12.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

12.5.3.4.1 Image Data Formats

To understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2- ,4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to Section 12.4.2.2, *Graphics Pipeline*.

For more information on the video data formats, please refer to Section 12.4.2.3, *Video Pipeline*.

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to Section 12.4.2.3.2, *Color Space Conversion*.

12.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. Figure 12-124 illustrates the principle steps for a 90-degree rotation.

Figure 12-124. 90° DMA Rotation Example

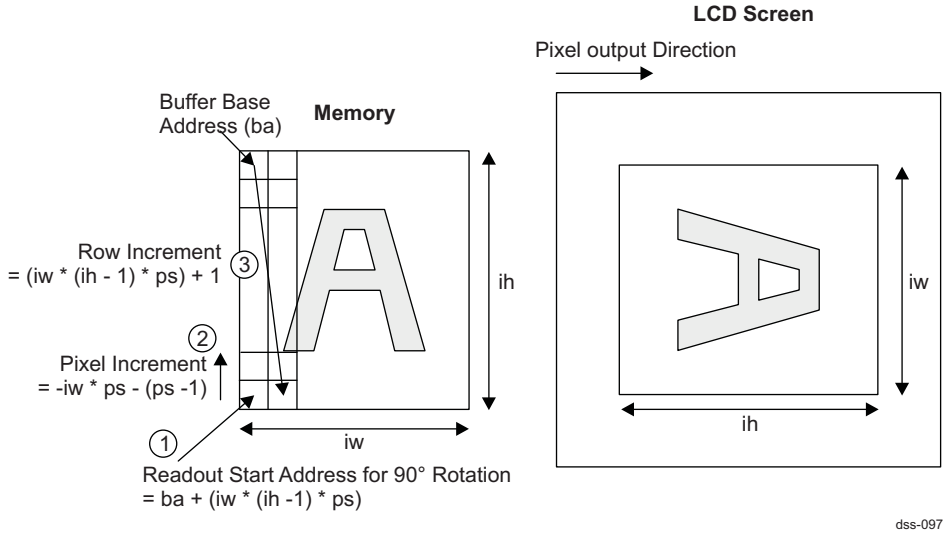

Table 12-48. 90-degree DMA Rotation Example Description

Parameter	Description	Additional parameters for formulas
ba	Buffer Base Address in Memory	
IW	Image Width in pixels	iw = IW-1
IH	Image Height in pixels	ih = IH-1
ps	Pixel Size (in bytes)	

Figure 12-124 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). To proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

12.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
  - DSS.DISPC_GFX_BAj
  - DSS.DISPC_GFX_PIXEL_INC
  - DSS.DISPC_GFX_ROW_INC
  - DSS.DISPC_GFX_ATTRIBUTES
  - DSS.DISPC_GFX_POSITION
  - DSS.DISPC_GFX_SIZE
  - DSS.DISPC_GFX_FIFO_THRESHOLD
- Video pipelines (VID) 1 and 2:
  - DSS.DISPC_VIDn_BAj
  - DSS.DISPC_VIDn_PIXEL_INC
  - DSS.DISPC_VIDn_ROW_INC
  - DSS.DISPC_VIDn_ATTRIBUTES
  - DSS.DISPC_VIDn_POSITION
  - DSS.DISPC_VIDn_SIZE
  - DSS.DISPC_VIDn_CONV_COEF0 to DSS.DISPC_VIDn_CONV_COEF4
  - DSS.DISPC_VIDn_FIFO_THRESHOLD
- DSS.DISPC_xxx_BAj: These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see Table 12-49 for the formulas). When using the LCD interface, the registers DISPC_xxx_BA0 are used. The registers DISPC_xxx_BA1 are only used for the TV output.
- DSS.DISPC_xxx_PIXEL_INC[15:0]: This bit field contains the DMA addressing increment after each pixel. This bit field is used to perform the DSS DMA rotation (see Table 12-49 for the formula).

NOTE: When the RGB24 packet format is selected, the only valid value is 1.

- DSS.DISPC_xxx_ROW_INC[31:0]: This bit field contains the DMA addressing increment after each row (line) of pixels. This bit field is used to perform the DSS DMA rotation (see Table 12-49 for the formula).

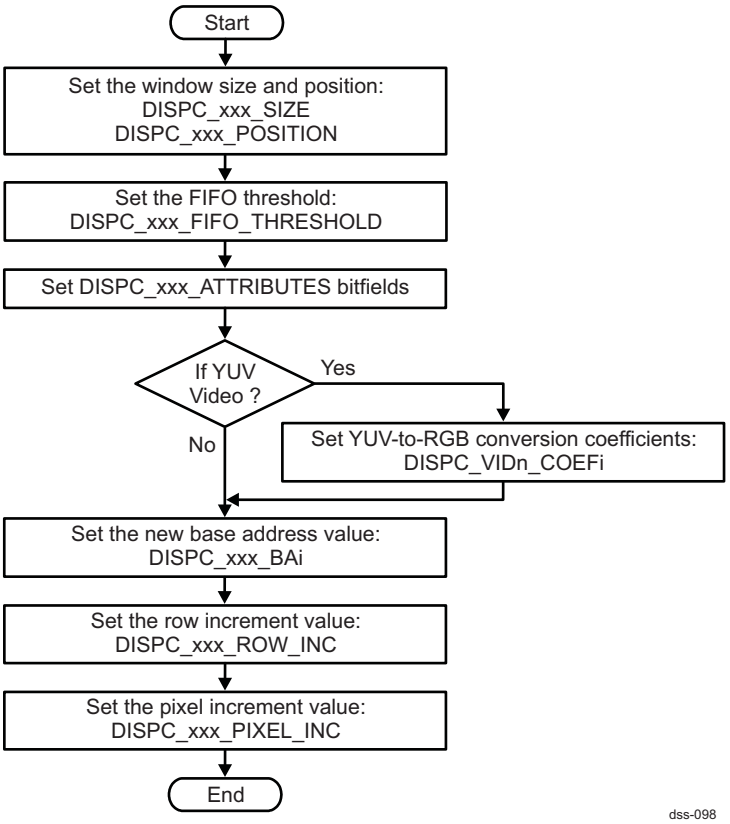
NOTE: When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

- DSS.DISPC_xxx_ATTRIBUTES: These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
  - The following bit fields are used by the graphics pipeline to set up the image format:
    - GFXENABLE: Set this field to activate the hardware path in use.
    - GFXFORMAT: Use this field to specify the format of the graphic frame.
    - GFXROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
    - GFXREPLICATIONENABLE: Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the MSB to fill the LSBs of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
    - GFXCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
  - The following bit fields for the two video pipelines:
    - VIDENABLE: Set this field to activate the hardware path in use.
    - VIDFORMAT: Use this field to specify the format of the video frame (RGB16 or YUV422).
    - VIDCOLORCONVENABLE: If the video is in YUV422 format, set this field to enabled.
    - VIDROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See Section 12.5.3.4.4 for more information.
    - VIDROWREPEATENABLE: Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See Section 12.5.3.4.4 for more information.
    - VIDCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
- DSS.DISPC_xxx_POSITION: Use this register to configure the position of the window.
- DSS.DISPC_xxx_SIZE: Use this register to configure the size of the window.
- DSS.DISPC_VIDn_CONV_COEF0, DSS.DISPC_VIDn_CONV_COEF1, DSS.DISPC_VIDn_CONV_COEF2, DSS.DISPC_VIDn_CONV_COEF3, and DSS.DISPC_VIDn_CONV_COEF4: These registers contain the conversion coefficients required for YUV-to-RGB color conversion.
- DSS.DISPC_xxx_FIFO_THRESHOLD: Set the low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

12.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring, use the following settings:

Figure 12-125. Rotation/Mirroring Settings



NOTE: These registers are shadow registers. To take into account the new values, software users must set the DSS.DISPC_CONTROL[5] GOLCD bit to 1.

Table 12-49 details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. Table 12-50 lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

Table 12-49. DMA Rotation Register Settings

Rotation	Registers	GFX/VIDx (1)
0 degree	DSS.DISPC_xxx_BAj	ba
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	1
90 degrees	DSS.DISPC_xxx_BAj	ba + (iw x (ih-1) x ps)
	DSS.DISPC_xxx_PIXEL_INC	-(iw x ps) - 1
	DSS.DISPC_xxx_ROW_INC	(iw x (ih-1)) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj	ba + (iw x ih-1) x ps
	DSS.DISPC_xxx_PIXEL_INC	-2 x ps
	DSS.DISPC_xxx_ROW_INC	-2 x ps

(1)
- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See Table 12-48 for more information of these parameters.

Table 12-49. DMA Rotation Register Settings (continued)

Rotation	Registers	GFX/VIDx [1]
270 degrees	DSS.DISPC_xxx_BAj	ba + (iw -1) x ps
	DSS.DISPC_xxx_PIXEL_INC	(iw -1) x ps + 1
	DSS.DISPC_xxx_ROW_INC	-(iw x (ih-1)) x ps - ps + 1

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

Table 12-50. Video Rotation Register Settings (With RGB24 Packet Format)

Rotation	Registers (with n = 1 or 2)	SDRAM Direct Access [1]
0 degree	DSS.DISPC_VIDn_BAj	ba
	DSS.DISPC_VIDn_PIXEL_INC	1
	DSS.DISPC_VIDn_ROW_INC	1
180 degrees	DSS.DISPC_VIDn_BAj	ba+(iw*ih*3)-4
	DSS.DISPC_VIDn_PIXEL_INC	-7
	DSS.DISPC_VIDn_ROW_INC	-7

(1)

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
- iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
- h = number of lines - 1 (original picture in system memory)
- ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV422: 4 bytes)

See Table 12-48 for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see Figure 12-126). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC_xxx_BAj, DISPC_xxx_PIXEL_INC, and DISPC_xxx_ROW_INC. Table 12-51 provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 12-126. 90° Rotation With Mirroring

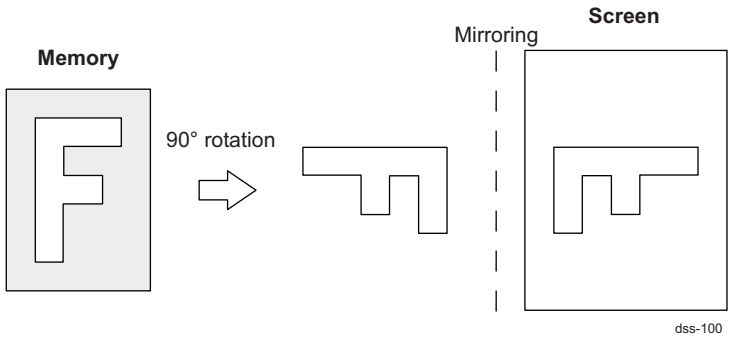


Table 12-51. Register Settings for DMA Rotation With Mirroring

Rotation	Registers	GFX/VIDx [1]
0 degree	DSS.DISPC_xxx_BAj	ba + (iw-1) x ps
	DSS.DISPC_xxx_PIXEL_INC	-2 x ps + 1
	DSS.DISPC_xxx_ROW_INC	2 x (iw-1) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj	ba
	DSS.DISPC_xxx_PIXEL_INC	(iw-1) x ps
	DSS.DISPC_xxx_ROW_INC	(-iw x (ih-1)) x ps
180 degrees	DSS.DISPC_xxx_BAj	ba + iw x (ih-1) x ps
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-2 x iw x ps
270 degrees	DSS.DISPC_xxx_BAj	ba + (iw x ih - 1) x ps
	DSS.DISPC_xxx_PIXEL_INC	(iw -1) x ps + 1
	DSS.DISPC_xxx_ROW_INC	- (iw x (ih-1)) x ps - ps + 1

(1)
- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See Table 12-48 for more information of these parameters.

12.5.3.4.3 Image Data from External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. To use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see Section 12.5.3.4.2, *Image Data from On-Chip SRAM*). The differences are in the setup of the following registers:

- DISPC_xxx_ROW_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, to reach the 2048-pixel line size of the VRFB (see Table 12-52 for the formula).
- DISPC_xxx_PIXEL_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see Table 12-52).

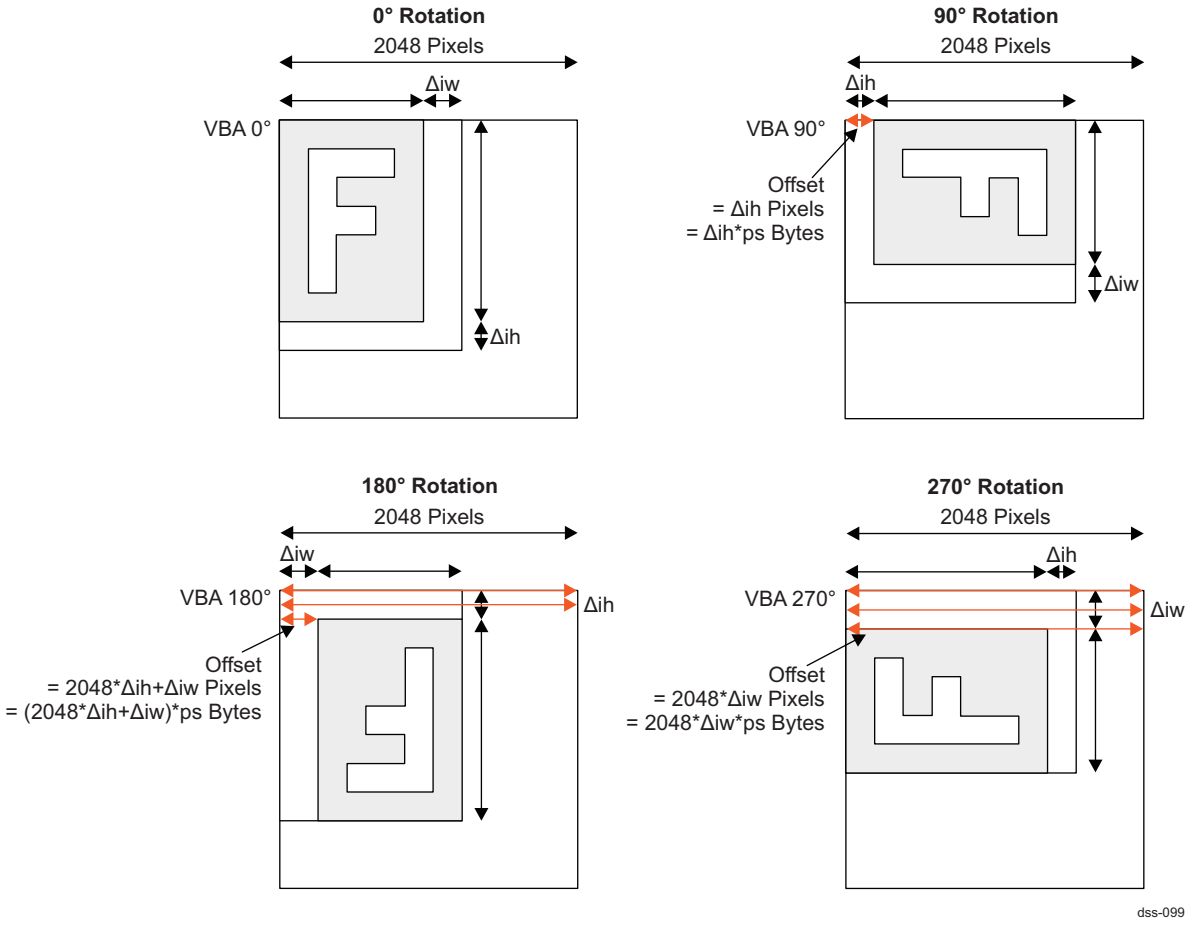
Table 12-52. VRFB Rotation - DMA Settings

Rotation	Registers	GFX/VIDx [1]
0 degree	DSS.DISPC_xxx_BAj	VBA0
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	(2048 - iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj	VBA90 + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	(2048 - ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj	VBA180 + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	(2048 - iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj	VBA270 + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	(2048 - ih) x ps + 1

(1)
- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 12-127 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 12-127 illustrates why this occurs and how the offset is calculated.

Figure 12-127. Offset for VRFB Rotation



Δiw = Image width delta between the actual image width and the programmed image width because of the page width

Δih = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree: Δih pixels = Δih x ps bytes
- Offset 180-degree: 2048 x Δih+ Δiw pixels = 2048 x Δih x ps+ Δiw x ps bytes
- Offset 270-degree: 2048 x Δiw pixels = 2048 x Δiw x ps bytes

In the example given above, the delta in the image height is 256 – 240 = 16 lines (Δih = 16), whereas the exact value of the width can be programmed (Δiw = 0). In that case, the resulting offset values are:

- YUV:
  - Offset 90-degree: 16 x 4 bytes
  - Offset 180-degree: 2048 x 16 x 4 bytes
  - Offset 270-degree: 0 bytes
- RGB:
  - Offset 90-degree: 16 x 2 bytes

- Offset 180-degree: 2048 x 16 x 2 bytes
- Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. Table 12-53 provides the DMA settings for VRFB rotation with mirroring.

Table 12-53. VRFB Rotation With Mirroring - DMA Settings

Rotation	Registers	GFX/VIDx (1)
0 degree	DSS.DISPC_xxx_BAj	VBA180 + 2048 x (ih - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj	VBA270 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj	VBA0 + 2048 x (ih - 1) x ps
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj	VBA90 + 2048 x (iw - 1) x ps + offset
	DSS.DISPC_xxx_PIXEL_INC	1
	DSS.DISPC_xxx_ROW_INC	-(2048 + ih) x ps + 1

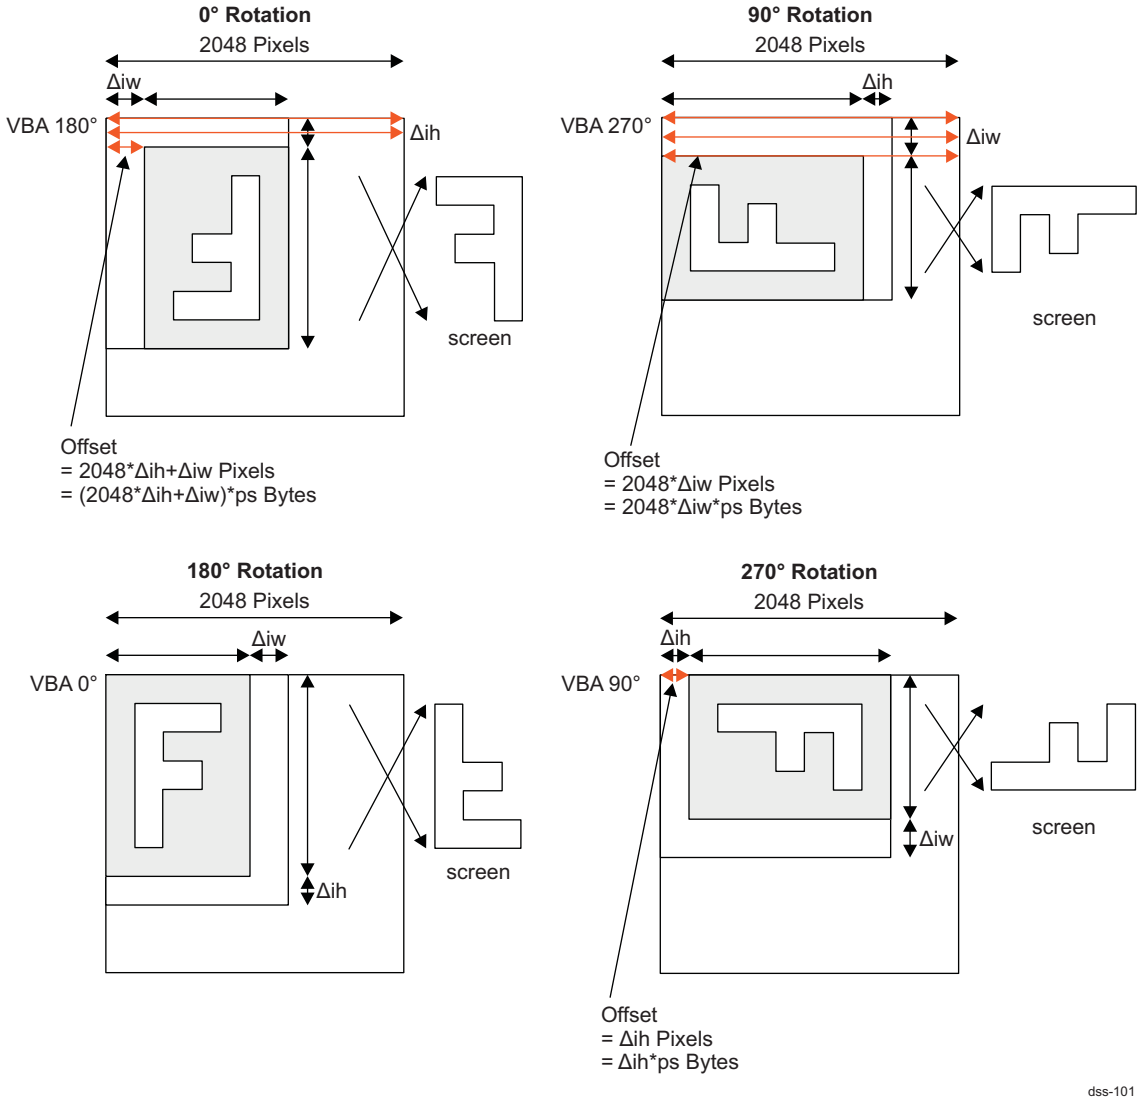
(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in Figure 12-128, this applies to 0-degree rotation with mirroring (using VBA 180°), 90° rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): 2048 x Δih + Δiw pixels = 2048 x Δih x ps + Δiw x ps bytes
- Offset 90-degree (mirroring): 2048 x Δiw pixels = 2048 x Δiw x ps bytes
- Offset 270-degree (mirroring): Δih pixels = Δih x ps bytes

Figure 12-128. Offset for VRFB Rotation With Mirroring



12.5.3.4.4 Additional configuration when using YUV format

The rotation flag (DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 12-54 and Table 12-55 describe the configuration of these registers.

Table 12-54. Video Rotation Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0

Table 12-54. Video Rotation Register Settings (YUV Only) (continued)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Table 12-55. Video Rotation With Mirroring Register Settings (YUV only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

NOTE: For YUV 4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV 4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

12.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=0)
- DSS.DISPC_TRANS_COLOR_m (m=0)
- DSS.DISPC_TIMING_H
- DSS.DISPC_TIMING_V
- DSS.DISPC_POL_FREQ
- DSS.DISPC_DIVISOR
- DSS.DISPC_SIZE_LCD
- DSS.DISPC_DATA_CYCLEk
- DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, DSS.DISPC_CPR_COEF_B

Setting/resetting the DSS.DISPC_CONTROL[0] LCDENABLE bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

12.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC_CONTROL[2]MONOCOLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC_CONTROL[3] STNTFT bit)
- Color depth (the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field)

- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

12.5.3.5.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSYNC:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSYNC pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSYNC rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSYNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CONFIG[6] HSYNCGATED bit)
- VSYNC gated (the DSS.DISPC_CONFIG[7] VSYNCGATED bit)

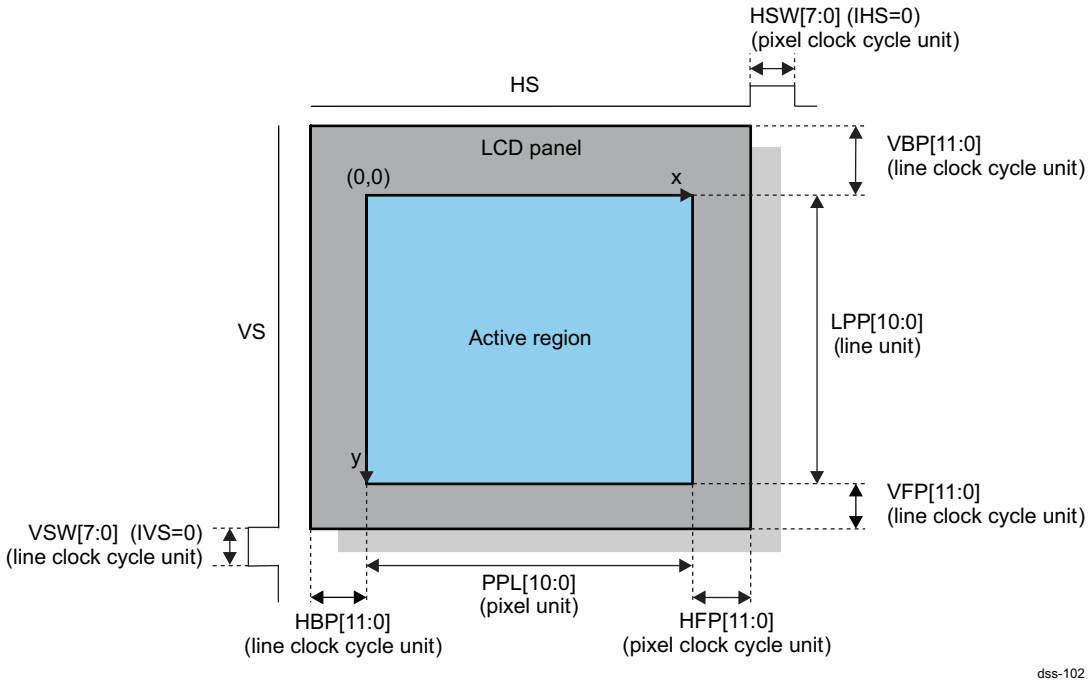
Table 12-56 describes the programming rules for LCD timing.

Table 12-56. Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) * PCD	> 8	> 10	> 20

Figure 12-129 shows the timing values description in the case of an active matrix display.

Figure 12-129. Timing Values Description (Active Matrix Display)



The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC_CONFIG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

Pixel Clock = (FunctionalClock/LCD[7:0])/PCD[7:0]

Table 12-57 through Table 12-60 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 12-57. Pixel Clock Frequency Limitations - RGB16 and YUV422 Active Matrix Display

Min PCD Values			Horizontal Resampling				
			Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off		2 (1)[(1)]	2 [(1)]	2	3	4
	Up		2 [(1)]	2 (1)[(1)]	2	3	4
	1:1 - 1:2	3-tap	2	2	4	6	8
		5-tap	PCDmin	PCDmin	PCDmin	PCDmin	PCDmin
	1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin	PCDmin

(1) The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

Table 12-58. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono4

Min PCD Values			Horizontal Resampling				
			Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off		4	4	8	12	16
	Up		4	4	8	12	16
	1:1 - 1:2	3-tap	8	8	16	24	32
		5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
	1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

Table 12-59. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono8

Min PCD Values			Horizontal Resampling				
			Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off		8	8	16	24	32
	Up		8	8	16	24	32
	1:1 - 1:2	3-tap	16	16	32	48	64
		5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin
	1:2 - 1:4		8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin

Table 12-60. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Color

Min PCD Values			Horizontal Resampling				
			Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off		3	3	6	9	12
	Up		3	3	6	9	12
	1:1 - 1:2	3-tap	6	6	12	18	24
		5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
	1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

NOTE: In case of RGB24 format, Figure 12-130 is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 12-130. PCDmin Formulas (V Down-Sampling Only)

$$h\_ratio = \frac{DISPC\_PPL\_SIZE\_LCD[10:0]PLL}{DISPC\_VIDn\_SIZE[10:0]VIDZSIZEX}$$

$$v\_ratio = \frac{DISPC\_VIDn\_PICTURE\_SIZE[10:0]VIDORGSIZEX}{DISPC\_VIDn\_SIZE[10:0]VIDSIZEX}$$

$$PCD\min = \frac{v\_ratio}{2 \times h\_ratio} \quad 1 < v\_ratio \le 2$$

$$PCD\min = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad 2 < v\_ratio \le 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n, *PCDmin = n*

For H+V downsampling, the formula is the following:

PCDmin = max(PCDmin H only, PCDmin V only) as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC_SIZE[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC_CONFIG[0] PIXELGATED bit).

12.5.3.5.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR0i register (i = 0))
- Transparency color key enable (the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=0).
- Alpha blender Enable (DSS.DISPC_CONFIG[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC_DATA_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC_DATA_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC_DATA_CYCLEk (k=2) register)
- Enable (the DSS.DISPC_CONTROL[20] TDMENABLE bit)
- Parallel mode (the DSS.DISPC_CONTROL[22:21] TDMPARALLEMODE field)
- Cycle format (the DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.DISPC_CONTROL[26:25] TDMUNUSEDBITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field) with:
  - 0x0 Spatial only (default value)

  - 0x1 Spatial + Temporal over two frames
  - 0x2 Spatial + Temporal over four frames
  - 0x3 Reserved
- Enable (the DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CONFIG[15] CPR bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 12-131 through Figure 12-134.

Figure 12-131. Color Phase Rotation Matrix

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

dss-E105

Figure 12-132. Color Phase Rotation Matrix (R Component Only)

$$Riout = \frac{1}{256} * (RR * Rin + RG * Gin + RB * Bin)$$

dss-E106

Figure 12-133. Color Phase Rotation Matrix (G Component Only)

$$Gout = \frac{1}{256} * (GR * Rin + GG * Gin + GB * Bin)$$

dss-E107

Figure 12-134. Color Phase Rotation Matrix (B Component Only)

$$Bout = \frac{1}{256} * (BR * Rin + BG * Gin + BB * Bin)$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. Figure 12-135 gives the example of a diagonal matrix and the corresponding equation of the output components.

Figure 12-135. Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\rightarrow \quad Rout = \frac{1}{256} * \left(RR * Rin \right)$$

$$\rightarrow \quad Gout = \frac{1}{256} * \left(GG * Gin \right)$$

$$\rightarrow \quad Bout = \frac{1}{256} * \left(BB * Bin \right)$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. Figure 12-136 gives the corresponding matrix and equations for each component.

Figure 12-136. Example - Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\rightarrow \quad Rout = \frac{1}{256} * \left(256 * Rin \right) \Rightarrow Rout = Rin$$

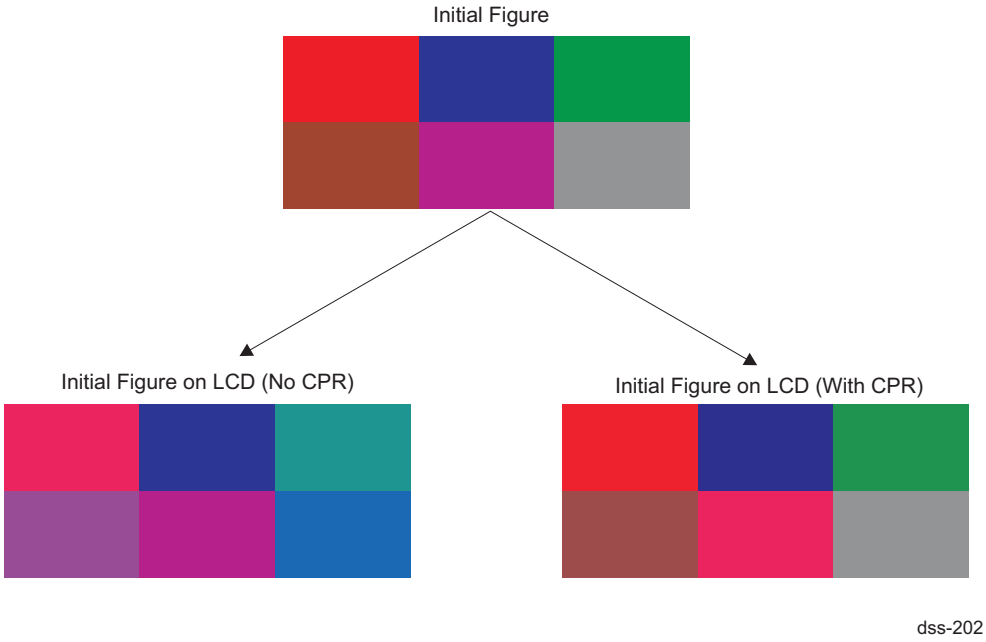
$$\rightarrow \quad Gout = \frac{1}{256} * \left(256 * Gin \right) \Rightarrow Gout = Gin$$

$$\rightarrow \quad Bout = \frac{1}{256} * \left(128 * Bin \right) \Rightarrow Bout = 0.5 * Bin$$

dss-201

Figure 12-137 shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 12-137. Image With and Without CPR (Diagonal Matrix)



A drawback of this diagonal matric is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

12.5.3.5.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B_offset) to the Blue component. Figure 12-138 shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

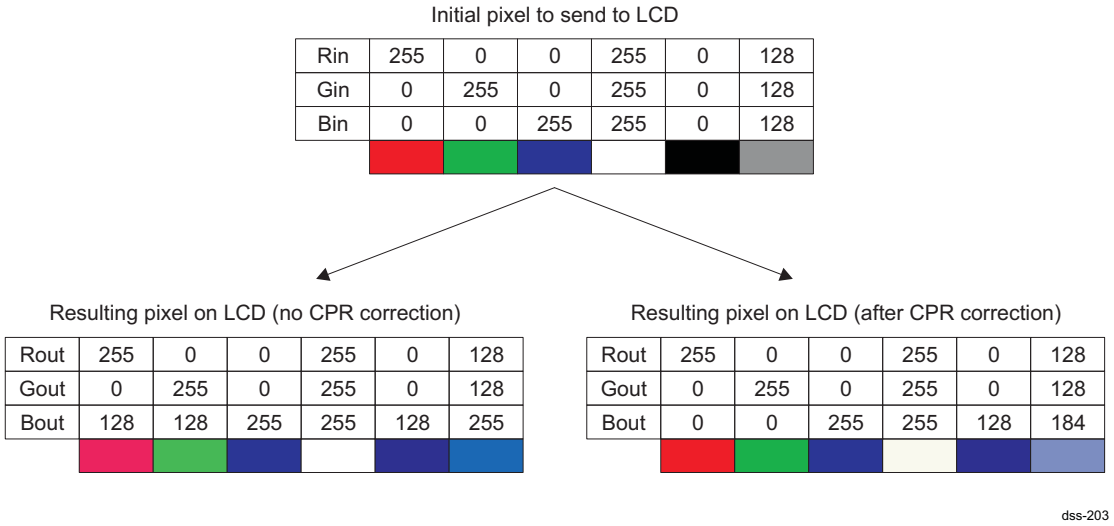
Figure 12-138. Example - Image With and Without CPR (Standard Matrix)

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\rightarrow \quad Rout = \frac{1}{256} * \left(256 * Rin \right)$$

$$\rightarrow \quad Gout = \frac{1}{256} * \left(256 * Gin \right)$$

$$\rightarrow \quad Bout = \frac{1}{256} * \left(-129 * Rin + -129 * Gin + 370 * Bin \right) + B\_offset$$



This CPR matrix gives inputs and outputs very close. However, black can not be corrected because of it's zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

12.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=1)
- DSS.DISPC_TRANS_COLOR_m (m=1)
- DSS.DISPC_SIZE_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC_CONTROL[1] DIGITALENABLE bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQENABLE[15]

SYNCLOSTDIGITAL bit to 1.

12.5.3.6.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC_CONTROL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

12.5.3.6.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL bit field)

12.5.3.6.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When this bit field is set to the appropriate values, set the DSS.DISPC_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[1] DIGITALENABLE bit will be set to 1.

12.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

12.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI_SYSCONFIG[1] SOFT_RESET bit to 1. The software can monitor the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional as an hardware reset is always performed on the DSI protocol engine at device reset.

12.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI_SYSCONFIG[0] AUTO_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

12.5.4.3 Interrupts

There is a single interrupt request: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ in a single interrupt request DSS_IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI_IRQENABLE register: This register indicates the enabled/disabled event for the VCs. Each event for the VC is configured in the DSS.DSI_VCn_IRQENABLE register dedicated to the VC number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).
- DSS.DSI_IRQSTATUS register : The register DSI_IRQSTATUS flags which VC(s) is/have generated an interrupt. Based on the VC number, the register DSI_VCn_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

12.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSI_PHY_SCP registers in the DSI complex I/O must be configured. Refer to Section 12.5.6 for more details. Table 12-61 details the register access width limitations for all the DSI modules.

Table 12-61. Register Access Width Limitations

Register Name	Register Access Width
All DSI complex I/O register (DSI_PHY_SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VCn_LONG_PACKET_HEADER	32-bit only
DSI_VCn_SHORT_PACKET_HEADER	32-bit only
DSI_VCn_LONG_PACKET_PAYLOAD	16-bit, 32-bit
All others DSI protocol engine registers	8-bit, 16-bit and 32-bit

CAUTION

In case of different access width detailed in Table 12-61, an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI_CTRL register. The interface to the complex I/O is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.DSI_CTRL[0] IF_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.DSI_CTRL[0] IF_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.DSI_CTRL[0] IF_EN bit. When using the video mode, the VC associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.DSI_CTRL[0] IF_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.DSI_VCn_CTRL[0] VC_EN
- Set the DSS.DSI_CTRL[0] IF_EN bit to 1

12.5.4.5 Virtual Channels

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSS.DSI_VCn_CTRL[4] MODE bit):
  - Video mode
  - Command mode
- Data type
- Source (DSS.DSI_VCn_CTRL[1] SOURCE bit)
  - Video port
  - L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
  - Short packets (DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit)
  - Long packets (DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
  - DMA request number (DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB bit field for RX FIFO and DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field for TX FIFO)
  - DMA threshold (DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit field for RX FIFO and DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSS.DSI_VCn_CTRL[9] MODE_SPEED bit)
- ECC transmission (DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit)
- CS transmission (DSS.DSI_VCn_CTRL[7] CS_TX_EN bit)

The VC ID not calculated by the DSI module but provided while writing into the registers DSI_VCn_SHORT_PACKET_HEADER and DSI_VCn_LONG_PACKET_HEADER.

12.5.4.6 Packets

The DSS.DSI_VCn_SHORT_PACKET_HEADER register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSS.DSI_CTRL[18] VP_HSYNC_END
- DSS.DSI_CTRL[17] VP_HSYNC_START
- DSS.DSI_CTRL[16] VP_VSYNC_END
- DSS.DSI_CTRL[15] VP_VSYNC_START

- DSS.DSI_CTRL[10] VP_HSYNC_POL
- DSS.DSI_CTRL[11] VP_VSYNC_POL
- DSS.DSI_VCn_CTRL[1] SOURCE

The DSS.DSI_VCn_LONG_PACKET_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the VC, it is not possible to transfer concurrently (interleaved in a frame) data using long packets received on the video port and on the L4 interconnect port since the DSS.DSI_VCn_LONG_PACKET_HEADER register is used by the video mode. The register can be unprogrammed by users to send long packets received on the L4 interconnect port only when software users know that there is no expected data on the video port. The software should correctly program the register to send sequentially long packets in video and command modes.

The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI_VCn_CTRL[7] CS_TX_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD, respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register can be followed by any access.
- A long packet header value with WC>0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register should be followed by one or more writes to the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI_VCn_LONG_PACKET_HEADER register.

CAUTION

If this sequence is not followed, no error is generated. The access to other DSI registers during this sequence is allowed.

12.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. See Section 12.5.6, *DSI Complex I/O Basic Programming Model*.

12.5.4.8 Video Mode

The DSS.DSI_VM_TIMING1, DSS.DSI_VM_TIMING2, DSS.DSI_VM_TIMING3, DSS.DSI_VM_TIMING4, DSS.DSI_VM_TIMING5, DSS.DSI_VM_TIMING6, and DSS.DSI_VM_TIMING7 registers define the timings of the video mode.

The DSS.DSI_CTRL[20] BLANKING_MODE bit defines if the long blanking packets or LPS state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.DSI_VCn_CTRL[9] MODE_SPEED bit is set to 1 (High-Speed mode) to keep the video mode transfer is HS mode during blanking periods (except for the last blanking period since it is required to go LPS at least once per frame).

The DSS.DSI_CTRL[21] HFP_BLANKING_MODE, DSS.DSI_CTRL[22] HBP_BLANKING_MODE and DSS.DSI_CTRL[23] HSA_BLANKING_MODE define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register DSS.DSI_VCn_LONG_PACKET_HEADER are correctly handled as header information for video mode long packets, the following registers should be programmed:

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1
- DSS.DSI_VCn_CTRL[4] MODE bit set to 1
- DSS.DSI_VCn_LONG_PACKET_HEADER register access

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1

NOTE: The DSS.DSI_VCn_CTRL[1] SOURCE and DSS.DSI_VCn_CTRL[9] MODE_SPEED bits are ignored by hardware when the video mode is selected (DSS.DSI_VCn_CTRL[4] MODE bit set to 1)

The interrupt events SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ indicates if the DSI protocol engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The RESYNCHRONIZATION_IRQ indicates software users that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events can be respectively monitored in DSS.DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSS.DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

The DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

12.5.4.9 Video Port Data Bus

The DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

12.5.4.10 Command Mode

12.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific VC should be done only when the VC is disabled.

Users should not enable the VC if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used to provide data for long packets. The register DSS.DSI_VCn_SHORT_PACKET_HEADER is used to provide data for short packets (32-bit long).

For each long packet, the DSS.DSI_VCn_LONG_PACKET_HEADER register should be written first and then the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the DSS.DSI_VCn_LONG_PACKET_HEADER register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests only for each VC to the TX FIFO should be kept in order while sending the data to the DSI_PHY inside the VC requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI_VCn_LONG_PACKET_HEADER register is not a multiple of the request threshold value defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the DT field. When the bytes are written into the DSS.DSI_VCn_SHORT_PACKET_HEADER, DSS.DSI_VCn_LONG_PACKET_HEADER, and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers, the hardware should store the information concerning long or short packet. A 1-bit flag should be used for each entry of the TX FIFO.

When the VC is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (threshold value bigger than space left in the TX FIFO for the VC).

NOTE: In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (TX_FIFO_ARBITRATION[3] DSI_CTRL bit = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets should be sent in HS mode, to ensure that there is no LP transition between them at least one of the following condition should be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chuck FIFO by:

- First disabling the VC resetting DSS.DSI_VCn_CTRL[0] VC_EN bit to 0
- Second change the size of the space of FIFO to 0 by writing the DSS.DSI_TX_FIFO_VC_SIZE VCn_FIFO_SIZE (n is the VC value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI_PHY, the flush of the FIFO should stop immediately the transfer. Because the FIFO is accessible to users, it must ensure that there are no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

Users can check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant DSS.DSI_VCn_CTRL[15] VC_BUSY bit or by using the interrupt PACKET_SENT_IRQ: All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit.

The DSS.DSI_CTRL[3] TX_FIFO_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled VCs with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC which has the least VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

If users want to use sequential arbitration for all requests for all channels, a single VC should be used. (the VC ID defined in the header provided to the hardware using either the DSS.DSI_VCn_LONG_PACKET_HEADER or DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used and not modified by the DSI protocol engine).

The register DSS.DSI_TX_FIFO_VC_SIZE defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO defined by DSS.DSI_TX_FIFO_VC_SIZE VCn_FIFO_SIZE (n corresponds to the VC number n) bit fields should be a multiple of the threshold defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 0. The whole FIFO may not be used by all the VCs at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 12-62 indicates the corresponding values for the size of the space allocated in the FIFO.

Table 12-62. Virtual Channel TX FIFO Size Values

DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3]	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of TX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 12-63 indicates the start address of the space in the FIFO.

Table 12-63. Virtual Channel TX FIFO Start Address

DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

When the TX FIFO is full:

- the overflow interrupt (FIFO_TX_OVF_IRQ) is generated. To monitor this interrupt request, users can read the DSS.DSI_VCn_IRQSTATUS[3] FIFO_TX_OVF_IRQ status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software must read the room in the space allocated for the VC in the TX FIFO by reading the DSS.DSI_TX_FIFO_VC_EMPTINESS register. In case there is no space allocated in the TX FIFO for the VC, the DSS.DSI_TX_FIFO_VC_EMPTINESS register indicates a value of 0 for the VC space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

12.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding VC locations to transfer data for a specific VC. The logic managing the FIFO must be able to extract 32-bit values in-order for a specific VC upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the VC information to provide the rest of the data during the next read request(s).

The register DSS.DSI_RX_FIFO_VC_SIZE defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs should be taken into account. to change the size of the space of the memory allocated for a specific VC, the VC should be disabled by resetting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 0. The whole FIFO may not be used by the entire VC at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 12-64 indicates the corresponding values for the size of the space allocated in the FIFO:

Table 12-64. Virtual Channel RX FIFO Size Values

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_SIZE[x = 0, 3]	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of RX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 12-65 indicates the start address of the space in the FIFO.

Table 12-65. Virtual Channel RX FIFO Start Address

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

While reading the received bytes in the RX FIFO, only the DSS.DSI_VCn_SHORT_PACKET_HEADER register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and can not check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

12.5.4.10.3 Command Mode DMA Requests

The DMA requests (DSI_DMA_REQ) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock (DSS_L4_ICLK) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. Users program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD and DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO respectively. The hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each VC should be a multiple of DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request should be asserted. So the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.DSI_VCn_LONG_PACKET_HEADER header register have been received, the DMA request is not asserted anymore even during the last transfer less than DMA_TX_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA_TX_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA should be programmed to read the exact number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSS.DSI_VCn_SHORT_PACKET_HEADER register is performed until the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the VC ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the VC. Software users are responsible for parsing the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.DSI_RX_FIFO_VC_FULLNESS register. Then the system DMA can be programmed to read the exact number of bytes from the RX FIFO. The BTA interrupt (BTA_IRQ) should be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user should read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit. The DMA request should not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the VC is expected to be overflow because the number of data to be received is greater than the space allocated for the VC, the previous programming model should be used. In place, the DMA request should be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: To obtain best efficiency of the transfer the size of the request (read or write, single or burst) should be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

12.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultralow-power state (ULPS).

NOTE: The DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3 and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is to take latency at low TxClkEsc frequencies into account.

12.5.4.11.1 Entering ULPS

To enter into ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and ensure that the DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is 0.
2. TxUlpsClk state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait for all TX_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition, for data lane #1, DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0)
2. TxRequestEsc state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2. LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

12.5.4.11.2 Exiting ULPS

To exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the

DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a clock lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO to OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit for clock lane to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GPtimer).
4. Wait for the time-out.
5. Change TxRequestEsc signals to INACTIVE state for the data lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO into OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxRequestEsc signals to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is

issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering/exiting into/from ULP state is started for specific lanes, users should wait for the completion of the sequence before changing the state of the same or other lanes.

12.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

NOTE: When the VC is used to send video mode data from the video port, the DSS.DSI_VCn_CTRL[9] MODE_SPEED and the DSS.DSI_VCn_CTRL[1] SOURCE bits are ignored.

12.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the display controller with the timing parameters.
2. Configure the DSS.DSI_VCn_CTRL register as follows:
   - SOURCE bit is ignored by hardware
   - BTA_LONG_EN bit is set to 0: No BTA on long packet
   - BTA_SHORT_EN bit is set to 0: No BTA on short packet
   - MODE bit set to 1: The video mode is selected
   - MODE_SPEED bit is ignored by hardware
3. Configure the DSS.DSI_VM_TIMING1 to DSS.DSI_VM_TIMING7 registers.
4. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
5. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
6. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1.
7. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
8. Enable the LCD video output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1

CAUTION

The restriction for stopping the video mode is that no frame should be sent by the display controller (DISPC) after disabling video mode in DSI.

12.5.4.12.2 Command Mode Transfer Example 1

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
   - SOURCE bit set to 0: The source is the L4 interconnect port

- BTA_LONG_EN bit is set to 0: No automatic BTA on long packet
- BTA_SHORT_EN bit is set to 0: No automatic BTA on short packet
- MODE bit set to 0: The command mode is selected

2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
3. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
5. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
6. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
7. For long packet:
   - Write the header value into the DSS.DSI_VCn_LONG_PACKET_HEADER register
   - Write the data into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload. Repeat step until WC is reached (see DSI_VCn_LONG_PACKET_HEADER)

   For the short packet:
   - Send short packets through the L4 interconnect:Write the header value into the DSS.DSI_VCn_SHORT_PACKET_HEADER register. Repeat step for each short packet.
8. Send one or more packets through L4 interconnect:
   - Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
   - Write the data into DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload.
   - Repeat step 5 for all the long packets
9. Send short packets through L4 interconnect:
   - Write the header value into DSS.DSI_VCn_SHORT_PACKET_HEADER register
   - Repeat step 6 for all the short packets
10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
11. The applicative software forces the bus turn-around:
    - Wait until the PACKET_SENT_IRQ has happened as many times as the number of sent packets
    - Set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1 to send manually a BTA
    - Wait until the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset to 0 by hardware
12. Receive the packets from the peripheral
    - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
    - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one word in the RX FIFO

12.5.4.12.3 Command Mode Transfer Example 2

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
   - SOURCE bit set to 0: The source is the L4 interconnect port
   - BTA_LONG_EN bit is set to 1: Automatic BTA on long packet
   - BTA_SHORT_EN bit is set to 1: Automatic BTA on short packet
   - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2]

PACKET_SENT_IRQ_EN bit to 1

3. Set the ForceTxStopMode bit to 1 in DSS.DSI_TIMING1 register.
4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
5. Configure the TX FIFO threshold and DMA requests parameters:
   - Program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field
   - Program the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field
6. Program the system DMA to be ready to send data to the L4 interconnect port
7. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
8. Poll the ForceTxStopMode bit to 0 in DSS.DSI_TIMING1 register.
9. Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
11. Receive the packets from the peripheral
    - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
    - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO
12. Repeat the steps 7 for all long packets.

12.5.5 DSI PLL Controller Basic Programming Model

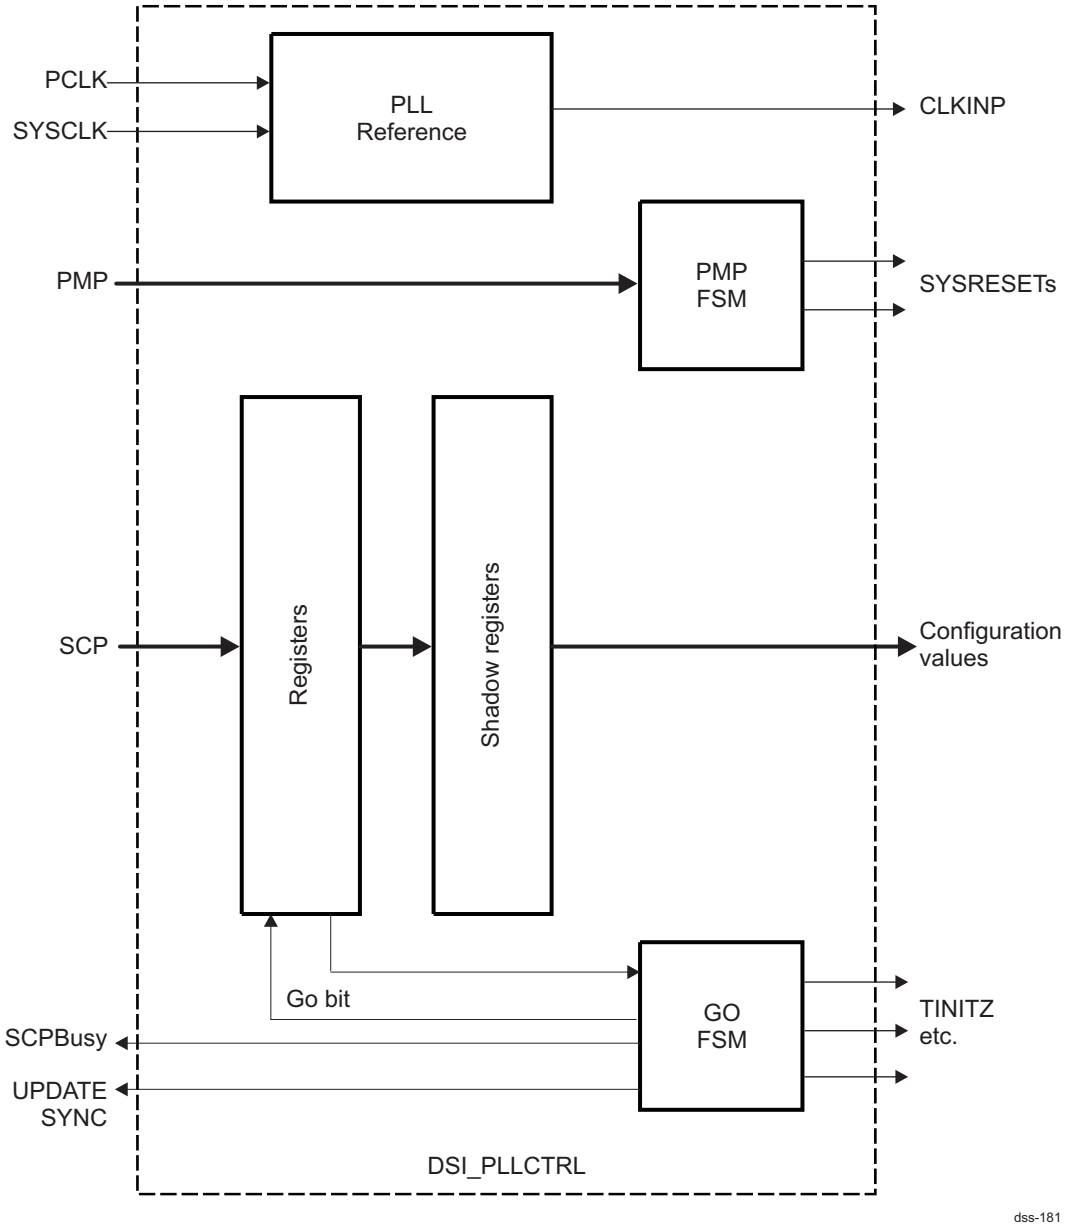
12.5.5.1 Software Reset

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, software users can monitor the reset status of the DSI PLL control module by reading the DSS.DSI_PLL_STATUS[0] DSI_PLLCTRL_RESET_DONE status bit.

12.5.5.2 DSI PLL Programming Blocks

Figure 12-139 shows the DSI PLL programming blocks.

Figure 12-139. DSI PLL Programming Blocks



12.5.5.3 DSI PLL Go Sequence

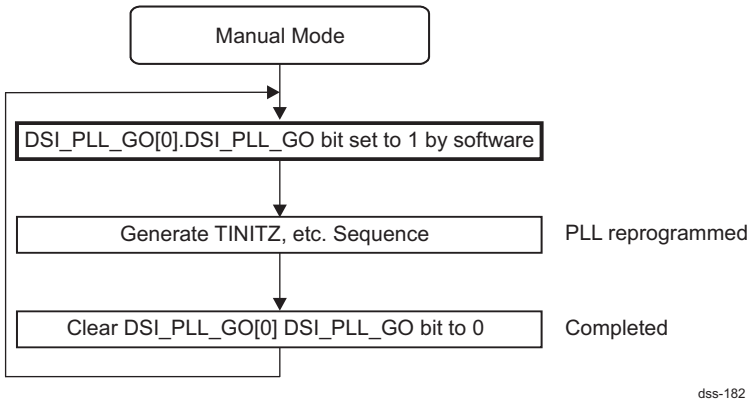
In Manual Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit should be set. The appropriate sequence should then be sent on the TINITZ, TENABLE & TENABLEDIV pins, respecting the timing requirements of the ADPLLV2. The DSS.DSI_PLL_GO[0] DSI_PLL_GO bit will be cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module, so that will be programmed at the same time. In this mode, the software should deassert CLKINEN by unsetting the DSS.DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN to 0 and to assert HSDIVBYPASS correctly by setting the DSS.DSI_PLL_CONFIGURATION2[20] DSI_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DSI_PHY and display subsystem during PLL locking. In manual mode the shadow register should be updated anyway so that valid values are present when later selecting automatic mode.

Figure 12-140 shows the DSI PLL Go flowchart in manual mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0).

Figure 12-140. DSI PLL Go Sequence (Manual Mode)

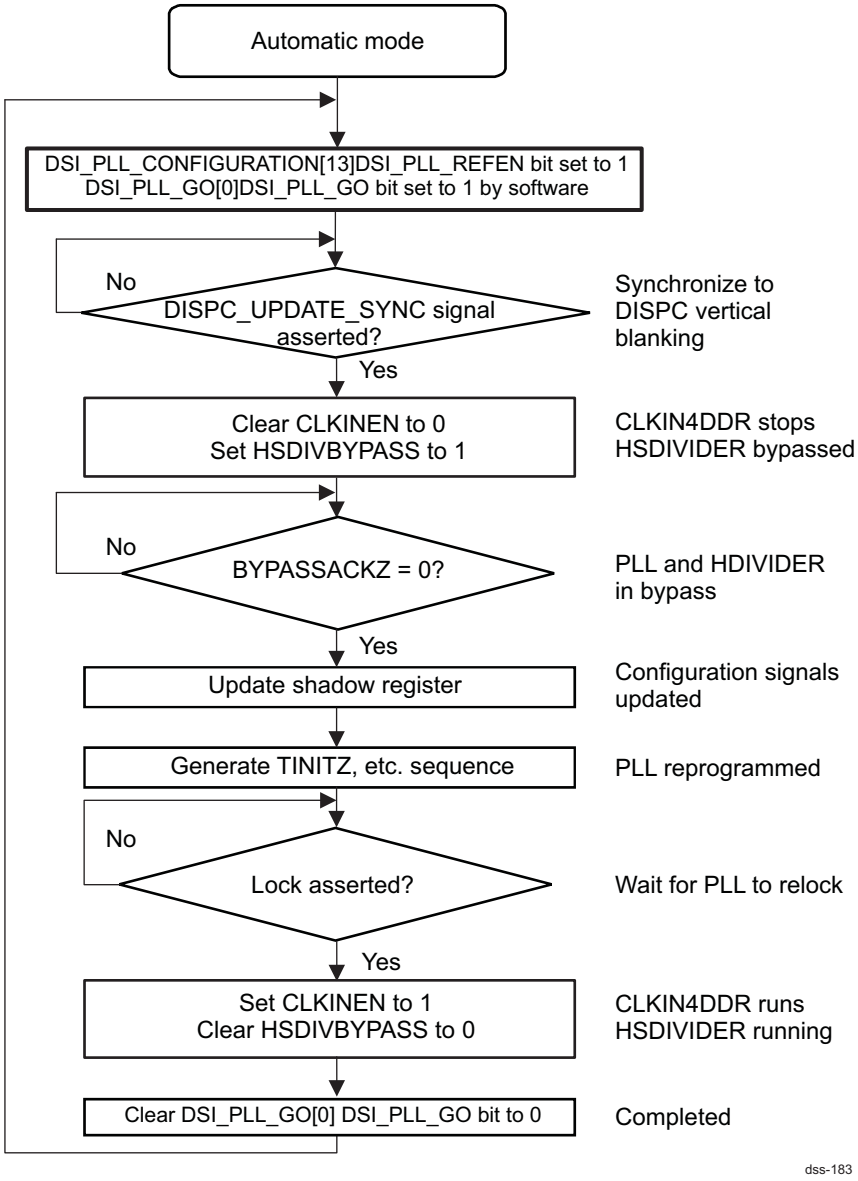


NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1),the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register will be deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN will be controlled automatically and the register value is overridden.

Figure 12-141 shows the DSI PLL Go flowchart in automatic mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1).

Figure 12-141. DSI PLL Go Sequence (Automatic Mode)



NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

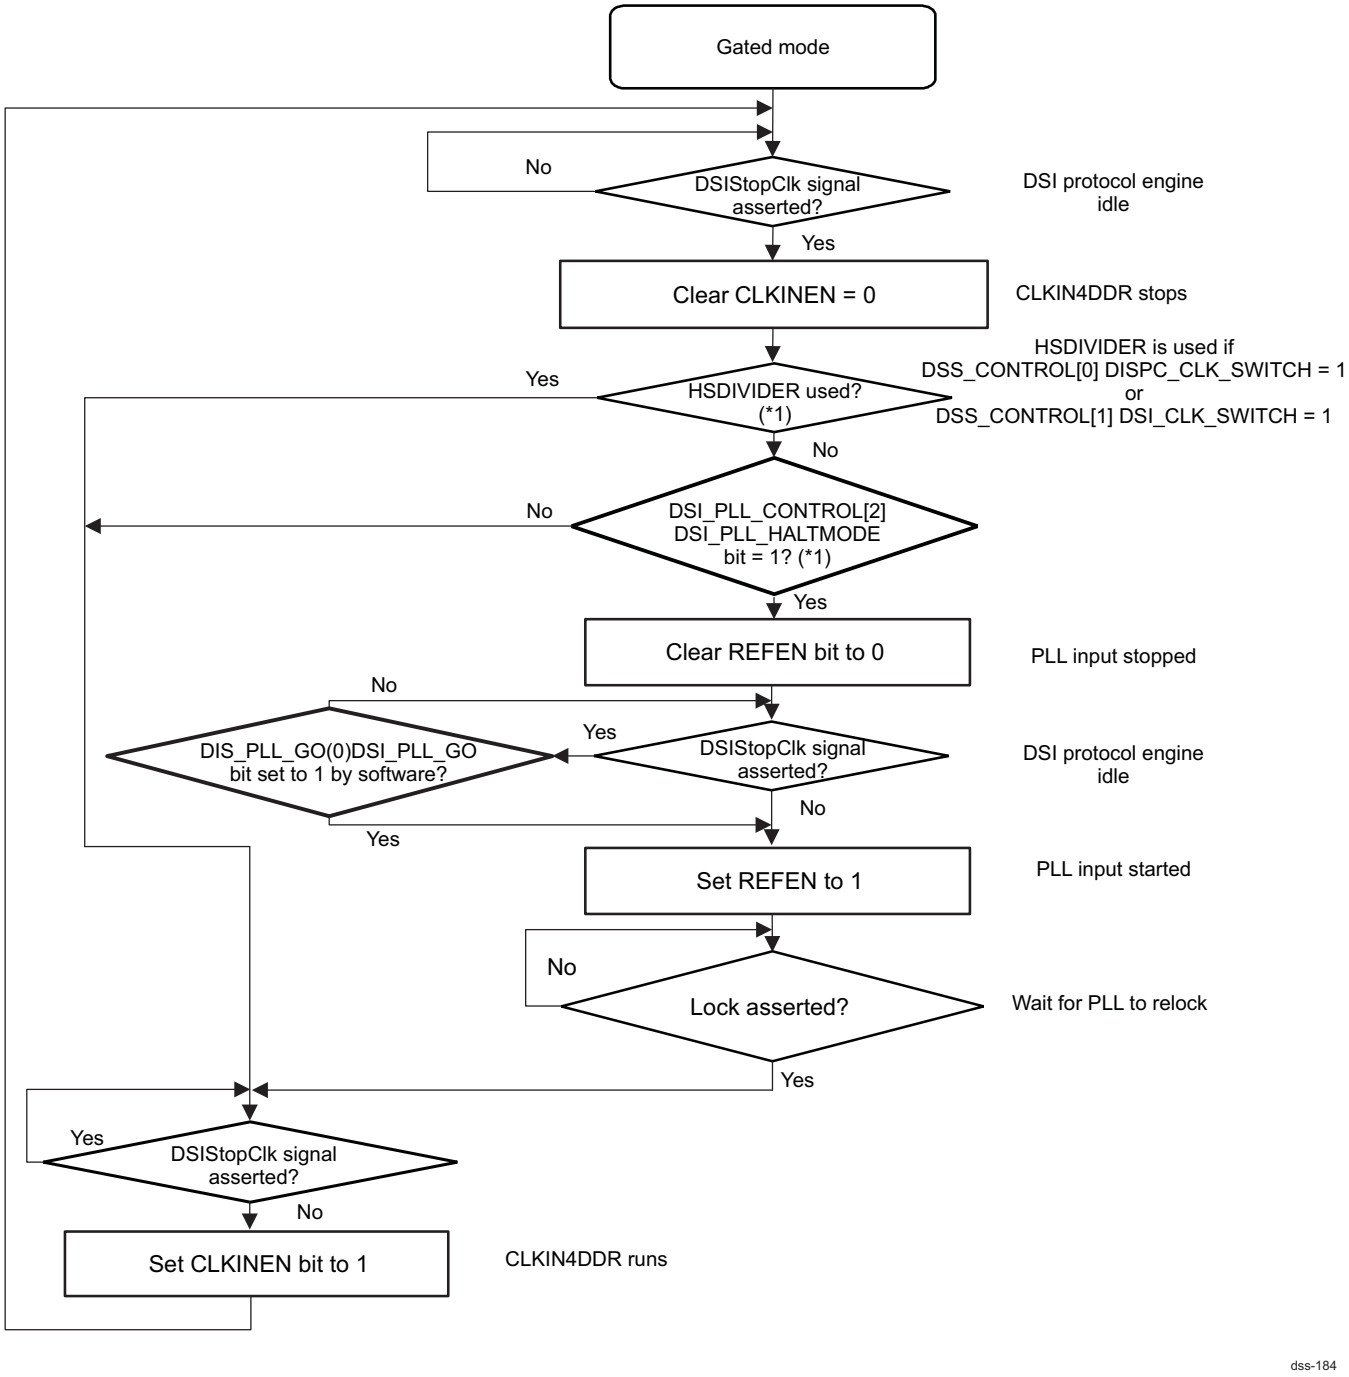
12.5.5.4 DSI PLL Clock Gating Sequence

Clock gating may be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, then the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstarted by inspecting the LOCK signal (DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit). Since TxByteClkHS is stopped when CLKIN4DDR is stopped, this should obviate the need for any explicit feedback that the clock has been unstarted in the other case. This flow chart should run even if the DSS.DSI_PLL_GO[0] DSI_PLL_GO bit has not been set.

Figure 12-142 shows the DSI PLL gated mode sequence.

Figure 12-142. Gated Mode Sequence



NOTE: All thick-outlined blocks show operations performed by software.

12.5.5.5 DSI PLL Lock Sequence

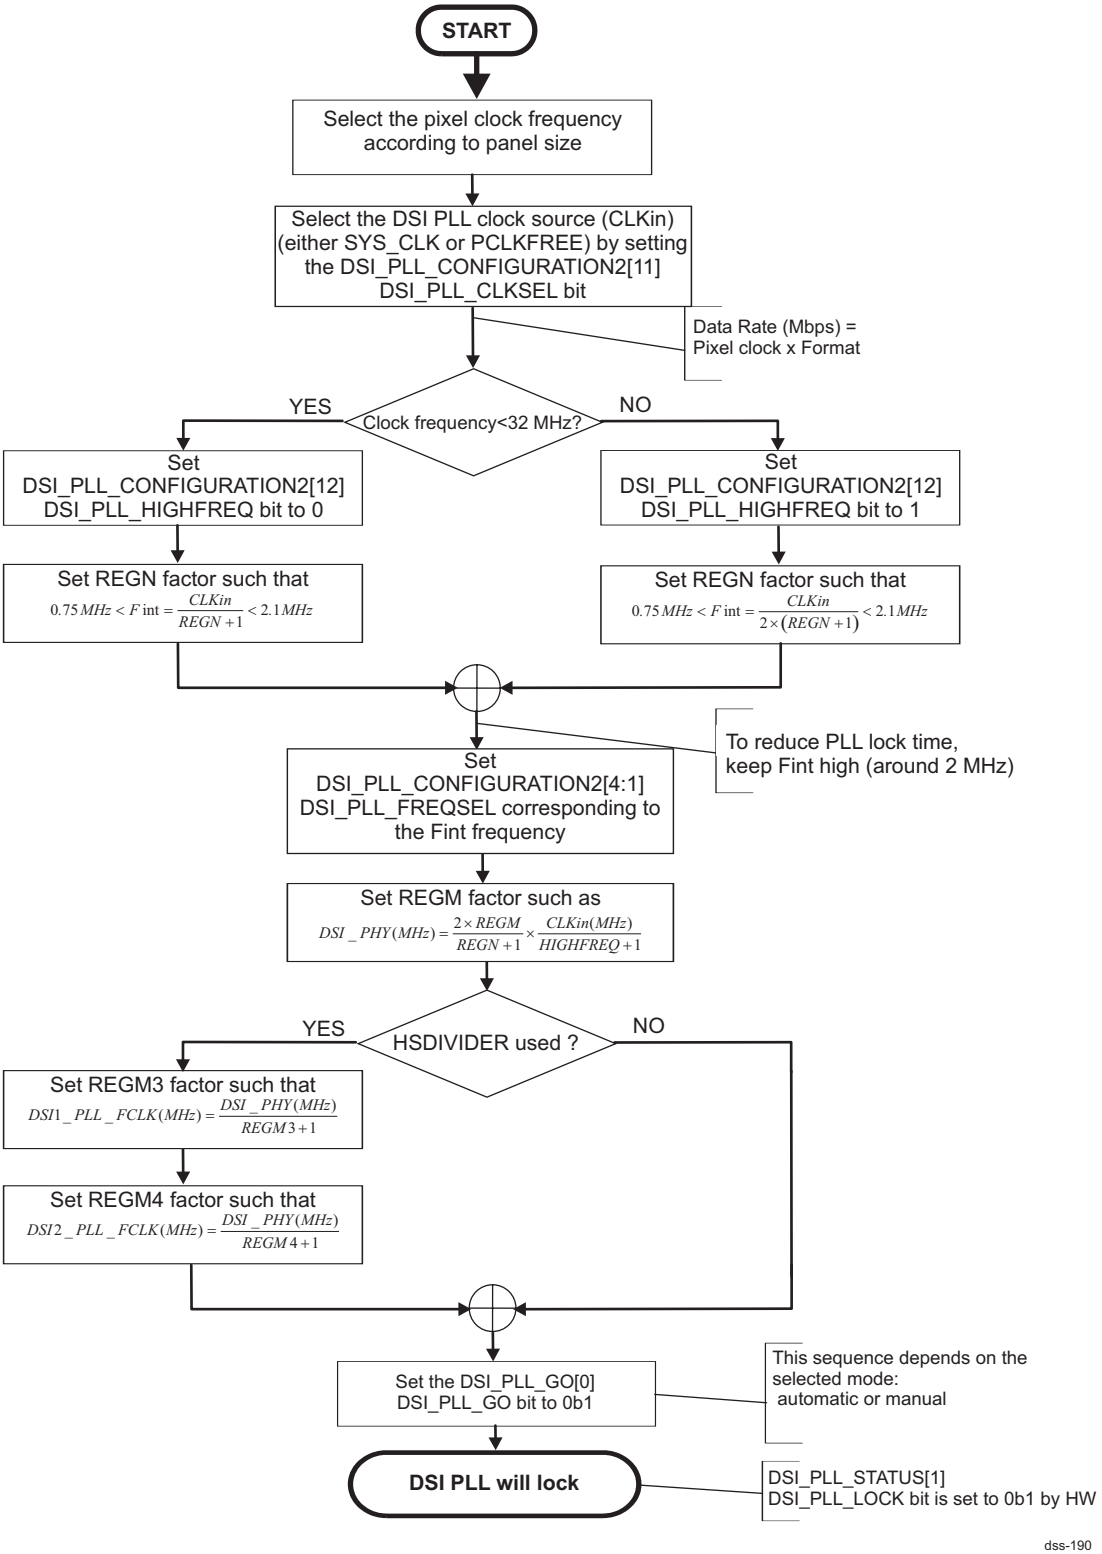
The DSI PLL (ADPLLv2) generates CLKIN4DDR. The HSDIVIDER generates two clocks: DSI1_PLL_FCLK connected to the display controller (DISPC) and the DSI2_PLL_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

CLKIN4DDR is twice the data rate and four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programed by DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field
- REGN factor is programed by DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field
- REGM3 factor is programed by DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV bit field
- REGM4 factor is programed by DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV bit field

Figure 12-143 shows the programming sequence.

Figure 12-143. DSI PLL Programming Sequence



NOTE:

- The REGM3 and REGM4 factors must according with the following conditions:
  - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be a multiple of the PCLK frequency (for proper settings of PCD and LCD factors in the DISPC)
  - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be lower than 173 MHz at nominal voltage (OPP3), and lower than 96 MHz at low voltage (OPP2).
- Most of the other DSI PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See Section 12.5.5.7 for details on DSI PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is 30 x 18 = 540 Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

To get CLKIN4DDR to 1080 MHz, set the REGM factor to 270 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x10E.

CLKIN4DDR = 2 x 270/13 x 26/1 = 1080 MHz

Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP3), and lower than 96 MHz at low voltage (OPP2), program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0xB:

DSI1_PLL_FCLK = DSI2_PLL_FCLK = 1080/12 = 90 MHz

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format

  The data rate is (60 x 16)/2 = 480 Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

  The frequency on the clock lane is 240 MHz (960 divided by 4).

  The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit to 0b0.

  Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 0b0 as the source clock frequency (SYS_CLK in this example) is lower than 32 MHz.

  Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

  To get CLKIN4DDR to 960 MHz, set the REGM factor to 240 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x0F0.

  CLKIN4DDR = 2 x 240/13 x 26/1 = 960 MHz

  Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP3), program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and

DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0x7:

DSI1_PLL_FCLK = DSI2_PLL_FCLK = 960/8 = 120 MHz

12.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

-
  - DSS.DSI_IRQSTATUS[9], PLL_RECAL_IRQ bit
  - DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ
  - DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ
- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL must be recalibrated. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored :

- The DSS.DSI_PLL_STATUS[3] DSI_PLL_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.DSI_PLL_STATUS[4] DSI_PLL_LIMP status bit informs about the DSI PLL limp status.

12.5.5.7 DSI PLL Recommended Values

Table 12-66 shows the DSI PLL recommended values.

Table 12-66. Recommended Programming Values

Field Name	Value	Description
DSI_HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_HALTMODE	-	See Section 12.5.5.4 for details
DSI_PLL_GATEMODE	-	See Section 12.5.5.4 for details
DSI_PLL_AUTOMODE	-	See Section 12.5.5.4 for details
DSI_PLL_GO	1->0	Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed
DSIPROTO_CLOCK_DIV	See (1)	DSI protocol engine clock divider
DSS_CLOCK_DIV	See (1)	DSS clock divider
DSI_PLL_REGM	See (1)	Feedback clock divider
DSI_PLL_REGN	See (1)	Reference clock divider
DSI_PLL_STOPMODE	1	Required to use GATEMODE bit
DSI_HSDIVBYPASS	0	PLL is controlling HSDIVIDER bypass
DSI_PROTO_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PROTO_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source

(1) The bit field value should be set according to the desired clock frequency.

Table 12-66. Recommended Programming Values (continued)

Field Name	Value	Description
DSS_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSS clock source
DSS_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSS clock source
DSI_BYPASSEN	0	To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit should be set to 1
DSI_PHY_CLKINEN	1	Enable CLKIN4DDR
DSI_PLL_REFEN	1	Enable PLL reference
DSI_PLL_HIGHFREQ	0/1	Set to 1 if the clock reference is higher than 32 MHz (21 MHz if DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN = 0)
DSI_PLL_CLKSEL	0/1	Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK.
DSI_PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt should be used to decide when to perform a PLL uncalibration No automatic uncalibration will be performed
DSI_PLL_TIGHTPHASELOCK	0	Normal criteria
DSI_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time
DSI_PLL_PLLLPMODE	0	Normal operation For smaller display sizes may be possible to set to 1
DSI_PLL_FREQSEL	See (2)	Must be set according to the PLL internal reference frequency (after N divider) See register descriptions for values
DSI_PLL_IDLE	0	PLL active

(2) The bit field value should be set according to the desired clock frequency.

12.5.6 DSI Complex I/O Basic Programming Model

12.5.6.1 Software Reset

The clock domain using the TxByteClkHS from the DSI complex I/O has dedicated reset done information in the DSS.DSI_COMPLEXIO_CFG1[29] RESET_DONE bit. The DSS.DSI_SYSCONFIG[1] SOFT_RESET bit is used to reset the TxByteClkHS power domain. A dummy read using the SCP interface to any DSI_PHY register is required after DSI_PHY reset to complete the reset of the DSI complex I/O.

12.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in DSS.DSI_PHY_CFG5 register:

- DSS.DSI_PHY_CFG5[31] RESETDONETXBYTECLK bit : Reset done for the TXBYTECLK domain.
- DSS.DSI_PHY_CFG5[28:26] RESETDONETXCLKESCi bits: Reset done for the TXCLKESC domain for lane i (i between 0 and 2).
- DSS.DSI_PHY_CFG5[30] RESETDONESCPCLK bit: Reset done for the SCP clock domain. Software

users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the RESETDONESCPCLK signal goes high and software users can read again the DSS.DSI_PHY_CFG5[30] RESETDONESCPCLK bit to ensure that the value is now 1.

NOTE: The software should not write in the DSI_PHY_SCP registers before the DSS.DSI_PHY_CFG5[30] RESETDONESCPCLK bit is set to 1.

- DSS.DSI_PHY_CFG5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state machine is complete when the RESETDONEPWRCLK signal goes high.

12.5.6.3 Pad Configuration

The number of lanes is configurable through the DSS.DSI_COMPLEXIO_CFG1 register.

It is not allowed to change on the fly the position (by modifying the DATAi_POSITION with i=1 or 2 and CLOCK_POSITION bit fields), P/N order (Positive/Negative order of the differential pair by modifying the DATAi_POL with i=1 or 2 and CLOCK_POL) or number of active data lanes (by modifying the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit reset value is 0).

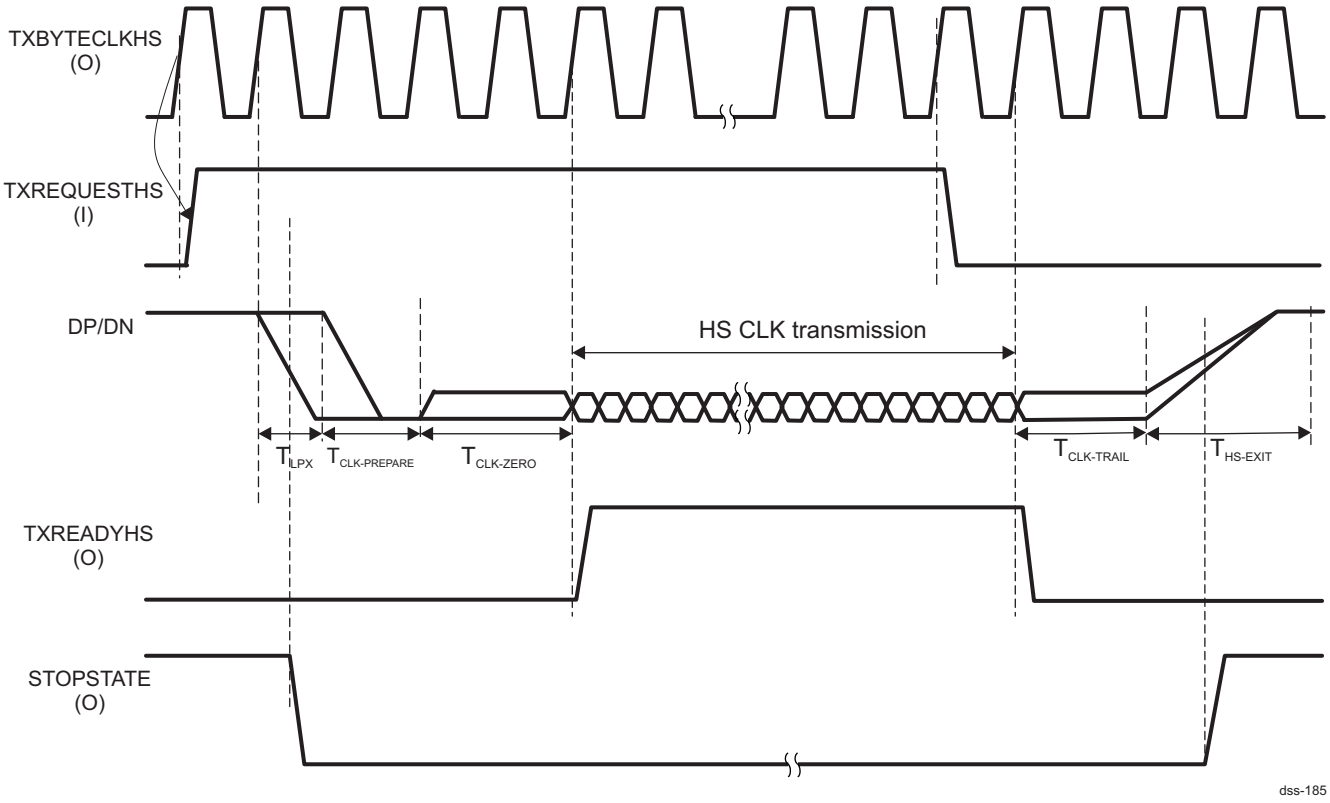
12.5.6.4 Display Timing Configuration

Depending on the CLKIN4DDR frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI complex I/O registers.

12.5.6.4.1 High-Speed Clock Transmission

Figure 12-144 shows an example of high-speed Clock Transmission.

Figure 12-144. High-Speed Clock Transmission



TXByteClkHS is an output clock which is derived by dividing the CLKIN4DDR clock by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_CFG1[20:16] TLPX_HALF bit field.
- THS-PREPARE timing is programmed by the DSS.DSI_PHY_CFG0[31:24] THS_PREPARE bit field.
- TCLK-ZERO timing is programmed by the DSS.DSI_PHY_CFG1[7:0] TCLK_ZERO bit field.

. TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSI_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSI_PHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.DSI_PHY_CFG1[15:8] TCLK_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_CFG0[7:0] THS_EXIT bit field.

The DSI_PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

It is requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

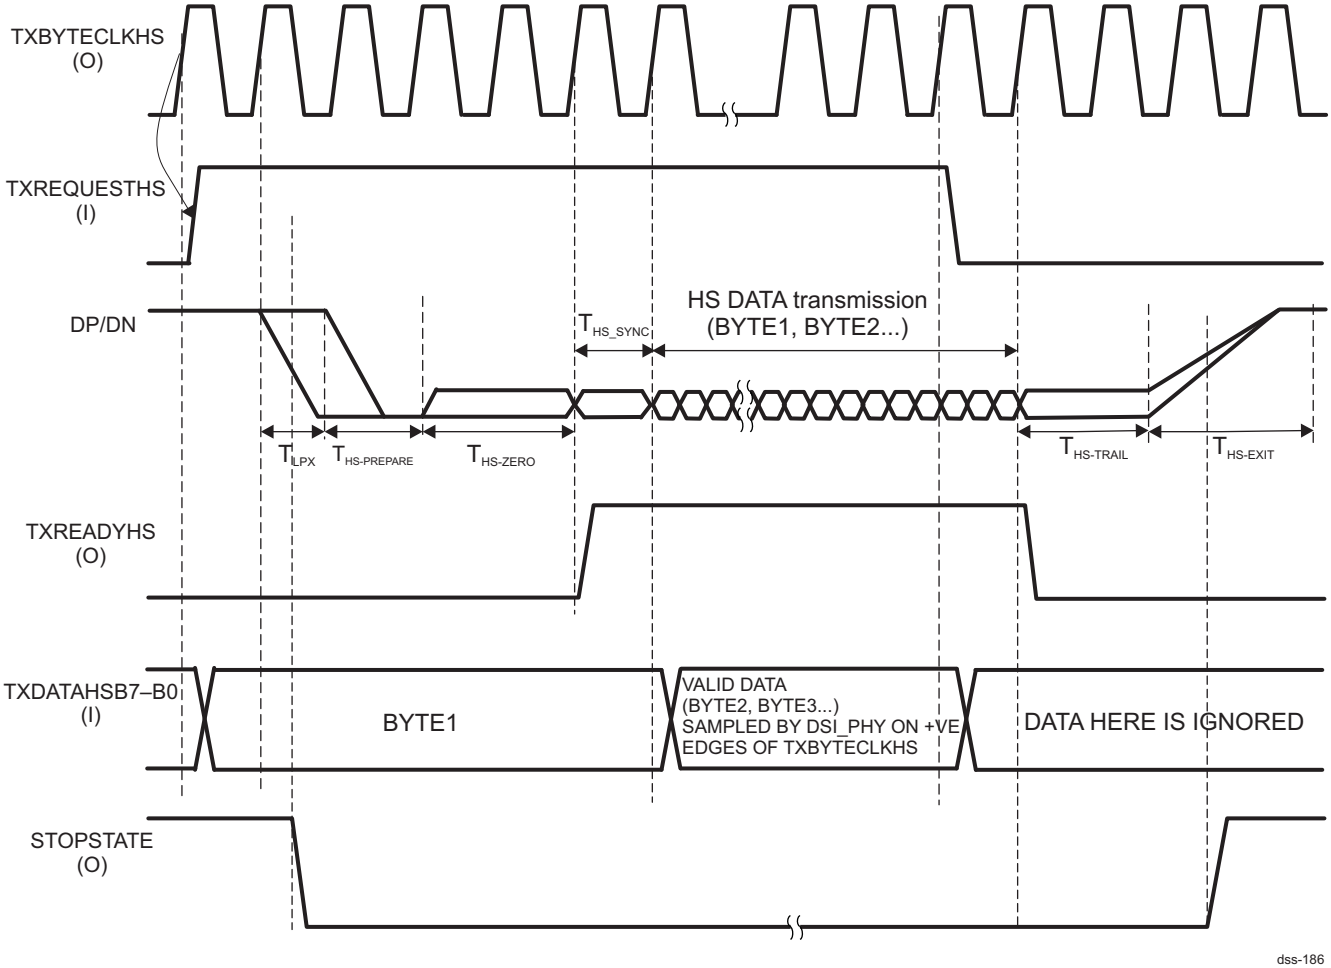
CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after TxRequestHS falling edge is received by DSI_PHY.

The DSI protocol engine should ensure that TXREQUESTESC, TXULPSCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

12.5.6.4.2 High-Speed Data Transmission

Figure 12-145 shows an example of high-speed Data Transmission.

Figure 12-145. High-Speed Data Transmission



TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_CFG1[20:16] TLPX_HALF bit field.
- THS-PREPARE + THS-ZERO timing is programmed by the DSS.DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO bit field.

THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is 8 high-speed bits, and can be configured through the tDSI_PHY_CFG2[31:24] HS_SYNC bit field.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and programmed by the following register bit fields:

- THS-TRAIL timing is programmed by the DSS.DSI_PHY_CFG0[15:8] THS_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_CFG0[7:0] THS_EXIT bit field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

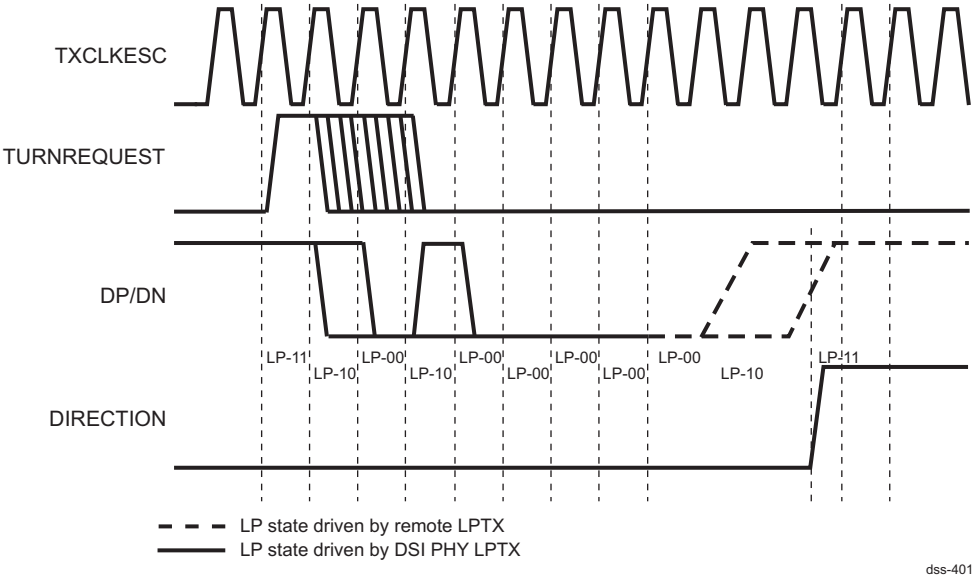
The Protocol should ensure that TXREQUESTESC, TXULPSCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

12.5.6.4.3 Turn-Around Request in Transmit Mode

When the DSI PHY is in transmit mode, the DSI protocol engine can request a turnaround by making the TurnRequest signal high for at least one clock cycle of TxClkEsc (see Section 12.4.3.7.3, *TurnRequest FSM*).

The DSI PHY transmits the turn-around request pattern (LP 11-10-00-10-00-00-00-00) (see Figure 12-146). The number of 00 states at the end of the pattern is defined by the $T_{TA\text{-}GO}$ timing parameter and is programmable through the DSS.DSI_PHY_CFG1[31:29] TTA_GO bit field, in number of TxClkEsc clocks. Following the transmission of the pattern, the DSI PHY disables its LP transmitters and waits for an acknowledgement from the remote device. The remote device detects the turn-around request and acknowledges it by driving LP-10, followed by the STOP state. When this acknowledgment is received (BTA_IRQ is asserted, as described in Section 12.4.3.8, *Bus Turnaround*), the DSI PHY switches to receive mode and indicates the completion of the turn-around procedure by changing the direction (BTA_EN = 0).

Figure 12-146. Turn-Around Request in Transmit Mode

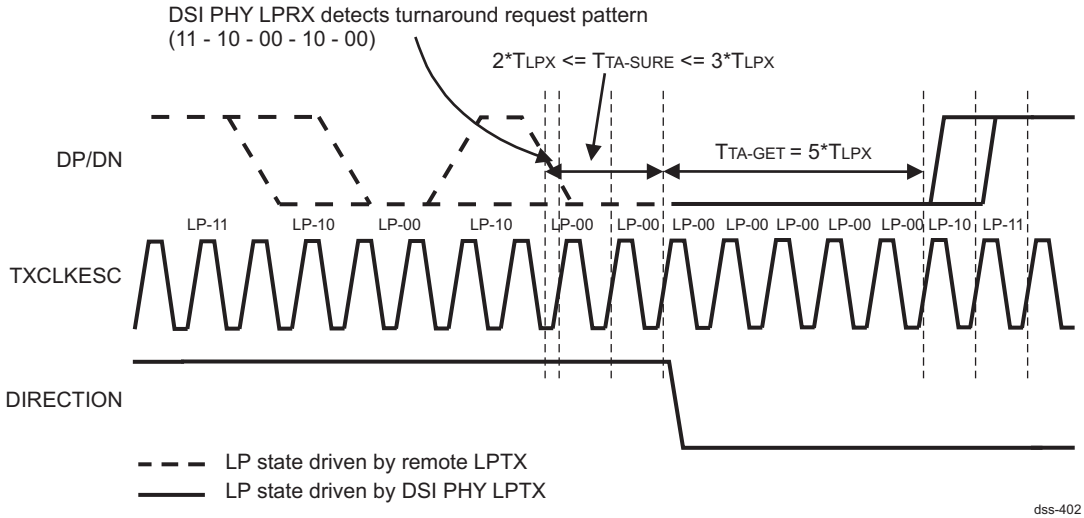


The DSI protocol engine must not stop TxClkEsc after the turn-around process completes (the DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit must be kept at 1), because TxClkEsc is also used in handling a turn-around request transmitted by a remote slave device (see Section 12.5.6.4.4, *Turn-Around Request in Receive Mode*.

12.5.6.4.4 Turn-Around Request in Receive Mode

When the DSI PHY is in the receive mode, an LP pattern of 11-10-00-10-00 on DP/DN lines indicates a turn-around request from the remote device (see Figure 12-147).

Figure 12-147. Turn-Around Request in Receive Mode



If the line stays in LP-00 for a time $T_{TA-SURE}$, the DSI PHY accepts the turn-around request, changes the direction, transmits LP-00 for a time T_{TA-GET}, and then transmits the acknowledgment pattern LP-10, followed by the STOP state.

This completes the turn-around procedure (BTA_IRQ is asserted, as described in Section 12.4.3.8, *Bus Turnaround*). The $T_{TA-SURE}$ and T_{TA-GET} timing parameters are programmable through DSS.DSI_PHY_CFG1 in number of TxClkEsc clocks:

- $T_{TA-SURE}$ can be configured in the [28:27] TTA_SURE bit field.

- T_{TA-GET} can be configured in the [26:24] TTA_GET bit field.

12.5.6.4.5 Other DSI_PHY Transmission and Reception

The timing of the following sequences defined in the DSI_PHY protocol cannot be programed by users:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP state command transmission on data lanes
- ULP state transmission on clock lane
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP state command on clock lane in receive mode
- ULP state command on data lane in receive mode

12.5.6.5 Error Handling

A dedicated register for the DSI complex I/O, DSS.DSI_COMPLEXIO_IRQSTATUS, indicates the state of each error provided by the DSI complex I/O error signals. The DSI_PHY reports the following errors:

- DSS.DSI_COMPLEXIO_IRQSTATUS[7:5] ERR_ESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[2:0] ERRSYNCESCi_IRQ: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESC is made high and remains high until the next change in line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[12:10] ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the DSS.DSI_COMPLEXIO_IRQSTATUS[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in DSS.DSI_COMPLEXIO_IRQSTATUS register happened, the DSS.DSI_IRQSTATUS[10] COMPLEXIO_ERR_IRQ bit is set to 1 at DSI protocol engine level.

The software must take appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral though reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

12.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

12.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.DISPC_CONTROL[11] STALLMODE bit. The DSS.DISPC_CONTROL[5] GOLCD bit should not be set to 1 but the display controller configuration (DMA engine, pipelines associated to the LCD output,..) should be set before enabling the LCD output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC_CONTROL[16] FIFOHANDCHECK should be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It should be disabled before resetting the DSS.DISPC_CONTROL[11] STALLMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See Figure 12-148.

12.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI_CONTROL
- DSS.RFBI_PIXEL_CNT
- DSS.RFBI_LINE_NUMBER

12.5.7.2.1 High Threshold

The DSS.RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register RFBI_DATA. It should be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

NOTE: Software users can access the RFBI_DATA location without using the DMA request and without programming the high threshold value (backward mode).

12.5.7.2.2 Bypass Mode

Setting the DSS.RFBI_CONTROL[1] BYPASSMODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

12.5.7.2.3 Enable

Setting/resetting the DSS.RFBI_CONTROL[0] ENABLE bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 12-67. RFBI Behavior

RFBI_CONTROL[1] BYPASSMODE bit value	RFBI_CONTROL[0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See Figure 12-148.

12.5.7.2.4 Configuration Selection

Setting the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

12.5.7.2.5 ITE Bit

Set the DSS.RFBI_CONTROL[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the DSS.RFBI_CONTROL[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.RFBI_CONTROL[0] ENABLE bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI_CONTROL[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

12.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI_CONTROL[0] ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the DSS.RFBI_PIXEL_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3 and DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0x0, an even number of write accesses to the data register should be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is 0x3 - meaning that 2 pixels are sent over 3 cycles -, the number of pixels to be programmed in the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field should be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3, DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0, and back to back register write is processed, the following registers should be written after the first data: RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS. The whole data transfer should first be performed before being able to write to any other registers (RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS).

12.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, the hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

12.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI_SYSCONFIG
- DSS.RFBI_SYSSTATUS
- DSS.RFBI_CONFIG0 (configuration 0) and DSS.RFBI_CONFIG1 (configuration 1)
- DSS.RFBI_VSYNC_WIDTH
- DSS.RFBI_HSYNC_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI_CONTROL[3:2] CONFIGSELECT bit field).

12.5.7.3.1 Parallel Mode

The DSS.RFBI_CONFIGi[1:0]PARALLELMODE bit field (with i = 0, 1) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

12.5.7.3.2 Trigger Mode

Setting the DSS.RFBI_CONFIG[3:2]TRIGGERMODE bit field configures the trigger on the external TE signal (RFBI_TE_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI_CONTROL[4] ITE bit.

12.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

12.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

12.5.7.3.5 Cycle Format

Setting the DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field (with i = 0, 1) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI_DATA_CYCLE_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 00) only

  or
- DSS.RFBI_DATA_CYCLE1_i and DSS.RFBI_DATA_CYCLE2_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 01)

  or
- DSS.RFBI_DATA_CYCLE1_i, DSS.RFBI_DATA_CYCLE2_i, and DSS.RFBI_DATA_CYCLE3_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI_DATA_CYCLE_i registers.

12.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI_CONFIGi[12:11] UNUSEDBITS bit field (with i = 0, 1) is used.

12.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the DSS.RFBI_CONFIGi[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to Table 12-68 for the bits configuration values.

- Chip-select assertion/deassertion time

  RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
  DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME bit field (with i = 0, 1).

  The chip-select deassertion time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME bit field (with i = 0, 1)

> **CAUTION**
>
> Configuring DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME = DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

  The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:
  DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH bit field (with i = 0, 1)

  It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

  - The DSS.RFBI_CYCLE_TIMEi [19] RRENABLE bit: Read-to-read access
  - The DSS.RFBI_CYCLE_TIMEi [20] WWENABLE bit: Write-to-write access
  - The DSS.RFBI_CYCLE_TIMEi [18] RWENABLE bit: Read-to-write access
  - The DSS.RFBI_CYCLE_TIMEi [21] WRENABLE bit: Write-to-read access

    By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

  The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:
  DSS.RFBI_CYCLE_TIMEi[27:22] ACCESSTIME bit field (with i = 0, 1)

  When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME, with i = 0, 1).

- Write enable cycle time

  The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:
  The DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME bit field (with i = 0, 1)

- Write enable assertion/deassertion time

  The WE assertion delay time from start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[13:10] WEONTIME bit field (with i = 0, 1)

  The WE deassertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[19:14] WEOFFTIME bit field (with i = 0, 1)

- Read enable cycle

  The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:
  The DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME bit field (with i = 0, 1)

- Read enable assertion/deassertion time

  The RE assertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[23:20] REONTIME bit field (with i = 0, 1)

  The RE deassertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH bit field = 0, with i = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 12-68 summarizes the configurations values for each timing bit.

Table 12-68. RFBI Timings Configuration

Configuration bits[1]	Granularity[2]	
	one	two
DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME	0 to 15	0 to 30

(1) Where i = 0 or 1.
(2) Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIGi[4] TIMEGRANULARITY bit.

Table 12-68. RFBI Timings Configuration (continued)

Configuration bits[1]	Granularity[2]	
	one	two
DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[27:22] ACCESSTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[13:10] WEONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[19:14] WEOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[23:20] REONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME	0 to 63	0 to 126

12.5.7.3.8 RFBI State-Machine

Referring to Table 12-37, the signals RFBI_A0, RFBI_RD, and RFBI_WR are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STATUS). When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The DSS.RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI_DATA only.

- Command register

  Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.

- Parameter register

  Write a parameter at a time by writing in the DSS.RFBI_PARAM register.

  If the previous parameter is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new parameter is stalled.

- Data register

  Write one or two pixels at a time by writing in the RFBI_DATA register (when DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT = 0x3 with i = 0, 1, two pixels must be written contiguously, no other access to RFBI registers except DSS.RFBI_DATA is allowed).

  The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.RFBI_CONFIGi[8:7] L4FORMAT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels

  If the previous data are not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, the access is not stalled.

- Read/status register

  Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI_READ or DSS.RFBI_STATUS registers. In this case, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.

  When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

12.5.7.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x0
- External trigger mode:
  - TE external trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x1
  - HSYNC/VSYNC external trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x2

Figure 12-148 gives an example of how to program and use the RFBI module:

Figure 12-148. How to Use RFBI

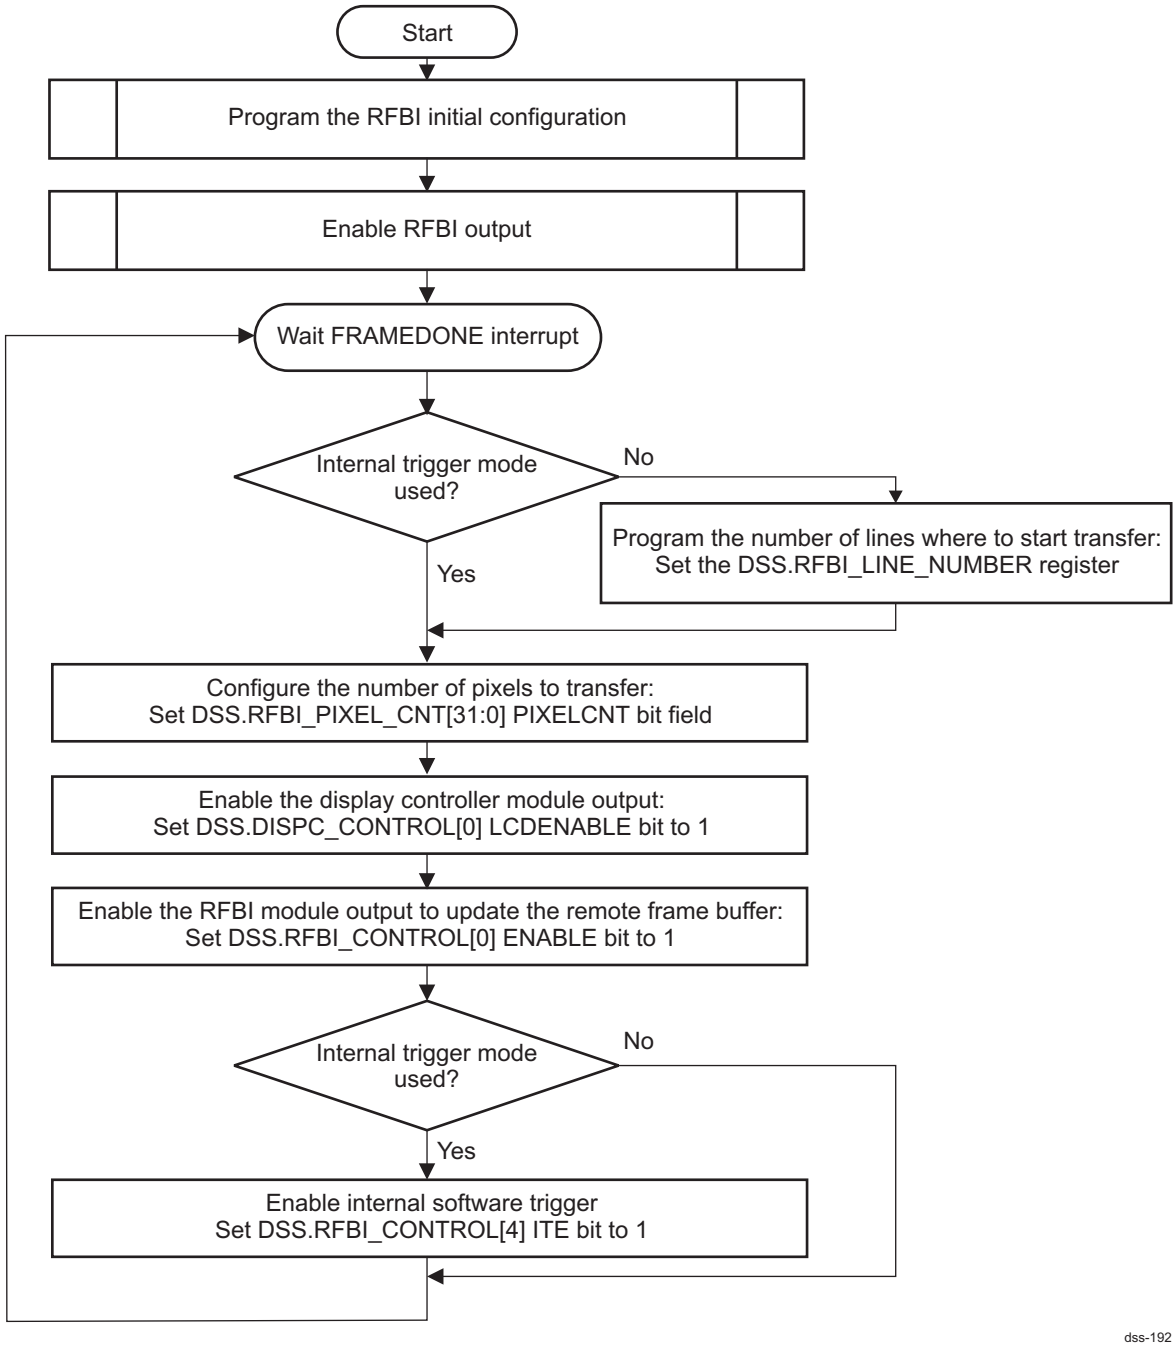


Figure 12-149 details how to configure the RFBI registers:

Figure 12-149. RFBI Initial Configuration

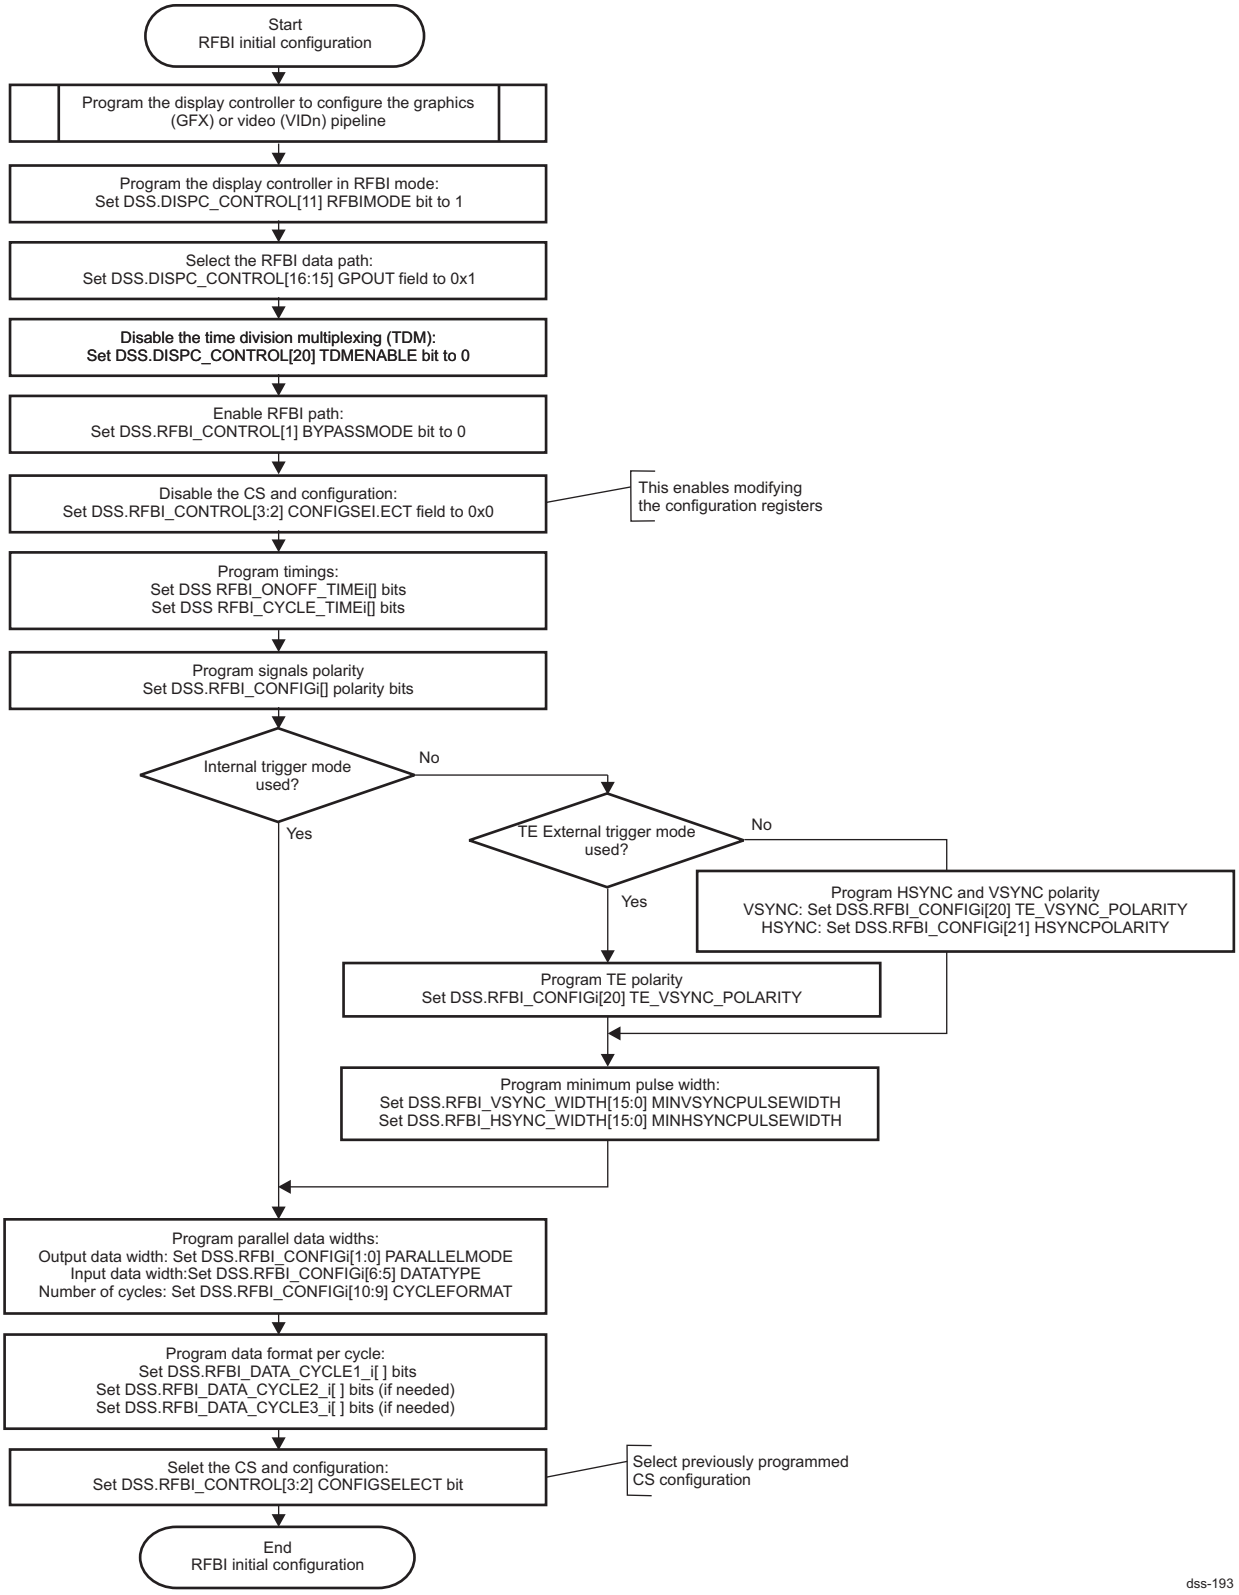

Figure 12-150 describes how to enable the RFBI module.

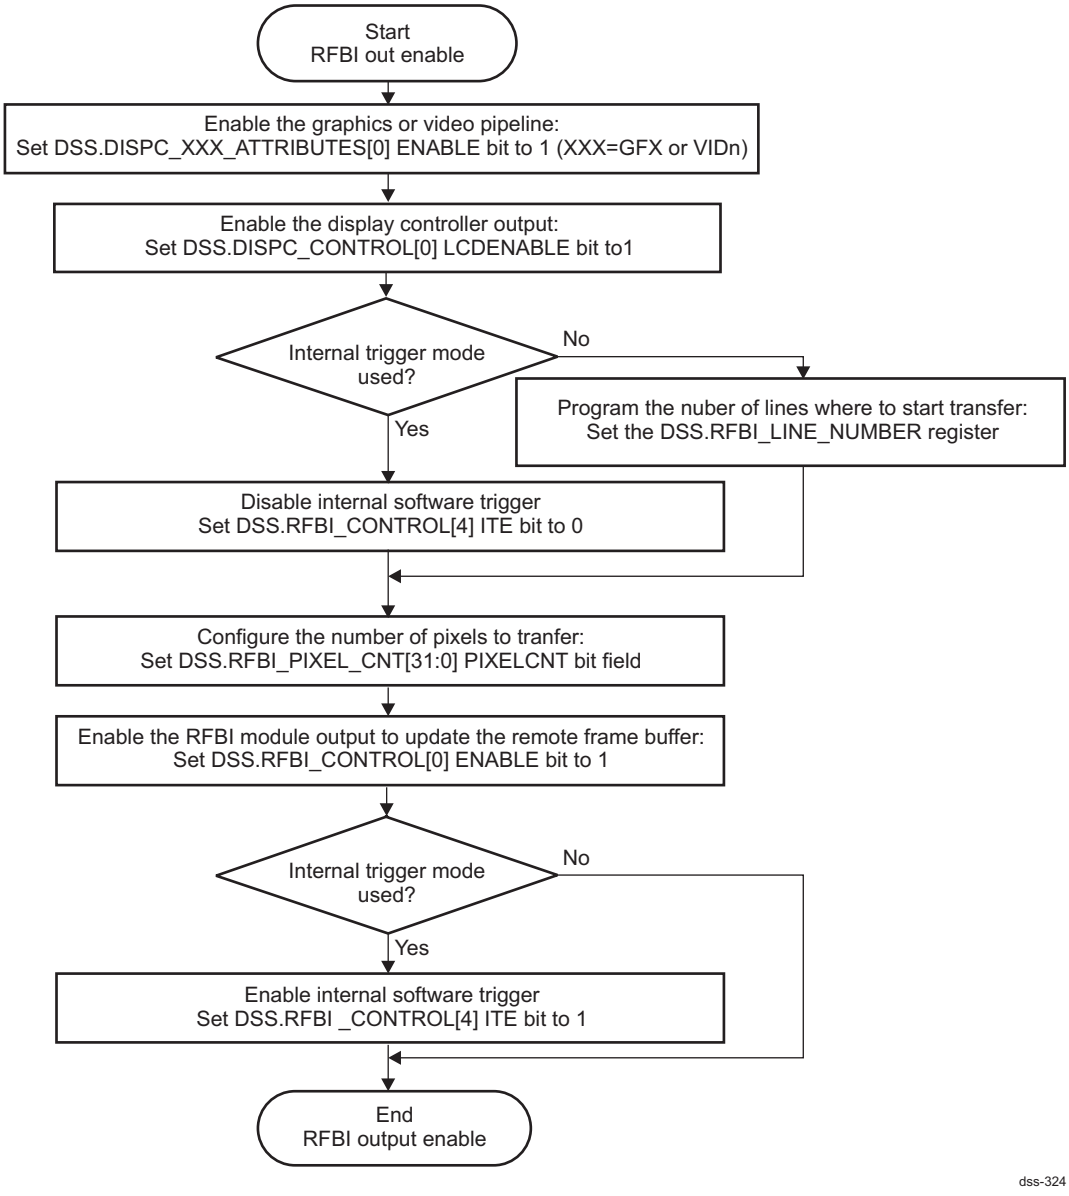
Figure 12-150. RFBI Output Enable



12.5.8 Video Encoder Basic Programming Model

12.5.8.1 Video Encoder Software Reset

By setting the DSS.VENC_F_CONTROL[8] RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

NOTE: Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

12.5.8.2 Video DAC Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or

- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2 (chroma analog signal)

  Selection is performed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit:

  - When VENC_OUT_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
  - When VENC_OUT_SEL bit is set to 1, video DAC1 is selected for luma signal

  One of the first VENC settings is to enable the output of the video DACs. This setting depends on the video output format:

  - CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE bit to 1
  - Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 1

12.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC_F_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in Table 12-69, depending on the video standard used (PAL or NTSC). The DSS.VENC_F_CONTROL and DSS.VENC_SYNC_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

12.5.8.4 Video Encoder Register Settings

For video encoder programming, see Table 12-69. This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

Table 12-69. Video Encoder Register Programming Values

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000
VENC_VIDOUT_CTRL	0x00000001	0x00000001
VENC_SYNC_CTRL	0x00008040	0x00000040
VENC_LLEN	0x00000359	0x0000035F
VENC_FLENS	0x0000020C	0x00000270
VENC_HFLTR_CTRL	0x00000000	0x00000000

NOTE: The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC_SIZE_DIG[10:0] PPL = 720 - 1 = 719 = 0x2CF
DSS.DISPC_SIZE_DIG[26:16] LPP = (482/2) - 1 = 240 = 0xF0
DSS.DISPC_GFX_BA0 or DSS.DISPC_VIDn_BA0 = Base address of even bit field data
DSS.DISPC_GFX_BA1 or DSS.DISPC_VIDn_BA1 = Base address of odd bit field data

12.5.9 SDI Basic Programming Model

This section describes how to configure the SDI module for FlatLink3G-compliant LCD panel support.

Configure the SDI, and then configure the display controller.

12.5.9.1 SDI Configuration

NOTE: To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode)
- Set the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS_SDI_CONTROL[1:0] SDI_BWSEL bit field to 0x2 (color depth is 24 bits)

12.5.9.1.1 SDI PLL Configuration

The programming of the PLL divisor must be consistent with the choice of the number of data pairs. The PLL divisor determines the multiplication factor from the pixel clock frequency to data rate.

Table 12-70 lists some example values of the PLL settings for TI FlatLink3G.

Table 12-70. PLL Divisor Example Values for TI FlatLink3G

		24-BPP data		
		1 data pair	2 data pairs	3 data pairs
Recommended values	Pixel clock frequency (MHz)	15	30	65
	DSS.DSS_PLL_CONTROL[16:11]			
	SDI_PLL_REGN bit field (N factor = SDI_PLL_REGN bit field value + 1)	0x7	0xE	0xF
	DSS.DSS_PLL_CONTROL[10:1]			
	SDI_PLL_REGM bit field (M factor)	0xF0	0xE1	0x140
	DDS.DSS_PLL_CONTROL[19]			
	SDI_PLL_HIGHFREQ	0	0	1
	Effective PLL divisor value (M/N)	30	15	10

For more details on SDI PLL programming settings, see Section 12.6.3.

12.5.9.1.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC_POL_FREQ[16] RF bit to drive HSYNC and VSYNC on the rising edge of PCLK.
- Set the DSS.DISPC_POL_FREQ[17] ONOFF bit.
- Clear the DSS.DISPC_POL_FREQ[14] IPC bit to drive the pixel data on the rising edge of PCLK.
- Set the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to set the LCD-enable signal active high.

The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:

- Set the DSS.DISPC_POL_FREQ[13] IHS bit to 1 to set HSYNC active low.
- Set the DSS.DISPC_POL_FREQ[12] IVS bit to 1 to set VSYNC active low.
- Clear the DSS.DISPC_POL_FREQ[15] IEO bit to set the data enable active high.

12.5.9.1.3 Number of Data Pairs

To select the number of data pairs used to transmit display data between the device and the display panel, set the DSS.DSS_SDI_CONTROL[3:2] SDI_PRSEL field.

Table 12-71 lists the different values for these bits based on the number of data pairs.

Table 12-71. SDI Pixel Data Format

	DSS.DSS_SDI_CONTROL[3:2] SDI_PRSEL
1 data pair (DATA1 pair)	00
2 data pairs (DATA1 and DATA2 pair)	01
3 data pairs (DATA1, DATA2, and DATA3 pair)	10

12.5.9.2 SDI Power-Management Programming Sequence

This section describes the software sequence for powering on and powering down the SDI module.

12.5.9.2.1 SDI Reset State

After DSS power domain reset or power-on reset, the SDI module is in low-power mode by default with the following configuration:

- Display SS pads multiplexing is in parallel mode and not in SDI mode:
  - CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 field values is 0x0: SDI_DATA1N/SDI_DATA1P signals are not mapped on dss_data10/dss_data11 pins.
  - CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field values is 0x0: SDI_DATA2N/SDI_DATA2P signals are not mapped on dss_data12/dss_data13 pins.
  - CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field values is 0x0: SDI_DATA3N/SDI_DATA3P signals are not mapped on dss_data14/dss_data15 pins.
  - CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field values is 0x0: SDI_VSYNC/SDI_HSYNC signals are not mapped on dss_data18/dss_data19 pins.
  - CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field values is 0x0: SDI_DEN/SDI_STP signals are not mapped on dss_data20/dss_data21 pins.
  - CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field values is 0x0: SDI_CLKP/SDI_CLKN signals are not mapped on dss_data22/dss_data23 pins.
- SDI PLL is in reset mode: the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit value is 0x0.

12.5.9.2.2 SDI Power_On Sequence

When exiting OFF mode, to power-on the SDI module, software users must program the following sequence:

1. Program the SDI pads multiplexing configuration:
   (a) Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA1P signal on dss_data11 pin.
   (b) For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA2P signal on dss_data13 pin.
   (c) For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA3P signal on dss_data15 pin.

(d) Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 bit field to 0x1 to select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field to 0x1 to select SDI_HSYNC signal on dss_data19 pin.

(e) Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 bit field to 0x1 to select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field to 0x1 to select SDI_STP signal on dss_data21 pin.

(f) Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 bit field to 0x1 to select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field to 0x1 to select SDI_CLKN signal on dss_data23 pin.

2. Wait 1 ms.
3. Release the SDI PLL reset signal by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x1.

NOTE: The same software sequence is needed when the DSS power domain is set to ON.

12.5.9.2.3 SDI Power-Down Sequence

To power down the SDI module, software users must program the following sequence:

1. Power down the SDI PLL by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x0.
2. Power-down the SDI pads:

(a) Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA1P signal on dss_data11 pin.

(b) For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA2P signal on dss_data13 pin.

(c) For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA3P signal on dss_data15 pin.

(d) Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_HSYNC signal on dss_data19 pin.

(e) Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 field to 0x0 to un-select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_STP signal on dss_data21 pin.

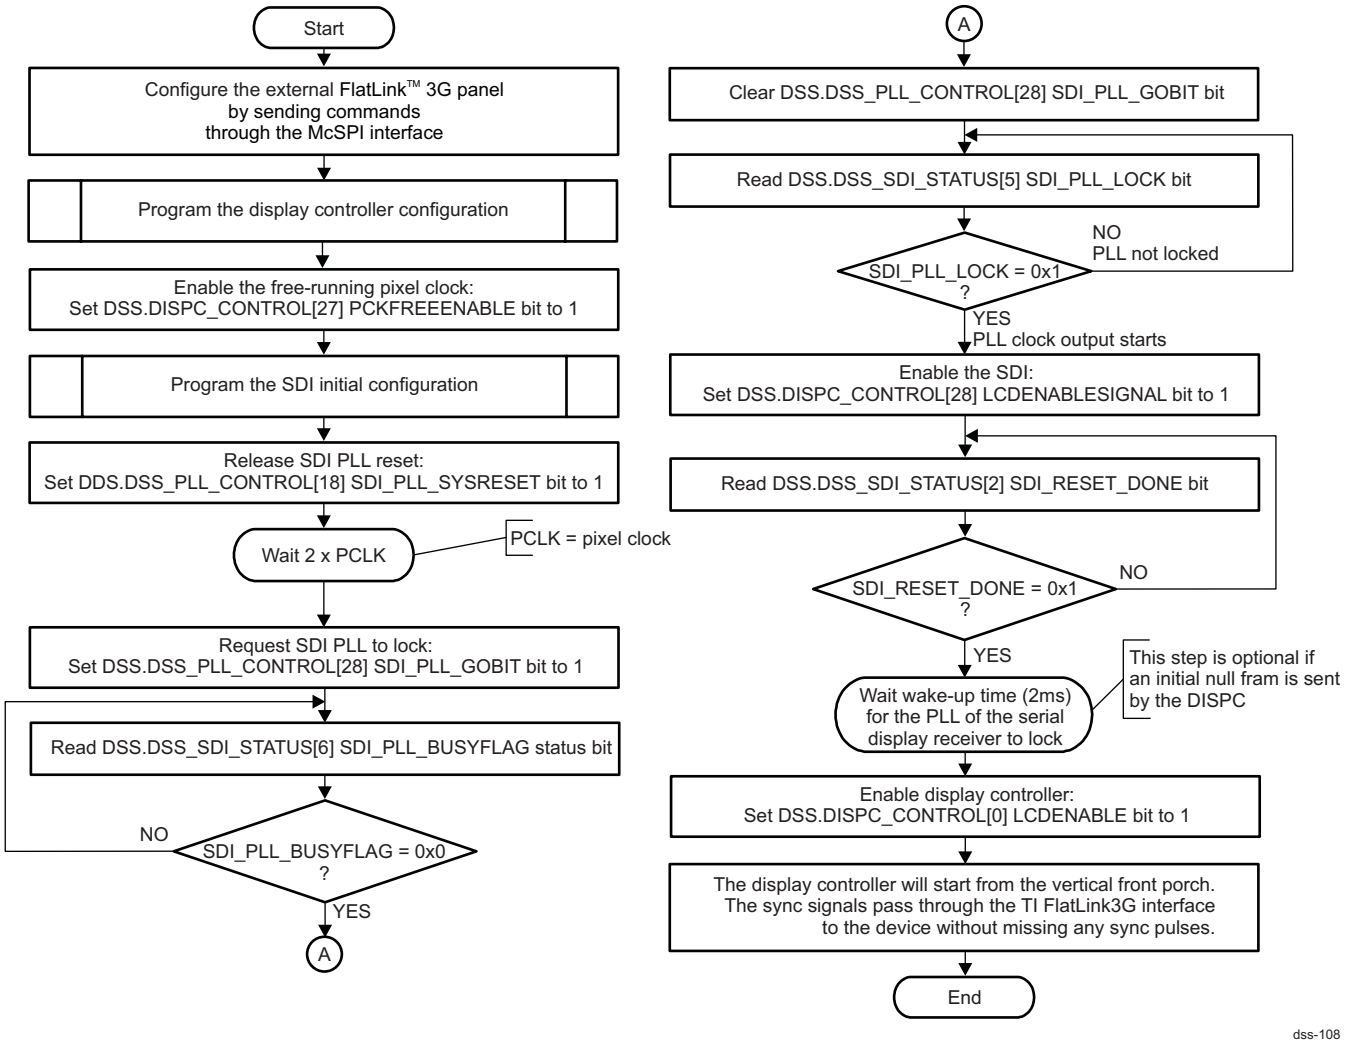
(f) Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_CLKN signal on dss_data23 pin.

NOTE: The same software sequence is needed to shut-down the DSS power domain.

12.5.9.3 SDI Start Sequence

Figure 12-151 describes the SDI start sequence.

Figure 12-151. SDI Start Sequence



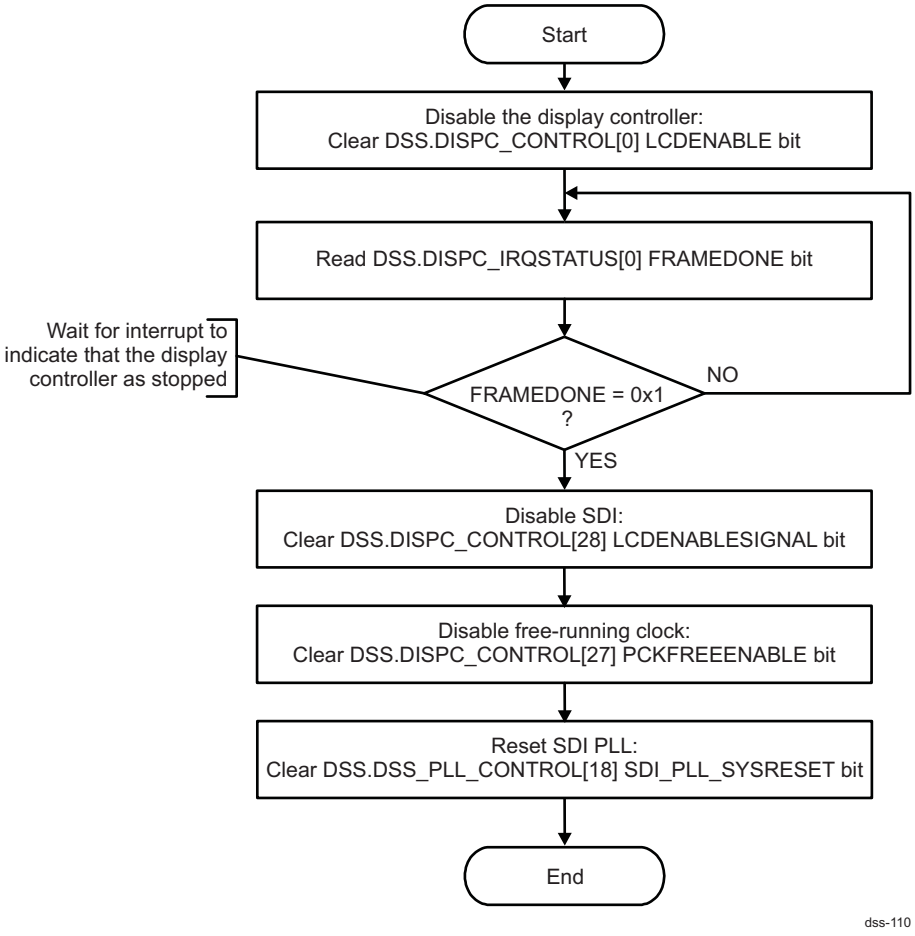
NOTE: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see Chapter 21, *General-Purpose Interface*.

NOTE: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

12.5.9.4 SDI Stop Sequence

Figure 12-152 describes the SDI stop sequence.

Figure 12-152. SDI Stop Sequence



12.5.9.5 Clock Source/Frequency Change Sequence

To change clock source or frequency, the simplest procedure is to follow the stop and start sequences documented above. If it is desired to change these without stopping the display a more rigorous procedure must be used as follows. The intent of this procedure is to perform the changes as quickly as possible during the vertical blanking interval and hence to minimize any visible display effect due to the increased blanking time.

12.5.9.5.1 Complete Sequence

Figure 12-153 and Figure 12-154 describe the clock source and frequency change sequence of the SDI.

Figure 12-153. SDI Clock Source/Frequency Change Sequence Part A

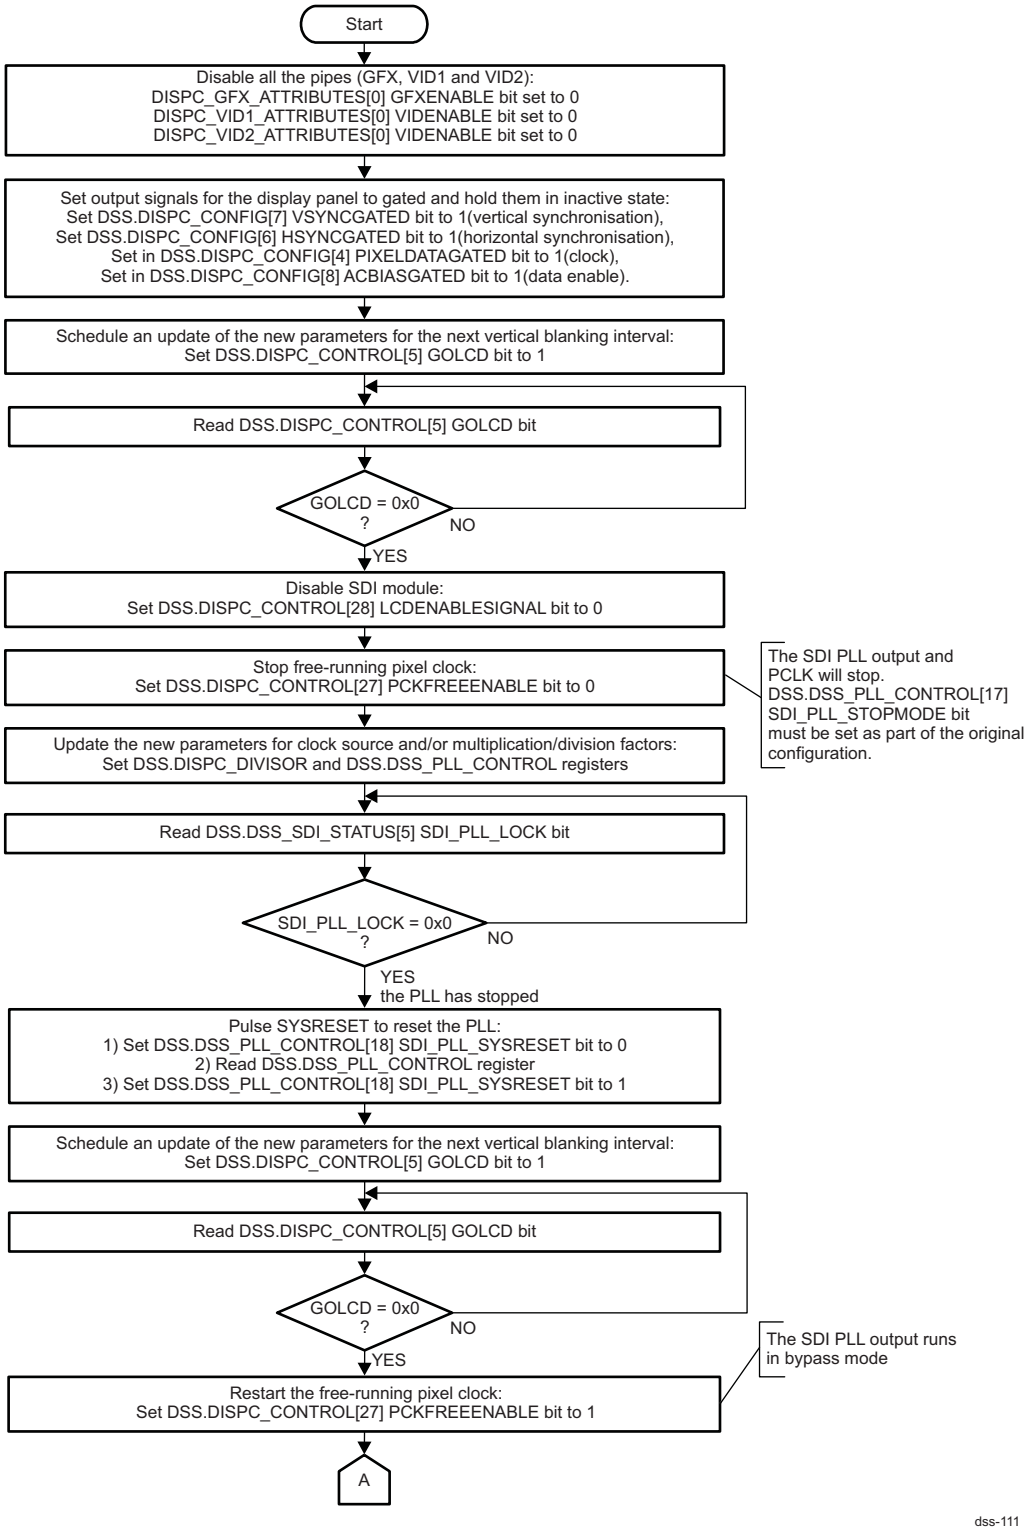


Figure 12-154. SDI Clock Source/Frequency Change Sequence Part B

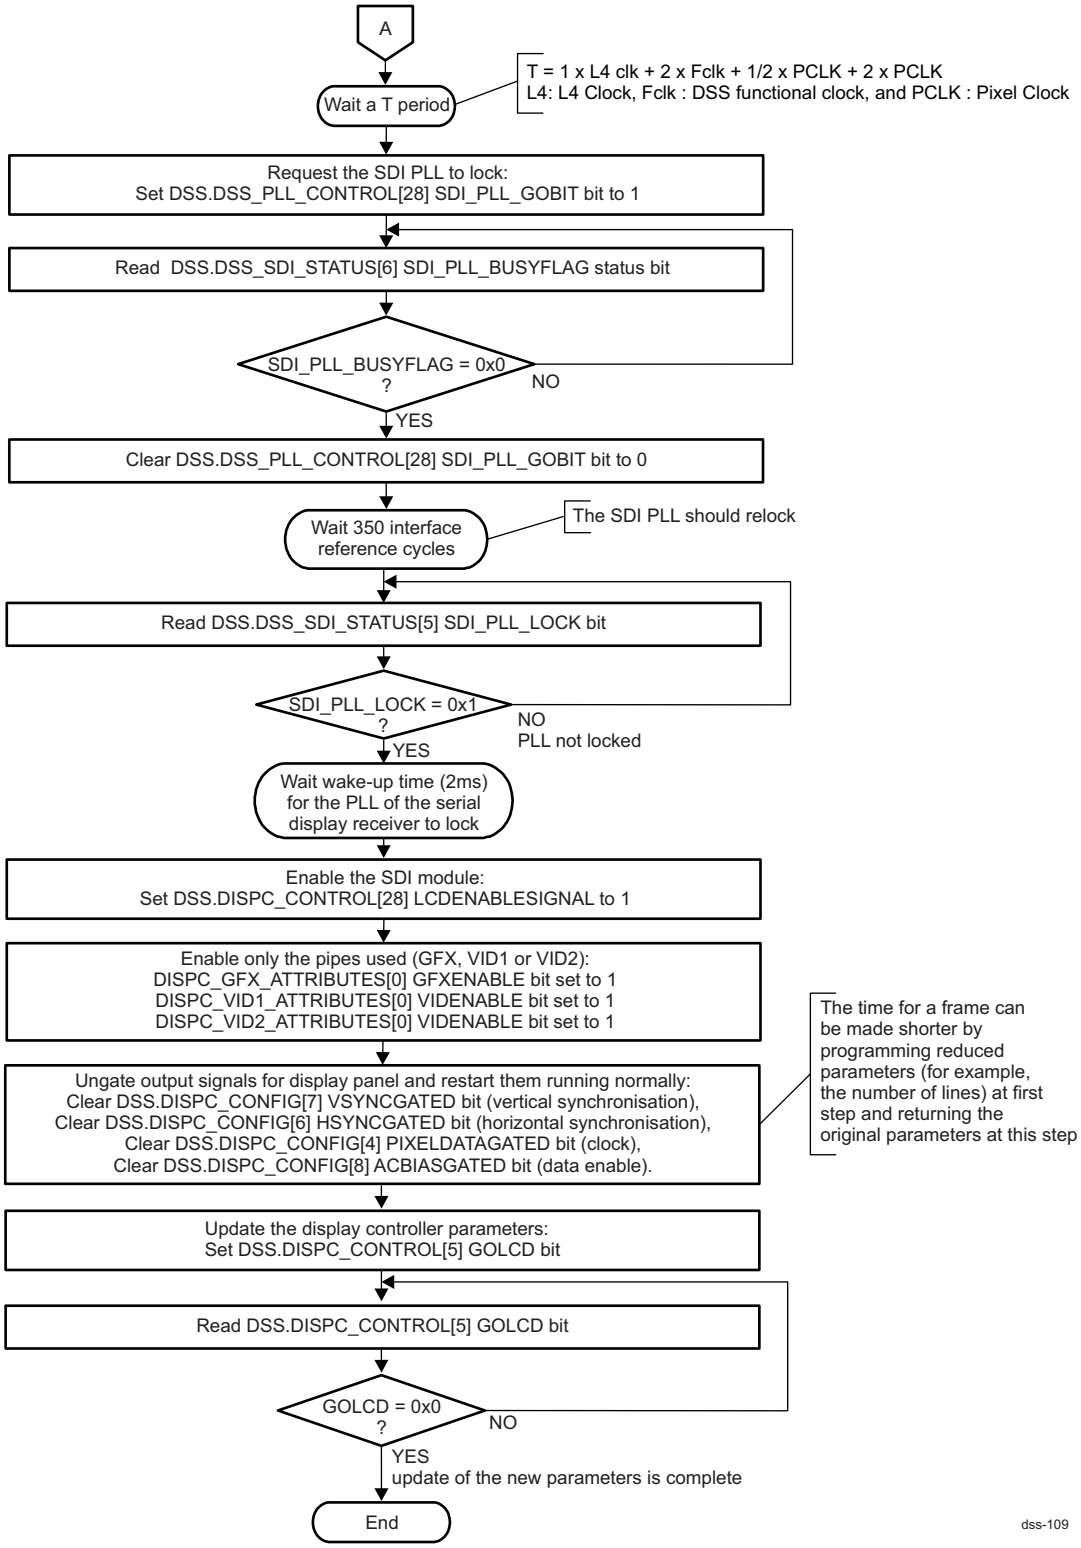


NOTE: One interface reference cycle is defined as follows:

Pixel Clock Frequency (PCLK)/SDI_PLL_REGN[5:0]/SDI_PLL_HIGHFREQ

Assuming the DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value is between 0xB and 0xF and the DSS.DSS_PLL_CONTROL[27:26] SDI_PLL_LOCKSEL bit field is set to 0x0.

NOTE: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see Chapter 21, *General-Purpose Interface*.

NOTE: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

12.5.9.5.2 Simplified Sequence When LCD and PCD Are Swapped

If the values in the DSS.DISPC_DIVISOR[23:16] LCD and DSS.DISPC_DIVISOR[7:0] PCD are exchanged (for example to reduce the internal display controller functional clock frequency while keeping the pixel clock frequency unchanged) with no other changes in the clock path, then there will be no discontinuity in the pixel clock. As a consequence the change will be transparent to the SDI module.

12.5.9.6 SDI Error Management

The DSS.DSS_SDI_STATUS[3] SDI_ERROR status bit indicates an internal buffer underflow/overflow. If such an error occurs, the SDI module must be disabled and enabled again to realign the buffer. This is done by setting the DSS.DISPC_CONTROL[28] LCDENABLESIGNAL bit to 0 (disabling) and to 1 (enabling). Ensure that the DSS.DSS_SDI_STATUS[2] SDI_RESET_DONE bit is set to 1. If this SDI error occurs during the debug phase, it is often due to programming incompatible values for MDIV, NDIV, and PDIV parameters for SDI PLL settings.

The SDI_ERROR internal signal is connected to the GPIO_82 internal signal of the GPIO3 module. Using the GPIO_82 signal, the GPIO3 bank generates two interrupts (GPIO3_MPU_IRQ and GPIO3_IVA2_IRQ) to alert the MPU or IVA2.2 subsystems, respectively, about any SDI error. For additional information, see Chapter 21, *General-Purpose Interface*.

12.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the display subsystem.

12.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously

12.6.1.1 Filtering

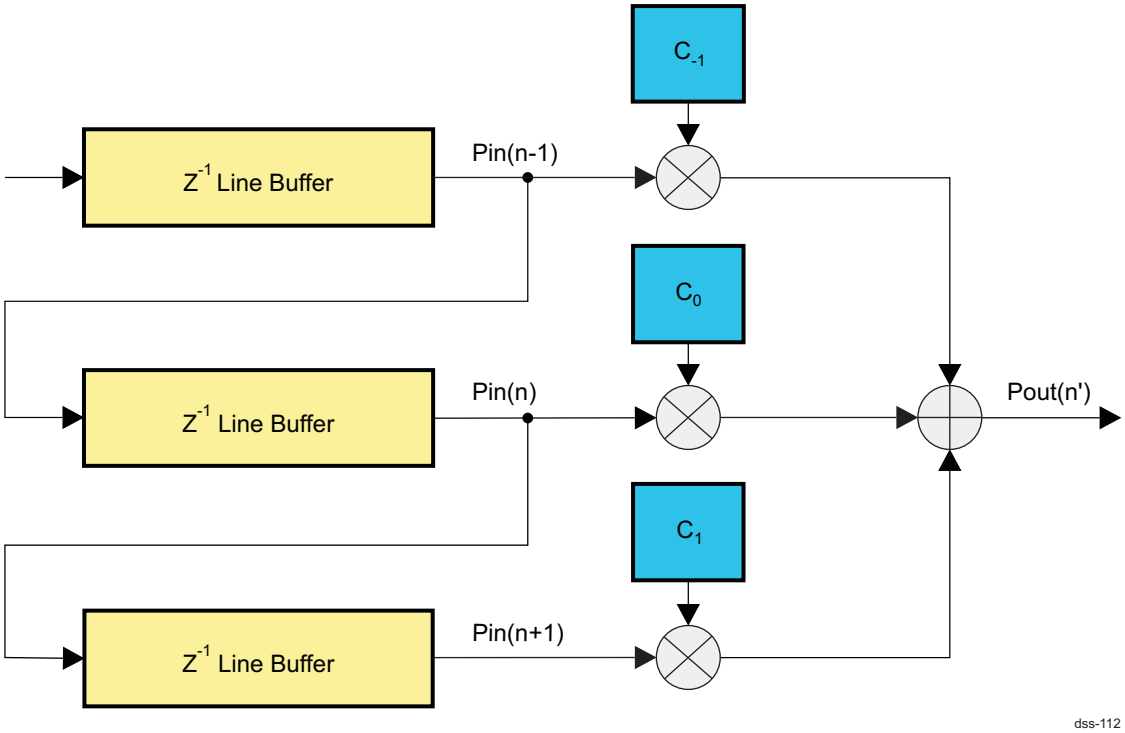
The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

12.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable

The vertical 3-tap filtering macro architecture is shown in Figure 12-155.

Figure 12-155. Vertical Filtering Macro Architecture (Three Taps)



For the 3-tap vertical up-/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad \text{dss-E067} \tag{9}$$

Legend:

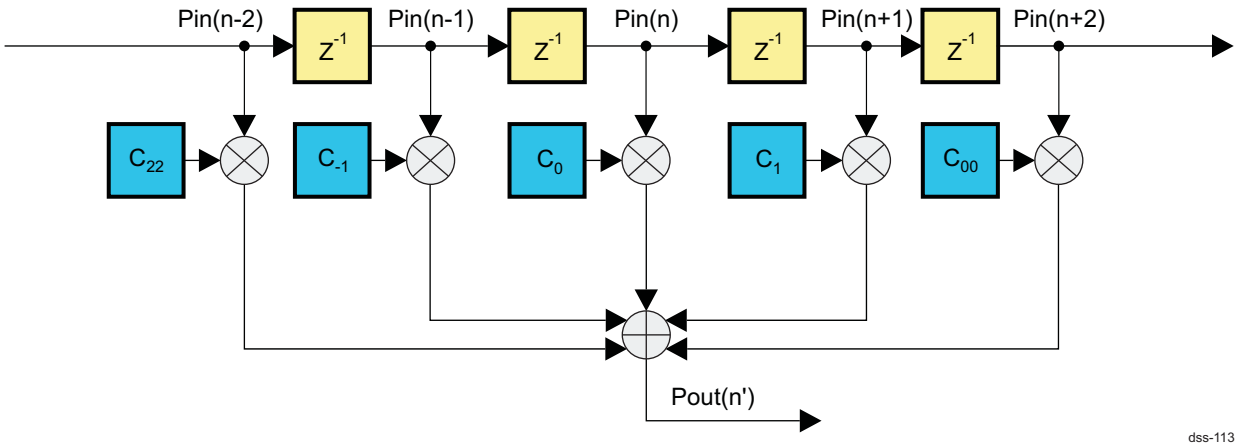
Rout: R component output
Ci():Vertical FIR coefficients
Rin: R component input
The line (n+1) is older than line (n).

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C_0(), which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in Figure 12-156.

Figure 12-156. Vertical Filtering Macro Architecture (Five Taps)



For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad \text{dss-E066} \qquad (10)$$

Legend:

Rout: R component output
Ci():Vertical FIR coefficients with $C_{+2}()=C_{00}()$ and $C_{-2}()=C_{22}()$
Rin: R component input
The line (n+1) is older than line (n).

NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture msut be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C0(), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

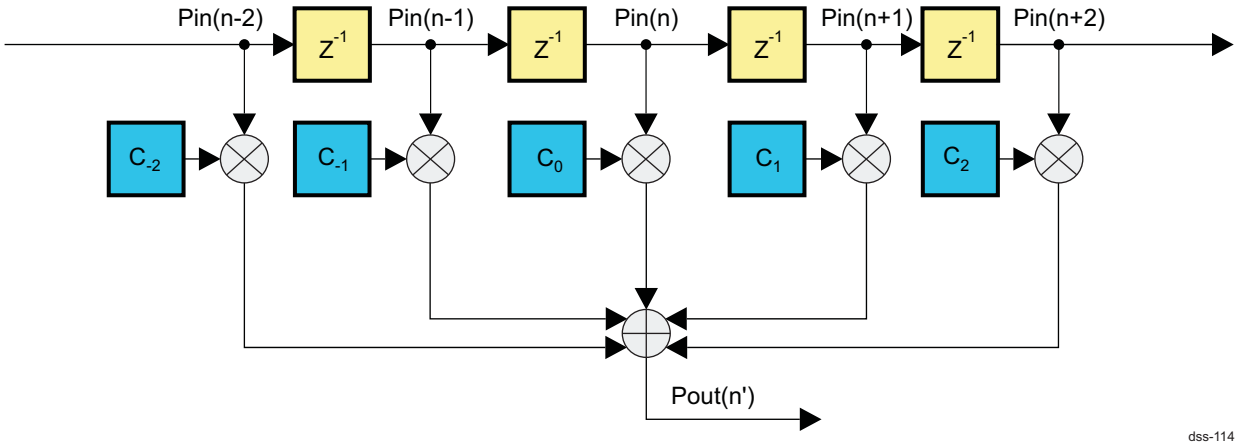
The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

12.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in Figure 12-157.

Figure 12-157. Horizontal Filtering Macro Architecture (Five Taps)



For the 5-tap horizontal up-/downsampling, the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-3}^{i=3} Ci(\Phi) \times Rin(n+i) \right) >> 7 \quad (11)$$

dss-E115

Legend:

Rout: R component output

Ci():Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C_0(), which is unsigned).

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

12.6.1.2 Scaling Algorithms

The up-/downsampling finite state machines (FSM) below are detailed in this section.

Figure 12-158 presents the vertical up-/downsampling FSM.

Figure 12-158. Vertical Up-/Down-Sampling Algorithm

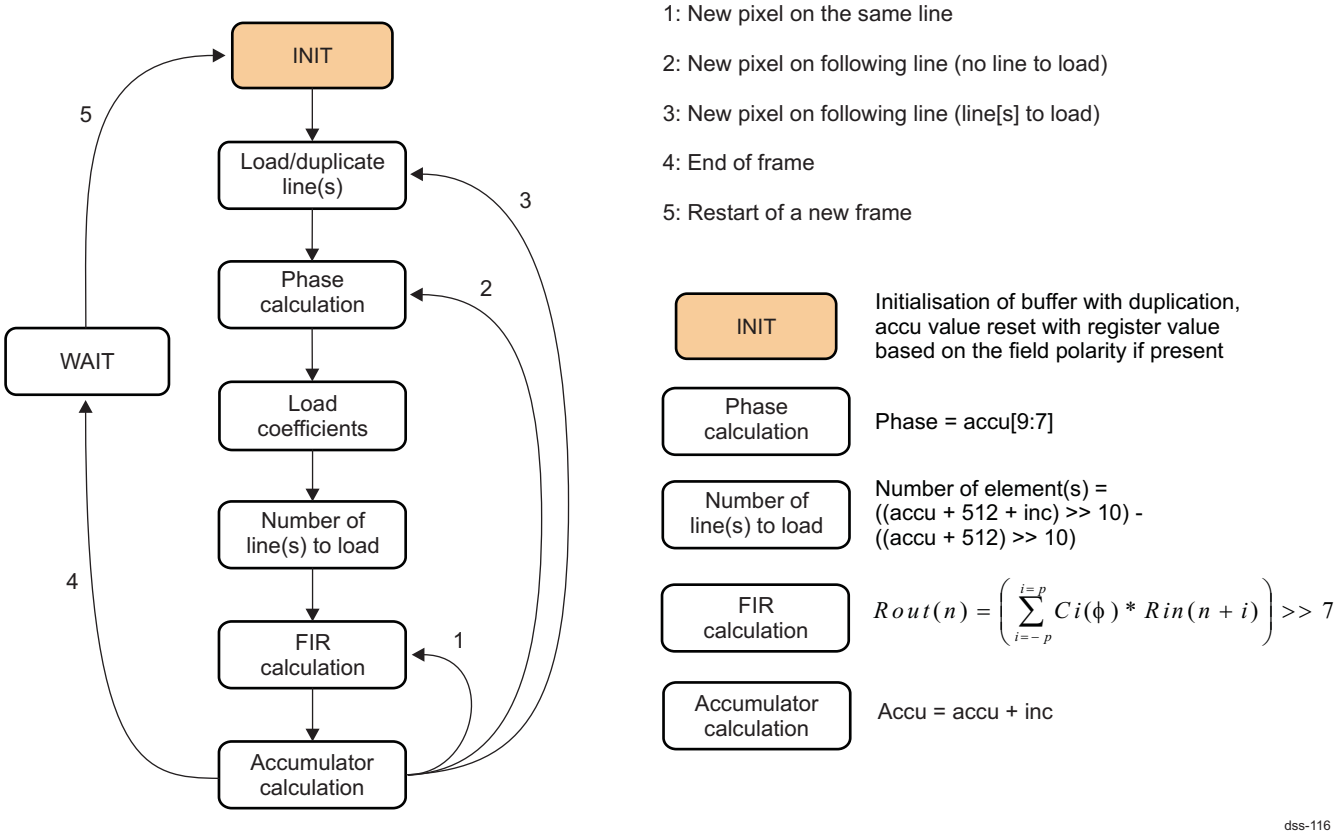


Figure 12-159 presents the horizontal up-/downsampling FSM.

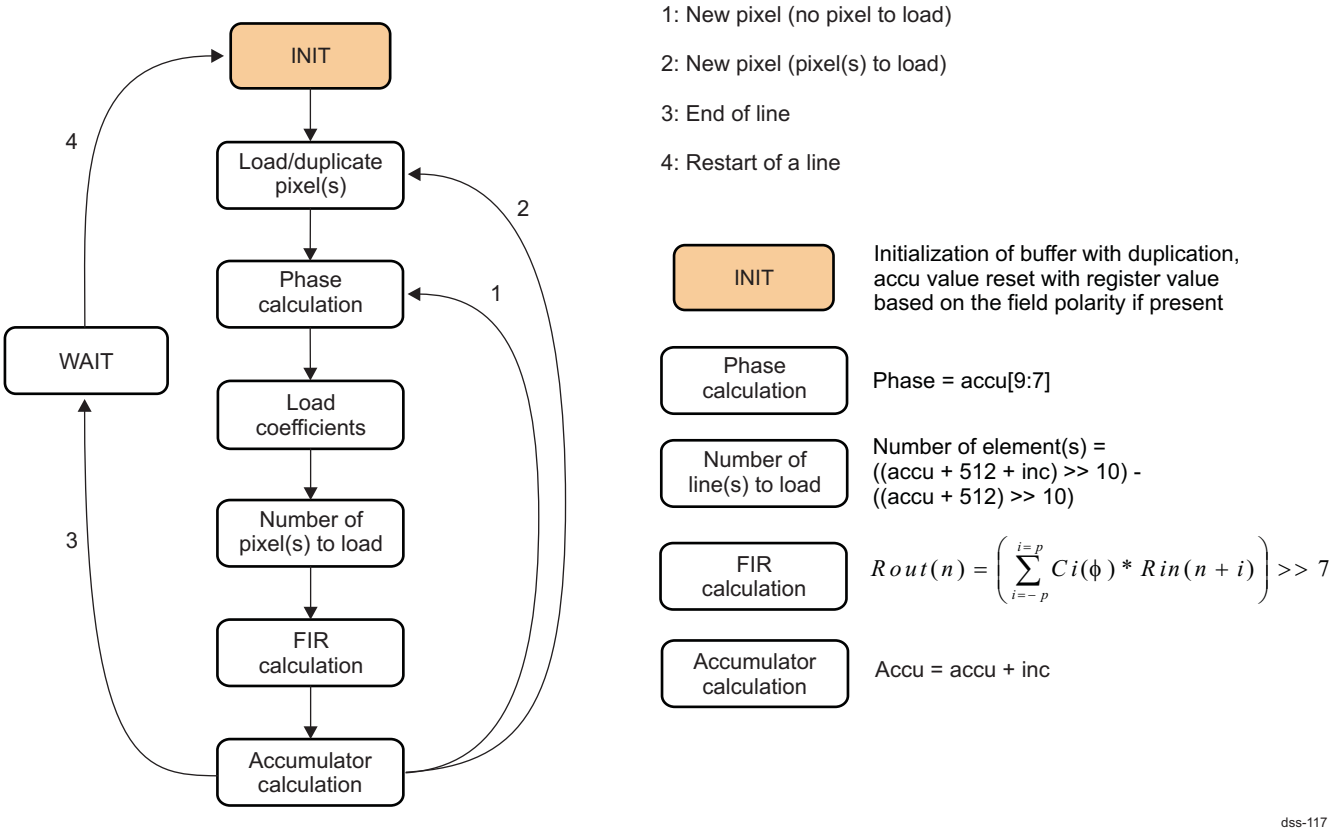
Figure 12-159. Horizontal Up-/Down-Sampling Algorithm



12.6.1.3 Scaling Settings

NOTE:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

12.6.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_ACCUI
- DSS.DISPC_VIDn_FIR_COEF_Hi
- DSS.DISPC_VIDn_FIR_COEF_HVi
- DSS.DISPC_VIDn_FIR_COEF_Vi

Table 12-72 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

Table 12-72. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)

C_x()	VidFIRVC$_x$()
C_{-1}()	VidFIRVC$_2$()
C_0()	VidFIRVC$_1$()

Table 12-72. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration) (continued)

$C_x()$	$VidFIRVC_x()$
$C_1()$	$VidFIRVC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $VidFIRVC_2()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] VIDFIRVC2
- $VidFIRVC_1()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] VIDFIRVC1
- $VidFIRVC_0()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] VIDFIRVC0

Table 12-73 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

Table 12-73. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$VidFIRVC_x()$
$C_{22}()$	$VidFIRVC_{22}()$
$C_{-1}()$	$VidFIRVC_2()$
$C_0()$	$VidFIRVC_1()$
$C_1()$	$VidFIRVC_0()$
$C_{00}()$	$VidFIRVC_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- $VidFIRVC_{22}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[15:8] VIDFIRVC22
- $VidFIRVC_2()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] VIDFIRVC2
- $VidFIRVC_1()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] VIDFIRVC1
- $VidFIRVC_0()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] VIDFIRVC0
- $VidFIRVC_{00}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[7:0] VIDFIRVC00

Table 12-74 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 12-74. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	$VidFIRHC_x()$
$C_{-2}()$	$VidFIRHC_4()$
$C_{-1}()$	$VidFIRHC_3()$
$C_0()$	$VidFIRHC_2()$
$C_1()$	$VidFIRHC_1()$
$C_2()$	$VidFIRHC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $VidFIRHC_4()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[7:0] VIDFIRHC4
- $VidFIRHC_3()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[31:24] VIDFIRHC3
- $VidFIRHC_2()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[23:16] VIDFIRHC2
- $VidFIRHC_1()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[15:8] VIDFIRHC1
- $VidFIRHC_0()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[7:0] VIDFIRHC0

12.6.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0].VIDENABLE bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up-/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE bit field:

- When the VIDRESIZEENABLE[1] bit is set to 1, the video vertical up-/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the VIDRESIZEENABLE[0] bit is set to 1, the video horizontal up-/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the VIDRESIZEENABLE[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

NOTE:

- Set a valid configuration before enabling the video up-/downsampling block.
- Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See Section 12.6.1.3.5 for more information concerning the filter coefficients.

12.6.1.3.3 Factor

The following register bit fields define the increment value of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[11:0] = 1024 \times \frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \quad \text{dss-E118} \tag{12}$$

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
- The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.

- Horizontal up-/downsampling increment value (the DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[11:0] = 1024 \times \frac{VIDORGSIZEX[10:0]}{VIDSIZEX[10:0]} \quad \text{dss-E119} \tag{13}$$

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.

12.6.1.3.4 Initial Phase

- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit fields

  The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.
- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 12-75 lists the vertical/horizontal accumulator values and phases

Table 12-75. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

NOTE: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

12.6.1.3.5 Coefficients

- **Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V)**

  The 3-tap vertical up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

  In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients (C_{22}() and C_{00}()).

  In case of 5-tap configuration, both sets of registers, DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC_VIDn_FIR_COEF_HV, is used.

- **Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HV)**

  The 5-tap horizontal up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up-/downsampling block.

  Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC_VIDn_FIR_COEF_HVi contains one 8-bit signed coefficient.

Table 12-76 through Table 12-81 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

12.6.1.3.5.1 Up-Sampling

Table 12-76 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 12-76. Up-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC$_2$()	VidFIRVC$_1$()	VidFIRVC$_0$()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 12-77 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

Table 12-77. Up-Sampling Vertical Filter Coefficients (Five Taps)

Phases	VidFIRVC$_{22}$()	VidFIRVC$_2$()	VidFIRVC$_1$()	VidFIRVC$_0$()	VidFIRVC$_{00}$()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 12-78 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 12-78. Up-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC$_4$()	VidFIRHC$_3$( )	VidFIRHC$_2$()	VidFIRHC$_1$()	VidFIRHC$_0$()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x037B02FF
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x00404000

- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x075920FE
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x027B0300

NOTE: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V04 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

12.6.1.3.5.2 Down-Sampling

Table 12-79 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 12-79. Down-Sampling Vertical Filter Coefficients (Three Taps)

Phases	$VidFIRVC_2()$	$VidFIRVC_1()$	$VidFIRVC_0()$
0	36	56	36
1	40	57	31
2	45	56	27
3	50	55	23
4	18	55	55
5	23	55	50
6	27	56	45

Phases	VidFIRVC$_2$()	VidFIRVC$_1$()	VidFIRVC$_0$()
7	31	57	40

Table 12-80 gives the 40 coefficients to program the vertical downsampling (5-tap configuration).

Table 12-80. Down-Sampling Vertical Filter Coefficients (Five Taps)

Phases	VidFIRVC$_{22}$()	VidFIRVC$_2$()	VidFIRVC$_1$()	VidFIRVC$_0$()	VidFIRVC$_{00}$()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

Table 12-81 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 12-81. Down-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC$_4$()	VidFIRHC$_3$( )	VidFIRHC$_{2(}$)	VidFIRHC$_{1(}$)	VidFIRHC$_0$()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804

- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3928FE

NOTE:
- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
- In this case, the downsampling factor must be higher than 1/2.

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28371F04
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2C361B08
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3035160C
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x113433F7
- DSS.DISPC_VIDn_FIR_COEF_V4 = 0x0000F711
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x163530F9
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000F90C
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B362CFB
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FB08
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3728FE
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x0000FE04

NOTE: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

12.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On an OMAP platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

12.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

NOTE: In the device, the display subsystem has its own power domain (the DSS power domain).

12.6.2.2 Display Subsystem Clock

12.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1_ALWON_FCLK) and DSI PLL functional clock 1 (DSI1_PLL_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.
- DSI1_PLL_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1_ALWON_FCLK or DSI1_PLL_FCLK by configuring the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit

NOTE: When the DSI PLL is in bypass mode, the DSI1_PLL_FCLK clock is the DSS2_ALWON_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

The LCD logic clock is determined by the DSS.DISPC_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS_CONTROL register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT bit field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

DPLL4_ALWON_FCLKOUTX2= DPLL4_ALWON_FCLK(266MHz) x 4/2 = 532 MHz

NOTE: The DPLL4_ALWON_FCLOUTX2 clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4X2_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

DSS1_ALWON_FCLK = DPLL4_M4X2_CLK

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field is set to 0x08:

$$\text{DSS1\_ALWON\_FCLK} = \frac{\text{DPLL4\_ALWON\_FCLKOUTX2}(532\text{MHz})}{8} = 66.5\ \text{MHz} \quad \text{dss-E120} \tag{14}$$

The DSS.DISPC_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{\text{DSS1\_ALWON\_FCLK}(66.5\text{MHz})}{1} = 66.5\ \text{Mhz} \quad \text{dss-E121} \tag{15}$$

The DSS.DISPC_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5\text{MHz})}{12} = 5.54\ \text{Mhz} \quad \text{dss-E122} \tag{16}$$

12.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

12.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

12.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

12.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1_ALWON_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1_ALWON_FCLK to DSI1_PLL_FCLK by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x1.

NOTE: Before switching to DSI1_PLL_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL bit to 0x1.
- Automatically: When setting the PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL bit field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96- MHz and 54- MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x0. The DSS1_ALWON_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1_ALWON_FCLK clock.

12.6.2.4 Autoidle and Smart Idle

12.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

12.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.DSS_SYSCONFIG[4:3] SIDLEMODE
- Display controller: DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE
- RFBI: DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE

12.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD
- DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO With the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

12.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

12.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. Figure 12-160 shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

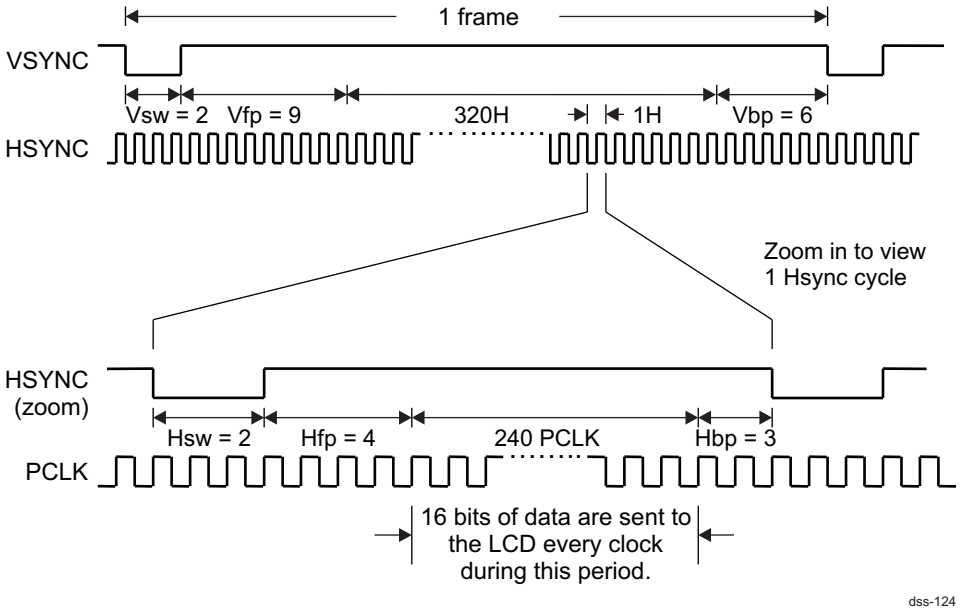
$$fps = \frac{1}{[(Hsw + 1) + (Hrp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vrp + 320 + Vbp)] \times (PCLK)} \quad \text{dss-E123} \qquad (17)$$

With:

- Hsw: DSS.DISPC_TIMING_H[7:0] HSW bit field value
- Hp: DSS.DISPC_TIMING_H[19:8] HFP bit field value
- Hbp: DSS.DISPC_TIMING_H[31:20] HBP bit field value
- Vsw: DSS.DISPC_TIMING_V[7:0] VSW bit field value
- Vp: DSS.DISPC_TIMING_V[19:8] VFP bit field value
- Vpb: DSS.DISPC_TIMING_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 12-160. QVGA LCD Timings



The fps for the example of 6-MHz pixel clock with the setting shown in Figure 12-160 is as follows:

$$fps = \frac{1}{[(2 + 1) + 4 + 240 + 3] \times [(2 + 1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}} \quad \text{dss-E125} \tag{18}$$

$$fps = 71Hz$$

12.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

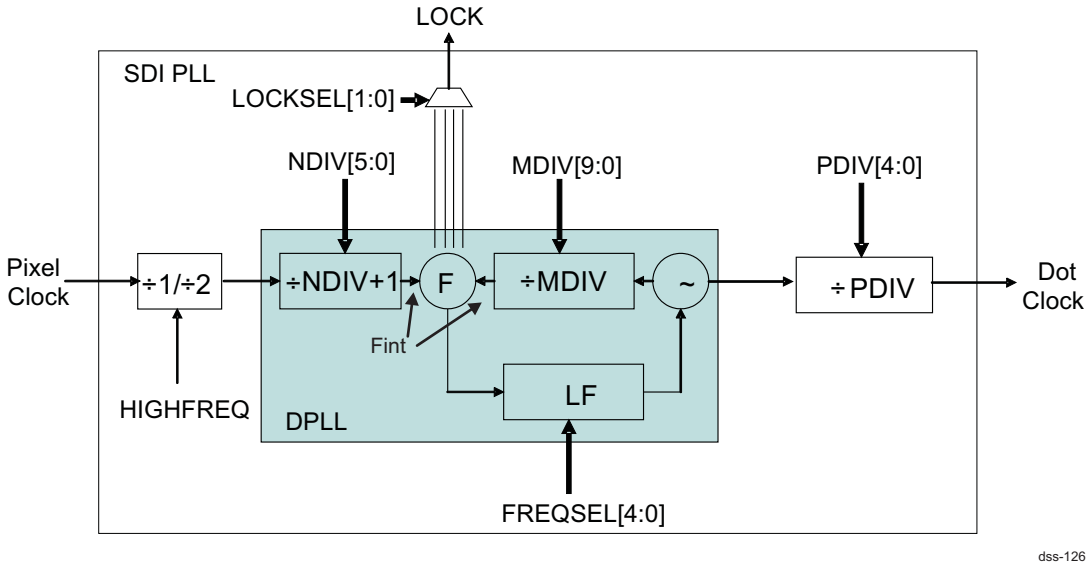
12.6.3 How to Configure the Serial Display Interface Module With FlatLink3G Protocol

This section describes the basic settings of Serial Display Interface (SDI) module and related Phase-Locked Loop (PLL).

12.6.3.1 SDI PLL Architecture

The SDI PLL architecture is based on the Digital Phase-Locked Loop (DPLL) that is described in , *Power, Reset, and Clock Management*. Figure 12-161 gives a functional description of the SDI PLL.

Figure 12-161. SDI PLL Architecture



NOTE:

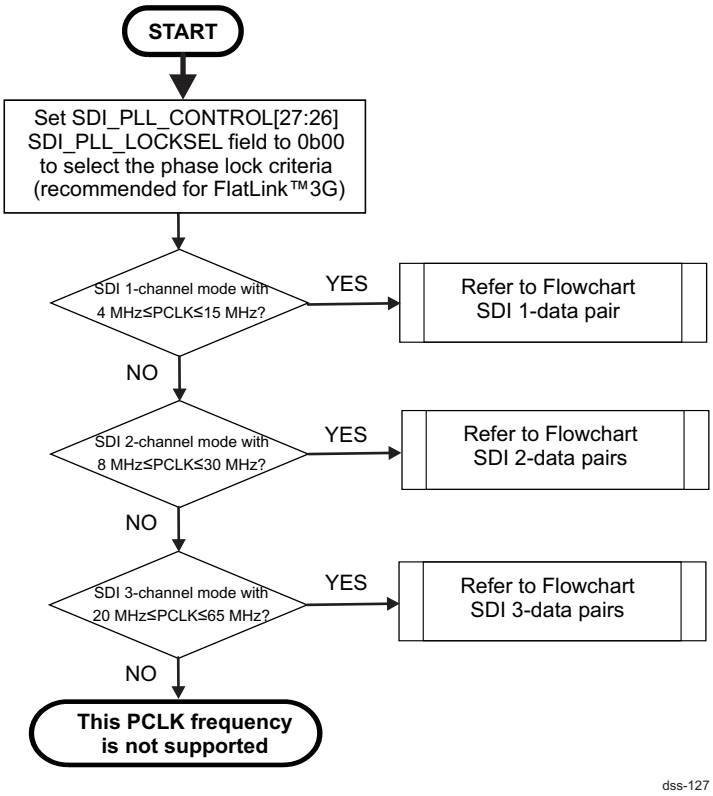
- FlatLink3G data rate is always at SCLK frequency.
- Software programmers must ensure that Pixel Clock = Dot Clock. If it is not the case the DSS.DSS_SDI_STATUS[3] SDI_ERROR status bit will be set indicating the pixel buffer overflow/underflow.

12.6.3.2 SDI PLL Configuration

The SDI PLL configuration depends on the pixel clock (PCLK), and on the number of data pairs in the FlatLink 3G protocol.

The following flowcharts detail the SDI PLL configuration from the PCLK frequency point of view. Figure 12-162 is the main flowchart. See Figure 12-163, Figure 12-164, and Figure 12-165 for details in PLL setting depending the PCLK input frequency.

Figure 12-162. Main Flowchart



NOTE: Compliance with the above ranges is required to meet the SN65LVDS302 receiver specifications.

Figure 12-163. Flowchart SDI 1-Data Pair

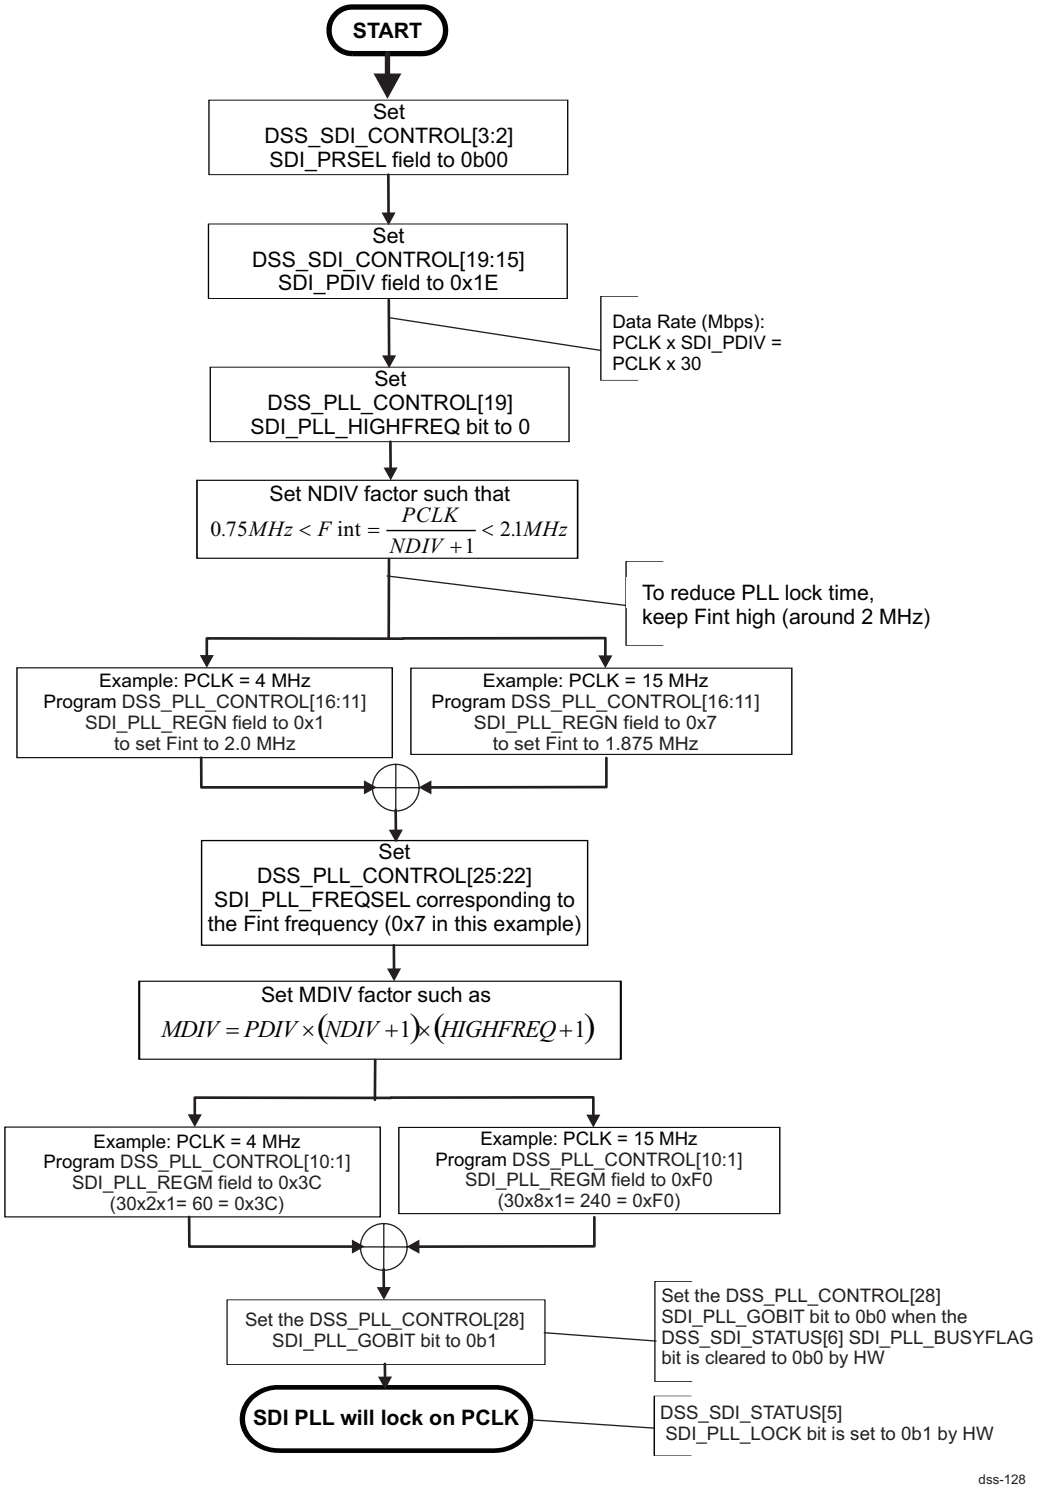


Figure 12-164. Flowchart SDI 2-Data Pairs

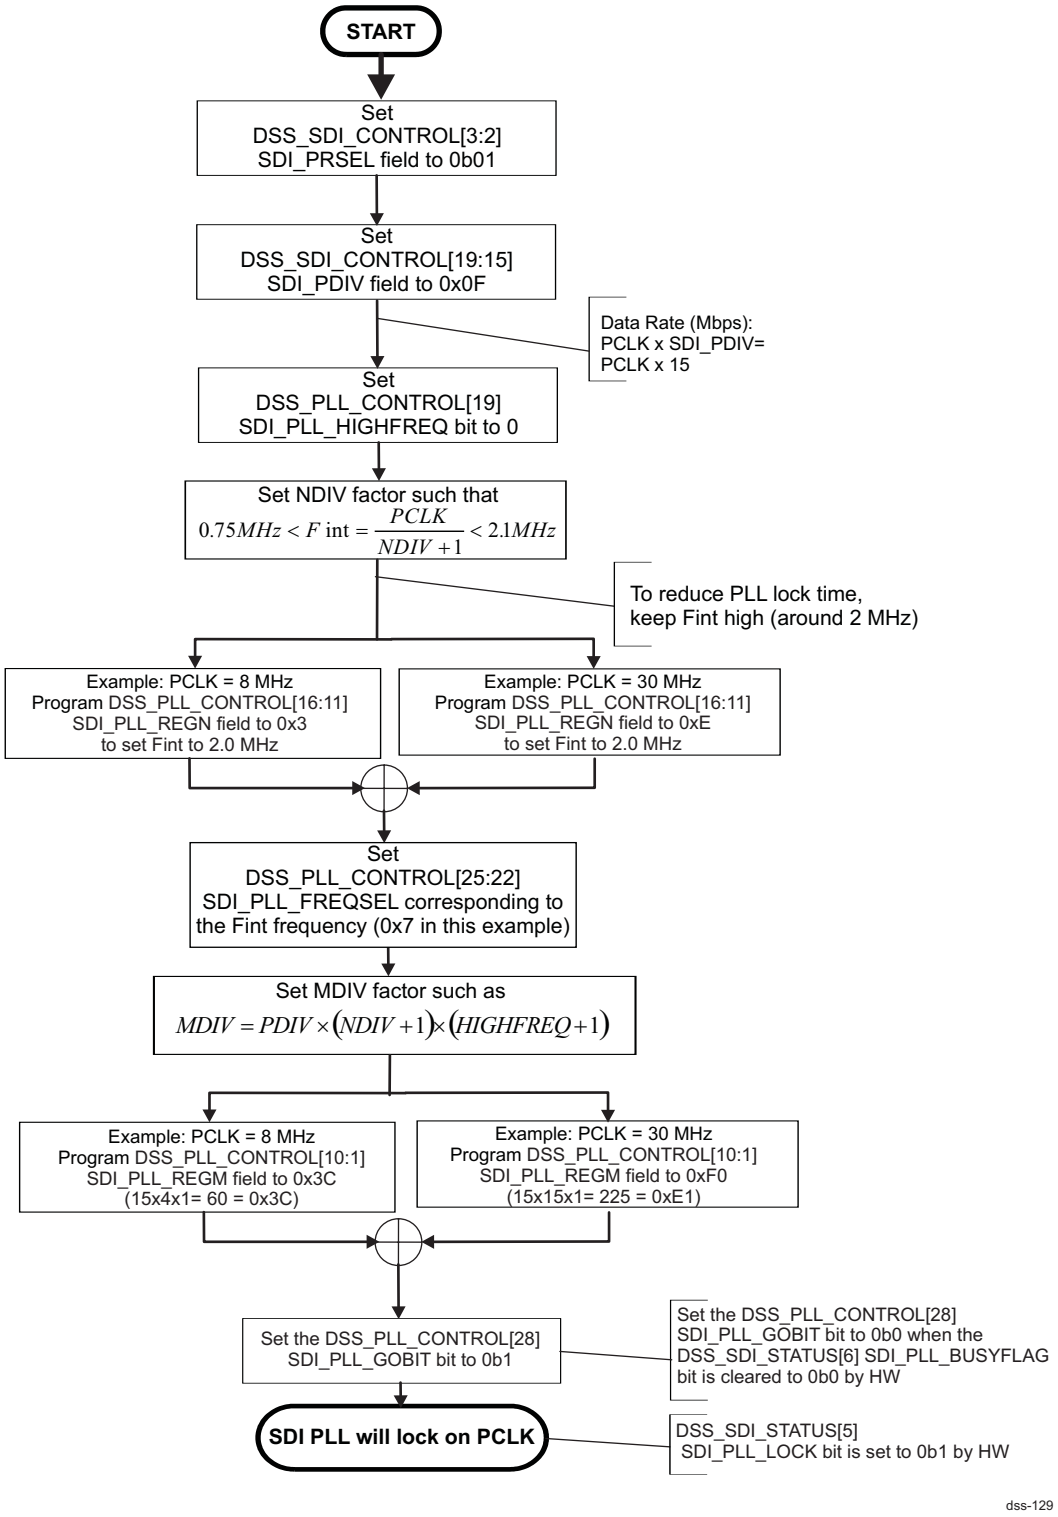

Figure 12-165. Flowchart SDI 3-Data Pairs

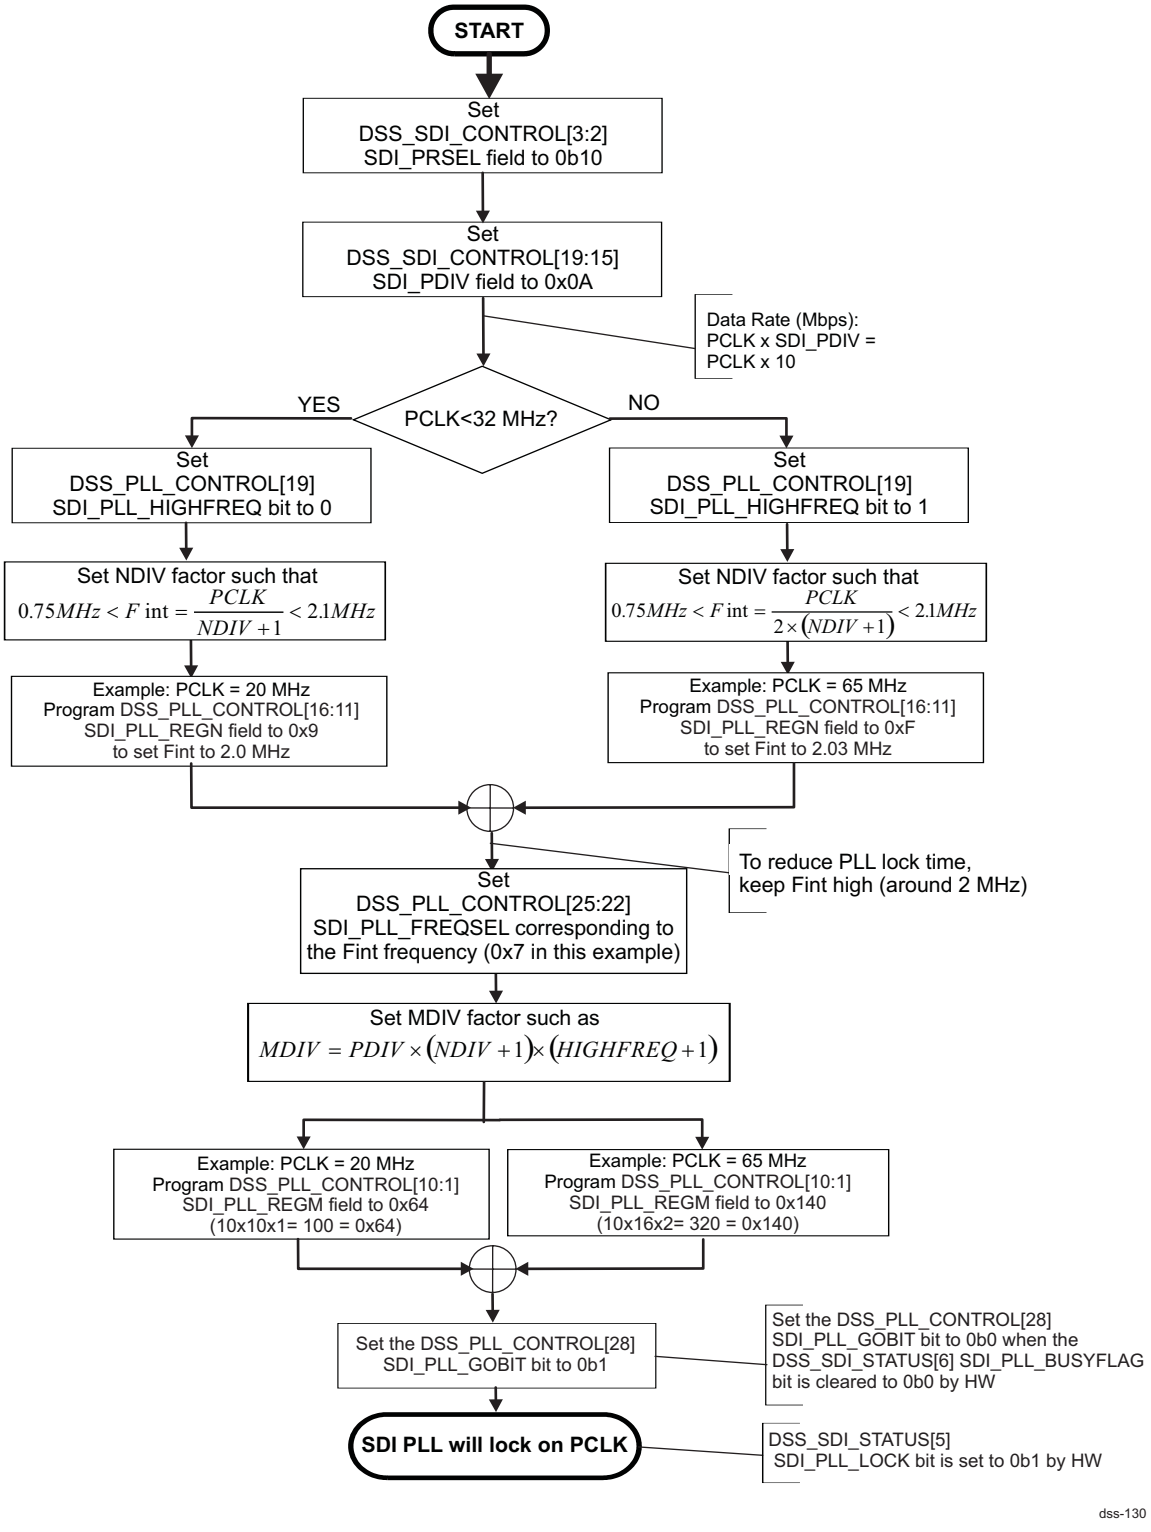


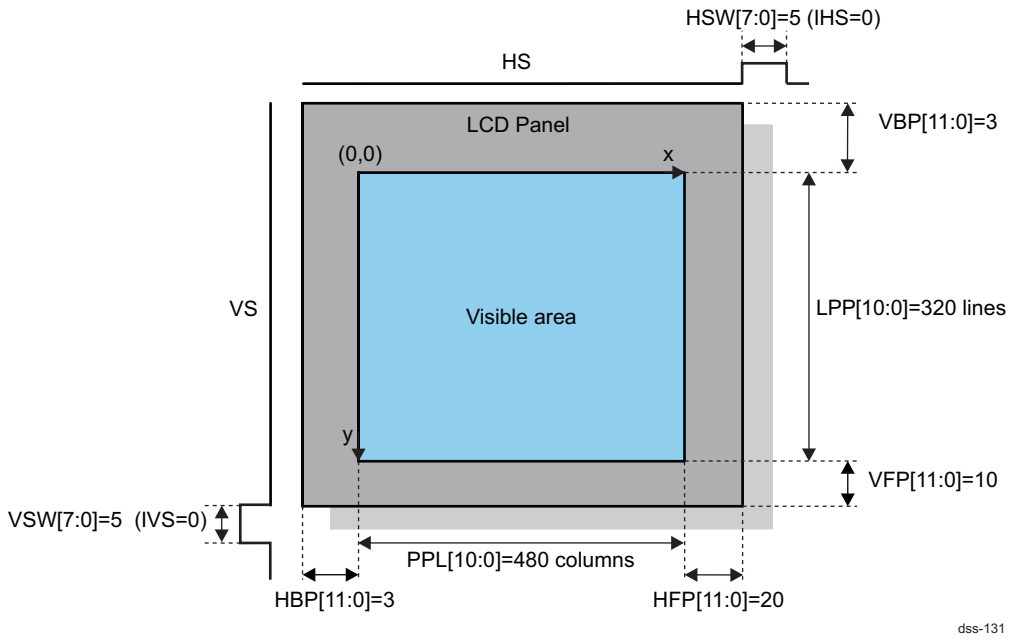
CAUTION

The PLL low-power mode (LP mode) can be activated with DSS.DSS_PLL_CONTROL[21] SDI_PLL_PLLLPMODE bit. By setting this bit to 1, software users reduce the power and increases the jitter. In LP mode, there is no effect on lock time; but in this mode, the SDI PLL allows only 0.75-2.1MHz range (DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value between 0x3 and 0x7). If software users are using the range 7.5 MHz to 21 MHz (DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value between 0xB and 0xF) in non-LP mode, and then switching to LP mode and setting the PLL in the range of 0.75 MHz to 2.1 MHz, there will be an effect on the lock time.

12.6.3.3 Application Example: HVGA Display

The following example details the SDI PLL settings for a half-VGA display with the following parameters shown in Figure 12-166.

Figure 12-166. HVGA Display



12.6.3.3.1 HVGA Display

- Display resolution: 320 x 480
- Frame refresh rate: 58.4 Hz
- Vertical visible pixel: 480 lines
- Vertical front porch: 20 lines
- Vertical sync: 5 lines
- Vertical back porch: 3 lines
- Horizontal visible pixel: 320 columns
- Horizontal front porch: 10 columns
- Horizontal sync: 5 columns
- Horizontal back porch: 3 columns

The calculation of the total number of pixel and Blanking overhead is as follows:

- Visible area pixel count: 480 x 320 = 153600 pixel
- Total frame pixel count: (480 + 20 + 5 + 3) x (320 + 10 + 5 + 3) = 171704 pixel
- Blanking overhead: (171704 153600)/153600 = 11.8%

This application requires the following SDI parameters:

- Pixel clock frequency: 171704 x 58.4 Hz = 10.03 MHz
- Serial data rate:
  - 1-channel mode: 10.03 MHz x 30 bit/channel = 300.9 Mbps
  - 2-channel mode: 10.03 MHz x 15 bit/channel = 150.45 Mbps

12.6.3.3.2 SDI PLL Settings for 1-Channel Mode:

- 1-data pair: Set DSS_SDI_CONTROL[3:2] SDI_PRSEL bit field to 0b00.
- Set the DSS_SDI_CONTROL[19:15] SDI_PDIV bit field to 0x1E.
- Set the DSS_PLL_CONTROL[19] SDI_PLL_HIGHFREQ bit to 0.
- Set the DSS_PLL_CONTROL[16:11] SDI_PLL_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the DSS_PLL_CONTROL[25:22] SDI-PLL_FREQSEL bit field to 0x7.
- Set DSS_PLL_CONTROL[10:1] SDI_PLL_REGM bit field to 0x96 (30x5x1 = 150 = 0x96).

12.6.3.3.3 SDI PLL Settings for 2-Channel Mode:

- 2-data pair: Set DSS_SDI_CONTROL[3:2] SDI_PRSEL bit field to 0b01.
- Set the DSS_SDI_CONTROL[19:15] SDI_PDIV bit field to 0x0F.
- Set the DSS_PLL_CONTROL[19] SDI_PLL_HIGHFREQ bit to 0.
- Set the DSS_PLL_CONTROL[16:11] SDI_PLL_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the DSS_PLL_CONTROL[25:22] SDI-PLL_FREQSEL bit field to 0x7.
- Set DSS_PLL_CONTROL[10:1] SDI_PLL_REGM bit field to 0x4B (15x5x1 = 75 = 0x4B).

12.6.4 How to Interface OMAP Device With SN65LVDS302 Receiver for an XGA Display Application

Texas Instruments Inc. provides a full FlatLink3G solution with the device associated to a SN65LVDS302 receiver. This section will also detail the hardware connections between these two devices and the basic software settings

This use case is based on the usage of a large (XGA) 16 Mega colors display requiring the three data channels and the complete output data bus to be used. Some adaptations may be adopted if the device is used in a less demanding use case

12.6.4.1 Hardware Connections

Figure 12-167 details the hardware connections with the device, the SN65LVDS302 receiver, the display panel and the power IC. The power IC can be the companion chip

Figure 12-167. Hardware Connections for FlatLink3G Application

NOTE: The SN65LVDS302 device was design-optimized for robustness to operate reliably in a dense environment with other digital switching ICs. In cell phone designs, the SN65LVDS302 often shares a power supply with the LCD display driver provided through the FPC interconnect. To minimize the power supply noise floor it is suggested to provide good decoupling near the SN65LVDS302 power pins. Using four capacitors (2x0.01F and 2x0.1F) was found to provide good performance. At the very least, it is recommended to install one 0.1F and one 0.01F capacitor near the SN65LVDS302. To avoid large current loops and trace inductance, the trace length between decoupling cap and IC power inputs pins must be minimized. Placing the capacitor underneath the SN65LVDS302 device on the bottom of the PCB is often a good choice

12.6.4.2 SN65LVDS302 Receiver Description

SN65LVDS302 is a serial interface receiver which converts the FlatlinkTM3G signals (3 sub-LVDS data pairs) into 27 signals (24 RGB bits, HS, VS and DE signals). It also provides a pixel clock (4 MHz to 65 MHz) which is formed from the sub-LVDS input clock pair, internally multiplied for data deserialization and then divided by same factor.

The device may operate in different modes, depending on the input data format. One, two or all of the three data pairs will be used, following the LS0 and LS1 configuration. The clock division rate will automatically be selected from 30 to 10. Pixel clock polarity can be chosen using the CPOL signal

The output bus order is configurable by SWAP pin configuration (R[7:0], G[7:0], B[7:0] or B[0:7], G[0:7], R[0:7]). Furthermore, the CMOS outputs rising/falling edges will be selected between slow or fast depending on F/S input to fit display timing constraints with regards to EMI and consumption consequences.

In the XGA display application detailed in Figure 7, the configuration is the following:

- LS1 = 1 and LS0 = 0: 3-data pairs mode is selected
- SWAP = 0: The data output format is R[7:0], G[7:0], B[7:0]
- F/S = 1: The CMOS bus time rise is selected in fast output
- CPOL = 0: The output clock polarity is rising edge

For more details on SN65LVDS302 receiver, please see the SN65LVDS302 data sheet (SLLS733)

The RXEN signal will enable the OMAP device to control SN65LVDS302 activity which will signal channel parity error through CPE signal. These two previous signals are connected to OMAP GPIO2 module

12.6.4.3 SDI Software Settings

12.6.4.3.1 SDI Configuration

To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC_CONTROL[3] STNTFT bit to 0b1 (active matrix display operation mode)
- Set the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS_SDI_CONTROL[1:0] SDI_BWSEL bit field to 0x2 (color depth is 24 bits)

12.6.4.3.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC_POL_FREQ[16] RF bit to 0b1 for driving HSYNC and VSYNC on the rising edge of PCLK.
- Set the DSS.DISPC_POL_FREQ[17] ONOFF bit to 0b1.
- Clear the DSS.DISPC_POL_FREQ[14] IPC bit to 0b0 for driving the pixel data on the rising edge of PCLK
- Set the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to 0b1 for setting the LCD-enable signal

active high.

The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:

- Clear the DSS.DISPC_POL_FREQ[13] IHS bit to 0b0 for setting HSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[12] IVS bit to 0b0 for setting VSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[15] IEO bit to 0b0 for setting the data enable active high.

12.6.4.3.3 SDI PLL Configuration

The SDI module settings for an XGA display application with 20% blanking overhead are detailed in this section.

- XGA display: 1024 x 768 = 786432 pixels
- 20% blanking overhead: 157286 pixels
- Visible are pixel count: 786432 + 157286 = 943718
- Frame Refresh Rate: 60 Hz
- Pixel Clock Frequency: 943718 x 60 = 56.6 MHz (in 20-65 MHz range for 3-data pairs).
- Serial Data rate: 3-channel mode : 56.6 MHz x 10 bit/channel = 566 Mbps

12.6.4.3.3.1 SDI PLL settings for 3-Channel Mode:

- 3-data pair: Set DSS_SDI_CONTROL[3:2] SDI_PRSEL bit field to 0b10
- Set the DSS_SDI_CONTROL[19:15] SDI_PDIV bit field to 0x0A
- Set the DSS_PLL_CONTROL[19] SDI_PLL_HIGHFREQ bit to 1 as PCLK>32 MHz
- Set the DSS_PLL_CONTROL[16:11] SDI_PLL_REGN bit field to 0xE. Thus Fint will be set to 2.02 MHz
- Set the DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field to 0x7
- Set DSS_PLL_CONTROL[10:1] SDI_PLL_REGM bit field to 0x12C (10x(14+1)x2 = 300 = 0x12C)

Set the SDI_PLL_CONTROL[27:26] SDI_PLL_LOCKSEL bit field to 0b00 to select the phase lock criteria to 0b00 (recommended for FlatLink3G mode)

12.6.4.4 SN65LVDS302 Receiver Settings

12.6.4.4.1 Receiver Power-Up

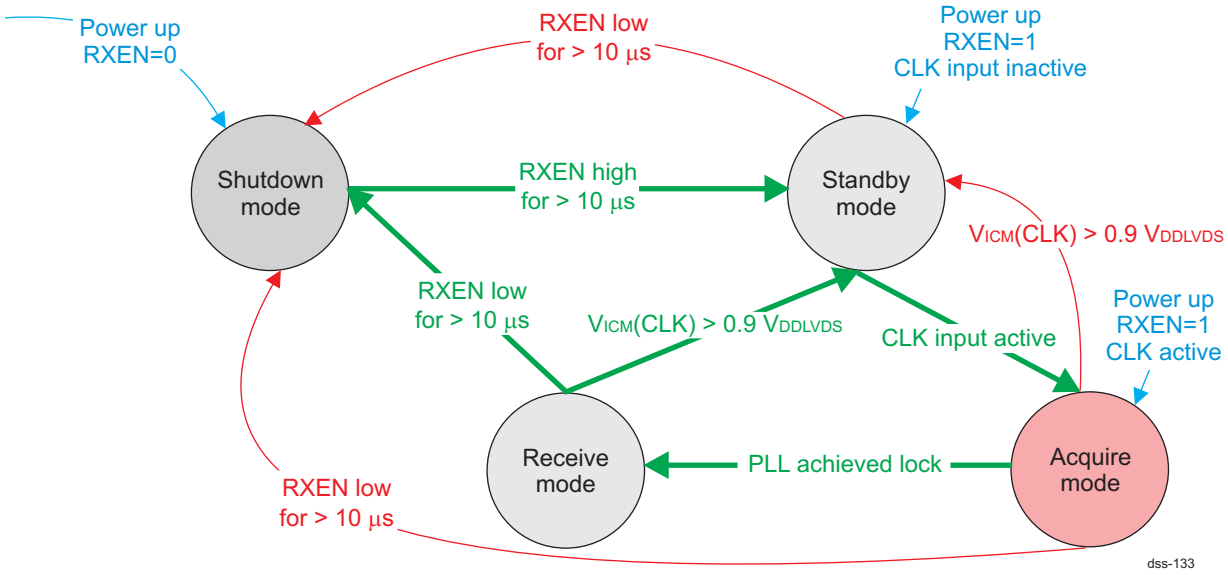
At power up, the receiver is enabled immediately if RXEN=1 (enters Acquire mode) and disabled if RXEN=0 (enters shutdown mode). The receiver may be turned off at any time by pulling RXEN low for at least 10 µs. This disables the CMOS drivers and turns off the receiver PLL, putting the device in shutdown mode. The RXEN signal is connected to the gpio_34 pin of the device. Thus the GPIO2 module can control the receiver power-up.

NOTE: The RXEN input incorporates glitch suppression logic to avoid unwanted switching. The input must be pulled continuously low for at least 10 µs to force the receiver to enter shutdown. The gpio_34 signal must be set continuously high by the OMAP device for at least 10 µs to activate the receiver. An input pulse shorter than 5 µs is interpreted as a glitch and is ignored.

12.6.4.4.2 Receiver Modes and Transitions

Figure 12-168 details the SN65LVDS302 receiver modes and transitions.

Figure 12-168. SN65LVDS302 Receiver Modes and Transitions



12.6.4.4.2.1 Modes Description

- Shutdown mode

  The SN65LVDS302 receiver may be put in Shutdown mode by holding the RXEN pin low. This turns off most of the receiver circuitry including the Sub-LVDS receivers, PLL, and deserializers. The Sub-LVDS input impedance remains 100- while any input signal becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Shutdown mode will be nearly zero

- Standby mode

  The SN65LVDS302 receiver will enter the Standby mode when the SN65LVDS302 receiver is not in Shutdown mode but the clock input common mode range on the Sub-LVDS clock input shifts to VDDLVDS. The CLK input incorporates a pull-up circuitry. This circuit will shift the Sub-LVDS clock input common mode voltage to VDDLVDS in the absence of any input signal. All circuitry, except for the Sub-LVDS clock input Standby monitor will be shutdown. The Sub-LVDS input impedance remains 100- while any input signal on the data inputs D0, D1, and D2 becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Standby mode will be very low.

- Active Modes

  The SN65LVDS302 receiver will be in active mode when the device is enabled by pulling RXEN high and VICM on the CLK input is driven below 0.9xVDD by an external input signal. Current draw in active mode will be dependent on operating frequency and the number of data transitions in the data payload

- Acquire Mode (PLL approaches lock)

  While the SN65LVDS302 receiver is enabled and a Sub-LVDS clock input present, the receiver PLL will pursue lock to the input clock. As long as the PLL is not locked the output data bus will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low.

- Receive Mode

  When the receiver PLL achieves lock, the receiver enters the normal receive mode with the output bus presenting the deserialized data.

12.6.4.4.2.2 Mode Transitions

Table 12-82. SN65LVDS302 Receiver Mode Transitions

Mode Transition	Use Case	Transition Specifics
Shutdown to Standby	Drive RXEN high to enable receiver	• 1. RXEN high for longer than 10 µs • 2. Receiver enters Standby mode – a. R[0:7]=G[0:7]=B[0:7]=VS=HS remain high and DE=PCLK low – b. receiver turns on clock input monitor
Standby to acquire	Transmitter activity detected	• 1. CLK input monitor detects clock input activity • 2. Outputs remain static • 3. the receiver PLL becomes enabled
Acquire to Receive	Link is ready to receive data from OMAP SDI module.	• 1. PLL is active and achieves lock within 2 µs • 2. D1, D2, and D3 become active • 3. first Data word was recovered • 4. parallel output bus switches from static output pattern to output first valid data word
Receive to Standby	Receiver requested to enter Standby mode by input common mode voltage V_{ICM}>0.9 V_{DDLVDS} (that is, transmitter output clock turns high-impedance)	• 1. Transmitter disables outputs • 2. RX Input monitor detects V_{ICM}>0.9 V_{DDLVDS} • 3. R[0:7]=G[0:7]=B[0:7]=VS=HS transition to high and DE=PCLK to low on next falling PLL clock edge • 4. PLL shuts down • 5. Clock activity input monitor remains active
Receive/Standby to Shutdown	Turn off receiver	• 1. RXEN pulled low for longer than 10 µs • 2. Receiver immediately puts all outputs into high impedance • 3. Most receiver blocks are shut down for least power consumption

12.6.4.4.3 Parity Error Detection and Handling

The SN65LVDS302 receiver performs an error checking on the basis of a parity bit that is transmitted across the LVDS interface from the transmitting device. Once the SN65LVDS302 detects the presence of the clock and the receiver PLL has locked onto PCLK, then the parity is checked. The parity bit covers the 27-bit data payload (reserved bits are not covered in the parity calculations). Odd Parity bit signaling is used. The parity error is output on the output CPE pin:

- If the sum of the 27 data bits and the parity bit result in an odd number, the receive data are assumed to be valid and CPE output will be held low.
- If the sum equals an even number, parity error is declared and CPE output will indicate high for half a PCLK period.

The CPE output will be set with the data bit transition and cleared after 1/2 the data bit time. The receiver CPE output pin is connected to gpio_35 pin. The OMAP device can use the gpio_35 input pin to generate an IRQ, respectively GPIO2_MPU_IRQ for MPU subsystem and GPIO2_IVA2_IRQ for IVA2.2 subsystem. This will allow the OMAP device to count every detected parity error with a simple counter triggered by GPIO2 module interrupt request.

When a parity error is detected, the data on that PCLK cycle is not output. Instead, the last valid data from a previous PCLK cycle is repeated on the output bus. This is to prevent any bit error that may occur on the LVDS link from causing perturbations in VS, HS or DE that may be visually disruptive to the display panel.

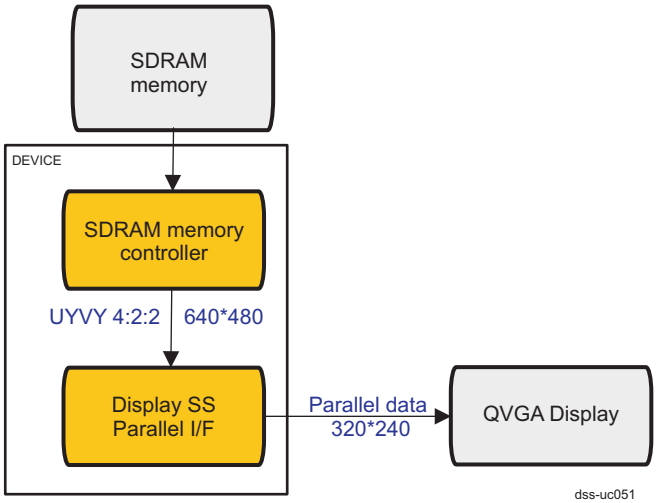
12.6.5 Camcorder Use Case: How to Configure the Display Subsystem When Connected With a QVGA LCD Panel

12.6.5.1 Overview

This section describes the configuration and used of a QVGA LCD panel through the parallel data interface (in RFBI by-pass mode).

The display subsystem reads each image from the SDRAM memory in the UYVY 4:2:2 format and converts it to a RGB18-666 pixel format to send to the QVGA LCD panel (see Figure 12-169).

Figure 12-169. Overview



The camcorder use case is configured as follows:

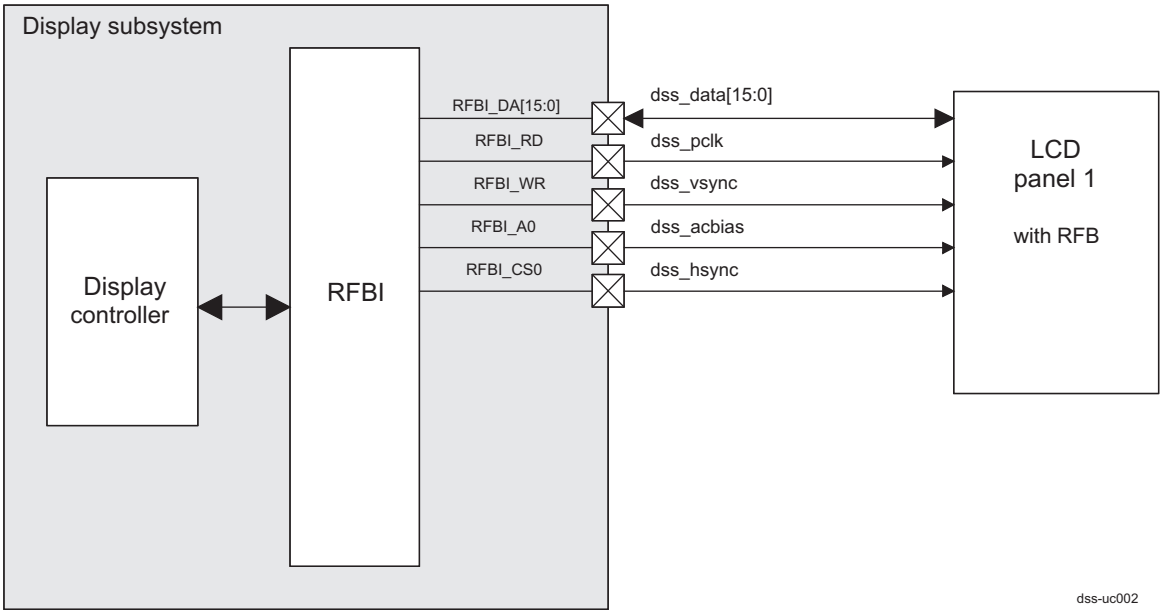
- Input Image: VGA 640*480 pixels , UYVY 4:2:2 format
- Output Image Pixel: QVGA 320*240 pixels , RGB18-666
- Pixel Clock (PCLK): 6 MHz to allow a video display of 60 frames per second
- No DMA requests to the system DMA, but the display subsystem uses its DMA controller to access the data into SDRAM
- VSYNC, SYNCLOST, VID1FIFOUNDERFLOW, and VID1ENDWINDOW interrupts used to monitor the video1 channel

12.6.5.2 Environment

In this use case, the display subsystem is connected to a QVGA LCD panel by the parallel interface.

Figure 12-170 details the OMAP device connections with the LCD panel.

Figure 12-170. Environment



12.6.5.2.1 LCD panel Features

The LCD panel includes the following features:

- Display format 320(H) x 240(V)
- Color mode: 18 bit/pixel R:5 G:6 B:5 (65 536 colors)

12.6.5.3 Data Path

In this use case, the display subsystem manages the following:

- Video stream (UYVY 4:2:2) between the SDRAM controller (SDRC) and the display controller through the internal DMA controller (L3 interconnect)
- Video stream (RGB16) between the display controller and the parallel module
- Video stream (parallel data) between the parallel module and the QVGA LCD panel

Figure 12-171 shows the data flow inside the display subsystem highlighted in red.

Figure 12-171. Display Subsystem Data Flow

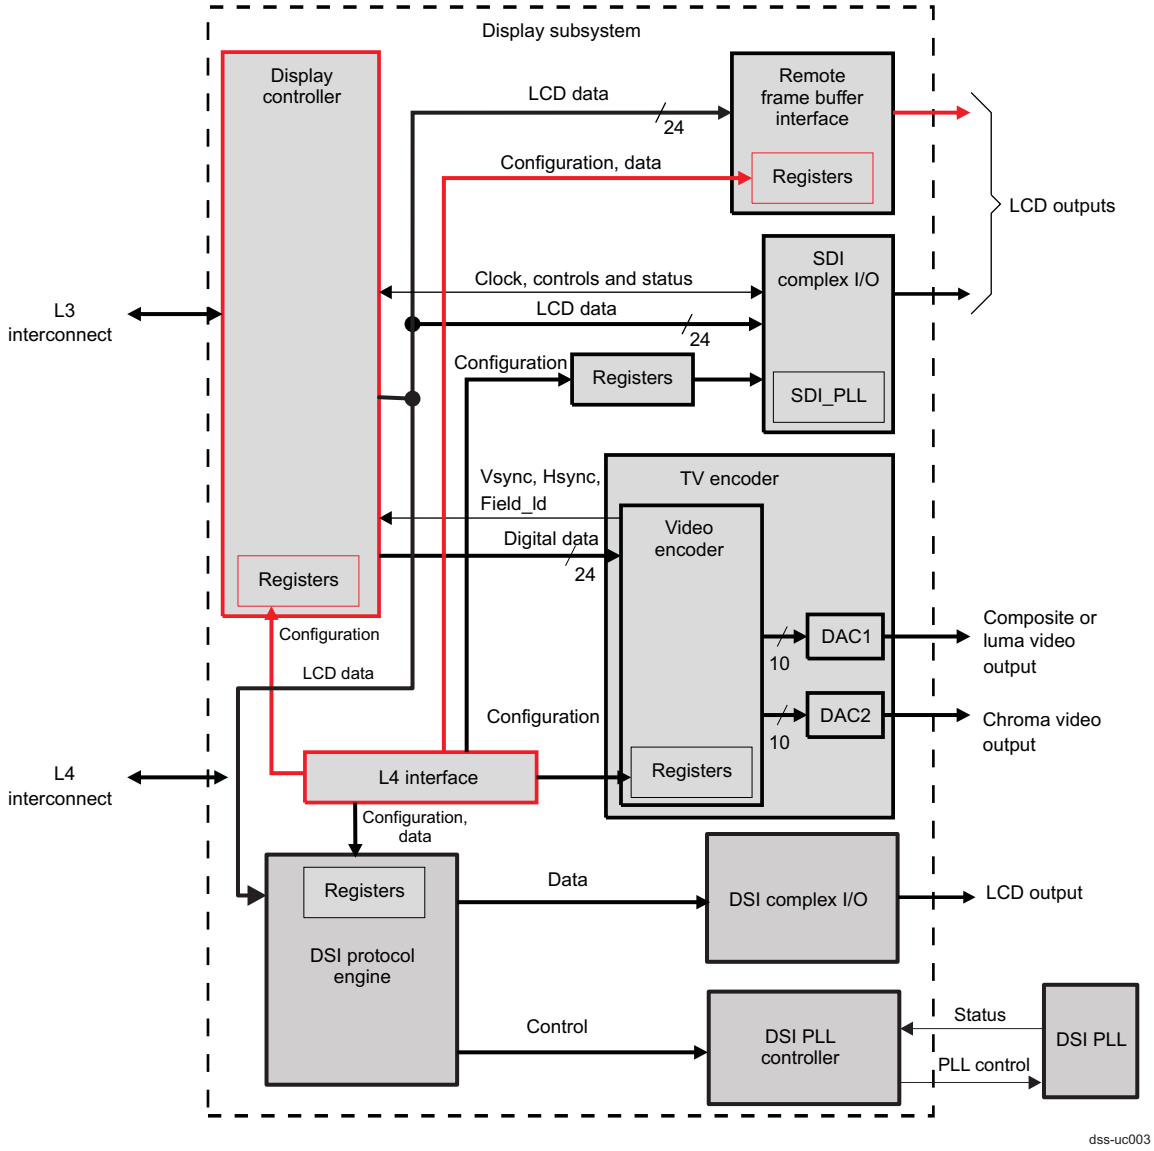


Figure 12-172 shows the data flow inside the display controller submodule highlighted in red.

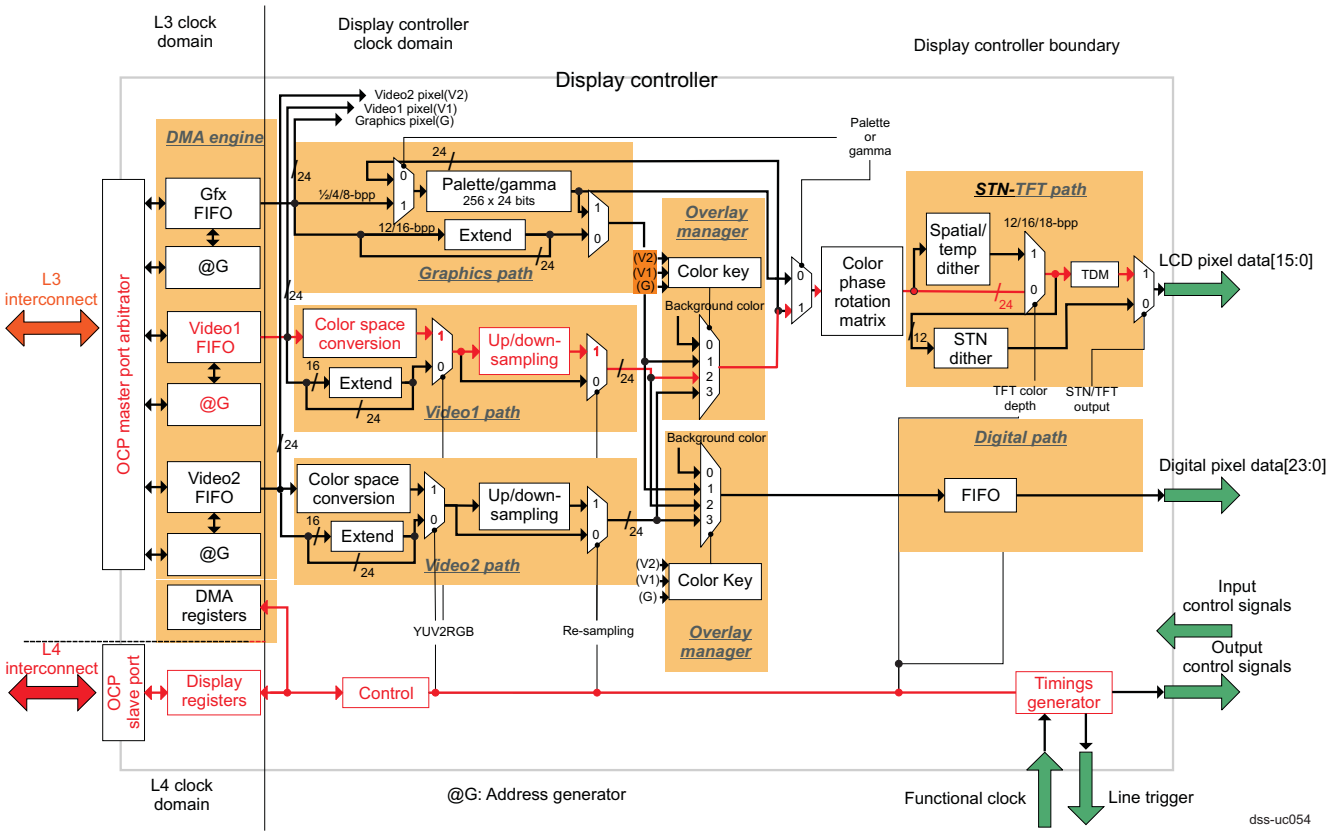
Figure 12-172. Display Controller Data Flow



12.6.5.4 Programming Flow

This section details the programming flow of the display panel configuration for the camcorder use case. The display panel is configured in 3 steps (see Figure 12-173).

Figure 12-173. Display Panel Configuration for the Camcorder Use Case

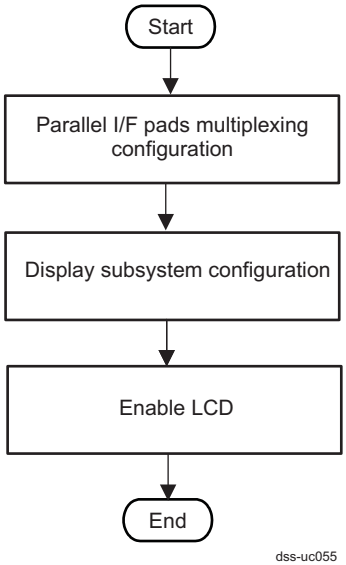


Figure 12-174 shows the programming flow of the display subsystem initial configuration, which consists of four steps:

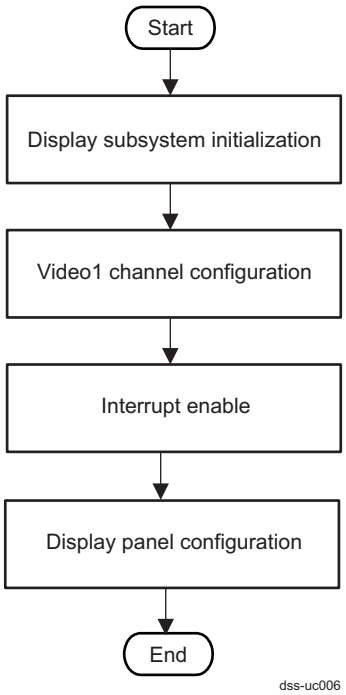
Figure 12-174. Display Subsystem Configuration for Camcorder Use Case



12.6.5.4.1 Pads Multiplexing Configuration

All parallel pads are multiplexed in mode 1 on the dss_data pins:

Table 12-83 shows all the System Control Module registers.

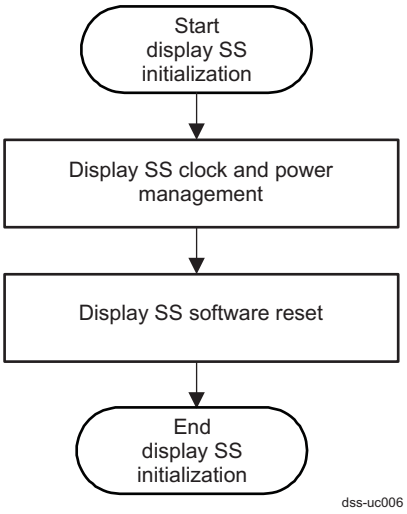
Table 12-83. Registers Print for QVGA LCD panel Pads Multiplexing Configuration

Register Name	Address	Value	Value Description
SCM.CONTROL_PADCONF_DSS_PCLK	0x4800 20D4	0x0110 0110	Configure dss_pclk and dss_hsync pads in mode 0
SCM.CONTROL_PADCONF_DSS_VSYNC	0x4800 20D8	0x0100 0110	Configure dss_vsync and dss_acbias pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA0	0x4800 20DC	0x0100 0100	Configure dss_data0 and dss_data1 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA2	0x4800 20E0	0x0100 0100	Configure dss_data2 and dss_data3 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA4	0x4800 20E4	0x0100 0100	Configure dss_data4 and dss_data5 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA6	0x4800 20E8	0x0100 0100	Configure dss_data6 and dss_data7 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA8	0x4800 20EC	0x0100 0100	Configure dss_data8 and dss_data9 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA10	0x4800 20F0	0x0100 0100	Configure dss_data10 and dss_data11 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA12	0x4800 20F4	0x0100 0100	Configure dss_data12 and dss_data13 pads in mode 0
SCM.CONTROL_PADCONF_DSS_DATA14	0x4800 20F8	0x0100 0100	Configure dss_data14 and dss_data15 pads in mode 0

12.6.5.4.2 Display Subsystem Initialization

Figure 12-175 details the display subsystem initialization.

Figure 12-175. Display Subsystem Initialization



12.6.5.4.2.1 Display Subsystem Clock and Power Management

The display subsystem clock (DSS1_ALWON_FCLK) is provided by the DPLL4 module in the PRCM (DPLL4_M4_X2). The software should set the following PRCM registers:

1. The DPLL4_ALWON_FCLKOUT clock is sourced by the system clock (SYS_CLK) and calculated as follows:

$$DPLL4\_ALWON\_FCLKOUT = \frac{SYS\_CLK(19.2\ MHz) \times 2 \times M\ (0xE1)}{N\ (0x9) + 1} = 864\ MHz$$

dss-uc020

   Set the M multiplier to 225 by setting the PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT bit field to 0xE1.

   Set the N divider to 9 by setting the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field to 0x09.

2. To follow the timing requirements for the use case, the DPLL4_M4_X2 clock frequency is calculated as follows:

$$DPLL4\_M4X2\_CLK = \frac{DPLL4\_ALWON\_FCLKOUT(864\ MHz)}{9} = 96\ MHz$$

dss-ucE007

   Set the DPLL4 ratio by programming to 0x9 the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

3. Enable the display subsystem functional clock (DSS1_ALWON_FCLK): Set the PRCM.CM_FCLKEN_DSS[0] EN_DSS1to 0x1.
4. Enable the display subsystem TV functional clock (DSS_TV_FCLK): Set the PRCM.CM_FCLKEN_DSS[2] EN_TV to 0x1.
5. Enable the display subsystem interface clock (DSS_L4_ICLK): Set the PRCM.CM_ICLKEN_DSS[0] EN_DSS to 0x1.

   Table 12-84 describes the registers from the PRCM to be configured for the display subsystem clock configuration step and the use case values.

Table 12-84. Registers Print for Display Subsytem Clock Management

Register Name	Address	Value	Value Description
PRCM.CM_FCLKEN_DSS	0x4800 4E00	0x0000 0005	Enable DSS1_LWON_FCLk and DSS_TV_FCLK
PRCM.CM_ICLKEN_DSS	0x4800 4E10	0x0000 0001	Enable DSS_L4_ICLK
PRCM.CM_CLKSEL2_PLL	0x4800 4D44	0x0000 E109	DPLL4 multiplier set to 0xE1 and divider set to 0x9
PRCM.CM_CLKSEL_DSS	0x4800 4E40	0x0001 0009	DPLL4 M4X2 divider set to 0x9

The display subsystem power management is programmed by the following PRCM registers:

1. Disable the autoidle mode: Set the PRCM.CM_AUTOIDLE_DSS register to 0x0.
2. Disable the DSS domain sleep dependency: Set the PRCM.CM_SLEEPDEP_DSS register to 0x0.
3. Disable the automatic transition between active and inactive: Set the PRMC.CM_CLKSTCTRL_DSS register to 0x0.

   Table 12-85 describes the registers from the PRCM to be configured for the display subsystem power management step and the use case values.

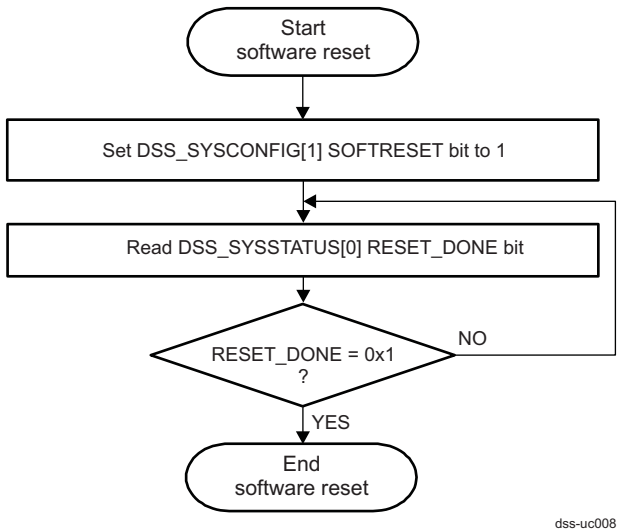
Table 12-85. Registers Print for Display Subsystem Power Management

Register Name	Address	Value	Value Description
PRCM.CM_AUTOIDLE_DSS	0x48004E30	0x0000 0000	Disable autoidle mode
PRCM.CM_SLEEPDEP_DSS	0x48004E44	0x0000 0000	Disable the DSS domain sleep dependency
PRCM.CM_CLKSTCTRL_DSS	0x48004E48	0x0000 0000	Disable the automatic clock state transition

12.6.5.4.2.2 Display Subsystem Software Reset

Perform a software reset as described in the following flowchart (see Figure 12-176).

Figure 12-176. Software Reset Flowchart



CAUTION

To update the RESETDONE status bit correctly, all interface and functional clocks, even for the TV output, must be provided to the display subsystem.

Table 12-86 describes the registers to be configured for the display subsystem software reset step and the use case values.

Table 12-86. Registers Print for Display Subsystem Software Reset

Register Name	Address	Value	Value Description
DSS_SYSCONFIG	0x4805 0010	0x0000 0002	Initiate a software reset. The DSS_SYSCONFIG[1] SOFTRESET is automatically reset by hardware
DSS_SYSSTATUS	0x4805 0014	0x0000 0001	The DSS_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done

12.6.5.4.3 Video1 Channel Configuration

The video1 channel is configured by programming the following steps:

1. Select the UYVY 4:2:2 format by programming the DSS.DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT bit field to 0xB.
2. Select the LCD data flow by programming the DSS.DISPC_VID1_ATTRIBUTES[16] VIDCHANNELOUT bit to 0x0.
3. Select the video DMA burst size to 16x32 by setting the DSS.DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE to 0x2.
4. Program the image base address by setting the DSS.DISPC_VID1_BA0 register.
5. Program the FIFO thresholds as follows:

   To set the FIFO high threshold to 1023 bytes (maximum value allowed), set the DSS.DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field to 0x3FF.

   Set the FIFO low threshold as described in the following equation:

$$\text{VIDFIFOLOWTHRESHOLD} = \text{VIDFIFOHIGHTHRESHOLD (0x3FF)} - \frac{\text{VIDBURSTSIZE(16x32)}}{8} = 959\ (0x3BF)$$

dss-ucE009

   Program the DSS.DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD to 0x3BF.
6. Program the windows X-position to 0 (first column starting on the left edge of the screen) and the window Y-position to 0 (first row starting at the top of the screen): Set the DSS.DISPC_VID1_POSITION[10:0] VIDPOSX and the DSS.DISPC_VID1_POSITION[26:16] VIDPOSY registers to 0x0.
7. Program the window width to 320 by setting the DSS.DISPC_VID1_SIZE[10:0] VIDSIZEX to 0x13F.
8. Program the window height to 240 by setting the DSS.DISPC_VID1_SIZE[26:16] VIDSIZEY to 0xEF.
9. Program the picture width to 640 by setting the DSS.DISPC_VID1_PICTURE_SIZE[10:0] VIDORGSIZEX to 0x27F.
10. Program the picture height to 480 by setting the DSS.DISPC_VID1_PICTURE_SIZE[26:16] VIDORGSIZEY to 0x1DF.
11. Because the video format is in UYVY, software users must program the color conversion module as follows:

    To enable the color conversion module, set the DSS.DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE bit to 1.

    To select a limited range for color space conversion, set the DSS.DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE bit to 0.

    The DSS.DISPC_VID1_COEFi registers (with i = 0 to 4) have nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline 1:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-ucE010

The nine coefficient values for color space conversion from UYVY 4:2:2 to RGB are as follows:
RY = 298, RCb = 0, RCr = 409
GY = 298, GCb = (unsigned) (-11), GCr = (unsigned) (-208)
BY = 298, BCb = 517, BCr = 0

12. Configure the video1 channel for VRFB rotation settings as shown in Table 12-87:

Table 12-87. VRFB Rotation Configuration

Rotation	Registers	Value
0 degree	DSS.DISPC_VID1_BA0	VBA0
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - iw) x ps + 1
90 degrees	DSS.DISPC_VID1_BA0	VBA90
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - ih) x ps + 1
180 degrees	DSS.DISPC_VID1_BA0	VBA180
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - iw) x ps + 1
270 degrees	DSS.DISPC_VID1_BA0	VBA270
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	(2048 - ih) x ps + 1

In the use case context, the input video format is UYVY for a VGA display (640 * 480). As a consequence, the VRFB configuration is as described in Table 12-88.

Table 12-88. VRFB Rotation Configuration for a VGA Display (UYVY format)

Rotation	Registers	Value
0 degree	DSS.DISPC_VID1_BA0	VBA0
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	6273
90 degrees	DSS.DISPC_VID1_BA0	VBA90
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	7233
180 degrees	DSS.DISPC_VID1_BA0	VBA180
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	6273
270 degrees	DSS.DISPC_VID1_BA0	VBA270
	DSS.DISPC_VID1_PIXEL_INC	1
	DSS.DISPC_VID1_ROW_INC	7233

For more information on VRFB module and settings, see the VRFB use case and tips section in , *Memory Subsystem*.

According to the rotation angle, program the DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION and the DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE bits as described in Table 12-89.

Table 12-89. Video Rotation Register Settings (UYVY Only)

Rotation	Registers Field Name	Registers Field Value
0 degree	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degrees	DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

13. Because the video size is in 640 * 480, the scaling unit must be used to downsample to a size of 320 * 240 using a 3 taps configuration.

    The video scaling block for the video pipeline 1 is set in downscaling for horizontal and vertical by setting the following bit field in DSS.DISPC_VIDn_ATTRIBUTES[6:5] :

    - VIDRESIZEENABLE bit field to 0x03
    - VIDHRESIZECONF bit field to 0x1
    - VIDVRESIZECONF bit field to 0x1

14. Program the downscaling of 2 by setting DSS.DISPC_VIDn_FIR to 0x0800 0800.

    All taps coefficients are programmed as in Table 12-90.

    Table 12-90 describes the registers to be configured for the video1 channel configuration step and the use case values.

Table 12-90. Registers Print for Video1 Channel Configuration

Register Name	Address	Value	Value Description
DISPC_VID1_ATTRIBUTES	0x4805 04CC	0x0000 8216 (for 0-degree rotation)	See the programming steps described above for details.
DISPC_VID1_BA0	0x4805 04BC	Base address value	Base address for an image in SDRAM. Depends on the rotation angle (see Table 12-88).
DISPC_VID1_FIFO_THRESHOLD	0x4805 04D0	0x03FF 03BF	FIFO high and low thresholds for DMA request generation
DISPC_VID1_POSITION	0x4805 04C4	0x0000 0000	No X-position and Y-position offsets
DISPC_VID1_SIZE	0x4805 04C8	0x00EF 013F	QVGA display:320*240
DISPC_VID1_PICTURE_SIZE	0x4805 04E4	0x01DF 027F	VGA display: 640*480
DISPC_VID1_CONV_COEF0	0x4805 0530	0x0199 012A	Color space conversion: RCR and RY coefficients
DISPC_VID1_CONV_COEF1	0x4805 0534	0x012A 0000	Color Space Conversion: GY and RCB coefficients
DISPC_VID1_CONV_COEF2	0x4805 0538	0x07F5 0730	Color Space Conversion: GCB and GCR coefficients
DISPC_VID1_CONV_COEF3	0x4805 053C	0x0000 012A	Color Space Conversion: BCR and BY coefficients
DISPC_VID1_CONV_COEF4	0x4805 0540	0x0000 0205	Color Space Conversion: BCB coefficient
DISPC_ROW_INC	0x4805 04D8	Image row increment	Image stride. Depends on the rotation angle (see Table 12-88).
DISPC_PIXEL_INC	0x4805 04DC	0x0000 0001	Pixel increment set to 1 because VRFB module is in charge of rotating the image
DISPC_VID1_FIR	0x4805 04E0	0x0800 0800	Vertical and horizontal ratio for downscaling

Table 12-90. Registers Print for Video1 Channel Configuration (continued)

DISPC_VID1_FIR_COEF_V_7	0x4805 05FC	0x0000FE04	

12.6.5.4.4 Interrupts Enable

The interrupts enable stage is as follows:

1. To clear all display controller IRQs, set the DSS.DISPC_IRQSTATUS register to 0xFFFF.
2. To enable the VSYNC interrupt, set the DSS.DISPC_IRQENABLE[1] VSYNC bit to 1.
3. To enable the VID1FIFOUNDERFLOW interrupt, set the DSS.DISPC_IRQENABLE[10] VID1FIFOUNDERFLOW bit to 1.
4. To enable the ENDVID1WINDOW interrupt, set the DSS.DISPC_IRQENABLE[11] ENDVID1WINDOW bit to 1.
5. To enable the SYNCLOST interrupt, set the DSS.DISPC_IRQENABLE[14] SYNCLOST bit to 1.

Table 12-91 describes the registers to be configured for the interrupts enable step and the use case values.

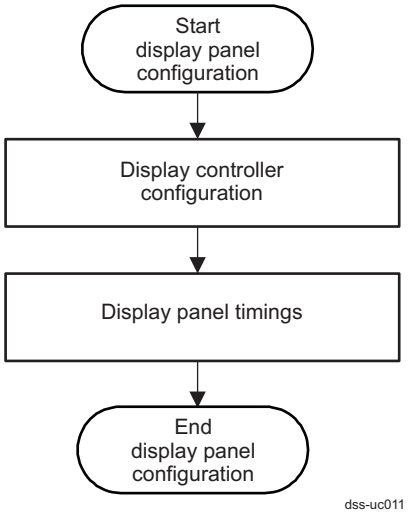
Table 12-91. Registers Print for Interrupts Enable

Register Name	Address	Value	Value Description
DISPC_IRQSTATUS	0x4805 0418	0xFFFF FFFF	Clear all DISPC interrupt requests. This register is automatically reset by hardware.
DISPC_IRQENABLE	0x4805 041C	0x0000 4C02	Enable the VSYNC, VID1FIFOUNDERFLOW, ENDVID1WINDOW, and SYNCLOST IRQs.

12.6.5.4.5 Display Panel Configuration

Figure 12-177 shows the structure of the display panel configuration stage:

Figure 12-177. Display Panel Configuration Flowchart



12.6.5.4.5.1 Display Controller Configuration

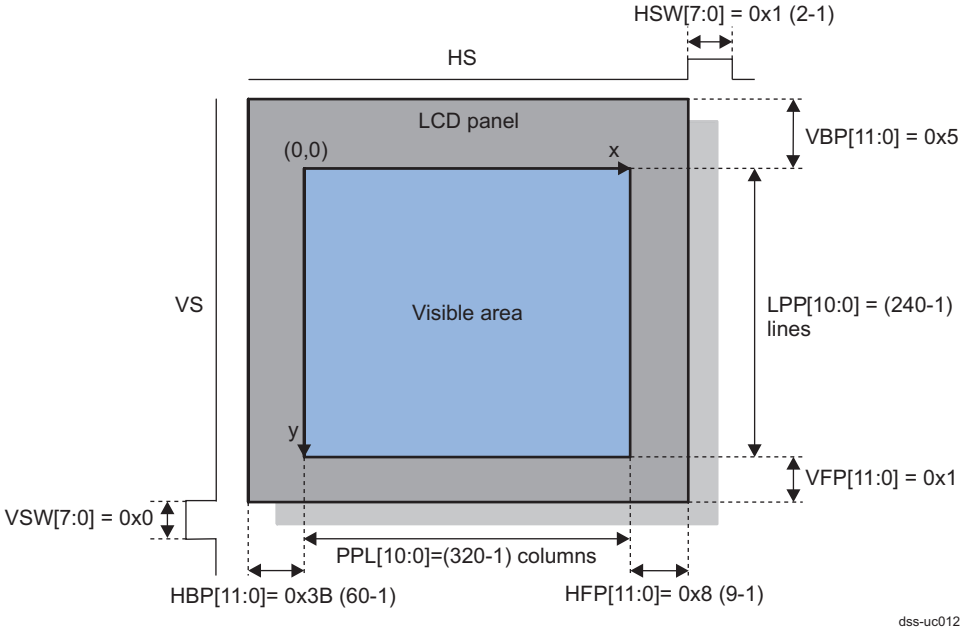
To interface the DISPC with the QVGA LCD panel (320*240), the following settings are required:

1. The QVGA LCD panel is an active matrix: set the DSS.DISPC_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode).
2. Select 16-bit data output by setting the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field to 0x1.
3. Bypass the RFBI module by setting the DSS.DISPC_CONTROL[16:15] GPOUT[1:0] bit field to 0x3.
4. Select the color panel option by setting the DSS.DISPC_CONTROL[2]MONOCOLOR bit to 0x0.
5. Program the LCD enable signal active high by setting the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to 1.
6. Disable the free-running pixel clock by setting the DSS.DISPC_CONTROL[27] PCKFREEENABLE bit to 0.
7. Program the number of lines per panel to 240 by setting the DSS.DISPC_SIZE_LCD[26:16] LPP bit field to 0xEF (239 = 240 -1).
8. Program the number of pixels per line to 320 by setting the DSS.DISPC_SIZE_LCD[10:0] PPL bit field to 0x13F (319 = 320 -1).
9. The pallette module is bypassed: set the DSS.DISPC_CONFIG[2:1] LOADMODE bit field to 0x2 (frame data only).

12.6.5.4.5.2 Display Panel Timings

Figure 12-178 details the timing values description for the QVGA LCD panel.

Figure 12-178. QVGA LCD Panel Timings



The following steps define the timing generation of HSYNC/VSYNC signals based on the QVGA LCD panel specification:

1. Program the horizontal front porch to 9 by setting the DSS.DISPC_TIMING_H[19:8] HFP bit field to 0x8 (9-1).
2. Program the horizontal back porch to 60 by setting the DSS.DISPC_TIMING_H[31:20] HBP bit field to 0x3B (60-1).
3. Program the horizontal synchronization pulse width to 2 by setting the DSS.DISPC_TIMING_H[7:0] HSW bit field to 0x1 (2-1).
4. Program the vertical front porch to 1 by setting the DSS.DISPC_TIMING_V[19:8] VFP bit field to 1.
5. Program the vertical back porch to 5 by setting the DSS.DISPC_TIMING_V[31:20] VBP bit field to 5.
6. Program the vertical synchronization pulse width to 0 by setting the DSS.DISPC_TIMING_V[7:0] VSW bit field to 0.
7. For QVGA LCD panel, the line clock signal is active high and inactive low. As a consequence, invert HSYNC by setting the DSS.DISPC_POL_FREQ[13] IHS bit to 0.
8. For QVGA LCD panel, the frame clock signal is active high and inactive low. As a consequence, invert VSYNC by setting the DSS.DISPC_POL_FREQ[12] IVS bit to 0.
9. Drive HSYNC and VSYNC on the falling edge of PCLK by setting the DSS.DISPC_POL_FREQ[16] RF bit to 0 and the the DSS.DISPC_POL_FREQ[17] ONOFF bit to 0.
10. Drive the pixel data on the rising edge of PCLK by clearing the DSS.DISPC_POL_FREQ[14] IPC bit to 0.
11. Set the data enable active high by clearing the DSS.DISPC_POL_FREQ[15] IEO bit to 0.

The visible pixel count is 320 * 240 = 76 800 pixels.

The Total Frame Pixel Count (with the values given above) is (320+8+59+1) x (240+5+1+0) = 95 448 pixels.

The camcorder application displays 60 frame per second.

The pixel clock required for 60 fps is: 95 448 x 60 Hz = 5,72688 MHz.

On the other hand, the pixel clock is defined by the following equation:

$$PixelClock = \frac{Functional\ Clock}{LCD\ factor \times PCD\ factor}$$
dss-ucE013

To program the pixel clock to 5.72688 MHz, software users must set:

1. Set the DSS.DISPC_DIVISOR[23:16] LCD bit field to 0x2.

$$LogicClock = \frac{DSS1\_ALWON\_FCLK}{2} = 48\ Mhz$$
dss-ucE014

2. Set the DSS.DISPC_DIVISOR[7:0] PCD bit field to 0x8.

$$PixelClock = \frac{LogicClock}{8} = 6\ Mhz$$
dss-ucE015

Table 12-92 describes the registers to be configured for the display panel configuration step and the use case values.

Table 12-92. Registers Print for Display Panel Configuration

Register Name	Address	Value	Value Description
DISPC_CONTROL	0x4805 0440	0x0001 8108	See Section 12.6.5.4.5.1, *Display Controller Configuration*, for more details.
DISPC_SIZE_LCD	0x4805 047C	0x00EF 013F	QVGA display: 320 * 240
DISPC_CONFIG	0x4805 0444	0x0000 0004	Disable the palette
DISPC_TIMING_H	0x4805 0464	0x03B0 0801	Program horizontal timings
DISPC_TIMING_V	0x4805 0468	0x0050 0100	Program vertical timings
DISPC_POL_FREQ	0x4805 046C	0x0000 0000	Program the HSYNC and VSYNC signals for QVGA LCD panel
DISPC_DIVISOR	0x4805 0470	0x0002 0008	Set the divisors to program the PCLK frequency at 6 MHz.

12.6.5.4.6 LCD Enable

The LCD enable step is composed of the following stages:

1. To enable the video1 layer, set the DSS.DISPC_VID1_ATTRIBUTES[0] VIDENABLE bit to 1. The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled.
2. To enable the display controller output, set the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1.
3. To account for all DISPC configuration done, set the DSS.DISPC_CONTROL[5] GOLCD bit to 1 to indicate that all shadow registers of the video1 pipeline connected to the LCD output are latched by the hardware. The hardware can now update the internal registers at the VFP start period and the image displayed on the panel.

Table 12-93 describes the registers to be configured for the LCD enable step and the use case values.

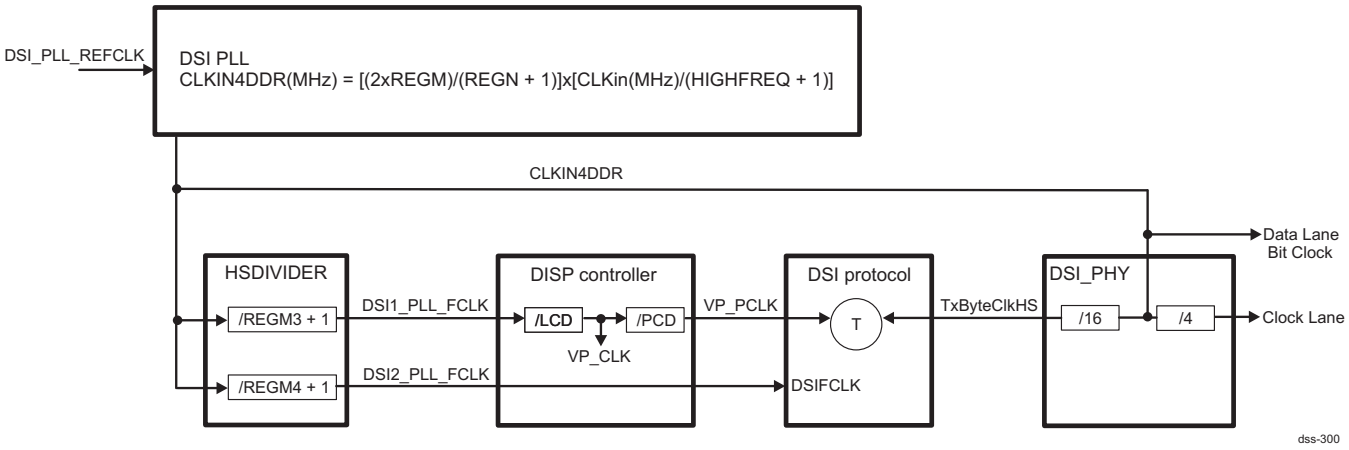
Table 12-93. Registers Print for LCD Enable

Register Name	Address	Value	Value Description
DISPC_CONTROL	0x4805 0440	0x0001 8129	Set DISPC_CONTROL[0] LCDENABLE and DISPC_CONTROL[5] GOLCD bits to 1.
DISPC_VID1_ATTRIBUTES	0x4805 04CC	0x0000 83F7	Enable the DISPC_VID1_ATTRIBUTES[0] VIDENABLE.

12.6.6 How to Configure the DSI PLL in Video Mode

Figure 12-179 shows a global overview of the DSI clock tree when used in video mode.

Figure 12-179. DSI Clock Tree in Video Mode



The settings of the DSI PLL registers can be summarized by four equations.

Equation 1

$$N * T_{VP\_CLK} = T_L * T_{TxByteClkHS} \quad \text{dss-301} \tag{19}$$

where

$T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}$

N is an integer

NDL: Number of data lane

WC: Word count or payload in bytes

T_{HS} and T_{HE} are equal to 4/NDL and 0 if they are disabled.

HSA_{DSI} is HSA period in video mode.

T_{HS} is the length of HSYNC start short packet in number of byte clock cycles (TxByteClkHS).

T_{HE} is the length of HSYNC end short packet in number of byte clock cycles (TxByteClkHS).

HBP_{DSI} is HBP period in video mode.

HFP_{DSI} is HFP period in video mode.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

$$R = T_{TxByteClkHS} / T_{VP\_PCLK} \quad \text{dss-302} \tag{20}$$

To synchronize DISPC and DSI protocol engine, users should follow the ratio R between TxByteClkHS and VP_PCLK as listed in Table 12-94.

Table 12-94. Ratio R

Number of Data Lanes	Pixel Format	Ratio R
1	16-bits pixel	1/2
1	18-bits pixel	4/9
1	24-bits pixel	1/3

Table 12-94. Ratio R (continued)

Number of Data Lanes	Pixel Format	Ratio R
2	16-bits pixel	1
2	18-bits pixel	8/9
2	24-bits pixel	2/3

All cases are covered by:

$F_{VP\_PCLK} * bits\_per\_pixel = F_{TxByteClkHS} * NDL * 8$

dss-310

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) * T_{TxByteClkHS}$$ dss-303 (21)

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} * bits\_per\_pixel) / (NDL * 8)) - (2 / NDL)$$ dss-309 (22)

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888
- 1-data lane
- LCD size 480*640 with $HSA_{\_DISP} = HFP_{\_DISP} = HBP_{\_DISP}$ =20, $VSA_{\_DISP} = VFP_{\_DISP} = VBP_{\_DISP}$ =2

Step 1. **Determine REGM and REGN**

To obtain correct stability, Fint should be kept between 0.75 MHz and 2.1 MHz. In this case, Fint is maintained at 2 MHz. For more information, refer to the DSI PLL programming model.

$$REGN = (F_{DSI\_PLL\_REFCLK} / F_{int}) – 1$$

$$REGN = 12$$

$$REGM = (REGN+1)*F_{CLKIN4DDR} / (2 * F_{DSI\_PLL\_REFCLK})$$

$$REGM = 150$$ dss-318

Where DSS2_ALWON_FCLK= 26 MHz is used as a reference clock for $F_{DSI\_PLL\_REFCLK}$

Step 2. **Determine VP_PCLK and TxByteClkHS clocks.**

TxByteClkHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12,5 MHz. The frame rate can be estimated by:

$$Frame\ rate = F_{VP\_PCLK} / (HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * (VSA_{DISPC} + VFP_{DISPC} + LPP + VBP_{DISPC})$$

$$Frame\ rate = 12,5\ MHz / (540) * (646)$$

$$Frame\ rate = 35,83\ frame/sec$$ dss-323

Step 3. **Determine LCD, PCD and REGM3**

$$T_{CLKIN4DDR} = T_{TxByteClkHS} / 16 = T_{VP\_PCLK} / ((REGM3 + 1) * LCD * PCD)$$

$$((REGM3 + 1) * LCD * PCD) = 16 * 3$$ dss-315

If LCD and PCD are set to 1 and 3 respectively, REGM3 is equal to 15.

Step 4. **Verify N as integer**

Firstly, TL must be determined

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} / T_{TxByteClkHS} = T_L = 1620$$ dss-316

From **Equation 1**,

$$N*T_{VP\_CLK} = T_L*T_{TxByteClkHS}$$

$$N= T_{TxByteclkHS}*T_L/T_{VP\_CLK}=T_L/(R*PCD)$$

$$N = 14580$$

N is an integer.

Step 5. **Determine HFP and HBP of the DSI protocol engine**

From **Equation 3**,

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP\_PCLK} / T_{TxByteClkHS}) - (4/NDL + (WC + 6)/NDL) = HFP_{DSI} + HBP_{DSI}$$

$$HFP_{DSI} + HBP_{DSI} = 170$$

dss-317

From **Equation 4**,

$HFP_{DSI} = ((HFP_{DISPC} * bits\_per\_pixel) / (NDL * 8)) - (2 / NDL)$

$$HFP_{DSI} = 58$$

$$HBP_{DSI} = 170 - 58 = 112$$

dss-321

12.6.7 DSI Video Mode Using the DISPC Video Port

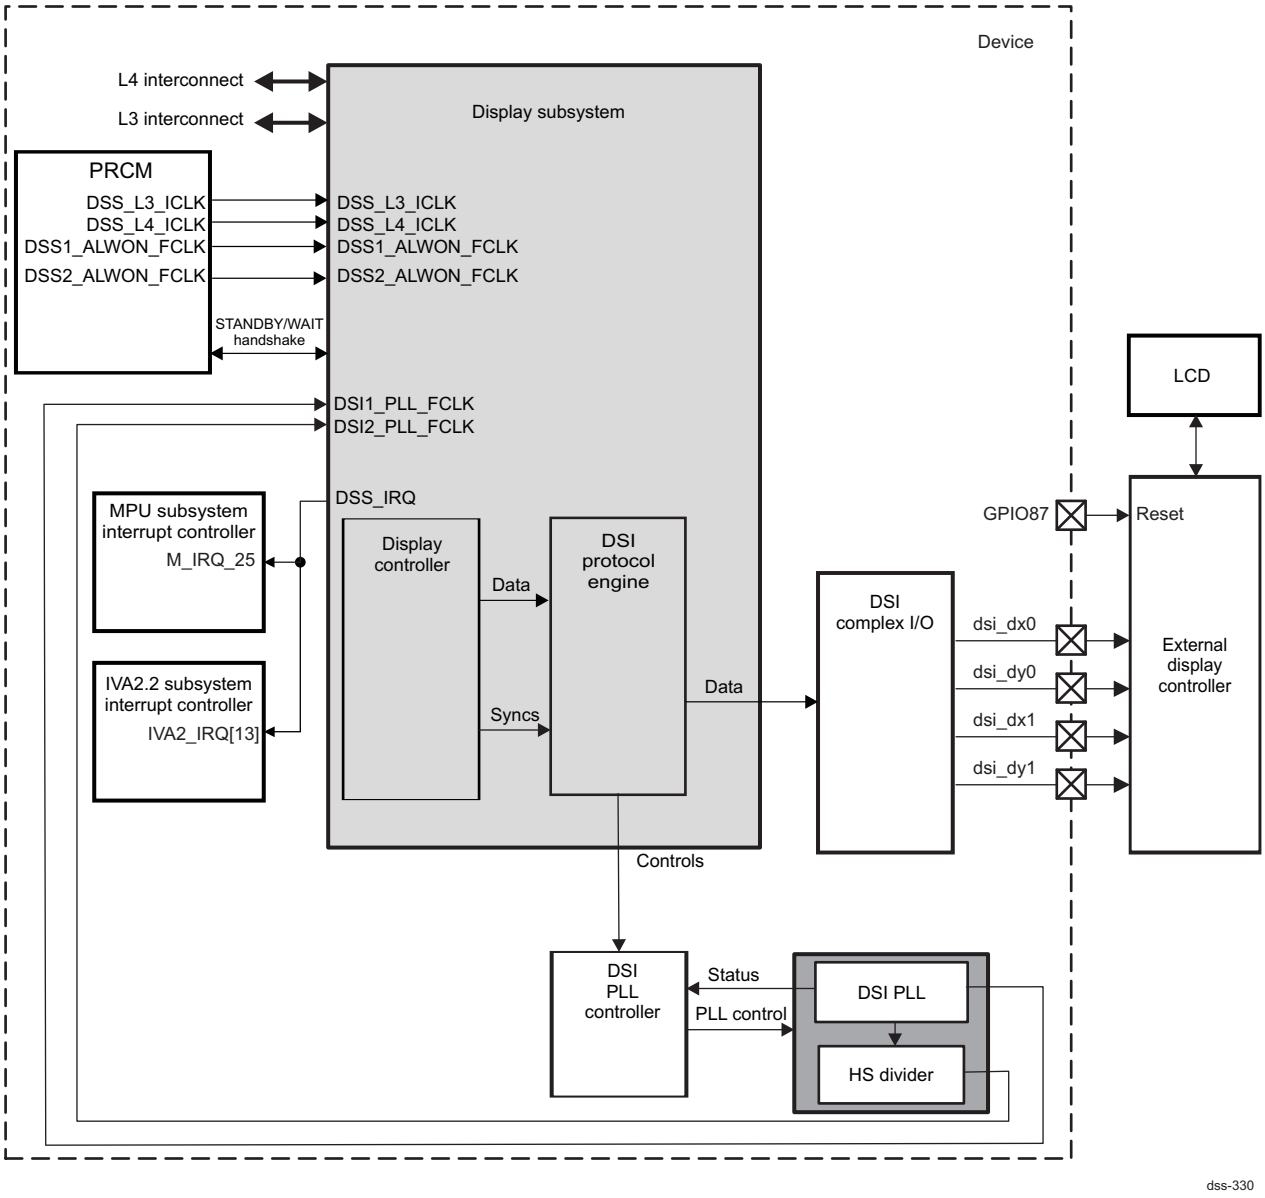
This section details the basic programming model of video mode using the DISPC video port.

The DSI interface is connected to an external MIPI display controller and the following parameters are used:

- 1 data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 × 480:
  - 480 pixels per line (PPL)
  - 680 lines per panel (LPP)
- Display controller input format: YUV
- Display controller output format: RGB888, that is 24 bits per pixel (BPP)
- Word Count: WC = 3 × PPL
- DSS2_ALWON_FLCK=26 MHz is used as a reference clock for DSI PLL
- Virtual channel 0 (VC0) is used for video mode.
- Interleaving is not used.
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 12-180 is an overview of the connections in the display subsystem.

Figure 12-180. Overview



The steps listed in Table 12-95 are described in the following sections.

Table 12-95. Main Steps

Steps	Section
Configure DSS clocks	Section 12.6.7.1, *Display Subsystem Clock Configuration*
Configure the DSI and DSI PLL	Section 12.6.7.2, *Configure DSI, DSI PLL and Complex I/O*
Configure the external MIPI display controller	Section 12.6.7.3, *Initialization of the External MIPI Display Controller*
Configure the DISPC	Section 12.6.7.4, *Configure the DISPC*
Enable video mode using the DISPC video port	Section 12.6.7.5, *Enable Video Mode Using the DISPC Video Port*

The programming model must be followed in the order of the following sections.

12.6.7.1 Display Subsystem Clock Configuration

Table 12-96 lists the steps required to enable the clocks.

Table 12-96. PRCM Registers

Steps	Registers	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[31:0]	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[31:0]	0x0
Automatic transition between active and inactive are disabled.	CM_CLKSTCTRL_DSS[31:0]	0x0
Enable DSS1, DSS2 and TV clock (DSS1_ALWON_FCLK, DSS2_ALWON_FCLK and TV_CLK). TV_CLK is only need for correct Reset.	CM_FCLKEN_DSS[31:0]	0x7
Enable the subsystem interface clock (DSS_L3_ICLK and DSS_L4_ICLK).	CM_ICLKEN_DSS[31:0]	0x1

12.6.7.2 Configure DSI, DSI PLL and Complex I/O

12.6.7.2.1 Reset DSI Modules

Table 12-97 lists the steps required to reset the DSI modules.

Table 12-97. Resets

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
OCP and functional clock are maintained during wakeup, smart idle, and reset DSI.	DSI_SYSCONFIG[31:0]	0x312
Wait until RESET_DONE ≠ 0.	DSI_SYSSTATUS[0] RESET_DONE	Read 0x1

12.6.7.2.2 Set Up DSI DPLL

Table 12-98 lists the steps required to configure DSI PLL.

Table 12-98. DSI PLL Configuration Registers

Steps	Registers	Value
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CTRL	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	Read 0x2
See the calculation following this table.	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
See the calculation following this table.	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
See the calculation following this table.	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
See calculation following this table.	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Enable PLLStopMode.	DSI_PLL_CONFIGURATION1[0]	0x1
The DSI protocol engine clock divider, DSS clock divider, CLKIN4DDR, and PLL reference clock are enabled. PLL internal reference frequency is between 1.75 and 2.1MHz.	DSI_PLL_CONFIGURATION2[31:0]	0x5600E
Manual mode	DSI_PLL_CONTROL[31:0]	0x0
Request PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Read until DSI_PLL_GO = 0	DSI_PLL_GO[0] DSI_PLL_GO	Read 0x0
PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	Read 0x1

Table 12-98. DSI PLL Configuration Registers (continued)

Steps	Registers	Value
Turn on PLL and HSDIVIDER; the DSI functional clock > 30-MHz sync is rising/rising; the DSIStopClk signal is automatically asserted/deasserted; the L3_ICLK clock to the DSI complex I/O is not gated; and LPCLKDIVISOR = 8	DSI_CLK_CTRL[31:0]	0x8024 4008

1. Calculate the divider value for the DSI protocol engine clock source:

   RegM4 = FCLKIN4DDR/DSI2_PLL_FCLK - 1

   FCLKIN4DDR = 4 x FCLKIN

   RegM4 = 5

2. Determine LCD, PCD, and REGM3:

   Calculate the divider value for DSS clock source: Same as Step 3.

   $$RegM3 = ((BPP \times 2)/(DISPC\_LCD \times DISPC\_PCD \times NDL)) - 1$$

   $$RegM3 = 15$$

   dss-E127

3. Calculate N Divider for PLL:

   $$FCLKIN4DDR = FCLKIN \times 4$$

   $$RegN = (FDSI\_PLL\_REFCLK / F\,INt) - 1$$

   $$FDSI\_PLL\_REFCLK = 26\ MHz\ (system\ clock)$$

   $$Fint = 2\ MHz\ (reduce\ PLL\ lock\ time)$$

   $$RegN = 12$$

   dss-E128

4. Calculate M divider for PLL:

   $$RegM = ((RegN + 1) \times (FCLKIN4DDR/(2 \times FDSI\_PLL\_REFCLK)))$$

   $$FCLKIN4DDR = 4 \times 150\ MHz$$

   $$RegM = 150$$

   dss-E129

12.6.7.2.3 Switch to DSI PLL Clock Source

Select the DSI_PLL1 clock as the DISPC functional clock, and select the DSI_PLL2 clock as the DSI functional clock: Set DSS_CONTROL to 0x3.

12.6.7.2.4 Set Up DSI Protocol Engine

12.6.7.2.4.1 Set Up DSI Control Registers

Table 12-99 lists the steps to set up the DSI control registers. Table 12-100 lists the steps to set up the DSI complex I/O registers.

Table 12-99. DSI Control Registers

Steps	Registers	Value
Enable SYNCLOST event.	DSI_IRQENABLE[31:0]	0x4 0000
Set PACKET_SENT_IRQ_EN.	DSI_VC0_IRQENABLE[31:0]	0x4
While the HSYNC START pulse is detected, the associated short packet HSYNC START is generated.	DSI_CTRL[17] VP_HSYNC_START	0x1
While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	DSI_CTRL[15] VP_VSYNC_START	0x1

Table 12-99. DSI Control Registers (continued)

Steps	Registers	Value
Set the trigger reset mode to *immediate.*	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
HSYNC signal on the video port is active high.	DSI_CTRL[10] VP_HSYNC_POL	0x1
VSYNC on the video port is active high.	DSI_CTRL[11] VP_VSYNC_POL	0x1
Set the Data Enable signal on the video port as active high.	DSI_CTRL[9] VP_DE_POL	0x1
Set the size of the video port data bus for the RGB format: 0x2 for RGB 888.	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
VP_CLK_RATIO is not used if video port is used to provide data in video mode	DSI_CTRL[4] VP_CLK_RATIO	0x0
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as Sequential Scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 12-100. DSI Complex I/O Registers

Steps	Registers	Value
GOBIT, complex I/O power ON, select data, and clock position	DSI_COMPLEXIO_CFG1	0x4800 0032
Clear Reg	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable IRQ	DSI_COMPLEXIO_IRQENABLE	0x0
Enable I/F	DSI_CTRL[0] IF_EN	0x1
Disable I/F	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0	DSI_CTRL[0] IF_EN	Read 0x0
Enable Low Power clock	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Reset is done.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	Read 0x1
Power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	Read 0x1
Reset is complete.	DSI_SYSSTATUS[0] RESETDONE	Read 0x1

12.6.7.2.4.2 Configure DSI Timing and Virtual Channels

Table 12-101 lists the steps to configure DSI timing and the virtual channels.

Table 12-101. DSI Timing Registers

Steps	Registers	Value
STOP_STATE_COUNTER_IO = 0x999	DSI_TIMING1[31:0]	0x0000 0999
HS_TX_TO_X8, HS_TX_TO_COUNTER = 0x0FD2, LP_RX_TO_X16, LP_RX_TO_COUNTER = 0x00CD	DSI_TIMING2[31:0]	0x2FD2 40CD
(HSA<<24)|(HFP<<12)|HBP	DSI_VM_TIMING1[31:0]	0x0000 700A
(WINDOW_SYNC<<24)|(VSA<<16)|(DSI_VFP <<8)|VBP	DSI_VM_TIMING2[31:0]	0x0401 0101
(TL<<16)|DSI_VACT	DSI_VM_TIMING3[31:0]	0x05BB 0280
(ENTER_HS_MODE_LATENCY<<16)|EXIT_H S_MODE_LATENCY	DSI_VM_TIMING7[31:0]	0x0000 C000A
DDR_CLK_PRE<<8|DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
HS speed, ECC generation for the Transmit, Enable CheckSum generation for the Payload.	DSI_VC0_CTRL[31:0]	0x2080 0390

- Freq TxByteClkHS :

$$FHSB = FCLKIN4DDR / 16$$

$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC\_LCD * DISPC\_PCD)$$

$$FVP = FCLKIN4DDR / (RegM3 + 1)$$

dss-E130

- Length of the line in video mode in Nb of byte clock cycles (TxByteClkHS):

$$TL = FHSB / FVPP \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

$$TL1f = (BPP / (8 \times NDL)) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

dss-E131

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC\_HSA + DISPC\_HBP + PPL + DISPC\_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP / THSB) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + (WC + 6) / NDL))$$

$$HBPplusHFP = (FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + WC + 6) / NDL$$

$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)) - ((HS + WC + 6) / NDL)$$

$$HFP = (DISPC\_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$

$$HBP = HBPplusHFP - HFP$$

dss-E132

12.6.7.2.5 Configure DSI_PHY

For the calculation of DSI_PHY timing, see Table 12-102. See Section 12.4.3.2, *Clock Requirements*, for details on timing calculation.

Table 12-102. Calculate DSI_PHY Timing

Steps	Registers	Value
See Section 12.4.3.2	DSI_PHY_CFG0[31:24] THS_PREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_CFG0[7:0] THS_EXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_CFG0[15:8] THS_TRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_CFG2[7:0] TCLK_PREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_CFG1[7:0] TCLK_ZERO	ceil(260 ns/DDR clock period)
	DSI_PHY_CFG1[15:0] TCLK_TRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_CFG120:16] TLPX_HALF	ceil(26.5 ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the DSI_PHY_CFG1 and DSI_PHY_CFG2 registers.

12.6.7.2.6 Drive Stop State

Table 12-103 lists the steps to Drive Stop State.

Table 12-103. Drive Stop State

Steps	Registers	Value
Force TX stop mode	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	Read 0x0

12.6.7.3 Initialization of the External MIPI Display Controller

1. Wait for the external MIPI display controller initialization after power up.
   In this example, the external MIPI display controller is reset using GPIO 87.
2. Configure the external MIPI display controller.

12.6.7.4 Configure the DISPC

12.6.7.4.1 Reset DISPC

Table 12-104 lists the step sequence to reset the DISPC.

Table 12-104. Reset DISPC

Steps	Registers	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
DISPC is reset.	DISPC_SYSCONFIG[0] RESETDONE	Read 0x1
No standby: MStandby is never asserted.	DISPC_SYSCONFIG [13:12] MIDLEMODE	0x1
Disable idle mode.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all interrupts.	DISPC_IRQENABLE[31:0]	0x0

12.6.7.4.2 Configure DISPC Timing, Window, and Color

Table 12-105 lists the steps to configure the DISPC registers. Table 12-106 lists the steps to configure the color space coefficient registers.

Table 12-107 lists the steps to configure DISPC_CONTROL.

Table 12-105. Configure DISPC Registers

Steps	Registers	Value
Set horizontal timings.	DISPC_TIMING_H	(HBP – 1<<20)|(HFP – 1<<8)|HSA – 1
Set vertical timing.	DISPC_TIMING_V	(HBP – 1<<20)|(HFP – 1<<8)|HSA – 1
Set LCD – PCD display controller and pixel clock divisor.	DISPC_DIVISOR	LDC = %1 PXLCLK = %4
Set the size of the LCD – 1.	DISPC_SIZE_LCD	(LPP – 1 + DSI_VFP)<<16|(PPL – 1)
Set default RGB value when there is no data.	DISPC_DEFAULT_COLOR0	0XFF
Set video FIFO height and low threshold.	DISPC_VID1_FIFO_THRESHOLD	0xfc00c0
Set the X Y location of the upper left pixel (0 = 0) to the upper left corner.	DISPC_VID1_POSITION	0x0
Set size of the window.	DISPC_VID1_SIZE	(LPP – 1) <<16|(PPL – 1)
Set the size of the picture.	DISPC_VID1_PICTURE_SIZE	(LPP – 1) <<16|(PPL – 1)
Set the input address picture.	DISPC_VID1_BA0	0x–

Table 12-106. Configure Color Space Coefficient Registers

Comments	Registers	Value
RCR and RY coefficients	DISPC_VID1_CONV_COEF0	0X0199012A
GY and RCB coefficients	DISPC_VID1_CONV_COEF1	0X012A0000
GCB and GCR coefficients	DISPC_VID1_CONV_COEF2	0X079C0730

LCD interface is disabled.	DISPC_CONTROL[0] LCDENABLE	0x0

The input image is converted from UYVY into RGB (see Table 12-108) :

Table 12-108. Configure DISPC_VID1_ATTRIBUTES

Comments	Registers	Value
Row of VIDn will not be read twice.	DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
8 x 32-bit bursts	DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE	0x1
Full range selected: Y is not modified before the color space conversion.	DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE	0x1
Enable color space conversion CbYCr to RGB.	DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE	0x1
UYVY	DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT	0xB
Video disabled	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x0

12.6.7.5 Enable Video Mode Using the DISPC Video Port

Table 12-109 lists the steps to enable DISPC to send frames continuously.

Table 12-109. Enable DISPC

Steps	Registers	Value
Set up long packet header	DSI_VC0_LONG_PACKET_HEADER[31:0]	0x0005 A03E
Enable VC0.	DSI_VC0_CTRL[1] VC_EN	0x1
Enable IF.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN ≠ 0.	DSI_CTRL[0] IF_EN	Read 0x0
Enable VID1.	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x1
Enable LCD interface.	DISPC_CONTROL[0] LCDENABLE	0x1
Enable GOLCD.	DISPC_CONTROL[5] GOLCD	0x1
Wait until GOLCD = 0.	DISPC_CONTROL[5] GOLCD	Read 0x0

12.6.8 DSI Command Mode Using the DISPC Video Port

This section presents some generic use cases and tips for setting the modules of the display subsystem.

12.6.8.1 Display Subsystem Use Cases and Tips

This section explains the basic programming model of command mode using the DISPC video port.

The DSI interface is connected to an external MIPI DISPC using the following parameters:

- One data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 × 480:
  - 480 PPL
  - 680 LPP
- DISPC input format: YUV
- DISPC output format: RGB888 (24 BPP)
- Word Count: WC = 3 × PPL
- DSS2_ALWON_FLCK = 26 MHz used as a reference clock for DSI PLL
- Virtual channel 1 (VC1) used for command mode to configure the externel DISPC, and virtual channel 0 (VC0) used to send data
- Automatic TE used for synchronization
- Interleaving not used
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 12-181 is an overview of the connections in the display subsystem.

Figure 12-181. Overview

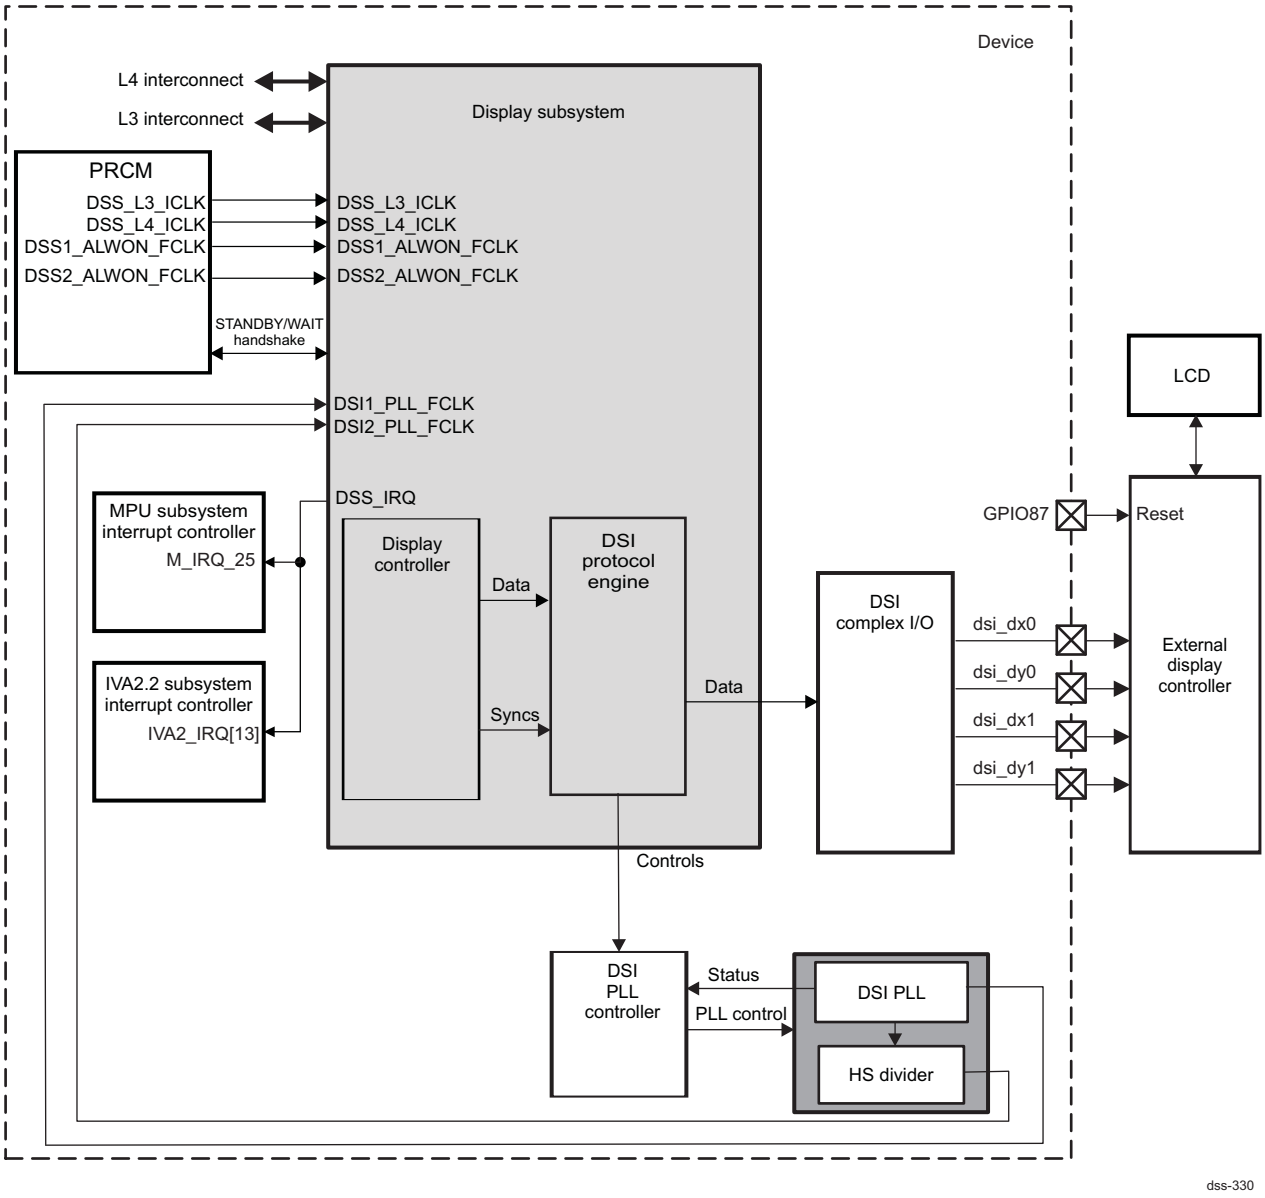

Table 12-110 lists the steps of the main sequence and the sections that describe them.

Table 12-110. Main Sequence

Steps	Register/Bit Field/Programming Model
Configure DSS clocks.	Section 12.6.8.1.1, *Configure DSS Clocks at the PRCM Module*
Configure the DSI protocol engine and DSI PLL.	Section 12.6.8.1.2, *Configure DSI Protocol Engine, DSI PLL, and Complex I/O*
Configure the external MIPI display controller.	Section 12.6.8.1.3, *Initialization of the External MIPI Display Controller*
Configure the DISPC.	Section 12.6.8.1.4, *Configure the DISPC*
Enable command mode using the DISPC video port.	Section 12.6.8.1.5, *Enable Command Mode Using the DISPC Video Port*
Send a frame data to LCD panel using automatic TE.	Section 12.6.8.1.6, *Send Frame Data to LCD Panel Using Automatic TE*

The programming model must follow the step sequence.

12.6.8.1.1 Configure DSS Clocks at the PRCM Module

Table 12-111 lists the steps required to enable the clocks.

Table 12-111. Configure DSS Clocks at the PRCM Module

Steps	Register/Bit Field/Programming Model	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[0] AUTO_DSS	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[2:0] EN_IVA2, EN_MPU, EN_CORE	0x0
Disable automatic transition.	CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS	0x0
Enable the DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, and TV_CLK functional clocks.(1)	CM_FCLKEN_DSS[2:0] EN_TV, EN_DSS2, EN_DSS1	0x7
Enable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks.	CM_ICLKEN_DSS[0] EN_DSS	0x1

(1) TV_CLK is required only for a correct reset.

12.6.8.1.2 Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Table 12-112 lists the steps to configure the DSI protocol engine, DSI PLL, and complex I/O and the sections that describe the sequence.

Table 12-112. Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Steps	Register/Bit Field/Programming Model
Reset DSI modules.	Section 12.6.8.1.2.1, *Reset DSI Modules*
Configure DSI DPLL.	Section 12.6.8.1.2.2, *Configure DSI PLL*
Switch to DSI PLL clock source.	Section 12.6.8.1.2.3, *Switch to DSI PLL Clock Source*
Configure DSI protocol engine.	Section 12.6.8.1.2.4, *Configure DSI Protocol Engine*
Configure DSI_PHY.	Section 12.6.8.1.2.5, *Configure DSI_PHY*
Drive stop state.	Section 12.6.8.1.2.6, *Drive Stop State*

12.6.8.1.2.1 Reset DSI Modules

Table 12-113 lists the steps required to reset the DSI modules.

Table 12-113. Reset DSI Modules

Steps	Register/Bit Field/Programming	Value
Clear DSI IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Maintain interface and functional clock during wakeup.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	0x3
Enable smart-idle for power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	0x2
Set DSI reset.	DSI_SYSCONFIG[1] SOFT_RESET	0x1
Wait until RESET_DONE = 1.	DSI_SYSSTATUS[0] RESET_DONE	

12.6.8.1.2.2 Configure DSI PLL

Table 12-114 lists the steps required to configure the DSI PLL.

Table 12-114. Configure DSI PLL

Steps	Register/Bit Field/Programming	Value
Enable PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	
Set the REGM4 value (see).	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
Set the REGM3 value (see).	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
Set the REGN value (see).	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Set the REGM value (see).	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
Enable PLL STOPMODE.	DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	0x1
Set the PLL internal reference frequency range between 1.75 and 2.1 MHz.	DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL	0x7
Enable PLL reference clock control.	DSI_PLL_CONFIGURATION2[13] DSI_PLL_REFEN	0x1
Enable CLKIN4DDR control.	DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN	0x1
Enable DSS clock divider.	DSI_PLL_CONFIGURATION2[16] DSS_CLOCK_EN	0x1
Enable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] DSI_PROTO_CLOCK_EN	0x1
Enable DSI configuration update with DISPC_UPDATE_SYNC.	DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE	0x0
Start PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Wait until DSI_PLL_GO = 0.	DSI_PLL_GO[0] DSI_PLL_GO	
Check whether PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	0x1
Set the LP mode clock ratio.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	0x8
Set L3_ICLK clock to the DSI complex I/O to not gated.	DSI_CLK_CTRL[14] CIO_CLK_ICG	0x1
Enable the automatic assertion/deassertion of the DSIStopClk signal.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	0x1
Specify that the DSI functional clock is higher than 30 MHz with a synchronization rising/rising.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	0x1
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2

1. Calculate the divider value for the DSI protocol engine clock source:

$$RegM4 = FCLKIN4DDR / FDSI\_PLL\_REFCLK - 1$$

$$FCLKIN4DDR = 4 \times FCLKIN$$

$$RegM4 = 5$$

dss-E126

2. Determine LCD, PCD, and REGM3:

   Calculate the divider value for the DSS clock source: Same as Step 3.

$$RegM3 = ((BPP \times 2)/(DISPC\_LCD \times DISPC\_PCD \times NDL)) - 1$$

$$RegM3 = 15$$

dss-E127

3. Calculate N divider for PLL:

$$FCLKIN4DDR = FCLKIN \times 4$$

$$RegN = (FDSI\_PLL\_REFCLK / F\,INt) - 1$$

$$FDSI\_PLL\_REFCLK = 26\ MHz\ (system\ clock)$$

$$Fint = 2\ MHz\ (reduce\ PLL\ lock\ time)$$

$$RegN = 12$$

dss-E128

4. Calculate M divider for PLL:

$$RegM = ((RegN + 1) \times (FCLKIN4DDR / (2 \times FDSI\_PLL\_REFCLK)))$$

$$FCLKIN4DDR = 4 \times 150\ MHz$$

$$RegM = 150$$

dss-E129

12.6.8.1.2.3 Switch to DSI PLL Clock Source

Table 12-115 lists the sequence to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 12-115. Switch to DSI PLL Clock Source

Steps	Register/Bit Field/Programming	Value
Switch DISPC clock to DSI1_PLL_FCLK.	DSS_CONTROL[0] DISPC_CLK_SWITCH	0x1
Switch DSI clock to DSI2_PLL_FCLK.	DSS_CONTROL[1] DSI_CLK_SWITCH	0x1

12.6.8.1.2.4 Configure DSI Protocol Engine

12.6.8.1.2.4.1 Set Up DSI Control Registers

Table 12-116 lists the steps required to set up the DSI control registers. Table 12-117 lists the steps to set up the DSI complex I/O registers.

Table 12-116. DSI Control Registers

Steps	Register/Bit Field/Programming	Value
Enable SYNCLOST event.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on VC1.	DSI_VC1_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Enable IRQ to indicate that packet has been sent on VC0.	DSI_VC0_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Set the trigger reset mode to *immediate.*	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate the two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
Set the size of the video port data bus to 24 bits (RGB 888).	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	0x1
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as sequential scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 12-117. DSI Complex I/O Registers

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	0x2
Determine the position of data 1 lane.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	0x3
Turn on COMPLEXIO.	DSI_COMPLEXIO_CFG[28:27] PWR_CMD	0x1
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear all COMPLEXIO IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable all COMPLEXIO IRQs.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable interface.	DSI_CTRL[0] IF_EN	0x1
Disable interface.	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0.	DSI_CTRL[0] IF_EN	
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Check whether reset is complete.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	0x1

Table 12-117. DSI Complex I/O Registers (continued)

Steps	Register/Bit Field/Programming	Value
Check whether power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	0x1
Check whether reset is complete.	DSI_SYSSTATUS[0] RESETDONE	0x1

12.6.8.1.2.4.2 Configure DSI Timing and Virtual Channels

Table 12-118 lists the steps to configure DSI timing and the virtual channels.

Table 12-118. DSI Timing Registers

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x999
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x0
Disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x0
Clear turn-around timer settings.	DSI_TIMING1[30:16]	0x0000
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x0CD
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x0
Enable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x1
Determine the number of TxByteClkHS clock cycles for the HS RX timer.	DSI_TIMING2[12:0] HS_TX_TO_COUNTER	0xFD2
Disable the multiplication factor of 8 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[13] HS_TX_TO_X8	0x0
Enable the multiplication factor of 16 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[14] HS_TX_TO_X16	0x1
DDR_CLK_PRE<<8|DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
Configuration of VC1		
Enable the checksum generation for the transmit payload.	DSI_VC1_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC1_CTRL[8] ECC_TX_EN	0x1
Disable DMA request for TX FIFO.	DSI_VC1_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC1_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration of VC0		
Selects source of data and enable VP_STALL.	DSI_VC0_CTRL[1] SOURCE	0x1
Enable the checksum generation for the transmit payload.	DSI_VC0_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC0_CTRL[8] ECC_TX_EN	0x1
Enable high-speed mode to send short and long packets to the peripheral.	DSI_VC0_CTRL[9] MODE_SPEED	0x1
Disable DMA request for TX FIFO.	DSI_VC0_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC0_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration TX and RX FIFO		

Table 12-118. DSI Timing Registers (continued)

Steps	Register/Bit Field/Programming	Value
Set size of the RX FIFO allocated for VC1 to 32 x 33 bits.	DSI_RX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x1
Set size of the TX and TX FIFO allocated for VC1 to 96 x 33 bits.	DSI_TX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x3

- Freq HSBYTE_CLK:

$$FHSB = FCLKIN4DDR / 16$$
$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC\_LCD * DISPC\_PCD)$$
$$FVP = FCLKIN4DDR / (RegM3 + 1)$$

dss-E130

- Length of the line in video mode in number of byte clock cycles (PPI clk):

$$TL = FHSB / FVPP \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$
$$TL1f = (BPP / (8 \times NDL)) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)$$

dss-E131

- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC\_HSA + DISPC\_HBP + PPL + DISPC\_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$
$$HBP + HFP = (TVPP / THSB) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + (WC + 6) / NDL))$$
$$HBPplusHFP = (FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP) - (HS + WC + 6) / NDL$$
$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC\_HSA + DISPC\_HFP + PPL + DISPC\_HBP)) - ((HS + WC + 6) / NDL)$$
$$HFP = (DISPC\_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$
$$HBP = HBPplusHFP - HFP$$

dss-E132

12.6.8.1.2.5 Configure DSI_PHY Timing

Table 12-119 summarizes DSI_PHY timing. For more details on timing calculation, see Section 12.4.3.2, *Clock Requirements*.

Table 12-119. Configure DSI_PHY Timing

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 12.4.3.2, *Clock Requirements*.	DSI_PHY_CFG0[31:24] THS_PREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_CFG0[7:0] THS_EXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_CFG0[15:8] THS_TRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_CFG2[7:0] TCLK_PREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_CFG1[7:0] TCLK_ZERO	ceil(260 ns/DDR clock period)
	DSI_PHY_CFG1[15:0] TCLK_TRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_CFG1[20:16] TLPX_HALF	ceil(26.5 ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the DSI_PHY_CFG1 and DSI_PHY_CFG2 registers.

12.6.8.1.2.6 Drive Stop State

Table 12-120 lists the steps to drive the stop state.

Table 12-120. Drive Stop State

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0.	DSI_TIMING[15] FORCE_TX_STOP_MODE_IO	

12.6.8.1.3 Initialization of the External MIPI LCD Controller

Table 12-121 lists the steps to initialize the external MIPI LCD controller.

Table 12-121. Initialization of the External MIPI LCD Controller

Steps	Register/Bit Field/Programming	Value
Reset the MIPI LCD controller using GPIO87.	–	0x1
Wait until initialization of the external MIPI LCD controller is finished after power up.	–	–
Configure the external MIPI LCD controller.	–	–

12.6.8.1.4 Configure the DISPC

12.6.8.1.4.1 Reset DISPC

Table 12-122 lists the steps to reset the DISPC.

Table 12-122. Reset DISPC

Steps	Register/Bit Field/Programming	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
Wait until RESETDONE = 1.	DISPC_SYSCONFIG[0] RESETDONE	
Disable master interface power management.	DISPC_SYSCONFIG [13:12] MIDLEMODE	0x1
Disable slave interface power management.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all DISPC interrupts.	DISPC_IRQENABLE[31:0]	0x0

12.6.8.1.4.2 Configure DISPC Timing, Window, and Color

Table 12-123 lists the steps to configure the DISPC registers. Table 12-106 lists the steps to configure the color space coefficient registers.

Table 12-124 lists the steps to configure DISPC_CONTROL.

Table 12-123. Configure DISPC Registers

Steps	Register/Bit Field/Programming	Value
Configure LCD output		
Set the logic clock divisor (LCD).	DISPC_DIVISOR[23:16] LCD	0x1
Set the pixel clock divisor (PCD).	DISPC_DIVISOR[7:0] PCD	0x4

Table 12-123. Configure DISPC Registers (continued)

Steps	Register/Bit Field/Programming	Value
Set the number of lines on the LCD panel.	DISPC_SIZE_LCD[26:16] LPP	0x2A7
Set the number of PPL on the LCD panel.	DISPC_SIZE_LCD[10:0] PPL	0x1DF
Set solid background color.	DISPC_DEFAULT_COLOR0	0XFF
Configure VIDEO pipeline VID1.		
Set VID1 FIFO low threshold.	DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD	0x0C0
Set VID1 FIFO high threshold.	DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD	0xFC0
Set the X position of the VID1 window.	DISPC_VID1_POSITION[10:0] VIDPOSX	0x0
Set the Y position of the VID1 window.	DISPC_VID1_POSITION[26:16] VIDPOSY	0x0
Set the number of lines of the VID1 window.	DISPC_VID1_SIZE[26:16] VIDSIZEY	0x2A7
Set the number of pixels of the VID1 window.	DISPC_VID1_SIZE[10:0] VIDSIZEX	0x1DF
Define the base address of the VID1 frame buffer.	DISPC_VID1_BA0	0x–

Table 12-124. Configure DISPC_CONTROL

Comments	Register/Bit Field/Programming	Value
Enable pixel clock free-running.	DISPC_CONTROL[27] PCLKFREEENABLE	0x1
Disable RFBI.	DISPC_CONTROL[16] GPOUT1	0x1
	DISPC_CONTROL[15] GPOUT0	0x1
Enable the stall mode.	DISPC_CONTROL[11] STALLMODE	0x1
Select size of DATALINES.	DISPC_CONTROL[9:8] TFTDATALINES	0x3
Select active matrix display operation mode.	DISPC_CONTROL[3] STNTFT	0x1
Disable LCD output interface.	DISPC_CONTROL[0] LCDENABLE	0x0
Update the internal DISPC registers.	DISPC_CONTROL[5] GOLCD	0x1

12.6.8.1.5 Enable Command Mode Using DISPC Video Port

Table 12-125 lists the steps to enable DISPC to send frames continuously. Two bus turn-arounds (BTA) must be generated (see the MIPI DSI specification for details):

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 12-125. Enable Command Mode and Automatic TE

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue code.	DSI_CTRL[25] DCS_CMD_CODE	0x0
Enable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_CTRL[24] DCS_CMD_ENABLE	0x1
Enable VC1.	DSI_VC1_CTRL[0] VC_EN	0x1
Enable VC0.	DSI_VC0_CTRL[0] VC_EN	0x1
Enable the interface.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN = 1.	DSI_CTRL[0] IF_EN	
Send the sequence to receive theTE trigger from the peripheral. In this use case, code 0x35 + 1 parameter VC = 0, data type = 0x15, DCS write + 1 parameter.	DSI_VC1_SHORT_PACKET_HEADER[31:0] HEADER	0x0000 3515
Wait until PACKET_SENT_IRQ = 1.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	
Write 1 to clear PACKET_SENT_IRQ.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	0x1

12.6.8.1.6 Send Frame Data to LCD Panel Using Automatic TE

Table 12-126 summarizes the steps to send a frame data to the LCD panel using automatic TE.

Table 12-126. Send Frame Data to LCD Panel Using Automatic TE

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	DISPC_CONTROL[0] LCDENABLE	0x1
Specify the number of bytes to send. When DCS insertions is used, word count (WC) must include this one DCS byte.	DSI_VC0_TE[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header. Send 0x39 DCS long write/write_LUT command packet used to send larger blocks of data to a display module that implements a DCS.	DSI_VC0_LONG_PACKET_HEADER[31:0] HEADER	(WC+1) << 8 + 0x39
Enable TE control.	DSI_VC0_TE[30] TE_EN	0x1
Wait until RX FIFO is empty, RX_FIFO_NOT_EMPTY = 0.	DSI_VC1_CTRL[20] RX_FIFO_NOT_EMPTY	0x0
Wait until TX FIFO is not full. TX_FIFO_FULL = 0.	DSI_VC1_CTRL[16] TX_FIFO_FULL	0x0
Enable first BTA to give bus possession to the display module.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Enable second BTA to get the TE trigger.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Wait until transfer is complete.	DSI_VC0_TE[30] TE_EN	Read 0x0

12.7 Display Subsystem Register Manual

CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access..
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

Table 12-127 summarizes the display subsystem instance.

Table 12-127. Instance Summary

Module Name	Base Address	Size
DSI Protocol Engine	0x4804 FC00	512 bytes
DSI_PHY	0x4804 FE00	64 bytes
DSI PLL Controller	0x4804 FF00	32 bytes
Display Subsystem	0x4805 0000	512 bytes
Display Controller	0x4805 0400	1K byte
Display Controller VID1	0x4805 0400	1K byte
Display Controller VID2	0x4805 0400	1K byte
RFBI	0x4805 0800	256 bytes
Video Encoder	0x4805 0C00	256 bytes

12.7.1 Display Subsystem Register Mapping Summary

Table 12-128 through Table 12-133 summarize the display subsystem register mapping.

Table 12-128. Display Subsystem Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

- Display Subsystem Register Mapping Summary: [0]

Table 12-139. DSS_SYSCONFIG

Address Offset	0x010		
Physical address	0x4805 0010	**Instance**	DISS
Description	This register controls the various parameters of the interconnect interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																											Reserved		Reserved		SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Write 0s for future compatibility. Reads return zero.	RW	0x00000000
4:3	Reserved	Reserved. Keep at reset value.	RW	0x0
2	Reserved	Write 0s for future compatibility . Reads return zero.	RW	0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0
0	AUTOIDLE	Enable power management capability 0x0: OCP clock is free-running 0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity	RW	1

6	VENC_OUT_SEL	Video DAC1 input selection: 0x0: CVBS VENC output selected for composite video mode 0x1: Luminance VENC output selected for s-video mode	RW	0
5	DAC_POWERDN_BGZ	DAC Power-Down Control 0x0: DAC Power-Down Band Gap powered down 0x1: DAC Power-Down Band Gap powered up	RW	0
4	DAC_DEMEN	DAC dynamic element matching enable 0x0: DAC Dynamic Element Matching Disabled 0x1: DAC Dynamic Element Matching Enabled	RW	0
3	VENC_CLOCK_4X_ ENABLE	VENC clock 4x enable 0x0: Disable 0x1: Enable	RW	0
2	VENC_CLOCK_MODE	VENC clock mode See Table 12-19*Possible Digital Clock Division for the Vidoe Encoder.* 0x0: Mode 0 All three balanced clocks, derived from DSS_TV_CLK, are provided to the VENC, if the VENC_CLOCK_4X_ENABLE [3] bit is set to 1 by software. 0x1: Mode 1 The VENC_CLOCK_4X_ENABLE [3] bit is used to control clock gating.	RW	0
1	DSI_CLK_SWITCH	Selects the clock source for the DSI functional clock 0x0: DSS1_ALWON_FCLK clock is selected (from PRCM) 0x1: DSI2_PLL_FCLK clock is selected (from DSI PLL)	RW	0
0	DISPC_CLK_SWITCH	Selects the clock source for the DISPC functional clock 0x0: DSS1_ALWON_FCLK clock is selected (from PRCM) 0x1: DSI1_PLL_FCLK clock is selected (from DSI PLL)	RW	0

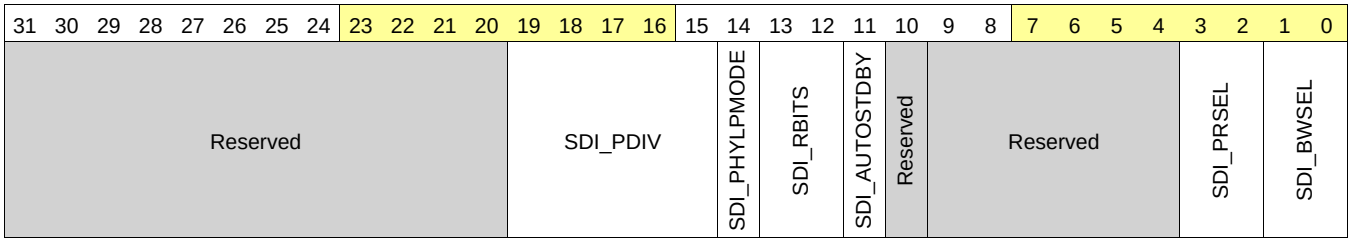
Table 12-147. DSS_SDI_CONTROL

Address Offset	0x044		
Physical address	0x4805 0044	**Instance**	DISS
Description	This register contains the display subsystem control bits.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:20	Reserved	Reserved. Write 0s for future compatibility. Read returns0.	RW	0x000
19:15	SDI_PDIV	Specifies the ratio of PLL output to pixel clock frequency	RW	0x00
14	SDI_PHYLPMODE	FlatLink3G output buffer low power option Disables the internal transmitter termination to reduce power. Requires reduced data and signal integrity verification 0x0: Standard mode 0x1: Low-power mode	RW	0
13:12	SDI_RBITS	FlatLink3G reserved bits F1 and F0	RW	0x0
11	SDI_AUTOSTDBY	FlatLink3G auto-standby 0x0: High-speed serial buffers only enabled when PLL is locked and SDI enable is active 0x1: High-speed serial buffers enabled while SDI enable is active	RW	0
10	Reserved	Must be programmed to the default value for SN65LVDS302 compatibility	RW	0
9:4	Reserved	Must be programmed to the default value	RW	0x0
3:2	SDI_PRSEL	Selection of the number of active data pairs 0x0: 1 pair: DATA0 0x1: 2 pairs: DATA0 and DATA1 0x2: 3 pairs: DATA0, DATA1, and DATA2	RW	0x0
1:0	SDI_BWSEL	Selects the color depth: must be programmed to 0x2 for FlatLink3G 0x0: Reserved 0x1: Reserved 0x2: Color depth is 24 bits.	RW	0x0

- Display Subsystem Register Mapping Summary: [0]

Table 12-155. DISPC_SYSCONFIG

Address Offset	0x010		
Physical address	0x4805 0410	**Instance**	DISC
Description	This register allows the control of various parameters of the interconnect interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																		MIDLEMODE		Reserved		CLOCKACTIVITY		Reserved			SIDLEMODE		ENWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00000
13:12	MIDLEMODE	Master interface power management, standby/waitcontrol	RW	0x0
		0x0: Force standby. MStandby is asserted only when the module is disabled.		
		0x1: No standby: MStandby is never asserted.		
		0x2: Smart Standby. MStandby is asserted based on the internal activity of the module.		
		0x3: Reserved		
11:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
9:8	CLOCKACTIVITY	Clock activity during wakeup mode period	RW	0x0
		0x0: interface and functional clocks can be switched off.		
		0x1: Functional clocks can be switched off and interface clocks are maintained during wakeup period.		
		0x2: Interface clocks can be switched off and functional clocks are maintained during wakeup period.		
		0x3: Interface and functional clocks are maintained during wakeup period.		
7:5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
4:3	SIDLEMODE	Slave interface power management, idle req/ack control	RW	0x0
		0x0: Force idle. An idle request is acknowledged unconditionally.		
		0x1: No idle. An idle request is never acknowledged.		
		0x2: Smart idle. Idle request is acknowledged based on the internal activity of the module.		
		0x3: Reserved		
2	ENWAKEUP	Wakeup feature control	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Wakeup is disabled. 0x1: Wakeup is enabled.		
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic L3 and L4 interface clock gating strategy is applied based on interface activity.	RW	1

Bits	Field Name	Description	Type	Reset
31:30	SPATIALTEMPORAL DITHERINGFRAMES	Spatial/Temporal dithering number of frames wr: VFP	RW	0x0
		0x0: Spatial only		
		0x1: Spatial and temporal over two frames		
		0x2: Spatial and temporal over four frames		

Bits	Field Name	Description	Type	Reset
		0x3: Reserved		
29	LCDENABLEPOL	LCD Enable Signal Polarity	RW	0
		0x0: Active low		
		0x1: Active high		
28	LCDENABLESIGNAL	LCD Enable Signal: LCD interface active/inactive	RW	0
		0x0: Signal disabled		
		0x1: Signal enabled		
27	PCKFREEENABLE	Pixel clock free-running enabled/disabled	RW	0
		0x0: Clock disabled		
		0x1: Clock enabled		
26:25	TDMUNUSEDBITS	State of unused bits (TDM mode only) WR: VFP	RW	0x0
		0x0: Low level (0)		
		0x1: High level (1)		
		0x2: Unchanged from previous state		
		0x3: Reserved		
24:23	TDMCYCLEFORMAT	Cycle format (TDM mode only) WR: VFP	RW	0x0
		0x0: 1 cycle for 1 pixel		
		0x1: 2 cycles for 1 pixel		
		0x2: 3 cycles for 1 pixel		
		0x3: 3 cycles for 2 pixels		
22:21	TDMPARALLELMODE	Output Interface width (TDM mode only) WR: VFP	RW	0x0
		0x0: 8-bit parallel output interface selected		
		0x1: 9-bit parallel output interface selected		
		0x2: 12-bit parallel output interface selected		
		0x3: 16-bit parallel output interface selected		
20	TDMENABLE	Enable the multiple cycle format (TDM mode used only for Active Matrix mode with the RFBI enable bit off). WR: VFP	RW	0
		0x0: TDM disabled		
		0x1: TDM enabled		
19:17	HT	Hold Time for digital output WR: EVSYNC Encoded value (from 0 to 7) holds time for digital output. The data will be held for (HT + 1) external digital clock periods.	RW	0x0
16	GPOUT1	General Purpose Output Signal	RW	0
		0x0: The GPout1 is reset.		
		0x1: The GPout1 is set.		
15	GPOUT0	General Purpose Output Signal	RW	0
		0x0: The GPout0 is reset.		
		0x1: The GPout0 is set.		
14	GPIN1	General Purpose Input Signal WR: VFP	R	0
		Read 0x0: The GPin1 has been reset.		
		Read 0x1: The GPin1 has been set.		
13	GPIN0	General Purpose Input Signal WR: VFP	R	0
		Read 0x0: The GPin0 has been reset.		

Bits	Field Name	Description	Type	Reset
		Read 0x1: The GPin0 has been set.		
12	OVERLAYOPTIMIZATION	Overlay Optimization (available when graphics format is NOT is 1-, 2, and 4-BPP) WR: VFP or EVSYNC 0x0: Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows. 0x1: Graphics data below video1 window not fetched from memory.	RW	0
11	STALLMODE	Stall mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI and DSI command modes.	RW	0
10	Reserved	Reserved for non-GP devices	RW	0
9:8	TFTDATALINES	Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0
7	STDITHERENABLE	Spatial temporal dithering enable WR: VFP 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0
6	GODIGITAL	Digital GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC.	RW	0
5	GOLCD	LCD GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.	RW	0
4	M8B	Mono 8-bit mode WR: VFP 0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode). 0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode).	RW	0

Bits	Field Name	Description	Type	Reset
3	STNTFT	LCD display type WR: VFP 0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled. 0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/Color WR: VFP 0x0: Color operation enabled (Passive Matrix mode only) 0x1: Monochrome operation enabled (Passive Matrix mode only)	RW	0
1	DIGITALENABLE	Digital enable 0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: Digital output enabled	RW	0
0	LCDENABLE	LCD enable 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

Table 12-165. DISPC_CONFIG

Address Offset	0x044		
Physical address	0x4805 0444	**Instance**	DISC
Description	This control register configures the display controller module. Shadow register, updated on VFP start period or EVSYNC		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												TVALPHABLENDERENABLE	LCDALPHABLENDERENABLE	FIFOFILLING	FIFOHANDCHECK	CPR	FIFOMERGE	TCKDIGSELECTION	TCKDIGENABLE	TCKLCDSELECTION	TCKLCDENABLE	FUNCGATED	ACBIASGATED	VSYNCGATED	HSYNCGATED	PIXELCLOCKGATED	PIXELDATAGATED	PALETTEGAMMATABLE	LOADMODE		PIXELGATED

Bits	Field Name	Description	Type	Reset
31: 20	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x00000
19	TVALPHABLENDER ENABLE	Selects the alpha blender (TV output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDER ENABLE	Selects the alpha blender (LCD output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
17	FIFOFILLING	Controls if the FIFO are refilled only when the LOW threshold is reached or if all FIFO are refilled when at least one of them reaches the LOW threshold. 0x0: Each FIFO is refilled when it reaches LOW threshold. 0x1: All FIFOs are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs should be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again).	RW	0
16	FIFOHANDCHECK	Controls the handshake between FIFO and RFBI STALL to prevent from underflow. The bit should be set to 0 when the module is not in STALL mode. 0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information to provide data to the RFBI module. 0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information to provide data to the RFBI module only when it does not generated FIFO underflow.	RW	0
15	CPR	Color phase rotation control wr: VFP 0x0: Color phase rotation disabled 0x1: Color phase rotation enabled	RW	0
14	FIFOMERGE	FIFO merge control wr: EVSYNC or VFP 0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline. 0x1: FIFO merge enabled All the FIFOS are merged into a single one to be used by the single active pipeline.	RW	0
13	TCKDIGSELECTION	Transparency color key selection (digital output) wr: EVSYNC 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0

Bits	Field Name	Description	Type	Reset
12	TCKDIGENABLE	Transparency color key enabled (digital output) wr: EVSYNC 0x0: Disable the transparency color key for digital output 0x1: Enable the transparency color key for digital output	RW	0
11	TCKLCDSELECTION	Transparency color key selection (LCD output) WR: VFP 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0
10	TCKLCDENABLE	Transparency color key enabled (LCD output) WR: VFP * 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD	RW	0
9	FUNCGATED	Functional clocks gated enabled WR: immediate 0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled WR: VFP 0x0: AcBias Gated Disabled 0x1: AcBias Gated Enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled WR: VFP 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled	RW	0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0
4	PIXELDATAGATED	Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0
3	PALETTEGAMMATABLE	Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0
2:1	LOADMODE	Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES. GfxEnable has to be set to 1). 0x2: Frame data only loaded every frame	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W).		
0	PIXELGATED	Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)	RW	0

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x0000
17	ONOFF	HSYNC/VSYNC Pixel clock Control On/Off 0x0: HSYNC and VSYNC are driven on opposite edges of pixel clock than pixel data 0x1: HSYNC and VSYNC are driven according to bit 16	RW	0
16	RF	Program HSYNC/VSYNC Rise or Fall 0x0: HSYNC and VSYNC are driven on falling edge of pixel clock (if bit 17 set to 1) 0x1: HSYNC and VSYNC are driven on the rising edge of pixel clock (if bit 17 set to 1)	RW	0
15	IEO	Invert output enable 0x0: Ac-bias is active high (active display mode) 0x1: Ac-bias is active low (active display mode)	RW	0
14	IPC	Invert pixel clock 0x0: Data is driven on the LCD data lines on the rising-edge of the pixel clock 0x1: Data is driven on the LCD data lines on the falling-edge of the pixel clock	RW	0
13	IHS	Invert HSYNC 0x0: Line clock pin is active high and inactive low 0x1: Line clock pin is active low and inactive high	RW	0
12	IVS	Invert VSYNC 0x0: Frame clock pin is active high and inactive low 0x1: Frame clock pin is active low and inactive high	RW	0

Bits	Field Name	Description	Type	Reset
11:8	ACBI	AC-bias pin transitions per interrupt Value (from 0 to 15) used to specify the number of AC Bias pin transitions	RW	0x0
7:0	ACB	AC-bias pin frequency Value (from 0 to 255) used to specify the number of line clocks to count before transitioning the ac-bias pin. This pin is used to periodically invert the polarity of the power supply to prevent DC charge build-up within the display.	RW	0x00

Table 12-195. DISPC_GFX_ATTRIBUTES

Address Offset	0x0A0		
Physical address	0x4805 04A0	**Instance**	DISC
Description	The register configures the graphics attributes. Shadow register, updated on VFP start period or EVSYNC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GFXSELFREFRESH	GFXARBITRATION	GFXROTATION		GFXFIFOPRELOAD	GFXENDIANNESS	GFXNIBBLEMODE	GFXCHANNELOUT	GFXBURSTSIZE		GFXREPLICATIONENABLE	GFXFORMAT				GFXENABLE

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000000
15	GFXSELFREFRESH	Enables the self refresh of the graphics window from its own FIFO only. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics FIFO is used. It takes effect after the frame has been loaded in the FIFO	RW	0
14	GFXARBITRATION	Determines the priority of the graphics pipeline. The graphics pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline.	RW	0
13:12	GFXROTATION	Graphics rotation flag (used only in case of RGB24 packed format) 0x0: No rotation 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees	RW	0x0
11	GFXFIFOPRELOAD	Graphics preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to high threshold value.	RW	0
10	GFXENDIANNESS	Graphics endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected.	RW	0
9	GFXNIBBLEMODE	Graphics Nibble Mode (only for 1-, 2- and 4-BPP) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0
8	GFXCHANNELOUT	Graphics Channel Out configuration wr: immediate 0x0: LCD output selected 0x1: 24-bit output selected	RW	0

Bits	Field Name	Description	Type	Reset
7:6	GFXBURSTSIZE	Graphics DMA Burst Size	RW	0x0

Table 12-215. DISPC_VIDn_ATTRIBUTES

Address Offset	0x0CC+ ((–1)* 0x90)	**Index**	n = 1 for VID1 or 2 for VID2
Physical address	0x4805 04CC+ ((–1)* 0x90)	**Instance**	DISC
Description	The register configures the attributes of video window #n such as format, resizeenable, shadow register, updated on VFP start period, or EVSYNC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								VIDSELFREFRESH	VIDARBITRATION	VIDLINEBUFFERSPLIT	VIDVERTICALTAPS	VIDDMAOPTIMIZATION	VIDFIFOPRELOAD	VIDROWREPEATENABLE	VIDENDIANNESS	VIDCHANNELOUT	VIDBURSTSIZE		VIDROTATION		VIDFULLRANGE	VIDREPLICATIONENABLE	VIDCOLORCONVENABLE	VIDVRESIZECONF	VIDHRESIZECONF	VIDRESIZEENABLE	VIDFORMAT					VIDENABLE

Bits	Field Name	Description	Type	Reset
31: 25	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
24	VIDSELFREFRESH	Enables the self refresh of the video window from its own FIFO only.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: The video pipeline accesses the interconnect to fetch data from the system memory 0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO		
23	VIDARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	VIDLINEBUFFER SPLIT	Video vertical line buffer split 0x0: Vertical line buffers are not split. 0x1: Vertical line buffers are split into two.	RW	0
21	VIDVERTICALTAPS	Video vertical resize tap number 0x0: Three taps are used for the vertical filtering logic. The other two taps are not used. 0x1: Five taps are used for the vertical filtering logic.	RW	0
20	VIDDMAOPTI MIZATION	Video optimization in case of 0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory).	RW	0
19	VIDFIFOPRELOAD	Video preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to the high threshold value.	RW	0
18	VIDROWREPEAT ENABLE	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0x0: Row of VIDn won't be read twice. 0x1: The Row data are fetched twice to extract both the Y components	RW	0
17	VIDENDIANNESS	Video Endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected.	RW	0
16	VIDCHANNELOUT	Video Channel Out configuration wr: Immediate 0x0: LCD output selected 0x1: 24 bit output selected	RW	0
15:14	VIDBURSTSIZE	Video DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved	RW	0x0
13:12	VIDROTATION	Video Rotation Flag 0x0: No rotation or VidFormat is RGB 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees	RW	0x0

Bits	Field Name	Description	Type	Reset
		0x3: Rotation by 270 degrees		
11	VIDFULLRANGE	VidFullRange	RW	0
		0x0: Limited range selected: 16 subtracted from Y before color space conversion		
		0x1: Full range selected: Y is not modified before the color space conversion		
10	VIDREPLICATION ENABLE	VidReplicationEnable	RW	0
		0x0: Disable Video replication logic		
		0x1: Enable Video replication logic		
9	VIDCOLORCONV ENABLE	VidColorConvEnable	RW	0
		0x0: Disable Color Space Conversion CbYCr to RGB		
		0x1: Enable Color Space Conversion CbYCr to RGB		
8	VIDVRESIZECONF	Video Vertical Resize Configuration	RW	0
		0x0: Up-sampling selected		
		0x1: Down-sampling selected		
7	VIDHRESIZECONF	Video Horizontal Resize Configuration	RW	0
		0x0: Up-sampling selected		
		0x1: Down-sampling selected		
6:5	VIDRESIZEENABLE	Video Resize Enable	RW	0x0
		0x0: Disable the resize processing		
		0x1: Enable the horizontal resize processing		
		0x2: Enable the vertical resize processing		
		0x3: Enable both horizontal and vertical resize processing		
4:1	VIDFORMAT (Video 1 channel)	Video1 channel Format; Other enums: Reserved (all other values between 0x0 and 0x3, 0x5, 0x7, and between 0xC and 0xF)	RW	0x0
		0x4: RGB12 (16-bit container)		
		0x6: RGB 16		
		0x8: RGB 24 (unpacked in 32-bit container)		
		0x9: RGB 24 (packed in24-bit container)		
		0xA: YUV2 4:2:2 co-sited		
		0xB: UYVY 4:2:2 co-sited

Table 12-265. RFBI_CONTROL

Address Offset	0x40		
Physical address	0x4805 0840	**Instance**	RFBI
Description	The control register allows configuration of the RFBI module.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							SMART_DMA_REQ	DISABLE_DMA_REQ	HIGHTHRESHOLD		ITE	CONFIGSELECT		BYPASSMODE	ENABLE

Bits	Field Name	Description	Type	Reset
31: 9	Reserved	Write 0s for future compatibility Read returns 0	RW	0x0000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if MIdlereq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and MIdlereq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.	RW	0x0

Bits	Field Name	Description	Type	Reset
7	DISABLE_DMA_REQ	Disable DMA request 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests.	RW	0x0
6:5	HIGHTHRESHOLD	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide	RW	0x0
4	ITE	Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.	RW	0
3:2	CONFIGSELECT	Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used)	RW	0x0
1	BYPASSMODE	Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected	RW	1
0	ENABLE	Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module	RW	0

Table 12-267. RFBI_PIXEL_CNT

Address Offset	0x44		
Physical address	0x4805 0844	**Instance**	RFBI
Description	The control register configures the RFBI pixel count value.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PIXELCNT																															

Bits	Field Name	Description	Type	Reset
31:0	PIXELCNT	Pixel counter value The S/W indicates the number of pixels to transfer to the LCD panel frame buffer. The value is set when the module is disabled. During the transfer the HW decrements the register when a pixel has been sent to the RFB.	RW	0x00000000

Table 12-333. VENC_S_CARR

Address Offset	0x50		
Physical address	0x4805 0C50	**Instance**	VENC
Description	Color Subcarrier Frequency Registers.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FSC																															

Bits	Field Name	Description	Type	Reset
31:0	FSC	These four bytes' data program the color subcarrier frequency and are determined by the following formula. S_CARR = ROUND((Fsc/Fclkenc) * 2^{32}) Where: Fsc = Frequency of the subcarrier Fclkenc = Frequency of the internal video encoding clock = 2*LLEN *Fh LLEN = Number of pixels in a scan line. For LLEN setting, please refer to the description of VENC_LLEN register (offset 0x1C). Fh = Line frequency For typical setting of the FSC field, refer to Table 12-40.	RW	0x21F07C1F

Table 12-337. VENC_LN_SEL

Address Offset	0x58		
Physical address	0x4805 0C58	**Instance**	VENC
Description	VENC_LN_SEL		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								LN21_RUNIN								Reserved								SLINE							

Bits	Field Name	Description	Type	Reset
31:26	Reserved	Reserved. Read returns 0s.	RW	0x00
25:16	LN21_RUNIN	The two bytes of the closed caption run in code position from the HSYNC.	RW	0x10B
15:5	Reserved	Reserved. Read returns 0s.	RW	0x000
4:0	SLINE	Selects the line where closed caption or extended service data are encoded. The value of the SLINE[4:0] bit field depends on the video standard: PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value 0x15 – 1 = 0x14. The default value is 0x15 + 1 = 0x16 (line 22). NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value 0x15 – 4 = 0x11. The default value is 0x15 + 4 = 0x19 (line 25).	RW	0x15

Table 12-339. VENC_L21_WC_CTL

Address Offset	0x5C		
Physical address	0x4805 0C5C	**Instance**	VENC
Description	VENC L21 & WC_CTL registers		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																INV	EVEN_ODD_EN		LINE					Reserved							L21EN

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Reserved. Read returns 0s.	RW	0x0000
15	INV	WSS inverter	RW	0
		0x0: No effect		
		0x1: Invert WSS data		
14:13	EVEN_ODD_EN	This bit controls the WSS encoding.	RW	0x0
		0x0: WSS encoding OFF		
		0x1: Enables encoding in 1st field (odd field)		
		0x2: Enables encoding in 2nd field (even field)		
		0x3: Enables encoding in both fields		
12:8	LINE	Selects the line where WSS data are encoded. The LINE[12:8] bit field value depends on the video standard: PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line 0x16 + 1 = 0x17 (23rd line). The default value is 0x14 + 1 = 0x15 (line 21). NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line 0x10 + 4 = 0x14 (20th line). The default value is 0x14 + 4 = 0x18 (line 24).	RW	0x14
7:2	Reserved	Reserved. Read returns 0s.	RW	0x00
1:0	L21EN	Those bits controls the Line21 closed caption encoding according to the mode.	RW	0x0
		0x0: Line21 encoding OFF		
		0x1: Enables encoding in 1st field (odd field)		
		0x2: Enables encoding in 2d field (even field)		
		0x3: Enables encoding in both fields

Table 12-379. VENC_OUTPUT_CONTROL

Address Offset	0x0000 00C4		
Physical Address	0x4805 0CC4	**Instance**	VENC
Description	Output channel control register Also contains some test control features		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LUMA_TEST								RESERVED								CHROMA_SOURCE	COMPOSITE_SOURCE	LUMA_SOURCE	TEST_MODE	VIDEO_INVERT	CHROMA_ENABLE	COMPOSITE_ENABLE	LUMA_ENABLE

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved. Read returns 0s.	RW	0x00
25:16	LUMA_TEST	In test mode, DAC 1 input value (if s-video video mode is selected)	RW	0x000
15:8	RESERVED	Reserved. Read returns 0s.	RW	0x00
7	CHROMA_SOURCE	Source of chroma video data in test mode 0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16] 0x1: Chroma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
6	COMPOSITE_ SOURCE	Source of composite video data in test mode 0x0: Composite test data comes from internal register OUTPUT_TEST[9:0] 0x1: Composite test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
5	LUMA_SOURCE	Source of luminance video data in test mode 0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16] 0x1: Luma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
4	TEST_MODE	This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits 0x0: Video outputs are in normal operation 0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port.	RW	0x0
3	VIDEO_INVERT	Controls the video output polarity. This may be used to correct for inversion in an external video amplifier. 0x0: Video outputs are inverted 0x1: Video outputs are normal polarity	RW	0x1
2	CHROMA_ENABLE	Enable the Chrominance output channel 0x0: Chroma output is disabled 0x1: Chroma output is enabled	RW	0x0
1	COMPOSITE_ ENABLE	Enable the Composite output channel 0x0: Composite output is disabled 0x1: Composite output is enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	LUMA_ENABLE	Enable the Luminance output channel 0x0: Luma output is disabled 0x1: Luma output is enabled	RW	0x0

Table 12-385. DSI_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4804 FC10	**Instance**	DSI_PROTOCOL_ENGINE
Description	SYSTEM CONFIGURATION REGISTER This register is the system configuration register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		RESERVED				CLOCKACTIVITY		RESERVED			SIDLEMODE		ENWAKEUP	SOFT_RESET	AUTO_IDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
13:10	RESERVED	Write 0s for future compatibility.	RW	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: Interface and Functional clocks can be switched off 0x1: Functional clocks can be switched off and Interface clocks are maintained during wake up period 0x2: Interface clocks can be switched off and Functional clocks are maintained during wake up period 0x3: Interface and Functional clocks are maintained during wake up period	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved	RW	0x2
2	ENWAKEUP	Wake-up mode enable bit 0x0: Wakeup is disabled. 0x1: Wakeup is enabled,	RW	0x0

Bits	Field Name	Description	Type	Reset
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied based on the module interface activity.	RW	0x1

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
20	TA_TO_IRQ	Turn-around Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
19	LDO_POWER_GOOD_IRQ	Transition of the status signal LDOPWRGOOD from the DSI_PHY indicating a state change for the supply VDDALDODSIPLL from up to down or down to up. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
18	SYNC_LOST_IRQ	Synchronization with Video port is lost (Video mode only) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
17	ACK_TRIGGER_IRQ	Acknowledge Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
16	TE_TRIGGER_IRQ	Tearing Effect Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
15	LP_RX_TO_IRQ	Interrupt for Low Power Rx Time out 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
14	HS_TX_TO_IRQ	Interrupt for high-speed Tx Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:11	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
10	COMPLEXIO_ ERR_IRQ	Error signaling from complex I/O: status of the complex I/O errors received from the complex I/O(events are defined in DSI_COMPLEXIO_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
9	PLL_RECAL_IRQ	PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
8	PLL_UNLOCK_IRQ	PLL un-lock event (deassertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
7	PLL_LOCK_IRQ	PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
5	RESYNCHRONIZATION_ IRQ	Video mode resynchronization Indicates that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI protocol engine may have to be modified to avoid the resynchronization to occur. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
4	WAKEUP_IRQ	Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
3	VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: Status of DSI Virtual Channel3 errors received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
2	VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: Status of DSI Virtual Channel2 errors received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
1	VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: Status of DSI Virtual Channel1 errors received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
0	VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: Status of the DSI Virtual Channel0 errors received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0

13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:11	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
9	PLL_RECAL_IRQ_EN	PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
8	PLL_UNLOCK_IRQ_EN	PLL un-lock event (deassertion of lock signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
7	PLL_LOCK_IRQ_EN	PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
6	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
5	RESYNCHRONIZATION_IRQ_EN	Resynchronization 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
4	WAKEUP_IRQ_EN	Wakeup 0x0: Event is masked 0x1: Event generates an interrupt when it occurs	RW	0x0
3:0	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Table 12-393. DSI_CTRL

Address Offset	0x0000 0040		
Physical Address	0x4804 FC40	**Instance**	DSI_PROTOCOL_ENGINE
Description	GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register should not be modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED					RGB565_ORDER	DCS_CMD_CODE	DCS_CMD_ENABLE	HSA_BLANKING_MODE	HBP_BLANKING_MODE	HFP_BLANKING_MODE	BLANKING_MODE	EOT_ENABLE	VP_HSYNC_END	VP_HSYNC_START	VP_VSYNC_END	VP_VSYNC_START	TRIGGER_RESET_MODE	LINE_BUFFER		VP_VSYNC_POL	VP_HSYNC_POL	VP_DE_POL	VP_CLK_POL	VP_DATA_BUS_WIDTH		TRIGGER_RESET	VP_CLK_RATIO	TX_FIFO_ARBITRATION	ECC_RX_EN	CS_RX_EN	IF_EN

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
26	RGB565_ORDER	Byte order for RBG565 command mode from video port 0x0: 0x1: Byte order as for video mode	RW	0
25	DCS_CMD_CODE	DCS command code value to insert between header and video port data when enabled by DCS_CMD_ENABLE 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted.	RW	0
24	DCS_CMD_ENABLE	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is not inserted when command mode traffic is coming from the Video Port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0x0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0x0
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0x0
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) regardless of the packets present in the TX FIFO ready to be sent	RW	0x0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS to LP transitions	RW	0
18	VP_HSYNC_END	HSYNC end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0x0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0x0

Bits	Field Name	Description	Type	Reset
16	VP_VSYNC_END	VSYNC end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0x0
15	VP_VSYNC_START	VSYNC start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	RW	0x0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is VC using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0x0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0x0
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0x0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0x0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	0x1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.	RW	0x0

Bits	Field Name	Description	Type	Reset
4	VP_CLK_RATIO	This bit indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0x0
3	TX_FIFO_ ARBITRATION	Defines the arbitration scheme for granting the VC pending ready requests in the TX FIFO 0x0: Round-Robin Scheme is used 0x1: Sequential Scheme is used	RW	0x0
2	ECC_RX_EN	Enables the ECC check for the received header (short and long packets for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0
0	IF_EN	Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register). It is not possible to change the bit fields in the DSI_CTRL register, except IF_EN when it is enabled. All the other registers can be changed except the ones that require DSI_VCn_CTRL[0] VC_EN to be equal to 0 to be modified. 0x0: The interface is disabled. If one of the VC uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other VCs in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested). 0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).	RW	0x0

Table 12-395. DSI_COMPLEXIO_CFG1

Address Offset	0x0000 0048		
Physical Address	0x4804 FC48	**Instance**	DSI_PROTOCOL_ENGINE
Description	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHADOWING	GOBIT	RESET_DONE	PWR_CMD		PWR_STATUS		RESERVED			LDO_POWER_GOOD_STATE	USE_LDO_EXTERNAL	RESERVED		RESERVED		RESERVED		RESERVED		DATA2_POL		DATA2_POSITION		DATA1_POL		DATA1_POSITION		CLOCK_POL		CLOCK_POSITION	

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration. 0x0: Disabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done only when the GO bit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active.	RW	0x0

Bits	Field Name	Description	Type	Reset
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case users decide to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the GObit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit must be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using TxByteClkHS from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ultralow-power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in ultralow-power state	R	0x0
24:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
21	LDO_POWER_GOOD_STATE	Indicates the state of the signal LDOPWRGOOD. VDDALDODSIPLL: 1.2-V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSI_PHY. 0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up	R	0x0
20	USE_LDO_EXTERNAL	Select the external LDO for the DSI_PHY. 0x0: DSI_PHY internal LDO is used. 0x1: External LDO is used. DSI_PHY LDO is tri-stated.	RW	0x0
19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
14:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1 (line 1). 0x2: Data lane 2 is at the position 2 (line 2). 0x3: Data lane 2 is at the position 3 (line 3). Other values: reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
7	DATA1_POL	+/- differential pin order of DATA lane 1 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. 0x1: Data lane 1 is at the position 1 (line 1). 0x2: Data lane 1 is at the position 2 (line 2). 0x3: Data lane 1 is at the position 3 (line 3). Other values: reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1 (line 1). 0x2: Clock lane is at the position 2 (line 2). 0x3: Clock lane is at the position 3 (line 3). Other values: reserved	RW	0x0

Table 12-401. DSI_CLK_CTRL

Address Offset	0x0000 0054		
Physical Address	0x4804 FC54	**Instance**	DSI_PROTOCOL_ENGINE
Description	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL_PWR_CMD		PLL_PWR_STATUS		RESERVED						LP_RX_SYNCHRO_ENABLE	LP_CLK_ENABLE	HS_MANUAL_STOP_CTRL	HS_AUTO_STOP_ENABLE	LP_CLK_NULL_PACKET_SIZE		LP_CLK_NULL_PACKET_ENABLE	CIO_CLK_ICG	DDR_CLK_ALWAYS_ON	LP_CLK_DIVISOR										

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	Command for power control of the DSI PLL Control module 0x0: Command to change to OFF state 0x1: Command to change to ON state for PLL only (HSDIVISER is OFF) 0x2: Command to change to ON state for both PLL and HSDIVISER 0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	RW	0x0
29:28	PLL_PWR_STATUS	Status of the power control of the DSI PLL Control module 0x0: DSI PLL Control module in OFF state 0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF) 0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER 0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	R	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
21	LP_RX_SYNCHRO_ ENABLE	Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.	RW	0x0

Bits	Field Name	Description	Type	Reset
20	LP_CLK_ENABLE	Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] bit field is not used and does not have to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] bit field is used and must be programmed.	RW	0x0
19	HS_MANUAL_STOP_CTRL	In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit field allows manual control of the assertion/deassertion of the signal DSIStopClk by users. 0x0: DSIStopClk deassertion unconditionally. 0x1: DSIStopClk assertion unconditionally.	RW	0x0
18	HS_AUTO_STOP_ENABLE	Enables the automatic assertion/deassertion of DSIStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled.	RW	0x0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0x0
14	CIO_CLK_ICG	Controls the signal for gating the L3_ICLK clock provided to the complex I/O 0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated. 0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated.	RW	0x0
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LP mode).	RW	0x0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency must be in the range between 20 MHz and 32 kHz.	RW	0x0001

Table 12-403. DSI_TIMING1

Address Offset	0x0000 0058		
Physical Address	0x4804 FC58	**Instance**	DSI_PROTOCOL_ENGINE
Description	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL.IF_EN is set to 1. It is used to indicate the number of DSI_FCLK clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER													FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO												

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	TA_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	0x1
29	TA_TO_X8	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.	RW	0x1FFF

Bits	Field Name	Description	Type	Reset
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal 0x0: Deassertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode	RW	0x0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 16x	RW	0x1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 4x	RW	0x1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

Table 12-405. DSI_TIMING2

Address Offset	0x0000 005C		
Physical Address	0x4804 FC5C	**Instance**	DSI_PROTOCOL_ENGINE
Description	TIMING2 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL.IF_EN is set to 1. It is used to indicate the number of TxByteClkHS clock cycles for the timers HS_TX_TIMER and LP_RX_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_TX_TO	HS_TX_TO_X16	HS_TX_TO_X8	HS_TX_TO_COUNTER													LP_RX_TO	LP_RX_TO_X16	LP_RX_TO_X4	LP_RX_TO_COUNTER												

Bits	Field Name	Description	Type	Reset
31	HS_TX_TO	Enables the HS TX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	HS_TX_TO_X16	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit field 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x	RW	0x1
29	HS_TX_TO_X8	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	HS_TX_TO_ COUNTER	HS_TX_TIMER counter. It indicates the number of TxByteClkHS function clock cycles for the HS TX timer. The value is from 0 to 8191.	RW	0x1FFF
15	LP_RX_TO	Enables the LP RX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
14	LP_RX_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x	RW	0x1
13	LP_RX_TO_X4	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x	RW	0x1
12:0	LP_RX_TO_ COUNTER	LP_RX_TIMER counter. It indicates the number of DSI_FCLK clock cycles for the LP RX timer. The value is from 0 to 8191.	RW	0x1FFF

Address Offset	0x0000 0064		
Physical Address	0x4804 FC64	**Instance**	DSI_PROTOCOL_ENGINE
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				WINDOW_SYNC				VSA								VFP								VBP							

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:24	WINDOW_SYNC	Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronization on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15.	RW	0x0
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

Table 12-413. DSI_CLK_TIMING

Address Offset	0x0000 006C		
Physical Address	0x4804 FC6C	**Instance**	DSI_PROTOCOL_ENGINE
Description	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register should not be modified while DSI_CTRL.IF_EN is set to 1.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DDR_CLK_PRE								DDR_CLK_POST							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15:8	DDR_CLK_PRE	Indicates the number of TxByteClkHS cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.	RW	0x01
7:0	DDR_CLK_POST	Indicates the number of TxByteClkHS cycles after the deassertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.	RW	0x01

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
17	LP_BUSY	Indicates when there are still pending operations for VCs configured for LP mode. Forced to 1 when at least one VC is enabled and configured for LP mode. Read 0x0: LP logic is idle Read 0x1: LP logic is active	R	0x0
16	HS_BUSY	Indicates when there are still pending operations for VCs configured for HS mode. Forced to 1 when at least one VC is enabled and configured for HS mode Read 0x0: HS logic is idle Read 0x1: HS logic is active	R	0x0
15:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
8	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
7	LANE3_ULPS_SIG2	Enables the ULPS for the lane #3. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #3 is a data lane. The state of the signal TxUlpsClk is change if lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: Active state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
6	LANE2_ULPS_SIG2	Enables the ULPS for the lane #2. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #2 is a data lane. The state of the signal TxUlpsClk is change if lane #2 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
5	LANE1_ULPS_SIG2	Enables the ULPS for the lane #1. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is change if lane #1 is a data lane. The state of the signal TxUlpsClk is change if lane #1 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
4	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
3	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
2	LANE3_ULPS_SIG1	Enables the ULPS for the lane #3. The HW should change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0

Bits	Field Name	Description	Type	Reset
1	LANE2_ULPS_SIG1	Enables the ULPS for the lane #2. The HW must change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0
0	LANE1_ULPS_SIG1	Enables the ULPS for the lane #1. The HW must change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if lane #3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective WRITE: Request to change to inactive state 0x1: READ: ACTIVE state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0x0

Table 12-431. DSI_VM_TIMING7

Address Offset	0x0000 0090		
Physical Address	0x4804 FC90	**Instance**	DSI_PROTOCOL_ENGINE
Description	Defines the maximum number of bytes of Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENTER_HS_MODE_LATENCY																EXIT_HS_MODE_LATENCY															

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_ LATENCY	Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000

Bits	Field Name	Description	Type	Reset
15:0	EXIT_HS_MODE_ LATENCY	Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TxByteClkHS clock cycles from deassertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29:27	DMA_RX_REQ_NB	Selection of the use of the DMA request (associated to the RX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
26:24	DMA_RX_THRESHOLD	Defines the threshold value for the DMA request (associated to the RX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
23:21	DMA_TX_REQ_NB	Selection of the use of the DMA request (associated to the TX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
20	RX_FIFO_NOT_EMPTY	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The RX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full	R	0x0

Bits	Field Name	Description	Type	Reset
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0x0: No pending operations for this VC 0x1: Pending operations for this VC	R	0x0
14	PP_BUSY	Line buffer busy status. 0x0: Software is permitted to write a new header for VP command mode traffic. 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0
13:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	MODE_SPEED	Selection of the mode. This bit is ignored by hardware when video mode is selected. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0x0
8	ECC_TX_EN	Enables the ECC generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0x0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW.	RW	0x0
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode allows users to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, must not be used). 0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.	RW	0x0
5	TX_FIFO_NOT_EMPTY	FIFO status 0x0: The TX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
4	MODE	Selection of the mode 0x0: Command mode. 0x1: Video mode.	RW	0x0
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
1	SOURCE	Selection of the source between L4 interconnect slave port and video port. This bit is ignored by hardware when video mode is selected. 0x0: All the data are provided by the L4 interconnect slave port. Any transfer on the video port is ignored for this VC. 0x1: If MODE=VIDEO_MODE. any data received on the video port (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END,) are sent on the VC (only one VC can be associated with the video port, the software must ensure that no more than one VC is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the L4 interconnect slave port.	RW	0x0
0	VC_EN	Enables the VC. 0x0: Disabled. The VC must be disabled for any register change in the DSI_VCn_XXX registers the corresponding VC ID. 0x1: Enabled. No change is allowed to the VC registers (except for setting the bit fields/registers: DSI_VCn_CTRL[6] BTA_EN, DSI_VCn_TE[15:0] TE_SIZE, DSI_VCn_TE[31] TE_START, DSI_VCn_LONG_XXX, DSI_VCn_SHORT_XXX, DSI_VCn_IRQXXX registers).	RW	0x0

Table 12-437. DSI_VCn_TE

Address Offset	0x0000 0104+ (n* 0x20)	**Index**	n = 0 to 3
Physical Address	0x4804 FD04+ (n* 0x20)	**Instance**	DSI_PROTOCOL_ENGINE
Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TE_START	TE_EN	RESERVED						TE_SIZE																							

Bits	Field Name	Description	Type	Reset
31	TE_START	Manual control of the start of the transfer. Users can use the TE interrupt to determine that the TE trigger has been received before setting the TE_START bit field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used to cancel the transfer if not already started. The FIFO must be flushed by software to ensure it contains no remaining data. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer completes. It is reset by hardware when the transfer completes.	RW	0
30	TE_EN	Tearing effect control 0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The interruption is used to know when the TE trigger is received. The hardware resets the bit field when the transfer completes(TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event.	RW	0
29:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
23:0	TE_SIZE	Defines the number of bytes (payload data excluding the check-sum) to be sent. Users must perform the write into the DSI_VCn_LONG_PACKET_HEADER register before sending data from the DSI_VCn_LONG_PACKET_PAYLOAD register. The register value is decremented for every byte of the DSI link that is sent. At the end of the transfer (TE_SIZE = 0), the TE_EN bit field is reset by hardware. The DMA_request is asserted when the trigger is received in order to receive data in the TX FIFO. It must not be used until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

Physical Address	0x4804 FD0C+ (n* 0x20)	**Instance**	DSI_PROTOCOL_ENGINE
Description	LONG PACKET PAYLOAD INFORMATION–virtual channel. This register sets the payload information (excluding Check-sum). Hardware must capture the word count in the packet header (in DSI_VCn_LONG_PACKET_HEADER register) to determine the last valid data (the VC ID can be different from VC). Byte1 is bit[7:0]; Byte2 is bit[15:8]; Byte3 is bit[23:16]; Byte4 is bit[31:24]; and Byten is sent before Byten+1 (least-significant byte first and least significant bit first).

Display Subsystem Register Manual • Display Subsystem Register Mapping Summary: [22]

Timers

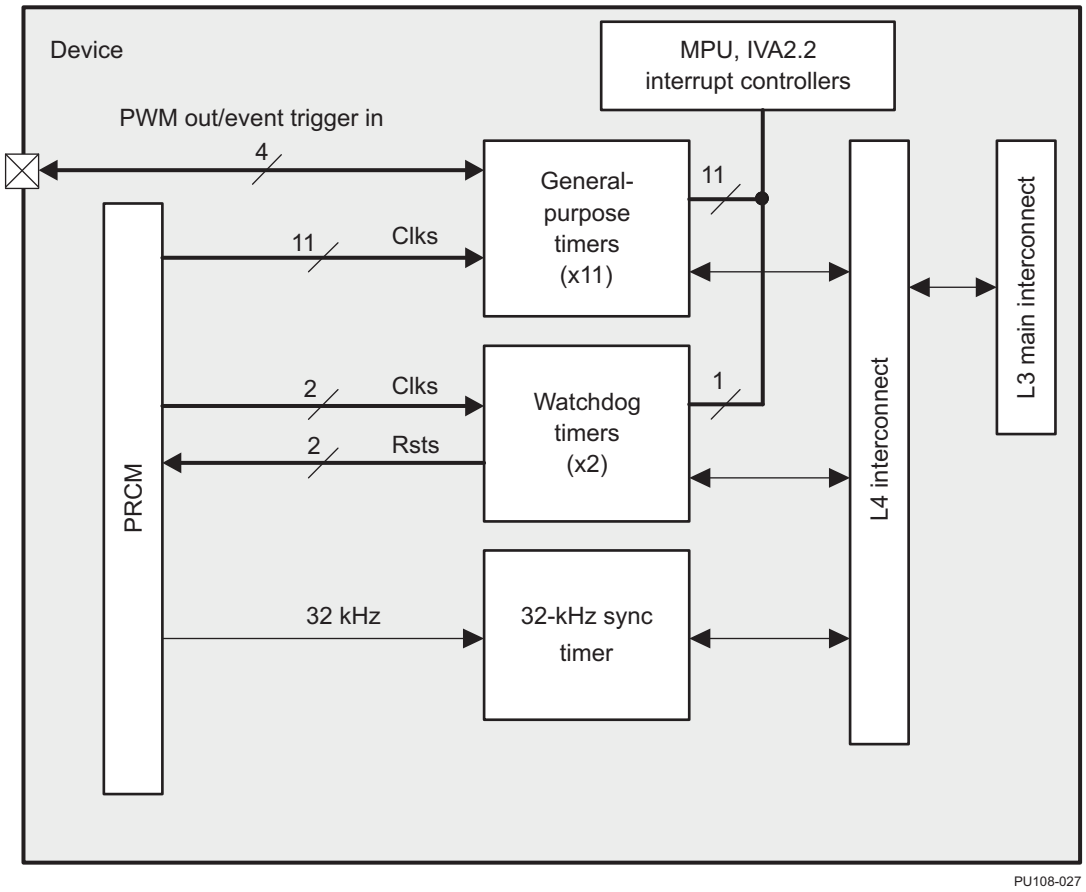
This chapter describes the timer modules.

Topic **Page**

13.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose timers (GP timers), 2 watchdog timers (WDTs), a 32-kHz synchronized timer. Figure 13-1 shows the counters in the device in a high-level block diagram.

Figure 13-1. Timers



The 2 WDTs are clocked with 32-kHz clocks. The 32-kHz synchronized timer, which is reset only at power up, provides the operating system with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

13.2 General-Purpose Timers

13.2.1 GP Timers Overview

The device has 11 GP timers: GPTIMER1 through GPTIMER11.

Each timer can be clocked from either the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of the clock source is made at the power, reset, clock management (PRCM) module level. For more information, see Section 13.2.3.1, *Clocking, Reset, and Power-Management Scheme*.

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA2.2 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). Figure 13-2 shows an overview of the GP timers.

Figure 13-2. GP Timers Overview

13.2.1.1 GP Timers Features

The following are the main features of the GP timers controllers:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Software-selectable nonposted or posted write/read internal resynchronization modes
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n with n = [0:8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general-purpose using GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768 Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

13.2.2 GP Timers Environment

13.2.2.1 GP Timers External System Interface

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only GPTIMER8 through GPTIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Figure 13-3 shows the external system interface for the GP timers, and Table 13-1 describes the GP timer inputs and outputs.

NOTE: Software must ensure that MUX mode is configured to select the gpt_x_pwm_evt (where x = 8 to 11) signal on only one pad. Other pad(s) on which the same signal is multiplexed must be configured in safe mode or non-gptimer mode to avoid two different pads driving the same signal

For more information about the gpt_8_pwm_evt through gpt11_pwm_evt I/O pad configuration, see Chapter 6, *System Control Module*.

Figure 13-3. GP Timers External System Interface

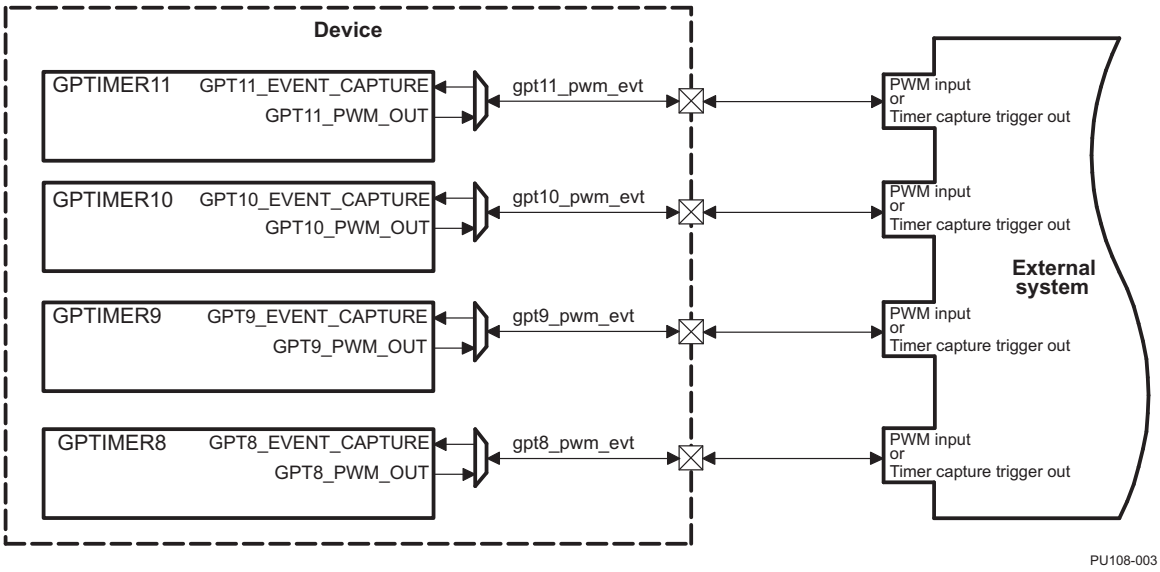


Table 13-1. Input/Output Description

Pin Name	Type [1]	Reset Value	Signal Name	Description
gpt8_pwm_evt	I/O	0	GPT8_EVENT_CAPTURE GPT8_PWM_OUT	GPTIMER8 trigger input/ PWM output
gpt9_pwm_evt	I/O	0	GPT9_EVENT_CAPTURE GPT9_PWM_OUT	GPTIMER9 trigger input/ PWM output
gpt10_pwm_evt	I/O	0	GPT10_EVENT_CAPTURE GPT10_PWM_OUT	GPTIMER10 trigger input/ PWM output
gpt11_pwm_evt	I/O	0	GPT11_EVENT_CAPTURE GPT11_PWM_OUT	GPTIMER11 trigger input/ PWM output

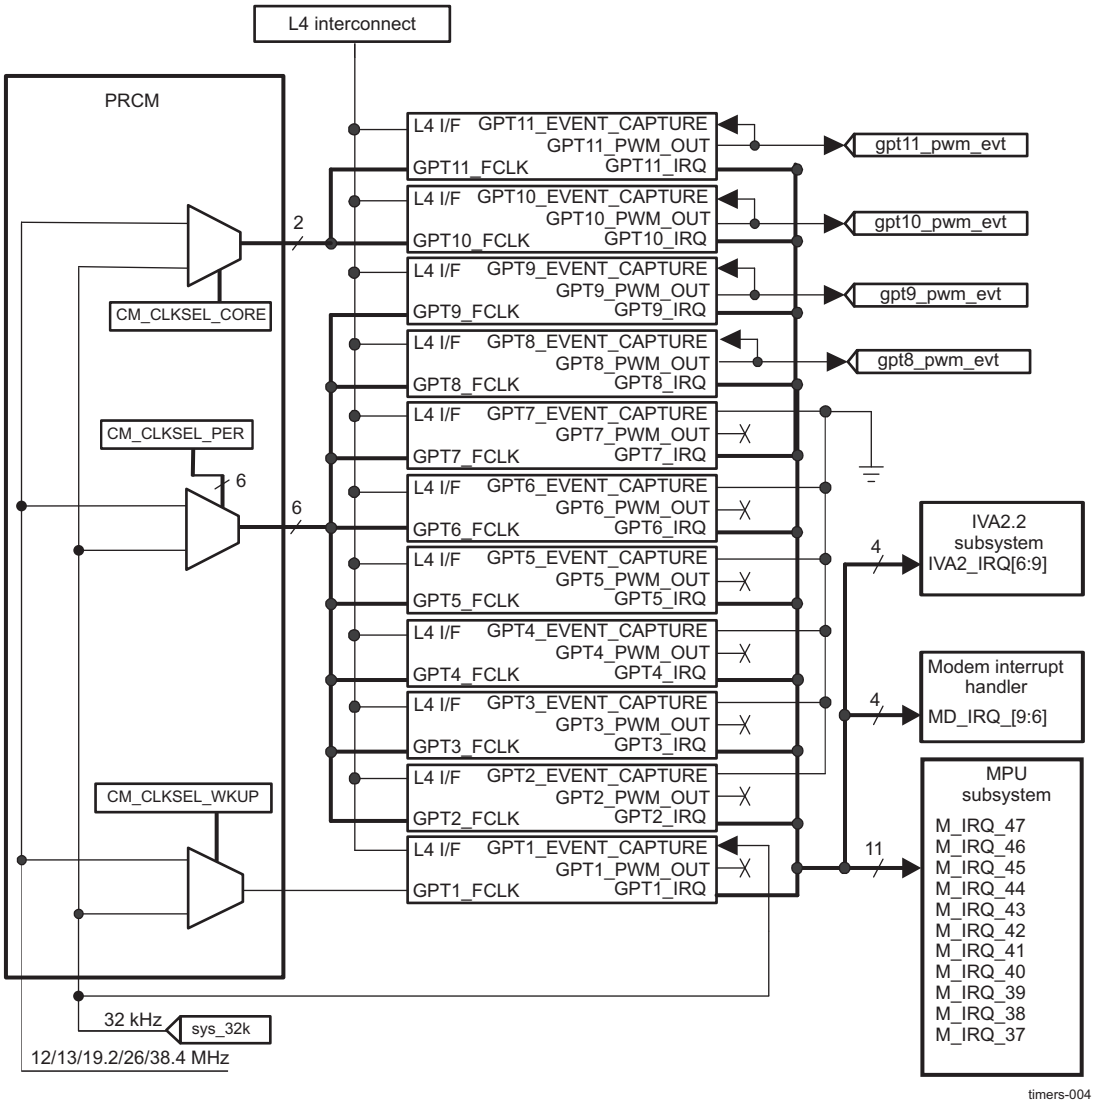
(1) When configured for that function; I = input, O = output

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

13.2.3 GP Timers Integration

Figure 13-4 shows the GP timer integration in the device.

Figure 13-4. GP Timer Integration



13.2.3.1 Clocking, Reset, and Power-Management Scheme

13.2.3.1.1 Clock Management

There are two clock domains in the GP timers:

- Functional clock domain: GPTi_FCLK is the GP timer functional clock. It is used to clock the GP timer internal logic.
- Interface clock domain: GPTi_ICLK is the GP timer interface clock. It is used to synchronize the GP timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to GPTi_ICLK.

Table 13-2 lists the source clocks for each GP timer in the device. For more information on clock control and domains, see , *Power, Reset, and Clock Management*.

Table 13-2. Clock, Power, and Reset Domains for GP Timers

Timer	Interface Clock	Functional Clock	Power Domain
GPTIMER1	WKUP_L4_ICLK	GPT1_FCLK	WKUP
GPTIMER2 through GPTIMER9	PER_L4_ICLK	GPTx_ALWON_FCLK (x = 2 through 9)	PER
GPTIMER10 and 11	CORE_L4_ICLK	GPTx_FCLK (x = 10 or 11)	CORE

GP timers can be selected as the source of GPTi_FCLK (32-kHz clock or 12, 13, 16.8, 19.2, 26, or 38.4 MHz) at the PRCM level in the corresponding registers. For more information, see , *Power, Reset, and Clock Management*. Table 13-3 lists the GP timer PRCM clock selection bits.

Table 13-3. GP Timer PRCM Clock Selection Bits

Name	Associated PRCM Clock Output	Selection Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_CLKSEL_WKUP[0] CLKSEL_GPT1
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_CLKSEL_PER [0:7] CLKSEL_GPT[2:9]
GPT10_FCLK	GPT10_FCLK	PRCM.CM_CLKSEL_CORE [6] CLKSEL_GPT10
GPT11_FCLK	GPT11_FCLK	PRCM.CM_CLKSEL_CORE [7] CLKSEL_GPT11

From a global system power-management perspective, when one or both of the GP timer clocks is no longer required, the GP timers can be deactivated at the PRCM level in the corresponding registers. Table 13-4 lists the GP timer PRCM clock control bits.

Table 13-4. GP Timer PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
GPT1_FCLK	GPT1_FCLK	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1 bit	N/A
GPT[2:9]_FCLK	GPT[2:9]_ALWON_FCLK	PRCM.CM_FCLKEN_PER [3:10] EN_GPT[2:9] bit	N/A
GPT10_FCLK	GPT10_FCLK	PRCM.CM_FCLKEN1_CORE [11] EN_GPT10 bit	N/A
GPT11_FCLK	GPT11_FCLK	PRCM.CM_FCLKEN1_CORE [12] EN_GPT11 bit	N/A
GPT1_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[0] EN_GPT1 bit	PRCM.CM_AUTOIDLE_WKUP[0] AUTO_GPT1 bit
GPT[2:9]_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[3:10] EN_GPT[2:9] bit	PRCM.CM_AUTOIDLE_PER[3:10] AUTO_GPT[2:9] bit
GPT10_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE[11] EN_GPT10 bit	PRCM.CM_AUTOIDLE1_CORE[11] AUTO_GPT10 bit
GPT11_ICLK		PRCM.CM_ICLKEN1_CORE[12] EN_GPT11 bit	PRCM.CM_AUTOIDLE1_CORE[12] AUTO_GPT11 bit

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM interface clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM AUTOIDLE bits are used to link/unlink the GP timers from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clock gating and domain transitions, see , *Power, Reset, and Clock Management.*

GP timer modules also have an internal bit, GPTi.TIOCP_CFG[0] AUTOIDLE. The GP timer AUTOIDLE bit is used to apply an internal interface clock gating strategy.

At the PRCM level, when all conditions to shut off the PRCM functional or interface output clocks are met (see , *Power, Reset, and Clock Management*, for details), the PRCM automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPTi.TIOCP_CFG[4:3] IDLEMODE bit. Table 13-5 lists the IDLEMODE settings and the related acknowledgement modes.

Table 13-5. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The GPTi.TIOCP_CFG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (GPTi_FCLK, GPTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and the associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 13-6 lists the CLOCKACTIVITY settings and the associated features.

Table 13-6. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	GPTi_ICLK Effects	GPTi_FCLK Effects	Description	Associated Features
00	OFF	OFF	Both GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means both GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request.	The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled.
01	ON	OFF	GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected.	
10	OFF	ON	GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected.	The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is finished during idle mode, the wake-up signal is asserted). The wake-up signal is enabled.
11	ON	ON	None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.	

CAUTION

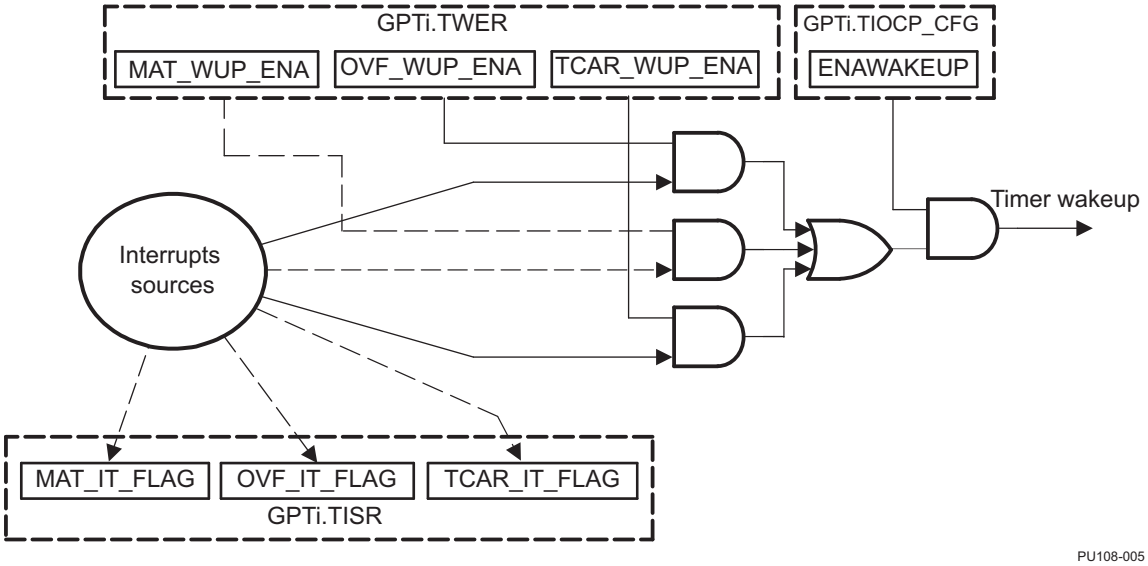
The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the GP timer is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

13.2.3.1.2 Wake-Up Capability

If the GPTi.TIOCP_CFG[4:3] IDLEMODE bit field sets the smart-idle mode, the timer module evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPTi.TIOCP_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 13-5 shows the wake-up request generation. For more information on the GP timer clock control, see Section 13.2.3.1.1, *Clock Management*.

Figure 13-5. Wake-Up Request Generation



The timer wake-up enable register (GPTi.TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPTi.TWER register is programmed synchronously with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPTi.TCRR), a timer match (the compare result of GPTi.TCRR and GPTi.TMAR matches the counter value), and a timer capture (an external pulse transition of the correct polarity is detected on the GPTi_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending wake-up event is reset when the set status bit is overwritten by 1.

NOTE: The status bit must be reset to re-enter idle mode.

13.2.3.1.3 Reset and Power Management

GPTIMER1 belongs to the WKUP power domain. As part of that domain, this GP timer is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and the WKUP_RST signal, see , *Power, Reset, and Clock Management*.

GPTIMER2 through GPTIMER9 belong to the PER power domain. As part of that domain, these GP timers are sensitive to a PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and the PER_RST signal, see , *Power, Reset, Clock Management*.

GPTIMER10 and GPTIMER11 belong to the CORE power domain. As part of that domain, these GP timers are sensitive to a CORE_RST signal issued by the PRCM module. For further details about the CORE power domain implementation and the CORE_RST signal, see , *Power, Reset, and Clock Management*.

13.2.3.2 Software Reset

Two bit fields (GPTi.TIOCP_CFG[1] SOFTRESET and GPTi.TSICR[1] SFT) can generate a software reset of the GP timer. For both of these bits, all read accesses return 0.

The GPTi.TIOCP_CFG[1] SOFTRESET bit allows resetting the functional and interface domains. The GPTi.TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPTi.TISTAT[0] RESETDONE bit. This bit field monitors the internal reset status.

13.2.3.3 GP Timer Interrupts

Table 13-7 lists the interrupt mapping from the 12 GP timers to the three internal processors.

Table 13-7. Timer Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
GPTIMER 1	GPT1_IRQ	M_IRQ_37	GPTIMER1 interrupt to MPU
GPTIMER2	GPT2_IRQ	M_IRQ_38	GPTIMER2 interrupt to MPU
GPTIMER3	GPT3_IRQ	M_IRQ_39	GPTIMER3 interrupt to MPU
GPTIMER4	GPT4_IRQ	M_IRQ_40	GPTIMER4 interrupt to MPU
GPTIMER5	GPT5_IRQ	M_IRQ_41	GPTIMER5 interrupt to MPU
		IVA2_IRQ[6]	GPTIMER5 interrupt to IVA2.2
GPTIMER6	GPT6_IRQ	M_IRQ_42	GPTIMER6 interrupt to MPU
		IVA2_IRQ[7]	GPTIMER6 interrupt to IVA2.2
		MD_IRQ_6	GPTIMER6 interrupt to modem subsystem (D2D)
GPTIMER7	GPT7_IRQ	M_IRQ_43	GPTIMER7 interrupt to MPU
		IVA2_IRQ[8]	GPTIMER7 interrupt to IVA2.2
		MD_IRQ_7	GPTIMER7 interrupt to modem subsystem (D2D)
GPTIMER8	GPT8_IRQ	M_IRQ_44	GPTIMER8 interrupt to MPU
		IVA2_IRQ[9]	GPTIMER8 interrupt to IVA2.2
		MD_IRQ_8	GPTIMER8 interrupt to modem subsystem (D2D)
GPTIMER9	GPT9_IRQ	M_IRQ_45	GPTIMER9 interrupt to MPU
		MD_IRQ_9	GPTIMER9 interrupt to modem subsystem (D2D)
GPTIMER10	GPT10_IRQ	M_IRQ_46	GPTIMER10 interrupt to MPU
GPTIMER11	GPT11_IRQ	M_IRQ_47	GPTIMER11 interrupt to MPU

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt enable register (GPTi.TIER). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending interrupt event is reset when the set status bit is overwritten by a1.

13.2.4 GP Timers Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPTi.TIER register for the interrupt features and a dedicated bit of the GPTi.TWER register for the wakeup. In addition, GPTIMER1, GPTIMER2, and GPTIMER10 have implemented a mechanism to generate an accurate tick interrupt.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see Section 13.2.1, *GP Timer Overview*).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

13.2.4.1 GP Timers Block Diagram

Figure 13-6 shows the block diagram of common GP timers, and Figure 13-7 shows the block diagram of GP timers with 1-ms tick generation module.

Figure 13-6. Block Diagram of GPTIMER3 through GPTIMER9 and GPTIMER11

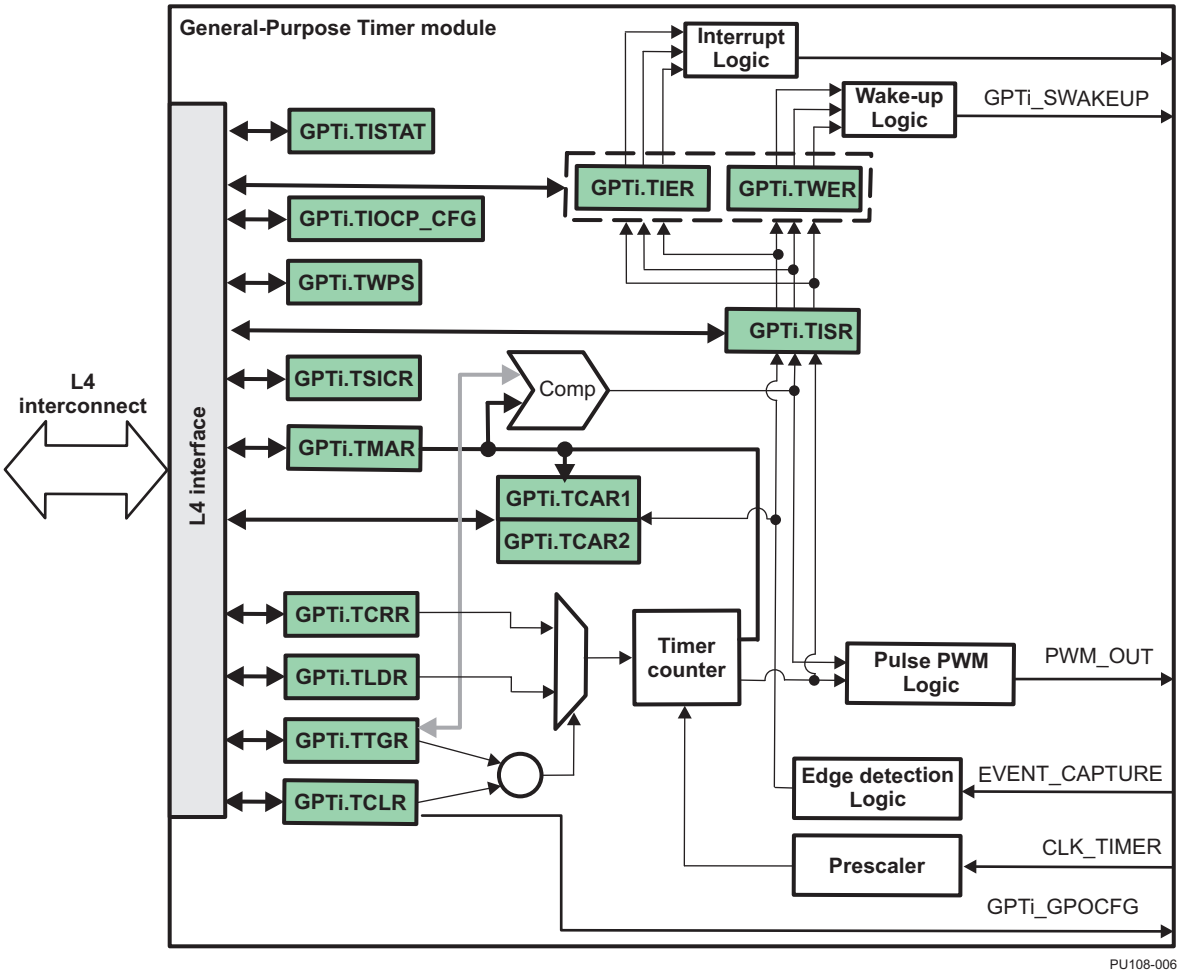


Figure 13-7. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

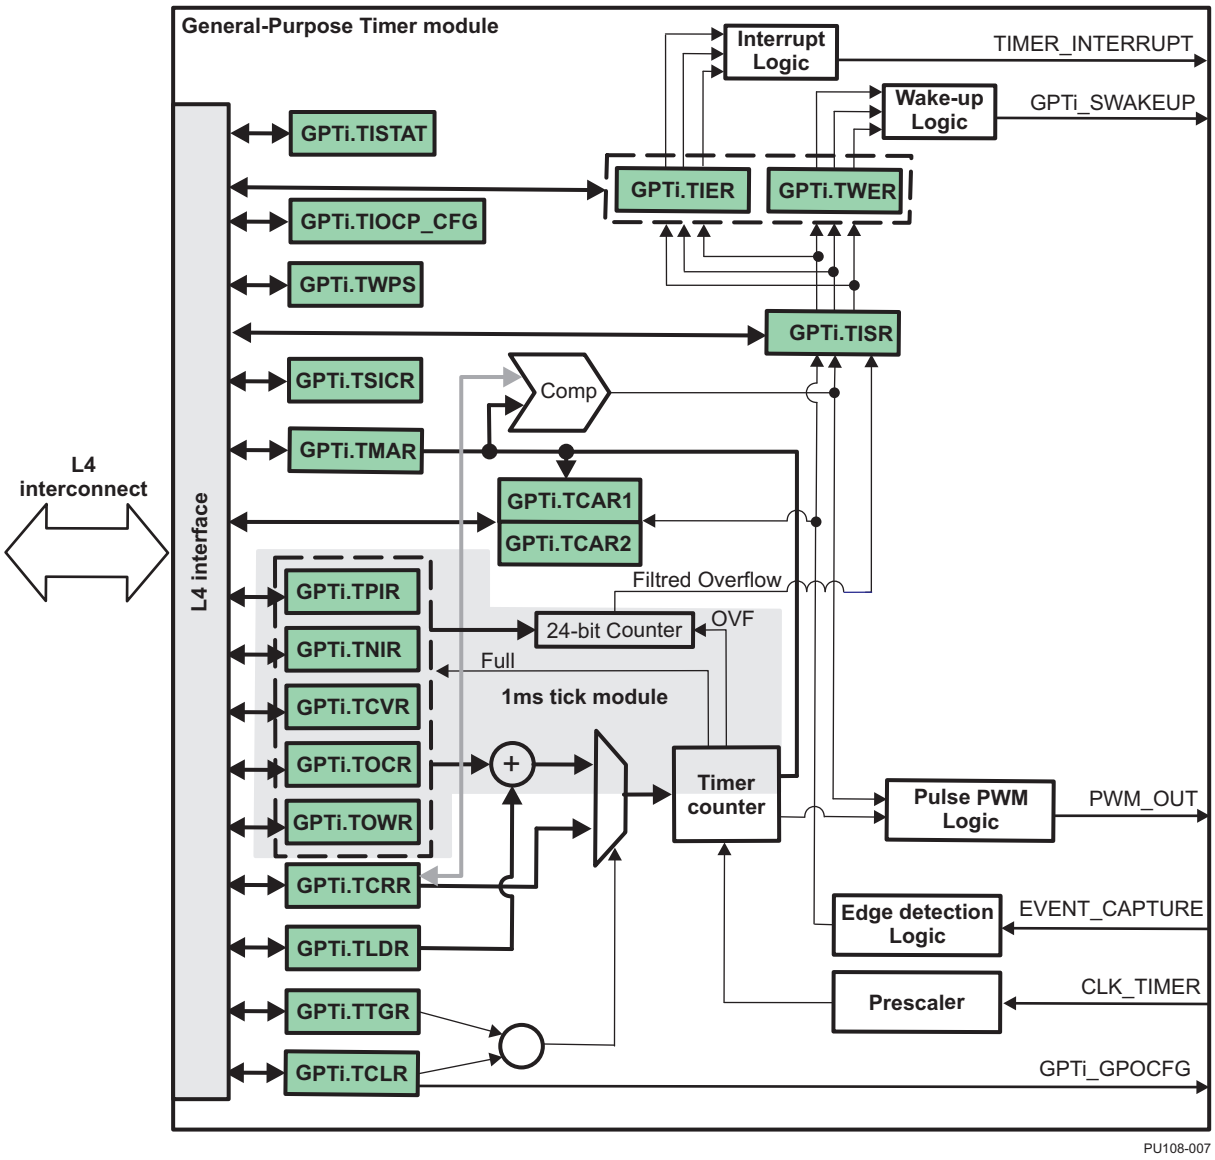


13.2.4.2 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPTi.TCLR[0] ST bit). The timer counter register (GPTi.TCRR) can be loaded when stopped or on-the-fly (while counting). GPTn.TCRR can be loaded directly by a GPTi.TCRR write access with a new timer value. The GPTi.TCRR register can also be loaded with the value held in the timer load register GPTi.TLDR by a trigger register (GPTi.TTGR) write access. The GPTi.TCRR loading is done regardless of the GPTi.TTGR written value. The timer counter register GPTi.TCRR value can be read when stopped or captured on-the-fly by a GPTi.TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPTi.TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPTi.TCLR[1] AR bit set to 1), the GPTi.TCRR register is reloaded with the timer load register (GPTi.TLDR) value after a counting overflow occurs.

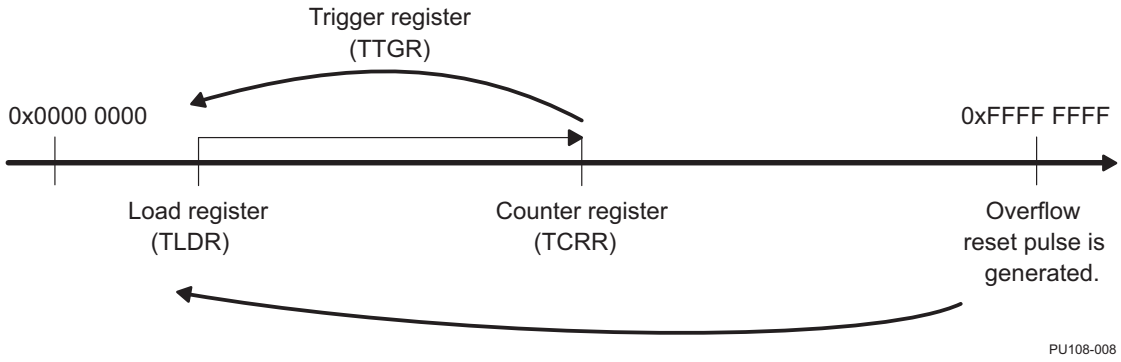
CAUTION

Do not put the overflow value (0xFFFFFFFF) in the GPTi.TLDR register because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer interrupt enable register (GPTi.TIER[1] OVF_IT_ENA bit set to 1), the interrupt is enabled after 10 * GPTi.ICLK clock cycles. A dedicated output pin (timer PWM) can be programmed in GPTi.TCLR[12] through GPTi.TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPTi.TCLR[12] PT bit selects pulse/toggle modulation (GPTi.TCLR[11:10] TRG bit field select trigger mode).

Figure 13-8 shows the GPTi.TCRR timing value.

Figure 13-8. GPTi.TCRR Timing Value



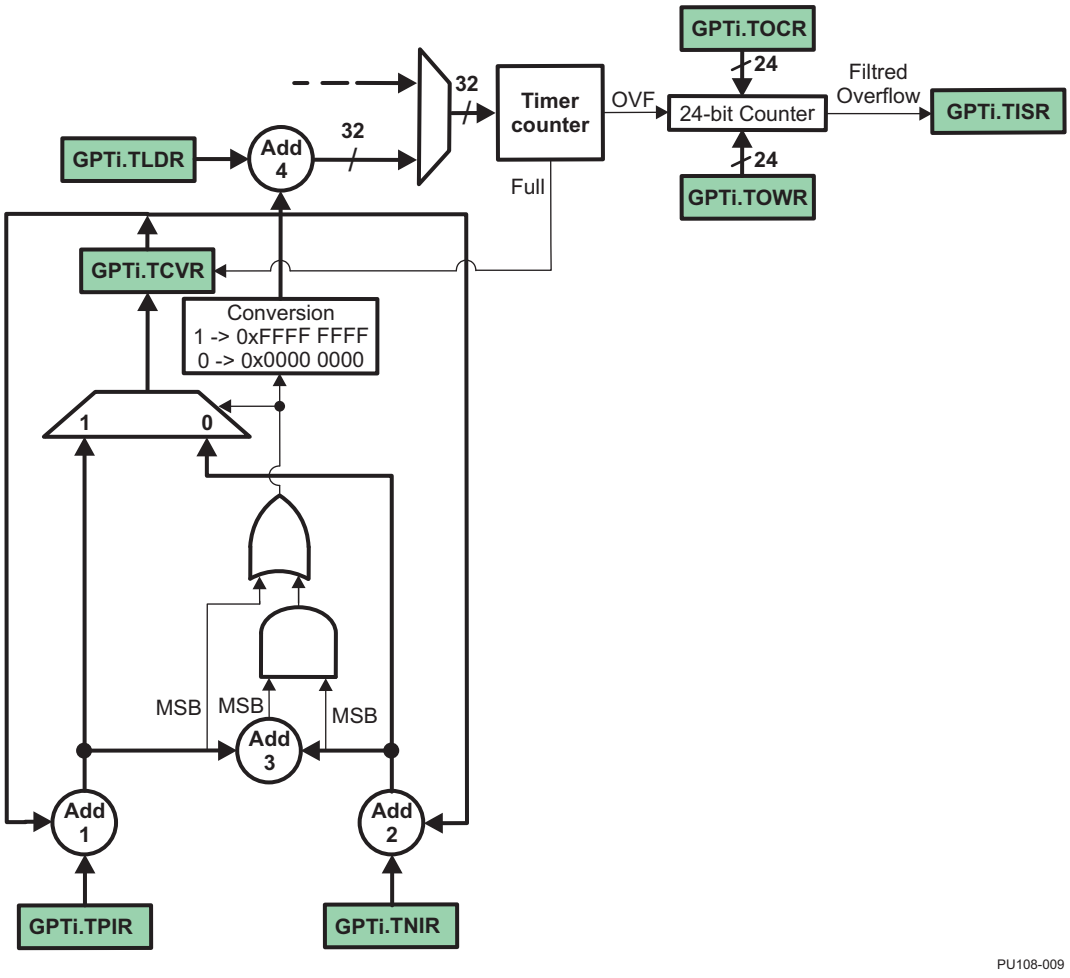
13.2.4.2.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

Because the timer input clock is 32,768 Hz, the interrupt period is not exactly 1 ms. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations to the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. Refer to Figure 13-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPTi.TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (GPTi.TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 13-9. Block Diagram of the 1-ms Tick Module



The GPTi.TPIR, GPTi.TNIR, and GPTi.TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPTi.TCRR[31:0] TIMER_COUNTER bit field) is the value of the GPTi.TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of GPTi.TLDR[31:0] LOAD_VALUE - 1 (period greater than 1 ms).

Table 13-8 lists the value loaded in the GPTi.TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 13-8. Value Loaded in GPTi.TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of GPTi.TCRR Register
0	0	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	0	1	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	0	GPTi.TLDR[31:0] LOAD_VALUE bit field
0	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	0	0	N/A
1	0	1	N/A
1	1	0	GPTi.TLDR[31:0] LOAD_VALUE - 1
1	1	1	GPTi.TLDR[31:0] LOAD_VALUE - 1

The values of the GPTi.TPIR and GPTi.TNIR registers are calculated using the following formula:

- Positive increment value = ((INTEGER[Fclk * Ttick] + 1) * 1e6) - (Fclk * Ttick * 1e6)
- Negative increment value = (INTEGER[Fclk * Ttick] * 1e6) - (Fclk * Ttick * 1e6)

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register (GPTi.TOCR) and the timer overflow wrapping register (GPTi.TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR register. When the 24-bit TOCR register values match the value in the 24-bit TOWR register and the timer overflow is asserted, the TOCR register is reset and an interrupt is generated to the TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPTi.TPIR[31:0] POSITIVE_INC_VALUE = 232000
- GPTi.TNIR[31:0] NEGATIVE_INC_VALUE = -768000
- GPTi.TLDR[31:0] LOAD_VALUE = 0xFFFFFFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the GPTi.TPIR, GPTi.TNIR, and GPTi.TLDR registers.

By default, the GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

13.2.4.3 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the GPTi.TCRR register can be captured and saved in the GPTi.TCAR1 or GPTi.TCAR2 register function of the mode selected in the GPTi.TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

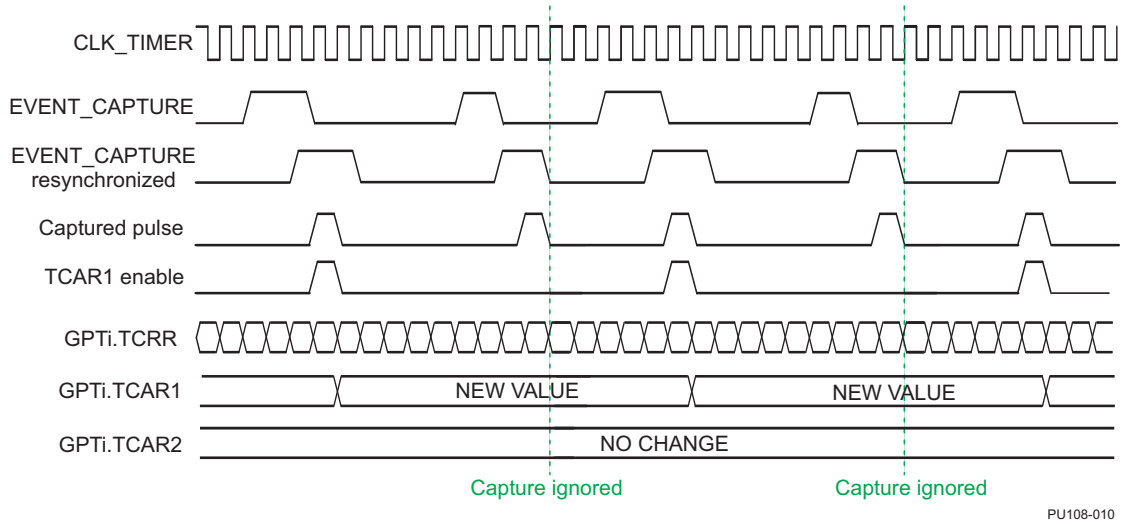
The rising edge, falling edge, or both, can be selected in the GPTi.TCLR[9:8] TCM field to trigger the timer counter capture. The module sets the GPTi.TISR[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value GPTi.TCRR is stored in timer capture register GPTi.TCAR1 or GPTi.TCAR2, as follows:

- If the GPTi.TCLR[13] CAPT_MODE bit is 0, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and all the next events are ignored (no update on the GPTi.TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it.
- If the GPTi.TCLR[13] CAPT_MODE bit is 1, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPTi.TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPTi.TCAR1/GPTi.TCAR2 and no interrupt triggering) until the detection logic is reset or GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is servedthe GPTi.TISR[2] TCAR_IT_FLAG bit (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPTi.TCLR[9:8] TCM field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). An input negative or positive pulse can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt enable bit is set in the GPTi.TIER[2] TCAR_IT_ENA bit. See the examples in Figure 13-10 and Figure 13-11.

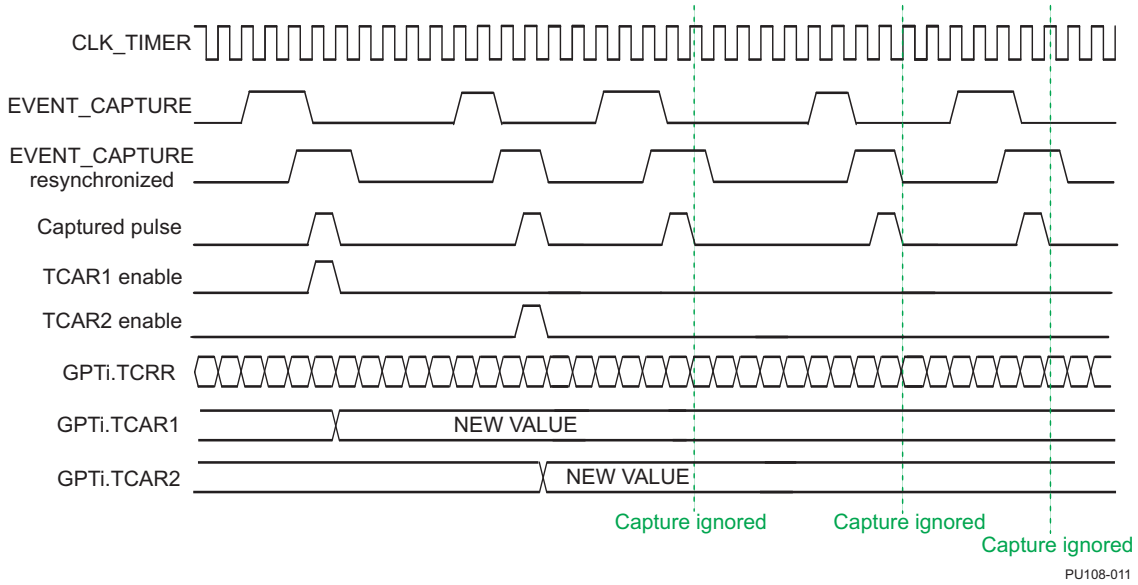
In Figure 13-10, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 and GPTi.TCAR2 registers, and only the GPTi.TCAR1 register updates.

Figure 13-10. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 0



In Figure 13-11, the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 register on the first enabled event, and the GPTi.TCAR2 register updates on the second enabled event.

Figure 13-11. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 1



13.2.4.4 Compare Mode Functionality

When the compare enable register GPTi.TCLR[6] CE bit is set to 1, the timer value (GPTi.TCRR[31:0] TIMER_COUNTER field) is continuously compared to the value held in the timer match register (GPTi.TMAR). The GPTi.TMAR[31:0] COMPARE_VALUE value can be loaded at any time (timer counting or stopped). When the GPTi.TCRR and the GPTi.TMAR values match, an interrupt is issued, if the GPTi.TIER[0] MAT_IT_ENA bit is set.

The dedicated output pin (timer PWM) can be programmed in the GPTi.TCLR[12] PT bit through the GPTi.TCLR[11:10] TRG field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

13.2.4.5 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPTi.TCLR[5] PRE bit is set. The GPTi.TCLR[4:2] PTV field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 13-9 lists the prescaler/timer reload values versus contexts.

Table 13-9. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	GPTi.TLDR[31:0]
TCRR write	Reset	GPTi.TCRR[31:0]
TTGR write	Reset	GPTi.TLDR[31:0]
Stop	Reset	Frozen

13.2.4.6 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPTi.TCLR[11:10] TRG field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

In toggle mode when GPTi.TCLR[11:10] TRG = 0x2 (overflow and match), the first event that will toggle the PWM line is an overflow event. If a match event occurs first, it will not toggle the PWM line. Figure 13-13 illustrates those.

The GPTi.TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPTi.TCLR[11:10] TRG field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 13-12, the internal overflow pulse is set each time (0xFFFF FFFF - GPTi.TLDR[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPTi.TMAR register value. According to the value of the GPTi.TCLR[12] PT and GPTi.TCLR[11:10] TRG bits, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPTi.TLDR and GPTi.TMAR registers must keep values smaller than the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPTi.TMAR register and the value in the GPTi.TLDR register must be at least two units. When match event is used, the compare mode GPTi.TCLR[6] CE bit must be set.

In Figure 13-12, the GPTi.TCLR[7] SCPWM bit is set to 0. In Figure 13-13, the GPTi.TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPTi.TCLR[7] SCPWM bit).

Figure 13-12. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 0

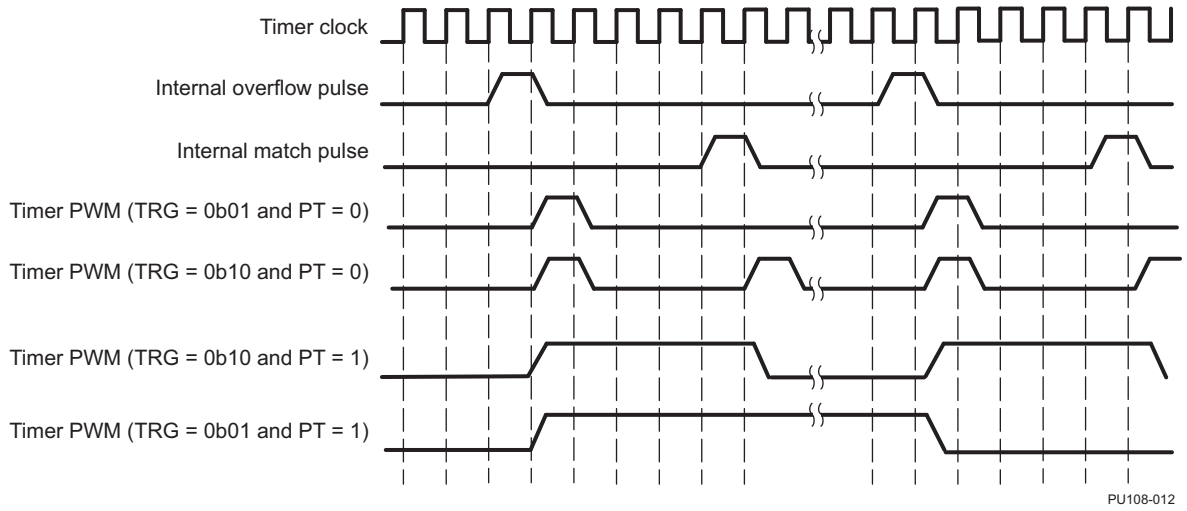


Figure 13-13. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 1

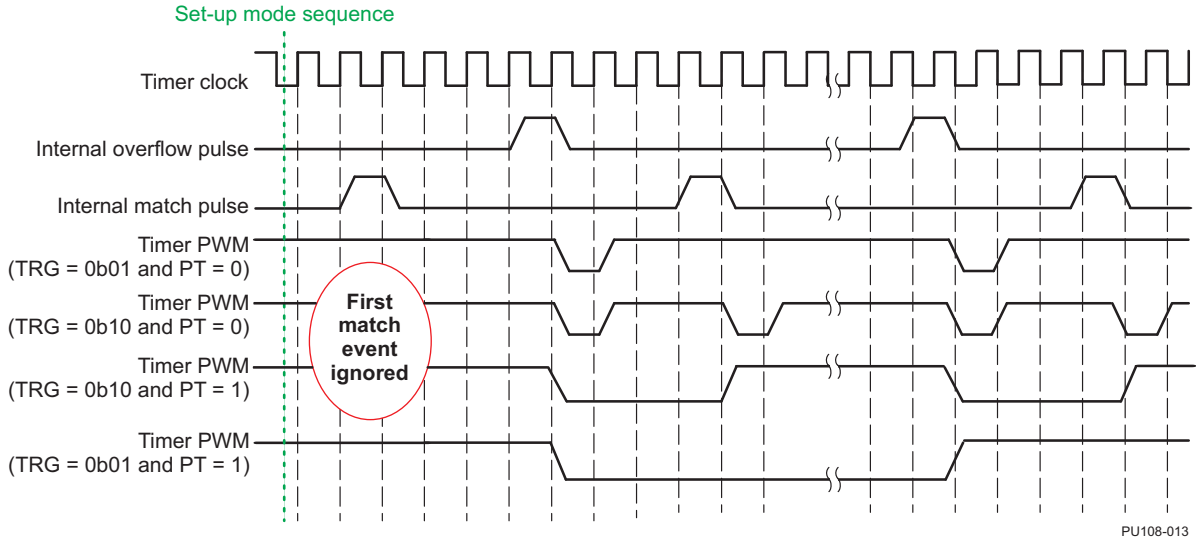

13.2.4.7 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (GPTi.TCLR[5] PRE bit and GPTi.TCLR[4:2] PTV field)
- Value loaded into the timer load register (GPTi.TLDR)

Table 13-10 lists prescaler clock ratio values.

Table 13-10. Prescaler Clock Ratio Values

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Table 13-10. Prescaler Clock Ratio Values (continued)

GPTi.TCLR[5] PRE	GPTi.TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow-rate is expressed as:

OVF_Rate = (0xFFFF FFFF - GPTn.TLDR + 1) * (timer-functional clock period) * PS

With (timer-functional clock period) = 1 / (timer-functional clock frequency) and PS = $2^{(PTV + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the GPTn.TCLR[1] ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPTn.TCLR_latency 3.5 * functional clock cycles

Remember to take this latency into account whenever the timer must be started or stopped by a software change to the GPTn.TCLR[1] ST bit.

CAUTION

- In the non-PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and a GPTn.TCLR[5] PRE field equal to 0, the timer output period is as listed in Table 13-11.

Table 13-11. Value and Corresponding Interrupt Period

GPTi.TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 µs
0xFFFF FFFE	65.5 µs

13.2.5 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPTi.TIOCP_CFG[5] EMUFREE bit.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (gpti_pwm_evt, with i=[9:12]) is internally synchronized on two timer-clock rising edges.

13.2.6 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration.

All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB). Write operations to the GP timer registers (GPTi.TIDR, GPTi.TIOCP_CFG, GPTi.TISR, GPTi.TIER, GPTi.TWER, and GPTi.TSICR) can skip the MSB access if it is not necessary to update the 16 MSBs of the register.

Write operations to any functional register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, and GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR , GPTi.TOCR , and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10) must be complete (the MSB must be written even if the MSB data is not used).

13.2.6.1 Writing to Timer Registers

The host uses the L4 interface to write the following registers synchronously with the timer interface clock:

- GPTi.TLDR
- GPTi.TCRR
- GPTi.TIER
- GPTi.TISR
- GPTi.TCLR
- GPTi.TIOCP_CFG
- GPTi.TWER
- GPTi.TTGR
- GPTi.TSICR
- GPTi.TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPTi.TPIR
- GPTi.TNIR
- GPTi.TCVR
- GPTi.TOCR
- GPTi.TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

13.2.6.1.1 Write Posting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later, because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status register GPTi.TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPTi.TCRR does not add any resynchronization latency; the current value is always available.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: freq(timer clock) freq(L4 interface clock)/4

13.2.6.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 0.

This mode uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

13.2.6.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPTi.TCRR, GPTi.TCAR1, and GPTi.TCAR2) captures the current timer counter value. This must be followed by reading the 16MSBs.

IVA2.2 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

13.3 General-Purpose Timers Register Manual

13.3.1 GP Timer Register Map

13.3.1.1 Instance Summary

Table 13-12 lists the base address and block size for the GP timer module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 13-12. GP Timer Instance Summary

Module Name	Base Address	Size
GPTIMER1	0x4831 8000	4K bytes
GPTIMER2	0x4903 2000	4K bytes
GPTIMER3	0x4903 4000	4K bytes
GPTIMER4	0x4903 6000	4K bytes
GPTIMER5	0x4903 8000	4K bytes
GPTIMER6	0x4903 A000	4K bytes
GPTIMER7	0x4903 C000	4K bytes
GPTIMER8	0x4903 E000	4K bytes
GPTIMER9	0x4904 0000	4K bytes
GPTIMER10	0x4808 6000	4K bytes
GPTIMER11	0x4808 8000	4K bytes

13.3.2 GP Timer Register Mapping Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 13-13 through Table 13-15 provide the register summary and associated offset addresses for the 11 GP timer internal registers. (Example: The physical address for the TCLR register of GPTIMER8 is 0x4903 E024.)

Table 13-13. GPTIMER1 to GPTIMER4 Register Summary

Description	This register controls optional features specific to the timer functionality.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																GPO_CFG	CAPT_MODE	PT	TRG		TCM		SCPWM	CE	PRE	PTV				AR	ST

Bits	Field Name	Description	Type	Reset
31:15	Reserved	Reads return 0.	R	0x00000
14	GPO_CFG	PWM output/event detection input pin direction control: 0x0: Configures the pin as an output (needed when PWM mode is required) 0x1: Configures the pin as an input (needed when capture mode is required)	RW	0
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Capture the first enabled capture event in TCAR1. 0x1: Capture the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle select bit 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode 0x0: No trigger 0x1: Overflow trigger 0x2: Overflow and match trigger 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode 0x0: No capture 0x1: Capture on rising edges of EVENT_CAPTURE pin. 0x2: Capture on falling edges of EVENT_CAPTURE pin. 0x3: Capture on both edges of EVENT_CAPTURE pin.	RW	0x0
7	SCPWM	Pulse-width-modulation output pin default setting when counter is stopped or trigger output mode is set to no trigger. 0x0: Default value of PWM_out output: 0 0x1: Default value of PWM_out output: 1	RW	0
6	CE	Compare enable 0x0: Compare disabled 0x1: Compare enabled	RW	0
5	PRE	Prescaler enable 0x0: Prescaler disabled 0x1: Prescaler enabled	RW	0
4:2	PTV	Trigger output mode 0x0: The timer counter is prescaled with the value: $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One-shot mode overflow 0x1: Autoreload mode overflow	RW	0
0	ST	Start/stop timer control 0x0: Stop the timer 0x1: Start the timer	RW	0

13.4 Watchdog Timers

13.4.1 WDTs Overview

The device includes two instances of the 32-bit WDT: WDT2 and WDT3. Figure 13-14 shows how each timer is connected in the device.

NOTE: WDTi (where i is the watchdog timer instance: i = 2 or 3) stands for the following:
- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA2 watchdog timer

Each WDT is an upward counter capable of generating both a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU WDT serves resets to the PRCM module (its interrupt outputs are unused), and the IVA2 WDT serves watchdog interrupts to the MPU (its reset outputs are unused).

The WDTs can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA2 WDTs have the 32-kHz clock for their timer clock input.

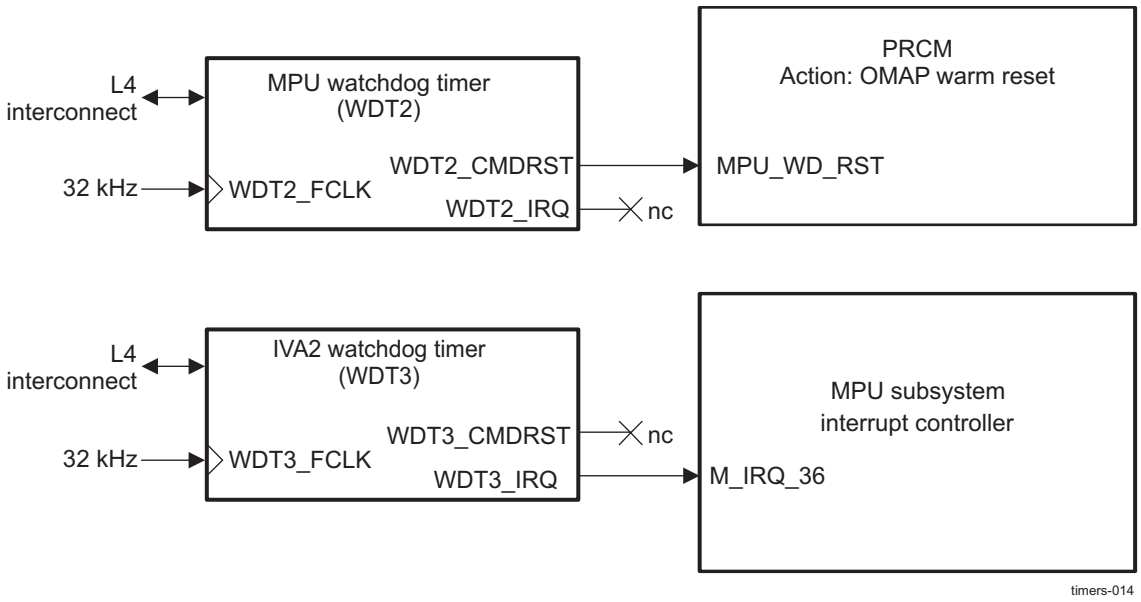
The MPU WDT directly generates a warm reset condition on overflow. The IVA2 WDT generates an MPU interrupt condition on overflow, which can be used by the application software via the PRCM to indirectly trigger a reset condition (that is, to the IVA2 subsystem).

The MPU WDT connects to a single target agent port on the L4 interconnect.

Table 13-56. WD Timers Default State for GP and EMU devices

Timer	Device			
	EMU		GP	
MPU WDTIMER2	Enabled	Running	Enabled	Running
IVA2 WDTIMER3	Enabled	NOT Running	Enabled	NOT Running

Figure 13-14. WDTs Block Diagram



13.4.1.1 WDT Features

The following are the main features of the WDT controllers:

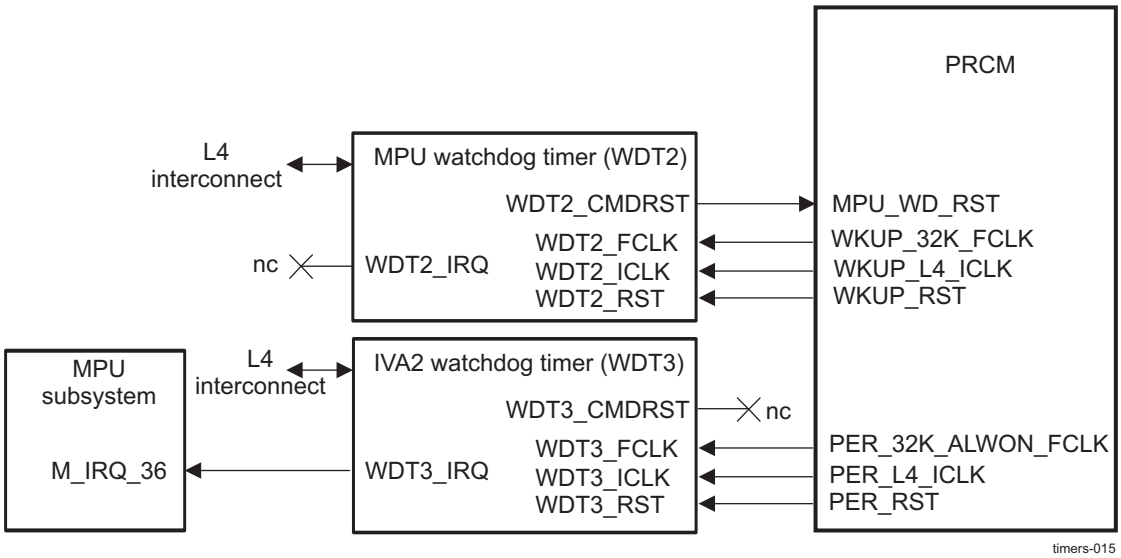
- L4 slave interface support:

  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Only posted write/read internal resynchronization mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n with n = [0:7])
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- WDTs are reset either on power-on or after a warm reset.
- Reset or interrupt actions when a timer overflow condition occurs
- WDT generates either a reset or an interrupt in its hardware integration (WDT2, or WDT3).

13.4.2 WDT Integration

Figure 13-15 shows the integration of the WDT in the device.

Figure 13-15. WDT Integration



13.4.2.1 Clocking, Reset, and Power-Management Scheme

13.4.2.1.1 Clock Management

There are two clock domains in the WDTs:

- Functional clock domain: WDTi_FCLK is the WDT functional clock. It is used to clock the WDT internal logic.
- Interface clock domain: WDTi_ICLK is the WDT interface clock. It is used to synchronize the WDT L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

Table 13-57 lists the the source clocks for each WDT in the device. For more information on clock control and domains, see , *Power, Reset, and Clock Management*.

Table 13-57. Clock, Power, and Reset Domains for WDTs

Timer	Interface Clock	Functional Clock	Power Domain
MPU WDT	WKUP_L4_ICLK	WKUP_32K_FCLK	WKUP
IVA2 WDT	PER_L4_ICLK	PER_32K_ALWON_FCLK	PER

From a global system power-management perspective, when one or both of the WDT clocks is no longer required, the WDTs can be deactivated at the PRCM level in the corresponding registers. Table 13-58 lists the WDT PRCM clock control bits.

Table 13-58. WDT PRCM Clock Control Bits

Name	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
WDT2_FCLK	WKUP_32K_FCLK	PRCM.CM_FCLKEN_WKUP[5] EN_WDT2 bit	N/A
WDT3_FCLK	PER_32K_ALWON_FCLK	PRCM.CM_FCLKEN_PER[12] EN_WDT3 bit	N/A
WDT2_ICLK	WKUP_L4_ICLK	PRCM.CM_ICLKEN_WKUP[5] EN_WDT2 bit	PRCM.CM_AUTOIDLE_WKUP[5] AUTO_WDT2 bit
WDT3_ICLK	PER_L4_ICLK	PRCM.CM_ICLKEN_PER[12] EN_WDT3 bit	PRCM.CM_AUTOIDLE_PER[12] AUTO_WDT3 bit

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient action.The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM interface clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient condition. The clock is effectively out when all PRCM conditions are fulfilled.For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM AUTOIDLE bits are used to link/unlink the WDTs from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clocks gating and domain transitions, see , *Power, Reset, and Clock Management.*

At the PRCM level, when the conditions to shut off the PRCM functional or interface output clocks are met (see , *Power, Reset, and Clock Management,* for details), the PRCM automatically launches a hardware handshake protocol to ensure the WDT is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the WDT.

Although this handshake is a hardware function and out of software control, the way the WDT acknowledges the PRCM IDLE request is configurable through the WDTi.WD_SYSCONFIG[4:3] IDLEMODE bit. Table 13-59 lists the IDLEMODE settings and the related acknowledgement modes.

Table 13-59. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The WDT acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The WDT never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures the clocks remain active; it is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.

Table 13-59. IDLEMODE Settings (continued)

IDLEMODE Value	Selected Mode	Description
10	Smart-idle	The WDT acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQs requests are treated. This is the best approach for efficient system power management.
11	Reserved	

When configured in smart-idle mode, the WDT also offers an additional granularity on WDTi_FCLK and WDTi_ICLK gating. The WDTi.WD_SYSCONFIG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (WDTi_FCLK, WDTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the WDT to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if WDTi_FCLK is not to be shut down on a PRCM IDLE request, the WDT considers only WDTi_ICLK and the associated pending activities before acknowledging the request.

Some WDT features are associated with WDTi_ICLK, and others are associated with WTDi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the WDT acknowledges an IDLE request.

Table 13-60 lists the CLOCKACTIVITY settings.

Table 13-60. CLOCKACTIVITY Settings

CLOCKACTIVITY Value	WDTi_ICLK Effects	WDTi_FCLK Effects	Description
00	OFF	OFF	Both WDTi_ICLK and WDTi_FCLK are considered for generating the acknowledge. This setting also means both WDTi_FCLK and WDTi_ICLK are likely to be shut down on a PRCM IDLE request.
01	OFF	ON	WDTi_FCLK is not shut down on a PRCM IDLE request; only WDTi_ICLK is concerned.
10	ON	OFF	WDTi_ICLK is not shut down on a PRCM IDLE request; only WDTi_FCLK is concerned.
11	ON	ON	None of the clocks are shut down. Therefore, the WDT can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the WDT CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the WDT is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the WDT clocks. This can lead to unpredictable behavior.

13.4.2.1.2 Reset and Power Management

The MPU WDT (WDT2) belong to the WKUP power domain. As part of that domain, this WDT is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and WKUP_RST signal, see , *Power, Reset, and Clock Management.*

The IVA WDT (WDT3) belongs to the PER power domain. As part of that domain, WDT3 is sensitive to the PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and PER_RST signal, see , *Power, Reset, and Clock Management.*

NOTE: WDT2 is reset on power-on or after a warm reset, and then it starts counting.

WDT3 is reset either on power-on or after a warm reset, and then it doesn't start counting.

13.4.2.2 Interrupts

Table 13-61 shows interrupt mapping from the three WDTs to the MPU.

Table 13-61. WDT Interrupt Names and Processor IRQ Mapping

Timer	Interrupt Name	Mapping	Comments
MPU WDT	WDT2_IRQ	Not connected	
IVA2 WDT	WDT3_IRQ	M_IRQ_36	IVA2 WDT overflow

13.4.3 WDTs Functional Description

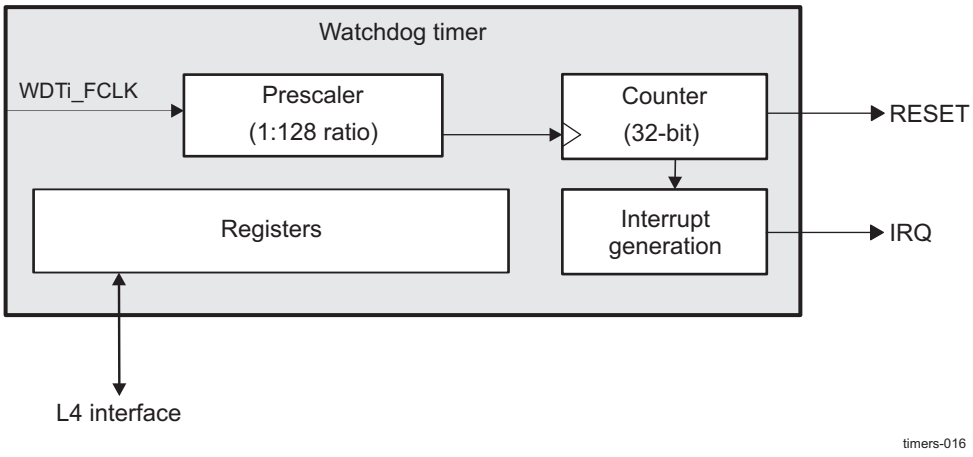
13.4.3.1 General WDT Operation

The WDTs are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 13-14. The interrupt generation mechanism is controlled through the WDTi.WIER and WDTi.WISR registers.

The prescaler ratio can be set between 1 and 128 by accessing the WDTi.WCLR[4:2] PTV and WDTi.WCLR[5] PRE fields of the watchdog control register (WDTi.WCLR).

The current timer value can be accessed on-the-fly by reading the WDT counter register (WDTi.WCRR), modified by accessing the WDT load register (WDTi.WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the WDT trigger register (WDTi.WTGR). A start/stop sequence applied to the WDT start/stop register (WDTi.WSPR) can start and stop the WDT.

Figure 13-16. 32-Bit WDT Functional Block Diagram



13.4.3.2 Reset Context

After reset, the WDTs are enabled. Table 13-62 lists the default reset values of the three WDT load registers (WDTi.WLDR) and prescaler ratios (WDTi.WCLR[4:2] PTV field). To get these values, software must read the corresponding WDTi.WCLR[4:2] PTV fields and the 32-bit register to retrieve the static configuration of the module.

Table 13-62. Count and Prescaler Default Reset Values

Timer	WLDR Reset Value	PTV Reset Value
OMAP WDT (WDT2)	0xFFFB 0000	0
IVA2 WDT (WDT3)	0xFFFB 0000	0

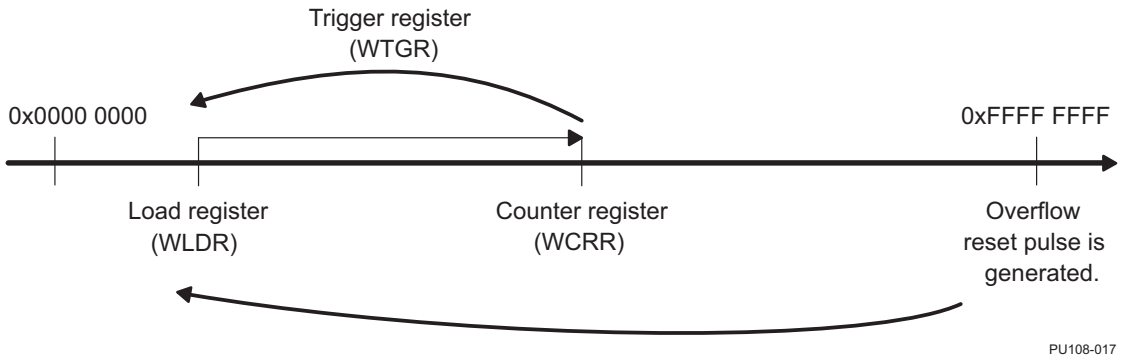
13.4.3.3 Overflow/Reset Generation

When the WDT counter register (WDTi.WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDTi.WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). Then, after the reset pulse output has been generated, the timer counter begins incrementing again.

Figure 13-17 shows a general functional view of the WDT.

Figure 13-17. WDT General Functional View



13.4.3.4 Prescaler Value/Timer Reset Frequency

Each WDT is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDTi.WCLR[5] PRE bit and the WDTi.WCLR[4:2] PTV field)
- Value loaded into the timer load register (WDTi.WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDTi.WCLR[4:2] PTV field) and is enabled with the WDTi.WCLR[5] PRE bit.

Table 13-63 lists the prescaler clock ratio values.

Table 13-63. Prescaler Clock Ratios

PRE Bit (in WDTi.WCLR Register)	PTV Bits (in WDTi.WCLR Register)	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

The watchdog timer overflow rate is expressed by: OVF_Rate = (0xFFFF FFFF - WDTn.WLDR + 1) * (wd-functional clock period) * PS

With wd-functional clock period = 1 / (wd-functional clock frequency) and PS = $2^{(PTV)}$.

CAUTION

Internal resynchronization causes any software write to GPTn.WSPR to have some latency before WSPR is updated with the programmed value:

1.5 * functional clock cycles ≤ write_WSPR_latency ≤ 2.5 * functional clock cycles

Remember to take this latency into account whenever the watchdog must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WDTi.WCLR[5] PRE bit = 1 (clock divider enabled), the reset period is as listed in Table 13-64.

Table 13-64. Reset Period Examples

WDTi.WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a WDT is enabled, the software must periodically trigger a reload before the counter overflows. Hence, the WDTi.WLDR[31:0] value must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDTi.WLDR[31:0] = 0xFFFF FFFF is a special case, although such a WDTi.WLDR value is meaningless. When WDTi.WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the WDT is stopped.

Table 13-65 lists the default reset periods for the WDTs.

Table 13-65. Default WDT Time Periods

WDTs	Clock Source	Default Reset Period
OMAP/IVA2 WDTs	32 kHz	10 s

13.4.3.5 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WDT trigger register (WDTi.WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT trigger register (WDTi.WTGR) differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without a reset pulse generation.

The timer counter is loaded with the WDT load register value (the WDTi.WLDR[31:0] TIMER_LOAD field), and the prescaler is reset.

13.4.3.6 Start/Stop Sequence for WDTs (Using WDTi.WSPR Register)

To start/stop a WDT, access must be made through the start/stop register (WDTi.WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in WDTi.WSPR.
2. Write 0xXXXX 5555 in WDTi.WSPR.

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in WDTi.WSPR.
2. Write 0xXXXX 4444 in WDTi.WSPR.

All other write sequences on WDTi.WSPR have no effect on the start/stop feature of the module.

13.4.3.7 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (WDTi.WCRR), prescaler ratio (the WDTi.WCLR[4:2] PTV field), or load value (the WDTi.WLDR[31:0] TIMER_LOAD field), the WDT must be disabled by using the start/stop sequence (the WDTi.WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (WDTi.WTGR).

13.4.3.8 Watchdog Counter Register Access Restriction (WDTi.WCRR Register)

Because the WDTi.WCRR register is directly related to the timer counter value and is updated on the timer clock (WDTi_FCLK), a 32-bit shadow register is implemented to read a coherent value of the WDTi.WCRR register. The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDTi_ICLK) is completely asynchronous with the timer clock (WDTi_FCLK), some synchronization is done to ensure that the WDTi.WCRR value is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is made directly from the accessed register.

To ensure that a coherent value is read inside WDTi.WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

13.4.3.9 WDT Interrupt Generation

The WDT issues an overflow interrupt if this interrupt is enabled in the WDT interrupt enable register (WDTi.WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDTi.WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when both status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. Writing 1 in the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status after). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WTDi.WISR register. Reading the WTDi.WISR register and writing the value back allows a fast acknowledge interrupt process.

NOTE: Writing 0 in the WDTi.WISR[0] OVF_IT_FLAG bit has no effect on it.

Because the interrupt event is generated on the functional clock domain (WDTi_FCLK), during the interrupt status register (WDTi.WISR) update, the two clock domains are resynchronized.

13.4.3.10 WDT Under Emulation

During emulation mode, the WDT can/cannot continue running, according on the value of the WDTi.WD_SYSCONFIG[5] EMUFREE bit of the system configuration register (WDTi.WD_SYSCONFIG).

- When EMUFREE is 1, WDT execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

13.4.3.11 Accessing Watchdog Timer Registers

Posted mode applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For a write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

NOTE: To ensure completion of successive writes in a WDT2/WDT3 functional clock domain register, user software must poll the appropriate WDT_WWPS status bit.

NOTE: To ensure coherent reading when a read transaction immediately follows a write access to a WDT2/WDT3 functional clock domain register, user software must check the appropriate WDT_WWPS status bit.

The synchronous registers in the timer interface clock domain are not affected by the posted mode mechanism; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The synchronous registers in the timer interface clock domain are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WIRQWAKEEN
- WDT_WWPS

NOTE: Accesses to the synchronous registers in the WDT2 and WDT3 functional clock domains are posted.

13.5 Watchdog Timer Register Manual

All registers are 32 bits wide and are accessible through the L4 interface with 16-bit or 32-bit access (read/write).

13.5.1 Instance Summary

Table 13-66 lists the base address and address space for the WDT module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 13-66. WDT Instance Summary

Module Name	Base Address	Size
WDTIMER2	0x4831 4000	4K bytes
WDTIMER3	0x4903 0000	4K bytes

13.5.2 WDT Register Mapping Summary

CAUTION

The WDT registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 13-67 lists the WDT2 registers and Table 13-68 lists the WDT3 registers.

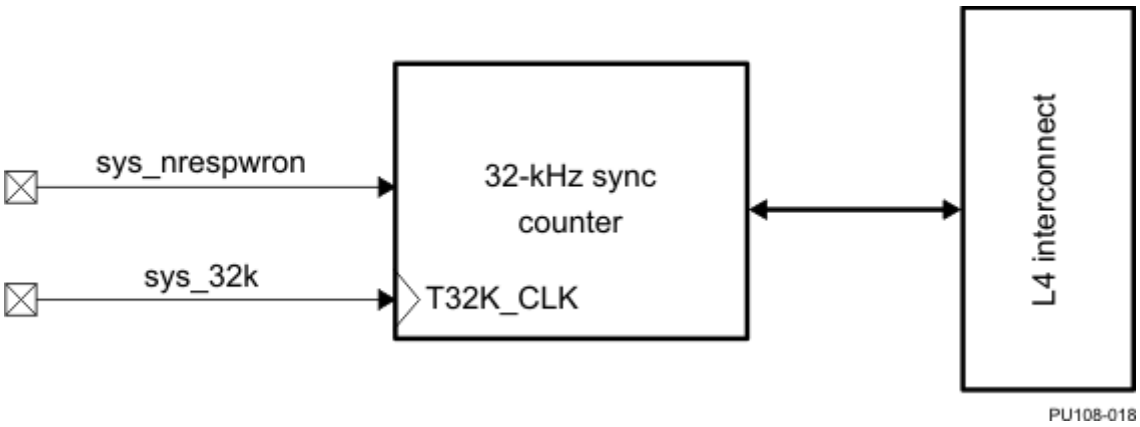
13.6 32-kHz Synchronized Timer

13.6.1 32-kHz Sync Timer Functional Description

The 32-kHz sync timer is a 32-bit counter, clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary I/O is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again. Figure 13-18 shows the block diagram of the 32-kHz sync timer.

NOTE: sys_nrespwron is an active low I/O.

Figure 13-18. 32-kHz Sync Timer Block Diagram



13.6.1.1 Reading the 32-kHz Sync Timer

The sync counter register is 32 bits wide and can be read using 32-bit and 16-bit access. For correct count capture using 16-bit access, the counter register must be accessed as 16-bit LSB access first and 16-bit MSB access next. The internal logic ensures the integrity and correctness of the read data from counter register when it is split into 16-bit data. Therefore, the read data corresponds to the data when the read command is issued. Internal synchronization logic allows reading of the counter value with 32KSYNC_ICLK while the counter is running. There is a read latency of one 32KSYNC_ICLK clock cycle, which is a synchronization delay. The time latency to read the counter is a minimum of one read cycle for 32-bit access, and two read cycles for 16-bit access, where each read cycle equals to three 32KSYNC_ICLK clock cycles. .

13.6.1.2 32-kHz Sync Timer Features

The following are the main features of the 32-kHz sync timer controller:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0, highest value reached (0xFFFF FFFF)

- On-the-fly read (while counting)

13.6.2 32-kHz Sync Timer Environment

The sync timer is accessible only through the L4 interface.

13.6.3 32-kHz Sync Timer Integration

13.6.3.1 Clocking, Reset, and Power-Management Scheme

Table 13-91 lists the power and reset domain and the source clock for the 32-kHz sync timer in the device. For more information on power, reset, and clock control and domains, see , *Power, Reset, and Clock Management*.

Table 13-91. Clock, Power, and Reset Domains for 32-kHz Sync Timer

Timer	Source Clock	Intertface Clock	Clock and Power Domain	Reset Domain
32-kHz sync timer	sys_32k	32KSYNC_ICLK	WKUP	SYNCT_RST(1)

13.6.3.2 Interrupts

The 32-kHz sync timer has no interrupt outputs.

13.6.3.3 Sync Timer 32k and MSuspend Signal

By default, the Sync Timer 32k is not stopped when the MPU or DSP is in *halt*. To activate its sensitivity to the MSuspend signal, the CONTROL.CONTROL_MSUSPEND_2[29:27] SyncTMMsctrl bit has been added to the system control module.

13.7 32-kHz Sync Timer Register Manual

13.7.1 32-kHz Sync Timer Instance Summary

Table 13-92 lists the base address and block size for the 32-kHz sync timer. It is memory mapped to the L4 peripheral bus memory space.

Table 13-92. 32-kHz Sync Timer Instance Summary

Module Name	Base Address	Size
32-kHz Sync Timer	0x4832 0000	4K bytes

13.7.2 32-kHz Sync Timer Register Mapping Summary

CAUTION

The 32-kHz sync timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 13-93 lists the 32-kHz sync timer registers. Table 13-94 through Table 13-98 describe the register bits.

UART/IrDA/CIR Module

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

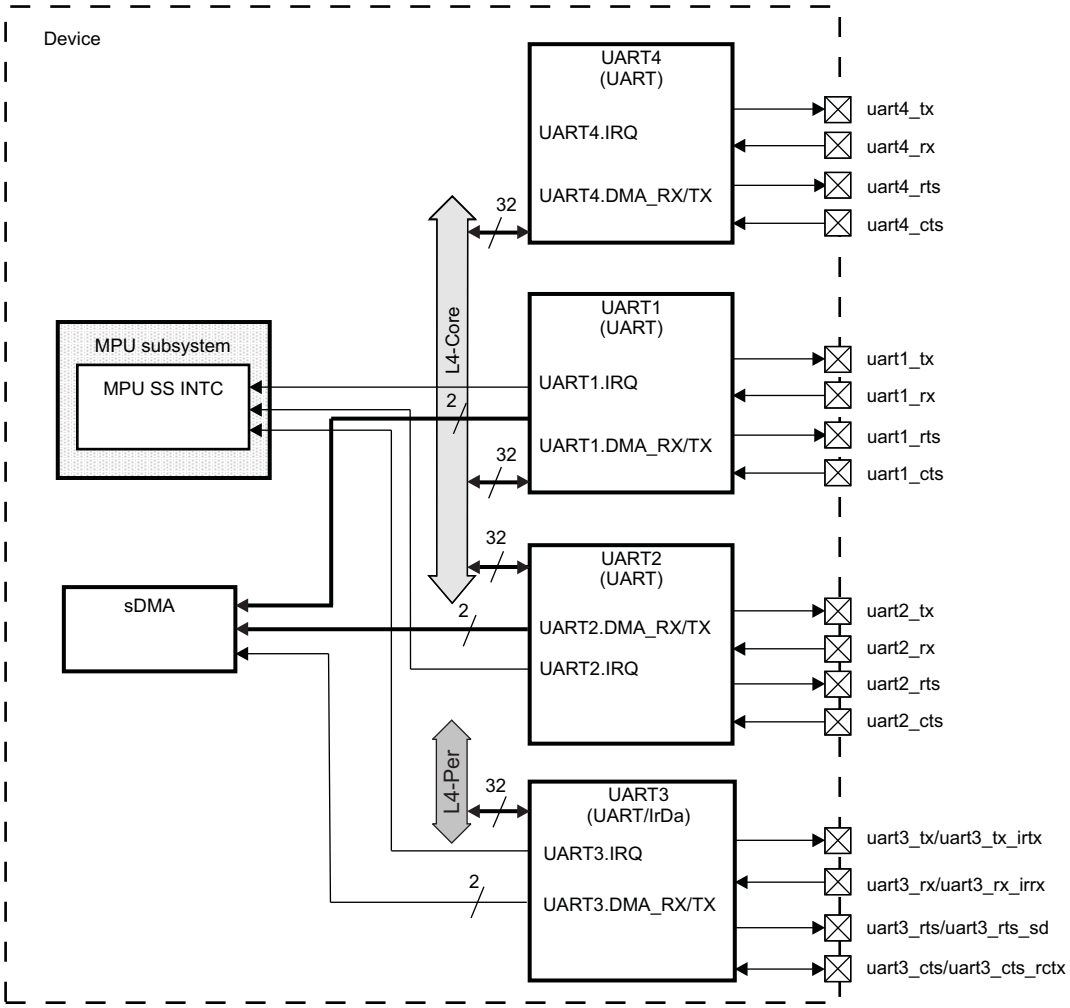
Topic **Page**

14.1 UART/IrDA/CIR Overview

The processor contains three universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see Figure 14-1):

- Three UART-only modules, UART1, UART2 and UART4 are pinned out for use as UART devices only. UART1, UART2 and UART3 must be programmed by setting the UARTi.MDR1_REG[2:0] MODE_SELECT field to one of the three UART operating modes.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

Figure 14-1. UART Module



14.1.1 UART Features

The UARTs (UART1, UART2, UART3, and UART4 when in UART mode) include the following key features:

- 16C750 compatibility
- 64-byte FIFO for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (N = 1…16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is either:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6M bits/s. Table 14-1 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 14-1. UART Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

NOTE: The maximum baud rate required of the module does not depend on the change of OPP.

14.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)
  - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
  - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

Table 14-2 lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 14-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM(1)	1	0

(1) PPM = pulse-position-modulation

14.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

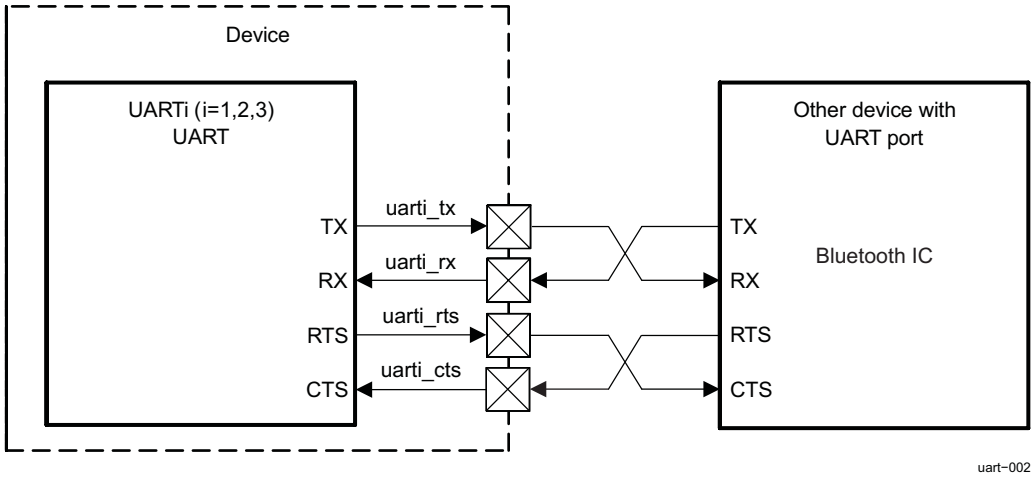
14.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

14.2.1 System Using UART Communication with Hardware Handshake

UART1, UART2, or UART3 can be connected easily to the UART port of an external IC (see Figure 14-2).

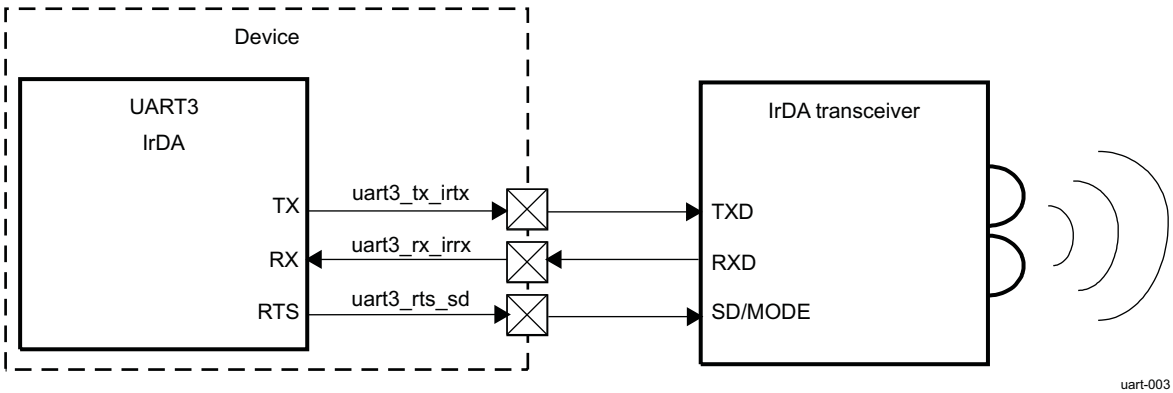
Figure 14-2. UART Mode Bus System Overview



14.2.2 System using IrDA Communication Protocol

As Figure 14-3 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

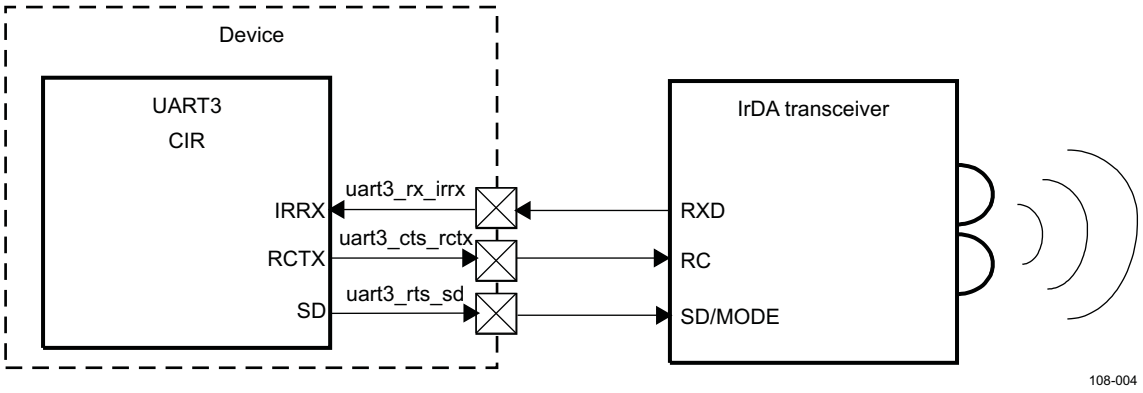
Figure 14-3. IrDA System Overview



14.2.3 System using CIR Communication Protocol with Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see Figure 14-4).

Figure 14-4. CIR System Overview



14.2.4 UART Interface Description

14.2.4.1 UART Interface Description

Table 14-3 describes the UART interface.

Table 14-3. UART I/O Pin Description

Signal	I/O[1]	Description	Reset
UART Modem Signals			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output Because this pin is active high in the IrDA mode and the output is muxed, this pin is set to low on reset (when UARTi.MDR1_REG[2:0] is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how UARTi.MDR1_REG is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	0
uarti_cts	I	Clear to send Active-low modem status signal. Reading the UARTi.MSR_REG[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.MSR_REG[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	0
uarti_rts	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.MCR_REG[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.MCR_REG[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	0

(1) I = Input, O = Output

14.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x mode (≤230.4K bits/s)
- UART 16x mode with autobauding (≥1200 bits/s and ≤115.2K bits/s)
- UART 13x mode (≥460.8K bits/s)

CAUTION

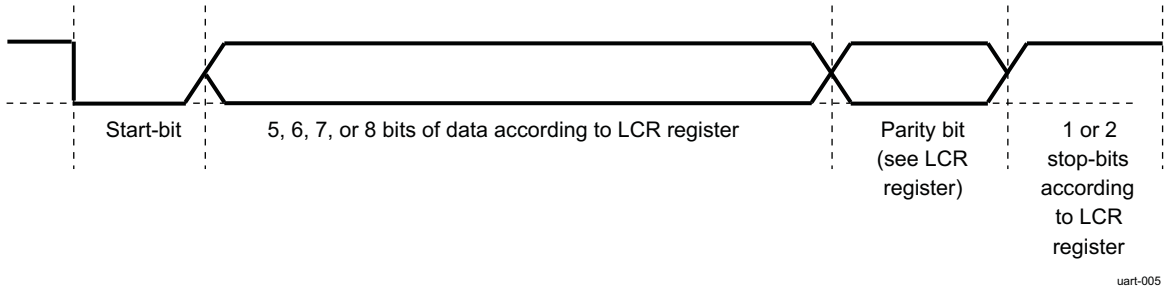
To be used as a UART, the operating mode must be programmed appropriately in the UARTi.MDR1_REG[2:0] MODE_SELECT field to select the UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 14-5 shows the UART frame data format.

Figure 14-5. UART Frame Data Format



14.2.5 IrDA Functional Interfaces

14.2.5.1 UART3 Interface Description

Table 14-4 describes the UART3 interface.

Table 14-4. UART3 I/O Description

Signal	I/O[1]	Description	Reset
IrDA Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

(1) I = Input, O = Output

14.2.5.2 IrDA Protocol and Data Format

14.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start bit, 8 data bits, and 1 stop bit, and is unaffected by the use and settings of the UART3.LCR_REG register.

The UART3.BLR_REG[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors, such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, and a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to find possible errors of the received frame.

NOTE: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG_REG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be either 1.6-us or 3/16th encoding, selected by the UART3.ACREG_REG[7] PULSE_TYPE bit. In 1.6-us encoding, the infrared pulse width is 1.6 µs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

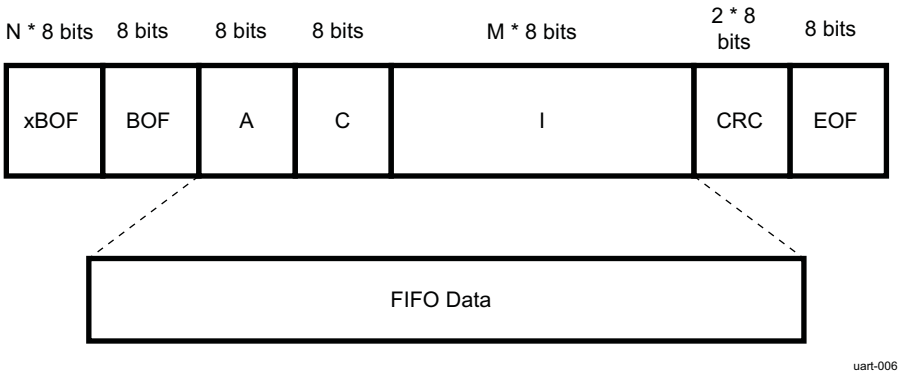
The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

NOTE: Reception supports variable-length stop-bits.

14.2.5.2.1.1 Frame Format

Figure 14-6 shows the IrDA SIR frame format.

Figure 14-6. IrDA SIR Frame Format



The CRC is applied on the address (A), control ©), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

14.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

- In reception:

  For the A, C, I, CRC field:

  – Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
  – If the byte is equal to the CE byte, discards the CE byte
  – Complements bit 5 of the byte following the CE
  – Sends the complemented byte to the CRC detector and stores it in the RX FIFO

14.2.5.2.1.3 Abort Sequence

The transmitter can decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

14.2.5.2.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6-µs pulse duration methods. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in transmit mode.

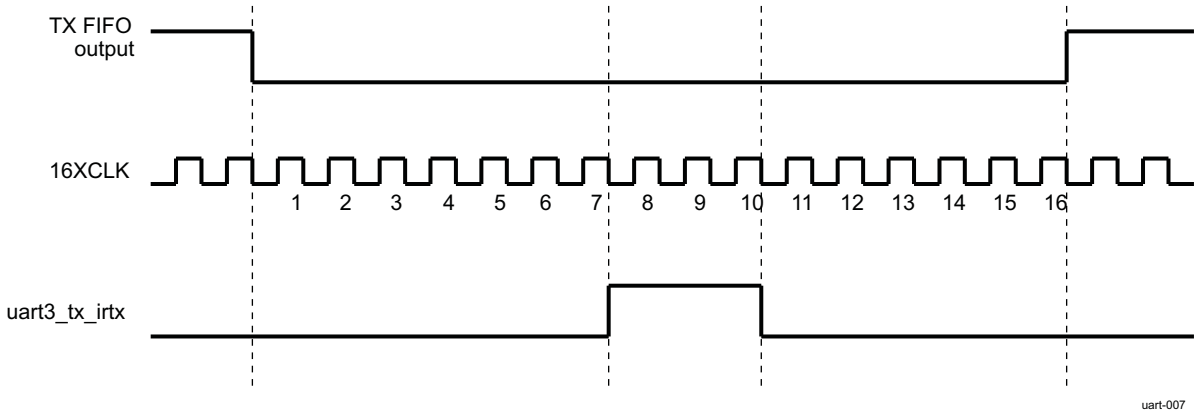
14.2.5.2.1.5 Encoder

Serial data from the transmit state-machine is encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_tx_irtx rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, uart3_tx_irtx falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 14-7 shows the IrDA SIR encoding mechanism.

Figure 14-7. IrDA SIR Encoding Mechanism

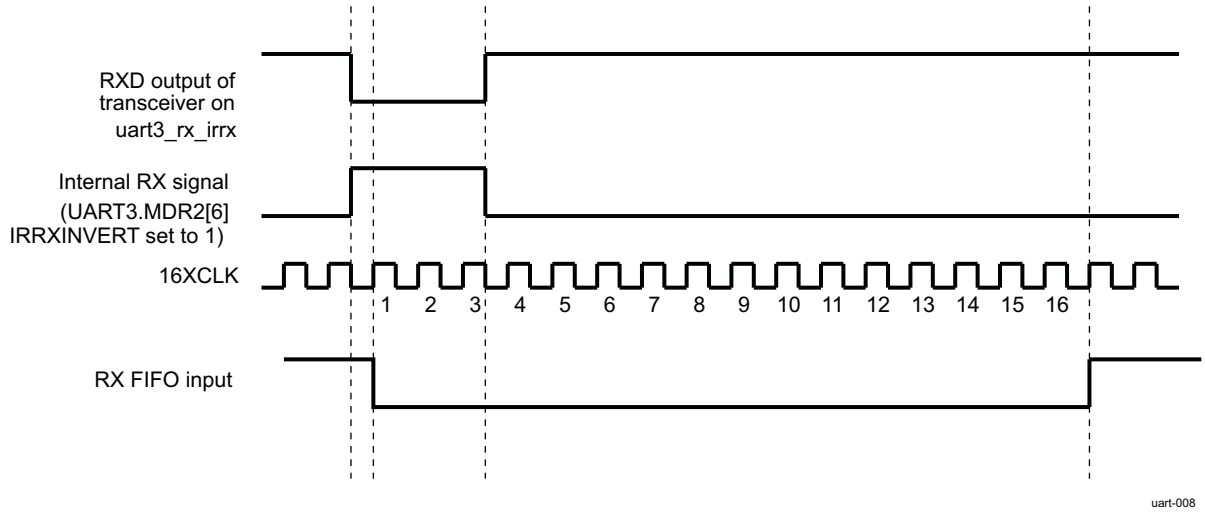


14.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 14-8 shows the IrDA SIR decoding mechanism.

Figure 14-8. IrDA SIR Decoding Mechanism



Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the uart3_rx_irrx input can be disabled using the UART3.ACREG_REG[5] DIS_IR_RX bit. Furthermore, the UART3.MDR2_REG[6] IRRXINVERT bit can invert the signal from the transceiver (RXD) pin to the IRRX logic inside the UART. This inversion is performed by default.

14.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting EFR_REG[1:0] (see Table 14-5), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the UART3.XON1_ADDR1_REG[7:0] field and the UART3.XON2_ADDR2_REG[7:0] field.

Table 14-5. EFR_REG[0-1] IR Address Checking Options

EFR_REG[1]	EFR_REG[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

14.2.5.2.2 SIR Free Format Mode

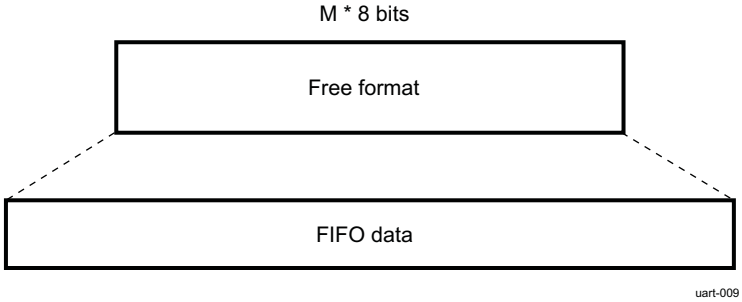
To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free format (FF) mode is a subfunction of the existing SIR mode; all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 14-9 shows the SIR free format mode.

Figure 14-9. SIR Free Format Mode

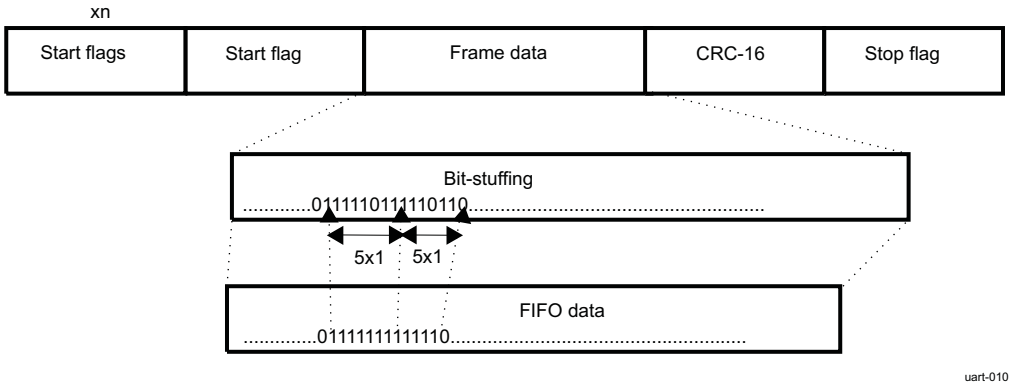


In the SIR free format mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

14.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152M bits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag (see Figure 14-10).

Figure 14-10. MIR Transmit Frame Format



On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

Contrary to SIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for both start and stop flags (unambiguously, not data, because of bit-stuffing).
- Abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit stuffing).
- Back-to-back frames are allowed with three or more stop flags in between. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

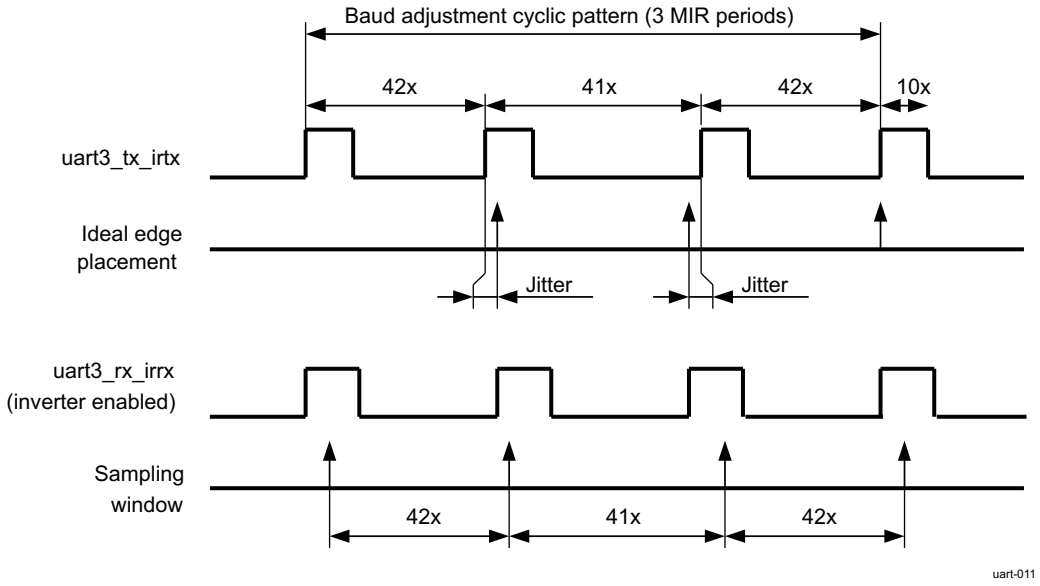
14.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of +/–0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 14-11 shows the MIR baud rate adjustment mechanism.

Figure 14-11. MIR Baud Rate Adjustment Mechanism

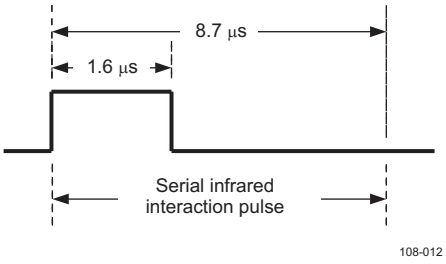


14.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

Figure 14-12 shows the SIP.

Figure 14-12. SIP



14.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4M bits/s. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Table 14-6 shows the FIR transmit frame format.

Table 14-6. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 14-7) and generates the SIP (see Section 14.2.5.2.3.2, *SIP Generation*).

Table 14-7. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 14-7 are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 14-8).

Table 14-8. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start Flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop Flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted the LSBs of each byte first (see Table 14-9).

Table 14-9. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

14.2.6 CIR Functional Interfaces

14.2.6.1 CIR Interface Description

Table 14-10 describes the CIR interface.

Table 14-10. CIR I/O Description

Signal	I/O[1]	Description	Reset
CIR Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit.	1

(1) I = Input, O = Output

14.2.6.2 CIR Protocol and Data Format

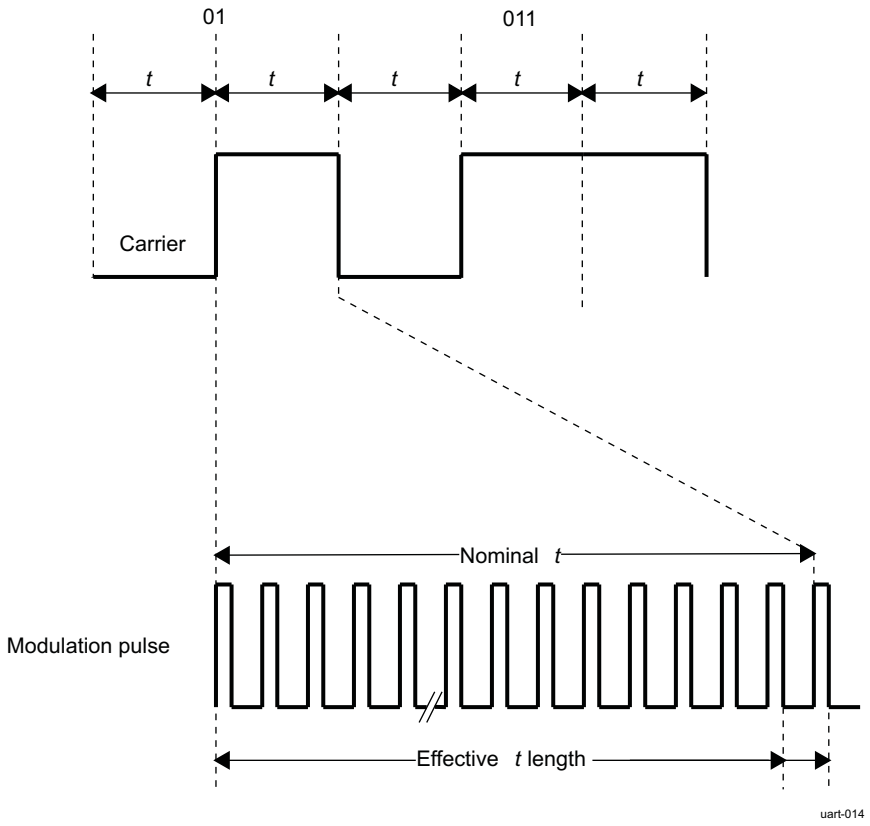
In the CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic transmits data packets based on the user-defined frame structure and packet content.

14.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 14-13).

Figure 14-13. CIR Pulse Modulation

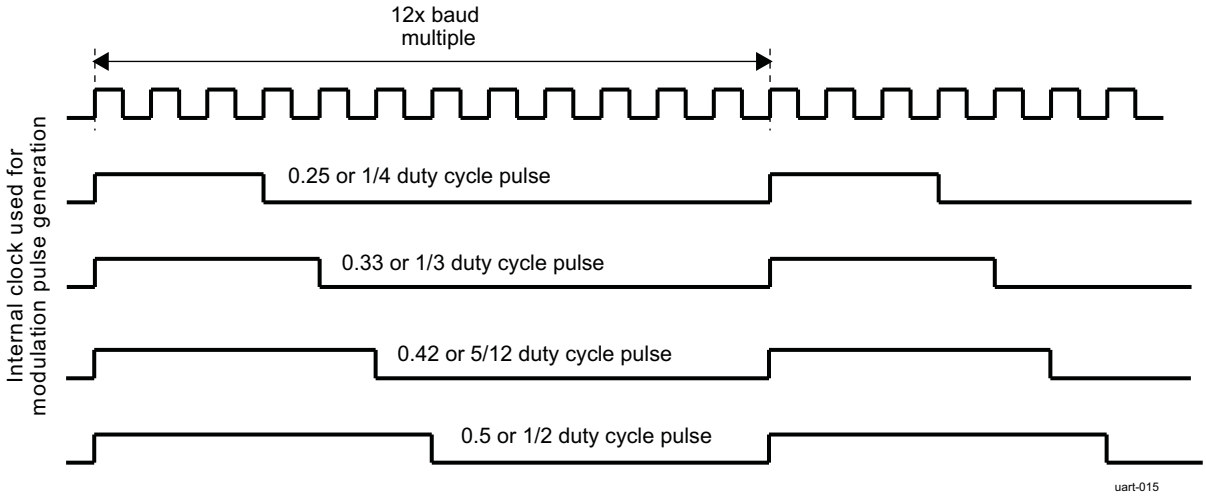


14.2.6.2.2 Pulse Duty Cycle

The programmer can choose between four possible duty cycles for modulation pulses by setting the appropriate value in the UART3.MDR2_REG[5:4] CIR_PULSE_MODE field (1/4, 1/3, 5/12, or ½).

Figure 14-14 shows the CIR modulation duty cycles.

Figure 14-14. CIR Modulation Duty Cycle



The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end needs it.

14.2.6.2.3 Consumer IR Encoding/Decoding

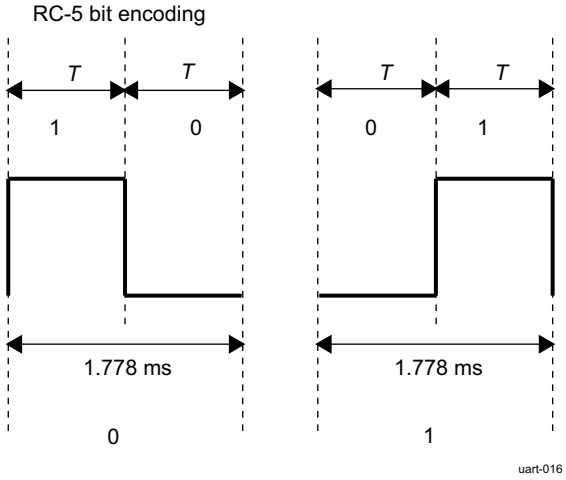
There are two methods of encoding for remote control applications. The first method uses time-extended bit forms (a variable pulse distance, or duration, in which the difference between a logic 1 and logic 0 is the length of the pulse width).

The second encoding method uses a biphase in which the encoding of the logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively. Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which the TX FIFO is transmitted as a modulated pulse with duration T.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 14-15.).

Figure 14-15. RC-5 Bit Encoding

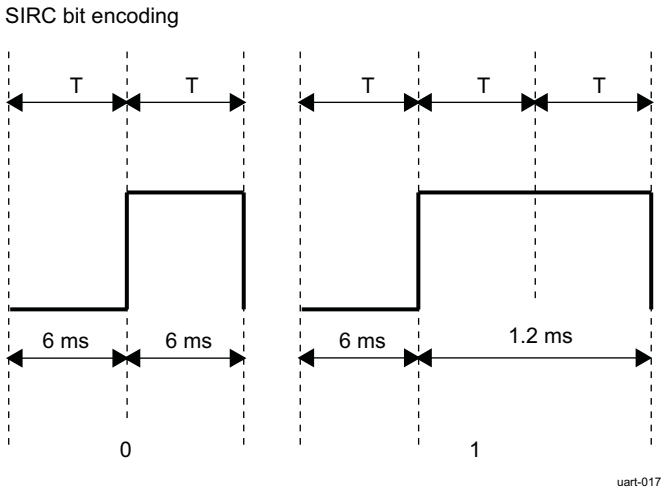


Because the CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (that is, multiples of T) is the method used to distinguish between 1 and 0. The following SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 14-16 shows SIRC bit encoding.

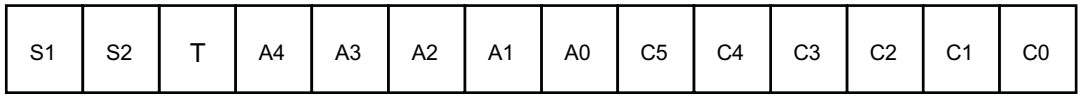
Figure 14-16. SIRC Bit Encoding



To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 14-17 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 14-17. RC-5 Standard Packet Format



Where:

S1, S2:	Start bits (always 1)
T:	Toggle bit
A4..A0:	Address (or system) bits
C5..C0:	Command bits

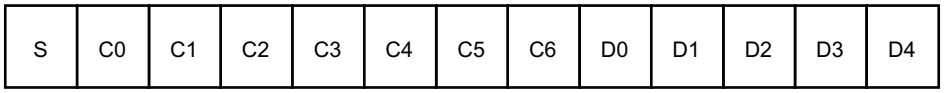
The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits inside the standard frame length varies.

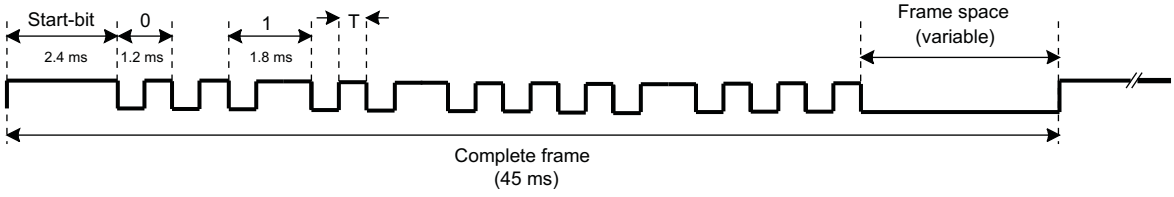
Figure 14-18 shows the packet format and bit encoding. As Figure 14-19 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 14-18. SIRC Packet Format



NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 14-19. SIRC Bit Transmission Example

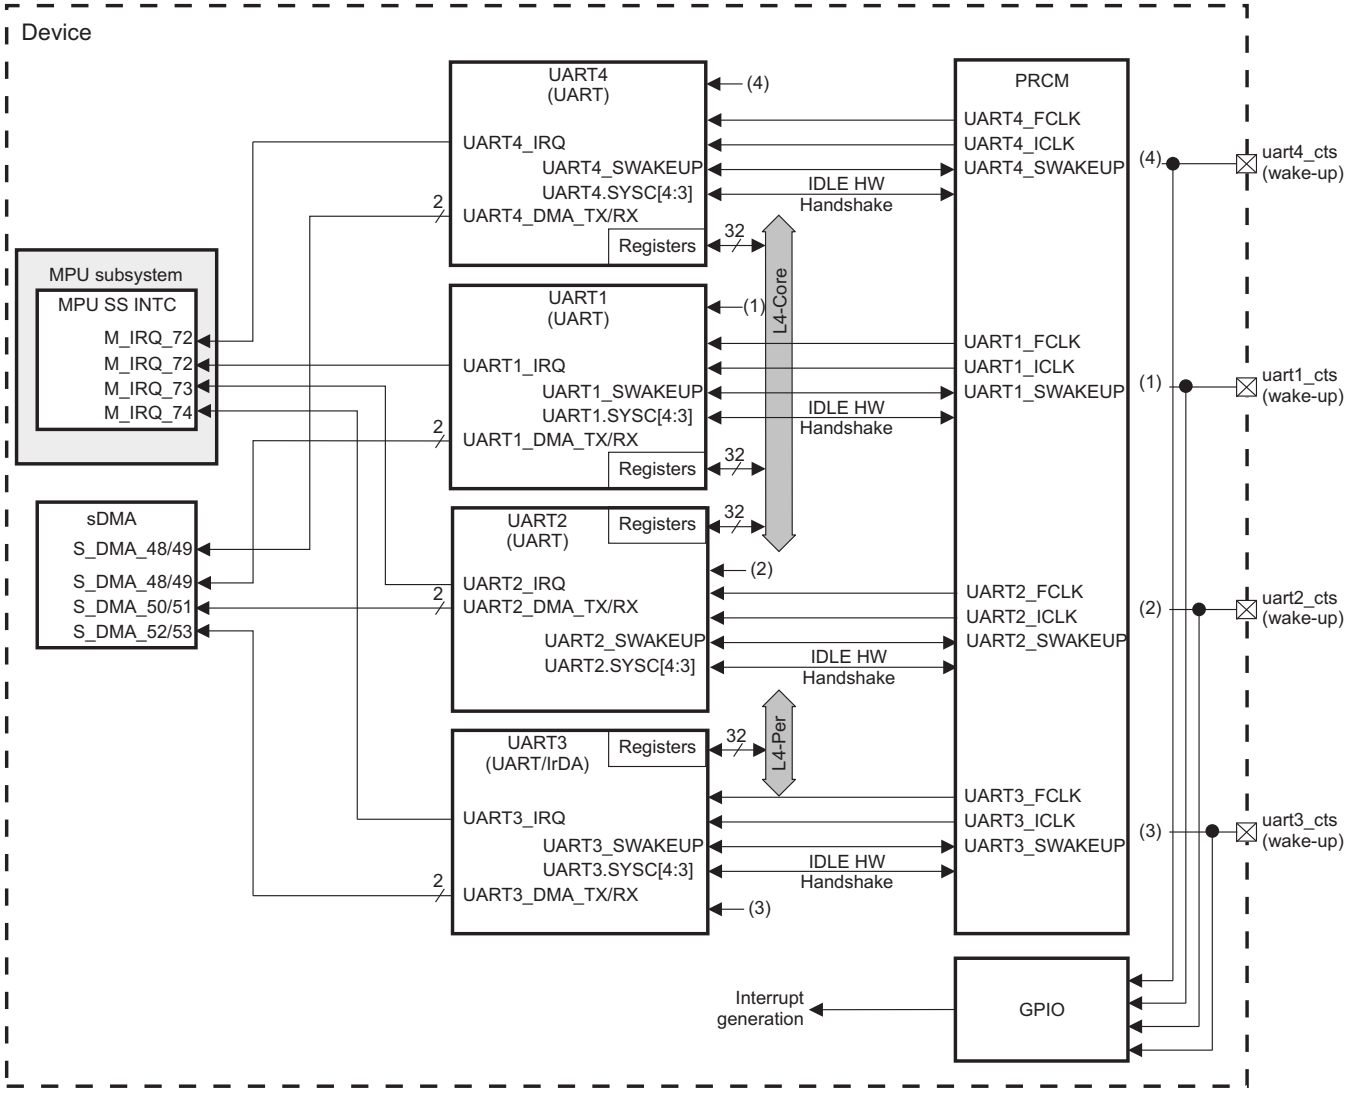


This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

14.3 UART/IrDA/CIR Integration

Figure 14-20 shows the internal connections with related modules for UART functions.

Figure 14-20. UART Functional Integration



14.3.1 Clocking, Reset, and Power-Management Scheme

14.3.1.1 Clocking

Each UART uses a 48-MHz functional clock for its logic and the generation of external interface signals. Each UART uses an interface clock for register accesses. The power, reset, and clock management (PRCM) module generates and controls all these clocks (for more information, see the *Power, Reset, and Clock Management* chapter).

Table 14-11 describes the UART clocks.

Table 14-11. UART Clocks

Clock Type	Frequency	Name	Comments
UART1			
Functional clock	CORE_48M_FCLK	UART1_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[13] EN_UART1 bit.
Interface clock	CORE_L4_ICLK	UART1_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[13] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[13] AUTO_UART1 bit.
UART2			
Functional clock	CORE_48M_FCLK	UART2_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[14] EN_UART2 bit.
Interface clock	CORE_L4_ICLK	UART2_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM. CM_ICLKEN1_CORE[14] EN_UART2 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_ CORE[14] AUTO_UART2 bit.
UART3			
Functional clock	PER_48M_FCLK	UART3_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[11] EN_UART3 bit.
Interface clock	PER_L4_ICLK	UART3_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM. CM_ICLKEN_PER[11] EN_UART3 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_ PER[11] AUTO_UART3 bit.
UART4			
Functional clock	CORE_48M_FCLK	UART4_FCLK	Source and gating is the PRCM module. Enable/disable this clock with the PRMC.CM_FCLKEN1_CORE[23] EN_UART4 bit.
Interface clock	CORE_L4_ICLK	UART4_ICLK	Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[23] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[23] AUTO_UART1 bit.

The idle and wake-up processes use a handshake protocol between the PRCM module and the UARTs (for a description of the protocol, see the *Power, Reset, and Clock Management* chapter). The UARTi.SYSC_REG[4:3] IDLEMODE field controls the UART idle mode.

14.3.1.2 Hardware Reset

Table 14-12 lists the UART reset domain.

Table 14-12. Reset Domain

Peripherals	Reset Domain
UART1	CORE_RST
UART2	CORE_RST
UART3	PER_RST
UART4	CORE_RST

14.3.1.3 Software Reset

The UARTi.SYSC_REG[1] SOFTRESET bit controls the software reset; writing 1 to this bit triggers a software-reset functionally equivalent to hardware reset.

14.3.2 Hardware Requests

14.3.2.1 Interrupts

Table 14-13 describes the UART interrupt mappings.

Table 14-13. Interrupt Mapping to MPU Subsystem

IRQ	Source	Description
M_IRQ_72	UART1_IRQ	UART module 1 interrupt to MPU
M_IRQ_73	UART2_IRQ	UART module 2 interrupt to MPU
M_IRQ_74	UART3_IRQ	UART module 3 interrupt to MPU
M_IRQ_84	UART4_IRQ	UART module 4 interrupt to MPU

14.3.2.2 DMA Requests

Table 14-14 describes the UART DMA requests.

Table 14-14. UART DMA Requests to System DMA

DMA[1]	Source	Description
S_DMA_48	UART1_DMA_TX	UART module 1 transmit request
S_DMA_49	UART1_DMA_RX	UART module 1 receive request
S_DMA_50	UART2_DMA_TX	UART module 2 transmit request
S_DMA_51	UART2_DMA_RX	UART module 2 receive request
S_DMA_52	UART3_DMA_TX	UART module 3 transmit request
S_DMA_53	UART3_DMA_RX	UART module 3 receive request
S_DMA_54	UART4_DMA_TX	UART module 4 transmit request
S_DMA_55	UART4_DMA_RX	UART module 4 receive request

(1) This table assumes that DMA mode 1 is used.

14.3.2.3 Wake-up Request

The UART can wake up the system on different events (see Section 14.6, *UART/IrDA/CIR Registers*).

One important wake-up generation is event detection on the uarti_cts pin when the system is idle. The uarti_cts pin uses an asynchronous path to transmit the wake-up request to the system (PRCM), which enables wake-up capabilities to be active even if all module clocks are off (see Table 14-15).

Table 14-15. Wake-Up Requests from PRCM

Wake-Up Pin	PRCM Input	Description
uart1_cts	UART1_SWAKEUP	Wake UART1 (system wake-up capabilities)
uart2_cts	UART2_SWAKEUP	Wake UART2 (system wake-up capabilities)
uart3_cts	UART3_SWAKEUP	Wake UART3 (system wake-up capabilities)

CAUTION

UARTs are not in the WAKEUP power domain, which implies limitations on wake-up capability. If the CORE power domain is off, UART1 and UART2 cannot wake up the system, because power is not supplied. If the PER power domain is off, UART3 cannot wake up the system, because power is not supplied. In these cases, a GPIO multiplexed on the uarti_cts pin can be used to capture the event and wake up the system. Software must enable this strategy, if required. See the *General-Purpose Interface* chapter for a full description of this mechanism.

14.4 UART/IrDA/CIR Functional Description

14.4.1 UART/IrDA/CIR Block Description

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two mode selections:

- Function mode selection: Route the data to the chosen functionality (UART, IrDA, or CIR) and enable the mechanism corresponding to the chosen functionality.
- Register mode selection, which enables conditional access to registers

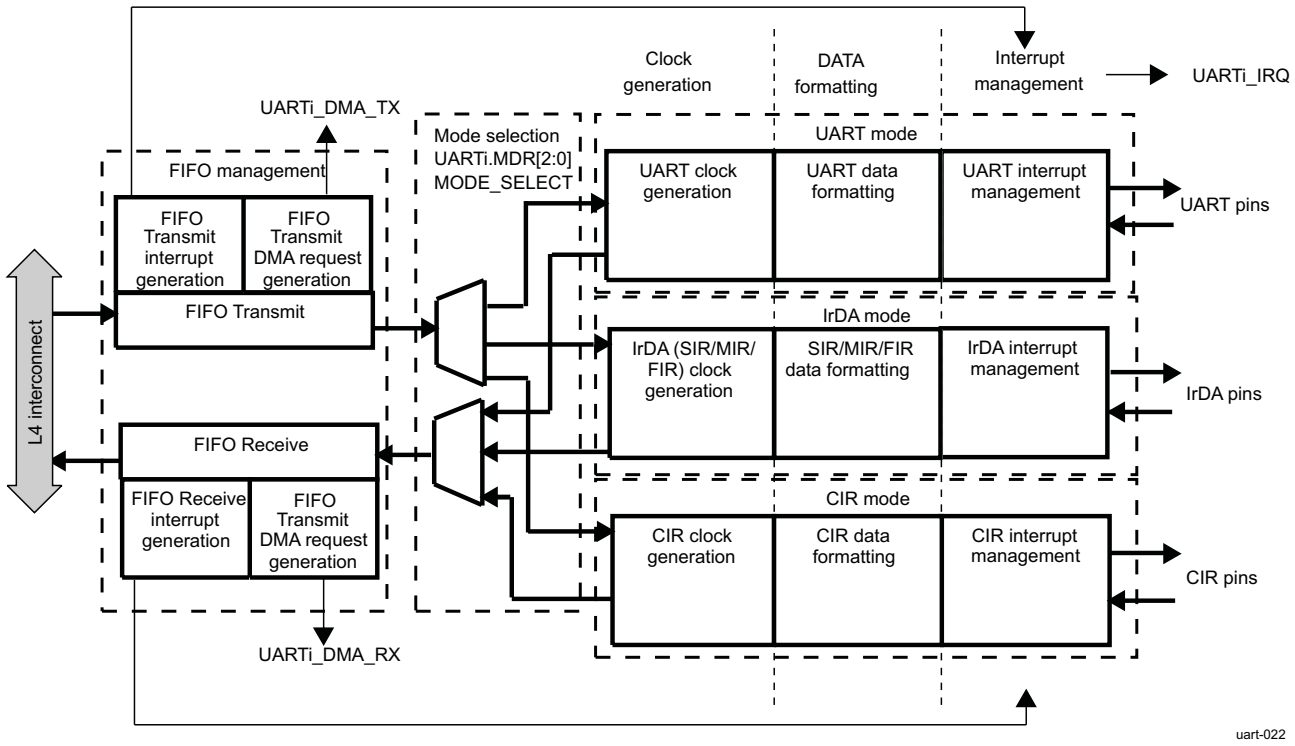
Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine, which assumes the transition between FIFO data and frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 14-21 is the UART/IrDA/CIR block diagram.

Figure 14-21. UART/IrDA/CIR Block Diagram



14.4.2 FIFO Management

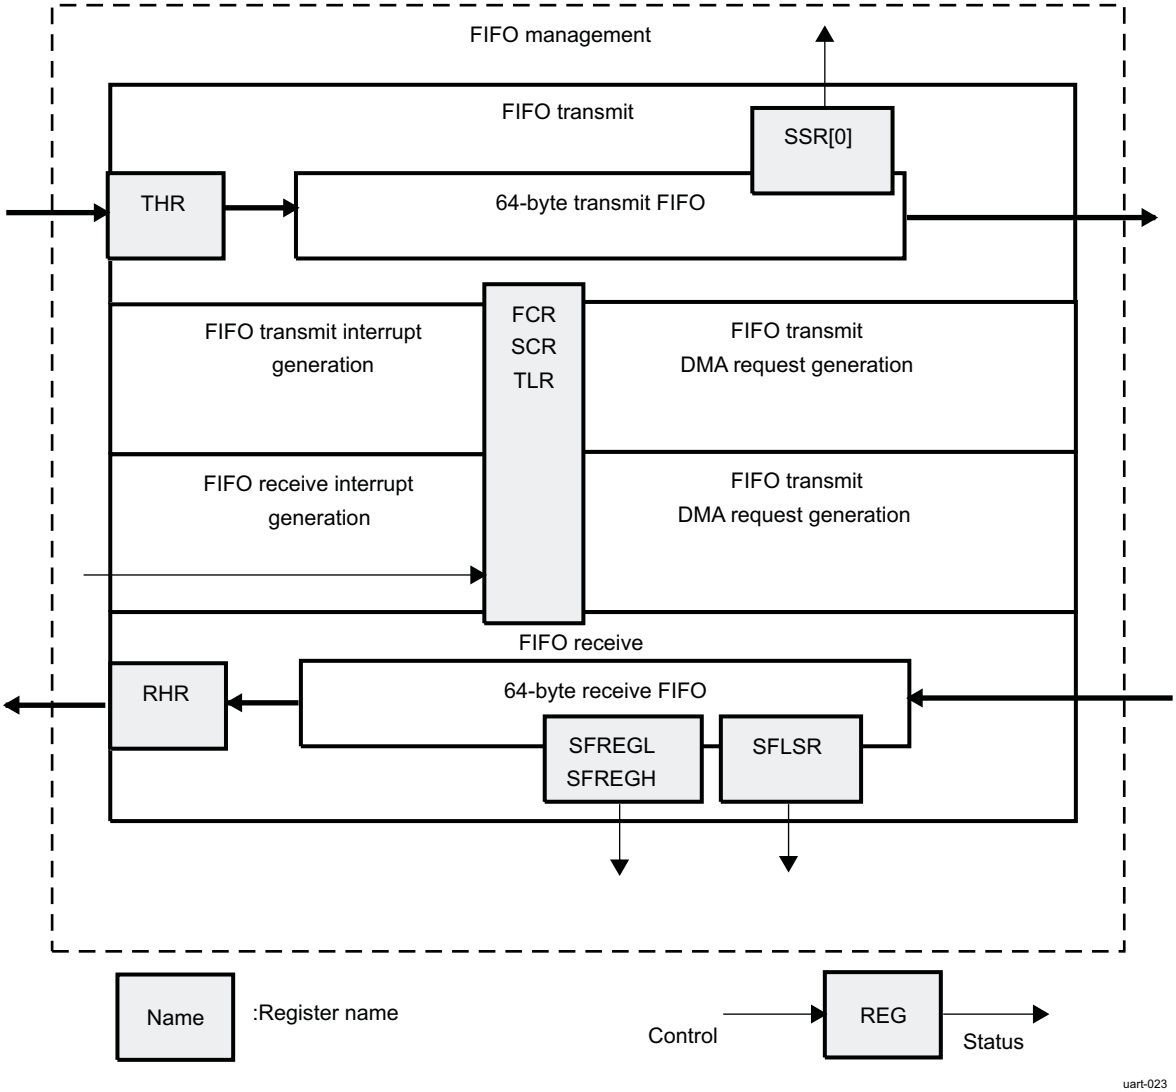
The FIFO is accessed by reading/writing the UARTi.RHR_REG and UARTi.THR_REG registers. Parameters are controlled using the FIFO control register (UARTi.FCR_REG) and supplementary control register (UARTi.SCR_REG). Reading the UARTi.SSR_REG[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.TLR_REG register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. Figure 14-22 shows the FIFO management registers.

NOTE: Data in the UARTi.RHR_REG register is not overwritten when an overflow occurs.

NOTE: The UARTi.SFLSR_REG, UARTi.SFREGL_REG, and UARTi.SFREGH_REG status registers are used in IrDA mode only. For use, see Section 14.4.4.2.3, *IrDA Data Formatting*.

Figure 14-22. FIFO Management Registers



14.4.2.1 FIFO Trigger

14.4.2.1.1 Transmit FIFO Trigger

Table 14-16 summarizes the transmit FIFO trigger level settings.

Table 14-16. TX FIFO Trigger Level Setting Summary

SCR_REG[6]	TLR_REG[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field (8,16, 32, or 56 spaces)
0	≠ 0x0	Defined by the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

14.4.2.1.2 Receive FIFO Trigger

Table 14-17 summarizes the receive FIFO trigger level settings.

Table 14-17. RX FIFO Trigger Level Setting Summary

SCR_REG[7]	TLR_REG[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field (8,16, 56, or 60 characters)
0	≠ 0x0	Defined by UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character). **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START and UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT fields.

- Trigger levels from 0 to 60 bytes are available with a granularity of four. (Trigger level = 4 x [4-bit register value])
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.
- In the FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the receive FIFO trigger level (either the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field); otherwise, FIFO operation stalls. In the FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

14.4.2.2 FIFO Interrupt Mode

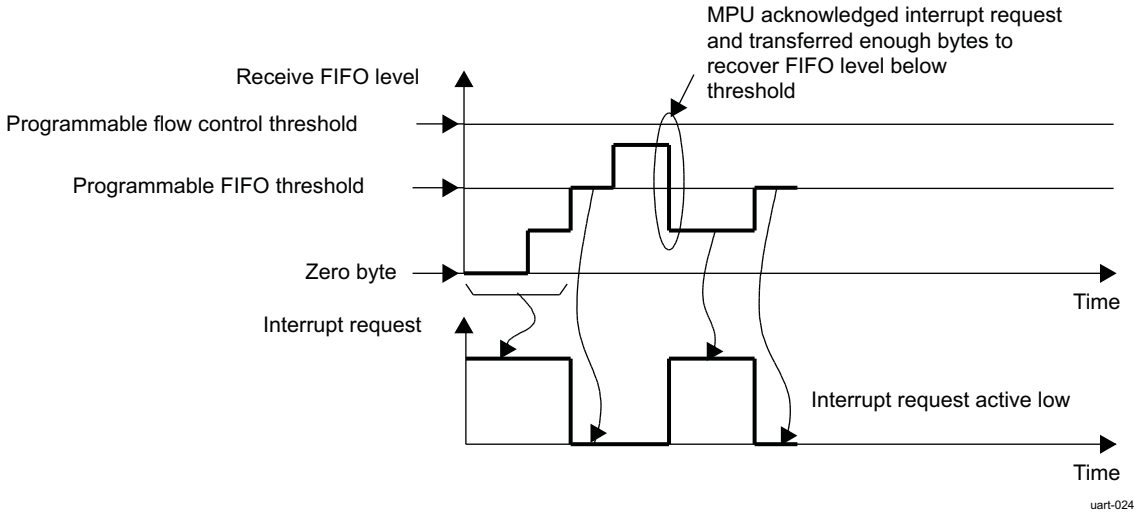
In the FIFO interrupt mode (the FIFO control register UARTi.FCR_REG[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.IER_REG register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (the UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA and UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA fields or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG and UARTi.FCR_REG[5:4] TX_FIFO_TRIG fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode).

When the UART flow control is enabled with the interrupt capabilities, the UART flow control FIFO threshold (UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field) must be greater than or equal to the receive FIFO threshold.

Figure 14-23 shows the generation of the receive FIFO interrupt request.

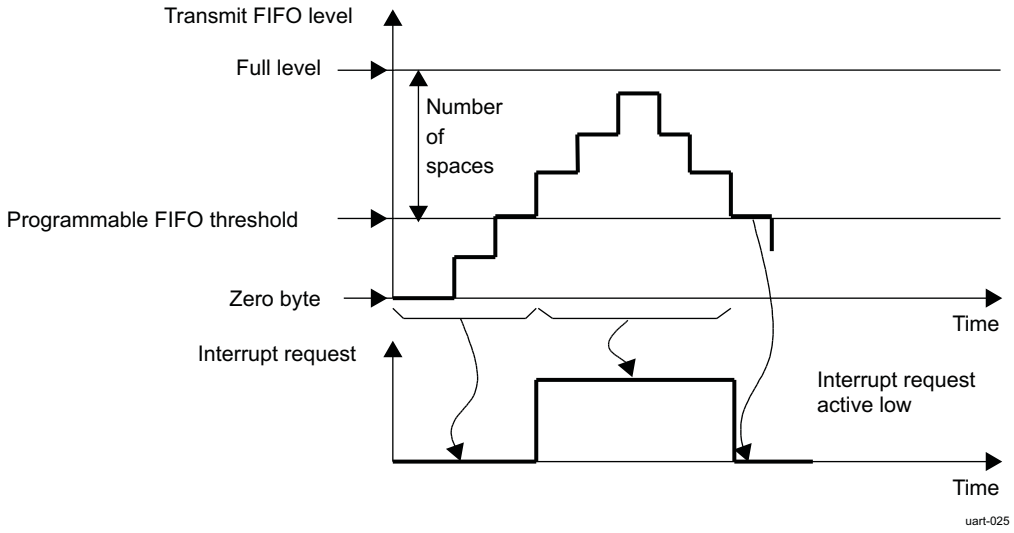
Figure 14-23. Receive FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 14-24 shows the generation of the transmit FIFO interrupt request.

Figure 14-24. Transmit FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

14.4.2.3 FIFO Polled Mode Operation

In the FIFO polled mode (the UARTi.FCR_REG[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.IER_REG register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.LSR_REG).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

14.4.2.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in Table 14-14 assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

The DMA requests in mode 2 and mode 3 use S_DMA_48, S_DMA_50, and S_DMA_52/D_DMA_10. S_DMA_49, S_DMA_51, and S_DMA_53/D_DMA_11 are not used by the module in mode 2 and mode 3 and can be selected as follows:

- When the UARTi.SCR_REG[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.FCR_REG[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the DMA_MODE bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.FCR_REG[2:1] DMA_MODE_2 field determines DMA mode 0 to 3 based on the supplementary control register (SCR_REG) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set either the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 01. (The DMA_MODE bit is discarded.)

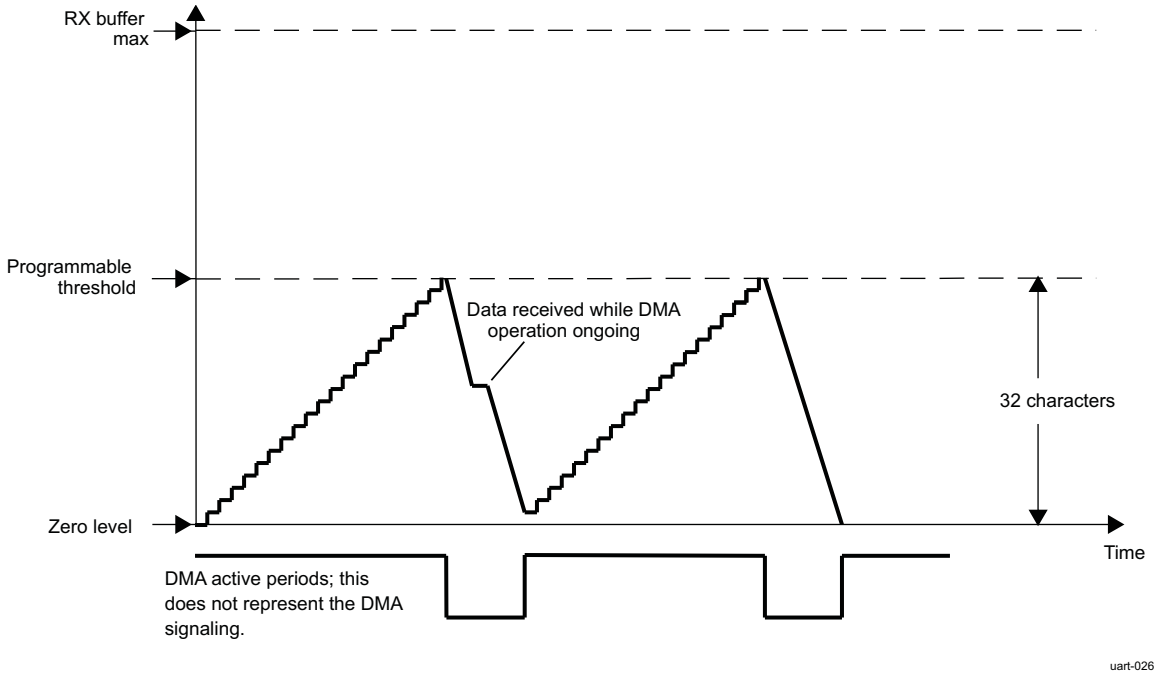
If the FIFOs are disabled (the UARTi.FCR_REG[0] FIFO_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

14.4.2.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 14-25 through Figure 14-28 show the supported DMA operations.

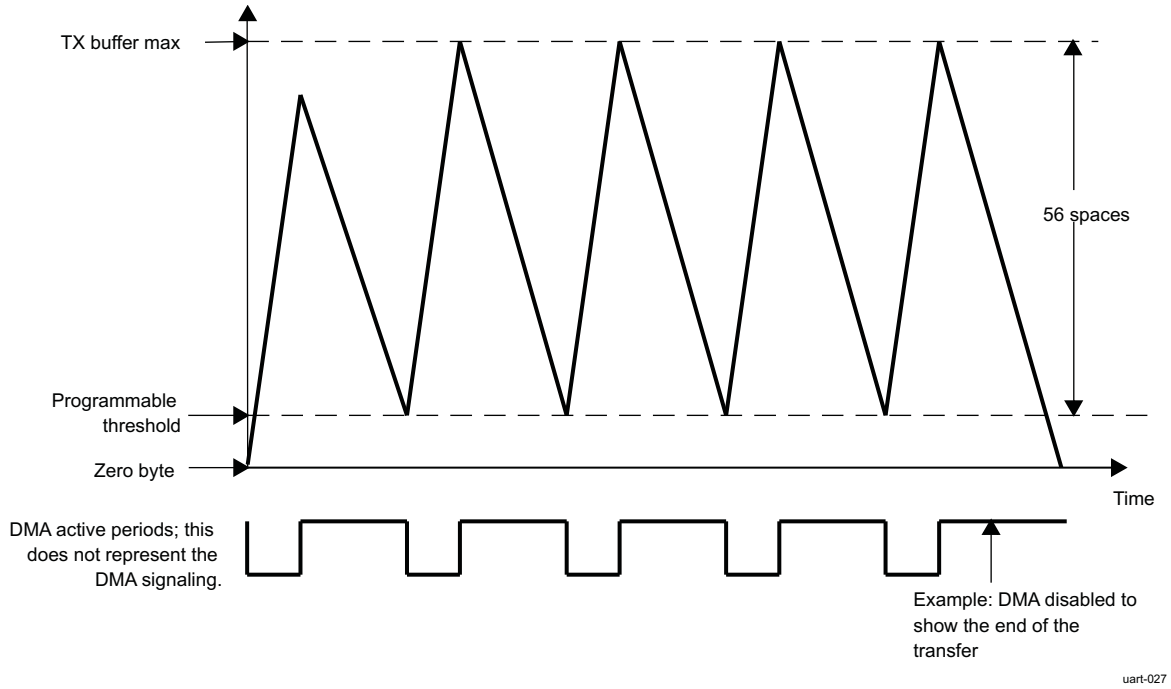
Figure 14-25. Receive FIFO DMA Request Generation (32 Characters)



In receive mode, a DMA request is generated when the receive FIFO reaches its threshold level defined in the trigger level register (UARTi.TLR_REG). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UARTi.TLR_REG) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 14-26. Transmit FIFO DMA Request Generation (56 Spaces)



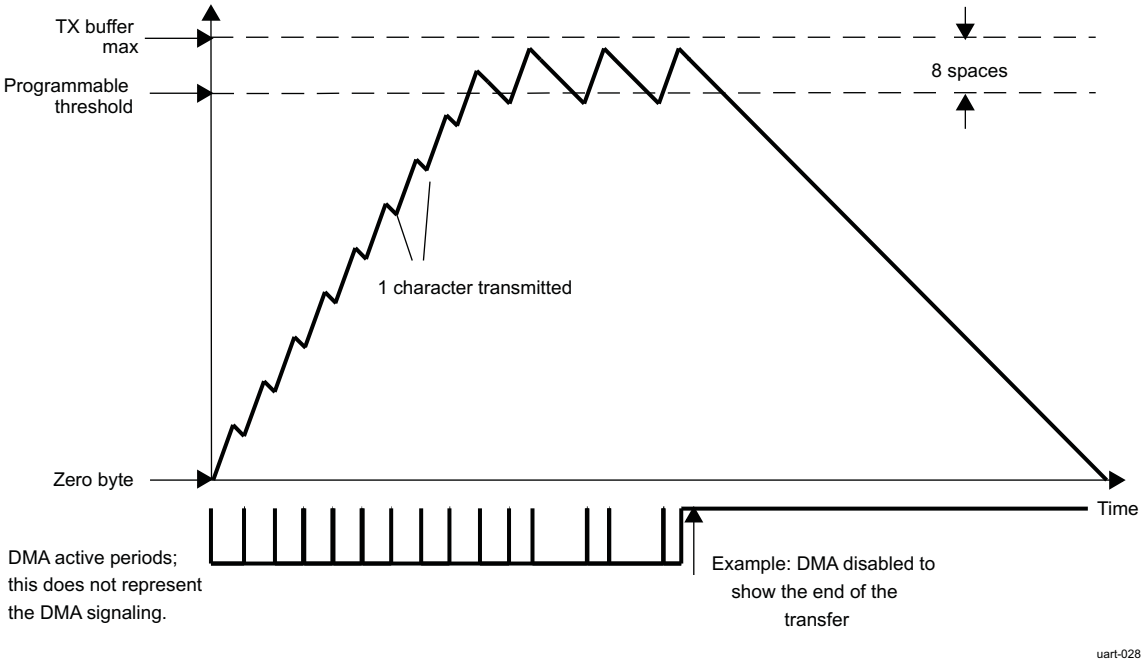
The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.TLR_REG register.

The threshold can be programmed in a number of ways. Figure 14-26 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field or the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field concatenated with the TX_FIFO_TRIG field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

Figure 14-27 shows an example with eight spaces to show the buffer level crossing the space threshold. Again, the local host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

Figure 14-27. Transmit FIFO DMA Request Generation (8 Spaces)

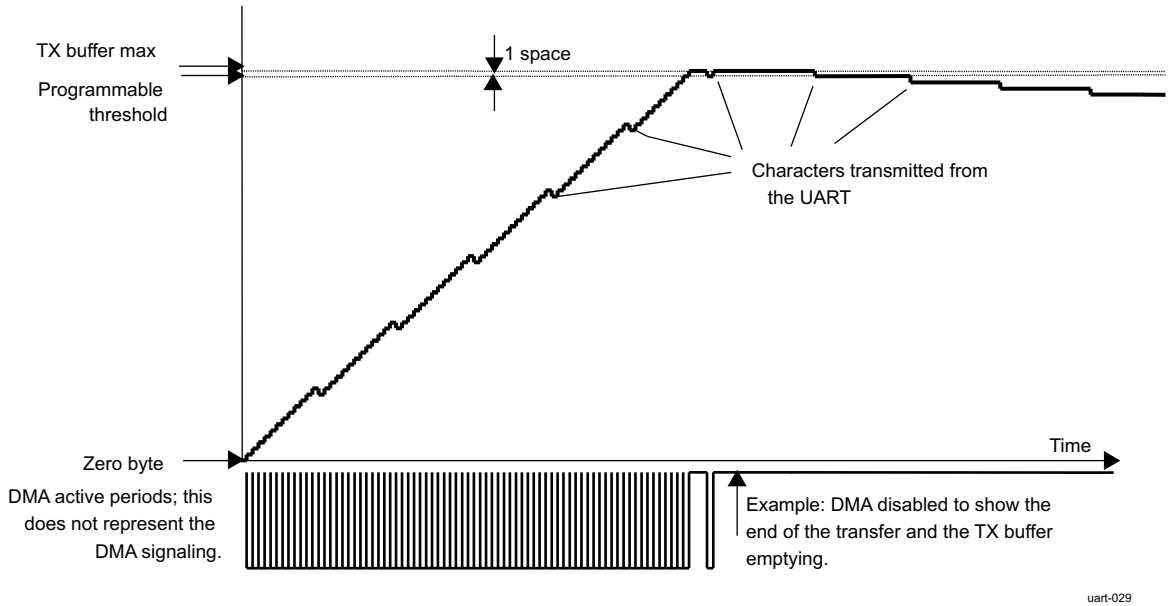


The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 14-28). The buffer is filled at a faster rate than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.DLL_REG and the UARTi.DLH_REG registers.

Again, the DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

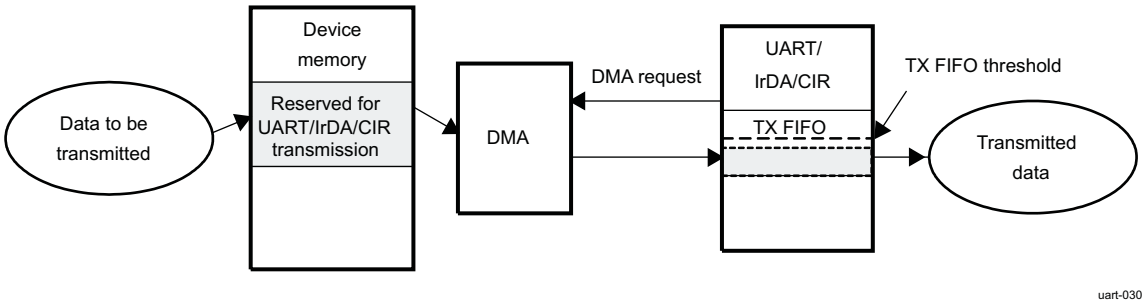
Figure 14-28. Transmit FIFO DMA Request Generation (1 Space)



14.4.2.4.2 DMA Transmission

Figure 14-29 shows the DMA transmission process.

Figure 14-29. Transmission Process



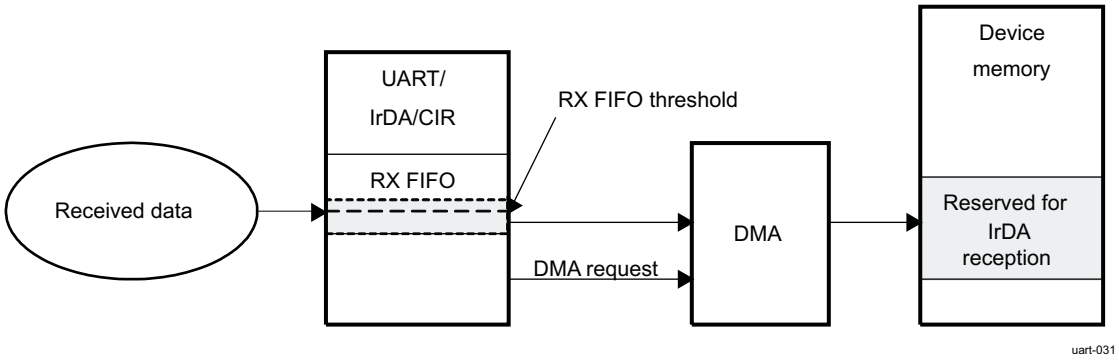
- Data to be transmitted are put in the device's memory reserved for UART/IrDA/CIR transmission by the DMA:
  - Until the TX FIFO trigger level is not reached, a DMA request is generated.
  - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR_REG empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR_REG register empties.

14.4.2.4.3 DMA Reception

Figure 14-30 shows the DMA reception process.

Figure 14-30. Reception Process



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
   - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

14.4.3 Mode Selection

14.4.3.1 Register Access Modes

14.4.3.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Both configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only in the initialization step or reconfiguration of the module.

The value of the UARTi.LCR_REG register determines the register access mode (see Table 14-18).

Table 14-18. UART/IrDA/CIR Register Access Mode Programming (Using LCR_REG)

Mode	Condition
Configuration_mode_A	LCR_REG[7] = 0x1 and LCR_REG[7:0]! = 0xBF
Configuration_mode_B	LCR_REG[7] = 0x1 and LCR_REG[7:0] = 0xBF
Operational_mode	LCR_REG[7] = 0x0

14.4.3.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional to the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Section 14.6, *UART/IrDA/CIR Registers*.

Table 14-19 through Table 14-21 summarize the register access submodes.

Table 14-19. Sub-Configuration_Mode_A Mode Summary

Mode	Condition
MSR_SPR	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

Table 14-20. Sub-Configuration_Mode_B Mode Summary

Mode	Condition
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1
XOFF	(EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)

Table 14-21. Sub-Operational_Mode Mode Summary

Mode	Condition
MSR_SPR	EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0)
TCR_TLR	EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1

14.4.3.1.3 Registers Available for the Register Access Modes

Table 14-22 lists the names of the register hits in each access register mode. Gray-shaded registers do not depend on the register access mode (available in all modes).

Table 14-22. UART/IrDA/CIR Register Access Mode Overview

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write
0x000	DLL_REG	DLL_REG	DLL_REG	DLL_REG	RHR_REG	THR_REG
0x004	DLH_REG	DLH_REG	DLH_REG	DLH_REG	IER_REG	IER_REG
0x008	IIR_REG	FCR_REG	EFR_REG	EFR_REG	IIR_REG	FCR_REG

(1) if MSR_SPR mode is active (see Section 14.4.3.1.2, *Register Access Submode*)
(2) if TCR_TLR mode is active (see Section 14.4.3.1.2, *Register Access Submode*)
(3) if XOFF mode is active (see Section 14.4.3.1.2, *Register Access Submode*)

14.4.3.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.MDR1_REG[2:0] MODE_SELECT field (see Table 14-23).

Table 14-23. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see Section 14.4.3.1, *Register Access Modes*).

14.4.3.2.1 Registers Available for the UART Function

Only the registers listed in Table 14-24 are used for the UART function.

Table 14-24. UART Mode Register Overview(1) (2)

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write
0x000	DLL_REG	DLL_REG	DLL_REG	DLL_REG	RHR_REG	THR_REG

(2) REGISTER_NAME[m:n] notation indicates that only register bits numbered m to n apply to the UART function.

14.4.4 Protocol Formatting

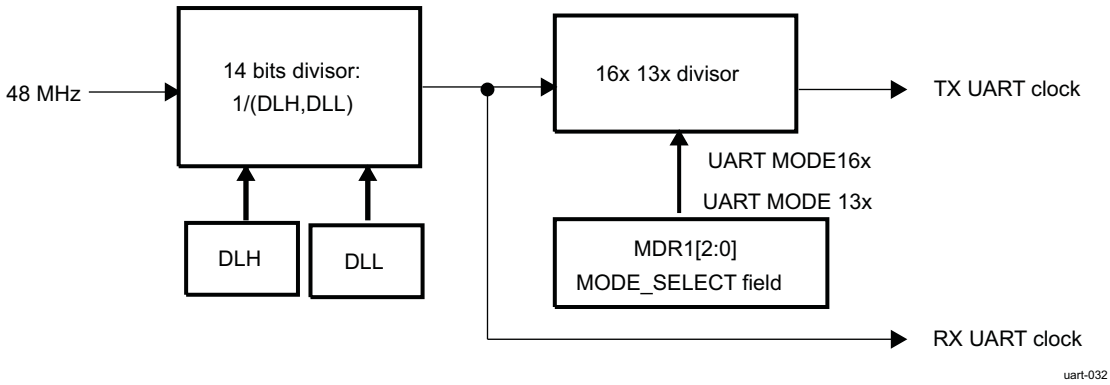
14.4.4.1 UART Mode

14.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 14-31 shows the baud rate generator and associated controls.

Figure 14-31. Baud Rate Generation



CAUTION

It is mandatory that MODE_SELECT = DISABLE (UARTi.MDR1_REG[2:0] = 0x7) before initializing or modifying clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG). Failure to observe this rule can result in unpredictable module behavior.

14.4.4.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 14-27 describes the UART baud rate settings.

Table 14-27. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	0x27, 0x10	0.3 Kbps	0
0.6 Kbps	16x	5000	0x13, 0x88	0.6 Kbps	0
1.2 Kbps	16x	2500	0x09, 0xC4	1.2 Kbps	0
2.4 Kbps	16x	1250	0x04, 0xE2	2.4 Kbps	0
4.8 Kbps	16x	625	0x02, 0x71	4.8 Kbps	0
9.6 Kbps	16x	312	0x01, 0x38	9.6153 Kbps	+0.16
14.4 Kbps	16x	208	0x00, 0xD0	14.423 Kbps	+0.16
19.2 Kbps	16x	156	0x00, 0x9C	19.231 Kbps	+0.16
28.8 Kbps	16x	104	0x00, 0x68	28.846 Kbps	+0.16
38.4 Kbps	16x	78	0x00, 0x4E	38.462 Kbps	+0.16
57.6 Kbps	16x	52	0x00, 0x34	57.692 Kbps	+0.16
115.2 Kbps	16x	26	0x00, 0x1A	115.38 Kbps	+0.16

Table 14-27. UART Baud Rate Settings (48-MHz Clock) (continued)

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
230.4 Kbps	16x	13	0x00, 0x0D	230.77 Kbps	+0.16
460.8 Kbps	13x	8	0x00, 0x08	461.54 Kbps	+0.16
921.6 Kbps	13x	4	0x00, 0x04	923.08 Kbps	+0.16
1.843 Mbps	13x	2	0x00, 0x02	1.846 Mbps	+0.16
3.6884 Mbps	13x	1	0x00, 0x01	3.6923 Mbps	+0.16

14.4.4.1.3 UART Data Formatting

The UART module can use hardware flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART module is enhanced with the autobauding function. In control mode, autobauding allows the speed, the number of bits per character, and the parity selected to be set automatically.

14.4.4.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.LCR_REG register.

Character length is specified using the UARTi.LCR_REG[1:0] CHAR_LENGTH field.

The number of stop bits is specified using the UARTi.LCR_REG[2] NB_STOP register bit.

The parity bit is programmed using the UARTi.LCR_REG[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 register bits (see Table 14-28).

Table 14-28. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE1	PARITY_TYPE2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

14.4.4.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming the UARTi.EFR_REG[7:6] AUTO_CTS_EN and AUTO_RTS_EN bits, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.TCR_REG register determine the levels at which uarti_rts is activated/deactivated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

- **Auto-RTS**

  Auto-RTS data flow control originates in the receiver block. The receiver FIFO trigger levels used in auto-RTS are stored in the UARTi.TCR_REG register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field. When the receiver FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) might send an additional byte after the trigger level is reached because it might not recognize the deassertion of RTS until it begins sending the additional byte.

uarti_rts is automatically reasserted when the receiver FIFO reaches the RESUME trigger level programmed by the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field. This reassertion requests the sending device to resume transmission.

In this case, uarti_rts is an active-low signal.

- **Auto-CTS**

  The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_cts is an active-low signal.

14.4.4.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.EFR_REG) and the modem control register (UARTi.MCR_REG). Different combinations of software flow control can be enabled by setting different combinations of UARTi.EFR_REG[3:0] (see Table 14-29).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.MCR_REG[5]): Operation resumes after receiving any character after recognition of the XOFF character.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.EFR_REG[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.IIR_REG[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.IIR_REG. The special character is transferred to the RX FIFO.

Table 14-29. EFR_REG[0-3] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	Tx, Rx Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2 (1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2 (1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.XON1_ADDR1_REG[7:0] XON_WORD1 field, XON2 is defined in UARTi.XON2_ADDR2_REG[7:0] XON_WORD2.
XOFF1 is defined in the UARTi.XOFF1_REG[7:0] XOFF_WORD1 field, XOFF2 is defined in UARTi.XOFF2_REG[7:0] XOFF_WORD2.

14.4.4.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character is complete. XOFF detection also sets UARTi.IIR_REG[4] (if enabled by UARTi.IER_REG[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, UARTi.IIR_REG[4] is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.EFR_REG[1:0] = 0x2, if XON1 and XOFF1 characters are received, they do not get written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.EFR_REG[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

14.4.4.1.3.3.2 Transmit (TX)

XOFF1: Two characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.TCR_REG[3:0].

XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed by UARTi.TCR_REG[7:4].

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

14.4.4.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an AT command (ASCII code). These characteristics are used to receive data after an “at” (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UASR_REG register reflects the correct settings for the baud rate detected. The interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character + space parity is not supported.

Autobauding mode is selected when the UARTi.MDR1_REG[2:0] MODE_SELECT field is set to 0x2. In the UART autobauding mode, UARTi.DLL_REG, UARTi.DLH_REG, UARTi.LCR_REG[5:0] settings are not used; instead, UASR_REG is updated with the configuration detected by the autobauding logic.

UASR_REG Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.LCR_REG, UARTi.DLL_REG, and UARTi.DLH_REG registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.MDR1_REG[2:0] MODE_ SELECT field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1,200 and 115,200 bps (10 possibilities)

14.4.4.1.3.5 Error Detection

When the UARTi.LSR_REG register is read, UARTi.LSR_REG[4:2] reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the UARTi.LSR_REG register and then reading the UARTi.RHR_REG register identifies errors in a character.

Reading the UARTi.RHR_REG register updates the BI, FE, and PE bits (see Table 14-30 for the UART mode interrupts).

The UARTi.LSR_REG [7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading UARTi.LSR_REG does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading UARTi.RHR_REG.

Reading UARTi.LSR_REG clears the OE bit if it is set (see Table 14-30 for the UART mode interrupts).

14.4.4.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with UARTi.IIR_REG[5:1] IT_TYPE = 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the system (MPU) must:

- Reset the RX FIFO

- Read the UARTi.RESUME_REG register (which clears the internal flag)

14.4.4.1.3.7 Time-Out and Break Conditions

14.4.4.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time equivalent to 4x programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.RHR_REG is read.

14.4.4.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.LCR_REG[6] BREAK_EN bit. The break condition is not aligned on word stream (that is, a break condition can occur in the middle of a character). The only way to send a break condition on a full character is as follows:

1. Reset the transmit FIFO (if enabled).
2. Wait for the transmit shift register to empty (UARTi.LSR_REG[6] TX_SR_E = 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

14.4.4.1.4 UART Mode Interrupt Management

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.IIR_REG) sets the UARTi.IIR_REG[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and provides the type of interrupt through UARTi.IIR_REG[5:1]. Table 14-30 summarizes the interrupt control functions.

Table 14-30. UART Mode Interrupts

IIR_REG[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR_REG. OE: Read LSR_REG.
001100	2	RX time-out	Stale data in RX FIFO	Read RHR_REG.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read RHR_REG until interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (THR_REG empty) (FIFO disable)	Write to THR_REG until interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	
000000	4	Modem status	See the MSR_REG register.	Read MSR_REG.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of IIR_REG, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read IIR_REG.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.LSR_REG[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.IIR_REG register.

14.4.4.1.4.1 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that is not designed the same way as other interrupts. This interrupt is enabled when the UARTi.SCR_REG[4] RX_CTS_WU_EN bit is set to 1. The UARTi.IIR_REG register is not modified when it occurs; the UART3.SSR_REG[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, the only way to clear it is to reset the UARTi.SCR_REG[4] RX_CTS_WU_EN bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

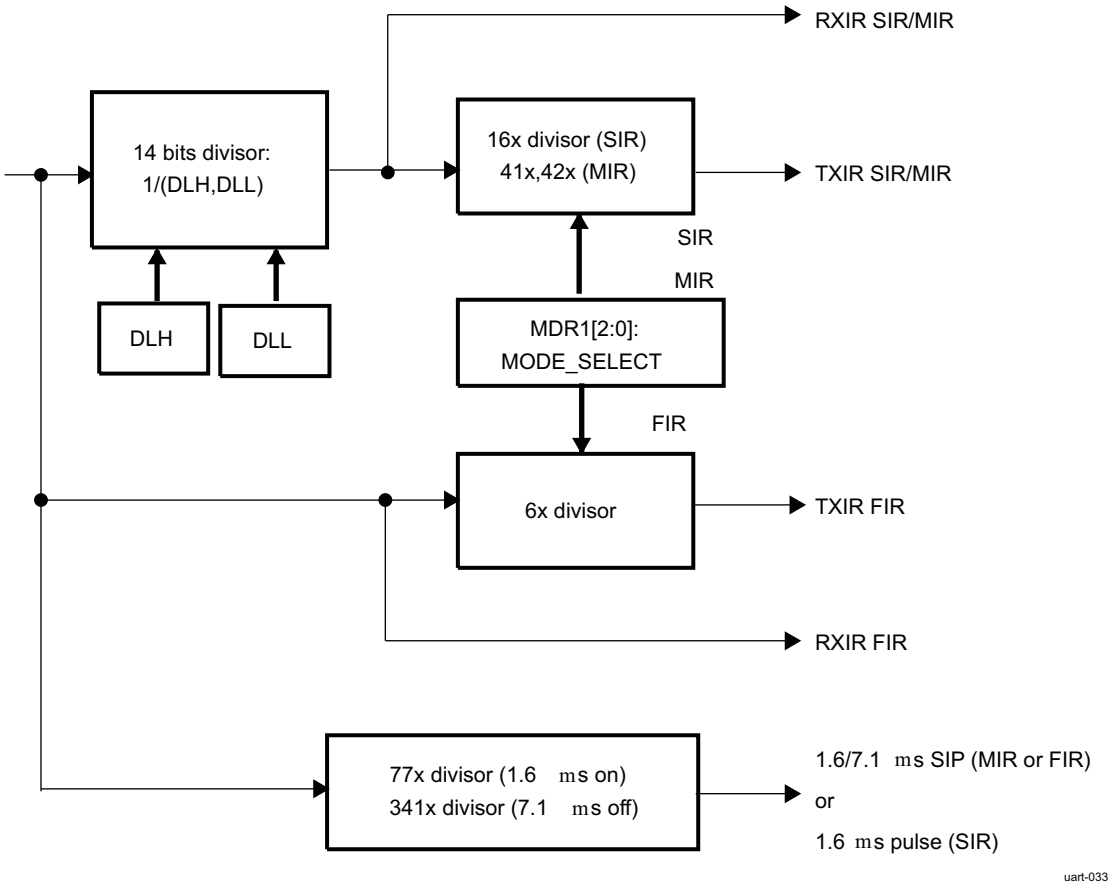
14.4.4.2 IrDA Mode (UART3 Only)

14.4.4.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 14-32 shows the baud rate generator and associated controls.

Figure 14-32. Baud Rate Generator



CAUTION

Before trying to initialize or modify clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG), it is mandatory to set MODE_SELECT=DISABLE (UARTi.MDR1_REG[2:0]=0x7).

Failure to observe this rule can result in unpredictable module behavior.

14.4.4.2.2 Choosing the Appropriate Divisor Value

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 14-31 lists the IrDA baud rate settings.

Table 14-31. IrDA Baud Rates Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)$	Source Jitter (%)	Pulse duration
2.4 Kbps	SIR	16x	3/16	1250	2.4 Kbps	0	0	78.1 µs
9.6 Kbps	SIR	16x	3/16	312	9.6153 Kbps	+0.16	0	19.5 µs
19.2 Kbps	SIR	16x	3/16	156	19.231 Kbps	+0.16	0	9.75 µs
38.4 Kbps	SIR	16x	3/16	78	38.462 Kbps	+0.16	0	4.87 µs
57.6 Kbps	SIR	16x	3/16	52	57.692 Kbps	+0.16	0	3.25 µs
115.2 Kbps	SIR	16x	3/16	26	115.38 Kbps	+0.16	0	1.62 µs
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps(1)	0	+1.63/- 0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps(1)	0	+1.63/- 0.80	208 ns
4 Mbps	FIR	6x	4 PPM	-	4 Mbps	0	0	125 ns

(1) Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

14.4.4.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

14.4.4.2.3.1 IRRX Polarity Control

The UART3.MDR2_REG[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART module to ensure that the protocol at the output of the transceiver module has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

14.4.4.2.3.2 IrDA Reception Control

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.ACREG_REG[5] DIS_IR_RX bit.

14.4.4.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives with the UART3.XON1_ADDR1_REG[7:0] XON_WORD1 and UART3.XON2_ADDR2_REG[7:0] XON_WORD2 fields.

Setting the EFR_REG[0] bit to 1 selects address1 checking. Setting the EFR_REG[1] bit to 1 selects address2 checking. Setting the EFR_REG[1:0] bit to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for both private and public addresses.

If address checking is disabled, all received frames write to the reception FIFO.

14.4.4.2.3.4 Frame Closing

A transmission frame can be correctly terminated in two ways:

- Frame-length method: The frame-length method is selected by setting the UART3.MDR1_REG[7] FRAME_END_MODE bit to 0. The MPU writes the frame-length value to the UART3.TXFLH_REG and UART3.TXFLL_REG registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the frame-length value.
- Set-EOT bit method: The set-EOT bit method is selected by setting the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.ACREG_REG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

14.4.4.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or a whole frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.ACREG_REG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.MDR1_REG[5] SCT bit to 1. This transmission method is different from the normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

14.4.4.2.3.6 Error Detection

When the UART3.LSR_REG register is read, the UART3.LSR_REG[4:2] field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (see Table 14-32 for IrDA mode interrupts). STATUS FIFO must be read until empty (a maximum of eight reads is required).

14.4.4.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the system (MPU) must:

- Reset the TX FIFO.
- Read the UART3.RESUME_REG register (which clears the internal flag).

This functionality can be disabled by the UART3.ACREG_REG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop bit in transmission if the TX FIFO is empty.

14.4.4.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same functionality as that for the UART mode (see Section 14.4.4.1.3.6, *Overrun During Receive*).

14.4.4.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading UART3.SFREGH_REG[3:0] (MSB) and UART3.SFREGL_REG[3:0] (LSB) obtains the frame length. The frame error status is read in the UART3.SFLSR_REG register. Reading the UART3.SFLSR_REG register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

14.4.4.2.4 SIR Mode DATA Formatting

This section provides specific instructions for SIR mode programming.

14.4.4.2.4.1 Abort Sequence

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.ACREG_REG[1] ABORT_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

CAUTION

When the transmit FIFO is not empty and the UART3.MDR1_REG[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.

14.4.4.2.4.2 Pulse Shaping

The SIR mode supports both the 3/16th or the 1.6-µs pulse duration methods. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

14.4.4.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.MDR1_REG[2:0] MODE_SELECT = 0x0) and the UART3.MDR2_REG[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format remains the same, some UART mode configuration registers must be set at specific values:

- UART3.LCR_REG[1:0] CHAR_LENGTH field = 0x3 (8 data bits)
- UART3.LCR_REG[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.LCR_REG[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many of them are not relevant (XOFF, RTS, CTS, modem status register, etc.).

14.4.4.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors in the received frame.

When the UART3.MDR1_REG[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.ACREG_REG[3] SEND_SIP bit.

The system (MPU) can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, which can reduce the overhead required.

14.4.4.2.6 IrDA Mode Interrupt Management

14.4.4.2.6.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER_REG and UART3.IIR_REG mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see Table 14-32). The interrupt line is activated when any of the eight interrupts is generated (there is no priority).

Table 14-32. IrDA Mode Interrupts

IIR_REG Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR_REG until interrupt condition disappears.
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read RHR_REG.
3	RX overrun	Write to RHR_REG when RX FIFO full.	Read RESUME_REG register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. THR_REG empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read RESUME_REG register. OR 2. Read IIR_REG.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read IIR_REG.

14.4.4.2.6.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see Section 14.4.4.1.4.1, *Wake-Up Interrupt*).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

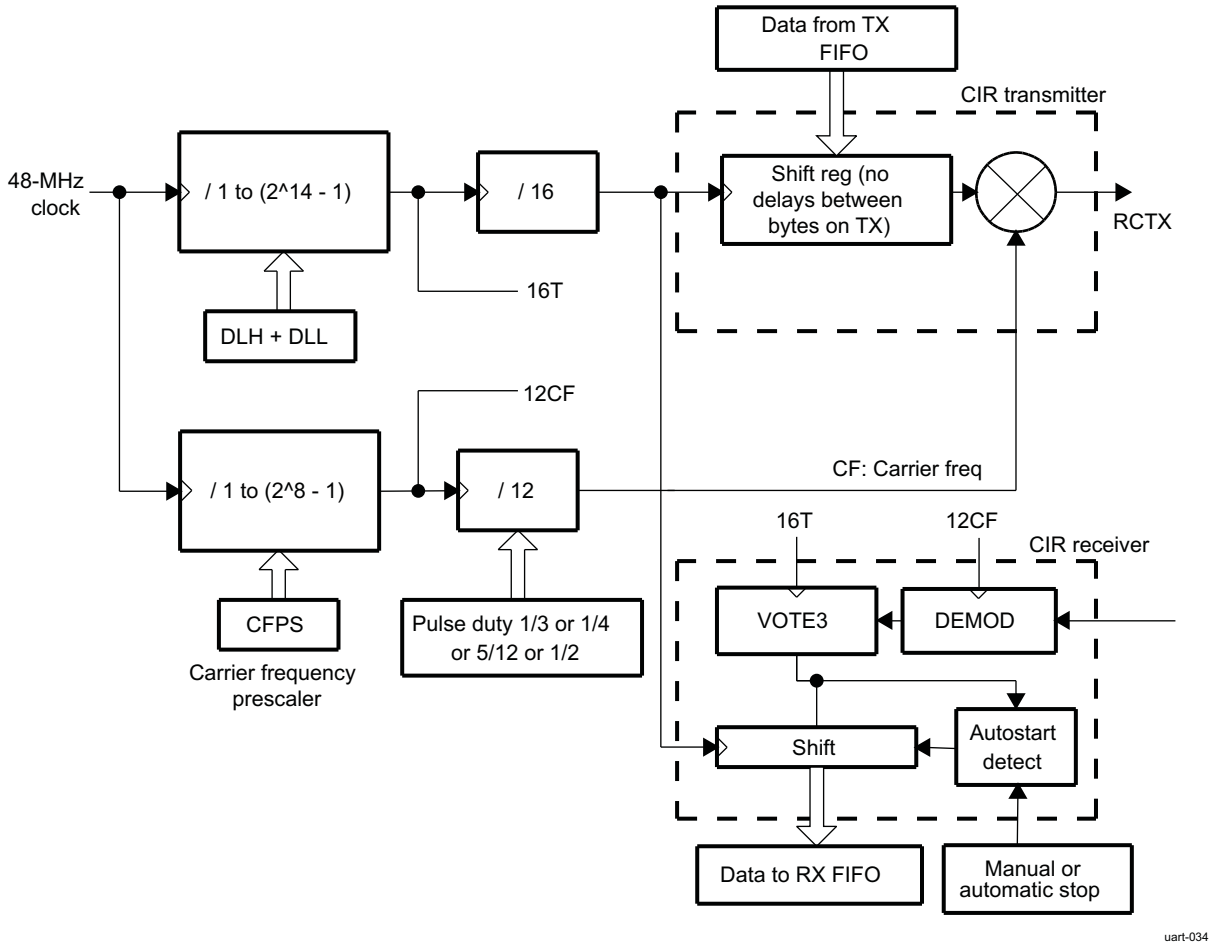
This does not ensure wake-up event generation as expected when configured in smart-idle mode and the system wakes up for a short period.

14.4.4.3 CIR Mode (UART3 Only)

14.4.4.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 14-33.

Figure 14-33. CIR Mode Block Components



Based on the requested modulation frequency, the UART3.CFPS_REG register must be set with the correct dividing value to provide the more accurate pulse frequency:

Dividing value = (FCLK/12)/MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the CFPS_REG value must be set to 111 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The UART3.CFPS_REG register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.MDR2_REG configuration register. Table 14-33 shows the duty cycle.

Table 14-33. Duty Cycle

MDR2_REG[5:4]	Duty Cycle (High Level)
00	1/4
01	1/3
10	5/12
11	½

14.4.4.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

14.4.4.3.2.1 IRRX Polarity Control

The IRRX polarity control for the CIR mode has the same functionality as that for the IrDA mode (see Section 14.4.4.2.3.1, *IRRX Polarity Control*).

14.4.4.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a *t* period
- Using an external system timer to control the delay either between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.MDR1_REG[5] SCT bit and UART3.ACREG_REG[2] SCTX_EN bit, depending on the timer status
  - Using the UART3.IIR_REG[5] TX_STATUS_IT interrupt to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

NOTE: There's a limitation when receiving data in UART CIR mode. The consumer IR transceivers on the market have a common characteristic that shrinks the hold time of the received modulation pulse. The UART filtering schema on receiving is based on the same encoding mechanism used in transmission.

Consider the following scenario:

- shift register period : 0.9 µs
- modulation frequency : 36 kHz
- duty cycle : 1/4 of a modulation frequency period

So the data sent in those conditions would look like 7µs pulses within 28µs period. The UART expects to receive similar incoming data on receive, but available transceiver timing characteristics typically send 2µs modulated pulses. Those will be filtered out and RX FIFO will not receive any data.

The transmission of data in UART CIR mode is not affected by this limitation.

14.4.4.3.3 CIR Mode Interrupt Management

14.4.4.3.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER_REG and UART3.IIR_REG mappings, depending on the selected mode.

Table 14-34 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.IIR_REG[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 14-34. CIR Mode Interrupts

IIR_REG Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR_REG until interrupt condition disappears.
2:4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR_REG.
6:7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

14.4.4.3.3.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see Section 14.4.4.1.4.1, *Wake-Up Interrupt*).

14.4.5 Power Management

14.4.5.1 UART Mode Power Management

14.4.5.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.IER_REG[4] SLEEP_MODE bit to 1 (when the UARTi.EFR_REG[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.SCR_REG[4] RX_CTS_WU_EN bit to 1. See Section 14.4.4.1.4.1, *Wake-Up Interrupt*, to understand how to manage the interrupt.

NOTE: There must be no writing to the divisor latches, UARTi.DLL_REG and UARTi.DLH_REG, to set the baud clock, BCLK, while in sleep mode. It is advisable to disable sleep mode using the UARTi.IER_REG[4] SLEEP_MODE bit before writing to the UARTi.DLL_REG register or the UARTi.DLH_REG register.

14.4.5.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. At the system level, power-reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol. This protocol is used at the system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.SYSC_REG[2] ENAWAKEUP bit and the UARTi.WER_REG register).

For more information, see the *Power, Reset, and Clock Management* chapter.

14.4.5.2 IrDA Mode Power Management (UART3 Only)

14.4.5.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

14.4.5.2.2 System Power Saving

System power saving for the IrDA mode has the same functionality as that for the UART mode (see Section 14.4.5.1.2, *System Power Saving*).

14.4.5.3 CIR Mode Power Management (UART3 Only)

14.4.5.3.1 Module Power Saving

Module power saving for the CIR mode has the same functionality as that for the IrDA mode (see Section 14.4.5.2.1, *Module Power Saving*).

14.4.5.3.2 System Power Saving

System power saving for the CIR mode has the same functionality as that for the UART mode (see Section 14.4.5.2.2, *System Power Saving*).

14.5 UART/IrDA/CIR Basic Programming Model

14.5.1 UART Programming Model

14.5.1.1 Quick Start

This section outlines the procedure for operating the UART module with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART module. It does not cover every UART module feature.

The first programming model covers software reset of the module. The second programming model deals with FIFO and DMA configuration. The last programming model deals with protocol, baud rate and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information see Section 14.4.3.1, *Register Access Modes*.

14.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
   Set the UARTi.SYSC_REG[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
   Poll the UARTi.SYSS_REG[0] RESETDONE bit until it equals 1.

14.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.EFR_REG register:
   (a) Save the current UARTi.LCR_REG value.
   (b) Set UARTi.LCR_REG to 0x00BF.
2. Enable register submode TCR_TLR to access UARTi.TLR_REG (part 1 of 2):
   (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
   (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.MCR_REG register:
   Set UARTi.LCR_REG to 0x0080.
4. Enable register submode TCR_TLR to access UARTi.TLR_REG (part 2 of 2):
   (a) Save the UARTi.MCR_REG[6] TCR_TLR value.
   (b) Set the UARTi.MCR_REG[6] TCR_TLR bit to 1.
5. Enable FIFO, load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
   Set the following bits to the desired values:
   - UARTi.FCR_REG[7:6] RX_FIFO_TRIG
   - UARTi.FCR_REG[5:4] TX_FIFO_TRIG
   - UARTi.FCR_REG[3] DMA_MODE
   - UARTi.FCR_REG[0] FIFO_ENABLE (0: Disable the FIFO/1: Enable the FIFO)

NOTE: The UARTi.FCR_REG register is not readable.

6. Switch to register configuration mode B to access the UARTi.EFR_REG register:
   Set UARTi.LCR_REG to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
   Set the following bits to the desired values:
   - UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
   - UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
   Set the following bits to the desired values:
   - UARTi.SCR_REG[7] RX_TRIG_GRANU1
   - UARTi.SCR_REG[6] TX_TRIG_GRANU1
   - UARTi.SCR_REG[2:1] DMA_MODE_2
   - UARTi.SCR_REG[0] DMA_MODE_CTL
9. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.MCR_REG register:
    Set UARTi.LCR_REG to 0x0080.
11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.LCR_REG value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See Section 14.4.2.1.1, *Transmit FIFO Trigger,* to choose the following values:

- UARTi.FCR_REG[5:4] TX_FIFO_TRIG
- UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
- UARTi.SCR_REG[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See Section 14.4.2.1.2, *Receive FIFO Trigger*, to choose the following values:

- UARTi.FCR_REG[7:6] RX_FIFO_TRIG
- UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
- UARTi.SCR_REG[7] RX_TRIG_GRANU1

DMA mode enables the different DMA requests. See Section 14.4.2.4, *FIFO DMA Mode Operation*, to choose the following values:

- UARTi.FCR_REG[3] DMA_MODE
- UARTi.SCR_REG[2:1] DMA_MODE_2
- UARTi.SCR_REG[0] DMA_MODE_CTL

14.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate and interrupt settings, perform the following steps:

1. Disable UART to access UARTi.DLL_REG and UARTi.DLH_REG:
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. Switch to register configuration mode B to access the UARTi.EFR_REG register:
   Set UARTi.LCR_REG to 0x00BF.
3. Enable access to UARTi.IER_REG[7:4]:
   (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
   (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.IER_REG register:
   Set UARTi.LCR_REG to 0x0000.

5. Clear the UARTi.IER_REG (UARTi.IER_REG[4] SLEEP_MODE bit to 0 to change UARTi.DLL_REG and UARTi.DLH_REG).Set UARTi.IER_REG to 0x0000.
6. Switch to register configuration mode B to access the UARTi.DLL_REG and UARTi.DLH_REG registers:

   Set UARTi.LCR_REG to 0x00BF.
7. Load the new divisor value:

   Set the UARTi.DLL_REG[7:0] CLOCK_LSB and UARTi.DLH_REG[5:0] CLOCK_MSB fields to the desired value.
8. Switch to register operational mode to access the UARTi.IER_REG register:

   Set UARTi.LCR_REG to 0x0000.
9. Load the new interrupt configuration.(0: Disable the interrupt/1: Enable the interrupt):

   Set the following bits to the desired values:
   - UARTi.IER_REG[7] CTS_IT
   - UARTi.IER_REG[6] RTS_IT
   - UARTi.IER_REG[5] XOFF_IT
   - UARTi.IER_REG[4] SLEEP_MODE
   - UARTi.IER_REG[3] MODEM_STS_IT
   - UARTi.IER_REG[2] LINE_STS_IT
   - UARTi.IER_REG[1] THR_IT
   - UARTi.IER_REG[0] RHR_IT
10. Switch to register configuration mode B to access the UARTi.EFR_REG register:

    Set UARTi.LCR_REG to 0x00BF.
11. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop bit, char length) and switch to register operational mode:

    Set UARTi.LCR_REG[7] DIV_EN to 0.

    Set UARTi.LCR_REG[6] BREAK_EN to 0.

    Set the following bits to the desired values:
    - UARTi.LCR_REG[5] PARITY_TYPE_2
    - UARTi.LCR_REG[4] PARITY_TYPE_1
    - UARTi.LCR_REG[3] PARITY_EN
    - UARTi.LCR_REG[2] NB_STOP
    - UARTi.LCR_REG[1:0] CHAR_LENGTH
13. Load the new UART mode:

    Set UARTi.MDR1_REG[2:0] MODE_SELECT to the desired value.

See Section 14.4.4.1.2, *Choosing the Appropriate Divisor Value*, to choose the following values:

- UARTi.DLL_REG[7:0] CLOCK_LSB
- UARTi.DLH_REG[5:0] CLOCK_MSB
- UARTi.MDR1_REG[2:0] MODE_SELECT

See Section 14.4.4.1.3.1, *Frame Formatting*, to choose the following values:

- UARTi.LCR_REG[5] PARITY_TYPE_2
- UARTi.LCR_REG[4] PARITY_TYPE_1
- UARTi.LCR_REG[3] PARITY_EN
- UARTi.LCR_REG[2] NB_STOP
- UARTi.LCR_REG[1:0] CHAR_LENGTH

14.5.1.2 Hardware and Software Flow Control Configuration

This section outlines the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 14.4.3.1, *Register Access Modes*.

14.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following procedure:

1. Switch to register configuration mode A to access the UARTi.MCR_REG register:
   (a) Save the current UARTi.LCR_REG.
   (b) Set UARTi.LCR_REG to 0x0080.
2. Enable register submode TCR_TLR to access UARTi.TCR_REG (part 1 of 2):
   (a) Save the UARTi.MCR_REG[6] TCR_TLR value.
   (b) Set UARTi.MCR_REG[6] TCR_TLR = 1.
3. Switch to register configuration mode B to access the UARTi.EFR_REG register:
   Set UARTi.LCR_REG to 0x00BF.
4. Enable register submode TCR_TLR to access the UARTi.TCR_REG register (part 2 of 2):
   (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
   (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
   Set the following bits to the desired values:
   - UARTi.TCR_REG[7:4] AUTO_RTS_START
   - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 4a.
   Set the following bits to the desired values:
   - UARTi.EFR_REG[7] AUTO_CTS_EN (0: Disable/1: Enable)
   - UARTi.EFR_REG[6] AUTO_RTS_EN (0: Disable/1: Enable)

   Restore UARTi.EFR_REG[4] ENHANCED_EN to the saved value.
7. Switch to register configuration mode A to access UARTi.MCR_REG:
   Set UARTi.LCR_REG to 0x0080.
8. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.LCR_REG value saved in Step 1a.

See Section 14.4.4.1.3.2, *Hardware Flow Control*, to choose the following values:

- UARTi.EFR_REG[7] AUTO_CTS_EN
- UARTi.EFR_REG[6] AUTO_RTS_EN
- UARTi.TCR_REG[7:4] AUTO_RTS_START
- UARTi.TCR_REG[3:0] AUTO_RTS_HALT

14.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following procedure:

1. Switch to register configuration mode B to access the UARTi.EFR_REG register.

(a) Save the current UARTi.LCR_REG.

(b) Set UARTi.LCR_REG to 0x00BF.

2. Enable register submode XOFF to access the UARTi.XOFF1_REG and UARTi.XOFF2_REG registers:

   (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.

   (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 0.

3. Load the new software flow control characters:

   Set the following bits to the desired values:

   - UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
   - UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
   - UARTi.XOFF1_REG[7:0] XOFF_WORD1
   - UARTi.XOFF2_REG[7:0] XOFF_WORD2

4. Enable access to UARTi.MCR_REG[7:5] and enable register submode TCR_TLR to access UARTi.TCR_REG (part 1 of 2):

   Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.

5. Switch to register configuration mode A to access the UARTi.MCR_REG register:

   Set UARTi.LCR_REG to 0x0080.

6. Enable register submode TCR_TLR to access UARTi.TCR_REG (part 2 of 2) and enable or disable XON any function:

   (a) Save the UARTi.MCR_REG[6] TCR_TLR value.

   (b) Set the UARTi.MCR_REG[6] TCR_TLR to 1.

   Set UARTi.MCR_REG[5] XON_EN to the desired value (0: Disable/1: Enable).

7. Switch to register configuration mode B to access the UARTi.EFR_REG register:

   Set UARTi.LCR_REG to 0x00BF.

8. Load the new start and halt trigger values for software flow control:

   Set the following bits to the desired values:

   - UARTi.TCR_REG[7:4] AUTO_RTS_START
   - UARTi.TCR_REG[3:0] AUTO_RTS_HALT

9. Enable or disable special char function and load the new software flow control mode and restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a:

   Set the following bits to the desired values:

   - UARTi.EFR_REG[5] SPEC_CHAR (0: Disable/1: Enable)
   - UARTi.EFR_REG[3:0] SW_FLOW_CONTROL

   Restore UARTi.EFR_REG[4] ENHANCED_EN to the saved value.

10. Switch to register configuration mode A to access the UARTi.MCR_REG register:

    Set UARTi.LCR_REG to 0x0080.

11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 6a.

12. Restore the UARTi.LCR_REG value saved in Step 1a.

See Section 14.4.4.1.3.3, *Software Flow Control*, to choose the following values:

- UARTi.EFR_REG[5] SPEC_CHAR
- UARTi.EFR_REG[3:0] SW_FLOW_CONTROL
- UARTi.TCR_REG[7:4] AUTO_RTS_START
- UARTi.TCR_REG[3:0] AUTO_RTS_HALT
- UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
- UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
- UARTi.XOFF1_REG[7:0] XOFF_WORD1
- UARTi.XOFF2_REG[7:0] XOFF_WORD2

14.5.2 IrDA Programming Model (UART3 Only)

14.5.2.1 SIR Mode

14.5.2.1.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with parity forced to '1', baud rate = 112.5Kbs, FIFOs disable, 2 stop bits, 8 bits word length

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
   UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (115.2Kbs)**
   UART3.DLL_REG = 0x1A
   UART3.DLH_REG = 0x00
4. **Set SIR Mode**
   UART3.MDR1_REG[2:0] MODE_SELECT = 0x1
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
   UART3.LCR_REG = 0x00
6. **Optional: Enable RHR interrupt**
   UART3.IER_REG[0] RHR_IT = 0x1

14.5.2.1.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 6 bytes frame with no parity, baud rate = 112.5Kbs, FIFOs disable, 3/16 encoding, 2 stop bits, 7 bits word length

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to EFR_REG**
   UART3.LCR_REG = 0xBF
3. **Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1)**
   UART3.EFR_REG = 0x10
4. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
   UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
5. **Load the new baud rate (115.2Kbs)**
   UART3.DLL_REG = 0x1A
   UART3.DLH_REG = 0x00
6. **Set SIR Mode (MDR1_REG[2:0] MODE_SELECT = 0x1)**
   UART3.MDR1_REG = 0x01
7. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
   UART3.LCR_REG = 0x00
8. **Force DTR output to active**
   UART3.MCR_REG[0] DTR = 0x1
9. **Optional: Enable THR interrupt**
   UART3.IER_REG[1] THR_IT = 0x1
10. **Set transmit frame length to 6 bytes**
    UART3.TXFLL_REG = 0x06
11. **Set 7 starts of frame transmission**
    UART3.EBLR_REG = 0x08
12. **Optional: Set SIR pulse width to be 1.6 us**
    UART3.ACREG_REG[7] PULSE_TYPE = 0x1
13. **Load THR_REG with the desired data to be transmitted**

14.5.2.2 MIR Mode

14.5.2.2.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
   UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (1.152Mbs)**
   UART3.DLL_REG = 0x01
   UART3.DLH_REG = 0x00
4. **Set MIR Mode**
   UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
   UART3.LCR_REG = 0x00
6. **Force DTR output to active (MCR_REG[0] DTR = 0x1)**
   Force RTS output to active (MCR_REG[1] RTS = 0x1)
   UART3.MCR_REG = 0x3
7. **Optional: Enable RHR interrupt**
   UART3.IER_REG[0] RHR_IT = 0x1

14.5.2.2.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 60 bytes frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
   UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (1.152Mbs)**
   UART3.DLL_REG = 0x01
   UART3.DLH_REG = 0x00
4. **Set MIR Mode**
   UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
   UART3.LCR_REG = 0x00
6. **Force DTR output to active**
   UART3.MCR_REG[0] DTR = 0x1
7. **Optional: Enable THR interrupt**
   UART3.IER_REG[1] THR_IT = 0x1
8. **Set frame length to 60 bytes**
   UART3.TXFLL_REG = 0x3C
9. **Optional: Transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)**
   UART3.EBLR_REG = 0x08
10. **SIP will be send at the end of transmission**
    UART3.ACREG_REG[3] = 0x1
11. **Load THR_REG with the desired data to be transmitted**

14.5.2.3 FIR Mode

14.5.2.3.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1**
   UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode.)
3. **FIFO clear and enable**
   FCR_REG = 0x7 (Tx/Rx FIFO trigger : FCR_REG[7:6] & FCR_REG[5:4])
   LCR_REG[7]=0
4. **Set FIR Mode**
   UART3.MDR1_REG[2:0] MODE_SELECT = 0x5
5. **Set frame length**
   RXFLL_REG = 0xA (Data + CRC + STO)
6. **Disable access to DLL_REG and DLH_REG and switch to register operational mode**
   UART3.LCR_REG[7] DIV_EN = 0x0.
7. **Optional: Enable RHR interrupt**
   UART3.IER_REG[0] RHR_IT = 0x1.

14.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit IrDA 4 bytes frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
   Set MDR1_REG[2:0] MODE_SELECT = 0x7).
2. **Grant access to EFR_REG**
   UART3.LCR_REG = 0xBF
3. **Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1)**
   UART3.EFR_REG = 0x10.
4. **FIFO clear and enable**
   FCR_REG = 0x7 (Tx/Rx FIFO trigger: FCR_REG[7:6] and FCR_REG[5:4])
   LCR_REG[7]=0
5. **Set FIR mode and enable auto-SIP mode**
   MDR1_REG = 0x45
6. **Set Frame Length**
   TXFLL_REG = 0x4
   TXFLH_REG = 0x0
   RXFLL_REG = 0xA (Data + CRC + STO)
   RXFLH_REG = 0x0
7. **Force DTR output to active**
   UART3.MCR_REG[0] DTR = 0x1
8. **Optional: Enable THR interrupt**
   UART3.IER_REG[1] THR_IT = 0x1
9. **Load THR_REG with the desired data to be transmitted**

14.6 UART/IrDA/CIR Registers

Table 14-35 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 14-35. Instance Summary

Module Name	Base Address	Size
UART1 (UART only)	0x4806 A000	1K byte
UART2 (UART only)	0x4806 C000	1K byte
UART3 (UART/IrDA/CIR)	0x4902 0000	1K byte
UART4	0x4809 E000	1K byte

14.6.1 UART/IrDA/CIR Register Mapping Summary

This section provides information about the UART/IrDA/CIR module instance in the device. Each register in the module instance is described separately in this section. This module has multiple modes. Table 14-36 summarizes register access for different modes.

Table 14-36. UART Mode Overview

Address Offset	Registers					
	Configuration_Mode_A		Configuration_Mode_B		Operational_Mode	
	Read	Write	Read	Write	Read	Write
0x000	DLL_REG	DLL_REG	DLL_REG	DLL_REG	RHR_REG	THR_REG

14.6.2 UART/IrDA/CIR Register Descriptions

14.6.2.1 DLL_REG

Table 14-50. DLL_REG

Address Offset	0x000		
Physical Address	0x4806 A000	**Instance**	UART1
	0x4806 C000		UART2
	0x4902 0000		UART3
	0x4809 E000		UART4
Description	Divisor latches low		
	This register, with DLH_REG, stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH_REG stores the most-significant part of the divisor. DLL_REG stores the least-significant part of the divisor.		
	Note: DLL_REG and DLH_REG can be written to only before sleep mode is enabled (before IER_REG[4] is set).		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								CLOCK_LSB							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	CLOCK_LSB	Stores the 8-bit LSB divisor value	RW	0x00

14.6.2.2 RHR_REG

Table 14-51. RHR_REG

Address Offset	0x000		
Physical Address	0x4806 A000	**Instance**	UART1
	0x4806 C000		UART2
	0x4902 0000		UART3
	0x4809 E000		UART4
Description	Receive holding register		
	The receiver section consists of the receiver holding register (RHR_REG) and the receiver shift register. The RHR_REG is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR_REG. If the FIFO is disabled, location zero of the FIFO is used to store the single data character.		
	Note: If an overflow occurs the data in the RHR_REG is not overwritten.		
Type	R		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RHR							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	RHR	Receive holding register	R	0x–

14.6.2.3 THR_REG

Table 14-52. THR_REG

Address Offset	0x000		
Physical Address	0x4806 A000	**Instance**	UART1
	0x4806 C000		UART2
	0x4902 0000		UART3
	0x4809 E000		UART4
Description	Transmit holding register		
	The transmitter section consists of the transmit holding register (THR_REG) and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR_REG. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.		
Type	W		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								THR							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Write has no functional effect.	W	0x00
7:0	THR	Transmit holding register	W	0x–

14.6.2.4 IER_REG

Table 14-53. IER_REG

Address Offset	0x004		
Physical Address	0x4806 A004	**Instance**	UART1
	0x4806 C004		UART2
	0x4902 0004		UART3
	0x4809 E000		UART4
Description	Interrupt enable register		
Type	RW		

14.6.2.4.1 UART Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								CTS_IT	RTS_IT	XOFF_IT	SLEEP_MODE	MODEM_STS_IT	LINE_STS_IT	THR_IT	RHR_IT

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00. Write has no functional effect.	RW	0x00
7	CTS_IT	Can be written only when EFR_REG[4] = 1	RW	0
		0x0: Disables the nCTS interrupt		
		0x1: Enables the nCTS interrupt		
6	RTS_IT	Can be written only when EFR_REG[4] = 1	RW	0
		0x0: Disables the interrupt		
		0x1: Enables the nRTS interrupt		
5	XOFF_IT	Can be written only when EFR_REG[4] = 1	RW	0
		0x0: Disables the XOFF interrupt		
		0x1: Enables the XOFF interrupt		
4	SLEEP_MODE	Can be only written when EFR_REG[4] = 1	RW	0
		0x0: Disables sleep mode		
		0x1: Enables sleep mode (stop baud rate clock when the module is inactive)		
3	MODEM_STS_IT		RW	0
		0x0: Disables the modem status register interrupt		
		0x1: Enables the modem status register interrupt		
2	LINE_STS_IT		RW	0
		0x0: Disables the receiver line status interrupt		
		0x1: Enables the receiver line status interrupt		
1	THR_IT		RW	0
		0x0: Disables the THR interrupt		
		0x1: Enables the THR interrupt		
0	RHR_IT		RW	0
		0x0: Disables the RHR interrupt and time out interrupt.		
		0x1: Enables the RHR interrupt and time out interrupt.		

14.6.2.4.2 IrDA Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								EOF_IT	LINE_STS_IT_I	TX_STATUS_IT	STS_FIFO_ TRIG_IT	RX_OVERRUN_ IT	LAST_RX_ BYTE_IT	THR_IT	RHR_IT

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0. Write has no functional effect.	RW	0x00
7	EOF_IT			
		0x0: Disables the received EOF interrupt		
		0x1: Enables the received EOF interrupt		
6	LINE_STS_IT_I		RW	0
		0x0: Disables the receiver line status interrupt		
		0x1: Enables the receiver line status interrupt		
5	TX_STATUS_IT	TX_STATUS_IT interrupt reflects two possible conditions. The MDR2_REG[0] must be read to determine the status in the event of this interrupt.	RW	0
		0x0: Disables the TX status interrupt		
		0x1: Enables the TX status interrupt		
4	STS_FIFO_ TRIG_IT		RW	0
		0x0: Disables status FIFO trigger level interrupt		
		0x1: Enables status FIFO trigger level interrupt.		
3	RX_OVERRUN_ IT		RW	0
		0x0: Disables the RX overrun interrupt		
		0x1: Enables the RX overrun interrupt		
2	LAST_RX_ BYTE_IT		RW	0
		0x0: Disables the last byte of frame in RX FIFO interrupt		
		0x1: Enables the last byte of frame in RX FIFO interrupt		
1	THR_IT		RW	0
		0x0: Disables the THR interrupt		
		0x1: Enables the THR interrupt		
0	RHR_IT		RW	0
		0x0: Disables the RHR interrupt		
		0x1: Enables the RHR interrupt		

14.6.2.4.3 CIR Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										TX_STATUS_IT	Reserved			THR_IT	Reserved

Bits	Field Name	Description	Type	Reset
15:6	Reserved	Read returns 0x00. Write has no functional effect.	RW	0x00
5	TX_STATUS_IT	In IR-CIR mode, contrary to the IR-IrDA mode, the TX_STATUS_IT has only one meaning corresponding to the case MDR2_REG[0] = 0.	RW	0
4:2	Reserved	Read returns 0. Write has no functional effect.	R	0
1	THR_IT	0x0: Disables the THR interrupt 0x1: Enables the THR interrupt	RW	0
0	Reserved	Reserved	R	0

14.6.2.5 DLH_REG

Table 14-54. DLH_REG

Address Offset	0x004		
Physical Address	0x4806 A004	**Instance**	UART1
	0x4806 C004		UART2
	0x4902 0004		UART3
	0x4809 E000		UART4
Description	Divisor latches high		
	This register, with DLL_REG, stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH_REG stores the most-significant part of the divisor. DLL_REG stores the least-significant part of the divisor.		
	Note: DLL_REG and DLH_REG can be written to only before sleep mode is enabled (before IER_REG[4] is set).		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved		CLOCK_MSB					

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:6	Reserved	Read returns 0x0.	R	0x0
5:0	CLOCK_MSB	Stores the 6-bit most-significant bit (MSB) divisor value	RW	0x00

14.6.2.6 FCR_REG

Table 14-55. FCR_REG

Address Offset	0x008		
Physical Address	0x4806 A008	**Instance**	UART1
	0x4806 C008		UART2
	0x4902 0008		UART3
	0x4809 E000		UART4
Description	FIFO control register		
Type	W		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RX_FIFO_TRIG		TX_FIFO_TRIG		DMA_MODE	TX_FIFO_CLEAR	RX_FIFO_CLEAR	FIFO_EN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Write has no functional effect.	W	0x00
7:6	RX_FIFO_TRIG	Sets the trigger level for the RX FIFO: If SCR_REG[7] = 0 and TLR_REG[7:4] ≠ 0000 RX_FIFO_TRIG is not considered. If SCR_REG[7] = 1, RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with the granularity 1. If SCR_REG[7] = 0 and TLR_REG[7:4] = 0000: 0x0: 8 characters 0x1: 16 characters 0x2: 56 characters 0x3: 60 characters	W	0x0
5:4	TX_FIFO_TRIG	Can be written only if EFR_REG[4] = 1. Sets the trigger level for the TX FIFO: If SCR_REG[6] = 0 and TLR_REG[3:0] ≠ 0000, TX_FIFO_TRIG is not considered. If SCR_REG[6] = 1, RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR_REG[6] = 0 and TLR_REG[3:0] = 0000: 0x0: 8 characters 0x1: 16 characters 0x2: 32 characters 0x3: 56 characters	W	0x0
3	DMA_MODE	Can be changed only when the baud clock is not running (DLL_REG and DLH_REG set to 0). This register is considered if SCR_REG[0] = 0. 0x0: DMA_MODE 0 (No DMA) 0x1: DMA_MODE 1 (UART_NDMA_REQ[0] in TX, UART_NDMA_REQ[1] in RX)	W	0
2	TX_FIFO_CLEAR	0x0: No change 0x1: Clears the transmit FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0

Bits	Field Name	Description	Type	Reset
1	RX_FIFO_CLEAR		W	0
		0x0: No change		
		0x1: Clears the receive FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.		
0	FIFO_EN	Can be changed only when the baud clock is not running (DLL_REG and DLH_REG set to 0).	W	0
		0x0: Disables the transmit and receive FIFOs. The transmit and receive holding registers are 1-byte FIFOs.		
		0x1: Enables the transmit and receive FIFOs. The transmit and receive holding registers are 64-byte FIFOs.		

14.6.2.7 IIR_REG

Table 14-56. IIR_REG

Address Offset	0x008		
Physical Address	0x4806 A008	**Instance**	UART1
	0x4806 C008		UART2
	0x4902 0008		UART3
	0x4809 E000		UART4
Description	Interrupt Identification register		
	The IIR_REG is a read-only register that provides the source of the interrupt in a prioritized manner.		
	Note: An interrupt source can be flagged only if enabled in the IER_REG register.		
Type	R		

14.6.2.7.1 UART Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FCR_MIRROR		IT_TYPE					IT_PENDING

Bits	Field Name	Description		Type	Reset
15:8	Reserved	Read returns 0x00.		R	0x00
7:6	FCR_MIRROR	Mirror the contents of FCR_REG[0] on both bits.		R	0x0
5:1	IT_TYPE	Seven possible interrupts in UART mode; other combinations never occur:		R	0x00
		0x0:	Modem interrupt. Priority = 4		
		0x1:	THR interrupt. Priority = 3		
		0x2:	RHR interrupt. Priority = 2		
		0x3:	Receiver line status error. Priority = 1		
		0x6:	Rx timeout. Priority = 2		
		0x8:	Xoff/special character. Priority = 5		
		0x10:	CTS, RTS change state from active (low) to inactive (high). Priority = 6		
0	IT_PENDING	0x0:	An interrupt is pending.	R	1
		0x1:	No interrupt is pending.		

14.6.2.7.2 IrDA Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								EOF_IT	LINE_STS_IT	TX_STATUS_IT	STS_FIFO_IT	RX_OE_IT	RX_FIFO_LB_IT	THR_IT	RHR_IT

Bits	Field Name	Description		Type	Reset
15:8	Reserved	Read returns 0x00.		R	0x00
7	EOF_IT				
		0x0:	Received EOF interrupt inactive		
		0x1:	Received EOF interrupt active		
6	LINE_STS_IT			R	0
		0x0:	Receiver line status interrupt inactive		
		0x1:	Receiver line status interrupt active		
5	TX_STATUS_IT			R	0
		0x0:	TX status interrupt inactive		
		0x1:	TX status interrupt active		
4	STS_FIFO_IT			R	0
		0x0:	Status FIFO trigger level interrupt inactive		
		0x1:	Status FIFO trigger level interrupt active		
3	RX_OE_IT			R	0
		0x0:	RX overrun interrupt inactive		
		0x1:	RX overrun interrupt active		
2	RX_FIFO_LB_IT		Receive FIFO last byte interrupt	R	0
		0x0:	Last byte of frame in RX FIFO interrupt inactive		
		0x1:	Last byte of frame in RX FIFO interrupt active		
1	THR_IT			R	0
		0x0:	THR interrupt inactive		
		0x1:	THR interrupt active		
0	RHR_IT			R	0
		0x0:	RHR interrupt inactive		
		0x1:	RHR interrupt active		

14.6.2.7.3 CIR Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

14.6.2.8 EFR_REG

Table 14-57. EFR_REG

Address Offset	0x008		
Physical Address	0x4806 A008	**Instance**	UART1
	0x4806 C008		UART2
	0x4902 0008		UART3
	0x4809 E000		UART4
Description	Enhanced feature register		
	This register enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR_REG[4] enables write accesses to FCR_REG[5:4], the TX trigger level, which is also used in IrDA modes.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								AUTO_CTS_EN	AUTO_RTS_EN	SPEC_CHAR	ENHANCED_EN	SW_FLOW_CONTROL			

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	AUTO_CTS_EN	Auto-CTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-CTS flow control is enabled; transmission is halted when the nCTS pin is high (inactive).	RW	0
6	AUTO_RTS_EN	Auto-RTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-RTS flow control is enabled; nRTS pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR_REG[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.	RW	0
5	SPEC_CHAR	(UART mode only) Special character detect 0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and IIR_REG bit 4 is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5] 0x1: Enables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5]	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit [3:0]. See Table 14-29. In IrDA mode, bits [1:0] select IR address to check. See Section 14.2.5.2.1.7, *IR Address Checking*.	RW	0x0

14.6.2.9 LCR_REG

Table 14-58. LCR_REG

Address Offset	0x00C		
Physical Address	0x4806 A00C	**Instance**	UART1
	0x4806 C00C		UART2
	0x4902 000C		UART3
	0x4809 E000		UART4
Description	Line control register		
	LCR_REG[6:0] define parameters of the transmission and reception for UART mode. LCR_REG[7] is used to put the module in operational mode or Configuration_Mode_A/B.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DIV_EN	BREAK_EN	PARITY_TYPE2	PARITY_TYPE1	PARITY_EN	NB_STOP	CHAR_LENGTH	

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00	R	0x00
7	DIV_EN	0x0: Operational mode 0x1: Divisor latch enable; put the module in Configuration_Mode_A/B. Allows access to DLL_REG, DLH_REG, and other registers (see Section 14.6.1, *UART/IrDA/CIR Register Mapping Summary*). Configuration_Mode_B: LCR_REG[7:0] = 0xBF Else, Configuration_Mode_A	RW	0
6	BREAK_EN	Break control bit. UART mode only. **Note:** When LCR_REG[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR_REG[6] = 1. 0x0: Normal operating condition 0x1: Forces the transmitter output to go low to alert the communication terminal. TX line is forced to 0 and remains in this state while BREAK_EN = 1.	RW	0
5	PARITY_TYPE2	Selects the forced parity format (if LCR_REG[3] = 1). UART mode only. If LCR_REG[5] = 1and LCR_REG[4] = 0, the parity bit is forced to 1 in the transmitted and received data. If LCR_REG[5] = 1 and LCR_REG[4] = 1, the parity bit is forced to 0 in the transmitted and received data.	RW	0
4	PARITY_TYPE1	UART mode only 0x0: Odd parity is generated (if LCR_REG[3] = 1). 0x1: Even parity is generated (if LCR_REG[3] = 1).	RW	0
3	PARITY_EN	UART mode only 0x0: No parity 0x1: A parity bit is generated during transmission, and the receiver checks for received parity.	RW	0
2	NB_STOP	Specifies the number of stop bits. UART mode only. 0x0: 1 stop bit (word length = 5, 6, 7, 8) 0x1: 1.5 stop bits (word length = 5)1 - 2 stop bits (word length = 6, 7, 8)	RW	0

Bits	Field Name	Description	Type	Reset
1:0	CHAR_LENGTH	Specifies the word length to be transmitted or received. UART mode only. 0x0: 5 bits 0x1: 6 bits 0x2: 7 bits 0x3: 8 bits	RW	0x0

14.6.2.10 MCR_REG

Table 14-59. MCR_REG

Address Offset	0x010		
Physical Address	0x4806 A010	**Instance**	UART1
	0x4806 C010		UART2
	0x4902 0010		UART3
	0x4809 E000		UART4
Description	Modem control register		
	MCR_REG[3:0] controls the interface with the modem, data set, or peripheral device that is emulating the modem.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved	TCR_TLR	XON_EN	LOOPBACK_EN	CD_STS_CH	RI_STS_CH	RTS	DTR

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	Reserved	Read returns 0. Write has no functional effect.	RW	0
6	TCR_TLR	Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: No action 0x1: Enables access to the TCR_REG and TLR_REG registers	RW	0
5	XON_EN	Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: Disable XON any function 0x1: Enable XON any function	RW	0
4	LOOPBACK_EN	0x0: Normal operating mode 0x1: Enable local loopback mode (internal). In this mode, the MCR_REG[3:0] signals are looped back into MSR_REG[7:4]. The transmit output is looped back to the receive input internally.	RW	0
3	CD_STS_CH	0x0: In loopback, forces nDCD input high and IRQ outputs to INACTIVE state. 0x1: In loopback, forces nDCD input low and IRQ outputs to INACTIVE state.	RW	0
2	RI_STS_CH	0x0: In loopback, forces nRI input inactive (high). 0x1: In loopback, forces nRI input active (low).	RW	0
1	RTS	In loop back, controls MSR_REG[4].If auto-RTS is enabled, the nRTS output is controlled by hardware flow control. 0x0: Force nRTS output to inactive (high). 0x1: Force nRTS output to active (low).	RW	0
0	DTR	0x0: Force DTR output (used in loop back mode) to inactive (high). 0x1: Force DTR output (used in loop back mode) to active (low).	RW	0

14.6.2.11 XON1_ADDR1_REG

Table 14-60. XON1_ADDR1_REG

Address Offset	0x010		
Physical Address	0x4806 A010	**Instance**	UART1
	0x4806 C010		UART2
	0x4902 0010		UART3
	0x4809 E000		UART4
Description	UART mode: XON1 character, IrDA mode: ADDR1 address		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								XON_WORD1							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00	R	0x00
7:0	XON_WORD1	Used to store the 8-bit XON1 character in UART modes and ADDR1 address 1 for IrDA modes	RW	0x00

14.6.2.12 LSR_REG

Table 14-61. LSR_REG

Address Offset	0x014		
Physical Address	0x4806 A014	**Instance**	UART1
	0x4806 C014		UART2
	0x4902 0014		UART3
	0x4809 E000		UART4
Description	Line status register		
Type	R		

14.6.2.12.1 UART Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RX_FIFO_STS	TX_SR_E	TX_FIFO_E	RX_BI	RX_FE	RX_PE	RX_OE	RX_FIFO_E

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	RX_FIFO_STS		R	0
		0x0: Normal operation		
		0x1: At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO.		
6	TX_SR_E		R	1
		0x0: Transmitter hold (TX FIFO) and shift registers are not empty.		
		0x1: Transmitter hold (TX FIFO) and shift registers are empty		
5	TX_FIFO_E		R	1
		0x0: Transmit hold register (TX FIFO) is not empty.		
		0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.		
4	RX_BI		R	0
		0x0: No break condition		
		0x1: A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame).		
3	RX_FE		R	0
		0x0: No framing error in data being read from RX FIFO		
		0x1: Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit).		
2	RX_PE		R	0
		0x0: No parity error in data being read from RX FIFO		
		0x1: Parity error in data being read from RX FIFO		
1	RX_OE		R	0
		0x0: No overrun error		
		0x1: Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full.		
0	RX_FIFO_E		R	0

Bits	Field Name	Description	Type	Reset
		0x0: No data in the receive FIFO		
		0x1: At least one data character in the RX FIFO		

14.6.2.12.2 IrDA Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								THR_EMPTY	STS_FIFO_FUL	RX_LAST_BYTE	FRAME_TOO_LONG	ABORT	CRC	STS_FIFO_E	RX_FIFO_E

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	THR_EMPTY		R	0
		0x0: Transmit holding register (TX FIFO) is not empty.		
		0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.		
6	STS_FIFO_FUL		R	1
		0x0: Status FIFO not full		
		0x1: Status FIFO full		
5	RX_LAST_BYTE	Receive last byte	R	1
		0x0: The RX FIFO (RHR_REG) does not contain the last byte of the frame to be read.		
		0x1: The RX FIFO (RHR_REG) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR_REG register.		
4	FRAME_TOO_LONG	Frame too long	R	0
		0x0: No frame-too-long error in frame		
		0x1: Frame-too-long error in the frame at the top of the STATUS FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH_REG and RXFLL_REG registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.		
3	ABORT		R	0
		0x0: No abort pattern error in frame		
		0x1: Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol.		
2	CRC		R	0
		0x0: No CRC error in frame		
		0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read)		
1	STS_FIFO_E		R	0
		0x0: Status FIFO not empty		
		0x1: Status FIFO empty		
0	RX_FIFO_E		R	1
		0x0: At least one data character in the RX FIFO		

Bits	Field Name	Description	Type	Reset
		0x1: No data in the receive FIFO		

14.6.2.12.3 CIR Bitfield Details

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								THR_EMPTY	Reserved						

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	THR_EMPTY		R	0
		0x0: Transmit holding register (TX FIFO) is not empty.		
		0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.

14.6.2.13 XON2_ADDR2_REG

Table 14-62. XON2_ADDR2_REG

Address Offset	0x014		
Physical Address	0x4806 A014	**Instance**	UART1
	0x4806 C014		UART2
	0x4902 0014		UART3
	0x4809 E000		UART4
Description			
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								XON_WORD2							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	XON_WORD2	Stores the 8-bit XON2 character in UART modes and ADDR2 address 2 for IrDA modes	RW	0x00

14.6.2.14 XOFF1_REG

Table 14-63. XOFF1_REG

Address Offset	0x018		
Physical Address	0x4806 A018	**Instance**	UART1
	0x4806 C018		UART2
	0x4902 0018		UART3
	0x4809 E000		UART4
Description	UART mode XOFF1 character		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								XOFF_WORD1							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00	R	0x00
7:0	XOFF_WORD1	Stores the 8-bit XOFF1 character used in UART modes	RW	0x00

14.6.2.15 TCR_REG

Table 14-64. TCR_REG

Address Offset	0x018		
Physical Address	0x4806 A018	**Instance**	UART1
	0x4806 C018		UART2
	0x4902 0018		UART3
	0x4809 E000		UART4
Description	Transmission control register.		
	This register stores the receive FIFO threshold levels to start/stop transmission during hardware flow control.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RX_FIFO_TRIG_ START				RX_FIFO_TRIG_ HALT			

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:4	RX_FIFO_TRIG_ START	RX FIFO trigger level to RESTORE transmission (0 to 60)	RW	0x0
3:0	RX_FIFO_TRIG_ HALT	RX FIFO trigger level to HALT transmission (0 to 60)	RW	0xF

14.6.2.16 MSR_REG

Table 14-65. MSR_REG

Address Offset	0x018		
Physical Address	0x4806 A018	**Instance**	UART1
	0x4806 C018		UART2
	0x4902 0018		UART3
	0x4809 E000		UART4
Description	Modem status register. UART mode only.		
	This register provides information about the current state of the control lines from the modem, data set, or peripheral device to the MPU. It also indicates when a control input from the modem changes state.		
Type	R		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								NCD_STS	NRI_STS	NDSR_STS	NCTS_STS	DCD_STS	RI_STS	DSR_STS	CTS_STS

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	NCD_STS	In loopback mode, it is equivalent to MCR_REG[3].	R	-
6	NRI_STS	This bit is the complement of the nRI input. In loopback mode, it is equivalent to MCR_REG[2].	R	-
5	NDSR_STS	In loopback mode, it is equivalent to MCR_REG[0].	R	-
4	NCTS_STS	This bit is the complement of the nCTS input. In loopback mode, it is equivalent to MCR_REG[1].	R	-
3	DCD_STS	Indicates that MCR_REG[3] in loopback changed. Cleared on a read.	R	0
2	RI_STS	Indicates that nRI input (or MCR_REG[2] in loopback) changed state from low to high. Cleared on a read.	R	0
1	DSR_STS	0x1: Indicates that MCR_REG[0] in loopback changed state. Cleared on a read.	R	0
0	CTS_STS	0x1: Indicates that nCTS input (or MCR_REG[1] in loopback) changed state. Cleared on a read.	R	0

14.6.2.17 SPR_REG

Table 14-66. SPR_REG

Address Offset	0x01C		
Physical Address	0x4806 A01C	**Instance**	UART1
	0x4806 C01C		UART2
	0x4902 001C		UART3
	0x4809 E000		UART4
Description	Scratchpad register		
	This read/write register does not control the module. It is a scratchpad register used by the programmer to hold temporary data.		
Type			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								SPR_WORD							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	SPR_WORD	Scratchpad register	RW	0x00

14.6.2.18 XOFF2_REG

Table 14-67. XOFF2_REG

Address Offset	0x01C		
Physical Address	0x4806 A01C	**Instance**	UART1
	0x4806 C01C		UART2
	0x4902 001C		UART3
	0x4809 E000		UART4
Description	UART mode XOFF2 character.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								XOFF_WORD2							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	XOFF_WORD2	Stores the 8-bit XOFF2 character used in UART modes	RW	0x00

14.6.2.19 TLR_REG

Table 14-68. TLR_REG

Address Offset	0x01C		
Physical Address	0x4806 A01C	**Instance**	UART1
	0x4806 C01C		UART2
	0x4902 001C		UART3
	0x4809 E000		UART4
Description	Trigger level register.		
	Stores the programmable transmit and receive FIFO trigger levels used for DMA and IRQ generation		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								RX_FIFO_TRIG_ DMA				TX_FIFO_TRIG_ DMA			

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:4	RX_FIFO_TRIG_ DMA	Receive FIFO trigger level	RW	0x0
3:0	TX_FIFO_TRIG_ DMA	Transmit FIFO trigger level	RW	0x0

14.6.2.20 MDR1_REG

Table 14-69. MDR1_REG

Address Offset	0x020		
Physical Address	0x4806 A020	**Instance**	UART1
	0x4806 C020		UART2
	0x4902 0020		UART3
	0x4809 E000		UART4
Description	Mode definition register 1.		
	The mode of operation can be programmed by writing to MDR1_REG[2:0]; therefore, the MDR1_REG must be programmed on startup after configuration of the configuration registers (DLL_REG, DLH_REG, LCR_REG). The value of MDR1_REG[2:0] must not be changed again during normal operation.		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FRAME_END_M ODE	SIP_MODE	SCT	SET_TXIR	IR_SLEEP	MODE_SELECT		

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	FRAME_END_ MODE	IrDA mode only	RW	0
		0x0: Frame-length method		
		0x1: Set EOT bit method		
6	SIP_MODE	MIR/FIR modes only. IrDA only.	RW	0
		0x0: Manual SIP mode: SIP is generated with the control of ACREG_REG[3].		
		0x1: Automatic SIP mode: SIP is generated after each transmission.		
5	SCT	Store and control the transmission.	RW	0
		0x0: Starts the infrared transmission when a value is written to THR_REG		
		0x1: Starts the infrared transmission with the control of ACREG_REG[2]		
		Note: Before starting any transmission, there must be no reception ongoing.		
4	SET_TXIR	Used to configure the infrared transceiver. IrDA only.	RW	0
		0x0: No action		
		0x1: IRTX pin output is forced high.		
3	IR_SLEEP		RW	0
		0x0: IrDA/CIR sleep mode disabled		
		0x1: IrDA/CIR sleep mode enabled		
2:0	MODE_SELECT	UART-IrDA-CIR mode selection	RW	0x7
		0x0: UART 16x mode		
		0x1: SIR mode		
		0x2: UART 16x auto-baud		
		0x3: UART 13x mode		

Bits	Field Name	Description	Type	Reset
		0x4: MIR mode		
		0x5: FIR mode		
		0x6: CIR mode		
		0x7: Disable (default state)		

14.6.2.21 MDR2_REG

Table 14-70. MDR2_REG

Address Offset	0x024		
Physical Address	0x4806 A024	**Instance**	UART1
	0x4806 C024		UART2
	0x4902 0024		UART3
	0x4809 E000		UART4
Description	Mode definition register 2		
	IR-IrDA and IR-CIR modes only		
	MDR2_REG[0] describes the status of the interrupt in IIR_REG[5]. The IRTX_UNDERRUN bit must be read after an IIR_REG[5] TX_STATUS_IT interrupt occurs. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1_REG[2:0].		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved	IRRXINVERT	CIR_PULSE_ MODE		UART_PULSE	STS_FIFO_TRIG		IRTX_UNDERRUN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	Reserved		R	0
6	IRRXINVERT	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_ MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x00
3	UART_PULSE	UART mode only. Used to allow pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with pulse shaping	RW	0
2:1	STS_FIFO_TRIG	Only for IR-IrDA mode Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x00
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the IIR_REG[5] interrupt occurs, the meaning of the interrupt is: 0x0: The last bit of the frame was transmitted successfully without error.	R	0

Bits	Field Name	Description	Type	Reset
		0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME_REG register is read.		

14.6.2.22 TXFLL_REG

Table 14-71. TXFLL_REG

Address Offset	0x028		
Physical Address	0x4806 A028	**Instance**	UART1
	0x4806 C028		UART2
	0x4902 0028		UART3
	0x4809 E000		UART4
Description	Transmit frame length register low		
	IrDA modes only		
	The registers TXFLL_REG and TXFLH_REG hold the 13-bit transmit frame length (expressed in bytes). TXFLL_REG holds the LSBs and TXFLH_REG holds the MSBs. The frame length value is used if the frame length method of frame closing is used.		
Type	W		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TXFLL							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Write has no functional effect.	W	0x00
7:0	TXFLL	LSB register used to specify the frame length	W	0x00

14.6.2.23 SFLSR_REG

Table 14-72. SFLSR_REG

Address Offset	0x028		
Physical Address	0x4806 A028	**Instance**	UART1
	0x4806 C028		UART2
	0x4902 0028		UART3
	0x4809 E000		UART4
Description	Status FIFO line status register		
	IrDA modes only		
	Reading this register effectively reads frame status information from the status FIFO (this register does not physically exist). Reading this register increments the status FIFO read pointer (SFREGL_REG and SFREGH_REG must be read first).		
Type	R		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Reserved			OE_ERROR	FTL_ERROR	ABORT_DETECT	CRC_ERROR	Reserved

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:5	Reserved		R	0x0
4	OE_ERROR		R	-
		0x1: Overrun error in RX FIFO when frame at top of RX FIFO was received. Top of RX FIFO = next frame to be read from RX FIFO.		
3	FTL_ERROR	Frame-too-long error	R	-
		0x1: Frame-length too long error in frame at top of RX FIFO		
2	ABORT_DETECT		R	-
		0x1: Abort pattern detected in frame at top of RX FIFO		
		0x1: CRC error in frame at top of RX FIFO		
1	CRC_ERROR		R	-
0	Reserved	Read returns 0.	R	0

14.6.2.24 RESUME_REG

	0x4806 C03C		UART2
	0x4902 003C		UART3
	0x4809 E000		UART4
Description	Auxiliary control register		
	IrDA-CIR mode only		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7	PULSE_TYPE	SIR pulse-width select: 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 µs	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 0x1: Disables RX input (permanent state; independent of transmit)	RW	0
4	DIS_TX_ UNDERRUN	0x0: Long stop bits cannot be transmitted. TX underrun is enabled. 0x1: Long stop bits can be transmitted. TX underrun is disabled.	RW	0
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and control TX start. When MDR1_REG[5] = 1 and the MPU writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The MPU can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.	RW	0

Bits	Field Name	Description	Type	Reset
0	EOT_EN	EOT (end-of-transmission) bit. The MPU writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the MPU writes to the THR_REG (TX FIFO).	RW	0

	0x4902 0048		UART3
	0x4809 E000		UART4
Description	BOF length register.		
	IR-IrDA mode only		
	In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOF.		
	In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								EBLR							

Bits	Field Name	Description	Type	Reset

	0x4902 005C		UART3
	0x4809 E000		UART4
Description	Wake-up enable register		
	The UART wake-up enable register is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/ or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such.		
Type	RW

		0x1: Event can wake up the system.		
4	EVENT_4_RX_ ACTIVITY		RW	1
		0x0: Event is not allowed to wake up the system.		
		0x1: Event can wake up the system.		
3	Reserved	Read returns 1. Must be set to 1 for correct behavior.	RW	1
2	EVENT_2_RI_ ACTIVITY		RW	1
		0x0: Event is not allowed to wake up the system.		
		0x1: Event can wake up the system.		
1	Reserved	Read returns 1. Must be set to 1 for correct behavior.	RW	1
0	EVENT_0_CTS_ ACTIVITY	UART mode only	RW	1
		0x0: Event is not allowed to wake up the system.		
		0x1: Event can wake up the system.		

14.6.2.39 CFPS_REG

Table 14-88. CFPS_REG

Address Offset	0x060		
Physical Address	0x4806 A060	**Instance**	UART1
	0x4806 C060		UART2
	0x4902 0060		UART3
	0x4809 E000		UART4
Description	Carrier frequency prescaler		
Type	RW		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								CFPS							

Bits	Field Name	Description	Type	Reset
15:8	Reserved	Read returns 0x00.	R	0x00
7:0	CFPS	Because the consumer IR works at modulation rates of 30-56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate remote-control requirements in BAUD multiples of 12x. The value of the CFPS at reset is 0105 (decimal), which equates to a 38.1-kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x BAUD multiple.	RW	0x69

Example:

Target Freq (kHz)	CFPS (decimal)	Actual Freq(kHz)
30	133	30.08
32.75	122	32.79
36	111	36.04
36.7	109	36.69
38	105	38.1
40	100	40
56.8	70	57.14

CFPS = 0 is not supported.

I^2C

This chapter describes the four high-speed I^2C controller modules.

Topic **Page**

15.1 High-Speed I²C Controller Overview

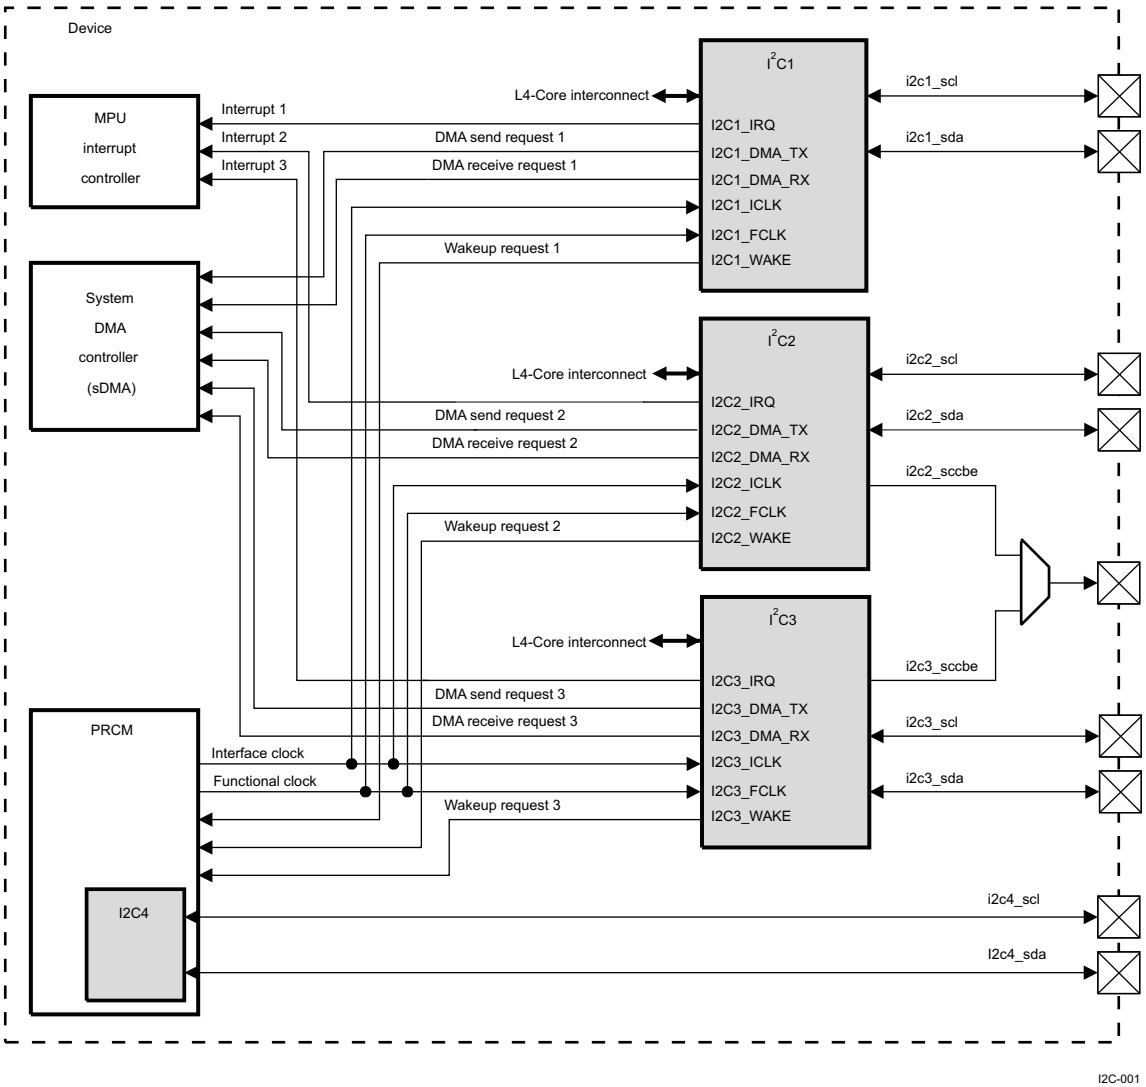
The device contains three multimaster high-speed (HS) inter-integrated circuit (I²C) controllers (I2Ci modules, where i = 1, 2, 3), each of which provides an interface between a local host (LH), such as the MPU subsystem, and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit/receive up to 8 bits of data to/from the LH device through the 2-wire I²C interface.

Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each multimaster HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I²C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains an additional master transmitter HS I²C interface (I2C4) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing. Texas Instruments provides a global solution with the device connected to power chips.

Figure 15-1 shows the HS I²C controllers in the device.

Figure 15-1. HS I²C Controllers



The three multimaster HS I²C controllers have the following features:

- Compliance with Philips I²C specification version 2.1

- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- Support for HS mode for transfer up to 3.4M bits/s
- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 module, up to 100K bits/s
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read or write
  - 8 bytes for I2C1 and I2C2
  - 64 bytes for I2C3
- Module enable/disable capability
- Programmable clock generation
- 8-bit-wide data access
- Low-power consumption design
- Two DMA channels
- Wide interrupt capability

The master transmitter HS I²C controller I2C4 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

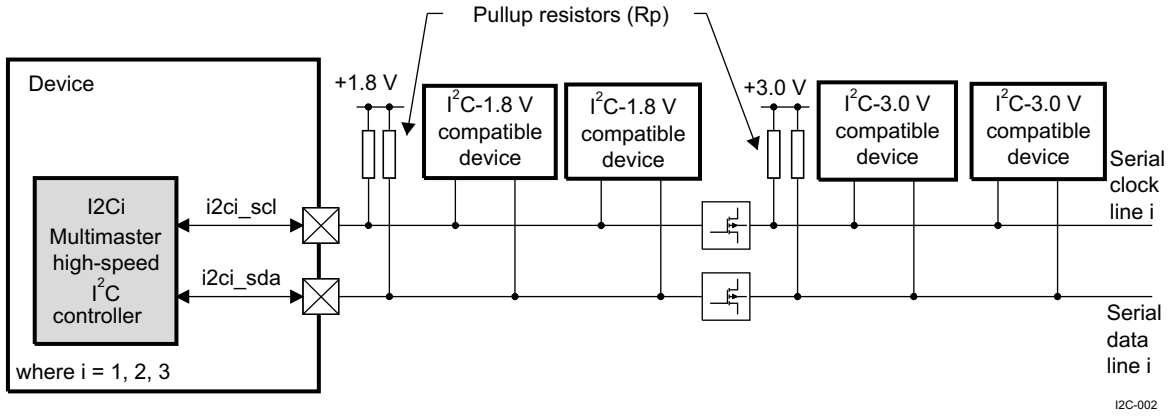
NOTE: Before using HS I²C mode, determine that the target device supports this mode.

15.2 High-Speed I²C Controller Environment

15.2.1 Multimaster HS I²C Controllers in I²C Mode

Figure 15-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices in I²C mode.

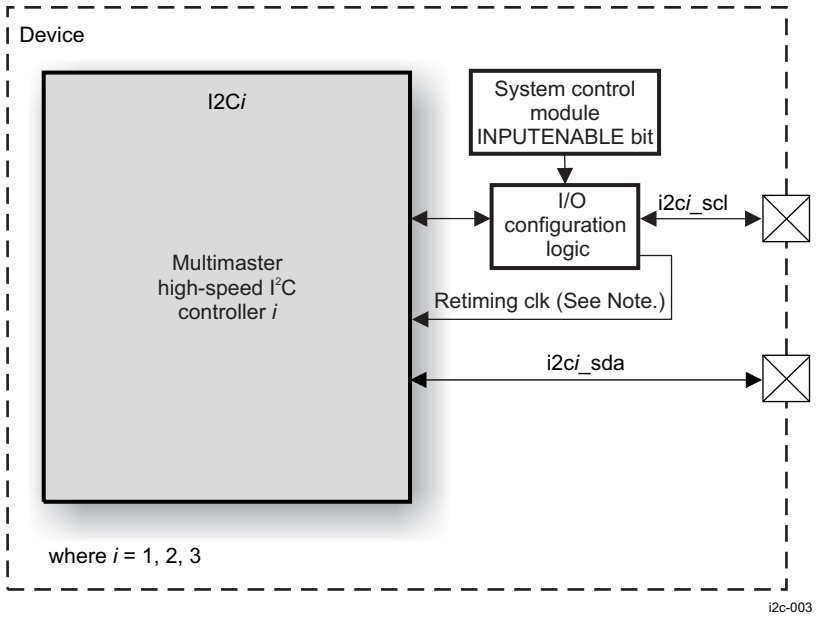
Figure 15-2. Multimaster HS I²C Controllers and Typical Connections to I²C Devices



15.2.1.1 Multimaster HS I²C Controller Pins for Typical Connections in I²C Mode

Figure 15-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

Figure 15-3. Multimaster HS I²C Controller Interface Signals in I²C Mode



NOTE: In master mode, the clock signal (IP clk configured as output) is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

15.2.1.2 I²C Interface Typical Connections

Table 15-1 lists the pins associated with the I²C interface.

Table 15-1. Input/Output

Signal	I/O[1]	Description	Reset Value
i2ci_scl	I/O(OD)	I²C serial clock line[2]. Open-drain output buffer. Requires external pullup resistor (Rp).	Hi-Z
i2ci_sda	I/O(OD)	I²C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z

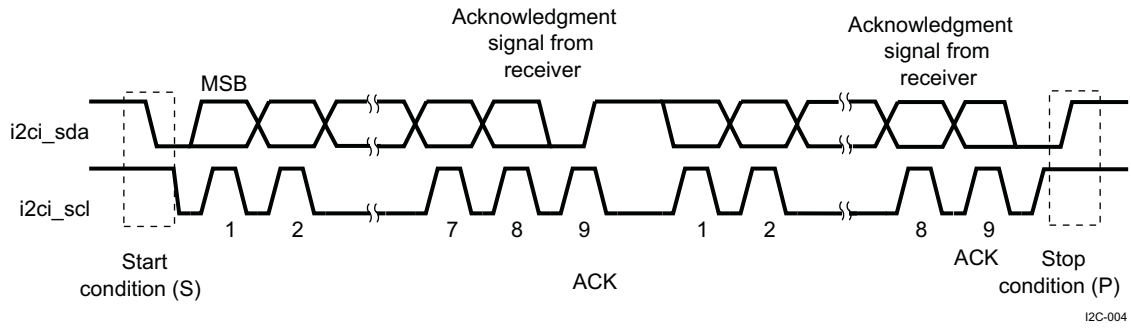
(1) I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance
(2) This signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

15.2.1.3 I²C Typical Connection Protocol and Data Format

15.2.1.3.1 Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line (i2ci_sda) is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 15-4 shows a typical I²C communication format.

Figure 15-4. I²C Data Transfer

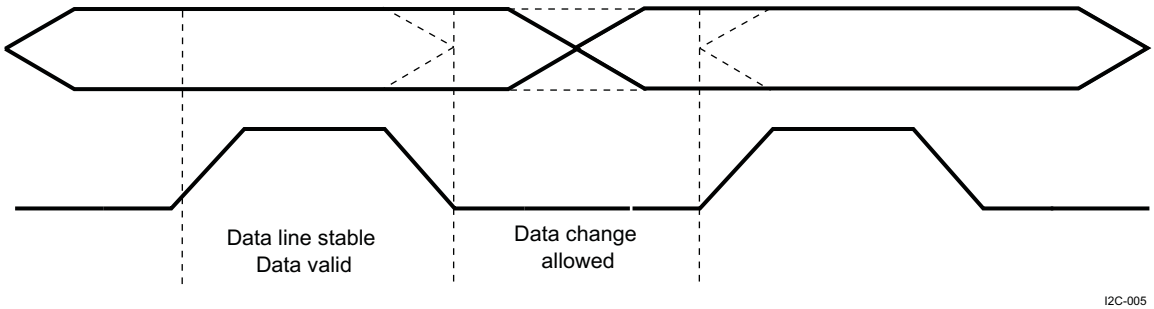


15.2.1.3.2 Data Validity

The data on the serial data line must be stable during the high period of the clock i2ci_scl. The high and low states of the data line can change only when the clock signal on the serial clock line is low.

Figure 15-5 is an example of data validity requirements.

Figure 15-5. Bit Transfer on the I²C Bus



15.2.1.3.3 Start and Stop Conditions

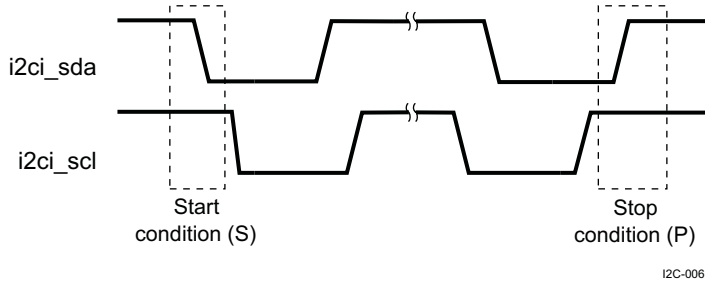
The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the i2ci_sda line while i2ci_scl is high.
- A P condition is a low-to-high transition on the i2ci_sda line while i2ci_scl is high.

The bus is considered busy after the S condition (the I2Ci.I2C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 15-6 shows the waveforms that occur during an S and a P condition.

Figure 15-6. S and P Condition Events



15.2.1.3.4 Addressing

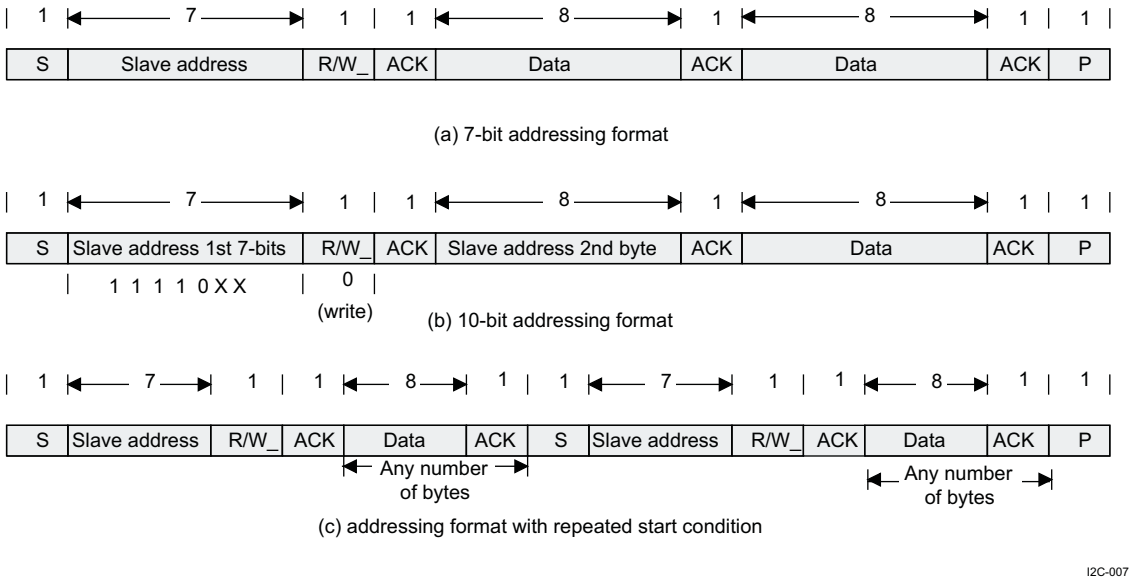
The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

15.2.1.3.4.1 Data Transfer Format in F/S Mode

Figure 15-7 shows the I²C data transfer format in F/S mode.

Figure 15-7. I²C Data Transfer Formats in F/S Mode



The first word after a S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

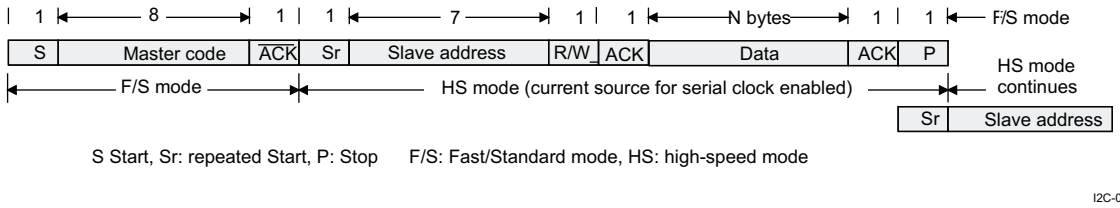
The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

15.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 15-8 shows the I²C data transfer format in HS mode.

Figure 15-8. I²C Data Transfers in HS Mode



Each multimaster HS I²C controller module can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 15-8.

NOTE: For more information, see *I²C Bus Specification v2.1*, January 2000.

15.2.1.3.5 Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on serial data line i2ci_sda in synchronization with the self-generated clock pulses on serial clock line i2ci_scl. When the intervention of the processor is required (I2Ci.I2C_STAT[10] XUDF bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low.

15.2.1.3.6 Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 15-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line i2ci_sda are shifted in synchronization with the self-generated clock pulses on i2ci_scl. When the intervention of the processor is required (I2Ci.I2C_STAT[11] ROVR bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low. At the end of a transfer, a P condition is generated.

15.2.1.3.7 Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 15-7), slave transmitter mode is entered if the slave address byte is the same as its own address, and when the R/W_ bit transmitted by the master transmitter is high. The slave transmitter shifts the serial data out on data line i2ci_sda in synchronization with the clock pulses generated by the master device. It does not generate the clock, but it can hold clock line i2ci_scl low when intervention of the LH is required (the I2Ci.I2C_STAT[10] XUDF bit).

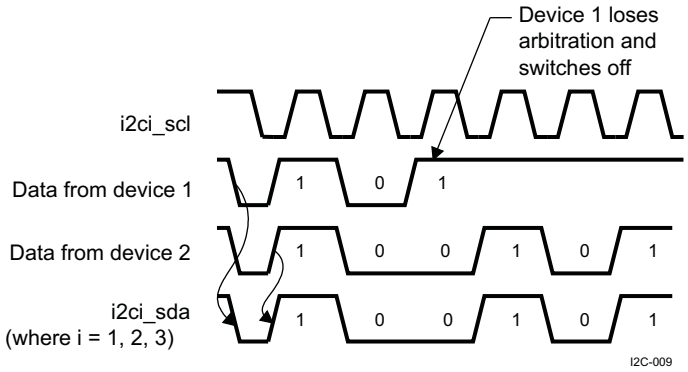
15.2.1.3.8 Slave Receiver

In slave receiver mode, serial data bits received on bus line i2ci_sda are shifted in in synchronization with the clock pulses on i2ci_scl generated by the master device. The slave receiver does not generate the clock, but it can hold the serial clock line low when intervention of the LH is required (the I2Ci.I2C_STAT[11] ROVR bit) after a byte is received.

15.2.1.3.9 Bus Arbitration

If two or more master transmitters start a transmission on the same bus simultaneously, an arbitration procedure is invoked. This arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to slave receiver mode, sets the arbitration lost flag (I2Ci.I2C_STAT[0] AL bit), and generates the arbitration lost interrupt. Figure 15-9 shows arbitration between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 15-9. Arbitration Between Master Transmitters



15.2.1.3.10 I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal i2ci_scl. During arbitration, however, there are two or more master devices, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that the device that first generates a low period of the clock line overrules the other devices. At this high-low transition, the clock generators of the other devices are forced to start generating their own low periods. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, all clock generators must enter the wait state. In this way, a slave can slow down a fast master, and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (Clock Stretching).

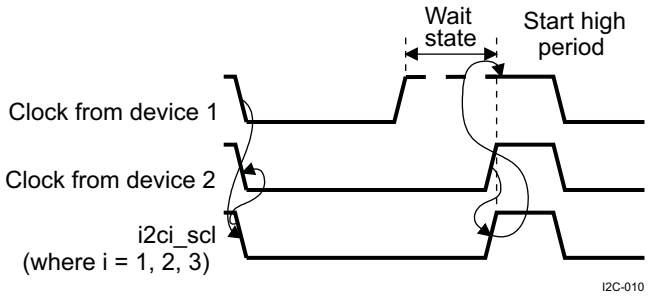
NOTE: In case the SCL or SDA lines are stuck low, the Bus Clear operation is supported:

If the clock line (SCL) is stuck low, the preferred procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.

If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 15-10 shows clock synchronization.

Figure 15-10. Synchronization of I²C Clock Generators



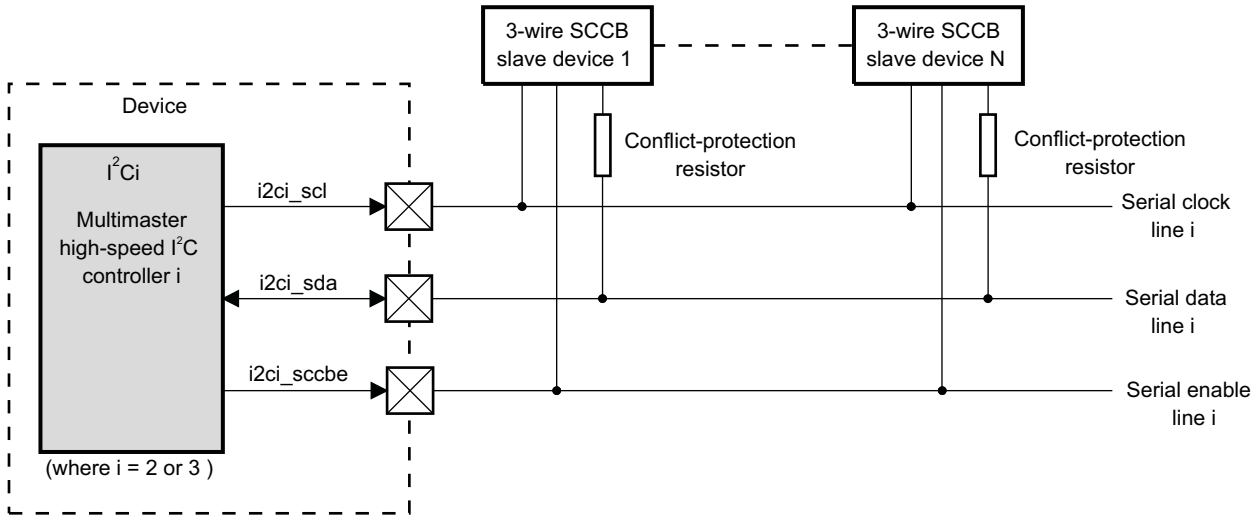
15.2.2 Multimaster High-Speed I²C Controllers in SCCB Mode

The SCCB is a 3-wire serial bus developed by Omnivision Technologies, Inc. The SCCB can also operate in a modified 2-wire serial mode. For details, see the SCCB specifications version 2.1 document at *http://www.ovt.com/pdfs/ds_note.pdf*.

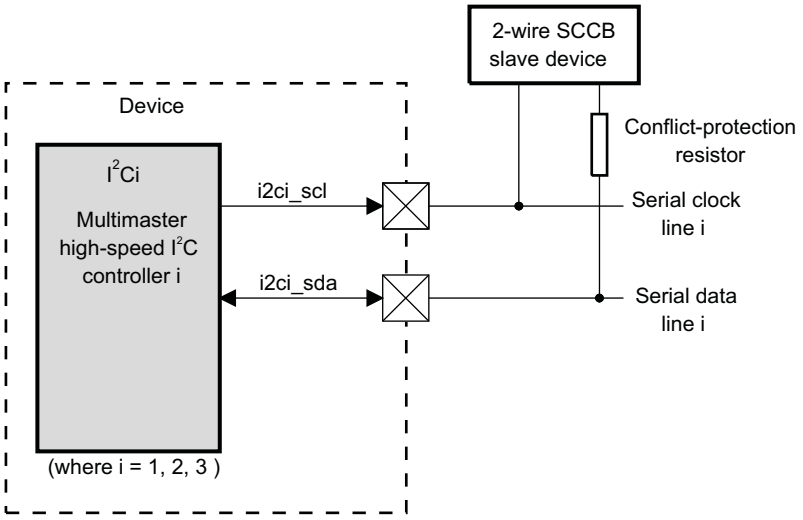
The multimaster HS I²C controllers support the 2-wire SCCB protocol in master mode. Only the I2C2 and I2C3 modules support the 3-wire SCCB protocol in master mode.

Figure 15-11 shows the multimaster HS I²C controllers and their related connections with 3-wire or 2-wire SCCB-compliant devices.

Figure 15-11. Multimaster HS I²C Controllers and Typical Connections to SCCB Devices



(a) Typical connection with 3-wire SCCB devices



(b) Typical connection with 2-wire SCCB devices

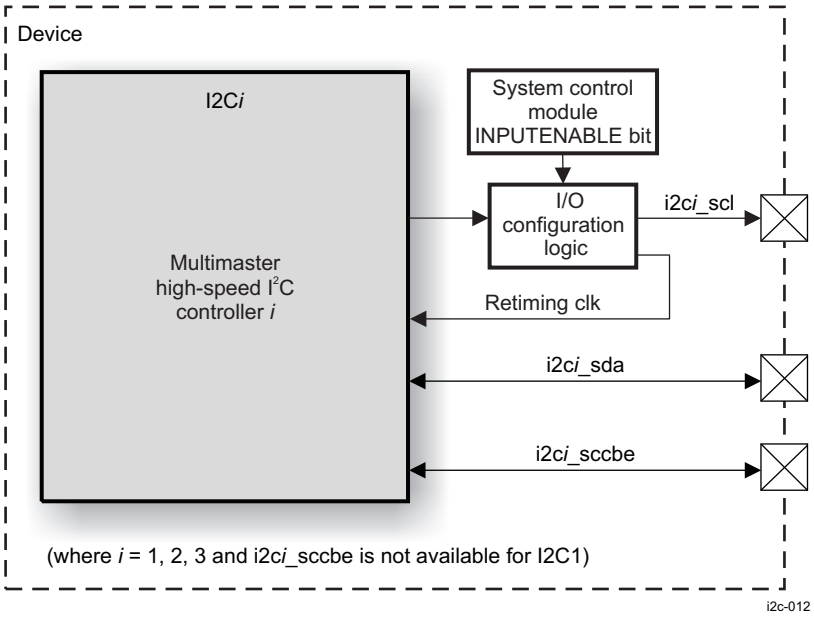
I2C-011

NOTE: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

15.2.2.1 Multimaster HS I²C Controller Pins for Typical Connections in SCCB Mode

Figure 15-12 shows the multimaster HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

Figure 15-12. Multimaster HS I²C Controller Interface Signals in SCCB Mode



15.2.2.2 SCCB Interface Typical Connections

Table 15-2 lists the pins associated with the SCCB interface.

Table 15-2. Input/Output

Signal	I/O[1]	Description	Reset Value	I2Ci.I2C_CON[15] I2C_EN bit = 0
i2ci_scl	O	SCCB serial clock line[2]. Standard CMOS output buffer.	Hi-Z	High
i2ci_sda	I/O(OD)	SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus.	Hi-Z	Hi-Z
i2ci_sccbe [3]	O	SCCB enable line. Standard CMOS output buffer.	High	High

(1) I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance
(2) This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).
(3) This signal is used for the 3-wire SCCB protocol only.

NOTE: Because they share the same ball, the i2c2_sccbe and i2c3_sccbe signals are not available at the same time. For detailed information about pin configuration, see Chapter 6, *System Control Module*.

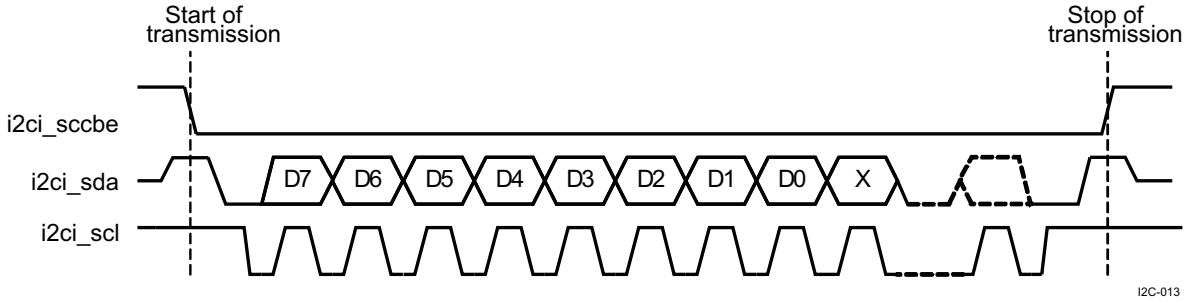
The I2C1 module does not provide any i2c1_sccbe signal at the chip boundary of the device; thus, this module does not support the 3-wire SCCB protocol

15.2.2.3 SCCB Typical Connection Protocol and Data Format

15.2.2.3.1 Serial Transmission Timing Diagram

Figure 15-13 is the timing diagram of the 3-wire SCCB data transmission.

Figure 15-13. 3-wire SCCB Transmission Timing Diagram

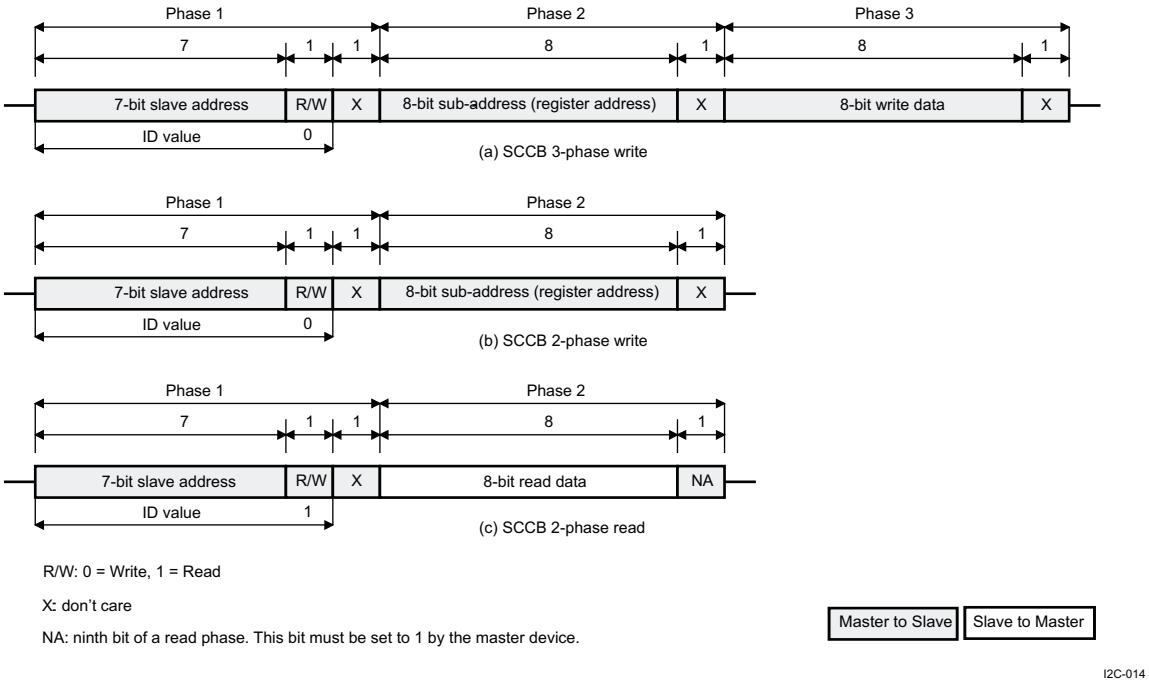


NOTE: When operating in 2-wire SCCB mode, the i2ci_sccbe signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

15.2.2.3.2 SCCB Transmission Data Formats

Figure 15-14 describes the data format of the three kinds of transmission.

Figure 15-14. SCCB Transmission Data Formats



The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- **3-phase write transmission**: The 3-phase write transmission cycle (see (a) of Figure 15-14) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave

address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).

- **2-phase write transmission**: The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of Figure 15-14) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).
- **2-phase read transmission**: Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of Figure 15-14) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

NOTE: A multimaster HS I²C controller configured in SCCB mode can perform two operations:

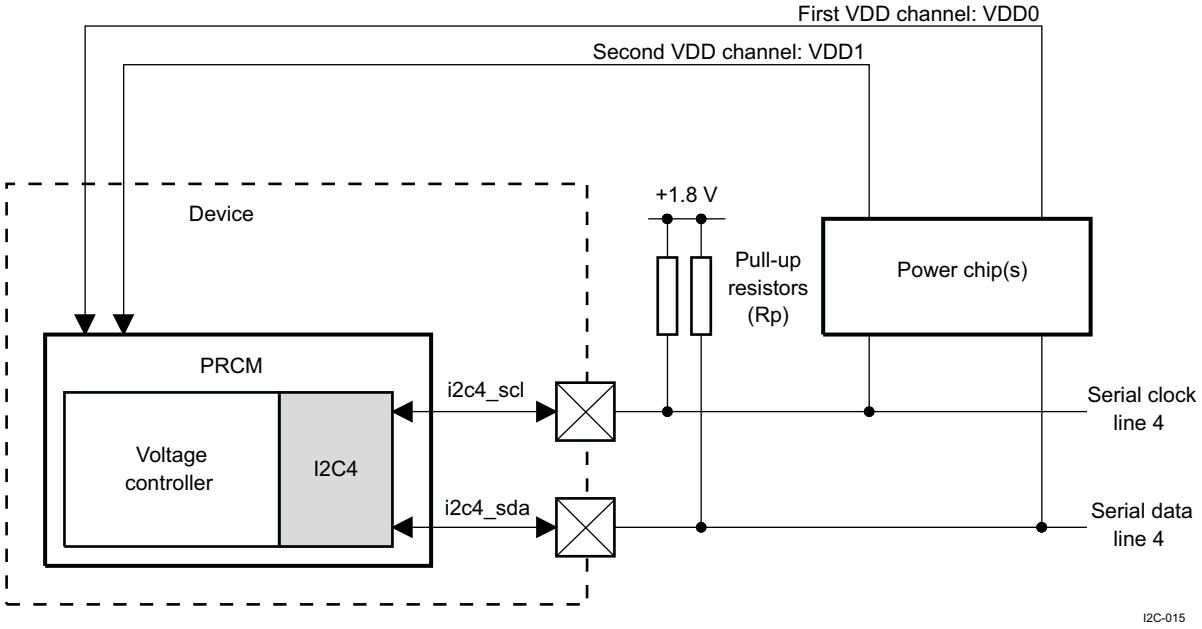
- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
- Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle

15.2.3 High-Speed I²C Controller for Communication With Power Chip(s)

The master transmitter HS I²C controller I2C4 interfaces between the and external power chip(s) for voltage control. This module is always configured as an I²C master transmitter; it does not support the SCCB protocol. For a definition of master transmitter mode, see Section 15.2.1.3.5, *Master Transmitter*.

Figure 15-15 shows a typical connection between the master transmitter HS I²C controller I2C4 of the device and external power chip(s).

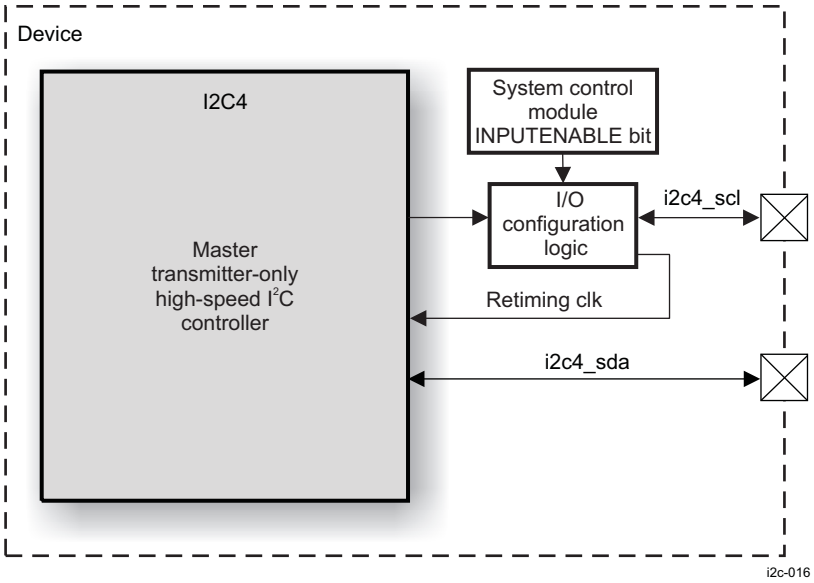
Figure 15-15. Typical Connection Between the HS I²C Controller and Power Chip(s)



15.2.3.1 HS I²C Controller I2C4 Pins for Typical Connections

Figure 15-16 shows the HS I²C controller I2C4 pins used for typical connections with power chips.

Figure 15-16. HS I²C Controller I2C4 Interface Signals



15.2.3.2 HS I²C Controller I2C4 Interface Typical Connections

Table 15-3 lists the pins associated with the I²C interface of the HS I²C controller I2C4 of the device.

Table 15-3. Input/Output Description

Signal	I/O[1]	Description	Reset Value
i2c4_scl	I/O(OD)	I²C serial clock line[2]. Open-drain output buffer. Requires external Rp.	Hi-Z
i2c4_sda	I/O(OD)	I²C serial data line. Open-drain output buffer. Requires external Rp.	Hi-Z

(1) I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

(2) This signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

15.2.3.3 I²C Typical Connections Protocol and Data Format for I2C4

15.2.3.3.1 Serial Data Format

The serial data format is the same as described in Section 15.2.1.3.1, *Serial Data Format*.

15.2.3.3.2 Data Validity

The data validity is the same as described in Section 15.2.1.3.2, *Data Validity*.

15.2.3.3.3 S and P Conditions

The S and stop P conditions are the same as described in Section 15.2.1.3.3, *Start and Stop Conditions*.

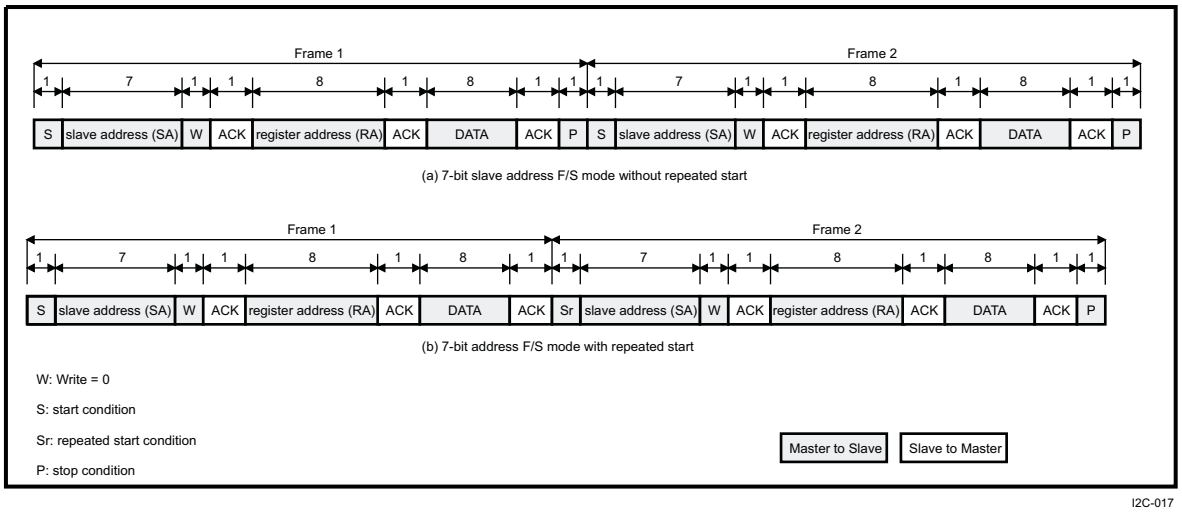
15.2.3.3.4 Addressing

The master transmitter HS I²C controller I2C4 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

15.2.3.3.4.1 Data Transfer Format in F/S Mode

Figure 15-17 shows the I²C data transfer format in F/S mode for the I2C4 module.

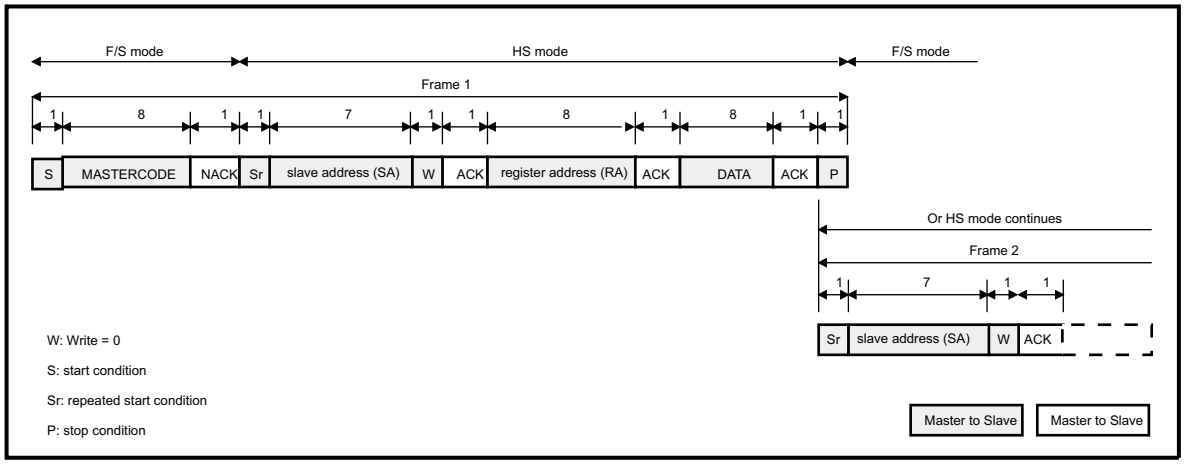
Figure 15-17. I²C Data Transfer Format in F/S Mode for the I2C4 Module



15.2.3.3.4.2 Data Transfer Format in HS Mode

Figure 15-18 shows the I²C data transfer format in HS mode for the I2C4 module.

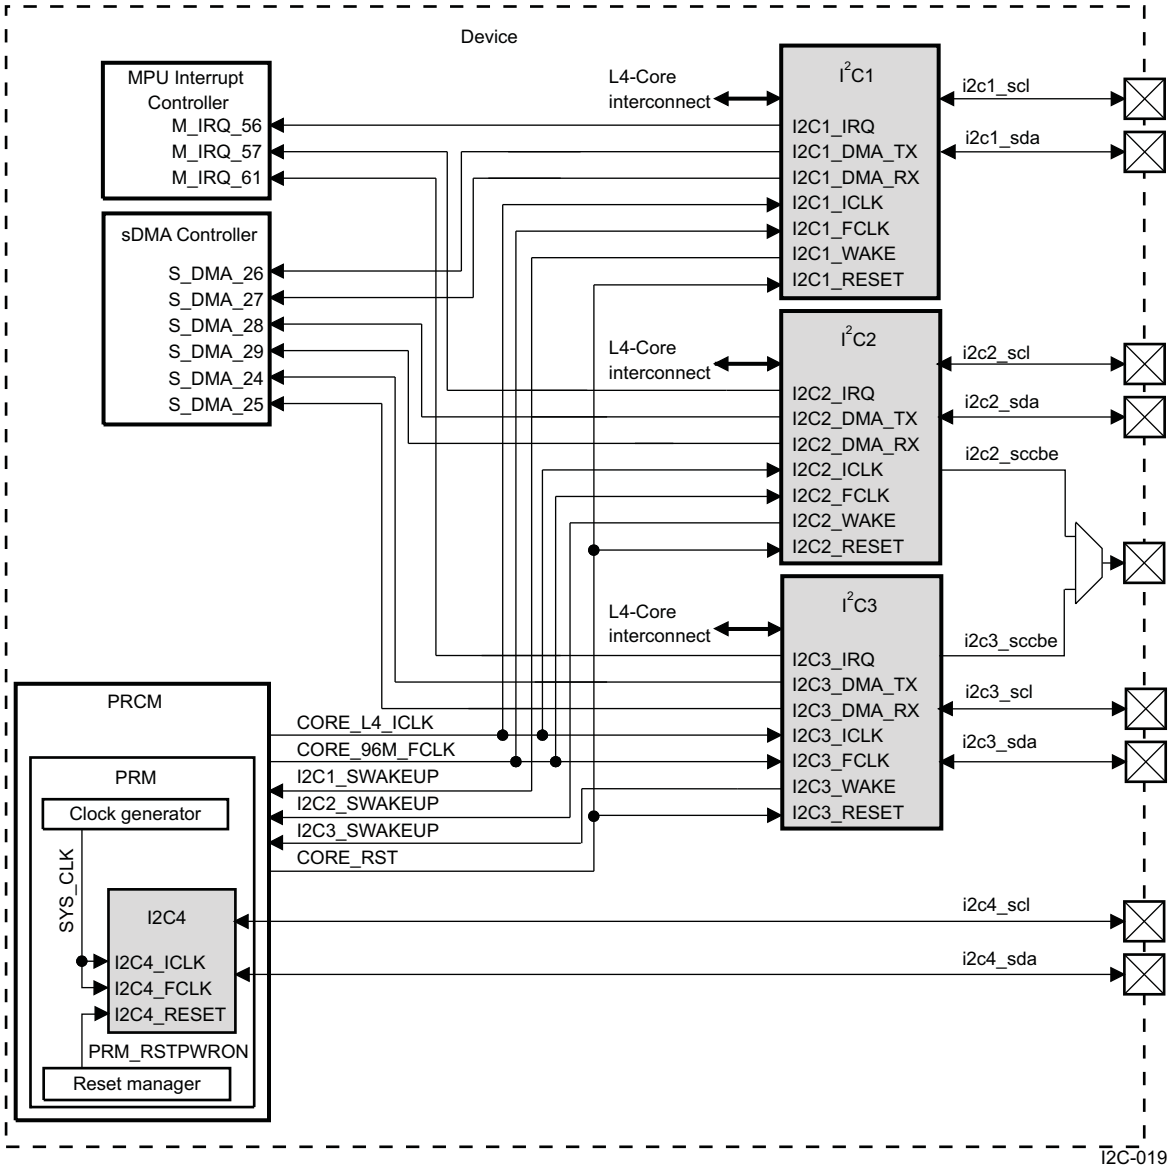
Figure 15-18. I²C Data Transfer Format in HS Mode for the I2C4 Module



15.3 High-Speed I²C Controller Integration

Figure 15-19 shows the integration of the four HS I²C controllers in the device.

Figure 15-19. HS I²C Controller Integration



15.3.1 Clocking, Reset, and Power-Management Scheme

15.3.1.1 Clocks

15.3.1.1.1 Module Clocks

Each multimaster HS I²C controller is clocked with an independent functional clock of 96 MHz (I2Ci_FCLK) and an interface clock (I2Ci_ICLK) for interfacing with the L4-Core interconnect. These clocks are provided by the PRCM module.

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C4. For detailed information about the module clocking, see , *Power, Reset, and Clock Management*.

The interface clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_ICLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module

- PRCM.CM_ICLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_FCLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module
- PRCM.CM_FCLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2Ci.I2C_PSC[7:0] PSC bit field (where i = 1, 2, 3) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci_FCLK/(I2Ci.I2C_PSC[7:0] PSC bit field value + 1, where i = 1, 2, 3).

NOTE: The I2C4.I2C_PSC[7:0] PSC bit field of the I2C4 module is not accessible by software. For details about the bit rates available for the I2C4 module, see Section 15.4.7.

15.3.1.2 Power Management

15.3.1.2.1 Module Power Saving

This section describes power-saving techniques for the multimaster HS I²C controllers. To conserve power, when no activity is detected on the L4-Core interconnect interface of the module, each of these modules supports an automatic idle mode that is enabled or disabled by setting the I2Ci.I2C_SYSC[0] AUTOIDLE bit.

When this bit is asserted (set to 1), if no activity is detected on the L4-Core interface, the automatic idle mode is enabled and the interface clock I2Ci_ICLK is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface of the module, the clock restarts with no latency penalty. After reset, the automatic idle mode is disabled; thus, this mode must be enabled by software for reduced power consumption.

15.3.1.2.2 System Power Management

As part of the system-wide power-management scheme, each multimaster HS I²C controller supports a communication protocol with the PRCM module to request the module to enter a low-power mode. When a module acknowledges a low-power mode request from the PRCM module, the interface and/or the functional clocks are gated off at the PRCM clock generator. Because the clocks are disabled at the source, the low-power mode offers lower power consumption than the internal clock autogating method used by local power management.

The PRCM.CM_ICLKEN1_CORE[15] EN_I2C1, PRCM.CM_ICLKEN1_CORE[16] EN_I2C2, and PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the interface clocks of the I2C1, I2C2, and I2C3 modules, respectively.

The PRCM.CM_FCLKEN1_CORE[15] EN_I2C1, PRCM.CM_FCLKEN1_CORE[16] EN_I2C2, and PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the functional clocks of the I2C1, I2C2, and I2C3 modules, respectively.

For details about clock enabling/disabling in the PRCM module, see , *Power, Reset, and Clock Management*.

Each multimaster HS I²C controller can be configured through the I2Ci.I2C_SYSC[4:3] IDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b00): The module immediately enters idle mode on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go to idle state.
- No-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b01): The module never enters idle mode.
- Smart-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b10): After receiving a low-power-mode request from the PRCM module, the module enters idle mode only after all asserted output interrupts are acknowledged and there is no pending internal event.

NOTE: The value I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b11 must not be used.

Table 15-4 describes the multimaster HS I²C controller power management modes.

Table 15-4. Multimaster HS I²C Controller Power Management Modes

Power management mode requested by the PRCM module	I2Ci.I2C_SYSC[4:3] IDLEMODE bit field value (where i = 1, 2, 3)
Force-idle	b00
No-idle	b01
Smart-idle	b10
Reserved (not used)	b11

The PRCM module gates the interface and/or the functional clocks after receiving the acknowledgment of the I2Ci module (where i = 1, 2, 3). The I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field indicates the state of the interface and functional clocks of the module when in idle mode. Table 15-5 lists the value of the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field and indicates the state of the interface and functional clocks at the PRCM clock generator output in idle mode.

Table 15-5. State of the Interface and Functional Clocks When the Module is in Idle Mode

I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field value (where i= 1, 2, 3)	Functional Clock	Interface Clock
b00	OFF	OFF
b01	OFF	ON
b10	ON	OFF
b11	ON	ON

NOTE: The PRCM.CM_AUTOIDLE1_CORE[15] AUTO_I2C1, PRCM.CM_AUTOIDLE1_CORE[16] AUTO_I2C2, and PRCM.CM_AUTOIDLE1[17] AUTO_I2C3 bits control, for each multimaster HS I²C controller, whether the L4-Core interconnect interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see , *Power, Reset, and Clock Management*).

NOTE: The voltage controller, in which the HS I²C controller I2C4 is implemented, has no idle request/acknowledge mechanism. The idle modes for the voltage controller are directly managed by the PRM module. For details, see , *Power, Reset, and Clock Management*.

15.3.1.2.3 Wake-Up Capability

Each multimaster HS I²C controller I2Ci can wake up the system by generating a wake-up request through the I2Ci_WAKE signal connected to the PRCM module.

The wake-up request is composed of the merge of all wake-up events. Each wake-up event can be separately enabled or disabled by setting the corresponding bit in the I2Ci.I2C_WE register.

The global wake-up capability of the module can be enabled or disabled by setting the I2Ci.I2C_SYSC[2] ENAWAKEUP bit (1: enabled, 0: disabled).

Figure 15-20 shows the wake-up generation flow.

Figure 15-20. Wake-up Generation Flow

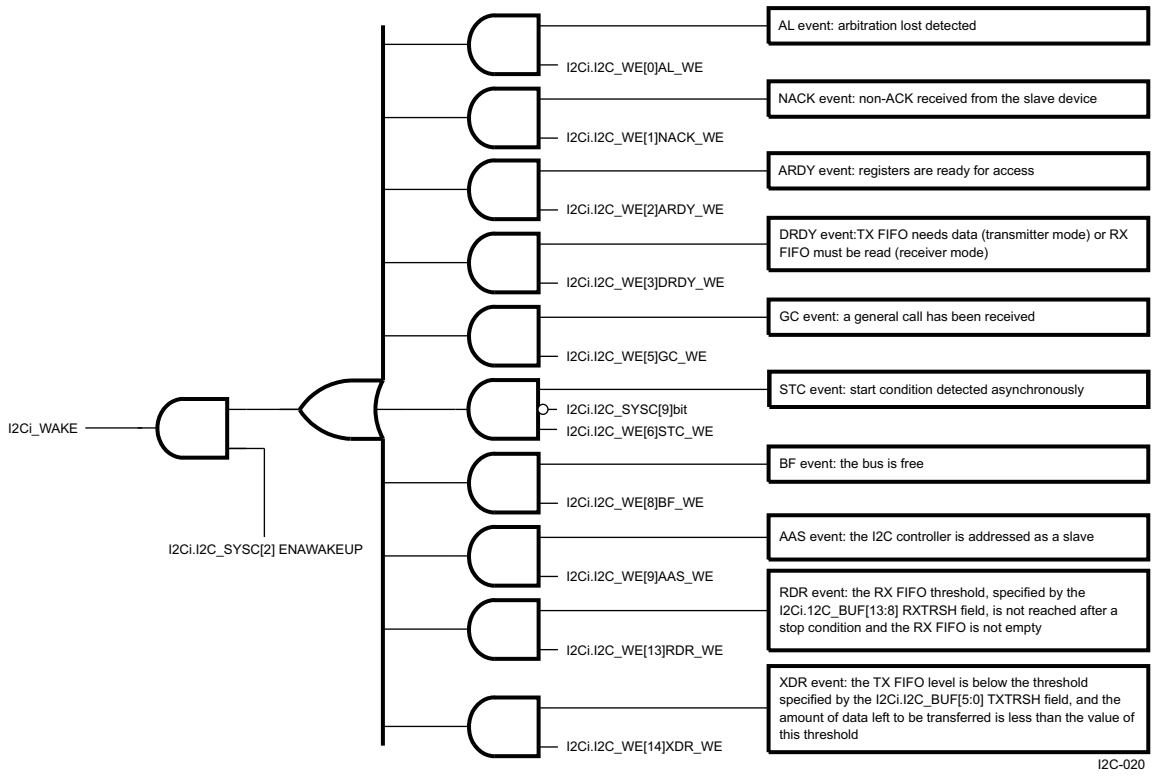


Table 15-6 lists all wake-up events with the corresponding enable/disable bit in the I2Ci.I2C_WE register.

Table 15-6. Wake-up Events

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit[1]	Event Generated When:
AL event	I²C mode only	I2Ci.I2C_WE[0] AL_WE	The I2Ci module in the device loses the arbitration of the I²C bus in master transmitter mode.
NACK event	I²C mode only	I2Ci.I2C_WE[1] NACK_WE	A nonacknowledgment has been generated on the I²C bus, indicating a transmission error.
ARDY event	I²C receive mode and SCCB read mode	I2Ci.I2C_WE[2] ARDY_WE	The current transaction is finished and the module registers can be accessed.
DRDY event	I²C and SCCB modes	I2Ci.I2C_WE[3] DRDY_WE	The TX FIFO needs some data to be transferred or the RX FIFO must be read.
GC event	I²C mode only	I2Ci.I2C_WE[5] GC_WE	A general call is received on the I²C bus.
STC event [2]	I²C mode only	I2Ci.I2C_WE[6] STC_WE	A start (S) condition is detected on the I²C bus.[3]
BF event	I²C and SCCB modes	I2Ci.I2C_WE[8] BF_WE	The bus is free and the LH can initiate its own transfer.

(1) To enable the corresponding wake-up event generation, set the bit to 1. To disable the corresponding wake-up event generation, set the bit to 0.
(2) Wake-up event asynchronously detected.
(3) This event must not be enabled if the functional clock cannot be disabled.

Table 15-6. Wake-up Events (continued)

Wake-up Event Name	Supported Configuration Mode	Enable/Disable bit[1]	Event Generated When:
AAS event	I²C mode only	I2Ci.I2C_WE[9] AAS_WE	An external master I²C device addresses the module of the device to inform the LH that it can check which of its own addresses was used by the external master I²C device to access the module of the device.
RDR event	I²C receive mode only	I2Ci.I2C_WE[13] RDR_WE	The module, configured as a receiver, has detected a stop (P) condition on the I²C bus and the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached and the RX FIFO is not empty. This allows the module to inform the LH that it can check the amount of data to be transferred from the RX FIFO.
XDR event	I²C master transmit mode only	I2Ci.I2C_WE[14] XDR_WE	The TXFIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the amount of data left to be transferred is less than this threshold. This allows the module to inform the LH that it can check the amount of data to be written to the TX FIFO.

NOTE: With the exception of the STC event, the functional clock must be active for wake-up event detection to occur. The HS I²C controller I2C4 has no wake-up capability.

15.3.1.3 Resets

15.3.1.3.1 Hardware Reset

The three multimaster HS I²C controllers receive their reset signal CORE_RST (the reset signal of the CORE power domain) from the PRCM module.

The master transmitter HS I²C controller I2C4 gets its reset signal PRM_RSTPWRON from the reset manager in the PRCM module.

15.3.1.3.2 Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset, 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done, 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.3.1.4 Power Domain

The three multimaster HS I²C controllers are connected to the CORE power domain, whereas the HS I²C controller I2C4 belongs to the WKUP power domain.

15.3.2 Hardware Requests

15.3.2.1 DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. Table 15-7 lists the DMA requests with mapping on the sDMA controller.

Table 15-7. Multimaster HS I²C Controller DMA Requests

Name	Source	Destination (sDMA controller)	Description
I2C1_DMA_TX	I2C1	S_DMA_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	S_DMA_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	S_DMA_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	S_DMA_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	S_DMA_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	S_DMA_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register

NOTE: The HS I²C controller I2C4 does not generate any DMA request.

15.3.2.2 Interrupt Requests

Each multimaster HS I²C controller can generate an interrupt I2Ci_IRQ to the MPU subsystem. Table 15-8 lists the interrupt requests with the mapping on the MPU interrupt controller.

Table 15-8. Multimaster HS I²C Controller Interrupt Requests

Name	Source	Destination (MPU interrupt controller)
I2C1_IRQ	I2C1	M_IRQ_56
I2C2_IRQ	I2C2	M_IRQ_57
I2C3_IRQ	I2C3	M_IRQ_61

An event can generate an interrupt request when the corresponding mask bit in the I2Ci.I2C_IE register is set to 1. Table 15-9 summarizes the events causing the generation of an interrupt request.

Table 15-9. Multimaster HS I²C Controller Interrupt Events

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
AL event	I²C mode only	I2Ci.I2C_STAT [0] AL	I2Ci.I2C_IE[0] AL_IE	Two or more I²C master devices initiate a transfer and the I²C module I2Ci in the device loses arbitration of the I²C bus.
NACK event	I²C mode only	I2Ci.I2C_STAT [1] NACK	I2Ci.I2C_IE[1] NACK_IE	A nonacknowledgment has been received. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1).

Table 15-9. Multimaster HS I²C Controller Interrupt Events (continued)

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
ARDY event	I²C and SCCB modes	I2Ci.I2C_STAT [2] ARDY	I2Ci.I2C_IE[2] ARDY_IE	One of the following cases occurs: • In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0, and the RX FIFO is empty. • In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is set to 1 and the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0. • In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is cleared to 0 and the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0. • In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0, and the RX FIFO is empty. • In I²C slave transmitter mode, a stop or start (S) condition is received from the external I²C master device. • In I²C slave receiver mode, a stop or start (S) condition is received from the external I²C master device and the RX FIFO is empty. • In SCCB master transmitter or receiver mode, a stop (P) condition is detected.
RRDY event	I²C receive mode and SCCB read mode	I2Ci.I2C_STAT [3] RRDY	I2Ci.I2C_IE[3] RRDY_IE	The RX FIFO level is above the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XRDY event	I²C transmit mode and SCCB write mode	I2Ci.I2C_STAT [4] XRDY	I2Ci.I2C_IE[4] XRDY_IE	The module requires new data to be served. A master transmitter module requests new data when the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the required amount of data to be transmitted specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field is greater than the threshold. A slave transmitter requests new data when the TX FIFO is below the threshold (if the I2Ci.I2C_BUF[5:0] XTRSH field value is greater than 1), or when there is a read request from the external master device (for each acknowledge received from the master) when the I2Ci.I2C_BUF[5:0] XTRSH field value is 1.
GC event	I²C mode only	I2Ci.I2C_STAT [5] GC	I2Ci.I2C_IE[5] GC_IE	The module detects a general call on the I²C bus (all bits of the address cleared to 0).
STC event	I²C mode only	I2Ci.I2C_STAT [6] STC	I2Ci.I2C_IE[6] STC_IE	The module is in idle mode and a start (S) condition is asynchronously detected on the I²C bus and signaled with a wakeup. When the active mode is restored and the interrupt generated, this bit indicates the reason for the wakeup. See (1).
AERR event	I²C and SCCB modes	I2Ci.I2C_STAT [7] AERR	I2Ci.I2C_IE[7] AERR_IE	A write access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the TX FIFO is full or a read access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the RX FIFO is empty. When the RX FIFO is empty, the read of the RX FIFO returns the previous read data value. When the TX FIFO is full, a write in the TX FIFO is ignored.
BF event	I²C and SCCB modes	I2Ci.I2C_STAT [8] BF	I2Ci.I2C_IE[8] BF_IE	The I²C bus becomes free (after a transfer is ended on the bus and a stop (P) condition is detected).
AAS event	I²C mode only	I2Ci.I2C_STAT [9] AAS	I2Ci.I2C_IE[9] AAS_IE	The module has recognized its own slave address or an alternate Own Address, or a general call (all address bits cleared to 0).

(1) The interrupt request generation on an STC event must be enabled only if the module is configured to allow the possibility of switching off the functional clock while in idle state (the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY field set to b00 or b01). The first transfer (corresponding to the detected start (S) condition) is lost, and is used only to restore the active mode of the module. On the I²C bus, the external master that generated the transfer detects this behavior as a nonacknowledge to the address phase and may possibly restart the transfer.

Table 15-9. Multimaster HS I²C Controller Interrupt Events (continued)

Event name	Supported configuration mode	Status bit	Mask bit	This event happens when:
RDR event	I²C receive mode only	I2Ci.I2C_STAT [13] RDR	I2Ci.I2C_IE[13] RDR_IE	The module is configured as a receiver, a stop (P) condition was received on the I²C bus, and the RX FIFO level is below the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1).
XDR event	I²C master transmit mode only	I2Ci.I2C_STAT [14] XDR	I2Ci.I2C_IE[14] XDR_IE	The module is configured as a master transmitter, the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1), and the amount of data still to be transferred is less than this threshold.

When an interrupt request is generated, the software must read the I2Ci.I2C_STAT register to check which event caused the interrupt request generation, process accordingly, and acknowledge each processed event by writing 1 to the corresponding bit in the I2Ci.I2C_STAT register.

NOTE: The I2Ci.I2C_STAT[9] AAS status bit, corresponding to the AAS event, can be cleared in two ways:

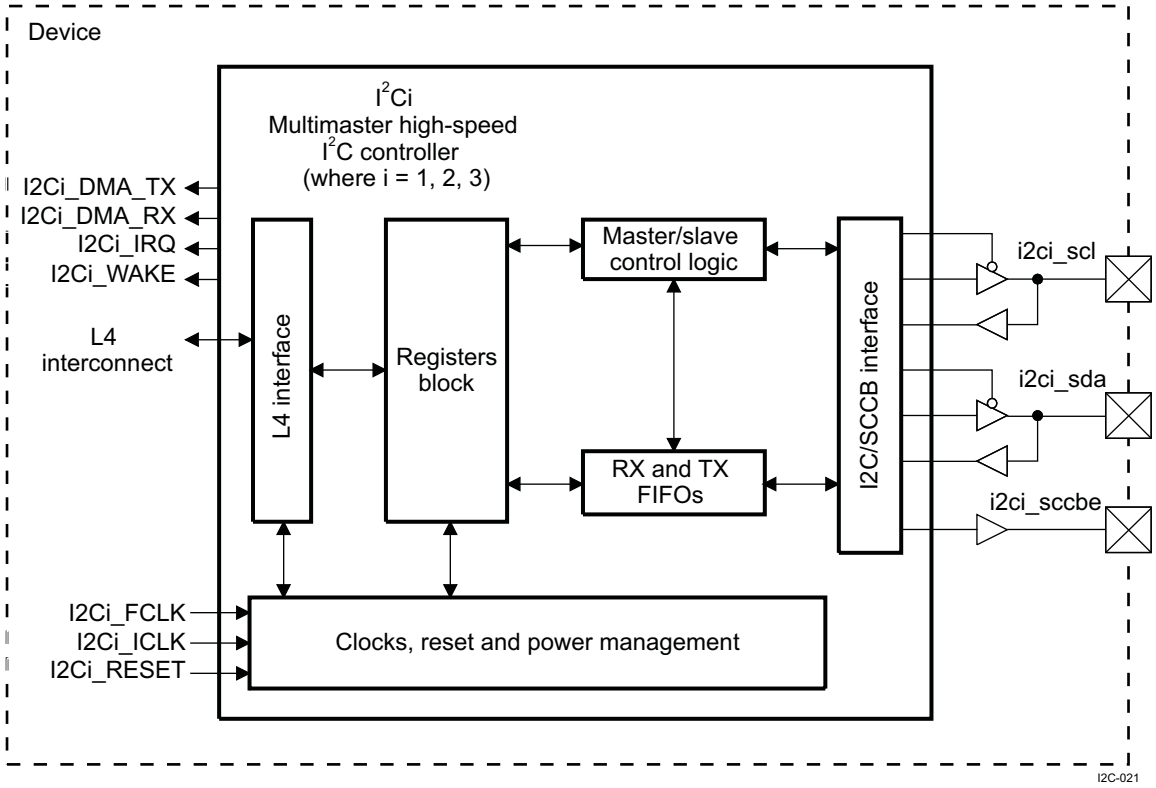
- If the I2Ci.I2C_IE[9] AAS_IE bit is set to 1 (interrupt generation enabled), the status bit is cleared by writing 1 to the I2Ci.I2C_STAT[9] AAS status bit
- If the I2Ci.I2C_IE[9] AAS_IE bit is cleared to 0 (interrupt generation disabled), the status bit is cleared when a new start or stop (P) condition is detected on the I²C bus.

15.4 High-Speed I²C Controller Functional Description

15.4.1 Block Diagram

Figure 15-21 is a functional block diagram of the multimaster I²C HS controller.

Figure 15-21. Multimaster HS I²C Controller Block Diagram



NOTE: The i2c1_sccbe signal is not available.

The three multimaster HS I²C controllers can be configured in F/S I²C mode, in HS I²C mode, or in SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE field. Table 15-10 lists the available operation modes.

Table 15-10. Operation Mode Selection

Operation Mode	I2Ci.I2C_CON[13:12] OPMODE field value
Fast/standard (F/S) I²C	0x0
High-speed (HS) I²C	0x1
SCCB	0x2
Reserved (not used)	0x3

15.4.2 Transmit Mode in I²C Mode

This mode is available for master or slave. The master and slave modes are configurable with the I2Ci.I2C_CON[10] MST bit (0: slave mode, 1: master mode).

In master mode, the transmit mode is configured by setting the I2Ci.I2C_CON[9] TRX bit to 1. The MPU subsystem puts the data to transmit in the TX FIFO by writing to the I2Ci.I2C_DATA[7:0] DATA bit field.

The transmitter can write new data to this register when the I2Ci.I2C_STAT[4] XRDY bit is set to 1, or when the I2Ci.I2C_STAT[14] XDR bit is set to 1 according to the draining mechanism description.

A master transmitter requests new data if the I2Ci.I2C_CNT[15:0] DCOUNT bit field value is not 0. A slave transmitter requests new data if a read is performed by the external master.

NOTE: The HS I2C controller I2C4 is configured in master transmitter mode, and its configuration cannot be changed.

15.4.3 Receive Mode in I²C Mode

This mode is available for master or slave. In master mode, it is configured by clearing the I2Ci.I2C_CON[9] TRX bit to 0.

The MPU subsystem can read new data from the I2Ci.I2C_DATA[15:0] DCOUNT bit field when the I2Ci.I2C_STAT[3] RRDY bit is set to 1, or when the I2Ci.I2C_STAT[13] RDR bit is set according to the draining mechanism description.

Each time the I2Ci.I2C_STAT[3] RRDY bit is set to 1, if the interrupt is enabled (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1), the I²C controller generates an interrupt to the MPU subsystem.

NOTE: In interrupt mode, the MPU subsystem must read this bit after each read in the I2Ci.I2C_DATA register to ensure that no other data is waiting for the FIFO to be read. For a new interrupt to be received, the I2Ci.I2C_STAT[3] RRDY bit must be cleared in the interrupt routine.

If the DMA receive mode is enabled (the I2Ci.I2C_BUF[15] RDMA_EN bit is set), this bit is forced to 0 and no interrupt is generated; instead, a DMA RX request to the sDMA controller is generated.

15.4.4 FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

Table 15-11 lists the depth of these FIFOs, depending on the instance of the I²C controller.

Table 15-11. RX and TX FIFO Depths

I²C Controller Instance	RX and TX FIFO Depth (in bytes)
I2C1	8
I2C2	8
I2C3	64

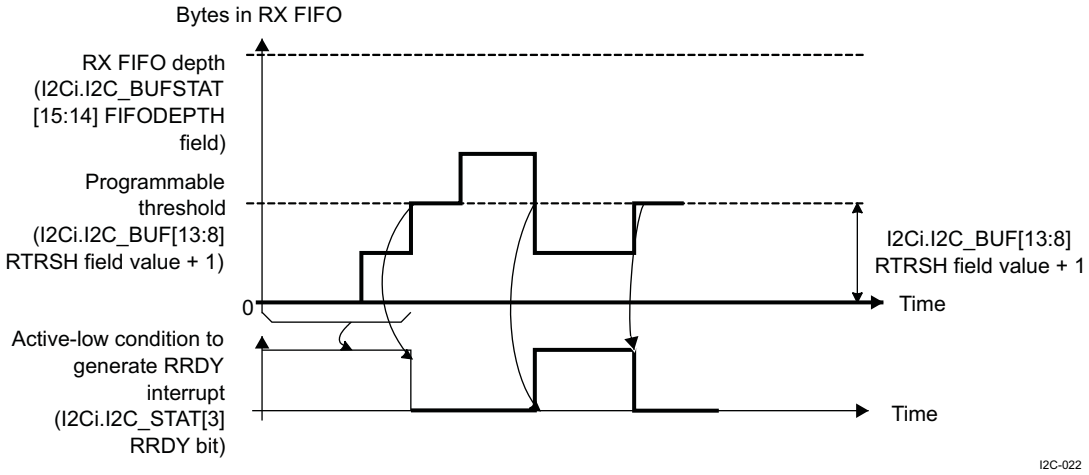
The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

15.4.4.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), the processor is informed of the receiver and transmitter status by an interrupt signal. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller module in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 15-22 and Figure 15-23 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 15-22. Receive FIFO Interrupt Request Generation

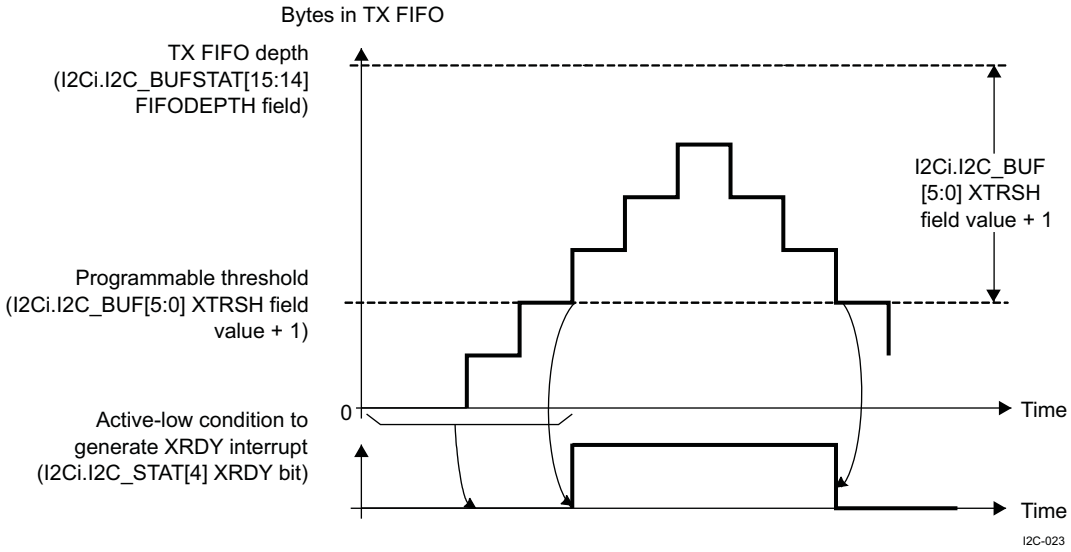


In Figure 15-22, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

Figure 15-23. Transmit FIFO Interrupt Request Generation



In Figure 15-23, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by writing 1 in the I2Ci.I2C_STAT[4] XRDY bit after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY/RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is no longer met.
- When detecting an interrupt request (XRDY/RRDY type), the LH can be programmed to write/read the number of data bytes specified by the corresponding FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY/RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 15.4.4.4).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

15.4.4.2 FIFO Polling Mode Operation

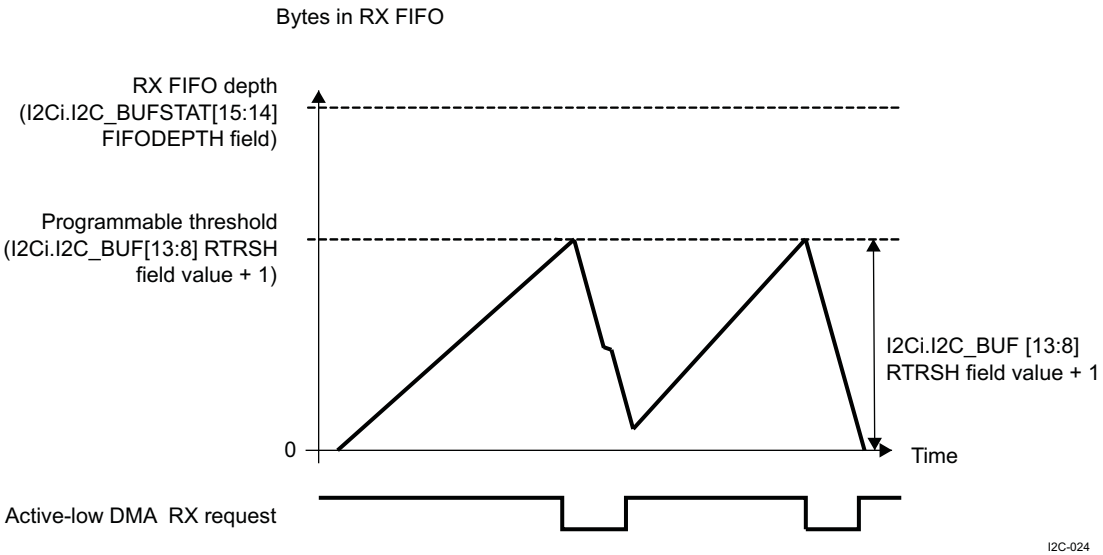
In FIFO polled mode (the I2Ci.I2C_IE[4] XRDY_IE and I2Ci.I2C_IE[3] RRDY_IE bits are disabled, and the I2Ci.I2C_BUF[15] RDMA_EN and I2Ci.I2C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_STAT[4] XRDY and the I2Ci.I2C_STAT[3] RRDY bits (the I2Ci.I2C_STAT[13] RDR and I2Ci.I2C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_STAT[4] XRDY and I2Ci.I2C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of the FIFO interrupt mode operation.

15.4.4.3 FIFO DMA Mode Operation (I²C Mode Only)

In receive mode, a DMA request is generated by the I2Ci_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA controller.

Figure 15-24 shows the DMA request generation in receive mode.

Figure 15-24. Receive FIFO DMA Request Generation



In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 15-25 and Figure 15-26 show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] XTRSH bit field.

Figure 15-25. Transmit FIFO Request Generation (High Threshold)

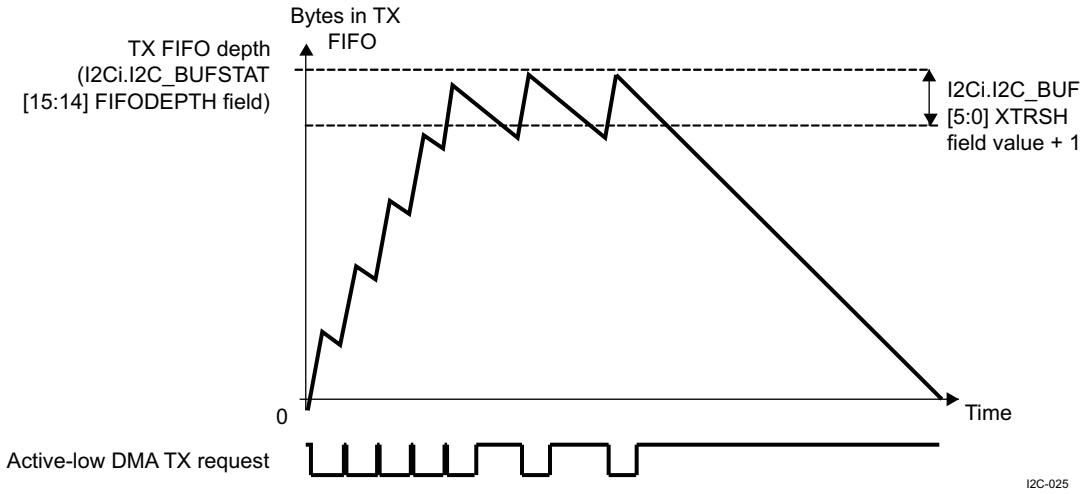


Figure 15-26. Transmit FIFO Request Generation (Low Threshold)

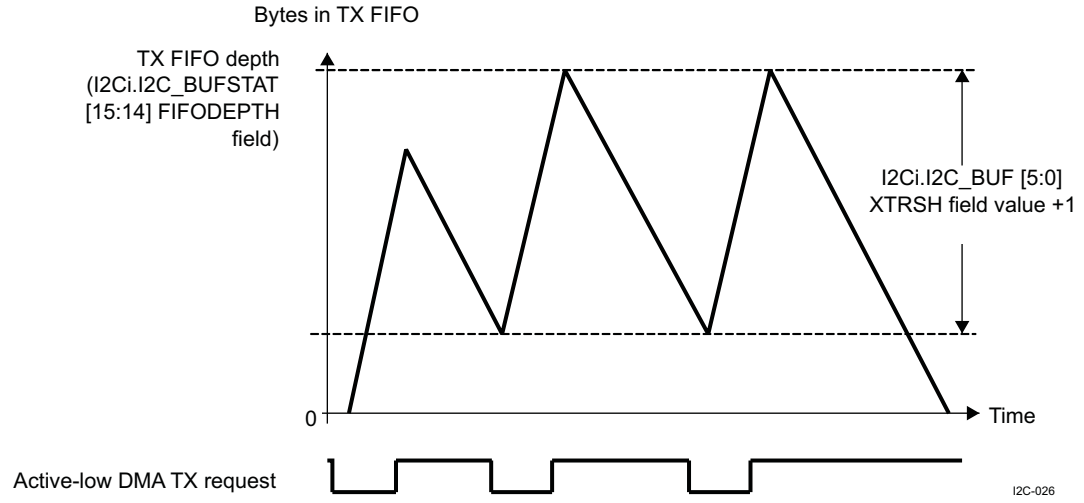


NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

The I²C module allows the user to clear the RX or TX FIFO by setting the I2Ci.I2C_BUF[14] RXFIFO_CLR and I2Ci.I2C_BUF[6] TXFIFO_CLR bits, which act like software reset for the FIFOs. In DMA mode, these bits also reset the DMA state-machines. The FIFO clearing feature can be used when the following conditions are met:

- The module is configured as a transmitter.
- The external receiver responds with a NACK in the middle of the transfer.
- Data in the TX FIFO are still waiting to be transferred.

15.4.4.4 Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold and I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold). It also offers the possibility of transferring the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR status bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or the I2Ci.I2C_STAT[14] XDR status bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached, but the transfer ends on the I²C bus and there is still data in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR status bit) is asserted to inform the LH that it can read the amount of data in the FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field value (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR status bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately skip the checking of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT field values, because it can obtain this information internally (by computing the the I2Ci.I2C_CNT[15:0] DATACOUNT field value modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] XTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold).

15.4.5 Programmable Multislave Channel Feature (I²C Mode Only)

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OAx registers (with x = 0, 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

15.4.6 Automatic Blocking of the I²C Clock Feature (I²C Mode Only)

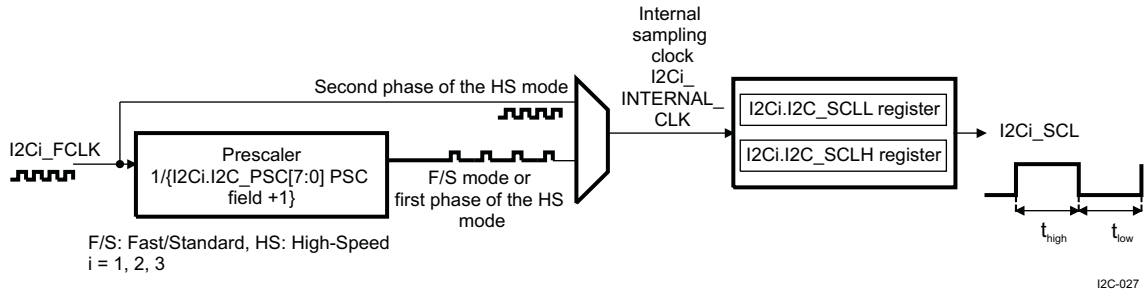
This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock (i2ci_scl signal, with i = 1, 2, 3) can be performed independently for each Own Address (I2Ci.I2C_OAi registers, with i = 0, 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

15.4.7 Clocking

Figure 15-27 shows the I²C clock generation of the HS I²C controllers.

Figure 15-27. I²C Clock Generation



Each multimaster HS I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by (I2Ci.I2C_PSC[7:0] PSC bit field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH bit field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

Table 15-12 lists the t_{LOW} and t_{HIGH} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 15-12. HS I²C t_{LOW} and t_{HIGH} Values of the I²C Clock

Mode	I2Ci_INTERNAL_CLK	t_{LOW}	t_{HIGH}
F/S, SCCB, or HS first phase	I2Ci_INTERNAL_CLK = I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] PSC field + 1)	(I2Ci.I2C_SCLL[7:0] SCLL bit field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[7:0] SCLH bit field value + 5) x I2Ci_INTERNAL_CLK period
HS second phase	I2Ci_FCLK	(I2Ci.I2C_SCLL[15:8] HSSCLL field value + 7) x I2Ci_INTERNAL_CLK period	(I2Ci.I2C_SCLH[15:8] HSSCLH bit field value + 5) x I2Ci_INTERNAL_CLK period

NOTE: The equations in Table 15-12 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual tlow and thigh periods may vary, depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

NOTE: For HS mode, both the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLL[7:0] SCLL fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, both the I2Ci.I2C_SCLH[15:8] HSSCLH and I2Ci.I2C_SCLH[7:0] SCLH fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

CAUTION

During active mode (I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes may result in unpredictable behavior.

NOTE: Each multimaster HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4M bps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASTER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASTER bit for I2C2, and the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASTER bit for I2C3.

The maximum bit rate specified by the SCCB specifications is 100K b/s.

15.4.8 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S and SCCB operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2Ci.I2C_PSC[7:0] PSC bit field.

15.4.9 System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. Table 15-13 lists the tests available for the multimaster HS I²C controllers.

Table 15-13. List of tests for the Multimaster HS I²C Controllers

I2Ci.I2C_SYSTEST[13:12] TMODE field value	Test	Description
b00	Functional mode	Normal operation mode
b01	Reserved (not used)	
b10	Test of i2ci_scl serial clock line	The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers.
b11	Loop-back mode + i2ci_scl/ i2ci_sda/ i2ci_sccbe input/output	In the master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbe lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits.

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE field = b11, the I²C controller must be configured in I²C F/S (I2Ci.I2C_CON[13:12] OPMODE = b00) or I²C HS mode (I2Ci.I2C_CON[13:12] OPMODE = b01). The loop-back mode is not available in SCCB mode (I2Ci.I2C_CON[13:12] OPMODE = b10).

NOTE: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccbe lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C_SYSTEST[15] ST_EN set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] status bits to 0. The I2Ci.I2C_STAT[5:0] status bits can be cleared to 0 only by writing 1 in the corresponding bits.

15.4.10 Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I²C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

15.4.11 Power Chip Communication Operations

The master transmitter HS I²C controller I2C4 inside the voltage controller of the PRM module is used to send configuration commands from the LH to external power chip(s).

For voltage control operations, the LH must set the slave address of the first power chip in the PRCM.PRM_VC_SMPS_SA[6:0] SA0 field, and the slave address of the second power chip (if necessary) in the PRCM.PRM_VC_SMPS_SA[22:16] SA1 field.

The LH must also configure the specific registers in the voltage controller of the PRCM module, for the voltage control and power-sequencing functions.

A high-priority bypass mode is available to allow the LH to configure the external power chip(s) through the I²C bus. To write an 8-bit data to the configuration registers of an external power chip, the LH must set the 7-bit external power chip slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, the configuration register address in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and the 8-bit data in the PRCM.PRM_BYPASS_VAL[23:16] register.

For details about voltage control, see , *Power, Reset, and Clock Management*.

15.5 High-Speed I²C Controller Basic Programming Model

15.5.1 Multimaster HS I²C Controller Basic Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

15.5.1.1 Main Program

15.5.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Section 15.3.1.1.1).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[3:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps or 400K bps. These values depend on the internal sampling clock frequency (see Table 15-12).
4. (Optional) Program the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLH[15:8] HSSCLH fields to obtain a bit rate of 400K bps or 3.4M bps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see Table 15-12).
5. (Optional) If a bit rate of 3.4M bps is used and the bus line capacitance exceeds 45 pF, program the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASTER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASTER bit for I2C2, or the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASTER bit for I2C3.
6. Configure the Own Address of the I²C controller by storing it in the I2Ci.I2C_OA0 register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OAi registers (with i = 0, 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0]XTRSH field to (TX threshold - 1) and the I2Ci.I2C_BUF[13:8]RTRSH field to (RX threshold - 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.5.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
   - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave, 1: master).
   - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. For a module that should work in master mode, set the CONTROL.CONTROL_PADCONF_x.INPUTENABLE bit for the corresponding I²C module to achieve the synchronous clock on the clock output.
3. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).
4. If using DMA to receive/transmit data, set to 1 the corresponding bit in the I2Ci.I2C_BUF register (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

15.5.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

15.5.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

15.5.1.1.5 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C_BUF[13:8]RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds the serial clock line i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

15.5.1.1.6 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the I2Ci.I2C_CNT[15:0] DCOUNT field value is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

15.5.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (I2Ci.I2C_STAT[0] AL status bit) and resolve accordingly.
2. Test for no acknowledgment (I2Ci.I2C_STAT[1] NACK status bit) and resolve accordingly.
3. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.

4. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
5. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.
6. Test for general call (I2Ci.I2C_STAT[5] GC status bit) and resolve accordingly.
7. Test for start (S) condition (I2Ci.I2C_STAT[6] STC status bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (I2Ci.I2C_STAT[7] AERR status bit) and resolve accordingly.
9. Test for bus free (I2Ci.I2C_STAT[8] BF status bit) and resolve accordingly.

15.5.1.3 Programming Flow Diagrams

Figure 15-28 through Figure 15-36 are procedure flowcharts for programming the F/S and HS I²C modes.

Figure 15-28. I²C Setup Procedure

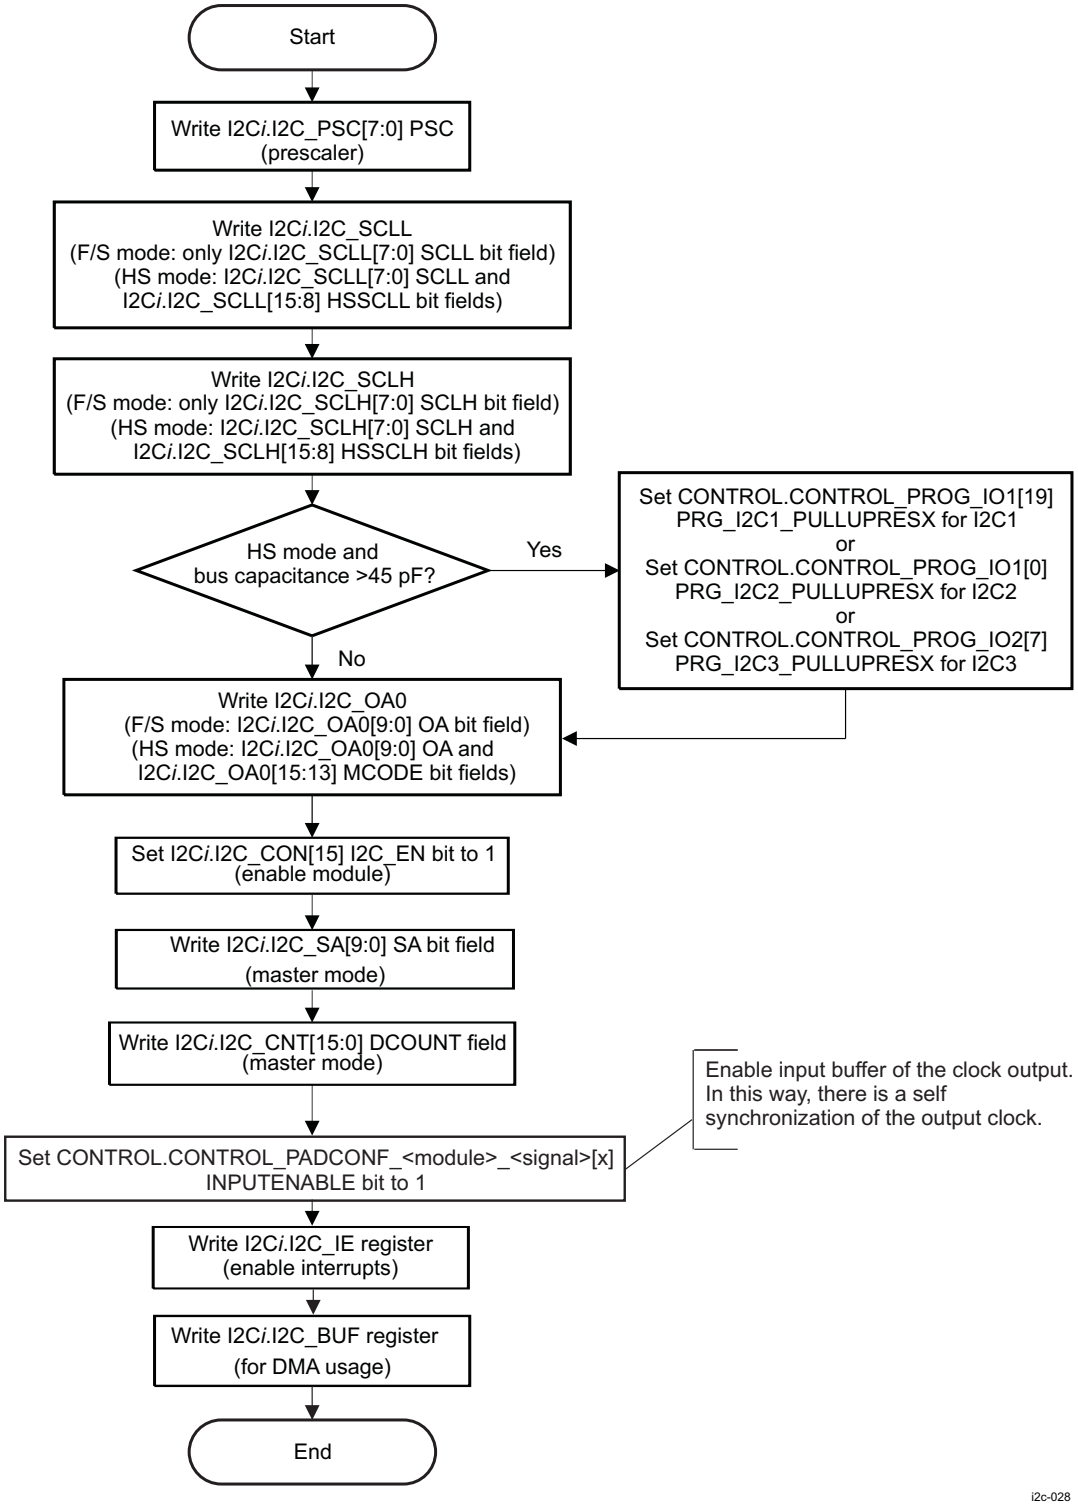


Figure 15-29. I²C Master Transmitter Mode, Polling Method, in F/S and HS Modes

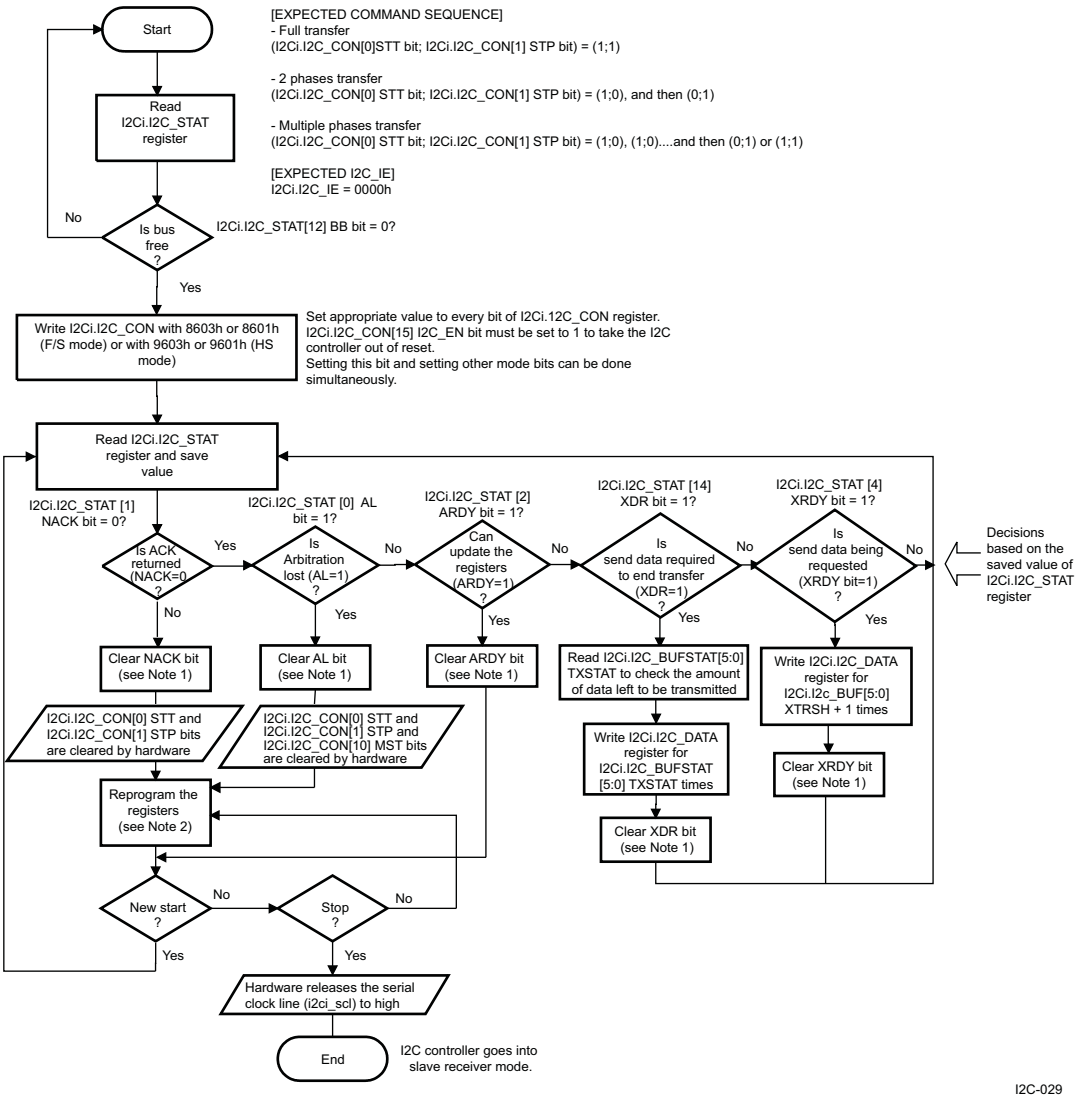
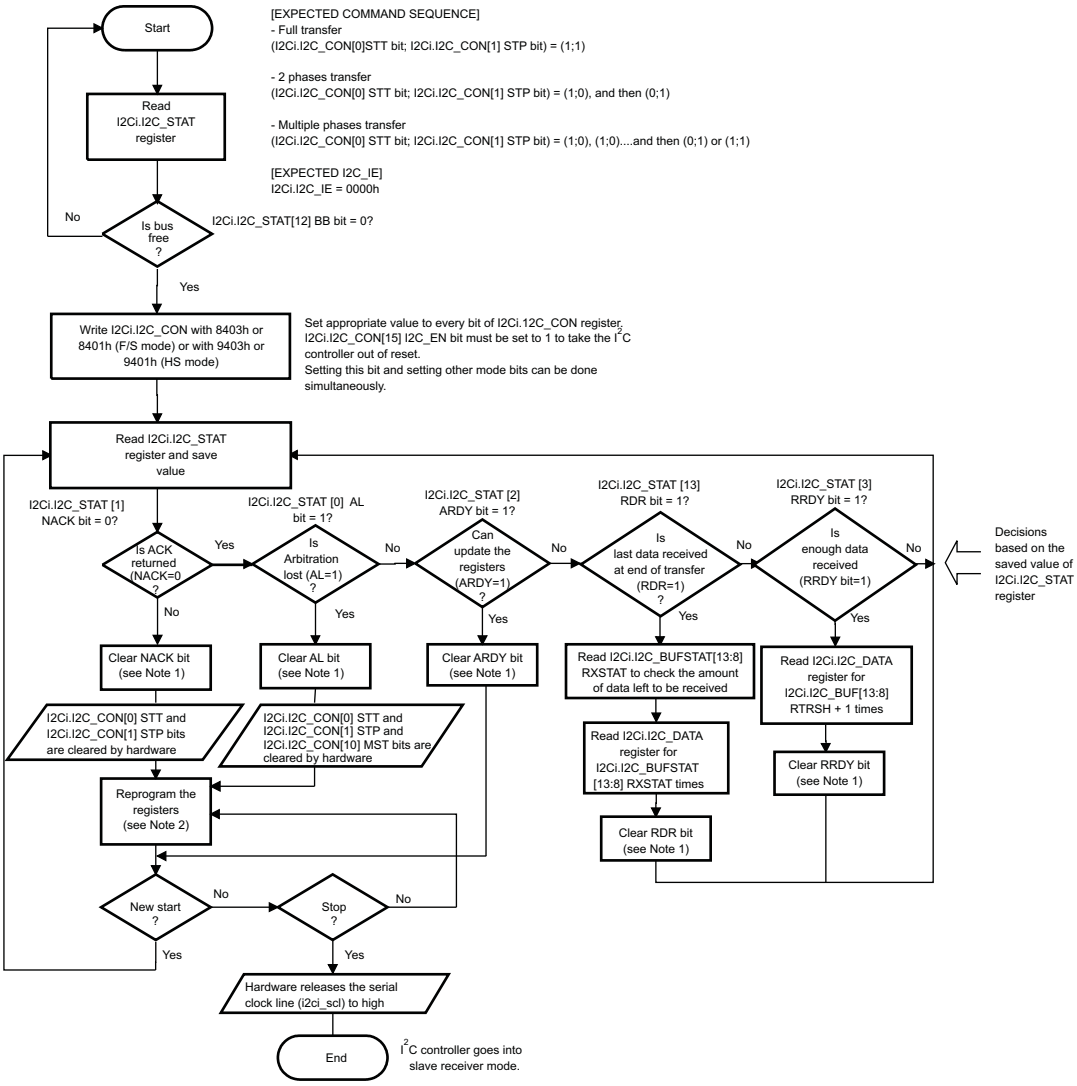


(1) The NAK, AL, ARDY, XDR, and XRDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.

(2) Reprogram the registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

NOTE: In HS mode, the repeated start (Sr) condition and the clock frequency switching are automatically generated by the multimaster HS I²C controller.

Figure 15-30. I²C Master Receiver Mode, Polling Method, in F/S and HS Modes



(1) The NAK, AL, ARDY, RDR, and RRDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.

(2) Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

(2) Reprogram registers means: I2Ci.I2C_CON[11] STB and/or I2Ci.I2C_CON[10] MST bit and/or I2Ci.I2C_SA[9:0] SA register and/or I2Ci.I2C_CNT[15:0] DCOUNT register and/or I2Ci.I2C_CON[0] STT bit and/or I2Ci.I2C_CON[1] STP bit.

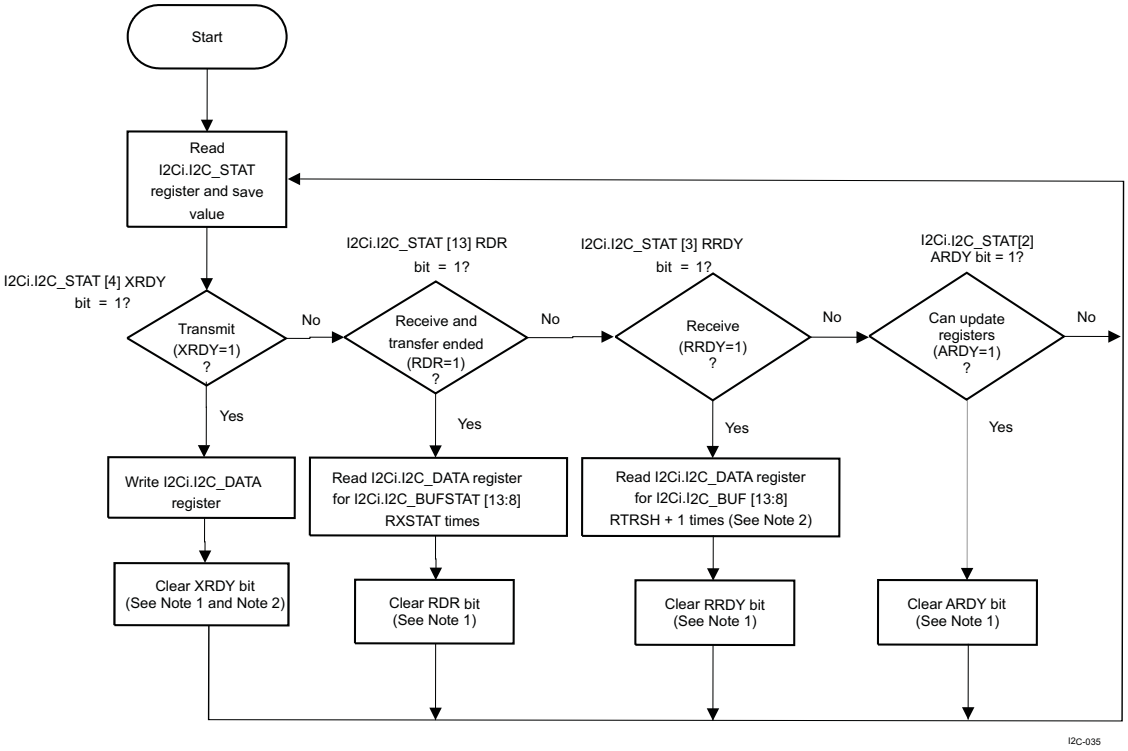
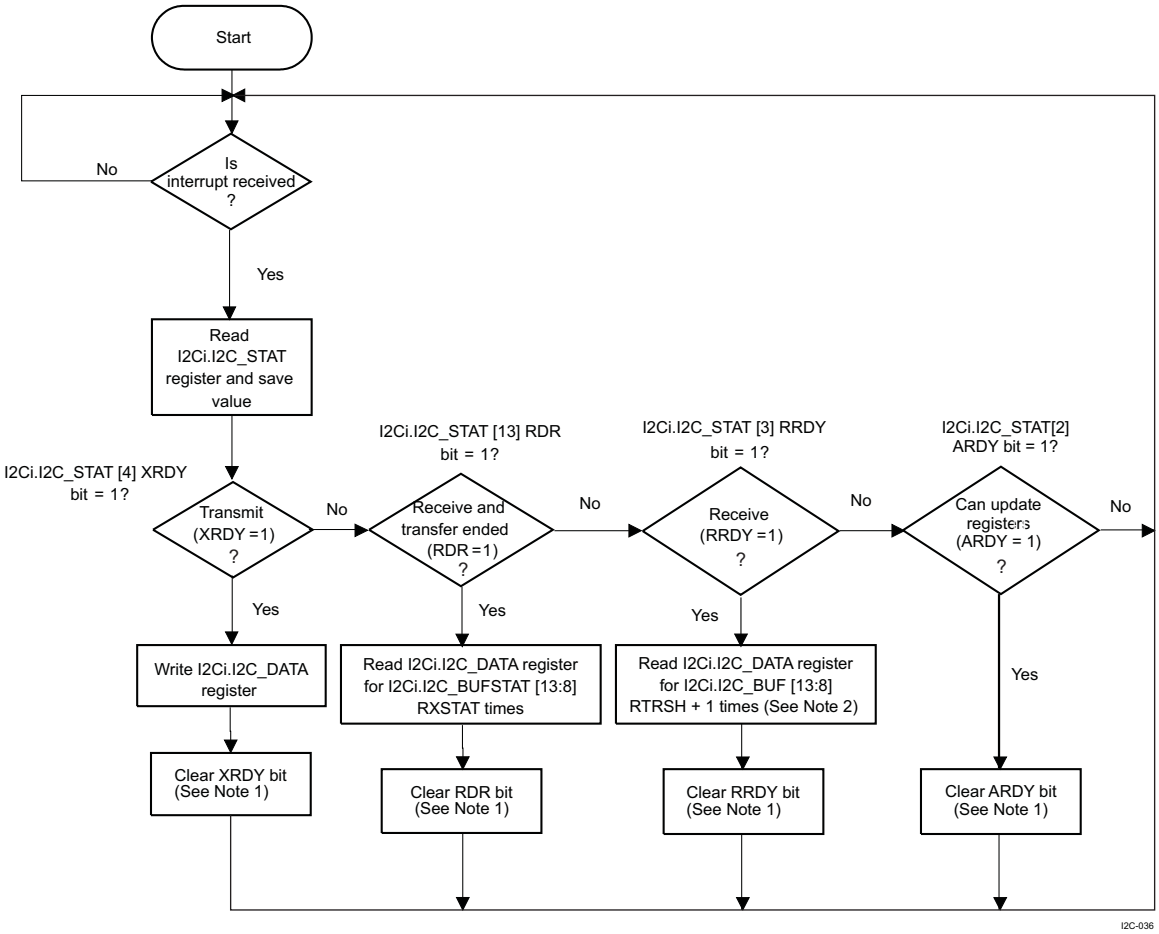
Figure 15-35. I²C Slave Transmitter/Receiver Mode, Polling



(1) The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.

(2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2Ci.I2C_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

Figure 15-36. I²C Slave Transmitter/Receiver Mode, Interrupt



(1) The XRDY, RDR, RRDY and ARDY bits are cleared by writing 1 to each corresponding bit in the I2Ci.I2C_STAT register.

(2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2Ci.I2C_BUF[5:0] XTRSH field must be configured to 0x0 (TX threshold = 1).

15.5.2 High-Speed I²C Controller Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

15.5.2.1 Main Program

15.5.2.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Section 15.3.1.1.1).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see Table 15-12).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.

6. Configure the I2Ci.I2C_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I2C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.5.2.1.2 Initialize the I2C Controller

To initialize the I2C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
   - In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
   - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. Set the CONTROL.CONTROL_PADCONF_x.INPUTENABLE bit for the corresponding I2C module to achieve synchronous clock on the clock output.
3. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).

15.5.2.1.3 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

15.5.2.1.4 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

15.5.2.1.5 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[5:0] XTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

15.5.2.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

15.5.2.3 Programming Flow Diagrams

Figure 15-37 through Figure 15-41 are procedure flowcharts for programming the SCCB mode.

Figure 15-37. SCCB Setup Procedure

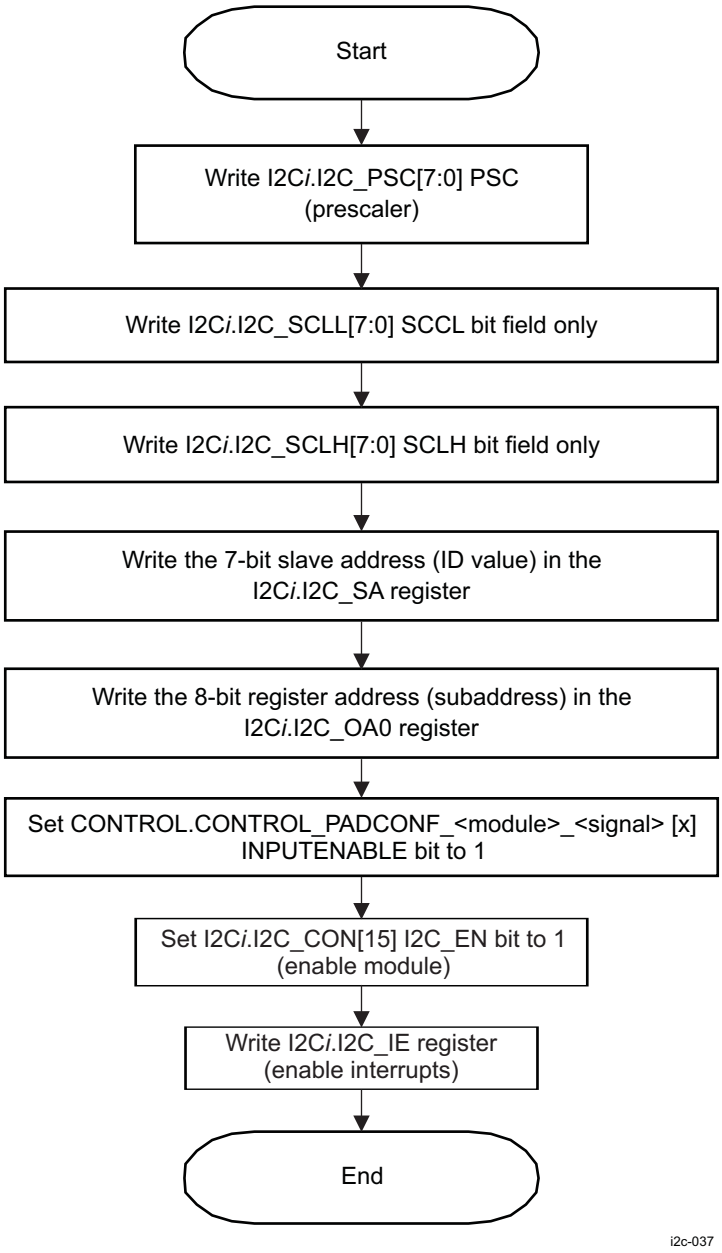


Figure 15-38. SCCB Master Transmitter Mode, Polling

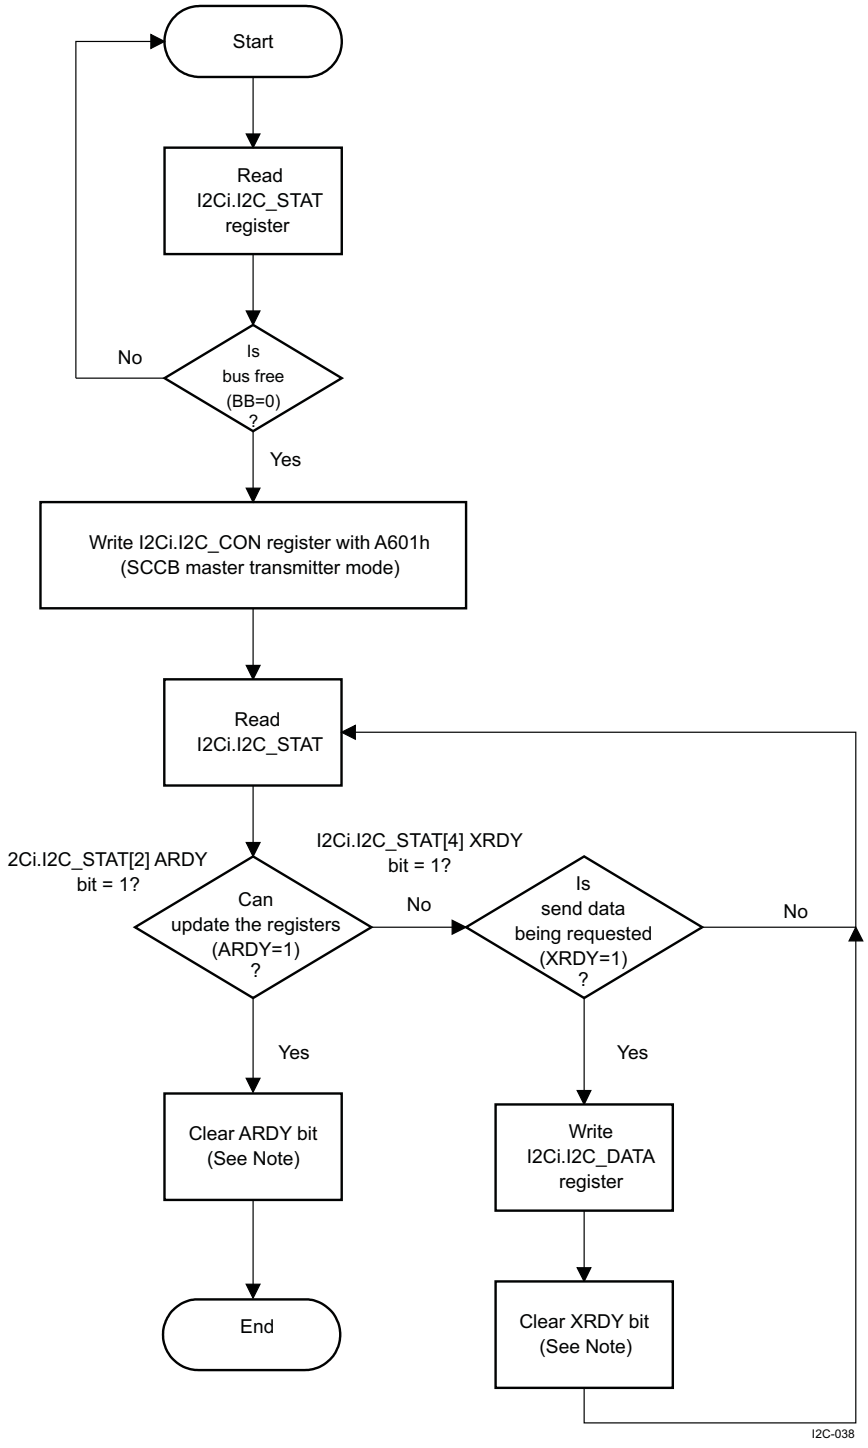
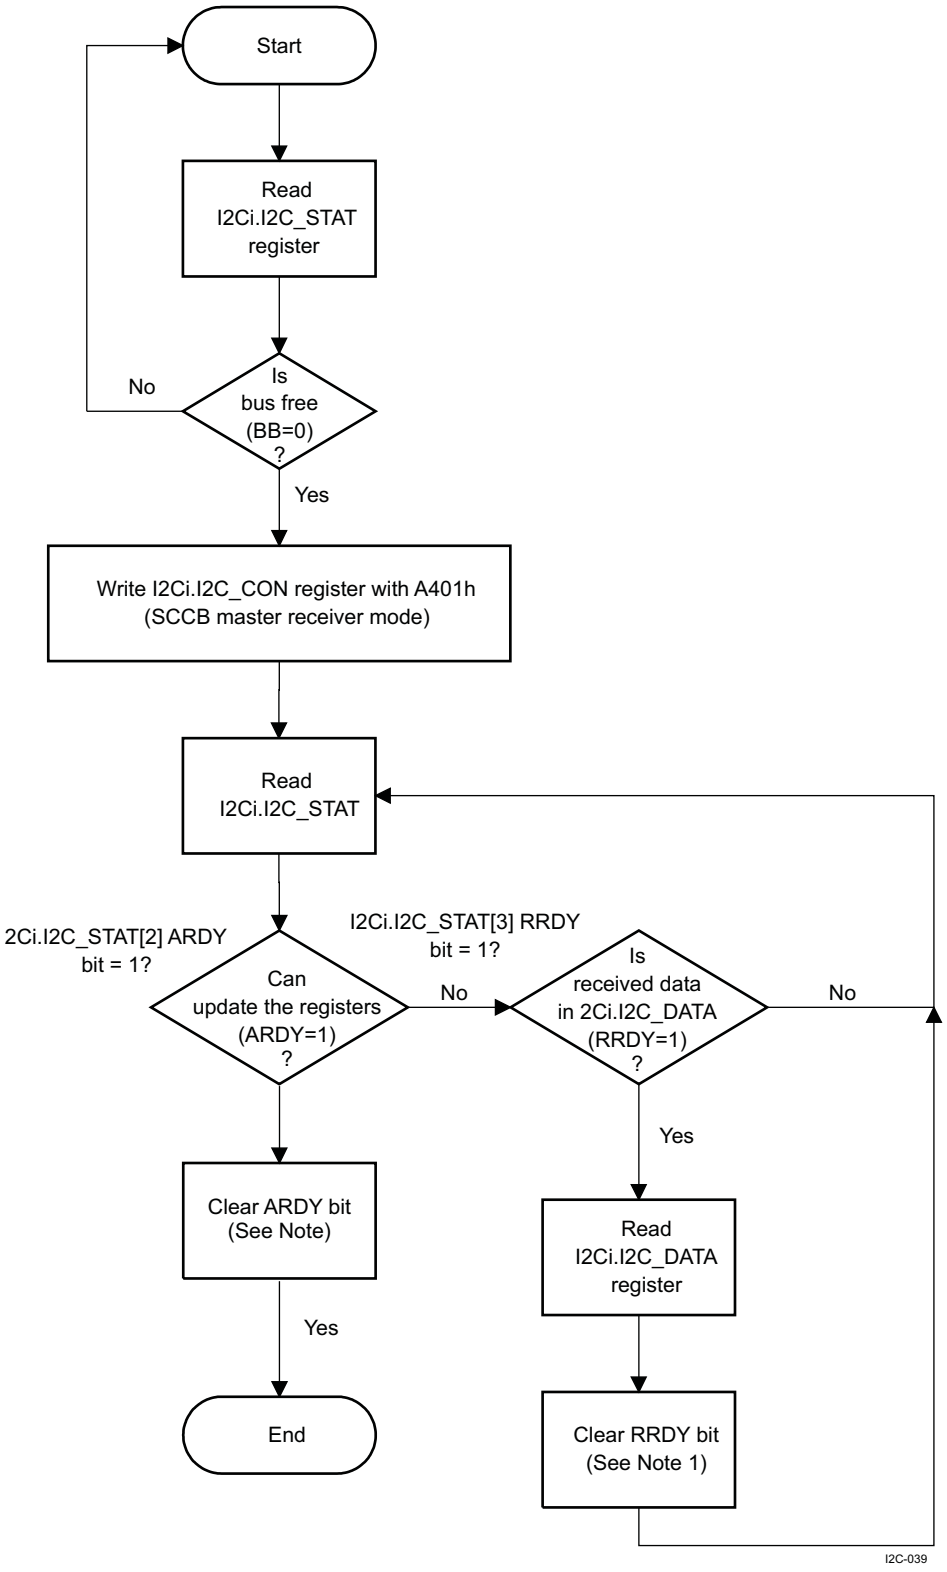


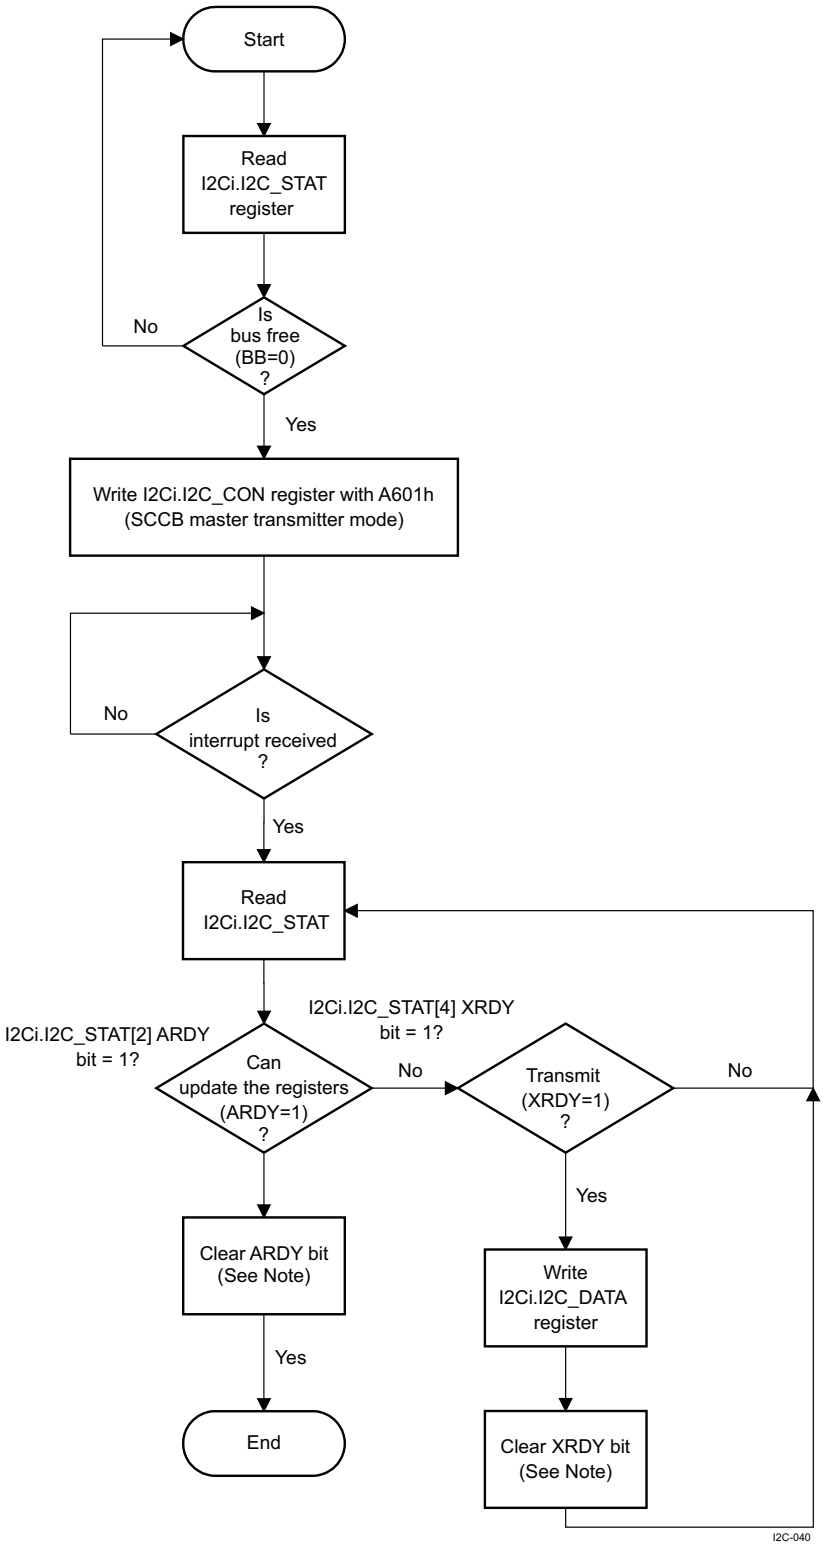
NOTE: The XRDY and ARDY bits are cleared by writing 1 to the corresponding bit in the I2Ci.I2C_STAT register.

Figure 15-39. SCCB Master Receiver Mode, Polling



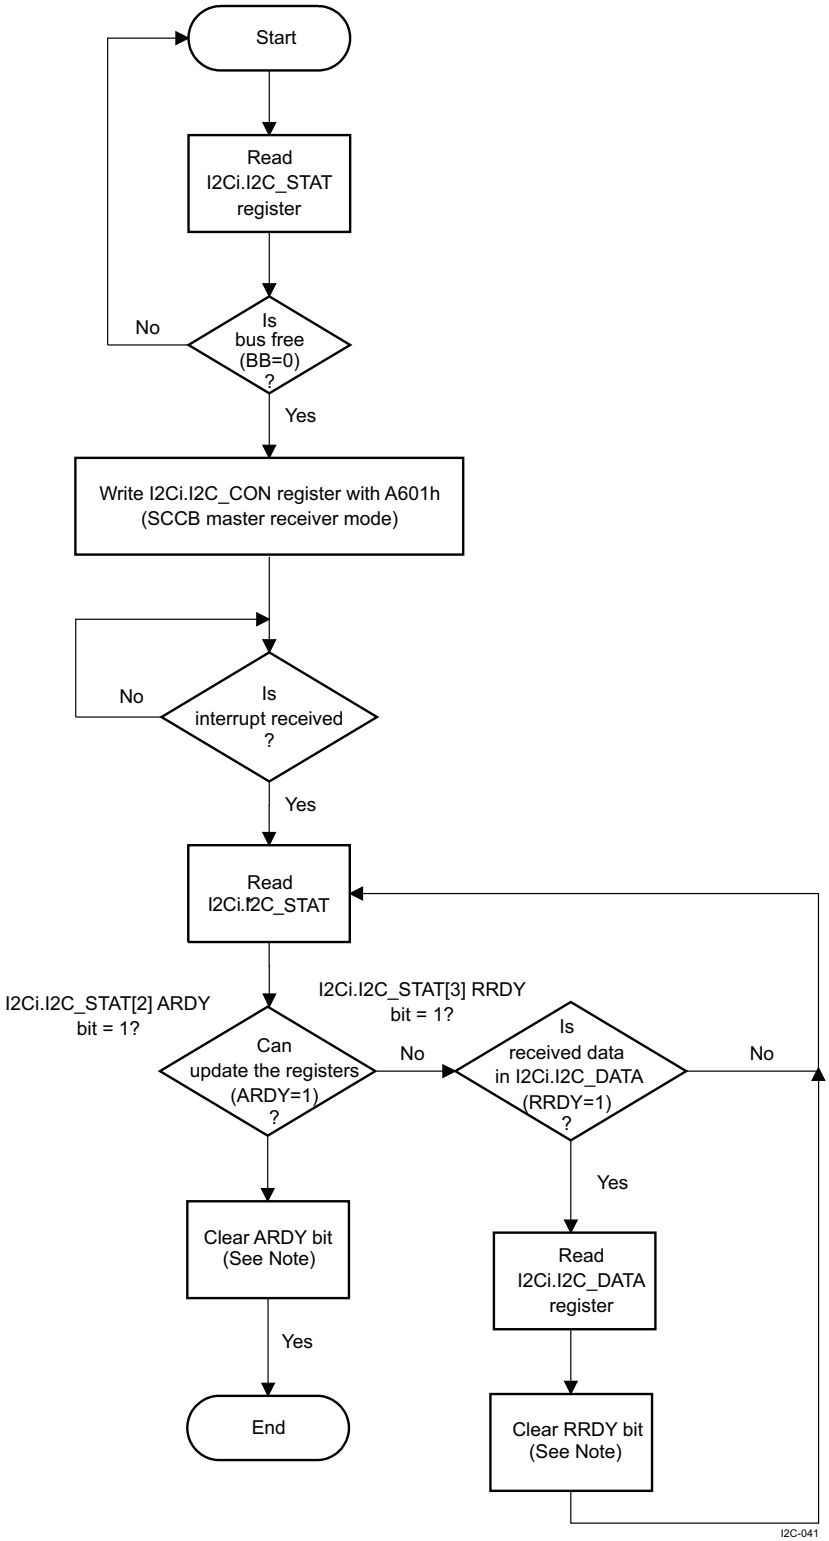
NOTE: The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

Figure 15-40. SCCB Master Transmitter Mode, Interrupt



NOTE: The XRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

Figure 15-41. SCCB Master Receiver Mode, Interrupt



NOTE: The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

15.5.3 Master Transmitter HS I²C Controller I2C4 Basic Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I²C controller I2C4 for communication with one or more power chips. The HS I²C controller I2C4 allowsthe two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

15.5.3.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the PRCM module:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_RA register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_CMD_RA register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the PRCM.PRM_VC_CMD_VAL_0 register for the first VDD channel and the PRCM.PRM_VC_CMD_VAL_1 register for the second VDD channel
- The VDD channels configuration selection in the PRCM.PRM_VC_CH_CONF register

For details about voltage controller register configuration, see , *Power, Reset, and Clock Management.*

15.5.3.2 Configure the Master Transmitter HS I²C Controller I2C4

At power-on reset, the I2C4 is in HS mode (PRCM.PRM_VC_I2C_CFG[3] HSEN bit). In HS mode, the LH must configure the master code value for the preamble I²C high-speed transmission by configuring the PRCM.PRM_VC_I2C_CFG[2:0] MCODE field. If the external power chips do not support the I²C HS mode, the HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_I2C_CFG[3] HSEN bit to 0.

By default, the repeated start operation is enabled (PRCM.PRM_VC_I2C_CFG[4] SREN bit set to 1 at power-on reset). In F/S mode, the repeated start operation can be disabled by clearing the PRCM.PRM_VC_I2C_CFG[4] SREN bit to 0.

15.5.3.3 Configure the External Power Chip(s)

The LH can send configuration commands from one bypass input to the external power chip(s), using the same I²C interface. To send a configuration command, the LH must process as follows:

- Check whether the transmission of a configuration command is ongoing by polling the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit (1: a transmission is ongoing, 0: a new transmission can start).
- Set the external power chip 7-bit slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, set the configuration register address of the external power chip in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and set the data to be written to the external power chip configuration register in the PRCM.PRM_VC_BYPASS_VAL[23:16] DATA field.
- Set the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit to 1 to send the configuration command to the external power chip.

15.6 High-Speed I²C Controllers Register Manual

CAUTION

The I2Ci registers are limited to 16 bit and 8 bit data accesses, 32 bit data access is not allowed and can corrupt register content.

NOTE: For details about the master transmitter HS I²C controller I2C4, see , *Power, Reset, and Clock Management*.

Table 15-14 provides the instance summary.

Table 15-14. Instance Summary

Module Name	Base Address	Size
I2C1	0x4807 0000	128 bytes
I2C2	0x4807 2000	128 bytes
I2C3	0x4806 0000	128 bytes

12	BB	Bus busy status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Bus is free. Read 0x1: Bus is occupied.	R	0
11	ROVR	Receive overrun status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Receiver overrun	R	0
10	XUDF	Transmit underflow status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Transmit underflow	R	0
9	AAS	Address recognized as slave IRQ status Read 0x0: No action Read 0x1: Address recognized	RW	0

Bits	Field Name	Description	Type	Reset
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
8	BF	Bus Free IRQ status	RW	0
		Read 0x0: No action		
		Read 0x1: Bus free		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
7	AERR	Access Error IRQ status	RW	0
		Read 0x0: No action		
		Read 0x1: Access error		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
6	STC	Start Condition IRQ status	RW	0
		Read 0x0: No action		
		Read 0x1: Start condition detected		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
5	GC	General Call IRQ status. Set to 1 when general call address detected. Interrupt signaled to MPU subsystem	RW	0
		Read 0x0: No general call detected		
		Read 0x1: General call address detected		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
4	XRDY	Transmit Data Ready IRQ status. Set to 1 in transmit mode when new data is requested for transmission. When this bit is set to 1, an interrupt is signaled to MPU subsystem	RW	0
		Read 0x0: No transmit data is requested for transmission		
		Read 0x1: Transmit data is requested for transmission		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
3	RRDY	Receive Data Ready IRQ status. Set to 1 when in receive mode, causing new data to be able to be read. When this bit is set to 1, an interrupt is signaled to MPU subsystem.	RW	0
		Read 0x0: No data available		
		Read 0x1: Receive data available		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
2	ARDY	Register Access Ready IRQ status. Setting this bit to 1 indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem.	RW	0
		Read 0x0: Module busy		
		Read 0x1: Access ready		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		
1	NACK	No Acknowledgment IRQ status. This bit is set when No Acknowledgment has been received. An interrupt is signaled to MPU subsystem. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1).	RW	0
		Read 0x0: Normal operation		
		Read 0x1: No Acknowledge detected		
		Write 0x0: No effect		
		Write 0x1: Clear this bit to 0.		

Bits	Field Name	Description	Type	Reset
0	AL	Arbitration Lost IRQ status. This bit is set automatically by the hardware when the I2C controller inside the device loses arbitration in master transmit mode. An interrupt is signaled to MPU subsystem. Read 0x0: Normal operation Read 0x1: Arbitration loss detected Write 0x0: No effect Write 0x1: Clear this bit to 0.	RW	0

		0x0: Transmit draining wakeup disabled		
		0x1: Transmit draining wakeup enabled		
13	RDR_WE	Receive draining wakeup enable	RW	0
		0x0: Receive draining wakeup disabled		
		0x1: Receive draining wakeup enabled		
12:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
9	AAS_WE	Address as slave wakeup enabled	RW	0
		0x0: Address as slave wakeup disabled		
		0x1: Address as slave wakeup enabled		
8	BF_WE	Bus Free wakeup enable	RW	0
		0x0: Bus Free wakeup disabled		
		0x1: Bus Free wakeup enabled		
7	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
6	STC_WE	Start Condition wakeup enable	RW	0
		0x0: Start condition wakeup disabled		
		0x1: Start condition wakeup enabled		
5	GC_WE	General call wakeup enable	RW	0
		0x0: General call wakeup disabled		
		0x1: General call wakeup enabled		
4	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0
3	DRDY_WE	Transmit/receive data ready wakeup enable. Mask or unmask the interrupt signaled by bit in I2C_STAT[RRDY]	RW	0
		0x0: Transmit/receive data ready wakeup disabled		
		0x1: Transmit/receive data ready wakeup enabled		
2	ARDY_WE	Register access ready wakeup enable	RW	0
		0x0: Register access ready wakeup disabled		
		0x1: Register access ready wakeup enabled		
1	NACK_WE	No Acknowledgment wakeup enable	RW	0
		0x0: No Acknowledgment wakeup disabled		
		0x1: No Acknowledgment wakeup enabled		
0	AL_WE	Arbitration lost wakeup enable	RW	0
		0x0: Arbitration lost wakeup disabled		
		0x1: Arbitration lost wakeup enabled

Bits	Field Name	Description	Type	Reset
31:16	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
15	ST_EN	System test enable	RW	0
		0x0: Normal mode		
		0x1: System test enabled. Permit other system test registers bits to be set		
14	FREE	Free-running mode	RW	0
		0x0: Stop mode (on breakpoint condition). If Master mode, it stops after completion of the ongoing bit transfer. In slave mode, it stops during the phase transfer when 1 byte is completely transmitted/received.		
		0x1: Free-running mode		
13:12	TMODE	Test mode select	R	0
		0x0: Functional mode (default)		
		0x1: Reserved		
		0x2: Test of SCL counters (SCLL, SCLH, PSC). SCL provides a permanent clock with master mode.		
		0x3: Loop back mode select + SDA/SCL IO mode select		
11	SSB	Set status bits	R	0
		0x0: No action		
		0x1: Set all interrupt status bits to 1		
10:5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
4	SCCBE_O	SCCBE line sense output value. Writing is possible only if ST_EN bit is set to 1	RW	0
		0x0: Write 0 to SCCBE line		
		0x1: Write 1 to SCCBE line		
3	SCL_I	SCL line sense input value	R	0
		0x0: Read 0 from SCL line		
		0x1: Read 1 from SCL line		
2	SCL_O	SCL line drive output value. Writing is possible only if ST_EN bit is set to 1	RW	0
		0x0: Write 0 to SCL line		
		0x1: Write 1 to SCL line		
1	SDA_I	SDA line sense input value	R	0
		0x0: Read 0 from SDA line		
		0x1: Read 1 from SDA line		
0	SDA_O	SDA line drive output value. Writing is possible only if ST_EN bit is set to 1	RW	0
		0x0: Write 0 to SDA line		
		0x1: Write 1 to SDA line

Multichannel SPI

This chapter describes the four multichannel serial port interface (McSPI) modules.

Topic **Page**

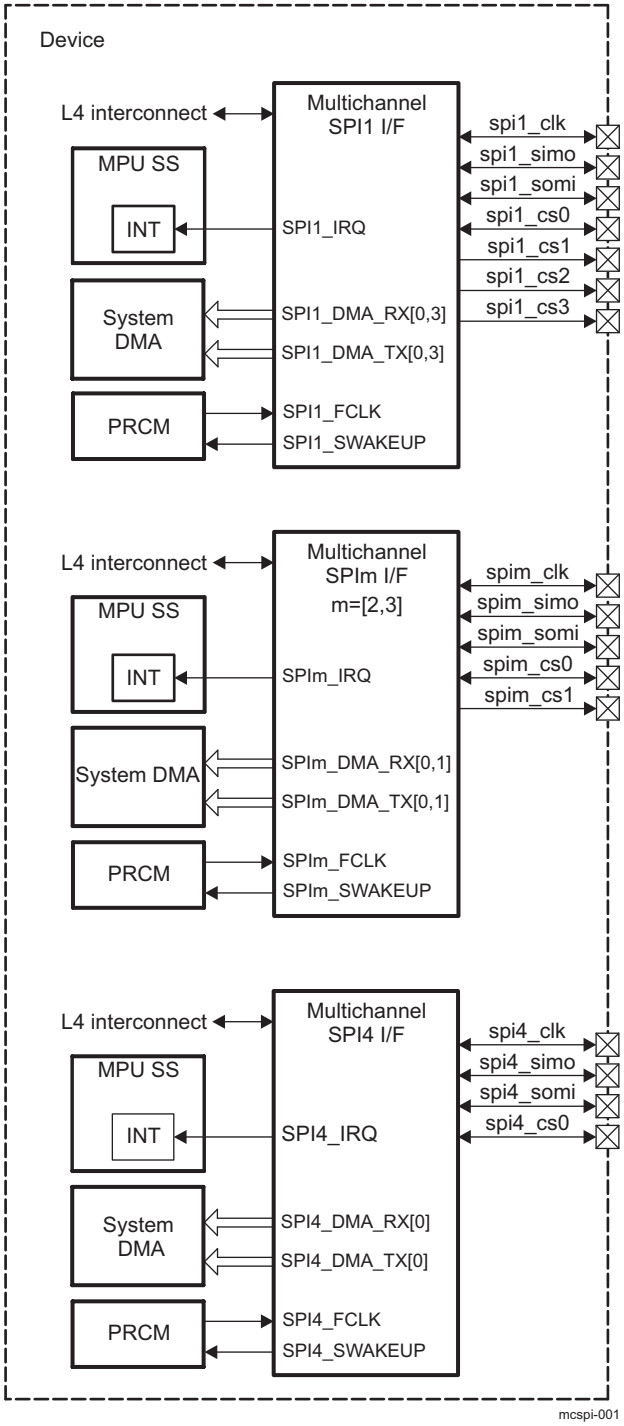
16.1 McSPI Overview

The multichannel serial port interface (McSPI) is a master/slave synchronous serial bus. There are four separate McSPI modules (SPI1, SPI2, SPI3, and SPI4) in the device (see Figure 16-1). The McSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

NOTE: In this chapter, *m=[1,4]* represents the module instance and *x* represents the channel in signal and register naming. There are four McSPI instances. Each module instance has different channel numbers:

- SPI1: 4 channels (if *m=1*, *x=4*)
- SPI2: 2 channels (if *m=2*, *x=2*)
- SPI3: 2 channels (if *m=3*, *x=2*)
- SPI4: 1 channel (if *m=4*, *x=1*)

Figure 16-1. Multichannel Modules SPI1, SPI2, SPI3, and SPI4



The McSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Up to four master channels or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes

  - Flexible I/O port controls per channel
  - Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Support start-bit write command
- Support start-bit pause and break sequence
- 64 bytes built-in FIFO available for a single channel
- Force CS mode for continuous transfers

16.2 McSPI Environment

Figure 16-2 shows a simplified overview of a typical application system using the McSPI. This example is based on a TFS chipset (TFS6040-0098), including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with the TSC2005 or TSC2006 touch-screen controller, powered by a power-management unit, and driven by the device. The McSPI device interface is set to master mode; the touch-screen McSPI controller interface operates in slave mode.

Figure 16-2. Typical Application Using the McSPI

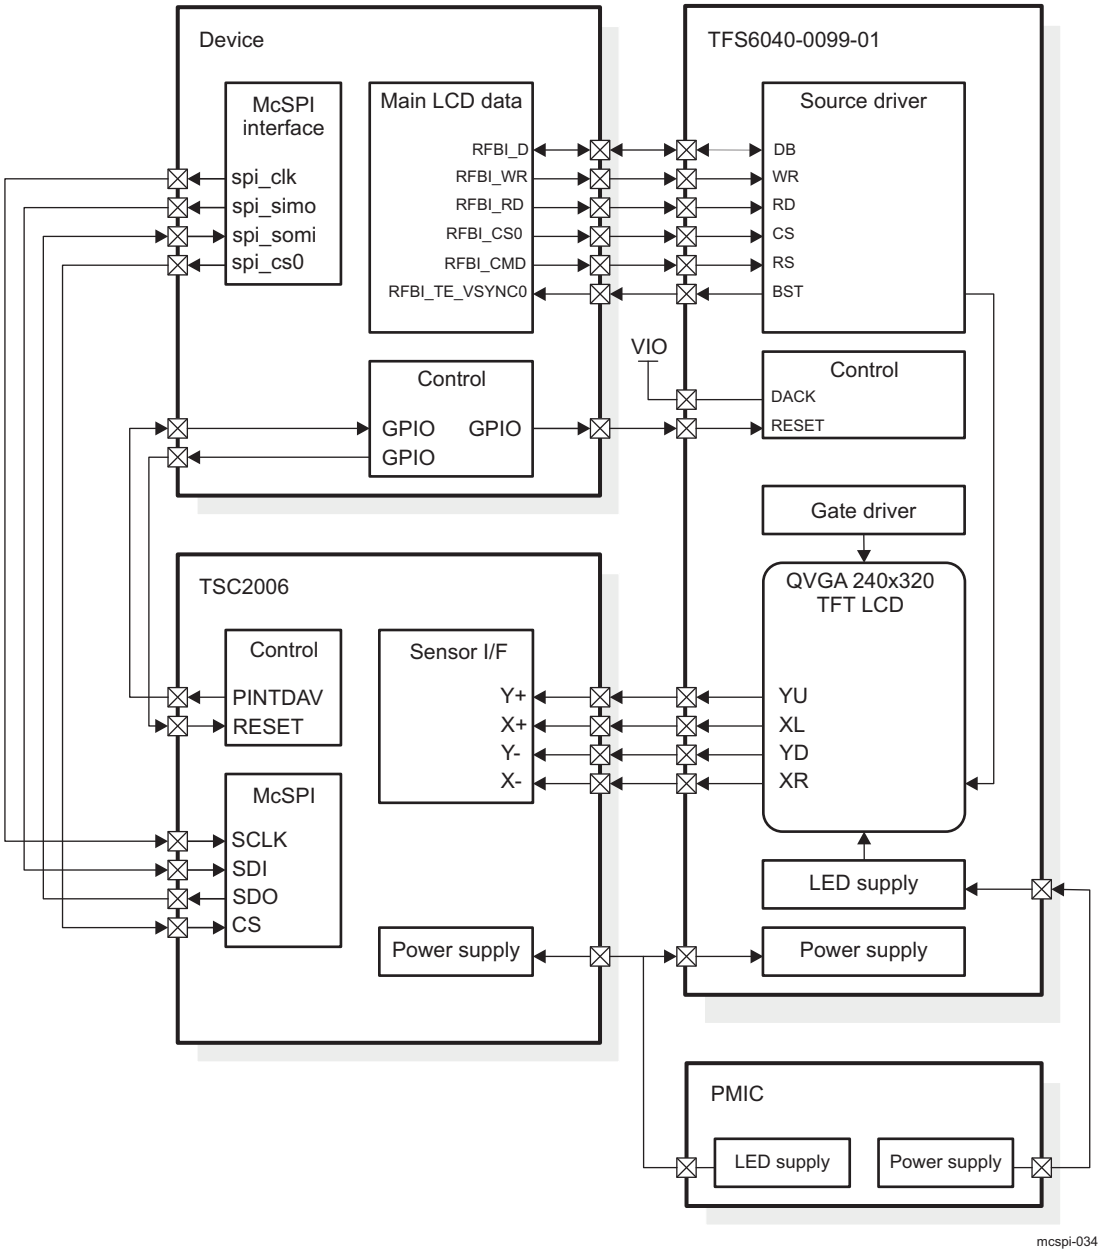


Figure 16-3 through Figure 16-8 show master mode and slave mode configurations. Each mode can be wired on a single-duplex or full-duplex configuration.

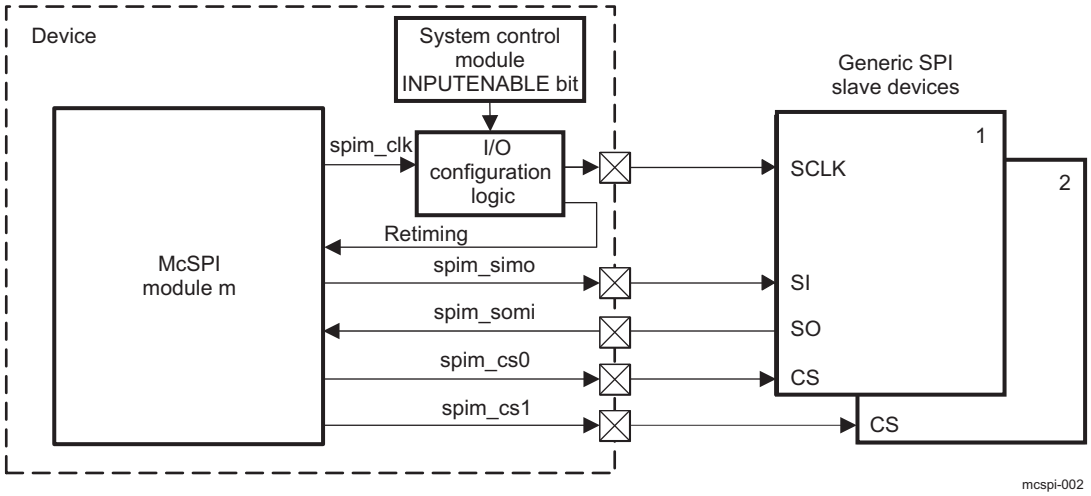
16.2.1 SPI Interface in Master Mode

Figure 16-3 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

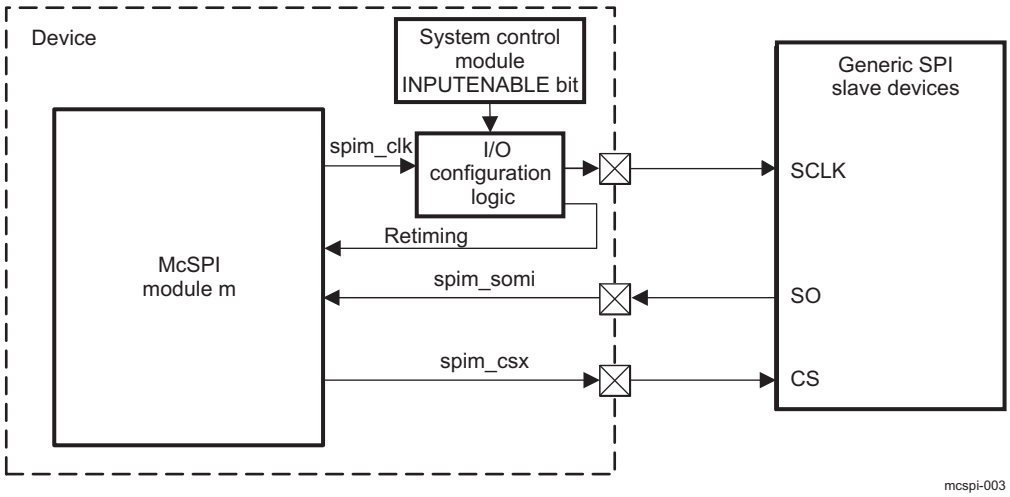
Figure 16-3. McSPI Master Mode (Full-Duplex)



NOTE: In this case m=[1,3].

Figure 16-4 shows the master single mode, which can also be configured in receive-only mode.

Figure 16-4. McSPI Master Single Mode (Receive-Only)



16.2.2 SPI Interface in Slave Mode

Figure 16-5 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, and only spin_cs0 can be used as a chip-enable in slave mode.

Figure 16-5. McSPI Slave Mode (Full Duplex)

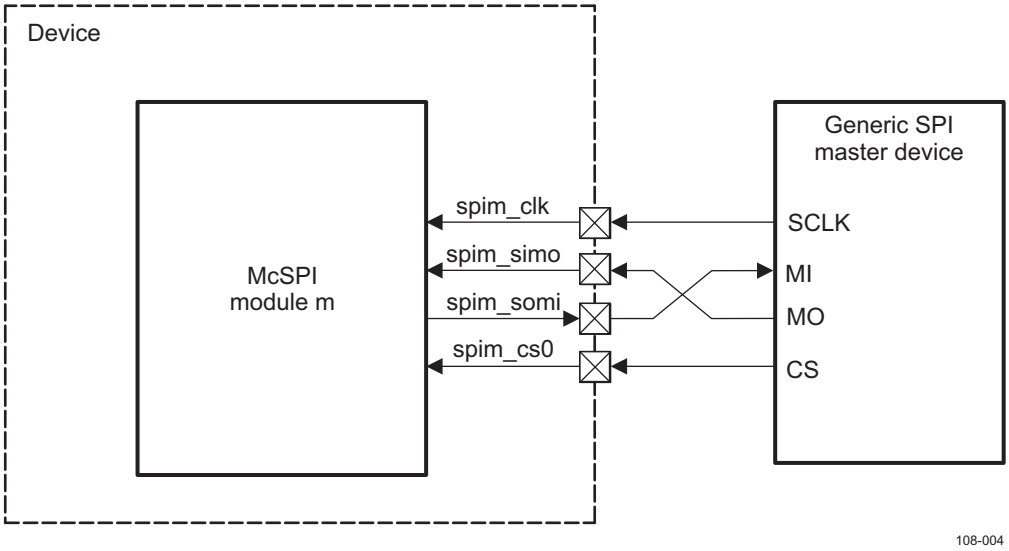


Figure 16-6 shows the slave single mode, which can also be configured in transmit-only mode.

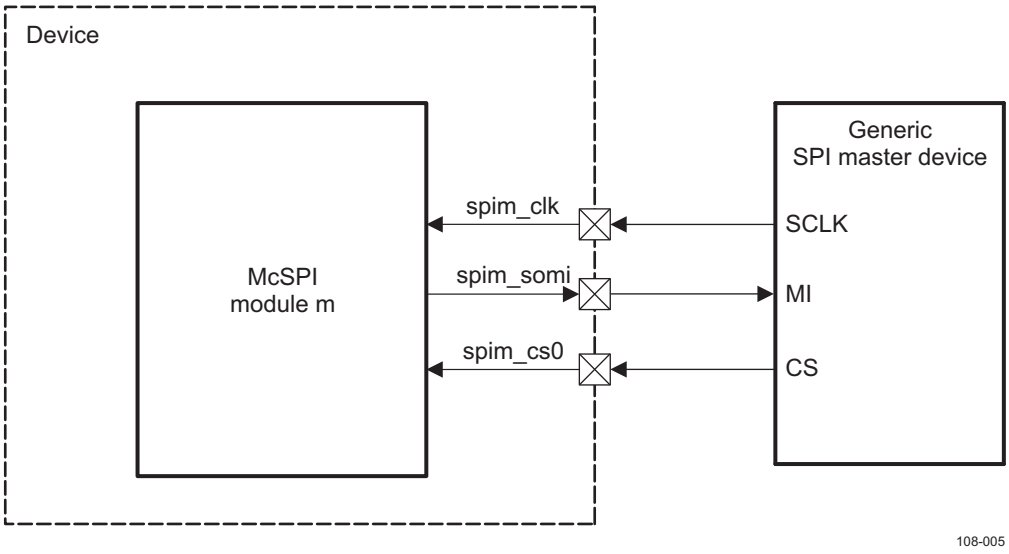
Figure 16-6. McSPI Slave Single Mode (Transmit Only)



16.3 McSPI Functional Interface

16.3.1 Basic McSPI Pins for Master Mode

Figure 16-7 shows all of the McSPI interface signals in master mode.

Figure 16-7. McSPI Interface Signals in Master Mode

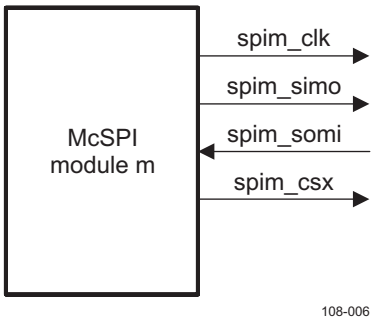


Table 16-1 describes the McSPI I/O in master mode.

Table 16-1. McSPI I/O Description (Master Mode)

Signal Name	I/O	Description	Reset [1]
spim_clk	O	SPIm module serial clock[2]	Unknown
spim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	I	SPIm module serial data master input (slave output, master input)	–
spim_csx	O	SPIm module chip-select x output	Low

(1) After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL]).

(2) This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

16.3.2 Basic McSPI Pins for Slave Mode

Figure 16-8 shows all of the McSPI interface signals in slave mode.

Figure 16-8. McSPI Interface Signals in Slave Mode

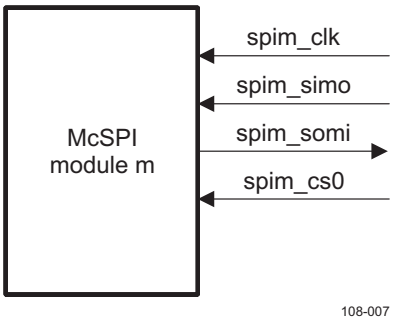

Table 16-2 describes the McSPI I/O in slave mode.

Table 16-2. McSPI I/O Description (Slave Mode)

Signal Name	I/O	Description	Reset [1]
spim_clk	I	SPIm module serial clock	Unknown
spim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
spim_somi	O	SPIm module serial data master input (slave output, master input)	–
spim_cs0	I/O	SPIm module chip-select 0 input	HiZ
spim_cs1/2/3	O	SPIm module chip-select 1/2/3 output	Low

(1) After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in Module Control Register (MCSPI_MODULCTRL).)

16.3.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (spim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

  McSPI supports any SPI word ranging from 4 bits to 32 bits long (SPIm.MCSPI_CHxCONF[11:7] WL field).

  SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.

- SPI enable (spim_csx, for channel x of instance m)

  The polarity of the SPI enable signals is programmable (SPIm.MCSPI_CHxCONF[6] EPOL bit). spim_csx signals can be active high or low.

  The assertion of the spim_csx signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. spim_csx can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.

  Two consecutive words for two different slave devices can go along with active spim_csx signals with different polarity (see the example in Section 16.6, *McSPI Basic Programming Model*).

- Programmable start-bit

  In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock
  - Bit rate

    In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). Table 16-3 gives the spim_clk bit rates obtained for data transfer when programming the clock divider (SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 16-3. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz

Table 16-3. SPI Master Clock Rates (continued)

Divider	Clock Rate
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192	~5.8 kHz
16384	~2.9 kHz
32768	~1.5 kHz

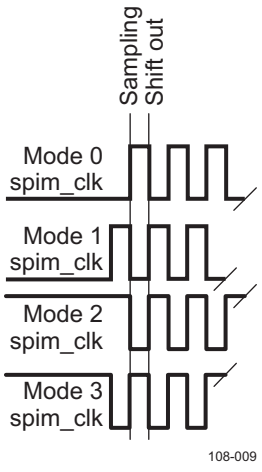
– Polarity and phase

The polarity (the SPIm.MCSPI_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (spim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See Table 16-4 and Figure 16-9.

Table 16-4. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	spim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	spim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	spim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	spim_clk is active low and sampling occurs on the rising edge.

Figure 16-9. Phase and Polarity Combinations



16.3.3.1 Transfer Format

In both master and slave modes, McSPI drives the data lines when spim_csx is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

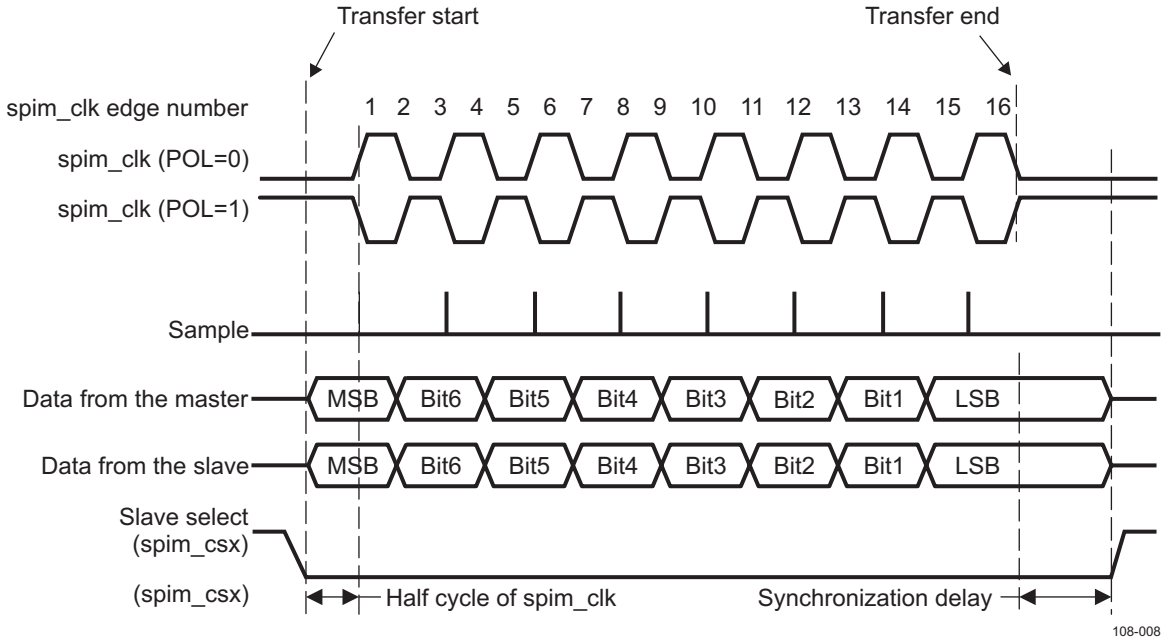
When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim_clk after the spim_csx assertion.

Therefore, the first edge of the spim_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next spim_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the spim_clk line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See Figure 16-10.

Figure 16-10. Full-Duplex Transfer Format With PHA = 0



- Transmission in mode 1 and mode 3 (PHA = 1)

  When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following spim_clk edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the spim_csx activation and the first spim_clk edge.

  The received data bit is shifted into the shift register on the third spim_clk edge.

  This process continues for a number of pulses on the spim_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

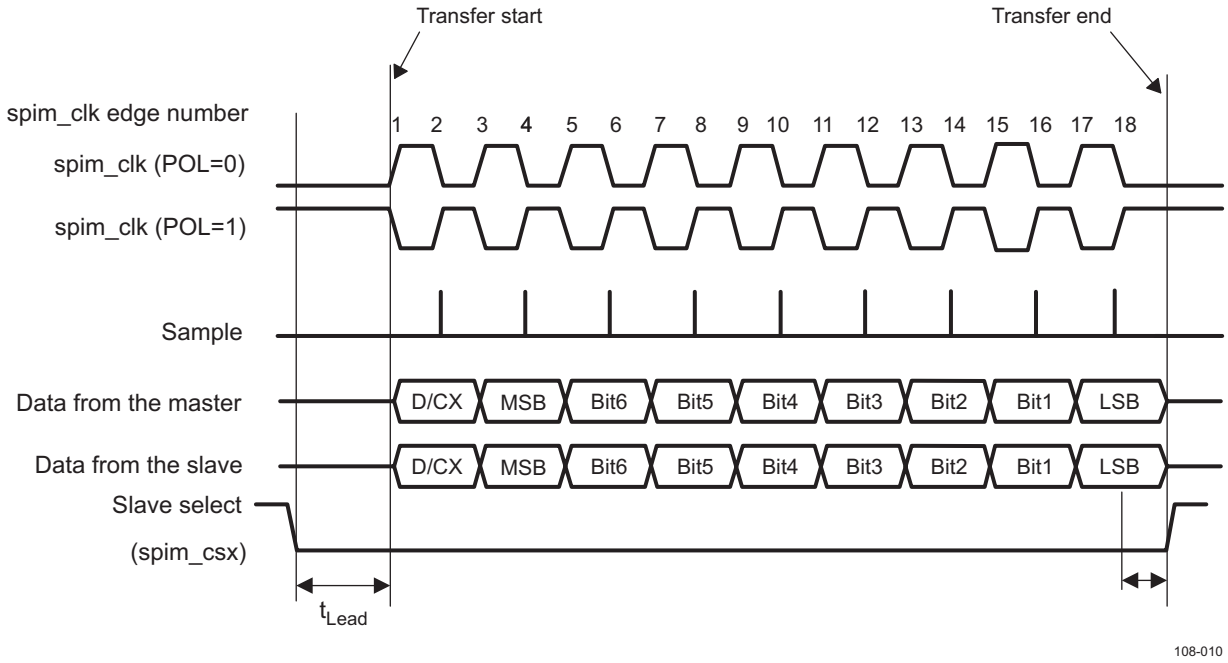
  NOTE: The minimum synchronization delay is one cycle of spim_clk, if the spim_clk frequency equals the SPIm_FCLK (McSPIm functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of spim_clk, if the spim_clk frequency is lower than the SPIm_FCLK frequency in both master and slave modes.

- Transmission with a start-bit (SBE = 1)

  When the SPIm.MCSPI_CHxCONF[23] SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

  Figure 16-11 shows an example of a data transfer with an extra start-bit.

Figure 16-11. Extended SPI Transfer With a Start-Bit (SBE = 1)

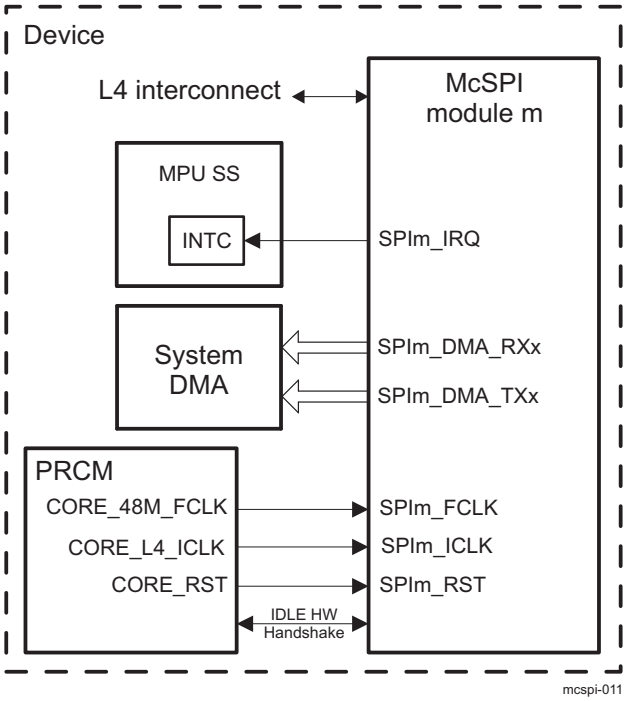


16.4 McSPI Integration

16.4.1 McSPI Description

Figure 16-12 highlights the McSPI module integration in the device.

Figure 16-12. McSPI Integration



16.4.2 Clocking, Reset, and Power-Management Scheme

16.4.2.1 Clocking

Each McSPI module is clocked with an independent functional clock of 48 MHz from the PRCM module (SPIm_FCLK with m = [1,4]) and with an interface clock, CORE_L4_ICLK (L4 interconnect):

- SPIm_FCLK is the McSPI module *m* functional clock and is used to clock the McSPI internal logic. The source of SPIm_FCLK is the PRCM CORE_48M_FCLK output clock.
- SPIm_ICLK is the McSPI module *m* interface clock and is used to synchronize the McSPI L4 port to the L4 interconnect. All accesses from the interconnect are synchronous with SPIm_ICLK. The source of SPIm_ICLK is the PRCM CORE_L4_ICLK output clock.

From a global system power management perspective, when one or both of the McSPI clocks is not required, the McSPI module can be deactivated at the PRCM level in the corresponding registers.

Table 16-5 describes the McSPI module PRCM clock control bits.

Table 16-5. McSPI Clocks

McSPI Clock	Associated PRCM Clock Output	Enable Bit	Autoidle Bit
SPIm_FCLK			
	CORE_48M_FCLK	PRCM.CM_FCLKEN1_CORE.EN_MCSPIm (with m=[1,4])	N/A
SPIm_ICLK			
	CORE_L4_ICLK	PRCM.CM_ICLKEN1_CORE.EN_MCSPIm (with m=[1,4])	PRCM.CM_AUTOIDLE1_CORE.AUTO_MCSPIm (with m=[1,4])

NOTE:

- The PRCM CORE_48M_FCLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM CORE_L4_ICLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM.CM_AUTOIDLE1_CORE bit is used to link/unlink the McSPI module from CORE_L4_ICLK-related clock domain transitions.

For more information about source clocks gating and domain transitions, see , *Power, Reset, and Clock Management*. For more information on power saving management, see Section 16.5.7.

16.4.2.2 Power Domain

The McSPI modules belong to the CORE power domain (see Table 16-6).

Table 16-6. Power Domain

Peripherals	Power Domain
McSPI modules	CORE power domain

16.4.2.3 Hardware Reset

As part of the CORE power domain, CORE_RST is issued by the PRCM module (for more information about the CORE power domain implementation and CORE_RST signal, see , *Power, Reset, and Clock Management*). The module is reset by hardware when an active-low reset signal is asserted. The hardware reset signal has a global reset effect on the module. All configuration registers and all state-machines are reset in all clock domains (see Table 16-7).

Table 16-7. McSPI Hardware Reset

Peripherals	Name	Comments
McSPI module	CORE_RST	Same as global reset

16.4.2.4 Software Reset

The SPIm.MCSPI_SYSCONFIG[1] SOFTRESET bit controls the software reset of the SPI interface. Writing 1 to this bit enables active software reset functionality, which is equivalent to a hardware reset. The bit is automatically reset by hardware.

NOTE: The SPIm.MCSPI_SYSCONFIG register is not sensitive to software reset.

16.4.3 Hardware Requests

16.4.3.1 DMA Requests

Each channel includes two DMA requests, one for reception and one for transmission (see Table 16-8).

Table 16-8. DMA Requests

Attributes	DMA Request	Name	Mapping	Comments
SPI1				
	8	SPI1_DMA_TX0	S_DMA_34	Destination is system DMA (sDMA).

SPI4				
	2	SPI4_DMA_TX0	S_DMA_69	Destination is sDMA.
		SPI4_DMA_RX0	S_DMA_70	

16.4.3.2 Interrupt Requests

Each McSPI module handles one interrupt line (see Table 16-9).

Table 16-9. Interrupt Requests

Attributes	Interrupt Request	Name	Mapping	Comments
SPI1				
	1	SPI1_IRQ	M_IRQ_65	Destination is the microprocessor unit (MPU) interrupt controller.
SPI2				
	1	SPI2_IRQ	M_IRQ_66	Destination is the MPU interrupt controller.
SPI3				
	1	SPI3_IRQ	M_IRQ_91	Destination the MPU interrupt controller.
SPI4				
	1	SPI4_IRQ	M_IRQ_48	Destination is the MPU interrupt controller.

16.4.3.3 Wake-Up Requests

Table 16-10 lists the wake-up requests.

Table 16-10. Wake-Up Requests

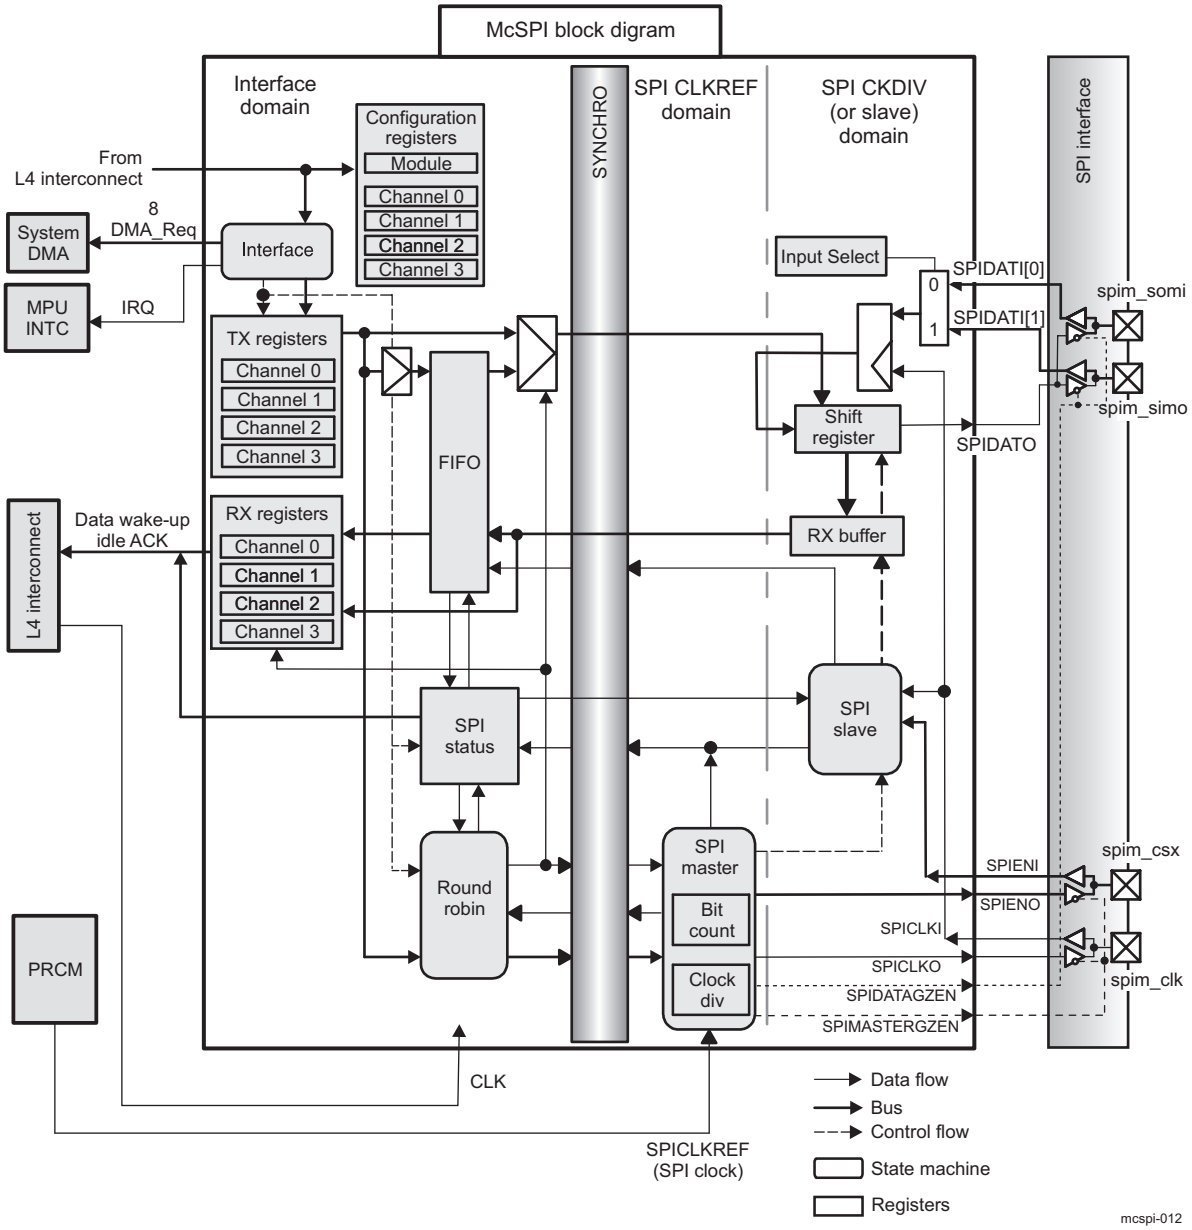
Attributes	Wake Request	Name	Mapping	Comments
SPI1				
	1	spi1_cs0	SPI1_ SWAKEUP	Destination is the PRCM module.
SPI2				
	1	spi2_cs0	SPI2_ SWAKEUP	Destination is the PRCM module.
SPI3				
	1	spi3_cs0	SPI3_ SWAKEUP	Destination is the PRCM module.
SPI4				
	1	spi4_cs0	SPI4_ SWAKEUP	Destination is the PRCM module.

16.5 McSPI Functional Description

16.5.1 McSPI Block Diagram

Figure 16-13 shows the McSPI module.

Figure 16-13. McSPI Block Diagram



16.5.2 Master Mode

16.5.2.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (spim_simo and spim_somi) and generates clock (spim_clk) and control signals (spim_csx).

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information on interrupts, see Section 16.5.5.1, *Interrupt Events in Master Mode*).

16.5.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on spim_simo) and received (shifted in serially on spim_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

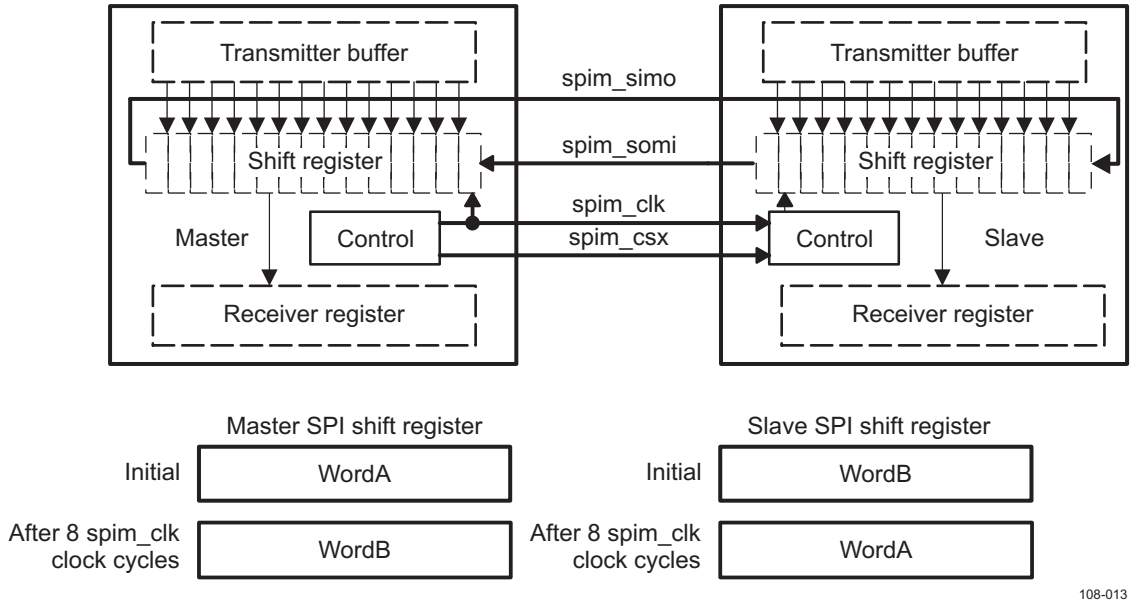
- Rule 1: Only enabled channels (the SPIm.MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TXx transmitter register is not empty (the SPIm.MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. Note that the SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPIm.MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (spim_clk) synchronizes shifting and sampling of the information on the two serial data lines (spim_simo and spim_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

Figure 16-14 shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock spim_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 16-14. SPI Full-Duplex Transmission (Example)



16.5.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the MCSPI_RXx register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM field). Transmission starts only after data is loaded into the MCSPI_TXx register.

Rule 1 and Rule 2, defined in Section 16.5.2.2, are applicable in this mode.

Rule 3, defined in Section 16.5.2.2, is not applicable.

In master transmit-only mode, the MCSPI_RXx register state FULL does not prevent transmission and the MCSPI_RXx register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the SPIm.MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the SPIm.MCSPI_CHxSTAT[2] EOT bit.

16.5.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the MCSPI_TXx register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the MCSPI_RXx register.

Rule 1 and Rule 3, defined in Section 16.5.2.2, are applicable in this mode.

Rule 2, defined in Section 16.5.2.2, is not applicable.

In the master receive-only mode, software must write dummy data to the MCSPI_TXx register and only after the TX buffer is empty (check the MCSPI_CH0STAT[2] bit in the software). Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the MCSPI_TXx register is always full (the TXx_EMPTY bits of SPIm.MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TXx register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TXx register, the TXx_EMPTY and TXx_UNDERFLOW bits in the SPIm.MCSPI_IRQSTATUS register are never set in receive-only mode.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RXx_FULL bits of the SPIm.MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RXx register. The SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

16.5.2.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel, the assertion of the spim_csx signal can be controlled in two different ways:

- If the MCSPI_MODULCTRL[0] SINGLE bit is set to 0, spim_csx assertion/deassertion after each SPI word is automatically controlled by the McSPI module (see subsections of Section 16.5.2.1, *Master Mode Features*.
- If the MCSPI_MODULCTRL[0] SINGLE bit and the MCSPI_CHxCONF[20] FORCE bit are set to 1: spim_csx assertion/deassertion is controlled by software (see Section 16.5.2.5.1, *Programming Tips When Switching to Another Channel*.

16.5.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the SPIm.MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

16.5.2.5.2 Force spim_csx Mode

Continuous transfers are manually allowed by keeping the spim_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the spim_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the spim_csx active mode is supported when:

- A single channel is used (with the SPIm.MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.MCSPI_CHxCONF).

  The state of the spim_csx signal is programmable.

  – Writing 1 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the spim_csx line high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. spim_csx is driven low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.

  – Writing 0 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the spim_csx line low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. spim_csx is driven high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.
- A single channel is enabled (the SPIm.MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the spim_csx line.

When the channel is enabled, the spim_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TXx register (the SPIm.MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RXx register (the SPIm.MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the SPIm.MCSPI_CHxCONF[13:12] TRM field) of the channel enabled.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the SPIm.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the spim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, spim_csx polarity and spim_clk phase and spim_clk polarity must not be modified when the spim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI_CHxCTRL[0] EN bit set to 0) and spim_csx can be forced to its inactive state using the SPIm.MCSPI_CHxCONF[20] FORCE bit.

Figure 16-15 and Figure 16-16 show successive transfers with spim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 16-15. Continuous Transfers With spim_csx Maintained Active (Single-Data-Pin Interface Mode)

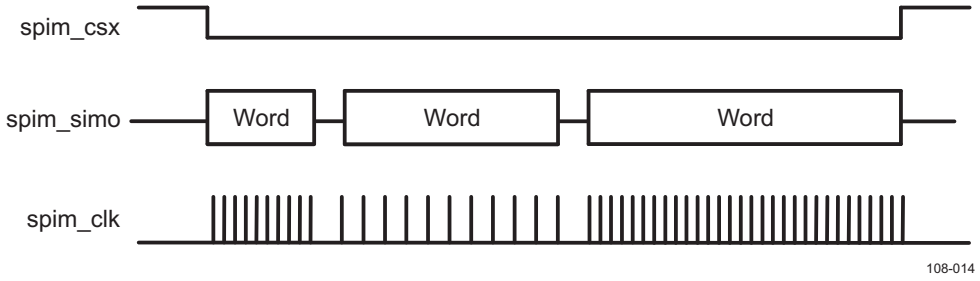


Figure 16-16. Continuous Transfers With spim_csx Maintained Active (Dual-Data-Pin Interface Mode)

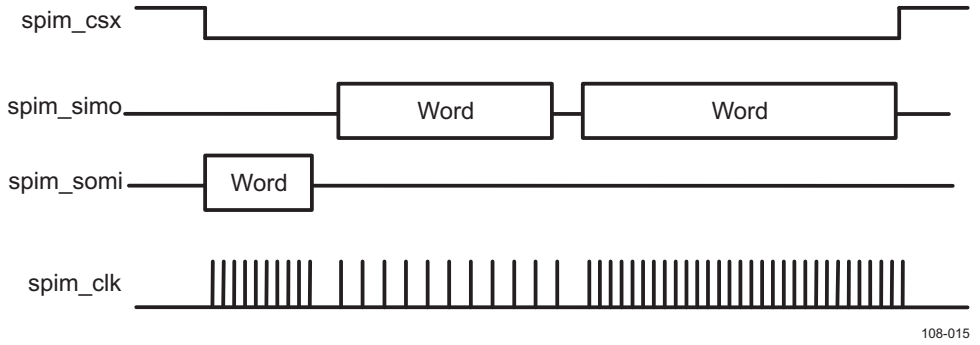


NOTE: The turbo mode described in Section 16.5.2.5.3, *Turbo Mode*, maintains spim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The SPIm.MCSPI_CHxCONF[19] TURBO bit is set to 1.)

16.5.2.5.3 Turbo Mode

The turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RXx register are full. The turbo mode is useful (time savings) when a transfer exceeds two words. This mode is programmable per channel (via the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 applies, but Rule 3 does not (see Section 16.5.2.2). An enabled channel can be scheduled if its receive register is full (the SPIm.MCSPI_CHxSTAT[0]) RXS bit) at the time of the shift-register assignment until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

16.5.2.6 Start Bit Mode

In start bit mode, an extended bit is added before the SPI word in order to indicate whether the next SPI word must be handled as a command or as data. This feature is only available in master mode. The start bit mode cannot be used at the same time as turbo mode and/or force spim_csx mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPIm.MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

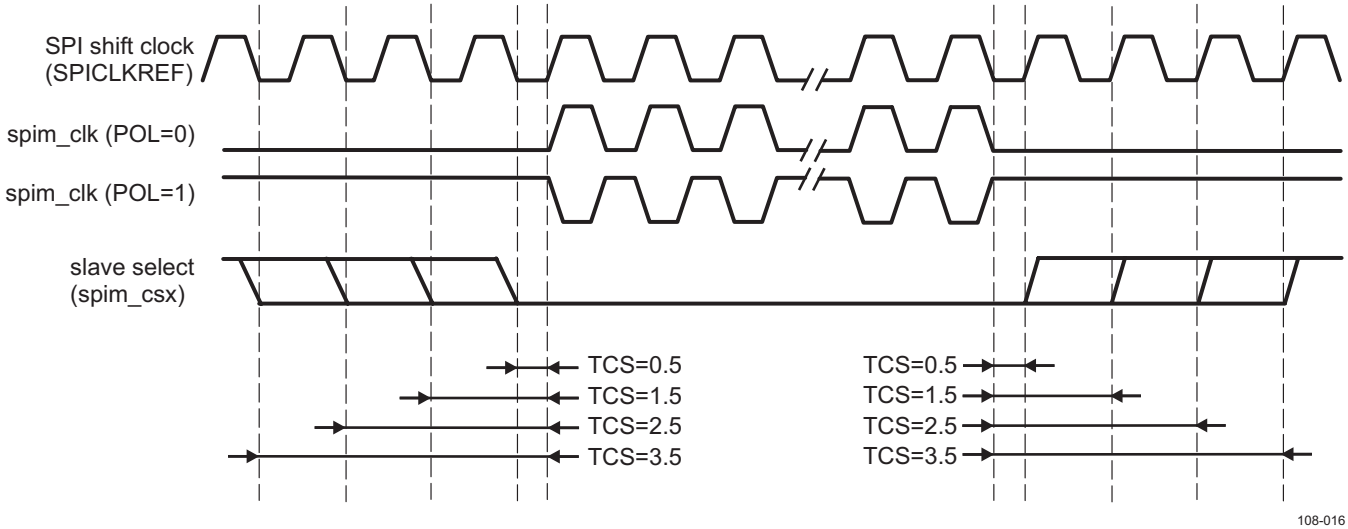
16.5.2.7 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (MCSPI_MODULCTRL[0] SINGLE bit field set to 0), to add a programmable delay between chip select assertion and first clock edge, or chip select removal and last clock edge.

This mode is programmable per channel (the TCS bit of the SPIm.MCSPI_CHxCONF register).

Figure 16-17 shows the chip-select SPIEN timing control.

Figure 16-17. Chip-Select SPIEN Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

16.5.2.8 Programmable SPI Clock (spim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD field) to generate the bit rate of the serial output clock spim_clk. Table 16-11 summarizes the supported divisor values.

Table 16-11. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192	~5.8 kHz
16384	~2.9 kHz
32768	~1.5 kHz

16.5.2.8.1 Clock Ratio Granularity

By default the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power of two granularity leading to a clock division in range 1 to 4096, in this case the duty cycle is always 50%. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle, in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for odd value of clock ratio the clock high level lasts one clock cycle more than low level depending on SPIm.MCSPI_CHxCONF[1] POL bit and SPIm.MCSPI_CHxCONF[0] PHA bit refer to Table 16-12.

Table 16-12. CLKSPIO High/Low Time Computation

Clock ratio Fratio	CLKSPIO High Time	CLKSPIO Low Time
1	Thigh_ref	Tlow_ref
Even ≥ 2	T_ref * (Fratio/2)	T_ref * (Fratio/2)
Odd ≥ 3 (POL=PHA)	T_ref * (Fratio-1) /2	T_ref * (Fratio+1) /2
Odd ≥ 3 (POL≠PHA)	T_ref * (Fratio+1) /2	T_ref * (Fratio-1) /2

NOTE: Fratio = spi1_clk frequency (Fout) division ratio.
Thigh = spi1_clk High Time period.
Tlow = spi1_clk Low Time period.
T_ref = SPI1_FCLK period.
Thigh_ref = SPI1_FCLK high Time period.
Tlow_ref = SPI1_FCLK low Time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1 as shown below:

Fratio - 1											
11	10	9	8	7	6	5	4	3	2	1	0
SPI1.MCSPI_CHxCTRL[15:8] EXTCLK bit field								SPI1.MCSPI_CHxCONF[5:2] CLKD bit field			
15	14	13	12	11	10	9	8	5	4	3	2

For odd ratio values, the duty cycle is calculated as below:

Duty_cycle = (1-1/Fratio)/2

Table 16-13 shows clock granularity examples with a clock source frequency of 48 MHz.

Table 16-13. Clock Granularity Examples

EXTCLK	CLKD	CLKG	Fratio	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50-50	48
X	1	0	2	X	X	20.8	20.8	41.6	50-50	24
X	2	0	4	X	X	41.6	41.6	83.2	50-50	12
X	3	0	8	X	X	83.2	83.2	166.4	50-50	6
0	0	1	1	X	X	10.4	10.4	20.8	50-50	48
0	1	1	2	X	X	20.8	20.8	41.6	50-50	24
0	2	1	3	1	0	41.6	20.8	62.4	66-33	16
0	2	1	3	1	1	20.8	41.6	62.4	33-66	16
0	3	1	4	X	X	41.6	41.6	83.2	50-50	12
5	0	1	81	1	0	852.8	832	1684.8	50.6-49.4	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50-50	0.545

16.5.3 Slave Mode

To select the McSPI slave mode, set the SPIm.MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (spim_simo and spim_somi) when it is selected by an active control signal (spim_csx) and receives an SPI clock (spim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the McSPI uses the edge of spim_csx to detect word length. For this reason, spim_csx must become inactive between each word.

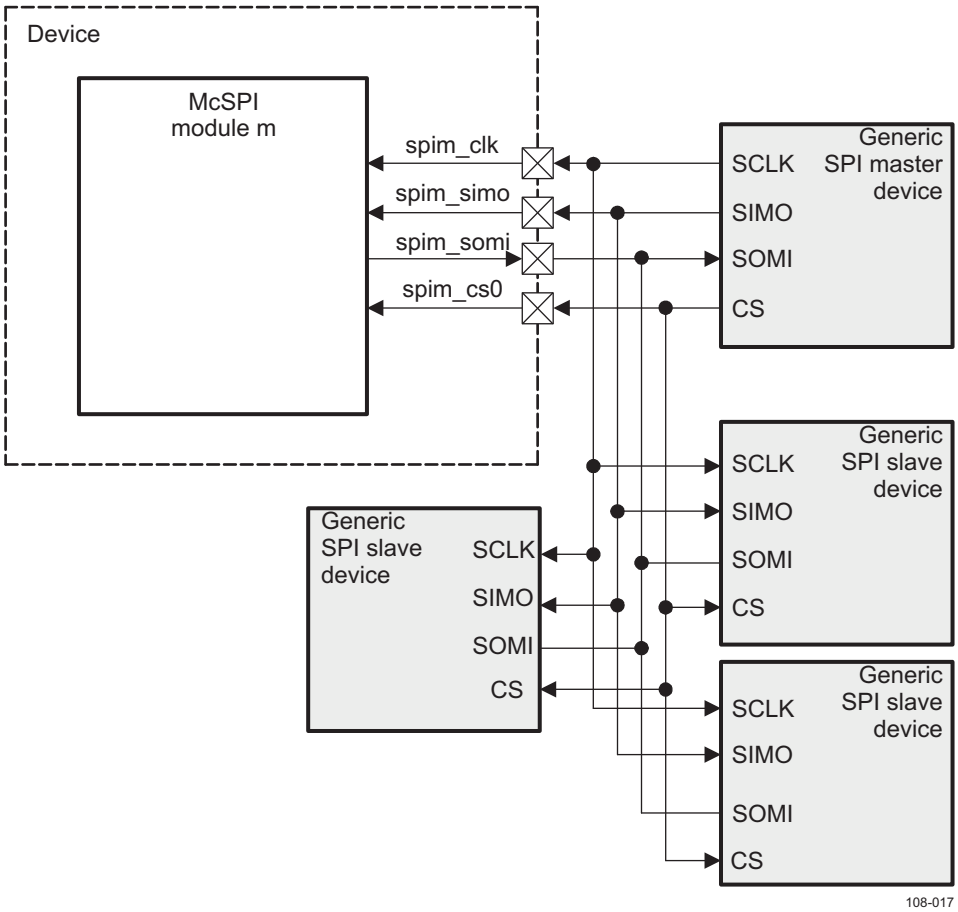
The McSPI does not support spim_csx active between SPI words. It uses the edge to detect word length.

16.5.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section registers name such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL where x=0 (channel 0 control register).

Figure 16-18 shows an example of four slaves wired on a single master device.

Figure 16-18. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0



The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI_CHxCTRL[0] EN bit (with x=0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected only on spin_cs0.
- Its own transmitter register, SPIm.MCSPI_TXx (with x=0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the SPIm.MCSPI_CHxSTAT[1] TXS bit (with x=0) is set. If McSPI is selected by an external master (the active signal on the spim_csx port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI_RXx (with x=0), on top of the common receive shift register. If the MCSPI_RXx register is full, the SPIm.MCSPI_CHxSTAT[0] RXS bit (with x=0) is set.

NOTE: The MCSPI_TXx register and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm. MCSPI_CHxCONF register (with x=0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
  - SPI word length, programmable with the WL bit
  - spim_csx polarity, programmable with the EPOL bit

– spim_clk polarity, programmable with the POL bit
– spim_clk phase, programmable with the PHA bit

The spim_clk frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD field (with x=0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (with x=0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (with x=0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (with x=0) for writing.
- Four interrupt events (see Section 16.5.5.2, *Interrupt Events in Slave Mode*)

16.5.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit (with x=0) set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state (see Section 16.5.5.2, *Interrupt Events in Slave Mode*).

16.5.3.3 Slave Transmit-Only Mode

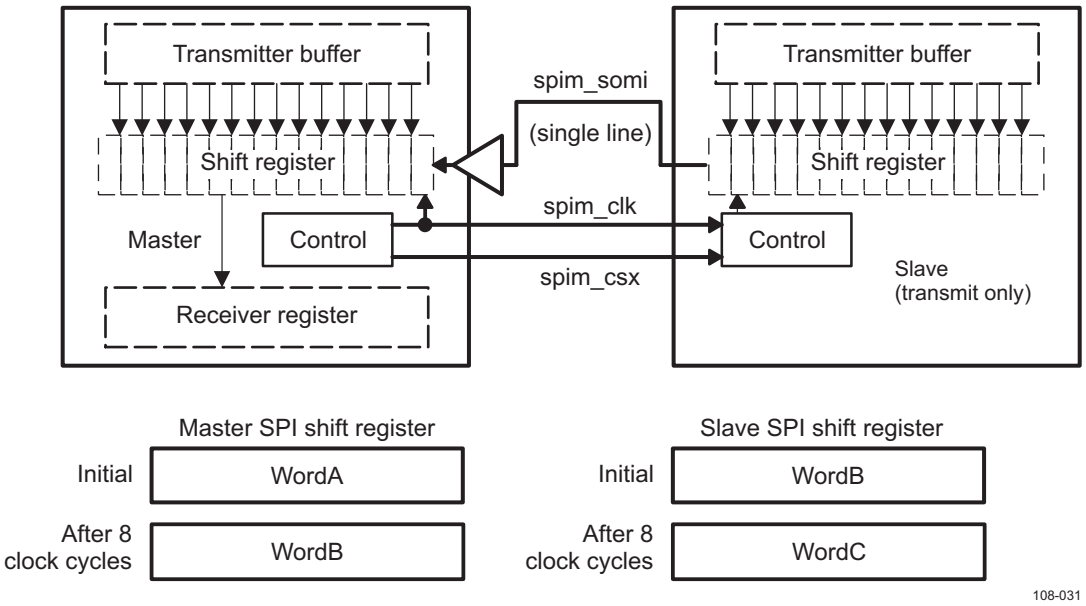
The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled because of the MCSPI_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (with x=0).

Figure 16-19 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 16-19. SPI Half-Duplex Transmission (Transmit-Only Slave)



16.5.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x1).

In receive-only mode, the MCSPI_TXx register must be loaded before the McSPI is selected by an external SPI master device. The MCSPI_TXx register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

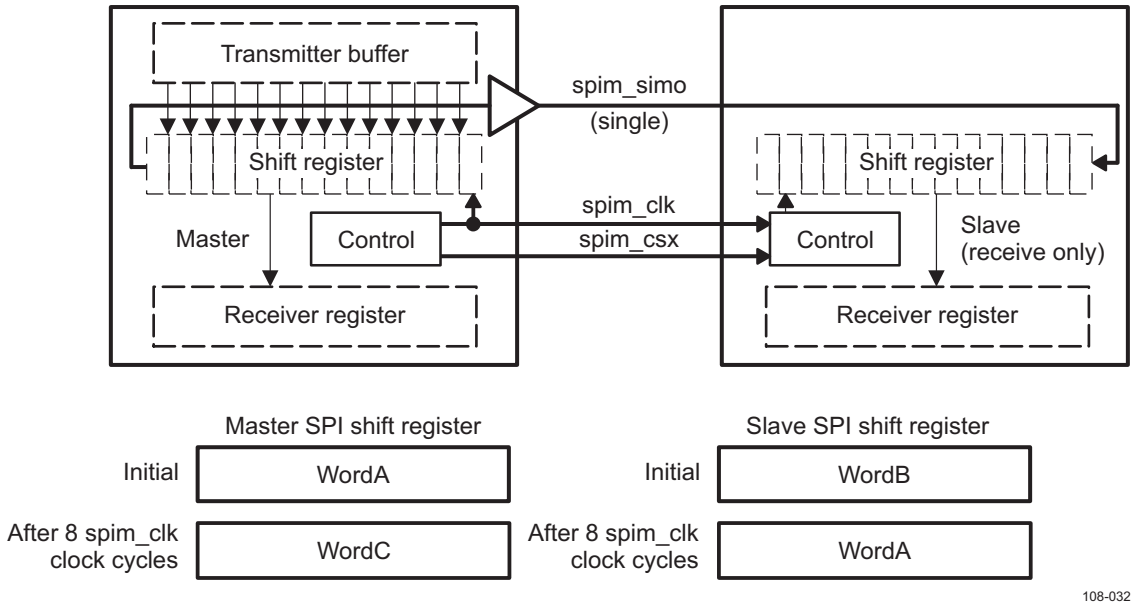
When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit (with x=0) is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the MCSPI_TXx register state.

For a full-duplex transmission, the serial clock (spim_clk) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If spim_clk synchronizes on a single serial data line, the data line should be half-duplex.

Figure 16-20 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock spim_clk, Word A transfers from the master to the slave.

Figure 16-20. SPI Half-Duplex Transmission (Receive-Only Slave)



16.5.4 FIFO Buffer Management

The McSPI controller has a built-in 64 bytes buffer to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at once and is selected by setting SPIm.MCSPI_CHxCONF[28] FFER bit or SPIm.MCSPI_CHxCONF[27] FFEW bit to 1. If several channel are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length SPIm.MCSPI_CHxCONF[11:7] WL are supported.

In transmit/receive mode, the buffer can be used in transmit (see Figure 16-21) or receive (see Figure 16-22) directions, or in both directions. If only one direction is chosen in transmit/receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction. See Figure 16-23.

Figure 16-21. Buffer Use in Transmit Direction Only

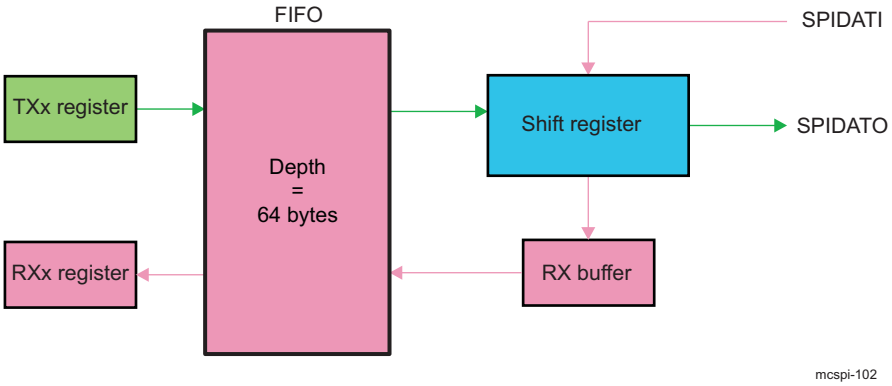


Figure 16-22. Buffer Use in Receive Direction Only

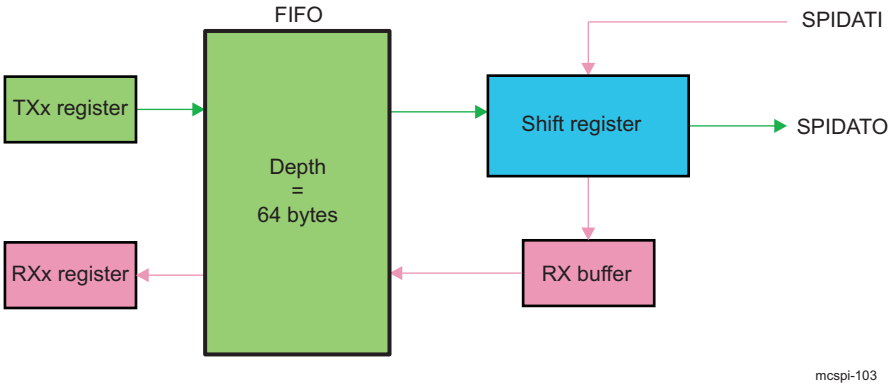

Figure 16-23. Buffer Used For Both Transmit/Receive Directions

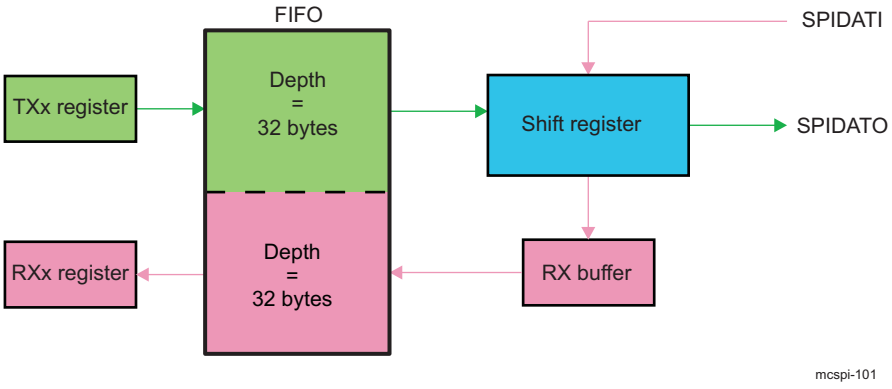


Two levels SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in WL. Table 16-14 shows the number of byte written in the FIFO depending on the word length.

Table 16-14. FIFO Writes, Word Length Relationship

SPI Word Length WL	3 ≤ WL ≤ 7	8 ≤ WL ≤ 15	16 ≤ WL ≤ 31
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

16.5.4.1 Buffer Almost Full

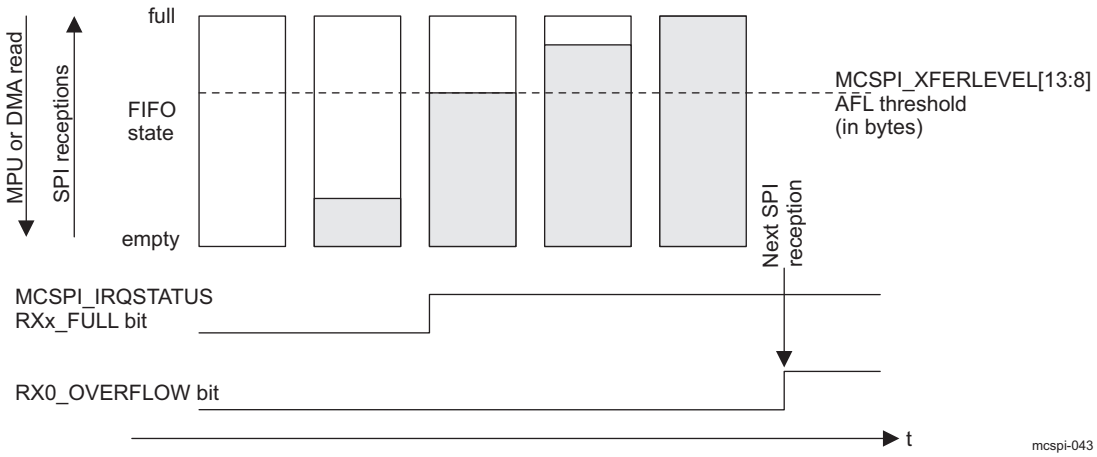
The MCSPI_XFERLEVEL[13:8] AFL bit field is needed when the buffer is used to receive SPI word from a slave (MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the Almost Full buffer status. See Figure 16-24.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable system to read AFL+1 bytes from Receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 16-24. Buffer Almost Full Level (AFL)



NOTE: MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions than the MCSPI_IRQSTATUS RXx_FULL flag.

16.5.4.2 Buffer Almost Empty

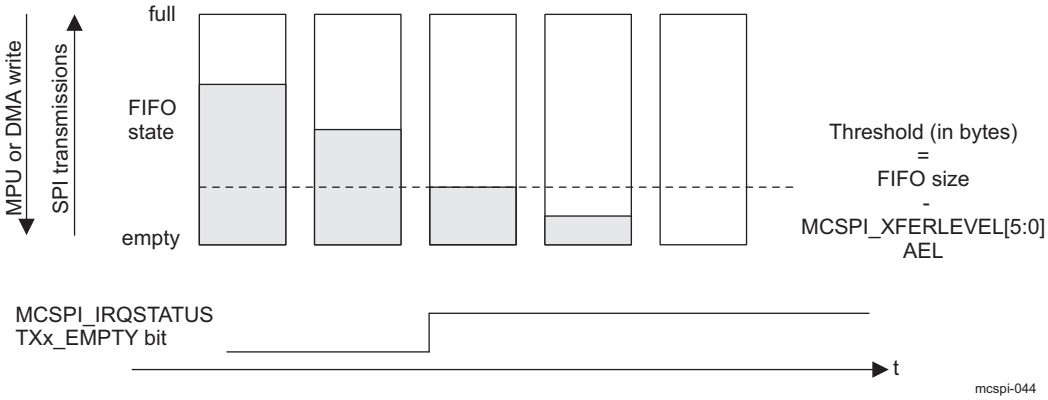
The MCSPI_XFERLEVEL[5:0] AEL bit field is needed when the buffer is used to transmit SPI word to a slave (MCSPI_CHxCONF[27] FFEW bit must be set to 1). It defines the Almost Empty buffer status. See Figure 16-25.

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the MPU to enable system to write AEL+1 bytes to Transmit register. Be careful AEL+1 must correspond to a multiple value of MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

Figure 16-25. Buffer Almost Empty Level (AEL)



NOTE: MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_TXx request is asserted on the same conditions than the MCSPI_IRQSTATUS TXx_EMPTY flag.

16.5.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user does not know how many SPI transfers have been done. For received words, software shall poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx Receive register to empty the FIFO buffer.

When the End Of Word count interrupt is generated (MCSPI_IRQSTATUS[17] EOW bit set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted again as long as system has not performed the right number of write accesses.

NOTE: The RXFFE status bit shows only the FIFO status. The data received are stored not only in the FIFO, but also in the shift register and the MCSPI_RX register. Therefore, the FIFO can be empty even after receiving two words.

16.5.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, ...) with x = [0,3] that indicate if service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

16.5.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the MCSPI_RXx register state is RXx_FULL.

16.5.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 16.5.2.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (MCSPI_CHxCONF[27] FFEW bit set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

16.5.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or if the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the MCSPI_TXx register since channel has been enabled. To avoid having TXx_UNDERFLOW event, the MCSPI_TXx register must be loaded seldom.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.1.3 RXx_ FULL

The RXx_FULL event is activated when channel is enabled and MCSPI_RXx register becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CHxCONF[28] FFER bit set to 1), the RXx_ FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into MCSPI_RXx. It is the responsibility of MPU to perform the right number of reads.

16.5.5.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enable and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the MCSPI_RXx register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

16.5.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (MCSPI_CHxCONF[27] FFEW bit set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of byte defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

16.5.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data is the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when data is not loaded into the MCSPI_TXx register because the channel is enabled.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

16.5.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register is being filled (transient event). When FIFO buffer is enabled (MCSPI_CHxCONF[28] FFER bit set to 1), RXx_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by the MCSPI_XFERLEVEL[13:8] AFL bit field.

The MCSPI_RXx register must be read to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into MCSPI_RXx. It is the responsibility of MPU to perform the right number of reads.

16.5.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the MCSPI_RXx register or FIFO is full when a new SPI word is received. The MCSPI_RXx register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

16.5.5.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.3 Interrupt-Driven Operation

An interrupt enable bit, in SPIm.MCSPI_IRQENABLE register, can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

- Read the SPIm.MCSPI_IRQSTATUS register to identify which event occurred.
- Read the MCSPI_RXx register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TXx register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_ UNDERFLOW, and RX0_OVERFLOW events.
- Write 1 into the corresponding bit of the SPIm.MCSPI_IRQSTATUS register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

16.5.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the SPIm.MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding MCSPI_RXx register.
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding MCSPI_TXx register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

16.5.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each McSPI channel can issue DMA requests if they are enabled. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted on read completion of the MCSPI_RXx register of the McSPI channel.

The DMA write request line is asserted when the McSPI channel is enabled and the MCSPI_TXx register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted on load completion of the MCSPI_TXx register of the channel.

16.5.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

16.5.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

16.5.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (see , *Power, Reset, and Clock Management*, for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM idle request is configurable through the McSPI.SYSCONFIG[4:3] SIDLEMODE bit.

The following list details the settings of the SIDLEMODE bit and the related acknowledgment modes:

- Force-idle mode (the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit set to 0x0): the McSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode the (SIDLEMODE bit set to 0x1): The McSPI module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The McSPI module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the McSPI module also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, the CORE_L4_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to McSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, McSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if McSPI acknowledges an idle request.

The following list details CLOCKACTIVITY settings and the associated features:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, both ICLK and FCLK are taken into account for generating the acknowledge. This setting also means that both FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means McSPI can potentially acknowledge the idle request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, the software must ensure consistent programming between the CLOCKACTIVITY and the PRCM CORE_48M_FCLK and CORE_L4_ICLK control bits. If the McSPI is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

16.5.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when both the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch the interface clock and the functional clock back. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the spim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF SPIENSLV field (with x=0) in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- *Before the beginning* of the second SPI word serialization when McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- *Before the end* of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (with x=0) before the completion of the second SPI word serialization.

Table 16-15 lists the supported cases in wake-up mode.

Table 16-15. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode.	No wake-up event

Table 16-15. Smart-Idle Mode and Wake-Up Capabilities (continued)

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the spim_csx port associated to channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

16.5.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SPIm.MCSPI_IRQENABLE and SPIm.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPI_IRQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

16.5.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0.

  In force-idle mode, McSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if both the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set.

  The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPI_IRQSTATUS register.

  In force-idle mode, the module must be disabled so the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.

  An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. The software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol.

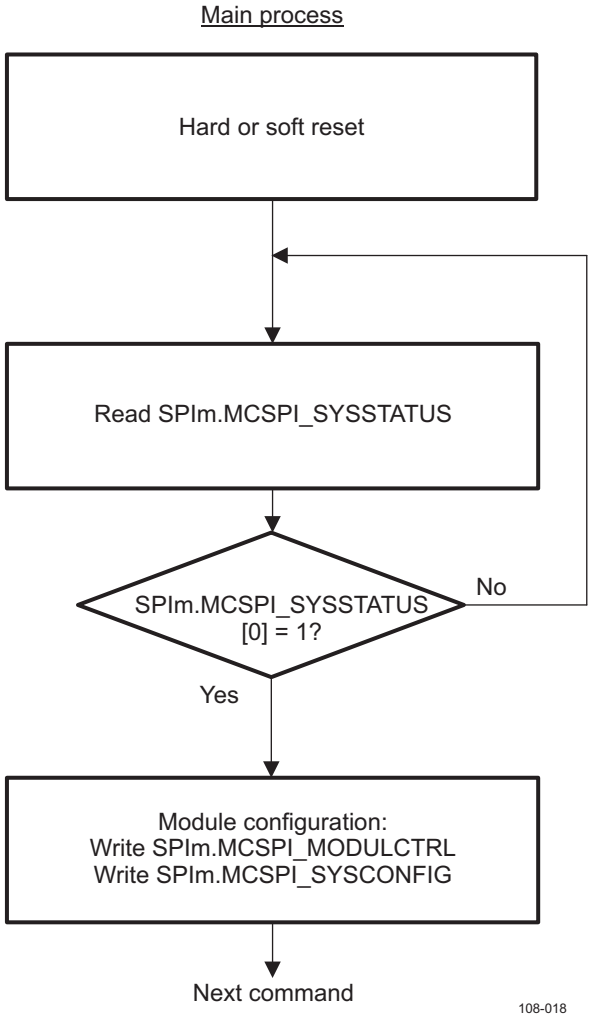
  The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

16.6 McSPI Basic Programming Model

16.6.1 Initialization of Modules

Figure 16-26 shows the overview of the module initialization flow process. Section 16.6.2 and Section 16.6.3 show the steps required to configure McSPI modes.

Figure 16-26. Module Initialization Flow



NOTE: Before the SPIm.MCSPI_SYSSTATUS[0] RESETDONE bit is set, the CLK and CLKSPIREF clocks must be provided to the module.

To avoid unpredictable behavior, reset the module before changing from master mode to slave mode, or vice versa.

16.6.2 Transfer Procedures without FIFO

In the subsections below, the transfer procedures are described without FIFO using (MCSPI_CHxCONF[27:28] FFER and FFEW = 0).

The McSPI allows the transfer of one or more words based on the different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

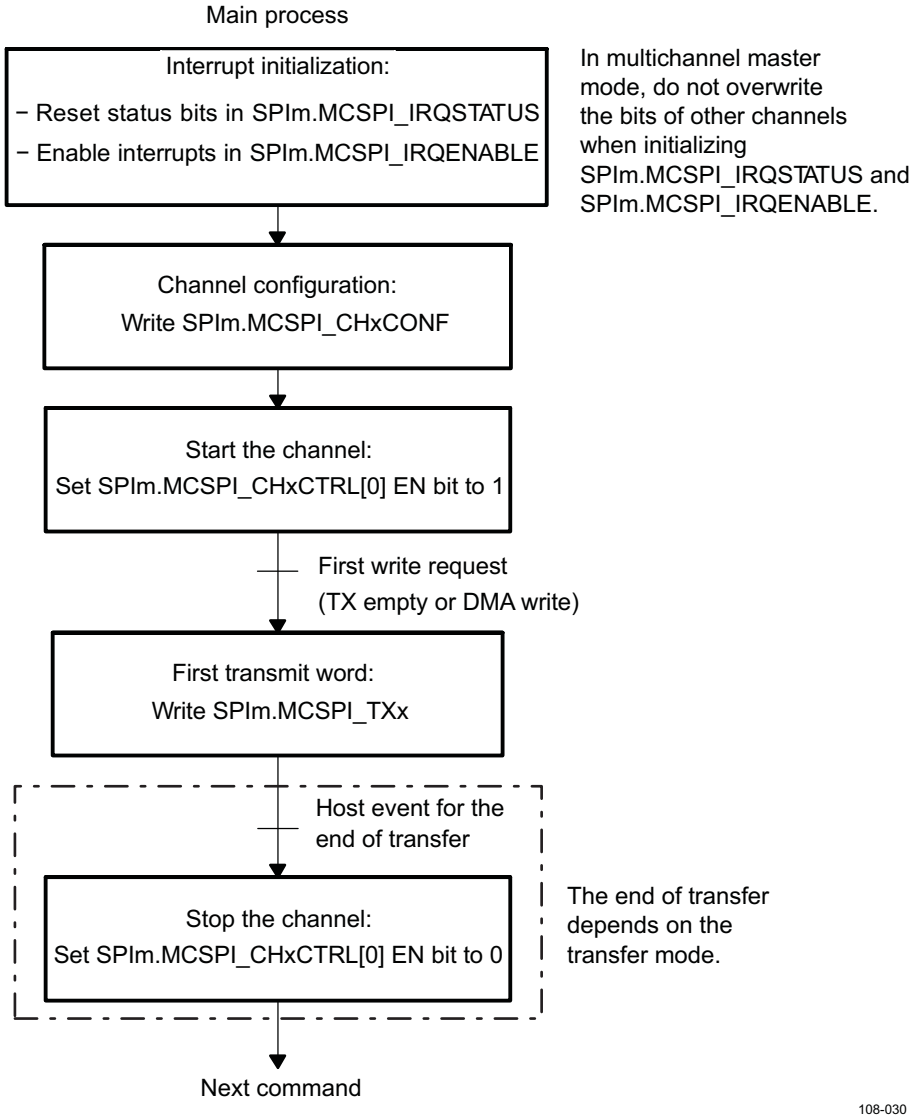
- spi1_csx line assertion/deassertion: Automatic, manual

For these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

16.6.2.1 Common Transfer Procedure

Figure 16-27 shows the main sequence common to all transfers. In multichannel master mode, the flows of different channels can be run simultaneously.

Figure 16-27. Common Transfer Sequence: Main Process



16.6.2.2 End-of-Transfer Procedure

For transfers carried out with DMA or interrupt mode, the end of transfer must be achieved by following the steps shown in the flowcharts corresponding to Table 16-16, which summarizes the end-of-transfer types per transfer mode and provides cross-references for further information.

Table 16-16. End-of-Transfer Sequences

		Transmit Receive		Transmit Only		Receive Only	
		Interrupt	DMA	Interrupt	DMA	Interrupt	DMA
Master normal	End of transfer sequence	See Section 16.6.2.3		See Section 16.6.2.4	See Section 16.6.2.4	See Section 16.6.2.5.1	See Section 16.6.2.5.1
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size[1]		w		w		w – 1
Master turbo	End of transfer sequence	See Section 16.6.2.3		See Section 16.6.2.4	See Section 16.6.2.4	See Section 16.6.2.5.2	See Section 16.6.2.5.2
	Minimum number of words	1	1	1	1	2	3
	DMA transfer size[1]		w		w		w – 2
Slave	End of transfer sequence	See Section 16.6.2.3		See Section 16.6.2.4	See Section 16.6.2.4	See Section 16.6.2.5.3	
	Minimum number of words	1	1	1	1	1	1
	DMA transfer size[2]		w		w	w	w

(1) w = number of words to transfer
(2) w = number of words to transfer

The different sequences can be merged in one process to manage transfers of several types. The end-of-transfer sequences are described from the start of the channel.

In these sequences and in later sections of this chapter, some software variables are used:

- WRITE_COUNT (= 0 at initialization): Contains the number of words to transfer
- READ_COUNT (= 0 at initialization): Contains the number of words to receive
- CHANNEL_ENABLE (= false at initialization)
- LAST_TRANSFER (= false at initialization): Indicates that the last word is in transmission
- LAST_REQUEST (= false at initialization): Indicates that the last request is in progress

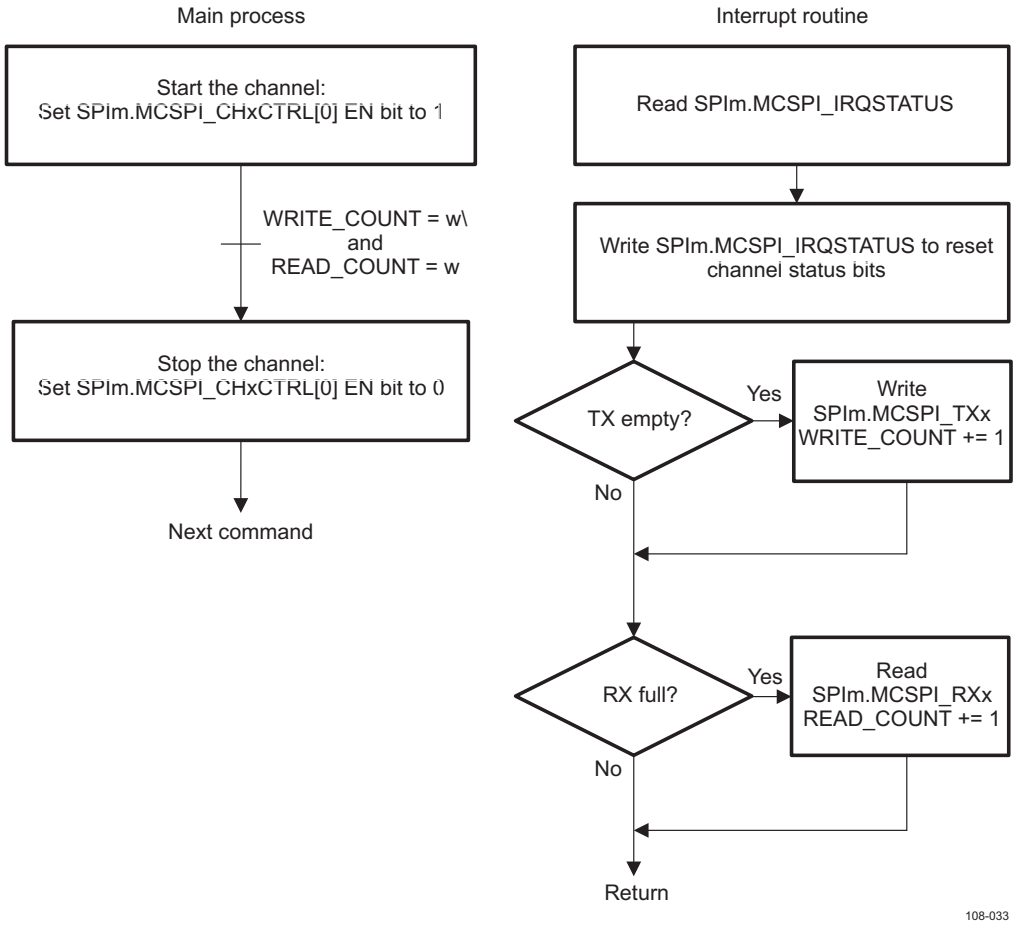
All variables are initialized before starting the channel.

16.6.2.3 Transmit and Receive Procedure

Figure 16-28 shows the handling procedure for words received and transmitted by interrupt in master and slave modes. The main process flow shows how the end of the transfer must be done after all words are received for this mode.

If the requests are configured in DMA, WRITE_COUNT and READ_COUNT are assigned with the value w when the DMA handler completes w interface accesses.

Figure 16-28. Transmit and Receive (Master and Slave)

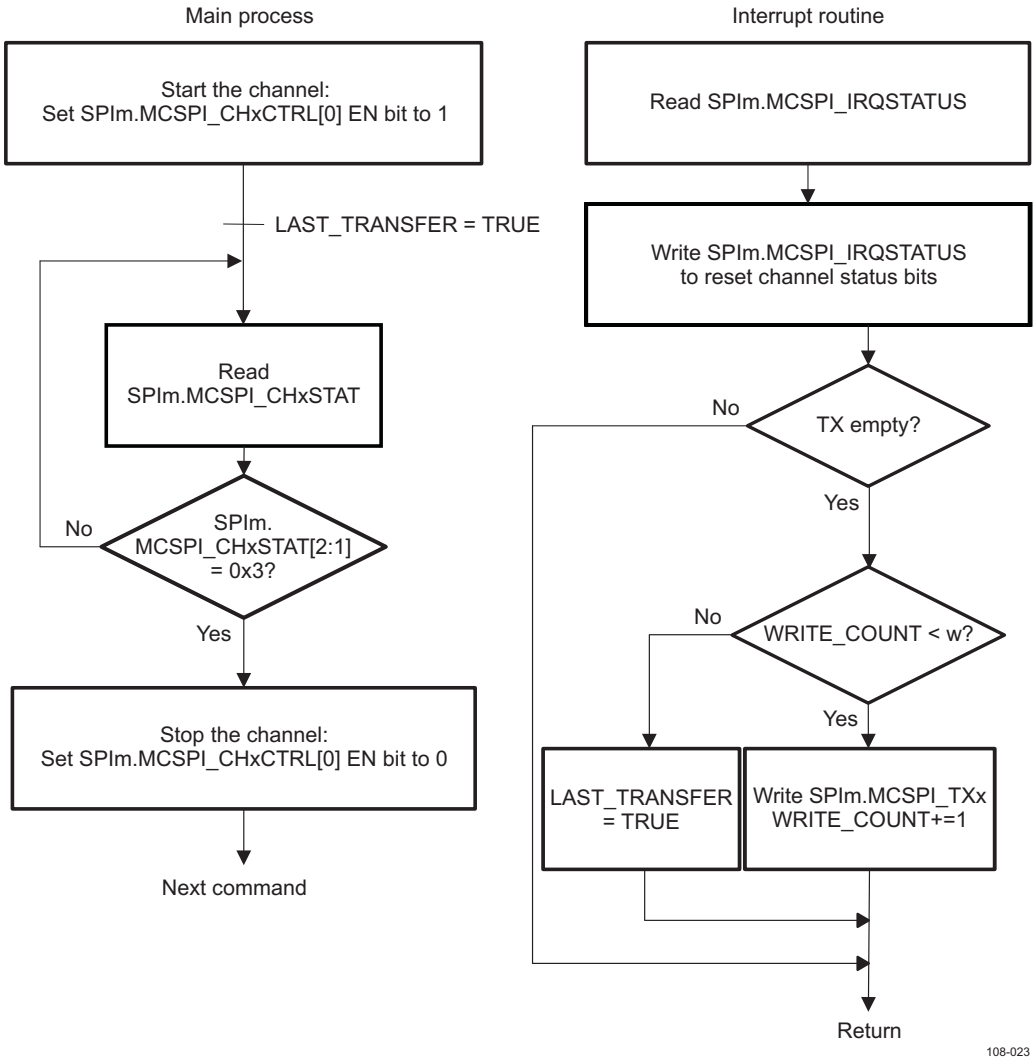


16.6.2.4 Transmit-Only Procedure

16.6.2.4.1 Based on Interrupt Requests

Figure 16-29 shows the handling procedure for words transmitted by interrupt in transmit-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 16-29. Transmit-Only With Interrupts (Master and Slave)

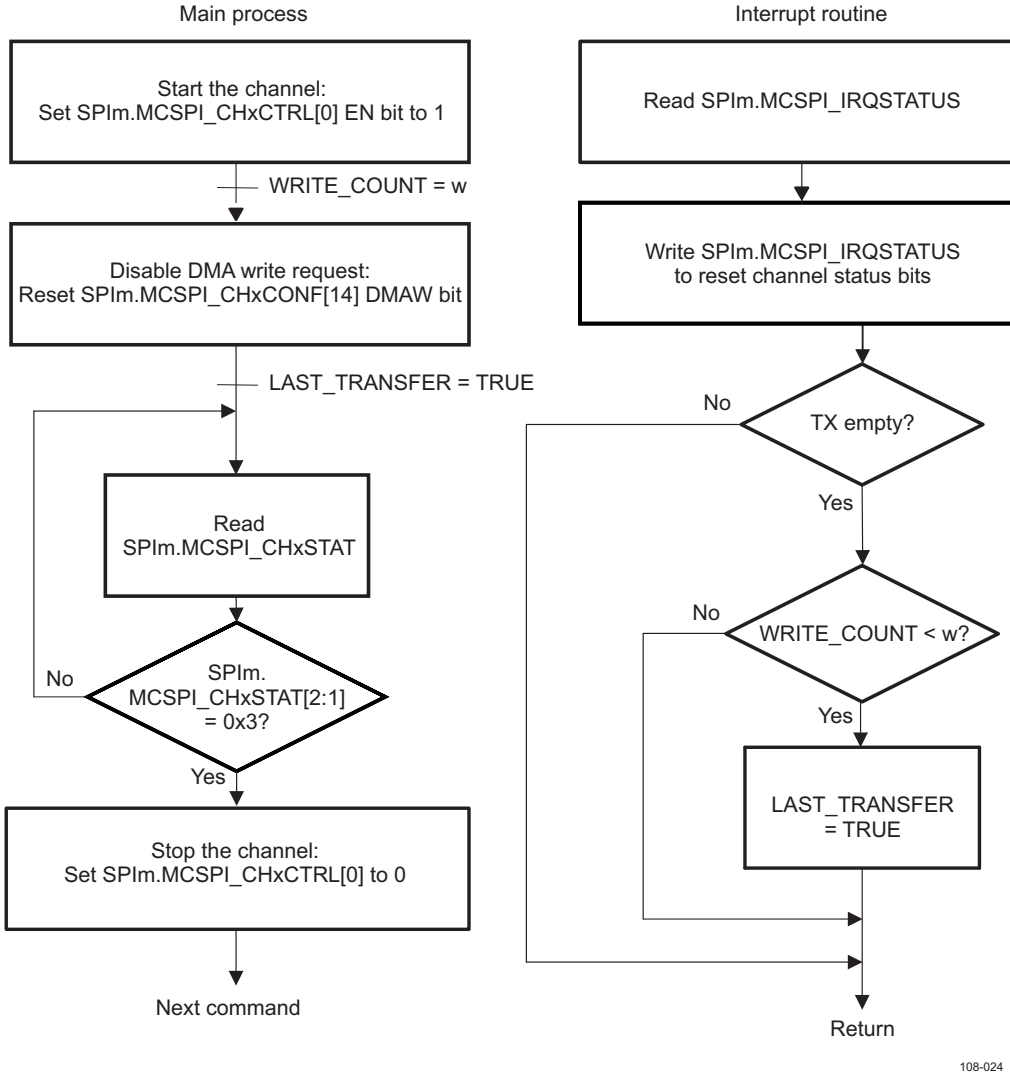


16.6.2.4.2 Transmit-Only Based on DMA Write Requests

In Figure 16-30, the main process shows completion of the transfer of words in transmit-only mode with DMA write requests.

When the DMA handler completes w interface accesses, WRITE_COUNT is assigned the value *w*.

Figure 16-30. Transmit-Only With DMA (Master and Slave)



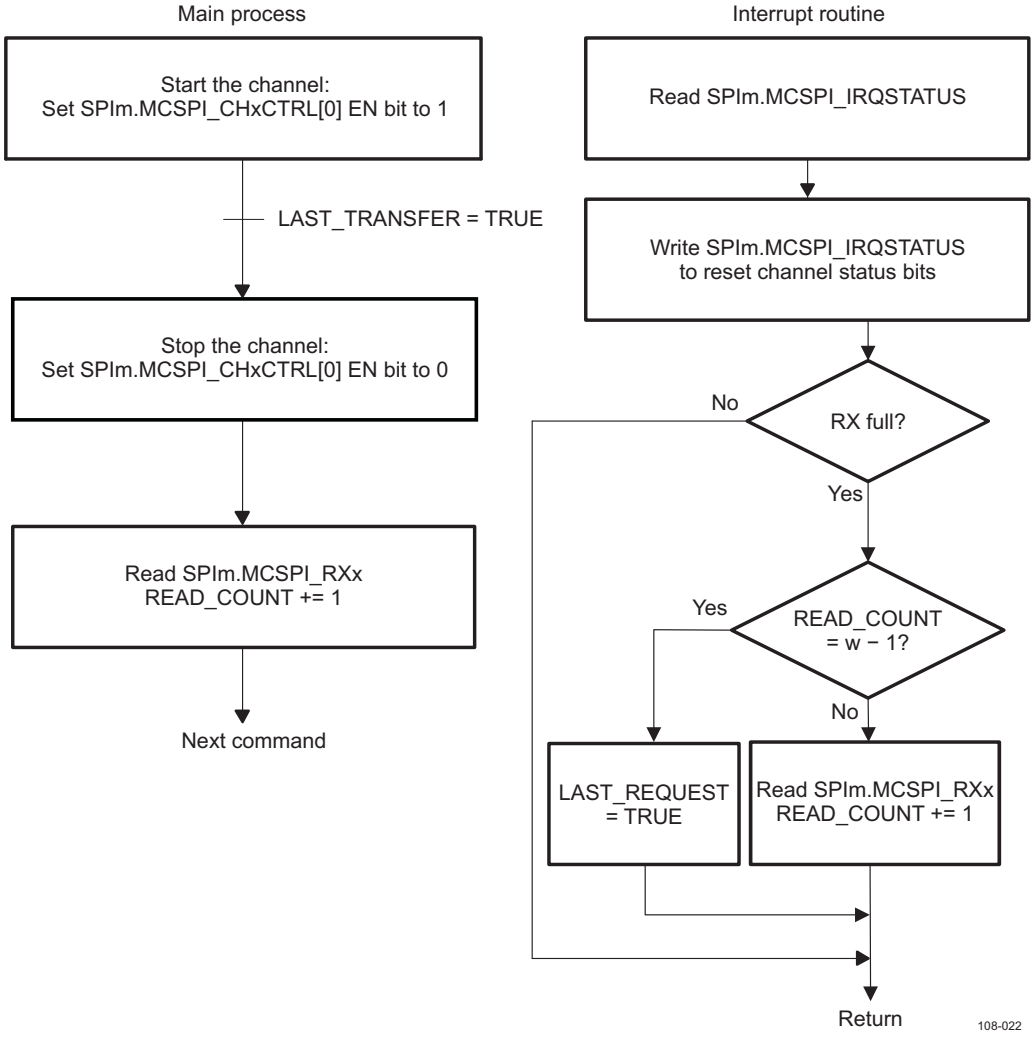
16.6.2.5 Receive-Only Procedure

16.6.2.5.1 Master Normal Receive-Only Procedure

16.6.2.5.1.1 Based on Interrupt Requests

Figure 16-31 shows the handling procedure for words received by interrupt in master normal receive-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 16-31. Receive Only With Interrupt (Master Normal)

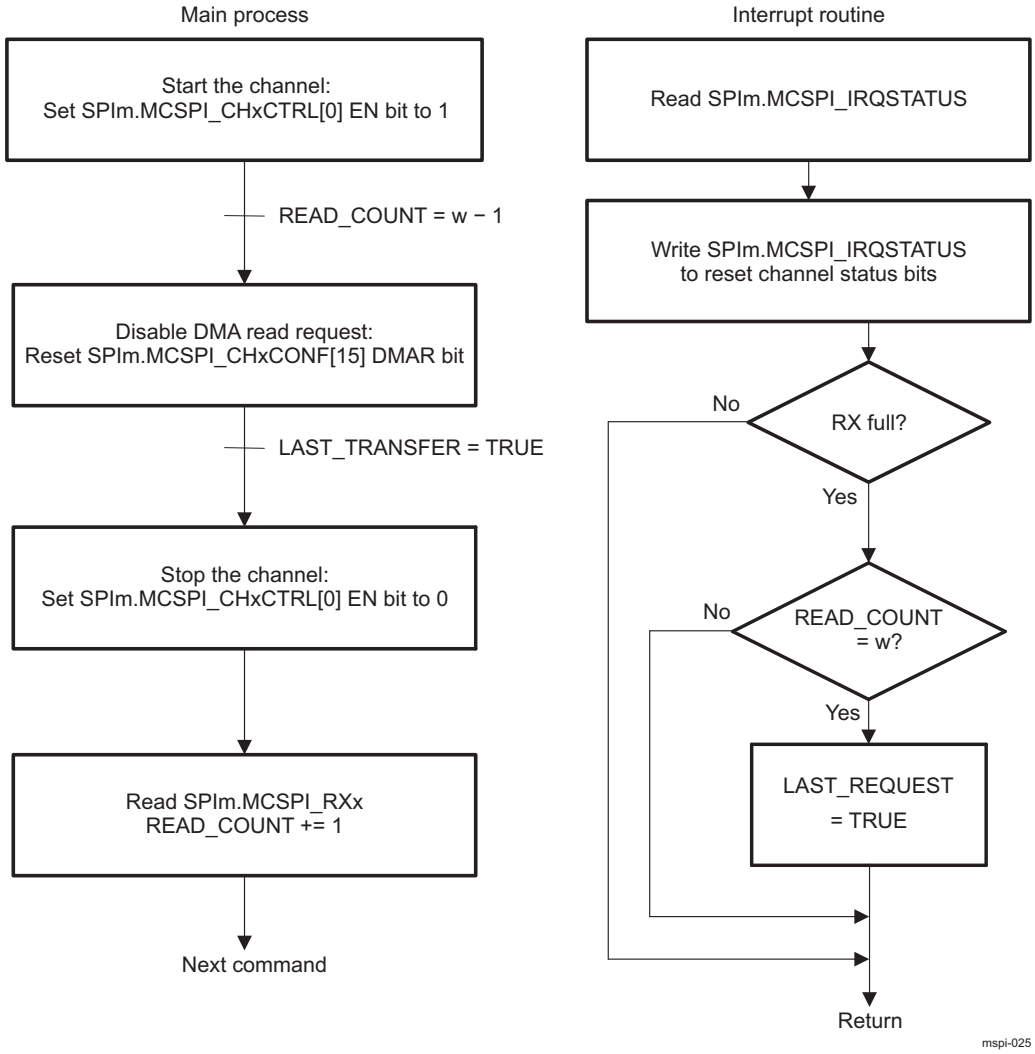


16.6.2.5.1.2 Receive-Only Based on DMA Read Requests

In Figure 16-32, the main process shows the completion of a word transfer in receive-only mode with DMA read requests.

When the DMA handler completes *w* - 1 interface accesses, READ_COUNT is assigned the value *w* - 1.

Figure 16-32. Receive-Only With DMA (Master Normal)

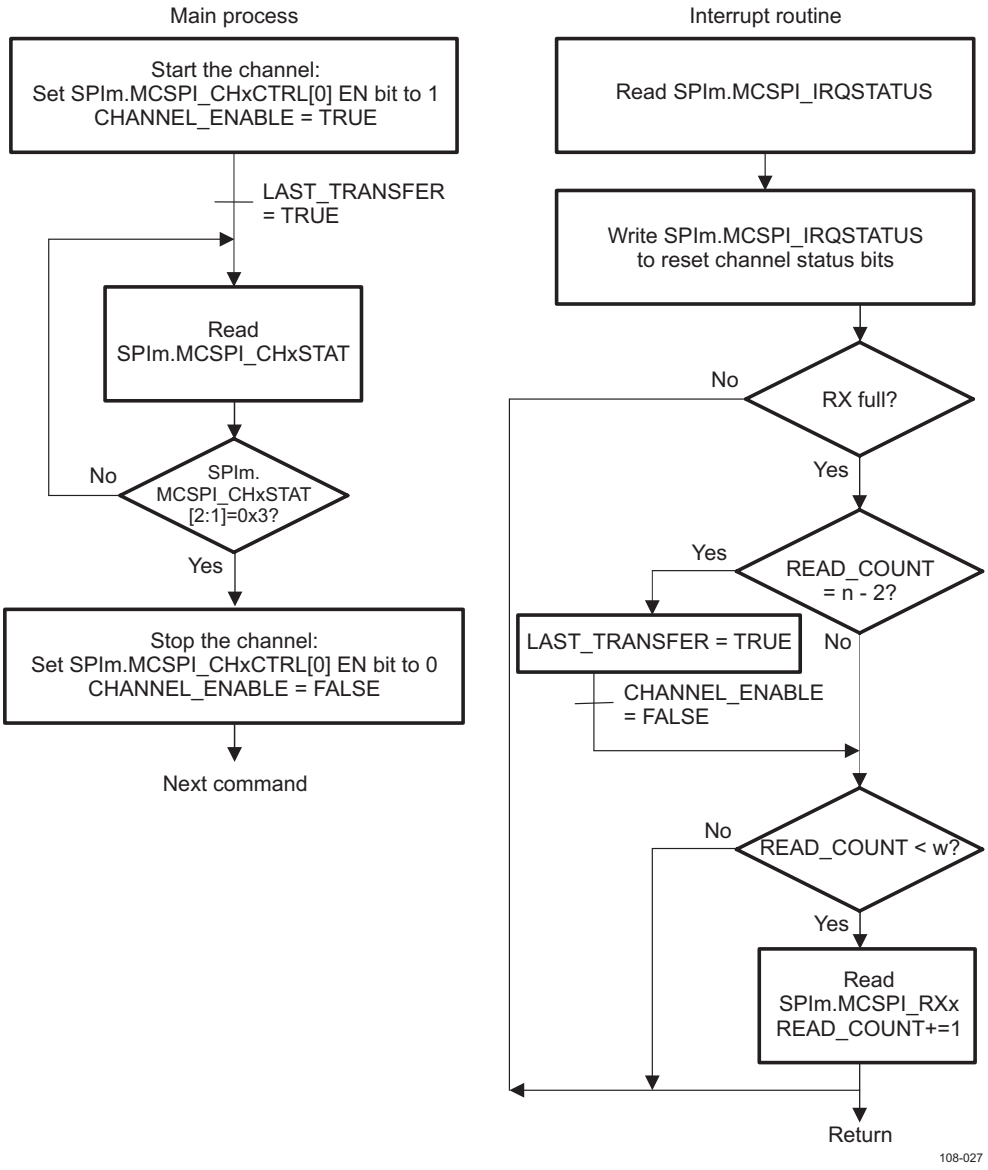


16.6.2.5.2 Master Turbo Receive-Only Procedure

16.6.2.5.2.1 Based on Interrupt Requests

Figure 16-33 shows the handling procedure for words received by interrupt in master turbo receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

Figure 16-33. Receive-Only With Interrupt (Master Turbo)

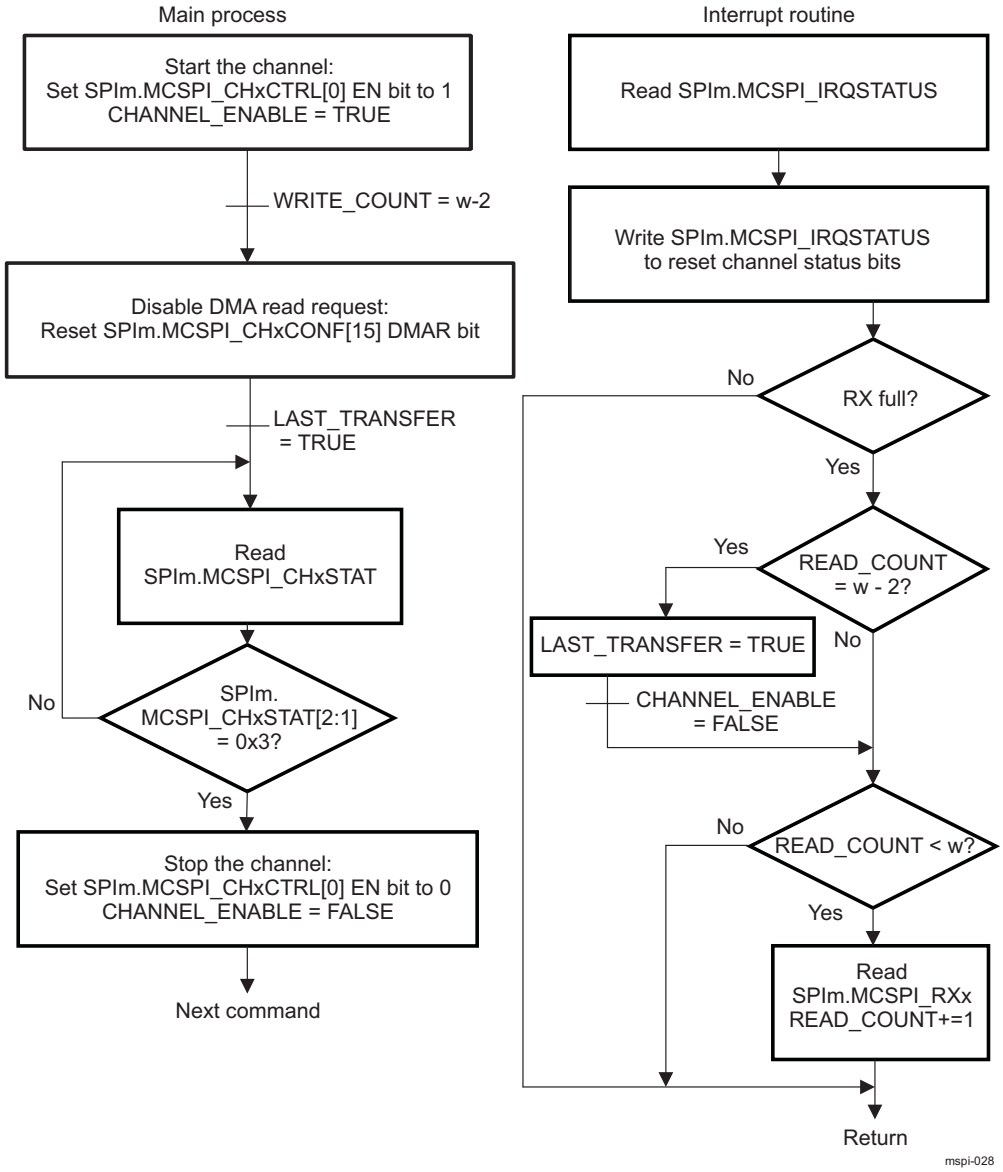


16.6.2.5.2.2 Based on DMA Read Requests

In Figure 16-34, the main process shows the completion of a word reception in master turbo receive-only mode with DMA write requests.

When the DMA handler completes *w* - 2 interface accesses, READ_COUNT is assigned the value *w* - 2.

Figure 16-34. Receive-Only With DMA (Master Turbo)

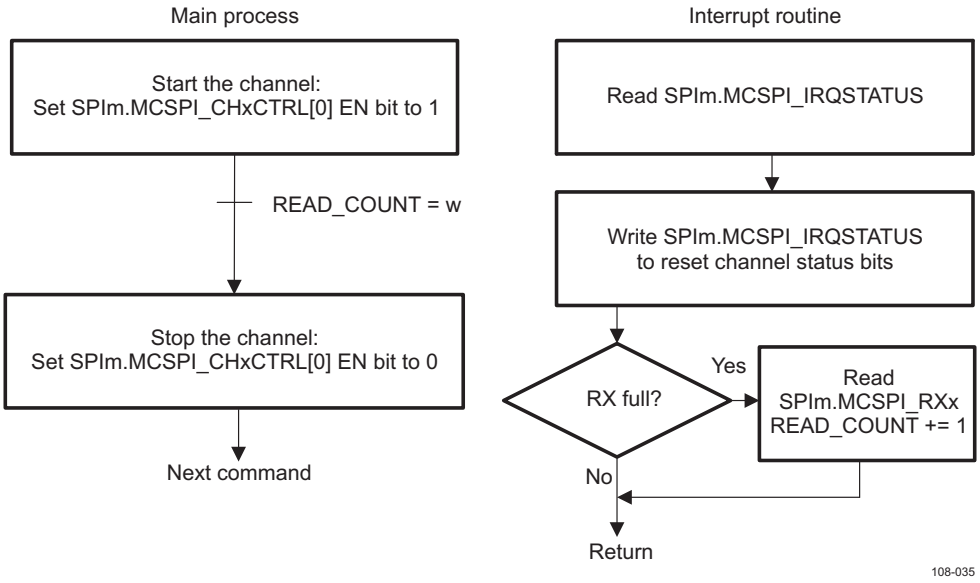


16.6.2.5.3 Slave Receive-Only Procedure

Figure 16-35 shows the handling procedure for words received by interrupt in slave receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

If the requests are configured in DMA, READ_COUNT is assigned the value *w* when the DMA handler completes *w* interface processes.

Figure 16-35. Receive Only (Slave)



16.6.2.6 McSPI Configuration and Operations Example

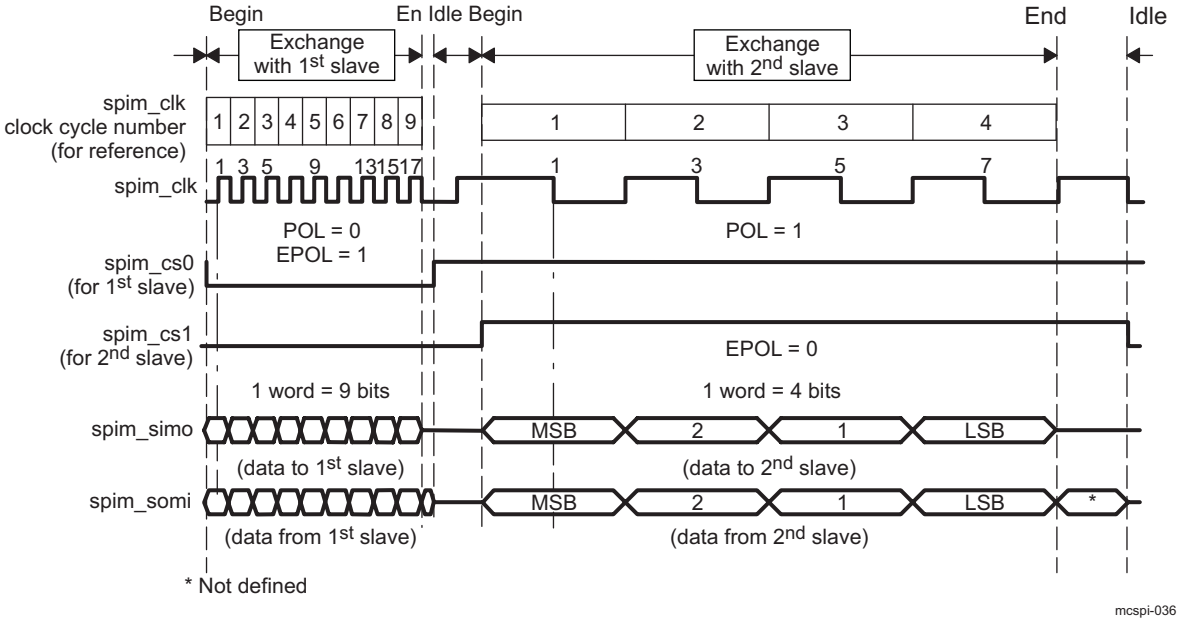
This section details an example of a typical configuration.

Figure 16-36 shows an implementation of successive transfers between two devices (slave) and the McSPI1 (master) in transmit-and-receive mode.

McSPI1 is the master, and spi1_simo shifts out the data to the external slaves. spi1_somi is connected to the data output port of two slave devices. The McSPI1 controls the first device with the spi1_cs0 signal (active low) for the exchange of 9-bit words synchronized with an active-high SPI clock.

The second device is controlled by the spi1_cs1 control signal (active high) for the exchange of 4-bit words synchronized with a SPI clock (active low) with a slower frequency than used with the first slave device.

Figure 16-36. Two SPI Transfers With PHA = 0 (Flexibility of McSPI)



This section details the steps required for this type of transmission.

16.6.2.6.1 McSPI Initialization Sequence

As shown in Figure 16-26, the McSPI module must first reset all registers and all state-machines.

For a software reset:

1. Set the SPI1.MCSPI_SYSCONFIG[1] SOFTRESET bit to 1.
2. Read the SPI1.MCSPI_SYSSTATUS[0] RESETDONE bit and check that it is set to 1.

16.6.2.6.2 Operations for the First Slave (On Channel 0)

16.6.2.6.2.1 Programming in Polling Mode

16.6.2.6.2.1.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 0) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CHxCONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CHxCONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CHxCONF[16] DPE0 bit to 1 for the spi1.simo pin in transmit mode.
3. Set the SPI1.MCSPI_CHxCONF[13:12] TRM field to 0x0 for transmit and receive mode.
4. Write 0x8 in the SPI1.MCSPI_CHxCONF[11:7] WL field for 9-bit word length.

5. Set the SPI1.MCSPI_CHxCONF[6] EPOL bit to 1 for spi1_cs0 activated low during active state.
6. Set the SPI1.MCSPI_CHxCONF[1] POL bit to 0 for spi1_clk held high during active state.
7. Set the SPI1.MCSPI_CHxCONF[0] PHA bit to 0 for data latched on odd-numbered edges of the SPI clock.

   Clock Initialization and spi1_cs0 Enable

   In master mode, the SPI must provide the clock and enable the channel:
8. Set the SPI1.MCSPI_MODULCTRL[2] MS bit to 0 to provide the clock.
9. Set the INPUTENABLE bit of the corresponding CONTROL_PADCONF_x register to achieve synchronous clock by using loopback through the output and input buffers of the pad.
10. Set the SPI1.MCSPI_CHxCTRL[0] EN bit to 1 (where x = 0) to enable channel 0.

16.6.2.6.2.1.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX0 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

16.6.2.6.2.1.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

16.6.2.6.3 Programming in Interrupt Mode

This section follows the flow of Figure 16-26.

1. Initialize software variables: WRITE_COUNT = 0 and READ_COUNT = 0.
2. Initialize interrupts: Write 0x7 in the SPI1.MCSPI_IRQSTATUS[3:0] field and set the SPI1.MCSPI_IRQENABLE[3:0] field to 0x7.
3. Follow the steps described in Section 16.6.2.6.2.1.1, *Mode Selection*.
4. If WRITE_COUNT = w and READ_COUNT = w, write SPI1.MCSPI_CHxCTRL[0] = 0x0 (x = 0) to stop the channel.

This interrupt routine follows the flow of Table 16-16 and Figure 16-28.

1. Read the SPI1.MCSPI_IRQSTATUS[3:0] field.
2. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1:

   (a) Write the command/address or data value in SPI1.MCSPI_TXx (where x = 0).

   (b) WRITE_COUNT + = 1

   (c) Write SPI1.MCSPI_IRQSTATUS[0] = 0x1.
3. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1:

   (a) Read SPI1.MCSPI_RXx (where x = 0)

   (b) READ_COUNT += 1

   (c) Write SPI1.MCSPI_IRQSTATUS[2] = 0x1

16.6.2.6.4 Operations for the Second Slave (on Channel 1) in Polling Mode

16.6.2.6.4.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 1) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CH1CONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CH1CONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CH1CONF[16] DPE0 bit to 1 for the spi1_somi pin in transmit mode.
3. Set the SPI1.MCSPI_CH1CONF[13:12] TRM field to 0x0 for transmit-and-receive mode.
4. Write 0x3 in the SPI1.MCSPI_CH1CONF[11:7] WL field.
5. Set the SPI1.MCSPI_CH1CONF[6] EPOL bit to 0 for spi1_cs1 activated high during the active state.
6. Set the SPI1.MCSPI_CH1CONF[1] POL bit to 1 for spi1_clk held low during the active state.
7. Set the SPI1.MCSPI_CH1CONF[0] PHA bit to 1 for data latched on even numbered edges of spi1_clk.

   Clock Initialization and spi1_cs1 Enable

   The SPI1.MCSPI_MODULCTRL[2] MS bit was set to 0 (providing the clock).

   In master mode, the SPI must provide the clock and enable the channel:
8. Set the SPI1.MCSPI_CH0CTRL[0] EN bit to 0 to disable channel 0, and set the SPI1.MCSPI_CH1CTRL[0] EN bit to 1 to enable channel 1.

NOTE: Read and write operations for the second slave are identical to those for the first slave.

16.6.2.6.4.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX1 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

16.6.2.6.4.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

16.6.3 Transfer Procedures with FIFO

In the subsections below, the transfer procedures are described with FIFO using (MCSPI_CHxCONF[27:28] FFER or/and FFEW = 1).

The MCSPI module allows the transfer of one or more words, according to different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

For these flows, the host process contains the main process and the interrupt routine, which is called on the IRQ signals or by an internal call if the module is used in polling mode.

16.6.3.1 Common Transfer Procedure

The common transfer sequence is the host sequence for a transfer of any type defined above.

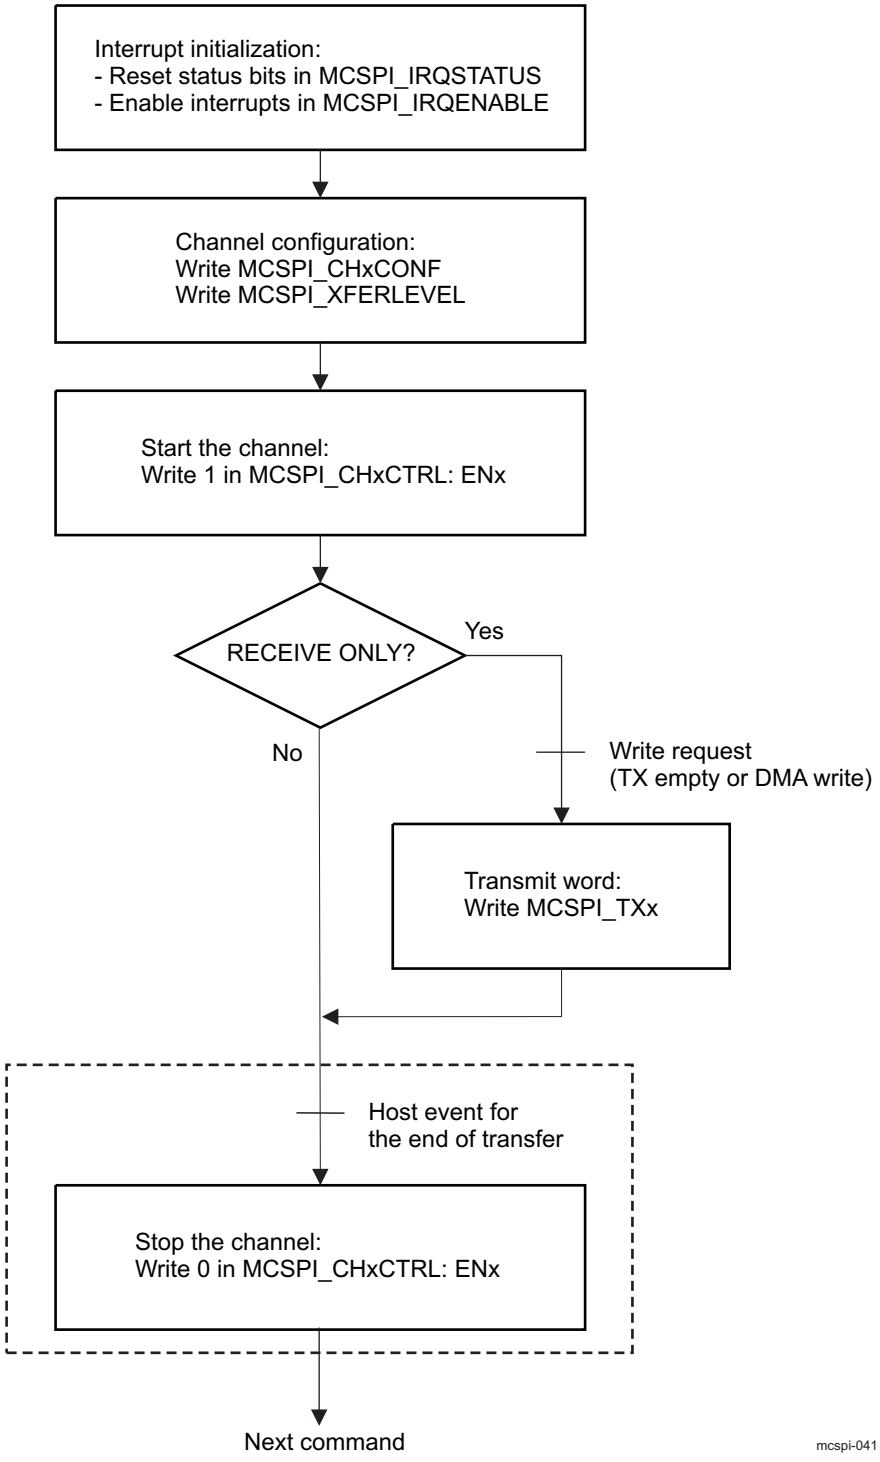
In multichannel, only one channel can use the FIFO. Before enabling the FIFO for a channel (FFExW and FFExR bits in the MCSPI_CHx_CONF register), the host must ensure that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit/receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In slave mode, only channel 0 only can be activated. The correct spim_csx line is chosen in the MCSPI_CH0CONF register with the SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request is released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case). Figure 16-37 shows the main process of the common transfer sequence.

Figure 16-37. Common Transfer Sequence/Main Process



The MCSPI module can start the transfer only after the first write request is released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case).

This first write request can be managed by the IRQ routine or DMA handler, as are as other requests. It appears in Figure 16-37 to show this point.

The end of the transfer (dotted line in Figure 16-37) is more complex and depends on the transfer type. Table 16-17 describes the different types of end-of-transfer and the transfer types to which they are applicable.

Table 16-17. End-of-Transfer Types

Word Count	Transmit/Receive	Transmit Only	Receive Only
Yes	See Section 16.6.3.2, *Transmit-Receive With Word Count*.	See Section 16.6.3.4, *Transmit-Only*.	See Section 16.6.3.5 , *Receive-Only With Word Count*.
No	See Section 16.6.3.3, *Transmit-Receive Without Word Count*.	See Section 16.6.3.4, *Transmit-Only*.	See Section 16.6.3.6, *Receive-Only Without Word Count*.

The sequence differs depending on whether word count is used (MCSPI_XFERLEVEL: WCNT is set or not). The AEL and/or AFL values can be different, but they must be multiples of the word size in the FIFO: 1, 2, or 4 bytes, according to word length.

In these sequences, the transfer to execute has a size of N words.

When accessing the FIFO, only one word is written or read for each OCP access.

In these sequences, the number of words written or read for each write or read FIFO request is:

- write_request_size
- read_request_size

If they are not submultiples of N, the last request sizes are:

- last_write_request_size (< write_request_size)
- ast_read_request_size. (< read_request_size)

The different sequences can be merged in one process to manage transfers of several types.

The end-of-transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

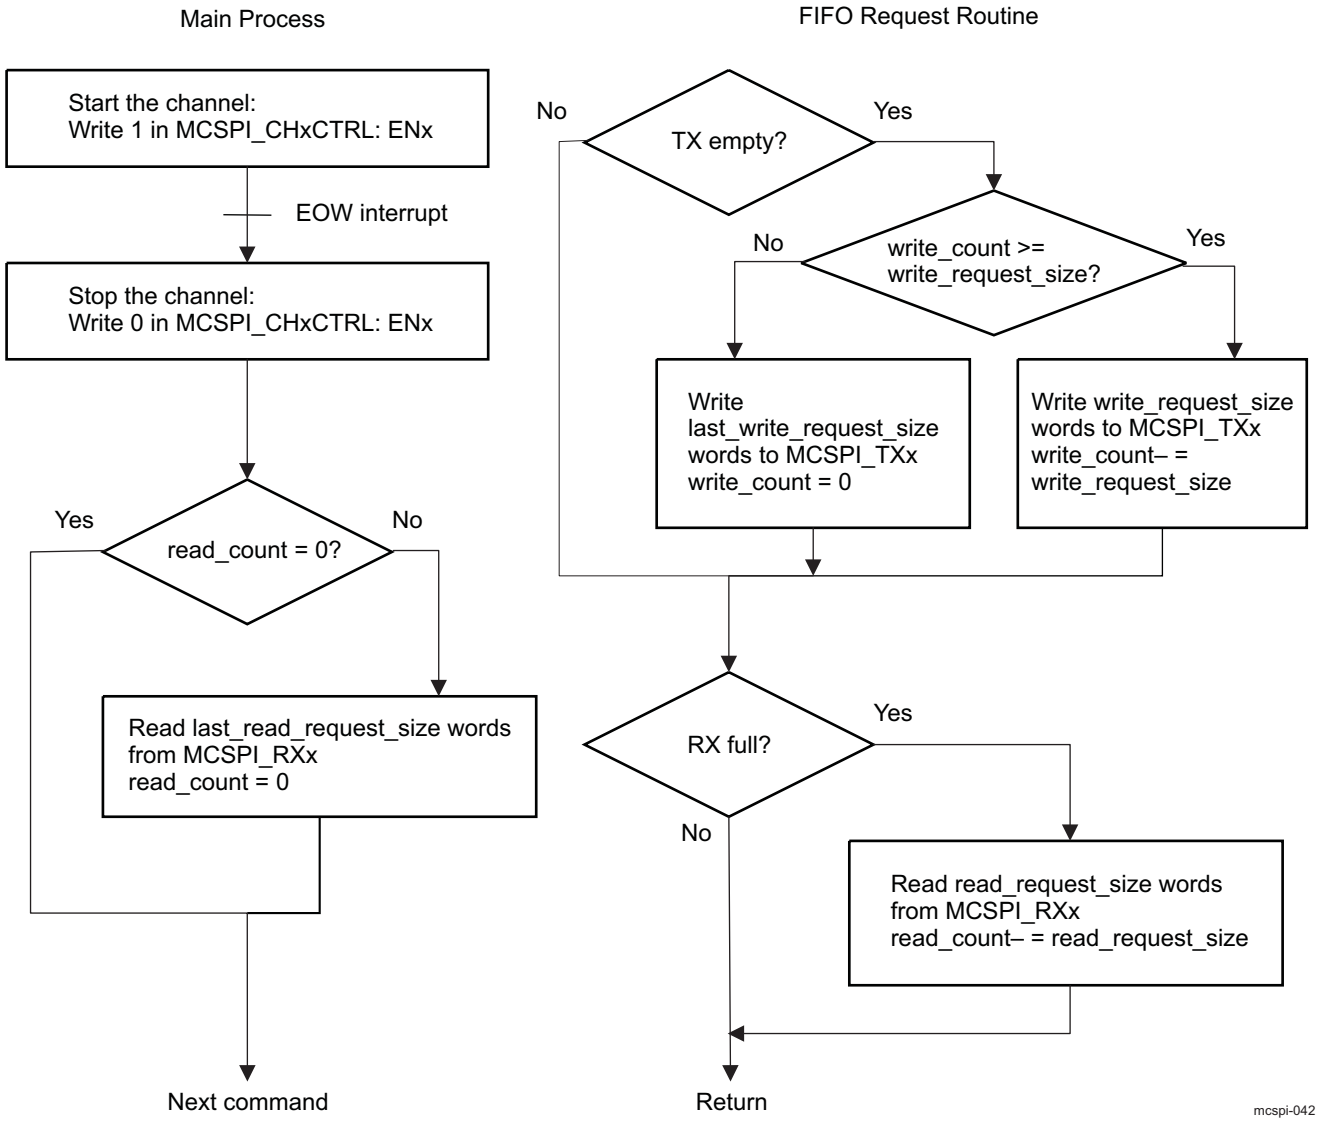
- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

16.6.3.2 Transmit-Receive Procedure With Word Count (WCNT≠0)

Figure 16-38 shows the flow of a transfer in transmit-receive mode, with word count.

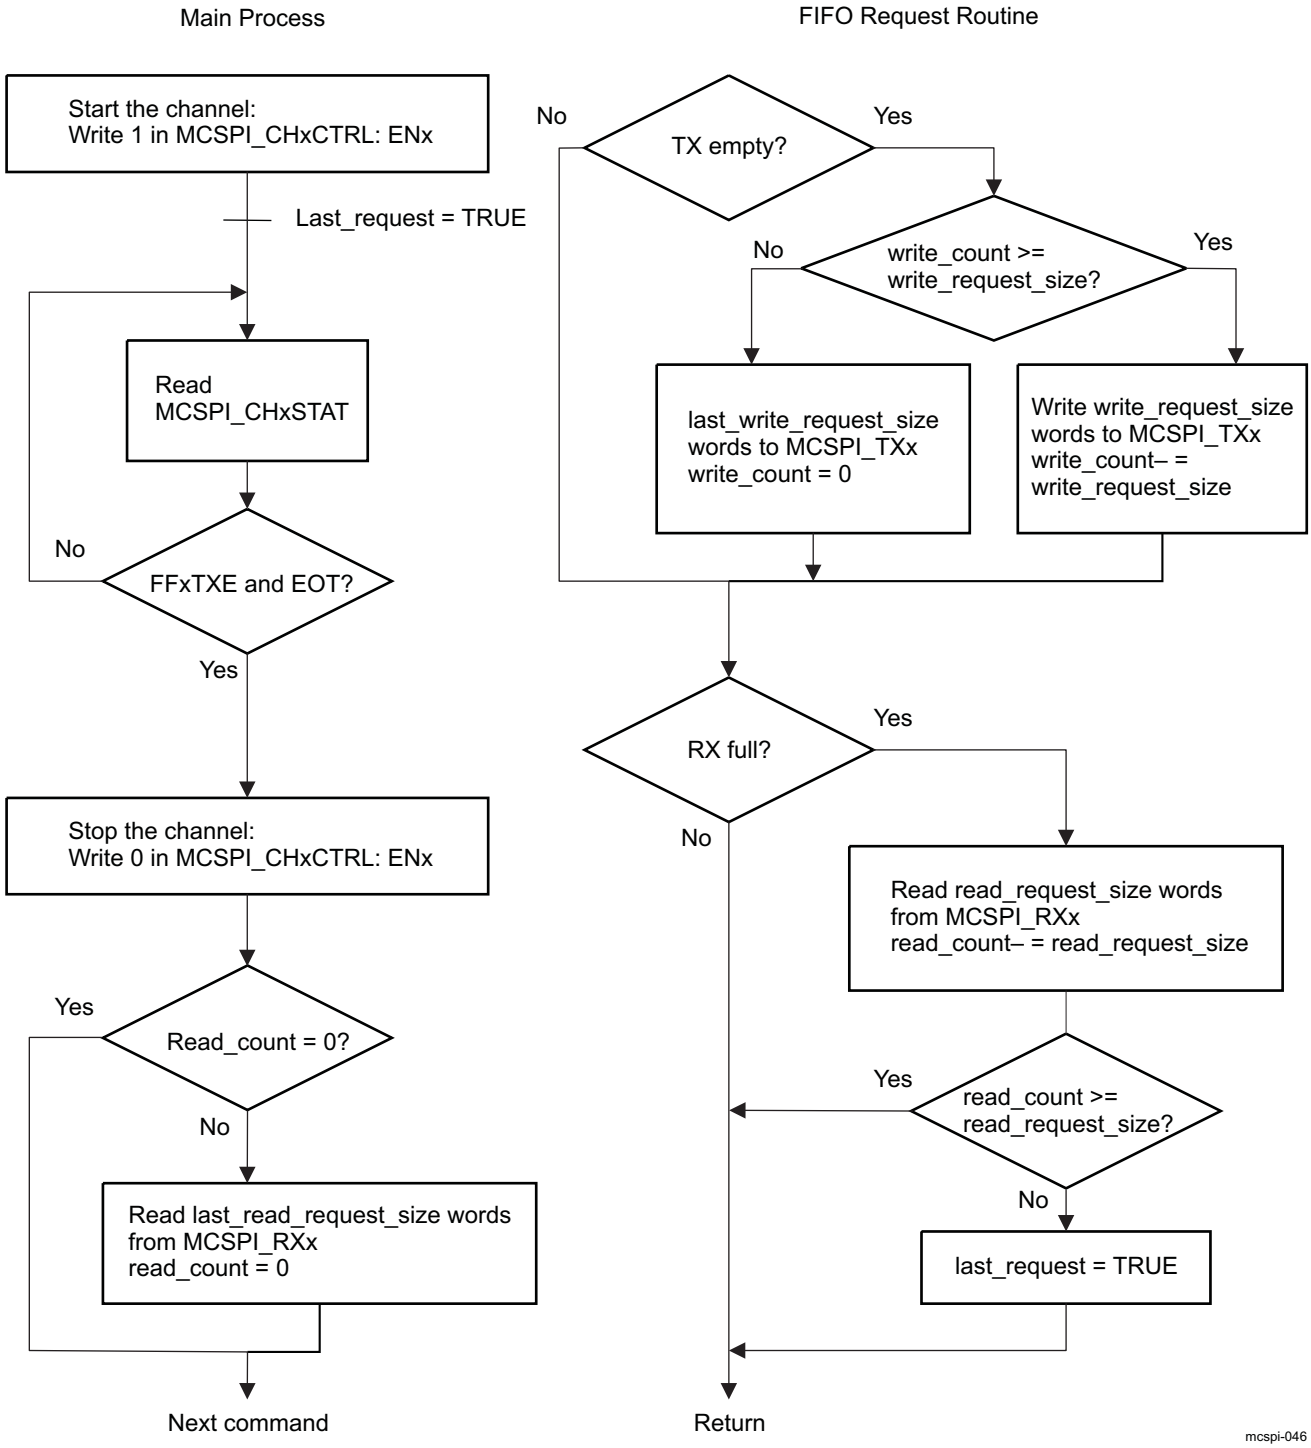
Figure 16-38. Transmit-Receive With Word Count



16.6.3.3 Transmit-Receive Procedure Without Word Count (WCNT=0)

Figure 16-39 shows the flow of a transfer in transmit-receive mode, without word count.

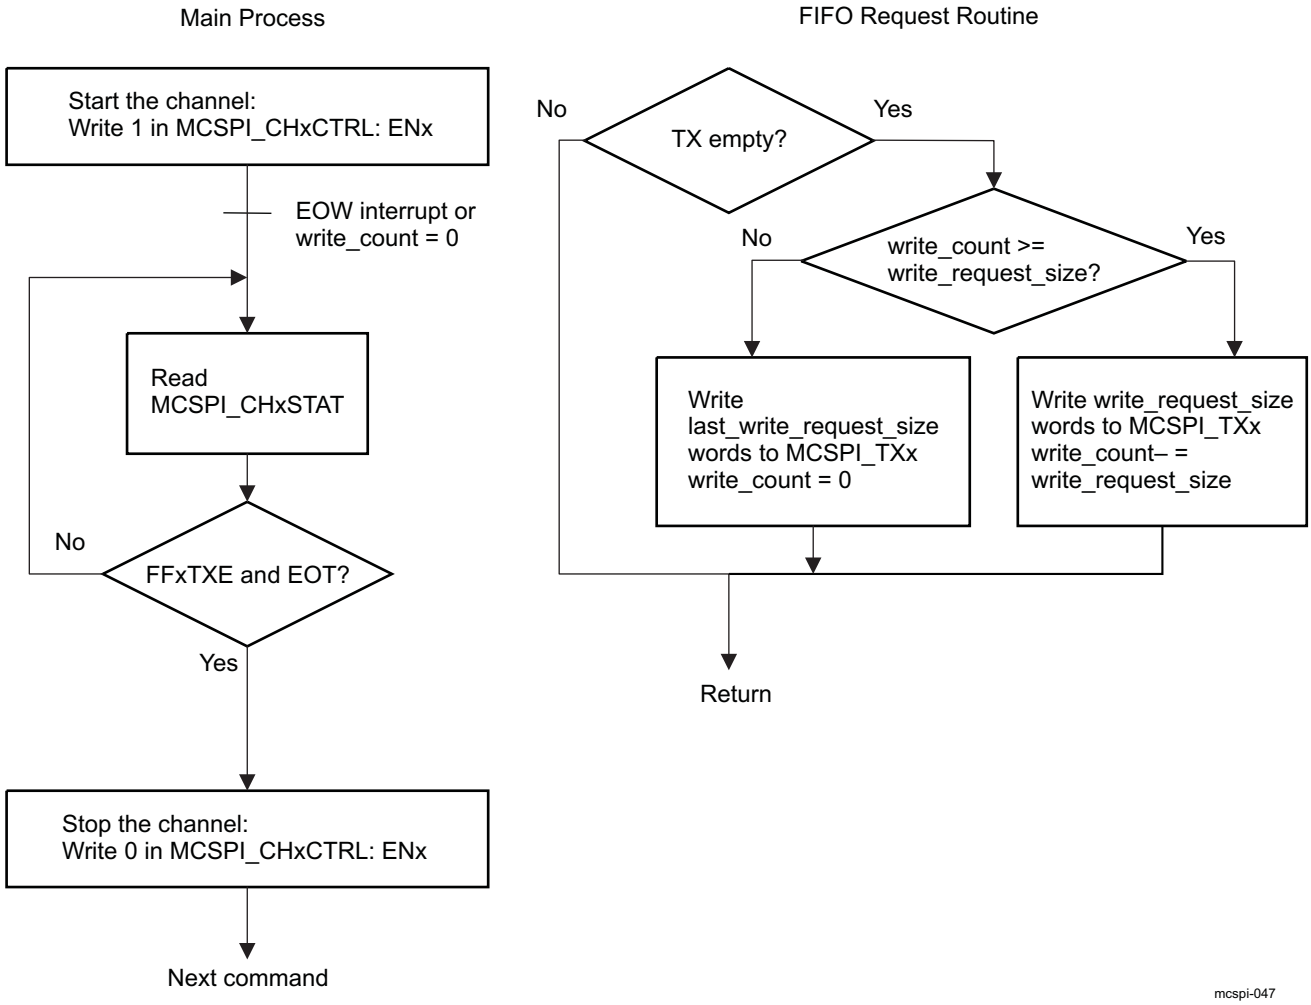
Figure 16-39. Transmit-Receive Without Word Count



16.6.3.4 Transmit-Only Procedure

Figure 16-40 shows the flow of a transfer in transmit only mode, with our without word count.

Figure 16-40. Transmit-Only



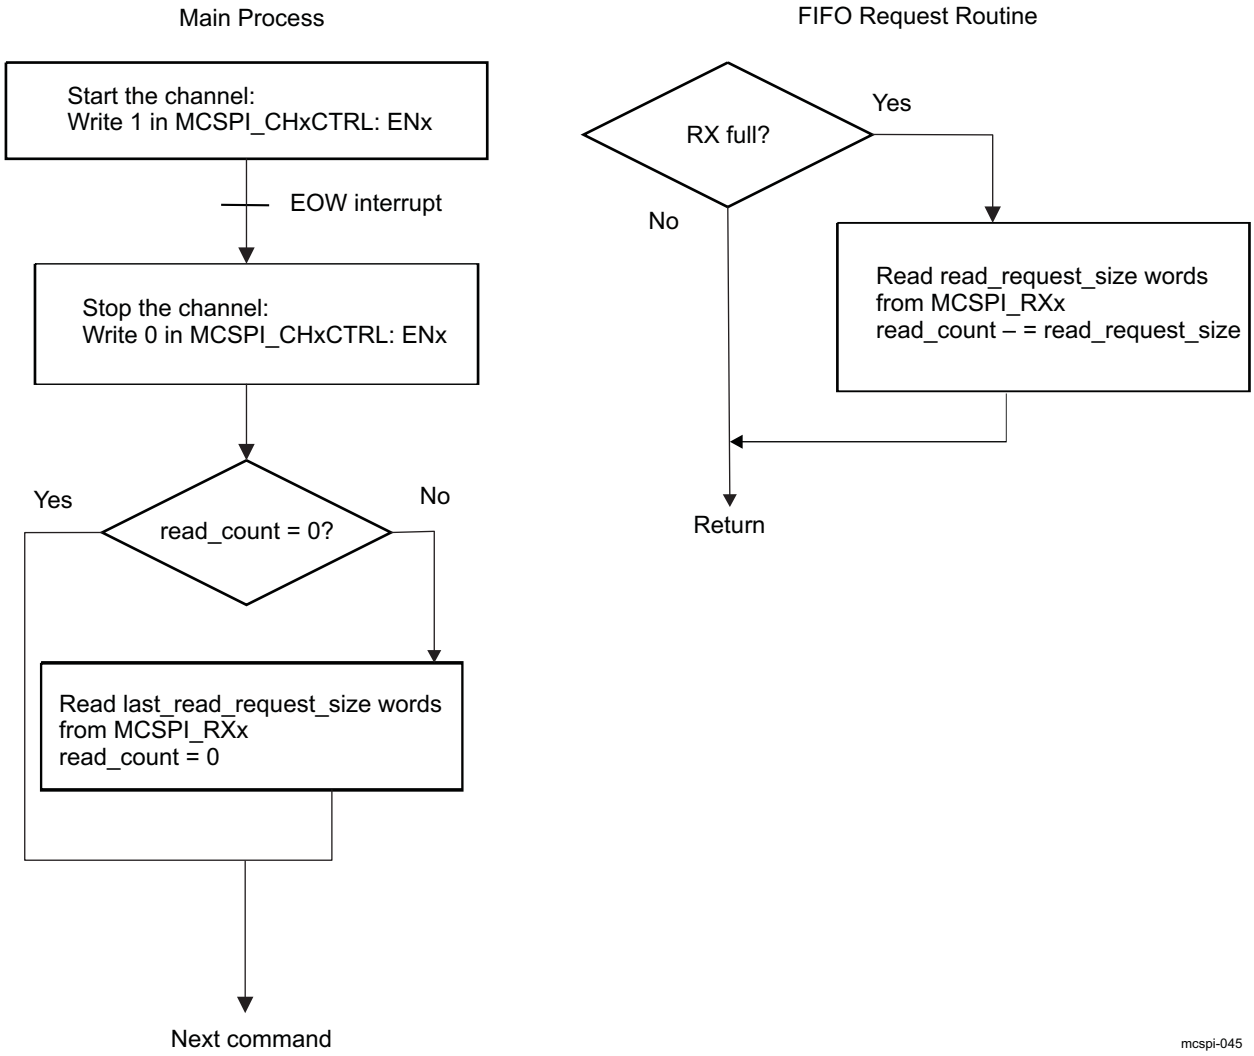
The difference between word count enabled or not is the condition after starting the channel:

- Word count enable: Wait for EOW interrupt.
- Word count disable: Wait for write_count = 0.

16.6.3.5 Receive-Only Procedure With Word Count (WCNT≠0)

Figure 16-41 shows the flow of a transfer in receive-only mode, with word count.

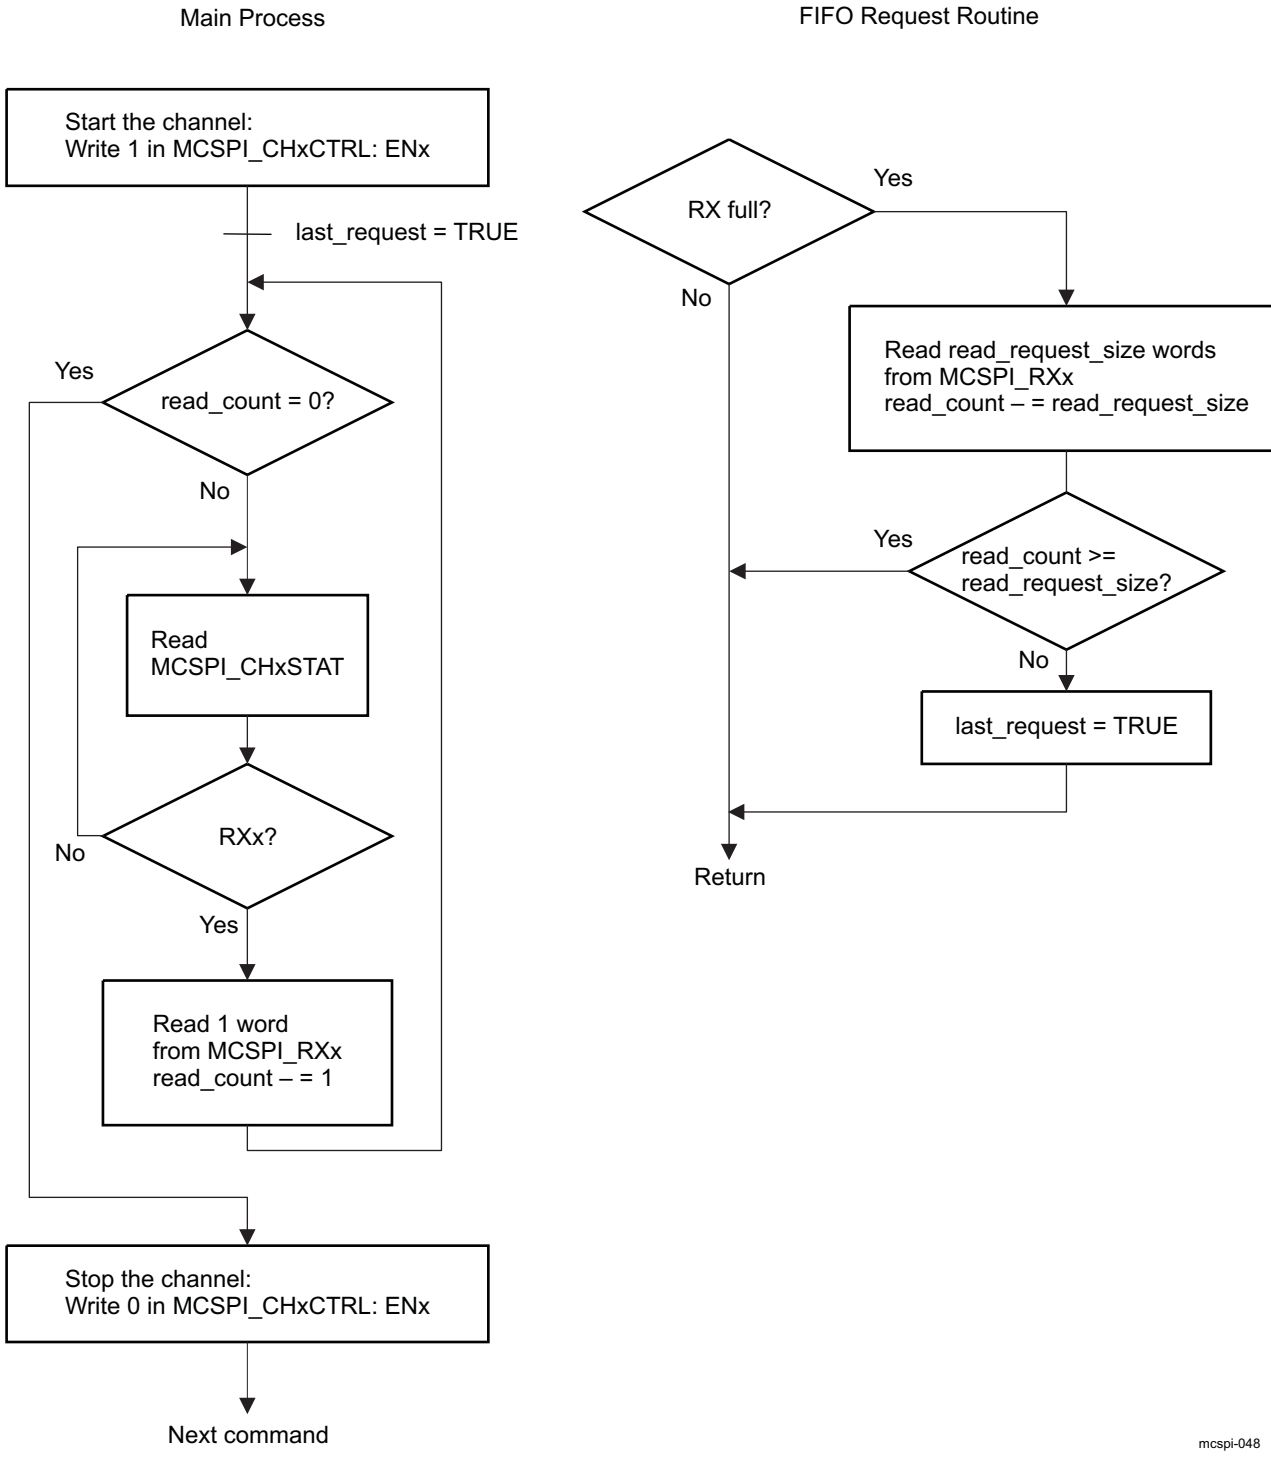
Figure 16-41. Receive-Only With Word Count



16.6.3.6 Receive-Only Procedure Without Word Count (WCNT=0)

Figure 16-42 shows the flow of a transfer in receive-only mode, without word count.

Figure 16-42. Receive-Only Without Word Count



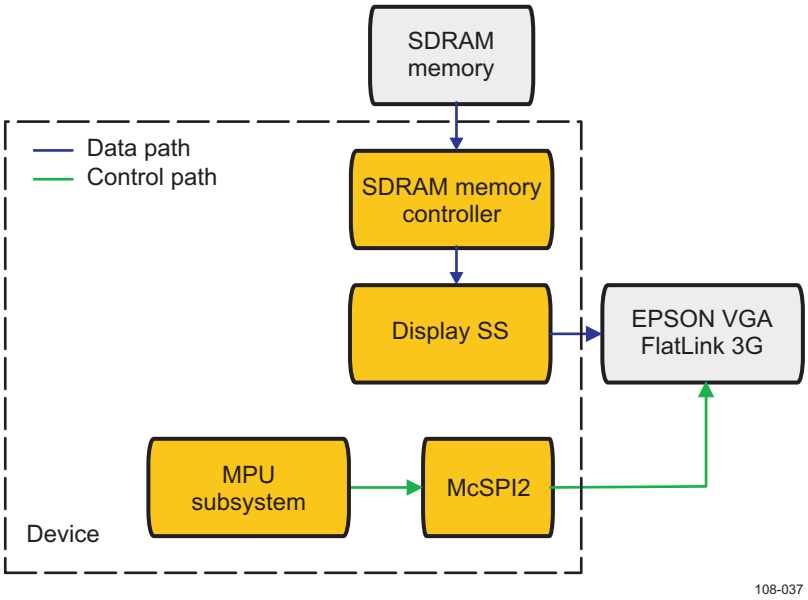
16.7 McSPI Use Cases and Tips

16.7.1 How to Configure the McSPI Interface When Connected with an EPSON VGA FlatLink™ 3G Device

16.7.1.1 Overview

This section deals with configuring an EPSON VGA FlatLink™3G device through the McSPI interface. Before transferring data from the external SDRAM memory to the external EPSON VGA display (Figure 16-43), the display subsystem must be set up via the McSPI interface. Several commands must be sent to the EPSON VGA for its configuration.

Figure 16-43. Overview



In this use case the configuration is the following:

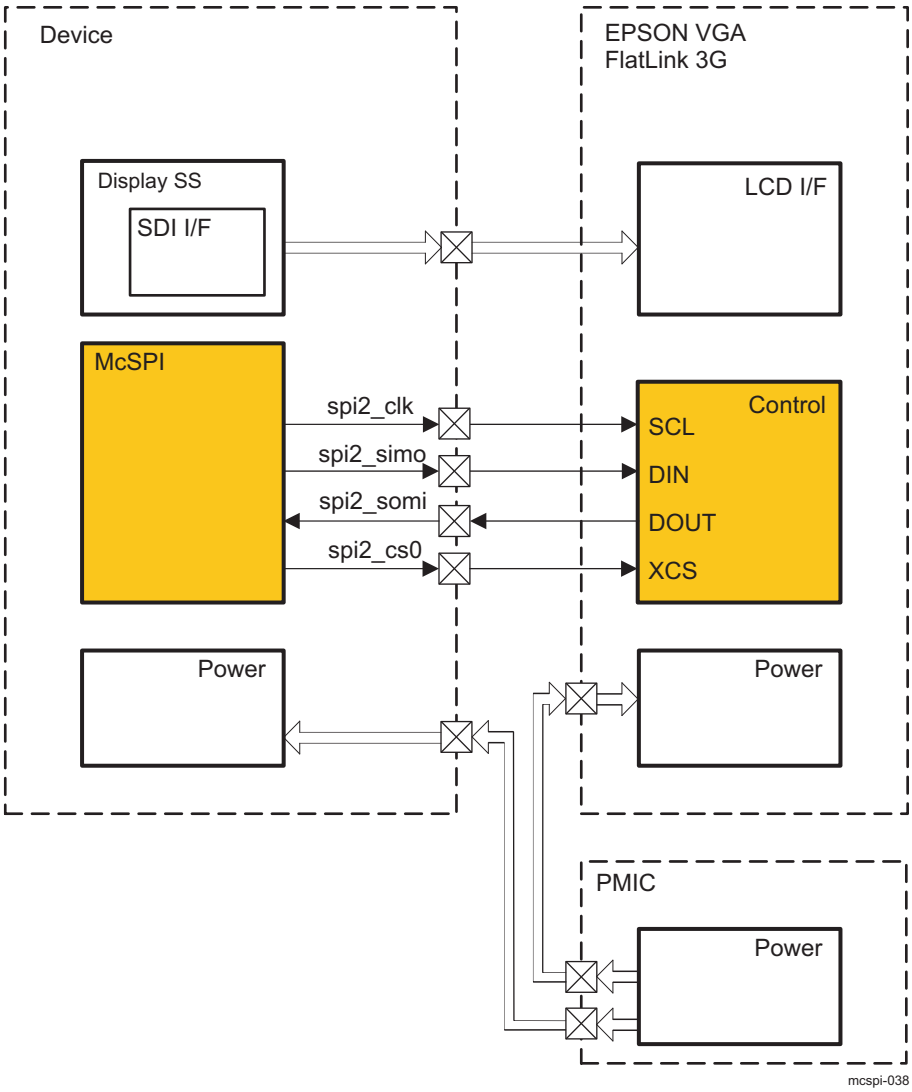
- McSPI2 channel 0 in master mode, EPSON VGA display in slave mode
- Transmit-only and receive-only modes
- No DMA requests and no interrupts used: transmit and receive flag polling

16.7.1.2 Environment

In this use case, the EPSON VGA is connected to the device through channel 0 of the McSPI instance 2 as shown in Figure 16-44 (through mcspi2_somi, mcspi2_simo, mcspi2_cs0).

The display clocks are provided to the EPSON VGA by the device display subsystem. The display configuration clock comes from the McSPI interface (mcspi2_clk).

Figure 16-44. Environment

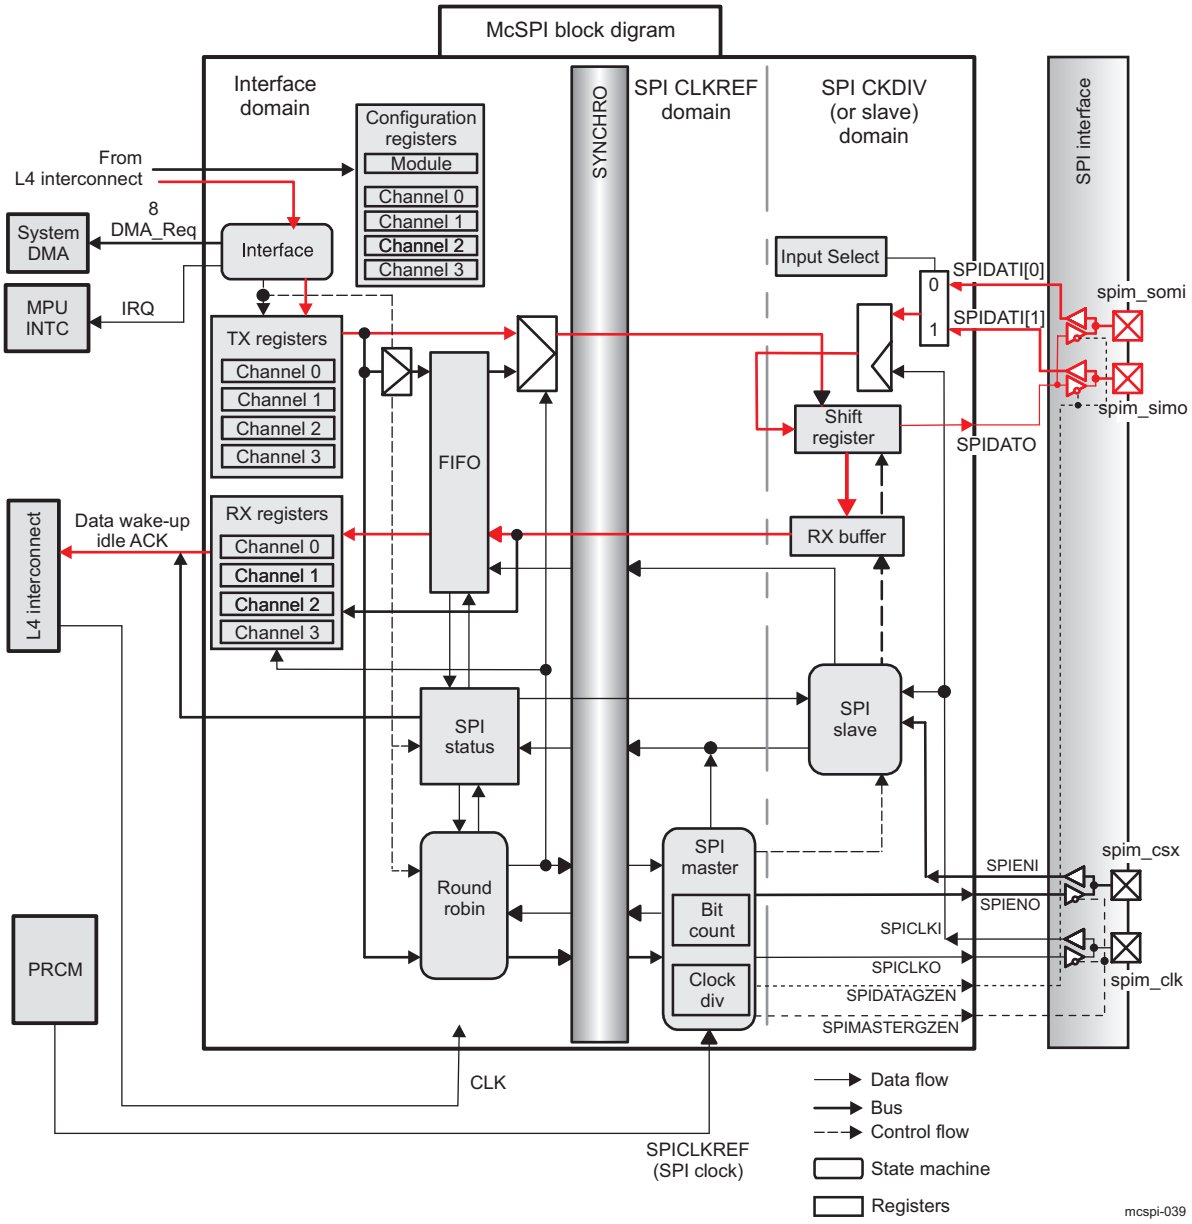


16.7.1.3 Data Path

In this use case, the McSPI2 manages the control path between the MPU subsystem and the EPSON VGA FlatLink™ 3G.

- Display configuration commands are transmitted via the channel 0 transmit register (TX Registers) and the shift register.
- A display status is read via the shift register, the receive buffer, and the channel 0 receive register (RX Registers).

Figure 16-45. McSPI Data Flow



16.7.1.4 Programming Flow

The initialization of the EPSON VGA is done in five steps:

1. McSPI module configuration
2. Send a 'SOFT RESET' command to the EPSON VGA
3. Send a 'SLEEP OUT' command
4. Send a 'DISPLAY ON' command
5. Send a 'READ DISPLAY STATUS' command and receive status data.

The four EPSON VGA commands needed in the EPSON VGA configuration are described in Table 16-18.

Table 16-18. EPSON VGA Configuration Commands

	D/CX	D7	D6	D5	D4	D3	D2	D1	D0	Dummy bit
SOFT RESET (001h)	0	0	0	0	0	0	0	0	1	n/a
SLEEP OUT (011h)	0	0	0	0	1	0	0	0	1	n/a
DISPLAY ON (029h)	0	0	0	1	0	1	0	0	1	n/a
READ DISPLAY STATUS (009h and dummy bit '0')	0	0	0	0	0	1	0	0	1	0

The following subsections describe each of these initialization steps.

16.7.1.4.1 McSPI Module Configuration

Before configuring the external display VGA, the multi-channel serial port interface must be initialized as detailed in the following steps:

1. Enable the McSPI2 functional and interface clocks through the PRCM.CM_FCLKEN1_CORE[18] EN_MCSPI2 and PRCM.CM_ICLKEN1_CORE[18] EN_MCSPI2 fields.
2. Proceed to a McSPI software reset through the MCSPI_SYSCONFIG[1] SOFTRESET field. The SOFTRESET bit is automatically reset by hardware.
3. Poll the MCSPI_SYSSTATUS[0] RESETDONE field to check the software reset status.
4. Disable channel 0 through the MCSPI_CHxCTRL[0] EN field (with x=0).
5. Disable all interrupts (MCSPI_IRQENABLE register) then clear interrupt status register (MCSPI_IRQSTATUS). Interrupts are disabled once at this stage. Even if some interrupts of the MCSPI_IRQSTATUS register are set, no interrupt can go out to the MPU subsystem.
6. Set the module in Master mode and multichannel mode through the MCSPI_MODULCTRL register.
7. Configure channel 0 in transmit-only mode, with a word length of 9-bit through the MCSPI_CHxCONF register (with x=0). A world length of 9 bits is required to transmit the required command (SOFT RESET, SLEEP OUT, or DISPLAY ON) to the EPSON display, as detailed in Table 16-18. Those 9 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0.

Table 16-19 shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 16-19. McSPI Configuration Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
PRCM.CM_FCLKEN1_CORE[18]	0x4800 4A00	0x1	Enable McSPI2 functional clock
PRCM.CM_ICLKEN1_CORE[18]	0x4800 4A10	0x1	Enable McSPI2 interface clock
MCSPI_SYSCONFIG[1]	0x4809 A010	0x1	Initiate a software reset
MCSPI_SYSSTATUS	0x4809 A014	0x0000 0001	The RESETDONE field is set at 1 when the reset is complete
MCSPI_CHxCTRL	0x4809 A034	0x0000 0000	Disable channel 0
MCSPI_IRQENABLE	0x4809 A01C	0x0000 0000	Disable all interrupts
MCSPI_IRQSTATUS	0x4809 A018	0x0001 777F	Clear all interrupts
MCSPI_MODULCTRL	0x4809 A028	0x0000 0000	Master mode, multichannel

Table 16-19. McSPI Configuration Registers Print (continued)

MCSPI_CHxCONF	0x4809 A02C	0x0001 2453	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 9-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo

16.7.1.4.2 'SOFT RESET', 'SLEEP OUT' and 'DISPLAY ON' Commands

Once the McSPI interface is configured, three commands must be send to the external display VGA: a software reset to reinitiate the external display, a 'SLEEP OUT' command to wake it up, and a 'DISPLAY ON' to turn on the display. Those three commands follow the same procedure, described here below, only the command opcode changes.

1. Enable channel 0 through the MCSPI_CHxCTRL[0] EN field (with x=0).
2. Write the command opcode to the MCSPI_TXx (with x=0) register so that it could be transmitted to the external display VGA. To transmit the SOFT RESET command, write 001h in the MCSPI_TXx (with x=0) register. To transmit a SLEEP OUT command write 011h and to transmit a DISPLAY ON command write 029h.
3. Poll the MCSPI_CHxSTAT[1] TXS field (with x=0) to check for transmit status. When the word has been transmitted, TXS is automatically set to 1.
4. Disable channel 0 through the MCSPI_CHxCTRL[0] EN field (with x=0).

Table 16-20 shows all registers to be configured with the required value for the those commands and the use case values.

Table 16-20. Display Configuration Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
MCSPI_CHxCTRL	0x4809 A034	0x0000 0001	Enable channel 0
MCSPI_TXx	0x4809 A038	0x001 0x011 0x029	Transmit a 'SOFT RESET' command to the EPSON VGA display Transmit a 'SLEEP OUT' command Transmit a 'DISPLAY ON' command
MCSPI_CHxSTAT[1]	0x4809 A030	0x1	The word in MCSPI_TXx has been transmitted when the TXS flag is set to 1
MCSPI_CHxCTRL	0x4809 A034	0x0000 0000	Disable channel 0

16.7.1.4.3 'READ DISPLAY STATUS' Command

Once the EPSON VGA display is initialized, a 'READ DISPLAY STATUS' command is sent to the external display VGA to read and check the status of the component, such as Partial mode, Sleep In mode, Display status, Horizontal and Vertical Synchronization On or Off states.

The 'READ DISPLAY STATUS' command is not 9- but 10-bit long because the EPSON VGA display requires a dummy cycle between the transmission of the last command bit (D0 in Table 16-18) and the reception of the first data bit (the display status data is 32-bit long). In other words, a dummy bit is added as less significant bit of the command. Hence, those 10 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0, dummy bit.

1. Set the module in Master mode and single channel mode through the MCSPI_MODULCTRL register.
2. Configure channel 0 in transmit-only mode, with a word length of 10-bit through the MCSPI_CHxCONF register (with x=0).
3. Enable channel 0 through the MCSPI_CHxCTRL[0] EN field.

4. Shift left of one bit the command opcode 009h so that the required dummy bit ('0') can be sent after the D/CX and D7 to D0 bits to the EPSON VGA display. Refer to Table 16-18 for more information. Then, write this command (012h) to the MCSPI_TXx (with x=0) register so that it could be transmitted to the EPSON VGA display.
5. Poll the MCSPI_CHxSTAT[1] TXS bit (with x=0) to check transmit status. When the word has been transmitted, TXS is automatically set to 1.
6. Read the MCSPI_CHxSTAT[1] RXS bit to check receive status. If data has already been received (RXS is set to 1) read the MCSPI_RXx (with x=0) receive register; this will automatically deactivate the RXS flag (RXS is automatically cleared).
7. Configure channel 0 in receive-only mode, with a word length of 32-bit through the MCSPI_CHxCONF register.
8. Poll the MCSPI_CHxSTAT[1] RXS bit to check receive status. When data has been received, RXS is automatically set to 1. The 32-bit display status information is available in the McSPI2 channel 0 receive register: MCSPI_RXx (with x=0).
9. Set channel 0 in transmit-only mode through the MCSPI_CHxCONF register.

Table 16-21 shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 16-21. Display Status Check Registers Print

Register Name (with x=0)	Physical Address	Value	Value Description
MCSPI_MODULCTRL	0x4809 A028	0x0000 0001	Master mode, single channel
MCSPI_CHxCONF	0x4809 A02C	0x0011 24D3	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 10-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo
MCSPI_CHxCTRL	0x4809 A034	0x0000 0001	Enable channel 0
MCSPI_TXx	0x4809 A038	0x0000 0012	Send a 'READ DISPLAY STATUS' command. See Table 16-18.
MCSPI_CHxSTAT[1] TXS	0x4809 A030	0x1	The word in MCSPI_TXx has been transmitted if the TXS flag is set to 1
MCSPI_CHxSTAT[0] RXS	0x4809 A030	-	Read RXS flag. Data has been received in MCSPI_RXx if the RXS flag is set to 1
MCSPI_RXx	0x4809 A03C	-	Read MCSPI_RXx only if the RXS bit is equal to 1 (this is a dummy read that will automatically clear the RXS flag)
MCSPI_CHxCONF	0x4809 A02C	0x0011 1FD0	CLKD = 4 (CLKSPIREF divided internally by 16) WL = 32-bit Receive-only Receive on spi2_somi Transmit on spi2_simo
MCSPI_CHxSTAT[0] RXS	0x4809 A030	0x0	Data has been received in MCSPI_RXx when the RXS flag is set to 1.
MCSPI_CHxCONF	0x4809 A02C	0x0011 2453	Back in transmit-only mode Receive on spi2_somi Transmit on spi2_simo

16.8 McSPI Register Manual

16.8.1 McSPI Instance Summary

Table 16-22 lists the McSPI instances.

Table 16-22. McSPI Instance Summary

Module Name	Base Address	Size
MCSPI1	0x4809 8000	4Kbytes
MCSPI2	0x4809 A000	4Kbytes

Address Offset	0x00		
Physical Address	0x4809 8000	**Instance**	MCSPI1
	0x4809 A000		MCSPI2
	0x480B 8000		MCSPI3
	0x480B A000		MCSPI4
Description	This register contains the hard coded RTL revision number.		
Type	R		
Write Latency	Not relevant		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								REV							

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reads returns 0	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision Example: 0x10 for 1.0, 0x21 for 2.1	R	See (1)

(1) TI internal data

Table 16-26. MCSPI_SYSCONFIG

Address Offset	0x10		
Physical Address	0x4809 8010	**Instance**	MCSPI1
	0x4809 A010		MCSPI2
	0x480B 8010		MCSPI3
	0x480B A010		MCSPI4
Description	This register allows control of various parameters of the module interface. It is not sensitive to software reset.		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																						CLOCKACTIVITY		Reserved			SIDLEMODE		ENAWAKEUP		SOFTRESET		AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	Reserved	Reads returns 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period	RW	0x0
		0x0: Interface and Functional clocks may be switched off.		
		0x1: Interface clock is maintained. Functional clock may be switched off.		
		0x2: Functional clock is maintained. Interface clock may be switched off.		
		0x3: Interface and Functional clocks are maintained.		
7:5	Reserved	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management	RW	0x0
		0x0: If an idle request is detected, the McSPI acknowledges it unconditionally and goes in Inactive mode. Interrupt, DMA requests and wake up lines are unconditionally de-asserted and the module wake-up capability is deactivated even if the bit MCSPI_SYSCONFIG[ENAWAKEUP] is set.		
		0x1: If an idle request is detected, the request is ignored and the module does not switch to wake up mode and keeps on behaving normally.		
		0x2: If an idle request is detected, the module will switch to wake up mode based on its internal activity and the wake up capability can be used if the bit MCSPI_SYSCONFIG[ENAWAKEUP] is set.		
		0x3: Reserved - do not use.		
2	ENAWAKEUP	Wake-up feature control	RW	0
		0x0: Wake-up capability disabled		
		0x1: Wake-up capability enabled		
1	SOFTRESET	Software reset. Read always returns 0.	RW	0
		0x0: Normal mode.		
		0x1: Trigger a module reset. This bit is automatically reset by hardware.		
0	AUTOIDLE	Internal interface Clock gating strategy	RW	0
		0x0: interface clock is free-running		
		0x1: Automatic interface clock gating strategy is applied, based on the module interface activity

Address Offset	0x18		
Physical Address	0x4809 8018	**Instance**	MCSPI1
	0x4809 A018		MCSPI2
	0x480B 8018		MCSPI3
	0x480B A018		MCSPI4
Description	The interrupt status regroups all the status of the module internal events that can generate an interrupt		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														EOW	WKS	Reserved	RX3_FULL	TX3_UNDERFLOW	TX3_EMPTY	Reserved	RX2_FULL	TX2_UNDERFLOW	TX2_EMPTY	Reserved	RX1_FULL	TX1_UNDERFLOW	TX1_EMPTY	RX0_OVERFLOW	RX0_FULL	TX0_UNDERFLOW	TX0_EMPTY

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Reads returns 0	RW	0x0000
17	EOW	End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by MCSPI_XFERLEVEL[31:16] WCNT bit field. Write 0x0: Event status bit unchanged. Read 0x0: Event false. Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
16	WKS	Wake-up event in slave mode when an active control signal is detected on the spim_csx line programmed in the MCSPI_CHxCONF[SPIENSLV] field (where x=0 only) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
15	Reserved	Reads returns 0.	RW	0x0
14	RX3_FULL	MCSPI_RX3 register is full (only when channel 3 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
13	TX3_UNDERFLOW	MCSPI_TX3 register underflow (only when channel 3 is enabled)(1) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
12	TX3_EMPTY	MCSPI_TX3 register is empty (only when channel 3 is enabled)(2) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
11	Reserved	Read returns 0.	RW	0x0
10	RX2_FULL	MCSPI_RX2 register full (only when channel 2 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
9	TX2_UNDERFLOW	MCSPI_TX2 register underflow (only when channel 2 is enabled)(1) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending.	RW	0x0
8	TX2_EMPTY	MCSPI_TX2 register empty (only when channel 2 is enabled)(2) Write 0x0: Event status bit unchanged Read 0x0: Event false	RW	0x0

(1) The MCSPI_TXx register is empty (not updated by host or DMA with new data) before its time slot assignment.
Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPI_TXx register since channel has been enabled.

(2) Enabling the channel automatically rises this event.

Bits	Field Name	Description	Type	Reset
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
7	Reserved	Read returns 0.	RW	0x0
6	RX1_FULL	MCSPI_RX1 register full (only when channel 1 is enabled)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
5	TX1_UNDERFLOW	MCSPI_TX1 register underflow (only when channel 1 is enabled)(1)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
4	TX1_EMPTY	MCSPI_TX1 register empty (only when channel 1 is enabled)(3)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
3	RX0_OVERFLOW	MCSPI_RX0 register overflow (only in slave mode)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
2	RX0_FULL	MCSPI_RX0 register full (only when channel 0 is enabled)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
1	TX0_UNDERFLOW	MCSPI_TX0 register underflow (only when channel 0 is enabled)(4)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		
0	TX0_EMPTY	MCSPI_TX0 register empty (only when channel 0 is enabled)(3)	RW	0x0
		Write 0x0: Event status bit unchanged		
		Read 0x0: Event false		
		Write 0x1: Event status bit is reset.		
		Read 0x1: Event is pending.		

(3) Enabling the channel automatically rises this event.

(4) The MCSPI_TXx register is empty (not updated by host or DMA with new data) before its time slot assignment.
Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPI_TXx register since channel has been enabled.

Table 16-36. MCSPI_SYST

Address Offset	0x24		
Physical Address	0x4809 8024	**Instance**	MCSPI1
	0x4809 A024		MCSPI2
	0x480B 8024		MCSPI3
	0x480B A024		MCSPI4
Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device IO pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		
Write Latency	Immediate		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																				SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	PIEN_2	SPIEN_1	SPIEN_0

Bits	Field Name	Description	Type	Reset
31:12	Reserved	Reads returns 0	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the MCSPI_ IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_ IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the MCSPI_IRQSTATUS register.	RW	0
10	SPIENDIR	Set the direction of the spim_cs lines and spim_clk line 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1] (spim_simo) 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0] (spim_somi) 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	spim_clk line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_clk line (high or low) and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_clk line is driven high or low according to the value written into this register.	RW	0
5	SPIDAT_1	spim_somi line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the spim_somi line is driven high or low according to the value written into this register.	RW	0

Bits	Field Name	Description	Type	Reset
		If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the spim_somi line (high or low) and a write into this bit has no effect.		
4	SPIDAT_0	spim_simo line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the spim_simo line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the spim_simo line (high or low) and a write into this bit has no effect.	RW	0
3	SPIEN_3	spim_cs3 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs3 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs3 line (high or low) and a write into this bit has no effect.	RW	0
2	SPIEN_2	spim_cs2 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs2 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs2 line (high or low) and a write into this bit has no effect.	RW	0
1	SPIEN_1	spim_cs1 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs1 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs1 line (high or low) and a write into this bit has no effect.	RW	0
0	SPIEN_0	spim_cs0 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs0 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs0 line (high or low) and a write into this bit has no effect.	RW	0

Reserved		CLKG	FFER	FFEW	TCS		SBPOL	SBE	Reserved		FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM		WL				EPOL	CLKD					POL	PHA

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Read returns 0s.	RW	0x00
29	CLKG	Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set, the MCSPI_CHxCTRL[15:8] EXTCLK bit field must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHxCONF[5:2] CLKD and EXTCLK values. 0x0: Clock granularity of power of two 0x1: One clock cycle ganularity	RW	0x0
28	FFER	FIFO enabled for Receive. Only one channel can have this bit field set. 0x0: The buffer is not used to Receive data 0x1: The buffer is used to Receive data	RW	0x0
27	FFEW	FIFO enabled for Transmit. Only one channel can have this bit field set. 0x0: The buffer is not used to Transmit data 0x1: The buffer is used to Transmit data	RW	0x0
26:25	TCS	Chip select time control Defines the number of interface clock cycles between CS toggling and first (or last) edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start bit polarity 0x0: Start bit polarity is held to 0 during SPI transfer. 0x1: Start bit polarity is held to 1 during SPI transfer.	RW	0x0
23	SBE	Start bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CHxCONF[SBPOL].	RW	0x0
22:21	Reserved	Write the reset value. Read returns the reset value.	RW	0x0
20	FORCE	Manual spim_csx assertion to keep spim_csx for channel x active between SPI words (single channel master mode only). The MCSPI_MODULCTRL[0] SINGLE bit must bit set to 1. 0x0: Writing 0 into this bit drives the spin_csx line low for channel x when MCSPI_CHxCONF [6] EPOL = 0, and drives it high when MCSPI_CHxCONF[6] EPOL = 1. 0x1: Writing 1 into this bit drives the spim_csx line high for channel x when MCSPI_CHxCONF[E6] EPOL = 0, and drives it low when MCSPI_CHxCONF[6] EPOL = 1.	RW	0x0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer) 0x1: Turbo is activated to maximize the throughput for multi-SPI word transfers.	RW	0x0
18	IS	Input select 0x0: Data Line 0 (spim_somi) selected for reception 0x1: Data Line 1 (spim_simo) selected for reception	RW	0x1

Bits	Field Name	Description	Type	Reset
17	DPE1	Transmission enable for data line 1 (spim_simo) 0x0: Data Line 1 (spim_simo) selected for transmission 0x1: No transmission on data Line 1 (spim_simo)	RW	0x1
16	DPE0	Transmission enable for data line 0 (spim_somi) 0x0: Data Line 0 (spim_somi) selected for transmission 0x1: No transmission on data Line 0 (spim_somi)	RW	0x0
15	DMAR	DMA Read request The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA Read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0x0
14	DMAW	DMA Write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TXx register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TXx register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0x0
13:12	TRM	Transmit/receive modes 0x0: Transmit and receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4-bit long 0x4: The SPI word is 5-bit long 0x5: The SPI word is 6-bit long 0x6: The SPI word is 7-bit long 0x7: The SPI word is 8-bit long 0x8: The SPI word is 9-bit long 0x9: The SPI word is 10-bit long 0xA: The SPI word is 11-bit long 0xB: The SPI word is 12-bit long 0xC: The SPI word is 13-bit long 0xD: The SPI word is 14-bit long 0xE: The SPI word is 15-bit long 0xF: The SPI word is 16-bit long 0x10: The SPI word is 17-bit long 0x11: The SPI word is 18-bit long 0x12: The SPI word is 19-bit long 0x13: The SPI word is 20-bit long 0x14: The SPI word is 21-bit long 0x15: The SPI word is 22-bit long 0x16: The SPI word is 23-bit long 0x17: The SPI word is 24-bit long	RW	0x00

Bits	Field Name	Description	Type	Reset
		0x18: The SPI word is 25-bit long		
		0x19: The SPI word is 26-bit long		
		0x1A: The SPI word is 27-bit long		
		0x1B: The SPI word is 28-bit long		
		0x1C: The SPI word is 29-bit long		
		0x1D: The SPI word is 30-bit long		
		0x1E: The SPI word is 31-bit long		
		0x1F: The SPI word is 32-bit long		
6	EPOL	spim_csx polarity for channel x	RW	0x0
		0x0: spim_csx is held high during the active state.		
		0x1: spim_csx is held low during the active state.		
5:2	CLKD	Frequency divider for spim_clk (for master device only) A programmable clock divider divides the SPI reference clock (CLKSPIREF) by a 4-bit value and results in a new spim_clk clock available to shift data in and out.	RW	0x0
		0x0: 1

WCNT																Reserved		AFL						Reserved		AEL					

Bits	Field Name	Description	Type	Reset
31:16	WCNT	Spi word counter: This register holds the programmable value of number of SPI word to be transferred on channel which is using the FIFO buffer. When transfer had started, a read back in this register returns the current SPI word transfer index. 0x0: Counter not used 0x1: One spi word 0xFFFE : 65534 spi word 0xFFFF : 65535 spi word	RW	0x0000
15:14	Reserved	Read returns 0s.	RW	0x0

Bits	Field Name	Description	Type	Reset
13:8	AFL	Buffer Almost Full: This register holds the programmable almost full level value used to determine almost full buffer condition. If the user wants an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least I bytes, then this bit field must be set to I-1. 0x0: One byte 0x1: 2 bytes 0x3E: 63 bytes 0x3F: 64 bytes	RW	0x00
7:6	Reserved	Read returns 0s.	RW	0x0
5:0	AEL	Buffer Almost Empty: This register holds the programmable almost empty level value used to determine almost empty buffer condition. If the user wants an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive I bytes, then this bit field must be set to I-1. 0x0: One byte 0x1: 2 bytes 0x3E: 63 bytes 0x3F: 64 bytes	RW	0x00

HDQ/1-Wire

This chapter describes the features and functions of the HDQ/1-Wire module.

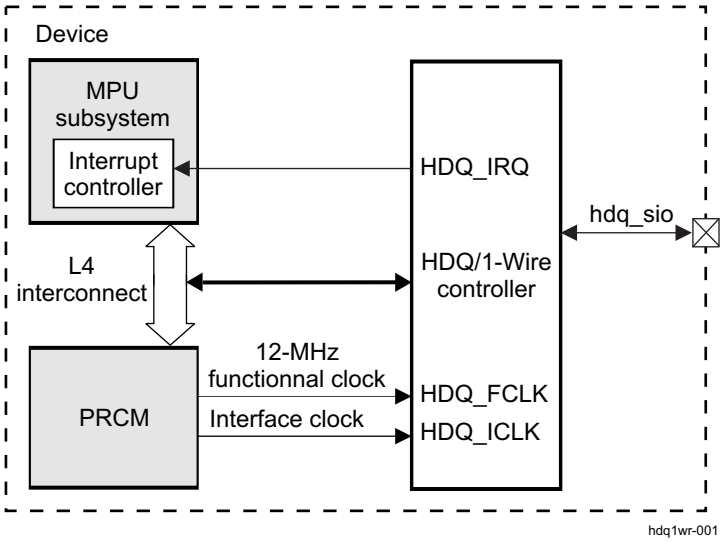
Topic **Page**

17.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the Benchmarq HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slave (HDQ/1-Wire external compliant device).

Figure 17-1 shows the HDQ/1-Wire controller module.

Figure 17-1. HDQ/1-Wire Highlight



The HDQ and 1-Wire module has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The HDQ operates from a fixed 12-MHz functional clock provided by the PRCM module.

Only the MPU subsystem uses the HDQ/1-Wire module.

The main features of the HDQ/1-Wire module support the following:

- Benchmarq HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire module provides a communication rate of 5K bits/s over an address space of 128 bytes.

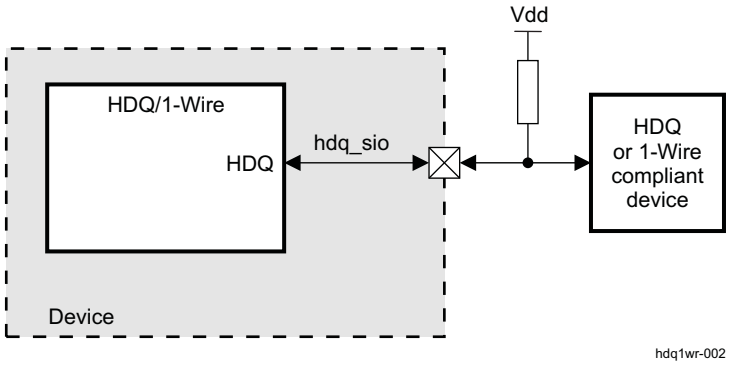
A typical application of the HDQ/1-Wire module is the communication with battery monitor (gas gauge) integrated circuits.

17.2 HDQ/1-Wire Environment

17.2.1 HDQ/1-Wire Functional Interface

Figure 17-2 shows a typical application using the HDQ/1-Wire connection.

Figure 17-2. HDQ/1-Wire Typical Application System Overview



An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command, the line is pulled to a logical high level).

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in Section 17.5).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 17-1 describes the external pullup signal from an HDQ or 1-Wire compliant device.

Table 17-1. I/O Description

Signal Name	I/O	Description	Value at Reset
hdq_sio	Bidir	Serial data input/output	1

17.2.2 HDQ and 1-Wire (SDQ) Protocols

17.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ.HDQ_CTRL_STATUS[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

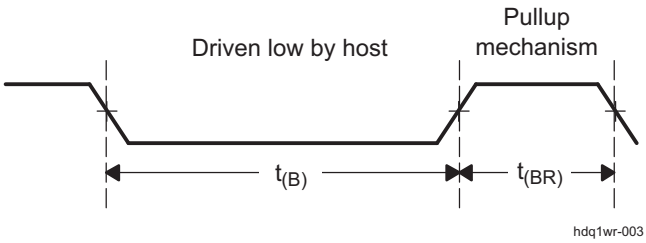
The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.HDQ_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time t(B) or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time t(BR). The slave is then ready for a command from the host processor. Figure 17-3 shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 17-3. HDQ Break-Pulse Timing Diagram

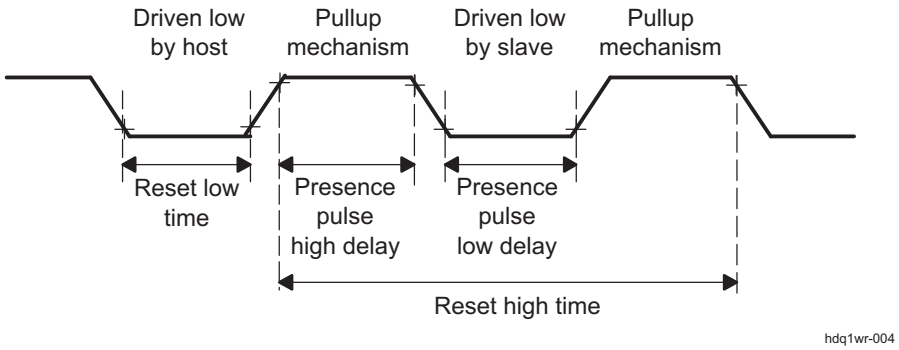


17.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in Figure 17-4 shows the 1-Wire (SDQ) reset sequence.

Figure 17-4. 1-Wire (SDQ) Reset Timing Diagram



The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

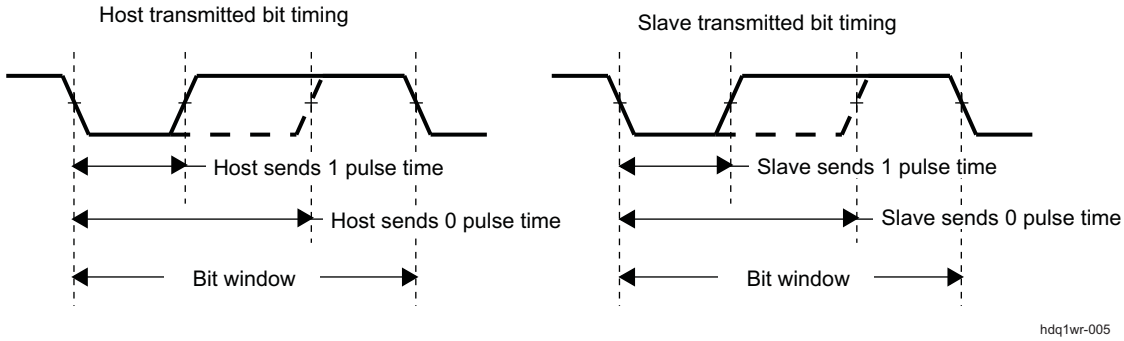
On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

17.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 17-5.

Figure 17-5. HDQ/1-Wire Transmitted Bit Timing



The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 17-2 lists the command byte values.

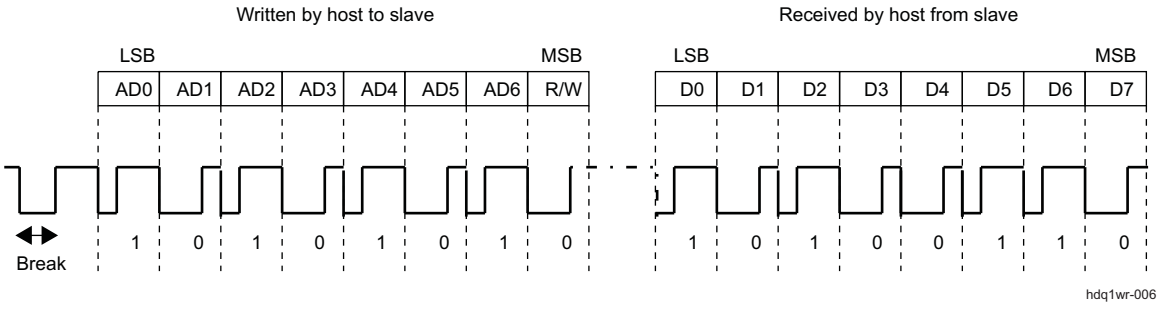
Table 17-2. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

R/W Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

AD6-AD0 Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed.
The communication sequence example in Figure 17-6 shows a read command at address 0x55; the received data is 0x65.

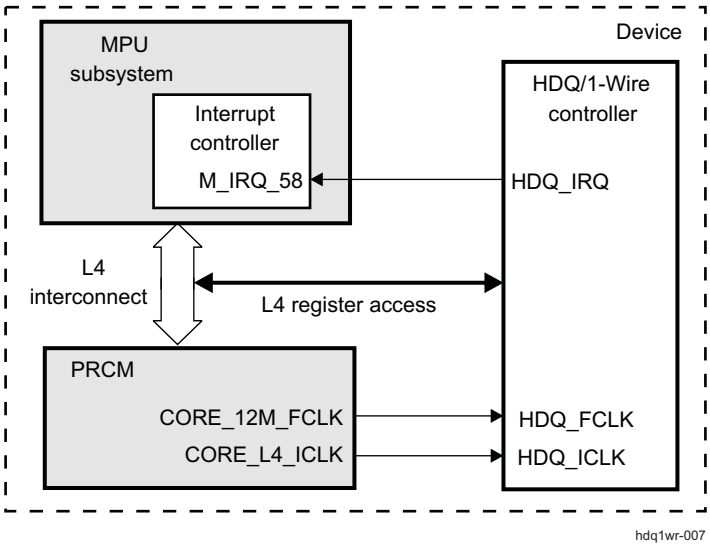
Figure 17-6. HDQ/1-Wire Communication Sequence



17.3 HDQ/1-Wire Integration

Figure 17-7 shows the HDQ/1-Wire module integration in the device.

Figure 17-7. HDQ/1-Wire Integration



17.3.1 Clocking, Reset, and Power Management Scheme

17.3.1.1 HDQ/1-Wire Clocks

There are two clock domains in the HDQ/1-Wire module: the functional clock domain and the interface clock domain. When these clocks are set in the PRCM module, the following rule must be observed: HDQ_ICLK ≥ HDQ_FCLK.

- HDQ_FCLK belongs to the functional clock domain. It is a fixed 12-MHz clock provided by the PRCM. It is used to clock the internal module logic.

  The HDQ_FCLK source is the CORE_12M_FCLK PRCM output, which is derived from the CORE_48M_FCLK clock signal (a 1/4 ratio is applied). The CORE_12M_FCLK clock is issued from the peripherals DPLL4. For more information about the clock, see , *Power, Reset, and Clock Management*.

  When the HDQ/1-Wire module no longer requires the HDQ_FCLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_FCLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

  For details about the PRCM register settings and DPLL4 configuration, see , *Power, Reset, and Clock Management*.

- HDQ_ICLK is the interface clock. It runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface. Its source is the PRCM CORE_L4_ICLK signal. It typically runs at L3/2 frequency.

  When the HDQ/1-Wire module no longer requires the HDQ_ICLK, the software can disable it at the PRCM level by setting the EN_HDQ bit (PRCM.CM_ICLKEN1_CORE[22]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

  It is also possible to activate an autoidle mode for this clock (AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] set to 1). In this case, HDQ_ICLK follows the CORE clock domain behavior. For more information, see , *Power, Reset, and Clock Management*.

17.3.1.2 HDQ/1-Wire Reset Scheme

Global reset of the module is done either by activating the CORE_RST signal in the CORE_RST domain (for more information, see , *Power, Reset, and Clock Management*) or by setting to 1 the SOFTRESET bit HDQ.HDQ_SYSCONFIG[1]. Setting this bit enables an active software reset functionality equivalent to a hardware reset.

17.3.1.3 HDQ/1-Wire Power Domain

The HDQ/1-Wire belongs to the CORE power domain. For more information about the CORE power domain, see , *Power, Reset, and Clock Management*.

17.3.2 Hardware Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_58.

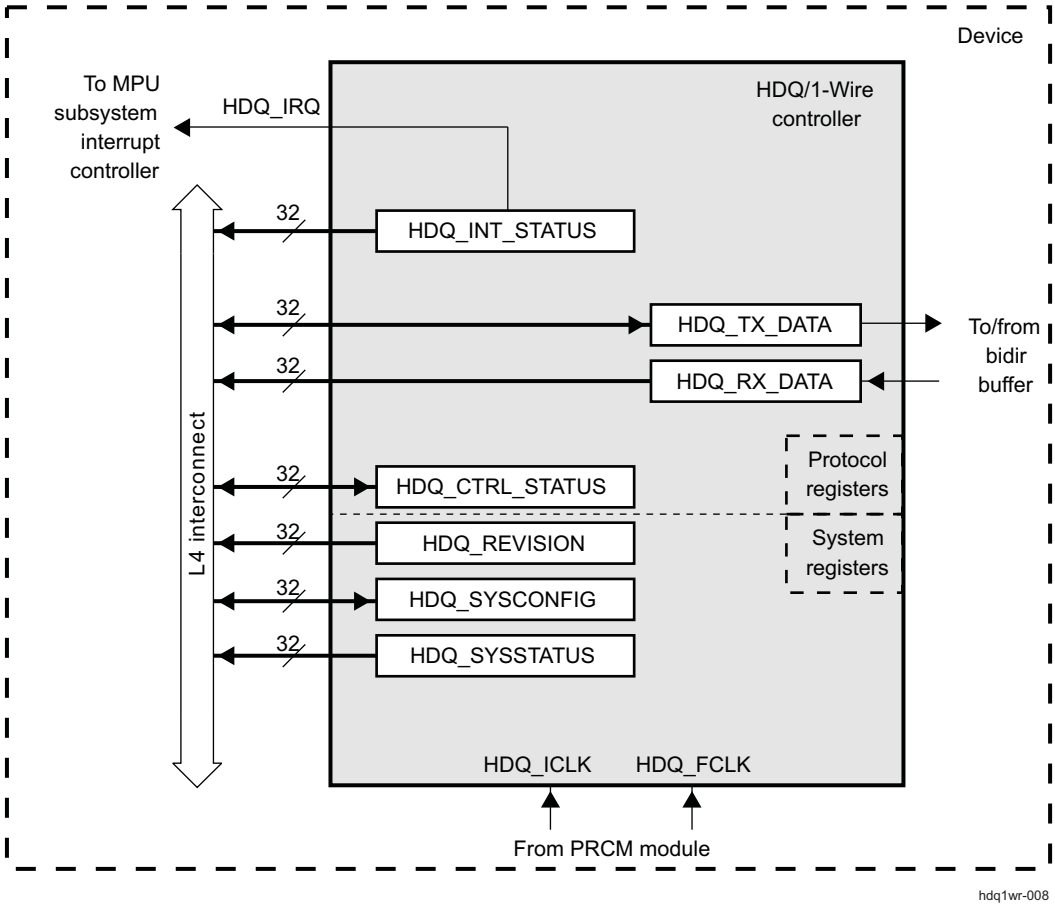
17.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

17.4.1 HDQ/1-Wire Block Diagram

Figure 17-8 shows the HDQ/1-Wire block diagram.

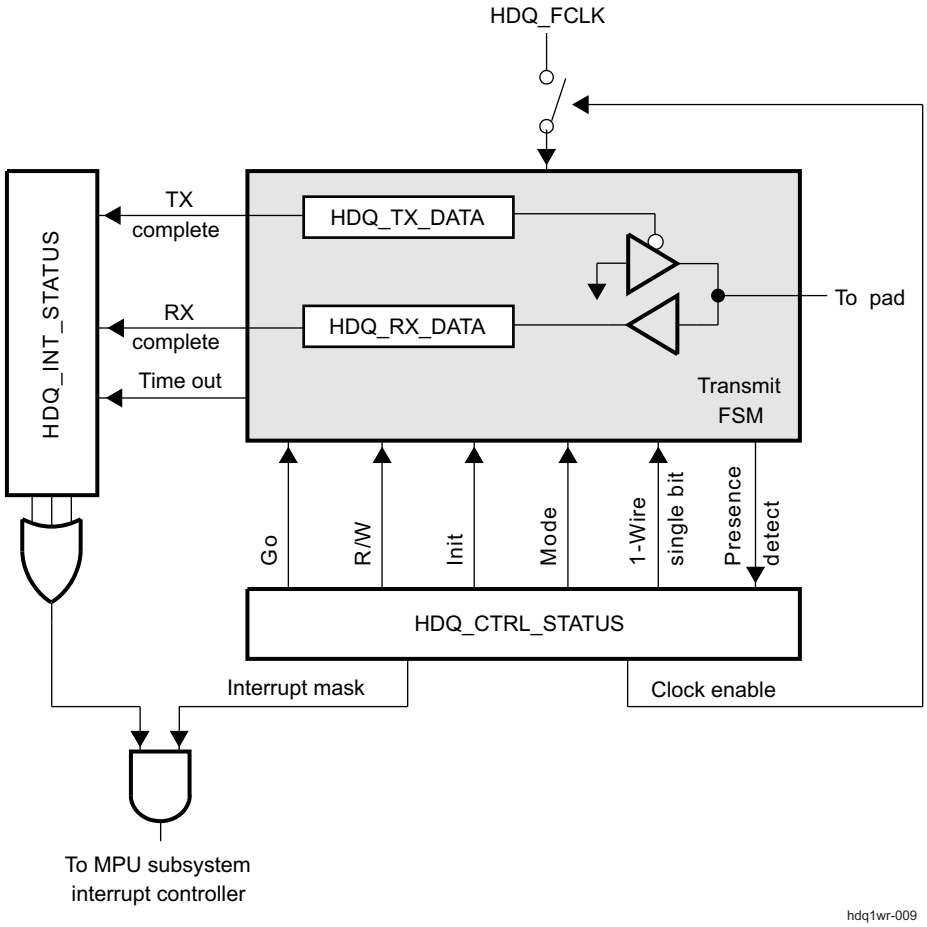
Figure 17-8. HDQ/1-Wire Block Diagram



The MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 17-9 shows the protocol-dedicated register scheme.

Figure 17-9. Protocol Registers Description



The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the OMAP device and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

17.4.2 HDQ Mode (Default)

17.4.2.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

17.4.2.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

17.4.2.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] set to 1) has no effect because the HDQ protocol supports only byte transfers.

17.4.2.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

   A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

2. Read complete:

   In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

3. Presence detect/time-out:

   In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

   In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

17.4.3 1-Wire Mode

17.4.3.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

17.4.3.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the PRESENCEDETECT bit HDQ.HDQ_CTRL_STATUS[3].

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register (HDQ.HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

17.4.3.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit to be sent.

17.4.3.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

   A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

2. Read complete:

   In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

3. Presence detect/time-out:

   In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

17.4.3.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ.HDQ_CTRL_STATUS[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

17.4.4 Module Power Saving

17.4.4.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

This mode is recommended to reduce power consumption.

17.4.4.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ.HDQ_CTRL_STATUS[5]) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

17.4.5 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see , *Power, Reset, and Clock Management*). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE_L4_ICLK and FUNC_12M_CLK belong to the L4 interconnect clock domain).

When the AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

17.5 HDQ/1-Wire Basic Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

17.5.1 Module Initialization Sequence

17.5.1.1 Mode Selection

MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

17.5.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] and the GO bit HDQ.HDQ_CTRL_STATUS[4]. The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] to 1 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ.HDQ_INT_STATUS[0]) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ.HDQ_CTRL_STATUS register to check whether the presence pulse has been received before starting any transfer.

17.5.2 HDQ Protocol Basic Programming Model

17.5.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ.HDQ_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to indicate a write.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to start the transmission.
   (a) The hardware sends the byte from the TX write register.
   (b) In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
   (c) When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
   (d) The GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

17.5.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt.

NOTE: Steps 3 and 4 can be performed simultaneously.

3. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a read.
4. Write 1 to GO bit HDQ.HDQ_CTRL_STATUS[4] to initiate the read.
   (a) The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ.HDQ_CTRL_STATUS[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
   (b) If a time-out occurs, the TIMEOUT bit HDQ.HDQ_CTRL_STATUS[0] is set.
   (c) Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]. If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
   (d) At the end of the read operation, the GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared. It is also cleared if a time-out is detected
5. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

NOTE: In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

17.5.3 1-Wire Mode (SDQ) Basic Programming Model

17.5.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ.HDQ_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 to indicate a write operation.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
   (a) The hardware sends the byte stored in the TX write register.
   (b) In a write operation, the TIMEOUT bit is always cleared.
   (c) When the operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ_INT_STATUS [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
   (d) The GO bit of the control and status register is cleared at the end of a write operation.

4. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

17.5.3.2 Read Operation

The read operation sequence is as follows:

1. Write the address to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.
3. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
4. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.

NOTE: Steps 5 and 6 can be performed simultaneously.

5. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a read.
6. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
   (a) The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB.
   (b) TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is always cleared in a read operation.
   (c) When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
   (d) GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
7. The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
8. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
9. Repeat step 1 through step 8 for each successive byte.

17.5.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit of data to be sent.

17.5.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ_ICLK and functional clock: HDQ_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0] set to 1) provides a safe transfer (the module wakes up the HDQ_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

17.5.4.1 Module Power-Down Mode

1. Before shutting off the HDQ_FCLK, wait for an RX-complete or a TX-complete interrupt.

- In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.
- In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/ address byte is sent; otherwise, the data is not written to the slave.

HDQ.HDQ_INT_STATUS must be read to clear the interrupt condition.

2. Set the CLOCKENABLE bit HDQ.HDQ_CTRL_STATUS[5] to 0 to disable the clock.

   Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

17.5.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see , *Power, Reset, and Clock Management*.

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ_FCLK can be cut if the EN_HDQ bit PRCM.CM_FCLKEN1_CORE [22] is set to 0 and no other modules require CORE_12M_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.

   In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.
2. Read the HDQ.HDQ_INT_STATUS to clear the read-complete interrupt flag.
3. Read the HDQ.HDQ_RX_DATA to retrieve the read data.
4. The HDQ_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.

   In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.
2. Read the HDQ.HDQ_INT_STATUS to clear the TX-complete interrupt flag.
3. The HDQ_ICLK can be shut off by entering the system idle mode.

Concerning HDQ_ICLK, two situations can occur:

- The clock is no longer required and EN_HDQ bit PRCM.CM_ ICLKEN1_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN_HDQ bit, the software must follow the steps described in this section.
- AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

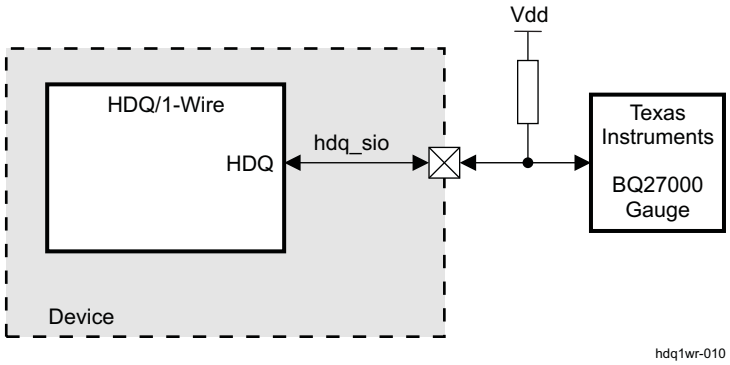
17.6 HDQ/1-Wire Use Cases and Tips

17.6.1 How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge

17.6.1.1 Environment

Figure 17-10 details the OMAP device connections with the BQ27000 gauge.

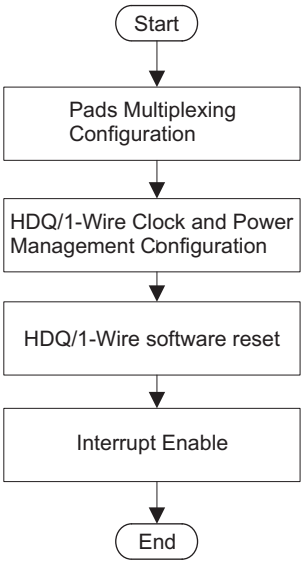
Figure 17-10. Environment



17.6.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. Figure 17-11 shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

Figure 17-11. HDQ/1-Wire Configuration in HDQ Mode



17.6.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

Table 17-3 shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

Table 17-3. Registers Print for HDQ/1-Wire Configuration

Register Name	Address	Value	Value description
SCM.CONTROL_PADCONF_I2C3_SDA	0x 4800 21C4	0x0118 0100	Configure hdq_sio pad in mode 0

Table 17-3. Registers Print for HDQ/1-Wire Configuration (continued)

Register Name	Address	Value	Value description
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x0020 0000	Enable HDQ/1-Wire Functional clock
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x0020 0000	Enable HDQ/1-Wire Interface clock
HDQ_CTRL_STATUS	0x480B 200C	0x0000 0020	Enable clocks and select the HDQ mode
HDQ_SYSCONFIG	0x480B 2014	0x0000 0000	Module clock is free-running (Disable autoidle mode)

17.6.1.4 HDQ/1-Wire Software Reset

Perform a software reset as described in Figure 17-12.

Figure 17-12. Software Reset Flowchart

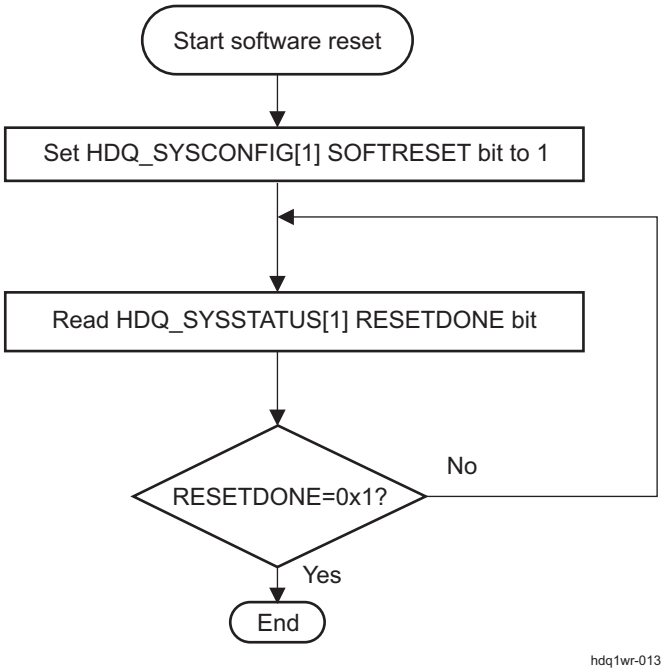


Table 17-4 describes the registers to be configured for the HDQ/1-Wire software reset step.

Table 17-4. Registers Print for HDQ/1-Wire Software Reset

Register Name	Address	Value	Value description
HDQ_SYSCONFIG	0x480B 2014	0x0000 0002	Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware.
HDQ_SYSSTATUS	0x480B 2018	0x0000 0001	The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done.

17.6.1.5 Interrupts Enable

Table 17-5 describes the registers to be configured for the interrupts enable step and the use case values.

Table 17-5. Registers Print for HDQ/1-Wire Interrupts Enable

Register Name	Address	Value	Value description
HDQ_CTRL_STATUS	0x480B 200C	0x0000 0060	Enable Interrupts

17.6.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in Section 17.5.2. Please, refer to this section to see how HDQ/1-Wire registers are configured for these operations.

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 gauge specification.

17.7 HDQ/1-Wire Register Manual

17.7.1 HDQ/1-Wire Instance Summary

Table 17-6 lists the HDQ/1-Wire instances.

Table 17-6. Instance Summary

Module Name	Base Address	Size
HDQ/1-Wire	0x480B 2000	4K bytes

CAUTION

All reserved bits must be written with 0. There is no synchronization between the register clock domain and the state-machine domain. Therefore, the following rules must be observed when accessing the module registers:

- A read from the interrupt status register or the receive buffer register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the control and status register, no access to the TX data register or the control and status register is allowed until the processor has been interrupted by the module.
- Polling of the interrupt status register by software to determine whether an interrupt was generated is not allowed.
- No access to the module registers should be done after the software puts the module in power-down mode (by setting bit 5 of the control and status register to 0) except to re-enable the clock.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

17.7.2 HDQ/1-Wire Register Mapping Summary

Table 17-7 lists the HDQ/1-Wire registers.

Table 17-7. HDQ/1-Wire Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	HDQ/1-Wire Physical Address
HDQ_REVISION	R	32	0x000	0x480B2000

Multichannel Buffered Serial Port

This chapter introduces the multichannel buffered serial port (McBSP).

Topic **Page**

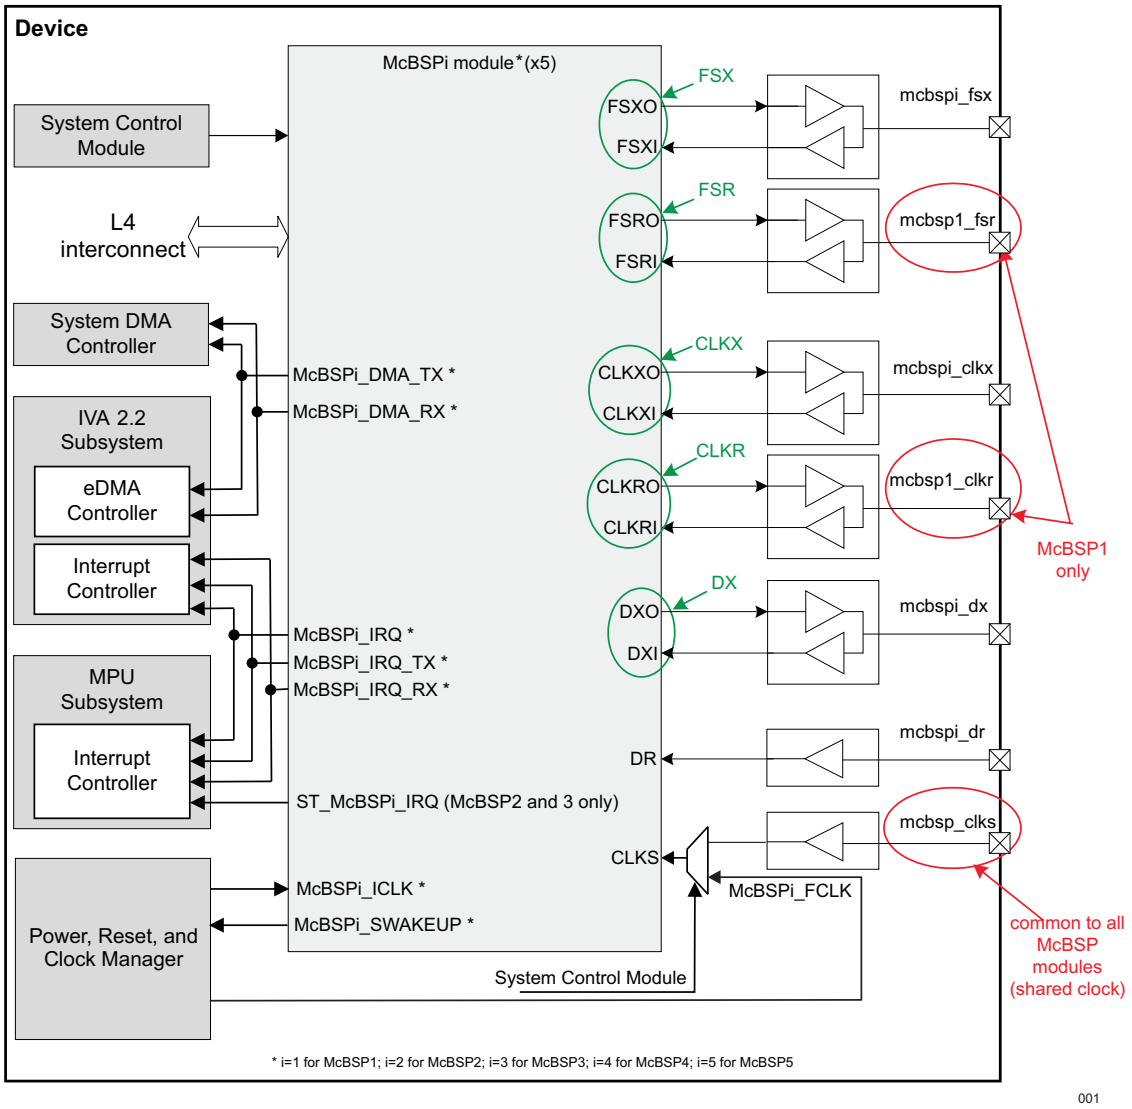
18.1 McBSP Overview

The multichannel buffered serial port provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec (power management device), etc. Because of its high level of versatility, it can accommodate to a wide range of peripherals and clocked frame oriented protocols (for details, see Section 18.1.1).

The device provides five instances of the McBSP module.

Figure 18-1 shows the McBSP overview in the device.

Figure 18-1. McBSP Highlight



18.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:
  - 32-bit data bus width
  - 32-bit access supported
  - 16- /8-bit access supported only by data registers
  - 10-bit address bus width

  - Burst mode not supported
  - Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations (McBSP1, 3, 4, 5)
- 5K bytes (1024 x 32 bits for audio buffer + 256 × 32 bits for buffer) for each buffer for transmit/receive audio operations (McBSP2 only)
- Interrupts configurable in legacy mode (2 requests) or PRCM compliant (1 request)
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- SIDETONE core support: Audio loopback capability (McBSP2 and 3 only)
- Multidrop support
- Serial interface description
  - 6 pin configuration (McBSP 1 only)
  - 4 pin configuration (McBSP2, 3, 4, 5)
  - Full-duplex communication
  - Multichannel selection modes
    - Support to enable or block transfers in each of the channels
    - 128 channels for transmission and for reception
  - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
    - Inter-IC sound (I2S) compliant devices
    - Pulse code modulation (PCM) devices
    - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for μ-law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

  - A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
  - Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
  - Independent clocking and framing for reception and for transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
  - Programmable polarity for frame-sync pulses and for clock signals

NOTE:

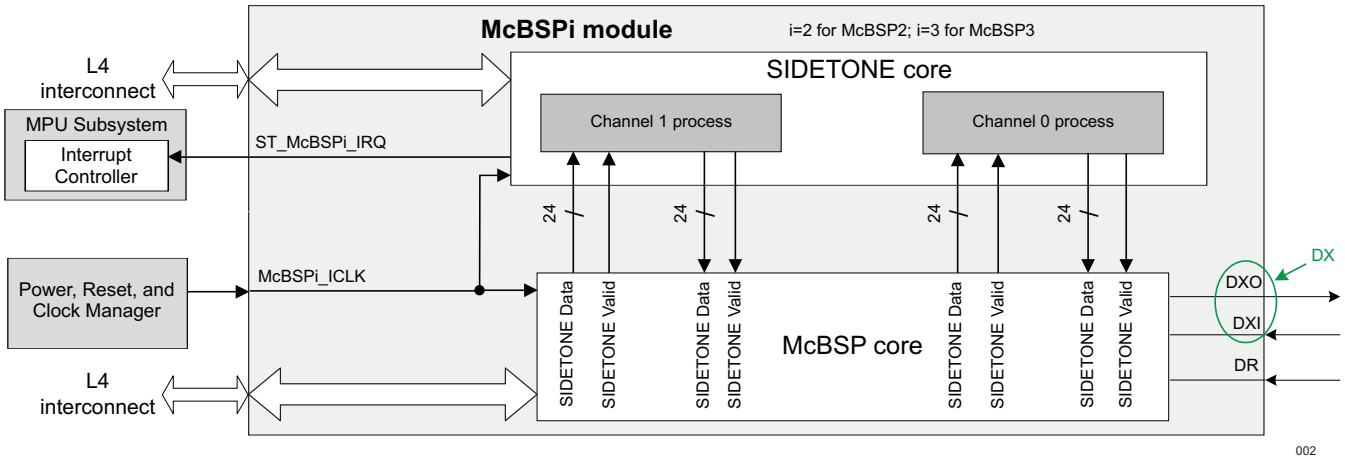
- McBSP modules do not support features such as re-transmit or re-receive of an erroneous frame or word.
- McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.

18.1.2 SIDETONE Core

The purpose of this section is to present the SIDETONE core implemented in McBSP2 and 3 modules. It is required that two of the audio input channels to be looped back, filtered, and mixed to the two corresponding audio output channels.

Data to be processed comes on two separate paths (one for each channel) through a simple interface. After filtering the data, gain is applied and outputted through a similar interface. For more details, see Figure 18-2).

Figure 18-2. SIDETONE Core Architecture



The SIDETONE core offers the following features:

- Filter coefficients are shared between the two channels (the filter coefficient is assumed to represent values in the range –1…+1)
- Gains are independent for the two channels (the gain coefficients are in the range –2…+2)
- The filter output is multiplied with the gain, and the result is rounded to output channel word width.
- The FIR filter length is 128 samples.
- Filtered loop back signals are added to the corresponding output signals, and saturation is applied if the result exceeds arithmetic range.
- Filter coefficients and gains are programmable:
  - Coefficients are changed while audio is stopped.
  - Gains are changed at any time (also during audio operation with SIDETONE enabled).

18.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

18.2.1 McBSP Functions

The device provides five instances of the McBSP module, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) Data
- McBSP2: Audio data with audio buffer and SIDETONE feature
- McBSP3: Bluetooth voice data with SIDETONE feature
- McBSP4: DBB voice data
- McBSP5: Midi data

Table 18-1 describes the functions and the corresponding application fields.

Table 18-1. Functions Description

Function	Application field	Recommended McBSP module	Description
Control and Data	Digital Base Band (DBB) Data	McBSP1	Serial interface to transfer data
Audio Data	Audio Data with Audio Buffer	McBSP2	Audio interface to transfer audio data with Inter-IC Sound codec (I2S)
	Audio Data with Audio Buffer and SIDETONE feature		
	Midi Data	McBSP5	
Voice Data	Bluetooth Voice Data	McBSP3	Voice interface to transfer voice data with Pulse Code Modulation codec (PCM)
	Bluetooth Voice Data with SIDETONE feature		
	DBB Voice Data	McBSP4	

18.2.2 McBSP Signals Descriptions

The five McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6 pins configuration (McBSP 1 only) or 4 pins configuration (McBSP2, 3, 4, 5).

For a McBSP module with 6 pins configuration, an internal loop back capability between Transmitter and Receiver clock signals, and both frame synchronization signals enables using the McBSP module with 4 pins configuration. The related internal multiplexers are controlled through the System Control Module on the device (see Section 18.3).

Table 18-2. Input/Output Description

Pin Name[1]	I/O[2]	Description	Internal Signal Name	Reset Value	Control and Data	Audio Data	Voice Data
mcbsp_clks	I	External clock (shared by all McBSP modules)	CLKS	-	✓	✓	✓
mcbspi_dr	I	Receive serial data	DR	-	✓	✓	✓
mcbspi_dx	I/O[3]	Transmit serial data	DX	0	✓	✓	✓
mcbspi_clkx	I/O [3]	Transmit clock[4]	CLKX	0	✓	✓	✓
mcbspi_fsx	I/O [3]	Transmit frame synchronization [5]	FSX	0	✓	✓	✓
mcbsp1_clkr	I/O [3]	Receive clock	CLKR	1	✓		
mcbsp1_fsr	I/O [3]	Receive frame synchronization	FSR	0	✓		

(1) I = 1 to 5
(2) I = Input; O = Output
(3) For details of the input/output selection, see Section 18.2.3.1.
(4) This signal is also used as CLKR when it is configured as output (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).
(5) This signal is also used as FSR when it is configured as output (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

- The mcbsp_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see Section 18.4.3). The CLKS signal of the McBSP modules is linked to an external signal through the mcbsp_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see Section 18.3.
- Data are transmitted to external devices interfacing with McBSP modules via the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

NOTE: The mcbspi_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated via the following pins: mcbspi_clkx (transmit clock), mcbsp1_clkr (receive clock), mcbspi_fsx (transmit frame-sync), and mcbsp1_fsr (receive frame-sync).

CAUTION

External pins mcbsp1_clkr and mcbsp1_fsr are connected to pads only for McBSP1 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Both reception and transmission use the same clock signal and the same frame synchronization signal.

18.2.3 McBSP Functions Description

18.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device
- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

1. Transmit and receive master mode
2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

NOTE: If the McBSP module has a serial interface with 4 pins configuration (McBSP2, 3, 4, 5), only modes 1 or 2 are possible.

Figure 18-3 shows the connection between the McBSP1 module (6 pins configuration) and an external device in transmit master mode and receive slave mode.

Figure 18-3. Mode Overview of McBSP1 Module

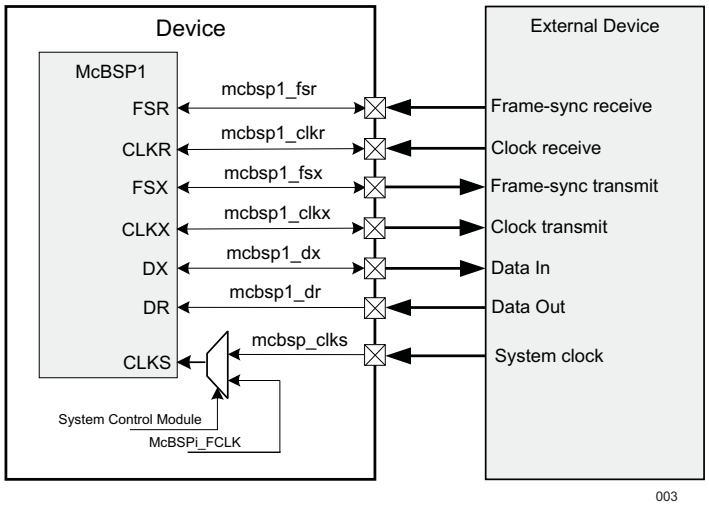


Figure 18-4 shows the connection between the McBSPi module, with I = 2, 3, 4 or 5 (4 pins configuration) and an external device in transmit and receive master mode.

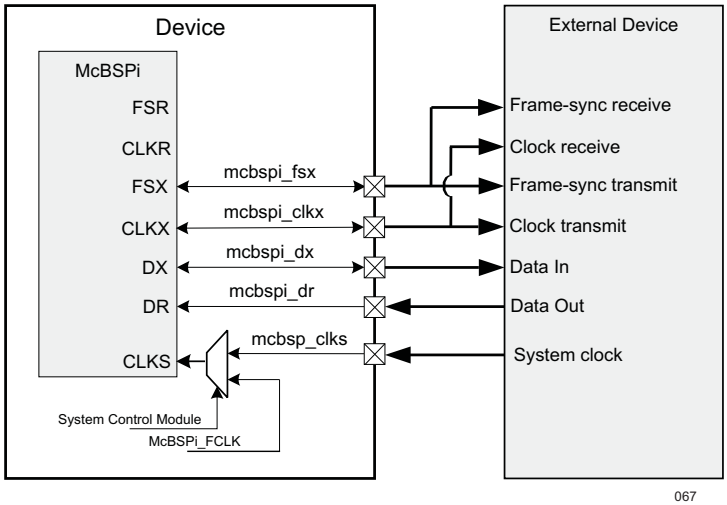
Figure 18-4. Mode Overview of McBSPi Module

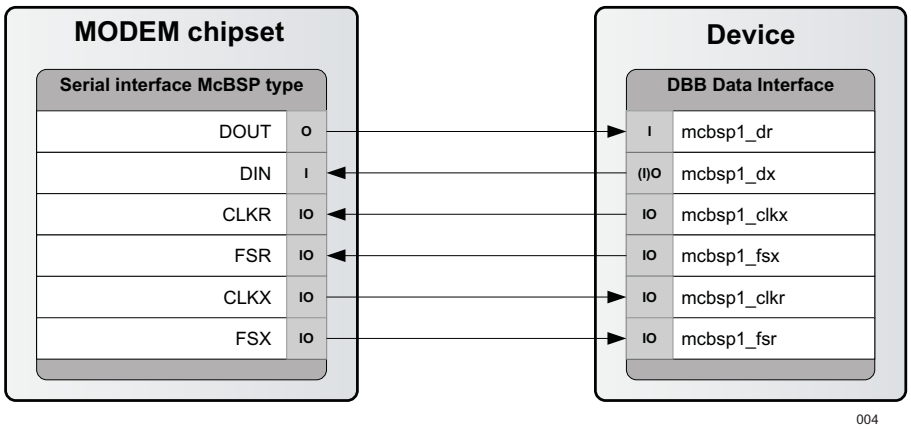


18.2.3.2 McBSP Functions

18.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 18-5 shows typical connections between device and modem chipset to illustrate DBB data application.

Figure 18-5. DBB Data Application



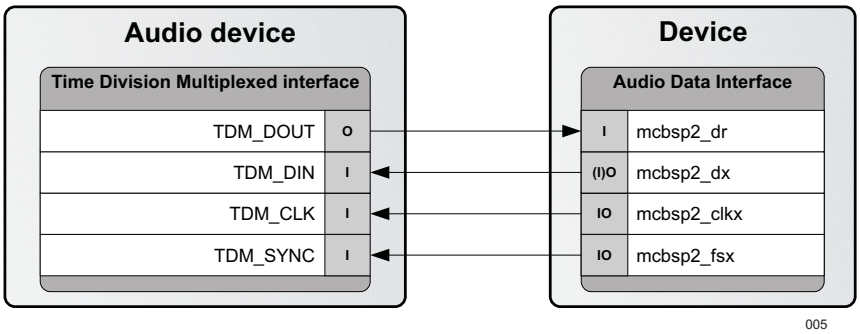
In Figure 18-5, the McBSP1 module is configured in transmit master mode and in receive slave mode.

18.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 18-6 shows typical connections between device and a typical device of analog audio interface (power managment device) to illustrate Audio Data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 18-6. Audio Data Application



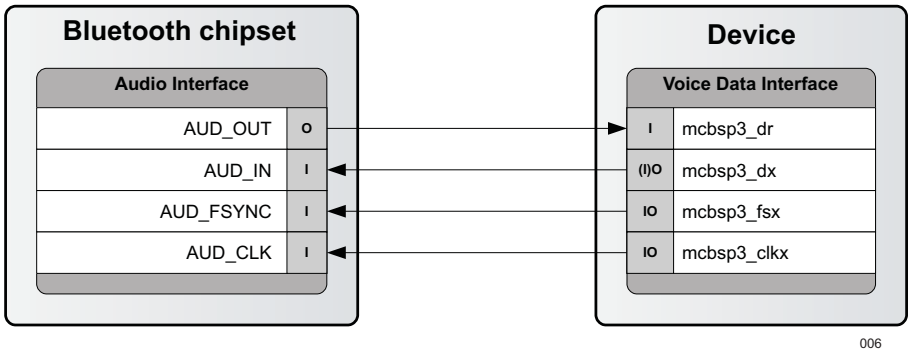
In Figure 18-6, the McBSP2 module is configured in transmit and receive master mode.

18.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be either modem chipsets, Bluetooth chipsets or others devices with voice data interface.

Figure 18-7 shows typical connections between device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 18-7. Voice Data Application



In Figure 18-7, the McBSP3 module is configured in transmit and receive master mode.

18.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

18.2.4.1 Words, Frames, and Phases Definitions

18.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field, McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field) and can be 8, 12, 16, 20, 24 or 32 bits (see Section 18.4.2.3). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

For more information, see Section 18.4.2.4.

18.2.4.1.2 Frames

One or more words (max 128) are transferred in a group called a frame. The McBSP module can transmit / receive a maximum of 128 words per frame, programmable via bits field of transmit and receive control registers (McBSPi.MCBSPLP_XCR1_REG/McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR1_REG/McBSPi.MCBSPLP_RCR2_REG). For more details, see Section 18.4.2.3.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR2_REG). For more information, see Section 18.4.4.6.3 and Section 18.4.4.3.3.

18.2.4.1.3 Phases

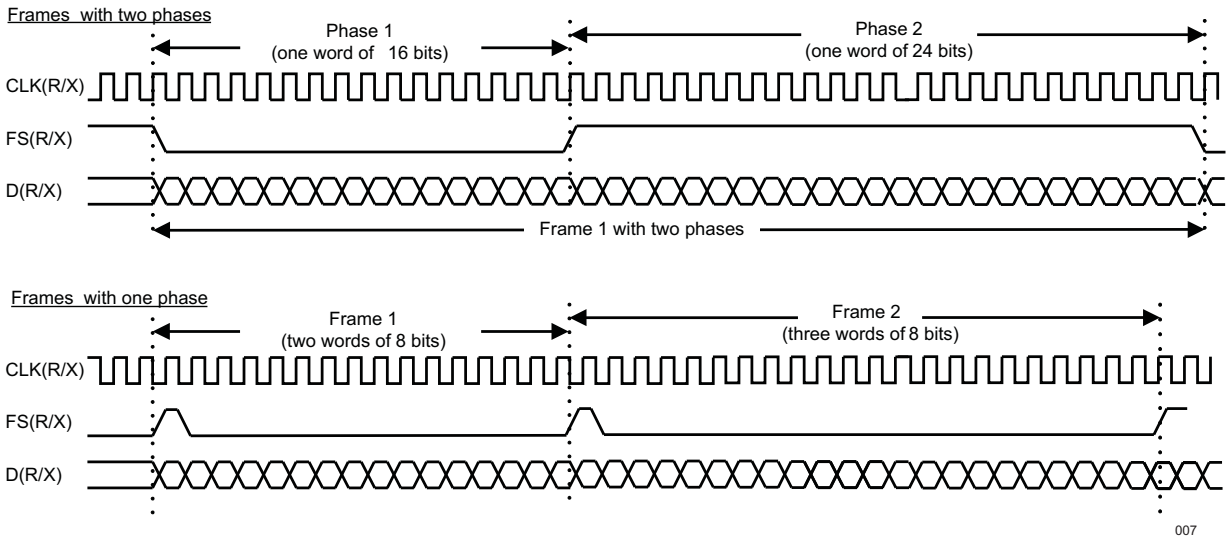
The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual phase frame is that the number of words per phase must be set to one for both first and second phase. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see Section 18.4.2.4.

Figure 18-8 shows signal activity for two possible reception/transmission scenarios.

Figure 18-8. McBSP Reception/Transmission Signal Activity



18.2.4.2 Serial Protocol and Data Formats

18.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

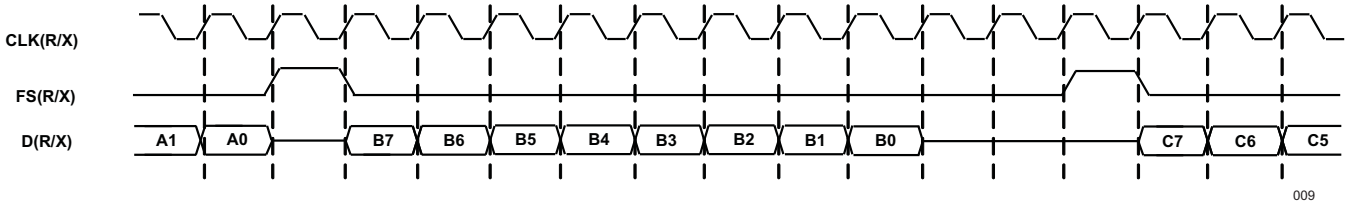
18.2.4.2.2 Data Format

Figure 18-9 shows typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0- , 1- , or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see Section 18.4 and Section 18.5.

Figure 18-9. Serial Data Formats



18.2.4.3 Audio Protocol and Data Formats

18.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8 KHz up to 48 KHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (Supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1 and 48 KHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

18.2.4.3.2 Data Formats

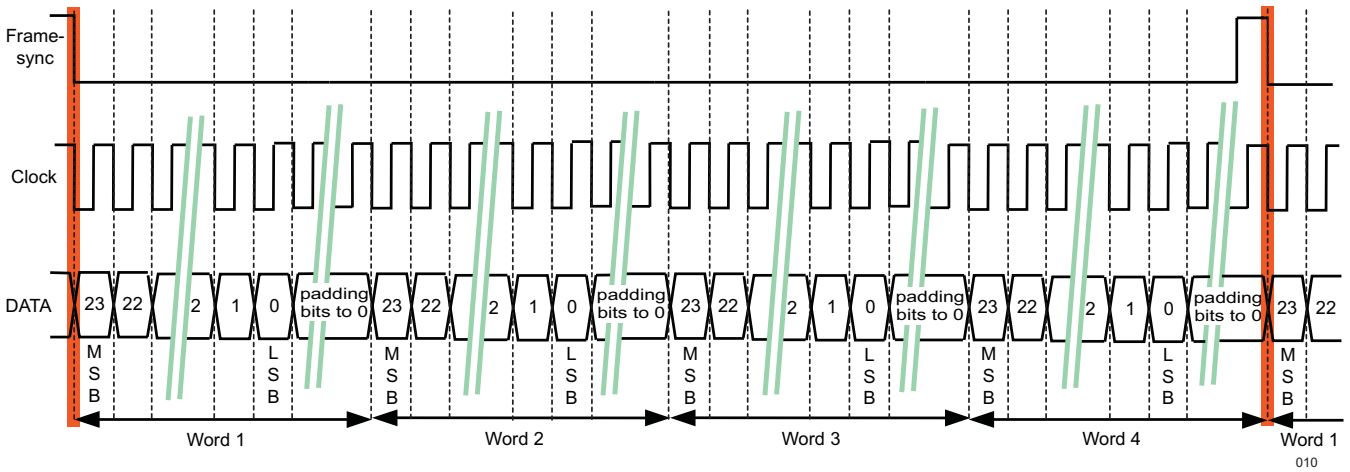
The I2S protocol supports TDM, I2S, left justified, and right justified data formats.

Bits of each word (sample) are clocked using clock signal. For each word, MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

18.2.4.3.2.1 TDM Data Format

Figure 18-10 shows that each frame of TDM data format is composed of four words (or channels).

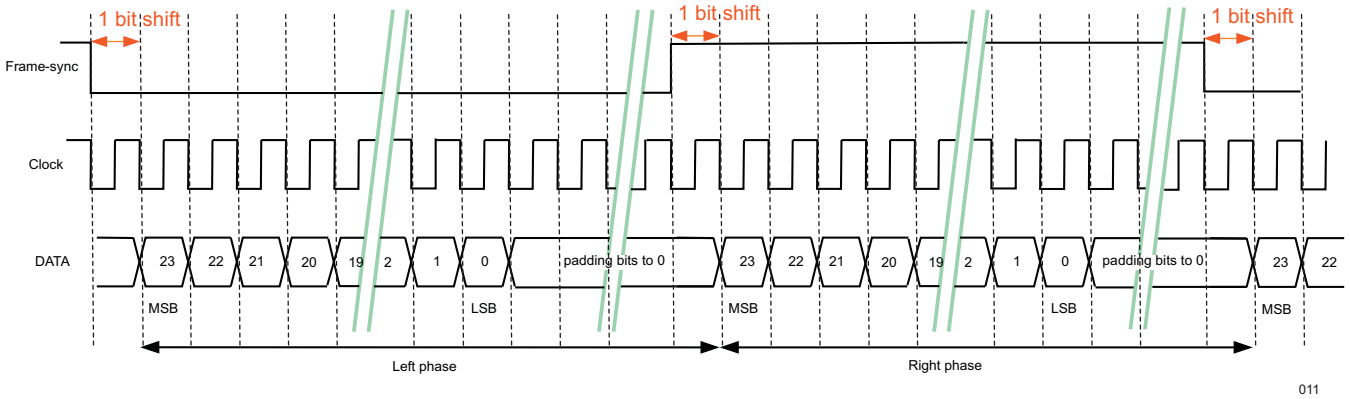
Figure 18-10. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits



18.2.4.3.2.2 I2S Data Format

Figure 18-11 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

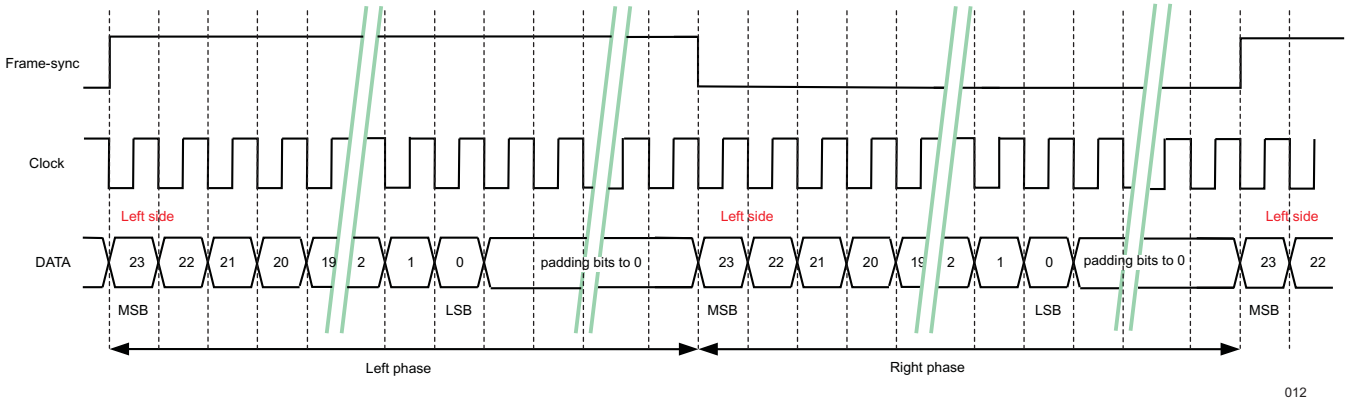
Figure 18-11. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits



18.2.4.3.2.3 Left Justified Data Format

Figure 18-12 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

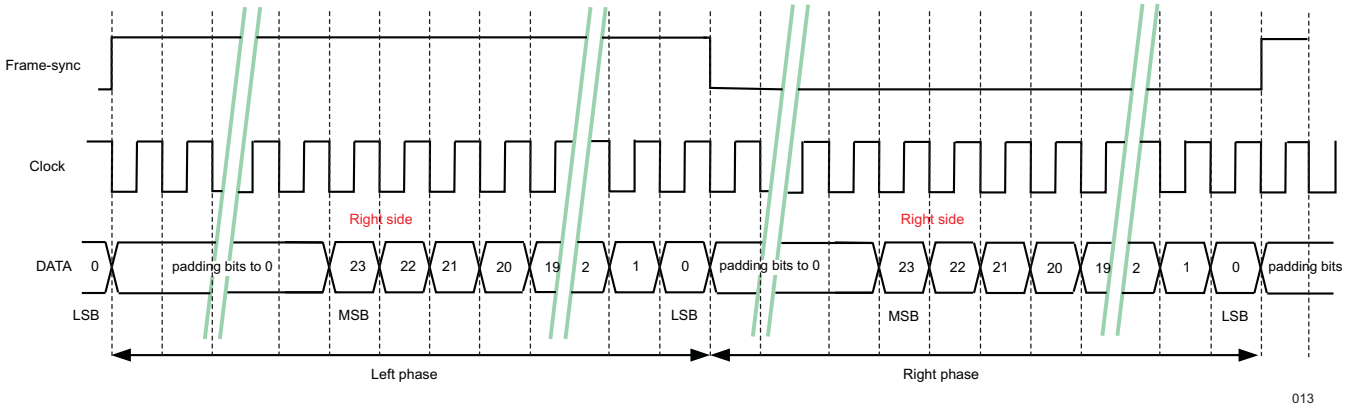
Figure 18-12. Left Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits



18.2.4.3.2.4 Right Justified Data Format

Figure 18-13 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

Figure 18-13. Right Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits



18.2.4.4 Voice Protocol and Data Formats

18.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8 kHz (default narrowband mode) or 16 kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using PCM clock signal, with MSB first.

18.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For these both modes, it has two types of operations: Mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of clock signal, and the frame-synchronization polarity.

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

Figure 18-14 and Figure 18-15 shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

Figure 18-14. PCM Protocol - Mode 1 Data Format

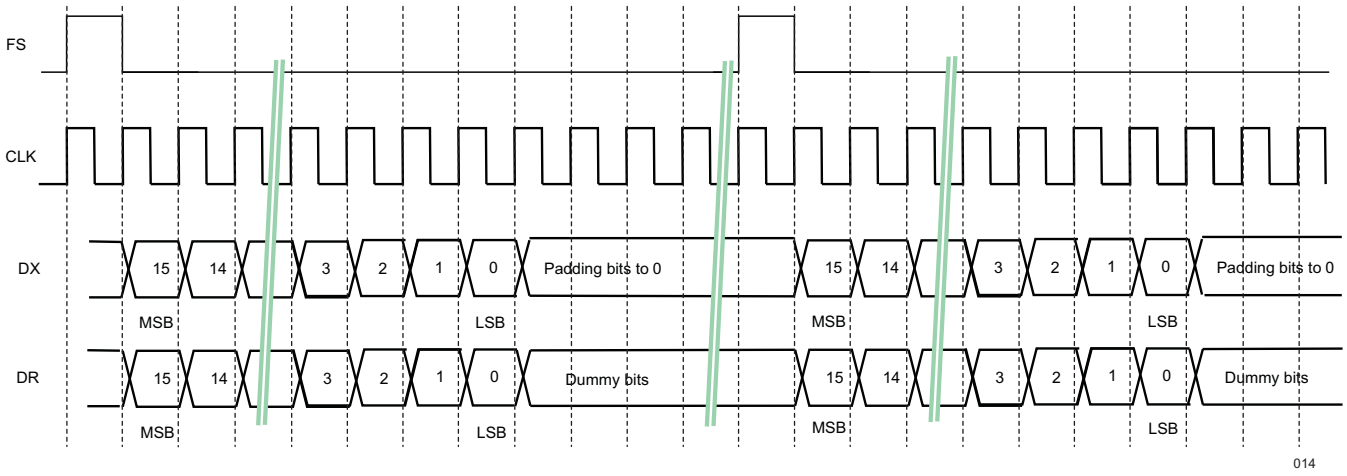


Figure 18-15. PCM Protocol - Mode 2 Data Format

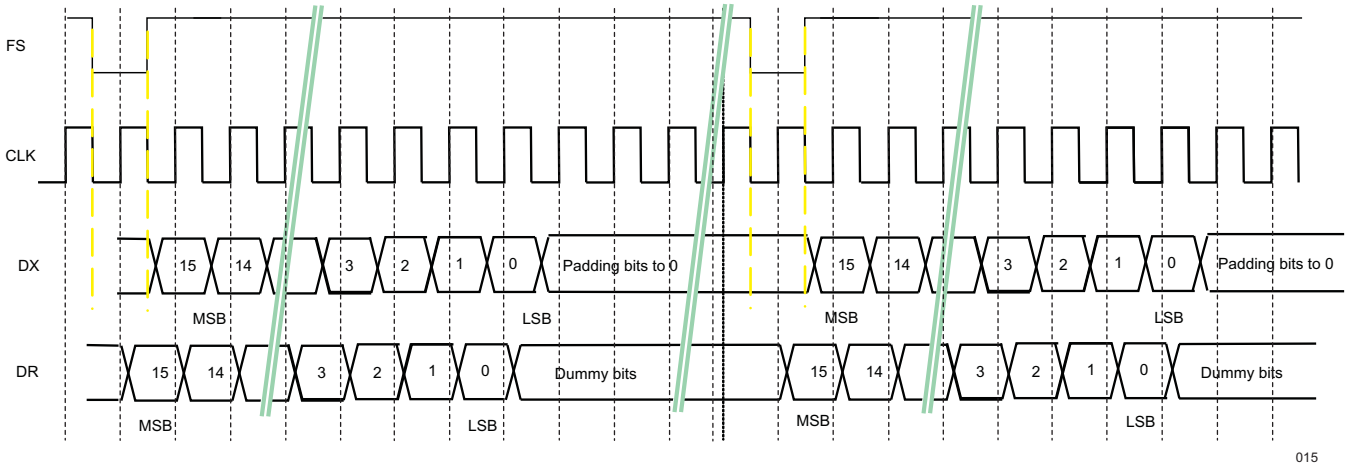

18.3 McBSP Integration

This section describes the McBSP modules integration inside the device and all the details about signal source controls, clocks, resets, power management, and hardware requests.

McBSP modules are divided into 2 families: McBSP modules that are gated in CORE domain (McBSP1 and 5), and McBSP modules that are gated in PER domain (McBSP2, 3, and 4).

For more details on CORE and PER domain, see , *Power, Reset and Clock Management*.

Figure 18-16 through Figure 18-20 highlight the integration of the McBSP modules in the device including interrupt handlers, DMA requests, clock generators, and interconnections.

Figure 18-16. McBSP1 Integration

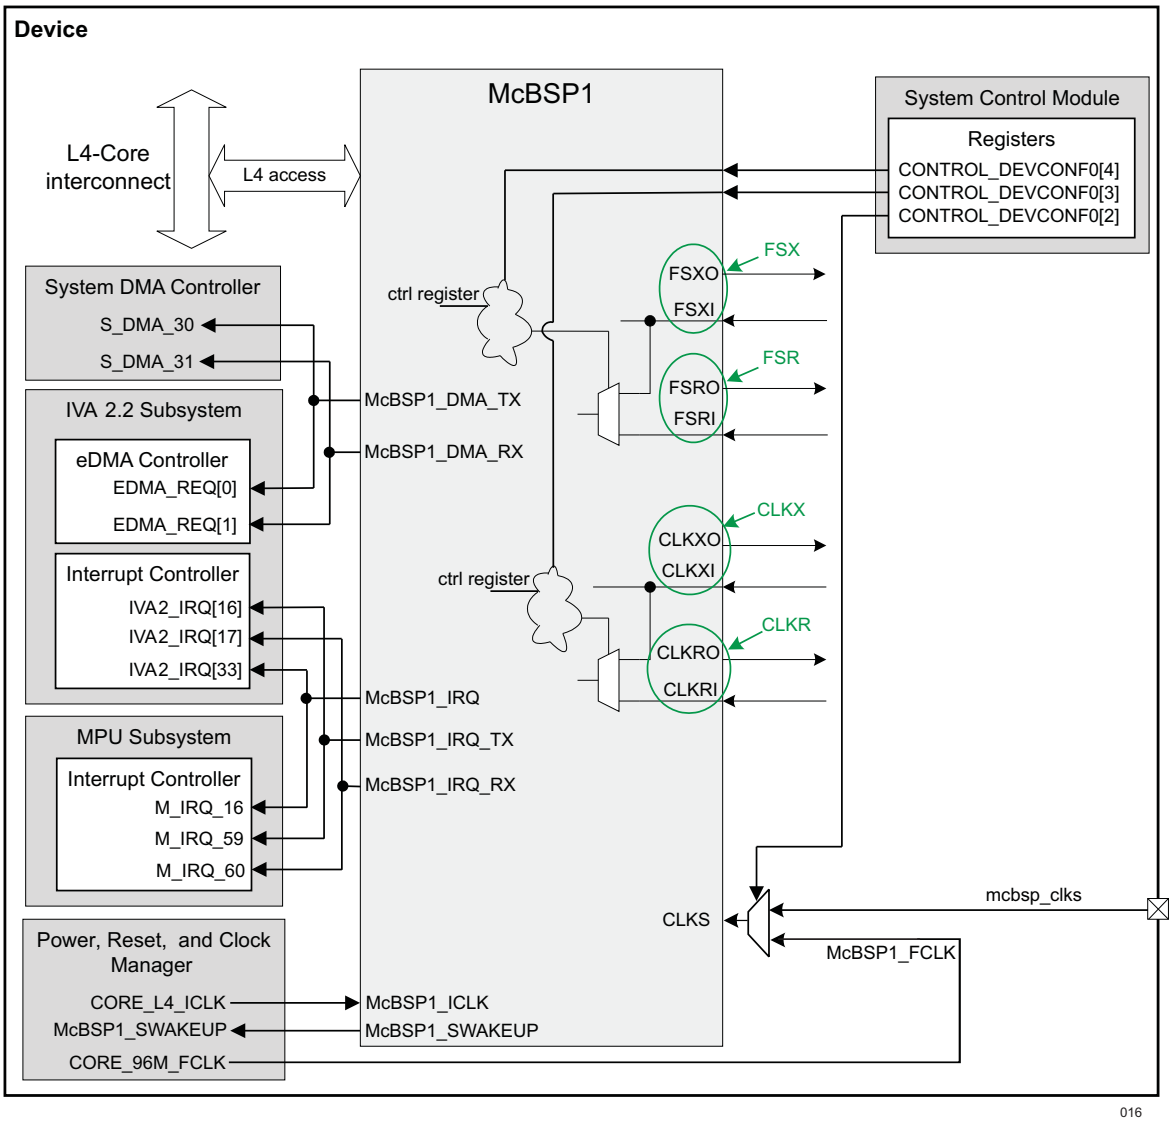

Figure 18-17. McBSP2 Integration

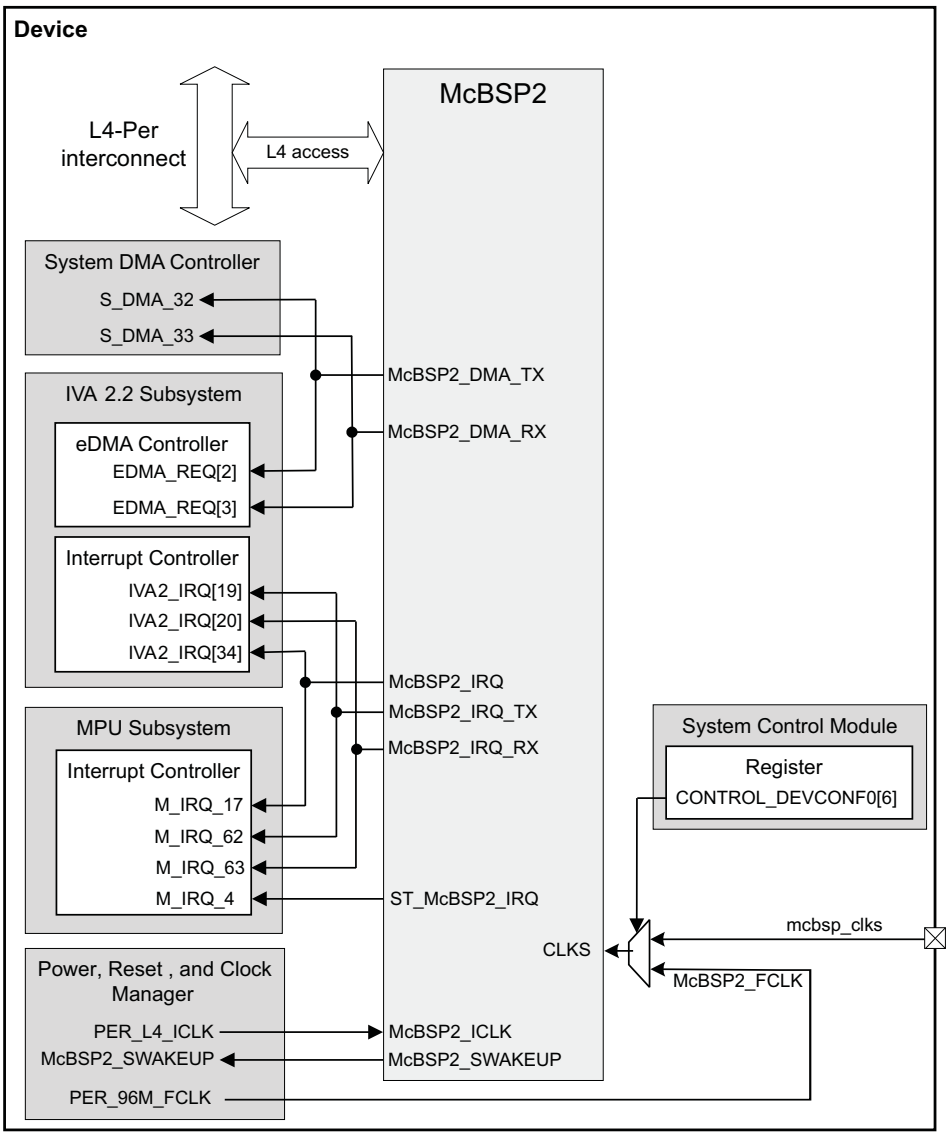

Figure 18-18. McBSP3 Integration

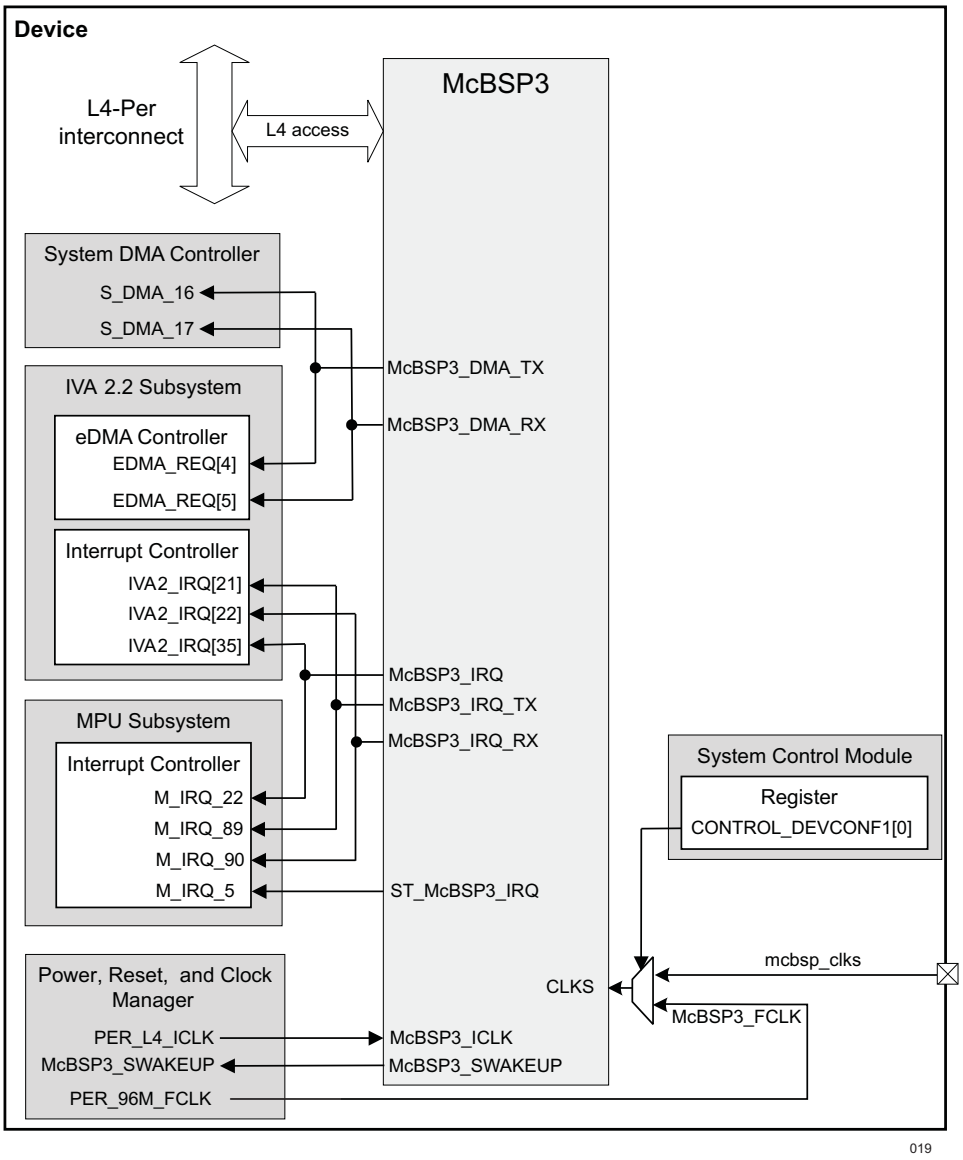

Figure 18-19. McBSP4 Integration

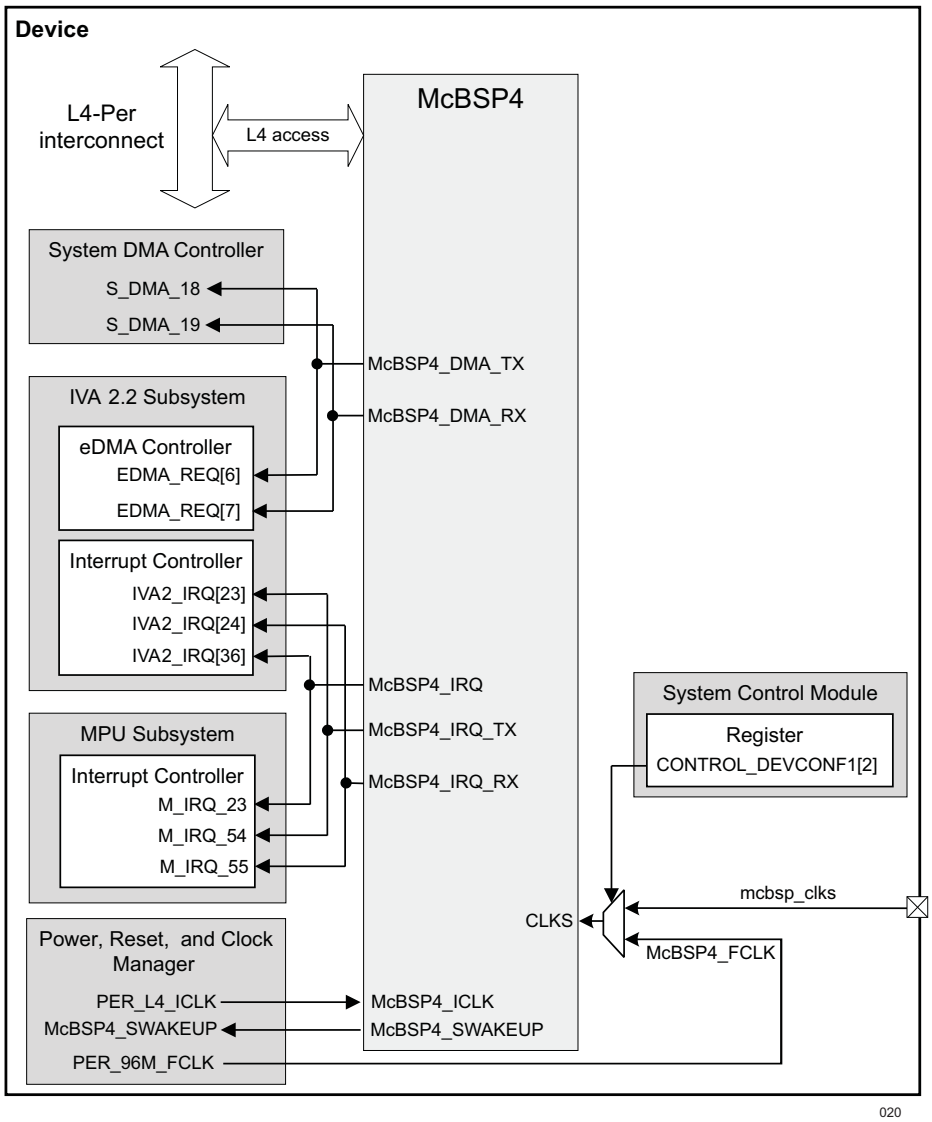

Figure 18-20. McBSP5 Integration

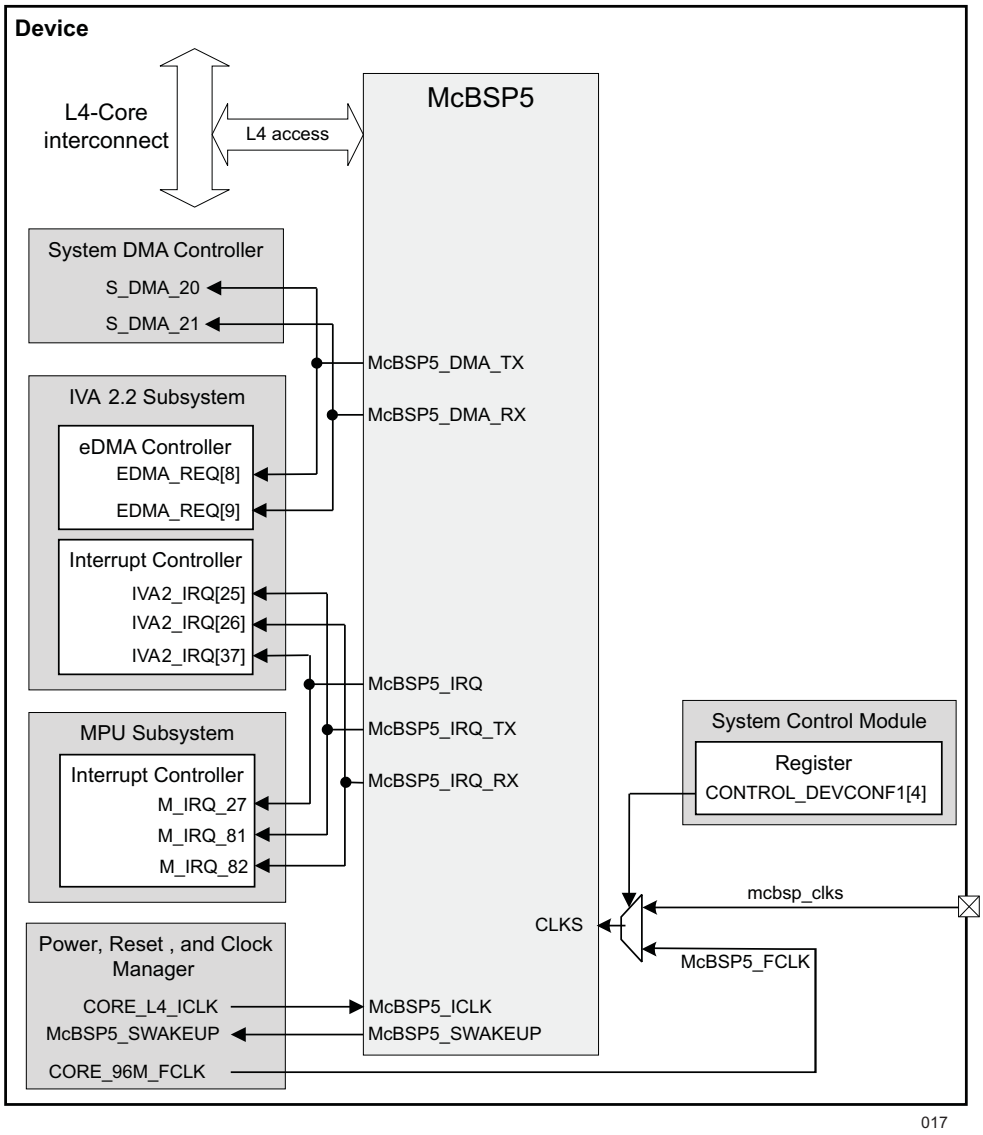

18.3.1 Signal Source Control

The FSR, CLKR and CLKS signals sources are defined by the system control module. The control registers of the system control module are used to select these signals sources.

18.3.1.1 McBSP1 Module (6 Pins Configuration)

The MCBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to ‘0’, the CLKS source is from the CORE_96M_FCLK
- When set to ‘1’, the CLKS source is from the mcbsp_clks pin

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to ‘0’, the CLKR source is from the CLKR input signal
- When set to ‘1’, the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to ‘0’, the FSR source is from the FSR input signal
- When set to ‘1’, the FSR source is from the FSX input signal

18.3.1.2 McBSP2, 3, 4, and 5 modules (4 pins configuration)

For these McBSPi modules, there are no external mcbspi_clkr and mcbspi_fxr pins (I=2, 3, 4, and 5).

Consequently, the system control module controls only the internal connection of CLKS input signals. The settings are explained in Section 18.3.2.2.2, Section 18.3.2.2.3, Section 18.3.2.2.4, and Section 18.3.2.2.5.

18.3.2 Clocking, Reset, and Power Management Scheme

18.3.2.1 Power Domain

McBSP1 and McBSP5 modules belong to the CORE domain, whereas the McBSP2, McBSP3, and McBSP4 modules belong to the PER (peripheral) domain. This separation of McBSP modules in two power domain allows major part of the device to be switched off while keeping active McBSP2, 3, and 4.

For more information about these power domains, see , *Power Reset and Clock Management*.

18.3.2.2 Clocks

There are two clock domains in the McBSP module:

- Functional clock domain
- Interface clock domain

Table 18-3. Clocking Signals Input to McBSP Module

Type	Name	Source	Description
Interface	McBSPi_ICLK	PER_L4_ICLK (McBSP2, 3, 4) (1)	The L4 interface clock is used for the module internal L4 interconnect slave interface and all depending parts of the Interface clock domain.
		CORE_L4_ICLK (McBSP1, 5) (1)	
Functional	CLKS	PER_96M_FCLK (McBSP2, 3, 4) (1)	McBSP module is running using either a functional clock generated internally (master mode) or supplied from its serial interface (slave mode) for the internal logic. Internal registers select the source of the functional clock and the divider ratio to apply. Functional clock after division in any mode is limited to maximum frequency divided by 2.
		CORE_96M_FCLK (McBSP1, 5) (1)	
		mcbsp_clks (external source common to all McBSP modules)	
Functional	CLKX	mcbspi_clkx (external source)	
Functional	CLKR (McBSP1 only)	mcbsp1_clkr (external source)	

(1) For more information about these sources, see , *Power Reset and Clock Management*.

18.3.2.2.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (McBSP1_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see Section 18.4). For McBSP1 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP1.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP1.MCBSPLP_SRGR2_REG[13] register.

  The CLKS signal of the McBSP1 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

  – 0: The CLKS source is from the CORE_96M_FCLK.

– 1: The CLKS source is from the mcbsp_clks pin.

For more information on this register , see Chapter 6, *System Control Module*.

NOTE: When the McBSP1 module does not require the PRCM functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_FCLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a **Hardware** handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see , *Power Reset and Clock Management*.

The CLKX and CLKR signals are connected either by mcbsp1_clkx or mcbsp1_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 18.4.3). Its source is the CORE_L4_ICLK signal.

NOTE: When the McBSP1 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_ICLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[9] register AUTO_MCBSP1 bit set to 1). In this case, McBSP1_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP2_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see Section 18.4). For McBSP2 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP2.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP2.MCBSPLP_SRGR2_REG[13] register.

  The CLKS signal of the McBSP2 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP2_CLKS bit of the CONTROL.CONTROL_DEVCONF0[6] register is used to select the McBSP2 module CLKS signal source:

  – 0: The CLKS source is from the PER_96M_FCLK.

  – 1: The CLKS source is from the mcbsp_clks pin.

  For more information, see Chapter 6, *System Control Module*.

NOTE: When the McBSP2 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_FCLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbsp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 18.4.3). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_ICLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[0] register AUTO_MCBSP2 bit set to 1). In this case, McBSP2_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP3_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see Section 18.4). For McBSP3 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP3.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP3.MCBSPLP_SRGR2_REG[13] register.

  The CLKS signal of the McBSP3 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP3_CLKS bit of the CONTROL.CONTROL_DEVCONF1[0] register is used to select the McBSP3 module CLKS signal source:

  – 0: The CLKS source is from the PER_96M_FCLK.
  – 1: The CLKS source is from the mcbsp_clks pin.

  For more information, see Chapter 6, *System Control Module*.

NOTE: When the McBSP3 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_FCLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbsp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 18.4.3). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP3 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_ICLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP4_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see Section 18.4). For McBSP4 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP4.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP4.MCBSPLP_SRGR2_REG[13] register.

  The CLKS signal of the McBSP4 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP4_CLKS bit of the CONTROL.CONTROL_DEVCONF1[2] register is used to select the McBSP4 module CLKS signal source:

  – 0: The CLKS source is from the PER_96M_FCLK.
  – 1: The CLKS source is from the mcbsp_clks pin.

  For more information, see Chapter 6, *System Control Module*.

NOTE: When the McBSP4 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_FCLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see , *Power Reset and Clock Management*.

Only the CLKX signal is connected by mcbsp4_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 18.4.3). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_ICLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[2] register AUTO_MCBSP4 bit set to 1). In this case, McBSP4_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.5 McBSP5 Clocks

The McBSP5 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP5_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see Section 18.4). For McBSP5 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP5.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP5.MCBSPLP_SRGR2_REG[13] register.

  The CLKS signal of the McBSP5 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbsp_clks pin of the device boundary. The MCBSP5_CLKS bit of the CONTROL.CONTROL_DEVCONF1[4] register is used to select the McBSP5 module CLKS signal source:

  – 0: The CLKS source is from the CORE_96M_FCLK.
  – 1: The CLKS source is from the mcbsp_clks pin.

  For more information, see Chapter 6, *System Control Module*.

NOTE: When the McBSP5 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_FCLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbsp5_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP5_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP5 L4 interface and McBSP5 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see Section 18.4.3). Its source is either the CORE_L4_ICLK signal.

NOTE: When the McBSP5 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_ICLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[10] register AUTO_MCBSP5 bit set to 1). In this case, McBSP5_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.6 SIDETONE Clock

The SIDETONE feature, in the McBSP2 and McBSP3 modules, is clocked only by an interface clock (McBSP2_ICLK or McBSP3_ICLK).

CAUTION

See Section 18.3.2.2.2 and Section 18.3.2.2.3 for information on McBSP2_ICLK and McBSP3_ICLK clocks.

When the SIDETONE feature does not require the clock anymore, the software can disable it at the SIDETONE level by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit in SIDETONE registers. To conserve power, when SIDETONE feature is not active or there is no activity on SIDETONE feature, the McBSPi_ICLK clock supports an automatic gating that is enabled or disabled by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit.

- When this bit is asserted (set to 1), the McBSPi_ICLK clock auto-gating is enabled and this clock is disabled internally to the SIDETONE feature, thus reducing power consumption, but not to the McBSP module that contains this feature.
  After reset, the automatic clock gating is enabled; thus, this bit must be disabled by software for activated SIDETONE feature.
- When this bit is set to 0, the McBSPi_ICLK clock auto-gating is disabled and this clock is enabled. The SIDETONE feature can be used normally.

18.3.2.3 Hardware and Software Reset

McBSP1 and McBSP5 modules belong to the CORE domain and their reset signal is the CORE_RST signal from the PRCM module, whereas McBSP2, 3 and 4 modules belong to the PER domain and their reset signal is the PER_RST signal from the PRCM module.

For more details about these signals, see , *Power Reset and Clock Management*.

Table 18-4. Software Reset Signals to All McBSP Modules

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	McBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver, including the RB.
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB.
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG

For more details about these signals, see Section 18.6. See Section 18.5.1.1, for a complete description of the McBSP initialization procedure.

18.3.2.4 Power Management

18.3.2.4.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- ACTIVE state: The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- IDLE state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wake-up features) and its clocks are likely to be switched off at PRCM level.

  When the McBSP goes into IDLE state, the McBSP internal state-machine clock switches from interface clock (L4_ICLK) to external serial clock (because OMAP is supposed to shut down all internal clocks). Then the McBSP can continue to process during IDLE state with the external clock provided by the external component/AUDIOBUFFER.

  The McBSP can exit IDLE state only if the external serial clock is active. After exiting IDLE state, the McBSP state-machine clock is provided by the OMAP interface clock (L4_ICLK).

NOTE: Idle request and idle acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

18.3.2.4.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Force Idle mode (SIDLEMODE bit = 0x0): An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity),

interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In Force Idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgment to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See Section 18.3.2.4.4) and external signals.

NOTE: The value MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field = 0x3 must not be used.

When configured in Smart Idle mode, McBSP module also offers an additional granularity on McBSPi_FCLK and McBSPi_ICLK gating. McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (McBSPi_FCLK, McBSPi_ICLK, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM idle request will be tested. As an example, if McBSPi_FCLK is said not to be shut down upon a PRCM idle request, this means McBSP module will only consider McBSPi_ICLK and the associated pending activities before acknowledging the request.

NOTE: Some of McBSP features are associated to McBSPi_ICLK and others to McBSPi_FCLK. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an idle request. For more information, see Section 18.3.2.4.4.

Table 18-5 lists the value of the bit field and indicates if the interface (McBSPi_ICLK) and PRCM functional (McBSPi_FCLK) clocks can be switched-off or not when an idle request is received by McBSP module.

Table 18-5. State of Clocks When the Module is in Idle State

CLOCKACTIVITY Value	Interface Clock (McBSPi_ICLK)	PRCM Functional Clock (CORE_96M_FCLK or PER_96M_FCLK)
0b00	OFF	OFF
0b01	OFF	ON
0b10	ON	OFF
0b11	ON	ON

NOTE: OFF means this clock can be switched-off.

ON means this clock must be maintained during wake up period.

CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field and PRCM 96M_FCLK and L4_ICLK control bits (for more information about clocks, see Section 18.3.2.2, *Clocks*). If McBSP module is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

The software can disable all clocks at the McBSP module level by setting the IDLE_EN bit in McBSPi.MCBSPLP_PCR_REG[14] registers. The IDLE_EN bit allows stopping all the clocks in the McBSP module (legacy):

- When set to ‘0’, the McBSP module is running
- When set to ‘1’, the clocks in the McBSP module are shut off when both IDLE_EN =1 and his power domain is in idle mode.

18.3.2.4.3 Wake-Up Capability

When configured in Smart Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to ‘0’, wake up capability is disabled
- Set to ‘1’, wake up capability is enabled

The McBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

18.3.2.4.3.1 Receive Wake-up

There are 4 receive possible wake up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from ‘0’ to ‘1’, indicating that received data is ready to be read).
- McBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.

- McBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request o the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from ‘0’ to ‘1’, indicating that a receive error occurred).

18.3.2.4.3.2 Transmit Wakeup

For transmit, there are also 5 possible wake-up configuration scenarios:

- McBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH2_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from ‘0’ to ‘1’, indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from ‘0’ to ‘1’, indicating that a transmit error occurred).

18.3.2.4.3.3 Notes

When mcbsp1_fsr/mcbspi_fsx pins is configured as an output, the FSR/FSX wake-up generation makes no sense (the module cannot be in Smart Idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbsp1_fsr/mcbspi_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake up capability in this mode is not available.

18.3.2.4.4 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is shown in Table 18-6 :

In this table, the CLKRM bit is in the McBSPi.MCBSPLP_PCR_REG register on position 8, CLKXM bit in the McBSPi.MCBSPLP_PCR_REG[9] register, and CLOCKACTIVITY bit in the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X signifies that the bit value is not significant.

Table 18-6. McBSP Smart Idle Mode Configuration Behavior

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	outside	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: • The transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (CLKR is not connected to the CLKX input pin). • Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	Receive master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: The receive part is disabled (RDISABLE) or under software reset (RRST) The Idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	
			CLKX	0bXX	When CLKX is used as source (functional clock is provided from outside) then the module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Table 18-6. McBSP Smart Idle Mode Configuration Behavior (continued)

CLKRM Bit	CLKXM Bit	McBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and Receive Master	McBSPi_ICLK	0b0X	The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen.
			CLKS	0bX0	
			McBSPi_ICLK	0b1X	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			CLKS	0bX1	

NOTE: The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and mcbsp1_fsr/mcbspi_fsx pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

18.3.3 Hardware Requests

18.3.3.1 DMA Requests

The DMA requests are shared between the IVA2.2 subsystem DMA controller (eDMA) and system DMA controller (sDMA). Each of the five McBSP modules can generate two DMA events:

- McBSPi_DMA_TX : McBSPi module transmit request
- McBSPi_DMA_RX : McBSPi module receive request

The following table summarizes the DMA events with the mapping on both DMA controllers.

Table 18-7. McBSP DMA Requests

Request Name	Mapping	Destination	Description
McBSP1_DMA_TX	EDMA_REQ[0] S_DMA_30	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP1_DMA_RX	EDMA_REQ[1] S_DMA_31	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP2_DMA_TX	EDMA_REQ[2] S_DMA_32	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP2_DMA_RX	EDMA_REQ[3] S_DMA_33	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP3_DMA_TX	EDMA_REQ[4] S_DMA_16	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP3_DMA_RX	EDMA_REQ[5] S_DMA_17	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP4_DMA_TX	EDMA_REQ[6] S_DMA_18	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP4_DMA_RX	EDMA_REQ[7] S_DMA_19	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request
McBSP5_DMA_TX	EDMA_REQ[8] S_DMA_20	IVA2.2 subsystem DMA controller system DMA controller	write (or transmit) request
McBSP5_DMA_RX	EDMA_REQ[9] S_DMA_21	IVA2.2 subsystem DMA controller system DMA controller	read (or receive) request

18.3.3.2 Interrupt Requests

18.3.3.2.1 McBSP Interrupt Requests

Each of the five McBSP modules can generate three interrupts, shared between the MPU subsystem and IVA2.2 subsystem interrupt controllers:

- McBSPi_IRQ: McBSPi module common interrupt request
- McBSPi_IRQ_TX: McBSPi module transmit interrupt request
- McBSPi_IRQ_RX: McBSPi module receive interrupt request

The following tables list the interrupt requests with the mapping.

Table 18-8. McBSP Common Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ	IVA2_IRQ[33] M_IRQ_16	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ	IVA2_IRQ[34] M_IRQ_17	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ	IVA2_IRQ[35] M_IRQ_22	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ	IVA2_IRQ[36] M_IRQ_23	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 18-8. McBSP Common Interrupt Requests (continued)

Request Name	Mapping	Destination
McBSP5_IRQ	IVA2_IRQ[37] M_IRQ_27	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 18-9. McBSP Transmit Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_TX	IVA2_IRQ[16] M_IRQ_59	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_TX	IVA2_IRQ[19] M_IRQ_62	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_TX	IVA2_IRQ[21] M_IRQ_89	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_TX	IVA2_IRQ[23] M_IRQ_54	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_TX	IVA2_IRQ[25] M_IRQ_81	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

Table 18-10. McBSP Receive Interrupt Requests

Request Name	Mapping	Destination
McBSP1_IRQ_RX	IVA2_IRQ[17] M_IRQ_60	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP2_IRQ_RX	IVA2_IRQ[20] M_IRQ_63	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP3_IRQ_RX	IVA2_IRQ[22] M_IRQ_90	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP4_IRQ_RX	IVA2_IRQ[24] M_IRQ_55	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller
McBSP5_IRQ_RX	IVA2_IRQ[26] M_IRQ_82	IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller

An event can generate an interrupt request when the corresponding mask bit in the McBSPi.MCBSPLP_IRQENABLE_REG register is set to '1'.

Table 18-11 and Table 18-12 summarize the events causing the generation of an interrupt request.

Table 18-11. McBSP Transmit Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Transmit buffer empty at end of frame	McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF	McBSPi.MCBSPLP_IRQENABLE_REG [14] XEMPTYEOFEN	This event happens when a complete frame was transmitted and the transmit buffer is empty .
Overflow	McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [12] XOVFLEN	This event happens when transmit data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG [11] XUNDFLEN	This event happens when transmit data buffer is empty and a new data is required to be transmitted.
Threshold reached	McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY	McBSPi.MCBSPLP_IRQENABLE_REG [10] XRDYEN	This event happens when the transmit buffer free locations are equal or above the THRSH2_REG value.
End of Frame	McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF	McBSPi.MCBSPLP_IRQENABLE_REG [9] XEOFLEN	This event happens when a complete frame was transmitted.

Table 18-11. McBSP Transmit Interrupt Events (continued)

Event Name	Status Bit	Mask Bit	Description
Frame-sync	McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX	McBSPi.MCBSPLP_IRQENABLE_REG [8] XFSXEN	This event happens when a new transmit frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR	McBSPi.MCBSPLP_IRQENABLE_REG [7] XSYNCERREN	This event happens when a transmit frame synchronization error is detected.

Table 18-12. McBSP Receive Interrupt Events

Event Name	Status bit	Mask bit	Description
Overflow	McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG[5] ROVFLEN	This event happens when receive data buffer is full and a new data is written in this buffer. The new data written is discarded.
Underflow	McBSPi.MCBSPLP_IRQSTATUS_REG[4] XUNDFLSTAT	McBSPi.MCBSPLP_IRQENABLE_REG[4] RUNDFLEN	This event happens when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined.
Threshold reached	McBSPi.MCBSPLP_RQSTATUS_REG[3] RRDY	McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN	This event happens when the receive buffer occupied locations are equal or above the THRSH1_REG value.
End of Frame	McBSPi.MCBSPLP_IRQSTATUS_REG[2] REOF	McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFLEN	This event happens when a complete frame was received.
Frame-sync	McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR	McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN	This event happens when a new receive frame synchronization is asserted.
Frame-sync error	McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR	McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN	This event happens when a receive frame synchronization error is detected.

Once an interrupt request is generated, the software must read the McBSPi.MCBSPLP_IRQSTATUS_REG register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register.

NOTE: All Status bits can be cleared in two ways:

- If the corresponding mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the corresponding mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the receiver/transmitter.

18.3.3.2.2 SIDETONE_McBSP Interrupt Requests

The McBSP2 and McBSP3 can generate another interrupt to the MPU subsystem interrupt controller:

- **ST_McBSPi_IRQ:** SIDETONE interrupt request for McBSPi module (where I = 2, 3).

Table 18-13. SIDETONE_McBSP Interrupt Requests

Request Name	Mapping	Destination
ST_McBSP2_IRQ	M_IRQ_4	MPU subsystem interrupt controller
ST_McBSP3_IRQ	M_IRQ_5	MPU subsystem interrupt controller

Table 18-14. SIDETONE_McBSP Interrupt Events

Event Name	Status Bit	Mask Bit	Description
Over-run	McBSPi.ST_IRQSTATUS_REG[0] OVRRERROR	McBSPi.ST_IRQENABLE_REG[0] OVRRERROREN	This event happens when a new data to be processed arrives before the previous one has ended.

Once an interrupt request has been generated, the software must read the McBSPi.ST_IRQSTATUS_REG register to check what event caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.ST_IRQSTATUS_REG register.

NOTE: The McBSPi.ST_IRQSTATUS_REG[0] OVRRERROR status bit can be cleared in two ways:

- If the McBSPi.ST_IRQENABLE_REG[0] OVRRERROREN mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the McBSPi.ST_IRQENABLE_REG[0] OVRRERROREN mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the SIDETONE channels.

18.4 McBSP Functional Description

This section is a functional description of the McBSP module.

18.4.1 Block Diagram

Figure 18-21, Figure 18-22, and Figure 18-23 show functional block diagrams of the five instances of the McBSP modules.

These figures regroup the McBSP modules by categories:

- McBSP module without audio buffer and SIDETONE core: McBSP1, McBSP4 and McBSP5
- McBSP module with audio buffer and SIDETONE core: McBSP2
- McBSP module without audio buffer, but with SIDETONE core: McBSP3

Figure 18-21. McBSP1, McBSP4 and McBSP5 Block Diagrams

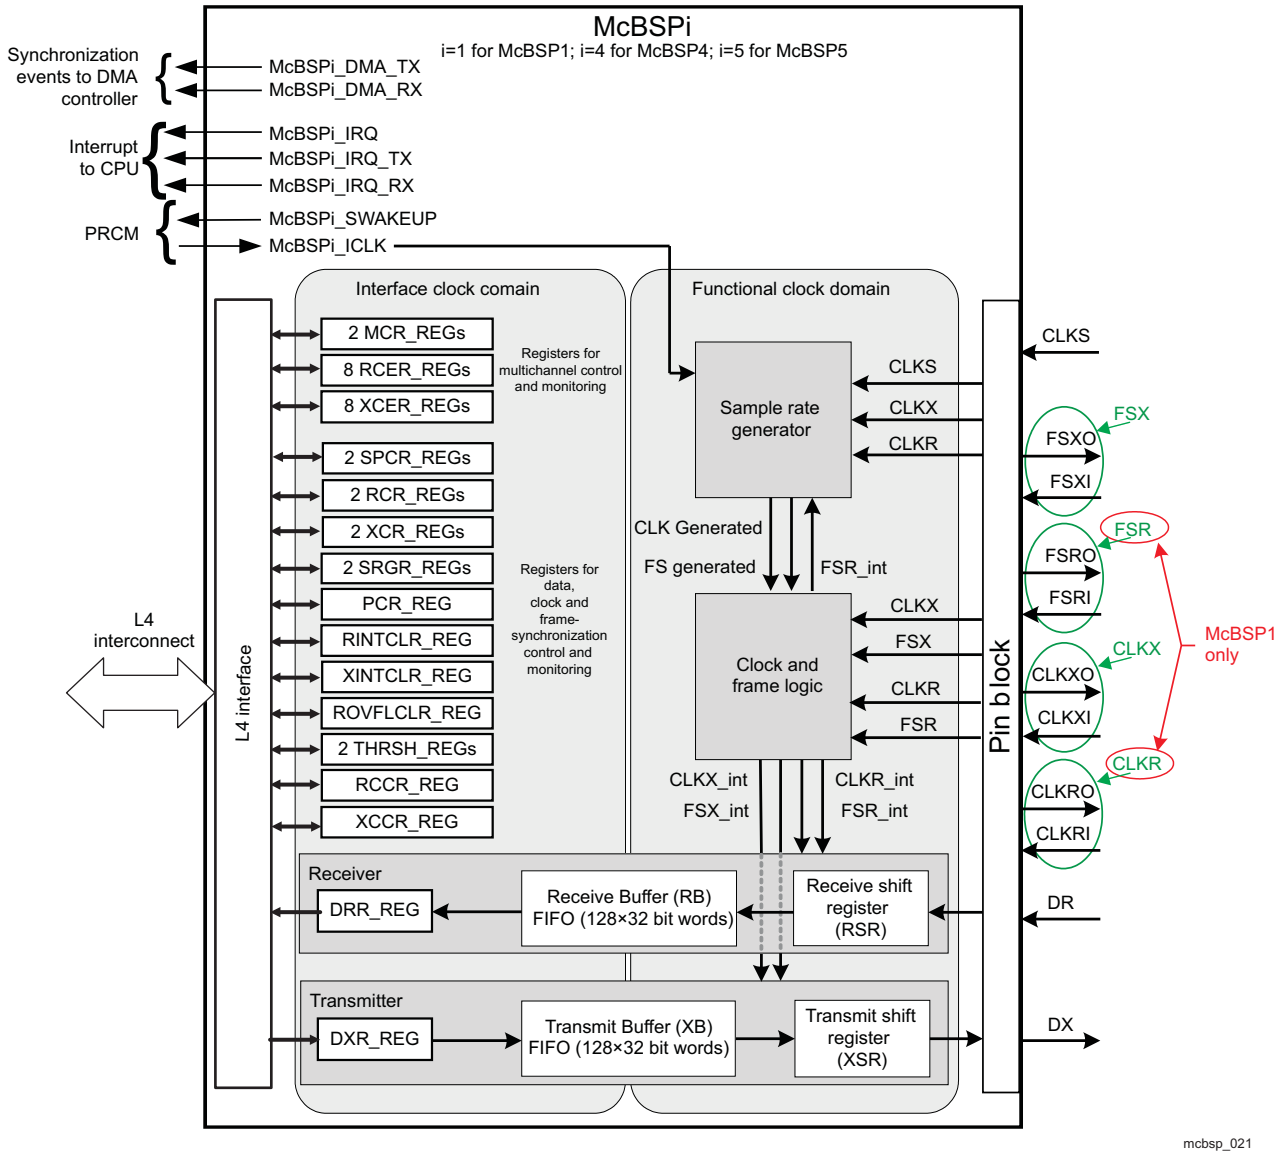

Figure 18-22. McBSP2 Block Diagram

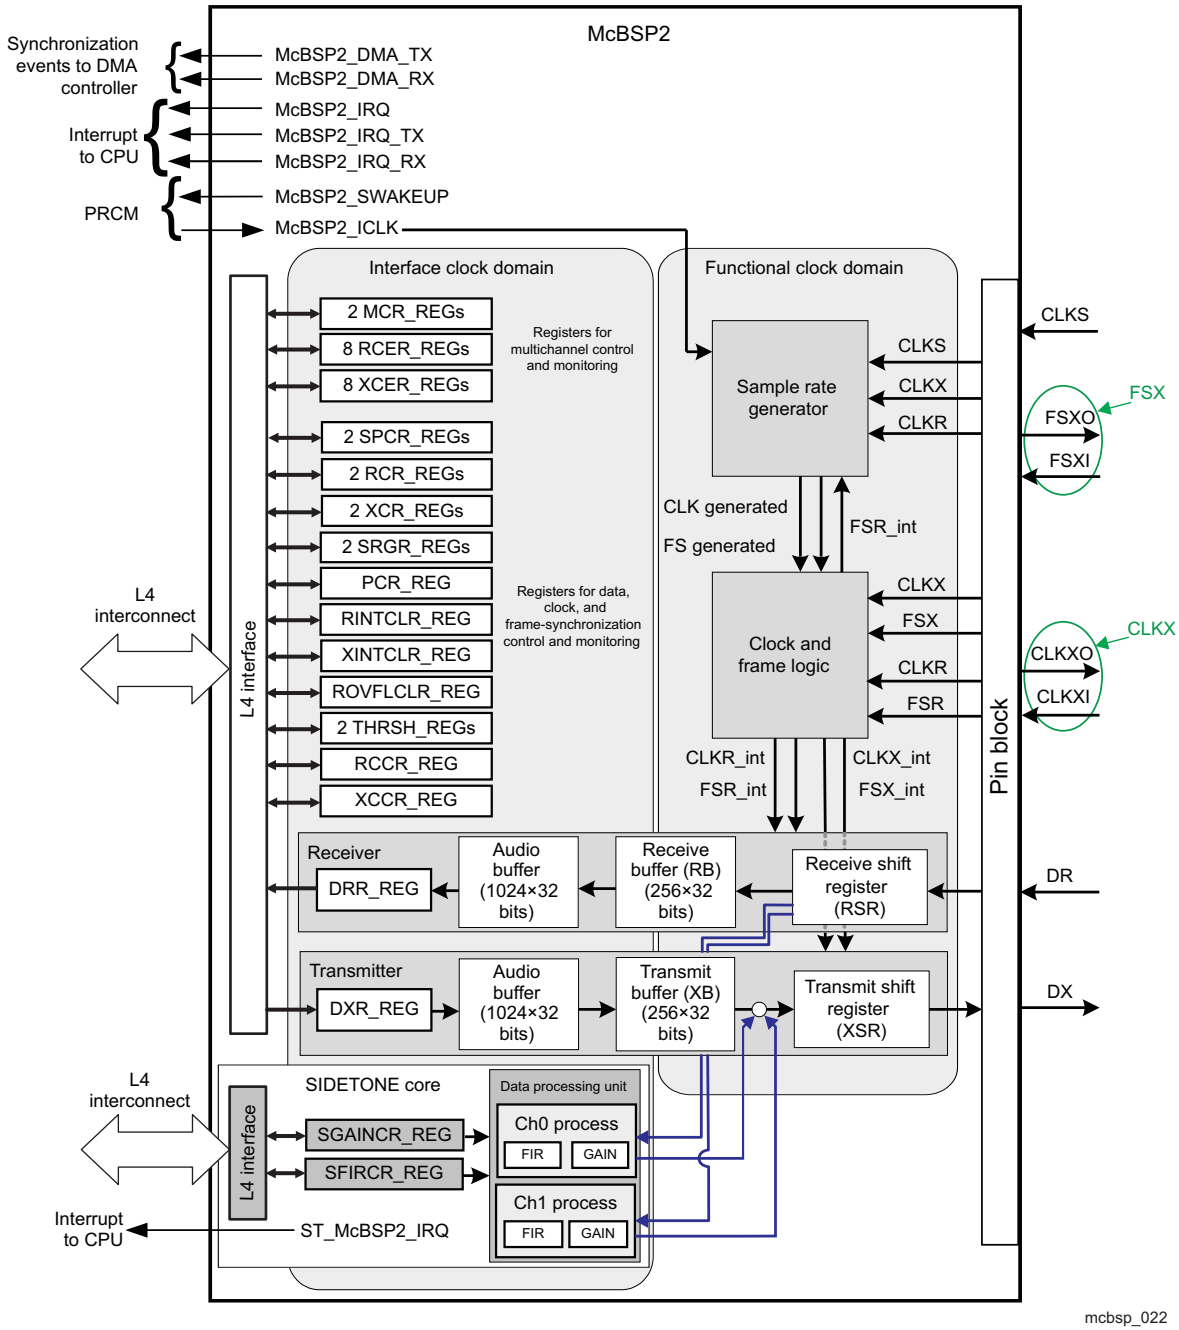

Figure 18-23. McBSP3 Block Diagram

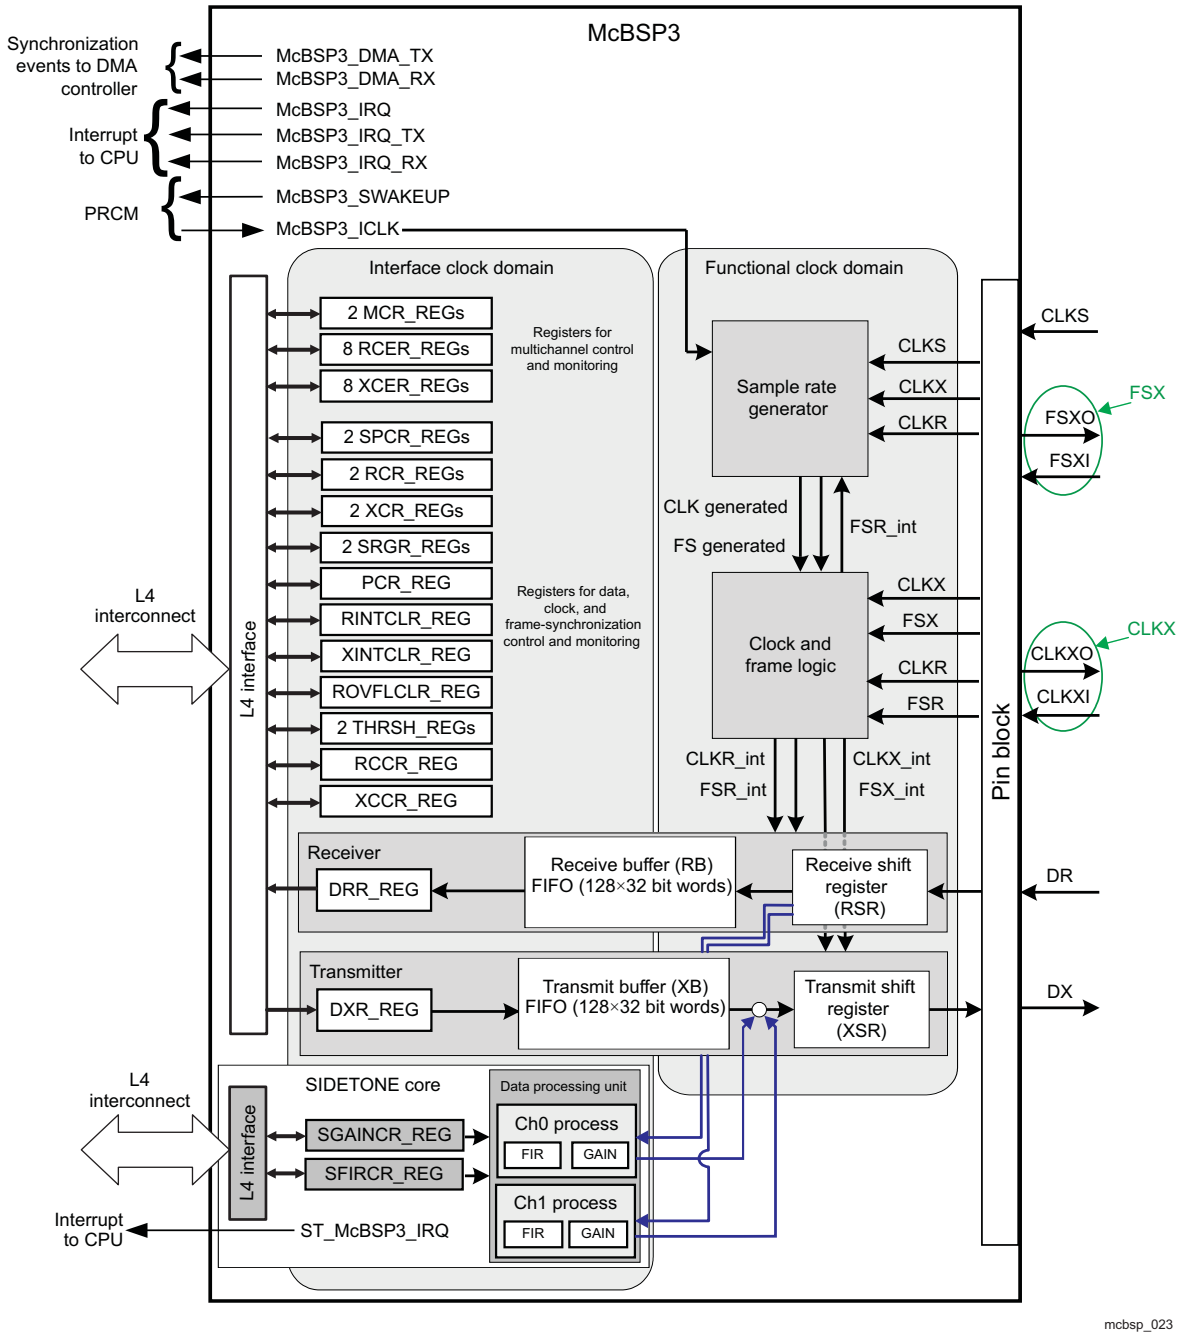

18.4.2 McBSP Data Transfer Process

For McBSP1, McBSP3, McBSP4, and McBSP5 modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

For the McBSP2 module, receive and transmit operations are quadruple-buffered (5K bytes buffers organized in 32-bit words are used). Receive and transmit buffers are separated in two memories: The same buffer as the others McBSP modules (1K bytes) and an audio buffer (4K bytes). The audio buffer is the largest one and is clocked by the interface clock, while the other buffer is used for synchronizing data to/from the audio buffer with the functional transmit/receive clock domains. Figure 18-25 shows this implementation in the McBSP2 data transfer paths.

All registers of McBSP data transfer paths are 32-bits wide. Figure 18-24 and Figure 18-25 illustrate the McBSP data transfer paths.

CAUTION

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

Figure 18-24. McBSP Data Transfer Paths

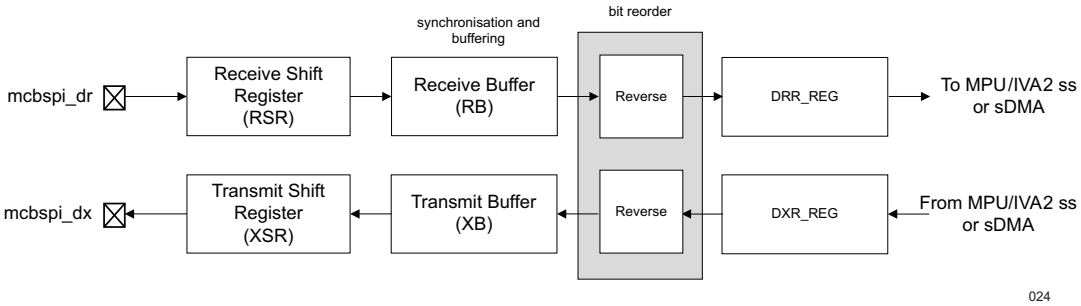

Figure 18-25. McBSP2 Data Transfer Paths

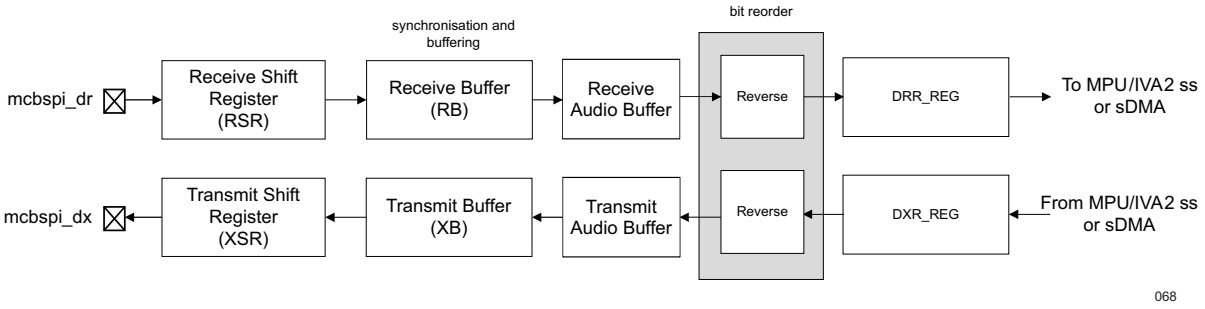


18.4.2.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

CAUTION

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, the IVA2.2 subsystem or the DMA controller to data transmit register (McBSPi.MCBSPLP_DXR_REG) using the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

18.4.2.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

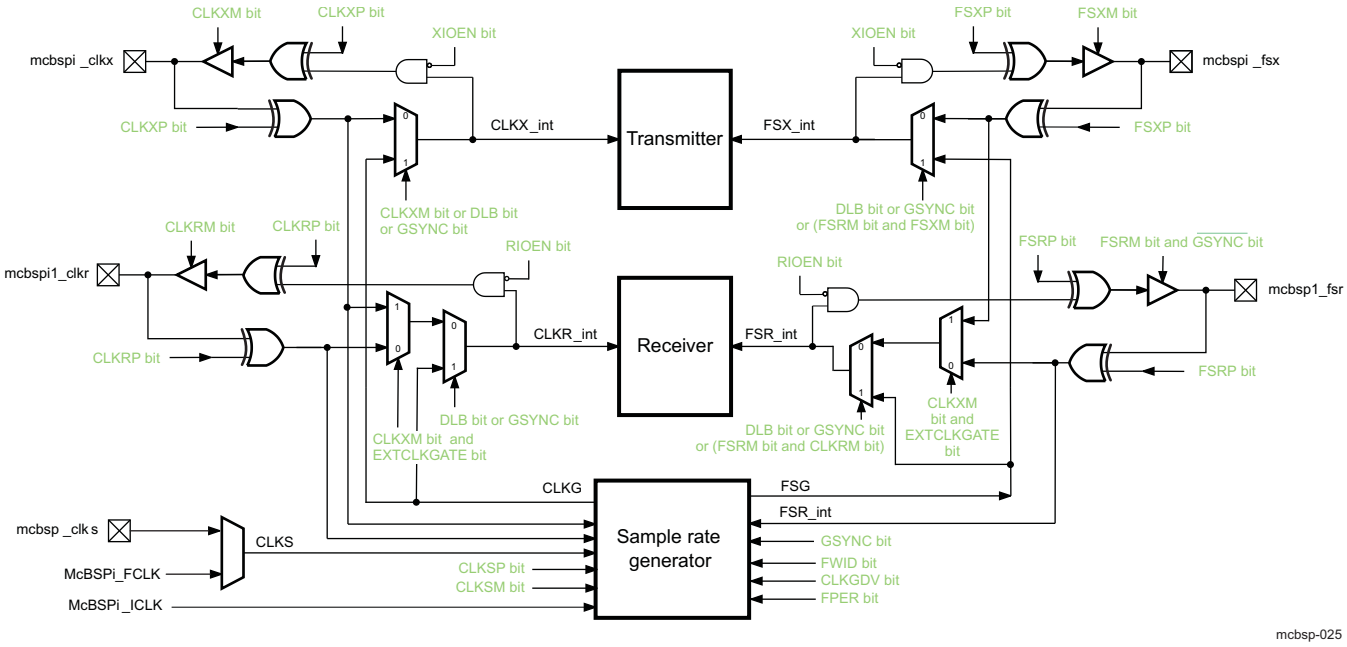
If you set McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE=0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE=0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8 up to 32-bit data length.

18.4.2.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 18-26. Conceptual Block Diagram for Clock and Frame Generation When MCBSPLP_SPCR1_REG[15] ALB = 0 and CONTROL_DEVCONF0[3] MCBSP1_CLKR = 0



The CLKR_int clock signal can be derived from three sources:

- The sample rate generator (CLKG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- mcbsp1_clkr pin (CLKR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0, and MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0
- mcbspi_clkx pin (CLKX): When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1, and MCBSPLP_XCCR_REG[5]DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0

The CLKX_int clock signal can be derived from two sources:

- The sample rate generator (CLKG): When MCBSPLP_PCR_REG[9] CLKXM = 1, MCBSPLP_XCCR_REG[5] DLB = 1, or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- mcbspi_clkx pin (CLKX): When MCBSPLP_PCR_REG[9] CLKXM = 0, MCBSPLP_XCCR_REG[5] DLB = 0, or MCBSPLP_SRGR2_REG[15] GSYNC = 0

The FSR_int frame-sync signal can be derived from three sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1, MCBSPLP_SRGR2_REG[15] GSYNC = 1, or MCBSPLP_PCR_REG[10] FSRM = 1 and MCBSPLP_PCR_REG[8] CLKRM = 1
- mcbsp1_fsr pin (FSR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0 and MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0, or MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0

- mcbspi_fsx pin (FSX): When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1, and MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0, or MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0

The FSX_int frame-sync signal can be derived from two sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1, or MCBSPLP_SRGR2_REG[12] FSGM = 1 and MCBSPLP_PCR_REG[11] FSXM = 1
- mcbspi_fsx pin (FSX): When MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0, or MCBSPLP_SRGR2_REG[12] FSGM = 0 and MCBSPLP_PCR_REG[11] FSXM = 0

18.4.2.3.1 Clocking

Data is shifted one bit at a time from the mcbspi_dr pin to the RSRs or from the XSRs to the mcbspi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the mcbspi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the mcbspi_dx pin. CLKR_int or CLKX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_clkr and mcbspi_clkx respectively) or derived from inside the McBSP module (see Figure 18-26). The clocks source is selected by programming the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit and the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit respectively.

When the McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit (transmitter clock mode) is set to:

- 0: CLKX_int is driven by an external clock and mcbspi_clkx is an input pin.
- 1: CLKX_int is driven by the internal sample rate generator and mcbspi_clkx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit (receiver clock mode), see Table 18-15.

Table 18-15. Receiver Clock Mode

Value	Digital loop back mode	mcbspi_clkr pin	Description
0x0	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	input	CLKR_int is driven by an external clock
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	High-impedance	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.
0x1	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0	output	CLKR_int is driven by the internal sample rate generator
	McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1	output	CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value.

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP defines the transmit clock polarity:

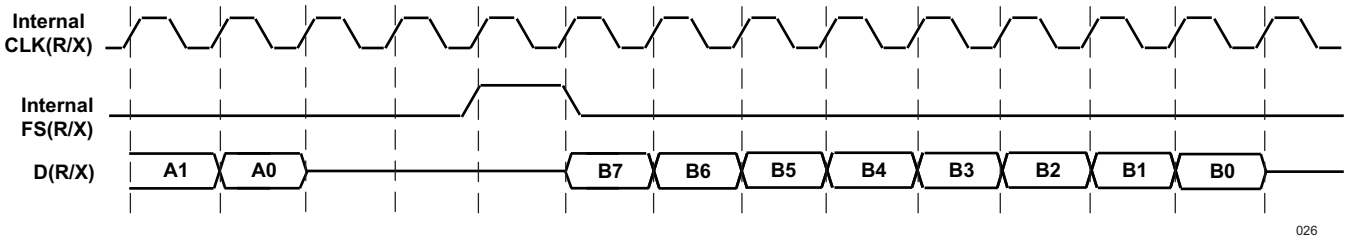
- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.MCBSPLP_PCR_REG[0] CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

Figure 18-27 gives an example where the clock signal controls the timing of each bit transfer on the pin.

Figure 18-27. Clock Signal Control of Bit Transfer Timing



NOTE: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

18.4.2.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi_dr or mcbspi_dx) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field.
- For the transmitter: the McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field.

The difference of use is explained to Section 18.4.2.4.1.

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see Section 18.6)

Bits coming from the mcbspi_dr pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the McBSPi.MCBSPLP_DRR_REG register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the mcbspi_dx pin.

In the example in Figure 18-27, an 8–bit word size was defined (see the transfer of the 8-bit word B).

18.4.2.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field.
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 field.

The difference between these registers is explained to Section 18.4.2.4.1. For the corresponding between field value and words number, see Section 18.6.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_fsr and mcbspi_fsx respectively) or derived from inside the McBSP module (see Figure 18-25). The frame-sync source is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit respectively.

When the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- 0: FSX_int is derived from an external source and mcbspi_fsx is an input pin.
- 1: FSX_int is determined by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and mcbspi_fsx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- 0: FSR_int is generated by an external source and mcbsp1_fsr is an input pin.
- 1: FSR_int is generated internally by sample rate generator. The mcbsp1_fsr is an output pin except when McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 0x1.

In the example in Figure 18-26, a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[3] FSXP defines the transmit frame-sync polarity:

- When set to 0, frame-sync pulse FSX is active high.
- When set to 1, frame-sync pulse FSX is active low.

The McBSPi.MCBSPLP_PCR_REG[2] FSRP defines the receive frame-sync polarity:

- When set to 0, frame-sync pulse FSR is active high.
- When set to 1, frame-sync pulse FSR is active low.

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

18.4.2.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the MPU/IVA2.2 subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see Section 18.5 for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.MCBSPLP_PCR_REG[0] FSRM bit/McBSPi.MCBSPLP_PCR_REG[1] FSXM bit and McBSPi.MCBSPLP_PCR_REG[2] FSRP bit/McBSPi.MCBSPLP_PCR_REG[3] FSXP bit still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (McBSPi_ICLK) and then sent to the MPU/IVA2.2 subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the MPU/IVA2.2 subsystem can take the serial port out of reset safely.

18.4.2.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see Section 18.4.4.3, or Section 18.4.4.6

18.4.2.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency/(Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses)

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

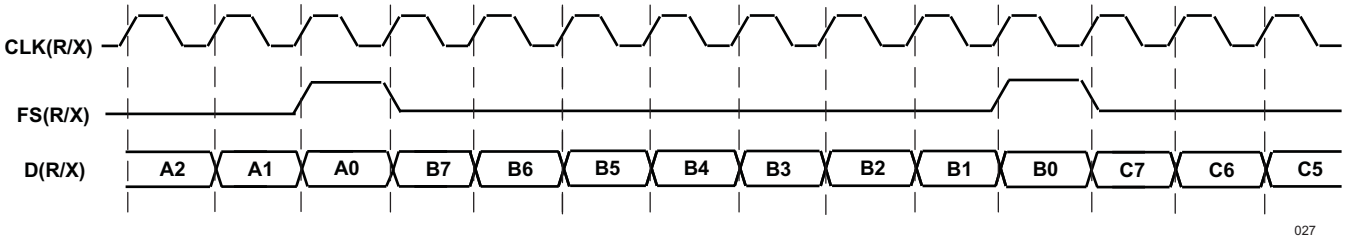
18.4.2.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = clock frequency/Number of bits per frame

Figure 18-28 below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 18-28. McBSP Operating at Maximum Packet Frequency



If there is a 1–bit data delay as shown in Figure 18-28, the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: For McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more details, see Section 18.5.1.6.2.2.5.

18.4.2.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

18.4.2.4.1 Number of Phases, Words, and Bits per Frame

Table 18-16 below shows which bit fields in the receive control registers (McBSPi.MCBSPLP_RCR1_REG and McBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (McBSPi.MCBSPLP_XCR1_REG and McBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE = McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE = McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFRLEN1 = McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field
- RFRLEN2 = McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field
- XFRLEN1 = McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field
- XFRLEN2 = McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 field
- RWDLEN1 = McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
- RWDLEN2 = McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field
- XWDLEN1 = McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
- XWDLEN2 = McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field

Table 18-16. Phases, Words and Bits per Frame Control Bit

Operation	Number of phases	Words per frame set with	Bits per word set with
Reception	1 (RPHASE=0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE=1)	RFRLEN1=0x0 and RFRLEN2=0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE=0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE=1)	XFRLEN1=0x0 and XFRLEN2=0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

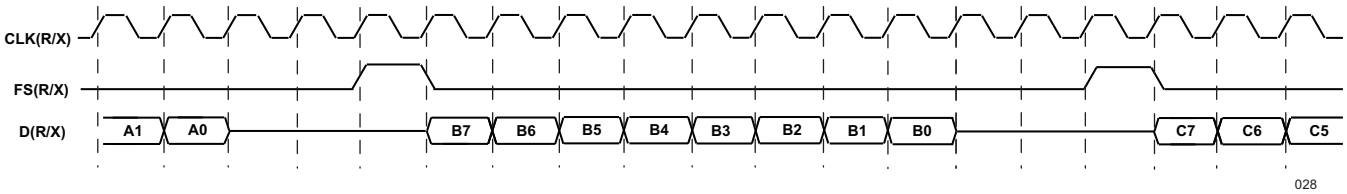
18.4.2.4.2 Single-Phase Frame Example

Figure 18-29 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi_dx and mcbspi_dr pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

Table 18-17. Assumptions for the Single-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	‘0’	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field
8-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
word length in register2	ignored	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	‘0’	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active–high frame–sync signals	‘0’	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
1-bit data delay	01b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

Figure 18-29. Single-Phase Frame for a McBSP Data Transfer



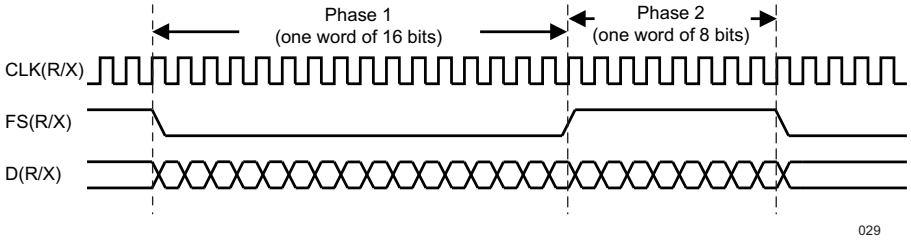
18.4.2.4.3 Dual-Phase Frame Example

Figure 18-30 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 18-18 shows the assumptions used to the example in Figure 18-30.

Table 18-18. Assumptions for the Dual-Phase Frame Example

Assumption	Value	Bit or Field name
Single-phase frame	'1'	McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
		McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
One word per frame	0x0	McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field
16-bit word length	0x0	McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
		McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
8-bit word length	0x2	McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 field
		McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field
Receive data clocked on falling edge	'0'	McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit
Transmit data clocked on rising edge		McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit
Active-high frame-sync signals	'0'	McBSPi.MCBSPLP_PCR_REG[2] FSRP bit
		McBSPi.MCBSPLP_PCR_REG[3] FSXP bit
0-bit data delay	00b	McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field
		McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field

Figure 18-30. Dual-Phase Frame for a McBSP Data Transfer



18.4.2.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see Section 18.5, Section 18.5.1.4, and Section 18.5.1.5.

Figure 18-31 and Figure 18-32 below show how reception occurs in the McBSP module. A description of the process follows the figures. Figure 18-31 shows the physical path for the data.

Figure 18-31. McBSP Reception Physical Data Path

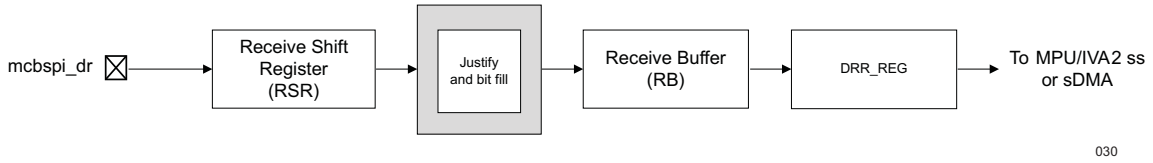


Figure 18-32 is a timing diagram showing signal activity for one possible reception scenario.

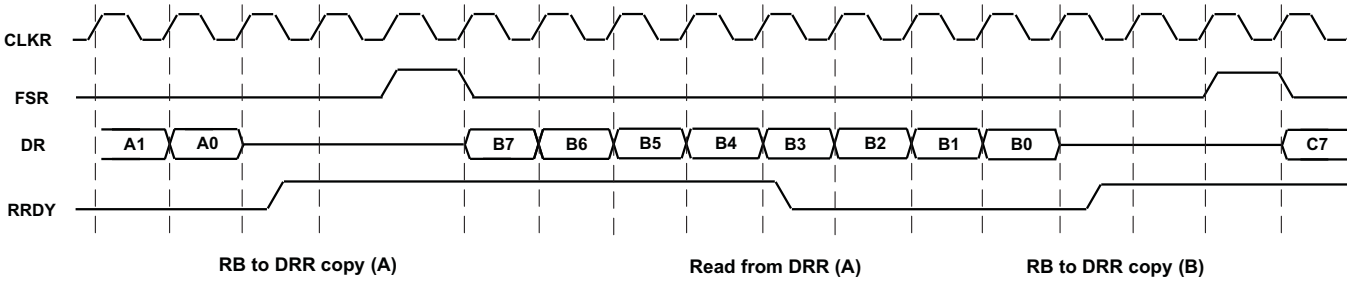
Figure 18-32. McBSP Reception Signal Activity



RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi_dr pin to the MPU/IVA2.2 subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on FSR_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi_dr pin and shifts them into the RSR. For details on choosing a word length, see Section 18.5.1.5.2.2.2.
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP_THRSH1_REG[10:0] RTHRESHOLD field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit). This indicates that receive data is ready to be read by the MPU/IVA2.2 subsystem or the sDMA controller by accessing McBSPi.MCBSPLP_DRR_REG register.

   The data copied from RB to McBSPi.MCBSPLP_DRR_REG is justified and bit filled according to the McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST field.
6. The MPU/IVA2.2 subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

18.4.2.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see Section 18.5, and Section 18.5.1.6.

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. Figure 18-33 shows the physical path for the data.

Figure 18-33. McBSP Transmission Physical Data Path

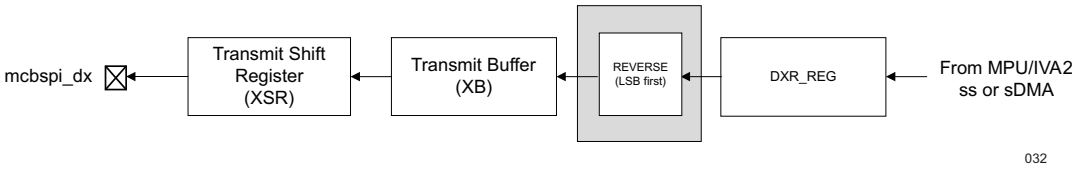


Figure 18-34 is a timing diagram showing signal activity for one possible transmission scenario.

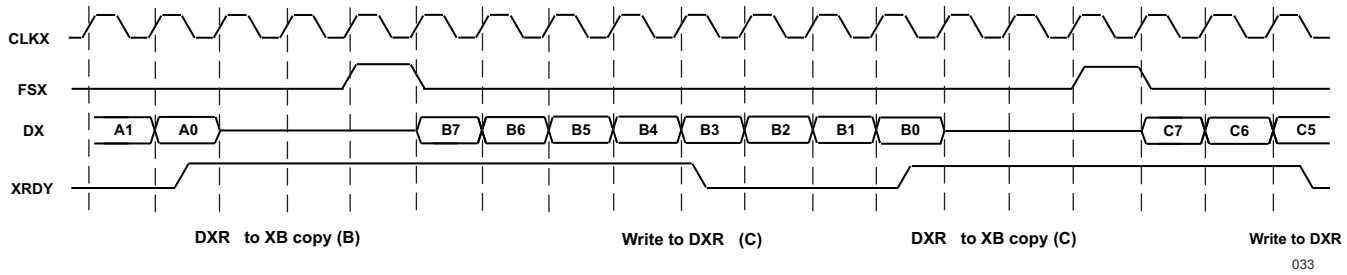
Figure 18-34. McBSP Transmission Signal Activity



XRDY: Status of transmitter ready bit (high is 1)

1. The MPU/IVA2.2 subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see Section 18.5.1.6.2.2.2.
2. When new data arrives in McBSPi.MCBSPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPLP_THRSH2_REG[10:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/IVA2.2 subsystem or the sDMA controller.
3. The McBSP module waits for a transmit frame-synchronization pulse on FSX_int.
4. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field.

   In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

18.4.2.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX / McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT field indicating the occupied/available buffer locations), since this register is an interface clock (McBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

18.4.2.8 MCBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit = 0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit = 0x0). These are the reset values.

In the following timing diagrams, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field = 0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field = 0x01), because data often follows a 1-cycle active frame-synchronization.

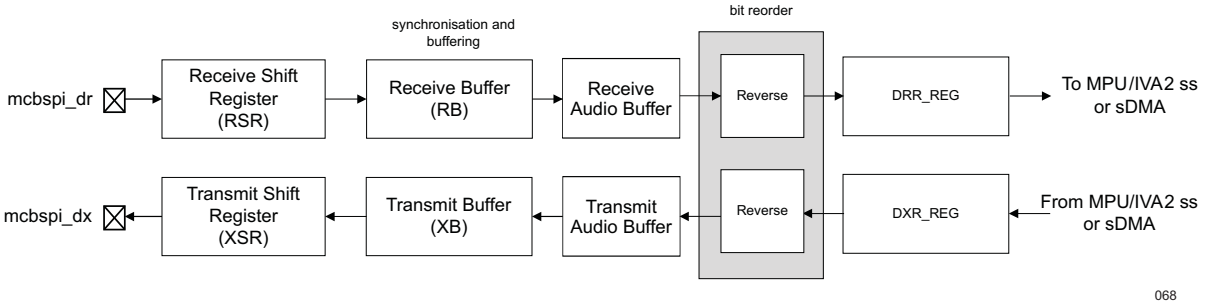
McBSP modules can support two edge selection modes for transmit and receive data transfer at the system level:

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). A new data is generated only every clock period, which permits to ensure the required hold time.

18.4.2.8.1 Transmit Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 18-35.

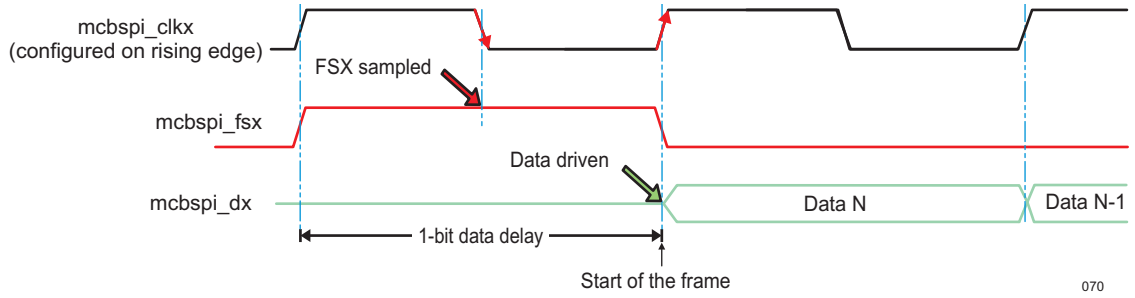
Figure 18-35. Transmit Full Cycle Timing Diagram



18.4.2.8.2 Transmit Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 18-36.

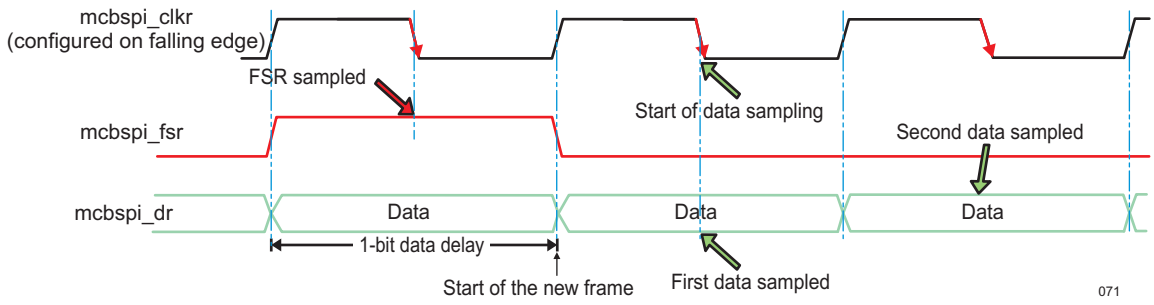
Figure 18-36. Transmit Half Cycle Timing Diagram



18.4.2.8.3 Receive Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 18-37.

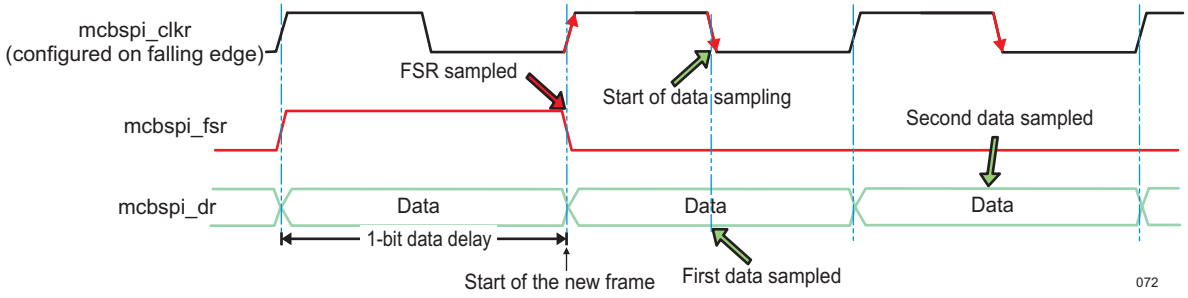
Figure 18-37. Receive Full Cycle Timing Diagram



18.4.2.8.4 Receive Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 18-38.

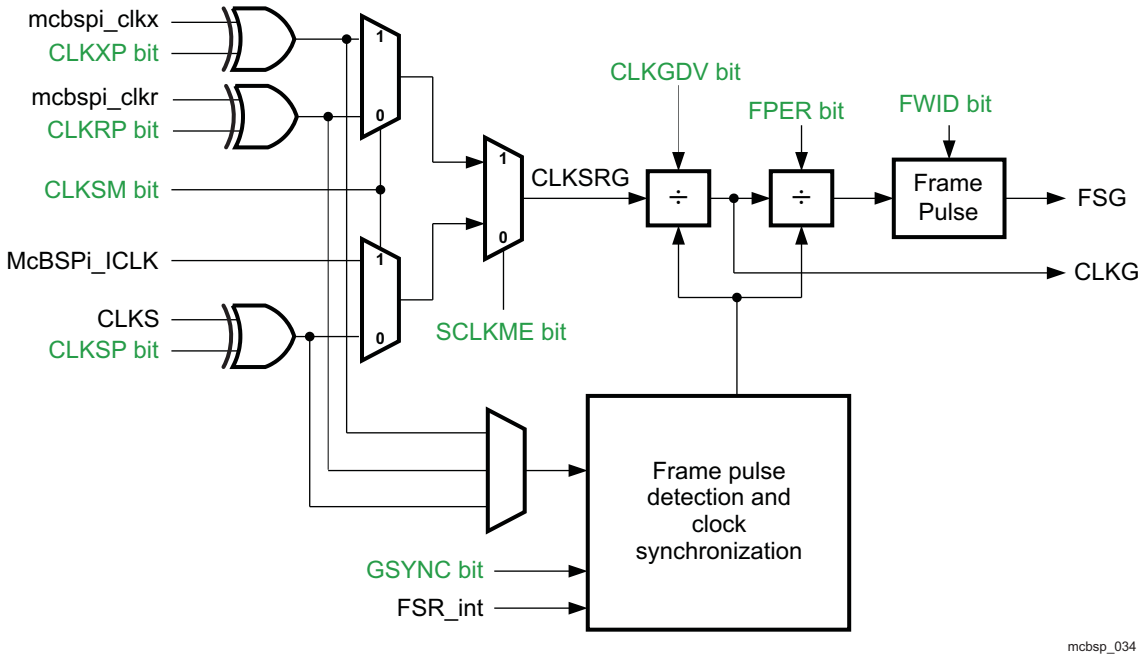
Figure 18-38. Receive Half Cycle Timing Diagram



18.4.3 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi_dr) and/or the data transmit pin (mcbspi_dx). FSG can be used to initiate frame transfers on mcbspi_dr pin and/or mcbspi_dx pin. Figure 18-39 is a conceptual block diagram of the SRG.

Figure 18-39. Conceptual Block Diagram of the Sample Rate Generator



The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by either the interface clock (McBSPi_ICLK), or the functional clock (CLKS input), or by an external pin (mcbspi_clkx, or mcbspi_clkr). The source is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit, or McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit).

The SRG has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field to control the width of each frame-synchronization pulse

NOTE: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbspi_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPi.MCBSPLP_PCR_REG[9] CLKXM / McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see Figure 18-26).

For details on getting the sample rate generator ready for operation, see Section 18.5.

18.4.3.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in Table 18-19. The ALB mode is selected with the McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the System Control Module (more details, refer Section 18.3.1)

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit =1).

Table 18-19. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM=1	DLB=0 and ALB = 0 (Digital and analog loop back mode disabled)	mcbsp1_clkr is an output pin driven by the SRG output clock (CLKG).
	DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbsp1_clkr is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by CLKX input signal provided by mcbspi_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input signal provided by mcbspi_fsx pin. The receive data is driven by the DX input loop-back pin (mcbspi_dx).
	DLB=1 ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 ALB = 1 (reserved mode)	Undefined functionality.

Table 18-19. Effects of DLB and ALB Bits on Clock Modes (continued)

Mode Bit Settings		Effect
CLKXM= 1	DLB=0 ALB = 0 (Digital analog loop back mode disabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=0 ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled)	mcbspi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB=1 ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled)	The SRG and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device.
	DLB=1 ALB = 1 (reserved mode)	Undefined functionality.
	SCM.CONTROL_DEVCONF0[3] MCBSP1_CLKR bit =1 (synchronous setting and DLB = 0 ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

18.4.3.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.MCBSPLP_PCR_REG[10] FSRM bit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbspi_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbspi_fsx pin.
- MCBSPLP_SRGR2_REG[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit=0).

18.4.3.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

18.4.3.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit =1, FSG pulses in response to an inactive-to-active transition on the mcbspi_fsr pin. Thus, an external device controls the frame-synchronization period.
- Otherwise, the software program the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field, and the

resulting frame-synchronization period is (FPER+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

18.4.3.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to configure the timing of FSG pulses.

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1, an inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG and generation of FSG.

18.4.3.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (McBSPi_ICLK), or the CLKS signal (PRCM functional clock or mcbsp_clks), or a signal at the mcbspi_clkr, or mcbspi_clkx pin. When an external clock (mcbsp_clks, or mcbspi_clkr, or mcbspi_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=1:

- An inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the mcbspi_fsr pin.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field.

18.4.3.3.1 Operating the Transmitter Synchronously with the Receiver

When the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (McBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1 and McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting McBSPi.MCBSPLP_PCR_REG[11] FSXM=0 and connecting FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit and McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

18.4.3.3.2 Synchronization Examples

Figure 18-40 and Figure 18-41 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbspi_fsr pin.

Each figure shows what happens to CLKG signal when the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. Figure 18-41 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field).

Figure 18-40. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

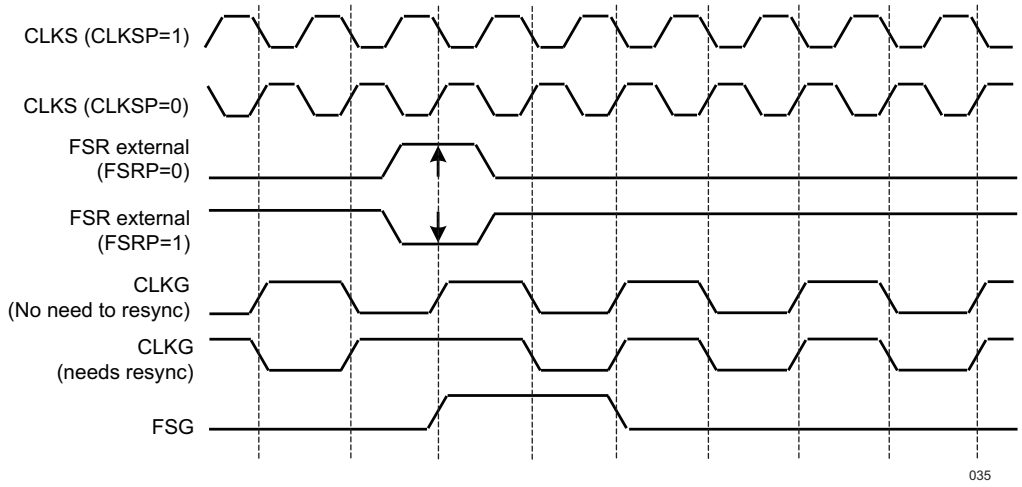


Figure 18-41. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)

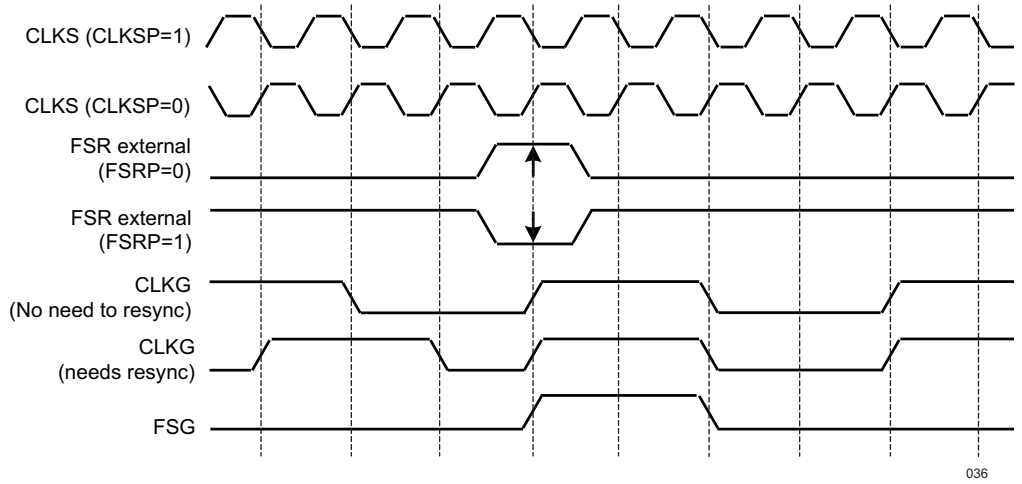


18.4.4 McBSP Exception/Error Conditions

18.4.4.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1)

  This occurs when RB is full and RSR are full with another new word shifted in from mcbspi_dr. Therefore, McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT (McBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi_dr and McBSPi.MCBSPLP_DRR_REG register is not read. For more details about overrun in the receiver, see Section 18.4.4.2.
- Unexpected receive frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[0]

RSYNCERR bit is set to 1, and legacy mode McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to 1).

This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see Section 18.4.4.3, *Unexpected Receive Frame-Sync Pulse*.

- Receiver underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to '1')

  This occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see Section 18.4.4.4.

- Transmitter underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to '0')

  If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see Section 18.4.4.5.

- Unexpected transmit frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit is set to '1')

  This occurs during transmission when an unexpected frame-synchronization pulse arrives. An unexpected pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more details see Section 18.4.4.6.

- Transmitter overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to '1')

  This occurs when sDMA controller or MPU/IVA2.2 subsystem writes data to a full XB. For more details about underflow in the receiver, see Section 18.4.4.7.

18.4.4.2 Overrun in the Receiver

When McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit set to '1', and McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP_DRR_REG is not read even if the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on mcbspi_dr is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

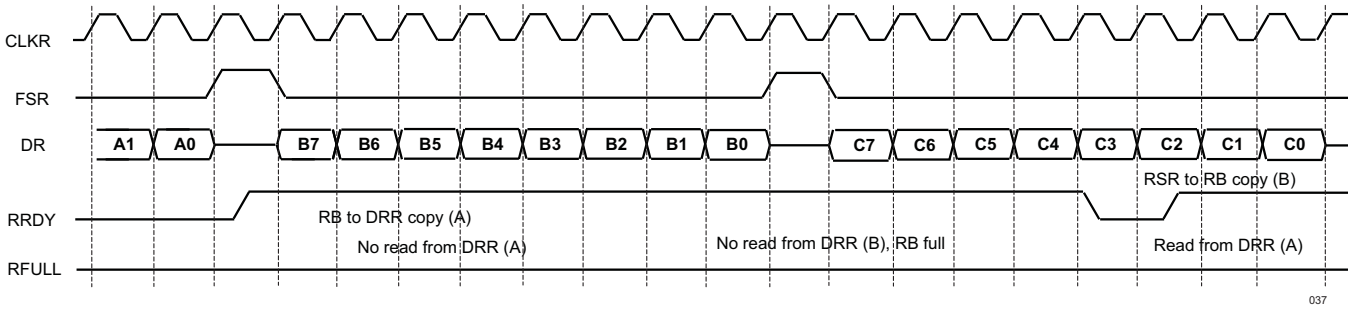
- The MPU/IVA2.2 subsystems or sDMA controller reads McBSPi.MCBSPLP_DRR_REG.
- The receiver is reset individually (McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

Figure 18-42 shows the receive overrun condition.

Figure 18-42. Overrun in the McBSP Receiver



18.4.4.3 Unexpected Receive Frame-sync Pulse

18.4.4.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit).

According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

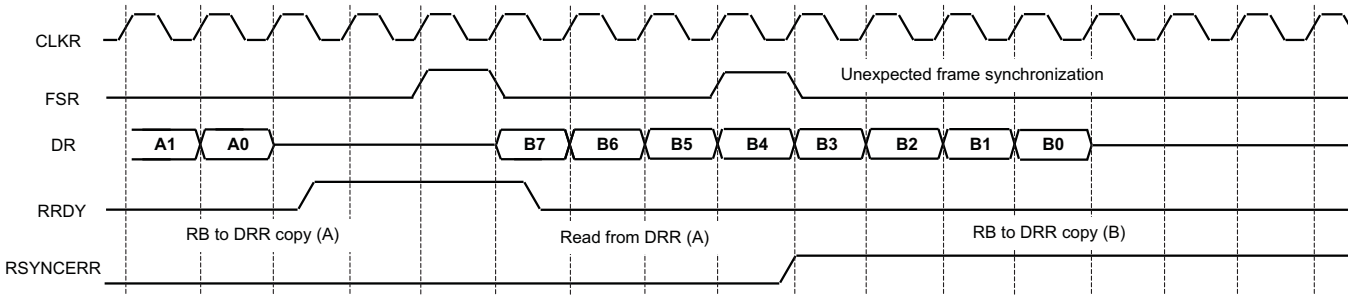
Using the legacy mode, McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM field. When RINTM = 0b11, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/IVA2.2 subsystems each time that RSYNCERR is set.

18.4.4.3.2 Example of an Unexpected Receive Frame-sync Pulse

Figure 18-43 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

NOTE: The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

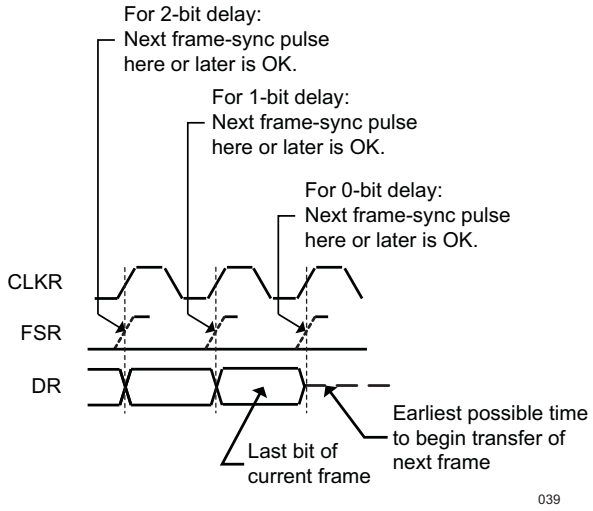
Figure 18-43. Unexpected Frame-sync Pulse During a McBSP Reception



18.4.4.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field. For each possible data delay, Figure 18-44 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 18-44. Proper Positioning of Receive Frame-sync Pulses



18.4.4.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty RB this happens only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

18.4.4.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit. Also the legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is cleared. Either of the following events activates XEMPTY bit (XEMPTY = 0):

- McBSPi.MCBSPLP_DXR_REG has not been loaded and XB is empty, and all bits of the data word in the XSR have been shifted out on the mcbspi_dx pin.
- The transmitter is reset (by forcing McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0, or by an global reset) and is then restarted.

XEMPTY bit is deactivated (XEMPTY=1) when a new word in McBSPi.MCBSPLP_DXR_REG is transferred to Transmit Buffer (XB). If McBSPi.MCBSPLP_PCR_REG[11] FSXM=1 and McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=0, the transmit frame-sync signal (FSX) is generated when Transmit Buffer (XB) is not empty. When McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=0, McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID are used to determine the frame-synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on mcbspi_dx.

When the transmitter is taken out of reset (McBSPi.MCBSPLP_SPCR2_REG[0] XRST=1), it is in a transmitter ready state (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit =1) and transmitter empty (McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY=0) state. If McBSPi.MCBSPLP_DXR_REG is loaded by the MPU/IVA2.2 subsystem or the sDMA controller before internal FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before McBSPi.MCBSPLP_DXR_REG is loaded, zeros are output on mcbspi_dx.

The McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

18.4.4.6 Unexpected Transmit Frame-sync Pulse

18.4.4.6.1 Possible Responses to Transmit Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

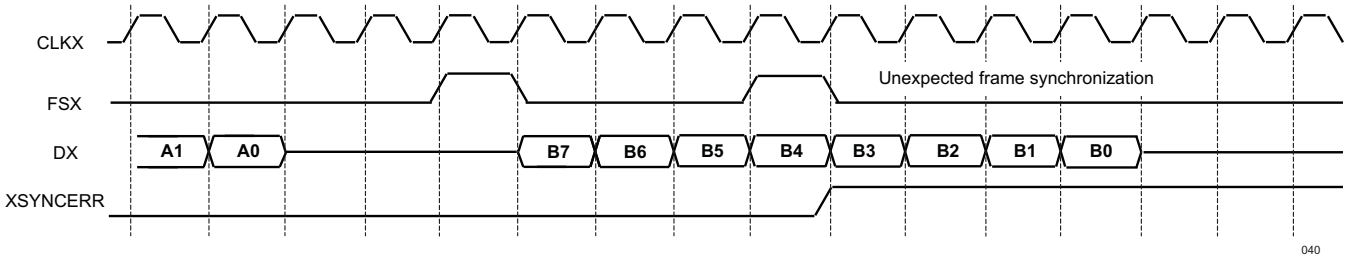
Using the legacy mode, McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/IVA2.2 subsystem each time that XSYNCERR is set.

18.4.4.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 18-45 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

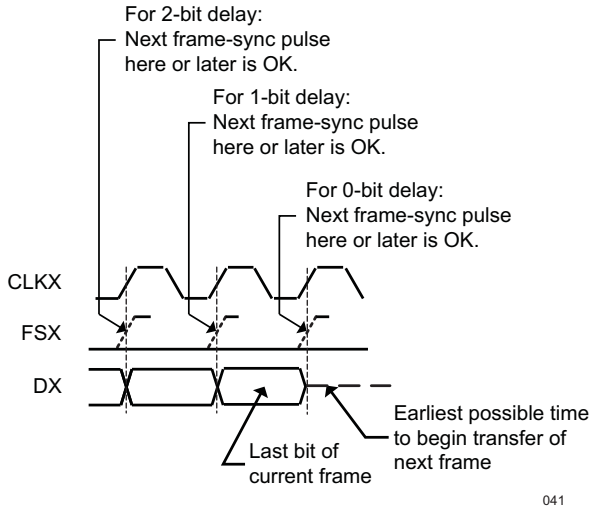
Figure 18-45. Unexpected Frame-sync Pulse During a McBSP Transmission



18.4.4.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field. For each possible data delay, Figure 18-46 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 18-46. Proper Positioning of Transmit Frame-sync Pulses



18.4.4.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem write data to a full XB (this may happen only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

18.4.5 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive McBSPi.MCBSPLP_SPCR1_REG[0] RRST and transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN, McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through McBSPi.MCBSPLP_THRSH1_REG and McBSPi.MCBSPLP_THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

NOTE: The MPU/IVA2.2 subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/IVA2.2 subsystem) and the common interrupt line (McBSPi_IRQ) can be used. The McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status McBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/IVA2.2 subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/IVA2.2 subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

18.4.6 Multichannel Selection Modes

18.4.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each:

- Block 0: Channels 0–15
- Block 1: Channels 16–31
- Block 2: Channels 32–47
- Block 3: Channels 48–63
- Block 4: Channels 64–79
- Block 5: Channels 80–95
- Block 6: Channels 96–111
- Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in Section 18.4.6.6, you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode Section 18.4.6.4, blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

18.4.6.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode Section 18.4.6.5, and three transmit multichannel selection modes Section 18.4.6.7.

18.4.6.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit = 0). Each frame represents a TDM data stream.

- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If RFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

18.4.6.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME = 1 for reception, McBSPi.MCBSPLP_MCR2_REG[9] XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK and McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK, and McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK and McBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bit fields are ignored, and the 16 channel blocks are assigned to the partitions as shown in Table 18-20 through Table 18-21. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 18-20. Eight Partitions – Receive Channel Assignment and Control

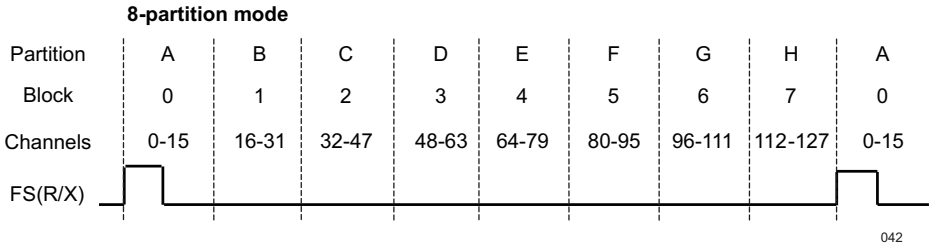
Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi.MCBSPLP_RCERA_REG
B	Block 1: Channels 16 through 31	McBSPi.MCBSPLP_RCERB_REG
C	Block 2: Channels 32 through 47	McBSPi.MCBSPLP_RCERC_REG
D	Block 3: Channels 48 through 63	McBSPi.MCBSPLP_RCERD_REG
E	Block 4: Channels 64 through 79	McBSPi.MCBSPLP_RCERE_REG
F	Block 5: Channels 80 through 95	McBSPi.MCBSPLP_RCERF_REG
G	Block 6: Channels 96 through 111	McBSPi.MCBSPLP_RCERG_REG
H	Block 7: Channels 112 through 127	McBSPi.MCBSPLP_RCERH_REG

Table 18-21. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0 through 15	McBSPi.MCBSPLP_XCERA_REG
B	Block 1: Channels 16 through 31	McBSPi.MCBSPLP_XCERB_REG
C	Block 2: Channels 32 through 47	McBSPi.MCBSPLP_XCERC_REG
D	Block 3: Channels 48 through 63	McBSPi.MCBSPLP_XCERD_REG
E	Block 4: Channels 64 through 79	McBSPi.MCBSPLP_XCERE_REG
F	Block 5: Channels 80 through 95	McBSPi.MCBSPLP_XCERF_REG
G	Block 6: Channels 96 through 111	McBSPi.MCBSPLP_XCERG_REG
H	Block 7: Channels 112 through 127	McBSPi.MCBSPLP_XCERH_REG

Figure 18-47 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 18-47. McBSP Data Transfer in 8-Partition Mode



18.4.6.5 Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:
  - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG to McBSPi.MCBSPLP_RCERH_REG). The channels are assigned to the McBSPi.MCBSPLP_RCERA_REG to McBSPi.MCBSPLP_RCERH_REG registers depends on the number of receive channel partitions (2 or 8), as defined by the McBSPi.MCBSPLP_MCR1_REG[9] RMCME bit.
  - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the mcbspi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the mcbspi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the mcbspi_dr pin in channel 39

18.4.6.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME = 0 for reception, McBSPi.MCBSPLP_MCR2_REG[9] XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A

(McBSPi.MCBSPLP_RCERA_REG).

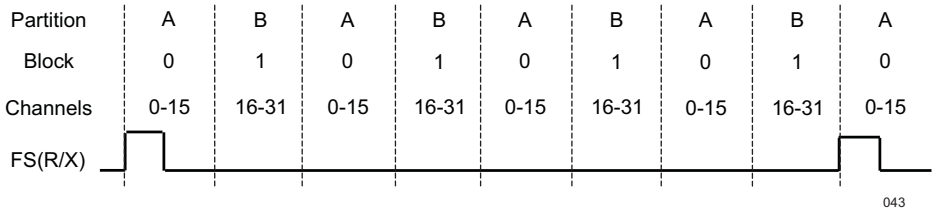
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK fields. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] XPBBLK field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP_XCERB_REG).

Figure 18-48 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 18-48. Alternating Between Partitions A and B Channels



18.4.6.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 18-22.

Table 18-22. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
0b00	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers.

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

18.4.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in Table 18-23 explain the channel control options:

Table 18-23. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through XB.
Masked channel	A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR–to–XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM=00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin.

18.4.6.7.2 Activity on McBSP Pins for Different Values of XMCM

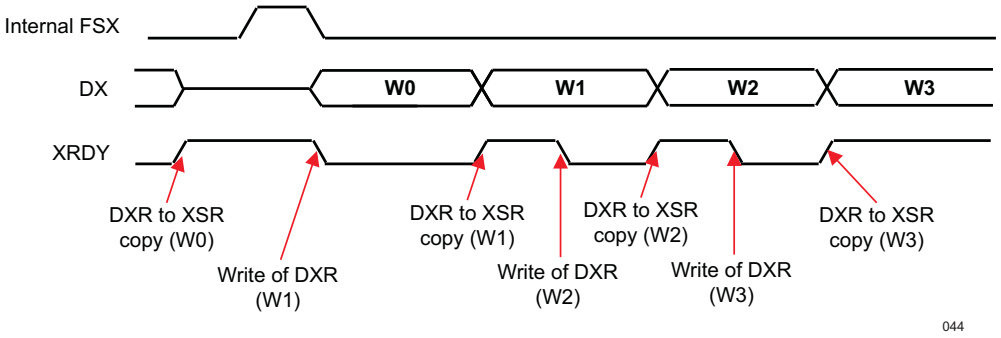
Figure 18-49 shows the activity on the McBSP pins for the various McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single–phase frame (required for multichannel selection modes)
- XFRLEN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2–partition mode (only partitions A and B used)

In the case where McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

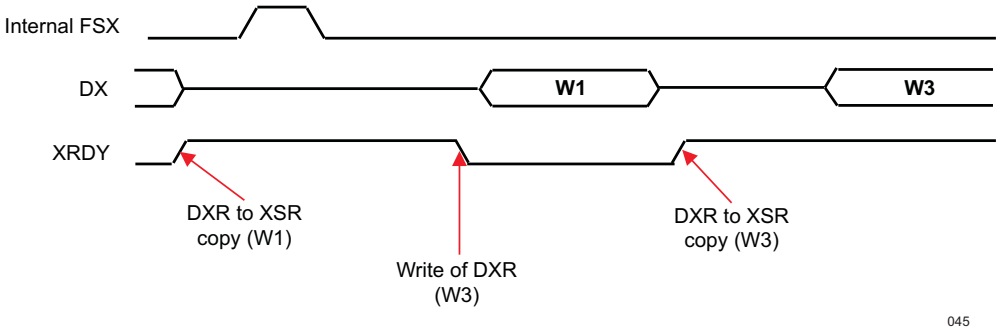
In Figure 18-49, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 18-49. Activity on McBSP Pins When XMCM=0b00



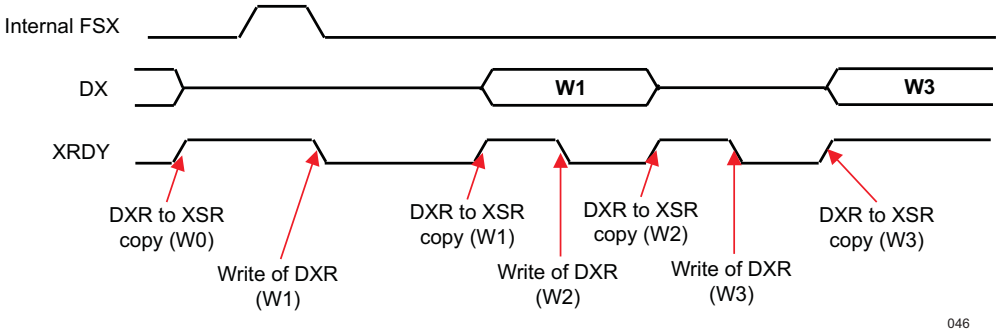
If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 18-50. Activity on McBSP Pins When XMCM=0b01



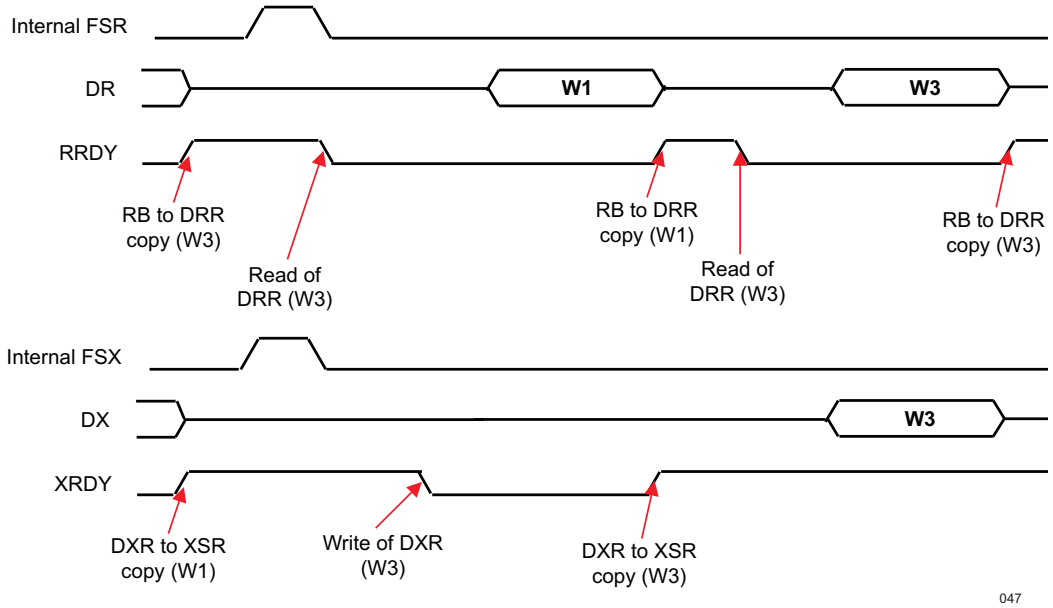
In Figure 18-50 if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 18-51. Activity on McBSP Pins When XMCM=0b10



In Figure 18-51 if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi_dx.

Figure 18-52. Activity on McBSP Pins When XMCM=0b11



In Figure 18-52 if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi_dx.

18.4.7 SIDETONE Mode (ALP)

18.4.7.1 Introduction

In multimedia-rich mobile communication devices, loopback signals from audio inputs to audio outputs are renamed. A traditional example is the telephone SIDETONE (that is, the telephone user expects to also hear his own voice in the earpiece).

Some of the features using the loopback have strict delay requirements.

It is required that two of the audio input channels be looped back, filtered, and mixed to the corresponding two audio output channels. The SIDETONE mode filters and applies gain to each sample received.

18.4.7.2 SIDETONE Interface

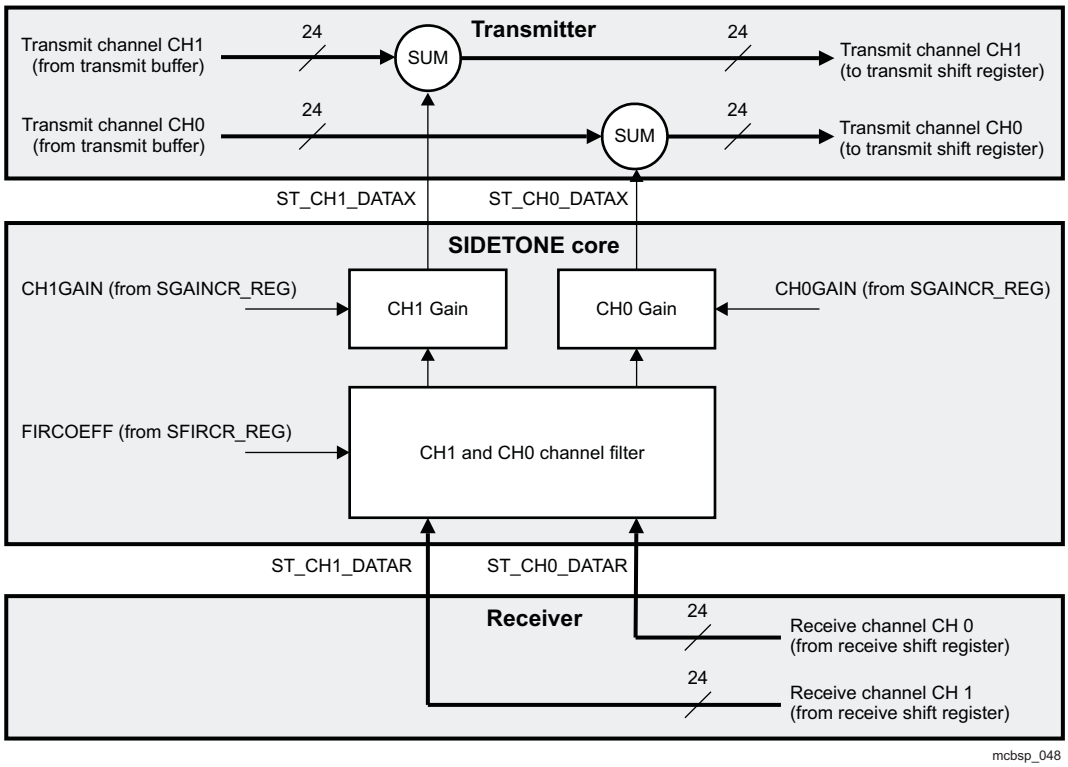
The data from digital microphone, two (out of four) channels, can be configured to be input in the external SIDETONE core. After filtering, the data from digital microphone data is mixed and sent out to the speaker output channels using two (out of eight) configured output channels (separate configuration bits are used). The McBSP module synchronizes the incoming data (filtered by the external SIDETONE core). The transmit and receive part of the McBSP module are not required to operate on the same functional frequency.

The SIDETONE interface offers the following features:

- Send out two 24-bit data channels for the configured SIDETONE received channels (channels can be the same)
- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 18-53 shows the SIDETONE external module data path:

Figure 18-53. SIDETONE Data Path



Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel and SIDETONE mode:

- Select a single–phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.MCBSPLP_MCR1_REG[0] RMCM=1 to select multichannel mode enable.
- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field) that includes the highest–numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see note).
- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN , McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit to 1.

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 18-54 describes the data exchange protocol between McBSP module and SIDETONE core:

Figure 18-54. McBSP to SIDETONE Data Exchange

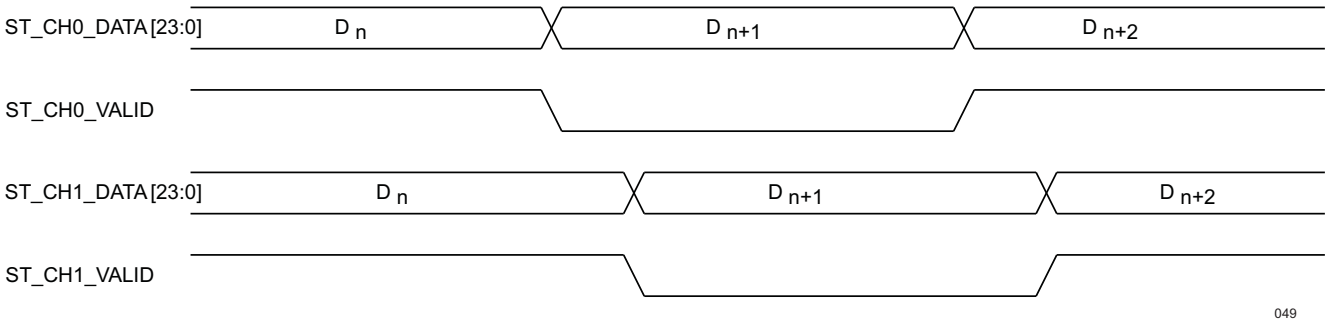


Figure 18-55 describes the data exchange protocol between SIDETONE core and McBSP module:

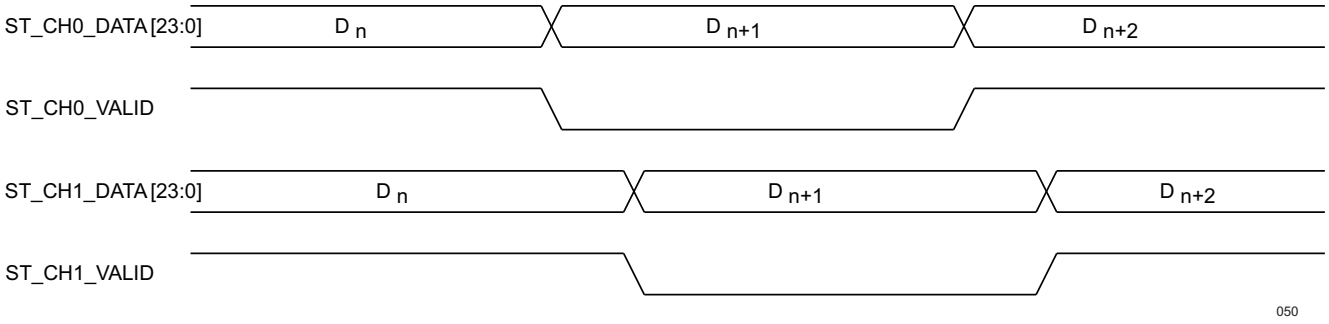
Figure 18-55. SIDETONE to McBSP Data Exchange



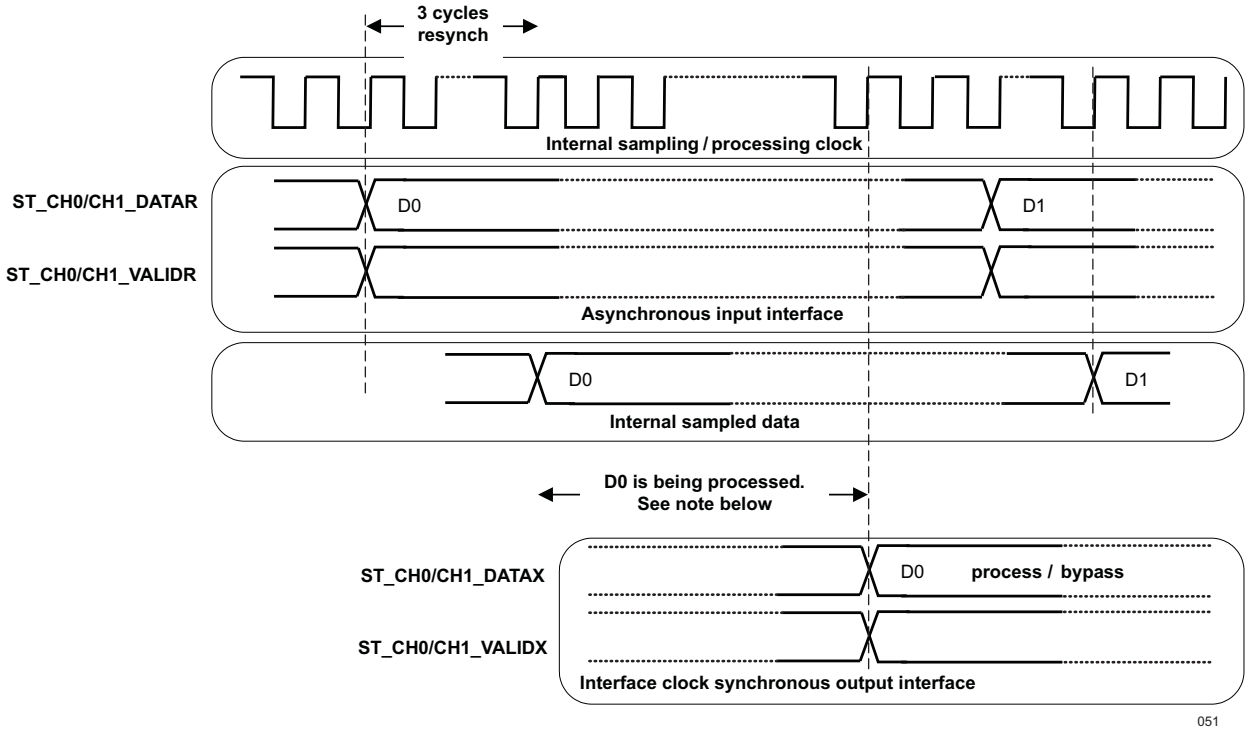
NOTE: To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

18.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

Figure 18-56 below describes how the data is sampled and output through the dedicated data interfaces.

Figure 18-56. SIDETONE Processed Data Interfaces



NOTE: The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The ST_CH0_VALIDR and ST_CH1_VALIDR are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from ST_CH0_DATAR / ST_CH1_DATAR.

The ST_CH0_VALIDX and ST_CH1_VALIDX are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus ST_CH0_DATAX / ST_CH1_DATAX.

18.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

18.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.
|C0| + |C1| + … + |C127| 1

CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

18.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.ST_SGAINCR_REG. The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

18.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.ST_SSELCR_REG[0] SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST_CH0/CH1_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.ST_SSELCR_REG[0] SIDETONEEN from 0 to 1 triggers this initialization process).

NOTE: After reset, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit is 0.

18.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the LSBs are truncated.

18.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled , the McBSPi.ST_IRQSTATUS_REG[0] OVRRERROR bit in is set and, if McBSPi.ST_IRQENABLE_REG[0] OVRRERROREN bit is set to 1, the interrupt line is asserted.

18.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

18.5.1 McBSP Core

CAUTION

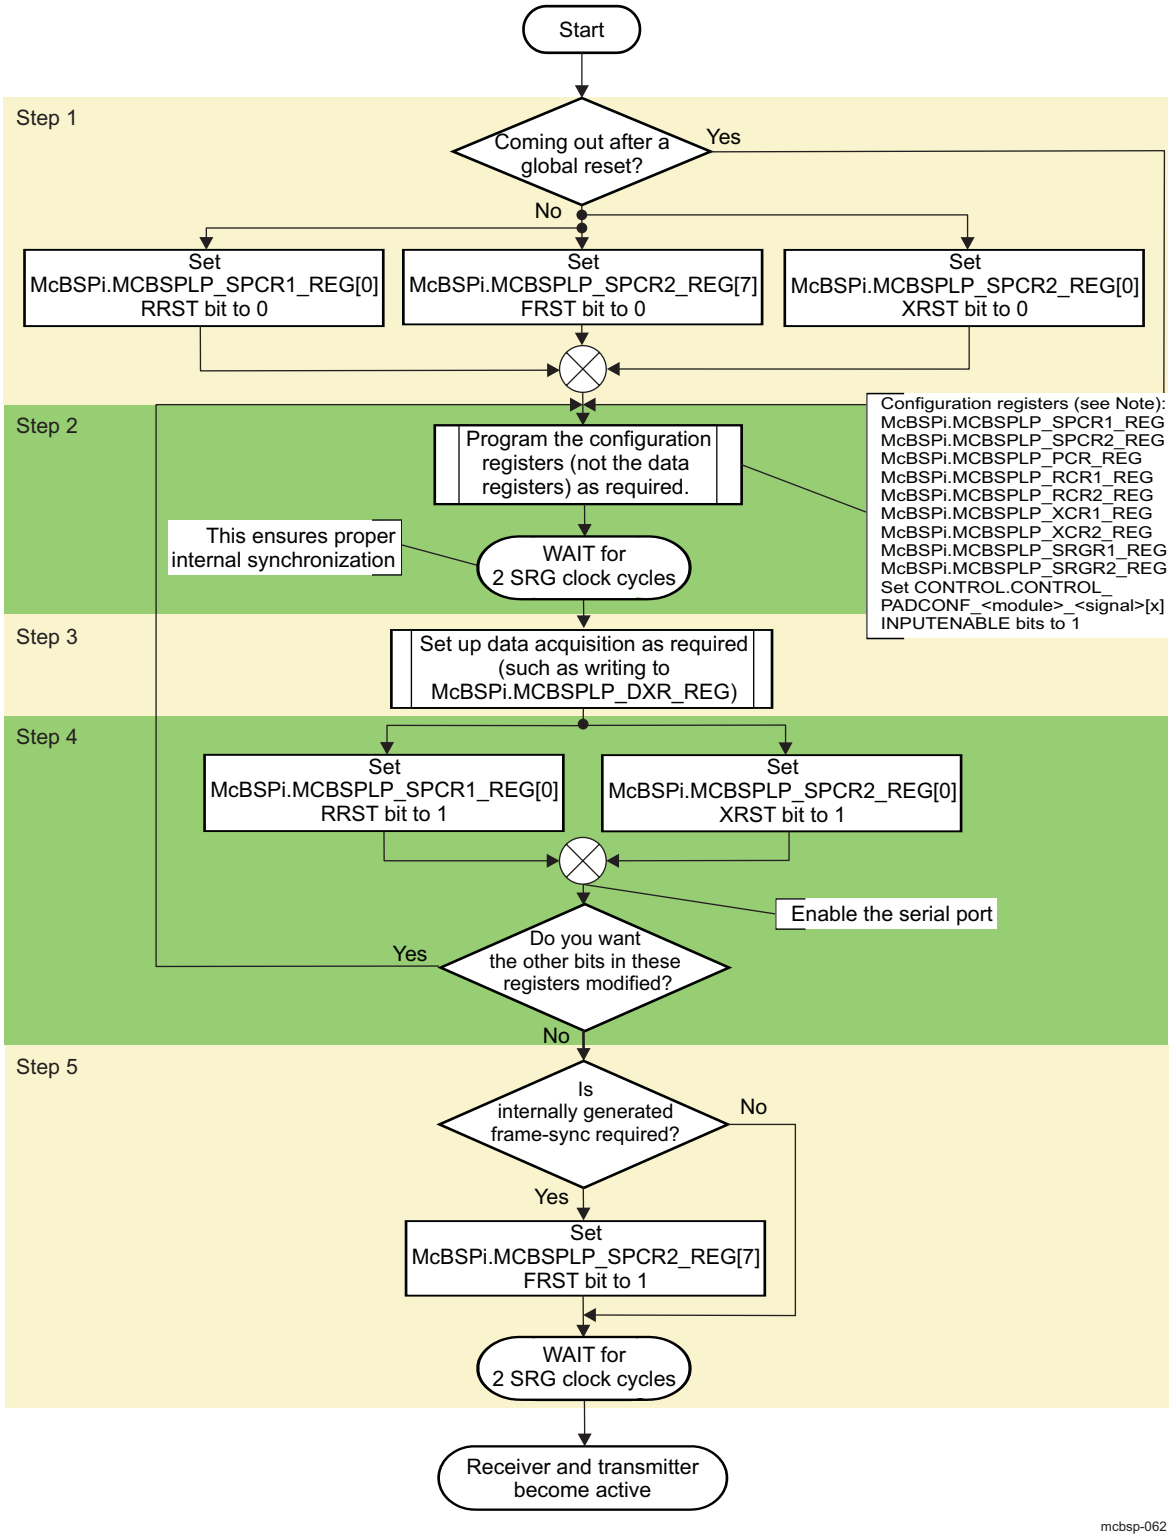
For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit and the McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit are their reset value (XFULL_CYCLE bit=0 and RFULL_CYCLE bit=1).

18.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

Figure 18-57 shows the serial port initialization procedure for master mode.

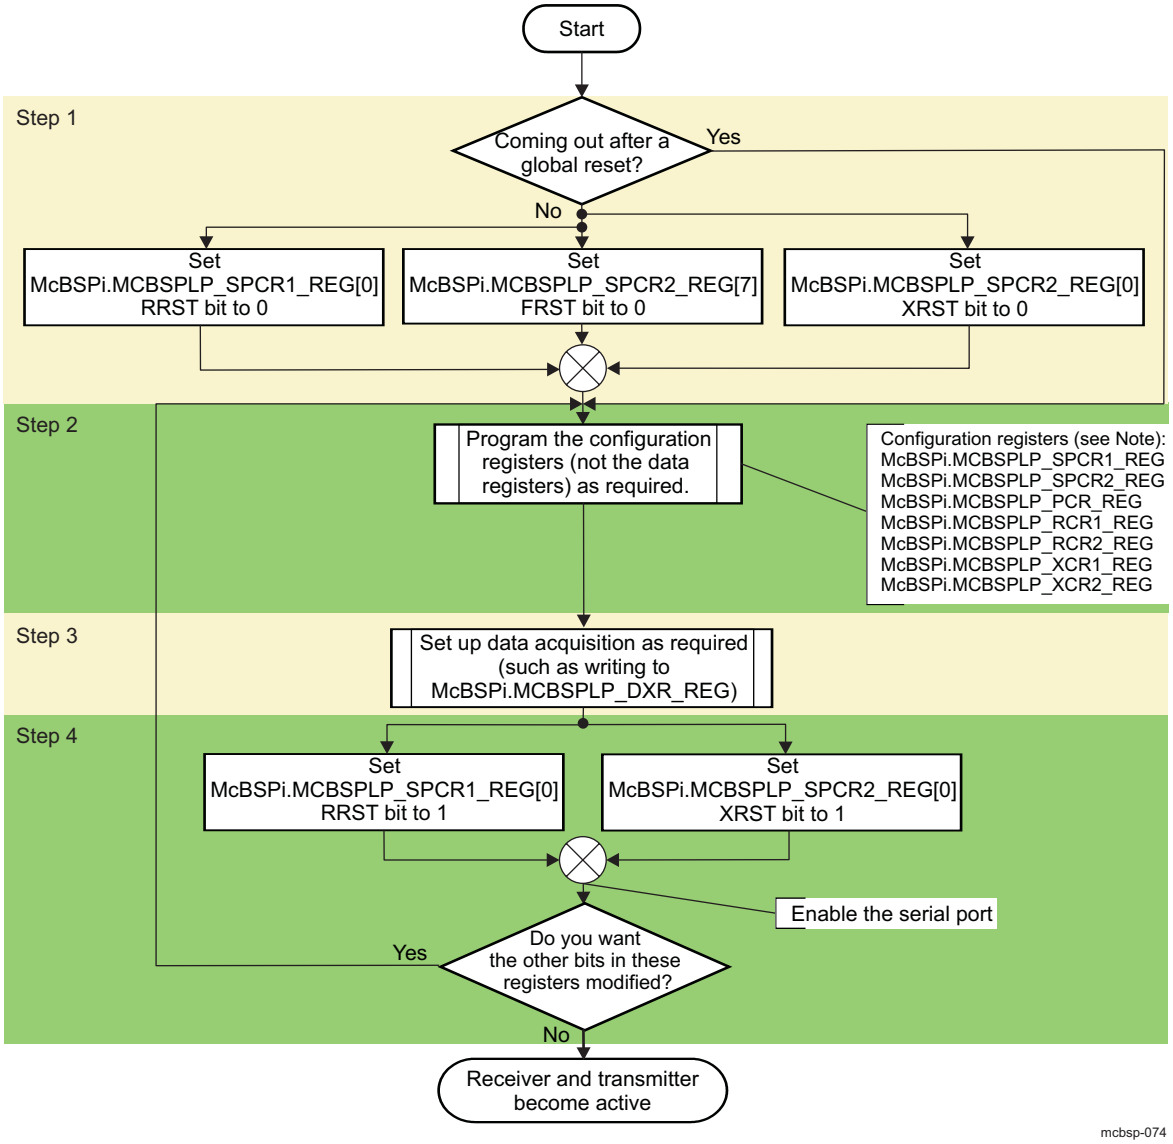
Figure 18-57. Flow Diagram of McBSP Initialization Procedure for Master Mode



Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit, respectively.

Figure 18-58 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 18-58. Flow Diagram of McBSP Initialization Procedure for Slave Mode



NOTE:

- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_THRSH2_REG, McBSPi.MCBSPLP_XCCR_REG, McBSPi.MCBSPLP_SYSCONFIG_REG, McBSPi.MCBSPLP_SRGR1_REG, and McBSPi.MCBSPLP_SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- Modification on-the-fly has no effect if a reset is not done first.

18.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.

  During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, RRST, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.MCBSPLP_SPCR2_REG[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.MCBSPLP_SPCR1_REG[0] RRST=0) and reset the Transmitter (McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit =0).
- Program the registers that affect the Sample Rate Generator.

  Program the Sample Rate Generator registers (McBSPi.MCBSPLP_SPCR1_REG and McBSPi.MCBSPLP_SPCR2_REG) as required for your application. Refer to Figure 18-59.

  If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. Table 18-24 presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

Table 18-24. McBSP Configuration in Function of the SRG Clock Source Selected

SRG Clock Source Selected	Module Configuration	McBSPi.MCBSPLP_PCR_REG Configuration			
		CLKRM bit [1]	CLKXM bit	FSRM bit [1]	FSXM bit
McBSPi_ICLK or CLKS	Master Transmitter and Slave Receiver	0	1	0	1
	Master Receiver and Slave Transmitter	1	0	1	0
	Master Transmitter and Receiver	1	1	1	1
CLKR	Master Transmitter and Slave Receiver	0	1	0	1

(1) This configuration is correct if McBSPi.MCBSPLP_XCCR_REG[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi_clkr pin) is driven by the CLKX clock, which is based on the CLKXM bit.

Table 18-24. McBSP Configuration in Function of the SRG Clock Source Selected (continued)

SRG Clock Source Selected	Module Configuration	McBSPi.MCBSPLP_PCR_REG Configuration			
		CLKRM bit [1]	CLKXM bit	FSRM bit [1]	FSXM bit
CLKX	Master Receiver and Slave Transmitter	1	0	1	0

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).

  Set McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to1 to enable the Sample Rate Generator.

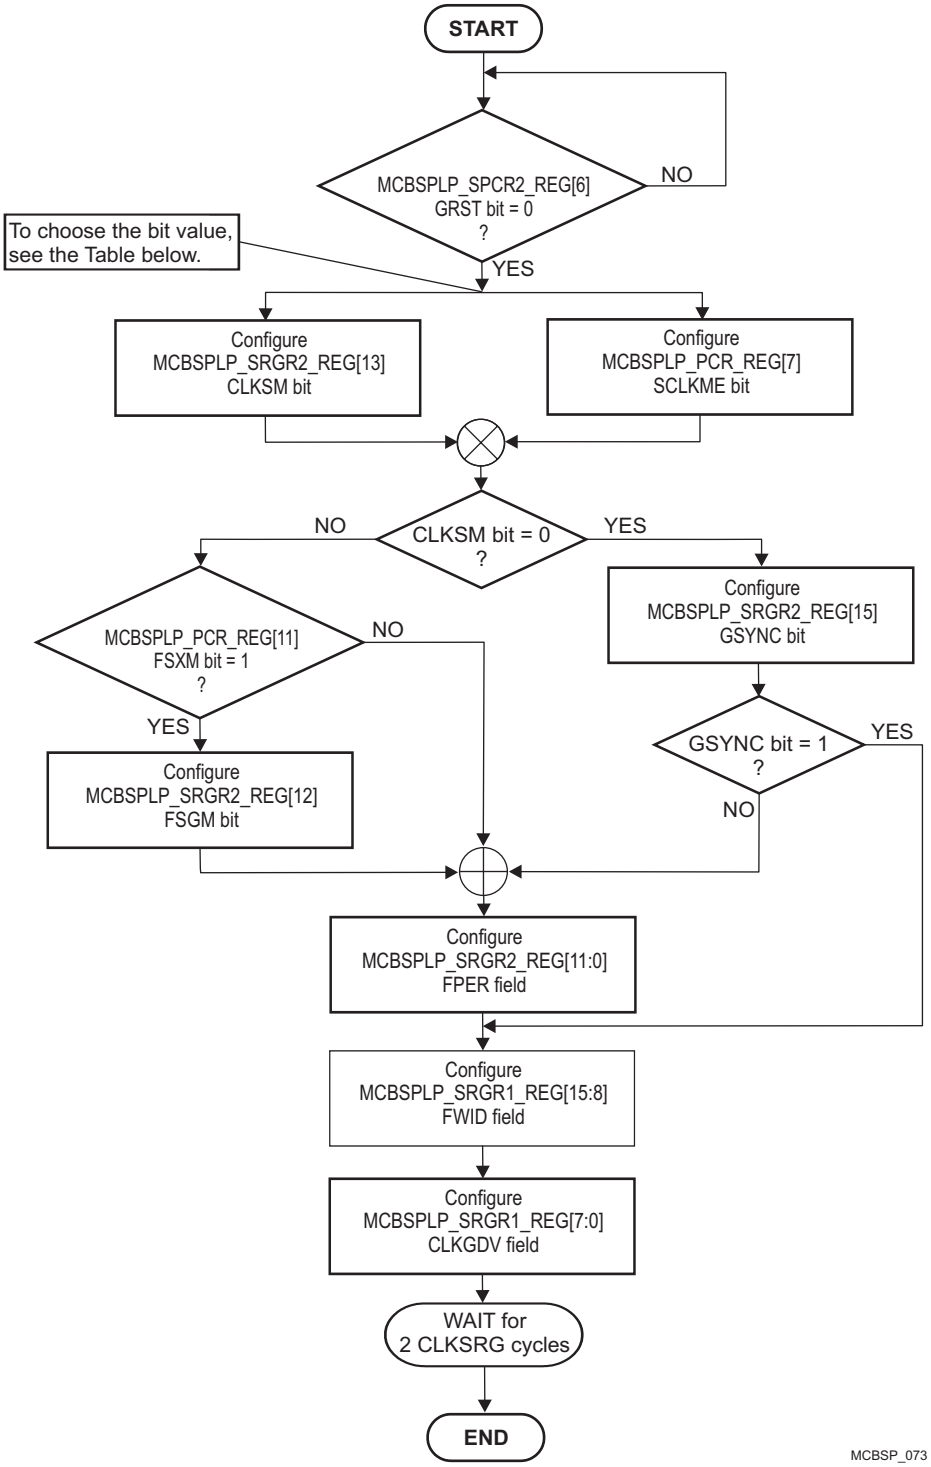
  After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.

  On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1).

- If necessary, enable the receiver and/or the transmitter.

  If necessary, remove the receiver and/or transmitter from reset by setting McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit and/or McBSPi.MCBSPLP_SPCR2_REG[0] XRST =1.

Figure 18-59. Flow Diagram for the SRG Registers Programmation



The input clock is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit in one of the following configurations (see Table 18-25):

Table 18-25. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on mcbsp_clks pin
0	1	McBSPi_ICLK clock
1	0	Signal on mcbsp_clkr pin
1	1	Signal on mcbsp_clkx pin

18.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi_DMA_RX and McBSPi_DMA_TX), perform the following procedure:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[4] RUNDFLEN bit.

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[12] XOVFLEN bit.

18.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

18.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.MCBSPLP_IRQENABLE_REG register. When the McBSPi.MCBSPLP_IRQSTATUS_REG bit is set and the corresponding McBSPi.MCBSPLP_IRQENABLE_REG bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

1. Transmit buffer empty at end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty .
2. Transmit buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
3. Transmit buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to one

when the transmit data buffer is empty, new data needs to be transmitted).

4. Transmit buffer threshold reached (McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2_REG + 1] value).
5. Transmit end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF is set to one when a complete frame was transmitted).
6. Transmit frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
7. Transmit frame synchronization Error (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
8. Receive buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
9. Receive buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
10. Receive buffer threshold Reached (McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1_REG + 1] value).
11. Receive end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[2] REOF is set to one when a complete frame was received).
12. Receive frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
13. Receive frame synchronization error (McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

18.5.1.4.2 Legacy Interrupt Line

McBSPi_IRQ_TX and McBSPi_IRQ_RX are legacy interrupts. Not to be used for new development. McBSPi_IRQ (common interrupt line) should be preferred.

18.5.1.4.2.1 Set the receive interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi_IRQ_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt .
- RINTM = 0b11: The receive interrupt generated when McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see Section 18.4.4.3.

The McBSP module also provides a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting

- REOFEN is equivalent with RINTM = 0b01setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- RFSREN is equivalent with RINTM = 0b10 setting
- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

18.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field determines which event generates a transmit interrupt request (McBSPi_IRQ_TX) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see Section 18.4.4.6.

The McBSP module provides also a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

18.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

18.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.

2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operations with frame synchronization generator also require using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

18.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 18-60 and Figure 18-61 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 18-60. Important Tasks to Configure the McBSP Receiver (Part 1)

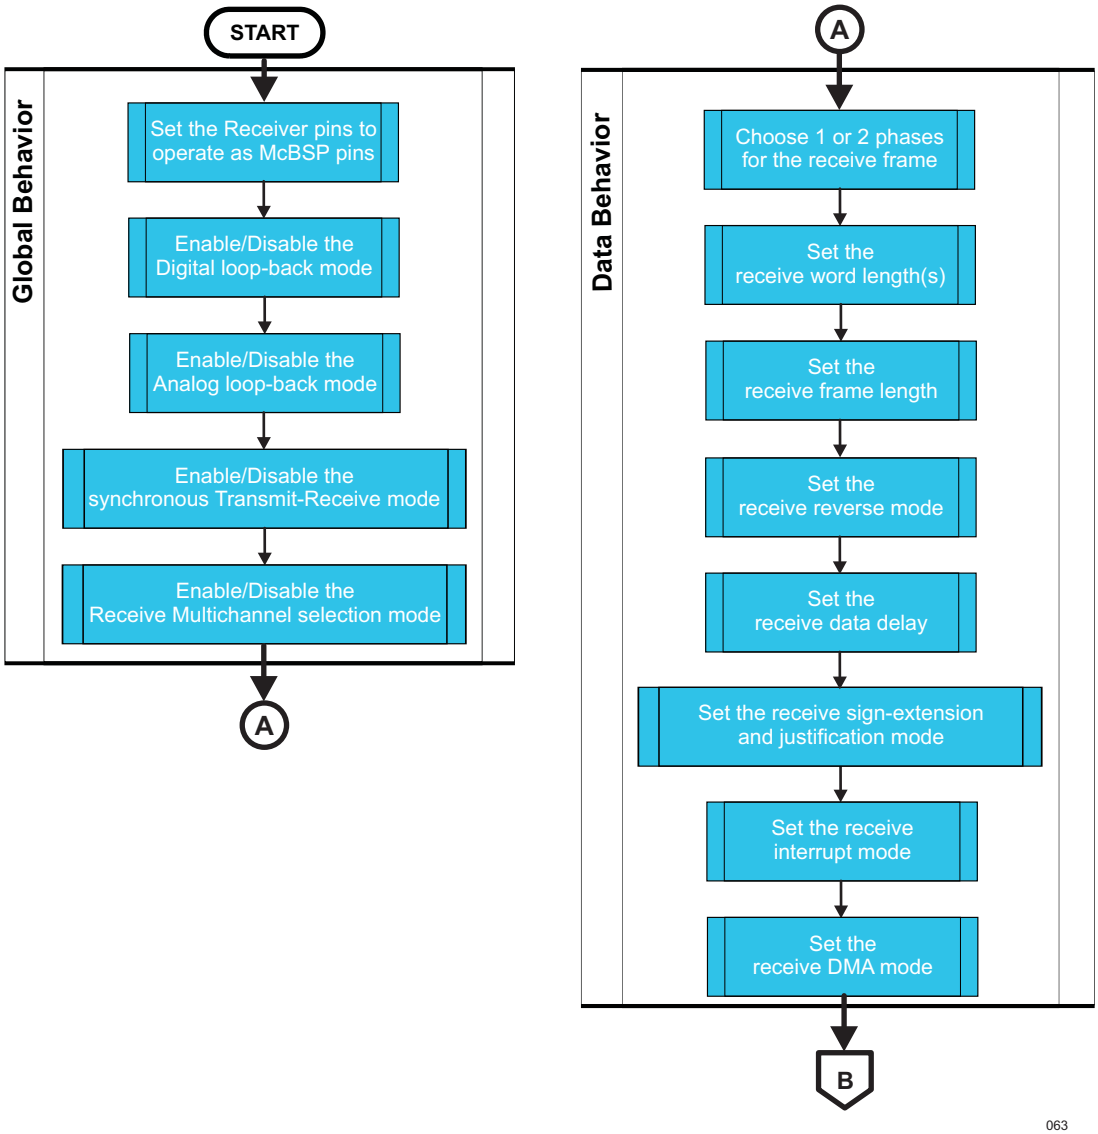


Figure 18-61. Important Tasks to Configure the McBSP Receiver (Part 2)

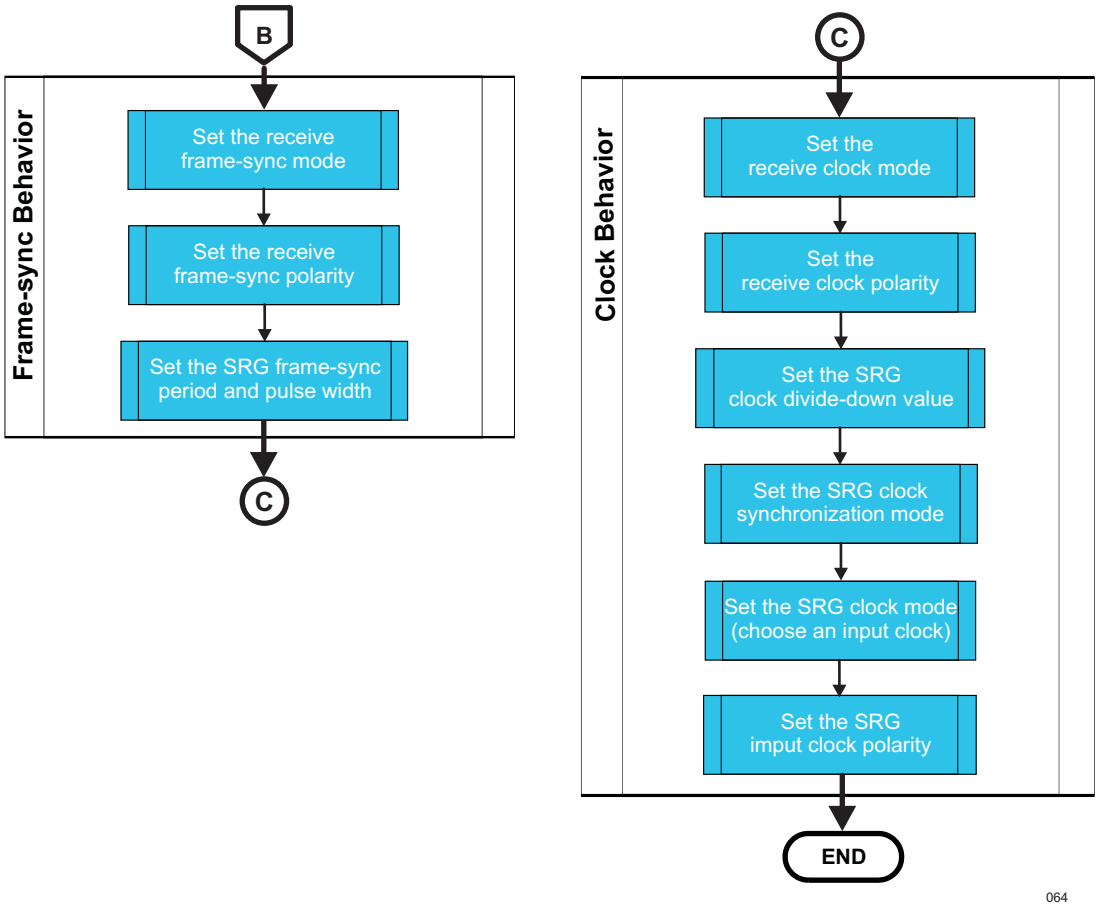


18.5.1.5.2.1 Global Behavior

18.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.MCBSPLP_PCR_REG[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general–purpose I/O pins (RIOEN bit=1).

Please refer to Section 18.5.1.7 which describes how to use McBSP pins as GPIO pins.

18.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.MCBSPLP_XCCR_REG[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

NOTE: That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

18.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

18.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

18.5.1.5.2.1.5 Enable/Disable the Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether the receive multichannel selection mode is on or off.

For further details, see Section 18.4.6.5.

18.5.1.5.2.2 Data Behavior

18.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

18.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual–phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

18.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words(one word for phase 1 plus the one word for phase 2). Others values must not be used.

The 7–bit RFRLEN1 field allows up to 128 words per phase when single-phase frame. See Table 18-26 below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFRLEN fields with [W - 1], where W represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFRLEN1.

Table 18-26. How to Calculate the Length of the Receive Frame

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 ≤ RFRLEN1 ≤ 127	Don't care	(RFRLEN1value +1) words
1	RFRLEN1 = 0	RFRLEN2 = 0	2 words

18.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see Section 18.4.2.2.

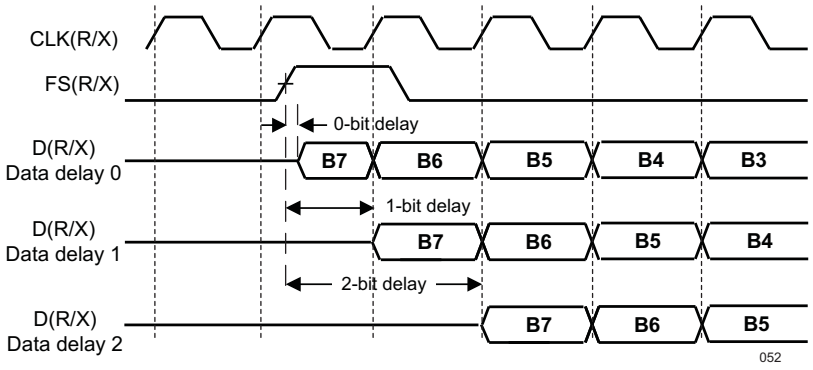
18.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit–clocks (RDATDLY=0b00–0b10), as shown in Figure 18-62 below. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1–cycle active frame-synchronization pulse.

Figure 18-62. Range of Programmable Data Delay



18.5.1.5.2.2.5.1 0-Bit Data Delay

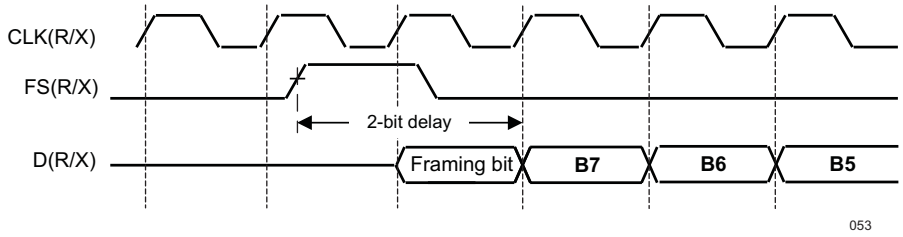
Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbsp_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbsp_dx pin.

18.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1–bit delay and data appears after a 2–bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 18-63. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on.

Figure 18-63. 2-Bit Data Delay Used to Skip a Framing Bit



18.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field determines whether data received by the McBSP module is sign–extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.MCBSPLP_DRR_REG register and whether unused bits in McBSPi.MCBSPLP_DRR_REG are filled with zeroes or with sign bits.

Table 18-27 and Table 18-28 show the effects of various RJUST values; the effect on an example 12–bit receive–data value 0xABC, and the effect on an example 20–bit receive–data value 0xABCDE, respectively.

Table 18-27. Example: Use of RJUST Bit Field With 12-bit Data Value 0xABC

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x0000 0ABC
0b01	Right	Sign extend data into MSBs	0xFFFF FABC
0b10	Left	Zero fill LSBs	0xABC0 0000
0b11	Reserved	Reserved	Reserved

Table 18-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCDE

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x000A BCDE
0b01	Right	Sign extend data into MSBs	0xFFFA BCDE
0b10	Left	Zero fill LSBs	0xABCD E000
0b11	Reserved	Reserved	Reserved

18.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to Section 18.5.1.4.2.1.

18.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi_DMA_RX) are active after the McBSPi.MCBSPLP_SPCR1_REG [0] RRST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

18.5.1.5.2.3 Frame-Sync Behavior

18.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[10] FSRM bit, McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbsp_fsr pin.

Table 18-29 below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbsp_fsr pin. The polarity of the signal on the mcbsp_fsr pin is determined by the McBSPi.MCBSPLP_PCR_REG[2] FSRP bit.

Table 18-29. FSRM and GSYNC Effects on Frame-Sync Signal and mcbsp_fsr Pin

FSRM	GSYNC	Source of Receive Frame Synchronization	MCBSPLP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP module through the mcbsp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR.	Input
1	0	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbsp_fsr pin.
1	1	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the mcbsp_fsr pin is used to synchronize CLKG and generate FSG pulses.

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see Section 18.4.3.

18.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The McBSPi.MCBSPLP_PCR_REG[2] FSRP bit determines whether frame-synchronization pulses are active high or active low on the mcbsp_fsr pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit. FSR is also affected by the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit. For information about the effects of FSRM and GSYNC, see Section 18.5.1.5.2.3.1, *Set the Receive Frame-Sync Mode*.

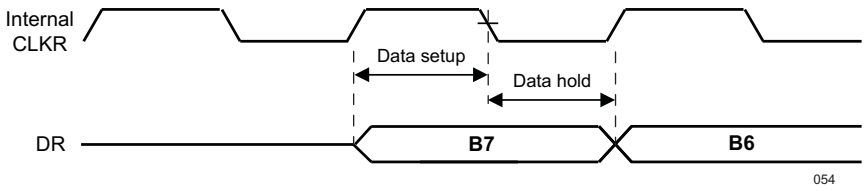
When FSR and FSX are inputs (FSXM = FSRM = 0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbspi_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the mcbsp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (McBSPi.MCBSPLP_PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

Figure 18-64 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 18-64. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge



18.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field is used to set the SRG frame-sync period and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field is used to set the SRG pulse width.

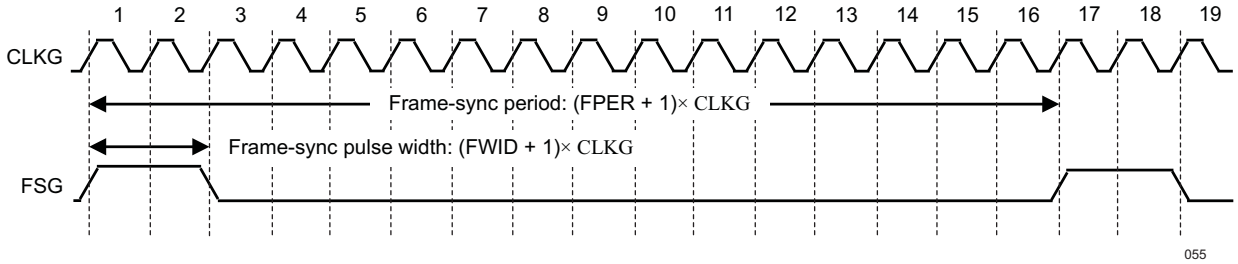
On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is (FPER+1) CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC=1, FPER is a don't care value.

Each pulse on FSG has a width of (FWID+1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down–counters. The 12–bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8–bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 18-65 shows a frame-synchronization period of 16 CLKG periods (FPER=15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID=1).

Figure 18-65. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods



When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

18.5.1.5.2.4 Clock Behavior

18.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit are used to set the receive clock mode.

Table 18-30 shows how to select various sources to provide the receive clock signal and affect the mcbsp_clkr pin. The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit determines the polarity of the signal on the mcbsp_clkr pin.

Table 18-30. CLKRM Effect on Receive Clock Signal and mcbsp_clkr Pin

CLKRM	Source of Receive Clock	mcbsp_clkr Pin Status
0	The mcbsp_clkr pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used.	Input
1	The SRG clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbsp_clkr pin.

In the digital loop-back mode (DLB=1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see Section 18.4.3.1.

18.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the mcbsp_clkr pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

18.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV+1) of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

18.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see Section 18.4.3.

18.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see Section 18.4.3.

18.5.1.5.2.4.6 Set the SRG Input Clock Polarity

McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit and McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the mcbsp_clks, mcbsp_clkx, or mcbsp_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbsp_clks pin, CLKXP for the mcbsp_clkx pin, CLKRP for the mcbsp_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

18.5.1.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

18.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operation with the Frame Synchronization Generator also requires using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

18.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 18-66 and Figure 18-67 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Figure 18-66. Important Tasks to Configure the McBSP Transmitter (Part 1)

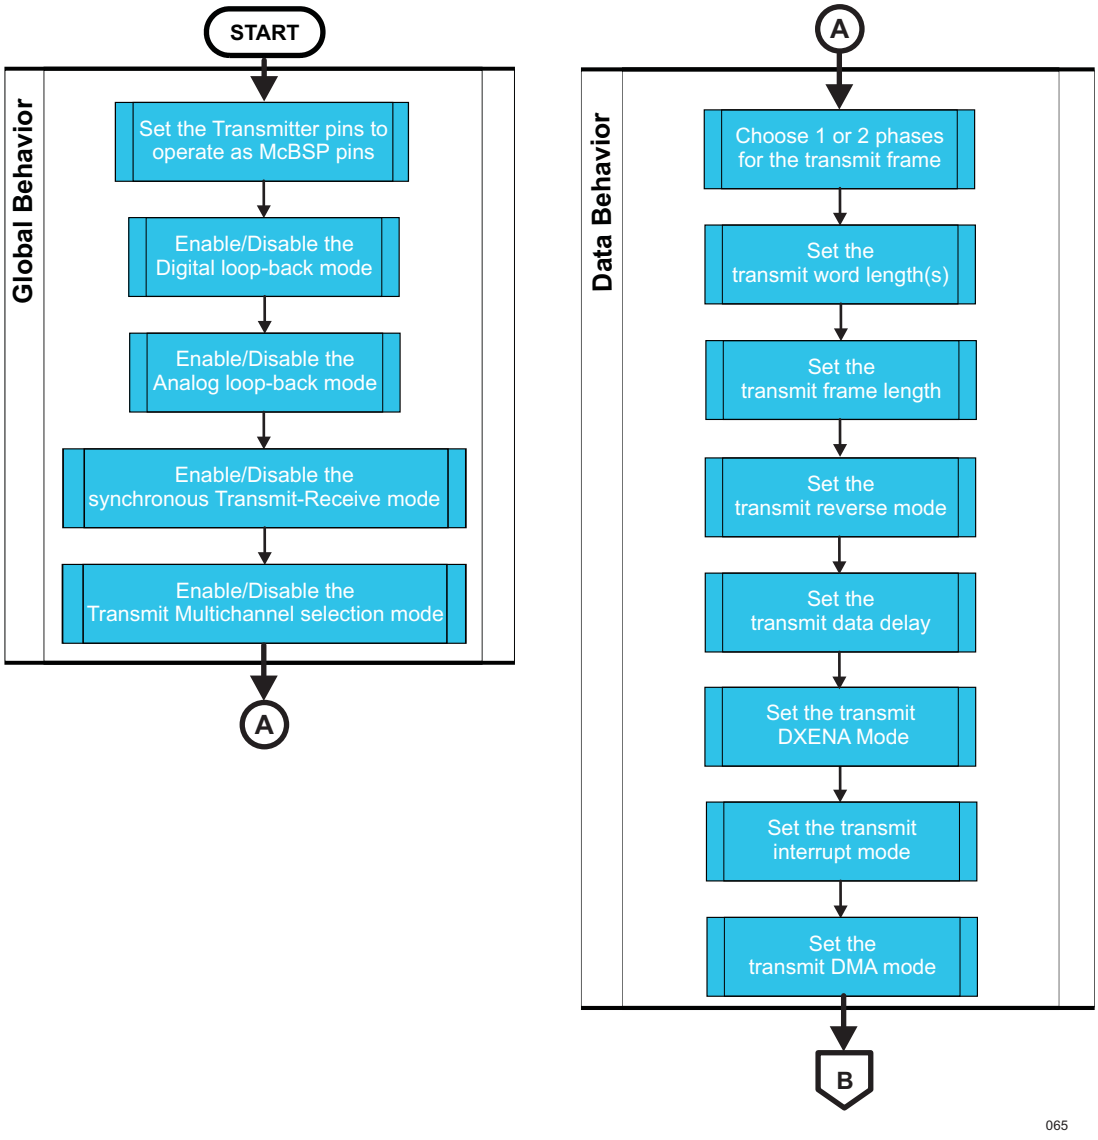


Figure 18-67. Important Tasks to Configure the McBSP Transmitter (Part 2)

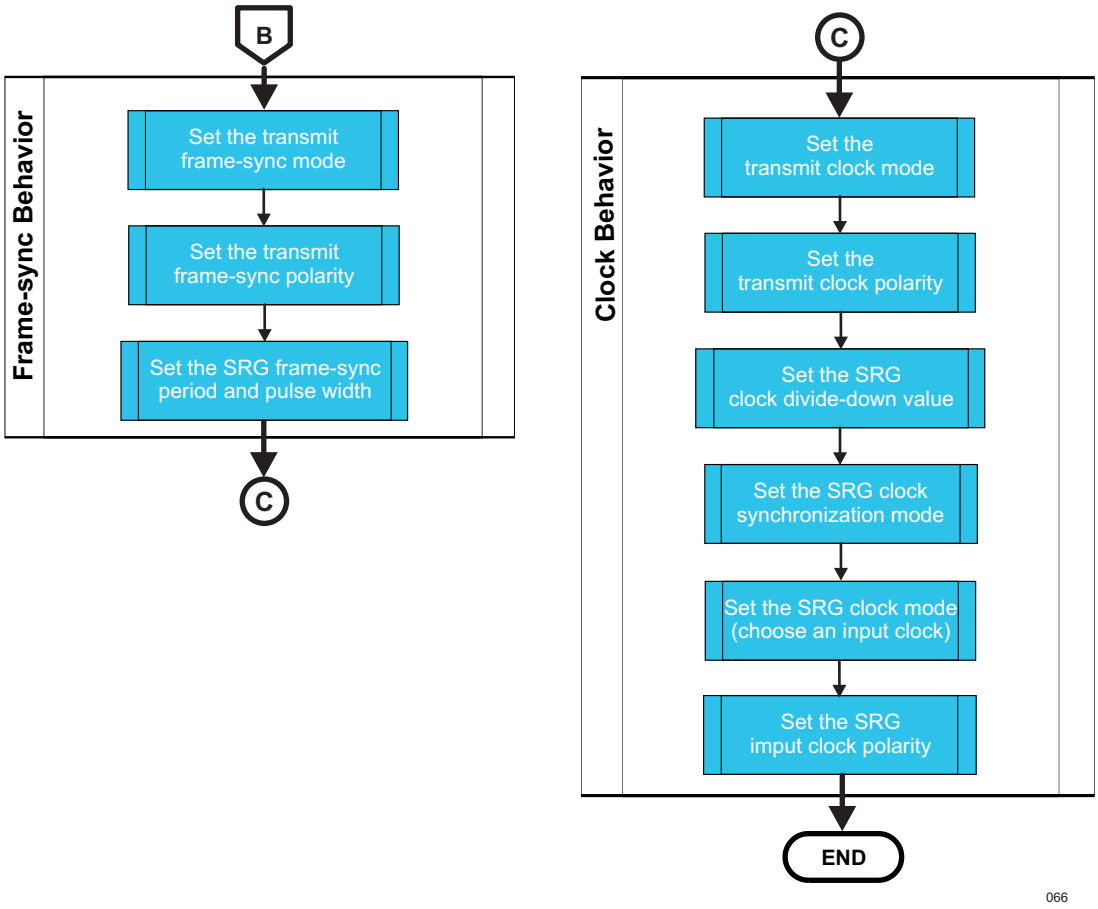


18.5.1.6.2.1 Global Behavior

18.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.MCBSPLP_PCR_REG[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general–purpose I/O pins (XIOEN=1).

Refer to Section 18.5.1.7 which describes how to use McBSP pins as GPIO pins.

18.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

Refer to it, Section 18.5.1.5.2.1.2.

18.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

Refer to it, Section 18.5.1.5.2.1.3.

18.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

Refer to it, Section 18.5.1.5.2.1.4.

18.5.1.6.2.1.5 Enable/Disable the Transmit Multichannel Selection

McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether the transmit multichannel selection mode is on or off.

Refer to Section 18.4.6.7.

18.5.1.6.2.2 Data Behavior

18.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

18.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single–phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual–phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

18.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual–phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7–bit XFRLEN fields allow up to 128 words per phase. See Table 18-31 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 18-31. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	0 ≤ XFRLEN1 ≤ 127	Don't care	(XFRLEN1value +1) words
1	XFRLEN1= 0	XFRLEN2 = 0	2 words

18.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see Section 18.4.2.2.

18.5.1.6.2.2.5 Set the Transmit Data Delay

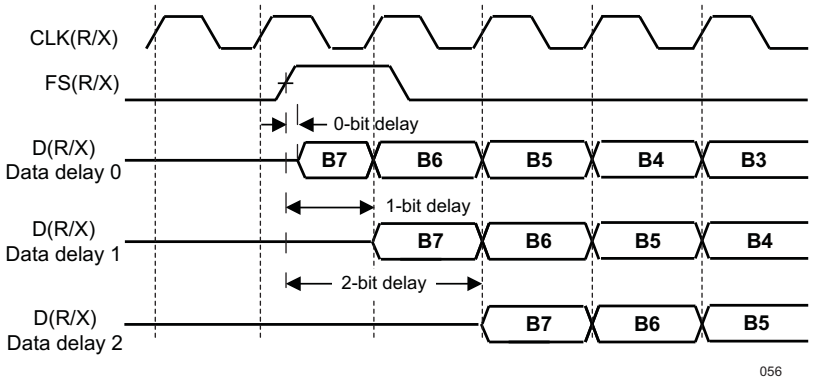
McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit–clocks (XDATDLY=00b–10b), as shown in Figure 18-68. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on.

NOTE: Typically a 1–bit delay is selected, because data often follows a 1–cycle active frame-synchronization pulse.

Figure 18-68. Range of Programmable Data Delay



18.5.1.6.2.2.5.1 0-Bit Data Delay:

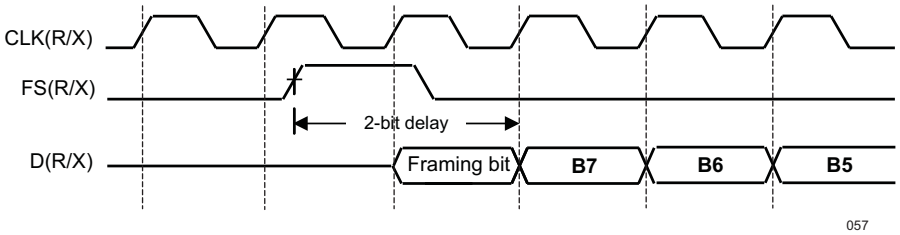
Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbsp_dx pin.

18.5.1.6.2.2.5.2 2-Bit Data Delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1–bit delay and data appears after a 2–bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 18-69. The data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on.

Figure 18-69. 2-Bit Data Delay Used to Skip a Framing Bit



18.5.1.6.2.2.6 Set the Transmit DXENA Mode

McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbsp_dx pin. Set DXENA to enable an extra delay for turn–on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 13 ns, 18 ns (default), 24 ns or 30 ns can be set using the McBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY field. If you tie together the mcbsp_dx pins of multiple McBSP modules, make sure DXENA=1, to avoid having more than one McBSP transmitting on the data line at one time.

18.5.1.6.2.2.7 Set the Transmit Interrupt Mode

Refer to Section 18.5.1.4.2.2.

18.5.1.6.2.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (McBSPi_DMA_TX) are active after the transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the THRSH2_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH2_REG value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

18.5.1.6.2.3 Frame-Synchronization Behavior

18.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit are used to set the transmit frame-sync mode.

Table 18-32 shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

Table 18-32 also shows the effect of each bit setting on the mcbsp_fsx pin. The FSXP bit determines the polarity of the signal on the mcbsp_fsx pin.

Table 18-32. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	mcbsp_fsx Pin Status
0	0 or 1	An external FSG enters the McBSP through the mcbsp_fsx pin. The signal is then inverted by FSXP bit before being used as internal FSX.	Input
1	1	Internal FSX is driven by the SRG FSG.	Output. FSG is inverted by FSXP bit before being driven out on mcbsp_fsx pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on mcbsp_fsx pin.

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the mcbsp_fsr pin. For more details, see Section 18.4.3.3.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see Section 18.4.3.2.

18.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

McBSPi.MCBSPLP_PCR_REG[3] FSXP bit determines whether frame-synchronization pulses are active high or active low on the mcbsp_fsx pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit. FSX is also affected by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit. For information about the effects of FSXM and FSGM, see Section 18.5.1.6.2.3.1).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the mcbsp_dr pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the mcbsp_dx pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active–high FSG are inverted before being sent to the FS(R/X) pin.

18.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See Section 18.5.1.5.2.3.3.

18.5.1.6.2.4 Clock Behavior

18.5.1.6.2.4.1 Set the Transmit Clock Mode

The McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit is used to set the transmit clock mode.

Table 18-33 shows how the CLKXM bit selects the transmit clock and the corresponding status of the mcbsp_clkx pin. The CLKXP bit determines the polarity of the signal on the mcbsp_clkx pin.

Table 18-33. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin

CLKXM	Source of Transmit Clock	mcbsp_clkx Pin Status
0	Internal CLKX is driven by an external clock on the mcbsp_clkx pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the SRG clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on mcbsp_clkx.

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the mcbsp_fsr pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see Section 18.4.3.1.

18.5.1.6.2.4.2 Set the Transmit Clock Polarity

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the mcbsp_clkx pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the mcbsp_clkr pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

18.5.1.6.2.4.3 Set the SRG Clock Divide-Down Value

See Section 18.5.1.5.2.4.3.

18.5.1.6.2.4.4 Set the SRG Clock Synchronization Mode

See Section 18.5.1.5.2.4.4.

18.5.1.6.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

See Section 18.5.1.5.2.4.5.

18.5.1.6.2.4.6 Set the SRG Input Clock Polarity

See Section 18.5.1.5.2.4.6.

18.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

Table 18-34 summarizes how to use the McBSP pins as general–purpose I/O pins. All the bits mentioned in the table except XRST and RRST bits are in the pin control register (McBSPi.MCBSPLP_PCR_REG). McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit are in the serial port control registers.

To use receiver pins mcbsp_clkr, mcbsp_fsr, and mcbsp_dr as general–purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit =0).
2. General–purpose I/O is enabled for the serial port receiver (McBSPi.MCBSPLP_PCR_REG[12] RIOEN=1).

The mcbsp_clkr and mcbsp_fsr pins can be individually configured as either input or output pins with the CLKRM and FSRM bits, respectively. The mcbsp_dr pin can only be an input pin. Table 18-34 shows, which bits in McBSPi.MCBSPLP_PCR_REG are used to read from/write to these pins.

For the transmitter pins mcbsp_clkx, mcbsp_fsx, and mcbsp_dx, you must meet two conditions:

1. The transmitter of the serial port is in reset (McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0).
2. General–purpose I/O is enabled for the serial port transmitter (McBSPi.MCBSPLP_PCR_REG[12] XIOEN=1).

The mcbsp_clkx and mcbsp_fsx pins can be individually configured as input or output pins with the CLKXM and FSXM bits, respectively. The mcbsp_dx pin can only be an output pin. Table 18-34 shows the bits in McBSPi.MCBSPLP_PCR_REG used to read from/write to these pins.

For the mcbsp_clks pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (RRST=0 and XRST=0).
2. General–purpose I/O is enabled for both the receiver and the transmitter (RIOEN=1 and XIOEN=1).

The mcbsp_clks pin can only be an input pin. To read the status of the signal on the mcbsp_clks pin, read the McBSPi.MCBSPLP_PCR_REG[6] CLKS_STAT bit.

Table 18-34. Using McBSP Pins for General-Purpose I/O

Pin	General–Purpose use enabled by this bit combination	Selected as output when	Output value driven from this bit	Selected as input when	Input value read from this bit
mcbsp_clkx	XRST = 0 XIOEN = 1	CLKXM = 1	CLKXP	CLKXM = 0	CLKXP
mcbsp_fsx	XRST = 0 XIOEN = 1	FSXM = 1	FSXP	FSXM = 0	FSXP
mcbsp_dx	XRST = 0 XIOEN = 1	Always	DX_STAT	Never	Does not apply
mcbsp_clkr	RRST = 0 RIOEN = 1	CLKRM = 1	CLKRP	CLKRM = 0	CLKRP
mcbsp_fsr	RRST = 0 RIOEN = 1	FSRM = 1	FSRP	FSRM = 0	FSRP
mcbsp_dr	RRST = 0 RIOEN = 1	Never	Does not apply	Always	DR_STAT
mcbsp_clks	RRST = XRST = 0 RIOEN = XIOEN = 1	Never	Does not apply	Always	CLKS_STAT

18.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

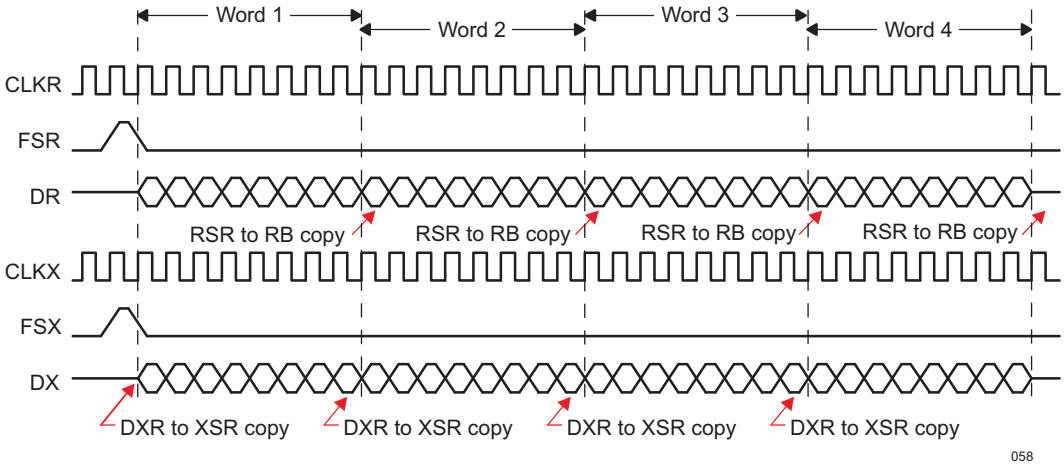
18.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in Figure 18-70. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from McBSPi.MCBSPLP_DRR_REG and four writes to McBSPi.MCBSPLP_DXR_REG are necessary for each frame.

Figure 18-70. Four 8-bit Data Words Transferred To/From McBSP Module

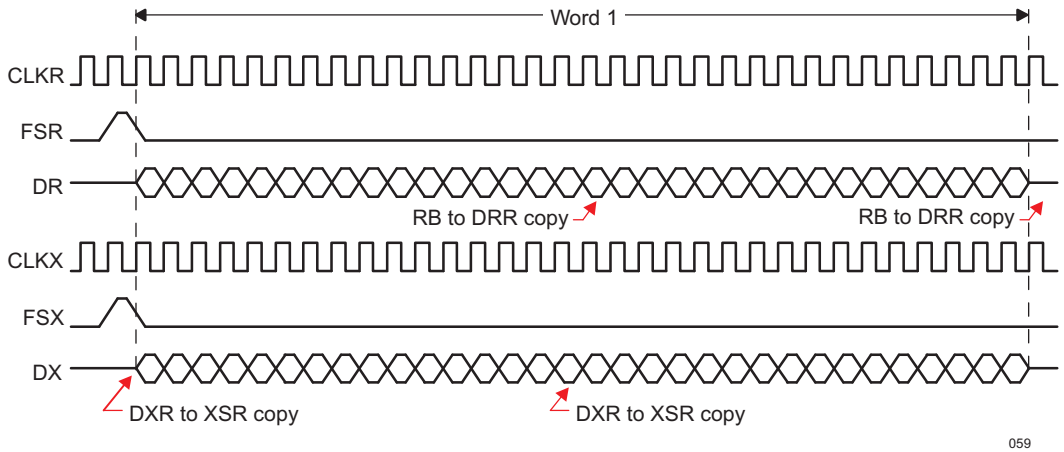


This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in Figure 18-71. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from McBSPi.MCBSPLP_DRR_REG and two writes to McBSPi.MCBSPLP_DXR_REG are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 18-71. One 32-bit Data Word Transferred To/From McBSP Module



18.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. Figure 18-72 shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 18-72. 8-bit Data Words Transferred at Maximum Packet Frequency

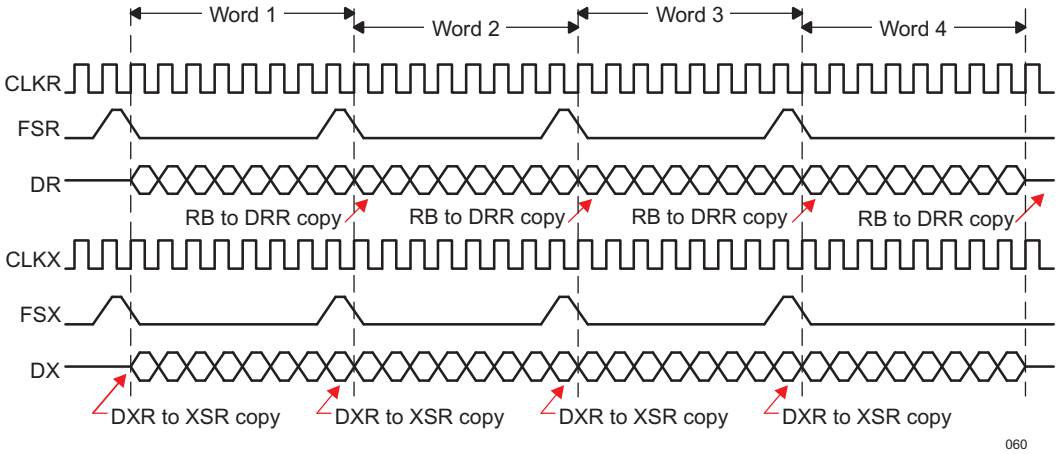


Figure 18-73 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

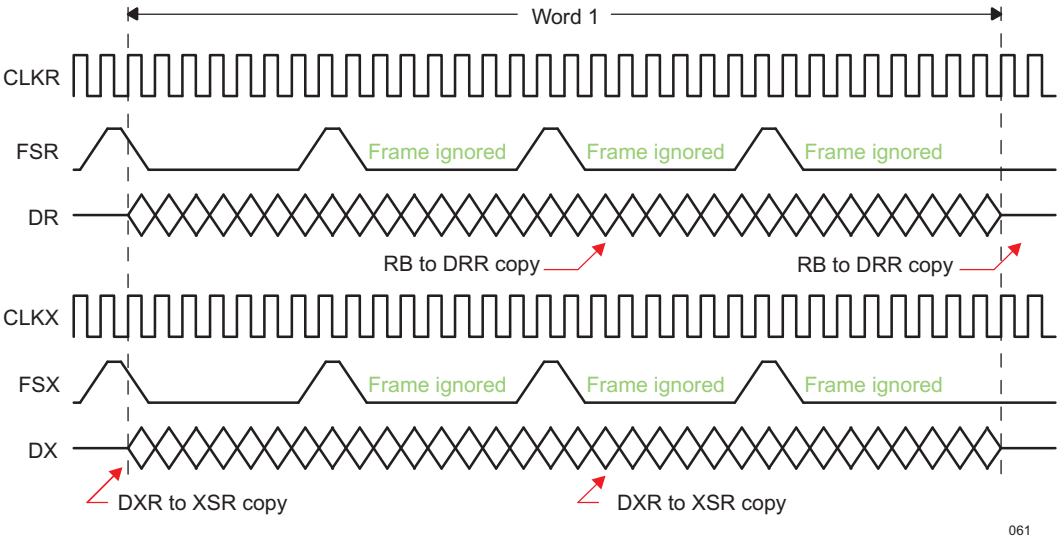
Figure 18-73. Configuring the Data Stream as a Continuous 32-bit Word



18.5.2 SIDETONE Feature

18.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel mode of the McBSP module:

- Select a single–phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit, to select multichannel mode enable.
- Set a frame length (McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field) that includes the highest–numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note

below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in Table 18-35:

Table 18-35. Selection of the SIDETONE Input and Output Channels

Bit field	Description
McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN	Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN	Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN	Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)
McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN	Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)

- Enable SIDETONE by setting 2 bits to 1:
  1. In McBSP module, the McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit
  2. In SIDETONE core, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

18.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field, the McBSPi.ST_SFIRCR_REG[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.ST_SGAINCR_REG[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.ST_SGAINCR_REG[15:0] CH0GAIN bit field for the first sidetone channel.

18.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable writing of the FIR coefficients, or write 0, and then write 1 in the COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on the McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit (it becomes 1 after the 128th coefficient is written).

18.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable reading of the FIR coefficients, or write 1, and then write 0 in the COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

18.6 McBSP Register Manual

Table 18-36 shows the base address and address space for the device module instances.

Table 18-36. Device Instance Summary

Module Name	Base Address (hex)	Size
McBSP1	0x4807 4000	4K bytes
McBSP5	0x4809 6000	4K bytes
McBSP2	0x4902 2000	4K bytes
McBSP3	0x4902 4000	4K bytes
McBSP4	0x4902 6000	4K bytes
SIDETONE_McBSP2	0x4902 8000	4K bytes
SIDETONE_McBSP3	0x4902 A000	4K bytes

18.6.1 McBSP Register Mapping Summary

CAUTION

The McBSP data registers (that is, DXR_REG for data transmit and DRR_REG for data receive) support 8/16/32-bit data accesses. All other McBSP registers are limited to 32-bit data accesses. 16-bit and 8-bit data accesses are not allowed and can corrupt register contents.

RESERVED																						FREE	SOFT	FRST	GRST	XINTM		XSYNCERR	XEMPTY	XRDY	XRST

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Read returns 0x0.	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0x0
8	SOFT	Soft Bit 0x0: SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion. 0x1: SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.	RW	0x0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-synchronization logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; i.e., all frame counters are loaded with their programmed values	RW	0x0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0x0
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: Transmit interrupt is driven by XRDY 0x1: Transmit interrupt generated by end-of-frame 0x2: Transmit interrupt generated by a new frame synchronization 0x3: Transmit interrupt generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	XEMPTY	Transmit Shift Register XSR Empty 0x0: XSR is empty 0x1: XSR is not empty	R	0x0
1	XRDY	Transmitter ready 0x0: Transmitter is not ready. 0x1: Transmitter is ready for new data in DXR	R	0x0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0x0

	0x4902 6014		McBSP4
Description	McBSPLP serial port control register 1		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ALB	RJUST	RESERVED						DXENA	RESERVED	RINTM		RSYNCERR	RFULL	RRDY	RRST

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	ALB	Analog loopback Mode	RW	0x0
		0x0: Analog loopback mode disabled		
		0x1: Analog loopback mode enabled		

Bits	Field Name	Description	Type	Reset
14:13	RJUST	Receive Sign-Extension and Justification Mode 0x0: Right-justify and zero-fill MSBs in DRR 0x1: Right-justify and sign-extend MSBs in DRR 0x2: Left-justify and zero-fill LSBs in DRR 0x3: Reserved	RW	0x0
12:8	RESERVED	Read returns 0x0.	R	0x00
7	DXENA	DX Enabler 0x0: DX enabler is off 0x1: DX enabler is on	RW	0x0
6	RESERVED	Read returns 0x0.	R	0x0
5:4	RINTM	Receive Interrupt Mode (legacy) 0x0: Receive Interrupt driven by RRDY (i.e. end of word) and end of frame in A-bis mode 0x1: Receive Interrupt generated by end-of-block or end-of-frame in multichannel operation 0x2: Receive Interrupt generated by a new frame synchronization 0x3: Receive Interrupt generated by RSYNCERR	RW	0x0
3	RSYNCERR	Receive Synchronization Error (writing 0 to this bit clear the legacy receive interrupt if asserted due to RSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	RFULL	Receive Shift Register (RSR) Full 0x0: RB is not in overrun condition 0x1: DRR is not read, RB is full and RSR is also full with new word	R	0x0
1	RRDY	Receiver Ready 0x0: Receiver is not ready 0x1: Receiver is ready with data to be read from DRR	R	0x0
0	RRST	Receiver reset. This resets and enables the receiver. 0x0: The serial port receiver is disabled and in reset state. 0x1: The serial port receiver is enabled.	RW	0x0

RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER											

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	GSYNC	Sample Rate Generator Synchronization Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0) 0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse.	RW	0x0
14	CLKSP	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG.	RW	0x0
13	CLKSM	McBSP SRG Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKR input pin. 0x1: SCLKME=0: SRG clock derived from the McBSPi_ICLK clock. SCLKME=1: SRG clock derived from the CLKX input pin.	RW	0x1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty. When FSGM=0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0x0
11:0	FPER	Frame Period. This value + 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

RESERVED																						XMCME	XPBBLK	XPABLK				RESERVED		XMCM	

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Read returns 0x0.	R	0x000000
9	XMCME	Transmit multichannel partition mode determines whether only 32 channels or all 128 channels are to be individually selectable. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is nonzero). 0x0: 2-partition mode: Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bits. If XMCM = 01b or 10b, assign 16 channels to partition A with the XPABLK bits. Assign 16 channels to partition B with the XPBBLK bits. If XMCM = 11b (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bits. Assign 16 channels to receive partition B with the RPBBLK bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels in partition A XCERB: Channels in partition B 0x1: 8-partition mode: All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels 0 through 15 XCERB: Channels 16 through 31 XCERC: Channels 32 through 47 XCERD: Channels 48 through 63 XCERE: Channels 64 through 79 XCERF: Channels 80 through 95 XCERG: Channels 96 through 111 XCERH: Channels 112 through 127	RW	0x0

8:7	XPBBLK	Transmit Partition B Block (legacy) 0x0: Block 1. Channel 16 to channel 31 0x1: Block 3. Channel 48 to channel 63 0x2: Block 5. Channel 80 to channel 95 0x3: Block 7. Channel 112 to channel 127	RW	0x0
6:5	XPABLK	Transmit Partition A Block (legacy) 0x0: Block 0. Channel 0 to channel 15 0x1: Block 2. Channel 32 to channel 47 0x2: Block 4. Channel 64 to channel 79 0x3: Block 6. Channel 96 to channel 111	RW	0x0
4:2	RESERVED	Reserved	R	0x0
1:0	XMCM	Transmit Multichannel Selection Enable 0x0: All channels enabled without masking (DX is always driven during transmission of data). 0x1: All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven. 0x2: All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked. 0x3: All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symmetric transmit and receive operation.	RW	0x0

RESERVED																IDLE_EN	XIOEN	RIOEN	FSXM	FSRM	CLKXM	CLKRM	SCLKME	CLKS_STAT	DX_STAT	DR_STAT	FSXP	FSRP	CLKXP	CLKRP	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read returns 0x0.	R	0x00000
14	IDLE_EN	Idle enable. This bit allows stopping all the clocks in the MCBSP module. (legacy) 0x0: The McBSP is running 0x1: The clocks in the McBSP are shut off when both IDLE_EN=1 and his power domain is in idle mode (Force idle or Smart idle)	RW	0x0
13	XIOEN	Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.	RW	0x0

Bits	Field Name	Description	Type	Reset
12	RIOEN	Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.	RW	0x0
11	FSXM	Transmit Frame-Synchronization Mode 0x0: Frame-synchronization signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-synchronization mode bit FSGM in SRGR2.	RW	0x0
10	FSRM	Receive Frame-Synchronization Mode 0x0: Frame-Synchronization pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.	RW	0x0
9	CLKXM	Transmitter Clock Mode When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKXM bit is ignored. The internal transmit clock (not the mcbspi_clkx pin) is driven by the internal SRG and mcbspi_clkx pin is in high-impedance. 0x0: Transmitter clock is driven by an external clock with CLKX as an input pin. 0x1: CLKX is an output pin and is driven by the internal SRG.	RW	0x0
8	CLKRM	Receiver Clock Mode When digital loop-back mode set (McBSPi.MCBSPLP_XCCR_REG[5] DLB=1), CLKRM bit is ignored. The internal receive lock (not the mcbsp1_clkr pin) is driven by the internal SRG and mcbsp1_clkr pin is in high-impedance. 0x0: Receive clock is an input driven by an external clock with CLKR as an input pin. 0x1: CLKR is an output pin and is driven by the internal SRG.	RW	0x0
7	SCLKME	The frequency of CLKG is: CLKG frequency = (Input clock frequency) / (CLKGDV + 1) SCLKME is used in conjunction with the CLKSM bit to select the input clock: 0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: McBSPi_ICLK clock 0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin	RW	0x0
6	CLKS_STAT	CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) 0x0: The signal on the CLKS pin is low 0x1: The signal on the CLKS pin is high	R	0x0

Bits	Field Name	Description	Type	Reset
5	DX_STAT	DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) 0x0: Drive the signal on the DX pin low 0x1: Drive the signal on the DX pin high	RW	0x0
4	DR_STAT	DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) 0x0: The signal on DR pin is low 0x1: The signal on DR pin is high	R	0x0
3	FSXP	Transmit Frame-Synchronization Polarity 0x0: Frame-synchronization pulse FSX is active high 0x1: Frame-synchronization pulse FSX is active low	RW	0x0
2	FSRP	Receive Frame-Synchronization Polarity 0x0: Frame-synchronization pulse FSR is active high 0x1: Frame-synchronization pulse FSR is active low	RW	0x0
1	CLKXP	Transmit Clock Polarity 0x0: Transmit data driven on rising edge of CLKX 0x1: Transmit data driven on falling edge of CLKX	RW	0x0
0	CLKRP	Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR	RW	0x0

Description	McBSPLP Interrupt Status register (OCP compliant IRQ line)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	XEMPTYEOF	RESERVED	XOVFLSTAT	XUNDFLSTAT	XRDY	XEOF	XFSX	XSYNCERR	RESERVED	ROVFLSTAT	RUNDFLSTAT	RRDY	REOF	RFSR	RSYNCERR

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Read returns 0x0.	R	0x00000
14	XEMPTYEOF	Transmit Buffer Empty at end of frame (XEMPTYEOF is set to one when a complete frame was transmitted and the transmit buffer is empty). Writing 1 to this bit clears the bit. 0x0: Transmit buffer NOT Empty at end of frame 0x1: Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.	RW	0x0
13	RESERVED	Read returns 0x0.	R	0x0
12	XOVFLSTAT	Transmit Buffer Overflow (XOVFLSTAT bit is set to one when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. 0x0: Transmit buffer NOT overflow 0x1: Transmit buffer overflow; Writing 1 to this bit clears the bit.	RW	0x0
11	XUNDFLSTAT	Transmit Buffer Underflow (XUNDFLSTAT bit is set to one when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit. 0x0: the transmit data buffer is NOT empty new data is required to be transmitted. 0x1: the transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.	RW	0x0
10	XRDY	Transmit Buffer Threshold Reached (XRDY bit is set to one when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit. 0x0: Transmit buffer occupied locations are below the THRSH2_REG value). 0x1: Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.	RW	0x0
9	XEOF	Transmit End Of Frame (XEOF is set to one when a complete frame was transmitted). Writing 1 to this bit clears the bit. 0x0: complete frame was NOT transmitted 0x1: complete frame was transmitted; Writing 1 to this bit clears the bit.	RW	0x0
8	XFSX	Transmit Frame Synchronization (XFSX bit is set to one when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit. 0x0: new transmit frame synchronization is NOT asserted 0x1: new transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.	RW	0x0

Bits	Field Name	Description	Type	Reset
7	XSYNCERR	Transmit Frame Synchronization Error (XSYNCERR is set to one when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit. 0x0: Transmit frame synchronization error is NOT detected 0x1: Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.	RW	0x0
6	RESERVED	Read returns 0x0.	R	0x0
5	ROVFLSTAT	Receive Buffer Overflow (ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. 0x0: receive buffer NOT overflow 0x1: receive buffer overflow; Writing 1 to this bit clears the bit.	RW	0x0
4	RUNDFLSTAT	Receive Buffer Underflow (RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit. 0x0: read operation is performed to the receive data register while receive buffer is NOT empty 0x1: read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.	RW	0x0
3	RRDY	Receive Buffer Threshold Reached (RRDY bit is set to one when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit. 0x0: receive buffer occupied locations are below the THRSH1_REG value). 0x1: receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.	RW	0x0
2	REOF	Receive End Of Frame (REOF is set to one when a complete frame was received). Writing 1 to this bit clears the bit. 0x0: complete frame was NOT received 0x1: complete frame was received; Writing 1 to this bit clears the bit.	RW	0x0
1	RFSR	Receive Frame Synchronization (RFSR bit is set to one when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit. 0x0: new receive frame synchronization is NOT asserted 0x1: new receive frame synchronization is asserted; Writing 1 to this bit clears the bit.	RW	0x0
0	RSYNCERR	Receive Frame Synchronization Error (RSYNCERR is set to one when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit. 0x0: receive frame synchronization error is NOT detected 0x1: receive frame synchronization error is detected. Writing 1 to this bit clears the bit.	RW	0x0

	0x4902 20AC		McBSP2
	0x4902 40AC		McBSP3
	0x4902 60AC		McBSP4
Description	McBSPLP transmit configuration control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																EXTCLKGATE	PPCONNECT	DXENDLY		XFULL_CYCLE	RESERVED			DLB	RESERVED	XDMAEN	RESERVED				XDISABLE

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	EXTCLKGATE	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable.	RW	0x0
14	PPCONNECT	Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. 0x0: non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit. 0x1: Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.	RW	0x0
13:12	DXENDLY	When McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is set to one, this field selects the added delay as follow: 0x0: 13 ns 0x1: 18 ns (default) 0x2: 24 ns 0x3: 30 ns	RW	0x1
11	XFULL_CYCLE	Transmit full cycle mode select: 0x0: McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data) 0x1: McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data)	RW	0x0
10:6	RESERVED	Read returns 0x0.	R	0x00
5	DLB	Digital Loop-Back 0x0: No DLB 0x1: DLB	RW	0x0
4	RESERVED	Read returns 0x0.	R	0x0
3	XDMAEN	Transmit DMA Enable bit. When set to zero this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset. 0x0: When set to zero this bit will gate the external transmit DMA request, 0x1: When set to one this bit will NOT gate the external transmit DMA request,	RW	0x1
2:1	RESERVED	Read returns 0x0.	R	0x0

Bits	Field Name	Description	Type	Reset
0	XDISABLE	Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary. 0x0: The transmit process will NOT stop at the next frame boundary. 0x1: The transmit process will stop at the next frame boundary.	RW	0x0

RESERVED																															CLKMUXSTATUS

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Read returns 0x0.	R	0x00000000
0	CLKMUXSTATUS	When going to/exiting from idle mode, the clock for the interface domain is switched between McBSP_ICLK and master serial clock to allow functioning in idle mode. This bit indicates that the status of clock switching and accesses to the McBSP registers are delayed during clock switching. To avoid such a situation, polling can be performed to the status register to evaluate when McBSPLP is ready. This information is relevant only for the McBSPLP having operating in slave mode (serial clock provided by external component). 0: McBSP registers can be accessed. 1: The response to a different register access is delayed until the muxing process is done. Only the MCBSPLP_STATUS_REG[CLKMUXSTATUS] register can be accessed under this condition. The McBSP cannot exit from IDLE state (the external clock must be restarted).	R	0x0

MMC/SD/SDIO Card Interface

This chapter describes the features and functions of the multimedia card/SD/SD I/O (MMC/SDIO) card interface.

Topic **Page**

19.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SD I/O (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are three MMC/SD/SDIO host controllers inside the device: Figure 19-1 gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and Figure 19-2 gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 19-1. MMC/SD/SDIO1 and 3 Overview

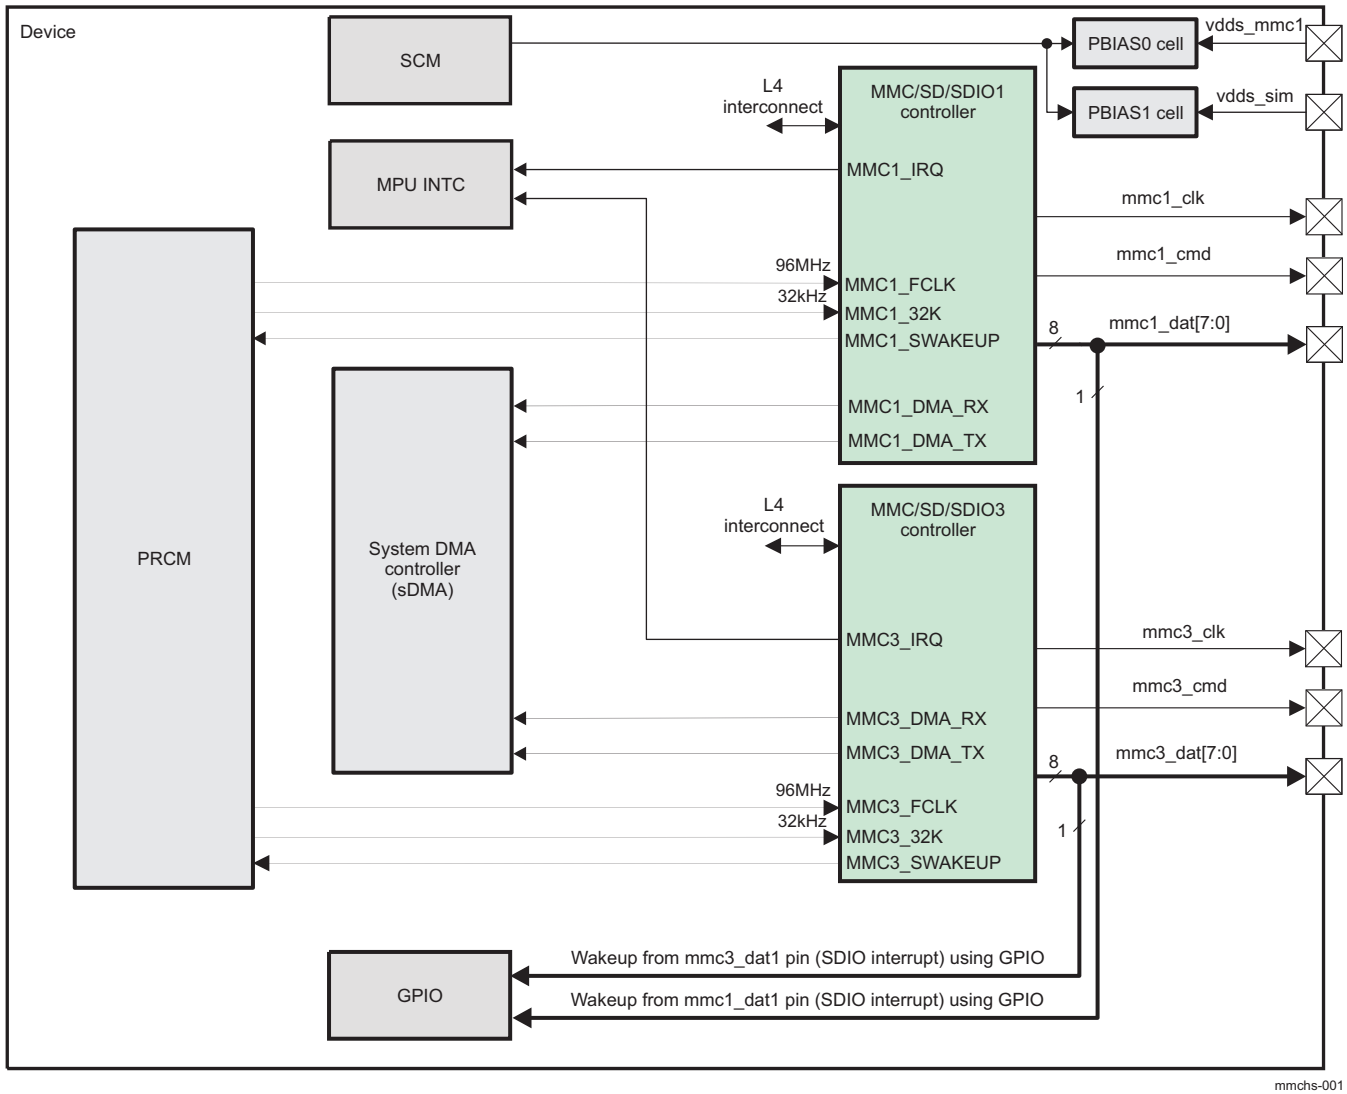

Figure 19-2. MMC/SD/SDIO2 Overview

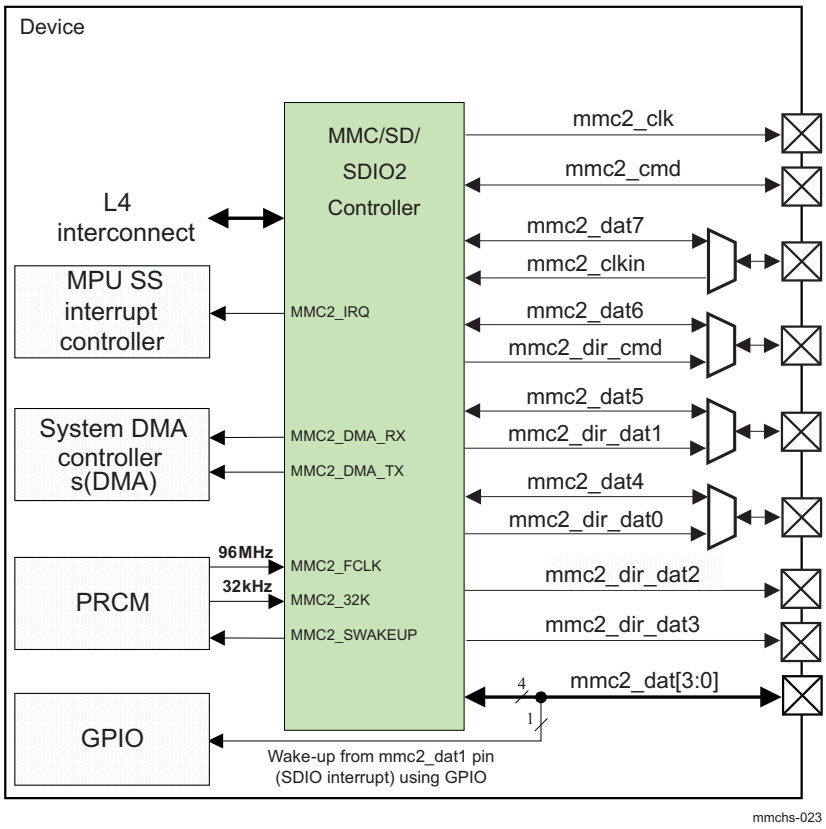


19.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification,* v4.2 including high-capacity (size > 2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0 including high-capacity SDHC cards up to 32GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
  - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
  - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)

- Designed for low power
- Programmable clock generation
- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

NOTE: MMC/e.MMC compliancy versus the *Multimedia Card System Specification*, v4.3 (or v4.4):

Full compliance with the MMC command/response sets and MMC bus testing procedure, as defined in the *Multimedia Card System Specification*, v4.2, does not prevent the use of e.MMC version 4.3 (or 4.4) devices with the OMAP34xx, because e.MMC devices are backward compatible. Only the e.MMC version 4.3 (or 4.4) boot operation is not supported in the OMAP34xx. Boot operation in the OMAP34xx follows the TI booting scheme, ID booting from standard memory array.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller are defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. A standard SD host controller is defined as a DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.

19.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

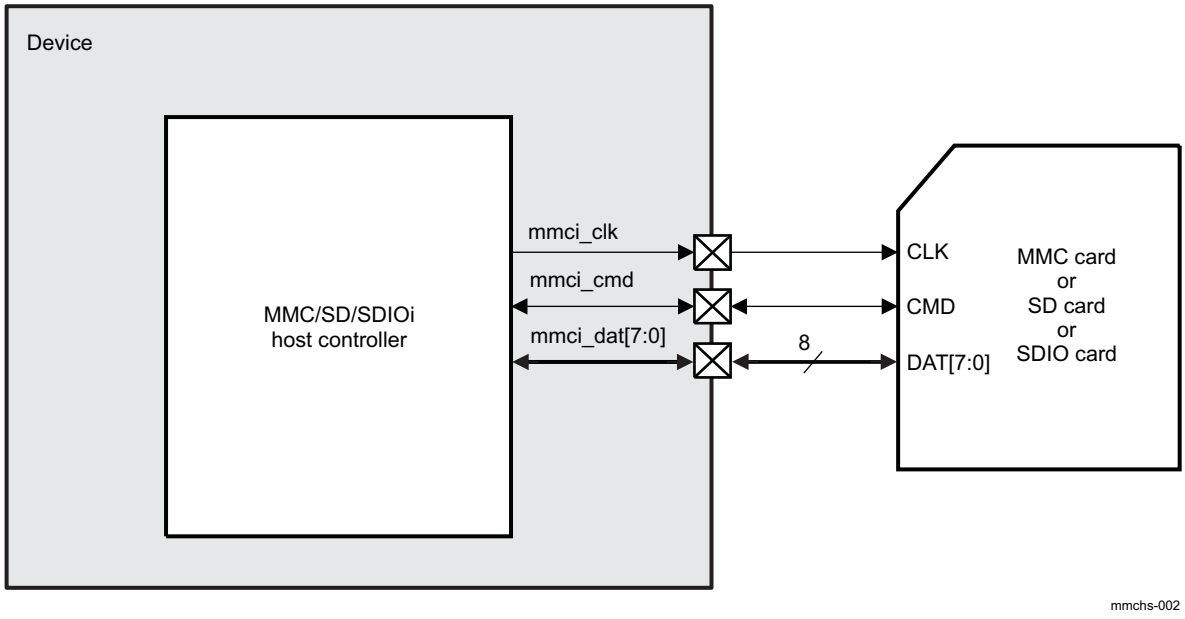
Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver.

19.2.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 19-3 shows MMC/SD/SDIOi host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

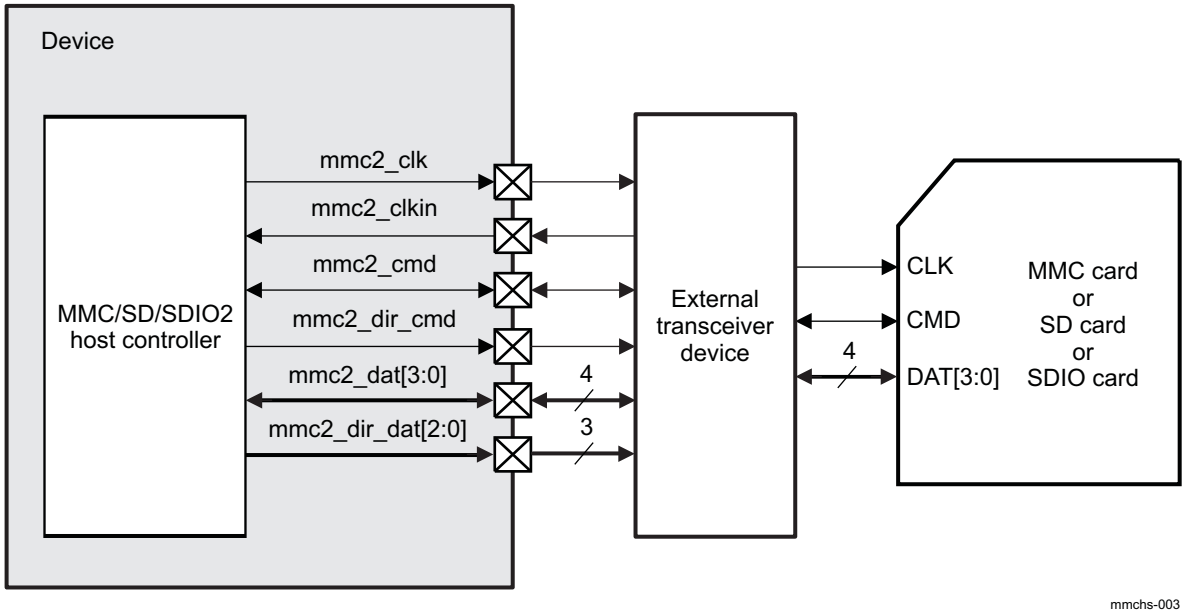
Figure 19-3. MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Without External Transceiver



19.2.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 19-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 19-4. MMC/SD/SDIO2 Connected to an MMC, an SD, or an SDIO Card with External Transceiver



19.2.3 MMC/SD/SDIO Functional Interfaces

19.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 19-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 19-5. MMC/SD/SDIOi Interface Signals

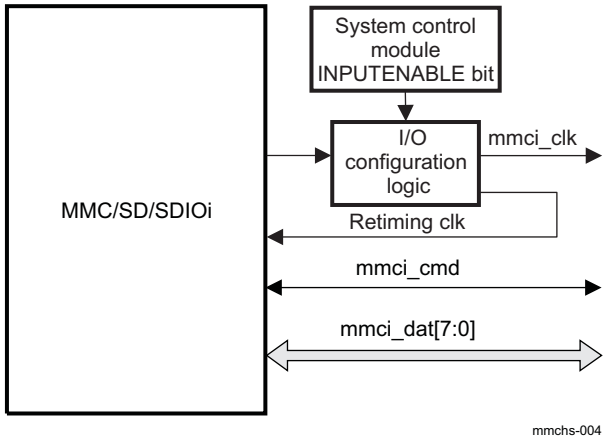


Table 19-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 19-1. MMC/SD/SDIOi I/O Description

Signal Name	I/O[1]	Description	Reset Value
mmci_clk	O	External clock for MMC/SD/SDIO card[2]	0
mmci_cmd	I/O	Command signal	0
mmci_dat[7:0]	I/O	Data signals	0

(1) I = Input; O = Output

(2) This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

19.2.3.2 Basic MMC/SD/SDIO2 Pins with External Transceiver

Figure 19-6 shows the MMC/SD/SDIO2 host controller interface signals.

Figure 19-6. MMC/SD/SDIO2 Interface Signals

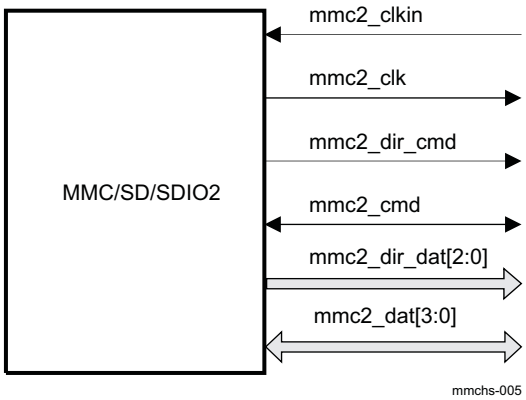

Table 19-2 describes the MMC/SD/SDIO2 inputs/outputs.

Table 19-2. MMC/SD/SDIO2 I/O Description

Signal Name	I/O	Description	Reset Value
mmc2_clk	O	External clock for MMC/SD/SDIO card	0
mmc2_clkin	I	Input clock from MMC/SD/SDIO card	0
mmc2_cmd	I/O	Command signal	0
mmc2_dir_cmd	O	Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive)	0
mmc2_dat[3:0]	I/O	Data signals	0
mmc2_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat1	O	Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat2	O	Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat3	O	Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmci_dat[7:4] are muxed with other direction control signals. See Chapter 6, *System Control Module* for further details on the pin multiplexing.	0

19.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmci_cmd line.

Response: a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmci_cmd line.

Data: data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: the mmci_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmci_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci_dat0 and starts the data programming procedure.

19.2.3.3.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, August 2004, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 19-7 and Figure 19-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

CAUTION

Stream commands are supported only by MMC cards.

Figure 19-7. Sequential Read Operation (MMC Cards Only)

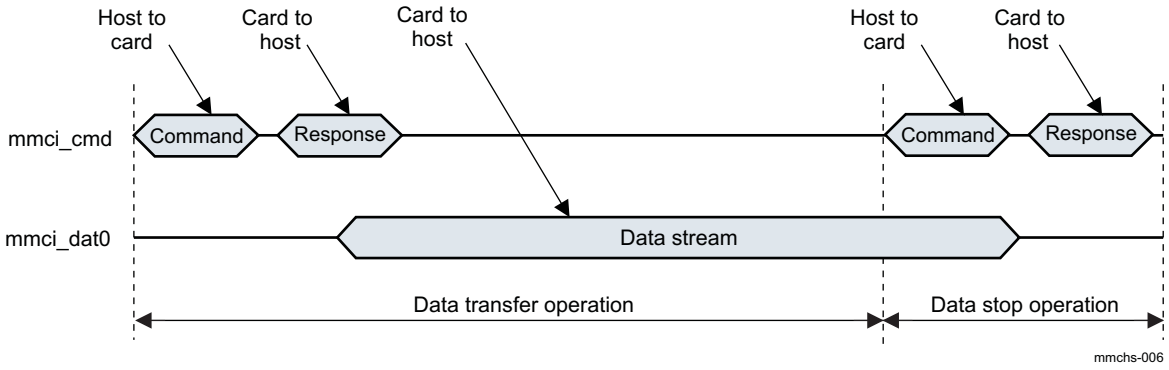

Figure 19-8. Sequential Write Operation (MMC Cards Only)

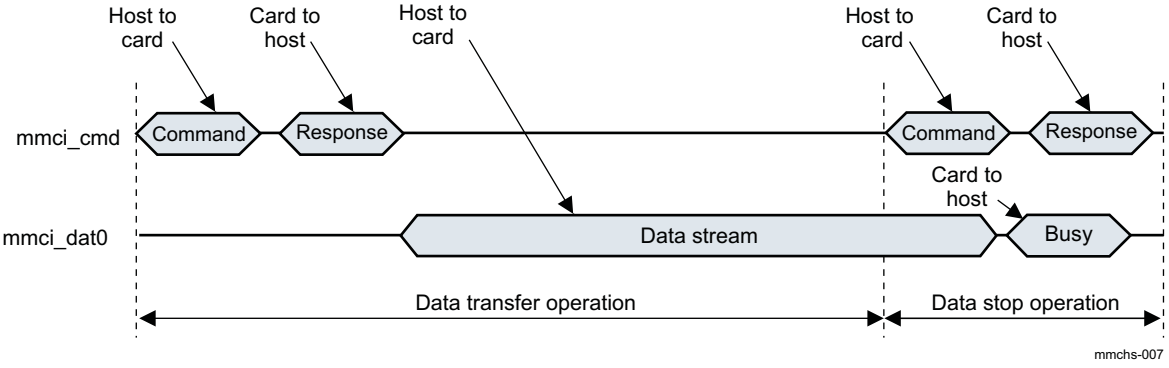

Figure 19-9 and Figure 19-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 19-9. Multiple Block Read Operation

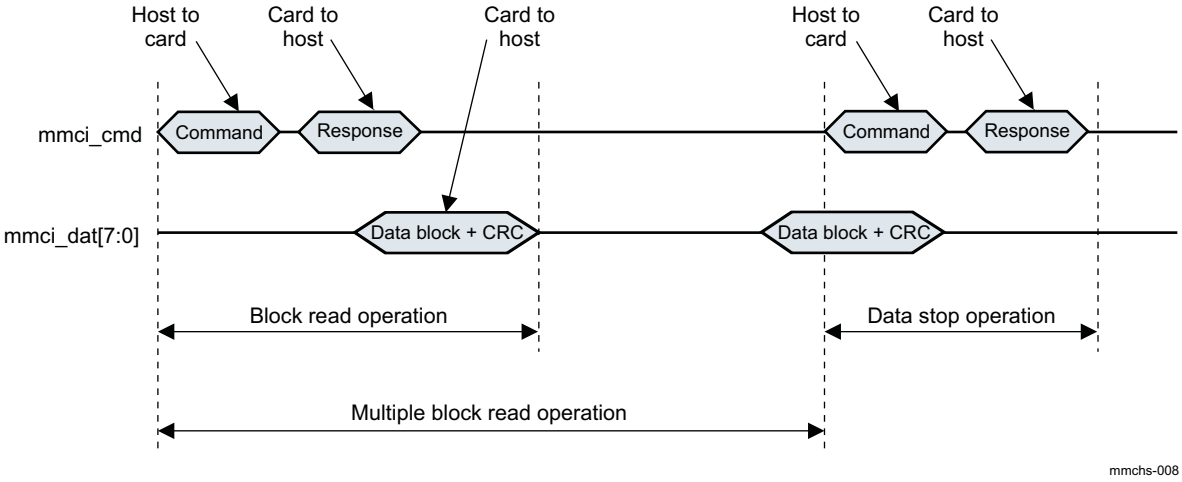

Figure 19-10. Multiple Block Write Operation with Card Busy Signal

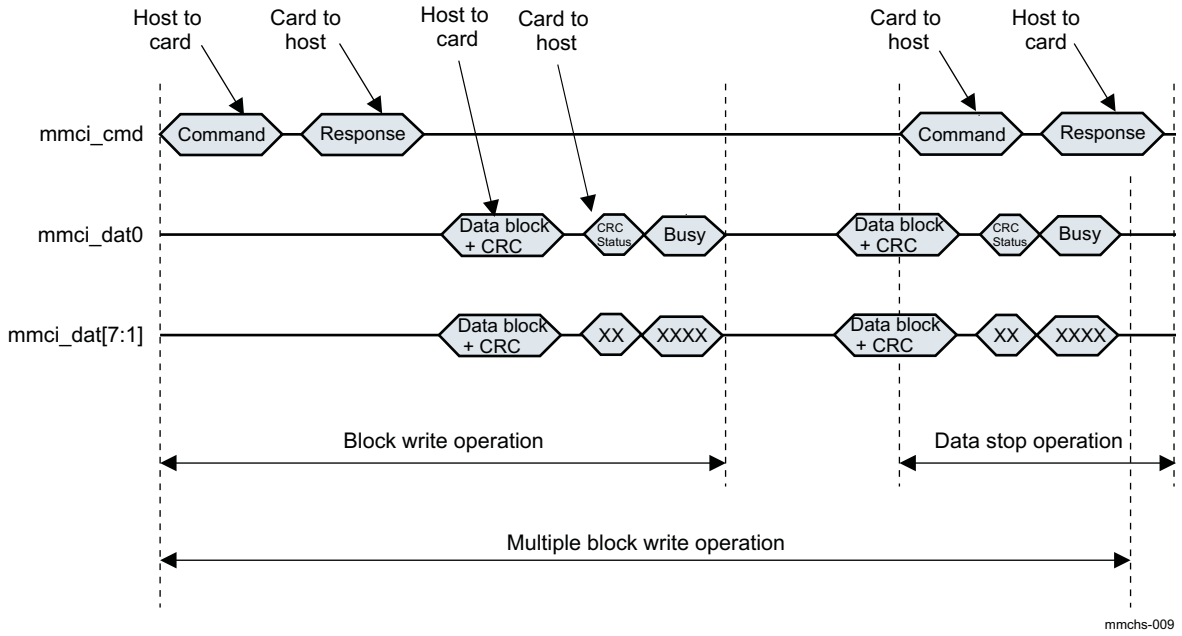


NOTE:

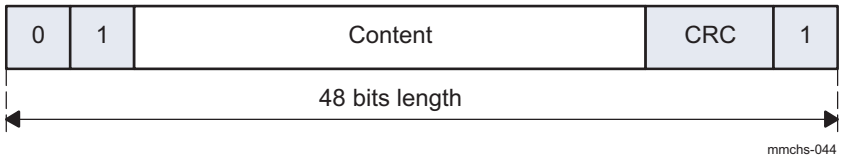
1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set MMCi.MMCHS_SYSCTL[26] SRD bit to 0x1) after data timeout to ensure mmci_clk is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

19.2.3.3.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 19-11).

Figure 19-11. Command Token Format



Coding Scheme for Response Token

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see Figure 19-12 and Figure 19-13). Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 19-3). For more details about response types, see the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, or the *SDIO Card Specification, Part E1*, v1.10.

Figure 19-12. Response Token Format (R1, R3, R4, R5, R6)

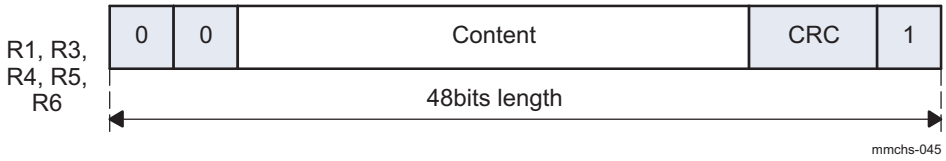


Figure 19-13. Response Token Format (R2)

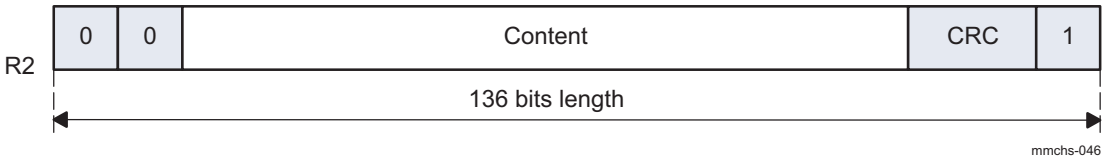

Table 19-3. Relation Between Configuration and Name of Response Type[1]

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5
11	1	1	R1b, R5b

(1) The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 19-14, Figure 19-15, and Figure 19-16).

Figure 19-14. Data Token Format for 1-Bit Transfers

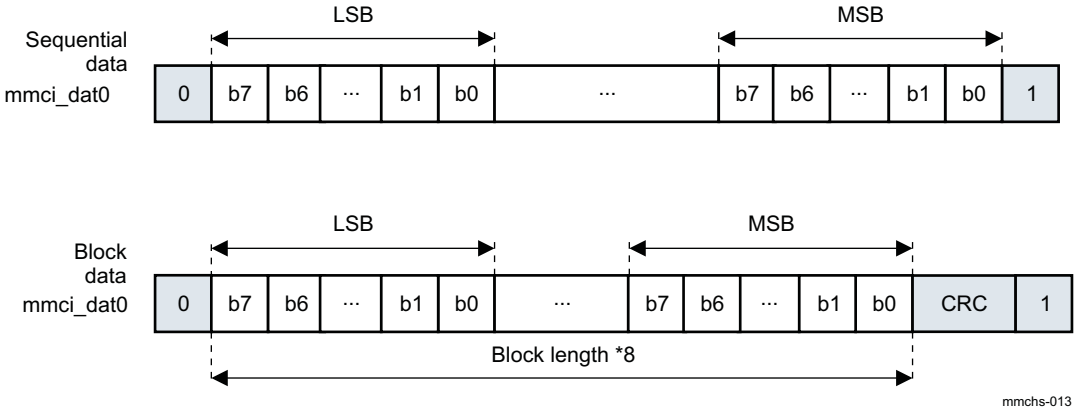

Figure 19-15. Data Token Format for 4-Bit Transfers

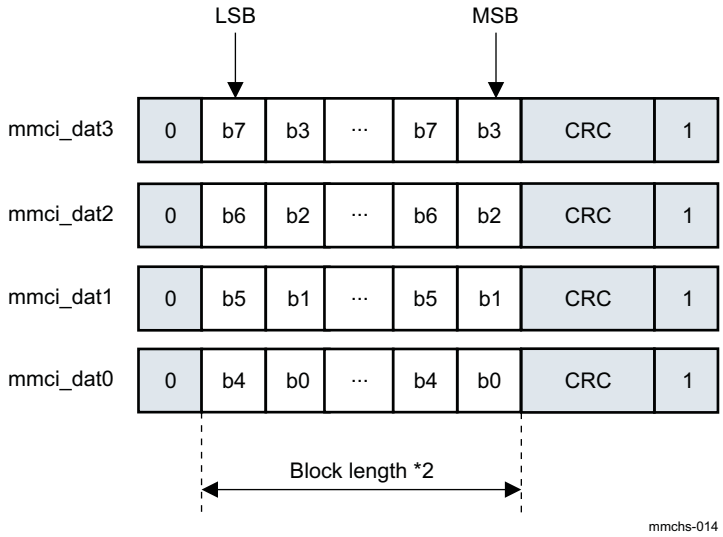

Figure 19-16. Data Token Format for 8-Bit Transfers

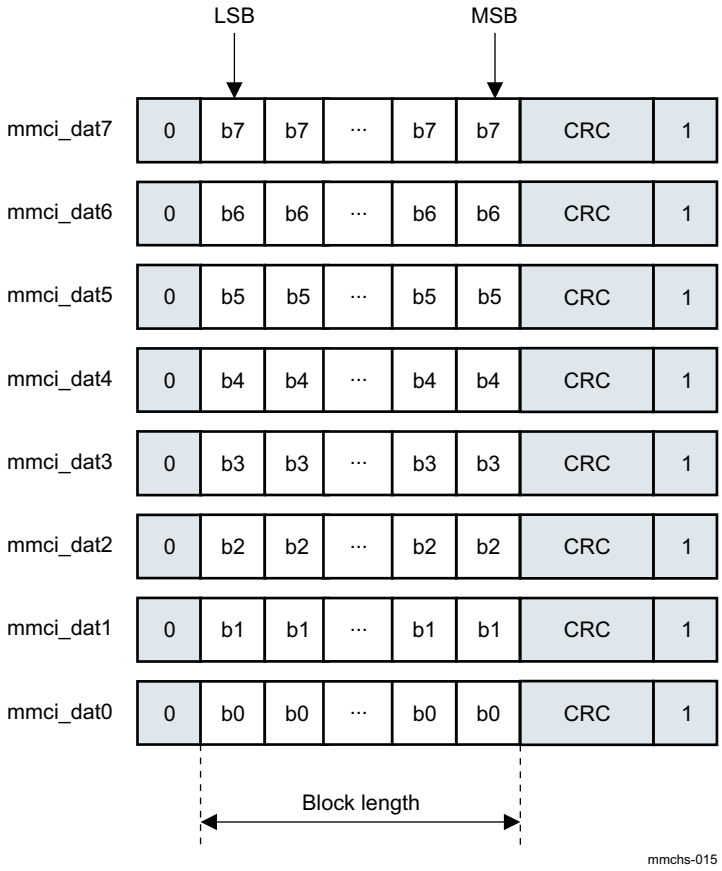
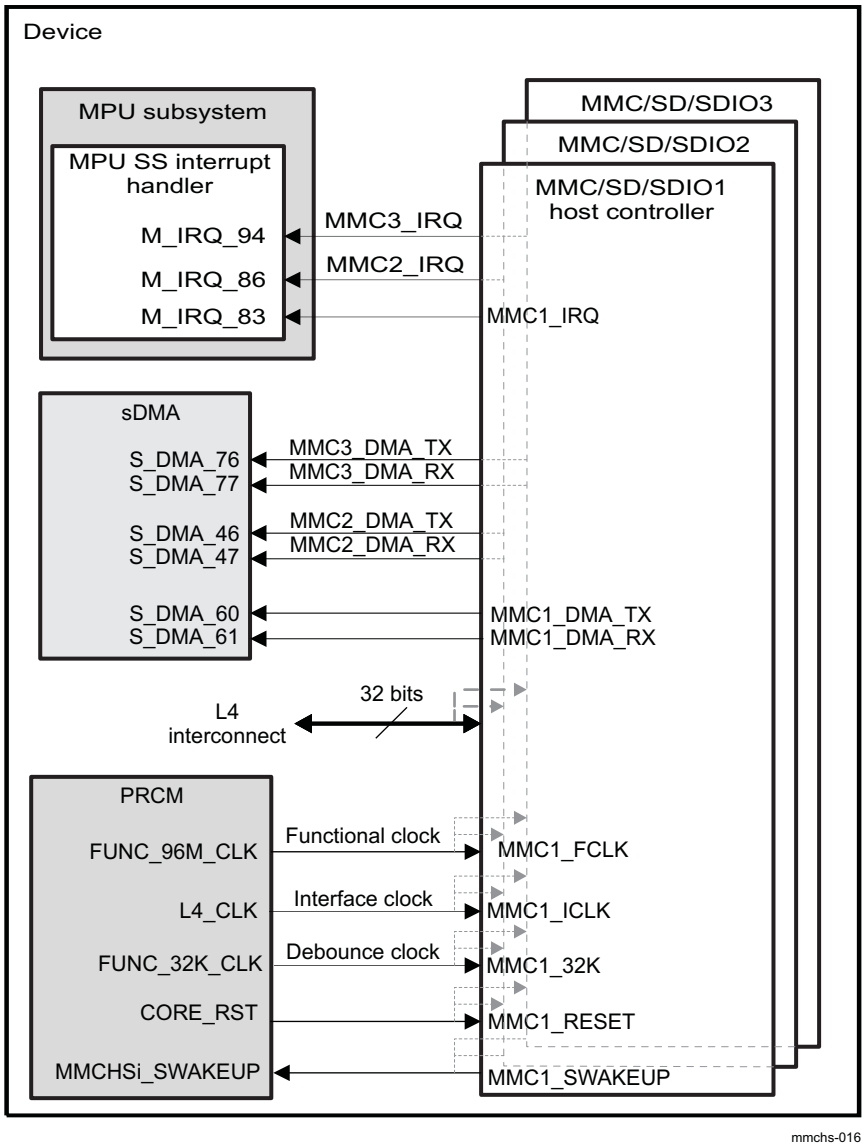


19.3 MMC/SD/SDIO Integration

Figure 19-17 shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 19-17. MMC/SD/SDIO1 Integration



19.3.1 Clocking, Reset, and Power-Management Scheme

19.3.1.1 Clocks

19.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMCi_FCLK) independent of the device external clock frequency
- An interface clock (the MMCi_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMCi_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see , *Power Reset and Clock Management* for more information).

19.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (I = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCi_ICLK clock autogated) even if MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off whatever the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY field.

Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCi_ICLK clock is alive. The PRCM.CM_IDLEST1_CORE[25] ST_MMC2 and (respectively the PRCM.CM_IDLEST1_CORE[24] ST_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on mmci_dat[1] signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1
- MMCi.MMCHS_HCTL[24] IWE bit is set to 0x1
- MMCi.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 19-4 lists the supported cases in smart-idle mode.

Table 19-4. Smart Idle Mode and Wake-Up Capabilities

Mode	MMCi_ICLK clock	MMCi_FCLK clock	Wake-up Event
Card interrupt	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request on detection of a card interrupt on mmci_dat[1] signal

(1) The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCi.MMCHS_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCi.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

19.3.1.2 Resets

19.3.1.2.1 Hardware Reset

The module is reinitialized by the hardware when the active-low reset signal (CORE_RST), synchronous to the MMCi_ICLK clock is asserted on the input pin MMCi_RESET (see , *Power, Reset, and Clock Management* for more information).

A global status bit RESETDONE is provided in the status register MMCi.MMCHS_SYSSTATUS[0]. This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

NOTE: Functional clock MMCi_FCLK, interface clock MMCi_ICLK, and debounce clock MMCi_32K must be provided to the module to allow the RESETDONE status bit to be set.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

19.3.1.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCi_RESET signal except for:

- Debounce logic
- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD bit
- MMCi.MMCHS_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines and status management that

handle data transfers on both the interface and functional side.

- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

19.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see , *Power Reset and Clock Management* for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see Chapter 21, *General-Purpose Interface*, for more information).

19.3.2 Hardware Requests

19.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00.

The DMA request is issued if the three following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S_DMA_60 (MMC1_DMA_TX)
- S_DMA_61 (MMC1_DMA_RX)
- S_DMA_46 (MMC2_DMA_TX)
- S_DMA_47 (MMC2_DMA_RX)
- S_DMA_76 (MMC3_DMA_TX)
- S_DMA_77 (MMC3_DMA_RX)

19.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCi_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN field.

The MMCi_DMA_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1.

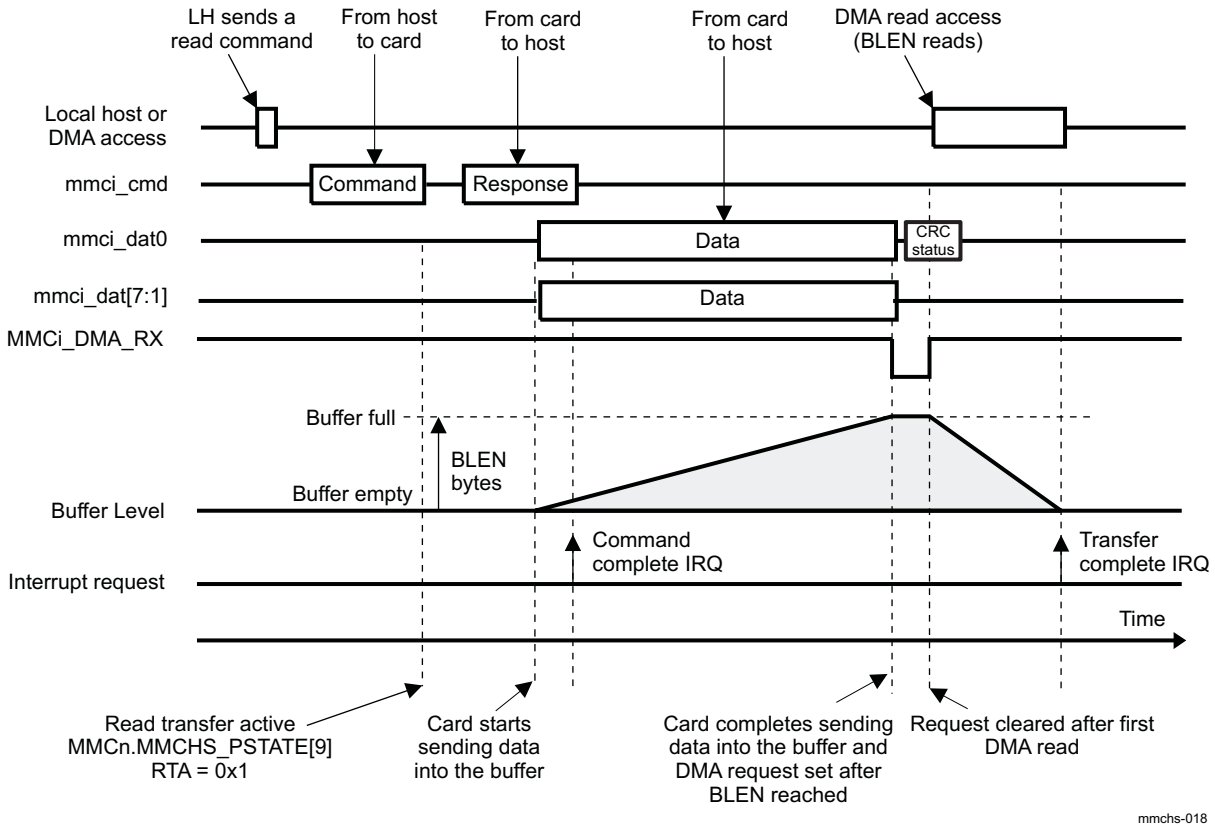
The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see Figure 19-18):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst

- One DMA request per block

Figure 19-18. DMA Receive Mode



19.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN field.

The MMCi_DMA_TX signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

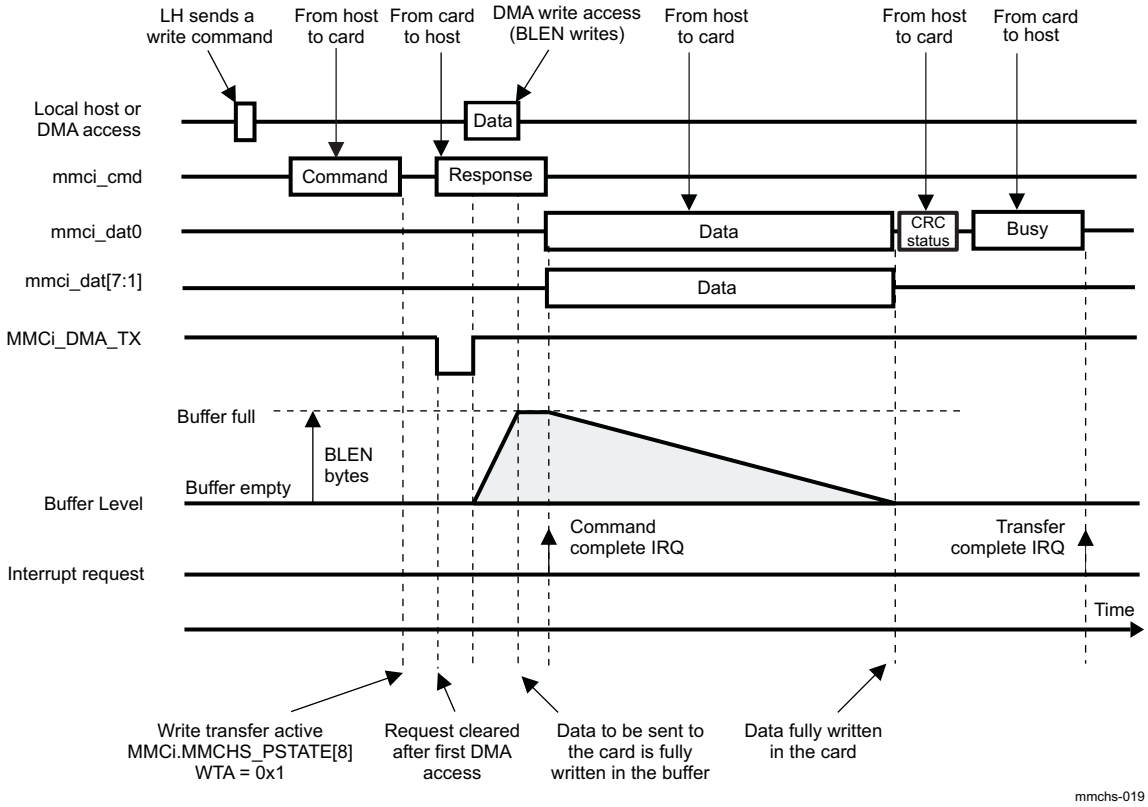
Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1) and if there is not enough memory space to write a complete block in the buffer.

Summary (see Figure 19-19):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 19-19. DMA Transmit Mode



19.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable/disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMCi_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If later a mask is applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCi.MMCHS_STAT or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1_IRQ is connected to M_IRQ_83 for MMC/SD/SDIO1 instance.
- MMC2_IRQ is connected to M_IRQ_86 for MMC/SD/SDIO2 instance.
- MMC3_IRQ is connected to M_IRQ_94 for MMC/SD/SDIO3 instance.

19.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCi.MMCHS_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the MMCi.MMCHS_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.
The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See Chapter 5, *Interconnect* for more information.
The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in MMCi.MMCHS_STAT[31:16] are cleared.

19.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: Refer to the previous note concerning CIRQ and ERRI bits clearing.

19.4 MMC/SD/SDIO Functional Description

19.4.1 Description

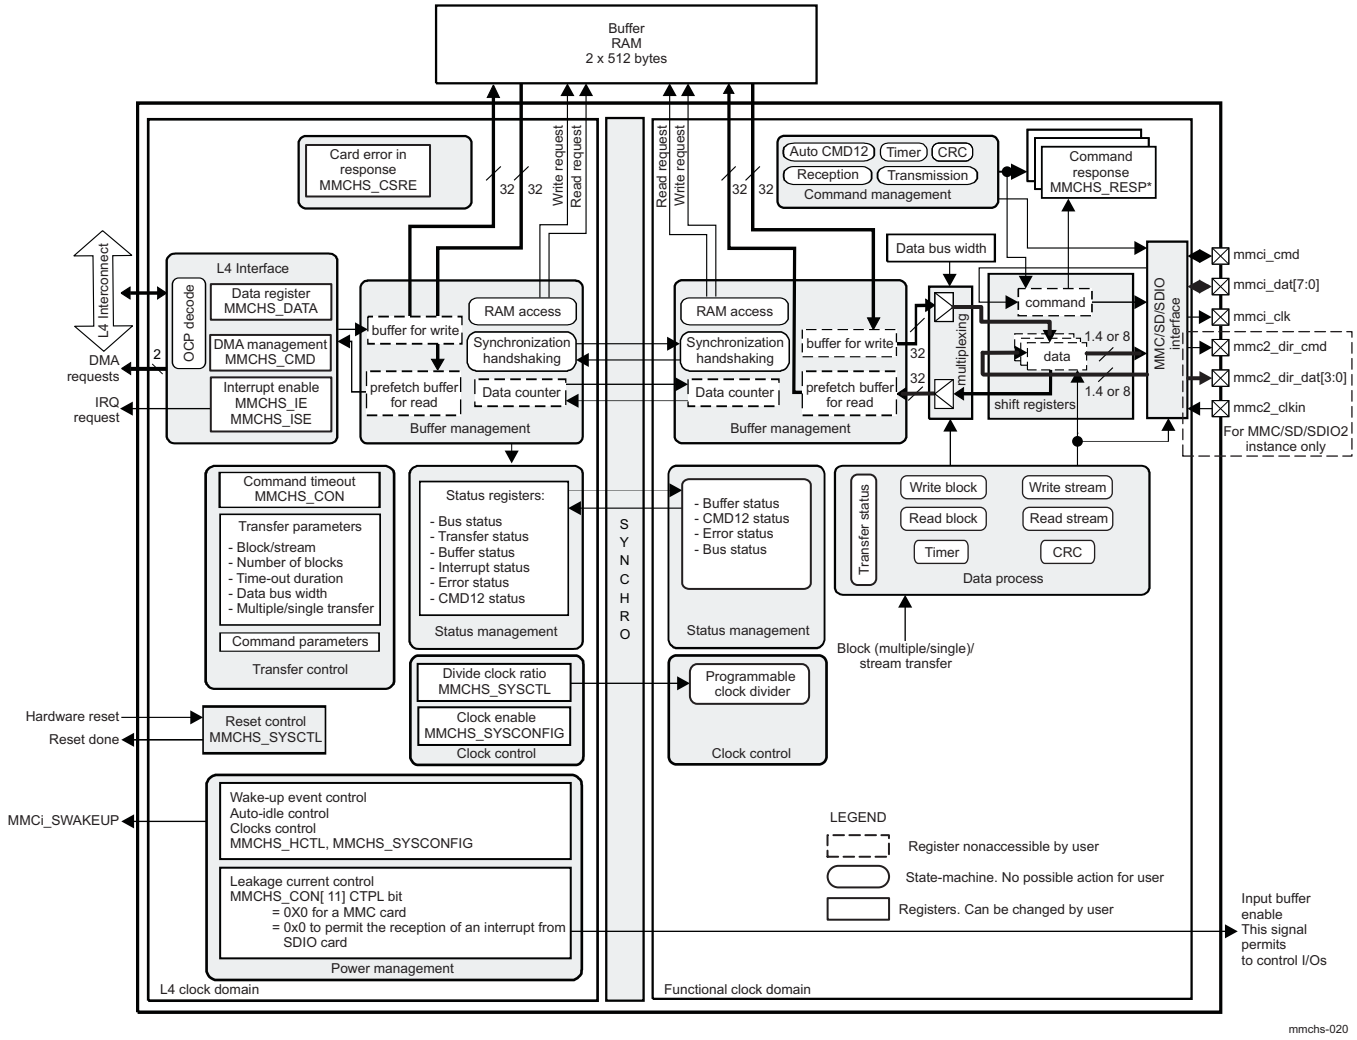
MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2*512 RAM).

Figure 19-20 shows a block diagram of the MMC/SD/SDIO host controller.

Figure 19-20. MMC/SD/SDIO Diagram



In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests

- Consult different status:
  - Bus
  - Buffer
  - Interrupts
  - Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS_RSPn registers: , , , and).

CAUTION

Read access to the command response registers is allowed only when the command process is completed.

19.4.2 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, v1.10, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

19.4.3 Buffer Management

19.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register MMCi.MMCHS_DATA. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of MMCi.MMCHS_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register MMCi.MMCHS_CAPA[17:16] MBL field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read enable status is set to 1 (MMCi.MMCHS_PSTATE[11] BRE); otherwise, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write enable status is set to 1 (MMCi.MMCHS_PSTATE[10] BWE); otherwise, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in BLEN is less than or equal to 0x200, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than, or equal to 0x200 (that is, less than, or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits x BLEN div by 4). Do not use a size greater than 2 times this value.

CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 19-21 and Figure 19-22 show the buffer management for a write and for a read, respectively.

Figure 19-21. Buffer Management for a Write

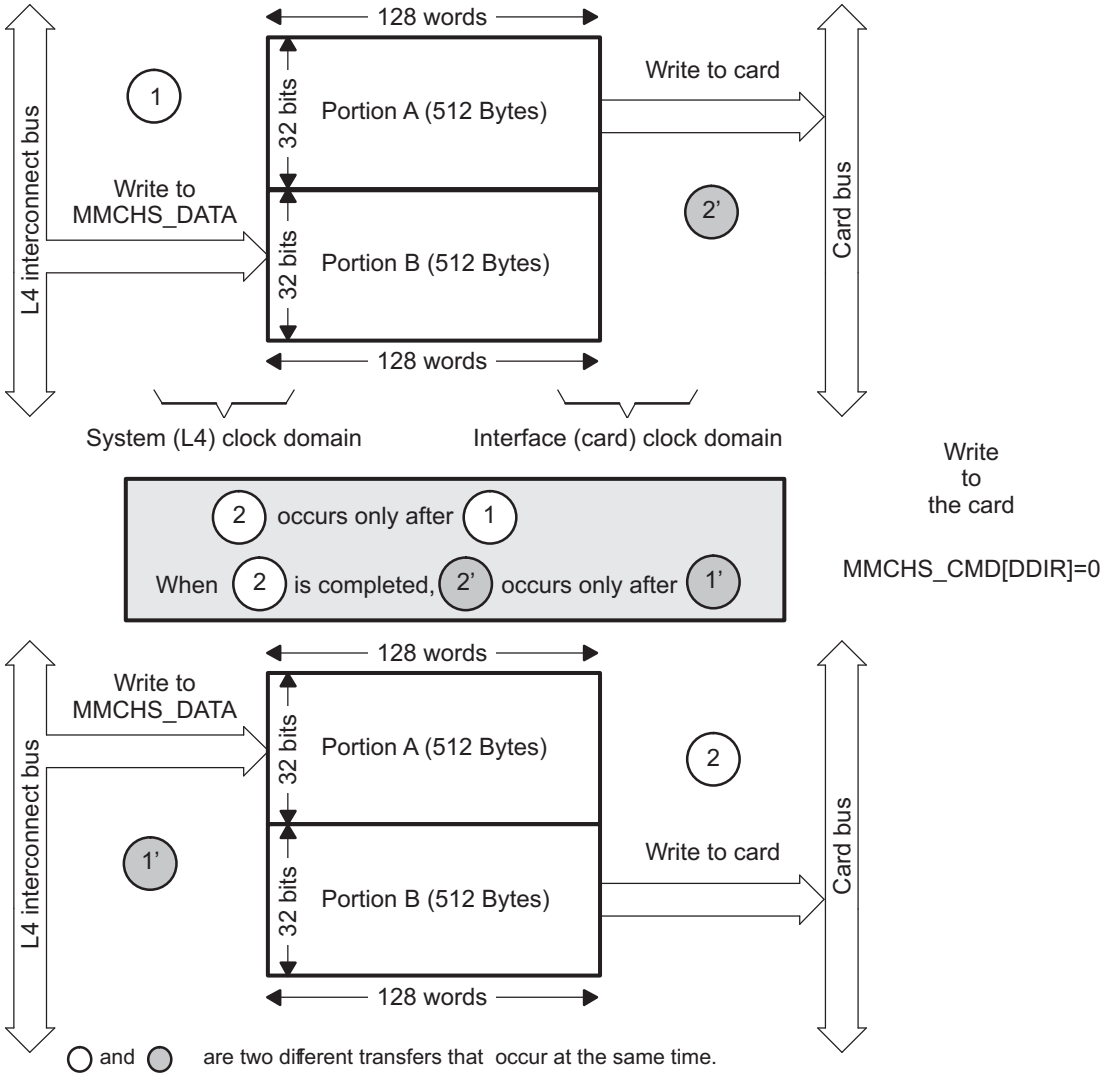


Figure 19-22. Buffer Management for a Read

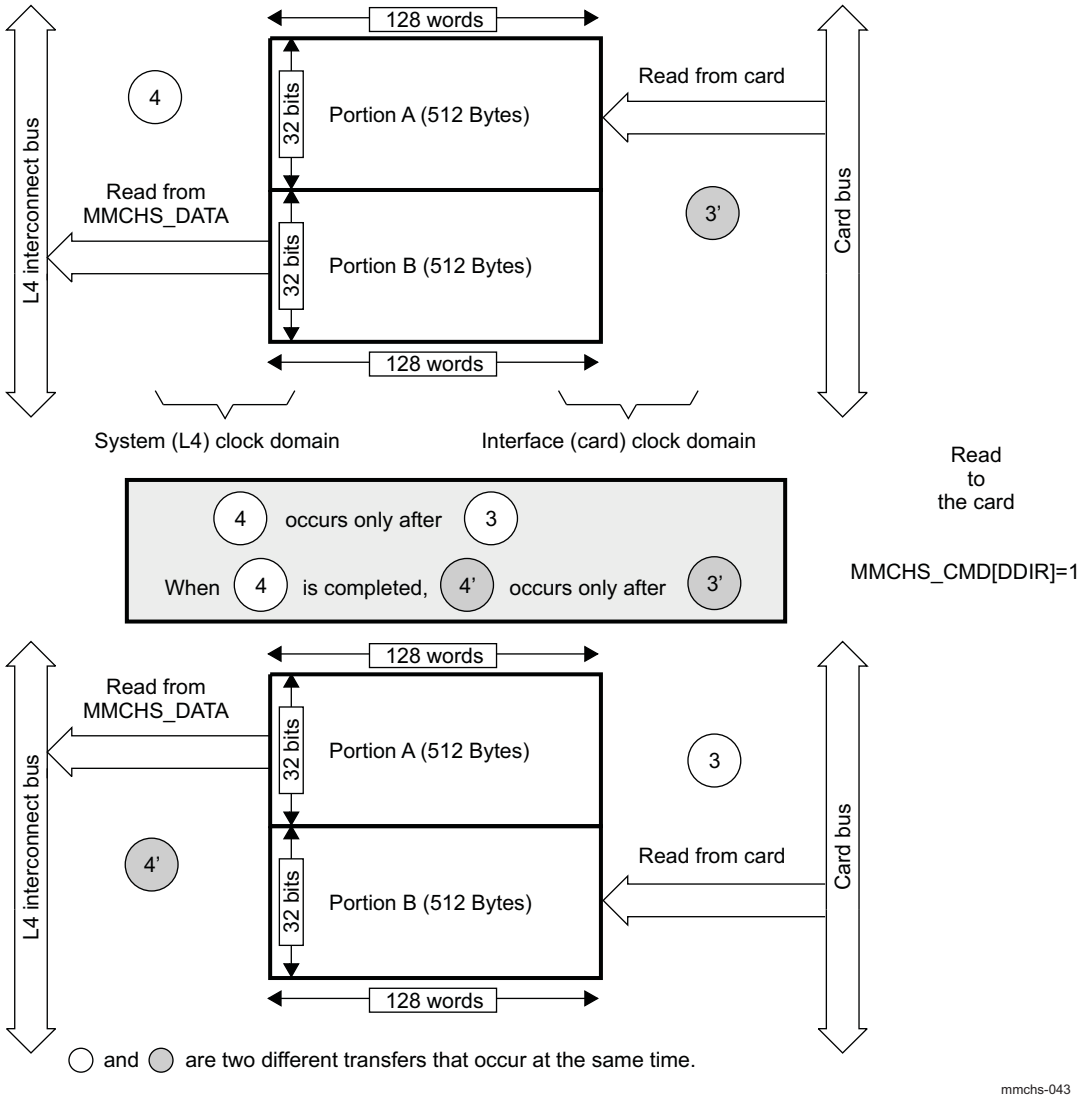


- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

19.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see):
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see):
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

19.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

19.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

19.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

Table 19-5 shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 19-5. MMC, SD, SDIO responses in the MMCHS_RSPxx registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6	RESP[39:8](1)	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8](1)	MMCHS_RSP76[31:0]
R2	RESP[127:0](1)	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS_RSP10 register and vice versa.

19.4.5 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 19-6 and register description for more details.

Table 19-6. CC and TC Values Upon Error Detected

Error hold in the MMCi.MMCHS_STAT register		CC	TC	Comments
29	BADA			No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.

Table 19-6. CC and TC Values Upon Error Detected (continued)

Error hold in the MMCi.MMCHS_STAT register		CC	TC	Comments
17	CCRC	1		CC can be set upon CCRC - See CTO comment
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears.

19.4.6 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

  This feature is enabled by setting the MMCi.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.
- Stop at block gap

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

NOTE: For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

Table 19-7 shows the common way to stop a transfer, indicating command to send and features to enable.

Table 19-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary

	WRITE transfer		READ transfer	
	SD / MMC	SDIO	SD / MMC	SDIO
Single block	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC

Table 19-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary (continued)

		WRITE transfer		READ transfer	
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	**If READ_WAIT supported** Stop at block gap Wait TC
					If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

19.4.7 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (MMCHS_CON[12] CEATA and MMCHS_CMD[2] ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- MMCHS_CON[12] CEATA is set to 1.
- MMCHS_CON[2] HR set to 1.
- Clear the MMCHS_ARG register.
- Write into MMCHS_CMD register with value 0x00000000.

When a command completion disable token was emitted (that is, MMCHS_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:

  An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

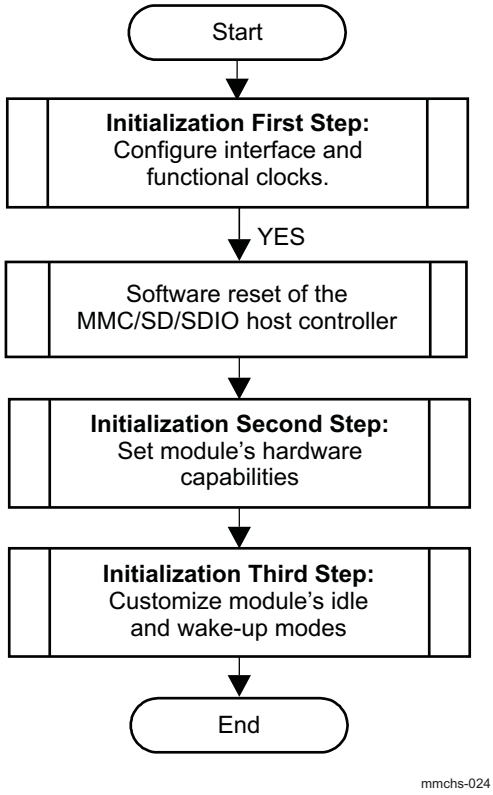
  Only the interrupt CIRQ is generated when CCS is detected.

19.5 MMC/SD/SDIO Basic Programming Model

19.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 19-23 shows the general boot process.

Figure 19-23. MMC/SD/SDIO Controller Meta Initialization Steps



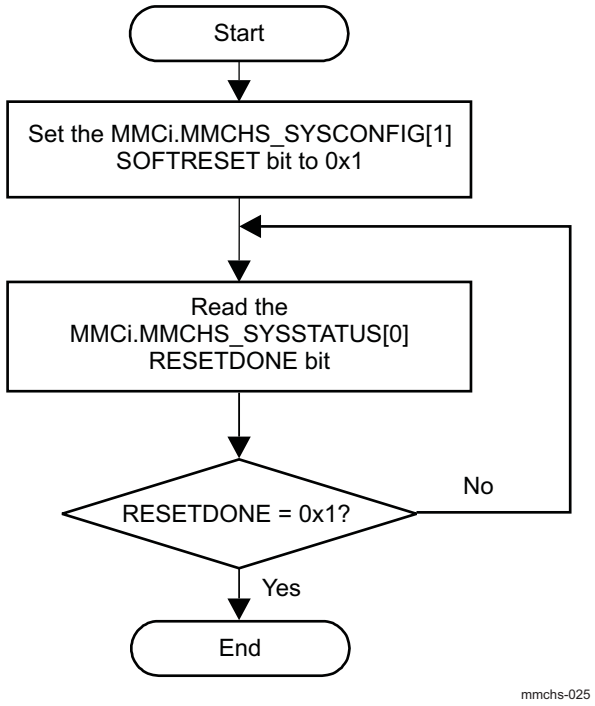
19.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM_ICLKEN1_CORE and PRCM.CM_FCLKEN1_CORE. Please refer to , *Power, Reset, and Clock Management*.

19.5.1.2 MMCHS Soft Reset Flow

Figure 19-24 shows the soft reset process of MMCHS controller.

Figure 19-24. MMC/SD/SDIO Controller Software Reset Flow



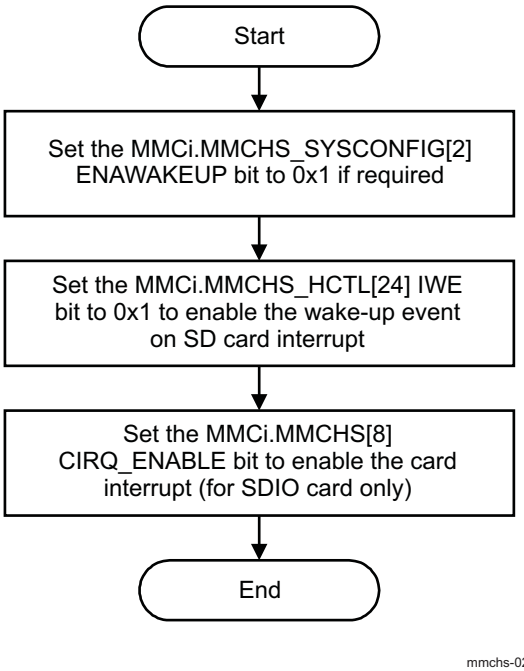
19.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

19.5.1.4 Wake-Up Configuration

Figure 19-25 details MMCHS controller wake-up configuration.

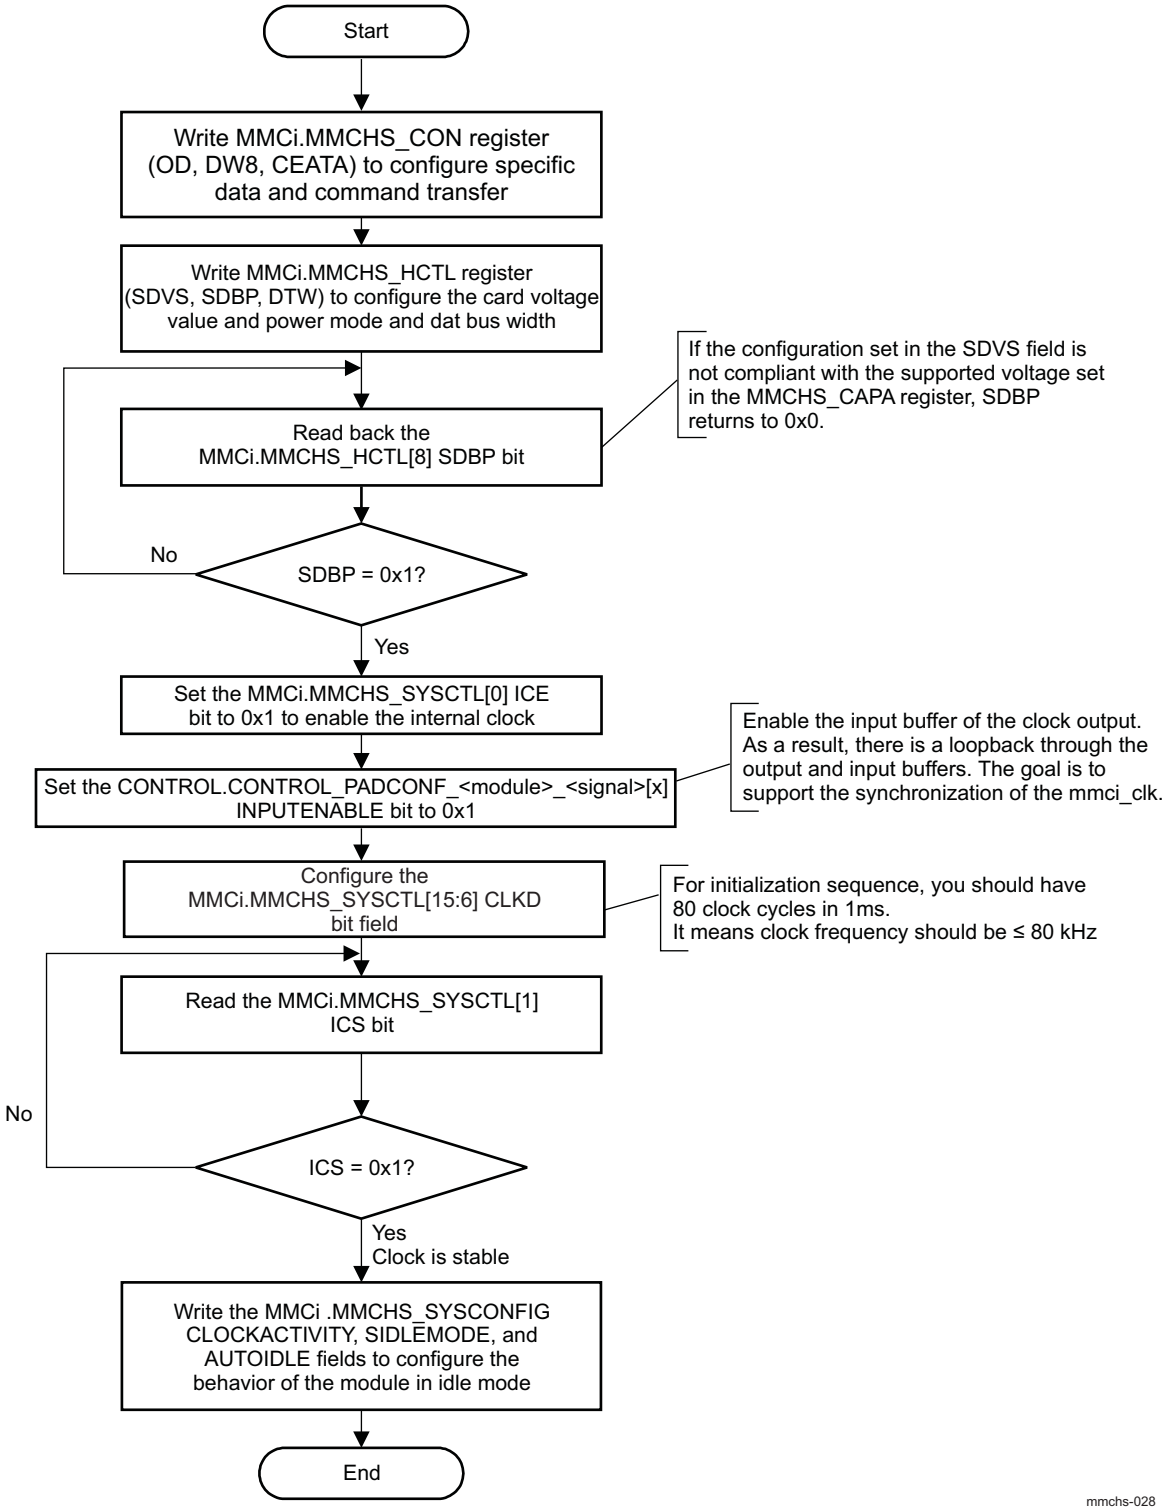
Figure 19-25. MMC/SD/SDIO Controller Wake-Up Configuration



19.5.1.5 MMC Host and Bus Configuration

Figure 19-26 details MMC bus configuration process.

Figure 19-26. MMC/SD/SDIO Controller Bus Configuration



19.5.2 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

19.5.2.1 Card Detection, Identification, and Selection

Figure 19-27 and Figure 19-28 show the card identification and selection process.

Figure 19-27. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

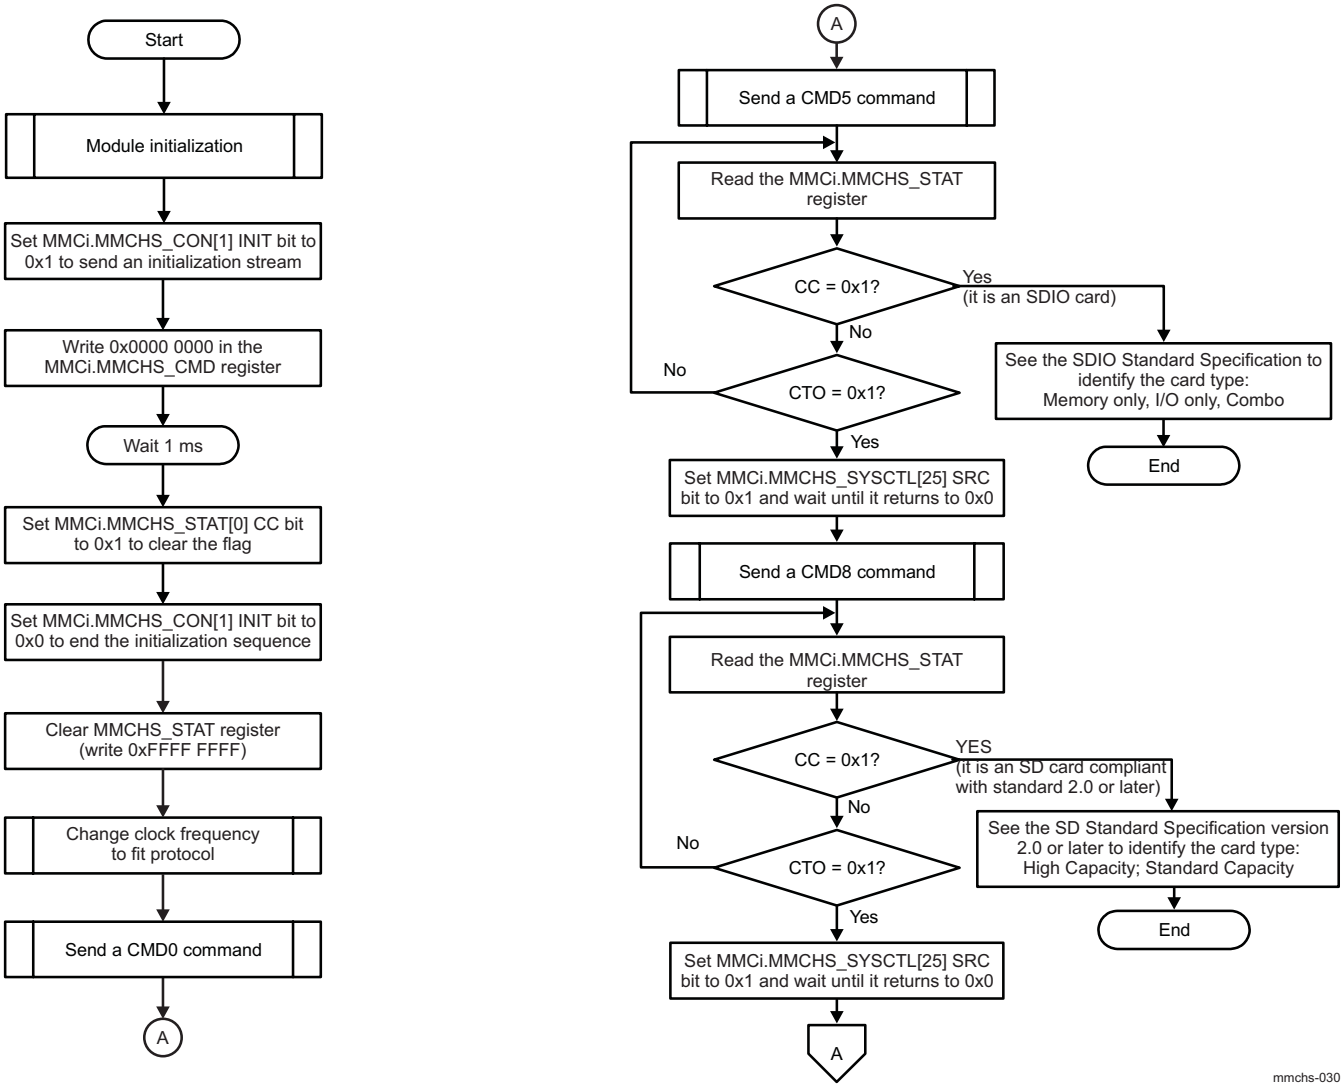


Figure 19-28. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

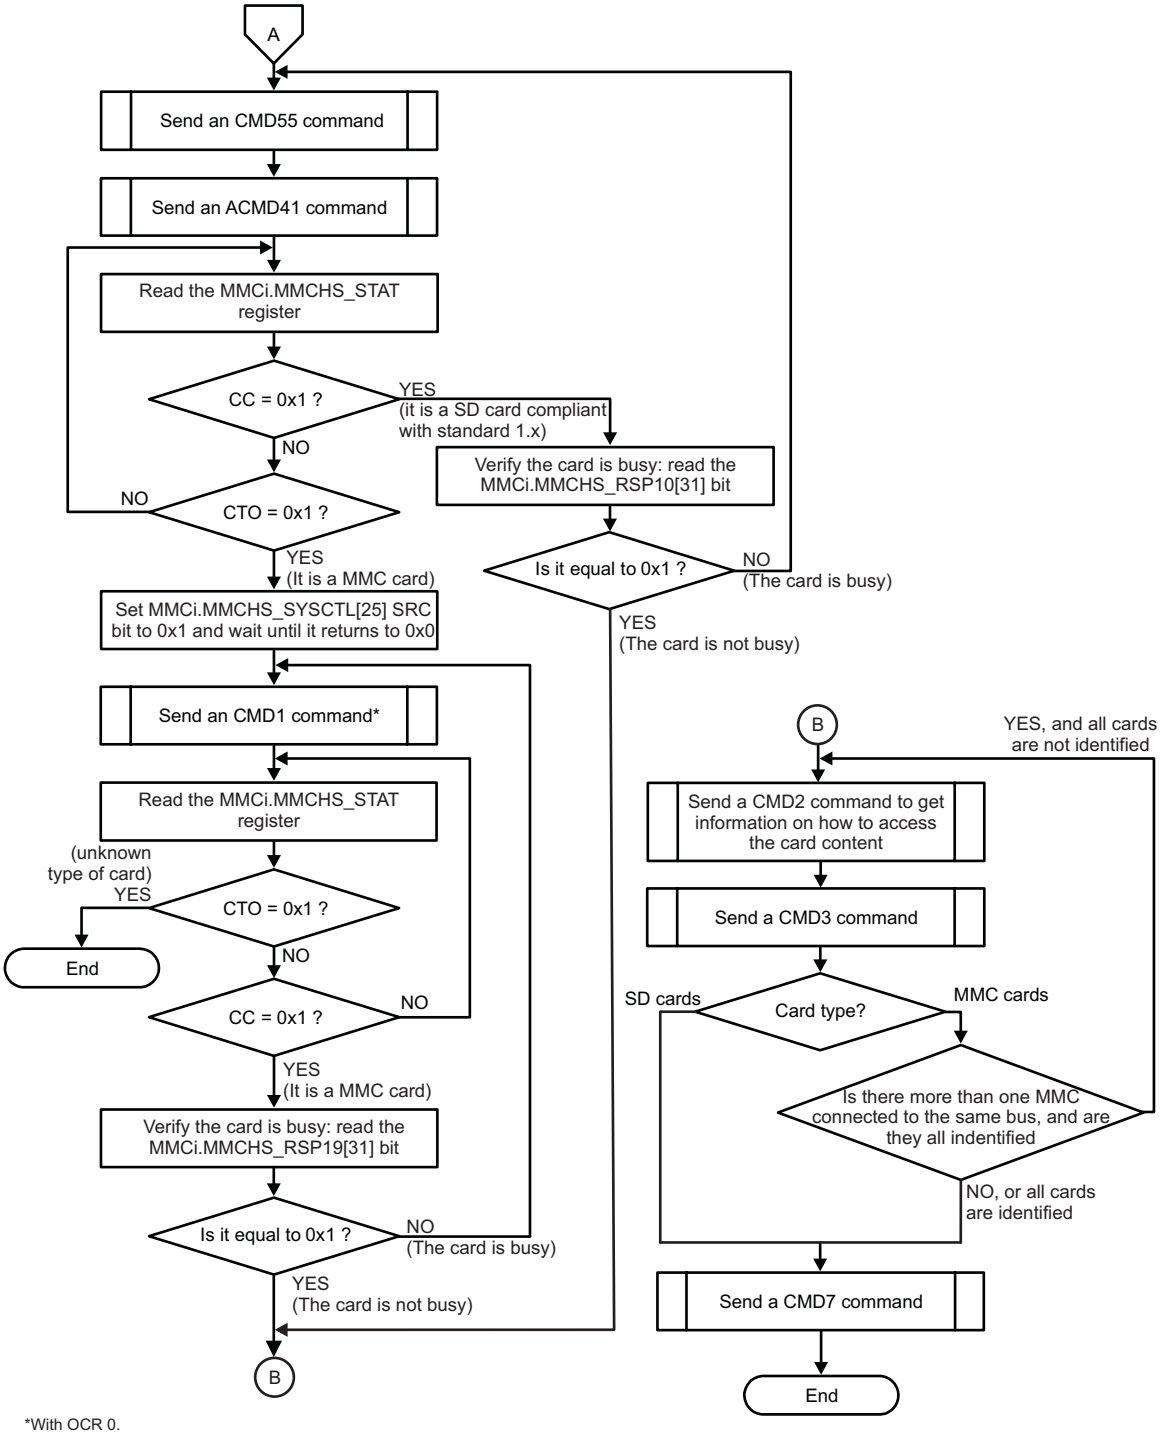


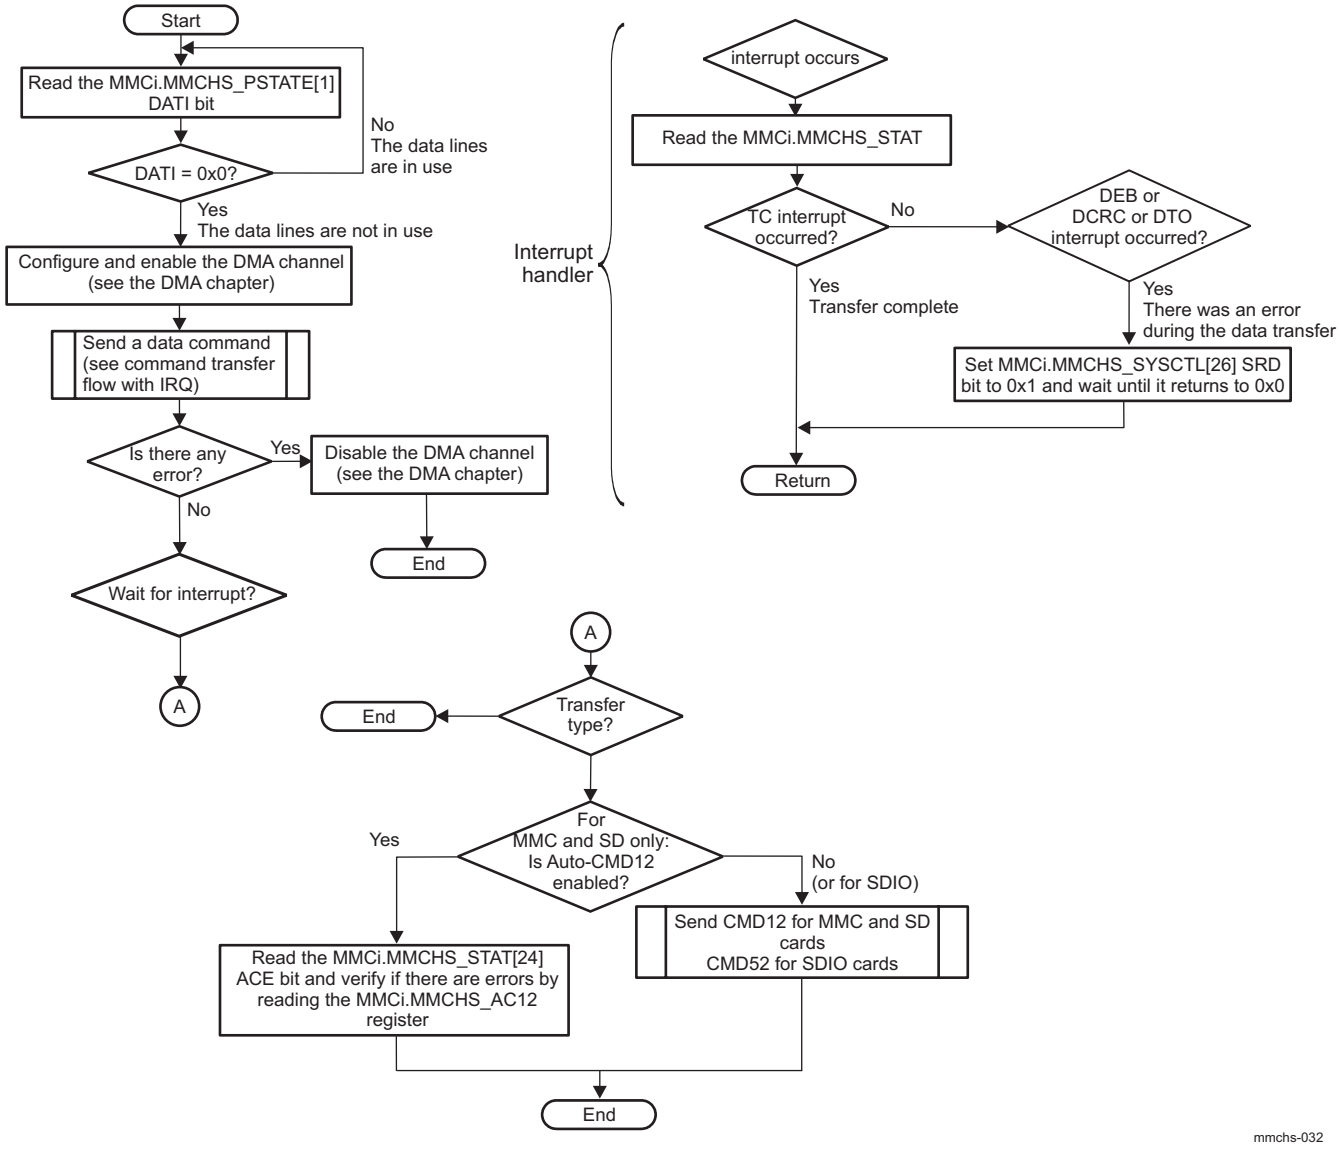
*With OCR 0.
In case of a CMD1 with OCR=0, a second CMD1 must be sent to the card with the "negociated" voltage.

108-031

19.5.2.2 Read/Write Transfer Flow in DMA Mode with Interrupt

Figure 19-29 describes the read and write protocol in DMA mode with interrupt signaling. Refer to Chapter 7, *DMA*, for more information on the DMA settings.

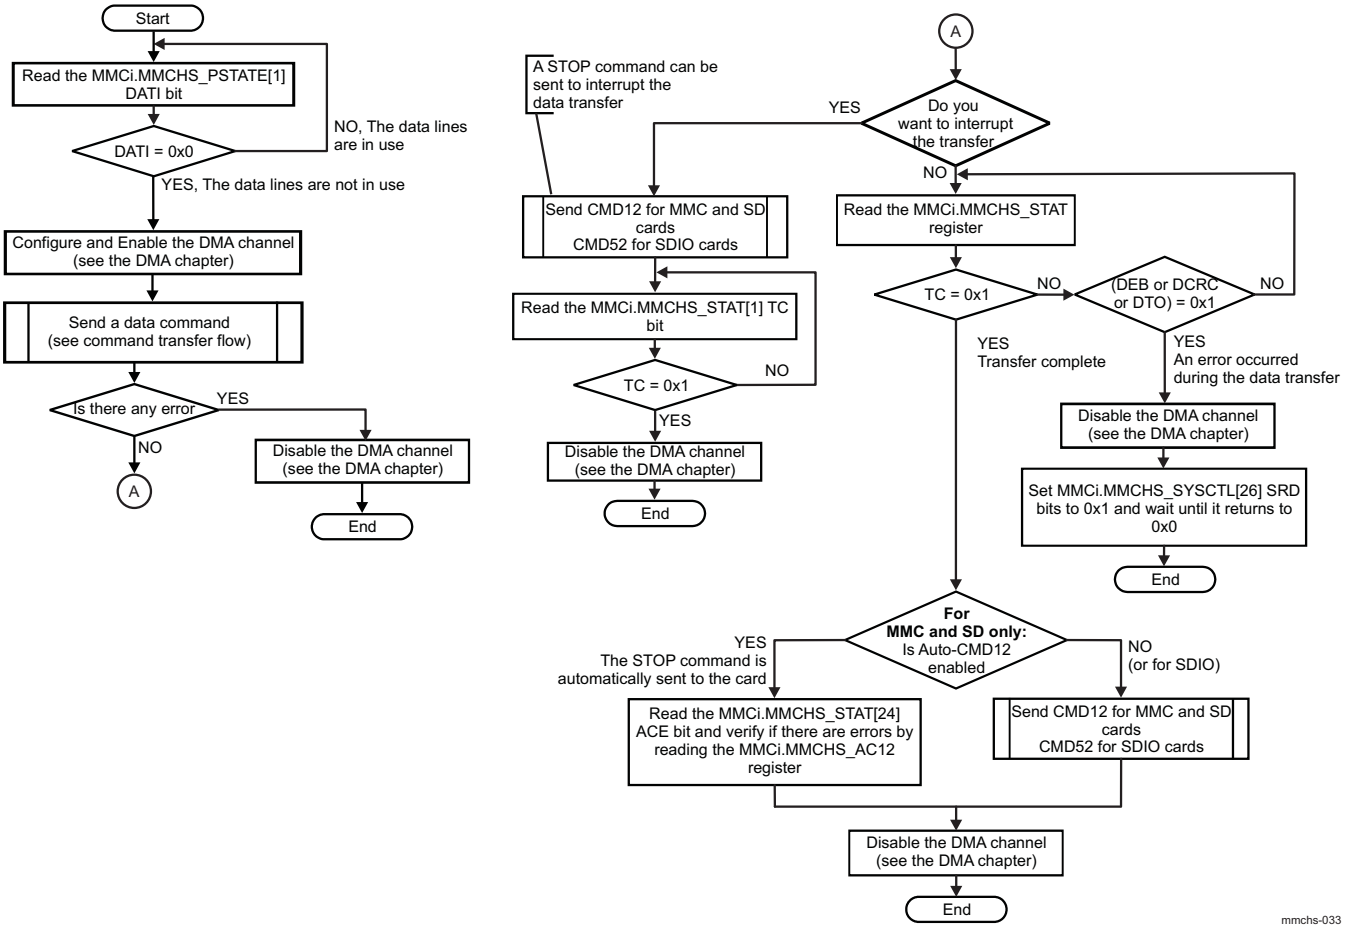
Figure 19-29. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Interrupt



19.5.2.3 Read/Write Transfer Flow in DMA Mode with Polling

Figure 19-30 describes the read and write protocol in DMA mode. Refer to Chapter 7, *DMA*, for more information on the DMA settings.

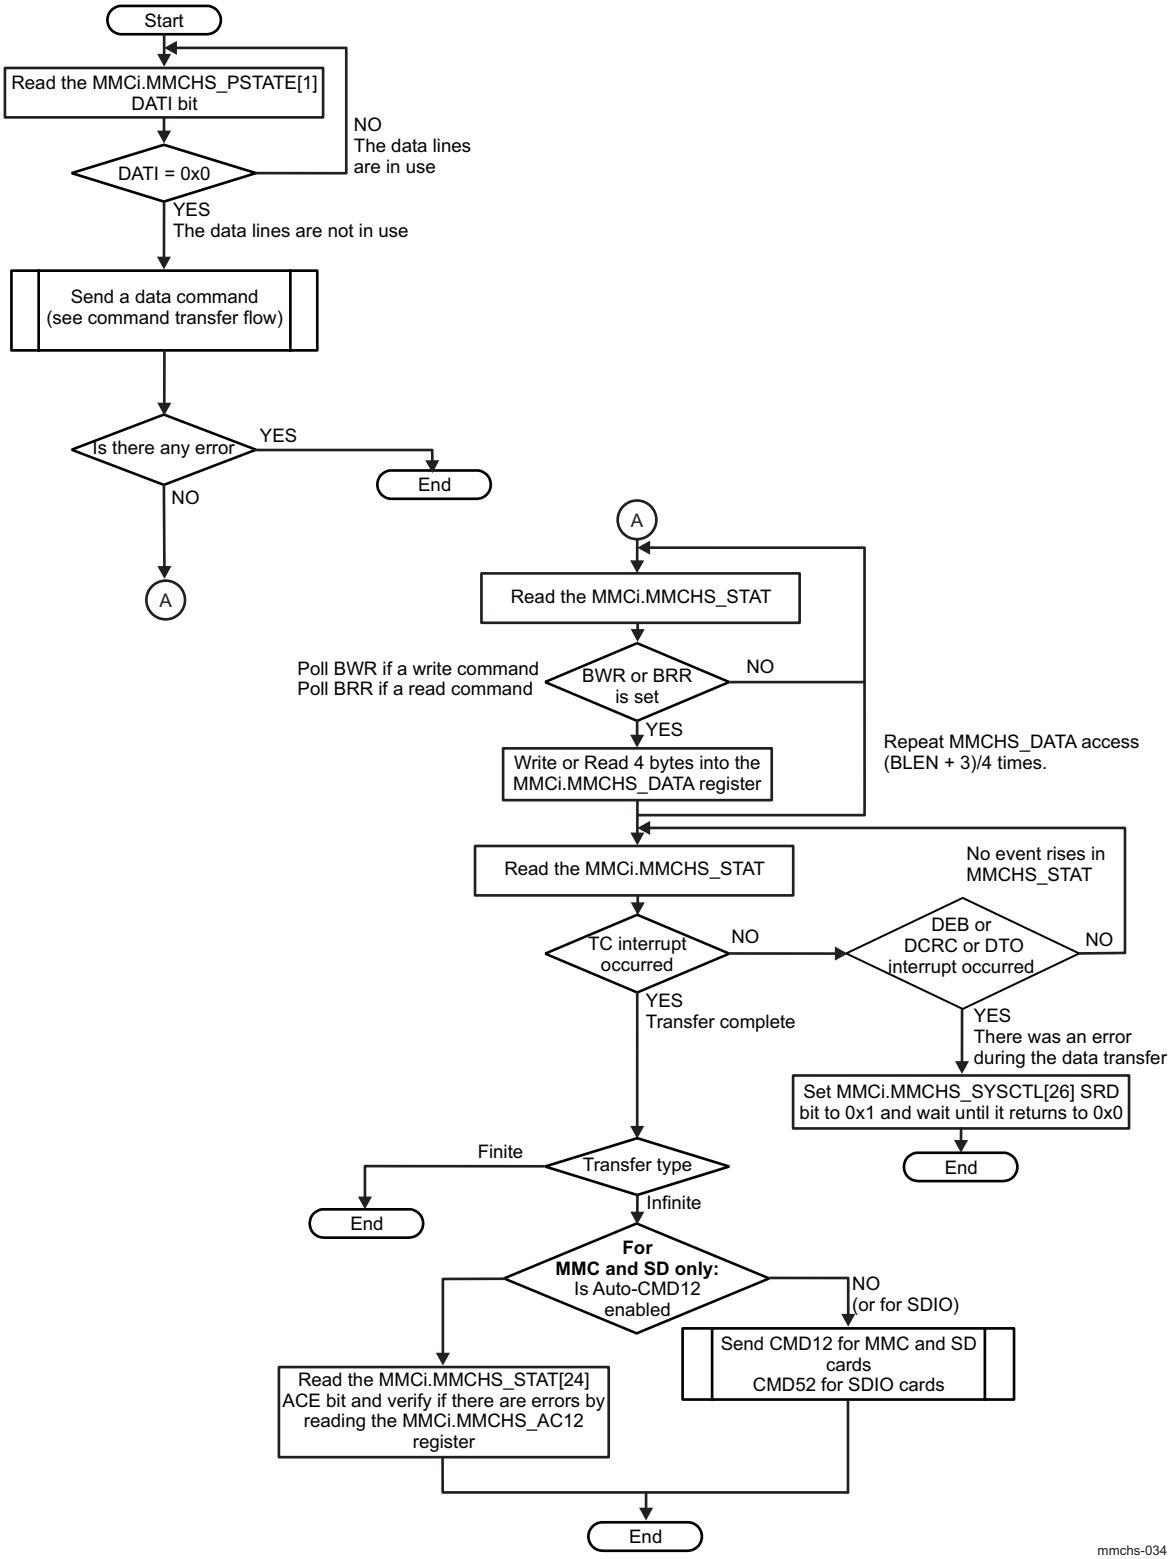
Figure 19-30. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Polling



19.5.2.4 Read/Write Transfer Flow without DMA with Polling

Figure 19-31 describes a read/write transfer without using the DMA and with polling.

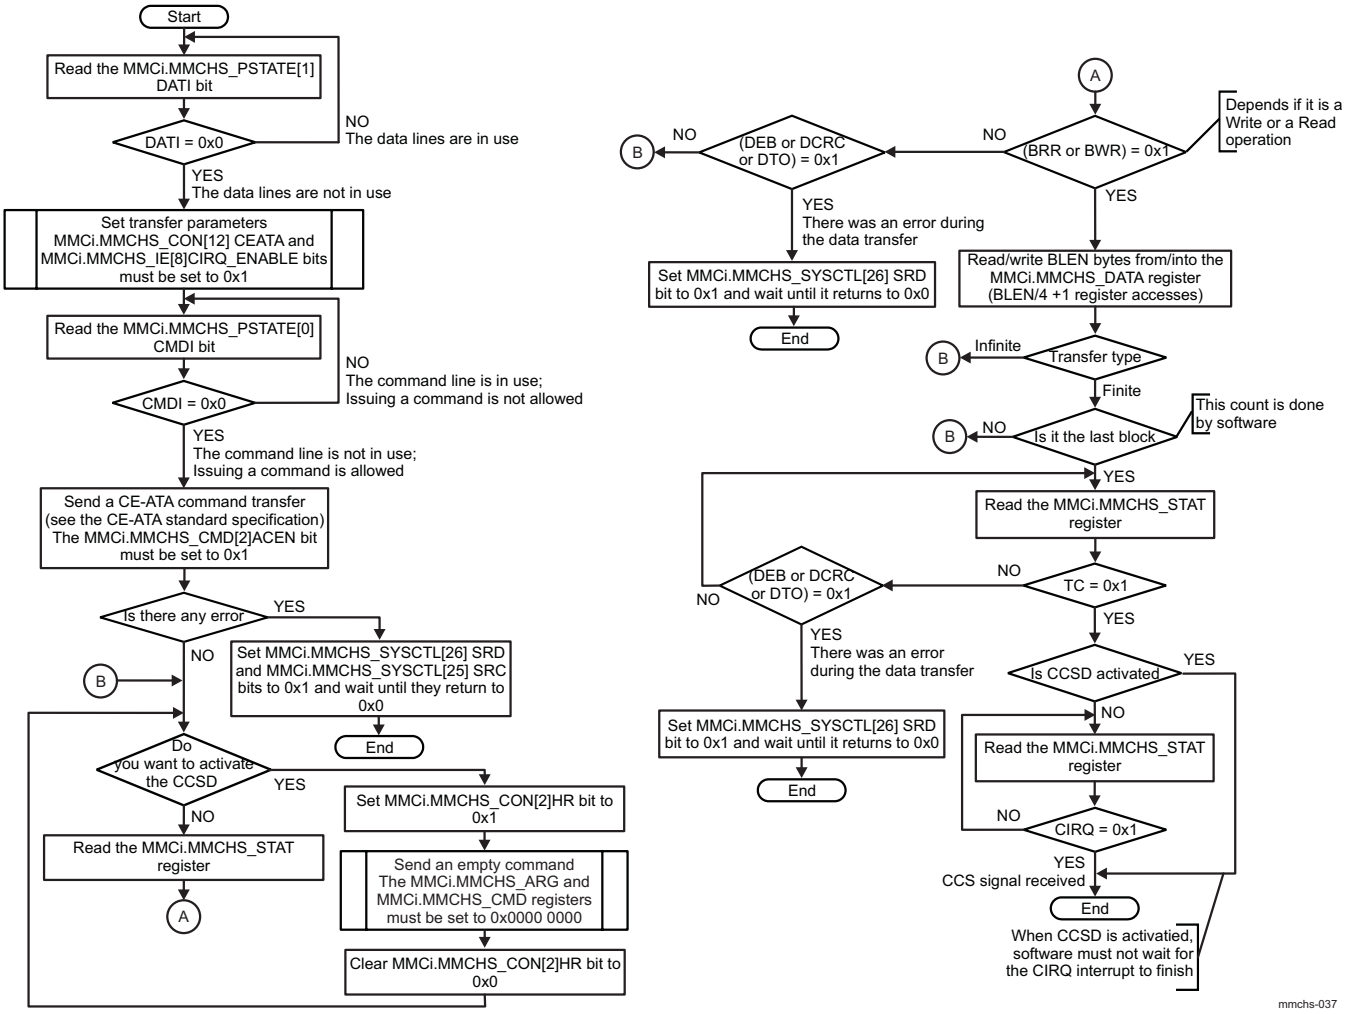
Figure 19-31. MMC/SD/SDIO Controller Read/Write Transfer Flow without DMA with Polling



19.5.2.5 Read/Write Transfer Flow in CE-ATA Mode

Figure 19-32 describes the read and write CE-ATA protocol when in Polling mode.

Figure 19-32. MMC/SD/SDIO Controller Read/Write in CE-ATA Mode



CAUTION

CE-ATA protocol is only supported by MMC cards.

In CE-ATA mode, issuing command during the transfer (except a CCSD command) is not allowed

In CE-ATA mode, infinite transfers are not allowed, only finite transfers are permitted.

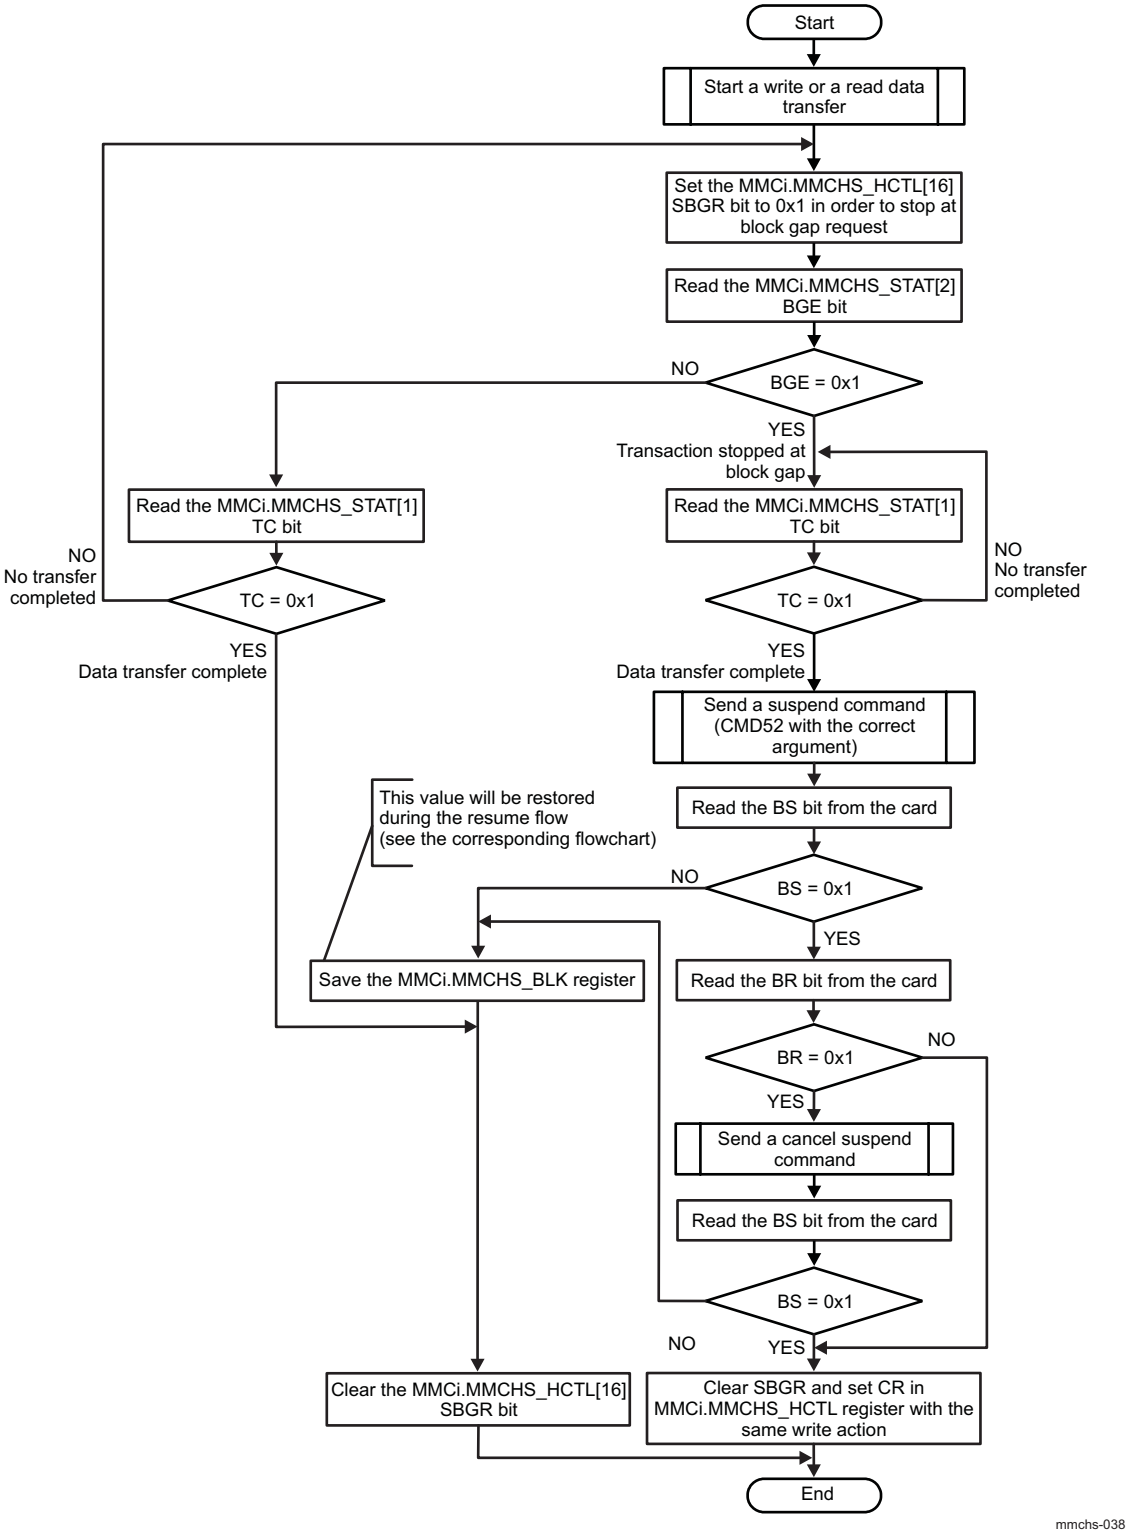
19.5.2.6 Suspend-Resume Flow

The suspend and resume feature is only supported by SDIO cards.

19.5.2.6.1 Suspend Flow

Figure 19-33 describes the suspend flow for SDIO cards.

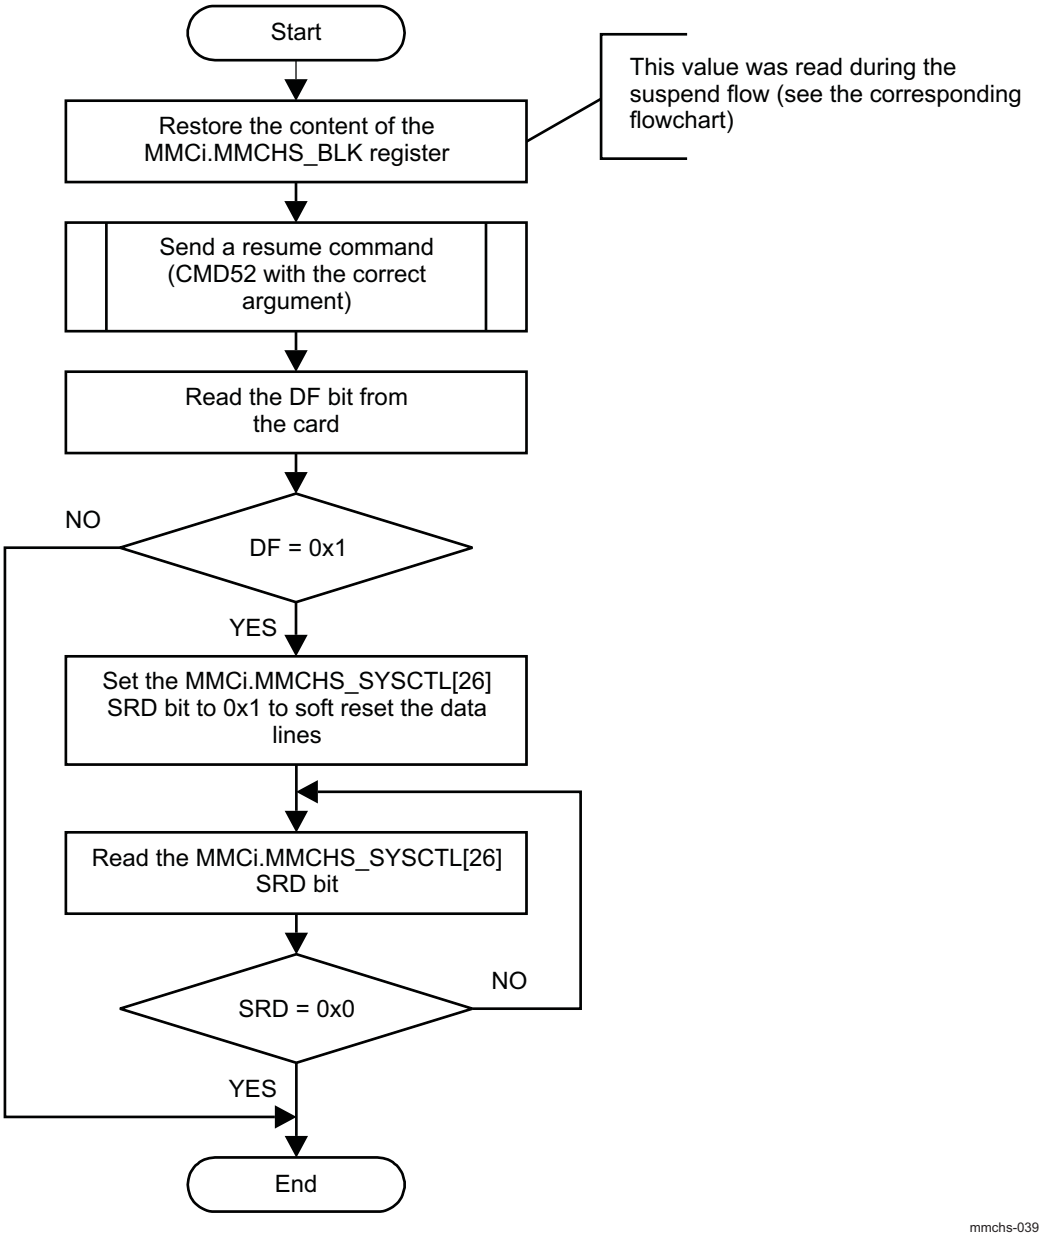
Figure 19-33. MMC/SD/SDIO Controller Suspend Flow



19.5.2.6.2 Resume Flow

Figure 19-34 describes the resume flow for SDIO cards.

Figure 19-34. MMC/SD/SDIO Controller Resume Flow



19.5.2.7 Basic Operations - Steps Detailed

19.5.2.7.1 Command Transfer Flow

Figure 19-35 describes how to send a command to the card using polling instead of interrupts for event signaling.

Figure 19-35. MMC/SD/SDIO Controller Command Transfer Flow with Polling

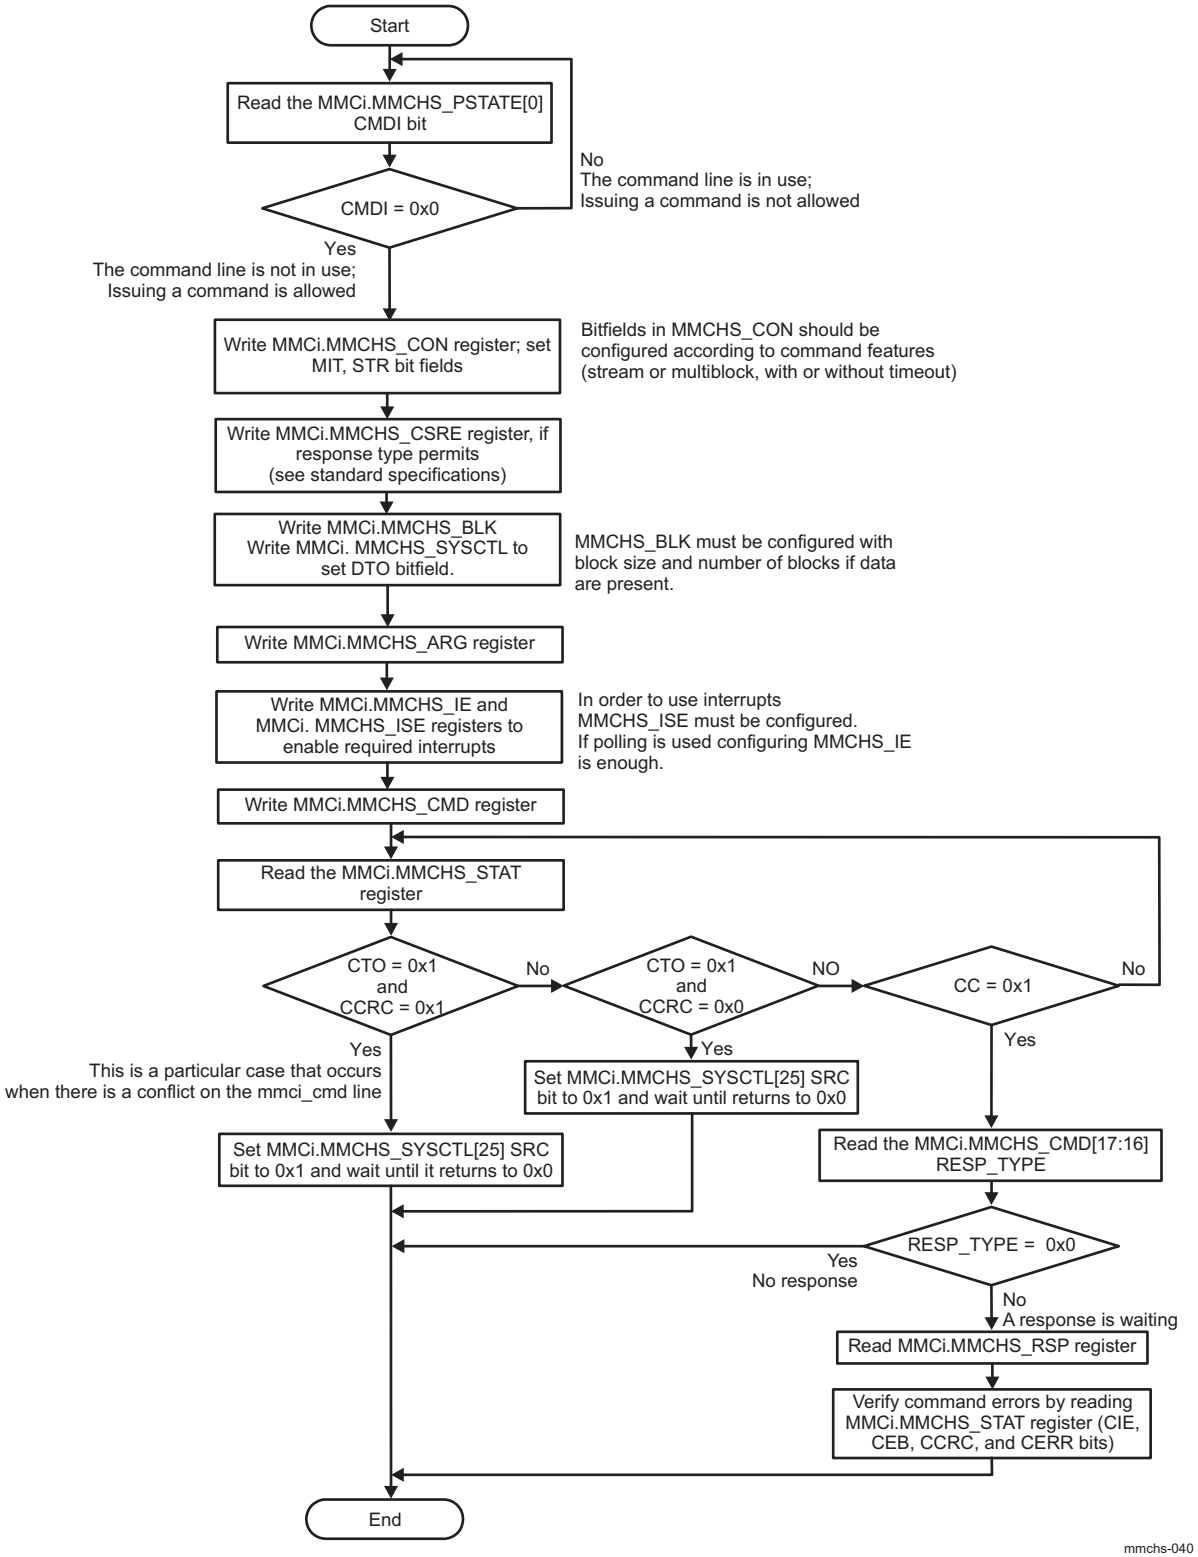


Figure 19-36 describes how to send a command to the card using interrupts for event signaling.

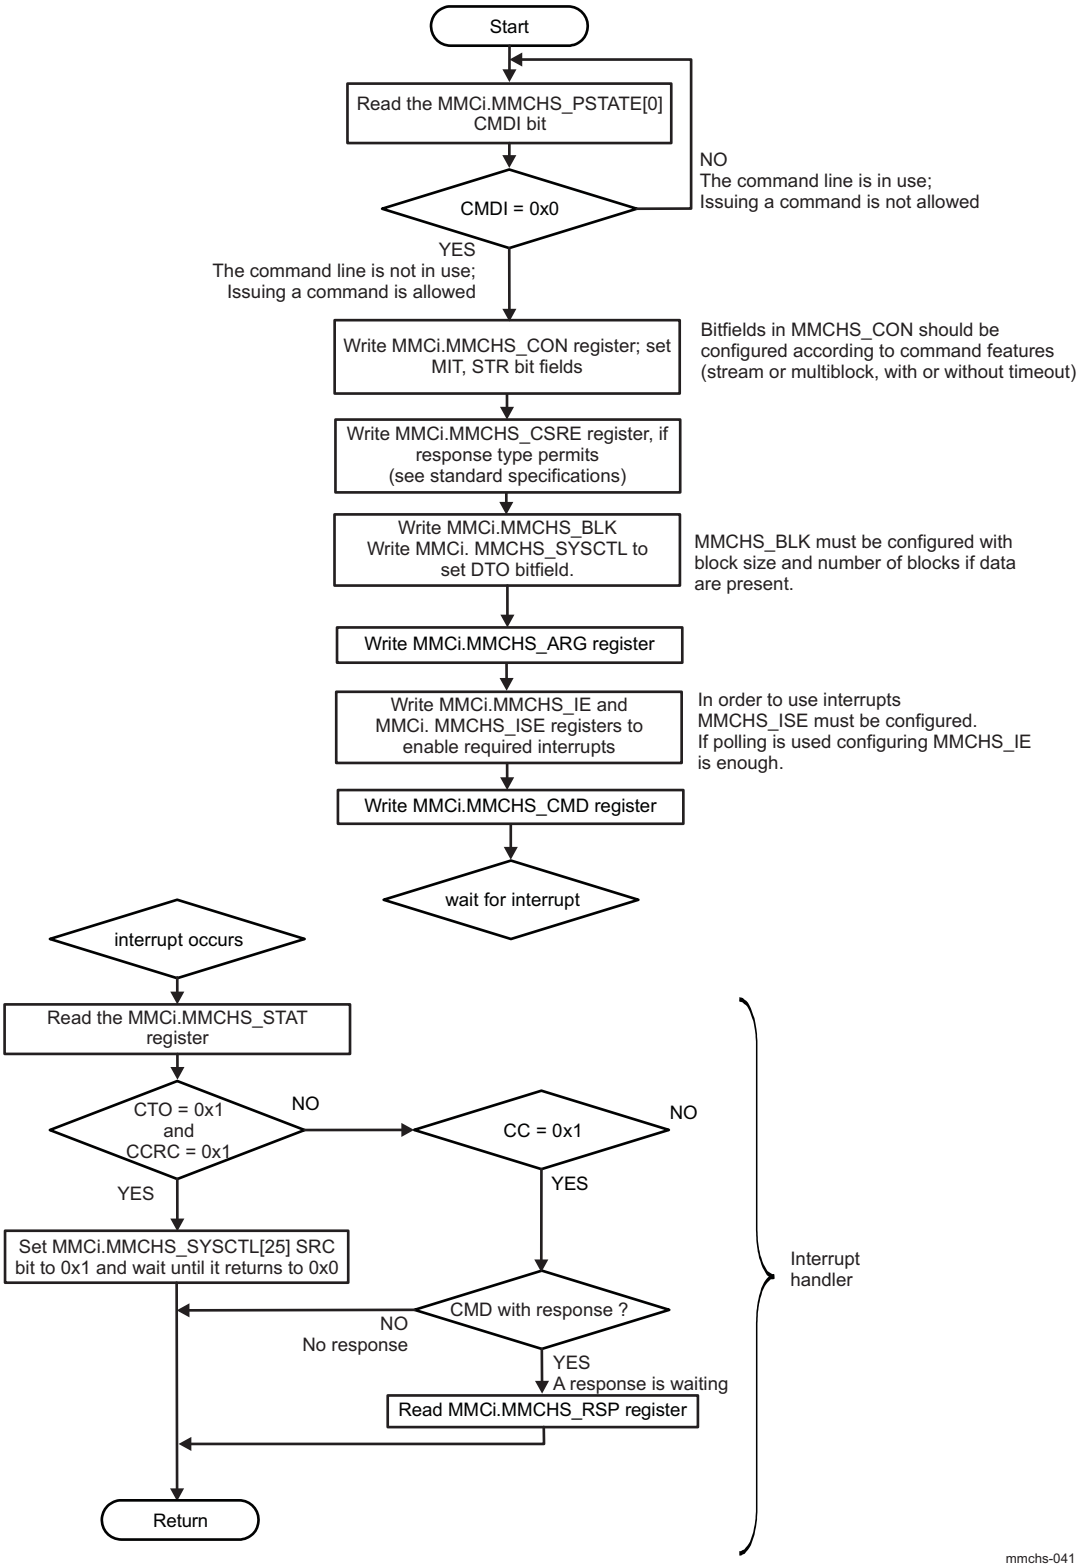
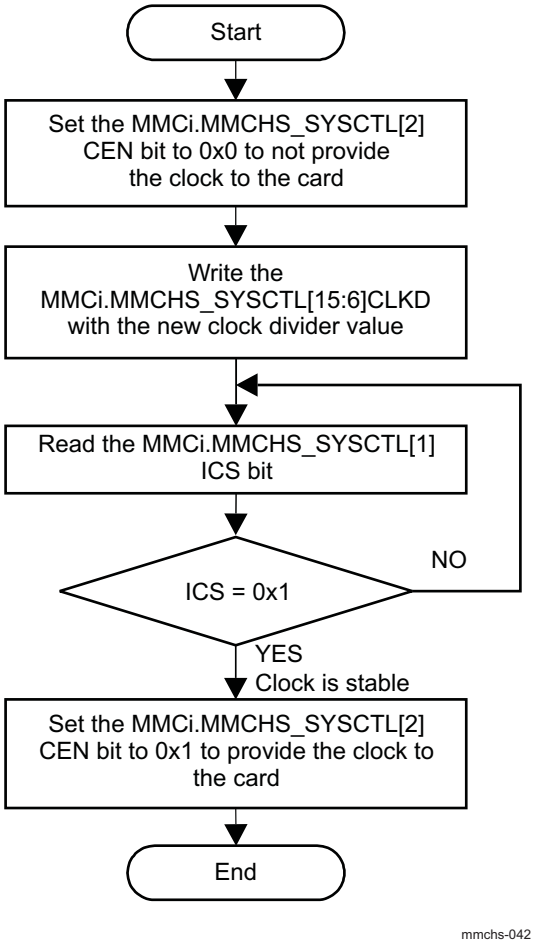
Figure 19-36. MMC/SD/SDIO Controller Command Transfer Flow with Interrupts



19.5.2.7.2 MMCHS Clock Frequency Change

Figure 19-37 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 19-37. MMC/SD/SDIO Controller Clock Frequency Change Flow



19.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL_PBIAS_LITE register settings.

See , *Extended-Drain I/O Pin and PBIAS Cell*, for more information about the PBIAS_LITE cell.

, *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide*, describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

CAUTION

The BIAS voltage must be set using the procedure described in , *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide*. Failure to follow this procedure can damage the MMCHS interface.

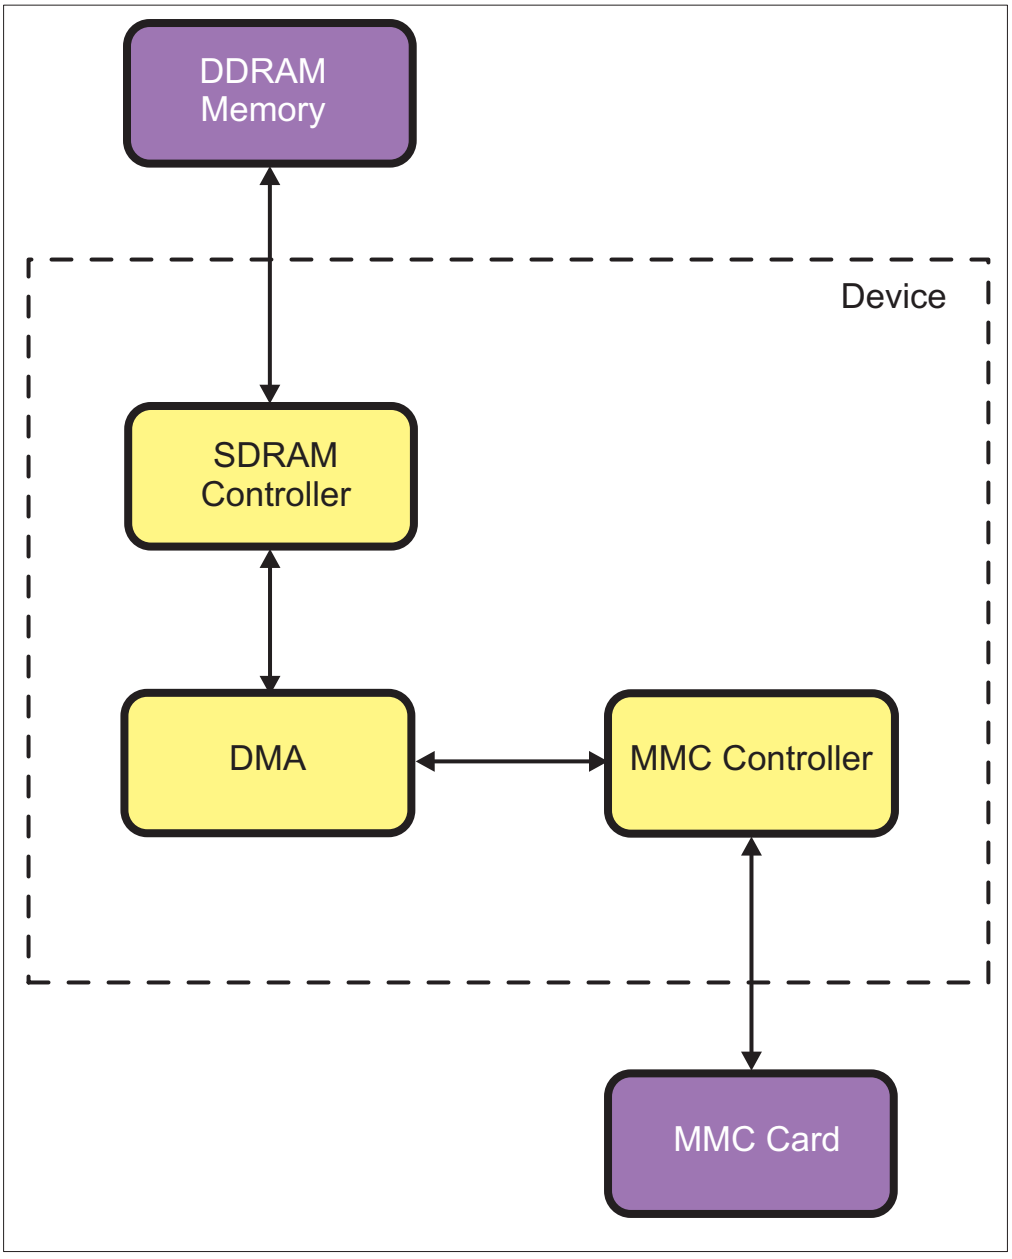
19.6 MMC/SD/SDIO Use Cases and Tips

19.6.1 MMCHS Controller Usage

19.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. Figure 19-38 gives an overview of MMCHS controller position in the use case.

Figure 19-38. Overview



For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 8 data lines.

- 1.8 V and 3.0 V voltage capabilities.

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. please refer to I2C TRM output to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

19.6.1.2 Environment

In order to operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. Figure 19-39 gives the environment picture of the MMCHS controller.

Figure 19-39. Environment

19.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

The data transfer type used by the MMCHS controller is a finite multiple block transfer. Figure 19-40 illustrates a command transfer without data. Figure 19-41 and Figure 19-42 illustrate a multiple block transfer between the MMCHS controller and the MMC card.

Figure 19-40. Command Transfer

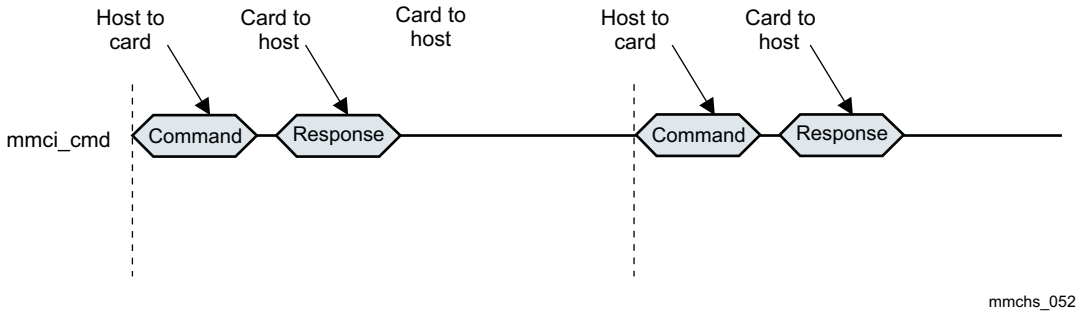


Figure 19-41. Data Read Transfer

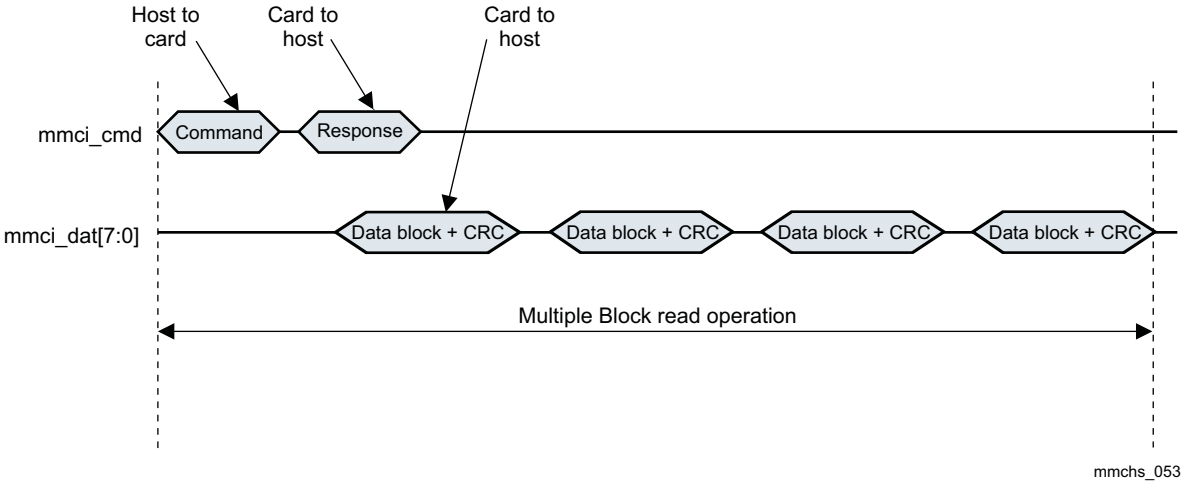

Figure 19-42. Data Write Transfer

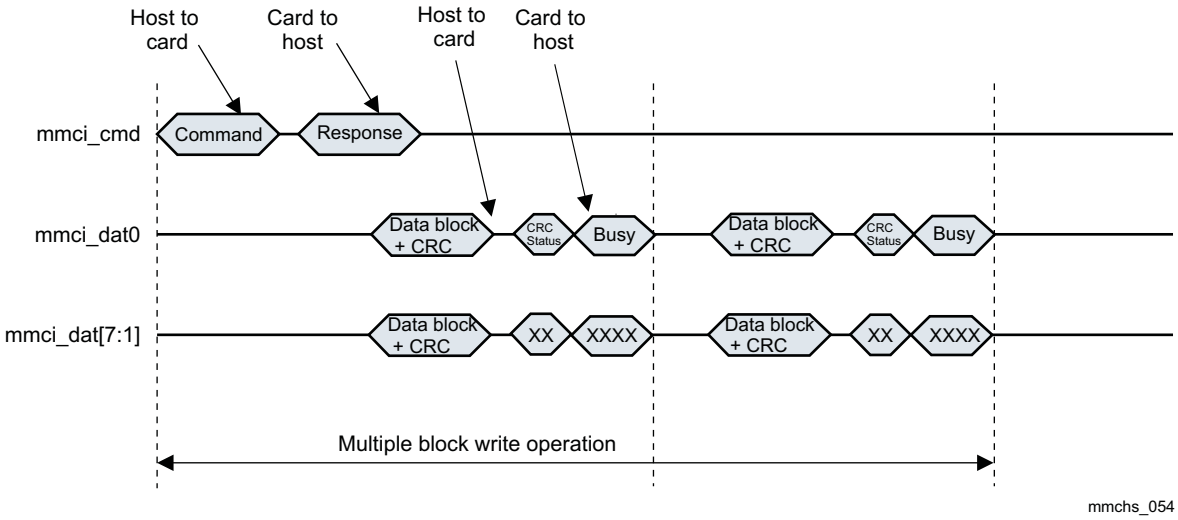

19.6.1.3 Programming Flow

19.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.
2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.
6. MMCHS controller pre-card identification configuration.

   For more information about different steps the MMCHS controller goes through during initial configuration refer to Section 19.5, *MMC/SD/SDIO Basic Programming Model*.

19.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM_ICLKEN1_CORE[24] EN_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM_FCLKEN1_CORE[24] EN_MMCHS1).

Table 19-8 shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

Table 19-8. Register Print for the MMCHS1 controller's clocks Initialization

Register Name	Register Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x01000000	MMCHS1 interface clock enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x01000000	MMCHS1 functional clock enabled

19.6.1.3.1.2 MMCHS Controller Software Reset

In order to software reset the MMCHS1 controller, the following steps must be done:

1. Write 0x2 in MMCHS1.MMCHS_SYSCONFIG register.
2. Wait until MMCHS1.MMCHS_SYSSTATUS[0] RESETDONE turns 1.

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCONFIG	0x4809 C010	0x00000002	Activate software reset
MMCHS1.MMCHS_SYSSTATUS	0x4809 C014	0x00000001	Reset is over.

19.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.MMCHS_CAPA. Refer to Table 19-9.

Table 19-9. MMCHS Controller Voltage Capabilities Initialization

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CAPA	0x4809 C140	current_value | 0x06000000	Activate VS18 and VS30 in MMCHS_CAPA register.

19.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values :

1. Default voltage support is set to 1.8 V in MMCHS1.MMCHS_HCTL[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.MMCHS_CON[0] OD.
3. MMC data bus width is set to 1 in MMCHS1.MMCHS_HCTL[1] DTW.
4. MMC Card's power is off.
5. MMC Card's clock is on in MMCHS1.MMCHS_SYSCTL[0] ICE and MMCHS1.MMCHS_SYSCTL[2] CEN.
6. MMCHS controller bus power up in MMCHS1.MMCHS_HCTL[8] SDBP.
7. MMC card's clock frequency is set to 150 KHz in MMCHS1.MMCHS_SYSCTL[15:6] CLKD.

Table 19-10 shows the values that should be written in the right register pool.

Table 19-10. MMC Controller Default Initialization Values

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x0000a007	card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

A small notice about MMCHS1.MMCHS_HCTL. Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller in not in a card state mode which sets automatically MMCHS_HCTL[8] SDBP bit to 0.

19.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 KHz.

The INIt procedure is executed by setting MMCHS1.MMCHS_CON[1] INIT bit field to 1 and by sending a dummy command, writing 0x00000000 in MMCHS1.MMCHS_CMD register.

To assure the synchronous clock on the clock output of the MMC1 controller, set the CONTROL.CONTROL_PADCONF_MMC1_CLK[8] bit. In this way, the clock output is also configured as input and the result is looped back through the output and input buffers of the pad.

Table 19-11 shows the values that should be written in the right register pool.

Table 19-11. MMCHS Controller INIT Procedure Start

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	current_value | 0x00000002	Sets MMCHS1.MMCHS_CON[1] INIT to 1
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends dummy command.
CONTROL.CONTROL_PADCONF_MMC1_CLK	0x4800 2144	0x100	Set the INPUTENABLE bit to assure synchronous clock.

19.6.1.3.1.6 MMCHS Controller Pre-card Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. MMC card's clock should now be 400 KHz according to MMC system spec requirements. Table 19-12 shows the values that should be written in the right register pool.

Table 19-12. MMCHS Controller Pre-Card Identification Configuration

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	Data bus width = 1, voltage = 1.8 V, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	Card's clock enable and card's clock frequency divider.
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

19.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS_STAT register and command response if any is read from MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, please refer to Section 19.5 *MMC/SD/SDIO Basic Programming Model*.

19.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see Table 19-13).

Table 19-13. Sending CMD0

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00040001	Enables CC and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00040001	Enables CC and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends CMD0 whose opcode is 0.

19.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see Table 19-14). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 19-14. Sending CMD5

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x05020000	Sends CMD5 whose opcode is 5 and response type is 48 bits.

19.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see Table 19-15). This command will fail if there is no SD card verison 2.X. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 19-15. Sending CMD8

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x81a0000	Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled.

19.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see Table 19-16). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success, the response will be received in MMCHS1.MMCHS_RSP10 register.

Table 19-16. Sending CMD55

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x371a0000	Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled.

19.6.1.3.2.4 Sending CMD1

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR.

This way, the card is notified of the Operating Voltage to work with.

Table 19-17. Sending CMD1

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x01020000	Sends CMD1 whose opcode is 1 and response type is 48 bits.

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software should compare card OCR and host OCR, and then send a second CMD1 command with the cross-checked OCR. This tells the card what operating voltage to use.

19.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see Table 19-18). The response is 128 bits wide and is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers.

Table 19-18. Sending CMD2

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x02090000	Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled.

19.6.1.3.2.6 Sending CMD3

This command sets MMC card address (see Table 19-19). Useful when MMCHS controller switches to addressed mode.

Table 19-19. Sending CMD3

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.

Table 19-19. Sending CMD3 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CMD	0x4809C10C	0x031a0000	Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

19.6.1.3.3 MMC Bus Setting Change After Card Identification

After CMD3 command transfer is completed successfully, an auto-negotiation on voltage value an start. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull. Table 19-20 gives several registers and their values.

Table 19-20. MMC Bus Setting Change Table

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	Bus is now in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000B00	Bus power is on, 1.8 V is selected.
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 240 which means that MMCHS controller is still supplying a 400 KHz clock.

19.6.1.3.4 Reading the CSD Register of a MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, read and write transfer latency timings.

19.6.1.3.4.1 Sending CMD9

This command asks the card to send its csd register's content (see Table 19-21). The 136 bit (128 bits are valid payload) response is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers. CMD9 is an addressed command which means that card's address must be written in MMCHS1.MMCHS_ARG register before the command is issued.

Table 19-21. Sending CMD9

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x09090000	Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled.

Table 19-21. Sending CMD9 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (please refer to MMC system specification from www.mmca.org).

Clock frequency change procedure is performed in several steps. Please refer to Section 19.5, MMC/SD/SDIO Basic Programming Model, Section 19.5.2.7.2, *MMCHS Clock Frequency Change*.

Table 19-22 shows the value written in MMCHS1.MMCHS_SYSCTL register.

Table 19-22. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000147	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz.

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). In order to enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

Table 19-23 shows the set of register impacted by CMD7 issue action.

Table 19-23. Sending CMD7

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x071a0000	Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used maximum data bus width 8. The second one enables high speed feature in the card.

19.6.1.3.4.1.1 Setting Data Bus Width to 8

Table 19-24 shows the set of registers impacted by issuing CMD6.

Table 19-24. Setting Data Bus Width with CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b70200	(3 << 24) | (byte_address << 16) | (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width. This is done by changing MMCHS1.MMCHS_CON configuration value.

Table 19-25. MMCHS_CON Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMCHS controller's data bus width is set to 8.

19.6.1.3.4.1.2 Enable High Speed Feature

Table 19-26 shows the set of registers impacted by issuing CMD6 issuing.

Table 19-26. Enabling High Speed with CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b90100	(3 << 24) | (byte_address << 16) | (byte_value << 8). byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

Table 19-27. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000087	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock.

19.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter, it is described in Chapter 7, *DMA*.

Before any data transfer begins, the card must selected by issuing CMD7 command (Table 19-23).

A write transfer is a finite multiple block write transfer. In order to perform a write transfer, the following steps must performed.

19.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 19-28. Setting Block Length

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x101a0000	Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000200	Block length is 512 = 0x200

19.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 19-29. Setting Number of Blocks

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.

Table 19-29. Setting Number of Blocks (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x171a0000	Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000008	Number of 512-byte blocks in 4 KB buffer is 8.

19.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to Chapter 7, *DMA*.

Table 19-30. CMD25 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x193a0023	Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) | (block_length)

19.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document, it is described in Chapter 7, *DMA*.

Before any data transfer begins, the card must selected by issuing CMD7 command (Table 19-23).

A read transfer is a finite multiple block write transfer. In order to perform a read transfer, the following steps must performed.

19.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. See Table 19-28.

19.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. See Table 19-29.

19.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to Chapter 7, *DMA*.

Table 19-31. CMD18 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000020	MMC bus is in push-pull mode. DW8 is enabled.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x123a0033	Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used.
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) | (block_length)

19.6.1.3.7 Dealing with High Capacity Cards

Unlike standard-capacity cards, memory addressing mode for high-capacity cards (SDHC and HC MMC) is in 512-byte block format instead of byte format. This means that byte and partial accesses are not allowed with high-capacity cards.

The 32-bit wide argument configured in the MMCHS_ARG register and sent in data transfer commands CMD17, CMD18, CMD24, and CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high-capacity cards, the block size is fixed at 512 bytes. Any data transfer, when the data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high-capacity card, which determines the capacity of the card block_count x 512 bytes, is accessible through field C_SIZE in the card s CSD register version 2.0 for SD cards, or through the SEC_COUNT field in the card s EXT_CSD register for MMC cards compliant with MMC specification version 4.x.

To write/read a packet whose size is less than 512 bytes to/from a high-capacity card, write/read the whole 512-byte block that contains the range of bytes to modify/read.

19.7 MMC/SD/SDIO Register Manual

19.7.1 MMC/SD/SDIO Instance Summary

Table 19-32 lists the instance summary.

Table 19-32. Instance Summary

Module Name	Base Address	Size
MMCHS1	0x4809 C000	512 bytes
MMCHS2	0x480B 4000	512 bytes
MMCHS3	0x480A D000	512 bytes

19.7.2 MMC/SD/SDIO Registers Mapping Summary

Table 19-33 lists the MMC/SD/SDIO1 to MMC/SD/SDIO3 registers. through describe the register bits.

CAUTION

The MMC/SD/SDIOi registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 19-33. MMC/SD/SDIO1 Register Summary

	0x480A D024		MMCHS3
	0x480B 4024		MMCHS2
Description	Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCi.MMCHS_CSRE[I] is set to 1, if the corresponding bit at the same position in the response MMCi.MMCHS_RSP10[I] is set to 1, the host controller indicates a card error (MMCi.MMCHS_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (MMCi.MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCi.MMCHS_RSP76) for possible card errors.

	0x480B 4028		MMCHS2
Description	System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCi.MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCi.MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCi.MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCi.MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCi.MMCHS_STAT[5] BRR bit) and DMA requests if enabled.		
Type	RW

- MMC/SD/SDIO Registers Mapping Summary: [0] [1] [2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24] [25] [26] [27] [28] [29] [30] [31] [32] [33] [34] [35] [36] [37] [38] [39] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49] [50] [51] [52] [53] [54] [55] [56] [57] [58] [59] [60] [61] [62] [63] [64] [65] [66] [67] [68] [69] [70] [71] [72]

Table 19-42. MMCHS_CON

Address Offset	0x02C		
Physical Address	0x4809 C02C	**Instance**	MMCHS1
	0x480A D02C		MMCHS3
	0x480B 402C		MMCHS2
Description	Configuration register This register is used: - to select the functional mode for any card. - to send an initialization sequence to any card. - to enable the detection on the mmci_dat[1] signal of a card interrupt for SDIO cards only. And also to configure: - specific data and command transfers for MMC cards only. - the parameters related to the card detect and write protect input signals.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CLKEXTFREE	PADEN	OBIE	OBIP	CEATA	CTPL	DVAL		WPP	CDP	MIT	DW8	MODE	STR	HR	INIT	OD

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Reserved bit field. Do not write any value	R	0x00000
16	CLKEXTFREE	External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCi.MMCHS_SYSCTL[2] CEN bit is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCi.MMCHS_SYSCTL[2] CEN bit is set.	RW	0
15	PADEN	Control Power for MMC Lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCi.MMCHS_CON[11] CTPL bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.	RW	0
14	OBIE	Out-of-Band Interrupt Enable (MMC cards only). This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled. 0x1: Out-of-Band interrupt detection enabled.	RW	0
13	OBIP	Out-of-Band Interrupt Polarity (MMC cards only). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: active high level. 0x1: active low level.	RW	0
12	CEATA	CE-ATA control mode (MMC cards compliant with CE-ATA): By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for mmci_dat[1] line (MMC and SD cards): By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.	RW	0
10:9	DVAL	Debounce filter value (All cards) This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period. 0x1: 231 us debounce period.	RW	0x3

Bits	Field Name	Description	Type	Reset
		0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period.		
8	WPP	Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
7	CDP	Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
6	MIT	MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCi.MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards)	RW	0
4	MODE	Mode select (All cards) These bits select the functional mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCi.MMCHS_CMD register. 0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer. 0x1: Stream oriented data transfer.	RW	0

Bits	Field Name	Description	Type	Reset
2	HR	Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCi.MMCHS_CON[12] CEATA bit is set to 1 and MMCi.MMCHS_ARG set to 0x00000000, when writing 0x00000000 into MMCi.MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (i.e. mmci_cmd line held to '0' during 47 cycles followed by a 1). 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.	RW	0
1	INIT	Send initialization stream (All cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmci_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCi.MMCHS_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCi.MMCHS_STAT[0] CC bit can be polled. 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0
0	OD	Card open drain mode (Only for MMC cards). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCi.MMCHS_CON[2] HR bit) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response	RW	0

Table 19-46. MMCHS_BLK

Address Offset	0x104		
Physical Address	0x4809 C104	**Instance**	MMCHS1
	0x480A D104		MMCHS3
	0x480B 4104		MMCHS2
Description	Transfer Length Configuration register This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																Reserved					BLEN										

Bits	Field Name	Description	Type	Reset
31:16	NBLK	Blocks count for current transfer. This register is enabled when Block count Enable (MMCi.MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0x0: Stop count 0x1: 1 block 0x2: 2 blocks 0xFFFF: 65535 blocks	RW	0x0000
15:11	Reserved	Reserved bit field. Do not write any value	R	0x00
10:0	BLEN	Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. 0x0: No data transfer 0x1: 1 byte block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x1FF: 511 bytes block length 0x200: 512 bytes block length 0x3FF: 1023 bytes block length 0x400: 1024 bytes block length	RW	0x000

Description	Command and transfer mode register MMCi.MMCHS_CMD[31:16] = the command register MMCi.MMCHS_CMD[15:0] = the transfer mode. This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCi.MMCHS_CMD[15:0] registers during data transfer has no effect. This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				INDX				CMD_TYPE		DP	CICE	CCCE	Reserved	RSP_TYPE		Reserved								MSBS	DDIR	Reserved		ACEN	BCE	DE	

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29:24	INDX	Command index Binary encoded value from 0 to 63 specifying the command number send to card	RW	0x00
		0x0: CMD0 or ACMD0		
		0x1: CMD1 or ACMD1		

Bits	Field Name	Description	Type	Reset
		0x3F: CMD63 or ACMD63		
23:22	CMD_TYPE	Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands. 0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command	RW	0x0
21	DP	Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line -Command with no data transfer but using busy signal on mmci_dat[0] -Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCi.MMCHS_STAT[19] CIE bit set to1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCi.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	Reserved	Reserved bit field. Do not write any value.	R	0
17:16	RSP_TYPE	Response type. This bits defines the response type of the command. 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response	RW	0x0
15:6	Reserved	Reserved bit field. Do not write any value.	R	0x000
5	MSBS	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCi.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCi.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCi.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3	Reserved	Reserved bit field. Do not write any value.	R	0

Bits	Field Name	Description	Type	Reset
2	ACEN	Auto CMD12 Enable. (SDIO does not support this feature.) When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. For CE-ATA commands (MMCi.MMCHS_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.	RW	0
1	BCE	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable. This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Table 19-60. MMCHS_DATA

Address Offset	0x120		
Physical Address	0x4809 C120	**Instance**	MMCHS1
	0x480A D120		MMCHS3
	0x480B 4120		MMCHS2
Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad		
Type	RW

Table 19-62. MMCHS_PSTATE

Address Offset	0x124		
Physical Address	0x4809 C124	**Instance**	MMCHS1
	0x480A D124		MMCHS3
	0x480B 4124		MMCHS2
Description	Present state register. The Host can get status of the Host Controller from this 32-bit read only register.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CLEV	DLEV				Reserved	Reserved	Reserved		Reserved				BRE	BWE	RTA	WTA	Reserved					DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Reserved bit field. Do not write any value.	R	0x00
24	CLEV	mmci_cmd line signal level. This status is used to check the mmci_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmci_cmd line level at that time. Read 0x0: The mmci_cmd line level is 0. Read 0x1: The mmci_cmd line level is 1.	R	-
23:20	DLEV	mmci_dat[3:0] line signal level mmci_dat[3] => bit 23 mmci_dat[2] => bit 22 mmci_dat[1] => bit 21 mmci_dat[0] => bit 20 This status is used to check mmci_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmci_dat[0]. The value of these registers after reset depends on the mmci_dat lines level at that time.	R	0x-
19	Reserved	Reserved bit field. Do not write any value	R	0
18	Reserved	Reserved bit field. Do not write any value This bit is not affected by soft reset.	R	1
17:16	Reserved	Reserved bit field. Do not write any value The value of these bits after soft reset is 0x0. These bits will be automatically set to 0x3 after debounce time. Debounce time is fixed to 256 x32kHz clock cycles.	R	00
15:12	Reserved	Reserved bit field. Do not write any value	R	0x0
11	BRE	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCi.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCi.MMCHS_STAT[5] BRR bit). Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.	R	0
10	BWE	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.	R	0
9	RTA	Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Read data transfer on going.	R	0
8	WTA	Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Write data transfer on going.	R	0
7:3	Reserved	Reserved bit field. Do not write any value	R	0x00

Bits	Field Name	Description	Type	Reset
2	DLA	mmci_dat line active. This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x0: mmci_dat Line inactive Read 0x1: mmci_dat Line active	R	0
1	DATI	Command inhibit (mmci_dat). This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit). Read 0x0: Issuing of command using the mmci_dat lines is allowed Read 0x1: Issuing of command using mmci_dat lines is not allowed	R	0
0	CMDI	Command inhibit(mmci_cmd). This status bit indicates that the mmci_cmd line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit). - After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared. Read 0x0: Issuing of command using mmci_cmd line is allowed Read 0x1: Issuing of command using mmci_cmd line is not allowed	R	0

Table 19-64. MMCHS_HCTL

Address Offset	0x128		
Physical Address	0x4809 C128	**Instance**	MMCHS1
	0x480A D128		MMCHS3
	0x480B 4128		MMCHS2
Description	Control register. This register defines the host controls to set power, wake up and transfer parameters. MMCi.MMCHS_HCTL[31:24] = Wake-up control MMCi.MMCHS_HCTL[23:16] = Block gap control MMCi.MMCHS_HCTL[15:8] = Power control MMCi.MMCHS_HCTL[7:0] = Host control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				OBWE	REM	INS	IWE	Reserved				IBG	RWC	CR	SBGR	Reserved				SDVS			SDBP	Reserved						DTW	Reserved

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Reserved bit field. Do not write any value.	R	0x00
27	OBWE	Wake-up event enable for 'Out-of-Band' Interrupt. This bit enables wake-up events for 'Out-of-Band' assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCi.MMCHS_CON[14] OBIE bit is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt. 0x1: Enable wakeup on 'Out-of-Band' Interrupt.	RW	0
26	REM	Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card removal. 0x1: Enable wakeup on card removal.	RW	0
25	INS	Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card insertion. 0x1: Enable wakeup on card insertion.	RW	0
24	IWE	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCi.MMCHS_IE[8] CIRQ_ENABLE bit). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	Reserved	Reserved bit field. Do not write any value	R	0x0
19	IBG	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmci_dat line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0
17	CR	Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0

Bits	Field Name	Description	Type	Reset
16	SBGR	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	Reserved	Reserved bit field. Do not write any value.	R	0x0
11:9	SDVS	SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMCi.MMCHS_CAPA[25] VS30 bit, MMCi.MMCHS_CAPA[24] VS33 bit) before starting a transfer. 0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) MMCHS2: This field must be set to 0x5. MMCHS3: This field must be set to 0x5.	RW	0x0
8	SDBP	SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7:2	Reserved	Reserved bit field. Do not write any value.	R	0x00
1	DTW	Data transfer width. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with *MMC standard specification 4.x* This register has no effect when the MMC 8-bit mode is selected (MMCi.MMCHS_CON[5] DW8 bit set to 1) For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (mmci_dat[0] used) 0x1: 4-bit Data width (mmci_dat[3:0] used)	RW	0
0	Reserved	Reserved bit field. Do not write any value.	R	0

	0x480A D12C		MMCHS3
	0x480B 412C		MMCHS2
Description	SD system control register. This register defines the system controls to set software resets, clock frequency management and data timeout. MMCHS_SYSCTL[31:24] = Software resets MMCHS_SYSCTL[23:16] = Timeout control MMCHS_SYSCTL[15:0] = Clock control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					SRD	SRC	SRA	Reserved				DTO				CLKD								Reserved					CEN	ICS	ICE

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved bit field. Do not write any value.	R	0x00
26	SRD	Software reset for mmci_dat line. This bit is set to 1 for reset and released to 0 when completed .mmci_dat finite state machine in both clock domain are also reset. Here below are the registers cleared by the MMCHS_SYSCTL[26] SRD bit: MMCi.MMCHS_DATA MMCi.MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI MMCi.MMCHS_HCTL: SBGR and CR MMCi.MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for mmci_dat line	RW	0
25	SRC	Software reset for mmci_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmci_cmd finite state machine in both clock domain are also reset. Here below the registers cleared by the MMCi.MMCHS_SYSCTL[25] SRC bit: MMCi.MMCHS_PSTATE: CMDI MMCi.MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for mmci_cmd line	RW	0
24	SRA	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	Reserved	Reserved bit field. Do not write any value.	R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which mmci_dat lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCi.MMCHS_CAPA[5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCi.MMCHS_STAT[20] DTO bit). The MMCi.MMCHS_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: TCF x 2^13 0x1: TCF x 2^14	RW	0x0

Bits	Field Name	Description	Type	Reset
		0xE: TCF x 2^27		
		0xF: Reserved		
15:6	CLKD	Clock frequency select These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmci_clk pin of either the memory card (MMC, SD or SDIO).	RW	0x000
		0x0: Clock Ref bypass		
		0x1: Clock Ref bypass		
		0x2: Clock Ref / 2		
		0x3: Clock Ref / 3		
		0x3FF: Clock Ref / 1023		
5:3	Reserved	Reserved bit field. Do not write any value	R	0x0
2	CEN	Clock enable. This bit controls if the clock is provided to the card or not.	RW	0
		0x0: The clock is not provided to the card . Clock frequency can be changed .		
		0x1: The clock is provided to the card and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCi.MMCHS_SYSCTL[1] ICS bit).		
1	ICS	Internal clock stable (status)This bit indicates either the internal clock is stable or not.	R	0
		Read 0x0: The internal clock is not stable.		
		Read 0x1: The internal clock is stable after enabling the clock (MMCi.MMCHS_SYSCTL[0] ICE bit) or after changing the clock ratio (MMCi.MMCHS_SYSCTL[15:6] CLKD bits).		
0	ICE	Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.	RW	0
		0x0: The internal clock is stopped (very low power state).		
		0x1: The internal clock oscillates and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) .

Table 19-68. MMCHS_STAT

Address Offset	0x130		
Physical Address	0x4809 C130	**Instance**	MMCHS1
	0x480A D130		MMCHS3
	0x480B 4130		MMCHS2
Description	Interrupt status register The interrupt status regroups all the status of the module internal events that can generate an interrupt. MMCHS_STAT[31:16] = Error Interrupt Status MMCHS_STAT[15:0] = Normal Interrupt Status		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		BADA	CERR	Reserved			ACE	Reserved	DEB	DCRC	DTO	CIE	CEB	CCRC	CTO	ERRI	Reserved					OBI	CIRQ	Reserved		BRR	BWR	Reserved	BGE	TC	CC

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29	BADA	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: - During a read access to the data register (MMCi.MMCHS_DATA) while buffer reads are not allowed (MMCi.MMCHS_PSTATE[11] BRE bit =0) - During a write access to the data register (MMCi.MMCHS_DATA) while buffer writes are not allowed (MMCi.MMCHS_PSTATE[10] BWE bit=0) Read 0x0: No Interrupt. Write 0x0: Status bit unchanged Read 0x1: Bad Access Write 0x1: Status is cleared	RW	0
28	CERR	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCi.MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCi.MMCHS_RSP76 register to detect error bits in the command response. Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Card error Write 0x1: Status is cleared	RW	0
27:25	Reserved	Reserved bit field. Do not write any value	R	0x0
24	ACE	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: AutoCMD12 error Write 0x1: Status is cleared	RW	0
23	Reserved	Reserved bit field. Do not write any value	R	0
22	DEB	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmci_dat line or at the end position of the CRC status in write mode. Read 0x0: No Error	RW	0

Bits	Field Name	Description	Type	Reset
		Write 0x0: Status bit unchanged		
		Read 0x1: Data end bit error		
		Write 0x1: Status is cleared		
21	DCRC	Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.	RW	0
		Read 0x0: No Error.		
		Write 0x0: Status bit unchanged		
		Read 0x1: Data CRC error		
		Write 0x1: Status is cleared		
20	DTO	Data timeout error. This bit is set automatically according to the following conditions: - Busy timeout for R1b, R5b response type. - Busy timeout after write CRC status. - Write CRC status timeout. - Read data timeout.	RW	0
		Read 0x0: No error		
		Write 0x0: Status bit unchanged		
		Read 0x1: Time out		
		Write 0x1: Status is cleared		
19	CIE	Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCi.MMCHS_CMD[20] CICE).	RW	0
		Read 0x0: No error		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command index error		
		Write 0x1: Status is cleared		
18	CEB	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.	RW	0
		Read 0x0: No error		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command end bit error		
		Write 0x1: Status is cleared		
17	CCRC	Command CRC Error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCi.MMCHS_CMD[19] CCCE).	RW	0
		Read 0x0: No Error		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command CRC error		
		Write 0x1: Status is cleared		
16	CTO	Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.	RW	0
		Read 0x0: No error		
		Write 0x0: Status bit unchanged		
		Read 0x1: Time Out		
		Write 0x1: Status is cleared		

Bits	Field Name	Description	Type	Reset
15	ERRI	Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCi.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI	Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCi.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCi.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared.	R	0
8	CIRQ	Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMCi.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCi.MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored. Read 0x0: No card interrupt Read 0x1: Generate card interrupt	R	0
7:6	Reserved	Reserved bit field. Do not write any value.	RW	00
5	BRR	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCi.MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Read 0x0: Not Ready to read buffer Write 0x0: Status bit unchanged Read 0x1: Ready to read buffer Write 0x1: Status is cleared	RW	0
4	BWR	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCi.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Read 0x0: Not Ready to write buffer Write 0x0: Status bit unchanged Read 0x1: Ready to write buffer Write 0x1: Status is cleared	RW	0

Bits	Field Name	Description	Type	Reset
3	Reserved	Reserved bit field. Do not write any value	R	0
2	BGE	Block gap event. When a stop at block gap is requested (MMCi.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCi.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt. Read 0x0: No block gap event Write 0x0: Status bit unchanged Read 0x1: Transaction stopped at block gap Write 0x1: Status is cleared	RW	0
1	TC	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCi.MMCHS_HCTL[16] SBGR bit). This bit is also set when exiting a command in a busy state (if the command has a busy notification capability). In Read mode: This bit is automatically set on completion of a read transfer (MMCi.MMCHS_PSTATE[9] RTA bit). In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCi.MMCHS_PSTATE[2] DLA bit). Read 0x0: No transfer complete Write 0x0: Status bit unchanged Read 0x1: Data transfer complete Write 0x1: Status is cleared	RW	0
0	CC	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCi.MMCHS_PSTATE[0] CMDI bit) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCi.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCi.MMCHS_STAT[0] CC bit). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Read 0x0: No Command complete Write 0x0: Status bit unchanged Read 0x1: Command complete Write 0x1: Status is cleared	RW	0

Table 19-74. MMCHS_AC12

Address Offset	0x13C		
Physical Address	0x4809 C13C	**Instance**	MMCHS1
	0x480A D13C		MMCHS3
	0x480B 413C		MMCHS2
Description	Auto CMD12 Error Status Register. The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMCi.MMCHS_AC12 register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled (MMCi.MMCHS_CMD[2] ACEN bit) and Auto CMD12Error (MMCi.MMCHS_STAT[24] ACE bit) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								CNI	Reserved		ACIE	ACEB	ACCE	ACTO	ACNE

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved bit field. Do not write any value.	R	0x0
7	CNI	Command not issue by Auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to Auto CMD12 error: ACEB, ACCE, ACTO or ACNE. Read 0x0: Not error Read 0x1: Command not issued	R	0
6:5	Reserved	Reserved bit field. Do not write any value.	R	0x0
4	ACIE	Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable (MMCi.MMCHS_CMD[20] CICE bit). Read 0x0: No error Read 0x1: Auto CMD12 Index Error	R	0
3	ACEB	Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response. Read 0x0: No error Read 0x1: AutoCMD12 End bit Error	R	0
2	ACCE	Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the MMCi.MMCHS_CMD[19] CCCE bit. Read 0x0: No error Read 0x1: Auto CMD12 CRC Error	R	0
1	ACTO	Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command. Read 0x0: No error Read 0x1: Auto CMD12 Time Out	R	0
0	ACNE	Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before Auto CMD12 starts. Read 0x0: Auto CMD12 Executed Read 0x1: Auto CMD12 Not Executed	R	0

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved bit field. Do not write any value.	R	0x00
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal). Read 0x0: 1.8 V Not Supported Write 0x0: 1.8 V Not supported Read 0x1: 1.8 V Supported Write 0x1: 1.8 V Supported MMCHS1, 2 and 3: This bit must be set to 1.	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.0 V Not Supported Write 0x0: 3.0 V Not supported Read 0x1: 3.0 V Supported Write 0x1: 3.0 V Supported MMCHS1: This bit must be set to 1. MMCHS2 and 3: This bit must be left to 0.	RW	0
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.3 V Not Supported Write 0x0: 3.3 V Not supported Read 0x1: 3.3 V Supported Write 0x1: 3.3 V Supported MMCHS1, 2 and 3: This bit must be left to 0.	RW	0
23	SRS	Suspend/Resume support (SDIO cards only)This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality.	R	1
22	DS	DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported	R	1

Bits	Field Name	Description	Type	Reset
21	HSS	High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported	R	1
20:18	Reserved	Reserved bit field. Do not write any value.	R	0x0
17:16	MBL	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	Reserved	Reserved bit field. Do not write any value	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See , *Power Reset and Clock Management*, for more information on the value of FUNC_96M_CLK clock signal.	R	0x00
7	TCU	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz	R	1
6	Reserved	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. **Note:** You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMCi.MMCHS_SYSCTL[15:6] CLKD bit field.	R	0x00

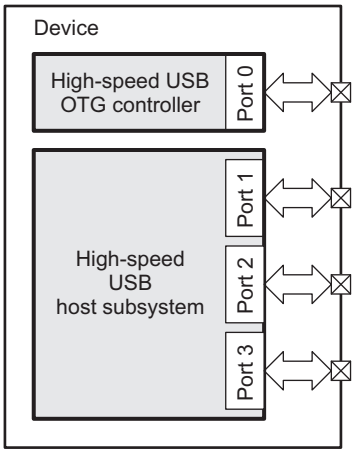
Universal Serial Bus (USB)

This chapter describes the high-speed USB On-The-Go (OTG) controller and the high-speed universal serial bus (USB) host subsystem.

Figure 20-1. USB Modules Overview



Topic **Page**

20.1 High-Speed USB OTG Controller

NOTE: The High-Speed USB OTG Controller is an instantiation of the MUSBMHDRC from Mentor Graphics Corporation.

Mentor Graphics is a registered trademark of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

The High-Speed USB OTG Controller is an instantiation of the MUSBMHDRC from Mentor Graphics Corporation.

20.1.1 Introduction

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller. The controller complies with the USB 2.0 standard high-speed and full-speed functions and low-speed, full-speed, and high-speed limited host mode operations. It also includes support for the Session Request and Host Negotiation Protocols used in point-to-point communications, details of which are given in the USB On-the-Go supplement to the USB 2.0 specification. In addition, the four test modes for high-speed operation described in the USB 2.0 specification. It also allows options that allow it to be forced into full-speed mode, high-speed mode or host mode which may be used in helping debug PHY problems in hardware.

20.1.1.1 Purpose of the Peripheral

The USB controller supports data throughput rates up to 480 Mbps. It provides a mechanism for data transfer between USB devices and also supports host negotiation.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, and your device-specific data manual.

20.1.2 Features Supported

- Contains 1 usb20otg_f modules, with the following features:
  - Built around the Mentor USB 2.0 OTG core (musbmhdrc)
  - Supports USB 2.0 peripheral at speeds HS (480 Mb/s) and FS (12 Mb/s)
  - Supports USB 2.0 Host or OTG at speeds HS (480 Mb/s), FS (12 Mb/s), and LS (1.5 Mb/s)
  - Supports all modes of transfers (control, bulk, interrupt, and isochronous)
  - Supports high bandwidth ISO mode
  - Supports 16 transmit (TX) and 16 receive (RX) endpoints including endpoint 0
  - Supports USB OTG extensions for session resume (SRP) and Host negotiation (HNP)
  - Includes a 32K endpoint FIFO RAM, and supports programmable FIFO sizes
  - Includes RNDIS mode for accelerating RNDIS type protocols using short packet termination over USB
  - Includes CDC Linux mode for accelerating CDC type protocols using short packet termination over USB
  - Included and RNDIS like mode for terminating RNDIS type protocols without using short packet termination for support of MSC applications
- Includes one USB2.0 OTG PHYs in GS60 process
- Connects to a standard charge pump for VBUS 5 V generation
- Interfaces to the CPU through a CBA 3.1 VBUSP slave port
- Includes a CPPI 4.1 compliant DMA controller sub-module with 15 RX and 15 TX simultaneous data connections
- Includes a CPPI 4.1 DMA scheduler

- DMA supports CPPI Host descriptor formats
- DMA supports stall on buffer starvation
- Supports data buffer sizes up to 4M bytes
- CPPI FIFO interface per TX/RX endpoint
- Provides a CPPI queue manager module with 96 queues for queuing/dequeuing packets

20.1.2.1 Features Not Supported

- 16-bit 30 MHz UTMI+ interface is not supported
- RNDIS, CDC, and Generic RNDIS mode acceleration for USB sizes that are not multiples of 64 bytes
- Endpoint max USB packet sizes that do not conform to the USB 2.0 spec (for FS/LS: 8, 16, 32, 64, and 1023 are defined; for HS: 64, 128, 512, and 1024 are defined)

20.1.3 Functional Description

20.1.3.1 Compliance to Standards

The module is compliant to the USB 2.0 specification as well as the OTG supplement. Refer to the Mentor specification for details.

20.1.3.2 Functional Operation

20.1.3.2.1 Overview

The USB 2.0 OTG subsystem consists of a CPPI 4.1 DMA controller and scheduler, an INTD interrupt distributer, a queue manager, a usb20otg_f USB controller subsystem, and a USB OTG PHY.

The USB 2.0 OTG F controller consists of the Mentor core, a packet processing unit, a switched central resource (SCR), and the bridge sub-modules. The core interfaces to the UTMI+ interface that is connected to a UTMI+ PHY. It also connects to the endpoint FIFO RAM. The module interfaces to a CPPI 4.1 compliant DMA controller through the Egress/Ingress CPPI FIFO interfaces in the PPU. The bridge sub-modules consist of additional new functions needed to connect the Mentor core and make the module PDR 3.5 compliant. The VBUSP to AHB (V2A) sub-module converts to the core's AHB slave port. The transfer (XFER) DMA sub-module controls transferring data from the endpoint FIFOs to the CPPI FIFOs. The interrupt sub-module implements PDR 3.5 compliant interrupts. The clock sub-module implements the CBA 3.1 compliant clocking protocols. The test sub-module implements the PDR 3.5 I/O test requirements. VBUSP retiming sub-modules are used to enhance VBUSP timing. And the SCR connects all the sub-modules together with the DMA state RAM. Figure 20-2 shows the top level block diagram of the sub-modules and their connections. Figure 20-3 shows the USB20OTG_F block diagram.

Figure 20-2. USB Subsystem Block Diagram

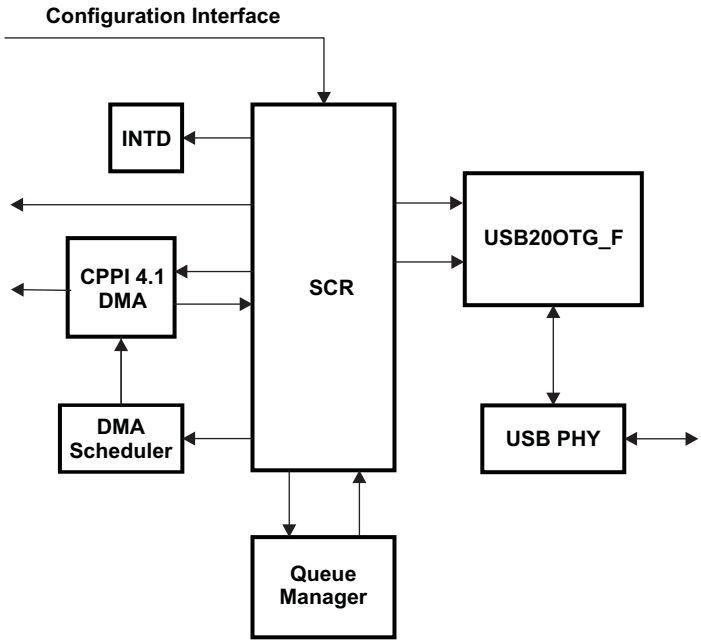


Figure 20-3. USB20OTG_F Block Diagram

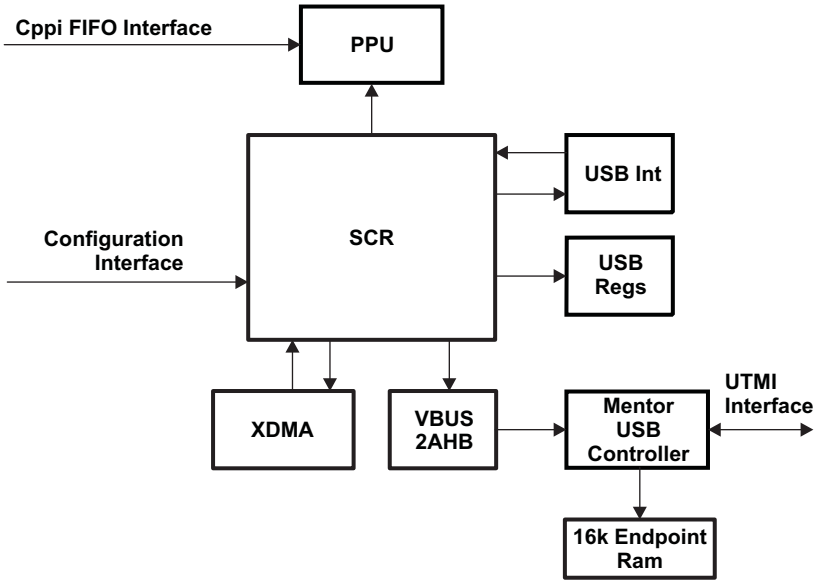

20.1.3.2.2 Mentor Core

The core of the USB 2.0 OTG controller is the Mentor USB 2.0 high-speed multi-point dual-role controller, musbmhdrc. This core is IP from Mentor and a detailed description of its operations is covered by the Mentor specification.

The Mentor core communicates to a UTMI+ PHY interface, an AHB slave interface, and a FIFO RAM interface, along with extra system signals. The connections for these interfaces and signals are described in Section 20.1.4.3.

20.1.3.2.3 USB OTG PHY

The USB OTG Subsystem integrates a USB OTG PHY. The PHY interfaces to the Mentor OTG controller via the UTMI+ interface.

The integrated PHY has the following features:

- OTG compliant.
- Has UTMI-plus Level 3 functionality. (Host and OTG devices. HS/FS/LS and preamble packet.)
- Supports OTG, SRP and HNP protocols.
- 8-bit data interface on the UTMI with 60 MHz clock

The integrated PHY does not contain a charge pump, so it will not provide power to VBUS.

20.1.3.2.4 CPPI 4.1 DMA Controller

The CPPI DMA module supports the transmission and reception of USB packets. The CPPI DMA is designed to facilitate the segmentation and reassembly of CPPI compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. Multiple Tx and Rx channels are provided within the DMA that allow multiple segmentation or reassembly operations to be effectively performed in parallel (but not actually simultaneously). The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs. The DMA controller has its mem1 port brought out to the top level of the subsystem as a VBUSP master interface. This is to allow simultaneous assess by the DMA and the Queue manager to the external switch.

20.1.3.2.4.1 Tx Channel Allocation

A total of 30 Tx channels are provided within the DMA for concurrent packet transfers to the various ports. Table 20-1 shows how the Tx channels are allocated.

Table 20-1. TX Channel Allocation

DMA Channel	Function	Channel Type	Port	Channel In Port	Tx Queue Count	Tx Queue Arbitration Type	Start Tx QM # : Queue #	Packet Type(s)
0	USB EP 1	Endpt	1	0	2	Fixed Priority	32	USB
1	USB EP 2	Endpt	2	0	2	Fixed Priority	34	USB
2	USB EP 3	Endpt	3	0	2	Fixed Priority	36	USB

6	USB EP 7	Endpt	7	0	2	Fixed Priority	44	USB
7	USB EP 8	Endpt	8	0	2	Fixed Priority	46	USB
8	USB EP 9	Endpt	9	0	2	Fixed Priority	48	USB
9	USB EP 10	Endpt	10	0	2	Fixed Priority	50	USB
10	USB EP 11	Endpt	11	0	2	Fixed Priority	52	USB
11	USB EP 12	Endpt	12	0	2	Fixed Priority	54	USB
12	USB EP 13	Endpt	13	0	2	Fixed Priority	56	USB
13	USB EP 14	Endpt	14	0	2	Fixed Priority	58	USB
14	USB EP 15	Endpt	15	0	2	Fixed Priority	60	USB

20.1.3.2.4.2 CPPI DMA Transmit Operation

Packet transmission is accomplished within the DMA by moving data from structures that are located in external memory into the PPU module of the USB Subsystem. This movement of data is performed in blocks whose size varies based on the type of each packet and is performed in compliance with the CPPI 4.1 specification. USB packets are fetched by the Tx DMA in 64 byte blocks.

The DMA performs the following sequence on the Tx Port FIFO interface for each cell that is transferred:

1. Transfer specified number of payload bytes (1 to 64) to the Tx Port FIFO.
2. Write the channel number, packet type, SOP, EOP, and valid cell byte count to the cell information register in the Tx Port FIFO. The cell byte count is calculated by the DMA as the number of valid payload bytes in the cell for this packet type. Valid cell byte counts range from 1 to 64.
3. Write to the cell advance register in the Tx Port FIFO.

20.1.3.2.4.3 Rx Channel Allocation

A total of 30 Rx channels are provided within the DMA for concurrent packet transfers from the various ports. Table 20-2 shows how the Rx channels are allocated.

Table 20-2. RX Channel Allocation

DMA Channel	Function	Channel Type	Src Tag Port	Src Tag Channel	Src Tag Sub-Channel	Rx Queue Count	Packet Type(s)
0	USB EP 1	Endpt	1	0	0	1	USB
1	USB EP 2	Endpt	2	0	0	1	USB
2	USB EP 3	Endpt	3	0	0	1	USB
3	USB EP 4	Endpt	4	0	0	1	USB
4	USB EP 5	Endpt	5	0	0	1	USB
5	USB EP 6	Endpt	6	0	0	1	USB
6	USB EP 7	Endpt	7	0	0	1	USB
7	USB EP 8	Endpt	8	0	0	1	USB
8	USB EP 9	Endpt	9	0	0	1	USB
9	USB EP 10	Endpt	10	0	0	1	USB
10	USB EP 11	Endpt	11	0	0	1	USB
11	USB EP 12	Endpt	12	0	0	1	USB
12	USB EP 13	Endpt	13	0	0	1	USB
13	USB EP 14	Endpt	14	0	0	1	USB
14	USB EP 15	Endpt	15	0	0	1	USB

20.1.3.2.4.4 CPPI DMA Receive Operation

Packet reception is accomplished within the DMA by moving data from Rx Port FIFOs within the Jupiter session router subsystem into structures that are located in external memory. This movement of data is performed in blocks whose size varies based on the type of each packet and is in compliance with the CPPI 4.1 specification. USB packets are stored by the Rx DMA in 64 byte blocks.

The DMA performs the following sequence on the Rx Port FIFO interface of the PPU for each cell that is transferred:

1. Read the channel number, packet type, SOP, EOP, and valid cell byte count from the cell information registers in the Rx Port FIFO.
2. Transfer specified number of payload bytes (1 to 64) from the Rx Port FIFO.
3. Write to the cell advance register in the Rx Port FIFO.

20.1.3.2.5 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads that are provided in the CPPI DMA controller. The following sections describe the details of the scheduler functionality. The scheduler table RAM is a two port memory which is organized as 64 words with storage for 4 scheduler entries in each word.

20.1.3.2.5.1 Scheduler Initialization

Before the scheduler can be used, the Host is required to initialize and enable the block. This initialization is as follows:

- The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
- The Host initializes an internal register in the scheduler that sets the actual size of the array; it can be less than 256 entries.
- The Host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

20.1.3.2.5.2 Scheduler Operation

Once the scheduler is enabled, it begins to process the entries in the table, and when appropriate, pass credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled, it begins with the table index set to 0.
2. The scheduler reads the entry pointed to by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted.
   - The DMA channel must be enabled, and
   - The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted).
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface, which is a point-to-point connection between the DMA scheduler and the DMA controller.
   - The DMA controller may not be ready to accept the credit immediately and is provided a sched_ready signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the sched_ready signal when it is in the IDLE state.
   - Once a credit has been accepted (indicated by sched_req and sched_ready both asserted), the scheduler will increment the index to the next entry and will start at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
5. Note that when the scheduler attempts to increment its index to the value programmed in the table size register, the index will reset to 0.

20.1.3.2.6 CP_INTD

The cp_intd module controls the distribution of the USB subsystem interrupts to a single or multiple Hosts in a SoC. It combines the functions of many previous pieces of support IP into a single configurable module that allows a central method to control IP interrupts and system interrupts as well as complete customization to a particular SoC's need. The module eliminates the confusion of handling IP interrupts from a PDR IP module without knowledge of the support IP by building interfaces that connect directly to the IP and Interrupt controllers for each Host leaving the SoC to just connect the wires.

The cp_intd encompasses six functions that used to be separate (if even available) pieces of support IP or additional glue logic at the SoC level. These functions are: enabling, status capture, counting, combining or aggregation, pacing and synchronization. There are also polarity and type conversion and EOI functions to support legacy IP. The descriptions of these functions are detailed in the CP_INTD module specification.

Mapping of the USB interrupts to the cp_intd controller is described in Section 20.1.4.2 of this document.

20.1.3.2.7 CPPI Queue Manager

The queue manager accelerates addition and deletion of descriptors from descriptor queues, tracking of queue emptiness, and queue diversion. The following sections describe various operations that the queue manager can do on the queues. See the CPPI 4.1 specification for more information on queues. The Queue Manager module in the USB subsystem provides 96 hardware queues.

Table 20-3. Queue Allocation

Start	Count	Name
0	15	Free Descriptor/Buffer Queues
16	16	Unassigned Queues
32	2	USB0 Endpoint 1 Transmit Queue
34	2	USB0 Endpoint 2 Transmit Queue
36	2	USB0 Endpoint 3 Transmit Queue
38	2	USB0 Endpoint 4 Transmit Queue
40	2	USB0 Endpoint 5 Transmit Queue
42	2	USB0 Endpoint 6 Transmit Queue
44	2	USB0 Endpoint 7 Transmit Queue
46	2	USB0 Endpoint 8 Transmit Queue
48	2	USB0 Endpoint 9 Transmit Queue
50	2	USB0 Endpoint 10 Transmit Queue
52	2	USB0 Endpoint 11 Transmit Queue
54	2	USB0 Endpoint 12 Transmit Queue
56	2	USB0 Endpoint 13 Transmit Queue
58	2	USB0 Endpoint 14 Transmit Queue
60	2	USB0 Endpoint 15 Transmit Queue
62	2	USB1 Endpoint 1 Transmit Queue
64	30	Unassigned
92	4	Completion Queues

20.1.3.2.8 USB20OTG_F Packet Processing Unit

The packet processing unit (PPU) provides an interface and FIFO storage between the CPPI 4.1 DMA controller and the XDMA. The PPU interfaces to the DMA controller via a standard CFIFO interface. Full/empty flags are asserted to the DMA and XDMA depending on cell availability in the PPU FIFO. The PPU contains 30 logical FIFOs with a depth of 2 64-bytes cells each. One FIFO is allocated to each RX and TX channel and cannot be changed.

20.1.3.2.9 USB20OTG_F VBUSP to AHB (V2A)

The core is accessed through an AHB slave interface. There are a few operations that need to access this port: a CPU access from the VBUSP slave port, a register read by the Interrupt sub-module, or a FIFO access by the XFER DMA controller. The V2A will convert the VBUSP slave bus from the SCR to the AHB slave bus on the core. The AHB interface is a split transaction bus, with an address phase followed by a data phase, and successive transfers can overlap their address phases with the previous data phase (see the ARM AMBA Specification for more information on the AHB bus). The VUBSP interface is a single phase bus, so the address is presented until the slave is ready with the data (see the CBA 3.0 Specification for more information on the VBUSP bus). The V2A performs the two AHB phases while holding off the single phase on the VBUSP. When the second phase on the AHB is ready, then the VBUSP is ready and advances to the next phase. This allows a very simple implementation with minimal logic gates. For typical CPU accesses without bursts, there is no way to achieve better performance, and the DMA performance to the endpoint FIFOs should be sufficient for the required bandwidth.

The core is set to big endian mode to match the DMA expectation of data in the FIFOs. The DMA performs endian adjustment to match the system endian specified by the big_endian signal. To match this behavior, accesses to the core from the CPU through the VBUSP slave input will also adjust the data based on the system endian.

The V2A bridge as well as the VBUSP slave port only support bursts in linear incrementing mode. Any other modes cannot be used with the USB 2.0 OTG module.

20.1.3.2.10 USB20OTG_F Transfer (XFER) DMA

The XFER DMA receives DMA requests from the core and initiates the DMAs to the PPU. The first step is receiving the DMA request from the core. The core sends out 30 DMA_req signals, 15 for TX endpoints 1 to 15, and 15 for RX endpoints 1 to 15. For TX endpoints, the DMA_req goes high when a TX buffer for that endpoint is empty and can hold new data. The CPPI DMA performs the requested DMA for that channel, and the PPU indicates to the XDMA that data is available for that channel. Then, the XFER DMA reads from the PPU FIFO and writes the data into the endpoint FIFO inside the core. When the TX buffer in the core is full, the DMA_req goes low. After all the data is written to the endpoint FIFO, the XFER DMA writes the trigger bit in the core endpoint register to enable that TX endpoint for transfer.

For RX endpoints, the DMA_req goes high when an RX buffer holds a completed USB packet. The XFER DMA must check if the PPU FIFO is empty for that RX channel. If the PPU FIFO is empty on that RX channel, then the XFER DMA reads the RX count register in the core to obtain the size of the RX data, and reads the data from the core endpoint FIFOs and writes it to the PPU FIFO. The PPU FIFO signals the CPPI DMA that data is available. Then, the CPPI DMA writes the data out to main memory. The core lowers DMA_req once all the RX data is read from the endpoint FIFO. The XFER DMA also writes the trigger bit in the core endpoint register to enable the RX endpoint buffer for the next transfer.

20.1.3.2.10.1 RNDIS Mode

The USB 2.0 OTG controller also supports accelerating RNDIS type packets over USB. RNDIS mode allows the hardware to recognize and automate large packets being sent over USB, such as how RNDIS utilizes USB. When using transparent mode (the default with no acceleration) each DMA is equivalent to a single USB packet, so each DMA must be for at most the USB max packet size (i.e., 64 bytes for FS Bulk or 512 bytes for HS Bulk) and is a start-of-packet (SOP) and an end-of-packet (EOP) (see the CPPI 4.1 Specification for details on SOP and EOP) upon reception. Similarly, transmit CPPI packets can be no more than the USB max packet size.

RNDIS transfers over USB form a simple protocol to send larger packet sizes than those supported by USB 2.0 specifications. This is accomplished by breaking the larger packet into smaller packets, which are not larger than the max USB packet size. The protocol defines the end of the larger packet by using a USB packet that is not the max USB packet size (called a short packet). In the case where the larger packet size is an exact multiple of the max USB packet length, then the terminating short packet must be a zero length packet after the last data packet. The receiver combines the data packets and completes the RNDIS packet when it combines a short packet at the end.

The XFER DMA supports accelerating RNDIS packets over USB by automating the packing, unpacking, generation, and detection of these larger packets. In RNDIS mode, the CPPI packet refers to the larger packet, and the XFER DMA sends the entire packet out as a sequence of USB packets. For transmission, the CPPI packet data is sent as multiple USB packets of up to the max USB packet size. If the last data matches the max USB packet size, then the XFER DMA generates a zero length packet immediately after the last data packet. For receiving, USB packet data is sent to the same CPPI packet until a short packet is received. Only upon receiving the short packet will the XFER DMA indicate to the CPPI packet that it is now the end-of-packet.

To use RNDIS acceleration, the USB max packet size of any RNDIS mode enabled endpoints must be a multiple of 64 bytes. RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

20.1.3.2.10.2 Linux CDC Mode

Linux CDC mode is supported. CDC packets act in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size. In transmit operation, if an endpoint is configured or CDC Linux mode, the XFER DMA then generates a packet containing 1 byte of data, whose value is 0x00, to indicate the end of the transfer, similar to the manner in which the XDMA generates a zero length packet to terminate an RNDIS packet that exactly matches the max USB packet size. During receive operation, the XFER DMA recognizes the one byte zero packet as a termination of the USB packet, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller.

20.1.3.2.10.3 Generic RNDIS Mode

The USB 2.0 OTG controller supports a generic RNDIS mode over USB. This mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where data is being received or transmitted and the last packet of a segment exactly matches the max USB packet size. Normally, this mode receives USB packets in the same manner as RNDIS mode, closing the CPPI packet when a USB packet is received that is less than the endpoint size. Otherwise, the packet is closed when the value in the generic RNDIS EP size register is reached. Using this register, a packet of up to 64k bytes can be received. This is to allow the Host software to program the USB module to receive a packet that is an exact multiple of the endpoint size without having to send an additional short packet to terminate. In transmit operation, this mode behaves like RNDIS mode, except if the CPPI packet is an exact multiple of the endpoint size, a zero byte packet is not sent by the XDMA controller. The generic RNDIS EP size register must be programmed with a value that is an integer multiple of the endpoint size. For example, if the endpoint size is programmed with a value of 64, the generic RNDIS EP size register for that endpoint must be programmed with a value that is an integer multiple of 64, (e.g., 64, 128, 192, 256, etc.).

As in RNDIS mode, the USB max packet size of any generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

20.1.3.2.10.4 Zero Length Packets

A special case is the handling of zero length packets with the CPPI 4.1 compliant DMA controller. Upon receiving a zero length USB packet, the XFER DMA sends a data block to the DMA controller with the byte count of zero, the EOP bit set, and the zero byte packet bit of INFO Word 1 set. The DMA controller then performs normal EOP termination of the packet, without transferring data. To the packet transmission case, if a packet has the SOP and EOP packet has the zero byte packet bit of the INFO Word 1 of the CFIFO interface set, the XFER DMA ignores the CPPI packet size and sends a zero byte packet to the USB core. It is not valid to have the zero byte packet bit of the INFO Word 1 set without the SOP and EOP bits of INFO word 0 also being set.

20.1.3.2.10.5 Teardown

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in the teardown register of the USB module must be set, and the FlushFIFO bit in the Mentor USB controller CSR register must be set. Writing to the USB OTG controller teardown register resets the CPPI FIFO occupancy value and pointers to 0. It also resets the current state of the XDMA for the endpoint selected, after any current operations have been completed.. Note that due to VBUSP bridge latency, the CPPI FIFO occupancy values are not reset immediately upon writing of the teardown register.

20.1.3.2.11 PDR Interrupts

The interrupt interface provided by the core is not PDR compliant. The core only provides one interrupt signal. The CPU would have to read registers inside the core to decide what the source of the interrupt actually is. While there are enable (mask) registers and the ability to clear interrupts, there is no ability to set interrupts as required by PDR. This sub-module creates a PDR compliant interrupt interface for the OTG module. The interrupt block accepts the core interrupt, reads the core registers to determine the source(s), and provides the required interface. This includes a new interrupt source set register, and the end-of-interrupt (EOI) register. The original interrupt from the core will also be sent out for those systems that do not need the PDR interrupt interface. These interrupts are in addition to those provided by the DMA controller. The interrupts that are output by this sub-module are then aggregated by the Intd module in a PDR compliant manner.

There is also an extra interrupt mode, for systems that do not need external interrupt aggregation logic or PDR interrupts altogether. The system can utilize the aggregator logic inside the Mentor core, and not use any part of the PDR interrupt style for the USB interrupts. All USB interrupt interaction must be with the Mentor core registers in this mode, since the PDR interrupt logic is disabled. This is only for the USB interrupts, though, as the DMA interrupts only support PDR mode.

20.1.3.2.12 VBUSP Retiming

To enhance the timing of the VBUSP interfaces to the system, a VBUSP retiming bridge is used to isolate the internal timings from the external system. This retiming bridge simply takes in a VBUSP bus and outputs a VBUSP bus. These bridges are located on the incoming VBUSP configuration slave bus and the outgoing Master from the module SCR.

20.1.3.2.13 PDR Clocking and IP Generics

This sub-module implements a PDR 3.5 compliant clock interface. This consists of a gated clock, clock stop request, and clock stop acknowledge signals. When a clock stop request is asserted, this block waits until all DMAs inside the module have ceased, and sends the clock stop acknowledge. Then the system may stop the gated clock. Software should disable all the necessary functions inside the DMA and core so that there is no continued activity when a clock stop is requested.

The module also performs the required PDR 3.5 emulation interface. Setting the emulation register sets the method the module uses to perform emulation stops based on the VBUSP emulation suspend signals.

There is a register bit in the control register that allows for fast responding to the clock stop request. If this bit is enabled, this module returns a clock stop ack in the next clock cycle and does not wait for current DMAs to finish. The system needs to be tolerant of a possible loss of the DMA request if this occurs.

20.1.3.2.14 Switched Central Resource (SCR)

SCRs allow connecting more than two VBUSP ports together onto a single bus. By using VBUSP ports for connecting not only to the system, but also to local RAMs or FIFOs, a generic interface is provided that can be upgraded without affecting the other sub-modules. An SCR is used to connect all the internal and external interfaces together. These interfaces include: the core's AHB slave through the V2A bridge, the XFER DMA, and all the configuration ports.

The USB 2.0 OTG SCR has been enhanced to allow the SSRAM port to be non-bursting, while the remainder support bursting.

20.1.4 Interrupt Conditions

20.1.4.1 CPU Interrupts

The following interrupts are generated by the USB 2.0 OTG controller:

Table 20-4. CPU Interrupts

Interrupt	Description
TX_ENDP[15:1]	TX endpoint ready or error for endpoints 16 to 0 (endpoint 0 is for TX and RX)
RX_ENDP[15:1]	RX endpoint ready or error for endpoints 16 to 0 (there is no interrupt for endpoint 0)
USB[8:0]	Nine USB conditions
USB_INT	Single interrupt signal from the core

20.1.4.2 Interrupt Description

20.1.4.2.1 USB Core PDR Interrupts

There are 4 general-purpose TX endpoints supported in addition to control endpoint 0, whose interrupt encapsulates both TX and RX readiness. The core generates a corresponding TX_ENDP interrupt when that TX endpoint successfully completes transmitting a packet and the buffer is empty and ready to send another packet or when the TX endpoint had an error condition. If the TXCSR is setup as required for the DMA (with DMAReqEnab and DMAReqMode set), then the TX endpoint interrupt only generates error condition interrupts, and not packet completion interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions. The TX endpoint interrupts are:

Table 20-5. TX Endpoint Interrupts

Interrupt	Description
TX_ENDP[15]	TX endpoint ready or error for endpoint 15
TX_ENDP[14]	TX endpoint ready or error for endpoint 14
TX_ENDP[13]	TX endpoint ready or error for endpoint 13
TX_ENDP[12]	TX endpoint ready or error for endpoint 12
TX_ENDP[11]	TX endpoint ready or error for endpoint 11
TX_ENDP[10]	TX endpoint ready or error for endpoint 10
TX_ENDP[9]	TX endpoint ready or error for endpoint 9
TX_ENDP[8]	TX endpoint ready or error for endpoint 8
TX_ENDP[7]	TX endpoint ready or error for endpoint 7
TX_ENDP[6]	TX endpoint ready or error for endpoint 6
TX_ENDP[5]	TX endpoint ready or error for endpoint 5
TX_ENDP[4]	TX endpoint ready or error for endpoint 4
TX_ENDP[3]	TX endpoint ready or error for endpoint 3
TX_ENDP[2]	TX endpoint ready or error for endpoint 2
TX_ENDP[1]	TX endpoint ready or error for endpoint 1
TX_ENDP[0]	TX or RX endpoint ready or error for endpoint 0

There are 4 general-purpose RX endpoints supported. The core generates a corresponding RX_ENDP interrupt when that RX endpoint successfully receives a packet and all the data is ready in the RX endpoint FIFO or when a receive error occurs. If the RXCSR is setup as required for the DMA (with DMAReqEnab set and DMAReqMode clear), then the RX endpoint interrupt only generates error condition interrupts, and not packet readiness interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions. The RX endpoint interrupts are:

Table 20-6. RX Endpoint Interrupts

Interrupt	Description
RX_ENDP[15]	RX endpoint ready or error for endpoint 15
RX_ENDP[14]	RX endpoint ready or error for endpoint 14
RX_ENDP[13]	RX endpoint ready or error for endpoint 13
RX_ENDP[12]	RX endpoint ready or error for endpoint 12
RX_ENDP[11]	RX endpoint ready or error for endpoint 11
RX_ENDP[10]	RX endpoint ready or error for endpoint 10
RX_ENDP[9]	RX endpoint ready or error for endpoint 9
RX_ENDP[8]	RX endpoint ready or error for endpoint 8
RX_ENDP[7]	RX endpoint ready or error for endpoint 7
RX_ENDP[6]	RX endpoint ready or error for endpoint 6
RX_ENDP[5]	RX endpoint ready or error for endpoint 5
RX_ENDP[4]	RX endpoint ready or error for endpoint 4
RX_ENDP[3]	RX endpoint ready or error for endpoint 3
RX_ENDP[2]	RX endpoint ready or error for endpoint 2
RX_ENDP[1]	RX endpoint ready or error for endpoint 1

The USB OTG module also generates 9 USB interrupts based on noteworthy USB conditions. The USB interrupts are:

Table 20-7. USB Interrupts

Interrupt	Description
USB[8]	DRVVBUS level change
USB[7]	VBUS < VBUS valid threshold
USB[6]	SRP detected
USB[5]	Device disconnected (host mode)
USB[4]	Device connected (host mode)
USB[3]	SOF started
USB[2]	Reset signaling detected (peripheral mode) Babble detected (host mode)
USB[1]	Resume signaling detected
USB[0]	Suspend signaling detected

Interrupts USB[0] to USB[7] are generated by the Mentor core, and converted to PDR 2.0 format by the PDR interrupt sub-module. For more details on these interrupts, see the Mentor core documentation. Interrupt USB[8] is generated outside the Mentor core by the PDR interrupt sub-module whenever the level of DRVVBUS changes. This is usually due to entering or leaving Host mode, or entering or leaving power saving mode.

The USB20OTG interrupts are also aggregated by the Interrupt Distributor module. The table below provides a list of USB Interrupts that INTD processes. Only one USB interrupt signals is provided on the outside and INTD provides the interrupt aggregation logic for all USB interrupts.

When the EOI register in the USB module is written to, the eoi_wr and eoi_wr_vector information is sent to INTD which in turn re-evaluates the interrupt and triggers it if necessary.

20.1.4.2.2 USB Core Non-PDR Interrupts

If the non-PDR interrupt mode is selected for the USB interrupts, then the previous list of USB PDR sources are not valid, and the core generates the CPU interrupt directly. The pin from the core is connected to the module output, USB_INT, and all interactions to clear and mask interrupts must be done with the core registers. This interrupt is an active high signal.

The additional USB interrupt for DRVVBUS level changes is not part of the core interrupt set, and therefore is not available when using non-PDR interrupt mode.

20.1.4.2.3 Completion Queue Interrupts

The pending bits for queues 92-95 are aggregated in the INTD controller. These bits correspond to dedicated completion queues used by the CDMA for returning completed transmit and receive packets. The pending signals are level sensitive and when low, indicate that there are no packets on the queue. When a packet is added to one of the completion queues, the pending bit goes to high, indicating packets are available on the queue. When the low to high transition occurs, an interrupt is generated by the INTD module on the cdma_int pin. The Host software must read the queue status register for the completion queues to determine which queue caused the interrupt. Once all packets have been removed from the queue, the corresponding pending signal returns to 0. Software may choose to use one of the unassigned queues if an interrupt is not wanted upon the completion of a packet.

20.1.4.3 Interrupt Condition Control

20.1.4.3.1 USB Core Interrupts

The USB core interrupts are originally generated inside the Mentor core. The core provides enable registers for each of the three types of interrupts. The INTRTXE register allows enabling of each TX endpoint interrupt The INTRRXE register allows enabling of each RX endpoint interrupt. The INTRUSBE register allows enabling of each general USB interrupt. Any enabled interrupt generates CPU interrupts in the form of the corresponding interrupt source, the module generated interrupt pulse, and the interrupt pulse from the Mentor core directly.

To comply with PDR interrupts, additional logic is built around the core. This adds a mask register along with mask set and mask clear registers. The USB Interrupt Mask register shows the current mask value, where each bit enables the corresponding interrupt source in the USB Interrupt Source register. The USB Interrupt Mask Set register allows writing a ‘1’ in bit positions to enable the corresponding interrupt source. Those bits written with a ‘0’ will not be modified. The USB Interrupt Mask Clear register allows writing a ‘1’ in bit positions to disable the corresponding interrupt source. Those bit written with a ‘0’ will not be modified. The mask is used to enable interrupt sources and generate the masked interrupt sources which are used to generate the CPU interrupt or by external logic to generate CPU interrupts.

20.1.4.4 Interrupt Handling

20.1.4.4.1 USB Core Interrupts

The Mentor core generates the interrupts and the additional logic generates the PDR 3.5 interrupt sources. In order to generate the interrupt sources, the additional logic must read the interrupt source registers inside the core. When these registers are read, the core clears all the interrupt source bits, so the CPU will not have to do this. Therefore, the CPU simply needs to handle the data for TX or RX endpoint interrupts, or the USB interrupts and acknowledge the interrupt in the usual method. The interrupt source can be cleared by writing a ‘1’ in the corresponding bit position to the USB Interrupt Source Clear register. Also, the End of Interrupt register functions as required by PDR To facilitate debugging, writing a ‘1’ to bit positions in the USB Interrupt Source Set register sets the corresponding interrupt source even if it wasn’t generated by the core.

20.1.5 I/O Description

20.1.5.1 Module I/O

20.1.5.1.1 Reset Interface

Pin Name	Type	Function
vbusp_rst_n	In	Main reset for CDMA/Queue Manager/INTD
vbusp_usb0_rst_n	In	Main reset for USB controller 0 submodule
vbusp_usb1_rst_n	In	Main reset for USB controller 1 submodule

20.1.5.1.2 Queue Manager Event Interface

Pin Name	Type	Function
qmgr_event_queue[6:0]	Out	Queue on which a push/pop operation was performed. See CPPI 4.1.7 spec for hookup details.
qmgr_event_strobe	Out	Queue Event Valid Indicator. See CPPI 4.1.7 spec for hookup details.
qmgr_event_type	Out	Queue Push/Pop Type indicator with push operation indicated by a 1 and pop by a 0. See CPPI 4.1.7 spec for hookup details.

20.1.5.1.3 USB Interface

Pin Name	Type	Function
PHY_DP	Inout	USB I/O pin
PHY_DM	Inout	USB I/O pin
PHY_VBUS	Inout	USB I/O pin
PHY_ID	Inout	USB I/O pin
PHY_UTMI_DRVVBUS	Out	Drive VBUS connection to external charge pump
PHY_UTMI_DRVVBUS_OE_N	Out	Output enable for drive VBUS

20.1.5.1.4 Interrupt Interface

Pin Name	Type	Function
Usb_int	Out	USB Interrupt request
cdma_int	Out	CDMA Starvation Interrupt Out

20.1.5.2 External Pins

The only external pin is for an external charge pump. The controller outputs DRVVBUS to indicate whether the charge pump should drive the VBUS pin or not. This pin need not be present when using an internal charge pump. There are no timing requirements for DRVVBUS since it is basically a static signal that only changes at major USB actions, such as going into suspend mode, or becoming a Host.

20.1.5.2.1 External Pin Table

Table 20-8. External Pin Information

Name	Dir	Description	I/O Type [1]	Timing Parameter	Minimum Value	Maximum Value
PHY_UTMI_DRVVBUS	O	Drive VBUS	LV-TTL			

(1) I/O Types: 5 V-Tol = 5 Volt Tolerant, TTL-3S = TTL Output Level Tri-Stateable, LV-TTL Low Voltage TTL

20.1.6 Teardown Procedure

In order to fully teardown a TX or RX channel, the following procedure must be followed. Software should guarantee that all steps have been completed before assuming teardown has completed successfully.

20.1.6.1 Transmit Teardown

First, the CPPI DMA teardown procedure must be implemented. This is to ensure that the DMA controller is aware of the teardown and can respond properly. See the CDMA and CPPI 4.1 specifications for more details on DMA transmit teardown.

Next, once the CDMA teardown is complete and any current packets the CDMA is transmitting on the channel have completed, the USB controller Teardown register must be written, setting the corresponding bit of the endpoint that is to be torn down set. This makes sure the CPPI FIFO interface is reset properly and no spurious data remains in the FIFOs.

Lastly, the FlushFIFO bit of the CSR Register of the endpoint that is to be torn down must be set. Make certain that the necessary bits are kept set if the entire register is written. See the Mentor core documentation for more information.

After these steps are complete, the DMA channel and endpoint must go through the normal reconfiguration procedure and then can resume normal operation.

20.1.6.2 Receive Teardown

Set the FlushFIFO bit of the CSR register of the endpoint that is to be torn down. See the Mentor core documentation for more detailed information.

Next, set the USB controller Teardown register for the designated endpoint. Lastly, initiate the CDMA receive teardown procedure as described in the CDMA specification. To ensure that no data corrution has occurred in the Mentor core FIFO, the FlushFIFO bit of the CSR register should be written a second time after the CDMA channel teardown. To ensure good operation, the Host should wait at least 100 VBUSP_CLK clock cycles after CDMA channel teardown and the second write of the FlushFIFO bit. At this time the endpoint has completed teardown and can be reinitialized according to the standard endpoint setup procedure and normal operation resumed.

20.1.7 USB Bus Reset Handling

After a USB bus reset, the Mentor core interrupts as well as clears many of its registers. This requires the software to teardown any TX DMA channels currently in use before setting up the DMA and core again. Failure to perform the teardown procedure as described previously may result in erratic behavior or unwanted TX data.

20.1.8 VBUSP Slave Port Bursting

The USB 2.0 OTG subsystem does not support bursting on the VBUSP slave port. All accesses should be single word (or smaller) accesses, and the first and last signals should always be high. Sending bursts to registers can result in unpredictable behavior.

20.1.9 Core Register Type Mixing

Software must take care when reading core registers larger than their original size to optimize reads. If the registers read are from different types (common, endpoint, or FIFO) then the core only reads the registers in the type of the initial address, and not the upper address registers in another type. An example is the DEVCTL common register at 0x460 with the TXFIFOSZ and RXFIFOSZ endpoint registers at 0x462 and 0x463. The core only reads the DEVCTL register in this case. To read the TXFIFOSZ and RXFIFOSZ registers, software must read starting at 0x462.

20.1.10 Zero Byte Packet Parameters

Zero-byte packets must be generated with the zero-byte bit of Info register 1 set (see the CPPI FIFO Info register 1) and the packet size should be 1 byte. The actual packet data is not used.

20.1.11 Interrupt Usage

The expected usage of the interrupts when using the DMA is as follows. The DMA generates interrupts after each CPPI packet is processed. With the expects TXCSR and RXCSR setup as required for the DMA, the TX endpiont and RX endpoint interrupts will only be generated when there is an error or stall condition from the core. Therefore, the CPU should not disable and ignore the endpoint interrupts unless error detection is not desired or polling is used.

20.1.12 Powerdown Handling

In order to safely powerdown the USB 2.0 OTG module, the SUSPENDM signal should be monitored. When low, the USB bus is going into suspend mode and the system can safely powerdown the OTG module. This includes disabling the clock, and disabling the PHY. Please refer to the PHY spec on how to safely powerdown the PHY.

In order to wakeup after suspend from a bus resume, the PHY must be powered on to drive the LINESTATE, VBUSVALID, and AVALID UTMI signals. The OTG controller uses these to asynchronously generate SUSPENDM, so it can drive SUSPENDM high even without a clock. When SUSPENDM goes high, the USB 2.0 OTG module and the PHY should be powered up again so that the USB operations can resume.

20.1.13 Clock Stop and Emulation Suspend

The USB module supports clock stop operation and CBA compliant emulation suspend. It should be noted that for clock stop operation, the UTMI clock is unaffected and the Mentor core continues to interact with the phy device unless the phy is powered down at the time. Similarly for emulation suspend, the XDMA state machine halts once the current packet processing is complete, but the Mentor controller is unaffected by the suspend unless the phy is also powered down at the same time.

The clock stop interface allows the DMA to be gracefully commanded to enter into a stopped clock state. When the *clkstop_req* input is asserted, the DMA suspend state is entered and, the DMA stops processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or transmission is completed normally without suspension. The *clkstop_ack* output is asserted when the DMA enters the IDLE state and all of the individual channels have indicated that they are stopped and are no longer in the middle of transmitting or receiving a packet. The *clkstop_ack* indicates that the clock, *vbusp_gclk*, may be stopped.

20.1.14 Registers

Table 20-9 lists the memory-mapped registers for the high speed universal serial bus (USB).

Table 20-9. Universal Serial Bus (USB) Registers

20.1.14.1 USB Control Register (Base Address + 0x0004)

The control register allows the CPU to control various aspects of the module.

The USB control register is shown in Figure 20-4 and described in Table 20-10.

Figure 20-4. USB Control Register

31	30	29														16
dis_deb	dis_srp	Reserved														
R/W	R/W	R														
15												5	4	3	2	1	0
Reserved													rndis	uint	RSVD	clkfack	Reset
R													R/W	R/W	R	R/W	R/W-1

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-10. USB Control Register Field Descriptions

Bit	Field	Value	Description
31	dis_deb		Disable the VBUS debouncer circuit fix
30	dis_srp		Disable the SRP a_valid circuit fix
29-5	Reserved	0	Always read as 0. Writes have no affect.
4	rndis		Global RNDIS mode enable for all endpoints.
3	uint		USB non-PDR interrupt enable
2	Reserved	0	Always read as 0. Writes have no effect.
1	clkfack		Clock stop fast ack enable.
0	Reset		Soft reset. Writing a 1 starts a module reset.

20.1.14.2 USB Status Register (Base Address + 0x0008)

The status register allows the CPU to check various aspects of the module.

The USB status register is shown in Figure 20-5 and described in Table 20-11.

Figure 20-5. USB Status Register

31	1	0
Reserved		drvvbus
		R

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-11. USB Status Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Always read as 0. Writes have no affect.
0	drvvbus		Current DRVVBUS value

20.1.14.3 USB Auto Req Register (Base Address + 0x0014)

The auto req register allows the CPU to enable an automatic IN token request generation for the Host mode RX operation per each RX endpoint. This features has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the Host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU has to manually set the ReqPkt bit for every USB packet. There are two modes that Auto Req can function: always or all except an end of packet (EOP). The always mode sets the ReqPkt bit after every USB packet the DMA receives generating a new IN token after each USB packet. The EOP mode sets the ReqPkt bit after every USB packet that isn't an EOP in the CPPI descriptor. For RNDIS, CDC, and generic RNDIS modes, the auto req stops when the EOP is received (either via a short packet for RNDIS,CDC, and generic RNDIS or the count is reached for generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode, every USB packet is an EOP CPPI packet so the auto req never functions and acts like it is disabled.

The USB auto req register is shown in Figure 20-6 and described in Table 20-12.

Figure 20-6. USB Auto Req Register

31	30	29	28	27	26	25	24

		01	Auto req on all but EOP
		10	Reserved
		11	Auto req always
1-0	Rx(N)_autoreq		RX endpoint N Auto Req enable
		00	No auto req
		01	Auto req on all but EOP
		10	Reserved
		11	Auto req always

20.1.14.4 USB Teardown Register (Base Address + 0x001C)

The teardown register controls the tearing down of rx and tx FIFOs in the USB controller. When a '1' is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared. This register must be used in conjunction with the CPPI DMA teardown mechanism. The Host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB controller registers to ensure a complete teardown of the endpoint. See the Mentor specification for details.

The USB teardown register is shown in Figure 20-7 and described in Table 20-13.

Figure 20-7. USB Teardown Register

31	17	16	15	1	0
tx_tdown		Reserved	rx_tdown		Reserved
R/W			R/W		

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-13. USB Teardown Register Field Descriptions

Bit	Field	Value	Description
31-17	tx_tdown		Tx Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 31 = Endpoint 15 ... Bit 17 = Endpoint 1
16	Reserved	0	Always read as 0. Writes have no affect.
15-1	rx_tdown		RX Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 15 = Endpoint 15 ... Bit 1 = Endpoint 1
0	Reserved	0	Always read as 0. Writes have no affect.

20.1.14.5 USB Endpoint Interrupt Source Register (Base Address + 0x0020)

The USB interrupt source register contains the status of the interrupt sources generated by the USB core (not the DMA).

The USB endpoint interrupt source register is shown in Figure 20-8 and described in Table 20-14.

Figure 20-8. USB Endpoint Interrupt Source Register

31	17	16	5	0
rx		Reserved	tx	
R			R	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-14. USB Endpoint Interrupt Source Register Field Descriptions

Bit	Field	Value	Description
31-17	rx		RX endpoint interrupt sources (N+15 to N).
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		TX endpoint interrupt sources (N+15 to N+1 plus endpoint 0).

20.1.14.6 USB Endpoint Interrupt Source Set Register (Base Address + 0x0024)

The USB interrupt source set register allows the USB interrupt sources to be manually triggered. A read of this register returns the USB interrupt source register value.

The USB endpoint interrupt source set register is shown in Figure 20-9 and described in Table 20-15.

Figure 20-9. USB Endpoint Interrupt Source Set Register

31	17	16	5	0
rx		Reserved	tx	
R/W			R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-15. USB Endpoint Interrupt Source Set Register Field Descriptions

Bit	Field	Value	Description
31-17	rx		Write a 1 to set equivalent RX endpoint interrupt source.
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		Write a 1 to set equivalent TX endpoint interrupt source.

20.1.14.7 USB Endpoint Interrupt Source Clear Register (Base Address + 0x0028)

The USB interrupt source clear register allows the CPU to acknowledge an interrupt source and turn it off. A read of this register returns the USB interrupt source register value.

The USB endpoint interrupt source clear register is shown in Figure 20-10 and described in Table 20-16.

Figure 20-10. USB Endpoint Interrupt Source Clear Register

31	17	16	5	0
rx		Reserved	tx	
R/W			R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-16. USB Endpoint Interrupt Source Clear Register Field Descriptions

Bit	Field	Value	Description
31-17	rx		Write a 1 to clear equivalent RX endpoint interrupt source.
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		Write a 1 to clar equivalent TX endpoint interrupt source.

20.1.14.8 USB Endpoint Interrupt Mask Register (Base Address + 0x002C)

The USB interrupt mask register contains the masks of the interrupt sources generated by the USB core (not the DMA). These masks are used to enable or disable interrupt sources generated on the masked source interrupts (the raw source interrupts are never masked). The bit positions are maintained in the same position as the interrupt sources in the USB interrupt source register.

The USB endpoint interrupt mask register is shown in Figure 20-11 and described in Table 20-17.

Figure 20-11. USB Endpoint Interrupt Mask Register

31	17	16	5	0
rx		Reserved	tx	
R			R	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-17. USB Endpoint Interrupt Mask Register Field Descriptions

Bit	Field	Value	Description
31-17	rx		Write a 1 to clear equivalent RX endpoint interrupt source.
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		Write a 1 to clar equivalent TX endpoint interrupt source.

20.1.14.9 USB Endpoint Interrupt Mask Set Register (Base Address + 0x0030)

The USB interrupt mask set register allows the USB interrupt masks to be individually enabled. A read to this register returns the USB interrupt mask register value.

The USB endpoint interrupt mask set register is shown in Figure 20-12 and described in Table 20-18.

Figure 20-12. USB Endpoint Interrupt Mask Set Register

31	17	16	5	0
rx		Reserved	tx	
R/W			R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Bit	Field	Value	Description
31-17	rx		Write a 1 to set equivalent RX endpoint interrupt mask.
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		Write a 1 to set equivalent TX endpoint interrupt mask.

20.1.14.10 USB Endpoint Interrupt Mask Clear Register (Base Address + 0x0034)

The USB interrupt mask clear register allows the USB interrupt masks to be individually disabled. A read to this register returns the USB interrupt mask register value.

The USB endpoint interrupt mask clear register is shown in Figure 20-13 and described in Table 20-19.

Figure 20-13. USB Endpoint Interrupt Mask Clear Register

31	17	16	5	0
rx		Reserved	tx	
R/W			R/W

31-17	rx		Write a 1 to clear equivalent RX endpoint interrupt mask.
16	Reserved	0	Always read as 0. Writes have no affect.
15-0	tx		Write a 1 to clear equivalent TX endpoint interrupt mask.

20.1.14.11 USB Endpoint Interrupt Source Masked Register (Base Address + 0x0038)

The USB endpoint interrupt source masked register contains the status of the interrupt sources generated by the USB core masked by the USB interrupt mask register values.

The USB endpoint interrupt source masked register is shown in Figure 20-14 and described in Table 20-20.

Figure 20-14. USB Endpoint Interrupt Source Masked Register

15-0	tx		TX endpoint interrupt sources masked.

20.1.14.12 USB Core Interrupt Source Register (Base Address + 0x0040)

The USB interrupt source register contains the status of the interrupt sources generated by the USB core (not the DMA).

The USB core interrupt source register is shown in Figure 20-15 and described in Table 20-21.

Figure 20-15. USB Core Interrupt Source Register

31	25	24	16	15	0
Reserved		usb		Reserved

15-0	Reserved	0	Always read as 0. Writes have no affect.

20.1.14.13 USB Core Interrupt Source Set Register (Base Address + 0x0044)

The USB interrupt source set register allows the USB interrupt sources to be manually triggered. A read of this register returns the USB interrupt source register value.

The USB core interrupt source set register is shown in Figure 20-16 and described in Table 20-22.

Figure 20-16. USB Core Interrupt Source Set Register

24-16	usb		Write a 1 to set equivalent USB interrupt source.
15-0	Reserved	0	Always read as 0. Writes have no affect.

20.1.14.14 USB Core Interrupt Source Clear Register (Base Address + 0x0048)

The USB interrupt source clear register allows the CPU to acknowledge an interrupt source and turn it off. A read of this register returns the USB interrupt source register value.

The USB core interrupt source clear register is shown in Figure 20-17 and described in Table 20-23.

Figure 20-17. USB Core Interrupt Source Clear Register

15-0	Reserved	0	Always read as 0. Writes have no affect.

20.1.14.15 USB Core Interrupt Mask Register (Base Address + 0x004C)

The USB interrupt mask register contains the masks of the interrupt sources generated by the USB core (not the DMA). These masks are used to enable or disable interrupt sources generated on the masked source interrupts (the raw source interrupts are never masked). The bit positions are maintained in the same position as the interrupt sources in the USB interrupt source register.

The USB core interrupt mask register is shown in Figure 20-18 and described in Table 20-24.

20.1.14.16 USB Core Interrupt Mask Set Register (Base Address + 0x0050)

The USB interrupt mask set register allows the USB interrupt masks to be individually enabled. A read to this register returns the USB interrupt mask register value.

The USB core interrupt mask set register is shown in Figure 20-19 and described in Table 20-25.

Figure 20-19. USB Core Interrupt Mask Set Register

20.1.14.17 USB Core Interrupt Mask Clear Register (Base Address + 0x0054)

The USB interrupt mask clear register allows the USB interrupt masks to be individually disabled. A read to this register returns the USB interrupt mask register value.

The USB core interrupt mask clear register is shown in Figure 20-20 and described in Table 20-26.

Figure 20-20. USB Core Interrupt Mask Clear Register

20.1.14.18 USB Core Interrupt Source Masked Register (Base Address + 0x0058)

The USB interrupt source masked register contains the status of the interrupt sources generated by the USB core masked by the USB interrupt mask register values.

The USB core interrupt source masked register is shown in Figure 20-21 and described in Table 20-27.

Figure 20-21. USB Core Interrupt Source Masked Register

20.1.14.19 USB End of Interrupt Register (Base Address + 0x0060)

The USB end of interrupt register allows the CPU to acknowledge completion of an interrupt by writing to the EOI. An eoi_write signal is generated, the EOI vector is updated to the written value, and another interrupt is triggered if interrupt sources remain.

The USB end of interrupt register is shown in Figure 20-22 and described in Table 20-28.

20.1.14.20 USB MOP/SOP Interrupt Enable Register (Base Address + 0x0064)

This register must be set to enable the DMA buffer starvation interrupt. When bit for the mop or sop interrupt is enabled, the interrupt to the INTD module triggers the first time the DMA issues that interrupt and then automatically disables itself, blocking future interrupts until the Host re-enables via this register.

The USB MOP/SOP interrupt enable register is shown in Figure 20-23 and described in Table 20-29.

Figure 20-23. USB MOP/SOP Interrupt Enable Register

20.1.14.21 USB Tx Mode Register (Base Address + 0x0070)

The mode register allows the CPU to individually enable RNDIS/generic/CDC modes for each endpoint. Using the global RNDIS enable in the control register overrides this register and enables RNDIS mode for all endpoints.

The USB Tx mode register is shown in Figure 20-24 and described in Table 20-30.

20.1.14.23 USB EP Count Mode Register (Base Address + 0x0078)

The EP count mode register is a special feature used only in conjunction with transparent mode that allows the XDMA to receive a preprogrammed number of USB packets and then halting until the count is reprogrammed. When the corresponding bit of this register is set and the endpoint is in transparent mode, the EP size register for that endpoint becomes a USB packet count register. After the XDMA receives a USB packet, it decrements this register by one. If auto request on all is enabled, it sets the packet request bit in the endpoint's CSR register in the Mentor controller. When the XDMA receives a packet and the count value is 1, the XDMA will not issue a packet request to the Mentor controller, but waits for the count value to be reprogrammed before continuing.

The USB EP count mode register is shown in Figure 20-26 and described in Table 20-32.

20.1.14.24 USB Generic RNDIS EP N Size Register (Base Address + 0x0080)

The generic RNDIS EP1 size register is programmed with a RNDIS packet size in bytes. When EP1 is in generic RNDIS mode, the received USB packets collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a “short” packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 0x10000, or 65536. When the controller is set in transparent EP count mode, this register is known as the EP count register and the number programmed is the number of USB packets to receive before halting.

The USB generic RNDIS EP N size register is shown in Figure 20-27 and described in Table 20-33??.

16-0	Ep(N)_size		Generic RNDIS packet size.

20.1.14.25 USB Queue Interrupt Threshold Enable Register (Base Address + 0x00C0)

The queue interrupt threshold enable register enables the threshold counts that are available for two of the completion queues. When the bit is set, the interrupt threshold mechanism for that queue is enabled.

The USB queue interrupt threshold enable register is shown in Figure 20-28 and described in Table 20-34.

Figure 20-28. USB Queue Interrupt Threshold Enable Register

Bit	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no affect.
1	Queue65_en		
		0	Threshold Disabled for Completion Queue 65
		1	Threshold Enabled for Completion Queue 65
0	Queue63_en		
		0	Threshold Disabled for Completion Queue 63
		1	Threshold Enabled for Completion Queue 63

20.1.14.26 USB Queue Threshold Register 0 (Base Address + 0x00C4)

The queue threshold register provides a programmable method to delay the completion interrupt until a number of interrupts have been detected. The Host software programs this register with a value between 1 and 255. When the DMA completes a packet designated for completion queue 63, an internal counter is incremented. When this counter reaches the value in this threshold register, an the interrupt and subsequent interrupts are enable to the INTD module, until the interrupt clear register is written and the internal count is reset.

The USB queue threshold register 0 is shown in Figure 20-29 and described in Table 20-35.

Figure 20-29. USB Queue Threshold Register 0

20.1.14.28 USB Queue Threshold Register 1 (Base Address + 0x00D4)

The queue threshold register provides a programmable method to delay the completion interrupt until a number of interrupts have been detected. The Host software programs this register with a value between 1 and 255. When the DMA completes a packet designated for completion queue 65, an internal counter is incremented. When this counter reaches the value in this threshold register, an the interrupt and subsequent interrupts are enable to the INTD module, until the interrupt clear register is written and the internal count is reset.

The USB queue threshold register 1 is shown in Figure 20-31 and described in Table 20-37.

20.1.14.30 USB Mentor Core Registers/FIFOs (Base Address + 0x400 – 0x59C)

A description of the Mentor core registers is available in the Mentor specification. The core registers are described starting at address 0x000, but they are located in the USB 2.0 OTG module starting at 0x400. To convert, just add 0x400 to the register address in the Mentor core specification.

*20.1.14.30.1 CDMA Tx Channel N Global Configuration Register (Base Address + 0x0800 + 32*N)*

The Tx channel configuration registers are used to initialize the behavior of each of the Tx DMA channels.

The CDMA Tx channel N global configuration register is shown in Figure 20-33 and described in Table 20-39.

Figure 20-33. CDMA Tx Channel N Global Configuration Register

Bit	Field	Value	Description
31	tx_enable		This field enables or disables the channel
		0	Channel is disabled
		1	Channel is enabled
			This field is cleared after a channel teardown is complete.
30	tx_teardown		Setting this bit will request the channel to be torn down. This field remains set after a channel teardown is complete.
29-14	Reserved	0	Always read as 0. Writes have no affect.
13-12	tx_default_qmgr		This field controls the default queue manager number that is used to queue teardown descriptors back to the Host.
11-0	tx_default_qnum		This field controls the default queue number within the selected queue manager onto which teardown descriptors are queued back to the Host.

20.1.14.30.2 CDMA Rx Channel N Global Configuration Register (Base Address + 0x0808 + 32*N)

The Rx channel global configuration registers are used to initialize the global (non descriptor type specific) behavior of each of the Rx DMA channels. If the enable bit is being set, the Rx channel global configuration register should only be written after all of the other Rx configuration registers have been initialized.

The CDMA Rx channel N global N configuration register is shown in Figure 20-34 and described in Table 20-40.

Figure 20-34. CDMA Rx Channel N Global Configuration Register

LEGEND: R/W = Read/Write; R = Read only; Write only; -*n* = value after reset

Table 20-40. CDMA Rx Channel N Global Configuration Register Field Descriptions

Bit	Field	Value	Description
31	rx_enable		This field enables or disables the channel.
		0	Channel is disabled
		1	Channel is enabled
			This field is cleared after a channel teardown is complete.
30	rx_teardown		This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field is set after a channel teardown is complete.
29-25	Reserved	0	Always read as 0. Writes have no affect.
24	rx_error_handling		This bit controls the error handling mode for the channel and is only used when channel errors (i.e., descriptor or buffer starvation occurs):
		0	Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to
		1	Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA returns to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added.
			Regardless of the value of this bit, the DMA asserts the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when **??**
23-16	rx_sop_offset		This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 – 255 bytes.

Table 20-40. CDMA Rx Channel N Global Configuration Register Field Descriptions (continued)

Bit	Field	Value	Description
15-14	rx_default_desc_type		This field indicates the default descriptor type to use:
		0	Reserved
		1	Host
		2	Reserved
		3	Reserved
			The actual descriptor type that is used for reception can be overridden by information provided in the CPPI FIFO data block.
13-12	rx_default_rq_qmgr		This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.
11-0	rx_default_rq_qnum		This field indicates the default receive queue that this channel should use. The actual receive queue that is used for reception can be overridden by information provided in the CPPI FIFO data block.

20.1.14.30.3 CDMA Rx Channel N Host Packet Configuration Register A (Base Address + 0x080C + 32*N)

The Rx channel Host packet configuration registers are used to initialize the behavior of each of the Rx DMA channels for reception of Host type packets.

The CDMA Rx channel N Host packet configuration register A is shown in Figure 20-35 and described in Table 20-41.

Figure 20-35. CDMA Rx Channel N Host Packet Configuration Register A

31-30	Reserved	0	Always read as 0. Writes have no affect.
29-28	rx_host_fdq1_qmgr		This field specifies which Buffer Manager should be used for the second Rx buffer in a Host type packet.
27-16	rx_host_fdq1_qnum		This field specifies which Free Descriptor / Buffer Pool should be used for the second Rx buffer in a Host type packet.
15-14	Reserved	0	Always read as 0. Writes have no affect.
13-12	rx_host_fdq0_qmgr		This field specifies which Buffer Manager should be used for the first Rx buffer in a Host type packet.
11-0	rx_host_fdq0_qnum		This field specifies which Free Descriptor / Buffer Pool should be used for the first Rx buffer in a Host type packet.

20.1.14.30.4 CDMA Rx Channel N Host Packet Configuration Register B (Base Address + 0x0810 + 32*N)

The Rx channel Host packet configuration registers are used to initialize the behavior of each of the Rx DMA channels for reception of Host type packets.

The CDMA Rx channel N Host packet configuration register B is shown in Figure 20-36 and described in Table 20-42.

Figure 20-36. CDMA Rx Channel N Host Packet Configuration Register B

Bit	Field	Value	Description
31-30	Reserved	0	Always read as 0. Writes have no affect.
29-28	rx_host_fdq1_qmgr		This field specifies which Buffer Manager should be used for the fourth or later Rx buffers in a Host type packet.
27-16	rx_host_fdq1_qnum		This field specifies which Free Descriptor queue should be used for the fourth or later Rx buffers in a Host type packet.
15-14	Reserved	0	Always read as 0. Writes have no affect.
13-12	rx_host_fdq0_qmgr		This field specifies which Buffer Manager should be used for the third Rx buffer in a Host type packet.
11-0	rx_host_fdq0_qnum		This field specifies which Free Descriptor / Buffer Pool should be used for the third Rx buffer in a Host type packet.

20.1.14.30.5 CDMA Scheduler Control Register (Base Address + 0x0C00)

The revision register contains the major and minor revisions for the module.

The CDMA scheduler control register is shown in Figure 20-37 and described in Table 20-43??.

Figure 20-37. CDMA Scheduler Control Register

31	30	8	7	0
Enable	Reserved		last_entry	
R/W			R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-43. CDMA Scheduler Control Register Field Descriptions

Bit	Field	Value	Description
31	Enable		This is the enable bit for the scheduler and is encoded as follows:
		0	Scheduler is disabled and will no longer fetch entries from the scheduler table or pass credits to the DMA controller
		1	Scheduler is enabled
			This bit should only be set after the table has been initialized.
30-8	Reserved	0	Always read as 0. Writes have no affect.
7-0	last_entry		This field indicates the last valid entry in the scheduler table. There are 64 words in the table and there are 4 entries in each word. The table can be programmed with any integer number of entries from 1 to 256. The corresponding encoding for this field is as follows:
		0	1 entry
		1	2 entries
		…	
		254	255 entries
		255	256 entries

20.1.14.30.6 CDMA Scheduler Table Word N Registers (Base Address + 0x0D00:0DC00 + 4*N)

The Tx channel configuration registers are used to initialize the behavior of each of the Tx DMA channels.

The CDMA scheduler table word N registers are shown in Figure 20-38 and described in Table 20-44.

Figure 20-38. CDMA Scheduler Table Word N Registers

31	30	28	27	24

W			W	

LEGEND: R/W = Read/Write; R = Read only; Write only; -*n* = value after reset

Table 20-44. CDMA Scheduler Table Word N Registers Field Descriptions

Bit	Field	Value	Description
31	entry3_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
30-28	Reserved	0	Always read as 0. Writes have no affect.
27-24	entry3_channel		This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number that is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
23	entry2_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
22-20	Reserved	0	Always read as 0. Writes have no affect.
19-16	entry2_channel		This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
15	entry1_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
14-12	Reserved	0	Always read as 0. Writes have no affect.
11-8	entry1_channel		This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
7	entry0_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel

Table 20-44. CDMA Scheduler Table Word N Registers Field Descriptions (continued)

Bit	Field	Value	Description
6-4	Reserved	0	Always read as 0. Writes have no affect.
3-0	entry0_channel		This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.

20.1.14.31 INTD Revision Register (Base Address + 0x3000)

The revision register contains the ID and revision information.

The INTD revision register is shown in Figure 20-39 and described in Table 20-45.

Figure 20-39. INTD Revision Register

31	30	29	16
scheme		modID	
R		R	

15	11	10	8	7	0
revrtl		revmaj		revmin

Table 20-45. INTD Revision Register Field Descriptions

Bit	Field	Value	Description
31-30	scheme		Always read as 1. Writes have no affect.
29-16	modID		Module ID field.
15-11	revrtl		RTL revision. Will vary depending on release.
10-8	revmaj		Major revision.
7-0	revmin		Minor revision.

20.1.14.32 INTD EOI Register (Base Address + 0x3010)

The EOI register allows the software to perform an end of interrupt handshake to interrupts with an IP that does not have an EOI register. The EOI handshake allows system interrupts to be re-evaluated for the associate logic with the EOI vector value to allow multiple logic paths to re-evaluate individually without separate EOI registers. The EOI occurs the cycle after the register is written.

The INTD EOI register is shown in Figure 20-40 and described in Table 20-46.

Figure 20-40. INTD EOI Register

31	8	7	0
Reserved		eoi_vector	
		R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-46. INTD EOI Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Always read as 0. Writes have no affect.
7-0	eoi_vector		EOI Vector value. This should be written with the value associate to the interrupt and Host combination given in the cp_intd configuration.

20.1.14.33 INTD EOI Interrupt Vector Register (Base Address + 0x3014)

The EOI interrupt vector register captures the active and prioritized interrupts so that software can quickly read the values rather than check every bit in the IP interrupt source register. The exact definition of this register is configuration dependent.

The INTD EOI interrupt vector register is shown in Figure 20-41 and described in Table 20-47.

Figure 20-41. INTD EOI Interrupt Vector Register

31	0
intr_vector

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-47. INTD EOI Interrupt Vector Register

Bit	Field	Value	Description
31-0	intr_vector		EOI interrupt vector value. This has the latest prioritized interrupt values. Dependent on configuration.

20.1.14.34 INTD Status Register 0 (Base Address + 0x3200)

The status register indicates which IP interrupts are active for the Host. There is at least one register per Host for up to 32 interrupts. The exact interrupt mapping is determined by the configuration and then those registers, could be more then 1, are replicated for each Host. The mapping of bits in this register matches that of the enable registers. For level interrupts the status bit is read only and is always determined by the input interrupt level.

The INTD status register 0 is shown in Figure 20-42 and described in Table 20-48.

Figure 20-42. INTD Status Register 0

20.1.14.37 INTD Status Register 3 (Base Address + 0x320C)

The status register indicates which IP interrupts are active for the Host. There is at least one register per Host for up to 32 interrupts. The exact interrupt mapping is determined by the configuration and then those registers, could be more then 1, are replicated for each Host. The mapping of bits in this register matches that of the enable registers. For level interrupts the status bit is read only and is always determined by the input interrupt level.

The INTD status register 3 is shown in Figure 20-45 and described in Table 20-51.

Figure 20-45. INTD Status Register 3

31 16	15 14	13 2	1 0
Reserved	Comp_int	Reserved	Comp_int
	R		R

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-51. INTD Status Register 3 Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Always read as 0. Writes have no effect.
15-14	Comp_int		Completion Interrupts for Queues 66 and 65 Status
		0	Not pending
		1	Pending
13-2	Reserved	0	Always read as 0. Writes have no effect.
1-0	Comp_int		Completion Interrupts for Queues 63 and 64 Status
		0	Not pending
		1	Pending

20.1.14.38 INTD Status Clear Register 0 (Base Address + 0x280)

The status clear register allows software to clear the pending status. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts. There is at least one register per Host for up to 32 interrupts. The mapping of bits in this register matches that of the enable registers.

The INTD status clear register 0 is shown in Figure 20-46 and described in Table 20-52.

Figure 20-46. INTD Status Clear Register 0

31	2	1	0
Reserved		status_clr	status_clr
		W	W

LEGEND: R/W = Read/Write; R = Read only; Write only; -*n* = value after reset

Table 20-52. INTD Status Clear Register 0 Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no affect.
1	status_clr		RX MOP Descriptor interrupt status.
		0	Not pending
		1	Pending
			Write a 1 in a bit position to clear that bit. Writing a 0 has no effect.
0	status_clr		RX SOP Descriptor Starve interrupt status.
		0	Not pending
		1	Pending
			Write a 1 in a bit position to clear that bit. Writing a 0 has no effect.

20.1.14.39 Queue Manager Revision Register (0x4000)

The revision register contains the major and minor revisions for the module. It does not support byte accesses.

The queue manager revision register is shown in Figure 20-47 and described in Table 20-53.

Figure 20-47. Queue Manager Revision Register

15-11	revrtl		RTL revision
10-8	revmaj		Major revision
7-6	revcustom		Custom revision
5-0	revmin		Minor revision

20.1.14.40 Queue Manager Queue Diversion Register (0x4008)

The queue diversion register is used to transfer the contents of one queue onto another queue. It does not support byte accesses.

The queue manager queue diversion register is shown in Figure 20-48 and described in Table 20-54.

Figure 20-48. Queue Manager Queue Diversion Register

Table 20-54. Queue Manager Queue Diversion Register Field Descriptions

Bit	Field	Value	Description
31	head_tail		head_tail indicates whether the queue contents should be merged onto the head or the tail of the destination queue. Clear this field for head and set for tail.
30	Reserved	0	Always read as 0. Writes have no effect.
29-16	dest_qnum		Destination Queue Number
15-14	Reserved	0	Always read as 0. Writes have no effect.
13-0	source_qnum		Source Queue Number

20.1.14.41 Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (0x4020)

The free descriptor/buffer queue starvation count register provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses.

The queue manager free descriptor/buffer starvation count register is shown in Figure 20-49 and described in Table 20-55.

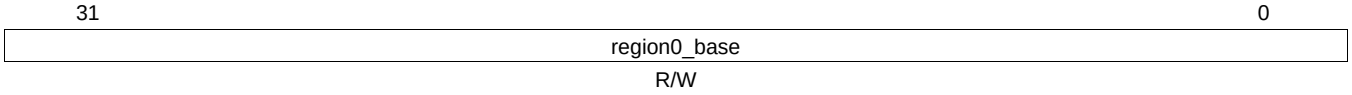
20.1.14.49 Queue Manager Linking RAM Region 0 Base Address Register (0x4080)

The linking RAM region 0 base address register is used to set the base address for the first portion of the linking RAM. This address must be 32-bit aligned. It is used by the queue manager to calculate the 32-bit linking address for a given descriptor index. It does not support byte accesses.

The queue manager linking RAM region 0 base address register is shown in Figure 20-57 and described in Table 20-63.

Figure 20-57. Queue Manager Linking RAM Region 0 Base Address Register



LEGEND: R/W = Read/Write; R = Read only; Write only; -*n* = value after reset

Table 20-63. Queue Manager Linking RAM Region 0 Base Address Register Field Descriptions

Bit	Field	Value	Description
31-0	region0_base		This field stores the base address for the first region of the linking RAM. This can be anywhere in 32-bit address space but would be typically located in on-chip memory.

20.1.14.50 Queue Manager Linking RAM Region 0 Size Register (0x4084)

The linking RAM region 0 size register is used to set the size of the array of linking pointers that are located in region 0 of linking RAM. The size specified the number of descriptors for which linking information is stored in this region. It does not support byte accesses.

The queue manager linking RAM region 0 size register is shown in Figure 20-58 and described in Table 20-64.

Figure 20-58. Queue Manager Linking RAM Region 0 Size Register

15	14	13	0
Reserved		region0_size	
		R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-64. Queue Manager Linking RAM Region 0 Size Register Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Always read as 0. Writes have no effect.
13-0			This field indicates the number of entries that are contained in the linking RAM region 0. A descriptor with index less than region0_size value has its linking location in region 0. A descriptor with index greater than region0_size has its linking location in region 1. The queue manager adds the index (left shifted by 2 bits) to the appropriate regionX_base_addr to get the absolute 32-bit address to the linking location for a descriptor.

20.1.14.51 Queue Manager Linking RAM Region 1 Base Address Register (0x4088)

The linking RAM region 1 base address register is used to set the base address for the second portion of the linking RAM. This base address is used by the queue manager to calculate the 32-bit linking address from the descriptor index. All descriptors with index higher than that given in linking RAM 0 size register have linking information stored in linking RAM region 1. It does not support byte accesses.

The queue manager linking RAM region 1 base address register is shown in Figure 20-59 and described in Table 20-65.

Figure 20-59. Queue Manager Linking RAM Region 1 Base Address Register

Table 20-70. Queue Manager Memory Region R Control Register Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Always read as 0. Writes have no effect.
29-16	start_index		This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
15-12	Reserved	0	Always read as 0. Writes have no effect.
11-8	desc_size		This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as 2^(5+desc_size) number of bytes. The settings of desc_size from 9-15 are reserved.
7-3	Reserved	0	Always read as 0. Writes have no effect.
2-0	reg_size		This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as 2^(5+reg_size) number of descriptors.

The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet add or a single burst read for each packet pop operation. The length of a burst to add or pop a packet varies depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N register D must always be written/read in the burst but the preceding words are optional depending on the required queue functionality.

20.1.14.57 Queue Manager Queue N Register A (0x6000 + 16xN)

The queue N register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N register is shown in Figure 20-65 and described in Table 20-71.

Figure 20-65. Queue Manager Queue N Register A

31	14	13	0
Reserved		queue_entry_count	
		R	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-71. Queue Manager Queue N Register A Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	Always read as 0. Writes have no effect.
13-0	queue_entry_count		This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

20.1.14.58 Queue Manager Queue N Register B (0x6000 + 16xN + 4)

The queue N register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. This register must be read prior to reading queue N register D during packet pop operation if the total size information is desired. It does not support byte accesses.

The queue manager queue N register B is shown in Figure 20-66 and described in Table 20-72.

Figure 20-66. Queue Manager Queue N Register B

31 28	27 0
Reserved	queue_byte_count
	R

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-72. Queue Manager Queue N Register B Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Always read as 0. Writes have no effect.
27-0	queue_byte_count		This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue.

20.1.14.59 Queue Manager Queue N Register C (0x6000 + 16xN + 8)

The queue N register C is used to provide additional information about the packet that is being pushed or popped from the queue. This register provides an option for the packet to be pushed onto either the tail of the queue (default) or the head of the queue (override). This register must be written prior to writing the queue N register D during packet write operations. This register must be read prior to reading queue N register D during pop operations if the packet size information is desired. It does not support byte accesses.

The queue manager queue N register c is shown in Figure 20-67 and described in Table 20-73.

Figure 20-67. Queue Manager Queue N Register C

31	30 14	13 0
head_tail	Reserved	packet_size
W		R/W

LEGEND: R/W = Read/Write; R = Read only; Write only; -*n* = value after reset

Table 20-73. Queue Manager Queue N Register C Field Descriptions

Bit	Field	Value	Description
31	head_tail		Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue.
30-14	Reserved	0	Always read as 0. Writes have no effect.
13-0	packet_size		This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation.

20.1.14.60 Queue Manager Queue N Register D (0x6000 + 16xN + C)

The queue N register D is written to add a packet to the queue and read to pop a packets off a queue. The packet is only pushed or popped to/from the queue when the queue register D is written. It does not support byte accesses.

The queue manager queue N register D is shown in Figure 20-68 and described in Table 20-74.

Figure 20-68. Queue Manager Queue N Register D

31	5	4	0
desc_ptr		desc_size	
		R/W	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-74. Queue Manager Queue N Register D Field Descriptions

Bit	Field	Value	Description
31-5	desc_ptr	0	Descriptor pointer. It is read as zero if the queue is empty. It indicates a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	desc_size		Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field returns a 0x0 when an empty queue is read.

20.1.14.61 Queue Manager Queue N Status Register A (0x6800 + 16xN)

The queue N status register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N status register A is shown in Figure 20-69 and described in Table 20-75.

Figure 20-69. Queue Manager Queue N Status Register A

31	14	13	0
Reserved		queue_entry_count	
		R	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Bit	Field	Value	Description
31-14	Reserved	0	Always read as 0. Writes have no effect.
13-0	queue_entry_count		This field indicates how many packets are currently queued on the queue.

20.1.14.62 Queue Manager Queue N Status Register B (0x6800 + 16xN + 4)

The queue N status register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N status register B is shown in Figure 20-70 and described in Table 20-76.

Figure 20-70. Queue Manager Queue N Status Register B

31 28	27 0
Reserved	queue_byte_count
	R

13-0	packet_size		This field indicates packet size of the head element of a queue.

20.2 High-Speed USB Host Subsystem

20.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

Each of the three external ports is owned by exactly one of the controllers at any time.

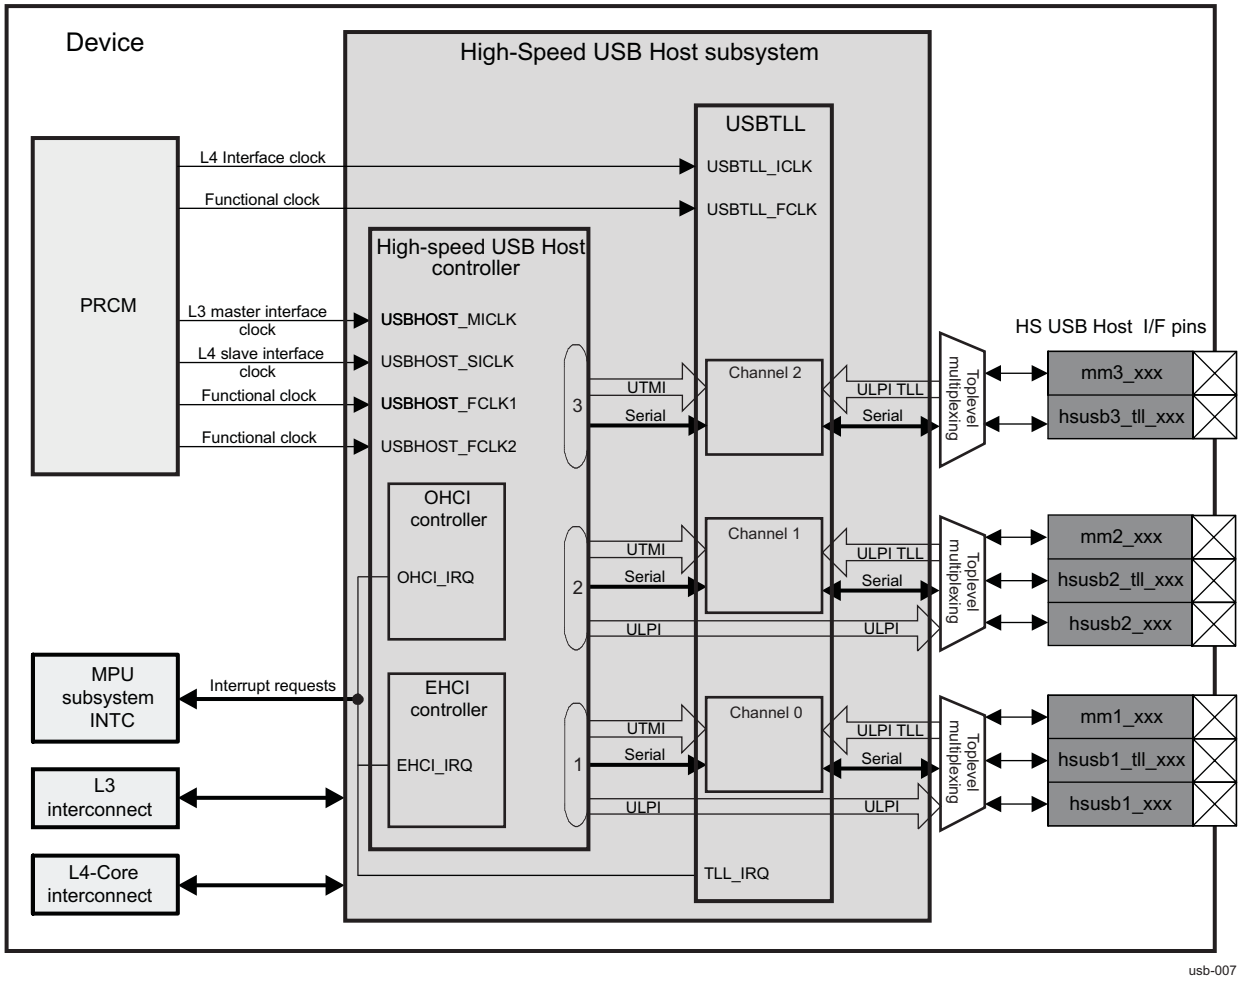
NOTE: If one port is configured as a high-speed ULPI transceiver interface, then all other ports must be likewise configured.

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

Figure 20-72 highlights the high-speed USB host subsystem.

Figure 20-72. High-Speed USB Host Subsystem Highlight



20.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- Multiport high-speed USB host controller:
  - Complies with the USB 2.0 standard for high-speed (480M bit/s) functions
  - USB 2.0 low-speed (1.5M bit/s) and full-speed (12M bit/s) over serial interface
  - High-speed (480M bit/s) operations over ULPI
  - Three downstream ports (3-port root hub)
  - Complies with EHCI (high-speed host controller)
  - Complies with OHCI (low-speed/full-speed host controller)
  - Supports suspend/resume and remote wakeup
  - Interface with ULPI PHYs (transceivers) on two ports
    - 12-pin/8-bit data single data rate (SDR) mode
    - 60-MHZ clock, generated by the host: ULPI "input" clocking mode

CAUTION

The HS USB host subsystem only supports PHYs that can accept a 60 MHZ input clock.

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

  - Hardware-driven save-and-restore of the suspended host hardware context
  - Two interrupt lines
- USBTLL module
  - Three channels
  - Three ports (A, C, and D) by channel
  - Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI “local” port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, “remote” ports).
    - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
    - 8-data-bit, 60-MHZ UTMI (HS/FS/LS-capable)
    - UTMI+ Level 3 extensions
    - Vcontrol/Vstatus (from UTMI)
    - Serial FS/LS “6-pin” mode
  - Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
    - SDR and dual data rate (DDR) ULPI capable (8/4-bit data width modes)
    - Supports optional 6-pin/3-pin serial modes
    - Supports optional input clocking mode
  - Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
    - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
    - All modes are supported for TLL or PHY interface configuration.
    - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
  - An interrupt line
  - OCP target slave interface (L4) for configuration
- USB port signal pins interface supporting:
  - External USB transceivers
    - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
    - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
  - TLL mode
    - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
    - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Table 20-78. USB Connectivity Modes

USB Connectivity Modes	Port 1	Port 2	Port 3
ULPI interface	√	√	
Serial 6-pin transceiver interfaces	√	√	√
ULPI TLL interfaces	√	√	√
Serial 6-pin TLL interfaces	√	√	√

NOTE: If either port 1 or port 2 is configured as a ULPI interface, then both ports must be configured as a ULPI interface.

Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

20.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

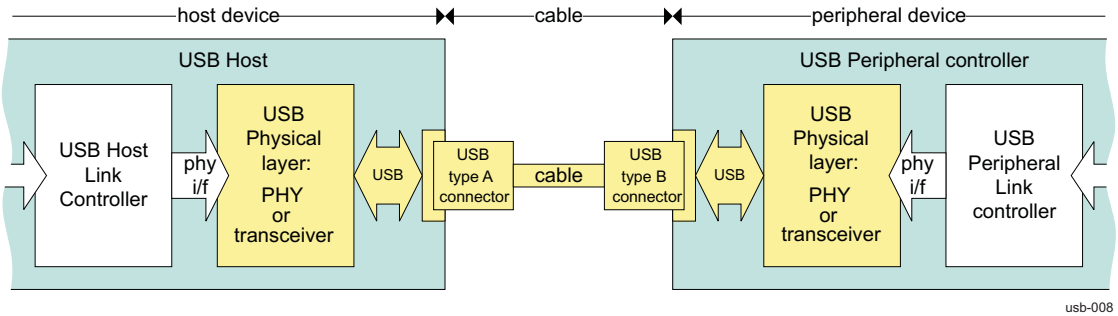
The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
  - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
  - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

20.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in Figure 20-73.

Figure 20-73. USB Connection



The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

20.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed from the system:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

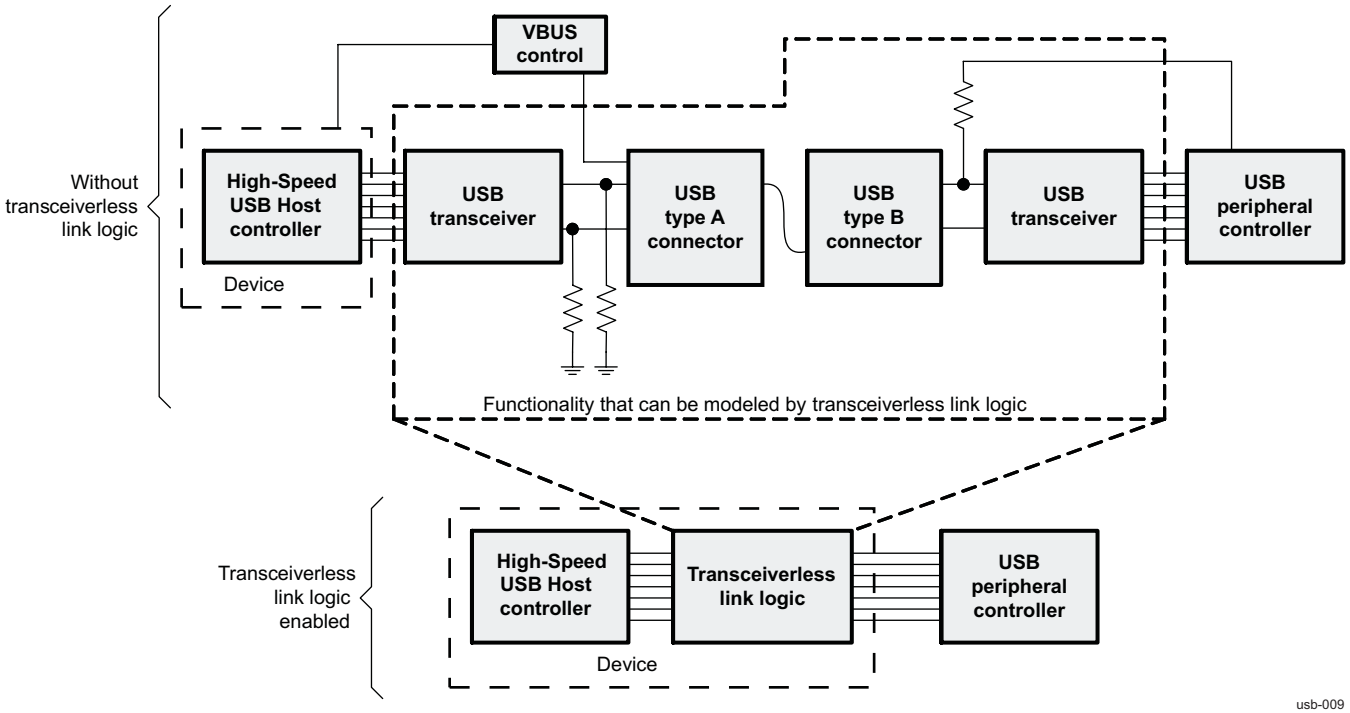
The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 20-74 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 20-74 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

Figure 20-74. High-Speed USB Host Controller Connection—With and Without TLL



NOTE: The USB bus lines (D+/D–) no longer appear in subsequent figures: They are emulated by the TLL.

20.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

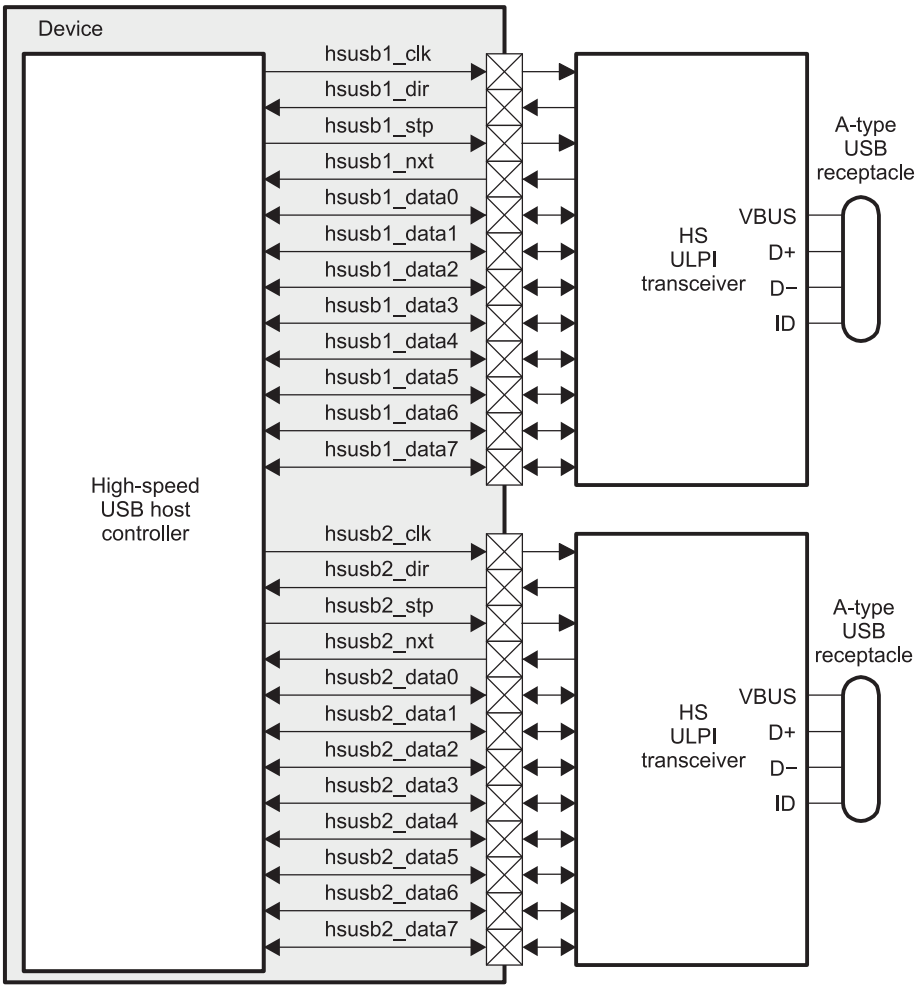
- External USB transceiver
  - ULPI interfaces: 12-pin/8-bit data SDR version supporting "input" clocking mode
- TLL
  - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

Figure 20-75 and Figure 20-76 show typical applications using the high-speed USB host subsystem with the ULPI and with the ULPI TLL, respectively.

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. An A-type external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

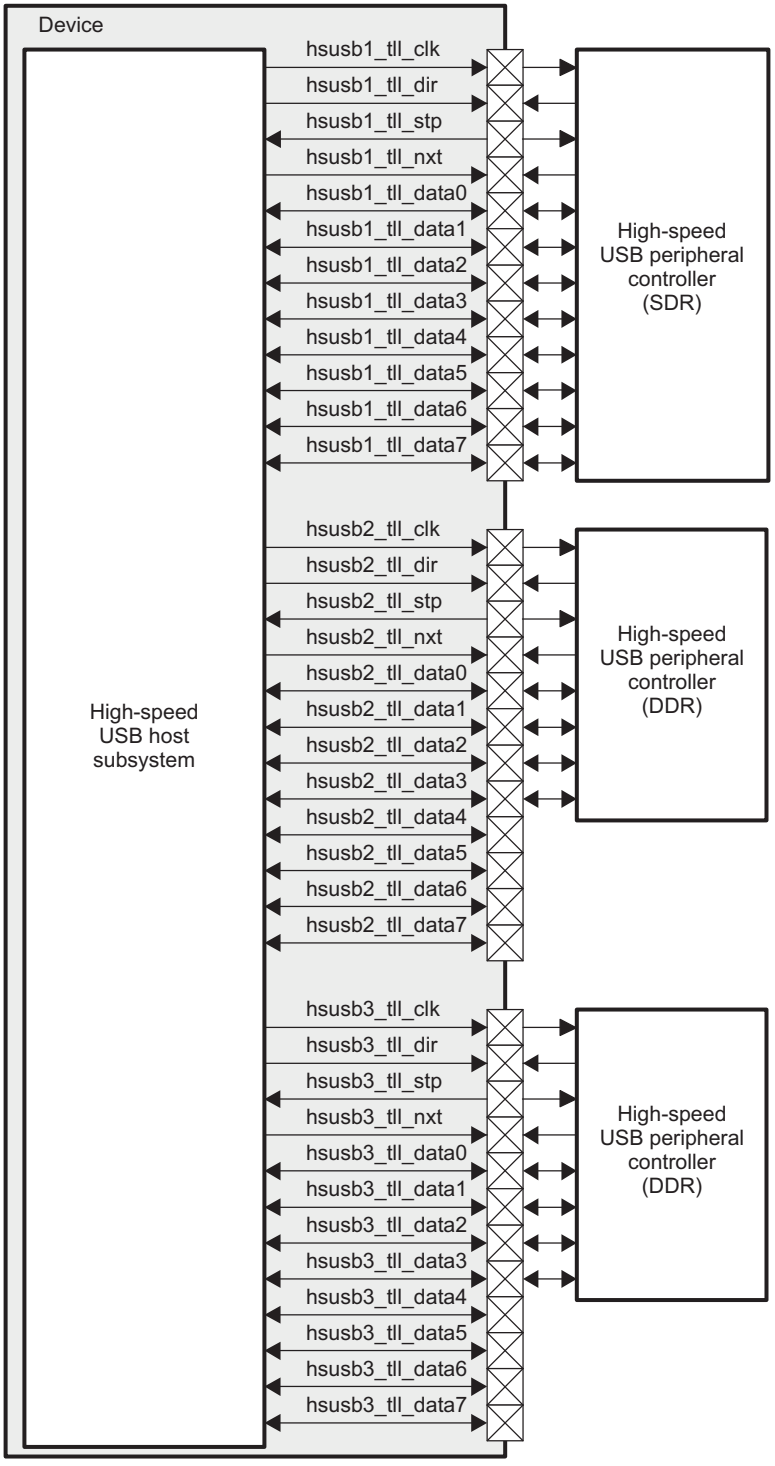
Figure 20-75. High-Speed USB Host Controller Typical Application System – ULPI Interfaces



ULPI Interfaces - USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers

usb–010

Figure 20-76. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces



ULPI TLL Interfaces -The high-speed USB host controller is coupled with the USBTLL module to compose the ULPITLL interface modes usb−032

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

20.2.2.3.1 Transceiver Interface Configurations

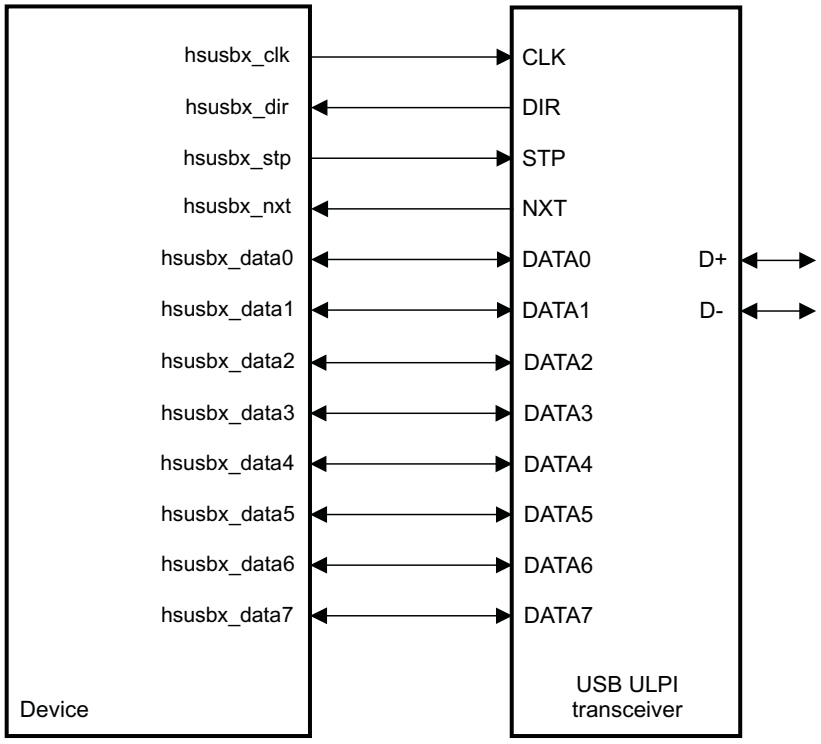
The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

NOTE: In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

The ULPI transceiver must support "input" clocking mode, that is, it must accept a 60 MHZ input clock.

Figure 20-77 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

Figure 20-77. ULPI Interfaces – 12-Pin/8-Bit Data SDR Version



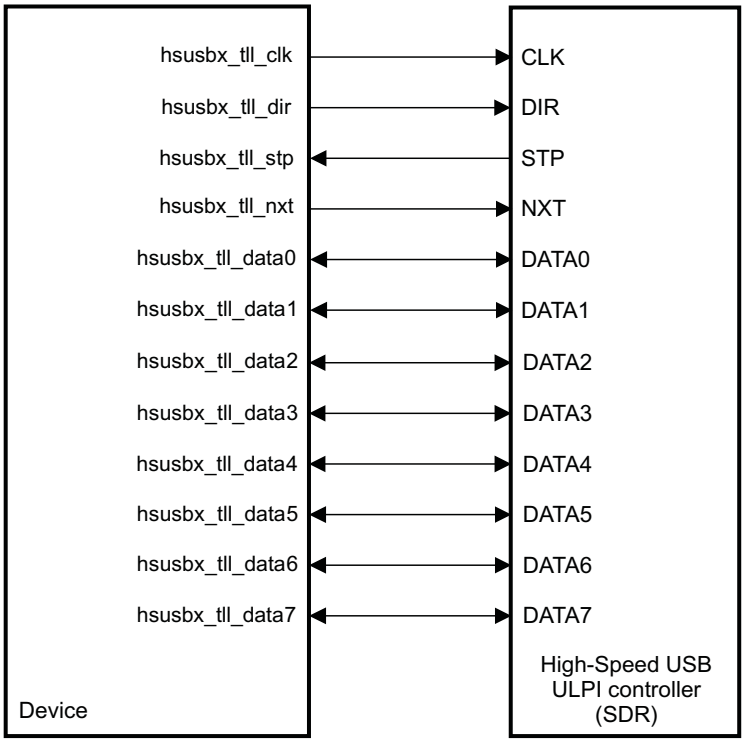
20.2.2.3.2 TLL Configurations

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host subsystem supports the 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions of the ULPI TLL interface mode.

Figure 20-78 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Figure 20-78. ULPI TLL Interfaces –12-Pin/8-Bit Data SDR Version



x is the USB port number (1, 2 or 3)

Figure 20-79 shows USB ports using the 8-pin/4-bit data DDR version of the ULPI TLL interface mode.

(3) This output signal is also used as re-timing input.

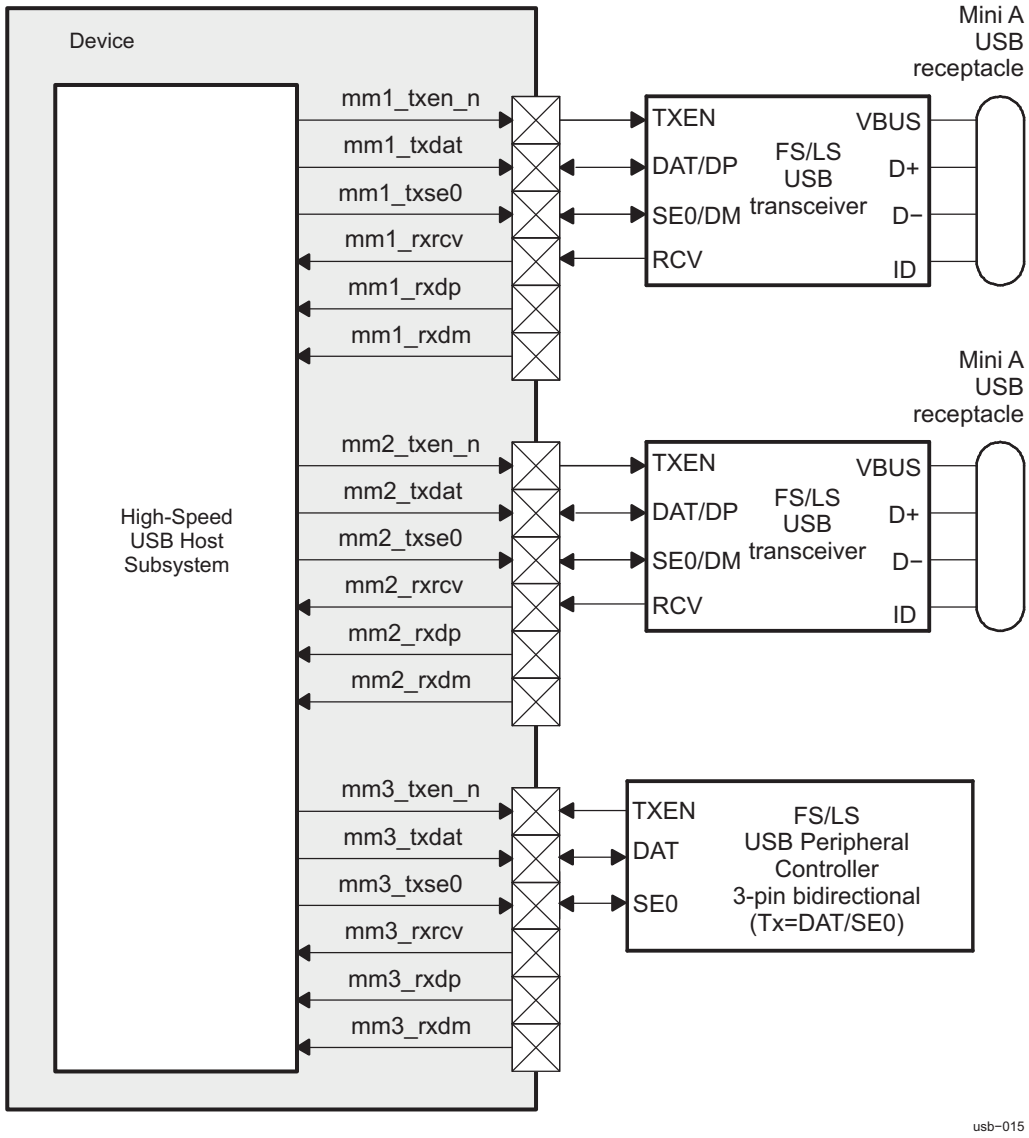
20.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 20-81 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

Figure 20-81. High-Speed USB Host Subsystem Typical Application System



The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

CAUTION

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

20.2.2.4.1 Encoding in Serial Mode

20.2.2.4.1.1 Unidirectional

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in Table 20-80 is used.

Table 20-80. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
			1	X	X	Undriven	Undriven
RCV	Input	Output	Output from transceiver differential receiver				
			D+	D-	RCV		
			0	0	X		
			0	1	0		
			1	0	1		
			1	1	X		
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+	DP			
			0	0			
			1	1			
DM	Input	Output	Output from transceiver single-ended D- signal receiver				
			D-	DM			
			0	0			
			1	1			

When a USB transceiver is connected to the device and used in 6-pin unidirectional DP/DM encoding mode, the encoding described in Table 20-81 is used.

Table 20-81. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
			1	X	X	Undriven	Undriven

Table 20-81. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling) (continued)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X
DP	Input	Output	Output from transceiver single-ended D+ signal receiver		
			D+	DP	
			0	0	
			1	1	
DM	Input	Output	Output from transceiver single-ended D- signal receiver		
			D-	DM	
			0	0	
			1	1	

20.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in Table 20-82 is used.

Table 20-82. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.				
	Output	Input	TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
	Input	Output	TXEN	D+	D-	DAT	SE0
			1	0	0	0	1
				0	1	0	0
				1	0	1	0
				1	1	Undefined	Undefined

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in Table 20-83 is used.

Table 20-83. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
TXEN	Output	Input	When low, USB transceiver drives D+ and D-.		
DM			Value driven to or received from D-		
	Output	Input	TXEN	DM	D-
			0	0	0
			0	1	1
	Input	Output	TXEN	D-	DM
			1	0	0
			1	1	1
DP			Value driven to or received from D+		
	Output	Input	TXEN	DP	D+
			0	0	0
			0	1	1
	Input	Output	TXEN	D+	DP
			1	0	0
			1	1	1
RCV	Input	Output	Output from transceiver single-ended D- signal receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

20.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D– pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I2C, UART, etc.)

Figure 20-82 and Figure 20-83 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 20-82 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in Section 20.2.4.2.4.1.1.

Figure 20-82. Serial Interface Sideband Integration - Transceiver Configuration

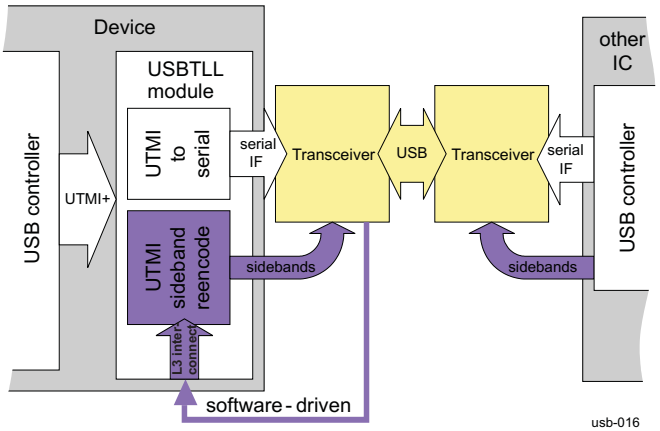


Figure 20-83 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

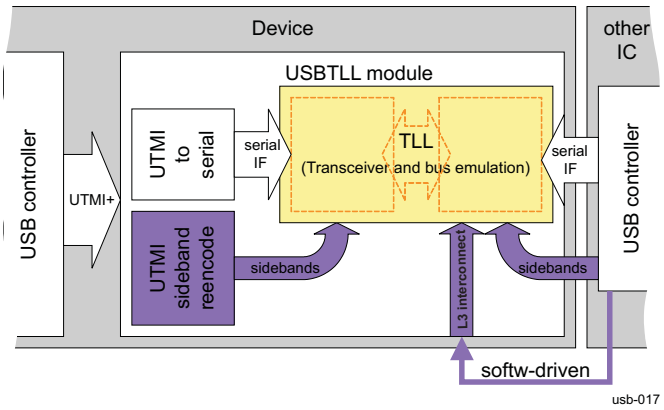
- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
  - Sideband input signals at the TLL module boundary (tllpuen, tlldrvvbus, tllvbusvalid, etc.)
  - The software-driven VBUS control procedure is described in Section 20.2.4.2.4.2.2

Figure 20-83. Serial Interface Sideband Integration - TLL Configuration



20.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I^2C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

20.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

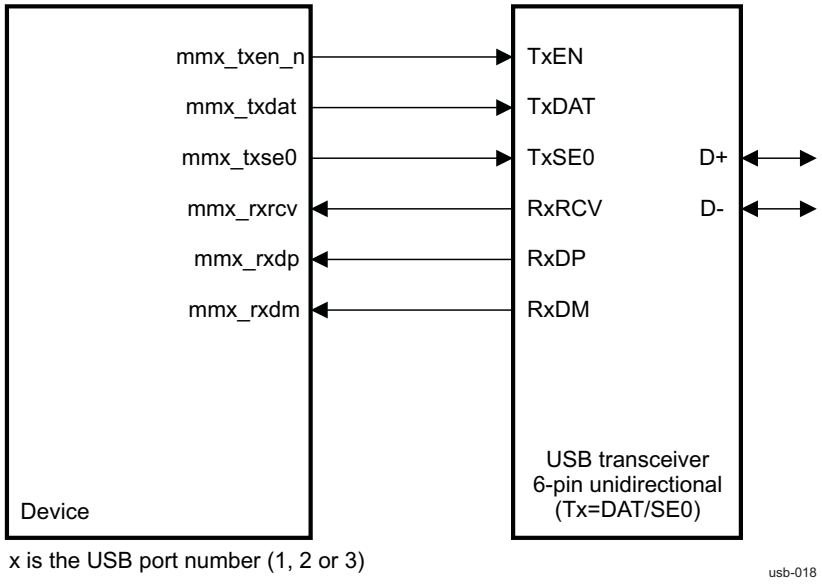
The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in Table 20-80 is used.

Figure 20-84 shows a USB port using DAT/SE0 encoding.

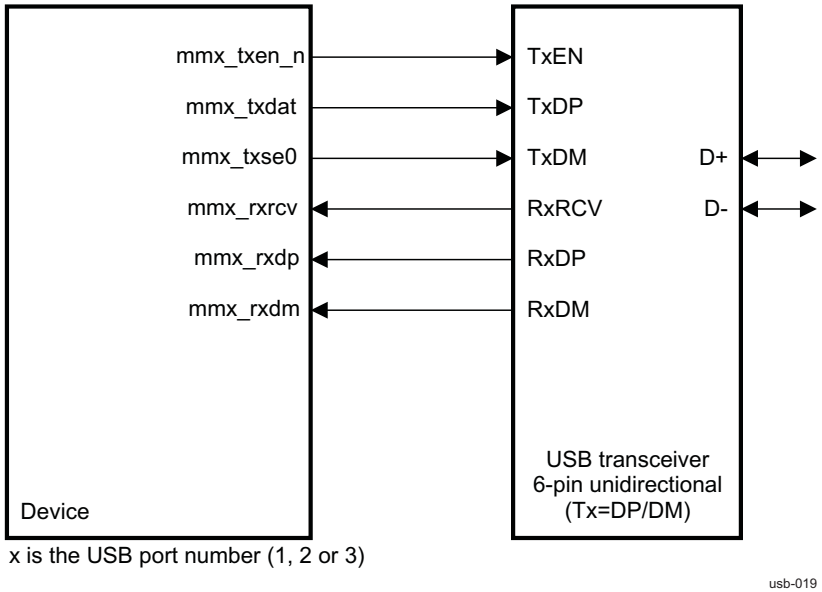
Figure 20-84. 6-Pin Unidirectional Using DAT/SE0 Signaling



When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in Table 20-81 is used.

Figure 20-85 shows a USB port using DP/DM encoding.

Figure 20-85. 6-Pin Unidirectional Using DP/DM Signaling



20.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

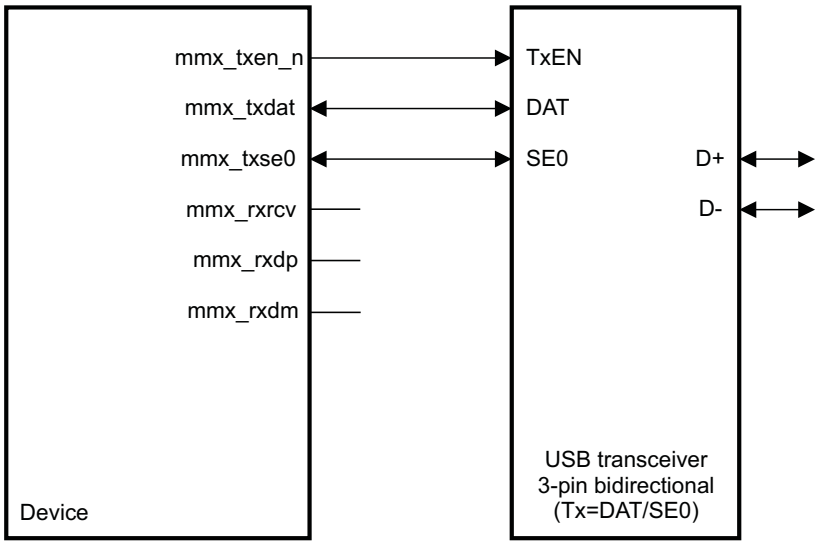
The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in Table 20-82 is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

Figure 20-86 shows a USB port using DAT/SE0 encoding.

Figure 20-86. 3-Pin Bidirectional Using DAT/SE0 Signaling

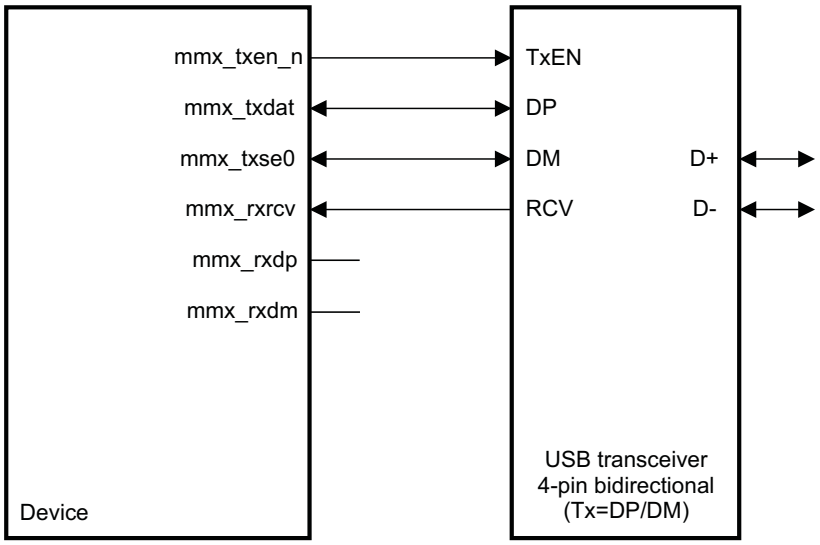


The signaling listed in Table 20-83 is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 20-87 shows a USB port using DP/DM encoding.

Figure 20-87. 4-Pin Bidirectional Using DP/DM Signaling



20.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

20.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 20-88 shows an external device using DAT/SE0 encoding.

Figure 20-88. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

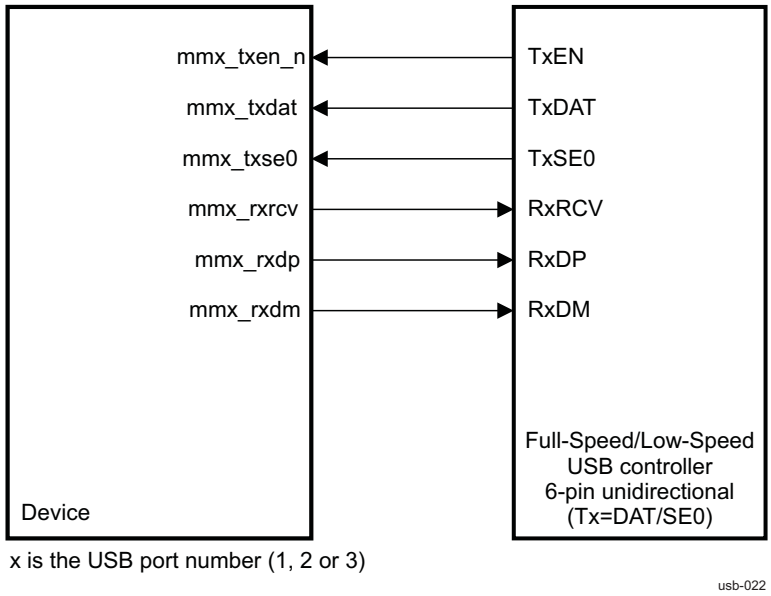


Figure 20-89 shows an external device using DP/DM encoding.

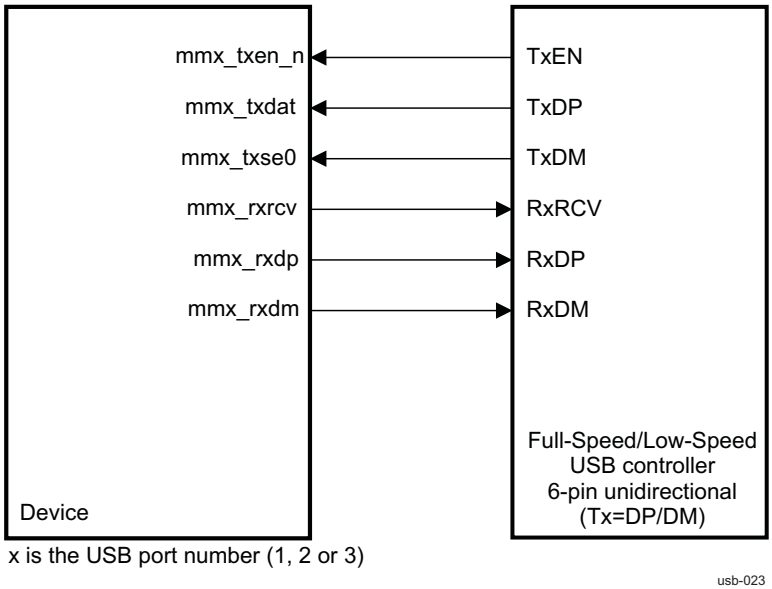
Figure 20-89. 6-Pin Unidirectional TLL Using DP/DM Signaling



20.2.2.4.4.2 Bidirectional TLL Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 20-90 shows an external device using DAT/SE0 encoding.

Figure 20-90. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

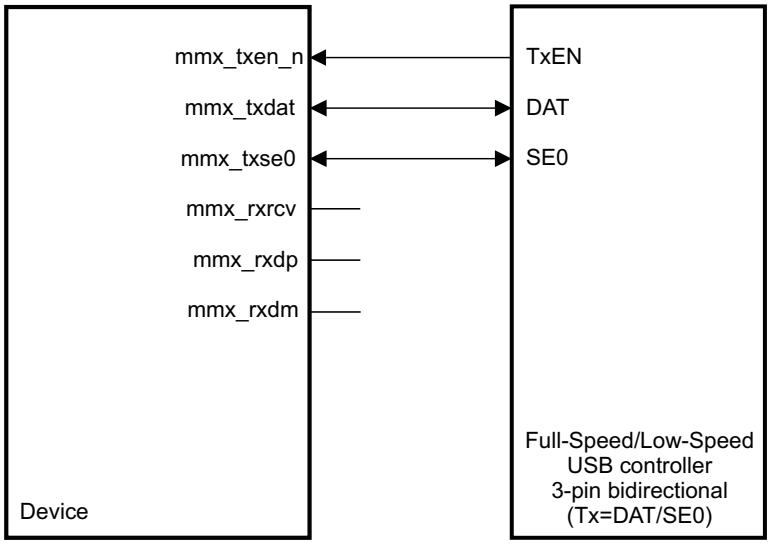


Figure 20-91 shows an external device using DP/DM encoding.

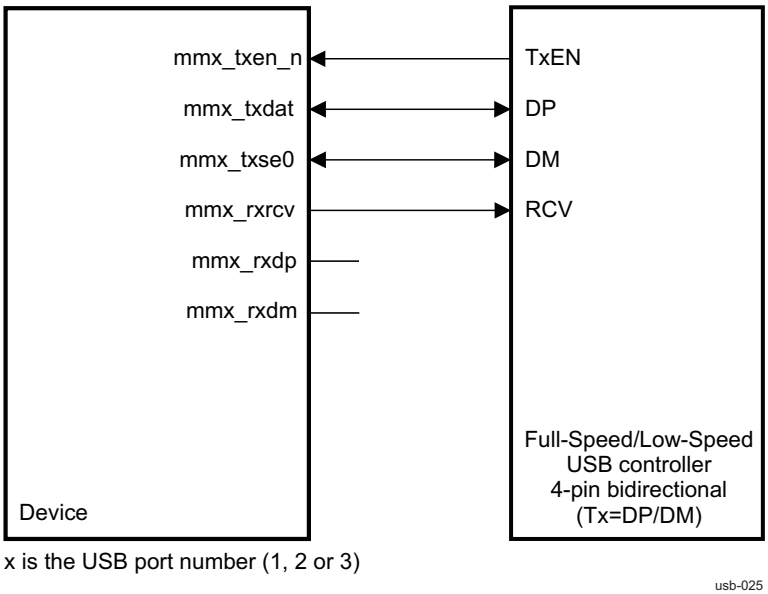
Figure 20-91. 4-Pin Bidirectional TLL Using DP/DM Signaling



The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 20-92 shows USB port using DP/DM encoding.

Figure 20-92. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

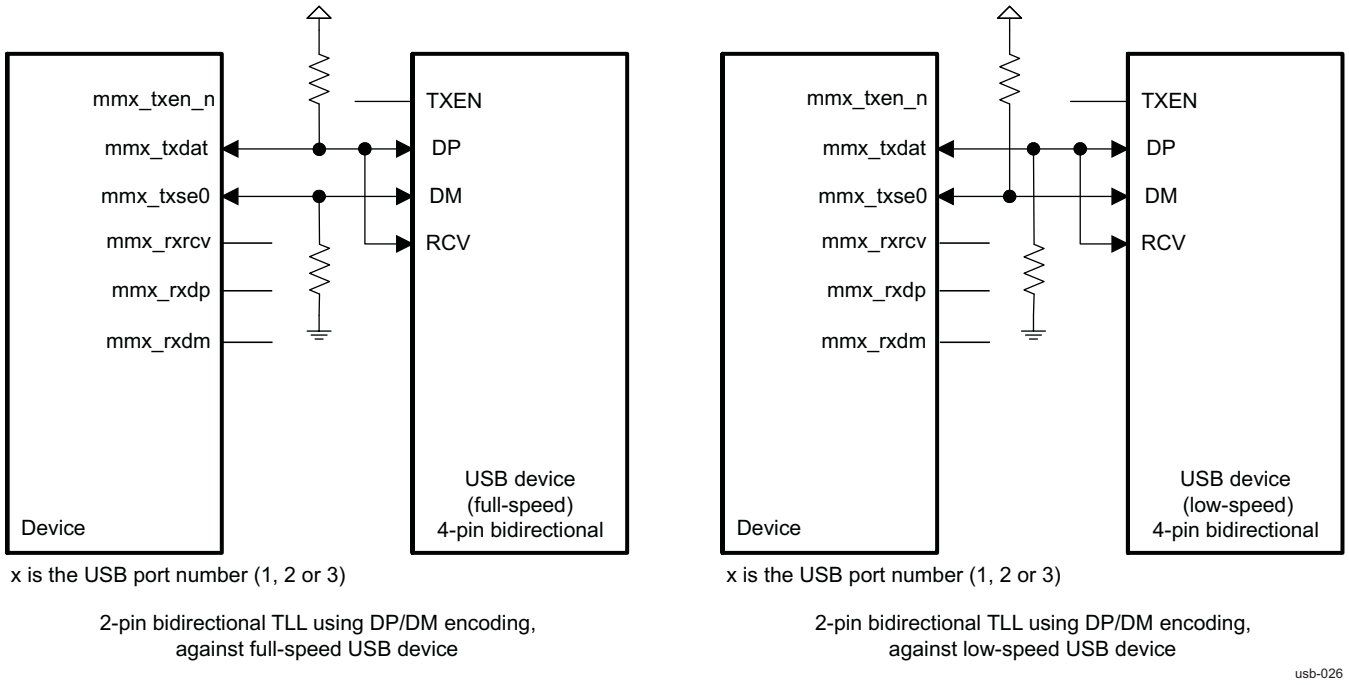


Table 20-84 shows the pullup/pulldown configuration for DP/DM encoding.

Table 20-84. Pullup/Pulldown Configuration for DP/DM Encoding

	Nonconnected Device (Any Speed)	Connected Low-Speed Device	Connected Full-Speed Device
DP	Pulldown	Pulldown	Pullup
DM	Pulldown	Pullup	Pulldown

Figure 20-93 shows a USB port using DAT/SE0 encoding.

Figure 20-93. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device

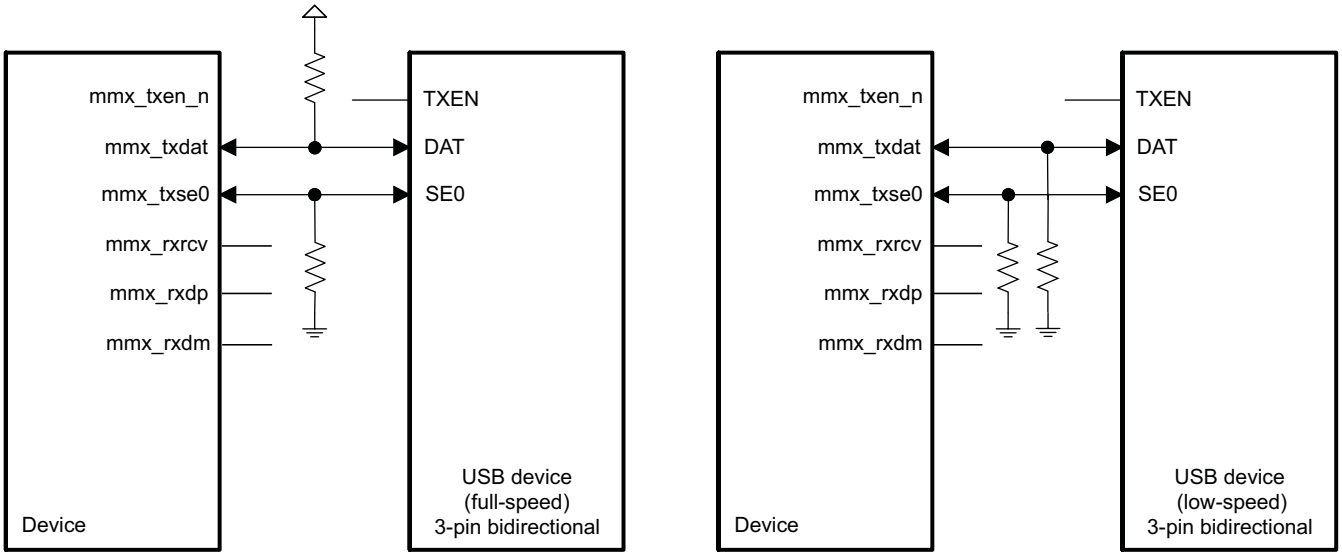

Table 20-85 shows pullup/pulldown configuration for DAT/SE0 encoding.

Table 20-85. Pullup/Pulldown Configuration for DAT/SE0 Encoding

	Nonconnected Device (Any Speed)	Connected Low-Speed Device	Connected Full-Speed Device
DAT	Pulldown	Pulldown	Pullup
SEO	Pullup	Pulldown	Pulldown

20.2.2.4.5 High-Speed USB Host Subsystem Interface Description

Table 20-86 describes the I/O of the high-speed USB host subsystem serial interfaces.

Table 20-86. I/O Description

Signal Name	I/O[1]	Description	Value at Reset
Multiple-Mode FS/LS Serial Interface: Port 1			
mm1_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode	
	I/O	SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DM-TLL input in 6-pin unidirectional DP/DM TLL mode	

(1) I = Input, O = Output

Table 20-86. I/O Description (continued)

Signal Name	I/O[1]	Description	Value at Reset
mm1_txdat	I/O	DAT function in 3-pin bidirectional DAT/SE0 mode	Unknown
	I/O	DP function in 4-pin bidirectional DP/DM mode	
	O	DAT output in 6-pin unidirectional DAT/SE0 mode	
	O	DP output in 6-pin unidirectional DAT/SE0 mode	
	I/O	DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DP-TLL in2-/4-pin bidirectional DP/DM TLL mode	
	I	DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DP-TLL input in 6-pin unidirectional DP/DM TLL mode

mm3_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional modes (not used in the 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes)	Unknown
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in the 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	

20.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

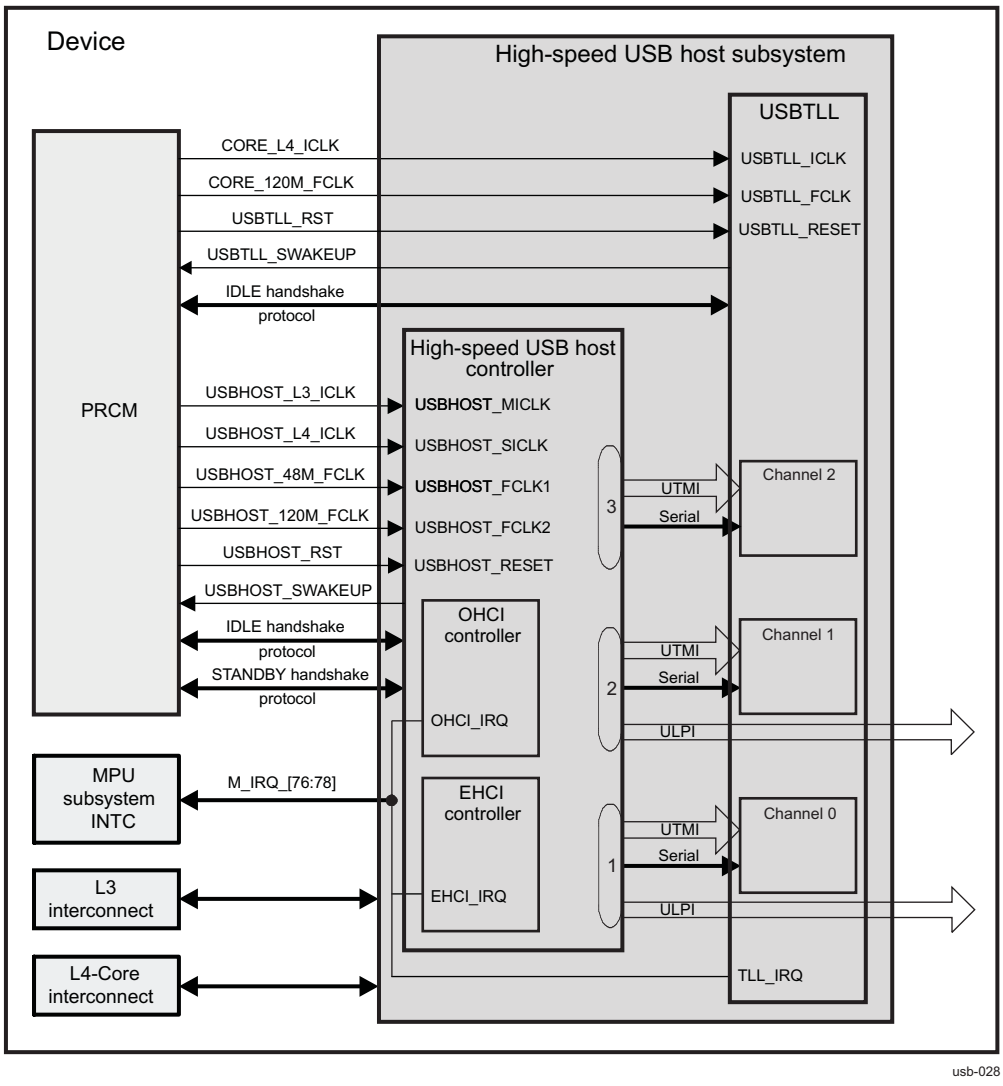
The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M_IRQ_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

Figure 20-94 highlights the high-speed USB host subsystem integration in the device.

Figure 20-94. High-Speed USB Subsystem Integration



20.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST_RST signal, see the *Power, Reset, and Clock Management* chapter.

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL_RST signal, see the *Power, Reset, and Clock Management* chapter.

20.2.3.1.1 High-Speed USB Host Subsystem Resets

Table 20-87 lists and describes all the high-speed USB host subsystem resets:

Table 20-87. High-Speed USB Host Subsystem Reset Description

Type	Name	Source	Polarity	Description
Software	USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit	High-speed USB host controller internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Software	USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit	USBTLL module internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Hardware	USBHOST_RESET	PRCM USBHOST_RST signal	Active low	The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see the *Power, Reset, and Clock Management* chapter).
Hardware	USBTLL_RESET	PRCM USBTLL_RST signal	Active low	The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see the *Power, Reset, and Clock Management* chapter).

20.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: the USBHOST_RST signal resets the module. The USBTLL module is attached to the CORE power domain: the USBTLL_RST signal resets asynchronously the module (see the *Power, Reset, and Clock Management* chapter). The hardware reset signal has a global reset action on the modules.

20.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the high-speed USB host controller, and through the USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

20.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI and EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_48M_FCLK output clock. USBHOST_FCLK1 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit (0: disabled; 1: enabled).
- USBHOST_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_120M_FCLK output clock. USBHOST_FCLK2 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit (0: disabled; 1: enabled).
- USBHOST_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the interconnect are synchronous to USBHOST_MICLK. Its source is the PRCM USBHOST_L3_ICLK output clock. USBHOST_MICLK is controlled by the PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit (enables/disables automatic control of the interface clock).
- USBHOST_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST_SICLK. Its source is the PRCM USBHOST_L4_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE_120M_FCLK output clock. UBTLL_FCLK is controlled by the PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled).
- USBTLL_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL_ICLK. Its source is the PRCM CORE_L4_ICLK output clock. USBTLL_ICLK is controlled by the PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit (enables/disables automatic control of the interface clock).

Table 20-88 summarizes the high-speed USB host subsystem clocks.

Table 20-88. High-Speed USB Host Subsystem Clocks

Attributes	Frequency	Name	Module	Mapping	Comments
Functional clock	48 MHZ	USBHOST_ FCLK1	High-speed USB Host controller	USBHOST_48M_FCLK	Source is PRCM module
Functional clock	120 MHZ	USBHOST_ FCLK2	High-speed USB Host controller	USBHOST_ 120M_FCLK	Source is PRCM module
L3 master interface clock	Depending on PRCM register settings	USBHOST_ MICLK	High-speed USB Host controller	USBHOST_L3_ICLK	Source is PRCM module
L4 slave interface clock	Depending on PRCM register settings	USBHOST_ SICLK	High-speed USB Host controller	USBHOST_L4_ICLK	Source is PRCM module
Functional clock	120 MHZ	USBTLL_FCLK	USBTLL	CORE_120M_FCLK	Source is PRCM module
L4 interface clock	Depending on PRCM register settings	USBTLL_ICLK	USBTLL	CORE_L4_ICLK	Source is PRCM module

20.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST_L3_ICLK) is used only by the high-speed USB host controller (USBHOST_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN_USBHOST[0] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE_USBHOST[0] (enables/disables automatic control of the interface clock)—see Table 20-89.

Table 20-89. High-Speed USB Controller L3 Master Interface Clock

PRCM.CM_AUTOIDLE_USBHOST[0]	PRCM.CM_ICLKEN_USBHOST[0]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

CAUTION

The L3 master interface clock shall not be less than 30 MHZ, ULPI clock divided by 2 (this can occur during DPLL3 relocking).

20.2.3.1.2.2 L4 Slave Interface Clock

The L4 slave interface clock (USBHOST_L4_ICLK) is used only by the high-speed USB host controller (USBHOST_SICLK) in the subsystem, and comes from the PRCM module.

20.2.3.1.2.3 L4 Interface Clock

The L4 interface clock (CORE_L4_ICLK) is used only by the USBTLL module (USBTLL_ICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN3_CORE[2] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE3_CORE[2] (enables/disables automatic control of the interface clock)—see Table 20-90.

Table 20-90. USBTLL Module Interface Clock

PRCM.CM_AUTOIDLE3_CORE[2]	PRCM.CM_ICLKEN3_CORE[2]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

20.2.3.1.2.4 Functional Clocks

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST_FLCK1 running at 48 MHZ (USBHOST_48M_FCLK) and USBHOST_FLCK2 running at 120 MHZ (USBHOST_120M_FCLK).

The USBHOST_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[0] (0 = disabled, 1 = enabled).

The USBHOST_FLCK2 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[1] (0 = disabled, 1 = enabled).

The CORE_120M_FCLK functional clock is used only by the USBTLL module (USBTLL_FCLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bit PRCM.CM_FCLKEN3_CORE[2] (0 = disabled, 1 = enabled).

20.2.3.1.3 Power-Management Scheme

20.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

20.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

Table 20-91 details the high-speed USB host controller module PRCM clock control bits.

Table 20-91. High-Speed USB Host Controller PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBHOST_FCLK1	USBHOST_48M_FCLK	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit	N/A
USBHOST_FCLK2	USBHOST_120M_FCLK	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit	N/A
USBHOST_MICLK	USBHOST_L3_ICLK	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit	PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit

NOTE:

- The PRCM USBHOST_48M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_120M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_L3_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST_L3_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

20.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see Figure 20-94).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH_SYSCONFIG[13:12] MIDLEMODE field.

Table 20-92. High-Speed USB Host Controller MIDLEMODE Settings

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally).
0x1	No-standby	The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted).
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

20.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH_SYSCONFIG[4:3] SIDLEMODE bit field. Table 20-93 details SIDLEMODE settings and the related acknowledgment modes.

Table 20-93. High-Speed USB Host Controller SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The USBHOST.UHH_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the interface clock internal gating while module is idle. Table 20-94 details the CLOCKACTIVITY settings.

Table 20-94. High-Speed USB Host Controller CLOCKACTIVITY Settings

CLOCKACTIVITY Value	Interface Clock Effect	Description
0	OFF	Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request.
1	ON	Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the high-speed USB host controller CLOCKACTIVITY and PRCM interface clock control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN_USBHOST register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

20.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the USBTLL module clocks are no longer required, the USBTLL module can be deactivated at PRCM level in the corresponding registers.

Table 20-95 details the USBTLL module PRCM clock control bits.

Table 20-95. USBTLL Module PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBTLL_FCLK	CORE_120M_FCLK	PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit	N/A
USBTLL_ICLK	CORE_L4_ICLK	PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit	PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTLL bit

NOTE:

- The PRCM CORE_120M_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE_L4_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit is used to link/unlink the USBTLL module from CORE_L4_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

At PRCM level, when all the conditions to shut off the USBTLL_FCLK or USBTLL_ICLK output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL_SYSCONFIG[4:3] SIDLEMODE bit field. Table 20-96 details SIDLEMODE settings and the related acknowledgment modes.

Table 20-96. USBTLL Module SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL_ICLK gating. The USBHOST.USBTLL_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the USBTLL_ICLK clock internal gating while the module is idle. Table 20-97 details the CLOCKACTIVITY settings.

Table 20-97. USBTLL Module CLOCKACTIVITY Settings

CLOCKACTIVITY Value	USBTLL_ICLK Effect	Description
0	OFF	USBTLL_ICLK is considered for generating the acknowledgment. This setting also means USBTLL_ICLK is shut down upon PRCM IDLE request.
1	ON	USBTLL_ICLK is not shut down upon PRCM IDLE request. The USBTLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN3_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

20.2.3.2 Hardware Requests

20.2.3.2.1 Interrupt Requests

Table 20-98 lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

Table 20-98. High-Speed USB Host Subsystem Interrupts

Name	Mapping	Comments
HS USB OHCI Host Controller Interrupt		
OHCI_IRQ	M_IRQ_76	Destination is MPU subsystem interrupt controller
HS USB EHCI Host Controller Interrupt		
EHCI_IRQ	M_IRQ_77	Destination is MPU subsystem interrupt controller
USBTLL Module Interrupt		
TLL_IRQ	M_IRQ_78	Destination is MPU subsystem interrupt controller

20.2.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

20.2.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

20.2.3.2.4 Wake-Up Request

Wake-up request signal USBHOST_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL_SWAKEUP is generated by the USBTLL module to the PRCM module.

20.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

20.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

20.2.4.1.1 High-Speed USB Host Controller Architecture

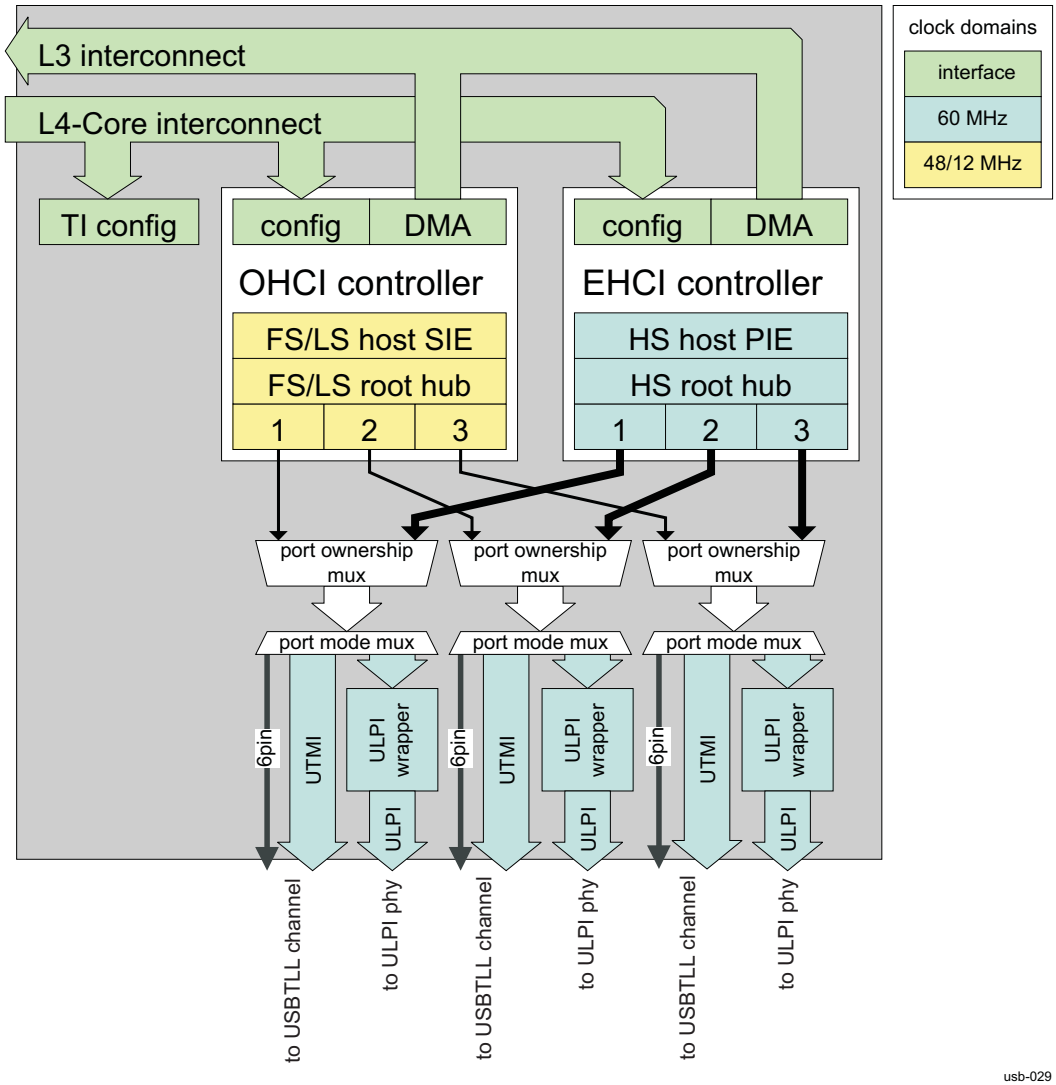
Figure 20-95 shows an overview of the high-speed USB host controller internal architecture: it contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.
- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

NOTE: If one port is connected to a high-speed ULPI transceiver, all other ports must be connected to high-speed ULPI transceivers or not used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 20-95. High-Speed USB Host Controller Architecture



20.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see Section 20.2.6.6, *OHCI Registers*). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- USBHOST.HCFMINTERVAL[30:16] FSMPS field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.
- USBHOST.HCRHDESCRIPTORA[7:0] NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- USBHOST.HCRHDESCRIPTORA[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.

- USBHOST.HCRHDESCRIPTORA[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- USBHOST.HCRHDESCRIPTORA[31:24] POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power rampup time is 10 x 2 ms = 20 ms.
- USBHOST.HCRHDESCRIPTORB[15:0] DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- USBHOST.HCRHDESCRIPTORB[31:16] PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

20.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*, and *UTMI+ specification Release 1.0*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the “outgoing“ packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don’t care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

20.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In ULPI mode (see *UTMI Low-Pin Interface (ULPI) specification Release 1.1*), all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the “outgoing“ packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don’t care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHZ) clock to the transceiver on the ULPI interface. This is called ULPI “input” clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, “output mode” (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports (only port 1 and port 2 are mapped) can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

20.2.4.1.5 Port Status

The USB port status is given through the USBHOST.UHH_HOSTCONFIG[10:8] bit field. The default value of the following bits is 1:

- USBHOST.UHH_HOSTCONFIG[8] P1_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[9] P2_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[10] P3_CONNECT_STATUS

CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, USBHOST.HCRHPORTSTATUS_1 for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the USBHOST.UHH_HOSTCONFIG bits to indicate the correct port connect status.

20.2.4.1.6 Save and Restore

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the "buried" flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_USBHOSTE[4] SAVEANDRESTORE bit enables the SAR mechanism for the high-speed USB host controller (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

20.2.4.1.7 Burst Control

To avoid buffer underflow bursts shall be enabled by writing 0x7 in USBHOST.UHH_HOSTCONFIG[4:2] and 0x0 in USBHOST.UHH_HOSTCONFIG[5] ENA_INCR_ALIGN.

20.2.4.2 USBTLL Module Functionality

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software "handles" should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

20.2.4.2.1 Channels and Ports

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An "input" goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an "output" goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. Table 20-99 summarizes the ports features.

20.2.4.2.2 Channel Architecture

Figure 20-96 shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

Figure 20-96. USBTLL Channel

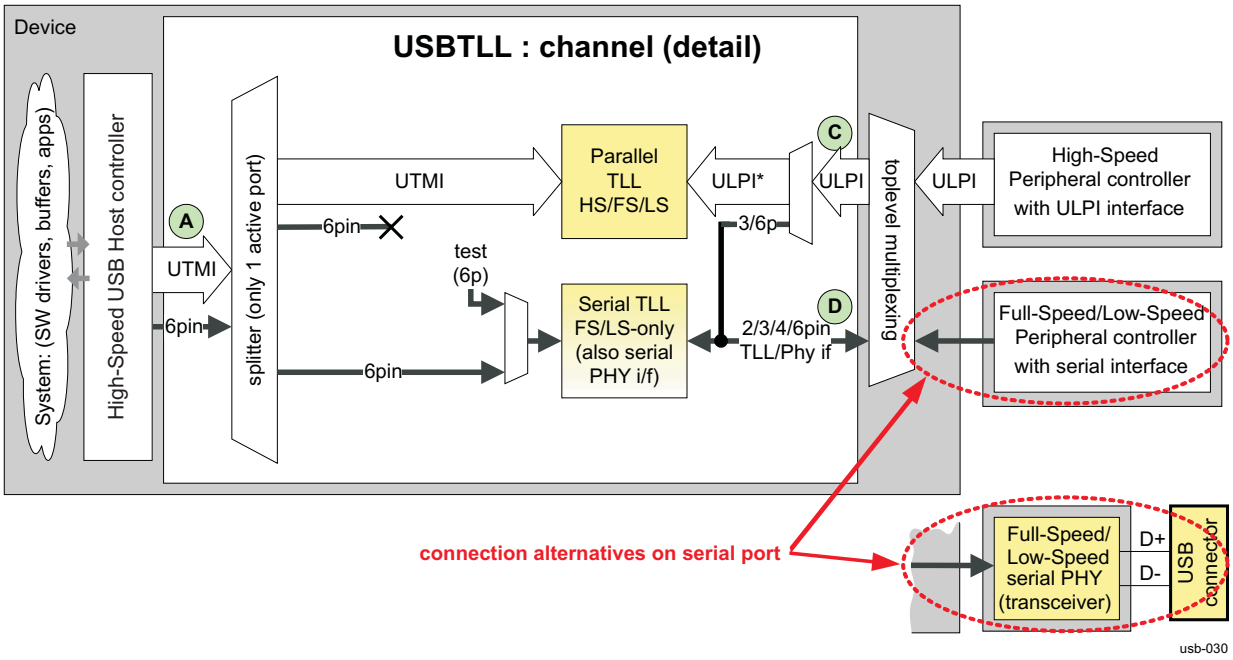


Table 20-99 summarizes the properties of each port.

Table 20-99. USBTLL Channel USB Ports

USBTLL Port	Port Description	Connect to Controller	Connect to Transceiver	Serial (Full-Speed/ Low-Speed only)	Parallel (High-Speed/ Full-Speed/Low-Speed)
A	PHY-side UTMI+	UTMI+ (L3)	No	6-pin	60-MHZ UTMI
C	PHY-side ULPI	ULPI TLL	No	6-pin	60-MHZ UTMI
D	Multimode Serial	6-/4-/3-/2-pin TLL	6-/4-/3-/2-pin	6-/4-/3-/2-pin TLL	No

20.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI “local” port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHZ UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS “6-pin” mode

20.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes
- Supports optional input clocking mode

20.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

20.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. Table 20-100, lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

Table 20-100 describes the available modes and the software settings required for each. Channel I has the following settings:

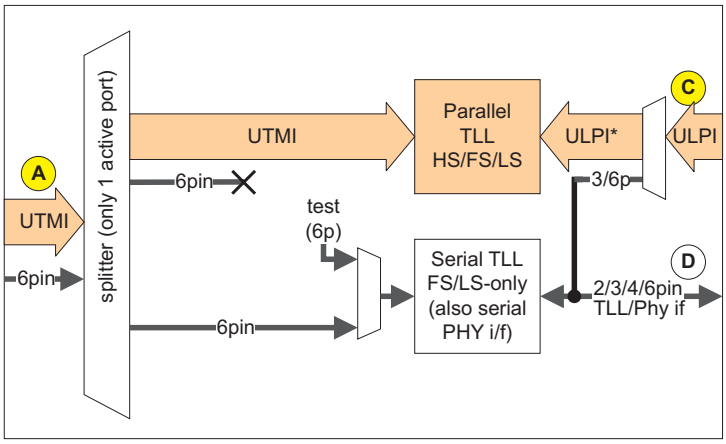
- CHANMODE: USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field
- FSLSMODE: USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field
- FSLSSERIALMODE_3PIN/6PIN: Either the ULPI PHY-side USBHOST.ULPI_INTERFACE_CTRL[1] FSLSSERIALMODE_3PIN bit or the USBHOST.ULPI_INTERFACE_CTRL[0] FSLSSERIALMODE_6PIN bit (only one can be set to 1 at a time)

Table 20-100. USBTLL Channel Configuration

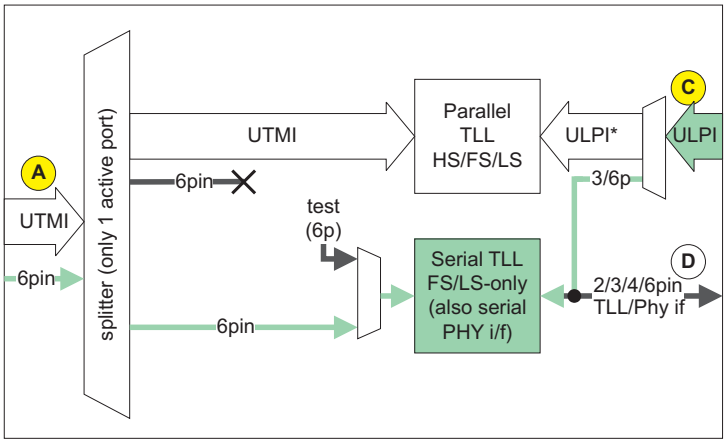
Configuration	Mode	CHAN MODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
2	ULPI synchronous TLL	0	N/A	FSLSSERIALMODE_ 3PIN/6PIN = 0	A–C	HFL	ULPI link (peripheral controller)
4	Serial UTMI to serial ULPI TLL	0	N/A	FSLSSERIALMODE_ 3PIN/6PIN = 1	A–C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
6	Serial UTMI to serial TLL	1	0x4 to 0x7; 0xA to 0xB	-	A–D	FL	Serial link (2-/3-/4-/6-pin)
6	Serial UTMI to serial PHY	1	0x0 to 0x3	-	A–D	FL	Serial transceiver (2-/3-/4-/6-pin)

Figure 20-97. Per-Configuration Datapath Through USBTLL

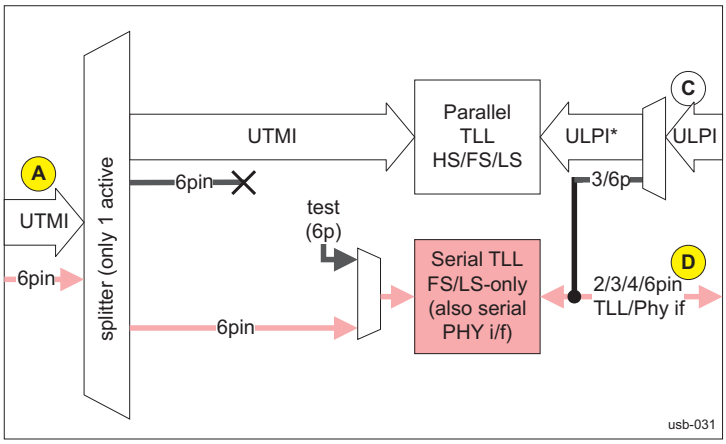
2: Sync UTMI to sync ULPI TLL config (HS/FS/LS)



4: Serial UTMI to serial ULPI TLL config (FS/LS)



6: Serial UTMI to serial ULPI, TLL or PHY config



20.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this bring no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see Figure 20-82 and Figure 20-83 and the related explanations.

20.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

20.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also Figure 20-82.

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup “charge”, VBUS pulldown “discharge”) is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the USBHOST.TLL_CHANNEL_CONF_i DRVVBUS and CHRGVBUS bits, as indicated in Table 20-101.

Table 20-101 lists the values to write to the USBHOST.TLL_CHANNEL_CONF_i register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields actual signification is:

- DRVVBUS: set to 1 to report a VBUS level greater than *VBUS valid.*
- CHRGVBUS: set to 1 to report a VBUS level greater than *Session valid*

Table 20-101. VBUS Level Software Reporting for Serial Transceiver Configuration

VBUS Status	USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit	USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

20.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a “don’t care”

20.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

Table 20-102 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 20-102. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

VBUS Controls (Actions)			VBUS Level	VBUS Status		
USBHOST.ULPI_OTG_CTRL[5] DRVVBUS Bit	USBHOST.ULPI_OTG_CTRL[4] CHRGVBUS Bit	USBHOST.ULPI_OTG_CTRL[3] DISCHRGVBUS Bit		USBHOST.ULPI_USB_INT_STATUS[1] VBUSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[2] SESSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[3] SESSEND Bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

20.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See Figure 20-83.

VBUS control can be done in software, by writing to the following fields of the USBHOST.TLL_CHANNEL_CONF_i register:

- DRVVBUS: set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

20.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

Table 20-103 shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 20-103. Serial Mode Description, Signal Functionality

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin usage	Unidirect	Unidirect	Bidirect	Bidirect	Unidirect	Unidirect	Bidirect	Bidirect	Bidirect	Bidirect
Pin count	6	6	3	4	6 or 5[1]	6 or 5[1]	3	4 or 3[2]	2	2
I/O Pad Function Per Mode										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDM	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDM	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

(1) RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

(2) Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

20.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL_CHANNEL_i[27:24] FSLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
  - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
  - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5KOhm resistor]), which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal — the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.
- USBHOST.TLL_CHANNEL_CONF_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): see Table 20-104.
- The 15kOhm pulldowns are implicit: because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

NOTE: Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require any custom additions.

Table 20-104. Pullup Enable Emulation in Serial TLL Modes

USBHOST.TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	On	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

20.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

Table 20-105 lists the USBTLL registers impacted by the SAR context.

NOTE: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 20-105. USBTLL Registers Impacted by the SAR Context

Register Name	Comments on SAR Policy
USBTLL_SYSCONFIG	Except the SOFTRESET bit (write-only)

20.2.5 High-Speed USB Host Subsystem Basic Programming Model

20.2.5.1 Selecting and Configuring USB Connectivity

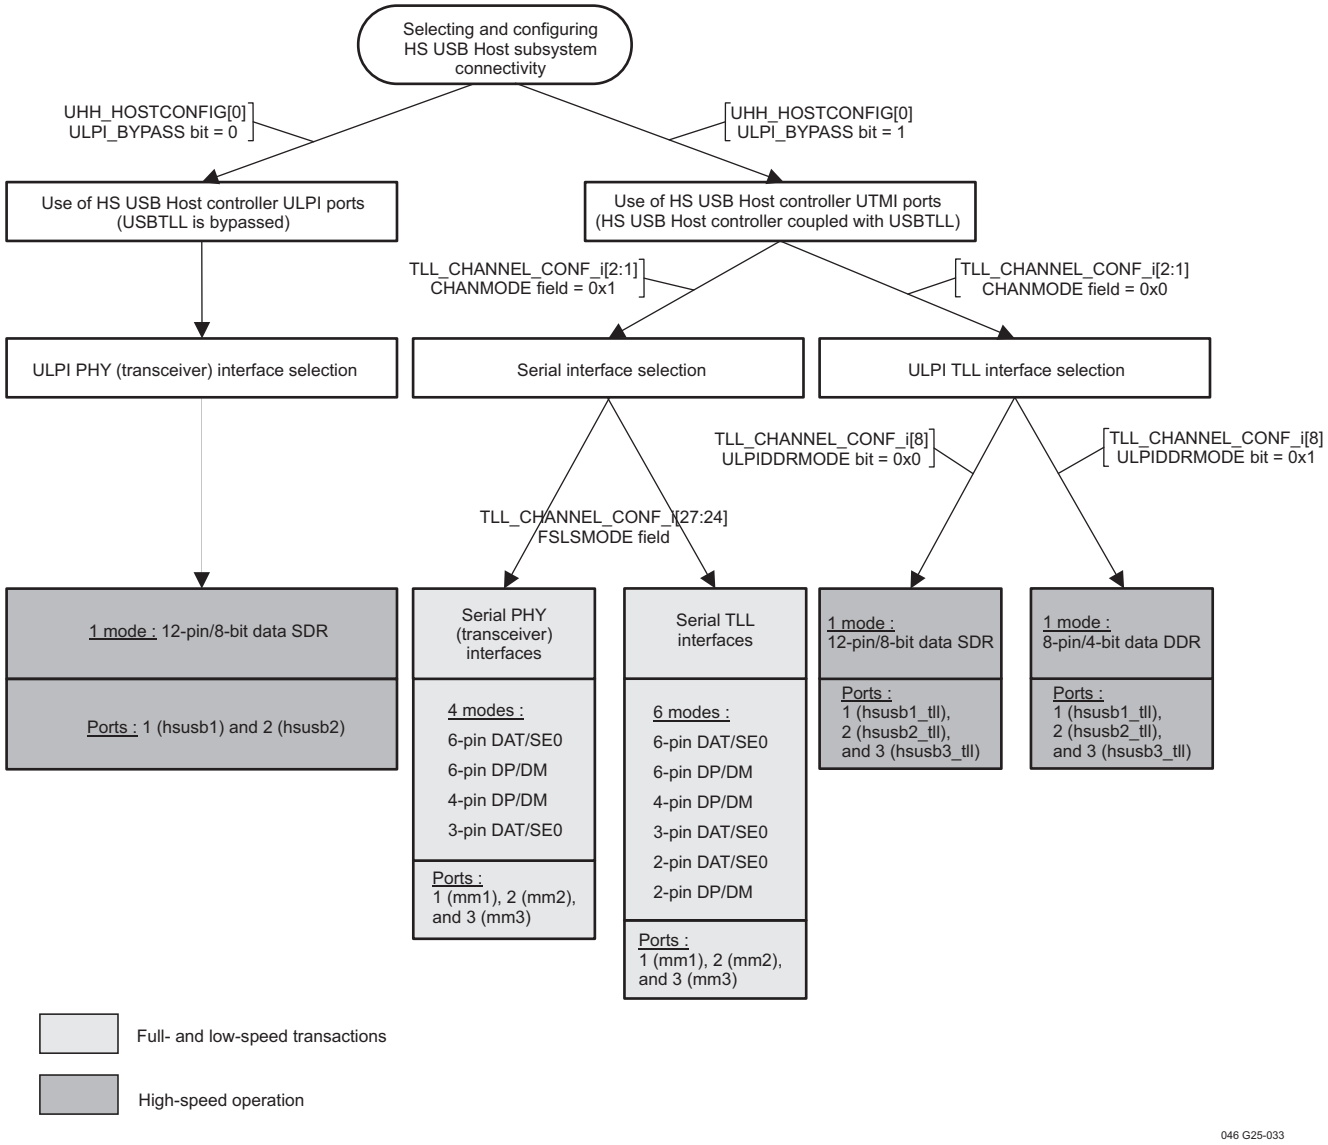
Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

Figure 20-98 shows how to select and configure the high-speed USB host subsystem connectivity.

Figure 20-98. Selecting and Configuring High-Speed USB Host Subsystem Connectivity



NOTE: When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 0 (ULPI transceiver interface selection), only the ULPI ports 1 and 2 of the high-speed USB host controller can be used. Only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported.

When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and the three ports can be configured in any ULPI TLL or serial mode.

20.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
  - ULPI interfaces: 12-pin/8-bit data version supporting "input" clocking mode
- TLL
  - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

20.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be cleared to 0. In ULPI mode, all ports are in ULPI mode.

20.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see Section 20.2.4.2.3), *Channel Configurations*.

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the USBHOST.TLL_CHANNEL_CONF_i[8] ULPIDDRMODE bit (0: SDR mode; 1: DDR mode).

20.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
  - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), and the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see Section 20.2.4.2.3, *Channel Configurations*).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field only when the main channel mode is serial (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1 = UTMI-to-serial mode).

Table 20-106. USB Connectivity Mode Description

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL Mode (Alt)	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNEL_CONF_i[27:24] FSLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin usage	Unidirect	Unidirect	Bidirect	Bidirect	Unidirect	Unidirect	Bidirect	Bidirect	Bidirect	Bidirect
Pin count	6	6	3	4	6 or 5[1]	6 or 5[1]	3	4 or 3[2]	2	2

(1) RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused
(2) Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

20.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

20.2.5.2.1 TLL Control and Status Registers

Those 32-bit registers configure the various channels. Those registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. Those registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

20.2.5.2.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. Upon resume, the ULPI register contents have been lost and can be restored over L4-Core

interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

CAUTION

The INSNREG04[5] bit must be set to 1 for proper behavior.

20.2.6 High-Speed USB Host Subsystem Registers

20.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x40- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x100- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED_SET_ACCESS in Table 20-107). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively _SET and _CLR. The register fields are described only once, at the write address (see Section 20.2.6.7, *EHCI Register Descriptions*).

NOTE: Some ULPI registers are cleared upon read.

Table 20-107. ULPI Register Mapping Summary (For a Single ULPI Port)

20.2.6.2 L4-Core Interconnect Register Space

Table 20-108 lists the base address and address space for the high-speed USB host subsystem.

Table 20-108. Instance Summary

Module Name	Base Address (hex)	Size
USBTLL	0x4806 2000	4096 bytes
UHH_CONFIG	0x4806 4000	1024 bytes
OHCI	0x4806 4400	1024 bytes
EHCI	0x4806 4800	1024 bytes

20.2.6.3 High-Speed USB Host Subsystem Register Mapping Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

Table 20-109 lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

Table 20-110, Table 20-111, and Table 20-112 list the high-speed USB host controller registers.

CAUTION

On ULPI PHY-side register access over L4-Core interconnect:

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: oversized read accesses to adjacent memory locations could cause unwanted clears.

Table 20-109. USBTLL Register Mapping Summary (L4-Core Interconnect Register Space)

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address	Section
USBTLL_REVISION	R	32	0x0000 0000	0x4806 2000	Section 20.2.6.4.1

20.2.6.4 USBTLL Register Descriptions

20.2.6.4.1 USBTLL_REVISION

Table 20-113. USBTLL_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4806 2000	**Instance**	USBTLL
Description	OCP standard revision number, BCD encoded		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								MAJOR				MINOR			

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x000000
7:4	MAJOR	Major revision number	R	0x0
3:0	MINOR	Minor revision number	R	0x1

20.2.6.4.2 USBTLL_SYSCONFIG

Table 20-114. USBTLL_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4806 2010	**Instance**	USBTLL
Description	OCP standard system configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITY	RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	reserved	R	0x000000
8	CLOCKACTIVITY	Enable autogating of OCP-derived internal clocks while module is idle. 0x0: OCP-derived internal clocks OFF during idle 0x1: OCP-derived internal clocks ON during idle	RW	0x0
7:5	RESERVED	reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management control. Idle Req/ack control 0x0: Force-Idle mode. Sidleack asserted after Idlereq assertion 0x1: No-idle mode. Sidleack never asserted. 0x2: Smart-idle mode. Sidleack asserted after Idlereq assertion when no more activity on the USB.	RW	0x0
2	ENAWAKEUP	Asynchronous wakeup generation control (Swakeup) 0x0: Wakeup generation disabled 0x1: Wakeup generation enabled	RW	0x0
1	SOFTRESET	Module software reset 0x0: no effect 0x1: Starts softreset sequence.	W	0x0
0	AUTOIDLE	Internal autogating control 0x0: Clock always running 0x1: When no activity on OCP, clock is cut off.	RW	0x1

20.2.6.4.3 USBTLL_SYSSTATUS

Table 20-115. USBTLL_SYSSTATUS

Address Offset	0x0000 0014		
Physical Address	0x4806 2014	**Instance**	USBTLL
Description	OCP standard system status register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															RESETDONE

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	reserved	R	0x00000000
0	RESETDONE	Indicates when the module has entirely come out of reset 0x0: Reset is ongoing 0x1: Reset is done	R	0x0

20.2.6.4.4 USBTLL_IRQSTATUS

Table 20-116. USBTLL_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x4806 2018	**Instance**	USBTLL
Description	OCP standard IRQ status vector. Write 1 to clear a bit.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													ACCESS_ERROR	FCLK_END	FCLK_START

Bits	Field Name	Description	Type	Reset
31:3	RESERVED		R	0x00000000
2	ACCESS_ERROR	Access error to ULPI register over OCP: USB clock must run for that type of access to succeed. 0x0: No event pending 0x1: Event pending	RW	0x0
1	FCLK_END	Functional clock is no longer requested for USB clocking 0x0: No event pending 0x1: Event pending	RW	0x0
0	FCLK_START	Functional clock is requested for USB clocking 0x0: No event pending 0x1: Event pending	RW	0x0

20.2.6.4.5 USBTLL_IRQENABLE

Table 20-117. USBTLL_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x4806 201C	**Instance**	USBTLL
Description	OCP standard IRQ enable vector		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													ACCESS_ERROR_EN	FCLK_END_EN	FCLK_START_EN

Bits	Field Name	Description	Type	Reset
31:3	RESERVED		R	0x00000000
2	ACCESS_ERROR_EN	Enable IRQ generation upon access error to ULPI register over OCP 0x0: IRQ event is masked 0x1: IRQ event is enabled	RW	0x0
1	FCLK_END_EN	0x0: IRQ event is masked 0x1: IRQ event is enabled	RW	0x0
0	FCLK_START_EN	0x0: IRQ event is masked 0x1: IRQ event is enabled	RW	0x0

20.2.6.4.6 TLL_SHARED_CONF

Table 20-118. TLL_SHARED_CONF

Address Offset	0x0000 0030		
Physical Address	0x4806 2030	**Instance**	USBTLL
Description	Common control register for all TLL channels		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								USB_90D_DDR_EN	USB_180D_SDR_EN	USB_DIVRATIO				FCLK_REQ	FCLK_IS_ON

Bits	Field Name	Description	Type	Reset
31:7	RESERVED		R	0x0000000
6	USB_90D_DDR_EN	Software enable/disable of the 90-degree phase shift scheme on output DDR data, when implemented. Read-only, always-0 when HDL generic ULPI_90DEG4DDR = 0. 0x0: ULPI DDR output DATA aligned with CLK 0x1: ULPI DDR output DATA delayed by 90 degree wrt CLK	RW	0x1
5	USB_180D_SDR_EN	Software enable/disable of the 180-degree phase shift scheme on output SDR data, when implemented. Read-only, always-0 when HDL generic ULPI_180DEG4SDR = 0 0x0: ULPI SDR output DATA aligned with CLK 0x1: ULPI SDR output DATA delayed by 180 degree wrt CLK	RW	0x1
4:2	USB_DIVRATIO	(Log2 of) division ratio from functional clock to USB (UTMI/ULPI) clock 0x0: div ratio is 2**0 = 1 : bypass 0x1: div ratio is 2**1 = 2 0x2: div ratio is 2**2 = 4 0x3: div ratio is 2**3 = 8 0x4: div ratio is 2**4 = 16 0x5: div ratio is 2**5 = 32 0x6: div ratio is 2**6 = 64 0x7: div ratio is 2**7 = 128	RW	0x0
1	FCLK_REQ	Functional clock request, ORed from all channels depending on their respective USB bus state. Combined with the Fclk_is_on status to generate fclk_start/end IRQs. 0x0: Func clock input is not requested by TLL 0x1: Func clock input is requested by TLL	R	0x0
0	FCLK_IS_ON	Status of the functional clock input, provided by the system to the TLL module. The TLL module will only use that clock if the current status indicated that it is ready. Combined with the Fclk_request to generate fclk_start/end IRQs. 0x0: Functional clock input is not guaranteed ON (can actually be ON, OFF, or unstable) 0x1: Functional clock input is guaranteed ON and stable	RW	0x0

20.2.6.4.7 TLL_CHANNEL_CONF_i

Table 20-119. TLL_CHANNEL_CONF_i

Address Offset	0x0000 0040 + (0x04 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2040 + (0x04 x I)	**Instance**	USBTLL
Description	Control and Status register for channel I.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		FSLSLINESTATE		FSLSMODE				RESERVED			TESTTXSE0	TESTTXDAT	TESTTXEN	TESTEN	DRVVBUS	CHRGVBUS	RESERVED			ULPINOBITSTUFF	ULPIAUTOIDLE	UTMIAUTOIDLE	ULPIDDRMODE	ULPIOUTCLKMODE	TLLFULLSPEED	TLLCONNECT	TLLATTACH	UTMIISADEV	CHANMODE		CHANEN

Bits	Field Name	Description	Type	Reset
31:30	RESERVED		R	0x0
29:28	FSLSLINESTATE	Line state for Full/Low speed serial modes Bit1 = D-/ Bit0 = D+ 0x0: Single-ended 0 0x1: Full-Speed J = differential 1 0x2: Full-Speed K = differential 0 0x3: Single-ended 1 (illegal in USB)	R	0x0
27:24	FSLSMODE	Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: "6pin" unidirectional PHY I/f mode. TX encoding is Dat/Se0 (default) 0x1: "6-pin" unidirectional PHY I/f mode. TX encoding is Dp/Dm 0x2: "3-pin" bidirectional PHY I/f mode. 0x3: "4-pin" bidirectional PHY I/f mode. 0x4: "6pin" unidirectional TLL mode. TX encoding is Dat/Se0 0x5: "6pin" unidirectional TLL mode. TX encoding is Dp/Dm 0x6: "3-pin" bidirectional TLL mode. 0x7: "4-pin" bidirectional TLL mode. 0xA: "2-pin" bidirectional TLL mode. Encoding is Dat/Se0 0xB: "2-pin" bidirectional TLL mode. Encoding is Dp/Dm	RW	0x0
23:21	RESERVED		R	0x0
20	TESTTXSE0	Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) 0x0: drive differential value on TX according to TestTXDat 0x1: drive SE0 on TX	RW	0x0
19	TESTTXDAT	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) or TestSe0 = 1 (tx = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1	RW	0x0
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: pullups determine line state)	RW	0x0

Bits	Field Name	Description	Type	Reset
17	TESTEN	Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled	RW	0x0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V	RW	0x0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge / pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0x0
14:12	RESERVED		R	0x0
11	ULPINOBITSTUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard)	RW	0x0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	0x1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMII goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	0x1
8	ULPIDDRMODE	Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit / 12 pin) 0x1: DDR mode (4 data bit / 8 pin)	RW	0x0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output	RW	0x1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tllpuen, register field TllConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	0x1
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected	RW	0x0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: cable detach emulated on serial TLL 0x1: cable attach emulated on serial TLL	RW	0x1

Bits	Field Name	Description	Type	Reset
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	0x1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unclocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0x0

20.2.6.4.8 ULPI_VENDOR_ID_LO_i

Table 20-120. ULPI_VENDOR_ID_LO_i

Address Offset	0x0000 0000 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2800 + (0x100 x I)	**Instance**	ULPI
Description	Lower byte of USB-IF-supplied vendor ID Value is set for all channels by HDL generic ULPI_VENDORID Default is Texas-Instruments Vendor ID = 0x0451		
Type	R

20.2.6.4.12 ULPI_FUNCTION_CTRL_i

Table 20-124. ULPI_FUNCTION_CTRL_i

Address Offset	0x0000 0004 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2804 + (0x100 x I)	**Instance**	ULPI
Description	Controls UTMI function settings of the PHY. Read / Write address.		
Type	RW		

7	6	5	4	3	2	1	0
RESERVED	SUSPENDM	RESET	OPMODE		TERMSELECT	XCVRSELECT	

Bits	Field Name	Description	Type	Reset
7	RESERVED		R	0x0
6	SUSPENDM	Active low PHY suspend: puts the ULPI bus in Low Power Mode. Automatically set back to '1' upon Low Power Mode exit. 0x0: PHY is in low-power mode 0x1: PHY is not in low-power mode	RW	0x1
5	RESET	Active high UTMI transceiver reset. Auto-cleared. Does not reset the ULPI interface or ULPI register set. 0x0: No ongoing reset/ no action 0x1: Ongoing reset / apply reset	RW	0x0
4:3	OPMODE	Select the required bit encoding style during transmit 0x0: Normal operation 0x1: Non-driving 0x2: Disable bit-stuff and NRZI encoding 0x3: Reserved	RW	0x0
2	TERMSELECT	Controls the internal 1.5Kohms pull-up resistor and 45ohms HS terminations. Control over bus resistors changes depending on XcvrSelect, OpMode, DpPulldown and DmPulldown. 0x0: HS termination enabled (other conditions) 0x1: FS termination enabled (other conditions)	RW	0x0
1:0	XCVRSELECT	Select the required transceiver speed. 0x0: Enable HS transceiver 0x1: Enable FS transceiver 0x2: Enable LS transceiver 0x3: Enable FS transceiver for LS packets (automatic FS preamble pre-pending)	RW	0x1

20.2.6.4.13 ULPI_FUNCTION_CTRL_SET_i

Table 20-125. ULPI_FUNCTION_CTRL_SET_i

Address Offset	0x0000 0005 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2805 + (0x100 x I)	**Instance**	ULPI
Description	Controls UTMI function settings of the PHY. Read / Set address (write 1 to a bit to set it to 1, writing 0 has no effect on bit value). See fields description at the Read/Write address of the same register.		
Type	RW		

20.2.6.4.14 ULPI_FUNCTION_CTRL_CLR_i

Table 20-126. ULPI_FUNCTION_CTRL_CLR_i

Address Offset	0x0000 0006 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2806 + (0x100 x I)	**Instance**	ULPI
Description	Controls UTMI function settings of the PHY. Read / Clear address (write 1 to a bit to clear it to 0, writing 0 has no effect on bit value). See fields description at the Read / Write address of the same register.		
Type	RW		

20.2.6.4.15 ULPI_INTERFACE_CTRL_i

Table 20-127. ULPI_INTERFACE_CTRL_i

Address Offset	0x0000 0007 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2807 + (0x100 x I)	**Instance**	ULPI
Description	Enables alternative interfaces and PHY features. Read / Write address.		
Type	RW		

7	6	5	4	3	2	1	0
INTERFACE_PROTECT_DISABLE	RESERVED		AUTORESUME	CLOCKSUSPENDM	RESERVED	FSLSSERIALMODE_3PIN	FSLSSERIALMODE_6PIN

Bits	Field Name	Description	Type	Reset
7	INTERFACE_PROTECT_DISABLE	Controls circuitry built into the PHY for protecting the ULPI interface when the link tri-states stp and data. 0x0: Enables the interface protect circuit 0x1: Disables the interface protect circuit	RW	0x0
6:5	RESERVED		R	0x0
4	AUTORESUME	Enables the PHY to automatically drive resume signaling. On by default. 0x0: AutoResume disabled 0x1: AutoResume enabled	RW	0x1
3	CLOCKSUSPENDM	Active low clock suspend for serial modes (6pin/3-pin). 0x0: ULPI clock will stop during serial modes. 0x1: ULPI clock will run during serial modes.	RW	0x0
2	RESERVED		R	0x0
1	FSLSSERIALMODE_3PIN	Sets the ULPI interface to 3-pin (FS/LS only) Serial Mode. Auto-cleared when serial mode is exited. 0x0: ULPI is not in 3-pin mode 0x1: ULPI in 3-pin serial mode	RW	0x0
0	FSLSSERIALMODE_6PIN	Sets the ULPI interface to 6-pin (FS/LS only) Serial Mode. Auto-cleared when serial mode is exited. 0x0: ULPI is not in 6-pin mode 0x1: ULPI in 6-pin serial mode	RW	0x0

20.2.6.4.16 ULPI_INTERFACE_CTRL_SET_i

Table 20-128. ULPI_INTERFACE_CTRL_SET_i

Address Offset	0x0000 0008 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2808 + (0x100 x I)	**Instance**	ULPI
Description	Enables alternative interfaces and PHY features. Read / Set address (write 1 to a bit to set it to 1, writing 0 has no effect on bit value). See fields description at the Read/Write address of the same register.		
Type	RW		

20.2.6.4.17 ULPI_INTERFACE_CTRL_CLR_i

Table 20-129. ULPI_INTERFACE_CTRL_CLR_i

Address Offset	0x0000 0009 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2809 + (0x100 x I)	**Instance**	ULPI
Description	Enables alternative interfaces and PHY features. Read / Clear address (write 1 to a bit to clear it to 0, writing 0 has no effect on bit value). See fields description at the Read / Write address of the same register.		
Type	RW		

20.2.6.4.18 ULPI_OTG_CTRL_i

Table 20-130. ULPI_OTG_CTRL_i

Address Offset	0x0000 000A + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 280A + (0x100 x I)	**Instance**	ULPI
Description	Controls UTMI+ OTG functions of the PHY. Read / Write address.		
Type	RW		

7	6	5	4	3	2	1	0
RESERVED		DRVVBUS	CHRGVBUS	DISCHRGVBUS	DMPULLDOWN	DPPULLDOWN	IDPULLUP

Bits	Field Name	Description	Type	Reset
7:6	RESERVED		R	0x0
5	DRVVBUS	Drive 5V on VBUS 0x0: no action 0x1: drive VBUS	RW	0x0
4	CHRGVBUS	Charge VBUS through a resistor for VBUS-pulsing SRP. 0x0: No action 0x1: Set the bit to 1	RW	0x0
3	DISCHRGVBUS	Discharge VBUS through a resistor, until the session-end VBUS state is reached. 0x0: no action 0x1: discharge VBUS	RW	0x0
2	DMPULLDOWN	Enables the 15k Ohm pull-down resistor on D- 0x0: Pull-down resistor not connected to D- 0x1: Pull-down resistor connected to D-	RW	0x1
1	DPPULLDOWN	Enables the 15k Ohm pull-down resistor on D+ 0x0: Pull-down resistor not connected to D+ 0x1: Pull-down resistor connected to D+	RW	0x1
0	IDPULLUP	Pull-up to the (OTG) ID line to allow its sampling 0x0: Disable sampling of ID line. 0x1: Enable sampling of ID line.	RW	0x0

20.2.6.4.19 ULPI_OTG_CTRL_SET_i

Table 20-131. ULPI_OTG_CTRL_SET_i

Address Offset	0x0000 000B + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 280B + (0x100 x I)	**Instance**	ULPI
Description	Controls UTMI+ OTG functions of the PHY. Read / Set address (write 1 to a bit to set it to 1, writing 0 has no effect on bit value). See fields description at the Read/Write address of the same register.		
Type	RW		

20.2.6.4.20 ULPI_OTG_CTRL_CLR_i

Description	Enables an interrupt event notification when the corresponding status bit changes from high to low. Read / Clear address (write 1 to a bit to clear it to 0, writing 0 has no effect on bit value). See fields description at the Read / Write address of the same register.		
Type	RW		

20.2.6.4.27 ULPI_USB_INT_STATUS_i

Table 20-139. ULPI_USB_INT_STATUS_i

Address Offset	0x0000 0013 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2813 + (0x100 x I)	**Instance**	ULPI
Description	Indicates the current value of the interrupt source signal.		
Type	R		

7	6	5	4	3	2	1	0
RESERVED			IDGND	SESSEND	SESSVALID	VBUSVALID	HOSTDISCONNECT

Bits	Field Name	Description	Type	Reset
7:5	RESERVED		R	0x0
4	IDGND	Value of UTMI+ IdDig output. Undefined unless IdPullup = 1 0x0: ID pin is grounded = OTG A = default Host 0x1: ID pin is floating = OTG B = default Peripheral	R	0x0
3	SESSEND	Current value of UTMI+ SessEnd output. 0x0: VBUS is above Session-End threshold 0x1: VBUS is below Session-End threshold	R	0x0
2	SESSVALID	Current value of UTMI+ SessValid output. SessValid is the same as UTMI+ AValid. 0x0: VBUS is below Session-Valid threshold 0x1: VBUS is above Session-Valid threshold	R	0x0
1	VBUSVALID	Current value of UTMI+ VbusValid output. 0x0: VBUS is below Vbus-Valid threshold 0x1: VBUS is above Vbus-Valid threshold	R	0x0
0	HOSTDISCONNECT	Current value of UTMI+ Hostdisconnect output. Applicable only in host mode. Automatically reset to 0 when Low Power Mode is entered. 0x0: Peripheral not disconnected or non-host mode 0x1: Peripheral disconnected	R	0x0

20.2.6.4.28 ULPI_USB_INT_LATCH_i

Table 20-140. ULPI_USB_INT_LATCH_i

Address Offset	0x0000 0014 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2814 + (0x100 x I)	**Instance**	ULPI
Description	Set by unmasked changes on the corresponding status bits to generate the ULPI interrupt. Cleared upon read, and when Low Power Mode or Serial Mode are entered.		
Type	R		

7	6	5	4	3	2	1	0
RESERVED			IDGND_LATCH	SESSEND_LATCH	SESSVALID_LATCH	VBUSVALID_LATCH	HOSTDISCONNECT_LATCH

Bits	Field Name	Description	Type	Reset
7:5	RESERVED		R	0x0
4	IDGND_LATCH	Set to 1 by the PHY when an unmasked event occurs on IdGnd. Cleared when this register is read.	R	0x0
3	SESSEND_LATCH	Set to 1 by the PHY when an unmasked event occurs on SessEnd. Cleared when this register is read.	R	0x0
2	SESSVALID_LATCH	Set to 1 by the PHY when an unmasked event occurs on SessValid. Cleared when this register is read. SessValid is the same as UTMI+ AValid.	R	0x0
1	VBUSVALID_LATCH	Set to 1 by the PHY when an unmasked event occurs on VbusValid. Cleared when this register is read.	R	0x0
0	HOSTDISCONNECT_LATCH	Set to 1 by the PHY when an unmasked event occurs on Hostdisconnect. Cleared when this register is read. Applicable only in host mode.	R	0x0

20.2.6.4.29 ULPI_DEBUG_i

Table 20-141. ULPI_DEBUG_i

Address Offset	0x0000 0015 + (0x100 x I)	**Index**	I = 0 to 2
Physical Address	0x4806 2815 + (0x100 x I)	**Instance**	ULPI
Description	Indicates the current value of various signals useful for debugging.		
Type	R		

7	6	5	4	3	2	1	0
RESERVED						LINESTATE	

Bits	Field Name	Description	Type	Reset
7:2	RESERVED		R	0x00
1:0	LINESTATE	Current state of the USB line: D+ (bit 0) and D- (bit 1). 0x0: SE0 (LS/FS), Squelch (HS/Chirp) 0x1: LS: 'K' State, FS: 'J' State, HS: !Squelch, Chirp: !Squelch & HS_Differential_Receiver_Output 0x2: LS: 'J' State, FS: 'K' State, HS: Invalid, Chirp: !Squelch & !HS_Differential_Receiver_Output 0x3: SE1 (LS/FS), Invalid (HS/Chirp)	R	0x0

20.2.6.6.1 HCREVISION

Table 20-165. HCREVISION

Address Offset	0x0000 0000		
Physical Address	0x4806 4400	**Instance**	OHCI
Description	OHCI revision number		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REV							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x000000
7:0	REV	OHCI specification revision the OHCI revision number upon which the USB host controller is based. Examples: 0x10 for 1.0 0x21 for 2.1	R	0x10

20.2.6.6.2 HCCONTROL

Table 20-166. HCCONTROL

Address Offset	0x0000 0004		
Physical Address	0x4806 4404	**Instance**	OHCI
Description	HC Operating Mode Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					RWE	RWC	IR	HCFS		BLE	CLE	IE	PLE	CBSR	

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Reserved	R	0x000000
10	RWE	Remote wake-up enable This bit is used to enable or disable the remote wakeup feature upon detection of upstream resume signaling.	RW	0x0
9	RWC	Remote wake-up connected. This bit indicates whether the host controller supports remote wakeup signaling.	RW	0x0
8	IR	Interrupt routing. This bit determines the routing of interrupts generated by events registered in USBHOST.HCINTERRUPTSTATUS. 0x0: All interrupts are routed to the normal host bus interrupt mechanism. 0x1: interrupts are routed to the system management Interrupt.	RW	0x0
7:6	HCFS	Host Controller Functional State 0x0: HCFS: USB Reset 0x1: HCFS: USB Resume 0x2: HCFS: USB Operational 0x3: HCFS: USB Suspend	RW	0x0
5	BLE	Bulk list processing enable. 0x0: Bulk ED list is not processed after the next SOF. 0x1: Enables processing of bulk ED list in the next frame.	RW	0x0
4	CLE	Control list processing enable. 0x0: Control ED list is not processed after the next SOF. 0x1: Enables processing of control ED list in the next frame.	RW	0x0
3	IE	Isochronous ED processing enabled by Host Controller Driver. 0x0: Isochronous EDs are not processed 0x1: Enables processing of isochronous EDs.	RW	0x0
2	PLE	Periodic list enable 0x0: Periodic ED lists are not processed after the next frame. 0x1: Enables processing of periodic ED lists in the next frame.	RW	0x0
1:0	CBSR	Control/bulk service ratio. Specifies the ratio between control and bulk EDs processed in a frame. 0x0: One control ED per bulk ED 0x1: Two control ED per bulk ED 0x2: Three control ED per bulk ED 0x3: Four control ED per bulk ED	RW	0x0

20.2.6.6.3 HCCOMMANDSTATUS

Table 20-167. HCCOMMANDSTATUS

Address Offset	0x0000 0008		
Physical Address	0x4806 4408	**Instance**	OHCI
Description	HC Command and Status		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SOC		RESERVED												OCR	BLF	CLF	HCR

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R	0x0000
17:16	SOC	Scheduling overrun count. This is used to monitor any persistent scheduling problems. These bits are incremented on each scheduling overrun error. It is initialized to 0x0 and wraps around at 0x3.	R	0x0
15:4	RESERVED	Reserved	R	0x000
3	OCR	Ownership change request. This bit is set to request a change of control of the host controller.	RW	0x0
2	BLF	Bulk list filled. This bit is used to indicate whether there are any TDs on the bulk list. It is set whenever it adds a TD to an ED in the bulk list.	RW	0x0
1	CLF	Control list filled. This bit is used to indicate whether there are any TDs on the control list. It is set whenever it adds a TD to an ED in the control list.	RW	0x0
0	HCR	Host controller reset. (software reset) Set this bit to initiate a USB host controller reset. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this register returns a 0. 0x0: No effect 0x1: USB host controller is reset.	RW	0x0

20.2.6.6.4 HCINTERRUPTSTATUS

Table 20-168. HCINTERRUPTSTATUS

Address Offset	0x0000 000C		
Physical Address	0x4806 440C	**Instance**	OHCI
Description	HC Interrupt Status		
Type	RW

Bits	Field Name	Description	Type	Reset
31:24	POTPG	Power-on to power-good time. Defines the minimum amount of time (2 ms * POTPG) between the USB host controller turning on power to a downstream port and when the USB host can access the downstream device.	RW	0x0A
23:11	RESERVED	Reserved	R	0x000
10	DT	Device type. Always reads 0x0: indicates that the USB host controller implemented is not a compound device.	R	0x0
9	NPS	No power switching 0x0: VBUS power switching is supported, either per-port or all-port switched per the power 0x1: VBUS power switching is not supported, power is available to all downstream ports.	RW	0x0
8	PSM	Power switching mode. 0x0: Indicates that all ports are powered at the same time 0x1: Individual port power switching is supported	RW	0x1
7:0	NDP	Number of downstream ports. These bits specify the number of downstream ports supported by the root hub. It is implementation-specific. The minimum number of ports is 1. The maximum number of ports supported by OHCI is 15.	R	0x03

20.2.6.6.20 HCRHDESCRIPTORB

Table 20-184. HCRHDESCRIPTORB

Address Offset	0x0000 004C		
Physical Address	0x4806 444C	**Instance**	OHCI
Description	HC Root Hub B Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPCM																DR															

Bits	Field Name	Description	Type	Reset
31:16	PPCM	Port power control mask. Each bit defines whether a corresponding downstream port has port power controlled by the global power control. When set the port's power state is only affected by per-port power control. When cleared the port is controlled by the global power switch. If the device is configured to global switch mode this field is not valid. bit 0: reserved, bit 1: Ganged-power mask on port #1, ..., bit 15: Ganged-power mask on port #15	RW	0x0000
15:0	DR	Device removable. Each bit defines whether a corresponding downstream port has a removable device. When cleared the attached device is removable. When set the attached device is not removable. Bit 0: reserved, bit 1 : Device attached to port #1, &, bit 15: Device attached to port #15	RW	0x0000

HCIVERSION																RESERVED								CAPLENGTH							

Bits	Field Name	Description	Type	Reset
31:16	HCIVERSION	Interface version number It contains a BCD encoding of the EHCI revision number supported by this host controller. [7:4] Major revision [3:0] Minor revision	R	0x0100
15:8	RESERVED	Reserved.	R	0x00
7:0	CAPLENGTH	Capability register length.	R	0x10

20.2.6.7.2 HCSPARAMS

Table 20-190. HCSPARAMS

Address Offset	0x0000 0004		
Physical Address	0x4806 4804	**Instance**	EHCI
Description	Host Controller Structural Parameters		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												RESERVED			P_INDICATOR	N_CC				N_PCC				PRR	RESERVED		PPC	N_PORTS			

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of Companion Controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: there are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.	R	0x1
11:8	N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port Routing Rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.	R	0
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port Power control This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches.	R	1
3:0	N_PORTS	Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

20.2.6.7.3 HCCPARAMS

Table 20-191. HCCPARAMS

Address Offset	0x0000 0008

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Reserved	R	0x00
23:16	ITC	Interrupt Threshold Control This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. 0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined	RW	0x08
15:12	RESERVED	Reserved	R	0x0
11	ASPME	Asynchronous Schedule Park Mode Enable 0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous Schedule Park Mode Count It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0x1 to 0x3. **The software must not write a 0 to this bit when Park Mode Enable is a 1 as this may result in undefined behavior.**	RW	0x3
7	LHCR	Light Host Controller Reset It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0

Bits	Field Name	Description	Type	Reset
6	IAAD	Interrupt on Asynchronous Advance Doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Write 0x1: Ring the doorbell. Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0
5	ASE	Asynchronous Schedule Enable This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule. 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule.	RW	0
4	PSE	Periodic Schedule Enable This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule. 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule.	RW	0
3:2	FLS	Frame List Size This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list vurrent index. 0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved	RW	0
1	HCR	Host Controller Reset This control bit is used by software to reset the host controller. Write 0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values. This bit is set to 0 by the host controller when the reset process is complete.	W	0
0	RS	Run/stop 0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. 0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts.	RW	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ASS	PSS	REC	HCH	RESERVED				IAA	HSE	FLR	PCD	USBEI	USBI		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	Asynchronous Schedule Status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled.	R	0
14	PSS	Periodic Schedule Status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_i[6] FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_i[13] PO bit.	RW	0
1	USBEI	USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt	RW	0

Bits	Field Name	Description	Type	Reset
		The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).

General-Purpose Interface

This chapter describes the general-purpose interface.

Topic **Page**

21.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pull up/down control, open-drain feature). For more information, see Chapter 6, *System Control Module*.

21.1.1 Global Features

The GPIO modules include the following global features:

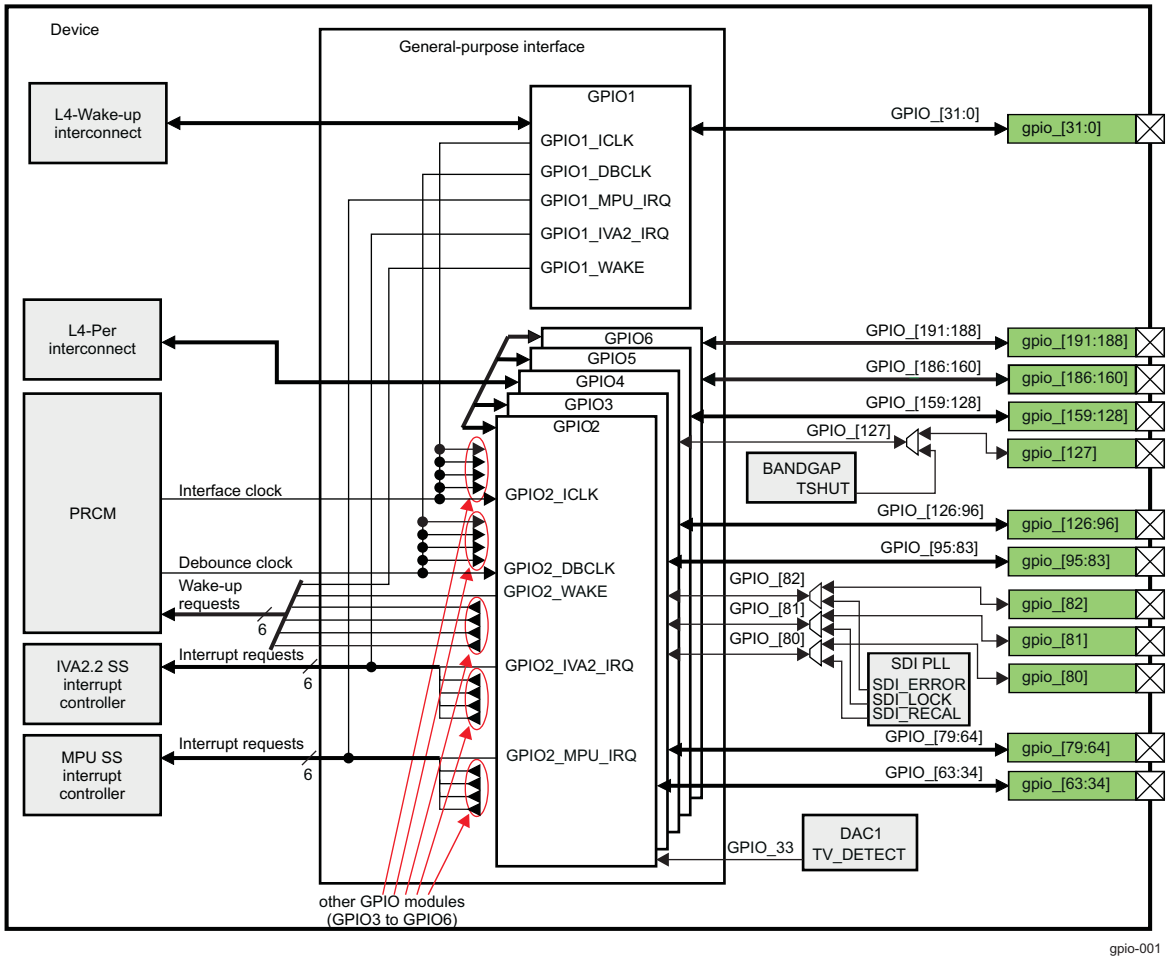
- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller and the other on the MPU subsystem interrupt controller.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Figure 21-1 shows an overview of the general-purpose interface.

Figure 21-1. General-Purpose Interface Overview



Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQENABLE1
- GPIOi.GPIO_IRQENABLE2
- GPIOi.GPIO_WAKEUPENABLE

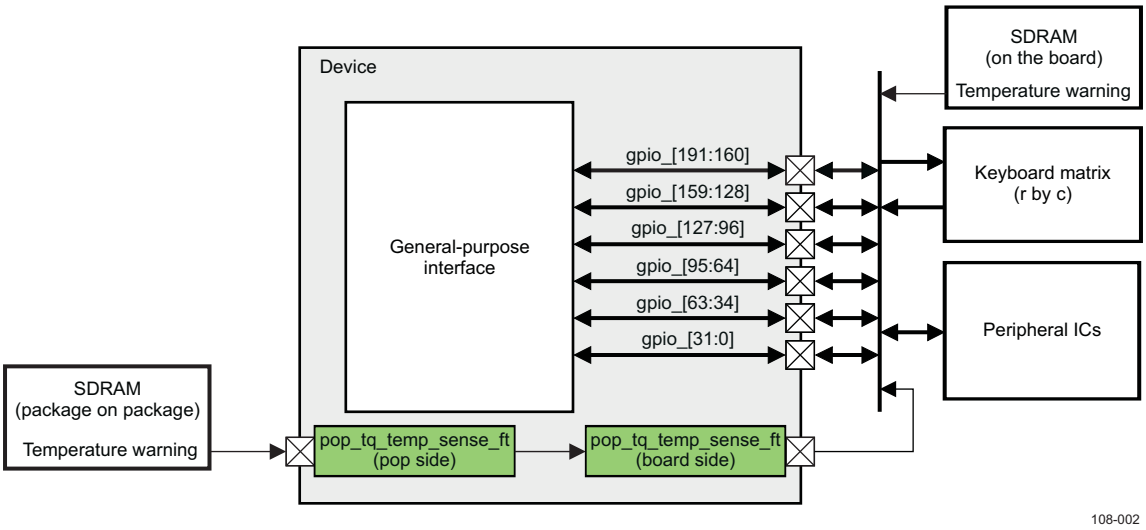
For these registers, the modules implement the set-and-clear protocol register update (see Section 21.5.2, *Set-and-Clear Instructions*).

21.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 21-2 shows a typical application using the general-purpose interface.

Figure 21-2. General-Purpose Interface Typical Application System Overview



NOTE: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the pop_tq_temp_sense_ft ball and a GPIO input. To do this, pop_tq_temp_sense_ft is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

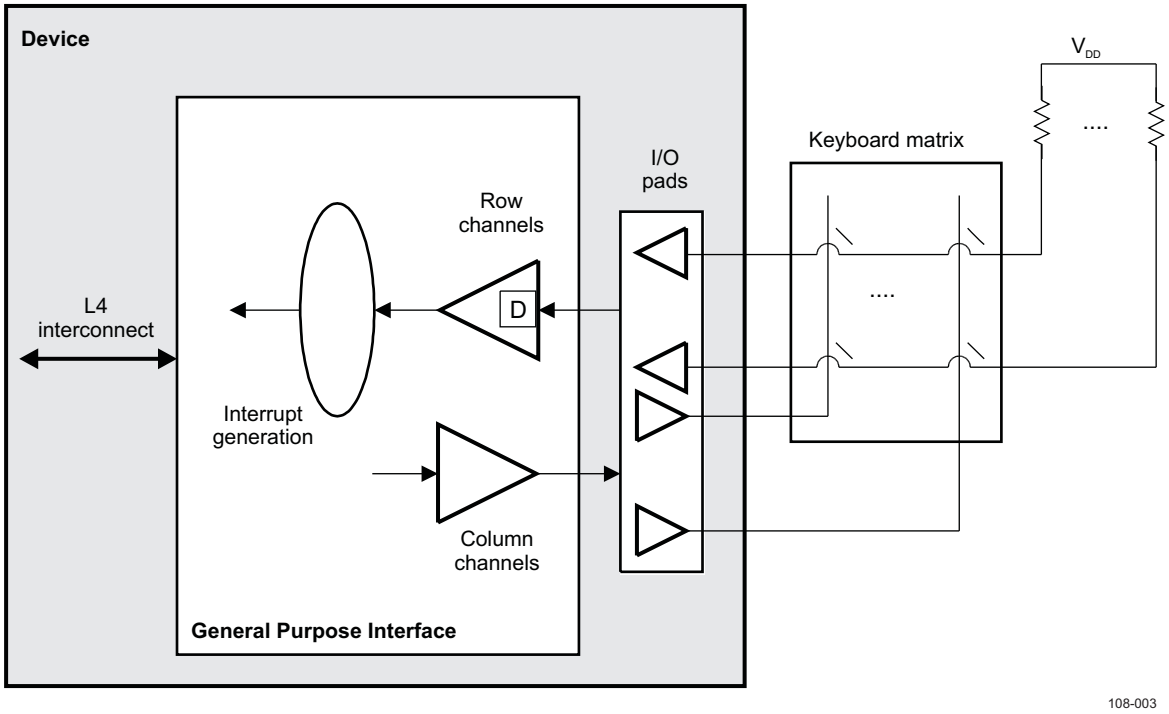
Due to buffer strength, an external serial resistor must be connected to the balls where gpio_120 through gpio_129 are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

21.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix (r * c). Figure 21-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 21-3. General-Purpose Interface Used as a Keyboard Interface



When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 21.5.3, *Interrupt and Wakeup*).

When the keyboard interrupt is received, the processor (MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

21.2.2 General-Purpose Interface Functional Interfaces

21.2.2.1 General-Purpose Interface Pins

Table 21-1 lists the interface pins of the general-purpose interface.

Table 21-1. I/O Pin Description

Signal Name	I/O[1][2]	Description[3][2]	Reset Value
gpio_[31:0]	I/O	GPIO in configuration mode 4.	HiZ

gpio_[191:188]	I/O	GPIO in configuration mode 4.	HiZ

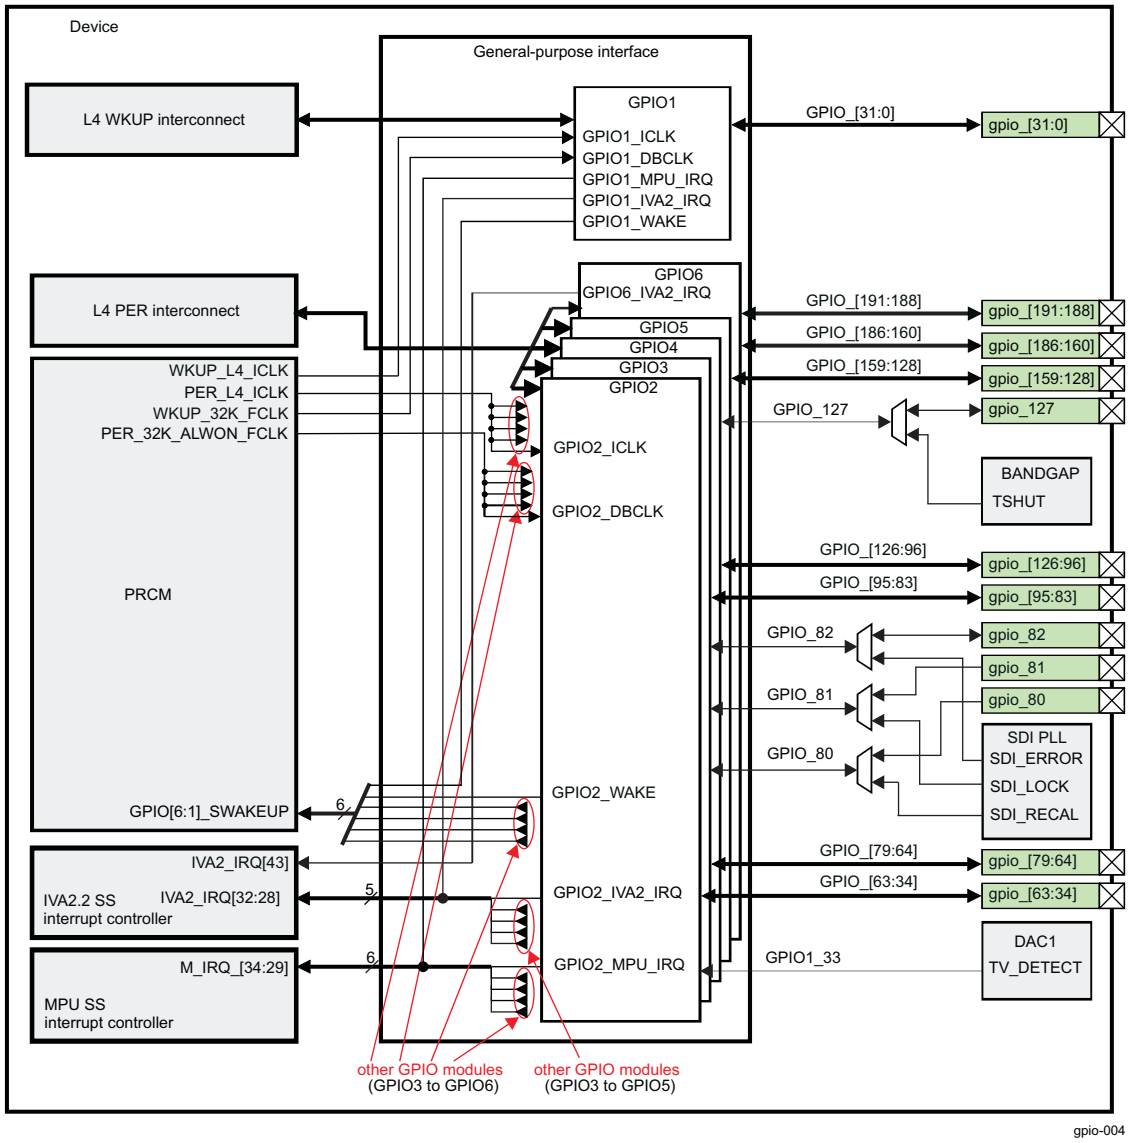
(1) I = Input, O = Output
(2) Some of the pins have special or restricted use. For more information, see Table 21-5.
(3) See Chapter 6, *System Control Module*, for more information about pin configuration modes.

21.3 General-Purpose Interface Integration

21.3.1 Description

Figure 21-4 highlights the general-purpose interface integration in the device.

Figure 21-4. General-Purpose Interface Integration Overview



21.3.1.1 Clocking, Reset, and Power-Management Scheme

21.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, GPIOi_DBCLK, (where i = 1, 2, 3, 4, 5, and 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

  For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_FCLKEN_PER (0: disabled, 1: enabled the clock). For GPIO1, this clock is controlled by EN_GPIO1 bit PRCM.CM_FCLKEN_WKUP[3] (0: disabled, 1: enabled the clock) for GPIO1.

- Interface clock: The interface clock, GPIOi_ICLK (where i = 1, 2, 3, 4, 5, and 6), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

  For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_ICLKEN_WKUP[3] (0: disabled, 1:enabled the clock) and AUTO_GPIO1 bit PRCM.CM_AUTOIDLE_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_ICLKEN_PER (0: disabled, 1: enabled the clock) and AUTO_GPIOi (where i = 2 to 6) bit PRCM.CM_AUTOIDLE_PER (enables/disables automatic control of the interface clock). Table 25-2 describes the GPIO module clocks.

Table 21-2. Clocks

Attribute	Frequency	Name	Mapping	Comments
Debounce clock	32 KHz	GPIOi_DBCLK, where I = 2 to 6	PER_32K_ALWON_FCLK	Source is PRCM module.
		GPIO1_DBCLK	WKUP_32K_CLK	
Interface clock	Depends on PRCM registers settings	GPIOi_ICLK, where I = 2 to 6	PER_L4_ICLK	
		GPIO1_ICLK	WKUP_L4_ICLK	

21.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO6 modules are attached to the PER_RST reset domain. The GPIO1 module is attached to the WKUP_RST reset domain.

  The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the RESETDONE bit GPIOi.GPIO_SYSSTATUS[0] monitors the internal reset status; it is set when the reset completes. For more information, see , *Power, Reset, and Clock Management*.
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one module or more.

  Writing 1 to SOFTRESET bit GPIOi.GPIO_SYSCONFIG[1](where i = 1, 2, 3, 4, 5, or 6) resets the module. Bit value 1 remains until the reset is complete. When the software reset is complete, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE is cleared during a software reset. This bit is set to 1 when the software reset is complete.

21.3.1.1.3 Power Domain

The GPIO1 module is attached to the WKUP power domain (see , *Power, Reset, and Clock Management*). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. The GPIO2 to GPIO6 modules are attached to the PER power domain (see , *Power, Reset, and Clock Management*). The PER power domain is not active continuously.

21.3.1.1.4 Power Management

21.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6) are sideband signals between the PRCM module and the general-purpose interface (see Section 21.3.1.2, *Hardware Requests*).

21.3.1.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

  If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

The idle and inactive modes are configured within the module and activated on request by the PRCM module (see , *Power, Reset, and Clock Management*) through sideband signals (see Section 21.3.1.1.4.3, *System Power Management and Wake-up*).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO_CTRL[0] DISABLEMODULE bit (0: the module is enabled and clocks are not gated; 1: the module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

21.3.1.1.4.3 System Power Management and Wake-Up

The PRCM module can require the GPIO modules to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see Figure 21-4 and Section 21.3.1.2, *Hardware Requests*): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode (recommended)

  When the GPIO module is configured in smart-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: PRCM.CM_FCLKEN_ WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_ GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared) ; and there is no access to GPIO.GPIO_DEBOUNCINGTIME register pending to be synchronized.

  Idle acknowledge is then asserted and the module enters in idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

  Idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

  When the expected transition occurs on an enabled GPIO input pin, the GPIO module exits from idle

mode, if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled), and the corresponding bit in the PRCM.PM_WKEN_PER register is also set to 1 for the GPIO2 to GPIO6 modules, and/or the PRCM.PM_WKEN_WKUP[3] EN_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

  When the GPIO module is configured in force-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [00]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_ WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_ GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

  When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

  When the GPIO module is configured in no-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [01]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_ WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0 or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_ GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module does not go to the idle mode and the idle acknowledge is never sent.

NOTE: The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM_IDLEST_PER register (0: active, 1: idle) and is idle only when the GPIO2 to GPIO6 modules are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM_IDLEST_WKUP[3] ST_GPIO1 bit (0: idle, 1: active) and is idle only when the GPIO1 module is configured in smart-idle mode and has asserted its idle acknowledge.

The GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM_WKST_PER register (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM_WKST_WKUP[3] ST_GPIO1 bit (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

21.3.1.1.4.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in register is not accessed.
- Clock gating for the event detection logic: EachGPIO module implements four clock groups used for the logic in the synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see Section 21.5.1, *Power Saving by Grouping the Edge/Level Detection*). All channels are also gated using a one-out-of-N scheme. N is the GATINGRATIO field GPIOi.GPIO_CTRL[2:1] and can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and

this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

  The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

21.3.1.2 Hardware Requests

21.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Table 21-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU subsystem and IVA2.2 subsystem interrupt cont

Table 21-3. Interrupts

Name	Mapping	Comments
GPIO1 Module		
GPIO1_MPU_IRQ	M_IRQ_29	Destination is the MPU subsystem interrupt controller.
GPIO1_IVA2_IRQ	IVA2_IRQ[28]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO2 Module		
GPIO2_MPU_IRQ	M_IRQ_30	Destination is the MPU subsystem interrupt controller.
GPIO2_IVA2_IRQ	IVA2_IRQ[29]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO3 Module		
GPIO3_MPU_IRQ	M_IRQ_31	Destination is the MPU subsystem interrupt controller.
GPIO3_IVA2_IRQ	IVA2_IRQ[30]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO4 Module		
GPIO4_MPU_IRQ	M_IRQ_32	Destination is the MPU subsystem interrupt controller.
GPIO4_IVA2_IRQ	IVA2_IRQ[31]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO5 Module		
GPIO5_MPU_IRQ	M_IRQ_33	Destination is the MPU subsystem interrupt controller.
GPIO5_IVA2_IRQ	IVA2_IRQ[32]	Destination is the IVA2.2 subsystem interrupt controller.
GPIO6 Module		
GPIO6_MPU_IRQ	M_IRQ_34	Destination is the MPU subsystem interrupt controller.
GPIO6_IVA2_IRQ	IVA2_IRQ[43]	Destination is the IVA2.2 subsystem interrupt controller.

21.3.1.2.1.1 Wake-Up Generation

The GPIO1 module of the general-purpose interface is attached to the WKUP power domain (see , *Power, Reset, and Clock Management)* and can wake up the system.

NOTE: The GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio_1, gpio_9, gpio_10, gpio_11, gpio_30, and gpio_31 can be used to generate a direct wake-up event. The other GPIO1 pins cannot be used to generate a direct wake-up event because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is off, the I/O pins of the GPIO1 module, which are supplied by VDD2, cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_WAKEUPENABLE register (where i = 1, 2, 3, 4, 5, and 6).

CAUTION

The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

Table 21-4 shows the wake-up signals mapping.

Table 21-4. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

Table 21-5 describes the GPIO channels.

Table 21-5. GPIO Channel Description

Channel Number	Type (1)	Mapping	Wake-Up Feature	Comments
GPIO1 Module				
[31:0]	I/O	gpio_[31:0]	Yes	GPIO (2)
GPIO2 Module				
[0]	I	-	No	Not available on external balls. Read value is always 0.
[1]	I	TV_DETECT	Yes (3)	Internal TV detection signal from the 10-bit composite/luma video DAC1
[31:2]	I/O	gpio_[63:34]	Yes (3)	GPIO (2)
GPIO3 Module				
[15:0]	I/O	gpio_[79:64]	Yes (3)	GPIO (2)
[16]	I/O	gpio_80	Yes (3)	GPIO (2)
	I	SDI_RECAL	Yes (3)	Internal SDI_RECAL signal from the SDI PLL module (4)
[17]	I/O	gpio_81	Yes (3)	GPIO (2)
	I	SDI_LOCK	Yes (3)	Internal SDI_LOCK signal from the SDI PLL module (4)
[18]	I/O	gpio_82	Yes (3)	GPIO (2)

(1) I = Input, O = Output
(2) Configuration mode 4. See Chapter 6, *System Control Module*.
(3) Only when the PER power domain is active
(4) All configuration modes except configuration mode 4. See Chapter 6, *System Control Module*.

Table 21-5. GPIO Channel Description (continued)

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
	I	SDI_ERROR	Yes [3]	Internal SDI_ERROR signal from the SDI PLL module [4]
[31:19]	I/O	gpio_[95:83]	Yes [3]	GPIO [2]
GPIO4 Module				
[30:0]	I/O	gpio_[126:96][5]	Yes [3]	GPIO [2]
[31]	I/O	gpio_127	Yes [3]	GPIO [2]
	I	TSHUT	Yes [3]	Internal TSHUT signal from the BANDGAP module for the SRAMs LDOs [4]
GPIO5 Module				
[31:0]	I/O	gpio_[159:128]	Yes [3]	GPIO [2]
GPIO6 Module				
[26:0]	I/O	gpio_[186:160]	Yes [3]	GPIO [2]
[27]	I	-	No	Not available on external balls. Read value is always 0.
[31:28]	I/O	gpio_[191:188]]	Yes [3]	GPIO [2]

[5] All signals are I/O type, except gpio_99, gpio_100, gpio_112, gpio_113, gpio_114, and gpio_115, which are input-only signals.

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is high during normal operation and goes low during a thermal shutdown event. When channel 31 of the GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; see Chapter 6, *System Control Module*, for more information about pin configuration), TSHUT is connected to channel 31 of the GPIO4, and an interrupt can be generated when a high-to-low transition occurs on TSHUT whether or not the interrupt generation for channel 31 of the GPIO4 is correctly configured.

21.4 General-Purpose Interface Functional Description

Figure 21-5 shows the general-purpose interface description.

Figure 21-5. General-Purpose Interface Description

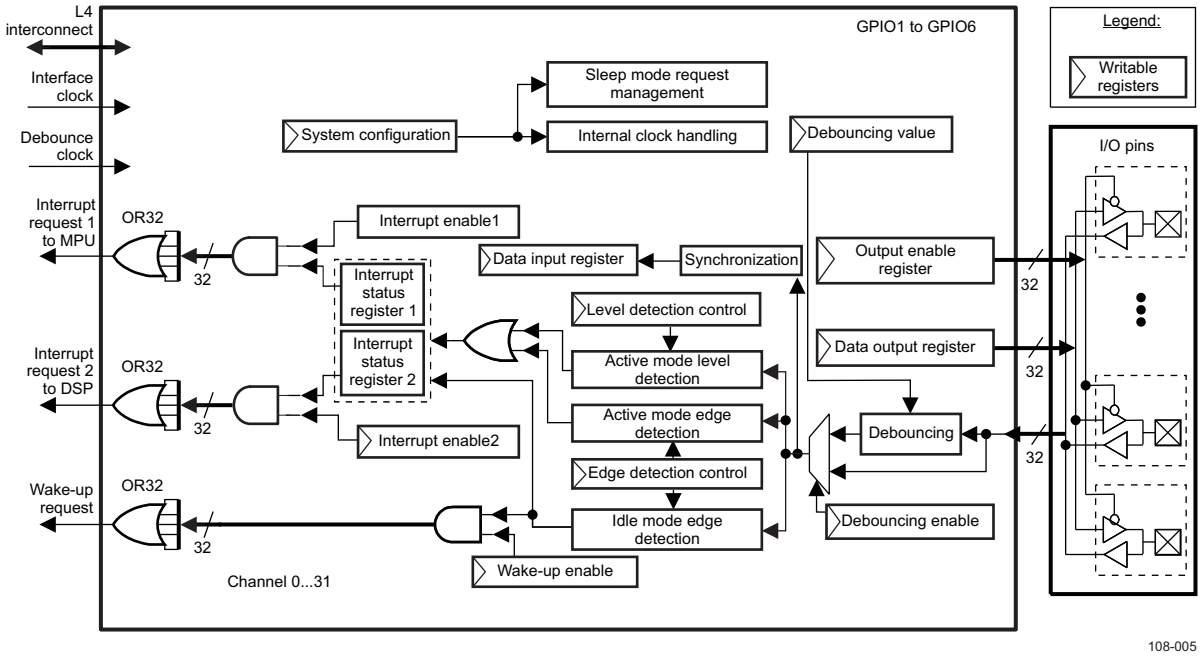


Figure 21-5 details the GPIO modules in the general-purpose interface block diagram with their configuration registers and their main functional paths:

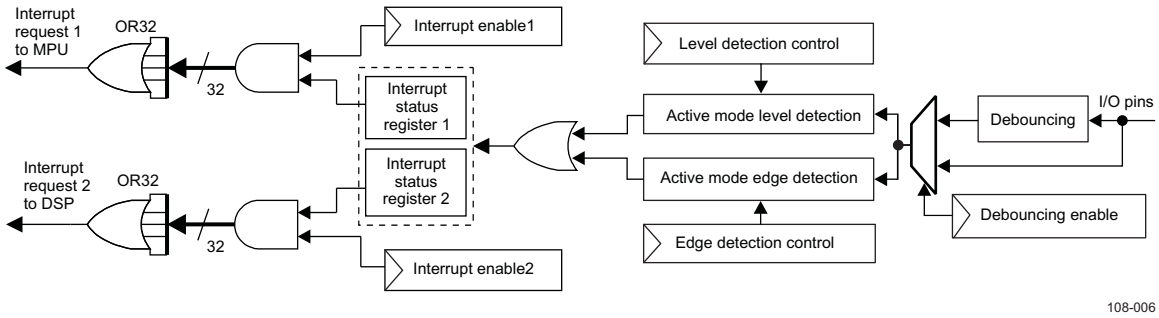
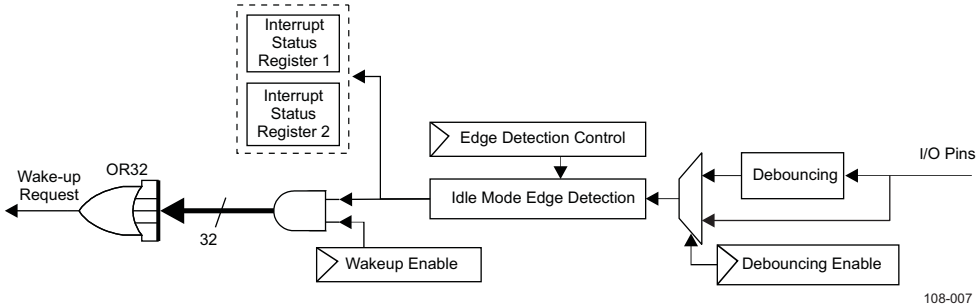
- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2). See Figure 21-6.

Figure 21-6. Synchronous Path



- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wake-up enable register. See Figure 21-7.

Figure 21-7. Asynchronous Path



- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

21.4.1 Interrupt and Wake-Up Features

21.4.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU subsystem) and GPIOi_IVA2_IRQ (used by the IVA2.2 subsystem), where i = 1, 2, 3, 4, 5, and 6.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt enable (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) and interrupt status (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) registers. The interrupt enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 21.5.3, *Interrupt and Wakeup*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 21.3.1.1.4.4, *Module Power Saving*). When an event matches the programmed settings (see Section 21.5.3, *Interrupt and Wakeup*), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals *N* times the interface clock period; see Section 21.3.1.1.4.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

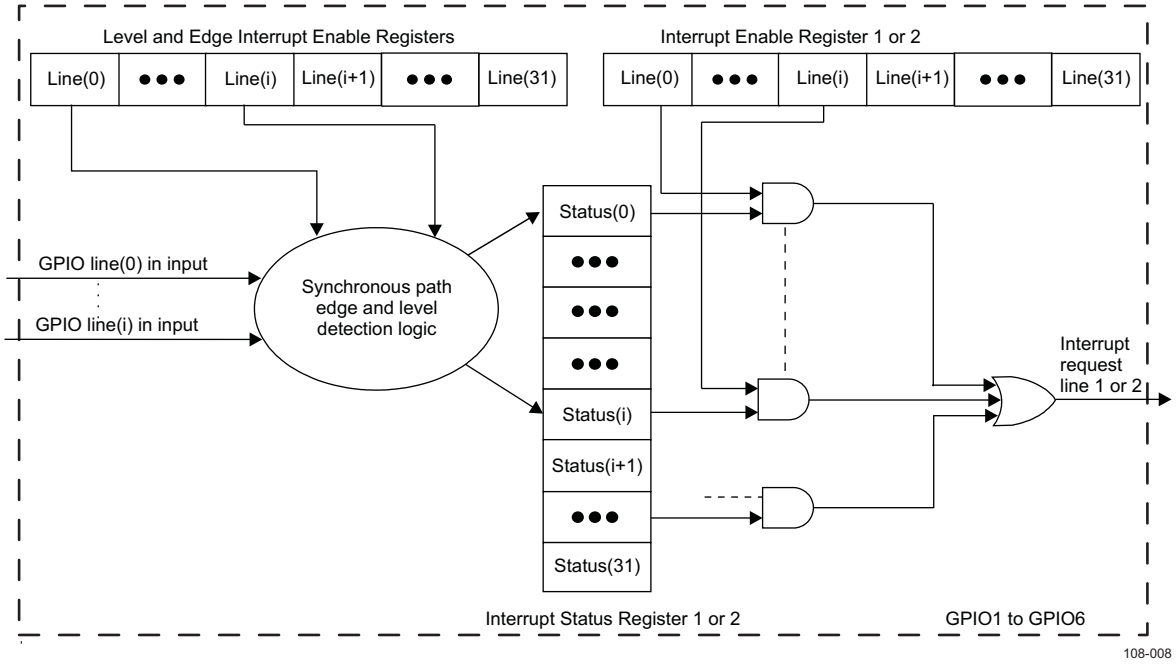
When the debounce feature is active, the latency depends on the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) value (see Section 21.5.5, *Debouncing Time*) and is less than three internally gated interface clock cycles + two interface clock cycle + GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles + three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.

Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Figure 21-8 shows an overview of the interrupt request generation.

Figure 21-8. Interrupt Request Generation



21.4.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up enable register (GPIOi.GPIO_WAKEUPENABLE) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 21.5.3, *Interrupt and Wakeup*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6), if the wake-up enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

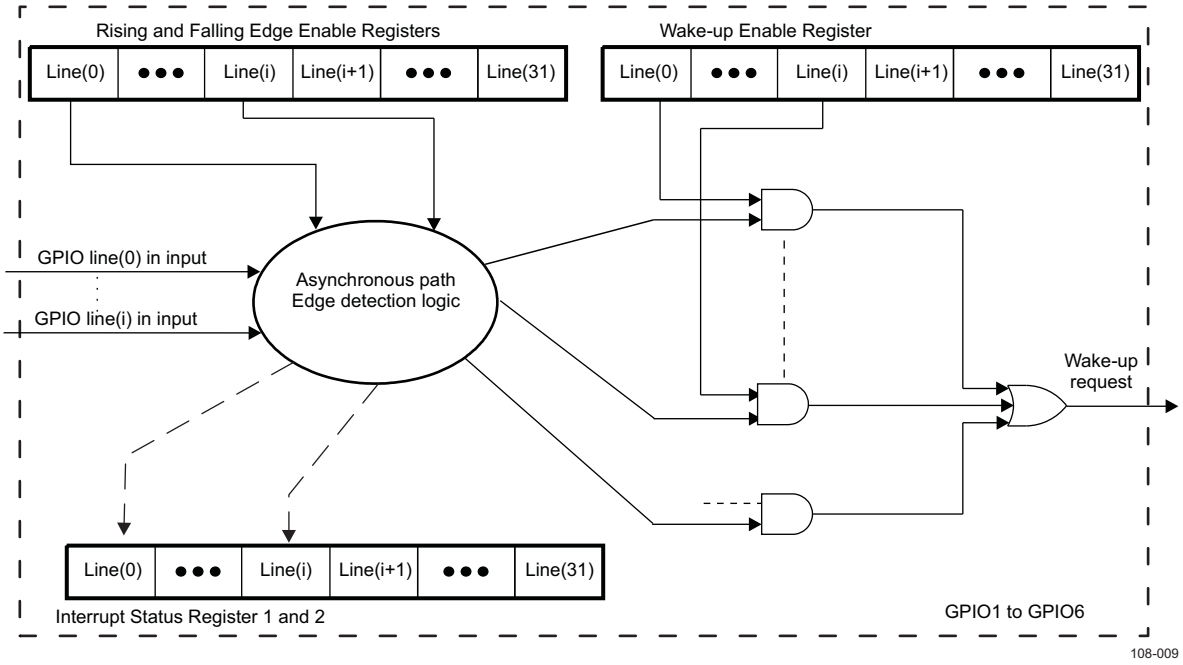
NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wake-up enable register (GPIOi.GPIO_WAKEUPENABLE) has no effect.

Figure 21-9 shows an overview of the wake-up request generation.

Figure 21-9. Wake-Up Request Generation



21.4.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt status register. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

21.5 General-Purpose Interface Basic Programming Model

21.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

GPIOi.GPIO_LEVELDETECT0
GPIOi.GPIO_LEVELDETECT1
GPIOi.GPIO_RISINGDETECT
GPIOi.GPIO_FALLINGDETECT

are set to 0x01 01 01 01, then all clocks are active (power consumption is high).

are set to 0x00 00 00 FF, then a single clock is active (power saving).

NOTE: When the clocks are enabled by writing to the GPIOi.GPIO_LEVELDETECT0, GPIOi.GPIO_LEVELDETECT1, GPIOi.GPIO_RISINGDETECT, and GPIOi.GPIO_FALLINGDETECT registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

21.5.2 Set-and-Clear Instructions

21.5.2.1 Description

The GPIO module implements the set-and-clear protocol register update for the GPIOi.GPIO_DATAOUT, GPIOi.GPIO_IRQENABLE1, GPIOi.GPIO_IRQENABLE2, and GPIOi.GPIO_WAKEUPENABLE registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

21.5.2.2 Clear Instruction

21.5.2.2.1 Clear Registers Addresses

Clear interrupt enable registers (GPIOi.GPIO_CLEARIRQENABLE1 and GPIOi.GPIO_CLEARIRQENABLE2).

A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register

Clear wake-up enable register (GPIOi.GPIO_CLEARWKUENA).

A write operation in the clear wake-up enable register clears the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wake-up enable register returns the value of the wake-up enable register.

Clear data output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

21.5.2.2.2 Clear Instruction Example

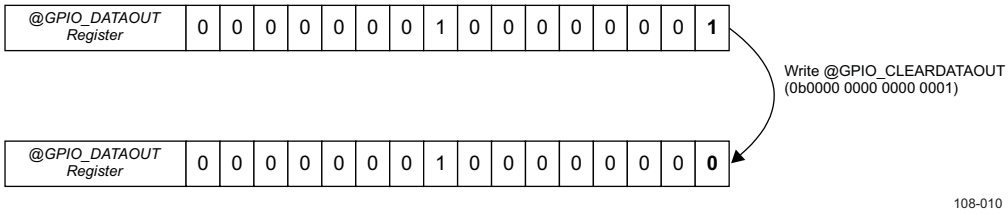
Assume the data output register (or one of the interrupt/wake-up enable register) contains the binary value, 0b0000 0001 0000 0001, and you want to clear the bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wake-up enable register). After this write operation, a reading of the data output register (or the interrupt/wake-up enable register) returns 0b0000 0001 0000 0000; the bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 21-10 shows an example of a clear instruction.

Figure 21-10. Write @GPIO_CLEARDATAOUT Register Example



21.5.2.3 Set Instruction

21.5.2.3.1 Set Registers Addresses

Set interrupt enable registers (GPIOi.GPIO_SETIRQENABLE1 and GPIOi.GPIO_SETIRQENABLE2).

A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

Set wake-up enable register (GPIOi.GPIO_SETWKUENA).

A write operation in the set wake-up enable register sets the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wake-up enable register returns the value of the wake-up enable register.

Set data output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

21.5.2.3.2 Set Instruction Example

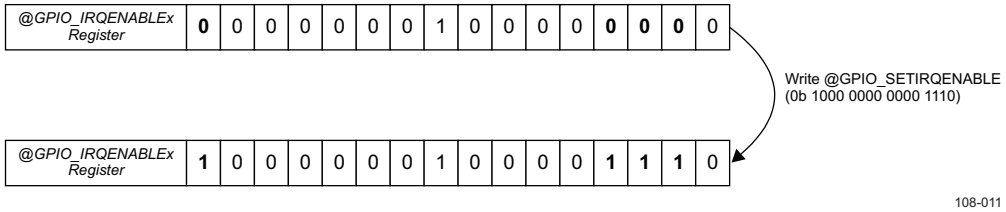
Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set the bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; the bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 21-11 shows an example of a set instruction.

Figure 21-11. Write @GPIO_SETIRQENABLEx Register Example



The set wake-up enable register offers the same feature with the wake-up enable register.

21.5.3 Interrupt and Wakeup

21.5.3.1 Involved Configuration Registers

- Interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2)

  The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt enable registers are programmed synchronously with the interface clock.

  These registers can be accessed with direct read/write operations or using the alternate set and clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt enable1 (or interrupt enable2) registers (or to the clear interrupt enable1 [or interrupt enable2] registers) address (see Section 21.5.2, *Set-and-Clear Instructions*).

- Wake-up enable register (GPIOi.GPIO_WAKEUPENABLE)

  The wake-up enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

  This register can be accessed with direct read/write operations or by using the alternate set and clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wake-up enable register (or to the clear wake-up enable register) address (see Section 21.5.2, *Set-and-Clear Instructions*).

  NOTE: It must be a correlation between Wake-up enable and interrupt enable registers. If a GPIO pin has a Wake-up configured on it, it should also have the corresponding interrupt enabled (on one of the 2 interrupt lines). Otherwise, it is possible to have a Wake-up event, but after exiting the Idle state, no interrupt will be generated, thus the corresponding bit from the interrupt status register will not be cleared, and the module will not acknowledge a future Idle Request.

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2)

  The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).

  When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wake-up). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected via an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO module is awake.

NOTE: The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

21.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or DSP subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt enable register (write 1or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT0), and/or high-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT1), and/or rising-edge interrupt/wake-up enable register (write 1or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT), and/or falling edge interrupt/wake-up enable register (write 1or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT).

   NOTE: Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rinsing detect enabling register (GPIOi.GPIO_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO_FALLINGDETECT) along with the interrupt enable by setting the corresponding bit to 1 in on one or both interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

   Enabling at the same time high level detection and low level detection for one given pin makes a constant interrupt generator.

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE2 register).

To configure a GPIO module to sent a wake-up request to the PRCM at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT) and/or falling-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT). The wake-up request can only be generated on edge transitions.
3. The GPIO channel must be enabled in the wake-up enable register (write 1 to the corresponding bit of the GPIOi.GPIO_WAKEUPENABLE).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must enable for the module (write 1 to the corresponding bit of the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP) .

CAUTION

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in Chapter 6 , *System Control Module*.

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt status register) before enabling an interrupt for the GPIO channel in the interrupt enable register (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

21.5.4 Data Input (Capture)/Output (Drive)

The output enable register (GPIOi.GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see Section 21.5.2, *Set-and-Clear Instructions*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_ WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers.

When configured as an input (the desired bit set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see Section 21.5.2, *Set-and-Clear Instructions*). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers to the interrupt and wake-up feature as needed.

21.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register)
2. The deboucing time must be set in the deboucing time register (GPIOi.GPIO_DEBOUNCINGTIME)

   The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

   The following formula describes the required input stable time to be propagated to the debounced output:

   Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVAL field value + 1) x 31 µs.

   where GPIOi.GPIO_DEBOUNCINGTIME[7:0] field DEBOUNCVAL value is from 0 to 255.
3. The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding bit of the GPIOi.GPIO_DEBOUNCENABLE register)

21.6 General-Purpose Interface Register Manual

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

Table 21-6 shows the base address and address space for the GPIO module instances.

Table 21-6. Instance Summary

Module Name	Base Address	Size
GPIO1	0x4831 0000	4K bytes
GPIO2	0x4905 0000	4K bytes
GPIO3	0x4905 2000	4K bytes
GPIO4	0x4905 4000	4K bytes
GPIO5	0x4905 6000	4K bytes
GPIO6	0x4905 8000	4K bytes

21.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 21-7 through Table 21-8 describe the GPIO register offset addresses.

Table 21-7. GPIO1 to GPIO3 Register Summary

The write latency for all the R/W registers is immediate (with respect to the interface clock)

NOTE: When two write accesses in the GPIOi.GPIO_DEBOUNCINGTIME register are performed in less than two debounce clock cycles (32 kHz) + four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, one bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

21.6.2 Register Descriptions

Table 21-9 through Table 21-59 describe the register bits.

Ethernet Media Access Controller (EMAC)/ Management Data Input/Output (MDIO) Module

22.1 Introduction

This document provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the device. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC subsystem module and is considered integral to the EMAC/MDIO peripheral.

22.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

22.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbit operation.
- CBA3.1 compliant DMA controllers with VBUSP data transfers.
- Selectable RMII Interface.
- Hardware Error handling including CRC.
- Little and Big Endian Support.
- Eight receive channels with VLAN tag discrimination for receive hardware QOS support.
- Eight transmit channels with round-robin or fixed priority for hardware QOS support.
- CPPI 3.0 compliant.
- EtherStats and 802.3Stats RMON statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selectable for reception on a single channel.
- Multicast frames selectable for reception on a single channel.
- Promiscuous receive mode selectable for reception on a single channel (all frames, all good frames, short frames, error frames).
- TI Adaptive Performance Optimization for improved half duplex performance.
- Configurable receive address matching/filtering.
- Emulation Support.
- EMAC Loopback Mode.
- 8K (2048 x 32) internal CPPI buffer descriptor memory.
- MDIO module for PHY Management.

- Programmable interrupt control with selected interrupt pacing.

22.1.3 Functional Block Diagram

After reset, initialization, configuration, and auto-negotiation the host may initiate transmit and receive operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the EMAC STATERAM block. The EMAC transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with the CPPI 3.0 protocol.

The EMAC receive DMA controller then writes packets to external memory in accordance with the CPPI 3.0 protocol. The EMAC is in configuration 2 (CFIG2). Configuration 2 is the 10/100 configuration with configurable address matching.

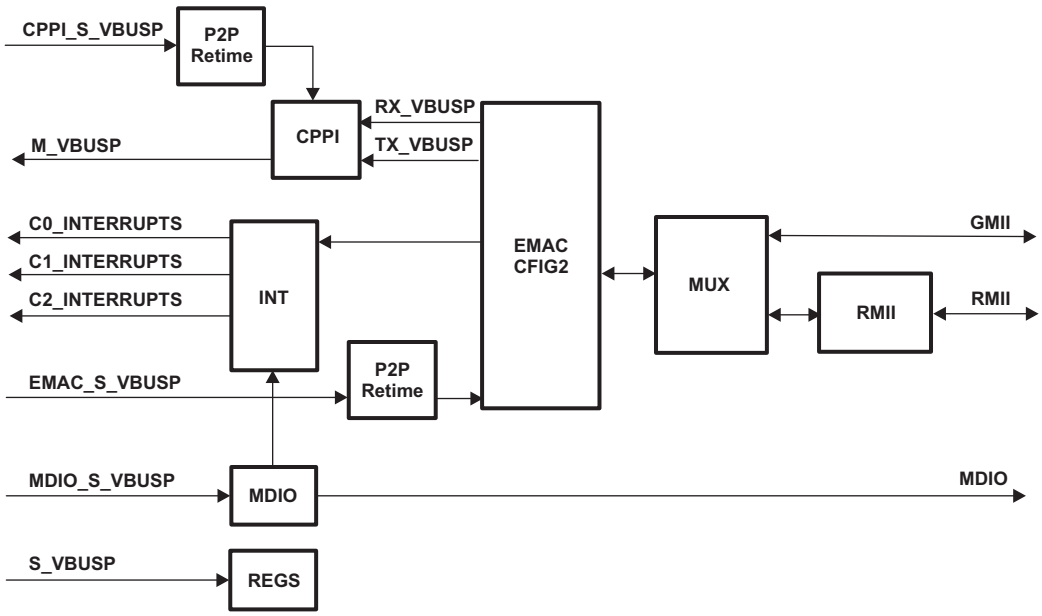
The CPPI block contains a 2048 by 32-bit memory (8K bytes) to be used for transmit and receive buffer descriptors. The CPPI block also contains a CBA 3.1 SCR (Switch Central Resource) to combine the EMAC transmit and receive VBUSP interfaces onto a single master VBUSP interface.

The host configures and initializes the device through the five module slave VBUSP interfaces. The CPPI, REGS, MDIO, and EMAC, modules have slave interfaces. The CPPI and EMAC slave interfaces are input directly to a VBUSP to VBUSP retiming bridge before being input to the switched central resource (SCR) inside the respective modules. The retiming bridges help to minimize long paths.

The SCR handles decode between multiple master/slaves inside the respective modules. The interrupt control block is used to select the interrupts from the EMAC and the MDIO for output to the three CPU's.

The signals required to support gigabit mode are included in the module. However gigabit transfer rates are not supported due to the small 3-cell transmit and receive FIFO's. The upper nibble of the GMII transmit and receive busses can be unused for MII pinout. Also, the RFTCLK input can be tied low for 10/100 operation.

Figure 22-1. EMAC and MDIO Block Diagram



22.1.4 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

22.2 Architecture

This section discusses the architecture and basic function of the EMAC peripheral.

22.2.1 Clock Control

All internal EMAC logic is clocked synchronously on one clock domain.

The MDIO clock is based on a divide-down of the peripheral clock and is specified to run up to 2.5 MHZ (although typical operation would be 1.0 MHz). Because the peripheral clock frequency is variable, the application software or driver must control the divide-down value. Interface clock is running at 166MHz and the VBUSP clock is running at 166MHz.

The clock sources are provided by the external PHY to the RMII reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The RMII interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

22.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is 2K × 32 bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories. There are some tradeoffs in terms of cache performance and throughput when descriptors are placed in the system memory, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

22.2.2.1 CPPI Descriptors

The base address of CPPI descriptors is 5C02 0000h.

The 8K bytes of CPPI memory begin at address 01E2 0000h from the EMAC perspective.

22.2.2.2 EMAC Subsystem Module

The base address of EMAC subsystem is 5C00 0000h.

22.2.2.3 EMAC Module

The base address of EMAC module is 5C01 0000h.

22.2.2.4 MDIO Module

The base address of MDIO module is 5C03 0000h.

22.2.3 Signal Descriptions

22.2.3.1 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (EMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII_RXER on any di-bit in the received packet will cause an MII_RXER assertion to the EMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII_CRS_DV toggle will issue an MII_RXER during the packet to the EMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5d is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMIII_CRS_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

22.2.3.2 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the EMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The EMAC does not source the transmit error (MII TXERR) signal. Any transmit frame from the EMAC with an error (i.e. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII_TXD[1:0] for each clock that RMII_TXEN is deasserted.

22.2.3.3 Reduced Media Independent Interface (RMII) Connections

Figure 22-2 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 22-1. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 22-2. Ethernet Configuration—RMII Connections

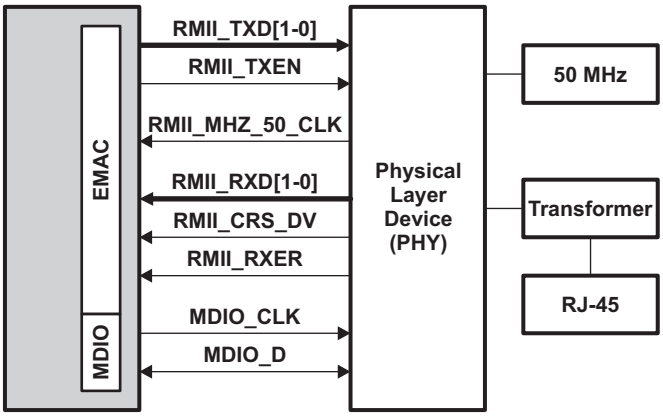


Table 22-1. EMAC and MDIO Signals for RMII Interface

Signal	Type	Description
RMII_TXD[1-0]	O	Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted.

Table 22-1. EMAC and MDIO Signals for RMII Interface (continued)

Signal	Type	Description
RMII_TXEN	O	Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_MHZ_50_CLK	I	RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RMII_RXD[1-0]	I	Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted.
RMII_CRS_DV	I	Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	I	Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_CLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL).
MDIO_D	I/O	Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

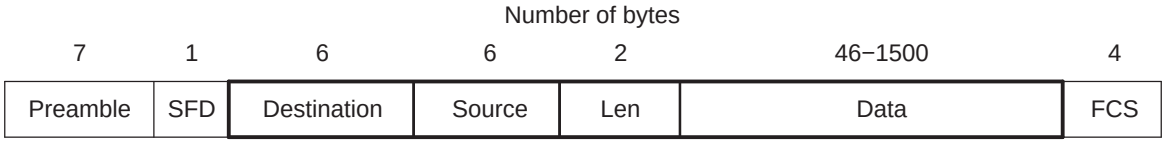
22.2.4 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

22.2.4.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in Figure 22-3 and described in Table 22-2. The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

Figure 22-3. Ethernet Frame Format



Legend: SFD=Start Frame Delimeter; FCS=Frame Check Sequence (CRC)

Table 22-2. Ethernet Frame Description

Field	Bytes	Description
Preamble	7	Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock.
SFD	1	Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data.
Destination	6	Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame.
Source	6	Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network.

Table 22-2. Ethernet Frame Description (continued)

Field	Bytes	Description
Len	2	Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying.
Data	46 to (RXMAXLEN - 18)	Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less then 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS.
FCS	4	Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured.

22.2.4.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

22.2.5 Programming Interface of Packet Descriptors

22.2.5.1 CPPI Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in Figure 22-4 and described in Table 22-3.

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in Figure 22-5.

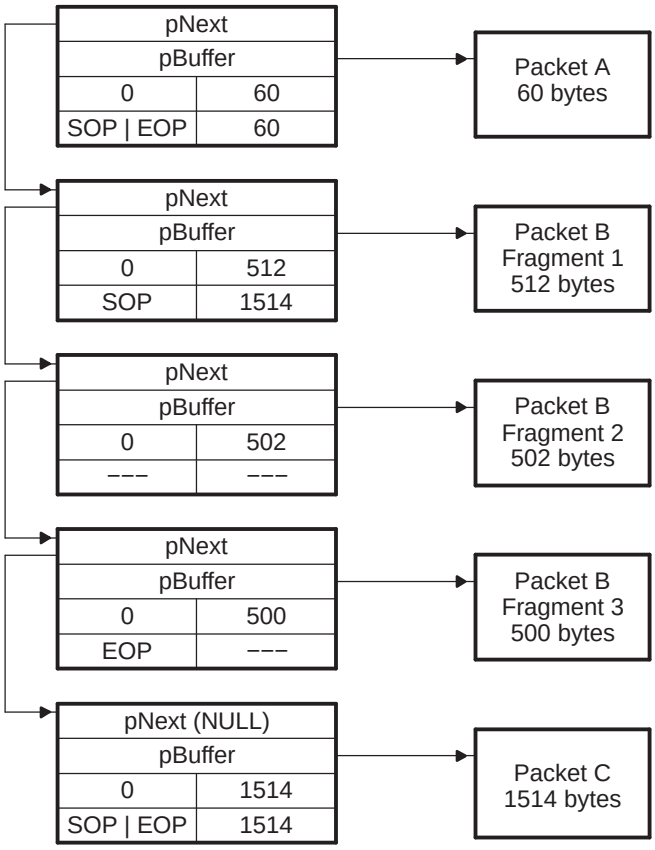
Figure 22-4. Basic Descriptor Format

	Bit Fields	
Word Offset	**31 16**	**15 0**
0	Next Descriptor Pointer	
1	Buffer Pointer	
2	Buffer Offset	Buffer Length
3	Flags	Packet Length

Table 22-3. Basic Descriptor Description

Word Offset	Field	Field Description
0	Next Descriptor Pointer	The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list.
1	Buffer Pointer	The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations.
2	Buffer Offset	The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data.
	Buffer Length	The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer.
3	Flags	The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in Section 22.2.5.4 and Section 22.2.5.5.
	Packet Length	The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers.

Figure 22-5. Typical Descriptor Linked List



22.2.5.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked lists as discussed in Section 22.2.5.1. The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). Since the EMAC supports eight channels for transmit and receive, there are eight head descriptor pointer registers for both transmit and receive. They are:

- TX*n*HDP - Transmit Channel *n* DMA Head Descriptor Pointer Register
- RX*n*HDP - Receive Channel *n* DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its “next” pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its “next descriptor” pointer must be initialized to 0.

The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL “next” pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the “next” pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor’s “next” pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list.

22.2.5.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in Section 22.2.5.1, using the linked list queue mechanism discussed in Section 22.2.5.2.

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

As the EMAC supports eight channels for both transmit and receive, there are eight completion pointer registers for both. They are:

- TX*n*CP - Transmit Channel *n* Completion Pointer (Interrupt Acknowledge) Register
- RX*n*CP - Receive Channel *n* Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

Interrupts in the interrupt control module of EMAC subsystem are routed to three independent interrupt cores which are then mapped to CPU interrupt controllers. The system configuration determines whether or not an active interrupt actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts for the appropriate interrupt core registers are set in the EMAC interrupt control module: C*n*RXEN and C*n*TXEN on core *n*
3. The CPU interrupt controller is configured to accept C*n*_RX_PULSE and C*n*_TX_PULSE interrupts from the interrupt control module of EMAC subsystem

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC subsystem interrupts.

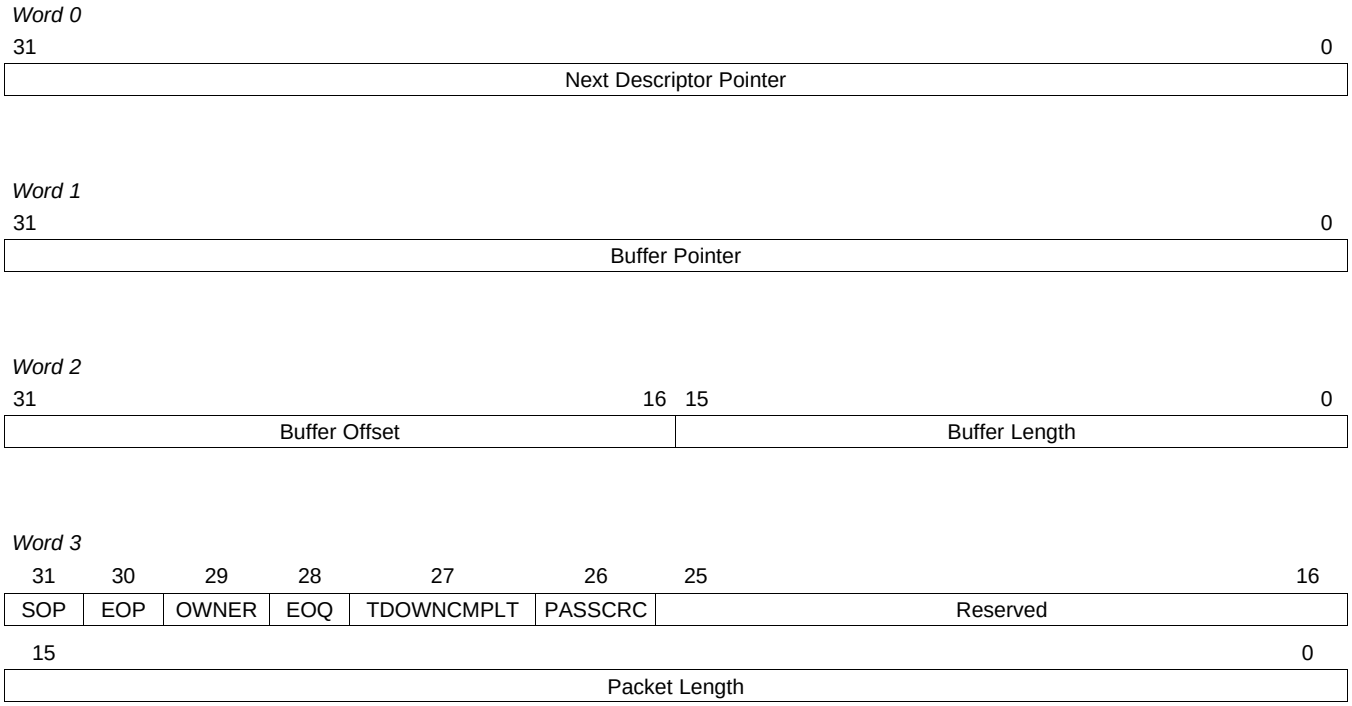
EMAC interrupts are acknowledged when the application software updates the value of TX*n*CP or RX*n*CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.

EMAC module interrupts are acknowledged when the application software writes the appropriate C*n*TX or C*n*RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC interrupt control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

22.2.5.4 CPPI Transmit Buffer Descriptor Format

Transmit buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Tx buffer descriptors provide information about the descriptor data buffer and channel queue. Four words are required, but protocol specific control information may be added by using as many extra words as necessary. Transmit buffer descriptors may be linked together to form packets. Buffer descriptor SOP and EOP bits are used to delimit packets. Packets in turn may be linked together to form transmit queues. Each queue consists of a chain of buffer descriptors linked together by Next Descriptor Pointers. The last buffer descriptor in a queue has a zero Next Descriptor Pointer. Each descriptor points to a data buffer yielding a queue of buffers. Each transmit buffer descriptor contains at least four 32-bit words.

Figure 22-6. Transmit Buffer Descriptor Format



Example 22-1. Transmit Buffer Descriptor in C Structure Format

```
/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
  struct _EMAC_Desc *pNext;     /* Pointer to next descriptor in chain  */
  Uint8             *pBuffer;   /* Pointer to data buffer               */
  Uint32            BufOffLen;  /* Buffer Offset(MSW) and Length(LSW)   */
  Uint32            PktFlgLen;  /* Packet Flags(MSW) and Length(LSW)    */
} EMAC_Desc;
/* Packet Flags                                                        */
#define EMAC_DSC_FLAG_SOP               0x80000000u
#define EMAC_DSC_FLAG_EOP               0x40000000u
#define EMAC_DSC_FLAG_OWNER             0x20000000u
#define EMAC_DSC_FLAG_EOQ               0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT        0x08000000u
#define EMAC_DSC_FLAG_PASSCRC           0x04000000u
```

22.2.5.4.1 Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

22.2.5.4.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

22.2.5.4.3 Buffer Offset

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte–aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

22.2.5.4.4 Buffer Length

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

22.2.5.4.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

22.2.5.4.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

22.2.5.4.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

22.2.5.4.8 Ownership (OWNER) Flag

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

22.2.5.4.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

22.2.5.4.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

22.2.5.4.11 Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

Table 22-4. Tx Buffer Descriptor Word 0

Bits	Name	Description
31:0	Next DescriptorPointer	Next Descriptor Pointer: The 32-bit word aligned memory address of the next buffer descriptor in the Tx queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next Descriptor Pointer.

Table 22-5. Tx Buffer Descriptor Word 1

Bits	Name	Description
31:0	Buffer Pointer	Buffer Pointer: The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer desc. The host sets the Buffer Pointer.

Table 22-6. Tx Buffer Descriptor Word 2

Bits	Name	Description
31:16	Buffer Offset	Buffer Offset: The Buffer Offset indicates how many unused bytes are at the start of the buffer (SOP buffers only). A value of zero indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The Buffer Offset is valid only on Start Of Packet buffer descriptors and must be zero otherwise. The host sets the Buffer Offset. The Buffer Offset must be less than the Buffer Length.
15:0	Buffer Length	Buffer Length: The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer Length.

Table 22-7. Tx Buffer Descriptor Word 3

Bits	Name	Description
31	SOP	Start of Packet: SOP Indicates that the descriptor buffer is the first buffer in the packet. The host sets the SOP bit. 0 = Not start of packet buffer 1 = Start of packet buffer
30	EOP	End of Packet: EOP Indicates that the descriptor buffer is the last buffer in the packet. The host sets the EOP bit. 0 = Not end of packet buffer. 1 = End of packet buffer.
29	Ownership	Ownership: The Ownership bit indicates ownership of the packet and is valid only on SOP. This bit is set by the host and cleared by the port when the packet has been transmitted. The host uses this bit to reclaim buffers. 0 = The packet is owned by the host 1 = The packet is owned by the port
28	EOQ	End Of Queue: The End of Queue bit is set by the port to indicate that all packets in the queue have been transmitted and the Tx queue is empty. This bit is valid only on EOP. 0 = The Tx queue has more packets to transfer. 1 = The port took this descriptor buffer as the last buffer descriptor in the last packet in the queue.
27:16	Protocol Specific	
15:0	Packet Length	Packet Length: The length of the packet in bytes. This field is valid only on SOP and is written by the host. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is a host error.

22.2.5.5 CPPI Receive Buffer Descriptor Format

Receive buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Rx buffer descriptors provide information about the associated data buffer and Rx queue. Four words are required, but protocol specific control information may be added using as many extra words as necessary. The protocol specific control information is valid only on SOP buffers.

Receive buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Rx buffer descriptors provide information about the associated data buffer and Rx queue. Four words are required, but protocol specific control information may be added using as many extra words as necessary. The protocol specific control information is valid only on SOP buffers. Receive buffer descriptors may be linked together to form packets. Buffer descriptor SOP and EOP bits are used to delimit packets. Packets in turn are linked together to form receive queues (although an Rx queue may consist of just one packet). Each queue consists of a chain of buffer descriptors linked together by Next Descriptor Pointers. The last buffer descriptor in a queue has a zero Next Descriptor Pointer. Each descriptor points to a data buffer yielding a queue of buffers. Each receive buffer descriptor contains at least four 32-bit words, as described below:

Table 22-8. Rx Buffer Descriptor Word 0

Bits	Name	Description
31:0	Next DescriptorPointer	Next Descriptor Pointer: The 32-bit word aligned memory address of the next buffer descriptor in the Rx queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. The current buffer is the last buffer in the queue if the value of this pointer is zero. The host sets the Next Descriptor Pointer

Table 22-9. Rx Buffer Descriptor Word 1

Bits	Name	Description
31:0	Buffer Pointer	Buffer Pointer: The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer Pointer.

Table 22-10. Rx Buffer Descriptor Word 2

Bits	Name	Description
31:16	Buffer Offset	Buffer Offset: The Buffer Offset indicates how many unused bytes are at the beginning of the SOP buffer. A value of 0x0000 indicates that there are no unused bytes at the beginning of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000f (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the buffer offset to zero on buffer initialization and the port overwrites the zero value on SOP packets with the Rx DMA State buffer offset value.
15:0	Buffer Length	Buffer Length: The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the buffer length on buffer initialization. The port will overwrite the host initialized value on an EOP buffer when the number of received data bytes is less than the host initiated value. The port will overwrite the host initialized value on SOP when the Buffer Offset is greater than zero, or the Packet Length is less than the buffer length.

Table 22-11. Rx Buffer Descriptor Word 3

Bits	Name	Description
31	SOP	Start of Packet: SOP Indicates that the descriptor buffer is the first buffer in the packet. The host sets the SOP bit. 0 = Not start of packet buffer 1 = Start of packet buffer
30	EOP	End of Packet: EOP Indicates that the descriptor buffer is the last buffer in the packet. The host sets the EOP bit. 0 = Not end of packet buffer. 1 = End of packet buffer.
29	Ownership	Ownership: The Ownership bit indicates ownership of the packet and is valid only on SOP. This bit is set by the host and cleared by the port when the packet has been received. 0 = The packet is owned by the host. 1 = The packet is owned by the port.
28	EOQ	End Of Queue: The End of Queue bit is set by the port to indicate that the queue empty condition exists. This bit is valid only on EOP. 0 = The Rx queue has more buffers available for reception. 1 = The Descriptor buffer is the last buffer in the last packet in the queue.
27:16	Protocol Specific	
15:0	Packet Length	Packet Length: The length of the packet in bytes. This field is valid only on SOP and is written by the port at the end of the packet reception.

22.2.5.5.1 Next Descriptor Pointer

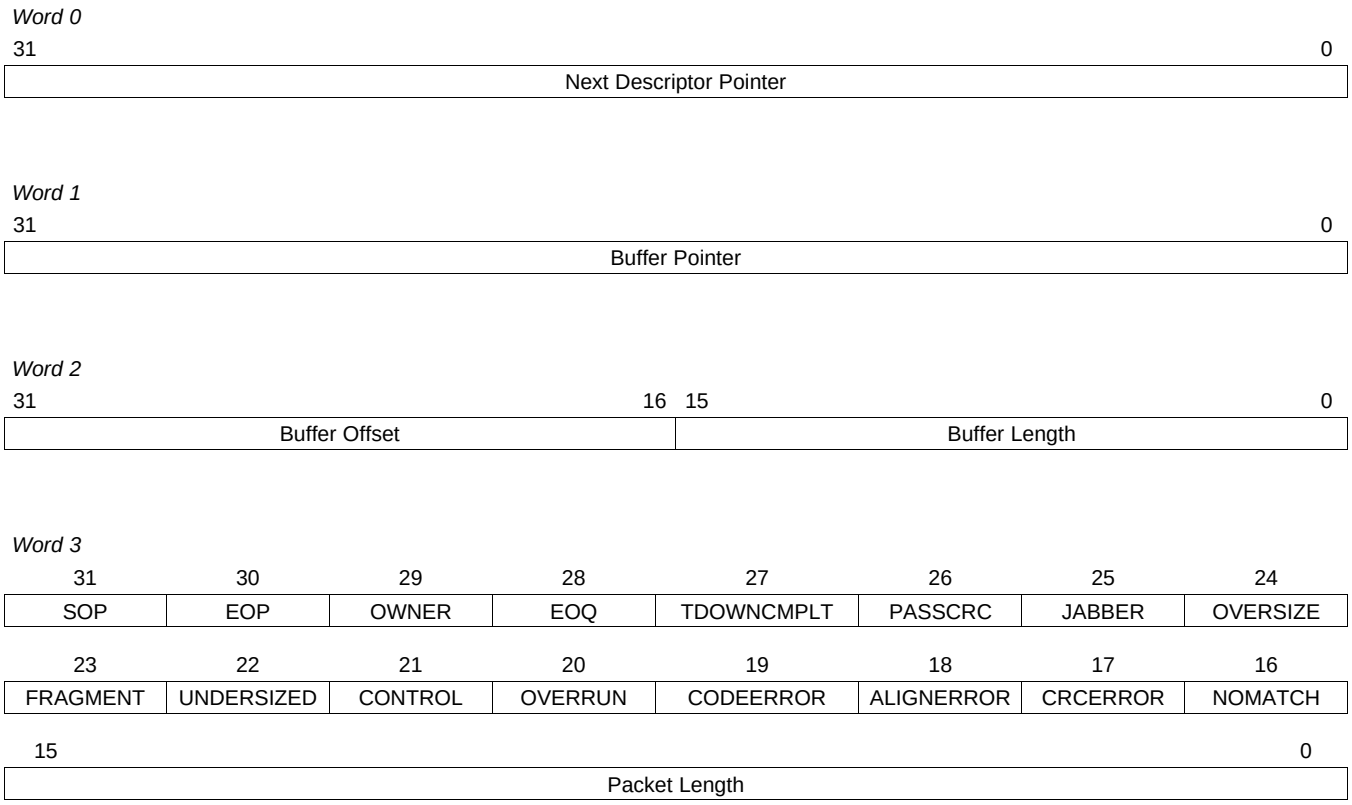
This pointer points to the 32–bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

22.2.5.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

Figure 22-7. Receive Buffer Descriptor Format



Example 22-2. Receive Buffer Descriptor in C Structure Format

```
/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
  struct _EMAC_Desc *pNext;     /* Pointer to next descriptor in chain  *
```

Example 22-2. Receive Buffer Descriptor in C Structure Format (continued)

```
  struct _EMAC_Desc *pNext;     /* Pointer to next descriptor in chain  *
  Uint32            BufOffLen;  /* Buffer Offset(MSW) and Length(LSW)   */
  Uint32
PktFlgLen;  /* Packet Flags(MSW) and Length(LSW)    */
} EMAC_Desc;

/* Packet Flags                                                        */

#define EMAC_DSC_FLAG_OWNER             0x20000000u
#define EMAC_DSC_FLAG_EOQ               0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMPLT        0x08000000u
#define EMAC_DSC_FLAG_PASSCRC           0x04000000u
#define EMAC_DSC_FLAG_JABBER            0x02000000u
#define EMAC_DSC_FLAG_OVERSIZE          0x01000000u
#define EMAC_DSC_FLAG_FRAGMENT          0x00800000u
#define EMAC_DSC_FLAG_UNDERSIZED        0x00400000u
#define EMAC_DSC_FLAG_CONTROL           0x00200000u
#define EMAC_DSC_FLAG_OVERRUN           0x00100000u
#define EMAC_DSC_FLAG_CODEERROR         0x00080000u
#define EMAC_DSC_FLAG_ALIGNERROR        0x00040000u
#define EMAC_DSC_FLAG_CRCERROR          0x00020000u
#define EMAC_DSC_FLAG_NOMATCH           0x00010000u
```

22.2.5.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

22.2.5.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

22.2.5.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

22.2.5.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

22.2.5.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

22.2.5.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

22.2.5.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

22.2.5.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

22.2.5.5.11 Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

22.2.5.5.12 Jabber Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

22.2.5.5.13 Oversize Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.14 Fragment Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.15 Undersized Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

22.2.5.5.16 Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

22.2.5.5.17 Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

22.2.5.5.18 Code Error (CODEERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.19 Alignment Error (ALIGNERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.20 CRC Error (CRCERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.21 No Match (NOMATCH) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

22.2.6 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

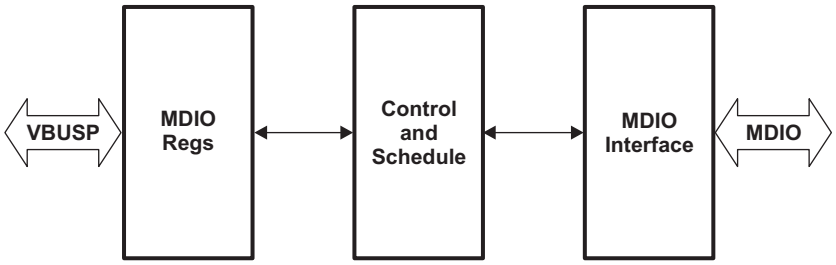
The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

22.2.6.1 MDIO Module Components

The VBUS MII management interface module consists of the following blocks:

- MDIO Regs
- Control and Schedule
- MDIO Interface

Figure 22-8. VBUS MII Management Interface Module



22.2.6.1.1 MDIO Regs

The MDIO regs block provides a VBUSP 2.0 compliant slave interface to the MII Management Interface module. Host interaction with this module is facilitated through the registers in this block.

22.2.6.1.2 Control and Schedule

The control and register logic in the MII Management Interface module contain the state machine and scheduling logic which control the wire side operation.

22.2.6.1.3 MDIO Interface

The MDIO interface block provides the serial interface to the MDIO interface.

22.2.6.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL*n*). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL*n*. Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS*n*).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS*n* causes ALIVE to be updated.

The USERPHYSEL*n* is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL*n*.

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS*n*. When the application sets the GO bit in USERACCESS*n*, the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS0 and USERACCESS1. The application software must check the status of the GO bit in USERACCESS*n* before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS*n* to determine the status of a read transaction.

22.2.6.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL*n*), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS*n*). Since only one PHY is used in this device, the application software can use one USERACCESS*n* to trigger a completion interrupt; the other USERACCESS*n* is not setup.

22.2.6.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS*n* corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS*n* for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

22.2.6.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS*n*) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS*n* corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS*n* after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS*n*. Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

22.2.6.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS*n*) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG_read(regadr, phyadr) — Start the process of reading a PHY register
- PHYREG_write(regadr, phyadr, data) — Start the process of writing a PHY register
- PHYREG_wait( ) — Synchronize operation (make sure read/write is idle)
- PHYREG_waitResults(results) — Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG_wait() after every write, and PHYREG_waitResults( ) after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in Example 22-3 (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS*n* on PHY register reads (does not follow the procedure outlined in Section 22.2.6.2.3). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

Example 22-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
        MDIO_REGS->USERACCESS0 =
             CSL_FMK(MDIO_USERACCESS0_GO,1u)                    |               /
             CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)            |               /
             CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)

#define PHYREG_write(regadr, phyadr, data)
        MDIO_REGS->USERACCESS0 =
             CSL_FMK(MDIO_USERACCESS0_GO,1u)                    |               /
             CSL_FMK(MDIO_USERACCESS0_WRITE,1)                  |               /
             CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)            |               /
             CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)            |               /
             CSL_FMK(MDIO_USERACCESS0_DATA, data)

#define PHYREG_wait()
        while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) )

#define PHYREG_waitResults( results ) {
        while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) );
        results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

22.2.7 EMAC Module

This section discusses the architecture and basic function of the EMAC module.

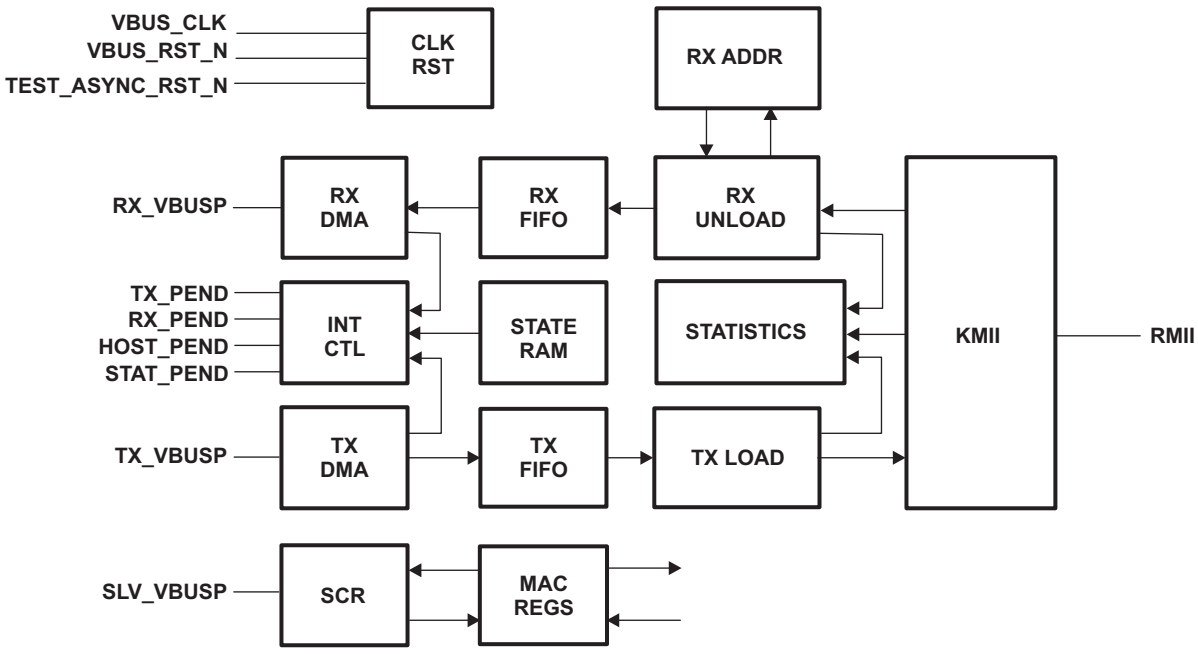
22.2.7.1 EMAC Module Components

The EMAC module (Figure 22-9) interfaces to the outside world Reduced Media Independent Interface (RMII). After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the transmit FIFO in 64-byte cells. When the threshold number of cells (configurable) have been written to the transmit FIFO, or a complete packet whichever is smaller, the transmit load block then initiates the packet transmission. The KMII block transmits the packet over the RMII in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics submodule.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The KMII submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the receive unload submodule which checks for address match (in conjunction with the receive address submodule) and processes errors. Accepted packets are then written to the receive FIFO in 64-byte cells. The receive DMA controller then writes the packet data to memory in accordance with CPPI 3.0 protocol. Receive statistics are counted by the statistics block.

The host configures and initializes the device through the five module slave VBUSP interfaces. The CPPI, REGS, MDIO, and EMAC, modules have slave interfaces. The CPPI and EMAC slave interfaces are input directly to a VBUSP to VBUSP retiming bridge before being input to the switched central resource (SCR) inside the respective modules. The retiming bridges help to minimize long paths. The SCR handles decode between multiple master/slaves inside the respective modules. The interrupt control block is used to select the interrupts from the EMAC and the MDIO for output to the three CPU's. The signals required to support gigabit mode are included in the module. However gigabit transfer rates are not supported due to the small 3-cell transmit and receive FIFO's. Also, the RFTCLK input can be tied low for 10/100 operation.

Figure 22-9. EMAC Module Block Diagram



22.2.7.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC subsystem (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

22.2.8 MAC Interface

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

22.2.8.1 Data Reception

22.2.8.1.1 Receive Control

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

22.2.8.1.2 Receive Inter-Frame Interval

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

22.2.8.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RX*n*FREEBUFFER) is less than or equal to the receive channel flow control threshold register (RX*n*FLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

22.2.8.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

22.2.8.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

22.2.8.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

22.2.8.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII_CRS) and collision-sensing (MII_COL) modes are disabled.

22.2.8.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

22.2.8.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG)delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

22.2.8.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII_CRS is deasserted within approximately 48 bit times of MII_TXEN being deasserted, then 96 bit times is measured from MII_TXEN. If the frame suffered a collision or MII_CRS is not deasserted until more than approximately 48 bit times after MII_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII_CRS.

22.2.8.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

22.2.8.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no affect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
  - The reserved multicast destination address 01.80.C2.00.00.01h
  - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

22.2.8.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

22.2.9 Packet Receive Operation

22.2.9.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel *n* DMA head descriptor pointer registers (RX*n*HDP) to 0.
- Write the MAC address hash *n* registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
  - the receive channel *n* free buffer count registers (RX*n*FREEBUFFER)
  - the receive channel *n* flow control threshold register (RX*n*FLOWTHRESH)
  - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET in EMAC module).
- Enable the receive interrupts of the desired channels in the *Interrupt Core Receive Interrupt Enable Registers* (EMAC subsystem).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0 and initialize RX*n*HDP.
- Enable the RX DMA controller by setting the RXEN bit in the RXCONTROL register.
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

22.2.9.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH*n*EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH*n*EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash *n* registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

22.2.9.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

22.2.9.4 VBUSP Latency

The transmit (and receive) FIFOs each contain a configurable number of 64-byte cells. The EMAC begins transmission of a packet on the wire after tx_cell_thresh cells, or a complete packet, are available in the FIFO. Transmit underrun cannot occur for packet sizes of tx_cell_thresh times 64 bytes (or less) because the entire packet is contained in the FIFO before the packet transmission is started. For larger packet sizes, transmit underrun can occur if the memory latency is greater than the time required to transmit a 64-byte cell on the wire (5.12us in 100 Mbit mode). The latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun will be prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire (5.12µs in 100 Mbit mode). The latency time includes any required buffer descriptor reads for the cell data.

22.2.9.5 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
  - The destination station's individual unicast address.
  - The destination station's multicast address (MACHASH1 and MACHASH2).
  - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) and the receive channel *n* free buffer count registers (RX*n*FREEBUFFER) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (RX*n*FREEBUFFER) for the frame channel is less than or equal to the filter low threshold (RXFILTERLOWTHRESH) value. Hardware QOS is enabled by the RXQOSEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

22.2.9.6 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (RX*n*FREEBUFFER). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. RX*n*FREEBUFFER only needs to be updated by the host if receive QOS or flow control is used.

22.2.9.7 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (RXTEARDOWN). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The TDOWNCMPLT flag is set in the next buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel *n* completion pointer register (RX*n*CP) contains the value FFFF FFFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to RX*n*CP (note that there is no buffer descriptor in this case). Software may read RX*n*CP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

22.2.9.8 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

22.2.9.9 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. Table 22-12 shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

Table 22-12. Receive Frame Treatment Summary

Address Match	RXCAFEN	RXCEFEN	RXCMFEN	RXCSFEN	Receive Frame Treatment
0	0	X	X	X	No frames transferred.
0	1	0	0	0	Proper frames transferred to promiscuous channel.
0	1	0	0	1	Proper/undersized data frames transferred to promiscuous channel.
0	1	0	1	0	Proper data and control frames transferred to promiscuous channel.
0	1	0	1	1	Proper/undersized data and control frames transferred to promiscuous channel.
0	1	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred.
0	1	1	0	1	Proper/undersized/fragment/oversize/jabber/code/ align/CRC data frames transferred to promiscuous channel. No control frames are transferred.
0	1	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred.
0	1	1	1	1	All nonaddress matching frames with and without errors transferred to promiscuous channel.
1	X	0	0	0	Proper data frames transferred to address match channel.
1	X	0	0	1	Proper/undersized data frames transferred to address match channel.
1	X	0	1	0	Proper data and control frames transferred to address match channel.
1	X	0	1	1	Proper/undersized data and control frames transferred to address match channel.
1	X	1	0	0	Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred.
1	X	1	0	1	Proper/oversize/jabber/fragment/undersized/code/ align/CRC data frames transferred to address match channel. No control frames are transferred.
1	X	1	1	0	Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred.

Table 22-12. Receive Frame Treatment Summary (continued)

Address Match	RXCAFEN	RXCEFEN	RXCMFEN	RXCSFEN	Receive Frame Treatment
1	X	1	1	1	All address matching frames with and without errors transferred to the address match channel

22.2.9.10 Big Endian Mode

When the BIG_ENDIAN input is asserted, the EMAC assumes that packet data is contained in memory in big endian format. When the BIG_ENDIAN input is deasserted, the EMAC assumes that packet data is contained in memory in little endian format. The BIG_ENDIAN input causes big endian packet data to go out on the wire in the same order that little endian packet data goes out on the wire when the input is not asserted (byte 0 first). The BIG_ENDIAN input has no effect on buffer descriptor data reads or writes because buffer descriptor data is a 32-bit quantity (unlike packet data which is an 8- bit quantity).

Table 22-13. Little Endian

High Add			Low Add
Byte 3	Byte 2	Byte 1	Byte 0
Byte 7	Byte 6	Byte 5	Byte 4
Byte 11	Byte 10	Byte 9	Byte 8

Table 22-14. Big Endian

High Add			Low Add
Byte 0	Byte 1	Byte 2	Byte 3
Byte 4	Byte 5	Byte 6	Byte 7
Byte 8	Byte 9	Byte 10	Byte 11

22.2.9.11 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO_SOF)
- FIFO middle of frame overrun (FIFO_MOF)
- DMA start of frame overrun (DMA_SOF)
- DMA middle of frame overrun (DMA_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. Table 22-15 shows how the overrun condition is handled for the middle of frame overrun.

Table 22-15. Middle of Frame Overrun Treatment

Address Match	RXCAFEN	RXCEFEN	Middle of Frame Overrun Treatment
0	0	X	Overrun frame filtered.
0	1	0	Overrun frame filtered.

Table 22-15. Middle of Frame Overrun Treatment (continued)

Address Match	RXCAFEN	RXCEFEN	Middle of Frame Overrun Treatment
0	1	1	As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize).
1	X	0	Overrun frame filtered with the appropriate overrun statistic(s) incremented.
1	X	1	As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated).

22.2.10 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

22.2.10.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel *n* DMA head descriptor pointer registers (TX*n*HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET in EMAC module).
- Enable the transmit interrupts of the desired channels in the *Interrupt Core Transmit Interrupt Enable Registers* (EMAC subsystem).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX*n*HDP with the pointer to the first descriptor to start transmit operations.

22.2.10.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel *n* completion pointer register (TX*n*CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX*n*CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX*n*CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

22.2.11 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12 µs in 100 Mbps mode and 51.2 µs in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12 µs in 100 Mbps mode, or 51.2 µs in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC subsystem.

22.2.12 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12 µs.
- Any single latency event in request servicing can be no longer than (5.12 × TXCELLTHRESH) µs.

22.2.13 Clock Stop

The clock stop interface allows the EMAC to be gracefully commanded to enter into a stopped clock state. When the (CLKSTOP_REQ) input is asserted, the EMAC suspend state is entered and the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. The (CLKSTOP_ACK) output will be asserted when the EMAC_F enters the IDLE state indicating that the clock (VBUSP_CLK) may be stopped. (For details on programming the clock stop, see the *System Control Module* chapter.)

22.2.14 Software Reset

The EMAC subsystem software reset register (REGS) and the EMAC submodule software reset register enable the EMAC subsystem to be reset by software. For the EMAC, the reset state is entered at packet boundaries, at which time the EMAC reset occurs. EMAC reset status is determined by reading or polling the EMAC soft reset bit. If the EMAC reset bit is read as a one, then the reset process has not yet completed. The EMAC soft reset process could take up to 2ms. The reset has completed if the EMAC reset bit is read as a zero. After the EMAC soft reset is complete, the EMAC subsystem software reset register bits may be written to complete the software reset operation.

22.2.14.1 Soft Reset of EMAC Submodule

The EMAC software reset register enables the EMAC to be reset by software. Soft reset will occur at frame boundaries. Soft reset occurs when both receive and transmit DMA controllers are not using their respective VBUS interfaces so that there is no VBUS lockup. The soft reset process could take up to 2ms. The reset has completed if the soft reset bit is read as a zero.

22.2.15 Initialization

22.2.15.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral may be in a disabled state. Before any EMAC specific initialization can take place, the EMAC needs to be enabled; otherwise, its registers cannot be written and the reads will all return a value of zero.

When first enabled, the EMAC peripheral registers are set to their default values. After enabling the peripheral, you may proceed with the module specific initialization.

22.2.15.2 EMAC Subsystem Module Initialization

The EMAC subsystem module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

The initialization of the EMAC subsystem module consists of three parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC subsystem module:
   - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, C*n*RXIMAX, and C*n*TXIMAX
   - Initializing the EMAC and MDIO modules
   - Enabling interrupts in the EMAC subsystem module using the EMAC control module interrupt control registers C*n*RXTHRESHEN, C*n*RXEN, C*n*TXEN, and CnMISCEN.

The process of mapping the EMAC interrupts to the CPU is done through the CPU interrupt controller. Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

22.2.15.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHZ. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL*n*) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50 µs to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

22.2.15.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC subsystem module interrupt control registers C*n*RXTHRESHEN, C*n*RXEN, C*n*TXEN, and C*n*MISCEN.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers (RX*n*HDP and TX*n*HDP) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel *n* free buffer count registers (RX*n*FREEBUFFER), receive channel *n* flow control threshold register (RX*n*FLOWTHRESH), and receive filter low priority frame threshold register (RXFILTERLOWTHRESH).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers (MACHASH1 and MACHASH2) to 0.
8. Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register (RXUNICASTCLEAR). If unicast is desired, it can be enabled now by writing the receive unicast set register (RXUNICASTSET). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register (RXINTMASKCLEAR) and the transmit interrupt mask clear register (TXINTMASKCLEAR).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register (RXINTMASKSET) and the transmit interrupt mask set register (TXINTMASKSET) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register (MACINTMASKSET).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to RX*n*HDP.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC subsystem module registers C*n*RXTHRESHEN, C*n*RXEN, C*n*TXEN, and C*n*MISCEN.

22.2.16 Interrupt Support

22.2.16.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND*n*: Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND*n*: Receive packet completion interrupt for receive channels 0 through 7
- RXTHRESHPEND*n*: Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

22.2.16.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND*n*). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC subsystem) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel *n* completion pointer register (TX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC subsystem module after processing packets by writing the appropriate C*n*RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND*n*). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel *n* completion pointer register (RX*n*CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC subsystem module after processing packets by writing the appropriate C*n*TX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.1.3 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must acknowledge the EMAC subsystem module after receiving statistics interrupts by writing the appropriate C*n*MISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.1.4 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC subsystem module after receiving host error interrupts by writing the appropriate C*n*MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt (RX*n*THRESHPEND). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the RXINTMASKSET register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED),respectively.

An RX*n*THRESHPEND interrupt bit is asserted when enabled and when the channel's associated free buffer count (RX*n*FREEBUFFER) is less than or equal to the channel's associated flow control threshold register (RX*n*FLOWTHRESH). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC subsystem module after receiving threshold interrupts by writing the appropriate C*n*RXTHRESH key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.1.6 Pulse Interrupts

EMAC generates both TX_PULSE[7:0] and RX_PULSE[7:0] pulse interrupts.

- **TX_PULSE[7:0]** - Transmit packet completion interrupts for transmit channels 7 to 0.
- **RX_PULSE[7:0]** - Receive packet completion interrupts for receive channels 7 to 0.

22.2.16.1.6.1 Pulse Interrupt Description

The following sections describe the pulse interrupts.

22.2.16.1.6.1.1 Transmit Packet Completion Interrupts

The transmit DMA controller has eight channels with each channel having a corresponding pulse interrupt (TX_PULSE[7:0]). Each of the eight channel pulse interrupts may be individually enabled by setting to one the appropriate bit in the Tx_IntMask_Set register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the Tx_IntMask_Clear register. When each CPPI packet DMA transmission is complete (not the complete packet transmission on the wire), the EMAC issues a single VBUSP_CLK wide interrupt pulse. No acknowledgment from the host is required.

22.2.16.1.6.1.2 Receive Packet Completion Interrupts

The receive DMA controller has eight channels with each channel having a corresponding pulse interrupt (RX_PULSE[7:0]). Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the Rx_IntMask_Set register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the Rx_IntMask_Clear register. When a packet DMA reception is complete, the EMAC issues a single VBUSP_CLK wide pulse interrupt. No acknowledgment from the host is required.

22.2.16.2 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC subsystem module.

For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC subsystem module registers C*n*RXTHRESHEN, C*n*RXEN, CnTXEN, CnMISCEN, and then reenable them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC subsystem module also uses the EMAC subsystem module registers INTCONTROL, C*n*TXIMAX, and C*n*RXIMAX to implement interrupt pacing. The application software must acknowledge the EMAC subsystem module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

EMAC modules do not support level interrupt outputs. External logic has been implemented to convert pulse interrupts into level interrupt. Once the MPU writes corresponding bits in this register, this logic registers the pulse interrupt generated by IP and clears the interrupt.

22.2.16.3 Interrupt Multiplexing

The EMAC subsystem module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (C*n*RXTHRESHPULSE, C*n*RXPULSE, C*n*TXPULSE, C*n*MISCPULSE) that are routed to three independent interrupt cores in the subsystem module. Each interrupt core is capable of relaying all four interrupt signals out of the subsystem module. Some devices may have an individual interrupt core dedicated to a specific CPU or interrupt controller. This configuration gives users of devices greater flexibility when allocating system resources for EMAC management.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (MACINVECTOR) located in the EMAC memory map. MACINVECTOR combines the status of the following 28 interrupt signals: TXPEND*n*, RXPEND*n*, RXTHRESHPEND*n*, STATPEND, HOSTPEND, LINKINT0, and USERINT0.

22.2.16.4 Pulse Interrupts in EMAC SubSystem

The following subsections describe the pulse interrupts that are generated by the EMAC subsystem.

22.2.16.4.1 C(0/1/2) RXTHRESHPULSE Interrupt Description

The C(0/1/2) RXTHRESHPULSEinterrupts are each an immediate (non-paced) pulse interrupt selected from the EMAC RXTHRESHPEND[7:0] interrupts. The receive threshold pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) RxThreshEn[7:0] register. The masked interrupt status can be read in the C(0/1/2) RxThreshStat[7:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) RxThreshStat[7:0] address location to determine which channel(s) caused the interrupt.
- Process received packets in order to add more buffers to any channel that is below the threshold value.
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x0, 0x4, or 0x8) to the to the MACEOIVector register in the emac slave address space.
- Write 1 to the bit 2 of LVL_INTR_CLEAR register (0x4800 2594) to clear the interrupt.

22.2.16.4.2 2 C(0/1/2) RXPULSE Interrupt Description

The C(0/1/2) RXPULSE interrupts are each a paced pulse interrupt selected from the EMAC RXPEND[7:0] interrupts. The receive pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) RxEn[7:0] register. The masked interrupt status can be read in the C(0/1/2) RxStat[7:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) RxStat[7:0] address location to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x1, 0x5, or 0x9) to the MACEOIVector register in the EMAC slave address space.
- Write 1 to the bit 1 in LVL_INTR_CLEAR register (0x4800 2594) to clear the interrupt.

22.2.16.4.3 C(0/1/2) TXPULSE Interrupt Description

The C(0/1/2) TXPULSE interrupts are each a paced pulse interrupt selected from the EMAC TXPEND[7:0] interrupts. The transmit pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) TxEn[7:0] register. The masked interrupt status can be read in the C(0/1/2) TxStat[7:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) TxStat[7:0] address location to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x2, 0x6, or 0xa) to the MACEOIVector register in the EMAC slave address space.
- Write 1 to the bit 3 in LVL_INTR_CLEAR register (0x4800 2594) to clear the interrupt.

22.2.16.4.4 C(0/1/2) MISCPULSE Interrupt Description

The C(0/1/2) MISCPULSE interrupts are each an immediate (non-paced) pulse interrupt selected from the miscellaneous interrupts (STATPEND, HOSTPEND, MDIOLINKINT[0], MDIOUSERINT[0]). The miscellaneous interrupt(s) is selected by setting one or more bits in the C(0/1/2) MiscEn[3:0] register. The masked interrupt status can be read in the C(0/1/2) MiscStat[3:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) MiscStat[3:0] address location to determine which channel(s) caused the interrupt.
- Process the interrupt.
- Write the appropriate value (0x3, 0x7, or 0xb) to the MACEOIVector register in the emac slave address space.
- Write 1 to the bit 0 in LVL_INTR_CLEAR register(0x48002594) to clear the interrupt.

NOTE: MDIOLINKINT[1] and MDIOUSERINT[1] are not connected.

The following 4 pulse interrupts are only connected from the EMAC module to ARM CPU.

- C0MISCPULSE – Core 0 Miscellaneous Interrupt
- C0RXPULSE – Core 0 Receive Interrupt
- C0RXTHRESHPULSE – Core 0 Receive Threshold Interrupt
- C0TXPULSE – Core 0 Transmit Interrupt.

C1 and C2 interrupts are not connected from EMAC Module to ARM CPU.

22.2.16.5 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (e.g. 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache. Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block

(six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1ms interval of time. At the end of each 1ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted.

The 1ms interval is derived from a 4µs pulse that is created from a prescale counter whose value is set in the INTPRESCALE value in the Interrupt Control register of EMAC subsystem. The INTPRESCALE value should be written with the number of VBUSP_CLK periods in 4µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4µs. It is reloaded each time a zero count is reached.

The value loaded into the pacing timer is calculated by hardware every 1ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
               pace_timer = 255;

    else if (intr_count > 1.5*intr_max)
               pace_timer = last_pace_timer*2 + 1;

    else if (intr_count > 1.0*intr_max)
               pace_timer = last_pace_timer + 1;

    else if (intr_count > 0.5*intr_max)
               pace_timer = last_pace_timer - 1;

    else if (intr_count != 0)
               pace_timer = last_pace_timer/2;

    else
               pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced' at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive indicating the target number of interrupts per milli-second.

22.2.16.6 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

22.2.16.6.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC subsystem after receiving MDIO interrupts by writing the appropriate C*n*MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.16.6.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW). USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC subsystem module after receiving MDIO interrupts by writing the appropriate C*n*MISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See Section 22.5.12 for the acknowledge key values.

22.2.17 Power Management

The clock stop interface allows the EMAC to be gracefully commanded to enter into a stopped clock state. When the (CLKSTOP_REQ) input is asserted, the EMAC suspend state is entered and the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. The (CLKSTOP_ACK) output will be asserted when the EMAC_F enters the IDLE state indicating that the clock (VBUSP_CLK) may be stopped.

22.2.18 Emulation Considerations

22.2.18.1 EMAC Subsystem

The emulation control input (TBEMUSUSP) and EMAC submodule emulation control register allows EMAC subsystem operation to be completely or partially suspended. There is one EMAC subsystem submodule that contains an emulation control register (EMAC). The EMAC submodule emulation control register must be accessed to facilitate EMAC subsystem emulation control. The EMAC subsystem module enters the emulation suspend state if the EMAC submodule is configured for emulation suspend and the emulation suspend input is asserted. EMAC Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

Table 22-16 shows the operation of the emulation control input and register bits.

Table 22-16. Emulation Control

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal operation
1	0	0	Normal operation
1	1	0	Emulation suspend
1	X	1	Normal operation

22.2.18.2 EMAC Submodule

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE in the EMCONTROL register) allow EMAC operation to be suspended. When the emulation suspend state is entered, the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

Table 22-17 shows the operation of the emulation control input and register bits:

Table 22-17. Emulation Control

TBEMUSUSP	SOFT	FREE	Description
0	X	X	Normal operation
1	0	0	Normal operation
1	1	0	Emulation suspend
1	X	1	Normal operation

22.3 EMAC Subsystem Registers

Table 22-18 lists the memory-mapped registers for EMAC subsystem.

The base address of these registers is 0x5c00 0000.

Table 22-18. EMAC Subsystem Registers

15	0
CLKDIV	
R/W-FFh	

LEGEND: R/W = R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

Table 22-34. MDIO Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
31	IDLE		State machine IDLE status bit.
		0	State machine is not in idle state.
		1	State machine is in idle state.
30	ENABLE		State machine enable control bit. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit.
		0	Disables the MDIO state machine.
		1	Enable the MDIO state machine.
29	Reserved	0	Reserved
28-24	HIGHEST_USER_CHANNEL	0-1Fh	Highest user channel that is available in the module. It is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel.
23-21	Reserved	0	Reserved
20	PREAMBLE		Preamble disable
		0	Standard MDIO preamble is used.
		1	Disables this device from sending MDIO frame preambles.
19	FAULT		Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit.
		0	No failure
		1	Physical layer fault; the MDIO state machine is reset.
18	FAULTENB		Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection.
		0	Disables the physical layer fault detection.
		1	Enables the physical layer fault detection.
17	INT_TEST_ENABLE		Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes.
		0	
		1	
16	Reserved	0	Reserved
15-0	CLKDIV	0-FFFFh	Clock Divider bits. This field specifies the division ratio between the peripheral clock and the frequency of MDIO_CLK. MDIO_CLK is disabled when CLKDIV is cleared to 0. MDIO_CLK frequency = peripheral clock frequency/(CLKDIV + 1).

22.4.3 PHY Acknowledge Status Register (ALIVE)

The PHY acknowledge status register (ALIVE) is shown in Figure 22-25 and described in Table 22-35.

Figure 22-25. PHY Acknowledge Status Register (ALIVE)

31	16
ALIVE	
R/WC-0	

15	0
ALIVE	
R/WC-0	

LEGEND: R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

Table 22-35. PHY Acknowledge Status Register (ALIVE) Field Descriptions

Bit	Field	Value	Description
31-0	ALIVE		MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.
		0	The PHY fails to acknowledge the access.
		1	The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY.

22.4.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in Figure 22-26 and described in Table 22-36.

Figure 22-26. PHY Link Status Register (LINK)

31	16
LINK	
R-0	

15	0
LINK	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 22-36. PHY Link Status Register (LINK) Field Descriptions

Bit	Field	Value	Description
31-0	LINK		MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect.
		0	The PHY indicates it does not have a link or fails to acknowledge the read transaction
		1	The PHY with the corresponding address has a link and the PHY acknowledges the read transaction.

22.4.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in Figure 22-27 and described in Table 22-37.

Figure 22-27. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

Reserved	
R-0	

15	2	1	0
Reserved		USERPHY1	USERPHY0
R-0		R/WC-0	R/WC-0

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

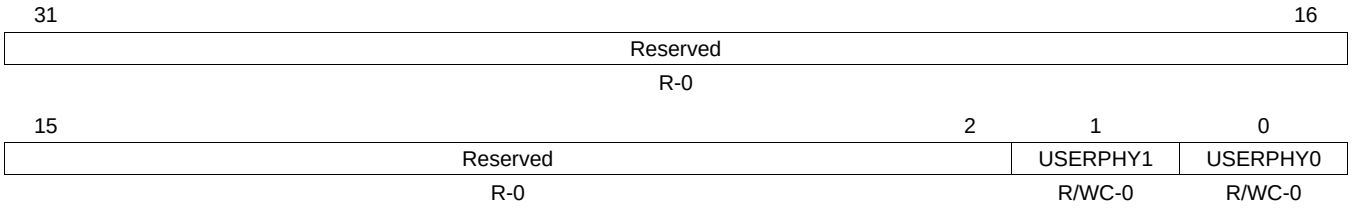
Table 22-37. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERPHY1		MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1
0	USERPHY0		MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0

22.4.6 MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)

The MDIO link status change interrupt (masked) register (LINKINTMASKED) is shown in Figure 22-28 and described in Table 22-38.

Figure 22-28. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)



LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

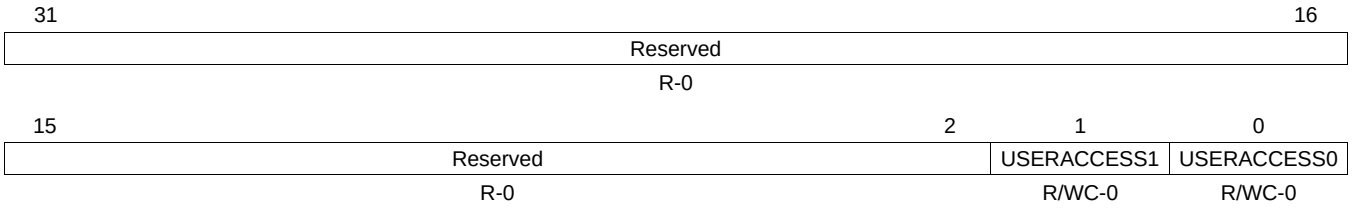
Table 22-38. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERPHY1		MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1 and the LINKINTENB bit in USERPHYSEL1 is set to 1.
0	USERPHY0		MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO link change event.
		1	An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 and the LINKINTENB bit in USERPHYSEL0 is set to 1.

22.4.7 MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

The MDIO user command complete interrupt (unmasked) register (USERINTRAW) is shown in Figure 22-29 and described in Table 22-39.

Figure 22-29. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)



LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

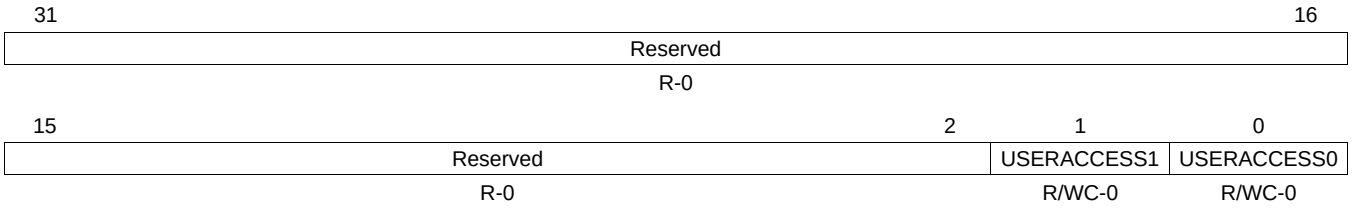
Table 22-39. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS1 register has completed. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed.
0	USERACCESS0		MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS0 register has completed. Writing a 1 will clear the event and writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed.

22.4.8 MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

The MDIO user command complete interrupt (masked) register (USERINTMASKED) is shown in Figure 22-30 and described in Table 22-40.

Figure 22-30. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)



LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

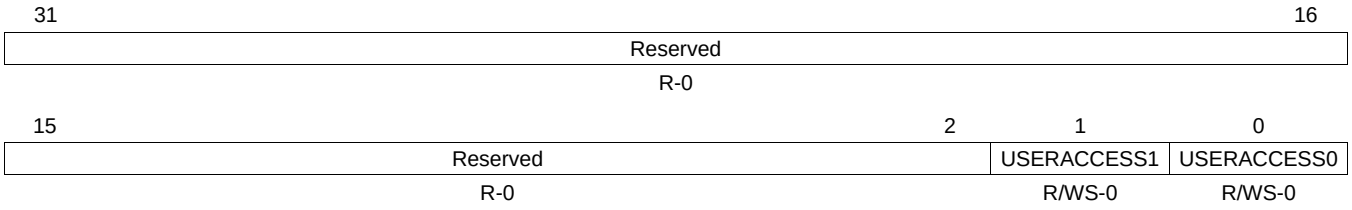
Table 22-40. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt and writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1.
0	USERACCESS0		Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt and writing a 0 has no effect.
		0	No MDIO user command complete event.
		1	The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1.

22.4.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

The MDIO user command complete interrupt mask set register (USERINTMASKSET) is shown in Figure 22-31 and described in Table 22-41.

Figure 22-31. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)



LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set; -*n* = value after reset

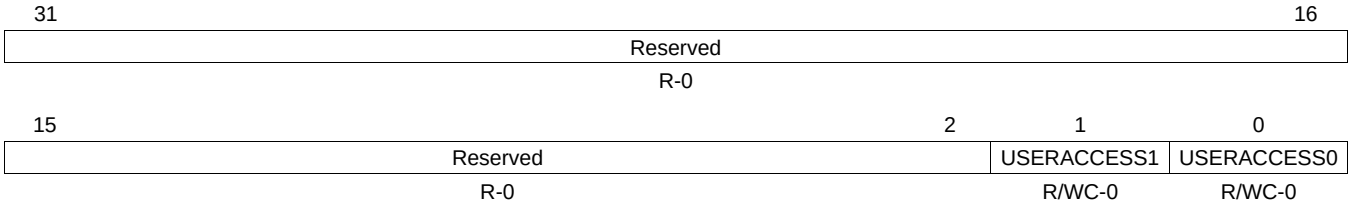
Table 22-41. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		MDIO user interrupt mask set for USERINTMASKED[1]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS1 register. MDIO user interrupt for USERACCESS1 is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect.
		0	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.
		1	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.
0	USERACCESS0		MDIO user interrupt mask set for USERINTMASKED[0]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS0 register. MDIO user interrupt for USERACCESS0 is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect.
		0	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.
		1	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.

22.4.10 MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

The MDIO user command complete interrupt mask clear register (USERINTMASKCLEAR) is shown in Figure 22-32 and described in Table 22-42.

Figure 22-32. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)



LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -*n* = value after reset

Table 22-42. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	USERACCESS1		MDIO user command complete interrupt mask clear for USERINTMASKED[1]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS1. Writing a 0 to this register has no effect.
		0	MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is enabled.
		1	MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is disabled.
0	USERACCESS0		MDIO user command complete interrupt mask clear for USERINTMASKED[0]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS0. Writing a 0 to this register has no effect.
		0	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled.
		1	MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled.

22.4.11 MDIO User Access Register 0 (USERACCESS0)

The MDIO user access register 0 (USERACCESS0) is shown in Figure 22-33 and described in Table 22-43.

Figure 22-33. MDIO User Access Register 0 (USERACCESS0)

LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set; -*n* = value after reset

Table 22-43. MDIO User Access Register 0 (USERACCESS0) Field Descriptions

Bit	Field	Value	Description
31	GO	0-1	Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1.
30	WRITE		Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read.
		0	The user command is a read operation.
		1	The user command is a write operation.
29	ACK	0-1	Acknowledge bit. This bit is set if the PHY acknowledged the read transaction.
28-26	Reserved	0	Reserved
25-21	REGADR	0-1Fh	Register address bits. This field specifies the PHY register to be accessed for this transaction
20-16	PHYADR	0-1Fh	PHY address bits. This field specifies the PHY to be accessed for this transaction.
15-0	DATA	0-FFFFh	User data bits. These bits specify the data value read from or to be written to the specified PHY register.

22.4.12 MDIO User PHY Select Register 0 (USERPHYSEL0)

The MDIO user PHY select register 0 (USERPHYSEL0) is shown in Figure 22-34 and described in Table 22-44.

Figure 22-34. MDIO User PHY Select Register 0 (USERPHYSEL0)

Table 22-68. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved
30	RXPASSCRC		Pass receive CRC enable bit
		0	Received CRC is discarded for all channels and is not included in the buffer descriptor packet length field.
		1	Received CRC is transferred to memory for all channels and is included in the buffer descriptor packet length.
29	RXQOSEN		Receive quality of service enable bit
		0	Receive QOS is disabled.
		1	Receive QOS is enabled.
28	RXNOCHAIN		Receive no buffer chaining bit
		0	Received frames can span multiple buffers.
		1	The Receive DMA controller transfers each frame into a single buffer, regardless of the frame or buffer size. All remaining frame data after the first buffer is discarded. The buffer descriptor buffer length field will contain the entire frame byte count (up to 65535 bytes).
27-25	Reserved	0	Reserved
24	RXCMFEN		Receive copy MAC control frames enable bit. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in MACCONTROL, regardless of the value of RXCMFEN. Frames transferred to memory due to RXCMFEN will have the CONTROL bit set in their EOP buffer descriptor.
		0	MAC control frames are filtered (but acted upon if enabled).
		1	MAC control frames are transferred to memory.
23	RXCSFEN		Receive copy short frames enable bit. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RXCSFEN will have the FRAGMENT or UNDERSIZE bit set in their EOP buffer descriptor. Fragments are short frames that contain CRC / align / code errors and undersized are short frames without errors.
		0	Short frames are filtered.
		1	Short frames are transferred to memory.

Table 22-68. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
22	RXCEFEN		Receive copy error frames enable bit. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame EOP buffer descriptor.
		0	Frames containing errors are filtered.
		1	Frames containing errors are transferred to memory.
21	RXCAFEN		Receive copy all frames enable bit. Enables frames that do not address match (includes multicast frames that do not hash match) to be transferred to the promiscuous channel selected by RXPROMCH bits. Such frames will be marked with the NOMATCH bit in their EOP buffer descriptor.
		0	Frames that do not address match are filtered.
		1	Frames that do not address match are transferred to the promiscuous channel selected by RXPROMCH bits.
20-19	Reserved	0	Reserved
18-16	RXPROMCH	0-7h	Receive promiscuous channel select
		0	Select channel 0 to receive promiscuous frames
		1h	Select channel 1 to receive promiscuous frames
		2h	Select channel 2 to receive promiscuous frames
		3h	Select channel 3 to receive promiscuous frames
		4h	Select channel 4 to receive promiscuous frames

		6h	Select channel 6 to receive promiscuous frames
		7h	Select channel 7 to receive promiscuous frames
15-14	Reserved	0	Reserved
13	RXBROADEN		Receive broadcast enable. Enable received broadcast frames to be copied to the channel selected by RXBROADCH bits.
		0	Broadcast frames are filtered.
		1	Broadcast frames are copied to the channel selected by RXBROADCH bits.
12-11	Reserved	0	Reserved
10-8	RXBROADCH	0-7h	Receive broadcast channel select
		0	Select channel 0 to receive broadcast frames
		1h	Select channel 1 to receive broadcast frames
		2h	Select channel 2 to receive broadcast frames
		3h	Select channel 3 to receive broadcast frames
		4h	Select channel 4 to receive broadcast frames
		5h	Select channel 5 to receive broadcast frames
		6h	Select channel 6 to receive broadcast frames
		7h	Select channel 7 to receive broadcast frames
7-6	Reserved	0	Reserved
5	RXMULTEN		RX multicast enable. Enable received hash matching multicast frames to be copied to the channel selected by RXMULTCH bits.
		0	Multicast frames are filtered.
		1	Multicast frames are copied to the channel selected by RXMULTCH bits.
4-3	Reserved	0	Reserved

Table 22-68. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
2-0	RXMULTCH	0-7h	Receive multicast channel select
		0	Select channel 0 to receive multicast frames
		1h	Select channel 1 to receive multicast frames
		2h	Select channel 2 to receive multicast frames
		3h	Select channel 3 to receive multicast frames
		4h	Select channel 4 to receive multicast frames
		5h	Select channel 5 to receive multicast frames
		6h	Select channel 6 to receive multicast frames
		7h	Select channel 7 to receive multicast frames

22.5.22 Receive Unicast Enable Set Register (RXUNICASTSET)

The receive unicast enable set register (RXUNICASTSET) is shown in Figure 22-58 and described in Table 22-69.

Figure 22-58. Receive Unicast Enable Set Register (RXUNICASTSET)

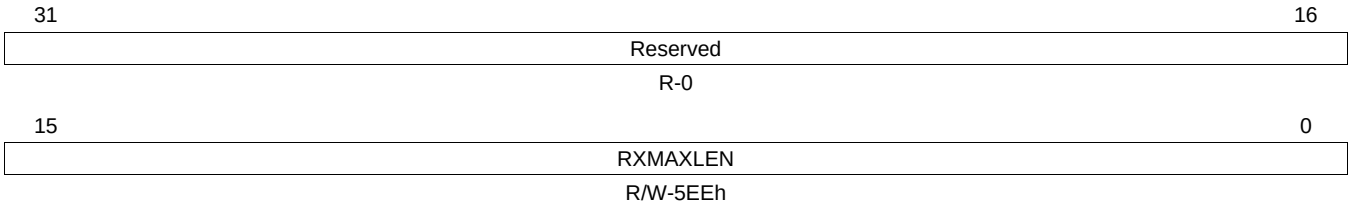
22.5.24 Receive Maximum Length Register (RXMAXLEN)

The receive maximum length register (RXMAXLEN) is shown in Figure 22-60 and described in Table 22-71.

Figure 22-60. Receive Maximum Length Register (RXMAXLEN)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

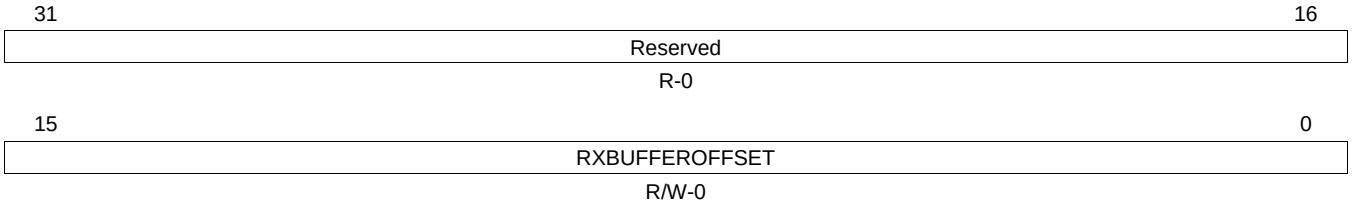
Table 22-71. Receive Maximum Length Register (RXMAXLEN) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RXMAXLEN	0-FFFFh	Receive maximum frame length. These bits determine the maximum length of a received frame. The reset value is 5EEh (1518). Frames with byte counts greater than RXMAXLEN are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames.

22.5.25 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in Figure 22-61 and described in Table 22-72.

Figure 22-61. Receive Buffer Offset Register (RXBUFFEROFFSET)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-72. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RXBUFFEROFFSET	0-FFFFh	Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

22.5.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in Figure 22-62 and described in Table 22-73.

Figure 22-62. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

Table 22-73. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RXFILTERTHRESH	0-FFh	Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired.

22.5.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX*n*FLOWTHRESH) is shown in Figure 22-63 and described in Table 22-74.

Figure 22-63. Receive Channel *n* Flow Control Threshold Register (RX*n*FLOWTHRESH)

31	16
Reserved	
R-0	

15	8	7	0

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RX*n*FLOWTHRESH	0-FFh	Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel *n* (when enabled).

22.5.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX*n*FREEBUFFER) is shown in Figure 22-64 and described in Table 22-75.

Figure 22-64. Receive Channel *n* Free Buffer Count Register (RX*n*FREEBUFFER)

R-0	

15	0
RX*n*FREEBUF	
WI-0	

LEGEND: R = Read only; WI = Write to increment; -*n* = value after reset

Table 22-75. Receive Channel *n* Free Buffer Count Register (RX*n*FREEBUFFER) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	RX*n*FREEBUF	0-FFh	Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX*n*FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow. If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing.

22.5.29 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in Figure 22-65 and described in Table 22-76.

LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

Table 22-76. MAC Control Register (MACCONTROL) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reserved.
18	MACEXTEN	0-1	External Enable. Enables the full duplex and gigabit mode to be selected from the EXTFULLDUPLEXSEL and EXTGIGSEL input signals and not from the full duplex and gig bits contained in this register. This register bit is also output on the MAC_EXT_EN signal.
17	GIGFORCE	0-1	Gigabit Mode Force. This bit is used to force the EMAC into gigabit mode if the input GMII_MTCLK has been stopped by the PHY. For RMII interface the value should be zero.
16	MACIFCTL_B	0-1	Interface Control B. Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc). For RMII interface this bit is unused.
15	MACIFCTL_A		Interface Control A – Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc). For GMII interface this bit is unused. For RMII Interface, it is used to select transmit and receive speed.
		0	Operate RMII interface in 10 Mbps speed mode.
		1	Operate RMII interface in 100 Mbps speed mode.
14	RXOFFLENBLOCK		Receive offset / length word write block.
		0	Do not block the DMA writes to the receive buffer descriptor offset / buffer length word.
		1	Block all EMAC DMA controller receive buffer descriptor offset / buffer length words during packet processing. When this bit is set, the EMAC will never write the third word to any receive buffer descriptor.
13	RXOWNERSHIP		Receive ownership write bit value.
		0	The EMAC writes the Receive ownership bit to 0 at the end of packet processing.
		1	The EMAC writes the Receive ownership bit to 1 at the end of packet processing. If you do not use the ownership mechanism, you can set this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.
12	Reserved	0	Reserved
11	CMDIDLE		Command Idle bit
		0	Idle is not commanded.
		1	Idle is commanded (read IDLE in the MACSTATUS register).
10	TXSHORTGAPEN		Transmit Short Gap Enable
		0	Transmit with a short IPG is disabled. Normal 96-bit time IPG is inserted between packets.
		1	Transmit with a short IPG is enabled. Shorter 88-bit time IPG is inserted between packets.

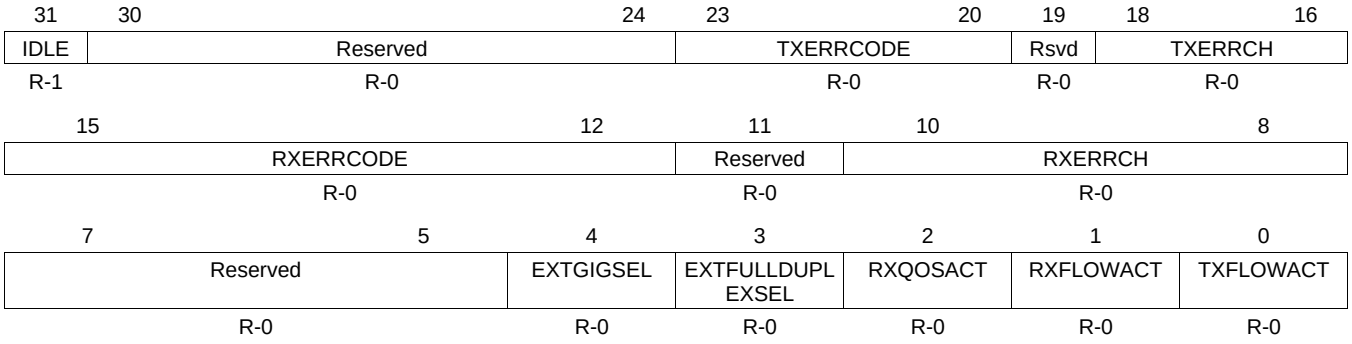
Table 22-76. MAC Control Register (MACCONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
9	TXPTYPE		Transmit queue priority type
		0	The queue uses a round-robin scheme to select the next channel for transmission.
		1	The queue uses a fixed-priority (channel 7 highest priority) scheme to select the next channel for transmission.
8	MEMTEST		FIFO RAM processor read/write enable (ram test mode)
		0	No host access to RX/TX FIFO RAM.
		1	Host read/write access to RX/TX FIFO RAMS.
7	Reserved	0	Reserved
6	TXPACE		Transmit pacing enable bit
		0	Transmit pacing is disabled.
		1	Transmit pacing is enabled.
5	GMIIEN		GMII enable bit
		0	GMII RX and TX are held in reset.
		1	GMII RX and TX are enabled for receive and transmit.
4	TXFLOWEN		Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of this bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory.
		0	Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon.
		1	Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon.
3	RXBUFFERFLOWEN		Receive buffer flow control enable bit
		0	Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent.
		1	Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered.
2	Reserved	0	Reserved
1	LOOPBACK		Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit. The loopback bit should be changed only when GMIIEN bit is deasserted.
		0	Loopback mode is disabled.
		1	Loopback mode is enabled.
0	FULLDUPLEX		Full duplex mode.
		0	Half-duplex mode is enabled.
		1	Full-duplex mode is enabled.

22.5.30 MAC Status Register (MACSTATUS)

The MAC status register (MACSTATUS) is shown in Figure 22-66 and described in Table 22-77.

Figure 22-66. MAC Status Register (MACSTATUS)



LEGEND: R = Read only; -*n* = value after reset

Table 22-77. MAC Status Register (MACSTATUS) Field Descriptions

Bit	Field	Value	Description
31	IDLE		EMAC idle bit. This bit is cleared to 0 at reset; one clock after reset, it goes to 1.
		0	The EMAC is not idle.
		1	The EMAC is in the idle state.
30-24	Reserved	0	Reserved
23-20	TXERRCODE	0-Fh	Transmit host error code. These bits indicate that EMAC detected transmit DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover. A 0 packet length is an error, but it is not detected.
		0	No error
		1h	SOP error; the buffer is the first buffer in a packet, but the SOP bit is not set in software.
		2h	Ownership bit not set in SOP buffer
		3h	Zero next buffer descriptor pointer without EOP
		4h	Zero buffer pointer
		5h	Zero buffer length
		6h	Packet length error (sum of buffers is less than packet length)
		7h-Fh	Reserved
19	Reserved	0	Reserved
18-16	TXERRCH	0-7h	Transmit host error channel. These bits indicate which transmit channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on transmit channel 0
		1h	The host error occurred on transmit channel 1
		2h	The host error occurred on transmit channel 2
		3h	The host error occurred on transmit channel 3
		4h	The host error occurred on transmit channel 4
		5h	The host error occurred on transmit channel 5
		6h	The host error occurred on transmit channel 6
		7h	The host error occurred on transmit channel 7

Table 22-77. MAC Status Register (MACSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
15-12	RXERRCODE	0-Fh	Receive host error code. These bits indicate that EMAC detected receive DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover.
		0	No error
		1h	Reserved
		2h	Ownership bit not set in SOP buffer
		3h	Reserved
		4h	Zero buffer pointer
		5h-Fh	Reserved
11	Reserved	0	Reserved
10-8	RXERRCH	0-7h	Receive host error channel. These bits indicate which receive channel the host error occurred on. This field is cleared to 0 on a host read.
		0	The host error occurred on receive channel 0
		1h	The host error occurred on receive channel 1
		2h	The host error occurred on receive channel 2
		3h	The host error occurred on receive channel 3
		4h	The host error occurred on receive channel 4
		5h	The host error occurred on receive channel 5
		6h	The host error occurred on receive channel 6
		7h	The host error occurred on receive channel 7
7-5	Reserved	0	Reserved
4	EXTGIGSEL	0-1	External GIG – This is the value of the EXTGIGSEL input.
3	EXTFULLDUPLEXSEL	0-1	External Fullduplex – This is the value of the EXTFULLDUPLEXSEL input.
2	RXQOSACT		Receive Quality of Service (QOS) active bit. When asserted, indicates that receive quality of service is enabled and that at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the RXFILTERLOWTHRESH value.
		0	Receive quality of service is disabled.
		1	Receive quality of service is enabled.
1	RXFLOWACT		Receive flow control active bit. When asserted, at least one channel freebuffer count (RX*n*FREEBUFFER) is less than or equal to the channel's corresponding RX*n*FILTERTHRESH value.
		0	Receive flow control is inactive.
		1	Receive flow control is active.
0	TXFLOWACT		Transmit flow control active bit. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted, except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.
		0	Transmit flow control is inactive.
		1	Transmit flow control is active.

22.5.31 Emulation Control Register (EMCONTROL)

The emulation control register (EMCONTROL) is shown in Figure 22-67 and described in Table 22-78.

Figure 22-67. Emulation Control Register (EMCONTROL)

31	16
Reserved	
R-0	

15	2	1	0
Reserved		SOFT	FREE
R-0		R/W-0	R/W-0

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-78. Emulation Control Register (EMCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	SOFT		Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1.
		0	Soft mode is disabled. EMAC stops immediately during emulation halt.
		1	Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation.
0	FREE		Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode.
		0	Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC.
		1	Free-running mode is enabled. During emulation halt, EMAC continues to operate.

22.5.32 FIFO Control Register (FIFOCONTROL)

The FIFO control register (FIFOCONTROL) is shown in Figure 22-68 and described in Table 22-79.

Figure 22-68. FIFO Control Register (FIFOCONTROL)

R-0	

15	2	1	0
Reserved		TXCELLTHRESH	
R-0		R/W-2h	

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-79. FIFO Control Register (FIFOCONTROL) Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	TXCELLTHRESH	0-3h	Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values.
		0-1h	Not a valid value.
		2h	Two 64-byte packet cells required to be in the transmit FIFO.
		3h	Three 64-byte packet cells required to be in the transmit FIFO.

22.5.33 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in Figure 22-69 and described in Table 22-80.

Figure 22-69. MAC Configuration Register (MACCONFIG)

31	24	23	16
TXCELLDEPTH		RXCELLDEPTH	
R-3h		R-3h	

15	8	7	0
ADDRESSTYPE		MACCFIG	
R-2h		R-2h	

LEGEND: R = Read only; -*n* = value after reset

Table 22-80. MAC Configuration Register (MACCONFIG) Field Descriptions

Bit	Field	Value	Description
31-24	TXCELLDEPTH	3h	Transmit cell depth. These bits indicate the number of cells in the transmit FIFO.
23-16	RXCELLDEPTH	3h	Receive cell depth. These bits indicate the number of cells in the receive FIFO.
15-8	ADDRESSTYPE	2h	Address type
7-0	MACCFIG	2h	MAC configuration value

22.5.34 Soft Reset Register (SOFTRESET)

The soft reset register (SOFTRESET) is shown in Figure 22-70 and described in Table 22-81.

Figure 22-70. Soft Reset Register (SOFTRESET)

31	16
Reserved	
R-0	

15	1	0
Reserved		SOFTRESET
R-0		R/W-0

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-81. Soft Reset Register (SOFTRESET) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	SOFTRESET		Software reset. Writing a 1 to this bit causes the EMAC logic to be reset. Software reset occurs when the receive and transmit DMA controllers are in an idle state to avoid locking up the Configuration bus. After writing a 1 to this bit, it may be polled to determine if the reset has occurred. If a 1 is read, the reset has not yet complete. If a 0 is read, then a reset has complete.
		0	Software reset complete status - read.
		1	Software reset is applied - write.

22.5.35 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in Figure 22-71 and described in Table 22-82.

Figure 22-71. MAC Source Address Low Bytes Register (MACSRCADDRLO)

Table 22-83. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions

Bit	Field	Value	Description
31-24	MACSRCADDR2	0-FFh	MAC source address bits 23-16 (byte 2)
23-16	MACSRCADDR3	0-FFh	MAC source address bits 31-24 (byte 3)
15-8	MACSRCADDR4	0-FFh	MAC source address bits 39-32 (byte 4)
7-0	MACSRCADDR5	0-FFh	MAC source address bits 47-40 (byte 5)

22.5.37 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash_fun) from the 48-bit destination address (DA) as follows:

```
Hash_fun(0)=DA(0) XOR DA(6) XOR DA(12) XOR DA(18) XOR DA(24) XOR DA(30) XOR DA(36) XOR DA(42);

Hash_fun(1)=DA(1) XOR DA(7) XOR DA(13) XOR DA(19) XOR DA(25) XOR DA(31) XOR DA(37) XOR DA(43);

Hash_fun(2)=DA(2) XOR DA(8) XOR DA(14) XOR DA(20) XOR DA(26) XOR DA(32) XOR DA(38) XOR DA(44);

Hash_fun(3)=DA(3) XOR DA(9) XOR DA(15) XOR DA(21) XOR DA(27) XOR DA(33) XOR DA(39) XOR DA(45);

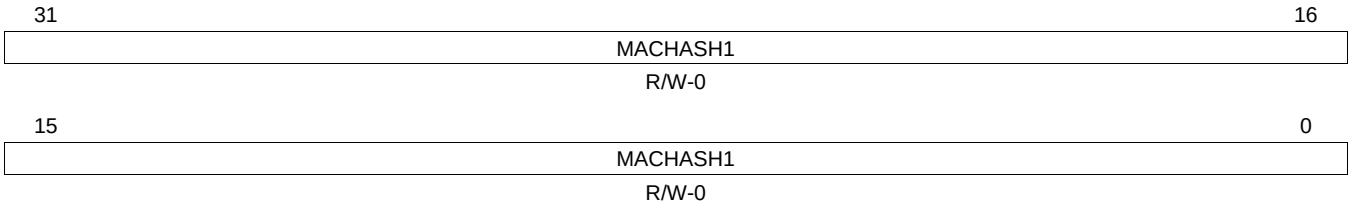
Hash_fun(4)=DA(4) XOR DA(10) XOR DA(16) XOR DA(22) XOR DA(28) XOR DA(34) XOR DA(40) XOR DA(46);

Hash_fun(5)=DA(5) XOR DA(11) XOR DA(17) XOR DA(23) XOR DA(29) XOR DA(35) XOR DA(41) XOR DA(47);
```

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in Figure 22-73 and described in Table 22-84.

Figure 22-73. MAC Hash Address Register 1 (MACHASH1)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-84. MAC Hash Address Register 1 (MACHASH1) Field Descriptions

Bit	Field	Value	Description
31-0	MACHASH1	0-FFFF FFFFh	Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

22.5.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in Figure 22-74 and described in Table 22-85.

Figure 22-74. MAC Hash Address Register 2 (MACHASH2)

31	16
MACHASH2	
R/W-0	

15	0
MACHASH2	
R/W-0	

LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset

Table 22-85. MAC Hash Address Register 2 (MACHASH2) Field Descriptions

Bit	Field	Value	Description
31-0	MACHASH2	0-FFFF FFFFh	Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted.

22.5.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in Figure 22-75 and described in Table 22-86.

Figure 22-75. Back Off Random Number Generator Test Register (BOFFTEST)

31	26	25	16
Reserved		RNDNUM	
R-0		R-0	

15	12	11	10	9	0
COLLCOUNT		Reserved		TXBACKOFF	
R-0		R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 22-86. Back Off Test Register (BOFFTEST) Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved
25-16	RNDNUM	0-3FFh	Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset.
15-12	COLLCOUNT	0-Fh	Collision count. These bits indicate the number of collisions the current frame has experienced.
11-10	Reserved	0	Reserved
9-0	TXBACKOFF	0-3FFh	Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

22.5.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in Figure 22-76 and described in Table 22-87.

Figure 22-76. Transmit Pacing Algorithm Test Register (TPACETEST)

31	16
Reserved	
R-0	

15	5	4	0
Reserved		PACEVAL	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

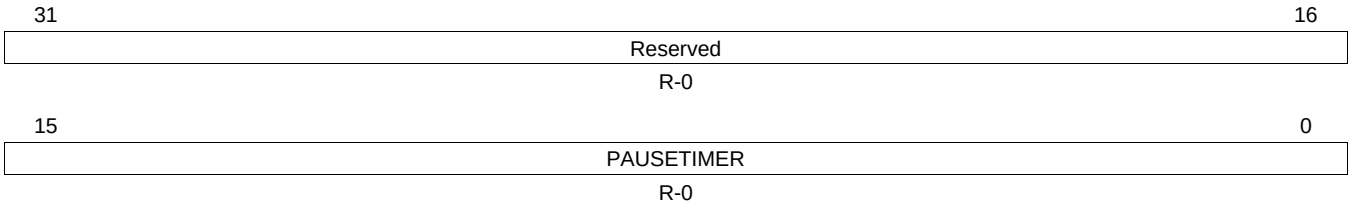
Table 22-87. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-0	PACEVAL	0-1Fh	Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth.

22.5.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in Figure 22-77 and described in Table 22-88.

Figure 22-77. Receive Pause Timer Register (RXPAUSE)



LEGEND: R = Read only; -*n* = value after reset

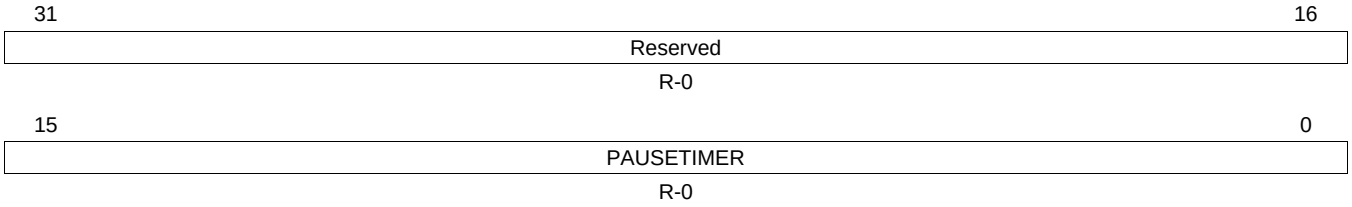
Table 22-88. Receive Pause Timer Register (RXPAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated.

22.5.42 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in Figure 22-78 and described in Table 22-89.

Figure 22-78. Transmit Pause Timer Register (TXPAUSE)



LEGEND: R = Read only; -*n* = value after reset

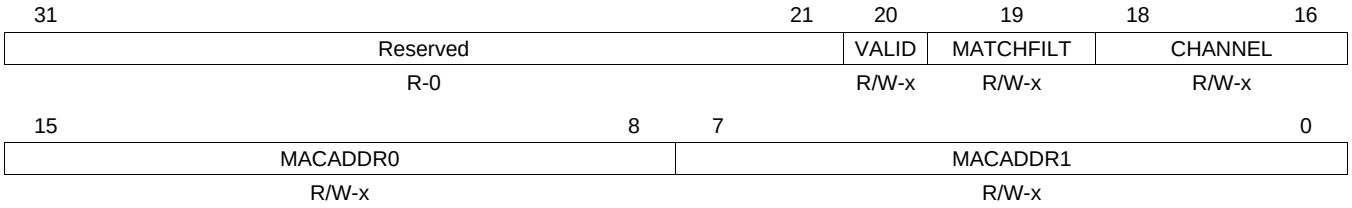
Table 22-89. Transmit Pause Timer Register (TXPAUSE) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	PAUSETIMER	0-FFh	Transmit pause timer value. These bits allow the contents of the transmit pause timer to be observed. The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented at slot time intervals down to 0, at which time EMAC transmit frames are again enabled.

22.5.43 MAC Address Low Bytes Register (MACADDRLO)

The MAC address low bytes register used in address matching (MACADDRLO), is shown in Figure 22-79 and described in Table 22-90.

Figure 22-79. MAC Address Low Bytes Register (MACADDRLO)



LEGEND: R = Read only; R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

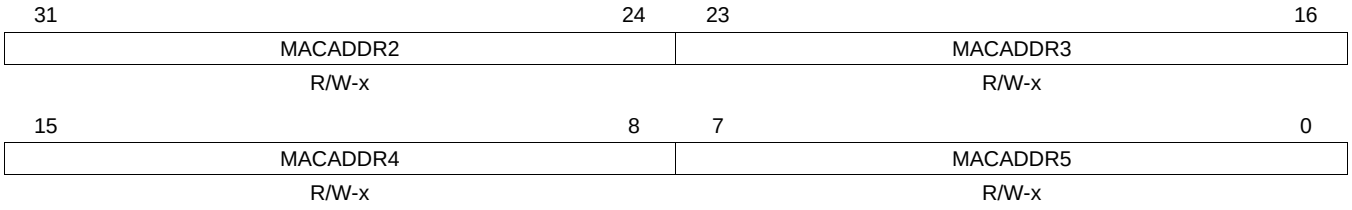
Table 22-90. MAC Address Low Bytes Register (MACADDRLO) Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Reserved
20	VALID		Address valid bit. This bit should be cleared to zero for unused address channels
		0	Address is not valid and will not be used for matching or filtering incoming packets
		1	Address is valid and will be used for matching or filtering incoming packets
19	MATCHFILT		Match or filter bit
		0	The address will be used (if the VALID bit is set) to filter incoming packet addresses
		1	The address will be used (if the VALID bit is set) to match incoming packet addresses
18-16	CHANNEL	0-7h	Channel select. Determines which receive channel a valid address match will be transferred to. The channel is a don't care if MATCHFILT is cleared to 0.
15-8	MACADDR0	0-FFh	MAC address lower 7-0 bits (byte 0)
7-0	MACADDR1	0-FFh	MAC address bits 15-8 (byte 1)

22.5.44 MAC Address High Bytes Register (MACADDRHI)

The MAC address high bytes register (MACADDRHI) is shown in Figure 22-80 and described in Table 22-91.

Figure 22-80. MAC Address High Bytes Register (MACADDRHI)



LEGEND: R/W = Read/Write; -x = value is indeterminate after reset

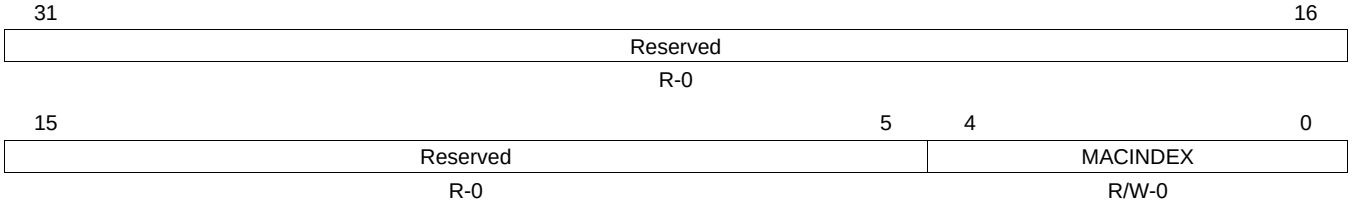
Table 22-91. MAC Address High Bytes Register (MACADDRHI) Field Descriptions

Bit	Field	Value	Description
31-24	MACADDR2	0-FFh	MAC source address bits 23-16 (byte 2)
23-16	MACADDR3	0-FFh	MAC source address bits 31-24 (byte 3)
15-8	MACADDR4	0-FFh	MAC source address bits 39-32 (byte 4)
7-0	MACADDR5	0-FFh	MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table.

22.5.45 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in Figure 22-81 and described in Table 22-92.

Figure 22-81. MAC Index Register (MACINDEX)



LEGEND: R = Read only; R/W = Read/Write; *-n* = value after reset

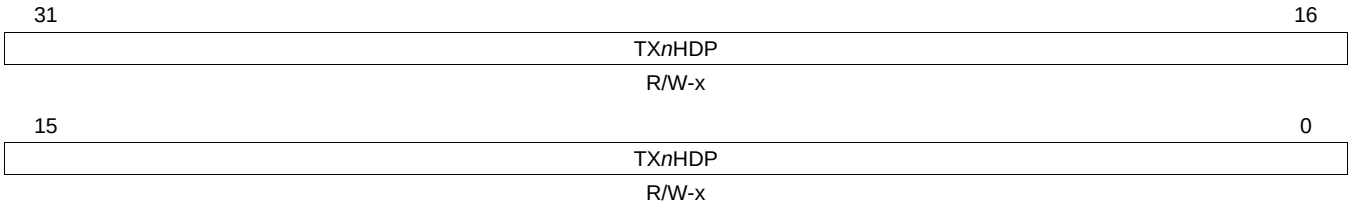
Table 22-92. MAC Index Register (MACINDEX) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4-0	MACINDEX	0-1Fh	Mac Address Index. The 53-bits of each address location are written with three consecutive 32-bit VBUS accesses. The host must write the index into the ram in the MACINDEX(4:0) register, followed by the upper 32-bits of address (which are stored in a holding register), followed by the lower 16- bits of address (with control bits). The 53-bit indexed ram location is written when the low location is written.

22.5.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX*n*HDP) is shown in Figure 22-82 and described in Table 22-93.

Figure 22-82. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

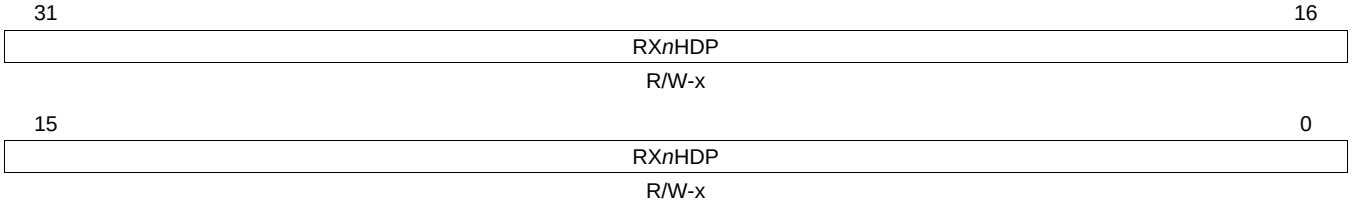
Table 22-93. Transmit Channel *n* DMA Head Descriptor Pointer Register (TX*n*HDP) Field Descriptions

Bit	Field	Value	Description
31-0	TX*n*HDP	0-FFFF FFFFh	Transmit channel *n* DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

22.5.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX*n*HDP) is shown in Figure 22-83 and described in Table 22-94.

Figure 22-83. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

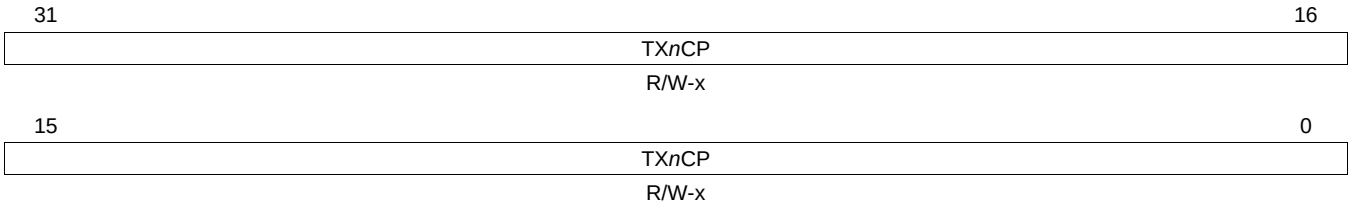
Table 22-94. Receive Channel *n* DMA Head Descriptor Pointer Register (RX*n*HDP) Field Descriptions

Bit	Field	Value	Description
31-0	RX*n*HDP	0-FFFF FFFFh	Receive channel *n* DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset.

22.5.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TX*n*CP) is shown in Figure 22-84 and described in Table 22-95.

Figure 22-84. Transmit Channel *n* Completion Pointer Register (TX*n*CP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

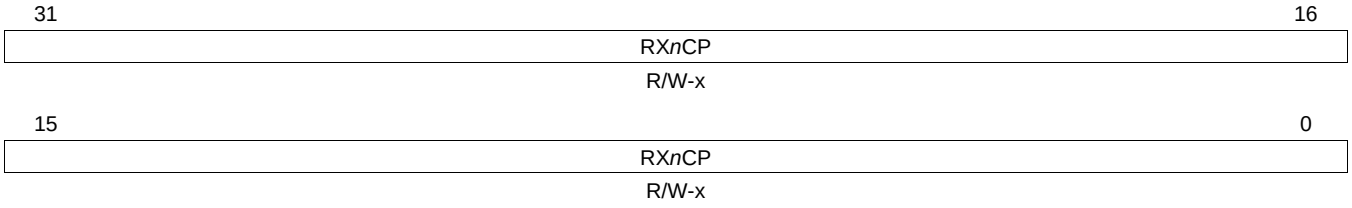
Table 22-95. Transmit Channel *n* Completion Pointer Register (TX*n*CP) Field Descriptions

Bit	Field	Value	Description
31-0	TX*n*CP	0-FFFF FFFFh	Transmit channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

22.5.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RX*n*CP) is shown in Figure 22-85 and described in Table 22-96.

Figure 22-85. Receive Channel *n* Completion Pointer Register (RX*n*CP)



LEGEND: R/W = Read/Write; -*n* = value after reset; -x = value is indeterminate after reset

Table 22-96. Receive Channel *n* Completion Pointer Register (RX*n*CP) Field Descriptions

Bit	Field	Value	Description
31-0	RX*n*CP	0-FFFF FFFFh	Receive channel *n* completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted.

NOTE: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPGMAC dma controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.

22.5.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP_RST_N. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see Figure 22-86) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

22.5.50.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See **Section 22.2.5.5** for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
  - A frame containing an even number of nibbles
  - Fails the frame check sequence test

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
  - An alignment error is defined as having all of the following:
    - A frame containing an odd number of nibbles
    - Fails the frame check sequence test, if the final nibble is ignored
  - A code error is defined as a frame that has been discarded because the EMACs MII_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

22.5.50.7 Receive Oversized Frames Register (RXOVERSIZED)

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.8 Receive Jabber Frames Register (RXJABBER)

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.9 Receive Undersized Frames Register (RXUNDERSIZED)

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.10 Receive Frame Fragments Register (RXFRAGMENTS)

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.11 Filtered Receive Frames Register (RXFILTERED)

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

22.5.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX*n*FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX*n*FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.13 Receive Octet Frames Register (RXOCTETS)

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See Section 22.2.5.5 for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.14 Good Transmit Frames Register (TXGOODFRAMES)

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES)

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

22.5.50.18 Deferred Transmit Frames Register (TXDEFERRED)

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

22.5.50.19 Transmit Collision Frames Register (TXCOLLISION)

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
  - Was destined for any unicast, broadcast, or multicast address
  - Was any size
  - Had no carrier loss and no underrun
  - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

22.5.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL)

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

22.5.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

22.5.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

22.5.50.23 Transmit Late Collision Frames Register (TXLATECOLL)

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

22.5.50.24 Transmit Underrun Error Register (TXUNDERRUN)

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

22.5.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

22.5.50.26 Transmit Octet Frames Register (TXOCTETS)

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64)

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

22.5.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

22.5.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

22.5.50.33 Network Octet Frames Register (NETOCTETS)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

22.5.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.5.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.5.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS)

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.6 EMAC/MDIO Glossary

Broadcast MAC Address— A special Ethernet MAC address used to send data to all Ethernet devices on the local network. The broadcast address is FFh-FFh-FFh-FFh-FFh-FFh. The LSB of the first byte is odd, qualifying it as a group address; however, its value is reserved for broadcast. It is classified separately by the EMAC.

Descriptor (Packet Buffer Descriptor)— A small memory structure that describes a larger block of memory in terms of size, location, and state. Descriptors are used by the EMAC and application to describe the memory buffers that hold Ethernet data.

Device — In this document, device refers to the processor.

Ethernet MAC Address (MAC Address)— A unique 6-byte address that identifies an Ethernet device on the network. In an Ethernet packet, a MAC address is used twice, first to identify the packet's destination, and second to identify the packet's sender or source. An Ethernet MAC address is normally specified in hexadecimal, using dashes to separate bytes. For example, 08h-00h-28h-32h-17h-42h.

The first three bytes normally designate the manufacturer of the device. However, when the first byte of the address is odd (LSB is 1), the address is a group address (broadcast or multicast). The second bit specifies whether the address is globally or locally administrated (not considered in this document).

Ethernet Packet (Packet)— An Ethernet packet is the collection of bytes that represents the data portion of a single Ethernet frame on the wire.

Full Duplex— Full-duplex operation allows simultaneous communication between a pair of stations using point-to-point media (dedicated channel). Full-duplex operation does not require that transmitters defer, nor do they monitor or react to receive activity, as there is no contention for a shared medium in this mode. Full-duplex mode can only be used when all of the following are true:

- The physical medium is capable of supporting simultaneous transmission and reception without interference.
- There are exactly two stations connected with a full duplex point-to-point link. As there is no contention for use of a shared medium, the multiple access (that is, CSMA/CD) algorithms are unnecessary.
- Both stations on the LAN are capable of, and have been configured to use, full-duplex operation.

The most common configuration envisioned for full-duplex operation consists of a central bridge (also known as a switch) with a dedicated LAN connecting each bridge port to a single device.

Full-duplex operation constitutes a proper subset of the MAC functionality required for half-duplex operation.

Half Duplex— In half-duplex mode, the CSMA/CD media access method is the means by which two or more stations share a common transmission medium. To transmit, a station waits (defers) for a quiet period on the medium, that is, no other station is transmitting. It then sends the intended message in bit-serial form. If, after initiating a transmission, the message collides with that of another station, then each transmitting station intentionally transmits for an additional predefined period to ensure propagation of the collision throughout the system. The station remains silent for a random amount of time (backoff) before attempting to transmit again.

Host— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port (EMAC) interrupts. In this document, host refers to the device.

Jabber— A condition wherein a station transmits for a period of time longer than the maximum permissible packet length, usually due to a fault condition.

Link— The transmission path between any two instances of generic cabling.

Multicast MAC Address— A class of MAC address that sends a packet to potentially more than one recipient. A group address is specified by setting the LSB of the first MAC address byte to 1. Thus, 01h-02h-03h-04h-05h-06h is a valid multicast address. Typically, an Ethernet MAC looks for only certain multicast addresses on a network to reduce traffic load. The multicast address list of acceptable packets is specified by the application.

Physical Layer and Media Notation— To identify different Ethernet technologies, a simple, three-field, type notation is used. The Physical Layer type used by the Ethernet is specified by these fields:

<data rate in Mb/s><medium type><maximum segment length (×100m)>

The definitions for the technologies mentioned in this document are in Table 22-97.

Table 22-97. Physical Layer Definitions

Term	Definition
10Base-T	IEEE 802.3 Physical Layer specification for a 10 Mb/s CSMA/CD local area network over two pairs of twisted-pair telephone wire.
100Base-T	IEEE 802.3 Physical Layer specification for a 100 Mb/s CSMA/CD local area network over two pairs of Category 5 unshielded twisted-pair (UTP) or shielded twisted-pair (STP) wire.
Twisted pair	A cable element that consists of two insulated conductors twisted together in a regular fashion to form a balanced transmission line.

Port— Ethernet device.

Promiscuous Mode— EMAC receives frames that do not match its address.

High-End CAN Controller (HECC)

This document contains a general description of the controller area network (CAN). The CAN uses established protocol to communicate serially with other controllers in harsh environments. This document describes the Standard CAN controller (SCC) and the High-End CAN controller (HECC) modules. Unless otherwise stated in the text, all information is related to both the SCC and HECC.

23.1 CAN Overview

The CAN controller is available in two different implementations that are both fully compliant with the CAN protocol, version 2.0B. The two different CAN controller versions use the same CAN protocol kernel module to perform the basic CAN protocol tasks. Only the message controller differs between the two CAN controller versions.

Key features of the CAN module include:

- Common CAN protocol kernel (CPK) to perform protocol tasks
- Standard CAN controller (SCC) for standard CAN applications
  - Sixteen message-object acceptance-filtering
- High-end CAN controller (HECC) for complex applications
  - Thirty-two message objects full-mask acceptance-filtering

Table 23-1. SCC and HECC Features Overview

Feature	SCC	HECC
Number of message objects	16 Receive/Transmit	32 Receive/Transmit
Number of receive identifier masks	3	32
CAN, version 2.0B compliant	X	X
Low-power mode	X	X
Programmable wake-up on bus activity	X	X
Programmable interrupt scheme	X	X
Automatic reply to a remote request	X	X
Automatic retransmission in case of error	X	X
Protect against reception of new message	X	X
32-bit time stamp		X
Local network time counter		X
Programmable priority register for each message		X
Programmable transmission and reception time-out		X

23.1.1 CAN Protocol Processor Features

The CAN protocol kernel (CPK) performs the basic CAN protocol tasks according to CAN protocol specification 2.0B. The CPK is the basic module of all CAN controller implementations. The CPK provides the following features:

- Full implementation of CAN protocol, version 2.0B
  - Standard and extended identifiers
  - Data and remote frames
- Bus speed of up to 1 Mbps

- Programmable prescaler from 1 to 256
- Programmable bit time according to the CAN specification
- Programmable sampling mode
  - One or three samples used to determine the received bit value
- Selectable edge of receive bit flow for synchronization
  - Both edges or falling edge only
- Automatic retransmission of a frame in case of loss of arbitration
- Low-power mode
- Bus failure diagnostic
  - Bus on/off
  - Error passive/active
  - Bus error warning
  - Bus stuck dominant
  - Frame error report: cyclic redundancy check (CRC), stuff, form, bit, and acknowledgment errors
  - Readable error counters
- Self-test mode
  - Operate in a loop-back mode (receiving its own message)
  - Dummy acknowledge

23.1.2 Standard CAN Controller (SCC) Features

The SCC provides the following features:

- All the CAN protocol kernel (CPK) features
  - Full implementation of CAN protocol, version 2.0B
- Sixteen message objects, each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard or extended identifier
  - Protects against reception of new message
  - Supports data and remote frame
  - Composed of 0 to 8 bytes of data
  - Employs a programmable interrupt scheme with two interrupt levels
  - Has a message priority based on object number
- Two programmable local identifier masks for objects 0-2 and 3-5
  - Configurable as standard or extended message identifier
  - Has an acceptance mask register for identifier extension bit
- One global programmable identifier mask for objects 6-15
  - Configurable as standard or extended message identifier
  - Has an acceptance mask register for identifier extension bit
- Low-power mode
- Programmable wake-up on bus activity
- Automatic reply to a remote request message
- Automatic retransmission of a frame in case of loss of arbitration or error

23.1.3 High-End CAN Controller (HECC) Features

The HECC provides the following features:

- All the CAN protocol kernel (CPK) features

  - Full implementation of CAN protocol, version 2.0B
- Thirty-two message objects, each with the following properties:
  - Configurable as receive or transmit
  - Configurable with standard or extended identifier
  - Has a programmable receive mask
  - Supports data and remote frame
  - Composed of 0 to 8 bytes of data
  - Uses a 32-bit time stamp on receive and transmit message
  - Protects against reception of new message
  - Holds the dynamically programmable priority of transmit message
  - Employs a programmable interrupt scheme with two interrupt levels
  - Employs a programmable alarm on transmission or reception time-out
- Low-power mode
- Programmable wake-up on bus activity
- Automatic reply to a remote request message
- Automatic retransmission of a frame in case of loss of arbitration or error
- 32-bit local network time counter synchronized by a specific message (communication in conjunction with mailbox 16)
- SCC-compatible mode
  - Upward-compatible software
  - Software written for the SCC can run without any changes on the HECC
  - SCC-compatible mode is automatically activated after RESET

23.2 CAN Network and Module Overview

The controller area network (CAN) uses a serial multimaster communication protocol that efficiently supports distributed real-time control, with a very high level of security, and a communication rate of up to 1 Mbps. The CAN bus is ideal for applications operating in noisy and harsh environments, such as in the automotive and other industrial fields that require reliable communication or multiplexed wiring.

Prioritized messages of up to eight bytes in data length can be sent on a multimaster serial bus using an arbitration protocol and an error-detection mechanism for a high level of data integrity.

23.2.1 CAN Protocol Overview

The CAN protocol supports four different frame types for communication:

- Data frames that carry data from a transmitter node to the receiver nodes
- Remote frames that are transmitted by a node to request the transmission of a data frame with the same identifier
- Error frames that are transmitted by any node on a bus-error detection
- Overload frames that provide an extra delay between the preceding and the succeeding data frames or remote frames.

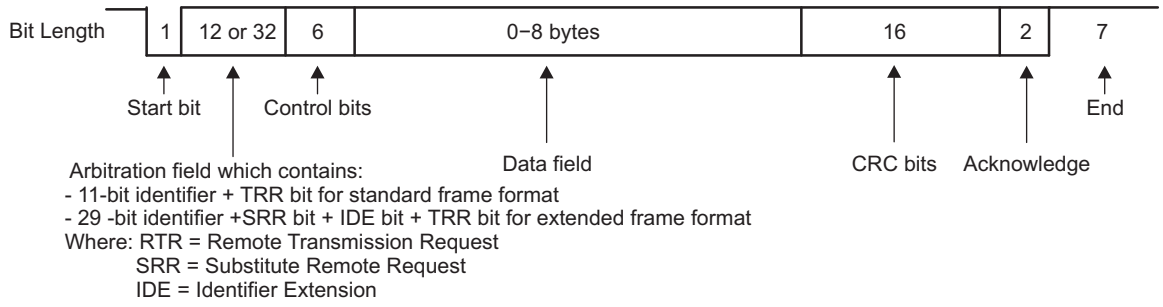
In addition, CAN specification version 2.0B defines two different formats that differ in the length of the identifier field: standard frames with an 11-bit identifier and extended frames with 29-bit identifier.

CAN standard data frames contain from 44 to 108 bits and CAN extended data frames contain 64 to 128 bits. Furthermore, up to 23 stuff bits can be inserted in a standard data frame, and up to 28 stuff bits in an extended data frame, depending on the data-stream coding. The overall maximum data frame length is then 131 bits for a standard frame and 156 bits for an extended frame.

Bit fields within the data frame, shown in Figure 23-1, identify:

- Start of the frame
- Arbitration field containing the identifier and the type of message being sent
- Control field containing the number of data bytes
- Up to 8 bytes of data
- Cyclic redundancy check (CRC)
- Acknowledgment
- End-of-frame bits

Figure 23-1. CAN Data Frame



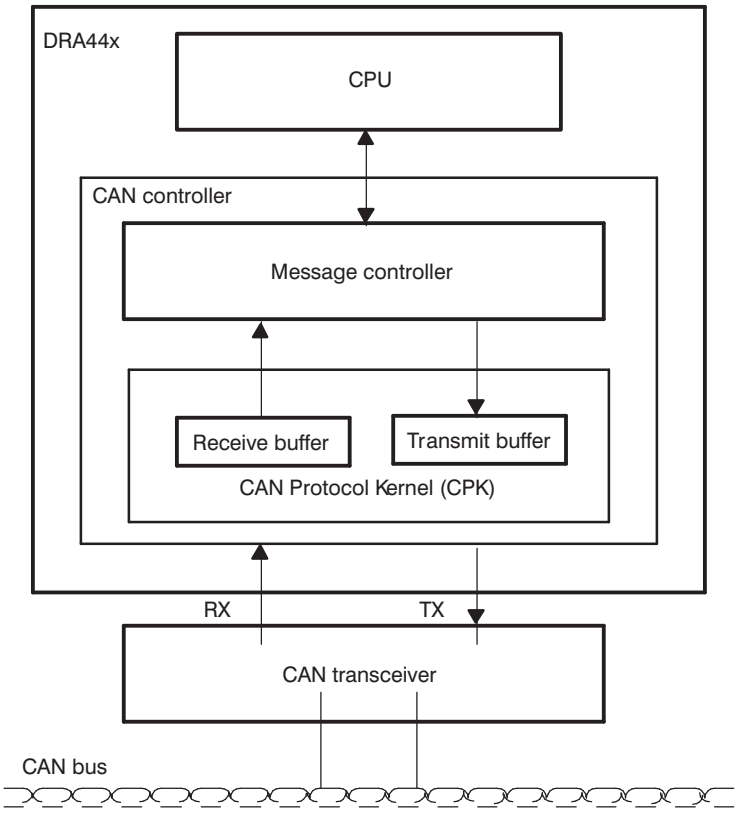
Note: Unless otherwise noted, numbers specify the number of bits in the field.

23.2.2 CAN Controller Overview

The CAN controllers provide the CPU with full functionality of the CAN protocol, version 2.0B. The CAN controller minimizes the CPU load in communication overhead and enhances the CAN standard by providing additional features.

The architecture of both the SCC and the HECC controllers is composed of a CAN protocol kernel (CPK) and a message controller (Figure 23-2).

Figure 23-2. Architecture of the SCC and HECC CAN Controllers



Two functions of the CAN protocol kernel (CPK) are to decode all messages received on the CAN bus according to the CAN protocol and to transfer these messages into a receive buffer. Another CPK function is to transmit messages on the CAN bus according to the CAN protocol.

The message controller of a CAN controller is responsible for determining if any message received by the CPK must be preserved for the CPU use or be discarded. At the initialization phase, the CPU specifies to the message controller all message identifiers used by the application. The message controller is also responsible for sending the next message to transmit to the CPK according to the message's priority.

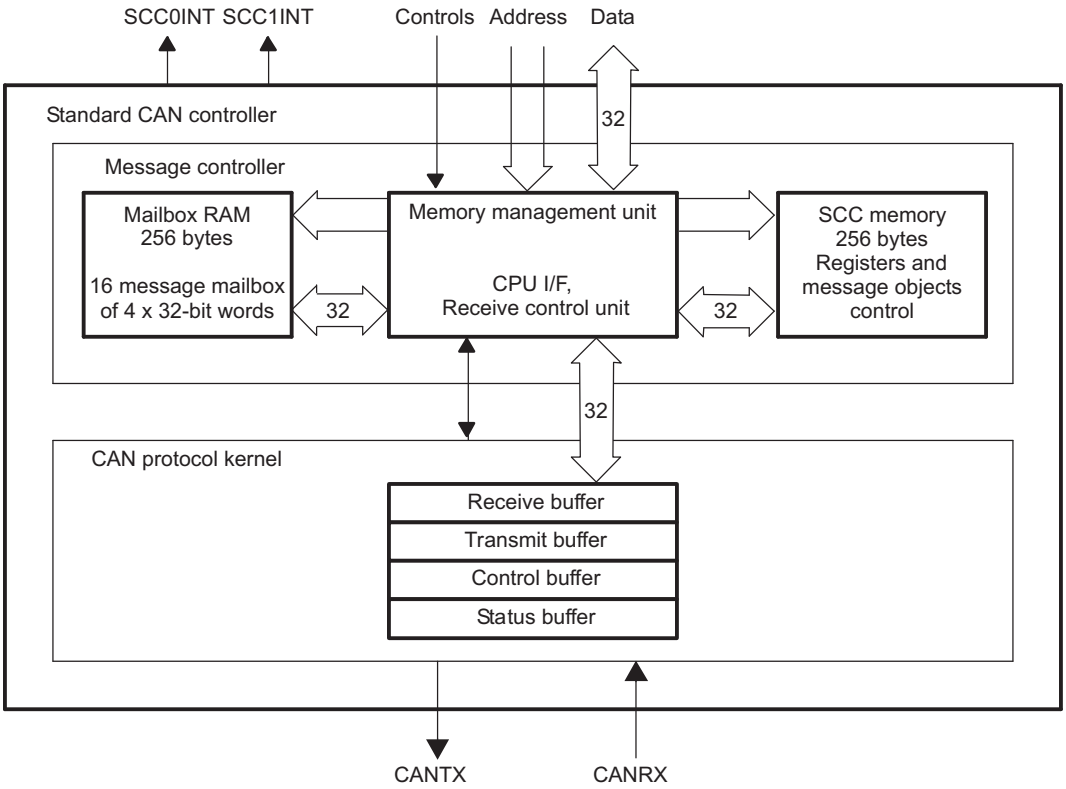
The SCC and the HECC differ only by their message controller - the CPK always offers the same services. The message management of the message controller is not part of the CAN protocol specification.

23.3 Standard CAN Controller (SCC) Overview

The SCC is a standard CAN controller with an internal 32-bit architecture, upwardly compatible with HECC. The SCC consists of:

- The CAN protocol kernel (CPK)
- The message controller:
  - The memory management unit (MMU) including the CPU interface and the receive control unit (acceptance filtering)
  - 256 bytes of mailbox RAM enabling the storage of 16 messages
  - 256 bytes of space register containing the global and the local identifier masks.

Figure 23-3. SCC Functional Block Diagram



After the reception of a valid message by the CAN protocol kernel (CPK), the receive control unit of the message controller determines if the message must be stored into one of the 16 message objects of the mailbox RAM. The receive control unit checks the state, the identifier, and the mask of all message objects to determine the appropriate mailbox location. The received message is stored into the first mailbox passing the acceptance filtering. If the receive control unit could not find any mailbox to store the received message, the message is discarded.

A message is composed of an identifier of 11 or 29 bits (contained in the arbitration field), a control field, and up to 8 bytes of data.

When a message must be transmitted, the message controller transfers the message into the transmit buffer of the CPK in order to start the message transmission at the next bus-idle state. When more than one message must be transmitted, the message with the highest priority is transferred into the CPK by the message controller.

The memory registers contain the global identifier mask and the two dedicated identifier masks for the message objects 0-2 and 3-5. After the reception of a valid identifier, the receive control unit checks the state and the identifier of all objects to determine if the received message must be stored into one of the message object's buffers.

To initiate a data transfer, the transmission-request bit has to be set in the corresponding control register. The entire transmission procedure and possible error handling is then done without any CPU involvement. If a mailbox has been configured to receive messages, the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

23.3.1 SCC Memory Map

The SCC module has two different offset addresses mapped in memory. The first offset address, *SCC_Offset*, is used to access the control and status registers, and the acceptance masks of the message objects. This memory range can only be accessed 32-bits wide. The second offset address, *Mailbox_RAM_Offset,* is used to access the message mailboxes. This memory range can be accessed 8-bits, 16-bits, and 32-bits wide. Each of these two memory blocks uses 256 bytes of address space.

The message storage is implemented by RAM that is addressed by the CAN controller or the CPU. The CPU controls the CAN controller by modifying the various mailboxes in the RAM or the additional registers. The contents of the various storage elements are used to perform acceptance filtering, message transmission, and interrupt handling.

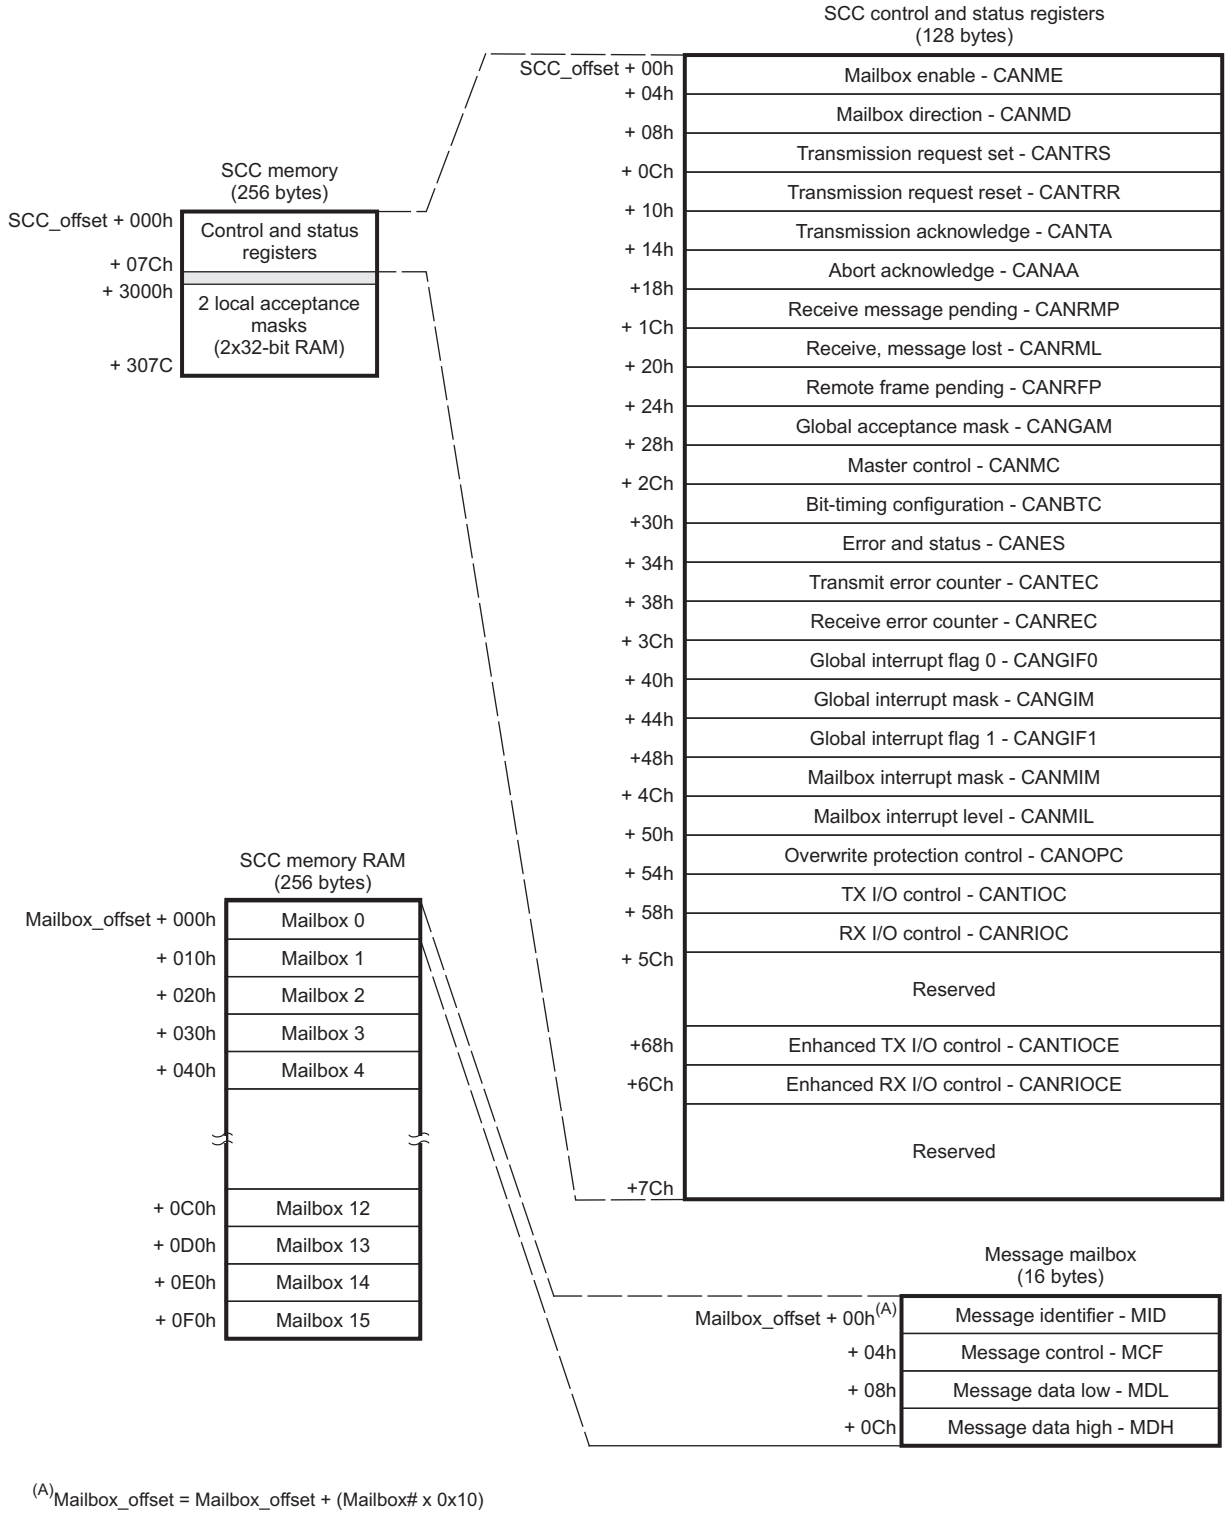
The mailbox module in the SCC provides 16 message mailboxes of 8-byte data lengths, a 29-bit identifier, and several control bits. Each mailbox can be configured to either transmit or receive data.

Unused Message Mailboxes

NOTE: All RAM areas are byte-writable and may be used as normal memory. In this case, it must be ensured that no CAN function uses the RAM area. This assurance is reached by disabling the corresponding mailbox or by disabling the corresponding functions.

The SCC and HECC registers, listed in Section 23.10, are used by the CPU to configure and control the CAN controller and the message objects

Figure 23-4. SCC Memory Map



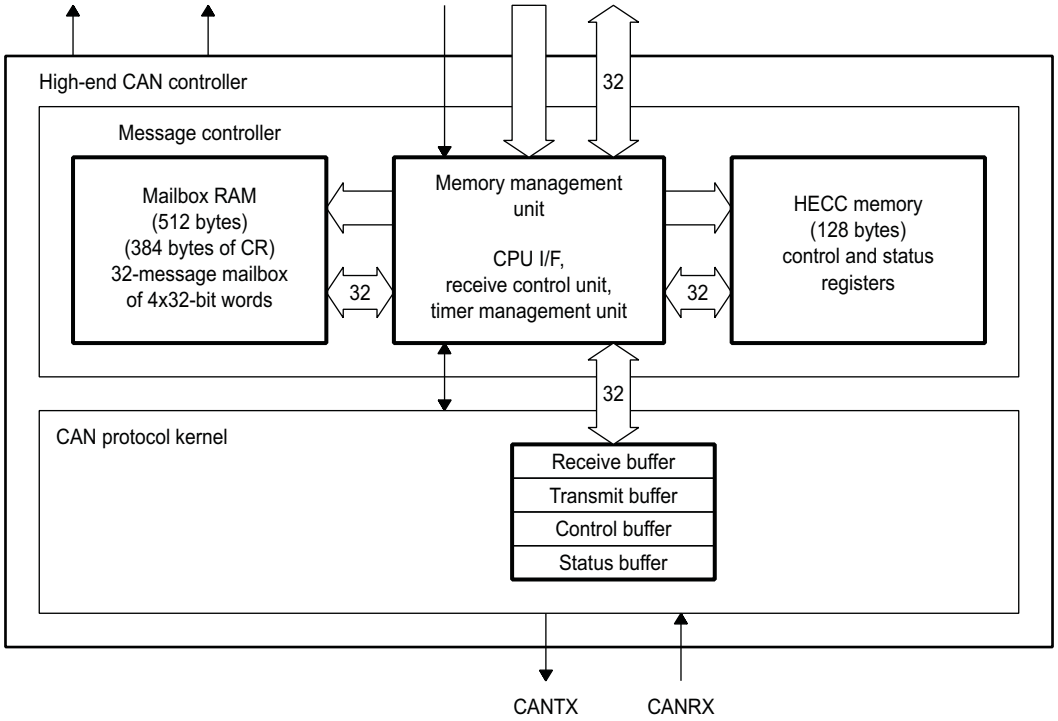
(A)Mailbox_offset = Mailbox_offset + (Mailbox# x 0x10)

23.4 High-End CAN Controller (HECC) Overview

The HECC is a new-generation, Texas Instruments, advanced CAN controller with an internal 32-bit architecture. The HECC, shown in Figure 23-5, consists of:

- The CAN protocol kernel (CPK)
- The message controller:
  - The memory management unit (MMU), including the CPU interface and the receive control unit (acceptance filtering), and the timer management unit
  - 512 bytes of mailbox RAM enabling the storage of 32 messages
  - 128 bytes of memory comprising the registers and the message objects control
  - 384 bytes of control RAM comprising the message objects control registers

Figure 23-5. HECC Functional Block Diagram



After the reception of a valid message by the CAN protocol kernel (CPK), the receive control unit of the message controller determines if the received message must be stored into one of the 32 message objects of the mailbox RAM. The receive control unit checks the state, the identifier, and the mask of all message objects to determine the appropriate mailbox location. The received message is stored into the first mailbox passing the acceptance filtering. If the receive control unit could not find any mailbox to store the received message, the message is discarded.

A message is composed of an identifier of 11 or 29 bits, a control field, and up to 8 bytes of data.

When a message must be transmitted, the message controller transfers the message into the transmit buffer of the CPK in order to start the message transmission at the next bus-idle state. When more than one message must be transmitted, the message with the highest priority (defined by the message-object-priority register) that is ready to be transmitted is transferred into the CPK by the message controller.

The timer management unit comprises a local network time counter and applies a time stamp to all messages received or transmitted. The timer management unit controls all message reception and transmission, and generates an alarm when a message has not been received or transmitted during an allowed period of time (time-out).

To initiate a data transfer, the transmission request bit has to be set in the corresponding control register. The entire transmission procedure and possible error handling are then performed without any CPU involvement. If a mailbox has been configured to receive messages, the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

23.4.1 SCC-Compatible Mode

The HECC can be used in SCC mode. In this mode, all functions specific to the HECC are not available and the HECC behaves exactly as the SCC. This mode is selected by default in order to allow any application software written for the SCC to run on the HECC without any modification. When using the HECC in SCC-compatible mode, you must refer to the SCC specification only. The SCC-compatible mode is selected with the SCM bit in the master control register (CANMC).

23.4.2 HECC Memory Map

The HECC module has two different offset addresses mapped in memory. The first offset address, *HECC_Offset*, is used to access the control register, the status register, the acceptance mask, the time stamp, and the time-out of the message objects. The access to the control and status registers (memory range: *HECC_Offset* ... *HECC_Offset* + *07Ch*) is limited to 32-bit-wide accesses. The local acceptance masks, the time stamp registers, and the time-out registers can be accessed 8-bits, 16-bits, and 32-bits wide. The second offset address, *Mailbox_RAM_Offset,* is used to access the mailboxes. This memory range can be accessed 8-bits, 16-bits, and 32-bits wide. Each of these two memory blocks uses 512 bytes of address space.

The message storage is implemented by RAM that can be addressed by the CAN controller or the CPU. The CPU controls the CAN controller by modifying the various mailboxes in the RAM or the additional registers. The contents of the various storage elements are used to perform the functions of the acceptance filtering, message transmission, and interrupt handling.

The mailbox module in the HECC provides 32 message mailboxes of 8-byte data lengths, a 29-bit identifier, and several control bits. Each mailbox can be configured as either transmit or receive. In the HECC, each mailbox has an individual acceptance mask.

Unused Message Mailboxes

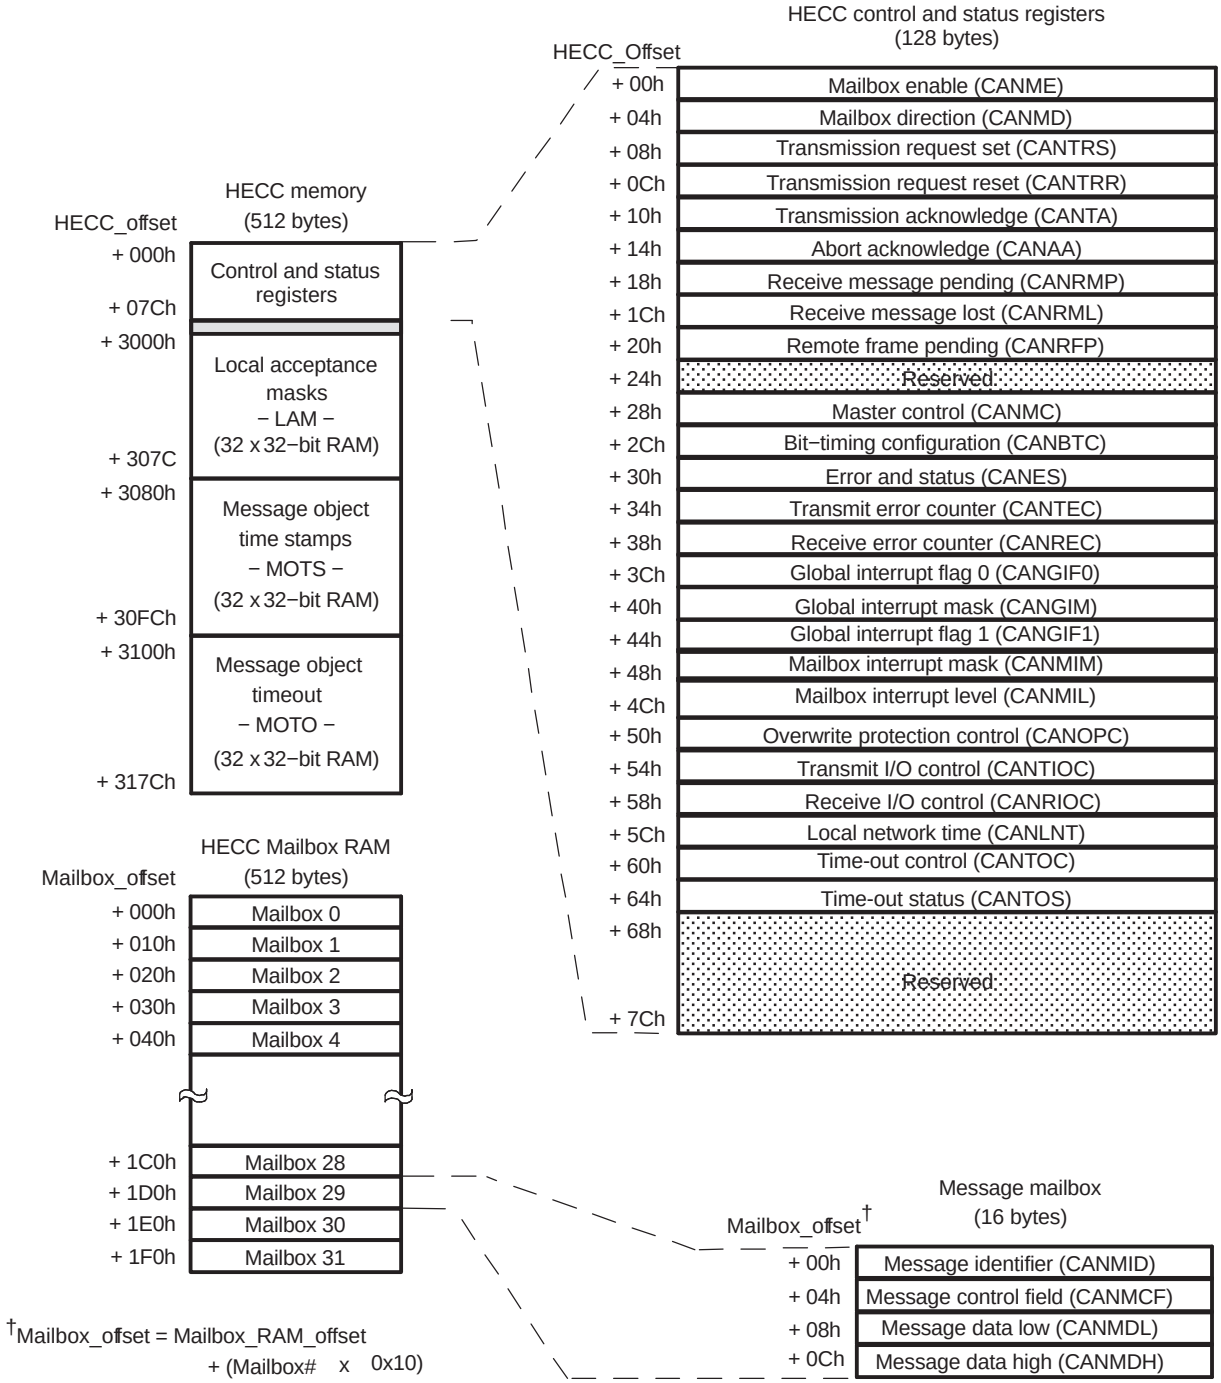
NOTE: All RAM areas are byte-writable and may be used as normal memory. In this case, it must be ensured that no CAN function uses the RAM area. This assurance is reached by disabling the corresponding mailbox or by disabling the corresponding functions.

HECC Used in SCC Mode

When the HECC is used in SCC mode, refer to the SCC memory map.

The SCC and HECC registers, listed in Section 23.10, are used by the CPU to configure and control the CAN controller and the message objects.

Figure 23-6. HECC Memory Map



23.5 Message Objects

23.5.1 SCC Message Objects

The message controller of the SCC handles 16 different mailboxes. Each mailbox is configured to either transmit or receive. In the SCC, mailboxes 0 to 2, 3 to 5, and 6 to 15 share the same acceptance masks.

An SCC mailbox consists of 20 bytes of RAM distributed, as shown in Table 23-2, as:

- A message mailbox RAM comprising
  - The 29-bit message identifier
  - The message control register
  - 8 bytes of message data
- A 29-bit acceptance mask

Furthermore, corresponding control and status bits located in the SCC registers allow control of the message objects.

Table 23-2. SCC Message Object Description

Offset Address[1]	Mnemonic	Name	Section
Mailbox_RAM_Offset + (Mailbox# + 10h) + 00h	CANMID	Message identifier	Section 23.10.4.1
Mailbox_RAM_Offset + (Mailbox# + 10h) + 04h	CANMCF	Message control field	Section 23.10.4.2
Mailbox_RAM_Offset + (Mailbox# + 10h) + 08h	CANMDL	Message data low word	Section 23.10.4.3
Mailbox_RAM_Offset + (Mailbox# + 10h) + 0Ch	CANMDH	Message data high word	Section 23.10.4.3
SCC_Offset + 3000h " for objects 0 to 2	CANLAM0	Local acceptance mask	Section 23.10.4.4
SCC_Offset + 300Ch " for objects 3 to 5	CANLAM3	Local acceptance mask	Section 23.10.4.4
SCC_Offset + 24h " for objects 6 to 15	CANGAM	Global acceptance mask	Section 23.10.1.10

(1) The actual addresses of the message objects are device-specific. See the device-specific datasheet to verify the SCC module memory offset and RAM offset.

Unused Message Mailboxes

NOTE: Message mailboxes not used by the application for CAN message (disabled in the CANME register) may be used as general memory by the CPU.

23.5.2 HECC Message Objects

The message controller of the HECC handles 32 different mailboxes. Each mailbox is configured to either transmit or receive. In the HECC, each mailbox has an individual acceptance mask.

A HECC mailbox consists of 28 bytes of RAM distributed, as shown in Table 23-3, as:

- A message mailbox RAM comprising
  - The 29-bit message identifier
  - The message control register
  - 8 bytes of message data
- A 29-bit acceptance mask
  - A 32-bit time stamp
  - A 32-bit time-out

Furthermore, corresponding control and status bits located in the HECC registers allow control of the message objects.

Table 23-3. HECC Message Object Description

Offset/Address[1]	Mnemonic	Name	Section
Mailbox_RAM_Offset + (Mailbox# + 10h) + 00h	CANMID	Message identifier	Section 23.10.4.1
Mailbox_RAM_Offset + (Mailbox# + 10h) + 04h	CANMCF	Message control field	Section 23.10.4.2
Mailbox_RAM_Offset + (Mailbox# + 10h) + 08h	CANMDL	Message data low word	Section 23.10.4.3
Mailbox_RAM_Offset + (Mailbox# + 10h) + 0Ch	CANMDH	Message data high word	Section 23.10.4.3
HECC_Offset + (Mailbox# x 4) + 3000h	CANLAM	Local acceptance mask	Section 23.10.4.4
HECC_Offset + (Mailbox# x 4) + 3080h	CANMOTS	Message object time stamp	Section 23.10.2.2
HECC_Offset + (Mailbox# x 4) + 3100h	CANMOTO	Message object time-out	Section 23.10.3.1

(1) The actual addresses of the message objects are device-specific. See the device-specific datasheet to verify the HECC module memory offset and RAM offset.

HECC Used in SCC Mode

NOTE: When the HECC is used in SCC mode, you must refer to the SCC message objects description (see Table 23-2).

Unused Message Mailboxes

NOTE: Message mailboxes not used by the application for CAN message (disabled in the CANME register) may be used as general memory by the CPU.

23.5.3 CAN Message Mailbox

The message mailboxes are the RAM area where the CAN messages are actually stored after they were received or before they are transmitted. The CPU may use the RAM area of the message mailboxes that are not used for storing messages as normal memory. This RAM area, unlike the register area, can be accessed by byte. Each mailbox contains:

- The message identifier
  - 29 bits for extended identifier
  - 11 bits for standard identifier
- Identifier extension (IDE) bit in the message identifier register (CANMID)
- Acceptance mask enable (AME) bit in the message identifier register (CANMID)
- Auto answer mode (AAM) bit in the message identifier register (CANMID)
- Remote transmission request (RTR) bit in the message control field register (CANMCF)
- Data length code (DLC) bits in the message control field register (CANMCF)
- Up to eight bytes for the data field
- On the HECC, transmit priority level (TPL) bits in the message control field register (CANMCF).

Each of the mailboxes can be configured as one of four message object types (see Table 23-4). Transmit and receive message objects are used for data exchange between one sender and multiple receivers (1-to-*n* communication link); whereas, request and reply message objects are used to set up a one-to-one communication link.

Table 23-4. Message Object Types

Message Object Types	MD*n* bit in CANMD	AAM bit in CANMID	RTR bit in CANMCF
Transmit message object	0	0	0
Receive message object	1	0	0
Request message object	1	0	1
Reply message object	0	1	0

23.5.3.1 Transmit Mailbox

The CPU stores the data to be transmitted in a mailbox configured as transmit mailbox. After writing the data and the identifier into the RAM, the message is sent if the corresponding TRS*n* bit in the transmit request set register (CANTRS) is set.

If more than one mailbox is configured as a transmit mailbox and more than one corresponding TRS*n* bit is set, the messages are sent one after another in descending order beginning with the mailbox with the highest priority.

In the SCC, the priority of the mailbox transmission depends on the mailbox number. The highest mailbox number (15) comprises the highest transmit priority.

In the HECC, the priority of the mailbox transmission depends on the setting of the TPL bits in the message control field register (CANMCF). The mailbox with the highest value in the TPL bits is transmitted first. Only when two mailboxes have the same value in the TPL bits is the higher numbered mailbox transmitted first. See Section 23.10.4.2 for more information about CANMCF.

If a transmission fails due to a loss of arbitration or an error, the message transmission is re-attempted. Before re-attempting the transmission, the CAN module checks if other transmissions are requested and then transmits the mailbox with the highest priority.

23.5.3.2 Receive Mailbox

The identifier of each incoming message is compared to the identifiers held in the receive mailboxes using the appropriate mask. When equality is detected, the received identifier, the control bits, and the data bytes are written into the matching RAM location. At the same time, the corresponding RMP*n* bit in the receive message pending register (CANRMP) is set and a receive interrupt is generated if enabled. If no match is detected, the message is not stored.

When a message is received, the message controller starts looking for a matching mailbox at the mailbox with the highest mailbox priority. Mailbox 15 of the SCC and of the HECC in SCC-compatible mode has the highest receive priority; mailbox 31 has the highest receive priority of the HECC in HECC mode.

NOTE: While operating in loop back mode:

- mailbox 0 receives data even if it is not programmed to receive data, or
- the last used reception mailbox, whether in loop back mode or normal operation mode, receives data even if none of the mailboxes is programmed to receive data.

The RMP*n* bit has to be reset by the CPU after reading the data. If a second message has been received for this mailbox and the RMP*n* bit is already set, the corresponding RML*n* bit in the receive message lost register (CANRML) is set. In this case, the stored message is overwritten with the new data if the corresponding OPC*n* bit in the overwrite protection control register (CANOPC) is cleared; otherwise, the next mailboxes are checked.

23.5.3.3 Handling of Remote Frames

If a remote frame is received (the incoming message has the RTR bit in the message control field register, CANMCF, set to 1), the CAN module compares the identifier to all identifiers of the mailboxes using the appropriate masks starting at the highest mailbox number in descending order.

- In the case of a matching identifier (with the message object configured as a send mailbox and the AAM bit in the message identifier register, CANMID, set to 1 in this message object), this message object is marked to be sent (corresponding TRS*n* bit in the transmit request set register (CANTRS) is set).
- In the case of a matching identifier (with the message object configured as a send mailbox and the AAM bit in CANMID cleared to 0 in this message object), this message is not received.

  After finding a matching identifier in a send mailbox, no further compare is done.
- In the case of a matching identifier and the message object configured as a receive mailbox, this message is handled like a data frame and the corresponding RMP*n* bit in the receive message pending register (CANRMP) is set. The CPU then has to decide how to handle this situation.

If the CPU wants to change the data in a message object that is configured as a remote frame mailbox (the AAM bit in CANMID is set to 1), the CPU has to set the MBNR bits and the CDR bit in the master control register (CANMC). The CPU may then perform the access and clear the CDR bit to inform the CAN module that the access is finished. Until the CDR bit is cleared, the transmission of this mailbox is not performed by the CAN module. Since CANTRS is not affected by the CDR bit, a pending transmission is started after the CDR bit is cleared; thus, the newest data is sent.

In order to change the identifier in that mailbox, the message object first must be disabled (the ME*n* bit in the mailbox enable register, CANME, is cleared to 0).

If the CPU wants to request data from another node, it may configure the message object as a receive mailbox and set the corresponding TRS*n* bit in CANTRS. In this case, the CAN module sends a remote frame request and receives the data frame in the same mailbox that sent the request. Therefore, only one mailbox is necessary to do a remote request. Note that the CPU must set the RTR bit in CANMCF to enable a remote frame transmission.

The behavior of the message object *n* is configured with the MD*n* bit in CANMD, the AAM bit in CANMID, and the RTR bit in CANMCF. Table 23-4 shows how to configure a message object according to the desired behavior.

To summarize, a message object can be configured with four different behaviors:

1. Transmit message object: only able to transmit messages.
2. Receive message object: only able to receive messages.
3. Request message object: able to transmit a remote request frame and to wait for the corresponding data frame.
4. Reply message object: able to transmit a data frame whenever a remote request frame is received for

the corresponding identifier.

Remote Transmission Request Bit

NOTE: When a remote transmission request is successfully transmitted with a message object configured in request mode, the TA*n* bit in the transmission acknowledge register (CANTA) is not set and no interrupt is generated. When the remote reply message is received, the behavior of the message object is the same as a message object configured in receive mode.

23.5.3.4 CPU Message Mailbox Access

Write accesses to the identifier is only accomplished when the mailbox is disabled (the ME*n* bit in the mailbox enable register, CANME, is cleared to 0). During access to the data field, it is critical that the data does not change while the CAN module is reading it; hence, a write access to the data field is disabled for a receive mailbox.

For send mailboxes, an access is usually denied if the TRS*n* bit in CANTRS or the TRR*n* bit in CANTRR is set. In these cases, an interrupt may be asserted. A way to access those mailboxes is to set the CDR bit in CANMC before accessing the mailbox data.

After the CPU access is finished, the CPU must clear the CDR bit in CANMC by writing a 0 to the CDR bit. The CAN module checks the CDR bit before and after reading the mailbox. If the CDR bit is set during those checks, the CAN module does not transmit the message but continues to look for other transmit requests. The setting of the CDR bit also stops the write-denied interrupt (WDI) from being asserted.

23.5.4 CAN Acceptance Filter

In the SCC and in the HECC there are two different implementations of the handling of the masks for the mailboxes. If the SCM bit is set in the master control register (CANMC), SCC-compatible mode is enabled and the HECC behaves like the SCC.

The identifier of the incoming message is first compared to the message identifier of the mailbox (that is stored in the mailbox). Then, the appropriate acceptance mask is used to mask out the bits of the identifier that should not be compared.

23.5.4.1 SCC Acceptance Filtering

In the SCC (or in the HECC in SCC-compatible mode), the global acceptance mask register (CANGAM) is used for mailboxes 6 to 15. An incoming message is stored in the highest numbered mailbox with a matching identifier. If there is no matching identifier in mailboxes 15 to 6, the incoming message is compared to the identifier stored in mailboxes 5 to 3 and then 2 to 0.

The mailboxes 5 to 3 use the local acceptance mask register CANLAM3 of the SCC registers. The mailboxes 2 to 0 use the local acceptance mask register CANLAM0 of the SCC registers. See Section 23.10.4.4.

To modify the two local acceptance mask registers of the SCC (CANLAM0 and CANLAM3), the CAN module must be set in the initialization mode. See Section 23.6.

23.5.4.2 HECC Acceptance Filtering

Each of the 32 mailboxes of the HECC has its own local acceptance mask register, CANLAM0 to CANLAM31. There is no global acceptance mask register in the HECC.

23.6 CAN Module Initialization

The CAN module must be initialized before being used. Initialization is only possible if the CAN module is in initialization mode, see Figure 23-7. Programming the CCR bit in the master control register (CANMC) to 1 sets the initialization mode. The initialization is performed only when the CCE bit in the error and status register (CANES) is set to 1. Afterwards, the configuration registers may be written.

In order to modify the two local acceptance mask registers of the SCC (CANLAM0 and CANLAM3), the CAN module also must be set in the initialization mode. The global acceptance mask register (CANGAM) can be modified in normal mode and initialization mode. The module is activated again by programming the CCR bit in CANMC to 0. After a hardware reset, the initialization mode is active.

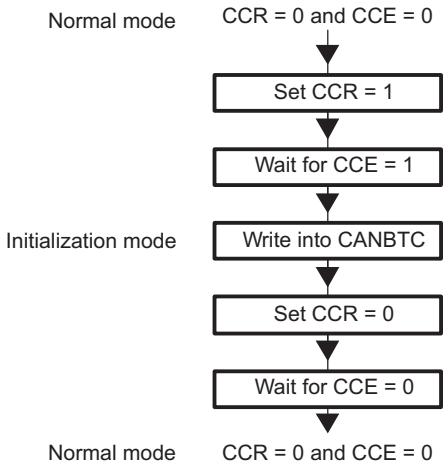
Bit-Timing Configuration Register (CANBTC) With Zero Value

NOTE: If the bit-timing configuration register (CANBTC) is programmed to 0, or left with the initial value, the CAN module never leaves the initialization mode; that is, the CCE bit in CANES remains set to 1 when clearing the CCR bit in CANMC.

Enter/Exit Initialization Mode

The transition between initialization mode and normal mode, and conversely, is performed in synchronization with the CAN network. That is, the CAN controller waits until it detects a bus idle sequence (11 recessive bits) before it changes the mode. In the event of a stuck-to-dominant bus error, the CAN controller cannot detect a bus-idle condition and is unable to perform a mode transition.

Figure 23-7. Configuration Sequence

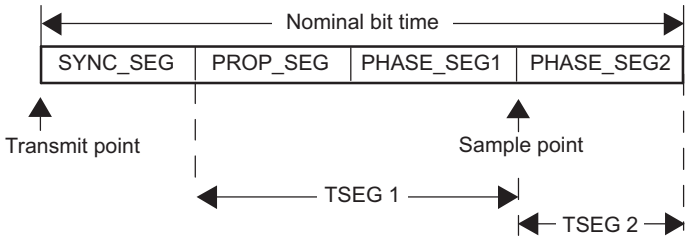


23.6.1 CAN Bit-Timing Configuration

As shown in Figure 23-8, the CAN protocol specification partitions the nominal bit time into four different time segments:

- SYNC_SEG: this part of bit time is used to synchronize the various nodes on the bus. An edge is expected to lie within this segment. This segment is always 1 TIME QUANTUM (TQ).
- PROP_SEG: this part of the bit time is used to compensate for the physical delay times within the network. It is twice the sum of the signal propagation time on the bus line, the input comparator delay, and the output driver delay. This segment is programmable from 1 to 8 TIME QUANTA (TQ).
- PHASE_SEG1: this phase is used to compensate for positive edge phase error. This segment is programmable from 1 to 8 TIME QUANTA (TQ) and can be lengthened by resynchronization.
- PHASE_SEG2: this phase is used to compensate for negative edge phase error. This segment is programmable from 2 to 8 TIME QUANTA (TQ) and can be shortened by resynchronization.

Figure 23-8. Partition of the Bit Time



All controllers on a CAN bus must have the same bit rate and bit length. At different clock frequencies of the individual controllers, the bit rate has to be adjusted by the time segments.

In the SCC/HECC modules, the length of a bit on the CAN bus is determined by the parameters in the bit-timing configuration register (CANBTC): TSEG1, TSEG2, and BRP (*BRPrescaler* is the binary value of BRP + 1).

TSEG1 combines the two time segments PROP_SEG and PHASE_SEG1 as defined by the CAN protocol. TSEG2 defines the length of the time segment PHASE_SEG2.

The following bit-timing rules have to be fulfilled when determining the bit segment values:

- $TSEG1_{CALC(min)} \geq TSEG2_{CALC}$
- IPT ≤ $TSEG1_{CALC} \leq$ 16 TQ (IPT = Information Processing Time)
- IPT ≤ $TSEG2_{CALC} \leq$ 8 TQ
- IPT = $3/BRP_{CALC}$ (the resulting IPT has to be rounded up to the next integer value)

NOTE: For the special case of baud rate prescaler value BRP_{CALC} = 1, the Information Processing Time (IPT) is equal to three time quanta. This is not compliant to the ISO 11898 Standard, where the Information Processing Time is defined to be less than or equal to two time quanta. Thus the usage of this mode (BRP_{CALC} = 1) is not allowed.

- 1 TQ ≤ $SJW_{CALC} \leq$ min[4 TQ, $TSEG2_{CALC}$] (SJW = Synchronization Jump Width)
- To utilize three-time sampling mode $BRP_{CALC} \geq 5$ has to be selected

23.6.2 CAN Bit Rate Calculation

The bit rate is calculated as follows (in bits per second):

$$Bitrate = \frac{InternalBus\ CLK}{BRPrescaler \times BitTime}$$

Where *BitTime* is the number of time quanta (TQ) per bit. *Internal Bus CLK* is the CAN module system clock frequency. *BRPrescaler* is the BRP bits in the bit-timing configuration register (CANBTC) + 1.

BRPrescaler = BRP + 1

BitTime (TQ) = TSEG1 + TSEG2 + 1

Example:

With *Internal Bus CLK* = 26 MHz and *BRPrescaler* = 4, if a bit rate of 0.8125 Mbits/s is required, the bit-timing parameters is programmed as follows:

$$TQ = \frac{InternalBus\ CLK}{BRPrescaler \times Bitrate} = \frac{26\,MHz}{4 \times 0.8125\,Mbits/s} = 8$$

TQ = TSEG1 + TSEG2 + 1 = 4 + 3 + 1 = 8

TSEG1 = 4 TQ and TSEG2 = 3 TQ, so TQ = 8.

With this setting, a threefold sampling of the bus is not possible; thus the SAM bit in the bit-timing configuration register (CANBTC) must be cleared to 0. Since the SJW bits in CANBTC are not allowed to be greater than TSEG2 (that is set to 3 TQ), SJW = 3. (See Section 23.10.1.12 for more information about CANBTC.)

BTC = 0000021Ah

The value programmed into CANBTC.SJW has to be decremented by 1, because of the 2-bit size of the binary SJW value:

SJWCANBTC = SJW - 1

23.7 CAN Interrupts

There are two different types of interrupts. One type of interrupt is a mailbox-related interrupt; for example, the receive-message-pending interrupt or the abort-acknowledge interrupt. The other type of interrupt is a system interrupt that handles errors or system-related interrupt sources; for example, the error-passive interrupt or the wake-up interrupt. See Figure 23-9.

The following events may initiate one of the two interrupts:

- Mailbox interrupts
  - Message reception interrupt: a message was received
  - Message transmission interrupt: a message was transmitted successfully
  - Abort-acknowledge interrupt: a sent transmission was aborted
  - Receive-message-lost interrupt: an old message was overwritten by a new message
  - Message alarm interrupt (HECC only): one of the messages was not transmitted or received within a predefined time frame
- System interrupts
  - Write-denied interrupt: the CPU tried to write to a mailbox but was not allowed to
  - Wake-up interrupt: this interrupt is generated after a wake up
  - Bus-off interrupt: the CAN module enters the bus-off state
  - Error-passive interrupt: the CAN module enters the error-passive mode
  - Warning level interrupt: one or both error counters are greater than or equal to 96
  - Time counter overflow interrupt (HECC only): the local network time stamp counter had an overflow

Figure 23-9. SCC Interrupts Scheme Block Diagram

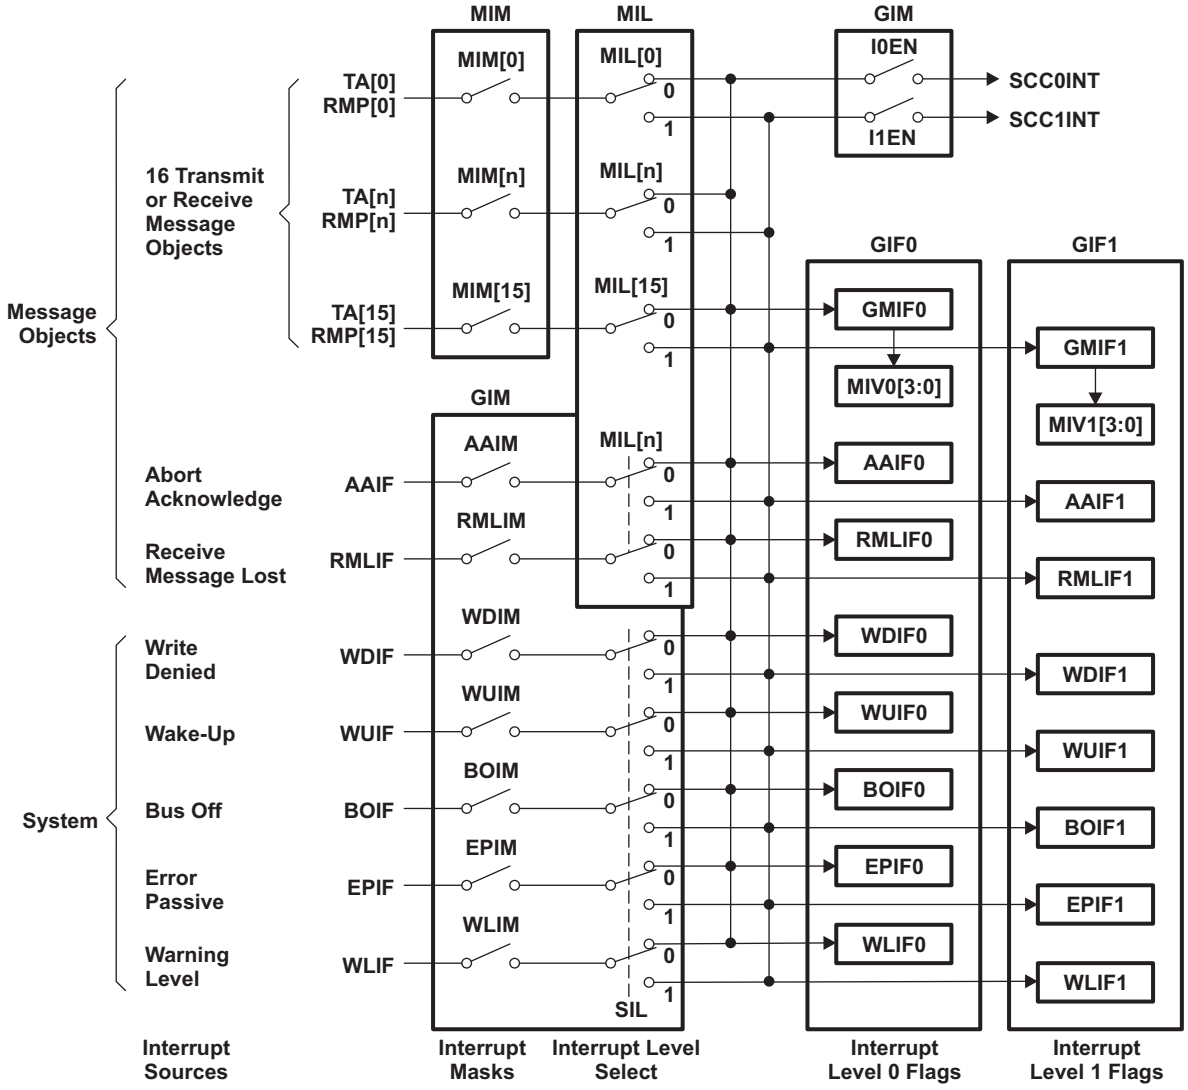


Figure 23-10. HECC Interrupts Scheme Diagram

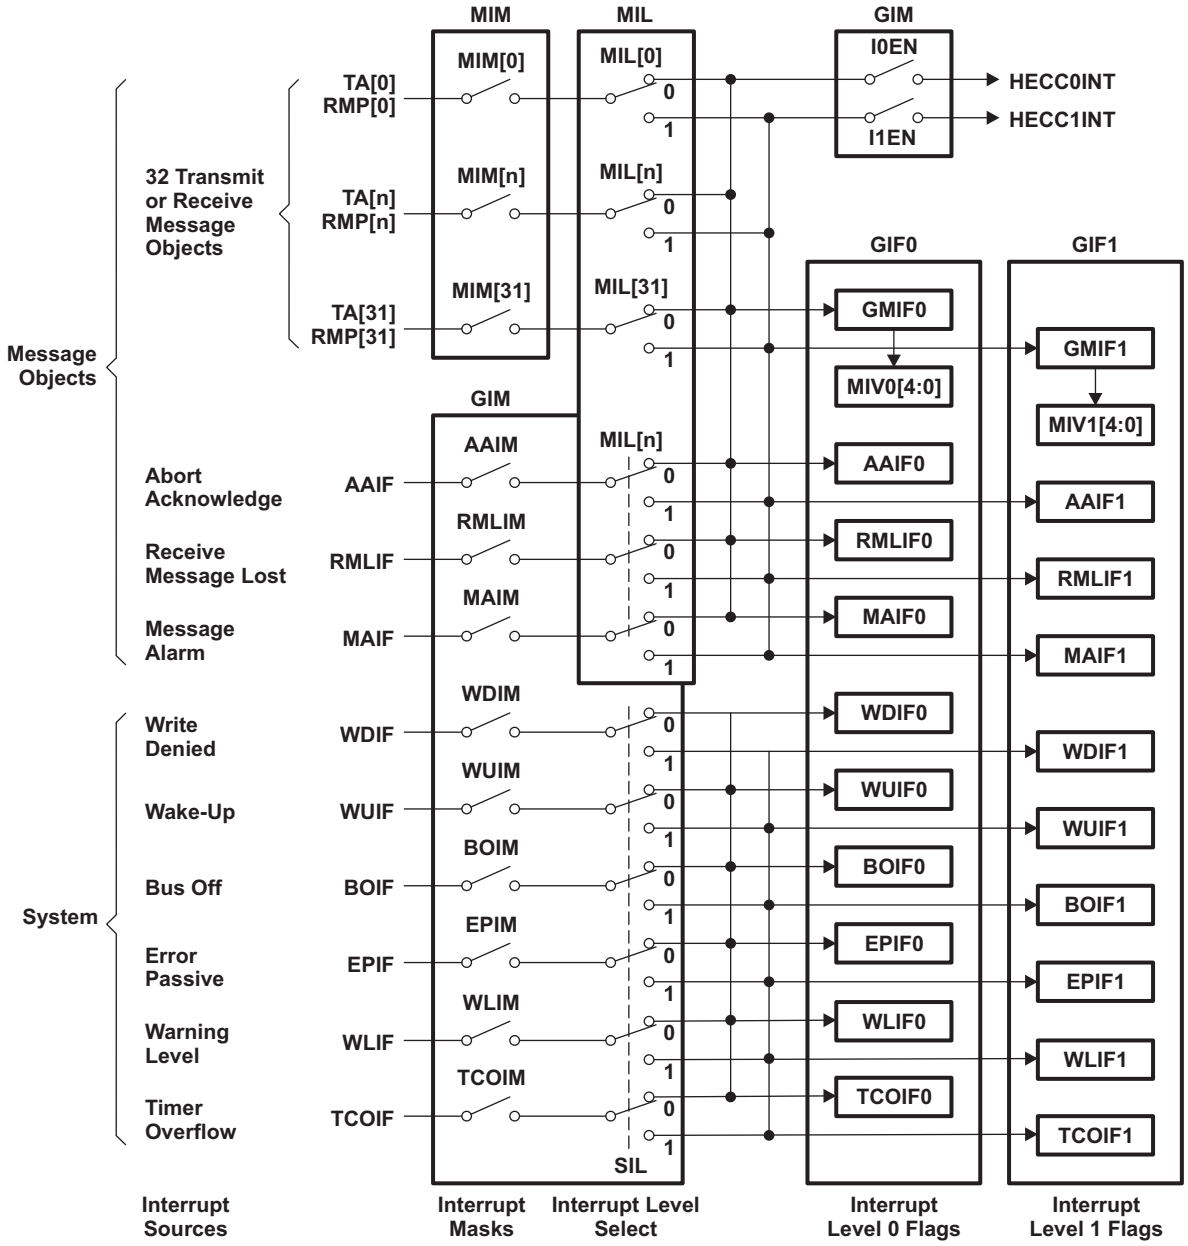

23.7.1 Interrupts Scheme

The GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) is set depending on the setting of the MIL*n* bit, in the mailbox interrupt level register (CANMIL), that corresponds to the mailbox originating that interrupt. If the MIL*n* bit is set, the corresponding message object interrupt flag sets the GMIF1 bit in CANGIF1; otherwise, it sets the GMIF0 bit in CANGIF0.

If all interrupt flags are cleared and a new interrupt flag is set, the CAN module interrupt output line (SCC0INT/HECC0INT or SCC1INT/HECC1INT) is activated if the corresponding interrupt mask bit is set. The interrupt line stays active until the interrupt flag is cleared by the CPU by writing a 1 to the appropriate bit.

The GMIF0 or GMIF1 bit must be cleared by writing a 1 to the appropriate bit in the transmission acknowledge register (CANTA) or in the receive message pending register (CANRMP) (depending on mailbox configuration) and cannot be cleared in CANGIF0/CANGIF1.

After clearing one or more interrupt flags, and one or more interrupt flags are still pending, a new interrupt is generated. The interrupt flags are cleared by writing a 1 to the corresponding bit location. If the GMIF0 or GMIF1 bit is set, the interrupt vector bit, MIV0 in CANGIF0 or MIV1 in CANGIF1, indicates the mailbox number of the mailbox that caused the setting of the GMIF0/GMIF1. It always displays the highest mailbox interrupt vector assigned to that interrupt line.

23.7.2 Message Object Interrupt

Each of the 32 mailboxes in the HECC or the 16 mailboxes in the SCC may initiate an interrupt on one of the two interrupt output lines 1 or 0. These interrupts are receive or transmit interrupts depending on the mailbox configuration.

There is one interrupt mask (MIM*n*) bit and one interrupt level (MIL*n*) bit dedicated to each mailbox. To generate a mailbox interrupt upon a receive/transmit event, the corresponding MIM*n* bit in the mailbox interrupt mask register (CANMIM) has to be set. If a CAN message is received in a receive mailbox (the RMP*n* bit in the receive message pending register, CANRMP, is set to 1) or is transmitted from a transmit mailbox (the TA*n* bit in the transmission acknowledge register, CANTA, is set to 1), an interrupt is asserted. If a mailbox is configured as a remote request mailbox (the MD*n* bit in the mailbox direction register, CANMD, is set to 1 and the RTR bit in the message control field register, MCF, is set to 1), an interrupt occurs upon reception of the reply frame. A remote reply mailbox generates an interrupt upon successful transmission of the reply frame (the MD*n* bit in CANMD is cleared to 0 and the AAM bit in the message identifier register, MID, is set to 1).

Setting the RMP*n* bit in CANRMP or the TA*n* bit in CANTA also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1), if the corresponding interrupt mask bit is set. The GMIF0/GMIF1 bit then generates an interrupt and the corresponding mailbox vector (mailbox number) is read from the MIV0/MIV1 bits in CANGIF0/CANGIF1. If more than one mailbox interrupts are pending, the actual value of the MIV0/MIV1 bits reflects the highest priority interrupt vector. The interrupt generated depends on the setting of the MIL*n* bit in the mailbox interrupt level register (CANMIL).

The AA*n* bit in the abort acknowledge register (CANAA) and the AAIF0/AAIF1 bit in CANGIF0/CANGIF1 are set when a transmit message is aborted by setting the TRR*n* bit in the transmit request reset register (CANTRR). An interrupt is asserted upon transmission abortion, if the AAIM bit in the global interrupt mask register (CANGIM) is set. Clearing the AA*n* bit(s) does not reset the AAIF0/AAIF1 bit. The interrupt bit has to be cleared separately. The interrupt line for the abort acknowledge interrupt is selected in accordance with the MIL*n* bit in CANMIL of the concerned mailbox.

A lost receive message is notified by setting the RML*n* bit in the receive message lost register (CANRML) and the RMLIF0/RMLIF1 bit in CANGIF0/CANGIF1. If an interrupt shall be generated upon the lost receive message event, the RMLIM bit in CANGIM has to be set. Clearing the RML*n* bit does not reset the RMLIF0/RMLIF1 bit. The interrupt bit has to be cleared separately. The interrupt line for the receive message lost interrupt is selected in accordance with the MIL*n* bit in CANMIL of the concerned mailbox.

Each mailbox of the HECC (in HECC mode only) is linked to a message object time-out register (CANMOTO). If a time-out event occurs (the TOS*n* bit in the time-out status register, CANTOS, is set to 1), a message alarm interrupt is asserted to one of the two interrupt lines if the MAIM bit in CANGIM is set. The interrupt line for the message alarm interrupt is selected in accordance with the MIL*n* bit in CANMIL of the concerned mailbox. Clearing the TOS*n* bit does not reset the MAIF0/MAIF1 bit in CANGIF0/CANGIF1.

23.8 CAN Power-Down Mode

There are two different power-down modes: the global power-down mode, when all clocks are stopped by the CPU; and the local power-down mode, when only the CAN module internal clock is deactivated by the CAN module itself. Therefore, it is possible to have a local power down, where only the clock of the CAN module logic is disabled, or a global power down when the clock for the complete device is disabled.

23.8.1 Local Power Down

The local power-down mode is requested by writing a 1 to the PDR bit in the master control register (CANMC). When the CAN module enters the local power-down mode, the power-down mode acknowledge (PDA) bit in the error and status register (CANES) is set to 1.

During local power-down mode, the clock of the CAN module is turned off and only the wake-up logic is still active. Since the clock is enabled for every access on an Internal Bus request, the contents of any register can be read-back even during power down.

The module leaves the local power-down mode when the PDR bit in CANMC is cleared or if any bus activity is detected on the CAN bus line (if the wake-up-on bus activity is enabled).

The automatic wake-up-on bus activity is enabled or disabled with the WUBA bit in CANMC. If there is any activity on the CAN bus line, the module begins its power-up sequence. The module waits until it detects 11 consecutive recessive bits on the CANRX pin and then it goes bus-active.

CAUTION

First Message Received During Power-Down Mode is Lost
The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

After leaving the sleep mode, the PDR and PDA bits in CANMC are cleared. The CAN error counters remain unchanged.

If the module is transmitting a message when the PDR bit is set, the transmission is continued until a successful transmission, a lost arbitration, or an error condition on the CAN bus line occurs. Then, the PDA bit is activated. Thus, the module causes no error condition on the CAN bus line.

To implement the local power-down mode, two separate clocks are used within the CAN module. One clock stays active all the time to ensure power-down operation (the wake-up logic). The other clock is enabled depending on the setting of the PDA bit or Internal Bus access.

Accessing HECC Mailboxes

NOTE: HECC mailboxes can be accessed in LPD mode. Contents of the mailbox registers can be READ or WRITTEN to even after the PDA bit is set in the CANES.

23.8.2 Global Power Down

Global power-down mode is requested by the system module (SYS LPM). When the module is able to enter the global power-down mode, all clocks to the CAN module are disabled.

During global power-down mode, a dominant signal on the CAN bus may generate a wake-up interrupt, thus enabling the CPU to exit global power-down mode. There is no internal filtering for the CAN bus line. The WUIF0/WUIF1 bit is set asynchronously to enable the assertion of an interrupt without any running clocks.

23.9 Timer Management Unit

Several functions are implemented in the HECC to control the time when messages are transmitted. A separate state machine is included in the HECC to handle the time-control functions. This state machine has lower priority than the CAN state machine when accessing the registers. Therefore, the time-control functions may be delayed by other on-going actions.

23.9.1 Time-Stamp Functions

To get an indication of the time of reception or transmission of a message, a free-running 32-bit local network time counter (LNT) is implemented in the module. The value of the LNT is stored in the local network time register (CANLNT). When a received message is stored or a message has been transmitted, the content of LNT is written into the message object time-stamp register (CANMOTS) of the corresponding mailbox.

The counter is driven from the bit clock of the CAN bus line. The timer is stopped during the initialization mode or if the module is in sleep or suspend mode. After power-up reset, the free-running counter is cleared.

The most-significant bit of the local network time register (CANLNT) is cleared by writing a 1 to the LNTM bit in the master control register (CANMC). The CANLNT may also be cleared when mailbox 16 transmitted or received a message successfully (depending on the setting of the MD16 bit in the mailbox direction register, CANMD) by setting the LNTC bit to 1 in CANMC. Therefore, it is possible to use mailbox 16 for global time synchronization of the network. The CPU can read and write the counter.

Overflow of the counter is detected by the LNT counter overflow interrupt (TCOIF0/TCOIF1) bit in the global interrupt flag register (CANGIF0/CANGIF1). An overflow occurs when the highest bit of the LNT counter changes to 1. Thus, the CPU has enough time to handle this situation.

See Section 23.10.2 for the time-stamp registers.

23.9.2 Time-Out Functions

To ensure that all messages are sent or received within a predefined period, each mailbox has its own message time-out register (CANMOTO). If a message has not been sent or received by the time indicated in CANMOTO and the corresponding TOC*n* bit in the time-out control register (CANTOC) is set to 1, a TOS*n* bit in the time-out status register (CANTOS) is set to 1.

For transmit mailboxes, the TOS*n* bit is cleared when the TOC*n* bit is cleared or when the corresponding TRS*n* bit in the transmit request set register (CANTRS) is cleared, no matter whether due to successful transmission or abortion of the transmit request. For receive mailboxes, the TOS*n* bit is cleared when the corresponding TOC*n* bit is cleared.

The CPU may also clear the TOS*n* bits by writing a 1 into CANTOS.

The CANMOTO is implemented as a RAM. The state machine scans all the CANMOTOs and compares them to the LNT counter value. If the value in CANLNT is equal to or greater than the value in CANMOTO, while the corresponding TRS*n* bit is set (applies to transmit mailboxes only) and the TOC*n* bit is set, then the appropriate TOS*n* bit is set. Since all the time-out registers are scanned sequentially, there may be a delay before the TOS*n* bit is set.

See Section 23.10.3 for the time-out registers.

23.9.3 Behavior/Usage of MAIF0/1 Bit in User Applications

The MAIF0/1 bit is automatically cleared by the CAN protocol kernel (CPK) (along with the CANTOS.n bit) upon transmission/reception by the mailbox, which asserted this flag in the first place. It can also be cleared by the user (via the CPU). On a time out condition, the MAIF0/1 bit (and the CANTOS.n bit) is set. On an (eventual) successful communication, these bits are automatically cleared by the CPK. The following are the possible behaviors/usages for the MAIF0/1 bit:

1. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. Communication is never successful, i.e., the frame was never transmitted (or received). An interrupt is asserted. Application handles the issue and eventually clears both MAIF0/1 and CANTOS.n bits.
2. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. However, communication is eventually successful, i.e., the frame gets transmitted (or received). Both the MAIF0/1 and CANTOS.n bits are cleared automatically by the CPK. When the interrupt service routine (ISR) scans the CANGIF register, it does not see the MAIF0/1 bit set. This is the phantom interrupt scenario. The application merely returns to the main code.
3. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. While executing the ISR pertaining to time-out, communication is successful. This situation must be handled carefully. The application must not re-transmit a mailbox if the mailbox is sent between the time the interrupt is asserted, and the time the ISR is attempting to take corrective action. One way of doing this is to poll the TM/RM bits in the CANES register. These bits indicate if the CPK is currently transmitting/receiving. If so, the application must wait until the communication is over and then check the CANTOS.n bit again. If the communication is still not successful, the application must take corrective action.

23.10 Registers

The SCC and HECC registers listed in Table 23-5 are used by the CPU to configure and control the CAN controller and the message objects. All CAN registers support 8-, 16-, and 32-bit accesses. Reserved register bits must be written as 0.

NOTE: System behavior is undefined for accesses to reserved registers and must be avoided.

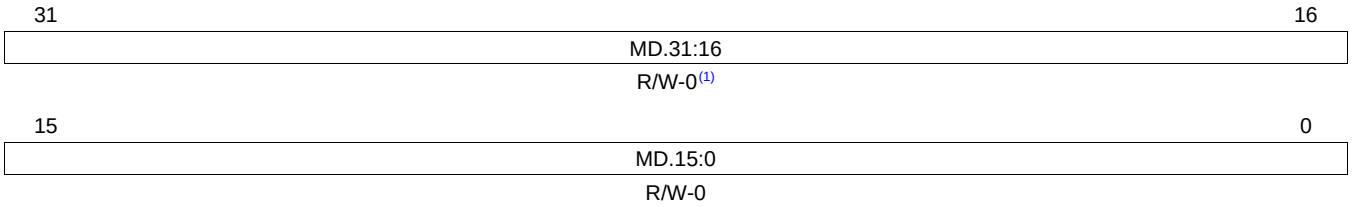
Table 23-6. Mailbox Enable Register (CANME) Field Descriptions

Bit	Field	Value	Description
31-0	ME		Mailbox Enable Register. After power-up, all bits in CANME are cleared to 0. Disabled mailboxes may be used as additional memory for the CPU.
		0	The corresponding mailbox *n* is disabled.
		1	The corresponding mailbox *n* is enabled for the CAN module. The mailbox must be disabled before writing to the contents of any identifier field. If the corresponding bit in CANME is set, the write access to the identifier of a message object is discarded.

23.10.1.2 Mailbox Direction Register (CANMD)

Each mailbox *n* is configured as a transmit or a receive mailbox by a corresponding bit *n* in this register.

Figure 23-12. Mailbox Direction Register (CANMD) [04h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

(1) HECC only, reserved in the SCC

Table 23-7. Mailbox Direction Register (CANMD) Field Descriptions

Bit	Field	Value	Description
31-0	MD		Mailbox Direction Register. After power-up, all bits in CANMD are cleared to 0.
		0	The corresponding mailbox *n* is configured as a transmit mailbox.
		1	The corresponding mailbox *n* is configured as a receive mailbox.

23.10.1.3 Transmission Request Set Register (CANTRS)

When mailbox *n* is ready to be transmitted, the CPU sets the corresponding TRS*n* bit to 1 in this register to start the transmission. A successful transmission also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates a global mailbox interrupt, if the corresponding mailbox interrupt mask (MIM*n*) bit in the mailbox interrupt mask register (CANMIM) is set.

The TRS*n* bit is set by the CPU and reset by the CAN module logic. It is also set by the CAN module in the case of a remote frame request. The TRS*n* bit is reset in the case of a successful transmission or an aborted transmission (if requested). If a mailbox *n* is configured as a receive mailbox (MD*n* bit in the mailbox direction register, CANMD, is set), the corresponding TRS*n* bit is ignored. If the TRS*n* bit of a remote request mailbox is set, a remote frame is transmitted. If the CPU tries to set a bit while the CAN module tries to clear it, the bit is set.

Setting the TRS*n* bit causes the particular message *n* to be transmitted. Several bits can be set simultaneously. Therefore, all messages with the TRS*n* bit set are transmitted in turn, starting with the mailbox having the highest mailbox number (highest priority).

The bits in CANTRS are set by writing a 1 from the CPU; writing a 0 has no effect. After power-up, all bits in CANTRS are cleared to 0.

Figure 23-13. Transmission Request Set Register (CANTRS) [08h]

(1) HECC only, reserved in the SCC

Table 23-8. Transmission Request Set Register (CANTRS) Field Descriptions

Bit	Field	Value	Description
31-0	TRS		Transmit Request Set Register. After power-up, all bits in CANTRS are cleared to 0.
		0	No operation
		1	If the corresponding message is configured as a transmit mailbox or remote request mailbox, the data or remote message of this mailbox will be transmitted.

23.10.1.4 Transmission Request Reset Register (CANTRR)

Setting the TRR*n* bit of the message *n* causes a transmission request to be cancelled, if it was initiated by the corresponding TRS*n* bit in the transmission request set register (CANTRS) and is not currently being processed. If the corresponding message is currently being processed, the TRR*n* bit is reset in the case of a successful transmission (normal operation) or an aborted transmission due to a lost arbitration or an error condition detected on the CAN bus line. In the case of an aborted transmission, the corresponding AA*n* bit in the abort acknowledge register (CANAA) is set; in the case of a successful transmission, the corresponding TA*n* bit in the transmission acknowledge register (CANTA) is set.

The TRR*n* bit is set by the CPU and reset by the internal logic. The TRR*n* bit is reset in the case of a successful transmission or an aborted transmission. If the CPU tries to set a bit while the CAN module tries to clear it, the bit is set.

If a transmission reset is requested for a transmit mailbox with the corresponding TRS*n* bit cleared in CANTRS, for a disabled mailbox, or for a receive mailbox, then the CAN module clears the TRR*n* bit and sets the AA*n* bit in order to respond to the request.

The bits in CANTRR are set by writing a 1 from the CPU; writing a 0 has no effect.

Bit	Field	Value	Description
31-0	TRR		Transmit Request Reset Register.
		0	No operation.
		1	Setting the TRR*n* bit causes a transmission request to be cancelled, if it was initiated by the corresponding TRS*n* bit in the transmission request set register (CANTRS) and is not currently being processed.

23.10.1.5 Transmission Acknowledge Register (CANTA)

If the message of mailbox *n* is transmitted successfully, the TA*n* bit is set in this register. A successful transmission also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates a global mailbox interrupt, if the corresponding mailbox interrupt mask (MIM*n*) bit in the mailbox interrupt mask register (CANMIM) is set.

The CPU resets the bits in CANTA by writing a 1. Writing a 1 also clears the interrupt, if an interrupt had been generated; writing a 0, has no effect. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. After power-up, all bits in CANTA are cleared to 0.

Bit	Field	Value	Description
31-0	TA		Transmit Acknowledge Register.
		0	The message is not sent.
		1	If the message of mailbox *n* is sent successfully, bit *n* is set.

23.10.1.6 Abort Acknowledge Register (CANAA)

If the transmission of the message in mailbox *n* is aborted, the corresponding abort acknowledge (AA*n*) bit is set in this register. An aborted transmission also sets the AAIF0/AAIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates an interrupt, if the corresponding AAIM bit in the global interrupt mask register (CANGIM) is set.

Additional Conditions That Set the AA *n* Bit

NOTE: The AA*n* bit is set if a transmission reset is requested and the TRSn bit in CANTRS of the corresponding transmit mailbox is not set, a receive mailbox or a disabled mailbox is concerned.

The CPU resets the bits in CANAA by writing a 1; writing a 0, has no effect. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. After power-up, all bits in CANAA are cleared to 0.

Bit	Field	Value	Description
31-0	AA		Abort Acknowledge Register.
		0	The transmission is not aborted.
		1	If the transmission of the message in mailbox *n* is aborted, bit *n* is set.

23.10.1.7 Receive Message Pending Register (CANRMP)

If mailbox *n* contains a received message, the RMP*n* bit in this register is set. The RMP*n* bit is only reset by the CPU and set by the internal logic. A new incoming message overwrites the stored message, if the OPC*n* bit in the overwrite protection control register (CANOPC) is cleared to 0; otherwise, the next mailboxes are checked for a matching identification. If a message is overwritten, the corresponding RML*n* bit in the receive message lost register (CANRML) is set. The bits in CANRMP and CANRML are cleared to 0 by a write access to the base address of CANRMP, with a 1 at the corresponding bit location. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set.

The proper sequence to clear RMP*n* bits is shown below.

1. Read the RMP*n* bits (don't clear it)
2. When RMP*n* is set, read the message
3. Clear the RMP*n* bit

A received message also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates an interrupt, if the corresponding MIM*n* bit in the mailbox interrupt mask register (CANMIM) is set.

31-0	RMP		Receive Message Pending Register.
		0	The mailbox does not contain a message.
		1	If mailbox *n* contains a received message, bit *n* is set.

23.10.1.8 Receive Message Lost Register (CANRML)

If an old message is overwritten by a new message in message object *n*, the RML*n* bit in this register is set. The RML*n* bit is only reset by the CPU and set by the internal logic. The RML*n* bit is cleared by a write access to the base address of the receive message pending register (CANRMP), with a 1 at the corresponding bit location. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. The content of CANRML is not changed, if the OPC*n* bit in the overwrite protection control register (CANOPC) is set.

If one or more of the RML*n* bits in CANRML are set, the RMLIF0/RMLIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) is set and initiates an interrupt, if the RMLIM bit in the global interrupt mask register (CANGIM) is set.

Bit	Field	Value	Description
31-0	RML		Receive Message Lost Register.
		0	No message was lost.
		1	An old unread message has been overwritten by a new one in that mailbox.

23.10.1.9 Remote Frame Pending Register (CANRFP)

Whenever a remote frame request is received by the CAN module, the corresponding RFP*n* bit in this register is set. If a remote frame is stored in a receive mailbox *n* (AAM = 0 in the message identifier register, CANMID, and MD*n* = 1 in the mailbox direction register, CANMD), the CPU has to initiate the reply frame transmission and has to reset the RFP*n* bit. If a mailbox configured in auto-answer mode (AAM = 1 and MD*n* = 0) receives a remote frame, the CAN module clears the RFP*n* bit after the reply frame has been successfully transmitted.

In order to prevent an auto-answer mailbox from replying to a remote frame request, the CPU clears the RFP*n* bit and the TRS*n* bit in the transmission request set register (CANTRS) by setting the corresponding TRR*n* bit in the transmission request reset register (CANTRR). The AAM bit may also be cleared by the CPU to stop the CAN module from sending the message.

If the CPU tries to reset the bit while the CAN module tries to set it, the bit is not set. The CPU cannot interrupt an on-going transfer.

31-0	RFP		Remote Frame Pending Register
		0	No remote frame request was received.
		1	A remote frame request was received by the CAN module.

23.10.1.10 Global Acceptance Mask Register (CANGAM)

The global acceptance mask is used by the SCC or HECC in SCC-compatible mode. The global acceptance mask is used for mailboxes 6 to 15, if the AME bit in the message identifier register (CANMID) of the corresponding mailbox is set. A received message is only stored in the first mailbox with a matching identifier.

The global acceptance mask is used for mailboxes 6 to 15 of the SCC.

Table 23-15. Global Acceptance Mask Register (CANGAM) Field Descriptions

Bit	Field	Value	Description
31	AMI		Acceptance Mask Identifier Extension bit.
		0	The identifier extension bit stored in the mailbox determines which messages shall be received.
		1	Standard and extended frames are received. In the case of an extended frame, all 29 bits of the identifier are stored in the mailbox and all 29 GAM bits are used for the filter. In the case of a standard frame, only the first 11 bits (28 to 18) of the identifier and the GAM bits are used.
30-29	Reserved		Reads are undefined and writes have no effect.
28-0	GAM		Global Acceptance Mask. These bits allow any identifier bits of an incoming message to be masked.
		0	Received identifier bit value must match the corresponding identifier bit in the message identifier register (CANMID).
		1	Accept a 0 or a 1 (don't care) for the corresponding bit of the received identifier.

23.10.1.11 Master Control Register (CANMC)

This register is used to control the settings of the CAN module.

Update Data With CDR Bit Mechanism

NOTE: When using the CDR bit to update the data field of a mailbox, the SCC and the HECC behave differently. The SCC always considers new data after an arbitration loss or bus error. The HECC tries to send the former data if the message was loaded into the internal transmit buffer prior to the data update. If the software wants to force the HECC to transmit updated data as soon as possible, it has to perform a dummy write to the transmit request set register (CANTRS), for example CANTRS = 0000 0000h, after the data update is finished (CDR bit is cleared).

(1) HECC only, reserved in the SCC

Table 23-16. Master Control Register (CANMC) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved		Reads are undefined and writes have no effect.
15	LNTC		Local Network Time Clear Bit.
		0	Local network time register (CANLNT) is not reset.
		1	Local network time register (CANLNT) is reset to zero after a successful transmission or reception of mailbox 16.
14	LNTM		Local Network Time MSB Clear Bit.
		0	Local network time register (CANLNT) is not changed.
		1	The most-significant bit of the local network time register (CANLNT) is reset to zero. The LNTM bit is reset after one clock cycle by the internal logic.
13	SCM		SCC-Compatibility Mode.
		0	HECC operates in SCC-compatibility mode only mailboxes 15 to 0 can be used. You must refer to the SCC specification in order to operate the HECC in this mode. Since this mode is selected by default, all software developed for the SCC runs without any change to the HECC module.
		1	HECC operates in normal mode.
12	CCR		Change Configuration Request.
		0	The CPU requests normal operation. This can only be done after the bit-timing configuration register (CANBTC) is set to the allowed values.
		1	The CPU requests write access to the bit-timing configuration register (CANBTC) and the acceptance mask registers (CANGAM, CANLAM0, and CANLAM3) of the SCC. After setting this bit, the CPU must wait until the CCE bit in the error and status register (CANES) is 1 before proceeding to CANBTC (see Section 23.10.1.12). This could also mean that the CAN module is in the bus off state (see the BO bit in CANES, Section 23.10.1.13).
11	PDR		Power-Down-Mode Request.
		0	The CAN module power-down mode is not requested (normal operation).

Table 23-16. Master Control Register (CANMC) Field Descriptions (continued)

Bit	Field	Value	Description
		1	The CAN module power-down mode is requested.
10	DBO		Data Byte Order. This bit selects the byte order of the message data field of the message data registers, CANMDL and CANMDH (see Section 23.10.4.3).
		0	The data is received or transmitted most-significant byte first.
		1	The data is received or transmitted least-significant byte first.
9	WUBA		Wake Up on Bus Activity.
		0	The CAN module leaves the power-down mode only after writing a 0 to the PDR bit.
		1	The CAN module leaves the power-down mode after detecting any bus activity.
8	CDR		Change Data Request. This bit allows fast data message update.
		0	The CPU requests normal operation.
		1	The CPU requests write access to the data field of the mailbox specified by the MBNR bits. The CPU must clear the CDR bit after accessing the mailbox. The CAN module does not transmit the mailbox content while the CDR bit is set. This is checked by the state machine before and after it reads the data from the mailbox to store it in the transmit buffer.
7	ABO		Auto Bus On.
		0	Bus-offstate can only be left by clearing the CCR bit after 128 • 11 recessive bits.
		1	After bus-off state, the module goes back automatically into the bus-on state after 128 • 11 recessive bits.
6	STM		Self-Test Mode.
		0	The CAN module is in normal mode.
		1	The CAN module is in self-test mode. In this mode, the CAN module generates its own acknowledge (ACK) signal, thus enabling operation without a bus connected to the module. The message is not sent, but read back and stored in the appropriate mailbox.
5	SRES		Software Reset. This is a write-only bit and is always read as zero.
		0	No effect
		1	A write access to this register causes a software reset of the CAN module, that is, all parameters, except the bits listed in Table 23-17, are reset to their default values. The mailbox contents and the error counters are not modified. Pending and on-going transmissions are canceled without disturbing the communication.
4-0	MBNR	0-1Fh	Mailbox Number. The CPU requests write access to the data field of the mailbox specified by the MBNR bits. This field is used in conjunction with the CDR bit.

23.10.1.12 Bit-Timing Configuration Register (CANBTC)

This register is used to configure the CAN node with the appropriate network-timing parameters. This register must be programmed before using the CAN module. This register can only be written in initialization mode, see Section 23.6.1.

CAUTION

Unallowable Configuration Values
To avoid unpredictable behavior of the CAN module, do not program CANBTC with values not allowed by the CAN protocol specification and by the bit timing rules listed in Section 23.6.1.

Figure 23-22. Bit-Timing Configuration Register (CANBTC) [2Ch]

R-x		R/W-0	R/W-0		R/W-0	R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset; -x = value is indeterminate after reset

Table 23-18. Bit-Timing Configuration Register (CANBTC) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved		Reads are undefined and writes have no effect.
23-16	BRP	0-FFh	Time Quantum Prescaler bits specify the duration of a time quantum (TQ) in CAN module system clock units. See Section 23.6.1.
			BRP PRESCALER is programmable from 1 to 256. The value programmed into CANBTC has to be decremented by 1, because of the 8-bit size of the BRP value:
			$BRP_{CANBTC.SJW}$ = BRP PRESCALER - 1
15-11	Reserved		Reads are undefined and writes have no effect.
10	ERM		Edge Resynchronization Mode bit selects the synchronization mode with the receive data stream on the CAN bus.
		0	The CAN module resynchronizes on the falling edge only.
		1	The CAN module resynchronizes on both rising and falling edges.
9-8	SJW	0-3h	Synchronization Jump Width bits indicate how many TQ units a bit is allowed to be lengthened or shortened when resynchronizing with the receive data stream on the CAN bus. The synchronization is performed either with the falling edge (ERM = 0) or with both edges (ERM = 1) of the bus signal.
			SJW is programmable from 1 to 4 TQ. The maximum value of SJW is determined by the minimum value of $TSEG2_{CALC}$ and 4TQ.
			$SJW_{CALC(max)} \leq \min[4TQ, TSEG2_{CALC}]$
			The value programmed into the CANBTC register has to be decremented by 1, because of the 2-bit size of the binary SJW value (SJW.1.0):
			$SJW_{BTC} = SJW_{CALC} - 1$
			SJW_{CALC} Result of the calculation.
			$1 \leq SJW_{CALC} \leq 4$
			SJW_{BTC} Value to be programmed into the CANBTC register.
			$0 \leq SJW_{BTC} \leq 3$
7	SAM		Sample point bits set the number of samples used by the CAN module to determine the actual level of the CAN bus. When the SAM bit is set, the level determined by the CAN bus corresponds to the result from the majority decision of the last three values. The sample points are at the sample point and twice before with a distance of ? TQ.
		0	The CAN module samples only once at the sampling point.

Table 23-18. Bit-Timing Configuration Register (CANBTC) Field Descriptions (continued)

Bit	Field	Value	Description
		1	The CAN module samples three times and makes a majority decision. The triple sample mode shall be selected only for bit rate prescale values greater than 4 (BRP > 4).
6-3	TSEG1	0-Fh	TSEG1 3:0 Time Segment 1
			This parameter specifies the length of the TSEG1 segment in TQ units. The value of TSEG1 is calculated as follows:
			TSEG1 = 1 + TSEG1.0 + (2*TSEG1.1) + (4*TSEG1.2) + (8*TSEG1.3)
			TSEG1 combines PROP_SEG and PHASE_SEG1 segments:
			TSEG1 = PROP_SEG + PHASE_SEG1
			Where PROP_SEG and PHASE_SEG1 are the length of these two segments in TQ units.
			$TSEG1_{CALC}$ value is programmable in the range of 1 TQ to 16 TQ and has to fulfill the following timing rule: TSEG1 must be greater than or equal to TSEG2 and IPT (for more details about IPT, refer to Section 23.6.1.
			The value programmed into the CANBTC register has to be decremented by 1 because of the 4-bit size of the binary TSEG1 value (TSEG1.3:0):
			$TSEG1_{BTC} = TSEG1_{CALC} - 1$
			$TSEG1_{CALC}$ Result of the calculation.
			$2 \leq TSEG1_{CALC} \leq 16$
			$TSEG1_{BTC}$ Value to be programmed into the CANBTC register.
			$1 \leq TSEG1_{BTC} \leq 15$
2-0	TSEG2	0-7h	TSEG2 2:0 Time Segment 2
			TSEG2 defines the length of the PHASE_SEG2 segment in TQ units, and is calculated as follows:
			TSEG2 = 1 + TSEG2.0 + (2*TSEG2.1) + (4 * TSEG2.2)
			$TSEG2_{CALC}$ is programmable in the range of 1 TQ to 8 TQ and has to fulfill the following timing rule: TSEG2 must be smaller than or equal to TSEG1 and must be greater than or equal to IPT. For more details about IPT, refer to Section 23.6.1.
			The value programmed into the CANBTC register has to be decremented by 1 because of the 3-bit size of the binary TSEG2 value (TSEG2 3:0):
			$TSEG2_{BTC} = TSEG2_{CALC} - 1$
			$TSEG2_{CALC}$ Result of the calculation.
			$TSEG2_{BTC}$ Value to be programmed into the CANBTC.

23.10.1.13 Error and Status Register (CANES)

The error and status register comprises information about the actual status of the CAN module and displays bus error flags as well as error status flags. The way of storing the bus error flags (FE, BE, CRCE, SE, and ACKE) and the error status flags (BO, EP, and EW) in this register is subject to a special mechanism. If one of these error flags is set, then the current state of all other error flags is frozen. In order to update this register to the actual values of the error flags, the error flag that is set has to be acknowledged by writing a 1 to it. This mechanism allows the software to distinguish between the first error and all following errors.

Figure 23-23. Error and Status Register (CANES) [30h]

LEGEND: R = Read only; R/WC = Read/write 1 to reset, write of 0 has no effect; -*n* = value after reset

Table 23-19. Error and Status Register (CANES) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved		Reads are undefined and writes have no effect.
24	FE		Form Error Flag. This bit is cleared when a 1 is written to this bit.
		0	No form error is detected.
		1	A form error occurred on the bus. This means that one or more of the fixed-form bit fields had the wrong level on the bus.
23	BE		Bit Error Flag. This bit is cleared when a 1 is written to this bit.
		0	No bit error is detected.
		1	The received bit does not match the transmitted bit outside of the arbitration field or during transmission of the arbitration field, a dominant bit was sent but a recessive bit was received.
22	SA1		Stuck at dominant error. This bit is always 1 after a hardware reset, a software reset, or a bus-off condition. This bit is cleared when a recessive bit is detected on the bus or when a 1 is written to this bit.
		0	The CAN module detected a recessive bit.
		1	The CAN module never detected a recessive bit.
21	CRCE		CRC Error. This bit is cleared when a 1 is written to this bit.
		0	The CAN module never received a wrong CRC.
		1	The CAN module received a wrong CRC.
20	SE		Stuff Error. This bit is cleared when a 1 is written to this bit.
		0	No stuff bit error occurred.
		1	A stuff bit error occurred.
19	ACKE		Acknowledge Error. This bit is cleared when a 1 is written to this bit.
		0	All messages have been correctly acknowledged.
		1	The CAN module received no acknowledge.
18	BO		Bus-Off State. The CAN module is in bus-offstate. This bit is cleared when a 1 is written to this bit.
		0	Normal operation
		1	There is an abnormal rate of errors on the CAN bus. This condition occurs when the transmit error counter register (CANTEC) reaches the limit of 256. During bus off, no messages are received or transmitted. The only ways to exit this state are by clearing the CCR bit in the master control register (CANMC) or by setting the ABO bit in CANMC. After leaving bus off, the error counters are cleared.
17	EP		Error Passive State. This bit is cleared when a 1 is written to this bit.

Table 23-19. Error and Status Register (CANES) Field Descriptions (continued)

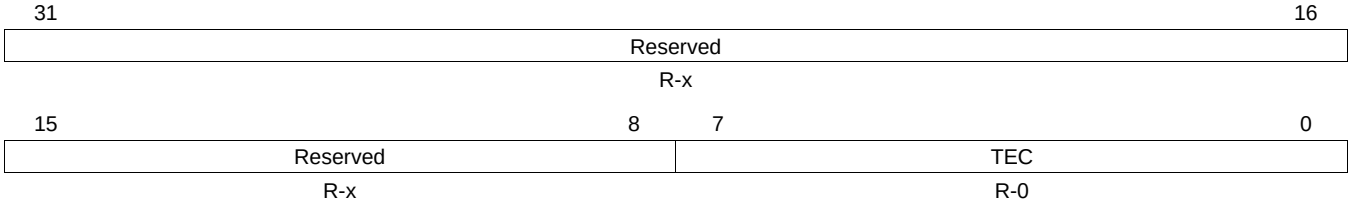
Bit	Field	Value	Description
		0	The CAN module is in error-active mode.
		1	The CAN module is in error-passive mode.
16	EW		Warning Status. This bit is cleared when a 1 is written to this bit.
		0	Both error counter registers (CANREC and CANTEC) are less than 96.
		1	One of the two error counter registers (CANREC or CANTEC) has reached the warning level of 96.
15-6	Reserved		Reads are undefined and writes have no effect.
5	SMA		Suspend Mode Acknowledge bit is set after a latency of one clock cycle—up to the length of one frame- after the suspend mode was activated. The suspend mode is activated with the debugger tool when the circuit is not in run mode. During the suspend mode, the CAN module is frozen and cannot receive or transmit any frame. However, if the CAN module is transmitting or receiving a frame when the suspend mode is activated, the module enters suspend mode only at the end of the frame.
		0	The CAN module is not in suspend mode.
		1	The CAN module has entered suspend mode.
4	CCE		Change Configuration Enable bit displays the configuration access. This bit is set after a latency of one clock cycle up to the length of one frame.
		0	The CPU is denied write access to the configuration registers.
		1	The CPU has write access to the configuration registers.
3	PDA		Power Down Mode Acknowledge.
		0	Normal operation
		1	The CAN module has entered the power-down mode.
2	Reserved		Reads are undefined and writes have no effect.
1	RM		CAN protocol kernel (CPK) Receive Mode bit reflects what the CPK is actually doing regardless of mailbox configuration.
		0	The CAN protocol kernel is not receiving a message.
		1	The CAN protocol kernel is receiving a message.
0	TM		CAN protocol kernel (CPK) Transmit Mode bit reflects what the CPK is actually doing regardless of mailbox configuration.
		0	The CAN protocol kernel is not transmitting a message.
		1	The CAN protocol kernel is transmitting a message.

23.10.1.14 Transmit Error Counter Register (CANTEC)

The CAN module contains two error counters: the receive error counter (CANREC) and the transmit error counter (CANTEC). The values of both counters are read by way of the CPU interface. These counters are incremented or decremented according to the CAN protocol specification version 2.0.

After reaching the bus-offstate, the transmit error counter is undefined while the receive error counter changes its function. After leaving initialization mode, the error counters are cleared.

Figure 23-24. Transmit Error Counter Register (CANTEC) [34h]



LEGEND: R = Read only; -*n* = value after reset; -x = value is indeterminate after reset

23.10.1.15 Receive Error Counter Register (CANREC)

The CAN module contains two error counters: the receive error counter (CANREC) and the transmit error counter (CANTEC). The values of both counters are read by way of the CPU interface. These counters are incremented or decremented according to the CAN protocol specification version 2.0.

After reaching or exceeding the error passive limit (128), the receive error counter is not incremented. When a message is received correctly, the counter is set again to a value between 119 and 127 (compare with CAN specification). After reaching the bus-offstate, the transmit error counter is undefined while the receive error counter changes its function.

After reaching the bus-off state, the receive error counter is cleared and is incremented after every 11 consecutive recessive bits on the bus. These 11 bits correspond to the gap between two frames on the bus. If the counter reaches 128, the CAN module automatically changes back to the bus-on status if this feature is enabled (ABO bit in the master control register, CANMC is set). All internal flags are reset and the error counters are cleared. After leaving initialization mode, the error counters are cleared.

Table 23-20. Global Interrupt Flag Registers (CANGIF) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved		Reads are undefined and writes have no effect.
17	MAIF		Message Alarm Flag.
		0	No time out for the mailboxes occurred.
		1	One of the mailboxes did not transmit or receive a message within the specified time frame.
16	TCOIF		Local Network Time Counter Overflow Flag.
		0	The MSB of the local network time register (CANLNT) is 0.
		1	The MSB of the local network time register (CANLNT) is 1.
15	GMIF		Global Mailbox Interrupt Flag
		0	No message has been transmitted or received.
		1	One of the mailboxes transmitted or received a message successfully.
14	AAIF		Abort-Acknowledge Interrupt Flag
		0	No transmission has been aborted.
		1	A transmission request has been aborted.

Table 23-20. Global Interrupt Flag Registers (CANGIF) Field Descriptions (continued)

Bit	Field	Value	Description
13	WDIF		Write-Denied Interrupt Flag
		0	The CPU write access to the mailbox was successful.
		1	The CPU write access to the mailbox was not successful.
12	WUIF		Wake-Up Interrupt Flag
		0	The CAN module is still in sleep mode or normal operation.
		1	During local power down, the CAN module has left sleep mode. During global power-down, there is activity on the CAN bus lines. This bit is also set when a global power-down is requested by the CPU, but the CAN module is not ready to enter power-down mode.
11	RMLIF		Receive-Message-Lost Interrupt Flag
		0	No message has been lost.
		1	At least for one of the receive mailboxes, an overflow condition has occurred.
10	BOIF		Bus-Off Interrupt Flag
		0	The CAN module is still in bus-on mode.
		1	The CAN module is in bus-off mode.
9	EPIF		Error-Passive Interrupt Flag
		0	The CAN module is not in error-passive mode.
		1	The CAN module is in error-passive mode.
8	WLIF		Warning Level Interrupt Flag
		0	None of the error counter registers (CANREC or CANTEC) has reached the warning level.
		1	At least one of the error counter registers (CANREC or CANTEC) has reached the warning level.
7-5	Reserved		Reads are undefined and writes have no effect.
4-0	MIV	0-1Fh	Message Interrupt Vector bits indicate the number of the message object that activated the global mailbox interrupt bit (GMIF0/GMIF1). These bits are held until the appropriate TA*n* bit in the transmission acknowledge register (CANTA) or RMP*n* bit in the receive message pending register (CANRMP) is cleared, or when a higher priority mailbox interrupt occurred. Then, the highest interrupt vector is displayed. In the HECC, mailbox 31 has the highest priority; in the SCC or SCC-compatible mode, mailbox 15 has the highest priority. When the GMIF0/GMIF1 bit is 0, the corresponding MIV0/MIV1 bits are undefined. MIV0.4 and MIV1.4 are not available in the SCC.

23.10.1.17 Global Interrupt Mask Register (CANGIM)

This register allows the various interrupts to be enabled. If a bit is set, the corresponding interrupt is enabled.

Figure 23-28. Global Interrupt Mask Register (CANGIM) [40h]

		0	EPIF interrupt is disabled.
		1	EPIF interrupt is enabled.
8	WLIM		Warning Level Interrupt Mask
		0	WLIF interrupt is disabled.
		1	WLIF interrupt is enabled.
7-3	Reserved		Reads are undefined and writes have no effect.

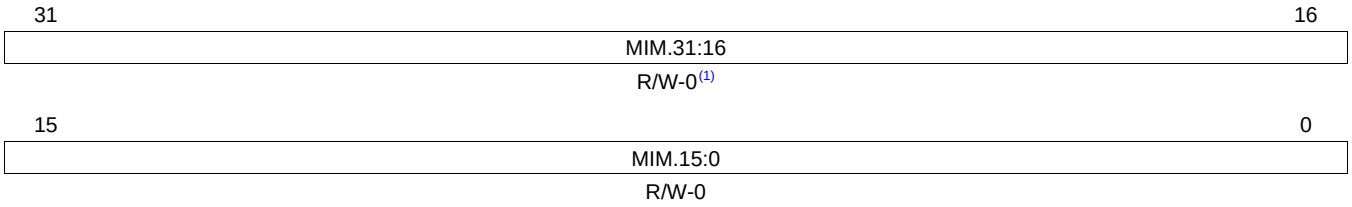
Table 23-21. Global Interrupt Mask Register (CANGIM) Field Descriptions (continued)

Bit	Field	Value	Description
2	SIL		System Interrupt Level. Define the interrupt level for TCOIF, WDIF, WUIF, BOIF, EPIF, AAIF, RMLIF and WLIF.
		0	All global interrupts are mapped to the HECC0INT/SCC0INT interrupt line.
		1	All system interrupts are mapped to the HECC1INT/SCC1INT interrupt line.
1	I1EN		Interrupt Line 1 Enable
		0	The HECC1INT/SCC1INT interrupt line is globally disabled.
		1	Globally enables all interrupts for the HECC1INT/SCC1INT interrupt line, if the corresponding masks are set.
0	I0EN		Interrupt Line 0 Enable
		0	The HECC0INT/SCC0INT interrupt line is globally disabled.
		1	Globally enables all interrupts for the HECC0INT/SCC0INT interrupt line, if the corresponding masks are set.

23.10.1.18 Mailbox Interrupt Mask Register (CANMIM)

There is one interrupt bit available for each mailbox. This may be a receive or a transmit interrupt depending on the configuration register. After power up, all interrupt mask bits are cleared and all interrupts are disabled.

Figure 23-29. Mailbox Interrupt Mask Register (CANMIM) [48h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

(1) HECC only, reserved in the SCC

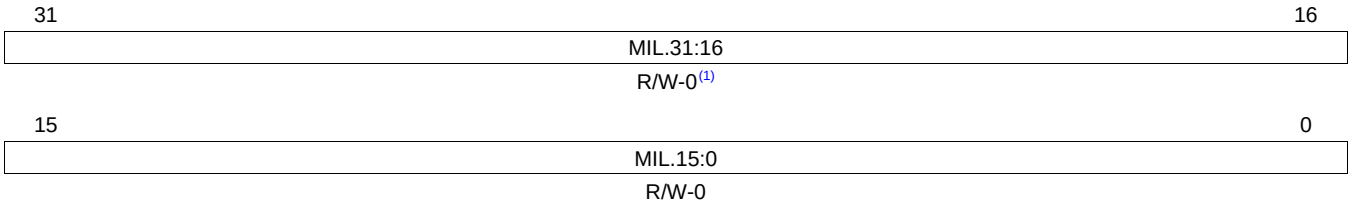
Table 23-22. Mailbox Interrupt Mask Register (CANMIM) Field Descriptions

Bit	Field	Value	Description
31-0	MIM		Mailbox Interrupt Mask bits allow any mailbox interrupt to be masked individually.
		0	Mailbox interrupt is disabled.
		1	Mailbox interrupt is enabled. An interrupt is generated if a message has been transmitted successfully (in case of a transmit mailbox) or if a message has been received without any error (in case of a receive mailbox).

23.10.1.19 Mailbox Interrupt Level Register (CANMIL)

Each mailbox may initiate an interrupt on one of the two interrupt lines. Depending on the setting in this register, the interrupt is generated on the HECC0INT/SCC0INT interrupt line (MIL*n* = 0) or on the HECC1INT/SCC1INT interrupt line (MIL*n* = 1).

Figure 23-30. Mailbox Interrupt Level Register (CANMIL) [4Ch]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

(1) HECC only, reserved in the SCC

Table 23-23. Mailbox Interrupt Level Register (CANMIL) Field Descriptions

Bit	Field	Value	Description
31-0	MIL		Mailbox Interrupt Level bits allow any mailbox interrupt level to be selected individually.
		0	The mailbox interrupt is generated on HECC0INT/SCC0INT interrupt line.
		1	The mailbox interrupt is generated on HECC1INT/SCC1INT interrupt line.

23.10.1.20 Overwrite Protection Control Register (CANOPC)

If there is an overflow condition for mailbox *n,* the RMP*n* bit in the receive message pending register (CANRMP) is set to 1 and a new receive message would fit for mailbox *n*, the new message is stored depending on the settings in CANOPC.

- If the corresponding OPC*n* bit is set to 1, the old message is protected against being overwritten by the new message; thus, the next mailboxes are checked for a matching identification. If no other mailbox is found, the message is lost without further notification.
- If the corresponding OPC*n* bit is cleared to 0, the old message is overwritten by the new message.

An overwrite condition is monitored by the setting of the corresponding RML*n* bit in the receive message lost register (CANRML).

Bit	Field	Value	Description
31-0	OPC		Overwrite Protection Control
		0	The old message may be overwritten by a new message
		1	An old message stored in that mailbox is protected against being overwritten by the new message.

23.10.1.21 Transmit I/O Control Register (CANTIOC)

The CANTX pin may be configured as a normal I/O pin, if the HECC/SCC is not used, using CANTIOC.

CANTX Pin

NOTE: When the CANTX pin is configured for CAN transmit functions (TXFUNC = 1), the TXDIR and TXOUT bits have no meaning and can be set to either 0 or 1. The TXIN bit always shows the actual value of the CANTX pin.

Figure 23-32. Transmit I/O Control Register (CANTIOC) [54h]

Table 23-25. Transmit I/O Control Register (CANTIOC) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved		Reads are undefined and writes have no effect.
3	TXFUNC		External Pin I/O Enable
		0	The CANTX pin is used as an I/O pin, the CAN protocol kernel (CPK) output is unconnected.
		1	The CANTX pin is used for the CAN transmit functions.
2	TXDIR		Transmit Pin Direction
		0	The CANTX pin is used as an input pin, if CANTX is configured as an I/O pin (TXFUNC = 0).
		1	The CANTX pin is used as an output pin, if CANTX is configured as an I/O pin (TXFUNC = 0).
1	TXOUT		Output value for CANTX pin. This value is output on the CANTX pin, if CANTX is configured as an I/O pin (TXFUNC = 0) and as an output (TXDIR = 1).
0	TXIN		Reflects the value on the CANTX pin.
		0	Logic 0 present on CANTX pin.
		1	Logic 1 present on CANTX pin.

23.10.1.22 Receive I/O Control Registers (CANRIOC)

The CANRX pin may be configured as a normal I/O pin, if the HECC/SCC is not used, using CANRIOC.

CANRX Pin

NOTE: When the CANRX pin is configured for CAN receive functions (RXFUNC = 1), the RXDIR and RXOUT bits have no meaning and can be set to either 0 or 1. The RXIN bit always shows the actual value of the CANRX pin.

Bit	Field	Value	Description
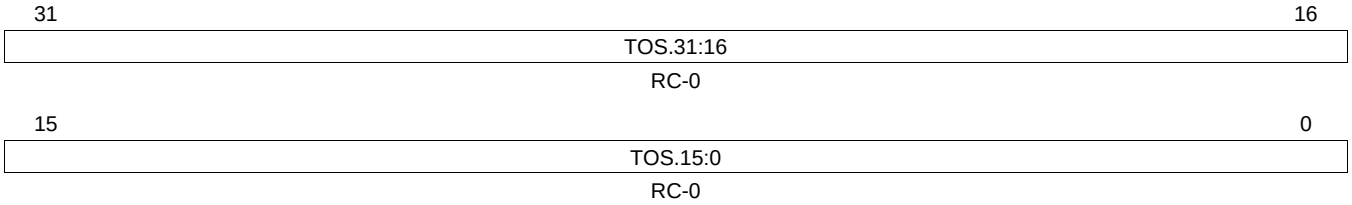
31-0	TOC		Time-Out Control Register.
		0	The time-out function is disabled. The TOS*n* bit is never set in the time-out status register (CANTOS).
		1	The TOC*n* bit has to be set by the CPU in order to enable the time-out function for mailbox *n*. Before setting the TOC*n* bit, load the corresponding message object time-out register (CANMOTO) with the time-out value relative to the local network time counter (LNT).

23.10.3.3 Time-Out Status Register (CANTOS)

Figure 23-38. Time-Out Status Register (CANTOS) [64h]



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 23-31. Time-Out Status Register (CANTOS) Field Descriptions

Bit	Field	Value	Description
31-0	TOS		Time-Out Status Register.
		0	No time-out occurred or a specified mailbox is disabled.
		1	The value in the local network time register (CANLNT) is larger or equal to the value in the message object time-out register (CANMOTO) that corresponds to mailbox *n* and the TOC*n* bit is set in the time-out control register (CANTOC).

23.10.4 Message Mailbox Registers

23.10.4.1 Message Identifier Register (CANMID)

This register is only written if mailbox *n* is disabled (the ME*n* bit in the mailbox enable register, CANME, is cleared to 0).

Figure 23-39. Message Identifier Register (CANMID) [00h]

Table 23-32. Message Identifier Register (CANMID) Field Descriptions

Bit	Field	Value	Description
31	IDE		Identifier Extension Bit
		0	Standard identifier (11 bits). The received message or the message to be sent has a standard identifier.
		1	Extended identifier (29 bits). The received message or the message to be sent has an extended identifier.
30	AME		Acceptance Mask Enable Bit. AME is only used for receiver mailboxes. It must not be set for automatic reply (AAM*n*=1, MD*n*=0) mailboxes; otherwise, the mailbox behavior is undefined. This bit is not modified by a message reception.
		0	No acceptance mask will be used, all identifier bits must match to receive the message.
		1	The corresponding acceptance mask is used.
29	AAM		Auto Answer Mode Bit. This bit is only valid for message mailboxes configured as transmit. For receive mailboxes, this bit has no effect: the mailbox is always configured for normal receive operation. This bit is not modified by a message reception.
		0	Normal transmit mode. The mailbox does not reply to remote requests. The reception of a remote request frame has no effect on the message mailbox.
		1	Auto answer mode. If a matching remote request is received, the CAN module answers to the remote request by sending the contents of the mailbox.
28-0	ID		Message Identifier.
			In standard identifier mode, if the IDE bit = 0, the message identifier is stored in ID bits 28-18. In this case, ID bits 17-0 have no meaning.
			In extended identifier mode, if the IDE bit = 1, the message identifier is stored in ID bits 28-0.

23.10.4.2 Message Control Field Register (CANMCF)

This register is only written if mailbox *n* is configured for transmission (MD*n* bit in the mailbox direction register, CANMD, is cleared to 0) or if the mailbox is disabled (ME*n* bit in the mailbox enable register, CANME, is cleared to 0).

Figure 23-40. Message Control Field Register (CANMCF) [04h]

LEGEND: R/W = Read at any time, write when the mailbox is disabled or configured in transmission; -*n* = value after reset; -x = value is indeterminate after reset

(1) HECC only, reserved in the SCC

Table 23-33. Message Control Field Register (CANMCF) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved		Reserved
13-8	TPL	0-3Fh	Transmit Priority Level. This 6-bit field in the HECC (reserved in the SCC) defines the priority of this mailbox as compared to the other 31 mailboxes. The highest number has the highest priority. In the case that two mailboxes have the same priority, the one with the higher mailbox number is transmitted. TPL applies only for transmit mailboxes. TPL is not used when in SCC-compatibility mode.
7-5	Reserved		Reserved
4	RTR		Remote Transmission Request Bit.
		0	No remote frame is requested.
		1	For receive mailbox: If the TRS*n* bit in the transmit request set register (CANTRS) is set, a remote frame is transmitted and the corresponding data frame will be received in the same mailbox. For transmit mailbox: If the TRS*n* bit in CANTRS is set, a remote frame is transmitted, but the corresponding data frame has to be received in another mailbox.
3-0	DLC	0-8h	Data Length Code. The number in these bits determines how many data bytes are sent or received. Valid value range is from 0 to 8. Values from 9 to 15 are not allowed.

23.10.4.3 Message Data Registers (CANMDL, CANMDH)

Eight bytes of the mailbox are used to store the data field of a CAN message. The setting of the DBO bit in the master control register (CANMC) determines the ordering of stored data. The data is transmitted or received from the CAN bus, starting with byte 0.

- When DBO = 1, the data is stored or read starting with the least-significant byte of CANMDL and ending with the most-significant byte of CANMDH.
- When DBO = 0, the data is stored or read starting with the most-significant byte of CANMDL and ending with the least-significant byte of CANMDH.

CANMDL*n* and CANMDH*n* are only written if mailbox *n* is configured for transmission (MD*n* bit in the mailbox direction register, CANMD, is cleared to 0) or if the mailbox is disabled (ME*n* bit in the mailbox enable register, CANME, is cleared to 0). If the TRS*n* bit in the transmission request set register (CANTRS) is set to 1, CANMDL*n* and CANMDH*n* cannot be written, unless the CDR bit in CANMC is set, with the MBNR bits in CANMC set to *n.* These settings also apply for a message object configured in reply mode (AAM bit in the message identifier register, CANMID, is set to 1).

Data Field

NOTE: The data field beyond the valid received data is modified by any message reception and is indeterminate.

23.10.4.4 Local Acceptance Mask Register (CANLAM)

The local acceptance filtering allows you to locally mask (don't care) any identifier bits of the incoming message.

In the SCC, the local acceptance mask register 0 (CANLAM0) is used for mailboxes 2 to 0. The local acceptance mask register 3 (CANLAM3) is used for mailboxes 5 to 3. For mailboxes 6 to 15, the global acceptance mask register (CANGAM) is used. CANLAM0 is located at address 80h of the SCC register memory; CANLAM3 is located at address 8Ch of SCC register memory.

After a hardware or a software reset of the SCC module, CANLAM0 and CANLAM3 are reset to zero. After a reset of the HECC, the CANLAM registers are not modified.

In the HECC, each mailbox (0 to 31) has its own mask register, CANLAM0 to CANLAM31. An incoming message is stored in the highest numbered mailbox with a matching identifier.

Figure 23-45. Local Acceptance Mask Register (CANLAM) [3000h]

Table 23-34. Local Acceptance Mask Register (CANLAM) Field Descriptions

Bit	Field	Value	Description
31	LAMI		Local Acceptance Mask Identifier Extension Bit.
		0	The identifier extension bit stored in the mailbox determines which messages shall be received.
		1	Standard and extended frames can be received. In case of an extended frame, all 29 bits of the identifier are stored in the mailbox and all 29 bits of the local acceptance mask register are used for the filter. In case of a standard frame, only the first eleven bits (bits 28 to 18) of the identifier and the local acceptance mask are used.
30-29	Reserved		Reads are undefined and writes have no effect.
28-0	LAM		Local Acceptance Mask. These bits enable the masking of any identifier bit of an incoming message.
		0	Received identifier bit value must match the corresponding identifier bit of the message identifier register (CANMID).
		1	Accept a 0 or a 1 (don't care) for the corresponding bit of the received identifier.

Applications Processor Initialization

This chapter introduces the general-purpose device initialization.

Topic **Page**

24.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the processor from power-on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavior expectations.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

24.1.1 Terminology

- Bootstrap: Initial software (SW) that is launched by the ROM code during the memory booting phase.
- Certificate: Data block plus trusted signature of the data block
- Downloaded SW: Initial SW that is downloaded into the internal SRAM by the ROM code during the peripheral booting phase
- eFuse: A one-time programmable memory location usually set at the factory
- Flash loader: Downloaded SW launched by the ROM code in preflashing. It also programs an image into external memories.
- GP device: General-purpose device. A type of device in which the security features, including the cryptographic HWA, are disabled. Intended for production.
- Initial SW: Software that is executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial SW is a generic term for bootstrap and downloaded SW.
- Memory booting: ROM code mechanism that consists of executing an Initial SW from external memory
- Peripheral booting: ROM code mechanism that consists of polling selected interfaces, downloading, and executing an Initial SW (in this, case called downloaded SW) in the internal RAM.
- Permanent booting device: Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset.
- Preflashing: A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- R&D certificate: Certificate where the data block contains development configuration parameters
- ROM code: The on-chip SW in the processor's ROM which implements booting and security features
- Secure environment: Execution and storage environment, built with hardware and SW components, whose access is enabled when the processor runs in secure mode
- Secure mode: MPU secure working state, active when the ARM secure state is set, and reinforced by secure state machine (SSM) policy and attack countermeasures.
- Secure RAM: Writable area of the OCM-RAM. Protected applications are loaded for execution and secure data is temporarily stored in this area. Can only be accessed when the processor is in secure mode, or by a secure DMA channel.
- Secure ROM: Read-only memory inside the chip. Programmed at the chip manufacturing phase. Can be accessed only when the processor is in secure mode.

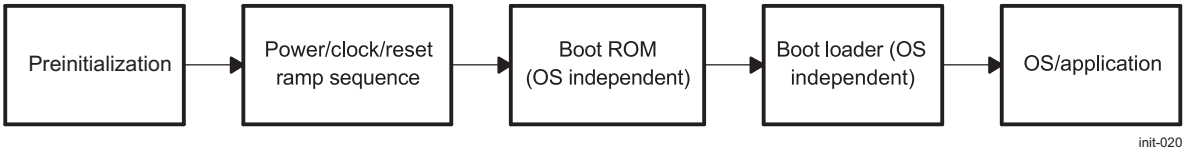
24.1.2 Initialization Process

A brief overview of the whole initialization process and its steps are shown in the Figure 24-1. Initialization consists of several steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader
- OS/application

Each of these steps, up to OS/applications running, is explained in detail in the following sections.

Figure 24-1. Initialization Process



The first two steps in the initialization process are hardware oriented; however, they do require a good understanding of the process of configuring those system interface pins (balls on the device), which have SW configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers which are vital for proper device initialization.

See your device data manual for more information regarding the use of multiplexing configuration.

24.2 Preinitialization

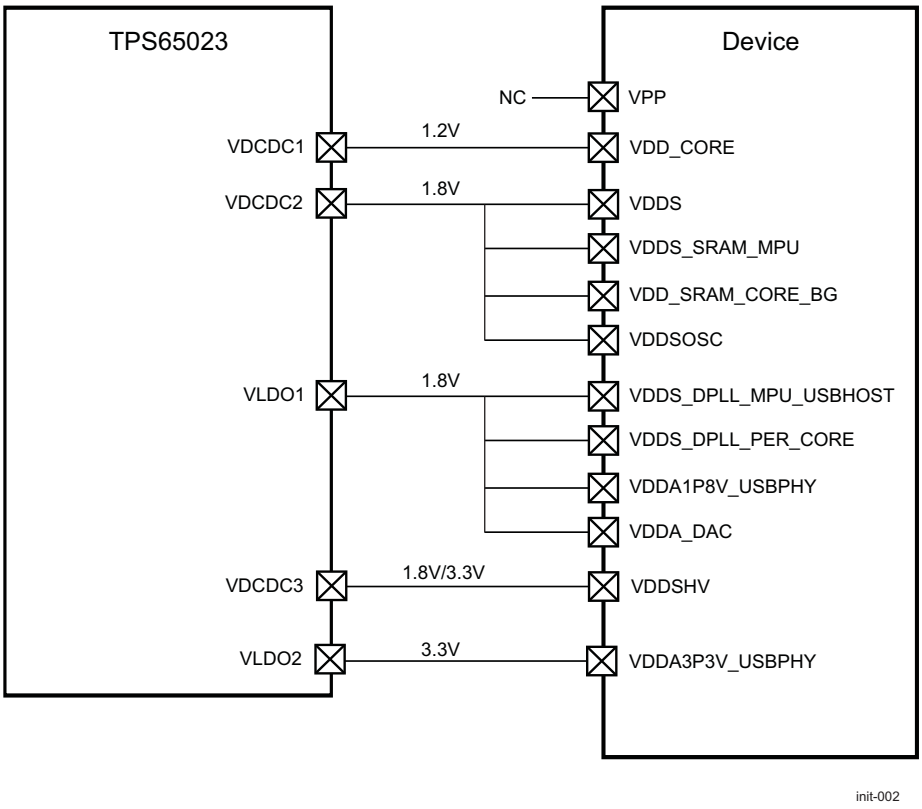
Certain hardware configuration settings must be made in order to accomplish a successful boot-up operation with a GP device. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven properly for successful device initialization. The following sections detail the specific requirements for the preinitialization stage.

24.2.1 Power Connections

The device can be supplied by an external power IC. Texas Instruments provides a global solution with the processor connected to the TPS65023 power IC.

Figure 24-2 shows the power connections between the device and the TPS65023 power IC.

Figure 24-2. Power Connections



NOTE: Figure 24-2 is an example of power connections between the device and the TPS65023.

NOTE:

- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

Table 24-1 describes of the power pins.

Table 24-1. Power Pin Descriptions

I/O Voltage Name	Description
VDD_CORE	Core power supply.
VDDS_SRAM_MPU	Analog power supply for MPU SLDO.
VDD_SRAM_CORE_BG	Analog power supply for CORE SLDO.
VDDSOSC	OSC VDDS supply.
VDDS_DPLL_MPU_USBHOST	Analog Power Supply for MPUSS/USBHOST DPLL.
VDDS_DPLL_PER_CORE	Analog supply for CORE/PER PLL & HSDIVIDER.
VDDA1P8V_USBPHY	1.8V supply for USB transceiver.
VDDA_DAC	Analog Power Supply for AVDAC.
VDDA3P3V_USBPHY	3.3V power supply for USB transceiver.
VDDSHV	1.8/3.3V IOs supply.
VDDS	Bias supply for IOs.
VPP	eFuse programming.

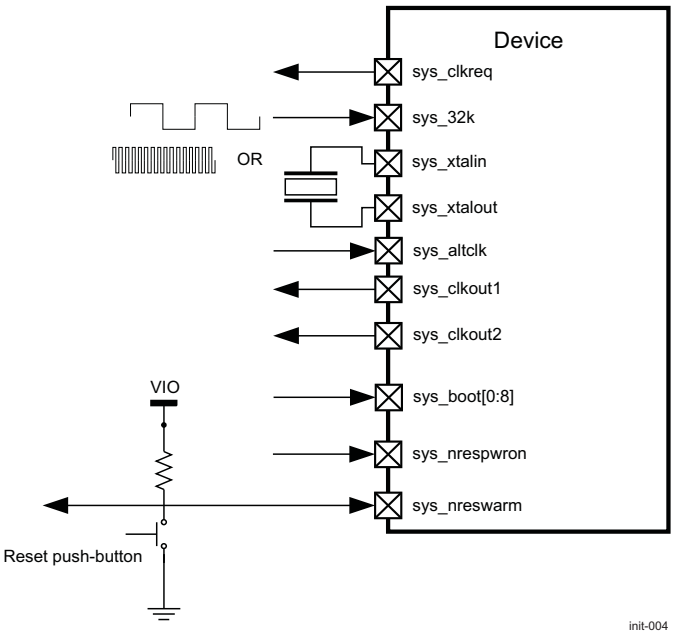
For a complete description of the power pins on the device package, see your device-specific data manual. For more information on power management, see the *Power, Reset, and Clock Management* chapter.

24.2.2 Clock and Reset

24.2.2.1 Clock and Reset Overview

Figure 24-3 shows the clock and reset environment which gathers the clocks and reset signals related at system level, as well as system expansion signals.

Figure 24-3. Clock and Reset Environment



The main features of the system interface are:

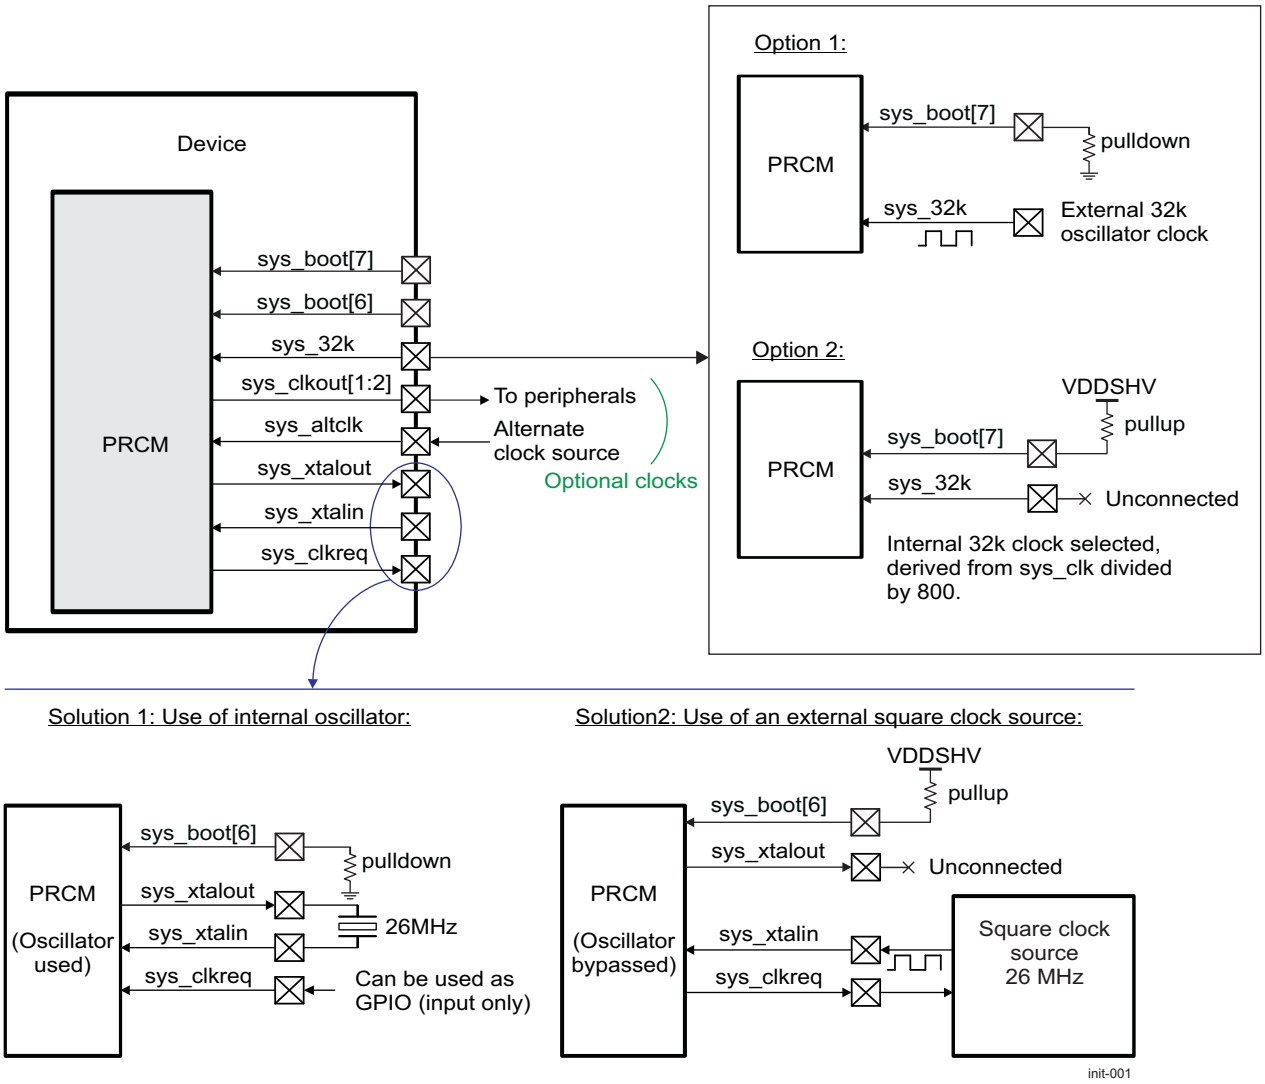
- A clock request output to an external square clock source
- 26MHz of system clock as reference clock input from either the external crystal oscillator or the digital clock input
- 32KHz clock for low frequency operation supplied either from external oscillator or generated internally
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Nine input signals to define the boot mode
- Two reset sources
  - Power-on reset (cold reset)
  - Bidirectional warm reset

24.2.2.2 Clock Configuration

24.2.2.2.1 Required System Input Clocks

Figure 24-4 shows the clocks interface.

Figure 24-4. Clock Interface



NOTE:

- The SYS_CLKOUT output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.
- Internal generation of 32K clock is enabled by providing pull-up on sys_boot[7] pin at power-on-reset.

The device operation requires two external input clocks as follows:

1. Sys_32k: The 32KHz clock for low frequency operation is supplied in following ways:
   - External – Supplied by an oscillator on sys_32K pin.
   - Internal – 32K clock generation using a fixed divider on HS system clock (26MHz).

2. Sys_xtal (in/out): The 26MHz system clock is the main clock source of the device. The system clock input can be connected in either of the two following ways:
   - Crystal quartz through the SYS_XTALIN and SYS_XTALOUT pins, using an internal oscillator.
   - CMOS digital clock (square clock) through the SYS_XTALIN pin. The oscillator is bypassed.

Table 24-2 lists the mapping for input sources.

Table 24-2. Mapping for Input Sources

Input Source	Mapping	Comment
Crystal quartz	SYS_XTALIN and SYS_XTALOUT	Requires use of internal oscillator
Square clock (1.8 CMOS signal)	SYS_XTALIN (SYS_XTALOUT unconnected)	Internal oscillator is bypassed

Only one source input at a time can be used because sys_32k, SYS_XTALIN and SYS_XTALOUT have permanently assigned pin locations with no pad configuration for these pins through a system control module register.

24.2.2.2.2 Optional System Input Clock: SYS_ALTCLK

An additional clock can be provided through the SYS_ALTCLK input pin to supply internal peripherals, phase-locked loops (PLLs), a precise clock for NTSC (54 MHz), USB full-speed controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the system control module CONTROL.CONTROL_PADCONF_I2C3_SDA register. As an example, to use the SYS_ALTCLK pin, the CONTROL.CONTROL_PADCONF_I2C3_SDA[18:16] MUXMODE1 field must be set to 0x01.

24.2.2.2.3 Optional System Output Clock: SYS_CLKOUT1 and SYS_CLKOUT2

Two output clocks (SYS_CLKOUT1 and SYS_CLKOUT2 pins) are available:

- SYS_CLKOUT1 can output the oscillator clock. Its OFF state polarity is programmable.
- SYS_CLKOUT2 can output the system clock (26MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. SYS_CLKOUT2 can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production. Please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

The clocks can be managed by SW with the appropriate register in the power, reset, clock, management (PRCM) module:

- SYS_CLKOUT1 is managed using PRCM.PRM_CLKOUT_CTRL and PRCM.PRM_POLCTRL[2].
- SYS_CLKOUT2 is managed using PRCM.CM_CLKOUT_CTRL and PRCM.CM_CLKSEL1_PLL[28:27].

24.2.2.3 Reset Configuration

The sys_nrespwron reset pin is used to reset the entire chip during the power-on reset.

The sys_nreswarm reset pin is used to reset the entire chip when the device is supplied and operating, except for the following:

- Part of Memory Subsystem
- Part of PRCM

- Control module
- Watchdog
- 32-kHz synchronization timer
- DPLLs

CAUTION

sys_nrespwron must be driven low during a power-up sequence.

sys_nreswarm is a bidirectional reset. When an internal reset occurs, sys_nreswarm goes low and resets all the peripherals.

Both sys_nrespwron and sys_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM_RSTST_MPU register and used by the boot ROM code.

24.2.3 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices used for booting. The sys_boot[6] pin is used to select whether the internal oscillator is bypassed. The sys_boot[7] pin is used to select whether to use external 32K clock supply or 32K clock is generated internally.

Boot configuration pins sys_boot[5:0] are sampled and latched onto CONTROL.CONTROL_STATUS register and sys_boot[8:7] are sampled and latched onto CONTROL.CONTROL_DEVCONF2 register following a power-on reset. After booting, these pins can optionally be used for other functions and the associated CONTROL.CONTROL_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see the *System Control Module* chapter.

NOTE: If used as GPIOs, these pins must be used in the output mode. To ensure the sys_boot[8:0] input values are selected by the pullup and pulldown on sys_boot[8:0] pins at power-on reset, these GPIOs must be used only in output mode. As these balls have no pullup or pulldown capacity, care must be taken when choosing to use these GPIOs.

Table 24-3, Table 24-4, and Table 24-5 are decoding tables for sys_boot pins. Depending on sys_boot pin configuration during the reset (first column), the ROM code tries to boot on the first device listed. If the boot failed on this first device, the ROM code tries the second device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
  - XIP: XIP memory without wait monitoring enabled (NOR flash memories)
  - XIP wait: XIP memory with wait monitoring
  - DOC: DiskOnChip™ memory (H3 device types)
  - NAND: NAND flash memories (non XIP)
  - OneNAND: OneNAND flash memories
  - MMC1: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the first multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO1) card interface
  - MMC2: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the second multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO2) card interface
- Peripheral interfaces:
  - Ethernet: EMAC RMII interface
  - USB: HS/FS USB
  - UART3: UART interface
- Permanent booting devices are in *italics*.

Table 24-3 and Table 24-4 list the sys_boot pin configuration after a power-on reset (POR).

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.

Table 24-3. Memory Booting Configuration Pins after POR

sys_boot [4:0]	Booting Sequence When SYS.BOOT[5] = 0

24.3 Power, Clocks, and Reset Power-Up Sequence

See the section *Power-Up Sequence* in the *Power, Reset, and Clock Management* chapter for the power-on sequence, including power supplies, clocks, and reset signals.

See your device data manual for more information regarding the device power-up sequence.

24.4 Device Initialization by ROM Code

This section describes the high-level booting concepts and provides basic knowledge of booting on the device.

24.4.1 Booting Overview

CAUTION

To use the level 2 (L2) cache with the device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

24.4.1.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting memories.

The ROM code has two functionalities for booting: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB, UART3 or EMAC) by using the sys_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

Table 24-6 lists the pin multiplexing according to boot peripheral.

Table 24-6. Pin Multiplexing According to Boot Peripheral

Boot Device	Pins
NAND/OneNAND	General-purpose memory controller (GPMC) pins in mode 0
XIP memory	GPMC pins in mode 0
DiskOnChip	GPMC pins in mode 0
MMC/SD1	MMC1 pins in mode 0
MMC/SD2	MMC2 pins in mode 0
UART3	UART3 pins in mode 0
EMAC	EMAC pins in mode 0

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.

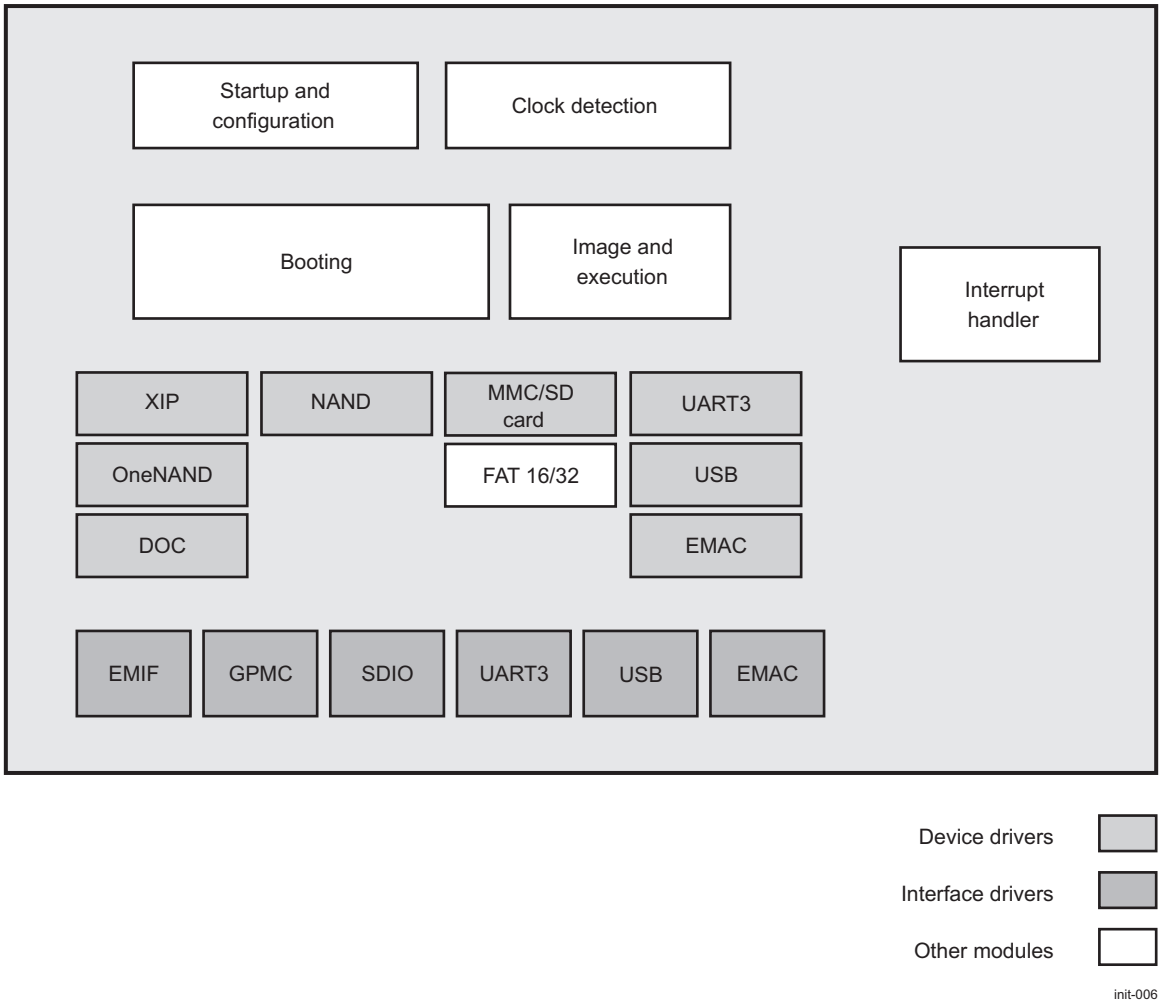
24.4.1.2 Main Features

The ROM code architecture is shown in Figure 24-5. The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control into the booting module.
- The clock detection module supports start-up.
- The booting module uses several device drivers as it must boot from one of the external devices.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used among all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

Figure 24-5 shows each module.

Figure 24-5. ROM Code Architecture

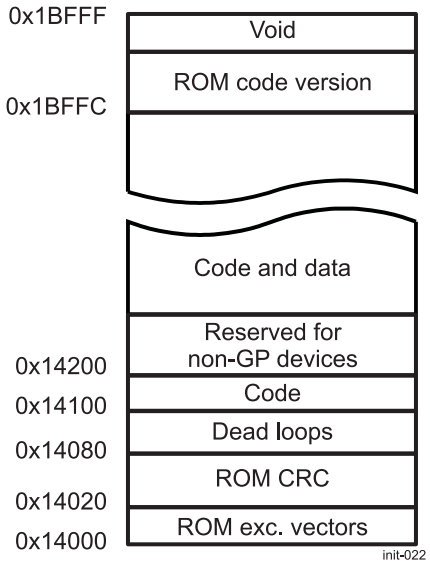


24.4.2 Memory Map

24.4.2.1 ROM Memory Map

Figure 24-6 shows the ROM memory map.

Figure 24-6. 32KB ROM Memory Map



- ROM exception vectors
  Exceptions are redirected to ROM exception vectors (see Table 24-7). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

Table 24-7. ROM Exception Vectors

Address	Exception	Content
14000h	Reset	Branch to the public ROM code startup
14004h	Undefined	PC = 4020FFC8h
14008h	Software interrupt (SWI)	PC = 4020FFCCh
1400Ch	Prefetch abort	PC = 4020FFD0h
14010h	Data abort	PC = 4020FFD4h
14014h	Unused	PC = 4020FFD8h
14018h	IRQ	PC = 4020FFDCh
1401Ch	FIQ	PC = 4020FFE0h

- ROM code cyclic redundancy check (CRC)
  The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h–1BFFFh. The 4-byte CRC code is stored at location 14020h, which is filled with FFFF FFFFh before the CRC is calculated.
- Dead loops
  Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see Table 24-8).

Table 24-8. Dead Loops

Address	Purpose
14080h	Undefined exception default handler
14084h	SWI exception default handler
14088h	Prefetch abort exception default handler
1408Ch	Data abort exception default handler
14090h	Unused exception default handler
14094h	IRQ exception default handler
14098h	FIQ exception default handler
1409Ch	Validation tests Pass
140A0h	Validation tests Fail
140A4h	Booting failed: No more devices
140A8h	Image not executed or returned
140ACh	Reserved
140B0h	Reserved
140B4h	Reserved
140B8h	Reserved
140BCh	Reserved

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

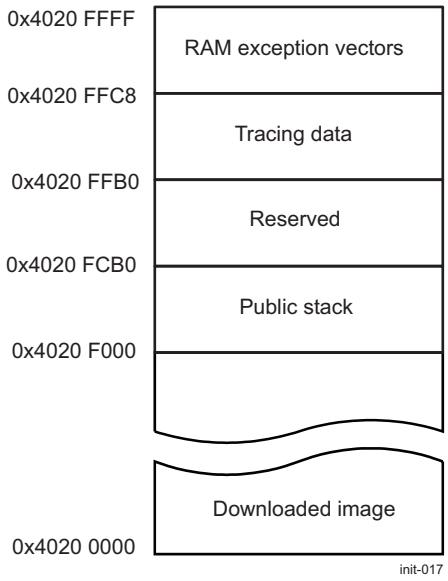
Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code
  This space is used to keep code.
- Code and data
  This space is used to keep code and other data.
- ROM code version
  The ROM code version consists of two decimal numbers: major and minor. The major number is always 14. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 14.04 is coded as a 3-bit word: 00001404h).

24.4.2.2 RAM Memory Map

Figure 24-7 shows RAM memory map. The shown partitioning of the on-chip SRAM is only used during the booting process.

Figure 24-7. 64KB RAM Memory Map of GP Devices



- Downloaded image
  This space is used by the public ROM code to store a downloaded booting image.
- Public stack
  Space reserved for stacks.
- Tracing data
  The public ROM code tracing data is described in Table 24-9. More information about ROM code tracing can be found in Section 24.4.9, *Tracing*.

Table 24-9. Tracing Data

Address	Size [bytes]	Description
0x4020FFB0	4	Current tracing vector, word 1
0x4020FFB4	4	Current tracing vector, word 2
0x4020FFB8	4	Current copy of the PRM_RSTST register (reset reasons)
0x4020FFBC	4	Cold reset run tracing vector, word 1
0x4020FFC0	4	Cold reset run tracing vector, word 2
0x4020FFC4	4	Reserved

- RAM exception vectors

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. Table 24-10 shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load into the PC the value located in the next seven addresses. Theses instructions are executed when an exception occurs, since they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to other handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

Table 24-10. RAM Exception Vectors

Address	Exception	Content
0x4020FFC8	Undefined	PC = [0x4020FFE4]
0x4020FFCC	SWI	PC = [0x4020FFE8]
0x4020FFD0	Pre-fetch abort	PC = [0x4020FFEC]
0x4020FFD4	Data abort	PC = [0x4020FFF0]

Table 24-10. RAM Exception Vectors (continued)

Address	Exception	Content
0x4020FFD8	Unused	PC = [0x4020FFF4]
0x4020FFDC	IRQ	PC = [0x4020FFF8]
0x4020FFE0	FIQ	PC = [0x4020FFFC]
0x4020FFE4	Undefined	0x14080
0x4020FFE8	SWI	0x14084
0x4020FFEC	Pre-fetch abort	0x14088
0x4020FFF0	Data abort	0x1408C
0x4020FFF4	Unused	0x14090
0x4020FFF8	IRQ	0x14094
0x4020FFFC	FIQ	0x14098

24.4.3 Overall Booting Sequence

Figure 24-8 shows the ROM code flowchart.

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code follows these steps:

Step 1. The ROM code performs basic configurations and initializations.

Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.

Step 3. A booting device list is created (see Section 24.4.4.3, *Booting Device List Setup*). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins.

Step 4. Once the booting device list is set, the booting procedure examines the devices on the list serially and either executes memory booting or peripheral booting, depending on current booting device type:

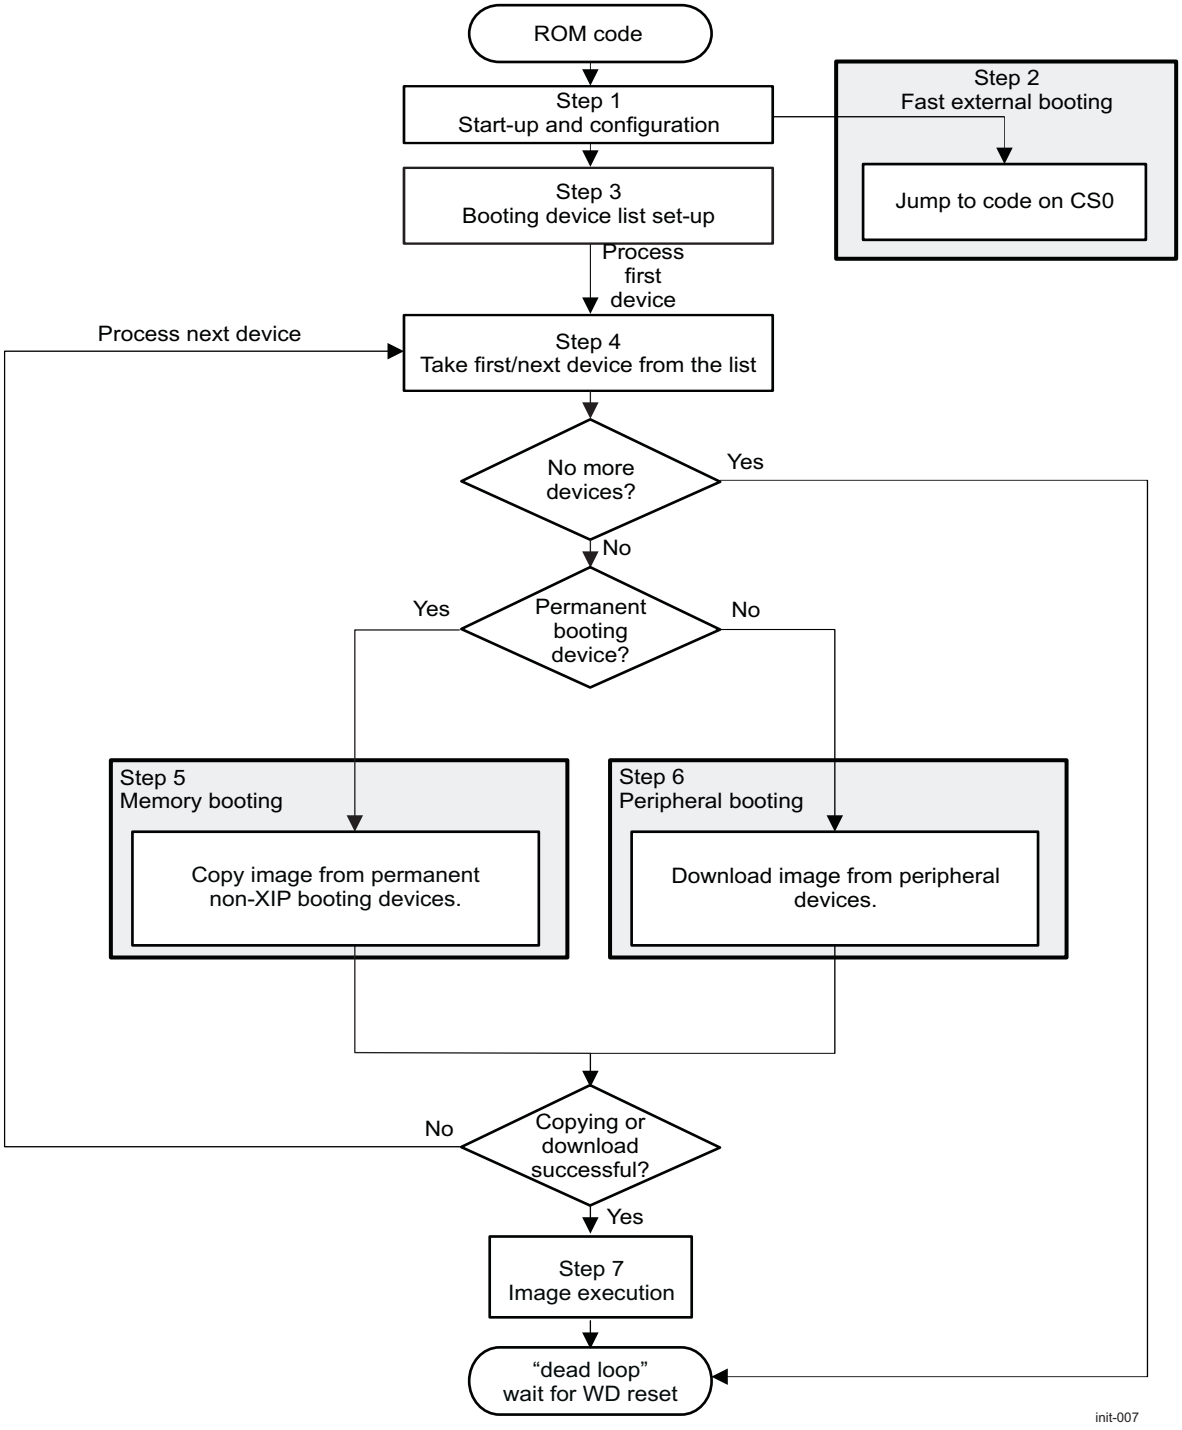
- Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip™, OneNAND, or MMC/SD cards.
- The peripheral booting is executed when device is temporary: USB, UART or EMAC.

Step 5. The memory booting procedure reads data from memory type devices. The memory booting is described in detail in Section 24.4.7, *Memory Booting*.

Step 6. The peripheral booting procedure downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the processor sends an ASIC ID structure to inform the host about peripheral booting start. Next, the host responds by sending a booting message that can have one of the following meanings: skip peripheral booting, continue peripheral booting, or change the booting device. If the message is to continue, the host sends the whole image preceded by its size. The peripheral booting is described in detail in Section 24.4.5, *Peripheral Booting*.

Step 7. The image is simply started.

Figure 24-8. Overall Booting Sequence



24.4.4 Start-Up and Configuration

24.4.4.1 Start-Up

The ROM code starts at address 0x0001 4000.

24.4.4.2 Clocking Configuration

The ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks.
- MPU DPLL, set to provide 48 MHz for the MPU.
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output.

The multipliers and dividers of the DPLLs are set to values which depend on the input clock.

Table 24-11 summarizes the ROM code default settings for key clocks.

Table 24-11. ROM Code Default Clock Settings

Clock	Frequency [MHz]	Source
CORE.CLK	192	CORE DPLL output
L3x2.CLK	192	CORE.CLK
L3.ICLK	96	CORE.CLK/2
L4.ICLK	48	L3.ICLK/2
RM clock	24	L4.ICLK/2
MPU	48	CORE.CLK/4 (MPU DPLL in bypass)

The DPLLs and other settings are configured by default after each type of reset to give the ROM code the same working conditions.

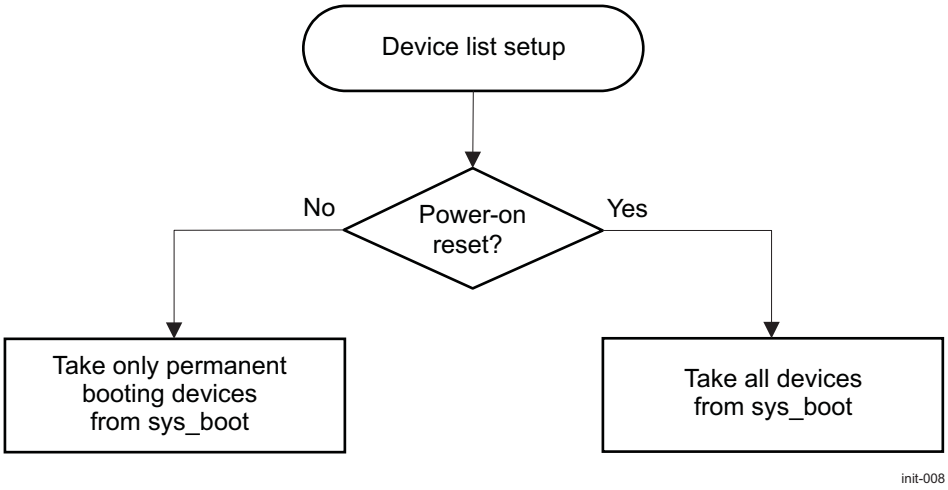
24.4.4.3 Booting Device List Set-Up

The ROM code creates the device list based on the values of sys_boot[5:0]. The sys_boot[5:0] pins are used to index the device table from which the list of devices is extracted.

Figure 24-9 shows how the ROM code sets up the device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is non power-on and devices are taken from the sys_boot pins.

Figure 24-9. Device List Set-Up



24.4.5 Peripheral Booting

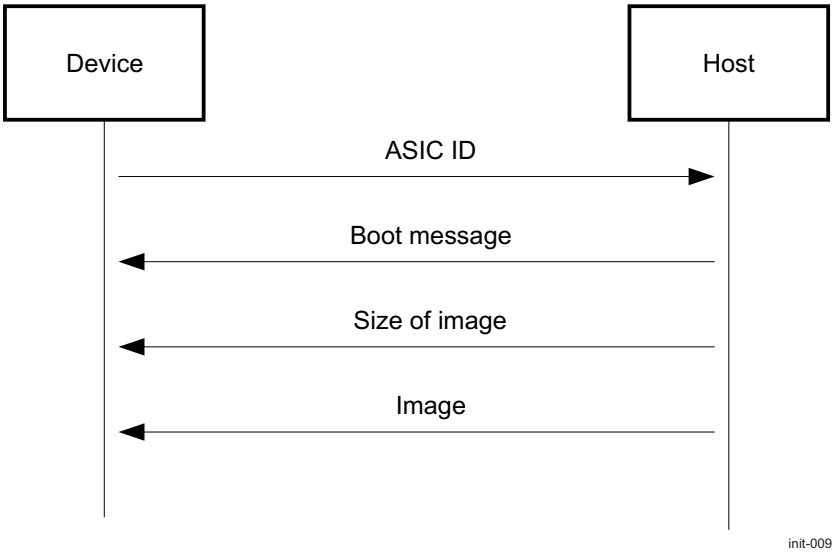
24.4.5.1 Overview

The ROM code can boot from different peripherals:

- HS/FS USB: High/Full-speed USB Interface.
- UART 3: Baud rate 115.2K bps, 8 bits, even parity, 1 stop-bit.
- Ethernet : EMAC RMII Interface.

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is mostly used for programming flash memories connected to the processor. The protocol used is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in Figure 24-10.

Figure 24-10. Common Peripheral Booting Protocol



The ROM code first initializes the interface and sends a message called ASIC ID to a host. The content of this message is summarized in Table 24-12. The host uses this message to send only appropriate data to the processor according to the identification codes sent.

The ROM code waits 300 ms for an answer from the host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

Table 24-12. ASIC ID Structure

ASIC ID Item	Size [Bytes]	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved for non-GP devices	4	Reserved
ID subblock	23	Identification data
Reserved for non-GP devices	23	Reserved
Checksum subblock	11	CRC (4 bytes)

The host can send different messages as described in Table 24-13. If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (as a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

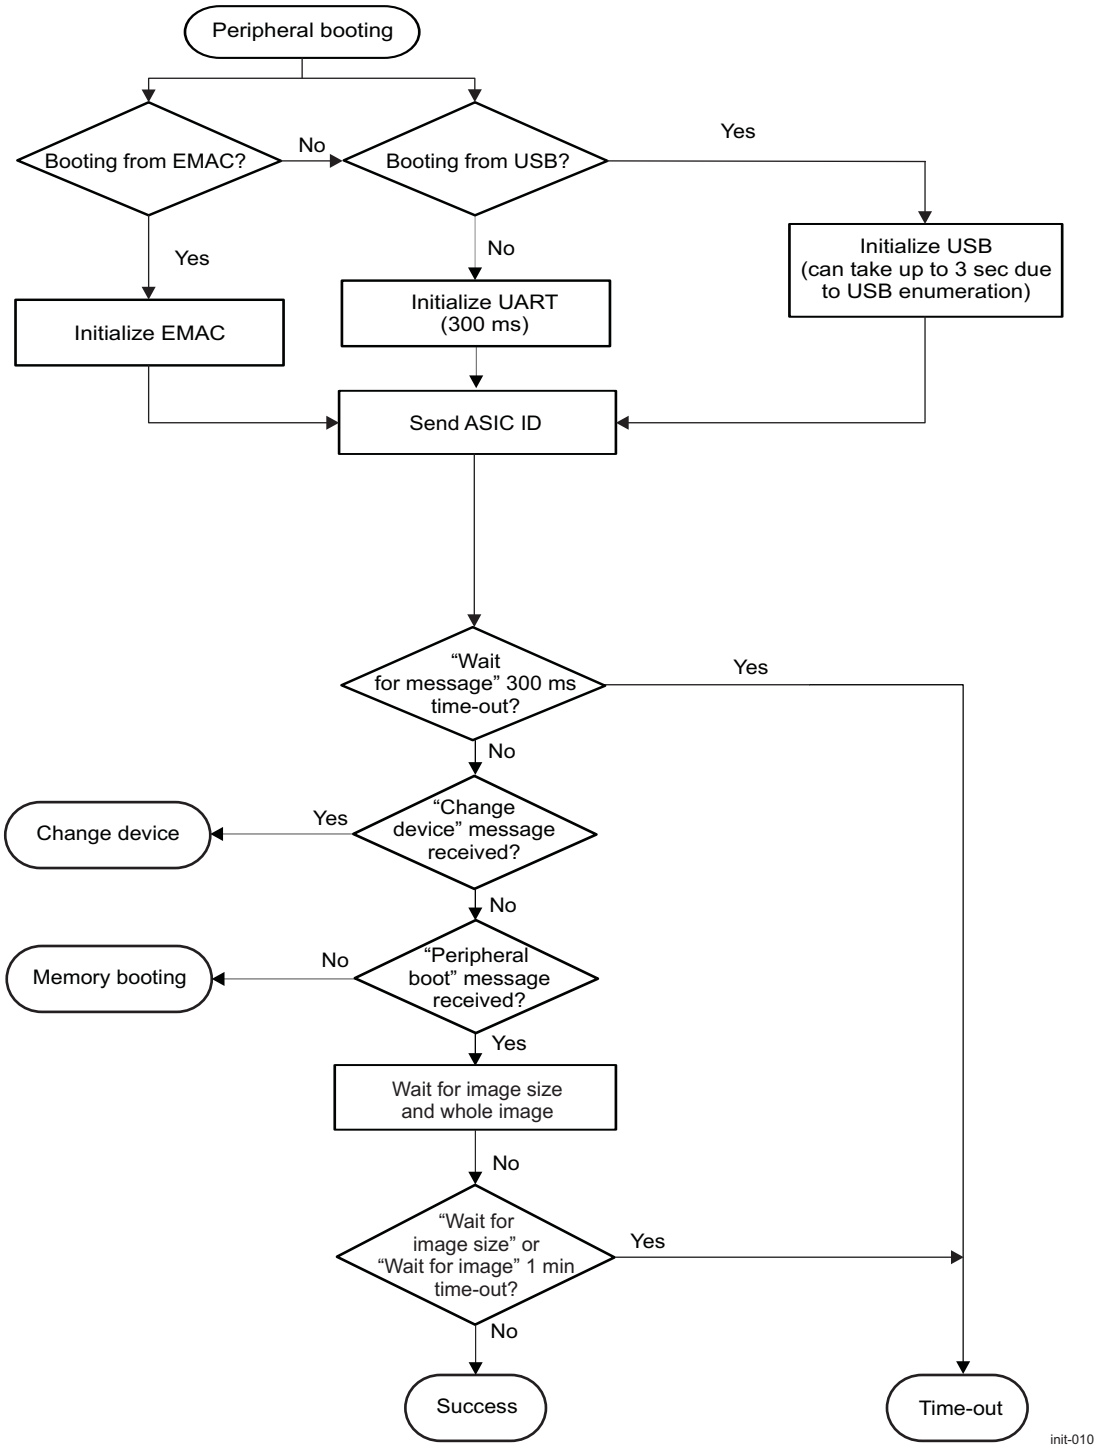
The ROM code waits up to one minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

Table 24-13. Boot Messages

Message Name	Value	Description
Peripheral boot	0xF003 0002	Continue peripheral booting.
Change device	0xF003XX06	Skip current peripheral booting and continue booting from device type indicated by XX: 0x00 - Void, no device 0x01 - XIP memory 0x02 - NAND 0x03 - OneNAND 0x04 - Reserved 0x05 - MMC/SD2 0x06 - MMC/SD1 0x07 - XIP memory with wait monitoring 0x08..0x0F - Reserved 0x10 - UART 0x11 - HS USB 0x12 - EMAC 0x13 - EMAC Others - Reserved
Next device	0xFFFF FFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

The peripheral booting procedure is summarized in Figure 24-11.

Figure 24-11. Peripheral Booting Procedure



24.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3.
- Communication parameters set to 115.2k baud, 8 bits, even parity, 1 stop-bit.
- Two-pin interface: RX/TX with SW flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART time-out is 300 ms.

24.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface.
- The enumeration time-out is 3 seconds.

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

24.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor.

A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor. Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required. Table 24-14 describes the device descriptors.

Table 24-14. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID
idProduct	0xD009	Product ID
bcdDevice	0x0000	Device release number
iManufacturer	See values in Section 24.4.5.3.2.	Index of string descriptor describing manufacturer
iProduct	See values in Section 24.4.5.3.2.	Index of string descriptor describing product

Table 24-14. Device Descriptor (continued)

Field	Value	Description
iSerialNumber	See values in Section 24.4.5.3.2.	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). Table 24-15 describes a device-qualifier descriptor.

Table 24-15. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See Table 24-16 for details.

Table 24-16. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wake-up
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See Table 24-17 for details.

Table 24-17. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request

Table 24-17. Other Speed Configuration Descriptor (continued)

Field	Value	Description
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wake-up
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

This descriptor describes a specific interface in a configuration. See Table 24-18 for details.

Table 24-18. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

  Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See Table 24-19 and Table 24-20 for details.

Table 24-19. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See (1).	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 24-20. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See (1).	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

  String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

  See the tables describing string descriptors:

  – The language ID string descriptor (Table 24-21)
  – The manufacturer ID string descriptor (Table 24-22)
  – The product ID string descriptor (Table 24-23)
  – The configuration string descriptor (Table 24-24)
  – The interface string descriptor (Table 24-25)

Table 24-21. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 24-22. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x06	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	TI	Manufacturer string

Table 24-23. Product ID String Descriptor

Field	Value	Description
bLength	0x0c	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	processor or specific vendor string	Product string

Table 24-24. Configuration String Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbc	Configuration string

Table 24-25. Interface String Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

24.4.5.3.2 USB Customized Descriptors

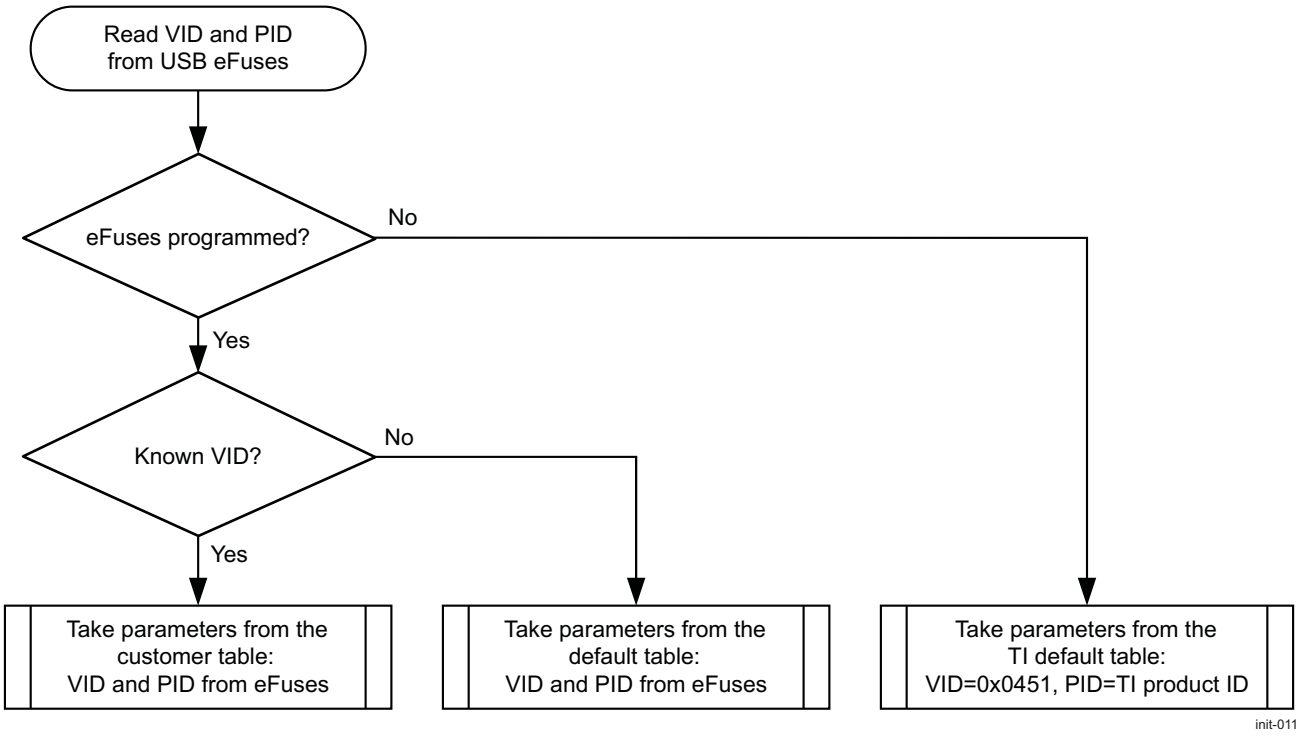
There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. Table 24-26 lists the parameters that depend on VID value.

Table 24-26. Customized Descriptor Parameters

Parameter	Size [Bytes]	Default Values	TI Default Values
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	TI
Product	String	processor or specific vendor string	processor or specific vendor string
Serial number	String	N/A	N/A

Figure 24-12 describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 24-12. Customer USB Descriptor Selection



24.4.5.3.3 USB Driver Functionality

- Transactions supported
  The following transactions are supported:
  - Control transactions: Used for standard device requests
  - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.

  The processor's USB device first attaches to the host as an FS device. In the reset mechanism, the

USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.

- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. Table 24-27 lists the standard device requests supported by the driver.

Table 24-27. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	No. Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	No. Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

24.4.5.4 EMAC

The ROM code supports boot over the network. The image obtained over the network is first shadowed into SRAM and then it is executed. The following requirements are to be met for using Ethernet boot.

- The EMAC is configured for full duplex, 100MBPS mode.
- Once the switch has been configured, the ROM code broadcasts the ASIC ID on the LAN using a UDP datagram.
- The ASIC ID packet is sent only once. The server then responds with hex value 0xF003 0002 (Boot Message). The server then sends the size of the boot image.
- The server then sends the boot image binary.
- The MAC address is obtained from below control module registers:
  - Ethernet MAC Address (LSB-24bits) --> 0x4800 2380 (Refer to system control module for more details.)
  - Ethernet MAC Address (MSB-24bits) --> 0x4800 2384 (Refer to system control module for more details.)
- The download address & max size of images used for EMAC boot are exactly the same as USB/UART boot.

24.4.5.4.1 Boot Host Servers

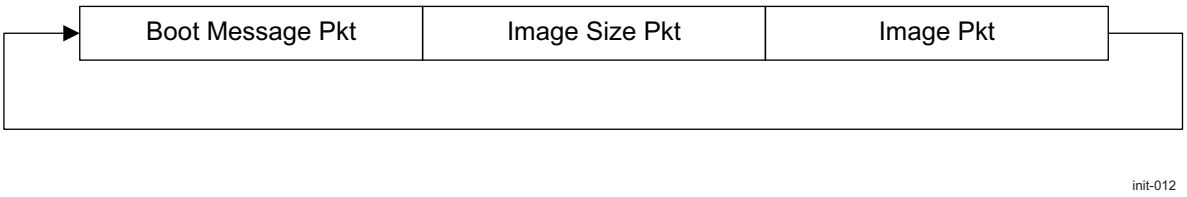
Host servers have two schemes that send the boot image over the LAN in response to broadcasted boot announce frame (which has ASIC ID).

- Dumb Server Response

- Smart Server Response

Dumb servers do not wait for ASIC ID to be received. Instead, dumb servers have a list of EMAC addresses that they use to transmit the boot message, image size, and the image packets. The dumb server sends the image binary packets continuously to every EMAC address.

Figure 24-13. Dumb Servers Boot Response



Smart servers can be present in each subnet or LAN, to respond to a boot announce frame which consists ASIC ID. As a back up, they can also use a statically configured list of EMAC addresses.

Once the smart boot server receives a boot announce frame, it starts transmitting the boot message, image size, and the image binary in subsequent packets to the MAC address that was sent in the boot announce frame. Each time the device receives a packet, it will send the sequence number of the successfully received packet to the smart boot server as acknowledgement.

When the boot server receives the ACK packet from the device, it will send the next packet. This sequence continues untill the entire image is transmitted.

Table 24-28. Boot Announce Frame

Field	Value
Destination MAC address	FF:FF:FF:FF:FF:FF
Source MAC address	From e-fuse
Protocol	IP (0x0800)
Header length and version	IPV4
Type of service	0
Total length of data and header	Calculated and stored
Identification	0x1 (unused)
Fragment offset field and flag	0
Time to live	0xFF (max)
Protocol	UDP (17)
Checksum	Calculated and stored
Source IP address	0:0:0:0
Destination IP address	255.255.255.255
UDP source port	55556
UDP destination port	55555
Length of UDP header and data	Calculated and stored
Checksum	0 (Not used)
Start of Data marker	Always 0xFF
Sequence number (8bit)	Incrementing, starting from 0
Data – ASIC ID	

24.4.5.4.2 EMAC Boot UseCase

If the device needs to boot a 768 byte image, the boot server will split the image into three 256 byte packages and continue looping while the packages are being transmitted. The boot server will keep increasing the sequence number in each package. In addition to the three 256 byte packets, the boot server will also send one packet with the boot message and one packet with the image size.

The messages will be sent in the following sequence:

1. On Power ON Reset the device transmits the Boot Announce frame with ASIC ID.
2. The boot server receives the boot announce frame, gets the MAC address of the device, and transmits the boot message to the device with the sequence number in the frame set to 0.
3. The boot server then transmits the size of the image binary to the device with the sequence number in the frame set to 1.
4. The boot server then splits the boot image binary into 256 byte chunks and transmits the chuncks to the device one by one, incrementing the sequence number for each frame.
5. The boot server repeats steps 2, 3, and 4 in a loop untill it gets an ACK packet from the device.
6. The device receives the frames transmitted by the boot server sequentially. If it receives a frame out of sequence, the device will discard it and wait untill it receives a frame with the correct sequence number. Once a frame is received, the device sends an ACK packet back to the boot server containing the sequence number of the frame it just received.
7. When the boot server receives the ACK sequence number, it stops sending that particular packet in the next cycle of packet transmission but continues to send the packets with next sequence number.
8. If the boot server is transmitting packets in a loop with the following sequence numbers 0-1-2-3-4-0-1-2-3-4-0-1-2-3-4…
9. The device receives packet sequence 0 and sends an ACK to the boot server.
10. The boot server then changes its transmit sequence to 1-2-3-4-1-2-3-4-1-2-3-4…
11. If the next packet the device receives has sequence number 2 (and the packet with sequence number 1 got lost in the network), the device will ignore packets 2, 3, and 4 and wait untill it sees packet 1 on the network again.
12. When the device finally receives packet 1, it will send the boot server an ACK for packet 1.
13. The boot server will change its transmit sequence to 2-3-4-2-3-4-2-3-4…

This process will continue untill the device ACKs packet 4 and then the boot server can stop transmitting.

Figure 24-14. EMAC Boot Packet Sequences

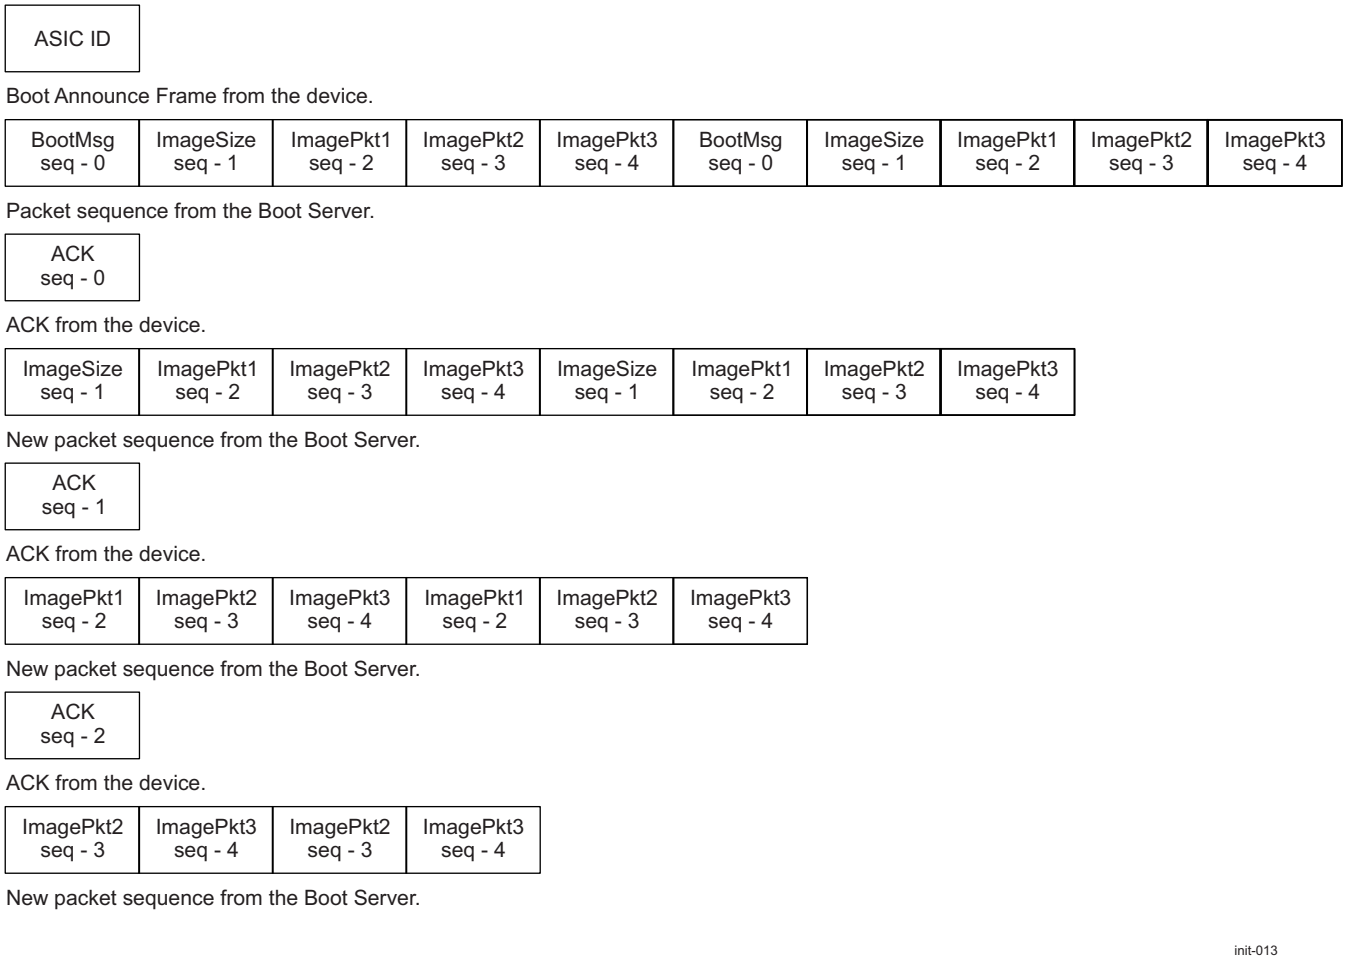


Table 24-29. Frame transmitted by the Boot Server

Field	Value
Destination MAC address	From the boot announce frame source MAC address
Source MAC address	Boot server's MAC address
Protocol	IP (0x0800)
Header length and version	IPV4
Type of service	0
Total length of data and header	Calculated and stored
Identification	0x1 (unused)
Fragment offset field and flag	0
Time to live	0xFF (max)
Protocol	UDP (17)
Checksum	Calculated and stored
Source IP address	Boot server's IP address
Destination IP address	255.255.255.255
UDP source port	55556
UDP destination port	55555
Length of UDP header and data	Calculated and stored
Checksum	0 (Not used)
Start of Data marker	Always 0xFF

Table 24-29. Frame transmitted by the Boot Server (continued)

Field	Value
Sequence number (8bit)	Incrementing, starting from 0
Data[1]	

(1)

(a) When the sequence number is 0, Data is the BOOT MESSAGE that ROM code frame work expects.

(b) When the sequence number is 1, Data is the size of the image binary.

(c) When the sequence number is greater than or equal to 2, Data is the image binary, split into 256byte chunks.

Table 24-30. ACK frame sent by the Device to the Boot Server

Field	Value
Destination MAC address	From the boot announce frame source MAC address
Source MAC address	From E-Fuse
Protocol	IP (0x0800)
Header length and version	IPV4
Type of service	0
Total length of data and header	Calculated and stored
Identification	0x1 (unused)
Fragment offset field and flag	0
Time to live	0xFF (max)
Protocol	UDP (17)
Checksum	Calculated and stored
Source IP address	0.0.0.0
Destination IP address	From the boot server frame source ip address
UDP source port	55556
UDP destination port	55555
Length of UDP header and data	Calculated and stored
Checksum	0 (Not used)
Start of Data marker	Always 0xFF
Sequence number (8bit)	From the last boot server frame
Pad – 24 bytes	To make the Ethernet packet greater than 64 bytes

24.4.6 Fast External Booting

24.4.6.1 Overview

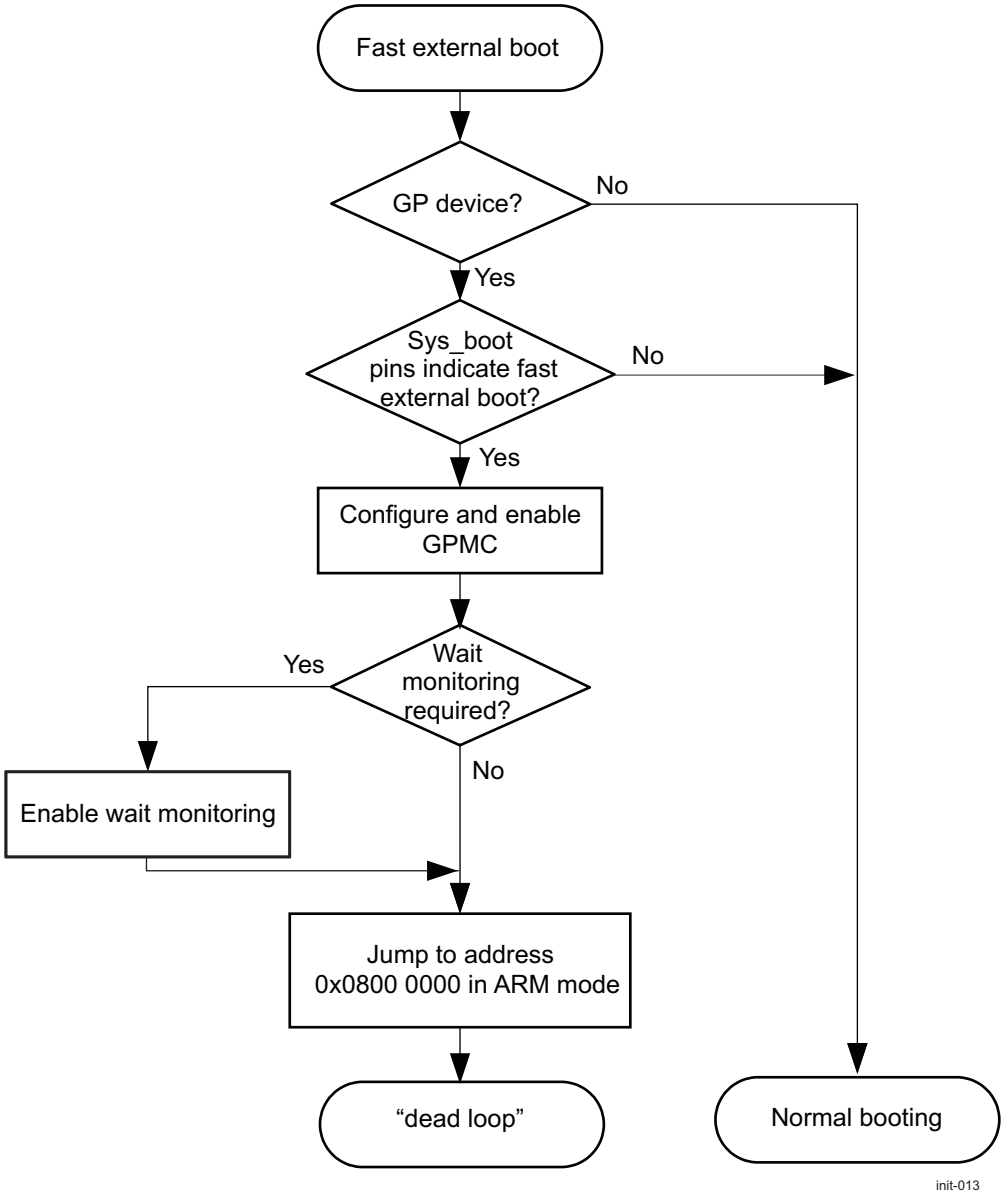
The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to CS0. Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

24.4.6.2 External Booting

Figure 24-15 shows the fast external boot procedure. The code is at the beginning of the public part and is written in assembly. The code does not use any RAM.

Figure 24-15. Fast External Boot



24.4.7 Memory Booting

24.4.7.1 Overview

The memory booting process takes care of starting an external code in memory type devices. These devices are called permanent booting devices because the processor always uses them for booting. The supported permanent booting devices are:

- NOR all devices up to 1G bit (128M bytes)
- NAND devices from 64M bits
- OneNAND devices from 512M bits
- SD/MMC flash cards with active primary partition of type FAT12/16/32
- DiskOnChip™ H3 devices
- SPI EEPROM

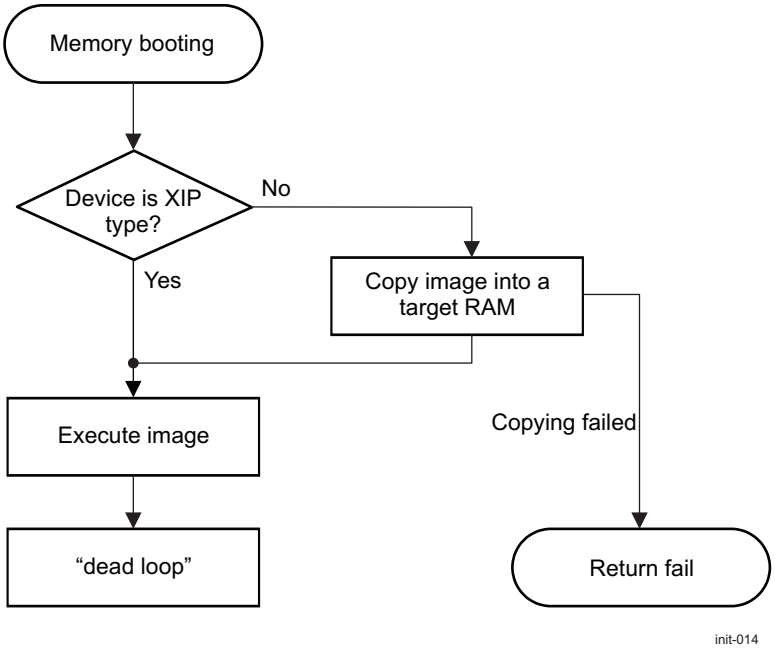
There are two main groups of permanent booting devices distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable device (non-XIP) into RAM, where the code can be executed. Directly addressable devices are called eXecute-in-place (XIP) devices.

The memory booting flowchart shown in Figure 24-16 is an overview of common procedure for all types of devices. The first step is to shadow the image, if the device is not XIP. The last step is image authentication and execution.

Unsuccessful authentication or return from image results in dead loop.

If shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

Figure 24-16. Memory Booting



24.4.7.2 Non-XIP Memory

Figure 24-17 details the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

Figure 24-17. Detailed Memory Booting for Non-XIP Devices

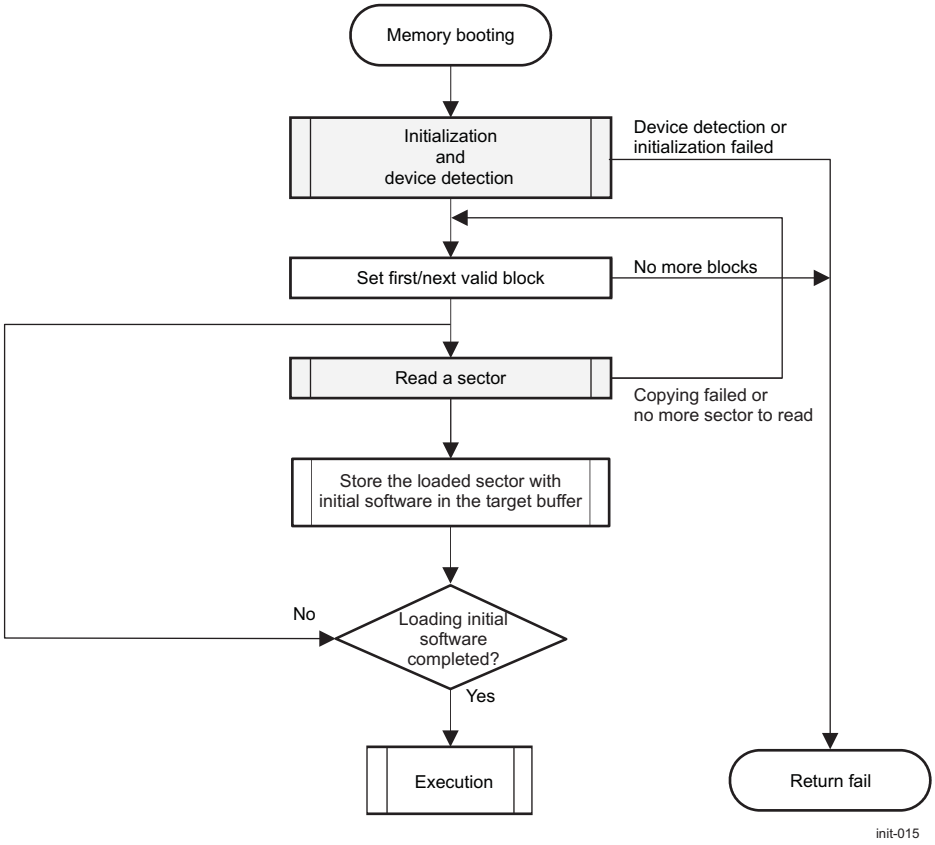


Table 24-31 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NANDs and OneNAND are organized with blocks, which are erasable units. DOC memory has only one block reserved for booting purposes, which overlaps the XIP part. MMC/SD card booting consists of reading a file. Since there is only one file read, it can be considered as one block trial.

Table 24-31. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block[1]
OneNAND	First 4	8
DOC[2]	1	4
MMC/SD	One file	1

(1) Depends on NAND type.

(2) DOC memory image must contain first sector filled with 0xFF or 0x00 because XIP booting always precedes DOC booting and the same data is used for XIP area. Therefore, a void sector at the beginning makes XIP booting failed and moves to DOC booting.

The following sections detail each supported device type.

For more details about the GPMC module, see the *Memory Subsystem* chapter.

24.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices. Typical XIP devices are NOR flash memories. Supported XIP devices have the following characteristics:

- The GPMC is used as the communication interface.
- Memories up to 1G bit (128M bytes) can be connected.

- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The device is connected to cs0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the sys_boot option, the GPMC can be configured to use the wait signal connected or not to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait monitoring is to be used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip™.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging.

The booting from an XIP device can be described in the following points:

1. Configure the GPMC for XIP device access.
2. Set the image location to 0x0800 0000.
3. Verify that a bootable image is present at the image location.
4. Execute the image if it is found.
5. If the image is not found, return from XIP booting to the main booting loop.

24.4.7.3.1 GPMC Initialization

Table 24-32 describes the timing settings of GPMC set for XIP and other address-data accessible devices, like DiskOnChip or OneNAND. Table 24-32 is included for debug information.

Table 24-32. XIP Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle time	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x03
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

24.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.

- Device from 64 Mb (8MB)
- x8 and x16 bus width
- Small page size (512 bytes + 16 bytes) and large page size (2048 bytes + 64 bytes)
- Chip enable (CE) don't care devices only
- Single level cell (SLC)
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging.

24.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection/verification.

- GPMC initialization

The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. Table 24-33 shows the GPMC configuration used during NAND boot. Table 24-33 is included for debug information.

Table 24-33. NAND Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (i = 0–7)	Reset Value
Write cycle time	20	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14.	0x11
Read cycle time	20	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14.	0x11
CS low time	0	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0.	0x1
OE low time	5	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x3
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	14	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE.	0xF

- Device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported device, the device parameters are extracted from an internal ROM code table. Table 24-34 lists the supported devices.

Table 24-34. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in KB
64Mb	E6h	8	512
128Mb	33h	8	512
128Mb	73h	8	512

512Mb	56h	16	512
512Mb	A2h	8	2048
512Mb	F2h	8	2048
512Mb	B2h	16	2048
512Mb	C2h	16	2048
1Gb	39h	8	512
1Gb	79h	8	512
1Gb	49h	16	512
1Gb	59h	16	512
1Gb	78h	8	512
1Gb	72h	16	512
1Gb	74h	16	512
1Gb	A1h	8	2048
1Gb	F1h	8	2048
1Gb	B1h	16	2048
1Gb	C1h	16	2048
2Gb	AAh	8	2048
2Gb	DAh	8	2048
2Gb	BAh	16	2048
2Gb	CAh	16	2048
2Gb	71h	8	512
2Gb	51h	16	512
2Gb	31h	8	512
2Gb	41h	16	512
4Gb	ACh	8	2048
4Gb	DCh	8	2048
4Gb	BCh	16	2048
4Gb	CCh	16	2048
8Gb	A3h	8	2048
8Gb	D3h	8	2048
8Gb	B3h	16	2048
8Gb	C3h	16	2048
16Gb	A5h	8	2048
16Gb	D5h	8	2048
16Gb	B5h	16	2048
16Gb	C5h	16	2048

Table 24-34. Supported NAND Devices (continued)

Capacity	Device ID	Bus Width	Page Size in KB
32Gb	A7h	8	2048
32Gb	B7h	16	2048
64Gb	AEh	8	2048
64Gb	BEh	16	2048

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512KB and to 128KB when the page size is 2048KB. Table 24-35 shows the fourth ID data byte encoding used in the ROM code.

Table 24-35. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page Size	1KB							0	0
	2KB							0	1
	4KB							1	0
	8KB							1	1
Block Size	64KB			0	0				
	128KB			0	1				
	256KB			1	0				
	512KB			1	1				

The detection procedure is described in Figure 24-18. If the device ID is not recognized, the ROM code tries to read ID2 from the device; the sequence is described in Figure 24-19. The description of the ID2 data content is summarized in Table 24-36. If the ROM code fails to identify device ID or ID2, it returns with FAIL. When the device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

Figure 24-18. NAND Device Detection

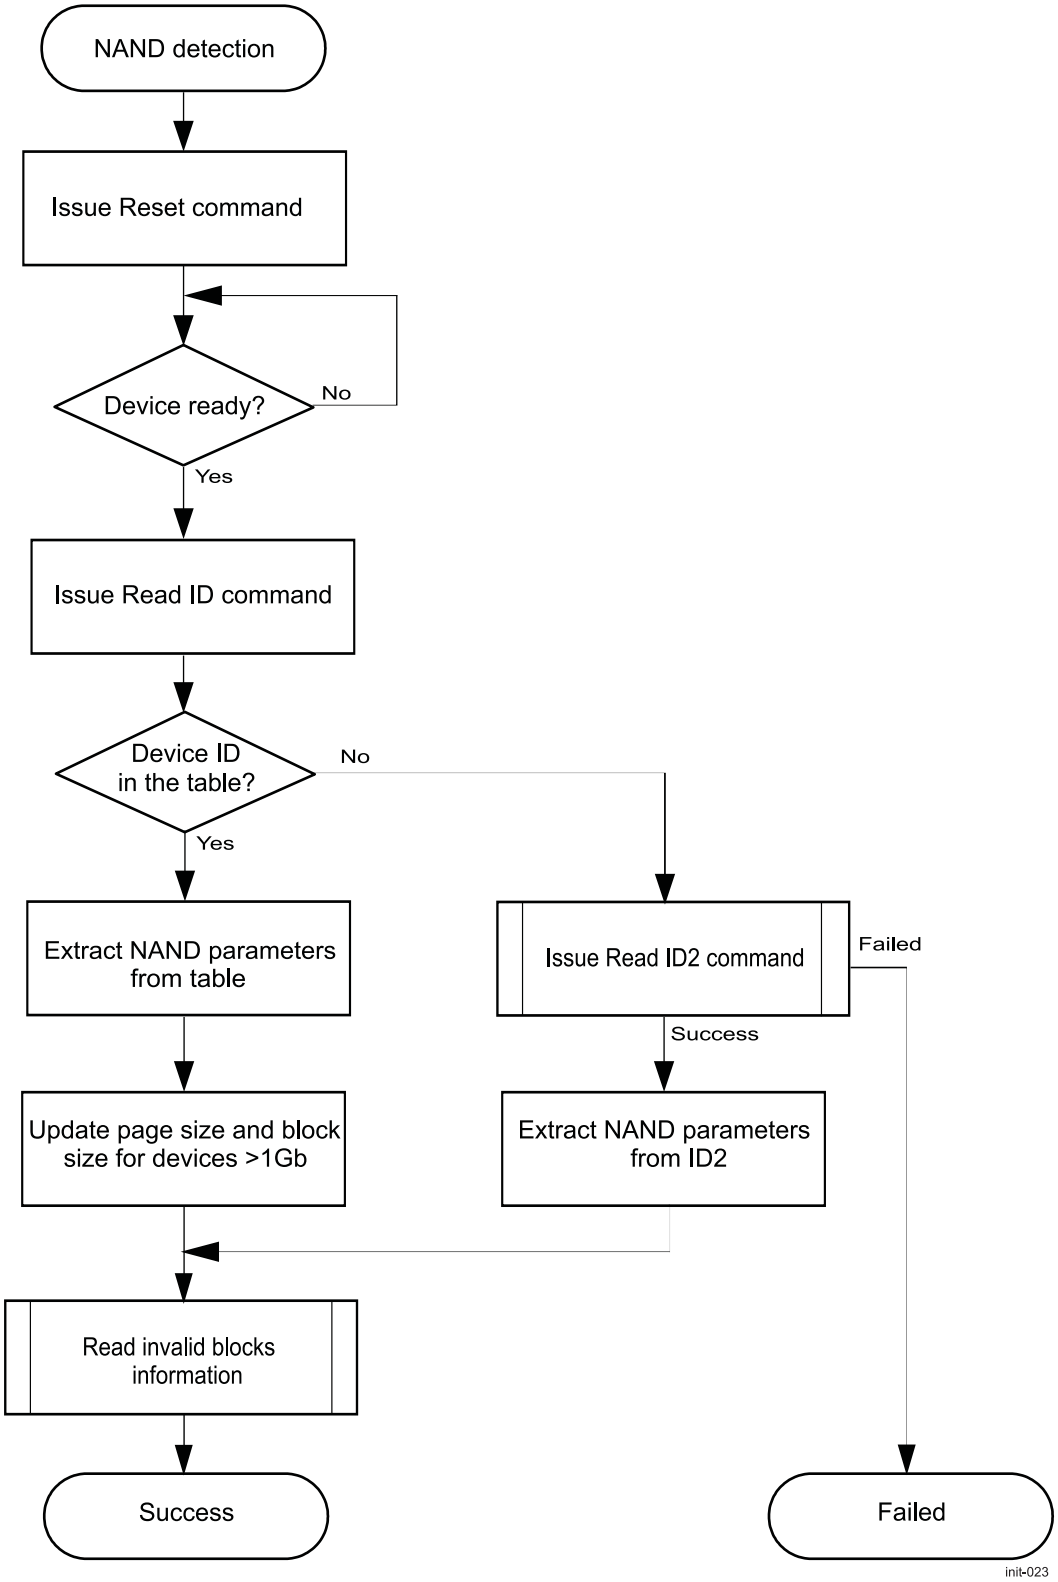

Figure 24-19. NAND ID2 Detection

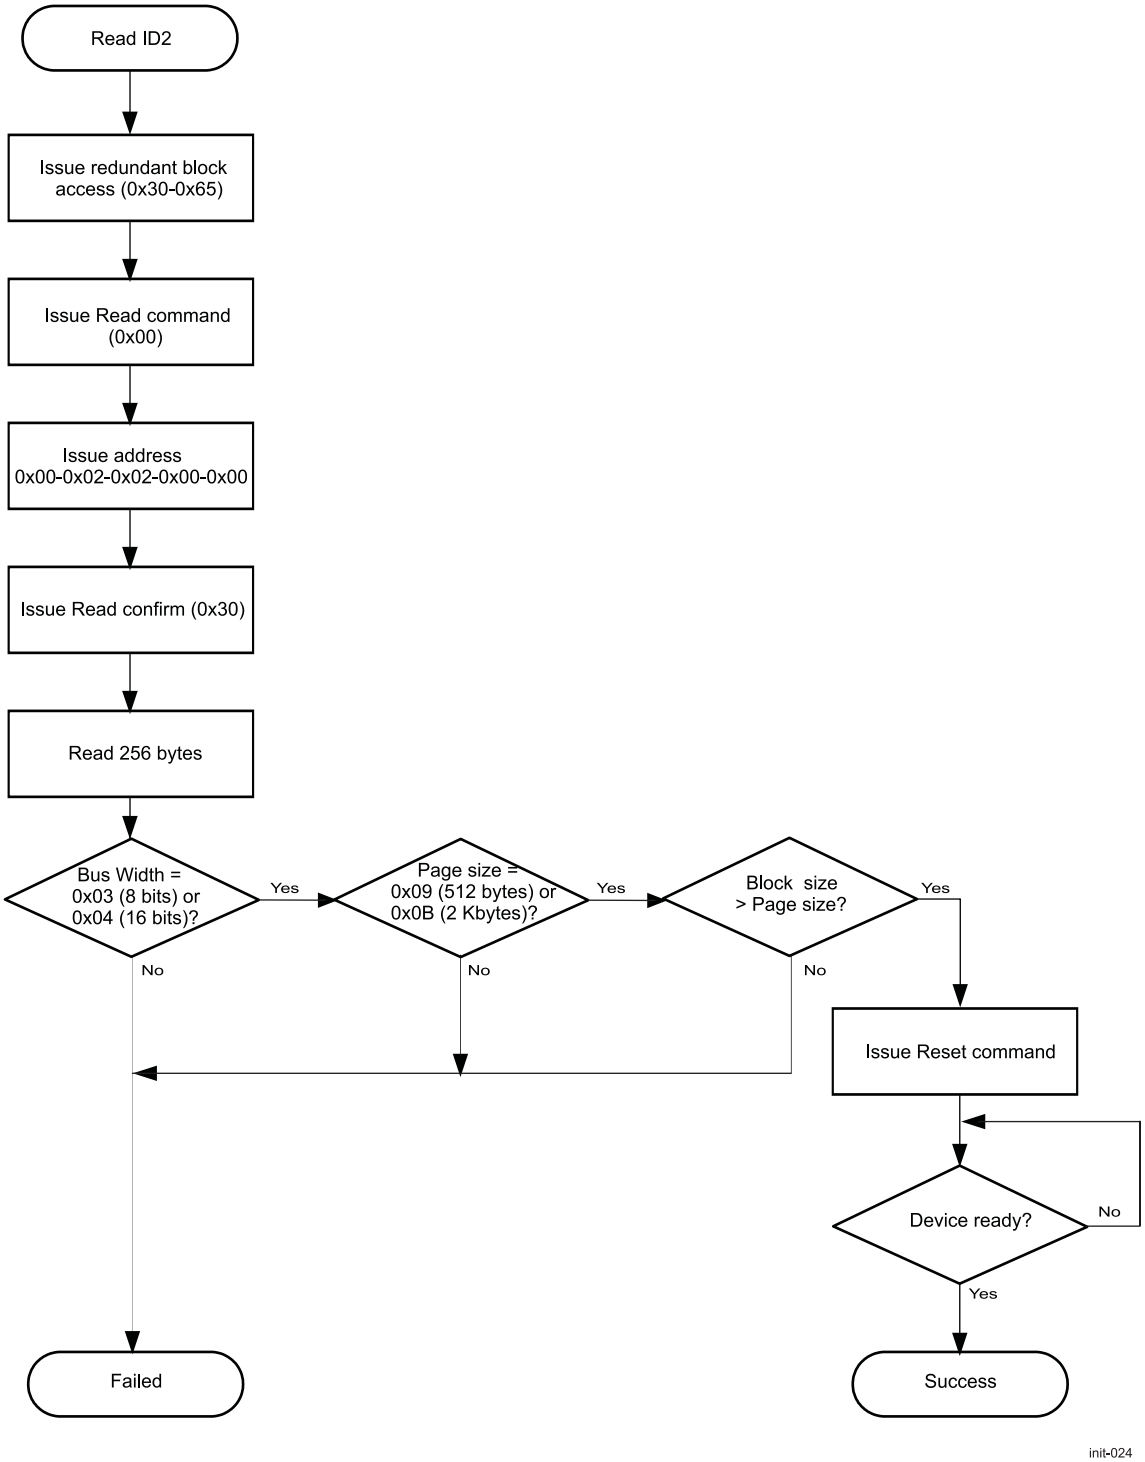

Table 24-36. ID2 Byte Description

Byte Number	Name	Value	Unit	Notes
1	Page size	2X	Bytes	00H = 1B 09H = 512B 0BH = 2KB
2	Block size	2X	Bytes	00H = 1B 0EH = 16KB 11H = 128KB
3	Block count	2X	Pcs	00H = 1 pc 0BH = 2048 pcs 0CH = 4096 pcs
4	Spare size	2X	Bytes	00H = 1B 04H = 16B 06H = 64B
5	Column address	X	Pcs	Higher nibble 1H = 1 column address sequence 2H = 2 column address sequence
	Row address	X	Pcs	Lower nibble 1H = 1 row address sequence 2H = 2 row address sequence
6	ECC type	X	Bit ECC	Higher nibble 0H = No ECC needed 1H = 1-bit ECC 4H = 4-bit ECC
	Bus width	2x	Width	Lower nibble 3H = 8-bit NAND interface 4H = 16-bit NAND interface
7	Number of CEs	X	Pcs	Higher nibble 1H = 1x CE# 2H = 2x CE#
	Cell type	X	Bit/cell	Lower nibble 1H = 1 bit per cell 2H = 2 bits per cell
8	Boot block	X	kB	0H = No boot block 1H = 1KB boot block 2H = 2KB boot block
9	Multiple page prg	X	Pcs	Higher nibble 1H = 1 plane 4H = 4 planes For future use
10	Partial prg count	X	Per page	1H = No partial prg allowed 2H = 2 per page
11	Read time maximum			
12	Prg time maximum

252nd 255th	Identification number	X		B2184D7Bh
256th	Register/spec version	XvX		Higher nibble: Major digit Lower nibble: Decimal digit Registers according to spec: 2v0: 20h

- Bad block detection/verification

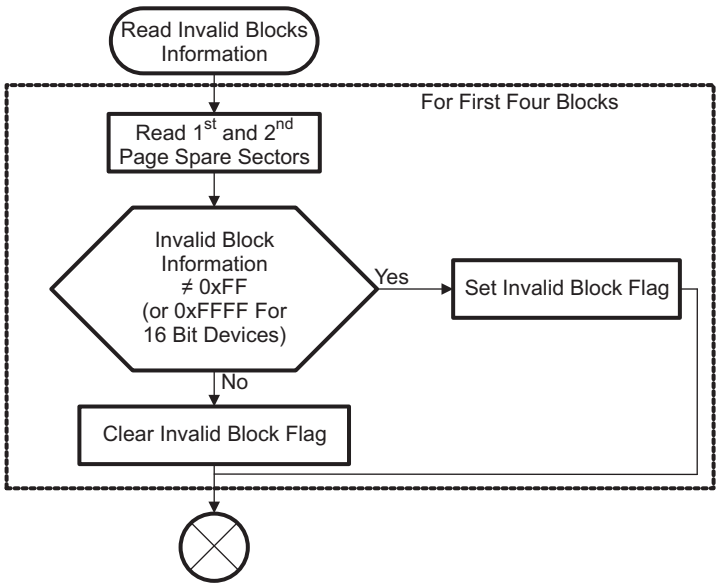
Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Blocks validity status is coded in the spare areas of the first two pages of a block. Table 24-37 describes validity status coding for all four NAND families.

Table 24-37. Bad Block Marks Locations in NAND Spare Areas

	Small Page NAND	Large Page NAND
8 bit Device		
Block invalid when any byte not equal FFh	6th byte in 1st page	1st byte in 1st page
	6th byte in 2nd page	1st byte in 2nd page
16 bit Device		
Block invalid when any work not equal FFFFh	1st word in 1st page	
	6th work in 1st page	1st word in 1st page
	1st word in 2nd page	1st work in 2nd page
	6th word in 2nd page	

Figure 24-20 depicts the invalid block detection routine. The routine consist in reading spare areas and checking data according to the conditions. The flags are used internally to convey information about each block validity.

Figure 24-20. NAND Invalid Block Detection



24.4.7.4.2 Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration. To correct these errors, the ROM code uses ECC, based on Hamming codes for SLC NAND. The computed ECC is compared to ECC stored in the spare area of the corresponding page. If there are uncorrectable errors, the ROM code returns with FAIL.

24.4.7.5 OneNAND

ROM code support for OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode

- GPMC reset default timings are used.
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.

The OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging.

24.4.7.5.1 Initialization and OneNAND Detection

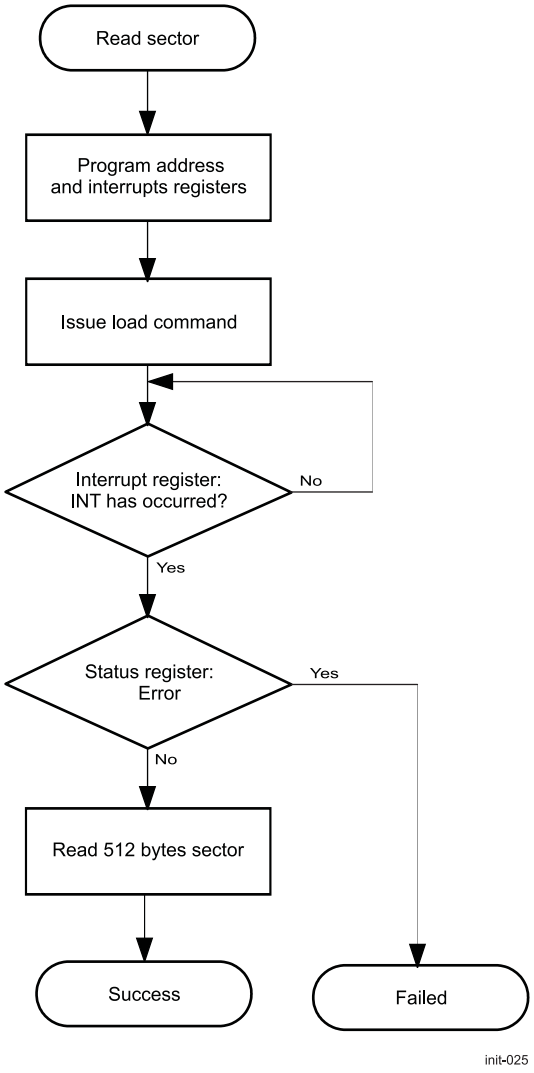
The initialization routine for OneNAND consists of two parts: GPMC initialization and device detection with parameter determination:

- GPMC initialization
  The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See Table 24-32.
- Device detection and parameters
  The ROM code identifies a OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

24.4.7.5.2 OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. Figure 24-21 shows this procedure.

Figure 24-21. OneNAND Read Sector



24.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v 2 .0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 1.8V or 3.3V I/O voltage on PORT 1
- 1.8V or 3.3V I/O voltage on PORT 2. External transceiver mode on PORT 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
  - Initialization sequence mode: 160 kHz
  - Identification mode: 400 kHz
  - Data transfer mode: 1/2 maximum detected rate
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).

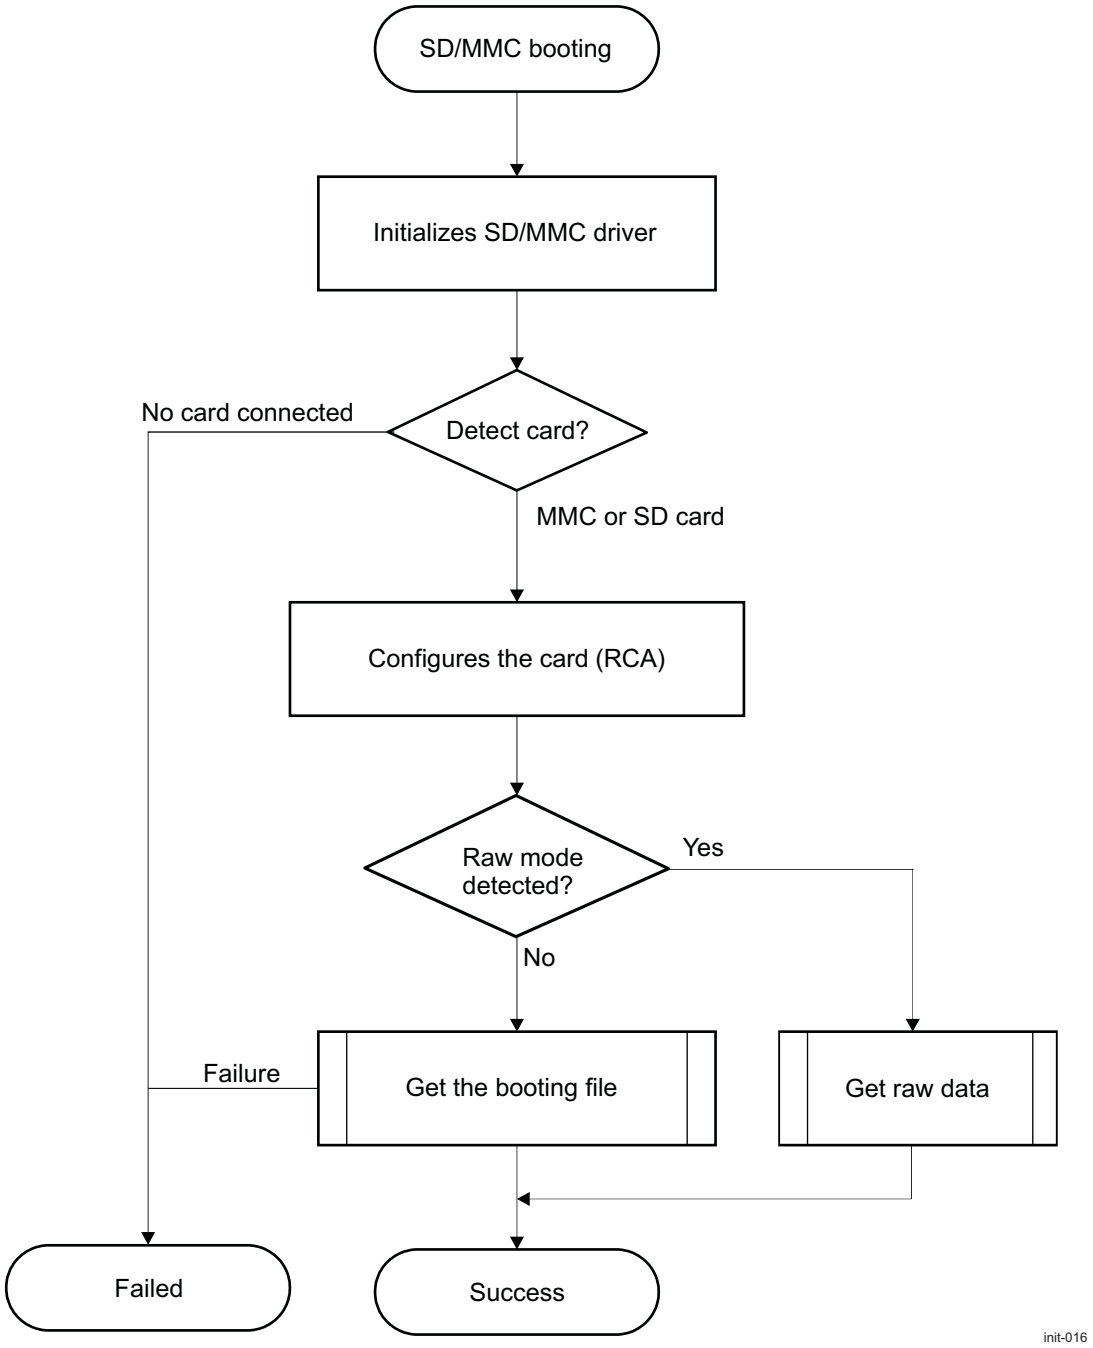
- In case of a FAT (12/16/32) formatted memory card, the booting file must not exceed 128 KB.
- In case of a raw mode memory card, the booting image must not exceed 128 KB.

For MMC memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only 1.8V or 3.3V MMC/SD cards, depending on VDDSHV.

The ROM code reads a booting file from the card file system and boots from it. Figure 24-22 shows the complete procedure.

Figure 24-22. MMC/SD Booting



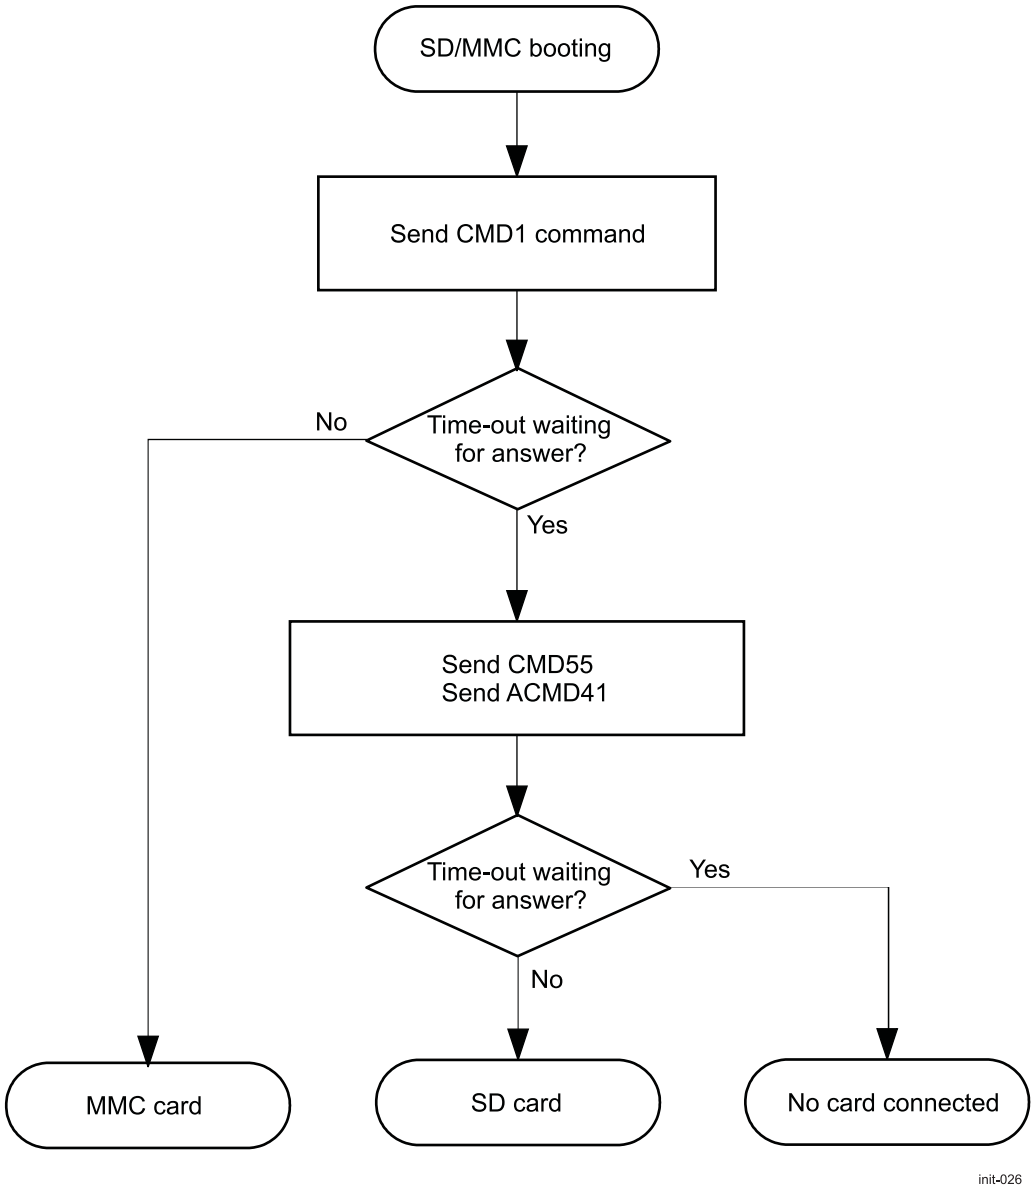
24.4.7.6.1 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the voltage dictated by VDDSHV.. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands, CMD1 and ACMD41. The ROM code uses this command difference to differentiate between MMC and SD cards;

that is, CMD1 is supported only by MMC and ACMD41 is supported only by SD. The ROM code first sends a CMD1 to the card and gets an answer only if an MMC card is connected. If no answer is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an answer is expected from an SD card. If no answer is received, no cards are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 24-23 shows the MMC/SD detection procedure.

Figure 24-23. MMC/SD Detection Procedure



24.4.7.6.2 Read Sector Procedure

- Raw mode
  In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0. ROM Code decides to switch into the raw mode if the first read sector contains a TOC structure with an MLO item. If raw mode is not detected, file system mode is assumed. Image data is read directly from continuous sectors of a card.
- File system handling
  The sector read procedure uses the standard MMC/SD read data procedure. The sector address is

generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

24.4.7.6.3 File System Handling

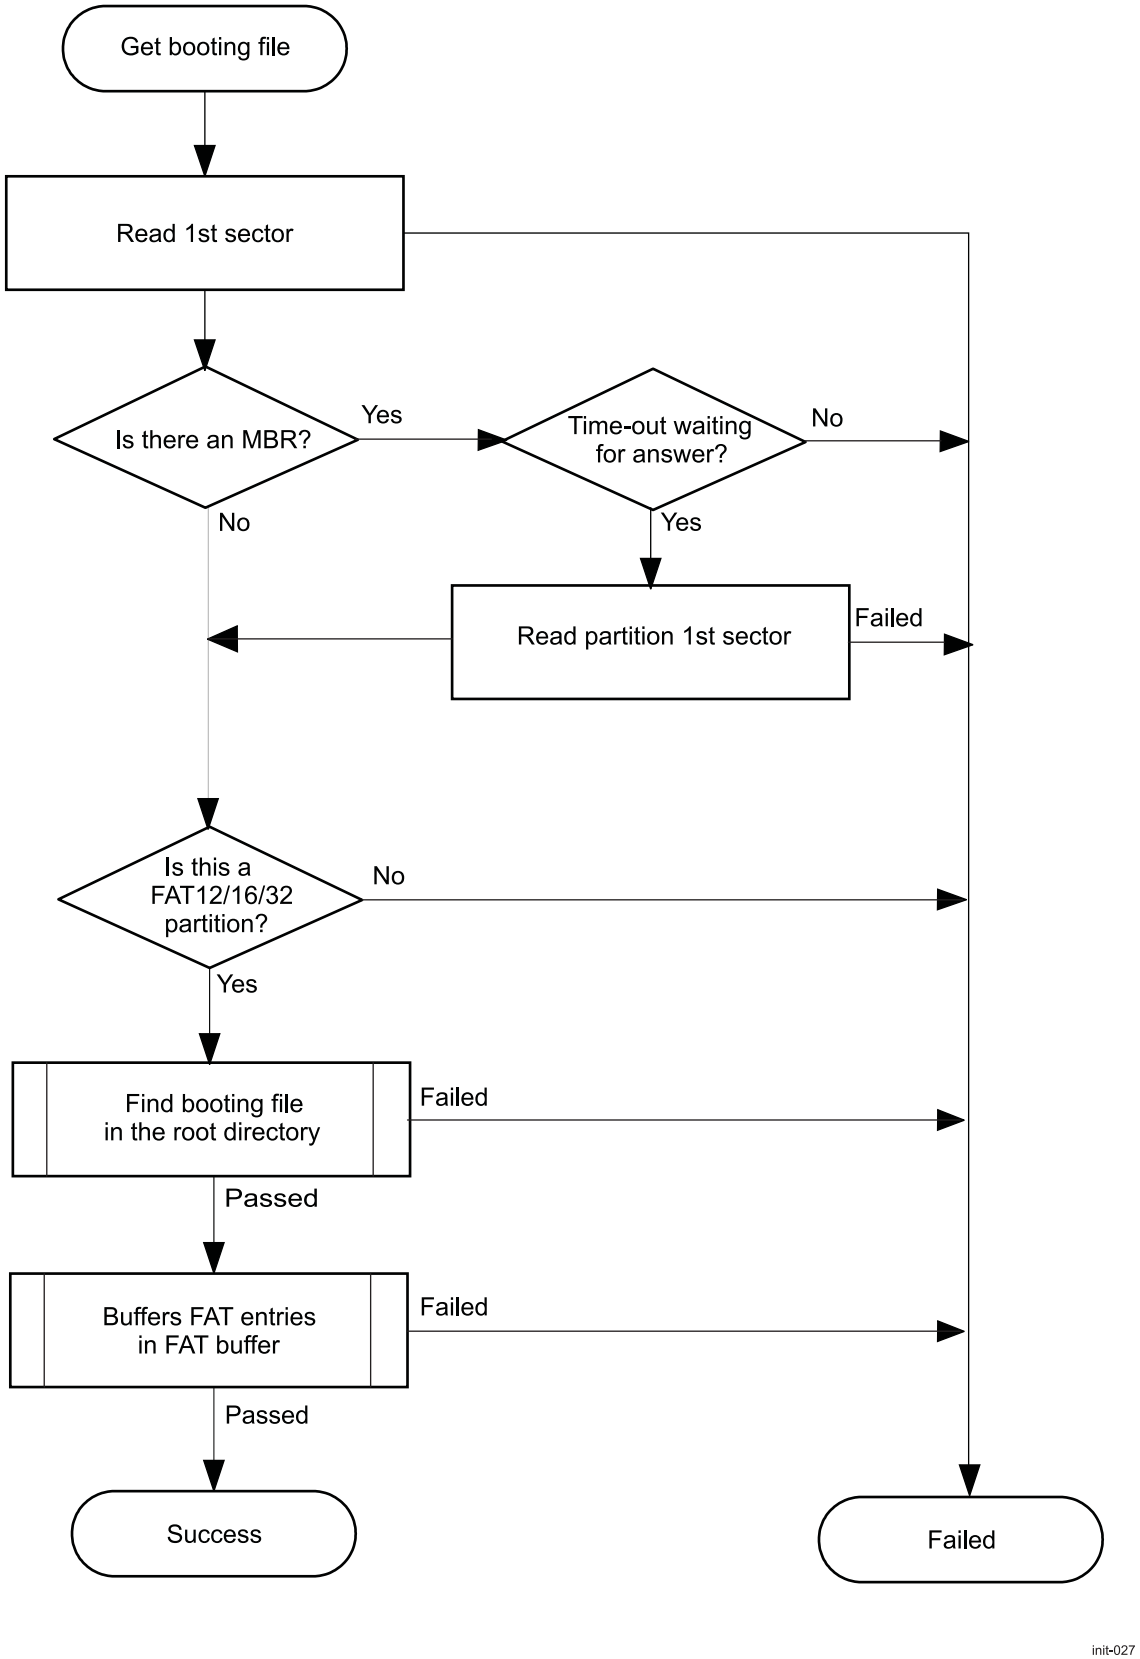
MMC/SD Cards may hold a file system which ROM Code reads. The image used by the Booting procedure is taken from a specific booting file named MLO. This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card should always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. Figure 24-24 shows the complete process.

Figure 24-24. SD/MMC Booting



- MBR and FAT file system

This paragraph describes functionalities used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in Table 24-38; partition table entry is described in Table 24-39.

Table 24-38. Master Boot Record Structure

Offset	Length [Bytes]	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (= 0xAA55)

Table 24-39. Partition Table Entry

Offset	Length [Bytes]	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S+ Hs.S+ Ss–1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S+ He.S+ Se–1 Nb s= LBAe–LBAs + 1

1. Find the booting file
   When a partition is found, the root directory entries are searched for a specific booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_NumFATs \cdot BPB\_FATSz + Cluster \cdot BPB\_SecPerCLus \quad \text{(23)}$$

init-E001

NOTE: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

NOTE: The BPB_HiddSec field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used.

Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e. filename, date of creation, rights, cluster location etc. This is described in Table 24-40.

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the following paragraph.

Table 24-40. FAT Directory Entry

Offset	Length [Bytes]	Name	Description	
0000h	11	DIR_Name	Short name (8 + 3)	
000Bh	1	DIR_Attr	File Attributes:	
			ATTR_READ_ONLY	01h
			ATTR_HIDDEN	02h
			ATTR_SYSTEM	04h
			ATTR_VOLUME_ID	08h
			ATTR_DIRECTORY	10h
			ATTR_ARCHIVE	20h
			ATTR_LONG_NAME	ATTR_READ_ONLY I ATTR_HIDDEN I ATTR_SYSTEM I ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved, set to 00h	
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation	
000Eh	2	DIR_CrtTime	Time file was created	
0010h	2	DIR_CrtDate	Date file was created	
0012h	2	DIR_LstAccDate	Last Access date	
0014h	2	DIR_FstClusHi	High work of this entry's first cluster number	
0016h	2	DIR_WrtTime	Time of last write	
0018h	2	DIR_WrtDate	Date of last write	
001Ah	2	DIR_FstClusLo	Low word of this entry's first cluster number	
001Ch	4	DIR_FileSize	File size in bytes	

2. Buffer FAT entries in the FAT buffer
When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies) located after the Boot Sector:

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_FatSz \cdot n \quad \text{(24)}$$

init-E002

The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in Table 24-41.

NOTE: For compatibility, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); ?FFFFFF8h and ?FFFFFFFh (for FAT32).

Table 24-41. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	?0000000h	Free Cluster
001h	0001h	?0000001h	Reserved Cluster
002h-FEFh	0002h-FFEFh	00000002h-?FFFFFEFh	Used Cluster; value points to next cluster
FF0h-FF6h	FFF0h-FFF6h	?FFFFFF0h-?FFFFFF6h	Reserved values
FF7h	FFF7h	?FFFFFF7h	Bad Cluster
FF8h-FFFh	FFF8h-FFFFh	?FFFFFFh-?FFFFFFFh	Last Cluster in File

NOTE: FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

24.4.7.7 DiskOnChip™

The ROM code support for DiskOnChip™ devices has the following characteristics:

- DiskOnChip™ H3
- 1.8-V power supply
- Density from 256M bits

The DiskOnChip™ contains an XIP part that can hold a boot image. In this case, the DiskOnChip™ is connected just like a regular NOR device, and uses the same procedure as for NOR described in Section 24.4.7.3.

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

SD/MMC booting consists of several steps:

1. MBR detection
   The ROM code first checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL.

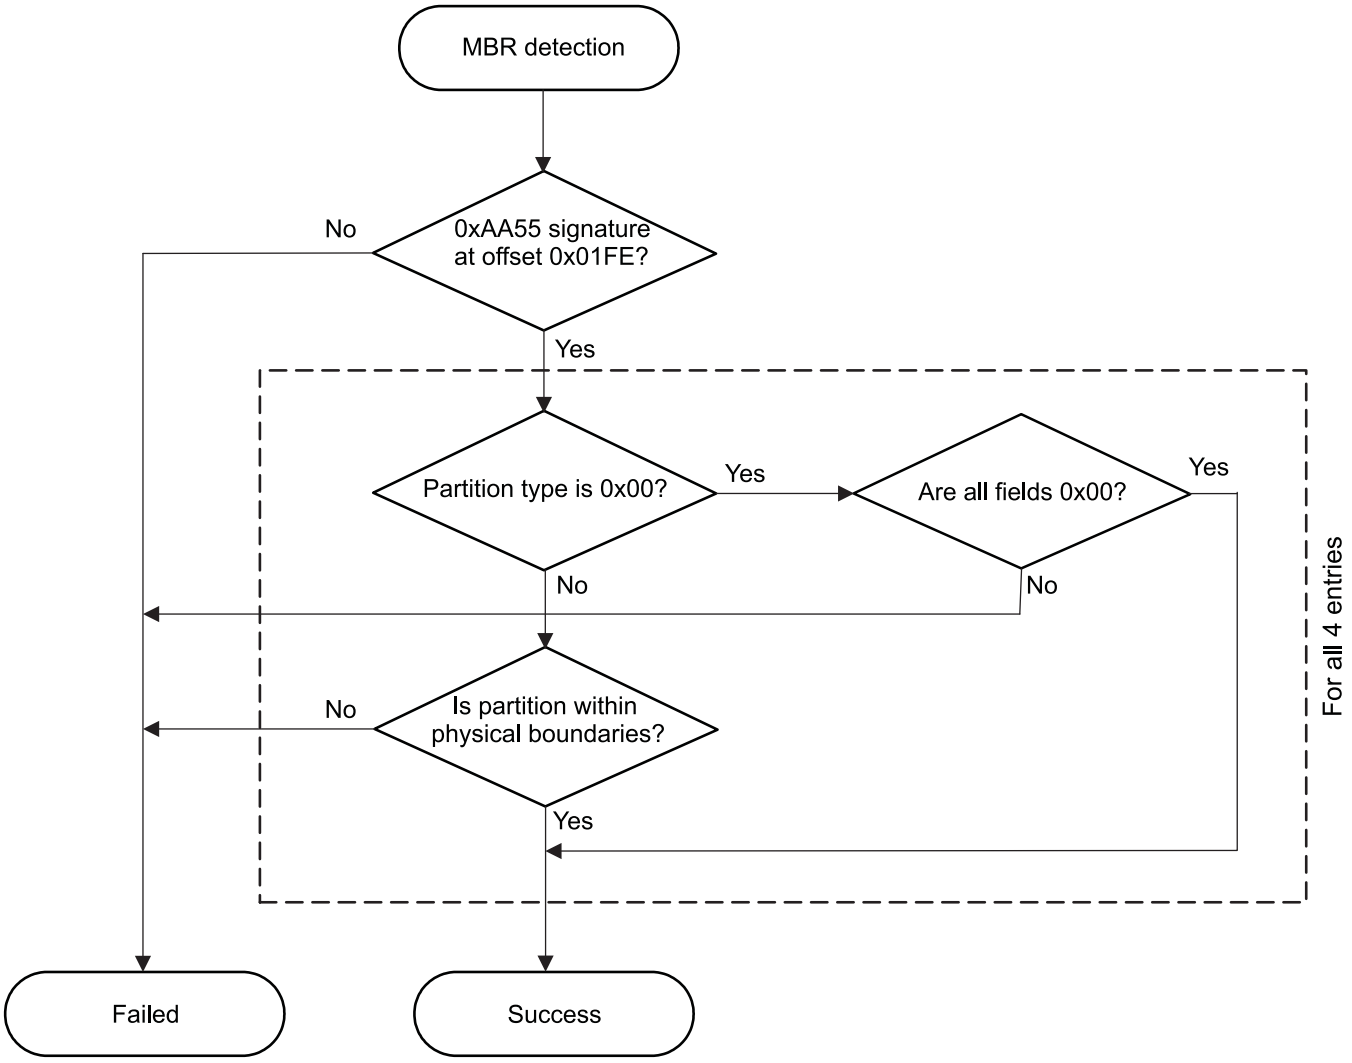
The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

(a) If its type is set to 00h, all fields in the entry must be 00h.

(b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See Figure 24-25 for more information about MBR detection.

Figure 24-25. MBR Detection Procedure

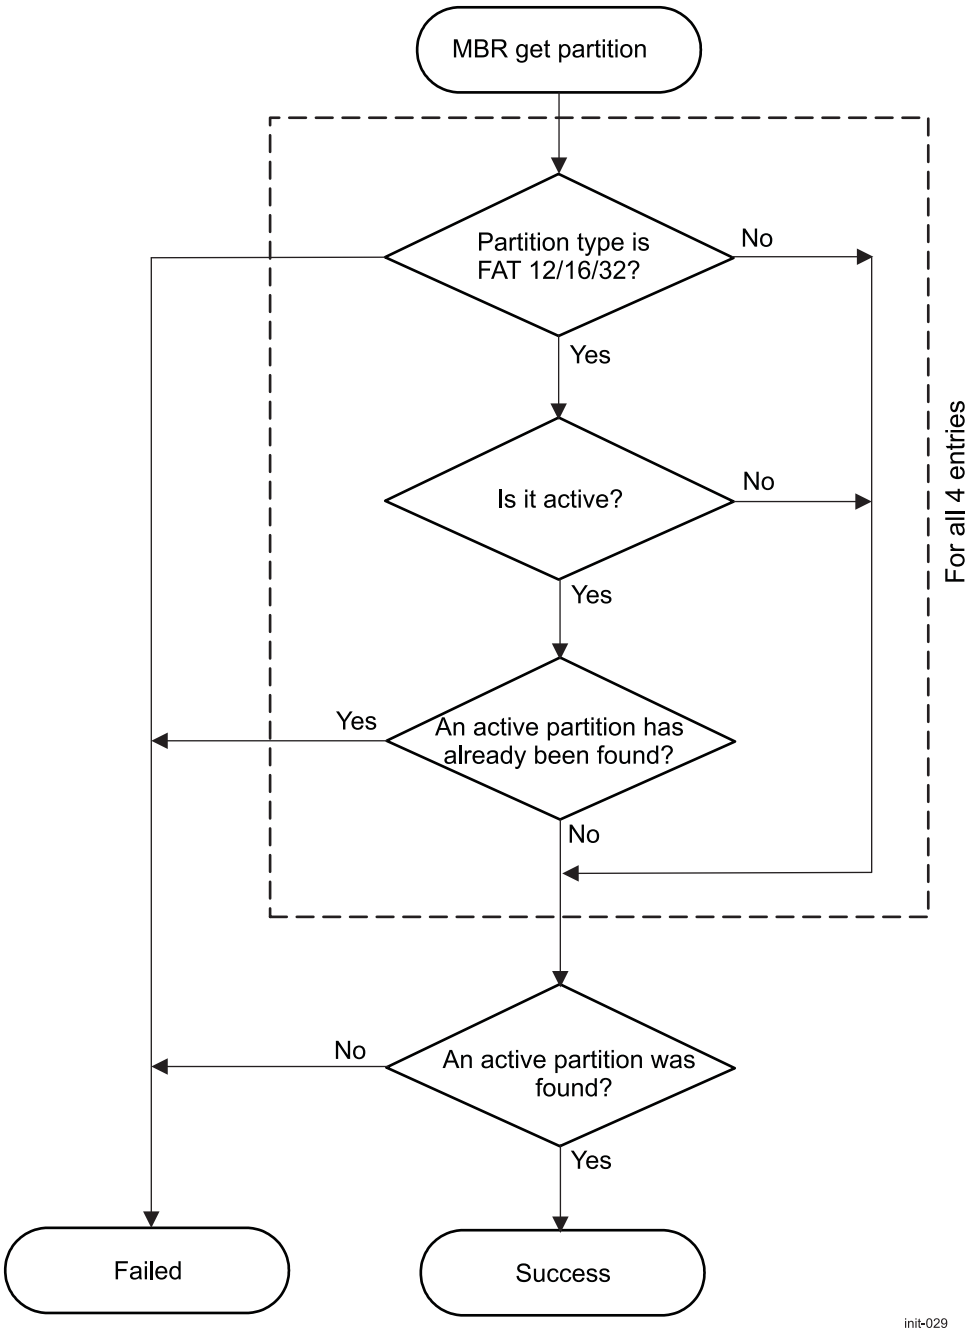


2. Get the MBR partition.
   Once identified, the ROM code gets the partition using the procedure described in Figure 24-25. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux® FS) or if the partition is not valid, the ROM code returns with FAIL. The FAT file system consists of several parts:
   - Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
   - FAT, which describes the use of each cluster of the partition

- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location).

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 24-26 shows more information about getting the MBR partition.

Figure 24-26. Get MBR Partition



24.4.7.8 SPI Flash

ROM code supports SPI flashes that have the following characteristics:

- Only 24 bit addressable flashes are supported
- Only flash sizes between 128KBytes and 16 MBytes are supported

- Only Mode 3 flashes are supported (Phase = 1, Polarity = 1)
- The SPI flash must be connected to CS0
- Only 4 pin mode is supported (spi_clk, spi_cs0, spi_somi, spi_simo)
- SPI clock frequency is 12 MHz

SPI Sector Read Procedure

The ROM code searches the first four sectors of the SPI flash looking for a valid image. If the first two words of any sector is neither 0x0000 0000 or 0xFFFF FFFF, then ROM code assumes a valid image is present.

Once the ROM code detects a valid image, it reads the size of the image from the header , copies the image to the destination address mentioned in the header and executes it.

The ROM code assumes one sector is 512 bytes. To read a particular address from the SPI flash, the ROM code issues a READ command (0x03) followed by the 24 bit address of the byte to be read from the flash. The ROM code then reads the desired number of bytes, 4 bytes at a time.

The chip select is controlled by the ROM code, and is asserted before sending the read command. It is de-asserted only once the required number of bytes are read.

24.4.8 Image Format

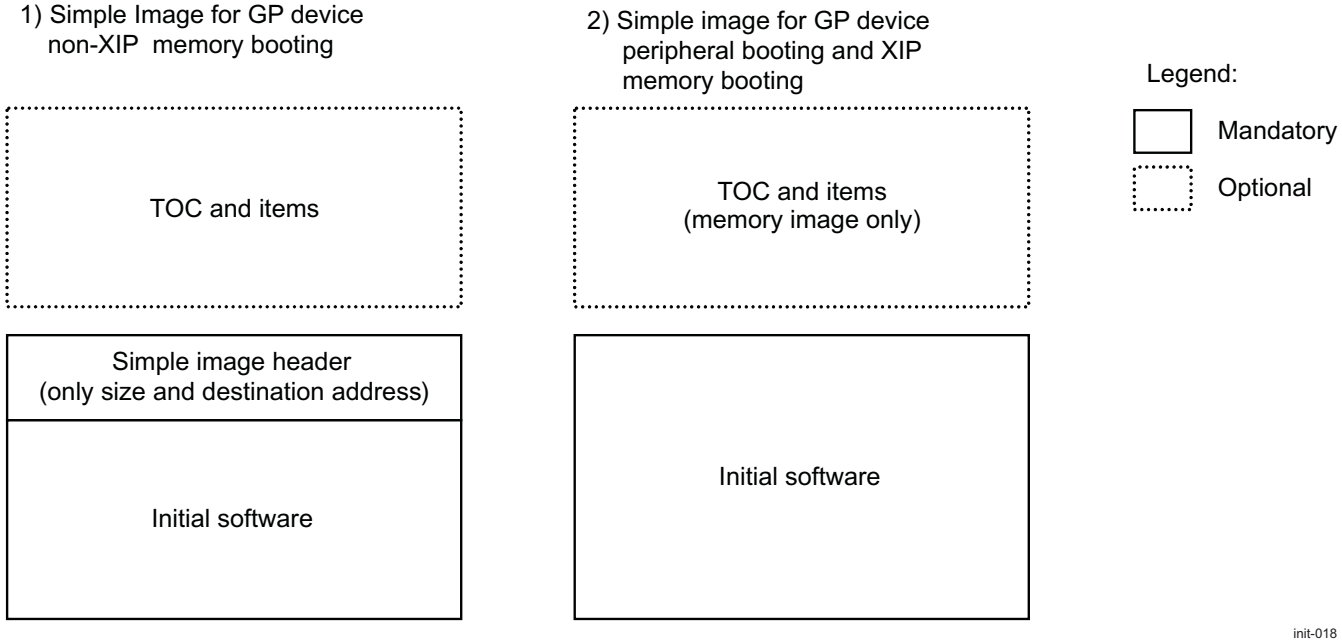
24.4.8.1 Overview

The image is the SW which is loaded into the memory and executed.

An overview of the image formats is shown in Figure 24-27. There are two image types for GP devices:

1. GP non-XIP memory booting:
   This image type is used for memories that require shadowing. The image must begin with a simple header that contains information on size to copy and destination. This format is detailed in Section 24.4.8.3, *Image Format for GP Devices*.
2. GP XIP memory booting and peripheral booting:
   GP image on XIP memory contains only code. The GP peripheral booting image contains only code.

Figure 24-27. Image Format



24.4.8.2 Image Header

The beginning of the image is a table of contents (TOC) pointing to each item. This is described in Figure 24-28. Each TOC item is a simple structure described in Table 24-42. The complete image header (TOC and items) should fit in a 512-byte sector.

The ROM code reads the first TOC item and if it contains a known string (MLO) then the TOC is identified and searched until a 0xFFFF FFFF offset is found.

Figure 24-28. Image Header Format

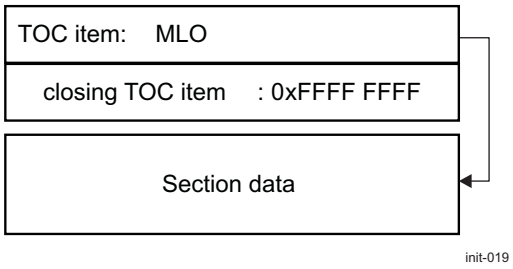


Table 24-42. TOC Item

Offset	Field	Size [bytes]	Description
0x0000	Start	4	Offset from the start address of TOC to the actual address of a section
0x0004	Size	4	Size of a section
0x0008	reserved	4	Unused
0x000C	reserved	4	Unused
0x0010	reserved	4	Unused
0x0014	Filename	12	12-character long name of a section, including the zero (\0) terminator.

24.4.8.3 Image Format for GP Devices

For a GP device, no security is enabled and, therefore, neither keys nor certificates are required. The image is simple and must contain a small header having the size of the SW to load and the destination address of where to store it when a device is other than XIP. The XIP device image is even simpler and starts with executable code. The image format is described in Table 24-43. The header is used only for memory booting. The peripheral booting image does not have any header and starts directly with executable code.

Table 24-43. GP Device SW Image

Filed	Non-XIP Device	XIP Device	Size (Bytes)	Description
	Offset	Offset		
Size	0x0000	-	4	Size of the image
Destination	0x0004	-	4	Address where to store the image
Image	0x0008	0x0000	x	The Image

24.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction inside the Initial SW. The execution address is the first word after the image header. After the branch, the ARM runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains some information about the booting process. Table 24-44 details the booting parameters structure.

Table 24-44. Booting Parameters Structure

Offset	Field	Size [Bytes]	Description
0x00	Booting message	4	Last received Booting Message.
0x04	Current booting device	1	Code of device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x10: UART 0x11: HS USB 0x12: EMAC 0x13: EMAC
0x05	Reserved	1	Reserved
0x06	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global SW reset [3]: Violation reset [4]: MPU watchdog reset [5]: Watchdog reset [6]: External warm reset Other bits: Reserved
0x07	Reserved	1	Reserved
0x08	Device descriptor	4	Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called.

24.4.9 Tracing

Tracing in the public ROM code consists in a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. Table 24-45 lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of the start-up phase.

There are two sets of tracing data: the first set is the current trace information, the second set holds tracing collected during the first ROM code run following a cold reset. This cold reset tracing is copied into its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging purposes.

Table 24-45. Tracing Vector

Bit No.	Group	Meaning
0	General	Reset
1	General	ROM code C main
2	General	ROM code runs after the cold reset
3	Boot	Booting started
4	Memory boot	Memory booting started
5	Boot	No more device to check
6	Peripheral boot	Peripheral booting started
7	Boot	Booting message change device
8	Boot	Booting message skip per. booting
9	Reserved	Reserved
10	Reserved	Reserved
11	Memory boot	Image header correct
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC ID sent
14	Peripheral boot	Booting message received
15	Peripheral boot	Image received
16	Peripheral boot	Peripheral booting failed
17	Peripheral boot	UART
18	Peripheral boot	USB
19	Peripheral boot	EMAC
20	Reserved	Reserved
21	Peripheral boot	NULL device
22	Execute	Image executed
23	Reserved	Reserved for non-GP devices
24	Reserved	Reserved for non-GP devices
25	Reserved	Reserved for non-GP devices
26	Reserved	Reserved for non-GP devices
27	Reserved	Reserved for non-GP devices
28	Reserved	Reserved for non-GP devices
29	Boot	Software booting configuration section 1 found
30	General	Software booting configuration clocking section found
31	Reserved	Reserved
32	Memory boot	Null device
33	Memory boot	XIP
34	Memory boot	NAND
35	Memory boot	OneNAND
36	Memory boot	DOC
37	Memory boot	MMC/SD2
38	Memory boot	MMC/SD1
39	Memory boot	XIP memory with wait monitoring
40	Memory boot	SPI

24.5 Debug Configuration

24.5.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the processor. The debug capability is accessible through the JTAG interface with a limited number of pins.

24.5.2 JTAG Port Signal Description

The target debug interface uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK), and the two instrumentations pins (EMU0, EMU1). For more information, see Table 24-46.

Table 24-46. Debug POR Signals

Pin	Type[1]	Name	Description
nTRST	I	Test logic reset	When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface
TCK	I	Test clock	This is the test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to the processor, this is a free-running clock or a gated clock, depending on RTCK monitoring.
RTCK	O	Returned test clock	Synchronized TCK. Depending on the emulator attached to the processor, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
TMS	I	Test mode select	Directs the next state of the IEEE 1149.1 TAP state-machine
TDI	I	Test data input	Scan data input to the device.
TDO	O	Test data output	Scan data output of the device.
EMU0	I/O	Emulation 0	Channel 0 trigger: Boot mode
EMU1	I/O	Emulation 1	Channel 1 trigger: Boot mode

(1) I = Input, O = Output

24.5.3 Initial Scan Chain Configuration

The general-purpose ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to serially link to 16 TAP controllers or to individually scan one TAP controller without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins should be pulled high at POR to configure the initial scan chain of the device to TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

24.5.4 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the device bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. Table 24-47 lists the modules that are mapped to the DAP address, and the address space detail.

Table 24-47. Debugger Address Space

Start Addr (Hex)	End Addr (Hex)	Size	Description
0xD401 0000	0xD401 0FFF	4KB	ARM embedded trace macrocell (ETM) module
0xD401 1000	0xD401 1FFF	4KB	Cortex-A8 module
0xD401 9000	0xD401 9FFF	4KB	Trace port interface unit (TPIU)
0xD401 B000	0xD401 BFFF	4KB	ARM embedded trace buffer (ETB) module

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0xD401 D030 in the DAP-APB address space.

24.6 Revision History

Table 24-48 lists the changes made since the previous version of this document.

Table 24-48. Document Revision History

Reference	Additions/Modifications/Deletions
Global	Removed SW Booting Configuration.
Section 24.2.3	Changed sys_boot[8:0] to sys_boot[5:0] in 2nd paragraph 1st sentence.
Table 24-3	Added new boot configuration to boot sequence.
Table 24-4	Added new boot configuration to boot sequence.
Table 24-5	Added new boot configuration to boot sequence.
Section 24.4.1.2	Changed 2nd bullet.
Section 24.4.3	Removed last 3 sentences from step 3 and deleted last paragraph.
Figure 24-8	Removed the check for configuration header in step 5 from figure.
Section 24.4.4.2	Removed software configuration information including: 2nd sentence of 4th paragraph, 5th paragraph, and last bulleted list.
Section 24.4.4.3	Changed 1st sentence and removed bulleted list.
Figure 24-9	Removed software configuration from the flow chart figure.
Section 24.4.7.1	Added last bullet and removed 2nd and 3rd sentence from 3rd paragraph.
Figure 24-16	Removed check for Configuration Header (CH) from figure.
Section 24.4.7.2	Removed 2nd paragraph.
Figure 24-17	Removed Configuration Header (CH) path from figure.
Section 24.4.7.3	Removed Configuration Header (CH) information from 3rd paragraph and from ordered list.
Section 24.4.7.4	Removed 2nd and 3rd sentences from 2nd paragraph.
Section 24.4.7.5	Removed 3rd and 4th sentences from 3rd paragraph.
Section 24.4.7.6	Updated 2nd and 3rd bullets and 3rd paragraph.
Section 24.4.7.6.1	Changed 1st sentence, 1st paragraph.
Section 24.4.7.6.2	Updated RAW mode bullet.
Section 24.4.7.8	Added subsection.
Figure 24-27	Removed Configuration header from figure.
Section 24.4.8.2	Removed 1st paragraph and bulleted list.
Figure 24-28	Updated figure.
	Removed CHSETTINGS subsection.
	Removed CHRAM subsection.
	Removed CHFLASH subsection.
	Removed CHMMCSD subsection.
Table 24-44	Changed Offset 0x07 to reserved.
Table 24-45	Changed bit 10 to reserved, bit 19 meaning to EMAC, and added bit 40.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have ***not*** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
