PRCM.CM_AUTOIDLE_PER AUTO_(GPIO[2..6], WDT3, UART3, GPT[2..9], and MCBSP[2..4])	Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
96M_ALWON_FCLK	Stopped	None	Always-on clock

For audio applications, the McBSP functional clocks are provided externally by the MCBSP_CLKS pin. This clock must be permanently supplied to allow McBSPs to function. If the external clock input is selected as the functional clock, the PER domain sleep transition is prevented.

4.7.7.12 Other Modules Clocks

Device IPs get their clocks from existing clock sources or externally from an IO. Figure 4-57 shows the clock connections for the HECC, VPFE, CPGMACSS_R, USB20OTGSS, EMIF4A, SMS, DDR PHY and Bridges/SCR.

Figure 4-57. Clock Sources for Other Modules



4.7.8 Clock Configurations

The device supports several clock configurations. A clock configuration is a consistent set of divider ratios programmed into PRCM to obtain a certain combination of clock speed to match the performance requirement.

In the device, the MPU is connected to the interconnects through asynchronous bridges. The functional frequency of the processor can be configured independently of its interface clock frequency.

4.7.8.1 Processor Clock Configurations

Generic processor operating performance points may be defined as:

- DPLL1 (MPU DPLL) synthesized clock frequency (CLKOUTX2) configured by setting the M and N parameters of the DPLL
- DPLL1 (MPU DPLL) output clock frequency (MPU_CLK) configured by setting the M2 parameter of the DPLL

NOTE: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

The frequency of the ARM processor clock (MPU_FCLK) can be configured. Table 4-51 identifies the processor clock, the source clock and the configuration register bits fields.

Table 4-51. Processor Clock Configuration Controls

Module	Clocks	Reference Clock	Multiplier (factors)	Divider (factors)	Configuration Bits
DPLL1	CLKOUTX2	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT
				N (0 ... 127)	PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV
	MPU_CLK[1]	CLKOUTX2		M2	PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV

(1) The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

Table 4-52. Processor Clock Configurations

CLOCK	BYPASS	LOCKED
MPU_CLK	DPLL1_FCLK (Bypass Clock from DPLL3)	(SYS_CLK * M * 2) / ([N+1] * M2)
ARM_FCLK	MPU_CLK	MPU_CLK / 2
MPUSS Internal Modules Clocks	ARM_FCLK / 2	ARM_FCLK / 2

4.7.8.2 Interface and Peripheral Functional Clock Configurations

The DPLL3 (CORE DPLL) generates the CORE_CLK which serves as the source clock for the L3_ICLK and L4_ICLK interface clocks of the device. The CORE_CLOCK is also used by the DPLL1as the bypass clock. The L3_ICLK is supplied to the SGX module as SGX_L3_ICLK and is used as its functional clock. The L4_ICLK is used by RM_L4_CLK as its source clock.

The interface and peripheral functional clocks frequencies can be configured according to the device performance requirements.

DPLL3 synthesized clock frequencies are configured as:

- $f_{CLKOUT} = (f_{SYS\_CLK} \times M) / (N+1)$
- $f_{CLKOUTX2} = f_{CLKOUT} \times 2$

DPLL3 output clock frequencies are configured as:

- $f_{CORE\_CLK} = f_{CLKOUT} / M2$
- $f_{COREX2\_CLK} = f_{CLKOUTX2} / M2$

L3_ICLK, L4_ICLK and RM_L4_ICLK frequencies are configured as:

- $f_{L3\_ICLK} = f_{CORE\_CLK} / DIV\_L3$
- $f_{L4\_ICLK} = f_{L3\_ICLK} / DIV\_L4$
- $f_{RM\_L4\_ICLK} = f_{L4\_ICLK} / DIV\_RM$

Table 4-53 identifies the interface clocks, their reference clocks, and the control bits for configuration of the interface clock frequencies.

Table 4-53. Interface Clock Configuration Controls

Module	Clock	Reference Clock	Multiplier (Factor)	Divider (Factor)	Configuration Bits
DPLL3	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT
	CLKOUTX2			N (0 ... 127)	PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_ DIV
CORE_CLK	CORE_CLK	CLKOUT		M2 (1 ... 31)	PRCM. CM_CLKSEL1_PLL[31 :27] CORE_DPLL_CLKOUT_DIV
	COREX2_CLK	CLKOUTX2			
L3 interconnect	L3_ICLK	CORE_CLK		DIV_L3 (1 ... 2)	PRCM. CM_CLKSEL_CORE[1:0] CLKSEL_L3
L4 interconnect	L4_ICLK	L3_ICLK		DIV_L4 (1 ... 2)	PRCM.CM_CLKSEL_CORE[3:2] CLKSEL_L4
RM clock	RM_L4_ICLK	L4_ICLK		DIV_RM (1 ... 2)	PRCM.CM_CLKSEL_WKUP[2:1] CLKSEL_RM

SGX_FCLK and DPLL1_FCLK (bypass mode) frequencies are configured as:

- $f_{SGX\_FCLK} = f_{CORE\_CLK} / DIV\_SGX$
- $f_{SGX\_FCLK} = f_{CM\_96M\_FCLK}$
- $f_{DPLL1\_FCLK} = f_{CORE\_CLK} / DIV\_DPLL1$

Table 4-54 identifies the functional clocks, their reference clocks and the control bits for configuration of the functional clock frequencies.

Table 4-54. Functional Clock Configuration Controls

Module	Clock	Reference Clock	Divider (Factor)	Configuration Bits
SGX	SGX_FCLK	CORE_CLK	DIV_SGX (3, 4, 6)	PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
		CM_96M_FCLK		PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
MPU HS bypass	DPLL1_FCLK	CORE_CLK	DIV_DPLL1 (1, 2, 4)	PRCM.CM_CLKSEL1_PLL_MPU[20:19] MPU_CLK_SRC

The rest of the functional clocks are issued from DPLL4 and DPLL5 and remain invariable, regardless of the interface clock configuration. In all clock configurations, any divider ratio to generate functional clocks is applicable, provided it complies with the maximum frequency specification.

4.8 PRCM Idle and Wake-Up Management

4.8.1 Overview

When a group of modules belonging to a clock domain do not require a clock (interface or functional), the PRCM can be programmed to automatically cut the clock to those modules, thereby reducing their power consumption. When all clocks in a domain are cut, the domain is idle.

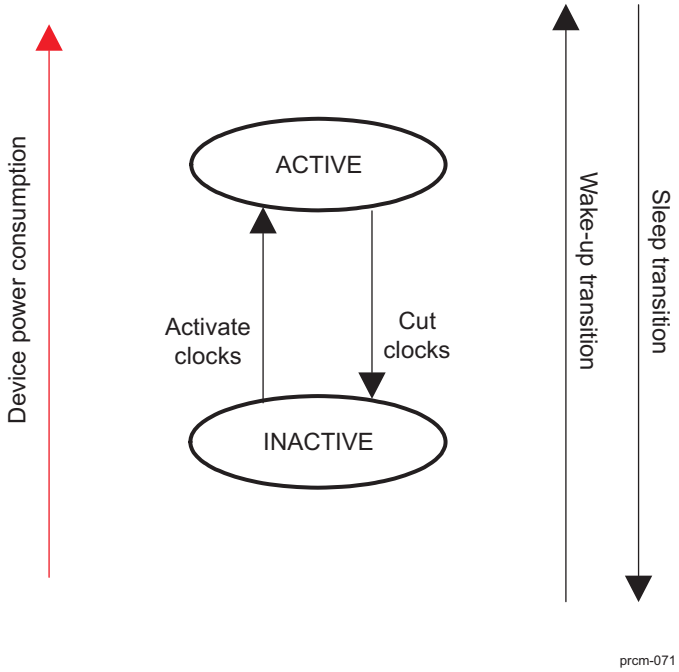
Similarly, when a module in low-power idle mode is required to switch to active mode, the PRCM activates the necessary clock signals to the module. This is a wake-up transition. Generally, a wake-up event triggers the wake-up transition.

A sleep/wake-up dependency can be defined between different domains. A sleep dependency ensures that a domain does not make a sleep transition unless all the dependent domains are in idle mode and do not require the domain. Similarly, a wake-up dependency ensures that a domain wakes up when any of its dependent domains wakes up.

The PRCM automatically handles the sequence clock-gating conditions for each domain, based on the configured dependencies between the domains and the clock-control bits of the modules.

Figure 4-58 shows the sleep/wake-up transition of the domains.

Figure 4-58. Domain Sleep/Wake-Up Transition



Functionally, the PRCM is composed of a single global control block and a power-control block for each domain. The domain power-control block handles wake-up events and clock-gating control for the domain. The domain power controllers communicate with each other for sleep dependencies and wake-up dependencies. All these blocks interact with the global control block that handles reset management, clock generation and distribution, and all PRCM registers.

Figure 4-59. Device Power Reset and Clock Controllers

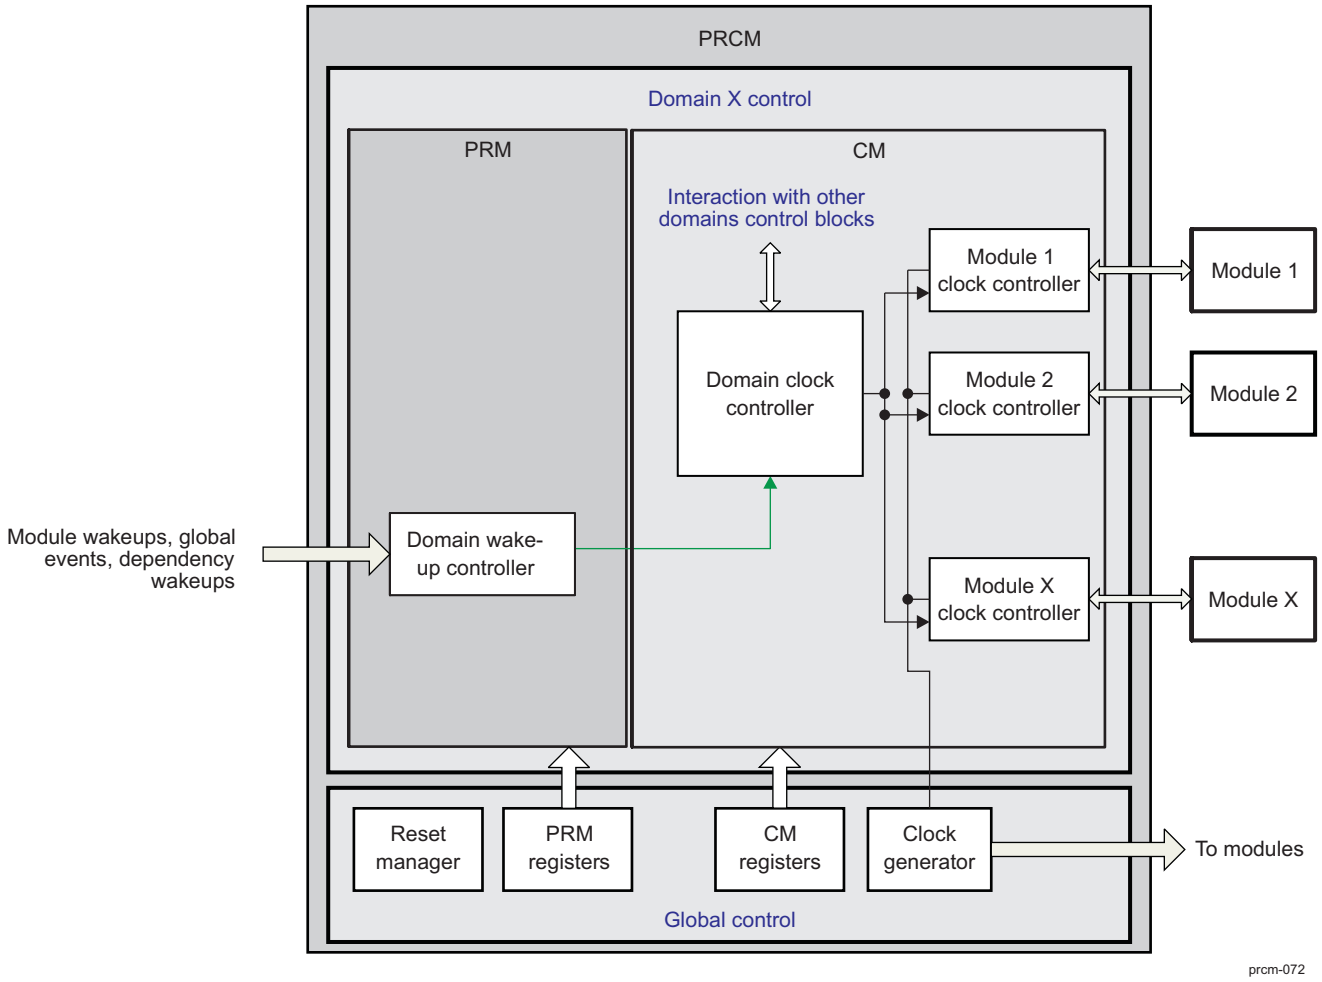


Figure 4-59 details the functions within one domain control block:

- A module clock controller (for example, module X clock controller) uses a hardware handshake protocol to communicate directly with the module. It controls the idle transition of the target module and responds to the standby requests of the initiator module (for details, see Section 4.1.3.2, *Autoidle Clock Control*). Depending on the mode, the clock controller sends clock commands (enable/disable) to the clock generator. The registers that control the functional and interface clocks in the module are directly mapped to the module clock controller.
- The domain clock controller gathers information from the following:
  - All module clock controllers of the domain
  - The domain wake-up controller
  - The other domain control blocks

  On a wake-up event, the domain clock controller starts the module domain clocks.
- The domain wake-up controller gathers all events that can wake up the domain.
- The reset manager globally controls all resets in the device. It gathers information from all domain control blocks to sequence the clocks, and resets the activation of each domain.
- The clock generator generates and distributes clocks over the device, depending on requests from all module clock controllers and on other global conditions.

4.8.2 Sleep Transition

The PRCM can initiate a domain sleep transition on a domain only if the domain meets the following conditions:

- All initiator modules are idle (they have completed their activity and idled themselves through software requests).
- All target modules are idle (automatically when all initiators are in standby mode or on software request).
- All sleep dependencies with other domains are met (can be set by software).

The domain state transition can be set to automatic (hardware controlled) or software-controlled by setting the PRCM. CM_CLKSTCTRL_<domain> CLKTRCTRL_<domain> bit field.

4.8.3 Wakeup

There are three types of wake-up events:

- Global: Generated on a particular device event (device wakeup, DPLL recalibration, etc.). Used mainly to wake up the MPU domain
- Module: Functional wake-up event issued from a module, which wakes up the domain where the module resides. It can also directly wake up the MPU depending on software settings in the PRCM.PM_MPUGRPSEL_<domain>.
- Dependency: A domain can wake up on the wakeup of another domain. The dependency is software-controllable by configuring the PRCM.PM_WKDEP_<domain> register.

4.8.4 Device Wake-Up Events

This section summarizes the wake-up events for each domain. Table 4-55 through Table 4-63 list the wake-up events, related control registers, and MPU interrupts.

The register PRCM.PRM_IRQENABLE_MPU enables the MPU interrupts. In some cases it can also enable the wake-up feature associated with the interrupt (DPLL recalibration requests and device wake-up event).

NOTE:

- The PRCM can be configured to generate an interrupt to the MPU subsystem as a result of a wake-up event from the CORE, WKUP, and PER domain modules to the MPU. However, these modules may also directly interrupt the MPU subsystem. To avoid a double interrupt (from the PRCM and one of these modules) as the result of a single event (wakeup), one interrupt must be masked when the other is unmasked. For further information on its interrupt capability, see the chapter of the corresponding module.
- The UART, GPIO, McSPI, and USIM OCP modules generate an asynchronous wake-up event (that is, their interface and functional clocks can be gated during the sleep period). However, because the GPTIMERs generate a synchronous wake-up event, they require their functional clock to be active during the sleep period; their interface clock can be gated. McBSP modules can generate a synchronous or asynchronous wake-up event, based on the mode configurations. For further information on its wake-up capability, see the chapter of the corresponding module.
- The ability of a module to generate a wake-up event depends on the state of the domain in which the module resides. If the domain is inactive (that is, both the functional and interface clocks of the domain are gated), only the asynchronous wake-up modules can wake up the domain. If only the interface clocks in the domain are gated, both synchronous and asynchronous wake-up modules can generate a wake-up event to activate the interface clock.

Table 4-55. MPU Domain Wake-Up Events

Internal Wake-Up Events	Source Module	PRCM Software Control	Wake-Up Event	Interrupt/Type	Interrupt to
CORE, DSS, and PER domain dependency	PRCM	PM_WKDEP_MPU	Yes	No	N/A

4.8.5 Sleep and Wake-Up Dependencies

4.8.5.1 Sleep Dependencies

The (clock activity) dependencies between domains are implemented to manage their sleep and wake-up transitions to ensure stable operation of the device.

A domain sleep transition is achieved when all its clock domains (that is, functional and interface) are gated. For the gating of a clock domain, the following conditions must be satisfied:

- All initiator modules in the clock domain are in standby mode, that is, they cannot initiate any new transitions.
- All target modules in the clock domain are in idle mode and have no pending transitions.
- If the domain depends on another domain (that is, has a sleep dependency), the clock domains of the other domain must be muted.

A clock domain is said to be muted when all its public initiator modules (that is, the initiator modules of the clock domain that can generate interconnect transactions towards targets outside the clock domain) are in standby mode, and the domain cannot initiate new interconnect transactions toward other domains.

Table 4-64 describes the mute conditions for the clock domains.

Table 4-64. Clock Domain Mute Conditions

Clock Domain Name	Clock Domain Composition	Mute Conditions
MPU	MPU domain and MPU INTC in CORE domain	MPU in stand-by, MPU INTC idle
SGX	SGX domain	SGX in stand-by
DSS	DSS domain	DSS in stand-by
PER	PER domain	N/A (No public Initiator)
CORE_L3	L3 interconnect, L3 targets/initiators in CORE domain	sDMA in standby
CORE_L4	L4 interconnect, L4 targets in CORE domain	N/A (No public Initiator)
USBHOST	USBHOST domain	USBHOST in stand-by
WKUP	WKUP domain	N/A (No public Initiator)

A sleep dependency prevents the PRCM from gating the clocks to a domain (for sleep transition to inactive from on state) if a dependent domain is active (i.e., its clocks are active). A domain may depend on several other domains.

A domain sleep dependency is programmed by setting the PRCM.CM_SLEEPDEP_<domain> register.

Example:

The PER domain has a programmable sleep dependency with the MPU domain, and a hardwired sleep dependency with the CORE domain. Therefore, if all software dependencies are enabled, the PER domain can go into idle mode only if the MPU and CORE-L3 clock domains are idle. If all software dependencies are disabled, the PER domain can go into idle mode, provided that the CORE-L3 clock domain is muted (no access to the PER domain can be pending).

Table 4-65 summarizes the programmable and hardwired sleep dependencies among the domains.

Table 4-65. Sleep Dependencies

		Sleep Dependency									
Power Domain	**Clock Domain**	**MPU**	**NEON**	**SGX**	**DSS**	**PER**	**CORE_ L3**	**CORE_ L4**	**CORE_ CM**	**USB HOST**	**WKUP**
MPU	MPU	n/a	0	0	0	0	0	0	0	0	0
NEON	MPU	1	n/a	0	0	0	0	0	0	0	0
SGX	SGX	RW	0	n/a	0	0	0	0	0	0	0
DSS	DSS	RW	0	0	n/a	0	RW	0	0	0	0
PER	PER	RW	0	0	0	n/a	1	0	0	0	0
CORE	CORE_L3	1	0	1	1	1	n/a	1	0	1	1
	CORE_L4	1	0	0	0	0	1	n/a	0	0	0
	CORE_CM	1	1	1	1	1	1	1	n/a	1	1
USBHOST	USBHOST	RW	0	0		0	0	0	0	n/a	0
WKUP	WKUP	1	0	0	0	0	1	0	0	0	n/a

Notes:

No software control (hardwired values):	0	Does not depend on
	1	Depends on
Software controllable	RW	Read and write
	n/a	Not applicable

NOTE: The first row of the table identifies the dependent domains for a domain listed in the first column. Therefore, to identify the sleep dependency of domain X, identify domain X in the first column and its sleep dependency with domains (of the first row) is identified by its row.

4.8.5.2 Wake-Up Dependencies

A wake-up dependency allows a domain to wake up (from inactive to on state) when another domain wakes up (from off to on state). For example, domain one (PD1) provides a service to domain two (PD2), which creates a dependency between the two domains. When the dependent domain (PD2) wakes up, it signals PD1 with a broadcasted wake-up event, causing PD1 to wake up.

A broadcasted wake-up event can originate from one of two sources:

- PD2 internal wake-up event (typically, a peripheral wake-up event)
- Abortion of the mute mode (at least one initiator in the domain exits standby mode) of PD2 when both the sleep dependency and wake-up dependency with PD1 are enabled.

NOTE: The domain wake-up dependency is a nontransitive property.

If a domain PD1 has wake-up dependency with domain PD2, i.e., PRCM.PM_WKDEP_PD1. EN_PD2 bit is set to 1 and if PD2 has wake-up dependency with domain PD3, i.e., PRCM.PM_WKDEP_PD2. EN_PD3 bit is set to 1.

However, if PD1does not have a direct wake-up dependency with PD3, i.e., PRCM.PM_WKDEP_PD1. EN_PD3 bit is set to 0. Then if the PD1 and PD2 are INACTIVE and PD3 is INACTIVE and is woken-up by a wake-up event, the PD2 is also woken-up but not the PD1.

Because a domain can depend on several other domains, it can broadcast the wake-up signal to each domain on which it depends.

A domain wake-up dependency can either be hardwired (set in the hardware) or programmable through software by configuring the PM_WKDEP_<domain> register for that domain. Continuing the example of PD2 as dependent on PD1, setting the PM_WKDEP_PD1.PD2 bit means that when PD2 wakes up, PD1 also wakes up.

The MPU domain can be wakened only by the DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP domains. All wake-up dependencies of the MPU domain are software-configurable.

When the wake-up dependency with other domains is software-programmable (that is, with the USBHOST, PER, CORE, and WKUP domains), two registers may need be configured: PM_WKDEP_<domain> and PM_<processor>GROUPSEL_<domain>.

The PM_WKDEP_<domain> register serves only to enable/disable the global wake-up dependency of the processor domain on these three domains. The PM_<processor>GROUPSEL_<domain> register must be configured to enable the particular wake-up event in these domains that will wake up the processor domain. Thus, the global wake-up dependency for a dependent domain must be enabled so that a wake-up event can occur, if it has been enabled in the corresponding GROUPSEL register.

For example, if the wake-up dependency of the MPU domain is to be enabled for a wake-up event from the GPIO2 module of the PER domain, the following configuration is required:

- PRCM.PM_MPUGRPSEL_PER[13] GRPSEL_GPIO2
- PRCM.PM_WKDEP_MPU[7] EN_PER

Table 4-66 summarizes the programmable and hardwired wake-up dependencies among the domains.

Table 4-66. Wake-Up Dependencies

		Wake-Up Dependency									
Power Domain	**Clock Domain**	**MPU**	**NEON**	**SGX**	**DSS**	**USB HOST**	**PER**	**CORE_ L3**	**CORE_ L4**	**CORE_ CM**	**WKUP**

	CORE_CM	1	0	0	1	1	1	1	1	n/a	1
WKUP	WKUP	1	0	0	0	1	1	1	1	0	n/a

Legend:

RW	Software wakeup dependency: dependency by PM_WKDEP_<> register.
RW*	Software wakeup dependency: dependency by PM_WKDEP_<> and PM_<>GRPSEL_<> registers.
RW**	Software wakeup dependency: dependency by PM_<>GRPSEL_<> registers.
1	Hardware wakeup dependency: dependency always enabled.
0	No wakeup dependency applicable.
n/a	Not applicable

4.8.6 Other Modules Idle/Wakeup Management

For the purposes of Idle and Wakeup Management in the device, a number of modules (HECC, CPGMAC, VPFE and USB20OTG) are grouped together in a domain called the IP subsystem (IPSS). The IPSS has a single Idle req/ack interface to the CM. When CM asserts ipss_idle_req signal to IPSS, ipss_idle_ack will be returned if all IPSS modules (HECC, CPGMAC, VPFE and USB20OTG) are clock gated. An MPU programmable register (IPSS_CLK_CTRL) is implemented in the system control module for gating the clocks to these modules.

To gate the VBUSP (interface) clock of a IPSS module, the MPU writes the <module>_vbusp_clk_en bit in IPSS_CLK_CTRL register. The MPU must poll the <module>_vbusp_clk_en_ack bit in IPSS_CLK_CTRL register to make sure that clock is gated. Due the clock gating procedure, the MPU must not send a VBUSP request to this module.

To exit clock gating mode for an IP, the MPU must clear <module>_vbusp_clk_en bit in IPSS_CLK_CTRL register. The <module>_vbusp_clk_en_ack bit will be updated to indicate when the clock is ungated.

The MPU can also gate the functional clock to a IPSS module by writing to the <module>_func_clk_en bit in the IPSS_CLK_CTRL register.

4.9 PRCM Interrupts

Table 4-67 lists the interrupts from the PRCM to the MPU.

Table 4-67. Interrupt Descriptions

Interrupt Name	Mapping	Description
PRCM_MPU_IRQ	M_IRQ_11	To MPU interrupt controller (MPU INTC)

Table 4-68 summarizes the event flags (in the PRM_IRQSTATUS_MPU register) and mask (in the PRM_IRQENABLE_MPU register) related to the events generating PRCM interrupts to the MPU.

Table 4-68. MPU Interrupt Event Descriptions

Event Flag	Event Mask	Map to	Automatic MPU Domain Wake-Up Event	Description
PRM_IRQSTATUS_ MPU[0] WKUP_ST	PRM_IRQENABLE_ MPU[0] WKUP_EN	PRCM_MPU_IRQ	No	MPU peripheral group wakeup
PRM_IRQSTATUS_ MPU[2] EVGENON_ST	PRM_IRQENABLE_ MPU[2] EVGENON_EN	PRCM_MPU_IRQ	No	Event generator end of on time
PRM_IRQSTATUS_ MPU[3] EVGENOFF_ST	PRM_IRQENABLE_ MPU[3] EVGENOFF_EN	PRCM_MPU_IRQ	No	Event generator end of off time
PRM_IRQSTATUS_ MPU[4] TRANSITION_ST	PRM_IRQENABLE_ MPU[4] TRANSITION_EN	PRCM_MPU_IRQ	No	A sleep or wake-up transition completion event for NEON, SGX, DSS, PER, EMU, USBHOST domains
PRM_IRQSTATUS_ MPU[5] CORE_DPLL_ST	PRM_IRQENABLE_ MPU[5] CORE_DPLL_ RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL3 recalibration event
PRM_IRQSTATUS_ MPU[6] PERIPH_DPLL_ST	PRM_IRQENABLE_ MPU[6] PERIPH_DPLL_ RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL4 recalibration event
PRM_IRQSTATUS_ MPU[7] MPU_DPLL_ST	PRM_IRQENABLE_ MPU[7] MPU_DPLL_ RECAL_EN	PRCM_MPU_IRQ	Yes	MPU DPLL recalibration event
PRM_IRQSTATUS_ MPU[9] IO_ST	PRM_IRQENABLE_ MPU[9] IO_EN	PRCM_MPU_IRQ	No	I/O pads wake-up event
PRM_IRQSTATUS_ MPU[25] SND_PERIPH_ DPLL_RECAL_ST	PRM_IRQENABLE_ MPU[25] SND_PERIPH_ DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL5 recalibration event

NOTE: The software must first read the event flag to know the interrupt cause, and then write 1 to it to clear the flag.

4.10 PRCM Voltage Management Functional Description

This section describes the voltage control architecture. It also explains the interactions between the device and the external power IC.

NOTE: For more information regarding the device power pads connection, please refer to your device-specific data manual.

4.11 PRCM Basic Programming Model

The PRCM supports an extensive set of module-specific registers that allow programming control over numerous features of the clocks, resets, and power-management signals for each domain of the device.

These registers are fully programmable and accessible by the MPU subsystem.

Logically, the registers are grouped into five categories:

- Global
- Clock management
- Reset management
- Power management
- Voltage management

4.11.1 Global Registers

4.11.1.1 Revision Information Registers

- CM_REVISION: Indicates the CM module revision code; it is read-only
- PRM_REVISION: Indicates the PRM module revision code; it is read-only

4.11.1.2 PRCM Configuration Registers

- CM_SYSCONFIG: Holds an AUTOIDLE bit to control the CM internal clock autogating feature
- PRM_SYSCONFIG: Holds an AUTOIDLE bit to control the PRM internal clock autogating feature

4.11.1.3 Interrupt Configuration Registers

The PRM can interrupt the MPU as a result of several events:

- PRM internal event (event generator, sleep transition, wake-up transition)
- Peripheral wake-up event for a peripheral with interrupt capability (GPTIMER[1..12], GPIO[1..6], McBSP[1..5], UART[1..3], IPSS, I2C[1..3], McSPI[1..4], MMC[1,2])
- Module/device-level event not associated with any interrupt (DPLL recalibration, I/O wakeup)

The PRM interrupt is enabled by programming the PRM_IRQENABLE_<processor_name> register; the interrupt status can be read from the PRM_IRQSTATUS_<processor_name> register.

The device has the following processor interrupt registers:

- PRM_IRQSTATUS_MPU
- PRM_IRQENABLE_MPU

4.11.1.3.1 MPU Interrupt Event Sources

The MPU interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the MPU interrupt controller.

Multiple events can activate this interrupt line:

- MPU peripheral group wake-up event
- Event-generator module end-of-on time and end-of-off time events
- Sleep or wake-up transition (SGX, USBHOST, PER, DSS, NEON, EMU domains)
- DPLL1/DPLL3/DPLL4/DPLL5 recalibration request
- I/O pad wake-up event

The end-of-on time period and end-of-off time period events of the event generator module are sources of interrupts to the MPU processor (the corresponding bits in the PRM_IRQENABLE_MPU are set to 1). The end-of-OFF time period is the source of wake-up events on the MPU domain.

The MPU can force a sleep or wake-up transition on some domains (SGX, USBHOST, PER, DSS, NEON, EMU). The PRM triggers the MPU interrupt when the domain enters a power state. The software must clear the CM_CLKSTCTRL_<domain_name> register only after getting the interrupt. If the software clears this bit before getting the interrupt, the interrupt never occurs, regardless of whether the transition occurs.

An interrupt for a peripheral with wake-up capability is enabled when the wake-up enable bit (PM_WKEN_<domain_name> register type) and group select bit (PM_<processor_name>GRPSEL_<domain_name> type of register) are set to 1.

The PRM triggers the MPU interrupt as long as the DPLL recalibration flag is set and the corresponding interrupt enable bit in the PRM_IRQENABLE_<processor_name> register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

4.11.1.3.2 MPU Interrupt Registers

4.11.1.3.2.1 PRM_IRQENABLE_MPU (MPU Interrupt Enable Register)

The MPU interrupt enable register allows independent masking/unmasking of each MPU internal interrupt source.

NOTE: If the following interrupts are enabled and the MPU domain is idled, then when the event occurs, the PRCM sets the interrupt that wakes up the domain:

- DPLL1/DPLL3/DPLL4/DPLL5 recalibration event

4.11.1.3.2.2 PRM_IRQSTATUS_MPU (MPU Interrupt Status Register)

The MPU interrupt status register provides the status of all PRCM internal events that can generate an MPU interrupt. Software must read this register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

4.11.1.4 Event Generator Control Registers

For details about the event generator module, see the public *ARM® Cortex™-A8 Technical Reference Manual*.

In the PRCM, three event generator registers allow configuration of the event generator module:

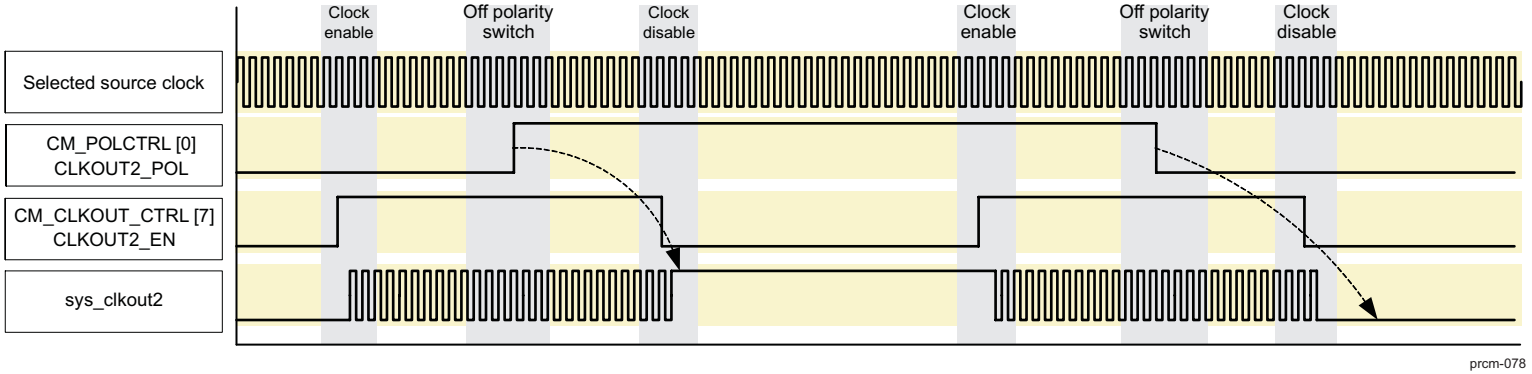
- PM_EVGENCTRL_MPU (event generator control register): Event-generator settings
- PM_EVGENONTIM_MPU (event generator on-time register): On-time duration setting
- PM_EVGENOFFTIM_MPU (event generator off-time register): Off-time duration setting

4.11.1.5 Output Signal Polarity Control Registers

4.11.1.5.1 CM_POLCTRL (CM Polarity Control Register)

The CM_POLCTRL register allows the setting of the polarity of sys_clkout2 when gated (disabled). sys_clkout2 can be gated to a low level or a high level, depending on the software programming of this register. Figure 4-60 shows the normal behavior of sys_clkout2 when gated.

Figure 4-60. sys_clkout2 Gating Polarity Control



4.11.1.5.2 PRM_POLCTRL (PRM Polarity Control Register)

The PRM polarity control register allows the setting of the polarity of the external signals controlled by the PRM. It contains the following polarity control bits:

- CLKOUT_POL: Polarity of sys_clkout1
- CLKREQ_POL: Polarity of sys_clkreq
- EXTVOL_POL: Polarity of both sys_nvmode signals: sys_nvmode1 and sys_nvmode2

At device power up, CLKREQ_POL = 1. Depending on the system hardware implementation, these signals may or may not be used during device power up. For details about using these signals, see Section 4.7, *Clock Manager Functional Description*,

4.11.2 Clock Management Registers

4.11.2.1 System Clock Control Registers

4.11.2.1.1 PRM_CLKSRC_CTRL (Clock Source Control Register)

The clock source control register is dedicated to the clock source controls of the device. It contains the following bit fields:

- SYSCLKSEL: Indicates the oscillator mode (oscillator/bypass) and is automatically updated at power up
- AUTOEXTCLKMODE: Enables autogating for the system clock, depending on the device power state. The clock can be configured to be automatically gated when all domains are in idle state. When the gating condition is satisfied, the internal oscillator is turned off, if it is used. Otherwise, sys_clkreq is asserted to notify the external clock source to turn off.

NOTE: Power consumption is reduced with the SYS_CLK off; however, wake-up latency is increased because of oscillator stabilization time after the clock is turned on again.

- SYSCLKDIV: Input divider (1, 2) of the system clock,

4.11.2.1.2 PRM_CLKSETUP (Source-Clock Setup Register)

The source-clock setup register allows the setting of the setup time of the oscillator system clock, based on the number of 32-kHz clock cycles. This duration corresponds to the time required by the oscillator to stabilize before propagating the system clock.

Because the reset lasts long enough for oscillator stabilization, this register is not used at power-on reset of the device. This is ensured either by the external reset source (power IC) or by the reset extension in the PRCM (RSTTIME0 timer). The PRM_CLKSETUP register is cleared on cold reset only.

4.11.2.1.3 PRM_CLKSEL (Source-Clock Selection Register)

The PRCM.PRM_CKSEL[2:0] SYS_CLKIN_SEL bit field is used to select the input frequency of the system clock (12, 13, 16.8, 19.2, 26 or 38.4 MHz).

4.11.2.2 External Clock Output Control Registers

4.11.2.2.1 PRM_CLKOUT_CTRL (Clock Out Control Register)

The PRM clock out control register provides control to enable and disable the gating of the sys_clkout1 output clock.

4.11.2.2.2 CM_CLKOUT_CTRL (Clock Out Control Register)

The CM clock out control register provides control over the device output clock sys_clkout2, which can be used externally for functional or test purposes. The register allows the following:

- Selection of the source clock for sys_clkout2:
  - CORE_CLK
  - SYS_CLK
  - 96-MHz clock
  - 54-MHz clock
- Dividing-down the selected source clock by 1, 2, 4, 8, or 16
- Enabling/disabling of the gating of sys_clkout2

4.11.2.3 DPLL Clock Control Registers

A set of registers controls the clock features of the five DPLLs (DPLL1, DPLL3, DPLL4, and DPLL5):

- CM_CLKSELn_PLL_<processor_name>
- CM_CLKSELn_PLL
- CM_CLKEN_PLL_processor_name>
- CM_CLKEN_PLL
- CM_AUTOIDLE_PLL_processor_name>
- CM_AUTOIDLE_PLL
- CM_IDLEST_PLL_<processor_name>
- CM_IDLEST_CKGEN
- CM_IDLEST2_CKGEN

The following sections describe the purposes of these registers.

4.11.2.3.1 CM_CLKSELn_PLL_<processor_name> (Processor DPLL Clock Selection Register)

The processor DPLL clock selection register controls the clock configuration of DPLL1, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Selection of the fast bypass clock (CORE_CLK or CORE_CLK/2) in bypass mode

- Configuration of DPLL output clock divider values (M2 factor)

The device has two DPLL clock selection registers for DPLL1:

- CM_CLKSEL1_PLL_MPU: DPLL1 multiplier, divider, and fast bypass clock selection
- CM_CLKSEL2_PLL_MPU: DPLL1 output clock divider selection

4.11.2.3.2 CM_CLKSELn_PLL (DPLL Clock Selection Register)

The DPLL clock selection register controls the clock configuration for DPLL3, DPLL4, and DPLL5, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Configuration of DPLL output clock divider values

The device has following DPLL clock selection registers for DPLL3, DPLL4, and DPLL5:

- CM_CLKSEL1_PLL: DPLL3 multiplier, divider, and output clock division configuration. Source selection for the 54-MHz and 48-MHz clock (48M_FCLK) between DPLL4 output and sys_altclk.
- CM_CLKSEL2_PLL: DPLL4 multiplier and divider configuration
- CM_CLKSEL3_PLL: Divider configuration for 96-MHz clock (96M_FCLK)
- CM_CLKSEL4_PLL: DPLL5 multiplier and divider configuration
- CM_CLKSEL5_PLL: Divider configuration for 120-MHz clock (120M_FCLK)

4.11.2.3.3 CM_CLKEN_PLL_<processor_name> (Processor DPLL Clock Enable Register)

The processor DPLL clock enable register allows the enabling or disabling of DPLL1. It allows an immediate setting of the DPLL.

The device clock enable registers for DPLL1 is CM_CLKEN_PLL_MPU: DPLL1.

The CM_CLKEN_PLL_<processor_name> register allows programmable control of the following DPLL features:

- Low-power bypass mode/lock mode selection
- Automatic recalibration enable/disable
- Programmable internal frequency range of the DPLL
- Frequency ramping feature disabled and enabled with programmable step duration (4 s, 20 s, or 40 s)
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transitions:
  - From bypass to lock
  - From stop mode to lock
  - From lock to relock

NOTE: DPLL1 enters its internal power state (MNBYPASS) after being released from reset or when a multiplier value of 0 or 1 is loaded into the DPLL. Therefore, even if the CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL bit field is reset to the low-power bypass mode, DPLL1 automatically transitions to MNBYPASS mode, because the multiplier value (the CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT bit field) resets to 0.

4.11.2.3.4 CM_CLKEN_PLL (DPLL Enable Register)

The DPLL enable register allows control of DPLL3 DPLL4, and DPLL5. It allows an immediate setting of the DPLLs. This register controls the following features of the two DPLLs:

- DPLL operation mode:
  - Low-power bypass, fast-relock bypass, and lock modes for DPLL3
  - Low-power bypass and lock modes for DPLL4
- Programmable automatic recalibration
- Programmable internal frequency range for the DPLL
- Frequency ramp-up feature disable/enable with programmable step duration
- The DPLL3 output M3X2 and the DPLL4 outputs M2X2, M3X2, M4X2, M5X2, and M6X2 clock paths can be powered down. However, the setting takes effect only when the output clock is gated. It is also powered down whenever the DPLL is in stop mode, regardless of the software settings.
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transition:
  - From bypass to lock
  - From stop mode to lock
  - From lock to relock

4.11.2.3.5 CM_AUTOIDLE_PLL_<processor_name> (Processor DPLL Autoidle Register)

The processor DPLL autoidle register allows the enabling/disabling of the automatic processor DPLL activity control. In automatic mode, the DPLL automatically enters low-power stop mode when the DPLL clock is not required. It is also restarted automatically.

The following is the device DPLL auto-control register:

- CM_AUTOIDLE_PLL_MPU: DPLL1 autoidle mode control.

4.11.2.3.6 CM_AUTOIDLE_PLL (DPLL Autoidle Register)

The DPLL autoidle register allows the enabling/disabling of the automatic mode-switching control for DPLL3 and DPLL4. This automatic mode takes effect only when the DPLLs are locked.

DPLL3 can be configured to automatically switch to either low-power bypass mode or low-power stop mode when the CORE domain clock is not required.

DPLL4 can be configured to automatically switch to low-power stop mode when the PER domain clock is not required.

4.11.2.3.7 CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register)

The DPLL5 autoidle register allows the enabling/disabling of the automatic mode-switching control. This automatic mode takes effect only when the DPLL is locked.

When enabled, DPLL5 is automatically switched to low-power stop mode whenever the 120-MHz output clock is gated.

4.11.2.3.8 CM_IDLEST_CKGEN (Source-Clock Idle-Status Register)

The source-clock idle-status register provides a status of DPLL3 and DPLL4 clock activity. It also provides the status of the functional clocks derived from DPLL4 output.

The activity status for DPLL3 and DPLL4 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The functional 96-MHz clock is active, or not.
- The functional 48-MHz clock is active, or not.
- The functional 12-MHz clock is active, or not.
- The functional 54-MHz clock is active, or not.

The functional 96-MHz clock and all other functional clocks derived from it are active only when DPLL4 is locked and the clock is required.

The functional 48-MHz and 12-MHz clocks are qualified as active only if the clock is required and when the external alternate clock is selected as the source clock.

The functional 54-MHz clock (DSS_TV_CLK) is active only when DPLL4 is locked, selected as the source clock, and required.

4.11.2.3.9 CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register)

The source-clock idle-status register provides the status of DPLL5 clock activity. It also provides the status of the functional clocks derived from DPLL5 output.

The activity status for DPLL5 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The 120-MHz functional clock is active, or not.
- The output stage of the 120-MHz functional clock is active, or not.

4.11.2.3.10 CM_IDLEST_PLL_<processor_name> (Processor DPLL Idle-Status Register)

The processor DPLL idle-status register indicates the status of the processor DPLL: whether it is in locked or bypass mode.

The device DPLL idle-status register is:

- CM_IDLEST_PLL_MPU: DPLL1 activity status.

4.11.2.4 Power-Domain Clock Control Registers

An identical set of registers controls the clock features of the domains in the device:

- CM_CLKSEL_<domain_name>
- CM_FCLKEN_<domain_name>
- CM_ICLKEN_<domain_name>
- CM_AUTOIDLE_<domain_name>
- CM_IDLEST_<domain_name>
- CM_CLKSTCTRL_<domain_name>
- CM_CLKSTST_<domain_name>
- CM_SLEEPDEP_<domain_name>

The following sections describe the purposes of these registers.

4.11.2.4.1 CM_CLKSEL_<domain_name> (Clock Select Register)

The clock select register controls the selection of the module or subsystem input clock frequency (except for the processor modules). Therefore, it deals only with modules or subsystems for which the frequency is scalable or selectable (the others have fixed and nonprogrammable frequencies). Both functional and interface clocks can be scaled. In most cases, their value is a divided value from the DPLL3 (CORE) or the DPLL4 (PER) output clock.

The device includes the following clock select registers:

- CM_CLKSEL_CORE: L3 and L4 interconnects and GPTIMER10 and 11 functional clocks
- CM_CLKSEL_DSS: DSS functional clock 1 and TV functional clock
- CM_CLKSEL_PER: GPTIMER2, 3, 4, 5, 6, 7, 8, and 9 functional clocks
- CM_CLKSEL_SGX: SGX subsystem functional clock
- CM_CLKSEL_WKUP: GPTIMER1 functional clock and reset manager counter clock and USIMOCP functional clock

The functional clock of the GPTIMER1 is selectable between the always-on 32K_FCLK and the system clock (SYS_CLK), but it is used with the 32-kHz clock.

The CM_CLKSEL_SGX register controls the SGX functional clock divider ratio, which is divided from the L3_ICLK source clock. Table 4-69 summarizes L3_ICLK ratio for different configurations of the register field.

Table 4-69. SGX Functional Clock Ratio Settings

CM_CLKSEL_SGX.CLKSEL_SGX	SGX_L3_FCLK
0x1	L3_ICLK
0x2	L3_ICLK/2
0x3	L3_ICLK/3
0x4	L3_ICLK/4

4.11.2.4.2 CM_FCLKEN_<domain_name> (Functional Clock Enable Register)

The functional clock enable register allows control of the functional clock activity of each module or subsystem. All module functional clocks are controllable by software, except for the MPU, interconnect, and memory subsystems, for which the clocks are automatically controlled by the PRCM.

The device has the following functional clock control registers:

- CM_FCLKEN1_CORE and CM_FCLKEN3_CORE: CORE domain nonsecure peripherals set
- CM_FCLKEN_DSS: DSS subsystem
- CM_FCLKEN_PER: PER domain peripherals set
- CM_FCLKEN_SGX: SGX subsystem
- CM_FCLKEN_WKUP: WKUP domain peripherals set
- CM_FCLKEN_USBHOST: HS USB Host subsystem

The software effect is immediate and direct. The functional clock is turned on as soon as the bit is set, and turned off if the bit is cleared and the clock is not required by any module. On module wakeup, the functional clock can be automatically restarted.

NOTE: The functional clock supplies the functional part of a module or subsystem, which is not operational without its functional clock. In some cases, a module or a subsystem may require multiple functional clocks.

4.11.2.4.3 CM_ICLKEN_<domain_name> (Interface Clock Enable Register)

The interface clock enable register allows control of the interface clock activity of each module or subsystem. This register provides control over each module in the device.

The device has following interface clock control registers:

- CM_ICLKEN1_CORE, CM_ICLKEN2_CORE, and CM_ICLKEN3_CORE: CORE domain peripherals set
- CM_ICLKEN_DSS: DSS subsystem
- CM_ICLKEN_PER: PER domain peripherals set
- CM_ICLKEN_SGX: SGX subsystem
- CM_ICLKEN_WKUP: WKUP domain peripherals set
- CM_ICLKEN_USBHOST: HS USB Host subsystem

This register has an immediate effect, causing the source of the interface clock to be effectively cut (if the appropriate bit is cleared and no module requires this clock) or activated (if the appropriate bit is set).

Independent functional and interface clock control registers provide potential power savings for each module. For example, because the configuration port and interface of the module are still active, disabling a functional clock of a module while keeping its interface clock active (leaving the module inactive but allowing access to its registers) reduces power consumption.

When the interface clock is disabled, the module cannot communicate with the reset of the device; therefore, it is in idle mode. For example, the interface clock of a peripheral can be disabled while its functional clock is active; it is then idled, from the device standpoint, while it can detect any external event. This configuration typically allows a main part of the device to go into idle mode while keeping a peripheral active and ready to wake up from an external event.

Because a module may or may not be able to function without its functional or interface clocks, power-management strategies must be adapted accordingly. This relation is programmable and is defined in the CLOCKACTIVITY bits of the module SYSCONFIG register; therefore, it requires consistent programming of the CM_FCLKEN and CM_ICLKEN registers.

NOTE: The interface clock ensures proper communication between any module and the interconnect (L3 or L4), in most cases supplying the module interface and registers.

4.11.2.4.4 CM_AUTOIDLE_<domain_name> (Autoidle Register)

The autoidle register holds an AUTOIDLE bit per module that belongs to the related domain. Each AUTOIDLE bit enables/disables automatic (hardware) gating of a module interface clock.

When AUTOIDLE and ICLKEN are set for a module, the module interface clock is managed automatically (that is, by hardware control) according to the domain clock activity; for example, stopped before a domain sleep transition and reenabled on wakeup. Table 4-70 lists the possible autoidle settings for the interface clock.

Table 4-70. Interface Clock Autoidle Settings

CM_AUTOIDLE.AUTO_<module>	CM_ICLKEN.EN_<module>	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

The device has the following autoidle control registers:

- CM_AUTOIDLE1_CORE, CM_AUTOIDLE2_CORE, and CM_AUTOIDLE3_CORE: CORE domain peripherals set
- CM_AUTOIDLE_DSS: DSS subsystem
- CM_AUTOIDLE_PER: PER domain peripherals set
- CM_AUTOIDLE_WKUP: WKUP domain peripherals set
- CM_AUTOIDLE_USBHOST: HS USB Host subsystem

NOTE: For the SGX module, the automatic idle mode is always enabled, and is not software-controllable.

4.11.2.4.5 CM_IDLEST_<domain_name> (Idle-Status Register)

The idle-status register allows checking whether a target module is in idle mode or if an initiator module is in standby mode. The software should not access to a target module in idle mode. A target access, in this state, can lead to an error.

The idle mode of any module can depend on the configuration of the CM_FCLKEN_<domain_name> and CM_ICLKEN_<domain_name> registers, or may be controlled automatically by hardware, depending on the configuration of the CM_AUTOIDLE_<domain_name> registers.

The device has the following idle status registers:

- CM_IDLEST_MPU: MPU subsystem
- CM_IDLEST1_CORE, CM_IDLEST2_CORE, and CM_IDLEST3_CORE: CORE domain peripherals set
- CM_IDLEST_DSS: DSS
- CM_IDLEST_PER: Peripheral domain peripherals set
- CM_IDLEST_NEON: NEON subsystem
- CM_IDLEST_SGX SGX subsystem
- CM_IDLEST_WKUP: WKUP domain peripherals set

- CM_IDLEST_USBHOST: HS USB Host subsystem

4.11.2.4.6 CM_CLKSTCTRL_<domain_name>(Clock State Control Register)

The clock state control register holds a CLKTRCTRL_<clock domain> bit field for each clock domain in the domain. It controls the hardware- and software-supervised state transitions between active and inactive states. Table 4-71 lists the clock state transition settings.

Table 4-71. Clock State Transition Settings

CM_CLKSTCTRL_<pwr domain>. CLKTRCTRL_<clk domain>	Description
0x0	The automatic hardware-supervised mode is disabled. The clocks in a clock domain cannot be cut automatically. This prevents any power transition on the domain.
0x1	Starts software-supervised (forced) sleep transition on the domain. All clocks in the clock domain are automatically cut whenever the initiators in the modules are in standby mode.
0x2	Starts software-supervised (forced) wake-up transition on the domain. The clocks in the clock domain are restarted.
0x3	The automatic hardware-supervised mode is enabled, and the clocks in the clock domain are automatically cut whenever the modules and subsystem in the clock domain are in idle or standby mode and the domain dependencies are met.

The hardware-supervised mode and the software-supervised (forced) sleep mode are mutually exclusive. It is a software decision to program one mode or another, and the software programs the PRCM accordingly.

The hardware-supervised mode is coupled to the sleep and wake-up dependencies programmed in the PRCM, whereas the software-supervised mode must be independent of those dependencies. Therefore, the sleep and wake-up dependencies must be disabled before the software forces a sleep transition on a domain; otherwise, the forced-domain will be wakened immediately because of the wake-up dependency.

The device has the following clock state control registers:

- CM_CLKSTCTRL_MPU: MPU subsystem clock domain
- CM_CLKSTCTRL_CORE: L3 and L4 clock domains
- CM_CLKSTCTRL_DSS: DSS clock domain
- CM_CLKSTCTRL_PER: Peripherals clock domain
- CM_CLKSTCTRL_NEON: NEON clock domain
- CM_CLKSTCTRL_SGX: Graphics clock domain
- CM_CLKSTCTRL_EMU: Emulation clock domain
- CM_CLKSTCTRL_USBHOST: HS USB Host clock domain

The CORE domain has three clock domains (L3 and L4); it does not have forced sleep and forced wake-up ability.

Although the sleep transition in the MPU domain cannot be initiated by software using this register, a software-initiated forced wake-up capability exists. This can be used to wake up the MPU domain if it does not wake up when the CORE domain wakes up (the MPU wake-up-dependency PM_WKDEP_MPU[0] EN_CORE bit is set to 0).

If the hardware-supervised mode is enabled, the following occur:

- The MPU domain clock is automatically cut if the MPU executes the wait-for-interrupt instruction.
- The L3 domain clock is automatically cut when all initiators are in standby mode and slave ports are idled.
- The L4 domain clock is automatically cut when all peripherals and slave ports are idled.
- The DSS interface clock is automatically cut when it stops fetching data from the frame buffer (provided the MPU is also in standby mode, if sleep dependency in the MPU domain is enabled). The display functional clock is controlled only by the CM_FCLKEN_DSS register.
- The PER domain clock is automatically cut when all initiators are in standby mode and all slave ports

are in idle (provided the MPU is standby mode and the CORE domain is INACTIVE, if sleep dependency in their domains is enabled).

- Because of the hardwired sleep dependency between NEON and the MPU domain, NEON can go into idle only if the MPU goes into standby mode. The MPU domain must also be configured in automatic hardware supervised mode for the NEON domain idle transition to occur.
- The USBHOST domain clock is automatically cut whenever the USBHOST is in standby mode (provided MPU is also in standby mode, if sleep dependency in the MPU domain is enabled).

NOTE: Hardware-supervised mode must not be used for the SGX domain when smart-standby is enabled.

4.11.2.4.7 CM_CLKSTST_<domain_name> (Clock State Status Register)

The clock state status register logs the activity status of the domain clock. This includes the activity of the interface clocks running only on the domain.

The device has following clock state status registers:

- CM_CLKSTST_MPU: MPU subsystem clock activity
- CM_CLKSTST_CORE: L3 clock domain activity and L4 clock domain activity
- CM_CLKSTST_DSS: DSS clock activity
- CM_CLKSTST_PER: PER clock domain activity
- CM_CLKSTST_SGX: Graphics subsystem clock activity
- CM_CLKSTST_EMU: Emulation clock activity
- CM_CLKSTST_USBHOST: USBHOST clock activity

4.11.2.4.8 CM_SLEEPDEP_<domain_name> (Sleep Dependency Control Register)

The sleep dependency control register allows the enabling or disabling of the sleep transition dependency of a domain with respect to other domains.

The device has following sleep dependency registers:

- CM_SLEEPDEP_DSS: Display domain sleep dependency with the MPU domain
- CM_SLEEPDEP_PER: PER domain sleep dependencies with the MPU and CORE domains
- CM_SLEEPDEP_SGX: SGX domain sleep dependency with the MPU domain
- CM_SLEEPDEP_USBHOST: USBHOST domain sleep dependency with the MPU domain

Although the CORE domain is composed of L3 and L4 clock domains, the sleep dependency with the L3 clock domain is always enabled (not programmable by software); there is no sleep dependency between the PER domain and the CORE_L4 clock domain.

The dependencies listed in Table 4-72 can be enabled or disabled by software.

Table 4-72. Sleep Dependency Settings

Dependent Domain	Parent Domain	MPU	CORE-L3
DSS		Software controlled	
PER		Software controlled	Always enabled
SGX		Software controlled	
USBHOST		Software controlled	

4.11.2.5 Domain Wake-Up Control Registers

The following modules have programmable wake-up control:

- CORE domain:
  - USBTLL

  - McBSP 1 and 5
  - GPTIMER[10, 11]
  - UART[1,2]
  - I2C[1..3]
  - McSPI[1..4]
  - MMC[1,2, 3]
- PER domain:
  - McBSP[2..4]
  - GPTIMER[2..9]
  - UART 3
  - WDTIMER3
  - GPIO[2..6]
- WKUP domain:
  - GPTIMER[1, 12]
  - GPIO1
  - I/O pad
  - USIM OCP
- DSS domain:
  - DSS subsystem
- USBHOST domain:
  - HS USB Host subsystem

The registers in the following sections control the wake-up settings.

4.11.2.5.1 PM_WKEN_<domain_name> (Wake-Up Enable Register)

The wake-up enable register applies only to modules that can generate wake-up events. It allows the enabling or disabling of the wakeup of the related domain on a module or subsystem wake-up event. Each EN_<module> bit in the register enables/disables the wake-up event from the module to the PRCM.

The device has the following wake-up enable registers:

- PM_WKEN1_CORE and PM_WKEN3_CORE: CORE domain modules wake-up control
- PM_WKEN_DSS: Display subsystem (DSS) wake-up control
- PM_WKEN_PER: Peripheral domain modules wake-up control
- PM_WKEN_WKUP: WKUP domain modules wake-up control
- PM_WKEN_USBHOST: HS USB Host subsystem wake-up control

NOTE:

- The wake-up capability of GPTIMER12 (the secure timer) is not programmable, but is always enabled.
- The wake-up signals issued from the MPU INTC are nonmaskable in the PRCM. However, they cannot be generated if the corresponding interrupts are masked in the INTC.

4.11.2.5.2 PM_WKST_<domain_name> (Wake-Up Status Register)

The wake-up status register logs wake-up events from all modules. Each ST_<module> bit of this register logs a given module-generated wake-up event.

The device has the following wake-up status registers:

- PM_WKST1_CORE and PM_WKST3_CORE: CORE domain modules wake-up event status
- PM_WKST_PER: Peripheral domain modules wake-up event status

- PM_WKST_WKUP: WKUP domain modules wake-up event status
- PM_WKST_USBHOST: HS USB Host subsystem wake-up control

The functional clock of the module causing the wakeup automatically restarts on the wakeup, but the software must enable the functional clock (CM_FCLKEN_<domain_name> register) before clearing the wake-up status bit.

NOTE:

- Software must clear this register before a new sleep transition request; otherwise, the register prevents the sleep transition from occurring.
- If the PRM interrupt is enabled on a module wakeup, the PM_WKST_<domain_name> must be cleared before clearing the PRM_IRQSTATUS_<processor_name> interrupt status register.

4.11.2.5.3 PM_WKDEP_<domain_name> (Wake-Up Dependency Register)

The wake-up dependency register allows the enabling/disabling of a wake-up dependency between domains. When a domain wakes up, it can wake up another domain.

The device has the following wake-up dependency registers:

- PM_WKDEP_MPU: MPU domain wake-up dependency with the following domains:
  - CORE
  - WKUP
  - DSS
  - PER
- PM_WKDEP _DSS: DSS domain wake-up dependency with the following domains:
  - MPU
  - WKUP
- PM_WKDEP _PER: The PER domain has programmable wake-up dependency with the following domains:
  - MPU
  - WKUP
  - CORE

  The PER domain can be wakened only by a wakeup of the L3 clock domain, not by an L4 clock domain.
- PM_WKDEP _NEON: The NEON domain has programmable wake-up dependency with the following domain:
  - MPU
- PM_WKDEP _SGX: The SGX domain has programmable wake-up dependency with the following domains:
  - MPU
  - WKUP
- PM_WKDEP _USBHOST: The USBHOST domain has programmable wake-up dependency with the following domains:
  - MPU
  - WKUP
  - CORE

There is no wake-up dependency control for the WKUP domain, because it is always on.

Because the CORE domain wake-up dependencies are not programmable, the CORE domain always wakes up on a wake-up event on the following domains:

- MPU

- WKUP
- DSS
- SGX
- PER
- USBHOST

4.11.2.5.4 PM_<processor_name>GRPSEL_<domain_name> (Processor Group Selection Register)

The processor group selection register allows defining the group of modules in the domain that can wake up the MPU domain. This bit is effective only if the module wake-up capability is enabled (PM_WKEN_<domain_name> register).

The device has the following processor group selection registers:

- PM_MPUGRPSEL1_CORE and PM_MPUGRPSEL3_CORE: CORE domain modules MPU wake-up control
- PM_MPUGRPSEL_PER: PER domain modules MPU wake-up control
- PM_MPUGRPSEL_WKUP: WKUP domain modules MPU wake-up control
- PM_MPUGRPSEL_USBHOST: HS USB Host subsystem MPU wake-up control

NOTE:

- The wake-up capability of GPTIMER12 (the secure timer) is always attached to the MPU group.

4.11.3 Reset Management Registers

4.11.3.1 Reset Control

4.11.3.1.1 PRM_RSTTIME (Reset Time Register)

The reset time register provides control over reset duration. Two durations are configurable:

- RSTIME1: Minimum duration (by default, two cycles of the 32-kHz clock) of the global warm reset (sys_nreswarm) assertion for external devices, such as flash memories. At power-up reset, DPLLs are reset.
- RSTIME2: Minimum duration (by default, 16 cycles of the RM_ICLK clock) to control domain resets when the domain clocks are on.

For global cold and warm resets, the reset is applied for the RSTIME1 + RSTIME2 duration.

RSTIME1 and RSTIME2 can be reprogrammed for different behavior after the initial power up.

4.11.3.1.2 RM_RSTCTRL_<domain_name> (Reset Control Register)

The reset control register provides control over the local domain software reset.

Most device modules include an individual software reset that can be controlled using the related module SYS_CONFIG register.

The RM_RSTCTRL_<domain_name> register is used for specific subsystems or modules that do not support this local reset or that require a specific system control.

The PRM_RSTCTRL register also handles the global software warm reset control.

The device includes the following reset control registers:

- PRM_RSTCTRL: This register allows control of the assertion of the global software reset and the DPLL3 software reset. These bits are automatically cleared. Assertion of the DPLL3 software reset triggers a device global cold reset. The reset condition of this register depends on the bit field:
  - The RST_GS bit is set on any global source of reset (warm or cold).

– The RST_DPLL3 bit is set only on a global cold source of reset.

4.11.3.1.3 RM_RSTST_<domain_name> (Reset Status Register)

The reset status register logs any source that has generated a reset in the related domain. Depending on the domain, several causes of reset can be logged:

- Global device cold reset
- Global device warm reset
- domain transition (INACTIVE to ACTIVE)
- Software reset
- Processor emulation reset

The PRM_RSTST register logs the source of the global reset:

- External warm reset
- Secure watchdog reset
- MPU watchdog reset
- Security violation reset
- Global software reset and DPLL3 software reset
- Global cold reset

The device includes the following reset status registers:

- RM_RSTST_MPU
- RM_RSTST_CORE
- RM_RSTST_DSS
- RM_RSTST_PER
- RM_RSTST_NEON
- RM_RSTST_SGX
- RM_RSTST_EMU
- PRM_RSTST
- RM_RSTST_USBHOST

Only the RM_RSTST_CORE and PRM_RSTST registers log software sources of reset.

Each bit of these registers is set on the effective release of the respective reset signal.

4.11.4 Power Management Registers

4.11.4.1 PM_PWSTST_<domain_name> (Power State Status Register)

The power state status register provides the status of the power state transition of the domain.

This register may hold the following bit fields:

- POWERSTATESTATUS: Indicates the current power state of the domain (ON or INACTIVE)
- INTRANSITION: Indicates an ongoing power state transition from ON power state to INACTIVE and from INACTIVE to ON power state

The device has the following power state status registers:

- PM_PWSTST_MPU: MPU domain power state status
- PM_PWSTST_CORE: CORE domain power state status
- PM_PWSTST_SGX: SGX domain power state status
- PM_PWSTST_DSS: DSS domain power state status
- PM_PWSTST_PER: PER domain power state status
- PM_PWSTST_NEON: NEON domain power state status
- PM_PWSTST_EMU: EMU domain power state status
- PM_PWSTST_USBHOST: USBHOST domain power state status

The MPU domain power state status register indicates the current domain state.

The CORE domain power state status register indicates the current domain state.

The SGX, DSS, PER, NEON, USBHOST, and EMU domain power state status registers indicate the current domain (ON or INACTIVE) power state or that the domain transition is in progress.

4.11.5 Generic Programming Examples

4.11.5.1 Clock Control

The module clock management is controlled through three programmable steps:

- Enabling or disabling the functional clocks
- Enabling or disabling the interface clocks
- Enabling or disabling the automatic idle mode for the interface clocks

4.11.5.1.1 Enabling and Disabling the Functional Clocks

The flow chart in Figure 4-61 shows how to enable or disable a functional clock.

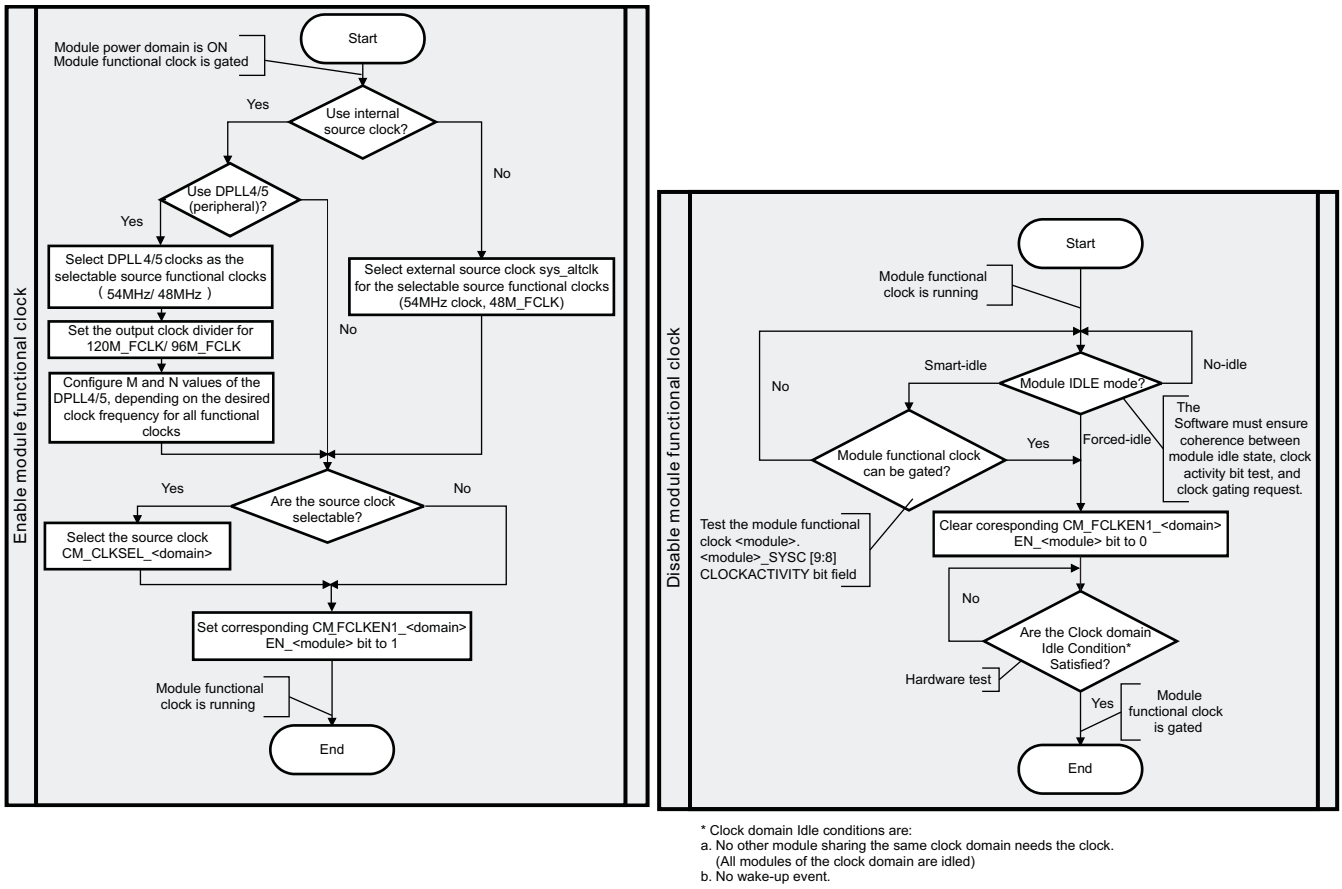
The first step before enabling a functional clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain_name>). It can be either an external source clock or an internal clock; that is, sys_altclk or DPLL4_M3X2_CLK for the DSS_TV_FCLK functional clock of the DSS.

If the source clock is a DPLL3 or DPLL4 output clock, the DPLL multiplier, divider, and output clock ratios are set in the CM_CLKSELn_PLL register, where n is from 1 to 3. The DPLL operating mode is set in the CM_CLKEN_PLL register.

The functional clock is enabled or disabled by writing the dedicated bit in the CM_FCLKEN_<domain_name> register. This bit has a direct effect on the clock activity:

- The functional clock is turned on if the bit is enabled and the clock is not yet active.
- The functional clock is turned off if the bit is disabled and the clock is not required by any other module.

Figure 4-61. Functional Clock Basic Programming Model



* Clock domain Idle conditions are:
a. No other module sharing the same clock domain needs the clock. (All modules of the clock domain are idled)
b. No wake-up event.

prcm-085

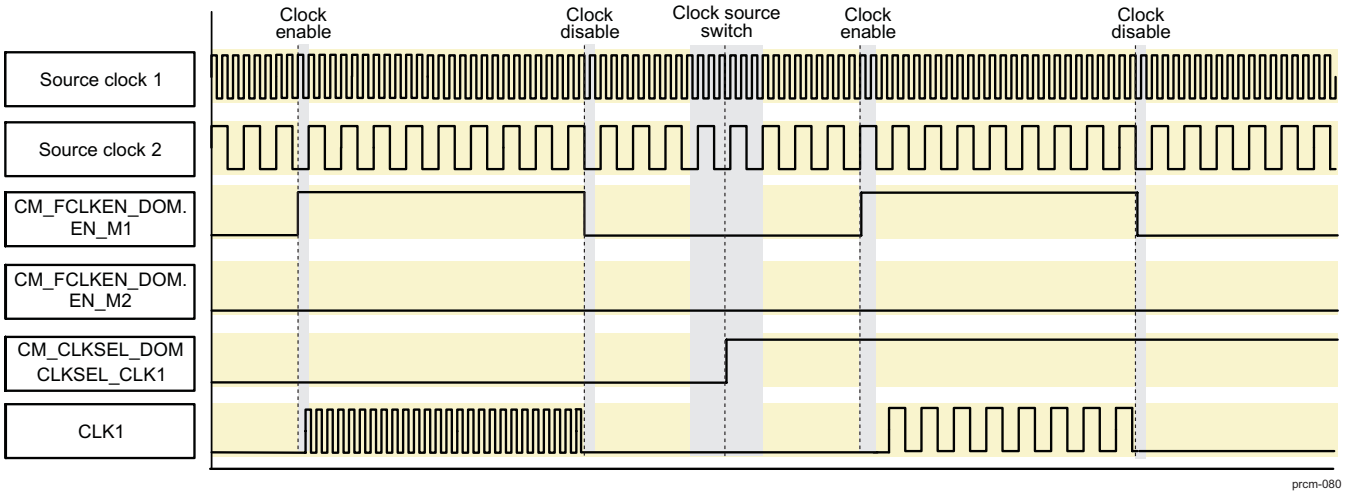
The functional clock must be disabled before switching or scaling its source clock. This means that all the modules using the particular functional clock must not be active during clock switching. To switch a source clock, perform the following sequence:

1. Disable the functional clock by setting the CM_FCLKEN_<domain>EN_<module> bits to 0.
2. Modify the CM_CLKSEL_<domain>CLKSEL_<clock> bits to select the new clock source or clock divider.
3. Enable the functional clock by setting the CM_FCLKEN_<domain>EN_<module> bits to 1.

The timing diagram in Figure 4-62 is a generic example of this sequencing for a functional clock (CLK1). The source clock can be switched between source clock 1 and source clock 2 using the CM_CLKSEL_DOM.CLKSEL_CLK1 bit (source clock 1 is selected when the bit is set to 0; otherwise, source clock 2 is selected). CLK1 can be requested by two modules, M1 and M2. The CM_FCLKEN_DOM.EN_M1 and CM_FCLKEN_DOM.EN_M2 bits control the functional clock enable for the two modules.

NOTE: The activation or deactivation of the clock is implementation-dependent, not one cycle of the source clock, as shown in Figure 4-62.

Figure 4-62. Functional Clock Switching



The following functional clocks require this switching sequence:

- sys_clkout2
- 48M_FCLK (and all gated versions of it)
- 12M_FCLK (and all gated versions of it)
- DSS_TV_CLK
- GPTx_FCLK (with x = 1, 10, and 11)
- GPTx_ALWON_FCLK (with x = 2 up to 9)

4.11.5.1.2 Enabling and Disabling the Interface Clocks

The flow chart in Figure 4-63 shows the enable/disable sequence of the interface clock.

The first step before enabling an interface clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain>). This register allows selection of the interconnect frequency (L3_ICLK, L4_ICLK) from among several divider ratios.

The interface clock is enabled or disabled by writing the dedicated bit in the CM_ICLKEN_<domain> register. This bit has a direct effect on the clock activity:

- The interface clock is turned on if the bit is enabled and the clock is not yet active.
- The interface clock is turned off if the bit is disabled and the clock is not required by any other module.

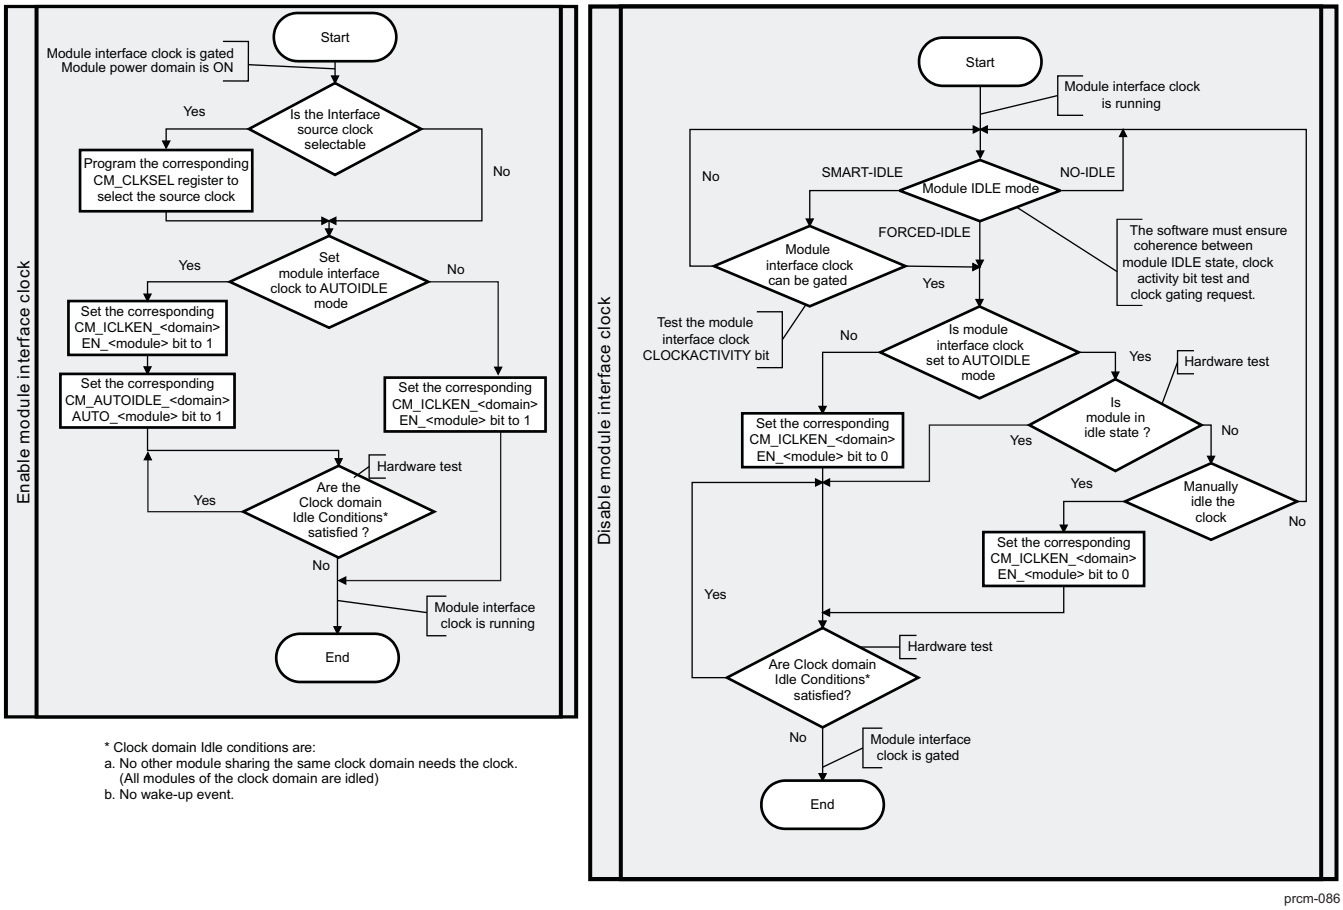
The interface clock can be automatically enabled or disabled by the PRCM, based on hardware conditions. This automatic clock activity control mode is enabled by writing the corresponding bit in the CM_AUTOIDLE_<domain > register. It takes effect only if the interface clock is enabled (the corresponding bit in the CM_ICLKEN_<domain > is set to 1).

The hardware conditions for automatic gating (deactivation) of the clock are as follows:

- The module activity; that is, the module is inactive.
- The domain activity; that is, all modules in the domain are inactive.

The software can read the idle status register CM_IDLESTAT_<domain> at any time to know whether the module is accessible. A module is inaccessible if its idle status bit is set. Accessing an idle module generates an error (if the interface clock is still running) or a time-out (if the interface clock is cut).

Figure 4-63. Interface Clock Basic Programming Model



The frequency ratio between the CORE_CLK, the L3_ICLK, and the L4_ICLK is configured by setting the corresponding CM_CLKSEL_CORE register bit fields. This configuration must be done before switching DPLL3 to lock mode. In this way, the clock ratio is switched while DPLL3 is operating at system clock frequency, and then only DPLL3 is switched to high-frequency locked mode.

If the configuration of the interface clock needs to be changed, first put DPLL3 in bypass mode, select the new configuration, and then relock DPLL3.

NOTE: When performing frequency scaling, the clock division can be done directly by programming the DPLL output divider. In this case, there is no need to change the configuration of the interface clock.

4.11.5.1.3 Enabling and Disabling the INACTIVE State

The flow chart in Figure 4-64 shows how to put a domain into INACTIVE state.

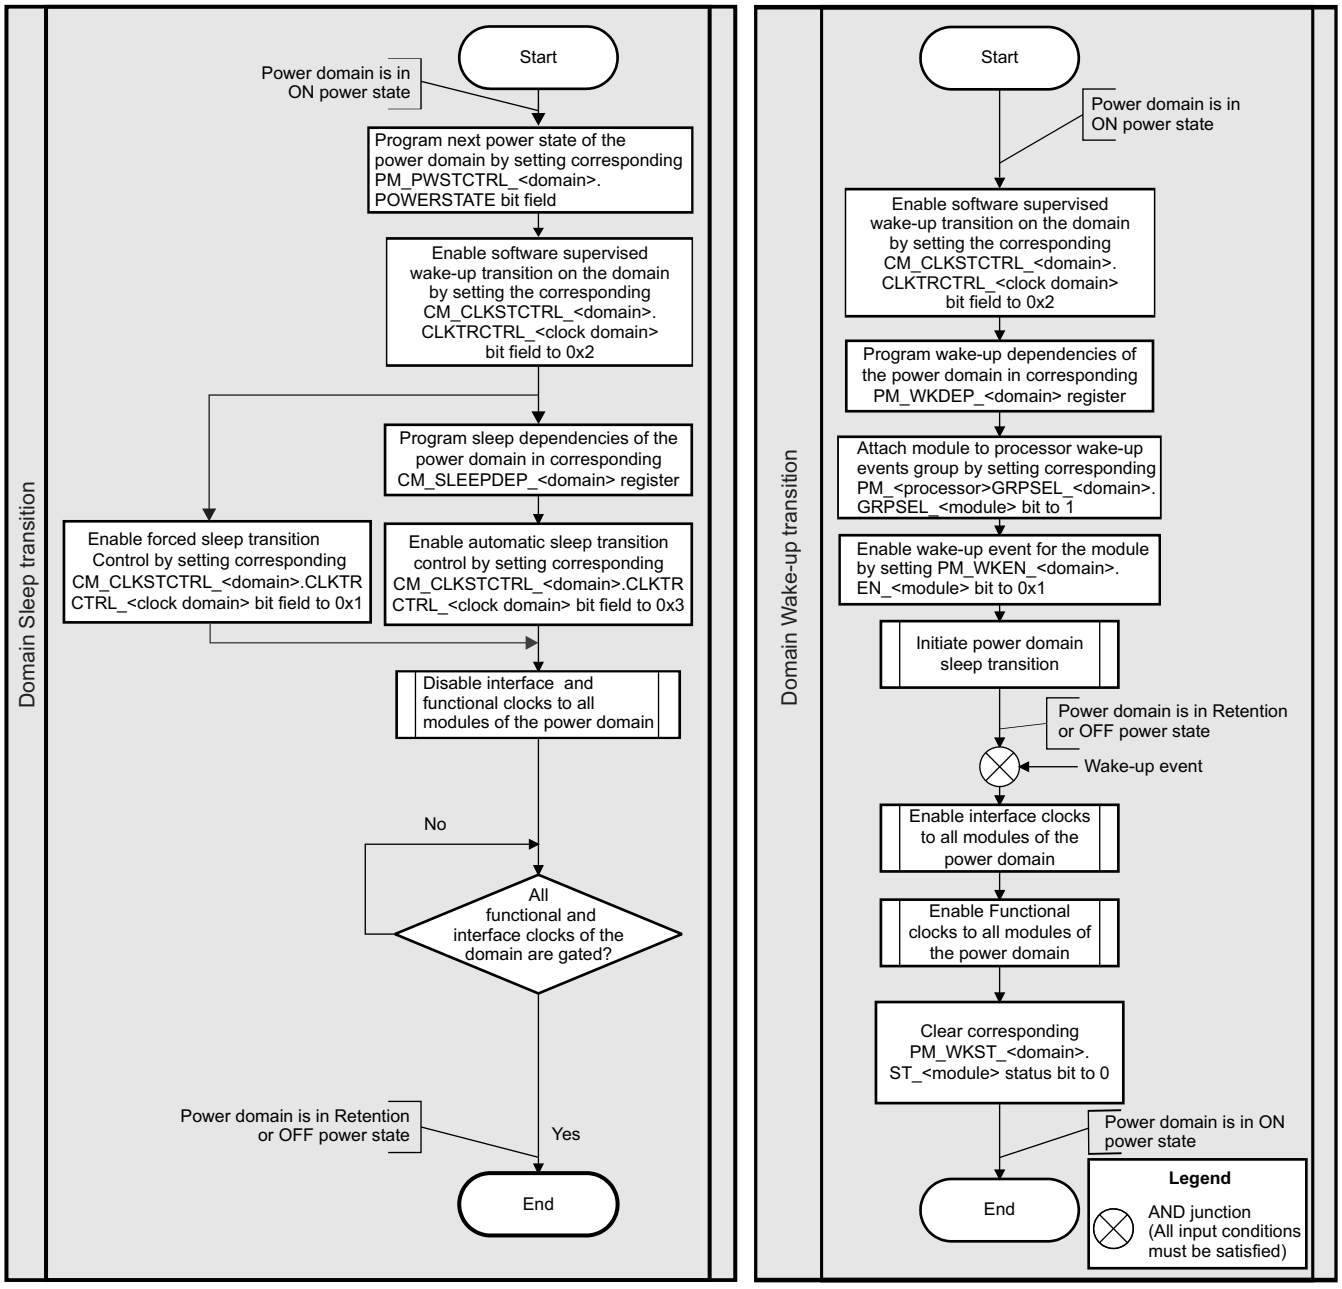
A domain is said to be in INACTIVE state if:

- All the functional and interface clocks of the domain are gated (deactivated).
- All the initiator modules are in standby mode.
- All the dependent domains have reached their mute state. The sleep dependency between the domains is configured by programming the CM_SLEEPDEP_<domain> register.

The domain transition from ACTIVE state to INACTIVE state is effective only if the CM_CLKSTCTRL_<domain> register is programmed for hardware-supervised state transition.

The CM_CLKSTST_<domain> register identifies whether a domain or a clock domain within the domain is accessible. A domain is inaccessible if its corresponding bit in the CM_CLKSTST_<domain > register is set to 1.

Figure 4-64. Domain INACTIVE STATE Basic Programming Model



prcm-087

4.11.5.1.4 Processor Clock Control

The flow chart in Figure 4-65 shows the control sequence of the processor clock.

The processor source clock is generated by the dedicated processor DPLL (DPLL1). After power up, the processor DPLL is in bypass or stop mode. This means the processor clock is either the system clock or is shut off.

The first step is to program the multiplier and divider ratios of the processor DPLL. Those two values are written in the CM_CLKSEL1_PLL_processor> register.

For frequency scaling, the processor DPLL integrates an additional divider to scale down the synthesized clock. The value of this second divider is written in the CM_CLKSEL2_PLL_processor> register. This divider can be configured dynamically (while the processor executes instructions), and the DPLL output clock is scaled without any glitches.

The processor DPLL must be locked at a desired frequency, provided the clock frequency is higher than the system clock. It can then be set to low-power bypass mode when the high-frequency clock is not required. The DPLL operating mode (locked or bypassed) is controlled by programming the CM_CLKEN_PLL_processor> register.

The processor clock can be switched automatically, based on hardware conditions, between the processor DPLL synthesized clock and a bypass clock. This mode is enabled by programming the corresponding mode in the CM_AUTOIDLE_PLL_processor> register. It takes effect only if the processor DPLL is locked (the CM_CLKEN_PLL_processor> register is set in lock mode).

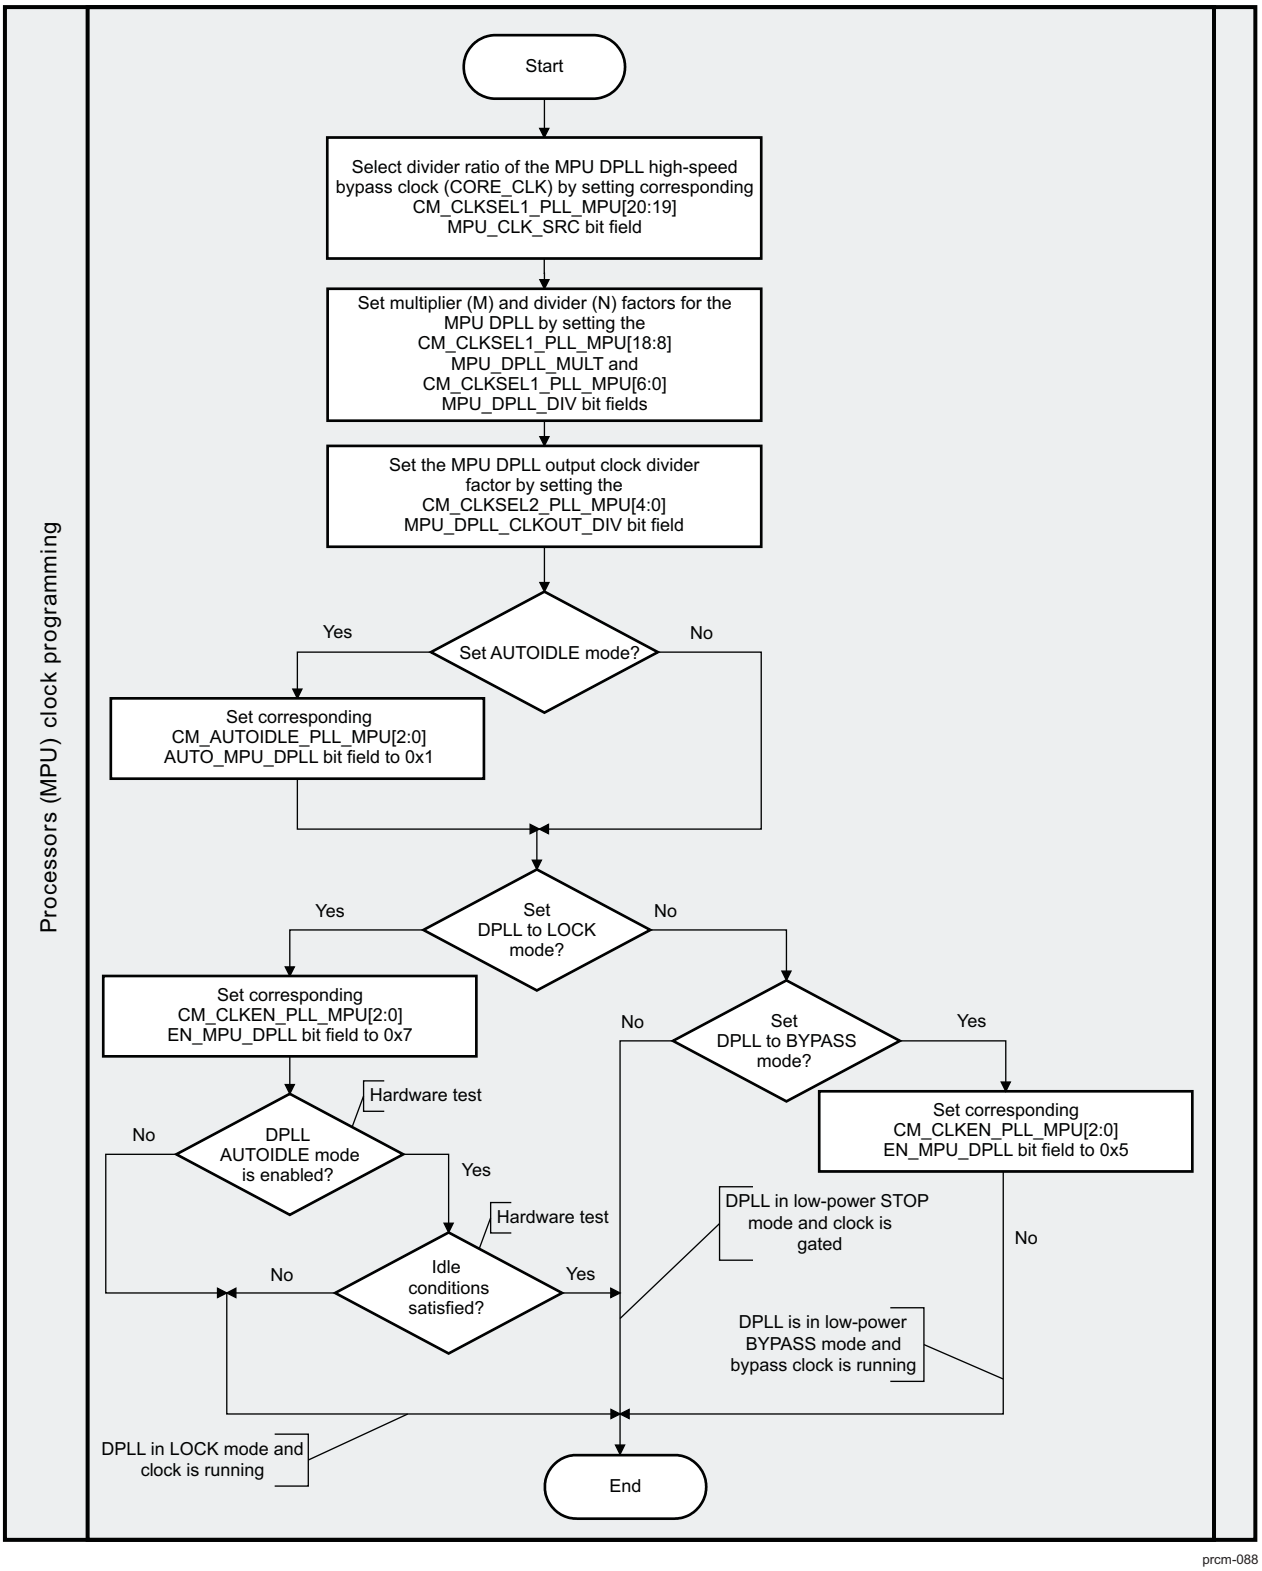
The HS bypass clock for the processor DPLL can be:

- The DPLL3 output clock (CORE_CLK)
- The DPLL3 output clock (CORE_CLK) divided by 2

The HS bypass clock is selected by programming the CM_CLKSEL1_PLL_processor > register.

The software can read the CM_IDLEST_PLL_<processor > register at any time to determine whether the DPLL is in lock mode (DPLL output is a high-frequency synthesized clock) or bypass mode (DPLL output is not the synthesized clock; the DPLL output is the bypass clock, or the DPLL is in transitioning state).

Figure 4-65. Processor Clock Basic Programming Model



4.11.5.2 Reset Management

The reset sequence is hardware-driven. On power on, once all the reset sources have been released, the PRM holds the entire device under reset long enough to ensure the stabilization of the power IC voltages and the oscillator system clock frequency. This reset delay is programmed in the PRM_RSTTIME register.

A domain reset status register (PRM_RSTST_domain>) identifies the source of the current reset applied to the domain. The software must clear this status bit after reset.

A global reset status register (PRM_RSTST) provides information on the global source of resets. All sources of warm reset are logged separately in this register, and all sources of cold reset are logged in a common status bit.

4.11.5.3 Wake-Up Control

The flow chart in Figure 4-66 shows the control sequence of the module wake-up event.

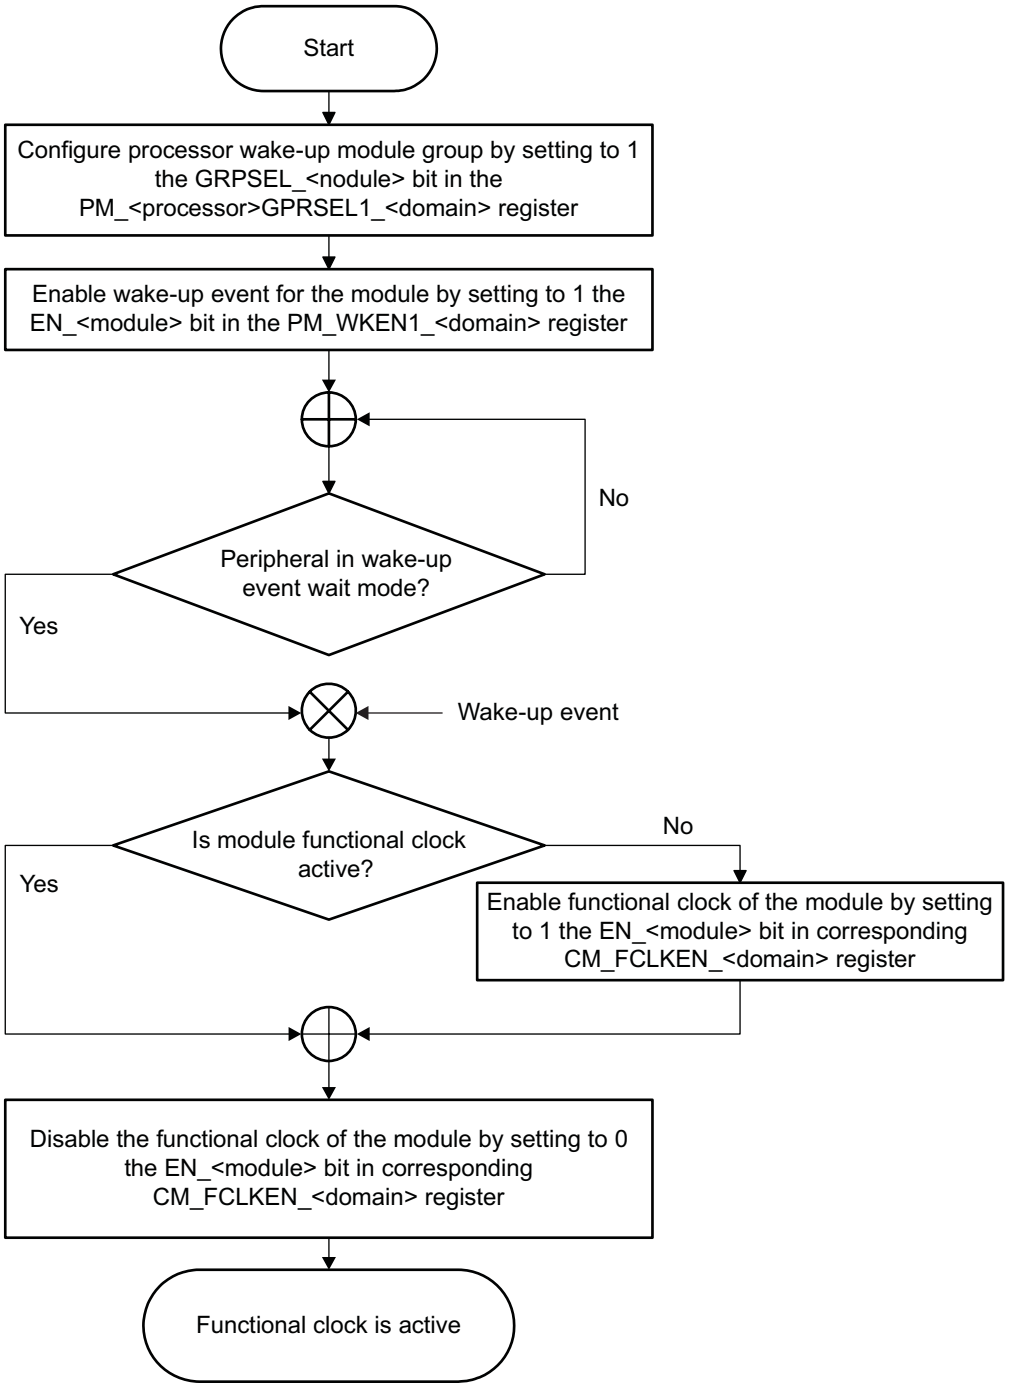
This procedure consists of the following steps:

1. Program the PRCM to consider the wake-up event.
2. Switch to idle mode and wait for the wake-up event.
3. Wake up on the wake-up event and activate the module functional clock.
4. Acknowledge the wake-up event.

The peripheral that can generate a wake-up event must be attached to a group of wake-up event generating modules for one or both processors by programming the PM_<processor>GRPSEL register. Writing 1 to this register allows the corresponding processor to be wakened on a peripheral wake-up event, assuming that the peripheral wake-up capability has been enabled by programming the register PM_WKEN_<domain>.

After this is configured, the PRCM initiates a wake-up procedure on receiving the peripheral wake-up event. The peripheral functional clock must be reenabled by programming the CM_FCLKEN_<domain > register, and then the wake-up event can be acknowledged by clearing the PM_WKST_<domain > register.

Figure 4-66. Wake-Up Basic Programming Model



A domain A can have a functional dependency on a domain B. Thus, when domain A wakes up, it may be necessary to wake up domain B. This wake-up dependency is hardcoded for the CORE domain, but is programmable for the other domains through the PM_WKDEP_<domain> register.

4.11.5.4 Event Generator Programming Examples

The event generator feature allows the MPU domain to be switched between on and idled modes. This is intended to implement an efficient activity modulation of the MPU power state with minimum software support.

When the event generator is activated, the PRCM ensures that the CORE domain always follows the MPU domain activity.

The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers of the event generator counter allow the configuration of the on and off durations (the number of system clock cycles) for the MPU domain. The PRCM.PM_EVGENCTRL_MPU register allows the enabling/disabling of the event generator feature and control of the way on and off values are loaded in the counter.

There are three ways to load the counter with the next counting value:

- Load on update of the corresponding PRCM.PM_EVGENONTIM_MPU or PRCM.PM_EVGENOFFTIM_MPU register.
- Load the on-time value when the MPU domain wakes up, and the off-time value when the MPU domain starts the sleep transition (the MPU executes the WFI instruction).
- Automatically load the on-time value when the off-time value expires, and automatically load the off-time value when the on-time value expires.

When the counter times out at the end of the on/off time, it triggers the interrupt/wake-up transition, respectively. The software can use the on-time interrupt to trigger the WFI processor instruction to idle the processor clock. Similarly, the wake-up event at the end of the off time restarts the processor clock and interrupts the processor. To enable the corresponding interrupts, the MPU interrupts mask must be set in the PRCM.PRM_IRQENABLE_MPU register.

4.12 PRCM Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that unavailable features and unused modules have clocks properly gated.

Table 4-73 lists the physical addresses of the CM modules. Table 4-74 through Table 4-85 provide register mapping summaries of the CM registers and describe the bits in the individual registers.

Table 4-165 lists the physical addresses of the PRM modules. Table 4-166 through Table 4-170 provide register mapping summaries of the PRM registers and describe the bits in the individual registers.

Table 4-86. CM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4800 4800	**Instance**	OCP_System_Reg_CM
Description	This register contains the IP revision code for the CM part of the PRCM		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REV							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	0x10

4.12.1.2.2 CM_SYSCONFIG

Table 4-87. CM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4800 4810	**Instance**	OCP_System_Reg_CM
Description	This register controls the various parameters of the interface clock		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved: keep at reset value.	R	0x00000000
0	AUTOIDLE	Internal clock gating strategy (for the CM part of the PRCM) 0x0: Interface clock is free-running 0x1: Automatic clock gating strategy is enabled, based on the interface activity.	RW	0x1

4.12.1.3 MPU_CM Register Descriptions

4.12.1.3.1 CM_CLKEN_PLL_MPU

Table 4-88. CM_CLKEN_PLL_MPU

Address Offset	0x0000 0004		
Physical Address	0x4800 4904	**Instance**	MPU_CM
Description	This register allows controlling the DPLL1 modes.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					EN_MPU_DPLL_LPMODE	MPU_DPLL_RAMPTIME		MPU_DPLL_FREQSEL				EN_MPU_DPLL_DRIFTGUARD	EN_MPU_DPLL		

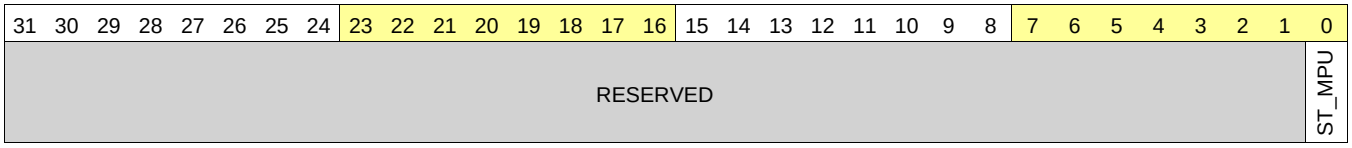
Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Reserved: keep at reset value.	R	0x000000
10	EN_MPU_DPLL_LPMODE	This bit allows to enable or disable the LP mode of the MPU DPLL. Writing this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL. 0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence. 0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.	RW	0x0
9:8	MPU_DPLL_RAMPTIME	The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and relock. The frequency ramping occurs in a maximum of four steps in frequency before the DPLL frequency lock indicator is asserted. The ramp step size is specified in the number of DPLL internal reference clock cycles. The internal DPLL reference clock cycle is given by: Fint = DPLL input reference clock frequency/(N + 1), where N is the value in the CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV bit field.This register is used to enable and disable the DPLL ramping feature. If enabled, it is also used to select a range of ramp step sizes. The step size used per range depends on the DPLL internal reference clock frequency: the lower the frequency, the smaller the ramp step size. 0x0: Disables the frequency ramping feature. 0x1: Ramp step size range is 2–40 Fint cycles. 0x2: Ramp step size range is 4–80 Fint cycles. 0x3: Ramp step size range is 12–240 Fint cycles.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:4	MPU_DPLL_FREQSEL	This bit field allows selecting the proper range of the DPLL1 internal frequency depending on the DPLL reference clock and the N divider. 0x3: 0.75 MHz—1.0 MHz 0x4: 1.0 MHz—1.25 MHz 0x5: 1.25 MHz—1.5 MHz 0x6: 1.5 MHz—1.75 MHz 0x7: 1.75 MHz—2.1 MHz 0xB: 7.5 MHz—10 MHz 0xC: 10 MHz—12.5 MHz 0xD: 12.5 MHz—15 MHz 0xE: 15 MHz—17.5 MHz 0xF: 17.5 MHz—21 MHz	RW	0x1
3	EN_MPU_DPLL_DRIFTGUARD	This bit allows to enable or disable the automatic recalibration feature of the MPU DPLL. The DPLL1 will automatically start a recalibration process upon assertion of the recal flag if this bit is set. 0x0: Disables the DPLL1 automatic recalibration mode 0x1: Enables the DPLL1 automatic recalibration mode	RW	0x0
2:0	EN_MPU_DPLL	DPLL1 control; Other enums: Reserved 0x5: Put the DPLL1 in low power bypass mode 0x7: Enables the DPLL1 in lock mode	RW	0x5

4.12.1.3.2 CM_IDLEST_MPU

Table 4-89. CM_IDLEST_MPU

Address Offset	0x0000 0020		
Physical Address	0x4800 4920	**Instance**	MPU_CM
Description	Modules access availability monitoring. This register is read only and automatically updated.		
Type	R		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x00000000
0	ST_MPU	MPU standby status. 0x0: MPU is active. 0x1: MPU is in standby mode.	R	0x1

Bits	Field Name	Description	Type	Reset
31	PWRDN_EMU_PERIPH	This bit allows to power-down or not the DPLL4_M6X2_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M6X2_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M6X2_CLK HSDIVIDER path. Writing this bit to 1 will take effect immediately.	RW	0x0
30	RESERVED	Reserved: keep at reset value.	R	0x0
29	PWRDN_DSS1	This bit allows to power-down or not the DPLL4_M4X2_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M4X2_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M4X2_CLK HSDIVIDER path. Writing this bit to 1 will take effect immediately.	RW	0x0
28	PWRDN_TV	This bit allows to power-down or not the DPLL4_M3X2_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M3X2_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M3X2_CLK HSDIVIDER path. Writing this bit to 1 will take effect immediately.	RW	0x0
27	PWRDN_96M	This bit allows to power-down or not the DPLL4_M2X2_CLK path. 0x0: Power-up the DPLL4_M2X2_CLK path. 0x1: Power-down the DPLL4_M2X2_CLK path. Writing this bit to 1 will take effect immediately.	RW	0x0
26	EN_PERIPH_DPLL_LPMODE	This bit allows to enable or disable the LP mode of the DPLL4. Writing this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL. 0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence. 0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.	RW	0x0

Bits	Field Name	Description	Type	Reset
25:24	PERIPH_DPLL_RAMPTIME	The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and relock. The frequency ramping occurs in a maximum of four steps in frequency before the DPLL frequency lock indicator is asserted. The ramp step size is specified in the number of DPLL internal reference clock cycles. The internal DPLL reference clock cycle is given by: Fint = DPLL input reference clock frequency/(N + 1), where N is the value in the CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field. This register is used to enable and disable the DPLL ramping feature. If enabled, it is also used to select a range of ramp step sizes. The step size used per range depends on the DPLL internal reference clock frequency: the lower the frequency, the smaller the ramp step size. 0x0: Disables the frequency ramping feature. 0x1: Ramp step size range is 2–40 Fint cycles. 0x2: Ramp step size range is 4–80 Fint cycles. 0x3: Ramp step size range is 12–240 Fint cycles.	RW	0x0
23:20	PERIPH_DPLL_FREQSEL	This bit field allows selecting the proper range of the DPLL4 internal frequency depending on the DPLL reference clock and the N divider. 0x3: 0.75 MHz—1.0 MHz 0x4: 1.0 MHz—1.25 MHz 0x5: 1.25 MHz—1.5 MHz 0x6: 1.5 MHz—1.75 MHz 0x7: 1.75 MHz—2.1 MHz 0xB: 7.5 MHz—10 MHz 0xC: 10 MHz—12.5 MHz 0xD: 12.5 MHz—15 MHz 0xE: 15 MHz—17.5 MHz 0xF: 17.5 MHz—21 MHz	RW	0x1
19	EN_PERIPH_DPLL_DRIFTGUARD	This bit allows to enable or disable the automatic recalibration feature of the DPLL4. The DPLL4 will automatically start a recalibration process upon assertion of the recal flag if this bit is set. 0x0: Disables the DPLL4 automatic recalibration mode 0x1: Enables the DPLL4 automatic recalibration mode	RW	0x0
18:16	EN_PERIPH_DPLL	DPLL4 control; Other enums: Reserved 0x1: Put the DPLL4 in low power stop mode 0x7: Enables the DPLL4 in lock mode	RW	0x1
15:13	RESERVED	Reserved: keep at reset value.	R	0x0
12	PWRDN_EMU_CORE	This bit allows to power-down or not the DPLL3_M3X2 HSDIVIDER path. 0x0: Power-up the DPLL3_M3X2 HSDIVIDER path. 0x1: Power-down the DPLL3_M3X2 HSDIVIDER path. Writing this bit to 1 will take effect immediately.	RW	0x0
11	RESERVED	Reserved: keep at reset value.	R	0x0
10	EN_CORE_DPLL_LPMODE	This bit allows to enable or disable the LP mode of the DPLL3. Writing this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL. 0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence. 0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.	RW	0x0

Bits	Field Name	Description	Type	Reset
9:8	CORE_DPLL_RAMPTIME	The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and relock. The frequency ramping occurs in a maximum of four steps in frequency before the DPLL frequency lock indicator is asserted. The ramp step size is specified in the number of DPLL internal reference clock cycles. The internal DPLL reference clock cycle is given by: Fint = DPLL input reference clock frequency/(N + 1), where N is the value in the CM_CLKSEL1_PLL[14:8] CORE_DPLL_DIV bit field. This register is used to enable and disable the DPLL ramping feature. If enabled, it is also used to select a range of ramp step sizes. The step size used per range depends on the DPLL internal reference clock frequency: the lower the frequency, the smaller the ramp step size. 0x0: Disables the frequency ramping feature. 0x1: Ramp step size range is 2–40 Fint cycles. 0x2: Ramp step size range is 4–80 Fint cycles. 0x3: Ramp step size range is 12–240 Fint cycles.	RW	0x0
7:4	CORE_DPLL_FREQSEL	This bit field allows selecting the proper range of the DPLL3 internal frequency depending on the DPLL reference clock and the N divider. 0x3: 0.75 MHz—1.0 MHz 0x4: 1.0 MHz—1.25 MHz 0x5: 1.25 MHz—1.5 MHz 0x6: 1.5 MHz—1.75 MHz 0x7: 1.75 MHz—2.1 MHz 0xB: 7.5 MHz—10 MHz 0xC: 10 MHz—12.5 MHz 0xD: 12.5 MHz—15 MHz 0xE: 15 MHz—17.5 MHz 0xF: 17.5 MHz—21 MHz	RW	0x1
3	EN_CORE_DPLL_DRIFTGUARD	This bit allows to enable or disable the automatic recalibration feature of the DPLL3. The DPLL3 will automatically start a recalibration process upon assertion of the recal flag if this bit is set. 0x0: Disables the DPLL3 automatic recalibration mode 0x1: Enables the DPLL3 automatic recalibration mode	RW	0x0
2:0	EN_CORE_DPLL	DPLL3 control; Other enums: Reserved 0x5: Put the DPLL3 in low power bypass 0x6: Put the DPLL3 in fast relock bypass 0x7: Enables the DPLL3 in lock mode	RW	0x5

4.12.1.8.7 CM_CLKSTCTRL_DSS

Table 4-140. CM_CLKSTCTRL_DSS

Address Offset	0x0000 0048		
Physical Address	0x4800 4E48	**Instance**	DSS_CM
Description	This register enables the domain power state transition. It controls the hardware supervised domain power state transition between ACTIVE and INACTIVE states.		
Type	RW		

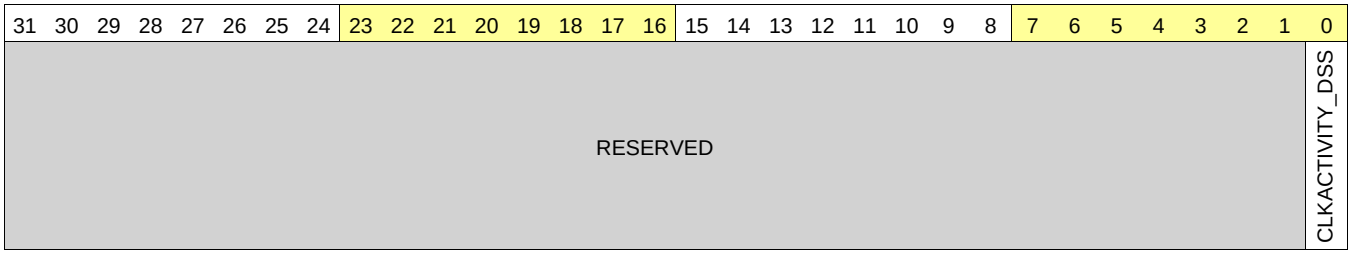
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														CLKTRCTRL_DSS	

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1:0	CLKTRCTRL_DSS	Controls the clock state transition of the DSS clock domain. 0x0: Automatic transition is disabled 0x1: Start a software supervised sleep transition on the domain 0x2: Start a software supervised wake-up transition on the domain 0x3: Automatic transition is enabled. Transition is supervised by the hardware.	RW	0x0

4.12.1.8.8 CM_CLKSTST_DSS

Table 4-141. CM_CLKSTST_DSS

Address Offset	0x0000 004C		
Physical Address	0x4800 4E4C	**Instance**	DSS_CM
Description	This register provides a status on the OCP interface clock activity in the domain.		
Type	R		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x00000000
0	CLKACTIVITY_DSS	Interface clock activity status 0x0: No domain Interface clock activity 0x1: Domain Interface clock is active	R	0x0

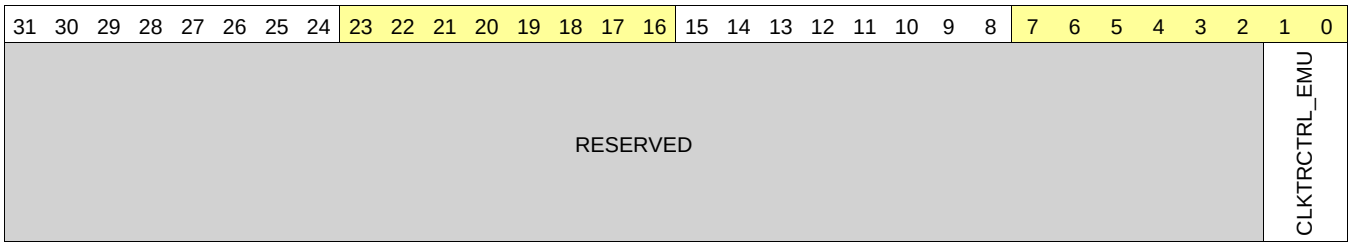
20:16	DIV_DPLL3	DPLL3_M3X2 clock divider factor (1 up to 16); Other enums: Reserved 0x1: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 1 0x2: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 2 0x3: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 3 0x4: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 4 0x5: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 5 0x6: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 6 0x7: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 7 0x8: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 8 0x9: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 9 0xA: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 10 0xB: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 11 0xC: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 12 0xD: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 13 0xE: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 14 0xF: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 15 0x10: EMU_CORE_ALWON_CLK is DPLL3 clock divided by 16	RW	0x10
15:14	RESERVED	Reserved: keep at reset value.	R	0x0
13:11	CLKSEL_TRACECLK	Selects the TRACE clock; Other enums: Reserved 0x1: TRACECLK.FCLK is the selected TRACE source clock divided by 1 0x2: TRACECLK.FCLK is the selected TRACE source clock divided by 2 0x4: TRACECLK.FCLK is the selected TRACE source clock divided by 4	RW	0x1
10:8	CLKSEL_PCLK	Selects the PCLK clock; Other enums: Reserved 0x2: PCLK.FCLK is the selected PCLK source clock divided by 2 0x3: PCLK.FCLK is the selected PCLK source clock divided by 3 0x4: PCLK.FCLK is the selected PCLK source clock divided by 4 0x6: PCLK.FCLK is the selected PCLK source clock divided by 6	RW	0x2
7:6	CLKSEL_PCLKX2	Selects the PCLKx2 clock; Other enums: Reserved 0x1: PCLKx2.FCLK is the selected PCLK source clock divided by 1 0x2: PCLKx2.FCLK is the selected PCLK source clock divided by 2 0x3: PCLKx2.FCLK is the selected PCLK source clock divided by 3	RW	0x1
5:4	CLKSEL_ATCLK	Selects the ATCLK clock; Other enums: Reserved 0x1: ATCLK.FCLK is the selected ATCLK source clock divided by 1 0x2: ATCLK.FCLK is the selected ATCLK source clock divided by 2	RW	0x1
3:2	TRACE_MUX_CTRL	Selection of TRACECLK.FCLK source clock 0x0: TRACE source clock is SYS_CLK 0x1: TRACE source clock is EMU_CORE_ALWON_CLK 0x2: TRACE source clock is EMU_PER_ALWON clock 0x3: TRACE source clock is EMU_MPU_ALWON clock	RW	0x0
1:0	MUX_CTRL	Selection of ATCLK.FCLK, PCLK.FCLK and PCLKx2.FCLK source clock 0x0: ATCLK, PCLK and PCLKx2 source clock is SYS_CLK 0x1: ATCLK, PCLK and PCLKx2 source clock is EMU_CORE_ALWON_CLK 0x2: ATCLK, PCLK and PCLKx2 source clock is EMU_PER_ALWON clock 0x3: ATCLK, PCLK and PCLKx2 source clock is EMU_MPU_ALWON_CLK	RW	0x0

4.12.1.10.2 CM_CLKSTCTRL_EMU

Table 4-151. CM_CLKSTCTRL_EMU

Address Offset	0x0000 0048		
Physical Address	0x4800 5148	**Instance**	EMU_CM
Description	This register allows to enable or disable software and hardware supervised transition between ACTIVE and INACTIVE states.		
Type	RW		

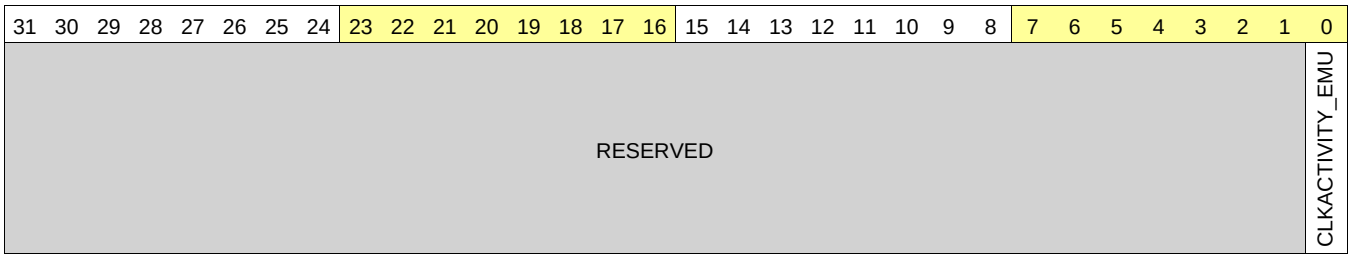


Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1:0	CLKTRCTRL_EMU	Controls the clock state transition of the EMULATION clock domain. 0x0: Reserved 0x1: Start a software supervised sleep transition on the domain 0x2: Start a software supervised wake-up transition on the domain or maintain emulation domain active. (force wakeup has to be kept asserted to keep Emulation domain ON) 0x3: Automatic transition is enabled. Transition is supervised by the hardware.	RW	0x2

4.12.1.10.3 CM_CLKSTST_EMU

Table 4-152. CM_CLKSTST_EMU

Address Offset	0x0000 004C		
Physical Address	0x4800 514C	**Instance**	EMU_CM
Description	This register provides a status on the clock activity in the domain (depends on the selected source clock).		
Type	R		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x00000000
0	CLKACTIVITY_EMU	Clock activity status (depends on the selected source clock) 0x0: No domain clock activity 0x1: Domain clock is active	R	0x0

4.12.1.10.4 CM_CLKSEL2_EMU

Table 4-153. CM_CLKSEL2_EMU

Address Offset	0x0000 0050		
Physical Address	0x4800 5150	**Instance**	EMU_CM
Description	This register provides override controls over the DPLL3.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved: keep at reset value.	R	0x000
19	OVERRIDE_ENABLE	This bit allows to enable or disable the emulation override controls 0x0: The emulation override controls are disabled 0x1: The emulation override controls are enabled	RW	0x0
18:8	CORE_DPLL_EMU_MULT	DPLL3 override multiplier factor (0 to 2047)	RW	0x000
7	RESERVED	Reserved: keep at reset value.	R	0x0
6:0	CORE_DPLL_EMU_DIV	DPLL3 override divider factor (0 to 127)	RW	0x00

4.12.1.10.5 CM_CLKSEL3_EMU

Table 4-154. CM_CLKSEL3_EMU

Address Offset	0x0000 0054		
Physical Address	0x4800 5154	**Instance**	EMU_CM
Description	This register provides override controls over the PERIPHERAL DPLL.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												OVERRIDE_ENABLE	PERIPH_DPLL_EMU_MULT											RESERVED	PERIPH_DPLL_EMU_DIV						

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved: keep at reset value.	R	0x000
19	OVERRIDE_ENABLE	This bit allows to enable or disable the emulation override controls 0x0: The emulation override controls are disabled 0x1: The emulation override controls are enabled	RW	0x0
18:8	PERIPH_DPLL_EMU_MULT	DPLL4 override multiplier factor (0 to 2047)	RW	0x000
7	RESERVED	Reserved: keep at reset value.	R	0x0
6:0	PERIPH_DPLL_EMU_DIV	DPLL4 override divider factor (0 to 127)	RW	0x00

4.12.1.11 Global_Reg_CM Register Descriptions

4.12.1.11.1 CM_POLCTRL

Table 4-155. CM_POLCTRL

Address Offset	0x0000 009C		
Physical Address	0x4800 529C	**Instance**	Global_Reg_CM
Description	This register allows setting the polarity of device outputs control signals.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															CLKOUT2_POL

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved: keep at reset value.	R	0x00000000
0	CLKOUT2_POL	Controls the external output clock 2 polarity when disabled 0x0: sys_clkout2 is gated low when inactive 0x1: sys_clkout2 is gated high when inactive	RW	0x0

4.12.1.12 NEON_CM Register Descriptions

4.12.1.12.1 CM_IDLEST_NEON

Table 4-156. CM_IDLEST_NEON

Address Offset	0x0000 0020		
Physical Address	0x4800 5320	**Instance**	NEON_CM
Description	Modules access availability monitoring. This register is read only and automatically updated.		
Type	R		

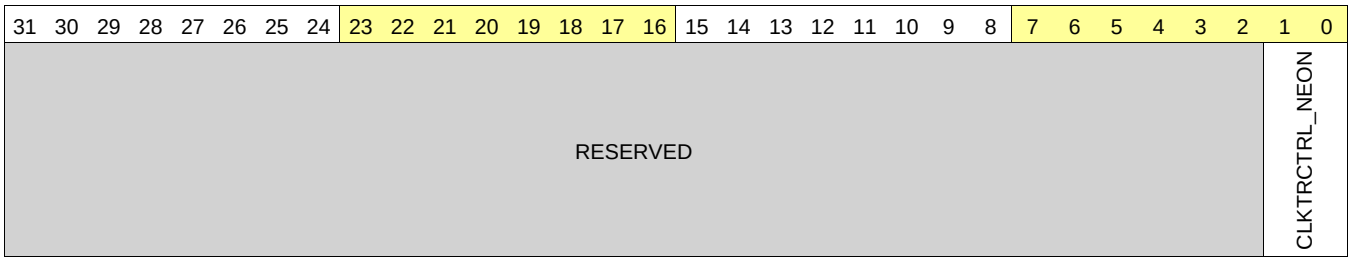
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															ST_NEON

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x00000000
0	ST_NEON	NEON standby status. 0x0: NEON is active 0x1: NEON is in standby mode	R	0x1

4.12.1.12.2 CM_CLKSTCTRL_NEON

Table 4-157. CM_CLKSTCTRL_NEON

Address Offset	0x0000 0048		
Physical Address	0x4800 5348	**Instance**	NEON_CM
Description	This register enables the domain power state transition. It controls the hardware supervised domain power state transition between ACTIVE and INACTIVE states.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1:0	CLKTRCTRL_NEON	Controls the clock state transition of the NEON clock domain. 0x0: Automatic transition is disabled 0x1: Start a software supervised sleep transition on the domain 0x2: Start a software supervised wake-up transition on the domain 0x3: Automatic transition is enabled. Transition is supervised by the hardware.	RW	0x0

4.12.1.13 USBHOST_CM Register Descriptions

4.12.1.13.1 CM_FCLKEN_USBHOST

Table 4-158. CM_FCLKEN_USBHOST

Address Offset	0x0000 0000		
Physical Address	0x4800 5400	**Instance**	USBHOST_CM
Description	Controls the modules functional clock activity.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														EN_USBHOST2	EN_USBHOST1

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	EN_USBHOST2	USB HOST 120-MHz functional clock control 0x0: USBHOST_120M_FCLK is disabled 0x1: USBHOST_120M_FCLK is enabled	RW	0x0
0	EN_USBHOST1	USB HOST 48-MHz functional clock control 0x0: USBHOST_48M_FCLK is disabled 0x1: USBHOST_48M_FCLK is enabled	RW	0x0

4.12.1.13.2 CM_ICLKEN_USBHOST

Table 4-159. CM_ICLKEN_USBHOST

Address Offset	0x0000 0010		
Physical Address	0x4800 5410	**Instance**	USBHOST_CM
Description	Controls the modules interface clock activity.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															EN_USBHOST

Bits	Field Name	Description	Type	Reset

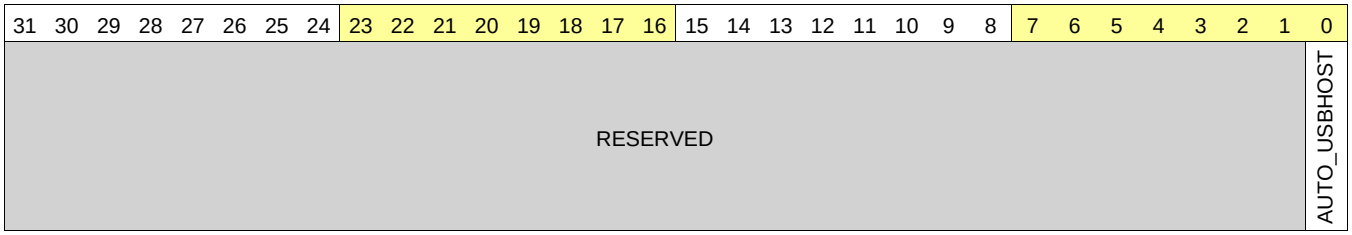
Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	R	0x00000000
1	ST_USBHOST_IDLE	USB HOST idle status. 0x0: USB HOST is active. 0x1: USB HOST is in idle mode and cannot be accessed.	R	0x1
0	ST_USBHOST_STDBY	USB HOST standby status. 0x0: USB HOST is active. 0x1: USB HOST is in standby mode.	R	0x1

4.12.1.13.4 CM_AUTOIDLE_USBHOST

Table 4-161. CM_AUTOIDLE_USBHOST

Address Offset	0x0000 0030		
Physical Address	0x4800 5430	**Instance**	USBHOST_CM
Description	This register controls the automatic control of the modules interface clock activity.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved: keep at reset value.	R	0x00000000
0	AUTO_USBHOST	USB HOST auto clock control. 0x0: USB HOST interface clock is unrelated to the domain state transition. 0x1: USB HOST interface clock is automatically enabled or disabled along with the domain state transition.	RW	0x0

4.12.1.13.5 CM_SLEEPDEP_USBHOST

Table 4-162. CM_SLEEPDEP_USBHOST

Address Offset	0x0000 0044		
Physical Address	0x4800 5444	**Instance**	USBHOST_CM
Description	This register allows enabling or disabling the sleep transition dependency of USB HOST domain with respect to other domain.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														EN_MPU	RESERVED

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	EN_MPU	MPU domain dependency 0x0: USB HOST domain sleep dependency with MPU domain is disabled. 0x1: USB HOST domain sleep dependency with MPU domain is enabled.	RW	0x0
0	RESERVED	Reserved: keep at reset value.	R	0x0

4.12.1.13.6 CM_CLKSTCTRL_USBHOST

Table 4-163. CM_CLKSTCTRL_USBHOST

Address Offset	0x0000 0048		
Physical Address	0x4800 5448	**Instance**	USBHOST_CM
Description	This register enables the domain power state transition. It controls the hardware supervised domain power state transition between ACTIVE and INACTIVE states.		
Type	RW		

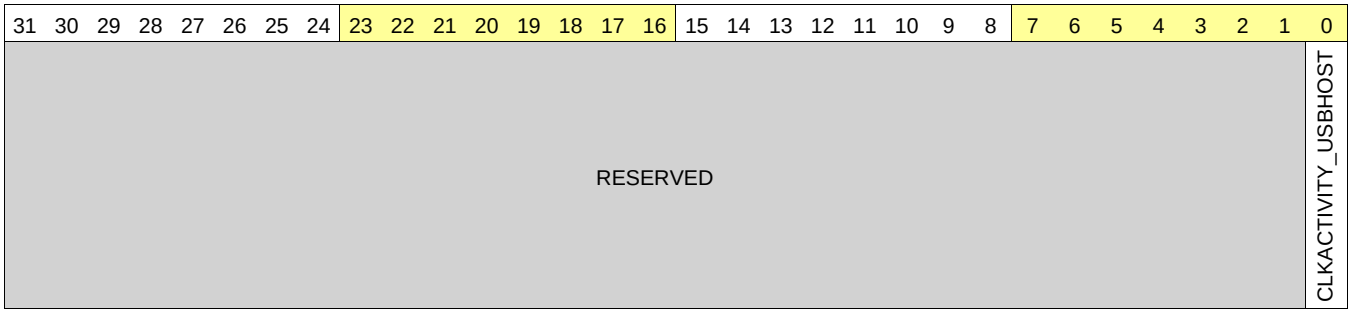
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														CLKTRCTRL_USBHOST	

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1:0	CLKTRCTRL_USBHOST	Controls the clock state transition of the USB HOST clock domain. 0x0: Automatic transition is disabled 0x1: Start a software supervised sleep transition on the domain 0x2: Start a software supervised wake-up transition on the domain 0x3: Automatic transition is enabled. Transition is supervised by the hardware.	RW	0x0

4.12.1.13.7 CM_CLKSTST_USBHOST

Table 4-164. CM_CLKSTST_USBHOST

Address Offset	0x0000 004C		
Physical Address	0x4800 544C	**Instance**	USBHOST_CM
Description	This register provides a status on the interface clock activity in the domain.		
Type	R		



Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x00000000
0	CLKACTIVITY_USBHOST	Interface clock activity status 0x0: No domain interface clock activity 0x1: Domain interface clock is active	R	0x0

4.12.2 PRM Module Registers

This section describes the PRM module registers.Table 4-165 lists the physical address of the PRM modules. Table 4-166 through Table 4-170 provide register mapping summaries and describe the bits in the individual registers.

Table 4-165. PRM Instance Summary

Module Name	Base address (hex)	Size	Section

4.12.2.2 OCP_System_Reg_PRM Register Descriptions

4.12.2.2.1 PRM_REVISION

Table 4-178. PRM_REVISION

Address Offset	0x0000 0004		
Physical Address	0x4830 6804	**Instance**	OCP_System_Reg_PRM
Description	This register contains the IP revision code for the PRM part of the PRCM		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REV							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	0x10

4.12.2.2.2 PRM_SYSCONFIG

Table 4-179. PRM_SYSCONFIG

Address Offset	0x0000 0014		
Physical Address	0x4830 6814	**Instance**	OCP_System_Reg_PRM
Description	This register controls the various parameters of the interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved: keep at reset value.	R	0x00000000
0	AUTOIDLE	Internal clock gating strategy (for the CM part of the PRCM) 0x0: Interface clock is free-running 0x1: Automatic clock gating strategy is enabled, based on the interface activity.	RW	0x1

4.12.2.2.3 PRM_IRQSTATUS_MPU

Table 4-180. PRM_IRQSTATUS_MPU

Address Offset	0x0000 0018		
Physical Address	0x4830 6818	**Instance**	OCP_System_Reg_PRM
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt. Write 1 to a given bit resets this bit. This registers applies on the interrupt line 0 mapped to the MPU interrupt controller.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

6	PERIPH_DPLL_RECAL_EN	DPLL4 recalibration mask 0x0: DPLL4 recalibration event is masked 0x1: DPLL4 recalibration event generates an interrupt	RW	0x0
5	CORE_DPLL_RECAL_EN	DPLL3 recalibration mask 0x0: DPLL3 recalibration event is masked 0x1: DPLL3 recalibration event generates an interrupt	RW	0x0
4	TRANSITION_EN	Software supervised transition completed event mask 0x0: Software supervised transition completed event is masked. 0x1: Software supervised transition completed event generates an interrupt.	RW	0x0
3	EVGENOFF_EN	Event Generator endOFFtime mask 0x0: End of OFF time event is masked 0x1: End of OFF time event generates an interrupt	RW	0x0
2	EVGENON_EN	Event Generator endONtime mask 0x0: End of ON time event is masked 0x1: End of ON time event generates an interrupt	RW	0x0
1	RESERVED	Reserved: keep at reset value.	R	0x0

Bits	Field Name	Description	Type	Reset
0	WKUP_EN	MPU peripherals group wake-up event mask 0x0: MPU peripherals group wake-up event is masked 0x1: MPU peripherals group wake-up event generates an interrupt	RW	0x0

4.12.2.3 MPU_PRM Register Descriptions

4.12.2.3.1 RM_RSTST_MPU

Table 4-182. RM_RSTST_MPU

Address Offset	0x0000 0058		
Physical Address	0x4830 6958	**Instance**	MPU_PRM
Description	This register logs the different reset sources of the MPU domain. Each bit is set upon release of the domain reset signal. Must be cleared by software.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				EMULATION_MPU_RST	RESERVED										GLOBALWARM_RST	GLOBALCOLD_RST

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reserved: keep at reset value.	R	0x00000
11	EMULATION_MPU_RST	Emulation reset Read 0x0: No emulation reset. Write 0x0: Status bit unchanged Read 0x1: MPU domain has been reset upon an emulation reset Write 0x1: Status bit is cleared to 0	RW	0x0
10:2	RESERVED	Reserved: keep at reset value.	R	0x000
1	GLOBALWARM_RST	Global warm reset Read 0x0: No global warm reset. Write 0x0: Status bit unchanged Read 0x1: MPU domain has been reset upon a global warm reset Write 0x1: Status bit is cleared to 0	RW	0x0
0	GLOBALCOLD_RST	Global cold reset Read 0x0: No global cold reset. Write 0x0: Status bit unchanged Read 0x1: MPU domain has been reset upon a global cold reset Write 0x1: Status bit is cleared to 0	RW	0x1

4.12.2.3.2 PM_WKDEP_MPU

Table 4-183. PM_WKDEP_MPU

Address Offset	0x0000 00C8		
Physical Address	0x4830 69C8	**Instance**	MPU_PRM
Description	This register allows enabling or disabling the wake-up of the MPU domain upon another domain wakeup events.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								EN_PER	RESERVED	EN_DSS	RESERVED				EN_CORE

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved: keep at reset value.	R	0x000000
7	EN_PER	PER domain dependency 0x0: MPU domain is independent of PER domain wake-up event. 0x1: MPU domain is woken-up upon PER domain wake-up event.	RW	0x1
6	RESERVED	Reserved: keep at reset value.	R	0x0
5	EN_DSS	DSS domain dependency 0x0: MPU domain is independent of DSS domain wake-up event. 0x1: MPU domain is woken-up upon DSS domain wake-up event.	RW	0x1
4:1	RESERVED	Reserved: keep at reset value.	R	0x2
0	EN_CORE	CORE domain dependency 0x0: MPU domain is independent of CORE domain wake-up event. 0x1: MPU domain is woken-up upon CORE domain wake-up event.	RW	0x1

4.12.2.3.3 PM_EVGENCTRL_MPU

Table 4-184. PM_EVGENCTRL_MPU

Address Offset	0x0000 00D4		
Physical Address	0x4830 69D4	**Instance**	MPU_PRM
Description	This register allows controlling the feature of the event generator.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											OFFLOADMODE			ONLOADMODE		ENABLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved: keep at reset value.	R	0x0000000
4:3	OFFLOADMODE	OFF load mode setting 0x0: Load on update of PM_EVGENOFFTIM_MPU 0x1: Reserved 0x2: Load on MPU standby signal assertion 0x3: Auto load	RW	0x2
2:1	ONLOADMODE	ON load mode setting 0x0: Load on update of PM_EVGENONTIM_MPU 0x1: Load on MPU standby signal de-assertion 0x2: Reserved 0x3: Auto load	RW	0x1
0	ENABLE	Event generator control 0x0: Disable event generator 0x1: Enable event generator	RW	0x0

4.12.2.3.4 PM_EVGENONTIM_MPU

Table 4-185. PM_EVGENONTIM_MPU

Address Offset	0x0000 00D8		
Physical Address	0x4830 69D8	**Instance**	MPU_PRM
Description	This register sets the ON count duration of the event generator (number of system clock cycles).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ONTIMEVAL																															

Bits	Field Name	Description	Type	Reset
31:0	ONTIMEVAL	Number of system clock cycles for the ON period.	RW	0x00000000

4.12.2.3.5 PM_EVGENOFFTIM_MPU

Table 4-186. PM_EVGENOFFTIM_MPU

Address Offset	0x0000 00DC		
Physical Address	0x4830 69DC	**Instance**	MPU_PRM
Description	This register sets the OFF count duration of the event generator (number of system clock cycles).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFTIMEVAL																															

Bits	Field Name	Description	Type	Reset
31:0	OFFTIMEVAL	Number of system clock cycles for the OFF period.	RW	0x00000000

4.12.2.3.6 PM_PWSTCTRL_MPU

Table 4-187. PM_PWSTCTRL_MPU

Address Offset	0x0000 00E0		
Physical Address	0x4830 69E0	**Instance**	MPU_PRM
Description	This register controls the MPU domain power state transition.		
Type	R/W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														L2CACHEONSTATE		RESERVED							L2CACHERETSTATE	RESERVED				MEMORYCHANGE	LOGICL1CACHERETSTATE	POWERSTATE	

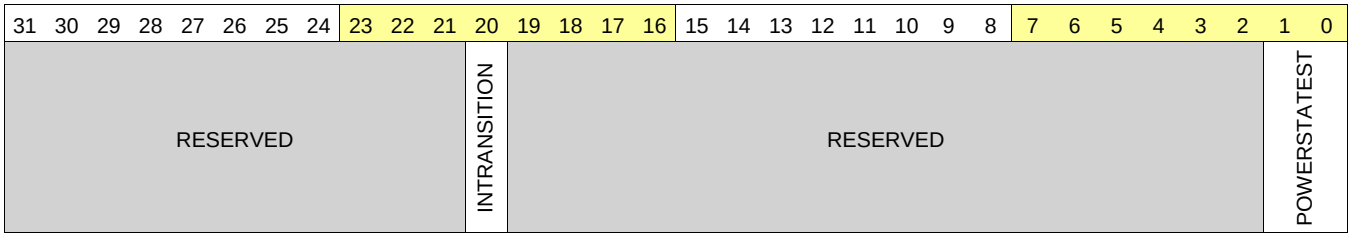
Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved: keep at reset value.	R	0x0000
17:16	L2CACHEONSTATE	L2 Cache memory state when domain is ON; Other enums: Reserved 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: L2 Cache memory is ON when domain is ON.	R/W	0x3
15:9	RESERVED	Reserved: keep at reset value.	R	0x00
8	L2CACHERETSTATE	L2 Cache memory state when domain is RETENTION 0x0:Reserved 0x1: L2 Cache memory is retained when domain is in RETENTION state.	R/W	0x1
7:4	RESERVED	Reserved: keep at reset value.	R	0x0
3	MEMORYCHANGE	Memory change control in ON state 0x0: Disable memory change 0x1: Enable memory change state in ON state. This bit is automatically cleared when memory state is effectively changed.	R/W	0x0
2	LOGICL1CACHERETSTATE	Logic and L1 Cache state when domain is RETENTION 0x0: Reserved 0x1: Logic and L1 Cache are retained when domain is in RETENTION state.	R/W	0x1
1:0	POWERSTATE	Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State	R/W	0x3

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.3.7 PM_PWSTST_MPU

Table 4-188. PM_PWSTST_MPU

Address Offset	0x0000 00E4		
Physical Address	0x4830 69E4	**Instance**	MPU_PRM
Description	This register provides a status on the MPU domain power state.		
Type	R		



Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved	R	0x000
20	INTRANSITION	Domain transition status 0x0: No transition 0x1: MPU domain transition is in progress.	R	0x0

4.12.2.4 CORE_PRM Register Descriptions

4.12.2.4.1 RM_RSTST_CORE

Table 4-190. RM_RSTST_CORE

Address Offset	0x0000 0058		
Physical Address	0x4830 6A58	**Instance**	CORE_PRM
Description	This register logs the different reset sources of the CORE domain. Each bit is set upon release of the domain reset signal. Must be cleared by software.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														GLOBALWARM_RST	GLOBALCOLD_RST

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	GLOBALWARM_RST	Global warm reset Read 0x0: No global warm reset. Write 0x0: Status bit unchanged Read 0x1: CORE domain has been reset upon a global warm reset Write 0x1: Status bit is cleared to 0	RW	0x0
0	GLOBALCOLD_RST	Global cold reset Read 0x0: No global cold reset Write 0x0: Status bit unchanged Read 0x1: CORE domain has been reset upon a global cold reset Write 0x1: Status bit is cleared to 0	RW	0x1

4.12.2.4.2 PM_WKEN1_CORE

Table 4-191. PM_WKEN1_CORE

Address Offset	0x0000 00A0		
Physical Address	0x4830 6AA0	**Instance**	CORE_PRM
Description	This register allows enabling/disabling modules wake-up events.		
Type	RW

1:0	LASTPOWERSTATEENTERED	Last power state entered 0x0: Reserved 0x1: PERIPHERAL domain was previously in RETENTION 0x2: PERIPHERAL domain was previously INACTIVE 0x3: PERIPHERAL domain was previously ON	R/W	0x0

4.12.2.10 EMU_PRM Register Descriptions

4.12.2.10.1 RM_RSTST_EMU

Table 4-224. RM_RSTST_EMU

Address Offset	0x0000 0058		
Physical Address	0x4830 7158	**Instance**	EMU_PRM
Description	This register logs the different reset sources of the EMU domain. Each bit is set upon release of the domain reset signal. Must be cleared by software.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														GLOBALWARM_RST	GLOBALCOLD_RST

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	GLOBALWARM_RST	Global warm reset Read 0x0: No global warm reset Write 0x0: Status bit unchanged Read 0x1: MPU domain has been reset upon a global warm reset Write 0x1: Status bit is cleared to 0	RW	0x0
0	GLOBALCOLD_RST	Global cold reset Read 0x0: No global cold reset Write 0x0: Status bit unchanged Read 0x1: MPU domain has been reset upon a global cold reset Write 0x1: Status bit is cleared to 0	RW	0x1

4.12.2.11 Global_Reg_PRM Register Descriptions

4.12.2.11.1 PRM_RSTCTRL

Table 4-225. PRM_RSTCTRL

Address Offset	0x0000 0050		
Physical Address	0x4830 7250	**Instance**	Global_Reg_PRM
Description	Global software and DPLL3 reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													RST_DPLL3	RST_GS	RESERVED

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Reserved: keep at reset value.	R	0x00000000
2	RST_DPLL3	DPLL3 software reset control. This bit is reset only upon a global cold source of reset. 0x0: DPLL3 software reset is cleared. 0x1: Asserts the DPLL3 software reset and induces a global cold reset on the whole chip. The software must ensure the SDRAM is properly put in sef-refresh mode before applying this reset.	RW	0x0
1	RST_GS	Global software reset control. This bit is reset upon any global source of reset (warm and cold). 0x0: Global software reset is cleared. 0x1: Asserts a global software reset.	RW	0x0
0	RESERVED	Reserved: keep at reset value.	R	0x0

4.12.2.11.2 PRM_RSTTIME

Table 4-226. PRM_RSTTIME

Address Offset	0x0000 0054		
Physical Address	0x4830 7254	**Instance**	Global_Reg_PRM
Description	Reset duration control.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								RSTTIME1							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved: keep at reset value.	R	0x000010
7:0	RSTTIME1	(Global) reset duration 1 (number of Func_32k.clk clock cycles)	RW	0x06

4.12.2.11.3 PRM_RSTST

Table 4-227. PRM_RSTST

Address Offset	0x0000 0058		
Physical Address	0x4830 7258	**Instance**	Global_Reg_PRM
Description	This register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Reserved: keep at reset value.	R	0x000000
10	ICECRUSHER_RST	IceCrusher reset event. This is a source of warm reset initiated by the emulation. Read 0x0: No IceCrusher reset Write 0x0: Status bit unchanged Read 0x1: IceCrusher reset occurred Write 0x1: Status bit is cleared to 0	RW	0x0
9	ICEPICK_RST	IcePick reset event. This is a source of warm reset initiated by the emulation. Read 0x0: No IcePick reset Write 0x0: Status bit unchanged Read 0x1: IcePick reset occurred Write 0x1: Status bit is cleared to 0	RW	0x0
8:7	RESERVED	Reserved: keep at reset value.	RW	0x0
6	EXTERNAL_WARM_RST	External warm reset event Read 0x0: No global warm reset Write 0x0: Status bit unchanged Read 0x1: Global external warm reset occurred Write 0x1: Status bit is cleared to 0	RW	0x0
5	SECURE_WD_RST	Secure watchdog reset event Read 0x0: No security watchdog reset Write 0x0: Status bit unchanged Read 0x1: Security watchdog reset has occurred Write 0x1: Status bit is cleared to 0	RW	0x0
4	MPU_WD_RST	MPU watchdog reset event Read 0x0: No MPU watchdog reset Write 0x0: Status bit unchanged Read 0x1: MPU wachtdog reset occurred Write 0x1: Status bit is cleared to 0	RW	0x0

Bits	Field Name	Description	Type	Reset
3	SECURITY_VIOL_RST	Security violation reset event Read 0x0: No security violation reset Write 0x0: Status bit unchanged Read 0x1: Security violation reset has occurred Write 0x1: Status bit is cleared to 0	RW	0x0
2	RESERVED	Reserved: keep at reset value.	R	0x0
1	GLOBAL_SW_RST	Global software reset event Read 0x0: No global software reset Write 0x0: Status bit unchanged Read 0x1: Global software reset occurred Write 0x1: Status bit is cleared to 0	RW	0x0
0	GLOBAL_COLD_RST	Power-up (cold) reset event Read 0x0: No power-on reset Write 0x0: Status bit unchanged Read 0x1: Power-on reset occurred Write 0x1: Status bit is cleared to 0	RW	0x1

4.12.2.11.4 PRM_CLKSRC_CTRL

Table 4-228. PRM_CLKSRC_CTRL

Address Offset	0x0000 0070		
Physical Address	0x4830 7270	**Instance**	Global_Reg_PRM
Description	This register provides control over the device source clock.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								SYSCLKDIV		RESERVED	AUTOEXTCLKMODE		RESERVED	SYSCLKSEL	

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved: keep at reset value.	R	0x000000
7:6	SYSCLKDIV	This field controls the system clock input divider 0x0: reserved 0x1: Syst_clk is external clock / 1 0x2: Syst_clk is external clock / 2 0x3: reserved	RW	0x1
5	RESERVED	Reserved: keep at reset value.	R	0x0
4:3	AUTOEXTCLKMODE	This field allows to control the external clock request (CLKREQ) and the oscillator 0x0: CLKREQ is kept asserted or the oscillator is always active (in master mode) 0x1: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) when all the voltages domains are SLEEP, RETENTION or OFF states. 0x2: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) when all the voltages domains are RETENTION or OFF states. 0x3: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) only when all the voltage domains are in OFF states.	RW	0x0
2	RESERVED	Reserved: keep at reset value.	R	0x0
1:0	SYSCLKSEL	This field reflects the mode of the oscillator. It is automatically set accordingly to the external tied-off configuration and its value is insignificant before the release of the power-on reset. 0x0: Bypass mode: the system clock is issued from an external square clock source 0x1: Oscillator mode: the system clock is issued from an external quartz 0x2: Reserved 0x3: Unknown state (not know before release of the power-on reset)	R	0x3

4.12.2.11.5 PRM_OBS

Table 4-229. PRM_OBS

Address Offset	0x0000 0080		
Physical Address	0x4830 7280	**Instance**	Global_Reg_PRM
Description	This register logs the observable signals (18 bits). This register is intended to be read through the debugger interface when the device is in standby mode.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Reserved: keep at reset value.	R	0x00000001
2	CLKOUT_POL	Controls the external output clock polarity when disabled 0x0: sys_clkout is gated low when inactive 0x1: sys_clkout is gated high when inactive	R/W	0x0
1	CLKREQ_POL	Controls the polarity of the SYS_CLKREQ signal 0x0: SYS_CLKREQ is active low 0x1: SYS_CLKREQ is active high	R/W	0x1
0	RESERVED	Reserved: keep at reset value.	R	0x0

4.12.2.12 NEON_PRM Register Descriptions

4.12.2.12.1 RM_RSTST_NEON

Table 4-232. RM_RSTST_NEON

Address Offset	0x0000 0058		
Physical Address	0x4830 7358	**Instance**	NEON_PRM
Description	This register logs the different reset sources of the NEON domain. Each bit is set upon release of the domain reset signal. Must be cleared by software.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														GLOBALWARM_RST	GLOBALCOLD_RST

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	GLOBALWARM_RST	Global warm reset Read 0x0: No global warm reset Write 0x0: Status bit unchanged Read 0x1: NEON domain has been reset upon a global warm reset Write 0x1: Status bit is cleared to 0	RW	0x0
0	GLOBALCOLD_RST	Global cold reset Read 0x0: No global cold reset Write 0x0: Status bit unchanged Read 0x1: NEON domain has been reset upon a global cold reset Write 0x1: Status bit is cleared to 0	RW	0x1

4.12.2.12.2 PM_WKDEP_NEON

Table 4-233. PM_WKDEP_NEON

Address Offset	0x0000 00C8		
Physical Address	0x4830 73C8	**Instance**	NEON_PRM
Description	This register allows enabling or disabling the wake-up of the NEON domain upon another domain wakeup.		
Type	RW		

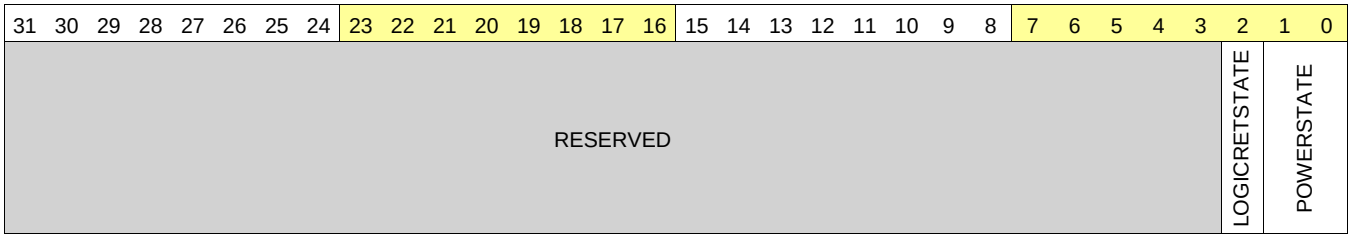
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																														EN_MPU	RESERVED

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved: keep at reset value.	R	0x00000000
1	EN_MPU	MPU domain dependency 0x0: NEON domain is independent of MPU domain wake-up. 0x1: NEON domain is woken-up upon MPU domain wake-up.	RW	0x1
0	RESERVED	Reserved: keep at reset value.	R	0x0

4.12.2.12.3 PM_PWSTCTRL_NEON

Table 4-234. PM_PWSTCTRL_NEON

Address Offset	0x0000 00E0		
Physical Address	0x4830 73E0	**Instance**	NEON_PRM
Description	This register controls the NEON domain power state transition.		
Type	R/W		



Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Reserved: keep at reset value.	R	0x00000000
2	LOGICRETSTATE	Logic state when RETENTION 0x1: Logic is always retained when domain is in RETENTION state.		0x1
1:0	POWERSTATE	Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State	R/W	0x3

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.12.4 PM_PWSTST_NEON

Table 4-235. PM_PWSTST_NEON

Address Offset	0x0000 00E4		
Physical Address	0x4830 73E4	**Instance**	NEON_PRM
Description	This register provides a status on the power state transition of the NEON domain.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Interconnect

This chapter describes the Interconnect.

NOTE:

- The L3 interconnect is an instantiation of the **SonicsMX®** interconnect from **Sonics, Inc**.
- The L4 interconnects are instantiations of the **Sonics3220™** interconnect from **Sonics, Inc**.

SMX is an abbreviated naming for SonicsMX.

Topic **Page**

5.1 Interconnect Overview

This chapter gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

5.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be both an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- OCP: Open-core protocol (www.ocpip.org) is point-to-point standard protocol between one master port and one slave port.
- OCP master port: Port that can generate OCP commands. An initiator includes at least one master port.
- OCP slave port: Port that responds to OCP commands. A target includes one slave port.
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- Register target (RT): Special TA used to access the interconnect internal configuration registers.
- Dataflow signal: Any OCP signal that is part of a clearly identified OCP transfer or dataflow (typically: command, address, byte enables, etc.). The signal behavior is defined by the OCP protocol semantics.
- Sideband signal: Any OCP signal whose behavior is not associated to a precise OCP transaction or dataflow. The OCP standard does not define specific semantics for these signals.icnt
- Out-of-band error: Any OCP signal whose behavior is associated to an error-reporting scheme of the device, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable security feature integrated in a target agent for each module requiring a secure data path. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- Thread: Logical entities that allow to have separate independent data flows on a single port.
- Multithreaded ports: A physical port able to simultaneously handle several outstanding transactions. On a multithreaded port, one physical channel (port) is used concurrently for several logical channels (threads). The transfer in each thread must remain in order with respect to each other, but the order between threads can change between requests and responses. Thread management is used for performance optimization purposes and is automatically handled by the system.
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which

uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted inband with the request and is used for security and error-logging mechanism.

- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 5-1 lists the commands encoded.

Table 5-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Not used
1 0 1	Write nonposted
1 1 0	Not used
1 1 1	Not used

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 5-2.

Table 5-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access
MReqSecure	0: Public transaction
	1: Secure transaction(1)

(1) In GP device MReqSecure = 1 (Secure value), is not supported.

- L3_PM_REQ_INFO_PERMISSION_i: Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction.

Table 5-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

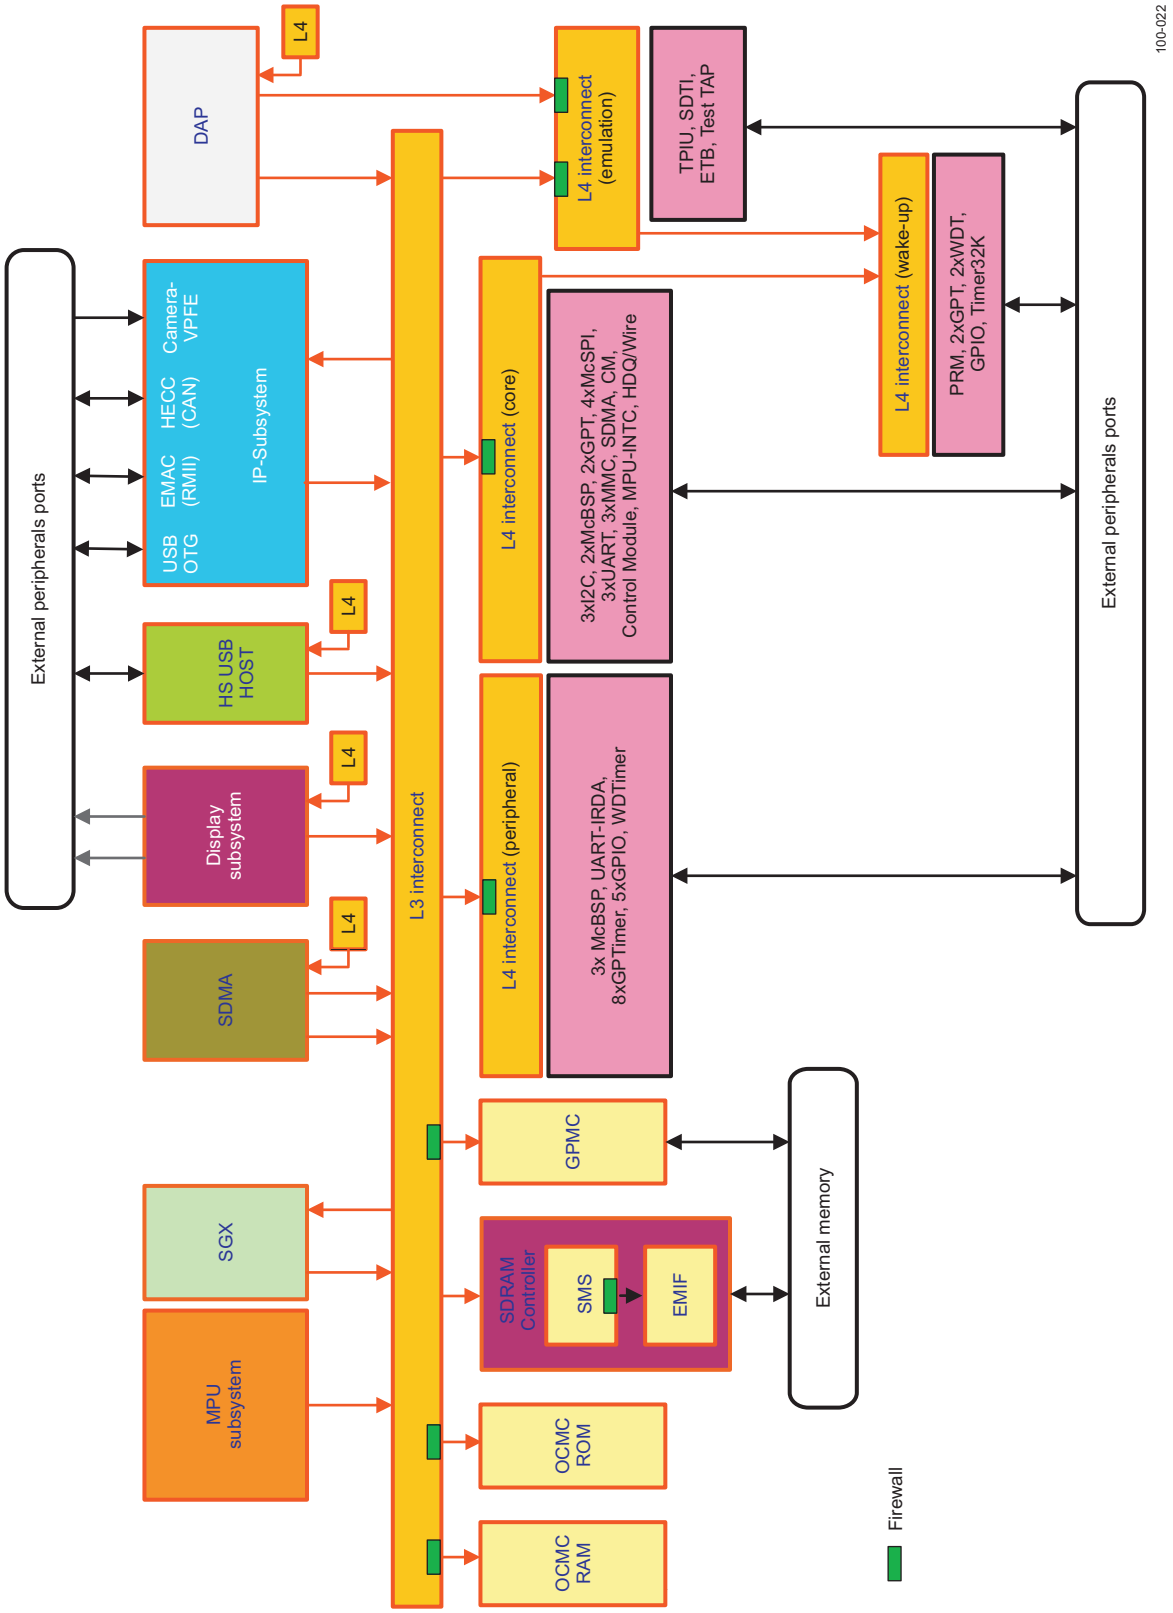
5.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core.
- L2 is included in the MPU subsystem.

- The chip-level interconnect consists of one L3 interconnect and four L4 interconnects. It enables communication among the modules and subsystems in the device. Figure 5-1 shows an overview of the L3 and L4 interconnect architecture.
  - L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
  - L4 is composed of the L4-Core, L4-Per, L4-Wakeup, and L4-Emu interconnects and handles data transfers to peripherals. It supports 32-bit data width transfer and is optimized to support the interconnection of many peripheral targets. These backplanes assume little-endian transactions for narrower targets (8-bit, 16-bit) when doing data packing and unpacking.

Figure 5-1. Interconnect Architecture Overview



Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access depending on the characteristics of the module.

To secure a data path, some TAs include configurable firewalls (FWs) for security purposes. A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default setting is fully functional; it enables all possible functional data paths and a minimal default security setting. However, it is possible to modify the interconnect parameters to fit user expectations.

5.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

Table 5-4 through Table 5-13 list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator and target agents
- L4-Core initiator and target agents
- L4-Per initiator and target agents
- L4-Emu initiator and target agents
- L4-Wakeup initiator and target agents

5.1.3.1 L3 Interconnect Agents

Table 5-4 and Table 5-5 list the IAs and TAs, respectively, of the L3 interconnect.

Table 5-4. L3 Initiator Agents

Module Name	Description
MPU SS	MPU subsystem port
Display SS	Display subsystem port
IPSS	IP-Subsystem initiator port (Camera-VPFE, USBOTG, and EMAC)
SGX SS	Graphics subsystem port
sDMA read	System DMA read port
sDMA write	System DMA write port
High-Speed (HS) USB Host	Universal serial bus High-Speed port Host Controller
DAP	Debug access port (JTAG/Emulation access to system resources)

Table 5-5. L3 Target Agents

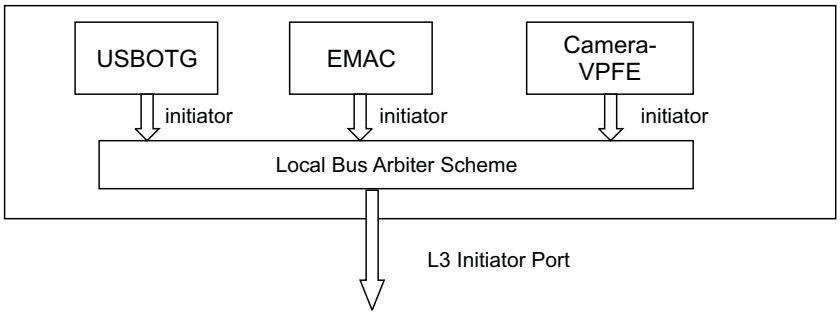
Module Name	Description
SMS	SDRAM memory scheduler port
GPMC	General-purpose memory controller (for flash memory, SRAM, SROM, etc.) port
OCM-ROM	On-chip memory ROM port
OCM-RAM	On-chip memory RAM port
SGX	Graphics subsystem port
IPSS	Register target port for IPSS
RT	Register target port to configure L3
L4-Core	Port for L4-Core interconnect
L4-Peripherals	Port for L4-Per interconnect
L4-Emu	Port for L4-Emu interconnect

NOTE: The IP-Subsystem (abbreviated as IPSS) integrates the following modules:

- Camera-VPFE
- EMAC
- USBOTG
- CAN-HECC

The camera-VPFE, EMAC and USBOTG are initiators on L3 and share one L3 initiator port as shown in Figure 5-2.

Figure 5-2. L3 Port Initiators



All IPSS modules (Camera-VPFE, EMAC, USBOTG, and CAN-HECC) have a register target port on L3.

For more details on the register target module, see Section 5.4.2, *Register Target*.

5.1.3.2 L4-Core Agents

Table 5-6. L4-Core Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

NOTE: A unique L3 port is used for communication with the L4-Core. For the list of initiators allowed to access the L4 Core peripherals, see Table 5-14.

Table 5-7. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
High-Speed (FS) USB Host	Universal serial bus High-Speed port Host controller
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
UART4	Universal asynchronous receiver transmitter port 4
I2C1	Multimaster interintegrated circuit 1
I2C2	Multimaster interintegrated circuit 2
I2C3	Multimaster interintegrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
SPI1	Serial peripheral interface 1

Table 5-7. L4-Core Target Agents (continued)

Module Name	Description
SPI2	Serial peripheral interface 2
MMCHS1	Multimedia memory controller SDIO 1
MMCHS2	Multimedia memory controller SDIO 2
MMCHS3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MG	MagicGate®
SPI1	Serial peripheral interface 1
SPI2	Serial peripheral interface 2
SPI3	Serial peripheral interface 3
SPI4	Serial peripheral interface 4
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

5.1.3.3 L4-Per Agents

Table 5-8. L4-Per Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

NOTE: A unique L3 port is used for communication with L4-Per. For the list of initiators allowed to access the L4-Per peripherals, see Table 5-14.

Table 5-9. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3

5.1.3.4 L4-Emu Agents

Table 5-10. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

NOTE: The L3 and DAP ports are used for communication with L4-Emu. For the list of initiators allowed to access the L4-Emu peripherals, see Table 5-14.

Table 5-11. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4 wake-up interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
DAPCTL	Debug access port

5.1.3.5 L4-Wakeup Agents

Table 5-12. L4-Wakeup Initiator Agent

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emulation interconnect port

NOTE: The L4-Emu and L4-Core ports are used to communicate with the L4-Wakeup. For the list of initiators allowed to access the L4-Wakeup peripherals, see Table 5-14.

Table 5-13. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset management
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
GPTIMER12[(1)]	General-purpose timer 12
WDTIMER1[(1)]	Secure watchdog timer
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer

(1) Not available in GP device.

5.1.4 Connectivity Matrix

Table 5-14 lists the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- Cell contains a + sign when a functional path exists.
- Cell is blank when no functional path exists.

Table 5-14. Connectivity Matrix

Initiator Ports	L4-Core Target (1)	L4-Per Target (1)	L4-Emu Target (1)	L4-Wakeup Target (1)	SMS Target	GPMC Target	OCM RAM Target	OCM ROM Target	RT Target	IPSS Target	SGX Target
MPU IA	+	+	+	+	+	+	+	+	+	+	+
SGX IA					+	+	+				
IPSS IA					+	+	+				
DSS IA					+		+				
USB Host IA					+	+	+				
sDMA RD IA	+	+	+	+	+	+	+				+
sDMA WR IA	+	+	+	+	+	+	+				+
DAP IA	+	+	+	+	+	+	+	+	+	+	+

(1) A functional data path always exists from L4 IAs (Core, Per, Emu, and Wakeup) to any L4 target module (Core, Per, Emu, and Wakeup). As a consequence, all L3 initiator modules for which a data path exists to an L4 TA can access L4 peripherals. Restrictions on peripheral access depend on the security settings and L4 protection mechanism programming. For more details, see Section 5.9.3, *L4 Security and Firewalls*.

5.2 L3 Interconnect

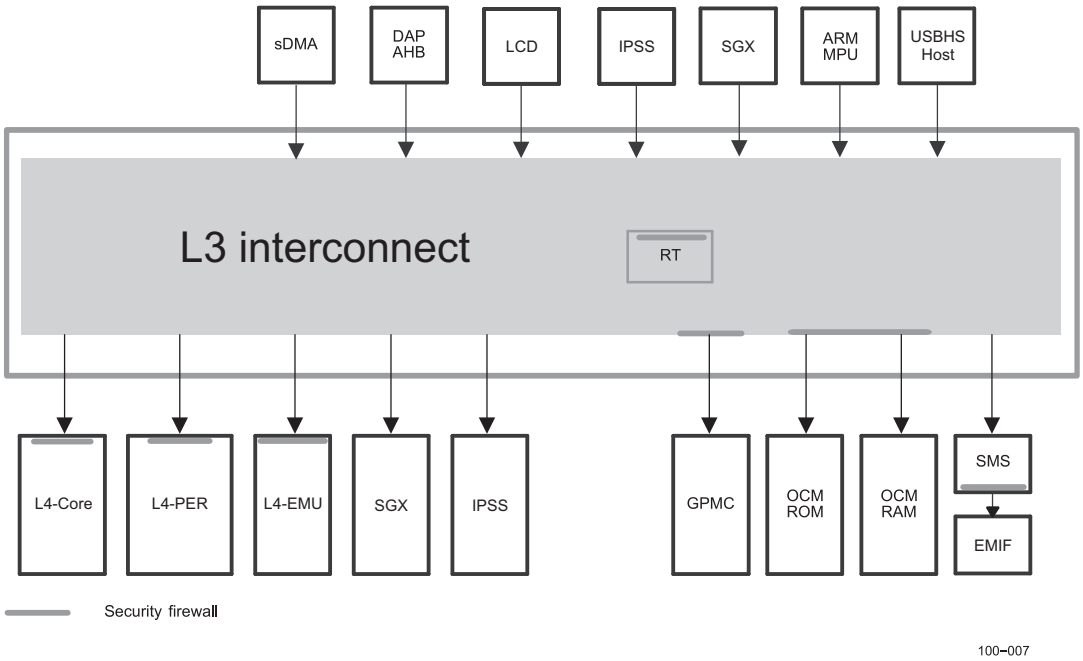
This section describes the L3 interconnect and its components. With the exception of register points, each component includes functionality for both the request and response network.

5.2.1 Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

Figure 5-3 shows the L3 interconnect.

Figure 5-3. L3 Interconnect Overview



The following are the main features of the L3 interconnect:

- 64-bit multipath interconnect to eliminate on-chip bottlenecks
- Special internal target for access to L3 registers (RT)
- Guaranteed quality of service for real-time hardware operators, while maintaining optimal memory latency for MPU accesses to memory resources
- True little-endian platform
- Transaction error tracking and logging
- Built-in security features:
  - Allow access only to authorized initiator
  - Distributed region-based firewalls for system resource sharing and protection management
- Signaling support for chip-level power management infrastructure
- Two interrupt line signaling transaction error

5.3 L3 Interconnect Integration

5.3.1 Clocking, Reset, and Power-Management Scheme

5.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides the L3_ICLK as the main clock to the L3 interconnect.

In addition to L3_ICLK, four additional sample signals are provided to module agents to allow internal synchronization. The modules are as follows:

- L4-Core
- L4-Per

For more details on the L3 clock and its setting, see the *Power, Reset, and Clock Management* chapter.

Table 5-15. L3 Interconnect Clocks

Type	Name	Source	Description
Interface/functional	L3_ICLK	PRCM	Main clock for L3 interconnect

5.3.1.2 Resets

The L3 interconnect receives a single reset signal, CORE_RST, from the PRCM module. CORE_RST is the reset signal to the core power domain. (For more details, see the *Power, Reset, and Clock Management* chapter.) When asserted, CORE_RST resets the L3 internal registers. There is no software reset for the L3 interconnect.

Table 5-16. L3 Interconnect Reset

Type	Reset Domain	Source	Description
Hardware	CORE_RST	PRCM	Asynchronous reset for the entire interconnect

5.3.1.3 Power Management

As part of the system-wide power-management scheme, the L3 interconnect enters an idle state at the request of the PRCM module. (For more details, see the *Power, Reset, and Clock Management* chapter.) The L3 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all transfer requests are serviced. This functionality is handled by hardware. The L3 interconnect sends an acknowledge signal back to the PRCM module when it enters the idle state.

5.3.2 Hardware Requests

5.3.2.1 Interrupt Requests

Three interrupt lines are present at the boundary of the L3 interconnect (see Table 5-17). They are used for hardware error management.

Table 5-17. L3 Interconnect Hardware Requests

Type	Name	Destination	Description
Interrupt	M_IRQ_9	MPU interrupt controller for debug errors	L3 interconnect provides a mechanism to group core-detected and internal interconnect errors. See Section 5.9.4, *Error Handling*.
Interrupt	M_IRQ_10	MPU interrupt controller for application errors	

5.4 L3 Interconnect Functional Description

5.4.1 Initiator Identification

An InitiatorID is assigned to every thread on every initiator socket. The ID uniquely identifies the initiator and thread for an interconnect transfer see Table 5-18. The interconnect uses InitiatorIDs for a number of purposes, including the following:

- Initiator source identification for the protection mechanism (see Section 5.4.3, *L3 Security and Firewalls*)
- Response route generation (performed internally to the TAs)
- Firewall error logging
- L3 interconnect error logging

Table 5-18. InitiatorID Definition

Initiator	InitiatorID
HS USB Host	0
IP-Subsytem (Camera-VPFE, USBOTG, and EMAC)	2
sDMA rd	3 , 4 , 5, 6
sDMA wr	7, 8
DAP	9
SGX	13
MPU SS	23, 24, 25, 26, 27
LCD	29

5.4.2 Register Target

An RT is a specialized TA used to access L3 interconnect internal configuration registers.

RT configuration options are a subset of those available for TAs. For more details, see Section 5.6.5.

5.4.3 L3 Security and Firewalls

Security in the device relies heavily on L3 firewalls and their configuration. Nine targets are protected through the use of firewalls. The number of protected regions varies on the target, with a maximum of eight regions. Table 5-19 lists the security configuration and the number of protected regions for each target.

Table 5-19. Target Firewall and Region Configuration

Target	Firewall	Number of Regions
SMS	Included in the SMS module	See the *Memory Subsystem* chapter.
GPMC	Yes	8
OCM-RAM	Yes	8
OCM-ROM	Yes	2
IP-Subsytem (Camera-VPFE, USBOTG, EMAC and CAN-HECC)	Yes	
L4-Core	Included in the L4 module	See Section 5.7, L4 Interconnect.
L4-Wakeup	Included in the L4 module	See Section 5.7, L4 Interconnect.
L4-Emu	Included in the L4 module	See Section 5.7, L4 Interconnect.
RT	Yes	2

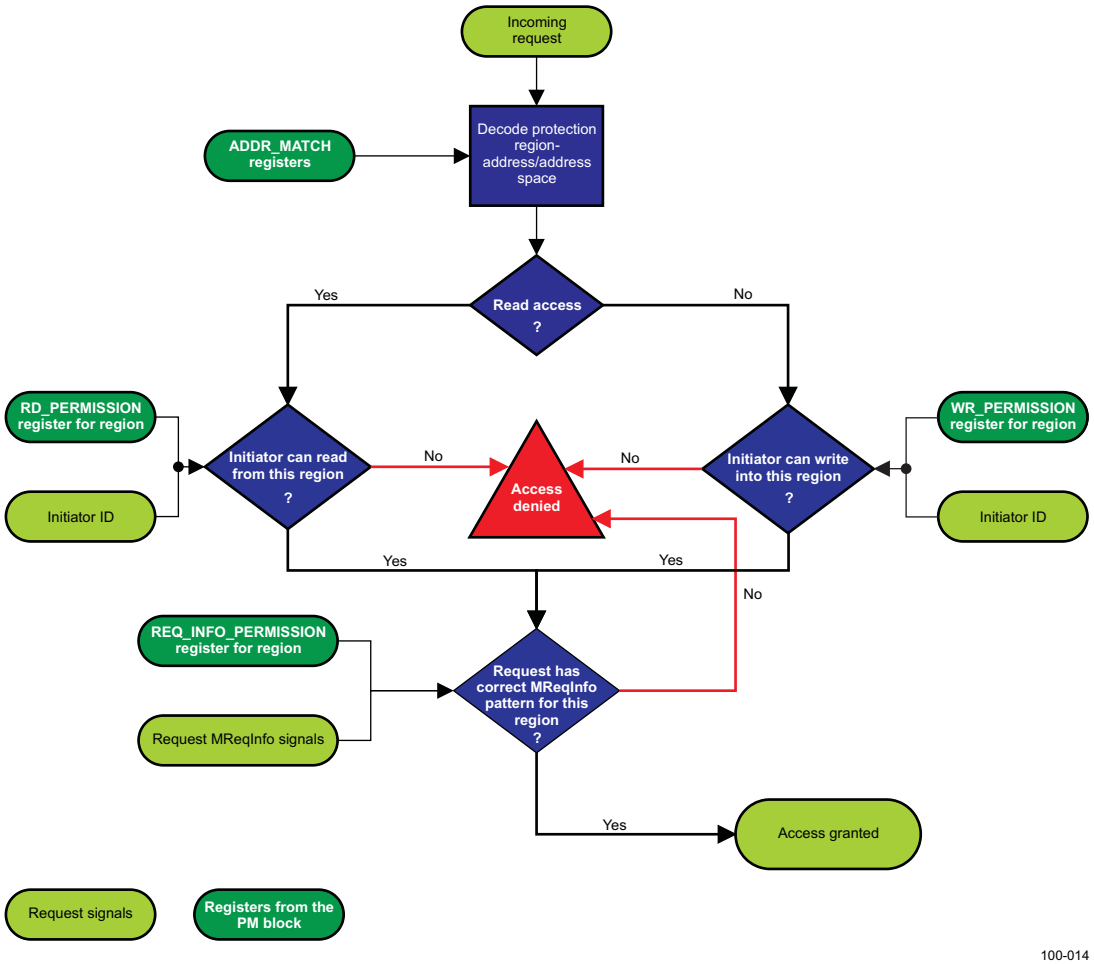
The protection mechanism designates protection regions within the address space of certain targets. Access to these regions is granted only for certain initiators, based on transaction attributes (transmitted through MReqInfo). Each protection region is characterized with several configurable attributes (base address, size, specific access rights, and priority setting).

The protection mechanism uses the following attributes of a request:

- The address field and the address space field are used to determine which region has been hit. The region ID selects one table entry of the firewall look-up table.
- The region ID points to a unique set of permission registers: Read_Permission, Write_Permission, ReqInfo_Permission.
- The Initiator ID is used to determine the permission of the initiator (read/write permission) with respect to the concerned region.
- The access types (read or write) and the transaction attributes (MReqInfo in-band qualifiers) are used to grant or reject the access.

The first check determines whether the type of incoming request (read or write) is allowed, according to the Initiator MConnID and its read and write permissions. The second check determines whether the MReqInfo bits of the incoming request are within the allowed pattern established by the MReqInfo permission bits. If both check results are positive, the request is allowed to access the target. Otherwise, the access is denied, the request is not forwarded to the target, an out-of-band error indication is reported, and an in-band error response is returned to the initiator (except for writes that were posted at the IA). Figure 5-4 shows the flow used to identify and accept a new request.

Figure 5-4. Flowchart of the Protection Mechanism



To summarize, firewalls accept or reject a request depending on the following:

- Initiator originating the request
- Command (read or write) requested
- MReqInfo bus state
- Region access in the target memory space

Software must configure the L3 firewalls properly to allow the right initiators, with the right MReqInfo access, on the well-defined size region. All the registers relative to the L3 firewalls are grouped in the protection mechanism (PM) register block.

NOTE: The PM qualifies the protection mechanism register associated with a firewall target. The targets protected by a firewall are listed in Table 5-19. These PM registers do not exist if no firewall is associated with the target.

5.4.3.1 Protection Region

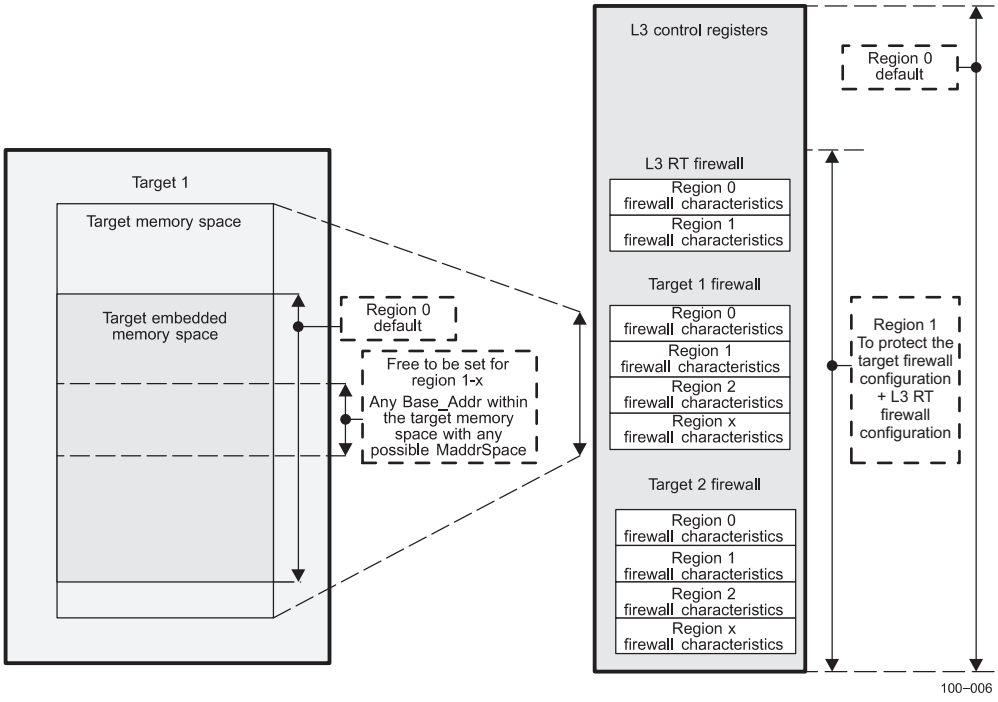
Two types of regions are distinguished in a target firewall (see Figure 5-5):

- Default region: Available in all targets; spans the entire target address range
- Normal region: Number varies in a target; they have identical capabilities

Each region has the following characteristics:

- A base address, relative to the target address itself, and an address space
- A size
- Specific access rights, as defined through the MReqInfo qualifiers
- A priority level, from 0 (lowest) to 3 (highest)

Figure 5-5. L3 Firewall Implementation



5.4.3.1.1 Default Region/Region0

Region 0 is the default region of a whole target; it spans the entire target address space.

The default region is always the lowest priority. This region is systematically overlapped when other regions are set.

The L3_PM_ADDR_MATCH_k register is not accessible. Its configuration corresponds to all the possible addresses for the target, including all of ADDR_SPACE. It is not possible to program multiple ADDR_SPACE addresses in a normal region.

5.4.3.1.2 Normal Regions

Normal regions have identical features.

A given request either maps into a specific protection region or is considered to have hit the default protection region if no normal region is hit.

The protection regions can only be configured for a memory space that is power-of-two in size and size-aligned using the SIZE bit field L3_PM_ADDR_MATCH_k [7:3] (as listed in Table 5-20). When the SIZE bit field L3_PM_ADDR_MATCH_k [7:3] is set to 0, the region is disabled.

NOTE: k denotes the region number. Depending on the target, n varies from 0 to 7.

Table 5-20 lists the size encoding for each value set in the SIZE bit field.

Table 5-20. L3 Firewall Size Parameter Definition

Possible Configuration		
Size[1]	**Region Size**	**Base_Addr**[2]
0x0	Region disabled	Any (nonsignificant)
0x1	1K-byte secure	0x0000000
		0x0000400
		0x0000800
		.
0x2	2K-byte secure	0x0000000
		0x0000800
		0x0001000
		...
...	...	...
0x17	2^(17-1)K-byte secure	
Others	Not allowed	-

(1) When the size parameter is set to 0, the region is disabled.
(2) The base address depends on user settings.

5.4.3.2 Priority Level Overview

Each L3 firewall region is prioritized. Depending on its priority level, a region can override the settings of another region.

- Region 0 is the only allowed priority 0 region (lowest priority).
- Region 1 is the only allowed priority 3 region (highest priority).
- Others regions are defined as priority 1 or 2.

CAUTION

LEVEL bitfield value of ADDR_MATCH_1 register (Region 1 firewall configuration) must be kept to his default reset value and must not be changed; otherwise, the result will be unpredictable and can create unexpected security holes or denial of service.

Protection level is defined by the LEVEL bit L3_PM_ADDR_MATCH_k , where n is greater than 2. Figure 5-6 represents the priority level with associated regions.

When an address hits two or more regions with different priority levels, the highest priority region protections are applied. The overlay region can overlap all or a part of a nonoverlay region.

CAUTION

Configuring two overlapping protection regions with the same priority level leads to undefined behavior.

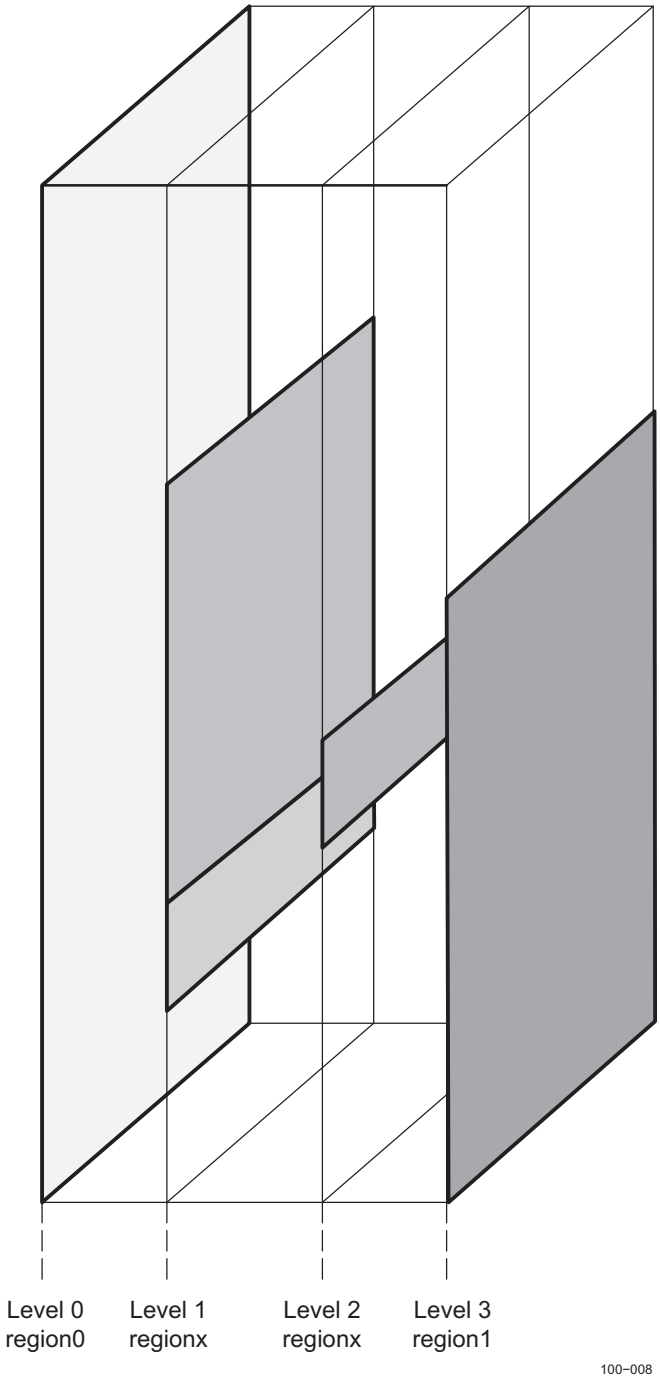
Hardware behavior in the case of overlapping protection regions is undefined. A region with higher priority must be used to mask a region that is being reprogrammed, and any security holes must be avoided during this reconfiguration.

To change the protection settings of a region, follow this procedure:

1. Ensure that a free region is available to be used as a high-priority region.
2. Program this region as a high-priority region so its parameters match the region to be changed. The final programming must be the L3_PM_ADDR_MATCH_k register, which includes the priority attribute and the size parameter to enable the region.
3. Disable the region to be configured or reconfigure it by setting the SIZE bit field to 0.
4. Set up all region control registers with the new configuration. The final programming must be the L3_PM_ADDR_MATCH_k register, which includes the size parameter to enable the region.
5. Disable the high-priority region by setting its size to 0.

This procedure must be used each time there is an overlap between the originally defined region and the newly defined region. The use of a high-priority region is required to keep security active during programming.

Figure 5-6. L3 Region Overlay and Priority Level Overview



5.4.3.3 Read and Write Permission

Read permission and write permission are configured using two registers:

- L3_PM_READ_PERMISSION_i
- L3_PM_WRITE_PERMISSION_i

The L3_PM_READ_PERMISSION_i and L3_PM_WRITE_PERMISSION_i registers allow the setting of read and write permission to one or more initiators. To grant read or write access, set the bit associated with the initiator to 1.

5.4.3.4 REQ_INFO_PERMISSION Configuration

The firewall comparison mechanism enables access to a protected target only when a correct combination of four MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 4-bit pattern that corresponds to a combination of the parameters MReqSecure, MRreqDebug, MrReqType, and MReqSupervisor.

NOTE: In GP device MReqSecure = 1 (Secure value), is not supported.

Different valid MReqInfo combinations can be defined for each L3 firewall region based on the L3_PM_REQ_INFO_PERMISSION_i value, which is programmed by software.

For each region, L3_PM_REQ_INFO_PERMISSION_i lists the possible MReqInfo combinations. Setting a Reqbit in this register determines the type of access allowed to the initiator.

Table 5-21 lists the MReqInfo combinations available and the Reqbit associated with it.

Table 5-21. MReqInfo Parameter Combinations

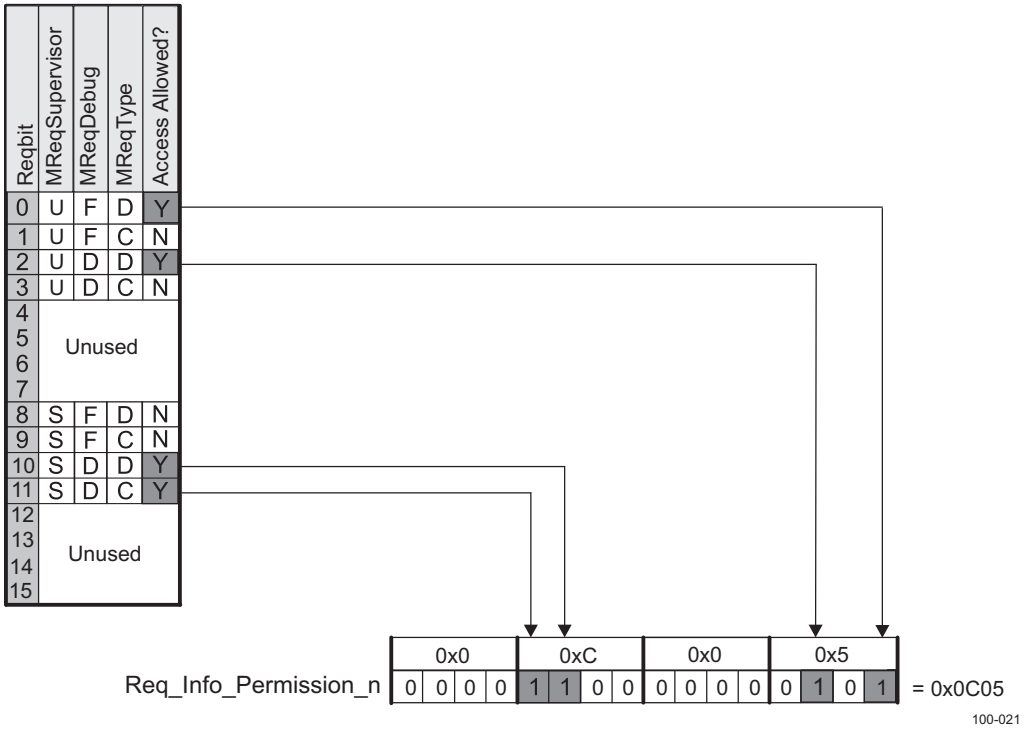
Reqbit	MReqInfo			
	MReqSupervisor	MReqSecure[1]	MReqDebug	MReqType
0	User	Public	Functional	Data
1	User	Public	Functional	Code
2	User	Public	Debug	Data
3	User	Public	Debug	Code
4	User	Secure[1]	Functional	Data
5	User	Secure[1]	Functional	Code
6	User	Secure[1]	Debug	Data
7	User	Secure[1]	Debug	Code
8	Supervisor	Public	Functional	Data
9	Supervisor	Public	Functional	Code
10	Supervisor	Public	Debug	Data
11	Supervisor	Public	Debug	Code
12	Supervisor	Secure[1]	Functional	Data
13	Supervisor	Secure[1]	Functional	Code
14	Supervisor	Secure[1]	Debug	Data
15	Supervisor	Secure[1]	Debug	Code

(1) In GP device MReqSecure = 1 (Secure value), is not supported.

Figure 5-7 shows an example of the L3_PM_REQ_INFO_PERMISSION_i setting. In this example, L3_PM_REQ_INFO_PERMISSION_i is set to 0x0C14 (16'b0000_1100_0001_0100) for a specific region, which will grant access only if the request:

- User + Public + Debug + Data
- User + Secure + Functional + Data
- Supervisor + Public + Debug + Data
- Supervisor + Public + Debug + Code

Figure 5-7. Example of REQ_INFO_PERMISSION Register



As another example, to configure a target accessible only for data and in a public mode, Reqbit 0, 2, 8, and 10 must be set. Therefore, the L3_PM_REQ_INFO_PERMISSION_i register must be set to 0x5050.

5.4.3.5 L3 Firewall Registers Overview

Table 5-22 lists the L3 firewall permission-setting registers. L3_PM_ADDR_MATCH_k, which is shown in this table, is not an accessible register.

Table 5-22. L3 Firewall Permission-Setting Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 0				This region is the default region. The default setting can be changed only with correct access according to L3 RT register.
L3_PM_ADDR_MATCH_k (k=0)	ADDR_SPACE[2:0]	Hard coded	Corresponds to all the target memory space	
	SIZE[7:3]	Hard coded	Corresponds to all the target memory space	
	Reserved		Default region: Level 0	
	BASE_ADDR[63:10]	Hard coded	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i (i=0)	REQ_INFO[15:0]	Yes	Type of access permitted. See Table 5-21.	
L3_PM_READ_PERMISSION_i (i=0)	READ_PERMISSION[15:0]	Yes	Initiator read permission, depending on connections. See Table 5-14.	
L3_PM_WRITE_PERMISSION_i (i=0)	WRITE_PERMISSION[15:0]	Yes	Initiator write permission, depending on connections. See Table 5-14.	

Table 5-22. L3 Firewall Permission-Setting Registers (continued)

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 1-7				The default settings can be changed only with correct access based on the L3 RT register.
L3_PM_ADDR_MATCH_k	ADDR_SPACE[2:0]	Yes		
	SIZE [7:3]	Yes	The regions are power-of-two in size and size-aligned with Base_Addr reference. When Size = 0x0, the firewall is deactivated.	
	LEVEL[9]	Yes	Protection region level 0x0: Level 1 0x1: Level 2 Region 1 is always Level 3.	
	BASE_ADDR[63:10]	Yes	Target-dependent	
L3_PM_REQ_INFO_PERMISSION_i	REQ_INFO[15:0]	Yes	Type of access permitted. See Table 5-21.	
L3_PM_READ_PERMISSION_i	READ_PERMISSION[15:0]	Yes	Initiators read permission ,depending on connections. See Table 5-14.	
L3_PM_WRITE_PERMISSION_i	WRITE_PERMISSION[15:0]	Yes	Initiators write permission, depending on connections. See Table 5-14.	

5.4.3.6 L3 Firewall Error-Logging Registers

Table 5-23 lists the L3 firewall error-logging registers.

Table 5-23. L3 Firewall Error Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
L3_PM_ERROR_LOG	CMD[2:0]	Read only	Log the OCP command of the request that caused a protection violation. See Table 5-1.
	REGION[6:4]	Read only	Log the region number targeted by the request that caused the protection violation.
	INITIATOR_ID[15:8]	Read only	Log the InitiatorID request that caused the protection violation. See Table 5-18
	REQ_INFO[20:16]	Read only	Log the MReqInfo bits of the request that caused the protection violation. See Table 5-21.
	CODE[27:24]	Read/write	Log the error that occurred. See Table 5-25.
	MULT[31]	Read/write	If a second error is detected before the first is cleared, the MULT bit is set. Once set by hardware, the CODE and MULT bits can be cleared only by software or a full hardware reset. Software clears the CODE and MULT bits by writing a non-zero value to the CODE field and writing 1 to the MULT bit.

NOTE: This error log can be cleared in public mode by a read access. For more details, see Section 5.5.3.2, *Acknowledging Errors*.

5.4.3.7 L3 Firewall and System Control Module

When a security violation occurs, an interrupt is sent to the MPU interrupt controller (if enabled). An in-band error is sent back, and an out-band error is logged in the CONTROL.CONTROL_SEC_ERR_STATUS register. Two logging registers are used, depending on the functional mode:

- In application mode:
  - CONTROL.CONTROL_SEC_ERR_STATUS [00]: OCM-ROM security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [01]: OCM-RAM security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [02]: GPMC security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [04]: SMS security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [07]: L4-Core security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [12]: L3 RT security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [16]: L4-Per security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS [17]: L4-Emu security violation
- In debug mode:
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [00]: OCM-ROM security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [01]: OCM-RAM security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [02]: GPMC security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [03]: SMS security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [12]: L3 RT security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[16]: L4-Per security violation
  - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17]: L4-Emu security violation

When a violation occurs, these bits are cleared when the L3 or L4 firewall embedded error log registers are cleared.

The L3 interconnect allows the inputting of the reset value of some of its internal registers from the system control module. This feature is used to configure the L3 firewalls in a secure state at start-up when required for the different targets. For more information on these registers, see the *System Control Module* chapter.

CAUTION

The exported reset value registers in the system control module can be accessed only when the MPU is in secure mode. They cannot be accessed on general-purpose devices. Outside secure mode, a read to this register returns 0.

5.4.4 Error Handling

5.4.4.1 Error Detection and Logging

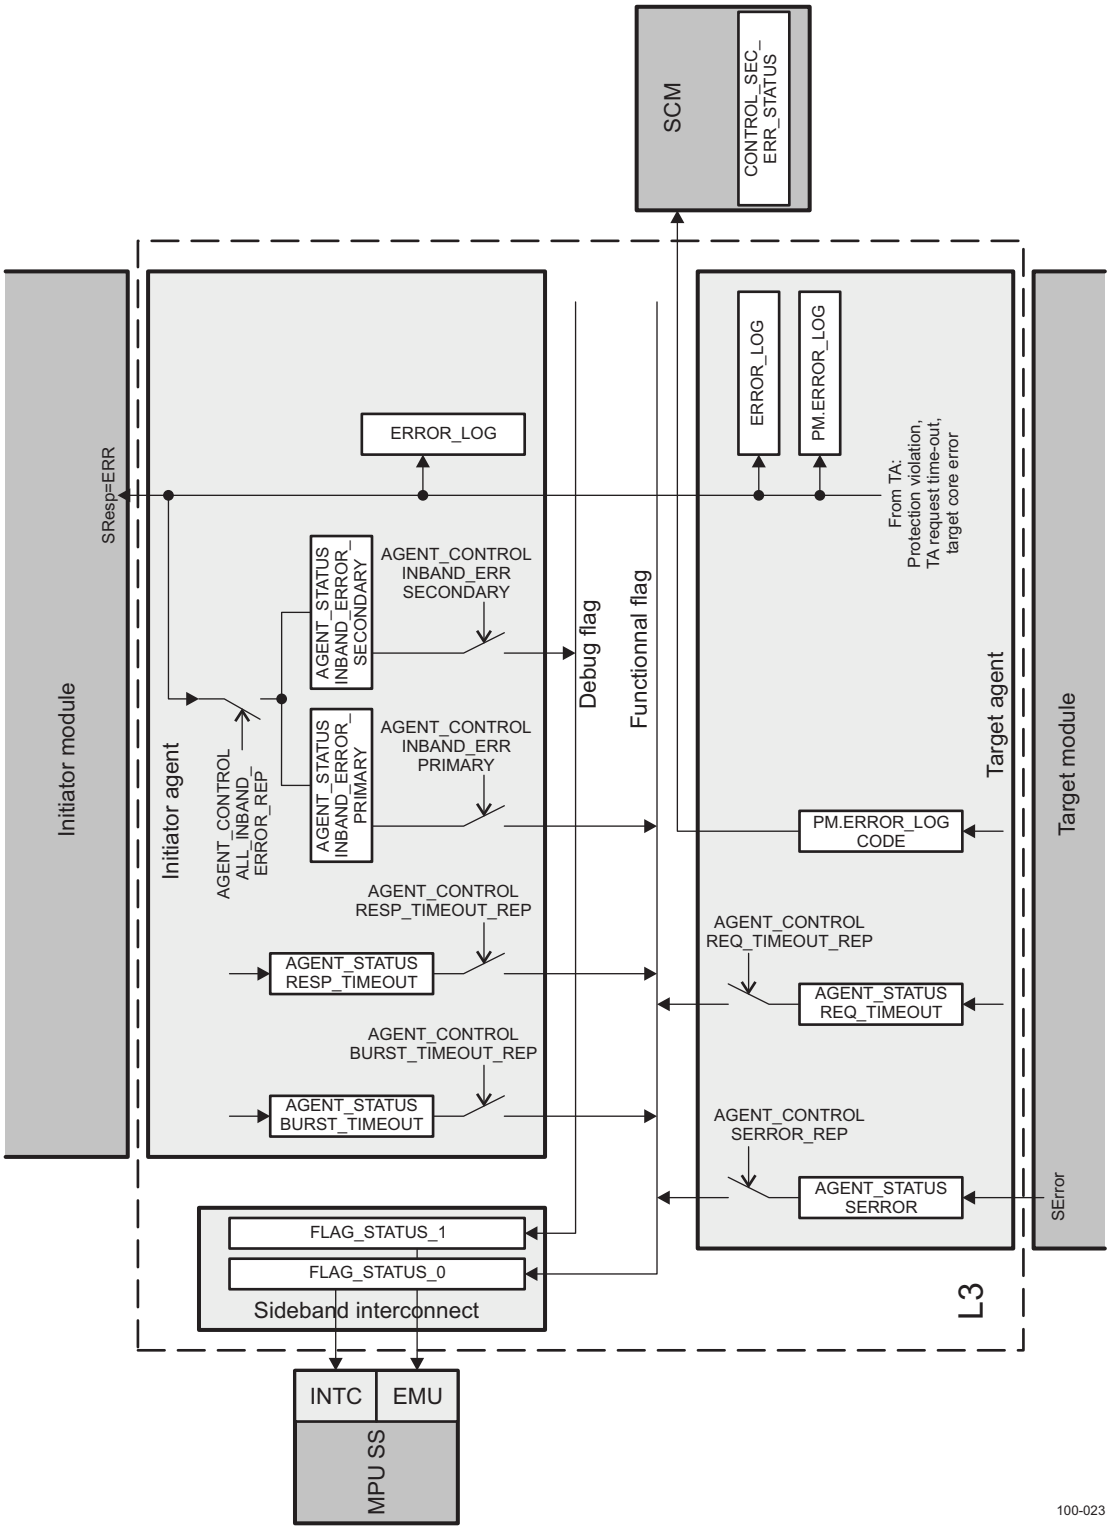
The L3 interconnect provides mechanisms for the detection, logging, and distribution of module-detected and internal interconnect errors. Hardware support is provided to assist in logging errors and cleaning up the state to allow error recovery software to run.

Two types of errors are identified by the L3 interconnect:

- Errors detected by modules and passed along by the interconnect:
  - SResp error: Using the SResp in-band qualifier from the target, the initiator is informed that its request was unsuccessful (see Table 5-3). This error is nonspecific and further analysis is required to find its cause.
  - SError: This out-of-band qualifier reports that the target is denied service due to an internal cause. No further analysis can be done in the L3 itself.
- Errors detected by the L3 interconnect:
  - Unsupported command: This error reports that the initiator sent a command that cannot be processed, because the target cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
  - Address hole: This error reports an unknown address for a request. The address map is local to each IA; therefore, an address hole error is reported each time an initiator requests an access to a target it is not logically connected to, even if this address exists in the global L3 address map. This error is detected only once per burst.
  - Protection violation: This error indicates a request was rejected by a firewall.
  - Requests time-out: This error reports that the module did not end or respond to the request presented by the TA in the correct time interval. If the time interval for any request exceeds the time-out period, a time-out occurs. The target stops servicing requests.
  - Response time-out: This error reports that the module did not end the response presented by the IA in the correct time interval. If the time interval for any response exceeds the time-out period, a time-out occurs. The initiator stops servicing responses.
  - Burst open time-out: This error reports that a burst or ReadEx/Write pair is open and no command is presented to the module to end it. If the time interval for any command exceeds the time-out period, a time-out occurs. The initiator does not complete a burst or ReadEx/Write pair.

Figure 5-8 shows a global view of the register link to the error reporting structure in an initiator and the target agents.

Figure 5-8. L3 Error Reporting Structure



Most errors are reported to the IA that originated the request, except for the following:

- Initiator time-outs are reported only out-of-band. Any time-out in the IA results in flagging it as unavailable. A software reset of the agent is required to accept any new requests from the attached core.

- Posted write request, because the IA immediately generates a valid response to the initiator core. This error is only in out-of-band.

Table 5-24 lists where the errors are detected and logged.

Table 5-24. Error Types

Error	Detection	Logging	In-band Report	Out-of-band Report
SResp error	None needed	At IA	Yes[1]	Yes
SError assertion from target	None needed	At TA	No	Yes
Unsupported command	At IA	At IA	Yes	Yes
Address hole	At IA	At IA	Yes	Yes
Protection violation	At TA	At protection mechanism agent	Yes[1]	Yes
Request time-out	At TA	At TA	Yes [1]	Yes
Response time out	At IA	At IA	No	Yes
Burst time-out	At IA	At IA	No	Yes

(1) In case of a posted write, errors cannot be reported in-band.

The time-out errors (request/response and burst) are persistent and require the software to reset both the module and the agent. No request can be processed in the agent until the reset is performed.

Other errors affect only the current request. Subsequent requests are treated normally. Errors are logged, however, and the information about the error used for debugging is kept until the software acknowledges the error.

Table 5-25 lists the information logged for each error code. Information logged in the two error-logging registers (L3_IA_ERROR_LOG, L3_IA_ERROR_LOG_ADDR, L3_TA_ERROR_LOG and L3_TA_ERROR_LOG_ADDR for each IA and TA) depends on the error itself. The CODE field ERROR_LOG[27:24] identifies the type of error occurring for the IA and TA.

Table 5-25. CODE Field Definition

		Type of Agent			Information Logged				
CODE[3:0]	Error Type	IA	TA	PM	REQ_INFO	Secondary	InitiatorID	CMD	Address
0	No error	x	x						
1	Unsupported command	x			x	x	x	x	x
2	Address hole	x			x	x	x	x	x
3	Protection violation			x	x		x	x	
4	In-band error	x				x	x		
5	Not used								
6	Not used								
7	Request time-out not accepted		x		x		x	x	x
8	Request time-out, no response		x				x		
9-15	Not used								

5.4.4.2 Time-Out

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled in the target agent and initiator agent register. When the mechanism is enabled for a target agent or initiator agent and commands are not accepted or responses are not returned within the expected delay, the L3 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit L3_TA_AGENT_STATUS[8] for a target agent time-out, the BURST_TIMEOUT bit L3_IA_AGENT_STATUS[16] bit for an initiator burst time-out, and the RESP_TIMEOUT bit L3_IA_AGENT_STATUS[8] for an initiator response time-out. The affected agent enters an error state that causes it to send error responses to any new request. To recover from this state, the target agent must be reset by system software.

The time-out is counted starting from the moment a command is presented to the target, whatever the target response to this command is. The L3 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected target agents. These four signals are referred to as 1x time-base, 4x time-base, 16x time-base, and 64x time-base.

The time-base circuit offers four possible sets of four time-base signals selected by programming the TIMEOUT_BASE field L3_RT_NETWORK_CONTROL[10:8]. Table 5-26 lists all of the values in the number of L3 clock cycles.

Each target agent can be programmed to refer to one of the four time-base signals. A time-out condition is detected when either the command acceptance or the response is not received after a delay of between one and three time-base periods. After the time-out is detected and logged, the behavior of the attached module is ignored. A new request to the module arriving at the timed-out target agent receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module using its internal soft-reset bit, and then the agent using software reset.

Table 5-26. L3 Timeout Register Target and Agent Programming

REQ_TIMEOUT[2:0], BURST_TIMEOUT[2:0], and RESP_TIMEOUT[2:0]					
TIMEOUT_BASE[2:0]	**0**	**1**	**2**	**3**	**4**
0	All L3 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

5.4.4.3 Error Steering

The error reporting structure consist of errors logged individually in the initiator or TAs. Some errors can be enabled and reported out-of-band by setting the following bits to 1:

- L3_IA_AGENT_CONTROL.BURST_TIMEOUT_REP bit for burst time-out
- L3_IA_AGENT_CONTROL.RESP_TIMEOUT_REP bit for response time-out
- L3_TA_AGENT_CONTROL.REQ_TIMEOUT_REP bit for request time-out
- L3_TA_AGENT_CONTROL.SERROR_REP bit for request time-out

  Setting the L3_IA_AGENT_CONTROL.ALL_INBAND_ERROR_REP bit causes all in-band errors returned to the IA to be reported out-of-band.

  IAs connected to processors capable of generating the debug-flagged requests (the MPU subsystems) use error steering. Any error linked to an application (nondebug) request is qualified as primary; any error linked to a debug request is qualified as secondary. Setting the IA.INBAND_ERROR_PRIMARY_REP or INBAND_ERROR_SECONDARY_REP bit to 1 allows the reporting of in-band to out-of-band primary and secondary errors.

  The level of the current error is indicated in SECONDARY bit L3_IA_ERROR_LOG[30]. If an error occurs while another error is pending, the following occurs:

  - If the pending error is primary, the new error is discarded at the IA level. MULTI bit L3_IA_ERROR_LOG[31] is set in the initiator error log register to indicate that another error has been detected; no further information can be stored.

- If both the pending error and the new error are secondary, the latest error is discarded and MULTI bit L3_IA_ERROR_LOG[31] is set.
- If the pending error is secondary and the incoming error is primary, MULTI bit L3_IA_ERROR_LOG[31] is set and all useful information about the new error (MCmd, MAddr, MReqInfo, etc.) is stored. All information relative to the secondary error is discarded.

For protection violation, errors are detected at the TA and steered to the control module (see Section 5.4.3.7, *L3 Firewall and System Control Module*).

5.4.4.4 Global Error Reporting

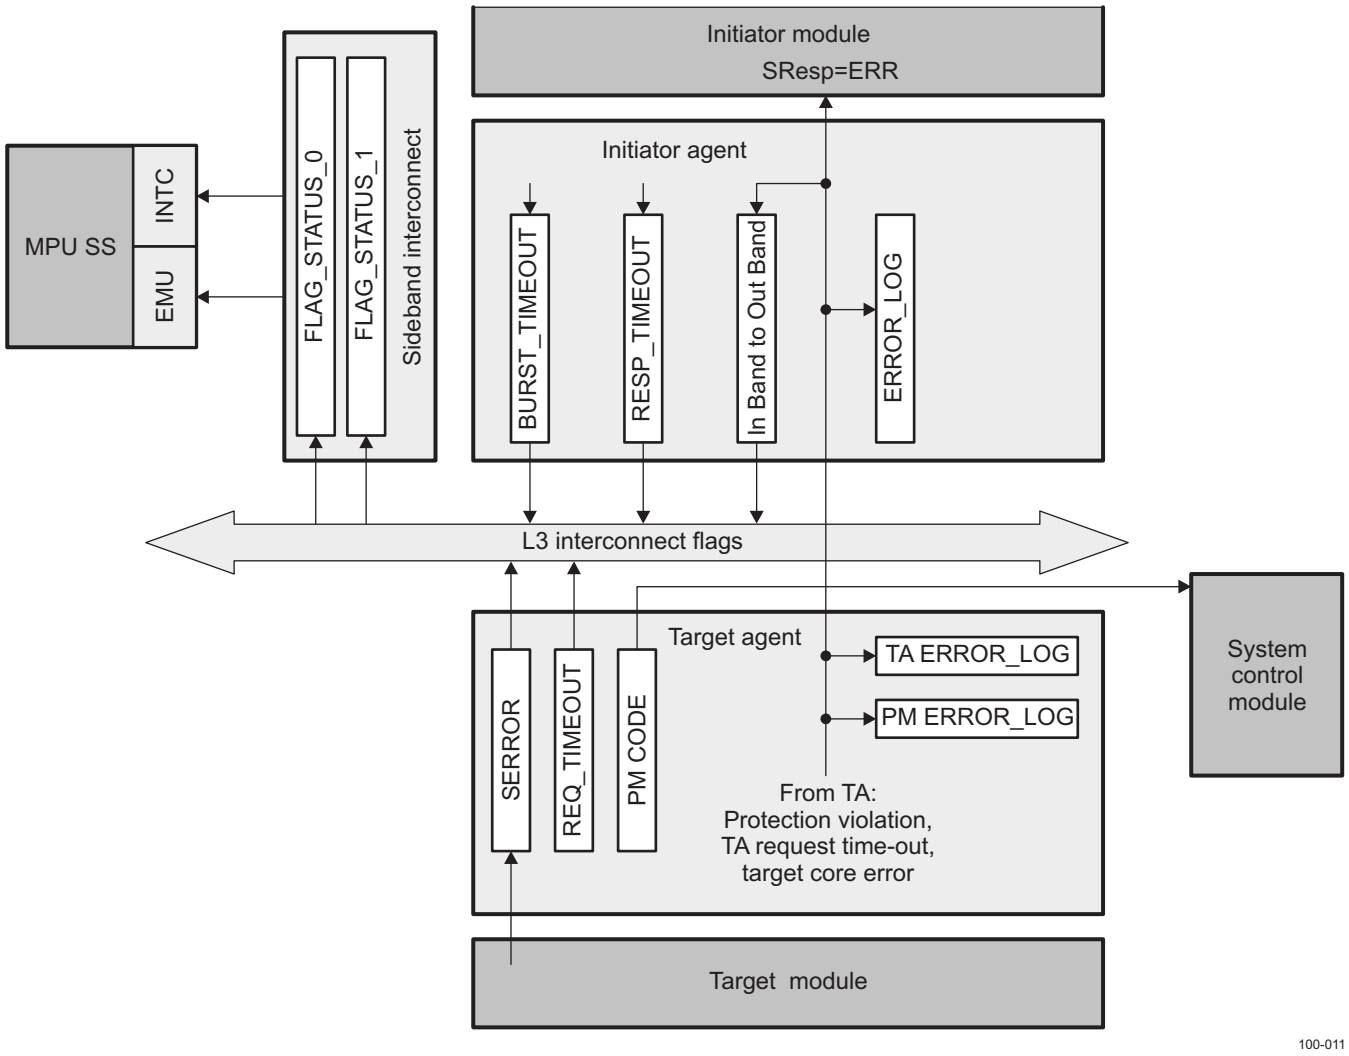
An out-of-band error refers to any flag output from the L3. It is not a formal error in the sense that it is not processed directly by the interconnect module; however, it is interpreted as such by one or several processors, typically by mapping it to an interrupt controller. All L3 out-of-band errors are ORed together and the result is transmitted to one or several interrupt controllers. All out-of-band errors are active high and must be acknowledged through a register access to be de-asserted.

Out-of-band errors are reported through error or flag signals, asynchronously to any other data flow, but synchronously to the clock.

All errors are reported out-of-band to the MPU subsystem simultaneously. The processors must check whether an error is relevant to the subsystems. These errors are routed not only to the MPU subsystem interrupt controllers, but also to their emulation logic (see Figure 5-9). Two composite flags help in asserting the error origin and criticality:

- The L3 application error flag reports application or nonattributable (not related to a request such as a time-out, SError) errors.
- The L3 debug error flag reports debug errors.

Figure 5-9. Global Error Routing



In addition to the SResp qualifier error reporting, some external targets use an SError signal to indicate that an internal error has occurred. Some resetting action may be required before any new request can be accepted, depending on the module and on the error itself. These signals are routed as flags internally to the L3. Table 5-27 lists the possible errors reported through an SError, propagated externally to the L3 interconnect, and aggregated to the L3 application error flag.

Table 5-27. L3 External Input Flags

Target	Flag	Description	Software Visible?
GPMC	SError	General-purpose error occurs in GPMC module	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Core	SError	General-purpose error occurs on L4-Core	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Emu	SError	General-purpose error occurs on L4-Emu	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
L4-Per	SError	General-purpose error occurs on L4-Per	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]

NOTE: The user must ensure that the corresponding IRQ lines are set correctly in the interrupt controllers of the MPU subsystem.

Figure 5-10 shows the routing of errors to the application and debug error composite flags.

Figure 5-10. L3 Error Routing

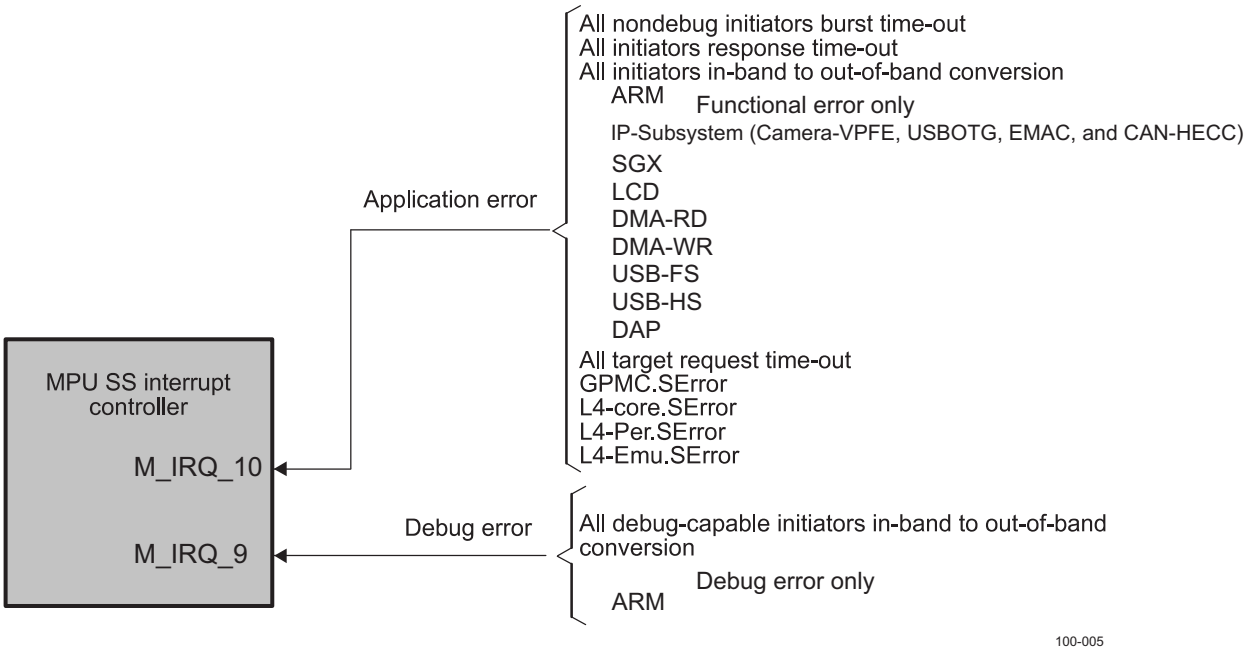


Table 5-28 lists the bit and source for the STATUS bit field L3_SI_FLAG_STATUS_0[63:0] for an application error, and Table 5-29 lists the bit and source for the STATUS bit field L3_SI_FLAG_STATUS_1[63:0] for an application error for a debug error.

Protection errors are reported in-band to the IA when possible. This may not be possible for posted writes, however. These errors are also reported asynchronously to the module.

Additionally, all protection errors (even posted writes) are seen by the in-band-to-out-of-band conversion logic in the IAs. Therefore, all protection errors feed into the L3 application error and L3 debug error composite flags, and hence back to the MPU subsystem.

The SMS, L4-Core, L-4 Per, and L4-Emu interconnects have internal firewalls that use the same reporting scheme. These errors are not routed directly to the L3 interconnect but are reported in-band to the initiator, which routes them to the composite flags. The SMS, L4-Core, L4-Per, and L4-Emu interconnects always provide an error on the in-band SResp qualifier for protection violations.

Table 5-28. L3_SI_FLAG_STATUS_0 for Application Error

5.5 L3 Interconnect Basic Programming Model

5.5.1 General Recommendation

The L3 interconnect registers must be read or written with little-endian attributes; otherwise, the result is undefined.

CAUTION

Overlapping between protection regions with the same priority level leads to unpredictable behavior and must be avoided.

5.5.2 Initialization

At the release of power on reset, the L3 firewall default configuration enables all accesses to target modules, except for a section of the OCM ROM for which default Region 0 is configured to enable access for the MPU with the secure attribute only (this section corresponds to the secure boot ROM in the device memory mapping).

Therefore, the settings of Region 1 in the OCM ROM firewall allow access to 32K bytes of the OCM (this accessible 32K bytes corresponds to the public boot ROM in memory space mapping). For more details, see the *Memory Mapping* chapter.

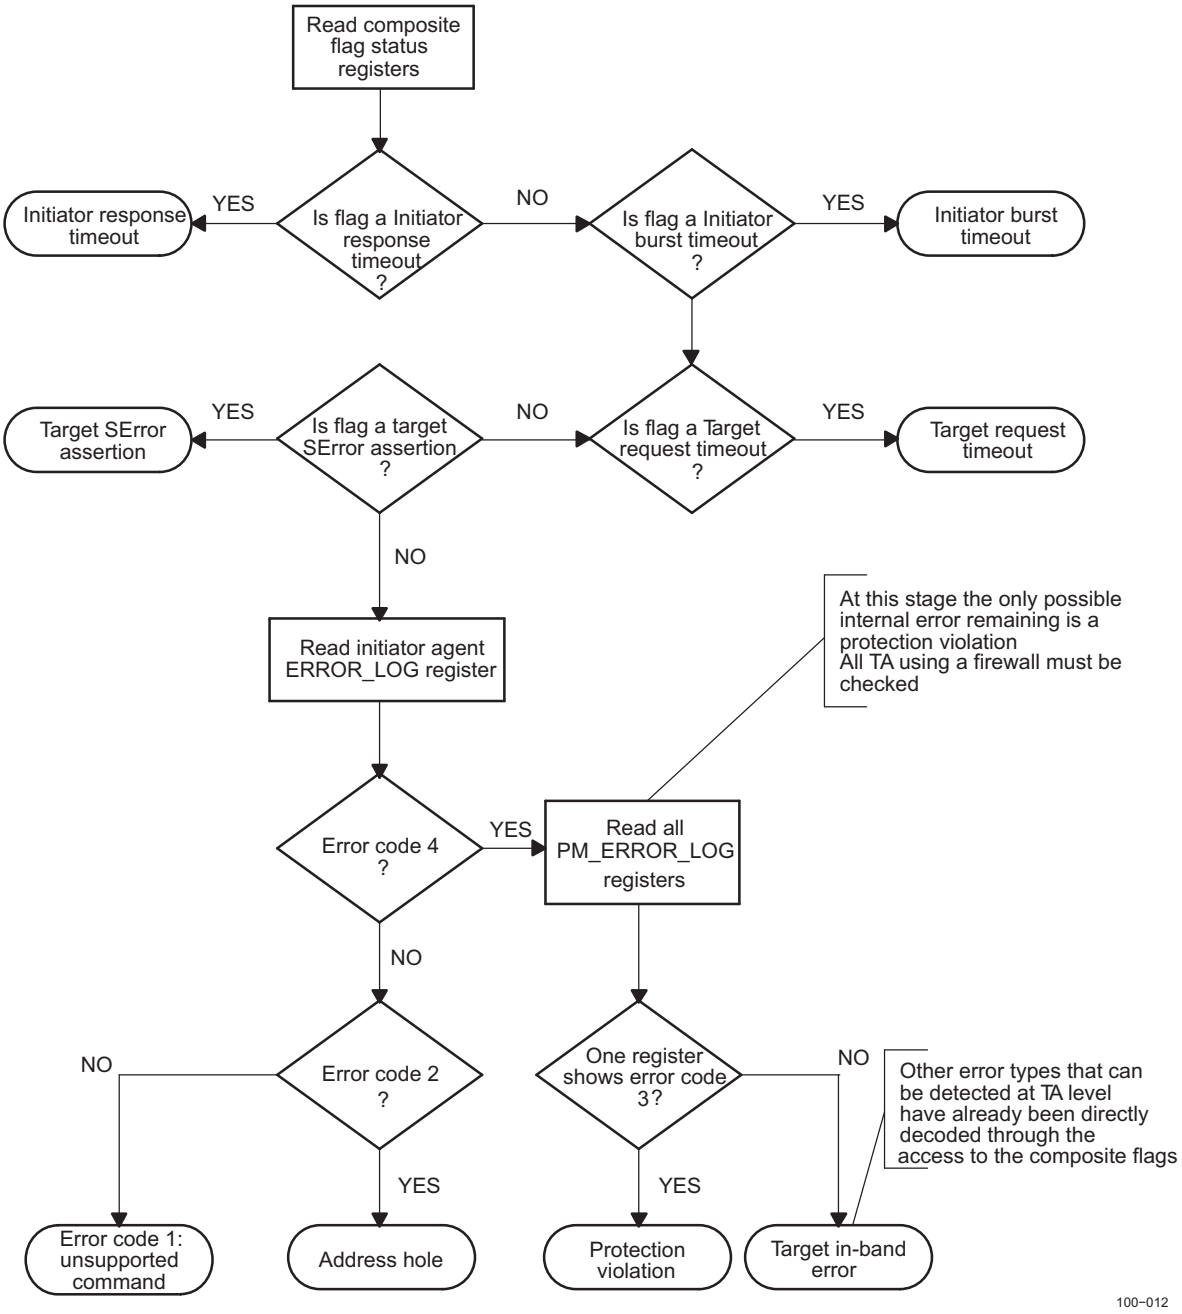
Generally, software must configure the firewall properly to avoid poor use of the hardware resources.

L3 time-out capabilities are also disabled at reset.

5.5.3 Error Analysis

The information required to analyze an error source is logged in several registers (see Table 5-25). The number of registers to access depends on the error source. When investigating the origin of an error, software reads a set of error log registers. At each stage, the register either states the current error or points to the next agent in which the error is logged. Figure 5-11 shows the software sequence required in most cases.

Figure 5-11. Typical Error Analysis Sequence



Errors that do not result from an in-band to out-of-band conversion can be extracted immediately from the application or debug error flag by reading the STATUS field L3_SI_FLAG_STATUS_0[63:0] and L3_SI_FLAG_STATUS_1[63:0] register; therefore, they do not require the whole analysis sequence shown in Table 5-25.

When analysis leads to a TA error, software must read the initiator agent ADDR field L3_IA_ERROR_LOG_ADDR[39:0] to extract the TA address causing the error.

5.5.3.1 Time-out Handling

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Example 1

In this example, the MPU interrupt handler detects an error from the L3 interconnect. A read access from the L3_SI_FLAG_STATUS_0 register reports a value of 0x40000. As described in Table 5-28, the error detected is a burst time-out from the sDMA read port.

As with any time-out error, the affected module is now considered to be out-of-service. If necessary, the error can be cleared by sending a soft reset command to the agent (set CORE_RESET bit L3_IA_AGENT_CONTROL[0] to 1, and then to 0). During this time the initiator is off-line. Although the rest of the system still behaves normally, a time-out error is usually severe enough to require a complete reset of the chip.

Before resetting the agent or the system, the error log registers can learn the status of the interconnect and determine the type of failure. Reading the IA_SDMA_RD.L3_IA_AGENT_STATUS register shows whether the time-out was detected during a burst or during a read/write sequence.

5.5.3.2 Acknowledging Errors

Time-out errors can never be acknowledged. To return to a normal operation after an error, the faulty agent must be reset . An agent can be reset by asserting CORE_RESET bit L3_IA_AGENT_CONTROL[0] or L3_TA_AGENT_CONTROL[0], or by resetting the L3 interconnect through the PRCM.

Functional errors, including an in-band signal reporting a protection error, must be inactived through software. Setting the INBAND_ERROR_PRIMARY and INBAND_ERROR_SECONDARY bits L3_IA_AGENT_STATUS[28-29] in an IA, or setting the SERROR bit L3_IA_AGENT_STATUS[24] in a TA clears the reported error. Table 5-30 lists the bit to clear and the associated type of error.

The L3_IA_ERROR_LOG or L3_TA_ERROR_LOG register must also be cleared by writing a nonzero value simultaneously to the CODE bit field and the values currently stored in the MULTI and SECONDARY fields.

Table 5-30. Error Clearing

Agent Type	Error	Register Field
Initiator	In-band primary (application) error	INBAND_ERROR_PRIMARY
	In-band secondary (debug) error	INBAND_ERROR_SECONDARY
Target	Target asserts SError	SERROR

The procedure to clear protection errors depends on the system security configuration:

- Write a nonzero value simultaneously into CODE bit field L3_PM_ERROR_LOG[27:24] and the value currently stored in the MULTI bit L3_PM_ERROR_LOG[31] of the corresponding PM register block.
- Alternately, read either L3_PM_ERROR_CLEAR_SINGLE or L3_PM_ERROR_CLEAR_MULTI, depending on the current value of the MULTI field in the L3_PM_ERROR_LOG register. This solution, which allows the clearing of protection errors without having a write access on other protection registers, preserves security.

L3_SI_FLAG_STATUS_0 or L3_SI_FLAG_STATUS_1 must be checked at the end of any error acknowledging sequence to confirm that the acknowledgement was successful and that no other error is pending.

5.6 L3 Interconnect Registers

Table 5-31 lists the base address and address space for all L3 register blocks.

Table 5-31. Instance Summary

Module Name	Base Address	Size

5.6.1 L3 Initiator Agent (L3 IA) Register Mapping Summary

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- SGX subsystem port
- High-Speed USB Host
- IP-Subsystem (Camera-VPFE, USBOTG, and EMAC)
- System DMA read port
- System DMA write port
- Display subsystem port
- DAP port

Table 5-32 through Table 5-35 list the IA registers and their physical addresses, depending on the module instance.

Table 5-32. Initiator Agent Common Register Mapping Summary

5.6.3 L3 Target Agent (L3 TA) Register Mapping Summary

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- IP-Subsystem (Camera-VPFE, USBOTG, EMAC and CAN-HECC)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

Table 5-40 through Table 5-43 lists all initiator target registers and their physical addresses depending on the module instance.

Table 5-44 through Table 5-47 describe the individual common registers in the module instance.

Table 5-40. Target Agent Common Register Mapping Summary

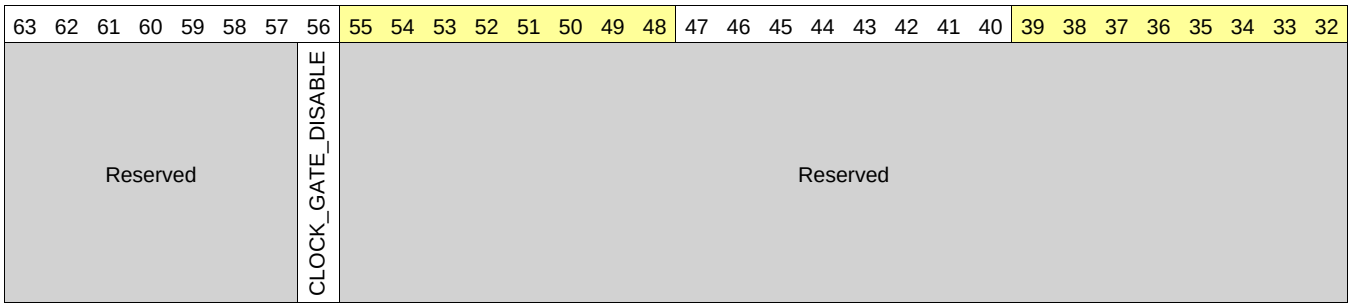
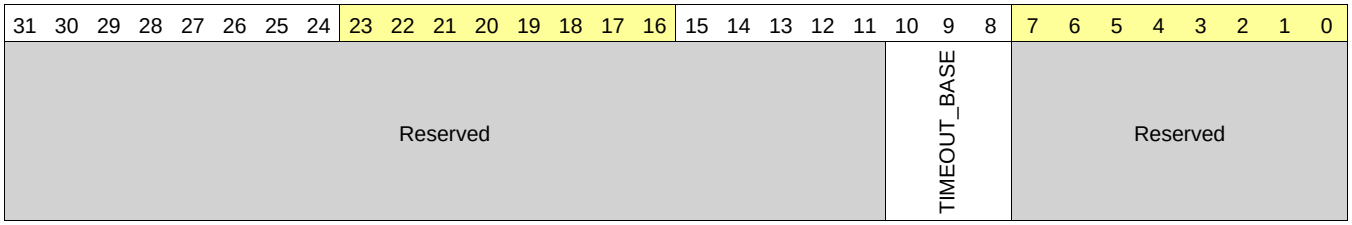
5.6.6.3 L3_RT_NETWORK_CONTROL

Table 5-51. L3_RT_NETWORK_CONTROL

Address Offset	0x068		
Physical address	0x6800 0078	**Instance**	RT
Description	It controls such interconnect wide functions as the timeout base scale and the disabling of fine grained hardware clock gating.		
Type	RW		





Bits	Field Name	Description	Type	Reset
63:57	Reserved	Reserved	R	0x00
56	CLOCK_GATE_ DISABLE	Overrides fine grained hardware clock gating	RW	0
55:11	Reserved	Reserved	R	0x000000000000
10:8	TIMEOUT_BASE	Timeout base period in register target clock cycles Program the timeout base period. Each of the agent timeout features is programmed as a multiple of the timeout base period. These timeout bases are: 0x0: Timeout disabled 0x1: L3 interconnect clock cycles divided by 64 0x2: L3 interconnect clock cycles divided by 256 0x3: L3 interconnect clock cycles divided by 1024 0x4: L3 interconnect clock cycles divided by 4096	RW	0x0
7:0	Reserved	Reserved	R	0x00

5.6.7 Protection Mechanism (PM) Register Mapping Summary

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IP-Subsystem (PM_IPSS module)

Table 5-52 and Table 5-54 list the protection registers and their physical addresses, depending on the module instance.

Table 5-55 through Table 5-60 describe the individual common registers in the module instance.

Table 5-52. Protection Mechanism Common Register Mapping Summary

Register Name	Type	Register Width (Bits)	PM_RT Physical Address	PM_GPMC Physical Address	Section

5.7 L4 Interconnects

5.7.1 Overview

To connect peripheral modules, the device uses four separate L4 interconnect structures. Although all L4 interconnects handle transfers with peripherals, the interconnects are in different power domains. The L4 interconnect is composed of the following:

- L4-Core: Includes the majority of the peripherals and the configuration interface for L3 interconnect system modules
- L4-Per: Includes peripherals that do not need to be mapped in the CORE power domain
- L4-Wakeup: Includes the peripherals attached to the WKUP power domain
- L4-Emu: Includes emulation peripherals attached to the EMU power domain

The following are the main features of the L4 interconnects:

- Single port to connect to L3 interconnect
  - L4-Core
  - L4-Per
- Dual ports for the following:
  - L4-Emu to connect to the L3 interconnect and DAP
  - L4-Wakeup to connect to the L4-Core and L4-Emu
- Single 32-bit initiator for the L3 port
- Multi target ports (one per target interface on the L4 interconnect)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian
- Non-blocking with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- Peak bandwidth of 2x M bytes/sec of L4 frequency (in MHz)
- Latency: Three cycles on request, one cycle on response
- Security logic provides user-configurable access control to targets by each initiator:
  - Firewall in L4-Core protects the core and wake-up peripherals.
  - Firewall in L4-Per protects per peripherals.
  - Firewall in L4-Emu protects emulation and wake-up peripherals

NOTE: L4-Wakeup has two input ports from L4-Core and L4-Emu. Therefore, wake-up peripherals appear in two locations in the memory mapping. Normally, L4-Emu limits its access except when debugging.

Figure 5-12 shows an overview of the L4 interconnects and the peripherals attached to them.

Figure 5-12. L4 Interconnect Overview

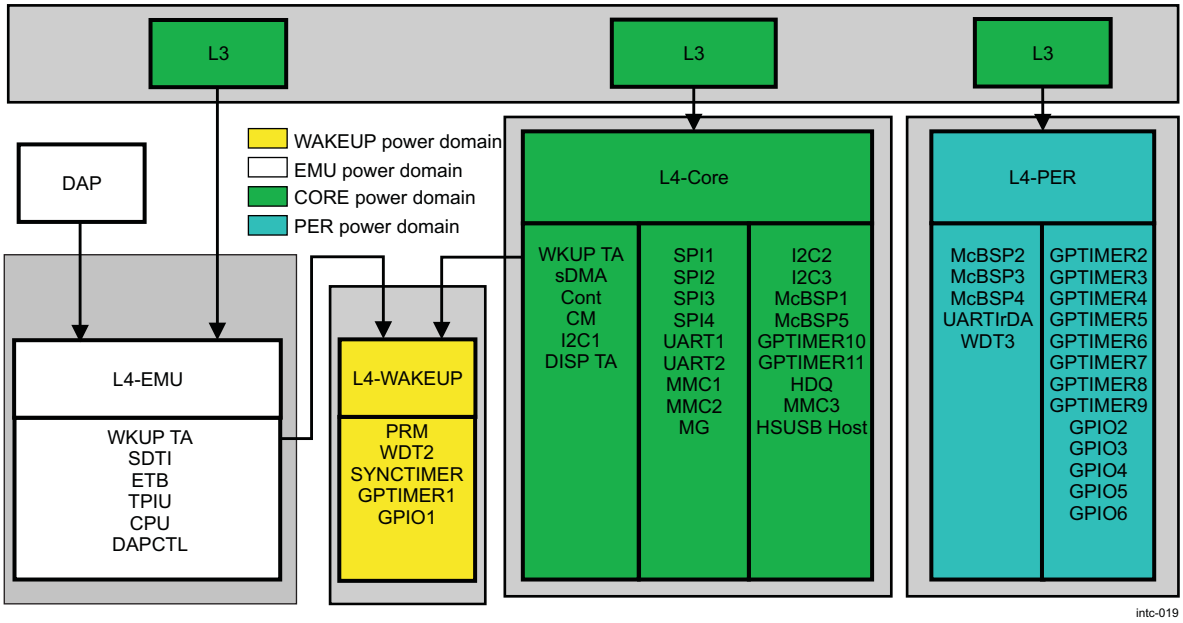

Figure 5-13 shows an internal view of the L4 interconnects in the overall interconnect. This architecture, with only one initiator module (the initiator subsystem) distributing transactions to all target modules (peripherals), enables the firewall functions of the L4 interconnects to be centralized at the L4 initiator level. The L4 firewall filters the accesses according to the configurable protection groups defined in the L4 address protection (AP) registers. Each module or agent is assigned to a protection group. Configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

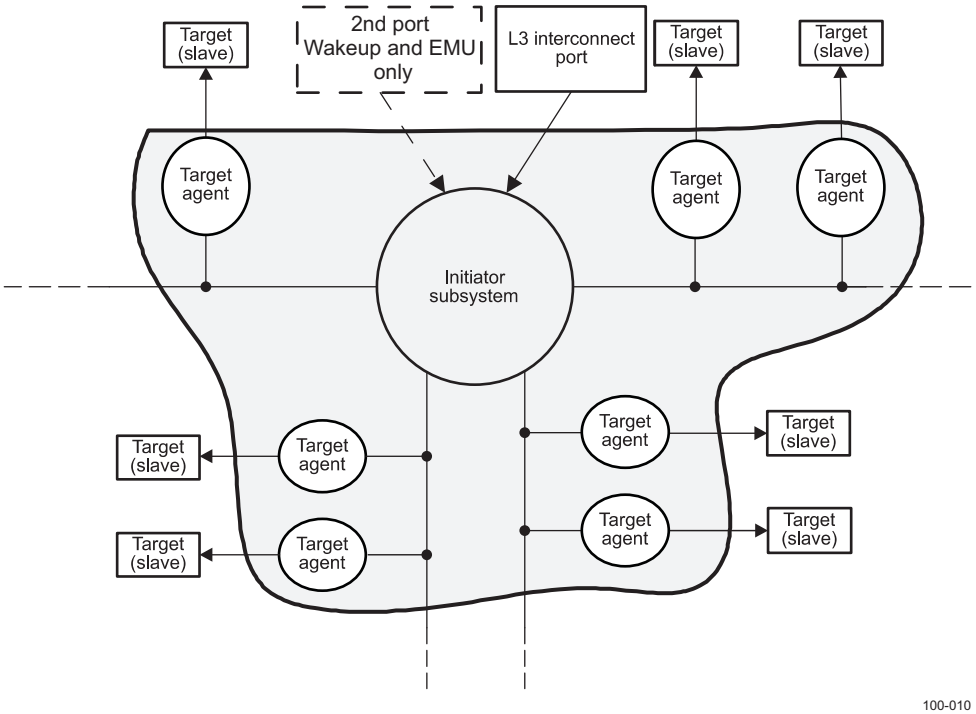
Figure 5-13. L4 Initiator-Target Connectivity for L4-Core and L4-Per



NOTE: As Figure 5-13 shows, targets are attached to branches. These branches have no functional effect and are present for timing closure reasons only.

5.7.1.1 L4-Core Interconnect

The L4-core interconnect handles only transfers to peripherals in the CORE power domain. Table 5-70 lists the TAs.

Table 5-70. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
USBHS Host	Universal serial bus High-Speed port Host
USBTLL	USB Transceiver Less Link
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
I2C1	Multimaster inter-integrated circuit 1
I2C2	Multimaster inter-integrated circuit 2
I2C3	Multimaster inter-integrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
SPI1	Serial peripheral interface 1
SPI2	Serial peripheral interface 2
MMCHS1	Multimedia memory controller SDIO 1
MMCHS2	Multimedia memory controller SDIO 2
MMCHS3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MG	MagicGate
SPI1	Serial peripheral interface 1
SPI2	Serial peripheral interface 2
SPI3	Serial peripheral interface 3
SPI4	Serial peripheral interface 4
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Core targets.

For the list of initiators authorized to access the L4-Core peripherals, see Table 5-14. For details on restricted access, see Section 5.9.3.1, *Protection Mechanism*.

5.7.1.2 L4-Per Interconnect

The L4-Per interconnect handles only transfers to peripherals in the PER power domain. Table 5-71 lists the TAs.

Table 5-71. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Per targets.

For the list of initiators authorized to access the L4-Per peripherals, see Table 5-14. For details on restricted access, see Section 5.9.3.1, *Protection Mechanism*.

5.7.1.3 L4-Emu Interconnect

The L4-Emu interconnect handles only transfers to peripherals in the EMU power domain. Table 5-72 lists the TAs.

Table 5-72. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4-Wakeup interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
DAPCTL	Debug access port

Not all initiators can access all the targets in the L4-Emu interconnect. Additional restrictions affect the ability of these initiators to access the L4-Emu peripherals. Table 5-73 lists which initiators can access the L4-Emu interconnect.

NOTE: For the list of initiators authorized to access the L4-Emu peripherals, see Table 5-14. For details on restricted access, see Section 5.9.3.1, *Protection Mechanism*.

Table 5-73. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

5.7.1.4 L4-Wakeup Interconnect

The L4-Wakeup interconnect handles only transfers to peripherals in the WKUP power domain. Table 5-74 lists the TAs.

Table 5-74. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset manager
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
GPTIMER12[1]	General-purpose timer 12
WDTIMER1[1]	Secure watchdog timer
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer

(1) Not available in GP device.

Initiators that can access the L4-Core or L4-Emu can access all the targets in the L4-Wakeup interconnect. Table 5-75 lists the initiators that can access the L4-Wakeup interconnect. For details on restricted access, see Section 5.9.3.1, *Protection Mechanism*.

Table 5-75. L4-Wakeup Initiator Agents

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emu interconnect port

5.8 L4 Interconnects Integration

5.8.1 Clocking, Reset, and Power-Management Scheme

5.8.1.1 Clocks

Four functional clocks are used in each L4 interconnect (see Table 5-76).

Table 5-76. L4 Interconnect Clocks

Clock	Frequency	Name	Comments
L4-Core interconnect clock	Up to Core_L3_ICLK/2	CORE_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Per interconnect clock	Up to Core_L3_ICLK/2	PER_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Emu clock		L4_EMU	Clock for emulation
L4-Wakeup interconnect clock		WKUP_L4_GICLK	Source, control, and gating handled by PRCM module

5.8.1.2 Resets

5.8.1.2.1 Hardware Reset

L4 interconnects receive a reset signal from the PRCM module, which is the reset signal to the CORE power domain. For more details, see the *Power, Reset, and Clock Management* chapter.

Table 5-77 lists the hardware reset for the L4-Core interconnect.

Table 5-77. L4 Interconnect Hardware Reset

Interconnect	Reset Domain
L4-Core interconnect	CORE_RST
L4-Per interconnect	PER_RST
L4-Wakeup interconnect	WKUP_RST
L4-Emu interconnect	EMU_RST

5.8.1.2.2 Software Reset

The L4 interconnects have hardware reset capabilities, but do not have software reset capabilities. The hardware reset capabilities are controlled by the PRCM module and are applied to the L4 interconnects and the connected L4 TAs and L4 target modules.

5.8.1.3 Power Domain

For more details on power voltage scaling, see the *Power, Reset, and Clock Management* chapter.

Table 5-78 lists the power domains for the L4-Core and L4-Wakeup interconnects.

Table 5-78. L4 Interconnect Power Domains

Interconnect	Power Domain
L4-Core interconnect	CORE
L4-Per interconnect	PER
L4-Emu interconnect	EMU
L4-Wakeup interconnect	WKUP

5.8.1.4 Power Management

5.8.1.4.1 Module Power-Saving

The L4 interconnect automatically performs internal clock autogating to reduce power consumption. Though not recommended, it is possible to deactivate clock autogating by writing 1 to the CLOCK_GATE_DISABLE bit L4_LA_NETWORK_CONTROL_H[24] of each L4 interconnect. Clock autogating is enabled by default.

5.8.1.4.2 System Power Management and Wakeup

As part of the system-wide power-management scheme, the L4 interconnect enters an idle state at the request of the PRCM module (for more information, see the *Power, Reset, and Clock Management* chapter). The L4 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all the transfer requests are complete. This functionality is handled by hardware. The L4 interconnect sends an acknowledge signal back to the PRCM module when it enters idle state.

5.9 L4 Interconnects Functional Description

5.9.1 L4-Interconnects Initiator Identification

In the device interconnect, a ConnID is an initiator module identifier. The L4 interconnect uses the same ConnID as L3.

5.9.2 Endianness Management

Both L4 interconnects are little-endian only. Any initiator accessing the L4 interconnect module must consider byte ordering and perform a conversion, if necessary.

5.9.3 L4 Security and Firewalls

5.9.3.1 Protection Mechanism

The following two parameters are used to set up access permission because of the large address spaces and the number of peripherals connected to the L4 interconnects:

- Programmable groups for initiators:
  - 8 protection groups for the L4-Core interconnect
  - 8 protection groups for the L4-Per interconnect
  - 6 protection groups for the L4-Emu interconnect
- Each segment is divided into regions of 2K bytes:
  - 100 regions for the L4-Core interconnect
  - 43 regions for the L4-Per interconnect
  - 26 regions for the L4-Emu interconnect

NOTE: Regions and segments are present for the L4-Wakeup interconnect but cannot be programmed. The L4-Wakeup protection is done through the L4-Core and L4-Emu interconnects.

A protection group is a group of targets that have the same security settings. Initiator access is defined by CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_k_L[15:0]. The initiators have the same access permission to all regions in this group.

A region is programmed to allow access to a unique selectable protection group by using PROT_GROUP_ID field L4_AP_REGION_l_H[22:20].

NOTE: k denotes the protection group number.

l denotes the region number.

5.9.3.2 Protection Group

A protection group defines which initiators with a given MReqInfo can access the targets agent protected by this group.

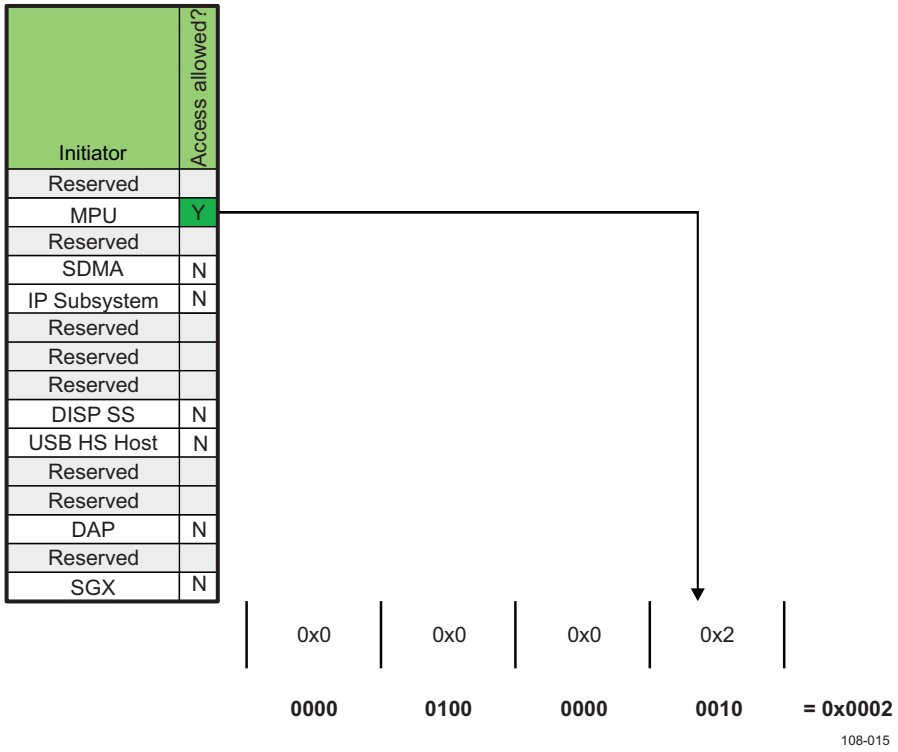
The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k[15:0] (see Figure 5-14) is a 1-bit vector that sets up initiator permission access regions. A protection group is accessible by an initiator if the bit position corresponding to its ConnID is set to one in the CONNID_BIT_VECTOR field.

The ENABLE field L4_AP_PROT_GROUP_ROLES_k[31:0] lists all possible MReqInfo combinations. Setting a Req bit in this register determines the type of access allowed to the initiator. See Section 5.4.3.4, *REQ_INFO_PERMISSION Configuration*, for more information. MReqInfo is used in L4 the same way it is used in the L3 firewall configuration.

NOTE: Permissions are identical for read and write accesses in L4 interconnect targets.

Figure 5-14 shows an example of CONNID_BIT_VECTOR.

Figure 5-14. Example of CONNID_BIT_VECTOR



Setting bits 1 and 4 in the PROT_GROUP_ID_1 defines a group initiator able to access targets in protection group 1, and includes:

- MPU SS

Protection group 1 (PG1) can be applied to multiple protection regions without limitation. Each protection region l that is configured with PG1 enables permission access to these two initiators only.

The firewall default configuration for the L4-Core interconnect contains eight protection groups to ensure security:

- Most regions are, by default, set with protection group 7 (PG7), which is configured for all access (see Table 5-79).
- Protection group 0 (PG0) is restricted to the MPU subsystem in public.
- By default, the hardware crypto-processors (DES, SHA1-MD5, AES, FPKA, RNG, and WDTIMER1 not available in GP device) are attached to PG1 and are publicly accessible by all the initiators that can access the L4-Core.
- The LCD is attached to protection group 2 (PG2).
- The GPTIMER12 of the L4-Wakeup interconnect is attached to protection group 4 (PG4) (not available in GP device).
- By default, PG5 to PG7 are configured for all access.

NOTE: System control module and secure watchdog timer have an embedded firewall.

The L4-Per interconnect contains eight protection groups:

- By default, PG0 to PG7 are configured for all access.
- By default, most regions are set with PG7, which is configured for all access (see Table 5-80).

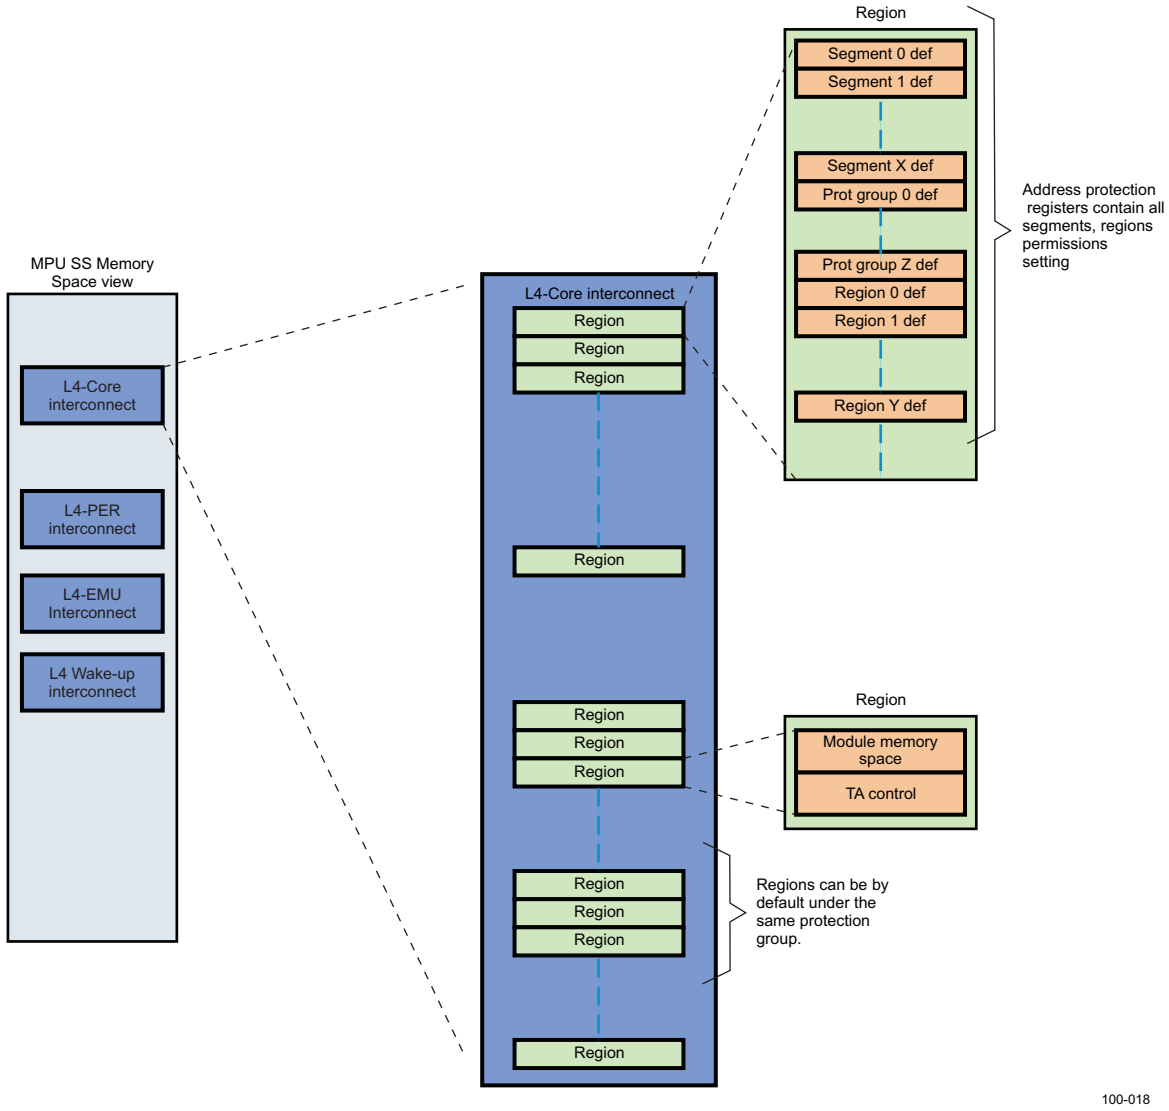
The L4-Emu interconnect contains six protection groups:

- By default, most regions are set with PG5, which is configured for all access (see Table 5-81).
- The AP is attached to PG0.
- The WDTIMER1 is attached to PG1 (not available in GP device).
- The GPTIMER12 is attached to PG2 (not available in GP device).
- The emulation organs are attached to PG3.

5.9.3.3 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation (see Figure 5-15). By default, some regions are attached to a specific protection group. This specificity allows the user to set up the permission access for certain types of modules that require the same access protection without managing the region allocation.

Figure 5-15. L4 Firewall Overview



All interconnect address spaces are covered by regions. Table 5-79to Table 5-81 list the module mapping, including the address, region number, and default protection group allocated to it.

By setting ENABLE bit L4_AP_REGION_y_H[0] to 0, the region becomes inactive and therefore inaccessible. Setting the bit to 1 activates the region.

Table 5-79. Region Allocation for L4-Core Interconnect

5.9.3.4 L4 Firewall Address and Protection Registers Setting

Table 5-82 lists the settings of the AP registers for an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 5-82. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L	23:0	Base	Segment base address
	L4_AP_SEGMENT_i_H	4:0	SIZE	Segment size equals to 2 power of SIZE
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L	15:0	CONNID_BIT_VECTOR	See Section 5.9.1 for L4ConnID).
	L4_AP_PROT_GROUP_ROLES_k_L	15:0	ENABLE	Refer to Table 5-21 for MReq description
Region setting	L4_AP_REGION_I_L	23:0	BASE	Define the base address of region in respect to its respective segment base address
	L4_AP_REGION_I_H	27:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	The protection group attached to the region
		19:17	BYTE_DATA_WIDTH_EXP	Determine the number of bytes in an access
		5:1	SIZE	Size of the region equals to 2 power of SIZE
		0	ENABLE	Enable the region protection

5.9.4 Error Handling

5.9.4.1 Overview

The L4 interconnect provides mechanisms for handling either internally detected errors or errors reported by modules attached to the L4 target ports. Hardware support facilitates logging errors and cleaning up the state to allow error recovery software to treat the error.

As an L3 target, the L4 interconnect reports errors to the L3 interconnect in-band whenever possible. In-band error reporting is the default and recommended configuration. It is assumed that INBAND_ERROR_REP bit L4_IA_AGENT_CONTROL_L[27] is set to 1.

NOTE: *L4_IA* denotes which interconnect is considered: L4-Core, L4-Per, L4-Emu, or L4-Wakeup.

L4_TA denotes the module name, such as UART1, McBSP1, etc.

The L4 interconnects handle three types of errors:

- No target core found or address hole
- Request protection violation
- Failure of the target to service a request before a time-out expires

5.9.4.2 Error Logging

5.9.4.2.1 No Target Core Found/Address Hole

This error indicates that a request was addressed to a hole in the L4 address map.

When this occurs, an in-band error response is returned to the L3 level.

The error is also logged into the INBAND_ERROR bit L4_IA_AGENT_STATUS_L[27].

Additionally, an address hole error code is logged into the CODE field L4_IA_ERROR_LOG_L[25:24].

The L4_IA_ERROR_LOG register also includes MULTI bit L4_IA_ERROR_LOG_L[31], which is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

5.9.4.2.2 Protection Violation

This error indicates that an initiator has accessed a restricted region. This error is reported using an in-band error. It is written to the INBAND_ERROR field. A protection violation error code is also saved in the CODE field L4_IA_ERROR_LOG_L[25:24].

The security violation is also logged in the CONTROL_SEC_ERR_STATUS [7] register of the system control module.

NOTE: There is no specific error signal for the security violation that goes out from the L4 interconnects. The out-band error that goes to the system control module indicates a SECURITY_VIOLATION, but it also indicates normal interconnect errors.

5.9.4.2.3 Time-Out

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled on a per-target basis in the L4_TA_AGENT_CONTROL_L register. If the mechanism is enabled for a TA, and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit L4_TA_AGENT_STATUS_L[8]. The affected TA enters an error state that causes it to send error responses to any new request targeted at it. To recover from this state, the TA must be reset by system software. The time-out is counted starting from the moment a command is presented to the target, regardless of how the target responds to the command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. These four signals are referred to as 1X-time base, 4X-time base, 16X-time base, and 64X-time base.

The time-base circuit offers four possible sets of time-base signals. Selection is done by programming TIMEOUT_BASE field L4_LA_NETWORK_CONTROL_L[10:8]. Table 5-83 lists the values in the number of L4 clock cycles.

Table 5-83. L4 Time-Out Link and TA Programming

	REQ_TIMEOUT[2:0]				
TIMEOUT_BASE[2:0]	**0**	**1**	**2**	**3**	**4**
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

The reset value is 0x4, resulting in the longest possible time-out.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, by using REQ_TIMEOUT field L4_TA_AGENT_CONTROL_L[10:8] (see Table 5-84).

Table 5-84. L4 Time-Out TA Programming

REQ_TIMEOUT	Target Agent Time-out Reference
0	Time-out locally disabled
1	1X-base cycle
2	4X-base cycle
3	16X-base cycle
4	64X-base cycle

A time-out condition is detected when the command acceptance or the response is not received after a delay of between one and three time-base periods.

Example:

- L4 frequency = 100 MHz
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for target agent A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for target agent B

At agent A, the time-base unit is 16384 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 164 µs to 492 µs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 2.6 ms to 7.8 ms.

On detection of a time-out condition, the agent automatically generates an error response to the inter_IA, which is forwarded to the L3. The agent also logs the time-out to REQ_TIMEOUT bit L4_TA_AGENT_STATUS_L[8].

After the time-out has been detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module by using its internal soft reset bit, and then the TA by using OCP_RESET bit L4_TA_AGENT_CONTROL_L[0].

5.9.4.3 TA Software Reset

Writing 1 to OCP_RESET bit L4_TA_AGENT_CONTROL_L[0] initiates the software reset period. The software reset must be asserted for at least 16 cycles of the target module OCP clock, which can be a divided clock with respect to the L4 clock.

During the software reset period the following occur:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to avoid getting unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Writing 0 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit terminates the software reset period.

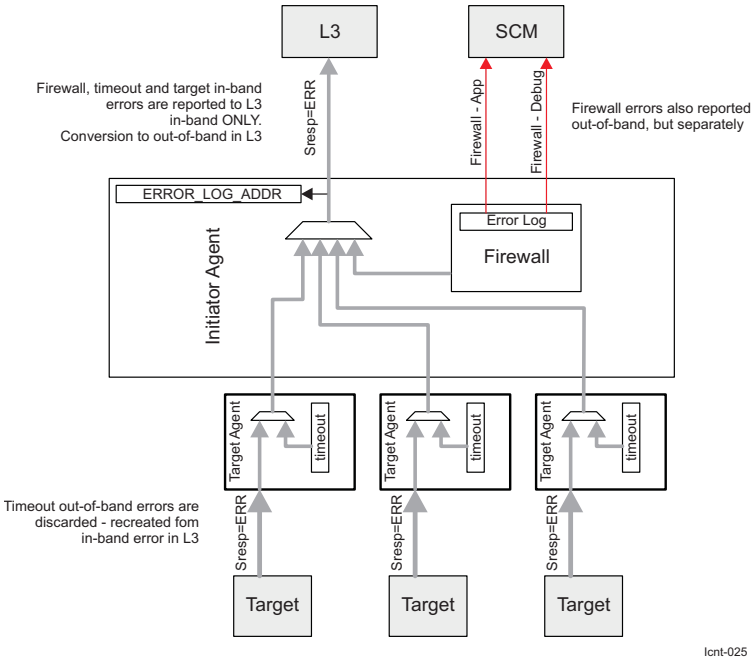
The attached module must then be reset to complete the recovery.

5.9.4.4 Error Reporting

Figure 5-16 illustrates the error-reporting scheme used in the L4_Core, L4_Per, and L4_EMU interconnects.

- Timeout error generation is enabled at each TA.
- Timeout error and target in-band errors are only reported in-band to the L3 initiator.
- Protection violations are reported out-of-band. Error steering is used to distinguish between application or debug errors.

Figure 5-16. L4 Error Reporting



5.10 L4 Interconnects Registers

A summary of the hardware interface for the L4-Core, L4-Per, L4-Emu and L4-Wkup interconnects is given in Table 5-85 to Table 5-88. Each module instance in the design is shown with the module register map and bit definitions for each bit field.

5.10.1 L4 Initiator Agent (L4 IA) Register Mapping Summary

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in Table 5-89 to Table 5-90.

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 5-89. L4 IA Register Mapping Summary (1)

5.10.2 L4 Initiator Agent (L4 IA) Register Descriptions

5.10.2.1 L4_IA_AGENT_CONTROL_L

Table 5-91. L4_IA_AGENT_CONTROL_L

Address Offset	0x020
Physical address	Please refer fromTable 5-89 to Table 5-90
Description	Enable error reporting on an initiator interface. The error reporting mechanism is enabled when the INBAND_ERROR_REP bit field is set to 1. The out-of-band OCP MError reporting mechanism is enabled when the MERROR_REP bit field is set to 1.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				INBAND_ERROR_REP	Reserved		MERROR_REP	Reserved																							

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27	INBAND_ERROR_REP	Setting this field to 1 reports on in-band errors using the INBAND_ERROR log bit of IA.AGENT_STATUS register.	R	1
26:25	Reserved	Read returns 0.	R	0x0
24	MERROR_REP	Enable MError reporting	R	0x0
23:0	Reserved	Read returns 0.	R	0x0000000

5.10.2.2 L4_IA_AGENT_STATUS_L

Table 5-92. L4_IA_AGENT_STATUS_L

Address Offset	0x028
Physical address	Please refer fromTable 5-89 to Table 5-90
Description	Stores status information for an initiator. The INBAND_ERROR and MERROR fields are read/write and are implemented as log bits.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				INBAND_ERROR_REP	Reserved		MERROR_REP	Reserved																							

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27	INBAND_ERROR_REP	0x0 No In-Band error present. 0x1 In-Band error present.	R 1toClr	0x0
26:25	Reserved	Read returns 0.	R	0x0
24	MERROR_REP	0x0 No MError error present. 0x1 MErorr error present.	R	0x0
23:0	Reserved	Read returns 0.	R	0x0000000

5.10.2.3 L4_IA_ERROR_LOG_L

Table 5-93. L4_IA_ERROR_LOG_L

Address Offset	0x058
Physical address	Please refer fromTable 5-89 to Table 5-90
Description	Log information about error conditions. The CODE field logs any protection violation or address hole errors detected by the initiator subsystem while decoding a request.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MULTI	Reserved						CODE	Reserved																							

Bits	Field Name	Description	Type	Reset
31	MULTI	While the CODE field is not zero, the MULTI bit is asserted whenever an additional error is detected. Once set by hardware, the MULTI bit can only be cleared by writing a 1 to it while writing a value other than zero to the CODE field.	RW	0
30:26	Reserved	Read returns 0.	R	0x00

Bits	Field Name	Description	Type	Reset
25:24	CODE	The error code of an initiator request. 0x00: No errors 0x01: Reserved 0x10: Address hole 0x11: Protection violation The CODE field, once set by hardware, can only be cleared by writing a non-zero value to it, in conjunction with writing a 1 to the MULTI bit field.	RW	0x0
23:0	Reserved	Read returns 0.	R	0x000000

5.10.3 L4 Target Agent (L4 TA) Register Mapping Summary

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in Table 5-94 to Table 5-122.

Table 5-94 to Table 5-123 provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

5.10.4.1 L4_TA_AGENT_CONTROL_L

Table 5-124. L4_TA_AGENT_CONTROL_L

Address Offset	0x020
Physical address	Please refer fromTable 5-94 to Table 5-123
Description	Enable error reporting
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							SERROR_REP	Reserved													REQ_TIMEOUT			Reserved							OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	Reserved	Read returns 0.		
10:8	REQ_TIMEOUT	Timeout Bound. Values are:0 - No timeout 1 - 1x base cycles 2 - 4x base cycles 3 - 16x base cycles 4 - 64x base cycles	RW	0x2
7:1	Reserved	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to de-assert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

5.10.4.2 L4_TA_AGENT_CONTROL_H

Table 5-125. L4_TA_AGENT_CONTROL_H

Address Offset	0x024
Physical address	Please refer fromTable 5-94 to Table 5-123
Description	Enable clock power management
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																							EXT_CLOCK	Reserved							

Bits	Field Name	Description	Type	Reset
31:9	Reserved	Read returns 0.	R	0x000000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on a target agent indicates when the target agent should shut off.	R	0
7:0	Reserved	Read returns 0.	R	0x00

5.10.4.3 L4_TA_AGENT_STATUS_L

Table 5-126. L4_TA_AGENT_STATUS_L

Address Offset	0x028
Physical address	See Table 5-94 to Table 5-123
Description	Error reporting
Type	RW

Reserved								Reserved															REQ_TIMEOUT	Reserved							

Bits	Field Name	Description	Type	Reset
31:24	Reserved	Read returns 0.	R	0x00
23:9	Reserved	Read returns 0.	R	0x0001
8	REQ_TIMEOUT	0x0: No request timeout 0x1: A request timeout has occurred	R 1toCLR	0
7:0	Reserved	Read returns 0.	R	0x00

5.10.5 L4 Link Register Agent (LA) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in Table 5-127.

The LA register block contains the initiator subsystem information register and the composite sideband signal mask and status registers.

Table 5-127. L4 LA Register Mapping Summary

Register Name	Type	Register Width (Bits)	CORE_LA Physical Address	PER_LA Physical Address	EMU_LA Physical Address	WKUP_LA Physical Address

5.10.6 L4 Link Register Agent (LA) Register Descriptions

5.10.6.1 L4_LA_NETWORK_H

Table 5-128. L4_LA_NETWORK_H

Address Offset	0x014
Physical address	Please refer to Table 5-127
Description	Identify the interconnect
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID																															

Bits	Field Name	Description	Type	Reset
31:0	ID	The ID field uniquely identifies this interconnect, and can serve as a chip ID.	R	0x00010000

5.10.6.2 L4_LA_INITIATOR_INFO_L

Table 5-129. L4_LA_INITIATOR_INFO_L

Address Offset	0x018
Physical address	Please refer to Table 5-127
Description	Contain initiator subsystem information.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				PROT_GROUPS				NUMBER_REGIONS								Reserved												SEGMENTS			

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0.	R	0x0
27:24	PROT_GROUPS	The number of protection groups. The PROT_GROUPS field contains read-only configuration information for the address mapping and security structure of the initiator subsystem. If the PROT_GROUPS field is set to 0, there are no protection group registers.	R	see Table 5-130
23:16	NUMBER_REGIONS	The number of regions. The NUMBER_REGIONS field contains read-only configuration information for the region register of the initiator subsystem.	R	see Table 5-130
15:4	Reserved	Read returns 0.	R	0x000
3:0	SEGMENTS	The number of segments. The SEGMENT fields contains read-only configuration information for the segment register of the initiator subsystem.	R	see Table 5-130

Table 5-130. Reset value for L4_LA_INITIATOR_INFO_L

Field Name	CORE_LA	PER_LA	EMU_LA	WKUP_LA
PROT_GROUPS	0x8	0x8	0x8	0x8
NUMBER_REGIONS	0x64	0x2B	0x1A	0x13
SEGMENTS	0x6	0x5	0x3	0x2

5.10.6.3 L4_LA_INITIATOR_INFO_H

Table 5-131. L4_LA_INITIATOR_INFO_H

Address Offset	0x01C
Physical address	Please refer to Table 5-127
Description	Contain initiator subsystem information.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													THREADS			Reserved	CONNID_WIDTH			Reserved	BYTE_DATA_WIDTH_EXP			Reserved			ADDR_WIDTH				

Bits	Field Name	Description	Type	Reset
31:19	Reserved	Read returns 0.	R	0x0000
18:16	THREADS	The THREADS field specifies the number of initiator threads connected to the interconnect. The field contains read-only configuration information for the initiator subsystem.	R	see Table 5-132
15	Reserved	Read returns 0.	R	0
14:12	CONNID_WIDTH	The initiator subsystem connID width. The CONNID_WIDTH field contains read-only configuration information for the initiator subsystem.	R	see Table 5-132
11	Reserved	Read returns 0.	R	0
10:8	BYTE_DATA_WIDTH_EXP	This field specifies the initiator subsystem data width. 1:2^1 bytes specifies a 16-bit data width and 2:2^2 bytes specifies a 32-bit data width. The BYTE_DATA_WIDTH_EXP field contains read-only configuration information for the initiator subsystem.	R	see Table 5-132
7:5	Reserved	Read returns 0.	R	0x0
4:0	ADDR_WIDTH	This field specifies the initiator subsystem address width. The ADDR_WIDTH field contains read-only configuration information for the initiator subsystem.	R	see Table 5-132

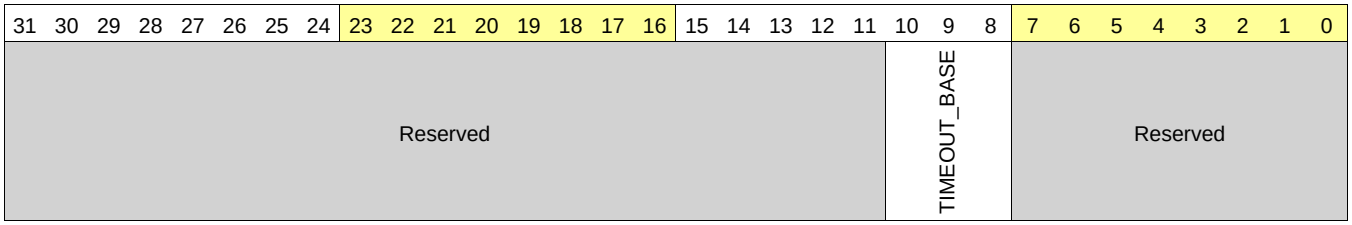
Table 5-132. Reset value for L4_LA_INITIATOR_INFO_H

Field Name	CORE_LA	PER_LA	EMU_LA	WKUP_LA
THREADS	0x4	0x4	0x2	0x2
CONNID_WIDTH	0x4	0x4	0x4	0x0
BYTE_DATA_WIDTH_EXP	0x2	0x2	0x2	0x2
ADDR_WIDTH	0x18	0x14	0x18	0x14

5.10.6.4 L4_LA_NETWORK_CONTROL_L

Table 5-133. L4_LA_NETWORK_CONTROL_L

Address Offset	0x020
Physical address	Please refer to Table 5-127
Description	Control interconnect minimum timeout values.
Type	RW



Bits	Field Name	Description	Type	Reset
31:11	Reserved	Read returns 0.	R	0x000000
10:8	TIMEOUT_BASE	The TIMEOUT_BASE field indicates the timeout period (that is, base cycles) for the highest frequency time-base signal sent from the L4 initiator subsystem to all target agents that have timeout enabled. Values for the field are: 0 - Timeout disabled 1 - L4 interconnect clock cycles divided by 64 2 - L4 interconnect clock cycles divided by 256 3 - L4 interconnect clock cycles divided by 1024 4 - L4 interconnect clock cycles divided by 4096	RW	0x4
7:0	Reserved	Read returns 0.	R	0x00

5.10.6.5 L4_LA_NETWORK_CONTROL_H

Table 5-134. L4_LA_NETWORK_CONTROL_H

Address Offset	0x024
Physical address	Please refer to Table 5-127
Description	Control interconnect global power control
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CLOCK_GATE_DISABLE	Reserved			THREAD0_PRI	Reserved											EXT_CLOCK	Reserved							

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	Reserved	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	Reserved	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	Reserved	Read returns 0.	R	0x00

5.10.7 L4 Address Protection (AP) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in Table 5-135.

The AP register block contains the segment, address region, and protection group registers that can be used to specify the addressing scheme or restrict the access of target address regions.

Table 5-135. L4 AP Register Mapping Summary

Register Name	Type	Register Width (Bits)	CORE_AP Physical Address	PER_AP Physical Address	Section

5.10.8 L4 Address Protection (AP) Register Descriptions

5.10.8.1 L4_AP_SEGMENT_i_L

Table 5-141. L4_AP_SEGMENT_i_L

Address Offset	0x100 + (0x08*i)	**Index**	i = 0 to 5 for CORE_AP, i = 0 to 4 for PER_AP, i = 0 to 2 for EMU_AP, i = 0 to 1 for WKUP_AP,
Physical address	Please refer to Table 5-135		
Description	Define the base address of each segments		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BASE																							

Bits	Field Name	Description	Type	Reset
31:24	Reserved	Read returns 0.	R	0x00
23:0	BASE	The base address of the segment (with 0s from bit 0 to bit SIZE-1).	R	see Table 5-142

Table 5-142. Reset Values for L4_AP_SEGMENT_i_L

BASE	CORE_AP	PER_AP	EMU_AP	WKUP_AP
i = 0	0x00 0000	0x00 0000	0x00 0000	0x00 0000
i = 1	0x04 0000	0x02 0000	0x40 0000	0x02 0000
i = 2	0x08 0000	0x03 0000	0x60 0000	N/A
i = 3	0x0C 0000	0x04 0000	N/A	N/A
i = 4	0x30 0000	0x05 0000	N/A	N/A
i = 5	0x32 0000	N/A	N/A	N/A

5.10.8.2 L4_AP_SEGMENT_i_H

Table 5-143. L4_AP_SEGMENT_i_H

Address Offset	0x104 + (0x08*i)	**Index**	i = 0 to 5 for CORE_AP, i = 0 to 4 for PER_AP, i = 0 to 2 for EMU_AP, i = 0 to 1 for WKUP_AP,
Physical address	Please refer to Table 5-135		
Description	Define the size of each segments		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								SIZE							

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Read returns 0.	R	0x0000000
4:0	SIZE	Segment size is a power of 2, where 2^SIZE is the byte size of a segment (all segment registers use the same size).	R	see Table 5-144

Table 5-144. Reset Values for L4_AP_SEGMENT_i_H

SIZE	CORE_AP	PER_AP	EMU_AP	WKUP_AP
For all i	0x12	0x10	0x15	0x11

5.10.8.3 L4_AP_PROT_GROUP_MEMBERS_k_L

Table 5-145. L4_AP_PROT_GROUP_MEMBERS_k_L

Address Offset	0x200 + (0x08*k)	**Index**	k = 0 to 7 for CORE_ AP and PER_AP. k = 0 to 5 for EMU_AP
Physical address	Please refer to Table 5-135		
Description	Define connID bit vectors for a protection group.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CONNID_BIT_VECTOR															

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Read returns 0	R	0x0000
15:0	CONNID_BIT_VECTOR	A bit of 1 in position n means that connID n is allowed in this protection group. Illegal connIDs have their bits set to 0s.	R	0xFFFF

5.10.8.4 L4_AP_PROT_GROUP_ROLES_k_L

Table 5-146. L4_AP_PROT_GROUP_ROLES_k_L

Address Offset	0x200 + (0x08*k)	**Index**	k = 0 to 7 for CORE_ AP and PER_AP. k = 0 to 5 for EMU_AP
Physical address	Please refer to Table 5-135		
Description	Define MReqInfo bit vectors for a protection group.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																ENABLE															

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Read returns 0	R	0x0000
15:0	ENABLE	Setting of type access allowed for the group of initiators see Table 5-21.	R	0xFFFF

5.10.8.5 L4_AP_REGION_l_L

Table 5-147. L4_AP_REGION_l_L

Address Offset	0x300 + (0x08*l)	**Index**	l = 0 to 99 for CORE_AP, l = 0 to 42 for PER_AP, l = 0 to 25 for EMU_AP, l = 0 to 18 for WKUP_AP,
Physical address	Please refer to Table 5-135		
Description	Define the base address of the region in respect to the segment it belongs to.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BASE																							

Bits	Field Name	Description	Type	Reset
31:24	Reserved	Read returns 0.	R	0x00
23:0	BASE	Sets the base address of this region relative to its segment base.	R	See Table 5-137 to Table 5-140

5.10.8.6 L4_AP_REGION_I_H

Table 5-148. L4_AP_REGION_I_H

Address Offset	0x304 + (0x08*I)	**Index**	I = 0 to 99 for CORE_AP, I = 0 to 42 for PER_AP, I = 0 to 25 for EMU_AP, I = 0 to 18 for WKUP_AP,
Physical address	Please refer to Table 5-135		
Description	Define the size, protection group^and segment ID of the region		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				SEGMENT_ID				Reserved	PROT_GROUP_ID			BYTE_DATA_WIDTH_EXP				Reserved								SIZE						ENABLE	

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Read returns 0	R	0x0
27:24	SEGMENT_ID	Identifies the segment to which the region is part of.	R	See Table 5-137 to Table 5-140
23	Reserved	Read returns 0.	R	0
22:20	PROT_GROUP_ID	The protection group containing this region.	RW	See Table 5-137 to Table 5-140
19:17	BYTE_DATA_WIDTH_EXP	The target OCP data byte width is 2^(BYTE_DATA_WIDTH_EXP) bytes. The value of this field is derived from the target OCP data_width parameter.	R	See Table 5-137 to Table 5-140
16:6	Reserved	Read returns 0.	R	0x0
5:1	SIZE	Define the size of the region in bytes. 2^SIZE equals the region.	R	See Table 5-137 to Table 5-140
0	ENABLE	0x0: Disable the region, no access allows 0x1: Enable the region, with access as define in registers	R	See Table 5-137 to Table 5-140

System Control Module

This document describes the system control module.

NOTE: This chapter gives information about all modules and features. See Chapter 1, to check availability of modules and features on your specific device.

Topic **Page**

6.1 System Control Module Overview

The system control module (SCM) allows software control of the various static modes supported by the device. The SCM is on the L4-Core interconnect, but it is sensitive only to the device internal power-on reset. It is not affected by the L4-Core reset.

For emulator devices, the power-on reset can also be controlled by the debugger through the JTAG interface.

The device uses the SCM as the primary point of control for these areas:

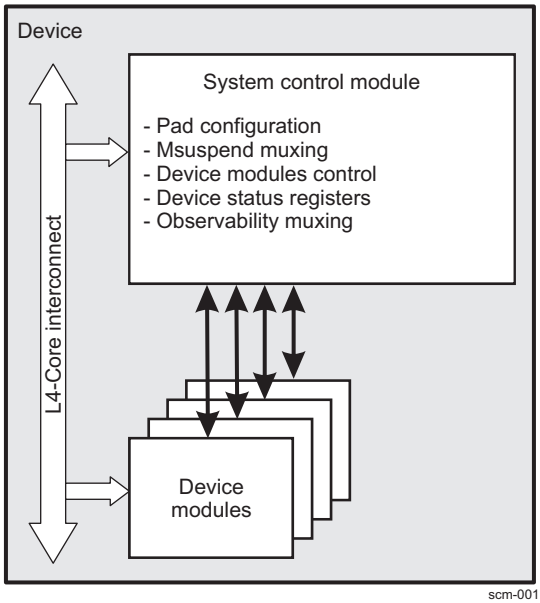
- Functional I/O multiplexing
- Pad configuration (pull-up or pull-down enable)
- Emulation controls
- Device status
- Peripheral sensitivity to the MPU MSuspend signals
- Static device configuration
- Debug and observability I/O multiplexing

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

NOTE: Power domains are not supported but the IP/Modules are still part of the logical design partition in the processor's domain partition architecture.

Figure 6-1 provides an overview of the SCM.

Figure 6-1. System Control Module Overview



The SCM primarily implements a bank of registers accessible by the software. Some are read-only registers that carry status information, and others are fully accessible (read/write).

The read/write registers are divided into the following classes:

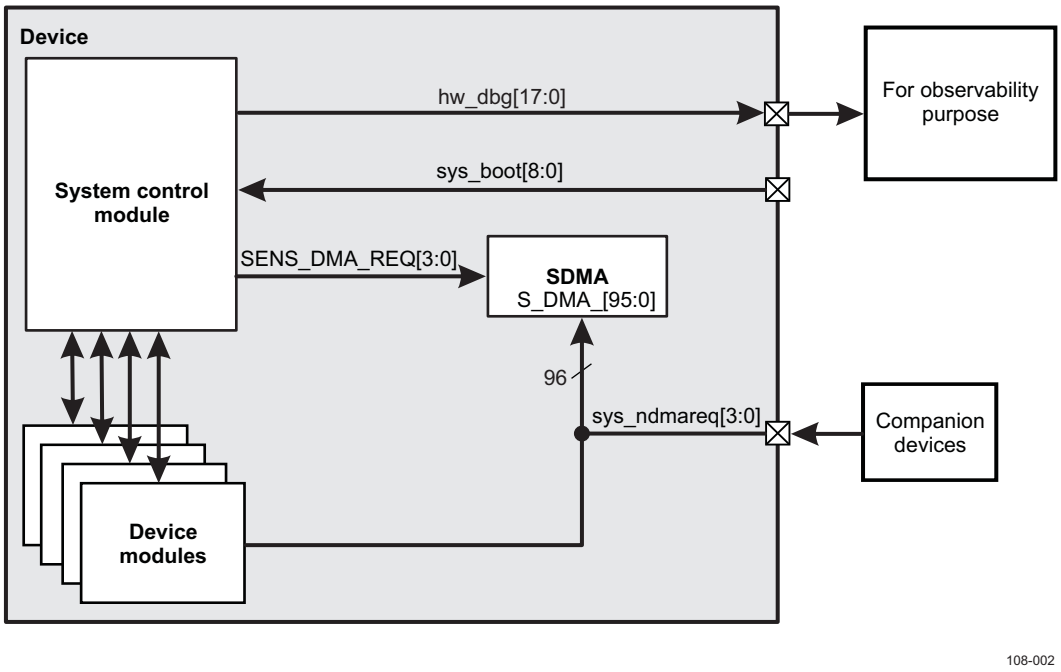
- Pad functional multiplexing and configuration registers (32-bit registers, one register per two pins)
- Debug and observability I/O multiplexing register (32-bit read/write register)
- Static device configuration registers (32-bit read/write registers for module specific configuration)
- Scratchpad memory bank (256* 32-bit)

6.2 System Control Module Environment

The SCM allows the setting of external system DMA (sDMA) request pin sensitivity and controls the multiplexing of device internal modules signals routed to external pins for hardware debug purposes. The SCM also integrates the decoding logic of sys_boot[8:0].

Figure 6-2 shows an overview of the SCM environment.

Figure 6-2. System Control Module Environment Overview



The seven sys_ndamreq[3:0] pins are optional external direct memory access (DMA) requests that can be managed directly by the sDMA controller. The SCM can configure these requests to either level sensitive (active low) or edge sensitive (falling edge) through the correct setting of the SENSDMAREQN bit (where N is between 0 and 3) in the CONTROL.CONTROL_DEVCONF0 and CONTROL.CONTROL_DEVCONF1 registers.

The sys_boot[5:0] pins are read-accessible in a status register (SYSBOOT field CONTROL.CONTROL_STATUS[5:0]) following a power-on reset. The SCM does not use sys_boot[6]. Sys_boot[8:7] are read accessible in CONTROL_DEVCONF2[18:19].

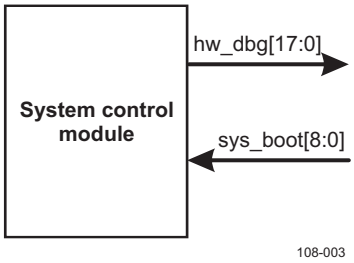
With the correct pad configuration, the SCM maps the hw_dbg[17:0] pins at the device boundary to observe hardware debug signals from device modules. The internal observable signals are PRCM signals, DMA requests, and interrupts.

6.2.1 Functional Interfaces

6.2.1.1 Basic System Control Module Pins

Figure 6-3 shows the SCM functional interface configured to observe device module debug signals.

Figure 6-3. System Control Module Interface Signals



6.2.1.2 System Control Module Interface Description

Table 6-1 lists the SCM input and output configured to observe device module debug signals.

Table 6-1. SCM I/O Description

Signal Name	I/O[1]	Description	Reset Value
hw_dbg[17:0]	O	Debug signals 0 to 17	N/A
sys_boot[8:0]	I	Boot configuration mode bits 0 to 8	Unknown

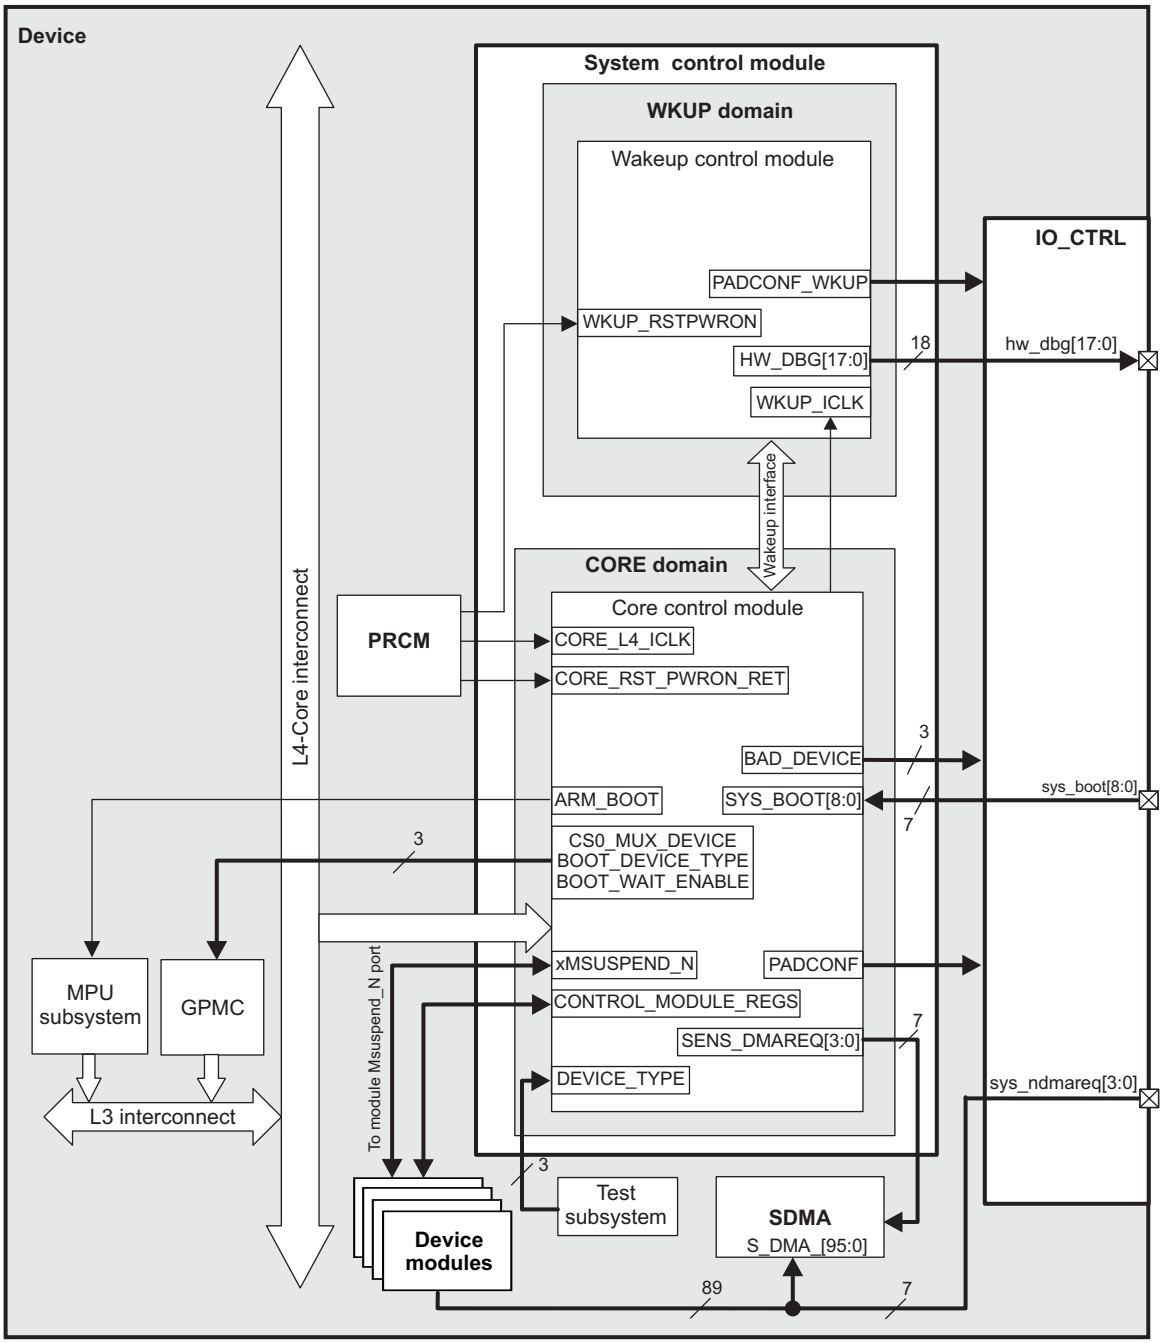
(1) I = Input, O = Output

6.3 System Control Module Integration

This section describes the integration of the SCM within the device.

Figure 6-4 shows the SCM integration in the device.

Figure 6-4. System Control Module Integration



The SCM is split into two blocks: the core control module in the CORE domain, and the wake-up control module in the WKUP domain. The wake-up control module contains some observability multiplexing, pad configurations, and security registers. For further information on the wake-up control module, see Section 6.4.3, *Wake-up Control Module*.

The software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by the software at any time and are effective immediately.

The SCM is connected on the L4-Core interconnect. The power, reset, and clock management (PRCM) module provides the module interface clock (CORE_L4_ICLK) and the power-on reset signal. The PRCM generates one global reset per domain (CORE_RST_PWRON_RET for the CORE domain and WKUP_RSTPWRON for the WKUP domain). The SCM does not respond to a warm reset or to an L4 reset.

6.3.1 Clocking, Reset, and Power-Management Scheme

6.3.1.1 Clock

The main sequential logic within the SCM is accessible in a register file through the L4-Core. The only clock provided to the SCM is the interface clock, CORE_L4_ICLK. This clock comes from the PRCM module and is controlled by the EN_SCMCTRL bit PRCM.CM_ICLKEN1_CORE[6] (0 = disables the clock, 1 = enables the clock) and the AUTO_SCMCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] (enables/disables automatic control of the interface clock).

The wake-up control module is configured through the L4-Core interface of the core control module and is accessed from the core control module through a dedicated interface. This interface uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2]. Only this wake-up interface clock (WKUP_ICLK) is propagated to the wake-up control module.

For further information, see the *Power, Reset, and Clock Management* chapter.

6.3.1.2 Resets

The SCM responds only to the internal power-on reset and to the device type (secure, emulator, general-purpose, test, or bad). The SOFTRESET bit CONTROL.CONTROL_SYSCONFIG[1] has no effect; the SCM is not affected by a warm reset.

The internal power-on reset is not a direct image of the power-on reset input pin (SYS_NRESPWRON). The PRCM module generates an internal power-on reset signal per domain and activates the internal power-on reset when the eFuse-related settings (such as the device type) are initialized. The core control module of the CORE domain responds to the CORE power-on reset (CORE_RST_PWRON_RET). The wake-up control module of the WKUP domain responds to the power-on reset (WKUP_RSTPWRON).

NOTE: References in the TRM to the power-on reset refer to the internal power-on reset as seen by the SCM.

On emulator devices, the debugger can also control the internal power-on reset signal though the JTAG interface.

For further information, see the *Power, Reset, and Clock Management* chapter.

6.3.1.3 Power Management

6.3.1.3.1 System Power Management

The PRCM module can require the SCM to be idled to save power. The SCM enters idle mode through the IDLEMODE field CONTROL.CONTROL_SYSCONFIG[4:3].

The PRCM module requests idle mode, and the SCM always accepts an idle command. Idle mode can be configured to either force-idle or smart-idle mode.

When the SCM is in force-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b00) and it receives an idle request from the PRCM module (PRCM.CM_ICLKEN1_CORE[6] set to 0 or PRCM.CM_AUTOIDLE1_CORE[6] set to 1 and the L4-Core interface clock idle transitions), the SCM waits unconditionally for active system clock gating by the PRCM module. Active system clock gating occurs only when all peripherals supplied by the same L4-Core interface clock domain are also ready for idle.

In smart-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b10), an idle command is accepted only when the save mechanism completes.

In idle mode (when the PRCM module has gated the interface clock), the SCM is not active and the interface clock paths are gated.

NOTE: The ST_SCMCTRL bit PRCM.CM_IDLEST1_CORE[6] (0b0 = active, 0b1 = idle) can check the SCM idle state.

The SCM idle mode is a function of the EN_SCMCTRL bit PRCM.CM_ICLKEN1_CORE[6] configuration and can be controlled automatically with hardware, depending on the AUTO_SCMCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] configuration.

6.3.1.3.2 Module Power Saving

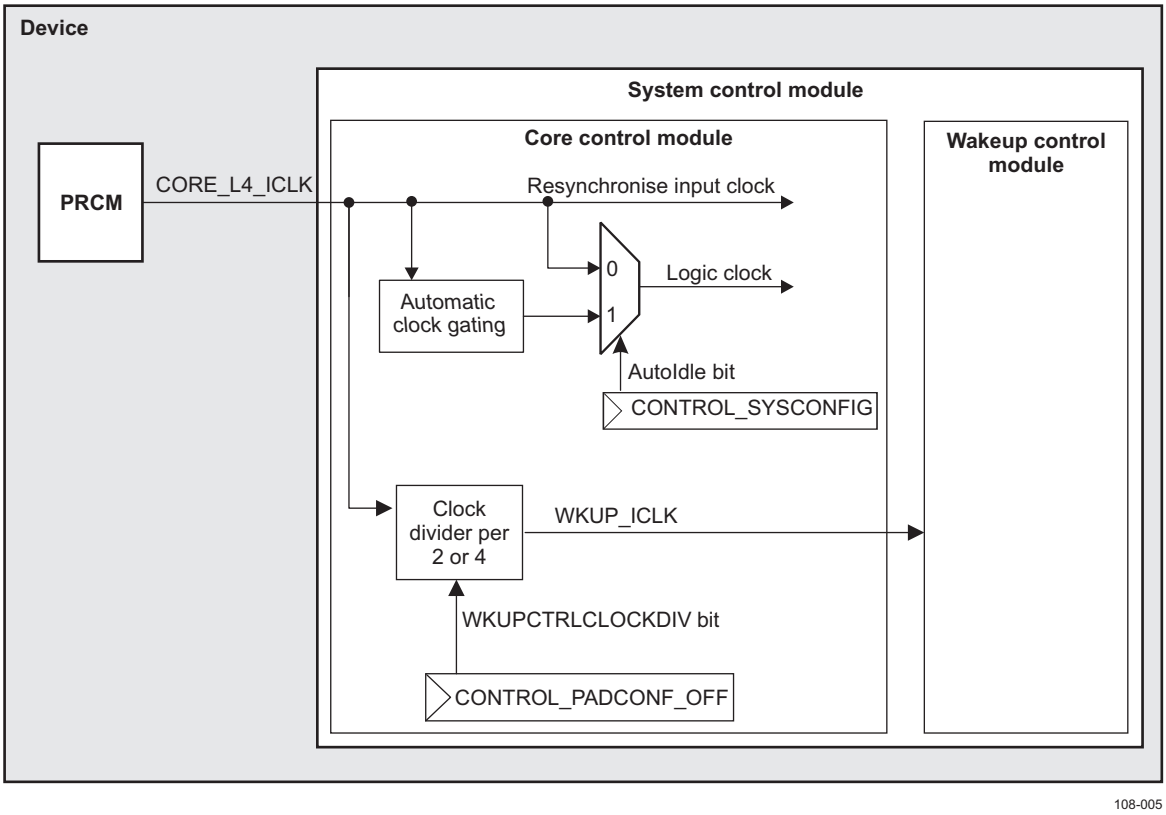
An internal interface clock-gating feature provides SCM local power management. The clock for the logic within the module can be gated when there is no access to the module according to the AUTOIDLE bit CONTROL.CONTROL_SYSCONFIG[0]. Otherwise, this logic is free-running on the interface clock CORE_L4_ICLK.

The L4-Core interface clock (CORE_L4_ICLK) is also used to synchronize and resample module inputs. The clock for those functions must always be free-running. Therefore, it is not gated.

The wake-up control module is clocked only by a local wake-up interface clock from the core control module. The wake-up interface clock (WKUP_ICLK) uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 to reduce power consumption according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2] (0 = divided by 4, 1 = divided by 2).

Figure 6-5 shows the SCM internal clock implementation.

Figure 6-5. Internal Clock Implementation



6.3.2 Hardware Requests

The SCM does not generate interrupt or wake-up requests.

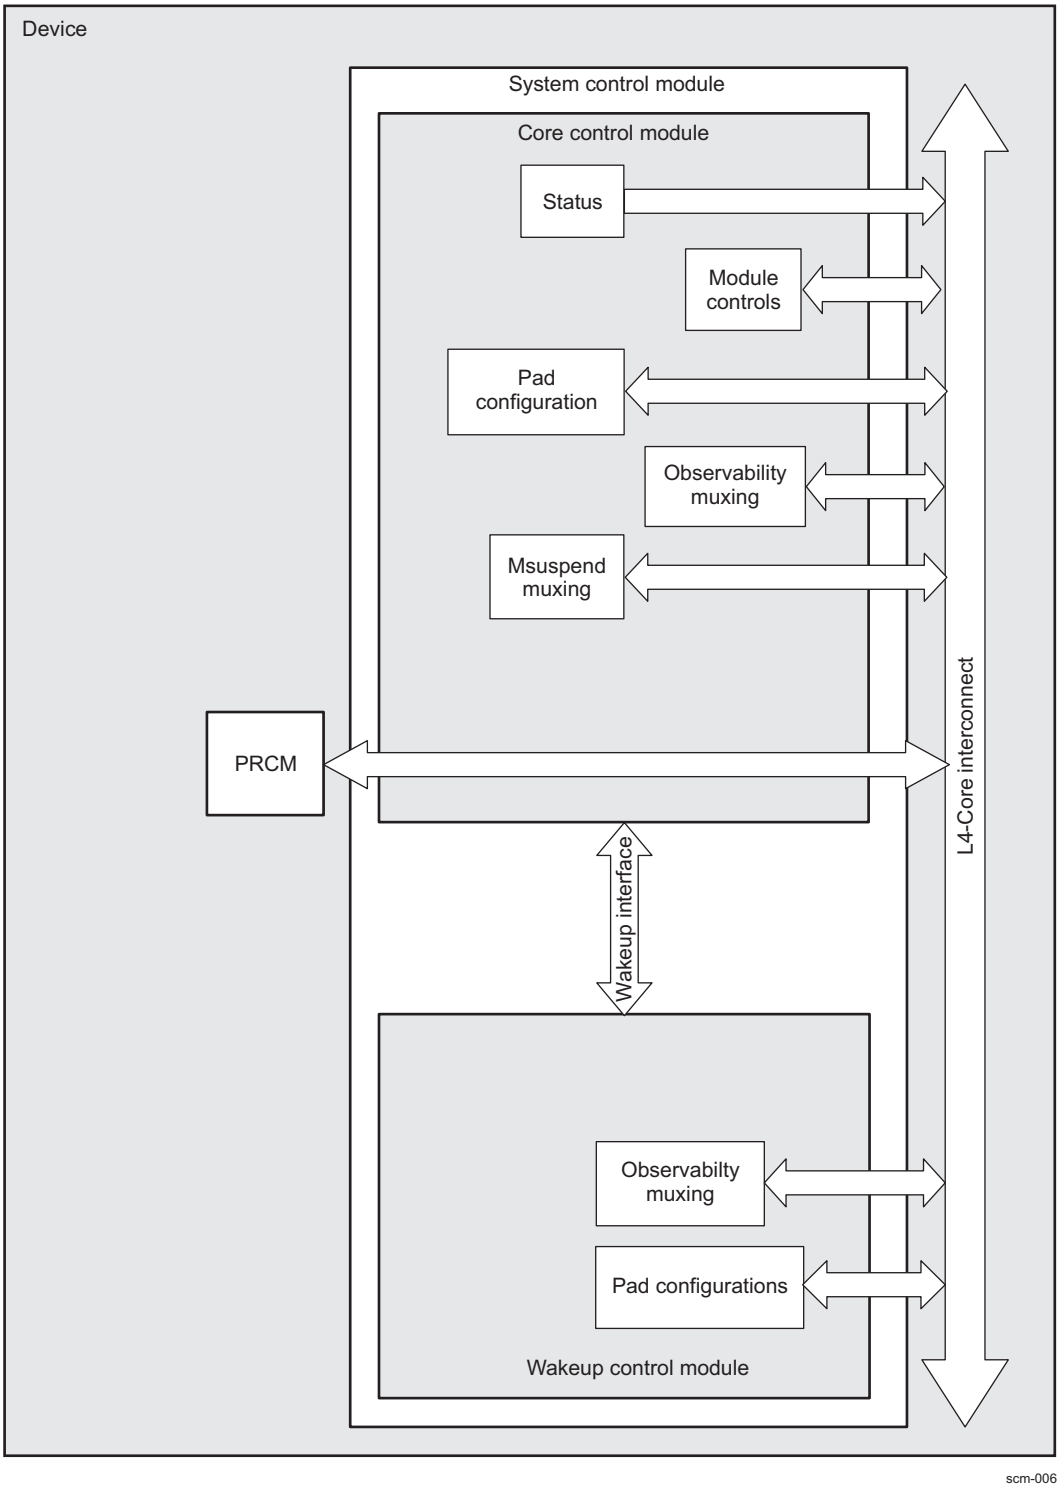
6.4 System Control Module Functional Description

6.4.1 Block Diagram

The SCM controls various device modules settings through register configuration and internal signals. It also controls the pad configuration and multiplexing and the routing of internal signals (such as PRCM signals or DMA requests) to observable pins for debug.

Figure 6-6 shows the SCM block diagram.

Figure 6-6. System Control Module Block Diagram



The following sections describe the functionality of the SCM registers.

6.4.2 System Control Module Initialization

The SCM responds only to the internal power-on reset and to the device type. At power-on, reset values for the registers define the safe state for the device. In the initialization mode, only modules used at boot time are associated with the pads. Other module inputs are internally tied, and outputs pads are turned off each time the feature is available.

For the pad configuration, pull-up/pull-down fields are set according to the device pin list. For further information, see the pin list tables in your device-specific data manual.

The device type (for example, emulator, secure, general-purpose) affects the reset values and access rights for some emulation and security-related configuration bits (see Section 6.6, *SCM Registers*).

General-purpose devices (that is, those with no secure mode available) include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

This technical reference manual focuses only on GP devices. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

6.4.3 Wake-Up Control Module

The wake-up control module in the SCM belongs to the WKUP domain. It contains a 1 K-byte memory which is used to save the pad configuration registers in the core control module before switching to off mode. Pad configuration registers driving the I/O pad control in the WKUP domain are also instantiated in the wake-up control module. In this module, there is also a subset of observability multiplexing registers dedicated to PRCM observable signals and security registers (CONTROL.CONTROL_SEC_TAP and CONTROL.CONTROL_SEC_EMU).

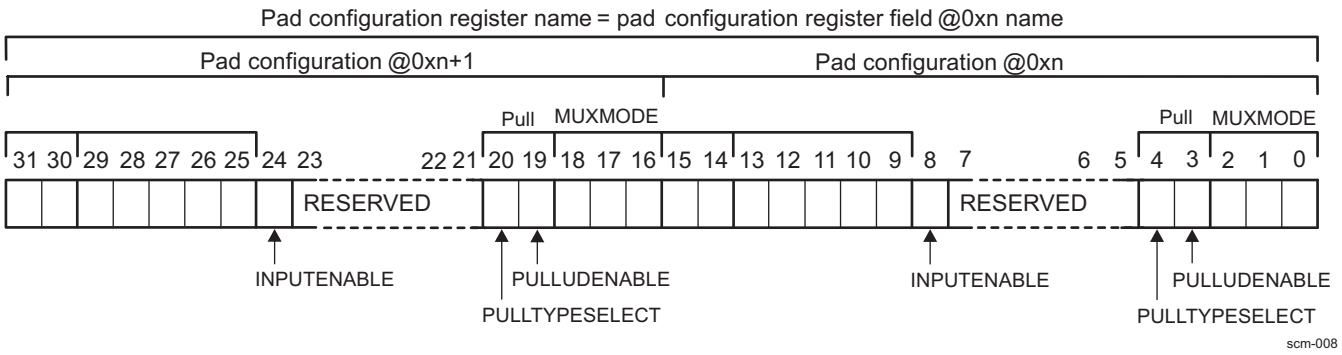
The wake-up control module is configured through the L4-Core interface in the core control module and is accessed from the core control module through a dedicated interface. This interface between the core control module and the wake-up control module uses the CORE_L4_ICLK clock divided by 4 or 2 to reduce power consumption in the WKUP domain.

6.4.4 Pad Functional Multiplexing and Configuration

After power-on reset, the software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers command directly the multiplexing of the pad configuration logic.

Each pin is configurable by software using its associated pad configuration register field, which is 16 bits wide (see Figure 6-7).

Figure 6-7. Pad Configuration Register Functionality



One pad configuration register field is available for each pin. Each 32-bit pad configuration register is grouped into two 16-bit pad configuration register fields. One pad configuration register provides control for two different pins.

Some pad configuration registers control the configuration of pads in the CORE domain. These registers are instantiated in the CORE domain of the SCM (core control module, physical addresses 0x4800 2030 to 0x4800 2260). Pad configuration registers also control the configuration of pads in the WKUP domain. These registers are instantiated in the WKUP domain of the SCM (wake-up control module, physical addresses 0x4800 2A00 to 0x4800 2A4C).

NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with six (0 to 5) possible functional modes for each pin.
- PULL (2 bits) for combinational pull-up/pull-down configuration:
  - PULLTYPESELECT: Pull-up/pull-down selection for the pin.
  - PULLUDENABLE: Pull-up/pull-down enable for the pin.
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
  - INPUTENABLE = 0: Input Disable. Pin is configured in output only mode.
  - INPUTENABLE = 1: Input Enable. Pin is configured in bi-directional mode.

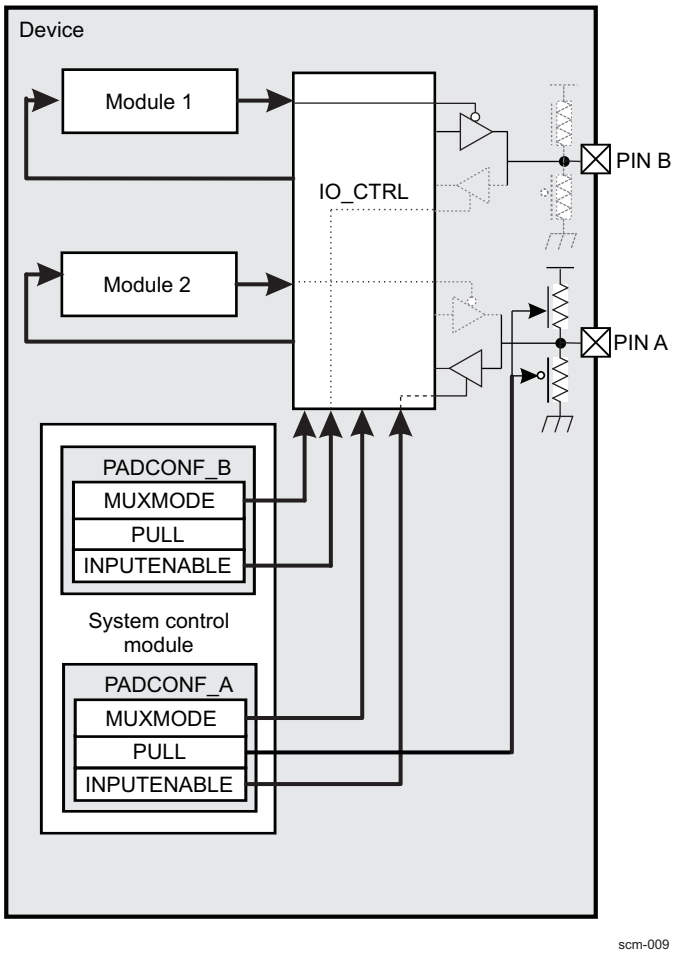
Table 6-2 lists the bit directions of the CONTROL_PADCONF_x registers.

Table 6-2. Bit Directions for CONTROL_PADCONF_x Registers

CONTROL_PADCONF_x Bit	Bit Direction	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal inactive	Input enable signal active

Figure 6-8 shows the pad configuration functionality when off mode is inactive.

Figure 6-8. Pad Configuration Diagram



6.4.4.1 Mode Selection

Table 6-3 lists the multiplexing modes and settings.

Table 6-3. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_PADCONF_X register defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b101; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_PADCONF_X register is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of power-on reset.

For more information about the configurable mode on each pin, see Table 6-5 .

6.4.4.2 Pull Selection

Whichever pull value is configured, pulls are automatically disabled when a pin is configured as an output (see Table 6-4).

Table 6-4. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pull-down selected but not activated
0b0	0b1	Pull-down selected and activated if pin is NOT configured as OUTPUT
0b1	0b0	Pull-up selected but not activated
0b1	0b1	Pull-up selected and activated if pin is NOT configured as OUTPUT

For more information on the pull available on each pin, see Table 6-5 .

6.4.4.3 Pad Multiplexing Register Fields

Table 6-5 provide for each pad configuration register field the address offset and the associated signal name for each multiplexing mode (as set by bit field MUXMODE). Mode 0 is always defined. Modes with no signal name are undefined for the given pad.

NOTE: Table 6-5 lists the pad configuration registers instantiated in the CORE domain and WKUP domain that drive the pads in the CORE domain and WKUP domain respectively. An empty cell indicates that the mode or pull is not available for this pin.

Table 6-5. Core and Wakeup Control Module Pad Configuration Registers

Register Name	Physical Address	Mode 0	Mode 1	Mode 2	Mode 3	Mode 4	Mode 5	Mode 6	Mode 7

For more information on the pad default states, please refer to your device-specific data manual.

6.4.5 Functional Register Description

6.4.5.1 Static Device Configuration Registers

Table 6-6 describes the static device configuration registers.

Table 6-6. Static Device Configuration Registers

Physical Address	Register Name	Description	Access
0x4800 2274	CONTROL_DEVCONF0	Module dedicated configurations	R/W
0x4800 22D8	CONTROL_DEVCONF1	Module dedicated configurations	R/W
0x4800 2580	CONTROL_DEVCONF2	Module dedicated configurations	R/W
0x4800 2584	CONTROL_DEVCONF3	Module dedicated configurations	R/W

These registers allow the static configuration of device modules such as USB, McBSP, and I^2C. For example, they allow selecting external or internal clocks for McBSP modules.

6.4.5.2 MPU MSuspend Configuration Registers

Table 6-7 describes the MPU MSuspend configuration registers.

Table 6-7. MSuspendMux Control Registers

Physical Address	Register Name	Description	Access
0x4800 2290	CONTROL_MSUSPENDMUX_0	Control the use of MSuspend signals at module level.	R/W
0x4800 2294	CONTROL_MSUSPENDMUX_1	Control the use of MSuspend signals at module level.	R/W
0x4800 2298	CONTROL_MSUSPENDMUX_2	Control the use of MSuspend signals at module level.	R/W
0x4800 22A0	CONTROL_MSUSPENDMUX_4	Control the use of MSuspend signals at module level.	R/W
0x4800 22A4	CONTROL_MSUSPENDMUX_5	Control the use of MSuspend signals at module level.	R/W
0x4800 22A8	CONTROL_MSUSPENDMUX_6	Control the use of MSuspend signals at module level.	R/W

These registers provide an entry for each module that must consider the MSuspend signals from the MPU processor . For each module, the sensitivity to the MSuspend signals is defined within possibilities (coded using 3 bits):

- 0b000: No sensitivity; no MSuspend signal reaches the module.
- 0b001: Sensitivity to the MPU MSuspend signal
- Other values: Reserved; other values are not supported.

The logic used to combine the MSuspend signals from the processor is implemented within the SCM. MSuspend signals are active low.

CAUTION

Not all modules use the MSUSPEND signal. See the TRM chapter for each module to determine whether the module supports the MSUSPEND signal.

All MSUSPEND signals coming out of the MPU and DSP are resynchronized within the SCM by using the control module interface clock.

6.4.5.3 Device Status Registers

Table 6-8 lists the status registers.

Table 6-8. Device Status Registers

Physical Address	Register Name	Description	Access
0x4800 22F0	CONTROL_STATUS	Device status register	Public privilege (R)

The CONTROL.CONTROL_STATUS register is read-only and has no access restriction.

The CONTROL_STATUS register bits[5:0] logs the status of sys_boot [5:0] pins at Power on Reset.

The lower three sys_boot[4:0] pins allow the selection of the booting sequence of interfaces or devices for ROM code when booting. Sys_boot[5] switches between memory (0) and peripheral (1) booting.

For further information on the configuration of the sys_boot pins, see the *Initialization* chapter.

After booting, these pins can be used optionally for other functions. When the pins are reused, the associated sysboot registers are not modified by the new functionality. It is recommended that the output function on the sys_boot pins be reused.

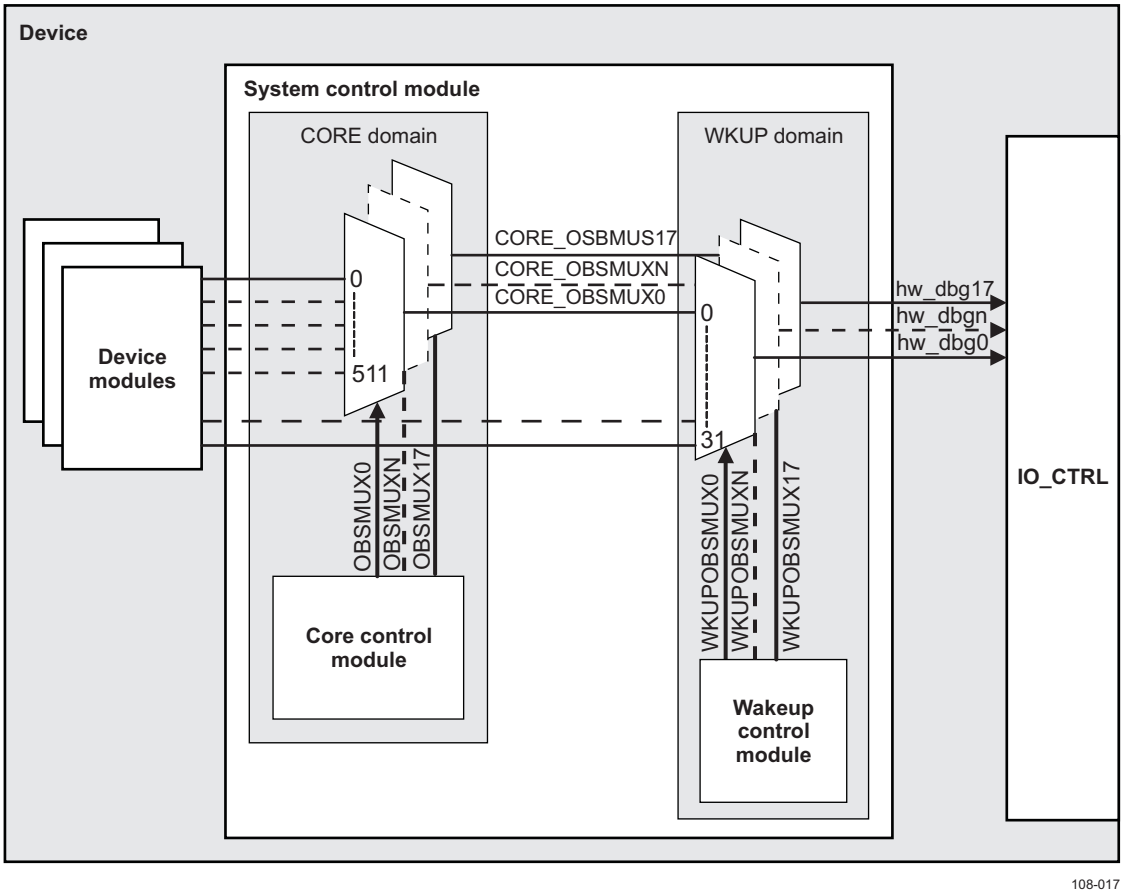
6.4.6 Debug and Observability

6.4.6.1 Description

NOTE: This feature is restricted to emulator and GP devices.

Figure 6-9 shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the domain boundary.

Figure 6-9. Overview of the Debug and Observability Register Functionality



Two layers of multiplexer are used to select the set of internal observable signals (PRCM signals, DMA requests, and interrupts) to be routed to the pins dedicated to the hardware debug.

The first layer is in the CORE domain. It is controlled by the core control module registers and selects the set of internal signals from the CORE domain to be routed. The second layer is in the WKUP domain. It is controlled by the wake-up control module registers and selects the set of internal signals from the WKUP domain.

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ CCDC _x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbgn).

Before selecting the CORE signals, the WKUPOBSMUX field of the CONTROL.CONTROL_WKUP_DEBOBS_n registers must be set to 0.

NOTE: The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ CCDC _x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbgn).

Table 6-9. Observability Registers

Physical Address	Register Name	Description	Access	
			Device Type	
			E/T/G	S/B
0x4800 2420	CONTROL_DEBOBS_0	Set and configure CORE observable signals 1 and 0	R/W	R
0x4800 2424	CONTROL_DEBOBS_1	Set and configure CORE observable signals 3 and 2	R/W	R
0x4800 2428	CONTROL_DEBOBS_2	Set and configure CORE observable signals 5 and 4	R/W	R
0x4800 242C	CONTROL_DEBOBS_3	Set and configure CORE observable signals 7 and 6	R/W	R
0x4800 2430	CONTROL_DEBOBS_4	Set and configure CORE observable signals 9 and 8	R/W	R
0x4800 2434	CONTROL_DEBOBS_5	Set and configure CORE observable signals 11 and 10	R/W	R
0x4800 2438	CONTROL_DEBOBS_6	Set and configure CORE observable signals 13 and 12	R/W	R
0x4800 243C	CONTROL_DEBOBS_7	Set and configure CORE observable signals 15 and 14	R/W	R
0x4800 2440	CONTROL_DEBOBS_8	Set and configure CORE observable signals 17 and 16	R/W	R
0x4800 2A68	CONTROL_WKUP_DEBOBS_0	Set and configure WKUP observable pins 3, 2, 1, 0	R/W	R
0x4800 2A6C	CONTROL_WKUP_DEBOBS_1	Set and configure WKUP observable pins 7, 6, 5, 4	R/W	R
0x4800 2A70	CONTROL_WKUP_DEBOBS_2	Set and configure WKUP observable pins 11, 10, 9, 8	R/W	R
0x4800 2A74	CONTROL_WKUP_DEBOBS_3	Set and configure WKUP observable pins 15, 14, 13, 12	R/W	R
0x4800 2A78	CONTROL_WKUP_DEBOBS_4	Set and configure WKUP observable pins 17, 16	R/W	R

The write capabilities of these registers differ according to the device type.

Perform the following steps to configure observability:

1. To configure the pads properly for hardware debug and observability, select the hardware debug (hw_dbg) function mode 5 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_ CCDC _x or mode 7 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_ETK_X registers.

2. For the observability pads, set the proper values of the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n. Up to 5 bits are used to select the signal set to be observed (0x00 selection sets the output to CORE_OSMUXn signal). For more information, see the description of each register in Section 6.4.6.2, *Observability Tables*.
3. To observe the CORE_OSMUXn signals from the first layer of the multiplexer, set the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n to 0x00, and then set the proper values of the OBSMUX field CONTROL.CONTROL_DEBOBS_n. A maximum of 7 bits is used to select the signal set to be observed (0b0000000 selection sets the output to 0).

For more information, see the description of each register in Section 6.4.6.2, *Observability Tables*.

6.4.6.2 Observability Tables

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

Table 6-10 through Table 6-45 define the mapped internal signals for each OBSMUX and WKUPOBSMUX value.

Table 6-10. Internal Signals Multiplexed on OBSMUX0

Out Signal Name	Muxed Signal Name	OBSMUX0 Field CONTROL.CONTROL_DEBOBS_0 [22:16] (dec)	Description	High State	Low State
CORE_OBSMUX0[(1)]	tie_low	0	Signal tied low	-	Active state low
	CM_96_FCLK	1	96 MHz functional clock of the CM module.	-	-
	CM_32K_CLK	2	32 kHz functional clock of the CM module.	-	-
	PRCM_DPLL3_enable	3	Signal used to enable DPLL3.	DPLL is enabled	DPLL is disabled
	Reserved	4	-	-	-
	PRCM_NEON_forceWakeup	5	Indicates if a wakeup of the NEON domain is forced.	Wakeup is forced	Wakeup is not forced
	PRCM_COREL4_domainNready	6	Indicates if the CORE_L4 domain is ready. In other words, is domain transition on-going ?	Domain is not ready	Domain is ready
	PRCM_WKUP_domainNready	7	Indicates if the WKUP domain is ready. In other words, is domain transition on-going ?	Domain is not ready	Domain is ready
	Reserved	(16:8)	-	-	-
	sdma_PI_DMAREQ	(87:17)	DMA requests lines mapped to the System DMA module. See the *DMA* chapter for more information about the System DMA request mapping.	-	-
	sgx_SINTERRUPTN	(104:88)	Interrupt lines from the SGX. See the *SGX* chapter for more information about the Interrupt Requests mapping.	-	-
	Reserved	(116:105)	-	-	-
	SD2D _PICLKOCP	117	Interface clock of SD2D	-	-
	Reserved	118	-	-	-
	SD2D _PICLKOCP	119	Interface clock of SD2D	-	-
	Reserved	(127:120)	-	-	-

6.4.7 Electromagnetic Interference Reduction for Clocking Generation (Spreading)

6.4.7.1 Overview

There are two major forms of digital signals: digital-data and digital-clock (CLK). Digital signals are the principal signal form in today's digital electronic products.

- A digital-data signal can be viewed as a sequence of pulses with different pulse widths
- A clock (CLK) signal is usually a string of rectangular pulses with the same pulse width

In the case of a clock, the generated signal has a predetermined frequency. Electromagnetic radiations such as radio frequency emissions are also generated from the constant frequency clock signals and their harmonics. Unfortunately, a problem exists with some devices such as communication devices for example in that the system clock generates unwanted spurious signals that interfere with the decoding of information from received signals by a receiver of the communication device. Note that data periodicity also causes interference.

This periodicity generates a significant power peak at the selected frequency, which in turn causes an EMI disturbance to the environment.

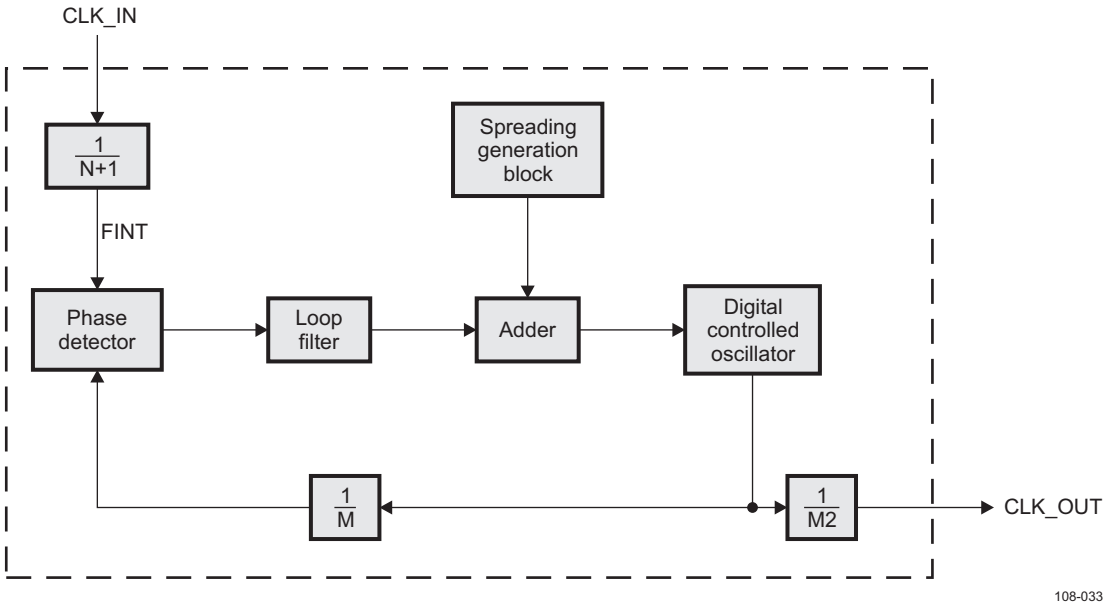
The harmonics of the generated signal system clock radiates in the other modules of the device, and the spurious energy can be enough to cause enough interference, which results in performance degradation (in the form of high bit error rates in case of a wireless communication interface for example).

In order to reduce the power peaks (and thus the energy of the electromagnetic noise generated for a specific frequency), an internal frequency modulation of the DPLL is used to distribute the energy to many different frequencies, thus reducing the power peaks.

This frequency modulation feature is directly integrated in some DPLLs of the device. The DPLLs that support this additional feature are called DPLL-D in the following.

Figure 6-10 shows a diagram of a DPLL that supports the EMI reduction feature.

Figure 6-10. DPLL with EMI Reduction Feature



The additional features of the DPLL compliant with EMI reduction are:

- EMI Reduction using Triangular frequency modulation, also called Spread Spectrum Clocking (SSC).

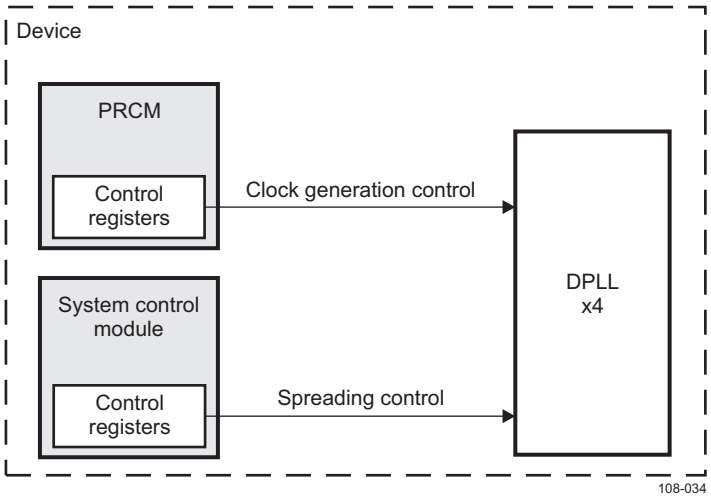
6.4.7.2 Integration

The four following DPLLs/Domains of the devices that support the EMI reduction feature are:

- DSS/DSI DPLL
- CORE domain DPLL
- PER domain DPLL
- USBHOST DPLL

Figure 6-11 highlights the four DPLL-D integration in the device.

Figure 6-11. DPLL-D Integration



The control of the DPLL is done both by the PRCM and the System Control Module:

- The PRCM controls the clocking generation of the DPLL. For more information, see the *Power Reset and Clock Management* chapter.
- The System Control Module contains all necessary bits that controls the EMI Reduction feature (Spread Spectrum Clocking).

6.4.7.2.1 Clocking, Reset, and Power Management Scheme

Please see the *Power Reset and Clock Management* chapter.

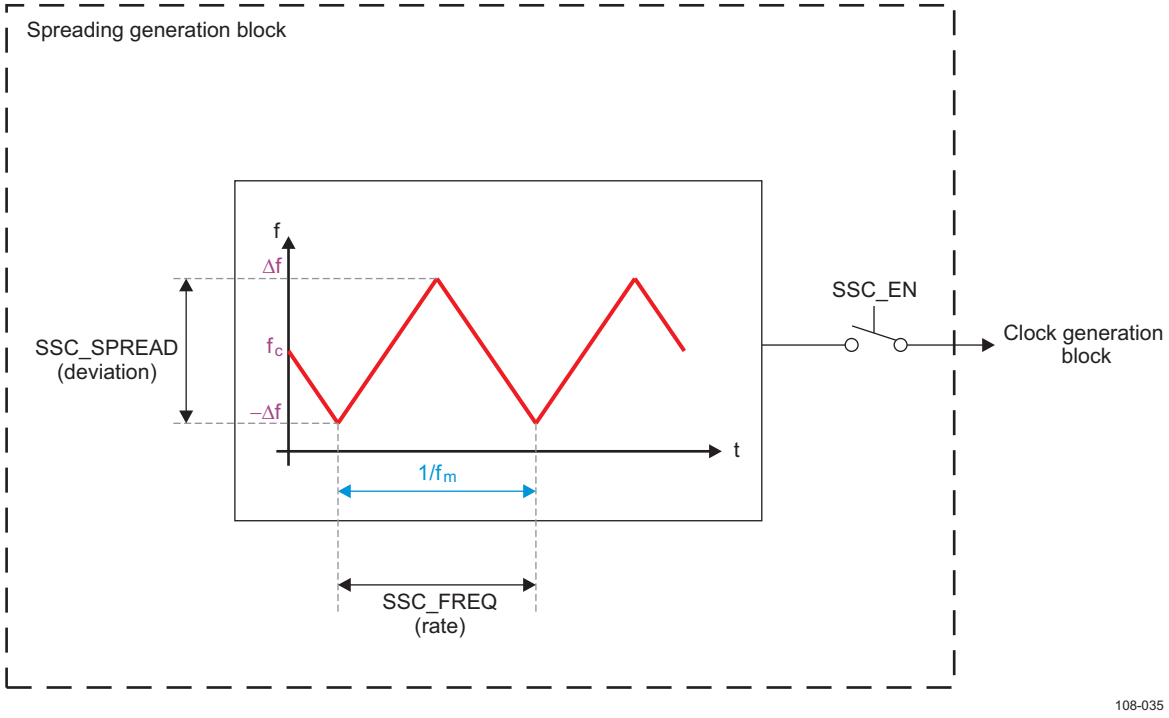
NOTE: DSI is not available on all devices. See Chapter 1, the *Device Family* section, to check availability of this module.

6.4.7.3 Functional Description

6.4.7.3.1 Spreading Generation Block

Figure 6-12 shows a diagram of the Spreading Generation block.

Figure 6-12. Spreading Generation Block Diagram



NOTE: Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf.

f_c is the original clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal in order to add some controlled deviation in the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces the Electomagnetic Interferences.

The **SSC_SPREAD** value handles the deviation (amplitude) of the generated signal from the original signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[3:2] XXX_SPREADING_AMPLITUDE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs). Note that this register contains only a spreading ratio K, which is equal to $\Delta f / f_m$.

The **SSC_FREQ** value controls the rate of the generated signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[1:0] XXX_SPREADING_RATE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs).

The **SSC_EN** signal enables/disables the frequency modulation feature of the DPLL. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[4] XXX_SPREADING_ENABLE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs).

In any case the frequency modulation will be programmed in the System Control Module and it is not generally something that needs to be changed in real time.

6.4.7.3.2 Spread Spectrum Clocking (SSC)

6.4.7.3.2.1 Definition

The aim of the Spread Spectrum Clocking is to add a variation in the frequency of an original clock, which spreads the generated interferences over a larger band of frequency.

In theory, Spread Spectrum Clocking means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 Mhz at one moment in time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be "spread" out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating a spread-spectrum clock by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.
- The modulation rate (f_m), which is used to determine the clock-frequency spreading-cycling rate, and is the time during which the generated clock frequency varies through Δf and returns to the original frequency.
- The modulation waveform, which describes the variation curve in term of time.

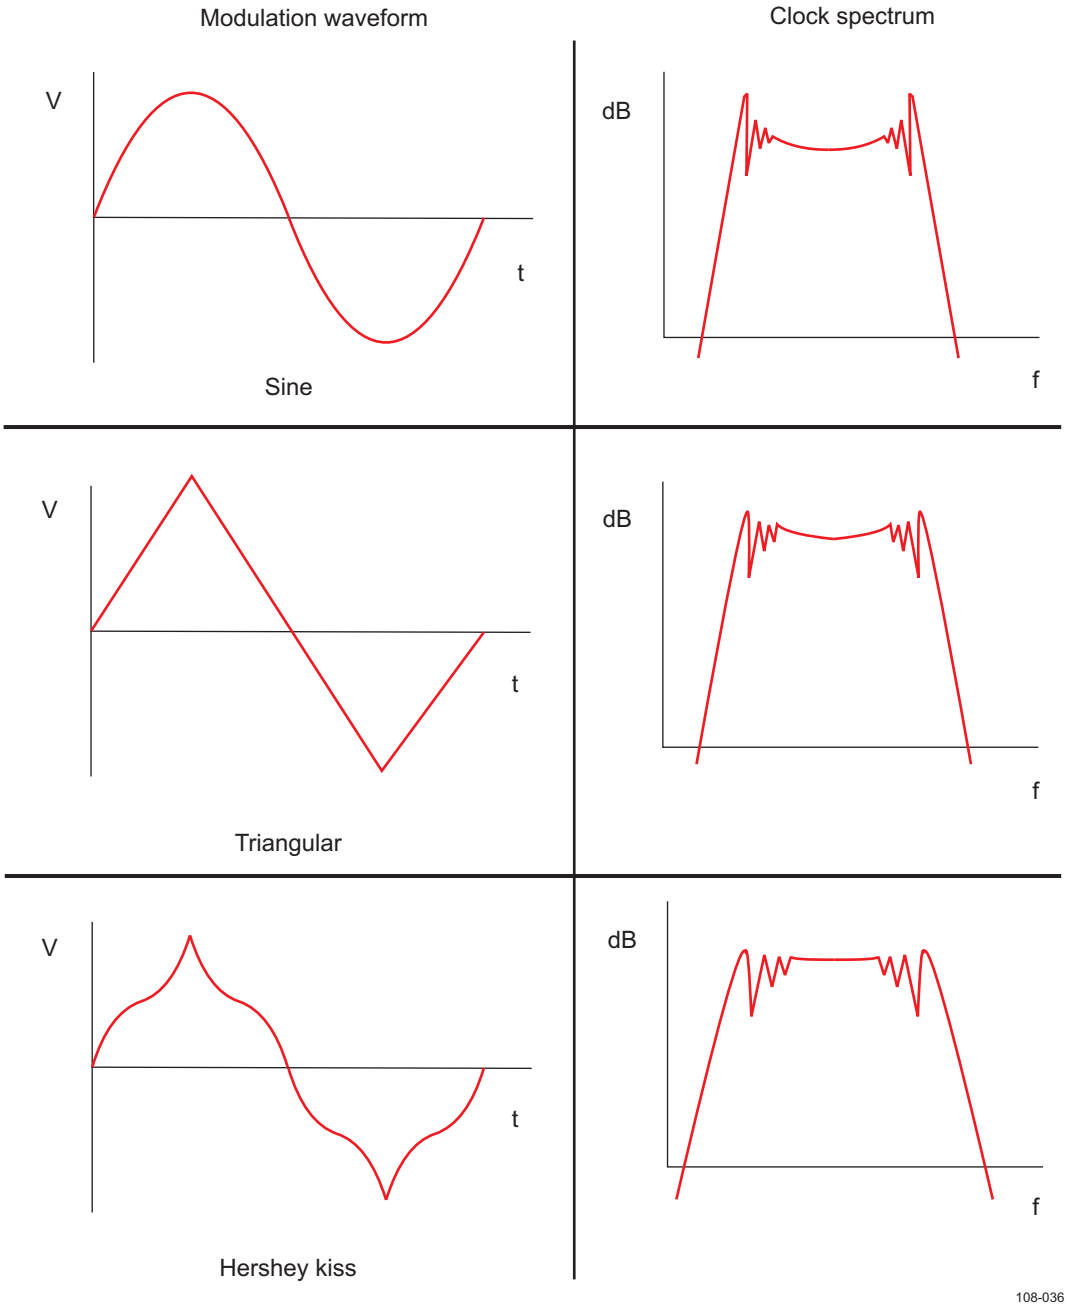
The spectral power reduction in the DPLL clocks is dependent on the Modulation Index (K) which is a ratio of spreading frequency, calculated from the frequency deviation (Δf) and the modulation rate (f_m).

6.4.7.3.2.2 The Modulation Waveforms

The shape (profile) of the generated clock signal depends on the modulation waveform that is used during the frequency modulation. Several profiles can be used, according to the desired shaping for the energy spreading.

Figure 6-13 shows three examples of modulation waveforms and the spectrum of the corresponding modulated clock signal.

Figure 6-13. Modulation Profiles



The triangular wave gives a relatively flat spectrum and is also easy to generate. The triangular waveform is used by the DPLL-D.

6.4.7.3.2.3 Effects on the Clock Signal

Figure 6-14 gives an example of the effect of a triangular spreading on a clock signal.

Figure 6-14. Effect of the SSC in Frequency

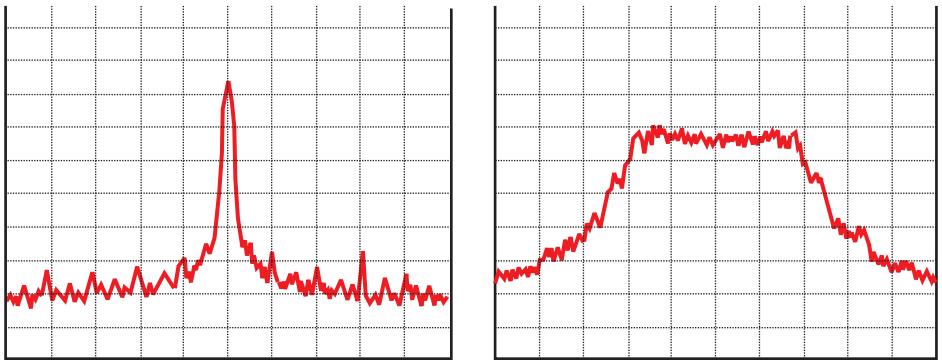


Figure 6-14 highlights the power reduction of the main peak, but also the flatter aspect of the modulated signal. One could notify that the minimum level of the second signal is higher than the first one. This effect is normal and is due to the "noise" added for the modulation.

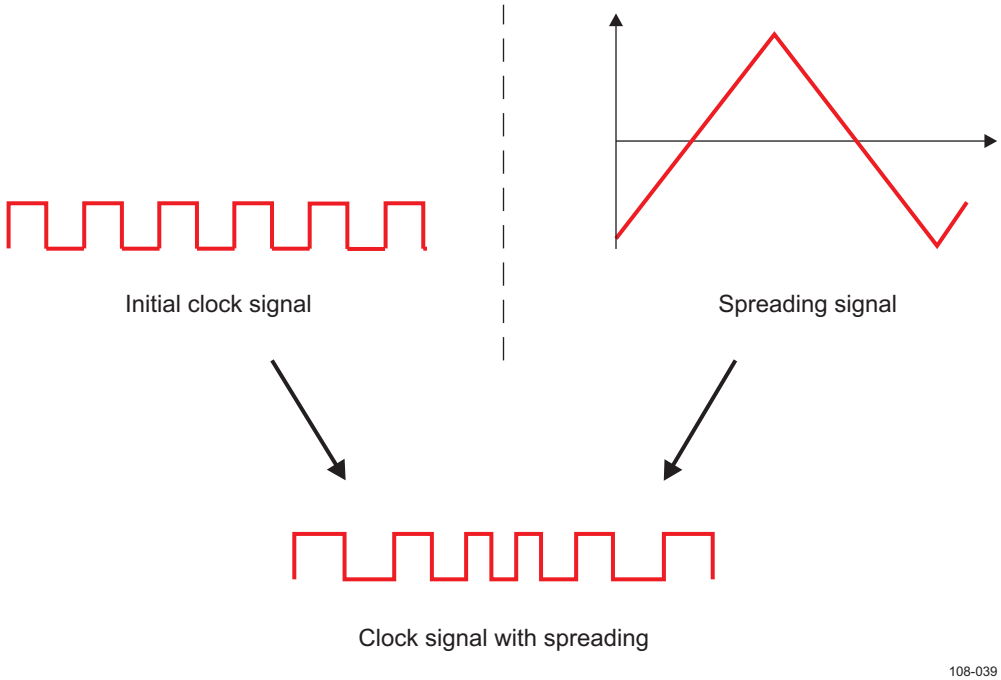
NOTE: The spreading technique "scatters" the energy of the peaks on the other frequencies, which reduces the power of the peaks but increases the global "noise" of the signal.

Figure 6-15 shows the effect of a triangular spreading on a clock signal in the Time Domain.

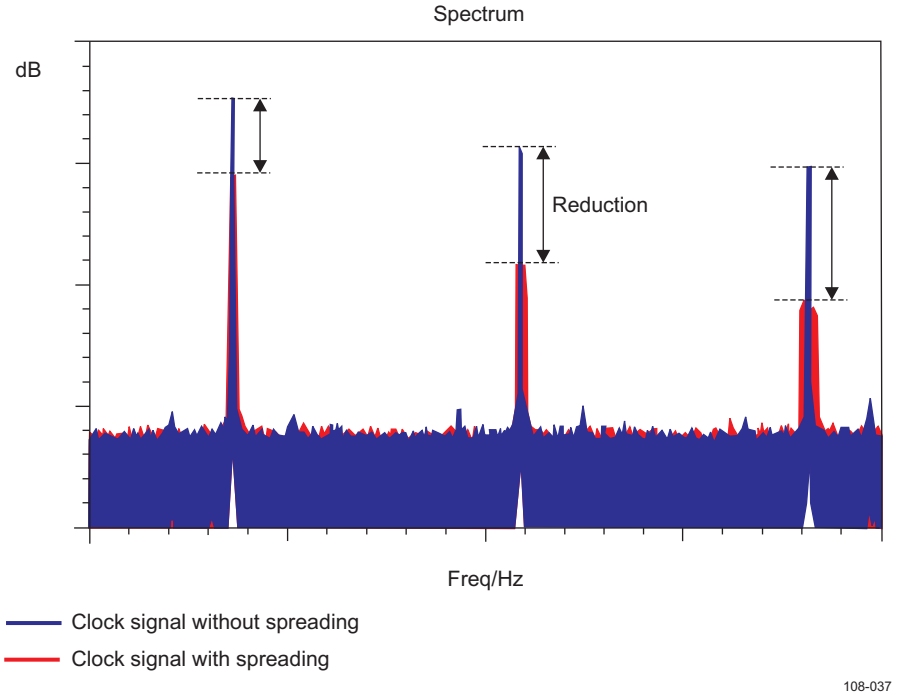
Figure 6-15. Effect of the SSC in the Time Domain



6.4.7.3.2.4 Estimation of the EMI Reduction Level

Figure 6-16 shows the effect of the spreading on a clock and its harmonics.

Figure 6-16. Peaks Reduction Due to Spreading



The electromagnetic interference reduction can be estimated with the following equation:

(1) Peak_power_reduction = 10 * log ((Deviation * f_c) / f_m)

With:

- Peak_power_reduction in dB
- Deviation in % of the initial clock frequency (f_c), equals to $\Delta f / f_c$
- f_c is the original clock frequency, in MHz
- f_m is the spreading frequency, in MHz

According to equation (1), it is also possible to compute the deviation, and then Δf, for a required peak power reduction:

(2) Deviation = (f_m / f_c) * $10^{(Peak\_power\_reduction\ /\ 10)}$

Example:

For f_c=400MHz, Deviation =1% peak from f_c(Δf = 4MHz) and f_m=400kHz, the estimated peak power reduction is 10dB.

6.4.7.3.2.5 Bandwidth Calculation (Carson Bandwidth Rule)

Carson's bandwidth rule defines the approximate bandwidth requirements of communications system components for a carrier signal that is frequency modulated by a continuous or broad spectrum of frequencies rather than a single frequency.

Carson's bandwidth rule is expressed by the relation CBR = 2 * (Δf + f_m) where CBR is the bandwidth requirement, Δf is the peak frequency deviation, and f_m is the highest frequency in the modulating signal.

For example, an FM signal with 5kHz peak deviation, and a maximum audio frequency of 3 kHz, would require an approximate bandwidth 2*(5+3) = 16 kHz.

Theoretically any FM signal will have an infinite number of sidebands and hence an infinite bandwidth but in practice all significant sideband energy (98% or more) is concentrated within the bandwidth defined by Carson's rule.

6.4.7.3.3 Frequency Limitations

There are some limitations on the use of the Spreading feature. Figure 6-17 shows the supported Spreading frequency and deviation.

Figure 6-17. Supported Spreading Frequency and Deviation

		SPREADING_AMPLITUDE (bits [3:2])			
		00	01	10	11
		K			
		4	6	8	10
SPREADING_RATE (bits [1:0])	Min to Max rate (kHz)	Frequency deviation +/- kHz			
00	62.5 to 125	250 to 500	375 to 750	500 to 1000	625 to 1250
01	125 to 250	500 to 1000	750 to 1500	1000 to 2000	1250 to 2500
10	250 to 500	1000 to 2000	1500 to 3000	2000 to 4000	2500 to 5000
11	500 to 1000	2000 to 4000	3000 to 6000	4000 to 8000	5000 to 10000

Not recommended. PLL jitter degradation and modulation amplitude not a linear function of FM.

108-040

Even if all the previous frequencies and deviations are supported by the DPLL-D, a range of "Safe operating regions" has been defined according to its impact on jitter.

Figure 6-17 shows the supported safe operating regions supported by the DPLL-D.

Figure 6-18. Supported Safe Operating Regions and Jitter Impact

CLKOUT FREQUENCY (25–900 MHz)	Recommended safe operating region	Max jitter impact in % due to spreading
400–900		+/– 1.25%
200–399		+/– 1.25%
100–199		+/– 1.25%
50–99		+/– 1.00%
25–49		+/– 2.00%

108-041

(1) Please see Figure 6-17 for color coding)

6.4.7.4 Basic Programming Model

6.4.7.4.1 Spread Spectrum Clocking Configuration

The configuration of the spreading feature is not mandatory when programming the DPLL. This feature is usually enabled when the DPLL clocks generate harmonics which can potentially interfere with the GSM carrier frequencies.

Once the "clock generation control" registers are configured, it is possible to configure the spreading on the clock signal.

The first thing to do is to calculate the *Deviation* and/or the *Spreading Rate* according to the desired peak power reduction. In addition to this, it is necessary to have K (modulation index), which value is equal to Δf / f_m.

Then, both XXX_SPREADING_AMPLITUDE and XXX_SPREADING_RATE bitfields can be configured with the calculated values.

Finally, the spreading has to be enabled using the XXX_SPREADING_ENABLE bit.

NOTE: It is necessary to carefully configure the spreading on a clock in order to avoid adding some "noise" on frequencies that are used by another module. For example, adding spreading on a clock to reduce noise on GSM frequencies can "move" the generated noise to the memory controller's frequency, and then degrade its performances.

Example:

For f_c=400MHz, Deviation =1% peak from f_c (Δf = 4MHz) and f_m=400kHz, the estimated peak power reduction is 10dB. K is then equal to 10. The DPLL can be configured as follow:

- XXX_SPREADING_RATE = 10 (250 to 500 KHz)
- XXX_SPREADING_AMPLITUDE = 11 (K = 10)
- XXX_SPREADING_ENABLE = 1

The state of the modulation feature can be monitored with the XXX_SPREADING_ENABLE_STATUS bit of the corresponding register.

NOTE:

- To support the spreading feature the DPLL Bandwidth is restricted to a max of 70KHz. This implies the Reference Clock frequency to be in range 0.75MHz to 2.1MHz, and then the XXX_DPLL_FREQSEL[3:0] bitfield to be in range "0011" to "0111".
- The required Δf (Frequency deviation) is targeted on the CLKOUT Frequency is achieved when M2 is programmed to 1. Otherwise the frequency deviation will be scaled down by the factor of M2 value. However, this does not affect the deviation, so frequency change of harmonics at GSM frequencies is the same.
- The spread of modulation frequency within each range is due to an internal auto-ranging function and specific frequencies cannot be selected.
- The lowest range (62.5 to 125 KHz) should only be selected when Reference Clock (PLL internal reference frequency) < 1.1 MHz is being used, to prevent the PLL feedback loop from canceling the modulation.

When deactivating the spreading (XXX_SPREADING_ENABLE = 0), the End-of-Spreading is synchronous to the internal spreading cycle. So there is no residual average frequency error. PER_DPLL_SPREADING_RATE option is not supported.

6.5 System Control Module Programming Model

6.5.1 Feature Settings

6.5.1.1 Video Driver

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

- TVOUTBYPASS bit CONTROL.CONTROL_DEVCONF1[18]:
  0b0: Dual 10-bit video DAC TV out bypass disable
  0b1: Dual 10-bit video DAC TV out bypass enable
- TVACEN bit CONTROL.CONTROL_DEVCONF1[11]:
  0b0: Enables dc coupling for TV output
  0b1: Enables ac coupling for TV output

For more details on video DACs, see the *Display Subsystem* chapter.

6.5.1.2 McBSP1 Internal Clock

The McBSP1 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP1.

- MCBSP1_FSR bit CONTROL.CONTROL_DEVCONF0[4]:
  0: FSR is from the pin mcbsp1_fsr.
  1: FSR is from the pin mcbsp1_fsx.
- MCBSP1_CLKR bit CONTROL.CONTROL_DEVCONF0[3]:
  0: CLKR is from the pin mcbsp1_clkr.
  1: CLKR is from the pin mcbsp1_clkx.
- MCBSP1_CLKS bit CONTROL.CONTROL_DEVCONF0[2]:
  0: CLKS is from the PRCM functional clock.
  1: CLKS is from the pin mcbsp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.3 McBSP2 Internal Clock

The McBSP2 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP2. The McBSP2 does not have mcbsp2_clkr and mcbsp2_fsr external pins. Clock input is from the mcbsp2_clkx pin; FSR input is from the mcbsp2_fsx pin.

- MCBSP2_CLKS register bit CONTROL.CONTROL_DEVCONF0[6]:
  0: Clock is from the PRCM functional clock.
  1: Clock is from the external pin mcbsp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.4 McBSP3 Internal Clock

The McBSP3 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP3. The McBSP3 does not have mcbsp3_clkr and mcbsp3_fsr external pins. Clock input is from the mcbsp3_clkx pin; FSR input is from the mcbsp3_fsx pin.

- MCBSP3_CLKS register bit CONTROL.CONTROL_DEVCONF1[0]:
  0: Clock is from the PRCM functional clock.
  1: Clock is from the external pin mcbsp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.5 McBSP4 Internal Clock

The McBSP4 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP4. The McBSP4 does not have mcbsp4_clkr and mcbsp4_fsr external pins. Clock input is from the mcbsp4_clkx pin; FSR input is from the mcbsp4_fsx pin.

- MCBSP4_CLKS register bit CONTROL.CONTROL_DEVCONF1[2]:
  0: Clock is from the PRCM functional clock.
  1: Clock is from the external pin mcbsp_clks.

For more details on McBSP, see the *McBSP* chapter.

6.5.1.6 McBSP5 Internal Clock

The McBSP5 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP5. The McBSP5 does not have mcbsp5_clkr and mcbsp5_fsr external pins. Clock input is from the mcbsp5_clkx pin; FSR input is from the mcbsp5_fsx pin.

- MCBSP5_CLKS register bit CONTROL.CONTROL_DEVCONF1[4]:
  0: Clock is from the PRCM functional clock.
  1: Clock is from the external pin mcbsp_clks.

For more details on McBSP, see the *McBSP* chapter.

6.5.1.7 MMC/SD/SDIO2 Module Input Clock Selection

- MMCSDIO2ADPCLKISEL bit CONTROL.CONTROL_DEVCONF1[6]:
  0: Input clock is from the external pin.
  1: Internal loopback, module input clock is copied from the module output clock.

6.5.1.8 Setting Sensitivity on SYS_NDMAREQ[3:0] Input Pins

The seven SYS_NDMAREQ0 to SYS_NDMAREQ6 input pins can be either level or edge sensitive.

- SENSDMAREQ0 bit CONTROL.CONTROL_DEVCONF0[0]:
  0: Level sensitivity
  1: Edge sensitivity
- SENSDMAREQ1 bit CONTROL.CONTROL_DEVCONF0[1]:
  0: Level sensitivity
  1: Edge sensitivity
- SENSDMAREQ2 bit CONTROL.CONTROL_DEVCONF1[7]:
  0: Level sensitivity
  1: Edge sensitivity
- SENSDMAREQ3 bit CONTROL.CONTROL_DEVCONF1[8]:
  0: Level sensitivity
  1: Edge sensitivity

For more details on DMA, see the *DMA* chapter.

6.5.1.9 Force MPU Writes to Be Nonposted

MPUFORCEWRNP bit CONTROL.CONTROL_DEVCONF1[9] bit is for debugging only. When this bit is set to 1 (for debugging), all writes are forced to nonposted and the cache attributes are ignored. By default, this bit should be set to 0 (posted writes). For the best performance, keep this bit at 0.

6.5.2 Pad Configuration Programming Points

To configure the pad, ensure that the following are done:

- Identify signals required on the interface based on the target application.

Example: You want to configure UART1 interface on balls. The required signals are: uart1_tx, uart1_rts, uart1_cts, and uart1_rx.

- Choose the pads used for those signals. Some signals could be available on several pads and/or may be multiplexed with other signals that can be need for an other application. Refer to Section 6.4.4.3, *Pad Multiplexing Register Fields.*

  Example: Each UART1 interface signals are available on two pads. These signals are multiplexed with a McBSP signal.

  Assume that the McBSP interface is required in the system. Therefore, for the UART1 interface signals, pads must be used where those signals are not multiplexed with the McBSP signal.

- Identify the pad configuration registers associated to the pads you will use in your application. Refer to Section 6.4.4.3, *Pad Multiplexing Register Fields.*

  Example: With the previous hypothesis the pad configuration registers to program are:

  – uart1_cts: CONTROL.CONTROL_PADCONF_DSS_DATA0[15:0]
  – uart1_rts: CONTROL.CONTROL_PADCONF_DSS_DATA0[31:16]
  – uart1_tx: CONTROL.CONTROL_PADCONF_DSS_DATA6[15:0]
  – uart1_rx: CONTROL.CONTROL_PADCONF_DSS_DATA6[31:16]

  NOTE: In that configuration, dss_datan (where n = 0) signals will not be available on these balls.

- Configure the MUXMODE field of each pad configuration registers (CONTROL.CONTROL_PADCONF_X) associated to the pads used. Section 6.4.4.3, *Pad Multiplexing Register Fields* lists the entire mode available for each pin. Write the binary value of the mode used in the MUXMODE field of the pad configuration registers.

  Example: UART1 signals are available in mode 2. So you should write 0b010 in the corresponding MUXMODE field of pad configurations registers to program.

- Configure the pull of the pad when you use it as input. When the pad is used as output the pull is automatically disabled. Section 6.4.4.3, *Pad Multiplexing Register Fields* lists the pull available on each pad and it reset value. Set the appropriate value for PULLTYPESELECT bit of the pad configuration register to set the pull value (0b0 = Pull Down selected, 0b1 = Pull Up selected) and set the PULLUDENABLE bit of the pad configuration register to enable the pull on the pad (0b0 = pull disabled, 0b1 = pull enabled)

  Example: uart1_rts and uart1_tx are output signals, so the pull will be automatically disabled on the pad. uart1_cts and uart1_rx are input signals, so you should configure the pull for these pads:

  – uart1_cts: enable pull-up (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
  – uart1_rx: enable pull-up (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)

- Set the INPUTENABLE bit of the pad configuration register if your pin is use as input.

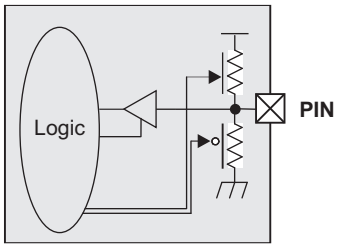
  Example: uart1_rts and uart1_tx are output signals, so clear the INPUTENABLE bit of the corresponding pad configuration register. uart1_cts and uart1_rx are input signals, so set the INPUTENABLE bit of the corresponding pad configuration register.

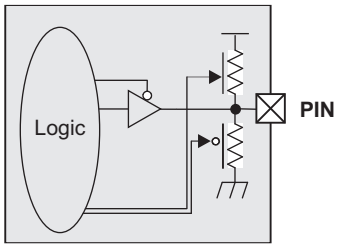
  NOTE: The order is unimportant for the previous setting of the pad configuration bits.

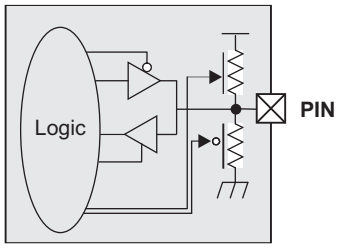
6.5.3 I/O Power Optimization Guidelines

In order to optimize I/O power, it is important to avoid unconnected or incorrectly-pulled pins. According to the type of the pins, the way to reduce power consumption can differ. Table 6-46 shows the 3 available pin (or ball) types.

Table 6-46. Existing Pin Types

Input	Output	Bidirectional
		






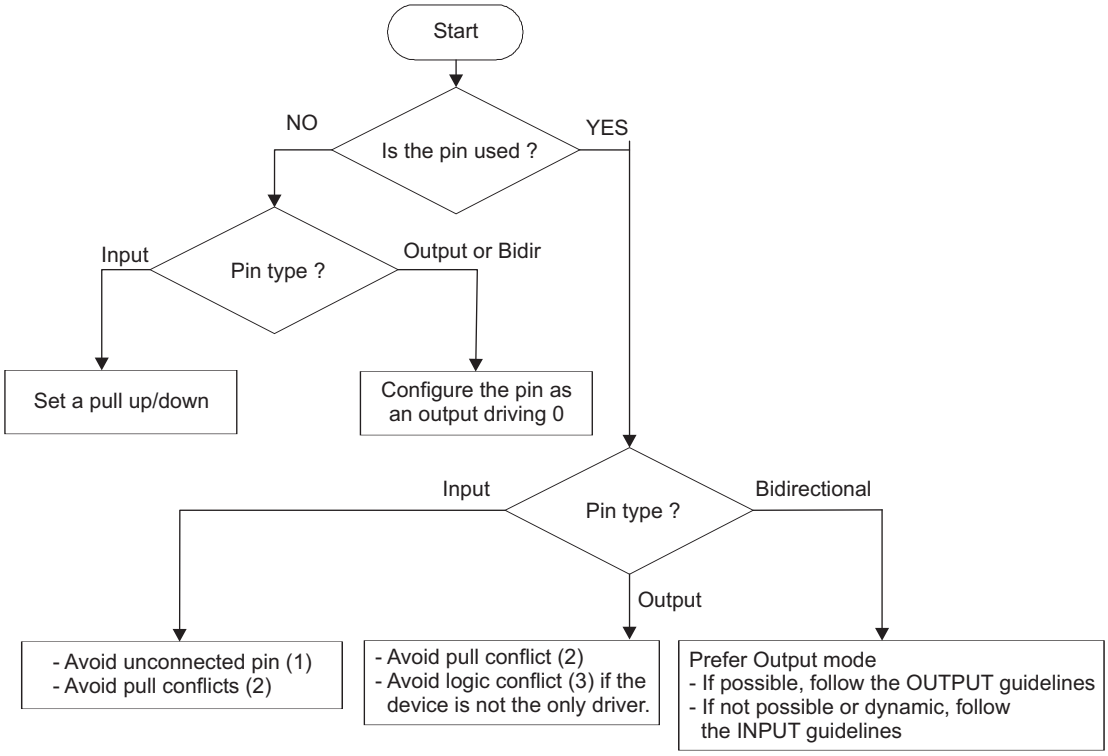
The configuration differs according to the I/O cell types. The following describes some pieces of advice which can be useful to avoid extra current leakage:

- For input pins, use a pull up/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

Figure 6-19 shows how to optimize the power consumption of pads.

Figure 6-19. I/O Power Optimization Flowchart



The following notes give additional explanations about the pin configuration.

1. In order to avoid unconnected pins, the configuration depends on its use:
   - If the pin is not driven externally, a pull up/down is required.
   - Otherwise, a pull up/down is not necessary.
2. Pull conflicts occur when there are different pulls on the same line. In order to correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
   - If no external device drives the line, configure the pin to drive a '0'.
   - If another device drives the line, either the same value has to be driven or the pin has to be disconnected (HZ).

NOTE: It is advised to use high impedance logical state either on the device or the external component when the line is driven by both components.

The I/O pads are software-controlled by:

- Writing to the CONTROL_PADCONF_X registers in the Control Module for input/output and pull up/down configuration.
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for input/output configuration.

For more information about how to configure the I/O pads, see Chapter 6, *System Control Module*.

For more information about the GPIO module, see the *General-Purpose Interface* chapter.

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), both the CONTROL_PADCONF_X and the GPIOi.GPIO_OE registers must be written.

For more information about the I/O cell types and the corresponding optimized configuration, please contact your TI representative.

6.6 System Control Module Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

Table 6-47 lists the base address and address space for the SCM instances.

Table 6-47. Instance Summary

Module Name	Base Address	Size
INTERFACE	0x4800 2000	36 bytes
PADCONFS	0x4800 2030	564 bytes
GENERAL	0x4800 2270	767 bytes
MEM_WKUP	0x4800 2600	1K byte
PADCONFS_WKUP	0x4800 2A00	80 bytes
GENERAL_WKUP	0x4800 2A60	31 bytes

Some register description tables in this section are divided into different device types and ModeSP according to their access rights and reset value. For example, CONTROL.CONTROL_EXT_SEC_CONTROL is divided into seven tables named "TypeAModeB Bitfield Details" where:

- *A* can take different expressions depending on the device type:
  - E: EMULATOR device
  - G: General-purpose device
  - T: TEST device
  - S: SECURE device
  - B: BAD device
  - X: DON'T CARE device

  These access rights are enumerated in register descriptions as needed.
- *B* can take different expressions depending on the mpu mode:
  - SP: SECURE PRIVILEGE mode
  - NSP: NON SECURE PRIVILEGE mode
  - X: DON'T CARE mode

6.6.1 System Control Module Register Mapping Summary

NOTE: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding).

Table 6-48 lists the INTERFACE registers.

Table 6-48. INTERFACE Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
CONTROL_REVISION	R	32	0x0000 0000	0x4800 2000	Section 6.6.2.1
CONTROL_SYSCONFIG	RW	32	0x0000 0010	0x4800 2010	Section 6.6.2.2

Table 6-49 lists the PADCONFS registers.

Table 6-49. PADCONFS Registers Mapping Summary

6.6.2 INTERFACE Register Descriptions

Table 6-150 through Table 6-55 describe the interface register bits.

6.6.2.1 CONTROL_REVISION

Table 6-54. CONTROL_REVISION

Address Offset	0x00		
Physical address	0x4800 2000	**Instance**	INTERFACE
Description	Control module Revision number		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REVISION							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns reset value.	R	0x000000
7:0	REVISION	Revision number	R	-

6.6.2.2 Control System Configuration Register (CONTROL_SYSCONFIG)

Table 6-55. Control System Configuration Register (CONTROL_SYSCONFIG)

Address Offset	0x10		
Physical address	0x4800 2010	**Instance**	INTERFACE
Description	Set various parameters relative to the Idle mode of the Control module		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE			ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Read returns reset value.	R	0x0000000
4:3	IDLEMODE	Power Management, req/ack control	R/W	0x0
		0x0: Force-idle. An idle request is acknowledged unconditionally		
		0x1: Reserved		
		0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module		
		0x3: Reserved		
2	ENAWAKEUP	Wake-up enable. Not used in the module	R	0x0
1	SOFTRESET	Software reset. Not used in the module	R	0x0
0	AUTOIDLE	Internal interface clock gating strategy	R/W	0x0
		0x0: Interface clock is free-running		
		0x1: Automatic interface clock gating strategy is applied, based on the interconnect interface activity		

6.6.3 PADCONFS Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [31:16]). See Figure 6-8 for more information about PADCONF registers.

According to the pad type, some features are configurable or not. Table 6-56 gives the description of a fully configurable pad.

Table 6-56. CONTROL_PADCONF_X

Address Offset	0x0000 0000 - 0x0000 05C8		
Physical address	See Table 6-49	**Instance**	SYSC_PADCONFS
Description	Pad configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							INPUTENABLE1	RESERVED			PULLTYPESELECT1	PULLUDENABLE1	MUXMODE1			RESERVED							INPUTENABLE0	RESERVED			PULLTYPESELECT0	PULLUDENABLE0	MUXMODE0		

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Reserved	R	0
24	INPUTENABLE1	Input enable value for pad_x	R/W	1
23:21	RESERVED	Reserved	R	0
20	PULLTYPESELECT1	Pull-Up/Down selection for pad_x: 0: Pull-Down selected 1: Pull-Up selected	R/W	Pad dependent
19	PULLUDENABLE1	Pull-Up/Down enable for pad_x: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	Pad dependent
18:16	MUXMODE1	Functional multiplexing selection for pad_x	R/W	Pad dependent
15:9	RESERVED	Reserved	R	0
8	INPUTENABLE0	Input enable value for pad_y	R/W	1
7:5	RESERVED	Reserved	R	0
4	PULLTYPESELECT0	Pull-Up/Down selection for pad_y: 0: Pull-Down selected 1: Pull-Up selected	R/W	Pad dependent
3	PULLUDENABLE0	Pull-Up/Down enable for pad_y: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled	R/W	Pad dependent
2:0	MUXMODE0	Functional multiplexing selection for pad_y	R/W	Pad dependent

NOTE: The Bits field gives the field number for the pairs of pads gathered in each register.

Table 6-57 describes the reset values and the corresponding register for each pad.

NOTE:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
- The reset value for Reserved bits is 0.
- In the MUX Reset States column and the PU/PD Reset States column of Table 6-57 , a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.

Table 6-57. CONTROL_PADCONF_CAPABILITIES

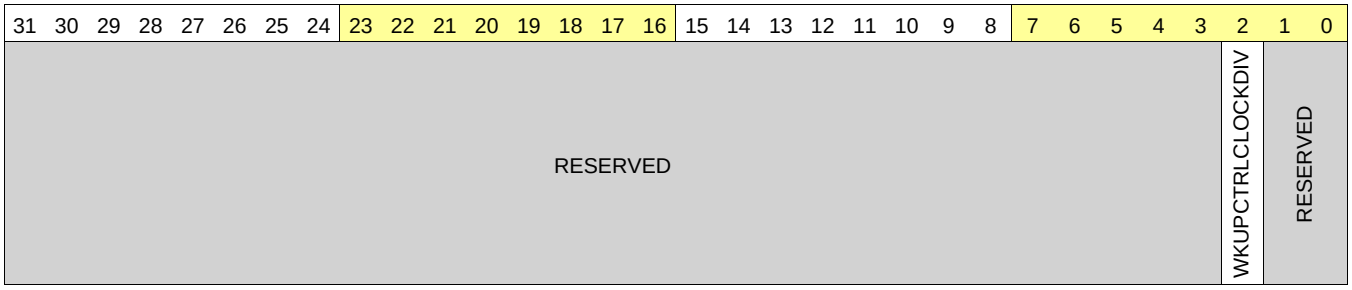
6.6.4 GENERAL Register Descriptions

Table 6-58 through Table 6-151 describe the GENERAL registers bits.

6.6.4.1 CONTROL_PADCONF_OFF

Table 6-58. CONTROL_PADCONF_OFF

Address Offset	0x0000 0000		
Physical address	0x4800 2270	**Instance**	GENERAL
Description	Off mode pad configuration register		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Read returns reset value.	R	0x0000000
2	WKUPCTRLCLOCKDIV	Wkup_ctrl module clock divider 0x0: Clock is divided by 4 0x1: Clock is divided by 2	R/W	0x0
1:0	RESERVED	Reserved	R	0x0

6.6.4.2 CONTROL_DEVCONF0

Table 6-59. CONTROL_DEVCONF0

Address Offset	0x0000 0004		
Physical address	0x4800 2274	**Instance**	GENERAL
Description	Static device configuration register-0. Module dedicated functions		
Type	R/W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RESERVED																	MCBSP2_CLKS	RESERVED	MCBSP1_FSR	MCBSP1_CLKR	MCBSP1_CLKS	SENSDMAREQ1	SENSDMAREQ0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved bits	R/W	0x00
26	RESERVED	Reserved bit	R/W	0x1
25	RESERVED	Reserved bit	R/W	0x0
24:7	RESERVED	Read returns reset value	R	0x000
6	MCBSP2_CLKS	Select the CLKS input for the module McBSP2 Note : There are no external pins McBSP2_CLKR and McBSP2_FSR for the module McBSP2. For this module, CLKR input is from the pin McBSP2_CLKX and FSR input is from the pin McBSP2_FSX 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS	R/W	0x0
5	RESERVED	Read returns reset value.	R	0
4	MCBSP1_FSR	Select the FSR input for the module McBSP1 0x0: FSR is from the pin McBSP1_FSR 0x1: FSR is from the pin McBSP1_FSX	R/W	0x0
3	MCBSP1_CLKR	Select the CLKR input for the module McBSP1 0x0: CLKR is from the pin McBSP1_CLKR 0x1: CLKR is from the pin McBSP1_CLKX	R/W	0x0
2	MCBSP1_CLKS	Select the CLKS input for the module McBSP1 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS	R/W	0x0
1	SENSDMAREQ1	Set sensitivity on SYS_NDMAREQ1 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0
0	SENSDMAREQ0	Set sensitivity on SYS_NDMAREQ0 input pin 0x0: Level sensitivity 0x1: Edge sensitivity	R/W	0x0

6.6.4.3 CONTROL_MEM_DFTRW0

Table 6-60. CONTROL_MEM_DFTRW0

Address Offset	0x0000 0008		
Physical address	0x4800 2278	**Instance**	GENERAL
Description	DFT Read and Write Controls for memory blocks		
Type	R/W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MEMORY4DFTGLXCTRL	MEMORY3DFTGLXCTRL	MEMORY2DFTWRITECTRL		MEMORY2DFTREADCTRL		RESERVED		MEMORY1DFTWRITECTRL		MEMORY1DFTREADCTRL		MEMORY0DFTGLXCTRL		MEMORY0DFTWRITECTRL		MEMORY0DFTREADCTRL	

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns reset value	R	0X0
15	MEMORY4DFTGLXCTRL	ETB memory DFT GLX ctrl	Refer to Table 6-61	0X0
14	MEMORY3DFTGLXCTRL	WKUP memory DFT GLX ctrl	Refer to Table 6-61	0X0
13:12	MEMORY2DFTWRITECTRL	McBSP2 memory DFT write ctrl	Refer to Table 6-61	0X0
11:10	MEMORY2DFTREADCTRL	McBSP2 memory DFT read ctrl	Refer to Table 6-61	0X0
9	RESERVED	Read returns reset value	R	0X0
8:7	MEMORY1DFTWRITECTRL	EMAC, USBOTG ,HECC, and VPFE memory DFT write ctrl	Refer to Table 6-61	0X0
6:5	MEMORY1DFTREADCTRL	EMAC, USBOTG ,HECC, and VPFE memory DFT read ctrl	Refer to Table 6-61	0X0
4	MEMORY0DFTGLXCTRL	SGX_ss memory DFT GLX ctrl	Refer to Table 6-61	0X0
3:2	MEMORY0DFTWRITECTRL	SGX_ss memory DFT write ctrl	Refer to Table 6-61	0X0
1:0	MEMORY0DFTREADCTRL	SGX_ss memory DFT read ctrl	Refer to Table 6-61	0X0

Table 6-61. Type Value For CONTROL_MEM_DFTRW0 Register

Field Name	MPU Mode	
	NSP	SP
MEMORY4DFTGLXCTRL	Read returns 0s	R/W
MEMORY3DFTGLXCTRL	Read returns 0s	R/W
MEMORY2DFTWRITECTRL	Read returns 0s	R/W

MEMORY1DFTWRITECTRL	Read returns 0s	R/W
MEMORY1DFTREADCTRL	Read returns 0s	R/W
MEMORY0DFTGLXCTRL	Read returns 0s	R/W
MEMORY0DFTWRITECTRL	Read returns 0s	R/W

Table 6-61. Type Value For CONTROL_MEM_DFTRW0 Register (continued)

Field Name	MPU Mode	
	NSP	SP
MEMORY0DFTREADCTRL	Read returns 0s	R/W

6.6.4.4 CONTROL_MEM_DFTRW1

Table 6-62. CONTROL_MEM_DFTRW1

Address Offset	0x0000 000C		
Physical address	0x4800 227C	**Instance**	GENERAL
Description	DFT Read and Write Controls for memory blocks		
Type	R/W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DFTREADWRITEENABLE	RESERVED							MEMORY10DFTWRITECTRL		MEMORY10DFTREADCTRL		MEMORY9DFTWRITECTRL		MEMORY9DFTREADCTRL		RESERVED				MEMORY7DFTWRITECTRL		MEMORY7DFTREADCTRL		MEMORY6DFTGLXCTRL	RESERVED								

Bits	Field Name	Description	Type	Reset
31	DFTREADWRITEENABLE	Control use of CONTROL_MEM_DFTRWx registers: 0x0: DFT Read/write setting is coming from the Test sub-system 0x1: DFT Read/write setting is coming from the CONTROL_MEM_DFTRWx registers	Refer to Table 6-63	0
30:26	RESERVED	Read returns reset value.	R	0x0
25:24	MEMORY10DFTWRITECTRL	DSI memory DFT write ctrl	Refer to Table 6-63	0x0
23:22	MEMORY10DFTREADCTRL	DSI memory DFT read ctrl	Refer to Table 6-63	0x0
21:20	MEMORY9DFTWRITECTRL	DISP_ss memory DFT write ctrl	Refer to Table 6-63	0x0
19:18	MEMORY9DFTREADCTRL	DISP_ss memory DFT read ctrl	Refer to Table 6-63	0x0
17:13	RESERVED	Reserved	R	0x0
12:11	MEMORY7DFTWRITECTRL	MPU_ss memory DFT write ctrl	Refer to Table 6-63	0x0
10:9	MEMORY7DFTREADCTRL	MPU_ss memory DFT read ctrl	Refer to Table 6-63	0x0
8	MEMORY6DFTGLXCTRL	OCMRAM memory DFT GLX ctrl	Refer to Table 6-63	0x0

Bits	Field Name	Description	Type	Reset
7:0	RESERVED	Read returns reset value	R	0x0

Table 6-63. Type Value For CONTROL_MEM_DFTRW1 Register

Field Name	MPU Mode	
	NSP	SP
DFTREADWRITEENABLE	Read returns 0s	R/OCO
MEMORY10DFTREADCTRL	Read returns 0s	R/W
MEMORY10DFTWRITECTRL	Read returns 0s	R/W
MEMORY9DFTREADCTRL	Read returns 0s	R/W
MEMORY9DFTWRITECTRL	Read returns 0s	R/W
MEMORY7DFTREADCTRL	Read returns 0s	R/W
MEMORY7DFTWRITECTRL	Read returns 0s	R/W
MEMORY6DFTGLXCTRL	Read returns 0s	R/W

NOTE: DSI is not available on all devices. See Chapter 1, the *Device Family* section, to check availability of this module.

6.6.4.5 CONTROL_MSUSPENDMUX_0

Table 6-64. CONTROL_MSUSPENDMUX_0

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved	R	0
26	VDD_HVMODEOUT	IO Voltage detect cell (CQdetect) output: 0 : 1.8V IO operation 1 : 3.3V IO operation	R	
25	FUSE_SECIP_DISABLE_GRP2	Gate the clocks of Group2 Security IPs: 2xAES, 2xDES/3DES, RNG 0: Enabled 1: Disabled	R	-
24	FUSE_SECIP_DISABLE_GRP1	Gate the clocks of Group1 Security IPs: PKA, SHA1/MD5, SHA2/MD5 0: Enabled 1: Disabled	R	-
23	USBPHY_GPIO_MODE	Selects the GPIO mode of USB PHY 0 : USB PHY normal mode operation 1 : UART3 Tx/Rx are coming on DP and DM pins of USBPHY	R/W	0
22:20	Reserved	Reserved	R	0
19	FUNC_SYS32K_SEL	Sys_boot7 value 0 : External 32K Oscillator is selected 1 : Internal 32K clock is selected which is derived from sys clock divided by 800	R	
18	FUNC_MODE_SEL	Sys_boot8 value 0 : Normal mode DDR 32 Bit 1 : Reduced package mode DDR 16 Bit	R	
17	Reserved	Reserved	R	0
16	FUSE_AVDAC_DISABLE	Goes high when AVDAC is disabled using efuse. 0 : AVDAC Disabled 1 : AVDAC Enabled	R	

Bits	Field Name	Description	Type	Reset
15:14	USBOTG_OTGMODE	These two bits will control whether the USB2.0 PHY comparators for VBUS and ID pins are used to drive the VBUSVALID, SESSVALID, SESSEND [3 different levels on VBUS in] and the IDDIG [ID pin value] to the USB controller. In cases where OTG is not needed, it may be more convenient to configure VBUS and ID from MMRs than actually having to drive the VBUS and ID pins to specific levels. Encoding is: OTGMODE = 00 : Do not override phy values. Let PHY drive signals to controller based on its comparators for the VBUS and ID pins. OTGMODE = 01 : Override phy values to force USB Host Operation OTGMODE = 10 : Override phy values to force USB Device Operation OTGMODE = 11 : Override phy values to force USB Host Operation with VBUS low	R/W	3
13	USBOTG_SESSENDEN	1 : Will turn on the Session end comparator	R/W	0
12	USBOTG_VBUSDETECTEN	1 : Will turn on all comparators (except session end comparator) on the vbus line	R/W	0
11:8	USBOTG_SELINPUTCLKFREQ	USB PHY PLL reference clock frequency 0001 : Reserved 0010 : Reserved 0011 : Reserved 0100 : Reserved 0101 : Reserved 0110 : Reserved 0111 : sys_clk 1000 : Reserved 1001 : Reserved	R/W	7
7	USBOTG_PWRCLKGOOD	Goes high when Clock is present from oscillator, all power sources are good and PLL is locked.	R	-
6	USBOTG_VBUSSENSE	Detects the presence of VBUS irrespective of the VDDA supplies. Goes high when VBUS goes above a threshold.	R	-
5	USBOTG_PHY_PLLON	0 : Turn off USB PHY PLL 1 : Turn on the USB PHY PLL	R/W	0
4	USBOTG_PHY_RESET	0 : USB PHY is out of Reset 1 : USB PHY is in Reset	R/W	1
3	USBOTG_PHY_PD	0 : USB PHY is Power Up 1 : USB PHY Power down	R/W	1
2	USBOTG_POWERDOWNOTG	0 : Power up the OTG module of USB PHY 1 : Power down the OTG module of USB PHY	R/W	1
1	USBOTG_DATAPOLARITY	0 : Inverted polarity 1 : Normal polarity	R/W	1
0	VPFE_PCLK_INVERT_EN	0 : Do not Invert the pclk clock coming from IO buffer and going to VPFE module 1 : Invert the pclk clock coming from IO buffer and going to VPFE module	R/W	0

NOTE: DSI is not available on all devices. See Chapter 1, the *Device Family* section, to check availability of this module.

6.6.4.67 CONTROL_DEVCONF3

Table 6-146. CONTROL_DEVCONF3

Address Offset	0x0000 0314

Bits	Field Name	Description	Type	Reset
31:12	Reserved	Reserved	R	0x000000
11	Reserved	Reserved	RW	0
10	VPFE_FUNC_CLK_EN	0 : Disable the Func clock of VPFE 1 : Enable the Func clock of VPFE	RW	1
9	CPGMAC_FUNC_CLK_EN	0 : Disable the Func clock of CPGMAC 1 : Enable the Func clock of CPGMAC	RW	1
8	USB20OTG_FUNC_CLK_EN	0 : Disable the Func clock of USBOTG 1 : Enable the Func clock of USBOTG	RW	1
7	HECC_VBUSP_CLK_EN_ACK	Status of HECC VBUSP clock 0 : Clock Gated 1 : Enabled	R	
6	VPFE_VBUSP_CLK_EN_ACK	Status of VPFE VBUSP clock 0 : Clock Gated 1 : Enabled	R	
5	CPGMAC_VBUSP_CLK_EN_ACK	Status of CPGMAC VBUSP clock 0 : Clock Gated 1 : Enabled	R	
4	USB20OTG_VBUSP_CLK_EN_ACK	Status of USB VBUSP clock 0 : Clock Gated 1 : Enabled	R	
3	HECC_VBUSP_CLK_EN	0 : Disable the VBUSP clock of HECC 1 : Enable the VBUSP clock of HECC	RW	1
2	VPFE_VBUSP_CLK_EN	0 : Disable the VBUSP clock of VPFE 1 : Enable the VBUSP clock of VPFE	RW	1
1	CPGMAC_VBUSP_CLK_EN	0 : Disable the VBUSP clock of CPGMAC 1 : Enable the VBUSP clock of CPGMAC	RW	1
0	USB20OTG_VBUSP_CLK_EN	0 : Disable the VBUSP clock of USBOTG	RW	1

Bits	Field Name	Description	Type	Reset
		1 : Enable the VBUSP clock of USBOTG		

6.6.4.72 CONTROL_IDCODE

Table 6-151. CONTROL_IDCODE

Address Offset	0x307F94		
Physical Address	0x4830 A204	**Instance**	SYSC_GENERAL1
Description	Device IDCODE.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VERSION				HAWKEYE												TI_IDM															Reserved

Bits	Field Name	Description	Type	Reset
31:28	VERSION	Revision number	R	See (1).
27:12	HAWKEYE	Hawkeye number	R	
11:1	TI_IDM	Manufacturer identity (TI)	R	See (1).
0	Reserved	Read returns reset value.	R	1

(1) For more information, see Section 1.5, *Distinguishing Between the Silicon Versions*, in Chapter 1, *Introduction*.

6.6.5 MEM_WKUP Register Descriptions

0x4800 2600 to 0x4800 29FC physical addresses are memories mapped for save and restore location (1Kbytes).

- 0x4800 2600 - 0x4800 2830: non accessible (pad configuration)
- 0x4800 2834 - 0x4800 29FC: user accessible

6.6.6 PADCONFS_WKUP Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [31:16]). See Figure 6-8 for more information about PADCONF registers.

According to the pad type, some features are configurable or not. Table 6-56 gives the description of a fully configurable pad.

Table 6-152 describes the reset values, the capabilities, and the corresponding register for each pad.

NOTE:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
- The reset value for Reserved bits is 0.
- In the MUX Reset States and PU/PD Reset States columns of Table 6-152 , a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.

Table 6-152. CONTROL_PADCONF_WKUP_CAPABILITIES

REGISTER NAME	Pad Name	Physical Address	Input Enable	Reserved	PU/PD	MUX Mode

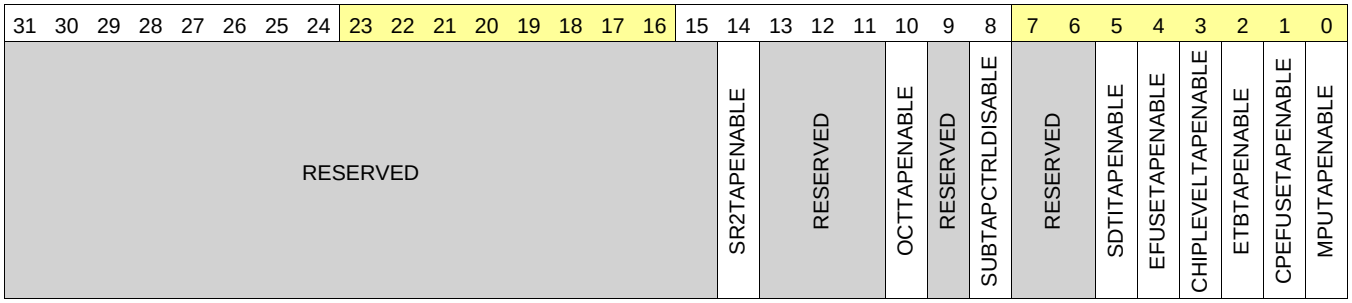
6.6.7 GENERAL_WKUP Register Descriptions

Table 6-153 through Table 6-169 describe the PADCONFS registers bits.

6.6.7.1 CONTROL_SEC_TAP

Table 6-153. CONTROL_SEC_TAP

Address Offset	0x0000 0000		
Physical Address	0x4800 2A60	**Instance**	GENERAL_WKUP
Description	Security TAP controllers register		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read returns reset value.	R	0x0000
14	SR2TAPENABLE	Smart Reflex2 TAP control 0x0: Smart Reflex2 TAP controller is disabled 0x1: Smart Reflex2 TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
13:11	RESERVED	Read returns reset value.	R	0x0
10	OCTTAPENABLE	OCT TAP Control 0x0: OCT TAP controller is disabled 0x1: OCT TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
9	RESERVED	Read returns reset value.	R	0x0
8	SUBTAPCTRLDISABLE	Restrict writable register list accessible through the Chip Level TAP 0x0: Writable register list is unrestricted 0x1: Writable register list is restricted	Refer to Table 6-154	0x0
7:6	RESERVED	Read returns reset value.	R	0x0
5	SDTITAPENABLE	SDTI TAP control 0x0: SDTI TAP controller is disabled 0x1: SDTI TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
4	EFUSETAPENABLE	E-Fuse TAP control 0x0: E-Fuse TAP controller is disabled 0x1: E-Fuse TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
3	CHIPLEVELTAPENABLE	Chip Level TAP control 0x0: Chip-Level TAP controller is disabled 0x1: Chip-Level TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
2	ETBTAPENABLE	ETB TAP control 0x0: ETB TAP controller is disabled 0x1: ETB TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155

Bits	Field Name	Description	Type	Reset
1	CPEFUSETAPENABLE	CP Efuse TAP control 0x0: CP Efuse TAP controller is disabled 0x1: CP Efuse TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155
0	MPUTAPENABLE	MPU / ICECrusher / ETM / PSA TAP control 0x0: MPU TAP controller is disabled 0x1: MPU TAP controller is enabled	Refer to Table 6-154	Refer to Table 6-155

6.7 Revision History

Table 6-171 lists the changes made since the previous version of this document.

Table 6-171. Document Revision History

Reference	Additions/Modifications/Deletions
Global	Removed CONTROL_SEC_CTRL register.
Global	Removed the CONTROL_GENERAL_PURPOSE_STATUS register.
Global	Removed CONTROL_MSUSPENDMUX_3 register.
Global	Changed CONTROL_CBA_PRIORITY address offset from 0x0000 031C to 0x0000 0320.
Global	Changed CONTROL_CBA_PRIORITY physical address from 0x4800 258C to 0x4800 2590.
Global	Changed CONTROL_LVL_INTR_CLEAR address offset from 0x0000 031C & 0x0000 0320 to 0x0000 0324.
Global	Changed CONTROL_LVL_INTR_CLEAR physical address from 0x4800 258C & 0x4800 2590 to 0x4800 2594.
Global	Changed CONTROL_IP_SW_RESET address offset from 0x0000 0320 & 0x0000 0324 to 0x0000 0328.
Global	Changed CONTROL_IP_SW_RESET physical address from 0x4800 2590 & 0x4800 2594 to 0x4800 2598.
Global	Changed CONTROL_IPSS_CLK_CTRL address offset from 0x0000 0324 & 0x0000 0328 to 0x0000 032C.
Global	Changed CONTROL_IPSS_CLK_CTRL physical address from 0x4800 2594 & 0x4800 2598 to 0x4800 259C.
Global	Deleted reserved register CONTROL_DEVCONF4.
Global	Changed CONTROL_PADCONF_SDRC_CKE physical address from 0x4800 2260 to 0x4800 2264.
Global	Changed CONTROL_PADCONF_SDRC_CKE address offset from 0x0000 0230 to 0x0000 0234.
Global	Changed CONTROL_PADCONF_SDRC_CKE0 physical address from 0x4800 2260 to 0x4800 2264.
Global	Changed CONTROL_PADCONF_SDRC_CKE0 address offset from 0x0000 0230 to 0x0000 0234.
Global	Changed CONTROL_PADCONF_SDRC_CKE1 physical address from 0x4800 2260 to 0x4800 2264.
Global	Changed CONTROL_PADCONF_SDRC_CKE1 address offset from 0x0000 0230 to 0x0000 0234.
Global	Removed CONTROL_RAND_KEY_0 register.
Global	Removed CONTROL_RAND_KEY_1 register.
Global	Removed CONTROL_RAND_KEY_2 register.
Global	Removed CONTROL_RAND_KEY_3 register
Global	Removed CONTROL_CUST_KEY_0 register.

Reference	Additions/Modifications/Deletions
Section 6.6.4.66	Changed bit 25 and 24 to reserved.
Section 6.6.7.1	Changed bit 31 to reserved.
	Removed Type Value For CONTROL_DEBOBS_0-8 Register tables.

DMA

This chapter describes the system direct memory access (SDMA).

Topic **Page**

7.1 SDMA Module Overview

The System Direct Memory Access (SDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

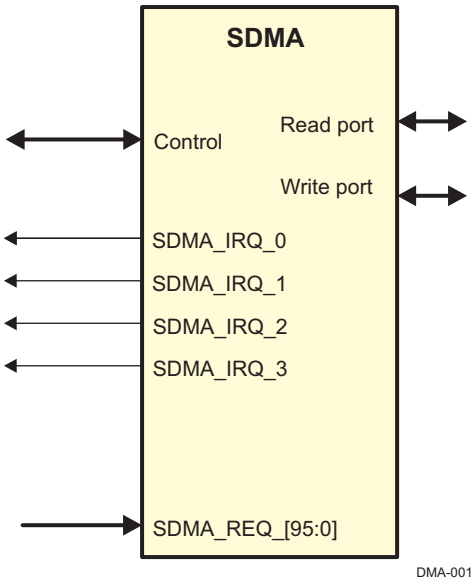
The device also embeds dedicated DMA controllers: the camera image signal processor (ISP) DMA; the enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem; the display DMA; and the universal serial bus (USB) high-speed (HS) DMA. For more information, see , *Camera ISP Subsystem*; , *IVA Subsystem*; Chapter 12, *Display Subsystem*; and Chapter 20, *High-Speed USB Controllers*.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write
  - Chained multiple-channel transfers
  - Endianism conversion
- First-come, first-serve DMA scheduling with fixed priority
- Up to 96 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- Software or hardware enabling
- FIFO depth: 256 x 32-bits
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power saving (DPS) between system power modes without MPU involvement

Figure 7-1 shows an overview of the SDMA module.

Figure 7-1. SDMA Overview



The SDMA module has two ports—one read and one write—and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports.

The MPU configures the SDMA through the L4 interconnect.

7.2 SDMA Controller Environment

7.2.1 Environment Overview

The read and write ports of the SDMA controller are connected to the device through the L3 interconnect. The control port is connected to the L4 interconnect. The SDMA interrupt lines are connected to the interrupt lines of the MPU interrupt controller. The SDMA can handle up to 96 DMA requests, including four external hardware DMA requests.

7.2.2 SDMA Request Scheme

The hardware DMA request line schemes can be either edge-sensitive or transition-sensitive.

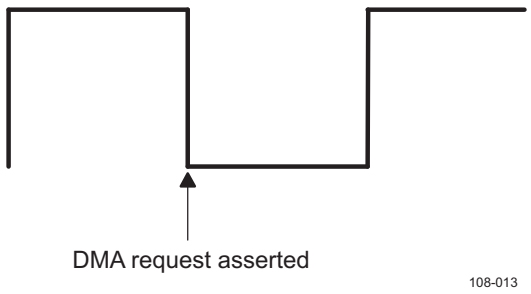
The sensitivity selection of the DMA request line can be configured in the system control module with the following register bits:

- CONTROL.CONTROL_DEVCONF0[0] SENSDMAREQ0 register bit for sys_ndmareq0
- CONTROL.CONTROL_DEVCONF0[1] SENSDMAREQ1 register bit for sys_ndmareq1
- CONTROL.CONTROL_DEVCONF1[7] SENSDMAREQ2 register bit for sys_ndmareq2
- CONTROL.CONTROL_DEVCONF1[8] SENSDMAREQ3 register bit for sys_ndmareq3

The default scheme is transition sensitive. All internal peripherals of the device use the transition-sensitive scheme.

Figure 7-2 shows the DMA request captured on a falling edge in the edge-sensitive scheme.

Figure 7-2. Edge-Sensitive DMA Request Scheme



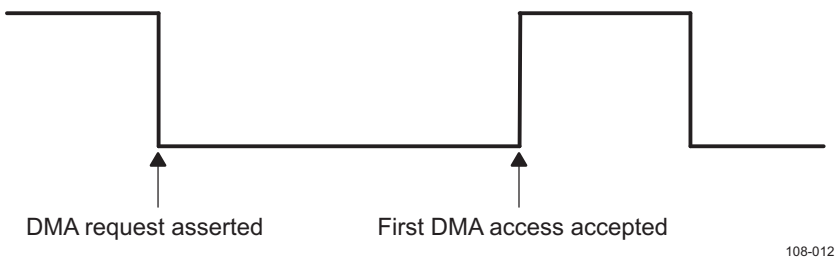
For a transition-sensitive DMA request (see Figure 7-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for a minimum of one clock cycle (CORE_L3_ICLK):

When the deassertion time is less than one clock cycle, the SDMA might not detect the deassertion.

When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.

When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

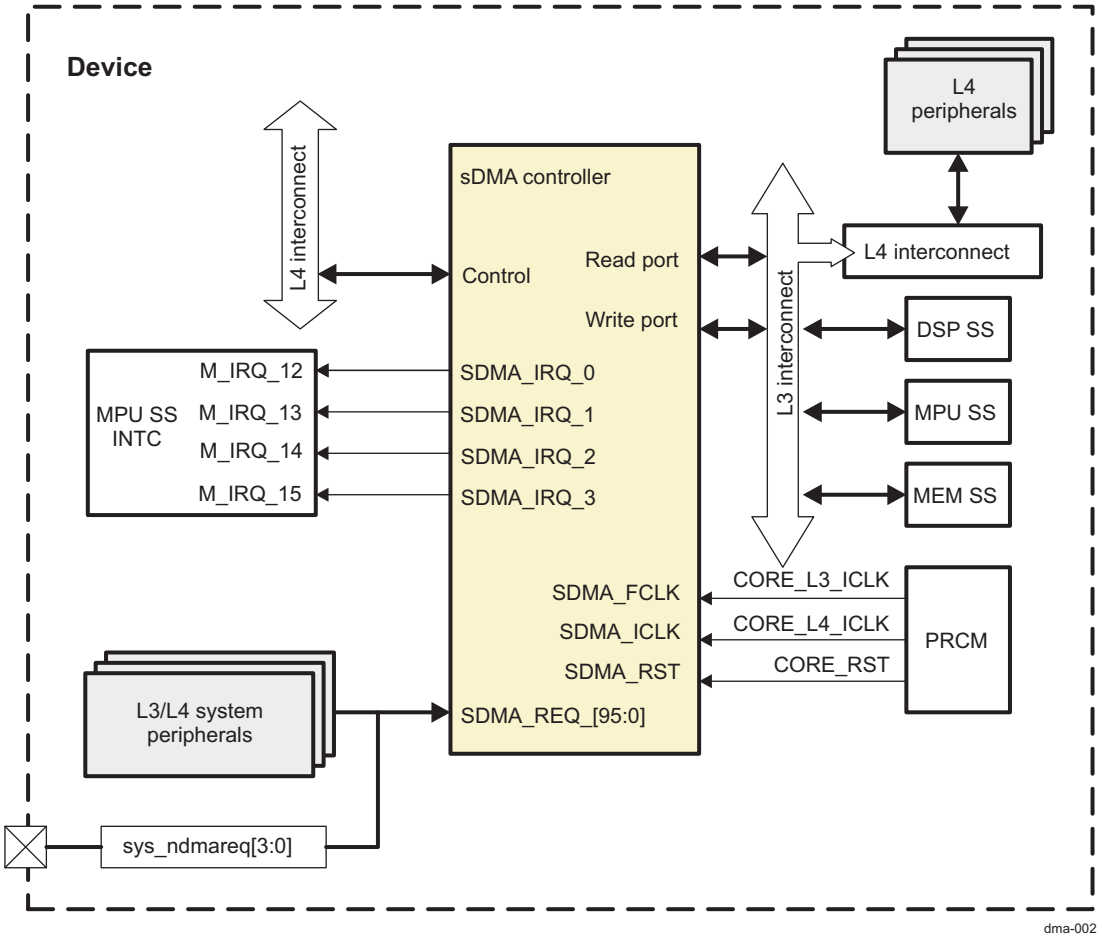
Figure 7-3. Transition-Sensitive DMA Request Scheme



7.3 SDMA Module Integration

Figure 7-4 highlights the SDMA controller integration.

Figure 7-4. SDMA Controller Integration



7.3.1 External SDMA Request Interface Description

The sys_ndmareq pins are optional external DMA requests used by external devices to establish direct hardware synchronization with the SDMA controller. A logical channel can be configured to respond to an external synchronization request. These requests can be configured to either active low on level or falling edge active by the control module.

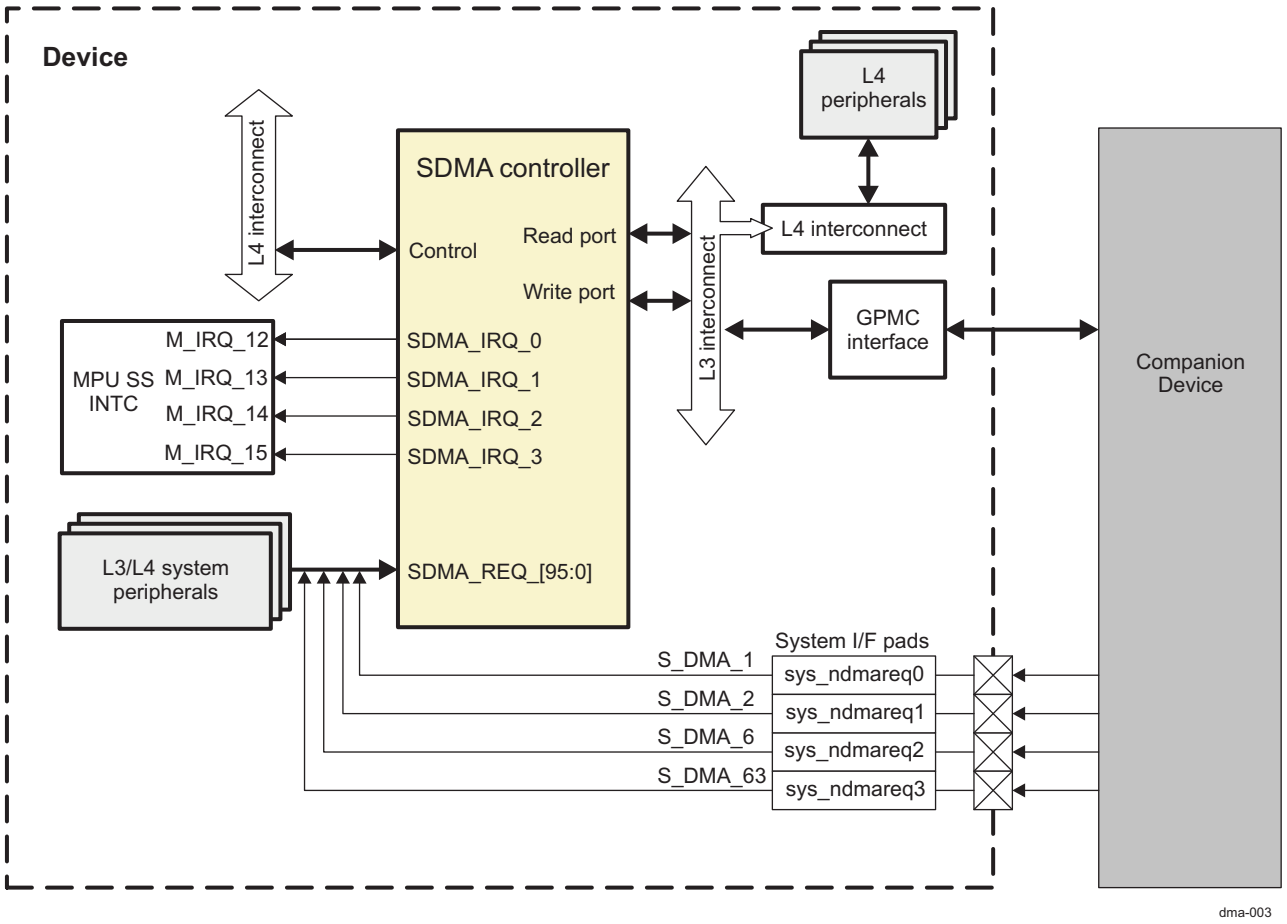
Table 7-1 shows the I/O description of the external DMA request pin.

Table 7-1. Description External DMA Request Pin

Signal Name	IO	Description	Reset
sys_ndmareq0	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq1	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq2	I	External DMA request to the SDMA controller	Unknown
sys_ndmareq3	I	External DMA request to the SDMA controller	Unknown

Figure 7-5 shows the SDMA environment with an example of how to use the external hardware DMA request pins.

Figure 7-5. Example of External DMA Requests Use to the SDMA Controller



For example, an external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

The external DMA request signals are not available on external pins by default after cold reset. See Chapter 6, *System Control Module*, for instructions on multiplexing out the seven signal lines to pins.

7.3.2 Clocking, Reset, and Power-Management Scheme

7.3.2.1 Clocking

The SDMA controller uses two clock domains:

- CORE_L4_ICLK supports the configuration port.
- CORE_L3_ICLK is both a functional clock for all internal logic and for the two master read and write ports.

The SDMA controller supports a software-controlled standby mode with an input clock shutoff. Setting the PRCM.CM_IDLEST1_CORE[2] ST_DMA status bit to 1 allows detection of the SDMA power mode.

For more information about power management and clock idle, see Section 7.4.20, *Power Management*.

7.3.2.2 Resets

7.3.2.2.1 Asynchronous Hardware Reset

The SDMA controller is part of the CORE_RST reset domain.

7.3.2.2.2 Software Reset Through the Configuration Port

The SDMA controller can be reset independently by software through the SDMA.DMA4_OCP_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset.

Hardware and software resets initialize all of the logic in the SDMA module and the global registers and some of the per-channel registers (such as the enable bit hardware request line number and link bit field) implemented in flip-flops. However, all remaining per-channel registers are memory-based and, therefore, are not reset.

7.3.2.3 Power Domain

The SDMA controller is part of the CORE power domain.

7.3.3 Hardware Requests

7.3.3.1 Interrupts to the MPU Subsystem

DMA4 has four interrupt lines, numbered Lj with j=0..3. Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. The software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- SDMA.DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the SDMA.DMA4_IRQENABLE_Lj bit *i* is 1, the channel *i* is the source of interrupt in line *j*. In contrast to the SDMA.DMA4_CSRi registers, the SDMA.DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the SDMA.DMA4_IRQENABLE_Lj registers.
- SDMA.DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the SDMA.DMA4_IRQENABLE_Lj bit *i* is set to 0, the channel interrupt *i* of the line *j* is masked.

Each logical channel can generate 10 different interrupt events when enabled (that is, set to 1) in the SDMA.DMA4_CICRi register. Each status bit is updated in the SDMA.DMA4_CSRi register only when the corresponding enable bit is enabled in the SDMA.DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*, you must:

- Identify the channel (LCH*i*) generating the interrupt.

  Read the SDMA.DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* SDMA.DMA4_CSRi. For example, if the drop event (the SDMA.DMA4_CSRi[1] DROP bit) is 1, there will be a request collision.

  The interrupt event status bit in the SDMA.DMA4_CSRi register is immediately reset after it is written to 1.

  The interrupt status bit in the SDMA.DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

Table 7-2 shows how the SDMA module interrupt lines are connected to the interrupt lines of the MPU interrupt controller.

Table 7-2. SDMA Interrupt Mapping to the MPU Subsystem

IRQ	Source	Description
M_IRQ_12	SDMA_IRQ_0	SDMA interrupt request 0
M_IRQ_13	SDMA_IRQ_1	SDMA interrupt request 1
M_IRQ_14	SDMA_IRQ_2	SDMA interrupt request 2
M_IRQ_15	SDMA_IRQ_3	SDMA interrupt request 3

7.3.3.2 DMA Requests to the SDMA Controller

This section gives information about all modules and features in the high-tier device. See Section 1.4, , to check availability of modules and features. Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.

All peripherals internal to the device use the transition-sensitive scheme for DMA requests. For more information on the transition-sensitive scheme, see Section 7.2.2, *SDMA Request Scheme*. Table 7-3 lists the SDMA request mapping.

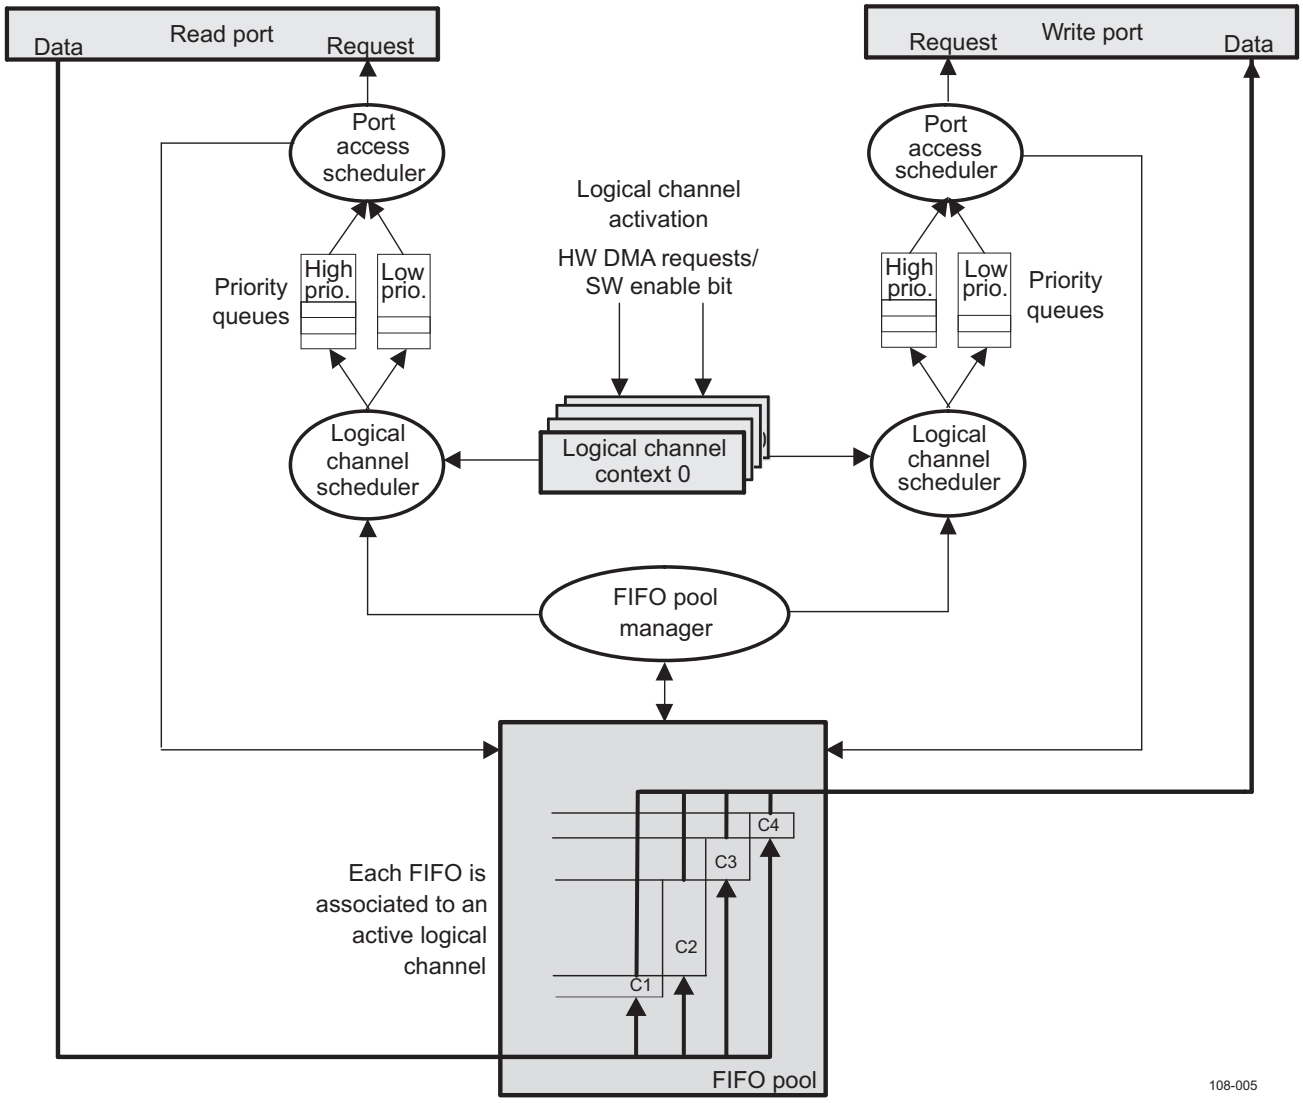
7.4 SDMA Functional Description

The SDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 7-6 shows the SDMA controller top-level block diagram.

Figure 7-6. SDMA Controller Top-Level Block Diagram



7.4.1 Logical Channel Transfer Overview

As Figure 7-6 shows, the SDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.

- Logical channel activation

  A logical channel becomes active as follows:

  - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel

- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, transfer size, the start address alignment, the addressing mode, and the configured maximum burst size, each transaction can be either a single access or a burst of accesses.

- Logical channel scheduling

  When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

  In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bit in the logical channel SDMA.DMA4_CCRi register determines if a logical channel is queued as high or low priority. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register (SDMA.DMA4_GCR).

NOTE: The SDMA.DMA4_GCR[23:16] ARBITRATION_RATE field is not dependent on the SDMA.DMA4_GCR[13:12] HI_THREAD_RESERVED field. The ARBITRATION_ RATE field is dependent on the SDMA.DMA4_CCRi[26] WRITE_PRIORITY bit and the SDMA.DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during a single transfer.

The SDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is active, one thread ID is allocated during the channel transfer. The access can be up to a 16 x 32-bit access (that is, 16 32-bit single access, four bursts of 16bytes, two bursts of 32bytes, or one burst of 64bytes) without rescheduling the channel at the end of each burst transfer.

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 7.4.12, *Interrupt Generation*).

7.4.2 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the SDMA.DMA4_GCR register. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) -1.

7.4.3 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements, and each element can have a size of 8, 16, or 32 bits, as follows:

transfer block size = number of frames x number of elements per frame x element size

The FN, number of elements per frame (EN), and size of elements are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the element size (ES), even across consecutive frames.
- Single-index: The address increases by the ES, plus the element index (EI) value minus one (even across consecutive frames).
- Double-index: The address increases by the ES, plus the EI value minus one within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and an address error interrupt occurs, if enabled (see Section 7.4.12, *Interrupt Generation*).

The SDMA.DMA4_CFNi register configures the FN in a block.

The SDMA.DMA4_CENi register configures the EN.

The SDMA.DMA4_CSDPi register configures the ES.

The SDMA.DMA4_CSSAi and SDMA.DMA4_CDSAi registers configure the source and destination start addresses.

The SDMA.DMA4_CCRi register configures the source and destination addressing modes.

The SDMA.DMA4_CSEi, SDMA.DMA4_CSFi, SDMA.DMA4_CDEi, and SDMA.DMA4_CDFi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n+1) = A(n)$$

Equation 2. Post-increment addressing:

$$A(n+1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n+1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n+1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n+1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride\ EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI - 1) * ES] + 1$$

where:

A(n): Byte address of the element n within the transfer.

ES is in bytes, ESε{1, 2, 4}.

EI is in bytes, specified in a configuration register, –32768 ≤ EI ≤ 32767.

Stride EI: The difference in the number of elements between the start of the current element, *n*, to the start of next element, n+1.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, SDMA.DMA4_CENi.

F is in bytes, specified in a configuration register, –2147483648 ≤ FI ≤ 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, SDMA.DMA4_CFNi.

Figure 7-7 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90Degrees clockwise image rotation example shown in Figure 7-11.) The double-index addressing example shown in Figure 7-7 has ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 7-7 through Figure 7-10 show examples of addressing mode configurations. Table 7-4 lists parameter values for the examples.

Figure 7-7. Example Showing Double-Index Addressing, Elements, Frames, and Strides

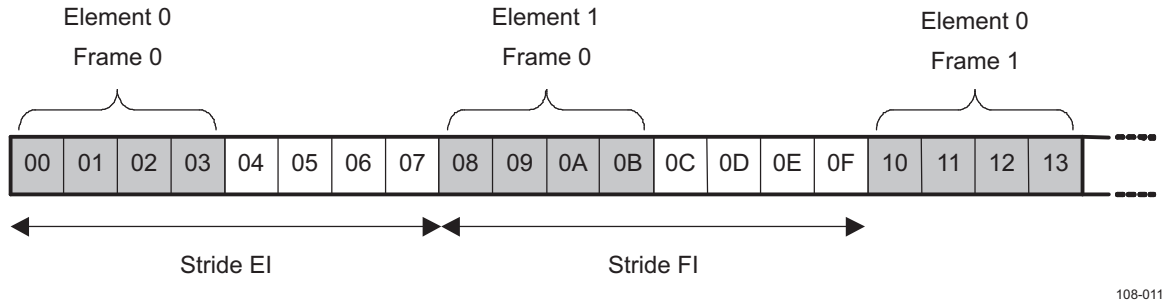


Figure 7-8. Addressing Mode Example (a)

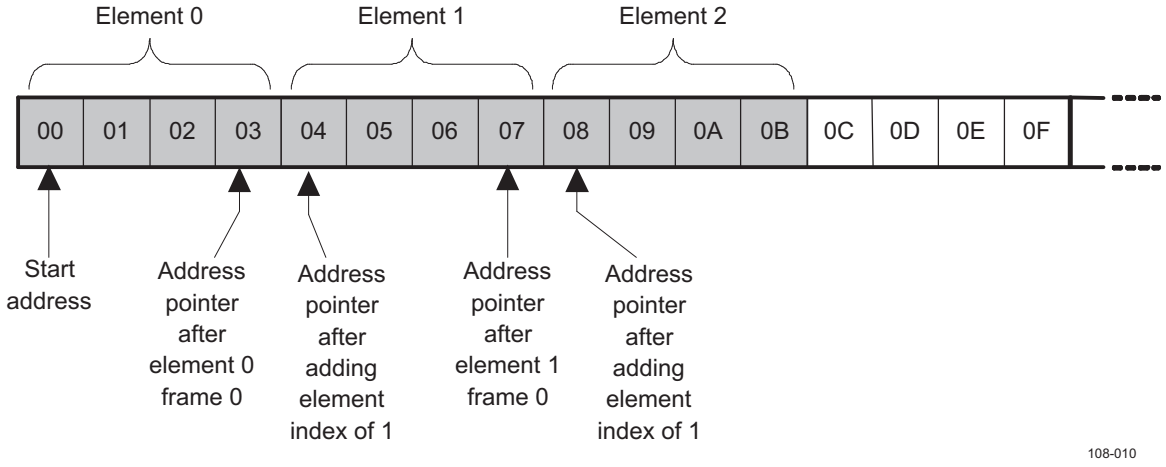

Figure 7-9. Addressing Mode Example (b)

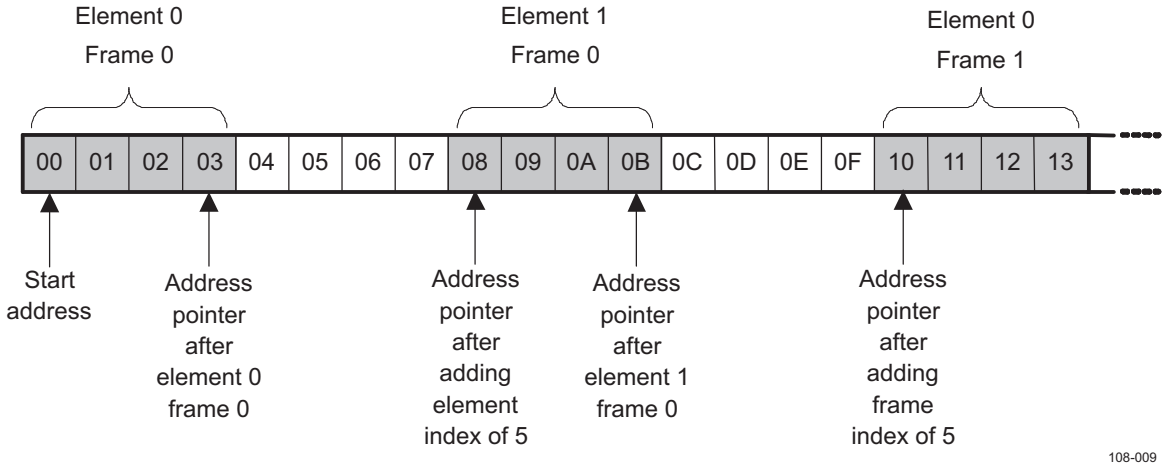

Figure 7-10. Addressing Mode Example (c)

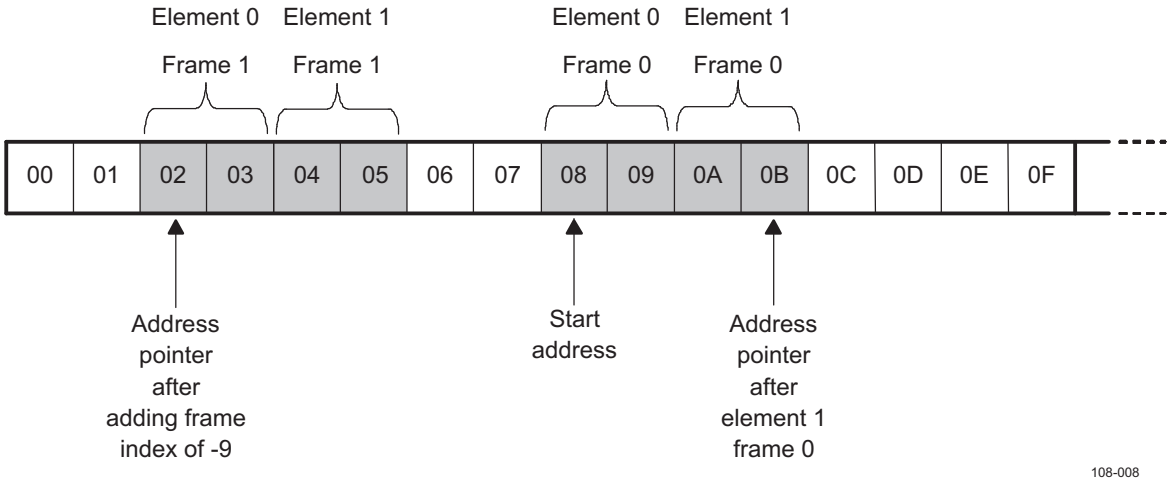

Table 7-4. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360-xx) degrees on source, and swapping x and y in them. The opposite is also true. Table 7-5 list the equations for rotation for 90, 180 and 270°.

Table 7-5. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y-1)	ES*(x*y-1)	ES*y*(x-1)
	Element index (EI)	ES*(y-1)+1	1-2*ES	1-ES*(y+1)
	Frame index (FI)	1 – ES*[(x-1)*y+2]	1-2*ES	1+ES*(x-1)*y
Double indexing on source (read)	Base address	ES*x*(y-1)	ES*(x*y-1)	ES*(x-1)
	Element index (EI)	1-ES*(x+1)	1-2*ES	ES*(x-1)+1
	Frame index (FI)	1+ES*(y-1)*x	1-2*ES	1 – ES*[(y-1)*x+2]

Table 7-6 and Figure 7-11 show the configuration required to perform a 90° clockwise image rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left-hand end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 7.5.7, *90° Clockwise Image Rotation*, describes how to program this example.

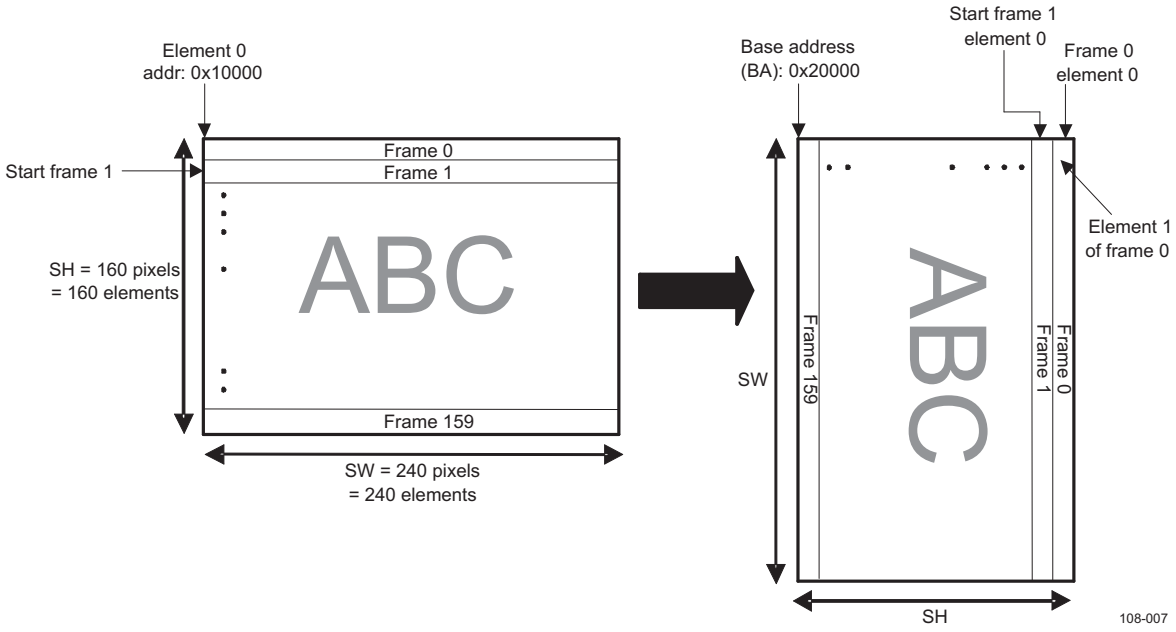
Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 7-6. Example Parameter Values for a 90° Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	-[(SW-1)*SH+1] = –38241 elements
Start address	0x100000	0x200000 + (SH – 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI – 1) * ES] + 1 = 1	[(Stride EI – 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI – 1) * ES] + 1= 1	[(Stride FI – 1) * ES] + 1 = –152967

Figure 7-11. Example of a 90° Clockwise Image Rotation



7.4.4 Packed Accesses

When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (that is, post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access may be maximized by specifying that the source or destination is packed through the channel SDMA.DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).
- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access might be only partially filled. This is indicated to the source or destination using the byte-enable signals.

NOTE: When a constant addressing mode is specified, only nonpacked accesses are used, and specifying the accesses as packed has no effect.

7.4.5 Burst Transactions

Transfer performance can be improved, where the source or destination and addressing profile supports it, by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equivalent to 16, 32, or 64 bytes through the SDMA.DMA4_CSDPi register, with the read burst size being programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses should be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: Except in the constant addressing mode, the source or destination must be specified as packed for burst transactions to occur.

7.4.6 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the SDMA.DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and the logical channel ES is less than the SDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that is equal to the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to inform the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel SDMA.DMA4_CSDPi register.

7.4.7 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

7.4.7.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19] to 0. The transfer starts as soon as the DMA register bit SDMA.DMA4_CCRi[7] is set (that is, enters the scheduling process).

7.4.7.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from either the source or destination target. A hardware synchronized transfer is specified by configuring the DMA request line number in the channel SDMA.DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 7-8).

Specify the DMA request number in the channel DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19]. After the DMA register bit SDMA.DMA4_CCRi[7] is set, the logical channel becomes enabled but not activated (that is, it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SDMA.DMA4_CCRi[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel SDMA.DMA4_CCRi register and the DMA register bits SDMA.DMA4_CCRi[5] and SDMA.DMA4_CCRi[18], respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by Data_type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independent of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify size of the packet.

To support the burst mode, the logical channel must also be configured to use the source-port packed access mode. The packed address mode cannot be used with a constant address mode: it must be configured to use a post-increment address mode.

The packet size is configured based on the source/destination synchronization select bit in the SDMA.DMA4_CCRi register through either the channel SDMA.DMA4_CDFi register (source synchronized) or the SDMA.DMA4_CSFi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

  The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 7.4.11, *Reprogramming an Active Channel*).

  For a source synchronized transfer, buffering can be enabled or disabled by setting the SDMA.DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary,

the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming the address is packed/burst aligned).

NOTE: Regardless of whether buffering is enabled or not, buffering is not performed between frames. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split into optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

  The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA register bit SDMA.DMA4_CCRi[23]. Data is prefetched on the read port side in advance of the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 7.4.2, *FIFO Queue Memory Pool*).

  Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Whether buffering is enabled or disabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the WRITE_MODE bit field of the SDMA.DMA4_CSDPi register = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering disable is enabled or disabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The BUFFERING_DISABLE bit field of the SDMA.DMA4_CCRi register must be filled with an allowed value, as specified in Table 7-7.

Table 7-7. Buffering Disable

	BUFFERING_DISABLE (0: buffering enable, 1: buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

Synchronized transfer monitoring using CDAC (SDMA.DMA4_CDACi):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, you can initialize the CDAC to monitor the transfer and determine if the transfer is started or not (see Section 7.5.4, *Synchronized Transfer Monitoring Using CDAC*, for more information).

NOTE: The CDAC register must be written or read so that the least-significant byte (LSByte) is read first; otherwise, the shadow registers do not update the CDAC registers.

This is not an issue for 32-bit read-write transactions. Nevertheless, for 16-bit transactions, start reading or writing the LSByte first to enable the register update.

7.4.8 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the concurrent channel number is superior to the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 7.5.5):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set on the global register SDMA.DMA4_GCR[13:12].

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the SDMA.DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- SDMA.DMA4_GCR[13:12] = 0x0 => No ThreadID is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are allocated for high-priority channels.

Write port priority thread reservation:

- SDMA.DMA4_GCR[13:12] = 0x0 => No ThreadID is allocated for high-priority channels
- SDMA.DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is allocated for high-priority channels.
- SDMA.DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is allocated for high-priority channels.

Regardless whether or not the enabled channels are of high priority, only the setting of the SDMA.DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit SDMA.DMA4_CCRi[26] is added for write priority, and the previous priority bit becomes read priority bit SDMA.DMA4_CCRi[6].

NOTE: The device has one priority bit per logical channel, not one per port.

7.4.9 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the SDMA.DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the SDMA.DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

7.4.10 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel SDMA.DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see Section 7.5, *SDMA Basic Programming Model*.

7.4.11 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the SDMA.DMA4_CCRi[7] ENABLE bit. When any ongoing transaction is complete and the read-active and write-active bits in the SDMA.DMA4_CCRi register (SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

7.4.12 Interrupt Generation

The SDMA module has four interrupt request output lines, SDMA_IRQ_0 to SDMA_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 7-8 occurs.

Table 7-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Synchronization error	A new DMA request arrived before completion of the transfer because of the previous DMA request.
Drain end	Drain is completed (SDMA.DMA4_CCRi[10] WR_ACTIVE becomes 0).
System transaction error	An error has occurred, for example, when an unauthorized initiator tries to set a normal channel to a System channel or tries to change a System channel to a normal channel or tries to access (write) any register of a System channel registers.
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the SDMA.DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel SDMA.DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the SDMA.DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel SDMA.DMA4_CSRi register.

7.4.13 Packet Synchronization

A packet transfer notion is related to the behavior of some peripheral, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:
maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block.
The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on RD port or WR port if source target or destination target is packet synchronized respectively.

Example:
Let's consider a camera interface, which have a FIFO_depth of 128 Words and a FIFO_element_number_threshold of 128 and a picture to transfer with a size 320 lines per 240 columns. If frame synchronization is associated to each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128 words long, which does not fit the size of a line. Then it's not possible to generate an interrupt at the end of line. However with introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows, making an enough long transfer within one channel context and perform rotation operation on big image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: typically this will be

Peripheral_element_number_threshold Number of elements in a packet shares the SDMA.DMA4_CSFIi and SDMA.DMA4_CDFIi configuration registers. Indeed if the peripheral is the source target, respectively destination target, that means the used addressing mode is constant, consequently SDMA.DMA4_CSFIi[15:0], respectively SDMA.DMA4_CDFI[15:0], is used to specify the packet data size (PKT_ELNT_NBR) and the bit fields [31:16] are unused. To specify the Packet data size in the SDMA.DMA4_CSFIi or SDMA.DMA4_CDFIi, the user must set the SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC respectively to 1 or 0.

NOTE: The packet size can be a sub-multiple or non sub-multiple of a frame size. If DMA Packet_Data_Size is aligned on DMA channel block data size boundary, DMA will transfer the last data in channel block boundary and stop at block boundary for the last packet DMA request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

The Packet synchronization mode is active when SDMA.DMA4_CCRi[5] FS = SDMA.DMA4_CCRi[18] BS = 1. Then

- if SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC=0; SDMA.DMA4_CDFIi[15:0] gives the number of element in packet and SDMA.DMA4_CDFIi[31:16] is unused for the packet size.
- if SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC=1; SDMA.DMA4_CSFIi[15:0] gives the number of element in packet and SDMA.DMA4_CSFIi[31:16] is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always: Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size. If the DMA channel packet/burst access is across packet boundary, DMA hardware automatically splits this packing/burst access into multiple smaller accesses, which will be aligned on packet boundary. Otherwise, the DMA transfers data as usual packing/burst access.

7.4.14 Graphics Acceleration Support

The SDMA supports two graphic acceleration features:

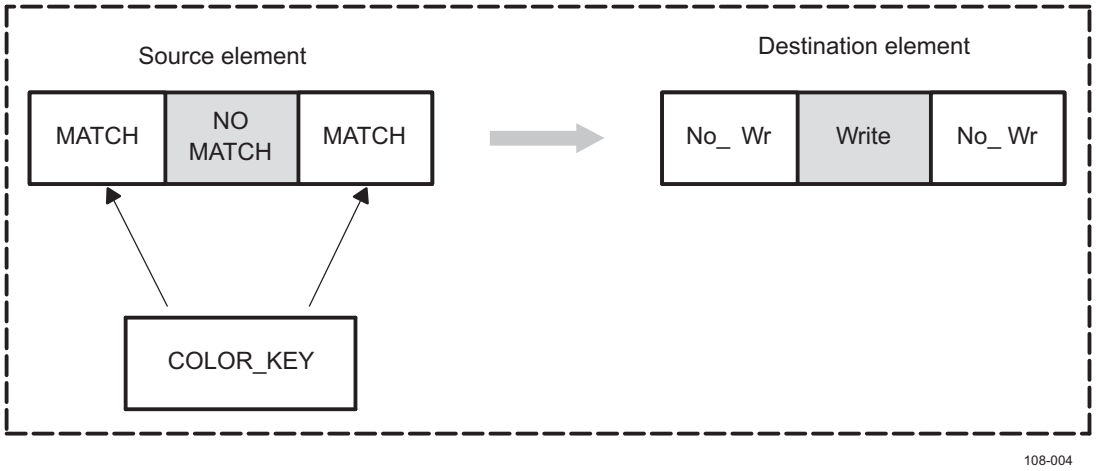
- Transparent copy
- Constant fill

Only one of these features can be enabled at any given time through the SDMA.DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the SDMA.DMA4_COLORi register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 7-12 shows the 2-D graphic transparent color block diagram.

Figure 7-12. 2-D Graphic Transparent Color Block Diagram



The constant fill feature provides the ability to specify a particular color through the SDMA.DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the SDMA.DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the most-significant 8 bits ([31:24]) are 0. Both features are compatible with packed and burst transactions.

7.4.15 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the corresponding bits in the channel SDMA.DMA4_CCRi register. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

7.4.16 Posted and Nonposted Writes

A logical channel can be configured in its DMA register bits SDMA.DMA4_CSDPi[17:16] to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

7.4.17 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel will undergo an abort, except if the channel was hardware source synchronized with buffering Enabled (SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0'). In that case, the fifo will be drained in order to avoid losing data. See Section 7.4.18 for details on this feature.

7.4.18 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel SDMA.DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the SDMA.DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no more active on the write port) and if the SDMA.DMA4_CICRi[12] DRAIN_END_IE is set to 1, the status bit DMA4_CSRi[12] DRAIN_END is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it needs to wait for SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE to become '0' before being re-enabled for a new transfer. The FIFO drain for a channel will happen only in the following cases:

- If the channel is a source synchronized channel and SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0' and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel

NOTE: In case of a self-linked or chain-linked channel, it is user responsibility to disable the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel will undergo an abort.

NOTE: If the channel intended to be used is a drain candidate, always enable DRAIN END INTERRUPT for that channel.

When the sDMA is in smart standby mode, before disabling a drain candidate channel (DMA4_CCRi[7] ENABLE = 0x0), the sDMA must be configured to be in force standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x0) or in no standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x1). After the occurrence of DRAIN END INTERRUPT EVENT from that channel, the sDMA can be switched back to smart standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x2).

7.4.19 Reset

Following a software or hardware reset, all fields in the logical channel registers have undefined values, except 5 bits in the SDMA.DMA4_CCRi and SDMA.DMA4_CICRi registers. Thus, when programming a channel for the first time, the remaining fields in all channel registers must be configured before enabling the channel.

NOTE: After a reset, the global registers take their specified reset values.

7.4.20 Power Management

The SDMA module provides two methods to reduce power consumption:

- Interconnect clock auto-idle
- Automatic standby mode

7.4.20.1 Interconnect Clock Auto-Idle

The interconnect clock auto-idle power-saving mode is enabled or disabled in DMA register bit SDMA.DMA4_OCP_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. After reset, this mode is disabled by default. Enabling this mode is recommended to reduce power consumption.

7.4.20.2 Automatic Standby Mode

As part of the system-wide power-management scheme, the module can go into a standby mode at the request of the power, reset, and clock management (PRCM) module (for more information, see , *Power, Reset, and Clock Management*).

The module can be configured to one of the following standby modes using the DMA register bits SDMA.DMA4_OCP_SYSCONFIG[13:12]:

- No standby mode: The module never goes into standby mode.
- Force standby mode: The module goes into standby mode only when all the DMA channels are disabled.
- Smart standby mode: The module enters standby mode when:
  - All DMA channels are disabled.
  - No nonsynchronized channel is enabled, no DMA request line is asserted, and no DMA request is pending in the module.

7.5 SDMA Basic Programming Model

7.5.1 Setup Configuration

After a software or hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the SDMA.DMA4_GCR register, and any required interrupts must be enabled through the SDMA.DMA4_IRQENABLE_Lj registers and the logical channel SDMA.DMA4_CICRi registers.

Software clears the SDMA.DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

7.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - SDMA.DMA4_CSDPi:
     - Transfer ES (8 bits, 16 bits, or 32 bits) and DMA register bits SDMA.DMA4_CSDPi[1:0]
     - Read and write port access types (single/burst), DMA register bits SDMA.DMA4_CSDPi[8:7] and SDMA.DMA4_CSDPi[15:14]
     - Source and destination endianism, DMA register bits SDMA.DMA4_CSDPi[21] and SDMA.DMA4_CSDPi[19]
     - Write mode (posted or nonposted) and DMA register bits SDMA.DMA4_CSDPi[17:16]
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits SDMA.DMA4_CSDPi[6] and SDMA.DMA4_CSDPi[13]
   - SDMA.DMA4_CENi: EN
   - SDMA.DMA4_CFNi: FN per transfer block
   - SDMA.DMA4_CSSAi and SDMA.DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - SDMA.DMA4_CCRi:
     - Read and write port addressing modes, DMA register bits SDMA.DMA4_CCRi[13:12] and SDMA.DMA4_CCRi[15:14]
     - Priority bit for both read and write ports, DMA register bits SDMA.DMA4_CCRi[6] and SDMA.DMA4_CCRi[26]
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits SDMA.DMA4_CCRi[4:0] = 0 and SDMA.DMA4_CCRi[20:19] = 0
   - SDMA.DMA4_CSEi, SDMA.DMA4_CSFi, SDMA.DMA4_CDEi, and SDMA.DMA4_CDFi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel SDMA.DMA4_CCRi register and DMA register bit SDMA.DMA4_CCRi[7]

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```
 UWORD32 RegVal = 0;
DMA4_t *DMA4;

DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));
/* Init. parameters */
DMA4->DataType = 0x2;                          // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0;                  // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0;                 // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0;                     // DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0;                // DMA4_CSDPi[19]
DMA4->WriteMode = 0;                           // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0;                        // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0;                   // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240;           // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160;     // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000;         // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000;    // DMA4_CDSAi
DMA4->SourceElementIndex = 1;                  // DMA4_CSEi
DMA4->SourceFrameIndex = 1;                    // DMA4_CSFi
DMA4->DestinationElementIndex = 1;             // DMA4_CDEi
DMA4->DestinationFrameIndex = 1;               // DMA4_CDFi
DMA4->ReadPortAccessMode = 1;                  // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1;                 // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0;                        // DMA4_CCRi[6]
DMA4->WritePriority = 0;                       // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0;                   // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0;                  // DMA4_CCRi[20:19]

/* 1) Configure the transfer parametres in the logical DMA registers */
/*-------------------------------------------------------------------*/
 /* a) Set the data type CSDP[1:0], the Read/Write Port access type CSDP[8:7]/[15:14], the

RegVal = ((RegVal & ~(0x1 << 6))  | (DMA4->ReadPriority << 6));
RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));
RegVal&= 0xFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/
DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* - Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

/* - Set the destination element index CDEI[15:0]*/
DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/* - Set the destination frame index CDFI[31:0]*/
DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-------------------------------------------------------------*/
//write enable bit
DMA4_CCR_CH10        |= 1 << 7; /* start */
```

7.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the SDMA.DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization SDMA.DMA4_CCRi[5] FS bit and the block synchronization SDMA.DMA4_CCRi[18] BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the SDMA.DMA4_CCRi[23] PREFETCH bit it is in conjunction with SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC bit .

- To configure an LCh to transfer one element per DMA request:

1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
3. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
4. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
5. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
6. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
7. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
8. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
9. Set both FS and BS to 0 in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
10. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.

- To configure an LCh to transfer one frame per DMA request:

1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
4. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
5. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
6. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
7. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
8. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
9. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
10. Set FS to 1 and BS to 0 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
11. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.

- To configure an LCh to transfer one block per DMA request:

1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
4. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
5. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
6. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
7. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
8. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
9. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
10. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
11. Set FS to 0 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
12. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.

- To configure an LCh to transfer one packet per DMA request:

1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
3. Set the number of element per packet to transfer: If the packet requestor is in the source, set SDMA.DMA4_CCR.Sel_Src_Dst_Sync to 1 and set the packet element number in the SDMA.DMA4_CSFIi register; else, if the packet requestor is in the destination, set the SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the SDMA.DMA4_CDFIi register.
4. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
5. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
6. Set the element number in the packet in the SDMA.DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant

addressing or post-incremented addressing modes are used in the source side. However, the number of elements in the packet is set in the SDMA.DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.

7. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
8. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
9. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.

NOTE: It is possible to stop a transfer by disabling the channel. This is done by resetting the ENABLE bit in the SDMA.DMA4_CCRi register.

7.5.4 Synchronized Transfer Monitoring Using CDAC

The SDMA.DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the SDMA.DMA4_CDACi
2. Enable the channel.
3. If timeout occurs, read SDMA.DMA4_CDACi
4. If SDMA.DMA4_CDACi!= SDMA.DMA4_CDACi reset value:

   Then transfer starts. User can then rely on SDMA.DMA4_CCENi and SDMA.DMA4_CCFNi element and frame counters.

   Else, if SDMA.DMA4_CDACi = SDMA.DMA4_CDACi reset value:

   Then transfer does not start.

7.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only, not the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread on the synchronized target side at least.

Even for multiple concurrent channels, thread reservation guarantees that as soon as an HW DMA request comes in, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider these six concurrent channels:

- Channels 0/1/2/3 are dedicated to memory-memory transfer: they are software triggered and not synchronized.
- Channel 4 is dedicated to memory→peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral→memory transfer, hardware triggered, and synchronized on the read side.

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port: Set SDMA.DMA4_GCR[13:12] = 0x1.

   Reserve one thread (Write ThreadID 0) on the write port: Set SDMA.DMA4_GCR[13:12] = 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: Set SDMA.DMA4_CCRi[26] = 1.

   Channel 5 is a read high priority channel: Set SDMA.DMA4_CCRi[6] = 1.

7.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers above.
2. For each channel in the chain, configure the SDMA.DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in DMA register bits SDMA.DMA4_CLNK_CTRLi[4:0].
   - Include the logical channel to the chain and enable link by setting the DMA register bit SDMA.DMA4_CLNK_CTRLi[15].
   - For a non-looping chain, the last logical channel in the chain must have the DMA register bit SDMA.DMA4_CLNK_CTRLi[15] set to 0 to indicate the end of the chain.
3. Enable the transfer via the enable bit in the first logical channel DMA register bit SDMA.DMA4_CCRi[7]. All other channels in the chain must be configured as disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the NEXTLCH_ID bit, DMA register bit SDMA.DMA4_CLNK_CTRLi[15](ENABLE_LNK bit set to 0x0), of the final channel transfer.

In the RAM to RAM copy example, to copy in loop it's possible to link channel 10 on itself. The following line can be added in the channel configuration :

```
 /* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 = 0x0000800A;
```

7.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 7.4.3, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - SDMA.DMA4_CSDPi:
     - Transfer ES = 32-bit (32 bpp), DMA register bits SDMA.DMA4_CSDPi[1:0]
     - Read and write port access types = maximum burst size supported by memory device, DMA register bits SDMA.DMA4_CSDPi[8:7] and SDMA.DMA4_CSDPi[15:14]
     - Source and destination endianism, DMA register bits SDMA.DMA4_CSDPi[21] and SDMA.DMA4_CSDPi[19]
     - Write mode = posted with last element nonposted, DMA register bits SDMA.DMA4_CSDPi[17:16]
     - Source and destination packed = Yes (although destination writes will not benefit because EI>1), DMA register bits SDMA.DMA4_CSDPi[6] and SDMA.DMA4_CSDPi[13]
   - SDMA.DMA4_CENi: EN = 240
   - SDMA.DMA4_CFNi: FN per transfer block = 160
   - SDMA.DMA4_CSSAi: Source start address = 0x100000
   - SDMA.DMA4_CDSAi: destination start address = 0x20013E
   - SDMA.DMA4_CCRi:
     - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA register bits SDMA.DMA4_CCRi[13:12] and SDMA.DMA4_CCRi[15:14]
     - Low or high priority, DMA register bit SDMA.DMA4_CCRi[6]
     - DMA request number = 0 (for software-triggered transfer), DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19]
   - SDMA.DMA4_CSEi: Source EI = 1
   - SDMA.DMA4_CSFi: Source frame index = 1

- SDMA.DMA4_CDEi: destination EI = 637
- SDMA.DMA4_CDFi: destination frame index = –152967

2. Start the transfer via the enable bit in the channel SDMA.DMA4_CCRi register.

Below are the parameters to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code as in Section 7.5.2:

```
 /* Init. parameters */
DMA4->DataType = 0x2;                       // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3;             // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0x3;            // DMA4_CSDPi[15:14]

```

7.5.8 Graphic Operations

- Transparent copy:
  - 1. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bit field to 1.
  - 2. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bit field to 0.
  - 3. Set the value of key the color in the SDMA.DMA4_COLORi[15:0] color_key bit field.

  To perform this graphic operation, the following lines can be added to the example of Section 7.5.2

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  - 1. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bit field to 1.
  - 2. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bit field to 0.
  - 3. Set the value of key the color in the DMA4_COLORi[15:0] solid_color bit field.

  To perform this graphic operation, the following lines can be added to the example of Section 7.5.2

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;
```

7.6 SDMA Use Cases and Tips

7.6.1 Camcorder Use Case: How to Configure SDMA to Handle Transfers With McBSP2

and MMC to External DRAM

7.6.1.1 Introduction

In this use case, the SDMA manages:

- The audio stream between the McBSP and the external DRAM
- The audio stream between the external DRAM and the MMC buffer
- The video stream between the external DRAM and the MMC buffer

The following sections describe how to configure the SDMA controller with MMC and McBSP in this use case.

7.6.1.2 SDMA Configuration to Transfer Data Between the McBSP and External DRAM

7.6.1.2.1 Overview

The SDMA gets data from the McBSP_DRR register and copies it into three rolling buffers in the external DRAM.

Figure 7-13 is an overview of the audio path.

Figure 7-13. Overview

For the camcorder use case, the DMA transfer data format is:

- Frame size = 2048 x 32 bits
- Three DMA channels to manage three transfers to three memory buffers
- Interrupt generated at the end of each frame transfer
- Transfer triggered by McBSP2

7.6.1.2.2 Environment

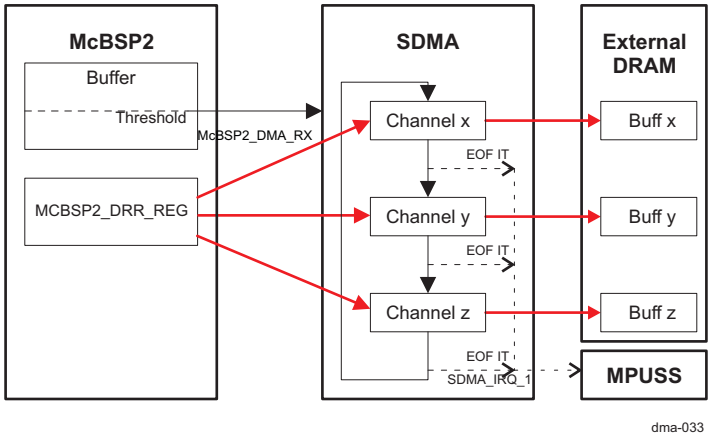
The DMA accesses MCBSP2_DRR_REG through the interconnect and receives a DMA request from this McBSP module for driving transfers. The DMA accesses the external DRAM through the interconnect. The McBSP is directly connected to the device. Figure 7-14 shows the environment of this scenario.

Figure 7-14. Environment

7.6.1.2.3 Data Path

The transfer is started when the DMA transfer is enabled and the MCBSP2_DMA_REQ is asserted (that is, when the MCBSP FIFO threshold is reached). The DMA starts copying the first frame into the first memory buffer. When a whole frame has been transferred (2048 data), an interrupt is asserted to the MPU, and then the second channel is enabled and fills the second buffer, and so on. Figure 7-15 shows the data flow.

Figure 7-15. Data Flow



7.6.1.2.4 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The McBSP2_DRR_REG register is 32 bits wide, but in the camcorder use case, only the 16 LSBs are used (monophonic 16-bit-wide audio channel).

The McBSP receives data in a FIFO buffer. As long as the occupied locations level in this read buffer is greater than or equal to the threshold value + 1 , the DMA request is asserted. After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted and then reasserted when the conditions are met again. Therefore, the DMA can receive at least threshold value data, with a threshold maximum value = 1280 elements = size of McBSP2 FIFO.

The frame synchronization transfer mode of the SDMA can be used with McBSP for frames with a size equal to the threshold. In the use case, however, the audio data frame is equal to 2048 elements, which is greater than the maximum transfer length possible with the McBSP.

Because the SDMA cannot be configured in frame synchronization mode, packet synchronization mode must be used. This mode enables to specify the maximum size of a transfer and to divide a frame into as many packet as needed. It is then possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The management of the three memory buffers is done by configuring three DMA channels linked between themselves: channel x is linked to channel y, channel y is linked to channel z, and channel z is linked to channel x. The three channels have the same configuration, except for the destination address, which corresponds to the three buffer addresses. Channels 11, 12, and 13 are used. Each channel generates the end-of-frame interrupts on the L1 interrupt line of the SDMA, to warn the MPU of the end of a frame transfer.

With these considerations, the DMA register of the three channels (i = 11, 12, and13) is configured as follows:

1. Channel source destination parameters: DMA4_CSDPi
   - DMA4_CSDPi[1:0] DATA_TYPE = 0x1: Read 16-bit elements from the McBSP_DRR_REG register.
   - DMA4_CSDPi[5:2] RD_ADD_TRSLT = 0: Not useful
   - DMA4_CSDPi[6] SRC_PACKED = 0x0: Cannot pack source data
   - DMA4_CSDPi[8:7] SRC_BURST_EN = 0x0: Cannot burst source
   - DMA4_CSDPi[12:9] WR_ADD_TRSLT = 0: Undefined
   - DMA4_CSDPi[13] DST_PACKED = 0x1: Pack two 16-bit elements in one 32-bit packet to optimize transfer.
   - DMA4_CSDPi[15:14] DST_BURST_EN = 0x3: Burst at 16x32-bit
   - DMA4_CSDPi[17:16] WRITE_MODE = 0x1: Write posted

- DMA4_CSDPi[18] DST_ENDIAN_LOCK = 0x0: Endianness adapt
- DMA4_CSDPi[19] DST_ENDIAN = 0x0: Little endian type at destination
- DMA4_CSDPi[20] SRC_ENDIAN_LOCK = 0x0: Endianness adapt
- DMA4_CSDPi[21] SRC_ENDIAN = 0x0: Little endian type at source
- DMA4_CSDPi[31:22] RESERVED = 0x0: For future compatibility

2. Channel control register: DMA4_CCRi
   - DMA4_CCRi[4:0] SYNCHRO_CONTROL = DmaReq & 0x1F = 0x2: 5 first bits of McBSP2_DMA_RX
   - DMA4_CCRi[5] FS = 1: Packet mode with BS = 0x1
   - DMA4_CCRi[6] READ_PRIORITY = 0x0: Low priority on read side
   - DMA4_CCRi[7] ENABLE = 0x0: The logical channel is disabled.
   - DMA4_CCRi[8] SUSPEND_SENSITIVE = 0
   - DMA4_CCRi[9] RD_ACTIVE: Read status, read-only access
   - DMA4_CCRi[10] WR_ACTIVE: Write status, read-only access
   - DMA4_CCRi[11] RESERVED = 0: Write 0s for future compatibility.
   - DMA4_CCRi[13:12] SRC_AMODE = 0x0: Constant address mode; DMA always reads McBSP2_DRR_REG.
   - DMA4_CCRi[15:14] DST_AMODE = 0x1: Post-incremented address mode
   - DMA4_CCRi[16] CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
   - DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
   - DMA4_CCRi[18] BS = 0x1: Packet mode with FS = 0x1
   - DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER = 0x1: Two MSBs of McBSP2_DMA_RX
   - DMA4_CCRi[22] SUPERVISOR = 0x0: Supervisor mode is disabled.
   - DMA4_CCRi[23] PREFETCH = 0x0: Prefetch mode is disabled, cannot prefetch a constant adressing source.
   - DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet element number is specified in the DMA4_CSFI register.
   - DMA4_CCRi[25] BUFFERING_DISABLE = 0x0
   - DMA4_CCRi[26] WRITE_PRIORITY = 0x0: Channel has low priority on Write side during the arbitration process.
   - DMA4_CCRi[31:27] RESERVED = 0x0: Write 0s for future compatibility.
3. Channel parameters: DMA4_CENi, DMA4_CFNi, DMA4_CSSAi, DMA4_CDSAi, DMA4_CSEi, DMA4_CSFi, DMA4_CDEi
   - DMA4_CENi[23:0] CHANNEL_ELMNT_NBR = 2048: 2048 elements
   - DMA4_CFNi[15:0] CHANNEL_FRAME_NBR = 1: One frame
   - DMA4_CSSAi[31:0] SRC_START_ADRS = 0x49022000: Channel source start address = MCBSP2_DRR_REG
   - DMA4_CDSAi[31:0] DST_START_ADRS= X, Y or Z: Channel destination start address in external DRAM, where X, Y, and Z represent the addresses of the three buffers
   - DMA4_CSEi[31:0] CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index
   - DMA4_CSFi[15:0] 16BIT_PKT_ELNT_NBR = 0x80: 16-bit Packet size = MCBSP_FIFO_THRESHOLD + 1
   - DMA4_CDEi[15:0] CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element index
4. Channel linking: DMA4_CLNK_CTRLi
   - DMA4_CLNK_CTRL11[31:0] = 0x0000800C: Channel 11 is linked to channel 12.
   - DMA4_CLNK_CTRL12[31:0] = 0x0000800D: Channel 12 is linked to channel 13.
   - DMA4_CLNK_CTRL13[31:0] = 0x0000800B: Channel 13 is linked to channel 11.
5. Interrupt management: DMA4_CICRi and DMA4_IRQENABLE_Lj

- DMA4_CICRi[31:0] = 0x00000008: Enables the end of frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)
- DMA4_IRQENABLE_L1[31:0] = 0x00001C00; interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1.

6. Launch transfer: DMA4_CCRi[7] ENABLE = 0x1: Enables the three channels, starting with channel 13, then 12, and finally 11; the last one triggers the others.

Table 7-9 lists the registers of DMA channel 11 after a first transfer.

Table 7-9. Registers Print

Register Name	Address	Value	Value Description
DMA4_IRQENABLE_L1	0x4805601c	0x00001C00	Interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1.
DMA4_CICR11	0x480564a8	0x00000008	End-of-frame interrupt enabled
DMA4_CCR11	0x480564a0	0x010c40a2	Channel control register
DMA4_CSDP11	0x480564b0	0x0001e001	Channel source destination parameters
DMA4_CEN11	0x480564b4	0x00000800	Channel element number
DMA4_CFN11	0x480564b8	0x00000001	Channel frame number
DMA4_CSSA11	0x480564bc	0x49022000	Channel source start address
DMA4_CDSA11	0x480564c0	0x81e00000	Channel destination start address
DMA4_CSFI11	0x480564c8	0x00000080	Packet size
DMA4_CSAC11	0x480564d4	0x49022000	Source address counter (read only)
DMA4_CDAC11	0x480564d8	0x81e01000	Destination address counter (read only)
DMA4_CCEN11	0x480564dc	0x00000800	Channel current transferred element number in the current frame (read only)
DMA4_CCFN11	0x480564e0	0x00000001	Channel current transferred frame number in the current transfer (read only)
DMA4_CLNK_CTRL11	0x480564a4	0x0000800C	Channel link control register: Link to channel 12

Channels 12 and 13 have a similar configuration; only the destination address and channel link change.

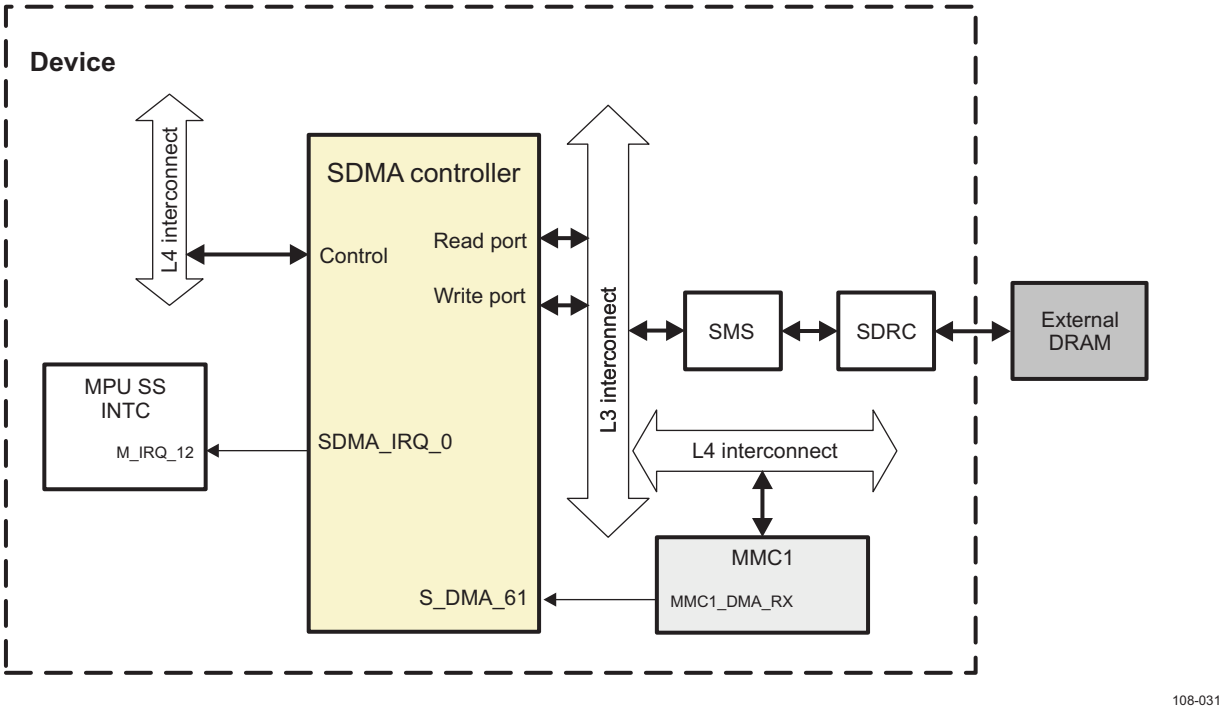
7.6.1.3 SDMA Configuration to Transfer Data Between MMC and External DRAM

7.6.1.3.1 Overview

The SDMA gets data from the MMC.MMCHS_DATA register and copies it into the external DRAM. The SDMA accesses the MMCHS_DATA through the interconnect and receives a DMA request from the MMC module for driving transfers. The DMA accesses the external DRAM through the interconnect. The transfer is started when the DMA transfer is enabled and the MMC1_DMA_REQ is asserted (that is, when the MMC buffer is ready).

Figure 7-16 is an overview of the path.

Figure 7-16. Overview



For the camcorder use case, the DMA transfer data format is:

- Frame size = 4096 x 32 bits
- packet size = 512 x 32 bits (512 elements ready in MMC when a DMA request is asserted)
- DMA channel to manage the transfer
- Interrupt generated a the end of each frame transfer
- Transfer triggered by MMC

7.6.1.3.2 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The MMCHS_DATA register is 32 bits wide.

The SDMA is configured in packet synchronization mode. This mode enables to specify the transfer of any size frame and then to divide the frame into as many packet as needed. It is therefore possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The MMC puts its received data into a 1K-byte ping-pong buffer. When 512 x 32 bits are ready in this buffer, the DMA request is asserted. Then the DMA controller transfers the defined amount of elements divided into packets of 512 x 32-bit element (PKT_ELNT_NBR) transfers.

In the use case, the size of the transfer is set at 4096 x 32 bits, chosen after performance benches.

With these considerations, the DMA register of channel i is configured as follows:

1. Channel source destination parameters: DMA4_CSDPi
   - DMA4_CSDPi[1:0] DATA_TYPE = 0x2: Read 32-bit elements from the MMCHS_DATA register.
   - DMA4_CSDPi[5:2] RESERVED: Write 0s for future compatibility. Read returns 0.
   - DMA4_CSDPi[6] SRC_PACKED = 0x0: Cannot pack source data
   - DMA4_CSDPi[8:7] SRC_BURST_EN = 0x0: Cannot burst source
   - DMA4_CSDPi[12:9] RESERVED: Write 0s for future compatibility. Read returns 0.

- DMA4_CSDPi[13] DST_PACKED = 0x0: No packing
- DMA4_CSDPi[15:14] DST_BURST_EN = 0x3: Burst at 16x32 bits
- DMA4_CSDPi[17:16] WRITE_MODE = 0x1: Write posted
- DMA4_CSDPi[18] DST_ENDIAN_LOCK = 0x0: Endianness adapt
- DMA4_CSDPi[19] DST_ENDIAN = 0x0: Little Endian type at destination
- DMA4_CSDPi[20] SRC_ENDIAN_LOCK = 0x0: Endianness adapt
- DMA4_CSDPi[21] SRC_ENDIAN = 0x0: Little endian type at source
- DMA4_CSDPi[31:22] RESERVED = 0x0: For future compatibility

2. Channel control register: DMA4_CCRi
   - DMA4_CCRi[4:0] SYNCHRO_CONTROL = DmaReq & 0x1F = 0x1E: 5 first bits of MMC1_DMA_RX(62)
   - DMA4_CCRi[5] FS = 1: Packet mode with BS = 0x1
   - DMA4_CCRi[6] READ_PRIORITY = 0x0: Low priority on read side
   - DMA4_CCRi[7] ENABLE = 0x0: The logical channel is disabled.
   - DMA4_CCRi[8] SUSPEND_SENSITIVE = 0
   - DMA4_CCRi[9] RD_ACTIVE: Read status, read-only access
   - DMA4_CCRi[10] WR_ACTIVE: Write status, read-only access
   - DMA4_CCRi[11] RESERVED = 0: Write 0s for future compatibility.
   - DMA4_CCRi[13:12] SRC_AMODE = 0x0: Constant address mode; DMA always reads the MMCHS_DATA.
   - DMA4_CCRi[15:14] DST_AMODE = 0x1: Post-incremented address mode
   - DMA4_CCRi[16] CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
   - DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
   - DMA4_CCRi[18] BS = 0x1: Packet mode with FS = 0x1
   - DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER = 0x1: Two MSB of MMC1_DMA_RX(62)
   - DMA4_CCRi[22] SUPERVISOR = 0x0: Supervisor mode is disabled.
   - DMA4_CCRi[23] PREFETCH = 0x0: Prefetch mode is disabled; cannot prefetch a constant adressing source.
   - DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet element number is specified in the DMA4_CSFI register.
   - DMA4_CCRi[25] BUFFERING_DISABLE = 0x0
   - DMA4_CCRi[26] WRITE_PRIORITY = 0x0: Channel has low priority on write side during the arbitration process.
   - DMA4_CCRi[31:27] RESERVED = 0x0: Write 0s for future compatibility.
3. Channel parameters: DMA4_CENi, DMA4_CFNi, DMA4_CSSAi, DMA4_CDSAi, DMA4_CSEi, DMA4_CSFi, DMA4_CDEi
   - DMA4_CENi[23:0] CHANNEL_ELMNT_NBR = 4096: 4096 elements
   - DMA4_CFNi[15:0] CHANNEL_FRAME_NBR = 1: One frame
   - DMA4_CSSAi[31:0] SRC_START_ADRS = 0x4809c120: Channel source start address = MMCHS_DATA
   - DMA4_CDSAi[31:0] DST_START_ADRS= X: Channel destination start address in external DRAM
   - DMA4_CSEi[31:0] CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index
   - DMA4_CSFi[15:0] 16BIT_PKT_ELNT_NBR = 0x200: Packet size = number odd data available in MMC after DMA req
   - DMA4_CDEi[15:0] CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element Index
4. Interrupt management: DMA4_CICRi and DMA4_IRQENABLE_Lj
   - DMA4_CICRi[31:0] = 0x00000008: Enables the end-of-frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)

- DMA4_IRQENABLE_L0[31:0] = 0xi: Interrupt of channel i is unmasked on IRQ line L0.

5. Launch transfer: DMA4_CCRi[7] ENABLE = 0x1: Enables the channel

Table 7-10 lists the DMA channel 2 registers after a first transfer.

Table 7-10. Registers Print

Register Name	Address	Value	Value Description
DMA4_IRQENABLE_L0	0x48056018	0x00000003	Interrupt of channel 2 is unmasked on IRQ line L0
DMA4_CICR2	0x48056148	0x00000008	End-of-frame interrupt enabled
DMA4_CCR2	0x48056140	0x010c403e	Channel control register
DMA4_CSDP2	0x48056150	0x0001c003	Channel source destination parameters
DMA4_CEN2	0x48056154	0x00000080	Channel element number
DMA4_CFN2	0x48056158	0x00000001	Channel frame number
DMA4_CSSA2	0x4805615c	0x4809c120	Channel source start address
DMA4_CDSA2	0x48056160	0x8071aafc	Channel destination start address
DMA4_CSFI2	0x48056168	0x00000080	Packet size

DMA4_CCFN12	0x48056180	0x00000000	Channel current transferred frame number in the current transfer (read only)
DMA4_CLNK_CTRL2	0x48056144	0x00000000	Channel link control register: No link

7.7 SDMA Registers Manual

This section provides a global view of the memory mapping as seen from the MPU for SDMA. Table 7-11 show the DMA register base address.

7.7.1 SDMA Instance Summary

Table 7-11. SDMA Instances Summary

Module Name	Base Address	Size
SDMA	0x4805 6000	4K bytes

7.7.2 SDMA Register Summary

Table 7-12 lists all DMA4 controller registers and their physical addresses. Table 7-13 through Table 7-67 describe the individual register bits.

Index *i* represents the logical channel number (i = 0 to 31). The offset address for some registers is calculated from channel *c* number. For example, register SDMA.DMA4_CCR10 (channel 10) has an offset address of 10*0x60 = 0x3C0, and so a physical address of 0x4800 A080 + 0x3C0 = 0x4800 A440.

Index *j* represents the interrupt line number (j = 0 to 3) The offset address for some registers is calculated from channel *c*number. For example, register SDMA.DMA4_IRQSTATUS_L3 (line 3) has an offset address of 3*0x4 = 0xC, and so a physical address of 0x4800 A008 + 0xC = 0x4800 A014.

Table 7-12. SDMA Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	SDMA Physical Address
DMA4_REVISION	R	32	0x0000 0000	0x4805 6000

7.7.3 SDMA Register Description

This section describes the registers used in the DMA4 controller.

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

The shadow registers are used to read run time registers such as CCEN, CCFN, CDAC, or CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers may change. This shadow register is used to hold the whole value to allow the next access to recover the remaining 24 bits or 16 bits.

The CSAC, CDAC, CCEN, and CCFN registers must be written or read in a way that enables the LSByte; otherwise, the shadow registers do not update the register.

There is no issue for 32-bit read-write transactions. For 16-bit transactions, read or write the LSByte first to enable the register update.

Table 7-13 through Table 7-67 describe the DMA register bits.

Table 7-13. DMA4_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4805 6000	**Instance**	SDMA
Description	This register contains the DMA revision code		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REV							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x000000
7:0	REV	[7:4] DMA4 major revision code [3:0] DMA4 minor revision code	R	TI internal data

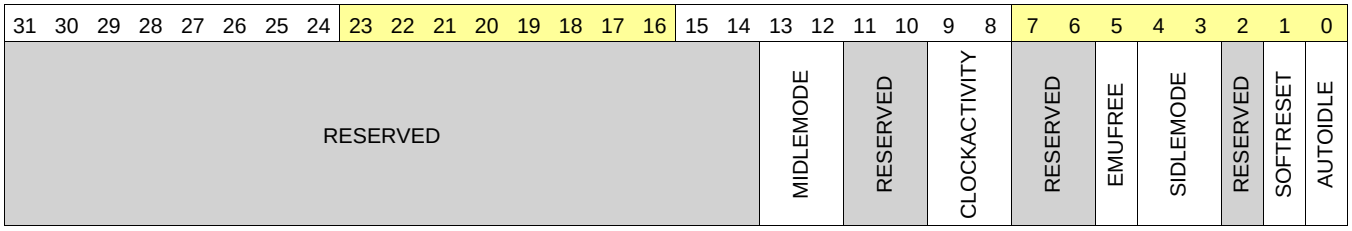
Table 7-21. DMA4_OCP_SYSCONFIG

Address Offset	0x0000 002C		
Physical Address	0x4805 602C	**Instance**	SDMA
Description	This register controls the various parameters of the OCP interface		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility, Reads return 0	RW	0x00000
13:12	MIDLEMODE	Read write power management, standby/wait control 0x0: Force-standby: MStandby is asserted only when all the DMA channels are disabled 0x1: No-Standby: MStandby is never asserted 0x2: Smart-Standby: MStandby is asserted if at least one of the following two conditions is satisfied: 1. All the channels are disabled, OR 2. There is no non-synchronized channel enabled AND [if hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced.] 0x3: reserved for second smart-standby mode if needed	RW	0x0
11:10	RESERVED	Reserved for clocks activities extension	RW	0x0
9:8	CLOCKACTIVITY	Clocks activities during wake-up Bit 8: OCP interface clock 0 OCP clock can be switched-off Bit 9: Functional clock 0 Functional clock can be switched-off	R	0x0
7:6	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
5	EMUFREE	Enable sensitivity to MSuspend 0x0: DMA4 freezes its internal logic upon MSuspend assertion 0x1: DMA4 ignores the MSuspend input	RW	0x0
4:3	SIDLEMODE	Configuration port power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Idle acknowledge is given by DMA4 if all of the conditions ar true: 1. All the channels are disabled. 2. If hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced. 3. All transactions are completed on all the DMA ports. 4. No interrupts are pending to be serviced. 0x3: reserved - do not use.	RW	0x0
2	RESERVED	Write 0s for future compatibility, Reads return 0	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: No effect 0x1: Reset	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy 0x0: OCP clock is free running 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity.	RW	0x0

Table 7-31. DMA4_GCR

Address Offset	0x0000 0078		
Physical Address	0x4805 6078	**Instance**	SDMA
Description	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget , per channel maximum FIFO depth)		
Type	RW		

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14	13 12	11 10 9 8	7 6 5 4 3 2 1 0
RESERVED	ARBITRATION_RATE	HI_LO_FIFO_BUDGET	HI_THREAD_RESERVED	RESERVED	MAX_CHANNEL_FIFO_DEPTH

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x00
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0

Bits	Field Name	Description	Type	Reset
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Description	Channel Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED					WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER		BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE		SRC_AMODE		RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL				

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x00
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process	RW	0x0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or blocks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks	RW	0x-
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register	RW	0x-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported	RW	0x0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled	RW	0x0
21	RESERVED	Reserved for non-GP devices	RW	0x0
20:19	SYNCHRO_CONTROL_ UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bit field.	RW	0x0
18	BS	Block synchronization This bit used with the fs to see how the DMA request is serviced in a synchronized transfer	RW	0x-
17	TRANSPARENT_COPY_ ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled	RW	0x-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled	RW	0x0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0x-
11	RESERVED	Reserved. Write 0s for future compatibility. Read returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	WR_ACTIVE	Indicates if the channel write context is active or not 0x0: Channel is not active on the write port 0x1: Channel is active on the write port	R	0x0
9	RD_ACTIVE	Indicates if the channel read context is active or not 0x0: Channel is not active on the read port 0x1: Channel is currently active on the read port	R	0x0
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions	RW	0x0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled	RW	0x0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process	RW	0x0
5	FS	Frame synchronization This bit used with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	0x-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SYNCHRO_CONTROL bits (formed by DMA_CCRi[20:19] and DMA4_CCRi[4:0]) must be set to 0x2 (DMA request number + 1).	RW	0x0

Table 7-34. Register Call Summary for Register DMA4_CCRi

SDMA Functional Description

- Logical Channel Transfer Overview: [0] [1] [2]
- Addressing Modes: [3]
- Software Synchronization: [4] [5] [6]
- Hardware Synchronization: [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18]
- Thread Budget Allocation: [19] [20]
- Reprogramming an Active Channel: [21] [22] [23] [24]
- Interrupt Generation: [25]
- Packet Synchronization: [26] [27] [28] [29] [30]
- Graphics Acceleration Support: [31]
- Supervisor Modes: [32]
- Disabling a Channel During Transfer: [33]
- FIFO Draining Mechanism: [34] [35] [36] [37] [38] [39]
- Reset: [40]

SDMA Basic Programming Model

- Software-Triggered (Nonsynchronized) Transfer: [41] [42] [43] [44] [45] [46] [47] [48] [49]
- Hardware-Synchronized Transfer: [50] [51] [52] [53] [54] [55] [56] [57] [58] [59] [60] [61] [62] [63] [64] [65] [66] [67] [68] [69] [70] [71] [72] [73] [74] [75] [76] [77] [78] [79] [80] [81] [82] [83] [84] [85]
- Concurrent Software and Hardware Synchronization: [86] [87]
- Chained Transfer: [88]
- 90° Clockwise Image Rotation: [89] [90] [91] [92] [93] [94] [95]
- Graphic Operations: [96] [97] [98] [99]

SDMA Use Cases and Tips

Interrupt Controller (INTC)

This chapter describes in detail the MPU subsystem interrupt controller (MPU_INTC) module used in the stand-alone processor.

NOTE: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

Topic **Page**

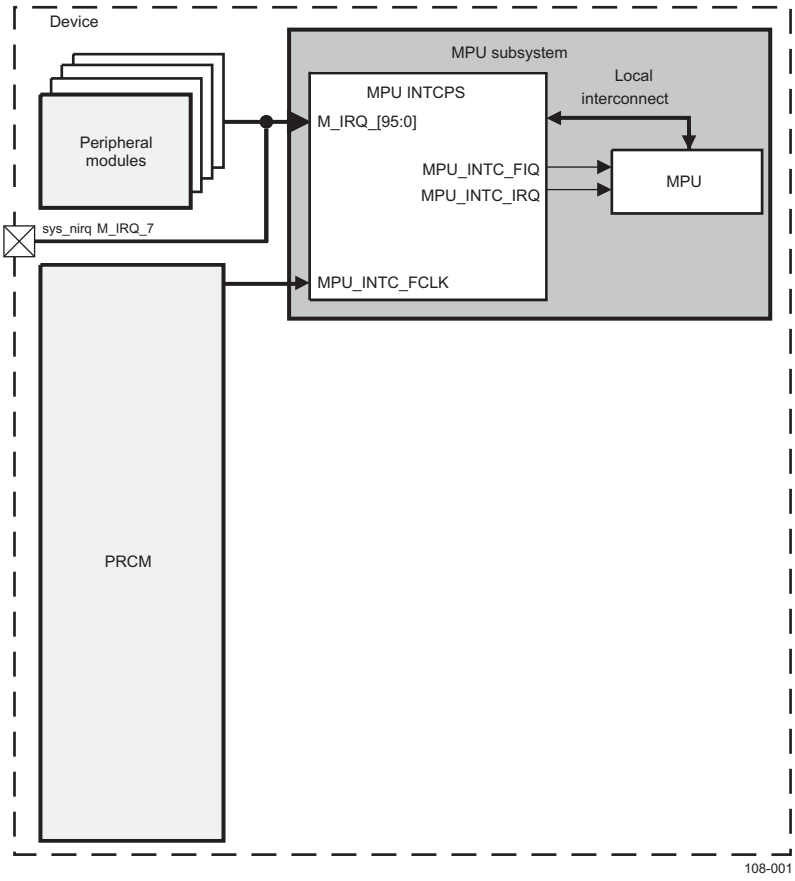
8.1 Interrupt Controller Overview

The device has one interrupt controller (INTC) module, the MPU subsystem INTC (INTCPS). This module handles all MPU-related events, using Priority Threshold and Security Features. It communicates with the ARM Cortex-A8™ processor using a private local interconnect, and runs at half the speed of the processor.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Figure 8-1 shows the internal interrupt scheme.

Figure 8-1. Interrupt Controller Highlight



8.2 Interrupt Controller Environment

The INTC can handle two types of interrupts originating from an external device:

- sys_nirq interrupt inputs:

  The MPU INTC handles external interrupts through a dedicated sys_nirq interrupt line that connects the INTC module with a TPS65950 power IC. An interrupt can generate a system wake-up event.

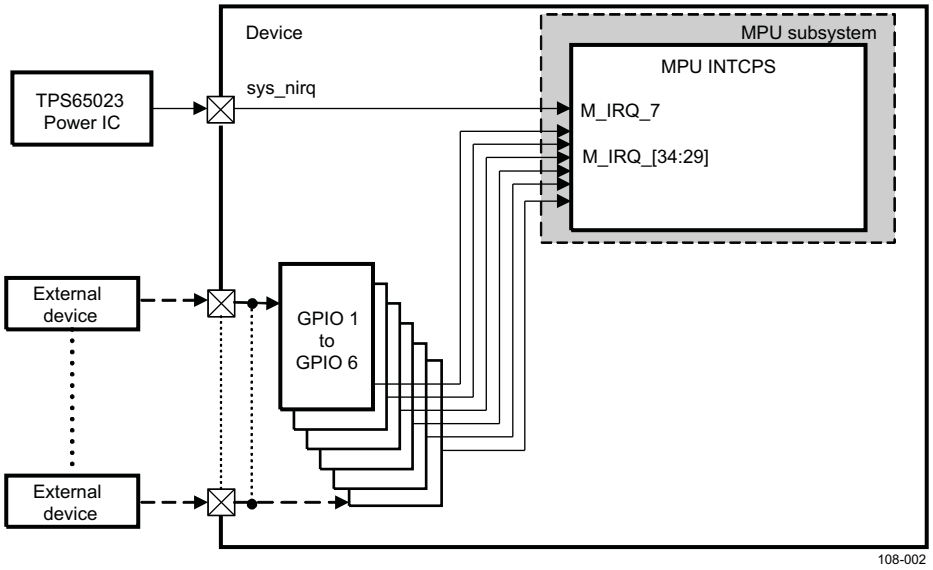
  If the system is idle and the external interrupt is masked, the interrupt cannot wake up the system. Like other interrupt lines, the external interrupt is active at low level and is acknowledged by the software according to the common programming model.

- GPIO interrupt inputs:

  External devices can also use GPIO modules to generate interrupts to the MPU. There are six dedicated interrupt lines to the MPU INTC. One interrupt line is associated with each GPIO module. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO features, see the *General-Purpose Interface* chapter.

Figure 8-2 shows the relationship between the device and external interrupts.

Figure 8-2. Interrupts from External Devices



The features specific to INTCPS are:

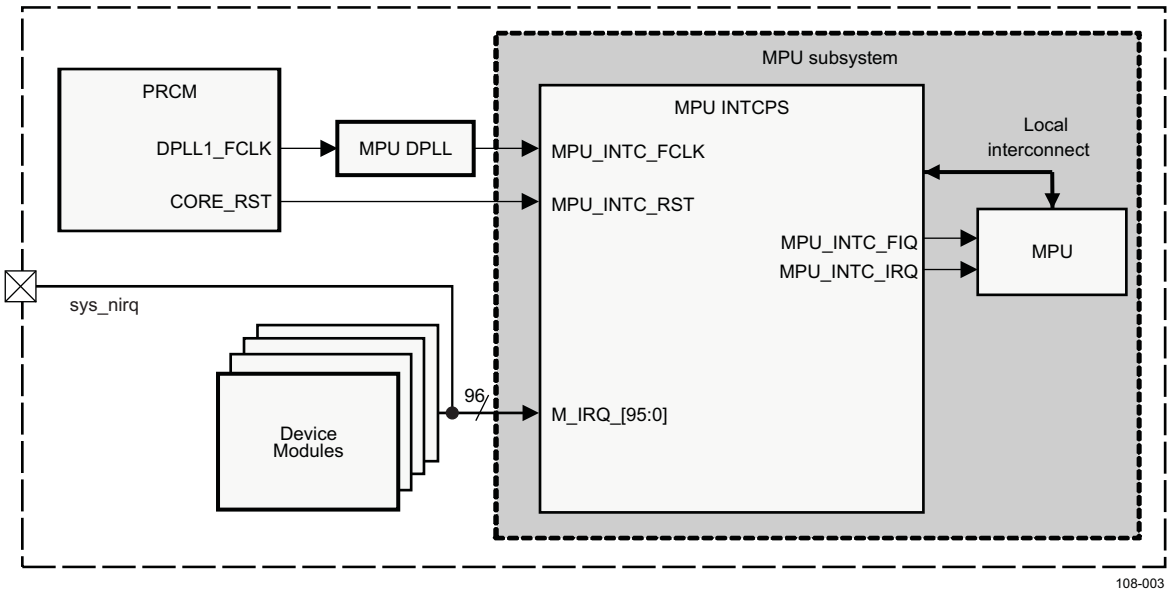
- Up to 96 level-sensitive interrupt inputs
- Individual priority (up to 64) for each interrupt input
- Interrupt lines connected to internal module interrupts
- One incoming interrupt line from an external device

8.3 MPU Subsystem INTCPS Integration

The INTCPS module is the interface between incoming interrupts and the two interrupt inputs of the MPU. It can handle up to 96 request inputs that can be configured as MPU FIQ or IRQ interrupt requests.

Figure 8-3 shows the integration of the INTCPS in the MPU subsystem.

Figure 8-3. MPU Subsystem INTCPS Integration



The MPU subsystem INTCPS is directly connected to the MPU by an MPU peripheral port. Consequently, the MPU subsystem INTCPS is accessible and visible only by the MPU.

8.3.1 Clocking, Reset, and Power Management Scheme

8.3.1.1 MPU Subsystem INTC Clocks

The MPU subsystem INTCPS runs at half the rate of the MPU functional clock (see the *MPU Subsystem* chapter).

The interface clock used for register access runs at the rate of the interconnect bus clock (equal to the rate of the MPU interface clock; see the *Power, Reset, and Clock Management* chapter).

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked.

Table 8-1 lists the MPU subsystem INTC clock rates.

Table 8-1. MPU Subsystem INTC Clock Rates

Clock	Frequency	Name	Comments
Functional	ARM_FCLK	MPU_INTC_FCLK	Source is the MPU DPLL.
Interface	ARM_FCLK	MPU_INTC_ICLK	Source is the PRCM module.
Synchronizer	MPU_INTC_FCLK	Synchronizer clock (module internal clock)	Source is the MPU_INTC_FCLK.

8.3.1.2 Hardware and Software Reset

Table 8-2 lists the MPU subsystem INTC resets.

Table 8-2. Hardware and Software Reset

Type	Name	Source	Activation	Domain
Hardware	CORE_RST	PRCM	Active low	CORE
Software	SOFTRESET	MPU_INTC.INTCPS_SYSCONFIG[1] SOFTRESET bit	Active at 1	MPU INTC internal

8.3.1.3 Power Management

The MPU subsystem INTC belongs to the CORE power domain. As part of CORE power domain, it is sensitive to a CORE_RST issued by the PRCM. For more information about the CORE power domain implementation and CORE_RST signal, see the *Power, Reset, and Clock Management* chapter.

The MPU INTC clocks come from the MPU DPLL. For more information about these clocks control, see the *MPU Subsystem* chapter.

8.3.2 Interrupt Request Lines

Table 8-3 lists the incoming and outgoing interrupt lines of the INTCPS.

Table 8-3. Interrupt Lines Incoming and Outgoing

Type	Number	Name	Mapping	Comments
Interrupt request inputs	Up to 96	M_IRQ_[95:0]	See Table 8-4	Inputs to INTCPS module, source from various modules.
Interrupt request outputs	2	MPU_INTC_FIQ	MPU_INTC_FIQ	Outgoing to MPU Fast Interrupt
		MPU_INTC_IRQ	MPU_INTC_IRQ	Outgoing to MPU Normal Interrupt

NOTE: Interrupt request signals are active at low level.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

Table 8-4 lists interrupt mappings to the MPU subsystem.

Table 8-4. Interrupt Mapping to the MPU Subsystem(1)

IRQ	Source	Description

M_IRQ_95	GPT12_IRQ	General purpose timer module 12

8.4 Interrupt Controller Functional Description

The main features of the INTCPS are:

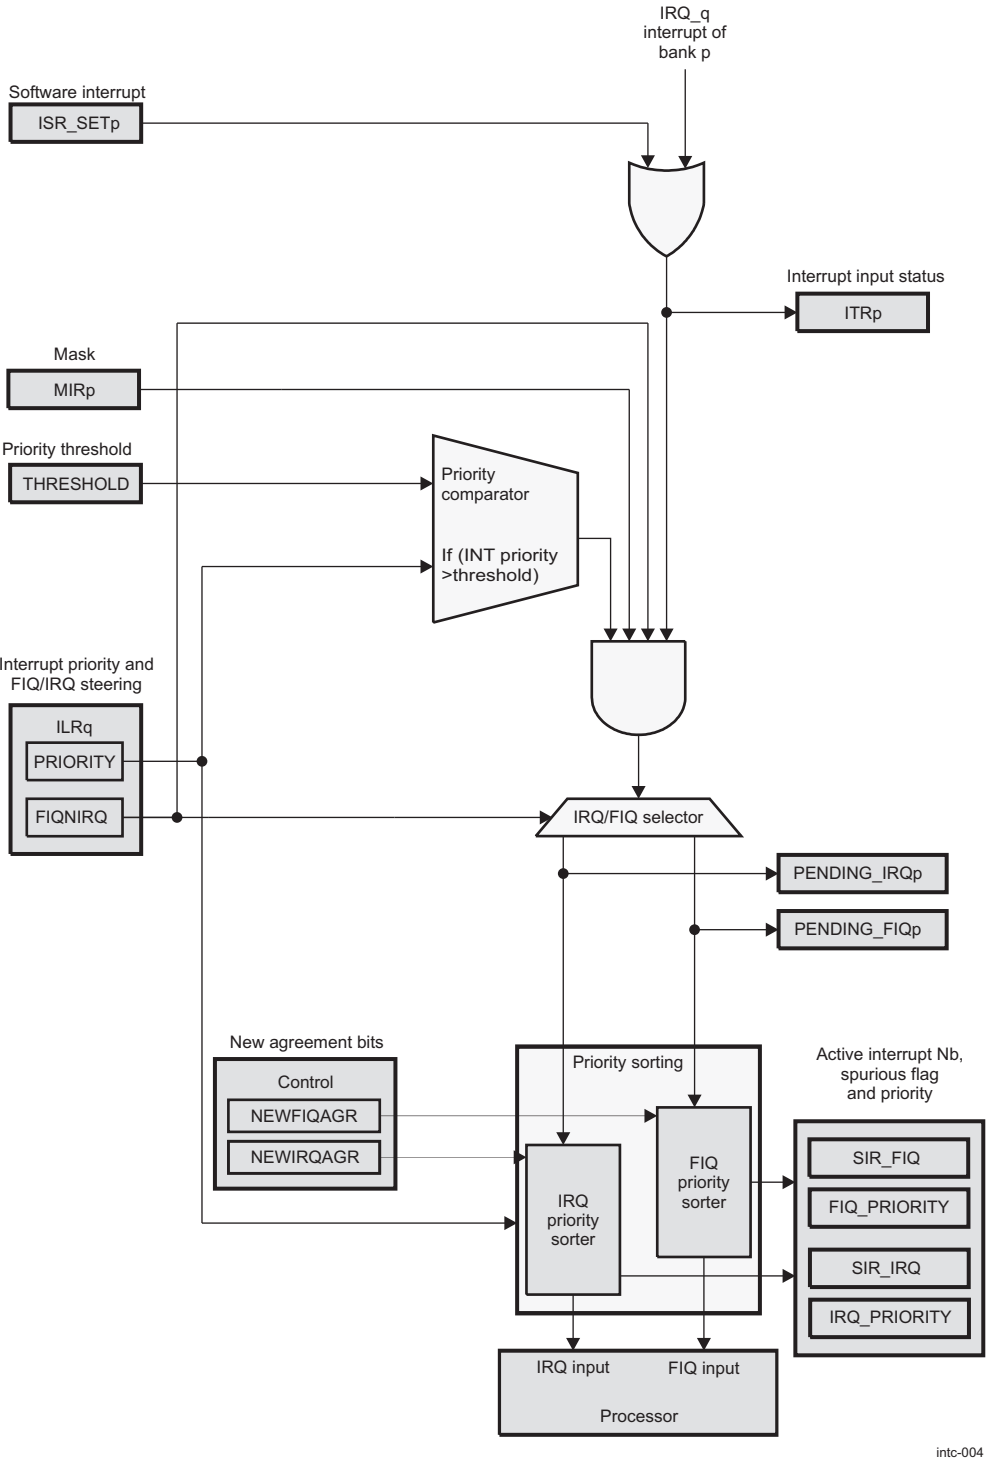
- Individual priority (up to 64 levels) for each interrupt input
- Ability for each interrupt to be steered to either FIQ or IRQ
- Independent priority sorting for FIQ and IRQ; FIQ sorting is processed concurrently with IRQ sorting.
- Priority masking: Interrupts can be masked based on the priority threshold register.
- Atomic bit set and clear capability for interrupt mask and software interrupt registers
- For high-security (HS) devices only:
  - Global interrupt mask
  - Protection for secure interrupts
- Power-management and wake-up support

- Auto-idle power-saving support

The INTCPS processes incoming interrupts by masking and priority sorting, then it generates the interrupt requests to the MPU.

Figure 8-4 shows the top-level view of the interrupt processing.

Figure 8-4. Top-Level Block Diagram



(1) Public Mask = SICR[3] PUBLICINHIBIT bit OR (SICR[2] AUTOINHIBIT bit AND SICR[0] SSMFIQSTATUS bit)

(2) The SCRn forces the interrupt priority to 0 (highest).

(3) The SCRn forces the interrupt to FIQ.

(4) The comparator output is TRUE only if the interrupt priority is higher than the threshold register priority. The highest priority is 0x0; the lowest priority is 0x3F (63).

8.4.1 Interrupt Processing

8.4.1.1 Input Selection

The INTCPS supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to de-assert the interrupt.

A software interrupt is generated if the corresponding bit in the MPU_INTC.INTCPS_ISR_SETn register is set (register bank number: n = [0,2] for the MPU subsystem INTCPS, 96 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU_INTC.INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

8.4.1.2 Masking

8.4.1.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU_INTC.INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTCPS can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit (m= [0,95]).

The current incoming interrupt status before masking is readable from the MPU_INTC.INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU_INTC.INTCPS_PENDING_IRQn and MPU_INTC.INTCPS_PENDING_FIQn registers.

8.4.1.2.2 Global Masking (HS Devices Only)

Software may use global masking for security purposes, but this feature must be used with care. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

8.4.1.2.3 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU_INTC.INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1.

PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x3F; 0x0 is the highest priority and 0x3F is the lowest priority.

When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTCPS.

8.4.1.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU_INTC.INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first.

When one or more unmasked incoming interrupts are detected, the INTCPS separates between IRQ and FIQ using the corresponding MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn

If no other interrupts are currently being processed, INTCPS asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel.

Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding MPU_INTC.INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set.

Once the interrupting peripheral device has been serviced and the incoming interrupt de-asserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTCPS the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTCPS restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is de-asserted.

8.4.2 Secure Interrupts (HS Devices Only)

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

8.4.3 Register Protection

If the MPU_INTC.INTCPS_PROTECTION[0] PROTECTION bit is set, access to the INTCPS registers is restricted to the supervisor mode. Access to the MPU_INTC.INTCPS_PROTECTION register is always restricted to privileged mode.

8.4.4 Module Power Saving

The INTCPS provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTCPS processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

To ensure optimal power consumption, INTC_INIT_REGISTER1[0] INIT1 and INTC_INIT_REGISTER2[1] INIT2 bits must be set to 1 during initialization.

8.4.5 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTCPS functional clock cycles (plus or minus one cycle) if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt.

These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. For information about power saving, see Section 8.4.4.

To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register is read.

8.5 Interrupt Basic Programming Model

8.5.1 Initialization Sequence

1. Program the MPU_INTC.INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU_INTC.INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU_INTC.INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNFIQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU_INTC.INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

NOTE: To program the MPU_INTC.INTCPS_MIRn register, the MPU_INTC.INTCPS_MIR_SETn and MPU_INTC.INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU_INTC.INTCPS_MIRn register.

8.5.2 MPU INTC Processing Sequence

After the MPU_INTC.INTCPS_MIRn and MPU_INTC.INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (MPU_INTC_IRQ/**FIQ**) are not currently asserted.
2. If the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit is set to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /**MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ** field with the current interrupt number.
4. During priority sorting, if the IRQ/**FIQ** is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows:

NOTE: The ARM host processor automatically performs the following actions in pseudo code.

```
LR = PC + 4                    /* return link                    */
SPSR = CPSR                    /* Save CPSR before execution     */
CPSR[5] = 0                    /* Execute in ARM state           */
CPSR[7] = 1                    /* Disable IRQ                    */
CPSR[8] = 1                    /* Disable Imprecise Data Aborts  */
CPSR[9] = CP15_reg1_EEbit      /* Endianness on exception entry  */
if interrupt == IRQ then
    CPSR[4:0] = 0b10010            /* Enter IRQ mode                 */
```

```
    if high vectors configured then
        PC = 0xFFFF0018
    else
        PC = 0x00000018              /* execute interrupt vector        */
else if interrupt == FIQ then
    CPSR[4:0] = 0b10001              /* Enter FIQ mode                  */
    CPSR[6] = 1                      /* Disable FIQ                     */
    if high vectors configured then
        PC = 0xFFFF001C
    else
        PC = 0x0000001C              /* execute interrupt vector        */
end if
```

5. The ISR saves the remaining context, identifies the interrupt source by reading the ACTIVEIRQ/**ACTIVEFIQ** field, and jumps to the relevant subroutine handler as follows:

> **CAUTION**
>
> The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
; INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044

; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F

_IRQ_ISR/_FIQ_ISR:

    ; Save the critical context
    STMFD SP!, {R0-R12, LR}             ; Save working registers and the Link register
    MRS R11, SPSR                   ; Save the SPSR into R11

    ; Get the number of the highest priority active IRQ/FIQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                  ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK   ; Apply the mask to get the active IRQ number

    ; Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]        ; PC base address points this instruction + 8
    NOP                             ; To index the table by the PC

    ; Table of handler start addresses
    .word IRQ0handler ;For IRQ0 of BANK0
    .word IRQ1handler
    .word IRQ2handler
```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and de-asserting the interrupt condition at the peripheral side.

```
; IRQ0 subroutine
IRQ0handler:

    ; Save working registers
    STMFD SP!, {R0-R1}

    ; Now read-modify-write the peripheral module status register
    ; to de-assert the M_IRQ_0 interrupt signal

    ; De-Assert the peripheral interrupt
    MOV R0, #0x7                    ; Mask for 3 flags
    LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
    STR R0, [R1]                    ; Clear the 3 flags
```

```
    ; Restore working registers
    LDMFD SP!, {R0-R1}

    ; Jump to the end part of the ISR
    B IRQ_ISR_end/FIQ_ISR_end
```

7. After the return of the subroutine, the ISR sets the NEWIRQAGR/**NEWFIQAGR** bit to enable the processing of subsequent pending IRQs/**FIQs** and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ/**FIQ** line is de-asserted before IRQ/**FIQ** enabling. After that, the INTC processes any other pending interrupts or de-asserts the MPU_INTC_IRQ/**MPU_INTC_FIQ** signal if there is no interrupt.

```
; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048

; NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02

IRQ_ISR_end/FIQ_ISR_end:

    ; Allow new IRQs/FIQs at INTC side
    ; The INTCPS_CONTROL register is a write only register so no need to write back others bits
    MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
    LDR R1, INTCPS_CONTROL_ADDR
    STR R0, [R1]                    ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQs

    ; Data Synchronization Barrier
    MOV R0, #0
    MCR P15, #0, R0, C7, C10, #4

    ; restore critical context
    MSR SPSR, R11                   ; Restore the SPSR from R11
    LDMFD SP!, {R0-R12, LR}         ; Restore working registers and Link register

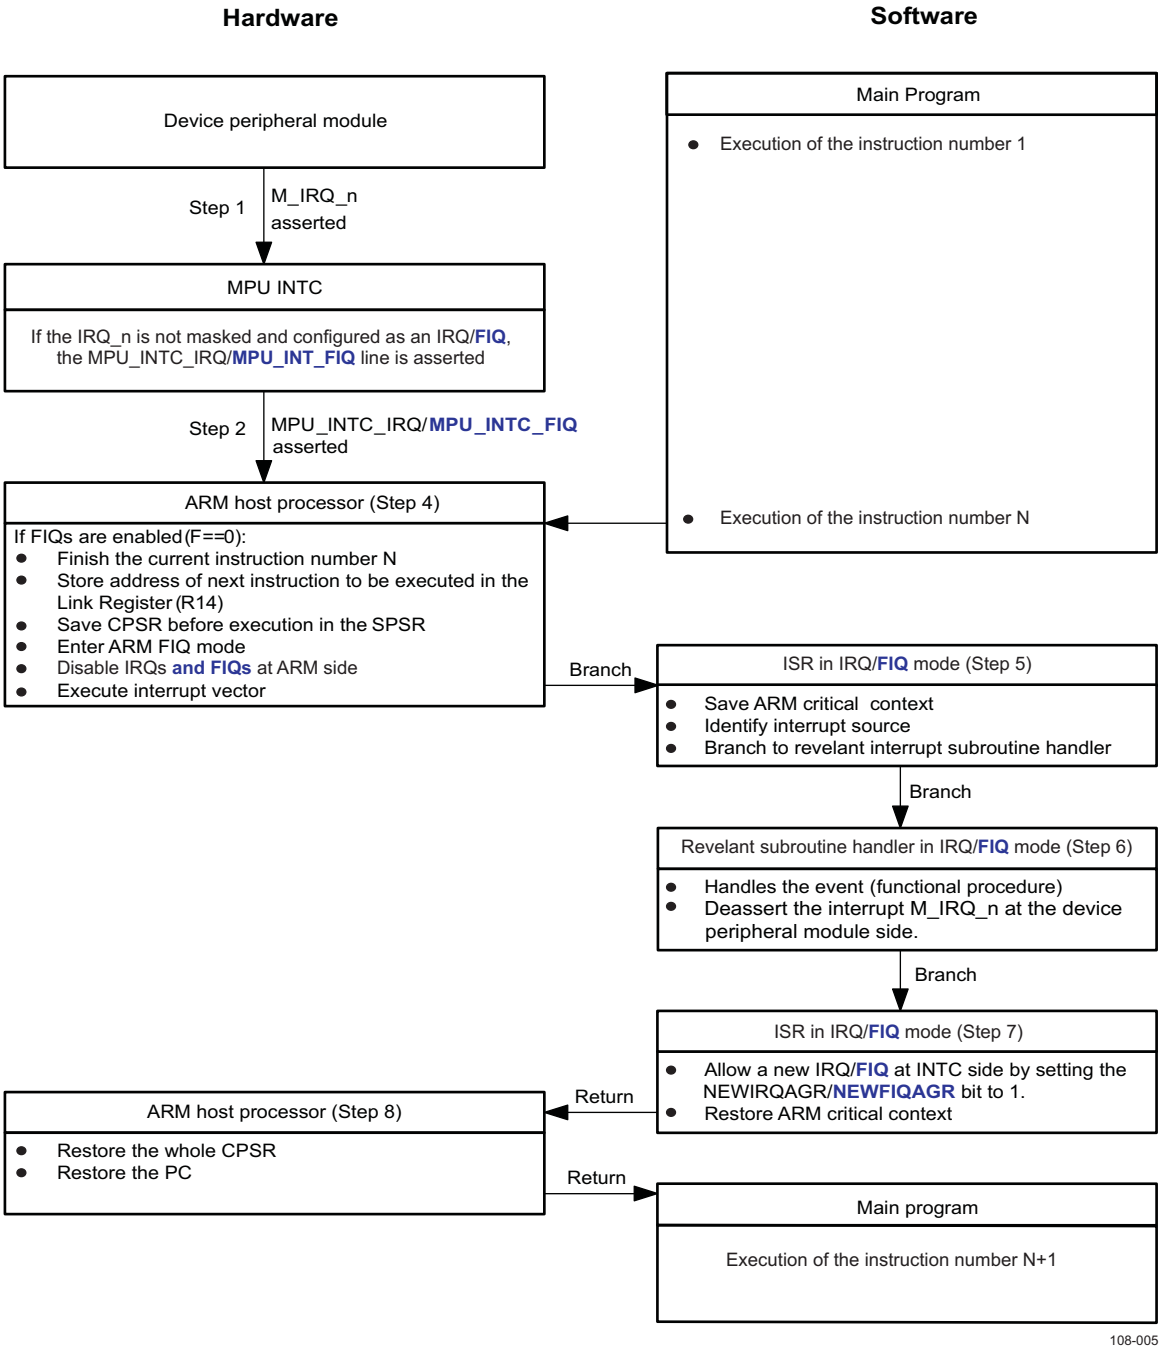
    ; Return after handling the interrupt
    SUBS PC, LR, #4
```

8. After the ISR return, the ARM automatically restores its context as follows:

```
CPSR = SPSR
PC = LR
```

Figure 8-5 shows the IRQ/**FIQ** processing sequence from the originating device peripheral module to the main program interruption.

Figure 8-5. IRQ/FIQ Processing Sequence



NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/**NEWFIQAGR** bit is set (priority sorting is reactivated).

8.5.3 MPU INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately.

Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

To enable IRQ/**FIQ** preemption by higher priority IRQs/**FIQs**, programers can follow this procedure to write the ISR:

At the beginning of an IRQ/**FIQ** ISR:

1. Save the ARM critical context registers.
2. Save the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the MPU_INTC.INTCPS_IRQ_PRIORITY IRQPRIORITY / **MPU_INTC.INTCPS_FIQ_PRIORITY FIQPRIORITY** field and write it to the PRIORITYTHRESHOLD(1) field.
4. Read the active interrupt number in the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ / **MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ** field to identify the interrupt source.
5. Write 1 to the appropriate MPU_INTC.INTCPS_CONTROL NEWIRQAGR **and** (2) **NEWFIQAGR** bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/**FIQ** enabling.
7. Enable IRQ/**FIQ** at ARM side.
8. Jump to the relevant subroutine handler.

The sample code below shows the previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
;  bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x3F

_IRQ_ISR:
    ; Step 1 : Save the critical context
    STMFD SP!, {R0-R12, LR}            ; Save working registers
    MRS R11, SPSR                      ; Save the SPSR into R11

    ; Step 2 : Save the INTCPS_THRESHOLD register into R12
    LDR R0, INTCPS_THRESHOLD_ADDR
    LDR R12, [R0]
```

(1) The priority-threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to 0x3F while reading it from the IRQPRIORITY and FIQPRIORITY fields. Writing a value of 0xFF (reset default) disables the priority-threshold mechanism. Values between 0x3F and 0xFF must not be used.
When the hardware-priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked; otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.

(2) When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally processed when the priority threshold falls to a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (providing all FIQ priorities are higher than all IRQ priorities).

```
    ; Step 3 : Get the priority of the highest priority active IRQ
    LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
    LDR R1, [R1]                        ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
    AND R1, R1, #ACTIVEPRIO_MASK        ; Apply the mask to get the priority of the IRQ
    STR R1, [R0]                        ; Write it to the INTCPS_THRESHOLD register

    ; Step 4 : Get the number of the highest priority active IRQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                      ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK       ; Apply the mask to get the active IRQ number

    ; Step 5 : Allow new IRQs and FIQs at INTC side
    MOV R0, #0x1/0x3                    ; Get the NEWIRQAGR and NEWFIQAGR bit position
    LDR R1, INTCPS_CONTROL_ADDR
    STR R0, [R1]                        ; Write the NEWIRQAGR and NEWFIQAGR bit

    ; Step 6 : Data Synchronization Barrier
    MOV R0, #0
    MCR P15, #0, R0, C7, C10, #4

    ; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
    MRS R0, CPSR                        ; Read the status register
    BIC R0, R0, #0x80/0x40              ; Clear the I/F bit
    MSR CPSR, R0                        ; Write it back to enable IRQs

    ; Step 8 : Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]           ; PC base address points this instruction + 8
    NOP                                 ; To index the table by the PC

    ; Table of handler start addresses
    .word IRQ0handler ;IRQ0 BANK0
    .word IRQ1handler
    .word IRQ2handler
```

After the return of the relevant IRQ/**FIQ** subroutine handle :

1. Disable IRQs/**FIQs** at ARM side.
2. Restore the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The sample code below shows the three previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
IRQ_ISR_end:

    ; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
    MRS R0, CPSR                        ; Read the CPSR
    ORR R0, R0, #0x80/0x40              ; Set the I/F bit
    MSR CPSR, R0                        ; Write it back to disable IRQs

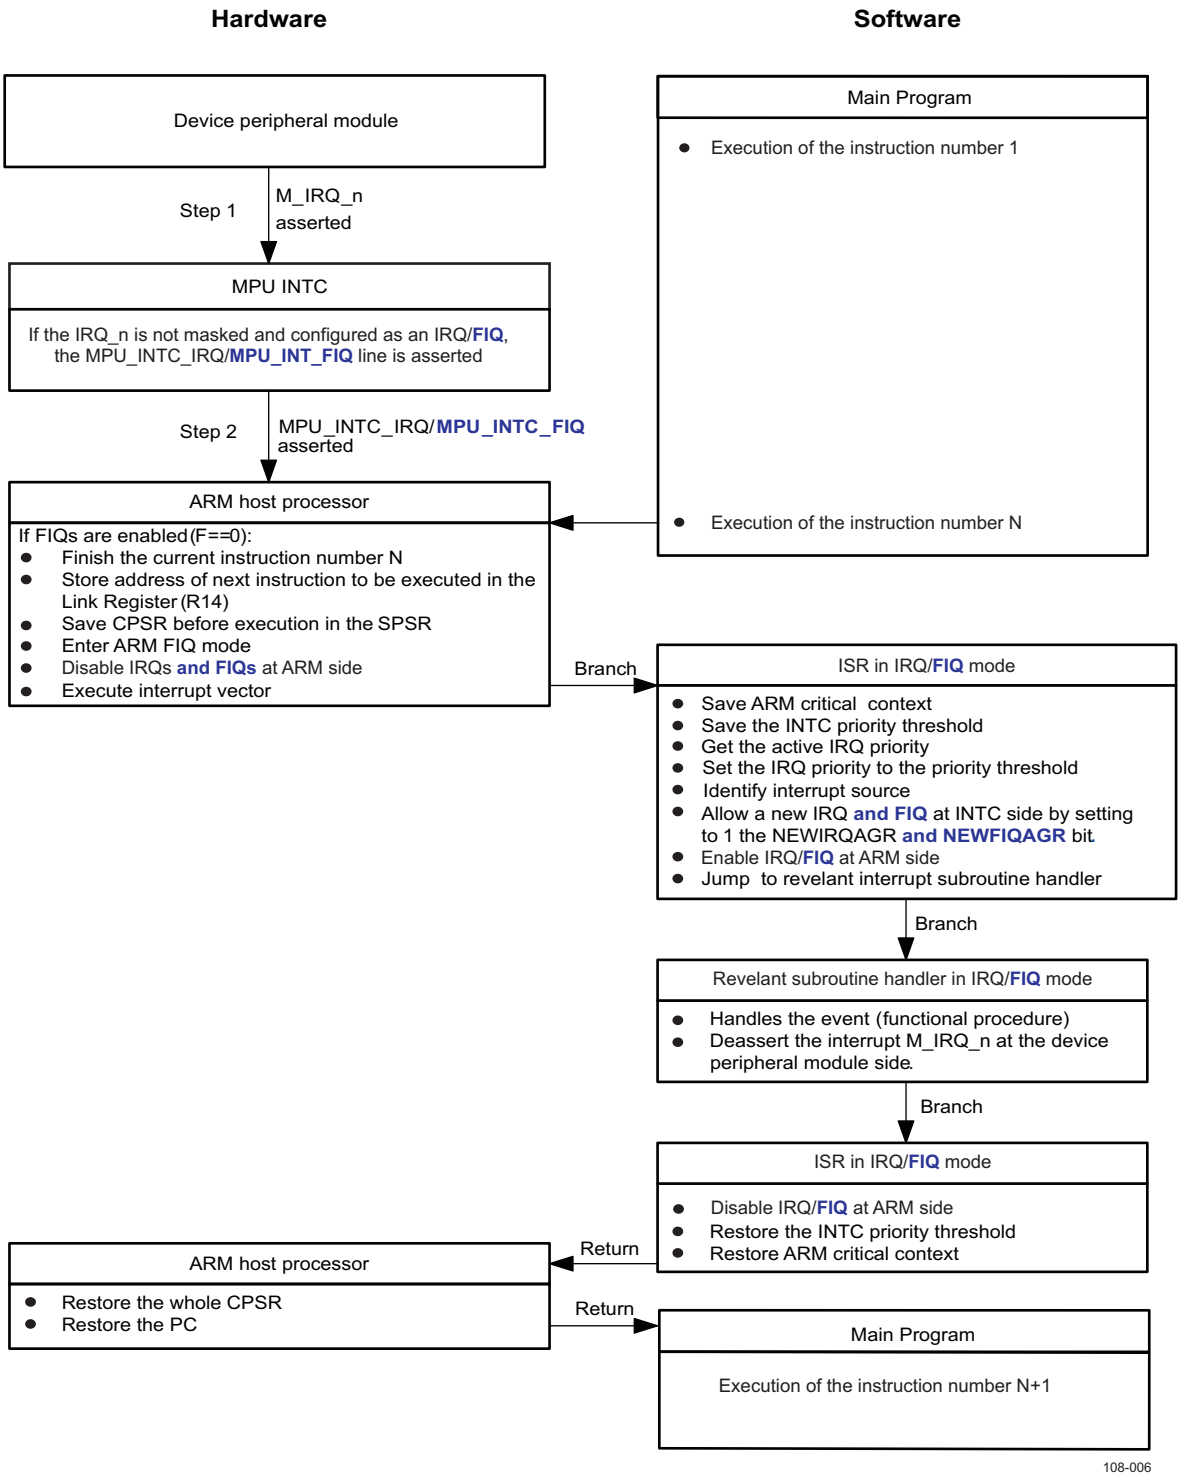
    ; Step 2 : Restore the INTCPS_THRESHOLD register from R12
    LDR R0, INTCPS_THRESHOLD_ADDR
    STR R12, [R0]

    ; Step 3 : Restore critical context
    MSR SPSR, R11                       ; Restore the SPSR from R11
    LDMFD SP!, {R0-R12, LR}             ; Restore working registers and Link register
```

```
; Return after handling the interrupt
SUBS PC, LR, #4
```

Figure 8-6 shows the nested IRQ/**FIQ** processing sequence from the originating device peripheral module to the main program interruption.

Figure 8-6. Nested IRQ/FIQ Sequence



NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

8.5.4 MPU INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the MPU_INTC.INTCPS_MIRn, MPU_INTC.INTCPS_ILRm, or MPU_INTC.INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. If these registers are changed within the 10-cycle window after the interrupt assertion, only the active interrupt input that triggered the sort can be masked before its turn in the sort. The resulting values of the following registers become invalid:

- MPU_INTC.INTCPS_SIR_IRQ
- MPU_INTC.INTCPS_SIR_FIQ
- MPU_INTC.INTCPS_IRQ_PRIORITY
- MPU_INTC. INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see Note 1) and SPURIOUSFIQFLAG (see Note 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The MPU_INTC.INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG field is a copy of the MPU_INTC.INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG field.
2. The MPU_INTC.INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG field is a copy of the MPU_INTC.INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG field.

8.6 Interrupt Controller Registers

Table 8-5 lists the base address and address space for the INTC.

Table 8-5. INTC Instance Summary

Module Name	Base Address	Size
MPU INTC	0x4820 0000	4K bytes

8.6.1 Register Mapping Summary

CAUTION

MPU INTC registers are limited to 32-bit and 16-bit data accesses. 8-bit is not allowed and can corrupt register content.

In Section 8.6.2, each register from MPU_INTC.INTCPS_ITRn to MPU_INTC.INTCPS_PENDING_FIQn contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the MPU_INTC.INTCPS_ITR0 register applies to interrupt line 0; bit 0 of the MPU_INTC.INTCPS_ITR1 register applies to interrupt line 32).

8.6.2 MPU INTC Register Descriptions

Table 8-8 through Table 8-26 describe the MPU INTC registers.

8.6.2.1 INTCPS_SYSCONFIG

Table 8-8. INTCPS_SYSCONFIG

Address Offset	0x010		
Physical Address	0x4820 0010	**Instance**	MPU INTC
Description	This register controls various parameters of the module interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																														SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility. Read returns reset value.	R	0x00000000
1	SOFTRESET	Software reset. Set this bit to trigger a module reset. The bit is automatically reset by the hardware. Read returns 0. Write 0x0: No functional effect Write 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface clock gating strategy is applied, based on the interface bus activity.	RW	0

8.6.2.2 INTCPS_SYSSTATUS

Table 8-9. INTCPS_SYSSTATUS

Address Offset	0x014		
Physical Address	0x4820 0014	**Instance**	MPU INTC
Description	This register provides status information about the module.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															RESETDONE

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Read returns reset value.	R	0x00000000
0	RESETDONE	Internal reset monitoring Read 0x0: Internal module reset is ongoing. Read 0x1: Reset complete	R	-

8.6.2.3 INTCPS_SIR_IRQ

Table 8-10. INTCPS_SIR_IRQ

Address Offset	0x040		
Physical Address	0x4820 0040	**Instance**	MPU INTC
Description	This register supplies the currently active IRQ interrupt number.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPURIOUSIRQFLAG																								ACTIVEIRQ							

Bits	Field Name	Description	Type	Reset
31:7	SPURIOUSIRQFLAG	Spurious IRQ flag	R	0x1FFFFFF
6:0	ACTIVEIRQ	Active IRQ number	R	0x00

8.6.2.4 INTCPS_SIR_FIQ

Table 8-11. INTCPS_SIR_FIQ

Address Offset	0x044		
Physical Address	0x4820 0044	**Instance**	MPU INTC
Description	This register supplies the currently active FIQ interrupt number.		
Type	R		

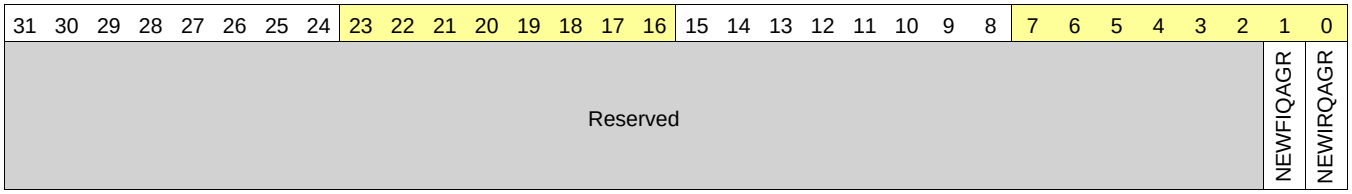
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPURIOUSFIQFLAG																								ACTIVEFIQ							

Bits	Field Name	Description	Type	Reset
31:7	SPURIOUSFIQFLAG	Spurious FIQ flag	R	0x1FFFFFF
6:0	ACTIVEFIQ	Active FIQ number	R	0x00

8.6.2.5 INTCPS_CONTROL

Table 8-12. INTCPS_CONTROL

Address Offset	0x048		
Physical Address	0x4820 0048	**Instance**	MPU INTC
Description	This register contains the new interrupt agreement bits.		
Type	RW		

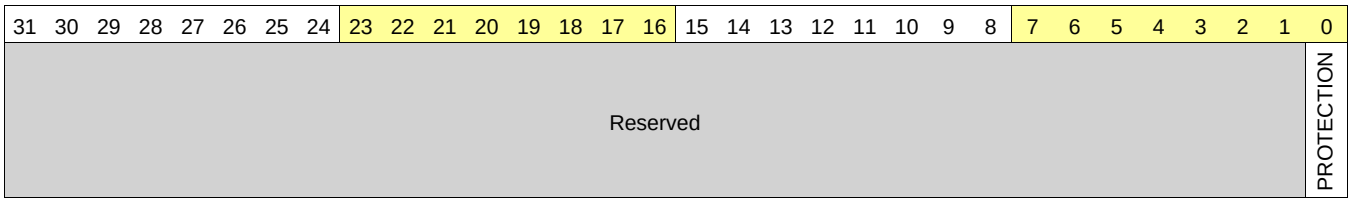


Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility. Read returns reset value.	R	0x00000000
1	NEWFIQAGR	Reset FIQ output and enable new FIQ generation.	W	-
		Write 0x0: No functional effect		
		Write 0x1: Reset FIQ output and enable new FIQ generation.		
0	NEWIRQAGR	New IRQ generation	W	-
		Write 0x0: No functional effect		
		Write 0x1: Reset IRQ output and enable new IRQ generation.		

8.6.2.6 INTCPS_PROTECTION

Table 8-13. INTCPS_PROTECTION

Address Offset	0x04C		
Physical Address	0x4820 004C	**Instance**	MPU INTC
Description	This register controls protection of the other registers. It can be accessed only in supervisor mode, regardless of the current value of the protection bit.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:1	Reserved	Write 0s for future compatibility. Read returns reset value.	R	0x00000000
0	PROTECTION	Protection mode	RW	0
		0x0: Protection mode is disabled (default).		
		0x1: Protection mode is enabled. When enabled, all the MPU INTC registers are accessible only in privileged mode.		

8.6.2.7 INTCPS_IDLE

Table 8-14. INTCPS_IDLE

Address Offset	0x050		
Physical Address	0x4820 0050	**Instance**	MPU INTC
Description	This register controls the functional clock auto-idle and the synchronizer clock auto-gating.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																														TURBO	FUNCIDLE

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility. Read returns reset value.	R	0x00000000
1	TURBO	Input synchronizer clock auto-gating	RW	0
		0x0: Input synchronizer clock is free-running (default).		
		0x1: Input synchronizer clock is auto-gated based on interrupt input activity.		
0	FUNCIDLE	Functional clock idle mode	RW	0
		0x0: Functional clock gating strategy is applied (default).		
		0x1: Functional clock is free-running.		

8.6.2.8 INTCPS_IRQ_PRIORITY

Table 8-15. INTCPS_IRQ_PRIORITY

Address Offset	0x060		
Physical Address	0x4820 0060	**Instance**	MPU INTC
Description	This register supplies the currently active IRQ priority level.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	Reserved	For optimal power consumption keep default value of 0 for this bit.	R	0

Memory Subsystem

This chapter describes the memory subsystem.

Topic **Page**

9.1 General-Purpose Memory Controller (GPMC)

9.1.1 General-Purpose Memory Controller Overview

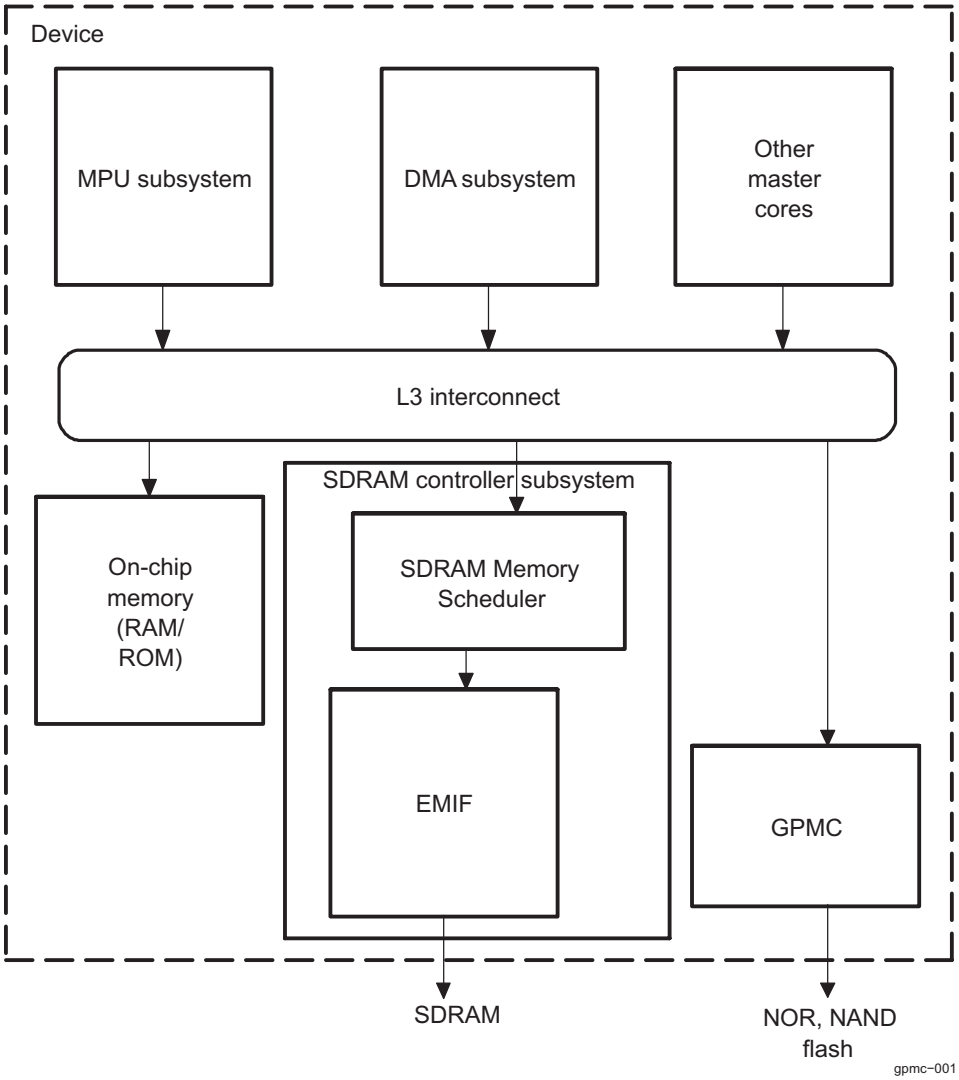
The general-purpose memory controller (GPMC) is dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

NOTE: Page mode is only available in non-muxed mode. The non-muxed mode is described in this chapter even though its use is very limited (address space limited to 2 KBytes).

Figure 9-1 shows the environment of the GPMC.

Figure 9-1. GPMC Environment



9.1.1.1 GPMC Features

The GPMC is a 16-bit external memory controller. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 Kbytes)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo SRAM (pSRAM) device

The GPMC supports up to eight chip-select regions of programmable size, and programmable base addresses in a total address space of 1 Gbyte.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

9.1.2 GPMC Environment

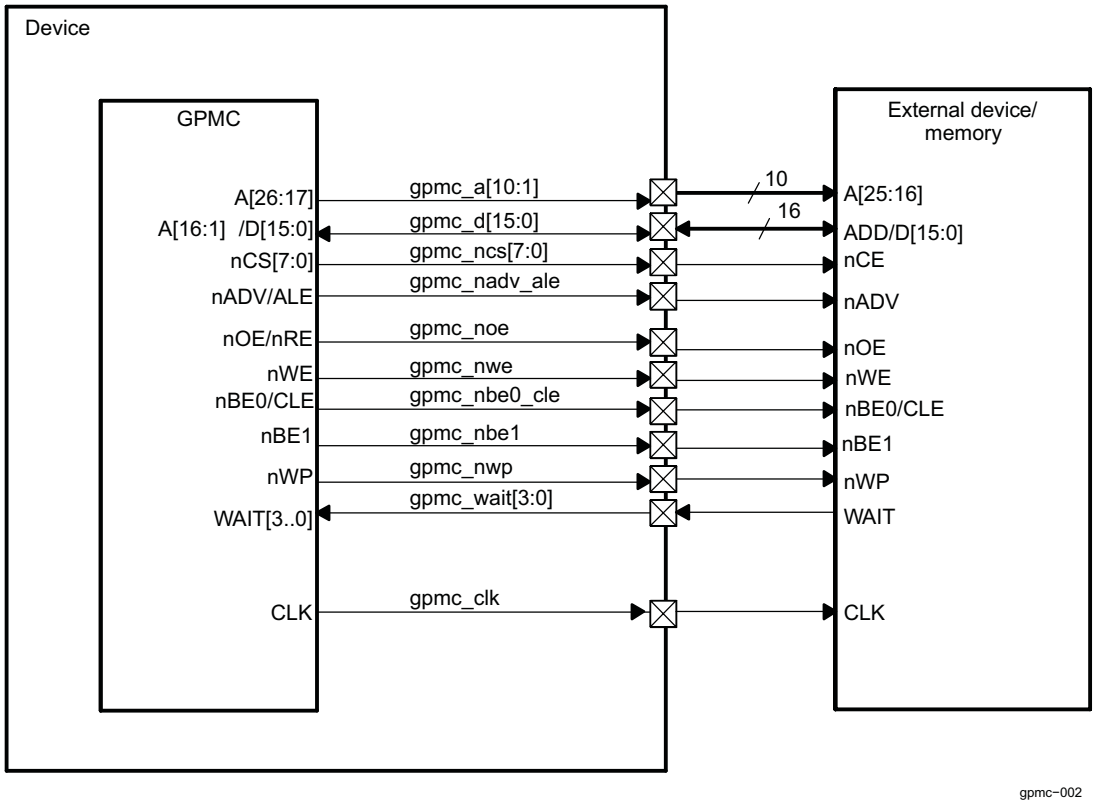
Figure 9-2 and Figure 9-3 show two GPMC external connection options:

- GPMC to 16-bit address/data-multiplexed memory

  Figure 9-2 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed external memory device.
- GPMC to 16-bit NAND device

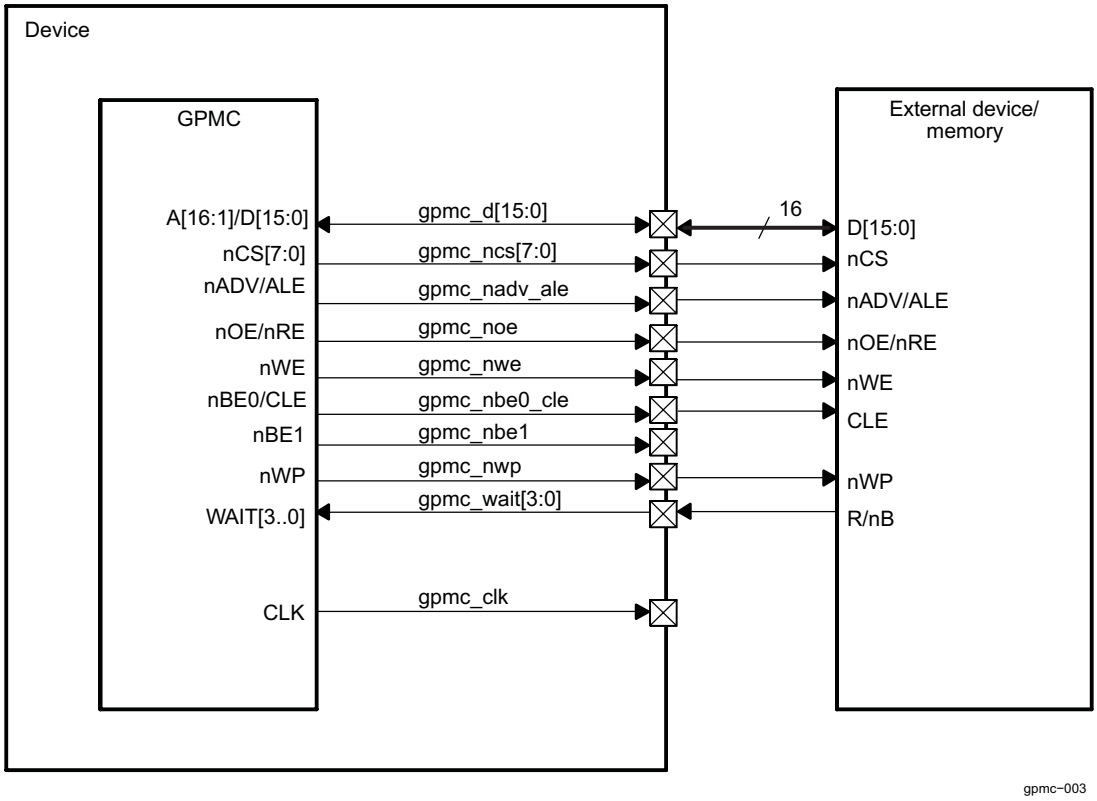
  Figure 9-3 shows a connection between the GPMC and a 16-bit NAND device.

Figure 9-2. GPMC to 16-Bit Address/Data-Multiplexed Memory



NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_d[7:0] data bus (rather than D[15:8] / gpmc_d[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 9-3. GPMC to 16-Bit NAND Device



NOTE: An 8-bit NAND must be connected to the D[7:0] data bus of the GPMC.

Table 9-1 lists the GPMC subsystem I/O pins.

Table 9-1. GPMC I/O Description

Pin Name	I/O	Description
gpmc_a[10:1]	O	Address
gpmc_d[15:0]	I/O	Data
gpmc_ncs[7:0]	O	Chip-selects (active low)
gpmc_clk	I/O	Clock(1)
gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
gpmc_nwe	O	Write enable (active low)
gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
gpmc_nbe1	O	Byte 1 enable (active low)
gpmc_nwp	O	Write protect (active low)
gpmc_wait[3:0]	I	External wait signal for NOR and NAND protocol memories
gpmc_io_dir	O	gpmc_d[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC)

(1) This output signal is also used as re-timing input.

Table 9-2 shows the use of address and data GPMC controller pins based on the type of external device.

Table 9-2. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED-ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[10]	A26	A10	Not used	Not used
gpmc_a[9]	A25	A9	Not used	Not used
gpmc_a[8]	A24	A8	Not used	Not used
gpmc_a[7]	A23	A7	Not used	Not used
gpmc_a[6]	A22	A6	Not used	Not used
gpmc_a[5]	A21	A5	Not used	Not used
gpmc_a[4]	A20	A4	Not used	Not used
gpmc_a[3]	A19	A3	Not used	Not used
gpmc_a[2]	A18	A2	Not used	Not used
gpmc_a[1]	A17	A1	Not used	Not used
gpmc_d[15]	A16/D15	D15	D15	Not used
gpmc_d[14]	A15/D14	D14	D14	Not used
gpmc_d[13]	A14/D13	D13	D13	Not used
gpmc_d[12]	A13/D12	D12	D12	Not used
gpmc_d[11]	A12/D11	D11	D11	Not used
gpmc_d[10]	A11/D10	D10	D10	Not used
gpmc_d[9]	A10/D9	D9	D9	Not used
gpmc_d[8]	A9/D8	D8	D8	Not used
gpmc_d[7]	A8/D7	D7	D7	D7
gpmc_d[6]	A7/D6	D6	D6	D6
gpmc_d[5]	A6/D5	D5	D5	D5
gpmc_d[4}	A5/D4	D4	D4	D4
gpmc_d[3]	A4/D3	D3	D3	D3
gpmc_d[2]	A3/D2	D2	D2	D2
gpmc_d[1]	A2/D1	D1	D1	D1
gpmc_d[0]	A1/D0	D0	D0	D0

Enabling the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only devices with 2 Kbytes of addressing space can be accessed using gpmc_a[10:1].

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

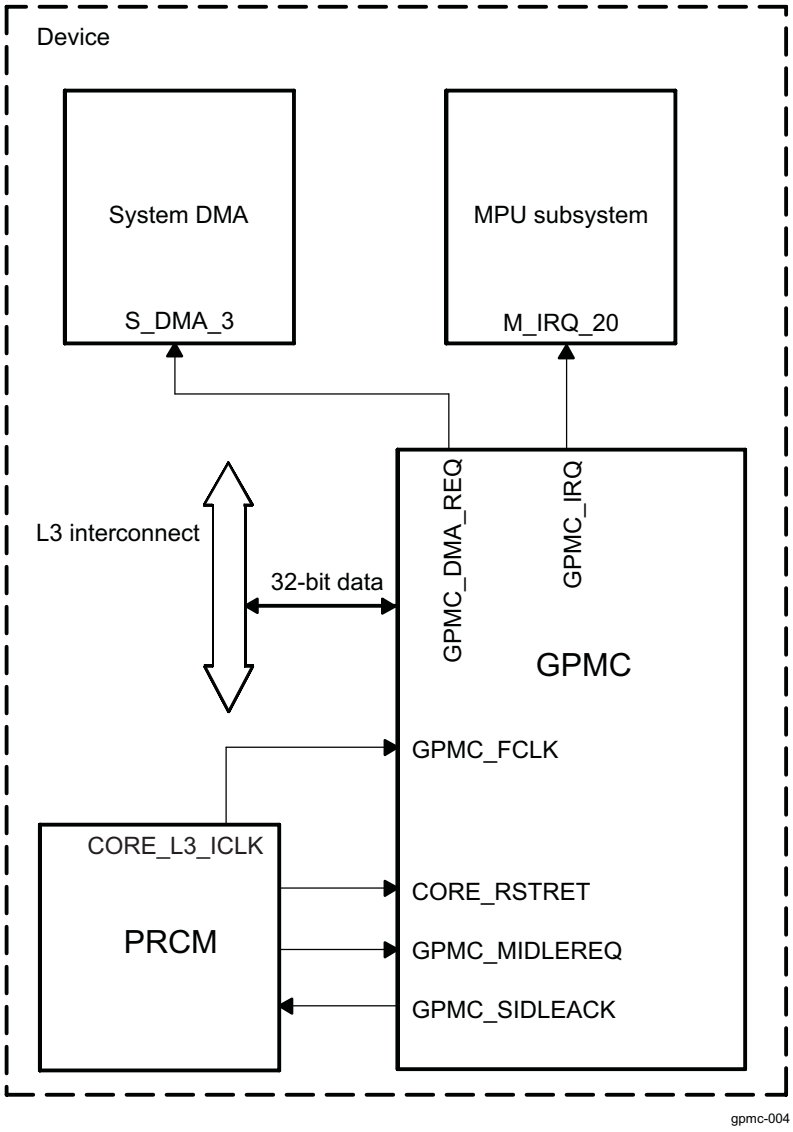
- To minimize the number of IC pins required for the external memory connection, the NOR flash memory controller supports multiplexed address and data memory devices without adding logic externally.
- Multiplexing mode can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

9.1.3 GPMC Integration

9.1.3.1 Description

Figure 9-4 shows how the GPMC interacts with other modules in the processor.

Figure 9-4. GPMC Integration in the Processor



9.1.3.2 Clocking, Reset, and Power Management Scheme

9.1.3.2.1 Clocking

The GPMC use a single clock, GPMC_FCLK, which comes internally from the power, reset, and clock-management (PRCM) module and runs at the L3 interconnect frequency. Its source is the PRCM module, CORE_L3_ICLK output. CORE_L3_ICLK belongs to the L3 interconnect clock domain.

For details, see the *Power, Reset, and Clock Management* chapter.

GPMC_CLK is the external clock provided to the attached synchronous memory or device. The GPMC_CLK clock frequency is the GPMC_FCLK clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where I = 0 to 7).

NOTE: When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

9.1.3.2.2 Hardware Reset

A global reset of the GPMC occurs through activation of the CORE_RSTRET signal (CORE power domain) controlled by the Power, Reset and Clock Management module (see the *Power, Reset, and Clock Management* chapter).
The CORE_RSTRET signal is activated during IC global power-on and global warm reset, and it resets the controller state machine and configuration registers.

9.1.3.2.3 Software Reset

GPMC modules can be reset under software control through the GPMC.GPMC_SYSCONFIG[1] SOFTRESET bit. When software reset bit is set, all registers and the finite state-machine (FSM) are reset immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit can be polled to check reset status.

9.1.3.2.4 Power Domain, Power Saving, and Reset Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

The GPMC reduces power consumption through auto-idle mode and the idle request/acknowledge process, both of which are configurable:

- Dynamic auto-idle (configurable through the GPMC.GPMC_SYSCONFIG[0] AUTOIDLE bit): To reduce power consumption, the GPMC internally disables the functional clock when no requests are pending and no accesses are ongoing.
- Idle request/acknowledge (one of three idle modes configurable through the GPMC.GPMC_SYSCONFIG[4:3] IDLEMODE field):
  - Force-idle: Immediately on receiving an idle request from the PRCM module, the GPMC sends an idle request/acknowledge to let the PRCM module correctly cut the GPMC source clock.
  - No-idle: The GPMC never goes to idle mode.
  - Smart-idle (strongly recommended): The GPMC goes to idle mode when all ongoing transactions are complete.

For detailed information about power management, see the *Power, Reset, and Clock Management* chapter.

9.1.3.2.5 Hardware Requests

The GPMC uses two hardware requests as shown in Figure 9-4 :

- One interrupt request goes from GPMC (GPMC_IRQ) to the microprocessor unit (MPU) subsystem : M_IRQ_20.
- One DMA request goes from GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

9.1.3.3 GPMC Address and Data Bus

The current application supports GPMC connection to address/data-multiplexed memory and a NAND device. Connection to a nonmultiplexed address/data memory is supported with an address range of only 2 Kbytes.

Depending on the GPMC configuration on each chip-select, address and data-bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

The current application supports GPMC connection to address/data-multiplexed memory, address/data-nonmultiplexed memory with limited address (2 Kbytes), and a NAND device:

- When the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, only gpmc_a[10:1] address lines are used. This limits the memory support to 2K-byte addressable memories.
- For address/data-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_d[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1] and GPMC I/O: gpmc_d[15:8].

CAUTION

Before trying to access a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

9.1.3.3.1 GPMC I/O Configuration Setting (In Default Pinout Mode 0)

NOTE: In this section, the I in GPMC_CONFIG1_i stands for the GPMC chip-select I where I = 0 to 7.

The address/data-nonmultiplexed device, which is limited to a 2K-byte address range, is selected by programming the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0x00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0
- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit = 1

NOTE: The LIMITEDADDRESS field applies only to address/data-nonmultiplexed devices; it has no effect on other device types (address/data-multiplexed, NAND).

To select the address/data-multiplexed device, program the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 1

To select the NAND device, program the following register field:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b10
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0

9.1.3.3.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Three additional pins are used to configure reset values in the GPMC.GPMC_CONFIG1_i register (where I = 0):
  - The bootwaiten input pin (GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where I = 0). Its value comes from the BOOT_WAIT_ENABLE signal generated by the system control module (SCM). When sys_boot[5:0] = 0b111111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read access.
  - The bootdevicesize input pin (GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE bits (where I = 0). A BOOT_DEVICE_SIZE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing a 16-bit wide external memory to be used.
  - The cs0muxdevice input pin (GPMC boundary) selects whether the attached device to chip-select 0 is a multiplexed address and data device or not. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (where I = 0). A CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing the attached device to be address/data-multiplexed.
  - The waitselectpin input pin selects the WAIT signal at IC reset release time between WAIT0 input pin or WAIT1 input pin. At IC reset release time, these two pins have different polarity.

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbyte address range device attached to CS0

At reset time, the IC may boot from the internal ROM or from the memory attached to the GPMC chip-select 0. This selection is made outside the GPMC.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

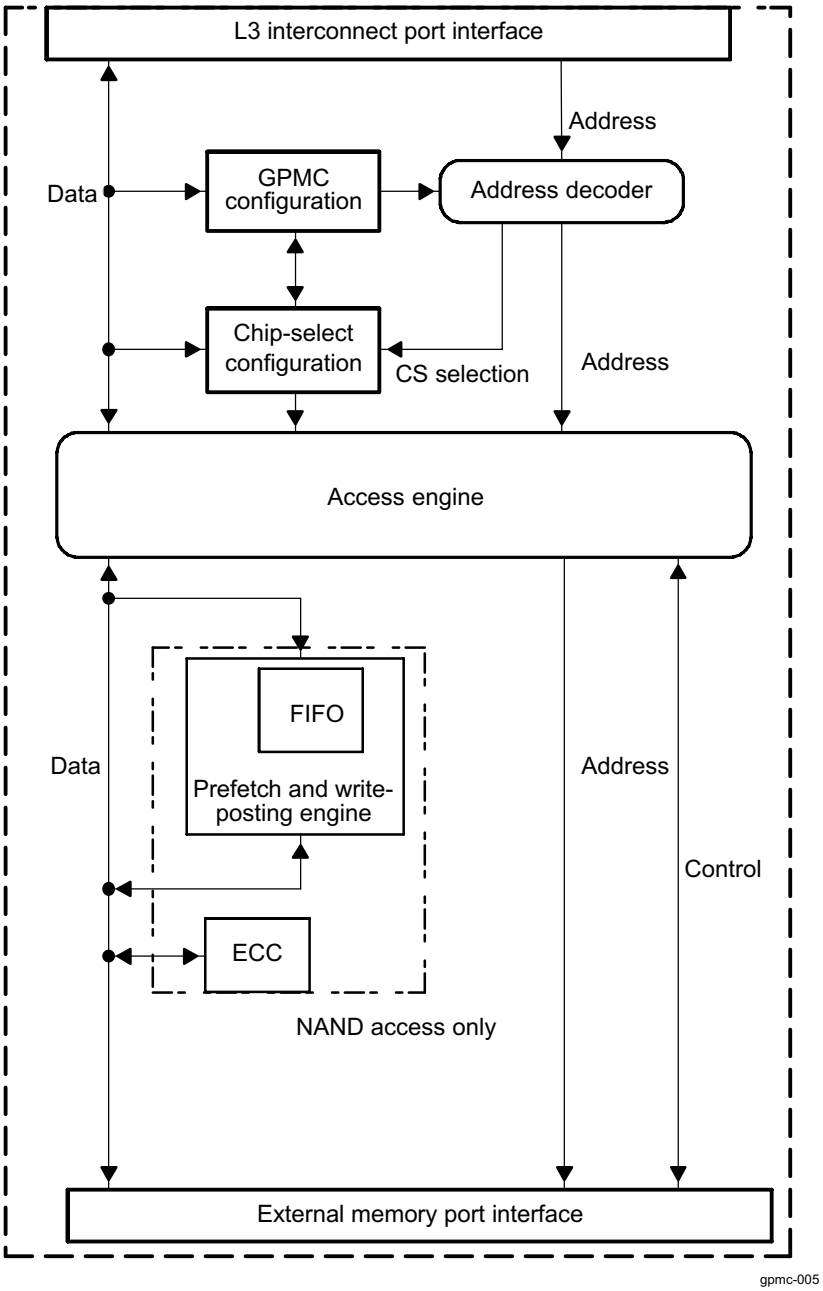
9.1.4 GPMC Functional Description

9.1.4.1 Description

As Figure 9-5 shows, the GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 9-5. GPMC Functional Diagram



The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

9.1.4.2 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 8 × 32-bit word write buffer.

Any device system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, or 8 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field (GPMC_CONFIG1_i[24:23]) according to the effective attached device page length and to enable WRAPBURST bit (GPMC_CONFIG1_i[31]) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

9.1.4.3 Address Decoder, GPMC Configuration, and Chip-Select Configuration Register File

Address-decoding logic selects for chip-selects according to the address request and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 9.1.7 of this chapter provides the GPMC register locations. For the map of GPMC memory locations, see the *Memory Mapping* chapter.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

9.1.4.4 Error Correction Code Engine (ECC)

The GPMC includes an ECC calculation engine that allows ECC calculation during data read or data program (write) operations.Two ECC algorithms are available depending on GPMC_ECC_CONFIG[16] ECCALGORITHM settings: Hamming code or BCH code (Bose-ChaudhurI-Hocquenghem).

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or Word16s read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC.GPMC_ECC_CONFIG[3:1] ECCCS bit field.

Refer to Section 9.1.5.14.3, for more information on ECC Calculation.

9.1.4.5 Prefetch and Write-Posting Engine

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

For more information about prefetch and write-posting engine programming, see Section 9.1.5.14.4, *Prefetch and Write-Posting Engine*.

9.1.4.6 External Device/Memory Port Interface

The external port interface controls all address, data, and control signals required for communication with GPMC-supported devices and memories.

9.1.5 GPMC Basic Programming Model

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, Word16, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single-synchronous or asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

9.1.5.1 Chip-Select Base Address and Region Size Configuration

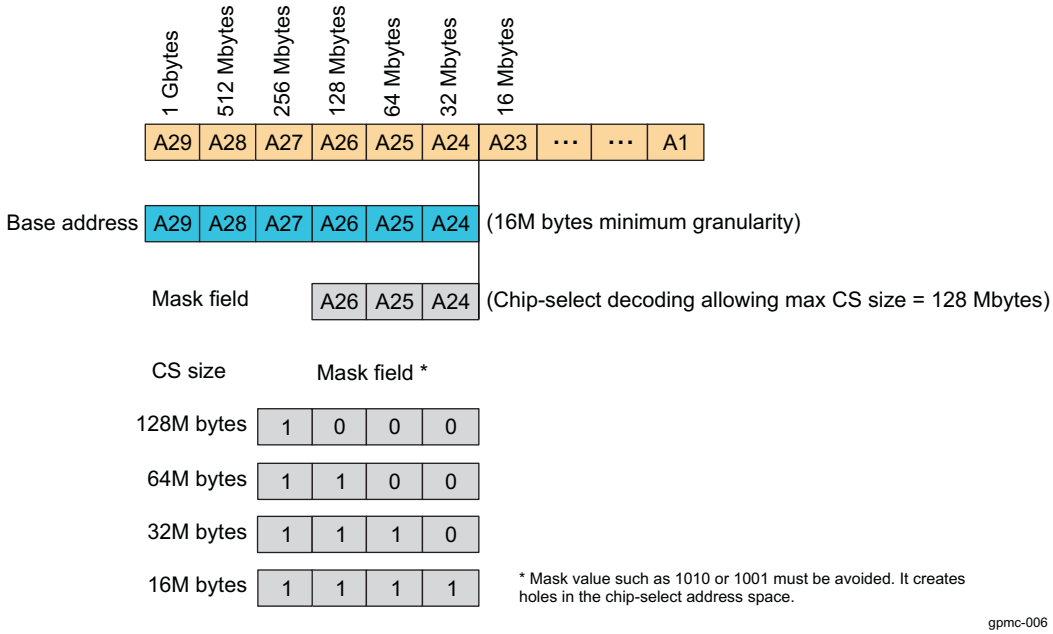
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see the *Memory Mapping* chapter.

The GPMC 1 Gbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 MBytes to 256 MBytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in Figure 9-6 (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 9-6. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC.GPMC_CONFIG7_i[6] CSVALID bit (where I stands for the GPMC chip-select value, I = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Conversely, before trying to access a chip-select, software must ensure that the chip-select is enabled. To account for prefetch engine effects, after the chip-select-enable instruction, an NOP instruction (equivalent to 64 bits) must be executed before the chip-select is accessed.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines at the value specified in your device-specific data manual. To have access to the device-specific data manual, please contact your TI representative.

9.1.5.2 Access Protocol Configuration

9.1.5.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where I =0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: NAND flash interfacing requires the parameter settings of generic chip-select 0. For more information about the NAND flash GPMC basic programming model and NAND support, see Section 9.1.5.14, *NAND Device Basic Programming Model*, and Section 9.1.5.14.1, *NAND Memory Device in Byte or Word 16 Stream Mode*.

9.1.5.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE field (I = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The processor does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

9.1.5.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 9.1.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See Section 9.1.5.14, *NAND Device Basic Programming Model*.

9.1.5.2.4 Address and Data Bus

See Section 9.1.3.3, *GPMC Address and Data Bus*.

9.1.5.2.5 Asynchronous and Synchronous Access

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC.GPMC_CONFIG1_i[29] READTYPE bit (I = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC.GPMC_CONFIG1_i[27] WRITETYPE bit (I = 0 to 7).

Asynchronous and synchronous read (write) access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

9.1.5.2.6 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC.GPMC_CONFIG1_i[28] WRITMULTIPLE bits (I = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are don't care).
- Not applicable to NAND device interfacing.

9.1.5.2.7 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, Word16, Word32 requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC.GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field (I = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple burst beats. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC.GPMC_CONFIG1_i[31] WRAPBURST bit (I = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPCM behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC.GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

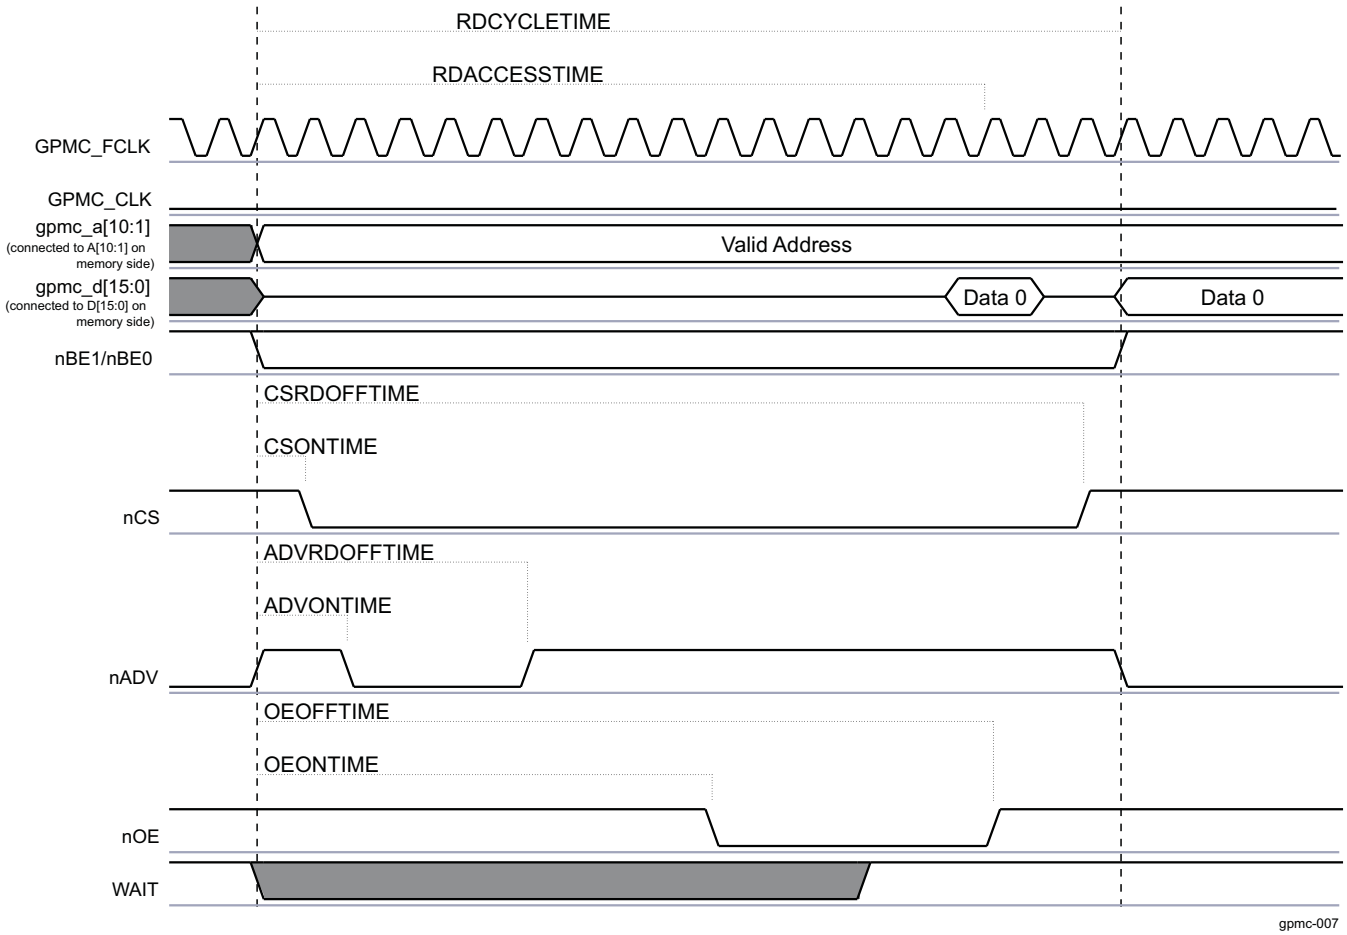
The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst beat.

NOTE: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

9.1.5.3 Timing Setting

The GPMC is a signal generator that offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For example, the timing diagram in Figure 9-7 shows an asynchronous single-read access performed on an asynchronous device. For more information on GPMC_CLK and GPMC_FCLK refer to Section 9.1.5.3.6.

Figure 9-7. Asynchronous Single Read on a Nonmultiplexed Address/Data Device



9.1.5.3.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME fields (I = 0 to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (NCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitchy transition. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC.GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where I = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY:

- The RDCYCLETIME and WRCYCLETIME bit fields are programmable in the GPMC.GPMC_CONFIG5_i register, I = 0 to 7.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 31 GPMC_FCLK cycles with a granularity of 1 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 62 GPMC._FCLK cycles with a granularity of 2 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 1.

9.1.5.3.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field (where I = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

For a read access, the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field defines the nCS signal deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field defines the nCS signal deassertion time relative to start access time.\

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

9.1.5.3.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY)

The GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field (where I = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

For a read access, the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Refer to Section 9.1.5.14 for more details on ADVONTIME, ADVRDOFFTIME and ADVWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

9.1.5.3.4 nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY)

The GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field (where I = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses.

OEONTIME and OEOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

The nOE/RE signal transitions as controlled through OEONTIME, and OEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nOE/nRE is not asserted during a write cycle.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

9.1.5.3.5 nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME /

WEEXTRADELAY)

The GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field (where I = 0 to 7) defines the nWE signal-assertion time relative to start access time. It applies only to write accesses.

The GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. It applies only to write accesses.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nWE is not asserted during a read cycle.

9.1.5.3.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where I = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

9.1.5.3.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.

- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

9.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.
RDACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[20:16] bit field (I = 0 to 7).
WRACCESSTIME is programmed in the GPMC.GPMC_CONFIG6_i[28:24] bit field (I = 0 to 7).
RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 0).
RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC_FCLK cycles with a granularity of two (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 1).

9.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see Section 9.1.5.4.

9.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see Section 9.1.5.4.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see Section 9.1.5.4.

9.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[27:24] bit field (I = 0 to 7).
PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC_FCLK cycles with a granularity of one (GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

9.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see Section 9.1.5.4.

9.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see Section 9.1.5.4.

9.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

9.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc_wait3, gpmc_wait2, gpmc_wait1, and gpmc_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.GPMC_CONFIG1_i[17:16] WAITPINSELECT field (I = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.GPMC_CONFIG1_i[29] READTYPE and GPMC.GPMC_CONFIG1_i[27] WRITETYPE bits).

9.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

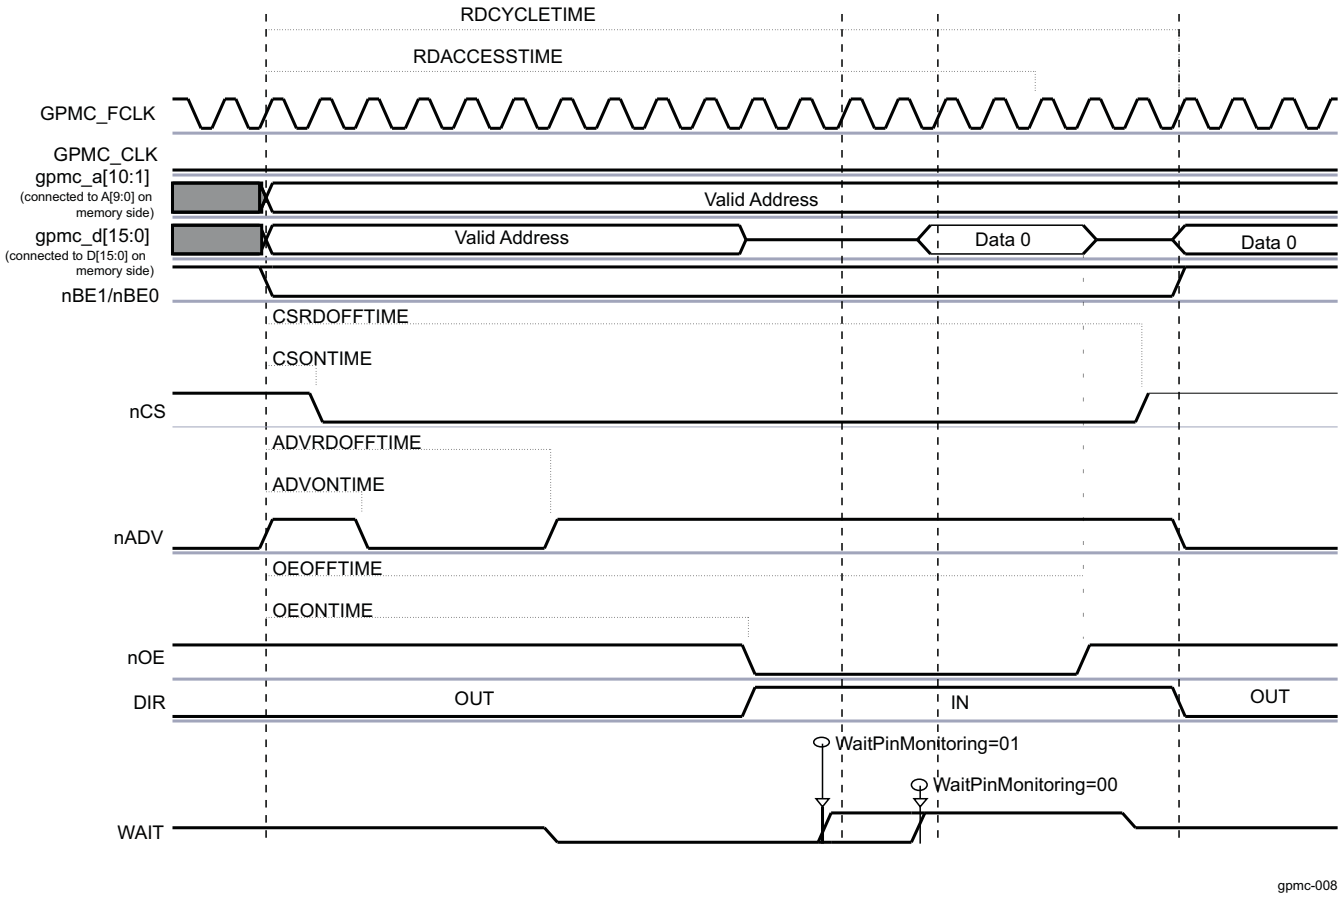
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (I = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 9-8 shows wait behavior during an asynchronous single read access.

Figure 9-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

9.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME fields (I = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

9.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (where I = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

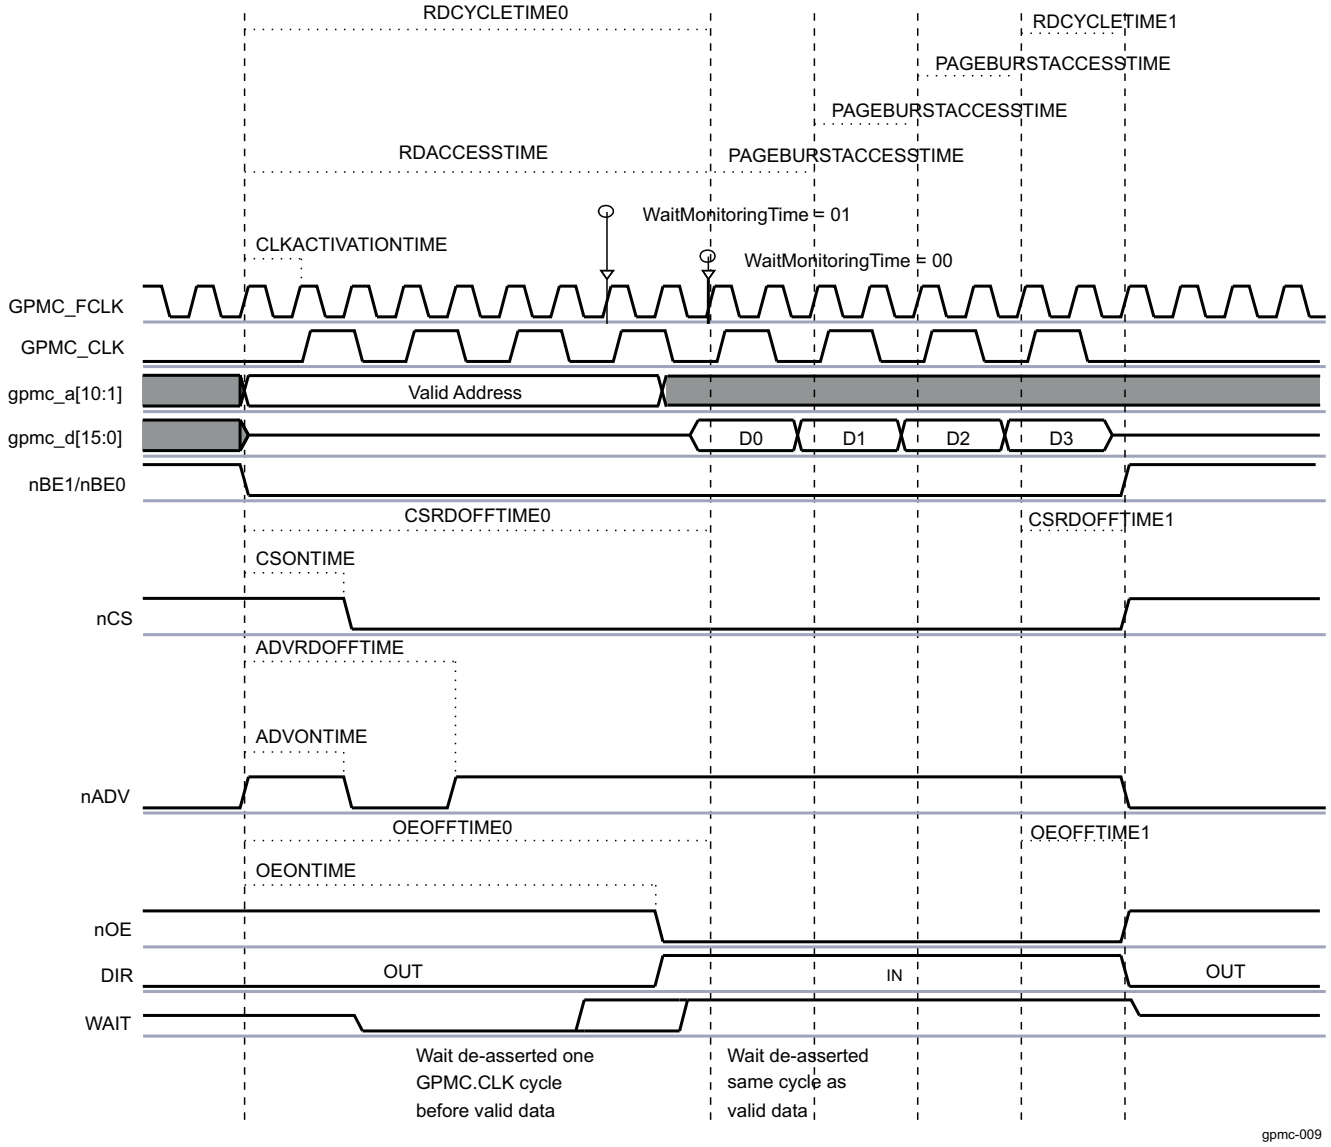
- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME ≠ 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 9-9 shows wait behavior during a synchronous read burst access.

Figure 9-9. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

9.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME ≠ 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the

CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x 0 (where I = 0 to 7) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

9.1.5.4.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see Section 9.1.5.14.2, *NAND Device-Ready Pin*.

9.1.5.4.6 Idle Cycle Control between Successive Accesses

9.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the GPMC.GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where I = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

9.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (I = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

9.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN,

CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in GPMC_CONFIG6_i registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See Section 9.1.5.4.6.1 for more details on bus turnaround.

Table 9-3 describes the configuration required for idle cycle insertion.

Table 9-3. Idle Cycle Insertion Configuration

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BTA cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BTA cycles are inserted.
R	> 0	W	Any	Any	0	0	BTA cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).

Table 9-3. Idle Cycle Insertion Configuration (continued)

1st Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

9.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where I stands for the GPMC chip-select value, I = 0 to 7). Increasing all access timing parameters allows support of slow devices.

9.1.5.5 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the processor, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see Section 9.1.5.3.10, *Bus Keeping Support*).

To prevent unnecessary toggling, the gpmc_io_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

Figure 9-10 shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

9.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. The PRCM specifications provide more information about external-device reset.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during processor's warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

9.1.5.7 Write Protect (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC.GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

9.1.5.8 Byte Enable (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

9.1.5.9 Asynchronous Access Description

In asynchronous operations:

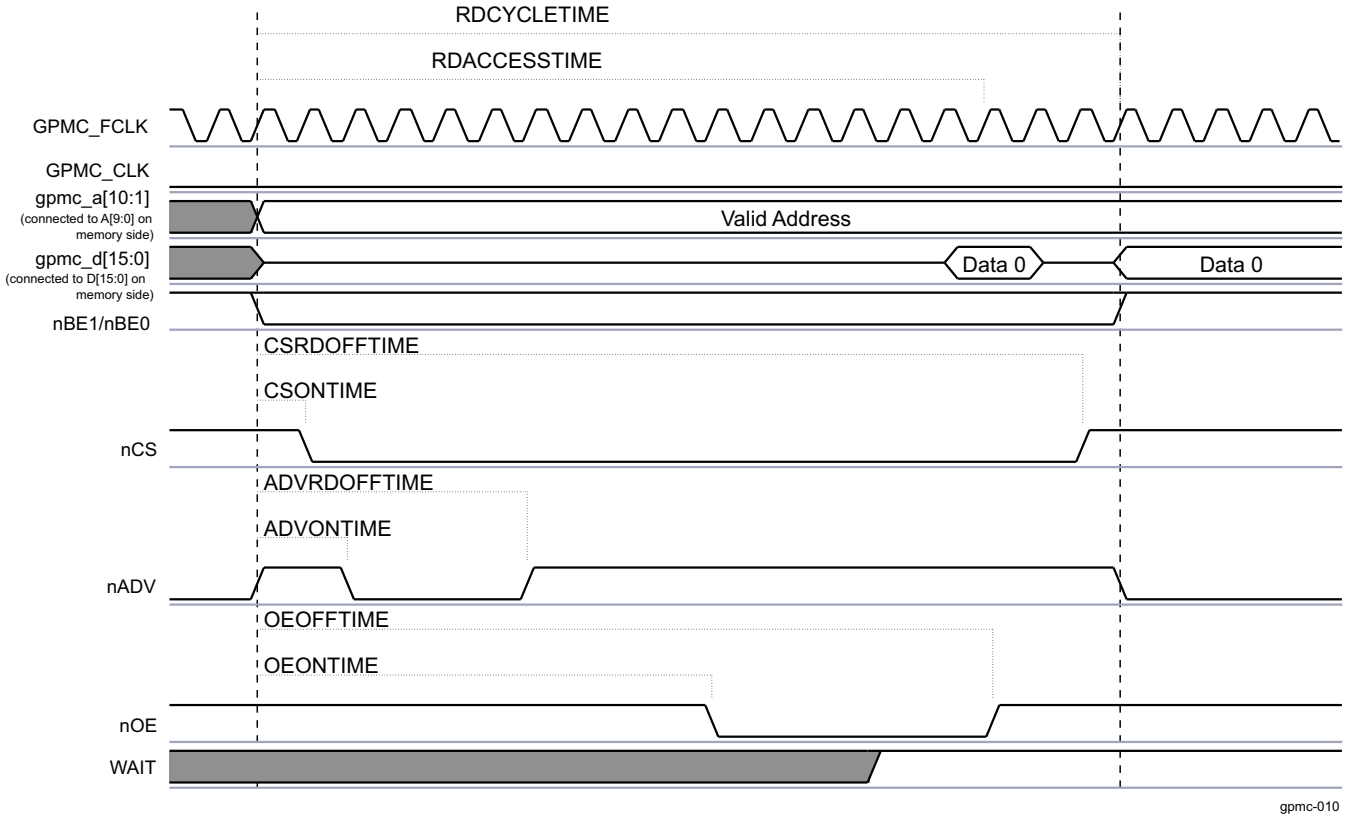
- GPMC_CLK is not provided outside the GPMC.
- GPMC_CLK is kept low.

9.1.5.9.1 Asynchronous Single Read

9.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 9-10 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 9-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
  - GPMC_CONFIG1_i[30] READMULTIPLE bit at 0 (read single access)
  - GPMC_CONFIG1_i[29] READTYPE bit at 0 (asynchronous read)
  - GPMC_CONFIG1_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME field.

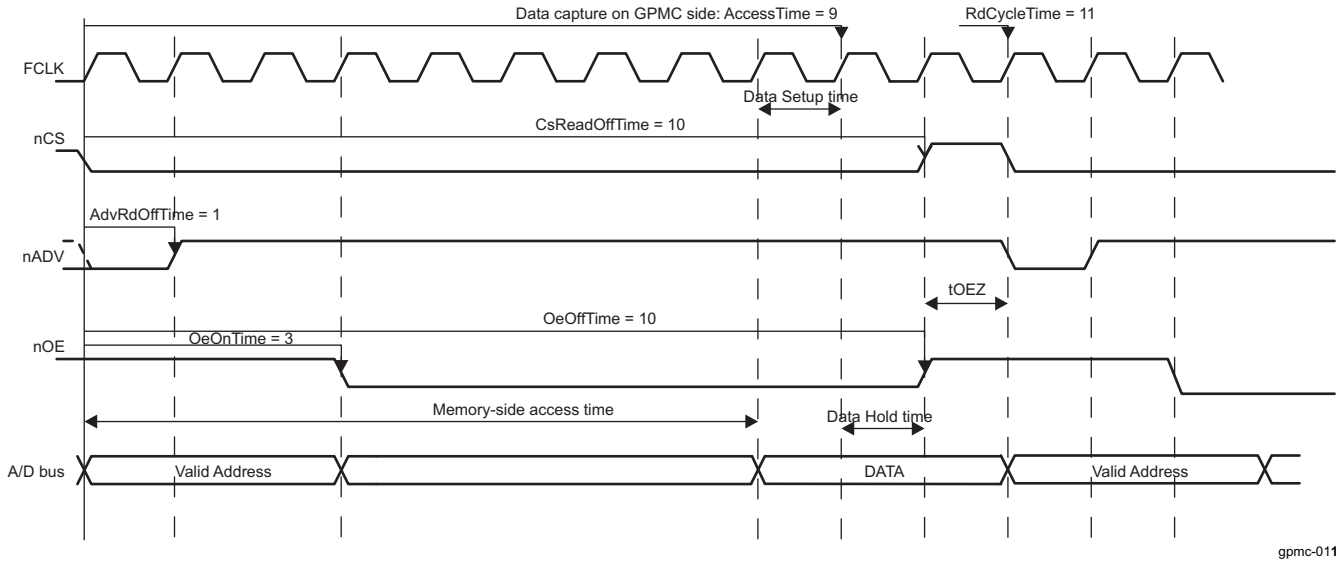
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.1.5.3.10, *Bus Keeping Support* for more details.

9.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 9-11 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 9-11. Asynchronous Single Read on an Address/Data-Multiplexed Device



When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 9.1.5.2.3, *Address/Data-Multiplexing Interface*.

GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

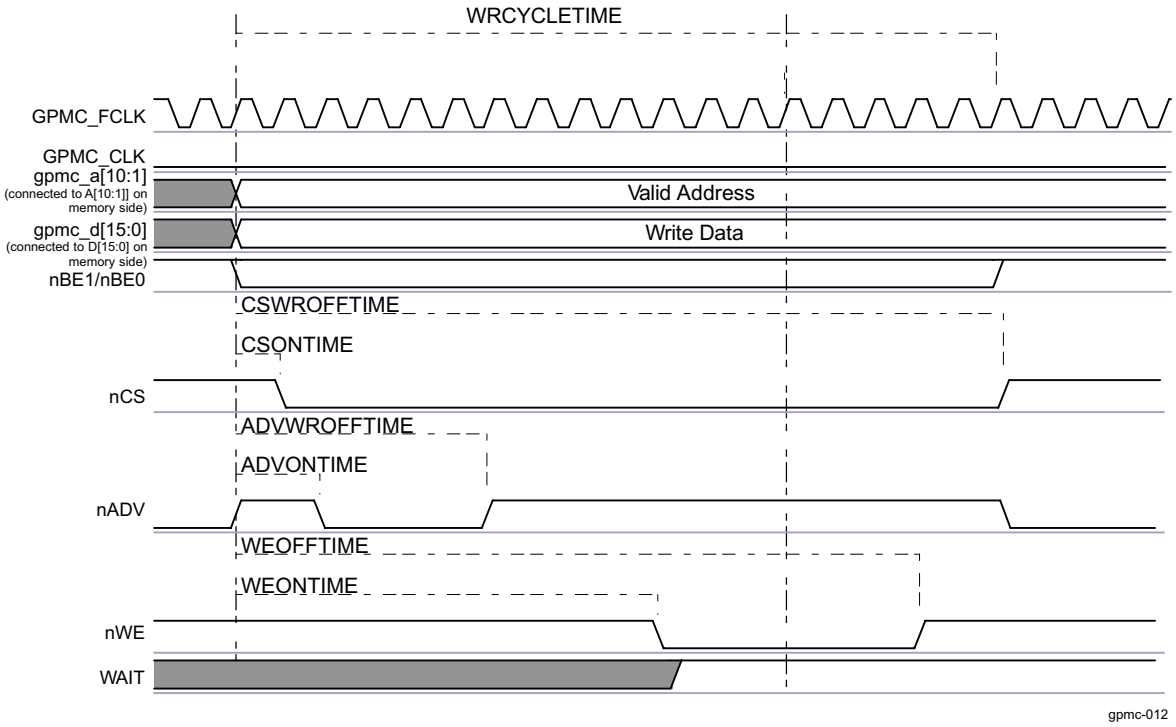
The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

9.1.5.9.2 Asynchronous Single Write

9.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 9-12 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 9-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
  - WRITEMULTIPLE bit at 0 (write single access)
  - WRITETYPE bit at 0 (write asynchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.
- Direction signal DIR:

DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.

  This write-cycle time is defined in the GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 9.1.5.3.10, *Bus Keeping Support*.

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see Section 9.1.5.2.7,*System Burst Versus External Device Burst Support*.

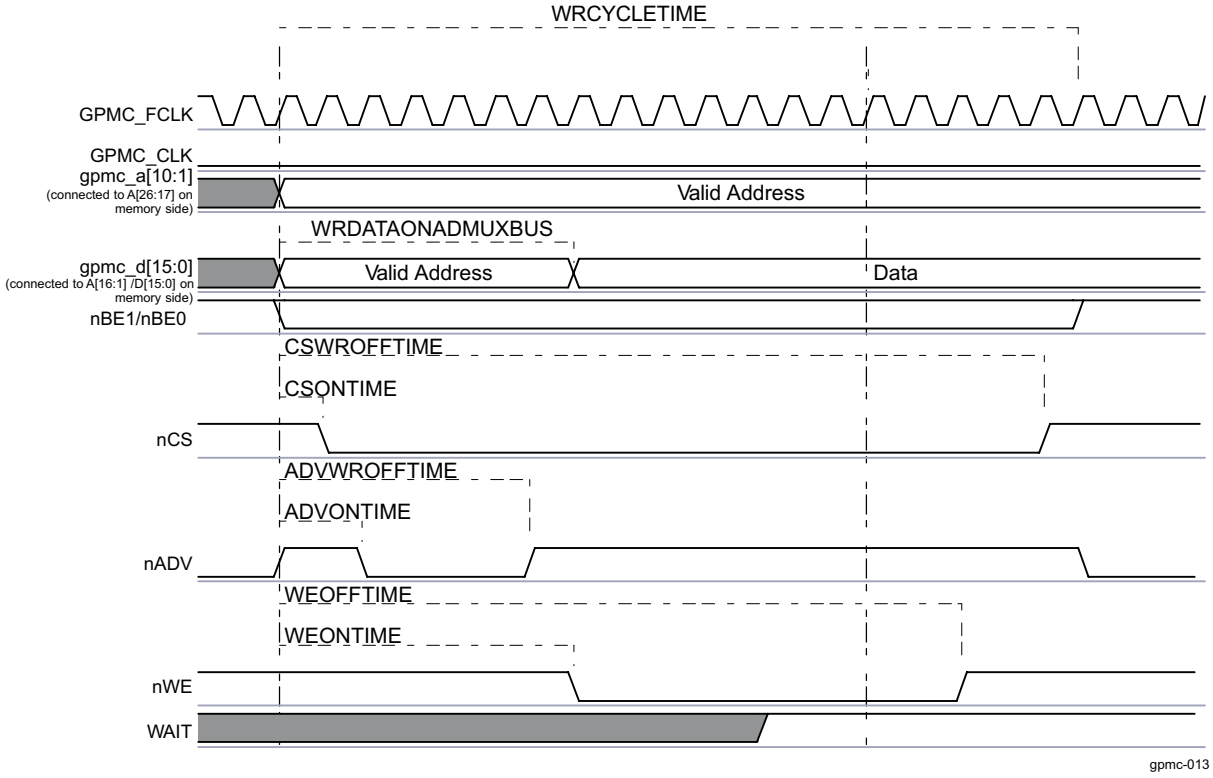
Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

9.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 9-13 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 9-13. Asynchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see Section 9.1.5.2.3, *Address/Data-Multiplexing Interface*.

GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

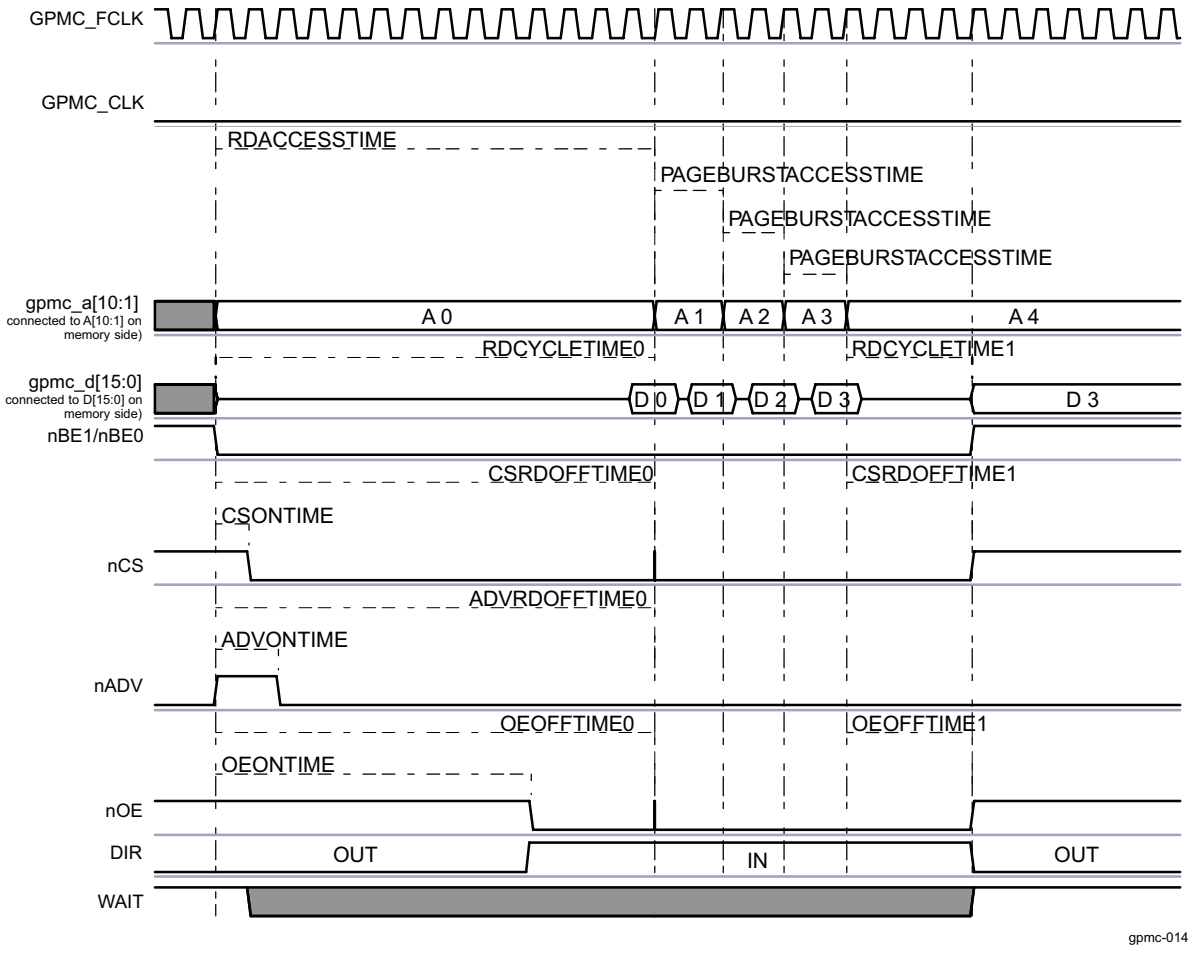
Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

9.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 9-14 shows an asynchronous multiple read operation.

Figure 9-14. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

For read access with GPMC.GPMC_CONFIG1_i register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In Figure 9-14, two Word32 read host accesses on the GPMC configured with READMULTIPLE = 1, READTYPE = 0, and MUXADDDATA = 0 are merged into one multiple-read access (page mode of four Word16) on the attached device.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures the address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by the RDACCESSTIME parameter.

  The access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the PAGEBURSTACCESSTIME parameter:
  - This timing is defined in the GPMC.GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME field.
  - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion plus the time from RDACCESSTIME to CSRDOFFTIME.
  - The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
  - In Figure 9-14, the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).
- Direction signal DIR:

  DIR goes from OUT to IN at the same time as nOE assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.1.5.3.10, *Bus Keeping Support*.

9.1.5.10 Synchronous Access

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field (where I = 0 to 7).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until CycleTime completes.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

9.1.5.10.1 Synchronous Single Read

Figure 9-15 and Figure 9-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 9-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

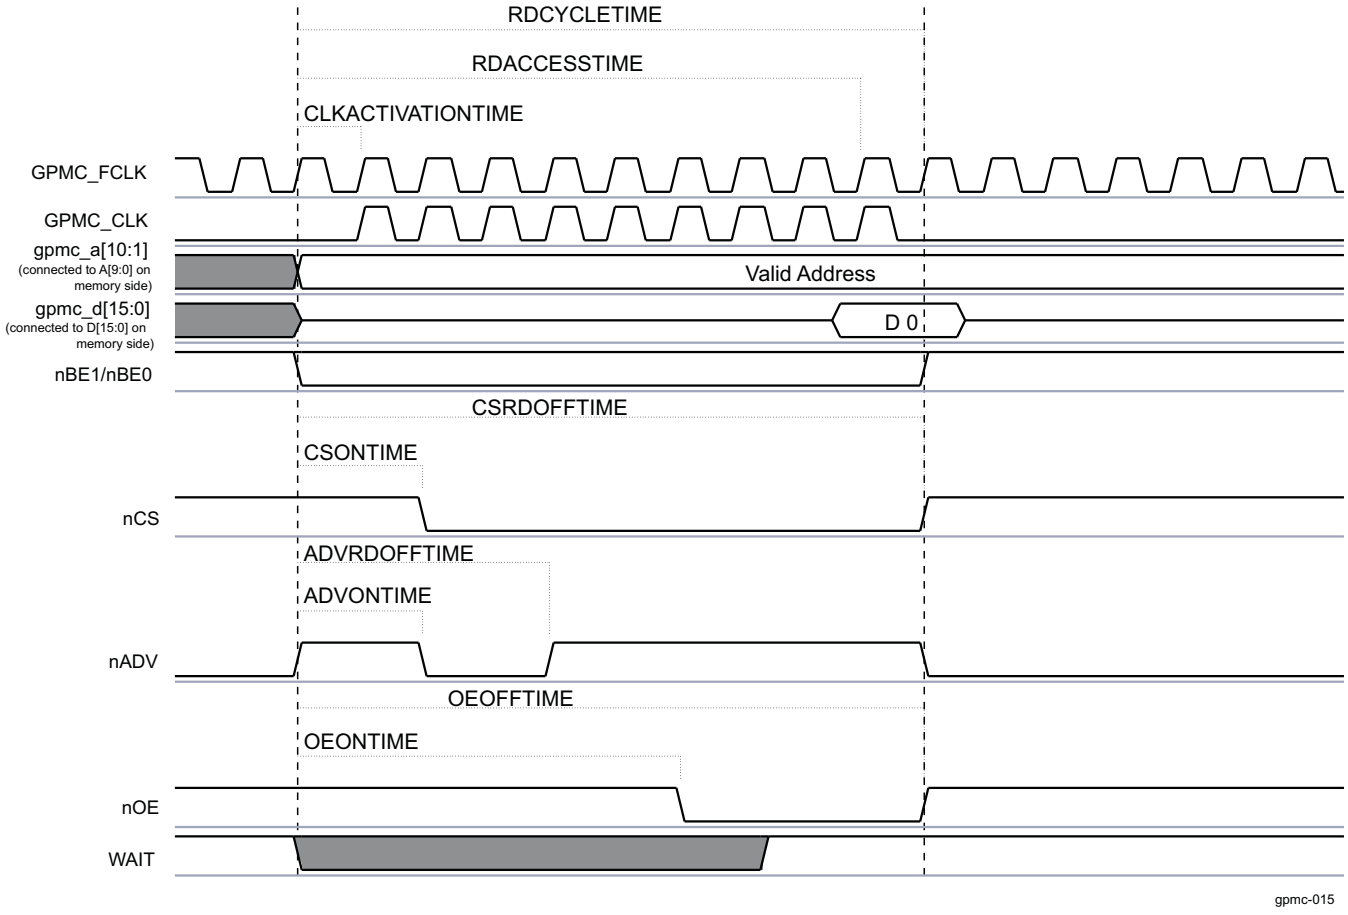


Figure 9-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

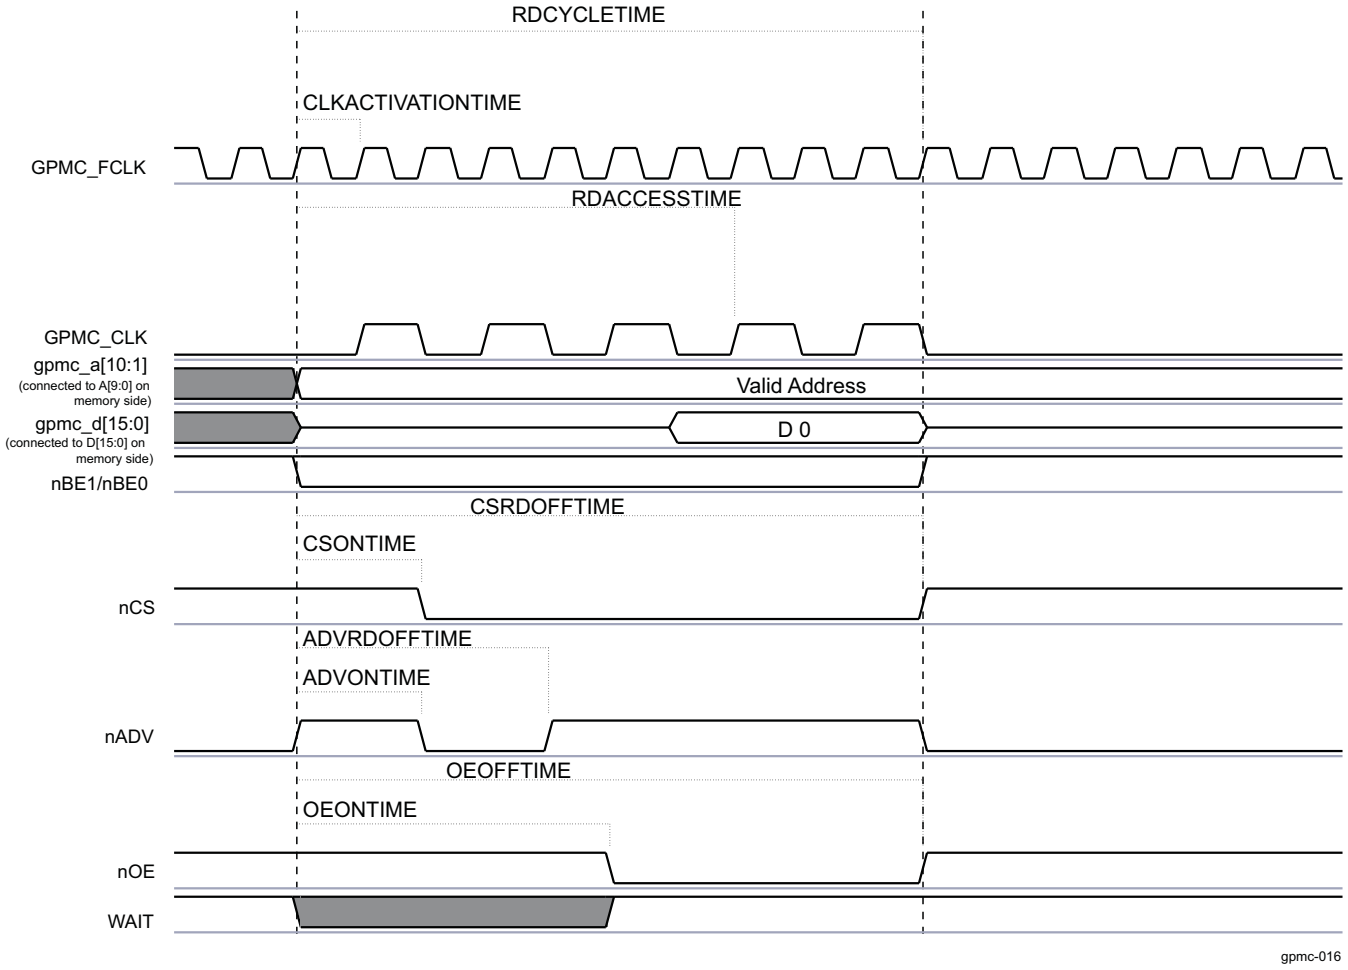


In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
  - READMULTIPLE bit at 0 (read single access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.

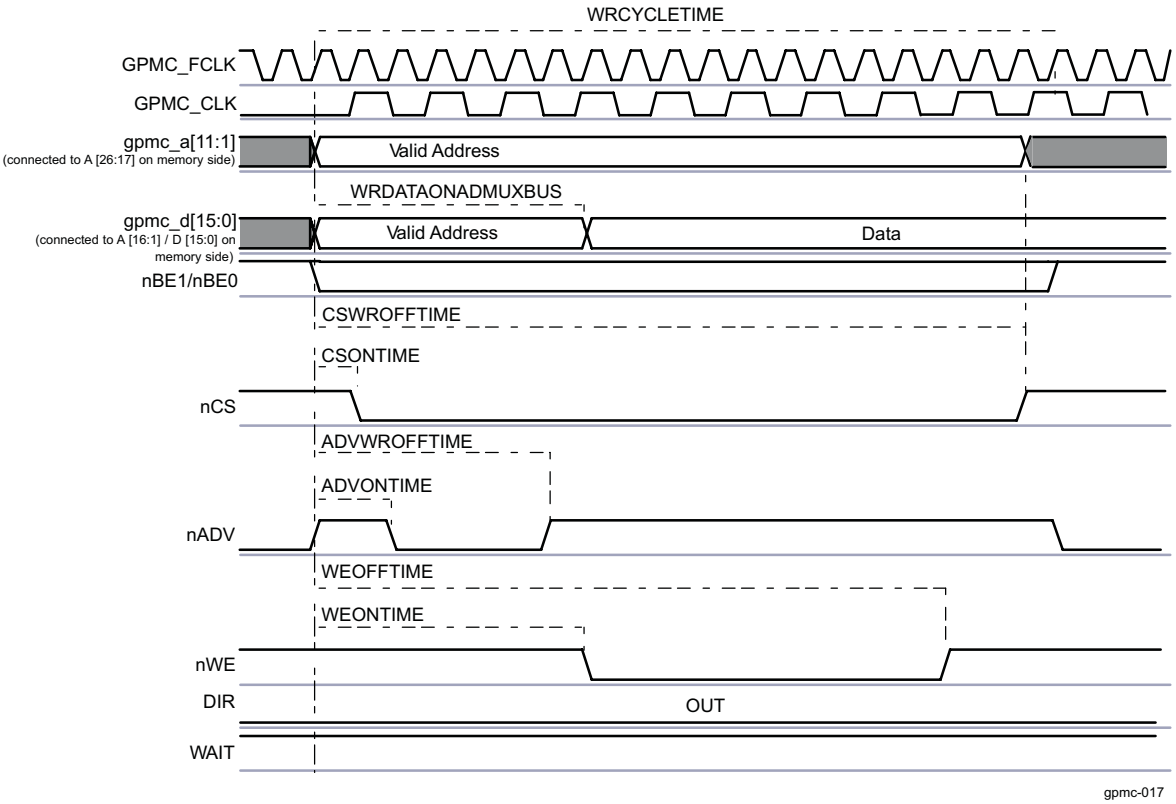
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR:

  DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.1.5.3.10, *Bus Keeping Support*.

9.1.5.10.2 Synchronous Single Write

Figure 9-17. Synchronous Single Write on an Address/Data-Multiplexed Device



NOTE: The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC_CONFIG6_i[19:16]).

The GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

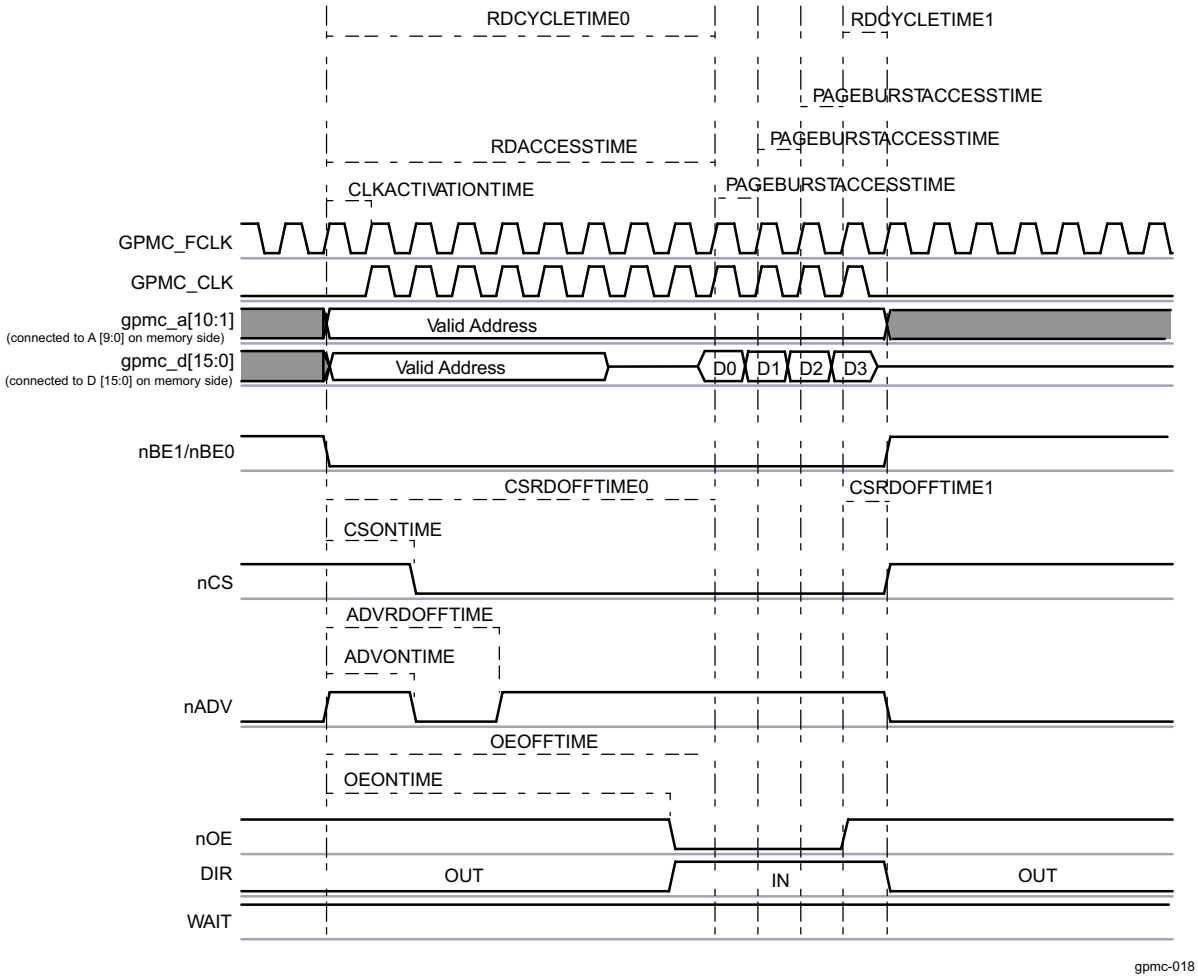
The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

9.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst with Wraparound Capability)

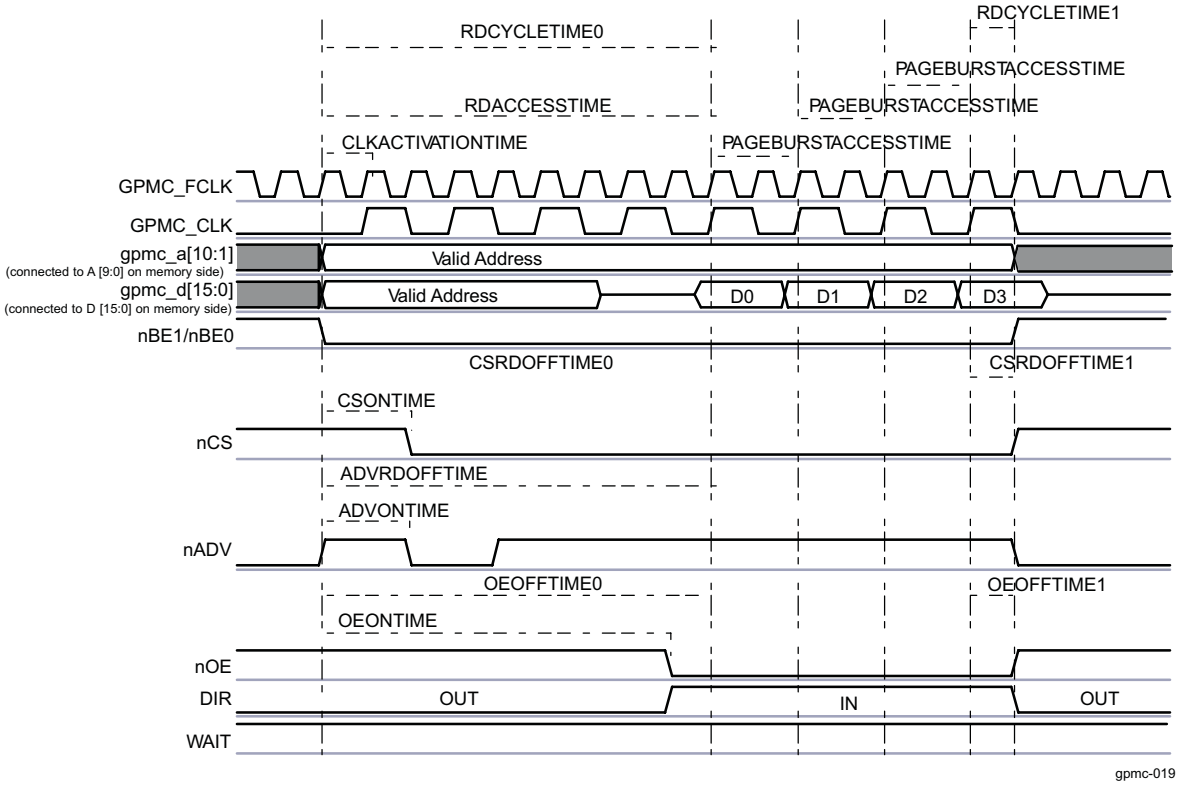
Figure 9-18 and Figure 9-19 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 9-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)



NOTE: The WAIT signal is active low.

Figure 9-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)



NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
  - READMULTIPLE bit at 1 (read multiple access)
  - READTYPE bit at 1 (read synchronous)
  - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
  - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the

memory-device internal configuration.

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
  - RDCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
  - In Figure 9-19, the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:

  DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.1.5.3.10, *Bus Keeping Support*.

- Burst wraparound

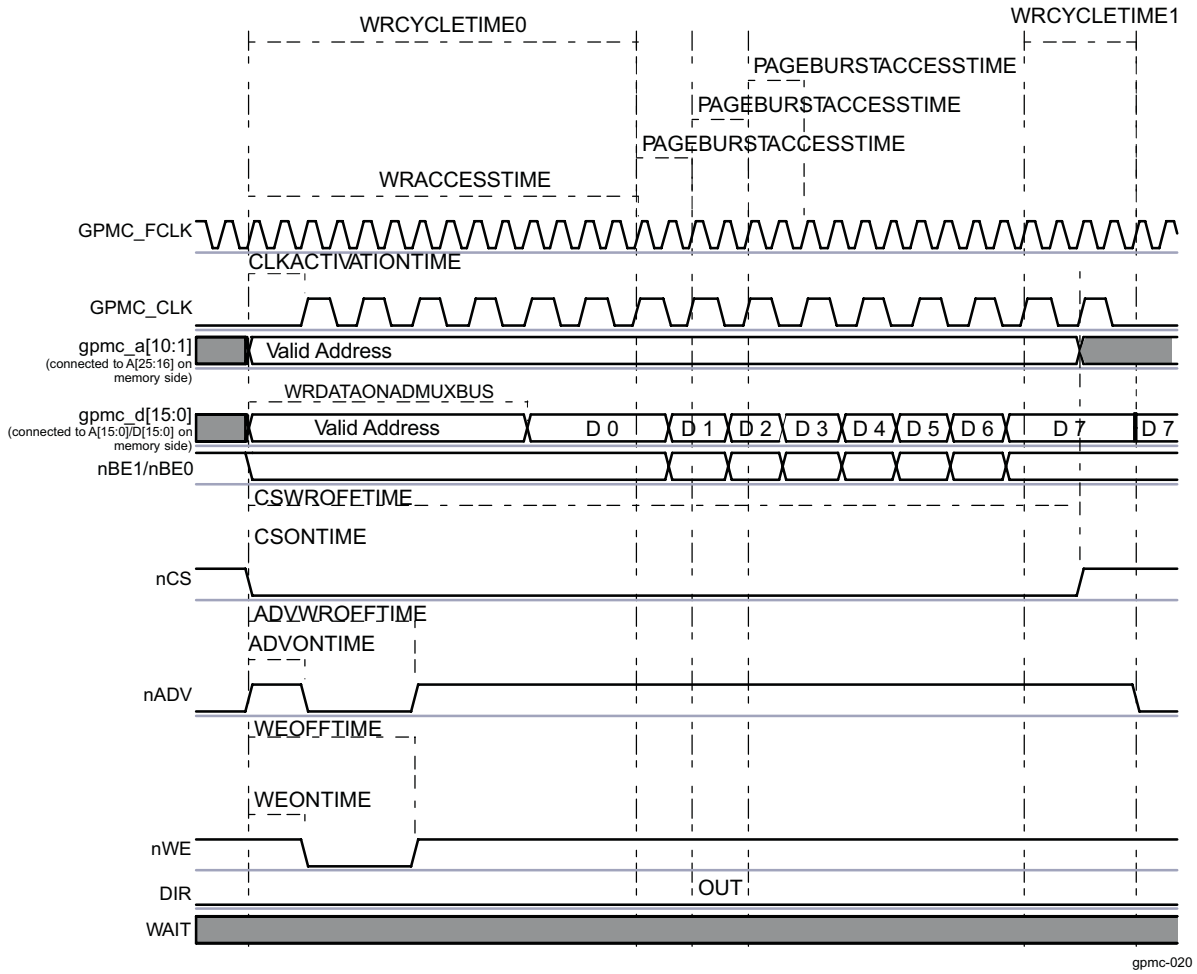
  The GPMC.GPMC_CONFIG1_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

9.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

Figure 9-20 shows a synchronous multiple (burst) write.

Figure 9-20. Synchronous Multiple (Burst) Write



NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
  - WRITEMULTIPLE bit at 1 (write multiple access)
  - WRITETYPE bit at 1 (write synchronous)
  - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
  - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.
- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
  - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

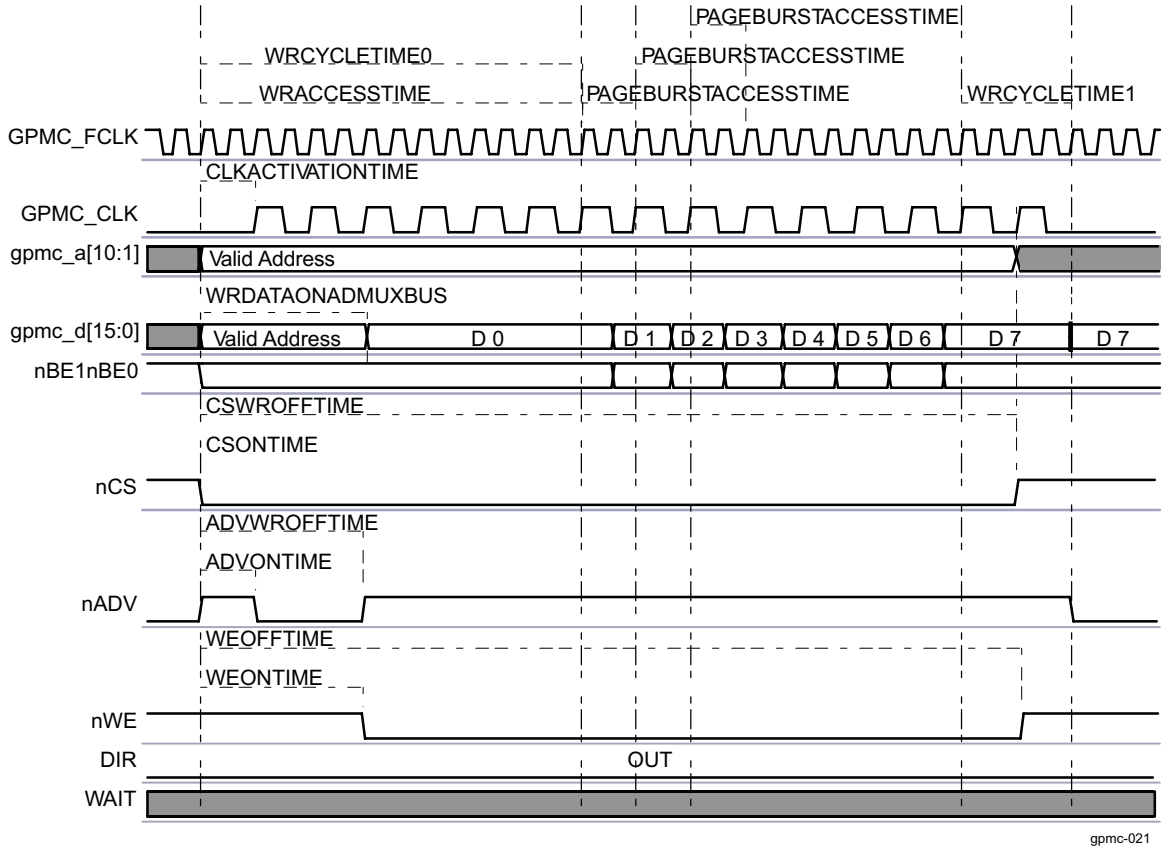
- First write data is driven by the GPMC at WRDATAONADMUXBUS (GPMC_CONFIG6_i[19:16]), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
  - WRACCESSTIME is defined in the GPMC.GPMC_CONFIG5_i register.
  - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
  - WRCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
  - In Figure 9-20, the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:

  DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 9.1.5.3.10, *Bus Keeping Support*.

Figure 9-21 shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 9-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode



The first data of the burst is driven on the a/d bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

9.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field (I = 0 to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

9.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC.GPMC_ERR_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC.GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.GPMC_TIMEOUT_CONTROL register and enabled with the GPMC.GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

9.1.5.13 Boot Configuration

See Section 9.1.3.3.2, *GPMC CS0 Default Configuration at IC Reset*.

9.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to chip enable don't care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

9.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

9.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.GPMC_CONFIG7_i register (where I = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC.GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in Table 9-4. Failure to comply with these settings corrupts the NAND interface protocol.

Table 9-4. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9]	0	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

(1) I = 0 to 7

The GPMC.GPMC_CONFIG1_i to GPMC.GPMC_CONFIG4_i register (where I = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

9.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i register locations (I = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.GPMC_NAND_COMMAND_i register location and to the GPMC.GPMC_NAND_ADDRESS_i register location must be posted for faster operations (I = 0 to 7). The GPMC.GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.GPMC_NAND_COMMAND_i and a GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

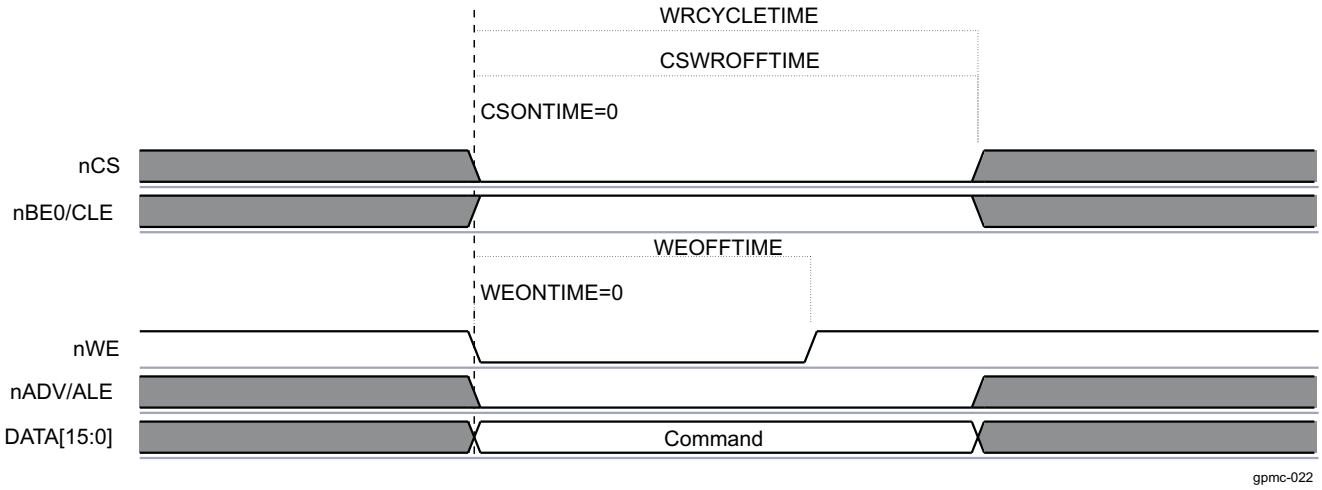
9.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.GPMC_NAND_COMMAND_i location (I = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 9-22 shows the NAND command latch cycle.

Figure 9-22. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

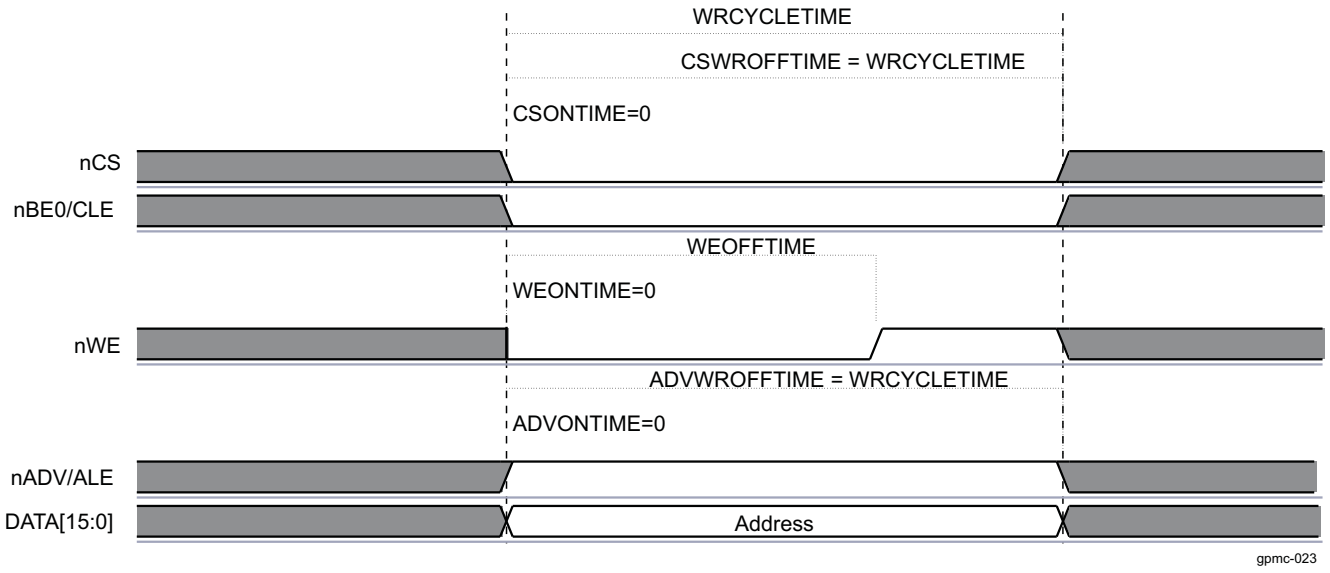
9.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC_NAND_ADDRESS_i location (I = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 9-23 shows the NAND address latch cycle.

Figure 9-23. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

9.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.GPMC_NAND_DATA_i location (I = 0 to 7) mapped in the chip-select-associated control register region. GPMC.GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

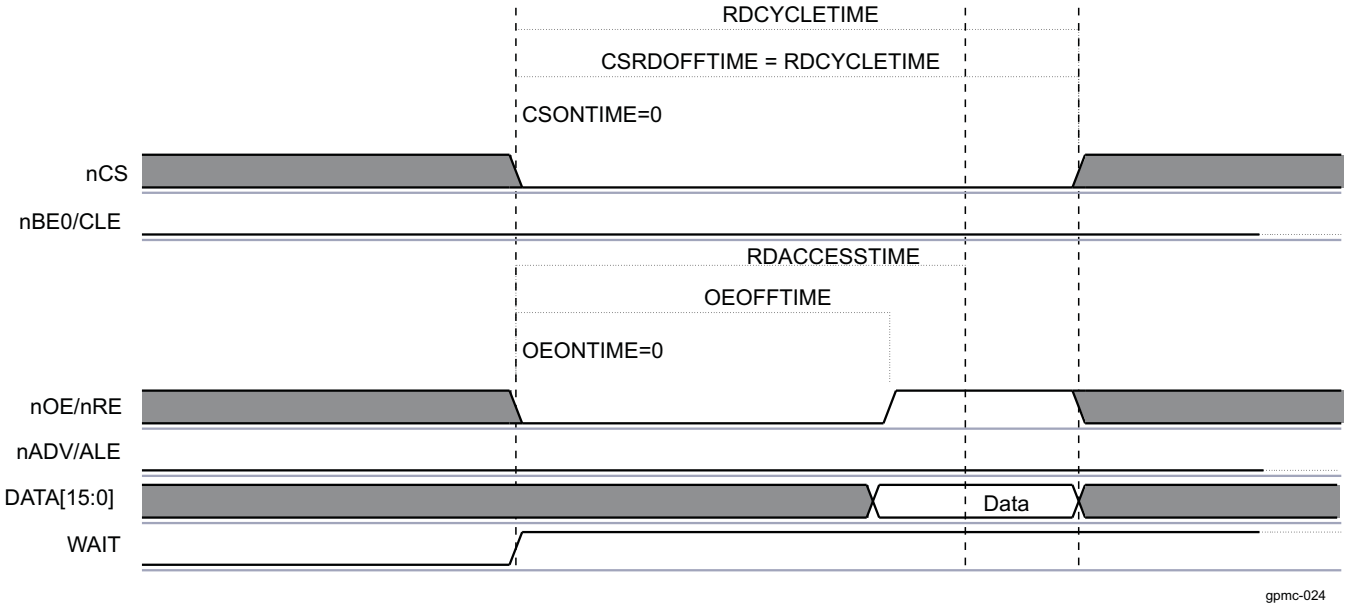
Reading data from the GPMC.GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and processor IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 9-24 shows the NAND data read cycle.

Figure 9-24. NAND Data Read Cycle

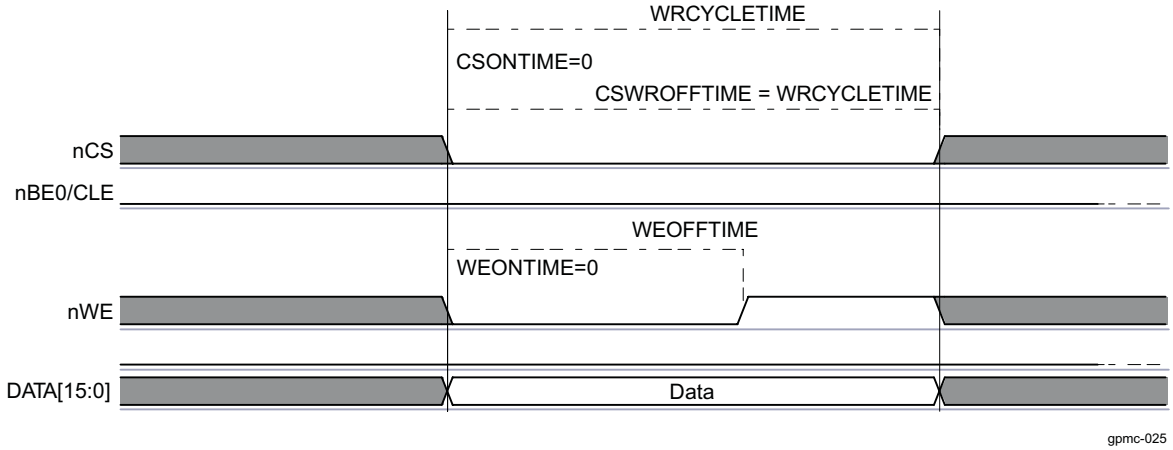


Writing data to the GPMC.GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 9-25 shows the NAND data write cycle.

Figure 9-25. NAND Data Write Cycle



9.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see Section 9.1.5.14.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

9.1.5.14.1.7 Read and Write Access Size Adaptation

9.1.5.14.1.7.1 8-bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

9.1.5.14.1.7.2 16-bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

9.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where I = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 3) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

9.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.GPMC_STATUS WAITxSTATUS bit (x = 0 to 3). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

9.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (x = 0 to 3) of the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

9.1.5.14.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities, Hamming code (for 1-bit error code correction) and BCH code (for 4- or 8-bit error correction) through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit. Only one ECC context can be active at any given time through the GPMC_ECC_CONFIG[3:1] ECCCS bit. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

9.1.5.14.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

9.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.GPMC_ECCj_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.GPMC_ECC_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.GPMC_ECCj_RESULT register value (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When GPMC.GPMC_ECCj_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.GPMC_ECCj_RESULT register, j = 1 to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (j = 1 to 9) in the GPMC.GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.GPMC_ECCj_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.GPMC_ECCj_RESULT registers (j) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

9.1.5.14.3.1.2 ECC Enabling

The GPMC.GPMC_ECC_CONFIG[3:0] ECCCS field selects the allocated chip-select. The GPMC.GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 9-5 describes the ECC enable settings.

Table 9-5. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-7	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0-7	Clears all ECC result registers

Table 9-5. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCPOINTER	GPMC_ECC_CONTROL	0-7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00-0xFF	Defines ECCSIZE0
ECCkRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

9.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 9-26 and Figure 9-27. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

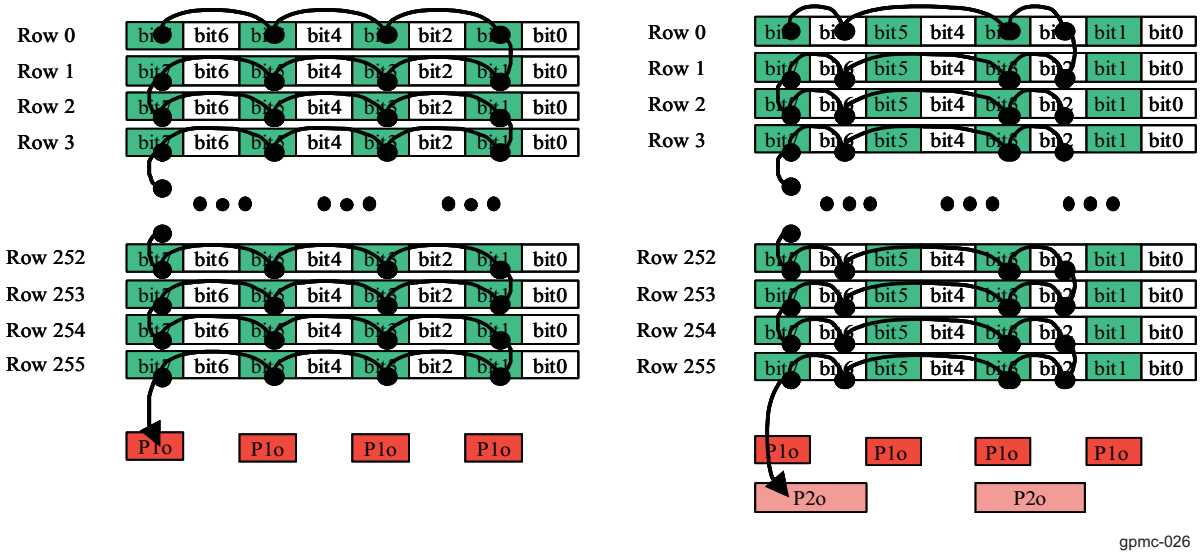
P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 9-26. Hamming Code Accumulation Algorithm (½)

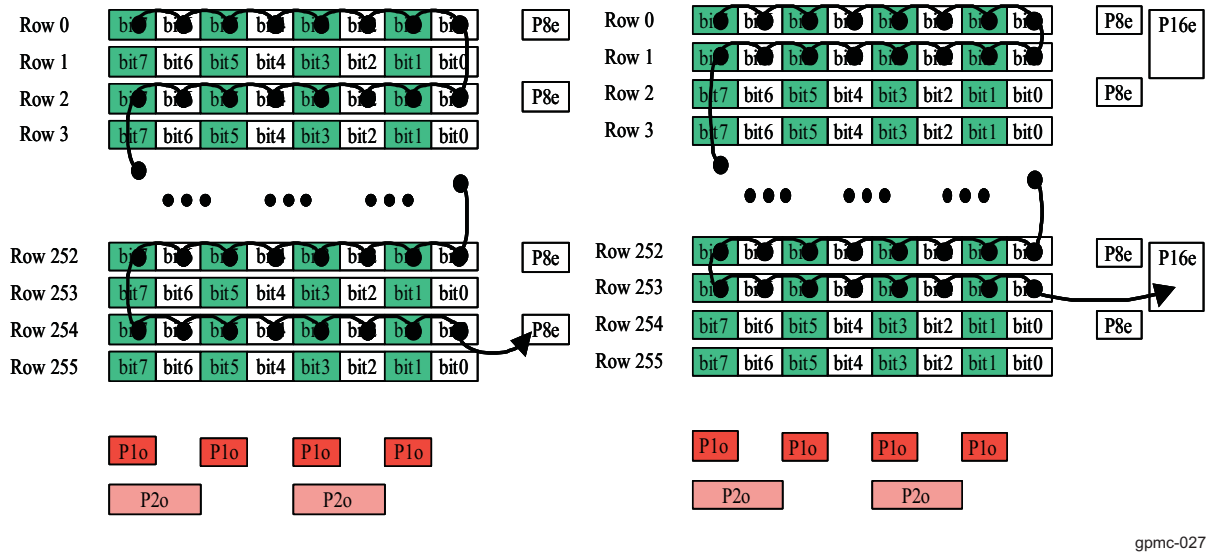


For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR XOR row254
P8o = row1 XOR row3 XOR row5 XOR XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR XOR row254 XOR row 255

Figure 9-27. Hamming Code Accumulation Algorithm (2/2)



Unused parity bits in the result registers are set to 0.

Figure 9-28 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 9-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

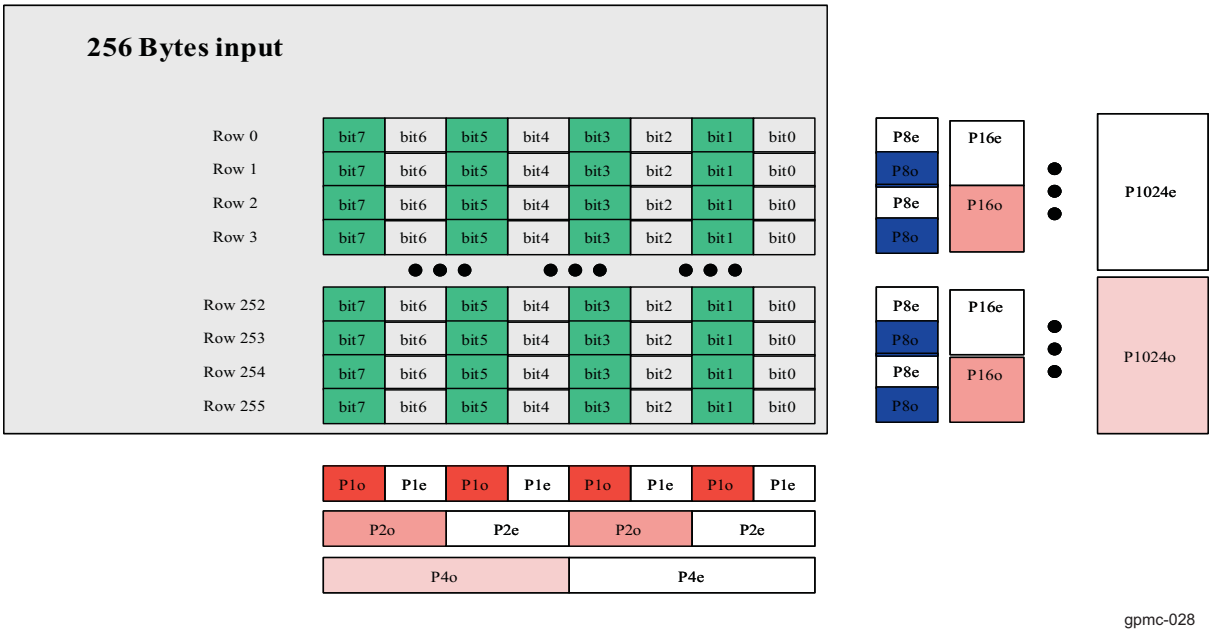


Figure 9-29 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

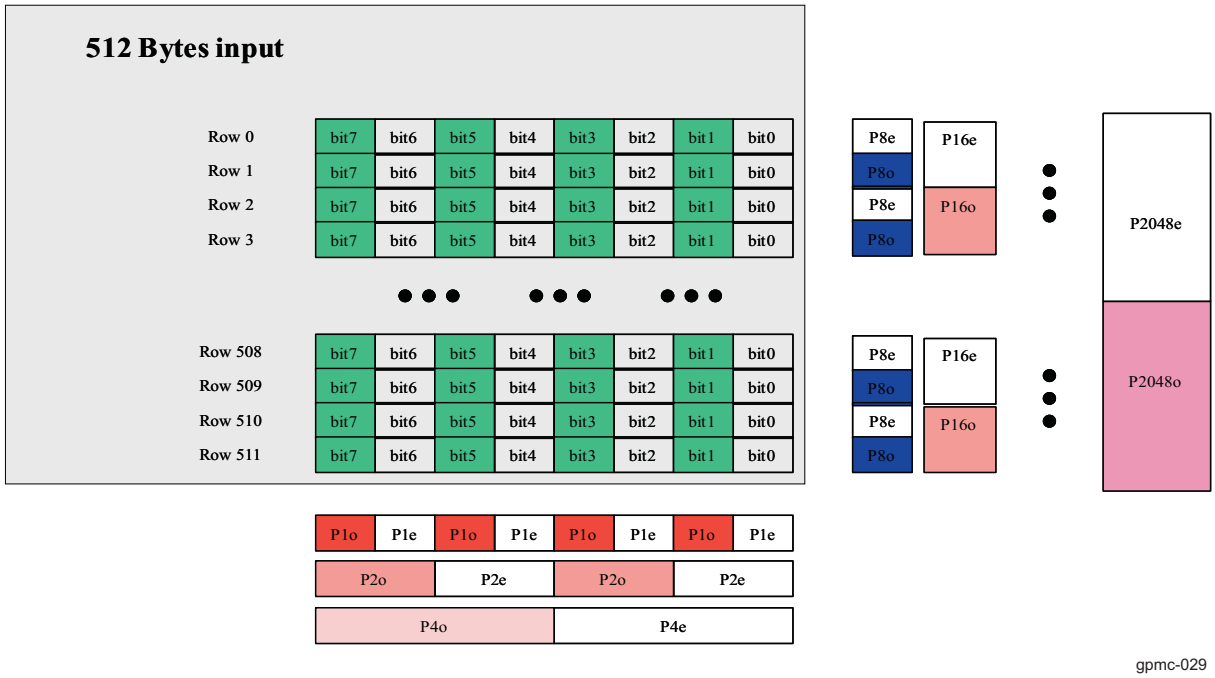
Figure 9-29. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (j = 1 to 9).

9.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

9.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

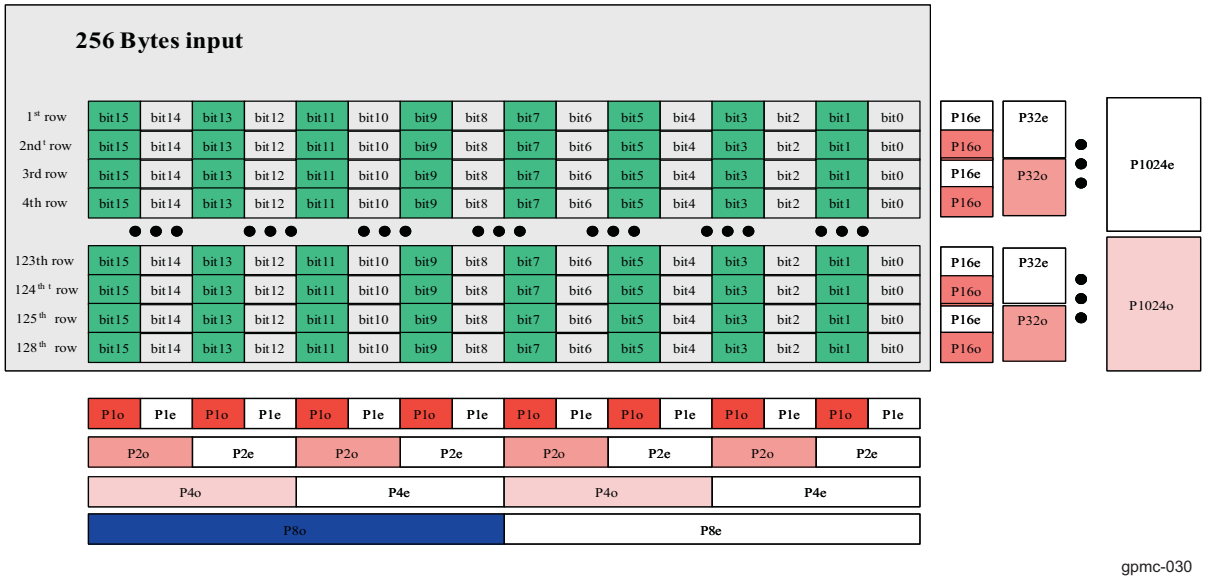
The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

9.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC.GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

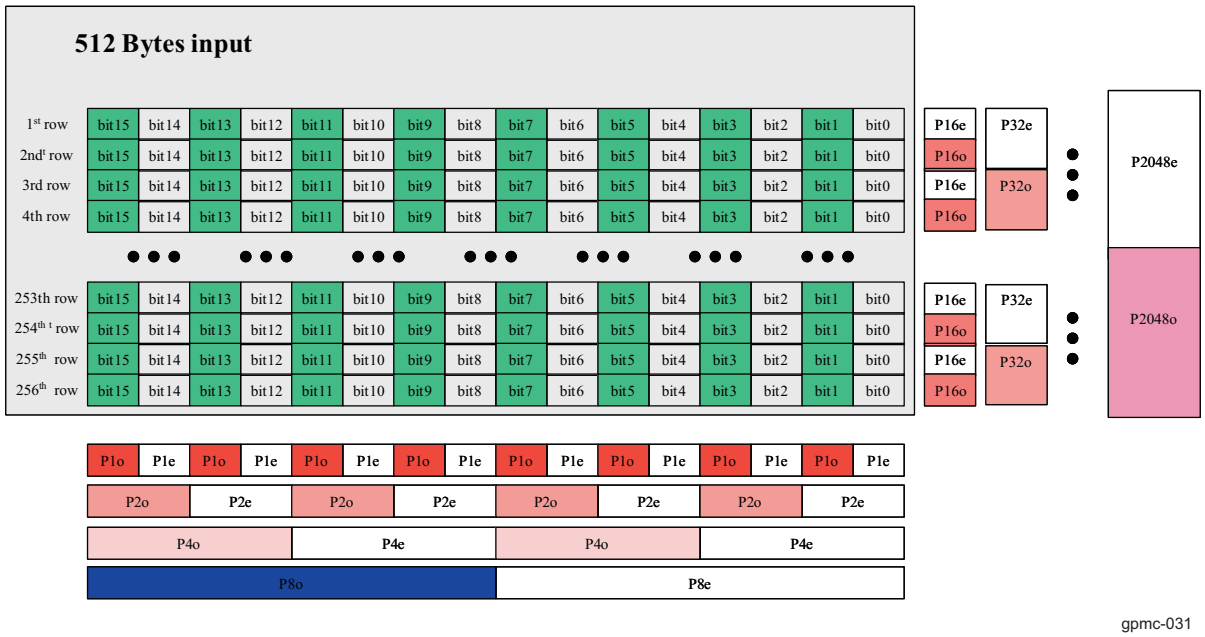
The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 9-30 and Figure 9-31 show a 128 Word 16 ECC computation scheme and a 256 Word 16 ECC computation scheme.

Figure 9-30. 128 Word 16 ECC Computation



gpmc-030

Figure 9-31. 256 Word 16 ECC Computation



gpmc-031

9.1.5.14.3.2 BCH Code

All references to Error Code Correction (ECC) in this subsection refer to the 4- or 8-bit error correction BCH code.

9.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.
   Typical page write sequence:
   - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.

2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
   The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

9.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree 2^{12} - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in Table 9-6.

Table 9-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) * 8) - 1 = 4119, for a total of 3+13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in GPMC_BCH_RESULT0_i, GPMC_BCH_RESULT1_i, GPMC_BCH_RESULT2_i, and GPMC_BCH_RESULT3_i (where I = 0 to 7).

9.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 * $x^{(7+I)}$ + b6 * $x^{(6+I)}$ + ... + b0 * x^{I}

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2^{12}-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 9-7. Aligned Message Byte Mapping in 8-bit NAND

Byte offset	8-bit word
0x000	(msb) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (lsb)

Table 9-8. Aligned Message Byte Mapping in 16-bit NAND

Byte offset	16-bit words MSB	16-bit words LSB
0x000	Byte 510 (0x1FE)	(msb) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(lsb) Byte 1 (0x1)

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 9-9. Aligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (lsb)

Table 9-10. Misaligned Nibble Mapping of Message in 8-bit NAND

Byte offset	8-bit word	
	4-bit most significant Nibble	4-bit less significant Nibble
1	(msb) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
(S+1)/2 - 2	Nibble 2	Nibble 1
(S+1)/2 - 1	Nibble 0 (lsb)	

Table 9-11. Aligned Nibble Mapping of Message in 16-bit NAND

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
S/2 - 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 - 2	Nibble 1	Nibble 0 (lsb)	Nibble 3	Nibble 2

Table 9-12. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S+1)/2 - 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S+1)/2 - 2	Nibble 0 (lsb)		Nibble 2	Nibble 1

Table 9-13. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S+2)/2 - 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S+2)/2 - 2			Nibble 1	Nibble 0 (lsb)

Table 9-14. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)

Byte offset	16-bit word			
	4-bit most significant Nibble		4-bit less significant Nibble	
0	Nibble S-3	Nibble S-4	(msb) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
...	...		...	
(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S+3)/2 - 2			Nibble 0 (lsb)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

9.1.5.14.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 ½ bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a software controlled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

9.1.5.14.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see Section 9.1.5.14.3.2.3.

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 ½ bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

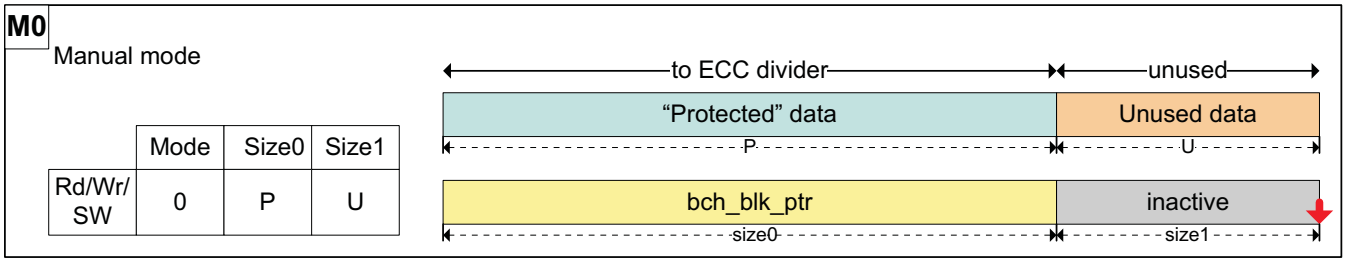
9.1.5.14.3.2.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

NOTE: In the following figures size and size0 are the same parameter.

Figure 9-32. Manual Mode Sequence and Mapping



Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

9.1.5.14.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.1.5.14.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

9.1.5.14.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

9.1.5.14.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.1.5.14.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 9.1.5.14.3.2.2.1.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

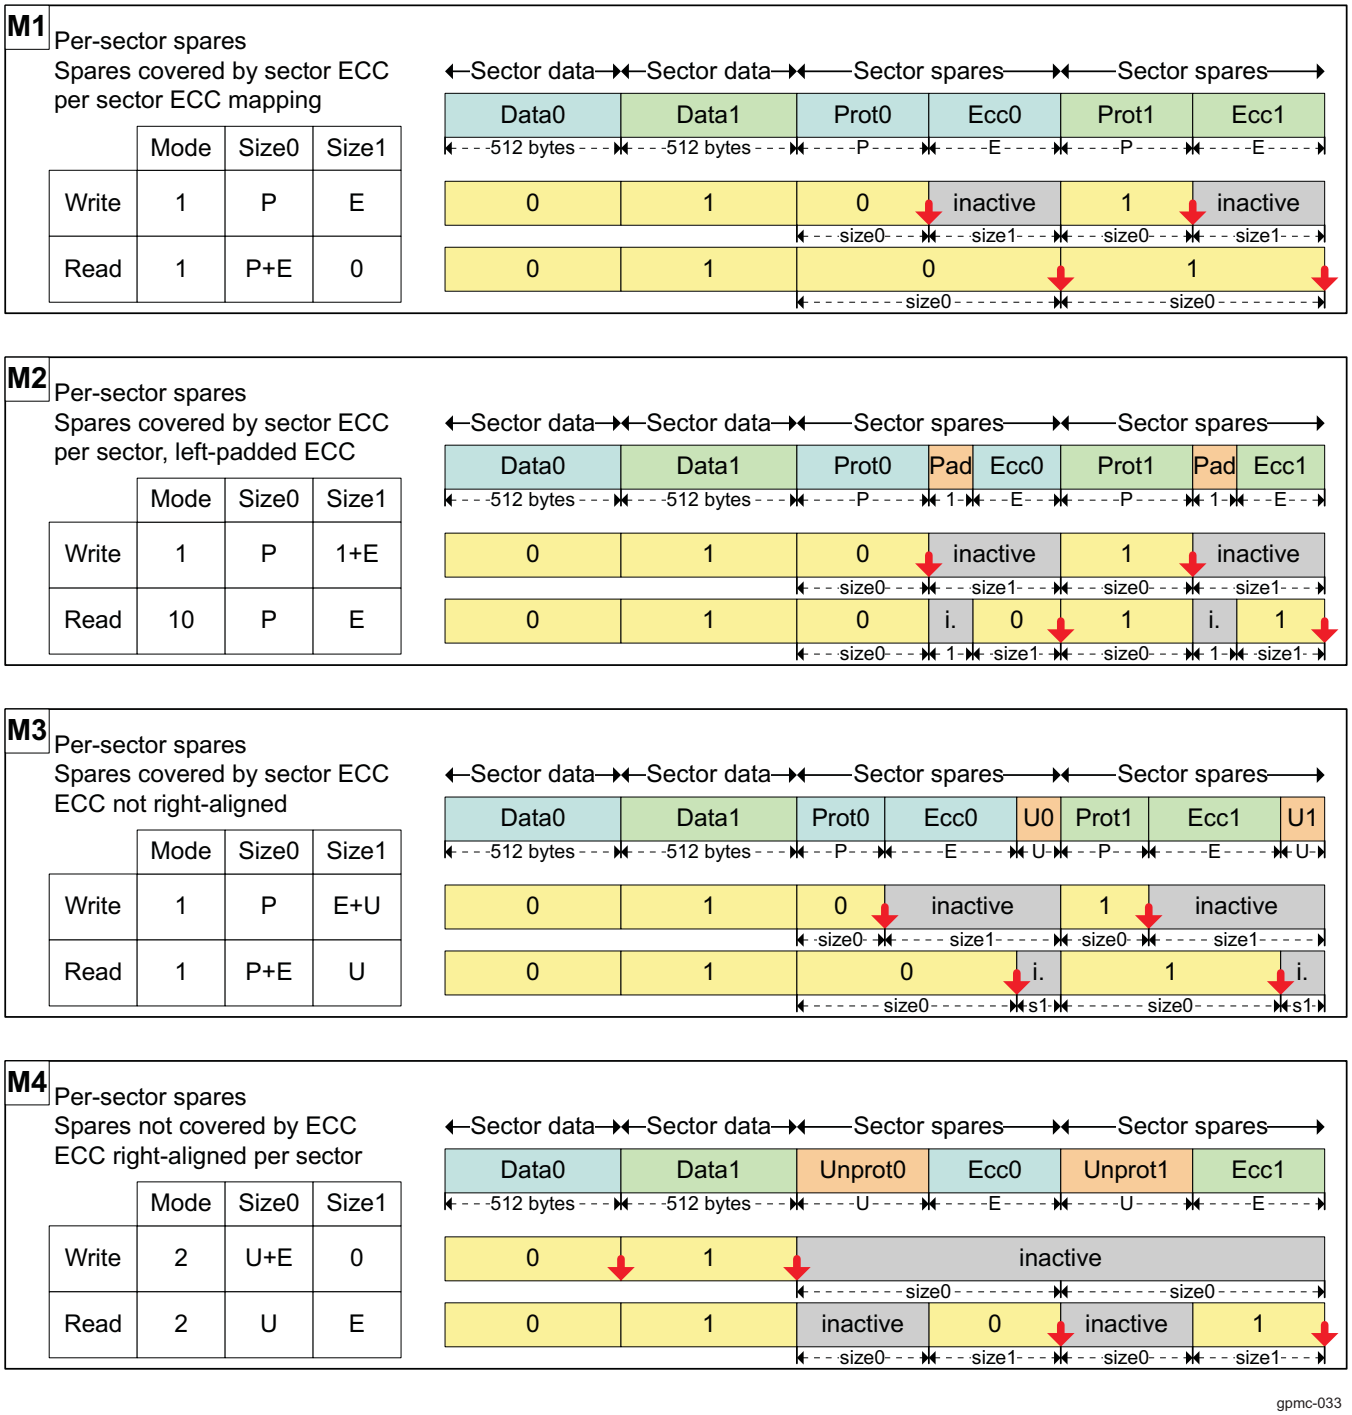
- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - sector 0 codeword: (512) + P + E
  - other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - all codewords (512) + E

9.1.5.14.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 9-33. NAND Page Mapping and ECC: Per-Sector Schemes

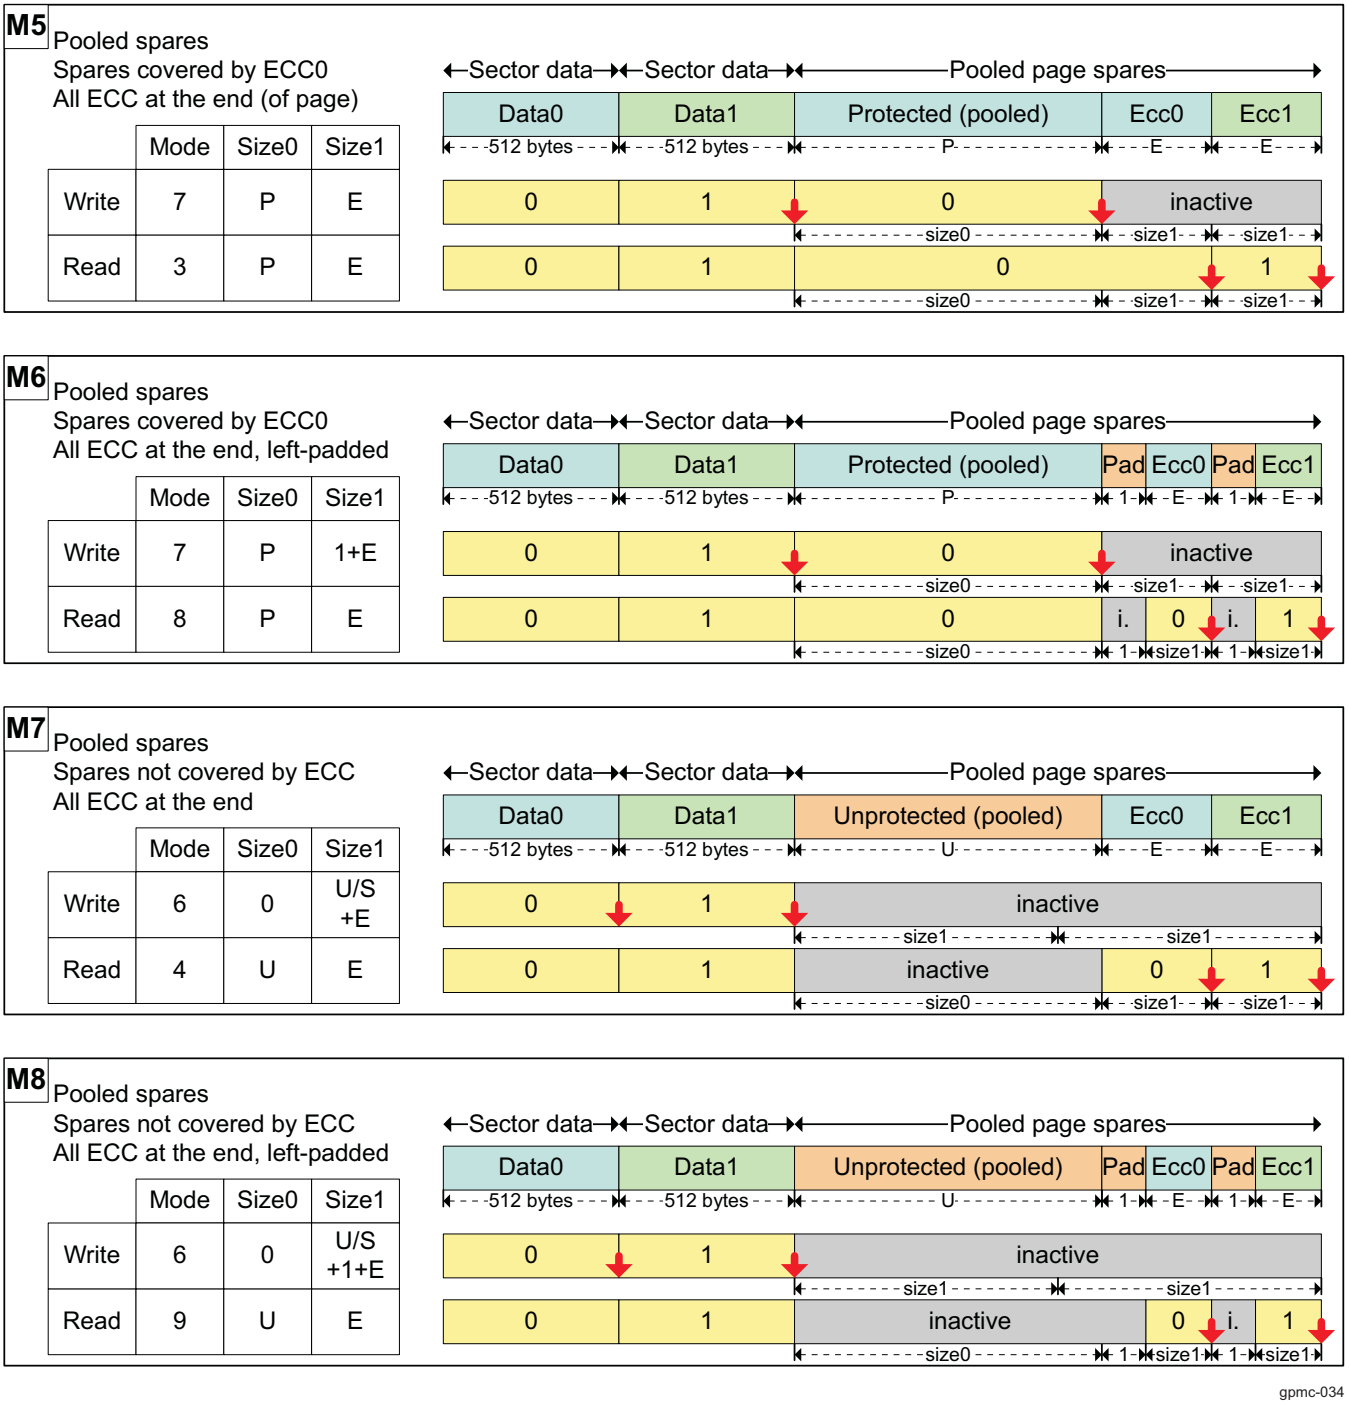


9.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 9-34. NAND Page Mapping and ECC: Pooled Spare Schemes

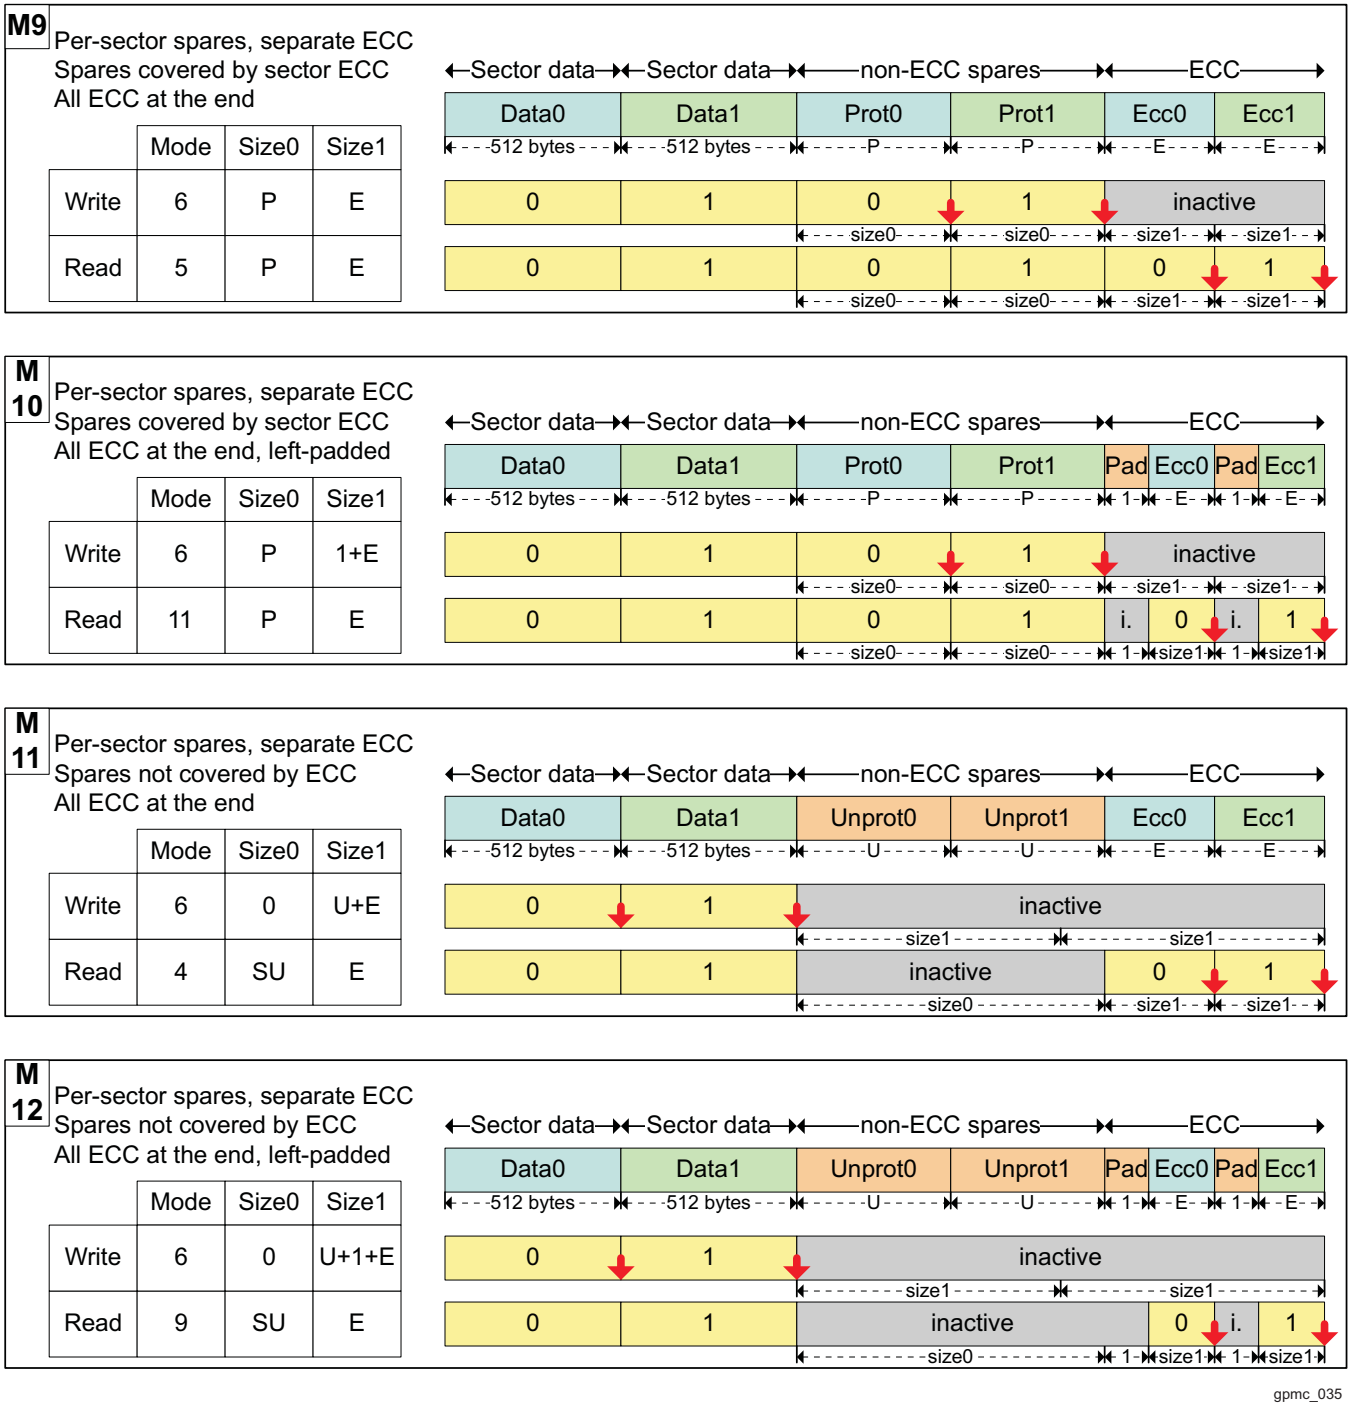


9.1.5.14.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 9-35. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC



9.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

9.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or Word16 access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of Word16.

When the GPMC.GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.GPMC_NAND_COMMAND_i, GPMC.GPMC_NAND_ADDRESS_i, and GPMC.GPMC_NAND_DATA_i registers (where I = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with Byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

9.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see Section 9.1.5.14.2.2. The GPMC.GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT field is completed.

Table 9-15. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request

Table 9-15. Prefetch Mode Configuration (continued)

Bit Field	Register	Value	Comments
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 3	(If SynchroMode = 1) Selects wait pin edge detector
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 9.1.5.14.4.6.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

9.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER field or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

9.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 9-16. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 7	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 9.1.5.14.4.6.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		

Table 9-16. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

9.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

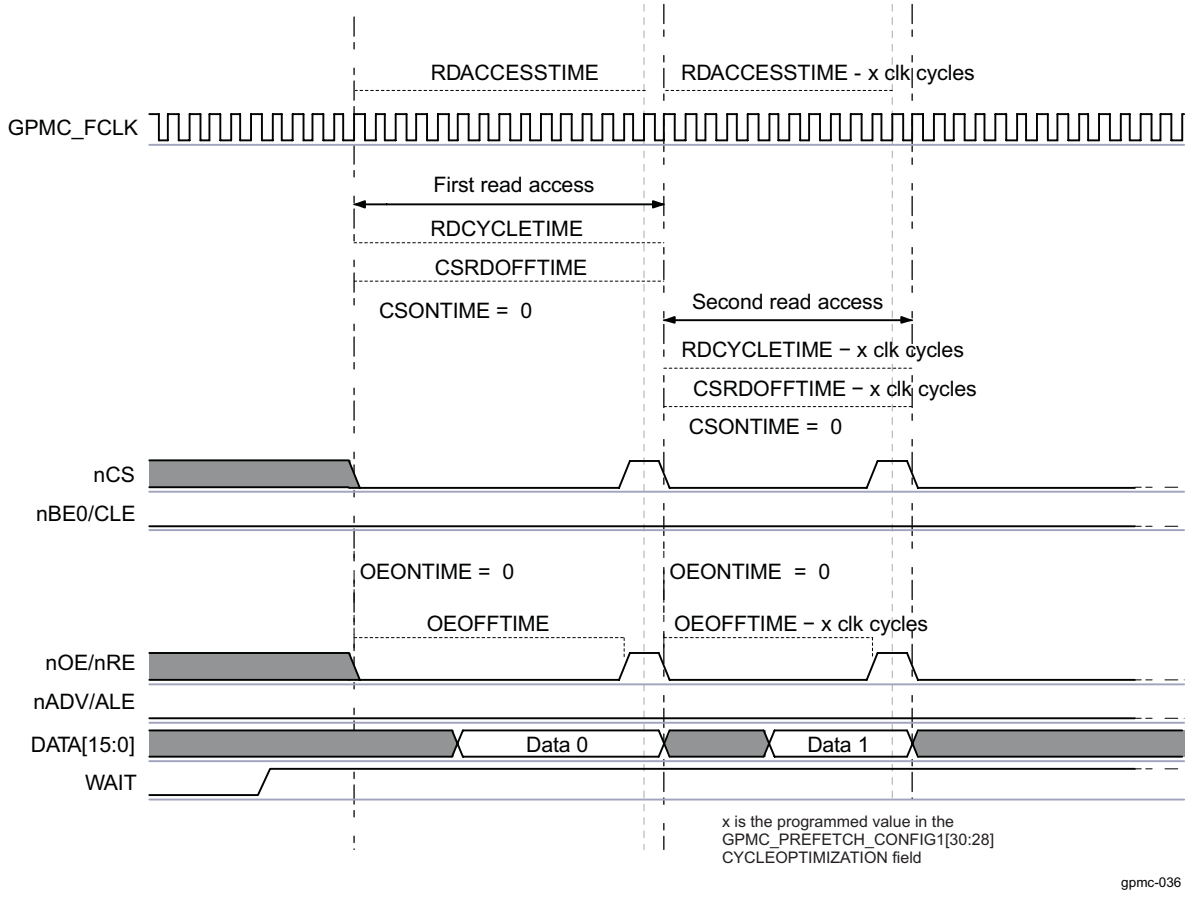
9.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC_NAND_DATA_i location, I = 0 to 7) are never optimized.

The GPMC.GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 9-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 9-36. NAND Read Cycle Optimization Timing Description



9.1.5.14.4.7 Interleaved Accesses between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

9.1.6 GPMC Use Cases and Tips

9.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

9.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Manufacturer: NOR Flash
- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

9.1.6.1.2 Typical GPMC Setup

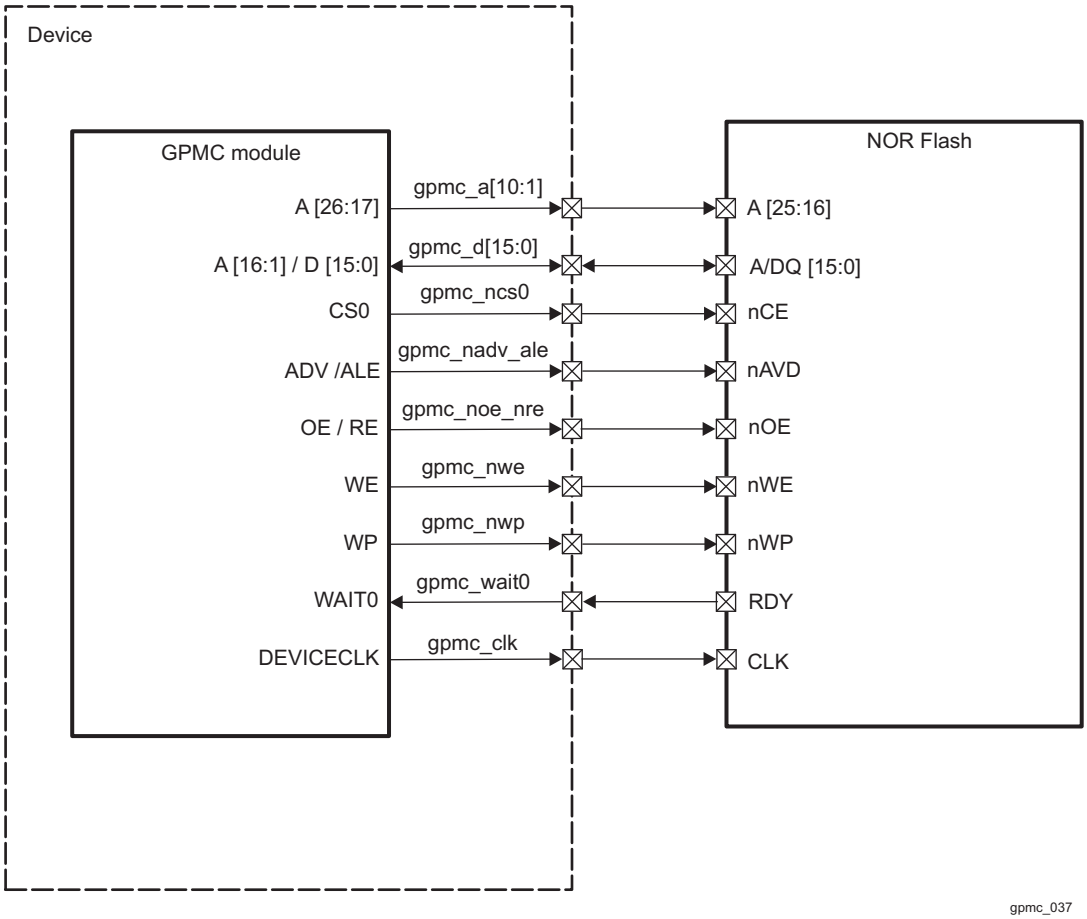
Table 9-17 lists some of the I/Os of the GPMC module.

Table 9-17. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk	I/O	External clock provided to the external device for synchronous operations
gpmc_a[10: 1]	O	Address
gpmc_d[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncs	O	Chip-select
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[3:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 9-37 shows the typical connection between the GPMC module and the attached NOR Flash memory.

Figure 9-37. GPMC Connection to External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

9.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 9-18 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-19 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-38 shows the synchronous burst read access.

Table 9-18. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80

Table 9-18. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

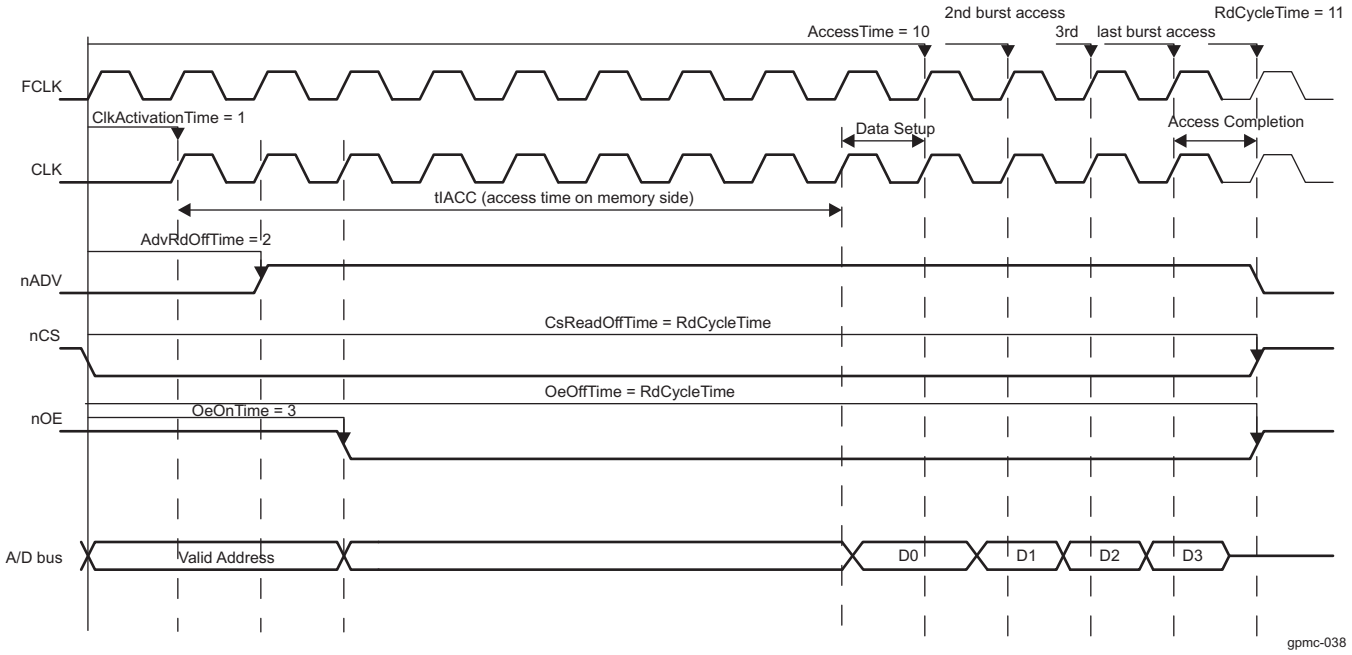
- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle (T = 9,615 ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 9-19. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94,03: (9,615 + 80 + 4,415)	10 : roundmax (94,03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5,2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	AccessTime + max (tCEZ, tOEZ)	101, 03: (94, 03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC)	-	3 for instance.	OEONTIME = 0x3
OeOffTime	RdCycleTime	-	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 9-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



9.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 9-20 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-21 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-39 shows the asynchronous read access.

Table 9-20. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 9-20: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

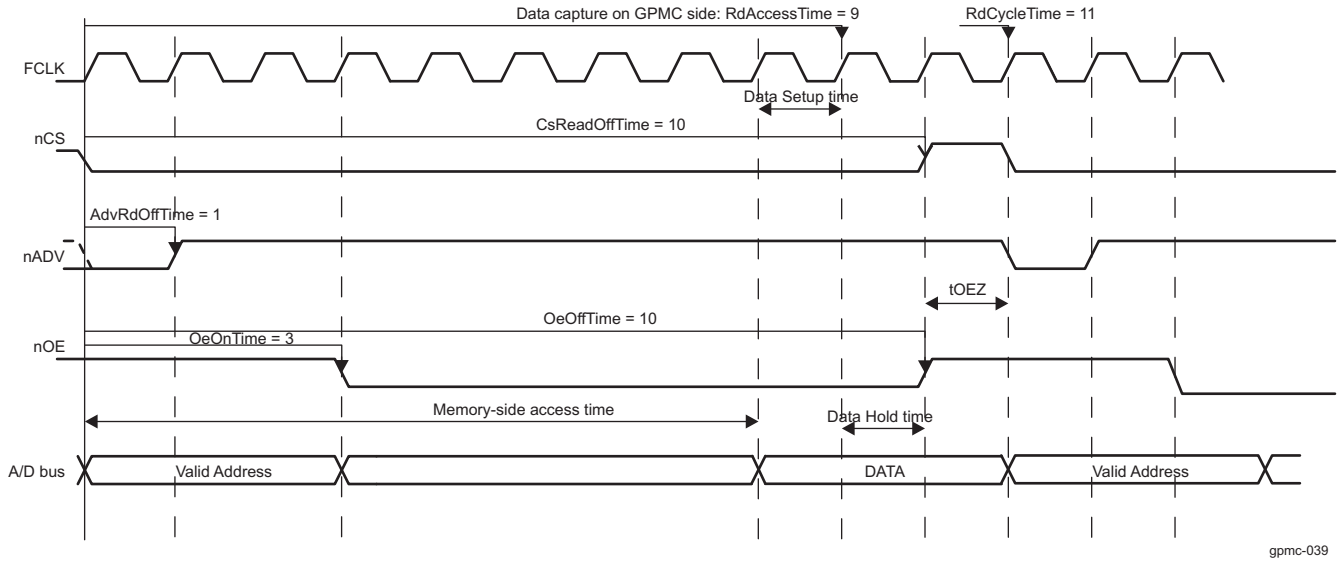
  The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (AccessTime + 1).

- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 9-21. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	9	ACCESSTIME = 0x09
PageBurstAccess Time	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = 0x0B
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = 0x0A
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3 for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFFTIME = 0x0A

Figure 9-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



9.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 9-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 9-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 9-40 shows the synchronous burst write access.

Table 9-22. AC Characteristics for Asynchronous Single Write (Memory Side)

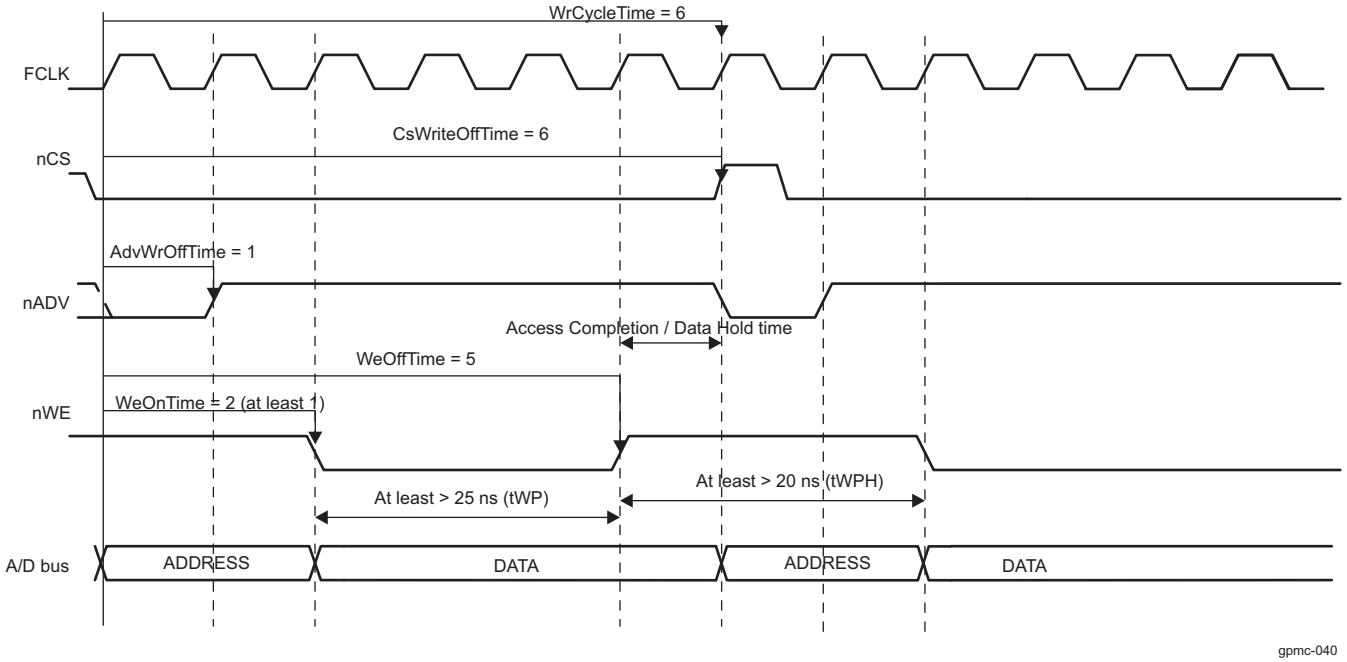
AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

Table 9-23. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

Figure 9-40. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)



9.1.6.2 How to Choose a Suitable Memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

9.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

9.1.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 9-24. Supported Memories Interfaces

Function	16-bit Address/Data muxed pSRAM or NOR Flash [1]	OneNAND	16-bit NAND	8-bit NAND
gpmc_a10	A26			
gpmc_a9	A25			
gpmc_a8	A24			
gpmc_a7	A23			
gpmc_a6	A22			
gpmc_a5	A21			
gpmc_a4	A20

gpmc_wait2	WAIT2		R/nB2	
gpmc_wait3	WAIT3		R/nB3	

9.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, i.e. read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 9-25 summarizes the NAND interface signals level applied to external device or memories.

Table 9-25. NAND Interface Bus Operations Summary

Bus operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H [2]	H [2]	H [2]	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L [3]

(1) RE stands for rising edge, FE stands for falling edge
(2) Can be either nCE high, or WE and nRE high.
(3) nWP should be biased to CMOS high or CMOS low for standby

9.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, i.e. is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 9-26 summarizes the NOR interface signals level applied to external device or memories.

Table 9-26. NOR Interface Bus Operations Summary

Bus operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

9.1.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

9.1.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum operating frequency provided externally: up to 100MHz (single device) with an L3-clock of 100MHz. Up to 83MHz (L3-clock divided by two) with an L3-clock of 166MHz. See the device-specific Data Manual for precise information.
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 128 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

9.1.7 GPMC Registers

This section provides information about the GPMC instance in this product. Table 9-28 provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

Table 9-27. Instance Summary

Module Name	Base Address	Size
GPMC	0x6E00 0000	16 Mbytes

9.1.7.1 GPMC Register Mapping Summary

Table 9-28. GPMC Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
GPMC_SYSCONFIG	RW	32	0x0000 0010	0x6E00 0010	Section 9.1.7.2.1

9.1.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

9.1.7.2.1 GPMC_SYSCONFIG

Table 9-29. GPMC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x6E00 0010	**Instance**	GPMC
Description	This register controls the various parameters of the Interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Reads return 0s.	RW	0x0000000
4:3	IDLEMODE	0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Do not use	RW	0x0
2	RESERVED	Write 0 for future compatibility Reads returns 0	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal Interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic Interface clock gating strategy is applied, based on the Interconnect activity	RW	0x0

9.1.7.2.2 GPMC_SYSSTATUS

Table 9-30. GPMC_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x6E00 0014	**Instance**	GPMC
Description	This register provides status information about the module, excluding the interrupt status information		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								RESERVED							RESETDONE

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reads returns 0	R	0x000000
7:1	RESERVED	Reads returns 0 (reserved for Interconnect-socket status information)	R	0x00
0	RESETDONE	Internal reset monitoring 0x0: Internal module reset in ongoing 0x1: Reset completed	R	0x-

9.1.7.2.3 GPMC_IRQSTATUS

Table 9-31. GPMC_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x6E00 0018	**Instance**	GPMC
Description	This interrupt status register regroups all the status of the module internal events that can generate an interrupt.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				WAIT3EDGEDETECTIONSTATUS	WAIT2EDGEDETECTIONSTATUS	WAIT1EDGEDETECTIONSTATUS	WAIT0EDGEDETECTIONSTATUS	RESERVED						TERMINALCOUNTSTATUS	FIFOEVENTSTATUS

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3EDGEDETECTION STATUS	Status of the Wait3 Edge Detection interrupt Read 0x0: A transition on WAIT3 input pin has not been detected Write 0x0: WAIT3EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT3 input pin has been detected Write 0x1: WAIT3EDGEDETECTIONSTATUS bit is reset	RW	0x0
10	WAIT2EDGEDETECTION STATUS	Status of the Wait2 Edge Detection interrupt Read 0x0: A transition on WAIT2 input pin has not been detected Write 0x0: WAIT2EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT2 input pin has been detected Write 0x1: WAIT2EDGEDETECTIONSTATUS bit is reset	RW	0x0
9	WAIT1EDGEDETECTION STATUS	Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected Write 0x0: WAIT1EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT1 input pin has been detected Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset	RW	0x0
8	WAIT0EDGEDETECTION STATUS	Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected Write 0x0: WAIT0EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT0 input pin has been detected Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00

Bits	Field Name	Description	Type	Reset
1	TERMINALCOUNTSTATUS	Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit unchanged Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset	RW	0x0
0	FIFOEVENTSTATUS	Status of the FIFOEvent interrupt Read 0x0: Indicates than less than FIFOThreshold bytes are available in prefetch mode and less than FIFOThreshold bytes free places are available in write-posting mode. Write 0x0: FIFOEVENTSTATUS bit unchanged Read 0x1: Indicates than at least FIFOThreshold bytes are available in prefetch mode and at least FIFOThreshold bytes free places are available in write-posting mode. Write 0x1: FIFOEVENTSTATUS bit is reset	RW	0x0

9.1.7.2.4 GPMC_IRQENABLE

Table 9-32. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x6E00 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				WAIT3EDGEDETECTIONENABLE	WAIT2EDGEDETECTIONENABLE	WAIT1EDGEDETECTIONENABLE	WAIT0EDGEDETECTIONENABLE	RESERVED						TERMINALCOUNTEVENTENABLE	FIFOEVENTENABLE

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3EDGEDETECTION ENABLE	Enables the Wait3 Edge Detection interrupt 0x0: Wait3EdgeDetection interrupt is masked 0x1: Wait3EdgeDetection event generates an interrupt if occurs	RW	0x0
10	WAIT2EDGEDETECTION ENABLE	Enables the Wait2 Edge Detection interrupt 0x0: Wait2EdgeDetection interrupt is masked 0x1: Wait2EdgeDetection event generates an interrupt if occurs	RW	0x0
9	WAIT1EDGEDETECTION ENABLE	Enables the Wait1 Edge Detection interrupt 0x0: Wait1EdgeDetection interrupt is masked 0x1: Wait1EdgeDetection event generates an interrupt if occurs	RW	0x0
8	WAIT0EDGEDETECTION ENABLE	Enables the Wait0 Edge Detection interrupt 0x0: Wait0EdgeDetection interrupt is masked 0x1: Wait0EdgeDetection event generates an interrupt if occurs	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTEVENT ENABLE	Enables TerminalCountEvent interrupt issuing in pre-fetch or write-posting mode 0x0: TerminalCountEvent interrupt is masked 0x1: TerminalCountEvent interrupt is not masked	RW	0x0
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt 0x0: FIFOEvent interrupt is masked 0x1: FIFOEvent interrupt is not masked	RW	0x0

9.1.7.2.5 GPMC_TIMEOUT_CONTROL

Table 9-33. GPMC_TIMEOUT_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x6E00 0040	**Instance**	GPMC
Description	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TIMEOUTSTARTVALUE												RESERVED			TIMEOUTENABLE

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
12:4	TIMEOUTSTARTVALUE	Start value of the time-out counter 0x000: Zero GPMC_FCLK cycle 0x001: One GPMC_FCLK cycle ... 0x1FF: 511 GPMC_FCLK cycles	RW	0x1FF
3:1	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
0	TIMEOUTENABLE	Enable bit of the TimeOut feature 0x0: TimeOut feature is disabled 0x1: TimeOut feature is enabled	RW	0x0

9.1.7.2.6 GPMC_ERR_ADDRESS

Table 9-34. GPMC_ERR_ADDRESS

Address Offset	0x0000 0044		
Physical Address	0x6E00 0044	**Instance**	GPMC
Description	The GPMC_ERR_ADDRESS register stores the address of the illegal access when an error occurs		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	ILLEGALADD																														

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
30:0	ILLEGALADD	Address of illegal access A30: 0 for memory region, 1 for GPMC register region A29-A0: 1 GBytes max	R	0x00000000

9.1.7.2.7 GPMC_ERR_TYPE

Table 9-35. GPMC_ERR_TYPE

Address Offset	0x0000 0048		
Physical Address	0x6E00 0048	**Instance**	GPMC
Description	The GPMC_ERR_TYPE register stores the type of error when an error occurs		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					ILLEGALMCMD			RESERVED			ERRORNOTSUPPADD	ERRORNOTSUPPMCMD	ERRORTIMEOUT	RESERVED	ERRORVALID

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10:8	ILLEGALMCMD	System Command of the transaction that caused the error	R	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	ERRORNOTSUPPADD	Not supported Address error 0x0: No error occurs 0x1: The error is due to a non supported Address	R	0x0
3	ERRORNOTSUPPMCMD	Not supported Command error 0x0: No error occurs 0x1: The error is due to a non supported Command	R	0x0
2	ERRORTIMEOUT	Time-out error 0x0: No error occurs 0x1: The error is due to a time out	R	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	ERRORVALID	Error validity status - Must be explicitly cleared with a write 1 transaction 0x0: All error fields no longer valid 0x1: Error detected and logged in the other error fields	RW	0x0

9.1.7.2.8 GPMC_CONFIG

Table 9-36. GPMC_CONFIG

Address Offset	0x0000 0050		
Physical Address	0x6E00 0050	**Instance**	GPMC
Description	The configuration register allows global configuration of the GPMC		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				WAIT3PINPOLARITY	WAIT2PINPOLARITY	WAIT1PINPOLARITY	WAIT0PINPOLARITY	RESERVED			WRITEPROTECT	RESERVED		LIMITEDADDRESS	NANDFORCEPOSTEDWRITE

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3PINPOLARITY	Selects the polarity of input pin WAIT3 0x0: WAIT3 active low 0x1: WAIT3 active high	RW	0x1
10	WAIT2PINPOLARITY	Selects the polarity of input pin WAIT2 0x0: WAIT2 active low 0x1: WAIT2 active high	RW	0x0
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	WRITEPROTECT	Controls the WP output pin level 0x0: WP output pin is low 0x1: WP output pin is high	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1	LIMITEDADDRESS	Limited Address device support 0x0: No effect 0x1: A26-A11 are not modified during an external memory access.	RW	0x0
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

9.1.7.2.9 GPMC_STATUS

Table 9-37. GPMC_STATUS

Address Offset	0x0000 0054		
Physical Address	0x6E00 0054	**Instance**	GPMC
Description	The status register provides global status bits of the GPMC		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				WAIT3STATUS	WAIT2STATUS	WAIT1STATUS	WAIT0STATUS	RESERVED							EMPTYWRITEBUFFERSTATUS

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
11	WAIT3STATUS	Is a copy of input pin WAIT3. (Reset value is WAIT3 input pin sampled at IC reset) 0x0: WAIT3 asserted (inactive state) 0x1: WAIT3 de-asserted	R	0x-
10	WAIT2STATUS	Is a copy of input pin WAIT2. (Reset value is WAIT2 input pin sampled at IC reset) 0x0: WAIT2 asserted (inactive state) 0x1: WAIT2 de-asserted	R	0x-
9	WAIT1STATUS	Is a copy of input pin WAIT1. (Reset value is WAIT1 input pin sampled at IC reset) 0x0: WAIT1 asserted (inactive state) 0x1: WAIT1 de-asserted	R	0x-
8	WAIT0STATUS	Is a copy of input pin WAIT0. (Reset value is WAIT0 input pin sampled at IC reset) 0x0: WAIT0 asserted (inactive state) 0x1: WAIT0 de-asserted	R	0x-
7:1	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x00
0	EMPTYWRITEBUFFERSTATUS	Stores the empty status of the write buffer 0x0: Write Buffer is not empty 0x1: Write Buffer is empty	R	0x1

9.1.7.2.10 GPMC_CONFIG1_i

Table 9-38. GPMC_CONFIG1_i

Address Offset	0x0000 0060 + (0x0000 0030 * I)	**Index**	I = 0 to 7
Physical Address	0x6E00 0060 + (0x0000 0030 * I)	**Instance**	GPMC
Description	The configuration register 1 sets signal control parameters per chip-select		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRAPBURST		READMULTIPLE		READTYPE		WRITEMULTIPLE		WRITETYPE		CLKACTIVATIONTIME				ATTACHEDDEVICEPAGELENGTH		WAITREADMONITORING		WAITWRITEMONITORING		RESERVED		WAITMONITORINGTIME				WAITPINSELECT		RESERVED		DEVICESIZE		DEVICETYPE		MUXADDDATA		RESERVED				TIMEPARAGRANULARITY		RESERVED		GPMCFCLKDIVIDER	

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read Asynchronous 0x1: Read Synchronous	RW	0x0
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write Asynchronous 0x1: Write Synchronous	RW	0x0
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0
24:23	ATTACHEDDEVICEPAGE LENGTH	Specifies the attached device page (burst) length 0x0: 4 Words 0x1: 8 Words 0x2: 16 Words 0x3: Reserved (1 Word = Interface size)	RW	0x0

Bits	Field Name	Description	Type	Reset
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is BOOTWAITEN input pin sampled at IC reset) 0x0: Wait pin is not monitored for read accesses 0x1: Wait pin is monitored for read accesses	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses 0x1: Wait pin is monitored for write accesses	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input WAIT pin for this chip-select (Reset value is BOOTWAITSELECT input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Wait input pin is WAIT0 0x1: Wait input pin is WAIT1 0x2: Wait input pin is WAIT2 0x3: Wait input pin is WAIT3	RW	0x-
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESIZE	Selects the device size attached (Reset value is BOOTDEVICESIZE input pin sampled at IC reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR Flash like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND Flash like devices, stream mode 0x3: Reserved	RW	0x0
9	MUXADDDATA	Enables the Address and data multiplexed protocol (Reset value is CS0MUXDEVICE input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Non Multiplexed attached device 0x1: Address and data multiplexed attached device	RW	0x-
8:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (Rd/WrCycleTime, Rd/WrAccessTime, PageBurstAccessTime, CSOnTime, CSRd/WrOffTime, ADVOnTime, ADVRd/WrOffTime, OEOnTime, OEOffTime, WEOnTime, WEOffTime, Cycle2CycleDelay, BusTurnAround, TimeOutStartValue) 0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0

Bits	Field Name	Description	Type	Reset
1:0	GPMCFCLKDIVIDER	Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency /4	RW	0x0

9.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem.

9.2.1 SDRC Subsystem Overview

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

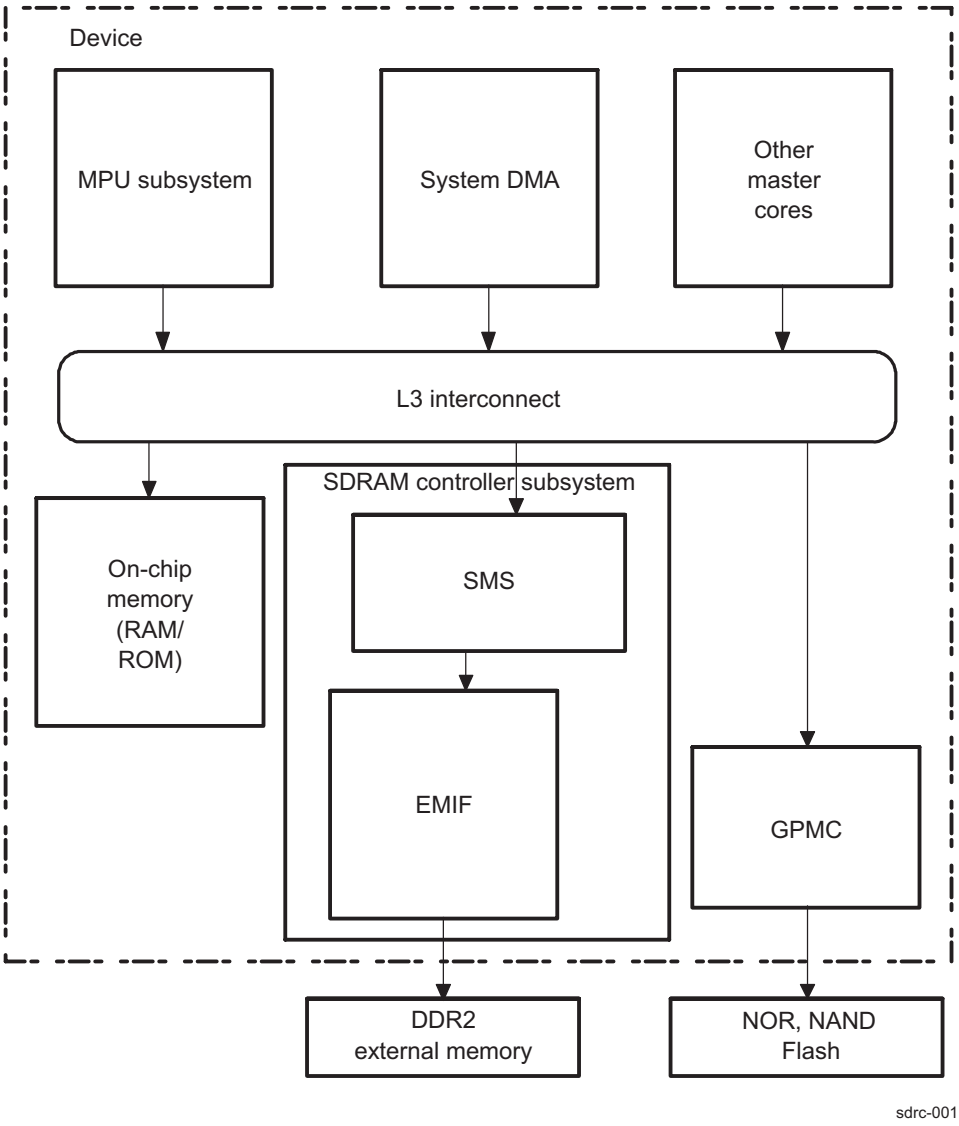
The SDRC subsystem module provides connectivity between the processor and external discrete DDR SDRAM.

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

- The SDRAM Memory Scheduler (SMS), consisting of scheduler, security firewall, and virtual rotated frame-buffer (VRFB) modules.
- EMIF (External Memory Interface).

Figure 9-41 shows the SDRC subsystem environment.

Figure 9-41. SDRC Subsystem Environment



9.2.1.1 Features

The main features of the SDRC subsystem module are:

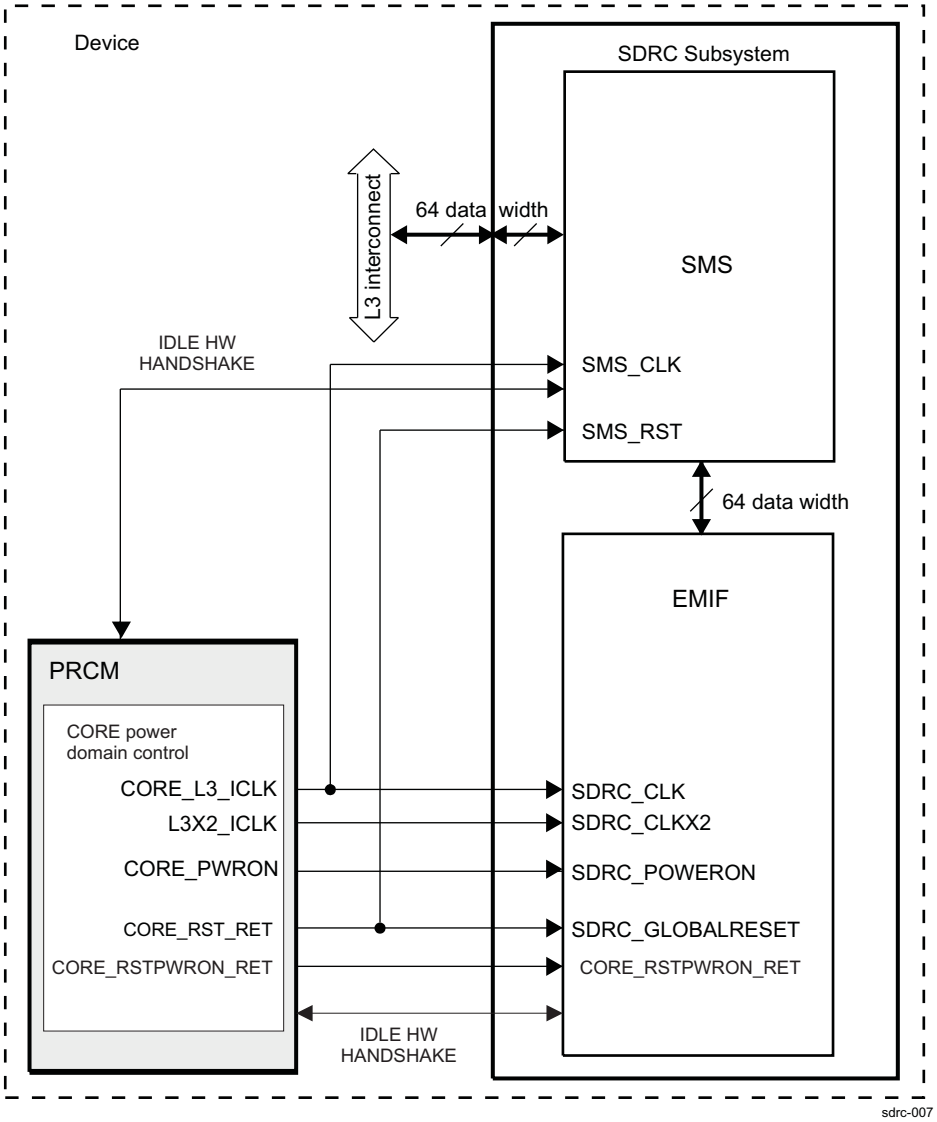
- Security firewall
  - Eight regions can be defined.
  - Independently programmable read/write access control
  - Independently programmable security control
- VRFB module
  - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
  - Supports rotations of 0, 90, 180, and 270 degrees
  - Transparent to software applications
  - 12 concurrent rotation contexts
- Memory-access scheduler
  - Optimizes latency and bandwidth usage between initiators
  - Supports secure transactions controlled by security firewall
  - Per-system initiator group quality-of-service (QoS) control
  - 8 × 8 × 64 request queue FIFO for optimal scheduling
  - Programmable arbitration scheme
  - Focus on real-time memory processes (LCD display, camera interface)
  - Focus on MPU memory latency
  - Fair arbitration between other system initiators (DMAs, video subsystem, SGX accelerator)
  - Exclusive read-write transaction support
  - Region-based security firewall in accordance with processor security management

For EMIF features see Section 9.2.3.4.1.1, *Features Supported*.

9.2.2 SDRC Subsystem Integration

Figure 9-42 shows how the SMS and EMIF modules are integrated into the processor and how they interact with the PRCM module.

Figure 9-42. SDRC Integration to the Processor



9.2.2.1 Clocking, Reset, and Power Management Scheme

9.2.2.1.1 Clocking

9.2.2.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the EMIF interface, and all internal operations.

SMS_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS_CLK is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

9.2.2.1.1.2 EMIF

The EMIF is a single-clock domain module. The same clock is used for both the interconnect and the memory interface. The SDRC_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC_CLK is also used as a functional clock for the EMIF .

The SDRC_CLK clock source is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

An SDRC_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC_CLK clock.

As a power-saving feature, when the EMIF no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN_SDRC bit in the PRCM.CM_ICKLEN1_CORE[1] register.

9.2.2.1.2 Hardware Reset

Global reset of the EMIF is done by activating the CORE_RST signal in the CORE_RST domain (see the *Power, Reset, and Clock Management* chapter).

There is one global reset signal, SDRC_GLOBALRESET, which is qualified by the signal SDRC_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC_POWERON = 0 and SDRC_GLOBALRESET is applied), all registers and state-machines within the EMIF are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC_POWERON = 1 when SDRC_GLOBALRESET is applied), the EMIF registers and the FSM are not reset, but the EMIF takes care of completing the ongoing access and putting the external memory into self-refresh mode.

9.2.2.1.3 Software Reset

The SMS modules can be reset under software control through the SMS.SMS_SYSCONFIG[1] SOFTRESET bit.

A software reset has the same action as a hardware cold reset, that is, the FSM and all registers are reset immediately and unconditionally.

9.2.3 SDRC Subsystem Functional Description

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A security firewall that controls access protection to the memory
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

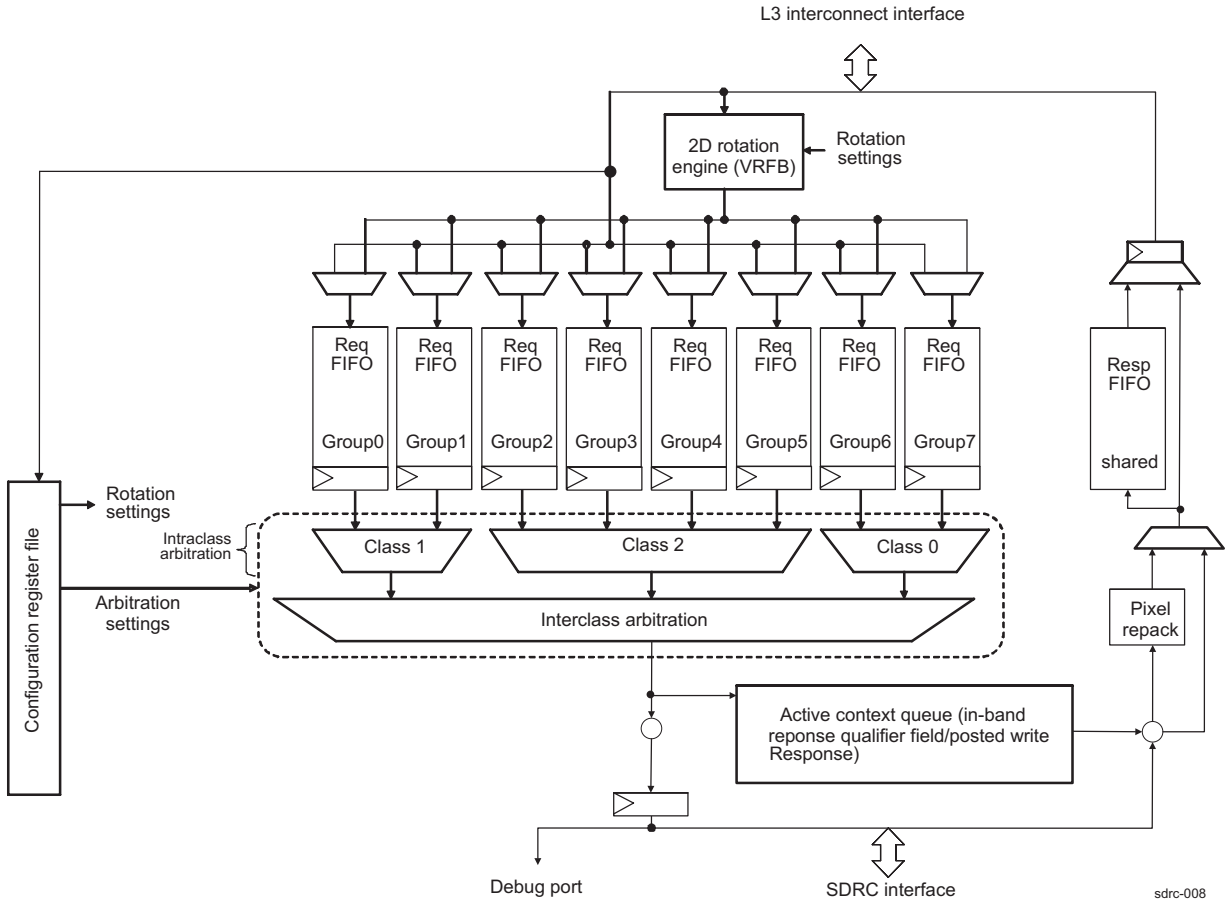
9.2.3.1 SDRAM Memory Scheduler

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: rotation engine (RE)
- Configuration register file
- Security check unit
- Request buffers
- Arbitration logic
- EMIF interface: master port
- Debug port
- Response buffer

Figure 9-43 shows the top-level diagram of the SMS.

Figure 9-43. SMS Top-Level Diagram



9.2.3.1.1 Memory Access Scheduling

NOTE: For a description of the SMS mode of operation and arbitration policy, see Section 9.2.5, *SDRC Use Cases and Tips*.

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues. Security firewall comes after the FIFOs.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- Class 0 (highest priority): For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. LCD or video display cores belong to this category.
- Class 1: For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- Class 2: For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

Table 9-61 shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

Table 9-61. Arbitration Class Allocation

Class	FIFO Queue	Source Device
0	7	Display
1	0	MPU subsystem (instruction and data access)
	1	
2	2	sDMA WR
	3	SGX
	4	USB (HS + FS), DAP, CCDC, USB-OTG, EMAC
	5	sDMA (read)

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

NOTE: In the register description, a group represents a FIFO queue of requests from the initiator.

9.2.3.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the EMIF . The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the EMIF .

- Intra-class arbitration: A first level of arbitration is done in parallel within each class between the different thread groups (request FIFOs).

- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

9.2.3.1.2.1 Arbitration Policy within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the EMIF request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the EMIF request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOfServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOfServices features.

9.2.3.1.2.2 Burst-Complete Feature (BURST-COMPLETE Field in SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, SMS_CLASS_ARBITER2)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS, or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the BURST-COMPLETE field of the SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, and SMS_CLASS_ARBITER2 registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

9.2.3.1.2.3 ExtendedGrant Feature (EXTENDEDGRANT Field in SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, SMS_CLASS_ARBITER2)

EXTENDEDGRANT is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). EXTENDEDGRANT is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the EXTENDEDGRANT field of the SMS_CLASS_ARBITER0, SMS_CLASS_ARBITER1, and SMS_CLASS_ARBITER2 registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOfServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

9.2.3.1.2.4 NOfServices Feature (SMS.SMS_CLASS_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOfServices is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS_CLASS_ROTATIONm registers. The allowable range is 1 to 31.

The NOfServices logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOfServices scheme of class 1/class 2. Within a NOfService window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOfServices completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOfservices window starts with the last NOfServices counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOfServices.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the EMIF side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOfServices counter is reloaded with its programmed value when it reaches 0.

9.2.3.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOfServices counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOfServices times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS_CLASS_ARBITER0[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOfServices strategy and then the grant is given to the high-priority thread.

9.2.3.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
  - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
  - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see Section 9.2.5.2.2.3.
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the

thread that is not in its high-priority window.

- NOfServices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
  - Current burst service lock (assuming subsequent burst requests available when required)
  - Class 0
  - ExtendedGrant and NOfServices atomicity (assuming subsequent burst requests available when required)
  - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
  - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

9.2.3.1.4 Security Firewall

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64 Kbytes granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0. This region has security attributes programmable in the same manner as the other regions.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.SMS_RG_RDPERMi register.
- The write permission is initiator-based and is controlled using the SMS.SMS_RG_WRPERMi register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Security, debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.SMS_RG_ATTi[31:0] REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.SMS_RG_ATTi[31:0] REQINFO field.

Table 9-62 lists the security ReqInfo parameters ordering.

Table 9-62. Security ReqInfo Parameters Ordering

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	**0: User 1: Supervisor**	**0: Public 1: Secure**	**0: Functional 1: Debug**	**0: Data Transfer 1: Opcode Fetch**		
N/A [1]						0b0…000000000
0	0	0	0	0	0	0b0…000000001
0	0	0	0	0	1	0b0…000000010
0	0	0	1	0	2	0b0…000000100
					…	
0	1	1	1	0	14	0b0…000001…00
0	1	1	1	1	15	0b0…00001…000
1	0	0	0	0	16	0b0…0001…0000
1	0	0	0	1	17	0b0…001…00000
					…	
1	1	1	0	1	29	0b0010…000000

(1) Access to the region is not allowed

Table 9-62. Security ReqInfo Parameters Ordering (continued)

Host	Privilege	Security	Debug	Type	Req Info	SMS.SMS_RG_ATTi[31:0] REQINFO Field
0: Nonhost 1: Host	0: User 1: Supervisor	0: Public 1: Secure	0: Functional 1: Debug	0: Data Transfer 1: Opcode Fetch		
1	1	1	1	0	30	0b0100…000000
1	1	1	1	1	31	0b1000…000000

When all SMS_RG_ATTi[31:0] REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Public-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Public-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Secure-Debug-Opcode accesses are permitted in this region.

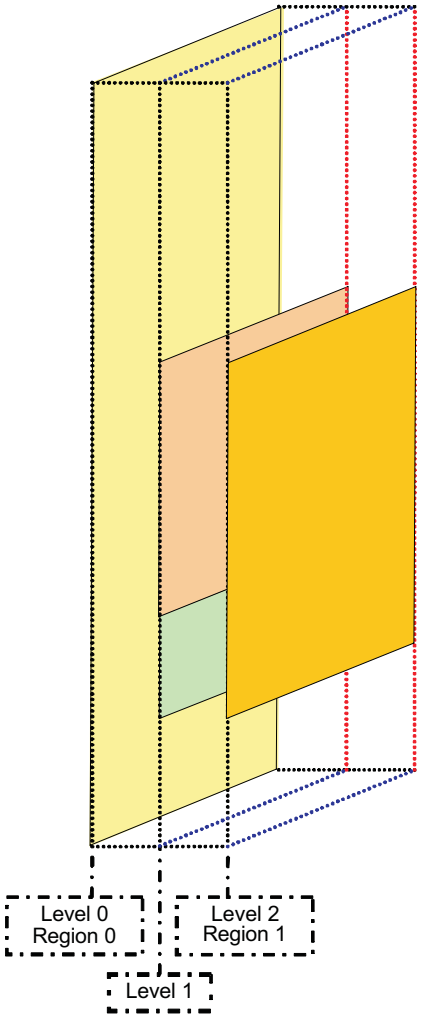
Any bit of the SMS_RG_ATTi[31:0] REQINFO field corresponds to a particular combination of the five attribute bits. When all SMS_RG_ATTi[31:0] REQINFO bits are set to 1 the region is full-access allowed.

The security unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of security regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (security, debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in security priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see Figure 9-44).

Figure 9-44. Security Region Organization



Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2–7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a security violation when an access to the concerned region occurs. This security violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a security violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular EMIF responses.

To program a rotation context, set the security level per context through the SMS.SMS_SECURITY_CONTROL ROTCTXTiLOCK bits (i = [0:11]). That is, on context i: are all transactions allowed or is access restricted to secure transactions only?

9.2.3.1.5 Rotation Engine

Applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU free for other tasks. For a description of the RE mechanism, see Section 9.2.5, *SDRC Use Cases and Tips*.

The SMS includes address processing support for rotated displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the EMIF .

NOTE: The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in Section 9.2.3.1.5.3, *VRFB Configuration Port*.

9.2.3.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768 Mbytes address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. Table 9-63 details the address space of each context.

Table 9-63. VRFB Contexts Virtual Address Spaces vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000

Table 9-63. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)

Context Number	0°	90°	180°	270°
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

CAUTION

There is no protection in hardware for accesses outside the image resolution. Users can access the full virtual address range for a given context (there is no error reporting). Accessing outside of the image resolution creates aliasing within the image and is also translated as an additional physical memory space requirement on the external memory (some data outside of the image range can be overwritten by mistake). The following formula can be used to calculate the extra memory that will be accessed:
extra_mem_size = (2048-image_width_roundedup) x page_heigth x pixel_size with image_width_roundedup = [ROUNDUP(image_width x pixel_size/page_width)] x page_width/pixel_size.

9.2.3.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

9.2.3.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 Mbytes (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field
- SMS.SMS_ROT_SIZEn[26:16] IMAGEHEIGHT and SMS.SMS_ROT_SIZEn[10:0] IMAGEWIDTH fields
- SMS.SMS_ROT_CONTROLn[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.SMS_ROT_CONTROLn[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.SMS_ROT_SIZEn[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see Section 9.2.4.2 , *VRFB Context Configuration*.

9.2.3.1.6 Register Security

For the following register groups, use the SMS.SMS_SECURITY_CONTROL register to independently restrict permission to write to the SMS registers to secure accesses:

- VRFB context configuration registers (independently for each context)

- Memory-access scheduler arbitration registers
- Firewall registers, soft reset bit, error registers, and the security control register itself

Writing restrictions to the security firewall memory region registers (including SMS.SMS_SECURITY_CONTROL) depend on the control module configuration.

If an illegal access is attempted (for example, a nonsecure write access to a register configured as secure), a security violation is indicated to the security module. The address where the security violation occurs and the type of violation can be read from the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers.

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

9.2.3.1.7 Security Violation Reporting

The SMS firewall can detect security violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access
- The out-of-band error signal generation using two out-of-band error signals

Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band security violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the SMS_ERR_TYPE register.

9.2.3.2 Module Power Saving

Power-saving is managed through the SMS.SMS_SYSCONFIG register.

The SMS_SYSCONFIG[4:3] SIDLEMODE field defines the power management strategy (Force Idle mode, No Idle mode, or Smart Idle mode). See Section 9.2.3.3 for more details on the system power management.

By default, the internal interface clock gating strategy is enabled as the SMS_SYSCONFIG[0] AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the SMS_POW_CTRL[7:0] IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

9.2.3.3 System Power Management

The SMS can be configured through the SMS.SMS_SYSCONFIG register to be in one of these idle modes:

- No-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x2): SidleAck is asserted once the module has confirmed there are no more outstanding transactions with the EMIF .

9.2.3.4 External Memory Interface Module (EMIF)

9.2.3.4.1 EMIF Overview

This document is intended to provide programmers with a functional presentation of the External memory Interface module. It provides a register description. In this specification, the External memory Interface will be named EMIF.

9.2.3.4.1.1 Features Supported

The main features of the controller are:

- Open Core Protocol 2.2 (OCP) compliant [7].
- Supports JEDEC standard compliant DDR2 [2] and LPDDR1 [4] devices.
  - SDRAM address range over 2 chip selects.
  - Supports following data bus widths:

OCP Data Bus Width	SDRAM Data Bus Width
64 and 128-Bit	16, 32, and 64-Bit

  - Supports following CAS latencies:

SDRAM Type	CAS Latencies
DDR2	2, 3, 4, 5, and 6
LPDDR1	2 and 3

  - Supports following number of internal banks:

SDRAM Type	Internal Banks
DDR2	1, 2, 4, and 8
LPDDR1	1, 2, and 4

  - Supports 256, 512, 1024, and 2048-word page sizes.
  - Supports following burst lengths:

SDRAM Type	Burst Length
DDR2	8 (4 not supported)
LPDDR1	8 (2 and 4 not supported)

  - Supports sequential burst type.
  - SDRAM auto initialization from reset or configuration change.
  - Supports Bank Interleaving across both the chip selects.
  - Supports Clock Stop mode for LPDDR1 for low power.
  - Supports Self Refresh and Precharge Power-Down modes for low power.
  - Supports Partial Array Self Refresh and Temperature Controlled Self Refresh modes for low power in LPDDR1.
  - Temperature Controlled Self Refresh is only supported for mobile SDRAM having on-chip temperature sensor.
  - Supports ODT on DDR2.
  - Supports prioritized refresh.
  - Programmable SDRAM refresh rate and backlog counter.
  - Programmable SDRAM timing parameters.
  - Supports only little endian.

9.2.3.4.1.2 Features Not Supported

- Interleave burst type not supported.
- Auto Precharge not supported for better Bank Interleaving performance.
- OCD calibration not supported for DDR2.
- Active Power-Down is not supported.

9.2.3.4.2 Functional Description

9.2.3.4.2.1 Functional Overview

The External Memory Interface (EMIF) is a TI developed re-usable IP component targeted for SOC designs, "4" is the major version number and "A" is the configuration type. The EMIF is an OCP slave peripheral providing an interface to a wide variety of DDR SDRAM. This memory controller is a soft macro and must be used with the DDR PHY hard macros to interface to the DDR SDRAM.

Figure 9-45. EMIF4 Top Level Block Diagram

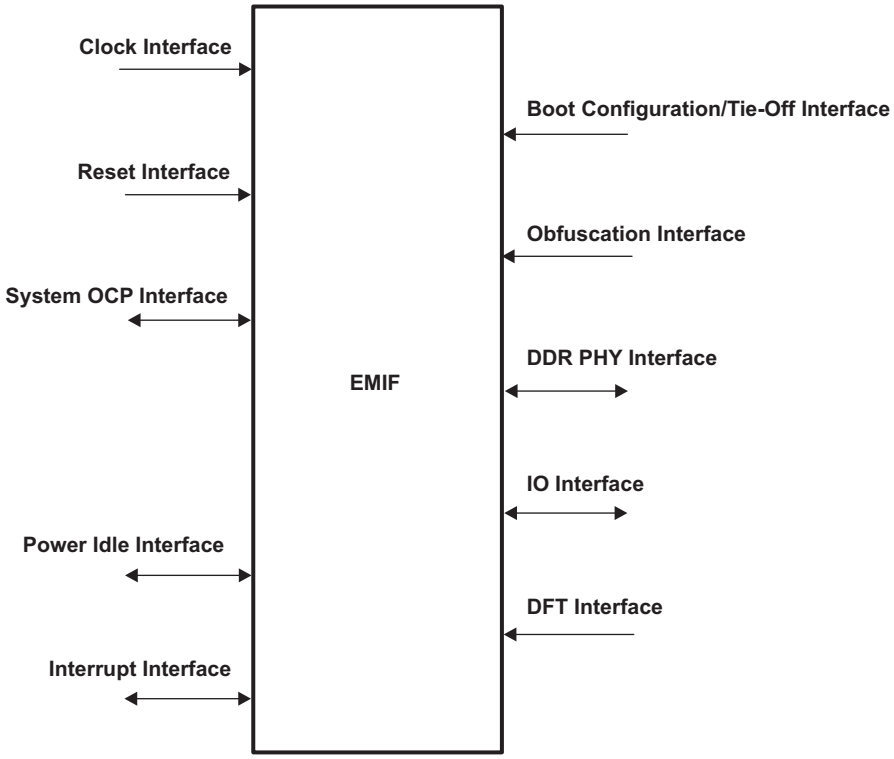


Table 9-64 shows the FIFO configurations of the EMIF.

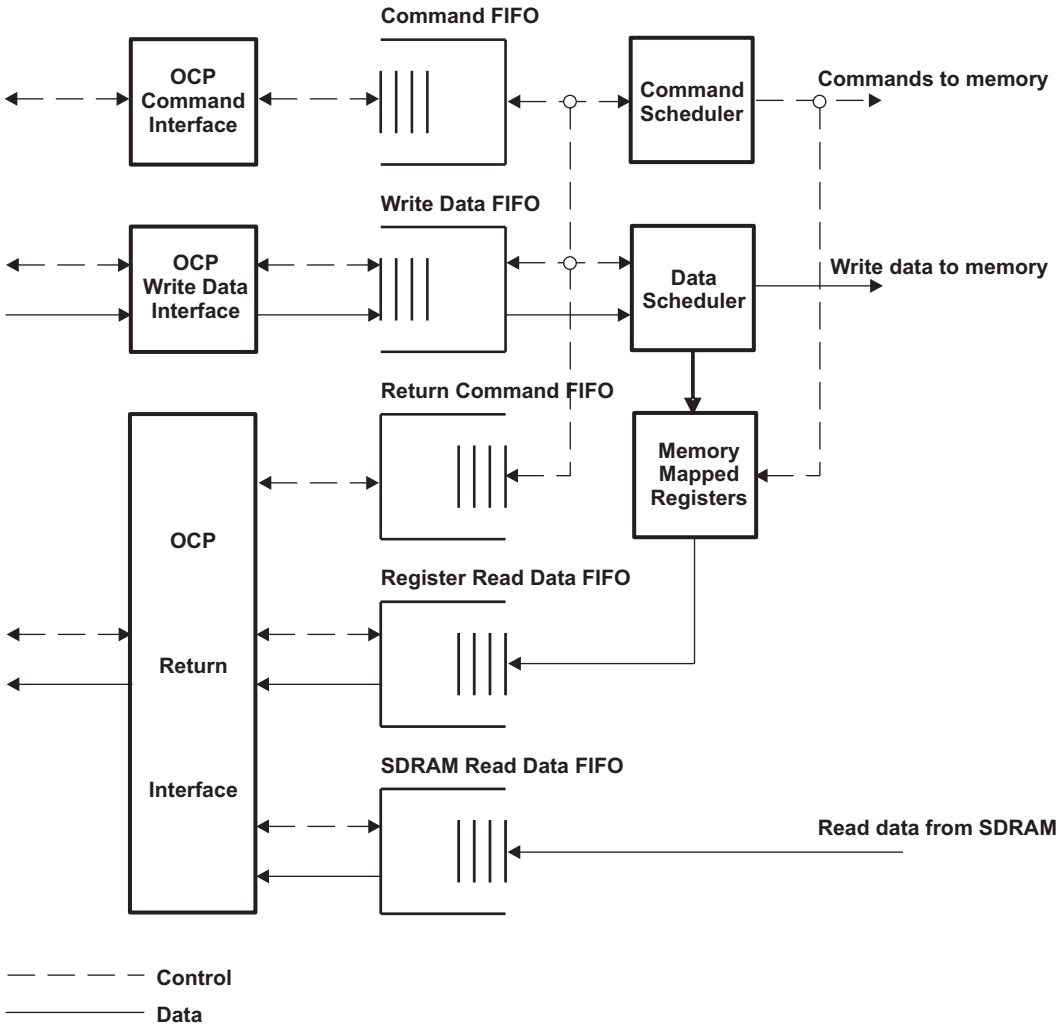
Table 9-64. EMIF4A Configuration

Parameter	Value
OCP and Memory Clock Domains	Asynchronous
Command FIFO Entries	7
Write Data FIFO Entries	14
Return Command FIFO Entries	22
SDRAM Read Data FIFO Entries	22
Register Read Data FIFO Entries	2

9.2.3.4.2.2 EMIF4 Architecture

Figure 9-46. EMIF4 Block Diagram



The EMIF contains a Command FIFO, a Write Data FIFO, a Return Command FIFO, and two Read Data FIFOs. These FIFOs are built using flip-flops.

The Command FIFO stores all the commands coming in on the OCP command interface. If the Write Data FIFO is not full, SCmdAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SCmdAccept.

The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface. If the Write Data FIFO is not full, SDataAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SDataAccept. The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface. If the Write Data FIFO is not full, SDataAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SDataAccept.

The Return Command FIFO stores all the return transactions that are to be issued to the OCP return interface. These include the write status return and the read data return commands.

There are two Read Data FIFOs that store the read data to be sent to the OCP return interface. One Read Data FIFO stores read data from the memory mapped registers. The other Read Data FIFO stores read data from external memory.

A write command is executed only when four OCP words of the corresponding data is received in the Write Data FIFO, or MDataLast is set, and if there is space in the Return Command FIFO. The EMIF will schedule a read only if the results can fit into both the Return Command FIFO and the corresponding Read Data FIFOs.

9.2.3.4.2.3 OCP Interface

The EMIF supports one OCP interface that connects to the system interconnect. This interface is used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to/from the EMIF. Table 9-65 shows the MAddrSpace mapping to different chip selects.

Table 9-65. MAddrSpace Mapping to Chip Selects

MAddrSpace	Chip Select	Description
0x0	pad_cs_o_n[1:0]	SDRAM
0x1	N/A	Reserved
0x2	N/A	Reserved
0x3	N/A	Internal registers

The EMIF only supports Idle, Write, Read, and WriteNonPost command types (as indicated by MCmd). If an access request for an unsupported command type is received, the EMIF will send out an interrupt and treat WriteConditional and Broadcast as a Write commands, and ReadEx and ReadLinked as a Read commands. In this case, the EMIF will perform writes on the memory bus with pad_dqm_o_n set to all ones. It will not perform writes to memory mapped registers. It will perform reads on the memory bus as well as memory mapped registers, but will return all zeros for read data.

The EMIF only supports incrementing, wrapping, and 2-dimensional block addressing modes (as indicated by MBurstSeq). If an access request for an unsupported addressing mode is received, the EMIF will send out an interrupt and treat the request as an incrementing request. In this case, the EMIF will perform writes on the memory bus with pad_dqm_o_n set to all ones. It will not perform writes to memory mapped registers. It will perform reads on the memory bus as well as memory mapped registers, but will return all zeros for read data.

If an access request to an unsupported MAddrSpace is received, the EMIF will send out an interrupt. In this case, the EMIF will not perform any writes or reads. However, it will return all zeros for read data.

For all of the above errored transactions, the EMIF will report an error (SResp = 3) on the OCP return interface. The EMIF will also log the MConnID, MCmd, MBurstSeq, and MAddrSpace for the first errored transaction in the OCP Error Log register.

The EMIF supports command priorities through the MReqPriority sideband signal. It supports 8 levels of priority. A value of 0 indicates highest priority and a value of 7 indicates lowest priority.

9.2.3.4.2.4 Arbitration

The EMIF looks at all the commands stored in the Command FIFO to schedule commands to the external memory. All commands with the same MTagID will complete in order, regardless of the MAddrSpace and MReqPriority. The EMIF does not guarantee ordering between commands with different MTagID. However, the EMIF will maintain data coherency. Therefore, the EMIF will block a command, regardless of priority, if that command is to the same block address (2048 bytes) as an older command.

Thus, the EMIF might have one pending read or write for each MTagID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of the above reordering, the EMIF might now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF might now have a final read and a final write command. If the Return Command FIFO and the Read Data FIFO has space and the external bus conflict

is resolved, the EMIF performs the final read command before the final write command. If the Return Command FIFO has space but the Read Data FIFO is full and the external bus conflict is resolved, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command to command counters are satisfied and the read to write or write to read turn around time is met.

The EMIF does not support tag interleaving (tag_interleave_size = 0). In other words, the EMIF completes executing an OCP command before it switches to another command.

The data coherency inside the EMIF is only guaranteed in a single level of OCP infrastructure. For example, if a write from a secondary OCP bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, in order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the OCP wait status, it must perform the following sequence of operations:

1. Perform the required write.
2. Perform a dummy write to the EMIF Module ID and Revision register.
3. Perform a dummy read to the EMIF Module ID and Revision register.
4. Indicate to the other master that the data is ready to be read after completion of read in step 3.

The completion of read in step 3 ensures that the previous writes were done.

Apart from reads and writes the EMIF also needs to open and close SDRAM banks, and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are as follows:

1. (Highest priority) SDRAM refresh request due to Refresh Must level of refresh urgency reached.
2. OCP request for a read without a higher priority write.
3. SDRAM refresh request due to Refresh Need level of refresh urgency reached.
4. OCP request for a write.
5. SDRAM Activate commands.
6. SDRAM Deactivate commands.
7. SDRAM Deep Power-Down request.
8. SDRAM clock stop request.
9. SDRAM refresh request due to Refresh May or Release level of refresh urgency reached.
10. (Lowest priority) SDRAM self-refresh or SDRAM Power-Down request.

While performing the above listed scheduling algorithm, the EMIF might run into following two conditions:

1. A continuous stream of high priority commands can block lower priority commands.
2. A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

To avoid a continuous blocking effect, the EMIF momentarily raises the priority of the oldest command over all other commands when the number or memory accesses equals to the value programmed in the reg_pr_old_count field of the OCP Configuration register.

On top of the above scheduling, the highest priority condition is a rising edge on the rst_por_arst_n or rst_main_arst_n port (i.e. removal of reset). If this condition occurs, the EMIF abandons whatever it is currently doing and commences its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also commences its start-up sequence whenever the SDRAM Configuration register is written and reg_initref_dis field in SDRAM Refresh Control register is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF will ensure that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize the external bus utilization. In other words accesses to an SDRAM are issued back to back such that there are minimum idle cycles between any two accesses. This includes the scheduling listed above to minimize the overhead of opening and closing of SDRAM banks. All of these is done while fulfilling the access timing requirements of an SDRAM.

9.2.3.4.2.5 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is loaded with the reg_refresh_rate field value at reset. The interval counter decrements by one each cycle until it reaches zero at which point it reloads from reg_refresh_rate and restarts decrementing. The counter also reloads and restarts decrementing whenever the reg_refresh_rate field is updated.

The refresh backlog counter records the number of AUTO REFRESH commands the EMIF currently has outstanding. The backlog counter increments by one each time the interval counter reloads (unless it has reached its maximum value of 15). The backlog counter decrements by one each time the EMIF issues an AUTO REFRESH command (unless it is already at zero). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF should perform an auto refresh cycle (in which it issues AUTO REFRESH commands), as follows:

- Refresh May level is reached whenever the backlog count is greater than 0, to indicate that there is a refresh backlog, so if the EMIF is not busy and none of the SDRAM banks are open, it should perform an auto refresh cycle.
- Refresh Release level is reached whenever the backlog count is greater than 4, to indicate that the refresh backlog is getting high, so if the EMIF is not busy it should perform an auto refresh cycle even if any banks are open.
- Refresh Need level is reached whenever the backlog count is greater than 5, to indicate that the refresh backlog is getting high and the EMIF should raise the priority of performing an auto refresh cycle above that of servicing new memory write requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.
- Refresh Must level is reached whenever the backlog count is greater than 7, to indicate that the refresh backlog is getting excessive and the EMIF should perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.

The refresh counters do not operate when SDRAM has been put into self-refresh mode. Also, the refresh counters start tracking the missed refreshes only after initialization is complete.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting t_rfc (refer to the SDRAM Timing 3 register) cycles before re-checking the refresh levels. If the Refresh Release level is not reached, the EMIF starts another auto refresh cycle, otherwise it returns to the idle state where it can issue any command.

9.2.3.4.2.6 SDRAM Initialization

9.2.3.4.2.6.1 LPDDR1 Initialization

On coming out of reset if the reg_sdram_type field in the SDRAM Config register is equal to 1 and the reg_initref_dis bit in the SDRAM Refresh Control register is set to 0, the EMIF performs a LPDDR1 SDRAM initialization sequence as follows:

1. Drives pad_cke_o high and starts to continuously issues NOP commands.
2. After 16 SDRAM refresh rate intervals, issues a PRECHARGE command with pad_a_o[10] held high to indicate all banks. The SDRAM refresh rate is as defined in the reg_refresh_rate field description (see description of SDRAM Refresh Control register).
3. After 2 AUTO REFRESH commands, issues a LOAD MODE REGISTER command to the mode register (pad_ba_o[2:0] = 0x0) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:7]	0x0	Normal operation.
pad_a_o[6:4]	reg_cl[2:0]	CAS latency from SDRAM Config register.
pad_a_o[3]	0x0	Sequential burst type.
pad_a_o[2:0]	0x3	Burst length of 8.

4. Issues a LOAD MODE REGISTER command to the extended mode register (pad_ba_o[2:0] = 0x2) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:7]	0x0	Reserved.
pad_a_o[6:5]	reg_sdram_drive	Drive strength from SDRAM Config register.
pad_a_o[4:3]	0x0	Internal temperature compensated self-refresh.
pad_a_o[2:0]	reg_pasr	Partial array self-refresh from SDRAM Refresh Control register.

5. The EMIF performs an auto refresh cycle (see Refresh Controller section) after which it enters its idle state.

The EMIF also performs the initialization sequence whenever either of the SDRAM Configuration register is written. But in this case, the EMIF starts at step 3.

The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some LPDDR1 data sheets. The EMIF does not perform any transactions until the LPDDR1 initialization sequence is complete.

The reg_refresh_rate value at reset is config_refresh_def_val port value. When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 * reg_refresh_rate / input frequency. It is up to the user to tie off the config_refresh_def_val port with a correct value to meet the typical LPDDR1 device specified delay time of 200us between power-up and the application of the PRECHARGE all command.

9.2.3.4.2.6.2 DDR2 Initialization

On coming out of reset if the reg_sdram_type field in the SDRAM Configuration register is equal to 2 and the reg_initref_dis bit in the SDRAM Refresh Control register is set to 0, the EMIF performs a DDR2 SDRAM initialization sequence as follows:

1. Drives pad_cke_o low.
2. After 16 SDRAM refresh rate intervals, issues a NOP command with pad_cke_o held high. The SDRAM refresh rate is as defined in the reg_refresh_rate field description (see description of SDRAM Refresh Control register).
3. After 1 SDRAM refresh rate interval, issues a PRECHARGE command with pad_a_o[10] held high to indicate all banks.
4. Issues a LOAD MODE REGISTER command to the extended mode register 2 (pad_ba_o[2:0] = 0x2) with pad_a_o[15:0] = 0x0.
5. Issues a LOAD MODE REGISTER command to the extended mode register 3 (pad_ba_o[2:0] = 0x3) with pad_a_o[15:0] = 0x0.
6. Issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:13]	0x0	Reserved
pad_a_o[12]	0x0	Output buffer enabled
pad_a_o[11]	0x0	RDQS disable
pad_a_o[10]	!reg_ddr2_ddqs	Differential DQS enable value from SDRAM Configuration register
pad_a_o[9:7]	0x0	Exit OCD calibration mode
pad_a_o[6]	reg_ddr_term[1]	DDR2 termination resistor value from SDRAM Configuration register
pad_a_o[5:3]	0x0	Additive latency = 0
pad_a_o[2]	reg_ddr_term[0]	DDR2 termination resistor value from SDRAM Configuration register
pad_a_o[1]	reg_sdram_drive	SDRAM drive strength from SDRAM Configuration register
pad_a_o[0]	0x0	Enable DLL

7. Issues a LOAD MODE REGISTER command to the mode register (pad_ba_o[2:0] = 0x0) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:13]	0x0	Reserved
pad_a_o[12]	0x0	Fast exit active power-down exit time
pad_a_o[11:9]	reg_t_wr	Write recovery for auto precharge from SDRAM Timing 1 register
pad_a_o[8]	0x1	DLL reset
pad_a_o[7]	0x0	Normal mode
pad_a_o[6:4]	reg_cl[2:0]	CAS latency from SDRAM Configuration register
pad_a_o[3]	0x0	Sequential burst type
pad_a_o[2:0]	0x3	Burst length of 8

8. After 200 clock cycles, issues a PRECHARGE command with pad_a_o[10] held high to indicate all banks.
9. After 2 AUTO REFRESH commands, issues a LOAD MODE REGISTER command to the mode register (pad_ba_o[2:0] = 0x0) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:9]	Equal to step 7	
pad_a_o[8]	0x0	DLL not reset
pad_a_o[7:0]	Equal to step 7	

10. Issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:10]	Equal to step 6	
pad_a_o[9:7]	0x7	Default OCD calibration
pad_a_o[6:0]	Equal to step 6	

11. Issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits equal to step 6.
12. If the reg_ddr_disable_dll bit in the SDRAM Configuration register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits, set as follows:

Bits	Value	Description
pad_a_o[15:1]	Equal to step 6	
pad_a_o[0]	0x1	Disable DLL

13. The EMIF performs an auto refresh cycle (see Refresh Controller section) after which it enters its idle state.

The EMIF also performs the initialization sequence whenever either of the SDRAM Configuration register is written. But in this case, the EMIF starts at step 3.

The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some DDR2 datasheets. The EMIF does not perform any transactions until the DDR2 initialization sequence is complete.

The reg_refresh_rate value at reset is config_refresh_def_val port value. When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 16 * reg_refresh_rate / input frequency. It is up to the user to tie off the config_refresh_def_val port with a correct value to meet the typical DDR2 device specified delay time of 200us between power-up and the application of the PRECHARGE all command.

9.2.3.4.2.7 EMIF Access Cycles

By default the EMIF keeps SDRAM chip selects active. To direct a command to just one of the SDRAMs it deasserts the chip select to the other SDRAM for the duration of the command. If reg_ebank field in the SDRAM Configuration register is set to 0, chip select 1 will always be driven high except during initialization and for refresh, Power Down, Self Refresh, and Deep Power Down commands.

The EMIF always performs burst accesses to SDRAM. Multiple SDRAM bursts may be needed to service a single OCP burst request. Figure 9-47 to Figure 9-51 show a few examples on how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Figure 9-51. 64-Byte Linear Read Starting at Address 0x18

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

EMIF will use the unused data phases in the above figure by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from single data rate to double data rate must be done outside the EMIF. The SDRAM_DQS signal generation (with right timing) from the phy_dqs_en signal must also be done outside the EMIF.

9.2.3.4.2.8 Turn Around Time

Table 9-66 shows the turn around time that the EMIF introduces on the data bus for various back-to-back accesses. Note that the EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turn around time on the data bus.

Table 9-66. Turn Around Time

Previous Access	Next Access	Turn Around Time (# of m_clk cycles)
SDRAM read	SDRAM read to same chip select	0
SDRAM read	SDRAM read to different chip select	2

Table 9-66. Turn Around Time (continued)

Previous Access	Next Access	Turn Around Time (# of m_clk cycles)
SDRAM read	SDRAM write	2
SDRAM write	SDRAM write	0
SDRAM write	SDRAM read	2

9.2.3.4.2.9 SDRAM Address Mapping

The SDRAM controller interleaves the internal banks for SDRAM connected to both the chip selects. From the system point of view, the external SDRAM is seen as one block of SDRAM. If smaller devices are used, the memory is seen to rollover. If two external 64 MB devices are used, a 128 MB memory block is observed. If two external 32 MB devices are used, a 64 MB block is observed.

When addressing SDRAM, if the reg_ibank_pos field in the SDRAM Configuration register is set to 0, the EMIF uses the 3 fields, reg_ibank, reg_ebank and reg_pagesize in the SDRAM Configuration register to determine the mapping from source address to SDRAM row, column, bank, and chip select. If the reg_ibank_pos field in the SDRAM Configuration register is set to 1, 2, or 3, the EMIF uses the 4 fields - reg_ibank, reg_ebank, reg_pagesize, and reg_rowsize in the SDRAM Configuration register to determine the mapping from source address to SDRAM row, column, bank, and chip select. In all cases the EMIF considers its SDRAM address space to be a single logical block regardless of the number of physical devices or whether the devices are mapped across 1 or 2 EMIF chip selects. For reg_ibank_pos = 0, Table 9-67 and Table 9-68 show which source address bits, MAddr, map to the SDRAM row, column, bank, and chip select bits for all combinations of reg_ibank, reg_ebank, and reg_pagesize. For reg_ibank_pos != 0, Table 9-69 to Table 9-71 shows which source address bits, MAddr, map to the SDRAM row, column, bank, and chip select bits for all combinations of reg_ibank, reg_ebank, reg_pagesize, and reg_rowsize. The tables also give the maximum size of the resulting SDRAM space.

Table 9-67. Address to SDRAM Address Mapping for 16-Bit SDRAM (reg_ibank_pos=0)

4096	1	2	3	row								cs	bank		col			
4096	0	3	3	row									bank		col			
4096	1	3	3	row								cs	bank		col			

For reg_ibank_pos = 0, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (pad_cs_o_n[0]). This movement along the banks of the current device continues until the page has been accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if reg_ebank = 1, pad_cs_o_n[1]) and proceeds through the same page in all its banks before moving over to the next page in the first device (pad_cs_o_n[0]). The EMIF exploits this traversal across internal banks and chip selects while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, and can interleave among all of them.

Table 9-69. OCP Address to SDRAM Address Mapping for reg_ibank_pos=1

MAddr[31:N][1]				
Bank Address[2]	**Row Address**	**Chip Select**	**Bank Address[1:0]**	**Column Address**
# of bits defined by reg_ibank	**# of bits defined by reg_rowsize**	**# of bits defined by reg_ebank**	**# of bits defined by reg_ibank**	**# of bits defined by reg_pagesize**
reg_ibank=0 => 0 bits	reg_rowsize=0 => 9 bits	reg_ebank=0 => 0 bits	reg_ibank=0 => 0 bits	reg_pagesize=0 => 8 bits
reg_ibank=1 => 0 bits	reg_rowsize=1 => 10 bits	reg_ebank=1 => 1 bit	reg_ibank=1 => 1 bit	reg_pagesize=1 => 9 bits
reg_ibank=2 => 0 bits	reg_rowsize=2 => 11 bits		reg_ibank=2 => 2 bits	reg_pagesize=2 => 10 bits
reg_ibank=3 => 1 bit	reg_rowsize=3 => 12 bits		reg_ibank=3 => 2 bits	reg_pagesize=3 => 11 bits
	reg_rowsize=4 => 13 bits			
	reg_rowsize=5 => 14 bits			
	reg_rowsize=6 => 15 bits			
	reg_rowsize=7 => 16 bits			

(1) N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 1, the EMIF interleaves banks the same as reg_ibank_pos = 0, but the interleaving of banks within a device (per chip select) is limited to 4 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 8 of them.

Table 9-70. OCP Address to SDRAM Address Mapping for reg_ibank_pos=2

MAddr[31:N][1]				
Bank Address[2:1]	**Row Address**	**Chip Select**	**Bank Address[0]**	**Column Address**
# of bits defined by reg_ibank	**# of bits defined by reg_rowsize**	**# of bits defined by reg_ebank**	**# of bits defined by reg_ibank**	**# of bits defined by reg_pagesize**
reg_ibank=0 => 0 bits	reg_rowsize=0 => 9 bits	reg_ebank=0 => 0 bits	reg_ibank=0 => 0 bits	reg_pagesize=0 => 8 bits
reg_ibank=1 => 0 bits	reg_rowsize=1 => 10 bits	reg_ebank=1 => 1 bit	reg_ibank=1 => 1 bit	reg_pagesize=1 => 9 bits
reg_ibank=2 => 1 bit	reg_rowsize=2 => 11 bits		reg_ibank=2 => 1 bit	reg_pagesize=2 => 10 bits
reg_ibank=3 => 2 bits	reg_rowsize=3 => 12 bits		reg_ibank=3 => 1 bit	reg_pagesize=3 => 11 bits
	reg_rowsize=4 => 13 bits			
	reg_rowsize=5 => 14 bits			
	reg_rowsize=6 => 15 bits			
	reg_rowsize=7 => 16 bits			

(1) N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 2, the EMIF interleaves banks the same as reg_ibank_pos = 0, but the interleaving of banks within a device (per chip select) is limited to 2 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 4 of them.

Table 9-71. OCP Address to SDRAM Address Mapping for ibank_pos=3

MAddr[31:N][1]			
Bank Address	**Row Address**	**Chip Select**	**Column Address**
# of bits defined by reg_ibank	**# of bits defined by reg_rowsize**	**# of bits defined by reg_ebank**	**# of bits defined by reg_pagesize**
reg_ibank=0 => 0 bits	reg_rowsize=0 => 9 bits	reg_ebank=0 => 0 bits	reg_pagesize=0 => 8 bits
reg_ibank=1 => 1 bit	reg_rowsize=1 => 10 bits	reg_ebank=1 => 1 bit	reg_pagesize=1 => 9 bits
reg_ibank=2 => 2 bits	reg_rowsize=2 => 11 bits		reg_pagesize=2 => 10 bits
reg_ibank=3 => 3 bits	reg_rowsize=3 => 12 bits		reg_pagesize=3 => 11 bits
	reg_rowsize=4 => 13 bits		
	reg_rowsize=5 => 14 bits		
	reg_rowsize=6 => 15 bits		
	reg_rowsize=7 => 16 bits		

(1) N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 3, the EMIF cannot interleave banks within a device (per chip select). However, it can still interleave banks between the two chip selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 2 of them.

Since the EMIF interleave among less number of banks when reg_ibank_pos != 0, these cases are lower in performance than the reg_ibank_pos = 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

9.2.3.4.2.10 Endian Support

The order in which bytes on the OCP port data bus is written to or read from devices that are not as wide as OCP port data bus is determined by the setting of the config_big_endian pin at the time of an access. The EMIF maintains the natural order of endian operations. That is, if a byte stream of data starting at any address n within any endian environment will always be accessed in the correct or incrementing byte order. The EMIF will always access address n prior to n+1 in all endian modes and in any byte width.

Since the endian mode must be known prior to the CPU booting, the endian mode pin on the EMIF and the booting CPU are normally registered by a boot options register at reset time. The setting of the config_big_endian pin is reflected in the be bit of the Status register.

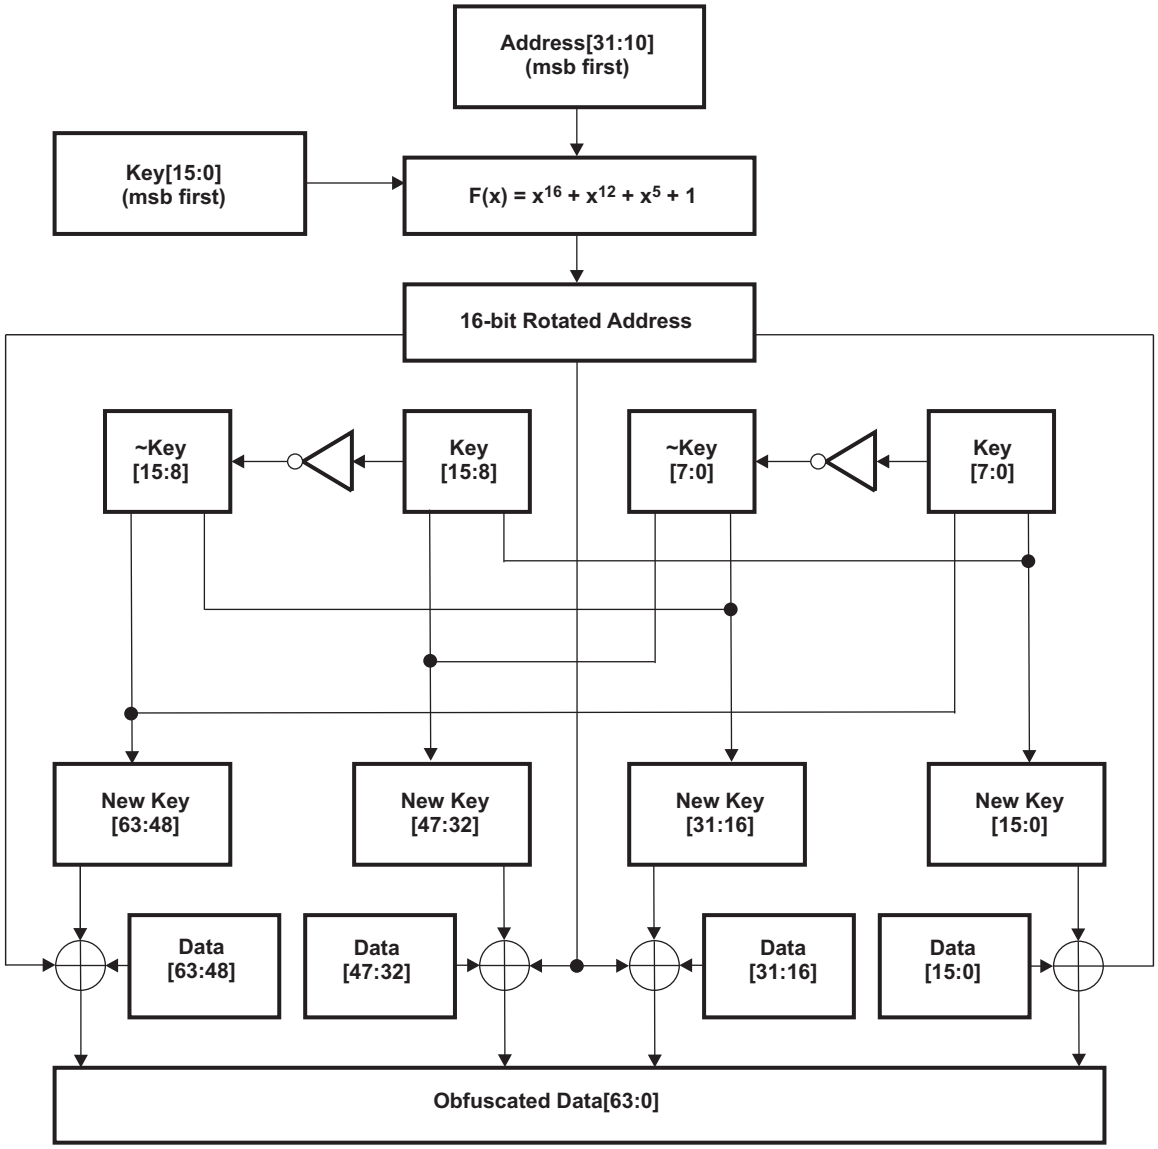
9.2.3.4.2.11 Data Bus Obfuscation

For security, the EMIF supports obfuscation for data written to the SDRAM. The obfuscation scheme for data written to the SDRAM is shown in Figure 9-52. The 16-bit key for obfuscation is sourced from the obfuscation_key port, The key can be a tie-off, or can come from a separate module at chip level, or can also come from efuse. Before it is used, the key is further modified, as shown in Figure 9-52, to create a 64-bit new key. Data will be obfuscated going out of the EMIF to the DDR PHY, and will be de-obfuscated going back to the master.

To ensure that the obfuscation is different for different regions of the memory, the upper address bits, MAddr[31:10], are taken through a LFSR function to generate a 16-bit rotated address. The obfuscation_key is used as a seed for the LFSR.

The data is then XOR'd with four copies of the 16-bit rotated address and the 64-bit new key. This ensures that the obfuscation will be different for each 1 KB page of the memory. It also helps EMIF to keep the obfuscation transparent to a master that reads or writes the memory in different transaction sizes.

Figure 9-52. Data Bus Obfuscation



9.2.3.4.2.12 Pipeline Latency

Following is the information on read latency through the EMIF and DDR PHY sub-system. EMIF is assumed to be idle, i.e., not performing any operations on the external interface and the Command FIFO is empty. Also, the read is assumed to be to an open row.

1 ocp_clk cycle - EMIF captures OCP command

1 ocp_clk cycle - SDRAM address calculation

3 m_clk cycles - synchronizer delay to memory clock (EMIF uses a 2 clock synchronizer plus 1 clock for the flop after the synchronizer)

1 m_clk cycle - command to external interface

1 m_clk cycle - SDRAM registers command

CL m_clk cycles - CAS latency

PL m_clk cycles - DDR PHY latency (minimum 1 to maximum 8 cycles depending on system round trip delay)

DC m_clk cycles - data capture/reassembly to Read Data FIFO

3 ocp_clk cycles - synchronizer delay to memory clock (EMIF uses a 2 clock synchronizer plus 1 clock for the flop after the synchronizer)

1 ocp_clk cycle - read request with data/status to OCP interface

((6 ocp_clk cycles) + ((6+CL+PL+DC) m_clk cycles)) total from request rising to first data produced on the OCP interface

SV and SM = 0 if ocp_clk and m_clk are synchronous

DC = 1 for OCP to SDRAM data width ratio of 1:2

DC = 2 for OCP to SDRAM data width ratio of 1:4

9.2.3.4.2.13 Special Operation for Integration with SMS

The EMIF supports a single bit sys_MReqMisc signal to enable a special operation for integration with SMS. This special mechanism is required by SMS to improve the overall system performance for high priority commands.

The EMIF will deassert sys_SCmdAccept output whenever the Command FIFO inside the EMIF has 4 commands that have the sys_MReqMisc signal set high. A fifth command with sys_MReqMisc high might already be in the pipe in front of the Command FIFO. In other words, either 4 or 5 command that have sys_MReqMisc signal high will be present inside the EMIF when EMIF drives sys_SCmdAccept low.

The SMS will ensure that the sys_MReqMisc signal is asserted high only for the commands required to be counted by the EMIF to apply back pressure. All other commands will have sys_MReqMisc set to 0. For systems without the SMS, the sys_MReqMisc signal must be tied low.

9.2.3.4.3 EMIF Registers

The following section describes the register map and register definition in ascending order. The state of each register after reset is shown.

For an EMIF with OCP data width greater than 32 bits, the 32-bit words are swapped internally depending on the endianness to keep the register memory map same for both little and big endian modes. This allows the same boot code to be run regardless of endianness. For example, for a 64-bit OCP data width, see Table 9-72.

Table 9-72. 64-bit OCP Data Width

Endian	Bits 63:32	Bits 31:0
Little	SDRAM Status Register	EMIF Module ID and Revision Register
Big	EMIF Module ID and Revision Register	SDRAM Status Register

9.2.3.4.3.2 Register Descriptions

9.2.3.4.3.2.1 EMIF Module ID and Revision Register (EMIF_MOD_ID_REV)

The EMIF Module ID and Revision Register (EMIF_MOD_ID_REV) is shown in Figure 9-53 and described in Table 9-74.

Figure 9-53. EMIF Module ID and Revision Register (EMIF_MOD_ID_REV)

Table 9-74. EMIF Module ID and Revision Register (EMIF_MOD_ID_REV) Field Descriptions

Bit	Field	Value	Description
31-30	REG_SCHEME	0-3h	Used to distinguish between old and current revision schemes. 0 means old scheme. 1 means new scheme. The present register format is compliant to the new scheme. Old scheme had a different format for this register.
29-28	Reserved	0	These reserved bit locations are always read as zeros. A value written to this field has no effect.
27-16	REG_MODULE_ID	0-FFFh	EMIF module ID.
15-11	REG_RTL_VERSION	0-Fh	RTL Version.
10-8	REG_MAJOR_REVISION	0-7h	Major Revision.
7-6	Reserved	0	Reserved.
5-0	REG_MINOR_REVISION	0-3Fh	Minor Revision.

9.2.3.4.3.2.2 SDRAM Status Register (STATUS)

The SDRAM Status Register (STATUS) is shown in Figure 9-54 and described in Table 9-75.

Figure 9-54. SDRAM Status Register (STATUS)

31	30	29	28	24

Table 9-75. SDRAM Status Register (STATUS) Field Descriptions

Bit	Field	Value	Description
31	REG_BE		Big Endian. Reflects the value on the config_big_endian port that defines whether the EMIF is in big or little endian mode.
30	REG_DUAL_CLK_MODE		Dual Clock mode. Reflects the value on the config_dual_clk_mode port that defines whether the ocp_clk and m_clk are asynchronous.
29	REG_FAST_INIT		Fast Initialization. Reflects the value on the config_fast_init port that defines whether the EMIF fast initialization mode has been enabled.
28-3	Reserved	0	Reserved.
2	REG_PHY_DLL_READY		DDR PHY Ready. Reflects the value on the phy_ready port (active high) that defines whether the DDR PHY is ready for normal operation.
1-0	Reserved	0	Reserved.

9.2.3.4.3.2.3 SDRAM Configuration Register (SDRAM_CONFIG)

The SDRAM Configuration Register (SDRAM_CONFIG) is shown in Figure 9-55 and described in Table 9-76.

NOTE:

1. This register can only be written if lock_config_ctrl port is set to 0.
2. A write to this register will cause the EMIF to start the SDRAM initialization sequence for DDR2.
3. If reg_cl field is changed, the read latency in the PHY Control 1 register must also be reprogrammed to the correct value.

Table 9-76. SDRAM Configuration Register (SDRAM_CONFIG) Field Descriptions

Bit	Field	Value	Description
31-29	REG_SDRAM_TYPE	0-7h	SDRAM Type selection. Set to 0 for DDR1, set to 1 for LPDDR1, set to 2 for DDR2. All other values are reserved.
28-27	REG_IBANK_POS	0-3h	Internal bank position. Set to 0 to assign internal bank address bits from OCP address as shown in Table 4, 5, and 6. Set to 1, 2, or 3 to assign internal bank address bits from OCP address as shown in Table 7, 8, or 9 respectively.
26-24	REG_DDR_TERM	0-7h	DDR2 termination resistor value. Set to 0 to disable termination. Set to 1 for 75 ohm, set to 2 for 150 ohm, and set to 3 for 50 ohm. All other values are reserved.
23	REG_DDR2_DDQS	0-1h	DDR2 differential DQS enable. Set to 0 for single ended DQS. Set to 1 for differential DQS.
22-21	RESERVED	0	Reserved.
20	REG_DDR_DISABLE_DLL	0-1h	Disable DLL select. Set to 1 to disable DLL inside SDRAM.
19-18	REG_SDRAM_DRIVE	0-3h	SDRAM drive strength. For DDR1, set to 0 for normal, and set to 1 for weak drive strength. For DDR2, set to 0 for full, and set to 1 for reduced drive strength. For LPDDR1, set to 0 for full, set to 1 for 1/2, set to 2 for 1/4, and set to 3 for 1/8 drive strength. All other values are reserved.
17-16	RESERVED	0	Reserved.
15-14	REG_NARROW_MODE	0-3h	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved.
13-10	REG_CL	0-Fh	CAS Latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 2, 3, 5, and 6 (CAS latency of 2, 3, 1.5, and 2.5) are supported for DDR1. Value of 2, 3, 4, 5, and 6 (CAS latency of 2, 3, 4, 5, and 6) are supported for DDR2. Value of 2 and 3 (CAS latency of 2 and 3) are supported for LPDDR1. All other values are reserved.

Table 9-76. SDRAM Configuration Register (SDRAM_CONFIG) Field Descriptions (continued)

Bit	Field	Value	Description
9-7	REG_ROWSIZE	0-7h	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, set to 1 for 10 row bits, set to 2 for 11 row bits, set to 3 for 12 row bits, set to 4 for 13 row bits, set to 5 for 14 row bits, set to 6 for 15 row bits, and set to 7 for 16 row bits. This field is only used when reg_ibank_pos field in SDRAM Config register is set to 1, 2, or 3.
6-4	REG_IBANK	0-7h	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, set to 1 for 2 banks, set to 2 for 4 banks, and set to 3 for 8 banks. All other values are reserved.
3	REG_EBANK	0-1h	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0].
2-0	REG_PAGESIZE	0-7h	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), set to 1 for 512-word page (9 column bits), set to 2 for 1024-word page (10 column bits), and set to 3 for 2048-word page (11 column bits). All other values are reserved.

9.2.3.4.3.2.4 SDRAM Refresh Control Register (SDRAM_REF_CTRL)

The SDRAM Refresh Control Register (SDRAM_REF_CTRL) is shown in Figure 9-56 and described in Table 9-77.

NOTE: The reg_refresh_rate is the number of clock cycles required to cause a refresh interval of 7.8 us or 15.7 us for the appropriate SDRAM used. This field is not byte writable, i.e., all 16 bits of this field need to be written simultaneously. A 125 MHz memory system requires a 15.7 * 125 = 1962 or 0x7AA value to be written to the SDRAM Refresh Control register. If the SDRAM requires a 7.8 us refresh rate instead of a 15.7 us, then one-half the value should be written.

Figure 9-56. SDRAM Refresh Control Register (SDRAM_REF_CTRL)

31	30	27	26	24
REG_INITREF_DIS	Reserved		REG_PASR

R/W-	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

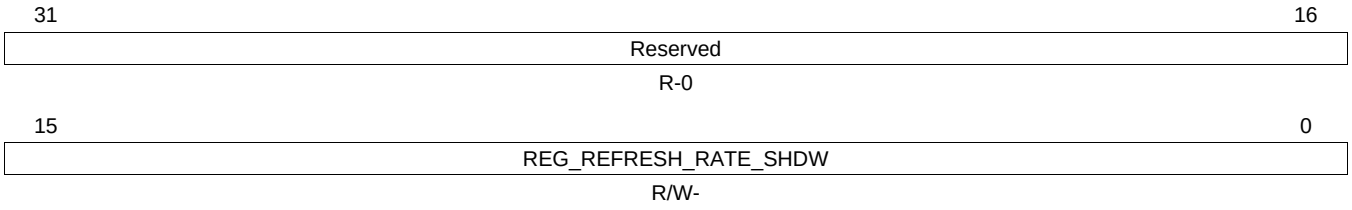
Table 9-77. SDRAM Refresh Control Register (SDRAM_REF_CTRL) Field Descriptions

Bit	Field	Value	Description
31	REG_INITREF_DIS	0-1h	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.
30-27	Reserved	0	Reserved.
26-24	REG_PASR	0-7h	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of an LPDDR1 during initialization. Set to 0 for full array, set to 1 for 1/2 array, set to 2 for 1/4 array, set to 5 for 1/8 array, and set to 6 for 1/16 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
23-16	Reserved	0	Reserved.
15-0	REG_REFRESH_RATE	0-FFFFh	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = EMIF rate / reg_refresh_rate where EMIF rate is equal to m_clk rate. If this value is less than 0x80 and the reg_t_rfc value in SDRAM Timing 3 register is less than 0x40, this field will be loaded with 0x80. If this value is less than reg_t_rfc times 2, than it is loaded with reg_t_rfc times 2.

9.2.3.4.3.2.5 SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW)

The SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW) is shown in Figure 9-57 and described in Table 9-78.

Figure 9-57. SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-78. SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-0	REG_REFRESH_RATE_SHDW	0-FFFFh	Shadow field for reg_refresh_rate. This field is loaded into reg_refresh_rate field in SDRAM Refresh Control register when SIdleAck is asserted.

9.2.3.4.3.2.6 SDRAM Timing 1 Register (SDRAM_TIM_1)

The SDRAM Timing 1 Register (SDRAM_TIM_1) is shown in Figure 9-58 and described in Table 9-79.

NOTE: If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.

Figure 9-58. SDRAM Timing 1 Register (SDRAM_TIM_1)

31 29	28 25	24 21	20 17	16

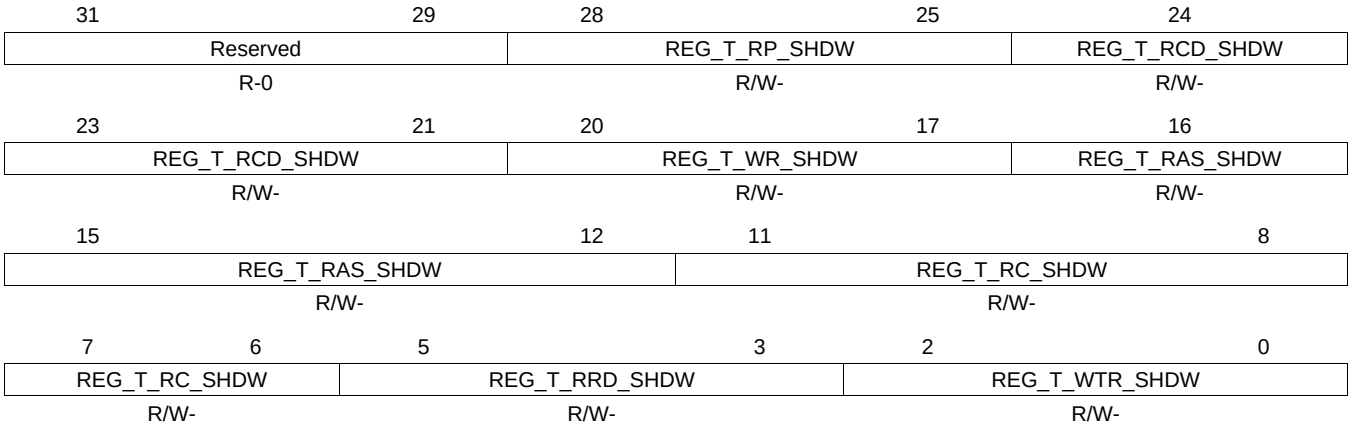
Table 9-79. SDRAM Timing 1 Register (SDRAM_TIM_1) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved.
28-25	REG_T_RP	0-Fh	Minimum number of m_clk cycles from Precharge to Activate or Refresh, minus one.
24-21	REG_T_RCD	0-Fh	Minimum number of m_clk cycles from Activate to Read or Write, minus one.
20-17	REG_T_WR	0-Fh	Minimum number of m_clk cycles from last Write transfer to Pre-charge, minus one. The SDRAM initialization sequence will be started when the value of this field is changed from the previous value and the EMIF is in DDR2 mode.
16-12	REG_T_RAS	0-1Fh	Minimum number of m_clk cycles from Activate to Pre-charge, minus one. reg_t_ras >= reg_t_rcd.
11-6	REG_T_RC	0-3Fh	Minimum number of m_clk cycles from Activate to Activate, minus one.
5-3	REG_T_RRD	0-7h	Minimum number of m_clk cycles from Activate to Activate for a different bank, minus one. For an 8-bank DDR2, this field must be equal to ((tFAW/(4*tCK))-1).
2-0	REG_T_WTR	0-7h	Minimum number of m_clk cycles from last Write to Read, minus one.

9.2.3.4.3.2.7 SDRAM Timing 1 Shadow Register (SDRAM_TIM_1_SHDW)

The SDRAM Timing 1 Shadow Register (SDRAM_TIM_1_SHDW) is shown in Figure 9-59 and described in Table 9-80.

Figure 9-59. SDRAM Timing 1 Shadow Register (SDRAM_TIM_1_SHDW)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-80. SDRAM Timing 1 Shadow Register (SDRAM_TIM_1_SHDW) Field Descriptions

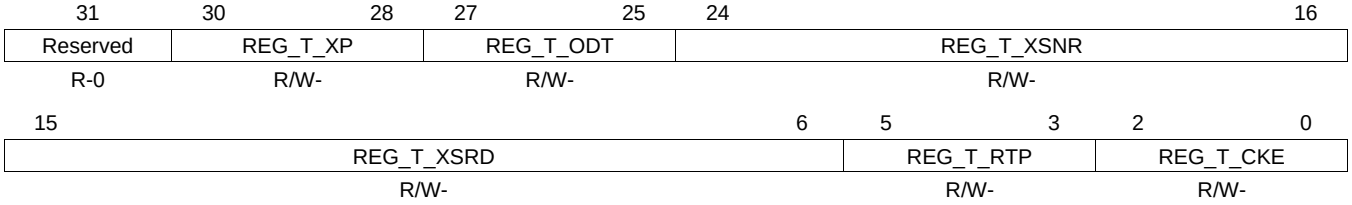
Bit	Field	Value	Description
31-29	Reserved	0	Reserved.
28-25	REG_T_RP_SHDW	0-Fh	Shadow field for reg_t_rp. This field is loaded into reg_t_rp field in SDRAM Timing 1 register when SIdleAck is asserted.
24-21	REG_T_RCD_SHDW	0-Fh	Shadow field for reg_t_rcd. This field is loaded into reg_t_rcd field in SDRAM Timing 1 register when SIdleAck is asserted.
20-17	REG_T_WR_SHDW	0-Fh	Shadow field for reg_t_wr. This field is loaded into reg_t_wr field in SDRAM Timing 1 register when SIdleAck is asserted. Initialization sequence will be started when the value of this field is changed from the previous value and the EMIF is in DDR2 mode.
16-12	REG_T_RAS_SHDW	0-1Fh	Shadow field for reg_t_ras. This field is loaded into reg_t_ras field in SDRAM Timing 1 register when SIdleAck is asserted.
11-6	REG_T_RC_SHDW	0-3Fh	Shadow field for reg_t_rc. This field is loaded into reg_t_rc field in SDRAM Timing 1 register when SIdleAck is asserted.
5-3	REG_T_RRD_SHDW	0-7h	Shadow field for reg_t_rrd. This field is loaded into reg_t_rrd field in SDRAM Timing 1 register when SIdleAck is asserted.
2-0	REG_T_WTR_SHDW	0-7h	Shadow field for reg_t_wtr. This field is loaded into reg_t_wtr field in SDRAM Timing 1 register when SIdleAck is asserted.

9.2.3.4.3.2.8 SDRAM Timing 2 Register (SDRAM_TIM_2)

The SDRAM Timing 2 Register (SDRAM_TIM_2) is shown in Figure 9-60 and described in Table 9-81.

NOTE: If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.

Figure 9-60. SDRAM Timing 2 Register (SDRAM_TIM_2)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

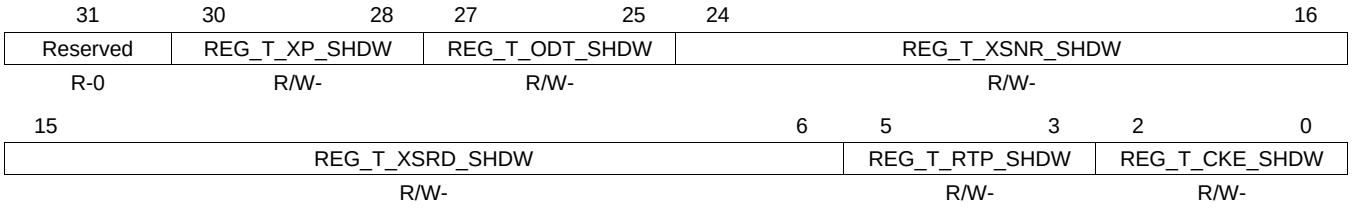
Bit	Field	Value	Description
31	Reserved	0	Reserved.
30-28	REG_T_XP	0-7h	Minimum number of m_clk cycles from Power-Down exit to any command other than aRead command, minus one. For DDR2 and LPDDR1, this field must satisfy greater of tXP or tCKE.
27-25	REG_T_ODT	0-7h	Minimum number of m_clk cycles from ODT enable to write data driven for DDR2.reg_t_odt must be equal to tAOND.
24-16	REG_T_XSNR	0-1FFh	Minimum number of m_clk cycles from Self-Refresh exit to any command other than aRead command, minus one.
15-6	REG_T_XSRD	0-3FFh	Minimum number of m_clk cycles from Self-Refresh exit to a Read command, minus one.
5-3	REG_T_RTP	0-7h	Minimum number of m_clk cycles from the last Read command to a Pre-chargecommand for DDR2, minus one.
2-0	REG_T_CKE	0-7h	Minimum number of m_clk cycles between pad_cke_o changes, minus one.

9.2.3.4.3.2.9 SDRAM Timing 2 Shadow Register (SDRAM_TIM_2_SHDW)

The SDRAM Timing 2 Shadow Register (SDRAM_TIM_2_SHDW) is shown in Figure 9-61 and described in Table 9-82.

Figure 9-61. SDRAM Timing 2 Shadow Register (SDRAM_TIM_2_SHDW)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-82. SDRAM Timing 2 Shadow Register (SDRAM_TIM_2_SHDW) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved.
30-28	REG_T_XP_SHDW	0-7h	Shadow field for reg_t_xp. This field is loaded into reg_t_xp field in SDRAM Timing 2 register when SIdleAck is asserted.
27-25	REG_T_ODT_SHDW	0-7h	Shadow field for reg_t_odt. This field is loaded into reg_t_odt field in SDRAM Timing 2 register when SIdleAck is asserted.
24-16	REG_T_XSNR_SHDW	0-1FFh	Shadow field for reg_t_xsnr. This field is loaded into reg_t_xsnr field in SDRAM Timing 2 register when SIdleAck is asserted.
15-6	REG_T_XSRD_SHDW	0-3FFh	Shadow field for reg_t_xsrd. This field is loaded into reg_t_xsrd field in SDRAM Timing 2 register when SIdleAck is asserted.
5-3	REG_T_RTP_SHDW	0-7h	Shadow field for reg_t_rtp. This field is loaded into reg_t_rtp field in SDRAM Timing 2 register when SIdleAck is asserted.
2-0	REG_T_CKE_SHDW	0-7h	Shadow field for reg_t_cke. This field is loaded into reg_t_cke field in SDRAM Timing 2 register when SIdleAck is asserted.

9.2.3.4.3.2.10 SDRAM Timing 3 Register (SDRAM_TIM_3)

The SDRAM Timing 3 Register (SDRAM_TIM_3) is shown in Figure 9-62 and described in Table 9-83.

NOTE:

1. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.
2. Value for reg_t_ras_max can be calculated as follows:
   - o If tRASmax = 120 us and tREFI = 15.7 us, then reg_t_ras_max = ((120/15.7)-1) = 6.64.
   - o Round down to the next lower integer. Therefore, the programmed value must be 6.

Table 9-85. Power Management Control Register (PWR_MGMT_CTRL) Field Descriptions

Bit	Field	Value	Description
31-30	REG_IDLEMODE	0-3h	Power-Idle IP Generic mode. Set to 0 for force-idle mo Power-Idle IP Generic mode. Set to 0 for force-idle mode, where EMIF acknowledges the system's idle requests unconditionally, i.e. regardless of the EMIF's internal requirements. Backup mode, for debug only. Set to 1 for no-idle mode, where EMIF will never enter idle state. Backup mode, for debug only. Set to 2 for smart-idle mode, where EMIF's idle state eventually follows (acknowledges) the system's idle requests, depending on EMIF's internal requirements. Setting of 3 (smart-idle wakeup-capable mode) is not supported.
31-11	Reserved	0	Reserved.
10	REG_DPD_EN	0-1h	Deep Power-Down enable. Set to 0 for normal operation. Set to 1 to enter Deep Power-Down mode. This mode will override the reg_lp_mode field setting.
9-8	REG_LP_MODE	0-3h	Automatic Power Management enable. Set to 1 for Clock Stop, set to 2 for Self Refresh, and set to 3 for Power-Down. Set to 0 to disable automatic power management. Reserved for future use.
7-4	Reserved	0	Reserved.
3-0	REG_PM_TIM	0-Fh	Power Management timer. The EMIF will put the external SDRAM in a power saving mode after the EMIF is idle for these number of m_clk cycles. The power saving mode is chosen by the reg_lp_mode field. Set to 0 to immediately enter the power savings mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks.

9.2.3.4.3.2.13 Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW)

The Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW) is shown in Figure 9-65 and described in Table 9-86.

Figure 9-65. Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW)

31	4	3	0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 9-90. IODFT Test Logic Global Control Register (IODFT_TLGC) Field Descriptions

Bit	Field	Value	Description
31-16	REG_TLEC	0-FFFFh	IODFT Test Logic Execution Counter. Contains the number of cycle that the MISR signature will be accumulated. Upon the expiration of the counter the MISR capture will be turned off.
15	Reserved	0	Reserved
14	REG_MT	0-1h	MISR on/off trigger command. 0x0 = inactive/no affect. 0x1 = MISR capture start on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when mc = 0x3. 0x1 = pattern generator starts on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when pc = 0x1, 0x2, 0x3, 0x5, 0x6, or 0x7. These bits are cleared when reg_tlec expires.
13	REG_ACT_CAP_EN	0-1h	Active cycles capture enable. If set to a 1 the MISRs and pattern generators will shift only during active cycles. If set to a 0 the MISRs and pattern generators will shift every clock cycle.
12	REG_OPG_LD	0-1h	Load pattern generators' initial value. Set to 1 to load an initial value in the pattern generators from reg_tlec.
11	Reserved	0	Reserved.
10	REG_RESET_PHY	0-1h	Reset DDR PHY. Writing a 1 to this bit will reset the DDR PHY. This bit will self clear to 0.
9	Reserved	0	Reserved.
8	REG_MMS	0-1h	Chooses the source of the MISR input. Set to 0 for output register, and set to 1 for input capture.
7-6	Reserved	0	Reserved.
5-4	REG_MC	0-3h	MISR state. Set to 0 to download results. Set to 1 to hold current value. Set to 2 to load initial value from pc bits. Set to 3 to enable MISR to capture signature.
3-1	REG_PC	0-7h	Pattern code. Defines the type of pattern that is selected for the pattern generators. Set to 0 for functional mode and set to 4 to hold current register value. Set to 5 for random XOR, set to 6 for random XNOR, and set to 7 for an 8 bit shifter. All other values are reserved.
0	REG_TM	0-1h	Functional mode enable. Set to 1 for functional mode, and set to 0 for IODFT mode.

9.2.3.4.3.2.18 IODFT Test Logic Control MISR Result Register (IODFT_CTRL_MISR_RSLT)

The IODFT Test Logic Control MISR Result Register is shown in Figure 9-70 and described in Table 9-91.

Figure 9-70. IODFT Test Logic Control MISR Result Register (IODFT_CTRL_MISR_RSLT)

Table 9-108. DDR PHY Control 1 Register (DDR_PHY_CTRL_1) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reserved
23	TESTIN_LB_CK_SELECT	0	This bit controls the value assigned to the TESTIN_LB_CK_SELECT input on the command macro.
22-16	Reserved	0	Reserved
15	CONFIG_VTP_DYNAMIC_UPDATE	0	This bit controls the value assigned to the CONFIG_VTP_DYNAMIC_UPDATE input on the command macro.
14-12	CONFIG_DLL_MODE	0	This bit controls the value assigned to the CONFIG_DLL_MODE input on the data macros.
11-9	Reserved	0	Reserved
8	DDR_16B_MODE_PWRSAVE	0	This bit can be set to gate the clock of second data macro when DDR is used in 16b mode.
7	CONFIG_EXT_STRBEN	1h	This bit controls the value assigned to the CONFIG_EXT_STRBEN input on the DDR PHY data macro.
6	CONFIG_PWRDN_DISABLE	0	This bit controls the value assigned to the CONFIG_PWRDNEN input on the DDR PHY data macro. 0: DDR receive IO buffer will be powered down (disabled) when there no read. 1: DDR receive IO buffer will be always enabled.
5-3	Reserved	0	Reserved
2-0	READ_LATENCY	3h	This field defines the latency for read data from DDR SDRAM in number of X1_CLK_OUT cycles. The value applied should be equal to the required value minus one. The maximum read latency supported by the DDR PHY is equal to CAS latency plus 2 X1_CLK_OUT CYCLES. The minimum read latency must be equal to CAS latency plus 1 X1_CLK_OUT CYCLES.

9.2.3.4.3.2.35 DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW)

The DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW) is shown in Figure 9-87 and described in Table 9-109.

Figure 9-87. DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW)

1	CONFIG_RX_DLL_BYPASS	0	This bit controls the value assigned to the CONFIG_RX_DLL_BYPASS input on the DDR PHY data macro.
0	CONFIG_TX_STRB_DATA_ALIGN	0	This bit controls the value assigned to the CONFIG_TX_STRB_DATA_ALIGN input on the DDR PHY data macro.

9.2.3.4.4 Interrupt Conditions

This section defines the module interrupt capabilities and requirements.

9.2.3.4.4.1 Interrupt Description

The EMIF sources one interrupt for the system OCP. The system OCP interrupts are sys_err_intr_req (pulse) and sys_err_intr_pend (level). The pulse and level interrupt signals for a particular interface are both sourced from the same raw interrupt for the corresponding interface internal to the module.

9.2.3.4.4.2 Interrupt Condition Control

The EMIF only supports Idle, Write, Read, and WriteNonPost command types (as indicated by MCmd). Also, the EMIF only supports incrementing, wrapping, and 2-dimensional block addressing modes (as indicated by MBurstSeq). If an access request for an unsupported command type or an unsupported addressing mode is received, the EMIF will set the reg_raw_sys bit in the Interrupt Raw Status register. The EMIF will also set the reg_raw_sys bit in Interrupt Raw Status register, if an access request to an unsupported MAddrSpace is received.

The EMIF will only output the interrupts on the interrupt lines if they are enabled by writing a 1 to the corresponding bits in the Interrupt Enable Set register. The interrupts can be disabled by writing a 1 to the corresponding bits in the Interrupt Enable Clear register.

When enabled, the corresponding bits in the Interrupt Status register will also be set if the above error condition occurs. The interrupts can be cleared once serviced by writing a 1 to the corresponding bits either in the Interrupt Raw Status or Interrupt Status register. The software must also write to the End of Interrupt register to indicate that the interrupt was serviced.

9.2.3.4.5 Power Management

This section defines the module Power Management capabilities and requirements.

9.2.3.4.5.1 SDRAM Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh after the EMIF is idle for reg_pm_tim number of m_clk cycles and the reg_lp_mode field is set to 2. The reg_lp_mode and reg_pm_tim fields can be programmed in the Power Management Control register. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of reg_pm_tim, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a SELF REFRESH command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM, by asserting the phy_sdramclkstop port. The EMIF maintains pad_cke_o low to maintain the self-refresh state.

When the SDRAM is in self-refresh, the EMIF services register accesses as normal.

If the reg_lp_mode field is set not equal to 2, or an SDRAM access is requested while it is in self-refresh, and reg_t_cke + 1 cycles have elapsed since the SELF-REFRESH command was issued, the EMIF will bring the SDRAM out of self-refresh. The value of reg_t_cke is taken from SDRAM Timing 2 register.

For DDR2 the EMIF:

- Drives phy_sdramclkstop low to enable clocks.
- Drives pad_cke_o high.
- Waits for reg_t_xsnr + 1 cycles. The value of reg_t_xsnr is taken from SDRAM Timing 2 register.
- If the reg_ddr_disable_dll bit in the SDRAM Configuration register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits set as follows:

Bits	Value	Description
pad_a_o[15:13]	0x0	Reserved
pad_a_o[12]	0x0	Output buffer enabled
pad_a_o[11]	0x0	RDQS disable
pad_a_o[10]	!reg_ddr2_ddqs	Differential DQS enable value from SDRAM Configuration register
pad_a_o[9:7]	0x0	Exit OCD calibration mode
pad_a_o[6]	reg_ddr_term[1]	DDR2 termination resistor value from SDRAM Configuration register
pad_a_o[5:3]	0x0	Additive latency = 0
pad_a_o[2]	reg_ddr_term[0]	DDR2 termination resistor value from SDRAM Configuration register
pad_a_o[1]	reg_sdram_drive[0]	SDRAM drive strength from SDRAM Configuration register
pad_a_o[0]	0x1	Disable DLL

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after reg_t_xsrd + 1 clock cycles have elapsed since pad_cke_o is driven high. The value of reg_t_xsrd is taken from SDRAM Timing 2 register.

To use partial array self-refresh, reg_pasr bits in the SDRAM Refresh Control register must be appropriately programmed. The EMIF performs bank interleaving when reg_ibank_pos = 0 in SDRAM Configuration register. Since the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that reg_ibank_pos be set to 1, 2, or 3 depending on the scheme used. If reg_ibank_pos is set to 0, it is the responsibility of software to move critical data into the banks that are going to be refreshed during partial array self-refresh.

For LPDDR1 the EMIF:

- Drives phy_sdramclkstop low to enable clocks.
- Drives pad_cke_o high.
- Waits for reg_t_xsnr + 1 cycles. The value of reg_t_xsnr is taken from SDRAM Timing 2 register.
- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any commands.

9.2.3.4.5.2 SDRAM Power-Down Mode

The EMIF also supports Power-Down mode for low power. The EMIF automatically puts the SDRAM into Power-Down after the EMIF is idle for reg_pm_tim number of m_clk cycles and the reg_lp_mode field is set to 3. The reg_lp_mode and reg_pm_tim fields can be programmed in the Power Management Control register. The EMIF will complete all pending refreshes before it puts the SDRAM into Power-Down. Therefore, after the expiration of reg_pm_tim, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a POWER-DOWN command to the SDRAM.

In Power-Down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains pad_cke_o low to maintain the Power-Down state.

When the SDRAM is in Power-Down, the EMIF services register accesses as normal.

If the reg_lp_mode field is set not equal to 3, or an SDRAM access is requested, or the Refresh Must level is reached while the SDRAM is in Power-Down, the EMIF will bring the SDRAM out of Power-Down.

For DDR2 the EMIF:

- Drives pad_cke_o high after reg_t_cke + 1 cycles have elapsed since the POWER-DOWN command was issued. The value of reg_t_cke is taken from SDRAM Timing 2 register.
- Waits for reg_t_xp + 1 cycles. The value of reg_t_xp is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

For LPDDR1 the EMIF:

- Drives pad_cke_o high.

- Waits for reg_t_xp + 1 cycles. The value of reg_t_xp is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

9.2.3.4.5.3 SDRAM Deep Power-Down Mode

For ultimate power savings, the EMIF supports Deep Power-Down mode for LPDDR1.

The SDRAM can be forced into Deep Power-Down through software by setting the reg_dpd_en field in the Power Management Control register to 1. In this case, the EMIF will continue normal operation until all SDRAM memory access requests have been serviced. At this point the EMIF will issue a DEEP POWER-DOWN command. The EMIF then maintains pad_cke_o low to maintain the Deep Power-Down state. In Deep Power-Down mode, the EMIF automatically stops the clocks to the SDRAM, by asserting the phy_sdramclkstop port.

Setting the reg_dpd_en field to 1 overrides the setting of reg_lp_mode field. Therefore, if the SDRAM is in Clock Stop, Self Refresh, or Power-Down mode, and reg_dpd_en field is set to 1, the EMIF will exit those modes and go into Deep Power-Down mode.

When the SDRAM is in Deep Power-Down, the EMIF services register accesses as normal. If the reg_dpd_en field is set to 0, or an SDRAM access is requested, the EMIF will bring the SDRAM out of Deep Power-Down.

The EMIF:

- Performs SDRAM initialization as specified in the LPDDR1 Initialization section.
- Enters its idle state and can issue any commands.

Since the EMIF performs initialization upon Deep Power-Down exit, the reg_refresh_rate field in the SDRAM Refresh Control register must be set appropriately to meet the 200us wait requirement for LPDDR1 during initialization.

9.2.3.4.5.4 Save and Restore

The EMIF supports save and restore mechanism to completely switch off power to the EMIF. The following sequence of operations is followed to put EMIF in off mode.

- An external master reads the following memory mapped registers using the system OCP interface and saves their value external to the EMIF.
  - SDRAM Configuration register
  - SDRAM Refresh Control register
  - SDRAM Refresh Control Shadow register
  - SDRAM Timing 1 register
  - SDRAM Timing 1 Shadow register
  - SDRAM Timing 2 register
  - SDRAM Timing 2 Shadow register
  - SDRAM Timing 3 register
  - SDRAM Timing 3 Shadow register
  - Power Management Control register
  - Power Management Control Shadow register
  - OCP Configuration register
  - System OCP Interrupt Enable Set Register
  - DDR PHY Control 1 register
  - DDR PHY Control 1 Shadow register
  - DDR PHY Control 2 register
- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=0.
- EMIF requests OCP disconnect on both OCP interfaces through the sys_SConnect port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the sys_MConnect

port.

- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- EMIF waits for all interrupts to be serviced.
- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The rst_por_arst_n reset is asserted.
- The clocks and power to the EMIF can now be switched off.

To restore power to the EMIF the following sequence of operations is followed:

- The power and clocks to the EMIF are switched on.
- The rst_por_arst_n reset is deasserted keeping prcm_deviceoff_wkup_core_rstactst=1 indicating to the EMIF that it is waking up from off mode. The prcm_deviceoff_wkup_core_rstactst port is synchronized inside the EMIF and therefore must be stable before rst_por_arst_n is deasserted.
- The EMIF does not perform SDRAM initialization and forces its state machine to be in Self Refresh.
- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The external master restores all of the above memory mapped registers.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.5 Clock Frequency Change

If dual_clk_mode port is set to 1, the ocp_clk and the m_clk are asynchronous to each other. In this case, the ocp_clk frequency can be changed at any time. However, the m_clk frequency can only be changed after putting the external SDRAM in Self Refresh.

If dual_clk_mode port is set to 0, the ocp_clk and the m_clk are synchronous to each other. In this case, the ocp_clk and the m_clk frequency can only be changed after putting the external SDRAM in Self Refresh. Thus the clock frequencies can be changed through software by putting the EMIF in Self Refresh.

In case software intervention is not required, EMIF supports two modes for clock frequency change. The first mode uses a similar sequence of operation as the Save and Restore mechanism. Following is the sequence of operations.

- All shadow memory mapped registers are programmed for target frequency values.
- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=0.
- EMIF requests OCP disconnect on both OCP interfaces through the sys_SConnect port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the sys_MConnect port.
- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers.
- EMIF waits for all interrupts to be serviced.
- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The frequency of clocks can now be changed.

The second mode allows lower latency by bypassing the OCP disconnect protocol. The config_freq_change port must be set to a 1 for this mode. This mode allows a use case where the system does not want to wait for the EMIF FIFOs to be drained to change the clock frequency. Following is the sequence of operations.

- All shadow memory mapped registers are programmed for target frequency values.
- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=1.
- EMIF completes the on-going access and then puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The frequency of clocks can now be changed.

To start performing access to SDRAM, the following sequence of operations is followed:

- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.6 Retention Mode

EMIF supports full-retention mode, i.e., if retention is required, all flip-flops must be retention flip-flops. It does not support partial retention. The following sequence of operations is followed to put EMIF in retention.

- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=0.
- EMIF requests OCP disconnect on both OCP interfaces through the sys_SConnect port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the sys_MConnect port.
- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- EMIF waits for all interrupts to be serviced.
- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The clocks to the EMIF can now be switched off.
- The can now be put into retention.

To exit retention state the following sequence of operations is followed:

- The EMIF flip-flops value is restored from retention flops and clocks to the EMIF are switched on.
- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.7 Global Warm Reset

EMIF supports global warm reset mode where the EMIF will follow the following sequence of operations.

- The prcm_globalwarm_rstactst port is asserted indicating to the EMIF that it needs to enter global warm reset mode.
- EMIF completes the on-going access and then puts the SDRAM in Self Refresh.
- EMIF clears all its FIFO contents and deasserts sys_SCmdAccept and sys_SDataAccept ports.

To exit global warm reset state the following sequence of operations is followed:

- The prcm_globalwarm_rstactst port is deasserted indicating to the EMIF that global warm reset has finished.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.6 Programming/Usage Guide

9.2.3.4.6.1 Connecting to SDRAM

Figure 9-89 and Figure 9-90 show the ODT signal connections between the EMIF and DDR2.

Figure 9-89. Connecting Two DDR2 on One Chip Select

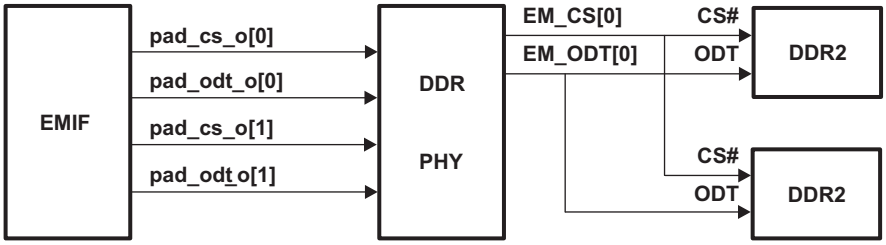

Figure 9-90. Connecting Two DDR2 on Two Chip Selects

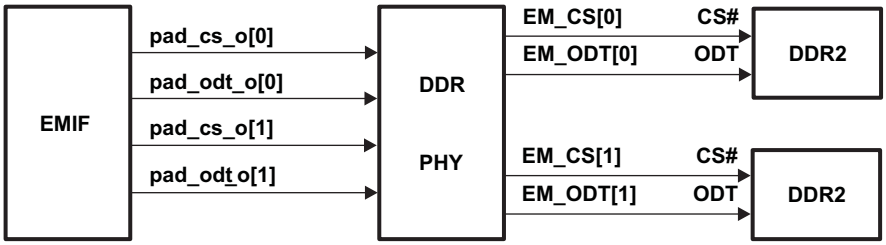


9.2.4 SMS Basic Programming Model

9.2.4.1 SMS Firewall Usage

Use the SMS.SMS_SECURITY_CONTROL register to allow access to the registers.

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.SMS_RG_ATTi register (where i is the region index from 0 to 7).
2. Set the SMS.SMS_RG_RDPERMi register.
3. Set the SMS.SMS_RG_WRPERMi register.
4. Set the SMS.SMS_RG_STARTj register (except for region 0. j is the region index from 1 to 7).
5. Set the SMS.SMS_RG_ENDj register (except for region 0. j is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.SMS_RG_STARTj[30:16] STARTADDRESS and SMS.SMS_RG_ENDj[30:16] ENDADDRESS registers (where j = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

If the secure system wants to restrict use of the firewall to secure mode, the security control register allows setting of a bit that locks the access to all registers to secure supervisor only.

On general-purpose (GP) devices, when all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

To program the SMS firewall region in secure and supervisor privilege only, the SMS_SECURITY_CONTROL register allows any transaction or only secure and supervisor privilege accesses to:

- Rotation context registers (only secure privilege required)
- Arbitration control registers (only secure privilege required)
- Region 1 security firewall registers
- Error log registers (only secure privilege required)
- Security control register configuration lock bit
- Firewall lock bit
- Soft-reset lock bit (only secure privilege required)

If these fields are programmed to 0x1 (meaning that secure and supervisor privilege transaction is required), then nonsecure and supervisor privilege accesses to corresponding registers do not modify the register values and generate an ERRORSECREG error in the SMS_ERR_TYPE register.

9.2.4.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.

   Consider an SDRAM device with 1024-byte pages. The page can be defined as a 16 × 64 array. The page is not necessarily a square (32 × 32 is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

   In terms of register settings, in any context that uses that page size:

   Page (page) width = 2^{pw} bytes (that is, pw = 6)

   Page (page) height = 2^{ph} rows (that is, ph = 4)

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.
   Example: Create a 400 × 300 frame buffer, 16 bits per pixel
   - Pixel size = 2^{ps} bytes (that is ps = 1)
   - Number of pages per line: 400 × 2/64 = 12.5, rounded up to 13
   - Number of pages per column: 300/16 = 18.75, rounded up to 19

   In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

   - Image width = w pixels (that is, w = 13 × 64 /2 = 416)
   - Image height = h pixels (that is, h = 19 × 16 = 304)

NOTE: In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

In terms of memory allocation (in the physical memory), this corresponds to a 416 ×304 × 2 = 252,928-byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

Example, context 1:

- Configure the physical base address of the frame buffer. Example: 512 Mbytes, start of CS0, SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA = 0x20000000 (where n = 1)

- Configure the image height and width:
  Image width (416): SMS.SMS_ROT_SIZEn[10:0] IMAGEWIDTH = 0x1A0 (where n = 1)
  Image height (304): SMS.SMS_ROT_SIZEn[26:16] IMAGEHEIGHT = 0x130
- Configure the control parameters:
  Pixel size (example: 2 bytes, 2^1 bytes): SMS.SMS_ROT_CONTROLn[1:0] PS = 0x1 (where n = 1)
  Page (page) size (example: 1024 bytes = 64 bytes × 16 bytes)
  Page height (example: 16 rows, 2^4 rows): SMS.SMS_ROT_CONTROLn[10:8] PH = 0x4
  Page width (example: 64 bytes, 2^6 bytes): SMS.SMS_ROT_CONTROLn[6:4] PW = 0x6

3. The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, LCD controller, etc.).

   From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

   - Context 1 0-degree view: 0x7400 0000
   - Context 1 90-degree view: 0x7500 0000
   - Context 1 180-degree view: 0x7600 0000
   - Context 1 270-degree view: 0x7700 0000

   The start address of the view corresponds to the logical origin of the image (x = 0, y = 0). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

   Example of usage by the application:

   In a system using an 400 × 300 LCD panel that has a native landscape orientation, the natural scan order is as shown in Figure 9-91.

Figure 9-91. Natural Scan Order

   The display buffer is the one created in the example sequence.

   When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

   - The LCD controller accesses the frame buffer using the 0-degree view.
   - The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

   When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

   - The LCD controller still accesses the frame buffer using the 0-degree view.
   - The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See Section 9.2.5.1.1.

9.2.4.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- Register security settings
  - SMS.SMS_SECURITY_CONTROL register
    - Arbitration control registers security level (SMS.SMS_SECURITY_CONTROL[5] ARBITRATIONREGSLOCK bit)
- For each of the three classes, the arbitration parameters are:
  - SMS.SMS_CLASS_ARBITER0 through SMS.SMS_CLASS_ARBITER2
    - One high-priority FIFO queue in the class (HIGHPRIOVECTOR field)
    - Number of consecutive transactions to perform (EXTENDEDGRANT field)
    - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

9.2.4.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.SMS_ERR_ADDR register. The error type is logged in the SMS.SMS_ERR_TYPE register. Once a faulty access is logged and the SMS.SMS_ERR_TYPE[0] ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.
- A protection region overlap is detected.
- A nonsecure or non-supervisor write access to the security control register is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

The security control register allows locking the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers to secure- and supervisor-only accesses. This configuration is highly recommended for high-security devices. For GP devices, ErrorLog can remain public.

9.2.5 SDRC Use Cases and Tips

9.2.5.1 How to Program the VRFB

9.2.5.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the processor, as shown in Figure 9-92 . It is configured in the SMS registers.

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the EMIF so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

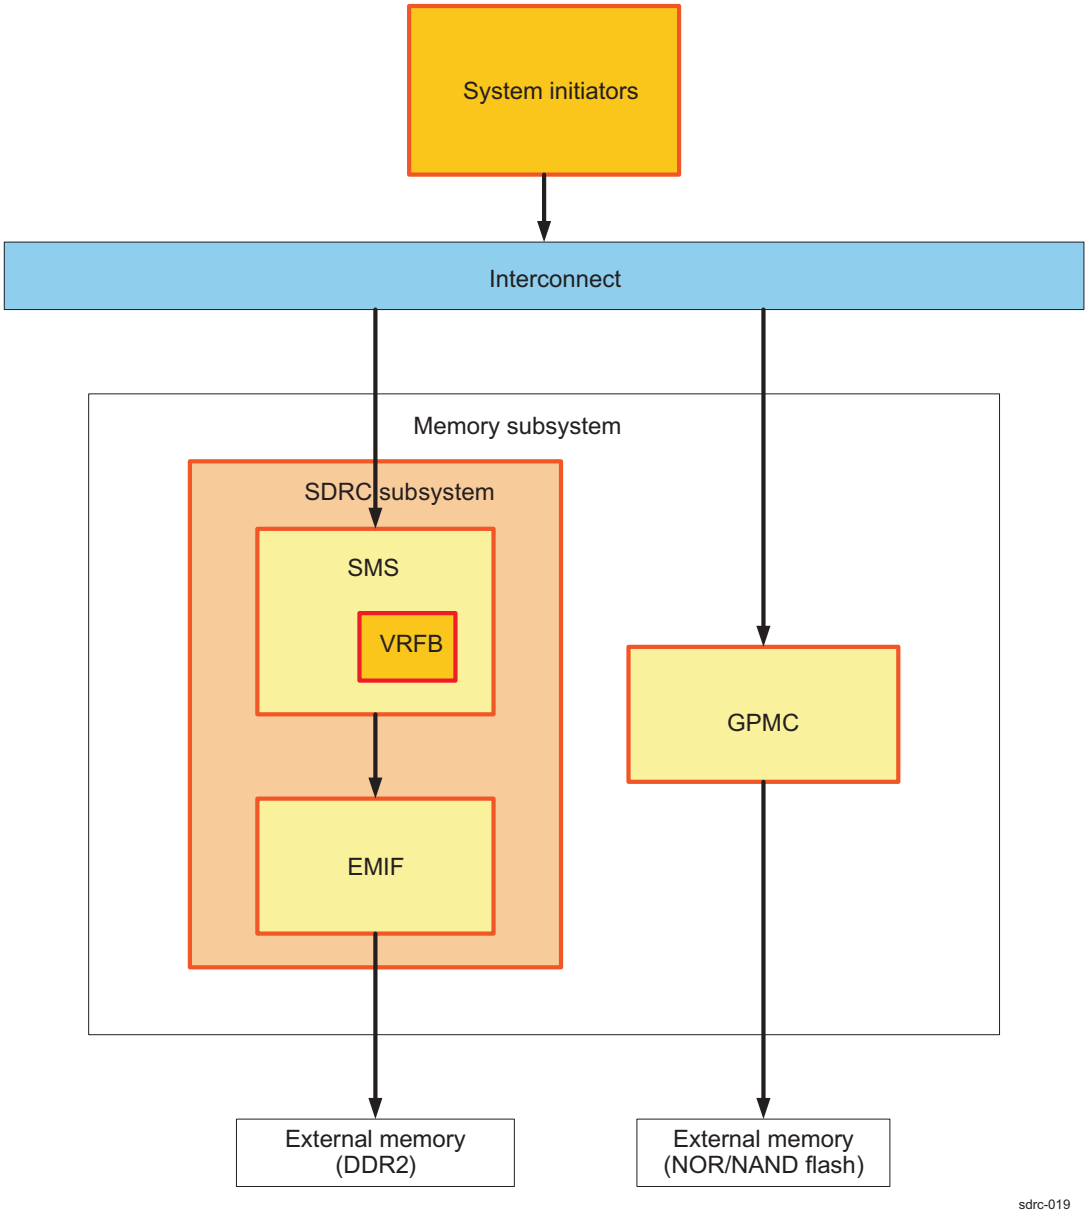
- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the processor can access up to 12 images simultaneously, each image having an independent context. These 12 contexts is considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

Figure 9-92. SDRC Subsystem Overview



9.2.5.1.2 Setting a VRFB Context

NOTE: YUV Format

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in Figure 9-93, pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

Figure 9-93 shows the pixel representation of the YUV format.

Figure 9-93. YUV Format: Pixel Representation

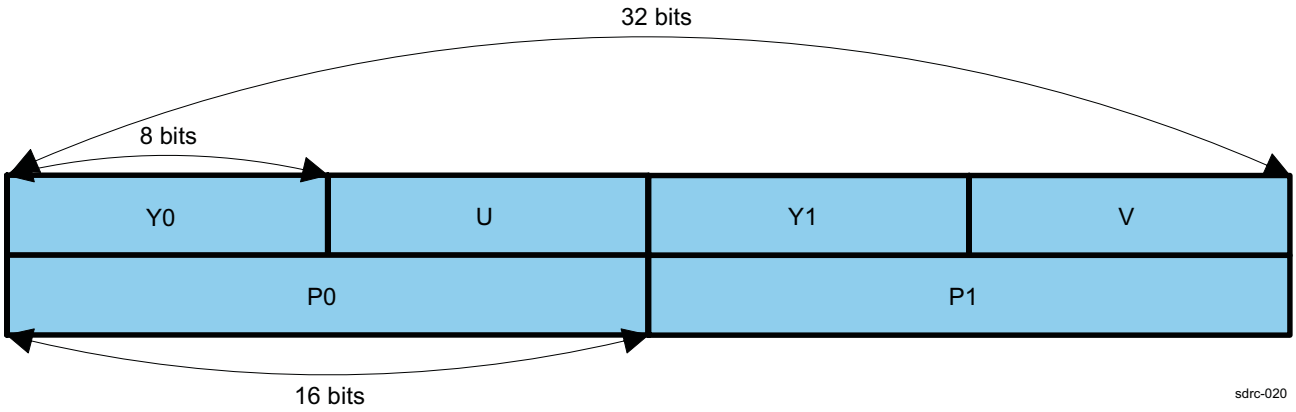


Figure 9-94 shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

Figure 9-94. VRFB Context Configuration

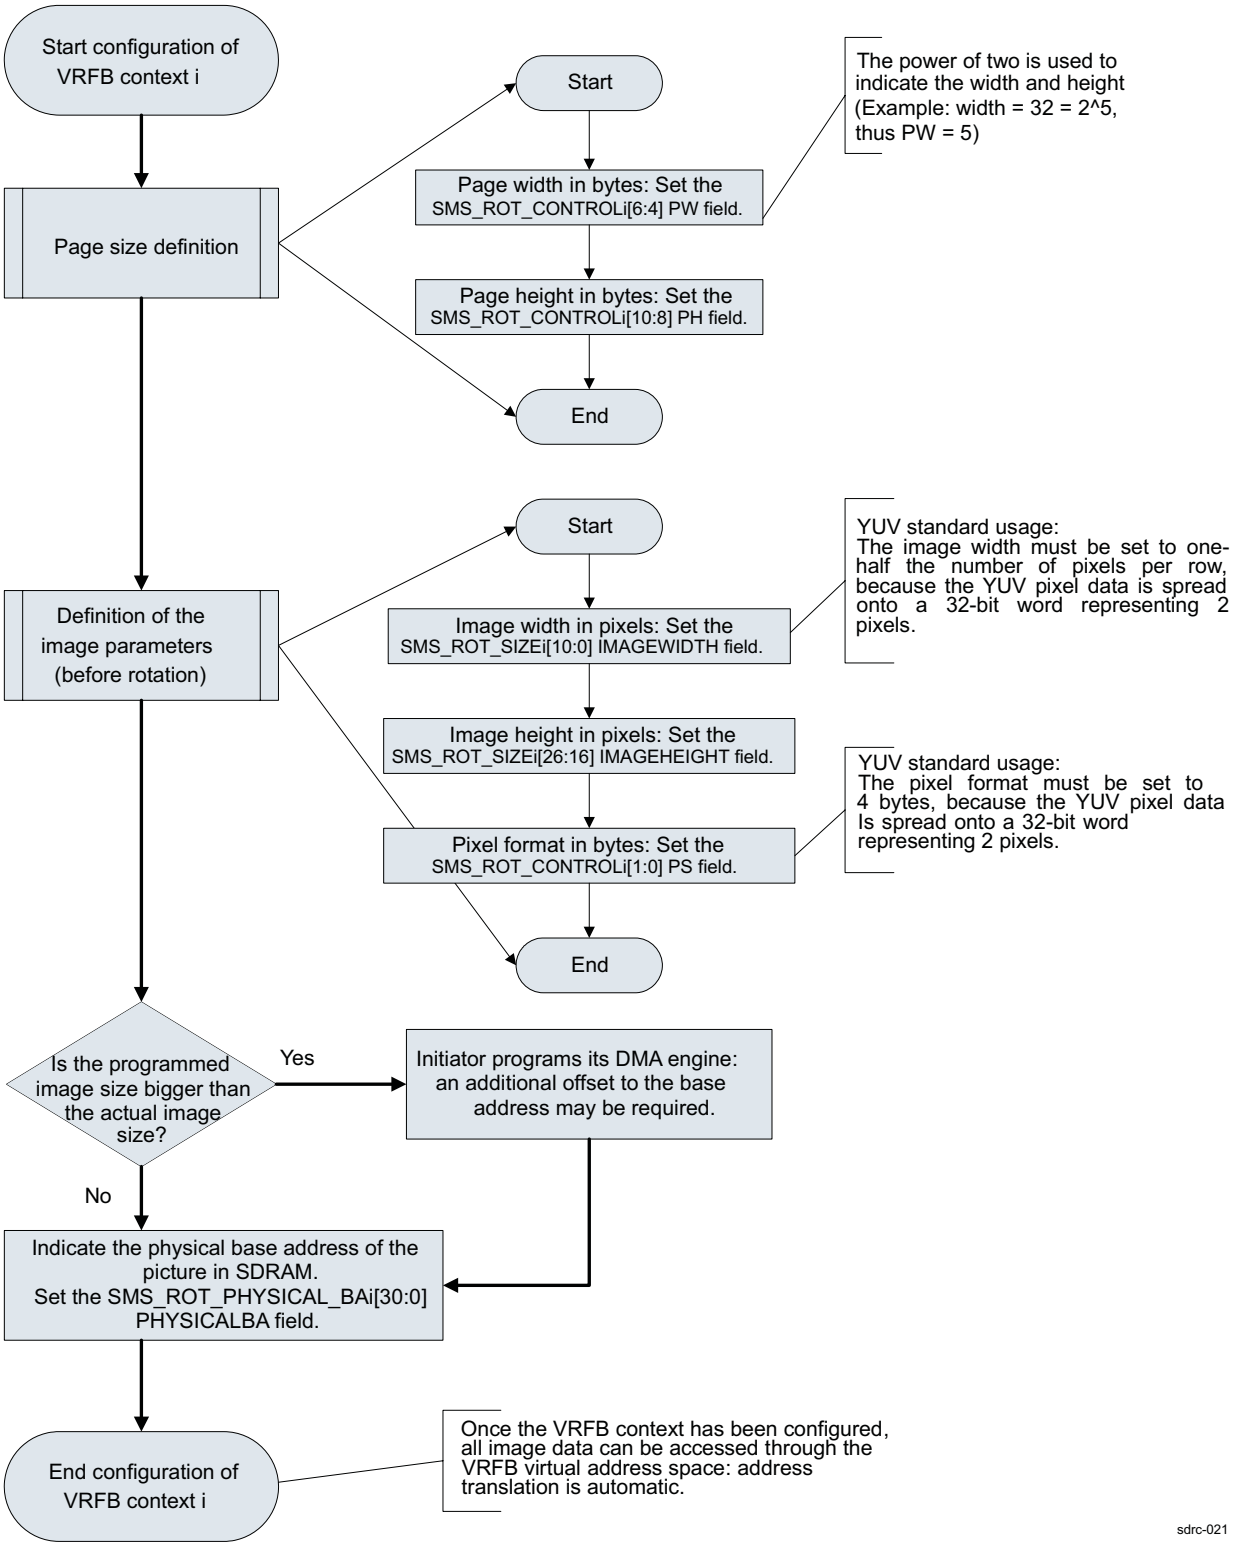

Figure 9-95 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 × 32 byte page) and a 240 × 240 image size using VRFB context 1.

Figure 9-95. Example of VRFB Context 1 Configuration

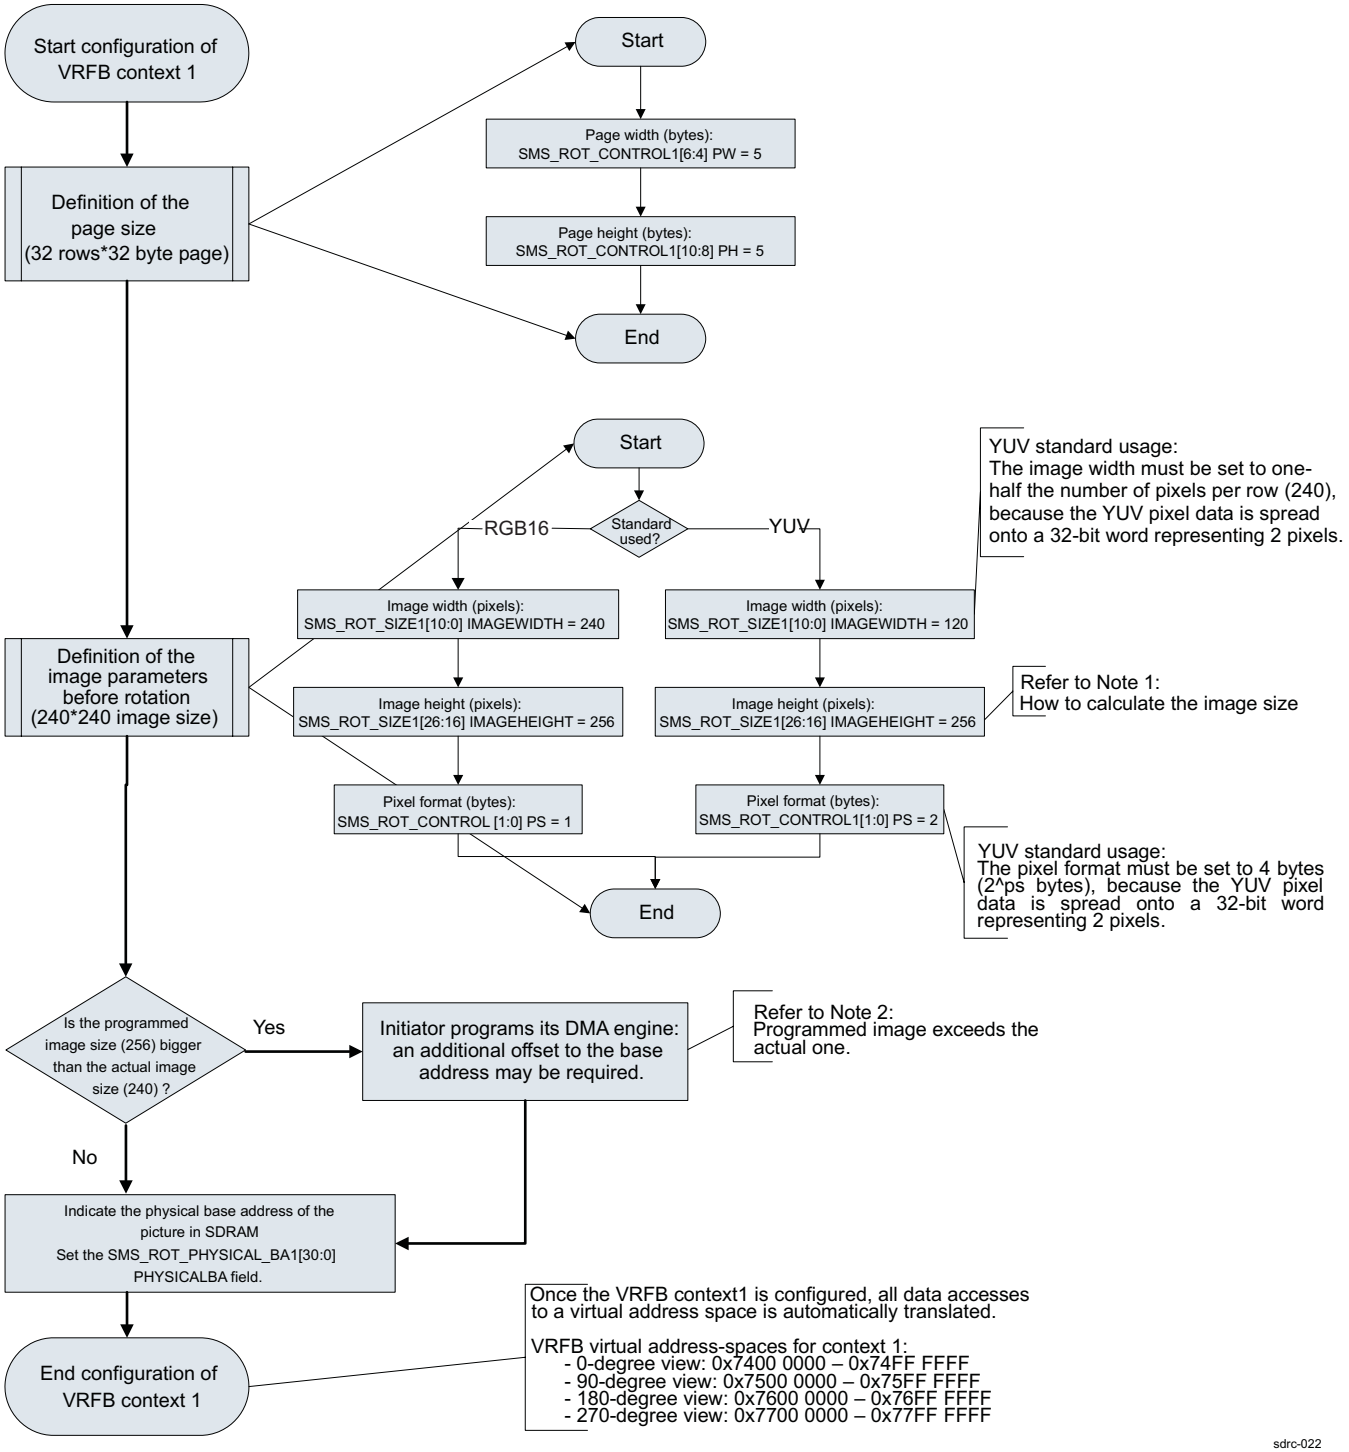

Table 9-111 lists guidelines for calculating image size.

Table 9-111. Calculating Image Size[1] [2]

Steps		RGB16 Format (16-bit Pixel Format)		YUV Format (32-bit Pixel Format)	
		IMAGEWIDTH	IMAGEHEIGHT	IMAGEWIDTH	IMAGEHEIGHT
1	Calculate the required number of pages per line and per column.	240 pixels/32 bytes × 2 bytes per pixel = 15 pages per line	240/32 rows = 7.5, rounded to 8 pages per column	120 pixels/32 bytes × 4 bytes per pixel format = 15	240/32 rows = 7.5, rounded to 8
2	Using the number of pages calculated in Step 1, calculate the image size in pixels.	15 × 32 bytes/2 bytes per pixel = 240	8 × 32 rows = 256	I5 × 32 bytes/4 bytes per pixel format = 120	256

(1) Working on a page basis, the image size must be a multiple of the page size.

(2) Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see the *Display Subsystem* chapter.

9.2.5.1.3 Applicative Use Case and Tips

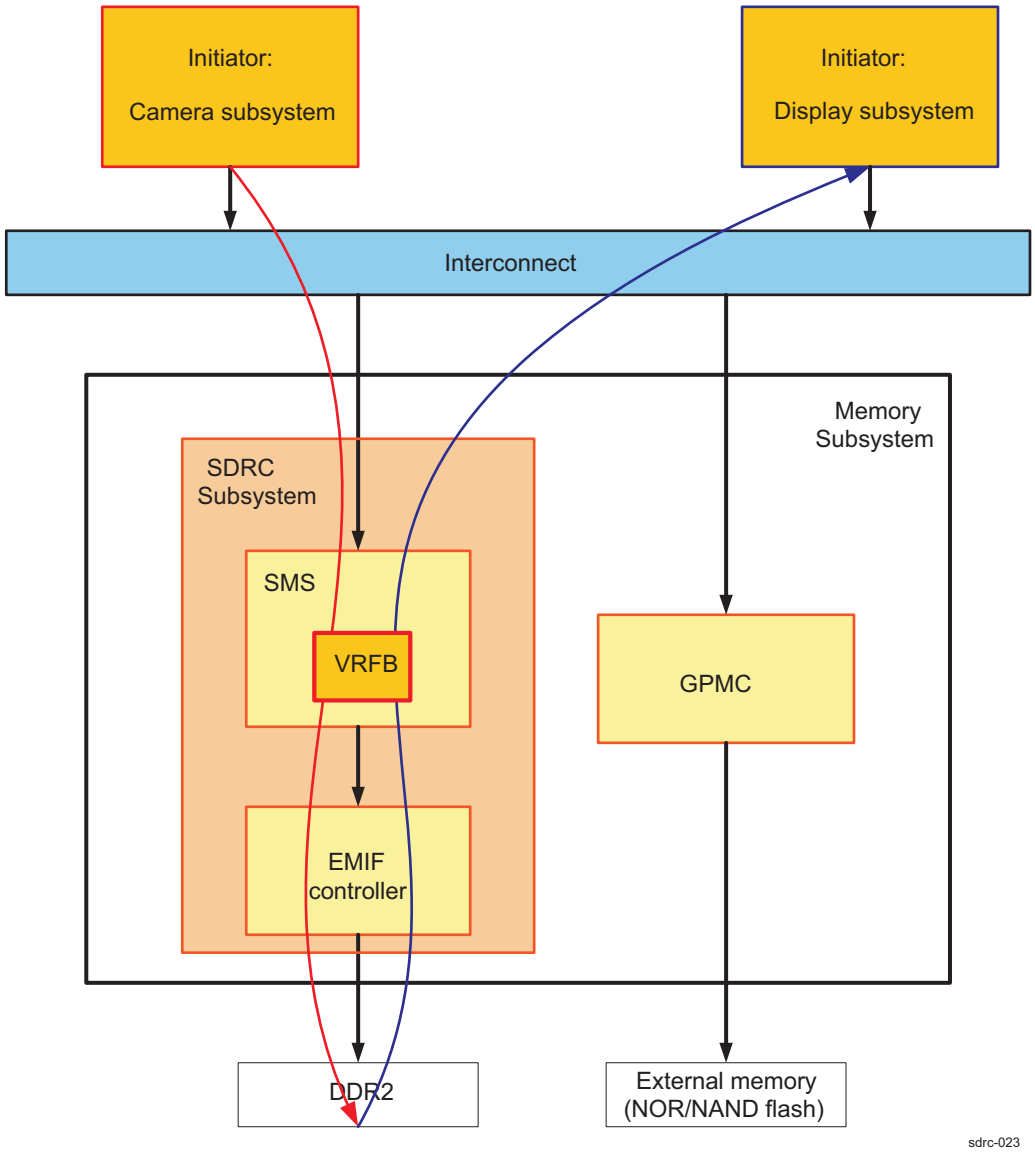
Use Case Scenario: Display a Rotated QVGA Image

Figure 9-96 this use case. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the LCD requires different orientation.

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

Figure 9-96. Display a Rotated QVGA Image



The following conditions exist for this application:

- QVGA image size is 320 × 240 (width × height).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR2 at 60 fps and displays them on the LCD screen.
- Read and write initiators use burst mode:
  - The camera uses 8 × 64-bit burst size.
  - The display uses 8 × 32-bit burst size.
  - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is 320 × 240- × 16-bit (or 160 × 240 × 32-bit).

- The camera subsystem uses its dedicated DMA channel 0.
- The display subsystem uses its video channel 1.

Configuring the VRFB through the SMS Registers

The size of the page supported by the DDR2 memory is 1K byte, which is arranged as 32 × 32 bytes page (width × height).

Configuring the page size:

- SMS_ROT_CONTROLn[6:4] PW = 5 (where n = 1)
- SMS_ROT_CONTROLn[10:8] PH = 5

Configuring the image parameters:

- SMS_ROT_SIZEn[10:0] IMAGEWIDTH = 160 (where n = 1)
- SMS_ROT_SIZEn[26:16] IMAGEHEIGHT = 256
- SMS_ROT_CONTROLn[1:0] PS = 2

Physical base address and rotation angle:

- SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 – 0x75FF FFFF.

CAUTION

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

Tips for Configuring Successful Rotation

The following guidelines ensure optimal image rotation:

- Page arrangement:

  Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.

  Using a 1024-byte page size, a 32 × 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 × 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- Virtual address memory arrangement:

  When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.

  In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 – IMAGEWIDTH) × PS bytes at the end of every line.
- Base address alignment:

  For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 × 32-byte page is aligned on 0x400 (to be adjusted on the base address).
- To improve performance on 90° rotation consider two things:
  - Because a read access can appear more critical than a write access, a posted write may be appropriate.
  - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.

    For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):

- Write in 270° and read in 0°.

9.2.5.2 SMS Mode of Operation

9.2.5.2.1 The SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

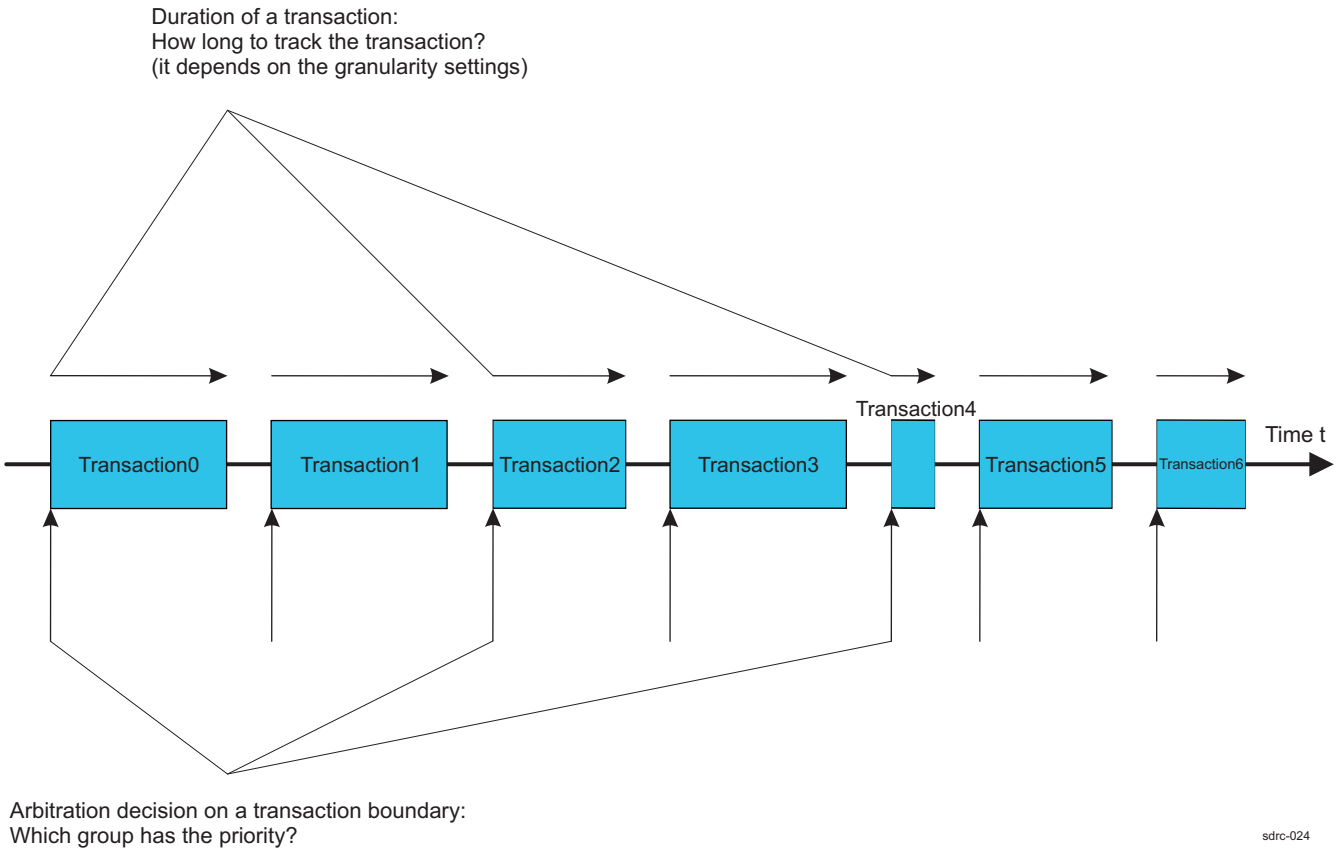
- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

Figure 9-97, shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

Figure 9-97. Arbitration Granularity Versus Arbitration Decision



9.2.5.2.2 The Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

9.2.5.2.2.1 Burst-Complete Mechanism

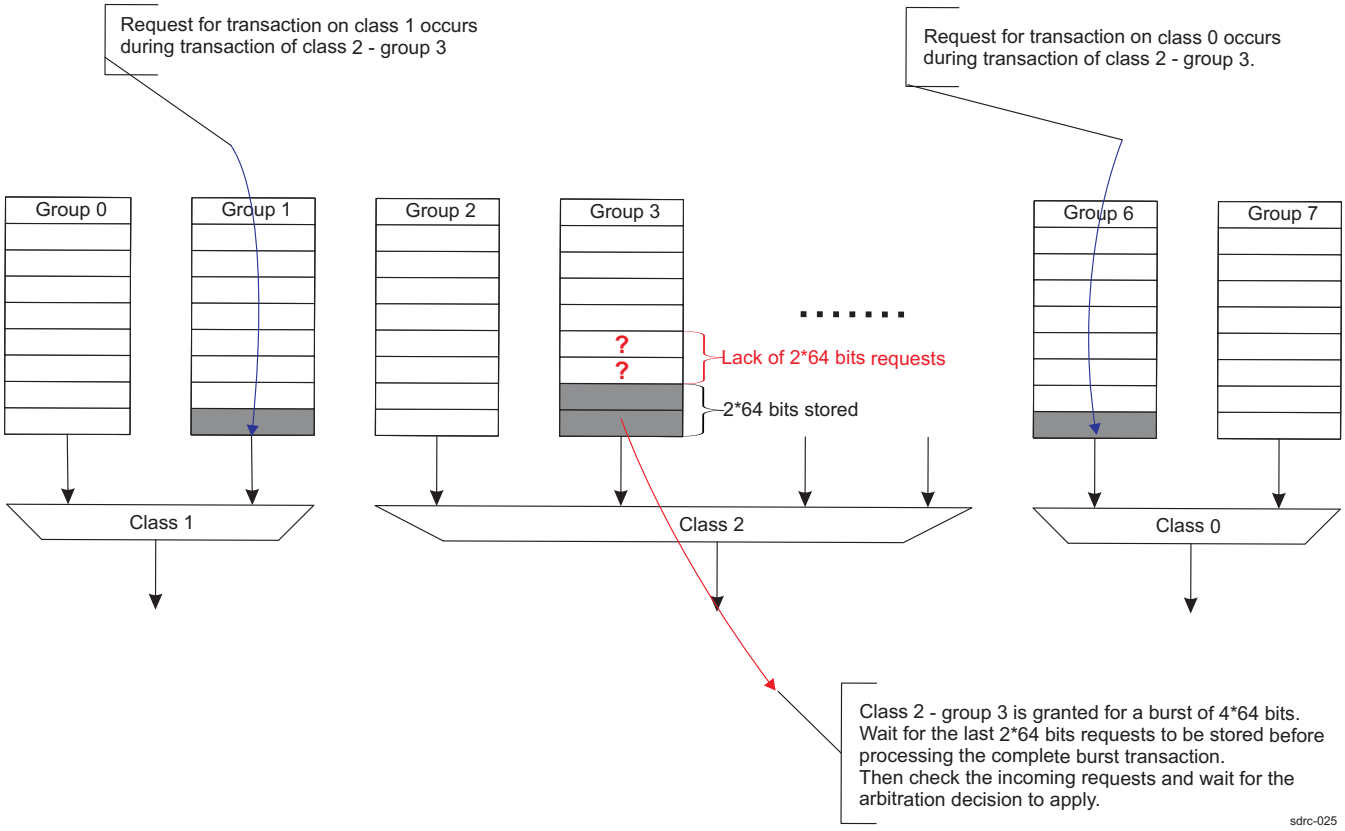
The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

Example:
There is no ongoing transaction on Class 0. The initiator requests a 4 × 64-bit burst on Group 3 of Class 2 (SMS_CLASS_ARBITER2[27] BURST-COMPLETE = 0x1). Only 2 × 64-bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last 2 × 64-bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the 4 × 64-bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced/granted?

Figure 9-98. BURST-COMPLETE on Class 2-Group 3



9.2.5.2.2.2 Priority Between Groups

The SMS.SMS_CLASS_ARBITERi[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

9.2.5.2.2.3 Priority Between Classes

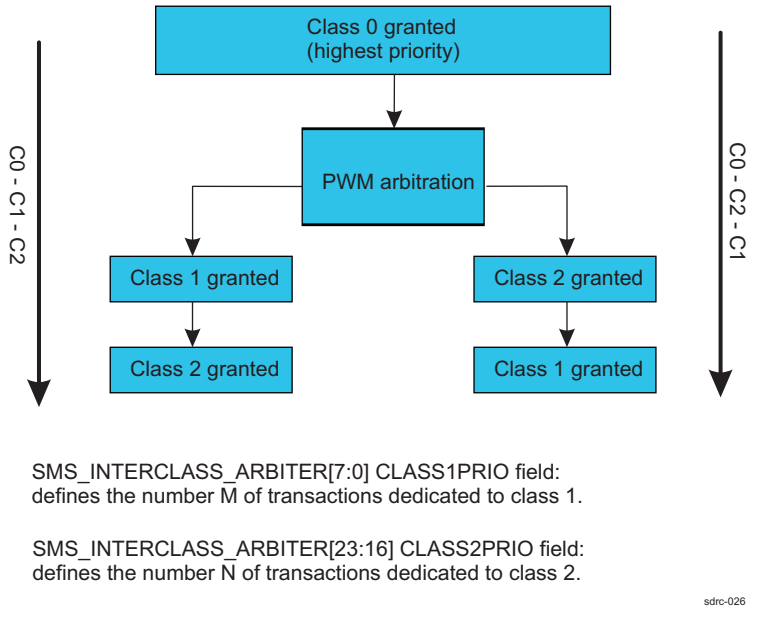
Class 0 always has the highest priority. Then you program a weight within the arbitration of Class 1 and Class 2:

- The SMS.SMS_INTERCLASS_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS_INTERCLASS_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, directly followed by service to Class 2 for N cycles. On the opposite, If Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in Figure 9-99, two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, then Class 1 (C0 - C2 - C1).

Figure 9-99. Priority Between Classes



9.2.5.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

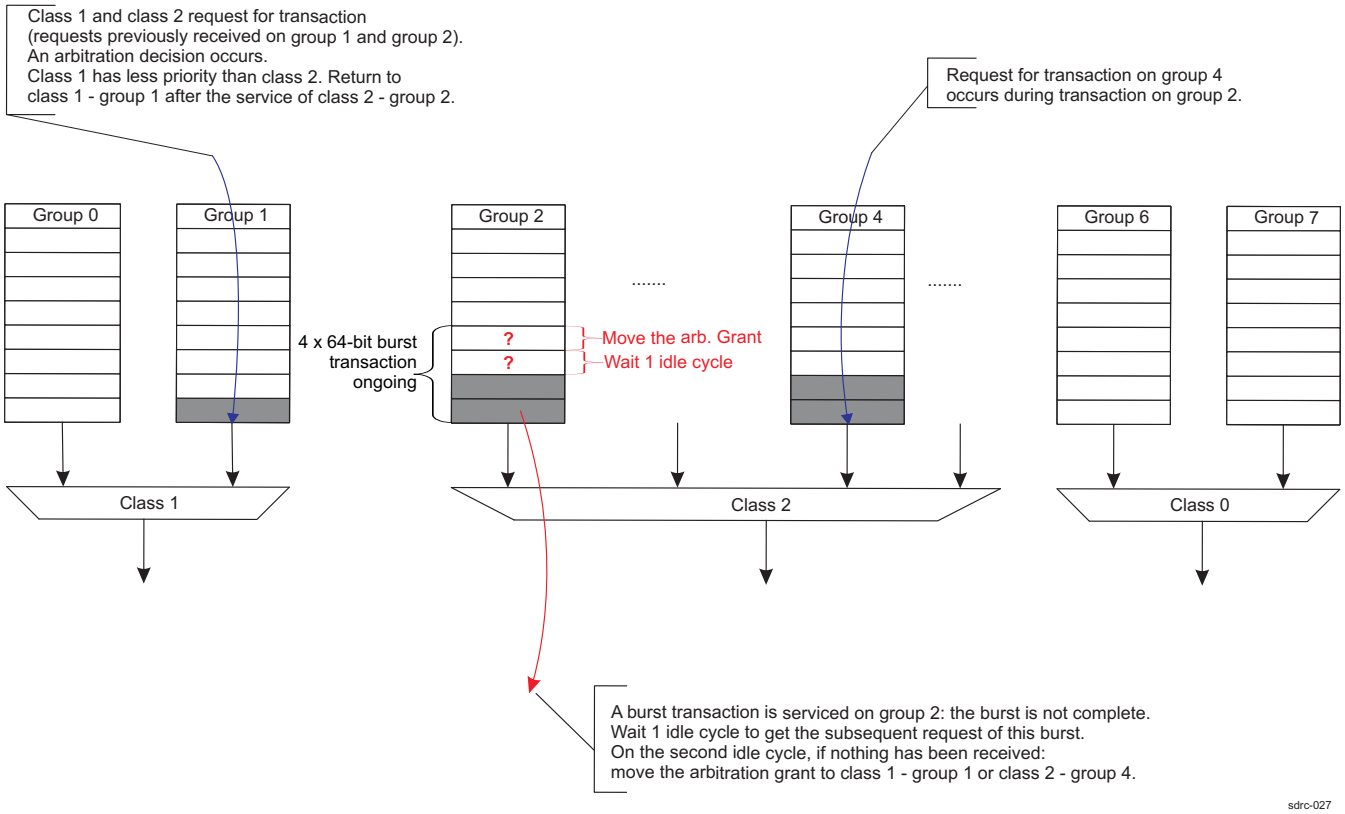
9.2.5.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see Figure 9-100 for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 – Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

Figure 9-100. Idle Cycle Mechanism within a Burst



Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

9.2.5.2.3.2 Extended-Grant Mechanism

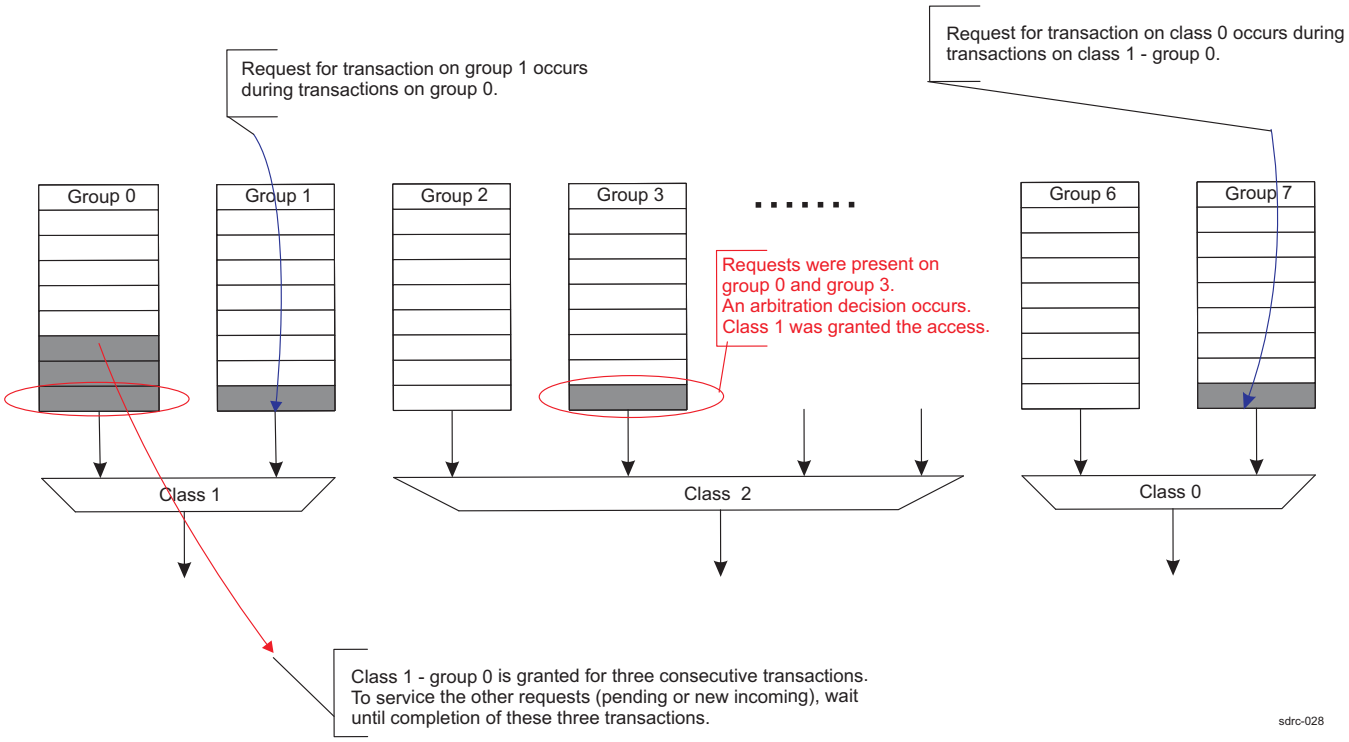
The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:
Requests were already available on Class 1-Group 0 and Class 2-Group 3.
An arbitration decision occurs: grant access to Class 1-Group 0.
A request is now being serviced on Class 1–Group 0 with SMS_CLASS_ARBITER1[9:8] EXTENDEDGRANT = 0x3 (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
  - Were there any incoming requests during the last transaction?
  - What is the next request to be serviced?

Figure 9-101 shows this mechanism on Class 1 - Group 0:

Figure 9-101. Example of EXTENDEDGRANT Mechanism



9.2.5.2.3.3 Number of Service Mechanism

The SMS_CLASS_ROTATIONm[4:0] NOFSERVICES field defines the number of consecutive transactions (from 1 to 31) the VRFB is granted. For more information on LRU policy and Number of Service, refer to Section 9.2.3.1.3.

9.2.5.2.4 How these Mechanisms Interact

As described in the previous sections, the arbitration within the SMS module is based on several mechanisms giving even more importance to the arbitration. Wen we need to grant the access on a transaction boundary, we recall that the question we have to answer is: what will be the next request to be serviced and for how long?
Thus, the two important concepts regarding the SMS mode of operation are:

- The arbitration decision: we choose the next request to be serviced and so we grant it the access to the external memory.
- The arbitration granularity: depending on the mechanism used, we define the boundary of the transaction: how long do we keep the grant?

Figure 9-102 describes the decision happening between classes.
Figure 9-103 explains the priority between groups within Class 1.
So far, the arbitration decision has taken place at class boundaries and within a class containing 2 groups.
Figure 9-104 recalls the generic way to service and so prioritize the requests within a class.
Finally, Figure 9-105 recalls mechanisms used to define the boundary of the transaction being serviced (how long do we keep the grant?).

Figure 9-102. Arbitration Between Classes

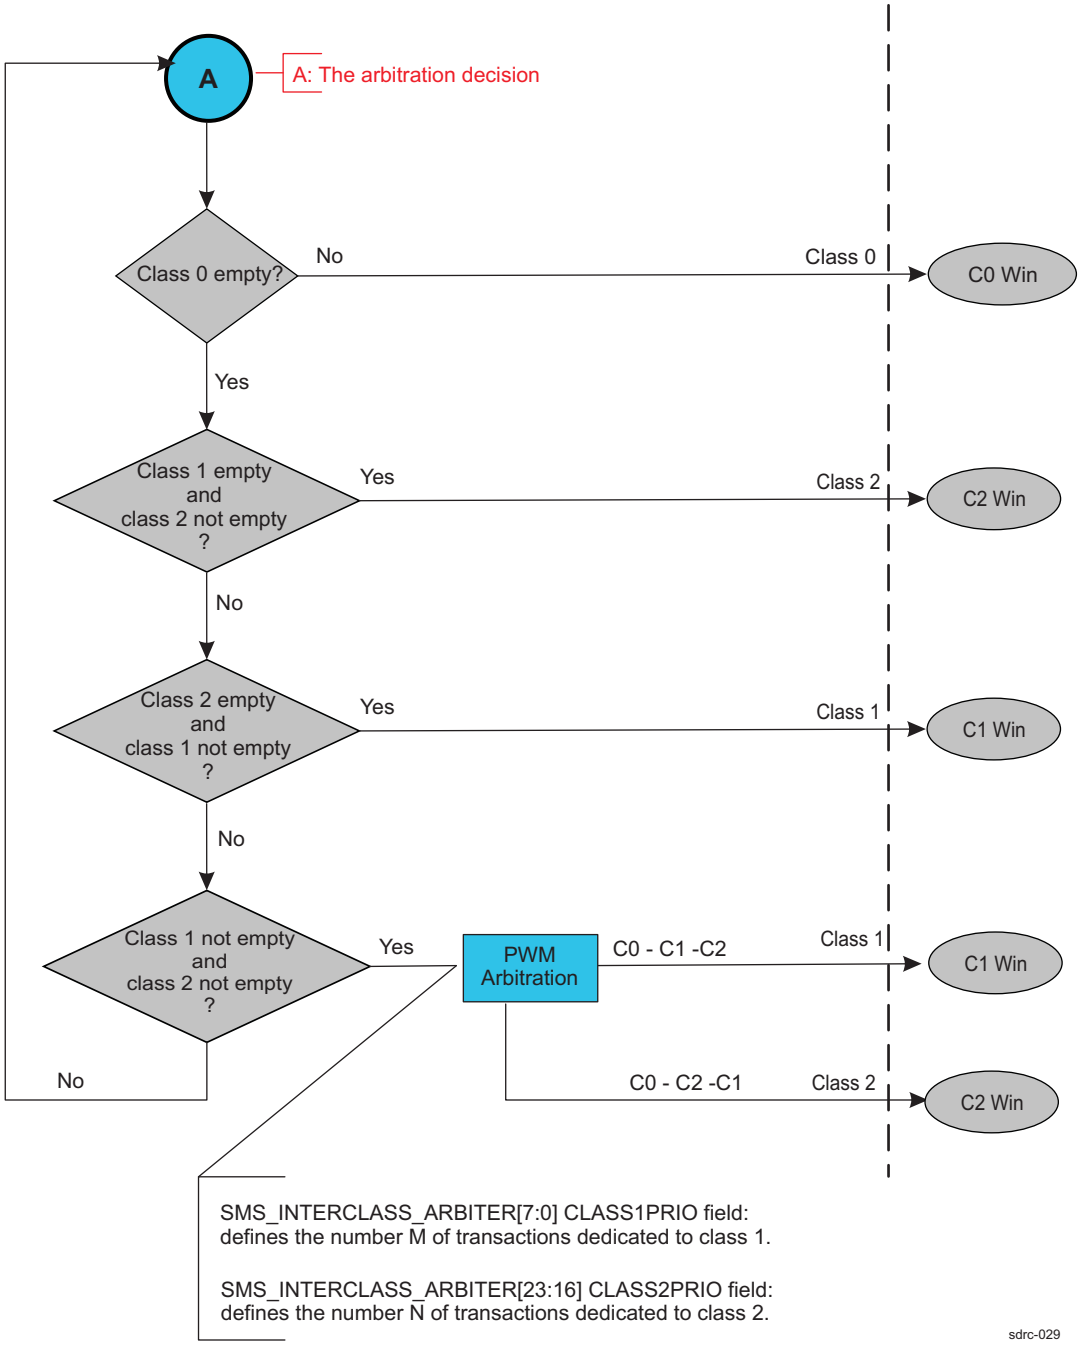


Figure 9-103. Arbitration within a Class

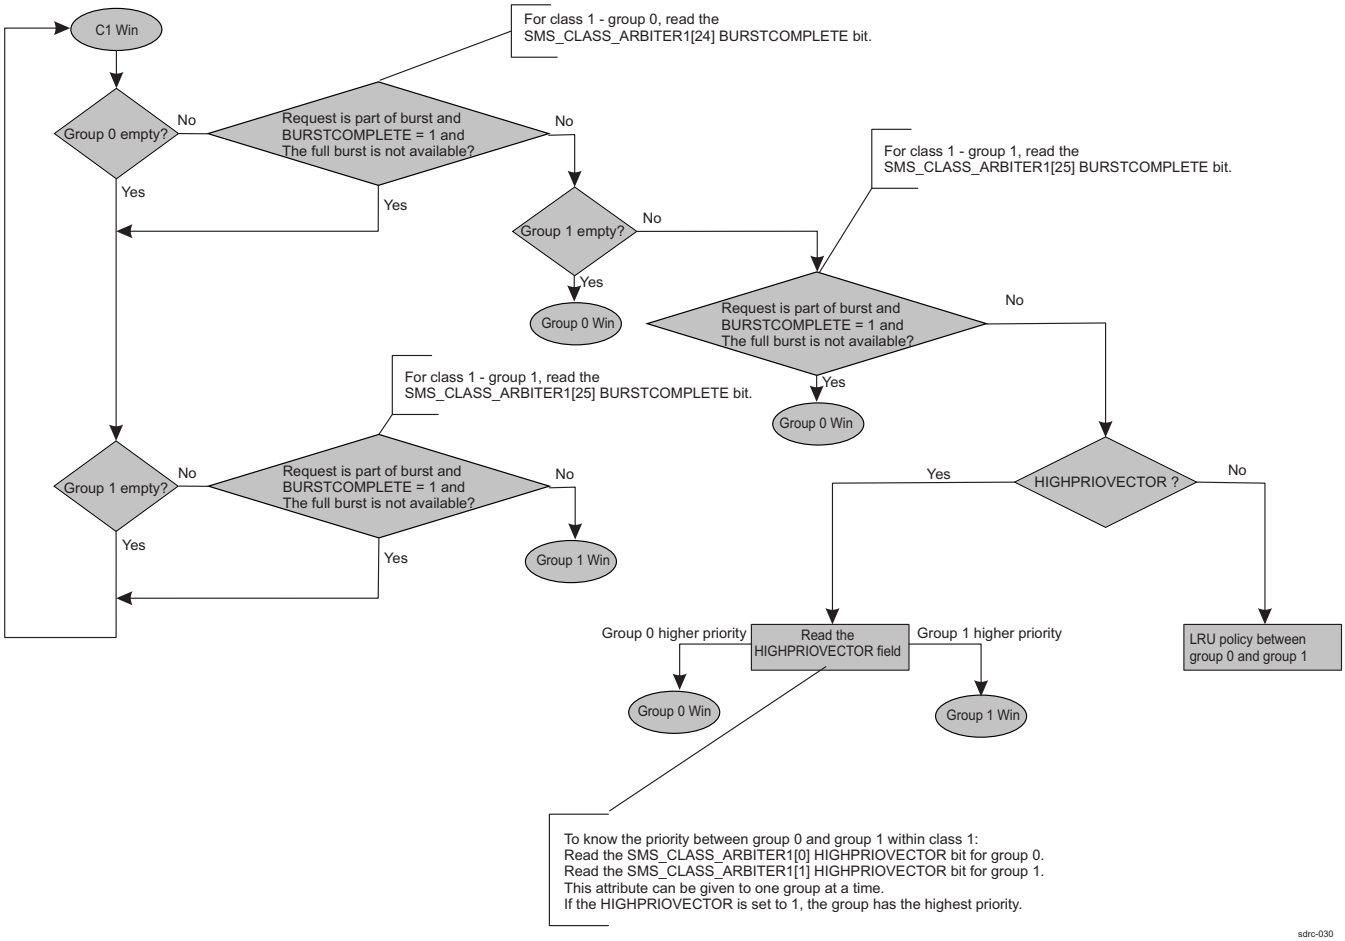

Figure 9-104. Generic Arbitration Decision

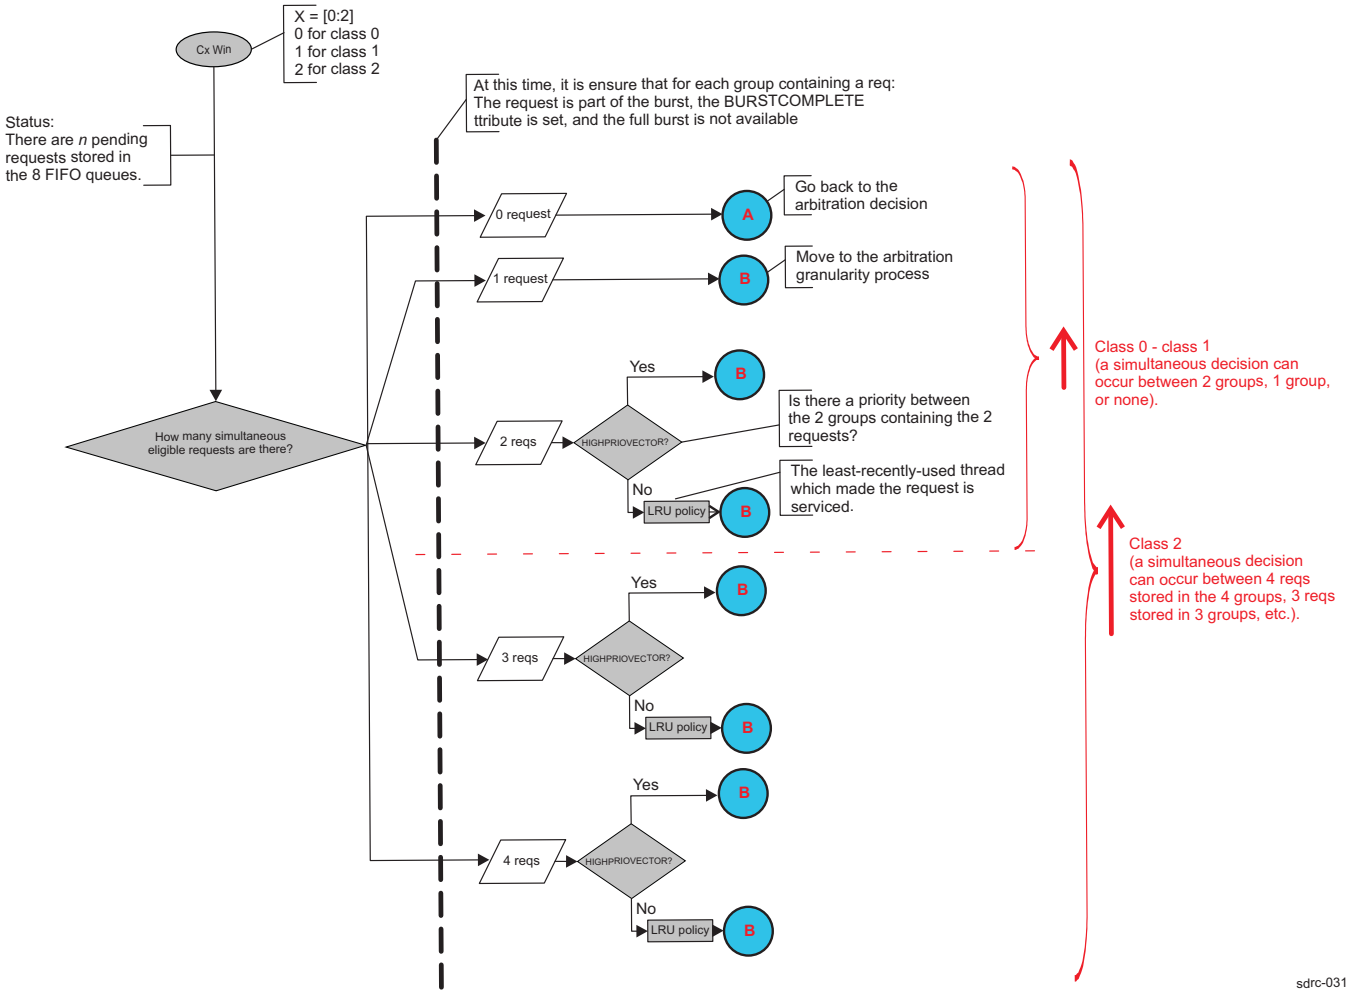

Figure 9-105. Arbitration Granularity

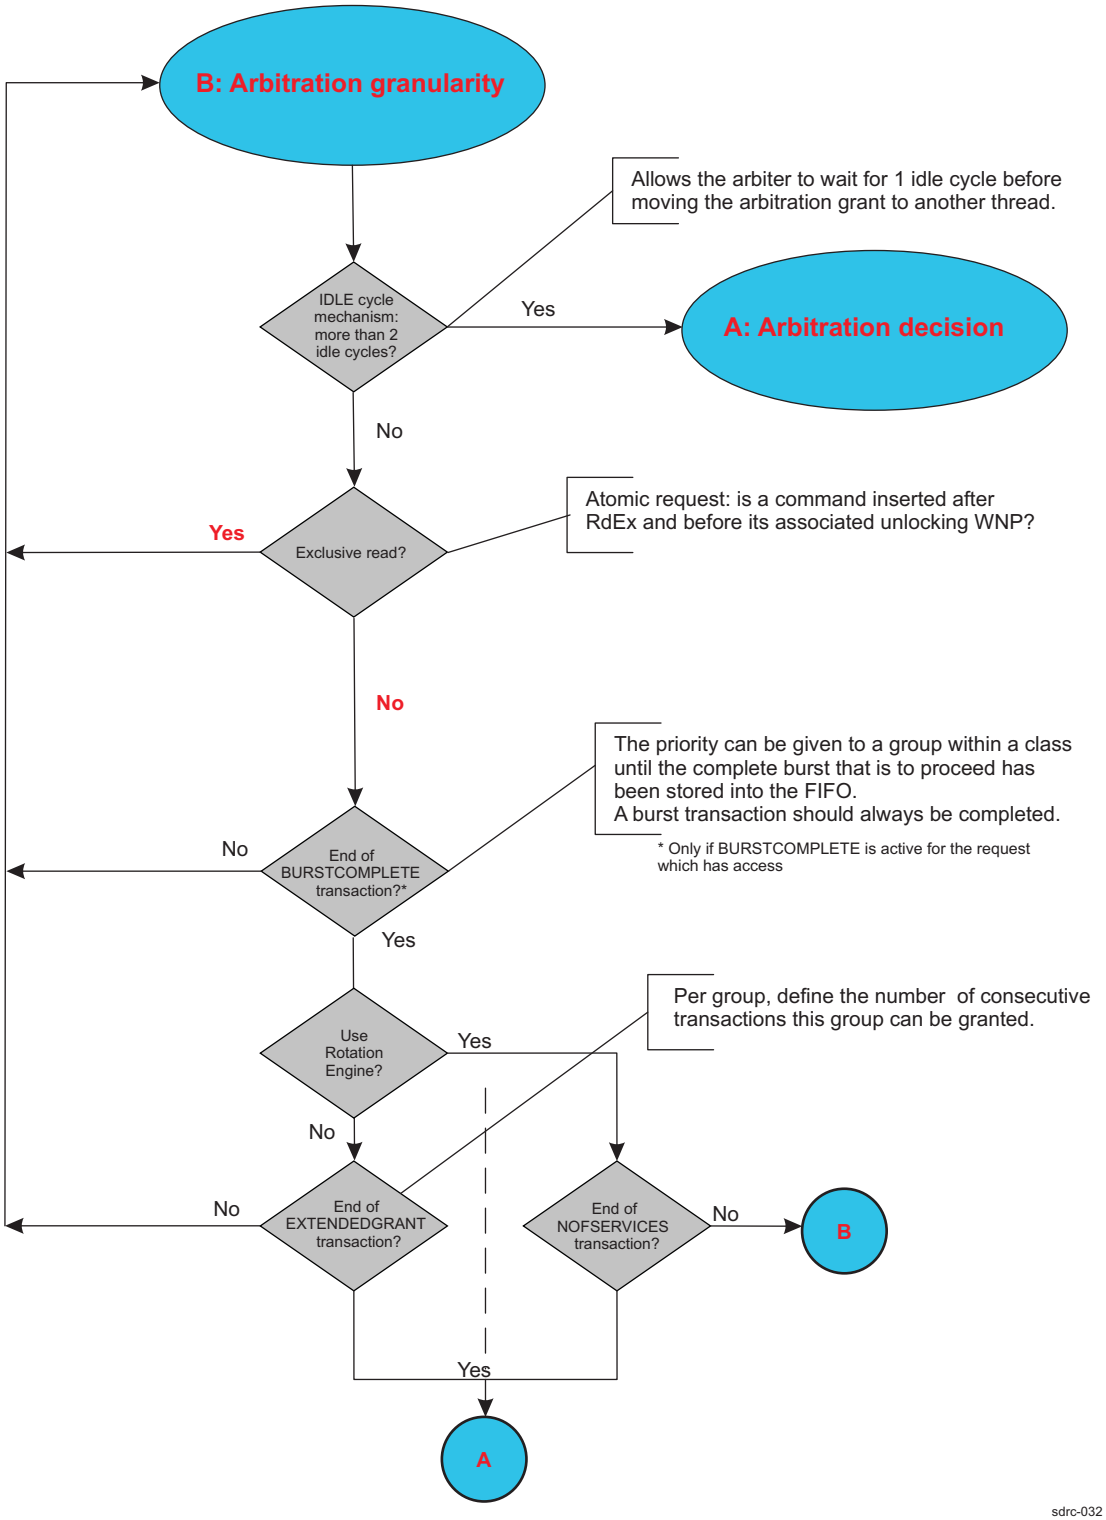
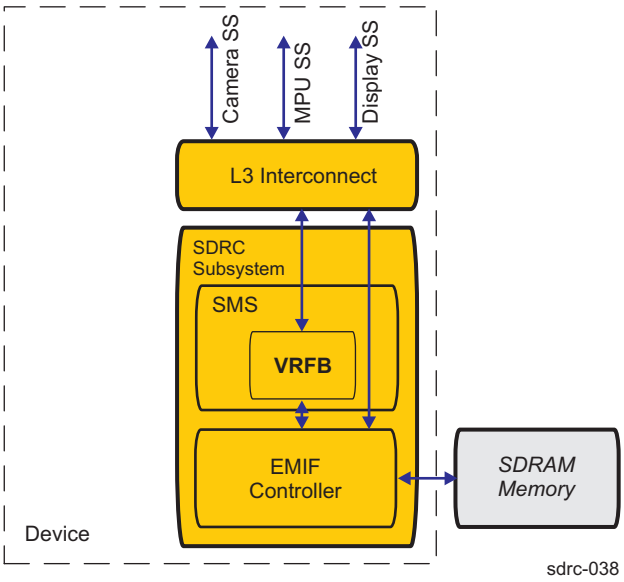


9.2.5.3 Camcorder Use Case: How to Configure the VRFB

9.2.5.3.1 Overview

This section discusses the configuration of the VRFB for rotating the video from the camera subsystem. The VRFB receives a video from the camera subsystem as a sequence of images. These images are then saved into SDRAM through the EMIF . Figure 9-106 is an overview of the VRFB in the camcorder use case.

Figure 9-106. SDRC Camcorder Use Case Overview



After the VRFB configuration, the rotation process is transparent to the MPU operations. Four buffers are required in SDRAM to ensure stabilization, a smooth encoding process, and a tearing-free preview on the LCD display. Each of the four buffers uses a concurrent context. For each context, the following parameters must be configured:

- Page and pixel size
- Picture parameter (image height and width)
- Buffer physical base address

9.2.5.3.2 Data Path

In this use case, the VRFB manages the rotation of the video stream, which is a sequence of images in YUV 4:2:2 format received from the camera subsystem.

- Write actual image received from the camera subsystem into SDRAM through the VRFB in the first view (0°).
- Display the image in SDRAM on the external display through the display subsystem in any of the four available VRFB views (0°, 90°, 180°, or 270°).

See Figure 9-96 for the VRFB data path of this use case.

The row increment in the SDRAM is programmed in the display subsystem registers and depends on the VRFB rotation angle.

9.2.5.3.3 Programming Flow

A main function automatically configures the VRFB contexts. This function is called four times to configure each of the four contexts. For each context, a set of parameters is given to the function:

- The actual image width and height (from the camera subsystem)
- The physical address (of the given context)

- The rotation of the context

The main function initializes the VFRB in three steps:

1. Virtual frame buffer configuration. This is done with a page size calculation function, as described in Section 9.2.5.3.3.1.
2. Image size configuration. This is done with a picture size calculation function, as described in Section 9.2.5.3.3.2.
3. Physical base address configuration, as described in Section 9.2.5.3.3.3.

9.2.5.3.3.1 Page Size Calculation Function

The page size is configured through three parameters: page width (PW), page height (PH), and pixel size (PS). The three page size parameters are configured into the SMS_ROT_CONTROLn registers, where n is the context number (n = 0 to 3):

- Page width: SMS_ROT_CONTROLn[6:4] PW. The PW parameter defines the page width according to the value of 2^{PW} bytes.
- Page height: SMS_ROT_CONTROLn[10:8] PH. The PH parameter defines the page height according to the value of 2^{PH} lines.
- Pixel format: SMS_ROT_CONTROLn[1:0] PS. The PS parameter defines the pixel size according to the value of 2^{PS} bytes. In this use case, the pixel size is a constant linked to the YUV 4:2:2 format. For more details about YUV 4:2:2 format, see Section 9.2.5.1.2, *Setting a VRFB Context*.

The recommendation is to have a squared page arrangement. The page can be defined as a 32-byte × 32-byte array (1024-byte page) or 16-byte × 16-byte array (256-byte page). This arrangement is pixel-based, which means the pixel size must be part of the calculation. Other settings are possible, but from a performance point of view it is recommended to have the page size consistent with the SDRAM page (that is, 2K bytes for the Mobile DDR SDRAM).

In this use case, however, the page size calculation function defines the page width and the page height. The pixel size is not part of the calculation. Hence, instead of having a 64 × 32 page (because a pixel takes 2 bytes) the function calculates a 32 × 32 page. This gives a page size of 1K-byte, and memory area usage is optimized.

First, the function checks whether the width of the image received from the camera is a multiple of 32 bytes. If the width is not a multiple of 32 bytes, the function checks whether the image is a multiple of 16 bytes. If the image from the camera is neither a multiple of 32 bytes nor 16 bytes, the function sets the page width to 32 bytes as the default. In this use case, the image received from the camera has a width of 736 pixels.

1. Check that 736 is a multiple of 32: 736 / 32 = 23. It is. As a consequence, the page width is 32 (bytes).
2. Configure a page width of 32 with the 2^{PW} bytes formula: SMS_ROT_CONTROLn[6:4] PW = 0x5.

   Then, the function checks whether the height of the image received from the camera is a multiple of 32 (rows). If the height is not a multiple of 32 (rows), the function checks whether the image is a multiple of 16 rows. If the image from the camera is neither a multiple of 32 rows nor 16 rows, the function sets the page height to 32 rows as the default. In this use case, the image received from the camera has a height of 560 lines.
3. Check that 560 is a multiple of 32: 560 / 32 = 17.5. It is not.
4. Check that 560 is a multiple of 16: 560 / 16 = 35. It is. As a consequence, the page height is 16 (lines).
5. Configure a page height of 16 with the 2^{PH} lines formula: SMS_ROT_CONTROLn[10:8] PH= 0x4.

   The pixel format of this use case is YUV 4:2:2. Two pixels are stored on 4 bytes.
6. Configure a pixel size of four bytes with the 2^{PS} bytes formula: SMS_ROT_CONTROLn[1:0] PS = 0x2.

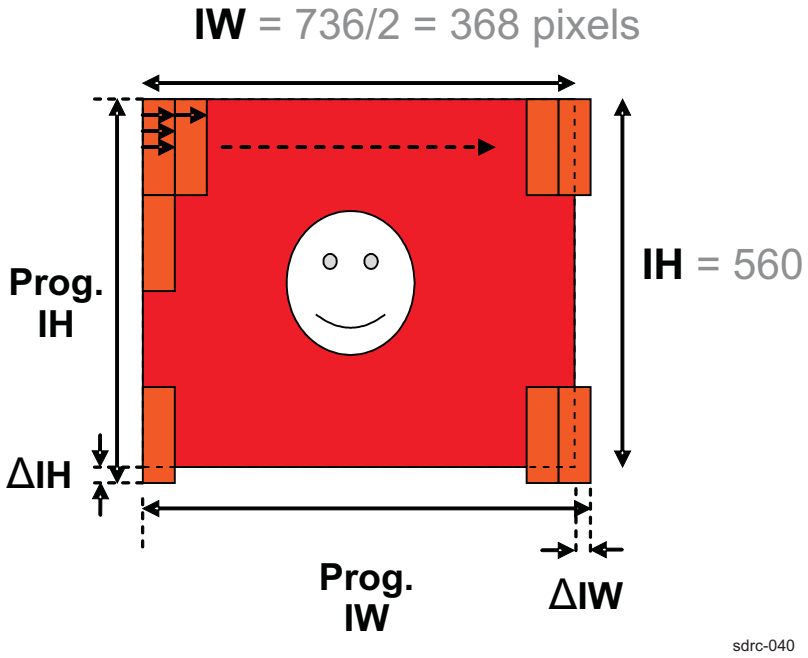
9.2.5.3.3.2 Picture Size Calculation Function

The picture size is configured through two parameters: image width (IMAGEWIDTH) and image height (IMAGEHEIGHT). Two sizes must be distinguished:

- Actual image width and actual image height . This is the size of the image received by the camera subsystem.
- Programmed image width and programmed image height. This is the size of the image programmed in the VRFB.

Figure 9-107 shows the actual image width (IW) and image height (IH) versus the programmed image width (IW + Δ_{IW}) and programmed image height (IH + Δ_{IH}).

Figure 9-107. VRFB Actual Image Size vs Programmed Image Size



The programmed image size parameters are configured into the SMS_ROT_SIZEn registers, where n is the context number (n = 0 to 3):

- Image width: SMS_ROT_SIZEn[10:0] IMAGEWIDTH. This parameter is expressed in the number of pixels.
- Image height: SMS_ROT_SIZEn[26:16] IMAGEHEIGHT. This parameter is expressed in the number of pixels.

The picture size calculation function determines the required number of pages per line and per column using the page size calculated previously. That is a page width of 8 pixels (32 bytes and 4-byte pixel) and a page height of 16 pixels.

1. Determine the required number of pages per line with the formula:
   [(actual_image_width / 2) *pixels* / page_width *bytes*] × pixel_size *bytes/pixel*
   This gives a required number of pages per line of [(736 / 2) / 32] × 4 = 46.
   If the number of pages per line is not an integer, it must be rounded up; for instance, if the result was 46.25 the number of pages required per line would be 47. Figure 9-107 shows this point.
2. Determine the required number of pages per column with the formula:
   (actual_image_height *pixels*) / page_height *lines*
   This gives a required number of pages per column of (560) / 16 = 35.
   If the number of pages per column is not an integer, it must be rounded up.

Finally, calculate the programmed image size in pixels using the number of pages calculated above:

1. Calculate the programmed image width with the formula:
   (rounded_up_number_of_pages_per_line × page_width *bytes*) / pixel_size *bytes/pixel*
   This gives a programmed image width of (46 × 32) / 4 = 368.

The function sets SMS_ROT_SIZEn[10:0] IMAGEWIDTH = 0x170.

2. Calculate the programmed image height with the formula:
   (rounded_up_number_of_pages_per_column × page_height *lines*)
   This gives a programmed image height of (35 × 16) = 560.
   The function sets SMS_ROT_SIZEn[26:16] IMAGEHEIGHT = 0x230.

Because the actual image is a multiple of the page size (both width and height, as explained in Section 9.2.5.3.3.1), the actual image size and the programmed size are the same. In other words, ΔIW and ΔIH are null in this use case.

9.2.5.3.3.3 Physical Base Address Configuration

The physical base address is the address of the picture in the external SDRAM. In this use case, the address space of CS0 is 512 Mbits, ranging from 0x8000 0000 to 0x83FF FFFF because the Mobile DDR SDRAM is a 512 Mbits memory device.

The physical address of the picture is a parameter entered by the user. It is directly written into the SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA bit field (where n = 0 to 11, for the 12 contexts).

9.2.5.3.3.4 VRFB Use Case Summarizing Register Values

Table 9-112 summarizes all the VRFB registers to be configured with the required values.

Table 9-112. VRFB Use Case Summarizing Register Print

Register Name	Context Number n	Physical Address	Value	Value Description
SMS_ROT_CONTROLn	0	0x6C00 0180	0x0000 0452	The page size is 8-pixel wide and 16-pixel high. This is a width of 32 bytes and a height of 16 lines. The pixel format is YUV 4:2:2 (2 pixels take 4 bytes).
	1	0x6C00 0190		
	2	0x6C00 01A0		
	3	0x6C00 01B0		
SMS_ROT_SIZEn	0	0x6C00 0184	0x0230 0170	Actual image size is 736 × 560. This gives 368 × 560 with the YUV 4:2:2 pixel format
	1	0x6C00 0194		
	2	0x6C00 01A4		
	3	0x6C00 01B4		
SMS_ROT_PHYSICAL_BAn	0	0x6C00 0188	0x8090 0000	Example of physical base address
	1	0x6C00 0198	0x8100 0000	
	2	0x6C00 01A8	0x8190 0000	
	3	0x6C00 01B8	0x8200 0000	

9.2.5.4 Understanding SDRAM Subsystem Address Spaces

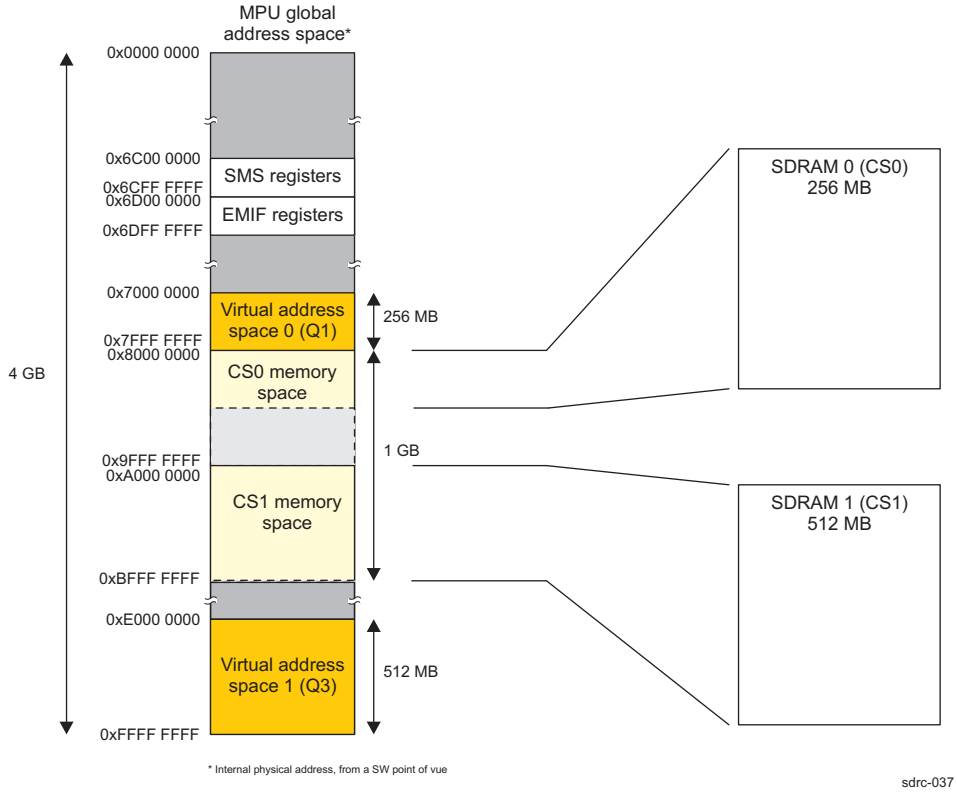
9.2.5.4.1 Physical vs Virtual Address Spaces

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only, i.e. when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as depicted in Figure 9-108 . The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the EMIF controller (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768 GBytes:

- 1 GByte of CS memory space (CS0 and CS1 memory spaces): the EMIF controller automatically accesses the two external memory devices through direct accesses (addresses are simply translated).
- 768 MBytes of virtual address space (address space 0 and address space 1): the EMIF controller automatically accesses the two external memory devices trough re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See section Section 9.2.5.4.1.2 for more information on VRFB contexts and rotation angles.

Figure 9-108. SDRC Address Space in MPU Global Address Space



Configuration registers space is detailed in the following table:

Table 9-113. EMIF and SMS Configuration Registers Space

Module	Start Address	End Address	Total Space
SMS	0x6C00 0000	0x6CFF FFFF	16MB
EMIF	0x6D00 0000	0x6DFF FFFF	16MB

9.2.5.4.1.1 Physical Address Space

The physical address space of the SDRC is 1 GByte (maximum addressing capability).

The EMIF has a memory device capacity of 16 Mbits to 2 Gbits. 16 Mbits / 2 MBytes is the smallest granularity of supported memory device.

9.2.5.4.1.2 Virtual Address Space

The SMS virtual memory space is a memory space used to access a subset of the EMIF memory space through the rotation engine (Virtual Rotation Frame Buffer). The virtual address space size is 768 MBytes split into two parts: the first 256-MByte part is in the second quarter (Q1) of the memory; the second 512-MByte part is in the fourth quarter (Q3) of the memory. See chapter 2, *Memory Mapping*, for more information on global memory mapping.

The VRFB is a rotation engine that:

- supports rotations of 0, 90, 180, and 270 degrees
- can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. Table 9-114 gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

Table 9-114. VRFB Contexts vs Rotation Angle

Context Number	0°	90°	180°	270°
0	0x7000 0000	0x7100 0000	0x7200 0000	0x7300 0000
1	0x7400 0000	0x7500 0000	0x7600 0000	0x7700 0000
2	0x7800 0000	0x7900 0000	0x7A00 0000	0x7B00 0000
3	0x7C00 0000	0x7D00 0000	0x7E00 0000	0x7F00 0000
4	0xE000 0000	0xE100 0000	0xE200 0000	0xE300 0000
5	0xE400 0000	0xE500 0000	0xE600 0000	0xE700 0000
6	0xE800 0000	0xE900 0000	0xEA00 0000	0xEB00 0000
7	0xEC00 0000	0xED00 0000	0xEE00 0000	0xEF00 0000
8	0xF000 0000	0xF100 0000	0xF200 0000	0xF300 0000
9	0xF400 0000	0xF500 0000	0xF600 0000	0xF700 0000
10	0xF800 0000	0xF900 0000	0xFA00 0000	0xFB00 0000
11	0xFC00 0000	0xFD00 0000	0xFE00 0000	0xFF00 0000

The physical address of a page is calculated with the formula:

Physical address = Physical base address + Base address of page (1)

where *Physical base address* is defined through the SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtain in function of the context number and rotation angle as given in Table 9-114.

9.2.6 SDRAM Memory Scheduler (SMS) Registers

Table 9-115 shows the base address and address space for the SMS module instances.

Table 9-115. SMS Instance Summary

Module Name	Base Address	Size
SMS	0x6C00 0000	64 Kbytes

9.2.6.1 SMS Register Mapping Summary

Table 9-116 summarizes the SMS register mapping.

Table 9-116. SMS Register Mapping Summary

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
30:0	PHYSICALBA	Physical base address of the frame buffer for context #n in SDRAM	RW	0x00000000

9.3 On-Chip Memory (OCM) Subsystem

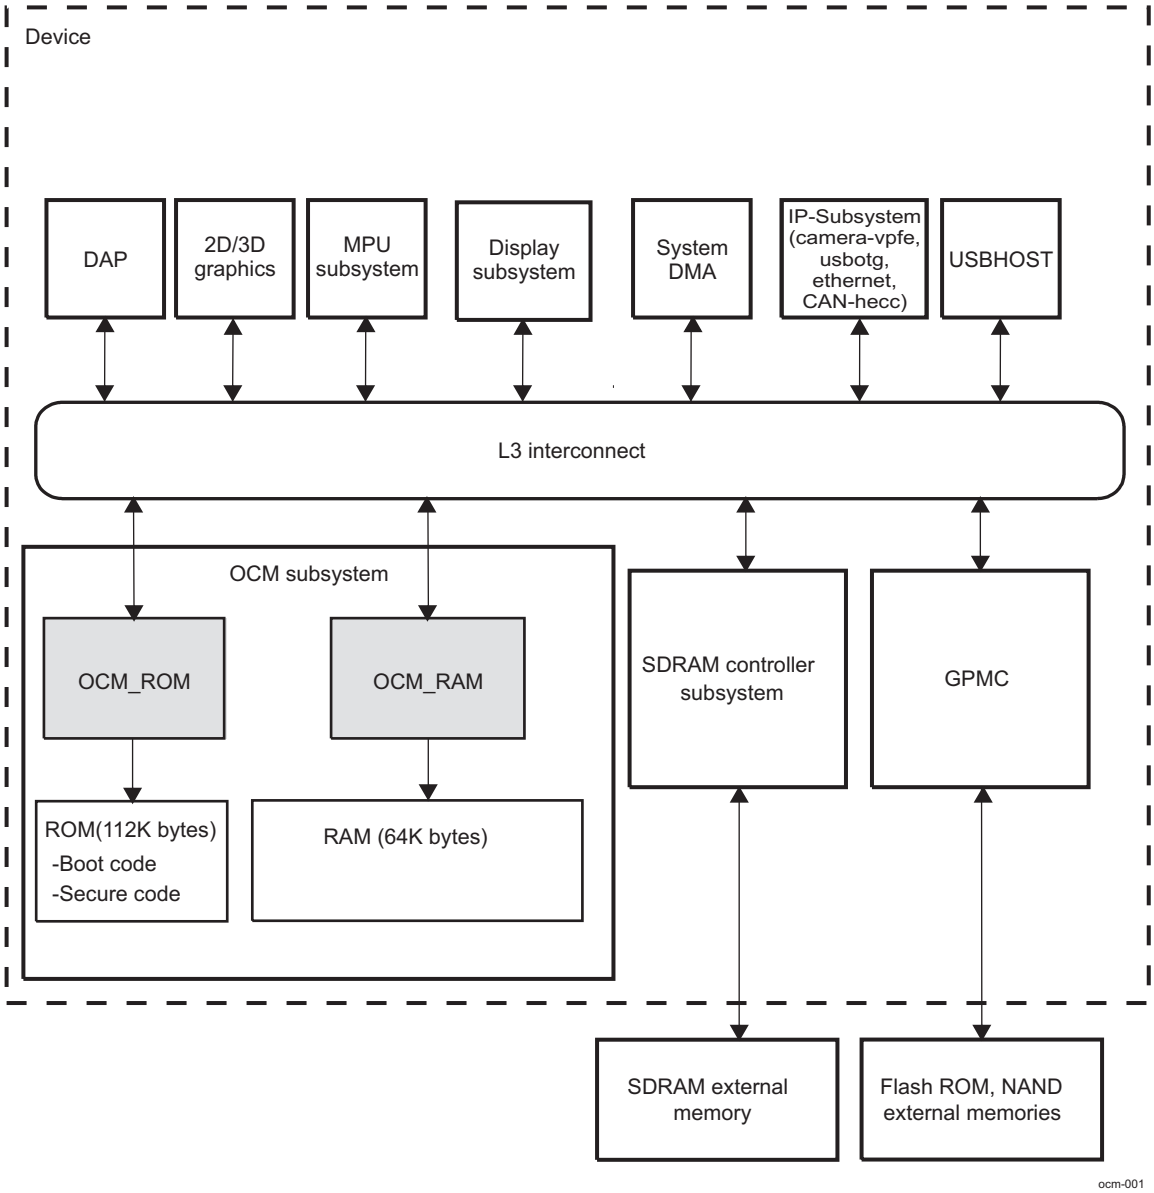
9.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM_ROM) and the other connected to an on-chip RAM (OCM_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Figure 9-109 is an overview of the OCM subsystem.

Figure 9-109. OCM Subsystem Overview



Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the IP subsystem, the display subsystem, and USBHOST.

ROM is used for direct boot code, boot from external NAND flash, and secure code.

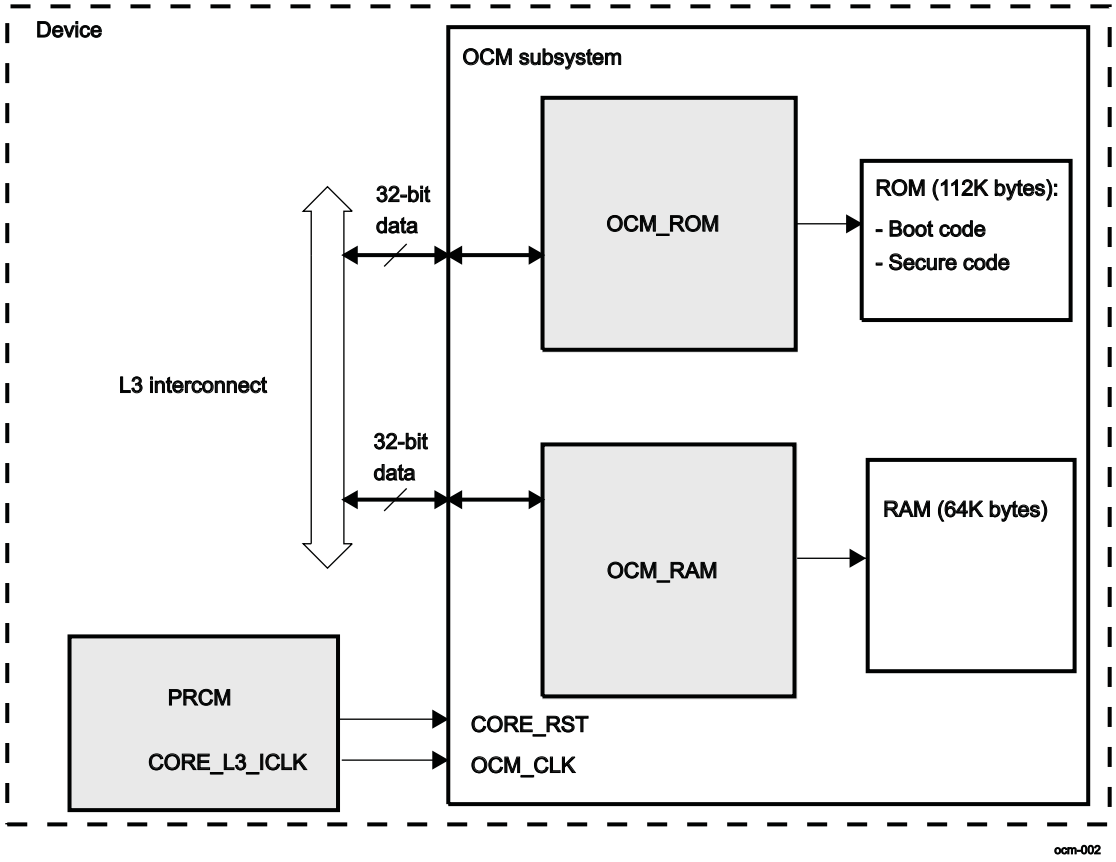
9.3.2 OCM Subsystem Integration

9.3.2.1 Description

The OCM_ROM and OCM_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 9-110 shows the integration of the OCM subsystem to the processor.

Figure 9-110. OCM Subsystem Integration to the Device



9.3.2.2 Clocking, Reset, and Power-Management Scheme

9.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM_CLK source is PRCM CORE_L3_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM_IDLEREQ/OCMROM_SIDLEACK (for ROM devices)
- OCMRAM_IDLEREQ/OCMRAM_SIDLEACK (for RAM devices)

OCM_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SIdleAck back to the PRCM module after reception of the MIdleReq request.

For details, see the *Power, Reset, and Clock Management* chapter.

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

9.3.2.2.2 Hardware Reset

Global reset of the module is performed by activation of the CORE_RST in the core reset domain (see the *Power, Reset, and Clock Management* chapter).

9.3.2.2.3 Power Domain

OCM power is supplied by the CORE power domain (see the *Power, Reset, and Clock Management* chapter).

9.3.3 OCM Subsystem Functional Description

9.3.3.1 OCM_ROM

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The ROM contains the boot area.
- The OCM_ROM supports single and burst access transactions.
- The OCM_ROM operates at full interconnect clock frequency.
- The COM_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

9.3.3.2 OCM_RAM

By default, only 2K bytes are nonsecure after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
  - A region-based partitioning (see the L3 firewall description)
  - The module owner of the access, with respect to its read and write permission to that region
  - The transaction attributes of the access, with respect to the region permission properties:
    - Secure/nonsecure
    - User/supervisor
    - Code/data access

The OCM_RAM can be partitioned using the L3 firewall (see the *Interconnect* chapter) and used as:

- Public RAM for normal RAM, or
- Secure RAM:
  - For secure data and instructions
  - For secure Level 2 data and instruction cache:
    - Secure stack
    - Secure global data
    - Secure heap
    - Secure decrypted applications
    - Crypto keys

The OCM_RAM can be partitioned using the L3 firewall and used as:

- Public RAM for a video frame buffer
- Secure RAM for a secure video frame buffer
- Secure RAM for computing heavy DRM applications such as real-time video decryption
- Secure RAM for any application

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

9.4 Revision History

Table 9-136 lists the changes made since the previous version of this document.

Table 9-136. Document Revision History

Reference	Additions/Modifications/Deletions
Section 9.2.3.4.1.1	Added LPDDR1 information to tables and list.
Section 9.2.3.4.2.6.1	Added subsection.
Figure 9-48	Added table.
Table 9-76	Updated bit descriptions.
Section 9.2.3.4.3.2.4	Added REG_PASR bit.
Section 9.2.3.4.3.2.5	Added REG_INITREF_DIS and REG_PASR bits.
Table 9-81	Updated bit descriptions.
Section 9.2.3.4.5.1	Added last bulleted list.
Section 9.2.3.4.5.2	Added last bulleted list.
Section 9.2.3.4.5.3	Added subsection.

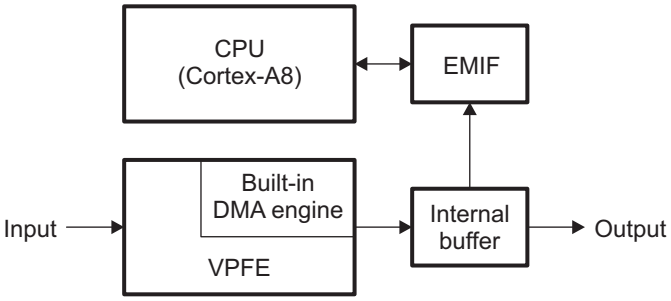
Video Processing Front End (VPFE)

10.1 Overview

The video processing subsystem (VPSS) includes a video processing front-end (VPFE) controller, which is the video input portion of the processor. The VPFE controller receives input video/image data from external capture devices and stores it to external memory. A built-in DMA engine transfers the capture data into the external memory. An internal buffer block provides a high bandwidth path between the VPSS module and the external memory. The CPU, Cortex-A8, will process the image data based on application requirements.

A simple LCD controller is available. Reference LCD chapter. Figure 10-1 illustrates the high-level block diagram of the VPSS module.

Figure 10-1. VPSS Module, Memory, and the CPU



10.1.1 Features

The VPFE controller supports the following features:

- It supports conventional Bayer pattern and Foveon sensor formats.
- It is flexible in synchronization timing generation. It can be programmed to synchronize to the external horizontal/vertical sync and field ID signals with various timings.
- It supports progressive and interlaced sensors (hardware support for up to two fields and firmware support for a higher number of fields, typically 3, 4, and 5-field sensors).
- The max pixel clock is 75 MHz.
- It supports the REC656/CCIR-656 standard.
- It supports YCbCr 422 format, either 8-bit or 16-bit with discrete horizontal and vertical sync signals.
- The input capture data can be up to 16 bits.
- It can generate optical black clamping signals.
- It has built-in digital clamping and black level compensation.
- 10-bit to 8-bit A-law compression hardware is provided.
- It has a low-pass filter that can be applied prior to writing the capture data to external memory. If this filter is enabled, two pixels in each the left and the right edges of each line are cropped from the output.
- The output data can range from 16 bits to 8 bits wide (8-bit width allows for a 50% savings in memory).
- It has a programmable culling block that can perform down-sampling of the input data.
- An external write enable signal is provided to control the timing of outputting data to the external memory.
- It supports up to 16K pixels (image size) in both the horizontal and vertical directions.

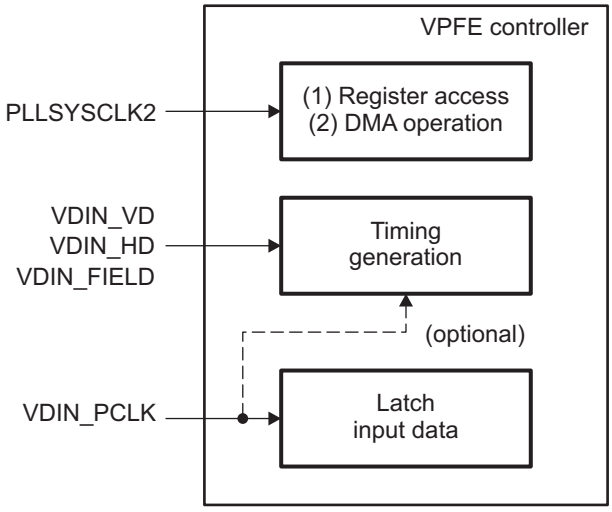
10.2 VPFE Controller - The System View

10.2.1 Clocks

The VFPE controller requires two clock sources:

- Internal clock source - PLLSYSCLK2. This clock is the reference clock used by the VPFE internal logic, including the built-in DMA operation.
- External clock source – External pixel clock signal VDIN_PCLK, which is used to generate internal synchronization signals to latch input data.

Figure 10-2. Clock Sources



10.2.2 Reset

The power, reset and clock management module can reset the VPFE controller. See the *Power, Reset and Clock Management* chapter for more details.

10.2.3 Interrupts

The VPFE controller can generate three interrupts to the CPU, as shown in Table 10-1.

Table 10-1. ARM Interrupts - VPFE

Interrupt Number	Acronym	Source
M_IRQ_88	CCDC_VD0_INT	VPFE
M_IRQ_92	CCDC_VD1_INT	VPFE
M_IRQ_93	CCDC_VD2_INT	VPFE

10.3 Functional Description

10.3.1 External IO Interface

The following subsections explains how to connect VPFE signal pins to various input devices.

10.3.1.1 Raw Data Mode

Raw data mode is a generic parallel interface that supports up to a 16-bit data path to a CMOS or CCD sensor. The signal interface is described in Table 10-2.

Table 10-2. CCD Interface Signals

Name	I/O	Function
VDIN_D[15:0]	I	Image data – A mode set by INPMOD (not R656ON). • Bit width is configurable between 8 and 16 bits (DATSIZ). • The polarity of the input image data is configurable (DATAPOL).
VDIN_VD	I	VSYNC - vertical sync signal
VDIN_HD	I	HSYNC - horizontal sync signal
VDIN_FIELD	I	Field identification signal (optional – FLDMODE) • This signal can be configured to be latched by the VD signal (FIDMD). • The polarity of the field identification signal is configurable (FLDPOL).
VDIN_WEN	I	VPFE write enable signal (optional – EXWEN) • The EXWEN signal determines when data is captured, processed, and saved to memory or sent for further processing. • If EXWEN is enabled, image data will be captured, processed, and saved to memory or sent for further processing, depending on the state of WENLOG. • Data can be saved either when VDIN_WEN is active and the pixels are within the internal frame (SPH, NPH, SLV, NLV) or when the pixels are within the internal frame (WENLOG).
VDIN_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz.

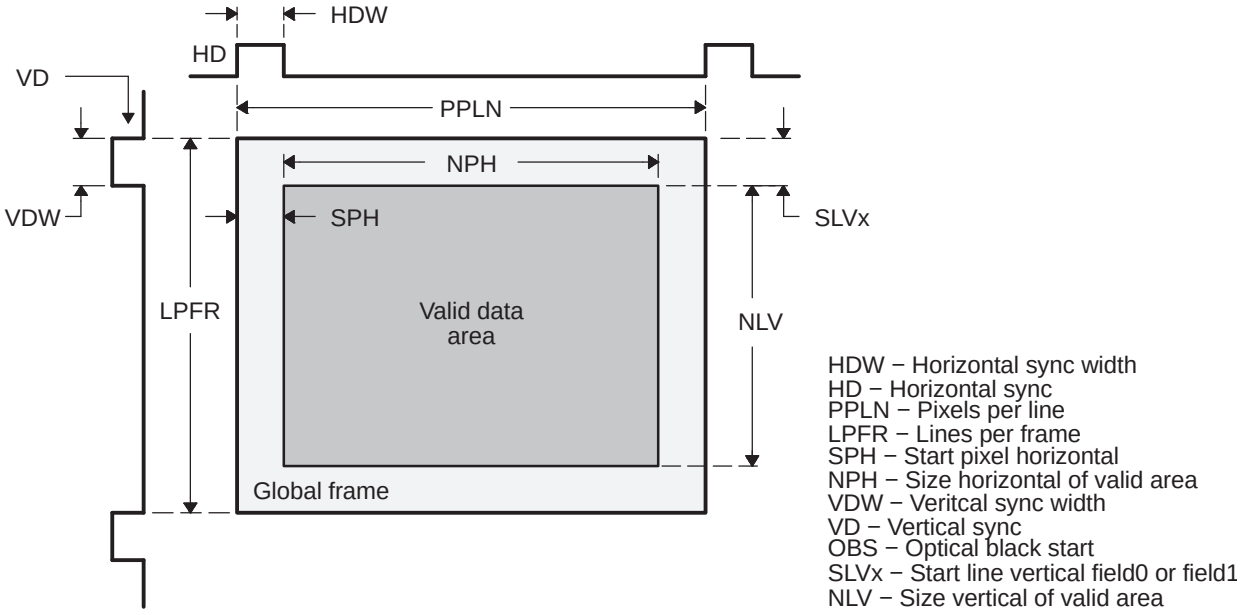
10.3.1.1.1 Mode Information – Always Required

- INPMOD – input mode
- DATSIZ – size (bit width) of input data – always stored in LSBs
- DATAPOL – polarity of input data
- VDPOL – VD polarity
- HDPOL – HD polarity
- FLDMOD – field mode

10.3.1.1.2 Timing Information – Optional, Depending on Control Signals and Sensor Mode

- If FLDMODE is enable
  - FLDPOL – VDIN_FIELD polarity
  - FIDMD – VDIN_FIELD latch information
- EXWEN – external VDIN_WEN signal
  - WENLOG – determines when data is valid along with frame settings

Figure 10-3. CCD Controller Frame and Control Signal Definitions



10.3.1.2 ITU-R BT.656 Interface

The BT.656 interface supports either 8-bit or 10-bit processing of input video YCbCr data. See Section 10.4 for instructions on how to configure this mode.

Since the data synchronization information is carried along with the data lines, no synchronization signals (i.e., VDIN_HD, VDIN_VD, and VDIN_FIELD) are necessary in this mode.

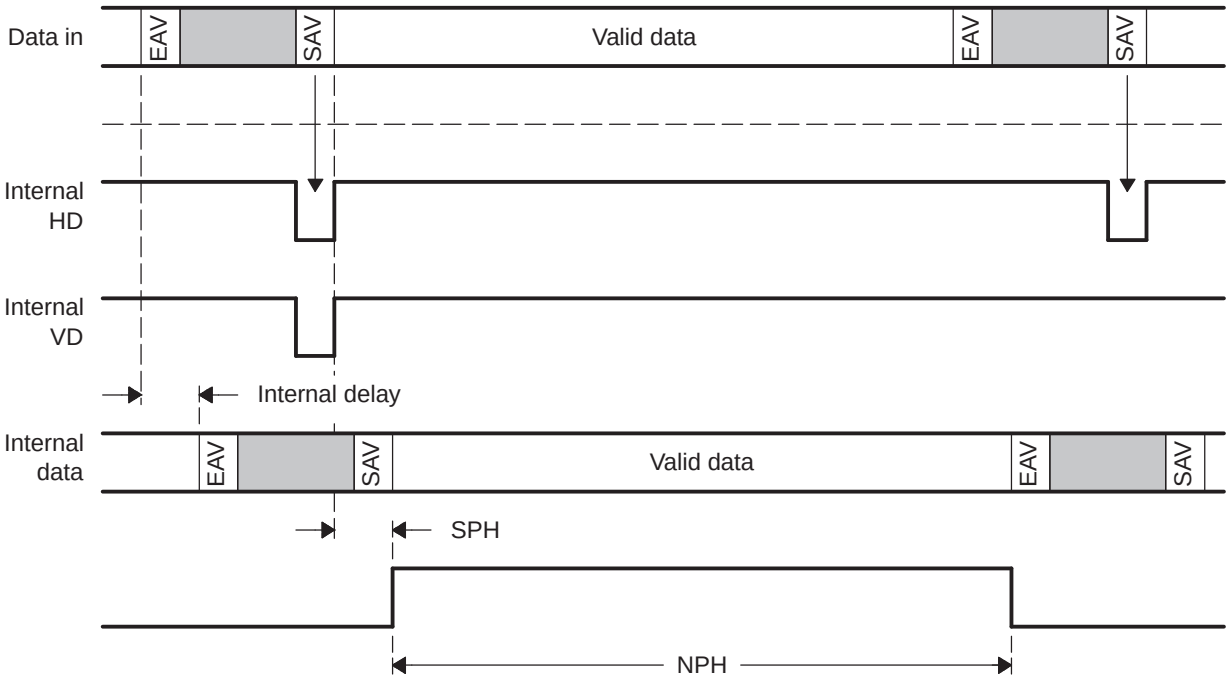
The signal interface is described in Table 10-3.

Table 10-3. ITU-R BT.656 Interface Signals

Name	I/O	Function
VDIN_D[9:0]	I	Image data – mode set by R656ON • Bit width is configurable to either eight or ten bits (BW656). • The polarity of the input image data is configurable (DATAPOL).
VDIN_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. (see for more details). • The maximum pixel clock rate is 75 MHz.

Two timing reference codes are transmitted as the synchronization signal. At the start and end of each video data block, two unique codes are sent, respectively. The start code is called the start of active video signal (SAV), and the end code is called the end of active video signal (EAV). The SAV and EAV codes proceed and follow valid data, as shown in Figure 10-4. The VPFE controller internally bases on SAV and EAV codes to generate the necessary synchronization signals, i.e., horizontal sync, vertical synx, and field ID.

Figure 10-4. BT.656 Signal Interface



Both timing reference signals, SAV and EAV, consist of a four-word sequence in the following format: FF 00 00 XY, where FF 00 00 are a set preamble and the fourth word defines the field identification, the state of vertical field blanking, the state of horizontal line blanking, and protection (error correction) codes. The bit format of the fourth word is shown in Table 10-4 and the definitions for bits, F, V, and H, are given in Table 10-5. F, V, and H are used in place of the usual horizontal sync, vertical sync, and blank timing control signals. Bits P3, P2, P1, and P0 are protection (error correction) bits for F, V, and H. The relationship the between F, V, and H and the protection (error correction) bits is given in Table 10-6. To enable error correction, set the ECCFVH bit in the REC656IF register. The VPFE controller automatically detects and applies error correction when the ECCFVH bit is set.

Table 10-4. Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 10-5. F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

Table 10-6. F, H, V Protection (error correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

NOTE: The VPFE controller outputs the XY code in the SAV and EAV into the external memory. In order to eliminate this, set the SPH register field to +1. Also set the NPH register field to accurately represent the number of active pixels.

10.3.1.3 Digital YCbCr Interface

The digital YCbCr interface supports either 8-bit or 16-bit devices. The signal interface is described in Table 10-7.

Unlike the BT.656 mode, discrete horizontal sync (VDIN_HD) and vertical sync (VDIN_VD) signals are required. An NTSC/PAL decoder is an example device that can be connected to the YCbCr interface.

You can use data lines YI[7:0] or CI [7:0] for input in 8-bit mode. Alternately, you can connect two separate devices; however, only one can be active at any given time. Setting the YCINSWP bit in the CCDCFG register determines which set of 8-bit inputs are active.

Use data lines YI [7:0] and CI[7:0] for input in 16-bit mode. Use the YCINSWP bit in the CCDCFG register to swap the Y and Cr/Cb data lines.

Table 10-7. CCD Interface Signals

Name	I/O	Function
VDIN_D [15:0] = YI [7:0] / CI [7:0]	I	Image data – mode set by INPMOD (not R656ON) • Bit width is only configurable to either 8 bits or 16 bits (INPMOD). • The polarity of the input image data is reversible (DATAPOL). • When the 16-bit interface is used, you can swap the Y and C inputs (YCINSWP). • When the 8-bit interface is used, you can connect either half of the bus (YCINSWP). • When the 8-bit interface is used, you can set the position of the Y data to either the even or odd pixel (Y8POS).
VDIN_VD	I	VSYNC - vertical sync signal
VDIN_HD	I	HSYNC - horizontal sync signal
VDIN_FIELD	I	Field identification signal (optional – FLDMODE) • This signal can be configured to be latched by the VD signal (FIDMD). • The polarity of the field identification signal is configurable (FLDPOL).
VDIN_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz.

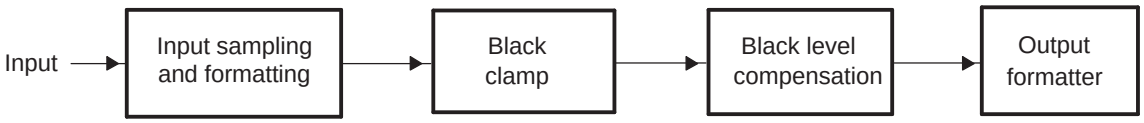
10.3.2 VPFE Data / Image Processing

This section describes the image/data processing of each module in the VPFE in more detail. Section 10.3.2.1 describes the raw data mode while Section 10.3.2.2 explains the YCbCr and BT656 modes.

10.3.2.1 Raw Data Mode

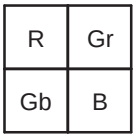
Raw data mode is enabled by setting SYN_MODE.INPMODE to 0 and setting REC656IF.REC656ON to 0. Figure 10-5 shows the corresponding data processing diagram.

Figure 10-5. Data Processing in Raw Data Mode



Typically, raw sensor data is one color per pixel in a color filter array (CFA). The color filter array applied is typically a Bayer pattern, as shown in Figure 10-6 for RGB color space. Alternatively, the special Foveon X3-family sensors capture R, G, and B lights at each pixel location. Both Bayer and Foveon sensors are supported by the VPFE controller.

Figure 10-6. Color Patterns



Bayer format with R/Gr and Gb/B in alternate lines
−Horizontal distance between same colors is 2.

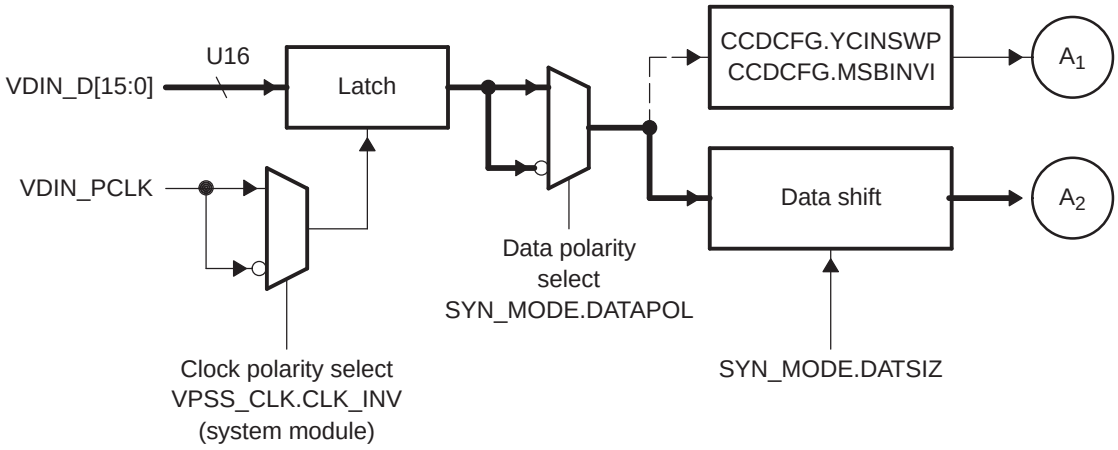
Foveon sensor with R, G, and B in same line
− Horizontal distance between same colors is 3.

10.3.2.1.1 Input Sampling and Formatting

The data path of raw data mode is shown in the thicker lines in Figure 10-7 (i.e., A2). Data path A1 is applicable to YUV input mode only.

- The pixel clock (VDIN_PCLK) latches the data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK).PCK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Data is right-shifted to align the data in the least significant bits of the data bus and provide the maximum dynamic range for the remainder of the processing (DATSIZ bit in the SYN_MODE register). This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment when it is written to external memory.

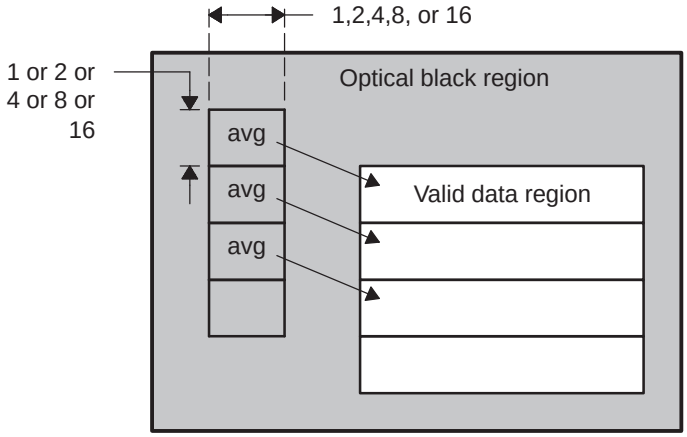
Figure 10-7. Input Formatter



10.3.2.1.2 Optical Black Clamping

Sensor manufacturers typically provide some optically masked pixels at the beginning/end of each line to allow you to determine the noise floor on any given frame of data. The optical black clamping function provides a means to average the optically black pixels and subtract that value from each input pixel as the first step in reducing the noise on the input pixels.

Figure 10-8. Optical Black Averaging & Application

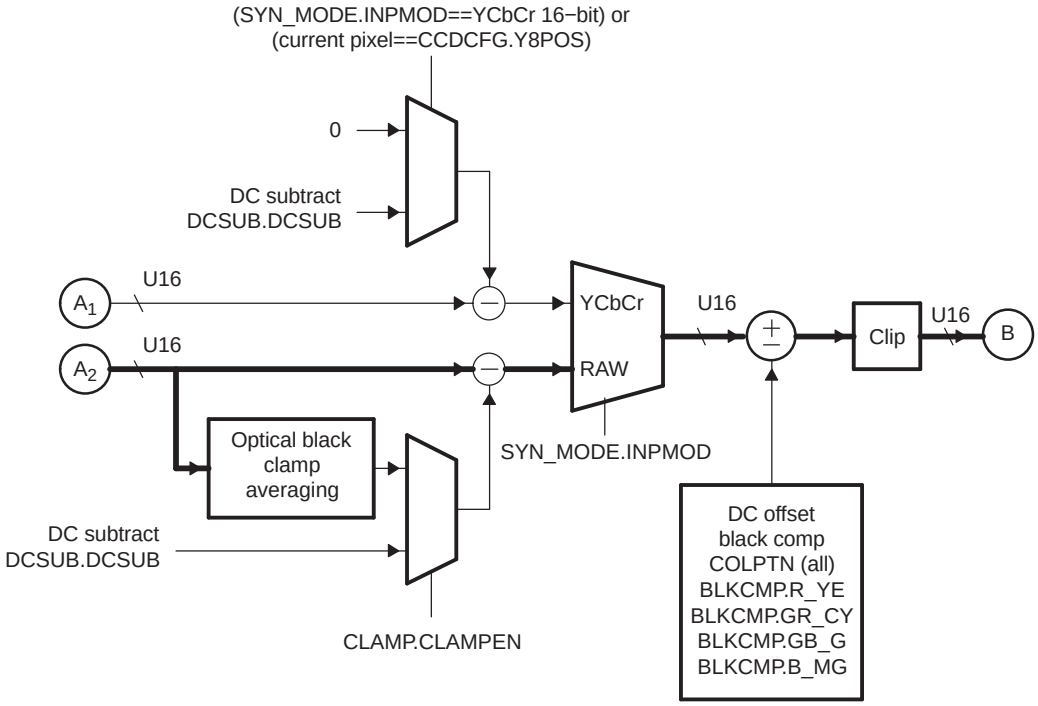


The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (OBST bit in the CLAMP register) of each line (OBSLEN bit in the CLAMP register) and for the number of indicated lines (OBSLN bit in the CLAMP register), plus an optional gain adjustment (OBGAIN bit in the CLAMP register). The resultant value is subtracted from the image data at the succeeding line. You can control the position of the black pixels, the number of pixels (8 or 16) in each line that are averaged, and the number of lines (8 or 16) that are averaged.

Alternately, you can disable black clamp averaging (CLAMPEN bit in the CLAMP register) and select a constant black value for subtraction (DCSUB bit in the DCSUB register) instead of using the calculated average value.

The corresponding data path is shown in the thicker lines in Figure 10-9.

Figure 10-9. Black Clamping and Black Level Compensation



10.3.2.1.3 Black Level Compensation

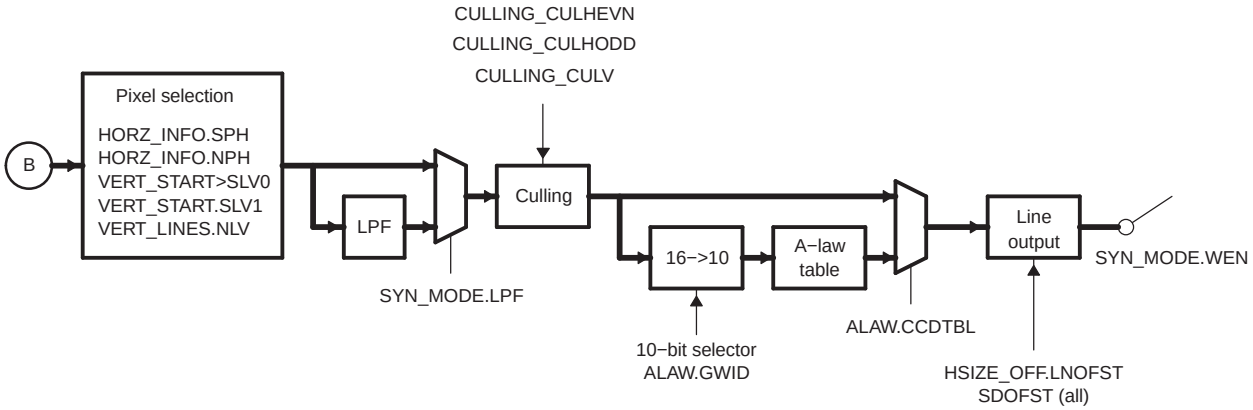
After the digital clamping is applied to the data, black level compensation is applied (Figure 10-9). In this operation, a fixed value is subtracted from the data depending on the color (i.e., R/Ye, Gr/Cy, Gb/G, and B/Mg). The offset (BLKCMP register, fields R_YE, GR_CY, GB_G, B_MG) that is applied to each data sample is selected according to the 0/1/2/3 phase and the color (0/1/2/3) specified for each phase (COLPTN). The color pattern definition is very flexible in order to accommodate many different capture devices, including normal Bayer CFA sampling, Foveon sensors, and VGA movie mode CCDs, whose VGA draft mode output does not follow the typical Bayer pattern.

10.3.2.1.4 Output Formatter

The final stage of VPFE processing is the output formatter, as shown in Figure 10-10. A framing selection is applied to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

NOTE: In addition to the framing applied at the beginning and end of the data formatter operation, you must apply a framing selection to limit the processing area. Please ensure that the settings are relative to that frame.

Figure 10-10. Output Formatter



10.3.2.1.4.1 Low Pass Filter

Use the LPF bit in the SYN_MODE register to apply an optional low-pass filter after the reframing. The low-pass filter consists of a simple 3-tap (¼ , ½ , ¼) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled.

10.3.2.1.4.2 Culling

Use the CULEVEN and CULODD bits in the CULLING register (8-bit repeating mask, one per field) to enable an optional culling operation, which culls (deletes) selected pixel data from a line. Use the CULV bit in the CULLING register to select lines from a frame.

Table 10-8 illustrates how the register values apply the decimation pattern to the data. The pixels in white will be saved to external memory and the shaded pixels are discarded.

In this case:

- CULLING = 0x59C40066, with
- CULHEVN = 0x59,
- CULHODD = 0xC4, and
- CULV = 0x66.

Table 10-8. Example for Decimation Pattern

		LSB								
	CULHEVN	0	0	1	0	0	0	1	1	
	CULHODD	1	0	0	1	1	0	1	0	0
0th line										1
1st line										1
2nd line										0
3rd line										0
4th line										1
5th line										1
6th line										0
7th line										CULV

10.3.2.1.4.3 A-Law Transformation

Use the CCDTBL bit in the ALAW register to apply an optional 10-to-8-bit A-Law transformation using a fixed A-Law table as the final processing stage. Using this causes the data width to reduce to 8 bits and allows packing to 8 bits/pixel when saving to external memory. Since the data resolution can be greater than 10 bits at this stage, you must select the 10 bits for input to the A-Law operation. Use the GWID bit in the ALAW register to select the 10 bits for input.

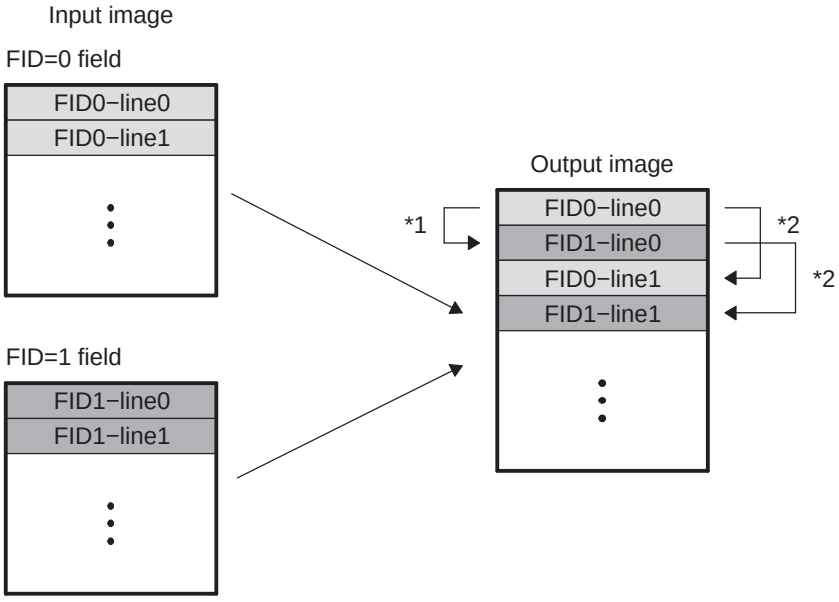
10.3.2.1.4.4 Line Output Control

The final stage of the raw data mode is the line output control, which controls how the input sensor lines are written to external memory. The value of the ADR bit in the SDR_ADDR register defines the starting address where the frame should be written in external memory. The value of the LNOFST bit in the HSIZE_OFF register defines the distance between the beginning of output lines in bytes. Both the starting address and line offset must be aligned to 32-byte boundaries (i.e., either 16 or 32 pixels, depending on the PACK8 bit in the SYN_MODE register). Use the SDOFST register to define additional offsets, depending on the field ID and the even/odd line numbers. Defining additional offsets provides a means to de-interlace an interlaced, two-field input and also inverts an input image vertically. See Figure 10-12 and Figure 10-13 for example usage.

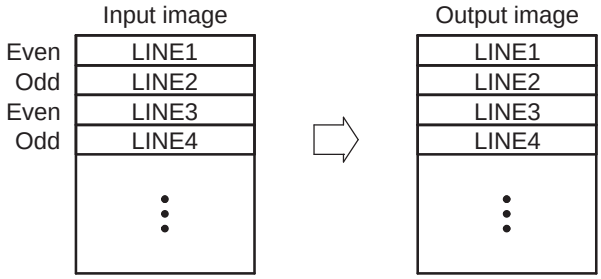
Figure 10-12. Image De-interfacing



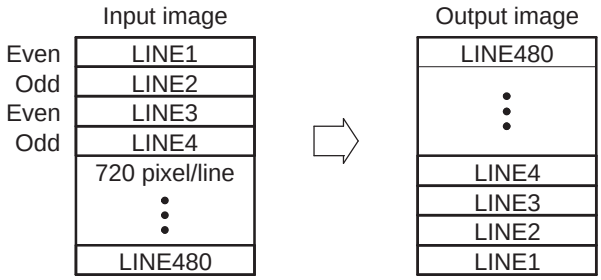
*1 − SDOFST[13:12]=00b, +1 line for FID=1 lines

*2 − SDOFST[11:9]=SDOFST[8:6]=SDOFST[5:3]=SDOFST[2:0]=001b, +2 lines

Figure 10-13. Non-inversed vs Inversed Format



SDOFST[14] = 0 ;Non inverse
SDOFST[13:12] = 00b ;+1 line when field ID is 1
SDOFST[11:9] = 001b ;+2 line, even line and field ID = 0
SDOFST[8:6] = 001b ;+2 line, odd line and field ID = 0
SDOFST[5:3] = 001b ;+2 line, even line and field ID = 1
SDOFST[2:0] = 001b ;+2 line, odd line and field ID = 1



SDOFST[14] = 1 ;Inverse
SDOFST[13:12] = 000b ;−1 line when field ID is 1
SDOFST[11:9] = 101b ;−2 line, even line and field ID = 0
SDOFST[8:6] = 101b ;−2 line, odd line and field ID = 0
SDOFST[5:3] = 101b ;−2 line, even line and field ID = 1
SDOFST[2:0] = 101b ;−2 line, odd line and field ID = 1

10.3.2.1.4.5 Output Format

The pixel data format in external memory is shown in Table 10-12.

- If pixel data format is 8-bit, every 16-bit word in external memory stores two pixel data.
- If pixel data format is greater than 8-bit, every 16-bit word in external memory stores one pixel data, and the unused bits are MSB which are filled with 0.

Table 10-11. Storage Format in external memory for Raw Data Mode

	Upper Word		Lower Word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
16-bit	Pixel1		Pixel0	
15-bit	0	Pixel1	0	Pixel0
14-bit	0	Pixel1	0	Pixel0
13-bit	0	Pixel1	0	Pixel0
12-bit	0	Pixel1	0	Pixel0
11-bit	0	Pixel1	0	Pixel0
10-bit	0	Pixel1	0	Pixel0
9-bit	0	Pixel1	0	Pixel0
8-bit	0	Pixel1	0	Pixel0
8-bit pack	Pixel3	Pixel2	Pixel1	Pixel0

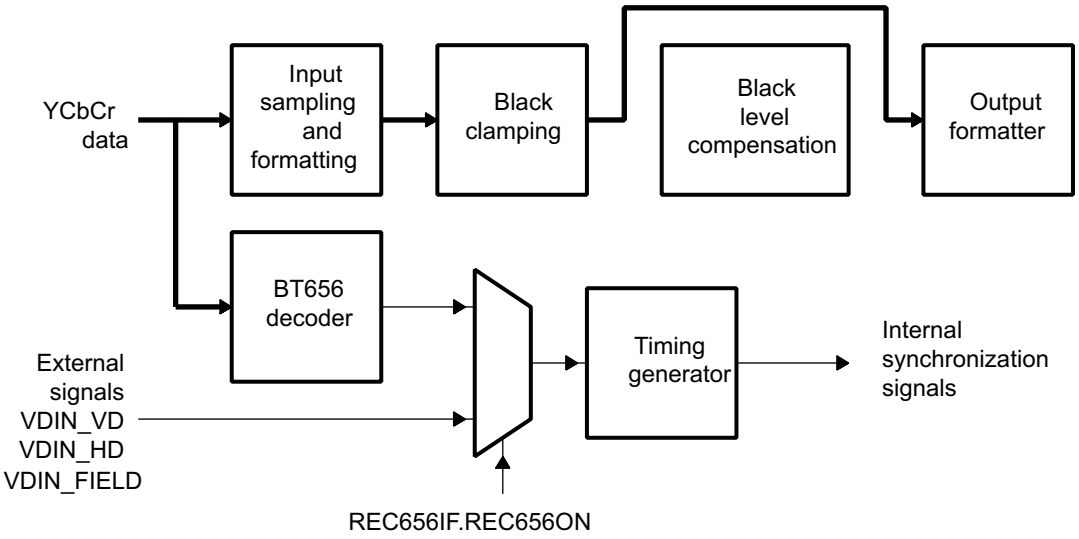
10.3.2.2 YCbCr and BT656 Modes

YCbCr mode and BT656 mode are similar in operation, as shown in Figure 10-14. The additional logic used in BT656 mode is the CCIR656 decoder, which extracts synchronization information from input YCbCr data and regenerates the corresponding timing for internal operation.

- YCbCr mode is enabled by setting field INPMODE in register SYN_MODE to 1 or 2 and clearing field REC656ON in register REC656IF.
- BT656 mode is enabled by setting REC656ON in register REC656IF to 1.

YCbCr mode typically has 8 bits per luma/choma sample while BT656 mode has 8 bits or 10 bits per luma/chroma sample.

Figure 10-14. Data Processing in YUV/BT656 Modes

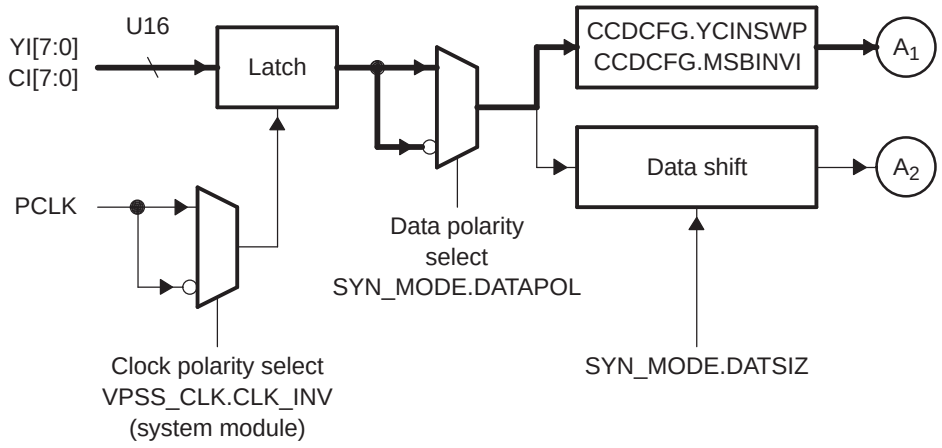


10.3.2.2.1 Input Sampling and Formatting

The data path of YCbCr/BT656 modes is shown in thicker lines in Figure 10-15 (i.e., A1). Data path A2 is applicable to raw data mode only.

- The pixel clock (VDIN_PCLK) latches data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK).PCLK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Bit YCINSWP in register CCDCFG can be used to swap the upper and lower portions of the 16-bit YCbCr data bus.
  - In 16-bit YCbCr mode, this swap bit determines which part of the bus luma and chroma samples occupy respectively.
  - In 8-bit mode, this swap bit determines which part of the bus is the effective 8-bit input. In other words, two external 8-bit YCbCr capture devices can be tied to VPFE module directly.
- Bit MSBINVI in register CCDCFG can be used to invert the MSB of the chroma signal.

Figure 10-15. CCD Controller

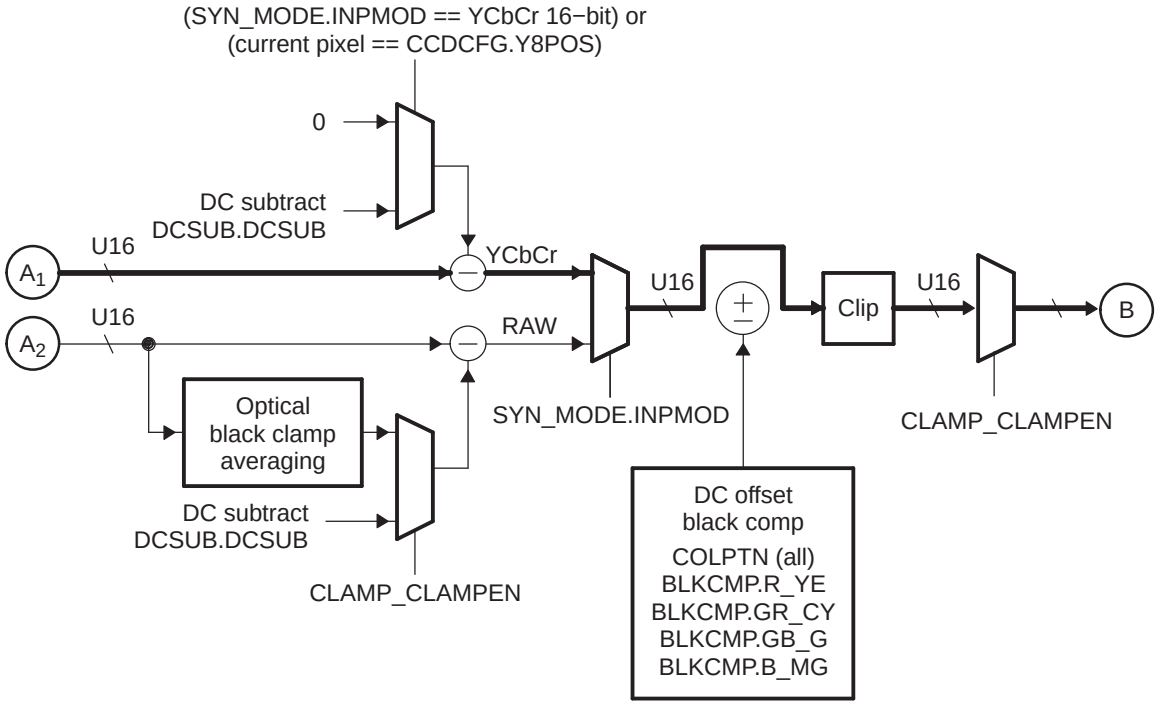


10.3.2.2.2 Black Clamping

The second step in BT.656/YCbCr processing is black clamping

Use the DCSUB bit in the DCSUB register to subtract a fixed value from the luma sample for YUV data. Set the subtraction value to zero to disable the operation. See Figure 10-16 for more details. You may notice that black compensation (BLKCMP) is not used in YCbCr and BT656 modes.

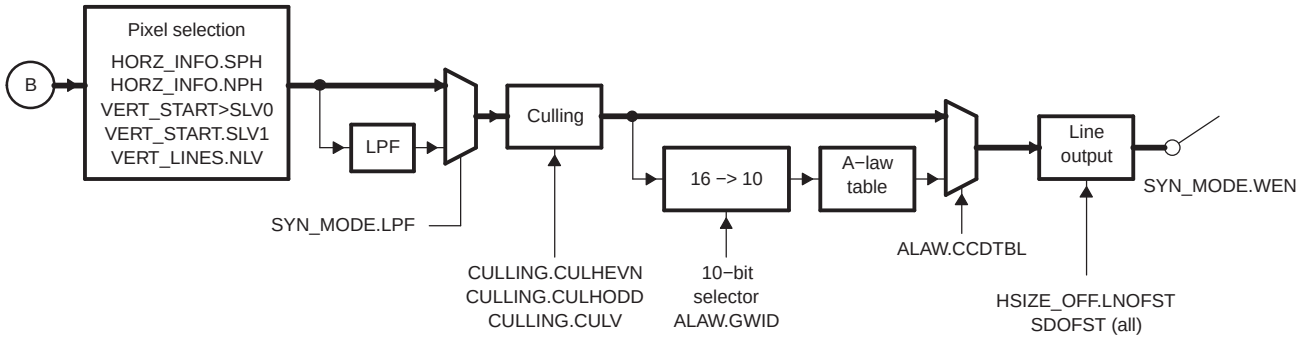
Figure 10-16. Black Clamping and Block Level Compensation



10.3.2.2.3 Output Formatter

The output formatter is the final stage of VPFE processing (as shown as thicker lines in Figure 10-17). Apply a framing selection to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

Figure 10-17. Output Formatter



- Use the LFP bit in the SYN_MODE register to disable the LPF by setting the LFP bit equal to 0.
- Culling can be used in YCbCr and BT656 modes; however, care must be taken to preserve the 422 output format.
- Do not use the A-Law transformation in YCbCr or BT.656 mode (the CCDTBL bit in the ALAW register = 0).

The pixel data in external memory is shown in Table 10-12.

Table 10-12. Storage Format in external memory for BT.656/YCbCr Modes

external memory Address	Upper word		Lower word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr2	Y2	Cb2
N + 2	Y5	Cr4	Y4	Cb4

10.4 Programming Model

The following programming procedures should be followed to enable the VPFE controller to receive video or image capture data.

1. Power-up the VPFE via the power sleep controller (PSC) module (see *TDRx40x/41x Automotive Digital Radio and Infotainment Applications Processor ARM Subsystem Reference Guide* (SPRUF07)
2. Disable the VPFE controller
3. Configure the VPFE registers to match the system requirements, including interrupt setup
4. Enable the VPFE controller

Once the VPFE controller is enabled, it starts to process input data continuously. No user intervention is necessary to re-start the process. As a result, the VPFE interrupt must be set up correctly in order to operate properly. Users can terminate its operation by disabling the VPFE controller.

The remaining sections describe the programming procedure in more detail.

10.4.1 Enabling and Disabling the VPFE Controller

The following steps describe how to enable and disable the VPFE controller:

- Clearing the ENABLE bit in the VPFE_PCR register disables the VPFE controller.
- Setting the ENABLE bit in the VPFE_PCR register enables the VPFE controller.
  - The VPFE controller should be enabled prior to data transmission from the external device to avoid data loss.

10.4.2 Configuring VPFE Registers

10.4.2.1 General Register Setup

Table 10-13 lists the minimum register fields that must be configured.

Table 10-13. Basic Configuration of VPFE Registers

Function	Register	Fields
External signal configuration (This includes signals VDIN_VD, VDIN_HD, VDIN_FIELD, and VDIN_WEN.)	SYN_MODE	VDHDEN VDPOL HDPOL FLDMODE FLDPOL EXWEN DATAPOL
	CCDCFG	VDLC
Input data mode	REC656	R656ON
	SYN_MODE	INPMOD
Color pattern	COLPTN	All
Black compensation	BLKCMP	All
Data path configuration	SYN_MODE	WEN

Table 10-14 describes additional configuration requirements when certain conditions are met.

Table 10-14. Conditional Configuration of VPFE Registers

Category	If...	Then program...
Interlace mode	Field FLDMODE in register SYN_MODE is 1	Field FIDMD in register CCDCFG
External WEN	Field EXWEN in register SYN_MODE is 1	Field WENLOG bit in register CCDCFG
REC656 input	Field R656ON in register REC656 is 1	Field ECCFVH in register REC656 Field BW656 in register CCDCFG
RAW input	Field INPMOD in register SYN_MODE is 0 and Field R656ON in register REC656 is 1	Field DATSIZ in register SYN_MODE Field CLAMPEN in register CLAMP
16-bit YCC input	Field INPMOD in register SYN_MODE is 1 and Field R656ON in register REC656 is 1	Field YCINSWP in register CCDCFG Field MSBINVI in register CCDCFG Register DCSUB
8-bit YCC input	Field INPMOD in register SYN_MODE is 2 and Field R656ON in register REC656 is 1	Field Y8POS in register CCDCFG
Optical black clamp enabled	Field CLAMPEN in register CLAMP is 1 and Field INPMOD in register SYN_MODE is 0	Field OBGAIN in register CLAMP Field OBST in register CLAMP Field OBSLN in register CLAMP Field OBSLEN in register CLAMP
Optical black clamp disabled	Field CLAMPEN in register CLAMP is 0 and Field INPMOD in register SYN_MODE is 0	Register DCSUB
Write to external memory	Field WEN in register SYN_MODE is 1	Field LPF in register SYN_MODE Field PACK8 in register SYN_MODE Field CCDTBL in register ALAW Field BSWD in register CCDCFG Register HORZ_INFO Register VERT_START Register VERT_LINES Register CULLING Register SDR_ADDR Register HSIZE_OFF Register SDOFST
A-law	Field CCDTBL in register ALAW is 1	Field GWID in register ALAW
Interrupt	Interrupts CCDC_VD0_INT and CCDC_VD1_INT are to be used	Register VDINT

10.4.2.2 Interrupts

The VPFE controller can generate three interrupts: CCDC_VD0_INT, CCDC_VD1_INT, and CCDC_VD2_INT.

NOTE: Enable the VDHDEN field in register SYN_MODE to receive any of these VPFE controller interrupts.

The CCDC_VD0_INT and CCDC_VD1_INT interrupts occur relative to the VD pulse, as shown in Figure 10-18 and Figure 10-19. Please note that field VDPOL in register SYN_MODE changes the trigger timing.

- If field VDPOL is 1, the VDINT0 and VDINT1 counters begin counting VDIN_HD pulses from the falling edge of signal VDIN_VD.
- If field VDPOL is 0, the VDINT0 and VDINT1 counters begin counting VDIN_HD pulses from the rising edge of signal VDIN_VD.

- Interrupts CCDC_VD0_INT and CCDC_VD1_INT occur after receiving the number of horizontal lines (VDIN_HD pulse signals) set in the VDINT0 bit in the VDINT register and the VDINT1 bit in the VDINT register, respectively.

Figure 10-18. VDPOL is 0

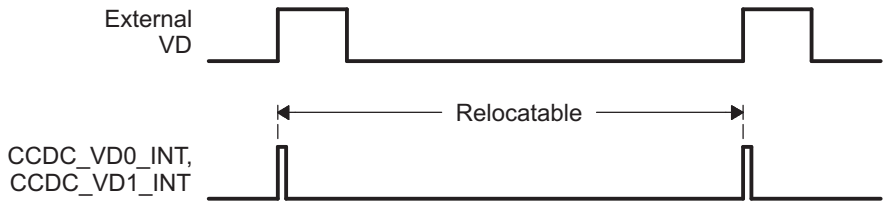


Figure 10-19. VDPOL is 1

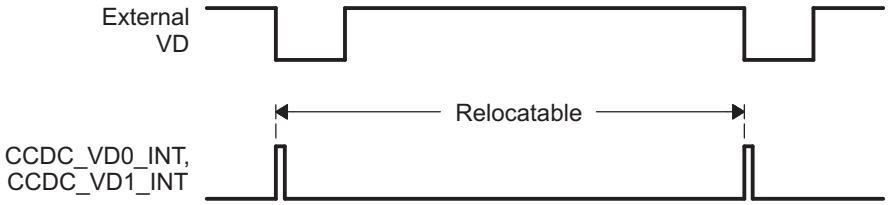
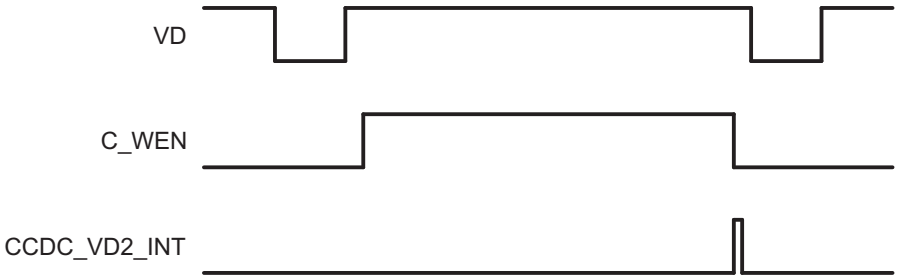


The CCDC_VD2_INT interrupt always occurs at the falling edge of the VDIN_WEN signal (via an external pin), as shown in Figure 10-20. There are no registers in the VPFE module to configure this interrupt.

Figure 10-20. CCDC_VD2_INT Interrupt



10.4.2.3 Status

The BUSY status bit in the VPFE_PCR register is set when the start of frame occurs (if the ENABLE bit in the VPFE_PCR register is 1 at that time). It automatically resets to 0 at the end of a frame.

10.4.2.4 VDIN_VD latched Registers

The VDLC field in register CCDCFG affects the access of the following registers and register fields.

Registers
VPFE_PCR
HORZ_INFO
VERT_START
VERT_LINES
CULLING
HSIZE_OFF
SDOFST
SDR_ADDR
Register Fields
WEN in SYN_MODE
LPF in SYN_MODE

Registers
CLAMPEN in CLAMP
YCINSWP in CCDCFG

NOTE:

1. If the VDLC field is 0, changes to the above registers/register fields will take effect immediately.
2. If the VDLC field is 1, changes to the above registers/register fields will take effect at the start of a new frame (i.e., the changes are latched by the VDIN_VD signal). Reads from these registers/register fields will return the most recent write value (even though these values may not take effect).

Be careful to avoid undesired effects when using the first approach.

10.4.2.5 Inter-frame Operations

As described in the previous section, the VPFE_PCR and SDR_ADDR registers will be latched by the VDIN_VD signal if the VDLC field in the CCDCFG register is 0. This important feature provides a reliable way for programmers to enable/disable the VPFE module and/or modify the memory pointers in-between frames. For example, the VPFE interrupt service routine (ISR) can program the SDR_ADDR register to a new value before the end of the current frame. By doing so, the current frame is received without any interruption and the new external memory address (SDR_ADDR register) will be used for receiving the next frame.

10.4.3 VPFE Limitations

The major limitations of the VPFE module are summarized as follows:

- The VDIN_PCLK (pixel clock) signal cannot be higher than 75 MHz.
- The SDR_ADDR and HSIZE_OFF registers should be programmed to values with 5 LBS bits as 0; namely, the memory space they point to should be on a 32-byte boundary.
- The COLPTN register should be set to 0 in YCbCr and BT.656 modes.
- The BLKCMP register should be set to 0 in YCbCr and BT.656 modes.
- Low-pass filter (LPF field in SYN_MODE register) should be disabled in YCbCr and BT.656 modes.
- A-LAW should be disabled in YCbCr and BT.656 modes.

10.5 Video Processing Front End (VPFE) Registers

Table 10-15 lists the memory-mapped registers for the VPFE controller.

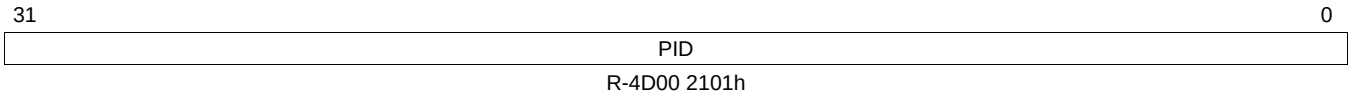
Table 10-15. CCD Controller (CCDC) Register Map

Offset	Acronym	Register Description	Section
00h	PID	Peripheral Revision and Class Information	Section 10.5.1
04h	VPFE_PCR	VPFE_Peripheral Control Register	Section 10.5.2
08h	SYN_MODE	SYNC and Mode Set Register	Section 10.5.3
Ch	Reserved	Reserved	
10h	Reserved	Reserved	
14h	HORZ_INFO	Horizontal Pixel Information	Section 10.5.4
18h	VERT_START	Vertical Line - Settings for the Starting Pixel	Section 10.5.5
1Ch	VERT_LINES	Number of Vertical Lines	Section 10.5.6
20h	CULLING	Culling Information in Horizontal and Vertical Directions	Section 10.5.7
24h	HSIZE_OFF	Horizontal Size	Section 10.5.8
28h	SDOFST	External memory/Line Offset	Section 10.5.9
2Ch	SDR_ADDR	External memory Address	Section 10.5.10
30h	CLAMP	Optical Black clamping settings	Section 10.5.11
34h	DCSUB	DC Clamp	Section 10.5.12
38h	COLPTN	CCD Color Pattern	Section 10.5.13
3Ch	BLKCMP	Black Compensation	Section 10.5.14
40h-44h	Reserved	Reserved	
48h	VDINT	VPFE Interrupt Control	Section 10.5.15
4Ch	ALAW	ALAW Configuration	Section 10.5.16
50h	REC656IF	REC656 Configuration	Section 10.5.17
54h	CCDCCFG	CCD Configuration	Section 10.5.18
58h - 94h	Reserved	Reserved	
98h	DMA_CNTL	DMA Status and Control	Section 10.5.19

10.5.1 Peripheral Revision and Class Information Register (PID)

The peripheral revision and class information register (PID) is shown in Figure 10-21 and described in Table 10-16 .

Figure 10-21. Peripheral Revision and Class Information Register (PID)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

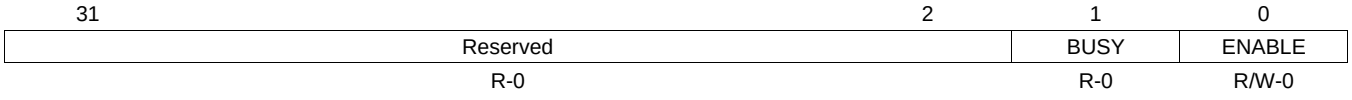
Table 10-16. Peripheral Revision and Class Information Register (PID) Field Descriptions

Bit	Field	Value	Description
31-0	PID	4D00 2101h	Peripheral identification that uniquely identifies the specific revision of the VPFE

10.5.2 VPFE_Peripheral Control Register (VPFE_PCR)

The VPFE_peripheral control register (VPFE_PCR) is shown in Figure 10-22 and described in Table 10-17.

Figure 10-22. VPFE_Peripheral Control Register (VPFE_PCR)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-17. VPFE_Peripheral Control Register (VPFE_PCR) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Any writes to these bit(s) must always have a value of 0.
1	BUSY		VPFE busy bit
		0	Not busy
		1	Busy
0	ENABLE		VPFE enable
		0	Disable
		1	Enable

10.5.3 SYN_MODE Format and Description Register (SYN_MODE)

The sync and mode set register (SYN_MODE) is shown in Figure 10-23 and described in Table 10-18.

Figure 10-23. Sync and Mode Set Register (SYN_MODE)

31																19	18	17	16

		R/W-0					R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-18. Sync and Mode Set Register (SYN_MODE) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Any writes to these bit(s) must always have a value of 0.
17	WEN		Data write enable. Controls whether or not input raw data is written to external memory. This bit is latched by VD.
		0	Disable
		1	Enable
16	VDHDEN		VD/HD enable. Activates internal timing generator to synchronize with external VD/HD signals. This bit should be set to 1 when HD and VD signals are used at any time.
		0	Disable
		1	Enable
15	FLDSTAT		Field status. Indicates the status of the current field when in interlaced mode.
		0	Odd field
		1	Even field
14	LPF		3-tap low-pass (anti-aliasing) filter. This bit is latched by VD.
		0	Off
		1	On
13-12	INPMOD	0-3h	Setting data input mode
		00	Raw data
		01	YCbCr 16-bit
		10	YCbCr 8-bit
		11	Reserved
11	PACK8		Pack to 8-bit/pixel (into external memory)
		0	Normal (16 bits/pixel)
		1	Pack to 8 bits/pixel
10-8	DATSIZ	0-7h	CCD data width is only valid when INPMOD is set to 0.
		000	16 bits
		001	15 bits
		010	14 bits
		011	13 bits
		100	12 bits
		101	11 bits
		110	10 bits
		111	8 bits
7	FLDMODE		Sensor field mode
		0	Non-interlaced (progressive)
		1	Interlaced

Table 10-18. Sync and Mode Set Register (SYN_MODE) Field Descriptions (continued)

Bit	Field	Value	Description
6	DATAPOL		Input data polarity
		0	Normal (no change)
		1	One's complement
5	EXWEN		External WEN selection. When set to 1 and when VDHDEN is set to 1, the WEN signal is used as the external memory write enable (to external memory). The data is stored to memory only when the external sync (HD and VD) signals are active.
		0	Do not use external WEN (write enable)
		1	Use external WEN (write enable)
4	FLDPOL		Field indicator polarity
		0	Positive
		1	Negative
3	HDPOL		HD sync polarity
		0	Positive
		1	Negative
2	VDPOL		VD sync polarity
		0	Positive
		1	Negative
1-0	Reserved	0	Any writes to these bit(s) must always have a value of 0.

10.5.4 Horizontal Pixel Information Register (HORZ_INFO)

The horizontal pixel information register (HORZ_INFO) is shown in Figure 10-24 and described in Table 10-19.

Figure 10-24. Horizontal Pixel Information Register (HORZ_INFO)

31	30	16
Reserved	SPH	
R-0	R/W-0	

15	14	0
Reserved	NPH	
R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-19. Horizontal Pixel Information Register (HORZ_INFO) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Any writes to these bit(s) must always have a value of 0.
30-16	SPH	0-7FFFh	Start pixel, horizontal. The SPH sets the pixel clock position at which data output to external memory begins, measured from the start of HD. This bit field is latched by VD.
15	Reserved	0	Any writes to these bit(s) must always have a value of 0.
14-0	NPH	0-7FFFh	Number of pixels, horizontal. NPH sets the number of horizontal pixels that is output to external memory = (NPH + 1) and 0xFFF0 (i.e., the number of horizontal output pixels truncates to multiples of 16). This bit field is latched by VD.

10.5.5 Vertical Line - Settings for the Starting Pixel Register (VERT_START)

The vertical line - settings for the starting pixel register (VERT_START) is shown in Figure 10-25 and described in Table 10-20.

Figure 10-25. Vertical Line - Settings for the Starting Pixel Register (VERT_START)

Table 10-20. Vertical Line - Settings for the Starting Pixel Register (VERT_START) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Any writes to these bit(s) must always have a value of 0.
30-16	SLV0	0-7FFFh	Start line, vertical (field 0). SLV0 sets line at which data output to external memory will begin, measured from the start of VD. This bit field is latched by VD
15	Reserved	0	Any writes to these bit(s) must always have a value of 0.
14-0	SLV1	0-7FFFh	Start line, vertical (field 1). SLV1 sets line at which data output to external memory will begin, measured from the start of VD. For a progressive sensor this field is ignored. This bit field is latched by VD

10.5.6 Number of Vertical Lines Register (VERT_LINES)

The number of vertical lines register (VERT_LINES) is shown in Figure 10-26 and described in Table 10-21.

Figure 10-26. Number of Vertical Lines Register (VERT_LINES)

31	16
Reserved	
R-0	

15	14	0

R-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-21. Number of Vertical Lines Register (VERT_LINES) Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Any writes to these bit(s) must always have a value of 0.
14-0	NLV	0-7FFFh	Number of lines, vertical. NLV sets the number of vertical lines that will be output to external memory. The number of lines output to external memory = (NLV + 1). This bit field is latched by VD.

10.5.7 Culling Information in Horizontal and Vertical Directions Register (CULLING)

The culling information in horizontal and vertical directions register (CULLING) is shown in Figure 10-27 and described in Table 10-22.

Figure 10-27. Culling Information in Horizontal and Vertical Directions Register (CULLING)

31	24	23	16
CULHEVN		CULHODD

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 10-22. Culling Information in Horizontal and Vertical Directions Register (CULLING) Field Descriptions

Bit	Field	Value	Description
31-24	CULHEVN	0-FFh	Horizontal Culling Pattern for Even Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD.
		0	CULLING (deletion)
		1	Retain (to be saved to external memory).
23-16	CULHODD	0-FFh	Horizontal Culling Pattern for Odd Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD.
		0	CULLING (deletion)
		1	Retain (to be saved to external memory).
15-8	Reserved	0	Any writes to these bit(s) must always have a value of 0.
7-0	CULV	0-FFh	Vertical Culling Pattern, 8-bit mask. LSB is first line, MSB is 8th line, then pattern repeats. This bit field is latched by VD.
		0	CULLING (deletion)
		1	Retain (to be saved to external memory).

10.5.8 Horizontal Size (HSIZE_OFF)

The horizontal size register (HSIZE_OFF) is shown in Figure 10-28 and described in Table 10-23.

Figure 10-28. Horizontal Size Register (HSIZE_OFF)

Reserved	
R-0	

15	0
LNOFST	
R/W-0	

LEGEND: R = Read only; -*n* = value after reset

Table 10-23. Horizontal Size Register (HSIZE_OFF) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Any writes to these bit(s) must always have a value of 0.
15-0	LNOFST	0 - FFFh	Address offset for each line. LNOFST Sets offset for each output line in external memory Either 16 or 32 pixels depending on setting of PACK8. The 5 LSB are ignored, and a zero is returned when read; the offset will be on a 32-byte boundary. For optimal performance in the system, the address offset should be on a 256-byte boundary. This bit field is latched by VD.

10.5.9 External Memory Line Offset Register (SDOFST)

The external memory line offset register (SDOFST) is shown in Figure 10-29 and described in Table 10-24.

Figure 10-29. External Memory Line Offset Register (SDOFST)

Table 10-29. Black Compensation Register (BLKCMP) Field Descriptions

Bit	Field	Value	Description
31-24	R_YE	0-FFh	Black level compensation for R/Ye pixels (-128:+127). 2's complement, MSB is sign bit.
23-16	GR_CY	0-FFh	Black level compensation for Gr/Cy pixels (-128:+127). 2's complement, MSB is sign bit.
15-8	GB_G	0-FFh	Black level compensation for Gb/G pixels (-128:+127). 2's complement, MSB is sign bit.
7-0	B_MG	0-FFh	Black level compensation for B/Mg pixels (-128:+127). 2's complement, MSB is sign bit.

10.5.15 VPFE Interrupt Control Register (VDINT)

The VPFE interrupt control (VDINT) register is shown in Figure 10-35 and described in Table 10-30.

Figure 10-35. VPFE Interrupt Control (VDINT) Register

Bit	Field	Value	Description
31-16	Reserved	0	Any writes to these bit(s) must always have a value of 0.
15	VDLC		Enable latching function registers on internal VSYNC. If this bit is set, all the register fields that are VSYNC latched will take on new value immediately. Care should be taken not to alter fields that can cause undesired behavior to the output data.
		0	Latched on VSYNC
		1	Not latched on VSYNC
14	Reserved	0	Any writes to these bit(s) must always have a value of 0.
13	MSBINVI		MSB of Chroma input signal stored to external memory inverted.
		0	Normal
		1	MSB inverted
12	BSWD		Byte Swap Data stored to external memory. Number of pixels must be even if byte packing is selected if this bit is set.
		0	Normal
		1	Swap Bytes
11	Y8POS		Location of Y signal when YCbCr 8bit data is input.
		0	Even pixel
		1	Odd pixel
10-9	Reserved		Any writes to these bit(s) must always have a value of 0.
8	WENLOG		Specifies CCD valid area
		0	Internal valid signal & WEN signal is ANDed logically
		1	Internal valid signal & WEN signal is Ored logically
7-6	FIDMD		Setting of FID detection function
		00	FID signal is latched at the VSYNC timing. The external Field signal is latched when the VD is active and the active edge of the HD signal
		01	FID signal is not latched. The field signal is not latched at all.
		10	FID signal is latched at edge of VD. The field signal is latched on the active edge of the VD signal.
		11	FID signal is latched based on phase of VD and HD. The field signal is latched when the VD signal is active and the HD signal is inactive (opposite phase).
5	BW656		The data width in CCIR656 input mode. BW656 takes precedence over the SYN_MODE fields INPMOD and DATSIZ if 656 mode is enabled.
		0	8-bits
		1	10-bits

Table 10-33. CCD Configuration Register (CCDCFG) Field Descriptions (continued)

Bit	Field	Value	Description
4	YCINSWP		Y input (YIN[7:0]) and C input (CIN[7:0]) are swapped. This bit is latched on the VSYNC/VD signal
		0	YIN[7:0] = Y signal/CIN[7:0] = C signal
		1	YIN[7:0] = C signal/CIN[7:0] = Y signal
3-0	Reserved	0	Any writes to these bit(s) must always have a value of 0.

10.5.19 DMA Control Register (DMA_CNTL)

The DMA control (DMA_CNTL) register is shown in Figure 10-39 and described in Table 10-34.

Figure 10-39. DMA Control (DMA_CNTL) Register

Table 10-34. DMA Control (DMA_CNTL) Field Descriptions

Bit	Field	Value	Description
31	OVERFLOW		DMA Overflow Flag. Flag bit that is set when data is dropped due to a delay in writing data out of the DMA interface. This bit remains set until a "1" is written by the software.
		0	No overflow has occurred
		1	Overflow has occurred
30-3	Reserved		Any writes to these bit(s) must always have a value of 0.
2-0	CPRIORITY		Command Priority. Sets the priority that all commands should be sent with on the DMA bus. This register should only be modified when the module is inactive or it could cause violations of the CBA specifications.
		0	Highest priority
		0x7	Lowest priority

2D/3D Graphics Accelerator

This chapter describes the 2D/3D graphics accelerator (SGX).

NOTE: The SGX subsystem is an instantiation by Texas Instruments of the POWERVR™ SGX530 core from Imagination Technologies Ltd.

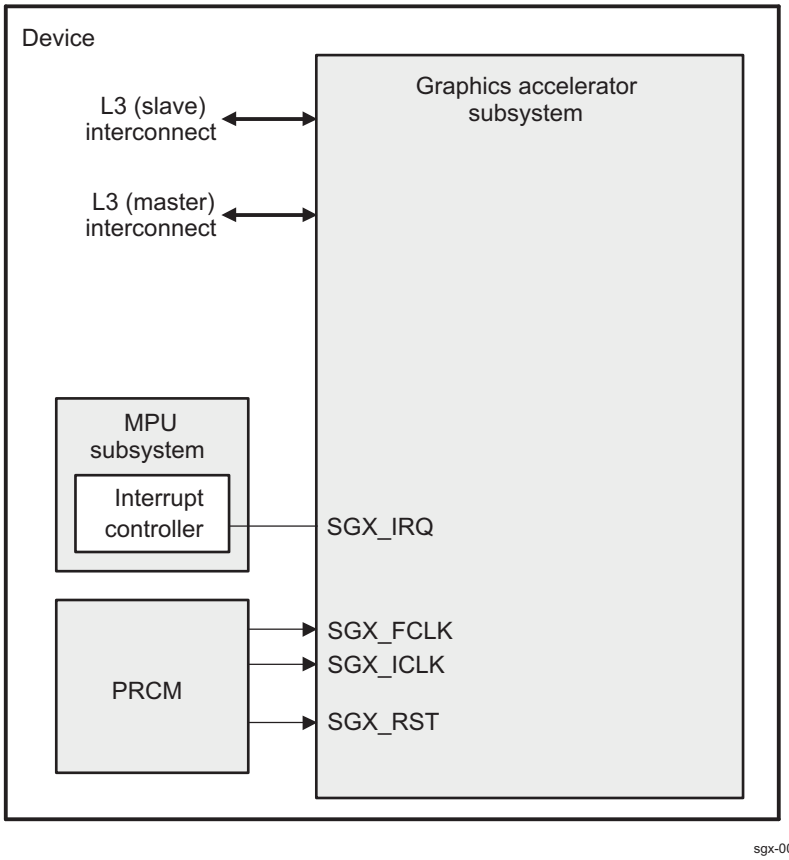
Topic **Page**

11.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR™ SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR™ SGX530 v1.2.1 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 11-1 shows the SGX subsystem in the device.

Figure 11-1. Graphics Accelerator Highlight



The SGX graphics accelerator efficiently processes a number of various multimedia data types concurrently:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved using a multithreaded architecture using two levels of scheduling and data partitioning enabling zero overhead task switching.

The SGX subsystem is connected by a 64-bit master and a 32-bit slave interface to the L3 interconnect.

11.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- USSE™ – multithreaded engine incorporating pixel and vertex shader functionality

- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0
- Industry standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualised memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]

11.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for all YUV formats
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).
  Note: Performance is limited when the on-chip memory is not available.

11.1.3 Universal Scalable Shader Engine (USSE) – Key Features

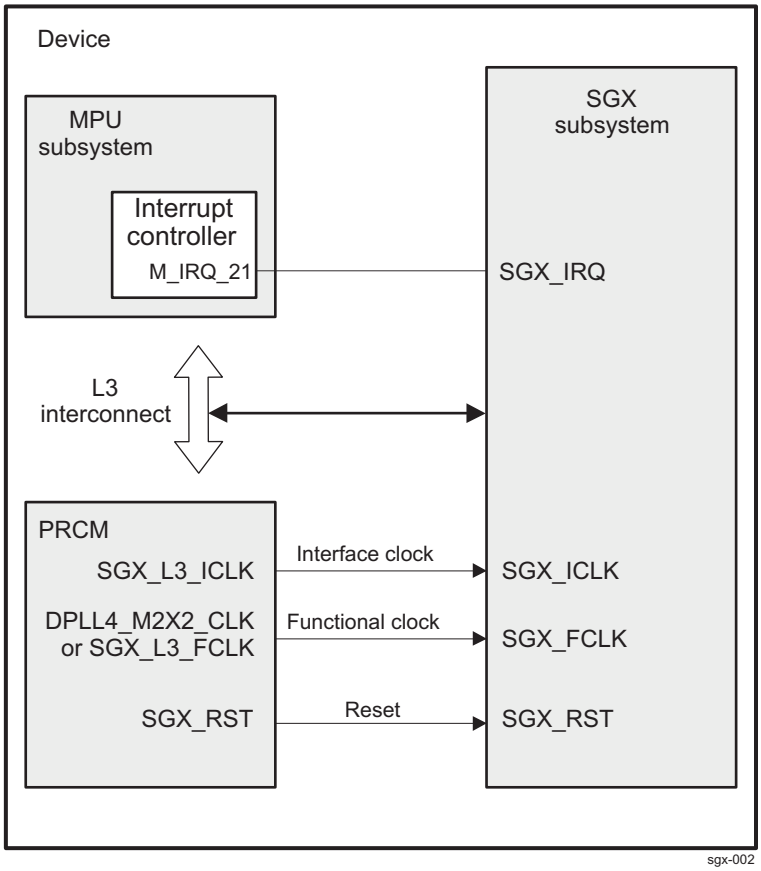
The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

11.2 SGX Integration

Figure 11-2 highlights the SGX subsystem integration in the device.

Figure 11-2. SGX Subsystem Integration



11.2.1 Clocking, Reset, and Power-Management Scheme

11.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in Figure 4-31, *SGX Power Domain Clocking Scheme*, in , *Power, Reset, and Clock Management*.

Table 11-1. Clock Descriptions

Signal Name	I/O[1]	Description
SGX_FCLK	I	Functional clock (two possible clock sources) -> Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) -> Interface clock domain

(1) I =Input, O=Output,

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports.

  The source of SGX_ICLK is the PRCM clock (SGX_L3_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see , *Power, Reset, and Clock Management*.

  When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM_ICLKEN_SGX[0] EN_SGX bit to 0. For more information, see

Figure 4-47, *SGX Power Domain Clock Controls*, in , *Power, Reset, and Clock Management*.

NOTE: SGX_ICLK is cut only if the SGX is ready to go into idle state. For more information, see , *Power, Reset, and Clock Management*.

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

  The source of SGX_FCLK is either the PRCM clock (SGX_L3_FCLK, which is derived from SGX_ICLK) or the peripheral DPLL clock DPLL4_M2X2_CLK as depicted in Figure 4-47, *SGX Power Domain Clock Controls*. Selection is made at the PRCM level by setting the PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX bit field. A divider of 3, 4, or 6 is applied to the SGX_FCLK frequency with regard to the PRCM SGX_L3_FCLK frequency. By default the SGX_FCLK clock is SGX_L3_FCLK / 3.

  Whether SGX_FCLK is provided by SGX_L3_FCLK or DPLL4_M2X2_CLK, its gating depends on the PRCM.CM_FCLKEN_SGX[1] EN_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level, if the module is ready to enter the idle state.For more information, see Section 4.5.5.6, *SGX Power Domain*, in , *Power, Reset, and Clock Management*

11.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_RSTCTRL_SGX[0] SGX_RST bit.

11.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See , *Power, Reset, and Clock Management*, for additional information about the SGX power domain.

As described in Section 11.2, *SGX Integration*, the SGX subsystem receives two clock signals from the PRCM module. The functional clock is either a division of the interface clock with a ratio of 1:3, 1:4, or 1:6, or a 96–MHz clock issued from a DPLL4. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see , *Power, Reset, and Clock Management*.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

11.2.2 Hardware Requests

11.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_21.

11.3 SGX Functional Description

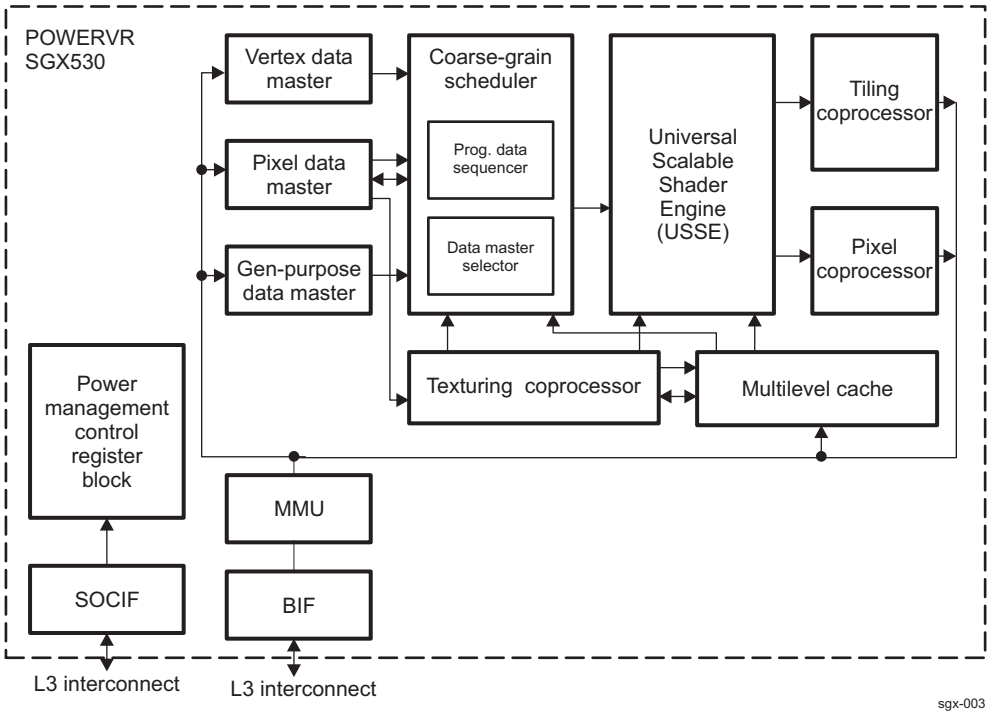
11.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR SGX530 core from Imagination Technologies. The architecture uses both programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable Data Sequencer (PDS)
  - Data Master Selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 11-3 shows a block diagram of the SGX cores.

Figure 11-3. SGX Block Diagram



11.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX Architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an

input control stream, which contains triangle index data, and state data. The state data indicates the PDS program, size of the vertices and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile which allows for optimum efficiency within each pipe due to locality of data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests into the multilevel cache. Data returned from the cache are then formatted according to the texture format selected and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

11.4 SGX Register Mapping

Table 11-2 describes the SGX memory mapping in the device.

Table 11-2. Instance Summary

Module Name	Start Address	End Address	Size
SGX	0x5000 0000	0x5000 FFFF	64K bytes

CAUTION

The SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Display Subsystem

This chapter describes the display subsystem.

Topic **Page**

12.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

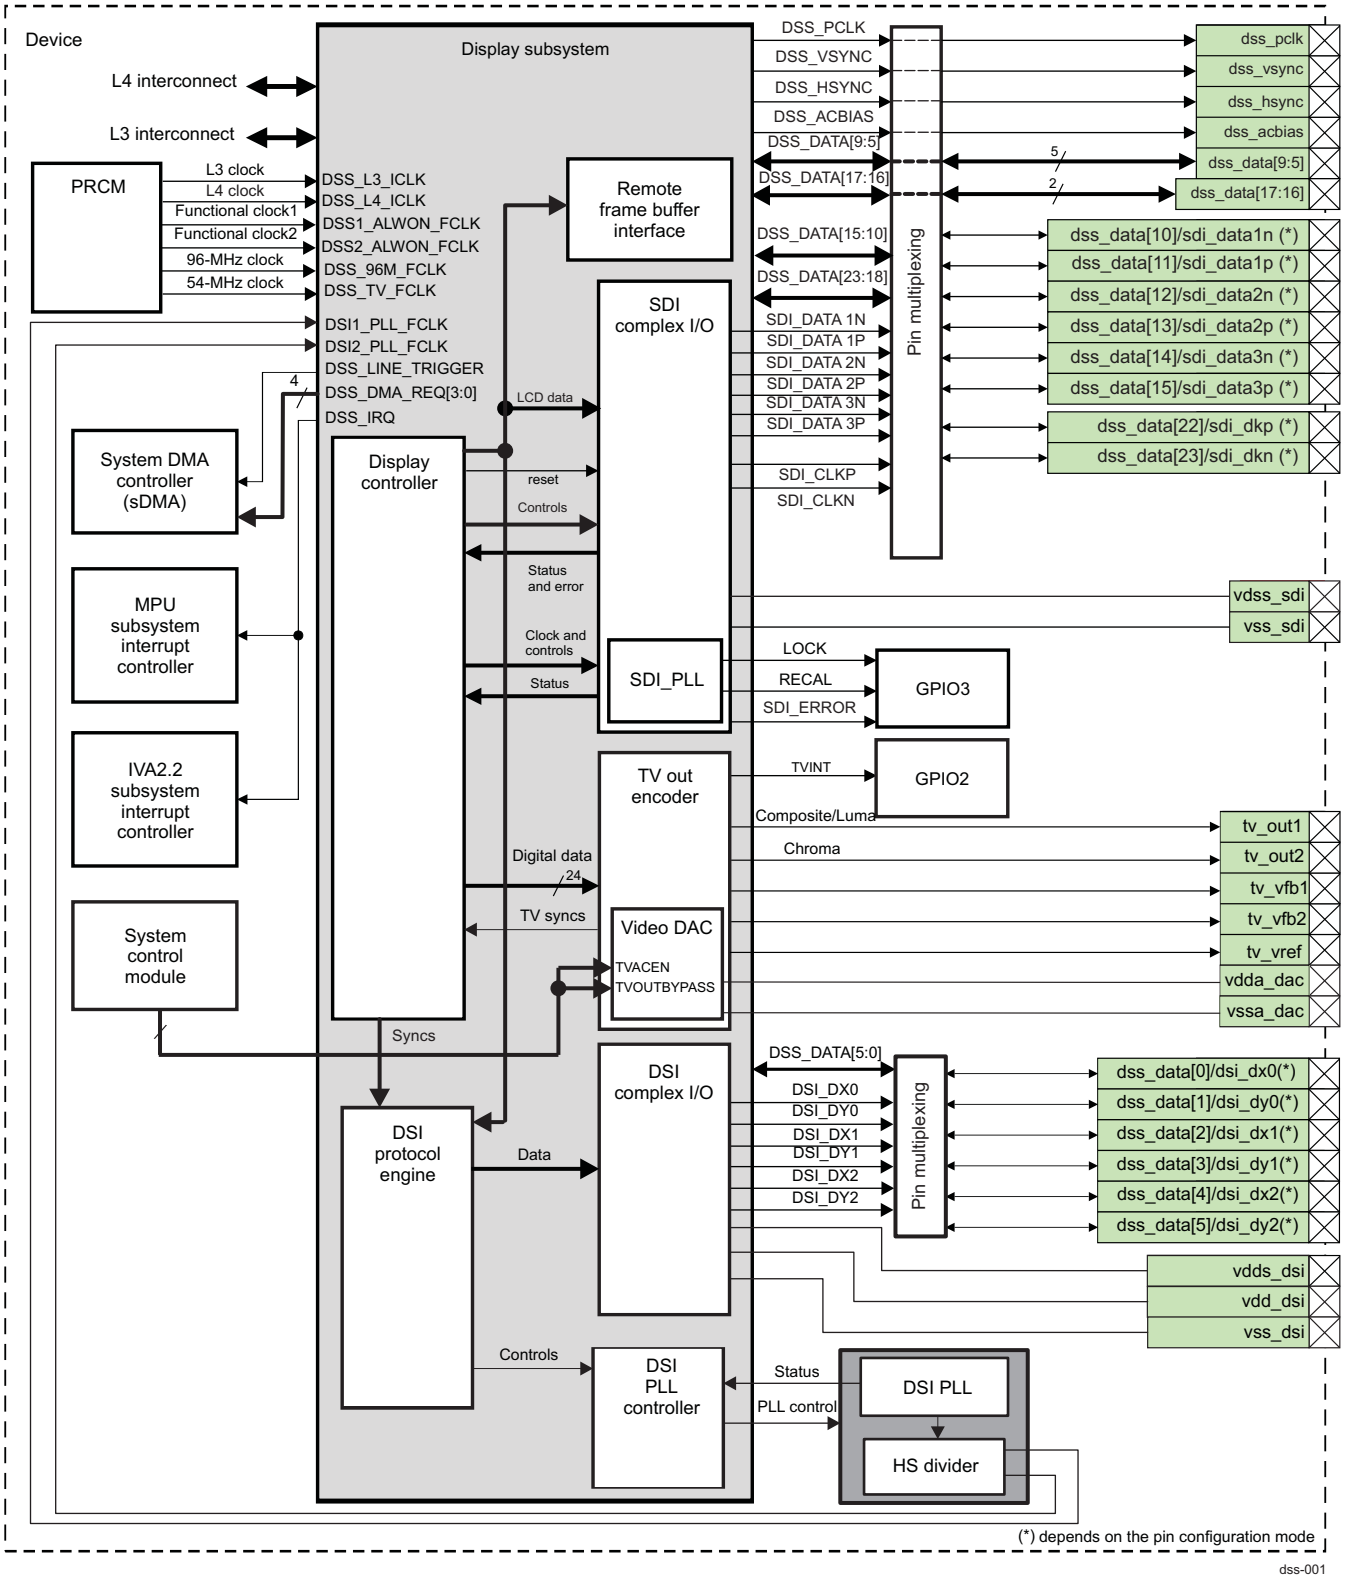
- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Serial display interface (SDI) complex input/output (I/O) module with the associated phased-locked loop (PLL)
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider.
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

NOTE: The SDI module, the DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

Figure 12-1 shows a block diagram of the display subsystem.

Figure 12-1. Display Subsystem Highlight



NOTE: For more information about connecting the LOCK, RECAL, SDI_ERROR, and TVINT signals through the GPIO2 and GPIO3 modules, see Chapter 21, *GPIO*.

The display subsystem includes the following main features:

- Display controller
  - Display modes
    - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
    - Programmable display size supported:
      - XGA - 1024 × 768 VESA timings at 60 fps (pixel clock = 63.5 MHz)
      - WXGA - 1280 × 800 VESA timings at 59.91 fps (pixel clock = 71 MHz)
      - SXGA+ - 1400 × 1050 direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75 MHz)
      - HD 720p - 1280 × 720 at 60 fps (pixel clock = 74.25 MHz)
    - 256 × 24-bit entries palette in red, green, and blue (RGB)
    - Programmable pixel rate up to 75 MHz

    NOTE: The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).

  - Display support
    - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
    - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
    - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
    - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
    - Remote frame buffer support through the RFBI module
    - Partial display through the RFBI module
    - Second 24-bit digital output
    - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
    - HDMI through external bridge
  - Signal processing
    - Overlay support for graphics (ARGB, RGBA, RGB, or Color Look-Up Table (CLUT)) and video1 (YCbCr 4:2:2, or ARGB, RGBA, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
    - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on input height
    - Rotation 90-, 180-, and 270-degrees
    - Transparency color key (source and destination)
    - Synchronized buffer update
    - Programmable video color space conversion YCbCr 4:2:2 into RGB
    - Hardware cursor
    - Gamma curve support on LCD output
    - Multiple-buffer support
    - Mirroring support
    - Programmable color phase rotation (CPR)
    - Alpha blending support (no rescaling in ARGB or RGBA formats)
  - Advanced

- Self-refresh using the DMA FIFO
- Arbitration between high/low priority (graphics video1 and video2)
- FIFO handcheck in STALL mode

– Power modes: Low-power saving modes

- RFBI (MIPI® DBI protocol)
  – Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
    - Sends commands to the RFB panel through the L4 interconnect
    - Sends data, received from the display controller or from the MPU through the DISPC pixel data bus, to the RFB panel
    - Reads data/status from the RFB to the L4 interconnect
  – RFB interface
    - 8-/9-/12-/16-bit 8086-series parallel interface
    - Two programmable configurations for two devices connected to the RFBI module
  – Data formats
    - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
    - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
  – Interconnect/FIFO
    - One slave port with DMA request and interconnect FIFO of 24x32-bit depth (for write access to DSS.RFBI_DATA register only)
    - One video port FIFO of 8 × 24-bit depth receiving data from the display controller
- SDI
  – TI Flatlink™ 3G display interface support
  – Pin multiplexing allows simultaneous operation with a single 9-bit RFBI-driven display (no support for simultaneous dual RFBI panel and SDI)

NOTE: The SDI pins are multiplexed with LCD parallel outputs.

- MIPI DSI
  – Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI DSI_PHY
  – The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage.
  – Supports video mode and command mode
  – Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  – Supports up to two data-configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
  – Maximum data rate of 800 Mbps per data pair
  – Data splitter for 2-data lane configuration
  – Error-correction code (ECC) and check-sum generation
  – Burst support for the video mode
  – RGB16, RGB18 packed and nonpacked, and RGB24 formats supported for video mode
  – Serial configuration port (SCP) for the DSI_PHY complex I/O and DSI PLL
  – Connection to the DSI_PHY complex I/O through PPI
  – Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
  – Data interleaving supports up to four interleaved asynchronous streams (command mode) from the

interconnect or video port when there is no video mode
  - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
  - Supports selection between low-power state and HS mode between HS packet transfers
  - Generic data type (DT) support

NOTE: The DSI pins are multiplexed with LCD parallel outputs.

- Video encoder
  - NTSC/PAL encoder outputs with the following standards:
    - NTSC-J, M
    - PAL-B, D, G, H, I
    - PAL-M
  - CGMS-A as described in the CEA-608-x Standard.
  - Input data interface compatible with the following protocols:
    - 24-bit input bus compatible with external sync
    - RGB 4:4:4
  - Dual output data 10-bit interface for internal digital-to-analog converter (DAC) that supports:
    - Composite video (CVBS)
    - Separate video (S-video)
  - TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
  - Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
  - Programmable horizontal sync, vertical timing, and waveforms
  - Programmable subcarrier frequency and SCH
  - Internal test pattern generation (color bar, flat field, color burst)
  - 2x/4x oversampling
  - Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

  - TV detection gating pulse generation

12.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

12.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

12.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.DISPC_CONTROL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see Table 12-1).

Table 12-1. I/O Pad Mode Selection

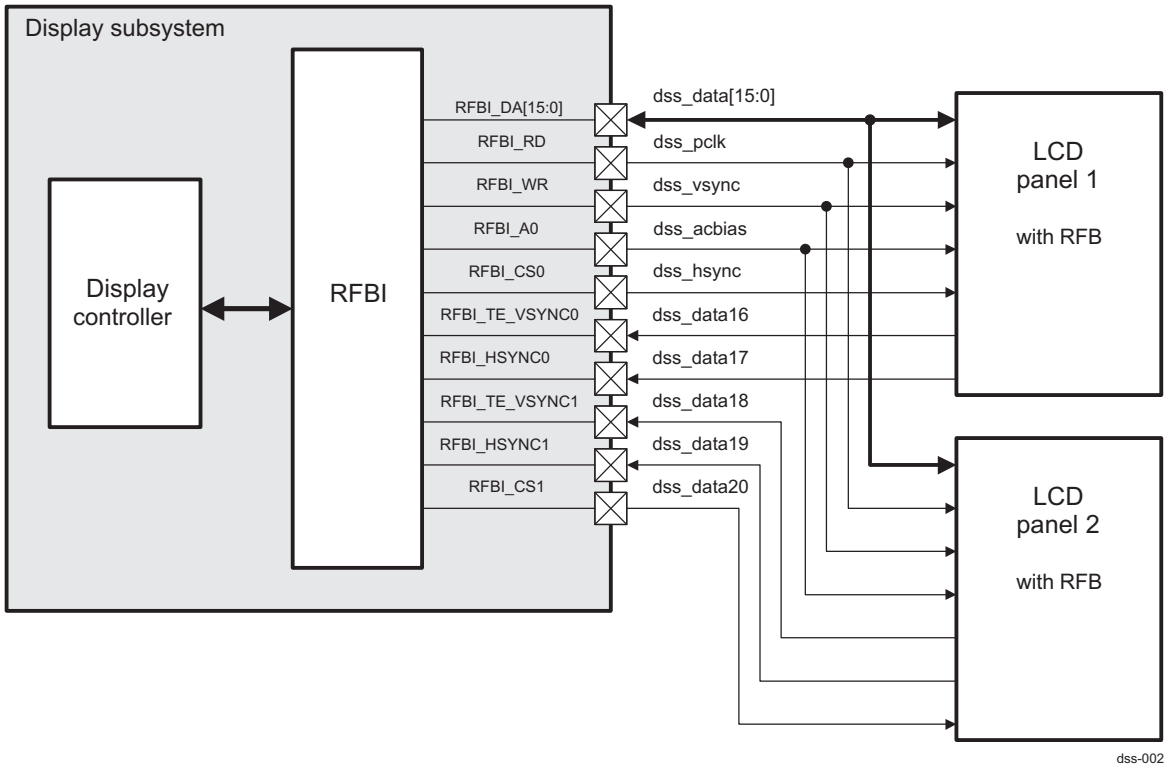
DSS.DISPC_CONTROL[16] GPOUT1	DSS.DISPC_CONTROL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is directly connected to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

12.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 12-2 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 12-2. LCD Support Parallel Interface (RFBI Mode)



NOTE: If the SDI is used, the second display device connected to RFB#1 is limited to 9-bit data.

Configure the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 12-2 describes the interface signals to/from the LCD panel in RFBI mode.

Table 12-2. LCD Interface Signals (RFBI Mode)

Signal Name	Type[1]	Description
RFBI_DA[15:0]	I/O	RFBI I/O data
RFBI_RD	O	Read access signal
RFBI_WR	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

(1) I = Input, O = Output

- RFBI_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

  Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI_DA is multiplexed at the chip-level boundary with dss_data [15:0].

- RFBI_RD: This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_pclk. The read is used to get status/data information from the LCD panel.
- RFBI_WR: The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_vsync.
- RFBI_A0: The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss_acbias.
- RFBI_CS*x*: The signal is the chip-select (CS*x*) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CS*x* must not be changed (*x* = 0 for LCD panel 1; *x* = 1 for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss_hsync, and CS1 is multiplexed at the chip-level boundary with dss_data[20].
- RFBI_TE_VSYNC*x*: Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI_TE_VSYNC*x* is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

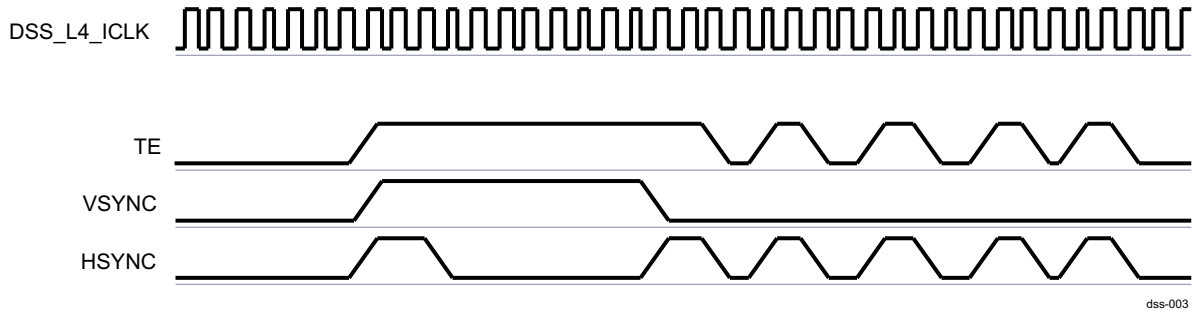
  To select the trigger mode, configure the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field (0x0: Internal trigger mode with the DSS.RFBI_CONTROL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI_TE_VSYNC*x*, 0x2: External trigger mode with the RFBI_TE_VSYNC*x*, and RFBI_HSYNC*x* signals with the programmable line counter).

  These signals are multiplexed at the chip-level boundary with dss_data[16] (RFBI_TE_VSYNC0) and dss_data[18] (RFBI_TE_VSYNC1) (LCD panel 1: *x* = 0; LCD panel 2: *x* = 1).
- RFBI_HSYNC*x*: The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss_data[17] (RFBI_HSYNC0) and dss_data[19] (RFBI_HSYNC1) (LCD panel 1: *x* = 0; LCD panel 2: *x* = 1).

12.2.1.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 12-3). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

Figure 12-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)



The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_VSYNC_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_HSYNC_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI_TE signal or use a bit field in the RFBI registers to start data capture.

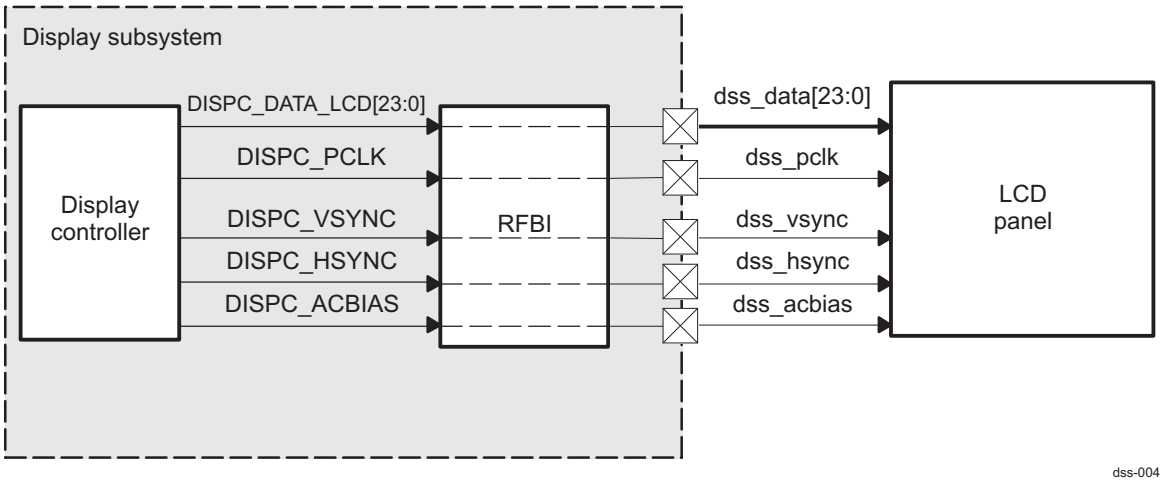
The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

12.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 12-4 shows the LCD support parallel interface in bypass mode.

Figure 12-4. LCD Support Parallel Interface (Bypass Mode)



NOTE: In bypass mode, the SDI and the parallel interface cannot be used at the same time.

Table 12-3 describes the interface signals to/from the LCD panel in bypass mode.

Table 12-3. LCD Interface Signals (Bypass Mode)

Signal Name	Type[1]	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

(1) I = Input, O = Output, I/O = Input/Output

- DISPC_DATA_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC_DATA_LCD is connected at the chip-level boundary with dss_data[23:0].
- DISPC_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss_pclk.
- DISPC_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss_vsync at the chip-level boundary.
- DISPC_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable

number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss_hsync.

- DISPC_ACBIAS: Uses the ac-bias signal from the display controller.
  - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
  - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss_acbias.

12.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 12-5 through Figure 12-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 12-4 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

Table 12-4. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

- Passive matrix technology, Monochrome mode

  Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

  Figure 12-5 and Figure 12-6 show 4- and 8-bit monochrome displays, respectively.

Figure 12-5. LCD Pixel Data Monochrome4 Passive Matrix

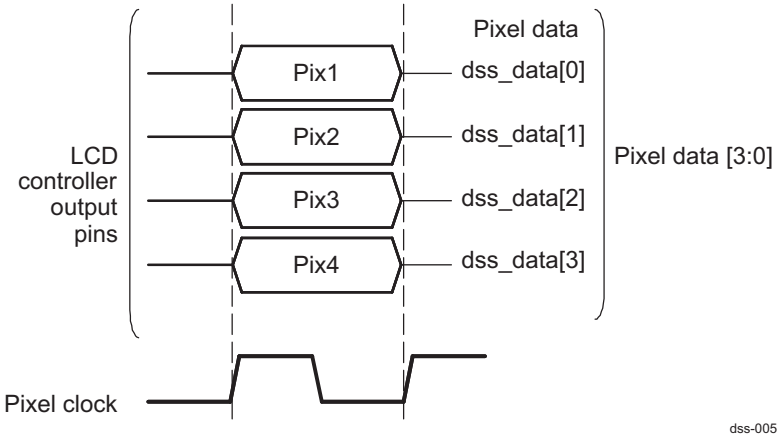


Figure 12-6. LCD Pixel Data Monochrome8 Passive Matrix

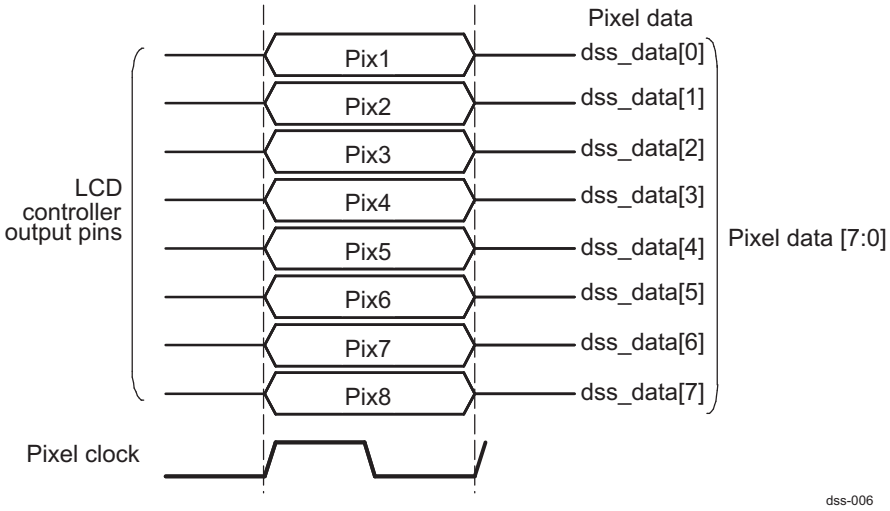
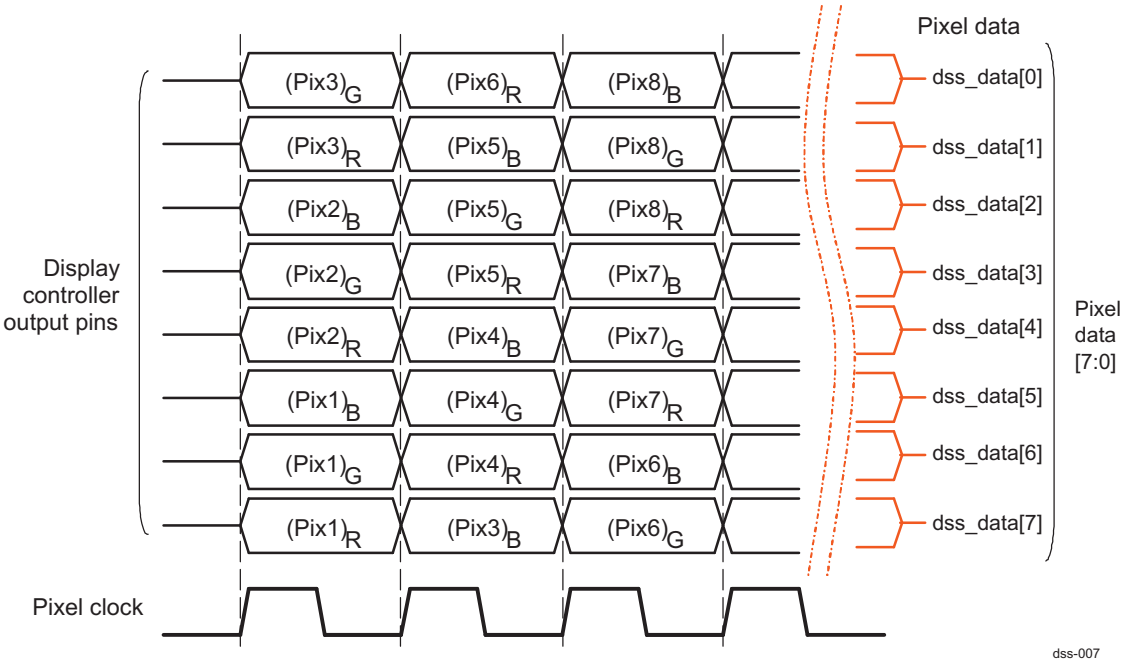


- Passive matrix technology, color mode

  Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).

  Figure 12-7 shows an 8-bit color passive matrix display.

Figure 12-7. LCD Pixel Data Color Passive Matrix



- Active matrix technology

  Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

  Figure 12-8 through Figure 12-11 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

Figure 12-8. LCD Pixel Data Color12 Active Matrix

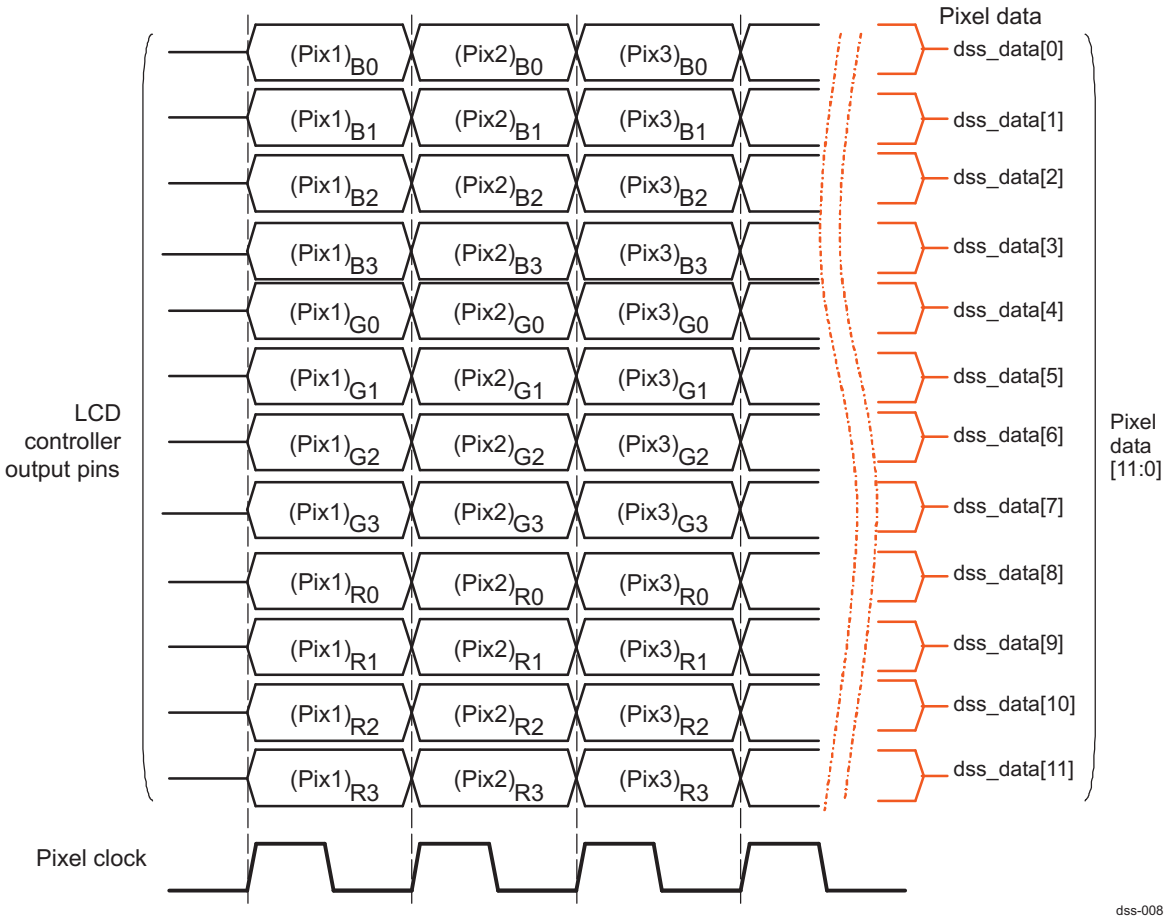


Figure 12-9. LCD Pixel Data Color16 Active Matrix

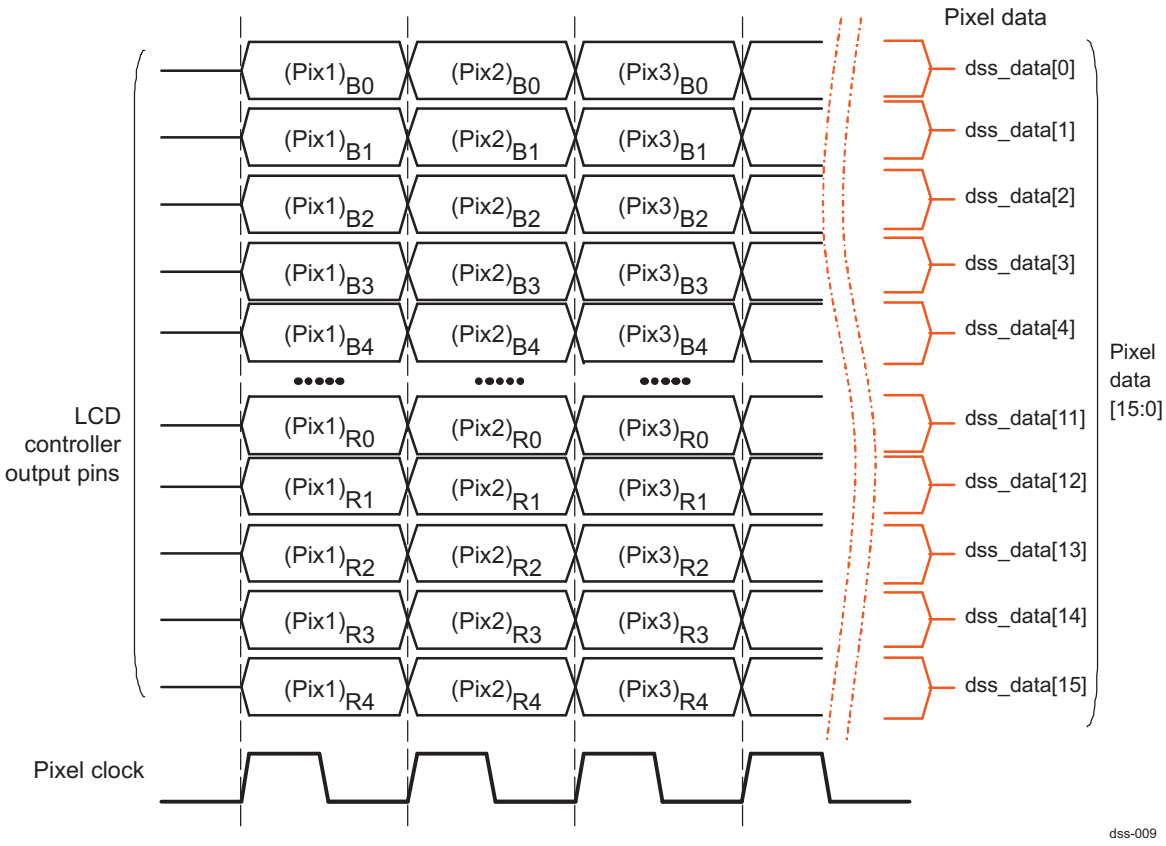

Figure 12-10. LCD Pixel Data Color18 Active Matrix

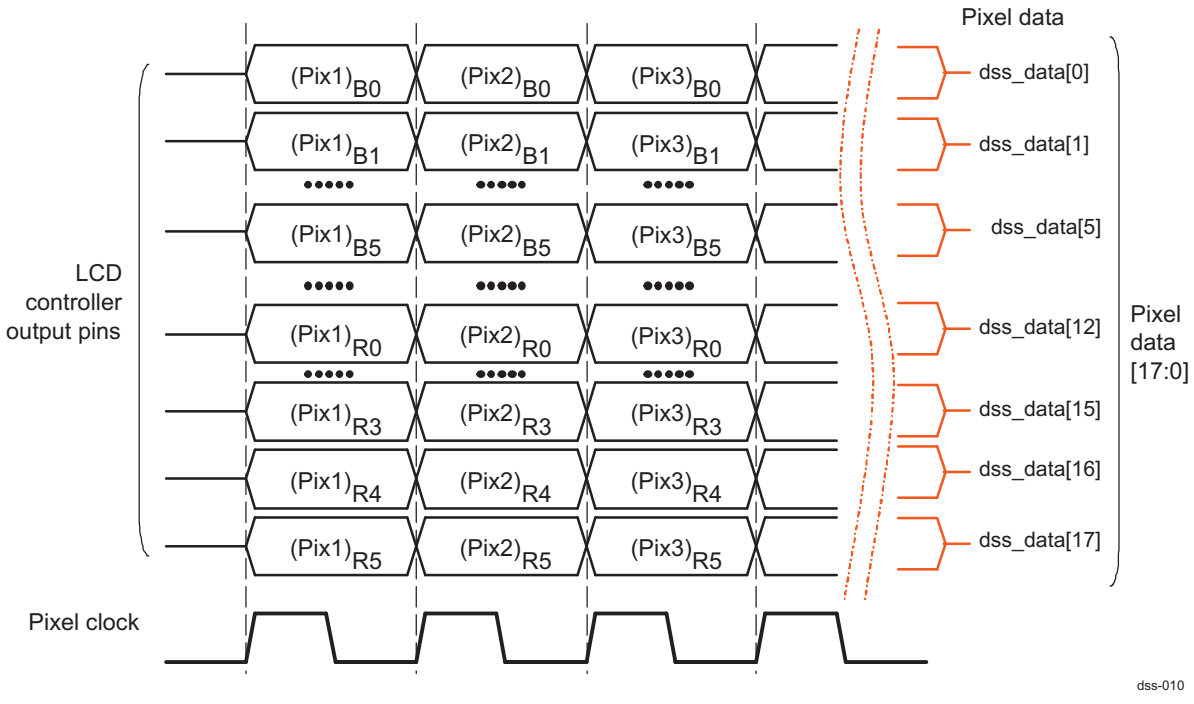

Figure 12-11. LCD Pixel Data Color24 Active Matrix

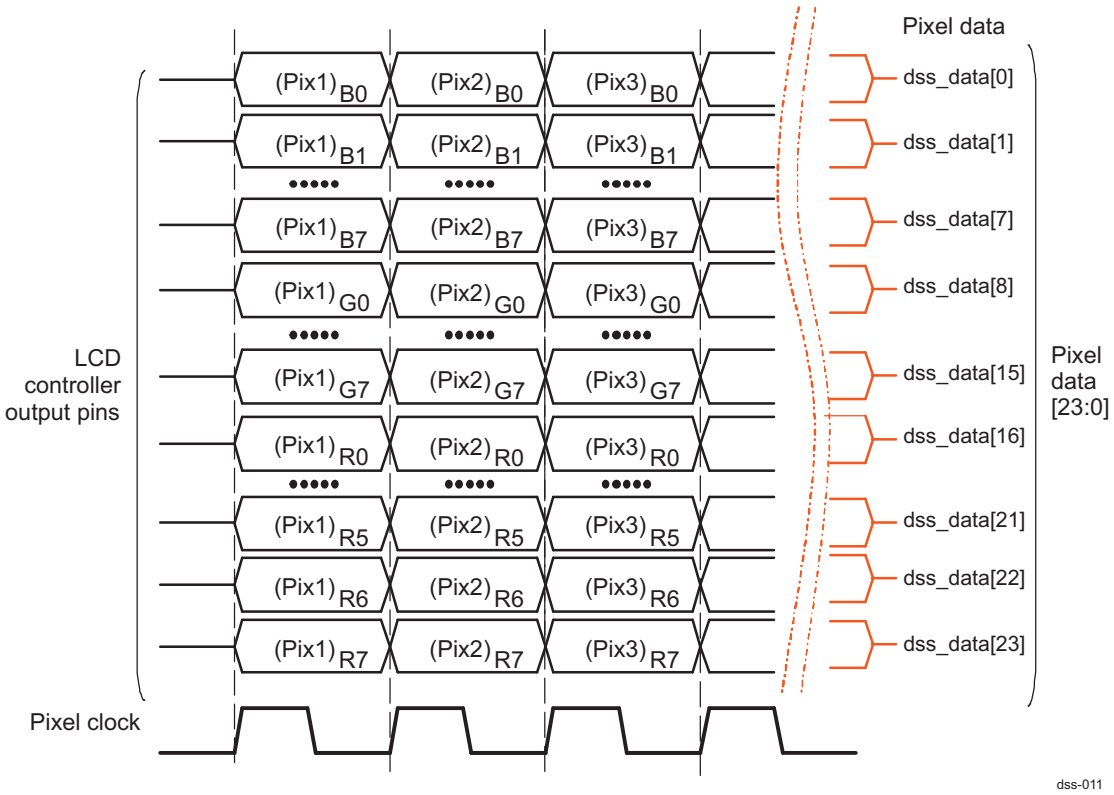
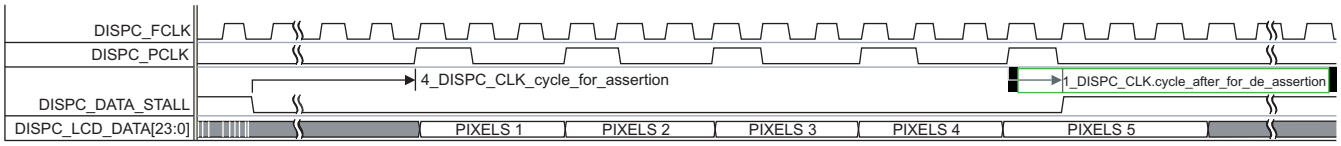


12.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
  - Stall signal

    The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

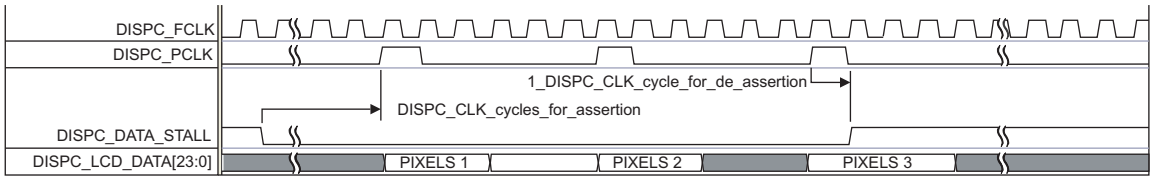
Figure 12-12. RFBI Data Stall Signal Diagram



To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC_CONFIG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC_CONTROL[11] STALLMODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow can not occur for the pipelines associated with the LCD output in RFBI mode. Figure 12-13 details the RFBI data stall with FIFO handcheck mode activated.

Figure 12-13. RFBI Data Stall Signal Diagram With Handcheck



– RFBI timing diagrams

Table 12-5 lists the programmable timing fields. Figure 12-14 through Figure 12-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

Table 12-5. Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME (with I = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME (with I = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIMEi[13:10] WEONTIME (with I = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIMEi[19:14] WEOFFTIME (with I = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIMEi[23:20] REONTIME (with I = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME (with I = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH (with I = 0 or 1)	The time when write cycle time or read cycle time completes

Figure 12-14. Command Data Write

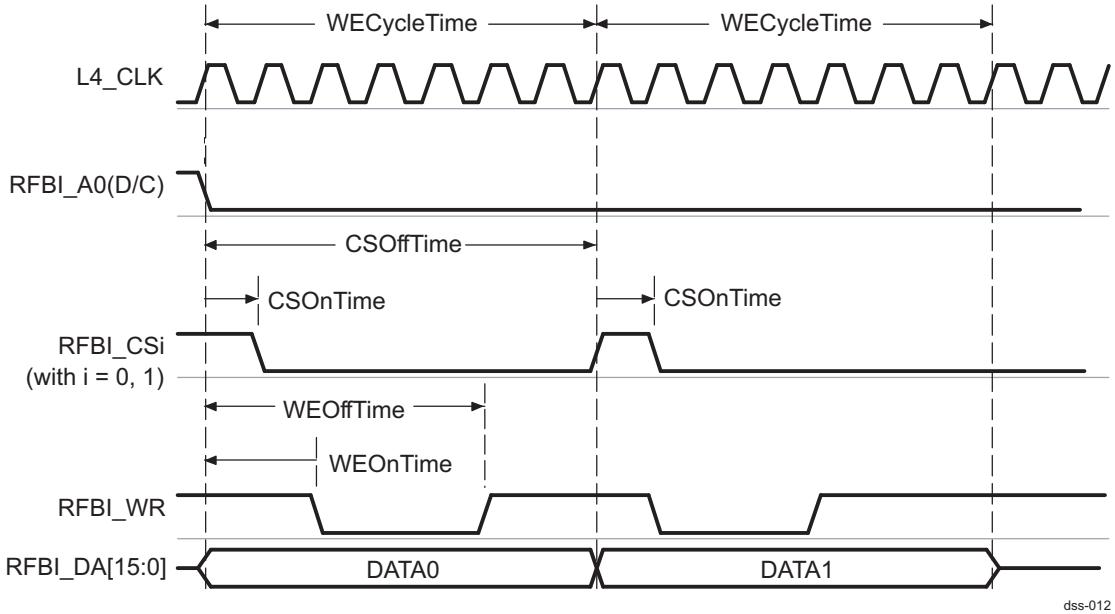


Figure 12-15. Display Data Read

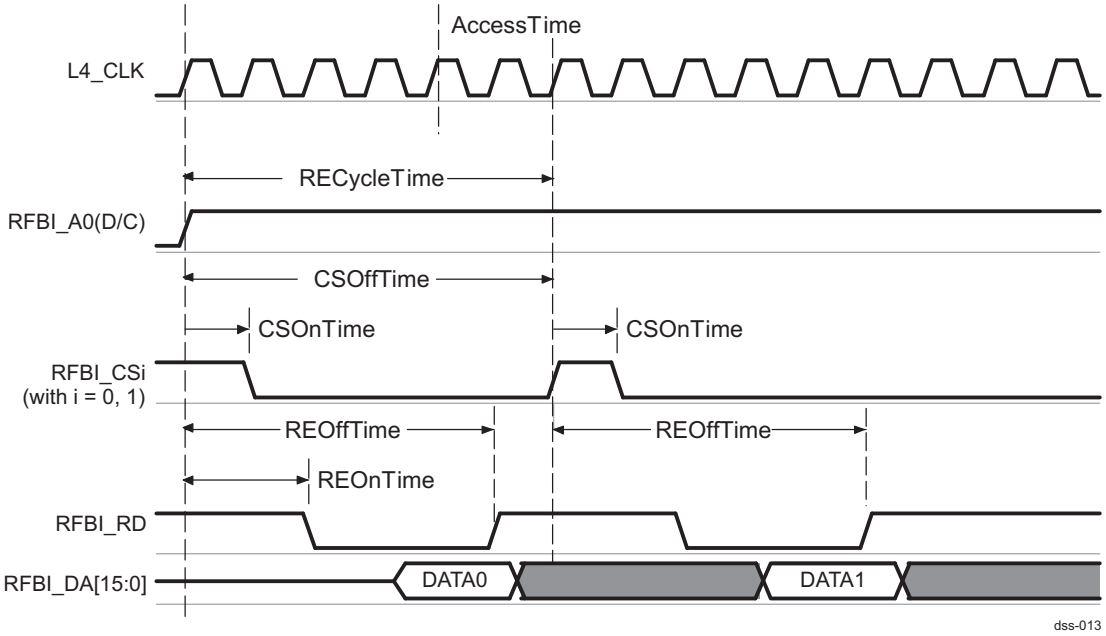

Figure 12-16. Read to Write and Write to Read

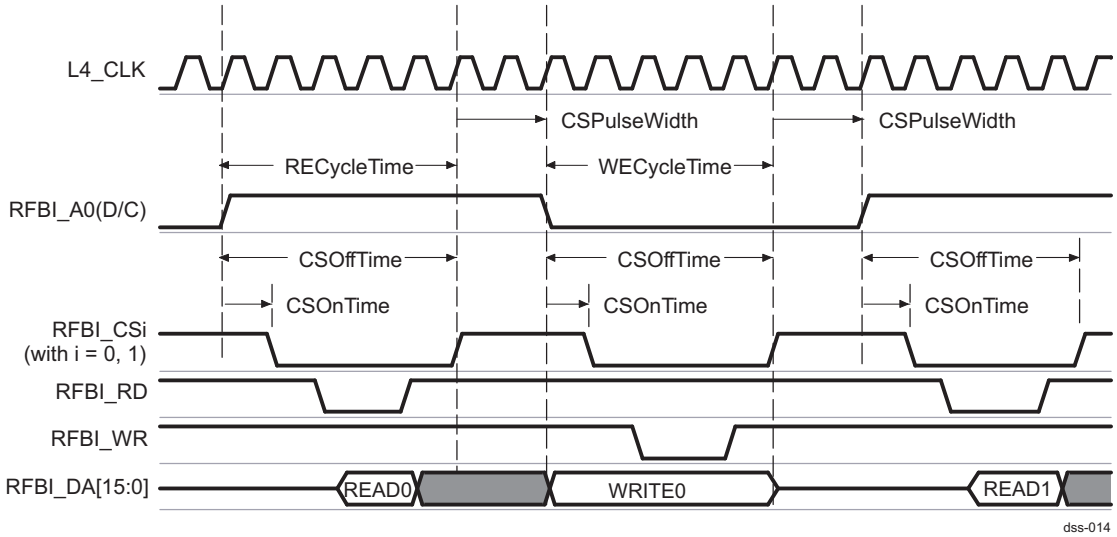

- Timing diagrams in bypass mode

  Figure 12-17 through Figure 12-32 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 12-6.

Table 12-6. Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1	Pixels per line (PPL)
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[31:20] HBP bit field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[19:8] HFP bit field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[7:0] HSW bit field value + 1	Horizontal synchronization pulse width
VBP	DSS.DISPC_TIMING_V[31:20] VBP bit field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[19:8] VFP bit field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[7:0] VSW bit field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK
IHS	DSS.DISPC_POL_FREQ[13] IHS bit	Invert DISPC_HSYNC
IVS	DSS.DISPC_POL_FREQ[12] IVS bit	Invert DISPC_VSYNC

- Active matrix timing configuration 1
  - DSS.DISPC_POL_FREQ[17] ONOFF bit = 0
  - DSS.DISPC_POL_FREQ[16] RF bit = 0

    The DISPC_HSYNC and DISPC_VSYNC signals are driven on the opposite edge of DISPC_PCLK from the pixel data.
  - DSS.DISPC_POL_FREQ[15] IEO = 0

    The DISPC_ACBIAS signal is active high.
  - DSS.DISPC_POL_FREQ[14] IPC = 0

    The pixel data are driven on the rising edge of DISPC_PCLK.

– DSS.DISPC_POL_FREQ[13] IHS = 0
The DISPC_HSYNC signal is active high.
– DSS.DISPC_POL_FREQ[12] IVS = 0
The DISPC_VSYNC signal is active high.

12.2.1.2 SDI Serial Interface

In the serial interface, the modules in the display subsystem path are the display controller and the SDI with its associated PLL. The display controller provides the required control signals to interface the memory frame buffer (either SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA to read the data from the system memory.

The SDI module is an additional display output mode that facilitates the connection of displays over relatively few conductors.

The SDI module implements the TI FlatLink3G protocol and converts the conventional parallel display signals (including pixel data) from the display controller to serial form. Texas Instruments provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver - SN65LVDS302 receiver for 3-data pair, SN65LVDS304 receiver for 2-data pair, and SN65LVDS306 receiver for 1-data pair.

The SDI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on 1 to 3 differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

NOTE: Only one 9-bit RFBI driven display can be run at the same time as the SDI.

Figure 12-33 shows a typical connection between the SDI module and a compliant panel display.

Figure 12-33. Typical SDI Connection

CAUTION

When routing the PCB, ensure that the connections between the OMAP device and the LCD panel meet FlatLink3G specifications, which are available in the 27-bit serial display interface receiver data sheet.

NOTE:

- The SDI pins are multiplexed in mode 1 with some LCD parallel pins. See Chapter 6, *System Control Module*, for more details on pad multiplexing.
- The connection from the vss_sdi pin of the device to the PCB digital ground must be as short as possible.
- The vdds_sdi dedicated power supply is provided by a power IC. Texas Instruments provides a global solution with the OMAP device associated with a power IC.

Table 12-7 describes the interface signals between the SDI module of the OMAP device and the LCD panel.

Table 12-7. Interface Signals Between the SDI Module and LCD Panel

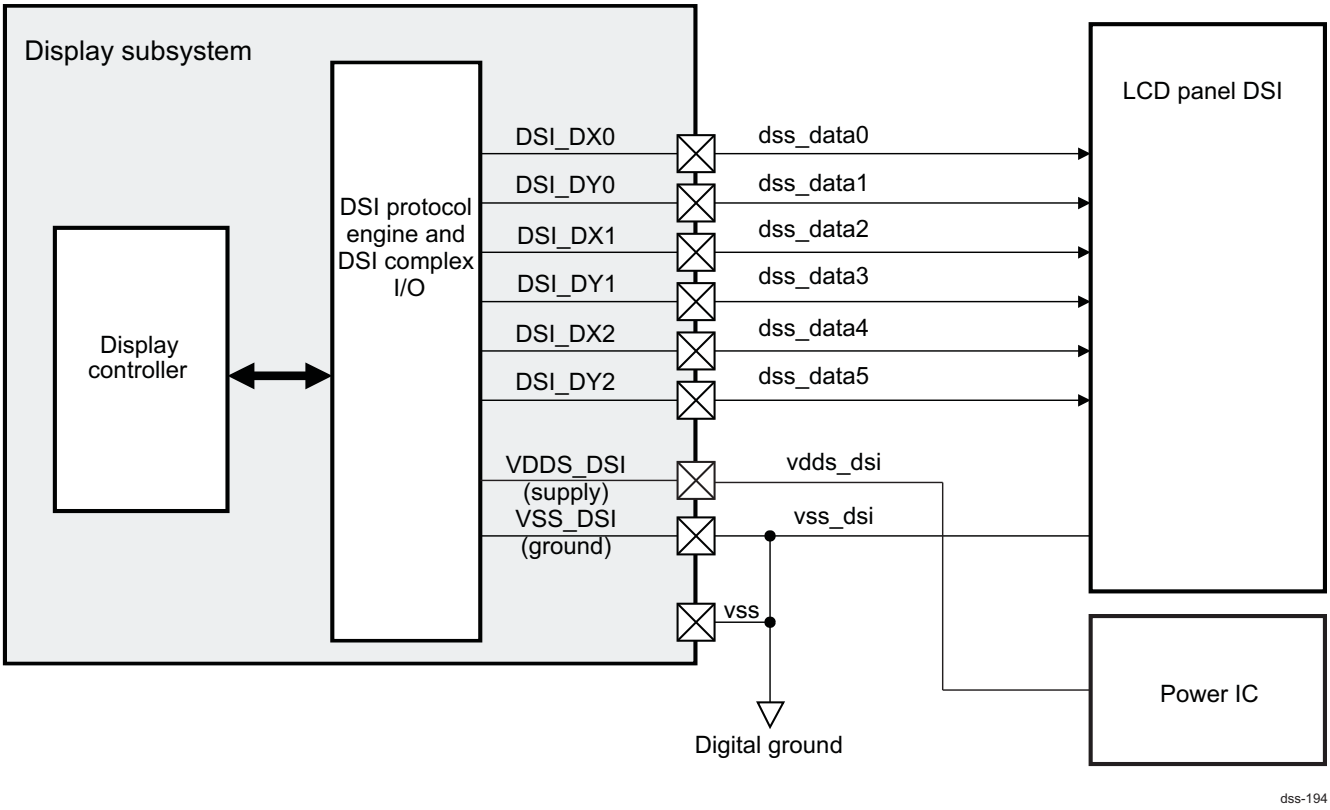
Signal Name	Type[1]	Description
SDI_DATA1N	O	First pair of differential data signals
SDI_DATA1P		
SDI_DATA2N	O	Second pair of differential data signals
SDI_DATA2P		
SDI_DATA3N	O	Third pair of differential data signals
SDI_DATA3P		
SDI_CLKN	O	Pair of differential clock signals
SDI_CLKP		
VDDS_SDI	PWR	Dedicated vdds power supply for SDI module
VSS_SDI	PWR	Dedicated vss ground for SDI module

(1) O=Output PWR=Power

12.2.1.3 DSI Serial Interface

Figure 12-34 shows a typical connection between the DSI modules and a compliant panel display.

Figure 12-34. Typical DSI Connection



NOTE: The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See Chapter 6, *System Control Module*, for more details on pad multiplexing.

12.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section summarizes the MIPI DSI1.0 protocol and data format.

12.2.2.1 Physical Layer

Table 12-8 lists the DSI interface I/O.

Table 12-8. I/O Description for DSI Serial Interface

Signal Name	I/O[1]	Description	Value at Reset	
dsi_dx0	line 1	I/O	Serial data/clock input/output	N/A
dsi_dy0				
dsi_dx1	line 2	I/O	Serial data/clock input/output	N/A
dsi_dy1				
dsi_dx2	line 3	I/O	Serial data/clock input/output	N/A
dsi_dy2				

(1) I/O = Input/Output

NOTE: Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

12.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode; otherwise, the clock is extracted from the received data in low-speed mode. The data is transmitted byte-wise least significant bit (LSB) first.
- The clock signal carries the DDR clock signal in high speed transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI_PHY into bytes.

Table 12-9 details all the DSI lanes configuration.

Table 12-9. DSI Lane Configuration

DSI DSI_PHY Lane Configuration	Data/Clock Lane Position			Description
	1	2	3	
Mode CLK + DATA1	CLK	DATA1	Not used	Single data lane
	CLK	Not used	DATA1	
	DATA1	CLK	Not used	
	Not used	CLK	DATA1	
	DATA1	Not used	CLK	
	Not used	DATA1	CLK	
Mode CLK + DATA1 + DATA2	CLK	DATA1	DATA2	Two data lanes
	CLK	DATA2	DATA1	
	DATA1	CLK	DATA2	
	DATA2	CLK	DATA1	
	DATA1	DATA2	CLK	

Table 12-9. DSI Lane Configuration (continued)

DSI DSI_PHY Lane Configuration	Data/Clock Lane Position			Description
	1	2	3	
	DATA2	DATA1	CLK	

NOTE:

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through programming of the DSS.DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL bit fields configure which lane transmits the clock and define its polarity. Four bit fields (DATA1_POSITION, DATA1_POL, DATA2_POSITION, and DATA2_POL) configure the data lanes and their polarity. The DATA2_POSITION bit field can be set to 0; in this case, only the data lane defined in the DATA1_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) should not be changed while DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For the hardware to recognize a new configuration of the complex I/O (done in DSS.DSI_COMPLEXIO_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI_CTRL[0] IF_EN bit to 1, next reset the DSS.DSI_CTRL[0] IF_EN to 0, then set DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE to 1, and finally, set again the DSS.DSI_CTRL[0] IF_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is undetermined.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bidirectional

12.2.2.1.2 ULPS

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the DSI module.
- For data lane 1, no BTA should have been sent. The DSI module should have control of the bus.

The control of each lane is independently controlled by the DSS.DSI_COMPLEXIO_CFG2 register.

12.2.2.2 Video Port (VP) Interface

NOTE: The signals described in this section are internal and not bounded outside the device. This section aims at helping software users understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

Table 12-10 summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data streams. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on the rising or falling edge of the pixel clock (VP_PCLK).

Table 12-10. Video Interface for DSI Protocol Engine

Signal Name	Type[(1)]	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23

(1) I = Input, O = Output

Table 12-10. Video Interface for DSI Protocol Engine (continued)

Signal Name	Type[1]	Description
VP_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP_CLK. The VP_PCLK is generated from VP_CLK through division. The clock ratio is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD bit field).
VP_DE	I	Data enable
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).
VP_CLK	I	Display controller internal clock. It is a free-running clock.

NOTE:

- The polarities of VP_HSYNC and VP_VSYNC are programmable by setting the DSS.DSI_CTRL register.
- The maximum frequency for VP_CLK is 173 MHz at nominal voltage, and 96 MHz at low voltage.
- Clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.
- VP_DE is connected to the dss_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC_POL_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, can not be used. Only the transparency burst mode is supported.

NOTE: The DSS.DSI_CTRL[13:12] LINE_BUFFER bit field defines the number of lines to be used for transferring data from the video port to the DSI link.

12.2.2.2.1 Video Port Used for Video Mode

If the video port is used for video mode, the VP_STALL is not used. Table 12-11 lists the active signals on the video port.

Table 12-11. Video Interface in the Context of Video Mode

Signal Name	Type[1]	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	Pixel clock.
VP_DE	I	Data enable
VP_CLK	I	It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage, and 96 MHz at low voltage.

(1) I = Input, O = Output

Three video modes are available:

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The ration of VP_CLK and the DSI high-speed (HS) clock period must ensure the same throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide such configuration).
- One line buffer:
  - The data are first stored in the line buffer; once all the data for one line are received, the DSI protocol engine sends the whole line. Software must adjust timings to allow for storing all line data into the line buffer before sending it to DSI outputs. The synchronization packets are never stored into the line buffer.
- Two line buffers:
  - One line is stored when the second line is output on the DSI port. It allows burst capability. While receiving the first line of the frame, there is no RGB packets sent because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored into the line buffer.

NOTE: If more active lines are received on the video port than the number defined in the DSS.DSI_VM_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

Figure 12-35 through Figure 12-37 show these three video modes.

NOTE:

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different than 0.
- The software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible:
  - The lane remains in ULPS, and the DSI_CTRL[20] BLANKING_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the DSI_CTRL[20] BLANKING_MODE bit set to 0x1; the number of sent bytes is determined by the DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field.

Figure 12-35. DSI Video Mode Without Burst (No-Line Buffer)

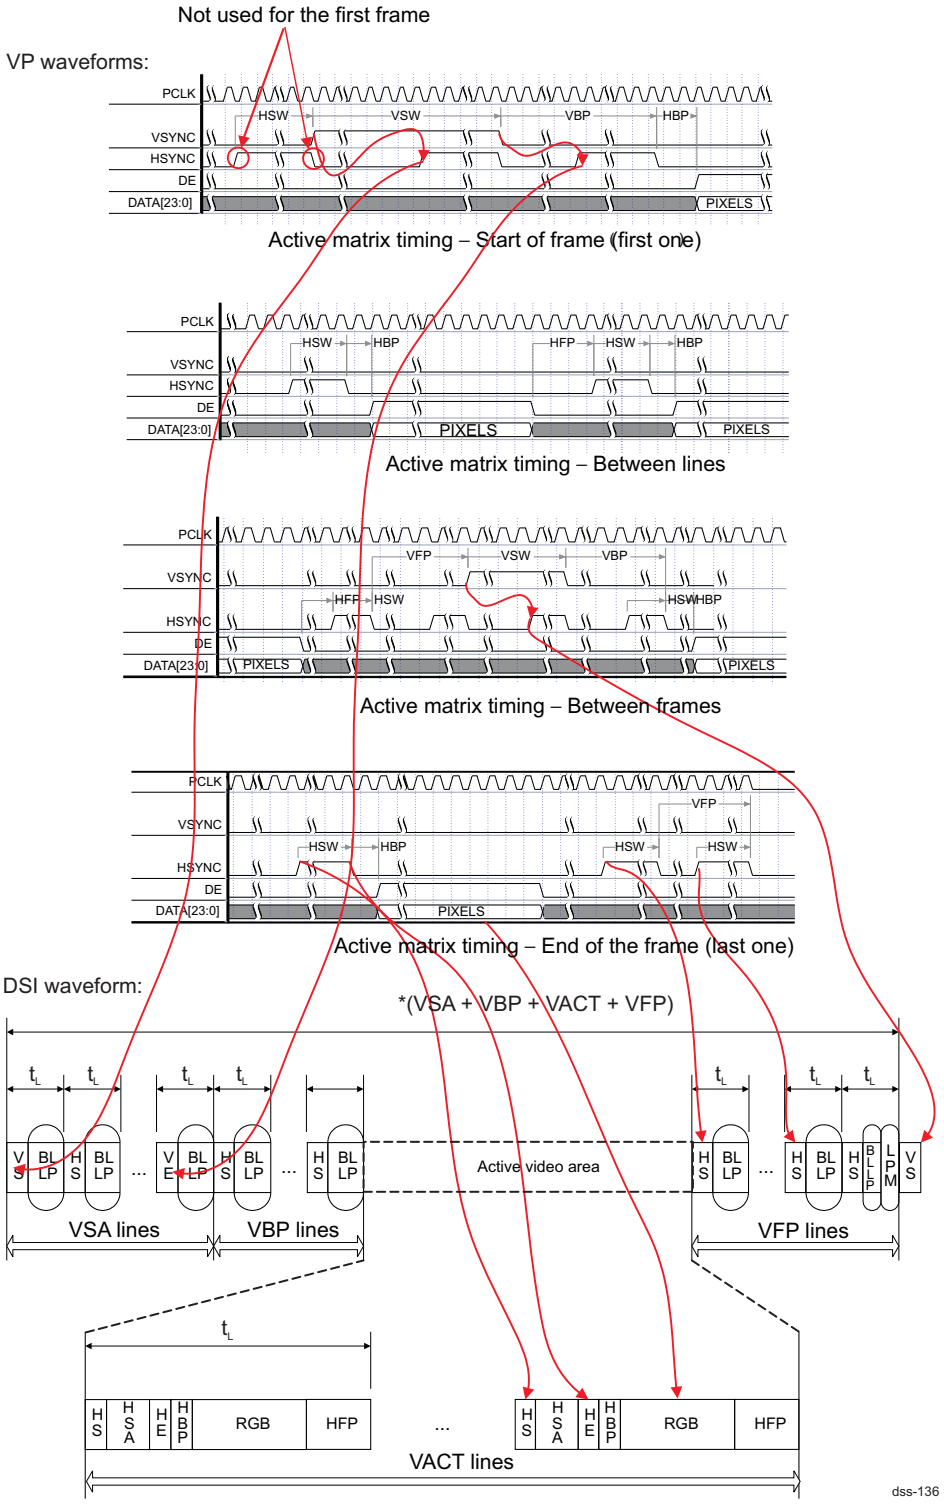


Figure 12-36. DSI Video Mode Without Burst (One-Line Buffer)

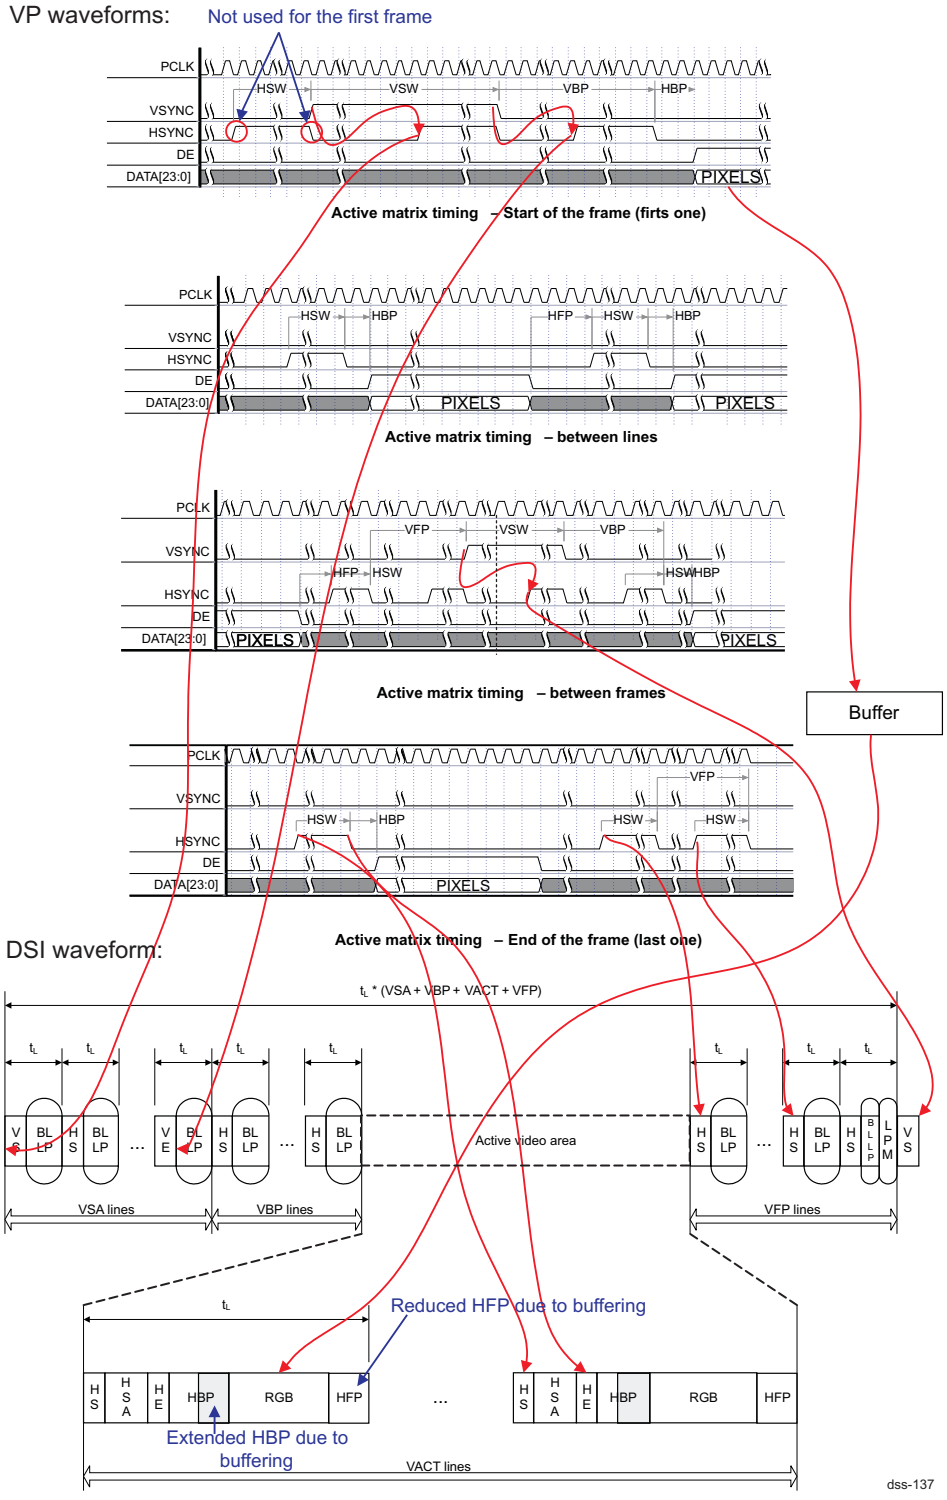

Figure 12-37. DSI Video Mode With Burst (Two-Line Buffers)

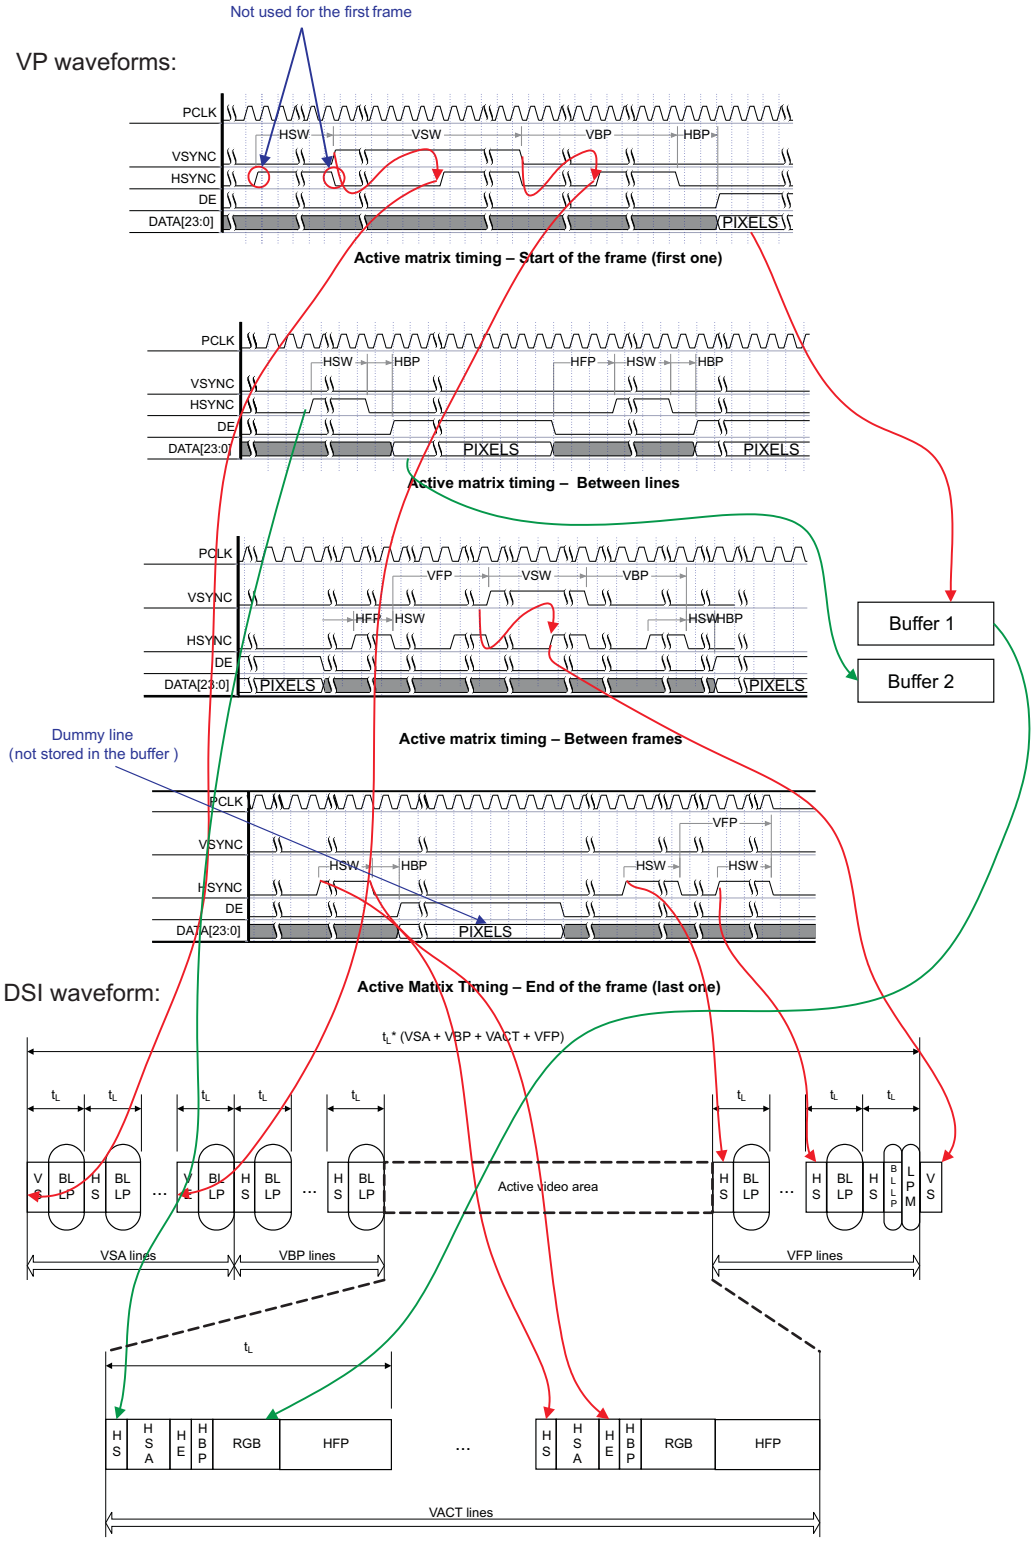

dss-138

If the signal VP_DE is not asserted during enough VP_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP_DE signal is asserted for too many VP_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS must check that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync should be generated and the interface must be disabled (DSS.DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field.

12.2.2.2.2 Video Port Used on Command Mode

If the video port is used for command mode, the VP_HSYNC, VP_VSYNC, and VP_DE signals are not used. Table 12-12 describes the active signals on the video port.

Table 12-12. Video Interface in the Context of Command Mode

Signal Name	Type[1]	Description
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	One pulse is generated every time new data is output on the data bus
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).
VP_CLK	I	Display controller internal clock: It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage and 96 MHz at low voltage.

(1) I = Input, O = Output

NOTE: The stall signal must be deasserted to receive pixels and asserted to stop receiving pixels.

Figure 12-38 and Figure 12-39 show the VP_STALL signal assertion and deassertion on rising and falling edges, respectively.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Figure 12-38. Stall Timing With Pixel on Rising Edge

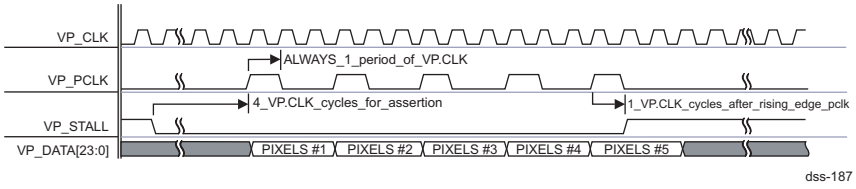

Figure 12-39. Stall Timing With Pixel on Falling Edge

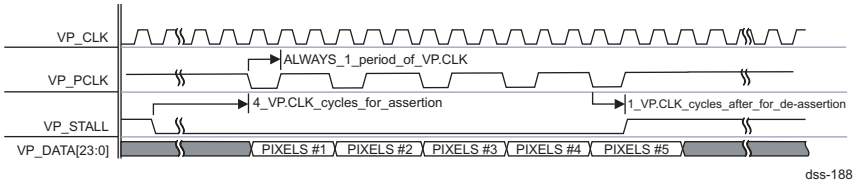


To stop the transfer, the VP_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through registers in the display controller module. The case with data output on falling edge of VP_PCLK is supported by the DSI protocol engine.

The VP_PCLK clock is generated from VP_CLK; these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on the rising edge of VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD bit field). In the DSI protocol engine, the information is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and should be aligned with the display controller configuration.

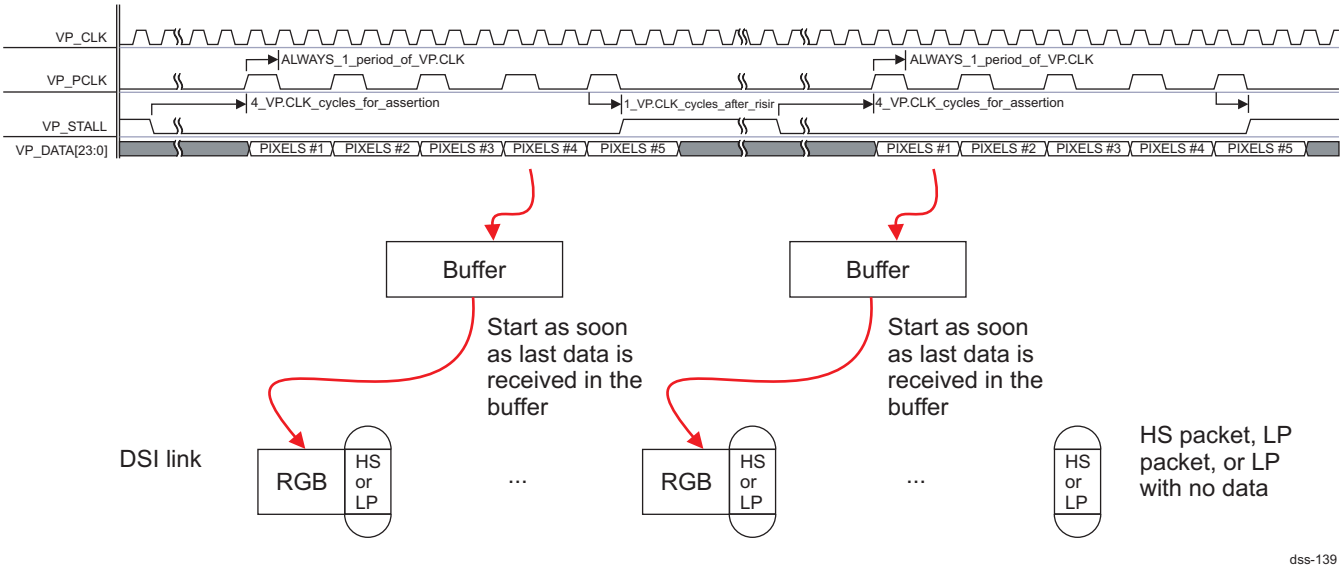
Deassertion of the VP_STALL signal should occur at least 4 VP_CLK cycles before assertion of VP_PCLK. Assertion of VP_STALL should occur one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the display controller under software control. It can be kept running between assertion and deassertion of VP_STALL.

The word count (WC) defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register for the virtual channel (VC)associated with the video port, indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and size of the line buffer). The total size defined in the WC of the header register can not exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.

Figure 12-40 shows the data flow in command mode using the video port.

Figure 12-40. Data Flow in Command Mode Using the Video Port



Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent.
- Two line buffers: The two lines are used if the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register is bigger than the line size; otherwise, one line buffer is used.

NOTE: In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

The packets can be sent using high-speed or low-speed.

NOTE: The DCS command in the payload can be inserted automatically using the DSI_CTRL[24] DCS_CMD_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

12.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

NOTE: The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They should be sent according to the video port timings.

12.2.2.3 Multilane Layer

Peripherals do not typically have high bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems should only use Lane 1 in LP mode for returning data from a peripheral to the host processor.

12.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its *valid data* signal into all lanes for which there is no further data. Although all lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

12.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). Figure 12-41 and Figure 12-42 show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using high-speed mode (HS). In low-power mode (LP), only one data lane is used (Lane 1).

Figure 12-41. Two Data Lane Configuration

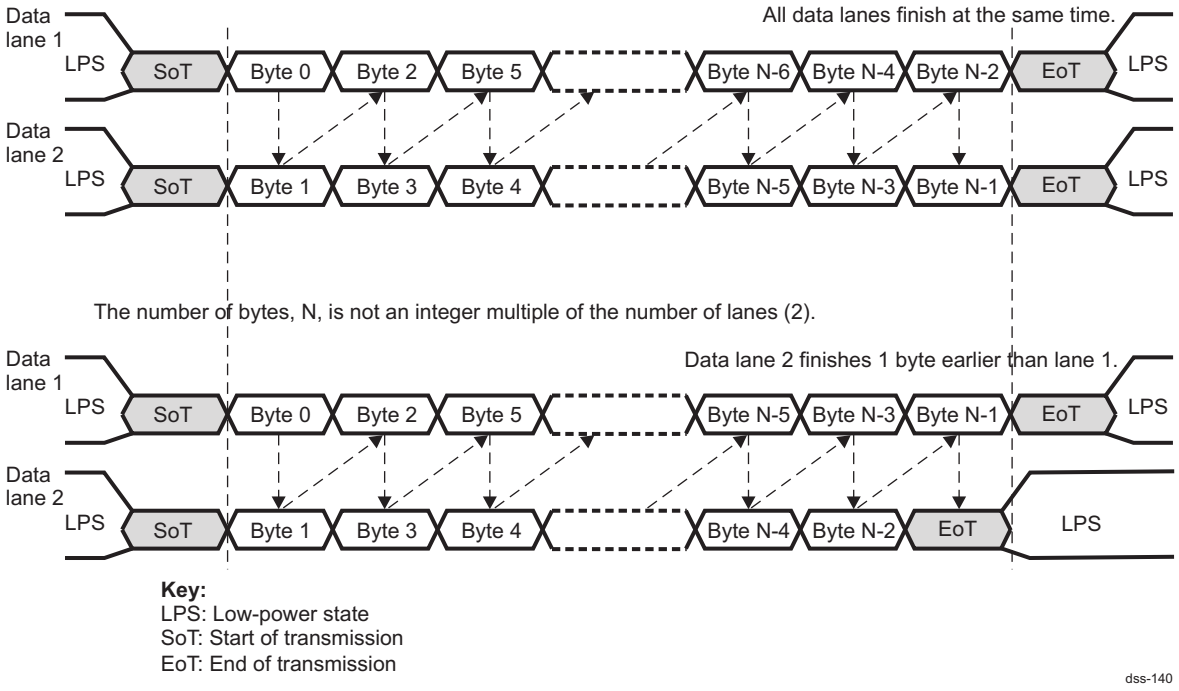


Figure 12-42. One Data Lane Configuration

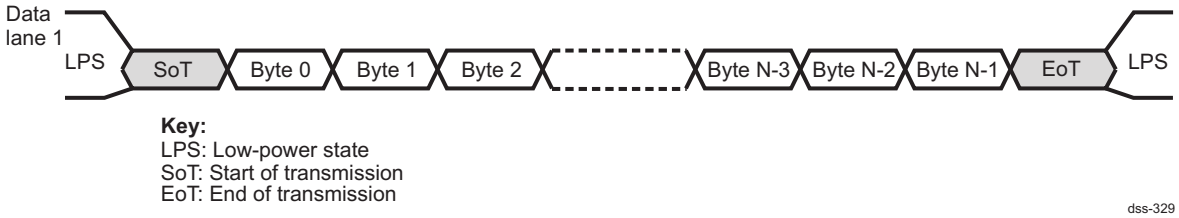
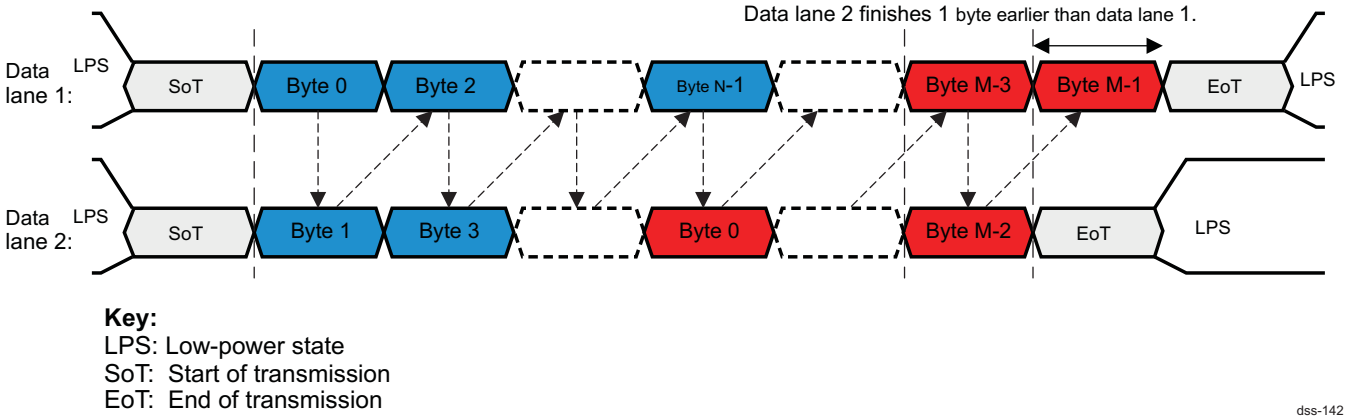


In case of back-to-back packets, the byte stream is considered as a single packet by the splitter module. Figure 12-43 shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

Figure 12-43. Two Packets Using Two-Data Lane Configuration (Example)



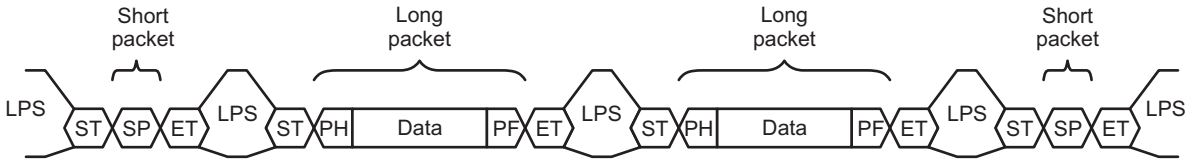
12.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using high-speed or low-speed mode. LLP is selected through DSI registers. The features of the DSI protocol layer are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 12-44 shows the protocol layer with short and long packets.

Figure 12-44. Protocol Layer With Short and Long Packets



Key:

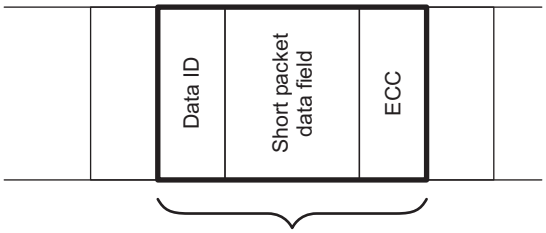
ST: Start of transmission	ET: End of transmission
PH: Packet header	PF: Packet footer
LPS: Low-power state	SP: Short packet

dss-143

12.2.2.4.1 Short Packet

Figure 12-45 shows the structure of the short packet. A short packet should contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC; a packet footer should not be present. Short packets should be four bytes in length. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

Figure 12-45. Short Packet Structure



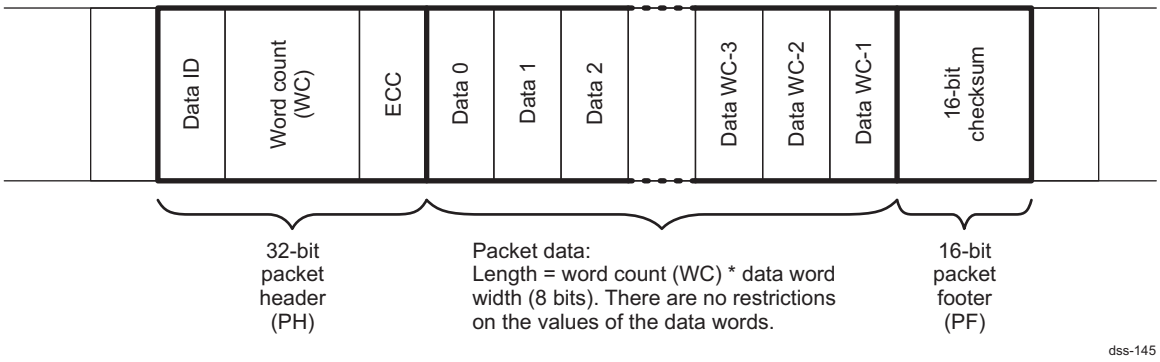
dss-144

NOTE: The short packets can be sent in low-power mode or in high-speed mode.

12.2.2.4.2 Long Packet

Figure 12-46 shows the structure of the low-level protocol long packet. A long packet must consist of three elements: A 32-bit packet header (PH), an application-specific data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header is further composed of three elements: An 8-bit data identifier, a 16-bit word count, and 8-bit ECC. The packet footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

Figure 12-46. Long Packet Structure



- The data identifier defines the VC for the data and the DT for the application-specific payload data.
- The word count defines the number of bytes in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer should be included in the word count.
- The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes the data identifier and the word count fields.

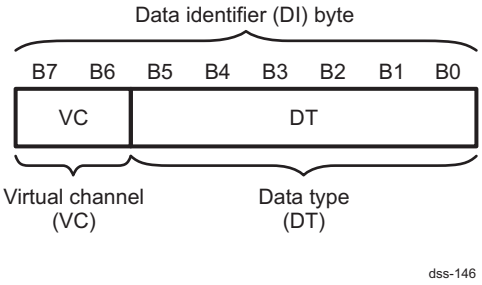
After the end of the packet header, the receiver reads the next word count * bytes of the data payload. There are no limitations on the value of a data word within the data payload block, that is, no embedded codes are used. Once the receiver has read the data payload, it reads the checksum in the packet footer. The host processor should always calculate and transmit a checksum in the packet footer. Peripherals are not required to calculate a checksum. Also note the special case of zero-byte data payload: If the payload has length 0, then the checksum calculation results in (0xFFFF). If the checksum is not calculated, the packet footer should consist of two bytes of all zeros (0x0000). In the generic case, the length of the data payload should be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, that is, multiple of four bytes. Each byte is transmitted LSB first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multibyte elements such as word count and checksum should be transmitted least-significant byte first.

NOTE: The long packets can be sent in low-power mode or in high-speed mode.

12.2.2.4.3 Data Identifier

The data identifier byte contains the virtual VC ID value and the DT value as illustrated in Figure 12-47. The VC ID is contained in the two MS bits of the data identifier byte. The DT value is contained in the six LSBs of the data identifier byte. DI[7:6]: These two bits identify the data as directed to one of four VCs. DI[5:0]: These six bits specify the DT.

Figure 12-47. Data Identifier Structure

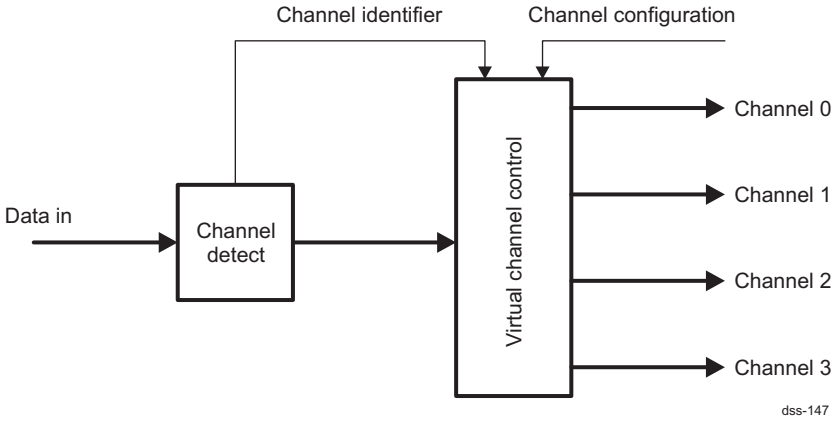


12.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that each packet sent in a single transmission have its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSS.DSI_VCn_SHORT_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_HEADER registers for short and long packets, respectively. It should not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 12-48 shows the VC controller.

Figure 12-48. Virtual Channel Controller



12.2.2.4.5 Data Type Field DT[5:0]

The DT field specifies whether the packet is a long or short packet type and the packet format. The DT field, along with the word count field for long packets, informs the receiver on how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start/end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

12.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. Table 12-13 summarizes the pixel formats supported by the DSI interface in video mode.

Table 12-13. Pixel Data Format in Video Mode

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666

Table 12-13. Pixel Data Format in Video Mode (continued)

Mode	Description
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

12.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to automatically generate the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transitions from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port prior to the first VSYNC should be ignored. Since the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should be no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. Table 12-14 summarizes the 6-bit DT synchronization code values.

Table 12-14. Synchronization Codes

Synchronization Code	Value	Comments
V sync start code (VSSC)	0x1	Optional
V sync end code (VSEC)	0x11	Optional
H sync start code (HSSC)	0x21	Optional
H sync end code (HSEC)	0x31	Optional

12.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long blanking packets are sent to the display. The DSS.DSI_VM_TIMINGi (I between 1 and 7) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

Table 12-15 defines the short packet values for the synchronization packets:

Table 12-15. Sync Short Packet Values

Virtual Channel ID	Sync Code	Header (1st Byte)	Header (2nd Byte): Data Field LSB	Header (3rd Byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See note following this table
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

NOTE:

- If the ECC is enabled by setting the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit to 1 for the VC in video mode, the check-sum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, since the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The link [lane(s) and clock separately] can be put in ULPS mode. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and t_L are defined in the DSS.DSI_VM_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and t_L are defined using the byte clock unit (TxByteClkHS) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking into account the 4-byte header and the 2-byte check sum).

The configuration of the display controller timing generator must be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period can not be used for sending any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC, or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC, by another VC, by trigger (BTA

for example), or by extra LP NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 12-49 and Figure 12-50 show a nonburst transfer in DSI video mode with, and without VE and HE, respectively.

Figure 12-49. DSI Video Mode: Nonburst Transfer With VE and HE

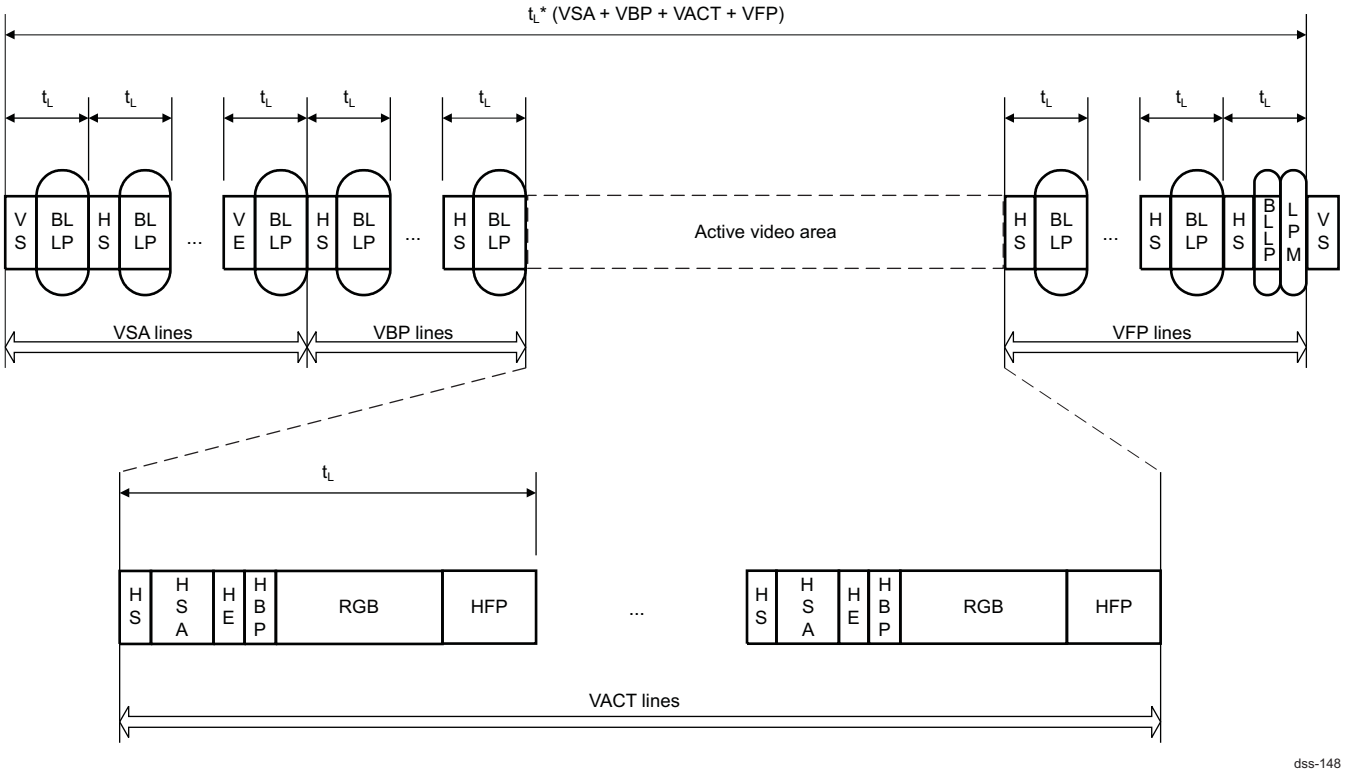


Figure 12-50. DSI Video Mode: Nonburst Transfer Without VE and HE

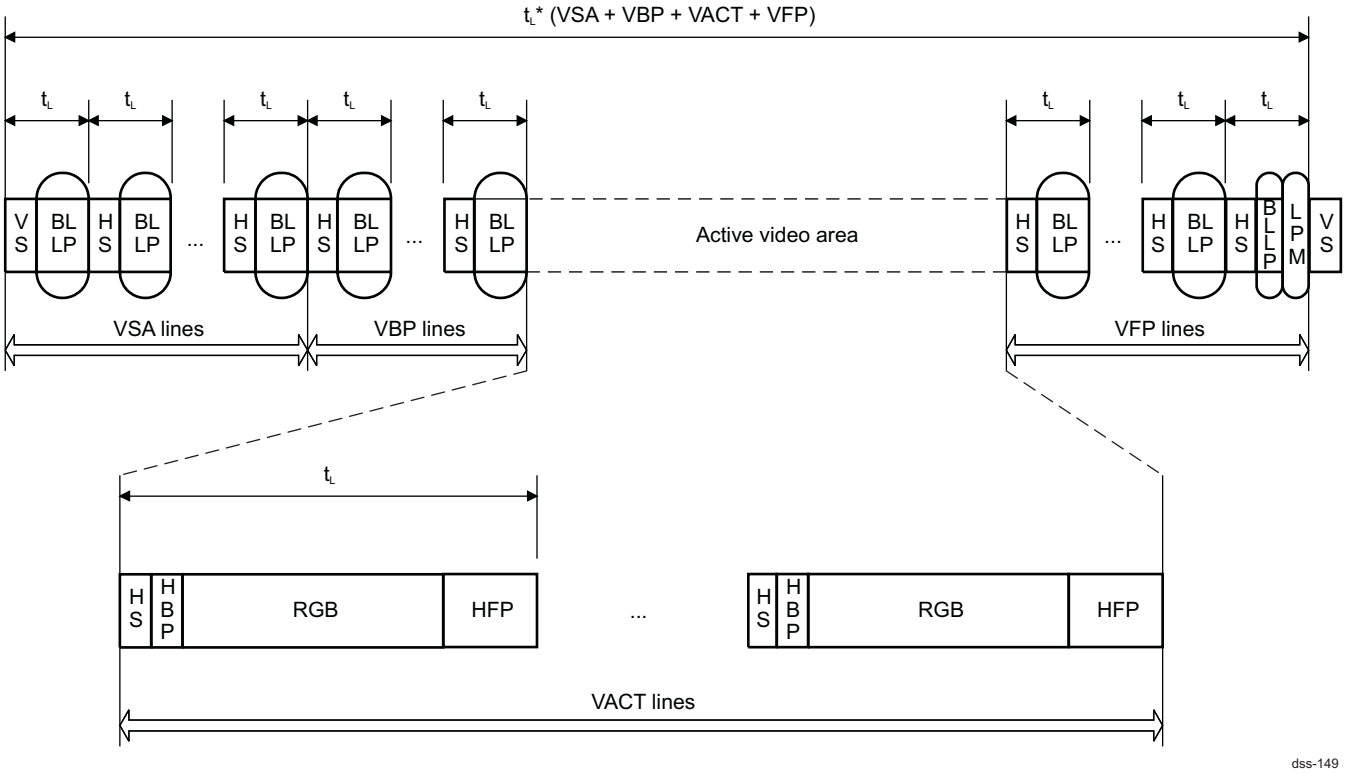
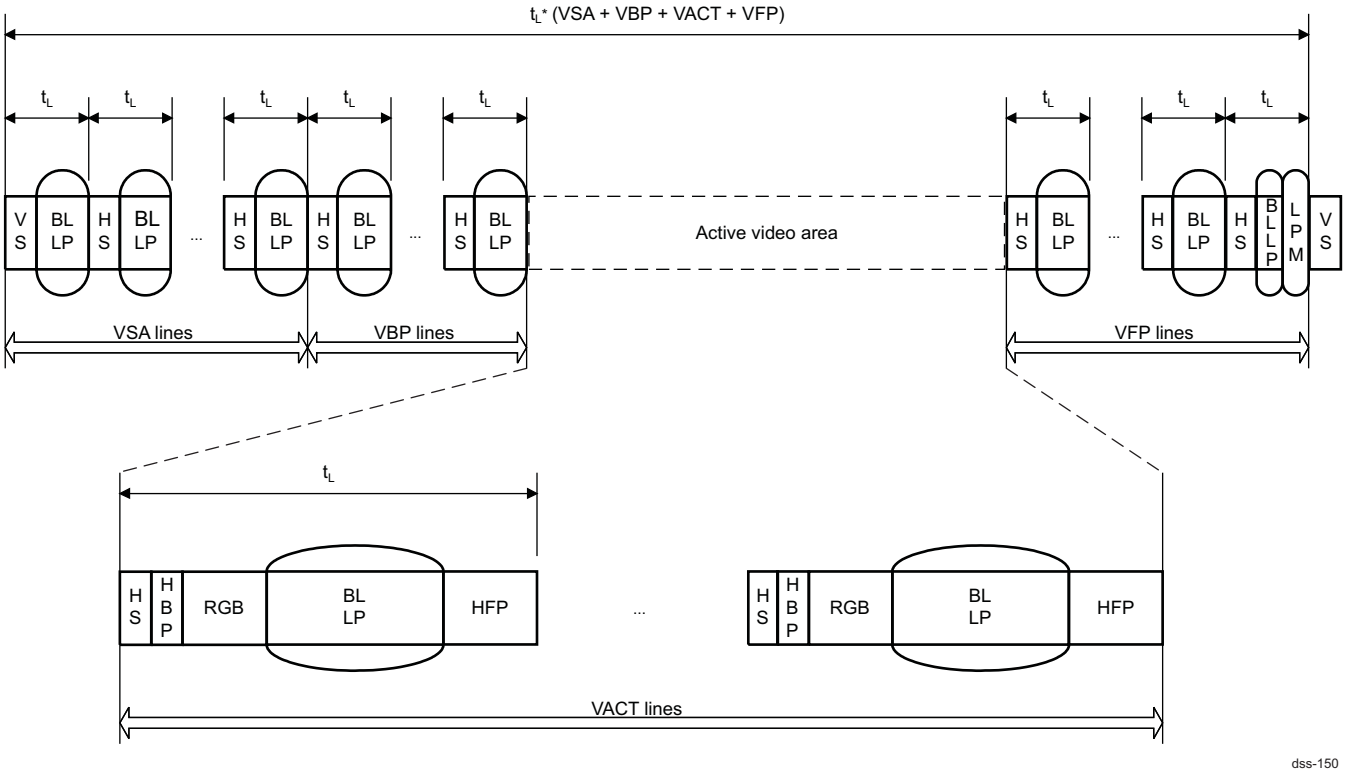


NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

Figure 12-51. DSI Video Mode: Burst Transfer Without VE and HE



NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

In Figure 12-50 and Figure 12-51, if HSync end short packet is not generated (HSA does not exist), HBP should be other than 0.

12.2.2.4.9 Frame Structures

Figure 12-52 shows the general DSI frame structure.

Figure 12-52. DSI General Frame Structure

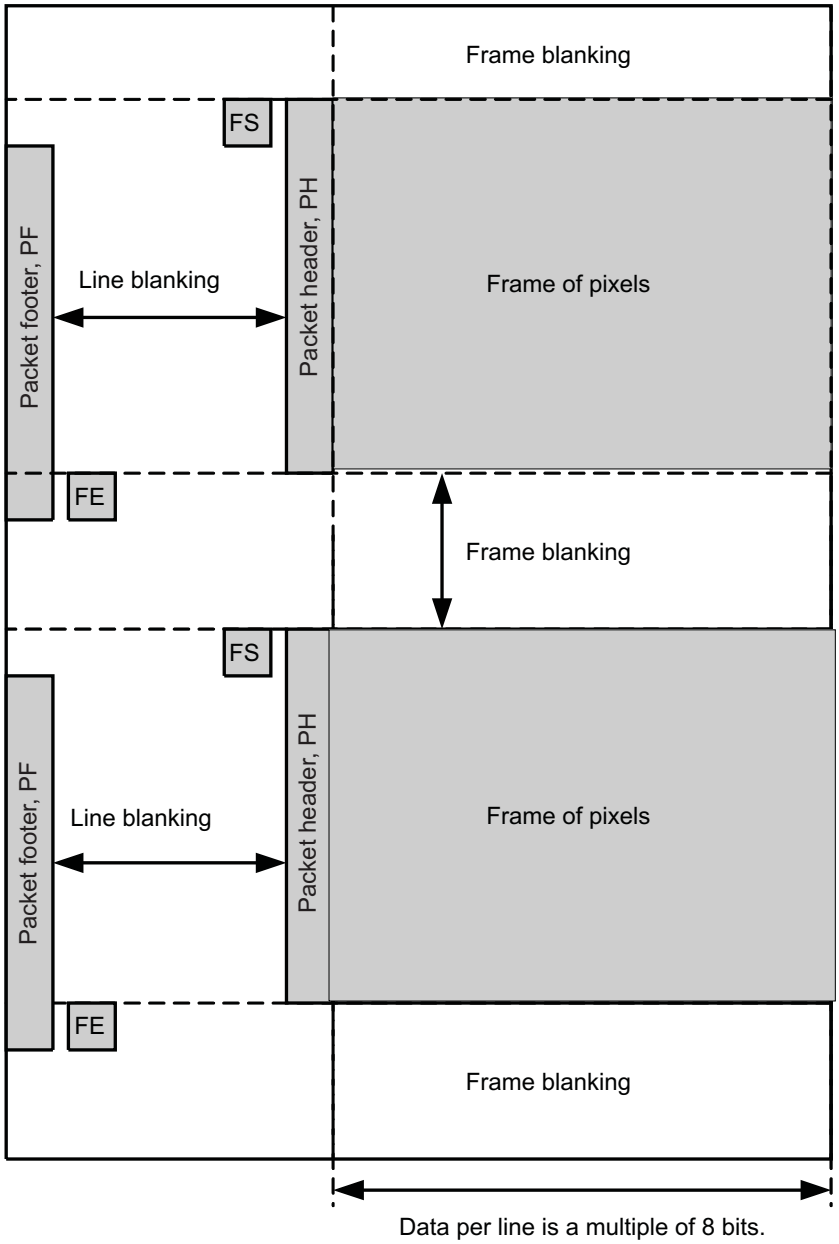


Figure 12-53 shows the general frame structure using burst mode.

Figure 12-53. DSI General Frame Structure Using Burst Mode

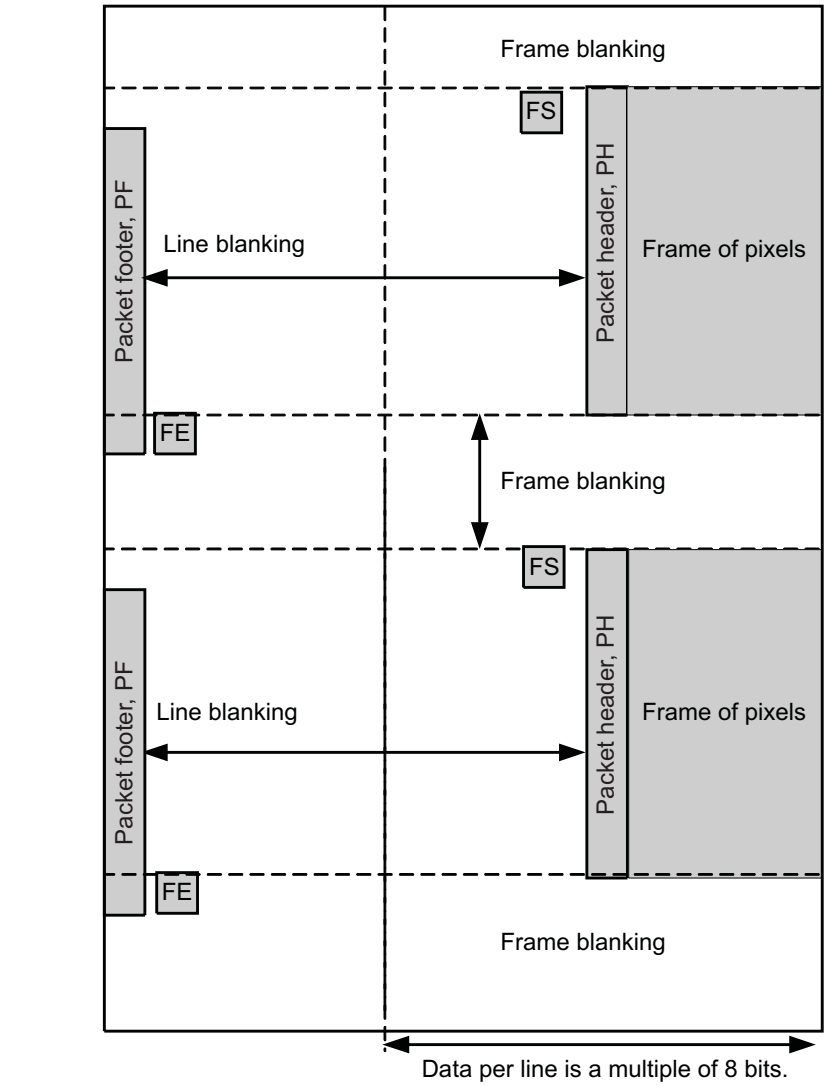

Figure 12-54 shows the general frame structure using burst mode and interleaving.

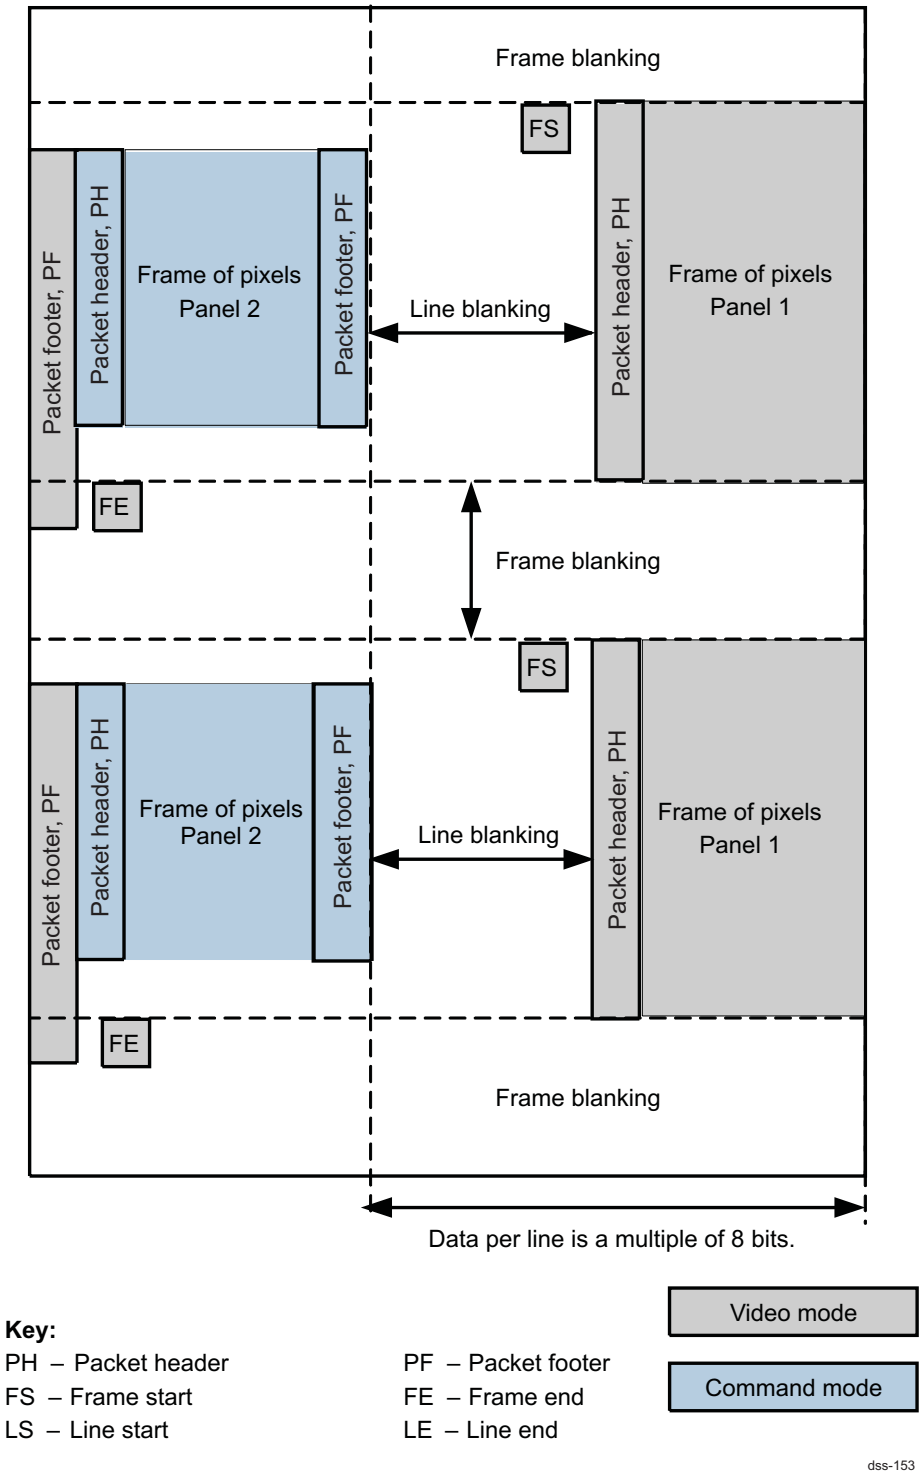
Figure 12-54. DSi General Frame Structure Using Burst Mode and Interleaving



12.2.2.4.10 Virtual Channels

The DSI protocol layer transports VCs. The purpose of VCs is to separate different data flows, which are interleaved in a same data stream. Each VC is identified by a unique channel identification number in the packet header. The channel identification number is encoded in 2-bits. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent VCs: Up to 4. Table 12-16 summarizes the VC values used for each channel.

Table 12-16. Virtual Channel Values

Virtual Channel Number	Value
Virtual channel 0	0x0
Virtual channel 1	0x1
Virtual channel 2	0x2
Virtual channel 3	0x3

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to root the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

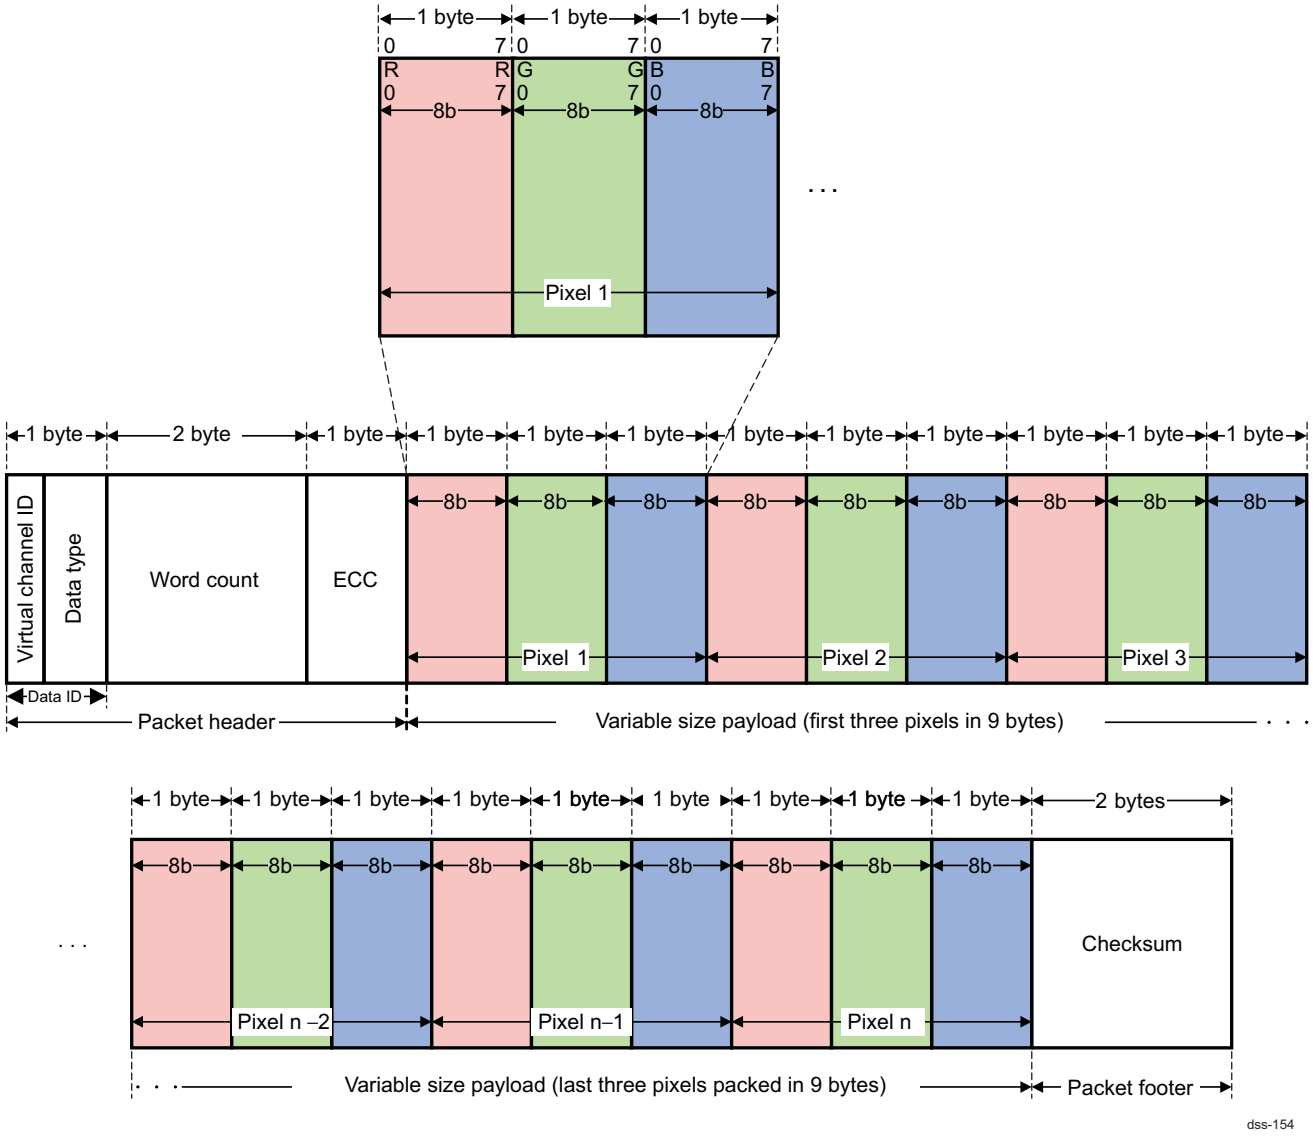
12.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in video mode are transmitted over the serial interface. For pixel formats in command mode. The DSI protocol engine can cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

12.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

Figure 12-55 shows the RGB888 format.

Figure 12-55. 24 Bits per Pixel RGB Color Format, Long Packet

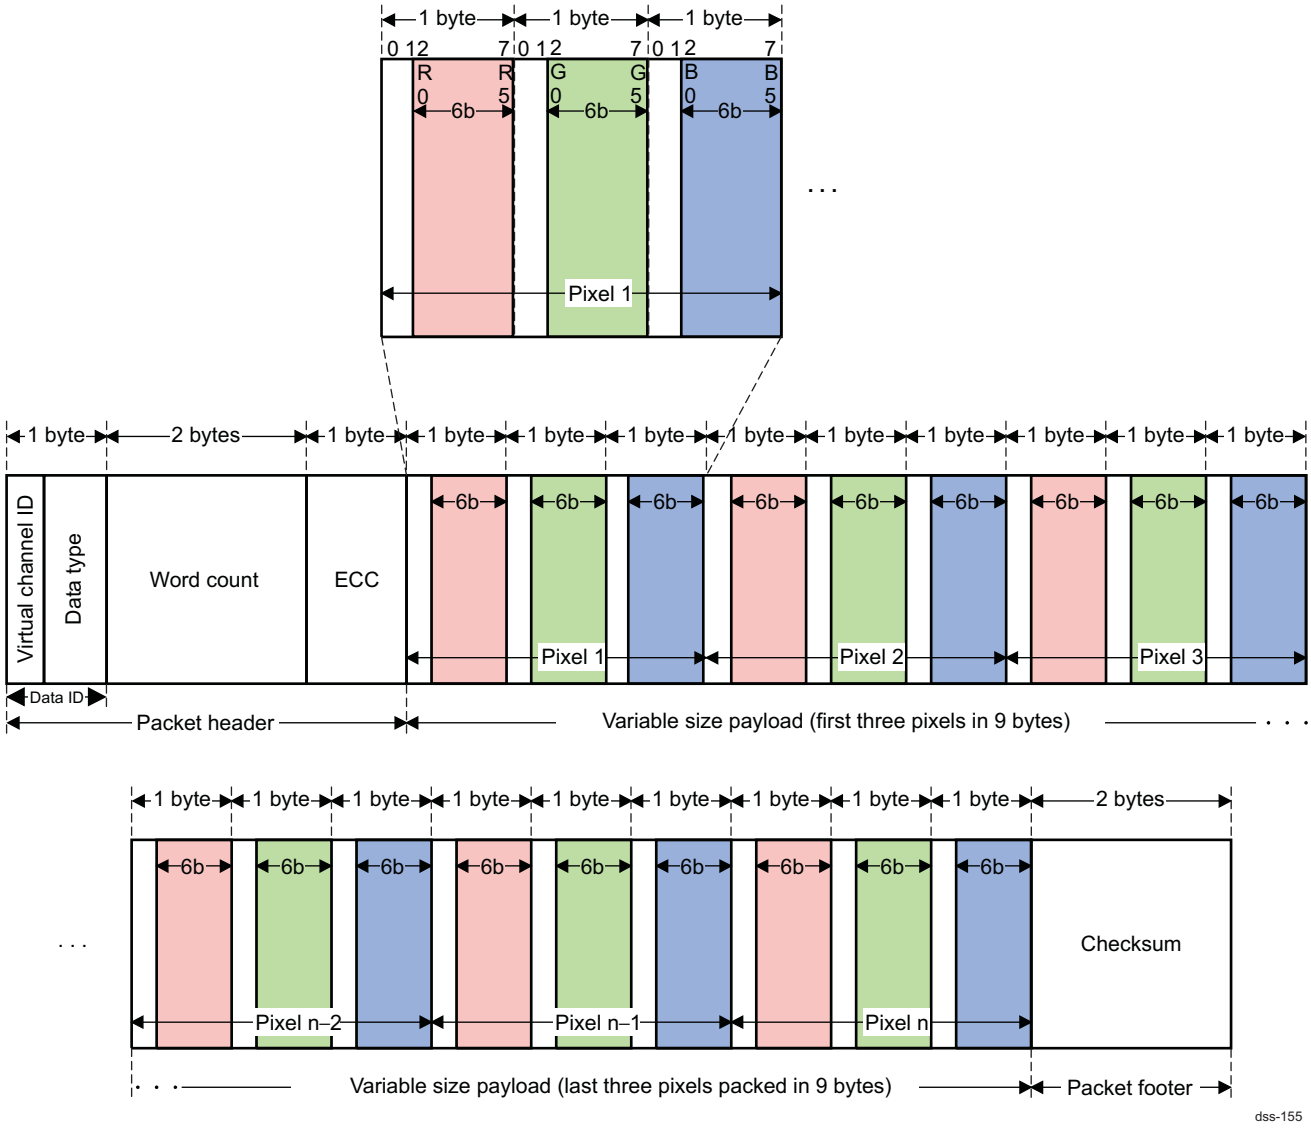


Packed pixel stream 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (8 bits), green (8 bits), and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

12.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 12-56 details the RGB666 format.

Figure 12-56. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

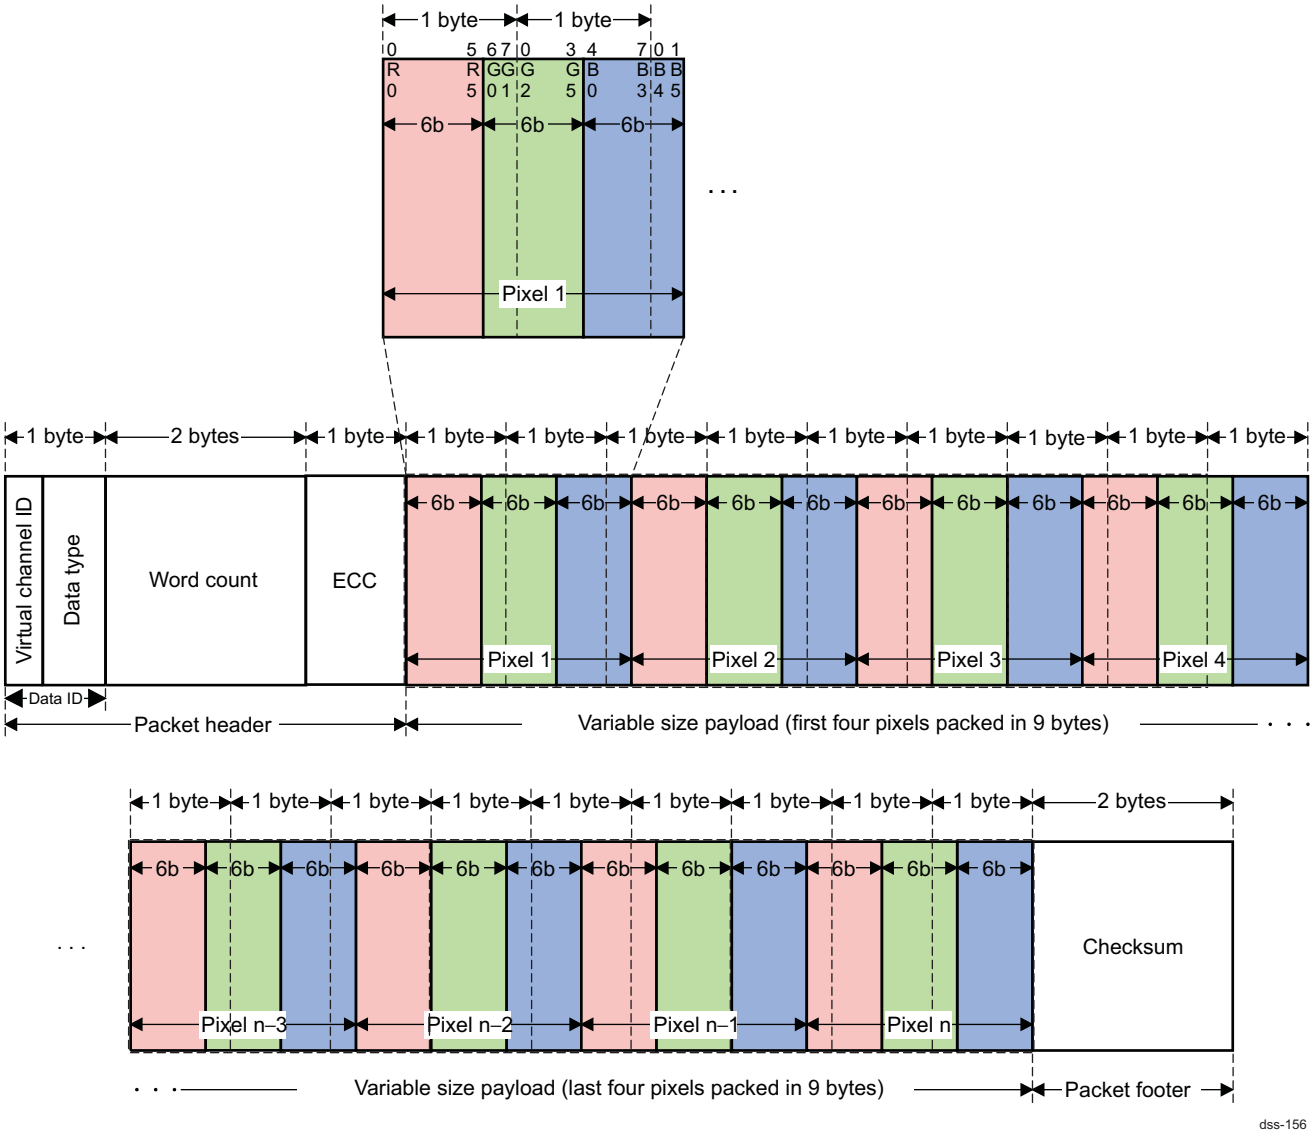


In the 18-bit pixel loosely-packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (6 bits), green (6 bits), and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

12.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 12-57 details the RGB666_PACKED format.

Figure 12-57. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet

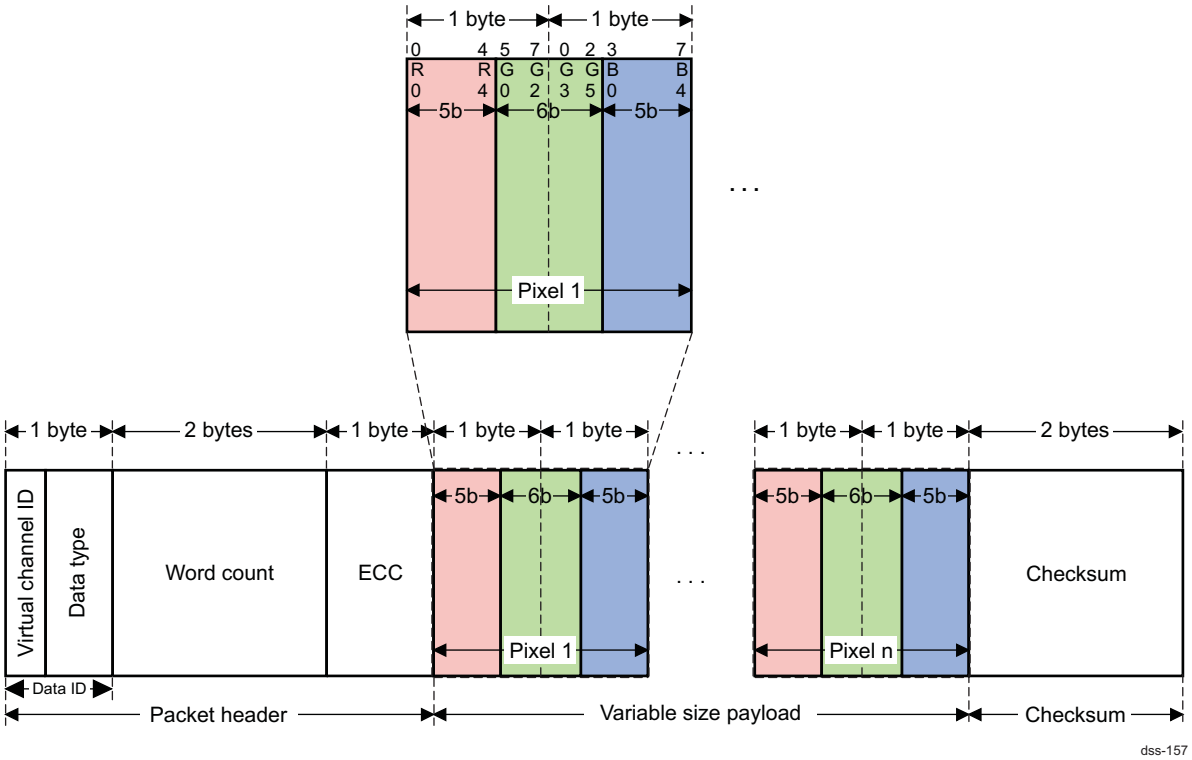


Packed pixel stream 18-bit format (packed) is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is red (6 bits), green (6 bits), and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

12.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 12-58 details the RGB565 format.

Figure 12-58. 16 Bits per Pixel RGB Color Format, Long Packet



Packed pixel stream 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the *green* component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

12.2.3 LCD Output With TI FlatLink3G Data Format for the SDI Module

The parallel-to-serial conversion of the 24-BPP pixel data depends on the number of data channels in use.

Figure 12-59 through Figure 12-61 summarize the pixel order for each data format of the TI FlatLink3G LCD panel.

The following apply to Figure 12-59 through Figure 12-61:

- VS: Vertical synchronization
- HS: Horizontal synchronizations
- DE: Data enable
- CP: Pixel parity. Parity of the whole 30-bit data is odd
- F1, F0: Reserved bits for the TI FlatLink3G protocol
- Clock channel: Differential clock signal between SDI_CLKP and SDI_CLKN

Figure 12-59. 24 Bits Per Pixel With One Data Channel

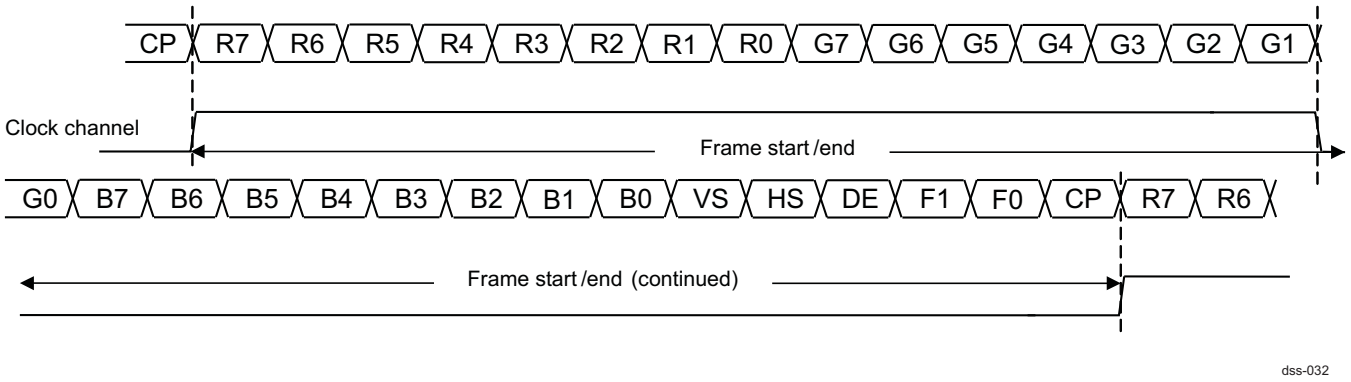


Figure 12-60. 24 Bits Per Pixel With Two Data Channels

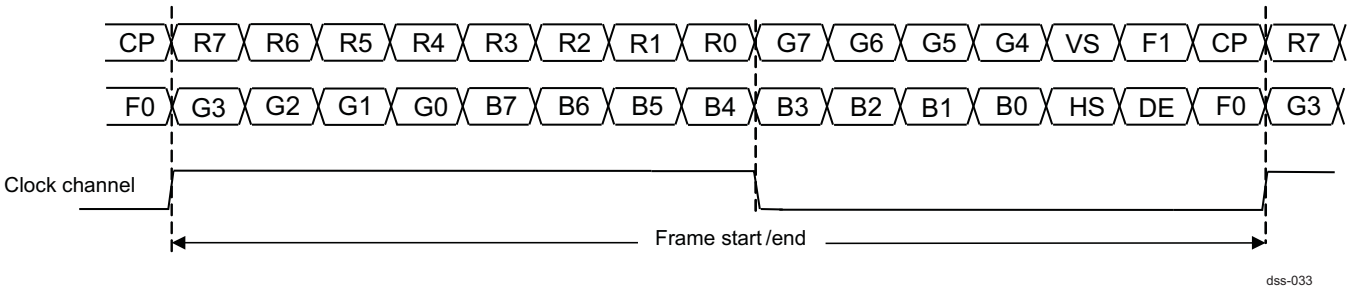

Figure 12-61. 24 Bits Per Pixel With Three Data Channels

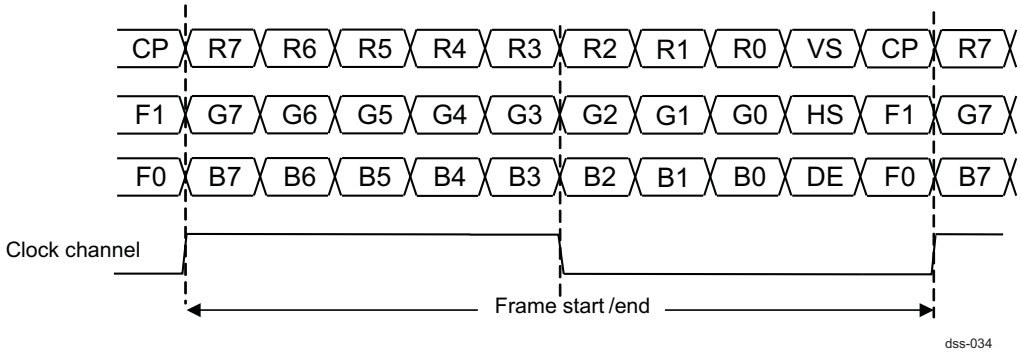


NOTE: The range of the data rates permitted is 120 Mbps per pair minimum (4 MHz pixel clock, one data pair) to 650 Mbps per pair maximum (65 MHz pixel clock, three data pairs).

12.2.4 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Dual 10-bit DAC with video amplifiers

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and a 2-channel video digital-to-analog converter (DAC) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

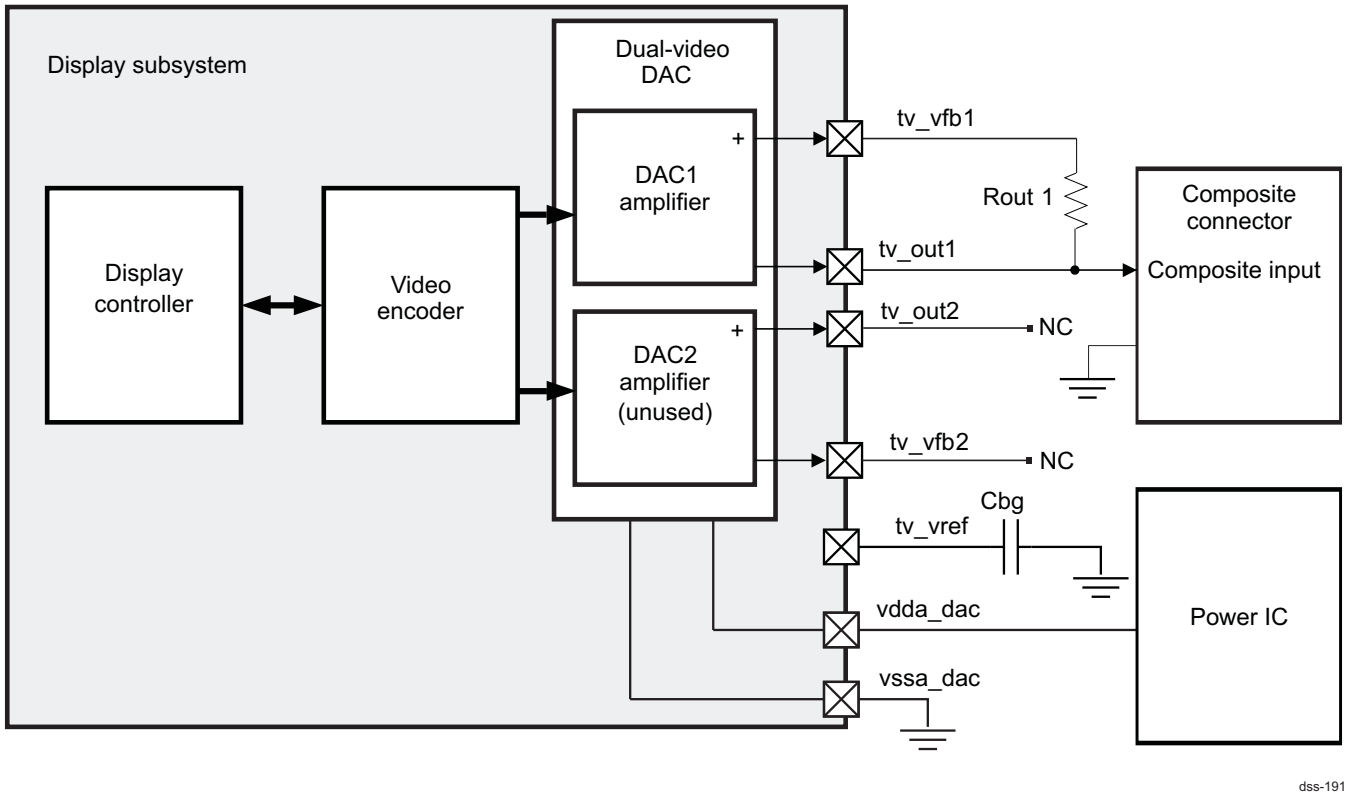
The video encoder also provides the synchronization signals to the display controller: VSYNC, active VIDeo (AVID), and field ID (FID).

Figure 12-62 is a block diagram of the TV display interface (s-video mode).

Figure 12-62. TV Display Interface (s-video mode)

Figure 12-63 is a block diagram of the TV display interface (composite mode).

Figure 12-63. TV Display Interface (Composite Mode)



NOTE: In composite video mode, the video DAC2 chroma output must be disabled by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 0.

Table 12-17 describes the interface signals to/from the TV set for TV display support.

Table 12-17. TV Display Interface Pins

Pin Name	Type[1]	Description
tv_out1	O	Analog luma or composite video output. An external resistor is connected between this node and the tv_vfb1 pin. The nominal value of Rout1 is 1650 Ω. Note that this is the output node that drives the load (75 Ω).
tv_out2	O	Analog chroma video output. An external resistor is connected between this node and the tv_vfb2 pin. The nominal value of Rout2 is 1650 Ω. This is the output node that drives the load (75 Ω).
tv_vfb1	O	Amplifier feedback node. An external resistor is connected between this node and tv_out1. The nominal value of Rout1 is 1650 Ω.

(1) O = Output, Power = Power pin

Table 12-17. TV Display Interface Pins (continued)

Pin Name	Type[1]	Description
tv_vfb2	O	Amplifier feedback node. An external resistor is connected between this node and tv_out2. The nominal value of Rout2 is 1650 Ω.
tv_vref	O	Reference output voltage from internal bandgap. A decoupling capacitor must be connected for optimum performance. tv_vref is generated internally to the OMAP device.
vdda_dac	Power	Analog supply voltage for the dual video DAC
vssa_dac	Power	Analog ground for the dual video DAC

CAUTION

- tv_out1 and tv_out2 are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. tv_vfb1 and tv_vfb2 pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins should be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the tv_vfb1/tv_vfb2 and TV OUT pins (tv_out1 and tv_out2). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the OMAP device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75 Ω starting from the closest possible place to the OMAP device pin output. For typical values of Rout1, Rout2, Cout, and Cbg, see the device data manual.
- If the TV output is not used, the analog pins tv_ref and vdda_dac must be grounded. The tv_out1, tv_out2, tv_vfb1, and tv_vfb2 pins can be grounded or left unconnected. To avoid current leakage, the following bits must be set to 0:
  - DSS.DSS_CONTROL[5] DAC_POWERDN_BGZ
  - DSS.VENC_OUTPUT_CONTROL[2:0]
  - PRCM.CM_FCLKEN_DSS[2] EN_TV
  - CONTROL.CONTROL_DEVCONF[18] TVOUTBYPASS

Texas Instruments provides a global solution with an OMAP device associated with a power IC. The power pin vdda_dac is software controlled by the power IC.

12.2.4.1 TV Output and Data Format

The output data to the TV set are the analog composite data from the DAC. The following video standards are supported:

- NTSC-J, M
- PAL-B, D, G, H, I
- PAL-M

12.2.4.2 Digital-to-Analog Converter

The DAC includes the following main features:

- 1.0-V-to-1.3-V digital power supply, 1.8-V analog power supply
- 10-bit resolution
- DNL within 1 LSB and INL within 1 LSB

- Sample rate of up to 60 megasamples per second (MSPS)
- Support composite/S-video dc or ac coupled output
- Full-scale voltage output: 0.88 Vpp with a 75-Ω load
- Internal TV detect feature
- Signal-to-noise ratio (SNR) is 54 dB (taking into account the ac coupling)
- Suitable for low-power wireless applications; total power: 10 mA (no load in dc-coupled mode)
- Power-down mode with less than 2.5-µA standby current
- Differential gain error and differential phase error: 1.5% and 1%, respectively

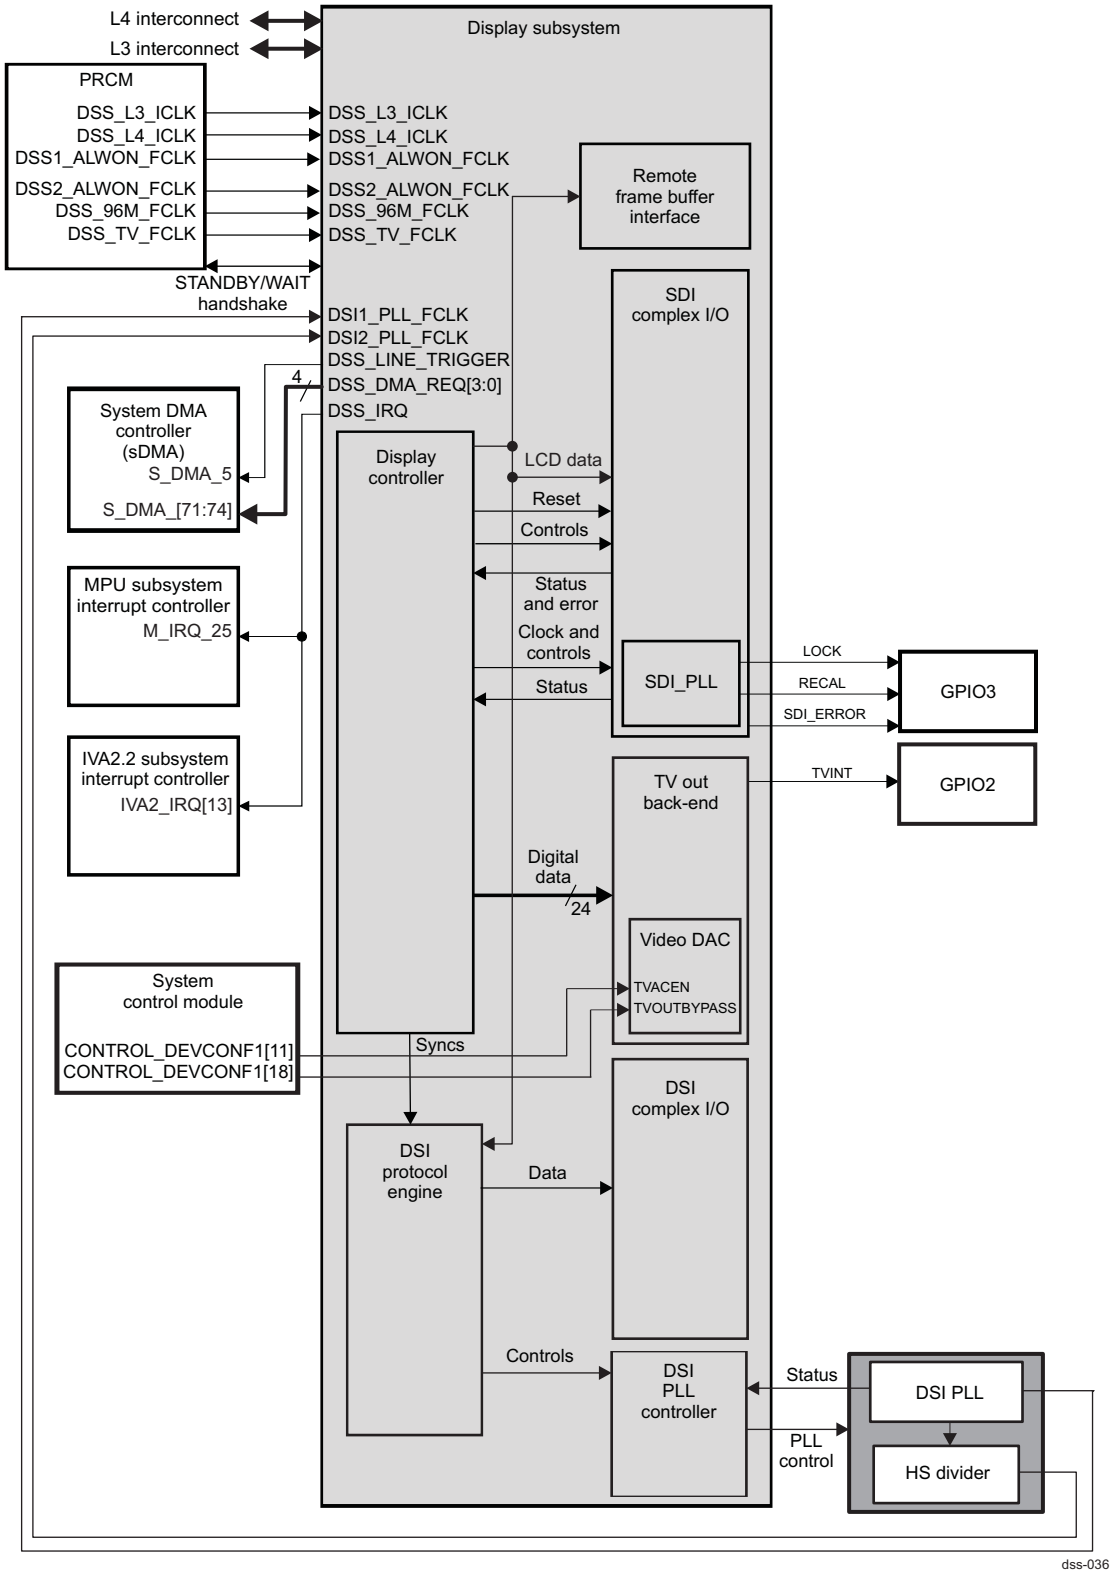
NOTE: To enhance the TV color display, it is highly recommended to set the DSS.DSS_CONTROL[4] DAC_DEMEN bit.

12.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

Figure 12-64 shows the integration of the display subsystem in the device.

Figure 12-64. Display Subsystem Integration



12.3.1 Clocking, Reset, and Power-Management Scheme

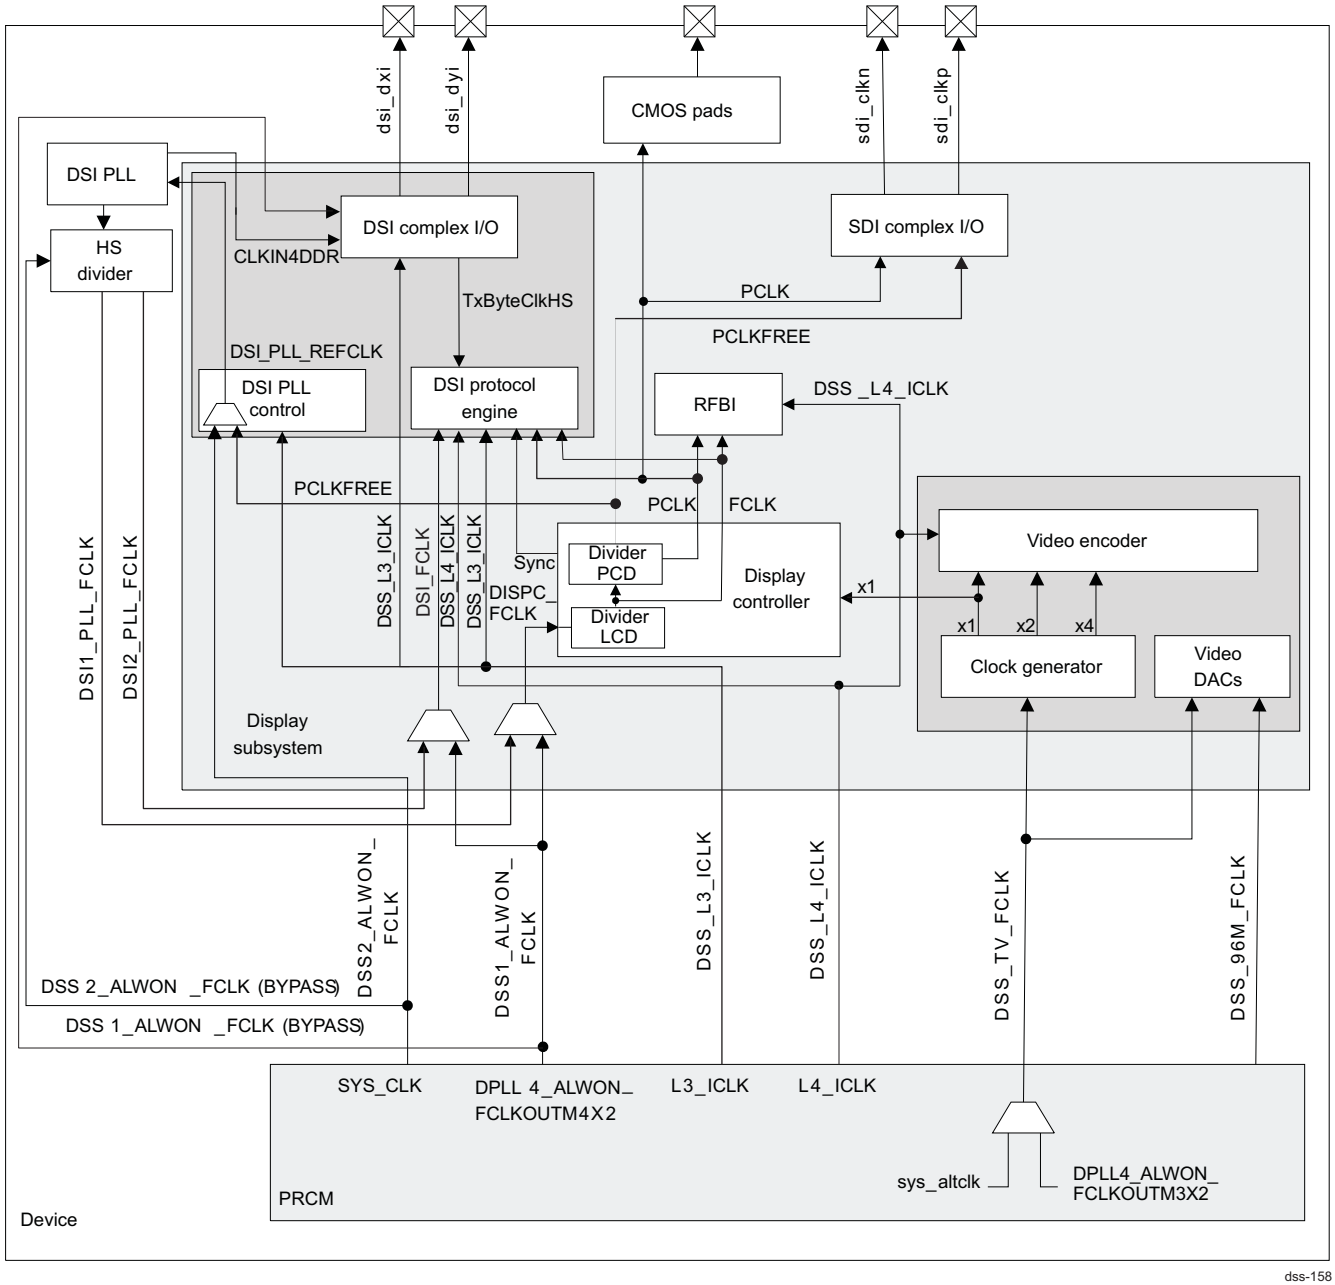
12.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides six clock signals to the display subsystem: The L3 interface clock (DSS_L3_ICLK) and the L4 interface clock (DSS_L4_ICLK), with frequencies equal to the L3 interconnect clock and the L4 interconnect clock, respectively; two configurable functional clocks (DSS1_ALWON_FCLK and DSS2_ALWON_FCLK); and two other functional clocks (DSS_TV_FCLK and DSS_96M_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1_PLL_FCLK and DSI2_PLL_FCLK.

Figure 12-65 details the clock tree for the display subsystem.

Figure 12-65. Display Subsystem Clock Tree



NOTE: A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal, named DISPC_UPDATE_SYNC, is used to inform the DSI protocol engine that it must be unsynchronized with the display controller.

Table 12-18 describes the different clocks with their possible frequency values.

Table 12-18. Display Subsystem Clocks

Clock Signal	Attribute	Module	Frequency	Comment
DSS_L3_ICLK	L3 interface clock	DSS	(See , *Power, Reset, and Clock Management*)	L3 interface clock from PRCM
DSS_L4_ICLK	L4 interface clock	DSS	(See , *Power, Reset, and Clock Management*)	L4 interface clock from PRCM
DSS1_ALWON_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage (OPP3), and up to 96 MHz at low voltage (OPP2)	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)
DSS2_ALWON_FCLK	Functional clock	DSI PLL	12/13/16.8/19.2/26/38.4 MHz	From PRCM: SYS_CLK
DSI1_PLL_FCLK	Functional clock	DISPC	Up to 173 MHz at nominal voltage (OPP3), and up to 96 MHz at low voltage (OPP2)	From DSI PLL and HS divider
DSI2_PLL_FCLK	Functional clock	DSI protocol engine	Up to 173 MHz at nominal voltage (OPP3), and up to 96 MHz at low voltage (OPP2)	From DSI PLL and HS divider
DSS_TV_FCLK	Functional clock	DSS, video mode DAC	54 MHz or	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or
			sys_alt_clk (up to 59 MHz)	External input clock (See , *PRCM*)
DSS_96M_FCLK	Functional clock	Video DAC	96 MHz	From PRCM: 96M_FCLK

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit to enable DSS1_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit to enable DSS2_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[2] EN_TV bit to enable DSS_TV_FCLK and DSS_96M_FCLK

To enable or disable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks, write (1: Enable, 0: Disable) to the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit.

NOTE: Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

  The DSS_L3_ICLK clock is only used by the display controller interface to fetch the pixel data. The DSS_L4_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

  NOTE: A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. The SDI module and all the display subsystem registers are configured through the display subsystem register.

- Display controller functional clocks

  The display controller can use either the DSS1_ALWON_FCLK or the DSI1_PLL_FCLK functional clock.

To select the DSS1_ALWON_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit; to select the DSI1_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit.

NOTE: The DSS1_ALWON_FCLK and DSI1_PLL_FCLK functional clocks must be active (the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC_CONTROL[5] GOLCD bit is set to 1.

Depending on the DPLL4 input clock frequency, the DSS1_ALWON_FCLK can be adjusted by setting the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

- DSI PLL functional clock (DSI_PLL_REFCLK)

  The DSI PLL controller module can use either the DSS2_ALWON_FCLK (from PRCM) or the PCLKFREE (from DISPC) functional clock. To select the DSS2_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit.

- DSI protocol engine functional clocks (DSI_FCLK)

  The DSI protocol engine can use either the DSS1_ALWON_FCLK (from PRCM) or the DSI2_PLL_FCLK (from DSI PLL) functional clock. To select the DSS1_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit; to select the DSI2_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit.

  NOTE: It is possible to switch between these two clocks, even when both of them are not active.

- There are five clock domains in the DSI module:
  - Byte clock domain:

    TxByteClkHS is generated from the bit clock and converted into a byte clock. The maximum frequency is 100 MHz (all OPPs). It is generated by the DSI complex I/O.
  - Functional clock domain

    The DSI_FCLK is the functional clock for the DSI protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 96 MHz (low voltage). It should always be equal to or higher than the byte (TxByteClkHS), L4 interconnect (DSS_L4_ICLK), and video port (VP_CLK) clocks. The software must configure the clocks correctly.
  - L4 interface clock domain

    The DSS_L4_ICLK is used in the L4 interconnect port domain. The maximum frequency is 166 MHz at nominal voltage and 83 MHz at low voltage.
  - The video port domain

    The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.
  - Serial Configuration Port (SCP) and Power Control (PWR) interfaces

    The DSS_L4_ICLK is the functional clock.

NOTE:

- There is no clock domain for RxClkEsc because it is used as an enable and not as a clock by the DSI protocol engine module
- The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR because both of them use DSS_L4_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface should be balanced.
- If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.

- Video encoder functional clock

  The DSS_TV_FCLK is divided into three balanced clocks, depending on the clock mode selected (see Table 12-19).

Table 12-19. Possible Digital Clock Division for the Video Encoder

Clock Output	Clock Mode	
	Clock mode 0	Clock mode 1
Video encoder clock 4x	DSS_TV_FCLK	DSS_TV_FCLK or 0 (gated)
Video encoder clock 2x	DSS_TV_FCLK/2	DSS_TV_FCLK
Video encoder clock 1x	DSS_TV_FCLK/4	DSS_TV_FCLK/2

The clock mode is defined by the the DSS_CONTROL[2] VENC_CLOCK_MODE bit:

- In the case of clock mode 1, the DSS_CONTROL[3] VENC_CLOCK_4X_ENABLE bit is used to control clock gating.
- In the case of clock mode 0, the VENC_CLOCK_4X_ENABLE bit must be set to 0x1 by software.

NOTE: After reset, clock mode 0 is selected by default and the DSS_TV_CLK clock is disabled. The DSS_TV_CLK / 4 in mode 0, or the DSS_TV_CLK / 2 in mode 1, is used in the DISPC module to send data to the video encoder.

NOTE: Clock mode 1 can be used for power-saving purposes, or if a 27-MHz external clock is provided to the video encoder.

DSS_TV_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV bit field. If the DPLL4 is selected, the DSS_TV_FCLK is provided by the DPLL4_ALWON_FCLKOUTM3X2 clock.

NOTE: If the DSS_TV_FCLK is not provided by DPLL4 but rather by the sys_alt_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel, and a 59-MHz clock is needed for PAL square pixel.

- Dual video DAC clocks

  The dual video DAC uses two distinct clocks: The DSS_TV_FCLK and the DSS_96M_FCLK. The video data are latched on the positive edge of the DSS_TV_FCLK clock. On the other hand, the video DAC uses the DSS_96M_FCLK fixed-frequency clock internally as the clock input for the switch capacitor resistor.

- SDI functional clock

  The display controller provides the functional clocks PCLK (pixel clock) and PCLKFREE (free-running pixel clock) of the SDI module, which is derived from the display controller functional clock. The SDI module functional clock drives the phase-locked loop SDI_PLL that multiplies and divides the PCLK frequency by two programmable factors for the serial connection.

NOTE: When using the SDI, configure the PCLK in the free-running mode by setting the DSS.DISPC_CONTROL[27] PCLKFREEENABLE bit to 1.

12.3.1.2 Resets

12.3.1.2.1 Hardware Reset

The display subsystem receives its reset signal DSS_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

12.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write to the DSS.DSS_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

NOTE: The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write to these registers.

CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

12.3.1.3 Power Domain

The display subsystem modules are on the display subsystem (DSS) power domain and on the VDD2 voltage domain, except for the dual video DACs, which are on the analog vdda_dac voltage domain.

12.3.1.4 Power Management

12.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured in one of the following clock activity modes:

- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched

off and the functional clocks are maintained during the wake-up period.

- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM_CLKSTST_DSS[0] CLKACTIVITY_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

NOTE: The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS bit:

- When the AUTO_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
- When the AUTO_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.

12.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

NOTE: All the bits listed above (except for the FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

12.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for RFBI.
- Smart-idle mode:
  - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).
    - The display controller does not use anymore the L4 interface clock (DSS_L4_ICLK).
  - DSI protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
    - All asserted output interrupts are acknowledged (no interrupt pending).

- The DSI protocol engine does not use the L4 interface clock (DSS_L4_ICLK) anymore.
- The SCP and PWR transactions are complete.
- No data remains in the TX FIFO (data waiting in the FIFO to be sent to the peripheral).

To configure the display subsystem in smart-idle mode, set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS_L4_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

12.3.1.4.4 SDI Idle Mode

To save power consumption, the PLL (SDI_PLL) of the SDI module can be configured in one of the operation modes shown in Table 12-20 when not locked.

Table 12-20. SDI PLL Operation Modes

SDI_PLL Operation Mode	Stop mode Low power[1]	Stop mode Low power[1]	Idle bypass Low power	Idle bypass Fast relock	Limp
	Output clock stopped Lowest power standby	Output clock stopped Fastest start-up time	Output clock at PCLK rate Lowest power standby	Output clock at PCLK rate Fastest start-up time	Output at full speed
DSS.DSS_PLL_CONTROL[0] SDI_PLL_IDLE	0	0	1	1	1 or PCLK stops
DSS.DSS_PLL_CONTROL[20] SDI_PLL_LOWCURRSTBY	1	0	1	0	X
DSS.DSS_PLL_CONTROL[17] SDI_PLL_STOPMODE	1	1	1	1	0

(1) Recommended

12.3.1.4.5 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

  If software users set the DSS.DISPC_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

  Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

12.3.1.4.6 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC_SYSCONFIG[13:12] MIDLEMODE bit field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
  - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
  - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM_IDLEST_DSS[0] ST_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

12.3.1.4.6.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:
  - Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
  - Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

12.3.1.4.6.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM_SLEEPDEP_DSS[1] EN_MPU bit:

- When the EN_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM_SLEEPDEP_DSS[2] EN_IVA2 bit:

- When the EN_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

12.3.1.4.6.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
  - DSS1_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit is set to 0 and the display subsystem is in standby mode.
  - DSS2_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit is set to 0 and the display subsystem is in standby mode.
  - DSS_L3_ICLK and DSS_L4_ICLK are controlled together. They are shut down when the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit is set to 0 and the display subsystem is in standby mode.

CAUTION

Do not stop DSS1_ALWON_FCLK, or DSS2_ALWON_FCLK clock (if used) if the display subsystem is not disabled.

CAUTION

DSS_TV_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS_TV_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see , *Power, Reset, and Clock Management*.

- Hardware- or software-supervised mode

  The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field:
  - When the CLKTRCTRL_DSS bit field is set to 0x0 (reset value), the automatic transition is disabled
  - When the CLKTRCTRL_DSS bit field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
  - When the CLKTRCTRL_DSS bit field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
  - When the CLKTRCTRL_DSS bit field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

12.3.1.4.6.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
  - Set the display subsystem in smart standby mode.
  - Manually enable DSS_L3_ICLK and DSS_L4_ICLK.
  - Manually enable DSS1_ALWON_FCLK or DSS2_ALWON_FCLK.
  - Manually enable DSS_TV_FCLK if the video encoder is used.
  - Set the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
  - Disable the display subsystem.
  - Manually disable DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, DSS_TV_FCLK, DSS_L3_ICLK, and DSS_L4_ICLK.

For more details on low-power programming settings, see Section 12.6.2.

12.3.2 Hardware Requests

12.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. Figure 12-66 details the DMA tree.

Figure 12-66. Display Subsystem DMA Tree

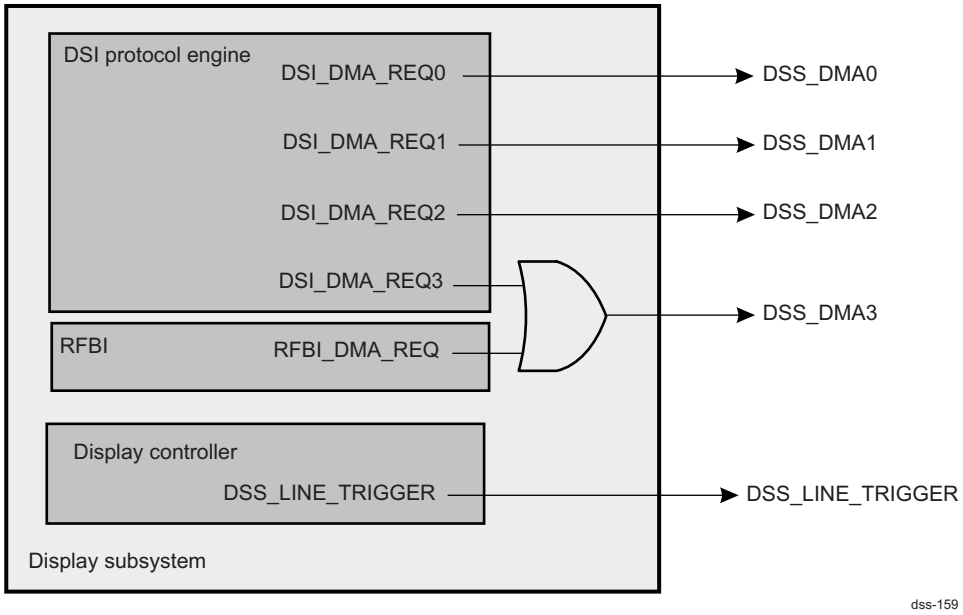


Table 12-21. DSS DMA Requests Description

DMA Request Name	DSS Module	Mapping	Description
DSS_LINE_TRIGGER	DISPC	S_DMA_5	See Section 12.3.2.1.1
DSI_DMA_REQ0	DSI protocol engine	S_DMA_71	See Section 12.3.2.1.2
DSI_DMA_REQ1	DSI protocol engine	S_DMA_72	See Section 12.3.2.1.2
DSI_DMA_REQ2	DSI protocol engine	S_DMA_73	See Section 12.3.2.1.2
DSI_DMA_REQ3	DSI protocol engine	S_DMA_74	See Section 12.3.2.1.2
RFBI_DMA_REQ	RFBI	S_DMA_74	See Section 12.3.2.1.3

NOTE: The DMA requests from the RFBI module (RFBI_DMA_REQ) and the DSI protocol engine (DSI_DMA_REQ3) are merged on line DSS_DMA3. The software must only use DSS_DMA3 on one module at a time (RFBI or DSI protocol engine).

12.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS_LINE_TRIGGER) is connected to the sDMA by the sDMA controller (S_DMA_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in Section 12.3.2.2, *Interrupt Requests*. This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS_LINE_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC_LINE_NUMBER[10:0] LINENUMBER bit field.

12.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported.

12.3.2.1.3 RFBI DMA Request

The RFBI_DMA_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

12.3.2.2 Interrupt Requests

The DSI protocol engine, the DSI complex I/O (DSI_IRQ), and the display controller (DISPC_IRQ) generate one interrupt request each. The DSI_IRQ and DISPC_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M_IRQ_25 input line)
- IVA interrupt handler (IVA2_IRQ[13] input line)

Figure 12-67 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

Figure 12-67. DSI Interrupt Tree

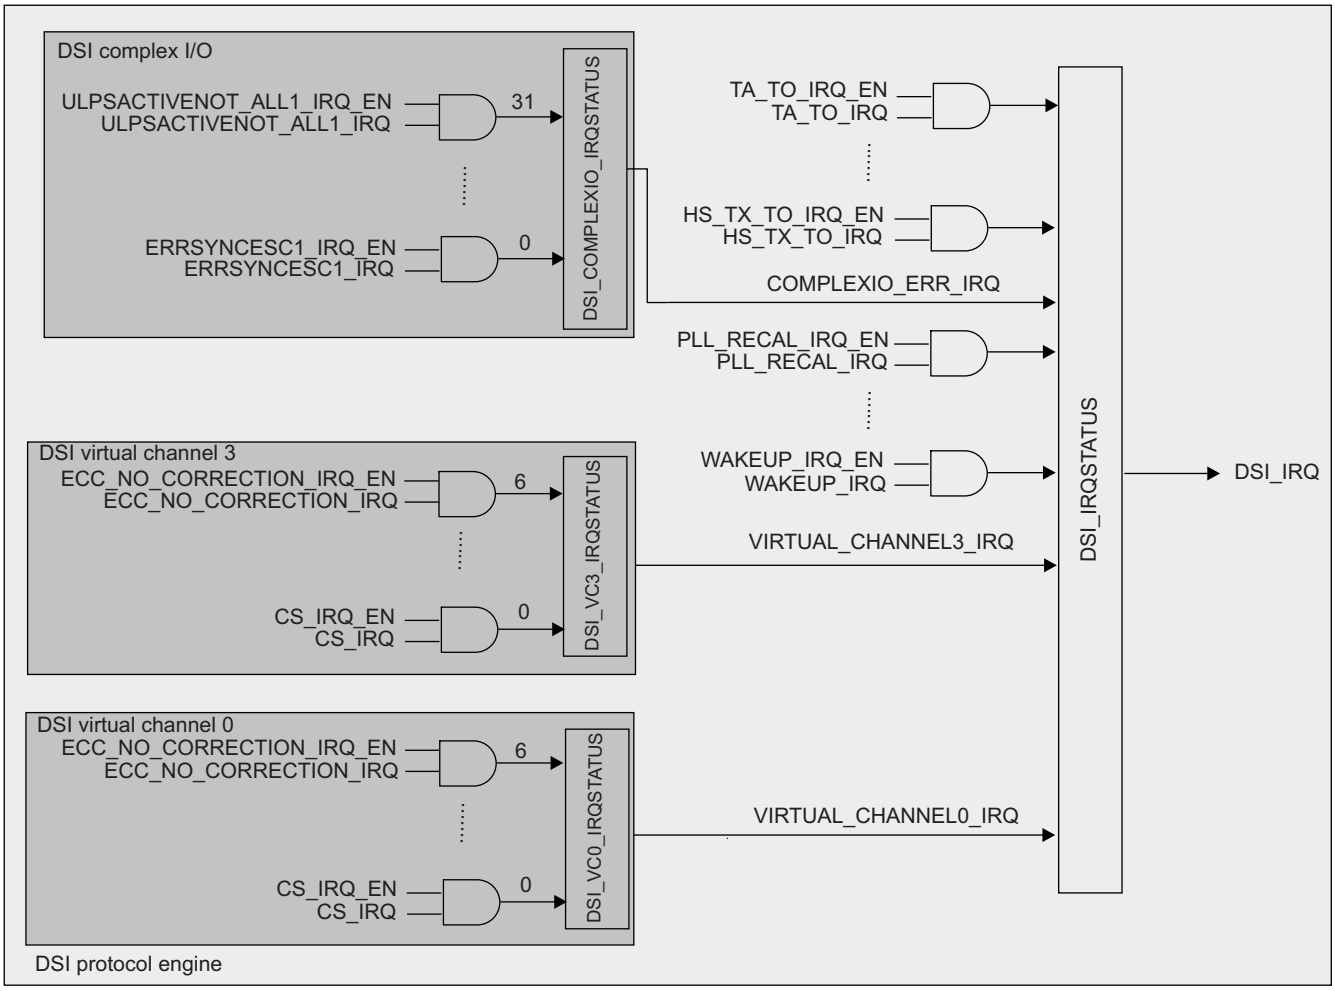

Figure 12-68 details the interrupt tree for the DISPC and the display subsystem.

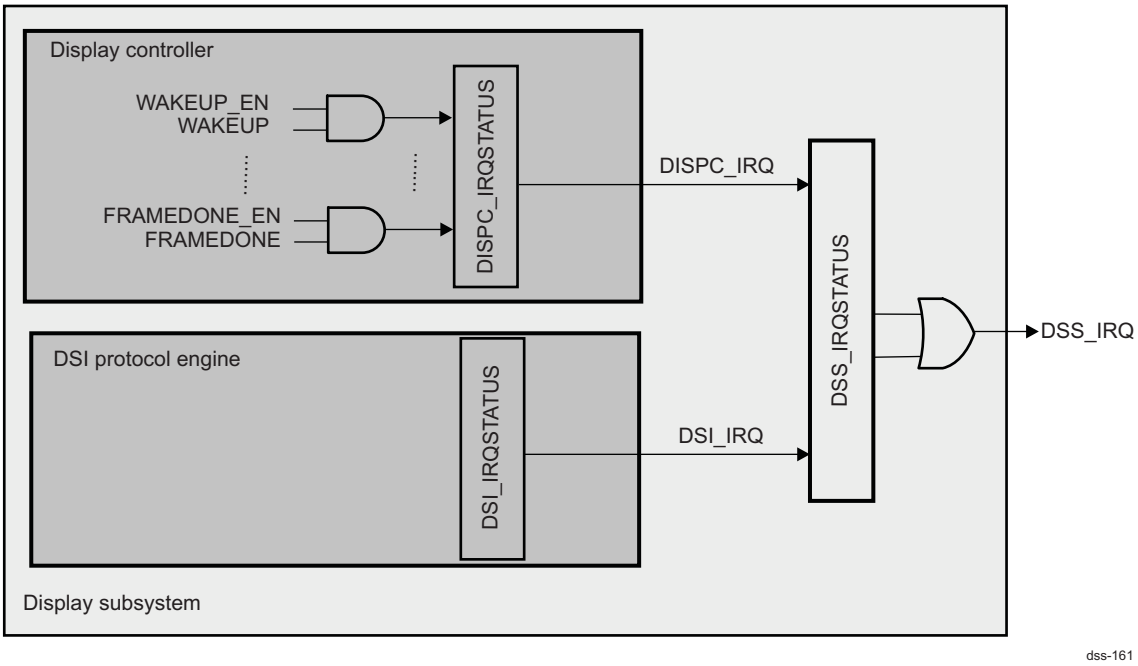
Figure 12-68. DISPC and DSS Interrupts Tree



12.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC_IRQSTATUS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See Section 12.7, *Display Subsystem Register Manual*, for more information on checking and clearing interrupt events.

Table 12-22 lists the display subsystem interrupt events.

Table 12-22. Display Subsystem Interrupts

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN[(1)]	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD[(1)]	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.

(1) EVYNC interrupts (EVSYNC_EVEN and EVSYNC_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

Table 12-22. Display Subsystem Interrupts (continued)

Interrupt Name	Description
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTDIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

NOTE: To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits.

   Check the interrupts.

   LCD: Verify that a FRAMEDONE interrupt occurs.

   TV : Verify that EVSYNC_EVEN or EVSYNC_ODD interrupts occur.
2. Set the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

NOTE: The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), should not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit.

12.3.2.2.2 DSI Interrupt Request

The DSI protocol engine requires a single interrupt line, DSI_IRQ. The DSS.DSI_IRQSTATUS register indicates the general interrupt events. Refer to Table 12-23. Each VC and complex I/O has a dedicated interrupt register: DSS.DSI_VCn_IRQSTATUS and DSS.DSI_COMPLEXIO_IRQSTATUS respectively. Refer to Table 12-24 and Table 12-25.

Table 12-23 indicates the DSI global interrupt events.

Table 12-23. DSI Global Interrupts

Interrupt Name	Description
RESYNCHRONIZATION_IRQ	Resynchronization in video mode
TA_TO_IRQ	Turn-around timer expired
LDO_POWER_GOOD_IRQ	Signal LDOPWRGOOD from the DSI_PHY changes its state for the supply VDDALDODSIPLL from up to down or down to up.
SYNC_LOST_IRQ	Synchronization with video mode port is lost (video mode only)
ACK_TRIGGER_IRQ	Acknowledge trigger is received
TE_TRIGGER_IRQ	Tearing effect trigger is received
WAKEUP_IRQ	Occurs when the SWakeUp signal is asserted
HS_TX_TO_IRQ	High speed TX Time-out Interrupt
LP_RX_TO_IRQ	Low speed RX Time-out Interrupt

Table 12-23. DSI Global Interrupts (continued)

Interrupt Name	Description
COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: The interrupt is triggered when any error is received from the complex I/O (events are defined in DSI_COMPLEXIO_IRQSTATUS).
PLL_RECAL_IRQ	PLL recal event (assertion of DSIRecal signal from the DSI PLL Control module)
PLL_UNLOCK_IRQ	PLL unlock event (deassertion of DSILock signal from the DSI PLL Control module)
PLL_LOCK_IRQ	PLL lock event (assertion of DSILock signal from the DSI PLL Control module)
VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: The interrupt is triggered when an error is received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQENABLE).
VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: The interrupt is triggered when an error is received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQENABLE).
VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: The interrupt is triggered when an error is received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQENABLE).
VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: The interrupt is triggered when an error is received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQENABLE).

Table 12-24 indicates the DSI complex I/O interrupt events.

Table 12-24. DSI Complex I/O Interrupts

Interrupt Name	Description
ULPSActiveNot_ALL0_IRQ	All signals ULPSActiveNOT are 0
ULPSActiveNot_ALL1_IRQ	All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high
STATEULPS3_IRQ	Lane #3 in ultralow-power state
STATEULPS2_IRQ	Lane #2 in ultralow-power state
STATEULPS1_IRQ	Lane #1 in ultralow-power state
ERRCONTROL3_IRQ	Control error for lane #3
ERRCONTROL2_IRQ	Control error for lane #2
ERRCONTROL1_IRQ	Control error for lane #1
ERRESC3_IRQ	Escape entry error for lane #3(edge trigger interrupt)
ERRESC2_IRQ	Escape entry error for lane #2 (edge trigger interrupt)
ERRESC1_IRQ	Escape entry error for lane #1 (edge trigger interrupt)
ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for lane #1
ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for lane #1
ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for lane #2
ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for lane #2
ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for lane #3
ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for lane #3
ERRSYNCESC3_IRQ	Low power Data transmission synchronization error for lane #3
ERRSYNCESC2_IRQ	Low power Data transmission synchronization error for lane #2
ERRSYNCESC1_IRQ	Low power Data transmission synchronization error for lane #1

NOTE: The error contention signals for DX and DY signals of each lane are ORed together.

Table 12-25 indicates the DSI VCs interrupt events

Table 12-25. DSI Virtual Channel Interrupts

Interrupt Name	Description
ECC_CORRECTION_IRQ	Virtual channel - ECC has been used to correct a 1-bit error (short and long packet only). Indicates whether a 1-bit error correction occurred using the ECC.
PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used
CS_IRQ	Virtual channel - Check-Sum of the payload mismatch detection
FIFO_RX_OVF_IRQ	RX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the DSI link has overflowed
FIFO_TX_OVF_IRQ	TX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the L4 interconnect slave port has overflowed
BTA_IRQ	Bus turnaround is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral is used to determine which VC is used to flag the interrupt)
ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error
FIFO_TX_UDF_IRQ	TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L4 interconnect port has under-flowed in the middle of a packet transfer

12.4 Display Subsystem Functional Description

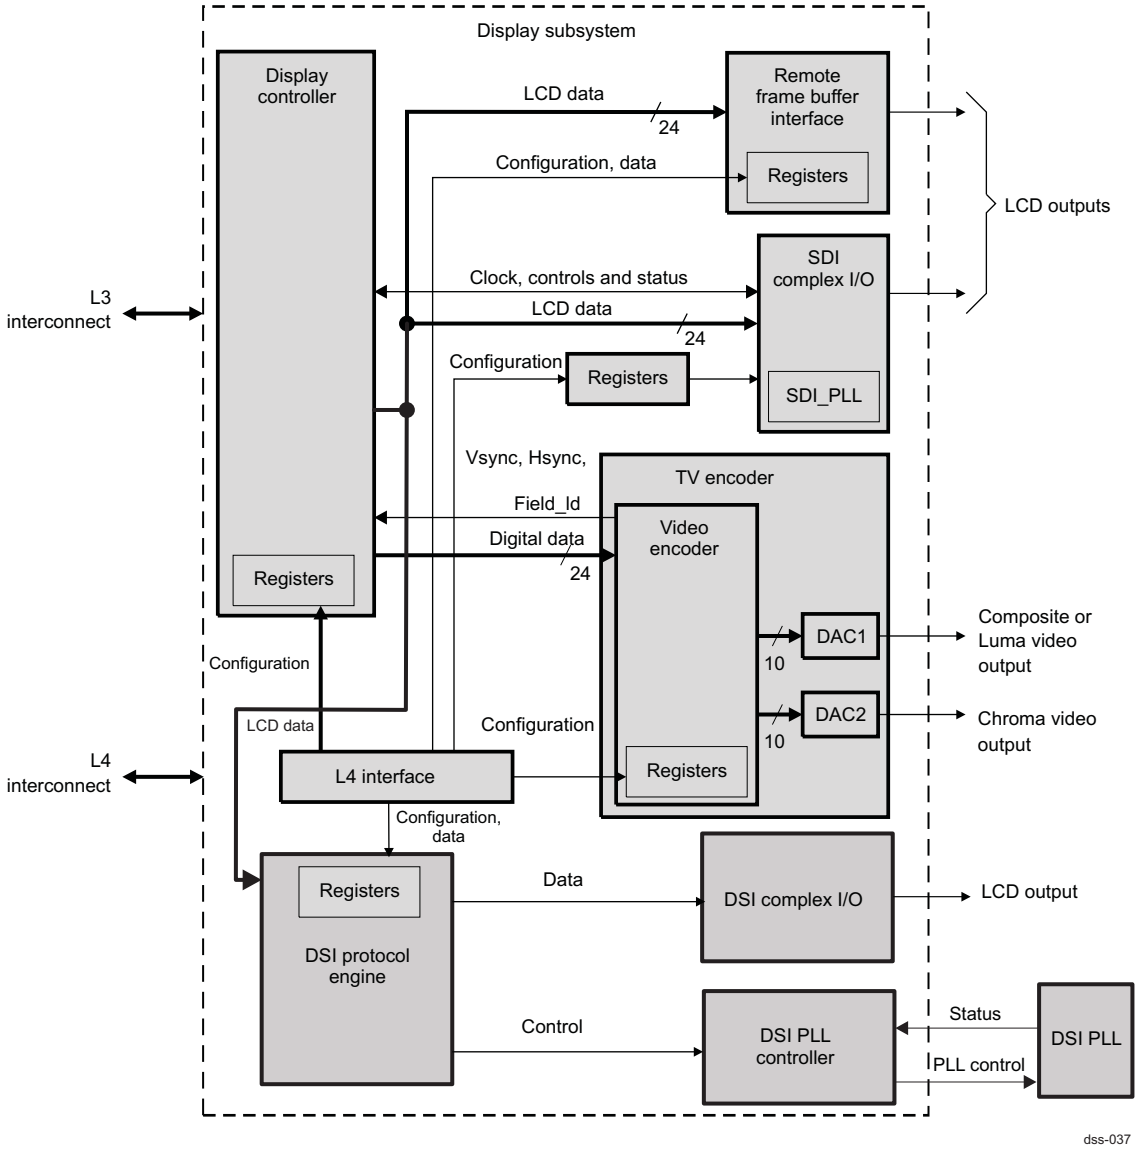
This section describes the functionalities of the LCD and TV display supports by describing the following modules: Display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI, SDI, and video encoder.

The functionalities of the display controller are common to both LCD and TV data paths; the RFBI and SDI functionalities are LCD-specific; and the video encoder functionalities are specific to the TV set.

12.4.1 Block Diagram

Figure 12-69 is a schematic of the display subsystem.

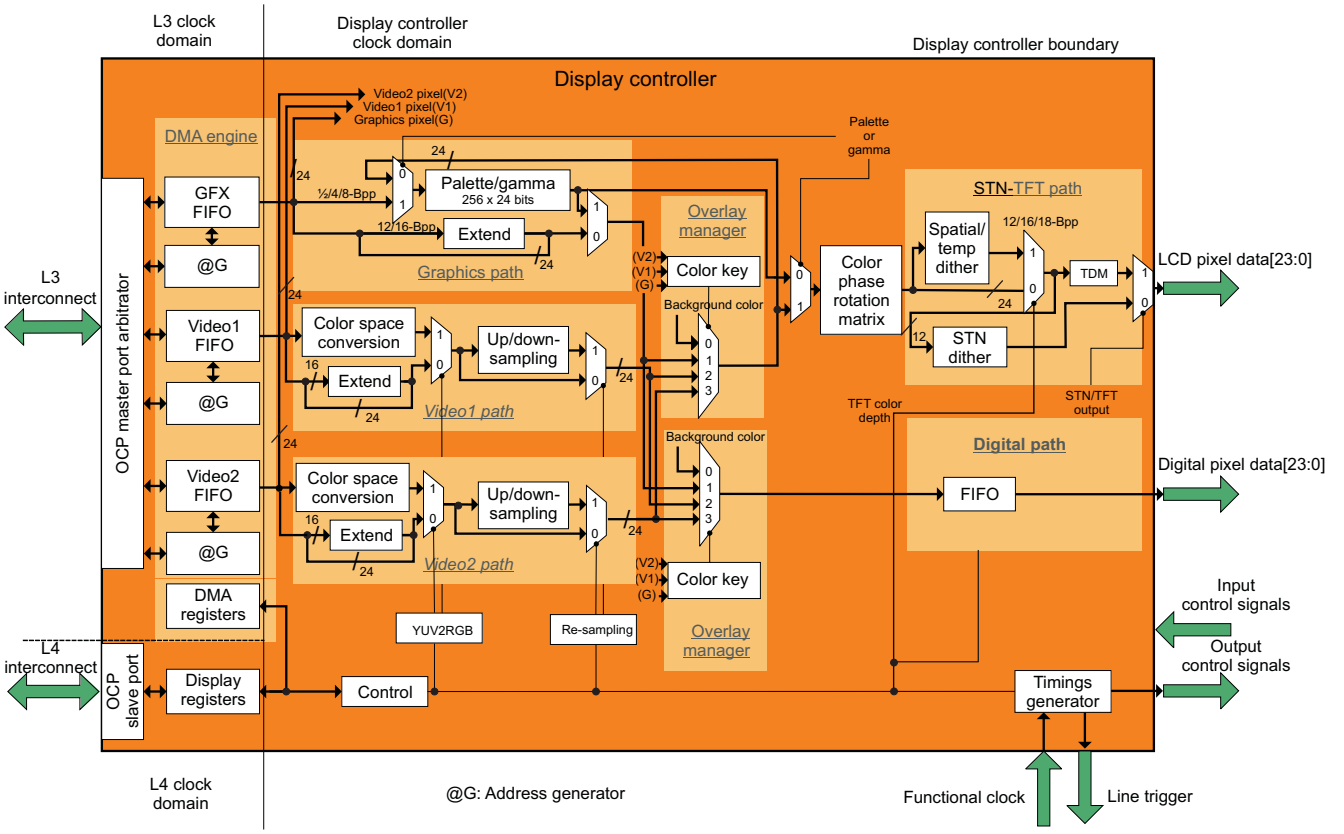
Figure 12-69. Display Subsystem Full Schematic



12.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 12-70).

Figure 12-70. Display Controller Architecture Overview



Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

12.4.2.1 Display Modes

12.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

12.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

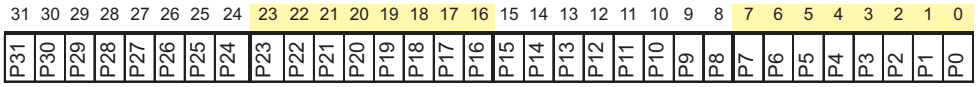
12.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

12.4.2.2.1 Graphics Memory Format

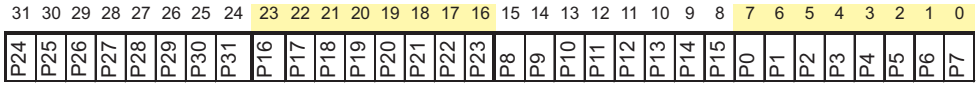
The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)



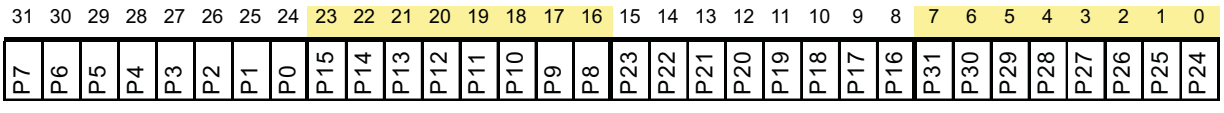
dss-T039

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)



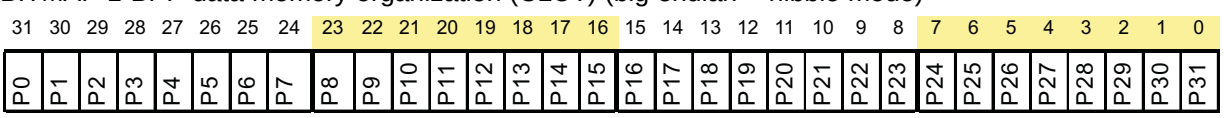
dss-T040

- BITMAP 1-BPP data memory organization (CLUT) (big endian)



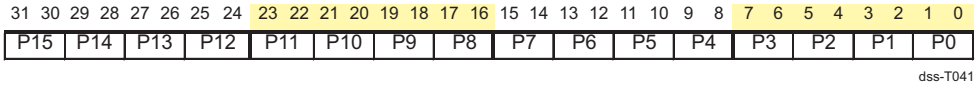
dss-T060

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

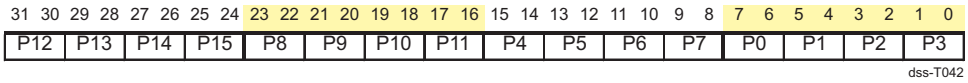


dss-T061

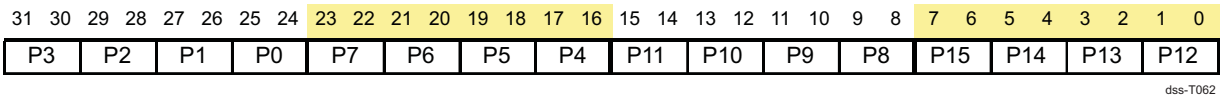
- BITMAP 2-BPP data memory organization (CLUT) (little endian)



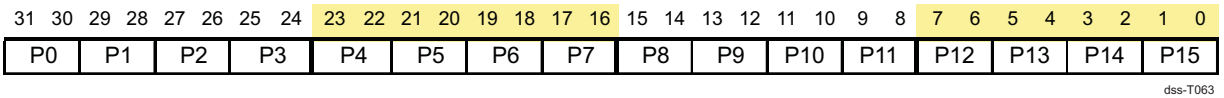
- BITMAP 2-BPP data memory organization (CLUT) (little endian + nibble mode)



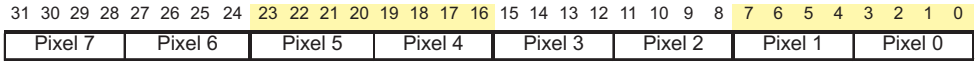
- BITMAP 2-BPP data memory organization (CLUT) (big endian)



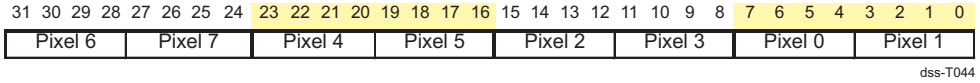
- BITMAP 2-BPP data memory organization (CLUT) (big endian + nibble mode)



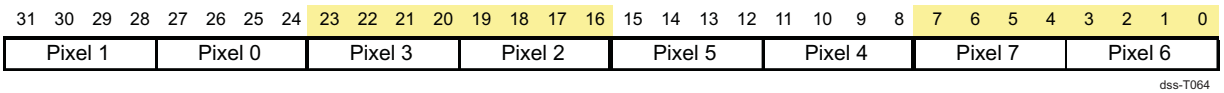
- BITMAP 4-BPP data memory organization (CLUT) (little endian)



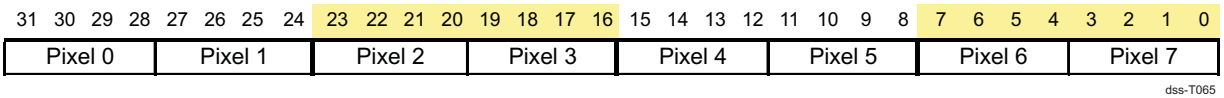
- BITMAP 4-BPP data memory organization (CLUT) (little endian + nibble mode)



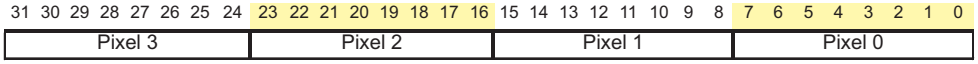
- BITMAP 4-BPP data memory organization (CLUT) (big endian)



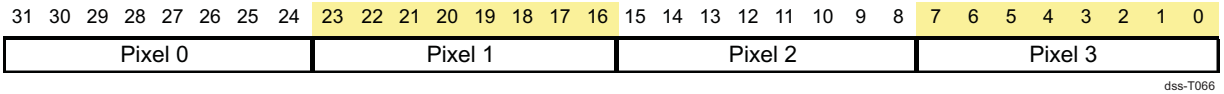
- BITMAP 4-BPP data memory organization (CLUT) (big endian + nibble mode)



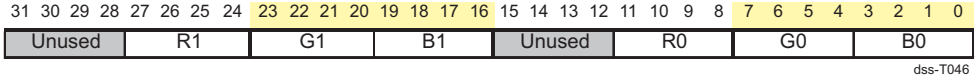
- BITMAP 8-BPP data memory organization (CLUT) (little endian)



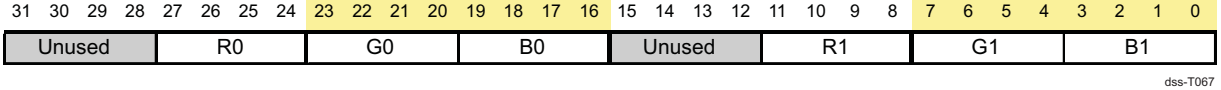
- BITMAP 8-BPP data memory organization (CLUT) (big endian)



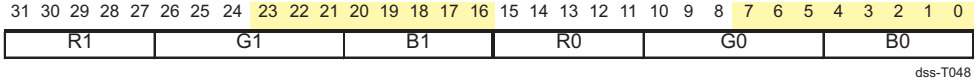
- RGB 12-BPP data memory organization (little endian)



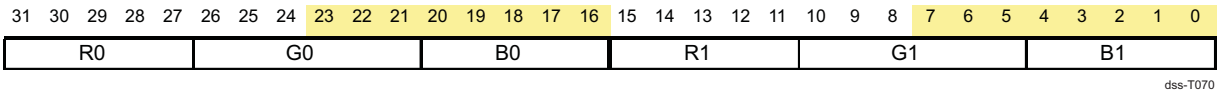
- RGB 12-BPP data memory organization (big endian)



- RGB 16-BPP data memory organization (little endian)

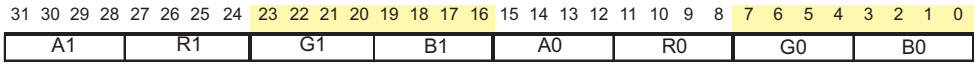


- RGB 16-BPP data memory organization (big endian)



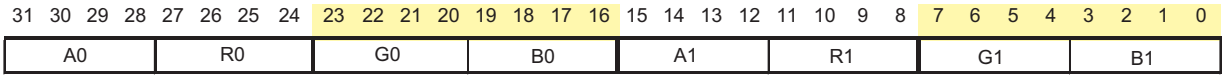
dss-T070

- ARGB 16-BPP data memory organization (little endian)



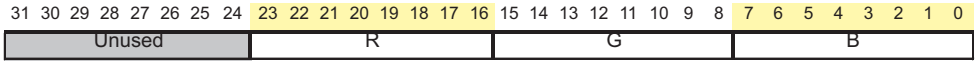
dss-T049

- ARGB 16-BPP data memory organization (big endian)



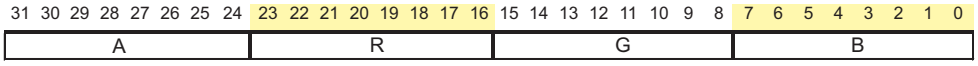
dss-T069

- RGB 24-BPP data memory organization (little or big endian)



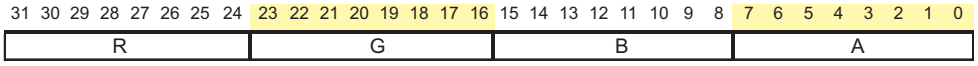
dss-T050

- ARGB 32-BPP data memory organization (little or big endian)



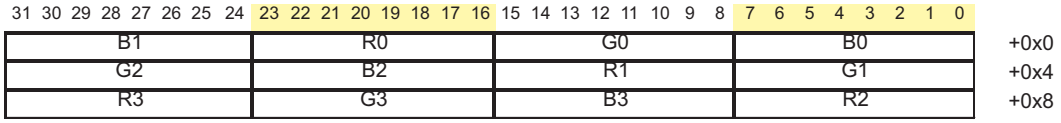
dss-T051

- RGBA 32-BPP data memory organization (little or big endian)



dss-T052

- RGB 24-BPP packet data memory organization (little or big endian)



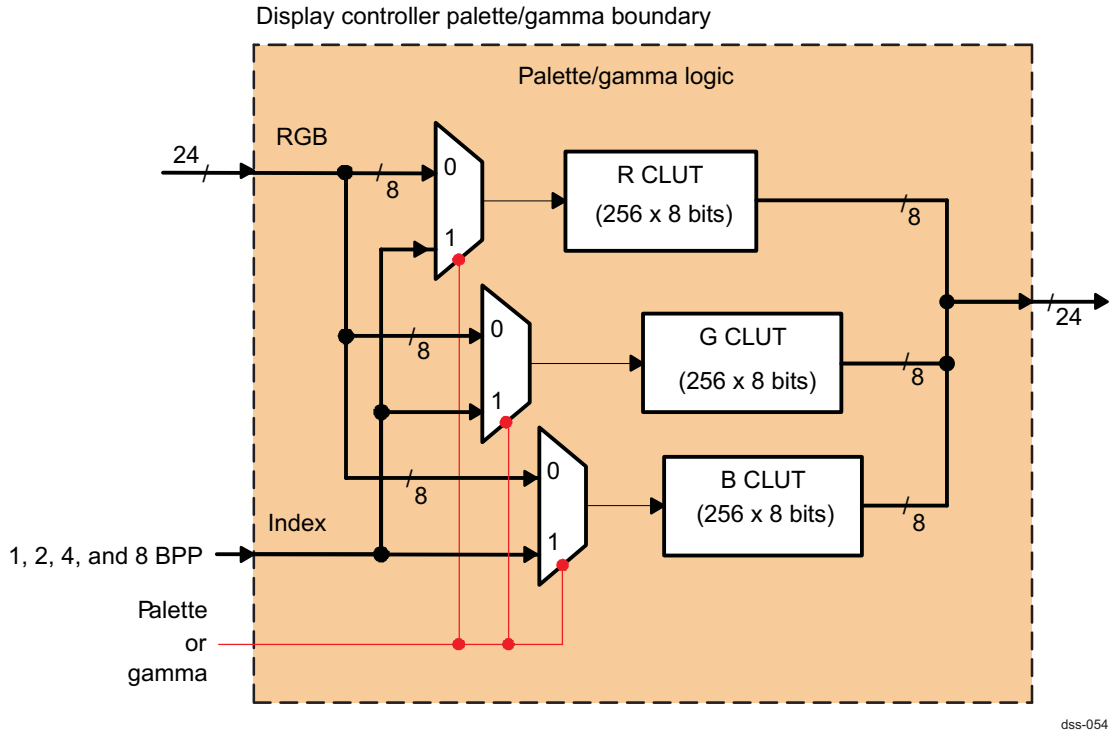
dss-T053

12.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. Figure 12-71 shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

Figure 12-71. Palette/Gamma Correction Architecture



12.4.2.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries).The format of one of the palette values in the memory is as follows:

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								R								G								B							

In monochrome mode, only one 8-bit value is present.

- 24-BPP Data Memory Organization (Llittle Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Unused								Unused								Gray							

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology

  The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology

The palette is bypassed in 12, 16, and 24 BPP, allowing up to 2^{24} = 16,777,216 colors to be displayed.

12.4.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component. The format of one of the gamma curve values in the memory is as follows:

- 24-BPP Data Memory Organization (Little or Big Endian)

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
Unused	Gamma-R	Gamma-G	Gamma-B

12.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	G5	G4	G3	G2	G1	G0	B4	B3	B2	B1	B0

dss-T055

- If replication logic is ON:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	R4	R3	R2	G5	G4	G3	G2	G1	G0	G5	G4	B4	B3	B2	B1	B0	B4	B3	B2

dss-T056

- If replication logic is OFF:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

dss-T057

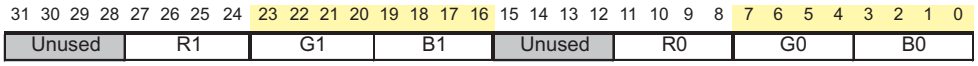
12.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV422 pixels.

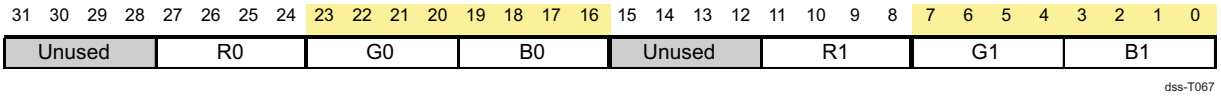
12.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

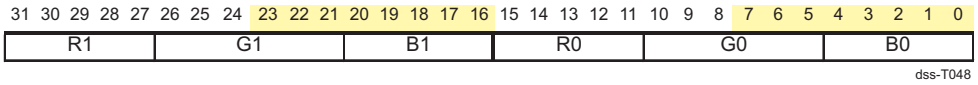
- RGB 12-BPP data memory organization (little endian)



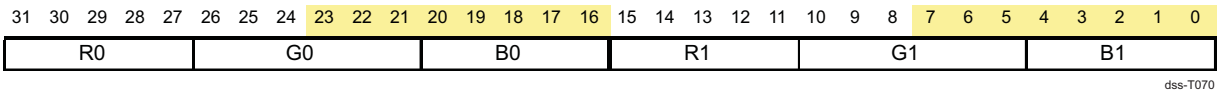
- RGB 12-BPP data memory organization (big endian)



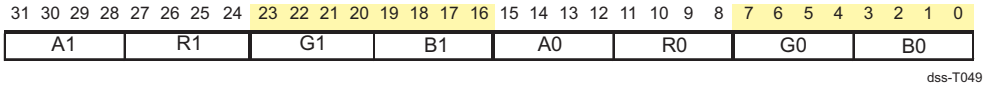
- RGB 16-BPP data memory organization (little endian)



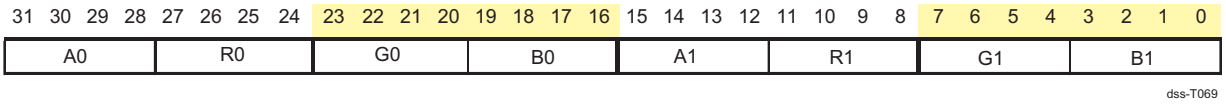
- RGB 16-BPP data memory organization (big endian)



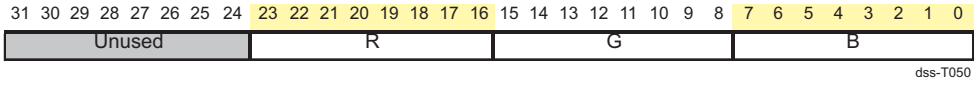
- ARGB 16-BPP data memory organization (little endian + video 2 channel only)



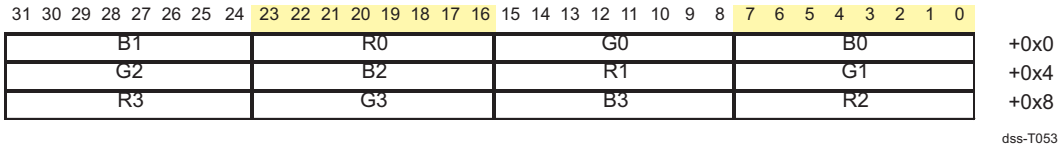
- ARGB 16-BPP data memory organization (big endian + video 2 channel only)



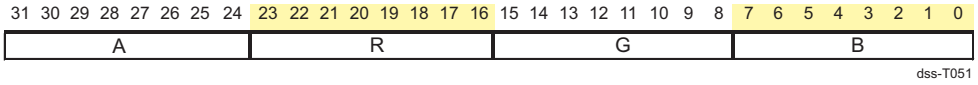
- RGB 24-BPP data memory organization (little or big endian)



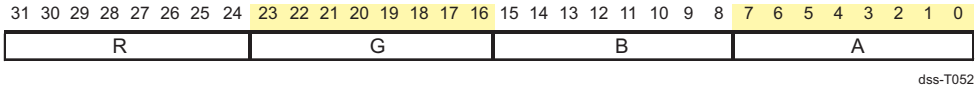
- RGB 24-BPP packet data memory organization (little or big endian)



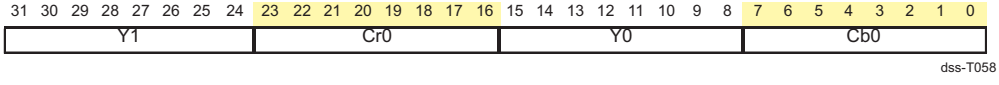
- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)



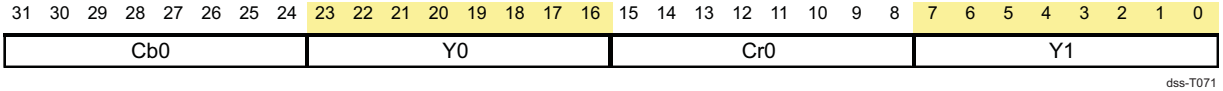
- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)



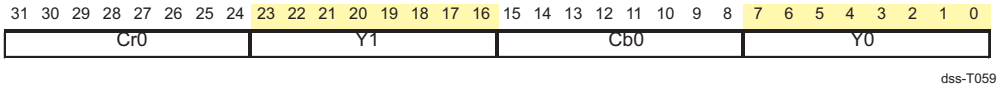
- UYVY 4:2:2 data memory organization (little endian)



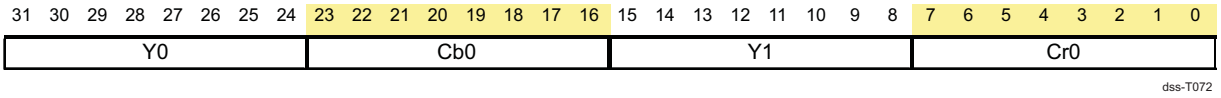
- UYVY 4:2:2 data memory organization (big endian)



- YUV2 4:2:2 data memory organization (little endian)



- YUV2 4:2:2 data memory organization (big endian)



12.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. Figure 12-72 and Figure 12-73 detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 12-72. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)

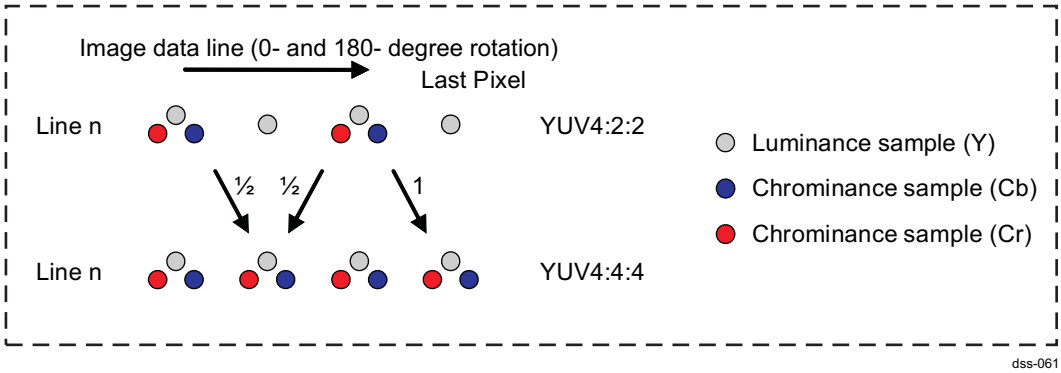


Figure 12-73. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)

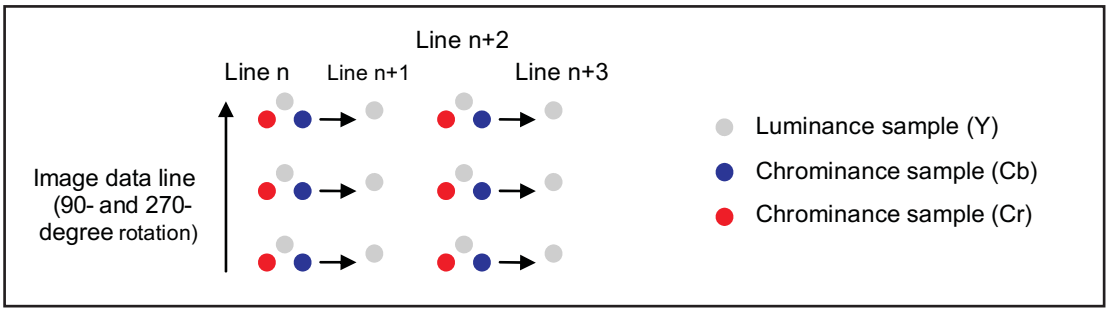


The interpolation of the missing chrominance component is given by the equation in Figure 12-74.

Figure 12-74. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from

the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.

- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

  In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

  Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

  In case of resampling, the YUV422 format is converted into YUV444. The YUV422-to-YUV444 processing is bypassed in the color space conversion unit.

  If the active range for the luminance samples (Y) is [16235] and [16240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in Figure 12-75 gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

Figure 12-75. YCbCr to RGB Registers (VIDFULLRANGE=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in Figure 12-76 gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

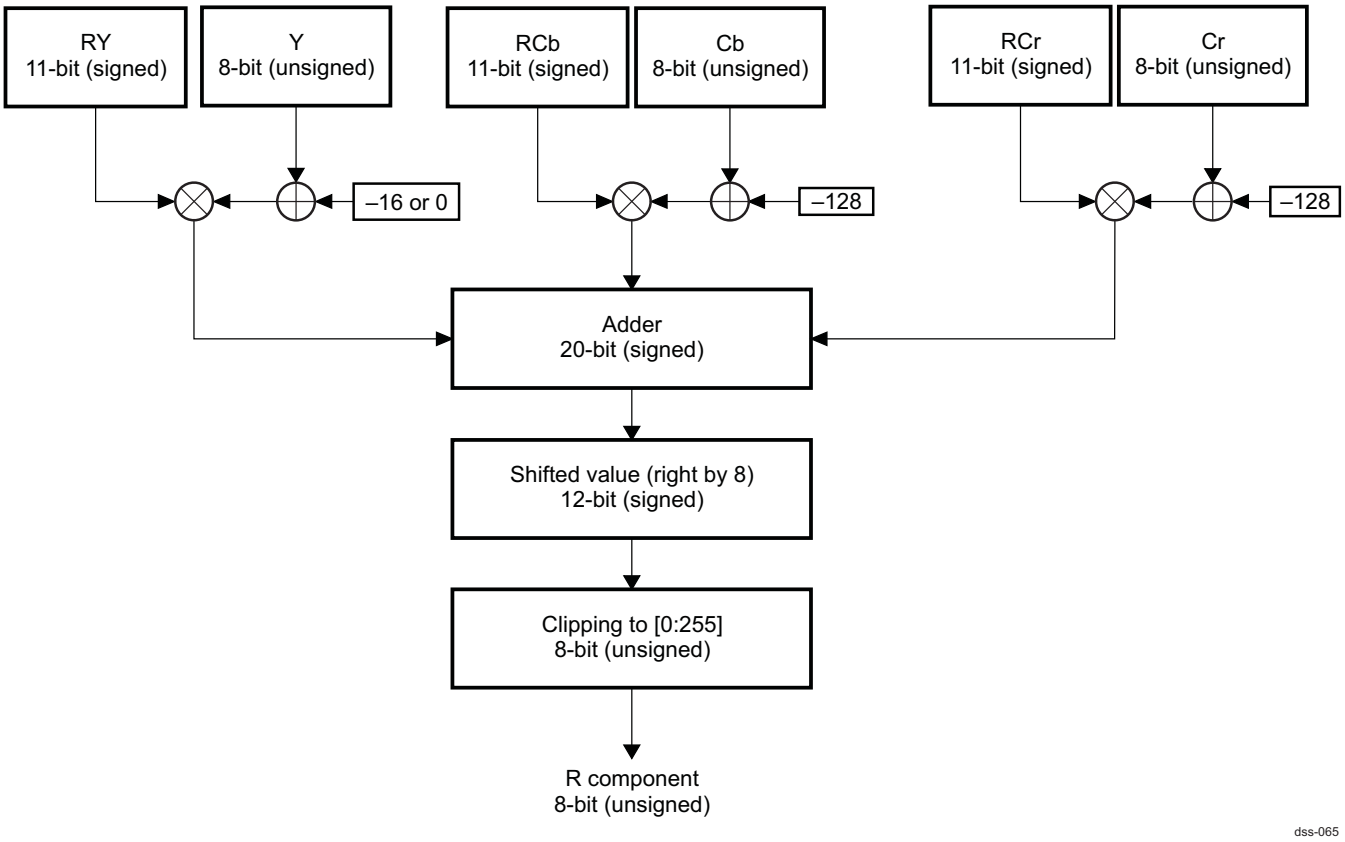
Figure 12-76. YCbCr to RGB Registers (VIDFULLRANGE=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

Figure 12-77 describes the computation for the calculation of the R component. The same computation applies for the G and B components:

Figure 12-77. Color Space Conversion Macro-Architecture



12.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

12.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV422

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently R, G, and B).

For the horizontal up-/downsampling, the equation is R component with five taps):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad \text{dss-E066} \qquad (2)$$

For the vertical up-/downsampling, the equation is R component with three taps):

$$Rout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad \text{dss-E067} \tag{3}$$

For the vertical up-/downsampling, the equation is R component with five taps):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad \text{dss-E068}$$

Rout: R component output

$Ci(\Phi)$ dss-E069 : FIR filter coefficients

Rin: R component input (4)

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

NOTE: The coefficients Ci() depend on the phase between input and output pixels.

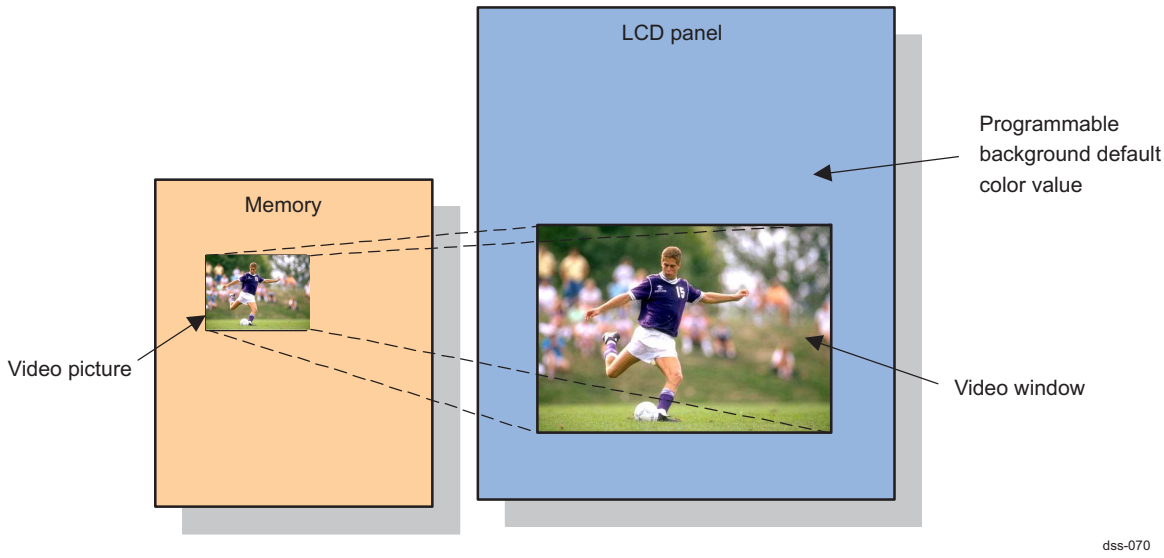
NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels.

DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1

DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even

Figure 12-78 shows an example of video upsampling.

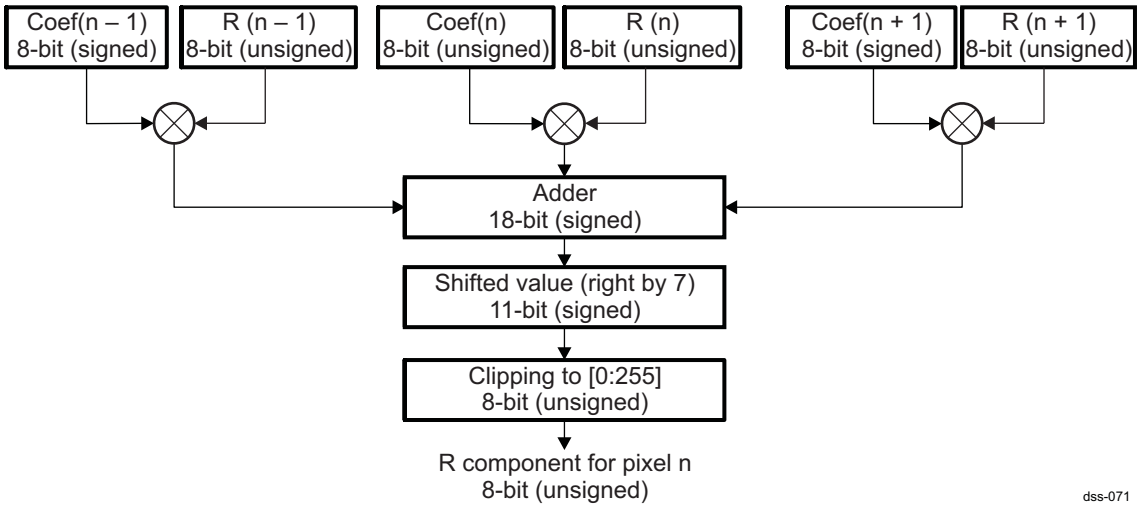
Figure 12-78. Video Upsampling



Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is/2. The downsampling ratio using 5-tap configuration is/4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 12-79 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

Figure 12-79. Resampling Macro-Architecture (3-Coefficient Processing)



To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with Table 12-26 and Table 12-27.

Ratio V when performing a vertical down-sampling only

$$h\_ratio = \frac{DISPC\_SIZE\_LCD.PPL}{DISPC\_VID\_SIZE.VidSizeX}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeY}{DISPC\_VID\_SIZE.VidSizeY}$$

$$Ratio = \frac{v\_ration}{2 \times h\_ratio} \qquad If \quad 1 < v\_ratio \le 2$$

$$Ratio = \max\left(\frac{v\_ration}{2 \times h\_ratio}, \frac{v\_ration - 2}{2 \times (h\_ratio - 1)}\right) \qquad If \quad 2 < v\_ratio \le 4$$

dss_swpu108-E135

NOTE: For frequency ratio calculation on the TV output, it is correct to replace DISPC_SIZE_LCD with DISPC_SIZE_DIG.

When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

Ratio H when performing a horizontal down-sampling only

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.VidOrgSizeX}{DISPC\_VID\_SIZE.VidSizeX}$$

dss_swpu108-E136

Ratio H+V when performing a horizontal and vertical down-sampling

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

Table 12-26. Functional Clock Frequency Requirement in RGB16 & YUV422—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Table 12-27. Functional Clock Frequency Requirement in RGB24—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Use case example:

An input picture of 1024*768 is scaled to an output picture of size of 800*600 and displayed onto a LCD of resolution1280*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

Ratio V: h_ratio = 1.6 and v_ratio = 1.28 then Ratio = 0.4

Ratio H: Ratio = 1.28

Ratio H+V: Ratio = max (1.28, 0.4) = 1.28

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from Table 12-26 and Table 12-27, If in RGB16-YUV422:

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio * PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 * Ratio * PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV422 in a 5-tap configuration.

12.4.2.4 Overlay Support

CAUTION

Enabling overlay optimization (setting the DSS.DISPC_CONTROL [12] OVERLAYOPTIMIZATION bit) if no overlay region effectively exists (the DSS.DISPC_VIDn_ATTRIBUTES [0] VIDENABLE bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see Figure 12-82).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

12.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see Figure 12-84).

Figure 12-80. Overlay Manager in Normal Mode

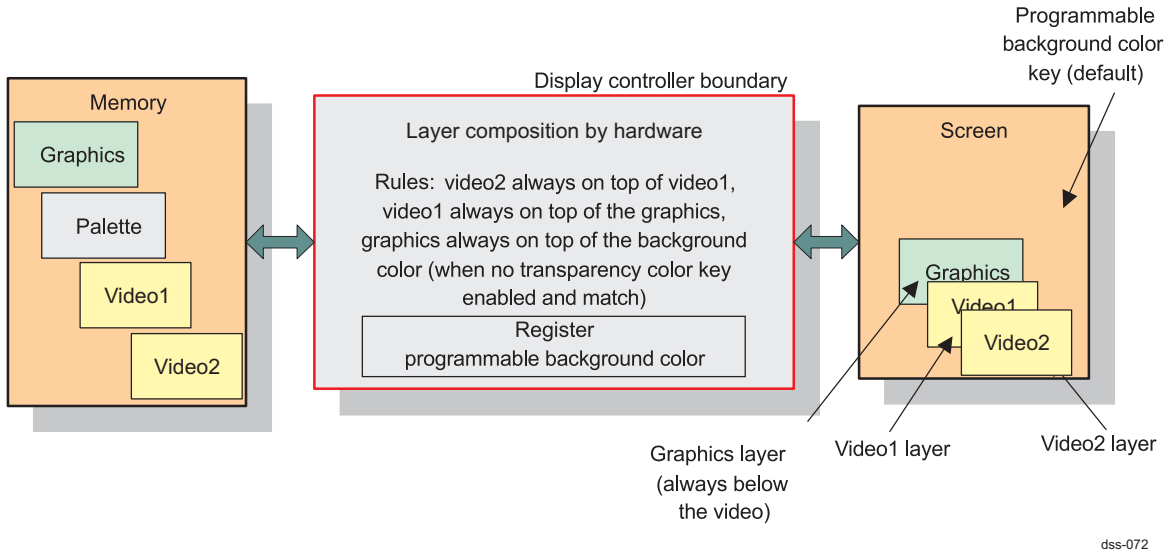


Figure 12-81. Display Attributes in Normal Mode

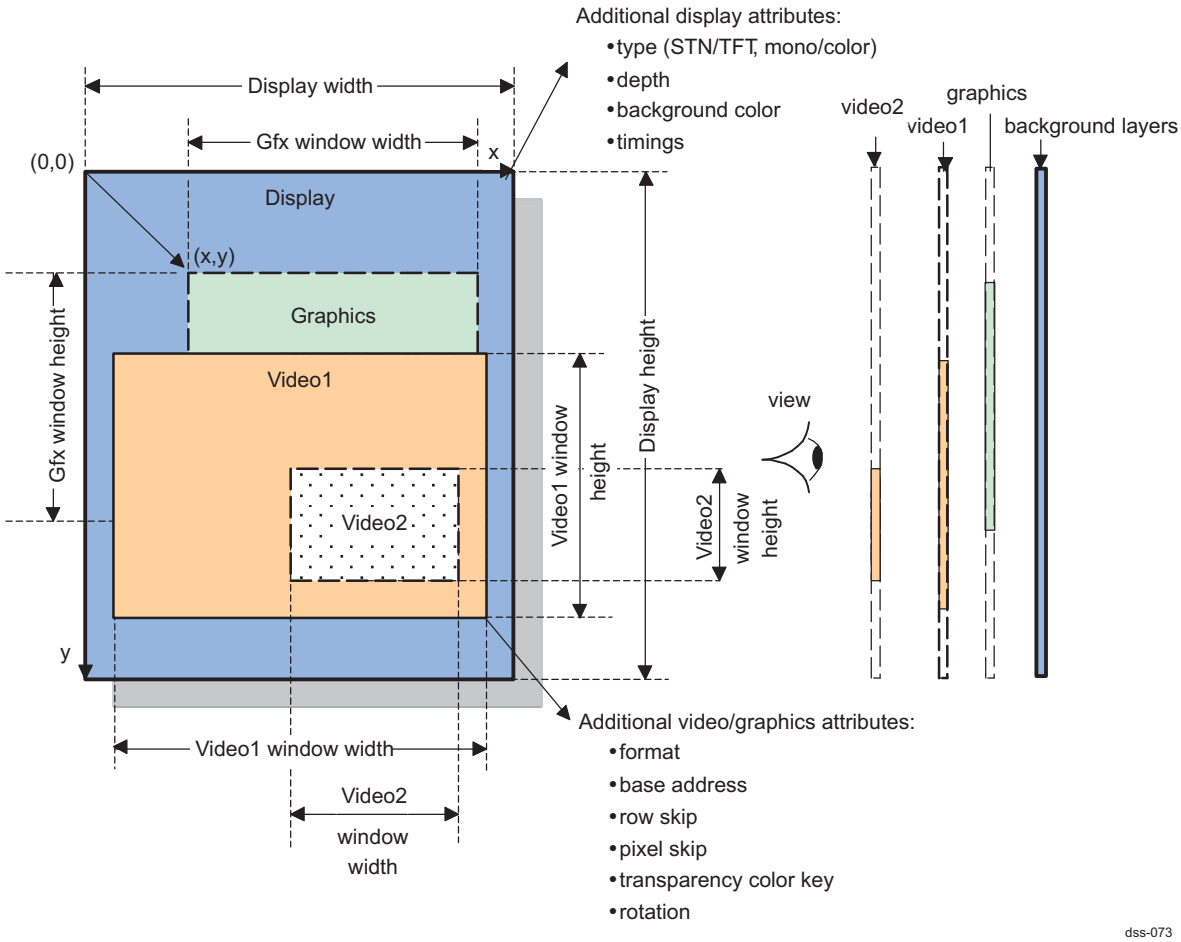

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see Figure 12-84).

Figure 12-82. Overlay Manager in Alpha Mode

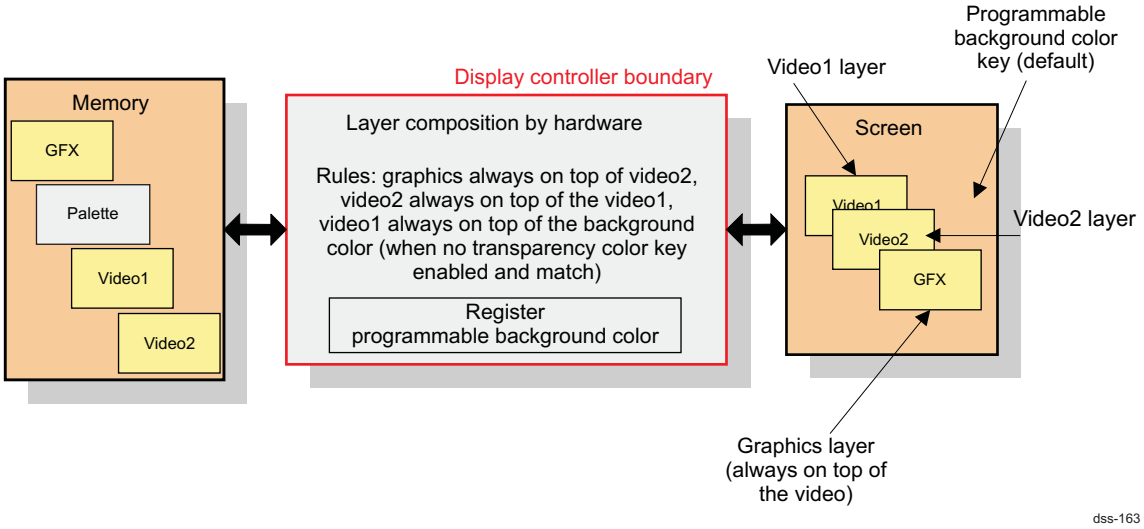

Figure 12-83. Display Attributes in Alpha Mode

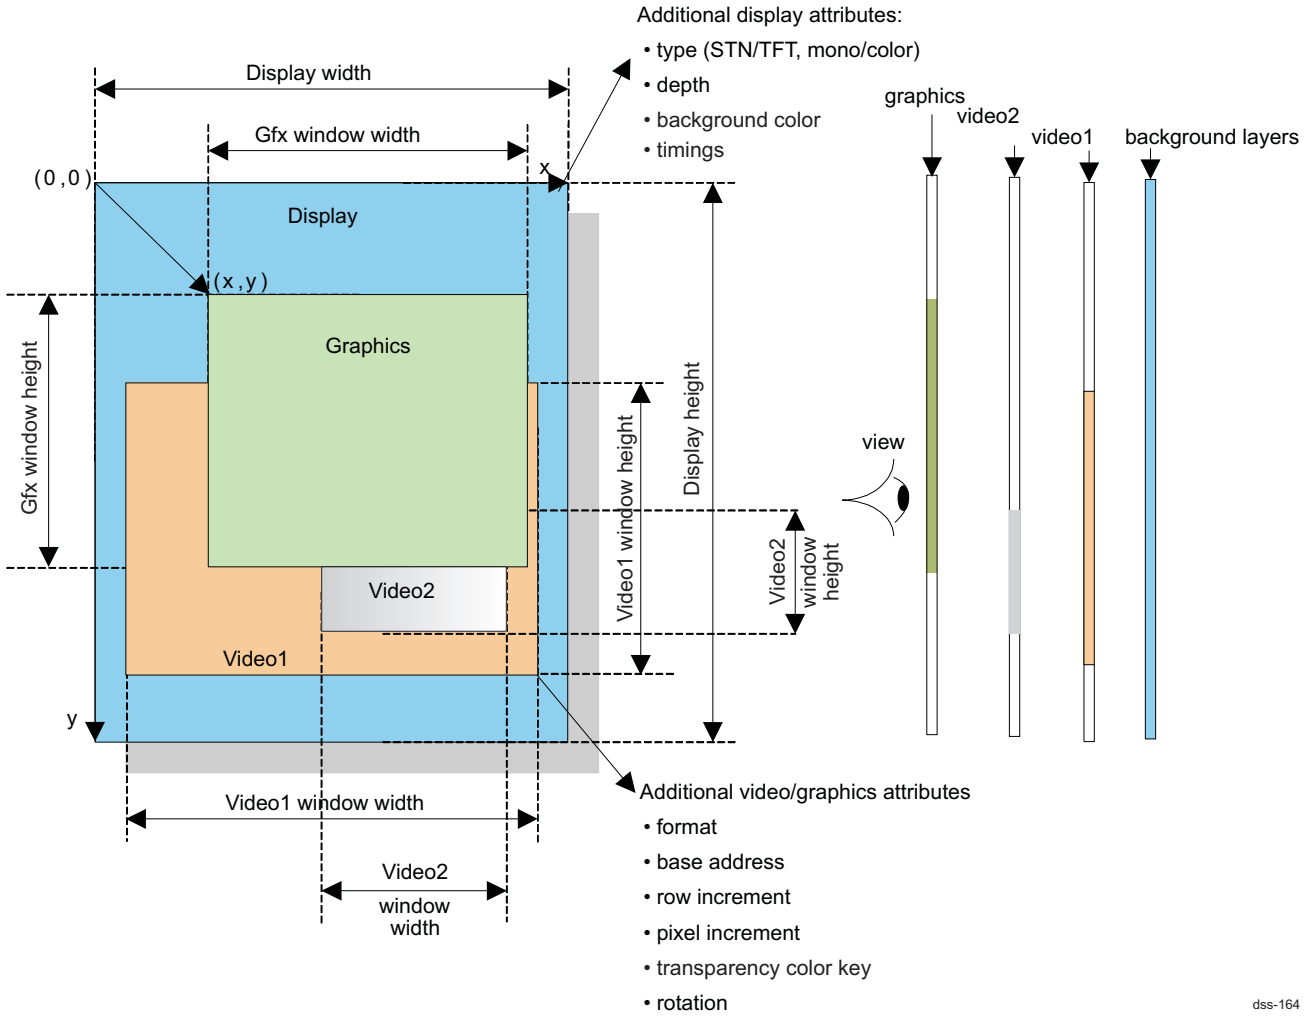

Figure 12-84 shows the alpha blending processing in detail.

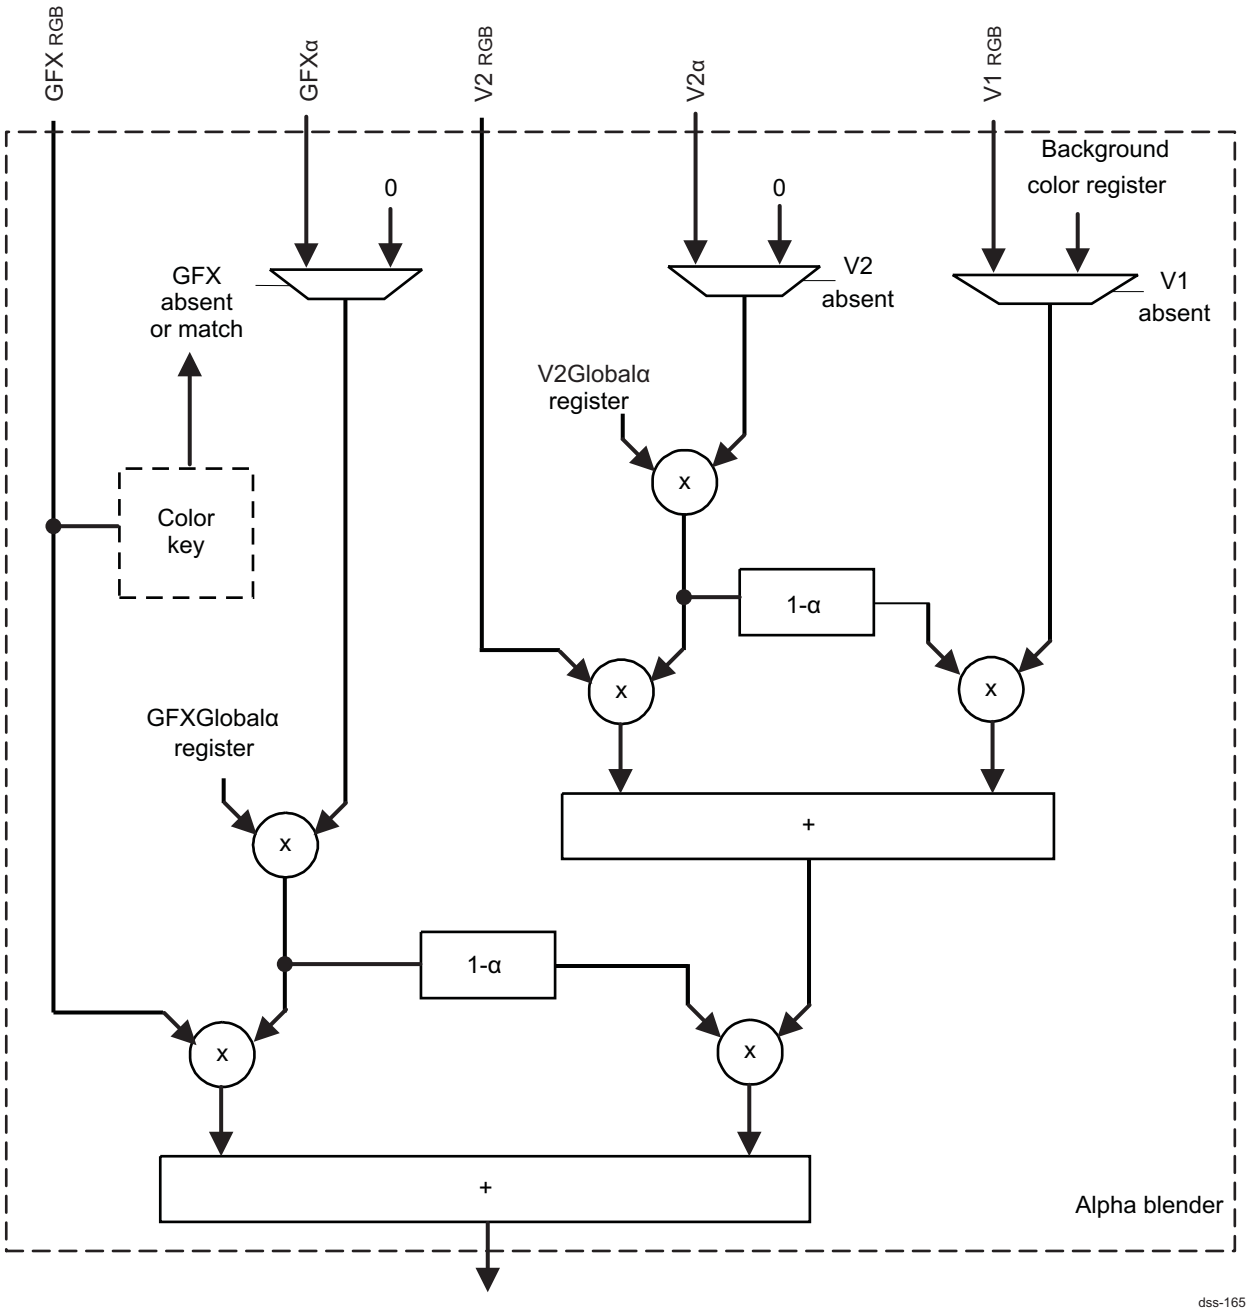
Figure 12-84. Alpha Blending Macro Architecture



NOTE: "1-alpha" operator corresponds to the basic 1's complement operation.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. Table 12-28 details the alpha blending 4-bit values and the corresponding blending percentage.

Table 12-28. Alpha Blending 4-Bit Values

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...	...	...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

12.4.2.4.2 Transparency Color Keys

12.4.2.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

NOTE: The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video source transparency color key value:

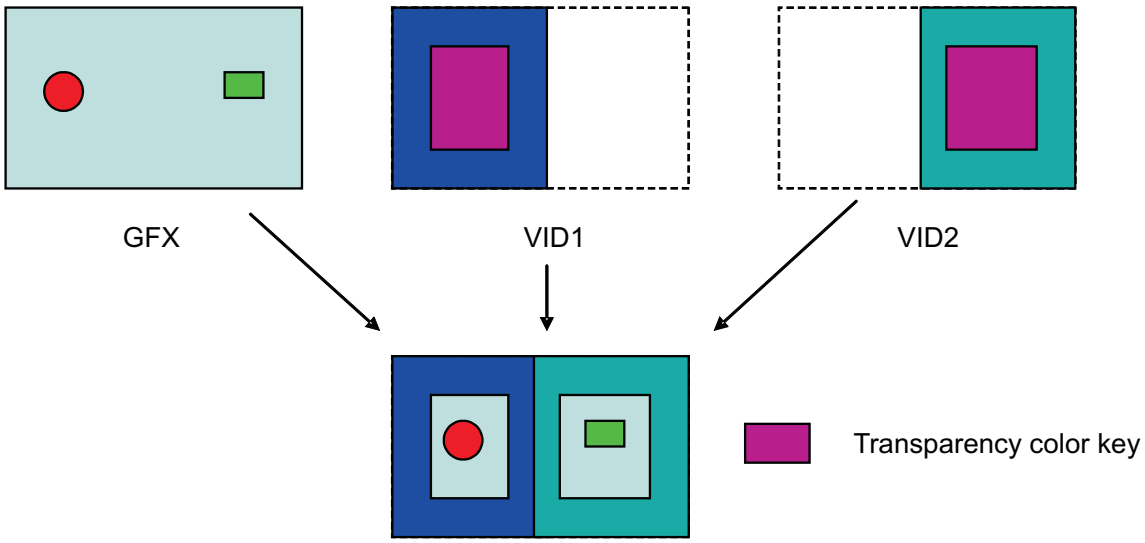
  The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

  The video source transparency color key can be used only if the color space conversion and the up-/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

  To enable the video source transparency color key, set to 0x1 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

  An example is shown in Figure 12-85: The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

Figure 12-85. Video Source Transparency Example



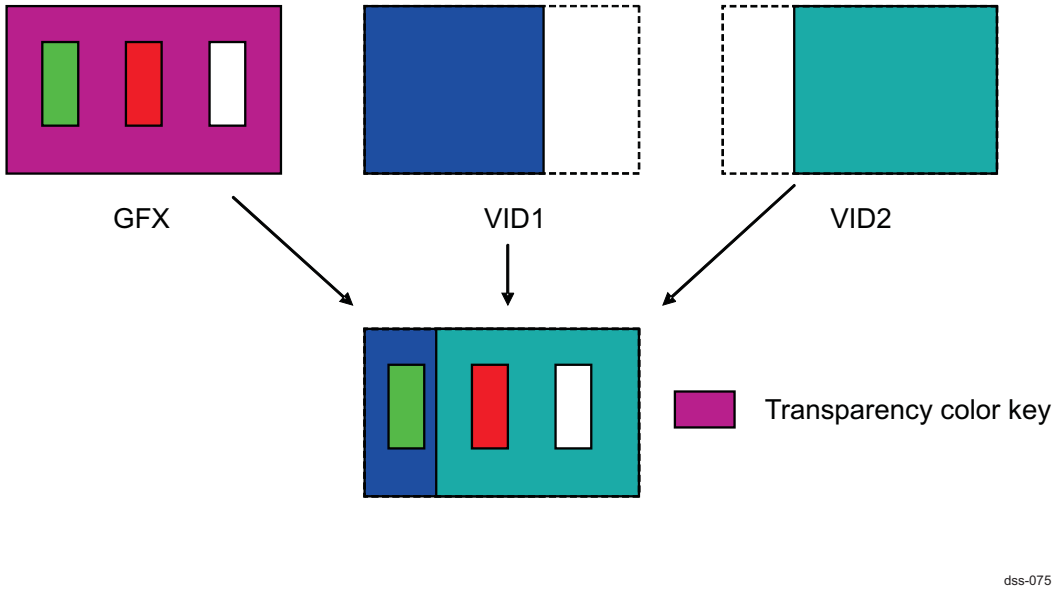
- Graphics destination transparency color key value:

  The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

  To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

  An example is shown in Figure 12-86: The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

Figure 12-86. Graphics Destination Transparency Example



12.4.2.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

12.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV422, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV422 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

12.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation

- Spatial/temporal dithering
- Passive matrix technology

12.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in Figure 12-87.

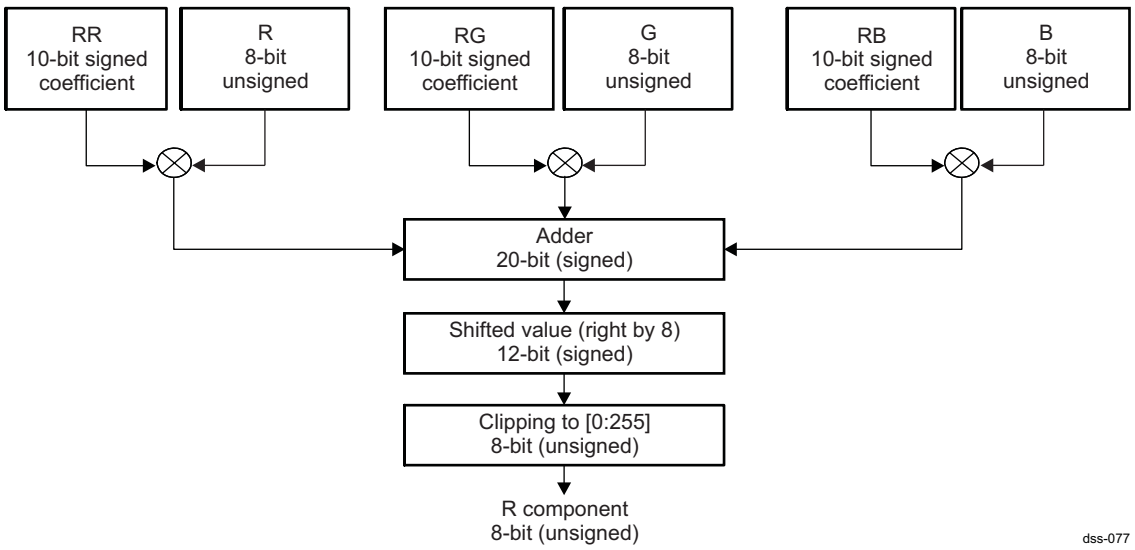
Figure 12-87. Color Phase Rotation Matrix

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

dss-E076

Figure 12-88 shows the color phase rotation macro-architecture.

Figure 12-88. Color Phase Rotation Macro Architecture



12.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- Passive Matrix Technology: The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of

the spatial/temporal dithering logic is RGB 12-bit (not configurable).

- Active Matrix Technology: The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

12.4.2.5.2 Passive Matrix Display Dithering Logic

- Passive matrix technology

  After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data.

  These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.

- Active matrix technology

  The passive matrix dithering logic is always bypassed in active displays.

NOTE: If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

12.4.2.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology

  The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.

- Active matrix technology

  The output FIFO is bypassed in active matrix mode.

12.4.2.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see Table 12-29):

- The DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC_DATA_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC_DATA_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).

- The DSS.DISPC_DATA_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

Table 12-29. 8-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

12.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). Table 12-30 lists the maximum width depending on the TAP configuration and the pixel format.

Table 12-30. Maximum Width Allowed

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV422	
5	RGB16	1024
	RGB24	
	YUV422	

12.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

12.4.2.8 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see , *Memory Subsystem*).

NOTE: It is highly recommended to use the VRFB Rotation engine when possible and not the display subsystem DMA engine for rotating frame buffer to have a good performance in the L3 interconnect and SDRAM memory efficiency.

The rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container) and ARGB16, RGB16, ARGB16, RGB24 (using 32-bit container) and ARGB32 and RGBA32 and YUV422 (YUV2 and YUYV). The formats not supported are BITMAP1, BITMAP2, BITMAP4 and RGB24 (using 24-bit container).

12.4.2.9 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

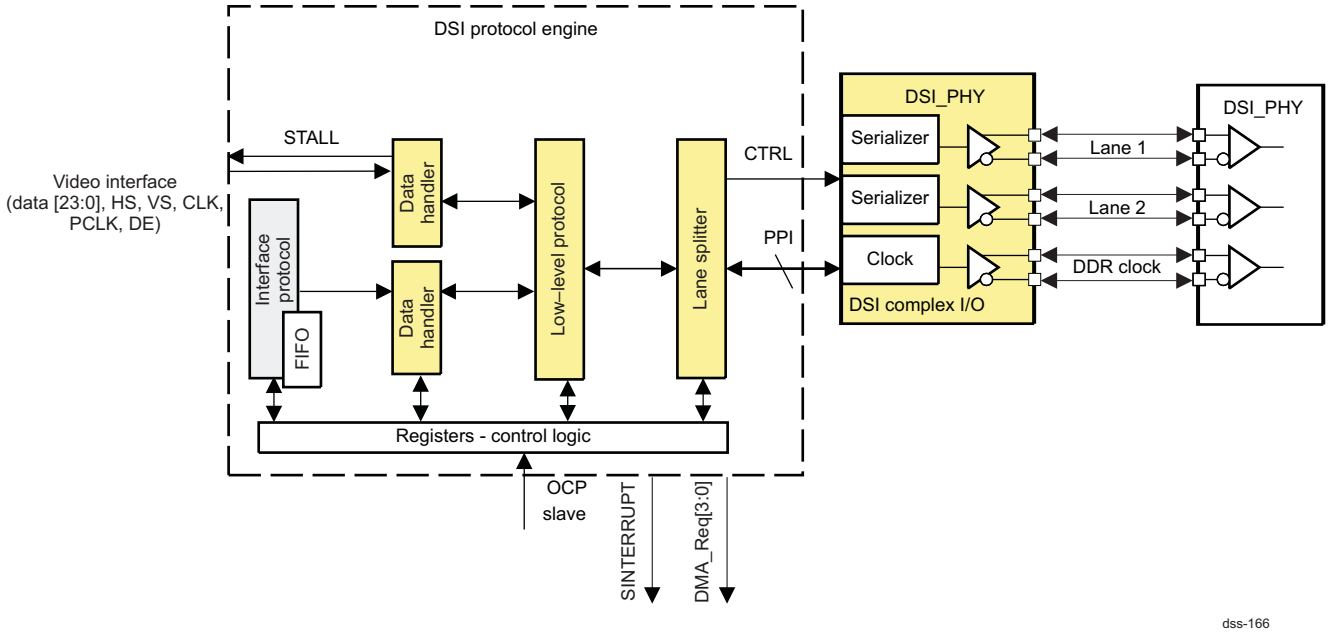
12.4.3 DSI Protocol Engine Functionalities

The DSI protocol engine integrates DSI interface to the display through the DSI DSI_PHY module, L4 interconnect interface and video interface from the display controller. The DSI DSI_PHY or complex I/O module is detailed in Section 12.4.5. The DSI Transmitter (Protocol Engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL Control module detailed in Section 12.4.4. The DSI Transmitter port can be used in video mode or/and command mode.

12.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the VC ID, generates the ECC and check-sum, and splits the data into byte stream to the DSI_PHY to be sent using the low-speed (LS) or high-speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bidirectional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. Figure 12-89 details the DSI protocol engine architecture.

Figure 12-89. DSI Protocol Engine

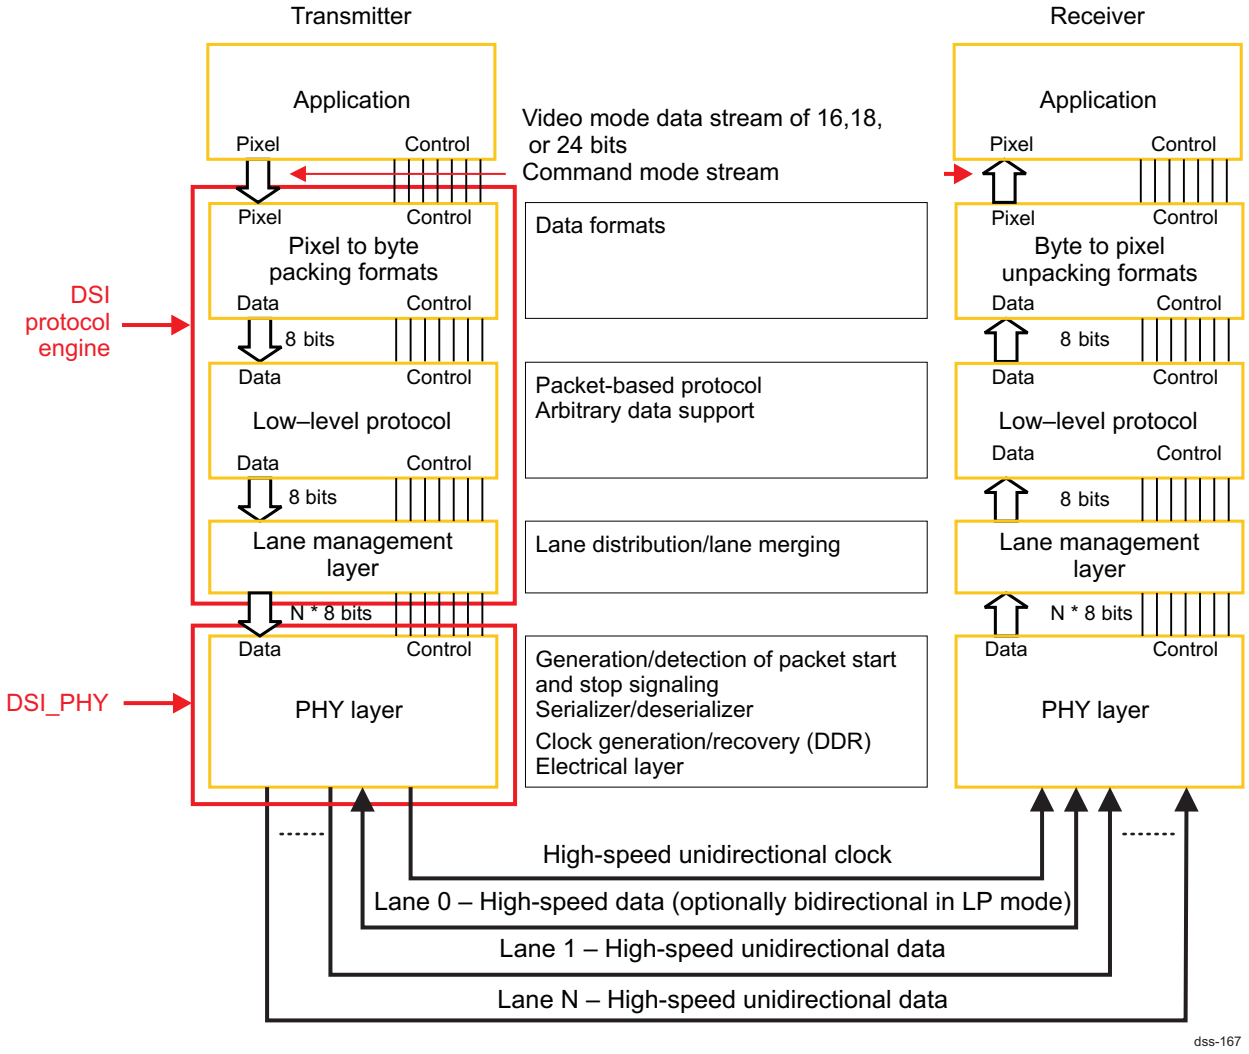


NOTE: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.DSI_COMPLEXIO_CFG1 register.

The DSI serial interface is a bidirectional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 800 Mbps per channel. The speed of the link can be software configured only when the DSI_PHY is in stop state or in ULPS.

Figure 12-90 shows the DSI transmitter/receiver high-level data flow.

Figure 12-90. DSI Transmitter/Receiver Data Flow



12.4.3.2 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit: This bit can be programmed only when the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field. The LP clock generated from DSI functional clock should be in the range of 20 MHz down to 32 KHz. The duty cycle should be 50/50 (tolerance of 45/55 for maximum value). LP clock frequency visible on the pads (DP xor DN) is half the frequency of TxClkEsc.

The DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is used to enable or disable the clock. When disabled, the value of DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field is ignored and does not have to be programmed by software users.

12.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 12-91 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 12-31 lists the LP to HS timing parameters.

Figure 12-91. LP to HS Timing

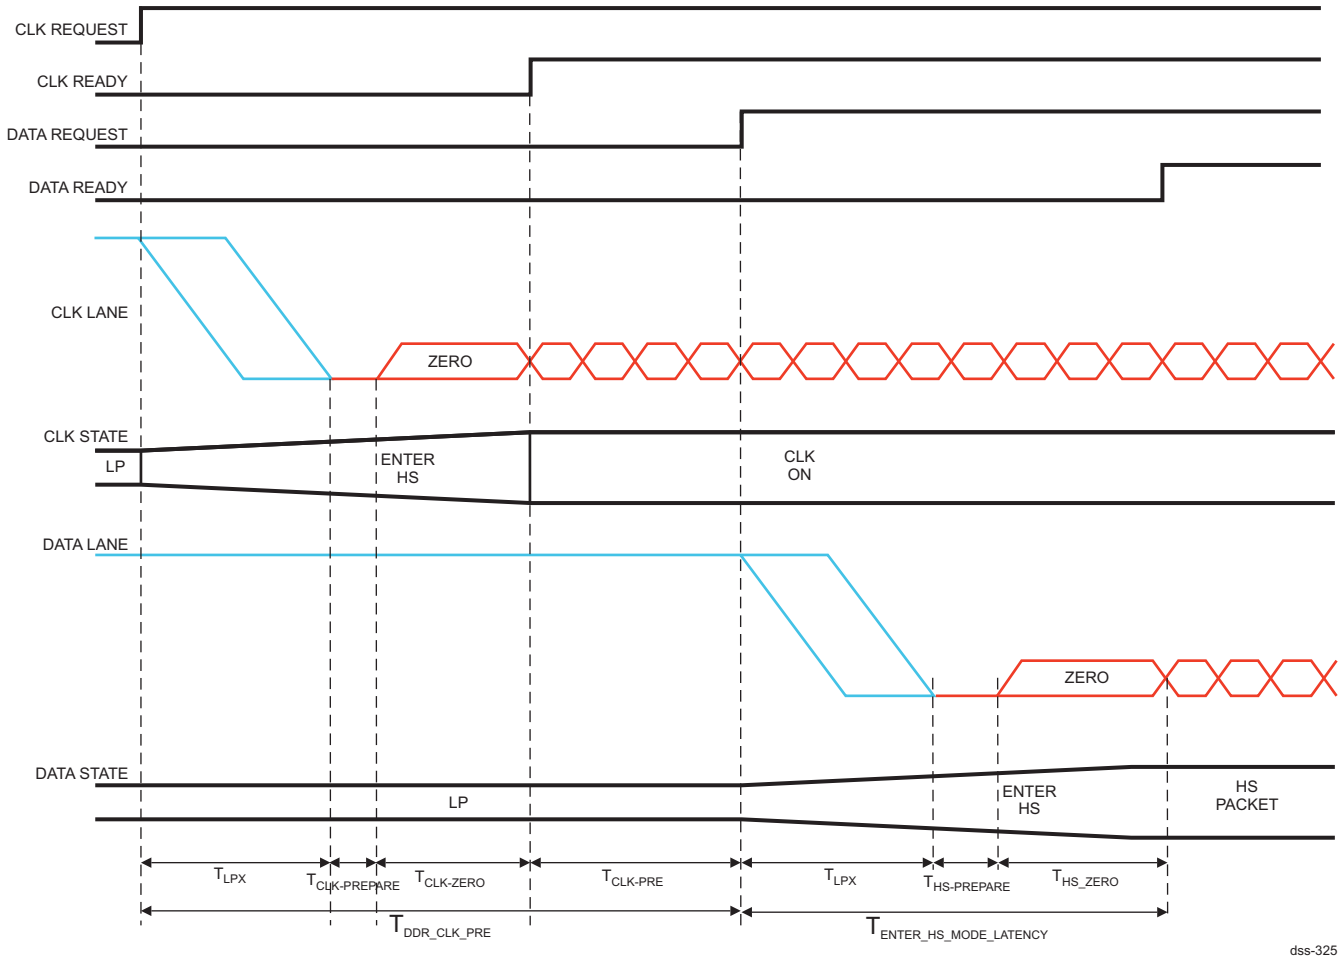


Table 12-31. LP to HS Timing Parameters

Timing	Description	Register
T_{LPX}	Length of any low-power state period. The value set in DSI_PHY_CFG1[20:16] TLPX_HALF bit field is half of the T_{LPX}.	DSI_PHY_CFG1[20:16] TLPX_HALF
$T_{CLK-PREPARE}$	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_CFG2[7:0] TCLK_PREPARE
$T_{CLK-ZERO}$	Time to drive the CLK lane to HS-0 state before starting the clock	DSI_PHY_CFG1[7:0]TCLK_ZERO
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode $T_{CLK-PRE}$ = DDR_CLK_PRE - T_{LPX} - $T_{CLK-PREPARE}$ - $T_{CLK-ZERO}$	See the MIPI DSI_PHY specification.
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_CFG0[31:24] THS_PREPARE
$T_{HS-ZERO}$	Time to drive the data lane to HS-0 state before the synchronous sequence. $T_{HS-ZERO}$= DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO - $T_{HS-PREPARE}$	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO

Table 12-31. LP to HS Timing Parameters (continued)

Timing	Description	Register
$T_{DDR\_CLK\_PRE}$	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING[15:8] DDR_CLK_PRE
$T_{ENTER\_HS\_MODE\_LATENCY}$ (1)	Time to enter into HS mode. It is critical that $T_{ENTER\_HS\_MODE\_LATENCY}$ = 1 + DIVROUNDUP (2 * TLPX_HALF, 4) + DIVROUNDUP (THS_PREPARE ,4) + DIVROUNDUP (THS_PREPARE_THS_ZERO - THS_PREPARE + 3, 4) (2)	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY

(1) The formula for ENTER_HS_MODE_LATENCY timing is relevant only in video mode. It does not need to be programmed in command mode.
(2) The formula DIVROUNDUP(value, div) is equivalent to ROUNDUP(value/div).

12.4.3.2.2 Timing Parameters for an HS to LP Transaction

Figure 12-92 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Figure 12-92 lists the HS to LP timing parameters.

Figure 12-92. HS to LP Timing

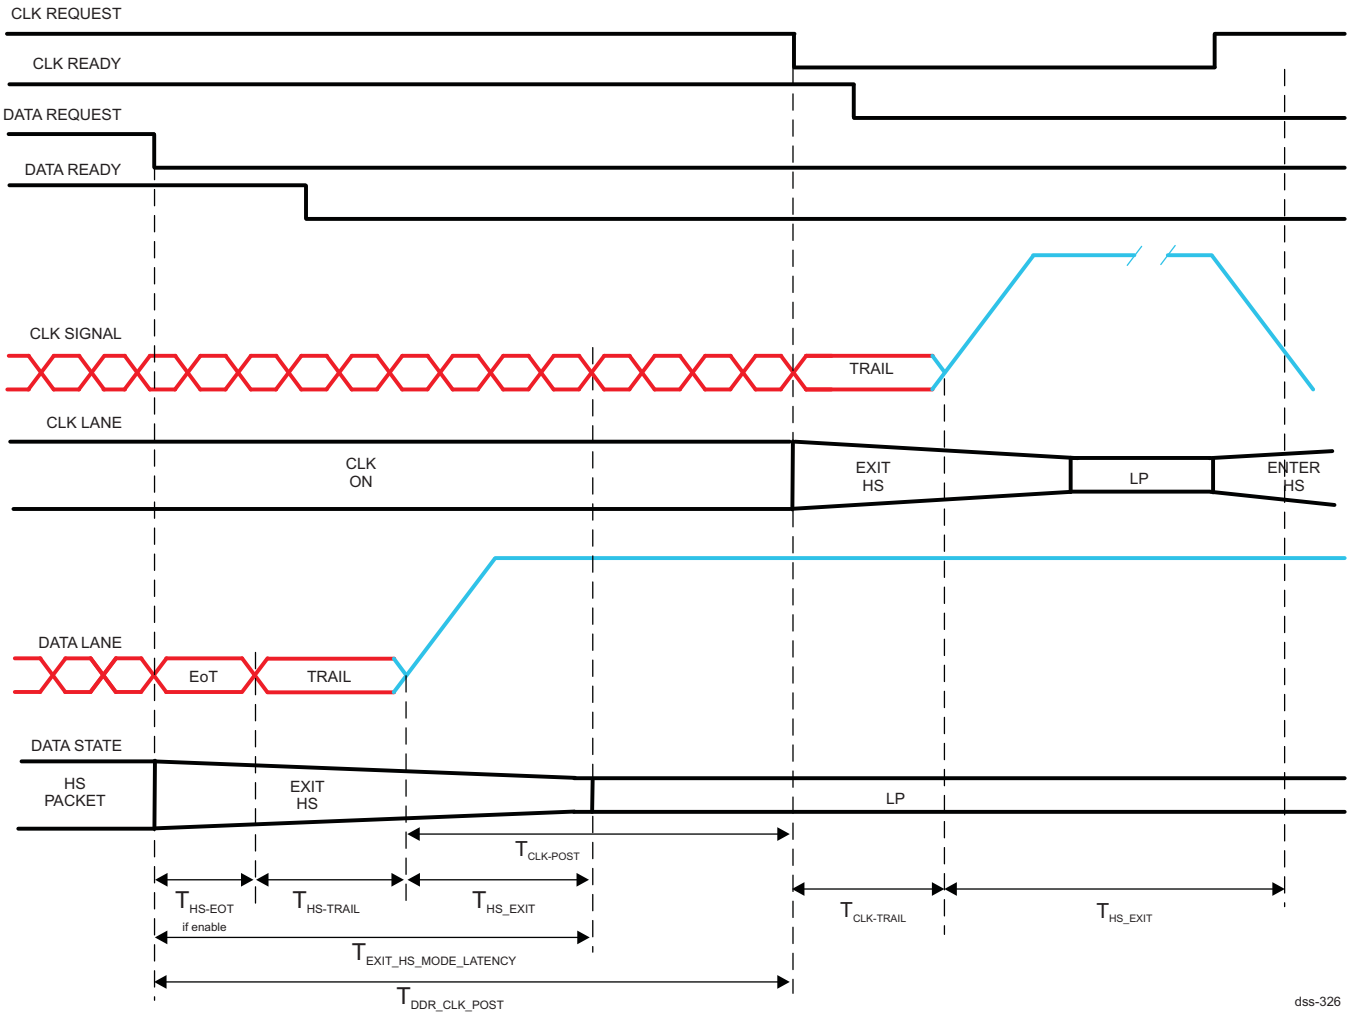

Table 12-32. HS to LP Timing Parameters

Timing	Description	Register
T_{HS-EOT}	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes, and is expressed with the following formula: THS-EOT = DIVROUNDUP (4, NB_DATA_LANES). Thus: 1 data lane = 4 DDR clocks 2 data lanes = 2 DDR clocks	
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of a HS transmission burst	DSI_PHY_CFG0[15:8] THS_TRAIL
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_CFG0[7:0] THS_EXIT
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	See the MIPI DSI-PHY specification.
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of a HS transmission burst	DSI_PHY_CFG1[15:8]TCLK_TRAIL
$T_{DDR\_CLK\_POST}$	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $T_{DDR\_CLK\_POST} \geq T_{HS-TRAIL} + T_{HS-EOT} + T_{CLK-POST}$	DSI_CLK_TIMING[7:0] DDR_CLK_POST
$T_{EXIT\_HS\_MODE\_LATENCY}$ (1)	Time to exit in HS mode. It is critical that $T_{EXIT\_HS\_MODE\_LATENCY}$ = DIVROUNDUP(($T_{HS-TRAIL}$ + $T_{HS-EXIT}$),4) + 1 + T_{HS-EOT} (2)	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY

(1) The formula for EXIT_HS_MODE_LATENCY timing is relevant only in video mode. It does not need to be programmed in command mode.

(2) The formula DIVROUNDUP(value, div) is equivalent to ROUNDUP(value/div).

12.4.3.2.3 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the VCs sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE bit field. The header value depends on the VC ID and the size of the payload as detailed in Table 12-33 and Table 12-34.

Table 12-33. Extra NULL Packet Header

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F
	1		0x1		0x05
	2		0x2		0x39
	3		0x3		0x23
0x2	0	0x89	0x0		0x10
	1		0x1		0x0A
	2		0x2		0x36
	3		0x3		0x2C
	0		0x0		0x06

Table 12-33. Extra NULL Packet Header (continued)

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
0x3	1	0xC9	0x1		0x1C
	2		0x2		0x20
	3		0x3		0x3A

Table 12-34. Extra NULL Packet Payload

Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Payload (1st byte)	Payload (2nd byte)	Payload (3rd byte)	Payload (CRC) LSB	Payload (CRC) MSB
0	NA	NA	NA	0xFF	0xFF
1	0	NA	NA	0x87	0x0F
2	0	0	NA	0xB8	0xF0
3	0	0	0	0x33	0x39

NOTE:

- In Table 12-33 and Table 12-34, both ECC and checksum are enabled.
- NA means not available.

12.4.3.3 DSI Transfer Modes

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels must be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that TE should be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

12.4.3.3.1 Video Mode

The video mode refers to the MIPI DPI 1.0 standard. The sync events and pixels should be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in DSS.DSI_VCn_LONG_PACKET_HEADER registers.

12.4.3.3.2 Command Mode

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in Section 12.4.3.3.1). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

The DSS.DSI_VCn_LONG_PACKET_HEADER registers are used for the header of long packets, the DSS.DSI_VCn_SHORT_PACKET_HEADER registers are used for the short packets.

The error correction code (ECC) can be provided while writing the ECC value directly into the DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers. The DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using DSS.DSI_VCn_SHORT_PACKET_HEADER registers, if the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 1, the ECC is calculated otherwise the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used. Each 32-bit PAYLOAD data is written into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER registers is used to determine the number of bytes to be sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers. The write into the DSS.DSI_VCn_LONG_PACKET_HEADER registers is required before accessing the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware should be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware takes into account the write into the DSS.DSI_VCn_LONG_PACKET_HEADER register only if the VC is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI_VCn_LONG_PACKET_HEADER register is used. The video port pixels are used for the payload. When the pixel data is coming from the display controller video port, the DSI protocol can add a DCS command byte between the packet header and pixel data by setting the DSS.DSI_CTRL[24] DCS_CMD_ENABLE bit to 0x1. The value will be either 0x2c (write_memory_start) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x1, or 0x3c (write_memory_continue) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x0.

When transmitting RGB 16-BPP data, the DSS.DSI_CTRL[26] RGB565_ORDER bit must be set to 0x1 to maintain the pixel byte order as in video mode.

A 2-line ping-pong buffer is implemented to allow the DSI protocol engine to store incoming pixels from the display controller through the video port while sending the DSI formatted frame to the DSI_PHY. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 *32 bits). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

The ping-pong buffer status can be checked by the DSI_VCn_CTRL[14] PP_BUSY bit.

- When PP_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, the user cannot update a new header.
- When PP_BUSY equals 0, at least one line buffer is empty; therefore, the user can update a new header. PP-BUSY is then set to 0x1. If both line buffers are empty, the user can write two headers, one following the other. PP_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after second header is written.

An IRQ is available to allow software to update header on events. The IRQ is enabled by setting the DSI_VCn_IRQENABLE[8] PP_BUSY_CHANGE_IRQ bit to 0x1, and its status is accessible on the DSI_VCn_IRQSTATUS[8] PP_BUSY_CHANGE_IRQ bit.

12.4.3.3.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels should be provided on the L4 interconnect only.

12.4.3.3.4 Burst Modes

- Frequency-burst mode The frequency-burst mode is used to reduce the high-speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption

reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.

- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

12.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

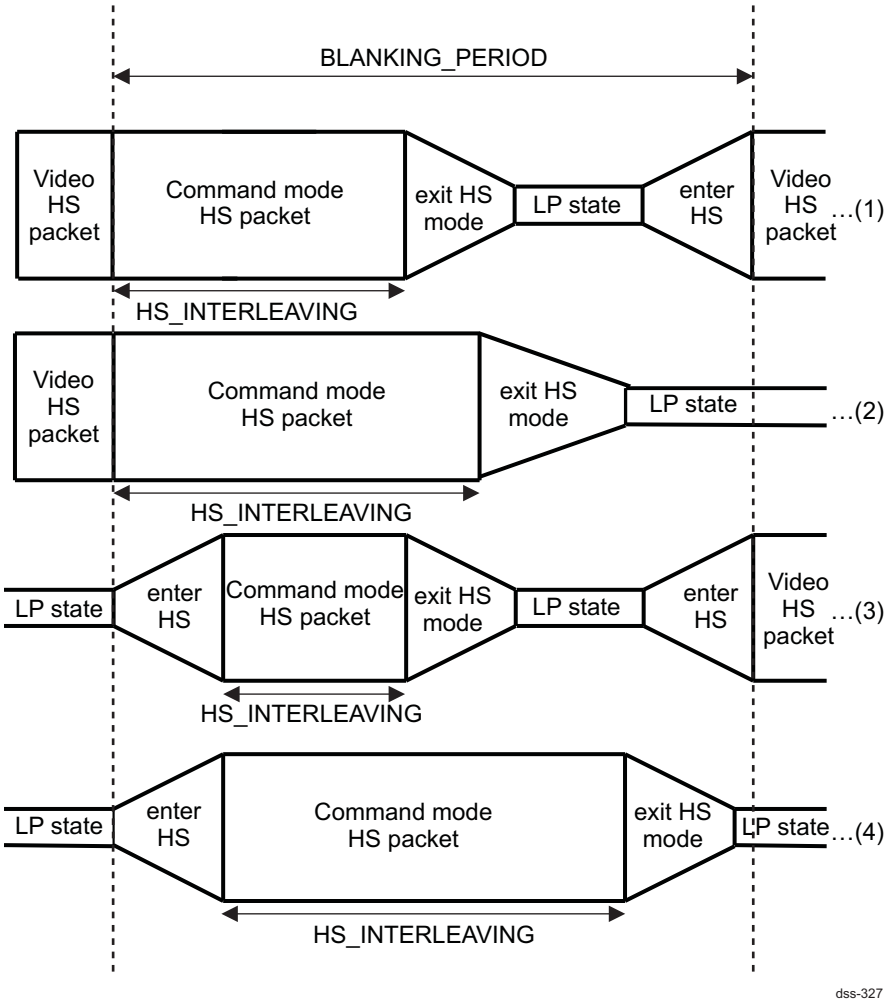
12.4.3.3.5.1 HS Command Mode Interleaving Programming Model

Figure 12-93 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL_HS_INTERLEAVING[31:16] DSI_VM_TIMING6 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP_HS_INTERLEAVING[7:0] DSI_VM_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP_HS_INTERLEAVING[15:8] DSI_VM_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA_HS_INTERLEAVING[23:16] DSI_VM_TIMING4 bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 12-93. HS Command Mode Interleaving



NOTE: For calculations and equations, the following abbreviations are used: EXIT_CLK_HS_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.
EXIT_CLK_HS_MODE = $T_{CLK\text{-}TRAIL}$ + $TH_{S\text{-}EXIT}$

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL_HS_INTERLEAVING, HSA_HS_INTERLEAVING, HBP_HS_INTERLEAVING, or HFP_HS_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr_clk_always_on.

- ddr_clk_always_on = 1: Clock lane is always active.
- ddr_clk_always_on = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - ddr_clk_always_on = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - ddr_clk_always_on = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{

ENTER_HS_MODE_LATENCY, 2} + 1)

HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + 1)

HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
  - ddr_clk_always_on = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)
  - ddr_clk_always_on = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + 3)

    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - ddr_clk_always_on = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - ddr_clk_always_on = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + 1)

    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2})
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
  - ddr_clk_always_on = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)
  - ddr_clk_always_on = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + 1)

    HS_INTERLEAVING = min{ HS_INTER1, HS_INTER2}

12.4.3.3.5.2 LP Command Mode Interleaving Programming Model

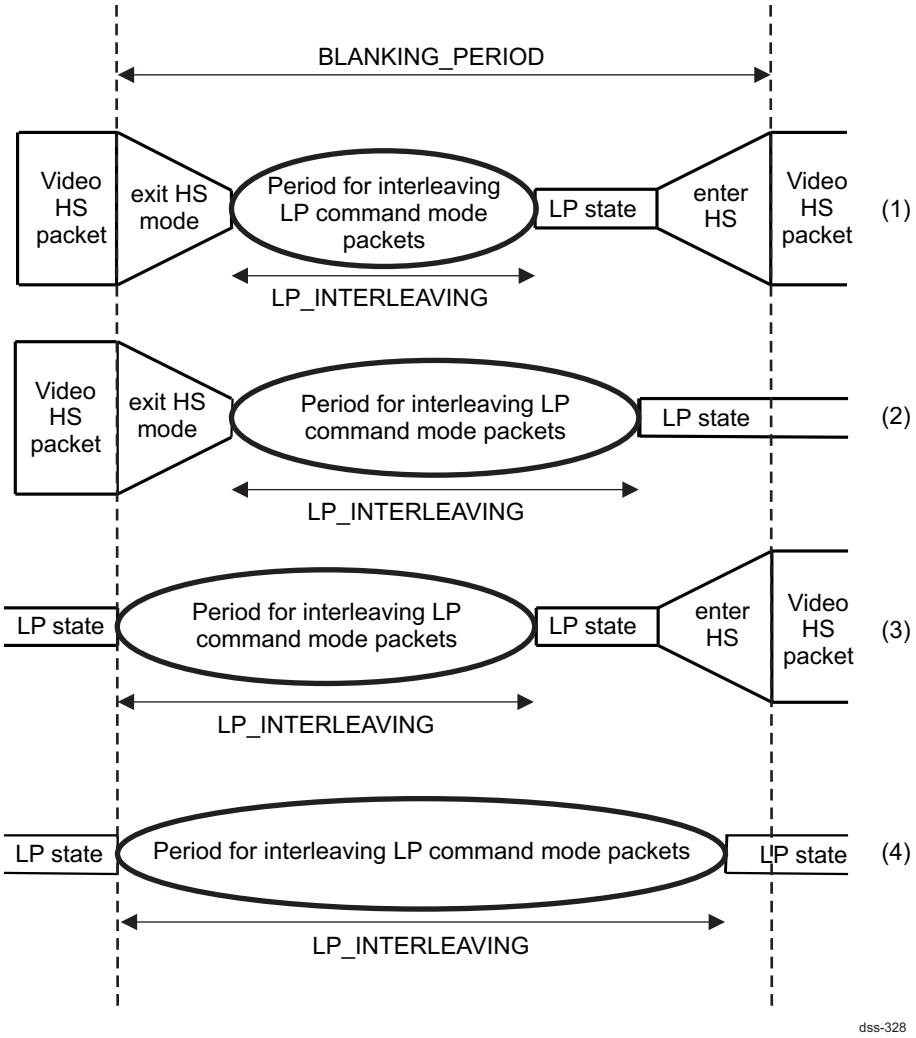
Figure 12-94 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of bytes of LP command mode packets that can be sent during a blanking period.

- BL_LP_INTERLEAVING bit field DSI_VM_TIMING6[15:0] defines the number of bytes of LP command mode packets that can be sent during a BLLP gap.
- HBP_LP_INTERLEAVING bit field DSI_VM_TIMING5[7:0] defines the number of bytes of LP command mode packets that can be sent during an HBP gap.
- HFP_LP_INTERLEAVING bit field DSI_VM_TIMING5[15:8] defines the number of bytes of LP command mode packets that can be sent during an HFP gap.
- HSA_LP_INTERLEAVING bit field DSI_VM_TIMING5[23:16] defines the number of bytes of LP command mode packets that can be sent during an HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

Figure 12-94. LP Command Mode Interleaving



For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The LP_INTERLEAVING period represents the maximal period in LP command mode packets. Its value is set in the BL_LP_INTERLEAVING, HSA_LP_INTERLEAVING, HBP_LP_INTERLEAVING, or HFP_LP_INTERLEAVING registers, depending on the blanking type.

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the LP_INTERLEAVING value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the LP_INTERLEAVING value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.

ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.

  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 1)
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (max{ ENTER_HS_MODE_LATENCY, 2} + 1)
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – 1

After finishing Step 1, the time period available for LP interleaving is known:

$T_{lp\_available}$ = ALLOWED_HSBYTE_CLOCKS_FOR_LP *T TxByteClkHS

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$LP\_INTERLEAVING < \left\lfloor \frac{\frac{Tlp\_available - 8*Thsbyte\_clk - 5*Tdsif\_clk}{Ttxclkesc}}{16} - 26 \right\rfloor$$

dss-E124

TxByteClkHS: Period of HS byte clock of DSI_PHY module

Tdsif_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

12.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO_CLK_ICG to gate the L3 interface clock (L3_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3_ICLK clock at DSI complex I/O level, set the DSS.DSI_CLK_CTRL[14] CIO_CLK_ICG bit to 1.

12.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users should take into account the delay in processing the transfer of the data from/to the slave port to/from the module.

12.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map should be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSI_PHY_CFG0 and DSS.DSI_PHY_CFG1) is done only when the DISPC_UPDATE_SYNC signal from the display controller is active and the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC_UPDATE_SYNC signal is asserted, the DSS.DSI_COMPLEXIO_CFG1[30] GObit is reset by hardware and there is no SCP transfer.
  - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the

DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

– If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer should complete prior to start the update of shadowing registers.

- When unsetting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI complex I/O are returned.

12.4.3.5.2 Busy Signal

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS_L3_ICLK clock.

12.4.3.6 Power Control

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

12.4.3.6.1 Complex I/O Power Control Commands

12.4.3.6.1.1 Complex I/O Power Control Commands

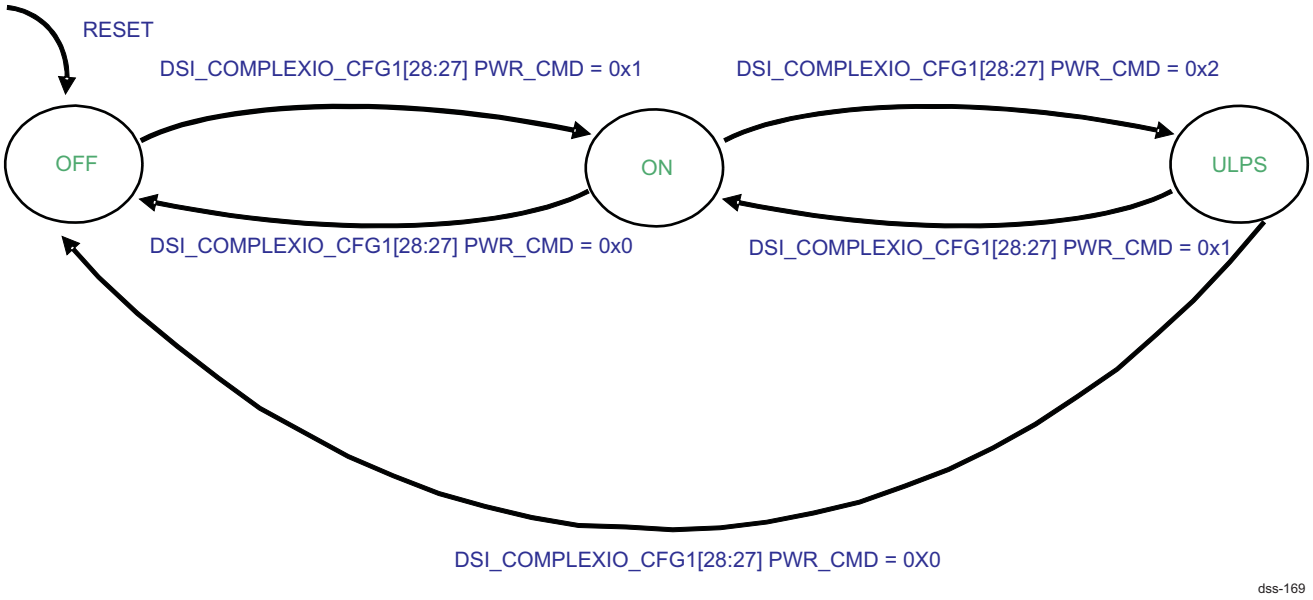
The DSI complex I/O can be set into three modes:

- OFF: In this power state, the complete DSI_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultralow-power state should only be used when all the three lanes are in ULPS (transmit or receive).

12.4.3.6.1.2 Complex I/O Power FSM

Figure 12-95 describes the power control FSM to control the power state of the complex I/O.

Figure 12-95. Complex I/O Power FSM



The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users should set the DSS.DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field to ask for a state change. The allowed transitions are: OFF -> ON and ON -> ULP and ULP -> OFF. The DSS.DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the DSI complex I/O.

CAUTION

- In automatic mode, the software should ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, users should ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot_ALL0_IRQ interrupt can be used by software users to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP status exit sequence (refer to Section 12.4.3.7.1 for details).

12.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

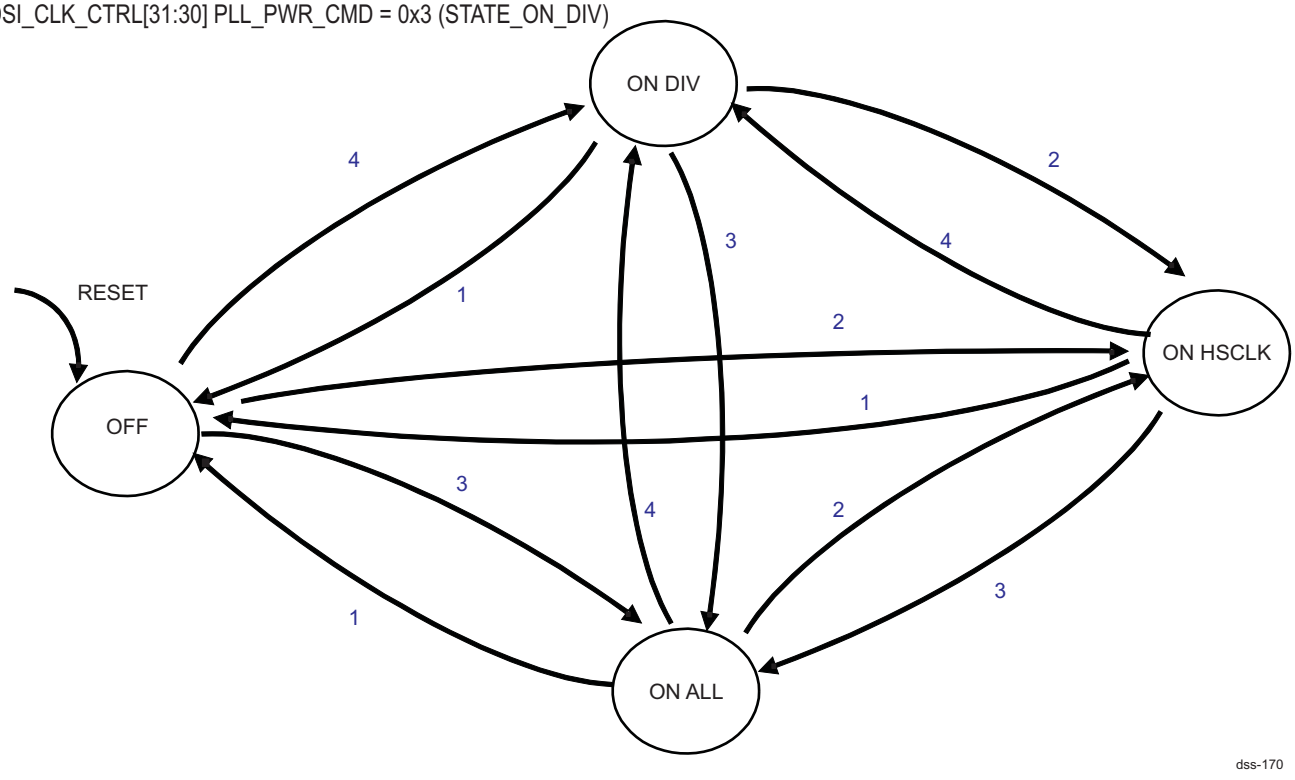
- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

12.4.3.6.2.1 DSI-PLL Power FSM

Figure 12-96 shows the DSI PLL power FSM.

Figure 12-96. DSI PLL Power FSM

1 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x0 (STATE_OFF)
2 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x1 (STATE_ON_HSCLK)
3 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x2 (STATE_ON_ALL)
4 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x3 (STATE_ON_DIV)



The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSClk controls the state transition of the DSI PLL control module. Software users should set the DSS.DSI_CLK_CTRL[31:30] PLL_PWR_CMD bit field to ask for a state change. The DSS.DSI_CLK_CTRL[29:28] PLL_PWR_STATUS bit field gives a status on the current state of the DSI PLL controller.

NOTE: In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL SYSRESET signals can be forced by the DSI PLL controller module by setting DSS.DSI_PLL_CONTROL[4] DSI_HSDIV_SYSRESET and DSS.DSI_PLL_CONTROL[3] DSI_PLL_SYSRESET bits, respectively. By setting these bits to 1, the SYSRESET signal is forced active (module is forced to reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

12.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI Protocol engine does not need to use the high-speed transfer mode (HS mode) and PLL HS output (HS_CLK clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the display controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0), the signal DSIStopClk is asserted.

The assertion of the DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
  - The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer should be on going or already scheduled
  - No VC active in video mode. No VC using the video mode is enabled; if the VC is enabled, the mode is command mode only (that is, DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1 and DSS.DSI_VCn_CTRL[4] MODE bit set to 0)
  - No command mode requiring high-speed transfer (one or more VCs using command mode can be active)
  - Or DSS.DSI_CTRL[0] IF_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required anymore).
- One video mode VC active
- At least one VC in command mode requiring high-speed transfer
- The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSS.DSI_CTRL[0] IF_EN bit should be reset to 0 for updating the DDR_CLK_ALWAYS_ON bit value)

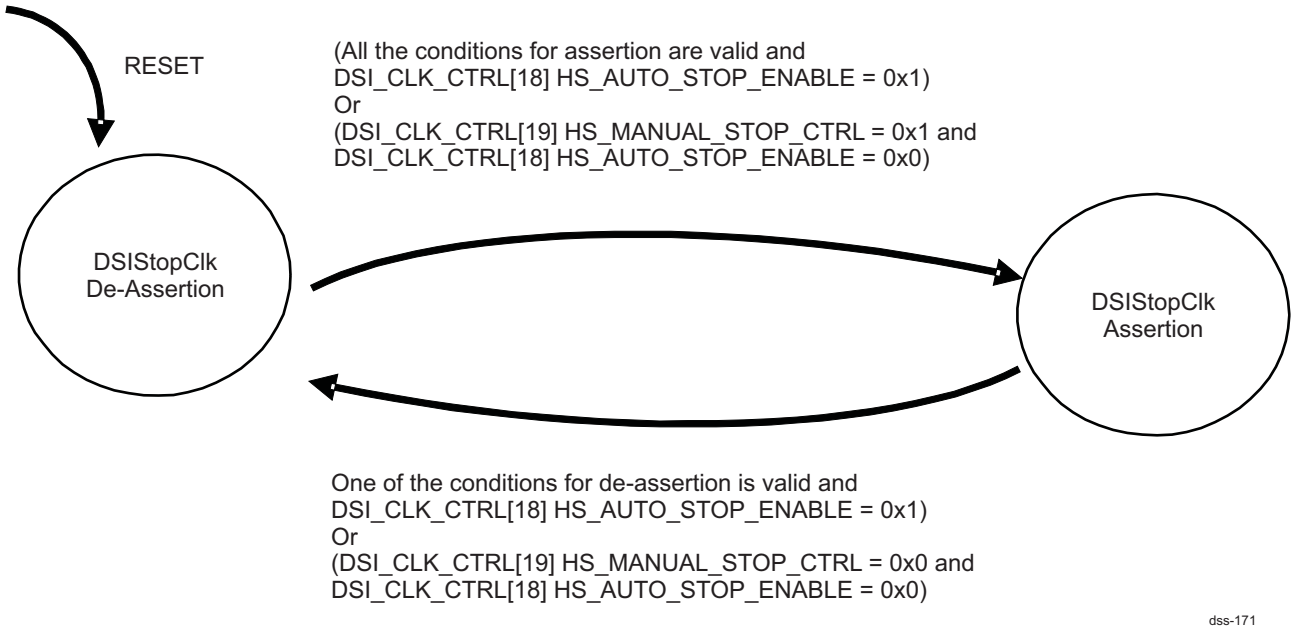
The automatic assertion/deassertion is enabled by using the DSS.DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

The manual mode can be used by setting/resetting the DSS.DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert/deassert the DSIStopClk signal.

12.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 12-97 shows the DSI PLL HS clock FSM.

Figure 12-97. DSI PLL HS Clock FSM



When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI_PHY) before TxByteClkHS is stopped. This latency must be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

CAUTION

The programmed value in the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field must be greater than ((3 x L3_ICLK period) + (5 x CLKIN4DDR period))/(DSI_FCLK period).

12.4.3.7 Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

12.4.3.7.1 Twakeup Timer

The T_{WakeUp} timer is not implemented in the DSI protocol engine. The software must use a general-purpose (GP) timer to handle this. This timer is used for existing ULP status mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI_COMPLEXIO_IRQSTATUS ULPSACTIVENOT_ALLi_IRQ bit fields (i = 0, 1).
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE

state for the data lane(s).

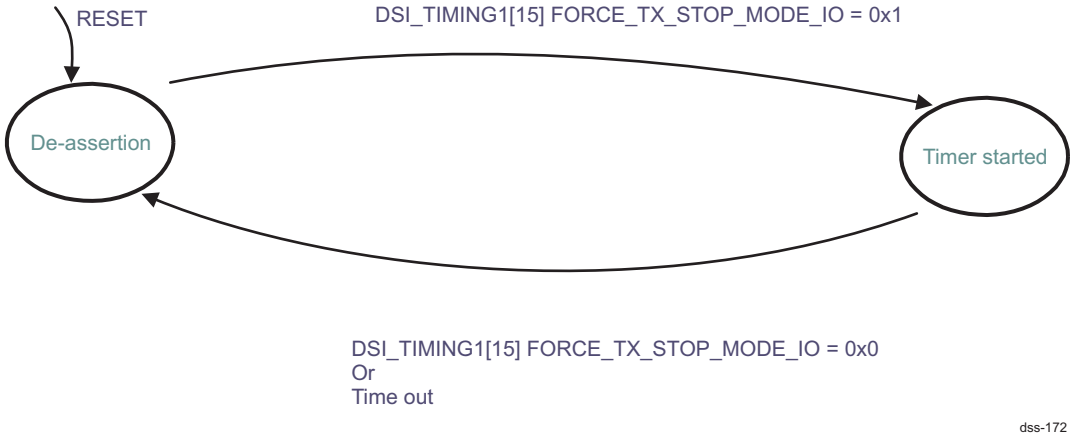
NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state should be change to active state. To enter ULPS mode for data lane, TxRequestEsc state should be changed to active state (TxUlpsEsc as well if it is not in active state already).

12.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). Figure 12-98 describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

Figure 12-98. ForceTxStopMode FSM



The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, Stop_State_x4_IO, Stop_State_x16_IO field DSI_TIMING1[15:0]. The FORCE_TX_STOP_MODE_IO bit is reset by hardware when the time is reached.

This bit can be reset by software.

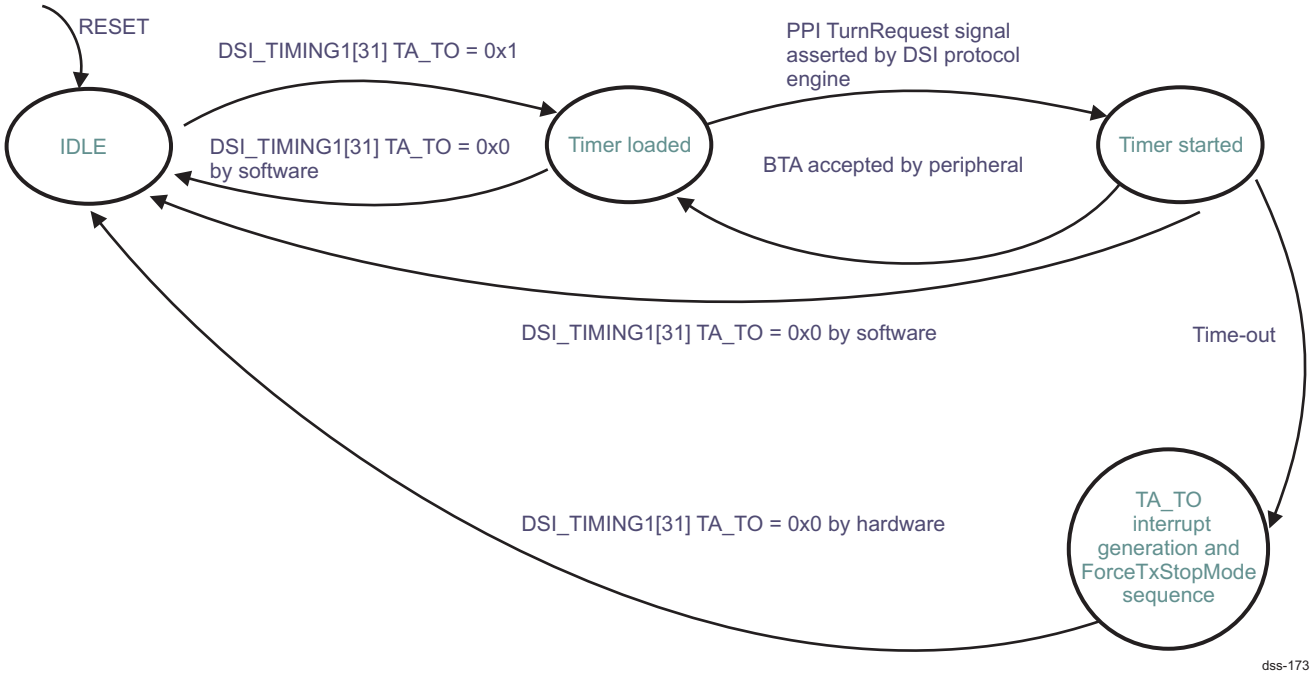
The calculation of the number of DSI_FCLK cycles assertion period is defined by:

Total period in DSI_FCLK cycles = DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO x ((DSI_TIMING1[14] STOP_STATE_X16_IO x 15) + 1) x ((DSI_TIMING1[13] STOP_STATE_X4_IO x 3) + 1)

12.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes can not be used in the reverse direction to receive data from the DSI receiver. Figure 12-99 describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 12-99. TurnRequest FSM



The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled through the DSS.DSI_VCn_CTRL[6] BTA_EN bit (for more information, see Section 12.4.3.8, *Bus Turnaround*. The DSS.DSI_TIMING1[31] TA_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI_FCLK cycles:

DSI_TIMING1[28:16] TA_TO_COUNTER x ((DSI_TIMING1[30] TA_TO_X16 x 15) + 1) x ((DSI_TIMING1[29] TA_TO_X8 x 7) + 1).

When the TA_TO_IRQ interrupt is generated (turn-around timer expired and procedure failed), the hardware automatically asserts ForceTXStopMode in order for the DSI_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset to 0 before starting the recovery sequence.

12.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer)should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

12.4.3.7.5 HS TX Timer

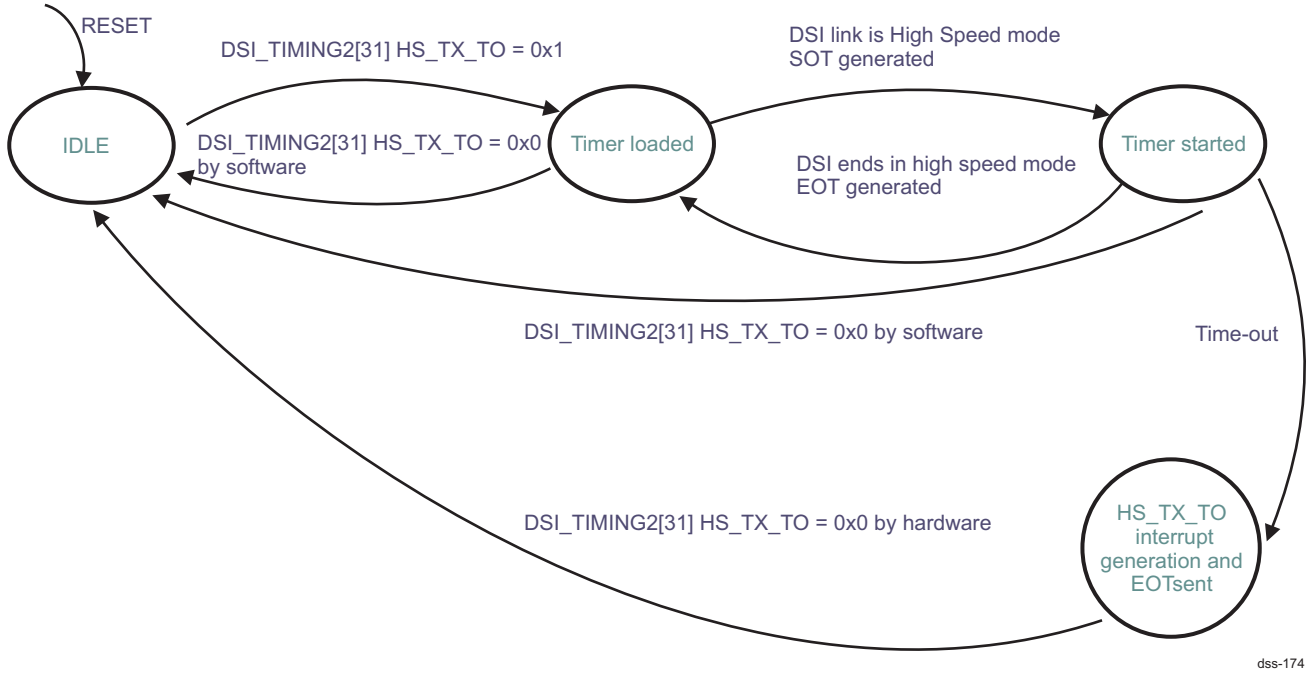
The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI_TIMING2[31] HS_TX_TO bit. The interrupt HS_TX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

DSI TIMING2[28:16] HS_TX_TO_COUNTER x ((DSI TIMING2[30] HS_TX_TO_X16 x 15) +1) x ((DSI TIMING2[29] HS_TX_TO_X8 x 7) +1)

Figure 12-100. High-Speed TX Timer FSM



When the time-out occurs, the hardware should sent EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI_CTRL[0] IF_EN bit.

The software should wait for the DSS.DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

12.4.3.7.6 LP RX Timer

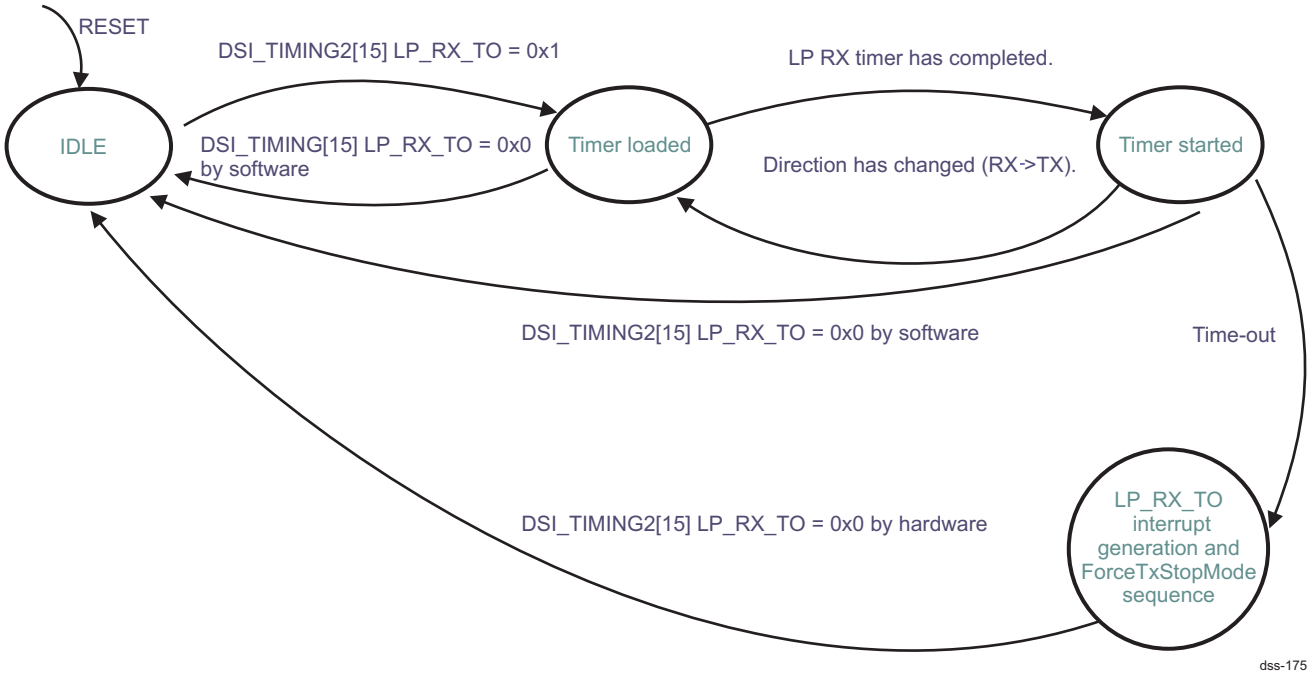
When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP_RX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI_TIMING2[15] LP_RX_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI_FCLK cycles:

DSI_TIMING2[12:0] LP_RX_TO_COUNTER x ((DSI_TIMING2[14] LP_RX_TO_X16 x 15) + 1) x ((DSI_TIMING2[13] LP_RX_TO_X4 x 3) + 1)

Figure 12-101. Low-Power RX Timer FSM



When the interrupt is generated, the hardware should automatically reset the DSS.DSI_TIMING2[15] LP_RX_TO bit and then assert ForceTXStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI_VCn_CTRL[0] VC_EN is set to 1).

12.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each VC ID. The VC can be enabled when DSS.DSI_VCn_CTRL[6] BTA_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. For more information about possible DSI PHY timing adjustments during the turn-around procedure, see Section 12.5.6.4.3, *Turn-Around Request in Transmit Mode*, and Section 12.5.6.4.4, *Turn-Around Request in Receive Mode*. When setting the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

Acknowledgment from the peripheral for successful BTA is indicated by asserting the BTA_IRQ interrupt, if it is enabled in the DSS.DSI_VCn_IRQENABLE[5] BTA_IRQ_EN bit. To monitor the BTA interrupt, the user must read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit.

CAUTION

The BTA should not be sent when the RX FIFO is not empty. Users should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN or the DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bits are set to 1.

NOTE: If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit is enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit is enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN and DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bits are both enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to send a BTA. Only one BTA is sent and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

As explained previously, two modes can be used for each VC ID:

- Automatic: After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.DSI_VCn_LONG_PACKET_HEADER register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.DSI_VCn_LONG_PACKET_PAYLOAD register).
- Manual: In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, users can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) users can not determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a VC in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET_SENT_IRQ) is provided to indicate users when the packet has been completely sent by the DSI complex I/O. The PACKET_SENT_IRQ can be monitored in DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit. Users can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.DSI_VCn_CTRL[6] BTA_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turnaround is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent, that is, when one of the following bits is set to 1:

- DSS.DSI_CTRL[20] BLANKING_MODE
- DSS.DSI_CTRL[21] HFP_BLANKING_MODE
- DSS.DSI_CTRL[22] HBP_BLANKING_MODE
- DSS.DSI_CTRL[23] HSA_BLANKING_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA_TO timer is started. If the direction signal is no changed according to the turn-around request, the TA_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). Refer toSection 12.4.3.7.3 for more details on the TA_TO timer.

12.4.3.9 PHY Triggers

The DSI protocol engine uses three triggers, which are supported only for data lane 1:

- Reset from host to display
- Tearing effect (TE) from display to host
- Acknowledge from display to host

CAUTION

Each trigger is associated with a dedicated user-configurable receive or transmit pattern, loaded in the DSI_PHY_CFG3 or DSI_PHY_CFG4 bit fields. The default (reset) values of the bit fields are aligned with the MIPI DSI_PHY specification v0.9. If the user must change any of these values, the following must be considered:

- If any of the bit fields is written with a non-default value, the other bit fields in the same register must also be configured with different values. This is to ensure that two different trigger bit fields are not programmed with the same pattern.
- If two or more bit fields are written with equal values, this may lead to unpredictable behavior of the DSI PHY module.

12.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY to send a reset to the display. The reset trigger pattern is configurable through the DSI_PHY_CFG3[31:24] TXTRIGGERESC3 bit field. To send the reset pattern to the peripheral, the DSS.DSI_CTRL[5] TRIGGER_RESET bit must be set to 1. When the software requires the trigger reset pattern to be sent, the DSI protocol engine resets its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is VC using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.DSI_CTRL[14] TRIGGER_RESET_MODE.

CAUTION

For both reset modes, the hardware should flush the FIFOs, synchronization buffers, and line buffers before resetting the DSS.DSI_CTRL[0] IF_EN bit.

12.4.3.9.2 Tearing Effect

The TE on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. Users are responsible for selecting the command mode for the VC using the TE feature.

The software must set and send the appropriate sequence to receive the TE trigger pattern from the peripheral. The value of the expected TE trigger pattern can be configured through the DSI_PHY_CFG4[23:16] RXTRIGGERESC2 bit field. When the TE trigger pattern is received, the DSI protocol engine generates the TE_TRIGGER_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.DSI_IRQENABLE[16] TE_TRIGGER_IRQ_EN bit. The DSS.DSI_IRQSTATUS[16] TE_TRIGGER_IRQ status bit indicates if the interrupt event has been generated.

One or multiple VCs can be synchronized using the same TE trigger. The DSS.DSI_VCn_TE[30] TE_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related VC. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI_VCn_TE[31] TE_START bit should be used when the automatic mode enabled by setting the DSS.DSI_VCn_TE[30] TE_EN bit is not used. It allows users to start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI_VCn_TE[15:0] TE_SIZE bit field should be set first to indicate that the following accesses to DSS.DSI_VCn_LONG_PACKET_HEADER register should be used for TE transfer.

The data can be provided from two sources (selection by setting the DSS.DSI_VCn_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI_DMA_REQi (where i =0 to 3) to should be asserted only when TE trigger is received or when the DSS.DSI_VCn_TE[31] TE_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field have been sent on the DSI link. The VC is associated with a DMA request (from DSI_DMA_REQ0 to DSI_DMA_REQ3) by programming the number in the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field. The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field (the check-sum value is not provided in the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI_CTRL[13:12] LINE_BUFFER bit field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI_VCn_TE[31] TE_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is not a multiple of the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI_VCn_TE[15:0] TE_SIZE bit field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field).

When the transfer is completed, the value of the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is equal to 0. The software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSS.DSI_VCn_CTRL[5] TX_FIFO_NOT_EMPTY status bit.

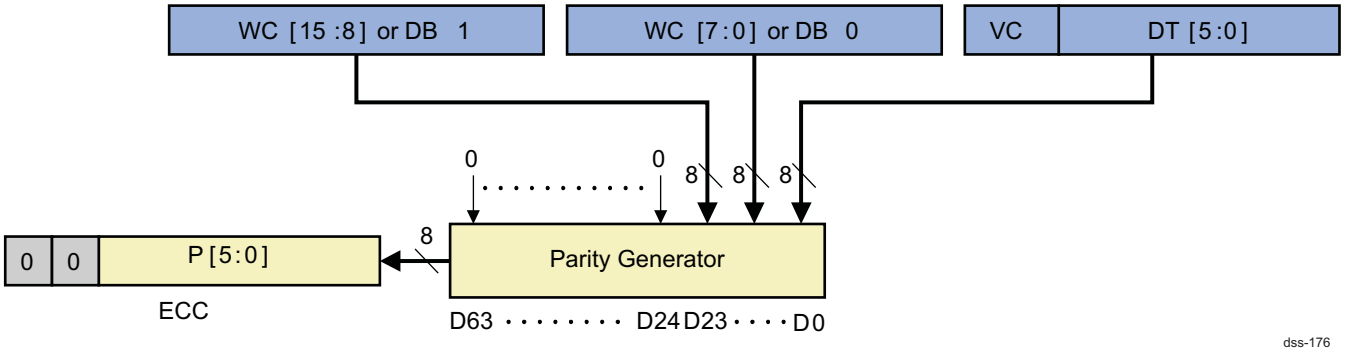
12.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK_TRIGGER_IRQ) is generated upon reception of the acknowledge trigger. The value of the expected acknowledge trigger pattern can be configured through the DSI_PHY_CFG4[15:8] RXTRIGGERESC1 bit field. To enable the acknowledge interrupt, set the DSS.DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSS.DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

12.4.3.10 ECC Generation

Note that the DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in Figure 12-102.

Figure 12-102. 64-Bit ECC Generation on TX Side



The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

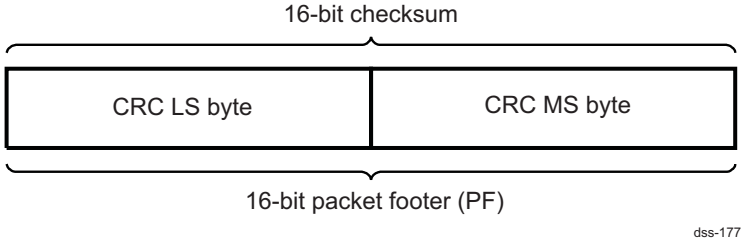
- The DSS.DSI_CTRL[2] ECC_RX_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit enables/disables the ECC generation in the transmit direction

12.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to 2^{16} - 1 bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals. It is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor should disable checksum checking for received long packets from peripherals that do not support checksum generation.

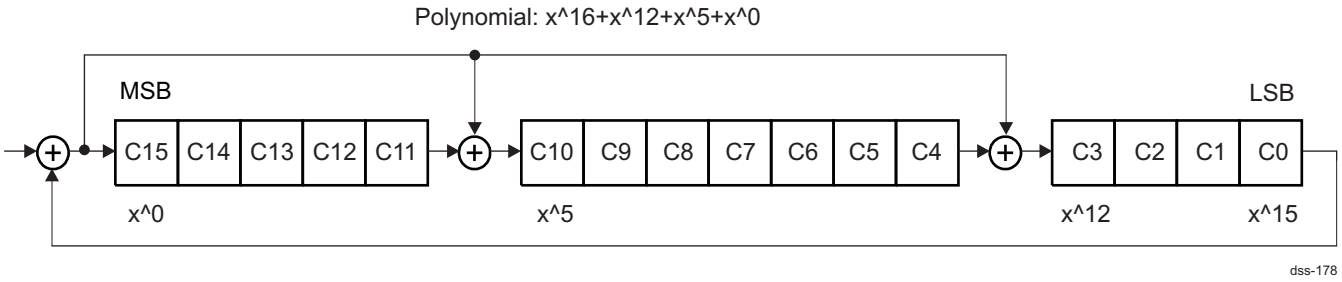
The checksum should be realized as a 16-bit CRC with a generator polynomial of x^16+x^12+x^5+x^0. The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

Figure 12-103. Checksum Transmission



The CRC implementation is presented in Figure 12-104. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

Figure 12-104. 16 Bit CRC Generation Using a Shift Register



The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI_CTRL[1] CS_RX_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI_VCn_CTRL[7] CS_TX_EN bit enables/disables the check-sum generation in the transmit direction

12.4.3.12 End of Transfer Packet

To allow the DSI protocol (rather than the DSI_PHY) at the display to detect the HS End Of Transfer (EOT), an EOT packet type is added. It is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the DSI_CTRL[19] EOT_ENABLE bit.

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more than one data lane is used, the bytes in the EOT packet are distributed across multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through the same as any other packet, but no internal decode or use is made of the EOT information.

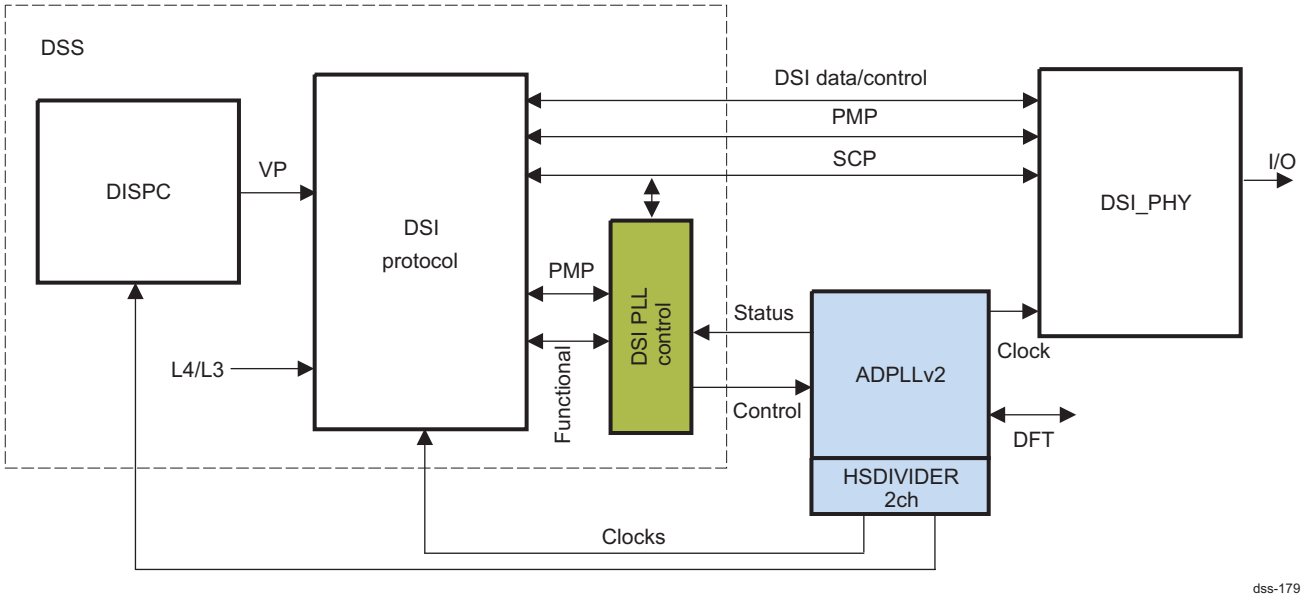
12.4.4 DSI PLL Controller Functionalities

12.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the display sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPLL and HSDIVIDER modules. Figure 12-105 provides an overview of the DSI PLL controller module inside the display subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

Figure 12-105. DSI PLL Controller Overview



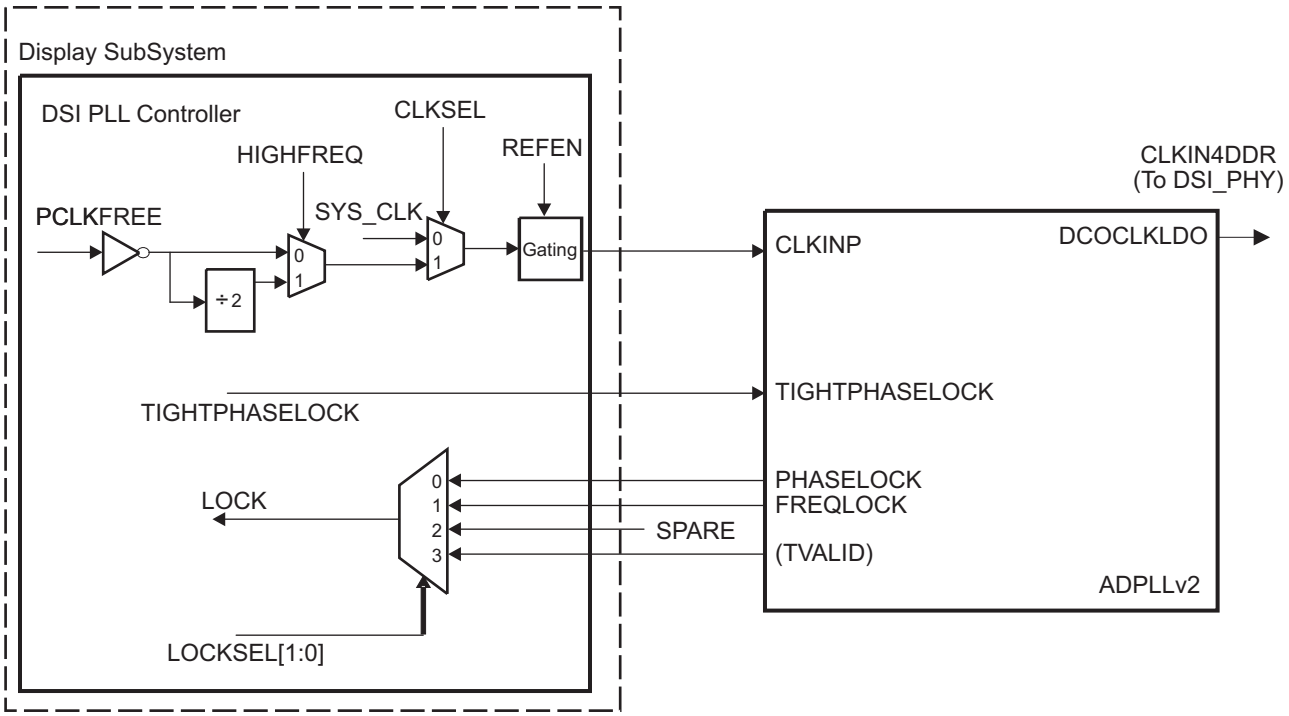
NOTE: The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

12.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLLv2 module. The pixel clock (PCLK) frequency range is 2 to 65 MHz. This may be divided by 2. This is performed by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

Figure 12-106 shows the internal DSI PLL reference diagram.

Figure 12-106. DSI PLL Reference Diagram



The DSI PLL clock output corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI_PLL_REFCLK clock. Depending on the setting in DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit, the reference clock can be either the DSS2_ALWON_FCLK provided by the PRCM or the PCLKFREE provided by the DISPC module.

12.4.4.3 DSI PLL Operations

The DSI PLL configuration signals operate according to Table 12-35. Table 12-35 indicates the operation when the PLL is not locked.

Table 12-35. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop mode Low power[1]	Stop mode Fast Relock[1]	Idle bypass
Mode Description	**Output clocks stopped Lowest power standby**	**Output clocks stopped Fastest start-up time**	**Selects when PLL and HSDIVIDER bypass clocks are used**
DSS.DSI_PLL_CONFIGURATION2[0] DSI_PLL_IDLE	0	0	1
DSS.DSI_PLL_CONFIGURATION2[6] DSI_PLL_LOWCURRSTBY	1	0	1
DSS.DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	1	1	X

(1) Recommended

When locked, the PLL output frequency is: [(2xREGM)/(REGN + 1)] x [CLKin(MHz)/(HIGHFREQ + 1)] where:

- M multiplier is programmed in DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field.
- N divider is programmed in DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field.
- HIGHFREQ divider by 2 is enabled by setting the DSS.DSI_PLL_CONFIGURATION2[12]

DSI_PLL_HIGHFREQ bit to 1.

12.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the display controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. Refer to Section 12.4.3.5.1 for more details.

12.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

12.4.5 DSI Complex I/O Functionalities

12.4.5.1 DSI Complex I/O Overview

DSI_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support high-speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things.

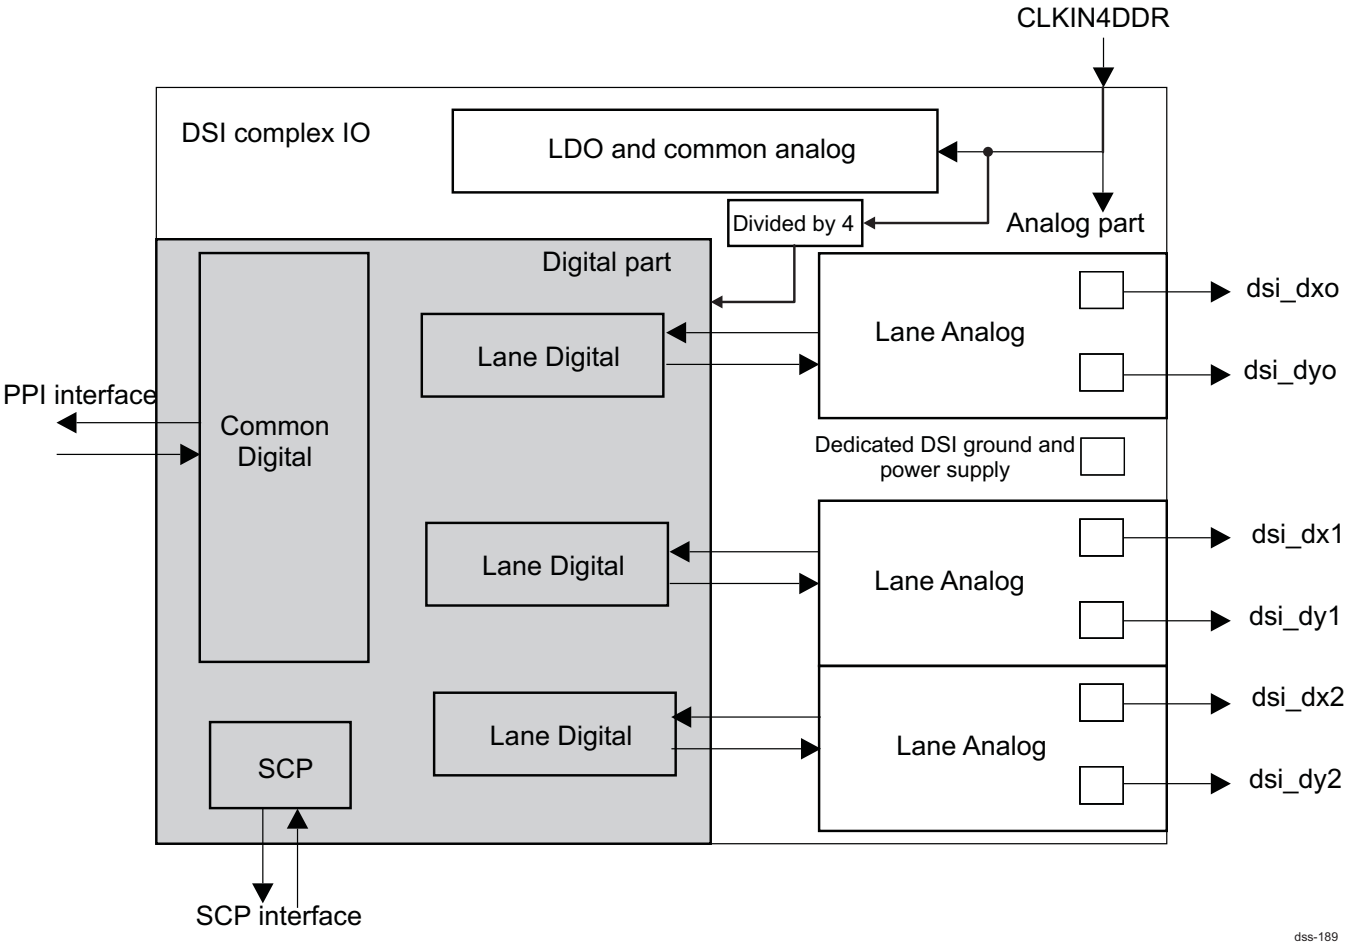
The maximum data rate supported in high-speed Mode is 800Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI_PHY spec.

DSI_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI_PHY supports GPIO operation on each of the six data pins.

12.4.5.2 DSI Complex I/O Architecture

Figure 12-107 shows the top-level block diagram of DSI_PHY. It has 3 lane module functions, and some common analog and digital functions. Each lane module has an analog and a digital part. The digital lane circuitry implements the protocol interface of MIPI DSI_PHY. It interacts with the DSI protocol engine.

Figure 12-107. DSI Complex I/O Architecture



The lane module analog circuit converts the digital levels to the LP and HS level signals for the link. It also converts the analog state of the link into digital levels.

For high-speed signals, the lane module analog also does the last stage untiming of HS data to obtain optimum quadrature with the HS clock.

DSI_PHY has an internal LDO to generate 1.2V supply. This LDO requires an off-chip decoupling capacitor and hence a dedicated pin. DSI_PHY expects a high frequency clock input in HS mode.

The clock input is required to have four times the frequency of the DDR clock, that is, twice the HS data rate. GPIO functions are supported on each dsi_dxi and dsi_dyi.

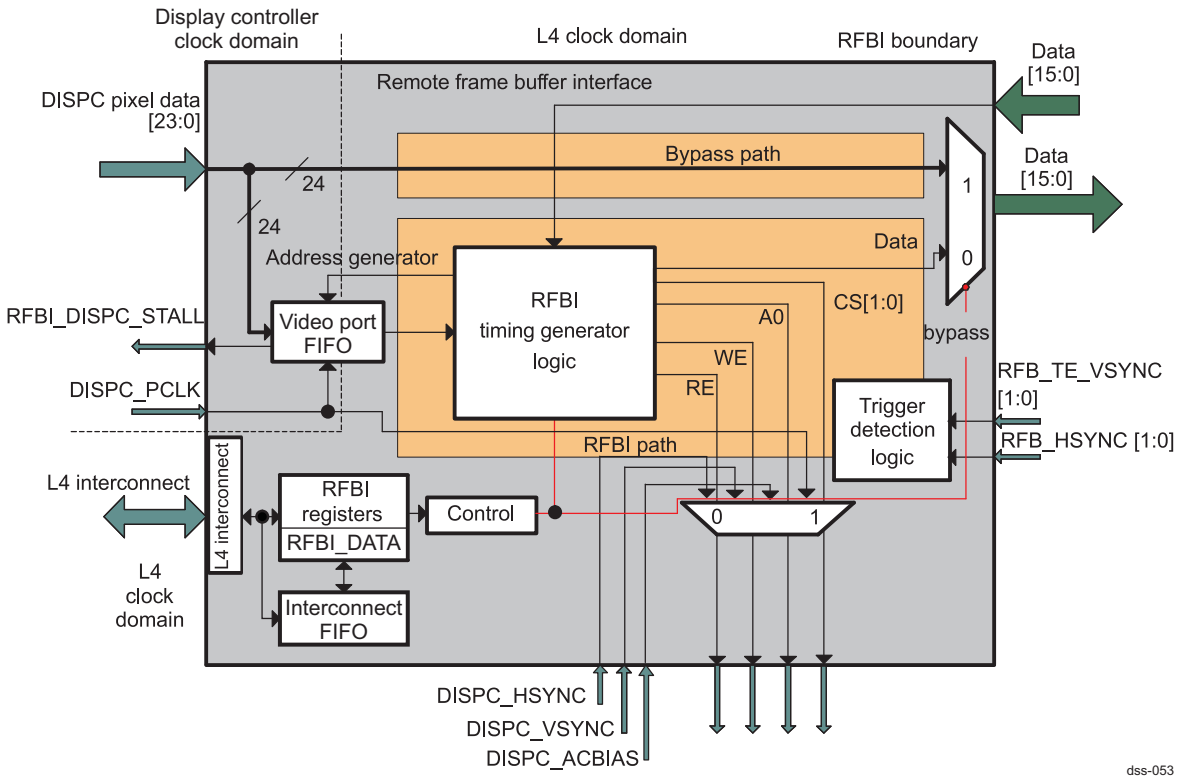
12.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

Figure 12-108 shows an overview of the RFBI architecture.

Figure 12-108. RFBI Architecture Overview



12.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 12.4.6.4, *Output Parallel Modes*, shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

12.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA).

12.4.6.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

12.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format (i = 0 or 1) (see also Table 12-36):

- The DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is set to 0x3 (three cycles for two pixels).

- The DSS.RFBI_DATA_CYCLE1_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI_DATA_CYCLE2_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI_DATA_CYCLE3_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

Table 12-36. 16-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

12.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

12.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

12.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

12.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WR signal), RE (RFBI_RD signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

Table 12-37 describes the read/write function.

Table 12-37. Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WR)	RE (RFBI_RD)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 12-38, is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

Table 12-38 indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 12-38. Minimum Cycle Time for CSx/WE Always Asserted

RFBI Performance	RFBI_CONFIGi[10:9] CYCLEFORMAT	RFBI_CONFIGi[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

12.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC (for more information, see Section 12.2, *Display Subsystem Environment*). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

Figure 12-109 shows an overview of the video encoder architecture.

Figure 12-109. Video Encoder Architecture Overview

NOTE: Output video mode can be either composite video (CVBS output) or Separate video (s-video: Luma and chroma outputs):

- Composite video: DAC1 is used
- Separate video (luma/chroma): Both DAC1 (luma) and DAC2 (chroma) are used
  The selection is programmed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit. Composite video is the default selection.

12.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field VENC_F_CONTROL[7:6] register to 0x1.

Table 12-39. 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16
Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

12.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC_GAIN_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC_BLACK_LEVEL and DSS.VENC_BLANK_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

12.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC_GAIN_U and DSS.VENC_GAIN_V register bits.

12.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$S\_CARR = ROUND ([F_{sc}/F_{clkenc}] \times 2^{32})$

where:

F_{sc} = Frequency of the subcarrier

F_{clkenc} = Frequency of the internal video encoder

The DSS.VENC_S_CARR register controls the subcarrier frequency. The DSS.VENC_C_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC_C_PHASE. Table 12-40 presents the VENC_S_CARR register values depending the standard and pixel type used.

Table 12-40. VENC_S_CARR Register Recommended Values

Standard	Pixel Type	Subcarrier Frequency (Fsc) (MHz)	Fclkenc (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I	ITU-R601	4.43361875	27	0x2A098ACB
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I	Square pixel	4.43361875	29.50	0x26798C0C

CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset
- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC_BSTAMP_WSS_DATA[6:0] BSTAP bit field sets the amplitude of the color burst. The DSS.VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC_M_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC_M_CONTROL[5] PALPHS bit selects one of these sequences.

12.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see Table 12-41).

Table 12-41. Closed-Caption Data Format

MSB							LSB
Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Odd parity

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[1] bit enables closed-caption encoding in even fields.

To select the scan line where the CC data are encoded, program the VENC_LN_SEL[4:0] SLINE bit field.

CAUTION

The setting of the value of the SLINE[4:0] bit field depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value 0x15 – 1 = 0x14. The default value is 0x15 + 1 = 0x16 (line 22).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value 0x15 – 4 = 0x11. The default value is 0x15 + 4 = 0x19 (line 25).

The DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC_LINE21[15:8] L21O and DSS.VENC_LINE21[7:0] L21O bit fields contain the first and the second bytes, respectively, of closed-caption data to be encoded in the odd field. The DSS.VENC_LINE21[31:24] L21E and DSS.VENC_LINE21[23:16] L21E bit fields contain the first and the second bytes, respectively, of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC_STATUS[4] CCE or DSS.VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC_STATUS[4] CCE bit or the DSS.VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in Figure 12-110, a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xfline) for NTSC-601. The closed-caption running clock common frequencies are detailed in Table 12-42.

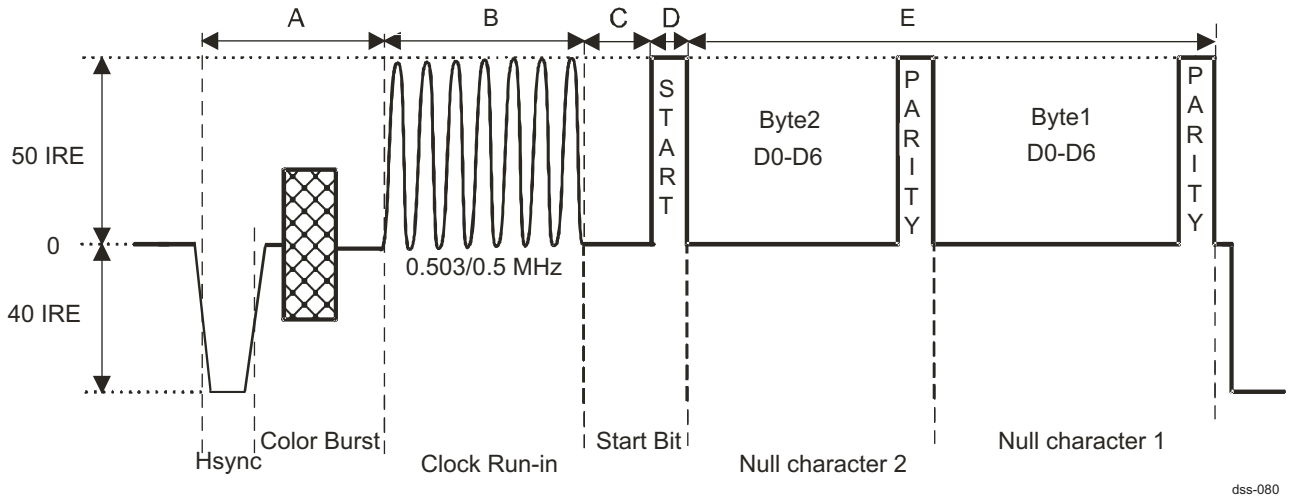
Table 12-42. Closed-Caption Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

Figure 12-110 shows the parameters of closed-caption line data implemented in different standards.

Figure 12-110. Closed Captioning Timing



NOTE:

- The interval A is controlled by the DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field.
- The interval B is controlled by DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field.

Table 12-43. Closed-Caption Standard Timing Values

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 µs	10.500 µs	10.750 µs	10.000 µs	10.500 µs	11.000 µs
B	Clock running		12.910 µs			12.910 µs	
C	Clock running to third start bit		3.972 µs			3.972 µs	
D	Start bit		1.986 µs			1.986 µs	
E	Data characters		31.778 µs			31.778 µs	

NOTE: All timing values listed in Table 12-43 are measured from the mid-point (half amplitude) on all edges.

For a complete description of copy protection including CGMS-A, please refer to CEA-608-x standard

12.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC_L21_WC_CTL[14:13] EVEN_ODD_EN bit and by programming the VENC_BSTAMP_WSS_DATA[27:8] WSS_DATA bit field.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in Table 12-44

Table 12-44. Wide-Screen Signaling Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.VENC_L21_WC_CTL[12:8] LINE bit field.

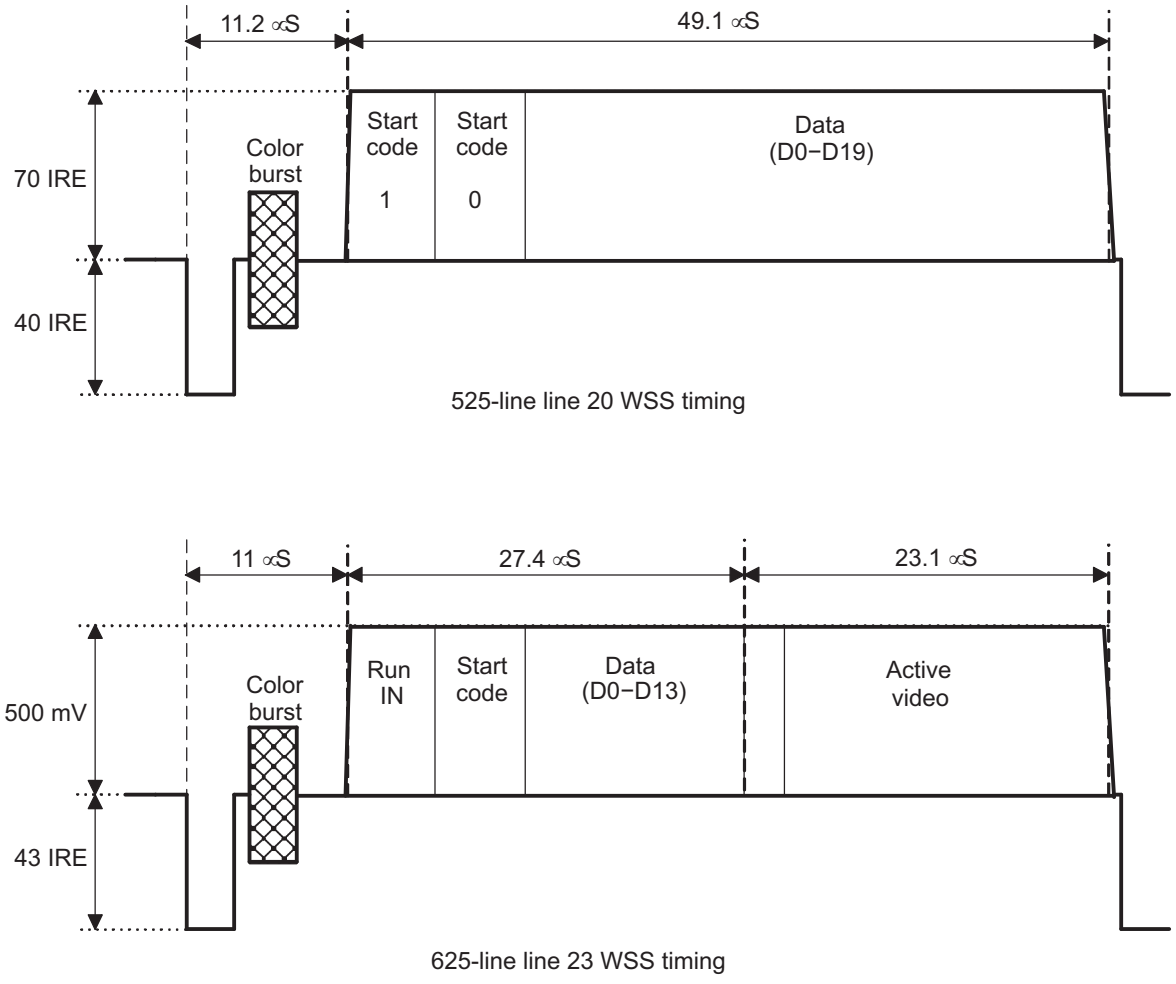
CAUTION

The setting of the LINE[12:8] bit field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line 0x16 + 1 = 0x17 (23rd line). Note that the default value is 0x14 + 1 = 0x15 (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line 0x10 + 4 = 0x14 (20th line). Note that the default value is 0x14 + 4 = 0x18 (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in Figure 12-111.

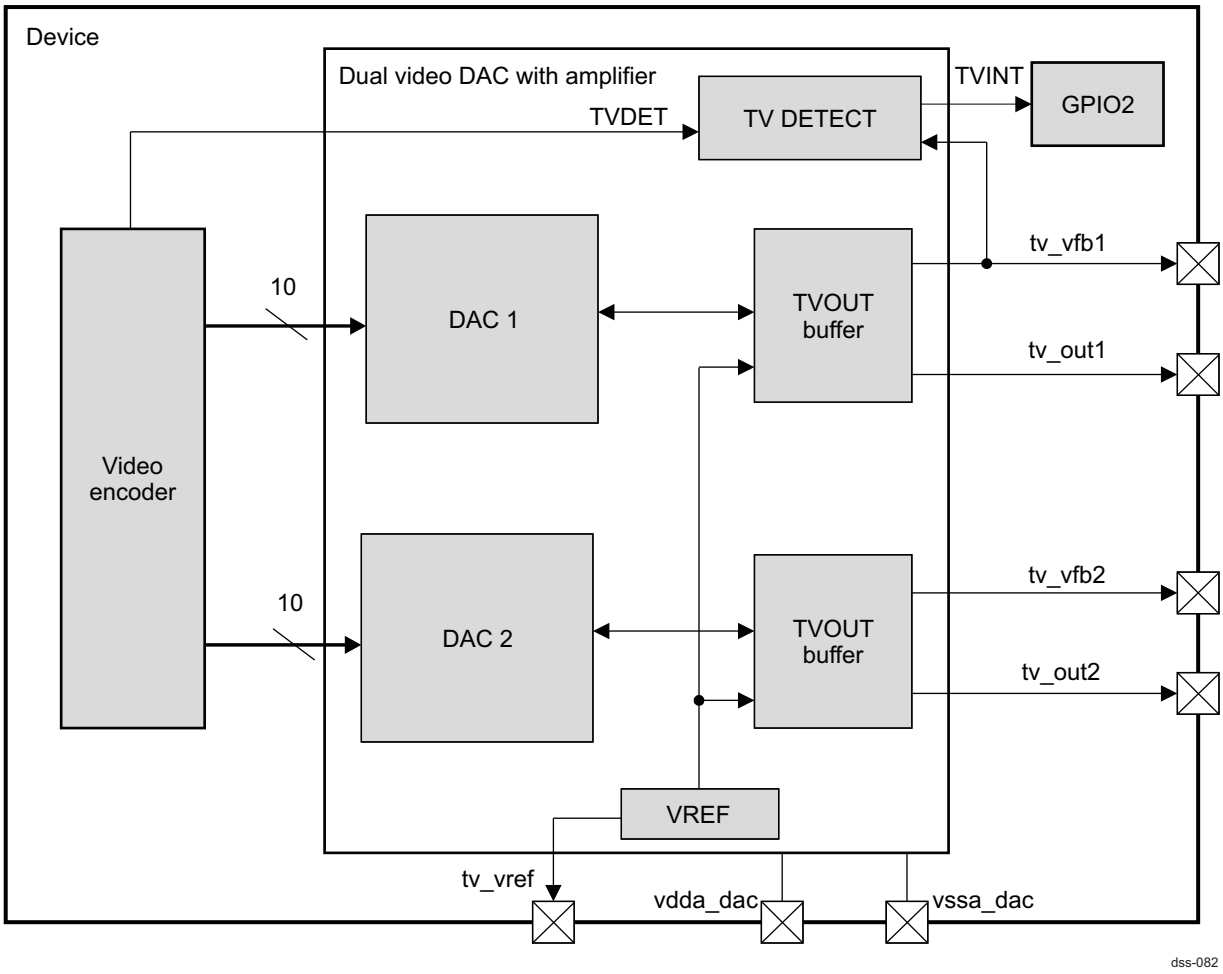
Figure 12-111. WSS Timing



12.4.7.7 Video DAC Architecture

Figure 12-112 shows the architecture of the dual 10-bit video DAC.

Figure 12-112. Dual 10-Bit Video DAC Architecture



The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering DAC is used to generate the video analog signal. The video mode DAC 1 (luma/composite) also includes the TV detection/disconnection and power-down mode features.

12.4.7.8 Video DC/AC Coupled TV Load

The dual 10-bit video DAC supports both dc-coupled and ac-coupled TV loads. The CONTROL.CONTROL_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: Dc coupling; 1: Ac coupling). This bit is the first one to be programed according to the TV load on the PCB board.

NOTE: When dc coupling is used, note that there is a 385-mV dc offset at the TVOUT output (tv_out1 for DAC1 and tv_out2 for DAC2).

12.4.7.9 TV Detection/Disconnection Pulse Generation and Usage

12.4.7.9.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the dual video DAC module.

NOTE:

- The TV detection/disconnection feature is supported only for VDAC1.
- The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output (tv_out1) to reference (tv_vref) voltages, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is ac or dc coupling to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC_TVDETGP_INT_START_STOP_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC_TVDETGP_INT_START_STOP_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC_GEN_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC_GEN_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

12.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
   - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
   - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
   - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. Set the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the vdda_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I^2C interface connected to the power IC .
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

CAUTION

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

12.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
   - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
   - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
   - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the vdda_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I^2C interface connected to the power IC.

CAUTION

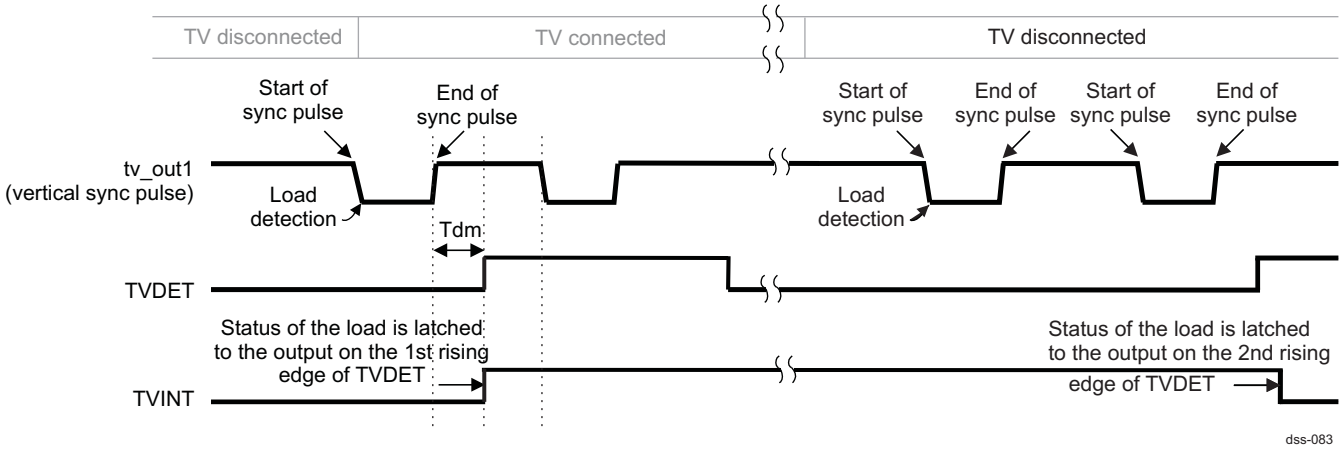
- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

12.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in Section 12.4.7.9.2, *TV Detection Procedure*, and in Section 12.4.7.9.3, *TV Disconnection Procedure* by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is Tdm, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

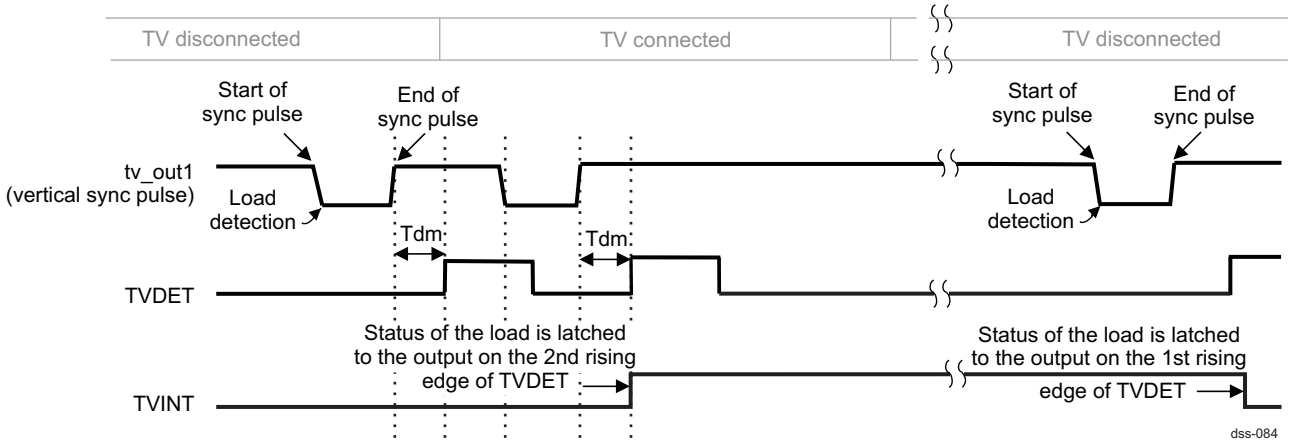
If dc-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. Figure 12-113 shows the waveforms for the dc-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 12-113. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected



If ac-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 12-114 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 12-114. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected



NOTE:

- When setting the DSS.VENC_TVDETGP_INT_START_STOP_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the tv_out1 output signal.

12.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For dc operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is connected. For ac operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For dc-coupling mode, see Figure 12-115 and for ac-coupling mode, see Figure 12-116

NOTE: Because the video DAC and the video encoder must be awake for connection detection, consider that the video DAC can take up to 10 µs to wake up.

Figure 12-115. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode

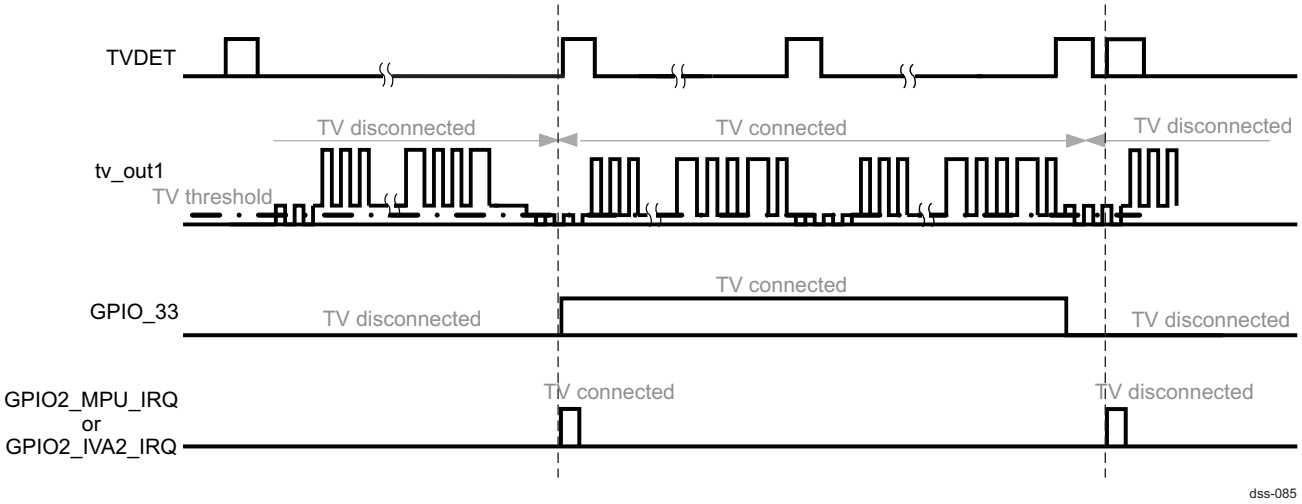


Figure 12-116. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode

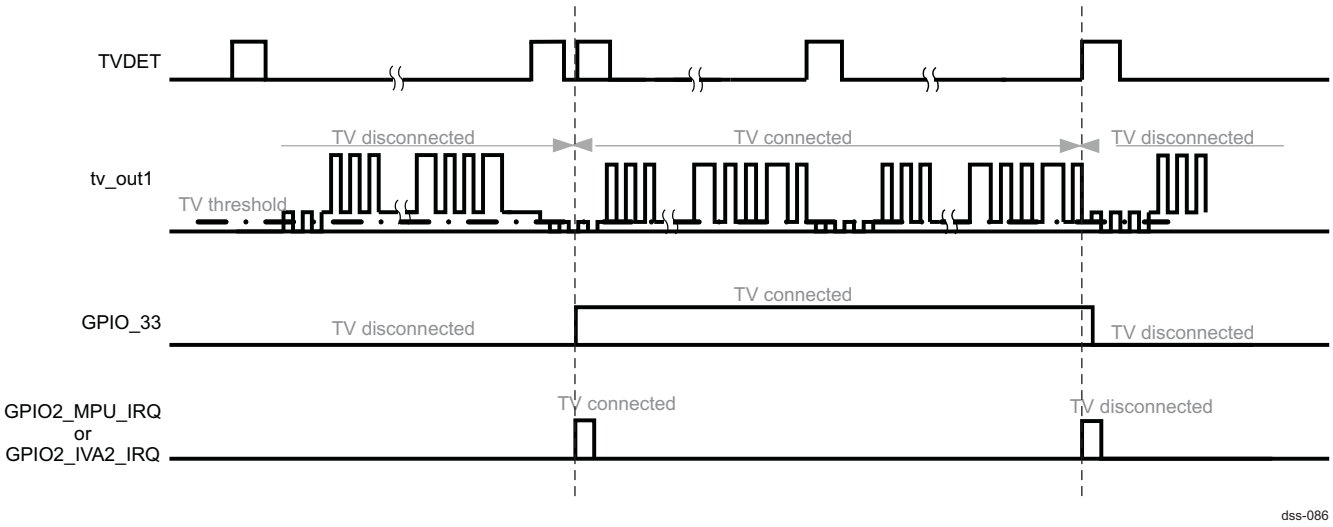

12.4.7.10 Video DAC Bypass Mode

The dual 10-bit video DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the VFB pins (tv_vfb1 for DAC1 and tv_vfb2 for DAC2).

This bypass mode is activated by setting the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

NOTE: In bypass mode:

- the tv_out1 pin requires a RSET resistor connected to the ground. The typical value of the RSET resistor is 3.92 K.
- both tv_vfb1and tv_vfb2 pins require a RLOAD resistor connected to the ground. The typical value of the RLOAD resistor is 976.

CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external amplifier is needed on the tv_vbf1 and tv_vbf2 pins.

12.4.7.11 Video Dual-DAC Test Mode

The DAC can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DAC. See Figure 12-117 for video DAC test in composite video mode, and see Figure 12-118 for video DAC test in separate video mode.

Figure 12-117. DAC Test Mode in Composite Video Mode

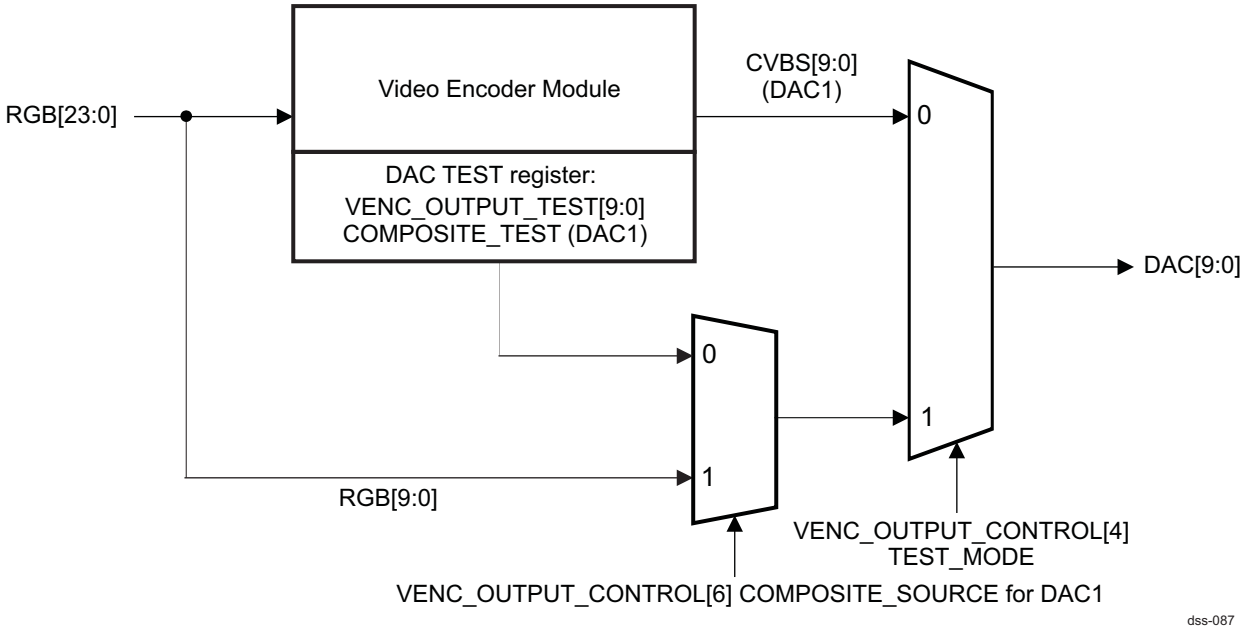

Figure 12-118. DAC Test Mode in Separate video Mode

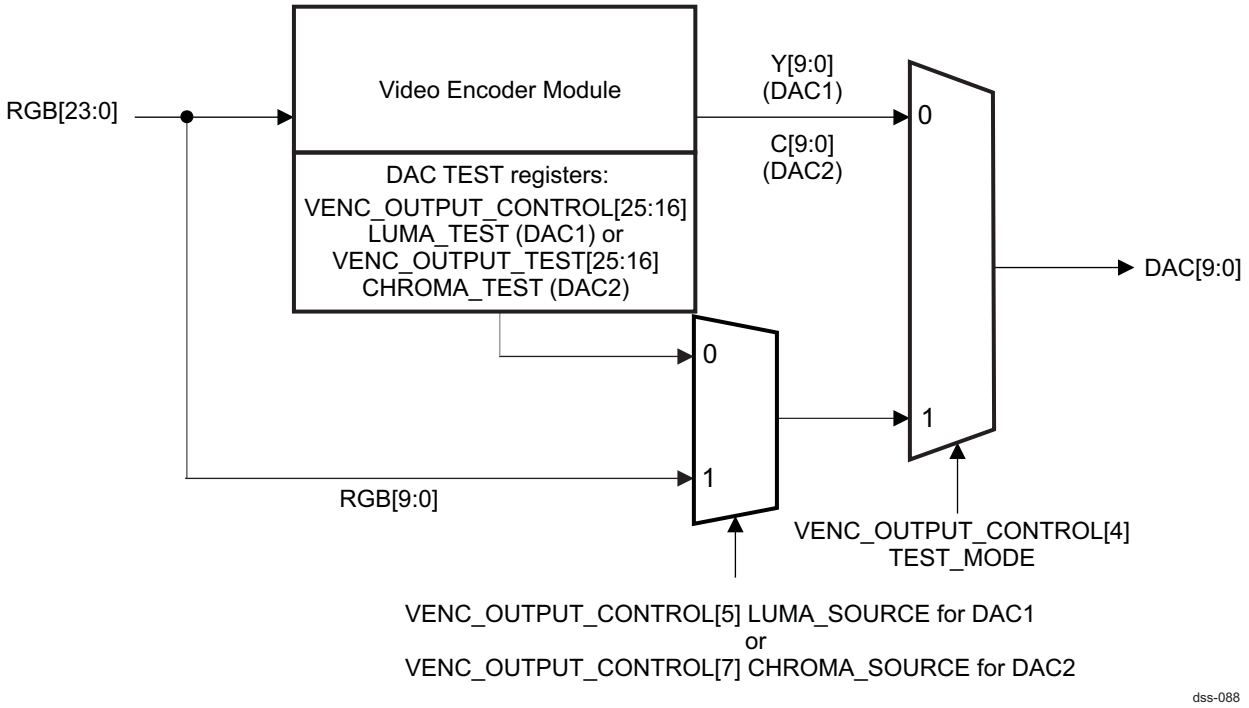


- Use the DSS.VENC_OUTPUT_CONTROL[4] TEST_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC_OUTPUT_CONTROL[7] CHROMA_SOURCE bit for DAC2 and either the DSS.VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit (in composite video mode) or the DSS.VENC_OUTPUT_CONTROL[5] LUMA_SOURCE bit (in s-video mode) for DAC1 to select the test mode:
  - 0x0: From the internal register DSS.VENC_OUTPUT_TEST[25:16] CHROMA_TEST bit field for DAC2 and either DSS.VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field (composite video) or DSS.VENC_OUTPUT_CONTROL[25:16] LUMA_TEST (s-video mode) for DAC1
  - 0x1: From the video port G[1:0], B[7:0]

NOTE: In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

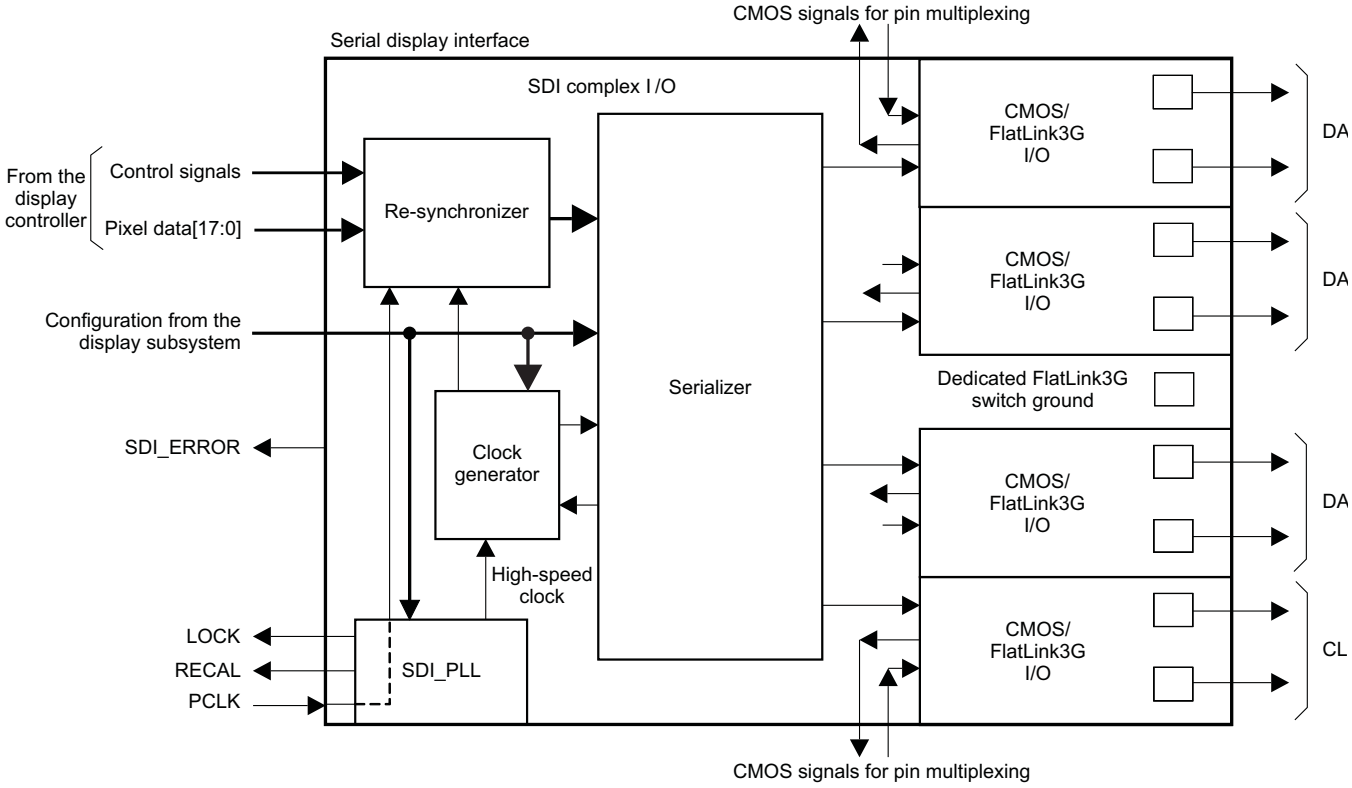
12.4.8 SDI Functionalities

The SDI interface has three main functions:

- A PLL (SDI_PLL) to multiply or divide the pixel clock frequency (PCLK) up to the required data rate. The pixel clock frequency range is 4-65 MHz. This clock may be divided by 2 above 32 MHz to meet the PLL input reference timing requirements.
- A specific IP block to output the data in the chosen serial format
- Output buffers to transmit the small swing differential signals

  The last two functions are combined in the complex I/O module. Figure 12-119 shows the SDI architecture.

Figure 12-119. SDI Architecture Overview



NOTE:

- The RECAL status indicates when the SDI_PLL must be recalibrated (0: No recalibration is required; 1: Recalibration is required).

  This status is connected to the GPIO_80 internal signal of the GPIO3 module. For additional information, see Chapter 21, *General-Purpose Interface*.
- The LOCK status indicates when the SDI_PLL is locked (0: PLL not locked; 1: PLL locked). This status is connected to the GPIO_81 internal signal of the GPIO3 module. For additional information, see Chapter 21, *General-Purpose Interface*.

For more information about lock and recalibration, see , *Power, Reset, and Clock Management*.

- The SDI_ERROR status indicated when the SDI module is in error mode (0: No error; 1: SDI in error). This status allows monitoring error conditions, such as inconsistent configuration or internal loss of synchronization. It is connected to the GPIO_82 internal signal of the GPIO3 module. For additional information, see Chapter 21, *General-Purpose Interface*.

12.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI, the SDI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)

  Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support

  Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support

  Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.
- TI FlatLink 3G-compliant LCD panel support

  Configure the SDI, configure the video encoder, and then configure the display controller.

12.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 0.

   (a) Reset the frame done status bit by writing 1 in the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit.

   (b) Wait until the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
   - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
   - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
   - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
   - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1

   Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

12.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS_CONTROL[2] VENC_CLOCK_MODE bit and the DSS.DSS_CONTROL[3] VENC_CLOCK_X4 bit for TV set support.
3. To configure the top level of the DAC, set the DSS.DSS_CONTROL[4] DAC_DEMEN bit for TV set support (if required).
4. Configure the TI FlatLink 3G-compliant LCD panel through the SPI interface to use the serial interface display.
5. Configure the RFBI module and/or the SDI module and/or the video encoder as needed.
6. Configure the display controller.

12.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC_CONTROL[5] GOLCD or DSS.DISPC_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 12-45 lists the shadow registers.

Table 12-45. Shadow Registers

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CONTROL	X(1)	X(1)
DSS.DISPC_CONFIG	X	X
DSS.DISPC_DEFAULT_COLOR_m (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR_m (m = 1)		X
DSS.DISPC_TRANS_COLOR_m (m = 0)	X	
DSS.DISPC_TRANS_COLOR_m (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X	
DSS.DISPC_SIZE_DIG		X
DSS.DISPC_SIZE_LCD	X	
DSS.DISPC_GFX_BAj (j = 0,1)	X	X
DSS.DISPC_GFX_POSITION	X	X
DSS.DISPC_GFX_SIZE	X	X
DSS.DISPC_GFX_ATTRIBUTES	X	X
DSS.DISPC_GFX_FIFO_THRESHOLD	X	X
DSS.DISPC_GFX_ROW_INC	X	X
DSS.DISPC_GFX_PIXEL_INC	X	X

12.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCONFIG
- DSS.DISPC_SYSSTATUS
- DSS.DISPC_IRQSTATUS
- DSS.DISPC_IRQENABLE

12.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

12.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_GFX_BAj
- DSS.DISPC_GFX_ATTRIBUTES
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THRESHOLD
- DSS.DISPC_GFX_TABLE_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256

bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

  – Active matrix (TFT) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
  – Color passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
  – Monochrome passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)

- Base address of the graphics buffer in system memory (DSS.DISPC_GFX_BAj registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC_GFX_BA0 defines the base address of the even field; and DSS.DISPC_GFX_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC_GFX_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD bit field) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC_CONFIG[3] PALETTEGAMMATABLE bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC_GFX_TABLE_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (DSS.DISPC_GFX_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC_GFX_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

– Frame t: The bit field should be set at anytime during frame

– Frame t+1: Fetch of the data in the DMA FIFO and display of the frame

– Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

– Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame

– Frame t+1: Fetch of the data from system memory using the L3 interconnect

12.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_GFX_POSITION
- DSS.DISPC_GFX_SIZE
- DSS.DISPC_GFX_ATTRIBUTES

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

12.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC_GFX_ATTRIBUTES[4:1] GFXFORMAT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC_GFX_POSITION[10:0] GFXPOSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC_GFX_POSITION[26:16] GFXPOSY bit field): The default value of this bit field at reset time is 0x0.The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC_GFX_SIZE[10:0] GFXSIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_GFX_ROW_INC register is not 1. When DSS.DISPC_GFX_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Graphics window height (DSS.DISPC_GFX_SIZE[26:16] GFXSIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen.

Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen

- Graphics data endianness (DSS.DISPC_GFX_ATTRIBUTES[10] GFXENDIANNESS bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
- Graphics data nible mode (DSS.DISPC_GFX_ATTRIBUTES[9] GFXNIBBLEMODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
- Graphics replication logic enable (DSS.DISPC_GFX_ATTRIBUTES[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.DISPC_CONTROL[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset. When the color key is used, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset.
- Graphics window skip (DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

  Figure 12-120 through Figure 12-123 give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

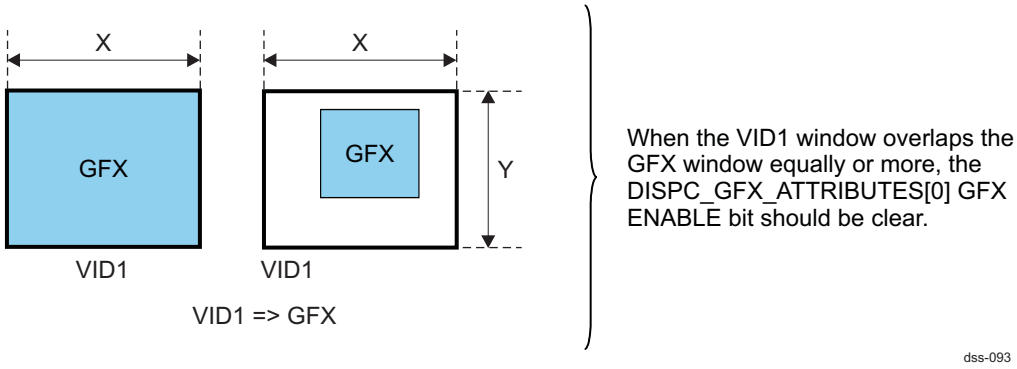
Figure 12-123. Overlay Optimization: Case 4



12.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

12.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_VIDn_BA0
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_ROW_INC
- DSS.DISPC_VIDn_PIXEL_INC
- DSS.DISPC_VIDn_FIFO_THRESHOLD
- DSS.DISPC_VIDn_PICTURE_SIZE

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_VIDn_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
  - Active matrix (TFT) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0xB0 (value is 176)
  - Color passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x110 (value is 272)
  - Monochrome passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x1B0 (value is 432)

- Base address of the video buffer in system memory (DSS.DISPC_VIDn_BAj registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.DISPC_VIDn_BA0 defines the base address of the even field, and DSS.DISPC_VIDn_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Video buffer width (DSS.DISPC_PICTURE_SIZE[10:0] VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.DISPC_PICTURE_SIZE[26:16] VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC_VIDn_ATTRIBUTES[17] VIDENDIANNESS bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

12.5.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_PICTURE_SIZE
- DSS.DISPC_VIDn_FIR_COEF_Hi (with i = 0 to 7)
- DSS.DISPC_VIDn_FIR_COEF_HVi (with i = 0 to 7)
- DSS.DISPC_VIDn_CONV_COEFi (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

12.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline).The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] VIDPOSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] VIDPOSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VIDSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).

  NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

  The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VIDSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.
  The sequence to activate the self-refresh is the following:
  - Frame t: The bit field should be set at anytime during frame
  - Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
  - Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

  The sequence to deactivate the self-refresh is the following:
  - Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
  - Frame t+1: Fetch of the data from system memory using the L3 interconnect

12.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up-/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[5] VIDRESIZEENABLE bit.

The video vertical up-/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[6] VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up-/downsampling block.

NOTE: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \right) \quad \text{dss-E093} \tag{5}$$

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
- The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.

- Horizontal up-/downsampling increment value (DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEX[10:0]}{VIDSIZEX[10:0]} \right) \quad \text{dss-E094} \tag{6}$$

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.

- Vertical up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 12-46).
- Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
- Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit must be set to 1.

- Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[20] VIDDMAOPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization.

NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1

DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even

- Horizontal up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 12-46).

Table 12-46. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up-/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

  In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC_VIDn_FIR_COEF_HVi is used.
- Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC_VIDn_FIR_COEF_Hi register and the DSS.DISPC_VIDn_FIR_COEF_HVi register define the 5-tap horizontal up-/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up-/downsampling block.

  Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC_VIDn_FIR_COEF_HVi register contains one 8-bit signed coefficient.

  The programmable coefficient for the FIR up-/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see Section 12.6.1.

12.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)
