		0	Bus Free wakeup disabled
		1	Bus Free wakeup enabled
7	Reserved	0	Reserved
6	STC_WE		Start condition IRQ wakeup set. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode (with the functional clock inactive) and a possible start condition is detected on the I2C line. The STC WakeUp is generated only if the I2C_SYSC.ClockActivity field indicates that the functional clock can be disabled. Note that if the functional clock is not active, the start condition is asynchronously detected (no filtering and synchronization is used). For this reason, it is possible that the signalized start condition to be a glitch. If the functional clock cannot be disabled (I2C_SYSC.ClockActivity = 10 or 11), the programmer should not enable this wakeup, since the module has other synchronously detected WakeUp event that might be used to exit from idle mode, only if the detected transfer is accessing the I2C module.
		0	Start condition wakeup disabled
		1	Start condition wakeup enabled
5	GC_WE		General call IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and a general call is received on I2C line.
		0	General call wakeup disabled
		1	General call wakeup enabled
4	Reserved	0	Reserved
3	DRDY_WE		Receive/Transmit data ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example module are set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such a transaction, the FIFO buffer needs more data to be transferred, CPU must be informed to write (in case of transmitter mode) or read (if receiver mode) in/from the FIFO.
		0	Transmit/receive data ready wakeup disabled
		1	Transmit/receive data ready wakeup enabled
2	ARDY_WE		Register access ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If the current transaction is finished, the module needs to inform CPU about transmission completion.
		0	Register access ready wakeup disabled
		1	Register access ready wakeup enabled
1	NACK_WE		No acknowledgment IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such of a transaction a Not Acknowledgment event is raised, the module needs to inform CPU about transmission error.
		0	Not Acknowledge wakeup disabled
		1	Not Acknowledge wakeup enabled

Table 11-12. I2C_WE Register (I2C Wakeup Enable) Field Descriptions (continued)

Bit	Field	Value	Description
0	AL_WE		Arbitration lost IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is configured as a master and it loses the arbitration. This wake up is very useful when the module is configured as a master transmitter, all the necessary data is provided in the FIFO Tx, STT is enabled and the module enters in Idle Mode. If the module loses the arbitration, an Arbitration Lost event is raised and the module needs to inform CPU about transmission error. **Note:** The AL wakeup must be enabled only for multimaster communication. If the AL_WE is not enabled and the scenario described above occurs, the module will not be able to inform the CPU about the state of the transfer and it will be blocked in an undetermined state.
		0	Arbitration lost wakeup disabled
		1	Arbitration lost wakeup enabled

11.3.10 I2C_DMARXENABLE_SET Register (Receive DMA Enable Set)

The 1-bit field enables a receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, that is, the register value is not modified. Note that the I2C_BUF.RDMA_EN field is the global (slave) DMA enabler, and that it is disabled by default. The I2C_BUF.RDMA_EN field should also be set to 1 to enable a receive DMA request.

Figure 11-23. I2C_DMARXENABLE_SET Register (Receive DMA Enable Set)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-20. I2C_BUF Register (Buffer Configuration) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	RDMA_EN		Receive DMA channel enable. When this bit is set to 1, the receive DMA channel is enabled and the receive data ready status bit (I2C_IRQSTATUS_RAW: RRDY) is forced to 0 by the core.
		0	Receive DMA channel disabled
		1	Receive DMA channel enabled
			Value after reset is low.
14	RXFIFO_CLR		Receive FIFO clear. When set, receive FIFO is cleared (hardware reset for RX FIFO generated). This bit is automatically reset by the hardware. During reads, it always returns 0.
		0	Normal mode
		1	Rx FIFO is reset
			Value after reset is low.
13-8	RXTRSH	0-3Fh	Threshold value for FIFO buffer in RX mode. The receive threshold value is used to specify the trigger level for data receive transfers. The value is specified from the Interface/OCP point of view.
		0	Receive Threshold value = 1
		1	Receive Threshold value = 2
		-	
		-	
		3Fh	Receive Threshold value = 64
			Value after reset is 00h.
			For the FIFO management description, see the FIFO Management subsection.
			Note1: programmed threshold cannot exceed the actual depth of the FIFO.
			Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).
7	XDMA_EN		Transmit DMA channel enable. When this bit is set to 1, the transmit DMA channel is enabled and the transmit data ready status (I2C_IRQSTATUS_RAW: XRDY) bit is forced to 0 by the core.
		0	Transmit DMA channel disabled
		1	Transmit DMA channel enabled
			Value after reset is low.
6	TXFIFO_CLR		Transmit FIFO clear. When set, transmit FIFO is cleared (hardware reset for TX FIFO). This bit is automatically reset by the hardware. During reads, it always returns 0.
		0	Normal mode
		1	Tx FIFO is reset
			Value after reset is low.

Table 11-20. I2C_BUF Register (Buffer Configuration) Field Descriptions (continued)

Bit	Field	Value	Description
5-0	TXTRSH	0-3Fh	Threshold value for FIFO buffer in TX mode. The Transmit Threshold value is used to specify the trigger level for data transfers. The value is specified from the OCP point of view.
		0	Transmit Threshold value = 1
		1	Transmit Threshold value = 2
		-	
		-	
		3Fh	Transmit Threshold value = 64
			Value after reset is 00h
			Note1: programmed threshold cannot exceed the actual depth of the FIFO.
			Note2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave).

11.3.18 I2C_CNT Register (Data Counter)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This read/write register is used to control the numbers of bytes in the I2C data payload.

Figure 11-31. I2C_CNT Register (Data Counter)

31	16	15	0
Reserved		DCOUNT	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-21. I2C_CNT Register (Data Counter) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-0	DCOUNT	0-FFFFh	Data count. I2C Master Mode only (receive or transmit; F/S). This 16-bit countdown counter decrements by 1 for every byte received or sent through the I2C interface. A write initializes DCOUNT to a saved initial value. A read returns the number of bytes that are yet to be received or sent. A read into DCOUNT returns the initial value only before a start condition and after a stop condition. When DCOUNT reaches 0, the core generates a stop condition if a stop condition was specified (I2C_CON.STP = 1) and the ARDY status flag is set to 1 in the I2C_IRQSTATUS_RAW register. Note that DCOUNT must not be reconfigured after I2C_CON.STT was enabled and before ARDY is received. **Note1:** In case of I2C mode of operation, if I2C_CON.STP = 0, then the I2C asserts SCL = 0 when DCOUNT reaches 0. The CPU can then reprogram DCOUNT to a new value and resume sending or receiving data with a new start condition (restart). This process repeats until the CPU sets to 1 the I2C_CON.STP bit. The ARDY flag is set each time DCOUNT reaches 0 and DCOUNT is reloaded to its initial value.
		0	Data counter = 65536 bytes (2^16)
		1	Data counter = 1 bytes
		-	
		-	
		FFFFh	Data counter = 65535 bytes (2^16 - 1) Values after reset are low (all 16 bits). **Note2:** Since for DCOUNT = 0, the transfer length is 65536, the module does not allow the possibility to initiate zero data bytes transfers.

11.3.19 I2C_DATA Register (Data Access)

This register is the entry point for the local host to read data from or write data to the FIFO buffer.

Figure 11-32. I2C_DATA Register (Data Access)

31	8	7	0
Reserved		DATA	
R-0		R/W-x	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 11-22. I2C_DATA Register (Data Access) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	DATA	0-FFh	Transmit/Receive data FIFO endpoint. When read, this register contains the received I2C data. When written, this register contains the byte value to transmit over the I2C data. In SYSTEST loop back mode (I2C_SYSTEST: TMODE = 11), this register is also the entry/receive point for the data. Values after reset are unknown (all 8-bits). **Note:** A read access, when the buffer is empty, returns the previous read data value. A write access, when the buffer is full, is ignored. In both events, the FIFO pointers are not updated and an Access Error (AERR) Interrupt is generated.

11.3.20 I2C_CON Register (I2C Configuration)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register (except STP enable). Changing it may result in an unpredictable behavior.

Figure 11-33. I2C_CON Register (I2C Configuration)

Table 11-23. I2C_CON Register (I2C Configuration) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	I2C_EN		I2C module enable. When this bit is cleared to 0, the I2C controller is not enabled and reset. When 0, receive and transmit FIFOs are cleared and all status bits are set to their default values. All configuration registers (I2C_IRQENABLE_SET, I2C_IRQWAKE_SET, I2C_BUF, I2C_CNT, I2C_CON, I2C_OA, I2C_SA, I2C_PSC, I2C_SCLL and I2C_SCLH) are not reset, they keep their initial values and can be accessed. The CPU must set this bit to 1 for normal operation.
		0	Controller in reset. FIFO are cleared and status bits are set to their default value.
		1	Module enabled
			Value after reset is low.
14	Reserved	0	Reserved
13-12	OPMODE		Operation mode selection. These two bits select module operation mode.
		0h	I2C Fast/Standard mode
		1h	Reserved
		2h	Reserved
		3h	Reserved
			Value after reset is 00.
11	STB		Start byte mode (I2C master mode only). The start byte mode bit is set to 1 by the CPU to configure the I2C in start byte mode (I2C_SA = 0000 0001). See the Philips I2C spec for more details [1].
		0	Normal mode
		1	Start byte mode
			Value after reset is low.
10	MST		Master/slave mode (I2C mode only). When this bit is cleared, the I2C controller is in the slave mode and the serial clock (SCL) is received from the master device. When this bit is set, the I2C controller is in the master mode and generates the serial clock.
			Note: This bit is automatically cleared at the end of the transfer on a detected stop condition, in case of arbitration lost or when the module is configured as a master but addressed as a slave by an external master.
		0	Slave mode
		1	Master mode
			Value after reset is low.

Table 11-23. I2C_CON Register (I2C Configuration) Field Descriptions (continued)

Bit	Field	Value	Description
9	TRX		Transmitter/receiver mode (i2C master mode only). When this bit is cleared, the I2C controller is in the receiver mode and data on data line SDA is shifted into the receiver FIFO and can be read from I2C_DATA register. When this bit is set, the I2C controller is in the transmitter mode and the data written in the transmitter FIFO via I2C_DATA is shifted out on data line SDA.
		0	Receiver mode
		1	Transmitter mode
			Value after reset is low.
			The operating modes are defined as follows:
			MST / **TRX** / **Operating Modes**: 0 / x / Slave receiver; 0 / x / Slave transmitter; 1 / 0 / Master receiver; 1 / 1 / Master transmitter
8	XSA		Expand slave address. (I2C mode only). When set, this bit expands the slave address to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
7	XOA0		Expand own address 0. (I2C mode only). When set, this bit expands the base own address (OA0) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
6	XOA1		Expand own address 1. (I2C mode only). When set, this bit expands the first alternative own address (OA1) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
5	XOA2		Expand own address 2. (I2C mode only). When set, this bit expands the second alternative own address (OA2) to 10-bit.
		0	7-bit address mode.
		1	10-bit address mode
			Value after reset is low.
4	XOA3		Expand own address 3. When set, this bit expands the third alternative own address (OA3) to 10-bit.
		0	7-bit address mode
		1	10-bit address mode
			Value after reset is low.
3-2	Reserved	0	Reserved
1	STP		Stop condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when DCOUNT passes 0.
			When this bit is not set to 1 before the end of the transfer (DCOUNT = 0), the stop condition is not generated and the SCL line is hold to 0 by the master, which can re-start a new transfer by setting the STT bit to 1.
		0	No action or stop condition detected
		1	Stop condition queried
			Value after reset is low

Table 11-23. I2C_CON Register (I2C Configuration) Field Descriptions (continued)

Bit	Field	Value	Description
0	STT		Start condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a start condition. It is reset to 0 by the hardware after the start condition has been generated. The start/stop bits can be configured to generate different transfer formats.
		0	No action or start condition detected
		1	Start condition queried
			Value after reset is low.

STT	STP	Conditions	Bus Activities
1	0	Start	S-A-D
0	1	Stop	P
1	1	Start-Stop (DCOUNT= n)	S-A-D..(n)..D-P
1	0	Start (DCOUNT= n)	S-A-D..(n)..D

Note: DCOUNT is data count value in I2C_CNT register.

11.3.21 I2C_OA Register (I2C Own Address)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the module's base I2C 7-bit or 10-bit address (base own address).

Figure 11-34. I2C_OA Register (I2C Own Address)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 11-24. I2C_OA Register (I2C Own Address) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA	0-3FFh	Own address. This field specifies either: • A 10-bit address coded on OA [9:0] when XOA (Expand Own Address, I2C_CON[7]) is set to 1. • A 7-bit address coded on OA [6:0] when XOA (Expand Own Address, I2C_CON[7]) is cleared to 0. In this case, OA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

11.3.22 I2C_SA Register (I2C Slave Address)

CAUTION

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the addressed I2C module 7-bit or 10-bit address (slave address).

Figure 11-35. I2C_SA Register (I2C Own Address)

31	10	9	0
Reserved		SA	
R-0		R/W-3FFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-25. I2C_SA Register (I2C Slave Address) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	SA	0-3FFh	Slave address. This field specifies either: • A 10-bit address coded on SA [9:0] when XSA (Expand Slave Address, I2C_CON[8]) is set to 1. • A 7-bit address coded on SA [6:0] when XSA (Expand Slave Address, I2C_CON[8]) is cleared to 0. In this case, SA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

11.3.23 I2C_PSC Register (I2C Clock Prescaler)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the internal clocking of the I2C peripheral core.

Figure 11-36. I2C_PSC Register (I2C Own Address)

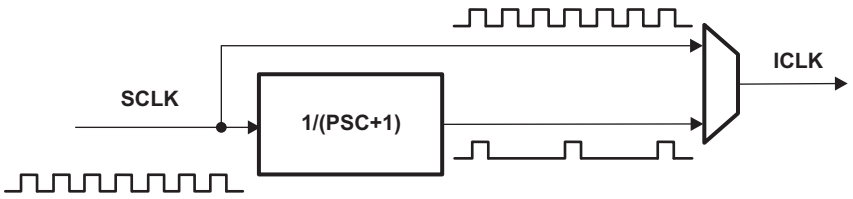
Reserved		PSC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-26. I2C_PSC Register (I2C Clock Prescaler) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	PSC	0-FFh	Fast/Standard mode prescale sampling clock divider value. The core uses this 8-bit value to divide the system clock (SCLK) and generates its own internal sampling clock (ICLK) for Fast and Standard operation modes. The core logic is sampled at the clock rate of the system clock for the module divided by (PSC + 1). 0h Divide by 1 1h Divide by 2 - - FFh Divide by 256 Value after reset is low (all 8 bits).

Figure 11-37. Clock Divider



11.3.24 I2C_SCLL Register (I2C SCL Low Time)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL low time value when master.

Figure 11-38. I2C_SCLL Register (I2C SCL Low Time)

31	8	7	0
Reserved		SCLL	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-27. I2C_SCLL Register (I2C SCL Low Time) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCLL	0-FFh	Fast/Standard mode SCL low time. I2C master mode only (FS). This 8-bit value is used to generate the SCL low time value (tLOW) when the peripheral is operated in master mode. t_{LOW} = (SCLL + 7) * I_{CLK} time period, Value after reset is low (all 8 bits).

11.3.25 I2C_SCLH Register (I2C SCL High Time)

CAUTION

During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to determine the SCL high time value when master.

Figure 11-39. I2C_SCLH Register (I2C SCL High Time)

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	SCLH	0-FFh	Fast/Standard mode SCL low time. I2C master mode only (FS). This 8-bit value is used to generate the SCL high time value (tHIGH) when the peripheral is operated in master mode. t_{HIGH} = (SCLH + 5 + floor[t_rise/I_{CLK} Period]) * I_{CLK} time period. Value after reset is low (all 8 bits).

11.3.26 I2C_SYSTEST Register (System Test)

CAUTION

Never enable this register for normal I2C operation

This register is used to facilitate system-level tests by overriding some of the standard functional features of the peripheral. It allows testing of SCL counters, controlling the signals that connect to I/O pins, or creating digital loop-back for self-test when the module is configured in system test (SYSTEST) mode. It also provides stop/non-stop functionality in the debug mode.

Figure 11-40. I2C_SYSTEST Register (System Test)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 11-29. I2C_SYSTEST Register (System Test) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	ST_EN		System test enable. This bit must be set to 1 to permit other system test registers bits to be set.
		0	Normal mode. All others bits in register are read only.
		1	System test enabled. Permit other system test registers bits to be set.
			Value after reset is low.
14	FREE		Free running mode (on breakpoint). This bit is used to determine the state of the I2C controller when a breakpoint is encountered in the HLL debugger.
			Note: This bit can be set independently of ST_EN value. FREE = 0: the I2C controller stops immediately after completion of the on-going bit transfer. Stopping the transfer is achieved by forcing the SCL line low. Note that in this case there will be no status register updates.
			FREE = 1: the I2C interface runs free. When Suspend indication will be asserted, there will be no accesses on the OCP Interface (the CPU is in debug mode) and consequently the FIFOs will reach full/empty state (according to RX or TX modes) and the I2C SDA line will be kept low. Note that the status registers will be updated, but no DMA, IRQ or WakeUp will be generated.
			The status registers likely to be updated in this mode are: I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK.
		0	Stop mode (on breakpoint condition). If Master mode, it stops after completion of the on-going bit transfer. In slave mode, it stops during the phase transfer when 1 byte is completely transmitted/received.
		1	Free running mode
			Value after reset is low.

Table 11-29. I2C_SYSTEST Register (System Test) Field Descriptions (continued)

Bit	Field	Value	Description
13-12	TMODE		Test mode select. In normal functional mode (ST_EN = 0), these bits are don't care. They are always read as 00 and a write is ignored. In system test mode (ST_EN = 1), these bits can be set according to the following table to permit various system tests.
		0	Functional mode (default)
		1h	Reserved
		2h	Test of SCL counters (SCLL, SCLH, PSC). SCL provides a permanent clock with master mode.
		3h	Loop back mode select + SDA/SCL IO mode select
			Values after reset are low (2 bits). SCL counter test mode: in this mode, the SCL pin is driven with a permanent clock as if mastered with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers. Loop back mode: in the master transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register via an internal path through the FIFO buffer. The DMA and interrupt requests are normally generated if enabled. SDA/SCL IO mode: in this mode, the SCL IO and SDA IO are controlled via the I2C_SYSTEST [5:0] register bits.
11	SSB		Set status bits. Writing 1 into this bit also sets the 6 read/clear-only status bits contained in I2C_IRQSTATUS_RAW register (bits 5:0) to 1. Writing 0 into this bit doesn't clear status bits that are already set; only writing 1 into a set status bit can clear it (see I2C_IRQSTATUS_RAW operation). This bit must be cleared prior attempting to clear a status bit.
		0	No action
		1	Set all interrupt status bits to 1
			Value after reset is low.
10-9	Reserved	0	Reserved
8	SCL_I_FUNC		SCL line input value (functional mode). This read-only bit returns the logical state taken by the SCL line (either 1 or 0). It is active both in functional and test mode
		Read:0	Read 0 from SCL line
		Read:1	Read 1 from SCL line
			Value after reset is low.
7	SCL_O_FUNC		SCL line output value (functional mode). This read-only bit returns the value driven by the module on the SCL line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Driven 0 on SCL line
		Read:1	Driven 1 on SCL line
			Value after reset is low.
6	SDA_I_FUNC		SDA line input value (functional mode). This read-only bit returns the logical state taken by the SDA line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Read 0 from SDA line
		Read:1	Read 1 from SDA line
			Value after reset is low.
5	SDA_O_FUNC		SDA line output value (functional mode). This read-only bit returns the value driven by the module on the SDA line (either 1 or 0). It is active both in functional and test mode.
		Read:0	Driven 0 to SDA line
		Read:1	Driven 1 to SDA line
			Value after reset is low.
4	Reserved	0	Reserved
3	SCL_I		SCL line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 & TMODE = 11), this read-only bit returns the logical state taken by the SCL line (either 1 or 0).
		Read:0	Read 0 from SCL line
		Read:1	Read 1 from SCL line
			Value after reset is low.

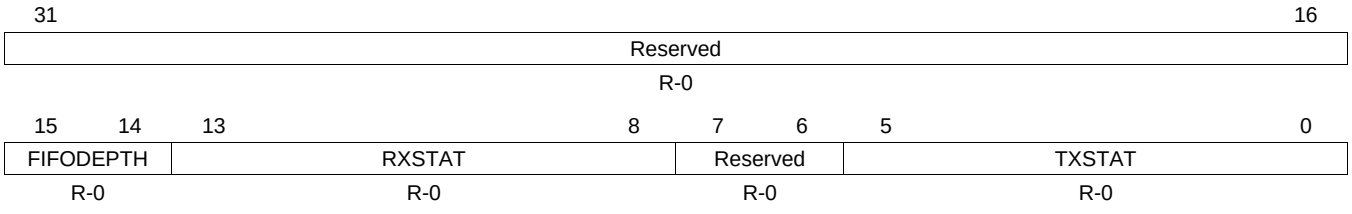
Table 11-29. I2C_SYSTEST Register (System Test) Field Descriptions (continued)

Bit	Field	Value	Description
2	SCL_O		SCL line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It always reads 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SCL line and a 1 puts the I2C output driver to a high-impedance state.
		Read:0	Forces 0 on the SCL data line
		Read:1	SCL output driver in high-impedance state
			Value after reset is low.
1	SDA_I		SDA line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 & TMODE = 11), this read-only bit returns the logical state taken by the SDA line (either 1 or 0).
		Read:0	Read 0 from SDA line
		Read:1	Read 1 from SDA line
			Value after reset is low.
0	SDA_O		SDA line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It reads as 0 and a write is ignored. In system test mode (ST_EN = 1 & TMODE = 11), a 0 forces a low level on the SDA line and a 1 puts the I2C output driver to a high-impedance state.
		0	Write 0 to SDA line
		1	Write 1 to SDA line
			Value after reset is low.

11.3.27 I2C_BUFSTAT Register (I2C Buffer Status)

This read-only register reflects the status of the internal buffers for the FIFO management (see the FIFO Management subsection).

Figure 11-41. I2C_BUFSTAT Register (I2C Buffer Status)



LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 11-30. I2C_BUFSTAT Register (I2C Buffer Status) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-14	FIFODEPTH		Internal FIFO buffers depth. This read-only bit indicates the internal FIFO buffer depth.
		0	8-bytes FIFO
		1h	16-bytes FIFO
		2h	32-bytes FIFO
		3h	64-bytes FIFO
			Value after reset is given by the boundary module generic parameter.
13-8	RXSTAT	0-3Fh	RX buffer status. This read-only field indicates the number of bytes to be transferred from the FIFO at the end of the I2C transfer (when RDR is asserted). It corresponds to the level indication of the RX FIFO (number of written locations).
			Value after reset is 0.
7-6	Reserved	0	Reserved
5-0	TXSTAT	0-3Fh	TX buffer status. This read-only field indicates the number of data bytes still left to be written in the TX FIFO (it's equal with the initial value of I2C_CNT.DCOUNT minus the number of data bytes already written in the TX FIFO through the OCP Interface).
			Value after reset is equal with 0.

11.3.28 I2C_OA1 Register (OA1) (Own Address 1)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 1 - OA1).

Figure 11-42. I2C_OA1 Register (OA1) (Own Address 1)

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA1	0-3FFh	Own address 1. This field specifies either: • A 10-bit address coded on OA1 [9:0] when XOA1 (Expand Own Address 1 - XOA1, I2C_CON[6]) is set to 1. • A 7-bit address coded on OA1 [6:0] when XOA1 (Expand Own Address 1 – XOA1, I2C_CON[6]) is cleared to 0. In this case, OA1 [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

11.3.29 I2C_OA2 Register (I2C Own Address 2)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 2 - OA2).

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA2	0-3FFh	Own address 2. This field specifies either: • A 10-bit address coded on OA2 [9:0] when XOA1 (Expand Own Address 2 - XOA2, I2C_CON[5]) is set to 1. • A 7-bit address coded on OA2 [6:0] when XOA2 (Expand Own Address 2 – XOA2, I2C_CON[5]) is cleared to 0. In this case, OA2 [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

11.3.30 I2C_OA3 Register (I2C Own Address 3)

CAUTION

During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior.

This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 3 - OA3).

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9-0	OA3	0-3FFh	Own address 2. This field specifies either: • A 10-bit address coded on OA3 [9:0] when XOA3 (Expand Own Address 3 - XOA3, I2C_CON[4]) is set to 1. • A 7-bit address coded on OA3 [6:0] when XOA1 (Expand Own Address 3 – XOA3, I2C_CON[4]) is cleared to 0. In this case, OA3 [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

11.3.31 I2C_ACTOA Register (Active Own Address)

This read-only register is used to indicate which one of the module's four own addresses the external master used when addressing the module. The CPU can read this register when the AAS indication was activated. The indication is cleared at the end of the transfer.

Figure 11-45. I2C_ACTOA Register (Active Own Address)

Table 11-34. I2C_ACTOA Register (Active Own Address) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	OA3_ACT		Own address 3 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
2	OA2_ACT		Own address 2 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
1	OA1_ACT		Own address 1 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.
0	OA0_ACT		Own address 0 active. When a bit location is set to 1 by the core, it signalizes to the Local Host that an external master using the corresponding own address addressed the module.
		0	Own address inactive
		1	Own address active
			Value after reset is low.

11.3.32 I2C_SBLOCK Register (I2C Clock Blocking Enable)

This read/write register controls the automatic blocking of I2C clock feature in slave mode. It is used for the Local Host to configure for which of the 4 own addresses, the core must block the I2C clock (keep SCL line low) right after the Address Phase, when it is addressed as a slave.

31-4	Reserved	0	Reserved
3	OA3_EN		Enable I2C clock blocking for own address 3. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field.
		0	I2C clock released
		1	I2C clock blocked
			Value after reset is low.
2	OA2_EN		Enable I2C clock blocking for own address 2. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field.
		0	I2C clock released
		1	I2C clock blocked
			Value after reset is low.
1	OA1_EN		Enable I2C clock blocking for own address 1. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field.
		0	I2C clock released
		1	I2C clock blocked
			Value after reset is low.
0	OA0_EN		Enable I2C clock blocking for own address 0. When the CPU sets a bit location to 1, if an external master using the corresponding own address addresses the core, the core will block the I2C clock right after the address phase. For releasing the I2C clock the CPU must write '0' in the corresponding field.
		0	I2C clock released
		1	I2C clock blocked
			Value after reset is low.

ARM Interrupt Controller (AINTC)

This chapter describes the ARM interrupt controller (AINTC)

Topic **Page**

12.1 Introduction

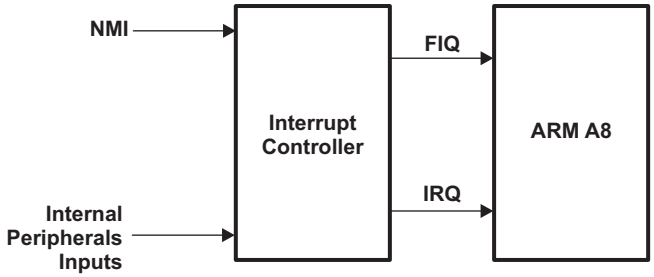
12.1.1 Overview

The Host ARM interrupt controller (AINTC) is responsible for prioritizing all service requests from the system peripherals and generating either nIRQ or nFIQ to the host. The type of the interrupt (nIRQ or nFIQ) and the priority of the interrupt inputs are programmable. It has the capability to handle up to 128 requests that can be prioritized as A8 nFIQ or nIRQ interrupt requests. The general features of the AINTC are:

- Up to 128 level sensitive interrupts inputs
- Individual priority for each interrupt input
- Each interrupt can be steered to nFIQ or nIRQ
- Independent priority sorting for nFIQ and nIRQ

Figure 12-1 shows the internal interrupt scheme.

Figure 12-1. Interrupt Controller



12.1.2 Functional Block Diagram

The interrupt controller processes incoming interrupts by masking and priority sorting to produce the interrupt signals for the processor to which it is attached. Figure 12-2 shows the top-level view of interrupt processing.

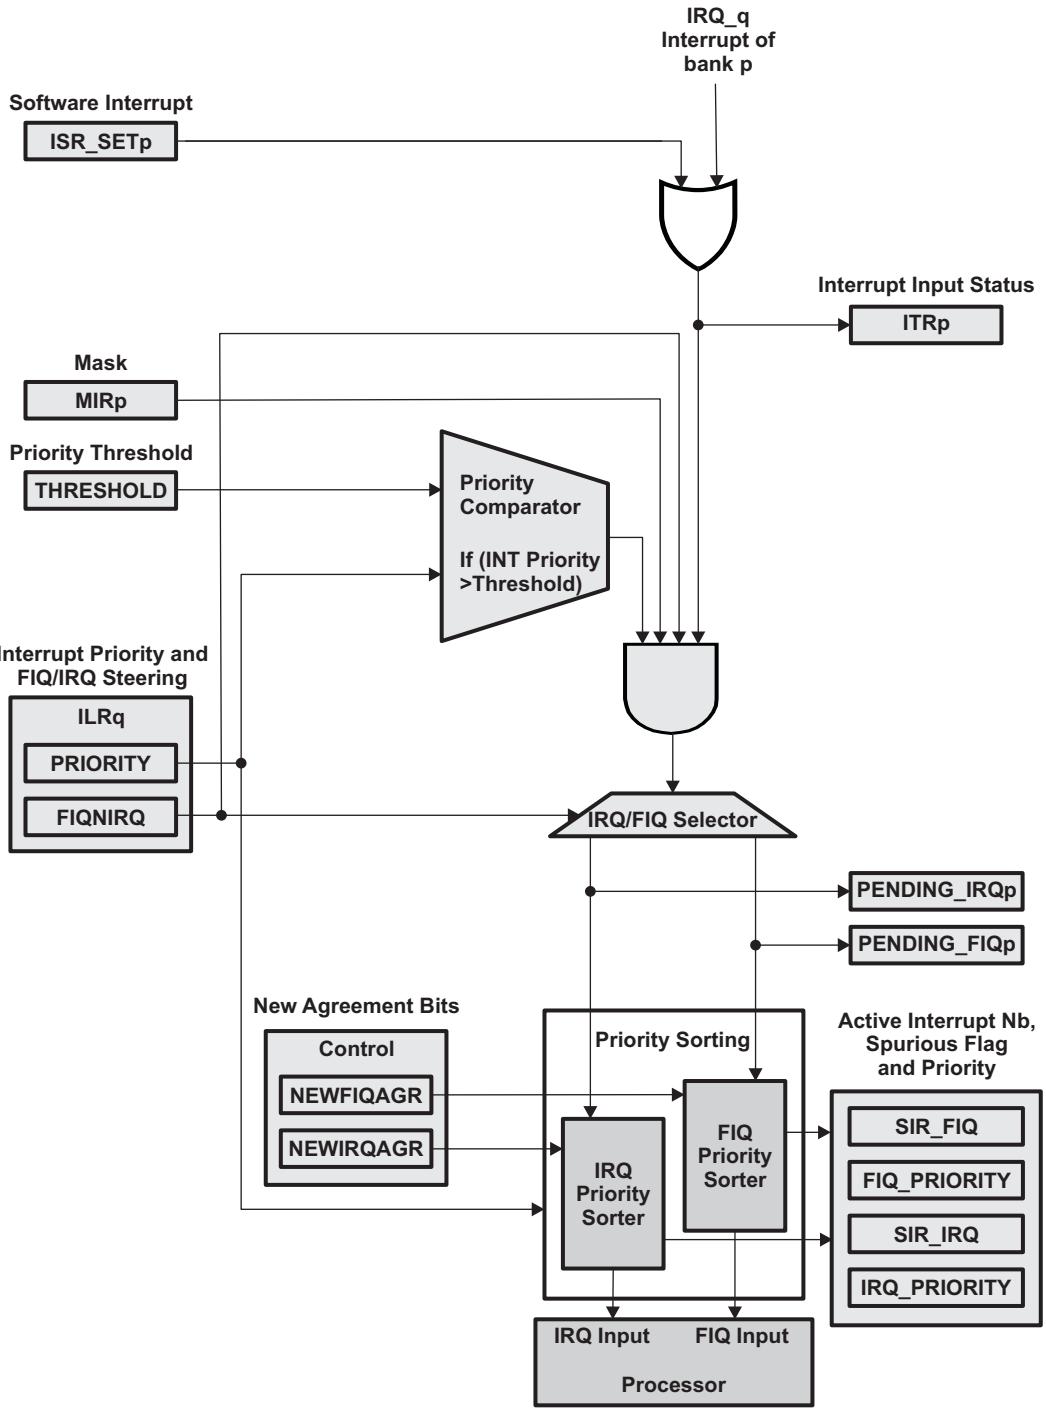
12.1.3 Environment

The sources of interrupt for AINTC are:

- External interrupts through NMI pin. Note that interrupts from external peripherals of SOC need to be routed through GPIO.
- Interrupt from peripherals inside the SOC and ARM A8.

All the unmasked interrupts can generate a wake up to the interrupt controller.

Figure 12-2. Interrupt Controller Block Diagram

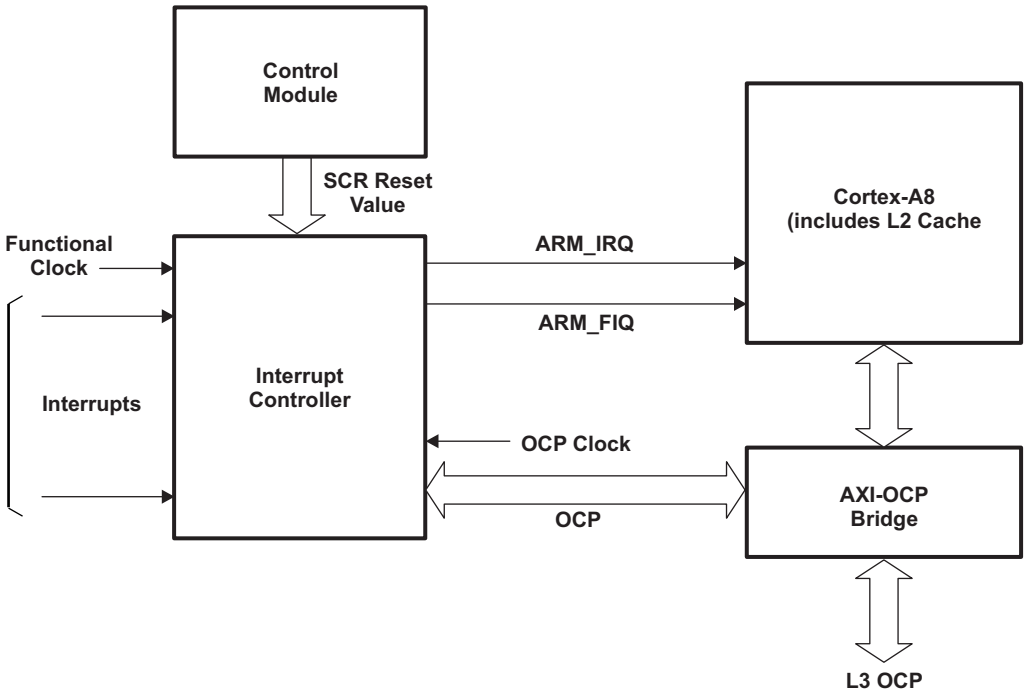


12.1.4 AINTC Integration

The ARM interrupt controller (AINTC) is the interface between the many incoming interrupts and the two interrupt inputs of the ARM A8. The two interrupts inputs to ARM are FIQ and IRQ. Figure 12-3 shows the integration of the interrupt controller in the ARM A8 subsystem.

The ARM A8 subsystem interrupt controller is directly connected to the ARM A8 by an ARM peripheral port. Consequently, the ARM A8 subsystem interrupt controller is accessible and visible only by the A8.

Figure 12-3. AINTC Integration



12.2 Architecture

This section discusses the architecture of the interrupt controller.

12.2.1 Clocking and Reset

12.2.1.1 ARM A8 Interrupt Controller Clocks

The ARM interrupt controller runs at half the rate of the ARM A8 functional clock. The interface clock, used for register access, runs at the rate of the interconnect bus clock (equal to the rate of the ARM A8 interface clock).

12.2.1.2 Hardware and Software Reset

Table 12-1 lists the ARM A8 subsystem interrupt controller resets.

Table 12-1. AINTC Resets

Type	Name	Source	Activation
Hardware	ARM A8 top-level Reset	PRCM	Active low
Software	SOFTRESET	INTCPS_SYSCONFIG[1]SOFTRESET bit, write 1 to clear. Read returns 0.	Active high

12.2.2 Interrupt Request Lines

Table 12-2 lists the incoming and outgoing interrupt lines of the AINTC.

For mapping of interrupt from various modules to the AINTC, refer to your device-specific data manual. Check availability of modules and features in a particular device. Ensure that interrupts of unavailable modules and features are masked in ARM A8 subsystem.

Table 12-2. AINTC Interrupt Inputs and Outputs

Type	Number	Name	Mapping	Comment
Interrupt request inputs	Up to 128	Refer to data manual	Refer to data manual	Inputs to AINTC module, source from various modules.
Interrupt request outputs	2	INTC_FIQ INTC_IRQ	INTC_FIQ INTC_IRQ	FIQ is fast interrupt to ARM IRQ is normal input to ARM A8

12.2.3 Interrupt Processing

12.2.3.1 Input Selection

The AINTC supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to deassert the interrupt. A software interrupt is generated if the corresponding bit in the INTCPS_ISR_SETn register is set (register bank number: n = [0,1,2,3] for the MPU subsystem interrupt controller, 128 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

12.2.3.2 Masking

12.2.3.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the AINTC can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the INTCPS_ILRm[0] FIQNIRQ bit (m= [0,127]). The current incoming interrupt status before masking is readable from the INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the INTCPS_PENDING_IRQn and INTCPS_PENDING_FIQn registers.

12.2.3.2.2 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1. PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0 and 7Fh; 0 is the highest priority and 7Fh is the lowest priority. When priority masking is not necessary, a priority threshold value of FFh disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTC.

12.2.3.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first. When one or more unmasked incoming interrupts are detected, the AINTC separates between IRQ and FIQ using the corresponding INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn. If no other interrupts are currently being processed, AINTC asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel. Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set. Once the interrupting peripheral device has been serviced and the incoming interrupt deasserted, you must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the AINTC the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the AINTC restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is deasserted.

12.2.4 Module Power Saving

The AINTC provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the INTCPS_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default. The functional clock auto-idle power-saving mode is enabled if the INTCPS_IDLE[0] FUNCIDLE bit is cleared to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the AINTC processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default. The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the INTCPS_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

12.2.5 Error Handling

The following accesses will cause error:

- Privilege violation (attempt to access PROTECTION register in user mode or any register in user mode if Protection bit is set).
- Unsupported commands.

The following will NOT cause any error response:

- Access to a non-decoded address.
- Write to a read-only register.

12.2.6 Interrupt Latency

The IRQ/FIQ interrupt generation takes four AINTC functional clock cycles (plus or minus one cycle) if the INTCPS_IDLE[1] TURBO bit is cleared to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt. These latencies can be reduced by one cycle by disabling functional clock auto-idle (INTCPS_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the INTCPS_SIR_IRQ or INTCPS_SIR_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the INTCPS_SIR_IRQ or INTCPS_SIR_FIQ register is read.

12.3 Basic Programming Model

12.3.1 Initialization Sequence

1. Program the INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNIRQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0 [highest]).
4. Program the INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

   To program the INTCPS_MIRn register, the INTCPS_MIR_SETn and INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the INTCPS_MIRn register.

12.3.2 AINTC Processing Sequence

After the INTCPS_MIRn and INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (IRQ/FIQ) are not currently asserted.
2. If the INTCPS_ILRm[0] FIQNIRQ bit is cleared to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The AINTC performs the priority sorting and updates the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ /INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field with the current interrupt number.
4. During priority sorting, if the IRQ/FIQ is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows.

   The ARM host processor automatically performs the following actions in pseudo code:

```
LR = PC + 4                    /* return link */
SPSR = CPSR                    /* Save CPSR before execution */
CPSR[5] = 0                    /* Execute in ARM state */
CPSR[7] = 1                    /* Disable IRQ */
CPSR[8] = 1                    /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit      /* Endianness on exception entry */
if interrupt == IRQ then
CPSR[4:0] = 0b10010            /* Enter IRQ mode */
if high vectors configured then
PC = 0xFFFF0018
else
PC = 0x00000018                /* execute interrupt vector */
else if interrupt == FIQ then
CPSR[4:0] = 0b10001            /* Enter FIQ mode */
CPSR[6] = 1                    /* Disable FIQ */
if high vectors configured then
PC = 0xFFFF001C
else
PC = 0x0000001C                /* execute interrupt vector */
endif
```

5. The ISR saves the remaining context, identifies the interrupt source by reading the ACTIVEIRQ/ACTIVEFIQ field, and jumps to the relevant subroutine handler as follows:

> **CAUTION**
>
> The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
 ;INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register address
INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR .word 0x48200040/0x48200044
 ; ACTIVEIRQ bit field mask to get only the bit field
ACTIVEIRQ_MASK .equ 0x7F
_IRQ_ISR/_FIQ_ISR:
 ; Save the critical context
STMFD SP!, {R0-R12, LR} ; Save working registers and the Link register
MRS R11, SPSR ; Save the SPSR into R11
 ; Get the number of the highest priority active IRQ/FIQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
 ; Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC
 ; Table of handler start addresses
.word IRQ0handler ;For IRQ0 of BANK0
.word IRQ1handler
.word IRQ2handler
```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and deasserting the interrupt condition at the peripheral side.

```
 ; IRQ0 subroutine
IRQ0handler:
 ; Save working registers
STMFD SP!, {R0-R1}
 ; Now read-modify-write the peripheral module status register
 ; to de-assert the M_IRQ_0 interrupt signal
 ; De-Assert the peripheral interrupt
MOV R0, #0x7 ; Mask for 3 flags
LDR R1, MODULE0_STATUS_REG_ADDR ; Get the address of the module Status Register
STR R0, [R1] ; Clear the 3 flags
 ; Restore working registers LDMFD SP!, {R0-R1}
 ; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end
```

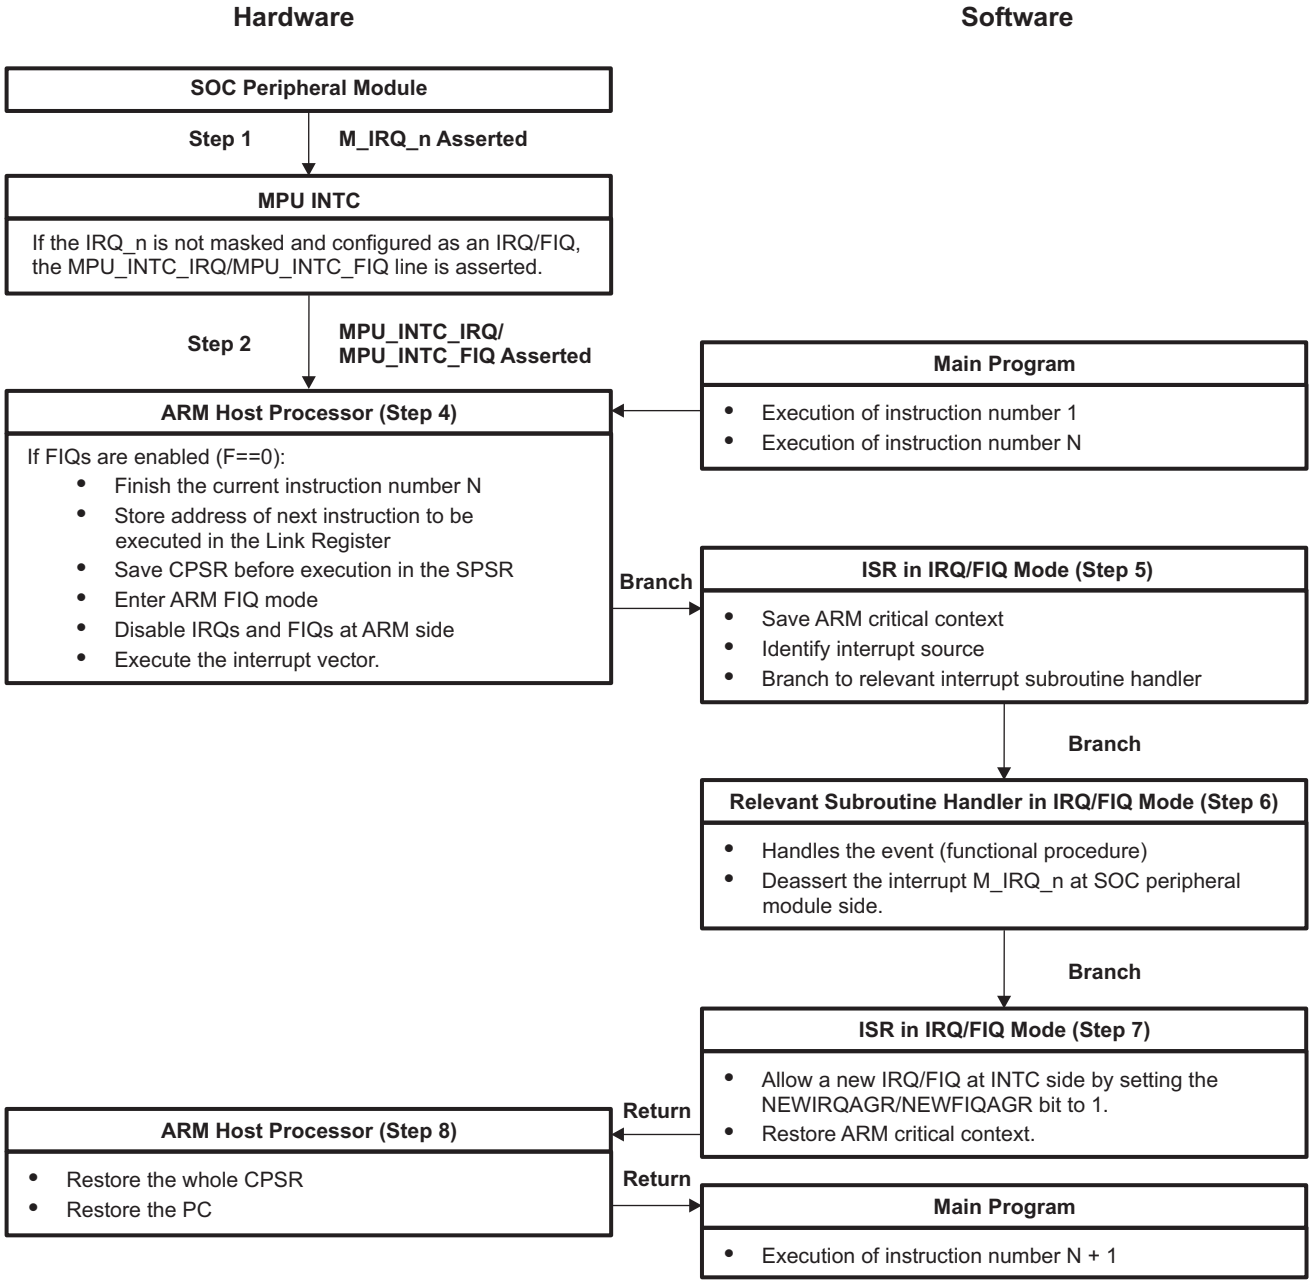
7. After the return of the subroutine, the ISR sets the NEWIRQAGR/NEWFIQAGR bit to enable the processing of subsequent pending IRQs/FIQs and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ/FIQ line is de-asserted before IRQ/FIQ enabling. After that, the AINTC processes any other pending interrupts or deasserts the IRQ/FIQ signal if there is no interrupt.

```
 ; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048;
NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02
IRQ_ISR_end/FIQ_ISR_end:
 ; Allow new IRQs/FIQs at INTC side
 ; The INTCPS_CONTROL register is a write only register so no need to write back others bits
MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQ
 ; Data Synchronization Barrier MOV R0, #0
MCR P15, #0, R0, C7, C10, #4
 ; restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and  Link register
 ; Return after handling the interrupt
SUBS PC, LR, #4
8. After the ISR return, the ARM automatically restores its context as follows:
CPSR = SPSR
PC = LR
```

Figure 12-4 shows the IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/NEWFIQAGR bit is set (priority sorting is reactivated).

Figure 12-4. IRQ/FIQ Processing Sequence



12.3.3 AINTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately. Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side. IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in the code below.

To enable IRQ/FIQ preemption by higher priority IRQs/FIQs, programers can follow this procedure to write the ISR.

At the beginning of an IRQ/FIQ ISR:

1. Save the ARM critical context registers.
2. Save the INTCPS_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the INTCPS_IRQ_PRIORITY IRQPRIORITY/INTCPS_FIQ_PRIORITY FIQPRIORITY field and write it to the PRIORITYTHRESHOLD(1) field.
4. Read the active interrupt number in the INTCPS_SIR_IRQ[6:0] ACTIVEIRQ/INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field to identify the interrupt source.
5. Write 1 to the appropriate INTCPS_CONTROL NEWIRQAGR and (2) NEWFIQAGR bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/FIQs, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/FIQ enabling.
7. Enable IRQ/FIQ at ARM side.
8. Jump to the relevant subroutine handler.

The following sample code shows the previous steps:

CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
 ; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x7F
_IRQ_ISR:
 ; Step 1 : Save the critical context
STMFD SP!, {R0-R12, LR} ; Save working registers
MRS R11, SPSR ; Save the SPSR into R11
 ; Step 2 : Save the INTCPS_THRESHOLD register into R12
LDR R0, INTCPS_THRESHOLD_ADDR
LDR R12, [R0]
(1) The priority-
threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to
0x7F. Writing a value of 0xFF (reset default) disables the priority-
threshold mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-
priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked
otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than
all IRQ priorities to maintain the relative priority of FIQ over IRQ.
(2) When handling FIQs using the priority-
threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure
that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not
have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the
source of the IRQ remains active and it is finally processed when the priority threshold falls to
a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ
Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (provided all FIQ
priorities are higher than all IRQ priorities).
 ; Step 3 : Get the priority of the highest priority active IRQ
LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ
STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register
 ; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number
 ; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit
 ; Step 6 : Data Synchronization Barrier
MOV R0, #0 MCR P15, #0, R0, C7, C10, #4
 ; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs
 ; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC
 ; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler
```

After the return of the relevant IRQ/FIQ subroutine handle:

1. Disable IRQs/FIQs at ARM side.
2. Restore the INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The following sample code shows the three previous steps:

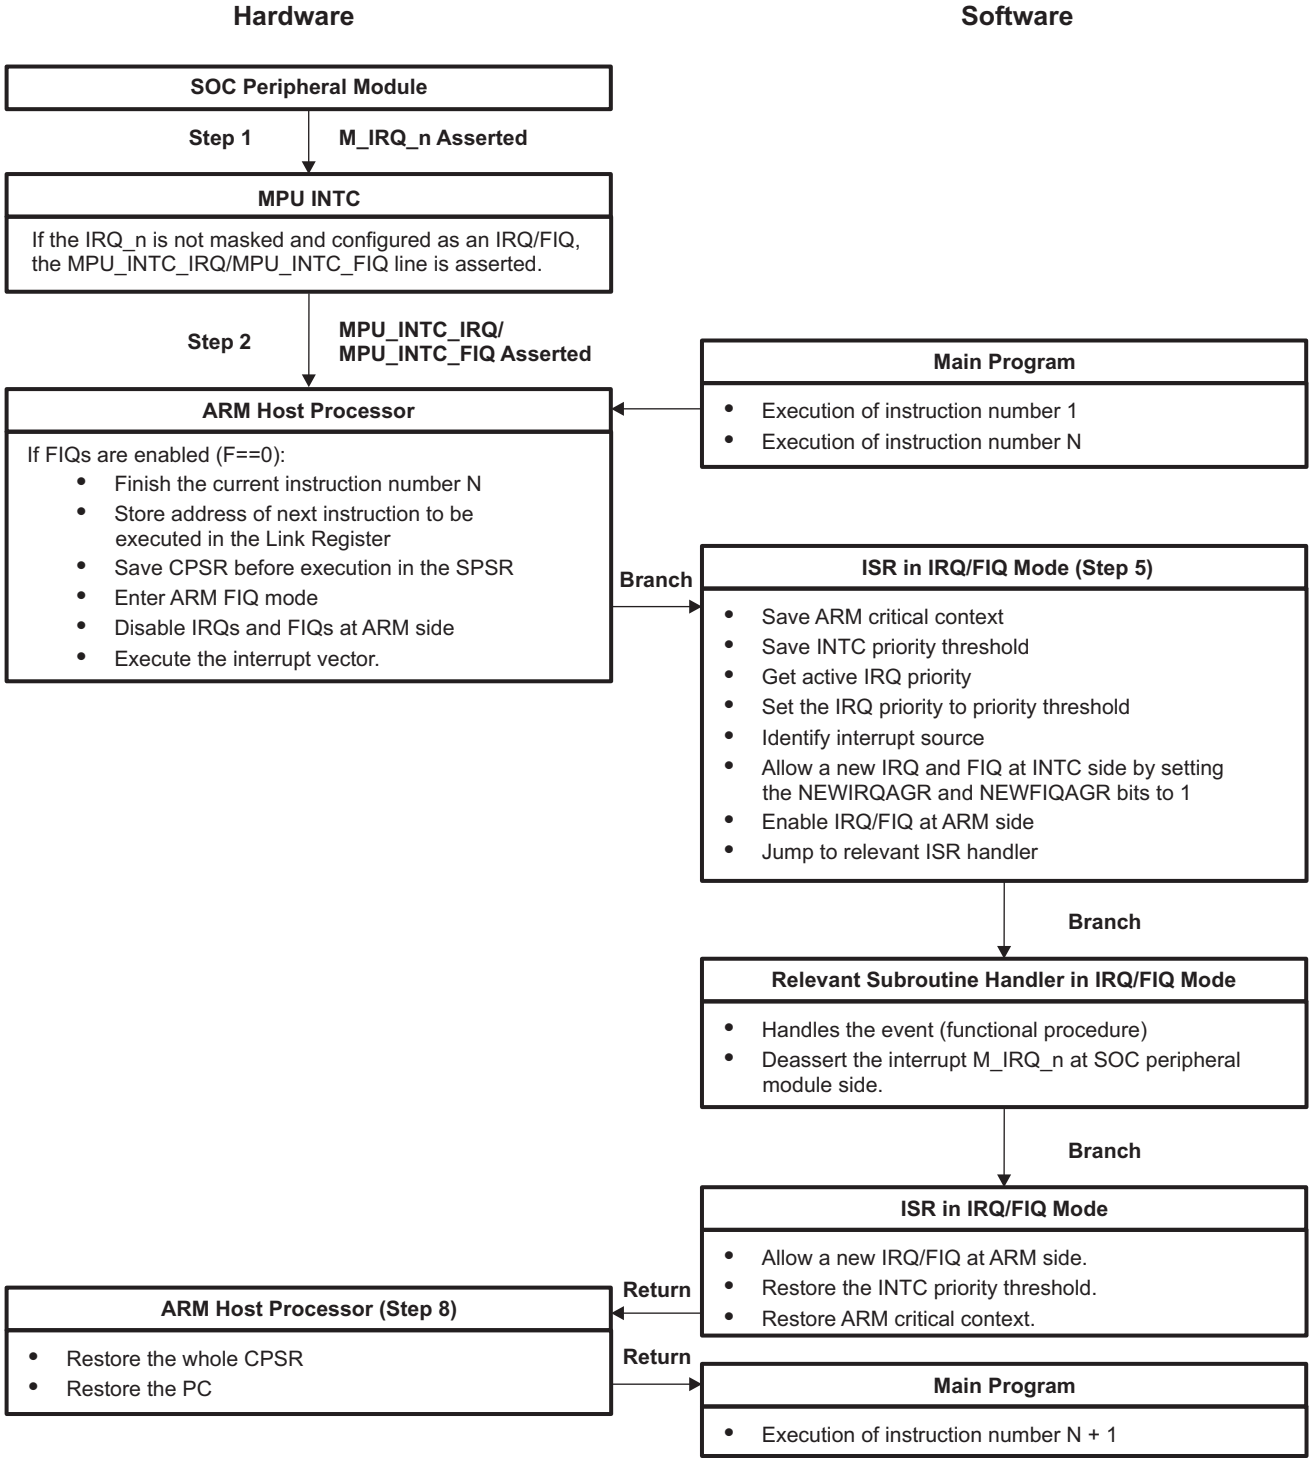
CAUTION

The following code is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```
IRQ_ISR_end:
 ; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the CPSR
ORR R0, R0, #0x80/0x40 ; Set the I/F bit
MSR CPSR, R0 ; Write it back to disable IRQs
 ; Step 2 : Restore the INTCPS_THRESHOLD register from R12
LDR R0, INTCPS_THRESHOLD_ADDR
STR R12, [R0]
 ; Step 3 : Restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register
 ; Return after handling the interrupt
SUBS PC, LR, #4
```

Figure 12-5 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

Figure 12-5. Nested IRQ/FIQ Processing Sequence



12.3.4 Interrupt Preemption

If wanting to enable pre-emption by higher priority interrupts, the ISR should read the active interrupt priority and write it to the priority threshold register. Writing a '1' to the appropriate NEW_IRQ_AGR or NEW_FIQ_AGR bits of the CONTROL register while still processing the interrupt will now allow only higher priority interrupts to pre-empt.

For each level of pre-emption, the programmer must save the threshold value before modifying it and restore it at the end of that ISR level.

The priority threshold mechanism is enabled automatically when writing a priority in the range of 0 to 7Fh as will be read from the IRQ_PRIORITY and FIQ_PRIORITY registers. Writing a value of FFh (reset default) disables the priority threshold mechanism.

When the hardware priority threshold is in use the priorities of interrupts selected as FIQ or IRQ become linked, otherwise they are independent. When linked, it is required that all FIQ priorities be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.

When handling FIQs using the priority threshold mechanism, it is required to write both New FIQ Agreement and New IRQ Agreement bits at the same time to cover the case that the new priority threshold is applied while an IRQ sorting is in progress. This IRQ will not have been seen by the ARM as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ will remain active and it will be finally processed when the priority threshold falls to a low enough priority. The precaution of writing to New FIQ Agreement (as well as New IRQ Agreement) is not required during an IRQ ISR as FIQ sorting will not be affected (provided all FIQ priorities are higher than all IRQ priorities).

12.3.5 AINTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 AINTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the INTCPS_MIRn, INTCPS_ILRm, or INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. Only the active interrupt input that triggered the sort can be masked before it turn on the sort. If these registers are changed within the 10-cycle window after the interrupt assertion. The resulting values of the following registers become invalid:

- INTCPS_SIR_IRQ
- INTCPS_SIR_FIQ
- INTCPS_IRQ_PRIORITY
- INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see NOTE 1) and SPURIOUSFIQFLAG (see NOTE 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG bit field is a copy of the INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG bit field.
2. The INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG bit field is a copy of the INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG bit field.

12.4 AINTC Registers

If the INTCPS_PROTECTION[0] PROTECTION bit is set, access to the AINTC registers is restricted to the supervisor mode. Access to the INTCPS_PROTECTION register is always restricted to privileged mode.

Each register from INTCPS_ITRn to INTCPS_PENDING_FIQn contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the INTCPS_ITR0 register applies to interrupt line 0; bit 0 of the INTCPS_ITR1 register applies to interrupt line 32).

CAUTION

The AINTC registers are limited to 32-bit and 16-bit data accesses; 8-bit data access is not allowed and can corrupt the register content.

Table 12-3 lists the memory-mapped registers for the AINTC. For the base address of these registers, see Table 1-15.

Secure Digital (SD)/ Secure Digital I/O (SDIO) Card Interface

This chapter describes the secure digital/secure digital I/O (SD/SDIO) card interface.

Topic **Page**

13.1 Introduction

13.1.1 Overview

This device contains a secure data/secure digital I/O (SD/SDIO) host controller that provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either SD memory cards, or SDIO cards and handles SD/SDIO transactions with minimal LH intervention.

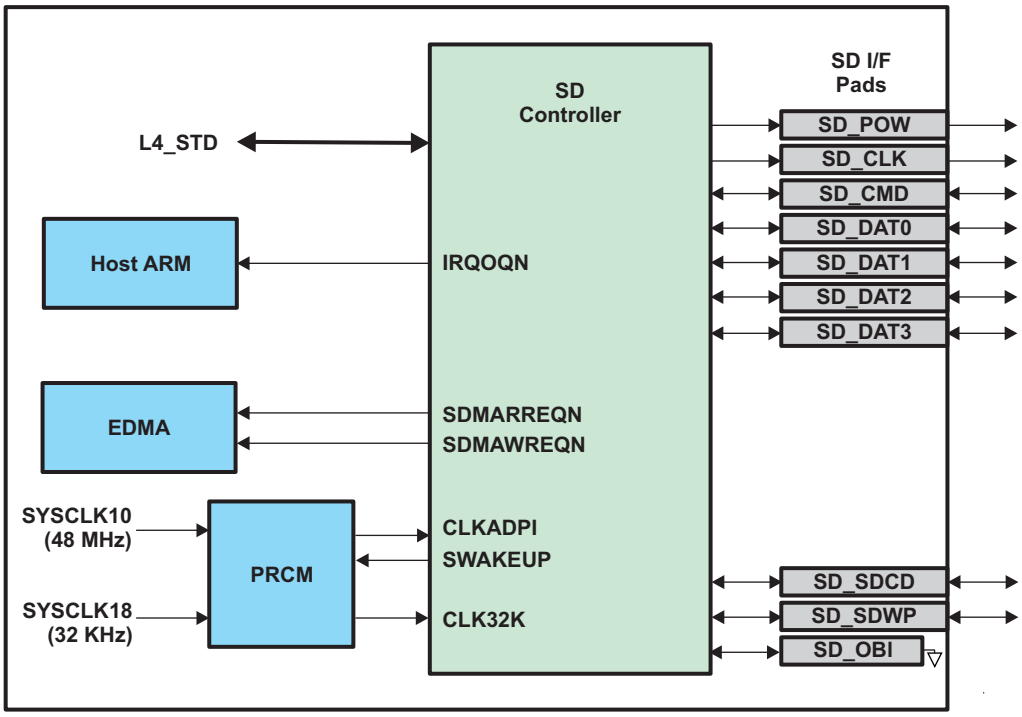
The application interface manages transaction semantics. The SD/SDIO host controller deals with SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The SD/SDIO host controller also supports two DMA channels.

Figure 13-1 gives an overview of the SD/SDIO1 controller instance.

Figure 13-1. SD/SDIO1 Overview



13.1.2 Features

The main features of the SD/SDIO host controller are:

- Built-in 1024-byte buffer for read or write
- Full compliance with SD command/response sets as defined in the *SD Physical Layer Specification*, v2.00.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*
- Flexible architecture allowing support for new command structure
- Support:
  - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
  - 3.3v cards
  - Built-in 1024-byte buffer for read or write
  - 32-bit-wide access bus to maximize bus throughput
  - Single interrupt line for multiple interrupt source events
  - Two slave DMA channels (1 for TX, 1 for RX)
  - Programmable clock generation
  - SDIO Read Wait and Suspend/Resume functions
  - Stop at block gap
  - SDA 2.0 Part A2 programming model
- Supported Data Rates
  - 96MHz functional clock source input
  - Up to 192Mbit/sec (24MByte/sec) in High-Speed SD mode 4-bit data transfer
  - Up to 24Mbit/sec (3MByte/sec) in Default SD mode 1-bit data transfer

13.2 Architecture

One SD/SDIO host controller can support one SD card, or one SDIO card.

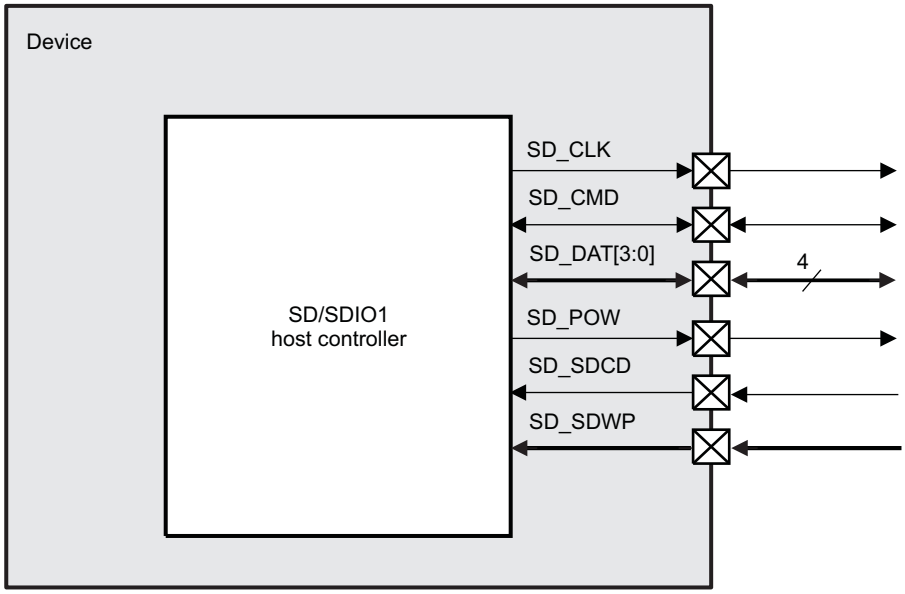
Other combinations (for example, two SD cards) are not supported through a single controller.

13.2.1 SD/SDIO Functional Modes

13.2.1.1 SD/SDIO Connected to an SD Card, or an SDIO Card

Figure 13-2 shows the SD/SDIO1 host controller connected to an SD or SDIO card and its related external connections.

Figure 13-2. SD1 Connectivity to an SD Card



The following SD/SDIO controller pins are used

- **SD_CLK** This pin provides the clock to the memory card from the SD controller.
- **SD_CMD** This pin is used for two-way communication between the connected card and the SD/SDIO controller. The SD/SDIO controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **SD_DAT3-0** Depending on the type of card you are using, you may need to connect 1 or 4 data lines. The number of DAT pins (the data bus width) is set by the Data Transfer Width (DTW) bit in the control register (SD_HCTL).
- **SD_POW** Used for SD card's cards on/off power supply control. When high, denotes power-on condition.
- **SD_SDCD** This input pin serves as the SD/SDIO carrier detect. This signal is received from a mechanical switch on the slot.
- **SD_SDWP** This input pin is used for the SD/SDIO card's write protect. This signal is received from a mechanical protect switch on the slot (system dependant). Applicable only for SD and SDIO cards that have a mechanical sliding tablet on the side of the card.

  Note: The SD_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

Table 13-1 provides a summary of these pins.

Table 13-1. SD/SDIO Controller Pins and Descriptions

Pin	Type	1-Bit Mode	4-Bit Mode
SD_CLK[1]	O	Clock Line	Clock Line
SD_CMD	I/O	Command Line	Command Line
SD_DAT0	I/O	Data Line 0	Data Line 0
SD_DAT1	I/O	(not used)	Data Line 1
SD_DAT2	I/O	(not used)	Data Line 2
SD_DAT3	I/O	(not used)	Data Line 3
SD_POW	O	SD Card Power Output Enable	SD Card Power Output Enable
SD_SDCD	I	SD Card Detect	SD Card Detect
SD_SDWP	I	SD Card Write Protect	SD Card Write Protect

(1) The SD_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

13.2.1.2 Protocol and Data Format

The bus protocol between the SD/SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the SD/SDIO host controller to the card on the SD_CMD line.

Response: A response is an answer to a command. The response is sent from the card to the SD/SDIO host controller. It is transferred serially on the SD_CMD line.

Data: Data are transferred from the SD/SDIO host controller to the card or from a card to the SD/SDIO host controller using the DATA lines.

Busy: The SD_DAT0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the SD_DAT0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on SD_DAT0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on SD_DAT0 and starts the data programming procedure.

13.2.1.2.1 Protocol

The SD/SDIO interface only supports block-oriented operation.

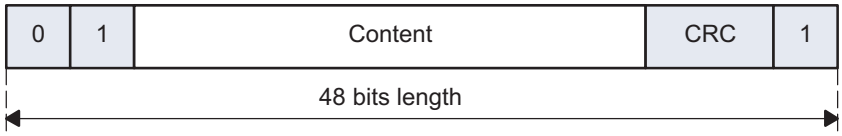
There are specific commands for block-oriented operation. See the *SD Memory Card Specifications* and the *SDIO Card Specification, Part E1* for details about commands and programming sequences supported by the SD and SDIO cards.

13.2.1.2.2 Data Format

Coding Scheme for Command Token

Command packets always start with 0 and end with 1. The second bit is a transmitter bit1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 13-3).

Figure 13-3. Command Token Format



Coding Scheme for Response Token

Response packets always start with 0 and end with a 1. The second bit is a transmitter bit0 for a card response. The content is different for each type of response (R1, R2, R3, R4, R5, and R6) and the content is protected by 7-bit CRC checksum. Depending on the type of commands sent to the card, the SD_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 13-2). For more details about response types, see the *SD Memory Card Specification*, or the *SDIO Card Specification*.

Figure 13-4 and Figure 13-5 depict the 48-bit and 136-bit response packets, respectively.

Table 13-2. Response Type Summary(1)

Response Type SD_CMD[17:16] RSP_TYPE	Index Check Enable SD_CMD[20] CICE	CRC Check Enable SD_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5 (R7 for SD cards)
11	1	1	R1b, R5b

(1) The SD/SDIO host controller assumes that both clocks may be switched off, whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Figure 13-4. 48-Bit Response Packet (R1, R3, R4, R5, R6)

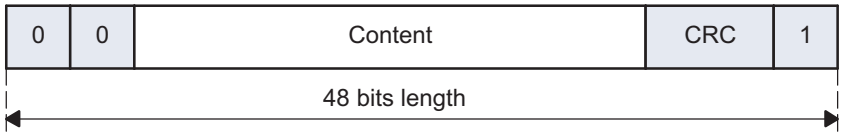


Figure 13-5. 136-Bit Response Packet (R2)

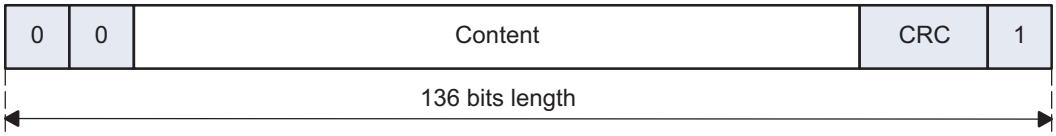

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 13-6, Figure 13-7, Figure 13-8).

Figure 13-6. Data Packet for Sequential Transfer (1-Bit)

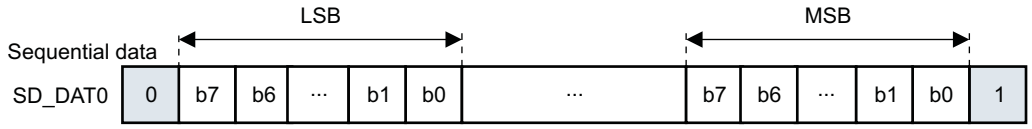

Figure 13-7. Data Packet for Block Transfer (1-Bit)

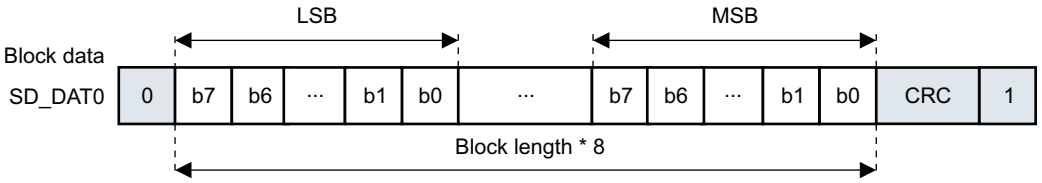

Figure 13-8. Data Packet for Block Transfer (4-Bit)

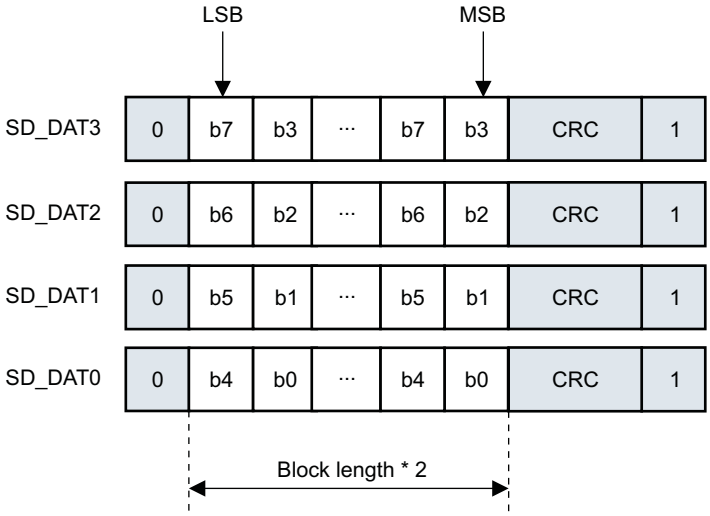


13.2.2 Resets

13.2.2.1 Hardware Reset

The module is reinitialized by the hardware.

The SD_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset in all clock domains.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

13.2.2.2 Software Reset

The module is reinitialized by software through the SD_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal except for:

- Debounce logic
- SD_PSTATE, SD_CAPA, and SD_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The SD_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The SD_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- SD_SYSCTL[26] SRD bit
- SD_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The SD_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The SD_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

NOTE: If **any** of the clock inputs are not present for the SD/SDIO peripheral, the software reset will not complete.

13.2.3 Power Management

The SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The SD/SDIO host controller is compliant with the PRCM module handshake protocol. When the SD/SDIO power domain is off, the only way to wake up the power domain and different SD/SDIO clocks is to monitor the SD_DAT1 input pin state via a different GPIO line for each SD/SDIO interface.

13.2.3.1 Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The SD_SYSCONFIG[0] AUTOIDLE bit is set to 1.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L3 (or L4) interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the SD/SDIO interface starts.

Then the SD/SDIO host controller enters in low-power state even if SD_SYSCONFIG[0] AUTOIDLE is cleared to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

13.2.3.2 Idle Mode

The clocks provided to SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request. The SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager

- Idle acknowledgment from the SD/SDIO host controller
- Wake-up request from the SD/SDIO host controller

The idle acknowledgment varies according to the SD_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0: Force-idle mode. The SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 1h: No-idle mode. The SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 2h: Smart-idle mode. The SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 3h: Smart-idle wake-up-capable mode. The SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in idle state (related to IRQ or DMA requests)

During the smart-idle mode period, the SD/SDIO host controller acknowledges that the OCP and Functional clocks may be switched off whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY field.

13.2.3.3 Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is set to 2h or 3h. The SD/SDIO host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity. The SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the SD_dat1 signal.

As long as the SD/SDIO controller does not acknowledge the idle request, if an event occurs, the SD/SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the SD/SDIO controller acknowledges the idle request from the PRCM:

- If Smart-Idle mode, the module does not assert any new interrupt or DMA request
- If Smart-Idle wake-up-capable mode, the module may generate wake-up events related to interrupt or DMA request.

13.2.3.4 Transition from Smart-Idle Mode to Normal Mode

The SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request. For the wake-up event, there is a corresponding interrupt status in the SD_STAT register. The SD/SDIO host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the SD_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SD_HCTL and SD_ISE registers. The overall consistency must be ensured by software.

The interrupt status register SD_STAT is updated with the event that caused the wake-up in the CIRQ bit when the SD_IE[8] CIRQ_ENABLE associated bit is enabled. Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The SD_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

13.2.3.5 Force-Idle Mode

Force-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is cleared to 0. Force-idle mode is an idle mode where the SD/SDIO host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the SD/SDIO host controller unconditionally deasserts interrupts and DMA request lines are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the SD_STAT register. In force-idle mode, the interrupt and DMA request lines are deasserted. Interface Clock (OCP) and functional clock (CLKADPI) can be switched off.

CAUTION

In Force-ilde mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the OCP clock is alive.

The module exits the force-idle mode when the PRCM deassertes the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

13.2.3.6 Local Power Management

Table 13-3 describes power-management features available for the SD/SDIO modules.

Table 13-3. Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	SD_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside module, by gating the OCP clock upon the interface activity or gating the CLKADPI clock upon the internal activity.
Slave Idle Modes	SD_SYSCONFIG SIDLEMODE bit	Force-idle, No-idle, and Smart-idle modes
Clock Activity	SD_SYSCONFIG CLOCKACTIVITY bit	See Table 13-4 for configuration details.
Master Standby Modes	SD_SYSCONFIG STANDBYMODE bit	Force-idle, No-idle, and Smart-idle modes
Global Wake-Up Enable	SD_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-Up Sources Enable	SD_HCTL register	This register holds one active high enable bit per event source able to generate wake-up signal.

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and clock PRCM control bits.

Table 13-4. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available when Module is in IDLE State	Wake-Up Events
	OCP Clock	CLKADPI		
00	OFF	OFF	None	Card Interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

13.2.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the SD_STAT register; it indicates which service is required.
- The interrupt status enable bits of the SD_IE register enable/disable the automatic update of the SD_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the SD_ISE register enable/disable the transmission of an interrupt request on the interrupt line IRQ (from the SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the SD_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the SD_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1 (the SD/SDIO host controller updates the status bit) in the SD_STAT register. If later a mask is applied on the interrupt in the SD_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the SD_STAT register and the corresponding mask is removed from the SD_ISE register, the interrupt status is not asserted again in the SD_STAT register and the SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the SD_STAT register, and the corresponding mask is removed, then the SD/SDIOi host controller will wait for the service of the interrupt without updating the status SD_STAT or transmitting an interrupt request.

Table 13-5 lists the event flags, and their mask, that can cause module interrupts.

Table 13-5. Events

Event Flag	Event Mask	Map To	Description
SD_STAT[29] BADA	SD_IE[29] BADA_ENABLE	IRQ	Bad Access to Data space. This bit is set automatically to indicate a bad access to buffer when not allowed. This bit is set during a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_STATE[10] BWE = 0)
SD_STAT[28] CERR	SD_IE[28] CERR_ENABLE	IRQ	Card Error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response errros SD_CSRE is set. There is not card detection for auto CMD12 command.
SD_STAT[25] ADMAE	SD_IE[25] ADMAE_ENABLE	IRQ	AMDA error. This bit is set when the host controller detects errors during ADMA based data transfer. The stat of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid = 0) at teh ST_FDS state.
SD_STAT[24] ACE	SD_IE[24] ACE_ENABLE	IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1
SD_STAT[22] DEB	SD_IE[22] DEB_ENABLE	IRQ	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.
SD_STAT[21] DCRC	SD_IE[21] DCRC_ENABLE	IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.

Table 13-5. Events (continued)

Event Flag	Event Mask	Map To	Description
SD_STAT[20] DTO	SD_IE[20] DTO_ENABLE	IRQ	Data Timeout error. This bit is set automatically according to the following conditions: A) busy timeout for R1b, R5b response. B) busy timeout after write CRC status. C) write CRC status timeout, or D) read data timeout.
SD_STAT[19] CIE	SD_IE[19] CIE_ENABLE	IRQ	Command Index Error. This bit is set automatically when response index differs from corresponding command index previously emitted. The check is enabled through SD_CMD[20] CICE bit.
SD_STAT[18] CEB	SD_IE[18] CEB_ENABLE	IRQ	Command End Bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
SD_STAT[17] CCRC	SD_IE[17] CCRC_ENABLE	IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the SD_CMD[19] CCCE bit.
SD_STAT[16] CTO	SD_IE[16] CTO_ENABLE	IRQ	Command Timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands the reply within 5 clock cycles, the timeout is still detected at 64 clock cycles.
SD_STAT[15] ERRI	SD_IE[15] ERRI_ENABLE	IRQ	Error Interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[24:15]) are set, the this bit is set to 1.
SD_STAT[10] BSR	SD_IE[10] BSR_ENABLE	IRQ	Boot Status Received interrupt. This bit is set automatically when SD_CON[18] BOOT_CF0 is set to 1 or 2h and boot status is received on the dat0 line.
SD_STAT[8] CIRQ	SD_IE[8] CIRQ_ENABLE	IRQ	Card Interrupt. This bit is only used for SD, SDIO, and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drive CMD line to zero during one cycle after data transmission end.
SD_STAT[5] BRR	SD_IE[5] BRR_ENABLE	IRQ	Buffer Read ready. This bit is set automatically during a read operation to the card when one block specified by SD_BLK[10:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffger and the local host needs to empty the buffer by reading it.
SD_STAT[4] BWR	SD_IE[4] BWR_ENABLE	IRQ	Buffer Write ready. This bit is automatically set during a write operation to the card when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the bugger and the local host is able to write one block of data into the buffer.
SD_STAT[3] DMA	SD_IE[3] DMA_ENABLE	IRQ	DMA interrupt. This status is set when an interrupt is required in the AMDA instruction and after the data transfer is complete.
SD_STAT[2] BGE	SD_IE[2] BGE_ENABLE	IRQ	Block Gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
SD_STAT[1] TC	SD_IE[1] TC_ENABLE	IRQ	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap requested (SD_HCTL[16 SBGR). In read mode, this bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA). In write mode, this bit is automatically set on completion of the DAT line use (SD_PSTATE[2] DLA).
SD_STAT[0] CC	SD_IE[0] CC_ENABLE	IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO) has higher priority than command complete (SD_STAT[0] CC). If a response is expected but none is received, the a Command Timeout error is detected and signaled instead of the Command Complete interrupt.

13.2.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the SD_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the SD_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the SD_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the SD_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The SD_STAT[8] CIRQ status bit must be masked by disabling the SD_IE[8] CIRQ_ENABLE bit (cleared to 0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR).

The SD_STAT[15] ERRI bit is automatically cleared when all status bits in SD_STAT[31:16] are cleared.

13.2.4.2 Polling

When the interrupt capability of an event is disabled in the SD_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the SD_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the SD_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the note in Section 13.2.4.1 concerning CIRQ and ERRI bits clearing.

13.2.5 DMA Modes

The device supports DMA slave mode only. In this case, the controller is slave on DMA transaction managed by two separated requests (SDMAWREQN and SDMARREQN)

13.2.5.1 DMA Slave Mode Operations

The SD/SDIO controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host (LH) of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification*and *SD Host Controller Standard Specification*.

The DMA request is issued if the following conditions are met:

- The SD_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the SD_cmd line.
- There is enough space in the buffer of the SD/SDIO controller to write an entire block (BLEN writes).

13.2.5.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal SDMARREQN is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMARREQN signal is deasserted to its inactive level when the sDMA has read one single word from the buffer. Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

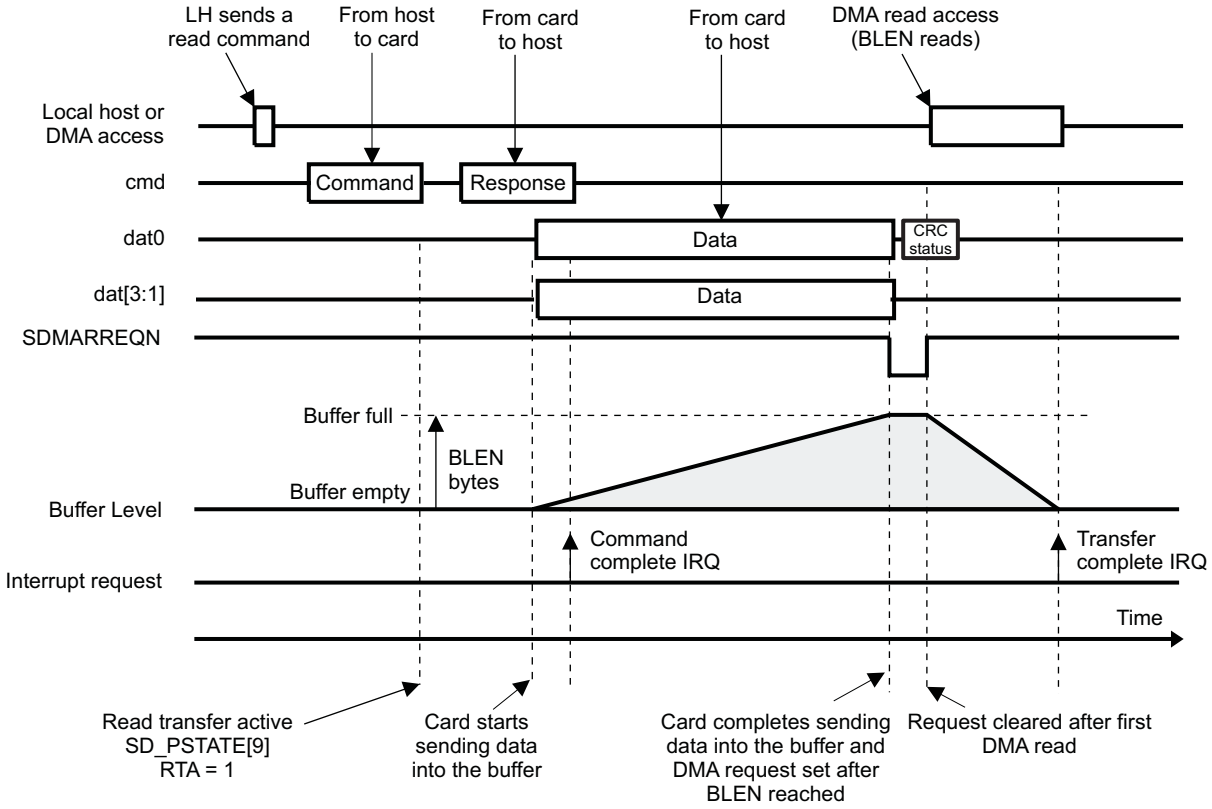
New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the CLK clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Figure 13-9 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 13-9. DMA Receive Mode



13.2.5.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal SDMAWREQN is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMAWREQN signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

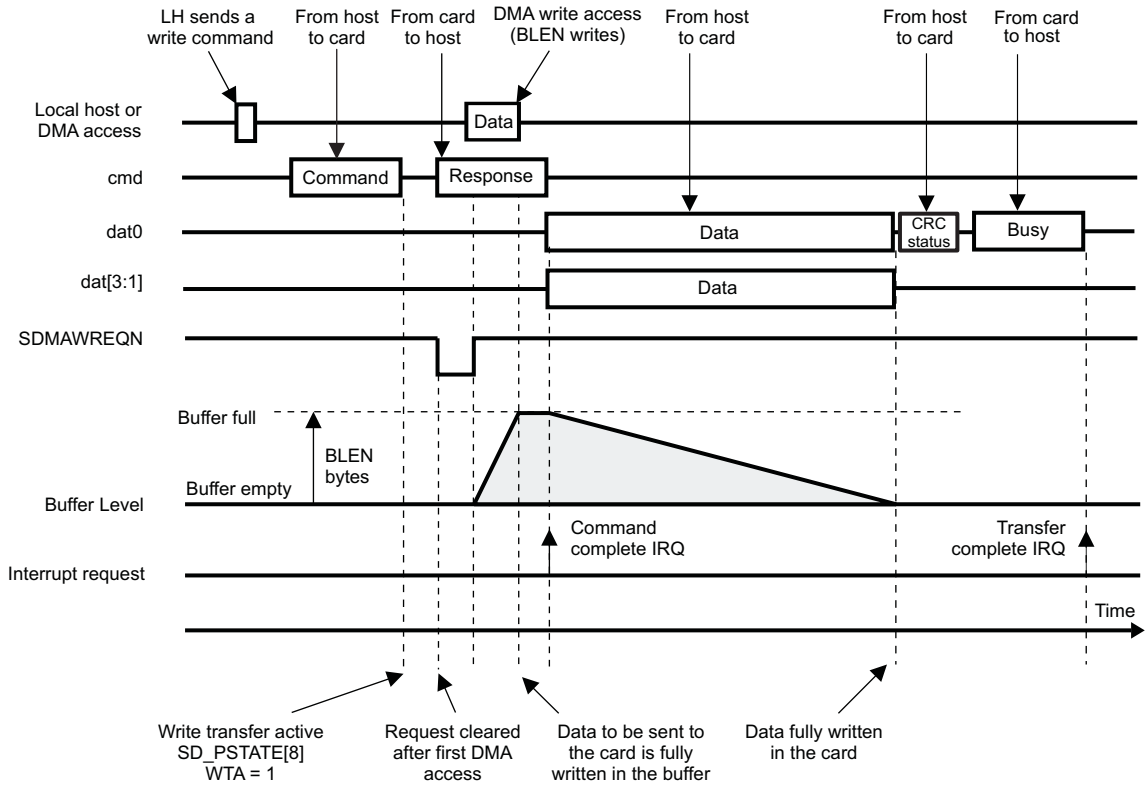
Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1) and if there is not enough memory space to write a complete block in the buffer.

Figure 13-10 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 13-10. DMA Transmit Mode



13.2.6 Buffer Management

13.2.6.1 Data Buffer

The SD/SDIO host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD or SDIO card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card). To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, the prefetch buffer, and the post-write buffer is the 32-bit register SD_DATA. A write access to the SD_DATA register followed by a read access from the SD_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the SD_DATA register and the data of the read access to the SD_DATA register are different.

The number of 32-bit accesses to the SD_DATA register that are needed to read (or write) a data block with a size of SD_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4. The maximum block size supported by the host controller is hard-coded in the register SD_CAPA[17:16] MBL field and cannot be changed.

A read access to the SD_DATA register is allowed only when the buffer read enable status is set to 1 (SD_PSTATE[11] BRE); otherwise, a bad access (SD_STAT[29] BADA) is signaled.

A write access to the SD_DATA register is allowed only when the buffer write enable status is set to 1 (SD_PSTATE[10] BWE); otherwise, a bad access (SD_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double buffering), two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The SD/SDIO controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than or equal to 200h (that is, less or equal to 512Bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32-bits x BLEN div by 4). Not more than this total size of 2 times 32-bits × BLEN div by 4 can be used.
- When the size of the data block to transfer is larger than MEM_SIZE/2, only one data transfer can occur from one data bus to the other data bus at a time. The SD/SDIO host controller uses the entire data buffer as a single portion. In this mode, a bad access (SD_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

CAUTION

The SD_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 13-11 shows the buffer management for writing and Figure 13-12 shows the buffer management for reading.

Figure 13-11. Buffer Management for a Write

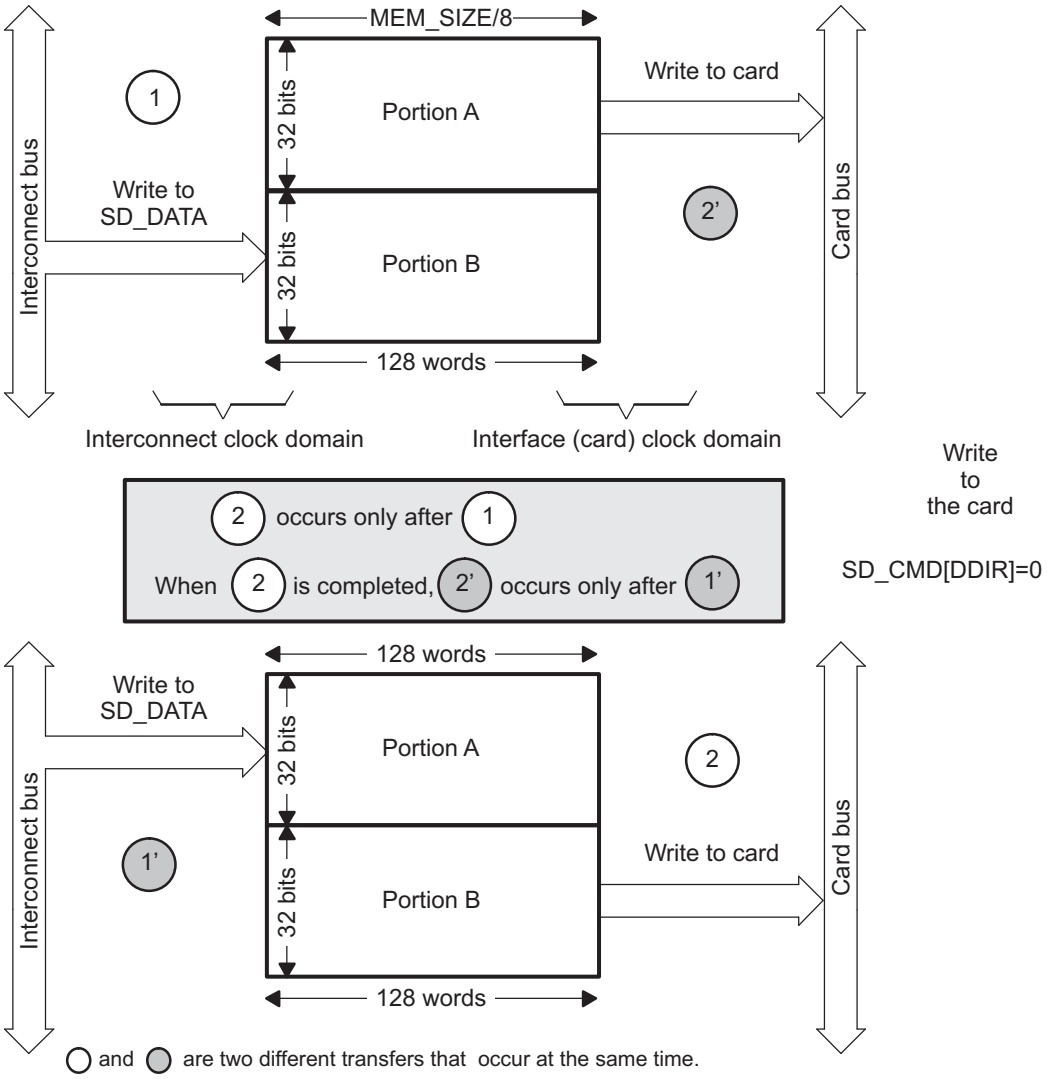


Figure 13-12. Buffer Management for a Read

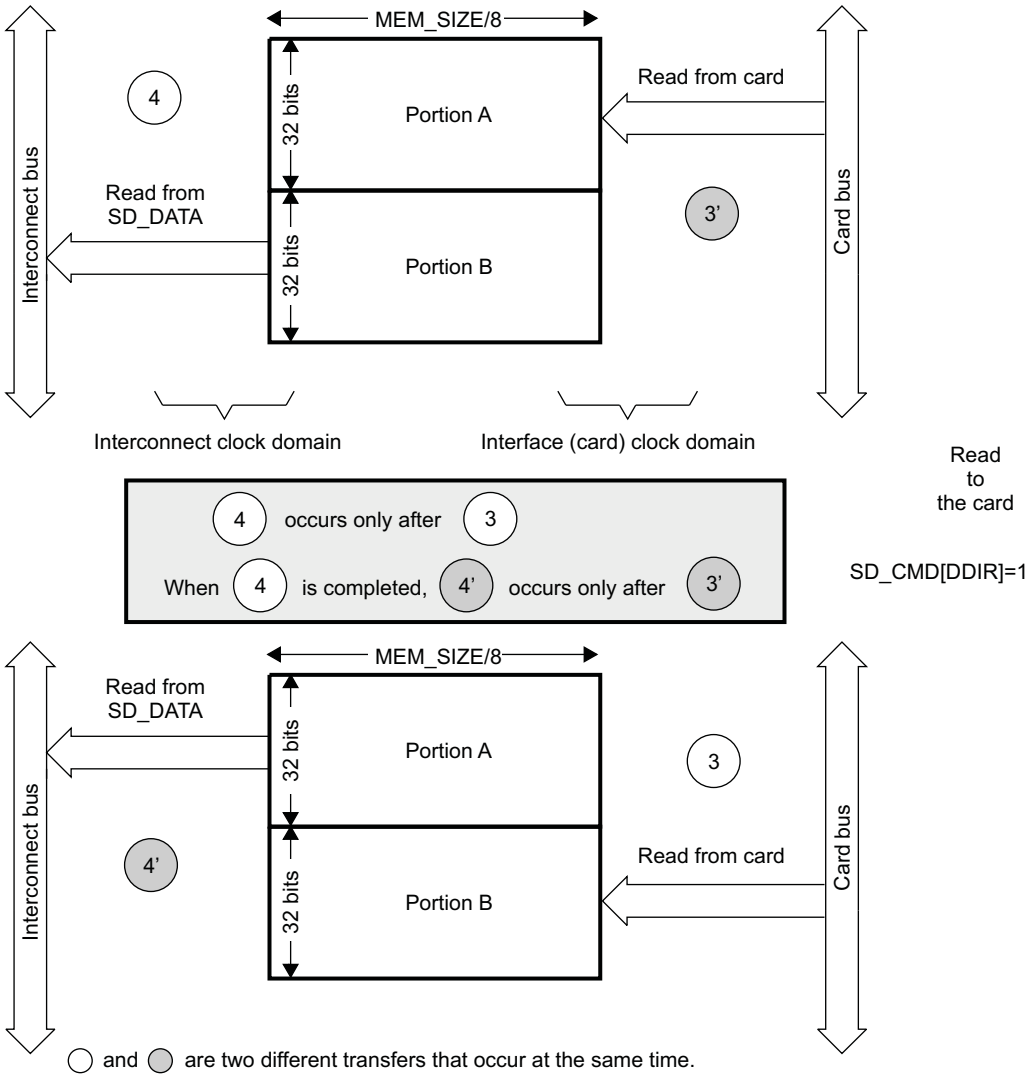


13.2.6.1.1 Memory Size, Block Length, and Buffer Management Relationship

The maximum block length and buffer management that can be targeted by a system depends on memory depth setting (see Table 13-6).

Table 13-6. Memory Size, BLEN, and Buffer Relationship

Memory Size([5:2] MEMSIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN <= 512	BLEN <= 1024	BLEN <= 2048
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024	1024 < BLEN <= 2048	N/A

13.2.6.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Figure 13-50):
  - SD_STAT[29] BADABad access to data space
  - SD_STAT[5] BRRBuffer read ready
  - SD_STAT[4] BWRBuffer write ready
- Status registers (see Figure 13-47):
  - SD_PSTATE[11] BREBuffer read enable
  - SD_PSTATE[10] BWEBuffer write enable

13.2.7 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

13.2.7.1 Different Types of Commands

Different types of commands are specific to SD or SDIO cards. See the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

13.2.7.2 Different Types of Responses

Different types of responses are specific to SD, or SDIO cards. See the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

Table 13-7 shows how the SD and SDIO responses are stored in the SD_RSPxx registers.

When the host controller modifies part of the SD_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the SD_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in SD_RSP10 register and vice versa.

Table 13-7. SD and SDIO Responses in the SD_RSPxx Registers

Kind of Response	Response Field[1]	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8]	SD_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8]	SD_RSP76[31:0]
R2	RESP[127:0]	SD_RSP76[31:0]
		SD_RSP54[31:0]
		SD_RSP32[31:0]
		SD_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned above.

13.2.8 Transfer or Command Status and Error Reporting

Flags in the SD/SDIO host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 13-8 and register description for more details.

Table 13-8. CC and TC Values Upon Error Detected

Error hold in the SD_STAT Register		CC	TC	Comments
29	BADA			No dependency with CC or TC. BADA is related to the register accesses. Its assertion is not dependent of the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC bit indicates a command abort due to a contention on CMD line. In this case no CC appears.

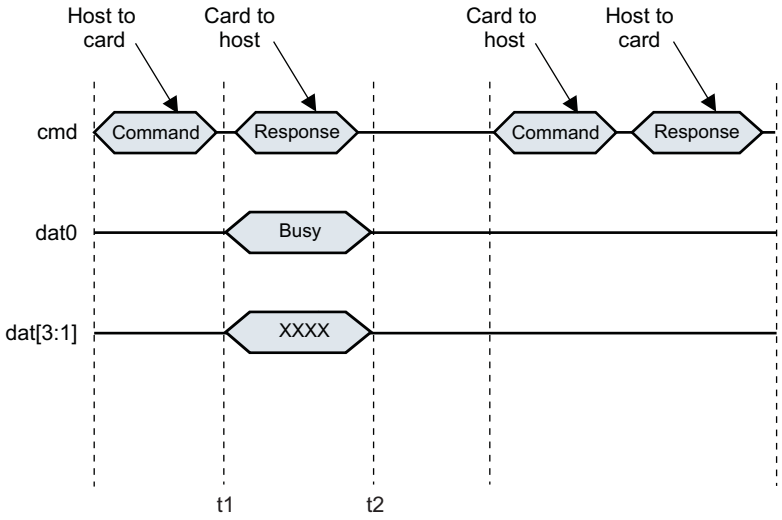
SD_STAT[21] DCRC event can be asserted in the following conditions:

- Busy timeout for R1b, R5b response type
- Busy timeout after write CRC status
- Write CRC status timeout
- Read data timeout
- Boot acknowledge timeout

13.2.8.1 Busy Timeout for R1b, R5b Response Type

Figure 13-13 shows DCRD event condition asserted when there is a busy timeout for R1b or R5b responses.

Figure 13-13. Busy Timeout for R1b, R5b Responses



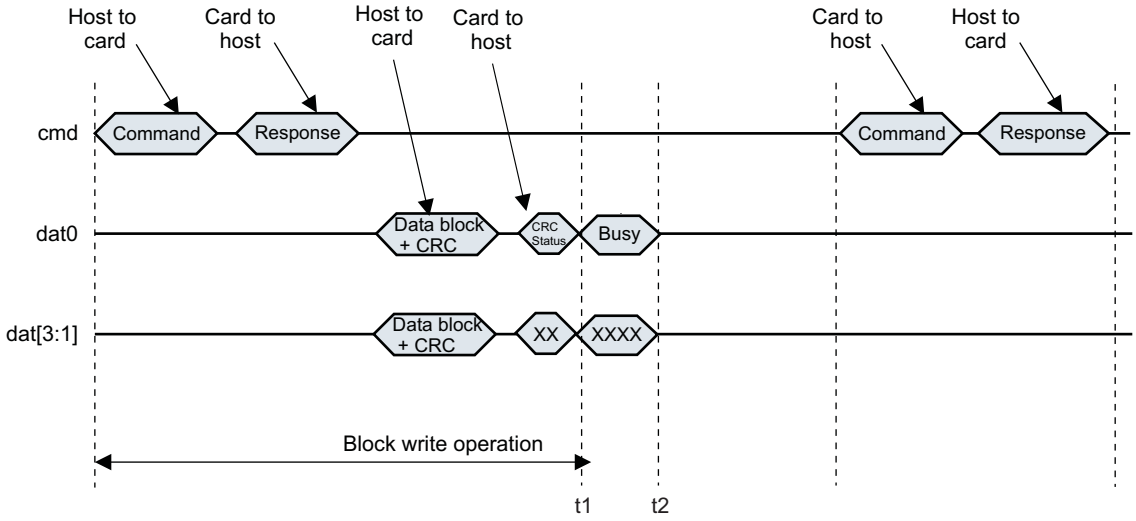
t1 - Data timeout counter is loaded and starts after R1b, R5b response type.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

13.2.8.2 Busy Timeout After Write CRC Status

Figure 13-14 shows DCRC event condition asserted when there is busy timeout after write CRC status.

Figure 13-14. Busy Timeout After Write CRC Status



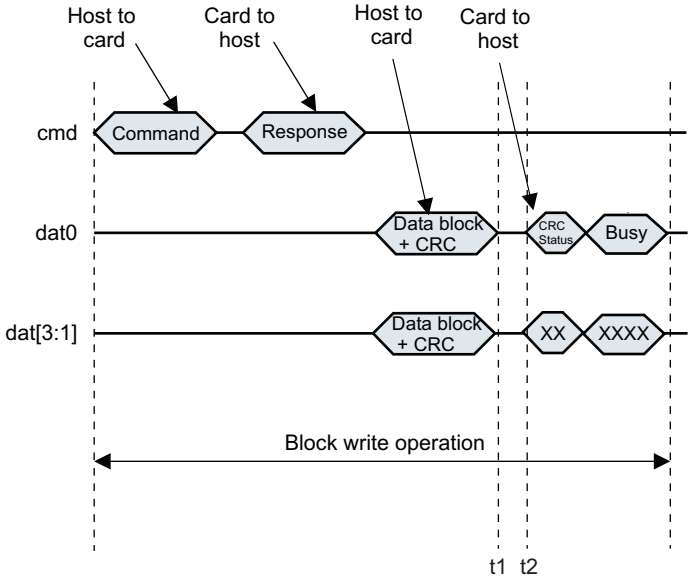
t1 - Data timeout counter is loaded and starts after CRC status.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

13.2.8.3 Write CRC Status Timeout

Figure 13-15 shows DCRC event condition asserted when there is write CRC status timeout.

Figure 13-15. Write CRC Status Timeout



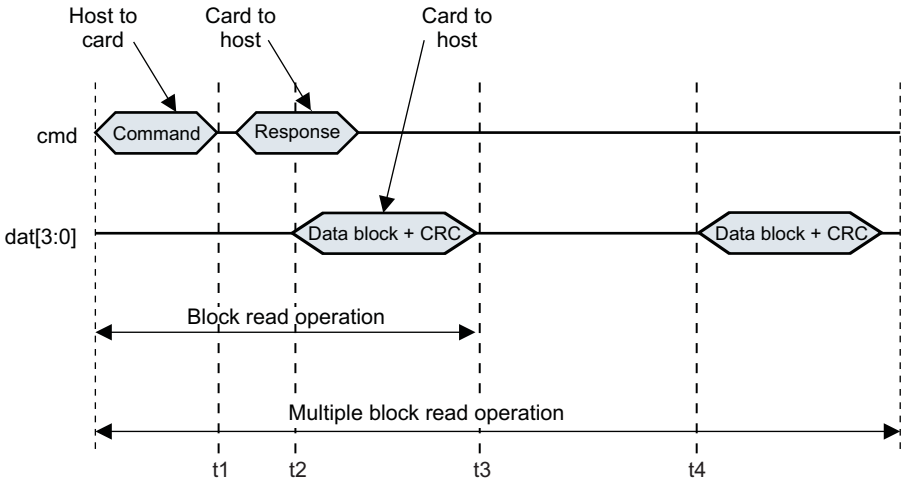
t1 - Data timeout counter is loaded and starts after Data block + CRC.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

13.2.8.4 Read Data Timeout

Figure 13-16 shows DCRC event condition asserted when there is read data timeout.

Figure 13-16. Read Data Timeout



t1 - Data timeout counter is loaded and starts after Command transmission.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

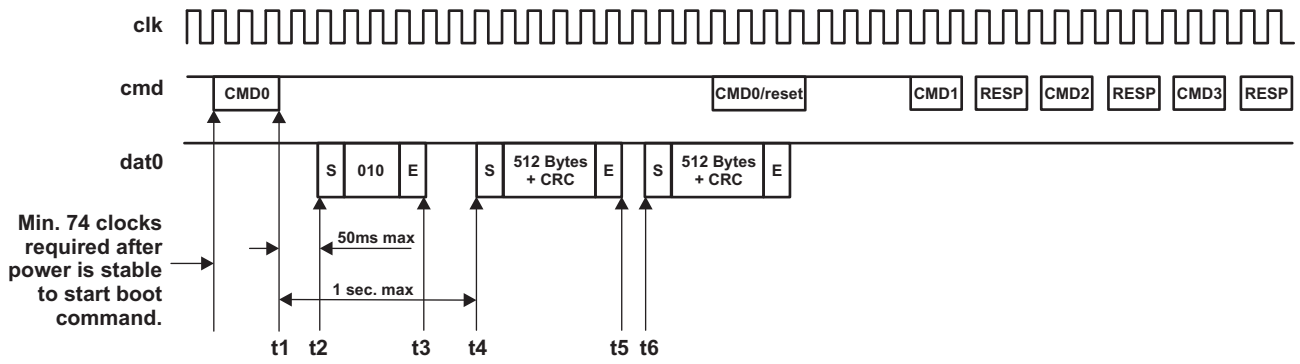
t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.

t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

13.2.8.5 Boot Acknowledge Timeout

Figure 13-17 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 13-17. Boot Acknowledge Timeout When Using CMD0



t1 - Data timeout counter is loaded and starts after CMD0.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

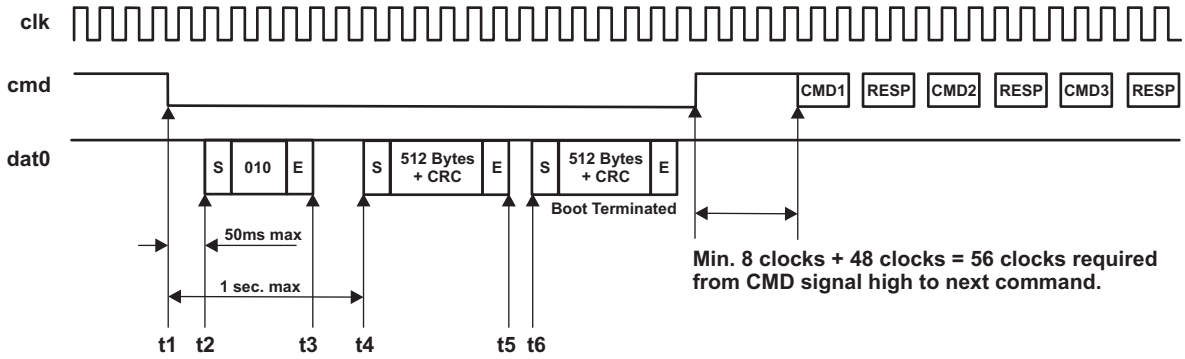
t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

Figure 13-18 shows DCRC event condition asserted when there is boot acknolwedge timeout and CMD line is held low.

Figure 13-18. Boot Acknowledge Timeout When CMD Held Low



t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

13.2.9 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for clocks up to 208, SD standard imposes a specific timing for Auto CMD12 "end bit" arrival.

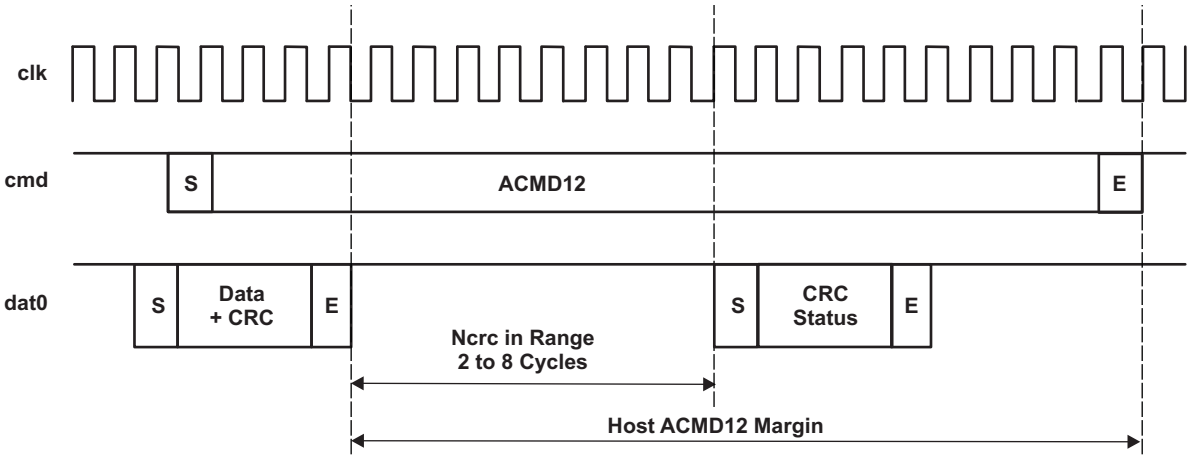
13.2.9.1 Auto Command 12 Timings During Write Transfer

A margin named Ncrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as auto command 12 'end bit' shall arrive after the CRC status "end bit".

Figure 13-19 shows auto CMD12 timings during write transfer.

The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on bus configuration, DDR or standard transfer, 1,4, or 8 bus width transfer.

Figure 13-19. Auto CMD12 Timing During Write Transfer



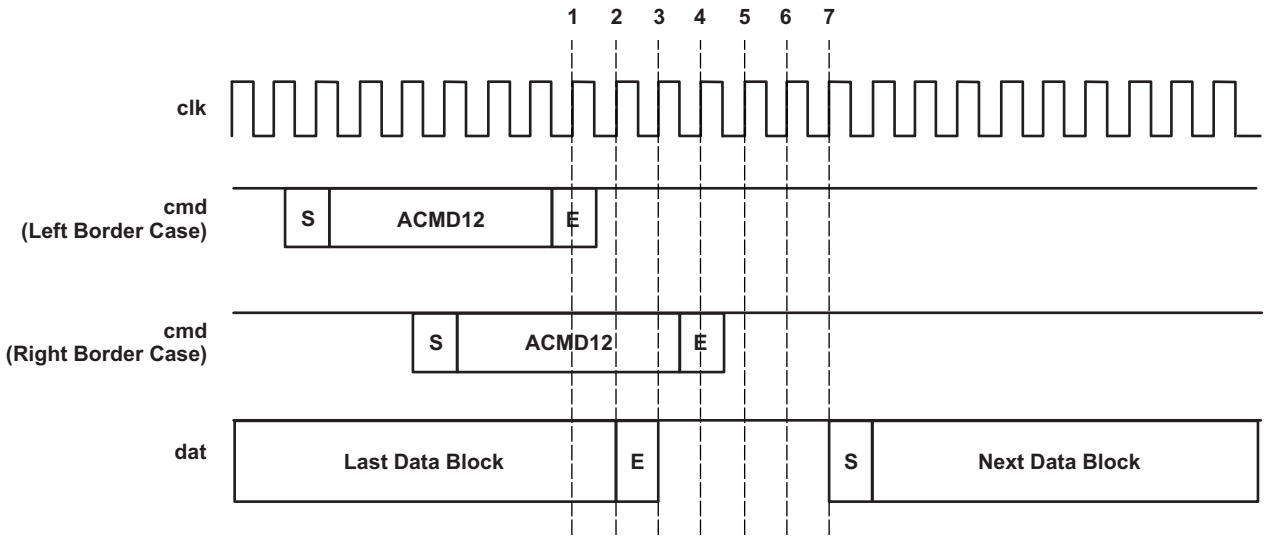
13.2.9.2 Auto Command 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way, it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. SD controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 13-20 shows auto CMD12 timings during read transfer.

The auto CMD12 arrival sent by the Host controller is not sensitive to the bus configuration whether it is DDR or standard transfer, 1,4, or 8 bit bus width transfer.

Figure 13-20. Auto CMD12 Timings During Read Transfer



13.2.10 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the SD/SDIO controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The SD/SDIO controller includes two features which make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for SD only).

  This feature is enabled by setting the SD_CMD[2] ACEN bit to 1 (this setting is relevant for a SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the SD/SDIO controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

  This feature is enabled by setting the SD_HCTL[16] SBGR bit to 1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Table 13-9 shows the common ways to stop a transfer, indicating command to send and features to enable.

Table 13-9. SD/SDIO Controller Transfer Stop Command Summary

		WRITE Transfer		READ Transfer	
		SD	SDIO	SD	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set SD_HCTL[16] SBGR bit to 1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	**If READ_WAIT supported** Stop at block gap Wait TC
					If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The SD/SDIO controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

13.2.11 Output Signals Generation

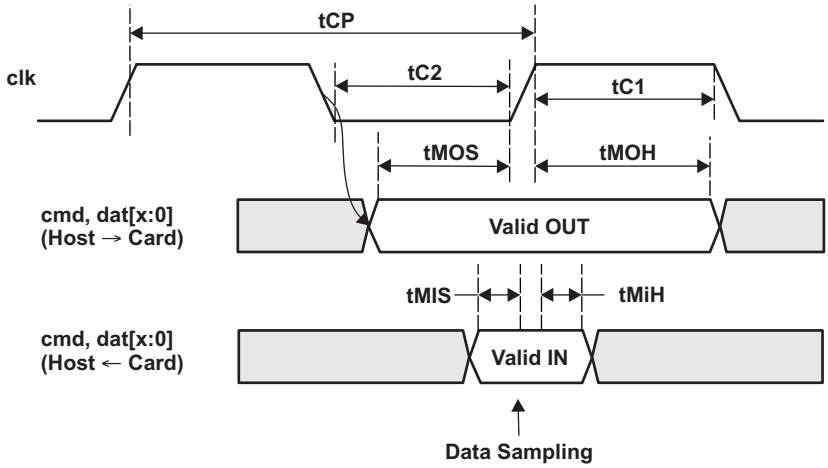
The SD/SDIO output signals can be driven on either falling edge or rising edge depending on the SD_HCTL[2] HSPE bit. This feature allows to reach better timing performance, and thus to increase data transfer frequency.

13.2.11.1 Generation on Falling Edge of Clock

The controller is by default in this mode to maximize hold timings. In this case, SD_HCTL[2] HSPE bit is cleared to 0.

Figure 13-21 shows the output signals of the module when generating from the falling edge of the clock.

Figure 13-21. Output Driven on Falling Edge



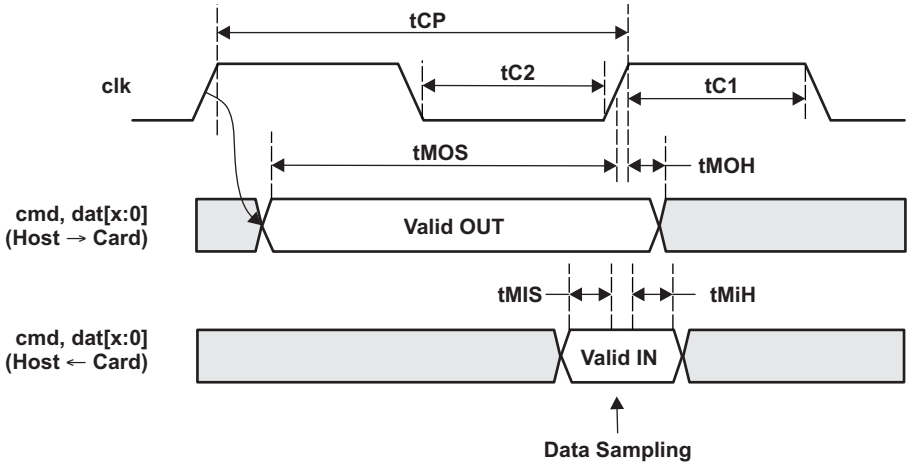
13.2.11.2 Generation on Rising Edge of Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting SD_HCTL[2] HSPE bit to 1. The controller shall be set in this mode to support SDR transfers.

NOTE: Do not use this feature in Dual Data Rate mode (when SD_CON[19] DDR is set to 1).

Figure 13-22 shows the output signals of the module when generating from the rising edge of the clock.

Figure 13-22. Output Driven on Rising Edge



13.2.12 Card Boot Mode Management

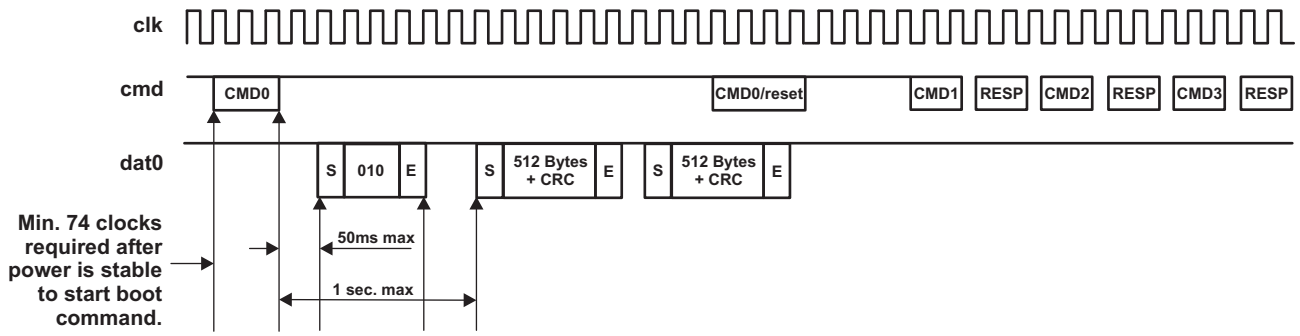
Boot Operation Mode allows the SD/SDIO host controller to read boot data from the connected slave by keeping CMD line low after power-on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from either boot area or user area, depending on register setting. Power-on boot defines a way for the boot-code to be accessed by the SD/SDIO host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (either issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

13.2.12.1 Boot Mode Using CMD0

Figure 13-23 shows the timing diagram of a boot sequence using CMD0.

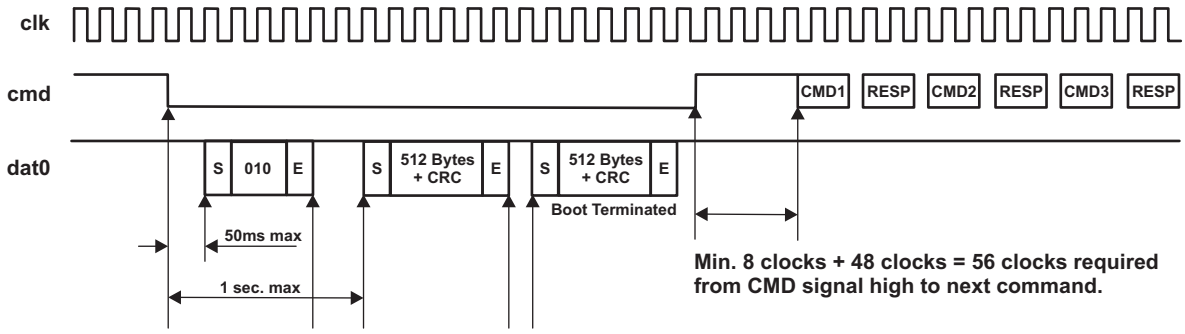
Figure 13-23. Boot Mode With CMD0



13.2.12.2 Boot Mode With CMD Held Low

Figure 13-24 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 13-24. Boot Mode With CMD Line Tied to 0



13.2.13 CE-ATA Command Completion Disable Management

The SD/SDIO controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (SD_CON[12] CEATA and SD_CMD[2] ACEN set to 1) is launched, the host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token follow:

- SD_CON[12] CEATA is set to 1.
- SD_CON[2] HR set to 1.
- Clear the SD_ARG register.
- Write into SD_CMD register with value 0000 0000h.

When a command completion disable token was emitted (that is, SD_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:

  An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

13.2.14 Test Registers

Test registers are available to be compliant with SD Host controller specification. This feature is useful to generate interrupts manually for driver debugging. The Force Event register (SD_FE) is used to control the Error Interrupt Status and Auto CMD12 Error Status. The System Test register (SD_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in system test (SD_CON[4] MODE = 1) mode for boundary connectivity verification.

13.2.15 SD/SDIO Hardware Status Features

Table 13-10 summarizes the SD/SDIO hardware status features.

Table 13-10. SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field/ Observability Control	Description
Interrupt flags		See Section 13.2.4.	
CMD line signal level	Status	[24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	[9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	[8] WTA	This status indicates a write transfer active.
Data line active	Status	[2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	[0] CMDI	Indicates whether issuing of command using CMD line is allowed

13.3 Low-Level Programming Models

13.3.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SD/SDIO modules.

Table 13-11. Global Initialization for Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see *Power, Reset, and Clock Management (PRCM)* chapter.
Control module	Module-specific pad muxing and configuration must be set in the control module. See Control Module section in *Chip Level Resources* chapter.
(optional) MPU INTC (or DSP INTC)	MPU INTC configuration must be done to enable the interrupts from the SD module. See *Interrupt Controller* chapter.
(optional) sDMA (or dDMA)	DMA configuration must be done to enable the module DMA channel requests. See SDMA chapter.
(optional) Interconnect	For more information about the interconnect configuration, see Bus Interconnect section in *Chip Level Resources* chapter.

NOTE: The MPU/DSP interrupt controller and the sDMA/dDMA configurations are necessary, if the interrupt and DMA based communication modes are used.

13.3.2 SD/SDIO Controller Initialization Flow

The next sections outline the four steps to initialize the SD/SDIO controller:

- Initialize Clocks
- Software reset of the controller
- Set module's hardware capabilities
- Set module's Idle and Wake-Up modes

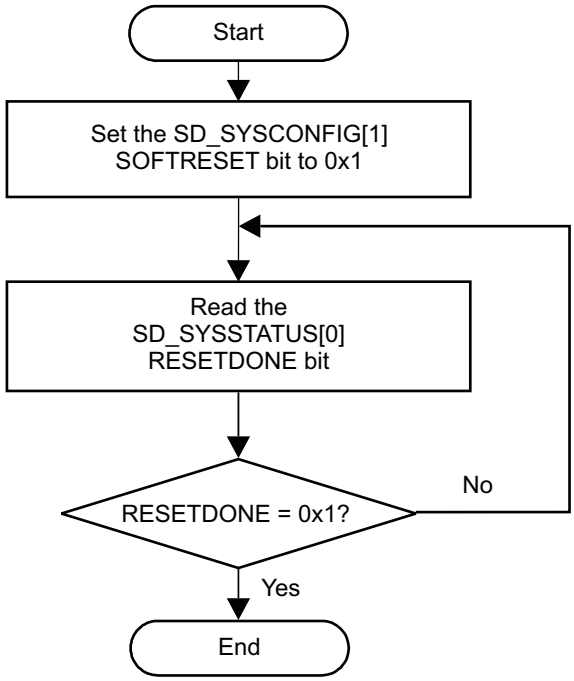
13.3.2.1 Enable OCP and CLKADPI Clocks

Prior to any SD register access one must enable the SD OCP clock and CLKADPI clock in PRCM module registers. Refer to the *Power, Reset, and Clock Management (PRCM)* chapter.

13.3.2.2 SD Soft Reset Flow

Figure 13-25 shows the soft reset process of SD/SDIO controller.

Figure 13-25. SD/SDIO Controller Software Reset Flow



13.3.2.3 Set SD Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) SD_CAPA[26:24] and SD_CUR_CAPA[23:0] registers before the SD/SDIO host driver is started.

13.3.2.4 Wake-Up Configuration

Table 13-12 details SD controller wake-up configuration.

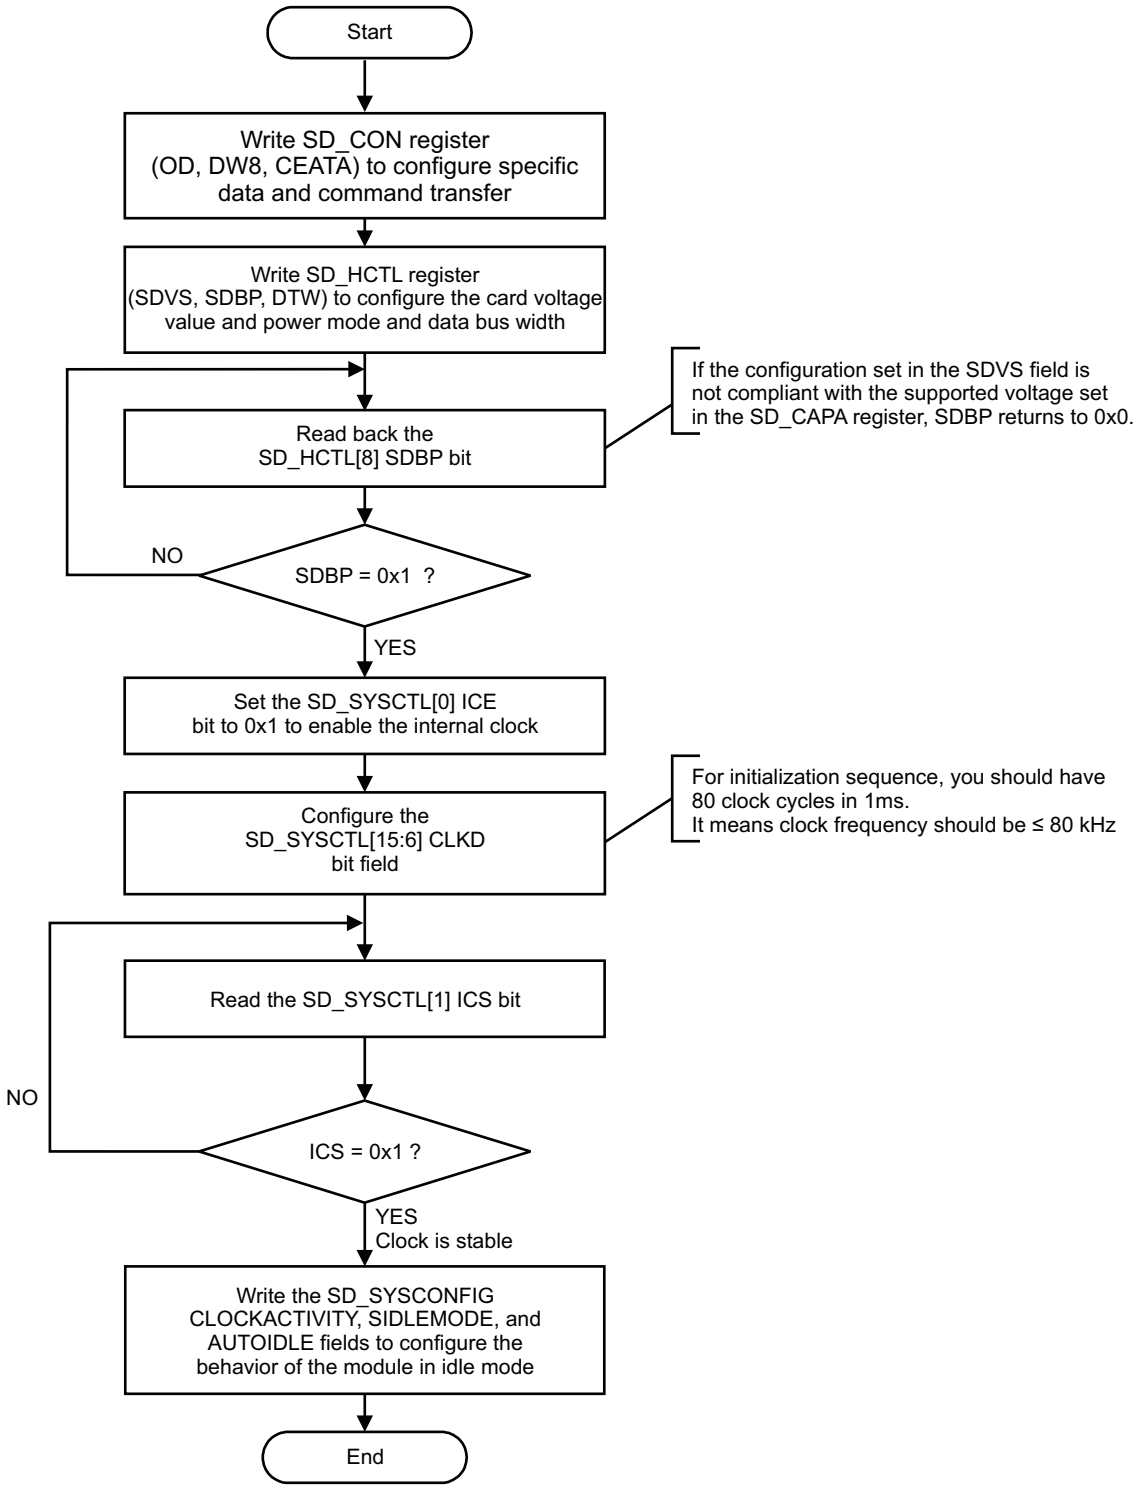
Table 13-12. SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model
Configure wake-up bit (if necessary).	W	SD_SYSCONFIG[2] ENAWAKEUP
Enable wake-up events on SD card interrupt (if necessary).	W	SD_HCTL[24] IWE
SDIO Card onlyEnable card interrupt (if necessary).	W	SD_IE[8] CIRQENABLE

13.3.2.5 Host and Bus Configuration

Figure 13-26 details the bus configuration process.

Figure 13-26. SD/SDIO Controller Bus Configuration Flow



13.3.3 Operational Modes Configuration

13.3.3.1 Basic Operations for SD/SDIO Host Controller

The SD/SDIO controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

13.3.3.2 Card Detection, Identification, and Selection

Figure 13-27 and Figure 13-28 show the card identification and selection process.

Figure 13-27. SD/SDIO Controller Card Identification and Selection - Part 1

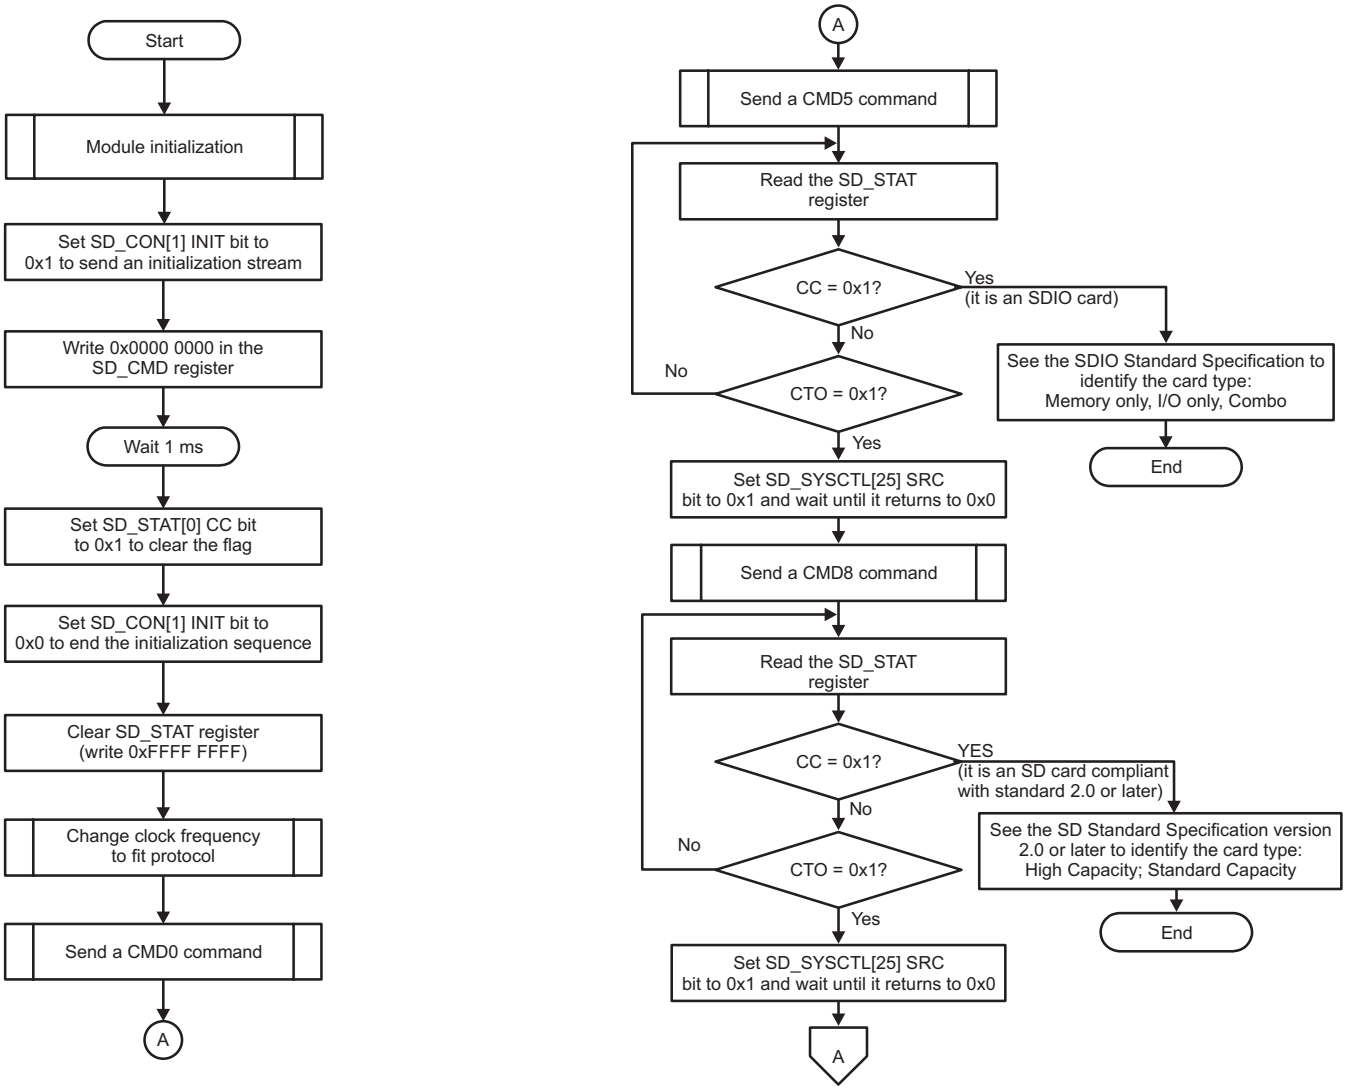


Figure 13-28. SD/SDIO Controller Card Identification and Selection - Part 2

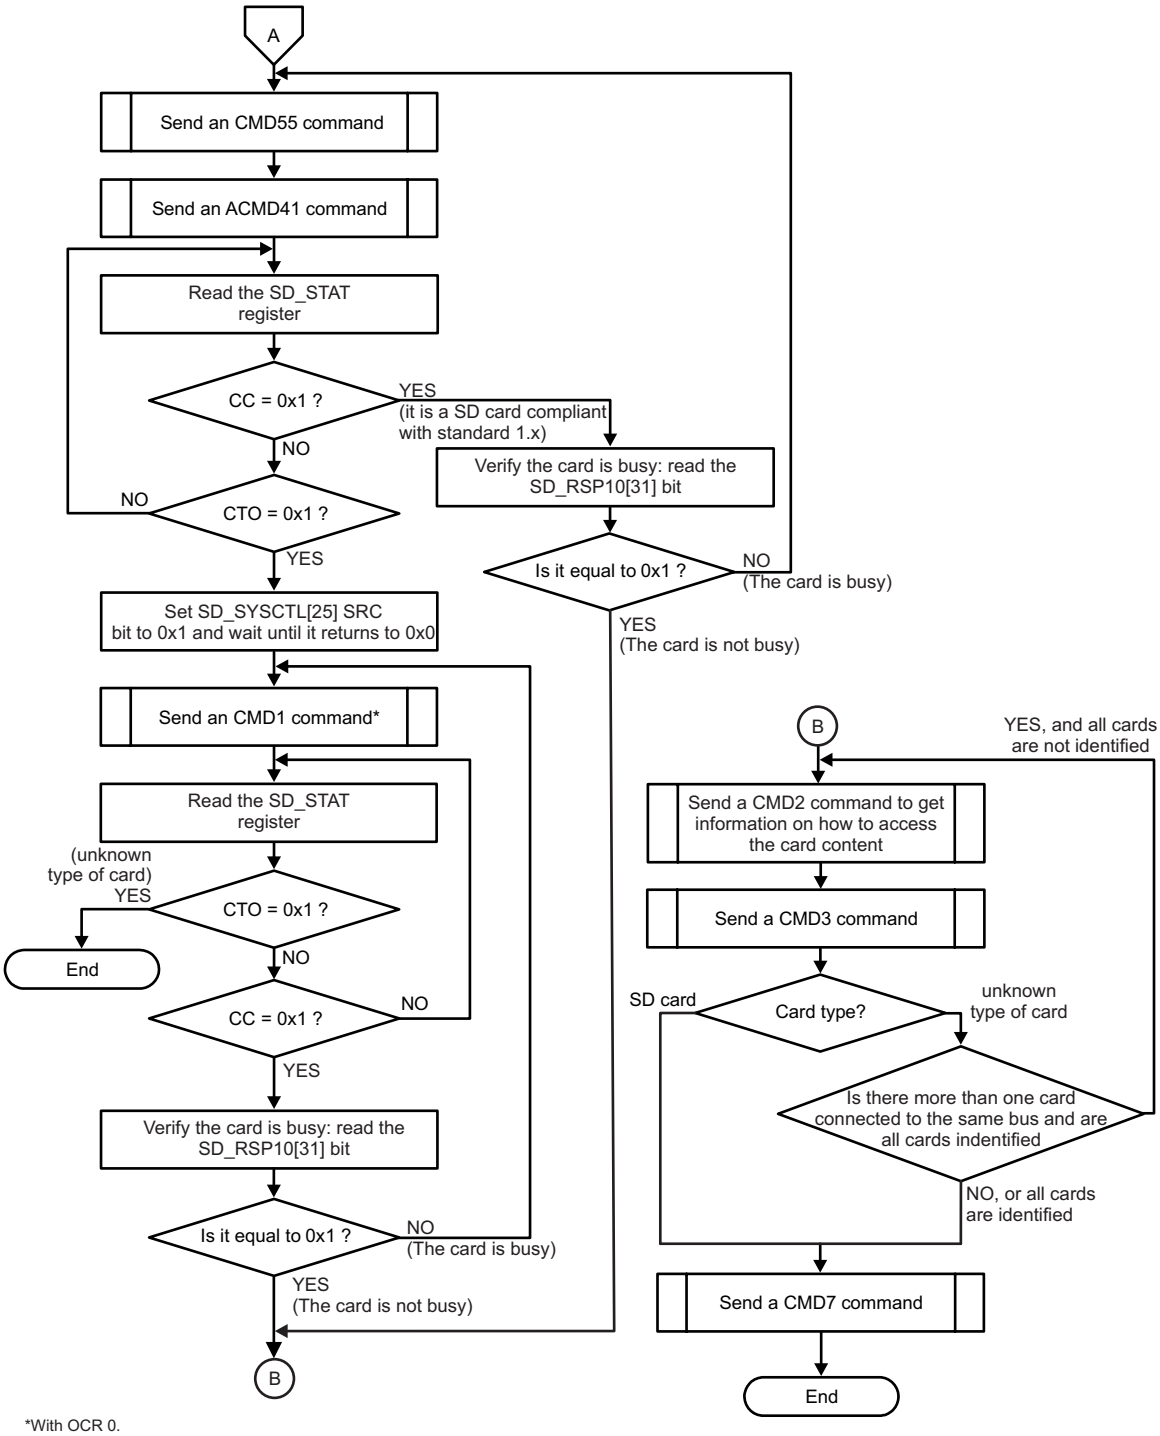

*With OCR 0.

13.4 SD/SDIO Registers

Table 13-13 lists the SD/SDIO registers. For the base address of these registers, see Table 1-12.

CAUTION

The SD/SDIO registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 13-13. SD/SDIO Registers

Address Offset	Acronym	Register Name	Section

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

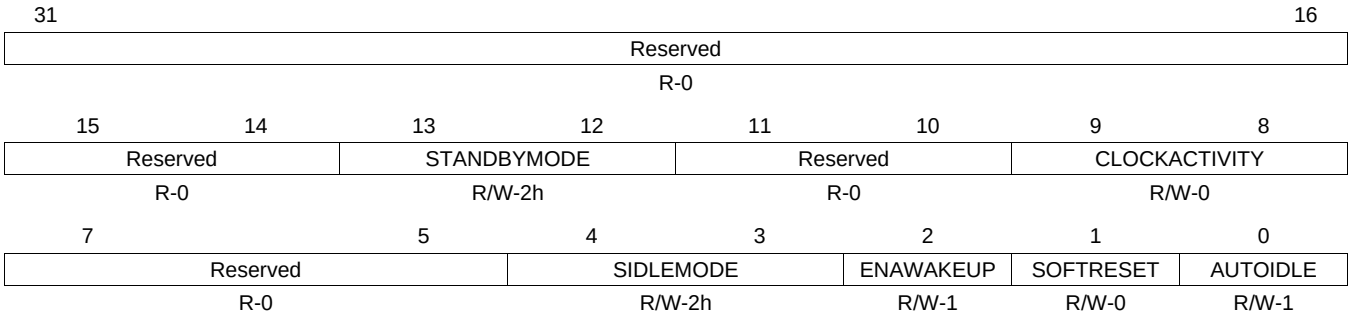
13.4.4 System Configuration Register (SD_SYSCONFIG)

This register allows controlling various parameters of the OCP interface. The system configuration register (SD_SYSCONFIG) is shown in Figure 13-32 and described in Table 13-14.

Figure 13-32. System Configuration Register (SD_SYSCONFIG)



LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-14. System Configuration Register (SD_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-14	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
13-12	STANDBYMODE		Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a 0.
		0	Force-standby. Mstandby is forced unconditionally.
		1h	No-standby. Mstandby is never asserted.
		2h	Smart-standby modelocal initiator standby status depends on local conditions, the module functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events.
		3h	Smart-Standby wake-up-capable modelocal initiator standby status depends on local conditions, the module functional requirement from the initiator. IP module can generate (master-related) wake-up events when in standby state. Mode is only relevant if the appropriate IP module "mwake-up" output is implemented. Functional clock is maintained. Interface clock may be switched off.
11-10	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
9-8	CLOCKACTIVITY		Clocks activity during wake up mode period.
		Bit 8	Interface clock
		Bit 9	Functional clock
		0	Interface and Functional clock may be switched off.
		1h	Interface clock is maintained. Functional clock may be switched-off.
		2h	Functional clock is maintained. Interface clock may be switched-off.
		3h	Interface and Functional clocks are maintained.
7-5	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
4-3	SIDLEMODE		Power management
		0	If an idle request is detected, the SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted.
		1h	If an idle request is detected, the request is ignored and the module keeps on behaving normally.
		2h	If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit SD_SYSCONFIG[2] ENAWAKEUP bit is set to 1).
		3h	Smart-idle Wake-up capable modelocal target's idle state eventually acknowledges the system's idle requests, depending on the IP modules internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in idle state. Mode is only relevant if the appropriate IP module "swake-up" output(s) is (are) implemented.

Table 13-14. System Configuration Register (SD_SYSCONFIG) Field Descriptions (continued)

Bit	Field	Value	Description
2	ENAWAKEUP		Wake-up feature control
		0	Wake-up capability is disabled.
		1	Wake-up capability is enabled.
1	SOFTRESET		Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0.
		Read 0	Normal mode
		Write 0	No effect
		Read 1	The module is reset.
		Write 1	Trigger a module reset.
0	AUTOIDLE		Internal Clock gating strategy
		Read 0	Clocks are free-running.
		Write 1	Automatic clock gating strategy is applied, based on the interconnect and interface activity.

13.4.5 System Status Register (SD_SYSSTATUS)

This register provides status information about the module excluding the interrupt status information. The system status register (SD_SYSSTATUS) is shown in Figure 13-33 and described in Table 13-15.

Figure 13-33. System Status Register (SD_SYSSTATUS)

31	1	0
Reserved		RESETDONE
R-0		R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-15. System Status Register (SD_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved bit field. Do not write any value.
0	RESETDONE		Internal Reset Monitoring. Notethe debounce clock , the interface clock and the functional clock shall be provided to the SD/SDIO host controller to allow the internal reset monitoring.
		Read 0	Internal module reset is on-going
		Read 1	Reset completed

13.4.6 Card Status Response Error (SD_CSRE)

This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit SD_CSRE[i] is set to 1, if the corresponding bit at the same position in the response SD_RSP10[I] is set to 1, the host controller indicates a card error (SD_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (SD_RSP10).

NOTE: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (SD_RSP76) for possible card errors.

The card status response error (SD_CSRE) is shown in Figure 13-34 and described in Table 13-16.

Figure 13-34. Card Status Response Error (SD_CSRE)

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-16. Card Status Response Error (SD_CSRE) Field Descriptions

Bit	Field	Value	Description
31-0	CSRE		Card status response error

13.4.7 System Test Register (SD_SYSTEST)

This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.

NOTE: In SYSTEST mode, a write into SD_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (SD_BLK[10:0] BLEN bits) and the Blocks count for current transfer (SD_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (SD_STAT[4] BWR bit) or a Buffer read ready interrupt (SD_STAT[5] BRR bit) and DMA requests if enabled.

The system test register (SD_SYSTEST) is shown in Figure 13-35 and described in Table 13-17.

Figure 13-35. System Test Register (SD_SYSTEST)

31						17	16

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-17. System Test Register (SD_SYSTEST) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved bit field. Do not write any value. Reads return 0.
16	OBI		Out-of-band interrupt (OBI) data value.
		0	The out-of-band interrupt pin is driven low.
		1	The out-of-band interrupt pin is driven high.
15	SDCD		Card detect input signal (SDCD) data value
		0	The card detect pin is driven low.
		1	The card detect pin is driven high.
14	SDWP		Write protect input signal (SDWP) data value
		0	The write protect pin SDWP is driven low.
		1	he write protect pin SDWP is driven high.
13	WAKD		Wake request output signal data value
		Read 0	No action. Returns 0.
		Write 0	The pin SWAKEUP is driven low.
		Read 1	No action. Returns 1.
		Write 1	The pin SWAKEUP is driven high.
12	SSB		Set status bit. This bit must be cleared prior attempting to clear a status bit of the interrupt status register (SD_STAT).
		Read 0	No action. Returns 0.
		Write 0	Clear this SSB bit field. Writing 0 does not clear already set status bits.
		Read 1	No action. Returns 1.
		Write 1	Force to 1 all status bits of the interrupt status register (SD_STAT) only if the corresponding bit field in the Interrupt signal enable register (SD_ISE) is set.

Table 13-17. System Test Register (SD_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
11	D7D		DAT7 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
10	D6D		DAT6 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
9	D5D		DAT5 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT5 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
8	D4D		DAT4 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT4 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT4 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
7	D3D		DAT3 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT3 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT3 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
6	D2D		DAT2 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT2 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT2 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.

Table 13-17. System Test Register (SD_SYSTEST) Field Descriptions (continued)

Bit	Field	Value	Description
5	D1D		DAT1 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
4	D0D		DAT0 input/output signal data value
		Read 0	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0.
		Write 0	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
		Write 1	If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
3	DDIR		Control of the DAT[7:0] pins direction
		Read 0	No action. Returns 0.
		Write 0	The DAT lines are outputs (host to card).
		Read 1	No action. Returns 1.
		Write 1	The DAT lines are inputs (card to host).
2	CDAT		CMD input/output signal data value
		Read 0	If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (low). If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 0 .
		Write 0	If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven low. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
		Read 1	If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (high) If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 1 .
		Write 1	If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven high. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
1	CDIR		Control of the CMD pin direction
		Read 0	No action. Returns 0.
		Write 0	The CMD line is an output (host to card).
		Read 1	No action. Returns 1.
		Write 1	The CMD line is an input (card to host) .
0	MCKD		clock output signal data value
		Read 0	No action. Returns 0.
		Write 0	The output clock is driven low.
		Read 1	No action. Returns 1.
		Write 1	The output clock is driven high.

13.4.8 Configuration Register (SD_CON)

This register is used:

- To select the functional mode for any card
- To send an initialization sequence to any card
- To send an initialization sequence to any card
- To enable the detection on the SD_DAT1 signal of a card interrupt for SDIO cards only

It also configures:

- The parameters related to the card detect and write protect input signals

The configuration register (SD_CON) is shown in Figure 13-36 and described in Table 13-18.

Figure 13-36. Configuration Register (SD_CON)

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-18. Configuration Register (SD_CON) Field Descriptions

Bit	Field	Value	Description
31-22	Reserved	0	Reserved bit field. Do not write any value.
21	SDMA_LnE		Slave DMA Level/Edge Request. The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to SD_DATA register or late de-assertion, request remains active until last allowed data written into SD_DATA.
		0	Slave DMA edge sensitive.
		1	Slave DMA level sensitive.
20	DMA_MnS		DMA Master or Slave selection. When this bit is set and the controller is configured to use the DMA, Ocp master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MADMA_EN is asserted to 1.
		0	The controller is slave on data transfers with system.
		1	Not available on this device.
19	DDR		Dual Data Rate mode. When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of SD_SYSCTL[CLKD], it is insensitive to SD_HCTL[HSPE] setting
		0	Standard modeData are transmitted on a single edge.
		1	Data Bytes and CRC are transmitted on both edges.

Table 13-18. Configuration Register (SD_CON) Field Descriptions (continued)

Bit	Field	Value	Description
18	BOOT_CF0		Boot Status Supported. This register is set when the CMD line needs to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in SD_CMD. The line is released when this bit field is de-asserted and aborts data transfer in case of a pending transaction.
		Read 0	CMD line not forced.
		Read 1	CMD line is released when it was previously forced to 0 by a boot sequence.
		Write 0	CMD line forced to 0 is enabled.
		Write 1	CMD line forced to 0 is enabled and will be active after writing into SD_CMD register.
17	BOOT_ACK		Book acknowledge received. When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.
		0	No acknowledge to be received.
		1	A boot status will be received on DAT0 line after issuing a command.
16	CLKEXTFREE		External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on SD_DAT1). The Clock will be maintain only if SD_SYSCTL[2] CEN bit is set.
		0	External card clock is cut off outside active transaction period.
		1	External card clock is maintain even out of active transaction period only if SD_SYSCTL[2] CEN bit is set.
15-12	Reserved	0	Reserved bit field. Do not write any value.
11	CTPL		Control Power for SD_DAT1 line (SD cards). By default, this bit is cleared to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.
			SDIO cards. When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of SD_DAT1 outside of a transaction in order to detect asynchronous card interrupt on SD_DAT1 line and minimize the leakage current of the buffers.
		0	Disable all the input buffers outside of a transaction.
		1	Disable all the input buffers except the buffer of SD_DAT1 outside of a transaction.
10-9	DVAL		Debounce filter value (all cards). This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	33 us debounce period
		1h	231 us debounce period
		2h	1 ms debounce period
		3h	8.4 ms debounce period
8	WPP		Write protect polarity (SD and SDIO cards only). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	Active high level
		1	Active low level
7	CDP		Card detect polarity (all cards). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.
		0	Active high level
		1	Active low level
6-5	Reserved	0	Reserved bit field. Do not write any value.
4	MODE		Mode select (all cards). This bit selects the functional mode.
		0	Functional mode. Transfers to the SD/SDIO cards follow the card protocol. The clock is enabled. SD transfers are operated under the control of the SD_CMD register.
		1	SYSTEST mode. SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.
3-2	Reserved	0	Reserved bit field. Do not write any value.

Table 13-18. Configuration Register (SD_CON) Field Descriptions (continued)

Bit	Field	Value	Description
1	INIT		Send initialization stream (all cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the SD_CMD line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (SD_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Notein this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. SD_STAT[0] CC bit can be polled.
		0	The host does not send an initialization sequence
		1	The host sends an initialization sequence
0	Reserved	0	Reserved bit field. Do not write any value.

13.4.9 Power Counter Register (SD_PWCNT)

This register is used to program a counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage. The power counter register (SD_PWCNT) is shown in Figure 13-37 and described in Table 13-19.

Figure 13-37. Power Counter Register (SD_PWCNT)

31	16	15	0
Reserved		PWRCNT	
R-0		R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-19. Power Counter Register (SD_PWCNT) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	These bits are initialized to zero, and writes to them are ignored. Reads return 0.
15-0	PWRCNT		Power counter register. This register is used to introduce a delay between the PAD ACTIVE pin assertion and the command issued.
		0	No additional delay added
		1h	TCF delay (card clock period)
		2h	TCF x 2 delay (card clock period)
		FFFEh	TCF x 65534 delay (card clock period)
		FFFFh	TCF x 65535 delay (card clock period)

13.4.10 SDMA System Address (SD_SDMASA)

This register is used to program a counter to delay command transfers after activating the PAD power. This value depends on PAD characteristics and voltage. The SDMA System address (SD_SDMASA) is shown in Figure 13-34 and described in Table 13-16.

Figure 13-38. Card Status Response Error (SD_SDMASA)

31	0
SDMA_SYSADDR	
R-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-20. Card Status Response Error (SD_SDMASA) Field Descriptions

Bit	Field	Value	Description
31-0	SDMA_SYSADDR		This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

13.4.11 Transfer Length Configuration Register (SD_BLK)

This register shall be used for any card. SD_BLK[BLEN] is the block size register. SD_BLK[NBLK] is the block count register.

The transfer length configuration register (SD_BLK) is shown in Figure 13-39 and described in Table 13-21.

Figure 13-39. Transfer Length Configuration Register (SD_BLK)

31 16	15 12	11 0
NBLK	Reserved	BLEN
R/W-0	R-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-21. Transfer Length Configuration Register (SD_BLK) Field Descriptions

Bit	Field	Value	Description
31-16	NBLK		Blocks count for current transfer. This register is enabled when Block count Enable (SD_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. NoteThe host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.
		0	Stop count
		1h	1 block
		2h	2 blocks
		FFFFh	65535 blocks
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-0	BLEN		Transfer block size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (SD_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.
		0	No data transfer
		1h	1 byte block length
		2h	2 bytes block length
		3h	3 bytes block length
		1FFh	511 bytes block length
		200h	512 bytes block length
		7FFh	2047 bytes block length
		800h	2048 bytes block length

13.4.12 Command Argument Register (SD_ARG)

This register contains command argument specified as bit 39-8 of Command-Format. These registers must be initialized prior to sending the command itself to the card (write action into the register SD_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

The command argument register (SD_ARG) is shown in Figure 13-40 and described in Table 13-22.

Figure 13-40. Command Argument Register (SD_ARG)

Table 13-22. Command Argument Register (SD_ARG) Field Descriptions

Bit	Field	Value	Description
31-0	ARG		Command argument bits [31:0] .

13.4.13 Command and Transfer Mode Register (SD_CMD)

- SD_CMD[31:16] = the command register
- SD_CMD[15:0] = the transfer mode

This register configures the data and command transfers. A write into the most significant byte send the command. A write into SD_CMD[15:0] registers during data transfer has no effect.

This register can be used for any card.

NOTE: In SYSTEST mode, a write into SD_CMD register will not start a transfer.

The command and transfer mode register (SD_CMD) is shown in Figure 13-41 and described in Table 13-23.

Bit	Field	Value	Description
		2Eh	CMD46 or ACMD46
		2Fh	CMD47 or ACMD47
		30h	CMD48 or ACMD48
		31h	CMD49 or ACMD49
		32h	CMD50 or ACMD5
		33h	CMD51 or ACMD5
		34h	CMD52 or ACMD5
		35h	CMD53 or ACMD5
		36h	CMD54 or ACMD5
		37h	CMD55 or ACMD5
		38h	CMD56 or ACMD5
		39h	CMD57 or ACMD5
		3Ah	CMD58 or ACMD5
		3Bh	CMD59 or ACMD5
		3Ch	CMD60 or ACMD60
		3Dh	CMD61 or ACMD61
		3Eh	CMD62 or ACMD62
		3Fh	CMD63 or ACMD63
23-22	CMD_TYPE		Command type. This register specifies three types of special commandSuspend, Resume and Abort. These bits shall be cleared to 0b00 for all other commands.
		0	Others commands
		1h	Upon CMD52 "Bus Suspend" operation
		2h	Upon CMD52 "Function Select" operation
		3h	Upon CMD12 or CMD52 "I/O Abort" command
21	DP		Data present select. This register indicates that data is present and SD_DAT line shall be used. It must be cleared to 0 in the following conditions: • Command using only SD_CMD line • Command with no data transfer but using busy signal on SD_DAT0 • Resume command
		0	Command with no data transfer
		1	Command with data transfer
20	CICE		Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (SD_STAT[19] CIE bit set to1) NoteThe CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued.
		0	Index check disable
		1	Index check enable
19	CCCE		Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (SD_STAT[17] CCRC bit set to 1). NoteThe CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.
		0	CRC7 check disable
		1	CRC7 check enable
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	RSP_TYPE		Response type. This bits defines the response type of the command.
		0	No response
		1h	Response Length 136 bits
		2h	Response Length 48 bits
		3h	Response Length 48 bits with busy after response

Table 13-23. Command and Transfer Mode Register (SD_CMD) Field Descriptions (continued)

Bit	Field	Value	Description
15-6	Reserved	0	Reserved bit field. Do not write any value.
5	MSBS		Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be cleared to 0.
		0	Single block. If this bit is 0, it is not necessary to set the register SD_BLK[31:16] NBLK bits.
		1	Multi block. When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.
4	DDIR		Data transfer Direction. Select This bit defines either data transfer will be a read or a write.
		0	Data Write (host to card)
		1	Data Read (card to host)
3	Reserved	0	Reserved bit field. Do not write any value.
2	ACEN		Auto CMD12 Enable (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12. For CE-ATA commands (SD_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated.
		0	Auto CMD12 disable
		1	Auto CMD12 enable or CCS detection enabled.
1	BCE		Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (SD_BLK[31:16] NBLK bits). When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer.
		0	Block count disabled for infinite transfer.
		1	Block count enabled for multiple block transfer with known number of blocks
0	DE		DMA Enable. This bit is used to enable DMA mode for host data access.
		0	DMA mode disable
		1	DMA mode enable

13.4.14 Command Response[31:0] Register (SD_RSP10)

This 32-bit register holds bits positions [31:0] of command response type R1, R1b, R2, R3, R4, R5, R5b, or R6. The command response[31:0] register (SD_RSP10) is shown in Figure 13-42 and described in Table 13-24.

31-16	RSP7		Command Response [127:112]
15-0	RSP6		Command Response [111:96]

13.4.18 Data Register (SD_DATA)

This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bitsx256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.

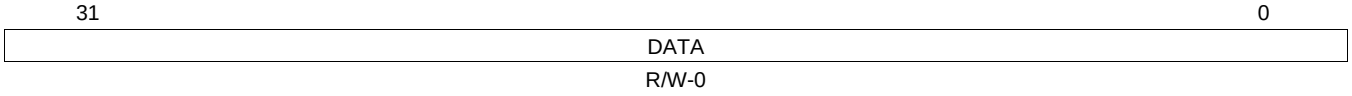
Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.

Example 1Byte or 16-bit access

- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK
- Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

The data register (SD_DATA) is shown in Figure 13-46 and described in Table 13-28.

Figure 13-46. Data Register (SD_DATA)



LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-28. Data Register (SD_DATA) Field Descriptions

Bit	Field	Value	Description
31-0	DATA		Data register [31:0]. In functional mode (SD_CON[4] MODE bit set to the default value 0): A read access to this register is allowed only when the buffer read enable status is set to 1 (SD_PSTATE[11] BRE bit), otherwise a bad access (SD_STAT[29] BADA bit) is signaled. A write access to this register is allowed only when the buffer write enable status is set to 1 (SD_PSTATE[10] BWE bit), otherwise a bad access (SD_STAT[29] BADA bit) is signaled and the data is not written.

13.4.19 Present State Register (SD_PSTATE)

The Host can get the status of the Host controller from this 32-bit read only register. The present state register (SD_PSTATE) is shown in Figure 13-47 and described in Table 13-29.

Figure 13-47. Present State Register (SD_PSTATE)

31	25	24	23	20	19	18	17	16
Reserved		CLEV	DLEV		WP	CDPL	CSS	CINS

15	12	11	10	9	8	7	3	2	1	0
Reserved		BRE	BWE	RTA	WTA	Reserved		DLA	DATI	CMDI
R-0		R-0	R-0	R-0	R-0	R-0		R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-29. Present State Register (SD_PSTATE) Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved bit field. Do not write any value.
24	CLEV		SD_CMD line signal level. This status is used to check the SD_CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the SD_CMD line level at that time.
		Read 0	The SD_CMD line level is 0.
		Read 1	The SD_CMD line level is 1.
23-20	DLEV		SD_DAT[3:0] line signal level • SD_DAT3 => bit 23 • SD_DAT2 => bit 22 • SD_DAT1 => bit 21 • SD_DAT0 => bit 20 This status is used to check SD_DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from SD_DAT0. The value of these registers after reset depends on the SD_DAT lines level at that time.
19	WP		Write Protect. SD/SDIO1 only. SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends one the protect input pin (SDWP) level at that time.
		Read 0	If SD_CON[8] WPP is cleared to 0 (default), the card is write protected, otherwise the card is not write protected.
		Read 1	If SD_CON[8] WPP is cleared to 0 (default), the card is not write protected, otherwise the card is write protected.
18			Card Detect Pin Level. SD/SDIO1 only. SDIO cards only. This bit reflects the inverse value of the card detect input pin (SDCD). Debouncing is not performed on this bit and is valid only when Card State is stable. (SD_PSTATE[17] is set to 1). This bit must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time.
		Read 0	The value of the card detect input pin (SDCD) is 1.
		Read 1	The value of the card detect input pin (SDCD) is 0.
17			Card State Stable. This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (SD_PSTATE[18] CPDL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by software reset.
		Read 0	Reset or Debouncing.
		Read 1	Reset or Debouncing.

Table 13-29. Present State Register (SD_PSTATE) Field Descriptions (continued)

Bit	Field	Value	Description
16			Card inserted. This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (SD_STAT[CINS]). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (SD_STAT[REM]). This bit is not affected by a software reset.
		Read 0	If SD_CON[CDP] is cleared to 0 (default), no card is detected. The card may have been removed from the card slot. If SD_CON[CDP] is set to 1, the card has been inserted.
		Read 1	If SD_CON[CDP] is cleared to 0 (default), the card has been inserted from the card slot. If SD_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot.
15-12	Reserved	0	Reserved bit field. Do not write any value.
11	BRE		Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by SD_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is cleared to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (SD_STAT[5] BRR bit).
		Read 0	Read BLEN bytes disable
		Read 1	Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE		Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data.
		Read 0	There is no room left in the buffer to write BLEN bytes of data.
		Read 1	There is enough space in the buffer to write BLEN bytes of data.
9	RTA		Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when all data have been read by the local host after last block or after a stop at block gap request.
		Read 0	No valid data on the SD_DAT lines.
		Read 1	Read data transfer on going.
8	WTA		Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when CRC status has been received after last block or after a stop at block gap request.
		Read 0	No valid data on the SD_DAT lines.
		Read 1	Write data transfer on going.
7-3	Reserved	0	Reserved bit field. Do not write any value.
2	DLA		SD_DAT line active. This status bit indicates whether one of the SD_DAT lines is in use. In the case of read transactions (card to host)This bit is set to 1 after the end bit of read command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card)This bit is set to 1 after the end bit of write command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.
		Read 0	SD_DAT line inactive
		Read 1	SD_DAT line active
1	DATI		Command inhibit (SD_DAT). This status bit is generated if either SD_DAT line is active (SD_PSTATE[2] DLA bit) or Read transfer is active (SD_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (SD_STAT[1] TC bit).
		Read 0	Issuing of command using the SD_DAT lines is allowed
		Read 1	Issuing of command using SD_DAT lines is not allowed

Table 13-29. Present State Register (SD_PSTATE) Field Descriptions (continued)

Bit	Field	Value	Description
0	CMDI		Command inhibit(SD_CMD). This status bit indicates that the SD_CMD line is in use. This bit is cleared to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is cleared to 0 in either the following cases: • After the end bit of the command response, excepted if there is a command conflict error (SD_STAT[17] CCRC bit or SD_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (SD_AC12[0] ACNE bit). • After the end bit of the command without response (SD_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (SD_STAT[19] CTO bit set to 1), this register is not automatically cleared.
		Read 0	Issuing of command using SD_CMD line is allowed
		Read 1	Issuing of command using SD_CMD line is not allowed

13.4.20 Control Register (SD_HCTL)

This register defines the host controls to set power, wake-up, and transfer parameters.

- SD_HCTL[31:24] = Wake-up control
- SD_HCTL[23:16] = Block gap control
- SD_HCTL[15:8] = Power control
- SD_HCTL[7:0] = Host control

The control register (SD_HCTL) is shown in Figure 13-48 and described in Table 13-30.

Figure 13-48. Control Register (SD_HCTL)

31	28	27	26	25	24	23	20	19	18	17	16
Reserved		OBWE	REM	INS	IWE	Reserved		IBG	RWC	CR	SBGR

15	12	11	9	8	7	6	5	4	3	2	1	0
Reserved		SDVS		SDBP	CDSS	CDTL	Rsvd	DMAS		HSPE	DTW	Rsvd
R-0		R/W-0		R/W-0	R/W-0	R/W-0	R-0	R/W-2h		R/W-0	R/W-0	R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-30. Control Register (SD_HCTL) Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved bit field. Do not write any value.
27	OBWE		Wake-up event enable for 'out-of-band' Interrupt. This bit enables wake-up events for 'out-of-band' assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when SD_CON[14] OBIE bit is not set.
		0	Disable wake-up on 'out-of-band' Interrupt
		1	Enable wake-up on 'out-of-band' Interrupt
26	REM		Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit).
		0	Disable wake-up on card removal
		1	Enable wake-up on card removal
25	INS		Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit).
		0	Disable wake-up on card insertion
		1	Enable wake-up on card insertion
24	IWE		Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (SD_IE[8] CIRQ_ENABLE bit).
		0	Disable wake-up on card interrupt
		1	Enable wake-up on card interrupt
23-20	Reserved	0	Reserved bit field. Do not write any value.
19	IBG		Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For SD card this bit should be cleared to 0.
		0	Disable interrupt detection at the block gap in 4-bit mode
		1	Enable interrupt detection at the block gap in 4-bit mode
18	RWC		Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (SD_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on SD_DAT line.
		0	Disable read wait control. Suspend/resume cannot be supported.
		1	Enable read wait control

Table 13-30. Control Register (SD_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
17	CR		Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (SD_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically cleared to 0 by the host controller when transfer has restarted, that is, SD_DAT line is active (SD_PSTATE[2] DLA bit) or transferring data (SD_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (SD_HCTL[16] SBGR bit =0) before setting this bit.
		0	No affect
		1	Transfer restart
16	SBGR		Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (SD_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (SD_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (SD_DATA).
		0	Transfer mode
		1	Stop at block gap
15-12	Reserved	0	Reserved bit field. Do not write any value.
11-9	SDVS		SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (SD_CAPA[26] VS18 bit, SD_CAPA[25] VS30 bit, SD_CAPA[24] VS33 bit) before starting a transfer.
		0-6h	Reserved
		7h	3.3 V (Typical)
8	SDBP		SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (SD_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically cleared to 0. If the module is power off, a write in the command register (SD_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (SD_CAPA[VS*]).
		0	Power off
		1	Power on
7	CDSS		Card Detect Signal Selection. This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing.
		0	SDCD# is selected (for normal use).
		1	The Card Detect Test Level is selected (for test purposes).
6	CDTL		Card Detect Test Level. This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not.
		0	No card
		1	Card inserted.
5	Reserved	0	Reserved bit field. Do not write any value.
4-3	DMAS		DMA Select. One of the supported DMA modes can be selected. The host driver shall check support of DMA modes by referencing the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is cleared to 0 the bit field is read only and returned value is 0.
		0-1h	Reserved
		2h	32-bit Address ADMA2 is selected.
		3h	Reserved
2	HSPE		High Speed Enable. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is cleared to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in SD_CON[DDR].
		0	Normal speed mode
		1	High speed mode

Table 13-30. Control Register (SD_HCTL) Field Descriptions (continued)

Bit	Field	Value	Description
1	DTW		Data transfer width. This bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.
		0	1-bit Data width (SD_DAT0 used)
		1	4-bit Data width (SD_DAT[3:0] used)
0	Reserved	0	Reserved bit field. Do not write any value.

13.4.21 SD System Control Register (SD_SYSCTL)

This register defines the system controls to set software resets, clock frequency management and data timeout.

- SD_SYSCTL[31:24] = Software resets
- SD_SYSCTL[23:16] = Timeout control
- SD_SYSCTL[15:0] = Clock control

The SD system control register (SD_SYSCTL) is shown in Figure 13-49 and described in Table 13-31.

Figure 13-49. SD System Control Register (SD_SYSCTL)

31	27	26	25	24	23	20	19	16
Reserved		SRD	SRC	SRA	Reserved		DTO	
R-0		R/W-0	R/W-0	R/W-0	R-0		R/W-0	

15	6	5	3	2	1	0
CLKD		Reserved		CEN	ICS	ICE
R/W-0		R-0		R/W-0	R-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-31. SD System Control Register (SD_SYSCTL) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved bit field. Do not write any value.
26	SRD		Software reset for SD_DAT line. This bit is set to 1 for reset and released to 0 when completed SD_DAT finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[26] SRD bit: • SD_DATA • SD_PSTATEBRE, BWE, RTA, WTA, DLA and DATI • SD_HCTLSBGR and CR • SD_STATBRR, BWR, BGE and TC Interconnect is reinitialized. **Note**If a soft reset is issued when an interrupt is asserted, data may be lost.
		0	Reset completed
		1	Software reset for SD_DAT line
25	SRC		Software reset for SD_CMD line. This bit is set to 1 for reset and released to 0 when completed. SD_CMD finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[25] SRC bit: • SD_PSTATECMDI • SD_STATCC Interconnect is reinitialized. **Note**If a soft reset is issued when an interrupt is asserted, data may be lost.
		0	Reset completed
		1	Software reset for SD_CMD line
24	SRA		Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.
		0	Reset completed
		1	Software reset for all the design
23-20	Reserved	0	Reserved bit field. Do not write any value.

Table 13-31. SD System Control Register (SD_SYSCTL) Field Descriptions (continued)

Bit	Field	Value	Description
19-16	DTO		Data timeout counter value and busy timeout. This value determines the interval by which SD_DAT lines timeouts are detected. The host driver needs to set this bit field based on: • The maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer) • The data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card • The timeout clock base frequency (SD_CAPA[5:0] TCF bits) If the card does not respond within the specified number of cycles, a data timeout error occurs (SD_STAT[20] DTO bit). The SD_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write.
		0	TCF x 2^13
		1h	TCF x 2^14
		Eh	TCF x 2^27
		Fh	Reserved
15-6	CLKD		Clock frequency select. These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the SD_CLK pin of either the memory card (SD or SDIO).
		0	Clock Ref bypass
		1h	Clock Ref bypass
		2h	Clock Ref / 2
		3h	Clock Ref / 3
		3FFh	Clock Ref / 1023
5-3	Reserved	0	Reserved bit field. Do not write any value.
2	CEN		Clock enable. This bit controls if the clock is provided to the card or not.
		0	The clock is not provided to the card . Clock frequency can be changed .
		1	The clock is provided to the card and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (SD_SYSCTL[1] ICS bit).
1	ICS		Internal clock stable (status)This bit indicates either the internal clock is stable or not.
		0	The internal clock is not stable.
		1	The internal clock is stable after enabling the clock (SD_SYSCTL[0] ICE bit) or after changing the clock ratio (SD_SYSCTL[15:6] CLKD bits).
0	ICE		Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. NoteThe activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.
		0	The internal clock is stopped (very low power state).
		1	The internal clock oscillates and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value).

13.4.22 Interrupt Status Register (SD_STAT)

The interrupt status regroups all the status of the module internal events that can generate an interrupt.

- SD_STAT[31:16] = Error Interrupt Status
- SD_STAT[15:0] = Normal Interrupt Status

The error bits are located in the upper 16 bits of the SD_STAT register. All bits are cleared by writing a 1 to them. Additionally, bits 15 and 8 serve as special error bits. These cannot be cleared by writing a 1 to them. Bit 15 (ERRI) is automatically cleared when the error causing to ERRI to be set is handled. (that is, when bits 31:16 are cleared, bit 15 will be automatically cleared). Bit 8 (CIRQ) is cleared by writing a 0 to SD_IE[8] (masking the interrupt) and servicing the interrupt.

The interrupt status register (SD_STAT) is shown in Figure 13-50 and described in Table 13-32.

Figure 13-50. Interrupt Status Register (SD_STAT)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved		BADA	CERR	Reserved		ADMAE	ACE	Rsvd	DEB	DCRC	DTO	CIE	CEB	CCRC	CTO
R-0		R/W-0	R/W-0	R-0		R/W-0	R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

15	14	10	9	8	7	6	5	4	3	2	1	0
ERRI	Reserved	BSR	OBI	CIRQ	CREM	CINS	BRR	BWR	DMA	BGE	TC	CC
R-0	R-0	R/W-0	R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-32. Interrupt Status Register (SD_STAT) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Reserved bit field. Do not write any value
29	BADA		Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: • During a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE bit =0) • During a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_PSTATE[10] BWE bit=0)
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	Bad access
		Write 1	Status is cleared.
28	CERR		Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error SD_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read SD_RSP76 register to detect error bits in the command response.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Card error
		Write 1	Status is cleared.
27-26	Reserved	0	Reserved bit field. Do not write any value

Table 13-32. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
25	ADMAE		ADMA Error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor.
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	ADMA error
		Write 1	Status is cleared.
24	ACE		Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	AutoCMD12 error
		Write 1	Status is cleared.
23	Reserved	0	Reserved bit field. Do not write any value
22	DEB		Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on SD_DAT line or at the end position of the CRC status in write mode.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Data end bit error
		Write 1	Status is cleared.
21	DCRC		Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Data CRC error
		Write 1	Status is cleared.
20	DTO		Data timeout error. This bit is set automatically according to the following conditions: • Busy timeout for R1b, R5b response type • Busy timeout after write CRC status • Write CRC status timeout • Read data timeout
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Time out
		Write 1	Status is cleared.
19	CIE		Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (SD_CMD[20] CICE).
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command index error
		Write 1	Status is cleared.

Table 13-32. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
18	CEB		Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command end bit error
		Write 1	Status is cleared.
17	CCRC		Command CRC error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (SD_CMD[19] CCCE).
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Command CRC error
		Write 1	Status is cleared.
16	CTO		Command timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.
		Read 0	No error
		Write 0	Status bit unchanged
		Read 1	Time Out
		Write 1	Status is cleared.
15	ERRI		Error interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.
		Read 0	No interrupt
		Read 1	Error interrupt event(s) occurred
14-11	Reserved	0	Reserved bit field. Do not write any value
10	BSR		Boot Status Received Interrupt. This bit is set automatically when SD_CON[BOOT] is set 1 or 2 and a boot status is received on DAT[0] line.
		Read 0	No interrupt
		Write 0	Status bit unchanged
		Read 1	Boot Status Received Interrupt occurred.
		Write 1	Status is cleared.
9	OBI		Out-of-band interrupt. This bit is set automatically when SD_CON[14] OBIE bit is set and an out-of-band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by SD_CON[13] OBIP bit. The out-of-band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.
		Read 0	No out-of-band interrupt
		Write 0	Status bit unchanged
		Read 1	Interrupt out-of-band occurs
		Write 1	Status is cleared.

Table 13-32. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
8	CIRQ		Card interrupt. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives SD_CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting SD_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as SD_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.
		Read 0	No card interrupt
		Read 1	Generate card interrupt
7	CREM		Card Removal. This bit is set automatically when SD_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).
		Read 0	Card State stable or debouncing
		Write 0	Status bit unchanged
		Read 1	Card Removed
		Write 1	Status is cleared
6	CINS		Card Insertion. This bit is set automatically when SD_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).
		Read 0	Card State stable or debouncing
		Write 0	Status bit unchanged
		Read 1	Card inserted
		Write 1	Status is cleared.
5	BRR		Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the SD_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. NoteIf the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.
		Read 0	Not ready to read buffer
		Write 0	Status bit unchanged
		Read 1	Ready to read buffer
		Write 1	Status is cleared.
4	BWR		Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. NoteIf the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.
		Read 0	Not ready to write buffer
		Write 0	Status bit unchanged
		Read 1	Ready to write buffer
		Write 1	Status is cleared.
3	DMA		DMA Interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.
		Read 0	DMA Interrupt detected
		Write 0	Status bit unchanged
		Read 1	No DMA Interrupt
		Write 1	Status is cleared.

Table 13-32. Interrupt Status Register (SD_STAT) Field Descriptions (continued)

Bit	Field	Value	Description
2	BGE		Block gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the SD_DAT line active status (SD_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.
		Read 0	No block gap event
		Write 0	Status bit unchanged
		Read 1	Transaction stopped at block gap
		Write 1	Status is cleared
1	TC		Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (SD_HCTL[16] SBGR bit). This bit is also set when exiting a command in a busy state (if the command has a busy notification capability). In Read modeThis bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA bit). In write modeThis bit is set automatically on completion of the SD_DAT line use (SD_PSTATE[2] DLA bit).
		Read 0	No transfer complete
		Write 0	Status bit unchanged
		Read 1	Data transfer complete
		Write 1	Status is cleared
0	CC		Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI bit) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO bit) has higher priority than command complete (SD_STAT[0] CC bit). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.
		Read 0	No command complete
		Write 0	Status bit unchanged
		Read 1	Command complete
		Write 1	Status is cleared

13.4.23 Interrupt SD Enable Register (SD_IE)

This register allows to enable/disable the module to set status bits, on an event-by-event basis.

- SD_IE[31:16] = Error Interrupt Status Enable
- SD_IE[15:0] = Normal Interrupt Status Enable

The interrupt SD enable register (SD_IE) is shown in Figure 13-51 and described in Table 13-33.

13.4.24 Interrupt Signal Enable Register (SD_ISE)

This register allows you to enable/disable the module to set status bits, on an event-by-event basis.

- SD_ISE[31:16] = Error Interrupt Signal Enable
- SD_ISE[15:0] = Normal Interrupt Signal Enable

The Interrupt Signal Enable Register (SD_ISE) is shown in Figure 13-52 and described in Table 13-34.

13.4.25 Auto CMD12 Error Status Register (SD_AC12)

The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this SD_AC12 register when an auto CMD12 error interrupt occurs.

This register is valid only when auto CMD12 is enabled (SD_CMD[2] ACEN bit) and auto CMD12Error (SD_STAT[24] ACE bit) is set to 1.

NOTE: These bits are automatically reset when starting a new adtc command with data.

The auto CMD12 error status register (SD_AC12) is shown in Figure 13-53 and described in Table 13-35.

Figure 13-53. Auto CMD12 Error Status Register (SD_AC12)

31	8	7	6	5	4	3	2	1	0

R-0		R-0	R-0		R-0	R-0	R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-35. Auto CMD12 Error Status Register (SD_AC12) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved bit field. Do not write any value.
7	CNI		Command not issue by auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to auto CMD12 error ACEB, ACCE, ACTO, or ACNE.
		Read 0	Not error
		Read 1	Command not issued
6-5	Reserved	0	Reserved bit field. Do not write any value.
4	ACIE		Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted.
			This bit depends on the command index check enable (SD_CMD[20] CICE bit).
		Read 0	No error
		Read 1	Auto CMD12 index error
3	ACEB		Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response.
		Read 0	No error
		Read 1	AutoCMD12 end bit error
2	ACCE		Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the SD_CMD[19] CCCE bit.
		Read 0	No error
		Read 1	Auto CMD12 CRC error
1	ACTO		Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command.
		Read 0	No error
		Read 1	Auto CMD12 time out
0	ACNE		Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before auto CMD12 starts.
		Read 0	Auto CMD12 executed
		Read 1	Auto CMD12 not executed

13.4.26 Capabilities Register (SD_CAPA)

This register lists the capabilities of the SD/SDIO host controller. The capabilities register (SD_CAPA) is shown in Figure 13-54 and described in Table 13-36.

Figure 13-54. Capabilities Register (SD_CAPA)

31	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-36. Capabilities Register (SD_CAPA) Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved bit field. Do not write any value.
28	64BIT		64 Bit System Bus Support. Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus.
		Read 0	32 bit System bus address
		Read 1	64 bit System bus address
27	Reserved	0	Reserved bit. Any write to this bit results in 0.
26	VS18		Voltage support 1.8 V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESET signal).
		Read 0	1.8 V not supported
		Write 0	1.8 V not supported
		Read 1	1.8 V supported
		Write 1	1.8 V supported
25	VS30		Voltage support 3.0V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESET signal)
		Read 0	3.0 V not supported
		Write 0	3.0 V not supported
		Read 1	3.0 V supported
		Write 1	3.0 V supported
24	VS33		Voltage support 3.3V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESET signal)
		Read 0	3.3 V not supported
		Write 0	3.3 V not supported
		Read 1	3.3 V supported
		Write 1	3.3 V supported
23	SRS		Suspend/resume support (SDIO cards only). This bit indicates whether the host controller supports Suspend/Resume functionality.
		Read 0	The Host controller does not suspend/resume functionality.
		Read 1	The Host controller supports suspend/resume functionality.
22	DS		DMA support. This bit indicates that the Host controller is able to use DMA to transfer data between system memory and the Host controller directly.
		Read 0	DMA not supported
		Read 1	DMA supported

Table 13-36. Capabilities Register (SD_CAPA) Field Descriptions (continued)

Bit	Field	Value	Description
21	HSS		High-speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card.
		Read 0	DMA not supported
		Read 1	DMA supported
20	Reserved	0	Reserved bit field. Do not write any value.
19	AD2S		This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN.
		Read 0	ADMA2 supported
		Read 1	ADMA2 not supported
18	Reserved	0	Reserved bit field. Do not write any value.
17-16	MBL		Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller.
			The host controller supports 512 bytes and 1024 bytes block transfers.
		Read 0	512 bytes
		Read 1	1024 bytes
		Read 2	2048 bytes
15-14	Reserved	0	Reserved bit field. Do not write any value.
13-8	BCF		Base clock frequency for clock provided to the card.
		Read 0	The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See the *Power, Reset, and Clock Management* chapter for more information on the value of FUNC_96M_CLK clock signal.
7	TCU		Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (SD_STAT[20] DTO bit).
		Read 0	kHz
		Read 1	MHz
6	Reserved	0	Reserved. This bit is initialized to zero, and writes to it are ignored.
5-0	TCF		Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (SD_STAT[20] DTO bit).
		Read 0	The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.

13.4.27 Maximum Current Capabilities Register (SD_CUR_CAPA)

This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (SD_CAPA).

Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization.

This register is only reinitialized by a hard reset (via RESET signal). The maximum current capabilities register (SD_CUR_CAPA) is shown in Figure 13-55 and described in Table 13-37.

Figure 13-55. Maximum Current Capabilities Register (SD_CUR_CAPA)

31 24	23 16	15 8	7 0

R-0	R/W-0	R/W-0	R/W-0

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-37. Maximum Current Capabilities Register (SD_CUR_CAPA) Field Descriptions

Bit	Field	Value	Description
31-24	Reserved	0	Reserved. This bit is initialized to zero, and writes to it are ignored.
23-16	CUR_1V8		Maximum current for 1.8 V
		Read 0	The maximum current capability for this voltage is not available. Feature not implemented.
15-8	CUR_3V0		Maximum current for 3.0 V
		Read 0	The maximum current capability for this voltage is not available. Feature not implemented.
7-0	CUR_3V3		Maximum current for 3.3 V
		Read 0	The maximum current capability for this voltage is not available. Feature not implemented.

13.4.28 Force Event Register for Error Interrupt Status (SD_FE)

The Force Event register is not a physically implemented register. Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register, if corresponding bit of the Error Interrupt Status Enable Register is set.

The force event register (SD_FE) is shown in Figure 13-56 and described in Table 13-38.

Figure 13-56. Interrupt Signal Enable Register (SD_ISE)

		Write 0	No effect; no interrupt
		Write 1	Interrupt forced.
1	FE_ACTO		Force Event Auto CMD12 timeout error
		Write 0	No effect; no interrupt
		Write 1	Interrupt forced.
0	FE_ACNE		Force Event Auto CMD12 not executed.
		Write 0	No effect; no interrupt
		Write 1	Interrupt forced.

13.4.29 ADMA Error Status Register (SD_ADMAES)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This sate is never set because do not generate ADMA error in this state.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In the case of a write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid = 0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

The ADMA error status register (SD_BLK) is shown in Figure 13-57 and described in Table 13-39.

Figure 13-57. ADMA Error Status Register (SD_ADMAES)

31	3	2	1	0
Reserved		LME	AES	
R-0		W-0	R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-39. ADMA Error Status Register (SD_ADMAES) Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved bit field. Do not write any value.
2	LME		ADMA Length Mismatch Error: • While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. • Total data length cannot be divided by the block length.
		0	No error
		1	Error
1-0	AES		ADMA Error State. This field indicates the state of ADMA when an error occurred during an ADMA data transfer. This field never indicates "10" because ADMA never stops in this state.
		Read 0	ST_STOP (Stop DMA). Contents of the SYS_SDR register
		Write 1h	ST_STOP (Stop DMA). Points to the error descriptor.
		Read 2h	Never set this state. (Not used)
		Write 3h	ST_TFR (Transfer Data). Points to the 'next' of the error descriptor.

13.4.30 ADMA System Address Low Bits Register (SD_ADMASAL)

This register holds the byte address of the executing command of the Descriptor table. The 32-bit Address Descriptor uses the lower 32 bits of this register. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table.

The ADMA System address low bits register (SD_ADMASAL) is shown in Figure 13-58 and described in Table 13-40.

Figure 13-58. ADMA System Address Low Bits (SD_ADMASAL)

31	0
ADMA_A32B	
R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-40. ADMA System Address Low Bits (SD_ADMASAL) Field Descriptions

Bit	Field	Value	Description
31-0	ADMA_A32B		The ADMA increments this register address, which points to the next line, whenever fetching a Descriptor line. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The Host Driver shall program the Descriptor Table on a 32-bit boundary and set the 32-bit boundary address to this register. ADMA2 ignores the lower 2 bits of this register and assumes it to be 00b.

13.4.31 ADMA System Address High Bits Register (SD_ADMASAH)

The ADMA System address high bits register (SD_ADMASAH) is shown in Figure 13-58 and described in Table 13-40.

Figure 13-59. ADMA System Address High Bits Register (SD_ADMASAH)

31	0
ADMA_A32B	
R/W-0	

LEGENDR/W = Read/Write; R = Read only; -*n* = value after reset

Table 13-41. ADMA System Address High Bits Register (SD_ADMASAH) Field Descriptions

Bit	Field	Value	Description
31-0	ADMA_A32B		

13.4.32 Versions Register (SD_REV)

This register contains the hard coded RTL vendor revision number, the version number of SD specification compliancy and a slot status bit.

- SD_REV[31:16] = Host Controller Version
- SD_REV[15:0] = Slot Interrupt Status

The versions register (SD_REV) is shown in Figure 13-60 and described in Table 13-42.

Figure 13-60. Versions Register (SD_REV)

31 24	23 16	15 1	0
VREV	SREV	Reserved	SIS
R-x	R-0	R-0	R-0

LEGENDR/W = Read/Write; R = Read only; *-n* = value after reset

Table 13-42. Versions Register (SD_REV) Field Descriptions

Bit	Field	Value	Description
31-24	VREV	0	Vendor Version Number. Bits [7:4] is the major revision, bits [3:0] is the minor revision. Examples: 10h for 1.0 21h for 2.1
23-16	SREV	Read 0	Specification Version Number. This status indicates the Standard SD Host Controller Specification Version. The upper and lower 4-bits indicate the version. SD Host Specification Version 1.0
15-1	Reserved	0	Reserved bit field. Do not write any value.
0	SIS		Slot Interrupt Status. This status bit indicates the inverted state of interrupt signal for the module. By a power on reset or by setting a software reset for all (SD_SYSCTL[24] SRA), the interrupt signal shall be deasserted and this status shall read 0.

Multichannel Audio Serial Port (McASP)

This chapter is a description of the IP of the multichannel audio serial port (McASP).

Topic **Page**

14.1 Introduction

14.1.1 Purpose of the Peripheral

The multichannel audio serial port (McASP) functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP is useful for time-division multiplexed (TDM) stream, Inter-Integrated Sound (I2S) protocols, and intercomponent digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony / Philips digital interface (S/PDIF) transmit physical layer component. The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes serializers that can be individually enabled to either transmit or receive.

Although intercomponent digital audio interface reception (DIR) mode (that is, S/PDIF stream receiving) is NOT natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

14.1.2 Features

Features of the McASP include:

- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Individually assignable serial data pins.
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT) supports (up to 10 transmit pins):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Extensive error checking and recovery.
  - Transmit underruns and receiver overruns due to the system not meeting real-time requirements.
  - Early or late frame sync in TDM mode.
  - Out-of-range high-frequency master clock for both transmit and receive.
  - External error signal coming into the AMUTEIN input.
  - DMA error due to incorrect programming.
- up to 16 serial data pins depending of the McASP instance in use (see your device-specific data manual) - each serializer having associated one transmit (Tx) and one receive (Rx) channel, which allows support of:
  - 16 data channels, each configurable to either transmit or receive at a time
  - A single 32-bit buffer per serializer for transmit and receive operations
  - One transmit interrupt request (AXINT) and one receive interrupt request (ARINT) linked with each of the 16 serializers

NOTE: Because a serializer receive and transmit channels data is shared on the same MCASP data pin, you can choose to have either Tx or Rx function from a serializer, NOT both at the same time.

14.1.3 Protocols Supported

The McASP supports a wide variety of protocols.

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks non-significant bits (sets to 0, 1, or extends value of another bit).

In DIT mode for McASP, additional features of the transmitter are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Bi-phase encoded 3.3 V output.
- Support for consumer and professional applications.
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

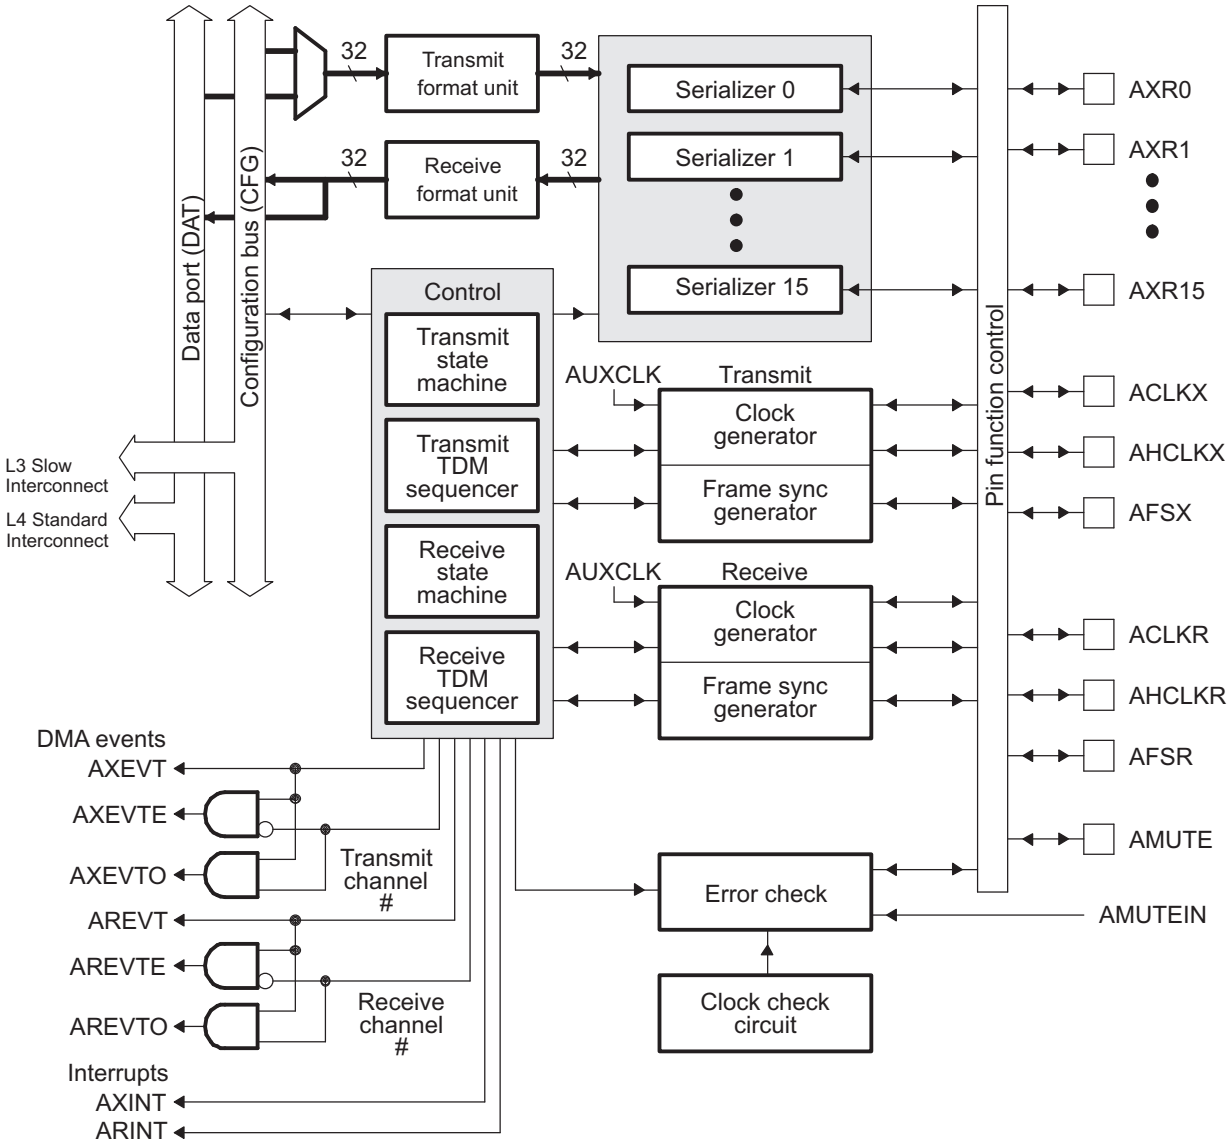
In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

The MCASP does NOT natively support DIR-mode reception (that is, receiving in the S/PDIF format). To allow this, the MCASP can use a DIR-input to I2S-output converter implemented by an external device (that is, external DIR component). To facilitate reception in this case, the TDM mode of MCASP receivers logic is extended to support a non-standard 384-slot TDM stream.

14.1.4 Functional Block Diagram

Figure 14-1 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators.

Figure 14-1. McASP Block Diagram



A McASP has up to 16 serial data pins depending of the McASP instance in use (see your device-specific data manual). When referring to AXRn data pins in this document, n will be up to 15.

B AMUTEIN is not a dedicated McASP pin, but typically comes from one of the external interrupt pins.

14.1.4.1 System Level Connections

Figure 14-2 through Figure 14-6 show examples of McASP usage in digital audio encoder/decoder systems.

14.1.5 Supported Use Case Statement

14.1.6 Industry Standard Compliance Statement

The McASP supports the following industry standard interfaces.

14.1.6.1 TDM Format

The McASP transmitter and receiver support the multichannel, synchronous time-division-multiplexed (TDM) format via the TDM transfer mode. Within this transfer mode, a wide variety of serial data formats are supported, including formats compatible with devices using the Inter-Integrated Sound (I2S) protocol. This section briefly discusses the TDM format and the I2S protocol.

14.1.6.1.1 TDM Format

The TDM format is typically used when communicating between integrated circuit devices on the same printed circuit board or on another printed circuit board within the same piece of equipment. For example, the TDM format is used to transfer data between the processor and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices.

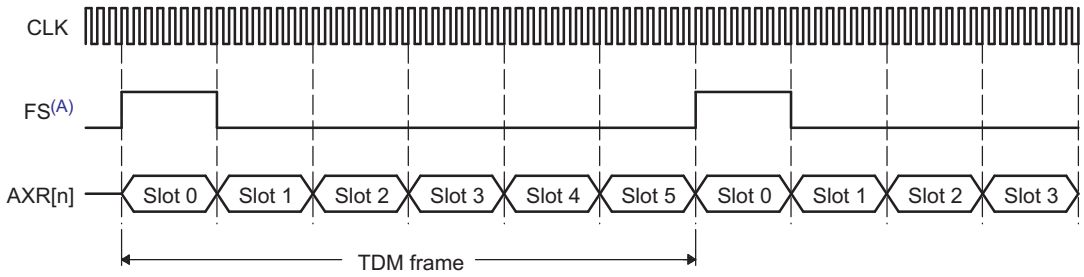
The TDM format consists of three components in a basic synchronous serial transfer: clock (CLK), data (AXRn), and the frame sync (FS). In a TDM transfer, all data bits (AXRn) are synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (as defined in Section 14.1.7). The "slots" are also commonly referred to as "time slots" or "channels" in TDM terminology. A frame consists of multiple slots (or channels). Each TDM frame is defined by the frame sync signal (AFSX or AFSR). Data transfer is continuous and periodic, since the TDM format is most commonly used to communicate with data converters that operate at a fixed sample rate.

There are no delays between slots. The last bit of slot N is followed immediately on the next serial clock cycle with the first bit of slot N + 1, and the last bit of the last slot is followed immediately on the next serial clock with the first bit of the first slot. However, the frame sync may be offset from the first bit of the first slot with a 0, 1, or 2-cycle delay.

It is required that the transmitter and receiver in the system agree on the number of bits per slot, since the determination of a slot boundary is not made by the frame sync signal (although the frame sync marks the beginning of slot 0 and the beginning of a new frame).

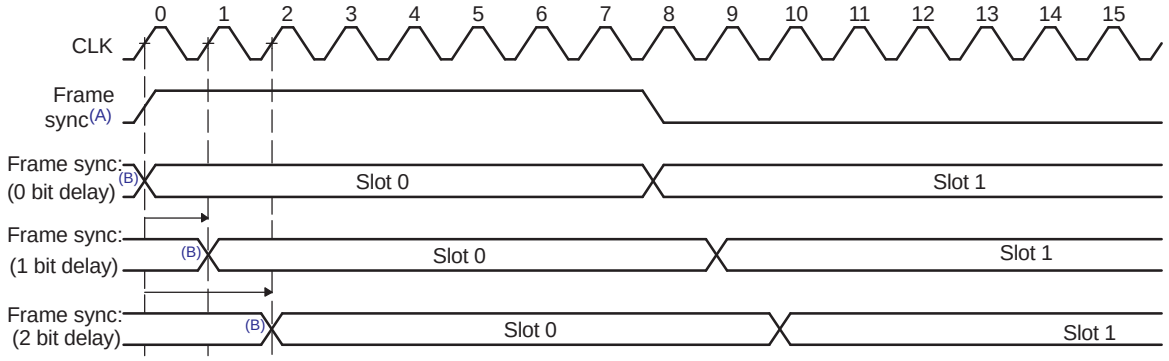
Figure 14-7 shows the TDM format. Figure 14-8 shows the different bit delays from the frame sync.

Figure 14-7. TDM Format–6 Channel TDM Example



A FS duration of slot is shown. FS duration of single bit is also supported.

Figure 14-8. TDM Format Bit Delays from Frame Sync



A FS duration of slot is shown. FS duration of single bit is also supported.

B Last bit of last slot of previous frame. No gap between this bit and the first bit of slot 0 is allowed.

In a typical audio system, one frame of data is transferred during each data converter sample period f_s. To support multiple channels, the choices are to either include more time slots per frame (thus operating with a higher bit clock rate), or to use additional data pins to transfer the same number of channels (thus operating with a slower bit clock rate).

For example, a particular six channel DAC may be designed to transfer over a single serial data pin AXRn as shown in Figure 14-7. In this case the serial clock must run fast enough to transfer a total of 6 channels within each frame period. Alternatively, a similar six channel DAC may be designed to use three serial data pins AXR[0,1,2], transferring two channels of data on each pin during each sample period. In the latter case, if the sample period remains the same, the serial clock can run three times slower than the former case. The McASP is flexible enough to support either type of DAC.

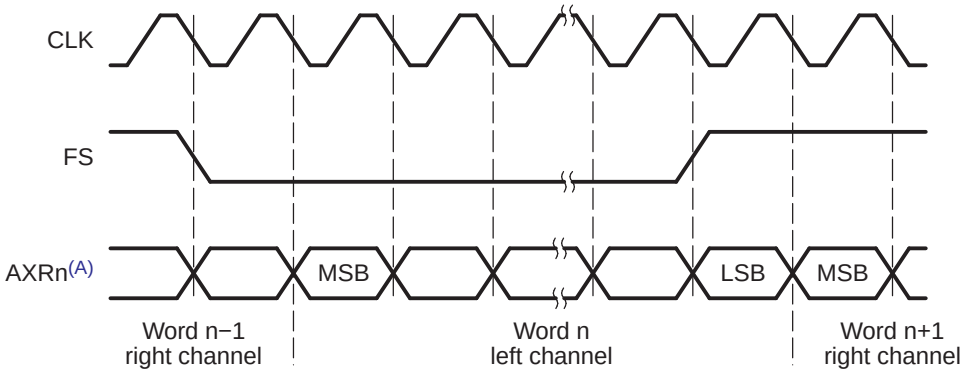
14.1.6.1.2 Inter-Integrated Sound (I2S) Format

The inter-integrated sound (I2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I2S format when configured to 2 slots per frame.

I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format is the same as the slot size. The frame signal is also referred to as "word select" in the I2S format. Figure 14-9 shows the I2S protocol.

The McASP supports transfer of multiple stereo channels over multiple AXRn pins.

Figure 14-9. Inter-Integrated Sound (I2S) Format



A 1 to 16 data pins may be supported.

14.1.6.2 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the digital audio interface transmit (DIT) transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

14.1.6.2.1 Biphase-Mark Code (BMC)

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). The clock, frame, and data are embedded in only one signal—the data pin AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals to the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 14-10 and Table 14-1 show how data is encoded to the BMC format.

As shown in Figure 14-10, the frequency of the clock is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 14.1.6.2.3 for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

Figure 14-10. Biphase-Mark Code (BMC)

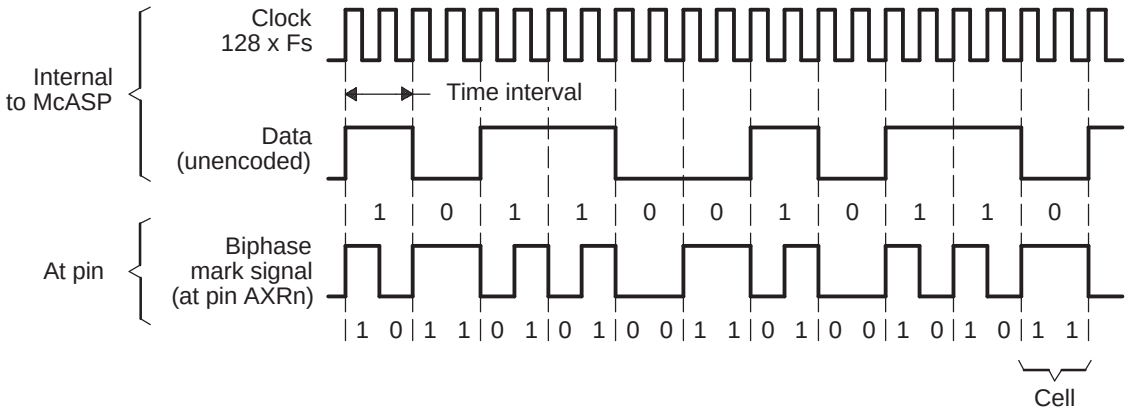


Table 14-1. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at AXRn
0	0	11
0	1	00
1	0	10
1	1	01

14.1.6.2.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered from 0 to 31. Figure 14-11 shows a subframe.

- **Time intervals 0-3** carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is *not* encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 14-2.
- **Time intervals 4-27** carry the audio sample word in linear 2s-complement representation. The most-significant bit (MSB) is carried by time interval 27. When a 24-bit coding range is used, the least-significant bit (LSB) is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4-7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (either 20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field may carry any other information.
- **Time interval 28** carries the validity bit (V) associated with the main data field in the subframe.
- **Time interval 29** carries the user data channel (U) associated with the main data field in the subframe.
- **Time interval 30** carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- **Time interval 31** carries a parity bit (P) such that time intervals 4-31 carry an even number of 1s and an even number of 0s (even parity). As shown in Table 14-2, the preambles (time intervals 0-3) are also defined with even parity.

Figure 14-11. S/PDIF Subframe Format

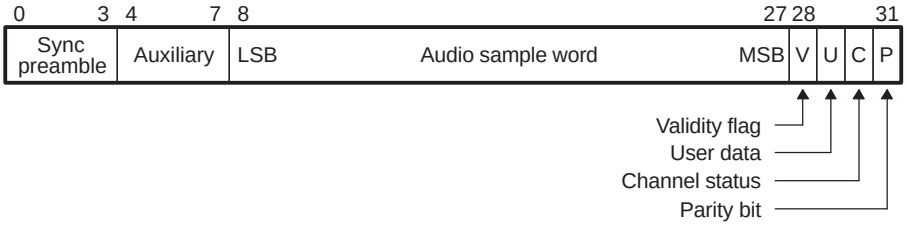

Table 14-2. Preamble Codes

Preamble Code[1]	Previous Logical State	Logical States on pin AXRn[2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, W. For use in professional applications, preambles are referred to as Z, X, Y, respectively.

(2) The preamble is not BMC encoded. Each logical state is synchronized to the serial clock. These 8 logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

As shown in Table 14-2, the McASP DIT only generates one polarity of preambles and it assumes the previous logical state to be 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

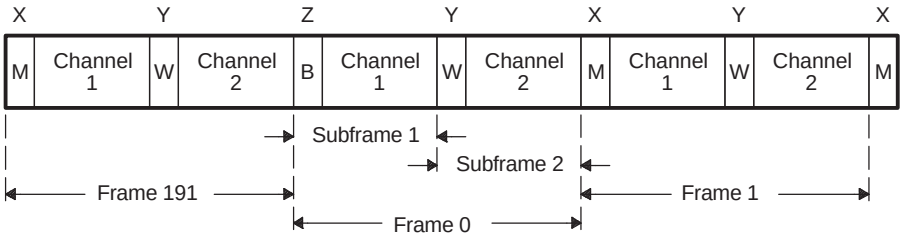
14.1.6.2.3 Frame Format

An S/PDIF frame is composed of two subframes (Figure 14-12). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells/subframe × 2 clocks/cell × 2 subframes/sample). For example, for an S/PDIF stream at a 192 kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (**left** or **A** channel in stereophonic operation and **primary** channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (**right** or **B** channel in stereophonic operation and **secondary** channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 14-12. S/PDIF Frame Format



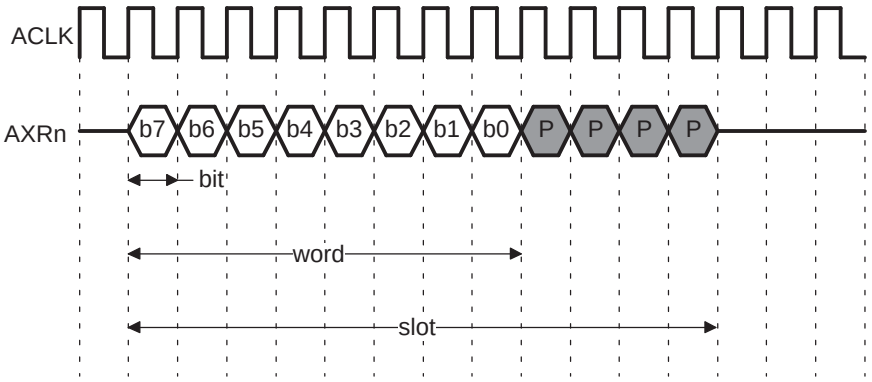
14.1.7 Definition of Terms

The serial bit stream transmitted or received by the McASP is a long sequence of 1s and 0s, either output or input on one of the audio transmit/receive pins (AXRn). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 14-13 shows two of the three basic components—the clock (ACLK) and the data (AXRn). Figure 14-13 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses ACLKX as the serial clock, and the receiver uses ACLKR as the serial clock. Optionally, the receiver can use ACLKX as the serial clock when the transmitter and receiver of the McASP are configured to operate synchronously.

Bit	A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A "1" is represented by a logic high on the AXRn pin for the entire duration of the bit. A "0" is represented by a logic low on the AXRn pin for the entire duration of the bit.
Word	A word is a group of bits that make up the data being transferred between the processor and the external device. Figure 14-13 shows an 8-bit word.
Slot	A slot consists of the bits that make up the word, and may consist of additional bits used to pad the word to a convenient number of bits for the interface between the processor and the external device. In Figure 14-13, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with 4 zeros (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits may be shifted in/out of the McASP on the AXRn pin either MSB or LSB first. When the word size is smaller than the slot size, the word may be aligned to the left (beginning) of the slot or to the right (end) of the slot. The additional bits in the slot not belonging to the word may be padded with 0, 1, or with one of the bits (the MSB or the LSB typically) from the data word. These options are shown in Figure 14-14.

Figure 14-13. Definition of Bit, Word, and Slot

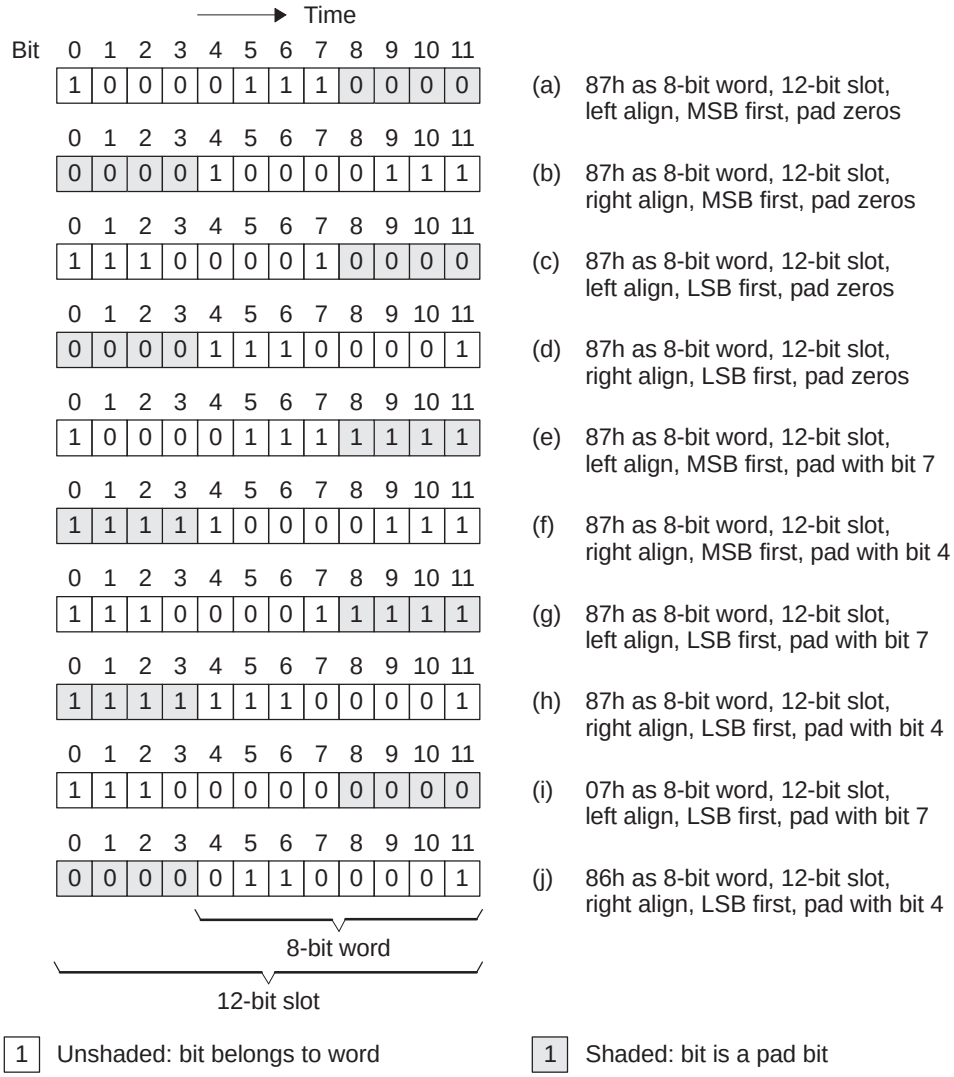


(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the four pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left aligned.

Figure 14-14. Bit Order and Word Alignment Within a Slot Examples

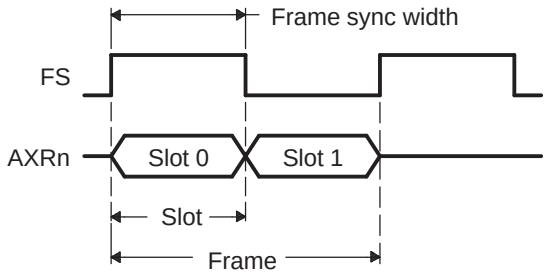


The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync (FS) in this document.

Frame	A frame contains one or multiple slots, as determined by the desired protocol. Figure 14-15 shows an example frame of data and the frame definitions. Figure 14-15 does not specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses AFSX and the receiver uses AFSR. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously.

This section only shows the generic definition of the frame sync. See Section 14.1.6 and Section 14.2.6.1 for details on the frame sync formats required for the different transfer modes and protocols (burst mode, TDM mode and I2S format, DIT mode and S/PDIF format).

Figure 14-15. Definition of Frame and Frame Sync Width



(1) In this example, there are two slots in a frame, and FS duration of slot length is shown.

Other terms used throughout the document:

TDM	Time-division multiplexed. See Section 14.1.6.1 for details on the TDM protocol.
DIR	Digital audio interface receive. The McASP does not natively support receiving in the S/PDIF format. The McASP supports I2S format output by an external DIR device.
DIT	Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on up to all data pins configured as outputs.
I2S	Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
Slot or Time Slot	For TDM format, the term time slot is interchangeable with the term slot defined in this section. For DIT format, a McASP time slot corresponds to a DIT subframe.

14.2 Architecture

14.2.1 Overview

Figure 14-1 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators, error-checking logic, and up to 16 serial data pins. Refer to the device-specific data manual for the features available on your device.

All the McASP pins on the device may be individually programmed as general-purpose I/O (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializers;
  - Data pins AXRn: Up to 16 pins per McASP.
- Transmit clock generator:
  - AHCLKX: McASP transmit high-frequency master clock.
  - ACLKX: McASP transmit bit clock.
- Transmit Frame Sync Generator;
  - AFSX: McASP transmit frame sync or left/right clock (LRCLK).
- Receive clock generator;
  - AHCLKR: McASP receive high-frequency master clock.
  - ACLKR: McASP receive bit clock.
- Receive Frame Sync Generator;
  - AFSR: McASP receive frame sync or left/right clock (LRCLK).
- Mute in/out;
  - AMUTEIN: McASP mute input (from external device).
  - AMUTE: McASP mute output.

14.2.2 Clock and Frame Sync Generators

The McASP clock generators are able to produce two independent clock zones: transmit and receive clock zones. The serial clock generators may be programmed independently for the transmit section and the receive section, and may be completely asynchronous to each other. The serial clock (clock at the bit rate) may be sourced:

- Internally - by passing through two clock dividers off the internal clock source (AUXCLK).
- Externally - directly from ACLKR/X pin, which are configured as inputs. In this case, the Rx/Tx high-speed clock logic is bypassed for the XCLK/RCLK generation.
- Mixed - an external high-frequency clock is input to the McASP on either the AHCLKX or AHCLKR pins, and divided down to produce the bit rate clock.

In the internal/mixed cases, the bit rate clock is generated internally and should be driven out on the ACLKX (for transmit) or ACLKR (for receive) pins. In the internal case, an internally-generated high-frequency clock may be driven out onto the AHCLKX or AHCLKR pins to serve as a reference clock for other components in the system.

The McASP requires a minimum of a bit clock and a frame sync to operate, and provides the capability to reference these clocks from an external high-frequency master clock. In DIT mode, it is possible to use only internally-generated clocks and frame syncs.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

14.2.2.1 Transmit Clock

The transmit bit clock, ACLKX, (Figure 14-16) may be either externally sourced from the ACLKX pin or internally generated, as selected by the CLKXM bit. If internally generated (CLKXM = 1), the clock is divided down by a programmable bit clock divider (CLKXDIV) from the transmit high-frequency master clock (AHCLKX).

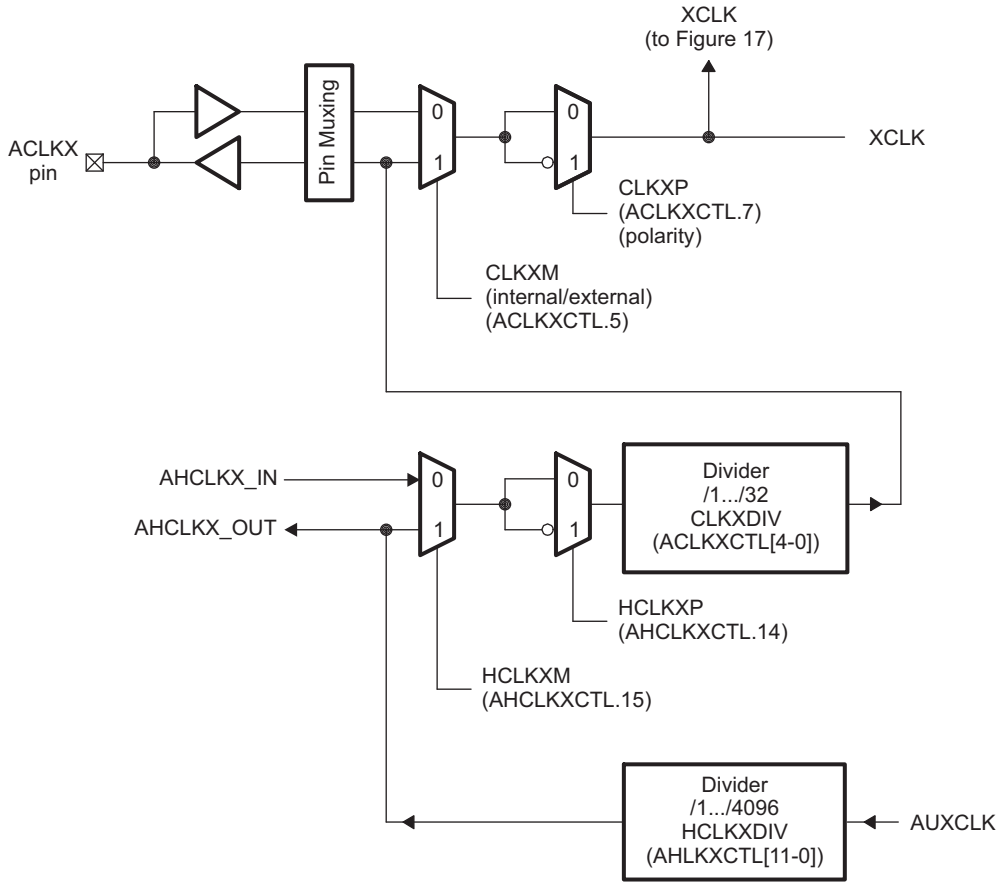
Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock, XCLK, (Figure 14-16). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If CLKXP = 0, the CLKXP mux directly passes ACLKX to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

The transmit high-frequency master clock, AHCLKX, may be either externally sourced from the AHCLKX pin or internally generated, as selected by the HCLKXM bit. If internally generated (HCLKXM = 1), the clock is divided down by a programmable high clock divider (HCLKXDIV) from McASP internal clock source AUXCLK. The transmit high-frequency master clock may be (but is not required to be) output on the AHCLKX pin where it is available to other devices in the system.

The transmit clock configuration is controlled by the following registers:

- ACLKXCTL
- AHCLKXCTL

Figure 14-16. Transmit Clock Generator Block Diagram



(1) Refer to the device-specific date manual for multiplexing options.

14.2.2.2 Receive Clock

The MCASP receive clock generator is built on a very similar circuit to the transmit clock generator (but independent) circuit. The receiver also has the option to operate synchronously from the ACLKX and AFSX signals. This is achieved when the ASYNC bit in the transmit clock control register (ACLKXCTL) is cleared to 0 (see Figure 14-17). The receiver may be configured with different polarity (CLKRP) and frame sync data delay options from those options of the transmitter.

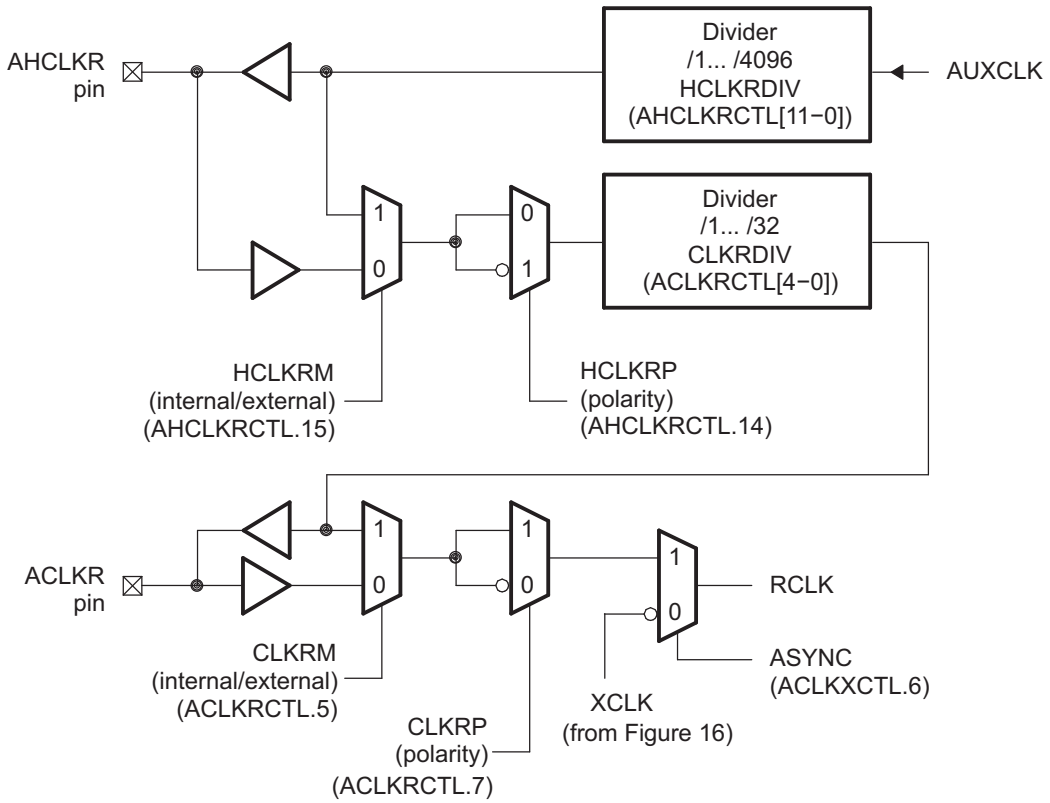
The receive clock configuration is controlled by the following registers:

- ACLKRCTL
- AHCLKRCTL

In case the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the CLKRM bit (from ACLKRCTL register) must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (CLKRDIV bit field in ACLKRCTL register) from the source signal. If the receive high-frequency master clock, AHCLKR, is also sourced internally, the HCLKRM bit (AHCLKRCTL register) must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (HCLKRDIV bit field in AHCLKRCTL register) from the MCASP internal clock source AUXCLK.

The receive high-frequency master clock, AHCLKR, may be (but is not required to be) output on the AHCLKR pin where it is available to other devices in the system. Regardless if AHCLKR is either internally generated or externally sourced, polarity of the high-frequency clock may be programmed via bit HCLKRP to be either rising or falling edge.

Figure 14-17. Receive Clock Generator Block Diagram



(1) Refer to the device-specific date manual for multiplexing options.

14.2.2.3 Frame Sync Generator

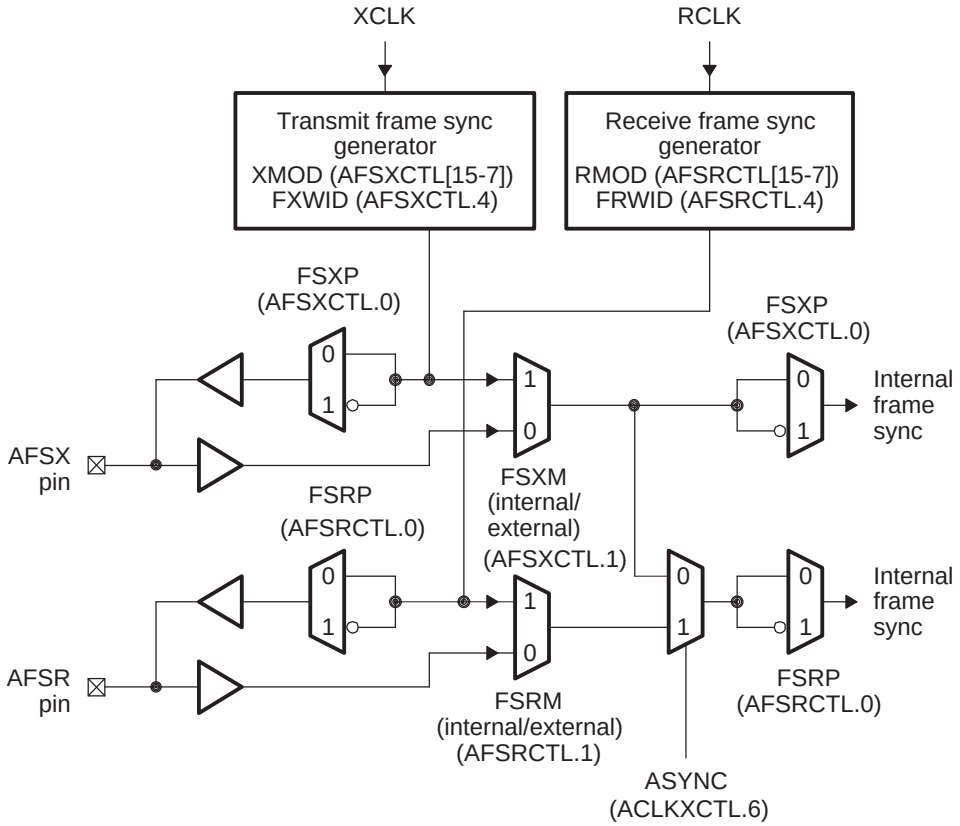
There are two different modes for frame sync: burst and TDM. A block diagram of the frame sync generator is shown in Figure 14-18. The frame sync options are programmed by the receive and transmit frame sync control registers (AFSRCTL and AFSXCTL). The options are:

- Internally-generated or externally-generated via configuring bit AFSXCTL[1] FSXM for transmit or AFSRCTL[1] FSRM for receive logic
- Frame sync polarity: rising edge or falling edge via configuring bit AFSXCTL[0] FSXP for transmit or AFSRCTL[0] FSRP for receive logic
- Frame sync width: single bit or single word via configuring bit AFSXCTL[4] FXWID for transmit or AFSRCTL[4] FRWID for receive logic
- Bit delay: 0, 1, or 2 cycles before the first data bit
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit, ACLKXCTL[6] ASYNC, used to define the receiver internal clock source.

The transmit frame sync pin is AFSX and the receive frame sync pin is AFSR. A typical usage for these pins is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

Regardless if the AFSX/AFSR is internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSRP/FSRP = 1, the frame sync polarity is falling edge.

Figure 14-18. Frame Sync Generator Block Diagram



14.2.2.4 Clocking Examples

Some examples of processes using the McASP clocking and frame flexibility are:

- Receive data from a DVD at 48 kHz, but output up-sampled or decoded audio at 96 kHz or 192 kHz. This could be accomplished by inputting a high-frequency master clock (for example, 512 × receive FS), receiving with an internally-generated bit clock ratio of divide-by-8, and transmitting with an internally-generated bit clock ratio of divide-by-4 or divide-by-2.
- Transmit/receive data based on one sample rate (for example, 44.1 kHz), and transmit/receive data at a different sample rate (for example, 48 kHz).

14.2.3 Memory Map

See the device-specific data manual for information describing the device memory-map.

14.2.4 Signal Descriptions

The signals used on the McASP audio interface are listed in Table 14-3.

Table 14-3. McASP Interface Signals

Pin[1]	I/O/Z	Device Reset (RESET = 0)	Description
		Transmitter Control	
AHCLKX	I/O/Z	Input	Transmit high-frequency master clock
AFSX	I/O/Z	Input	Transmit frame sync or left/right clock (LRCLK)
ACLKX	I/O/Z	Input	Transmit bit clock
		Receiver Control	
AHCLKR	I/O/Z	Input	Receive high-frequency master clock
AFSR	I/O/Z	Input	Receive frame sync or left/right clock (LRCLK)
ACLKR	I/O/Z	Input	Receive bit clock
		Mute	
AMUTE	I/O/Z	Input	Mute output
AMUTEIN	I/O/Z	Input	Mute input
		Data	
AXRn	I/O/Z	Input	TX/RX data pins. Up to 16 data pins are supported (n = 0 to 15).

(1) Due to pinout restrictions, not all interface signals are supported on all devices or all McASP instances. Refer to your device-specific data manual for details.

14.2.5 Pin Multiplexing

The McASP signals share pins with other processor functions. For detailed information on the McASP pin multiplexing and configuration, see the pin multiplexing information in the device-specific data manual.

14.2.6 Transfer Modes

14.2.6.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

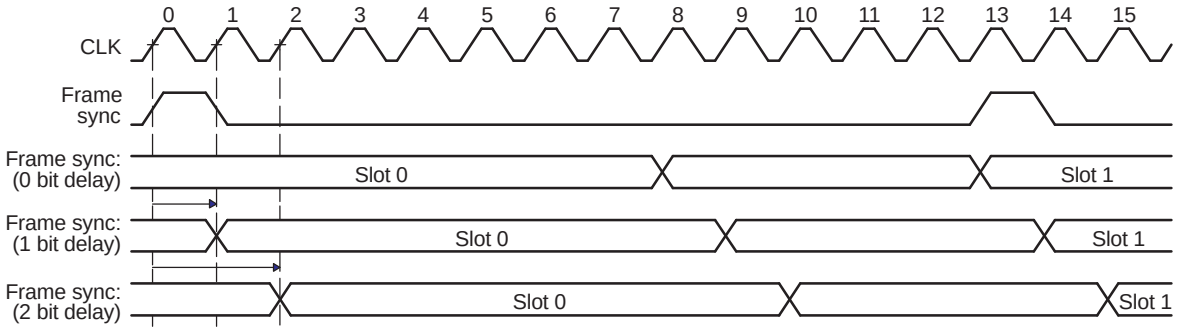
When operating in burst frame sync mode (Figure 14-19), as specified for transmit (XMOD = 0 in AFSXCTL) and receive (RMOD = 0 in AFSRCTL), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (FRWID = 0 in AFSRCTL, FXWID = 0 in AFSXCTL).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF[n] (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF[n] (for every serializer set to operate as a receiver) has been read.

Figure 14-19. Burst Frame Sync Mode



The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 14.2.10.2 to configure this register.
- AMUTE: Not applicable. Leave at default.
- DLBCTL: If loopback mode is desired, configure this register according to Section 14.2.8.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 14.2.7.2 and Section 14.2.8.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 14.2.8.3.
- AFSRCTL/AFSXCTL: Clear **RMOD/XMOD** bits to 0 to indicate burst mode. Clear **FRWID/FXWID** bits to 0 for single bit frame sync duration. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 14.2.2.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 14.2.2.

- RTDM/XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Not applicable. Leave at default.
- SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

14.2.6.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 14.1.6.1.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock.
- AFSX - transmit frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

The transmitter has the option to receive the ACLKX bit clock as an input, or to generate the ACLKX bit clock by dividing down the AHCLKX high-frequency master clock. The transmitter can either generate AHCLKX internally or receive AHCLKX as an input. See Section 14.2.2.1.

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

The receiver has the option to receive the ACLKR bit clock as an input or to generate the ACLKR bit clock by dividing down the AHCLKR high-frequency master clock. The receiver can either generate AHCLKR internally or receive AHCLKR as an input. See Section 14.2.2.2 and Section 14.2.2.3.

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 14.2.10.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: If loopback mode is desired, configure this register according to Section 14.2.8.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select TDM mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 14.2.7.2 and Section 14.2.8.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 14.2.8.3.
- AFSRCTL/AFSXCTL: Set **RMOD/XMOD** bits to 2-32 for TDM mode. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 14.2.2.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 14.2.2.
- RTDM/XTDM: Program all fields according to the time slot characteristics desired.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Program all fields according to serializer operation desired.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

14.2.6.2.1 TDM Time Slots

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring XTDM and/or RTDM (this allows multiple processors to communicate on the same TDM serial bus).

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either XTDM or RTDM to determine if the McASP should transmit/receive in that time slot.

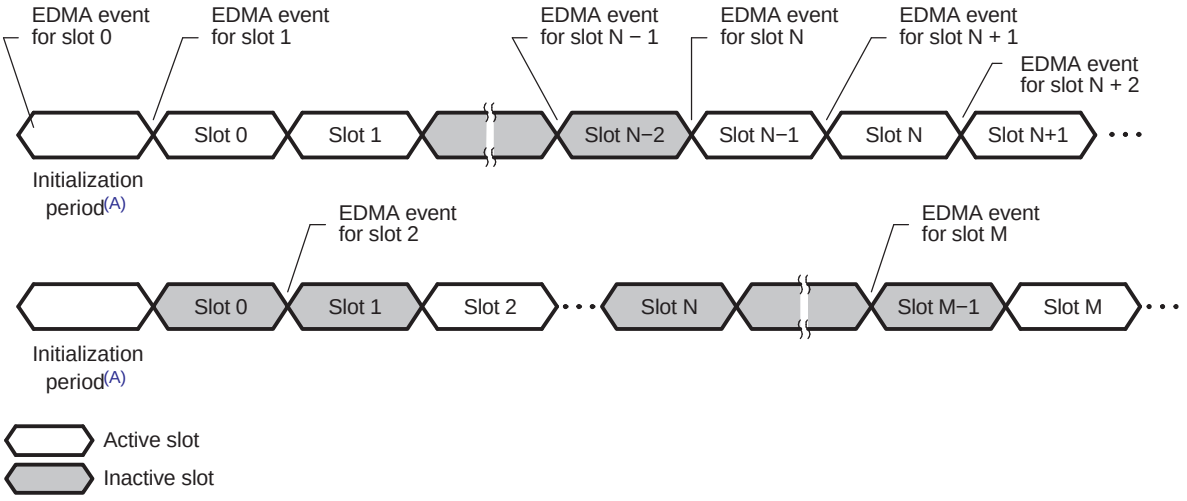
If the transmit/receive bit is active, the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. Transmit pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bit DISMOD in SRCTL[n].

Figure 14-20 shows when the transmit DMA event AXEVT is generated. See Section 14.2.8.1.1 for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless if the previous time slot (slot N - 1) is active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF[n] to XRSR[n] generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA request generation does not need this capability, since the receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 14-20. Transmit DMA Event (AXEVT) Generation in TDM Time Slots



A See Section 14.2.10.2, step 7a.

14.2.6.2.2 Special 384 Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF, AES-3, IEC-60958 receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The advantage to using the 384 time slot TDM mode is that interrupts may be generated synchronous to the S/PDIF, AES-3, IEC-60958, such as the last slot interrupt.

The receive TDM time slot register (RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).

To receive data in the DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock). In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK.
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in AFSRCTL to 384 to receive 384 time slots.

14.2.6.3 Digital Audio Interface Transmit (DIT) Transfer Mode

In addition to the TDM and burst transfer modes, which are suitable for transmitting audio data between ICs inside the same system, the digital audio interface transmit (DIT) transfer mode of the McASP also supports transmission of audio data in the S/PDIF, AES-3, or IEC-60958 format. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode only applies to serializers configured as transmitters, not receivers. Refer to Section 14.1.6.2 for a description of the S/PDIF format.

14.2.6.3.1 Transmit DIT Encoding

The McASP operation in DIT mode is basically identical to the 2 time slot TDM mode, but the data transmitted is output as a biphase mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in the DIT mode, the following pins are typically needed:

- AHCLKX - transmit high-frequency master clock.
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

AHCLKX is optional (the internal clock source may be used instead), but if used as a reference, the processor provides a clock check circuit that continually monitors the AHCLKX input for stability.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23-0 after passing through the first three stages of the transmit format unit.

For left-aligned Q31 data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 010 (rotate right by 8 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = FFFF FF00h-FFFF 0000h (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

For right-aligned data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 000 (rotate right by 0 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = 00FF FFFFh to 0000 FFFFh (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

14.2.6.3.2 Transmit DIT Clock and Frame Sync Generation

The DIT transmitter only works in the following configuration:

- In transmit frame control register (AFSXCTL):
  - Internally-generated transmit frame sync, FSXM = 1.
  - Rising-edge frame sync, FSXP = 0.
  - Bit-width frame sync, FXWID = 0.
  - 384-slot TDM, XMOD = 1 1000 0000b.
- In transmit clock control register (ACLKXCTL), ASYNC = 1.
- In transmit bitstream format register (XFMT), XSSZ = 1111 (32-bit slot size).

All combinations of AHCLKX and ACLKX are supported.

This is a summary of the register configurations required for DIT mode. The DIT mode specific bit fields are in bold face:

- PFUNC: The data pins (AXRn) must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function.
- PDIR: The data pins (AXRn) must be configured as outputs. If AHCLKX is used as an input reference, it should be configured as input. If internal clock source AUXCLK is used as the reference clock, it may be output on the AHCLKX pin by configuring AHCLKX as an output.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable for DIT operation. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 14.2.10.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: Not applicable. Loopback is not supported for DIT mode. Leave at default.
- DITCTL: **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- RMASK: Not applicable. Leave at default.
- RFMT: Not applicable. Leave at default.
- AFSRCTL: Not applicable. Leave at default.
- ACLKRCTL: Not applicable. Leave at default.
- AHCLKRCTL: Not applicable. Leave at default.
- RTDM: Not applicable. Leave at default.
- RINTCTL: Not applicable. Leave at default.
- RCLKCHK: Not applicable. Leave at default.
- **XMASK**: Mask desired bits according to the discussion in this section, depending upon left-aligned or right-aligned internal data.

- **XFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XPBIT** = default (not applicable). **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. **XROT** bit is configured according to the discussion in this section, either 0 or 8-bit rotate.
- **AFSXCTL**: Configure the bits according to the discussion in this section.
- **ACLKXCTL**: **ASYNC** = 1. Program CLKXDIV bits to obtain the bit clock rate desired. Configure CLKXP and CLKXM bits as desired, because CLKX is not actually used in the DIT protocol.
- **AHCLKXCTL**: Program all fields according to high-frequency clock desired.
- **XTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- XINTCTL: Program all fields according to interrupts desired.
- XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Set **SRMOD** = 1 (transmitter) for the DIT pins. DISMOD field is don't care for DIT mode.
- **DITCSRA[n], DITCSRB[n]**: Program the channel status bits as desired.
- **DITUDRA[n], DITUDRB[n]**: Program the user data bits as desired.

14.2.6.3.3 DIT Channel Status and User Data Register Files

The channel status registers (DITCSRA*n* and DITCSRB*n*) and user data registers (DITUDRA*n* and DITUDRB*n*) are not double buffered. Typically the programmer uses one of the synchronizing interrupts, such as last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a requirement that the software avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it will be indeterminate whether the old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 14.1.6.2.2. The channel status information (C) and User Data (U) are defined in these DIT control registers:

- DITCSRA0 to DITCSRA5: The 192 bits in these six registers contain the channel status information for the LEFT channel within each frame.
- DITCSRB0 to DITCSRB5: The 192 bits in these six registers contain the channel status information for the RIGHT channel within each frame.
- DITUDRA0 to DITUDRA5: The 192 bits in these six registers contain the user data information for the LEFT channel within each frame.
- DITUDRB0 to DITUDRB5: The 192 bits in these six registers contain the user data information for the RIGHT channel within each frame.

The S/PDIF block format is shown in Figure 14-12. There are 192 frames within a block (frame 0 to frame 191). Within each frame there are two subframes (subframe 1 and 2 for left and right channels, respectively). The channel status and user data information sent on each subframe is summarized in Table 14-4.

Table 14-4. Channel Status and User Data for Each DIT Block

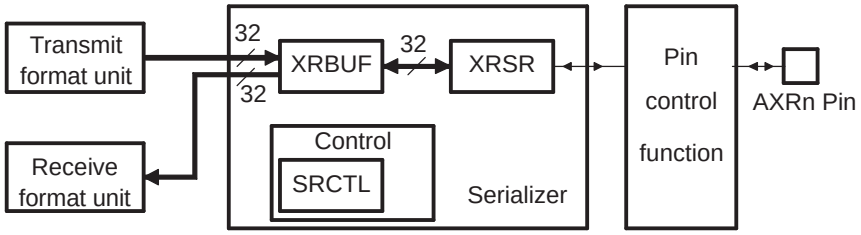
14.2.7 General Architecture

14.2.7.1 Serializers

Figure 14-21 shows the block diagram of the serializer and its interface to other units within the McASP. The serializers take care of shifting serial data in and out of the McASP. Each serializer consists of a shift register (XRSR), a data buffer (XRBUF), a control register (SRCTL), and logic to support the data alignment options of the McASP. For each serializer (XRSRn), there is a dedicated serial data pin (AXRn) and a dedicated control register (SRCTL[n]). The control register allows the serializer to be configured as a transmitter, receiver, or as inactive. When configured as a transmitter the serializer shifts out data to the serial data pin AXRn. When configured as a receiver, the serializer shifts in data from the AXRn pin. The serializer is clocked from the transmit/receive section clock (ACLKX/ACLKR) if configured to transmit/receive respectively.

All serializers that are configured to transmit operate in lock-step. Similarly, all serializers that are configured to receive also operate in lock-step. This means that at most there are two zones per McASP, one for transmit and one for receive.

Figure 14-21. Individual Serializer and Connections Within McASP



For receive, data is shifted in through the AXRn pin to the shift register XRSR. Once the entire slot of data is collected in the XRSR, the data is copied to the data buffer XRBUF. The data is now ready to be read by the processor through the RBUF register, which is an alias of the XRBUF for receive. When the processor reads from the RBUF, the McASP passes the data from RBUF through the receive format unit and returns the formatted data to the processor.

For transmit, the processor services the McASP by writing data into the XBUF register, which is an alias of the XRBUF for transmit. The data automatically passes through the transmit format unit before actually reaching the XRBUF register in the serializer. The data is then copied from XRBUF to XRSR, and shifted out from the AXRn synchronously to the serial clock.

In DIT mode, in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.).

The serializer configuration is controlled by SRCTL[n]. A serializer n is configured as inactive via setting bitfield SRCTLn[1:0] SRMOD to 0. For a transmitting serializer, the SRCTLn[3:2] DISMOD bitfield defines the AXRn pin output state during inactive slots (logic high, logic low, or 3-state). A serializer n is configured in a transmit function via setting bitfield SRCTLn[1:0] SRMOD to 1. A serializer n is configured in a receive function via setting bitfield SRCTLn[1:0] SRMOD to 2h.

14.2.7.2 Format Unit

The McASP has two data formatting units, one for transmit and one for receive. These units automatically remap the data bits within the transmitted and received words between a natural format for the processor (such as a Q31 representation) and the required format for the external serial device (such as "I2S format"). During the remapping process, the format unit also can mask off certain bits or perform sign extension.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP will not transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers. However, the McASP can transmit in one format while receiving in a completely different format.

This formatting unit consists of three stages:

- Bit mask and pad (masks off bits, performs sign extension)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

The MCASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size ≤ Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register, (R/X)FMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

Figure 14-22 shows a block diagram of the receive formatting unit, and Figure 14-23 shows the transmit formatting unit. Note that the order in which data flows through the three stages is different between the transmit and receive formatting units.

As shown in Figure 14-23, the data to the transmit format unit (TFU) can come from the configuration port (CFG) or the data port (DATA). The selection is made through the RFMT[3] RBUSEL bit. According to port type selected, data transfer has different behavior.

Figure 14-22. Receive Format Unit

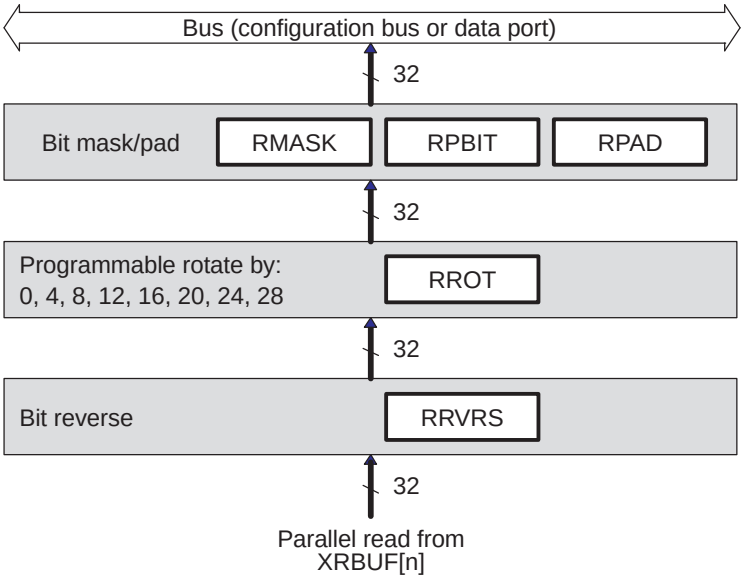


Figure 14-23. Transmit Format Unit

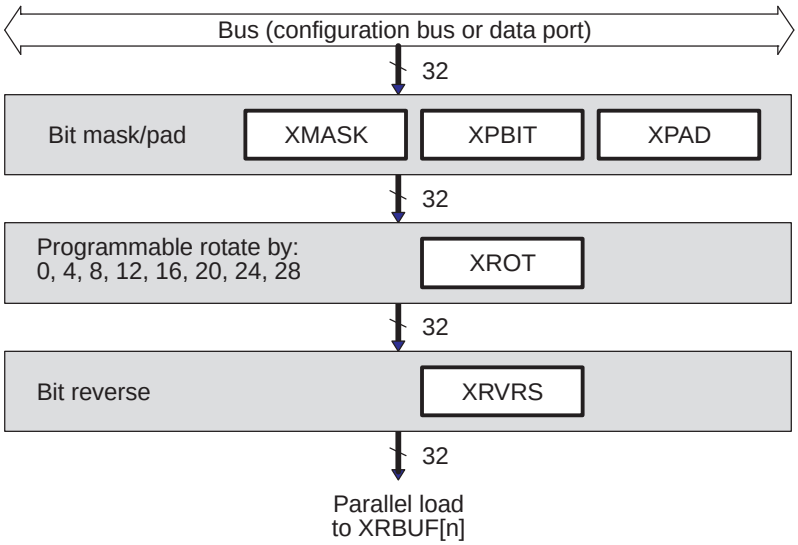


The bit mask and pad stage includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits.

The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the (R/X)FMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation.

The bit reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

Finally, note that the (R/X)DATDLY bits in (R/X)FMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, (R/X)DATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay.

The combination of all the options in (R/X)FMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal processor representation.

Section 14.2.8.3 provides more detail and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

14.2.7.3 State Machine

The receive and transmit sections have independent state machines. Each state machine controls the interactions between the various units in the respective section. In addition, the state machine keeps track of error conditions and serial port status.

No serial transfers can occur until the respective state machine is released from reset. See initialization sequence for details (Section 14.2.10).

The receive state machine is controlled by the RFMT register, and it reports the McASP status and error conditions in the RSTAT register. Similarly, the transmit state machine is controlled by the XFMT register, and it reports the McASP status and error conditions in the XSTAT register.

14.2.7.4 TDM Sequencer

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of (R/X)TDM and determines if the McASP should receive/transmit in that time slot.

If the McASP should participate (transmit/receive bit is active) in the time slot, the McASP functions normally. If the McASP should not participate (transmit/receive bit is inactive) in the time slot, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot. In addition, the serializers programmed as transmitters place their data output pins in a predetermined state (logic low, high, or high impedance) as programmed by each serializer control register (SRCTL). Refer also to Section 14.2.6.2 for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

The receive TDM sequencer is controlled by register RTDM and reports current receive slot to RSLOT. The transmit TDM sequencer is controlled by register XTDM and reports current transmit slot to XSLOT.

14.2.7.5 Clock Check Circuit

A common source of error in audio systems is a serial clock failure due to instabilities in the off-chip DIR circuit. To detect a clock error quickly, a clock-check circuit is included in the McASP for both transmit and receive clocks, since both may be sourced from off chip.

The clock check circuit can detect and recover from transmit and receive clock failures. See Section 14.2.8.4.6 for implementation and programming details.

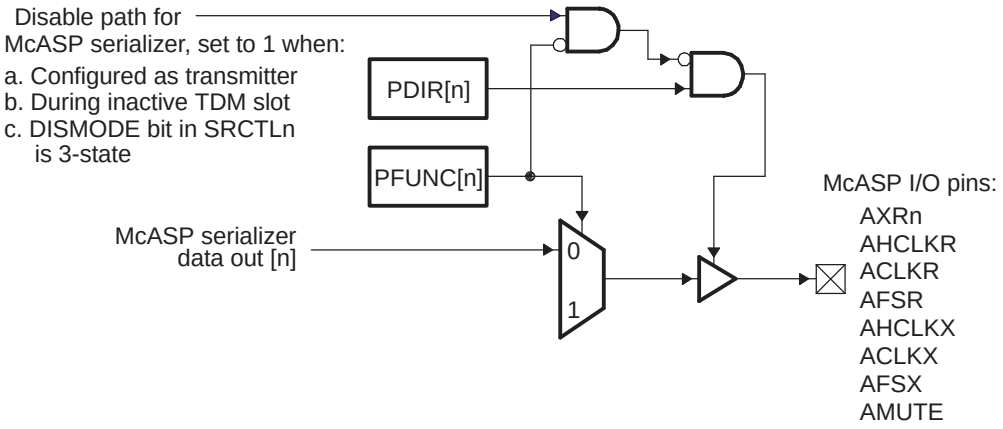
14.2.7.6 Pin Function Control

All McASP pins except AMUTEIN are bidirectional input/output pins. In addition, these bidirectional pins function either as McASP or general-purpose I/O (GPIO) pins. The following registers control the pin functions:

- Pin function register (PFUNC): selects pin to function as McASP or GPIO.
- Pin direction register (PDIR): selects pin to be input or output.
- Pin data input register (PDIN): shows data input at the pin.
- Pin data output register (PDOUT): data to be output at the pin if the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1). Not applicable when the pin is configured as McASP pin (PFUNC[n] = 0).
- Pin data set register (PDSET): alias of PDOUT. Writing a 1 to PDSET[n] sets the respective PDOUT[n] to 1. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).
- Pin data clear register (PDCLR): alias of PDOUT. Writing a 1 to PDCLR[n] clears the respective PDOUT[n] to 0. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).

See the register descriptions in Section 14.3 for details on the mapping of each McASP pin to the register bits. Figure 14-24 shows the pin control block diagram.

Figure 14-24. McASP I/O Pin Control Block Diagram



14.2.7.6.1 McASP Pin Control-Transmit and Receive

You must correctly set the McASP GPIO registers PFUNC and PDIR, even when McASP pins are used for their serial port (non-GPIO) function.

Serial port functions include:

- Clock pins (ACLKX, ACLKR, AHCLKX, AHCLKR, AFSX, AFSR) used as clock inputs and outputs.
- Serializer data pins (AXRn) used to transmit or receive.
- AMUTE used as a mute output signal.

When using these pins in their serial port function, you must clear PFUNC[n] to 0 for each pin.

Also, certain outputs require PDIR[n] = 1, such as clock pins used as clock outputs, serializer data pins used to transmit, and AMUTE used as mute output.

Clock inputs and serializers configured to receive must have PDIR[n] = 0.

PFUNC and PDIR do not control the AMUTEIN signal, it is usually tied to a device level interrupt pin (consult device datasheet). If used as a mute input, this pin needs to be configured as an input in the appropriate peripheral.

Finally, there is an important advantage to having separate control of pin direction (by PDIR), and the choice of internal versus external clocking (by CLKRM/CLKXM). Depending on the specific device and usage, you might select an external clock (CLKRM = 0), while enabling the internal clock divider, and the clock pin as an output in the PDIR register (PDIR[ACLKR] = 1). In this case, the bit clock is an output (PDIR[ACLKR] = 1) and, therefore, routed to the ACLKR pin. However, because CLKRM = 0, the bit clock is then routed back to the McASP module as an "external" clock source. This may result in less skew between the clock inside the McASP and the clock in the external device, thus producing more balanced setup and hold times for a particular system. As a result, this may allow a higher serial clock rate interface.

14.2.8 Operation

This section discusses the operation of the McASP.

14.2.8.1 Data Transmission and Reception

The processor services the McASP by writing data to the XBUF register(s) for transmit operations, and by reading data from the RBUF register(s) for receive operations. The McASP sets status flag and notifies the processor whenever data is ready to be serviced. Section 14.2.8.1.1 discusses data ready status in detail.

The XBUF and RBUF registers can be accessed through one of the two peripheral ports of the device:

- The data port (DAT): This port is dedicated for data transfers on the device.
- The configuration bus (CFG): This port is used for both data transfers and peripheral configuration control on the device.

Section 14.2.8.1.2 and Section 14.2.8.1.3 discuss how to perform transfers through the data port and the configuration bus.

Either the CPU or the DMA can be used to service the McASP through any of these two peripheral ports. The CPU and DMA usages are discussed in Section 14.2.8.1.4 and Section 14.2.12.2.

14.2.8.1.1 Data Ready Status and Event/Interrupt Generation

14.2.8.1.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the XSTAT register reflects the status of the XBUF register. The XDATA flag is set when data is transferred from the XRBUF[n] buffers to the XRSR[n] shift registers, indicating that the XBUF is empty and ready to accept new data from the processor. The transmit data ready event is individually indicated per serializer in its corresponding control register SRCTLn[4] XRDY status bit. When this bit is set to 1, it notifies to the host that this serializer Tx buffer must be serviced (written). When XBUFn is written to by the host, the SRCTLn[4] XRDY is deasserted to 0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA = 1). The XRDY flags have to be sequentially scanned by user software to determine which serializer TXBUFn register has to be currently written. Once all requested TXBUFn are written, the serializers control XRDY flags are cleared to 0. As a consequence, XDATA flag is deasserted to 0 to indicate to software that write operation is completed for all serializers. The global XDATA flag can be cleared when the XSTAT[5] XDATA bit is written to 1 or once TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, an DMA event AXEVT is automatically generated to notify the DMA of the XBUF empty status. An interrupt AXINT is also generated if XDATA interrupt is enabled in the XINTCTL register (See Section 14.2.11.1 for details).

For DMA requests, the McASP does not require XSTAT to be read between DMA events. This means that even if XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

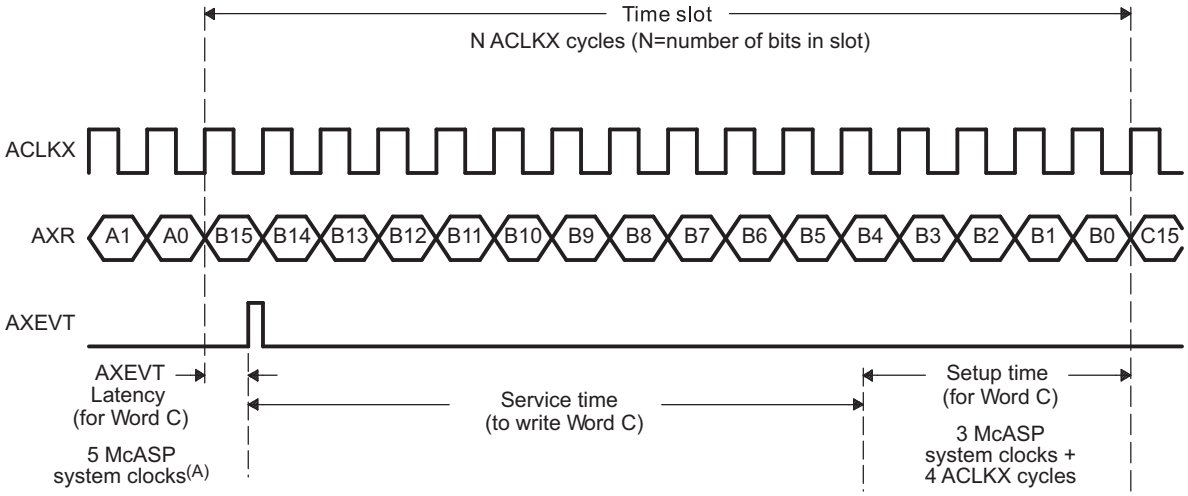
Since all serializers act in lockstep, only one DMA event is generated to indicate that all active transmit serializers are ready to be written to with new data.

Figure 14-25 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to 5 McASP system clocks (AXEVT Latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the processor can begin servicing the McASP by writing Word C into the XBUF (Processor Service Time). The processor must write Word C into the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 14-25) can be calculated as:

Processor Service Time = Time Slot - AXEVT Latency - Setup Time

Figure 14-25. Processor Service Time Upon Transmit DMA Event (AXEVT)



A Refer to the device-specific data manual for the McASP system clock source. This is not the same as AUXCLK.

Example 14-1. Processor Service Time Calculation for Transmit DMA Event (AXEVT)

The following is an example to show how to calculate Processor Service Time. Assume the following setup:

- Device: C64x+ DSP at 300 MHz.
- McASP transmits in I2S format at 192 kHz frame rate. Assume slot size is 32 bit.

With the above setup, we obtain the following parameters corresponding to Figure 14-25:

- Calculation of McASP system clock cycle:
  - C64x+ DSP uses SYSCLK2 as the McASP system clock. It runs at 150 MHz (half of device frequency).
  - Therefore, McASP system clock cycle = 1/150 MHz = 6.7 ns.
- Calculation of ACLKX clock cycle:
  - This example has two 32-bit slots per frame, for a total of 64 bits per frame.
  - ACLKX clock cycle is (1/192 kHz)/64 = 81.4 ns.
- Time Slot between AXEVT events:
  - For I2S format, McASP generates two AXEVT events per 192 kHz frame.
  - Therefore, Time Slot between AXEVT events is (1/192 kHz)/2 = 2604 ns.
- AXEVT Latency:
  = 5 McASP system clocks
  = 6.7 ns × 5 = 33.5 ns
- Setup Time
  = 3 McASP system clocks + 4 ACLKX cycles
  = (6.7 ns × 3) + (81.4 ns × 4)
  = 345.7 ns
- Processor Service Time
  = Time Slot - AXEVT Latency - Setup Time
  = 2604 ns - 33.5 ns - 345.7 ns
  = 2225 ns

14.2.8.1.1.2 Receive Data Ready

Similarly, the receive data ready flag, RDATA, in the RSTAT register reflects the data ready status of XRBUFn buffers for all of the active slot receiving serializers. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer, RXBUFn, already contains received data (that is, a buffer is full) and is ready to transfer it to the host (MPU). The receive data ready event is individually indicated per serializer in its corresponding control register SRCTLn [5] RRDY status bit. When this bit is set to 1, it notifies to host that this serializer Rx buffer must be serviced (read). When RXBUF[n] is read from the host, the SRCTLn [5] RRDY is deasserted to 0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA = 1). The RRDY flags have to be sequentially scanned by user software to determine which serializer RXBUFn register has to be currently read. Once all requested RXBUFn are read, the serializers control RRDY flags are cleared to 0. As a consequence, RDATA flag is deasserted to 0, to indicate to software that read operation is completed for all n serializers. The global RDATA flag can be cleared when the RSTAT[5] RDATA bit is written to 1 or once RXBUFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host. (See Section 14.2.11.2 for details).

For DMA requests, the McASP does not require RSTAT to be read between DMA events. This means that even if RSTAT already has the RDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active receive serializers are ready to receive new data.

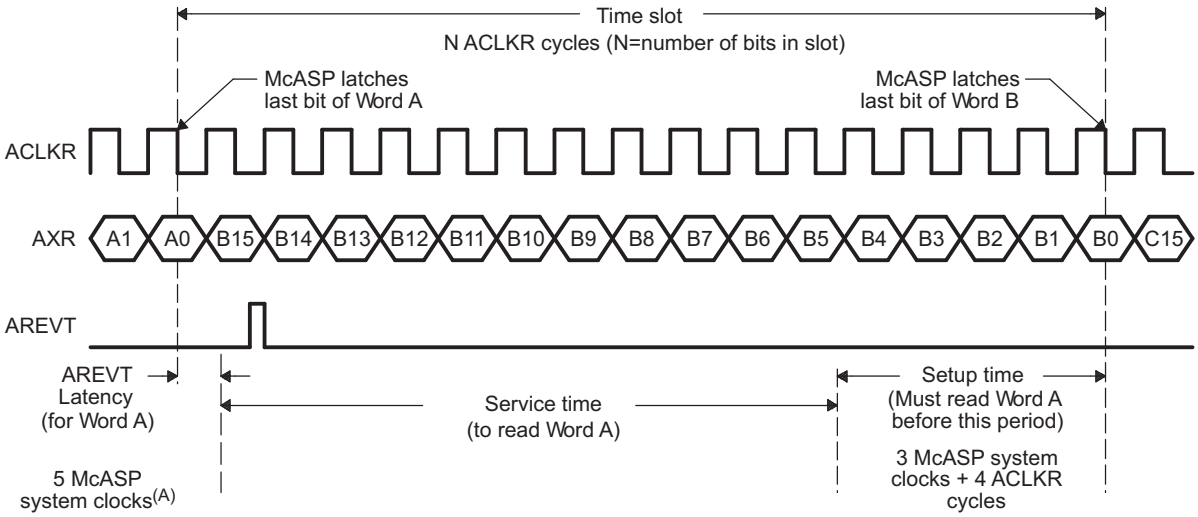
Figure 14-26 shows the timing details of when AREVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to 5 McASP system clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the processor can begin servicing the McASP by reading Word A from the RBUF (Processor Service Time). The processor must read Word A from the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 14-26) can be calculated as:

Processor Service Time = Time Slot - AREVT Latency - Setup Time

The Processor Service Time calculation for receive is similar to the calculation for transmit. See Example 14-1 for Processor Service Time calculation using transmit as an example.

Figure 14-26. Processor Service Time Upon Receive DMA Event (AREVT)



A The device uses SYSCLK2 as the McASP system clock source.

14.2.8.1.2 Transfers Through the Data Port (DAT)

NOTE: The data port (DAT) addresses are located in L3 and L4 tables in the device data sheet for the appropriate data peripheral registers. To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

Typically, you will access the McASP XRBUF registers through the data port. To access through the data port, simply have the CPU or DMA access the XRBUF through its data port location. Refer to the device-specific data manual for the exact memory address. Through the data port, the DMA/CPU can service all the serializers through a single address. The McASP automatically cycles through the appropriate serializers.

For transmit operations through the data port, the DMA/CPU should write to the same XBUF data port address to service all of the active transmit serializers. In addition, the DMA/CPU should write to the XBUF for all active transmit serializers in incremental (although not necessarily consecutive) order. For example, if serializers 0, 4, and 5, are set up as active transmitters, the DMA/CPU should write to the XBUF data port address four times with data for serializers 0, 4, and 5, upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Similarly, for receive operations through the data port, the DMA/CPU should read from the same RBUF data port address to service all of the active receive serializers. In addition, reads from the active receive serializers through the data port return data in incremental (although not necessarily consecutive) order. For example, if serializers 1, 2, and 3, are set up as active receivers, the DMA/CPU should read from the RBUF data port address four times to obtain data for serializers 1, 2, and 3, in this exact order, upon each receive data ready event.

When transmitting, the DMA/CPU must write data to each serializer configured as "active" (active slot in XTDM register) and "transmit" (Tx enabled in SCRCTLn register) within each time slot. Failure to do so results in a buffer underrun condition (Section 14.2.8.4.2). Similarly, when receiving, data must be read from each serializer configured as "active" (active slot in RTDM register) and "receive" (Rx enabled in SCRCTLn register) within each time slot. Failure to do results in a buffer overrun condition (Section 14.2.8.4.3).

To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers.

14.2.8.1.3 Transfers Through the Configuration Bus (CFG)

NOTE: To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

In this method, the DMA/CPU accesses the XRBUF registers through the configuration bus address. The exact XRBUF register address for any particular serializer is determined by adding the offset for that particular serializer to the base address for the particular McASP (found in the device-specific data manual). XRBUF for the serializers configured as transmitters is given the name XBUF*n*. For example, the XRBUF associated with transmit serializer 2 is named XBUF2. Similarly, XRBUF for the serializers configured as receivers is given the name RBUF*n*.

Accessing the XRBUF registers through the data port is different because the CPU/DMA only needs to access one single address. When accessing through the configuration bus, the CPU/DMA must provide the exact XBUF*n* or RBUF*n* address for each access.

When transmitting, DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 14.2.8.4.2). Similarly when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition (Section 14.2.8.4.3).

To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers.

14.2.8.1.4 Using the CPU for McASP Servicing

The CPU can be used to service the McASP through interrupt (upon AXINT/ARINT interrupts) or through polling the XDATA bit in the XSTAT register and the RDATA bit in the RSTAT register. As discussed in Section 14.2.8.1.2 and Section 14.2.8.1.3, the CPU can access XRBUF serializer buffer through either the data port or through the configuration bus.

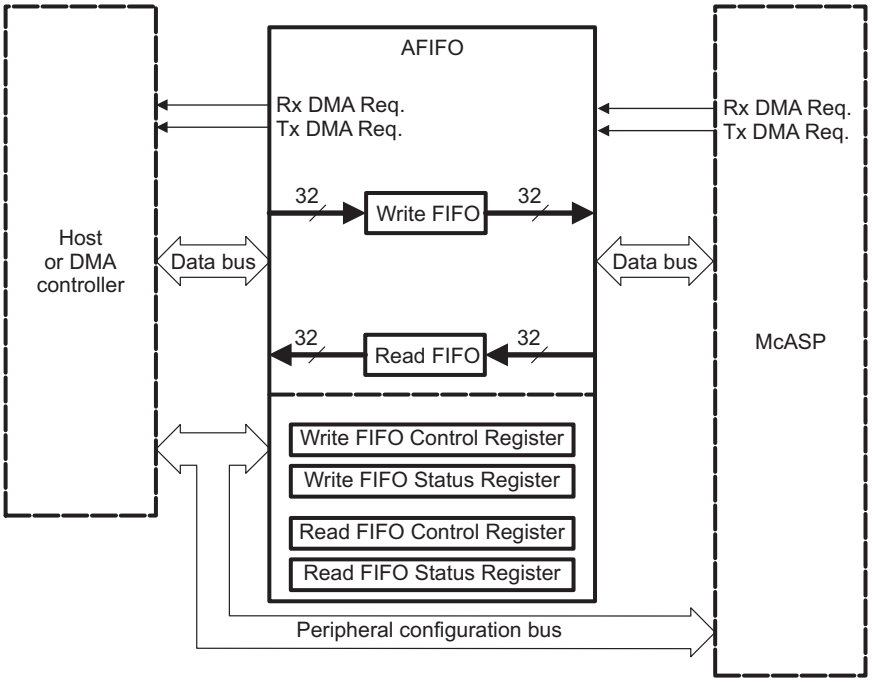
To use the CPU to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective XINTCTL/RINTCTL registers, to generate interrupts AXINT/ARINT to the CPU upon data ready.

14.2.8.2 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 14-27 for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP (see Section 14.2.10.2 for details).

Figure 14-27. McASP Audio FIFO (AFIFO) Block Diagram



14.2.8.2.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes *WNUMDMA* 32-bit words to the McASP if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes *WNUMDMA* words to the McASP. (See description for WFIFOCTL.WNUMDMA in Section 14.3.43.)

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

14.2.8.2.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the FIFO, it checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, WFIFOCTL.WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL.WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL.WNUMEVT should be set equal to the value in WFIFOCTL.WNUMDMA.

14.2.8.2.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McASP, if and when the RFIFO has space for *RNUMDMA* words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads *RNUMDMA* words from the McASP. (See description for RFIFOCTL.RNUMDMA in Section 14.3.45.)

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the FIFO.

14.2.8.2.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, RFIFOCTL.RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL.RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL.RNUMEVT should be set equal to the value in RFIFOCTL.RNUMDMA.

14.2.8.2.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

14.2.8.3 Formatter

14.2.8.3.1 Transmit Bit Stream Data Alignment

The McASP transmitter supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the transmit bitstream format register (XFMT):

- XRVRS: bit reverse (1) or no bit reverse (0).
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

XSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

Table 14-5 and Figure 14-28 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size (SLOT in Table 14-5) and word size (WORD in Table 14-5) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit (see Figure 14-23), and the data is aligned in the same representation as it is written to the transmitter by the processor (typically Q31 or integer).

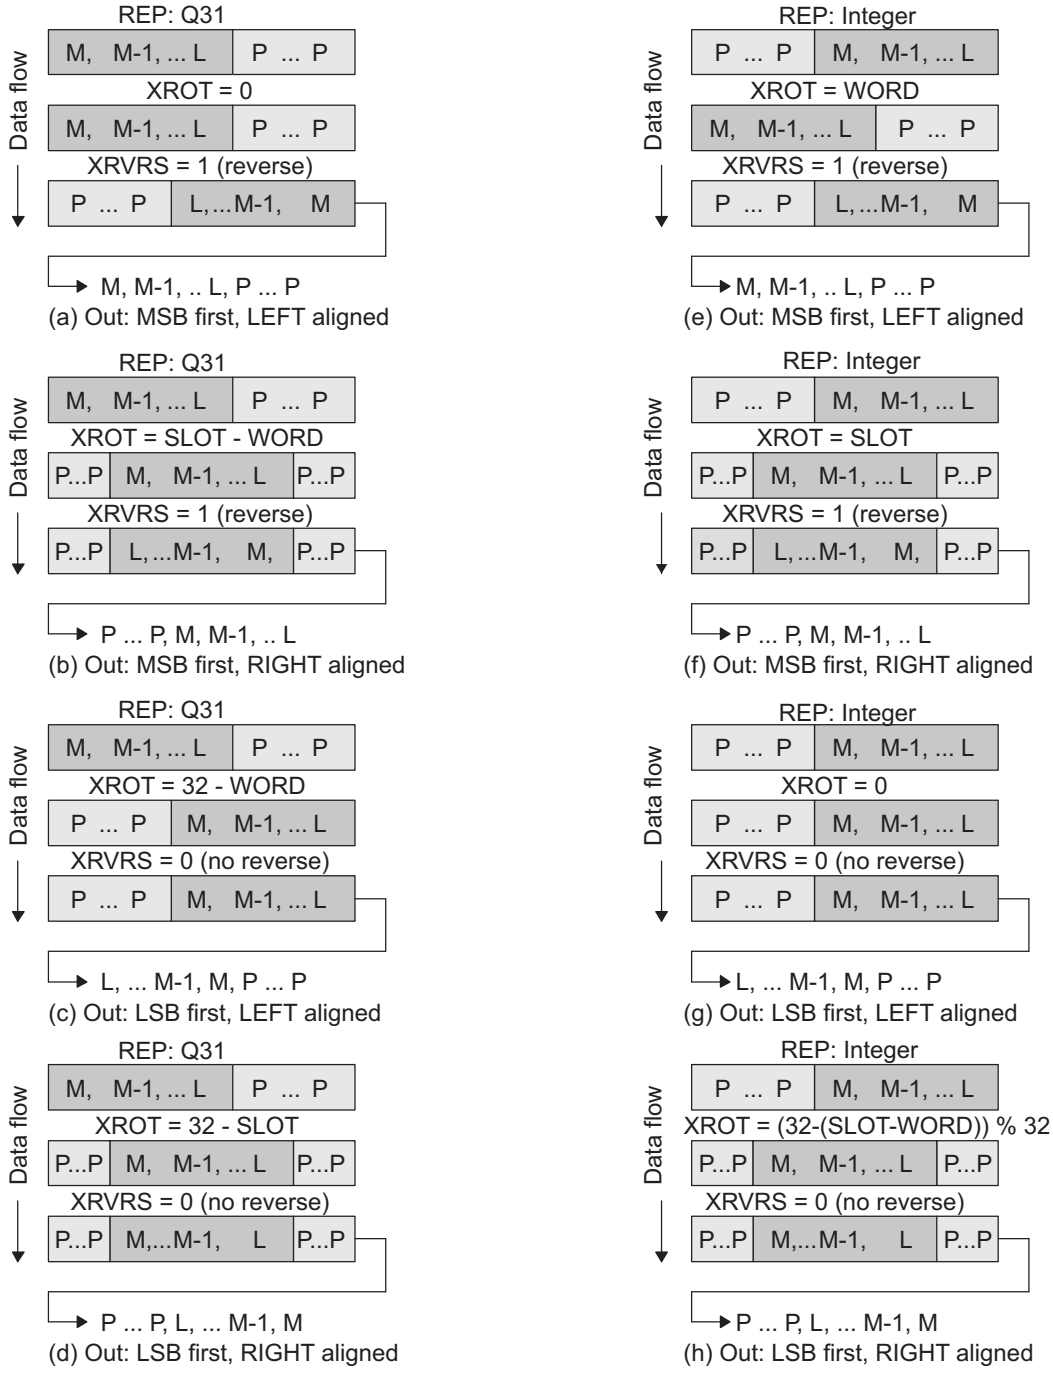
Table 14-5. Transmit Bitstream Data Alignment

Figure 14-28	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	XFMT Bit	
				XROT[1]	XRVRS
(a)[2]	MSB first	Left aligned	Q31 fraction	0	1
(b)	MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
(c)	LSB first	Left aligned	Q31 fraction	32 - WORD	0
(d)	LSB first	Right aligned	Q31 fraction	32 - SLOT	0
(e)[2]	MSB first	Left aligned	Integer	WORD	1
(f)	MSB first	Right aligned	Integer	SLOT	1
(g)	LSB first	Left aligned	Integer	0	0
(h)	LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, use MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

Figure 14-28. Data Flow Through Transmit Format Unit, Illustrated



14.2.8.3.2 Receive Bit Stream Data Alignment

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register (RFMT):

- RRVRS: bit reverse (1) or no bit reverse (0).
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

RSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 14-6 and Figure 14-29 show the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 14-22), and the data is aligned in the same representation as it is read from the receiver by the processor (typically Q31 or integer).

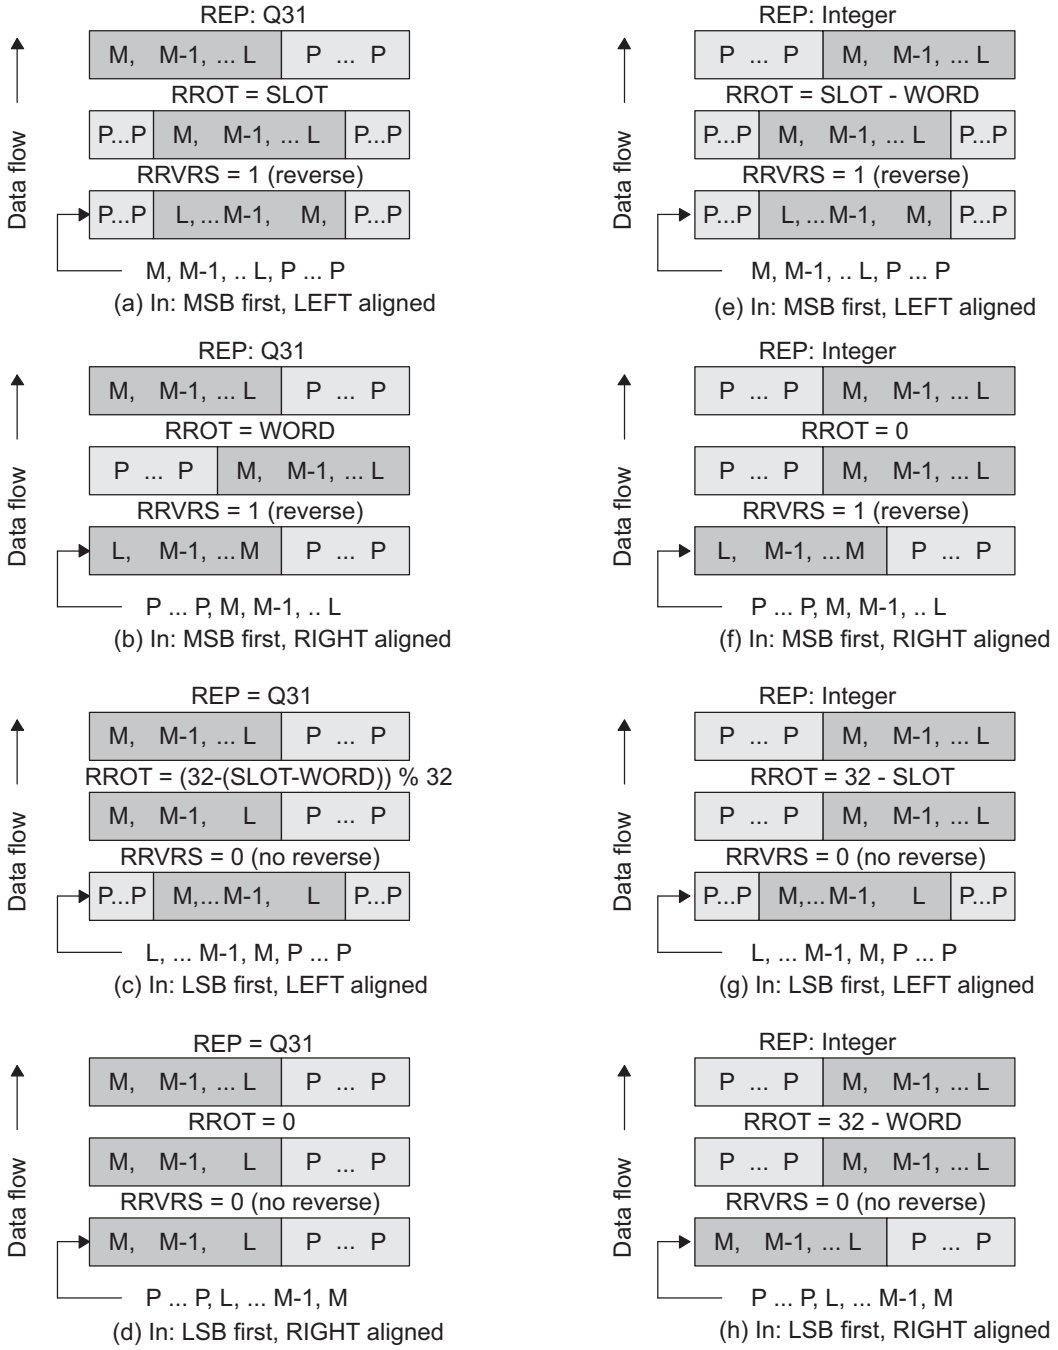
Table 14-6. Receive Bitstream Data Alignment

Figure 14-29	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	RFMT Bit	
				RROT[1]	RRVRS
(a)[2]	MSB first	Left aligned	Q31 fraction	SLOT	1
(b)	MSB first	Right aligned	Q31 fraction	WORD	1
(c)	LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
(d)	LSB first	Right aligned	Q31 fraction	0	0
(e)[2]	MSB first	Left aligned	Integer	SLOT - WORD	1
(f)	MSB first	Right aligned	Integer	0	1
(g)	LSB first	Left aligned	Integer	32 - SLOT	0
(h)	LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

Figure 14-29. Data Flow Through Receive Format Unit, Illustrated



14.2.8.4 Error Handling and Management

To support the design of a robust audio system, the McASP includes error-checking capability for the serial protocol, data underrun, and data overrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX/AHCLKR clock cycles. The timer value can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

Upon the detection of any one or more errors (software selectable), or the assertion of the AMUTEIN input pin, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt may be generated if desired, based on any one or more of the error sources.

14.2.8.4.1 Unexpected Frame Sync Error

An unexpected frame sync occurs when:

- In burst mode, when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- In TDM mode, a further constraint is that the frame sync must occur exactly during the correct bit clock (not a cycle earlier or later) and only before slot 0. An unexpected frame sync occurs if this condition is not met.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. Early: An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. Late: A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in both burst mode and TDM mode; however, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

14.2.8.4.2 Buffer Underrun Error - Transmitter

A buffer underrun can only occur for serializers programmed to be transmitters. A buffer underrun occurs when the serializer is instructed by the transmit state machine to transfer data from XRBUF[n] to XRSR[n], but XRBUF[n] has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the processor explicitly writes a 1 to the XUNDRN bit to clear the XUNDRN bit.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 × fs). By shifting out a pair of zeros, a clock may be recovered on the receiver. To recover, reset the McASP and start again with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

14.2.8.4.3 Buffer Overrun Error - Receiver

A buffer overrun can only occur for serializers programmed to be receivers. A buffer overrun occurs when the serializer is instructed to transfer data from XRSR[n] to XRBUF[n], but XRBUF[n] has not yet been read by either the DMA or the processor. When this occurs, the receiver state machine sets the ROVRN flag. However, the individual serializer writes over the data in the XRBUF[n] register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the processor catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the processor explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

14.2.8.4.4 DMA Error - Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the XSTAT register, occurs when the DMA (or CPU) writes more words to the DAT port of the McASP than it should. For each DMA event, the DMA should write exactly as many words as there are serializers enabled as transmitters.

XDMAERR indicates that the DMA (or CPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP transmitter and the DMA to resynchronize them.

14.2.8.4.5 DMA Error - Receiver

A receive DMA error, as indicated by the RDMAERR flag in the RSTAT register, occurs when the DMA (or CPU) reads more words from the DAT port of the McASP than it should. For each DMA event, the DMA should read exactly as many words as there are serializers enabled as receivers.

RDMAERR indicates that the DMA (or CPU) read too many words from the McASP for a given receive DMA event. Reading too few words results in a receiver overrun error setting ROVRN in RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP receiver and the DMA to resynchronize them.

14.2.8.4.6 Clock Failure Detection

14.2.8.4.6.1 Clock-Failure Check Startup

It is expected, initially, that the clock-failure circuits will generate an error until at least one measurement has been taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not immediately be enabled, but be enabled only after a specific startup procedure. The startup procedure is:

1. For the transmit clock failure check:
   (a) Configure transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (XCLKCHK).
   (b) Clear transmit clock failure flag (XCKFAIL) in the transmit status register (XSTAT).
   (c) Wait until first measurement is taken (> 32 AHCLKX clock periods).
   (d) Verify no clock failure is detected.
   (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   (f) After the transmit clock is measured and falls within the acceptable range, the following may be enabled:
      (i) transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (XINTCTL).
      (ii) mute option (XCKFAIL) in the mute control register (AMUTE).
2. For the receive clock failure check:
   (a) Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (RCLKCHK).
   (b) Clear receive clock failure flag (RCKFAIL) in the receive status register (RSTAT).
   (c) Wait until first measurement is taken (> 32 AHCLKR clock periods).
   (d) Verify no clock failure is detected.
   (e) Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   (f) After the receive clock is measured and falls within the acceptable range, the following may be enabled:
      (i) receive clock failure interrupt enable bit (RCKFAIL) in the receiver interrupt control register (RINTCTL).
      (ii) mute option (RCKFAIL) in the mute control register (AMUTE).

14.2.8.4.6.2 Transmit Clock Failure Check and Recovery

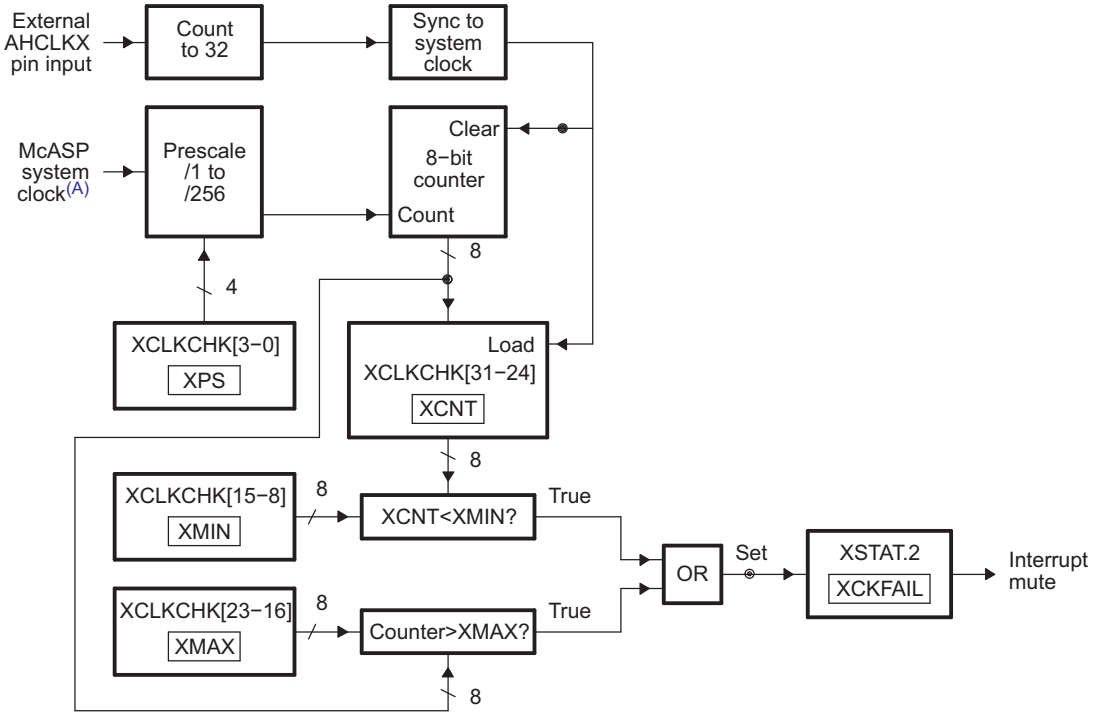
The transmit clock failure check circuit (Figure 14-30) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (XCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in XSTST) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than XMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (XMAX). This is in case the external clock completely stops, so that the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. Note that the XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected, or that the audio source has changed and a new sample rate is being used.

In order for the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKX is internally generated or externally sourced.

Figure 14-30. Transmit Clock Failure Detection Circuit Block Diagram



A Refer to the device data manual for the McASP system clock source. This is not the same as AUXCLK.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in XSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in XINTCTL is set.

14.2.8.4.6.3 Receive Clock Failure Check and Recovery

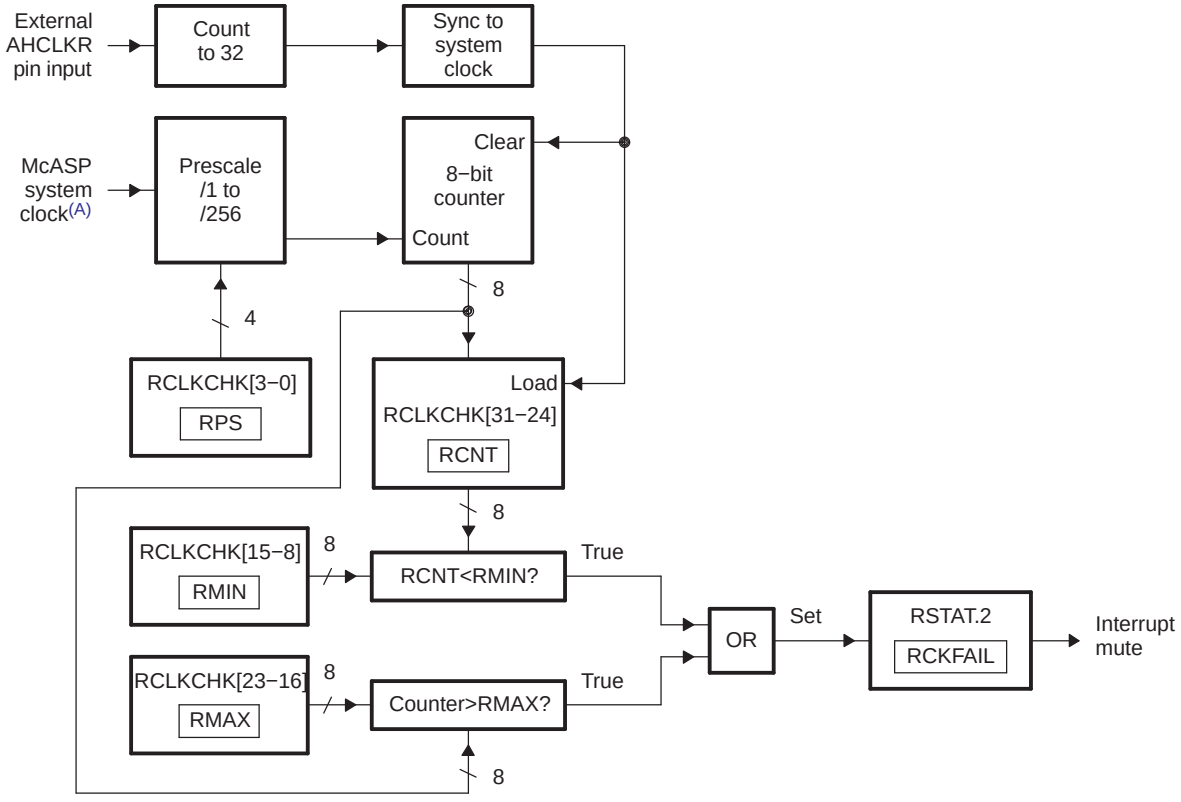
The receive clock failure check circuit (Figure 14-31) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an interrupt (RCKFAIL in RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR is internally generated or externally sourced.

Figure 14-31. Receive Clock Failure Detection Circuit Block Diagram



A Refer to device data manual for the McASP system clock source. This is not the same as AUXCLK.

14.2.8.5 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows testing of the McASP code in TDM mode with a single processor device. In loopback mode, output of the transmit serializers is connected internally to the input of the receive serializers. Therefore, you can check the receive data against the transmit data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 180h) or burst mode (XMOD = 0).

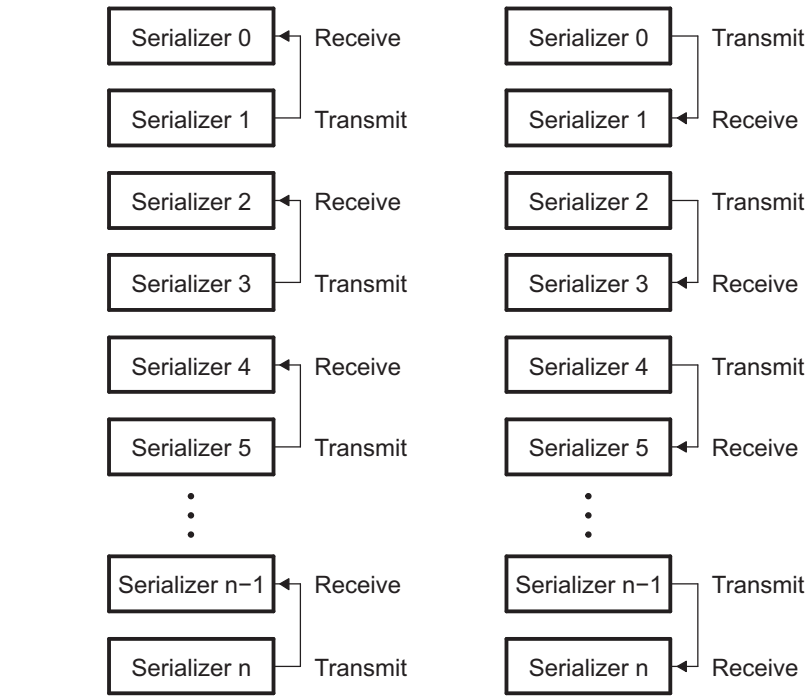
Figure 14-32 shows the basic logical connection of the serializers in loopback mode. Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register (DLBCTL) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, you should configure odd serializers to be transmitters and even serializers to be receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, you should configure even serializers to be transmitters and odd serializers to be receivers.

Data can be externally visible at the I/O pin of the transmit serializer if the pin is configured as a McASP output pin by setting the corresponding PFUNC bit to 0 and PDIR bit to 1.

In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bit of the DLBCTL register to 01b and the ASYNC bit of the ACLKXCTL register to 0.

Figure 14-32. Serializers in Loopback Mode



(a) DLBEN = 1 (loopback enabled) and ORD = 0 (even receive, odd transmit)

(b) DLBEN = 1 (loopback enabled) and ORD = 1 (odd receive, even transmit)

14.2.8.5.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The DLBEN bit in DLBCTL must be set to 1 to enable loopback mode.
- The MODE bits in DLBCTL must be set to 01b for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The ORD bit in DLBCTL must be programmed appropriately to select odd or even serializers to be transmitters or receivers. The corresponding serializers must be configured accordingly.
- The ASYNC bit in ACLKXCTL must be cleared to 0 to ensure synchronous transmit and receive operations.
- RMOD field in AFSRCTL and XMOD field in AFSXCTL must be set to 2h to 20h to indicate TDM mode. Loopback mode does not apply to DIT or burst mode.

14.2.9 Reset Considerations

The McASP has two reset sources: software reset and hardware reset.

14.2.9.1 Software Reset Considerations

The transmitter and receiver portions of the McASP may be put in reset through the global control register (GBLCTL). Note that a valid serial clock must be supplied to the desired portion of the McASP (transmit and/or receive) in order to assert the software reset bits in GBLCTL. see Section 14.2.10.2for details on how to ensure reset has occurred.

The entire McASP module may also be reset through the Power and Sleep Controller (PSC). Note that from the McASP perspective, this reset appears as a hardware reset to the entire module.

14.2.9.2 Hardware Reset Considerations

When the McASP is reset due to device reset, the entire serial port (including the transmitter and receiver state machines, and other registers) is reset.

14.2.10 Setup and Initialization

This section discusses steps necessary to use the McASP module.

14.2.10.1 Considerations When Using a McASP

The following is a list of things to be considered for systems using a McASP:

14.2.10.1.1 Clocks

For each receive and transmit section:

- External or internal generated bit clock and high frequency clock?
- If internally generated, what is the bit clock speed and the high frequency clock speed?
- Clock polarity?
- External or internal generated frame sync?
- If internally generated, what is frame sync speed?
- Frame sync polarity?
- Frame sync width?
- Transmit and receive sync or asynchronous?

14.2.10.1.2 Data Pins

For each pin of each McASP:

- McASP or GPIO?
- Input or output?

14.2.10.1.3 Data Format

For each transmit and receive data:

- Internal numeric representation (integer, Q31 fraction)?
- I2S or DIT (transmit only)?
- Time slot delay (0, 1, or 2 bit)?
- Alignment (left or right)?
- Order (MSB first, LSB first)?
- Pad (if yes, pad with what value)?
- Slot size?
- Rotate?
- Mask?

14.2.10.1.4 Data Transfers

- Internal: DMA or CPU?
- External: TDM or burst?
- Bus: configuration bus (CFG) or data port (DAT)?

14.2.10.2 Transmit/Receive Section Initialization

You must follow the following steps to properly configure the McASP. If external clocks are used, they should be present prior to the following initialization steps.

1. Reset McASP to default values by setting GBLCTL = 0. Poll the bits to ensure that the active reset value (0) is successfully latched into the GBLCTL register.
2. Configure all McASP registers except GBLCTL in the following order:
   (a) Receive registers: RMASK, RFMT, AFSRCTL, ACLKRCTL, AHCLKRCTL, RTDM, RINTCTL, RCLKCHK. If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the GBLCTL register.
   (b) Transmit registers: XMASK, XFMT, AFSXCTL, ACLKXCTL, AHCLKXCTL, XTDM, XINTCTL, XCLKCHK. If external clocks AHCLKX and/or ACLKX are used, they must be running already for proper synchronization of the GBLCTL register.
   (c) Serializer registers: SRCTL[n].
   (d) Global registers: Registers PFUNC, PDIR, DITCTL, DLBCTL, AMUTE. Note that PDIR should only be programmed after the clocks and frames are set up in the steps above. This is because the moment a clock pin is configured as an output in PDIR, the clock pin starts toggling at the rate defined in the corresponding clock control register. Therefore you must ensure that the clock control register is configured appropriately before you set the pin to be an output. A similar argument applies to the frame sync pins. Also note that the reset state for the transmit high-frequency clock divide register (HCLKXDIV) is divide-by-1, and the divide-by-1 clocks are not gated by the transmit high-frequency clock divider reset enable (XHCLKRST).
   (e) DIT registers: For DIT mode operation, set up registers DITCSRA[n], DITCSRB[n], DITUDRA[n], and DITUDRB[n].
3. Start the respective high-frequency serial clocks AHCLKX and/or AHCLKR. This step is necessary even if external high-frequency serial clocks are used:
   (a) Take the respective internal high-frequency serial clock divider(s) out of reset by setting the RHCLKRST bit for the receiver and/or the XHCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be held at 0.
   (b) Software must read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

4. Start the respective serial clocks ACLKX and/or ACLKR. This step can be skipped if external serial clocks are used and they are running:
   (a) Take the respective internal serial clock divider(s) out of reset by setting the RCLKRST bit for the receiver and/or the XCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
5. Setup data acquisition as required:
   (a) If DMA is used to service the McASP, set up data acquisition as desired and start the DMA in this step, before the McASP is taken out of reset.
   (b) If CPU interrupt is used to service the McASP, enable the transmit and/ or receive interrupt as required.
   (c) If CPU polling is used to service the McASP, no action is required in this step.
6. Activate serializers.
   (a) Before starting, clear the respective transmitter and receiver status registers by writing XSTAT = FFFFh and RSTAT = FFFFh.
   (b) Take the respective serializers out of reset by setting the RSRCLR bit for the receiver and/or the XSRCLR bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (c) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
7. Verify that all transmit buffers are serviced. Skip this step if the transmitter is not used. Also, skip this step if time slot 0 is selected as inactive (special cases, see Figure 14-20, second waveform). As soon as the transmit serializer is taken out of reset, XDATA in the XSTAT register is set, indicating that XBUF is empty and ready to be serviced. The XDATA status causes an DMA event AXEVT to be generated, and can cause an interrupt AXINT to be generated if it is enabled in the XINTCTL register.
   (a) If DMA is used to service the McASP, the DMA automatically services the McASP upon receiving AXEVT. Before proceeding in this step, you should verify that the XDATA bit in the XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the DMA.
   (b) If CPU interrupt is used to service the McASP, interrupt service routine is entered upon the AXINT interrupt. The interrupt service routine should service the XBUF registers. Before proceeding in this step, you should verify that the XDATA bit in XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the CPU.
   (c) If CPU polling is used to service the McASP, the XBUF registers should be written to in this step.
8. Release state machines from reset.
   (a) Take the respective state machine(s) out of reset by setting the RSMRST bit for the receiver and/or the XSMRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
9. Release frame sync generators from reset. Note that it is necessary to release the internal frame sync generators from reset, even if an external frame sync is being used, because the frame sync error detection logic is built into the frame sync generator.
   (a) Take the respective frame sync generator(s) out of reset by setting the RFRST bit for the receiver, and/or the XFRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   (b) Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

10. Upon the first frame sync signal, McASP transfers begin. The McASP synchronizes to an edge on the frame sync pin, not the level on the frame sync pin. This makes it easy to release the state machine and frame sync generators from reset.
    (a) For example, if you configure the McASP for a rising edge transmit frame sync, then you do not need to wait for a low level on the frame sync pin before releasing the McASP transmitter state machine and frame sync generators from reset.

14.2.10.3 Separate Transmit and Receive Initialization

In many cases, it is desirable to separately initialize the McASP transmitter and receiver. For example, you may delay the initialization of the transmitter until the type of data coming in on the receiver is recognized. Or a change in the incoming data stream on the receiver may necessitate a reinitialization of the transmitter.

In this case, you may still follow the sequence outlined in Section 14.2.10.2, but use it for each section (transmit, receive) individually. The GBLCTL register is aliased to RGBLCTL and XGBLCTL to facilitate separate initialization of transmit and receive sections.

14.2.10.4 Importance of Reading Back GBLCTL

In Section 14.2.10.2, steps 3b, 4b, 6c, 8b, and 9b state that GBLCTL should be read back until the bits that were written are successfully latched. This is important, because the transmitter and receiver state machines run off of the respective bit clocks, which are typically about tens to hundreds of times slower than the processor's internal bus clock. Therefore, it takes many cycles between when the processor writes to GBLCTL (or RGBLCTL and XGBLCTL), and when the McASP actually recognizes the write operation. If you skip this step, then the McASP may never see the reset bits in the global control registers get asserted and de-asserted; resulting in an uninitialized McASP.

Therefore, the logic in McASP has been implemented such that once the processor writes GBLCTL, RGBLCTL, or XGBLCTL, the resulting write is not visible by reading back GBLCTL until the McASP has recognized the change. This typically requires two bit clocks plus two processor bus clocks to occur.

Also, if the bit clocks can be completely stopped, any software that polls GBLCTL should be implemented with a time-out. If GBLCTL does not have a time-out, and the bit clock stops, the changes written to GBLCTL will not be reflected until the bit clock restarts.

Finally, please note that while RGBLCTL and XGBLCTL allow separate changing of the receive and transmit halves of GBLCTL, they also immediately reflect the updated value (useful for debug purposes). Only GBLCTL can be used for the read back step.

14.2.10.5 Synchronous Transmit and Receive Operation (ASYNC = 0)

When ASYNC = 0 in ACLKXCTL, the transmit and receive sections operate synchronously from the transmit section clock and transmit frame sync signals (Figure 14-16). The receive section may have a different (but compatible in terms of slot size) data format.

When ASYNC = 0, the receive frame sync generator is internally disabled. If the AFSX pin is configured as an output, it serves as the frame sync signal for both transmit and receive. The AFSR pin should not be used because the transmit frame sync generator output, which is used by both the transmitter and the receiver when ASYNC = 0, is not propagated to the AFSR pin (Figure 14-18).

When ASYNC = 0, the transmit and receive sections must share some common settings, since they both use the same clock and frame sync signals:

- DITEN = 0 in DITCTL (TDM mode is enabled).
- The total number of bits per frame must be the same (that is, RSSZ × RMOD must equal to XSSZ × XMOD).
- Both transmit and receive should either be specified as burst or TDM mode, but not mixed.
- The settings in ACLKRCTL are irrelevant.
- FSXM must match FSRM.
- FXWID must match FRWID.

For all other settings, the transmit and receive sections may be programmed independently.

14.2.10.6 Asynchronous Transmit and Receive Operation (ASYNC = 1)

When ASYNC = 1 in ACLKXCTL, the transmit and receive sections operate completely independently and have separate clock and frame sync signals (Figure 14-16, Figure 14-17, and Figure 14-18). The events generated by each section come asynchronously.

14.2.11 Interrupts

14.2.11.1 Transmit Data Ready Interrupt

The transmit data ready interrupt (XDATA) is generated if XDATA is 1 in the XSTAT register and XDATA is also enabled in XINTCTL. Section 14.2.8.1.1 provides details on when XDATA is set in the XSTAT register.

A transmit start of frame interrupt (XSTAFRM) is triggered by the recognition of transmit frame sync. A transmit last slot interrupt (XLAST) is a qualified version of the data ready interrupt (XDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended was next-to-last TDM slot, current slot is last slot).

14.2.11.2 Receive Data Ready Interrupt

The receive data ready interrupt (RDATA) is generated if RDATA is 1 in the RSTAT register and RDATA is also enabled in RINTCTL. Section 14.2.8.1.2 provides details on when RDATA is set in the RSTAT register.

A receiver start of frame interrupt (RSTAFRM) is triggered by the recognition of a receiver frame sync. A receiver last slot interrupt (RLAST) is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

14.2.11.3 Error Interrupts

Upon detection, the following error conditions generate interrupt flags:

- In the receive status register (RSTAT):
  - Receiver overrun (ROVRN).
  - Unexpected receive frame sync (RSYNCERR).
  - Receive clock failure (RCKFAIL).
  - Receive DMA error (RDMAERR).
- In the transmit status register (XSTAT):
  - Transmit underrun (XUNDRN).
  - Unexpected transmit frame sync (XSYNCERR).
  - Transmit clock failure (XCKFAIL).
  - Transmit DMA error (XDMAERR).

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (RINTCTL) and transmit interrupt control register (XINTCTL). If the enable bit is set in RINTCTL or XINTCTL, an interrupt is requested when the interrupt flag is set in RSTAT or XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

14.2.11.4 Audio Mute (AMUTE) Function

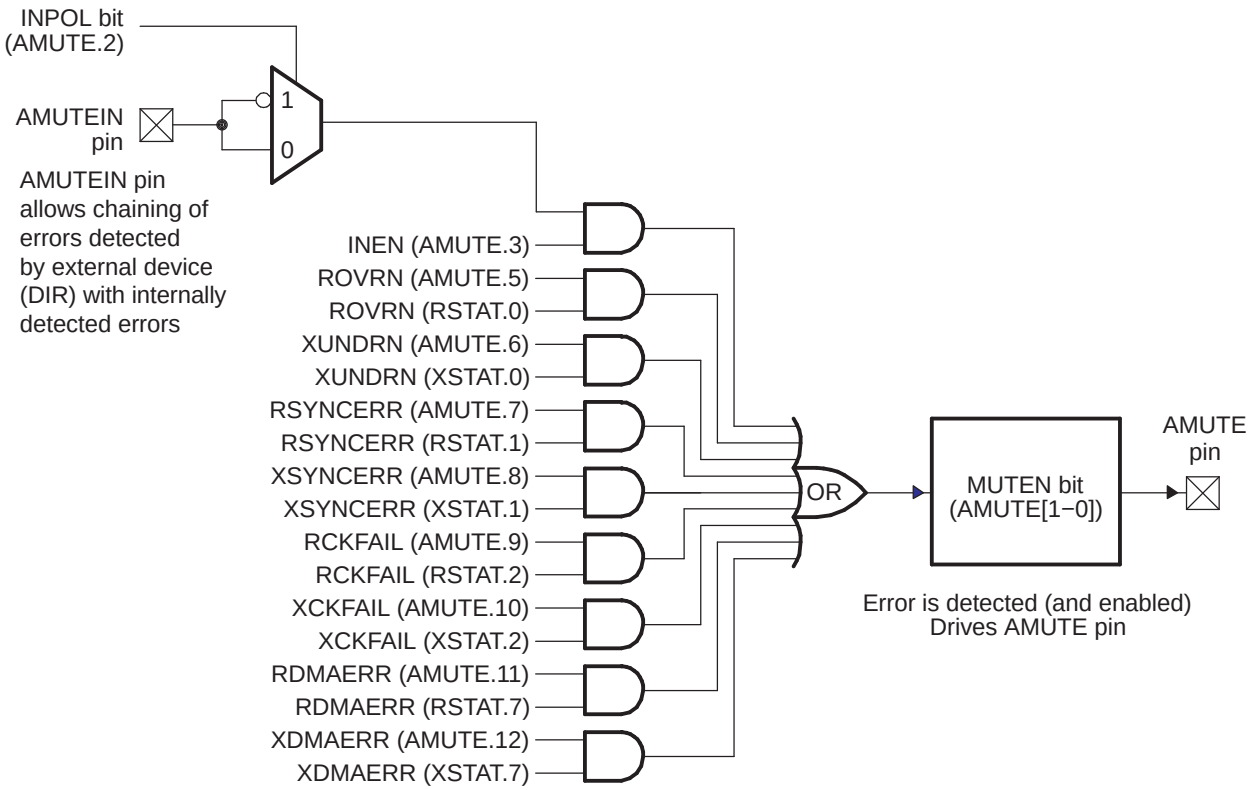
The McASP includes an automatic audio mute function (Figure 14-33) that asserts in hardware the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the AMUTEIN input. Typically, the AMUTEIN input is shared with a device interrupt pin (for example EXT_INT4).

The AMUTEIN input allows the on-chip logic to consider a mute input from other devices in the system, so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in AMUTE, and it must be enabled explicitly.

In addition to the external AMUTEIN input, the AMUTE pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in AMUTE.

When one or more of the errors is detected and enabled, the AMUTE pin is driven to an active state that is selected by MUTEN in AMUTE. The active polarity of the AMUTE pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the AMUTEIN is inactive.

Figure 14-33. Audio Mute (AMUTE) Block Diagram



14.2.11.5 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in RSTAT or XSTAT is set and the interrupt is enabled in RINTCTL or XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit/receive interrupt ports, but that request has not yet been serviced.
- **Serviced:** The CPU writes to RSTAT or XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in XSTAT and the interrupt enabled in XINTCTL generates a request on the McASP transmit interrupt port AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to XSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit interrupt port.

The receiver operates in a similar way, but using RSTAT, RINTCTL, and the McASP receive interrupt port ARINT.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

14.2.12 EDMA Event Support

14.2.12.1 EDMA Events

There are six EDMA events.

14.2.12.2 Using the DMA for McASP Servicing

The most typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus. Two possibilities exist for using the DMA events to service the McASP:

1. Use **AXEVT/AREVT**: Triggered upon each XDATA/RDATA transition from 0 to 1.
2. Use **AXEVTO/AREVTO** and **AXEVTE/AREVTE**: Alternating AXEVT/AREVT events for odd/even slots. Upon AXEVT/AREVT, AXEVTO/AREVTO is triggered if the event is for an odd channel, and AXEVTE/AREVTE is triggered if the event is for an even channel.

NOTE: Check the device-specific data manual to see if AXEVTO/AREVTO and AXEVTE/AREVTE are supported. These are optional.

Figure 14-34 and Figure 14-35 show an example audio system with six audio channels (LF, RF, LS, RS, C, and LFE) transmitted from three AXRn pins on the McASP. Figure 14-34 and Figure 14-35 show when events AXEVT, AXEVTO, and AXEVTE are triggered. Figure 14-34 and Figure 14-35 also apply for the receive audio channels and show when events AREVT, AREVTO, and AREVTE are triggered.

You can either use the DMA to service the McASP upon events AXEVT and AREVT (Figure 14-34) or upon events AXEVTO, AREVTO, AXEVTE, and AREVTE (Figure 14-35).

Figure 14-34. DMA Events in an Audio Example–Two Events (Scenario 1)

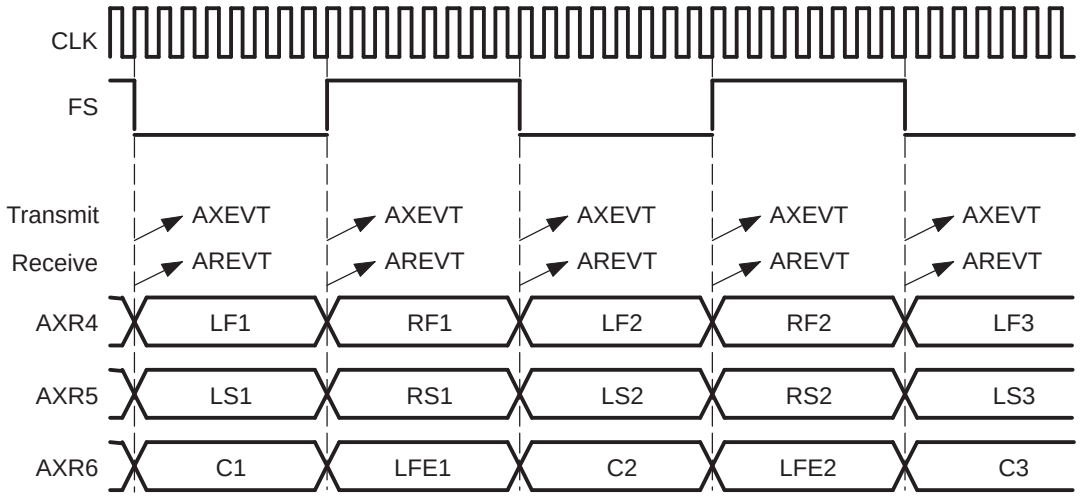


Figure 14-35. DMA Events in an Audio Example–Four Events (Scenario 2)

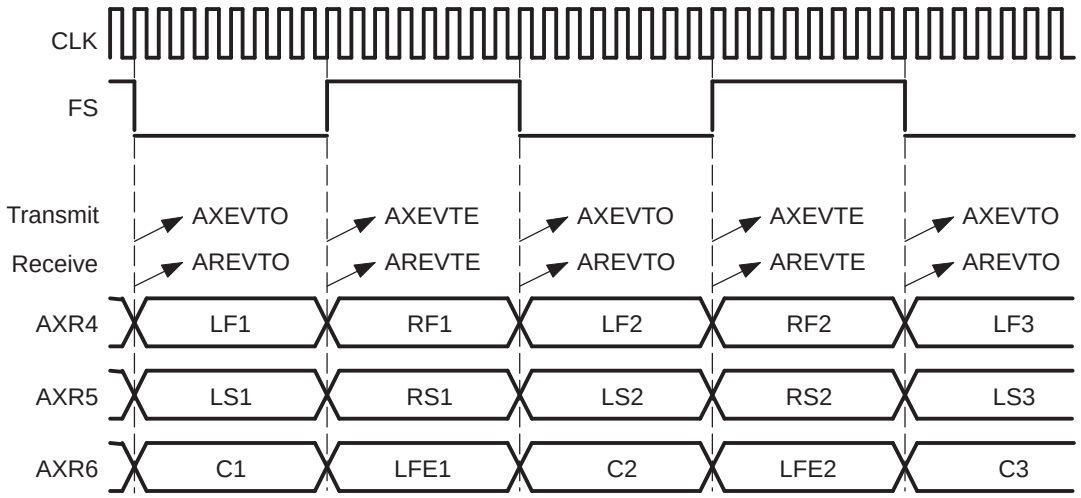


In scenario 1 (Figure 14-34), a DMA event AXEVT/AREVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (Time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Similarly, AREVT is triggered for each of the receive audio channel time slot. Scenario 1 allows for the use of a single DMA to transmit all audio channels, and a single DMA to receive all audio channels.

In scenario 2 (Figure 14-35), two alternating DMA events are triggered for each time slot. In the example, AXEVTE (even) is triggered for the time slot for the even audio channels (LF, LS, C) and AXEVTO (odd) is triggered for the time slot for the odd audio channels (RF, RS, LFE). AXEVTO and AXEVTE alternate in time. The same is true in the receive direction with the use of AREVTO and AREVTE. This scenario allows for the use of two DMA channels (odd and even) to transmit all audio channels, and two DMA channels to receive all audio channels.

Here are some guidelines on using the different DMA events:

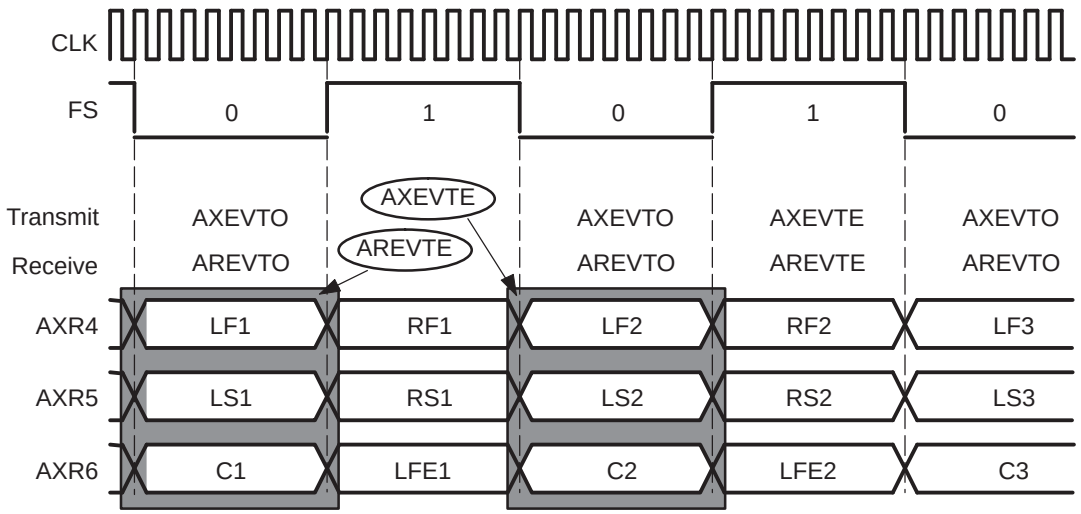
- Either use AXEVT, or the combination of AXEVTO and AXEVTE, to service the McASP. Never use all three at the same time. Similarly for receive, either use AREVT, or the combination of AREVTO and AREVTE.
- The McASP generates transmit DMA events independently from receive DMA events; therefore, separate schemes can be used for transmit and receive DMA. For example, scenario 1 could be used for the transmit data (AXEVT) and scenario 2 could be used for the receive data (AREVTO, AREVTE), and conversely.

Note the difference between DMA event generation and the CPU interrupt generation. DMA events are generated automatically upon data ready; whereas CPU interrupt generation needs to be enabled in the XINTCTL/RINTCTL register.

In Figure 14-35, scenario 2, each transmit DMA request is for data in the next time slot, while each receive DMA request is for data in the previous time slot. For example, Figure 14-36 shows a circled AXEVTE event for an even time slot transmit DMA request. The transmitter always requests a DMA transfer for data it will need to transmit during the next time slot. So, in this example, the circled event AXEVTE is a request for data for samples LF2, LS2, and C2.

On the other hand, the circled AREVTE event is an even time slot receive DMA request. The receiver always requests a DMA transfer for data it received during the previous time slot. In this example, the circled event AREVTE is a request for samples LF1, LS1, and C1.

Figure 14-36. DMA Events in an Audio Example



14.2.13 Power Management

The McASP can be placed in reduced power modes to conserve power during periods of low activity.

14.2.14 Emulation Considerations

NOTE: The receive buffer registers (RBUF*n*) and transmit buffer registers (XBUF*n*) should not be accessed by the emulator when the McASP is running. Such an access will cause the RRDY/XRDY bit in the serializer control register *n* (SRCTL*n*) to be updated.

The McASP does not support the emulation suspend. If the McASP is placed into a suspended state, software needs to ensure that the registers/internal logic is reset to its default values by performing a module power cycle before restarting the initialization sequence.

14.3 McASP Registers

Table 14-7 lists the control registers for the McASP. For the base address of these registers, see Table 1-12. The control registers are accessed through the configuration bus of the device. The receive buffer registers (RBUF*n*) and transmit buffer registers (XBUF*n*) can also be accessed through the data port of the device, as listed in Table 14-8.

Control registers for the McASP Audio FIFO (AFIFO) are summarized in Table 14-9. Note that the AFIFO Write FIFO (WFIFO) and Read FIFO (RFIFO) have independent control and status registers. The AFIFO control registers are accessed through the peripheral configuration port.

Table 14-8. McASP Registers Accessed Through Data Port

Hex Address	Register Name	Register Description
Read Accesses	RBUF[1]	Receive buffer data peripheral register address. Cycles through receive serializers, skipping over transmit serializers and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if XBUSEL = 0. See the device specific data manual for address location.
Write Accesses	XBUF[1]	Transmit buffer data peripheral register address. Cycles through transmit serializers, skipping over receive and inactive serializers. Starts at the lowest serializer at the beginning of each time slot. DAT BUS only if RBUSEL = 0. See the device specific data manual for address location.

(1) RBUF and XBUF are at the same address location. Reads access RBUF and writes access XBUF.

Table 14-9. McASP AFIFO Registers Accessed Through Peripheral Configuration Port

Offset	Acronym	Register Description	Section

Table 14-10. Revision Identification Register (REV) Field Descriptions

Bit	Field	Value	Description
31-0	REV	4430 7302h	Identifies revision of peripheral.

14.3.2 Pin Function Register (PFUNC)

The pin function register (PFUNC) specifies the function of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either a McASP pin or a general-purpose input/output (GPIO) pin. The PFUNC is shown in Figure 14-38 and described in Table 14-11.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 14-38. Pin Function Register (PFUNC)

31	30	29	28	27	26	25	24

Table 14-11. Pin Function Register (PFUNC) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Determines if AFSR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
30	AHCLKR		Determines if AHCLKR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
29	ACLKR		Determines if ACLKR pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
28	AFSX		Determines if AFSX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
27	AHCLKX		Determines if AHCLKX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
26	ACLKX		Determines if ACLKX pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
25	AMUTE		Determines if AMUTE pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Determines if AXRn pin functions as McASP or GPIO.
		0	Pin functions as McASP pin.
		1	Pin functions as GPIO pin.

14.3.3 Pin Direction Register (PDIR)

The pin direction register (PDIR) specifies the direction of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. The PDIR is shown in Figure 14-39 and described in Table 14-12. Refer to the device-specific data manual for the number of pins available on your device.

Regardless of the pin function register (PFUNC) setting, each PDIR bit must be set to 1 for the specified pin to be enabled as an output and each PDIR bit must be cleared to 0 for the specified pin to be an input.

For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output).

When AXRn is configured to transmit, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). Similarly, when AXRn is configured to receive, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be cleared to 0 (an input).

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Table 14-12. Pin Direction Register (PDIR) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Determines if AFSR pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
30	AHCLKR		Determines if AHCLKR pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
29	ACLKR		Determines if ACLKR pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
28	AFSX		Determines if AFSX pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
27	AHCLKX		Determines if AHCLKX pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
26	ACLKX		Determines if ACLKX pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
25	AMUTE		Determines if AMUTE pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Determines if AXRn pin functions as an input or output.
		0	Pin functions as input.
		1	Pin functions as output.

14.3.4 Pin Data Output Register (PDOUT)

The pin data output register (PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by PDOUT is not affected by writing to PDIR and PFUNC. However, the data value in PDOUT is driven out onto the McASP pin only if the corresponding bit in PFUNC is set to 1 (GPIO function) and the corresponding bit in PDIR is set to 1 (output).

When reading data, it returns the corresponding PDOUT[n] bit value and does not return the input from I/O pin. When writing data, it writes to the corresponding PDOUT[n] bit.

The PDOUT is shown in Figure 14-40 and described in Table 14-13.

PDOUT has these aliases or alternate addresses:

- PDSET - when written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in PDOUT to 1; writing a 0 has no effect and keeps the bits in PDOUT unchanged.
- PDCLR - when written to at this address, writing a 1 to a bit in PDCLR clears the corresponding bit in PDOUT to 0; writing a 0 has no effect and keeps the bits in PDOUT unchanged.

There is only one set of data out bits, PDOUT[31-0]. The other registers, PDSET and PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Table 14-13. Pin Data Output Register (PDOUT) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Determines drive on AFSR output pin when the corresponding PFUNC[31] and PDIR[31] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
30	AHCLKR		Determines drive on AHCLKR output pin when the corresponding PFUNC[30] and PDIR[30] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
29	ACLKR		Determines drive on ACLKR output pin when the corresponding PFUNC[29] and PDIR[29] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
28	AFSX		Determines drive on AFSX output pin when the corresponding PFUNC[28] and PDIR[28] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
27	AHCLKX		Determines drive on AHCLKX output pin when the corresponding PFUNC[27] and PDIR[27] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
26	ACLKX		Determines drive on ACLKX output pin when the corresponding PFUNC[26] and PDIR[26] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
25	AMUTE		Determines drive on AMUTE output pin when the corresponding PFUNC[25] and PDIR[25] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Determines drive on AXR[n] output pin when the corresponding PFUNC[n] and PDIR[n] bits are set to 1.
		0	Pin drives low.
		1	Pin drives high.

14.3.5 Pin Data Input Register (PDIN)

The pin data input register (PDIN) holds the I/O pin state of each of the McASP pins. PDIN allows the actual value of the pin to be read, regardless of the state of PFUNC and PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. The PDIN is shown in Figure 14-41 and described in Table 14-14.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 14-41. Pin Data Input Register (PDIN)

Table 14-14. Pin Data Input Register (PDIN) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Logic level on AFSR pin.
		0	Pin is logic low.
		1	Pin is logic high.
30	AHCLKR		Logic level on AHCLKR pin.
		0	Pin is logic low.
		1	Pin is logic high.
29	ACLKR		Logic level on ACLKR pin.
		0	Pin is logic low.
		1	Pin is logic high.
28	AFSX		Logic level on AFSX pin.
		0	Pin is logic low.
		1	Pin is logic high.
27	AHCLKX		Logic level on AHCLKX pin.
		0	Pin is logic low.
		1	Pin is logic high.
26	ACLKX		Logic level on ACLKX pin.
		0	Pin is logic low.
		1	Pin is logic high.
25	AMUTE		Logic level on AMUTE pin.
		0	Pin is logic low.
		1	Pin is logic high.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Logic level on AXR[n] pin.
		0	Pin is logic low.
		1	Pin is logic high.

14.3.6 Pin Data Set Register (PDSET)

The pin data set register (PDSET) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDSET bit sets the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic high on the pin. PDSET is useful for a multitasking system because it allows you to set to a logic high only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDSET is shown in Figure 14-42 and described in Table 14-15.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Figure 14-42. Pin Data Set Register (PDSET)

31	30	29	28	27	26	25	24

Table 14-15. Pin Data Set Register (PDSET) Field Descriptions

Bit	Field	Value	Description
31	AFSR		Allows the corresponding AFSR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[31] bit is set to 1.
30	AHCLKR		Allows the corresponding AHCLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[30] bit is set to 1.
29	ACLKR		Allows the corresponding ACLKR bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[29] bit is set to 1.
28	AFSX		Allows the corresponding AFSX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[28] bit is set to 1.
27	AHCLKX		Allows the corresponding AHCLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[27] bit is set to 1.
26	ACLKX		Allows the corresponding ACLKX bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[26] bit is set to 1.
25	AMUTE		Allows the corresponding AMUTE bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[25] bit is set to 1.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Allows the corresponding AXR[n] bit in PDOUT to be set to a logic high without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[n] bit is set to 1.

14.3.7 Pin Data Clear Register (PDCLR)

The pin data clear register (PDCLR) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDCLR bit clears the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic low on the pin. PDCLR is useful for a multitasking system because it allows you to clear to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. The PDCLR is shown in Figure 14-43 and described in Table 14-16.

CAUTION

Writing to Reserved Bits

Writing a value other than 0 to reserved bits in this register may cause improper device operation.

Bit	Field	Value	Description
31	AFSR		Allows the corresponding AFSR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[31] bit is cleared to 0.
30	AHCLKR		Allows the corresponding AHCLKR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[30] bit is cleared to 0.
29	ACLKR		Allows the corresponding ACLKR bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[29] bit is cleared to 0.
28	AFSX		Allows the corresponding AFSX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[28] bit is cleared to 0.
27	AHCLKX		Allows the corresponding AHCLKX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[27] bit is cleared to 0.
26	ACLKX		Allows the corresponding ACLKX bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[26] bit is cleared to 0.
25	AMUTE		Allows the corresponding AMUTE bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[25] bit is cleared to 0.
24-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-0	AXR[15-0]		Allows the corresponding AXR[n] bit in PDOUT to be cleared to a logic low without affecting other I/O pins controlled by the same port.
		0	No effect.
		1	PDOUT[n] bit is cleared to 0.

14.3.8 Global Control Register (GBLCTL)

The global control register (GBLCTL) provides initialization of the transmit and receive sections. The GBLCTL is shown in Figure 14-44 and described in Table 14-17.

The bit fields in GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before GBLCTL is programmed, you must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, you should select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL, and ACLKRCTL before GBLCTL is programmed. Also, after programming any bits in GBLCTL you should not proceed until you have read back from GBLCTL and verified that the bits are latched in GBLCTL.

R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-17. Global Control Register (GBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST		Transmit frame sync generator reset enable bit.
		0	Transmit frame sync generator is reset.
		1	Transmit frame sync generator is active. When released from reset, the transmit frame sync generator begins counting serial clocks and generating frame sync as programmed.
11	XSMRST		Transmit state machine reset enable bit.
		0	Transmit state machine is held in reset. AXRn pin state: If PFUNC[n] = 0 and PDIR[n] = 1; then the serializer drives the AXRn pin to the state specified for inactive time slot (as determined by DISMOD bits in SRCTL).
		1	Transmit state machine is released from reset. When released from reset, the transmit state machine immediately transfers data from XRBUF[n] to XRSR[n]. The transmit state machine sets the underrun flag (XUNDRN) in XSTAT, if XRBUF[n] have not been preloaded with data before reset is released. The transmit state machine also immediately begins detecting frame sync and is ready to transmit. Transmit TDM time slot begins at slot 0 after reset is released.
10	XSRCLR		Transmit serializer clear enable bit. By clearing then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun will occur.
		0	Transmit serializers are cleared.
		1	Transmit serializers are active. When the transmit serializers are first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in XSTAT is set to indicate XBUF is ready to be written.
9	XHCLKRST		Transmit high-frequency clock divider reset enable bit.
		0	Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Transmit high-frequency clock divider is running.
8	XCLKRST		Transmit clock divider reset enable bit.
		0	Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Transmit clock divider is running.

Table 14-17. Global Control Register (GBLCTL) Field Descriptions (continued)

Bit	Field	Value	Description
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST		Receive frame sync generator reset enable bit.
		0	Receive frame sync generator is reset.
		1	Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.
3	RSMRST		Receive state machine reset enable bit.
		0	Receive state machine is held in reset.
		1	Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.
2	RSRCLR		Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed.
		0	Receive serializers are cleared.
		1	Receive serializers are active.
1	RHCLKRST		Receive high-frequency clock divider reset enable bit.
		0	Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Receive high-frequency clock divider is running.
0	RCLKRST		Receive clock divider reset enable bit.
		0	Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Receive clock divider is running.

14.3.9 Audio Mute Control Register (AMUTE)

The audio mute control register (AMUTE) controls the McASP audio mute (AMUTE) output pin. The value after reset for register 4 depends on how the pins are being driven. The AMUTE is shown in Figure 14-45 and described in Table 14-18.

Figure 14-45. Audio Mute Control Register (AMUTE)

Table 14-18. Audio Mute Control Register (AMUTE) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XDMAERR		If transmit DMA error (XDMAERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit DMA error, AMUTE is active and is driven according to MUTEN bit.
11	RDMAERR		If receive DMA error (RDMAERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receive DMA error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive DMA error, AMUTE is active and is driven according to MUTEN bit.
10	XCKFAIL		If transmit clock failure (XCKFAIL), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit clock failure, AMUTE is active and is driven according to MUTEN bit
9	RCKFAIL		If receive clock failure (RCKFAIL), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receive clock failure is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receive clock failure, AMUTE is active and is driven according to MUTEN bit.
8	XSYNCERR		If unexpected transmit frame sync error (XSYNCERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of unexpected transmit frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected transmit frame sync error, AMUTE is active and is driven according to MUTEN bit.
7	RSYNCERR		If unexpected receive frame sync error (RSYNCERR), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of unexpected receive frame sync error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of unexpected receive frame sync error, AMUTE is active and is driven according to MUTEN bit.
6	XUNDRN		If transmit underrun error (XUNDRN), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of transmit underrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of transmit underrun error, AMUTE is active and is driven according to MUTEN bit.

Table 14-18. Audio Mute Control Register (AMUTE) Field Descriptions (continued)

Bit	Field	Value	Description
5	ROVRN		If receiver overrun error (ROVRN), drive AMUTE active enable bit.
		0	Drive is disabled. Detection of receiver overrun error is ignored by AMUTE.
		1	Drive is enabled (active). Upon detection of receiver overrun error, AMUTE is active and is driven according to MUTEN bit.
4	INSTAT		Status of mute in pin, determines drive on AXRn pin when PFUNC[n] and PDIR[n] bits are set to 1.
		0	AMUTEIN pin is inactive.
		1	AMUTEIN pin is active. Audio mute in error is detected.
3	INEN		Drive AMUTE active when AMUTEIN error is active (INSTAT = 1).
		0	Drive is disabled. AMUTEIN is ignored by AMUTE.
		1	Drive is enabled (active). INSTAT = 1 drives AMUTE active.
2	INPOL		Audio mute in (AMUTEIN) polarity select bit.
		0	Polarity is active high. A high on AMUTEIN sets INSTAT to 1.
		1	Polarity is active low. A low on AM UTEIN sets INSTAT to 1.
1-0	MUTEN	0-3h	AMUTE pin enable bit (unless overridden by GPIO registers).
		0	AMUTE pin is disabled, pin goes to tri-state condition.
		1h	AMUTE pin is driven high if error is detected.
		2h	AMUTE pin is driven low if error is detected.
		3h	Reserved

14.3.10 Digital Loopback Control Register (DLBCTL)

The digital loopback control register (DLBCTL) controls the internal loopback settings of the McASP in TDM mode. The DLBCTL is shown in Figure 14-46 and described in Table 14-19. Note that loopback is NOT supported if McASP is configured in DIT mode.

Figure 14-46. Digital Loopback Control Register (DLBCTL)

15	4	3	2	1	0
Reserved		MODE		ORD	DLBEN
R-0		R/W-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-19. Digital Loopback Control Register (DLBCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-2	MODE	0-3h	Loopback generator mode bits. Applies only when loopback mode is enabled (DLBEN = 1).
		0	Default and reserved on loopback mode (DLBEN = 1). When in non-loopback mode (DLBEN = 0), MODE should be left at default (00). When in loopback mode (DLBEN = 1), MODE = 00 is reserved and is not applicable.
		1h	MODE must be set to 01 when McASP operates in loopback mode (DLBEN = 1). This is necessary to allow transmit clock and frame sync generators to be used by both transmit and receive sections.
		2h-3h	Reserved.
1	ORD		Loopback order bit when loopback mode is enabled (DLBEN = 1).
		0	Odd serializers N + 1 transmit to even serializers N that receive. The corresponding serializers must be programmed properly.
		1	Even serializers N transmit to odd serializers N + 1 that receive. The corresponding serializers must be programmed properly.
0	DLBEN		Loopback mode enable bit.
		0	Loopback mode is disabled (normal McASP operation)
		1	Loopback mode is enabled (TDM mode only).

14.3.11 Digital Mode Control Register (DITCTL)

The DIT mode control register (DITCTL) controls DIT operations of the McASP. The DITCTL is shown in Figure 14-47 and described in Table 14-20.

Figure 14-47. Digital Mode Control Register (DITCTL)

31	16

Table 14-20. Digital Mode Control Register (DITCTL) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3	VB		Valid bit for odd time slots (DIT right subframe).
		0	V bit is 0 during odd DIT subframes.
		1	V bit is 1 during odd DIT subframes.
2	VA		Valid bit for even time slots (DIT left subframe).
		0	V bit is 0 during even DIT subframes.
		1	V bit is 1 during even DIT subframes.
1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	DITEN		DIT mode enable bit. DITEN should only be changed while the XSMRST bit in GBLCTL is in reset (and for startup, XSRCLR also in reset). However, it is not necessary to reset the XCLKRST or XHCLKRST bits in GBLCTL to change DITEN.
		0	DIT mode is disabled. Transmitter operates in TDM or burst mode.
		1	DIT mode is enabled. Transmitter operates in DIT encoded mode.

14.3.12 Receiver Global Control Register (RGBLCTL)

Alias of the global control register (GBLCTL). Writing to the receiver global control register (RGBLCTL) affects only the receive bits of GBLCTL (bits 4-0). Reads from RGBLCTL return the value of GBLCTL. RGBLCTL allows the receiver to be reset independently from the transmitter. The RGBLCTL is shown in Figure 14-48 and described in Table 14-21. See Section 14.3.8 for a detailed description of GBLCTL.

Table 14-21. Receiver Global Control Register (RGBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST	x	Transmit frame sync generator reset enable bit. A read of this bit returns the XFRST bit value of GBLCTL. Writes have no effect.
11	XSMRST	x	Transmit state machine reset enable bit. A read of this bit returns the XSMRST bit value of GBLCTL. Writes have no effect.
10	XSRCLR	x	Transmit serializer clear enable bit. A read of this bit returns the XSRCLR bit value of GBLCTL. Writes have no effect.
9	XHCLKRST	x	Transmit high-frequency clock divider reset enable bit. A read of this bit returns the XHCLKRST bit value of GBLCTL. Writes have no effect.
8	XCLKRST	x	Transmit clock divider reset enable bit. A read of this bit returns the XCLKRST bit value of GBLCTL. Writes have no effect.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST		Receive frame sync generator reset enable bit. A write to this bit affects the RFRST bit of GBLCTL.
		0	Receive frame sync generator is reset.
		1	Receive frame sync generator is active.
3	RSMRST		Receive state machine reset enable bit. A write to this bit affects the RSMRST bit of GBLCTL.
		0	Receive state machine is held in reset.
		1	Receive state machine is released from reset.
2	RSRCLR		Receive serializer clear enable bit. A write to this bit affects the RSRCLR bit of GBLCTL.
		0	Receive serializers are cleared.
		1	Receive serializers are active.
1	RHCLKRST		Receive high-frequency clock divider reset enable bit. A write to this bit affects the RHCLKRST bit of GBLCTL.
		0	Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Receive high-frequency clock divider is running.
0	RCLKRST		Receive clock divider reset enable bit. A write to this bit affects the RCLKRST bit of GBLCTL.
		0	Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Receive clock divider is running.

14.3.13 Receive Format Unit Bit Mask Register (RMASK)

The receive format unit bit mask register (RMASK) determines which bits of the received data are masked off and padded with a known value before being read by the CPU or DMA. The RMASK is shown in Figure 14-49 and described in Table 14-22.

Figure 14-49. Receive Format Unit Bit Mask Register (RMASK)

31	0
RMASK[*n*]	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 14-22. Receive Format Unit Bit Mask Register (RMASK) Field Descriptions

Bit	Field	Value	Description
31-0	RMASK[31-0]		Receive data mask *n* enable bit.
		0	Corresponding bit of receive data (after passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (RPAD and RPBIT bits in RFMT).
		1	Corresponding bit of receive data (after passing through reverse and rotate units) is returned to CPU or DMA.

14.3.14 Receive Bit Stream Format Register (RFMT)

The receive bit stream format register (RFMT) configures the receive data format. The RFMT is shown in Figure 14-50 and described in Table 14-23.

Figure 14-50. Receive Bit Stream Format Register (RFMT)

Table 14-23. Receive Bit Stream Format Register (RFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	RDATDLY	0-3h	Receive frame sync delay of AXRn.
		0	0-bit delay. The first receive data bit, AXRn, occurs in same ACLKR cycle as the receive frame sync (AFSR).
		1h	1-bit delay. The first receive data bit, AXRn, occurs one ACLKR cycle after the receive frame sync (AFSR).
		2h	2-bit delay. The first receive data bit, AXRn, occurs two ACLKR cycles after the receive frame sync (AFSR).
		3h	Reserved.
15	RRVRS		Receive serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in receive format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in receive format bit reverse unit.
14-13	RPAD	0-3h	Pad value for extra bits in slot not belonging to the word. This field only applies to bits when RMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by RPBIT bits.
		3h	Reserved.
12-8	RPBIT	0-1Fh	RPBIT value determines which bit (as read by the CPU or DMA from RBUF[n]) is used to pad the extra bits. This field only applies when RPAD = 2h.
		0	Pad with bit 0 value.
		1h-1Fh	Pad with bit 1 to bit 31 value.

Table 14-23. Receive Bit Stream Format Register (RFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	RSSZ	0-Fh	Receive slot size.
		0-2h	Reserved
		3h	Slot size is 8 bits.
		4h	Reserved
		5h	Slot size is 12 bits.
		6h	Reserved
		7h	Slot size is 16 bits.
		8h	Reserved
		9h	Slot size is 20 bits.
		Ah	Reserved
		Bh	Slot size is 24 bits
		Ch	Reserved
		Dh	Slot size is 28 bits.
		Eh	Reserved
		Fh	Slot size is 32 bits.
3	RBUSEL		Selects whether reads from serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port.
		0	Reads from XRBUF[n] originate on data port. Reads from XRBUF[n] on configuration bus are ignored.
		1	Reads from XRBUF[n] originate on configuration bus. Reads from XRBUF[n] on data port are ignored.
2-0	RROT	0-7h	Right-rotation value for receive rotate right format unit.
		0	Rotate right by 0 (no rotation).
		1h	Rotate right by 4 bit positions.
		2h	Rotate right by 8 bit positions.
		3h	Rotate right by 12 bit positions.
		4h	Rotate right by 16 bit positions.
		5h	Rotate right by 20 bit positions.
		6h	Rotate right by 24 bit positions.
		7h	Rotate right by 28 bit positions.

14.3.15 Receive Frame Sync Control Register (AFSRCTL)

The receive frame sync control register (AFSRCTL) configures the receive frame sync (AFSR). The AFSRCTL is shown in Figure 14-51 and described in Table 14-24.

Figure 14-51. Receive Frame Sync Control Register (AFSRCTL)

Table 14-24. Receive Frame Sync Control Register (AFSRCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-7	RMOD	0-1FFh	Receive frame sync mode select bits.
		0	Burst mode.
		1h	Reserved.
		2h-20h	2-slot TDM (I2S mode) to 32-slot TDM.
		21h-17Fh	Reserved.
		180h	384-slot TDM (external DIR IC inputting 384-slot DIR frames to McASP over I2S interface).
		181h-1FFh	Reserved.
6-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	FRWID		Receive frame sync width select bit indicates the width of the receive frame sync (AFSR) during its active period.
		0	Single bit.
		1	Single word. Single word is not supported if RMOD is set to burst mode.
3-2	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
1	FSRM		Receive frame sync generation select bit.
		0	Externally-generated receive frame sync.
		1	Internally-generated receive frame sync.
0	FSRP		Receive frame sync polarity select bit.
		0	A rising edge on receive frame sync (AFSR) indicates the beginning of a frame.
		1	A falling edge on receive frame sync (AFSR) indicates the beginning of a frame.

14.3.16 Receive Clock Control Register (ACLKRCTL)

The receive clock control register (ACLKRCTL) configures the receive bit clock (ACLKR) and the receive clock generator. The ACLKRCTL is shown in Figure 14-52 and described in Table 14-25.

Figure 14-52. Receive Clock Control Register (ACLKRCTL)

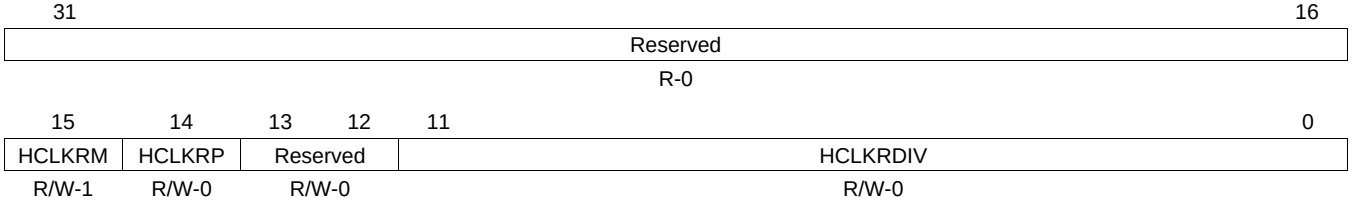
Table 14-25. Receive Clock Control Register (ACLKRCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	CLKRP		Receive bitstream clock polarity select bit.
		0	Falling edge. Receiver samples data on the falling edge of the serial clock, so the external transmitter driving this receiver must shift data out on the rising edge of the serial clock.
		1	Rising edge. Receiver samples data on the rising edge of the serial clock, so the external transmitter driving this receiver must shift data out on the falling edge of the serial clock.
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	CLKRM		Receive bit clock source bit. Note that this bit does not have any effect, if ACLKXCTL.ASYNC = 0.
		0	External receive clock source from ACLKR pin.
		1	Internal receive clock source from output of programmable bit clock divider.
4-0	CLKRDIV	0-1Fh	Receive bit clock divide ratio bits determine the divide-down ratio from AHCLKR to ACLKR. Note that this bit does not have any effect, if ACLKXCTL.ASYNC = 0.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-1Fh	Divide-by-3 to divide-by-32.

14.3.17 Receive High-Frequency Clock Control Register (AHCLKRCTL)

The receive high-frequency clock control register (AHCLKRCTL) configures the receive high-frequency master clock (AHCLKR) and the receive clock generator. The AHCLKRCTL is shown in Figure 14-53 and described in Table 14-26.

Figure 14-53. Receive High-Frequency Clock Control Register (AHCLKRCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

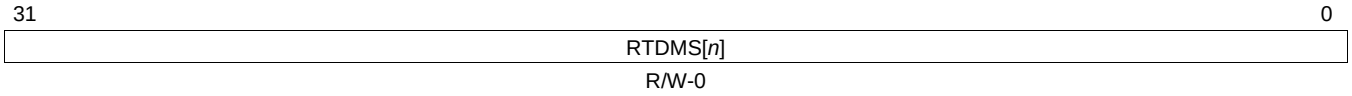
Table 14-26. Receive High-Frequency Clock Control Register (AHCLKRCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15	HCLKRM		Receive high-frequency clock source bit.
		0	External receive high-frequency clock source from AHCLKR pin.
		1	Internal receive high-frequency clock source from output of programmable high clock divider.
14	HCLKRP		Receive bitstream high-frequency clock polarity select bit.
		0	AHCLKR is not inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
		1	AHCLKR is inverted before programmable bit clock divider. In the special case where the receive bit clock (ACLKR) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKRDIV = 0 in ACLKRCTL), AHCLKR is directly passed through to the ACLKR pin.
13-12	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
11-0	HCLKRDIV	0-FFFh	Receive high-frequency clock divide ratio bits determine the divide-down ratio from AUXCLK to AHCLKR.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-FFFh	Divide-by-3 to divide-by-4096.

14.3.18 Receive TDM Time Slot Register (RTDM)

The receive TDM time slot register (RTDM) specifies which TDM time slot the receiver is active. The RTDM is shown in Figure 14-54 and described in Table 14-27.

Figure 14-54. Receive TDM Time Slot Register (RTDM)



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 14-27. Receive TDM Time Slot Register (RTDM) Field Descriptions

Bit	Field	Value	Description
31-0	RTDMS[31-0]		Receiver mode during TDM time slot *n*.
		0	Receive TDM time slot *n* is inactive. The receive serializer does not shift in data during this slot.
		1	Receive TDM time slot *n* is active. The receive serializer shifts in data during this slot.

14.3.19 Receiver Interrupt Control Register (RINTCTL)

The receiver interrupt control register (RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. The RINTCTL is shown in Figure 14-55 and described in Table 14-28. See Section 14.3.20 for a description of the interrupt conditions.

Figure 14-55. Receiver Interrupt Control Register (RINTCTL)

Table 14-28. Receiver Interrupt Control Register (RINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	RSTAFRM		Receive start of frame interrupt enable bit.
		0	Interrupt is disabled. A receive start of frame interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive start of frame interrupt generates a McASP receive interrupt (RINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RDATA		Receive data ready interrupt enable bit.
		0	Interrupt is disabled. A receive data ready interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive data ready interrupt generates a McASP receive interrupt (RINT).
4	RLAST		Receive last slot interrupt enable bit.
		0	Interrupt is disabled. A receive last slot interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive last slot interrupt generates a McASP receive interrupt (RINT).
3	RDMAERR		Receive DMA error interrupt enable bit.
		0	Interrupt is disabled. A receive DMA error interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive DMA error interrupt generates a McASP receive interrupt (RINT).
2	RCKFAIL		Receive clock failure interrupt enable bit.
		0	Interrupt is disabled. A receive clock failure interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receive clock failure interrupt generates a McASP receive interrupt (RINT).
1	RSYNCERR		Unexpected receive frame sync interrupt enable bit.
		0	Interrupt is disabled. An unexpected receive frame sync interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. An unexpected receive frame sync interrupt generates a McASP receive interrupt (RINT).
0	ROVRN		Receiver overrun interrupt enable bit.
		0	Interrupt is disabled. A receiver overrun interrupt does not generate a McASP receive interrupt (RINT).
		1	Interrupt is enabled. A receiver overrun interrupt generates a McASP receive interrupt (RINT).

14.3.20 Receiver Status Register (RSTAT)

The receiver status register (RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The RSTAT is shown in Figure 14-56 and described in Table 14-29.

Figure 14-56. Receiver Status Register (RSTAT)

31						9	8
Reserved							RERR
R-0							R/W-0

R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0	R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect.; -*n* = value after reset

Table 14-29. Receiver Status Register (RSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	RERR		RERR bit always returns a logic-OR of:ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error interrupt has occurred.
		0	No errors have occurred.
		1	An error has occurred.
7	RDMAERR		Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the data port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receive DMA error did not occur.
		1	Receive DMA error did occur.
6	RSTAFRM		Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	No new receive frame sync (AFSR) is detected.
		1	A new receive frame sync (AFSR) is detected.
5	RDATA		Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	No new data in RBUF.
		1	Data is transferred from XRSR to RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).
4	RLAST		Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Current slot is not the last slot in a frame.
		1	Current slot is the last slot in a frame. RDATA is also set.
3	RTDMSLOT		Returns the LSB of RSLOT. Allows a single read of RSTAT to determine whether the current TDM time slot is even or odd.
		0	Current TDM time slot is odd.
		1	Current TDM time slot is even.
2	RCKFAIL		Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error (see *Clock Failure Detection*). Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receive clock failure did not occur.
		1	Receive clock failure did occur.

Table 14-29. Receiver Status Register (RSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	RSYNCERR		Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Unexpected receive frame sync did not occur.
		1	Unexpected receive frame sync did occur.
0	ROVRN		Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect.
		0	Receiver overrun did not occur.
		1	Receiver overrun did occur.

14.3.21 Current Receive TDM Time Slot Registers (RSLOT)

The current receive TDM time slot register (RSLOT) indicates the current time slot for the receive data frame. The RSLOT is shown in Figure 14-57 and described in Table 14-30.

Figure 14-57. Current Receive TDM Time Slot Registers (RSLOT)

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8-0	RSLOTCNT	0-17Fh	Current receive time slot count. Legal values: 0 to 383 (17Fh). TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to receive a DIR block (transferred over TDM format). In I2S mode, this should only be read by the DSP since frame sync initializes it to zero.

14.3.22 Receive Clock Check Control Register (RCLKCHK)

The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit. The RCLKCHK is shown in Figure 14-58 and described in Table 14-31.

Figure 14-58. Receive Clock Check Control Register (RCLKCHK)

31	24	23	16
RCNT		RMAX	
R-0		R/W-0	

15	8	7	4	3	0
RMIN		Reserved		RPS	
R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-31. Receive Clock Check Control Register (RCLKCHK) Field Descriptions

Bit	Field	Value	Description
31-24	RCNT	0-FFh	Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.
23-16	RMAX	0-FFh	Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	RMIN	0-FFh	Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-0	RPS	0-Fh	Receive clock check prescaler value.
		0	McASP system clock divided by 1.
		1h	McASP system clock divided by 2.
		2h	McASP system clock divided by 4.
		3h	McASP system clock divided by 8.
		4h	McASP system clock divided by 16.
		5h	McASP system clock divided by 32.
		6h	McASP system clock divided by 64.
		7h	McASP system clock divided by 128.
		8h	McASP system clock divided by 256.
		9h-Fh	Reserved.

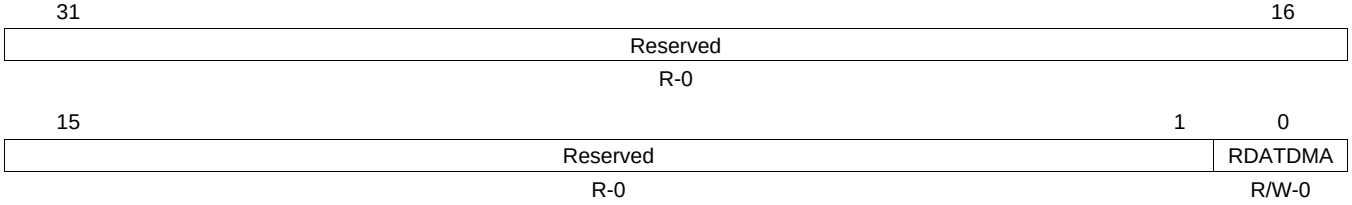
14.3.23 Receiver DMA Event Control Register (REVTCTL)

The receiver DMA event control register (REVTCTL) contains a disable bit for the receiver DMA event. The REVTCTL is shown in Figure 14-59 and described in Table 14-32.

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

Figure 14-59. Receiver DMA Event Control Register (REVTCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-32. Receiver DMA Event Control Register (REVTCTL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	RDATDMA		Receive data DMA request enable bit. If writing to this bit, always write the default value of 0.
		0	Receive data DMA request is enabled.
		1	Reserved

14.3.24 Transmitter Global Control Register (XGBLCTL)

Alias of the global control register (GBLCTL). Writing to the transmitter global control register (XGBLCTL) affects only the transmit bits of GBLCTL (bits 12-8). Reads from XGBLCTL return the value of GBLCTL. XGBLCTL allows the transmitter to be reset independently from the receiver. The XGBLCTL is shown in Figure 14-60 and described in Table 14-33. See Section 14.3.8 for a detailed description of GBLCTL.

Figure 14-60. Transmitter Global Control Register (XGBLCTL)

Table 14-33. Transmitter Global Control Register (XGBLCTL) Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0-FFh	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
12	XFRST		Transmit frame sync generator reset enable bit. A write to this bit affects the XFRST bit of GBLCTL.
		0	Transmit frame sync generator is reset.
		1	Transmit frame sync generator is active.
11	XSMRST		Transmit state machine reset enable bit. A write to this bit affects the XSMRST bit of GBLCTL.
		0	Transmit state machine is held in reset.
		1	Transmit state machine is released from reset.
10	XSRCLR		Transmit serializer clear enable bit. A write to this bit affects the XSRCLR bit of GBLCTL.
		0	Transmit serializers are cleared.
		1	Transmit serializers are active.
9	XHCLKRST		Transmit high-frequency clock divider reset enable bit. A write to this bit affects the XHCLKRST bit of GBLCTL.
		0	Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1.
		1	Transmit high-frequency clock divider is running.
8	XCLKRST		Transmit clock divider reset enable bit. A write to this bit affects the XCLKRST bit of GBLCTL.
		0	Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input.
		1	Transmit clock divider is running.
7-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	RFRST	x	Receive frame sync generator reset enable bit. A read of this bit returns the RFRST bit value of GBLCTL. Writes have no effect.
3	RSMRST	x	Receive state machine reset enable bit. A read of this bit returns the RSMRST bit value of GBLCTL. Writes have no effect.
2	RSRCLR	x	Receive serializer clear enable bit. A read of this bit returns the RSRSCLR bit value of GBLCTL. Writes have no effect.
1	RHCLKRST	x	Receive high-frequency clock divider reset enable bit. A read of this bit returns the RHCLKRST bit value of GBLCTL. Writes have no effect.
0	RCLKRST	x	Receive clock divider reset enable bit. A read of this bit returns the RCLKRST bit value of GBLCTL. Writes have no effect.

14.3.25 Transmit Format Unit Bit Mask Register (XMASK)

The transmit format unit bit mask register (XMASK) determines which bits of the transmitted data are masked off and padded with a known value before being shifted out the McASP. The XMASK is shown in Figure 14-61 and described in Table 14-34.

Figure 14-61. Transmit Format Unit Bit Mask Register (XMASK)

31	0
XMASK[*n*]	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 14-34. Transmit Format Unit Bit Mask Register (XMASK) Field Descriptions

Bit	Field	Value	Description
31-0	XMASK[31-0]		Transmit data mask *n* enable bit.
		0	Corresponding bit of transmit data (before passing through reverse and rotate units) is masked out and then padded with the selected bit pad value (XPAD and XPBIT bits in XFMT), which is transmitted out the McASP in place of the original bit.
		1	Corresponding bit of transmit data (before passing through reverse and rotate units) is transmitted out the McASP.

14.3.26 Transmit Bit Stream Format Register (XFMT)

The transmit bit stream format register (XFMT) configures the transmit data format. The XFMT is shown in Figure 14-62 and described in Table 14-35.

Figure 14-62. Transmit Bit Stream Format Register (XFMT)

Table 14-35. Transmit Bit Stream Format Register (XFMT) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
17-16	XDATDLY	0-3h	Transmit frame sync delay of AXRn.
		0	0-bit delay. The first transmit data bit, AXRn, occurs in same ACLKX cycle as the transmit frame sync (AFSX).
		1h	1-bit delay. The first transmit data bit, AXRn, occurs one ACLKX cycle after the transmit frame sync (AFSX).
		2h	2-bit delay. The first transmit data bit, AXRn, occurs two ACLKX cycles after the transmit frame sync (AFSX).
		3h	Reserved.
15	XRVRS		Transmit serial bitstream order.
		0	Bitstream is LSB first. No bit reversal is performed in transmit format bit reverse unit.
		1	Bitstream is MSB first. Bit reversal is performed in transmit format bit reverse unit.
14-13	XPAD	0-3h	Pad value for extra bits in slot not belonging to word defined by XMASK. This field only applies to bits when XMASK[n] = 0.
		0	Pad extra bits with 0.
		1h	Pad extra bits with 1.
		2h	Pad extra bits with one of the bits from the word as specified by XPBIT bits.
		3h	Reserved.
12-8	XPBIT	0-1Fh	XPBIT value determines which bit (as written by the CPU or DMA to XBUF[n]) is used to pad the extra bits before shifting. This field only applies when XPAD = 2h.
		0	Pad with bit 0 value.
		1-1Fh	Pad with bit 1 to bit 31 value.

Table 14-35. Transmit Bit Stream Format Register (XFMT) Field Descriptions (continued)

Bit	Field	Value	Description
7-4	XSSZ	0-Fh	Transmit slot size.
		0-2h	Reserved.
		3h	Slot size is 8 bits.
		4h	Reserved.
		5h	Slot size is 12 bits.
		6h	Reserved.
		7h	Slot size is 16 bits.
		8h	Reserved.
		9h	Slot size is 20 bits.
		Ah	Reserved.
		Bh	Slot size is 24 bits.
		Ch	Reserved.
		Dh	Slot size is 28 bits.
		Eh	Reserved.
		Fh	Slot size is 32 bits.
3	XBUSEL		Selects whether writes to serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port.
		0	Writes to XRBUF[n] originate from the data port. Writes to XRBUF[n] from the configuration bus are ignored with no effect to the McASP.
		1	Writes to XRBUF[n] originate from the configuration bus. Writes to XRBUF[n] from the data port are ignored with no effect to the McASP.
2-0	XROT	0-7h	Right-rotation value for transmit rotate right format unit.
		0	Rotate right by 0 (no rotation).
		1h	Rotate right by 4 bit positions.
		2h	Rotate right by 8 bit positions.
		3h	Rotate right by 12 bit positions.
		4h	Rotate right by 16 bit positions.
		5h	Rotate right by 20 bit positions.
		6h	Rotate right by 24 bit positions.
		7h	Rotate right by 28 bit positions.

14.3.27 Transmit Frame Sync Control Register (AFSXCTL)

The transmit frame sync control register (AFSXCTL) configures the transmit frame sync (AFSX). The AFSXCTL is shown in Figure 14-63 and described in Table 14-36.

Figure 14-63. Transmit Frame Sync Control Register (AFSXCTL)

Table 14-36. Transmit Frame Sync Control Register (AFSXCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15-7	XMOD	0-1FFh	Transmit frame sync mode select bits.
		0	Burst mode.
		1h	Reserved.
		2h-20h	2-slot TDM (I2S mode) to 32-slot TDM.
		21h-17Fh	Reserved.
		180h	384-slot DIT mode.
		181h-1FFh	Reserved.
6-5	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
4	FXWID		Transmit frame sync width select bit indicates the width of the transmit frame sync (AFSX) during its active period.
		0	Single bit.
		1	Single word. Single word is not supported if XMOD is set to burst mode.
3-2	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
1	FSXM		Transmit frame sync generation select bit.
		0	Externally-generated transmit frame sync.
		1	Internally-generated transmit frame sync.
0	FSXP		Transmit frame sync polarity select bit.
		0	A rising edge on transmit frame sync (AFSX) indicates the beginning of a frame.
		1	A falling edge on transmit frame sync (AFSX) indicates the beginning of a frame.

14.3.28 Transmit Clock Control Register (ACLKXCTL)

The transmit clock control register (ACLKXCTL) configures the transmit bit clock (ACLKX) and the transmit clock generator. The ACLKXCTL is shown in Figure 14-64 and described in Table 14-37.

Figure 14-64. Transmit Clock Control Register (ACLKXCTL)

Table 14-37. Transmit Clock Control Register (ACLKXCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	CLKXP		Transmit bitstream clock polarity select bit.
		0	Rising edge. External receiver samples data on the falling edge of the serial clock, so the transmitter must shift data out on the rising edge of the serial clock.
		1	Falling edge. External receiver samples data on the rising edge of the serial clock, so the transmitter must shift data out on the falling edge of the serial clock.
6	ASYNC		Transmit/receive operation asynchronous enable bit.
		0	Synchronous. Transmit clock and frame sync provides the source for both the transmit and receive sections. Note that in this mode, the receive bit clock is an inverted version of the transmit bit clock.
		1	Asynchronous. Separate clock and frame sync used by transmit and receive sections.
5	CLKXM		Transmit bit clock source bit.
		0	External transmit clock source from ACLKX pin.
		1	Internal transmit clock source from output of programmable bit clock divider.
4-0	CLKXDIV	0-1Fh	Transmit bit clock divide ratio bits determine the divide-down ratio from AHCLKX to ACLKX.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-1Fh	Divide-by-3 to divide-by-32.

14.3.29 Transmit High-Frequency Clock Control Register (AHCLKXCTL)

The transmit high-frequency clock control register (AHCLKXCTL) configures the transmit high-frequency master clock (AHCLKX) and the transmit clock generator. The AHCLKXCTL is shown in Figure 14-65 and described in Table 14-38.

Figure 14-65. Transmit High-Frequency Clock Control Register (AHCLKXCTL)

Table 14-38. Transmit High-Frequency Clock Control Register (AHCLKXCTL) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
15	HCLKXM		Transmit high-frequency clock source bit.
		0	External transmit high-frequency clock source from AHCLKX pin.
		1	Internal transmit high-frequency clock source from output of programmable high clock divider.
14	HCLKXP		Transmit bitstream high-frequency clock polarity select bit.
		0	AHCLKX is not inverted before programmable bit clock divider. In the special case where the transmit bit clock (ACLKX) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKXDIV = 0 in ACLKXCTL), AHCLKX is directly passed through to the ACLKX pin.
		1	AHCLKX is inverted before programmable bit clock divider. In the special case where the transmit bit clock (ACLKX) is internally generated and the programmable bit clock divider is set to divide-by-1 (CLKXDIV = 0 in ACLKXCTL), AHCLKX is directly passed through to the ACLKX pin.
13-12	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
11-0	HCLKXDIV	0-FFFh	Transmit high-frequency clock divide ratio bits determine the divide-down ratio from AUXCLK to AHCLKX.
		0	Divide-by-1.
		1h	Divide-by-2.
		2h-FFFh	Divide-by-3 to divide-by-4096.

14.3.30 Transmit TDM Time Slot Register (XTDM)

The transmit TDM time slot register (XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). XTDM operates modulo 32, that is, XTDMS specifies the TDM activity for time slots 0, 32, 64, 96, 128, etc. The XTDM is shown in Figure 14-66 and described in Table 14-39.

Figure 14-66. Transmit TDM Time Slot Register (XTDM)

Table 14-39. Transmit TDM Time Slot Register (XTDM) Field Descriptions

Bit	Field	Value	Description
31-0	XTDMS[31-0]		Transmitter mode during TDM time slot *n*.
		0	Transmit TDM time slot *n* is inactive. The transmit serializer does not shift out data during this slot.
		1	Transmit TDM time slot *n* is active. The transmit serializer shifts out data during this slot according to the serializer control register (SRCTL).

14.3.31 Transmitter Interrupt Control Register (XINTCTL)

The transmitter interrupt control register (XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. The XINTCTL is shown in Figure 14-67 and described in Table 14-40. See Section 14.3.32 for a description of the interrupt conditions.

Figure 14-67. Transmitter Interrupt Control Register (XINTCTL)

Table 14-40. Transmitter Interrupt Control Register (XINTCTL) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
7	XSTAFRM		Transmit start of frame interrupt enable bit.
		0	Interrupt is disabled. A transmit start of frame interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit start of frame interrupt generates a McASP transmit interrupt (XINT).
6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	XDATA		Transmit data ready interrupt enable bit.
		0	Interrupt is disabled. A transmit data ready interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit data ready interrupt generates a McASP transmit interrupt (XINT).
4	XLAST		Transmit last slot interrupt enable bit.
		0	Interrupt is disabled. A transmit last slot interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit last slot interrupt generates a McASP transmit interrupt (XINT).
3	XDMAERR		Transmit DMA error interrupt enable bit.
		0	Interrupt is disabled. A transmit DMA error interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit DMA error interrupt generates a McASP transmit interrupt (XINT).
2	XCKFAIL		Transmit clock failure interrupt enable bit.
		0	Interrupt is disabled. A transmit clock failure interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmit clock failure interrupt generates a McASP transmit interrupt (XINT).
1	XSYNCERR		Unexpected transmit frame sync interrupt enable bit.
		0	Interrupt is disabled. An unexpected transmit frame sync interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. An unexpected transmit frame sync interrupt generates a McASP transmit interrupt (XINT).
0	XUNDRN		Transmitter underrun interrupt enable bit.
		0	Interrupt is disabled. A transmitter underrun interrupt does not generate a McASP transmit interrupt (XINT).
		1	Interrupt is enabled. A transmitter underrun interrupt generates a McASP transmit interrupt (XINT).

14.3.32 Transmitter Status Register (XSTAT)

The transmitter status register (XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated. The XSTAT is shown in Figure 14-68 and described in Table 14-41.

Figure 14-68. Transmitter Status Register (XSTAT)

31							9	8
Reserved								XERR
R-0								R/W-0
7	6	5	4	3	2	1		0
XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR		XUNDRN
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0	R/W1C-0	R/W1C-0		R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Writing a 1 clears this bit; writing a 0 has no effect; -*n* = value after reset

Table 14-41. Transmitter Status Register (XSTAT) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
8	XERR		XERR bit always returns a logic-OR of:XUNDRN | XSYNCERR | XCKFAIL | XDMAERR Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.
		0	No errors have occurred.
		1	An error has occurred.
7	XDMAERR		Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the data port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmit DMA error did not occur.
		1	Transmit DMA error did occur.
6	XSTAFRM		Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	No new transmit frame sync (AFSX) is detected.
		1	A new transmit frame sync (AFSX) is detected.
5	XDATA		Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	XBUF is written and is full.
		1	Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).
4	XLAST		Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Current slot is not the last slot in a frame.
		1	Current slot is the last slot in a frame. XDATA is also set.
3	XTDMSLOT		Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.
		0	Current TDM time slot is odd.
		1	Current TDM time slot is even.
2	XCKFAIL		Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error (see *Clock Failure Detection*). Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmit clock failure did not occur.
		1	Transmit clock failure did occur.

Table 14-41. Transmitter Status Register (XSTAT) Field Descriptions (continued)

Bit	Field	Value	Description
1	XSYNCERR		Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Unexpected transmit frame sync did not occur.
		1	Unexpected transmit frame sync did occur.
0	XUNDRN		Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect.
		0	Transmitter underrun did not occur.
		1	Transmitter underrun did occur. For details on McASP action upon underrun conditions, see *Buffer Underrun Error - Transmitter*.

14.3.33 Current Transmit TDM Time Slot Register (XSLOT)

The current transmit TDM time slot register (XSLOT) indicates the current time slot for the transmit data frame. The XSLOT is shown in Figure 14-69 and described in Table 14-42.

Figure 14-69. Current Transmit TDM Time Slot Register (XSLOT)

Reserved	
R-0	

15	10	9	0
Reserved		XSLOTCNT	
R-0		R-17Fh	

LEGEND: R = Read only; -*n* = value after reset

Table 14-42. Current Transmit TDM Time Slot Register (XSLOT) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
9-0	XSLOTCNT	0-17Fh	Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for >32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block.

14.3.34 Transmit Clock Check Control Register (XCLKCHK)

The transmit clock check control register (XCLKCHK) configures the transmit clock failure detection circuit. The XCLKCHK is shown in Figure 14-70 and described in Table 14-43.

Figure 14-70. Transmit Clock Check Control Register (XCLKCHK)

31	24	23	16
XCNT		XMAX	
R-0		R/W-0	

15	8	7	4	3	0
XMIN		Reserved		XPS	
R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-43. Transmit Clock Check Control Register (XCLKCHK) Field Descriptions

Bit	Field	Value	Description
31-24	XCNT	0	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.
23-16	XMAX	0-FFh	Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	XMIN	0-FFh	Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
3-0	XPS	0-Fh	Transmit clock check prescaler value.
		0	McASP system clock divided by 1.
		1h	McASP system clock divided by 2.
		2h	McASP system clock divided by 4.
		3h	McASP system clock divided by 8.
		4h	McASP system clock divided by 16.
		5h	McASP system clock divided by 32.
		6h	McASP system clock divided by 64.
		7h	McASP system clock divided by 128.
		8h	McASP system clock divided by 256.
		9h-Fh	Reserved.

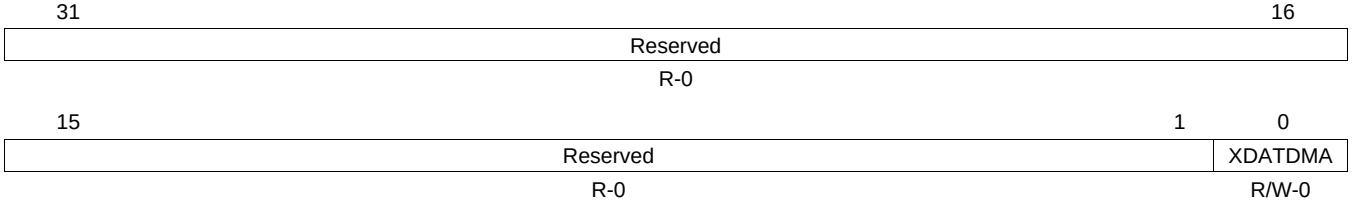
14.3.35 Transmitter DMA Event Control Register (XEVTCTL)

The transmitter DMA event control register (XEVTCTL) contains a disable bit for the transmit DMA event. The XEVTCTL is shown in Figure 14-71 and described in Table 14-44.

NOTE: Device-specific registers

Accessing REVTCTL not implemented on a specific device may cause improper device operation.

Figure 14-71. Transmitter DMA Event Control Register (XEVTCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 14-44. Transmitter DMA Event Control Register (XEVTCTL) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
0	XDATDMA		Transmit data DMA request enable bit. If writing to this bit, always write the default value of 0.
		0	Transmit data DMA request is enabled.
		1	Reserved

14.3.36 Serializer Control Registers (SRCTL*n*)

Each serializer on the McASP has a serializer control register (SRCTL). There are up to 16 serializers per McASP. The SRCTL is shown in Figure 14-72 and described in Table 14-45.

NOTE: Device-specific registers

Accessing SRCTL*n* not implemented on a specific device may cause improper device operation.

Figure 14-72. Serializer Control Registers (SRCTL*n*)

Table 14-45. Serializer Control Registers (SRCTL*n*) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved. The reserved bit location always returns the default value. A value written to this field has no effect. If writing to this field, always write the default value for future device compatibility.
5	RRDY		Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to RBUF.
		0	Receive buffer (RBUF) is empty.
		1	Receive buffer (RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.
4	XRDY		Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0).
		0	Transmit buffer (XBUF) contains data.
		1	Transmit buffer (XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.
3-2	DISMOD	0-3h	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0).
		0	Drive on pin is 3-state.
		1h	Reserved.
		2h	Drive on pin is logic low.
		3h	Drive on pin is logic high.
1-0	SRMOD	0-3h	Serializer mode bit.
		0	Serializer is inactive.
		1h	Serializer is transmitter.
		2h	Serializer is receiver.
		3h	Reserved.

14.3.37 DIT Left Channel Status Registers (DITCSRA0-DITCSRA5)

The DIT left channel status registers (DITCSRA) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers (Figure 14-73) can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

LEGEND: R/W = Read/Write; -*n* = value after reset

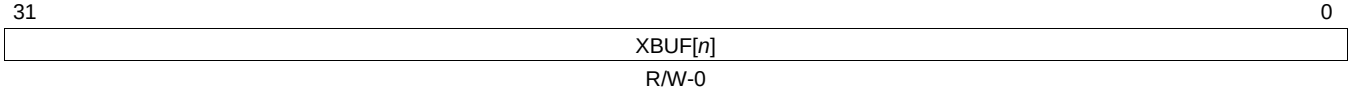
14.3.41 Transmit Buffer Registers (XBUF*n*)

The transmit buffers for the serializers (XBUF) hold data from the transmit format unit. For transmit operations, the XBUF (Figure 14-77) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing XBUF registers not implemented on a specific device may cause improper device operation.

Figure 14-77. Transmit Buffer Registers (XBUFn)



LEGEND: R/W = Read/Write; -*n* = value after reset

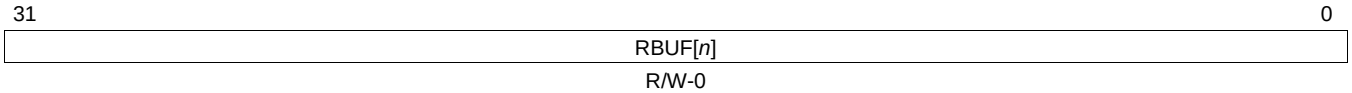
14.3.42 Receive Buffer Registers (RBUF*n*)

The receive buffers for the serializers (RBUF) hold data from the serializer before the data goes to the receive format unit. For receive operations, the RBUF (Figure 14-78) is an alias of the XRBUF in the serializer.

NOTE: Device-specific registers

Accessing RBUF registers not implemented on a specific device may cause improper device operation.

Figure 14-78. Receive Buffer Registers (RBUF*n*)



LEGEND: R/W = Read/Write; -*n* = value after reset

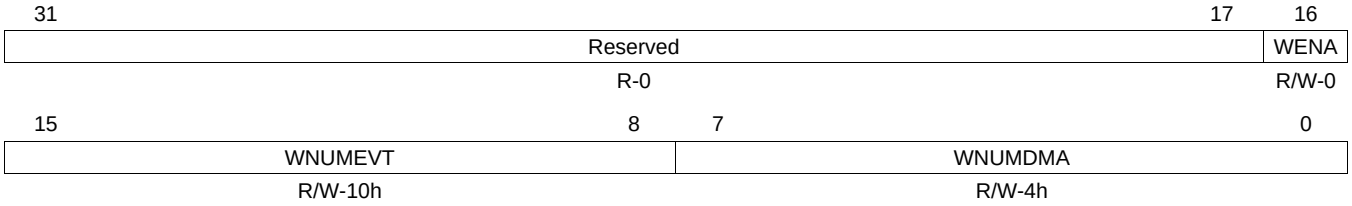
14.3.43 Write FIFO Control Register (WFIFOCTL)

Note that this register is only available if the Write FIFO is configured. The Write FIFO control register (WFIFOCTL) is shown in Figure 14-79 and described in Table 14-46.

NOTE: The WNUMEVT and WNUMDMA values must be set prior to enabling the Write FIFO.

If the Write FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 14-79. Write FIFO Control Register (WFIFOCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

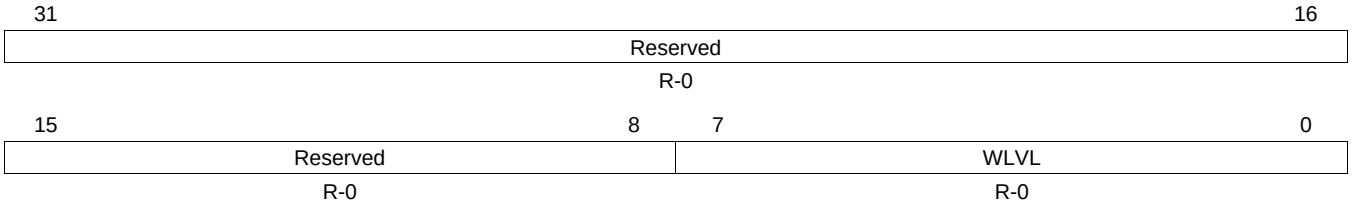
Table 14-46. Write FIFO Control Register (WFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	WENA		Write FIFO enable bit.
		0	Write FIFO is disabled. The WLVL bit in the Write FIFO status register (WFIFOSTS) is reset to 0 and pointers are initialized, that is, the Write FIFO is “flushed.”
		1	Write FIFO is enabled. If Write FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	WNUMEVT	0-FFh	Write word count per DMA event (32-bit). When the Write FIFO has space for at least WNUMEVT words of data, then an AXEVT (transmit DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	WNUMDMA	0-FFh	Write word count per transfer (32-bit words). Upon a transmit DMA event from the McASP, WNUMDMA words are transferred from the Write FIFO to the McASP. This value must equal the number of McASP serializers used as transmitters. This value must be set prior to enabling the Write FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-10h	3-16 words
		11h-FFh	Reserved

14.3.44 Write FIFO Status Register (WFIFOSTS)

Note that this register is only available if the Write FIFO is configured. The Write FIFO status register (WFIFOSTS) is shown in Figure 14-80 and described in Table 14-47.

Figure 14-80. Write FIFO Status Register (WFIFOSTS)



LEGEND: R = Read only; -*n* = value after reset

Table 14-47. Write FIFO Status Register (WFIFOSTS) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	WLVL	0-FFh	Write level (read-only). Number of 32-bit words currently in the Write FIFO.
		0	0 words currently in Write FIFO.
		1h	1 word currently in Write FIFO.
		2h	2 words currently in Write FIFO.
		3h-40h	3 to 64 words currently in Write FIFO.
		41h-FFh	Reserved

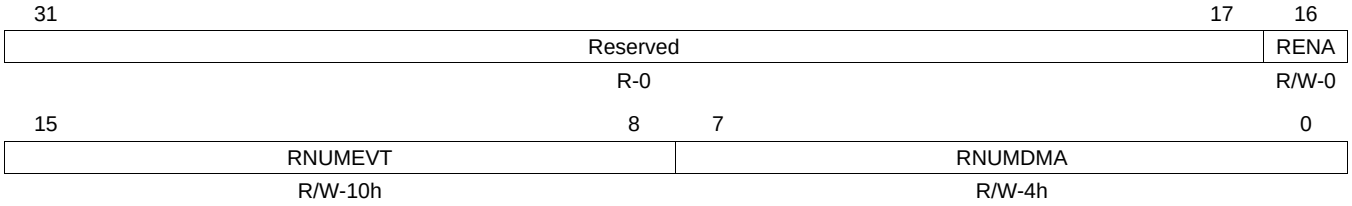
14.3.45 Read FIFO Control Register (RFIFOCTL)

Note that this register is only available if the Read FIFO is configured. The Read FIFO control register (RFIFOCTL) is shown in Figure 14-81 and described in Table 14-48.

NOTE: The RNUMEVT and RNUMDMA values must be set prior to enabling the Read FIFO.

If the Read FIFO is to be enabled, it must be enabled prior to taking the McASP out of reset.

Figure 14-81. Read FIFO Control Register (RFIFOCTL)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

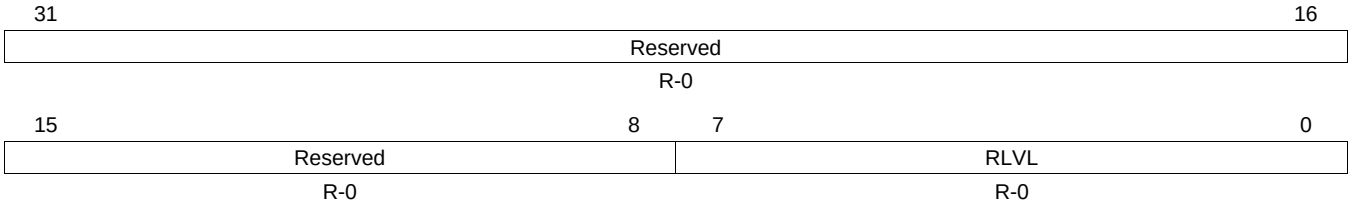
Table 14-48. Read FIFO Control Register (RFIFOCTL) Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	RENA		Read FIFO enable bit.
		0	Read FIFO is disabled. The RLVL bit in the Read FIFO status register (RFIFOSTS) is reset to 0 and pointers are initialized, that is, the Read FIFO is “flushed.”
		1	Read FIFO is enabled. If Read FIFO is to be enabled, it must be enabled prior to taking McASP out of reset.
15-8	RNUMEVT	0-FFh	Read word count per DMA event (32-bit). When the Read FIFO contains at least RNUMEVT words of data, then an AREVT (receive DMA event) is generated to the host/DMA controller. This value should be set to a non-zero integer multiple of the number of serializers enabled as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1h	1 word
		2h	2 words
		3h-40h	3 to 64 words
		41h-FFh	Reserved
7-0	RNUMDMA	0-FFh	Read word count per transfer (32-bit words). Upon a receive DMA event from the McASP, the Read FIFO reads RNUMDMA words from the McASP. This value must equal the number of McASP serializers used as receivers. This value must be set prior to enabling the Read FIFO.
		0	0 words
		1	1 word
		2	2 words
		3h-10h	3-16 words
		11h-FFh	Reserved

14.3.46 Read FIFO Status Register (RFIFOSTS)

Note that this register is only available if the Read FIFO is configured. The Read FIFO status register (RFIFOSTS) is shown in Figure 14-82 and described in Table 14-49.

Figure 14-82. Read FIFO Status Register (RFIFOSTS)



LEGEND: R = Read only; -*n* = value after reset

Table 14-49. Read FIFO Status Register (RFIFOSTS) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RLVL	0-FFh	Read level (read-only). Number of 32-bit words currently in the Read FIFO.
		0	0 words currently in Read FIFO.
		1h	1 word currently in Read FIFO.
		2h	2 words currently in Read FIFO.
		3h-40h	3 to 64 words currently in Read FIFO.
		41h-FFh	Reserved

Multichannel Buffered Serial Port (McBSP)

This chapter describes the multichannel buffered serial port (McBSP).

Topic **Page**

15.1 Introduction

15.1.1 Overview

The multichannel buffered serial port (McBSP) provides a full duplex direct serial interface between the host chip and other devices in a system such as application chips, codecs. It can accommodate to a wide range of peripherals and protocols thanks to its high level of versatility.

15.1.2 Features

The main features of the McBSP modules are:

- OCP-IP2.0 compliant interface (32-bit data bus)
- 512-byte internal buffer for transmit operation (fixed size)
- 512-byte internal buffer for receive operation (fixed size)
- Auto-gating clocks for power saving
- Power Management interface
- Full-duplex communication
- Buffered transmission and reception that allows a continuous data stream
- Independent clocking and framing for reception and for transmission
- Capability to generate interrupts or DMA requests on internal events
- 128 channels for transmission and for reception
- Multi-channel selection modes that allow to enable or block transfers in each one of the channels
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices (I2S compliant devices)
- Support for external generation of clock signals and frame-synchronization (frame-synchronization) signals
- A programmable sample rate generator for internal generation and control of clock signals and frame-synchronization signals
- Programmable polarity for frame-synchronization pulses and for clock signals
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive LSB)
- Status bits for flagging exception/error conditions
- Full/Half cycle mode on both transmit and receive side

The McBSP supports dual phase frames in order to provide I2S fully compliant capabilities. The limitation on dual phase frame is that the number of words per phase must be set to 1 for both first and second phase.

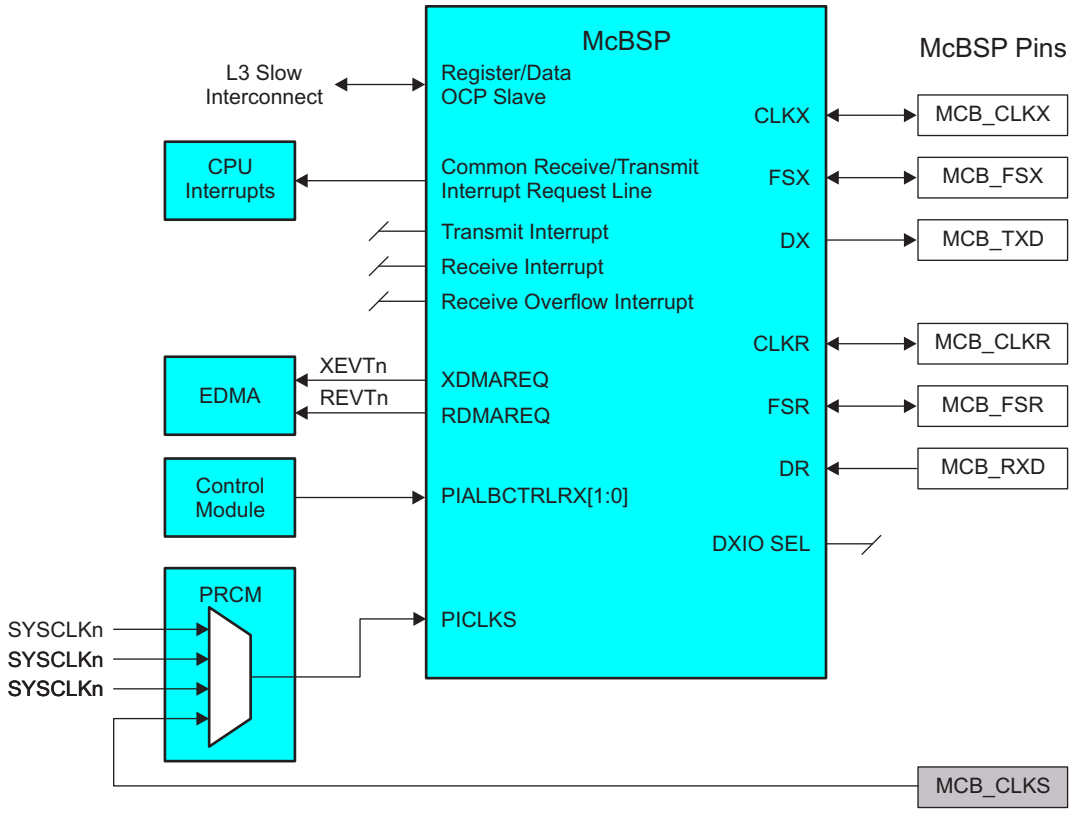
Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupts and DMA requests can be generated according to the configuration and the external signals.
- **Smart Idle mode:** the module is in a waiting state, interface/functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according the configuration and external signals.
- **Force Idle mode:** the module has no activity, interface clock can be stopped, no interrupts and DMA requests can be generated, and the wake-up feature is inhibited. The software must disable the McBSP module (receive/transmit parts) prior to enter Force Idle mode.
- **No Idle mode:** the module is active but cannot respond to host interface requests.

The Smart/Force Idle modes are configured within the module and activated on request by the host processor through system interface sideband signals.

15.1.3 Block Diagram

Figure 15-1. McBSP Block Diagram



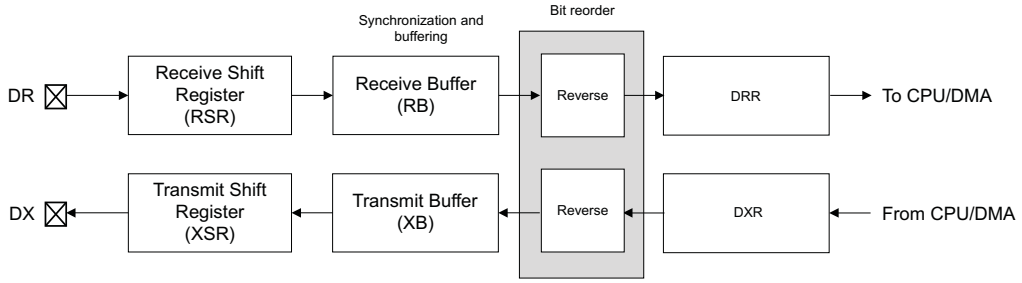
Note: The number of SYSCLKn varies per device implementation.
See Control Module Chapter for details.

15.2 Architecture

15.2.1 McBSP Data Transfer Process

Figure 15-2 shows the McBSP data transfer paths. McBSP receive operations and transmit operations are buffered (up to 512-byte buffers organized on 32-bit words are used). Input/output registers are 32-bit long words.

Figure 15-2. McBSP Data Transfer Paths



15.2.1.1 Data Transfer Process for 8/12/16/20/24/32-bit Long Words

Receive data arrives on the McBSP.DR pin and is shifted into receive shift register. When a full word is received, the content of the shift register is copied into receive buffer under condition receive buffer is not full. When the receive buffer threshold is reached, the McBSP asserts DMA or interrupt request and the receive buffer content is then transferred to the host (the CPU or the DMA controller reads the data receive register DRR_REG).

Transmit data is written by the CPU or the DMA controller to data transmit register DXR_REG using the byte enable input (when a byte is not enabled the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register, the value from the transmit buffer is copied to transmit shift register; otherwise, the content is copied to transmit shift register when the last bit of the previous data is shifted out on the McBSP.DX pin.

Note that the byte enable is used for transmit data register DXR_REG only and the value is ignored when the CPU accesses are targeting other registers. When writing to DXR_REG, the bytes are independently enabled by the byte enable pattern (for example, byte enable is “0001” then only the less significant byte will be written).

15.2.1.2 Bit Reordering (option to transfer LSB first)

Generally, the McBSP transmits or receives all data with the most significant bit (MSB) first. However, certain data protocols require the least significant bit (LSB) to be transferred first.

If you set XREVERSE = 01b in XCR2_REG[4:3], the bit ordering of the data words is reversed (LSB first) before being sent to the serial port.

If you set RREVERSE = 01b in RCR2_REG[4:3], the bit ordering of the data words is reversed during reception.

This feature is available for all the data formats from 8 up to 32-bit data length.

15.2.1.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

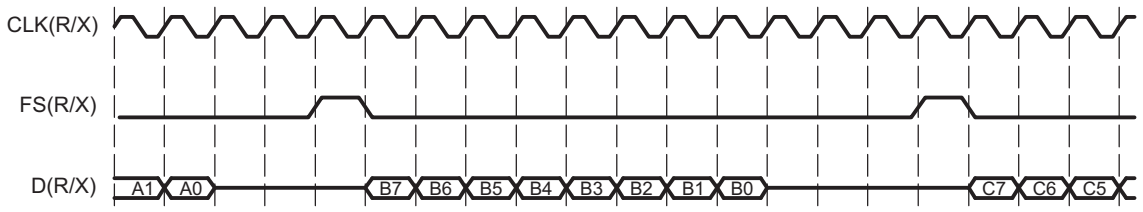
15.2.1.3.1 Clocking

Data is shifted one bit at a time from the McBSP.DR pin to the receive shift registers or from the transmit shift registers to the McBSP.DX pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR) controls bit transfers from the McBSP.DR pin to the receive shift registers. The transmit clock signal (CLKX) controls bit transfers from the transmit shift registers to the McBSP.DX pin. CLKR or CLKX can be derived from a pin at the boundary of the McBSP (McBSP.CLKR and McBSP.CLKX respectively) or derived from inside the McBSP. The polarities of CLKR and CLKX are programmable.

Figure 15-3 gives an example in which the clock signal controls the timing of each bit transfer on the pin.

Figure 15-3. Clock Signal Control of Bit Transfer Timing



The McBSP is constrained to operate at an internal functional frequency up to 55 MHz while CPU interface (OCP compliant interface) can operate at a frequency up to 110 MHz. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to 110 MHz) and divide down value (CLKGDV). Please see the device datasheet for maximum McBSP CLKX cycle time supported on your device.

15.2.1.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (McBSP.DR or McBSP.DX) are transferred in a group called a serial word. You can define how many bits are in a word.

Bits coming in on the McBSP.DR pin are held in RSR until RSR holds a full serial word. Only then is the word passed to the receive buffer RB (and ultimately to the DRR_REG register).

During transmission, XSR accept new data from transmit buffer XB after a full serial word has been passed from XSR to the McBSP.DX pin.

In the example in Figure 15-3, an 8–bit word size was defined (see bits 7 through 0 of word B being transferred).

15.2.1.3.3 Frames and Frame Synchronization

One or more words are transferred in a group called a frame. You can define how many words are in a frame. All of the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP uses frame–synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame–synchronization signal, the McBSP begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP receives/transmits the next frame, and so on. Pulses on the receive frame–synchronization (FSR) signal initiate frame transfers on McBSP.DR. Pulses on the transmit frame–synchronization (FSX) signal initiate frame transfers on McBSP.DX. FSR or FSX can be derived from a pin at the boundary of the McBSP (McBSP.FSR and McBSP.FSX respectively) or derived from inside the McBSP. In the example in Figure 15-3, a one–word frame is transferred when a frame–synchronization pulse occurs. In McBSP operation, the inactive–to–active transition of the frame–synchronization signal indicates the start of the next frame. For this reason, the frame–synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occurs.

15.2.1.3.4 Detecting Frame–Synchronization Pulses, Even in Reset State

The McBSP can generate receive and transmit interrupts to the CPU to indicate specific events in the McBSP. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame–synchronization pulses. Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating RINT when the receiver is in reset). In this case, FSRM/FSXM and FSRP/FSXP still select the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the CPU clock and then sent to the CPU in the form of RINT and XINT at the point at which they feed the receiver and transmitter of the serial port. Consequently, a new frame–synchronization pulse can be detected, and after this occurs the CPU can take the serial port out of reset safely.

15.2.1.3.5 Ignoring Frame–Synchronization Pulses

The McBSP ignores transmit and/or receive frame–synchronization pulses while the frame transfer has been already started by a previous frame–synchronization pulse (unexpected frame–synchronization pulses). The McBSP does not support features like re-transmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame–synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame–synchronization pulses, see Section 15.2.3.2 and Section 15.2.3.5.

15.2.1.3.6 Frame Frequency

The frame frequency is determined by the period between frame–synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency / (Number of clock cycles between frame – synchronization pulses)

The frame frequency can be increased by decreasing the time between frame–synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

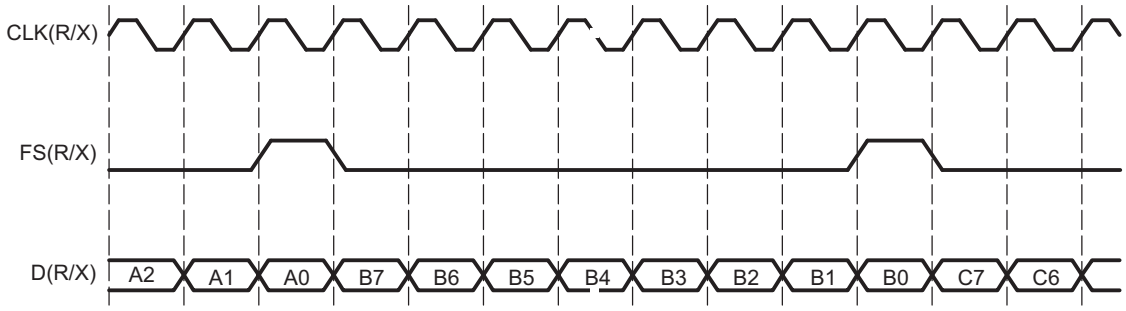
15.2.1.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = Clock frequency / Number of bits per frame

Figure 15-4 shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 15-4. McBSP Operating at Maximum Packet Frequency



If there is a 1–bit data delay as shown in this figure, the frame–synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

For XDATDLY = 0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX).

15.2.1.4 Frame Phases (dual phase frame I2S support)

The McBSP allows you to configure each frame to contain one or two phases. The support for dual phase frames is required in order to provide I2S fully compliant capabilities. The limitation on dual phase frame support is that the number of words per phase must be set to 1 for both first and second phase.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

15.2.1.4.1 Number of Phases, Words, and Bits per Frame

Table 15-1 shows which bit fields in the receive control registers (RCR1_REG and RCR2_REG) and in the transmit control registers (XCR1_REG and XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single–phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE = RCR2_REG[15]
- XPHASE = XCR2_REG[15]
- RFRLEN1 = RCR1_REG[14:8] (cleared to 0 if using dual-phase)
- RFRLEN2 = RCR2_REG[14:8] (cleared to 0 if using dual-phase)
- XFRLEN1 = XCR1_REG[14:8] (cleared to 0 if using dual-phase)
- XFRLEN2 = XCR2_REG[14:8] (cleared to 0 if using dual-phase)
- RWDLEN1 = RCR1_REG[7:5]
- RWDLEN2 = RCR2_REG[7:5]
- XWDLEN1 = XCR1_REG[7:5]
- XWDLEN2 = XCR2_REG[7:5]

Table 15-1. Phases, Words and Bits Per Frame Control Bits

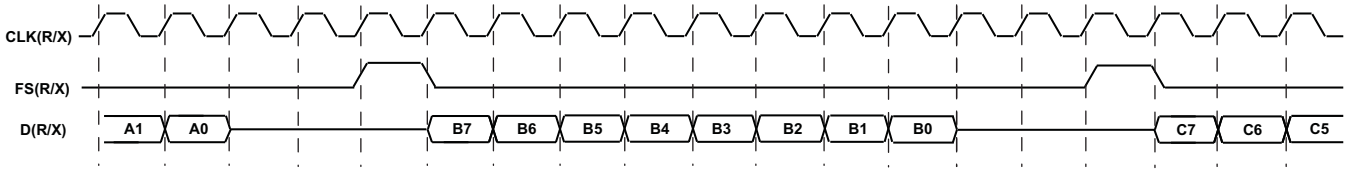
Operation	Number of Phases
Reception	1 (RPHASE = 0)
Reception	2 (RPHASE = 1)
Transmission	1 (XPHASE = 0)
Transmission	2 (XPHASE = 1)

15.2.1.4.2 Single-phase Frame Example

Figure 15-5 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the McBSP.DX and McBSP.DR pins are available one clock cycle after FS(R/X) goes active. The figure makes the following assumptions:

- RPHASE (RCR2_REG[15]) and XPHASE (XCR2_REG[15]) = 0: Single-phase frame
- RFRLEN1 (RCR1_REG[14:8]) and XFRLEN1 (XCR1_REG[14:8]) = 0: 1 word per frame
- RWDLEN1 (RCR1_REG[7:5]) and XWDLEN1 (XCR1_REG[7:5]) = 0: 8-bit word length
- RFRLEN2 (RCR2_REG[14:8]) and XWDLEN2 (XCR2_REG[14:8]) are ignored
- CLKRP (PCR_REG[0]) and CLKXP (PCR_REG[1]) = 0: Receive data clocked on falling edge; transmit data clocked on rising edge
- FSRP (PCR_REG[2]) and FSXP (PCR_REG[3]) = 0: Active–high frame–synchronization signals
- RDATDLY (RCR2_REG[1:0]) and XDARDLY (XCR2_REG[1:0]) = 01b: 1–bit data delay

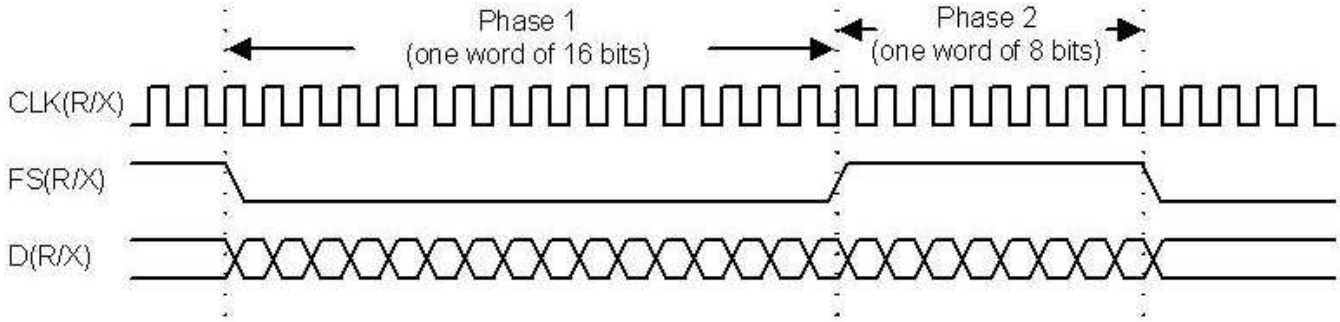
Figure 15-5. Single-Phase Frame for a McBSP Data Transfer



15.2.1.4.3 Dual-Phase Frame Example

Figure 15-6 shows an example of a frame where the first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases.

Figure 15-6. Dual-Phase Frame for a McBSP Data Transfer



15.2.1.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP.

Figure 15-7 and Figure 15-8 show how reception occurs in the McBSP. Figure 15-7 shows the physical path for the data. Figure 15-8 is a timing diagram showing signal activity for one possible reception scenario. A description of the process follows the figures.

Figure 15-7. McBSP Reception Physical Data Path

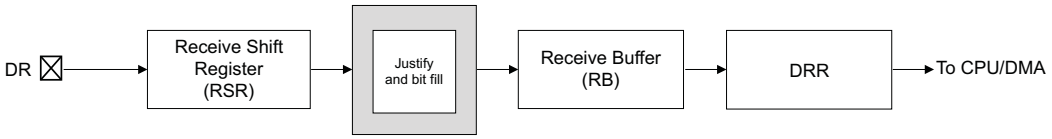


Figure 15-8. McBSP Reception Signal Activity

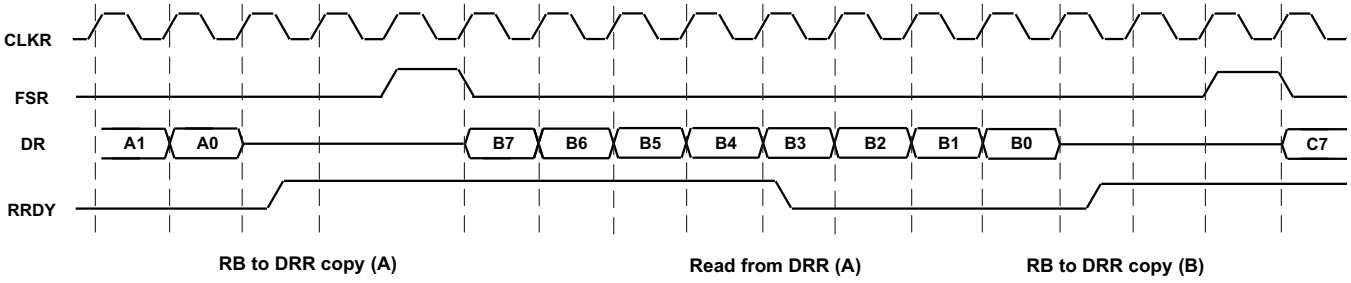

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the McBSP.DR pin to the CPU or to the DMA controller:

1. The McBSP waits for a receive frame-synchronization pulse on internal FSR.
2. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the RDATDLY bits of RCR2_REG[1:0] register. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP accepts data bits on the McBSP.DR pin and shifts them into the receive shift register.
4. When a full word is received, the McBSP copies the contents of the receive shift register to the receive buffer, provided that RB is not full.
5. When the programmed receive threshold is reached the McBSP asserts the receiver ready bit (RRDY) in SPCR1_REG. This indicates that receive data is ready to be read by the CPU or the DMA controller by accessing DRR_REG register. The data copied from RB to DRR_REG is justified and bit filled according to the RJUST bits.
6. The CPU or the DMA controller reads the data from the data receive register. When the receive buffer is empty, RRDY bit is cleared.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Overrun in the Receiver
- Underflow in the receiver
- Unexpected Receive Frame–Synchronization Pulse

15.2.1.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP. Figure 15-9 and Figure 15-10 show how transmission occurs in the McBSP.

Figure 15-9 shows the physical path for the data. Figure 15-10 is a timing diagram showing signal activity for one possible transmission scenario. A description of the process follows the figures.

Figure 15-9. McBSP Transmission Physical Data Path

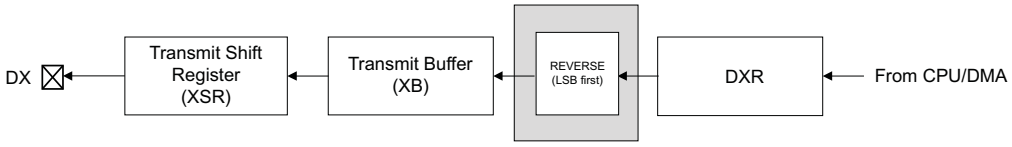

Figure 15-10. McBSP Transmission Signal Activity

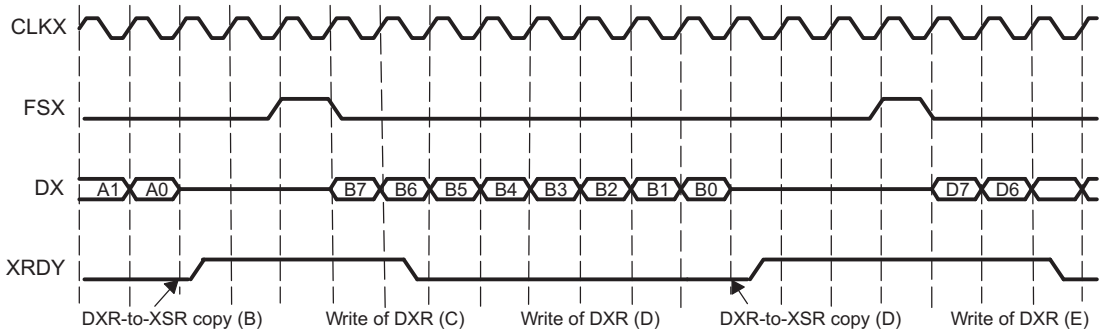


The following process shows how.....

1. The CPU or the DMA controller writes data to the data transmit register. When the transmit buffer is reached the transmitter ready bit (XRDY) is cleared in SPCR2_REG[1] register to indicate that the transmitter is not ready for new data.
2. When new data arrives in DXR_REG register, the McBSP copies the content of the data transmit register to the transmit buffer. In addition, the Transmit Ready bit (XRDY) is set as long as the buffer contains at least the transmit threshold number of free locations. This indicates that the transmitter is ready to accept new data from the CPU or the DMA controller.
3. The McBSP waits for a transmit frame–synchronization pulse on internal FSX.
4. When the pulse arrives, the McBSP inserts the appropriate data delay that is selected with the XCR2_REG[1:0] register XDATDLY bits. In the preceding timing diagram, a 1-bit data delay is selected.
5. The McBSP shifts data bits from the transmit shift register to the McBSP.DX pin.

When activity is not properly timed, errors can occur. See the following topics for more details:

- Underflow in the transmitter
- Overflow in the transmitter
- Unexpected transmit frame-synchronization pulse

15.2.1.7 Enable/Disable the Transmit and Receive Processes

The McBSP has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable XDISABLE/RDISABLE bit in XCCR_REG/RCCR_REG register is set, the McBSP will stop the transmit/receive operation at the next frame boundary (frame corruption avoided).

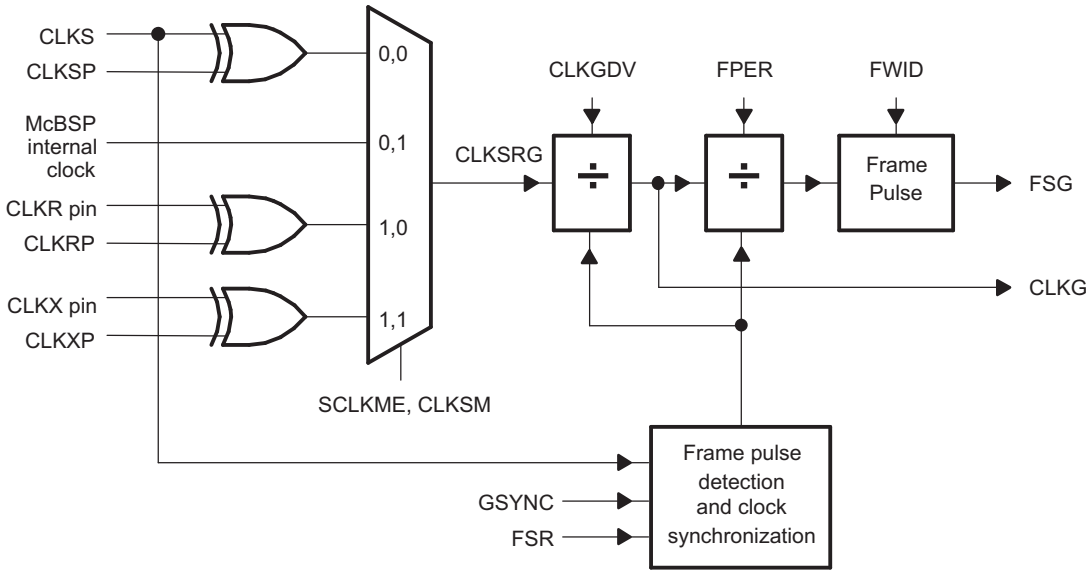
As soon as the XDISABLE/RDISABLE bit is cleared, the transmit/receive process will resume at the next frame boundary.

Note that it is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (XBUFFSTAT/RBUFFSTAT indicating the occupied/available buffer locations), since this register is a CPU (OCP) clock synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

15.2.2 McBSP Sample Rate Generator

The McBSP contains a sample rate generator that can be used to generate an internal data clock (CLKG) and an internal frame–synchronization signal (FSG). CLKG can be used for bit shifting on the data receive (McBSP.DR) pin and/or the data transmit (McBSP.DX) pin. FSG can be used to initiate frame transfers on McBSP.DR and/or McBSP.DX. Figure 15-11 is a conceptual block diagram of the sample rate generator.

Figure 15-11. Sample Rate Generator Block Diagram



The source clock for the sample rate generator (labeled CLKSRG in the diagram) can be supplied by either the FCLK functional clock (OCP interface clock), or by an external pin (McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR). The source is selected with the SCLKME bit of the PCR_REG[7] register and the CLKSM bit of the SRGR2_REG[13] register.

If a pin is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (CLKSP bit of SRGR2_REG[14] register, CLKXP bit of PCR_REG register, or CLKRP bit of PCR_REG[0] register).

The sample rate generator has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down. The source clock is divided according to the SRGR1_REG[7:0] register CLKGDV bits to produce CLKG .
- Frame period divide-down. CLKG is divided according to the SRGR2_REG[11:0] register FPER bit field to control the period from the start of a frame–pulse to the start of the next pulse.
- Frame-synchronization pulse-width countdown. CLKG cycles are counted according to the SRGR1_REG[15:8] register FWID bits to control the width of each frame-synchronization pulse.

Note: The McBSP cannot operate at an internal functional frequency faster than 55 MHz. Choose an input clock frequency and a CLKGDV value such that CLKG is less than or equal to 55 MHz. Please see the device datasheet for maximum McBSP CLKX cycle time supported on your device.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the McBSP.FSR pin. This feature is enabled or disabled with the SRGR2_REG[15] register GSYNC bit.

CLKG is used as source in order to generate the output clocks CLKX/CLKR when the CLKXM/CLKRM indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting given by the CLKXP/CLKRP as follows: when falling edge, the CLKX/CLKR is CLKG inverted.

15.2.2.1 Clock Generation in the Sample Rate Generator

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the sample rate generator to drive clocking is controlled by the clock mode bits (CLKRM and CLKXM) in the pin control register (PCR_REG[8] and PCR_REG[9] respectively) and polarity mode bits (CLKRP and CLKXP).

When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal sample rate generator output clock (CLKG) according with the polarity setting.

The effects of CLKRM = 1 and CLKXM = 1 on the McBSP are partially affected by the use of the digital loop back mode, the analog loop back mode and by the synchronous receive/transmit setting, respectively, as described in Table 15-2. The analog loop back mode is selected with the SPCR1_REG[15] register ALB bit. The digital loop back mode is selected with the DLB bit of the XCCR_REG register. The synchronous mode is controlled by the ALBRXCTRL input pin.

When using the sample rate generator as a clock source, make sure the sample rate generator is enabled (GRST = 1).

Table 15-2. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM = 1	DLB = 0 & ALB = 0 (Digital & analog loop back mode disabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 0 & ALB = 1 (Analog loop back mode enabled)	CLKR is an output pin driven by the sample rate generator output clock (CLKG). The receive functional part internal clock is driven by CLKX input pin CLKXI. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input pin (FSXI). The receive data is driven by the DX loop back pin (DXI).
	DLB = 1 & ALB = 0 (Digital loop back mode enabled)	CLKR is not driven. The sample rate generator and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the receive input data. Note that in digital loop back mode no serial link activity will be seen by the remote device because CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active.
	DLB = 1 & ALB = 1 (reserved mode)	Undefined functionality.

Table 15-2. Effects of DLB and ALB Bits on Clock Modes (continued)

Mode Bit Settings		Effect
CLKXM = 1	DLB = 0 & ALB = 0 (Digital & analog loop back mode disabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 0 & ALB = 1 (Analog loop back mode enabled)	CLKX is an output pin driven by the sample rate generator output clock (CLKG).
	DLB = 1 & ALB = 0 (Digital loop back mode enabled)	CLKX is not driven. The sample rate generator and the frame synchronization generator need to be enabled. The internal transmit and receive clocks are driven by SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the receive input data. Note that in digital loop back mode no serial link activity will be seen by the remote device because CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active.
	DLB = 1 & ALB = 1 (reserved mode)	Undefined functionality.
	ALBRXCTRL[0] = 1 (synchronous mode DLB = 0 & ALB = 0)	CLKX is an output pin driven by the sample rate generator output clock (CLKG). CLKR is connected to the CLKX.

15.2.2.2 Frame Synchronization Generation in the Sample Rate Generator

The sample rate generator can produce a frame–synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure PCR_REG[10] register FSRM bit = 1. (When FSRM = 0, receive frame synchronization is supplied via the McBSP.FSR pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- FSXM = 1 in PCR_REG[11] register: This indicates that transmit frame synchronization is supplied by the McBSP itself rather than from the McBSP.FSX pin
- FSGM = 1 in SRGR2_REG[12] register: This indicates that when FSXM = 1, transmit frame synchronization is supplied by the sample rate generator. (When FSGM = 0 and FSXM = 1, the transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty. When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the sample rate generator must be enabled (SPCR2_REG[6] register GRST bit = 1) and the frame–synchronization logic in the sample rate generator must be enabled (SPCR2_REG[7] register FRST bit = 0).

15.2.2.2.1 Choosing the Width of the Frame-Synchronization Pulse

Each pulse on FSG has a programmable width. You program the SRGR1_REG[15:8] register FWID bits, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

15.2.2.2.2 Controlling the Period Between the Starting Edges of the Frame-Synchronization Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the sample rate generator:

- If the sample rate generator is using an external input clock and SRGR2_REG[15] register GSYNC bit = 1, FSG pulses in response to an inactive–to–active transition on the McBSP.FSR pin. Thus, an external device controls the frame–synchronization period.
- Otherwise, you program the FPER bits of SRGR2_REG[11:0] register, and the resulting frame–synchronization period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the sample rate generator.

15.2.2.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the sample rate generator, the GSYNC bit of SRGR2_REG15] register and the McBSP.FSR pin can be used to configure the timing of FSG pulses.

GSYNC = 1 ensures that the McBSP and an external device are dividing down the input clock with the same phase relationship. If GSYNC = 1, an inactive–to–active transition on the McBSP.FSR pin triggers a resynchronization of CLKG and generation of FSG.

15.2.2.3 Synchronizing Sample Rate Generator Outputs to an External Clock

The sample rate generator can produce a clock signal (CLKG) and a frame–synchronization signal (FSG) based on an input clock signal that is either the FCLK functional clock signal or a signal at the McBSP.CLKS, McBSP.CLKR, or McBSP.CLKX pin. When an external clock is selected to drive the sample rate generator, the GSYNC bit of SRGR2_REG[15] register and the McBSP.FSR pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock.

Make GSYNC = 1 when you want the McBSP and an external device to divide down the input clock with the same phase relationship. If GSYNC = 1:

- An inactive–to–active transition on the McBSP.FSR pin triggers a resynchronization of CLKG and a pulsing of FSG.
- CLKG always begins with a high state after synchronization.
- FSR is always detected at the same edge of the input clock signal that generates CLKG, no matter how long the FSR pulse is.
- The SRGR2_REG[11:0] register FPER bits are ignored because the frame–synchronization period on FSG is determined by the arrival of the next frame–synchronization pulse on the McBSP.FSR pin.

If GSYNC = 0, CLKG runs freely and is not resynchronized, and the frame–synchronization period on FSG is determined by FPER.

15.2.2.3.1 Operating the Transmitter Synchronously with the Receiver

When GSYNC = 1, the transmitter can operate synchronously with the receiver, provided that:

- FSX is programmed to be driven by FSG (FSGM = 1 in SRGR2_REG[12] register and FSXM = 1 in PCR_REG[11] register). If the input FSR has appropriate timing so that it can be sampled by the falling edge of CLKG, it can be used, instead, by setting FSXM = 0 and connecting FSR to FSX externally.
- The sample rate generator clock drives the transmit and receive clocking (PCR_REG[8] CLKRM bit and PCR_REG[9] CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

15.2.2.3.2 Synchronization Examples

Figure 15-12 and Figure 15-13 show the clock and frame–synchronization operation with various polarities of CLKS (the chosen input clock) and FSR. These figures assume FWID = 0 in SRGR1_REG[15:8] register, for an FSG pulse that is one CLKG cycle wide. The FPER bits of SRGR2_REG[11:0] register are not programmed; the period from the start of a frame–synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive–to–active transition on the McBSP.FSR pin. Each of the figures shows what happens to CLKG when it is initially synchronized and GSYNC = 1, and when it is not initially synchronized and GSYNC = 1. Figure 15-13 has a slower CLKG frequency (it has a larger divide–down value in the CLKGDV bits of SRGR1_REG[7:0] register).

Figure 15-12. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 1)

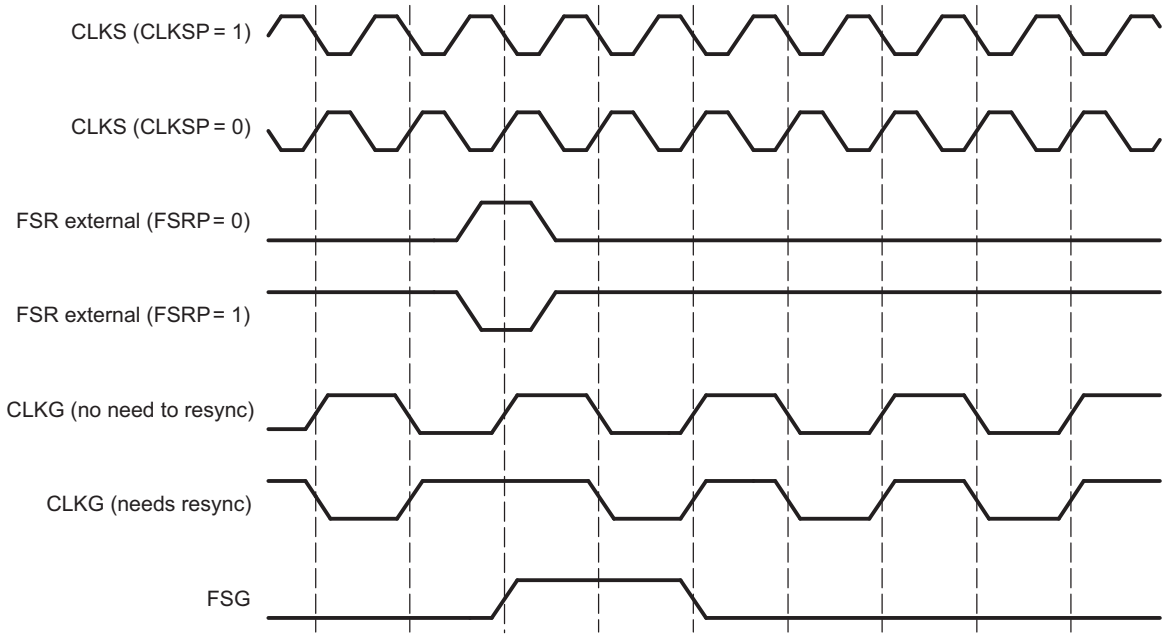


Figure 15-13. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 3h)

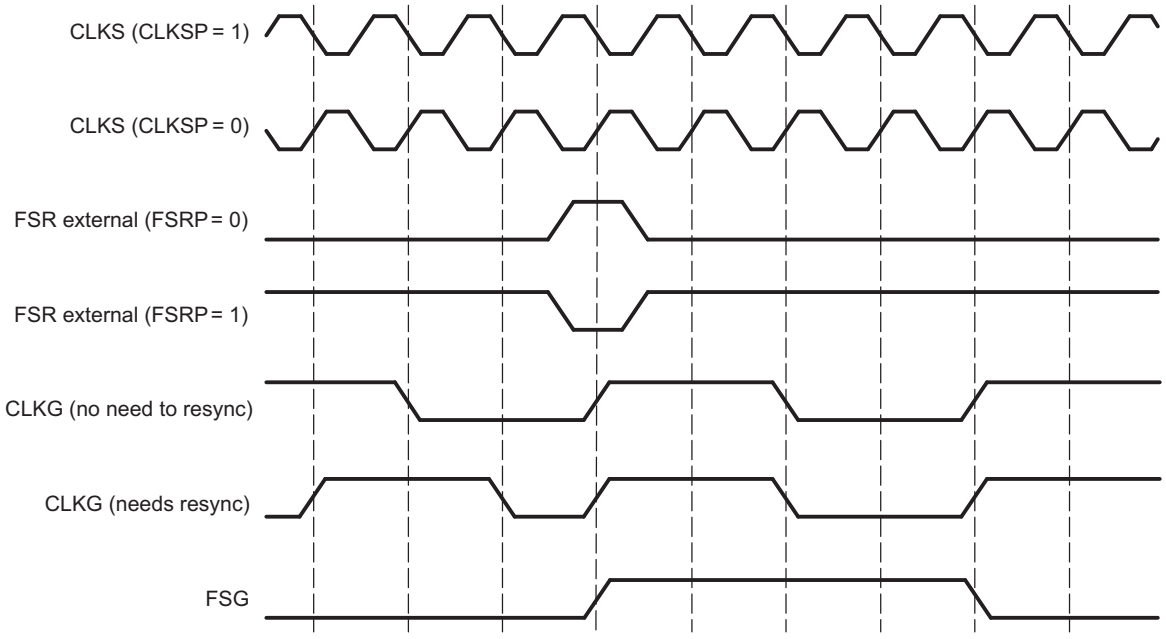


15.2.3 McBSP Exception/Error Conditions

There are several serial port events that can constitute a system error. Any of this error conditions may be sources of an interrupt:

- Receiver Overrun

(ROVFLSTAT bit is set to 1 in IRQSTATUS register, and legacy mode RFULL bit is set to 1 in SPCR1_REG register)

This occurs when receive buffer is full and RSR(s) are full with another new word shifted in from McBSP.DR. Therefore, ROVFLSTAT (RFULL) indicates an error condition wherein any new data that can arrive at this time on McBSP.DR replaces the contents of the RSR, and the previous word is lost. The RSR continue to be overwritten as long as new data arrives on McBSP.DR and DRR_REG register is not read.

- Unexpected Receive Frame-Synchronization Pulse

(RSYNCERR bit is set to 1 in IRQSTATUS register, and legacy mode RSYNCERR bit is set to 1 in SPCR1_REG register)

This occurs during reception when an unexpected frame–synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the RSYNCERR bit in SPCR1_REG.

- Receiver Underflow

(RUNDFLSTAT bit is set to 1 in IRQSTATUS register)

This occurs when DMA controller or CPU reads data from an empty receive buffer.

- Transmitter Underflow

(XUNDFLSTAT bit is set to 1 in IRQSTATUS register, and legacy mode XEMPTY bit is cleared to 0 in SPCR2_REG register)

If a new frame–synchronization signal arrives when transmit buffer is empty, the previous data in the XSR is sent again. This procedure continues for every new frame–synchronization pulse that arrives until DXR_REG register is loaded with new data (and the XB buffer will be no longer empty).

- Unexpected Transmit Frame-Synchronization Pulse

(XSYNCERR bit is set to 1 in IRQSTATUS register, and legacy mode XSYNCERR bit is set to 1 in SPCR2_REG register)

This occurs during transmission when an unexpected frame–synchronization pulse arrives. An unexpected frame–synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the XSYNCERR bit in SPCR2_REG.

- Transmitter Overflow

(XOVFLSTAT bit is set to 1 in IRQSTATUS register)

This occurs when DMA controller or CPU write data to a full transmit buffer.

15.2.3.1 Overrun in the Receiver

(ROVFLSTAT bit set to 1 in IRQSTATUS register, and legacy mode RFULL bit set to 1 in SPCR1_REG register)

Indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

- DRR_REG is not read even if the RRDY bit in IRQSTATUS register is set (legacy mode: RRDY bit in SPCR1_REG register) and DMA or interrupt request has been asserted.
- RB is full
- RSR is full

As previously described, data arriving on McBSP.DR is continuously shifted into. Once a complete word is shifted into the RSR, an RSR–to–RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode RFULL bit and allows subsequent transfers to be read properly:

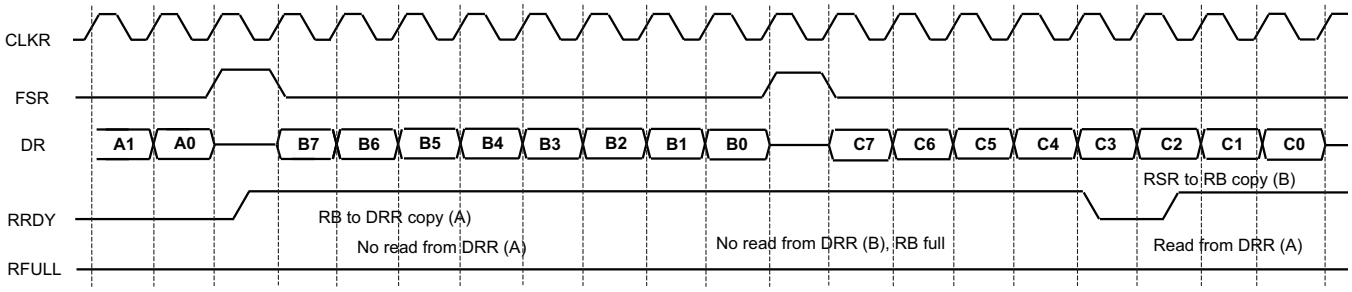
- The CPU or DMA controller reads DRR_REG.
- The receiver is reset individually (SPCR1_REG[0] register RRST bit = 0) or as part of an Global reset.

Another frame–synchronization pulse is required to restart the receiver.

According to the IRQENABLE register setting, this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

Figure 15-14 shows the receive overrun condition.

Figure 15-14. Overrun in the McBSP Receiver



15.2.3.2 Unexpected Receive Frame-Synchronization Pulse

15.2.3.2.1 Possible Responses to Receive Frame-Synchronization Pulses

If a frame–synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame–synchronization pulse, and the receiver sets the receive frame–synchronization error bit RSYNCERR in IRQSTATUS (and the legacy RSYNCERR bit SPCR1_REG[3]) register.

According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

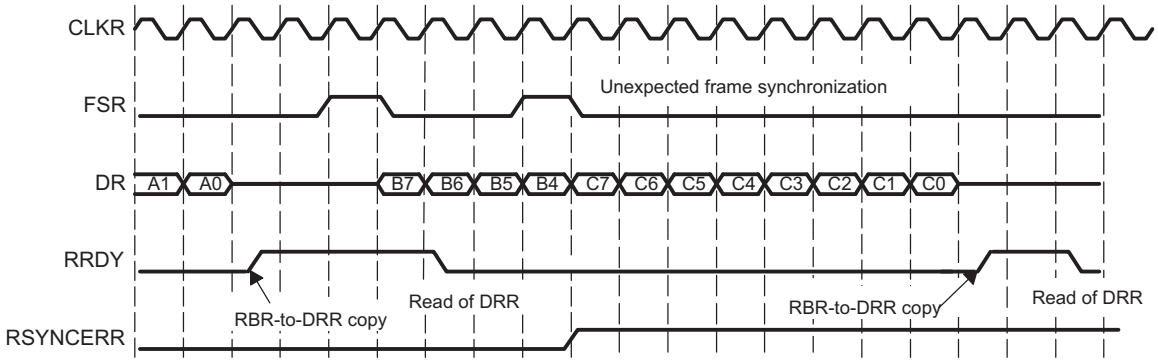
Using the legacy mode, RSYNCERR bit in SPCR1_REG can be cleared only by a receiver reset or by a write of 0 to this bit. If you want the McBSP to notify the CPU of receive frame–synchronization errors, you can set the legacy mode receive interrupt with the SPCR1_REG[5:4] register RINTM bits. When RINTM = 11b, the McBSP sends a receive interrupt (legacy mode RINT) request to the CPU each time that RSYNCERR is set.

15.2.3.2.2 Example of an Unexpected Receive Frame-Synchronization Pulse

Figure 15-15 shows an unexpected receive frame–synchronization pulse during normal operation of the serial port, with time intervals between data packets.

Note that the unexpected receive frame–synchronization pulse does not influence the data receive process, being ignored by the data receive state machine.

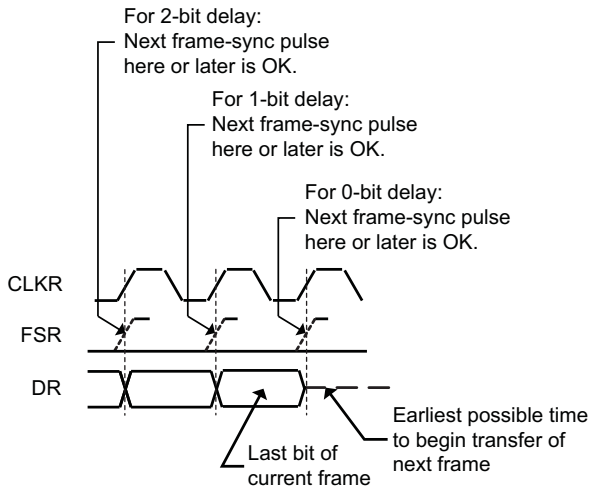
Figure 15-15. Unexpected Frame-Synchronization Pulse During a McBSP Reception



15.2.3.2.3 Preventing Unexpected Receive Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the RCR2_REG[1:0] RDATDLY bits. For each possible data delay, Figure 15-16 shows when a new frame–synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 15-16. Proper Positioning of Receive Frame-Synchronization Pulses



15.2.3.3 Underflow in the Receiver

The McBSP indicates a receiver underflow condition by setting the RUNDFLSTAT bit in IRQSTATUS register. This error occurs when DMA controller or CPU reads data from an empty receive buffer (this may happen only if the CPU or DMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before reading data. According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

15.2.3.4 Underflow in the Transmitter

The McBSP indicates a transmitter empty (or underflow) condition by setting the XUNDFLSTAT bit in IRQSTATUS register. Also the legacy mode XEMPTY bit in SPCR2_REG[2] register is cleared. Either of the following events activates XEMPTY (XEMPTY = 0):

- DXR_REG has not been loaded and transmit buffer is empty, and all bits of the data word in the XSR have been shifted out on the McBSP.DX pin.
- The transmitter is reset (by forcing XRST = 0 in SPCR2_REG[0] register, or by an Global reset) and is then restarted.

XEMPTY is deactivated (XEMPTY = 1) when a new word in DXR_REG is transferred to XB. If FSXM = 1 in PCR_REG[11] and FSGM = 0 in SRGR2_REG[12], the transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty. When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame–synchronization pulse before sending out the next frame on McBSP.DX.

When the transmitter is taken out of reset (XRST = 1), it is in a transmitter ready state (SPCR2_REG[1] register XRDY bit = 1) and transmitter empty (XEMPTY = 0) state. If DXR_REG is loaded by the CPU or the DMA controller before internal FSX goes active high, a valid XB–to–XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame–synchronization pulse is generated or detected. Alternatively, if a transmit frame–synchronization pulse is detected before DXR_REG is loaded, zeros are output on McBSP.DX.

The XUNDFLSTAT in IRQSTATUS register indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

15.2.3.5 Unexpected Transmit Frame-Synchronization Pulse

15.2.3.5.1 Possible Responses to Transmit Frame-Synchronization Pulses

If a frame–synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame–synchronization pulse, and the transmitter sets the transmit frame–synchronization error bit XSYNCERR in IRQSTATUS (and the legacy XSYNCERR bit in SPCR2_REG[3]) register.

According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

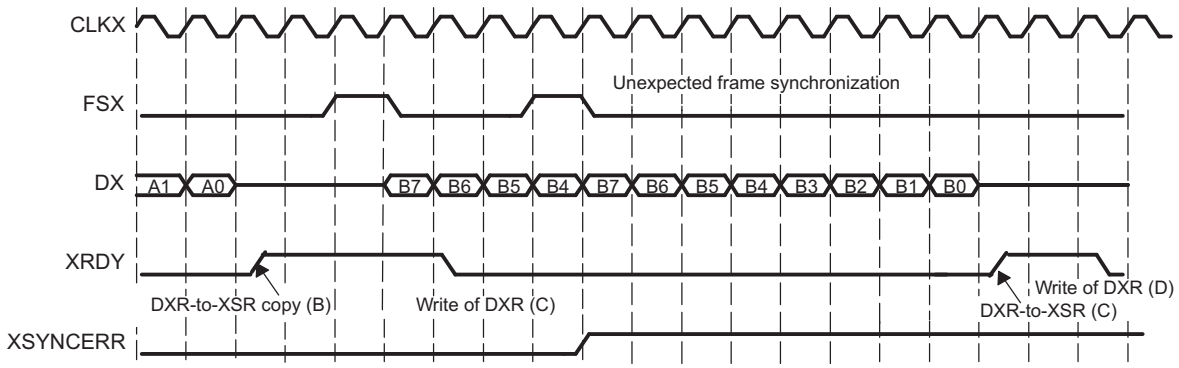
Using the legacy mode, XSYNCERR bit in SPCR2_REG can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP to notify the CPU of frame–synchronization errors, you can set a special transmit interrupt mode with the SPCR2_REG[5:4] register XINTM bits. When XINTM = 11b, the McBSP sends a transmit interrupt (XINT) request to the CPU each time that XSYNCERR is set.

15.2.3.5.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 15-17 shows an unexpected transmit frame–synchronization pulse during normal operation of the serial port with intervals between the data packets.

Note that the unexpected transmit frame–synchronization pulse does not influence the data transmit process, being ignored by the data transmit state machine.

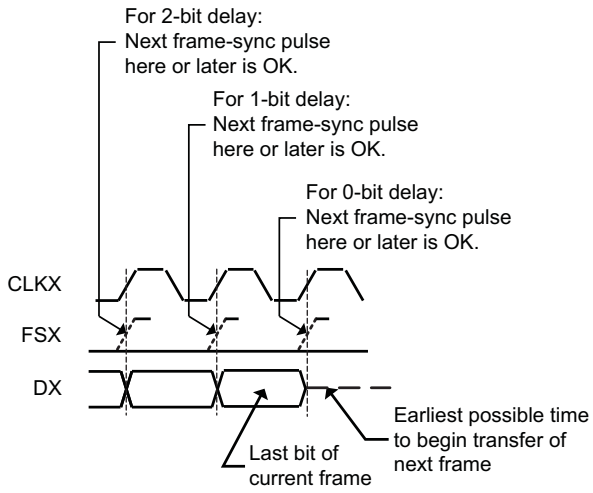
Figure 15-17. Unexpected Frame-Synchronization Pulse During a McBSP Transmission



15.2.3.5.3 Preventing Unexpected Transmit Frame-Synchronization Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the XCR2_REG[1:0] register XDATDLY bits. For each possible data delay, Figure 15-18 shows when a new frame–synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 15-18. Proper Positioning of Transmit Frame-Synchronization Pulses



15.2.3.6 Overflow in the Transmitter

The McBSP indicates a transmitter overflow condition by setting the XOVFLSTAT bit in IRQSTATUS[11] register. This error occurs when DMA controller or CPU write data to a full transmit buffer (this may happen only if the CPU or DMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data. According to the IRQENABLE register settings this condition can generate the COMMONIRQ line to be asserted low. Writing 1 to the corresponding bit in status register will clear the interrupt.

15.2.4 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive RRST and transmit XRST are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting zero the RDMAEN, XDMAEN bits in RCCR_REG respectively XCCR_REG. When disabling the DMA the DMA request line is deasserted even if a DMA transfer is pending and the DMA state machine is not reset.

The DMA threshold and length configuration is done through THRSH1_REG and THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the THRSH1_REG value plus one, the DMA request will be asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request (McBSP.REVNT) will be deasserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the THRSH2_REG value plus one the DMA request will be asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request (McBSP.XEVNT) will be deasserted and reasserted as soon as the conditions are met again.

Note that the CPU may decide not to use the DMA to transfer the data. In this case the DMA must be disabled (or the DMA request can be ignored by CPU) and the common interrupt line can be used. The RRDY bit for receive and XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status RBUFFSTAT_REG register and transmit buffer status XBUFFSTAT_REG register the CPU may decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the CPU needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the receive buffer status register value and to transfer the remaining data without using the DMA or interrupt indication.

15.2.5 Multichannel Selection Modes

15.2.5.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into 8 blocks that each contains 16 contiguous channels:

Table 15-3. Channels, Block, Partitions

Block 0: Channels 0–15	Block 4: Channels 64–79
Block 1: Channels 16–31	Block 5: Channels 80–95
Block 2: Channels 32–47	Block 6: Channels 96–111
Block 3: Channels 48–63	Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the 2–partition mode, you assign one even–numbered block (0, 2, 4, or 6) to partition A and one odd–numbered block (1, 3, 5, or 7) to partition B. In the 8–partition mode, blocks 0 through 7 are automatically assigned to partitions, A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

15.2.5.2 Multichannel Selection

When a McBSP uses a time–division multiplexed (TDM) data stream while communicating with other McBSPs or serial devices, the McBSP may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP has one receive multichannel selection mode and three transmit multichannel selection modes.

15.2.5.3 Configuring a Frame for Multichannel Selection

Before you enable a multichannel selection mode, make sure you properly configure the data frame:

- Select a single–phase frame (RCR2_REG[15] register RPHASE bit and XCR2_REG[15] register XPHASE bit = 0). Each frame represents a TDM data stream.
- Set a frame length (in RCR1_REG[14:8] register RFRLEN1 bit field and in XCR1_REG[14:8] register XFRLEN1 bit field) that includes the highest–numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If XFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

15.2.5.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions. If you choose the 8–partition mode (RMCME = 1 for reception, XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame–synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame–synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8–partition mode, the (R/X)PABLK and (R/X)PBBLK bits are ignored and the 16–channel blocks are assigned to the partitions as shown in the following tables. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Figure 15-19 shows an example of the McBSP using the 8–partition mode. In response to a frame–synchronization pulse, the McBSP begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128–word frame.

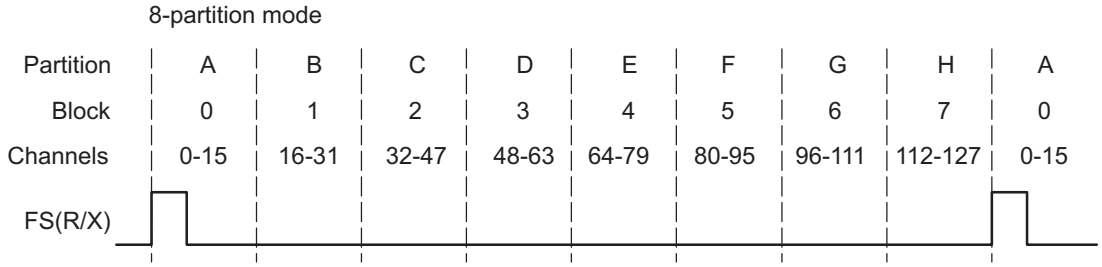
Table 15-4. Eight Partitions – Receive Channel Assignment and Control

Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	RCERA_REG
B	Block 1: channels 16 through 31	RCERB_REG
C	Block 2: channels 32 through 47	RCERC_REG
D	Block 3: channels 48 through 63	RCERD_REG
E	Block 4: channels 64 through 79	RCERE_REG
F	Block 5: channels 80 through 95	RCERF_REG
G	Block 6: channels 96 through 111	RCERG_REG
H	Block 7: channels 112 through 127	RCERH_REG

Table 15-5. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: channels 0 through 15	XCERA_REG
B	Block 1: channels 16 through 31	XCERB_REG
C	Block 2: channels 32 through 47	XCERC_REG
D	Block 3: channels 48 through 63	XCERD_REG
E	Block 4: channels 64 through 79	XCERE_REG
F	Block 5: channels 80 through 95	XCERF_REG
G	Block 6: channels 96 through 111	XCERG_REG
H	Block 7: channels 112 through 127	XCERH_REG

Figure 15-19. McBSP Data Transfer in the 8-Partition Mode



15.2.5.5 Receive Multichannel Selection Mode

The MCR1_REG[0] register RMCM bit determines whether all channels or only selected channels are enabled for reception. When RMCM = 0, all 128 receive channels are enabled and cannot be disabled. When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:

- Channels can be individually enabled or disabled. The only channels enabled are those selected in the appropriate receive channel enable registers (RCER[A,H]_REG). The way channels are assigned to the RCER[A,H]_REG registers depends on the number of receive channel partitions (two or eight), as defined by the MCR1_REG[9] register RMCME bit.
- If a receive channel is disabled, any bits received in that channel are not transferred to the receive buffer (RB), and as a result, does not set the receiver ready bit (RRDY). Therefore, no DMA synchronization event (REVT) is generated and, if the receiver interrupt mode depends on RRDY (RINTM = 00b), no interrupt is generated.

As an example of how the McBSP behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP:

- Accepts bits shifted in from the McBSP.DR pin in channel 0
- Ignores bits received in channels 1–14
- Accepts bits shifted in from the McBSP.DR pin in channel 15
- Ignores bits received in channels 16–38
- Accepts bits shifted in from the McBSP.DR pin in channel 39

15.2.5.6 Using Two Partitions (legacy only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2–partition mode (RMCME = 0 for reception, XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame–synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame–synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

15.2.5.6.1 Assigning Blocks to Partitions A and B

For reception, any two of the eight receive–channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point in time. Similarly, any two of the eight transmit–channel blocks (up 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

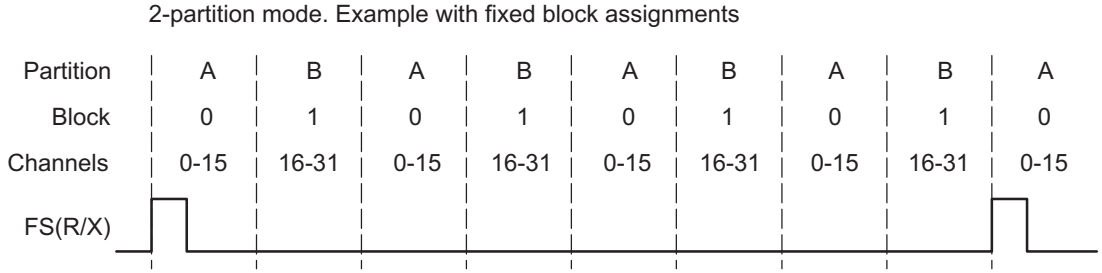
- Assign an even–numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the RPABLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (RCERA_REG).
- Assign an odd–numbered block (1, 3, 5, or 7) to receive partition B with the RPBBLK bits. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (RCERB_REG).

For transmission:

- Assign an even–numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the XPABLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (XCERA_REG).
- Assign an odd–numbered block (1, 3, 5, or 7) to transmit partition B with the XPBBLK bits. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (XCERB_REG).

Figure 15-20 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame–synchronization pulse, the McBSP begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 15-20. Alternating Between Partitions A and B Channels



15.2.5.7 Transmit Multichannel Selection Modes

The MCR2_REG[1:0] register XMCM bits determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP has three transmit multichannel selection modes (XMCM = 01b, XMCM = 10b, and XMCM = 11b), which are described in Table 15-6.

As an example of how the McBSP behaves in a transmit multichannel selection mode, suppose that XMCM = 01b (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP:

- Shifts data to the McBSP.DX pin in channel 0
- Places the McBSP.DX pin in the high impedance state in channels 1–14
- Shifts data to the McBSP.DX pin in channel 15
- Places the McBSP.DX pin in the high impedance state in channels 16–38
- Shifts data to the McBSP.DX pin in channel 39

Table 15-6. Selecting a Transmit Multichannel Selection Mode with the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
00b	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
01b	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (XCER[A,H]_REG). If enabled, a channel in this mode is also unmasked.
	The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in the XCER[A,H]_REG registers.
10b	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (XCER[A,H]_REG).
	The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in the XCER[A,H]_REG registers.
11b	This mode is used for symmetric transmission and reception.
	All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (RCER[A,H]_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (XCER[A,H]_REG).
	The MCR2_REG[9] register XMCME bit determines whether 32 channels or 128 channels are selectable in RCER[A,H]_REG registers and XCER[A,H]_REG registers.

15.2.5.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

Table 15-7. McBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (DXR_REG) to the transmit shift register (XSR) through XB.
Masked channel	A channel that cannot complete transmission. The McBSP.DX pin is held in the high impedance state; data cannot be shifted out on the McBSP.DX pin.
	In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked.
	Because no DXR–to–XB copy occurs, the SPCR2_REG[1] register XRDY bit is not set. Therefore, no DMA synchronization event (XEVT) is generated, and if the transmit interrupt mode depends on XRDY (XINTM = 00b in SPCR2_REG[5:4]), no interrupt is generated.
	The SPCR2_REG[2] register XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the McBSP.DX pin.

15.2.5.7.2 Activity on McBSP Pins for Different Values of XMCM Bit

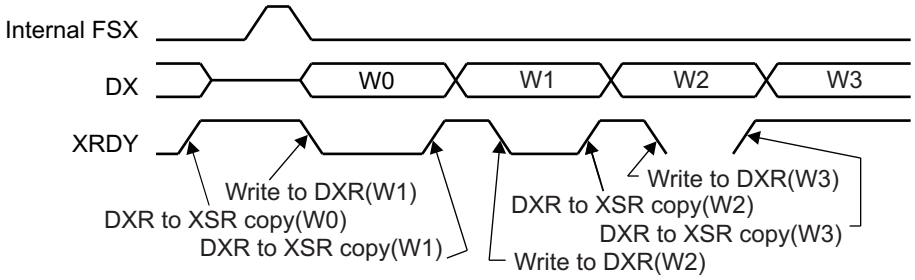
Figure 15-21 shows the activity on the McBSP pins for the various XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single–phase frame (required for multichannel selection modes)
- XFRLEN1 = 0000011b: 4 words per frame
- XWDLEN1 = 000b: 8 bits per word
- XMCME = 0: 2–partition mode (only partitions A and B used)

In the case where XMCM = 11b, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively. In Figure 15-21, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

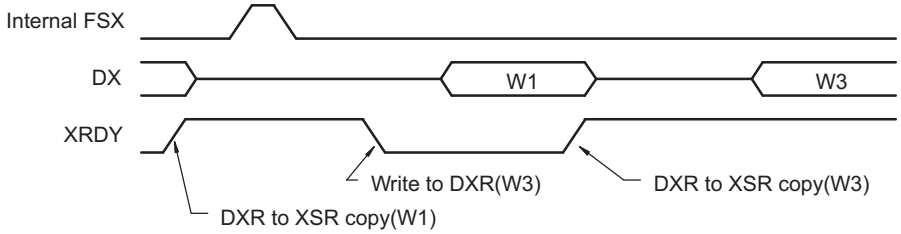
Figure 15-21. Activity on McBSP Pins for the Possible Values of XMCM Bit

(a) XMCM = 00b: All channels enabled and unmasked.



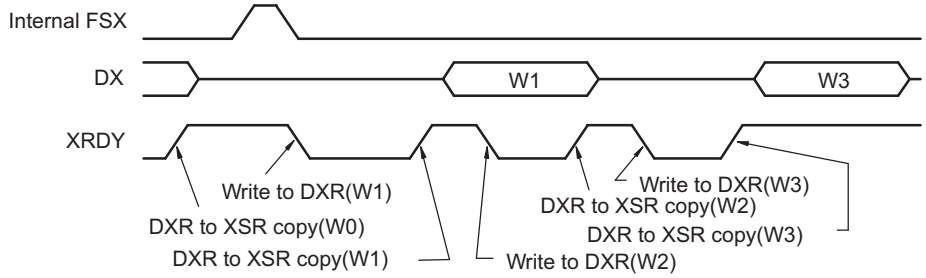
Words W0, W1, W2, W3 are written to the transmit buffer and W0, W1, W2, W3 from the transmit buffer are transferred by McBSP.DX

(b) XMCM = 01b, XPABLK = 00b, XCERA = 1010b: Only channels 1 and 3 enabled and unmasked



Words W1, W3 are written to the transmit buffer and W1, W3 from the transmit buffer are transferred by McBSP.DX

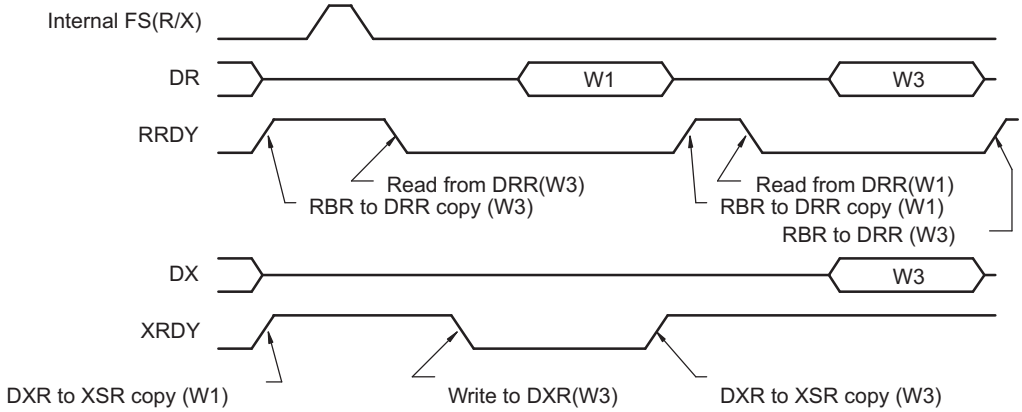
(c) XMCM = 10b, XPABLK = 00b, XCERA = 1010b: All channels enabled, only 1 and 3 unmasked



Words W0, W1, W2, W3 are written to the transmit buffer but only W1 and W3 from the transmit buffer are transferred by McBSP.DX

(d) XMCM = 11b, RPABLK = 00b, XPABLK = X, RCERA = 1010b, XCERA = 1000b

Receive channels: 1 and 3 enabled; Transmit channels: 1 and 3 enabled, but only 3 unmasked



Words W1, W3 are written to the transmit buffer but only W3 from the transmit buffer is transferred by McBSP.DX

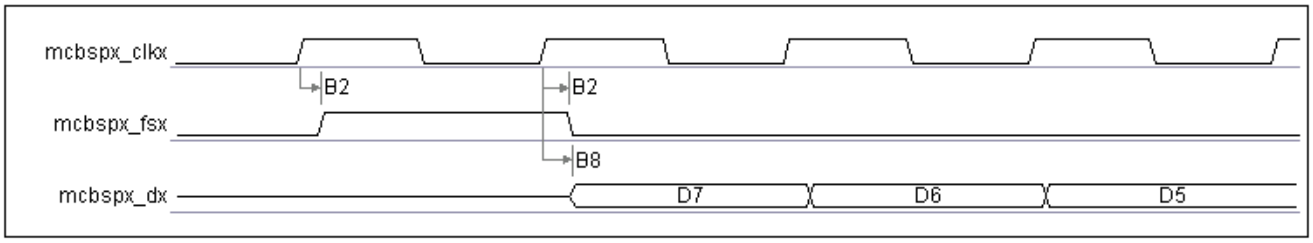
15.2.6 McBSP Full/Half Cycle Modes

The following figures are for data delay set to 1.

15.2.6.1 Transmit Full Cycle Mode

When configured in full cycle mode (XCCR[11] register, XFULL_CYCLE bit field), the FSX is sampled on the configured CLKX edge and the data is driven on the same configured edge:

Figure 15-22. Transmit Full Cycle Mode

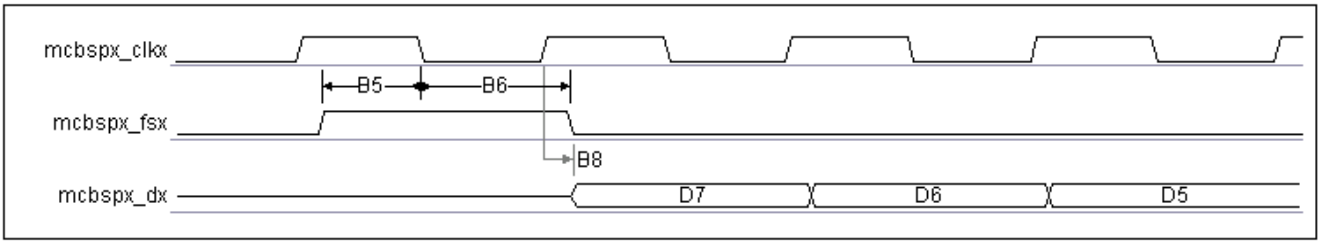


Data driven on positive CLKX edge, FSX sampled on positive CLKX edge.

15.2.6.2 Transmit Half Cycle Mode

When configured in half cycle mode (XCCR[11] register, XFULL_CYCLE bit field), the FSX is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge:

Figure 15-23. Transmit Half Cycle Mode

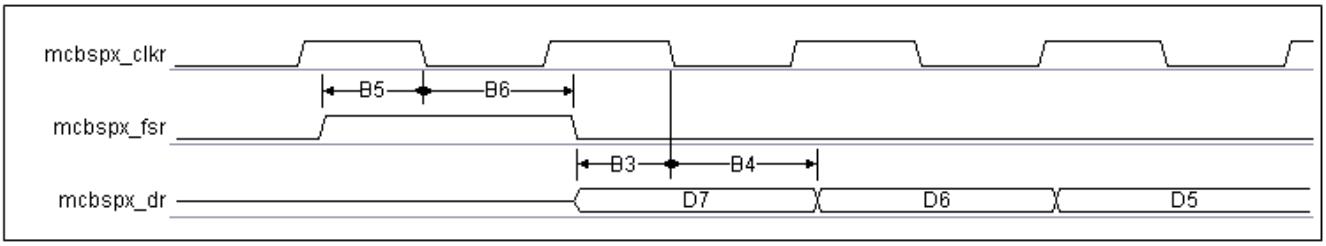


Data driven on positive CLKX edge, FSX sampled on negative CLKX edge.

15.2.6.3 Receive Full Cycle Mode

When configured in full cycle mode (RCCR[11] register, RFULL_CYCLE bit field), the FSR is sampled on the configured CLKR edge and the data is sampled on the same configured edge:

Figure 15-24. Receive Full Cycle Mode

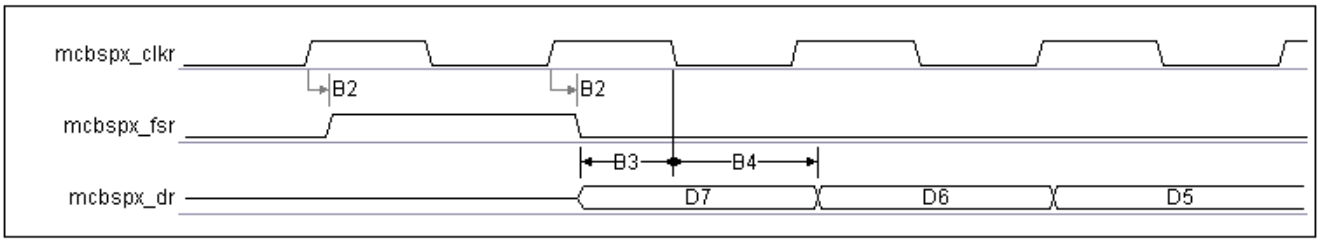


Data sampled on negative CLKR edge, FSR sampled on negative CLKR edge.

15.2.6.4 Receive Half Cycle Mode

When configured in half cycle mode (RCCR[11] register, RFULL_CYCLE bit field), the FSR is sampled on the opposite configured CLKR edge and the data is sampled on the next configured edge:

Figure 15-25. Receive Half Cycle Mode



Data sampled on negative CLKR edge, FSR sampled on positive CLKR edge.

15.2.7 Power Management

15.2.7.1 ForceIdle Behavior

When configured in ForceIdle the module should respond immediately (according to the OCP guideline description) to a McBSP.MIDLEREQ, regardless of the internal state of the module. Entering in this mode, the module will freeze all the internal activity when the clocks are switched off by the power management external module. If the functional part, transmit or receive, is running within this period of time, the internal state of the module will not be idle (FSM states, processes, etc.), and when the module exits from the ForceIdle state unexpected behavior may happen in both receiver and transmitter. In order to avoid this both receive and transmit parts need to be disabled by software prior to MIdleReq assertion.

15.2.7.2 SmartIdle Behavior

When configured in SmartIdle, the sources for wake-up generation are a subset of the interrupt sources. The wakeup sources are enabled by setting the corresponding bit in WAKEUPEN register.

For receive WAKEUP there are 4 possible configuration scenarios:

- **RRDYEN** - The McBSP asserts the McBSP.WAKEUP request when the RB reaches the high threshold (THRSH1_REG + 1) register value. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the RRDY bit changes from 0 to 1, indicating that receive data is ready to be read).
- **REOFEN** - The McBSP asserts the McBSP.WAKEUP request at the end of the frame. If the corresponding bit is set in IRQENABLE register McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exit from idle mode.
- **RSYNCERREN** - The McBSP asserts the McBSP.WAKEUP request when an unexpected receive frame-synchronization pulse is detected. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request o the CPU when exiting from idle mode (interrupt will be asserted once the RSYNCERR bit changes from 0 to 1, indicating that a receive error occurred).

For transmit WAKEUP there are four possible configuration scenarios:

- **XRDYEN** - The McBSP asserts the McBSP.WAKEUP request when the XB reaches the high threshold (THRSH2_REG + 1) register value. If the corresponding bit is set in IRQENABLE register, McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- **XEOFEN** - The McBSP asserts the McBSP.WAKEUP request at the end of the frame. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode.
- **XFSXEN** - The McBSP sends a McBSP.WAKEUP request when a transmit frame-synchronization pulse is detected while the module is in idle mode. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode.
- **XSYNCERREN** - The McBSP asserts the McBSP.WAKEUP request when an unexpected transmit frame-synchronization pulse is detected. If the corresponding bit is set in IRQENABLE register, the McBSP sends an interrupt (McBSP.COMMONIRQ) request to the CPU when exiting from idle mode (interrupt will be asserted once the XSYNCERR bit changes from 0 to 1, indicating that a transmit error occurred).

15.2.7.2.1 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is depicted in Table 15-8.

Table 15-8. Analysis of the Receiver Smart Idle Behavior

CLKRM	CLKXM	Behavior
0	0	McBSP is configured as a slave, (functional clocks are provided from outside). The module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	McBSP is configured as a transmit master (the source clock can be CLKS, CLKR or OCP). When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless: • the transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (ALBCTRLRX[0] pin is asserted). • both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The SmartIdle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable. When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached). When CLKR is used as source (functional clock is provided from outside) then the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	McBSP is configured as a receive master (the source clock can be CLKS, CLKX or OCP). When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless: • the receive part is disabled (RDISABLE) or under software reset (RRST). The acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable. When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached). When CLKX is used as source (functional clock is provided from outside) then the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Table 15-8. Analysis of the Receiver Smart Idle Behavior (continued)

CLKRM	CLKXM	Behavior
1	1	McBSP is configured as transmit and receive master (the source clock can be CLKS or OCP). When OCP clock is used as source clock and CLOCKACTIVITY is indicating that the OCP clock will be switched off, or CLKS clock is used as source clock and CLOCKACTIVITY is indicating that the functional clock is switched off, the McBSP will not acknowledge the SmartIdle request unless: • both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The SmartIdle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames where completed in case of transmit and/or receive disable. Note that no wakeup event will be available in this mode since the entire McBSP and remote device activity will be frozen. When OCP or CLKS is used as source clock and the CLOCKACTIVITY indicates that the corresponding clock will not be switched off, the module will acknowledge the SmartIdle mode request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).

Notes:

- The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (functional and OCP) are switched off and McBSP.FSR/McBSP.FSX is configured as input. The frame synchronization-pulse is asynchronously detected during idle.
- The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP only by a remote module implementing such a feature, to use this type of error in order to trigger a wake-up. This mode requires functional clock to be active.
- When McBSP.FSR/McBSP.FSX is configured as an output, the McBSP.FSR/ McBSP.FSX wake-up generation makes no sense (the module cannot be in SmartIdle mode).
- Detection of RSYNCERR/XSYNCERR during idle mode can be used only when McBSP.FSR/ McBSP.FSX is configured as an input and the remote system knows to assert such an error in order to trigger the wake-up of the McBSP.
- The module does not implement IRQ assertion when configured as GPIO; also a wake-up capability in this mode is not available.

15.2.8 Programming Model

15.2.8.1 McBSP Initialization Procedure

The serial port initialization procedure is as follows:

1. Clear SPCR1_REG[0] register RRST bit, SPCR2_REG[7] register FRST bit, and SPCR2_REG[0] register XRST bit to 0. If coming out of a global reset, this step is not required.
2. While the serial port is in the reset state, program only the McBSP configuration registers (not the data registers) as required.
3. Wait for two clock cycles. This ensures proper internal synchronization
4. Set SPCR1_REG[0] register RRST bit and SPCR2_REG[0] register XRST bit to 1 to enable the serial port. Make sure that as you set these reset bits, you do not modify any of the other bits in SPCR1_REG and SPCR2_REG registers. Otherwise, you would change the configuration set in step 2.
5. Set up data acquisition as required (such as writing to DXR_REG register).
6. Set SPCR2_REG[7] register FRST bit to 1 if internally generated frame synchronization is required.
7. Wait for two clock cycles for the receiver and transmitter to become active.

Alternatively, on write (step 1 or 5), the transmitter and receiver can be placed in or taken out of reset by modifying the desired bit.

The previous procedure for reset/initialization can be applied in general when the receiver or transmitter has to be reset during its normal operation, and also when the sample rate generator is not used for either operation.

Notes:

- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (SPCR1_REG, PCR_REG, RCR1_REG, RCR2_REG, XCR1_REG, XCR2_REG, SRGR1_REG and SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (DXR_REG) should be loaded by the CPU or the DMA controller only when the transmitter is enabled (XRST = 1). An exception to this rule is when these registers are used for loop back internal data.
- The bits of the channel control registers (MCR1_REG, MCR2_REG, RCER{A-H}_REG and XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode
- The sample rate generator is reset by clearing SPCR2_REG[6] register GRST bit to 0.

15.2.8.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the sample rate generator:

1. Place the McBSP/sample rate generator in reset. During a Global reset, the sample rate generator, the receiver, and the transmitter reset bits (GRST, RRST, and XRST) are automatically forced to 0. Otherwise, during normal operation, the sample rate generator can be reset by making GRST = 0 in SPCR2_REG[6] register, provided that CLKG and/or FSG is not used by any portion of the McBSP. Depending on your system you may also want to reset the receiver (RRST = 0 in SPCR1_REG[0]) and reset the transmitter (SPCR2_REG[0] register XRST bit = 0).
2. Program the registers that affect the sample rate generator. Program the sample rate generator registers (SPCR1_REG and SPCR2_REG) as required for your application. If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP (the receiver or transmitter) is in reset. After the sample rate generator registers are programmed, wait 2 CLKSRG cycles. This ensures proper synchronization internally.
3. Enable the sample rate generator (take it out of reset). In SPCR2_REG[6], set GRST bit to 1 to enable the sample rate generator. After the sample rate generator is enabled, wait two CLKG cycles for the sample rate generator logic to stabilize. On the next rising edge of CLKSRG, CLKG transitions to 1 and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1) where the input clock is selected with the SCLKME bit of PCR_REG[7] register and the SRGR2_REG[13] register CLKSM bit in one of the following configurations:

Table 15-9. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on McBSP.CLKS pin
0	1	McBSP_FCLK clock
1	0	Signal on McBSP.CLKR pin
1	1	Signal on McBSP.CLKX pin

4. If necessary, enable the receiver and/or the transmitter. If necessary, remove the receiver and/or transmitter from reset by setting RRST and/or XRST = 1.
5. Necessary, enable the frame–synchronization logic of the sample rate generator. After the required data acquisition setup is done (DXR_REG is loaded with data), set GRST = 1 in SPCR2_REG[6] if an internally generated frame–synchronization pulse is required. FSG is generated with an active–high edge after the programmed number of CLKG clocks (FPER + 1) has elapsed.

15.2.8.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests, perform the following procedure:

1. Write the receive THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG + 1 number of words, the receive DMA request (McBSP.REVNT) will be deasserted and reasserted as soon as the conditions are met again.
   Note that in case of a number of transfers that exceed the number of the programmed DMA length the McBSP will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by RUNDFL_EN bit in IRQENSTAT_REG register.
2. Write the transmit THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG + 1 number of words, the transmit DMA request (McBSP.XEVNT) will be deasserted and reasserted as soon as the conditions are met again.
   Note that in case of a number of transfers that exceed the number of the programmed DMA length the McBSP will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by XOVFL_EN bit in IRQENSTAT_REG register

15.2.8.4 Interrupt Configuration

The McBSP offers two interrupt schemes:

- OCP compliant interrupt request scheme using a common receive/transmit interrupt request line.
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the receive overflow interrupt line.

The OCP compliant interrupt line can be configured by using the IRQENABLE register. When the IRQSTATUS bit is set and the corresponding IRQENABLE bit is set to 1, the interrupt line is asserted. Writing one to a bit in IRQSTATUS register will clear the bit.

There are several conditions, which may be configured to generate an interrupt as follows:

- Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded).
- Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted).
- Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the (THRSH2_REG + 1) value).
- Transmit End of Frame (XEOF is set to 1 when a complete frame was transmitted).
- Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted).
- Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected).
- Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded).
- Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
- Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the (THRSH1_REG + 1) value).
- Receive End of Frame (REOF is set to 1 when a complete frame was received).
- Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted).
- Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected).

15.2.8.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP/receiver in reset.
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

15.2.8.5.1 Programming the McBSP Registers for the Desired Receiver Configuration

The following is a list of important tasks to be performed when you are configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields. Note that SRG is Sample Rate Generator.

Global Behavior

1. Set the receiver pins to operate as McBSP pins.
2. Enable/disable the digital loop back mode.
3. Enable/disable the analog loop back mode.
4. Enable/disable the synchronous transmit-receive mode.
5. Enable/disable the receive multichannel selection mode.

Data behavior:

1. Choose 1 or 2 phases for the receive frame.
2. Set the receive word length(s).
3. Set the receive frame length (one word per phase if dual-phase selected).
4. Enable/disable the receive frame–synchronization ignore function.
5. Set the receive data delay.
6. Set the receive sign–extension and justification mode.
7. Set the receive interrupt mode.

Frame–synchronization behavior:

1. Set the receive frame–synchronization mode.
2. Set the receive frame–synchronization polarity.
3. Set the sample rate generator (SRG) frame–synchronization period and pulse width.

Clock behavior:

1. Set the receive clock mode.
2. Set the receive clock polarity.
3. Set the SRG clock divide–down value.
4. Set the SRG clock synchronization mode.
5. Set the SRG clock mode (choose an input clock).
6. Set the SRG input clock polarity.

15.2.8.5.2 Resetting and Enabling the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following two ways:

- A global reset places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST, FRST, RRST and XRST bits = 0, keeping the entire serial port in the reset state.
- The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the SPCR1_REG register. The sample rate generator can be reset directly using the GRST bit in SPCR2_REG[6] register.

15.2.8.5.3 Set the Receiver Pins to Operate as McBSP Pins

The RIOEN bit (PCR_REG[12]) determines whether the receiver pins are McBSP pins or general–purpose I/O pins.

Refer to Section 15.2.8.7 for further information.

15.2.8.5.4 Enable/Disable the Synchronous Transmit-Receive Mode

The ALBCTRLRX input pin is used to configure the synchronous transmit-receive mode. The ALBCTRLRX[0/1] input pin selection is determined by programming the Control Module AUD_CTRL Register.

The ALBCTRLRX [0] controls the multiplexer which connects the functional receive input clock (CLKR is connected to the CLKX input pin CLKXI when ALBCTRLRX[0] = 1).

The ALBCTRLRX[1] controls the multiplexer which connects the receive frame synchronization (FSR is connected to the FSX input pin FSXI when ALBCTRLRX[1] = 1).

15.2.8.5.5 Enable/Disable the Analog Loop Back Mode

The ALB bit (SPCR1_REG[15]) determines whether the analog loop-back mode is on or off.

In the analog loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals (DR is connected to transmit loop back data on DXI pin, FSR is connected to FRX input pin FSXI, and CLKR is connected to the CLKX input pin CLKXI). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is done through pads testing also the IO buffers.

15.2.8.5.6 Enable/Disable the Digital Loop Back Mode

The DLB bit (XCCR_REG) determines whether the digital loop-back mode is on or off. In the digital loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals (DR is connected to transmit data on DX output pin DXO, FSR is connected to FRX output pin FSXO, and CLKR is connected to the CLKX output pin CLKXO). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is not done through pads, all output signals being disabled (CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active).

Note that in digital loop back mode the sample rate generator and the frame synchronization generator need to be enabled in order to generate the CLKX and FSX signals.

15.2.8.5.7 Enable/Disable the Receive Multichannel Selection Mode

The RMCM bit (MCR1_REG[0]) determines whether the receive multichannel selection mode is on or off.

15.2.8.5.8 Choose 1 or 2 Phases for the Receive Frame

The RPHASE bit (RCR2_REG[15]) determines whether the receive data frame has one or two phases. When dual-phase is selected the number of words per phase must be set to 1.

15.2.8.5.9 Set the Receive Word Length(s)

The RWDLEN1 (RCR1_REG[7:5]) and RWDLEN2 (RCR2_REG[7:5]) bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

Each frame can have one or two phases, depending on the value that you load into the RPHASE bit. If a single–phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual–phase frame is selected, RWDLEN1 and RWDLEN2 must be cleared to 0 (one word per phase).

15.2.8.5.10 Set the Receive Frame Length

The RFRLEN1 (RCR1_REG[14:8]) and RFRLEN2 (RCR2_REG[14:8]) bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

The receive frame length is the number of serial words in the receive frame. Each frame can have one or two phases, depending on value that you load into the RPHASE bit.

If a single–phase frame is selected (RPHASE = 0), the frame length is equal to the length of phase 1. If a dual–phase frame is selected (RPHASE = 1), the frame length is the length is two (one word for phase 1 plus the one word for phase 2).

The 7–bit RFRLEN1 field allow up to 128 words per phase when single-phase frame. See Table 15-10 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame–synchronization pulse.

Program the RFRLEN fields with [w minus 1], where w represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into RFRLEN1.

Table 15-10. How to Calculate the Length of the Receive Frame

RPHASE	RFRLEN1	RFRLEN2	Frame Length
0	0 <= RFRLEN1 <= 127	Don't care	(RFRLEN1 + 1) words
1	RFRLEN1 = 0	RFRLEN2 = 0	2 words

15.2.8.5.11 Set the Receive Reverse Mode

The RREVERSE bit field (RCR2_REG[4:3]) determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

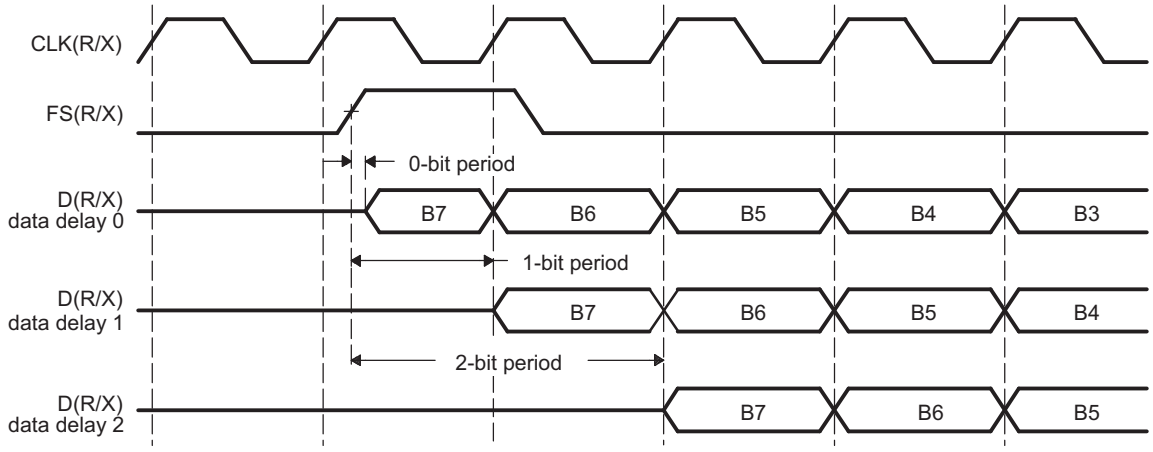
15.2.8.5.12 Set the Receive Data Delay

The RDATDLY bit field (RCR2_REG[1:0]) determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

RDATDLY specifies the data delay for reception. The range of programmable data delay is 0 to 2 bit–clocks (RDATDLY = 00b–10b), as shown in Figure 15-26. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on. Typically a 1–bit delay is selected, because data often follows a 1–cycle active frame–synchronization pulse.

Figure 15-26. Range of Programmable Data Delay



0-bit data delay:

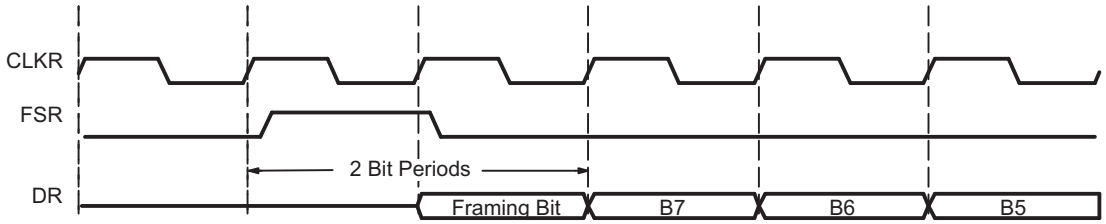
Normally, a frame–synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on McBSP.DX. The transmitter then asynchronously detects the frame–synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the McBSP.DX pin.

2-bit delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1–bit delay and data appears after a 2–bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 15-27. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on.

Figure 15-27. 2-Bit Data Delay Used to Skip a Framing Bit



15.2.8.5.13 Set the Receive Sign-Extension and Justification Mode

The RJUST bit field (SPCR1_REG[14:13]) determines whether data received by the McBSP is sign–extended or not and how it is justified.

RJUST bit field selects whether data in RB is right– or left–justified (with respect to the MSB) in DRR_REG register and whether unused bits in DRR_REG are filled with zeroes or with sign bits.

The following tables show the effects of various RJUST values. Table 15-11 shows the effect on an example 12–bit receive–data value ABCh, Table 15-12 shows the effect on an example 20–bit receive–data value ABCDEh.

Table 15-11. Example: Use of RJUST Bit Field with 12-Bit Data Value ABCh

RJUST	Justification	Extension	Value in DRR_REG
00b	Right	Zero fill MSBs	0000 0ABCh
01b	Right	Sign extend data into MSBs	FFFF FABCh
10b	Left	Zero fill LSBs	ABC0 0000h
11b	Reserved	Reserved	Reserved

Table 15-12. Example: Use of RJUST Bit Field with 20-Bit Data Value ABCDE

RJUST	Justification	Extension	Value in DRR_REG
00b	Right	Zero fill MSBs	000A BCDEh
01b	Right	Sign extend data into MSBs	FFFA BCDEh
10b	Left	Zero fill LSBs	ABCD E000h
11b	Reserved	Reserved	Reserved

15.2.8.5.14 Set the Receive Interrupt Mode (legacy only)

The RINTM bit field (SPCR1_REG[5:4]) determines which event generates a receive interrupt request to the CPU. The receive interrupt (RINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM = 00: RINT generated when the RRDY bit (SPCR1_REG[1]) changes from 0 to 1. Interrupt on every serial word by tracking the RRDY bit in the SPCR1_REG register. Regardless of the value of RINTM, RRDY can be read to detect the RRDY = 1 condition.
- RINTM = 01: RINT generated by an end–of–frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 10: RINT generated by a new receive frame–synchronization pulse. Interrupt on detection of receive frame–synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame–synchronization pulse to the CPU clock and sending it to the CPU via RINT.
- RINTM = 11: RINT generated when RSYNCERR is set. Interrupt on frame–synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see Section 15.2.3.2.

The McBSP provides also a common interrupt line McBSP.COMMONIRQ, which can be used by setting the IRQENABLE register. All the above settings have equivalent enable bits in the IRQENABLE register in order to enable the common interrupt line (RRDYEN is equivalent with RINTM = 00, REOFEN is equivalent with RINTM = 01 (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode), RFSREN is equivalent with RINTM = 10 and RSYNCERREN is equivalent with RINTM = 11 setting). This interrupt line has its own status register.

15.2.8.5.15 Set the Receive Frame-Synchronization Mode

FSRM bit (PCR_REG[10]), GSYNC bit (SRGR2_REG[15]), ALB bit (SPCR1_REG[15]) and DLB bit field (XCCR_REG) are used to determine the source for receive frame synchronization and the function of the McBSP.FSR pin.

Table 15-13 shows how you can select various sources to provide the receive frame–synchronization signal and the effect on the McBSP.FSR pin. The polarity of the signal on the McBSP.FSR pin is determined by the FSRP bit.

In digital loop-back mode (DLB = 1), the transmit frame–synchronization signal is used as the receive frame–synchronization signal.

Also in the analog loop back mode, the internal receive clock signal (CLKR), the internal receive frame–synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

Table 15-13. FSRM and GSYNC Effects on Frame-Synchronization Signal and McBSP.FSR Pin

FSRM	GSYNC	Source of Receive Frame Synchronization	McBSP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP through the McBSP.FSR pin. The signal is then inverted as determined by FSRP before being used as internal FSR.	Input
1	0	Internal FSR is driven by the sample rate generator frame–synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP before being driven out on the McBSP.FSR pin.
1	1	Internal FSR is driven by the sample rate generator frame–synchronization signal (FSG).	Input. The external frame–synchronization input on the McBSP.FSR pin is used to synchronize CLKG and generate FSG pulses.

15.2.8.5.16 Set the Receive Frame-Synchronization Polarity

The FSRP bit (PCR_REG[2]) determines whether frame–synchronization pulses are active high or active low on the McBSP.FSR pin.

Receive frame–synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[10] register FSRM mode bit. FSR is also affected by the SRGR2_REG[15] register GSYNC bit. For information about the effects of FSRM and GSYNC, see the Frame Synchronization Generation in the Sample Rate Generator section. Similarly, receive clocks can be selected to be inputs or outputs by programming the PCR_REG[8] register CLKRM mode bit (see the Clock Generation in the Sample Rate Generator section).

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX.

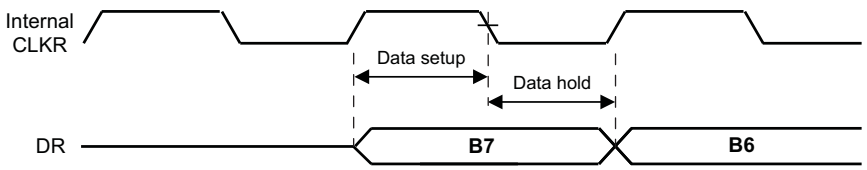
FSRP, FSXP, CLKRP, and CLKXP bits in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active–high frame–synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge. Figure 15-28 shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 15-28. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge



15.2.8.5.17 Set the SRG Frame-Synchronization Period and Pulse Width

FPER bit field (SRGR2_REG[11:0]) is used to set the SRG frame-synchronization period and FWID bit field (SRGR1_REG[15:8]) is used to set the SRG pulse width. The sample rate generator can produce a clock signal, CLKG, and a frame–synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame–synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame–synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

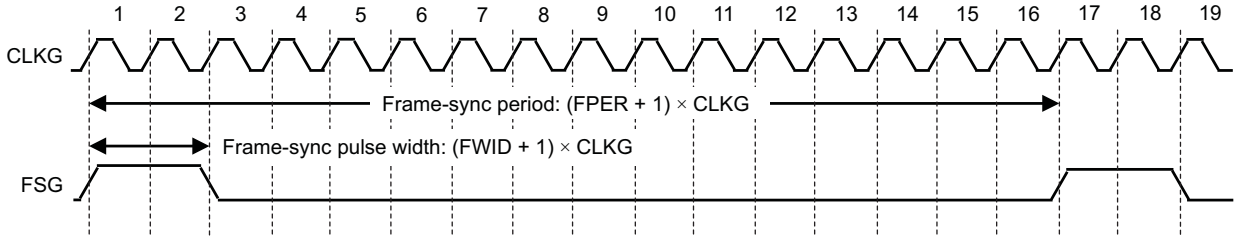
Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down–counters. The 12–bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8–bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 15-29 shows a frame–synchronization period of 16 CLKG periods (FPER = 15 or 0000 1111b) and a frame–synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame–synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

Figure 15-29. Frame of 16 CLKG Periods and Active Width of 2 CLKG Periods



15.2.8.5.18 Set the Receive Clock Mode

CLKRM bit (PCR_REG[8]), ALB bit (SPCR1_REG[15]) and DLB bit field (XCCR_REG) are used to set the receive clock mode.

Table 15-14 shows how you can select various sources to provide the receive clock signal and affect the McBSP.CLKR pin. The CLKRP bit determines the polarity of the signal on the McBSP.CLKR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal.

Table 15-14. CLKRM Effect on Receive Clock Signal and McBSP.CLKR Pin

CLKRM	Source of Receive Clock	McBSP.CLKR Pin Status
0	The McBSP.CLKR pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP before being used.	Input
1	The sample rate generator clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the McBSP.CLKR pin.

15.2.8.5.19 Set the Receive Clock Polarity

CLKRP bit (PCR_REG[0]) is used to set the receive clock polarity.

Receive frame–synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[10] register FSRM mode bit. FSR is also affected by the GSYNC bit in SRGR2_REG[15]. Similarly, receive clocks can be selected to be inputs or outputs by programming the PCR_REG[8] register CLKRM mode bit.

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX. FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active–high frame–synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

15.2.8.5.20 Set the SRG Clock Divide-Down Value

CLKGDV bit field (SRGR1_REG[7:0]) is used to set the sample rate generator clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV + 1) of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

15.2.8.5.21 Set the SRG Clock Synchronization Mode

GSYNC bit (SRGR2_REG[15]) is used to set the SRG clock synchronization mode.

15.2.8.5.22 Set the SRG Clock Mode (choose an input clock)

SCLKME bit (PCR_REG[7]) and CLKSM bit (SRGR2_REG[13]) are used to set the SRG clock mode.

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

15.2.8.5.23 Set the SRG Input Clock Polarity

CLKSP bit (SRGR2_REG[14]), CLKXP bit (PCR_REG[1]) and CLKRP bit (PCR_REG[0]) are used to set the SRG input clock polarity.

The sample rate generator can produce a clock signal (CLKG) and a frame–synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the McBSP.CLKS pin, CLKXP for the McBSP.CLKX pin, CLKRP for the McBSP.CLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

15.2.8.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter
3. Take the transmitter out of reset

These three steps are detailed in the following subsections.

15.2.8.6.1 Programming the McBSP Registers for the Desired Transmitter Operation

The following is a list of important tasks to be performed when you are configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Global behavior:

1. Set the transmitter pins to operate as McBSP pins.
2. Enable/disable the digital loop back mode.
3. Enable/disable the analog loop back mode.
4. Enable/disable the synchronous transmit-receive mode.
5. Enable/disable transmit multichannel selection.

Data behavior:

1. Choose 1 or 2 phases for the transmit frame.
2. Set the transmit word length(s).
3. Set the transmit frame length (one word per phase if dual-phase selected).
4. Enable/disable the transmit frame–synchronization ignore function.
5. Set the transmit data delay.
6. Set the transmit DXENA mode.
7. Set the transmit interrupt mode.

Frame-synchronization behavior:

1. Set the transmit frame–synchronization mode.
2. Set the transmit frame–synchronization polarity.
3. Set the SRG frame–synchronization period and pulse width.

Clock behavior:

1. Set the transmit clock mode.
2. Set the transmit clock polarity.
3. Set the SRG clock divide–down value.
4. Set the SRG clock synchronization mode.
5. Set the SRG clock mode (choose an input clock).
6. Set the SRG input clock polarity.

15.2.8.6.2 Resetting and Enabling the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset). The serial port can be reset in the following two ways:

1. A global reset places the receiver, transmitter, and sample rate generator in reset. When the device reset is removed, GRST, FRST, RRST and XRST bits = 0, keeping the entire serial port in the reset state.
2. The serial port transmitter and receiver can be reset directly using the RRST and XRST bits in the SPCR1_REG register. The sample rate generator can be reset directly using the GRST bit in SPCR2_REG register.

15.2.8.6.3 Set the Transmitter Pins to Operate as McBSP Pins

The XIOEN bit (PCR_REG[13]) determines whether the transmitter pins are McBSP pins or general–purpose I/O pins.

Refer to Section 15.2.8.7 for further information.

15.2.8.6.4 Enable/Disable the Digital Loop Back Mode

The DLB bit (XCCR_REG) determines whether the digital loop-back mode is on or off. In the digital loop-back mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals (DR is connected to transmit data on DX output pin DXO, FSR is connected to FRX output pin FSXO, and CLKR is connected to the CLKX output pin CLKXO). This mode allows testing of serial port; the McBSP receives the data it transmits. This loop back mode is not done through pads, all output signals being disabled (CLKREN, CLKXEN, FSREN, FSRXEN, DXEN are not active).

Note that in digital loop back mode the sample rate generator and the frame synchronization generator need to be enabled in order to generate the CLKX and FSX signals.

15.2.8.6.5 Enable/Disable the Transmit Multichannel Selection

The XMCM bit field (MCR2_REG[1:0]) determines whether the transmit multichannel selection mode is on or off.

15.2.8.6.6 Choose 1 or 2 Phases for the Transmit Frame

The XPHASE bit (XCR2_REG[15]) determines whether the transmit data frame has one or two phases.

15.2.8.6.7 Set the Transmit Word Length(s)

The XWDLEN1 (XCR1_REG[7:5]) and XWDLEN2 (XCR2_REG[7:5]) bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

Each frame can have one or two phases, depending on the value that you load into the XPHASE bit. If a single–phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame. If a dual–phase frame is selected, XWDLEN1 determines the length of the serial words in phase 1 of the frame and XWDLEN2 determines the word length in phase 2 of the frame.

15.2.8.6.8 Set the Transmit Frame Length

The XFRLEN1 (XCR1_REG[14:8]) and XFRLEN2 (XCR2_REG[14:8]) bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

The transmit frame length is the number of serial words in the transmit frame. Each frame can have one or two phases, depending on value that you load into the XPHASE bit. If a single–phase frame is selected (XPHASE = 0), the frame length is equal to the length of phase 1. If a dual–phase frame is selected (XPHASE = 1), the frame length is 2, the length of phase 1 (one word) plus the length of phase 2 (one word).

The 7–bit XFRLEN fields allow up to 128 words per phase. See Table 15-15 for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame–synchronization pulse.

Program the XFRLEN fields with [w minus 1], where w represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 15-15. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	0 <= XFRLEN1 <= 127	Don't care	(XFRLEN1 + 1) words
1	XFRLEN1= 0	XFRLEN2 = 0	2 words

15.2.8.6.9 Set the Transmit Reverse Mode

The XREVERSE bit field (XCR2_REG[4:3]) determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

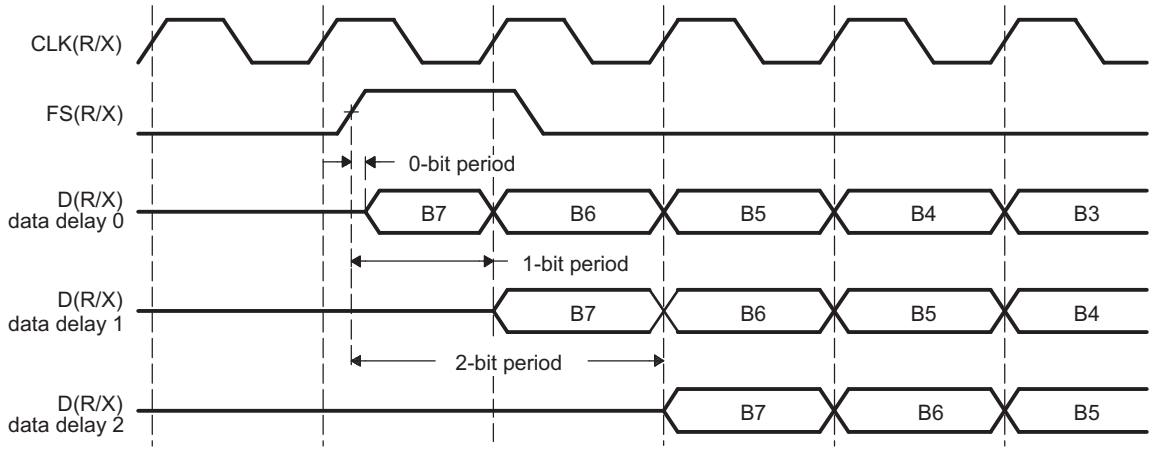
15.2.8.6.10 Set the Transmit Data Delay

The XDATDLY bit field (XCR2_REG[1:0]) determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is 0 to 2 bit–clocks (XDATDLY = 00b–10b), as shown in Figure 15-30. In this figure, the data transferred is an 8–bit value with bits labeled B7, B6, B5, and so on. Typically a 1–bit delay is selected, because data often follows a 1–cycle active frame–synchronization pulse.

Figure 15-30. Range of Programmable Data Delay

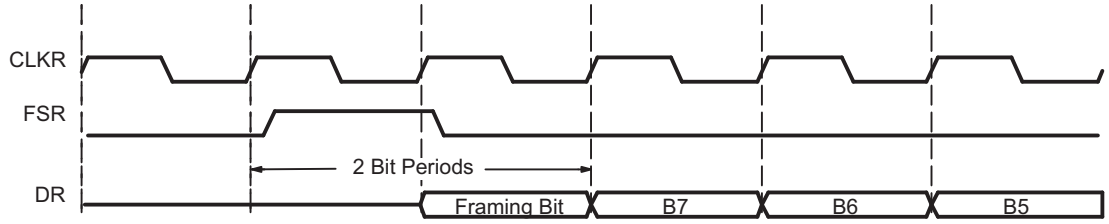


0-bit data delay:

Normally, a frame–synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0–bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active–high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on McBSP.DX. The transmitter then asynchronously detects the frame–synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the McBSP.DX pin.

Figure 15-31. 2-Bit Data Delay Used to Skip a Framing Bit



15.2.8.6.11 Set the Transmit DXENA Mode

DXENA bit (SPRC1_REG[7]) is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the McBSP.DX pin. Set DXENA to enable an extra delay for turn–on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 7 ns, 14 ns (default), 20 ns or 28 ns can be set using the DXENDLY bit field in XCCR_REG register. If you tie together the McBSP.DX pins of multiple McBSPs, make sure DXENA = 1 to avoid having more than one McBSP transmitting on the data line at one time.

15.2.8.6.12 Set the Transmit Interrupt Mode (legacy only)

The XINTM bit field (SPCRX_REG[5:4]) determines which event generates a transmit interrupt request to the CPU.

The transmit interrupt (XINT) informs the CPU of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 00: XINT generated when the XRDY bit (SPCR2_REG[1]) changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit in the SPCR2_REG register. Regardless of the value of XINTM, XRDY can be read to detect the XRDY = 1 condition.
- XINTM = 01: XINT generated by an end–of–frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 10: XINT generated by a new transmit frame–synchronization pulse. Interrupt on detection of transmit frame–synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame–synchronization pulse to the CPU clock and sending it to the CPU via XINT.
- XINTM = 11: XINT generated when XSYNCERR is set. Interrupt on frame–synchronization error. Regardless of the value of XINTM, XSYNCERR can be read to detect this condition.

The McBSP provides also a common interrupt line McBSP.COMMONIRQ, which can be used by setting the IRQENABLE register. All the above settings have equivalent enable bits in the IRQENABLE register in order to enable the common interrupt line (XDYEN is equivalent with XINTM = 00, XEOFEN is equivalent with XINTM = 01 (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode), XFSXEN is equivalent with XINTM = 10 and XSYNCERREN is equivalent with XINTM = 11 setting). This interrupt line has its own status register.

15.2.8.6.13 Set the Transmit Frame-Synchronization Mode

FSXM bit (PCR_REG[11]) and FSGM bit (SRGR2_REG[12]) are used to set the transmit frame-synchronization mode.

Table 15-16 shows how FSXM and FSGM select the source of transmit frame–synchronization pulses. The three choices are:

1. External frame–synchronization input
2. Sample rate generator frame–synchronization signal (FSG)
3. Sample rate generator frame–synchronization signal (FSG) gated by the transmit buffer XB empty condition.

Table 15-16 also shows the effect of each bit setting on the McBSP.FSX pin. The FSXP bit determines the polarity of the signal on the McBSP.FSX pin.

Table 15-16. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	McBSP.FSX Pin Status
0	0 or 1	An external frame–synchronization signal enters the McBSP through the McBSP.FSX pin. The signal is then inverted by FSXP before being used as internal FSX.	Input
1	1	Internal FSX is driven by the sample rate generator frame–synchronization signal (FSG).	Output. FSG is inverted by FSXP before being driven out on McBSP.FSX pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame–synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame–synchronization pulse is inverted as determined by FSXP before being driven out on McBSP.FSX pin.

If the sample rate generator creates a frame–synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the McBSP.FSR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

15.2.8.6.14 Set the Transmit Frame-Synchronization Polarity

The FSXP bit (PCR_REG[3]) determines whether frame–synchronization pulses are active high or active low on the McBSP.FSX pin.

Transmit frame–synchronization pulses can be generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[11] register FSXM mode bit. FSX is also affected by the FSGM bit (SRGR2_REG[12]). Similarly, transmit clocks can be selected to be inputs or outputs by programming the PCR_REG[9] register CLKXM mode bit.

When FSR and FSX are inputs (FSXM = FSRM= 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected and the polarity bit FS(R/X)P = 1, the internal active–high frame–synchronization signals are inverted before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1, and internal clocking selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin.

Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

15.2.8.6.15 Set the SRG Frame-Synchronization Period and Pulse Width

FPER bit field (SRGR2_REG[11:0]) is used to set the SRG frame-synchronization period and FWID bit field (SRGR1_REG[15:8]) is used to set the SRG pulse width. The sample rate generator can produce a clock signal, CLKG, and a frame–synchronization signal, FSG. If the sample rate generator is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

On FSG, the period from the start of a frame–synchronization pulse to the start of the next pulse is (FPER + 1) CLKG cycles. The 12 bits of FPER allow a frame–synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When GSYNC = 1, FPER is a don't care value.

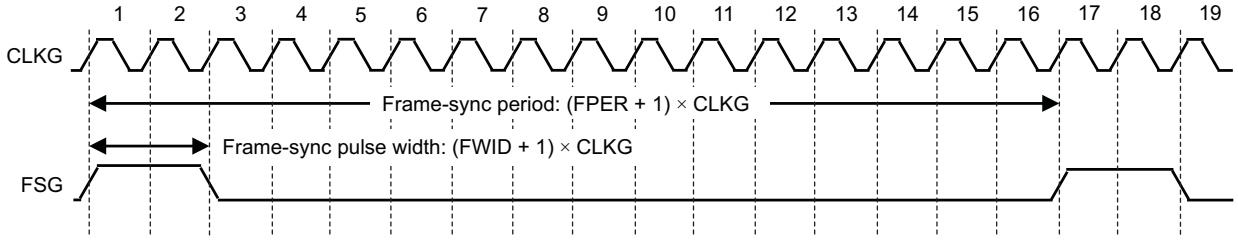
Each pulse on FSG has a width of (FWID + 1) CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down–counters. The 12–bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8–bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 15-32 shows a frame–synchronization period of 16 CLKG periods (FPER = 15 or 0000 1111b) and a frame–synchronization pulse with an active width of 2 CLKG periods (FWID = 1).

When the sample rate generator comes out of reset, FSG is in its inactive state. Then, when GRST = 1 and FSGM = 1, a frame–synchronization pulse is generated. The frame width value (FWID + 1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER + 1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

Figure 15-32. Frame of 16 CLKG Periods and Active Width of 2 CLKG Periods



15.2.8.6.16 Set the Transmit Clock Mode

CLKXM bit (PCR_REG[9]) is used to set the transmit clock mode

Table 15-17 shows how the CLKXM bit selects the transmit clock and the corresponding status of the McBSP.CLKX pin. The CLKXP bit determines the polarity of the signal on the McBSP.CLKX pin.

If the sample rate generator creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the McBSP.FSR pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal.

Table 15-17. CLKXM Bit Effect on Transmit Clock and McBSP.CLKX Pin

CLKXM	Source of Transmit Clock	McBSP.CLKX Pin Status
0	Internal CLKX is driven by an external clock on the McBSP.CLKX pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the sample rate generator clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on McBSP.CLKX.

15.2.8.6.17 Set the Transmit Clock Polarity

CLKXP bit (PCR_REG[1]) is used to set the transmit clock polarity.

Transmit frame–synchronization pulses can be either generated internally by the sample rate generator or driven by an external source. The source of frame synchronization is selected by programming the PCR_REG[11] register FSXM mode bit. FSX is also affected by the FSGM bit (SRGR2_REG[12]). Similarly, transmit clocks can be selected to be inputs or outputs by programming the PCR_REG[9] register CLKXM mode bit.

When FSR and FSX are inputs (FSXM = FSRM = 0, external frame–synchronization pulses), the McBSP detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the McBSP.DR pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the sample rate generator clock (CLKG) internal to the McBSP.

When FSR and FSX are outputs, implying that they are driven by the sample rate generator, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the McBSP.DX pin is output on the rising edge of internal CLKX. FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame–synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and FSRP = FSXP = 1, the external active–low frame–synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC = 0) is selected, the internal active–high frame–synchronization signals are inverted, if the polarity bit FS(R/X)P = 1, before being sent to the FS(R/X) pin.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP = 1 and external clocking is selected (CLKXM = 0 and CLKX is an input), the external falling–edge triggered input clock on CLKX is inverted to a rising–edge triggered clock before being sent to the transmitter. If CLKXP = 1 and internal clocking is selected (CLKXM = 1 and CLKX is an output pin), the internal (rising–edge triggered) clock, internal CLKX, is inverted before being sent out on the McBSP.CLKX pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising–edge triggered input clock on CLKR is inverted to a falling–edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling–edge triggered clock is inverted to a rising–edge triggered clock before being sent out on the McBSP.CLKR pin. Note that CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

15.2.8.6.18 Set the SRG Clock Divide-Down Value

CLKGDV bit field (SRGR1_REG[7:0]) is used to set the sample rate generator clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to 1/(CLKGDV + 1) of sample rate generator input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

15.2.8.6.19 Set the SRG Clock Synchronization Mode

GSYNC bit (SRGR2_REG[15]) is used to set the SRG clock synchronization mode.

15.2.8.6.20 Set the SRG Clock Mode (choose an input clock)

SCLKME bit (PCR_REG[7]) and CLKSM bit (SRGR2_REG[13]) are used to set the SRG clock mode.

The sample rate generator can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

15.2.8.6.21 Set the SRG Input Clock Polarity

CLKSP bit (SRGR2_REG[14]), CLKXP bit (PCR_REG[1]) and CLKRP bit (PCR_REG[0]) are used to set the SRG input clock polarity.

The sample rate generator can produce a clock signal (CLKG) and a frame–synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the sample rate generator must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the McBSP.CLKS, McBSP.CLKX, or McBSP.CLKR pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the McBSP.CLKS pin, CLKXP for the McBSP.CLKX pin, CLKRP for the McBSP.CLKR pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

15.2.8.7 General-Purpose I/O on the McBSP Pins (legacy only)

Table 15-18 summarizes how to use the McBSP pins as general–purpose I/O pins. All of the bits mentioned in the table except XRST and RRST bits are in the pin control register (PCR_REG). XRST and RRST are in the serial port control registers (SPCR2_REG[0] and SPCR1_REG[0], respectively.

To use receiver pins McBSP.CLKR, McBSP.FSR, and McBSP.DR as general–purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (SPCR1_REG[0] RRST bit = 0).
2. General–purpose I/O is enabled for the serial port receiver (RIOEN = 1 in PCR_REG[12]).

The McBSP.CLKR and McBSP.FSR pins can be individually configured as either input or output pins with the CLKRM and FSRM bits, respectively. The McBSP.DR pin can only be an input pin. The following table shows, which bits in PCR_REG are used to read from/write to these pins.

For the transmitter pins McBSP.CLKX, McBSP.FSX, and McBSP.DX, you must meet two conditions:

1. The transmitter of the serial port is in reset (XRST = 0 in SPCR2_REG[0]).
2. General–purpose I/O is enabled for the serial port transmitter (XIOEN = 1 in PCR_REG[12]).

The McBSP.CLKX and McBSP.FSX pins can be individually configured as input or output pins with the CLKXM and FSXM bits, respectively. The McBSP.DX pin can only be an output pin.

For the McBSP.CLKS pin, all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (RRST = 0 and XRST = 0).
2. General–purpose I/O is enabled for both the receiver and the transmitter (RIOEN = 1 and XIOEN = 1).

The McBSP.CLKS pin can only be an input pin. To read the status of the signal on the McBSP.CLKS pin, read the CLKS_STAT bit in PCR_REG.

Table 15-18. Using McBSP Pins for General-Purpose I/O

Pin	General–Purpose Use Enabled by This Bit Combination	Selected as Input When ...	Input Value Read From This Bit
McBSP.CLKX	XRST = 0 XIOEN = 1	CLKXM = 0	CLKXP
McBSP.FSX	XRST = 0 XIOEN = 1	FSXM = 0	FSXP
McBSP.DX	XRST = 0 XIOEN = 1	Never	Does not apply
McBSP.CLKR	RRST = 0 RIOEN = 1	CLKRM = 0	CLKRP
McBSP.FSR	RRST = 0 RIOEN = 1	FSRM = 0	FSRP
McBSP.DR	RRST = 0 RIOEN = 1	Always	DR_STAT
McBSP.CLKS	RRST = XRST = 0 RIOEN = XIOEN = 1	Always	CLKS_STAT

15.3 McBSP Registers

Table 15-19 lists the registers for the McBSP.

Table 15-19. McBSP Registers

Address Offset	Acronym	Register Name	Section
0h	REVNB	Revision Number Register	Section 15.3.1
10h	SYSCONFIG_REG	System Configuration Register	Section 15.3.2
20h	EOI	End of Interrupt Register	Section 15.3.3
24h	IRQSTATUS_RAW	Interrupt Status Raw Register	Section 15.3.4
28h	IRQSTATUS	Interrupt Status Register	Section 15.3.5

15.3.1 Revision Number Register (REVNB)

The Revision Number (REVNB) register is shown in Figure 15-33 and described in Table 15-20.

This read-only register contains the hard-coded revision number of the module. A write to this register has no effect.

Figure 15-33. Revision Number Register (REVNB)

			Write: Initiate software reset.
0	Reserved	0	Reserved.

15.3.3 End of Interrupt Register (EOI)

The End of Interrupt (EOI) register is shown in Figure 15-35 and described in Table 15-22.

Figure 15-35. End of Interrupt Register (EOI)

31	1	0
Reserved		LINE_NUMBER
R-0		W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-22. End of Interrupt Register (EOI) Field Descriptions

Bits	Field Name	Value	Description
31-1	Reserved	0	Reserved.
0	LINE_NUMBER		Software End Of Interrupt (EOI) control. Write number of interrupt output. Write a value of 0 to force the output interrupt to re-assert if any enabled interrupts are pending.

15.3.4 Interrupt Status Raw Register (IRQSTATUS_RAW)

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled ones). The fields are read-write. Writing a 1 to a bit will set it to 1, for example, trigger the IRQ when also enabled (mostly for debug). Writing a 0 will have no effect, for example, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Status Raw (IRQSTATUS_RAW) register is shown in Figure 15-36 and described in Table 15-23.

Figure 15-36. Interrupt Status Raw Register (IRQSTATUS_RAW)

Table 15-23. Interrupt Status Raw Register (IRQSTATUS_RAW) Field Descriptions

Bits	Field Name	Value	Description
31-15	Reserved	0	Reserved.
14	XEMPTYEOF		Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty. Writing a 0 will have no effect.
		1	XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit will set it to 1.
13	Reserved	0	Reserved.
12	XOVFLSTAT		Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty . Writing a 0 will have no effect.
		1	XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit will set it to 1.
11	XUNDFLSTAT		Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	The transmit data buffer is NOT empty new data is required to be transmitted. Writing a 0 will have no effect.
		1	The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit will set it to 1.
10	XRDY		Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Transmit buffer occupied locations are below the THRSH2_REG value). Writing a 0 will have no effect.
		1	Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit will set it to 1.
9	XEOF		Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Complete frame was NOT transmitted. Writing a 0 will have no effect.
		1	Complete frame was transmitted. Writing 1 to this bit will set it to 1.
8	XFSX		Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	New transmit frame synchronization is NOT asserted. Writing a 0 will have no effect.
		1	New transmit frame synchronization is asserted. Writing 1 to this bit will set it to 1.
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Transmit frame synchronization error is NOT detected. Writing a 0 will have no effect.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit will set it to 1.
6	Reserved	0	Reserved.
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit will set it to 1. Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Receive buffer NOT overflow . Writing a 0 will have no effect.
		1	Receive buffer overflow; Writing 1 to this bit will set it to 1.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Read operation is performed to the receive data register while receive buffer is NOT empty. Writing a 0 will have no effect.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit will set it to 1.

Table 15-23. Interrupt Status Raw Register (IRQSTATUS_RAW) Field Descriptions (continued)

Bits	Field Name	Value	Description
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Receive buffer occupied locations are below the THRSH1_REG value). Writing a 0 will have no effect.
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit will set it to 1.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Complete frame was NOT received. Writing a 0 will have no effect.
		1	Complete frame was received; Writing 1 to this bit will set it to 1.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Wr Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	New receive frame synchronization is NOT asserted. Writing a 0 will have no effect.
		1	New receive frame synchronization is asserted; Writing 1 to this bit will set it to 1.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit will set it to 1. Writing a 0 will have no effect.
		0	Receive frame synchronization error is NOT detected. Writing a 0 will have no effect.
		1	Receive frame synchronization error is detected. Writing 1 to this bit will set it to 1.

15.3.5 Interrupt Status Register (IRQSTATUS)

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, for example, clear the IRQ. Writing a 0 will have no effect, for example, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Status (IRQSTATUS) register is shown in Figure 15-37 and described in Table 15-24.

		0	Complete frame was NOT transmitted.
		1	Complete frame was transmitted; Writing 1 to this bit clears the bit.

Table 15-24. Interrupt Status Register (IRQSTATUS) Field Descriptions (continued)

Bits	Field Name	Value	Description
8	XFSX		Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New transmit frame synchronization is NOT asserted.
		1	New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Transmit frame synchronization error is NOT detected.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		0	Receive buffer NOT overflow.
		1	Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit.
		0	Read operation is performed to the receive data register while receive buffer is NOT empty.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
		0	Receive buffer occupied locations are below the THRSH1_REG value).
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT received.
		1	Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New receive frame synchronization is NOT asserted.
		1	New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

15.3.6 Interrupt Enable Set Register (IRQENABLE_SET)

All 1-bit fields enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit will enable the field. Writing a 0 will have no effect, for example, the register value will not be modified.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Enable Set (IRQENABLE_SET) register is shown in Figure 15-38 and described in Table 15-25.

Figure 15-38. Interrupt Enable Set Register (IRQENABLE_SET)

		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

15.3.7 Interrupt Enable Clear Register (IRQENABLE_CLR)

All 1-bit fields clear a specific interrupt event. Writing a 1 to a bit will disable the interrupt field. Writing a 0 will have no effect, for example, the register value will not be modified.

Interrupts can either be serviced using the highlander standard IRQSTATUS, IRQSTATUS_RAW, IRQENABLE_SET, and IRQENABLE_CLR set of registers, or the legacy IRQSTATUS_REG and IRQENABLE_REG registers, but not both in the same system.

The Interrupt Enable Clear (IRQENABLE_CLR) register is shown in Figure 15-39 and described in Table 15-26.

Figure 15-39. Interrupt Enable Clear Register (IRQENABLE_CLR)

Table 15-26. Interrupt Enable Clear Register (IRQENABLE_CLR) Field Descriptions

Bits	Field Name	Value	Description
31-15	Reserved	0	Reserved.
14	XEMPTYEOF		Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty).
		0	XEMPTYEOF is NOT set to when a complete frame was transmitted and the transmit buffer is empty.
		1	XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty. Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT		Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		0	Transmit buffer NOT overflow.
		1	Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT		Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit.
		0	The transmit data buffer is NOT empty new data is required to be transmitted.
		1	The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY		Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
		0	Transmit buffer occupied locations are below the THRSH2_REG value).
		1	Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF		Transmit End Of Frame (XEOF is set to 1 when a complete frame was transmitted). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT transmitted.
		1	Complete frame was transmitted; Writing 1 to this bit clears the bit.

Table 15-26. Interrupt Enable Clear Register (IRQENABLE_CLR) Field Descriptions (continued)

Bits	Field Name	Value	Description
8	XFSX		Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New transmit frame synchronization is NOT asserted.
		1	New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Transmit frame synchronization error is NOT detected.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.
		0	Receive buffer NOT overflow.
		1	Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit.
		0	Read operation is performed to the receive data register while receive buffer is NOT empty.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
		0	Receive buffer occupied locations are below the THRSH1_REG value).
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT received.
		1	Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit.
		0	New receive frame synchronization is NOT asserted.
		1	New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set to 1 when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit.
		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

15.3.8 DMA Rx Enable Set Register (DMARXENABLE_SET)

The 1-bit field enables a Receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, for example, the register value is not modified. Note that the RCCR_REG.RDMAEN field is the global (slave) DMA enabler, and that it is disabled by default. The field RCCR_REG.RDMAEN should also be set to 1 to enable a Receive DMA Request.

The DMA Rx Enable Set (DMARXENABLE_SET) register is shown in Figure 15-40 and described in Table 15-27.

Figure 15-40. DMA Rx Enable Set Register (DMARXENABLE_SET)

Table 15-27. DMA Rx Enable Set Register (DMARXENABLE_SET) Field Descriptions

Bits	Field Name	Value	Description
31-1	Reserved	0	Reserved.
0	DMARX_ENABLE_SET		Receive DMA channel enable set.

15.3.9 DMA Tx Enable Set Register (DMATXENABLE_SET)

The 1-bit field enables a Transmit DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, for example, the register value is not modified. Note that the XCCR_REG.XDMAEN field is the global (slave) DMA enabler, and that it is disabled by default. The field XCCR_REG.XDMAEN should also be set to 1 to enable a Transmit DMA Request.

The DMA Tx Enable Set (DMATXENABLE_SET) register is shown in Figure 15-41 and described in Table 15-28.

Figure 15-41. DMA Tx Enable Set Register (DMATXENABLE_SET)

31-1	Reserved	0	Reserved.
0	DMATX_ENABLE_SET		Transmit DMA channel enable set.

15.3.10 DMA Rx Enable Clear Register (DMARXENABLE_CLR)

The 1-bit field disables a Receive DMA request. Writing a 1 to a bit will clear it to 0. Another result of setting to '1' the DMARX_ENABLE_CLEAR field, is the reset of the DMA RX request and wakeup lines. Writing a 0 will have no effect, for example, the register value is not modified.

The DMA Rx Enable Clear (DMARXENABLE_CLR) register is shown in Figure 15-42 and described in Table 15-29.

Figure 15-42. DMA Rx Enable Clear Register (DMARXENABLE_CLR)

31-1	Reserved	0	Reserved.
0	DMATX_ENABLE_CLEAR		Transmit DMA channel enable clear.

15.3.12 DMA Rx Wake Enable Register (DMARXWAKE_EN)

All 1-bit fields listed above enable a specific (synchronous) DMA request source to generate an asynchronous wakeup (on the appropriate wakeup line). Note that the SYSCONFIG_REG.ENAWAKEUP field is the global (slave) wakeup enabler, and that it is disabled by default.

The DMA Rx Wake Enable (DMARXWAKE_EN) register is shown in Figure 15-44 and described in Table 15-31.

Figure 15-44. DMA Rx Wake Enable Register (DMARXWAKE_EN)

Table 15-35. McBSP_SPCR2_REG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	FREE		Free Running Mode (When this bit is set, the module ignores the Msuspend input)
		0	Free running mode is disabled
		1	Free running mode is enabled
8	SOFT		Soft bit.
		0	SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion.
		1	SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.
7	FRST		Frame-Synchronization Generator Reset.
		0	Frame-Synchronization logic is reset. Frame-Synchronization signal FSG is not generated by the sample-rate generator.
		1	Frame-Synchronization signal FSG is generated after (FPER+1) number of CLKG clocks; all frame counters are loaded with their programmed values.
6	GRST		Sample-Rate Generator Reset.
		0	SRG is reset.
		1	SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])
5-4	XINTM		Transmit Interrupt Mode (legacy).
		0	Transmit interrupt is driven by XRDY.
		1h	Transmit interrupt generated by end-of-frame.
		2h	Transmit interrupt generated by a new frame synchronization.
		3h	Transmit interrupt generated by XSYNCERR.
3	XSYNCERR		Transmit Synchronization Error. (Writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition).
		0	No synchronization error.
		1	Synchronization error detected by McBSP.
2	XEMPTY		Transmit Shift Register XSR Empty.
		0	XSR is empty.
		1	XSR is not empty.
1	XRDY		Transmitter ready.
		0	Transmitter is not ready.
		1	Transmitter is ready for new data in DXR.
0	XRST		Transmitter reset. This resets and enables the transmitter.
		0	The serial port transmitter is disabled and in reset state.
		1	The serial port transmitter is enabled.

15.3.17 McBSP Serial Port Control Register 1 (SPCR1_REG)

The McBSP_SPCR1_REG register is shown in Figure 15-49 and described in Table 15-36.

R/W-0	R/W-0	R/W-1	R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 15-41. McBSP_SRGR2_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	GSYNC		Sample Rate Generator (SRG) Synchronization
			Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0).
		0	The SRG clock (CLKG) is free running.
		1	The SRG clock (CLKG) is running, but CLKG is resynchronized and frame-synchronization signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR).
			Also, frame period, FPER, is a don't care because the period is dictated by the external frame-synchronization pulse.
14	CLKSP		CLKS Polarity Clock Edge Select
			Only used when the external clock CLKS drives the SRG clock (CLKSM=0).
		0	Rising edge of CLKG and FSG.
		1	Falling edge of CLKG and FSG.
13	CLKSM		McBSP SRG Clock Mode
		0	SCLKME = 0: SRG clock derived from the CLKS pin.
			SCLKME = 1: SRG clock derived from the the CLKRI pin.
		1	SCLKME = 0: SRG clock derived from the OCP clock.
			SCLKME = 1: SRG clock derived from the CLKXI pin.
12	FSGM		Sample Rate Generator Transmit Frame-Synchronization Mode. Used when FSXM=1 in the PCR.
		0	Transmit frame-synchronization signal (FSX) is generated when transmit buffer is not empty.
			When FSGM = 0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).
		1	Transmit frame-synchronization signal driven by the SRG frame-synchronization signal, FSG.
11-0	FPER	0-FFFh	Frame Period. This value + 1 determines when the next frame-synchronization signal becomes active.
			Range: 1 to 4096 CLKG periods.

15.3.23 McBSP Sample Rate Generator Register 1 (SRGR1_REG)

The McBSP_SRGR1_REG register is shown in Figure 15-55 and described in Table 15-42.

Figure 15-55. McBSP_SRGR1_REG

31 16	15 8	7 0
Reserved	FWID	CLKGDV
R-0	R/W-0	R/W-1

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 15-42. McBSP_SRGR1_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15-8	FWID	0-FFh	Frame Width. This value + 1 determines the width of the frame-synchronization pulse, FSG, during its active period. Range: 1 to 256 CLKG periods.
7-0	CLKGDV	1-FFh	Sample Rate Generator Clock Divider. This value is used as the divide-down number to generate the required SRG clock frequency. Default value is 1.

15.3.24 McBSP Multichannel Register 2 (MCR2_REG)

The McBSP_MCR2_REG register is shown in Figure 15-56 and described in Table 15-43.

Figure 15-56. McBSP_MCR2_REG

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-43. McBSP_MCR2_REG Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	XMCME		XMCME Transmit multichannel partition mode bit 0. XMCME is only applicable if channels can be individually disabled/enabled or masked/unmasked for transmission (XMCM is non-zero). XMCME determines whether only 32 channels or all 128 channels are to be individually selectable.
		0	**2-partition mode (legacy only):** Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bits. If XMCM = 01b or 10b, assign 16 channels to partition A with the XPABLK bits. Assign 16 channels to partition B with the XPBBLK bits. If XMCM = 11b (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bits. Assign 16 channels to receive partition B with the RPBBLK bits You control the channels with the appropriate transmit channel enable registers: XCERA: Channels in partition A. XCERB: Channels in partition B.
		1	**8-partition mode:** All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels 0 through 15 XCERB: Channels 16 through 31 XCERC: Channels 32 through 47 XCERD: Channels 48 through 63 XCERE: Channels 64 through 79 XCERF: Channels 80 through 95 XCERG: Channels 96 through 111 XCERH: Channels 112 through 127
8-7	XPBBLK		Transmit Partition B Block (legacy only)
		0	Block 1. Channel 16 to channel 31
		1h	Block 3. Channel 48 to channel 63
		2h	Block 5. Channel 80 to channel 95
		3h	Block 7. Channel 112 to channel 127
6-5	XPABLK		Transmit Partition A Block (legacy only)
		0	Block 0. Channel 0 to channel 15
		1h	Block 2. Channel 32 to channel 47
		2h	Block 4. Channel 64 to channel 79
		3h	Block 6. Channel 96 to channel 111

Table 15-43. McBSP_MCR2_REG Field Descriptions (continued)

Bit	Field	Value	Description
4-2	Reserved	0	Reserved
1-0	XMCM		Transmit Multichannel Selection Enable
		0	All channels enabled without masking (DX is always driven during transmission of data).
		1h	All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven.
		2h	All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked.
		3h	All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symmetric transmit and receive operation.

15.3.25 McBSP Multichannel Register 1 (MCR1_REG)

The McBSP_MCR1_REG register is shown in Figure 15-57 and described in Table 15-44.

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-49. McBSP_PCR_REG Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved.
14	IDLE_EN		Idle enable (legacy only).
			This bit allows stopping all the clocks in the McBSP module. (legacy)
		0	The McBSP is running
		1	The clocks in the McBSP are shut off when both IDLE_EN = 1 and this power domain is in idle mode (Force idle or Smart idle)
13	XIOEN		Transmit General Purpose I/O Mode only when XRST = 0 in SPCR[1,2]. (legacy only)
		0	DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os.
		1	DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.
12	RIOEN		Receive General Purpose I/O Mode when RRST = 0 in SPCR[1,2]. (legacy)
		0	DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os.
		1	DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.
11	FSXM		Transmit Frame-Synchronization Mode.
		0	Frame-synchronization signal derived from an external source.
		1	Frame synchronization is determined by the SRG frame-synchronization mode bit FSGM in SRGR2.
10	FSRM		Receive Frame-Synchronization Mode.
		0	Frame-Synchronization pulses generated by an external device. FSR is an input pin.
		1	Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.
9	CLKXM		Transmitter Clock Mode.
			When digital loop-back mode set (McBSPi.McBSP_XCCR_REG[5] DLB = 1), CLKXM bit is ignored. The internal transmit clock (not the mcbspi_clkx pin) is driven by the internal SRG and mcbspi_clkx pin is in high-impedance.
		0	Transmitter clock is driven by an external clock with CLKX as an input pin.
		1	CLKX is an output pin and is driven by the internal SRG.

Table 15-49. McBSP_PCR_REG Field Descriptions (continued)

Bit	Field	Value	Description
8	CLKRM		Receiver Clock Mode.
		0	Case 1: Analog loop back mode not set (ALB = 0) in SPCR1:
			Receive clock (CLKR) is an input driven by an external clock.
			Case 2: Analog loop back mode set (ALB = 1) in SPCR1:
			Receive clock (not the CLKR pin) is driven by transmit clock (CLKX), which is based on the CLKXM bit in the PCR. CLKR pin is in high-impedance.
		1	Case 1: Analog loop back mode not set (ALB = 0) in SPCR1:
			CLKR is an output pin and is driven by the internal sample rate generator.
			Case 2: Analog loop back mode set (ALB = 1) in SPCR1:
			CLKR is an output pin and is driven by the transmit clock. The transmit clock is derived based on the CLKRM bit in the PCR.
7	SCLKME		SCLKME Sample rate generator input clock mode bit 0.
			The sample rate generator can produce a clock signal, CLKG. The frequency of CLKG is:
			CLKG frequency = (Input clock frequency) / (CLKGDV + 1)
			SCLKME is used in conjunction with the CLKSM bit to select the input clock:
		0	CLKSM = 0: Signal on CLKS pin.
			CLKSM = 1: McBSP_OCP clock.
		1	CLKSM = 0: Signal on CLKR pin.
			CLKSM = 1: Signal on CLKX pin.
6	CLKS_STAT		CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy)
		0	The signal on the CLKS pin is low.
		1	The signal on the CLKS pin is high.
5	DX_STAT		DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy)
		0	Drive the signal on the DX pin low.
		1	Drive the signal on the DX pin high.
4	DR_STAT		DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy)
		0	The signal on DR pin is low.
		1	The signal on DR pin is high.
3	FSXP		Transmit Frame-Synchronization Polarity.
		0	Frame-synchronization pulse FSX is active high.
		1	Frame-synchronization pulse FSX is active low.
2	FSRP		Receive Frame-Synchronization Polarity.
		0	Frame-synchronization pulse FSR is active high.
		1	Frame-synchronization pulse FSR is active low.
1	CLKXP		Transmit Clock Polarity.
		0	Transmit data driven on rising edge of CLKX.
		1	Transmit data driven on falling edge of CLKX.
0	CLKRP		Receive Clock Polarity.
		0	Receive data sampled on falling edge of CLKR.
		1	Receive data sampled on rising edge of CLKR.

15.3.31 McBSP Receive Channel Enable Register Partition C (RCERC_REG)

The McBSP_RCERC_REG register is shown in Figure 15-63 and described in Table 15-50.

Figure 15-63. McBSP_RCERC_REG

31	16	15	0
Reserved		RCERC	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-0	RCERG		Receive Channel Enable. RCERG n = 0. Disables reception of n-th channel in block 6 in partition G. RCERG n = 1. Enables reception of n-th channel in block 6 in partition G.

15.3.40 McBSP Receive Channel Enable Register Partition H (RCERH_REG)

The McBSP_RCERH_REG register is shown in Figure 15-72 and described in Table 15-59.

Figure 15-72. McBSP_RCERH_REG

31	16	15	0
Reserved		RCERH	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-59. McBSP_RCERH_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-0	RCERH		Receive Channel Enable. RCERH n = 0. Disables reception of n-th channel in block 7 in partition H. RCERH n = 1. Enables reception of n-th channel in block 7 in partition H.

15.3.41 McBSP Transmit Channel Enable Register Partition G (XCERG_REG)

The McBSP_XCERG_REG register is shown in Figure 15-73 and described in Table 15-60.

Figure 15-73. McBSP_XCERG_REG

31	16	15	0
Reserved		XCERG	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-60. McBSP_XCERG_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-0	XCERG		Transmit Channel Enable. XCERG n = 0. Disables transmission of n-th channel in block in partition G. XCERG n = 1. Enables transmission of n-th channel in block in partition G.

15.3.42 McBSP Transmit Channel Enable Register Partition H (XCERH_REG)

The McBSP_XCERH_REG register is shown in Figure 15-74 and described in Table 15-61.

Figure 15-74. McBSP_XCERH_REG

31	16	15	0
Reserved		XCERH	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-61. McBSP_XCERH_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-0	XCERH		Transmit Channel Enable. XCERH n = 0. Disables transmission of n-th channel in block in partition H. XCERH n = 1. Enables transmission of n-th channel in block in partition H.

15.3.43 McBSP Transmit Buffer Threshold Register (DMA or IRQ Trigger) (THRSH2_REG)

The McBSP_THRSH2_REG register is shown in Figure 15-75 and described in Table 15-62.

Figure 15-75. McBSP_THRSH2_REG

31	12	11	0
Reserved		XTHRESHOLD	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 15-62. McBSP_THRSH2_REG Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11-0	XTHRESHOLD		Transmit buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) will be triggered if the number of free locations inside transmit buffer are above or equal to the XTHRESHOLD value + 1. Also, this value (XTHRESHOLD value + 1) indicates the number of words transferred during a transmit data DMA request, if transmit DMA is enabled.

15.3.44 McBSP Receive Buffer Threshold Register (DMA or IRQ trigger) (THRSH1_REG)

The McBSP_THRSH1_REG register is shown in Figure 15-76 and described in Table 15-63.

Figure 15-76. McBSP_THRSH1_REG

31	12	11	0

Table 15-64. McBSP_IRQSTATUS_REG Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14	XEMPTYEOF		Transmit Buffer Empty at end of frame (XEMPTYEOF is set to 1 when a complete frame was transmitted and the transmit buffer is empty).
		0	Transmit buffer NOT Empty at end of frame.
		1	Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.
13	Reserved	0	Reserved.
12	XOVFLSTAT		Transmit Buffer Overflow (XOVFLSTAT bit is set to 1 when transmit buffer overflow; the data which is written while overflow condition is discarded).
		0	Transmit buffer NOT overflow.
		1	Transmit buffer overflow; Writing 1 to this bit clears the bit.
11	XUNDFLSTAT		Transmit Buffer Underflow (XUNDFLSTAT bit is set to 1 when the transmit data buffer is empty new data is required to be transmitted).
		0	The transmit data buffer is NOT empty new data is required to be transmitted.
		1	The transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.
10	XRDY		Transmit Buffer Threshold Reached (XRDY bit is set to 1 when the transmit buffer free locations are equal or above the THRSH2_REG value).
		0	Transmit buffer occupied locations are below the THRSH2_REG value).
		1	Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.
9	XEOF		Transmit End Of Frame (XEOF is set to 1when a complete frame was transmitted).
		0	Complete frame was NOT transmitted.
		1	Complete frame was transmitted; Writing 1 to this bit clears the bit.
8	XFSX		Transmit Frame Synchronization (XFSX bit is set to 1 when a new transmit frame synchronization is asserted).
		0	New transmit frame synchronization is NOT asserted.
		1	New transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.
7	XSYNCERR		Transmit Frame Synchronization Error (XSYNCERR is set to 1 when a transmit frame synchronization error is detected).
		0	Transmit frame synchronization error is NOT detected.
		1	Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.
6	Reserved	0	Reserved.

Table 15-64. McBSP_IRQSTATUS_REG Field Descriptions (continued)

Bit	Field	Value	Description
5	ROVFLSTAT		Receive Buffer Overflow (ROVFLSTAT bit is set to 1 when receive buffer overflow; the data which is written while overflow condition is discarded).
		0	Receive buffer NOT overflow.
		1	Receive buffer overflow; Writing 1 to this bit clears the bit.
4	RUNDFLSTAT		Receive Buffer Underflow (RUNDFLSTAT bit is set to 1 when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
		0	Read operation is performed to the receive data register while receive buffer is NOT empty.
		1	Read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit.
3	RRDY		Receive Buffer Threshold Reached (RRDY bit is set to 1 when the receive buffer occupied locations are equal or above the THRSH1_REG value).
		0	Receive buffer occupied locations are below the THRSH1_REG value).
		1	Receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit.
2	REOF		Receive End Of Frame (REOF is set to 1 when a complete frame was received). Writing 1 to this bit clears the bit.
		0	Complete frame was NOT received.
		1	Complete frame was received; Writing 1 to this bit clears the bit.
1	RFSR		Receive Frame Synchronization (RFSR bit is set to 1 when a new receive frame synchronization is asserted).
		0	New receive frame synchronization is NOT asserted.
		1	New receive frame synchronization is asserted; Writing 1 to this bit clears the bit.
0	RSYNCERR		Receive Frame Synchronization Error (RSYNCERR is set RW 0x0 to 1 when a receive frame synchronization error is detected).
		0	Receive frame synchronization error is NOT detected.
		1	Receive frame synchronization error is detected. Writing 1 to this bit clears the bit.

15.3.46 McBSP Interrupt Enable Register (OCP compliant IRQ line) (IRQENABLE)

The McBSP_IRQENABLE_REG register is shown in Figure 15-78 and described in Table 15-65.

		0	Receive Frame Synchronization Error WK enable is NOT active.
		1	Receive Frame Synchronization Error WK enable is active.

15.3.48 McBSP Transmit Configuration Control Register (XCCR_REG)

The McBSP_XCCR_REG register is shown in Figure 15-80 and described in Table 15-67.

Figure 15-80. McBSP_XCCR_REG

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
R-0															

15	14	13	12	11	10	9	8
EXTCLKGATE	PPCONNECT	DXENDLY		XFULL_CYCLE	Reserved		
R/W-0	R/W-0	R/W-1		R/W-0	R-0		

7	6	5	4	3	2	1	0
Reserved		DLB	Reserved	XDMAEN	Reserved		XDISABLE
R-0		R/W-0	R-0	R/W-1	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 15-67. McBSP_XCCR_REG Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15	EXTCLKGATE		External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive uses the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer.
		0	External clock gating disabled.
		1	External clock gating enable.
14	PPCONNECT		Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output.
		0	non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit.
		1	Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.
13-12	DXENDLY		When McBSPi.McBSP_SPCR1_REG[7] DXENA bit is set to 1, this field selects the added delay as follow:
		0	8 ns
		1h	14 ns (default)
		2h	20 ns
		3h	28 ns
11	XFULL_CYCLE		Transmit full cycle mode select:
		0	McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data).
		1	McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data).
10-6	Reserved	0	Reserved.
5	DLB		Digital Loopback. When this bit is set the transmit FSX, CLKX and DX are connected to FSR, CLKR, DR. The outputs of the McBSP (CLKR/CLKX, FSR/FSX, DX are not enabled)
		0	No DLB.
		1	DLB.
4	Reserved	0	Reserved

Table 15-67. McBSP_XCCR_REG Field Descriptions (continued)

Bit	Field	Value	Description
3	XDMAEN		Transmit DMA Enable bit. When cleared to 0 this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset.
		0	Will gate the external transmit DMA request.
		1	Will NOT gate the external transmit DMA request.
2-1	Reserved	0	Reserved
0	XDISABLE		Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary.
		0	The transmit process will NOT stop at the next frame boundary.
		1	The transmit process will stop at the next frame boundary.

15.3.49 McBSP Receive Configuration Control Register (RCCR_REG)

The McBSP_RCCR_REG register is shown in Figure 15-81 and described in Table 15-68.

Figure 15-81. McBSP_RCCR_REG

31	12	11	10	4	3	2	1	0
Reserved		RFULL_CYCLE	Reserved		RDMAEN	Reserved		RDISABLE
R-0		R/W-1	R-0		R/W-1	R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 15-68. McBSP_RCCR_REG Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11	RFULL_CYCLE		Receive full cycle mode select:
		0	McBSP module operates in receive half-cycle mode (receive frame synchronization is sampled by the opposite edge of the clock used to sample receive data).
		1	McBSP module operates in receive full-cycle mode (receive frame synchronization is sampled by the same edge of the clock used to sample receive data).
10-4	Reserved	0	Reserved
3	RDMAEN		Receive DMA Enable bit. When cleared to 0 this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during receive reset.
		0	When cleared to 0 this bit will gate the external transmit DMA request.
		1	When set to 1 this bit will NOT gate the external transmit DMA request.
2-1	Reserved	0	Reserved
0	RDISABLE		Receive Disable bit. When this bit is set the receive process will stop at the next frame boundary.
		0	The receive process will NOT stop at the next frame boundary.
		1	When this bit is set the receive process will stop at the next frame boundary.

15.3.50 McBSP Transmit Buffer Status Registers (XBUFFSTAT_REG)

The McBSP_XBUFFSTAT_REG registers are shown in Figure 15-82 and described in Table 15-69.

Figure 15-82. McBSP_XBUFFSTAT_REG

31	8	7	0
Reserved		XBUFFSTAT	
R-0		R-80h	

LEGEND: R = Read only; -*n* = value after reset

Table 15-69. McBSP_XBUFFSTAT_REG Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	XBUFFSTAT	80h	Transmit buffer status (indicates the number of free locations inside transmit buffer). The XBUFFSTAT value reflects the buffer status on the OCP clock domain and it can be smaller than the real number of the free locations which are seen by the transmit state machine.

15.3.51 McBSP Receive Buffer Status Registers (RBUFFSTAT_REG)

The McBSP_RBUFFSTAT_REG registers are shown in Figure 15-83 and described in Table 15-70.

Figure 15-83. McBSP_RBUFFSTAT_REG

31	8	7	0
Reserved		RBUFFSTAT	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 15-70. McBSP_RBUFFSTAT_REG Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7-0	RBUFFSTAT	0	Receive Buffer Status (indicates the number of occupied locations inside receive buffer). The RBUFFSTAT value reflects the buffer status on the OCP clock domain and it can be smaller than the real number of the occupied locations which are seen by the receive state machine.

15.3.52 McBSP_STATUS_REG

The McBSP_STATUS_REG register is shown in Figure 15-84 and described in Table 15-71.

Figure 15-84. McBSP_STATUS_REG

31	1	0
Reserved		CLKMUXSTATUS
R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 15-71. McBSP_STATUS_REG Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	CLKMUXSTATUS		Indicates that the McBSP AUDIOBUFFER clock muxing is done after exiting SmartIdle mode. When this bit is set one the response to a different register access is delayed until the muxing process is done. In order to avoid such a situation pooling can be performed to status register in order to evaluate when McBSP is ready. Note that this information is relevant only for the McBSP having AUDIOBUFFER.

Serial Port Interface (SPI)

This chapter describes the master/slave multichannel serial port interface (SPI) module.

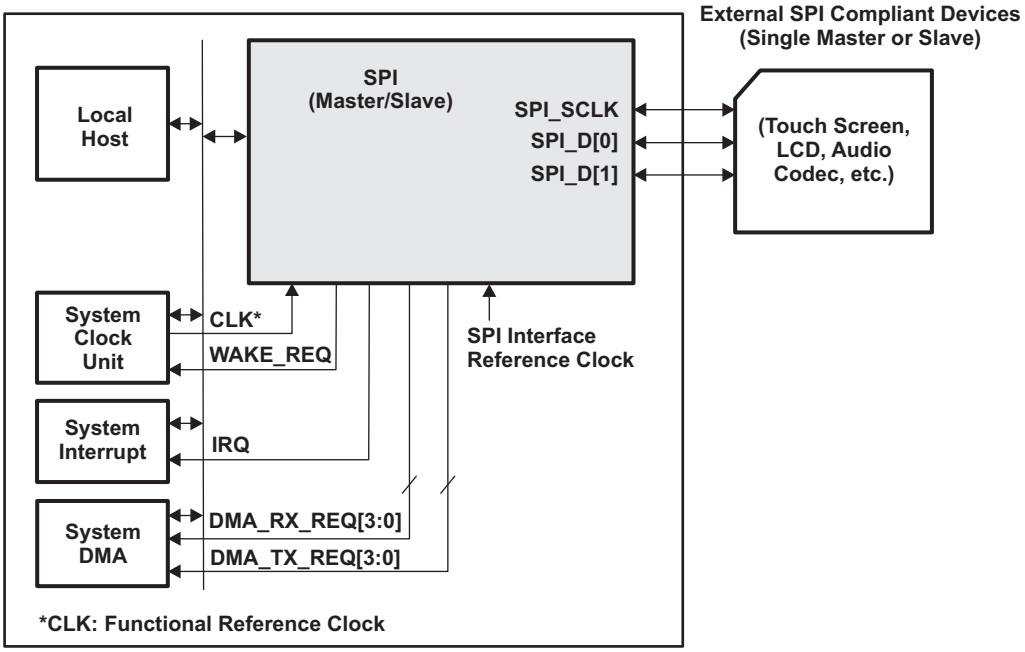
Topic **Page**

16.1 Introduction

16.1.1 Overview

SPI is a general-purpose receive/transmit master/slave controller that can interface with up to four slave external devices or one single external master. It allows a duplex, synchronous, serial communication between a CPU and SPI compliant external devices (slaves and masters). Figure 16-1 shows a high-level overview of a SPI system.

Figure 16-1. SPI System Overview



16.1.2 Features

The SPI includes these distinctive features:

- Serial clock with programmable frequency, polarity and phase
- It supports maximum frequency of 48 MHz.
- Clock frequency granularity can be changed: power of two or one single clock cycle.
- SPI enable generation programmable
- SPI enable with programmable polarity
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Master / Slave modes
- Master multichannel mode:
  - SPI interface provides supports for up to four SPI channels
  - SPI word Transmit / Receive slot assignment based on round robin arbitration
  - SPI configuration per channel (clock definition, enable polarity and word width)
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes
  - Flexible I/O port controls per channel
  - Programmable clock granularity
- Independent DMA requests (read/write) per channel

- Single interrupt line for multiple interrupt source events
- 32-bit-wide bus, for system configuration and data transfer
- Programmable delay before the first SPI word transmitted
- No dead cycle between two successive words in slave mode
- Multiple SPI word access with a channel using a FIFO enabled
- Programmable timing control between chip select and external clock generation
- Support DMA providing 256 bit aligned addresses when FIFO is used
- Built-in FIFO available for a single channel. FIFO size of up to 64 bytes is supported.

16.2 Architecture

16.2.1 SPI Interface

This section lists the name and description of the SPI interface used for connection to external SPI compliant devices. SPI has a total of seven external SPI signals shown in Table 16-1.

Table 16-1. SPI Interface Pins

Pin	Type	Description
SPI_SCLK	I/O	SPI serial clock (output when master, input when slave)
SPI_D[0]	I/O	Can be configured as either input or output (MOSI or MISO)
SPI_D[1]	I/O	Can be configured as either input or output (MOSI or MISO)
$\overline{\text{SPI\_SCS[0]}}$	I/O	SPI chip select 0 output when master, input when slave (active low)
$\overline{\text{SPI\_SCS[1]}}$	I/O	SPI chip select 1 output when master, input when slave (active low)
$\overline{\text{SPI\_SCS[2]}}$	I/O	SPI chip select 2 output when master, input when slave (active low)
$\overline{\text{SPI\_SCS[3]}}$	I/O	SPI chip select 3 output when master, input when slave (active low)

16.2.2 SPI Transmission

This section describes the transmissions supported by SPI. The SPI protocol is a synchronous protocol that allows a master device to initiate serial communication with a slave device. Data is exchanged between these devices. A slave select line ($\overline{\text{SPI\_SCS[n]}}$) can be used to allow selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities. Connected to multiple external devices, SPI exchanges data with a single SPI device at a time through two main modes:

- Two data pins interface mode. (See Section 16.2.2.1)
- Single data pin interface mode (recommended for half-duplex transmission). (See Section 16.2.2.2)

The flexibility of SPI allows exchanging data with several formats through programmable parameters described in Section 16.2.2.3.

16.2.2.1 Two Data Pins Interface Mode

The two data pins interface mode, allows a full duplex SPI transmission where data is transmitted (shifted out serially) and received (shifted in serially) simultaneously on separate data lines SPI_D[0] and SPI_D[1]. Data leaving the master exits on transmit serial data line also known as MOSI: MasterOutSlaveIn. Data leaving the slave exits on the receive data line also known as MISO: MasterInSlaveOut.

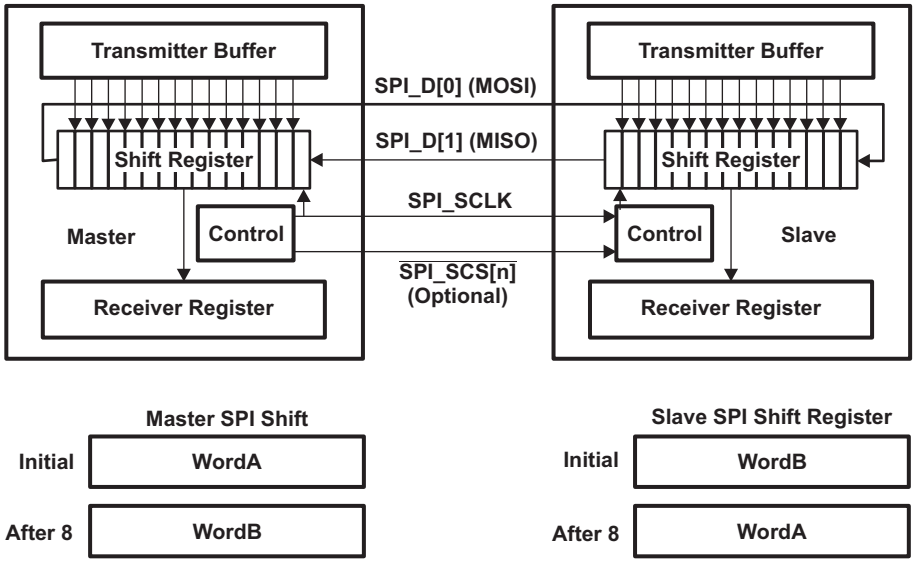
SPI has a unified SPI port control: SPI_D[1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

The serial clock (SPI_SCLK) synchronizes shifting and sampling of the information on the two serial data lines (SPI_D[1:0]). Each time a bit is transferred out from the Master, one bit is transferred in from Slave.

Figure 16-2 shows an example of a full duplex system with a Master device on the left and a Slave device on the right. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the master to the slave. At the same time, the WordB has been transferred from the slave to the master.

When referring to the master device, the control block transmits the clock SPI_SCLK and the enable signal ($\overline{\text{SPI\_SCS[n]}}$) (optional depends on MCSPI_MODULECTRL[PIN34] bit field).

Figure 16-2. SPI Full-Duplex Transmission



16.2.2.2 Single Data Pin Interface Mode

In single data pin interface mode, under software control, a single data line is used to alternatively transmit and receive data (Half duplex transmission).

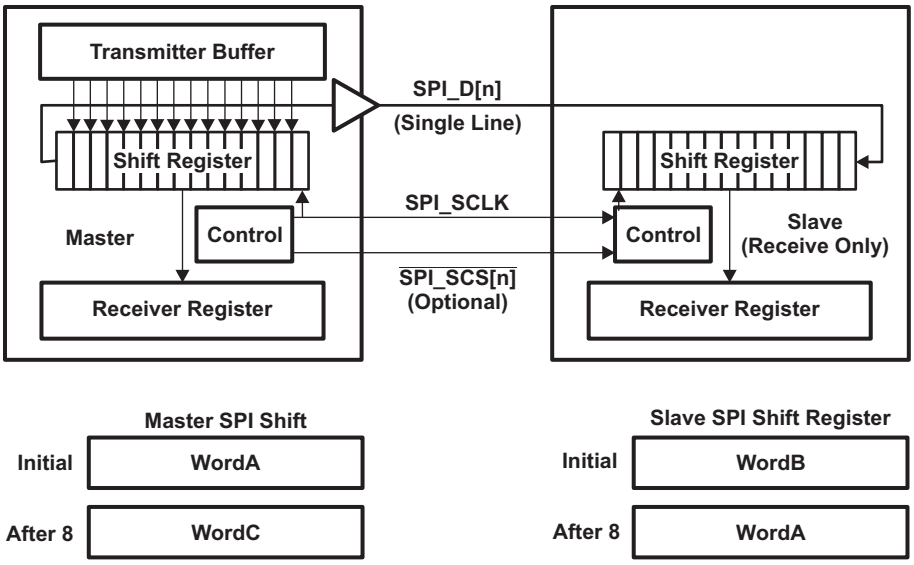
SPI has a unified SPI port control: SPI_D[1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

As for a full duplex transmission, the serial clock (SPI_SCLK) synchronizes shifting and sampling of the information on the single serial data line.

16.2.2.2.1 Example With a Receive-Only Slave

Figure 16-3 shows a half duplex system with a Master device on the left and a receive-only Slave device on the right. Each time a bit is transferred out from the Master, one bit is transferred in the Slave. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the master to the slave.

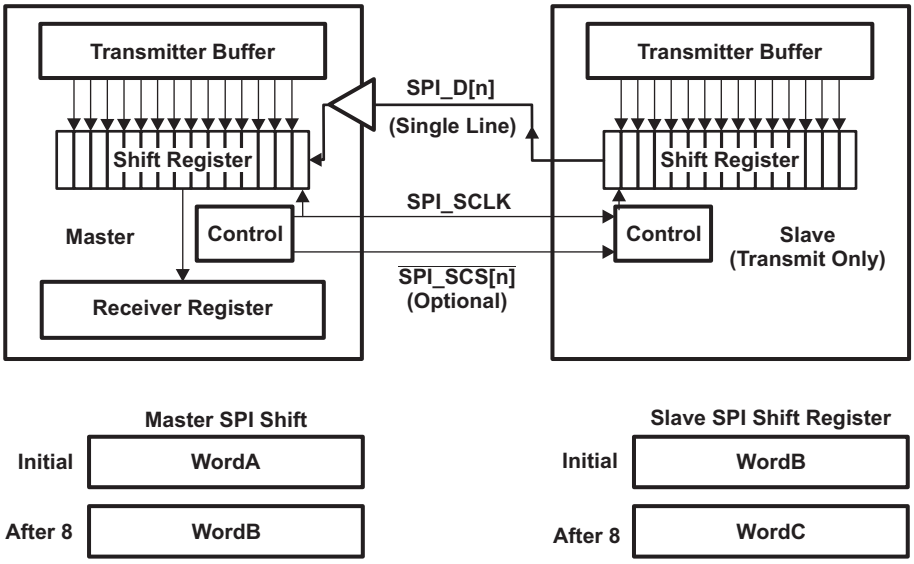
Figure 16-3. SPI Half-Duplex Transmission (Receive-only Slave)



16.2.2.2.2 Example With a Transmit-Only Slave

Figure 16-4 shows a half duplex system with a Master device on the left and a transmit-only Slave device on the right. Each time a bit is transferred out from the Slave, one bit is transferred in the Master. After 8 cycles of the serial clock SPI_SCLK, the WordA has been transferred from the slave to the master.

Figure 16-4. SPI Half-Duplex Transmission (Transmit-Only Slave)



16.2.2.3 Transfer Formats

This section describes the transfer formats supported by SPI.

The flexibility of SPI allows setting the parameters of the SPI transfer:

- SPI word length
- SPI enable generation programmable
- SPI enable assertion
- SPI enable polarity
- SPI clock frequency
- SPI clock phase
- SPI clock polarity

The consistency between SPI word length, clock phase and clock polarity of the master SPI device and the communicating slave device remains under software responsibility.

16.2.2.3.1 Programmable Word Length

SPI supports any SPI word from 4 to 32 bits long.

The SPI word length can be changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

16.2.2.3.2 Programmable SPI Enable Generation

SPI is able to generate or not the SPI enable, if management of chip select is de-asserted a point to point connection is mandatory. Only a single master of slave device can be connected to the SPI bus.

16.2.2.3.3 Programmable SPI Enable ($\overline{\text{SPI\_SCS[n]}}$)

The polarity of the $\overline{\text{SPI\_SCS[n]}}$ signals is programmable. $\overline{\text{SPI\_SCS[n]}}$ signals can be active high or low.

The assertion of the $\overline{\text{SPI\_SCS[n]}}$ signals is programmable: $\overline{\text{SPI\_SCS[n]}}$ signals can be manually asserted or can be automatically asserted.

Two consecutive words for two different slave devices may go along with active $\overline{\text{SPI\_SCS[n]}}$ signals with different polarity.

16.2.2.3.4 Programmable SPI Clock (SPI_SCLK)

The phase and the polarity of the SPI serial clock are programmable when SPI is a SPI master device or a SPI slave device. The baud rate of the SPI serial clock is programmable when it is a SPI master.

When SPI is operating as a slave, the serial clock SPI_SCLK is an input from the master.

16.2.2.3.5 Bit Rate

In Master Mode, an internal reference clock CLKSPIREF is used as an input of a programmable divider to generate bit rate of the serial clock SPI_SCLK. Granularity of this clock divider can be changed.

16.2.2.3.6 Polarity and Phase

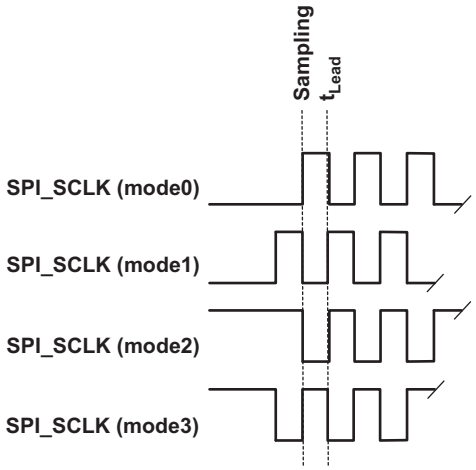
SPI supports four sub-modes of the SPI format transfer that depend on the polarity (POL) and the phase (PHA) of the SPI serial clock (SPI_SCLK). Table 16-2 and Figure 16-5 show a summary of the four sub-modes. Software selects one of four combinations of serial clock phase and polarity.

Two consecutive SPI words for two different slave devices may go along with active SPI_SCLK signal with different phase and polarity.

Table 16-2. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	mode0	SPI_SCLK active high and sampling occurs on the rising edge.
0	1	mode1	SPI_SCLK active high and sampling occurs on the falling edge.
1	0	mode2	SPI_SCLK active low and sampling occurs on the falling edge.
1	1	mode3	SPI_SCLK active low and sampling occurs on the rising edge.

Figure 16-5. Phase and Polarity Combinations



16.2.2.3.7 Transfer Format With PHA = 0

This section describes the concept of a SPI transmission with the SPI mode0 and the SPI mode2.

In the transfer format with PHA = 0, $\overline{\text{SPI\_SCS[n]}}$ is activated a half cycle of SPI_SCLK ahead of the first SPI_SCLK edge.

In both master and slave modes, SPI drives the data lines at the time of $\overline{\text{SPI\_SCS[n]}}$ is asserted.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines , the first bit of SPI word is valid a half cycle of SPI_SCLK after the $\overline{\text{SPI\_SCS[n]}}$ assertion.

Therefore, the first edge of the SPI_SCLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPI_SCLK edge, the received data bit is shifted into the shift register, and a new data bit is transmitted on the serial data line.

This process continues for a total of pulses on the SPI_SCLK line defined by the SPI word length programmed in the master device, with data being latched on odd numbered edges and shifted on even numbered edges.

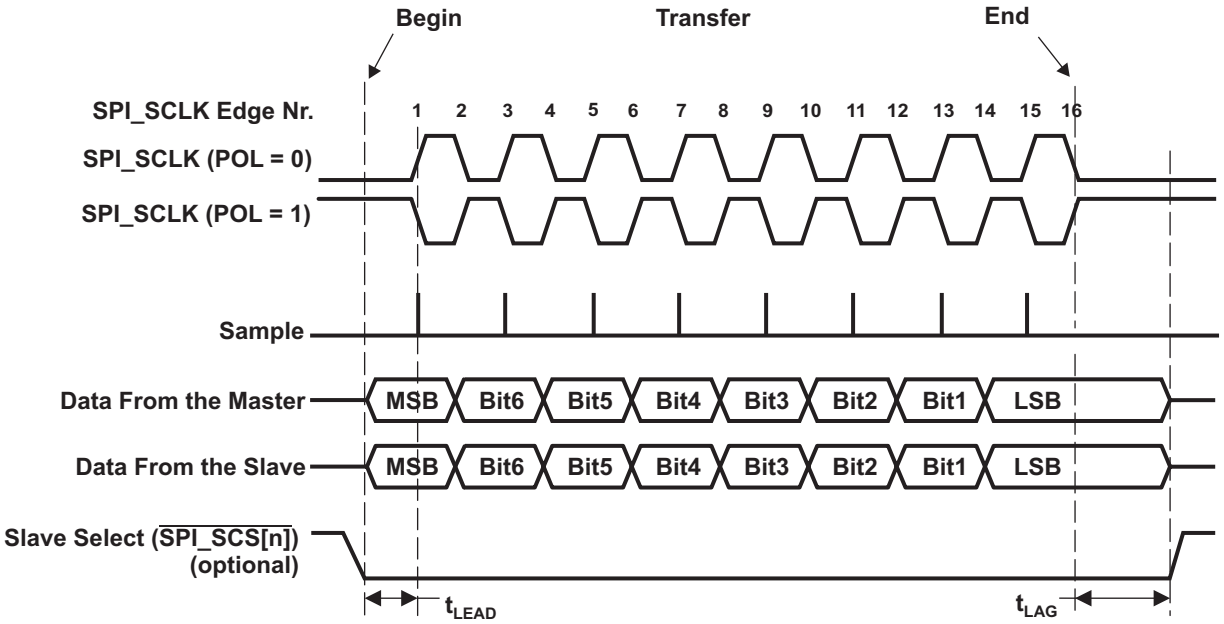
Figure 16-6 is a timing diagram of a SPI transfer for the SPI mode0 and the SPI mode2, when SPI is master or slave, with the frequency of SPI_SCLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements.

When SPI is in slave mode, if the $\overline{\text{SPI\_SCS[n]}}$ line is not de-asserted between successive transmissions then the content of the Transmitter register is not transmitted, instead the last received SPI word is transmitted.

In master mode, the $\overline{\text{SPI\_SCS[n]}}$ line must be negated and reasserted between each successive SPI word. This is because the slave select pin freezes the data in its shift register and does not allow it to be altered if PHA bit equals 0.

In 3-pin mode without using the $\overline{\text{SPI\_SCS[n]}}$ signal, the controller provides the same waveform but with $\overline{\text{SPI\_SCS[n]}}$ forced to low state. In this mode, $\overline{\text{SPI\_SCS[n]}}$ is useless.

Figure 16-6. Full Duplex Single Transfer Format with PHA = 0



16.2.2.3.8 Transfer Format With PHA = 1

This section describes SPI full duplex transmission with the SPI mode1 and the SPI mode 3.

In the transfer format with PHA = 1, $\overline{\text{SPI\_SCS[n]}}$ is activated a delay (t_{Lead}) ahead of the first SPI_SCLK edge.

In both master and slave modes, SPI drives the data lines on the first SPI_SCLK edge.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines , the first bit of SPI word is valid on the next SPI_SCLK edge, a half cycle of SPI_SCLK later. It is the sampling edge for both the master and slave.

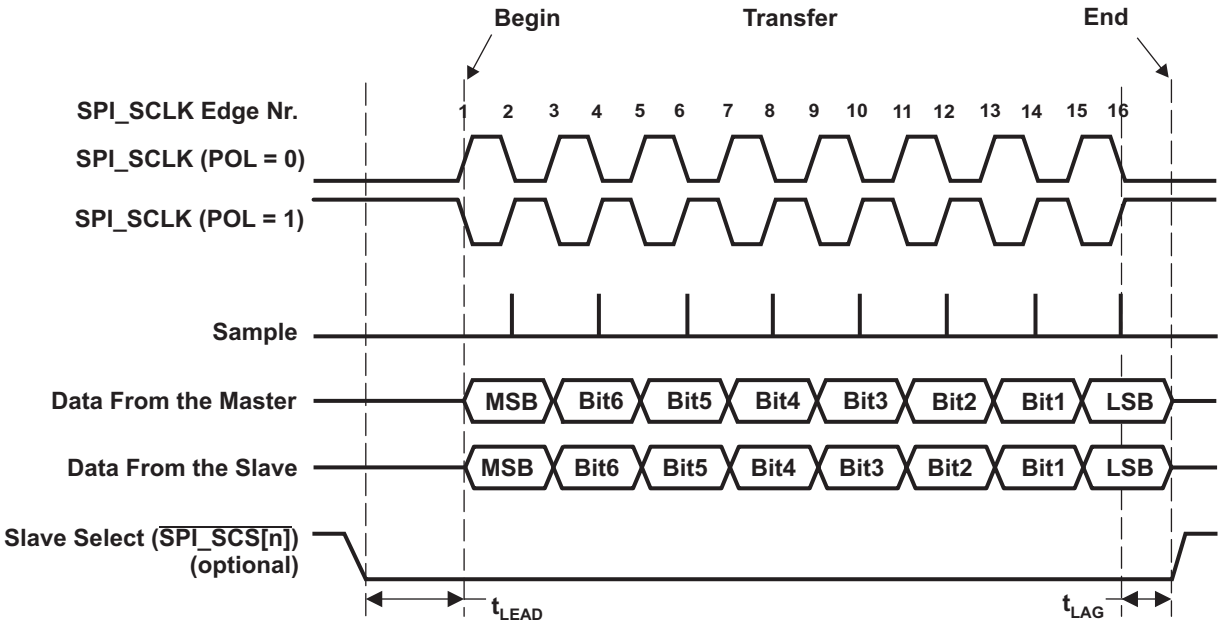
When the third edge occurs, the received data bit is shifted into the shift register. The next data bit of the master is provided to the serial input pin of the slave.

This process continues for a total of pulses on the SPI_SCLK line defined by the word length programmed in the master device, with data being latched on even numbered edges and shifted on odd numbered edges.

Figure 16-7 is a timing diagram of a SPI transfer for the SPI mode1 and the SPI mode3, when SPI is master or slave, with the frequency of SPI_SCLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements.

The $\overline{\text{SPI\_SCS[n]}}$ line may remain active between successive transfers. In 3-pin mode without using the $\overline{\text{SPI\_SCS[n]}}$ signal, the controller provides the same waveform but with $\overline{\text{SPI\_SCS[n]}}$ forced to low state. In this mode, $\overline{\text{SPI\_SCS[n]}}$ is useless.

Figure 16-7. Full Duplex Single Transfer Format With PHA = 1



16.2.3 Master Mode

SPI is in master mode when the MS bit of the register MCSPI_MODULCTRL is cleared.

In master mode SPI supports multi-channel communication with up to four independent SPI communication channel contexts. SPI initiates a data transfer on the data lines (SPI_D[1:0]) and generates clock (SPI_SCLK) and control signals ($\overline{\text{SPI\_SCS[n]}}$) to a single SPI slave device at a time.

16.2.3.1 Dedicated Resources Per Channel

In the following sections, the letter “I” indicates the channel number that can be 0, 1, 2, or 3. Each channel has the following dedicated resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH(I)CTRL. Disabling the channel, outside data word transmission, remains under user responsibility.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH(I)STAT is set.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH(I)STAT is set.
- A fixed SPI ENABLE line allocation ($\overline{\text{SPI\_SCS[I]}}$ port for channel I), SPI enable management is optional.
- Its own communication configuration with the following parameters via the register (I)CONF
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - SPI_SCS[n] polarity, programmable with the bit EPOL.
  - SPI_SCS[n] kept active between words, programmable with the bit FORCE.
  - Turbo mode, programmable with the bit TURBO.
  - SPI_SCLK frequency, programmable with the bit CLKD, the granularity of clock division can be changed using CLKG bit, the clock ratio is then concatenated with MCSPI_CHCTRL[EXTCLK] value.
  - SPI_SCLK polarity, programmable with the bit POL
  - SPI_SCLK phase, programmable with the bit PHA.
  - Start bit extension enable, programmable with the bit SBE to support LoSSI transfer specification.
  - Start bit polarity, programmable with the bit SBPOL
  - Use a FIFO Buffer or not( ), programmable with FFER and FFEW, depending on transfer mode TRM.
- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of SPI. The DMA requests are enabled with the bits DMAR and DMAW.
- Three interrupts events

The transfers will use the latest loaded parameters of the register (I)CONF.

The configuration parameters SPI_SCS[n] polarity, Turbo mode, SPI_SCLK phase and SPI_SCLK polarity can be loaded in the (I)CONF register only when the channel is disabled. The user has the responsibility to change the other parameters of the (I)CONF register when no transfer occurs on the SPI interface.

16.2.3.2 Interrupt Events in Master Mode

In master mode, the interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt event related to the receiver register state is RX_full.

16.2.3.2.1 TX_empty

The event TX_empty is activated when a channel is enabled and its transmitter register becomes empty (transient event). Enabling channel automatically raises this event, except for the Master receive only mode. (See Section 16.2.3.5). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be loaded to remove the source of the interrupt and the TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source) . (See Section 16.2.5).

When FIFO is enabled, no new TX_empty event will be asserted as soon as CPU has not performed the number of write into transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of CPU to perform the right number of writes.

16.2.3.2.2 TX_underflow

The event TX_underflow is activated when the channel is enabled and if the transmitter register or FIFO is empty (not updated with new data) at the time of shift register assignment.

The TX_underflow is a harmless warning in master mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

To avoid having TX_underflow event the Transmitter register must be loaded seldom.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

Note: Be careful, when more than one channel have a FIFO enable bit field FFER or FFEW set, the module force no use of FIFO, software must take care that only one enabled channel is configured to use the FIFO buffer.

16.2.3.2.3 RX_ full

The event RX_full is activated when channel is enabled and receiver register becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFER] set to 1), the RX_full is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source).

When FIFO is enabled, no new RX_full event will be asserted as soon as CPU has not performed the number of read into receive register defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of CPU to perform the right number of reads.

16.2.3.2.4 End of Word Count

The event end of word count (EOW) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[WCNT] is not reloaded and channel re-enabled.

End of Word interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.2.3.3 Master Transmit and Receive Mode

This mode is programmable per channel (bits TRM of the register (I)CONF).

The channel access to the shift registers, for transmission/reception, is based on its transmitter and receiver register state and round robin arbitration.

The channel that meets the rules below is included in the round robin list of already active channels scheduled for transmission and/or reception. The arbiter skips the channel that does not meet the rules and search for the next following enabled channel, in rotation.

Rule 1: Only enabled channels (bit EN of the register MCSPI_CH(I)CTRL), can be scheduled for transmission and/or reception.

Rule 2: An enabled channel can be scheduled if its transmitter register is not empty (bit TXS of the register MCSPI_CH(I)STAT) or its FIFO is not empty in case of buffer use for the corresponding channel (bit FFE of the register MCSPI_CH(I)STAT), that is updated with new data, at the time of shift register assignment. If the transmitter register or FIFO is empty, at the time of shift register assignment, the event TX_underflow is activated and the next enabled channel with new data to transmit is scheduled. (See also transmit only mode).

Rule 3: An enabled channel can be scheduled if its receive register is not full (bit RXS of the register MCSPI_CH(I)STAT)) or its FIFO is not full in case of buffer use for the corresponding channel (bit FFF of the register MCSPI_CH(I)STAT) at the time of shift register assignment. (See also receive only mode). Therefore the receiver register of FIFO cannot be overwritten. The RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the updated transmitter register of the next scheduled channel is loaded into the shift register. This bit is meaningless when using the Buffer for this channel. The serialization (transmit and receive) starts according to the channel communication configuration. On serialization completion the received data is transferred to the channel receive register.

The built-in FIFO is available in this mode and can be configured in one data direction Transmit or Receive, then the FIFO is seen as a unique FFNBYTE bytes buffer, or it can also be configured in both data direction Transmit and Receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management, in this last case the definition of AEL and AFL levels is based on FFNBYTE/2 bytes and is under CPU responsibility.

16.2.3.4 Master Transmit-Only Mode

This mode avoids the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

The master transmit only mode is programmable per channel (bits TRM of the register (I)CONF).

In master transmit only mode, transmission starts after data is loaded into the transmitter register.

Rule 1 and **Rule 2**, defined in Section 16.2.3.3, are applicable in this mode.

Rule 3, defined in Section 16.2.3.3, is not applicable: In master transmit only mode, the receiver register or FIFO state “full” does not prevent transmission, and the receiver register is always overwritten with the new SPI word. This event in the receiver register is not significant when only transmission is meaningful. So, the RX_overflow bit, in the MCSPI_IRQSTATUS register is never set in this mode.

The SPI module automatically disables the RX_full interrupt status. The corresponding interrupt request and DMA Read request are not generated in master transmit only mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFEW bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

16.2.3.5 Master Receive-Only Mode

This mode avoids the CPU to refill the transmitter register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (bits TRM of the register (I)CONF).

The master receive only mode enables channel scheduling only on empty state of the receiver register.

Rule 1 and **Rule 3**, defined in Section 16.2.3.3, are applicable in this mode.

Rule 2, defined in Section 16.2.3.3, is not applicable: In master receive only mode, after the first loading of the transmitter register of the enabled channel, the transmitter register state is maintained as full. The content of the transmitter register is always loaded into the shift register, at the time of shift register assignment. So, after the first loading of the transmitter register, the bits TX_empty and TX_underflow, in the MCSPI_IRQSTATUS register are never set in this mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

16.2.3.6 Single-Channel Master Mode

When the SPI is configured as a master device with a single enabled channel, the assertion of the SPIM_CSX signal can be controlled in two different ways:

- In 3 pin mode : MCSPI_MODULCTRL[1] PIN34 and MCSPI_MODULCTRL[0] SINGLE bits are set to 1, the controller transmit SPI word as soon as transmit register or FIFO is not empty.
- In 4 pin mode : MCSPI_MODULCTRL[1] PIN34 bit is cleared to 0 and MCSPI_MODULCTRL[0] SINGLE bit is set to 1, SPI_SCS[n] assertion/deassertion controlled by Software. (See Section 16.2.3.6.1) using the MCSPI_CHxCONF[20] FORCE bit.

16.2.3.6.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

16.2.3.6.2 Keep $\overline{\text{SPI\_SCS[n]}}$ Active Mode (Force $\overline{\text{SPI\_SCS[n]}}$)

Continuous transfers are manually allowed by keeping the $\overline{\text{SPI\_SCS[n]}}$ signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the $\overline{\text{SPI\_SCS[n]}}$ line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the $\overline{\text{SPI\_SCS[n]}}$ active mode is supported when:

- A single channel is used (MCSPI_MODULCTRL[Single] bit is set to 1).
- Transfer parameters of the transfer are loaded in the configuration register (MCSPI_CH(I)CONF) in the appropriate channel.

  The state of the $\overline{\text{SPI\_SCS[n]}}$ signal is programmable.
  - Writing 1 into the bit FORCE of the register MCSPI_CH(I)CONF drives high the $\overline{\text{SPI\_SCS[n]}}$ line when MCSPI_CHCONF(I)[EPOL] is cleared to 0, and drives it low when MCSPI_CHCONF(I)[EPOL] is set.
  - Writing 0 into the bit FORCE of the register MCSPI_CH(I)CONF drives low the $\overline{\text{SPI\_SCS[n]}}$ line when MCSPI_CHCONF(I)[EPOL] is cleared to 0, and drives it high when MCSPI_CHCONF(I)[EPOL] is set.
- A single channel is enabled (MCSPI_CH(I)CTRL[En] set to 1) . The first enabled channel activates the $\overline{\text{SPI\_SCS[n]}}$ line.

Once the channel is enabled, the SPI_SCS[n] signal is activated with the programmed polarity.

As in multi-channel master mode, the start of the transfer depends on the status of the transmitter register, the status of the receiver register and the mode defined by the bits TRM in the configuration register (transmit only, receive only or transmit and receive) of the enabled channel.

The status of the serialization completion of each SPI word is given by the bit EOT of the register MCSPI_CH(I)STAT. The bit RX_full in the MCSPI_IRQSTATUS register is set when a received data is loaded from the shift register to the receiver register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPI_SCS[n] signal is activated the user must insure that the configuration is changed only between SPI words, in order to avoid corrupting the current transfer.

NOTE: The SPI_SCS[n] polarity, the SPI_SCLK phase and SPI_SCLK polarity must not be modified when the SPI_SCS[n] signal is activated. The Transmit/Receive mode, programmable with the bit TRM can be modified only when the channel is disabled. The channel can be disabled and enabled while the SPI_SCS[n] signal is activated.

The delay between SPI words that requires the connected SPI slave device to switch from one configuration (Transmit only for instance) to another (receive only for instance) must be handled under software responsibility.

At the end of the last SPI word, the channel must be deactivated (MCSPI_CH(I)CTRL[En] is cleared to 0) and the SPI_SCS[n] can be forced to its inactive state (MCSPI_CH(I)CONF[Force]).

Figure 16-8 and Figure 16-9 show successive transfers with SPI_SCS[n] kept active low with a different configuration for each SPI word in respectively single data pin interface mode and two data pins interface mode. The arrows indicate when the channel is disabled before a change in the configuration parameters and enabled again.

Figure 16-8. Continuous Transfers With SPI_SCS[n] Maintained Active (Single-Data-Pin Interface Mode)

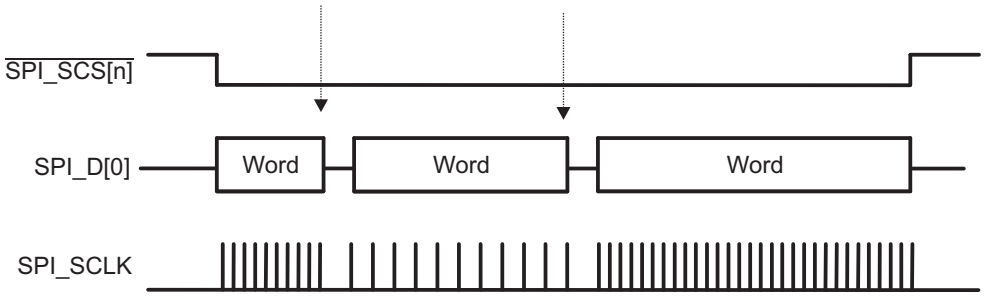


Figure 16-9. Continuous Transfers With SPI_SCS[n] Maintained Active (Dual-Data-Pin Interface Mode)

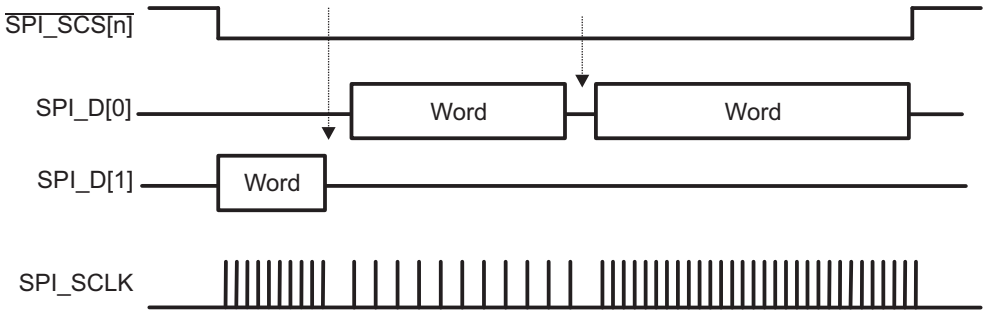


NOTE: The turbo mode is also supported for the Keep $\overline{\text{SPI\_SCS[n]}}$ active mode when the following conditions are met:

- A single channel will be explicitly used (MCSPI_MODULCTRL[Single] bit is set to 1).
- The turbo mode is enabled in the configuration of the channel (Turbo bit of the register (i)CONF).

16.2.3.6.3 Turbo Mode

The purpose of the Turbo mode is to improve the throughput of the SPI interface when a single channel is enabled, by allowing transfers until the shift register and the receiver register are full.

This mode is programmable per channel (bit Turbo of the register (I)CONF). When several channels are enabled, the bit Turbo of the registers MCSPI_CH(I)CONF has no effect, and the channel access to the shift registers remains as described in Section 16.2.3.3.

In Turbo mode, **Rule 1** and **Rule 2** defined in Section 16.2.3.3 are applicable, but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(I)STAT) at the time of shift register assignment until the shift register is full.

The receiver register cannot be overwritten in turbo mode. In consequence the RX_overflow bit, in MCSPI_IRQSTATUS register is never set in this mode.

16.2.3.7 Start Bit Mode

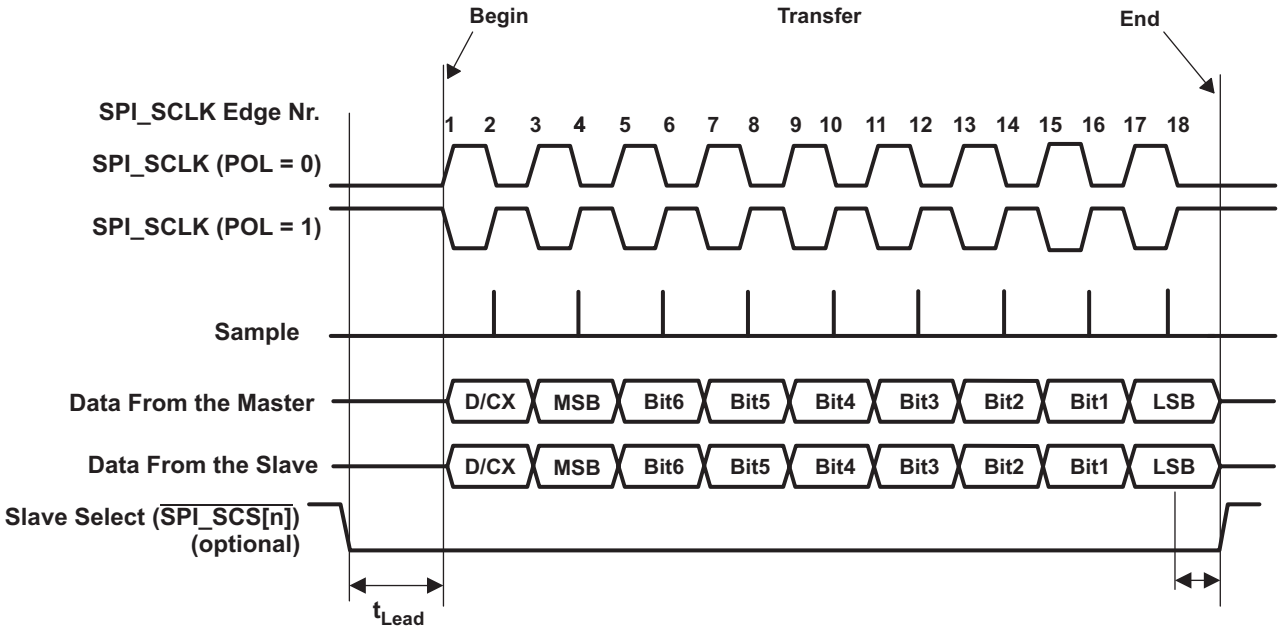
The purpose of the start bit mode is to add an extended bit before the SPI word transmission specified by word length WL (see Figure 16-10). This feature is only available in master mode. This mode is compliant with write command/data format as specified in LoSSI protocol.

This mode is programmable per channel (Start bit enable (SBE) bit of the register MCSPI_CH(I)CONF).

The polarity of the extended bit is programmable per channel and it indicates whether the next SPI word must be handled as a command when SBPOL is cleared to 0 or as a data or a parameter when SBPOL is set to 1. Moreover, start bit polarity SBPOL can be changed dynamically during start bit mode transfer without disabling the channel for reconfiguration, in this case you have the responsibility to configure the SBPOL bit before writing the SPI word to be transmitted in TX register.

The start bit mode could be used at the same time as turbo mode and/or manual chip select mode. In this case, only one channel could be used, no round-robin arbitration is possible.

Figure 16-10. Extended SPI Transfer With Start Bit PHA = 1

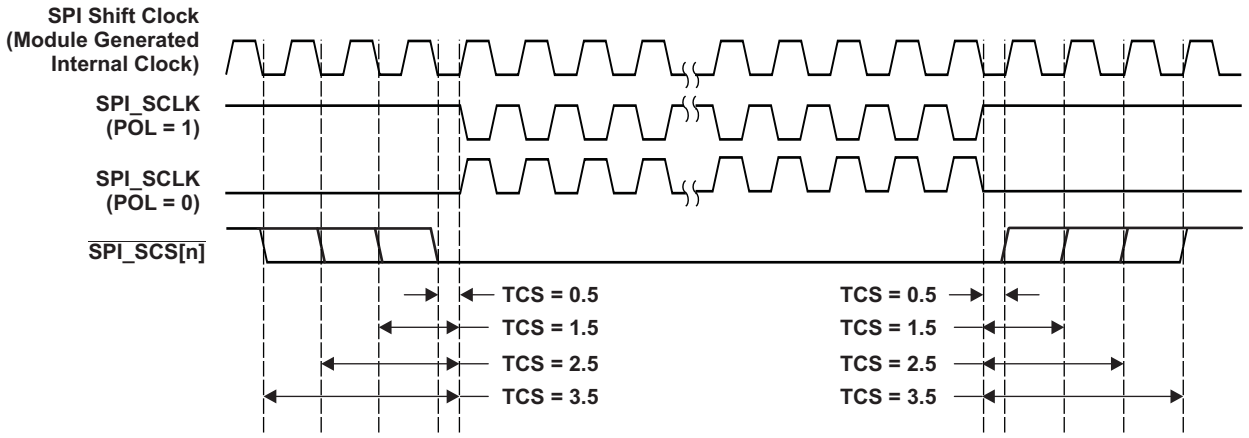


16.2.3.8 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (FORCE bit field is cleared to 0), to add a programmable delay between chip select assertion and first clock edge or chip select removal and last clock edge. The option is available only in 4 pin mode MCSPI_MODULCTRL[1] PIN34 is cleared to 0.

This mode is programmable per channel (TCS bit of the register MCSPI_CH(I)CONF). Figure 16-11 shows the chip-select SPI_SCS[n] timing control.

Figure 16-11. Chip-Select SPI_SCS[n] Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

With an odd clock divider ratio which occurs when granularity is one clock cycle, that means that MCSPI_CH(I)CONF[CLKG] is set to 1 and MCSPI_CH(I)CONF[CLKD] has an even value, the clock duty cycle is not 50%, then one of the high level or low level duration is selected to be added to TCS delay.

Table 16-3 summarizes all delays between chip select and first (setup) or last (hold) clock edge.

In 3-pin mode this option is useless, the chip select SPI_SCS[n] is forced to low state.

T_ref = CLKSPIREF period in ns

F_{ratio} = SPI clock division ratio

Table 16-3. Chip Select ↔ Clock Edge Delay Depending on Configuration

Clock Ratio F_{ratio}	Clock Phase PHA	Chip Select ↔ Clock Edge Delay	
		Setup	Hold
1	0	T_ref × (TCS + ½)	T_ref × (TCS + 1)
	1	T_ref × (TCS + 1)	T_ref × (TCS + ½)
Even ≥ 2	x	T_ref × F_{ratio} × (TCS + ½)	T_ref × F_{ratio} × (TCS + ½)
Odd ≥ 3 (only with MCSPI_CH(I)CONF[CLKG] set to 1	0	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]
	1	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]

The clock divider ratio depends on divider granularity MCSPI_CH(I)CONF[CLKG]:

- MCSPI_CH(I)CONF[CLKG] = 0 : granularity is power of 2.
  $F_{ratio} = 2^{MCSPI\_CH(I)CONF[CLKD]}$
- MCSPI_CH(I)CONF[CLKG] = 1 : EXTCLK concatenated with CLKD + 1.
  F_{ratio} = MCSPI_CH(I)CNTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1

16.2.3.9 Clock Ratio Granularity

By default the clock division ratio is defined by the register MCSPI_CH(I)CONF[CLKD] with power of 2 granularity leading to a clock division in range 1 to 32768, in this case the duty cycle is always 50%. With bit MCSPI_CH(I)CONF[CLKG] the clock division granularity can be changed to one clock cycle, in that case the register MCSPI_CH(I)CTRL[EXTCLK] is concatenated with MCSPI_CH(I)CONF[CLKD] to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (MCSPI_CH(I)CONF[CLKG] set to 1), for odd value of clock ratio the clock duty cycle is kept to 50-50 using falling edge of clock reference CLKSPIREF.

Table 16-4. CLKSPIO High/Low Time Computation

Clock Ratio F_{ratio}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{high}_ref	T_{low}_ref
Even ≥ 2	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)
Odd ≥ 3	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)

T_ref = CLKSPIREF period in ns. T_{high}_ref = CLKSPIREF high Time period in ns. T_{low}_ref = CLKSPIREF low Time period in ns. F_{ratio} = SPI clock division ratio

F_{ratio} = MCSPI_CH(I)CTRL[EXTCLK].MCSPI_CH(I)CONF[CLKD] + 1

For odd ratio value the duty cycle is calculated as:

Duty_cycle = ½

Granularity examples: With a clock source frequency of 48 MHz:

Table 16-5. Clock Granularity Examples

MCSPI_CH(I) CTRL	MCSPI_CH(I) CONF	MCSPI_CH(I) CONF		MCSPI_CH(I) CONF	MCSPI_CH(I) CONF	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)

16.2.3.10 FIFO Buffer Management (Optional USEFIFO = 1)

The SPI controller has a built-in FFNBYTE bytes buffer in order to unload DMA or interrupt handler and improve data throughput. The instantiation of this Buffer is optional it depends on a generic parameter USEFIFO, the FIFO is instantiated when it is set to 1. Allowed FIFO depth up to 64 bytes is supported and is defined by generic parameter FFNBYTE. When the FIFO is not instantiated writes in registers MCSPI_XFERLEVEL, MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] have no functional effect, nevertheless read back is allowed to check written value.

This buffer can be used by only one channel at once and is selected by setting MCSPI_CH(I)CONF[FFER] or MCSPI_CH(I)CONF[FFEW] to 1.

If several channel are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length MCSPI_CH(I)CONF[WL] are supported.

Two levels AEL and AFL located in MCSPI_XFERLEVEL register rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in MCSPI_CH(I)CONF[WL]. The number of byte written in the FIFO depends on word length (see Table 16-6).

Table 16-6. FIFO Writes, Word Length Relationship

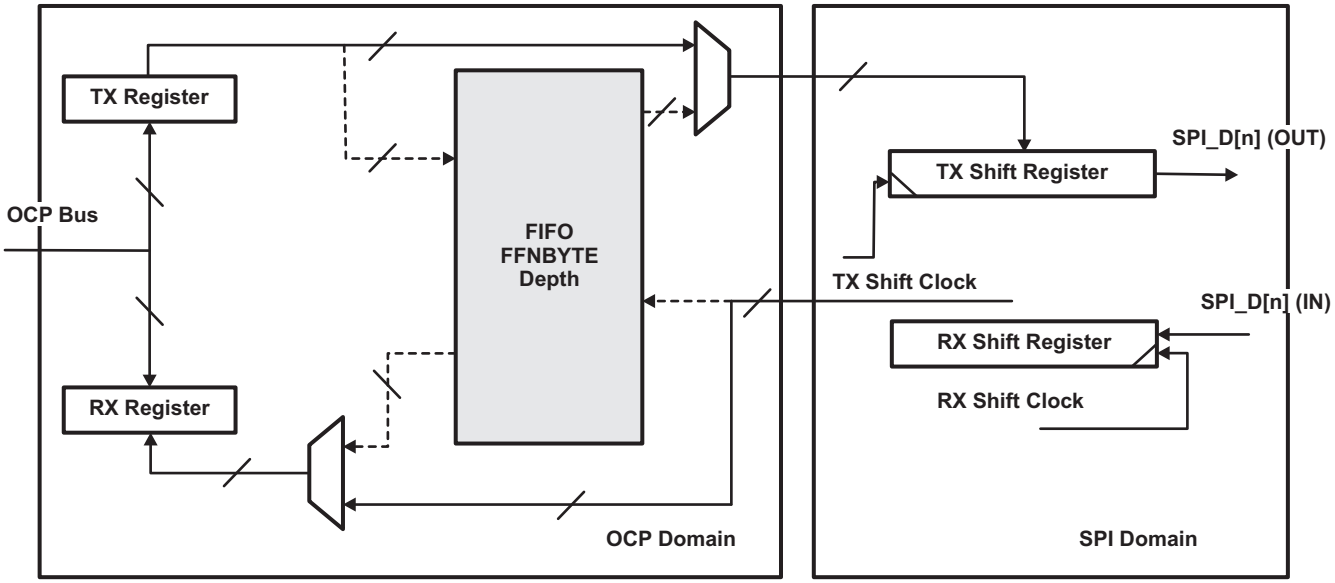
	SPI Word Length WL		
	3 ≤ WL ≤ 7	**8 ≤ WL ≤ 15**	**16 ≤ WL ≤ 31**
Number of byte written in the FIFO	1 byte	2 bytes	4 byte

16.2.3.10.1 Split FIFO

The FIFO can be split into two parts when the module is configured in transmit/receive mode MCSPI_CH(I)CONF[TRM] is cleared to 0 and MCSPI_CH(I)CONF[FFER] and MCSPI_CH(I)CONF[FFEW] asserted. Then system can access a FFNBYTE/2 byte depth FIFO per direction.

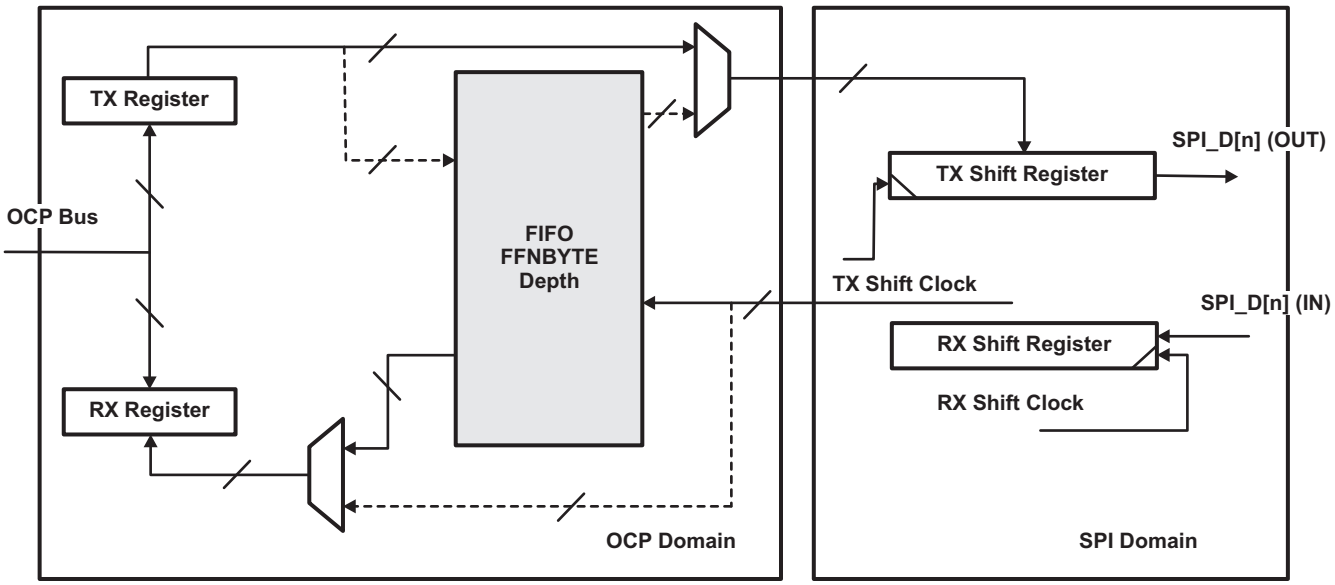
The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

Figure 16-12. Transmit/Receive Mode With No FIFO Used



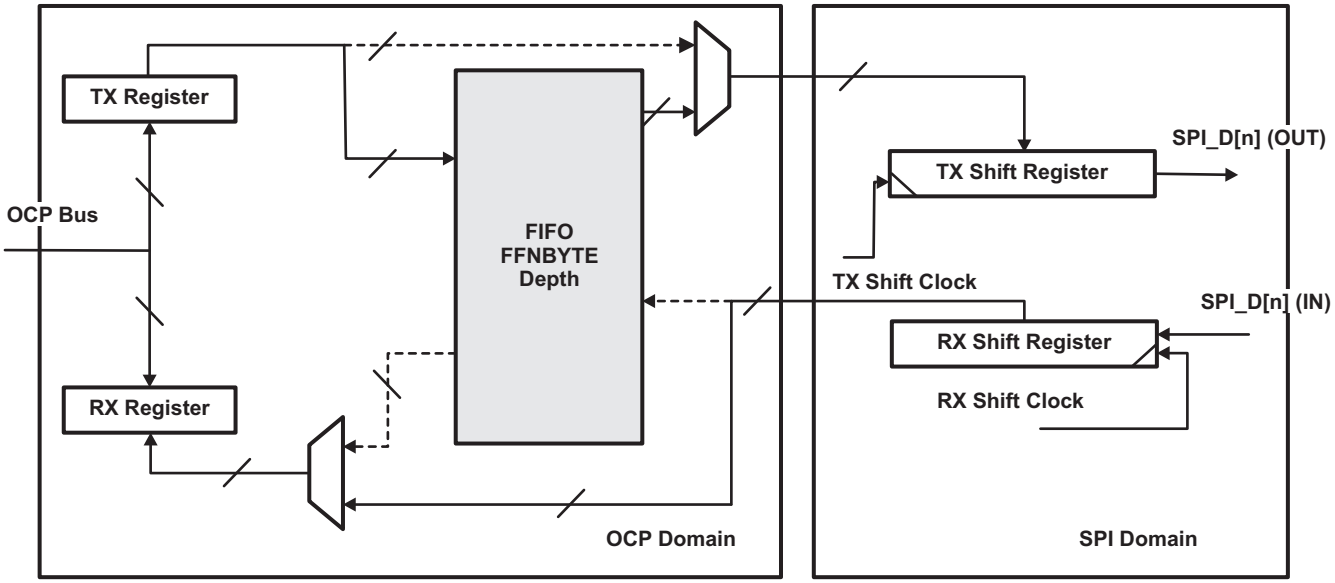
Configuration:
MCSPI_CH(i)CONF[TRM]= 0 (Transmit/receive mode)
MCSPI_CH(i)CONF[FFER] = 0 (FIFO disabled on receive path)
MCSPI_CH(i)CONF[FFEW] = 0 (FIFO disabled on transmit path)

Figure 16-13. Transmit/Receive Mode With Only Receive FIFO Enabled



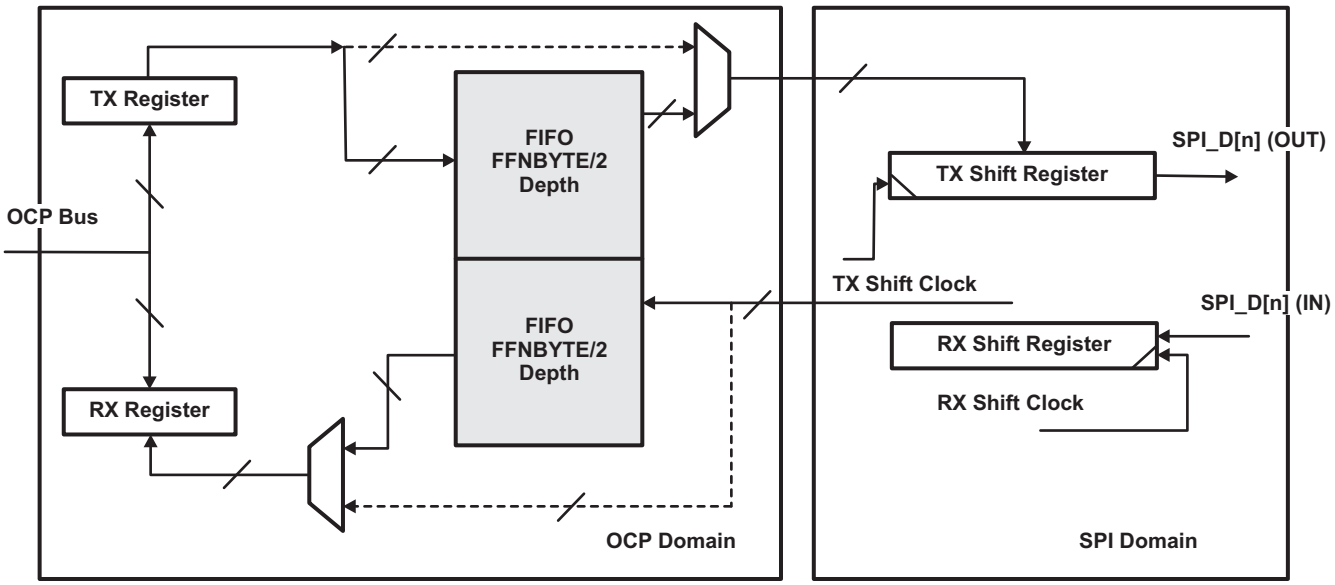
Configuration:
MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
MCSPI_CH(i)CONF[FFEW] = 0 (FIFO disabled on transmit path)

Figure 16-14. Transmit/Receive Mode With Only Transmit FIFO Used



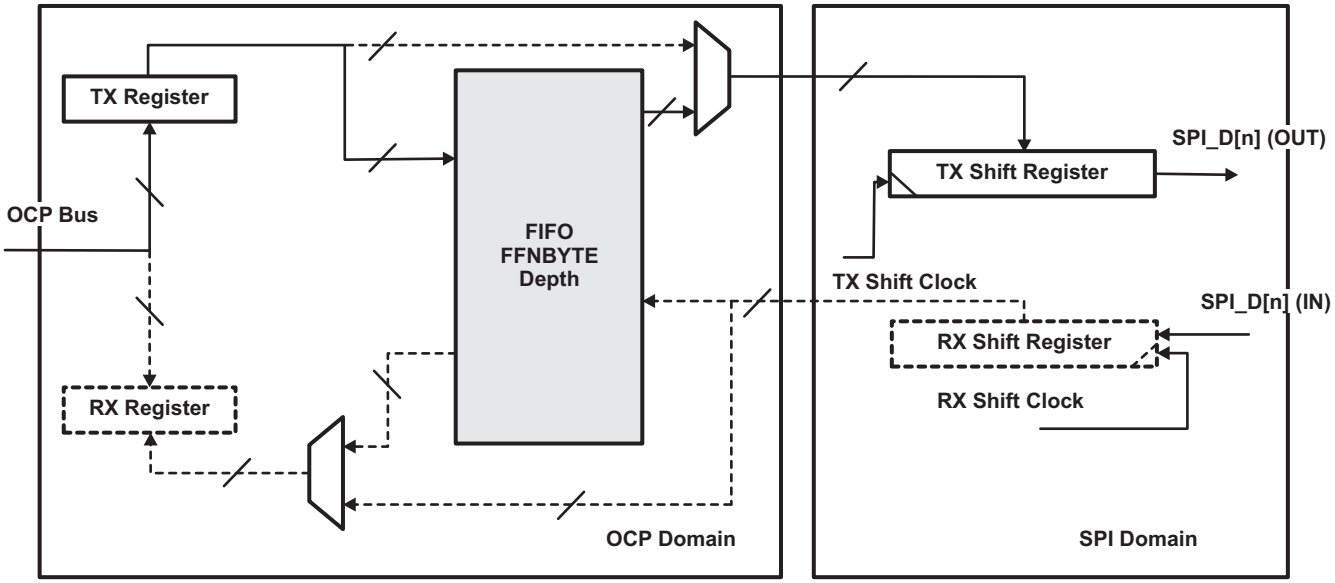
Configuration:
MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
MCSPI_CH(i)CONF[FFER] = 0 (FIFO disabled on receive path)
MCSPI_CH(i)CONF[FFEW] = 1 (FIFO enabled on transmit path)

Figure 16-15. Transmit/Receive Mode With Both FIFO Direction Used



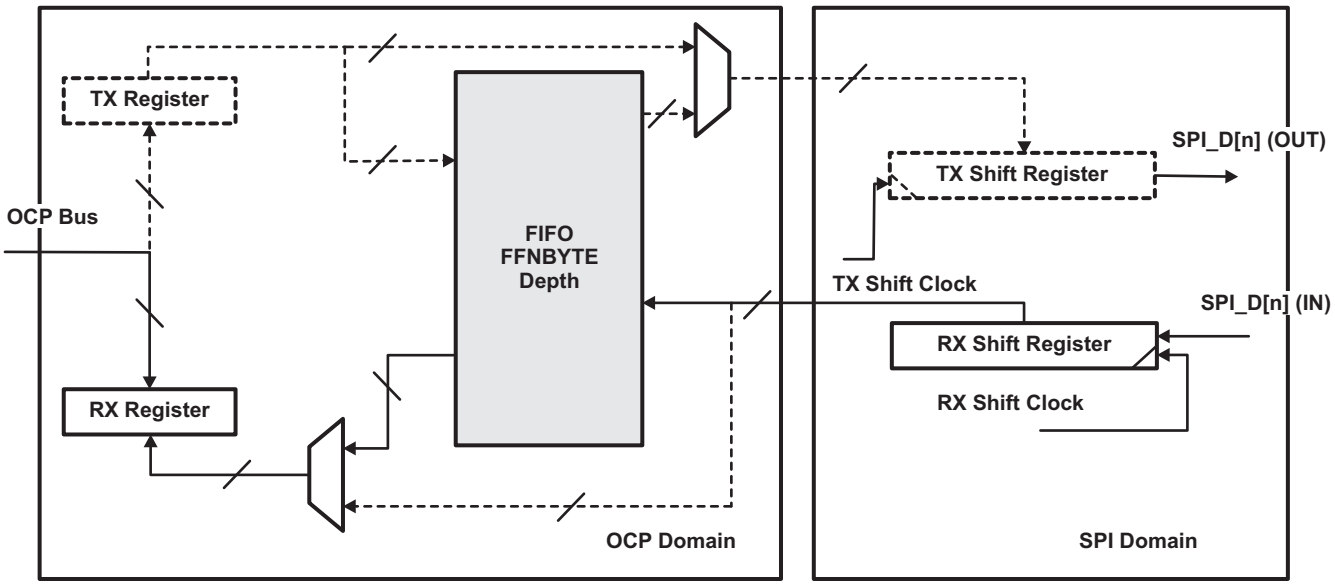
Configuration:
MCSPI_CH(i)CONF[TRM] = 0 (Transmit/receive mode)
MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
MCSPI_CH(i)CONF[FFEW] = 0 (FIFO disabled on transmit path)

Figure 16-16. Transmit-Only Mode With FIFO Used



Configuration:
MCSPI_CH(i)CONF[TRM] = 2h (Transmit-only mode)
MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on transmit path)
MCSPI_CH(i)CONF[FFEW] (not applicable)

Figure 16-17. Receive-Only Mode With FIFO Used



Configuration:
MCSPI_CH(i)CONF[TRM] = 1 (Receive-only mode)
MCSPI_CH(i)CONF[FFER] = 1 (FIFO enabled on receive path)
MCSPI_CH(i)CONF[FFEW] (not applicable)

16.2.3.10.2 Buffer Almost Full

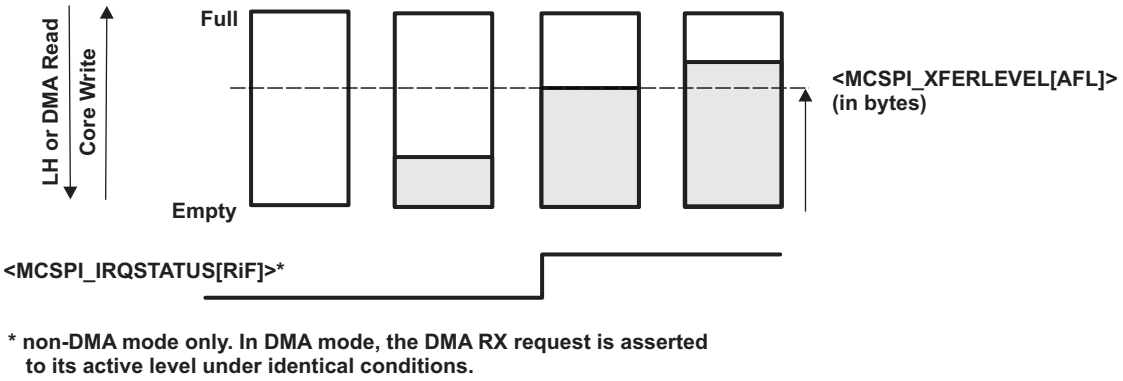
The bit field MCSPI_XFERLEVEL[AFL] is needed when the buffer is used to receive SPI word from a slave (MCSPI_CH(I)CONF[FFER] must be set to 1) and register width depends on the generic parameter FFNBYTE value. It defines the almost full buffer status.

When FIFO pointer reaches this level, an interrupt or a DMA request is sent to the CPU to enable the system to read AFL + 1 bytes from receive register. Be careful, AFL + 1 must correspond to a multiple value of MCSPI_CH(I)CONF[WL].

When DMA is used, the request is de-asserted after the first receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 16-18. Buffer Almost Full Level (AFL)



*** non-DMA mode only. In DMA mode, the DMA RX request is asserted to its active level under identical conditions.**

.

NOTE: SPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RX*n* request is asserted on the same conditions than the SPI_IRQSTATUS RX*n*_FULL flag.

16.2.3.10.3 Buffer Almost Empty

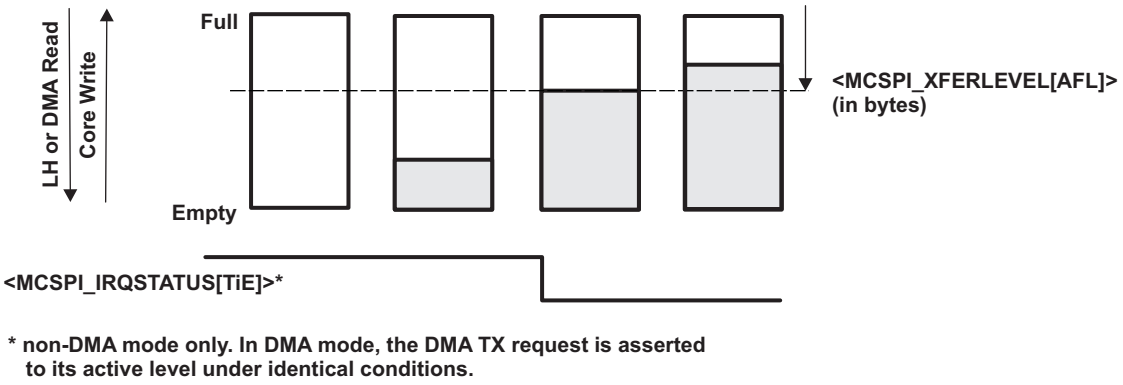
The bit field MCSPI_XFERLEVEL[AEL] is needed when the buffer is used to transmit SPI word to a slave (MCSPI_CH(I)CONF[FFEW] bit must be set to 1) and register width depends on the generic parameter FFNBYTE value. It defines the almost empty buffer status.

When FIFO pointer has not reached this level, an interrupt or a DMA request is sent to the CPU to enable the system to write AEL + 1 bytes to transmit register. Be careful, AEL + 1 must correspond to a multiple value of MCSPI_CH(I)CONF[WL].

When DMA is used, the request is de-asserted after the first transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

Figure 16-19. Buffer Almost Empty Level (AEL)



.

16.2.3.10.4 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the WCNT bit field to define the number of Spi word to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of Spi word transfer. If WNCT is cleared to 0, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user doesn't know how many SPI transfers have been done. For receive transfer, software shall poll the corresponding FFE bit field and read the Receive register to empty the FIFO buffer.

When End Of Word count interrupt is generated, the user can disable the channel and poll on MCSPI_CH(I)STAT[FFE] register to know if SPI word is still there in FIFO buffer and read last words.

NOTE: If the FIFO buffer is enabled, the module is configured to use the WCNT feature in the master mode, and the software uses the TX_EMPTY interrupt to load data into the FIFO, then the WCNT value must be a multiple of the Almost Empty Level (AEL).

16.2.3.10.5 Multiple SPI Word Access

The CPU has the ability to perform multiple SPI word access to the receive or transmit registers within a single 32-bit OCP access by setting the bit field MCSPI_MODULCTRL[MOA] to 1 under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- The bit field MCSPI_MODULCTRL[MOA] is set to 1.
- Only 32-bit OCP access and data width can be performed to receive or transmit registers, for other

kind of access the CPU must de-assert MCSPI_MODULCTRL[MOA] bit fields.

- The Level MCSPI_XFERLEVEL[AEL] and MCSPI_XFERLEVEL[AFL] must be 32-bit aligned , it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI_XFERLEVEL[WCNT] is used it must be configured according to SPI word length.
- The word length of SPI words allows to perform multiple SPI access, that means that MCSPI_CH(I)CONF[WL] < 16

Number of SPI word access depending on SPI word length:

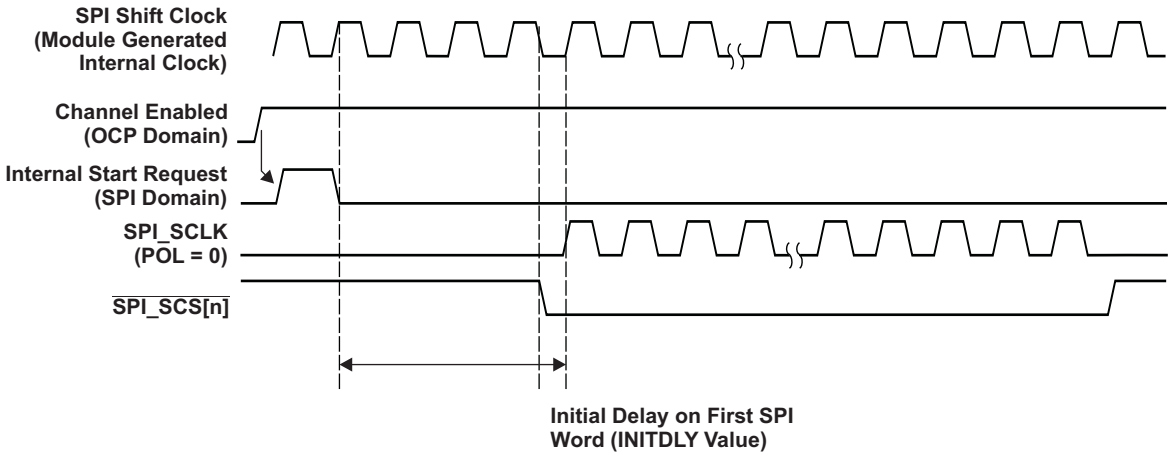
- 3 ≤ WL ≤ 7, SPI word length smaller or equal to byte length, four SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0] = WCNT[1] = 0
- 8 ≤ WL ≤ 15, SPI word length greater than byte or equal to 16-bit length, two SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0] = 0
- 16 ≤ WL multiple SPI word access not applicable.

16.2.3.11 First SPI Word Delayed

The SPI controller has the ability to delay the first SPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first SPI word after SPI channel enabled and first write in Transmit register. It is based on output clock frequency.

This option is meaningful in master mode and single channel mode MCSPI_MODULECTRL[SINGLE] asserted.

Figure 16-20. Master Single Channel Initial Delay



Few delay values are available: No delay, 4/8/16/32 SPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

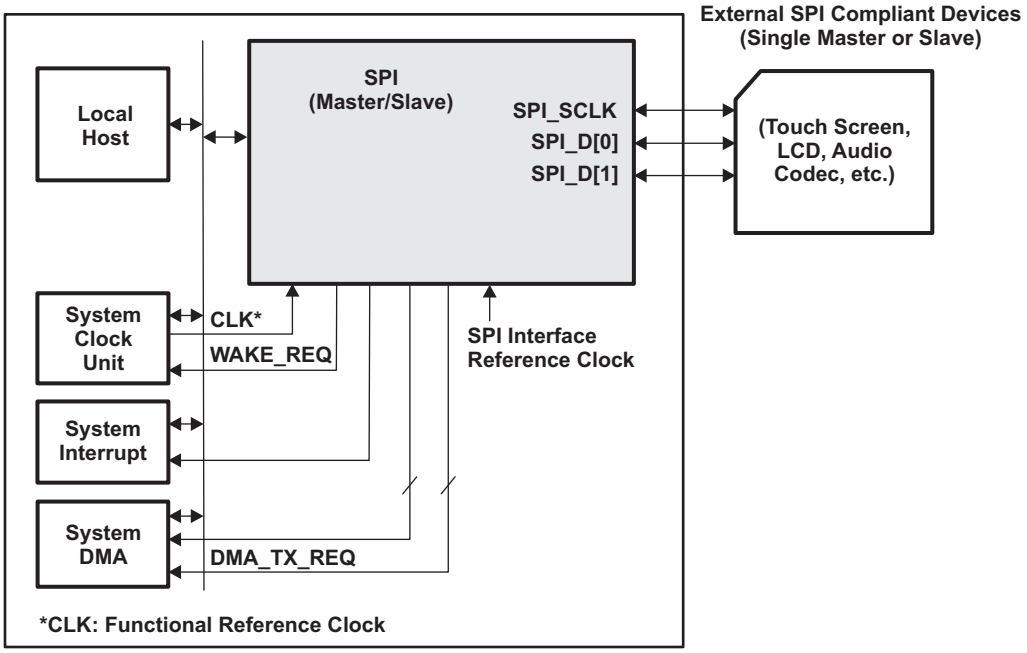
16.2.3.12 3-Pin or 4-Pin Mode

External SPI bus interface can be configured to use a restricted set of pin using the bit field MCSPI_MODULCTRL[1] PIN34 and depending on targeted application:

- If MCSPI_MODULECTRL[34] is cleared to 0 (default value), the controller is in 4-pin mode using the SPI pins: SPI_SCLK, SPI_D[0], SPI_D[1], and SPI_SCS[n].
- If MCSPI_MODULECTRL[34] is set to 1, the controller is in 3-pin mode using the SPI pins: SPI_SCLK, SPI_D[0], and SPI_D[1].

In this mode it is mandatory to put the controller in single channel master mode (MCSPI_MODULECTRL[SINGLE] asserted) and to connect only one SPI device on the bus.

Figure 16-21. 3-Pin Mode System Overview



In 3-pin mode all options related to chip select management are useless:

- MCSPI_CHxCONF[EPOL]
- MCSPI_CHxCONF[TCS0]
- MCSPI_CHxCONF[FORCE]

The chip select pin $\overline{\text{SPI\_SCS[n]}}$ is forced to 0 in this mode.

16.2.4 Slave Mode

SPI is in slave mode when the bit MS of the register MCSPI_MODULCTRL is set.

In slave mode, SPI can be connected to up to 4 external SPI master devices. SPI handles transactions with a single SPI master device at a time.

In slave mode, SPI initiates data transfer on the data lines (SPI_D[1:0]) when it receives an SPI clock (SPI_SCLK) from the external SPI master device.

The controller is able to work with or without a chip select $\overline{\text{SPI\_SCS[n]}}$ depending on MCSPI_MODULCTRL[1] PIN34 bit setting. It also support transfers without dead cycle between two successive words.

16.2.4.1 Dedicated Resources

In slave mode, enabling a channel that is not channel 0 has no effect. Only channel 0 can be enabled. The channel 0, in slave mode has the following resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH0CTRL. This channel should be enabled before transmission and reception. Disabling the channel, outside data word transmission, remains under user responsibility.
- Any of the 4 ports $\overline{\text{SPI\_SCS[3:0]}}$ can be used as a slave SPI device enable. This is programmable with the SPIENSLV bits of the register MCSPI_CH0CONF.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH0STAT is set. When SPI is selected by an external master (active signal on the $\overline{\text{SPI\_SCS[n]}}$ port assigned to channel 0), the transmitter register content of channel0 is always loaded in shift register whether it has been updated or not. The transmitter register should be loaded before SPI is selected by a master.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH0STAT is set.

NOTE: The transmitter register and receiver registers of the other channels are not used. Read from or Write in the registers of a channel that is not channel 0 has no effect.

- Its own communication configuration with the following parameters via the register MCSPI_CH0CONF:
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - $\overline{\text{SPI\_SCS[n]}}$ polarity, programmable with the bit EPOL.
  - SPI_SCLK polarity, programmable with the bit POL.
  - SPI_SCLK phase, programmable with the bit PHA.
  - Use a FIFO buffer or not, programmable with FFER and FFEW, depending on transfer mode TRM.

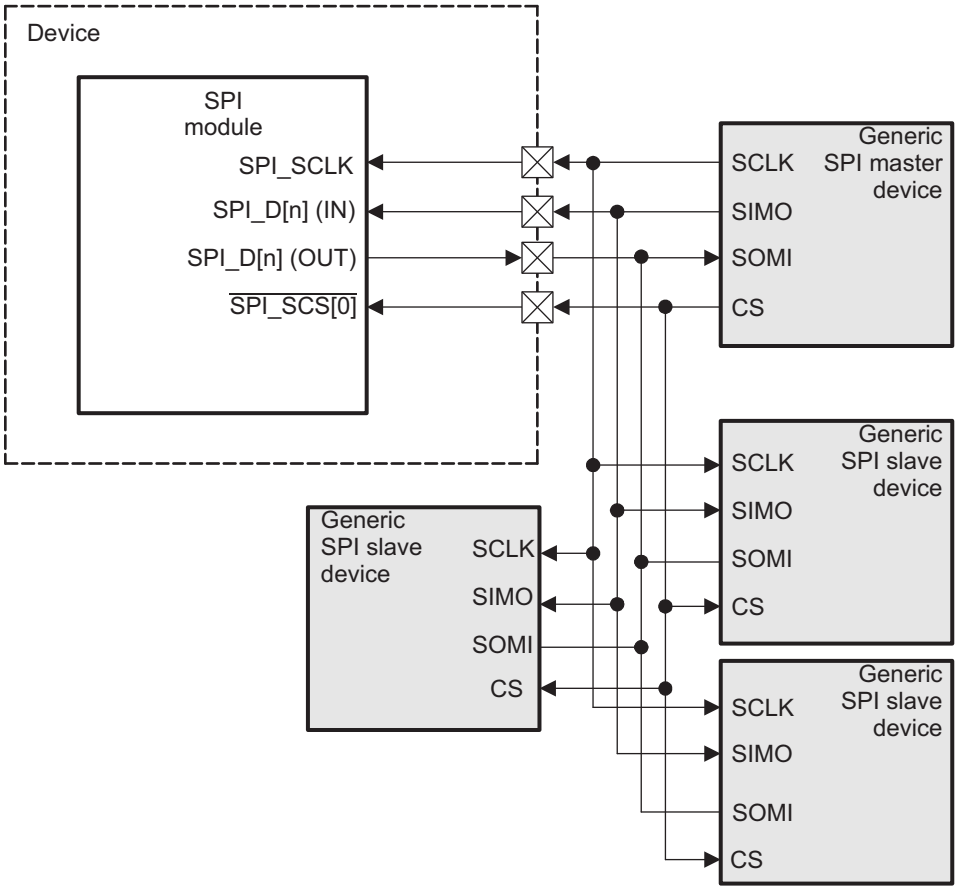
The SPI_SCLK frequency of a transfer is controlled by the external SPI master connected to SPI. The bits CLKD0 of the register 0CONF are not used in slave mode.

NOTE: The configuration of the channel can be loaded in the 0CONF register only when the channel is disabled.

- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of SPI. The DMA requests are enabled with the bits DMAR and DMAW of the register 0CONF.
- Four interrupts events.

Figure 16-22 shows an example of four slaves wired on a single master device.

Figure 16-22. Example of SPI Slave with One Master and Multiple Slave Devices on Channel 0



16.2.4.2 Interrupt Events in Slave Mode

The interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt events related to the receiver register state are RX_full and RX_overflow.

16.2.4.2.1 TX_EMPTY

The event TX_empty is activated when the channel is enabled and its transmitter register becomes empty. Enabling channel automatically raises this event. When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be load to remove source of interrupt and TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new TX_empty event will be asserted as soon as Local Host has not performed the number of write into transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of Local Host to perform the right number of writes.

16.2.4.2.2 TX_UNDERFLOW

The event TX_underflow is activated when channel is enabled and if the transmitter register or FIFO (if use of buffer is enabled) is empty (not updated with new data) when an external master device starts a data transfer with SPI (transmit and receive).

When FIFO is enabled the data emitted while underflow event is raised is not the last data written in the FIFO.

The TX_underflow indicates an error (data loss) in slave mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.2.4.2.3 RX_FULL

The event RX_full is activated when channel is enabled and receiver becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(I)CONF[FFER] set to 1), the RX_full is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new RX_full event will be asserted as soon as Local Host has not performed the number of read into receive register defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of Local Host to perform the right number of reads.

16.2.4.2.4 RX_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the SPI_RX*n* register or FIFO is full when a new SPI word is received. The SPI_RX*n* register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The SPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

16.2.4.2.5 End of Word Count

The event EOW (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[WCNT] is not reloaded and channel re-enabled.

End of Word interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.2.4.3 Slave Transmit-and-Receive Mode

The slave transmit and receive mode is programmable (bits TRM cleared to 0 in the register MCSPI_CH(I)CONF).

After the channel is enabled, transmission and reception proceed with interrupt and DMA request events.

In slave transmit and receive mode, transmitter register should be loaded before SPI is selected by an external SPI master device.

Transmitter register or FIFO (if use of buffer enabled) content is always loaded in shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured in one data direction Transmit or Receive, then the FIFO is seen as a unique FFNBYTE bytes buffer, or it can also be configured in both data direction Transmit and Receive, then the FIFO is split into two separate FFNBYTE/2 bytes buffer with their own address space management, in this last case the definition of AEL and AFL levels is based on FFNBYTE bytes and is under Local Host responsibility.

16.2.4.4 Slave Receive-Only Mode

The slave receive mode is programmable (bits TRM set to 01 in the register (I)CONF).

In receive only mode, the Transmitter register should be loaded before SPI is selected by an external SPI master device. Transmitter register or FIFO (if use of buffer enabled) content is always loaded in shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

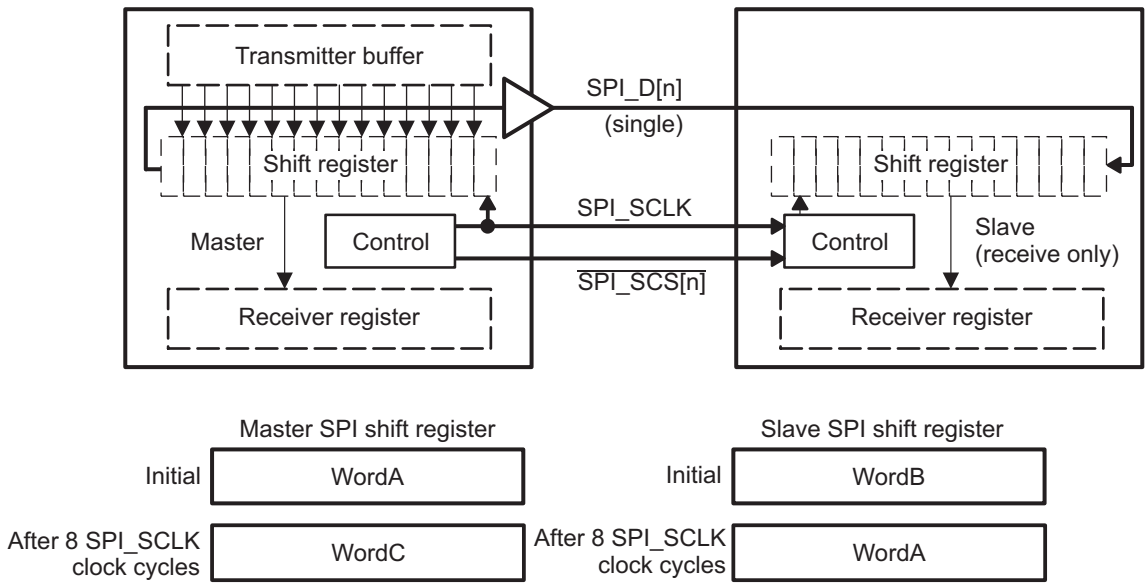
When an SPI word transfer completes (the SPIm.SPI_CH*n*STAT0[2] EOT bit (with *n* = 0) is set to 1), the received data is transferred to the channel receive register.

To use SPI as a slave receive only device with MCSPI_CH(I)CONF[TRM] = 00, the user has the responsibility of the inhibition of the TX_empty and TX_underflow interrupts and DMA write requests due to the transmitter register sate.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(I)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel. The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Figure 16-23 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock spim_clk, Word A transfers from the master to the slave.

Figure 16-23. SPI Half-Duplex Transmission (Receive-Only Slave)



16.2.4.5 Slave Transmit-Only Mode

The slave transmit only mode is programmable (TRM bit set to 10 in the register MCSPI_CH(I)CONF). This mode avoids the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

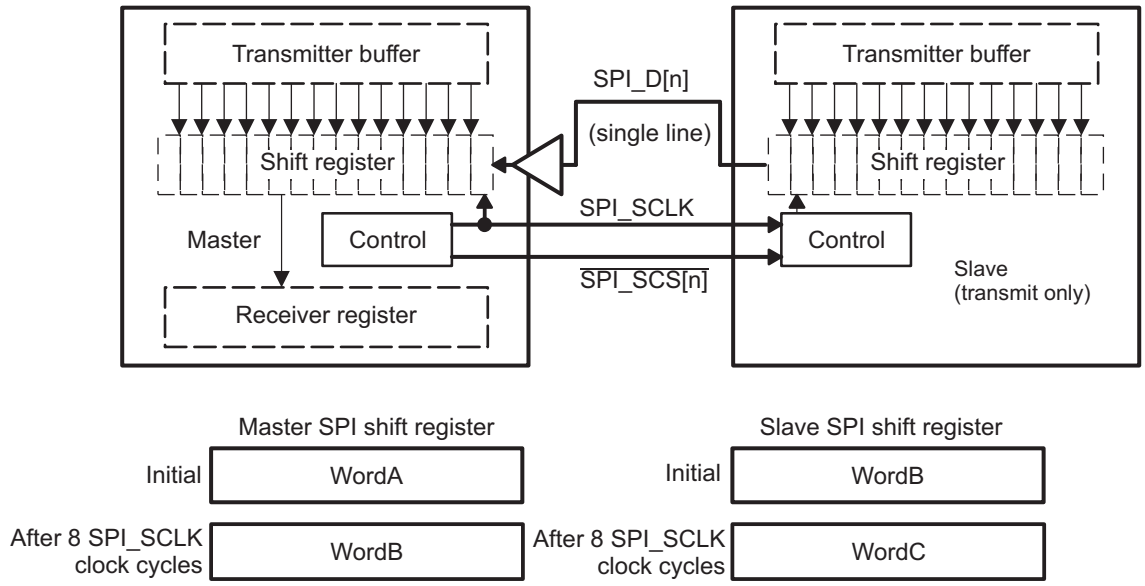
To use SPI as a slave transmit only device with (I)CONF[TRM] = 00, the user should inhibit the RX_full and RX_overflow interrupts and DMA read requests due to the receiver register sate.

On completion of SPI word transfer the bit EOT of the register MCSPI_CH(I)STAT is set. This bit is meaningless when using the buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(I)CONF register, then the FIFO is seen as a unique FFNBYTE bytes buffer.

Figure 16-24 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 16-24. SPI Half-Duplex Transmission (Transmit-Only Slave)



16.2.5 Interrupts

According to its transmitter register state and its receiver register state each channel can issue interrupt events if they are enabled.

The interrupt events are listed in the Section 16.2.3.2 and in Section 16.2.4.2.

Each interrupt event has a status bit, in the MCSPI_IRQSTATUS register, which indicates service is required, and an interrupt enable bit, in the MCSPI_IRQENABLE register, which enables the status to generate hardware interrupt requests.

When an interrupt occurs and later a mask is applied on it (IRQENABLE), the interrupt line is not asserted again even if the interrupt source has not been serviced.

SPI supports interrupt driven operation and polling.

16.2.5.1 Interrupt-Driven Operation

Alternatively, an interrupt enable bit, in the MCSPI_IRQENABLE register, can be set to enable each of the events to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the CPU must:

- Read the MCSPI_IRQSTATUS register to identify which event occurred,
- Read the receiver register that corresponds to the event, to remove the source of an RX_full event, or Write into the transmitter register that corresponds to the event, to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Write a 1 into the corresponding bit of MCSPI_IRQSTATUS register to clear the interrupt status, and release the interrupt line.

The interrupt status bit should always be reset after channel enabling and before event are enabled as interrupt source.

16.2.5.2 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQENABLE register, the interrupt line is not asserted and:

- The status bits in the MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.
- Once the expected event occurs, CPU must: Read the receiver register that corresponds to the event, to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event, to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Writing a 1 into the corresponding bit of MCSPI_IRQSTATUS register clears the interrupt status and does not affect the interrupt line state.

16.2.6 DMA Requests

SPI can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host of the data transfers.

According to its transmitter register state, its receiver register state or FIFO level (if use of buffer for the channel) each channel can issue DMA requests if they are enabled.

The DMA requests need to be disabled in order to get TX and RX interrupts, in order to define either the end of the transfer or the transfer of the last words for the modes listed below:

- Master Transmit On
- Master normal receive only mode
- Master turbo receive only mode
- Slave Transmit Only

There are 2 DMA request lines per channel. The management of DMA requests differ according to use of FIFO buffer or not:

16.2.6.1 FIFO Buffer Disabled

The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted (OCP compliant) on read completion of the receive register of the channel.

The DMA Write request line is asserted when the channel is enabled and the transmitter register of the channel is empty. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is deasserted (OCP compliant) on load completion of the transmitter register of the channel.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive register.

16.2.6.2 FIFO Buffer Enabled

The DMA Read request line is asserted when the channel is enabled and a number of bytes defined in MCSPI_XFERLEVEL[AFL] bit field is hold in FIFO buffer for the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(I)CONF. The DMA Read request line is de-asserted (OCP compliant) on the first SPI word read completion of the receive register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of read accesses defined by MCSPI_XFERLEVEL[AFL] it is under user responsibility.

The DMA Write request line is asserted when the channel is enabled and the number of bytes hold in FIFO buffer is below the level defined by the MCSPI_XFERLEVEL[AEL] bit field. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(I)CONF. The DMA Write request line is de-asserted (OCP compliant) on load completion of the first SPI word in the transmitter register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of write accesses defined by MCSPI_XFERLEVEL[AEL] it is under user responsibility.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive FIFO.

16.2.6.3 DMA 256 Bit Aligned Addresses

The controller has two registers, MCSPI_DAFTX and MCSPI_DAFRX, used only with an enabled channel that manages the FIFO to be compliant the a DMA handler providing only 256-bit aligned addresses.

This features is activated when the bit field MCSPI_MODULCTRL[8] FDAA is set to 1 and only one enabled channel has its bit field MCSPI_CH(I)CONF[27] FFE(I)W or MCSPI_CH(I)CONF[28] FFE(I)R enabled.

In this case, the registers MCSPI_TX(I) and MCSPI_RX(I) are not used and data are managed through registers MCSPI_DAFTX and MCSPI_DAFRX.

16.2.7 Emulation Mode

The MReqDebug input differentiates a regular access of a processor (application access), from an emulator access.

Application access: MReqDebug = 0

In functional mode, the consequences of a read of a receiver register MCSPI_RX(i) are the following:

- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is removed, if it was enabled in the MCSPI_IRQENABLE register.
- The RXiS status bit in the MCSPI_IRQSTATUS register is cleared.
- In master mode, depending on the round robin arbitration, and the transmitter register state, the channel may access to the shift register for transmission/reception.

Emulator access: MReqDebug = 1

In emulation mode, SPI behavior is the same as in functional mode but a read of a receiver register MCSPI_RX(i) is not intrusive:

- MCSPI_RX(i) is still considered as not read. When the FIFO buffer is enabled, pointers are not updated.
- The source of an RXi_Full event in the MCSPI_IRQSTATUS register is not removed. The RXiS status bit in the MCSPI_CH(i)STAT register is held steady.

In emulation mode, as in functional mode, based on the ongoing data transfers, the status bits of the MCSPI_CH(i)STAT register may be optionally updated, the interrupt and DMA request lines may be optionally asserted.

16.2.8 Power Saving Management

Independently of the module operational modes (Transmit and/or Receive), two modes of operations are defined from a power management perspective: normal and idle modes.

The two modes are temporally fully exclusive.

SPI is compliant with the profile “IdleReq / SIdleAck / Swakup” in the Idle mode.

16.2.8.1 Normal Mode

Both the OCP clock and SPI clock (CLKSPIREF) provided to SPI must be active for both master and slave modes. The auto-gating of the module OCP clock and SPI clock occurs when the following conditions are met:

- The bit AutoIdle of the register MCSPI_SYSCONFIG is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the SPI is not selected by the external SPI master device and no OCP accesses.

Autogating of the module OCP clock and SPI clock stops when the following conditions are met:

- In master mode, an OCP access occurs.
- In slave mode, an OCP access occurs or SPI is selected by an external SPI master device.

16.2.8.2 Idle Mode

The OCP clock and SPI clock provided to SPI may be switched off on system power manager request and switched back on module request.

SPI is compliant with the power management handshaking protocol: idle request from the system power manager, idle acknowledgment from SPI.

The idle acknowledgment in response to an idle request from the system power manager varies according to a programmable mode in the MCSPI_SYSCONFIG register: No idle mode, force idle mode, and smart idle mode.

- When programmed for no idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to 01), the module ignores the system power manager request, and behaves normally, as if the request was not asserted.
- When programmed for smart idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to 10), the module acknowledges the system power manager request according to its internal state.
- When programmed for force idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to 00), the module acknowledges the system power manager request unconditionally.

The OCP clock will be optionally switched off, during the smart idle mode period, if the bit ClockActivity of the register MCSPI_SYSCONFIG is set.

The SPI clock will be optionally switched off, during the smart idle mode period, if the second bit ClockActivity of the register MCSPI_SYSCONFIG is set.

SPI assumes that both clocks may be switched off whatever the value set in the field ClockActivity of the register MCSPI_SYSCONFIG.

16.2.8.2.1 Transitions from Normal Mode to Smart-Idle Mode

The module detects an idle request when the synchronous signal IdleReq is asserted.

When IdleReq is asserted, any access to the module will generate an error as long as the OCP clock is alive.

When configured as a slave device, SPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of the current transfer ($\overline{\text{SPI\_SCS[n]}}$) slave selection signal deasserted by the external master) and if interrupt or DMA request lines are not asserted.

As a master device, SPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of all the channel data transfers and if interrupt or DMA request lines are not asserted.

As long as SIdleAck is not asserted, if an event occurs, the module can still generate an interrupt or a DMA request after IdleReq assertion. In this case, the module ignores the idle request and SIdleAck will not get asserted: The system power manager will abort the power mode transition procedure. It is then the responsibility of the system to de-assert IdleReq before attempting to access the module.

When SIdleAck is asserted, the module does not assert any new interrupt or DMA request.

16.2.8.2.2 Transition From Smart-Idle Mode to Normal mode

SPI detects the end of the idle period when the idle request signal (IdleReq) is deasserted.

Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational.

16.2.8.2.3 Force-Idle Mode

Force-idle mode is enabled as follows:

- The bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to 00 (Force Idle).

  The force idle mode is an idle mode where SPI responds unconditionally to the idle request by asserting the SIdleAck signal and by deasserting unconditionally the interrupt and DMA request lines if asserted.

  The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTATUS register.

  In force-idle mode, the module is supposed to be disabled at that time, so the interrupt and DMA request lines are likely deasserted. OCP clock and SPI clock provided to SPI can be switched off.

  An idle request during an SPI data transfer can lead to an unexpected and unpredictable result, and is under software responsibility.

  Any access to the module in force idle mode will generate an error as long as the OCP clock is alive and IdleReq is asserted.

The module exits the force idle mode when:

- The idle request signal (IdleReq) is de-asserted.

  Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational. The interrupt and DMA request lines are optionally asserted a clock cycle later.

16.2.9 System Test Mode

SPI is in system test mode (SYSTEST) when the bit System_Test of the register MCSPI_MODULCTRL is set.

The SYSTEST mode is used to check in a very simple manner the correctness of the system interconnect either internally to interrupt handler, or power manager, or externally to SPI I/Os.

I/O verification can be performed in SYSTEST mode by toggling the outputs and capturing the logic state of the inputs. (See MCSPI_SYST register definition in Section 16.3.10)

16.2.10 Reset

16.2.10.1 Internal Reset Monitoring

The module is reset by the hardware when an active-low reset signal, synchronous to the OCP interface clock is asserted on the input pin RESETN.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset, in all clock domains.

Additionally, the module can be reset by software through the bit SoftReset of the register MCSPI_SYSCONFIG. This bit has exactly the same action on the module logic as the hardware RESETN signal. The register MCSPI_SYSCONFIG is not sensitive to software reset. The SoftReset control bit is active high. The bit is automatically reset to 0 by the hardware.

A global ResetDone status bit is provided in the status register MCSPI_SYSSTATUS. This bit is set to 1 when all the different clock domains resets (OCP domain and SPI domains) have been released (logical AND).

The global ResetDone status bit can be monitored by the software to check if the module is ready-to-use following a reset (either hardware or software).

The clock CLKSPIREF must be provided to the module, in order to allow the ResetDone status bit to be set.

When used in slave mode, the clock CLKSPIREF is needed only during the reset phase. The clock CLKSPIREF can be switched off after the ResetDone status is set.

16.2.10.2 Reset values of registers

The reset values of registers and signals are described in Section 16.3.

16.2.11 Access to Data Registers

This section details the supported data accesses (read or write) from/to the data receiver registers MCSPI_RX(i) and data transmitter registers MCSPI_TX(i).

Supported access:

SPI supports only one SPI word per register (receiver or transmitter) and does not support successive 8-bit or 16-bit accesses for a single SPI word.

The SPI word received is always right justified on LSB of the 32-bit register MCSPI_RX(i), and the SPI word to transmit is always right justified on LSB of the 32-bit register MCSPI_TX(i).

The upper bits, above SPI word length, are ignored and the content of the data registers is not reset between the SPI data transfers.

The coherence between the number of bits of the SPI Word, the number of bits of the access and the enabled byte remains under the user's responsibility. Only aligned accesses are supported.

In Master mode, data should not be written in the transmit register when the channel is disabled.

16.2.12 Programming Aid

16.2.12.1 Module Initialization

- Hard or soft reset.
- Read MCSPI_SYSSTATUS.
- Check if reset is done.
- Module configuration: (a) Write into MCSPI_MODULCTRL (b) Write into MCSPI_SYSCONFIG.
- Before the ResetDone bit is set, the clocks CLK and CLKSPIREF must be provided to the module.
- To avoid hazardous behavior, it is advised to reset the module before changing from MASTER mode to SLAVE mode or from SLAVE mode to MASTER mode.

16.2.12.2 SPI Operational Modes Configuration

The selection of the working mode is done through the MCSPI_CHxCONF register (where x = 0, 1, 2 and 3). Table 16-7 through Table 16-9 list the possible operating modes and their configurations.

Table 16-7. SPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode.	MCSPI_CHxCONF[13:12] TRM	0x1
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held high during active state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 16-8. SPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit mode.	MCSPI_CHxCONF[13:12] TRM	0x2
Set the word length.	MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	MCSPI_MODULCTRL[2] MS MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during active state	MCSPI_CHxCONF[6] EPOL	0x1
Clock held high during active state	MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	MCSPI_IRQSTATUS	0x0

Table 16-9. SPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value

Reset the status bits.	MCSPI_IRQSTATUS	0x0

16.2.12.2.1 Common Transfer Procedures Without FIFO – Polling Method

16.2.12.2.1.1 Receive-Only Procedure – Polling Method

Table 16-10 lists the receive-only procedure using the polling method. The SPI is acting as slave.

Table 16-10. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 16-7.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until receive register is full?	MCSPI_RXx	= 0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

16.2.12.2.1.2 Receive-Only Procedure – Interrupt Method

Table 16-11 lists the receive-only procedure using the interrupt method. The SPI is acting as slave. Channel 0 is used. For the rest channels (1, 2 and 3) the same logic applies.

Table 16-11. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-7.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX0_FULL_ENABLE	0x1
Read the status register.	MCSPI_IRQSTATUS[2] RX0_FULL	0x0
Disable the interrupt.	MCSPI_IRQENABLE[2] RX0_FULL_ENABLE	0x0
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read the receiver register.	MCSPI_RX0	xxxx

16.2.12.2.1.3 Transmit-Only Procedure – Polling Method

Table 16-12 lists the transmit-only procedure using the polling method. The SPI is acting as master.

Table 16-12. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-8	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of transfer?	MCSPI_CHxSTAT[2:1]	= 0x2
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

16.2.12.2.1.4 Transmit-and-Receive Procedure – Polling Method

Table 16-12 lists the transmit-and-receive procedure using the polling method. The SPI is acting as master and slave.

Table 16-13. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-9.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until transmit/receive word?	MCSPI_CHxSTAT[2:0]	= 0x3
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

16.2.12.2.2 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the SPI module can start the transfer only after the first write request is released by writing the MCSPI_TXx register (where x = 0, 1, 2 and 3). The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See Table 16-12 through Table 16-19.

In multi-channel master mode, be careful not to overwrite the bits of the other channels when initializing the MCSPI_IRQSTATUS and MCSPI_IRQENABLE registers.

16.2.12.2.2.1 Receive-Only Procedure With Word Count – Polling Method

Table 16-14. Receive-Only Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-7.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPI_IRQSTATUS[17] EOW	= 0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	xxxx

16.2.12.2.2.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 16-15. Transmit-Only Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-8.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPI_IRQSTATUS[17] EOW	= 0x1
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT MCSPI_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

16.2.12.2.2.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 16-16. Transmit-Only Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-8.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX1_EMPTY_ENABLE	0x1
End of word count.	MCSPI_IRQSTATUS[17] EOW	= 0x1
End of transfer	MCSPI_CHxSTAT[2] EOT MCSPI_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Clear the interrupt.	MCSPI_IRQENABLE[17] EOWKE	= 0x0

Step	Register/Bit Field/Programming Model	Value
Disable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX1_EMPTY_ENABLE	0x0
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0

16.2.12.2.2.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 16-17. Transmit-and-Receive Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-9.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	MCSPI_IRQSTATUS[17] EOW	= 0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	xxxx

16.2.12.2.2.5 Transmit-and-Receive Procedure with Word Count – Interrupt Method

Table 16-18. Transmit-and-Receive Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-9.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX0_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX1_EMPTY_ENABLE	0x1
End of word count?	MCSPI_IRQSTATUS[17] EOW	= 0x1
Clear the interrupt.	MCSPI_IRQENABLE[17] EOWKE	= 0x0
Disable the interrupt for the receiver register.	MCSPI_IRQENABLE[2] RX0_FULL_ENABLE	0x0
Disable the interrupt for the transmit register.	MCSPI_IRQENABLE[4] TX1_EMPTY_ENABLE	0x0
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	xxxx

16.2.12.2.2.6 Transmit-and-Receive Procedure Without Word Count – Polling Method

Table 16-19. Transmit-and-Receive Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 16-9.	
Start the channel.	MCSPI_CHxCTRL[0] EN	0x1
Wait until end of transfer?	MCSPI_CHxSTAT[2] EOT MCSPI_CHxSTAT[3] TXFFE	= 0x1 = 0x1
Stop the channel.	MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	MCSPI_RXx	xxxx

16.2.13 Interrupt and DMA Events

SPI has two DMA requests (Rx and Tx) per channel. It also has one interrupt line for all the interrupt requests.

16.3 SPI Registers

Table 16-20 lists the SPI registers. For the base address of these registers, see Table 1-12.

Table 16-20. SPI Registers

Offset Address	Acronym	Register Name	Section
0h	MCSPI_HL_REV	McSPI IP revision register	Section 16.3.1

16.3.1 McSPI IP Revision Register (MCSPI_HL_REV)

The McSPI IP revision register (MCSPI_HL_REV) holds the IP revision identifier information. The MCSPI_HL_REV is shown in Figure 16-25 and described in Table 16-21.

Figure 16-25. McSPI IP Revision Register (MCSPI_HL_REV)

31	30	29	28	27	16
SCHEME		Reserved		FUNC

R-0		R-0		R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 16-21. McSPI IP Revision Register (MCSPI_HL_REV) Field Descriptions

Bit	Field	Value	Description
31-30	SCHEME	0-3h	Identifies scheme.
29-28	Reserved	0	Reserved for module specific status information. Read returns 0.
27-16	FUNC	0-FFFh	Indicates a software compatible module family.
15-11	R_RTL	0-1Fh	RTL version (R).
10-8	X_MAJOR	0-7h	Major revision (X).
7-6	CUSTOM	0-3h	Indicates a special version for a particular device.
5-0	Y_MINOR	0-3Fh	Minor revision (Y).

16.3.2 McSPI IP Hardware Information Register (MCSPI_HL_HWINFO)

The McSPI IP hardware information register (MCSPI_HL_HWINFO) provides information about the IP hardware configuration. The MCSPI_HL_HWINFO is shown in Figure 16-26 and described in Table 16-22.

Figure 16-26. McSPI IP Hardware Information Register (MCSPI_HL_HWINFO)

Table 16-22. McSPI IP Hardware Information Register (MCSPI_HL_HWINFO) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved.
5-1	FFNBYTE		FIFO number of byte generic parameter. Defines the value of FFNBYTE generic parameter.
		0	Reserved
		1h	FIFO 16 bytes depth
		2h	FIFO 32 bytes depth
		3h	Reserved
		4h	FIFO 64 bytes depth
		5h-7h	Reserved
		8h	FIFO 128 bytes depth
		9h-Fh	Reserved
		10h	FIFO 256 bytes depth
		11h-1Fh	Reserved
0	USEFIFO		Use of a FIFO enable.
		0	FIFO not implemented in design
		1	FIFO and its management implemented in design with depth defined by FFNBYTE generic.

16.3.3 McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG)

The McSPI IP system configuration register (MCSPI_HL_SYSCONFIG) allows control of the clock management. The MCSPI_HL_SYSCONFIG is shown in Figure 16-27 and described in Table 16-23.

Figure 16-27. McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG)

31	16

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 16-23. McSPI IP System Configuration Register (MCSPI_HL_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved.
3-2	IDLEMODE		Configuration of the local target state management mode. The target can handle read/write transactions as long as it is out of IDLE state.
		0	Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally,that is, regardless of the IP module's internal requirements.
		1h	No-idle mode: local target never enters idle state.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
		3h	Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	FREEEMU		Sensitivity to emulation (debug) suspend input signal.
		0	IP module is sensitive to emulation suspend.
		1	IP module is not sensitive to emulation suspend.
0	SOFTRESET		Software reset.
		Write 0	No action
		Read 0	Reset done, no pending action
		Write 1	Initiate software reset
		Read 1	Reset (software or other) ongoing

16.3.4 McSPI Revision Register (MCSPI_REVISION)

The McSPI revision register (MCSPI_REVISION) contains the hard-coded RTL revision number. The MCSPI_REVISION is shown in Figure 16-28 and described in Table 16-24.

Figure 16-28. McSPI Revision Register (MCSPI_REVISION)

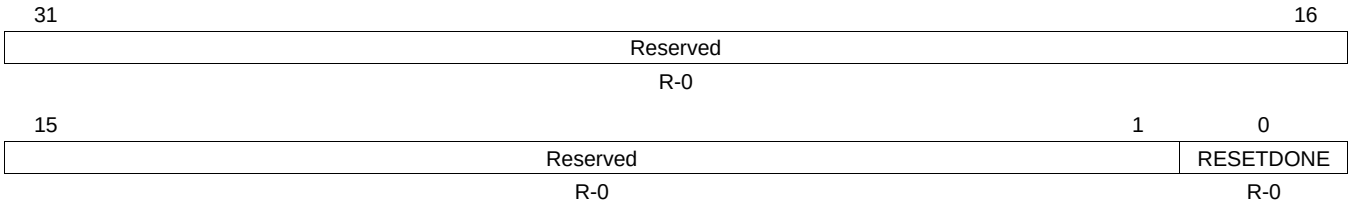
Table 16-25. McSPI System Configuration Register (MCSPI_SYSCONFIG) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reads returns 0
9-8	CLOCKACTIVITY		Clocks activity during wake-up mode period.
		0	OCP and Functional clocks may be switched off.
		1h	OCP clock is maintained. Functional clock may be switched-off.
		2h	Functional clock is maintained. OCP clock may be switched-off.
		3h	OCP and Functional clocks are maintained.
7-5	Reserved	0	Reads returns 0
4-3	SIDLEMODE		Power management
		0	If an idle request is detected, the McSPI acknowledges it unconditionally and goes in Inactive mode. Interrupt, DMA requests are unconditionally de-asserted.
		1h	If an idle request is detected, the request is ignored and keeps on behaving normally.
		2h	Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements.
		3h	Reserved
2	ENAWAKEUP		Enable Wakeup.
		0	Wakeup capability is disabled.
		1	Wakeup capability is enabled.
1	SOFTRESET		Software reset. During reads it always returns 0.
		0	(write) Normal mode
		1	(write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.
0	AUTOIDLE		Internal OCP Clock gating strategy
		0	OCP clock is free-running
		1	Automatic OCP clock gating strategy is applied, based on the OCP interface activity

16.3.6 McSPI System Status Register (MCSPI_SYSSTATUS)

The McSPI system status register (MCSPI_SYSSTATUS) provides status information about the module excluding the interrupt status information. The MCSPI_SYSSTATUS is shown in Figure 16-30 and described in Table 16-26.

Figure 16-30. McSPI System Status Register (MCSPI_SYSSTATUS)



LEGEND: R = Read only; -*n* = value after reset

Table 16-26. McSPI System Status Register (MCSPI_SYSSTATUS) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved for module specific status information. Read returns 0.
0	RESETDONE		Internal Reset Monitoring
		0	Internal module reset is on-going
		1	Reset completed

16.3.7 McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

The McSPI interrupt status register (MCSPI_IRQSTATUS) regroups all the status of the module internal events that can generate an interrupt. The MCSPI_IRQSTATUS is shown in Figure 16-31 and described in Table 16-27.

NOTE: In SYSTEST mode, the bits of this register have no meaning and always read 0.

Figure 16-31. McSPI Interrupt Status Register (MCSPI_IRQSTATUS)

31							18	17	16
Reserved								EOW	Rsvd
R/W-0								R/W-0	R-0

Table 16-27. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads returns 0
17	EOW		End of word (EOW) count event when a channel is enabled using the FIFO buffer and the channel has sent the number of McSPI words defined by the MCSPI_XFERLEVEL[WCNT].
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
16	Reserved	0	Reserved
15	Reserved	0	Reads returns 0
14	RX3_FULL		Receiver register is full or almost full. Only when Channel 3 is enabled. This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPI_CH3CONF[FFE3R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
13	TX3_UNDERFLOW		Transmitter register underflow. Only when Channel 3 is enabled. The transmitter register is empty (not updated by Host or DMA with new data) before its time slot assignment. Exception: No TX_underflow event when no data has been loaded into the transmitter register since channel has been enabled.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.

Table 16-27. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
12	TX3_EMPTY		Transmitter register is empty or almost empty. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPI_CH3CONF[FFE3W] is set).
			Note: Enabling the channel automatically raises this event.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
11	Reserved	0	Reads returns 0
10	RX2_FULL		Receiver register full or almost full. Channel 2 This bit indicate FIFO almost full status when built-in FIFO is used for receive register (MCSPI_CH3CONF[FFE2R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
9	TX2_UNDERFLOW		Transmitter register underflow. Channel 2
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
8	TX2_EMPTY		Transmitter register empty or almost empty. Channel 2. This bit indicate FIFO almost full status when built-in FIFO is used for transmit register (MCSPI_CH3CONF[FFE2W] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
7	Reserved	0	Reads returns 0
6	RX1_FULL		Receiver register full or almost full. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for receive register (MCSPI_CH3CONF[FFE1R] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
5	TX1_UNDERFLOW		Transmitter register underflow. Channel 1.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
4	TX1_EMPTY		Transmitter register empty or almost empty. Channel 1. This bit indicate FIFO almost full status when built-in FIFO is use for transmit register (MCSPI_CH3CONF[FFE1W] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
3	RX0_OVERFLOW		Receiver register overflow (slave mode only). Channel 0.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.

Table 16-27. McSPI Interrupt Status Register (MCSPI_IRQSTATUS) Field Descriptions (continued)

Bit	Field	Value	Description
2	RX0_FULL		Receiver register full or almost full. Channel 0. Receiver register full or almost full. Channel 0
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
1	TX0_UNDERFLOW		Transmitter register underflow. Channel 0.
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.
0	TX0_EMPTY		Transmitter register empty or almost empty. Channel 0. This bit indicate FIFO almost full status when built-in FIFO is use for transmit register (MCSPI_CH3CONF[FFE0W] is set).
		Write 0	Event status bit is unchanged.
		Read 0	Event false.
		Write 1	Event status bit is reset.
		Read 1	Event is pending.

16.3.8 McSPI Interrupt Enable Register (MCSPI_IRQENABLE)

This McSPI interrupt enable register (MCSPI_IRQENABLE) enables/disables the module internal sources of interrupt, on an event-by-event basis. The MCSPI_IRQENABLE is shown in Figure 16-32 and described in Table 16-28.

Figure 16-32. McSPI Interrupt Enable Register (MCSPI_IRQENABLE)

Table 16-28. McSPI Interrupt Enable Register (MCSPI_IRQENABLE) Field Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reads return 0
17	EOWKE		End of word count interrupt enable.
		0	Interrupt is disabled.
		1	Interrupt is enabled.
16	Reserved		Reserved
15	Reserved	0	Reads return 0
14	RX3_FULL_ ENABLE		MCSPI_RX3 receiver register full or almost full interrupt enable (channel 3).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
13	TX3_UNDERFLOW_ ENABLE		MCSPI_TX3 transmitter register underflow interrupt enable (channel 3).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
12	TX3_EMPTY_ ENABLE		MCSPI_TX3 transmitter register empty or almost empty interrupt enable (channel 3).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
11	Reserved	0	Reads return 0
10	RX2_FULL_ ENABLE		MCSPI_RX2 receiver register full or almost full interrupt enable (channel 2).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
9	TX2_UNDERFLOW_ ENABLE		MCSPI_TX2 transmitter register underflow interrupt enable (channel 2).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
8	TX2_EMPTY_ ENABLE		MCSPI_TX2 transmitter register empty or almost empty interrupt enable (channel 2).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
7	Reserved	0	Reads return 0

Table 16-28. McSPI Interrupt Enable Register (MCSPI_IRQENABLE) Field Descriptions (continued)

Bit	Field	Value	Description
6	RX1_FULL_ ENABLE		MCSPI_RX1 receiver register full or almost full interrupt enable (channel 1)
		0	Interrupt is disabled.
		1	Interrupt is enabled.
5	TX1_UNDERFLOW_ ENABLE		MCSPI_TX1 transmitter register underflow interrupt enable (channel 1).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
4	TX1_EMPTY_ ENABLE		MCSPI_TX1 transmitter register empty or almost empty interrupt enable (channel 1).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
3	RX0_OVERFLOW_ ENABLE		MCSPI_RX0 receivier register overflow interrupt enable (channel 0).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
2	RX0_FULL_ ENABLE		MCSPI_RX0 receiver register full or almost full interrupt enable (channel 0).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
1	TX0_UNDERFLOW_ ENABLE		MCSPI_TX0 transmitter register underflow interrupt enable (channel 0).
		0	Interrupt is disabled.
		1	Interrupt is enabled.
0	TX0_EMPTY_ ENABLE		MCSPI_TX0 transmitter register empty or almost empty interrupt enable (channel 0).
		0	Interrupt is disabled.
		1	Interrupt is enabled.

16.3.9 McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE)

The McSPI wakeup enable register (MCSPI_WAKEUPENABLE) allows you to enable/disable the module internal sources of wakeup on an event-by-event basis. The MCSPI_WAKEUPENABLE is shown in Figure 16-33 and described in Table 16-29.

Figure 16-33. McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE)

Table 16-29. McSPI Wakeup Enable Register (MCSPI_WAKEUPENABLE) Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved. Read returns 0.
0	WKEN		Wakeup functionality in slave mode when an active control signal is detected on the $\overline{\text{SPI\_SCS[n]}}$ line programmed in MCSPI_CH(i)CONF[SPIENSLV].
		0	The event is not allowed to wakeup the system, even if MCSPI_SYSCONFIG[ENAWAKEUP] is set.
		1	The event is allowed to wakeup the system if MCSPI_SYSCONFIG[ENAWAKEUP] is set.

16.3.10 McSPI System Test Register (MCSPI_SYST)

This McSPI system test register (MCSPI_SYST) is used to configure the system interconnect either internally to the peripheral bus or externally to the device I/O pads, when the module is configured in the system test (SYSTEST) mode. The MCSPI_SYST is shown in Figure 16-34 and described in Table 16-30.

Figure 16-34. McSPI System Test Register (MCSPI_SYST)

Table 16-30. McSPI System Test Register (MCSPI_SYST) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reads returns 0
11	SSB		Set status bit. This bit must be cleared prior attempting to clear a status bit of the MCSPI_ IRQSTATUS register.
		0	No action. Writing 0 does not clear already set status bits.
			This bit must be cleared prior attempting to clear a status bit of the <MCSPI_IRQSTATUS> register.
		1	Writing 1 sets to 1 all status bits contained in the MCSPI_IRQSTATUS register.
			Writing 1 into this bit sets to 1 all status bits contained in the <MCSPI_IRQSTATUS> register.
10	SPIENDIR		Sets the direction of the $\overline{\text{SPI\_SCS}}$[3:0] lines and SPI_SCLK line.
		0	Output (as in master mode).
		1	Input (as in slave mode).
9	SPIDATDIR1		Sets the direction of the SPI_D[1].
		0	Output
		1	Input
8	SPIDATDIR0		Sets the direction of the SPI_D[0].
		0	Output
		1	Input
7	Reserved	0	Reserved
6	SPICLK		SPI_SCLK line (signal data value)
			If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect.
			If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.
5	SPIDAT_1		SPI_D[1] line (signal data value)
			If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPI_D[1] line is driven high or low according to the value written into this register.
			If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPI_D[1] line (high or low), and a write into this bit has no effect.
4	SPIDAT_0		SPI_D[0] line (signal data value)
			If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPI_D[0] line is driven high or low according to the value written into this register.
			If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPI_D[0] line (high or low), and a write into this bit has no effect.

Table 16-30. McSPI System Test Register (MCSPI_SYST) Field Descriptions (continued)

Bit	Field	Value	Description
3	SPIEN_3		$\overline{\text{SPI\_SCS}}$[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI\_SCS}}$[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI\_SCS}}$[3] line (high or low), and a write into this bit has no effect.
2	SPIEN_2		$\overline{\text{SPI\_SCS}}$[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI\_SCS}}$[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI\_SCS}}$[2] line (high or low), and a write into this bit has no effect.
1	SPIEN_1		$\overline{\text{SPI\_SCS}}$[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI\_SCS}}$[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI\_SCS}}$[1] line (high or low), and a write into this bit has no effect.
0	SPIEN_0		$\overline{\text{SPI\_SCS}}$[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the $\overline{\text{SPI\_SCS}}$[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the $\overline{\text{SPI\_SCS}}$[0] line (high or low), and a write into this bit has no effect.

16.3.11 McSPI Module Control Register (MCSPI_MODULCTRL)

This McSPI module control register (MCSPI_MODULCTRL) is used to configure the serial port interface. The MCSPI_MODULCTRL is shown in Figure 16-35 and described in Table 16-31.

Figure 16-35. McSPI Module Control Register (MCSPI_MODULCTRL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7	6	5	4	3	2	1	0
MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE
R/W-0	R/W-0			R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 16-31. McSPI Module Control Register(MCSPI_MODULCTRL) Field Descriptions

Bit	Field	Value	Description
31-9	Reserved	0	
8	FDAA		FIFO DMA Address 256-bit aligned. This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256 bit aligned address. If this bit is set the enabled channel which uses the FIFO has its datas managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers.
		0	FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers.
		1	FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.
7	MOA		Multiple word ocp access. This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16.
		0	Multiple word access disabled
		1	Multiple word access enabled with FIFO
6-4	INITDLY		Initial SPI delay for first transfer. This register is an option only available in single master mode, The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock, No clock output provided to the boundary and chip select is not active in 4 pin mode within this period.
		0	No delay for first SPI transfer
		1h	The controller wait 4 SPI bus clock
		2h	The controller wait 8 SPI bus clock
		3h	The controller wait 16 SPI bus clock
		4h	The controller wait 32 SPI bus clock
		5h-Fh	Reserved
3	SYSTEM_TEST		Enables the system test mode
		0	Functional mode
		1	System test mode (SYSTEST)
2	MS		Master/ Slave
		0	Master - The module generates the SPI_SCLK and $\overline{\text{SPI\_SCS[3:0]}}$
		1	Slave - The module receives the SPI_SCLK and $\overline{\text{SPI\_SCS[3:0]}}$
1	PIN34		Pin mode selection. This register is used to configure the SPI pin mode, in master or slave mode. If asserted, the controller only use SPI_D[0], SPI_D[1], and SPI_SCLK clock pin for SPI transfers.
		0	$\overline{\text{SPI\_SCS[n]}}$ is used as a chip select.
		1	$\overline{\text{SPI\_SCS[n]}}$ is not used. In this mode all related option to chip select have no meaning.

Table 16-31. McSPI Module Control Register(MCSPI_MODULCTRL) Field Descriptions (continued)

Bit	Field	Value	Description
0	SINGLE		Single channel / Multichannel (master mode only) For master mode, the user has to set this bit to 0 for Multi or 1 for Single. For Slave mode, this bit has to be set to 0.
		0	More than one channel will be used in master mode.
		1	Only one channel will be used in master mode. This bit must be set in Force $\overline{\text{SPI\_SCS[n]}}$ mode.

16.3.12 McSPI Channel (i) Configuration Register (MCSPI_CH(i)CONF)

The McSPI channel *i* configuration register (MCSPI_CH(i)CONF) is used to configure channel*i*. The (MCSPI_CH(i)CONF) is shown in Figure 16-36 and described in Table 16-32.

Figure 16-36. McSPI Channel (*i*) Configuration Register (MCSPI_CH(i)CONF)

Table 16-32. McSPI Channel (*i*) Configuration Register (MCSPI_CH(i)CONF) Field Descriptions

Bit	Field	Value	Description
31-30	Reserved	0	Read returns 0
29	CLKG		Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity.
			When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then The clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values.
		0	Clock granularity of power of 2
		1	1 clock cycle granularity
28	FFER		FIFO enabled for receive. Only one channel can have this bit set.
		0	The buffer is not used to receive data.
		1	The buffer is used to receive data.
27	FFEW		FIFO enabled for transmit. Only one channel can have this bit set.
		0	The buffer is not used to transmit data.
		1	The buffer is used to transmit data.
26-25	TCS		Chip select time control. This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock.
		0	0.5 clock cycles
		1h	1.5 clock cycles
		2h	2.5 clock cycles
		3h	3.5 clock cycles
24	SBPOL		Start bit polarity.
		0	Start bit polarity is held to 0 during SPI transfer.
		1	Start bit polarity is held to 1 during SPI transfer.
23	SBE		Start bit enable for SPI transfer.
		0	Default SPI transfer length as specified by WL bit field.
		1	Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CH(i)CONF[SBPOL].

Table 16-32. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description
22-21	SPIENSLV		Channel 0 only and slave mode only: SPI slave select signal detection.
		0	Detection enabled only on $\overline{\text{SPI\_SCS[0]}}$
		1h	Detection enabled only on $\overline{\text{SPI\_SCS[1]}}$
		2h	Detection enabled only on $\overline{\text{SPI\_SCS[2]}}$
		3h	Detection enabled only on $\overline{\text{SPI\_SCS[3]}}$
20	FORCE		Manual $\overline{\text{SPI\_SCS[n]}}$ assertion to keep $\overline{\text{SPI\_SCS[n]}}$ active between SPI words. (single channel master mode only)
		0	Writing 0 into this bit drives the $\overline{\text{SPI\_SCS[n]}}$ line when MCSPI_CHCONF(i)[EPOL] = 0, and drives it high when MCSPI_CHCONF(i)[EPOL] = 1.
		1	Writing 1 into this bit drives the $\overline{\text{SPI\_SCS[n]}}$ line when MCSPI_CHCONF(i)[EPOL] = 0, and drives it low when MCSPI_CHCONF(i)[EPOL] = 1.
19	TURBO		Turbo mode.
		0	Turbo is deactivated (recommended for single SPI word transfer).
		1	Turbo is activated to maximize the throughput for multi-SPI word transfers.
18	IS		Input select
		0	Data line 0 (SPI_D[0]) selected for reception.
		1	Data line 1 (SPI_D[1]) selected for reception.
17	DPE1		Transmission enable for data line 1 (SPIDATAGZEN[1])
		0	Data line 1 (SPI_D[1]) selected for transmission
		1	No transmission on data line 1 (SPI_D[1])
16	DPE0		Transmission enable for data line 0 (SPIDATAGZEN[0])
		0	Data line 0 (SPI_D[0]) selected for transmission
		1	No transmission on data line 0 (SPI_D[0])
15	DMAR		DMA read request. The DMA read request line is asserted when the channel is enabled and new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel.
		0	DMA read request is disabled.
		1	DMA read request is enabled.
14	DMAW		DMA write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TX*n* register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TX*n* register of the channel.
		0	DMA write request is disabled.
		1	DMA write request is enabled.
13-12	TRM		Transmit/receive modes.
		0	Transmit and receive mode
		1h	Receive-only mode
		2h	Transmit-only mode
		3h	Reserved

Table 16-32. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description
11-7	WL		SPI word length.
		0-2h	Reserved
		3h	The SPI word is 4-bits long.
		4h	The SPI word is 5-bits long
		5h	The SPI word is 6-bits long
		6h	The SPI word is 7-bits long
		7h	The SPI word is 8-bits long
		8h	The SPI word is 9-bits long
		9h	The SPI word is 10-bits long
		Ah	The SPI word is 11-bits long
		Bh	The SPI word is 12-bits long
		Ch	The SPI word is 13-bits long
		Dh	The SPI word is 14-bits long
		Eh	The SPI word is 15-bits long
		Fh	The SPI word is 16-bits long
		10h	The SPI word is 17-bits long
		11h	The SPI word is 18-bits long
		12h	The SPI word is 19-bits long
		13h	The SPI word is 20-bits long
		14h	The SPI word is 21-bits long
		15h	The SPI word is 22-bits long
		16h	The SPI word is 23-bits long
		17h	The SPI word is 24-bits long
		18h	The SPI word is 25-bits long
		19h	The SPI word is 26-bits long
		1Ah	The SPI word is 27-bits long
		1Bh	The SPI word is 28-bits long
		1Ch	The SPI word is 29-bits long
		1Dh	The SPI word is 30-bits long
		1Eh	The SPI word is 31-bits long
		1Fh	The SPI word is 32-bits long
6	EPOL		$\overline{\text{SPI\_SCS[n]}}$ polarity
		0	$\overline{\text{SPI\_SCS[n]}}$ is held high during the active state.
		1	$\overline{\text{SPI\_SCS[n]}}$ is held low during the active state.

Table 16-32. McSPI Channel *(i)* Configuration Register (MCSPI_CH(i)CONF) Field Descriptions (continued)

Bit	Field	Value	Description
5-2	CLKD		Frequency divider for SPI_SCLK. (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (CLKSPIREF) with a 4-bit value, and results in a new clock SPI_SCLK available to shift-in and shift-out data. By default the clock divider ratio has a power of two granularity when MCSPI_CHCONF[CLKG] is cleared, Otherwise this register is the 4 LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHCTRL[EXTCLK] register.
			The value description below defines the clock ratio when MCSPI_CHCONF[CLKG] is cleared to 0.
		0	Divide by 1
		1h	Divide by 2
		2h	Divide by 4
		3h	Divide by 8
		4h	Divide by 16
		5h	Divide by 32
		6h	Divide by 64
		7h	Divide by 128
		8h	Divide by 256
		9h	Divide by 512
		Ah	Divide by 1024
		Bh	Divide by 2048
		Ch	Divide by 4096
		Dh	Divide by 8192
		Eh	Divide by 16384
		Fh	Divide by 32768
1	POL		SPI_SCLK polarity
		0	SPI_SCLK is held high during the active state
		1	SPI_SCLK is held low during the active state
0	PHA		SPI_SCLK phase
		0	Data are latched on odd numbered edges of SPI_SCLK
		1	Data are latched on even numbered edges of SPI_SCLK

1	1	1	Not supported (unpredictable result)	Supported	Not supported (unpredictable result)

16.3.13 McSPI Channel (*i*) Status Register (MCSPI_CH(i)STAT)

The McSPI channel *i* status register register (MCSPI_CH(i)STAT) provides status information about the McSPI channel *i* FIFO transmit buffer register (MCSPI_TX*n*) and the McSPI channel *i* FIFO receive buffer register (MCSPI_RX*n*) of channel *i*. The (MCSPI_CH(i)STAT) is shown in Figure 16-37 and described in Table 16-34.

Figure 16-37. McSPI Channel *(i)* Status Register (MCSPI_CH(i)STAT)

R-0	R-0	R-0	R-0	R-0	R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 16-34. McSPI Channel *(i)* Status Register (MCSPI_CH(i)STAT) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Read returns 0
6	RXFFF		Channel *i* FIFO receive buffer full status.
		0	FIFO receive buffer is not full.
		1	FIFO receive buffer is full.
5	RXFFE		Channel *i* FIFO receive buffer empty status.
		0	FIFO receive buffer is not empty.
		1	FIFO receive buffer is empty.
4	TXFFF		Channel *i* FIFO transmit buffer full status.
		0	FIFO transmit buffer is not full.
		1	FIFO transmit buffer is full.
3	TXFFE		Channel *i* FIFO transmit buffer empty status.
		0	FIFO transmit buffer is not empty.
		1	FIFO transmit buffer is empty.
2	EOT		Channel *i* end-of-transfer status. The definitions of beginning and end of transfer vary with master versus slave and the transfer format (transmit/receive mode, turbo mode).
		0	This flag is automatically cleared when the shift register is loaded with the data from the transmitter register (beginning of transfer).
		1	This flag is automatically set to one at the end of an SPI transfer.
1	TXS		Channel *i* transmitter register status. The bit is cleared when the host writes the most significant byte of the SPI word in the MCSPI_TX(i) register. The bit is set when enabling the channel *i* , and also when the SPI word is transferred from the MCSPI_TX(i) register to the shift register.
		0	Register is full.
		1	Register is empty.
0	RXS		Channel *i* receiver register status. The bit is cleared when enabling the channel *i*, and also when the host reads the most significant byte of the received SPI word from the MCSPI_RX(i) register. The bit is set when the received SPI word is transferred from the shift register to the MCSPI_RX(i) register.
		0	Register is empty.
		1	Register is full.

16.3.14 McSPI Channel *(i)* Control Register (MCSPI_CH(I)CTRL)

The McSPI channel *i* control register (MCSPI_CH*i*CTRL) is used to enable channel *i*. The MCSPI_CH*i*CTRL is shown in Figure 16-38 and described in Table 16-35.

Figure 16-38. McSPI Channel *(i)* Control Register (MCSPI_CH(I)CTRL)

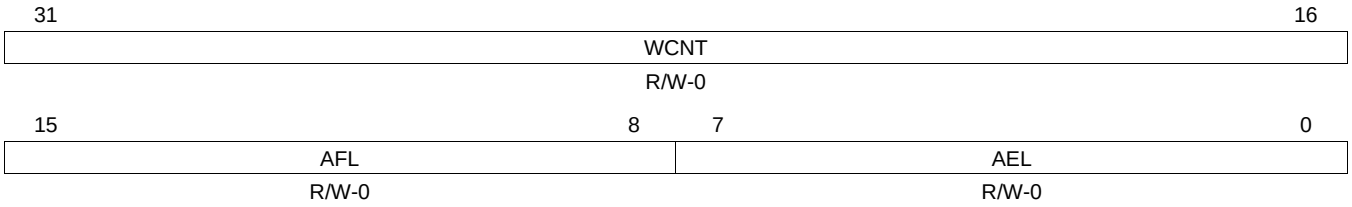
16.3.17 McSPI Transfer Levels Register (MCSPI_XFERLEVEL)

The McSPI transfer levels register (MCSPI_XFERLEVEL) provides the transfer levels needed while using the FIFO buffer during transfer. The MCSPI_XFERLEVEL is shown in Figure 16-41 and described in Table 16-38.

Figure 16-41. McSPI Transfer Levels Register (MCSPI_XFERLEVEL)



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 16-38. McSPI Transfer Levels Register (MCSPI_XFERLEVEL) Field Descriptions

Bit	Field	Value	Description
31-16	WCNT		SPI word counter. Holds the programmable value of the number of SPI words to be transferred on the channel that is using the FIFO buffer. When the transfer has started, a read back of this register returns the current SPI word transfer index.
		0	Counter not used
		1	1 SPI word
		...	...
		FFFEh	65534 SPI word
		FFFFh	65535 SPI word
15-8	AFL		Buffer almost full. Holds the programmable almost full level value used to determine almost full buffer condition. If you want an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least *n* bytes, then the buffer MCSPI_XFERLEVEL[AFL] must be set with n - 1.
		0	1 byte
		1	2 bytes
		...	...
		FFh	256 bytes
7-0	AEL		Buffer almost empty. Holds the programmable almost empty level value used to determine almost empty buffer condition. If you want an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive *n* bytes, then the buffer MCSPI_XFERLEVEL[AEL] must be set with n - 1.
		0	1 byte
		1	2 bytes
		...	...
		FFh	256 bytes

16.3.18 DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

The DMA address aligned FIFO transmitter register (MCSPI_DAFTX) contains the SPI words to transmit on the serial link when the FIFO used and the DMA address is aligned on 256 bits. MCSPI_DAFTX is an image of one of MCSPI_TX*(i)* register corresponding to the channel that has its FIFO enabled. The MCSPI_DAFTX is shown in Figure 16-42 and described in Table 16-39.

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.
- The SPI words are transferred with MSB first.

Figure 16-42. DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX)

DAFTDATA	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 16-39. DMA Address Aligned FIFO Transmitter Register (MCSPI_DAFTX) Field Descriptions

Bit	Field	Value	Description
31-0	DAFTDATA	0-FFFF FFFFh	FIFO data to transmit with DMA 256 bit aligned address. This register is only is used when MCSPI_MODULCTRL[FDAA] is set to 1 and only one of the MCSPI_CH(i)CONF[FFEW] of enabled channels is set. If these conditions are not respected, any access to this register returns a null value.

16.3.19 DMA Address Aligned FIFO Receiver Register (MCSPI_DAFRX)

The DMA address aligned FIFO receiver register (MCSPI_DAFRX) contains the SPI words to receive on the serial link when the FIFO used and the DMA address is aligned on 256 bits. MCSPI_DAFRX is an image of one of MCSPI_RX*(i)* register corresponding to the channel that has its FIFO enabled. The MCSPI_DAFRX is shown in Figure 16-43 and described in Table 16-40.

- Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h.

31-0	DAFRDATA	0-FFFF FFFFh	FIFO received data with DMA 256 bit aligned address. This register is only is used when MCSPI_MODULCTRL[FDAA] is set to 1 and only one of the MCSPI_CH(i)CONF[FFER] of enabled channels is set. If these conditions are not respected, any access to this register returns a null value.

Peripheral Component Interconnect Express (PCIe)

This chapter describes the PCIe Subsystem (PCIESS). The PCIESS provides a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

Topic **Page**

17.1 Introduction

17.1.1 Overview

The PCI Express (PCIe) module is a multi-lane I/O interconnect that provides low pin count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane per direction, for serial links on backplanes and printed wiring boards. It is a 3rd Generation I/O Interconnect technology succeeding PCI and ISA bus that is designed to be used as a general-purpose serial I/O interconnect in multiple market segments, including desktop, mobile, server, storage and embedded communications. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and so on.

The PCIESS contains the Synopsys DesignWare core (DWC) PCIe Dual Mode core and Texas Instruments SERDES PHY. The Dual Mode (DM) core operates as either Endpoint (EP) mode or Root Complex (RC) Port mode. The core supports a single In-Port and a single Out-Port. The role of the PCIe core, EP or RC, is configured based on the value sampled from the BOOTMODE[4:0] pins and by application software configuring PCIE_CFG[PCIE_DEVTYPE] register.

The incumbent design, PCI, is a parallel bus architecture that is increasingly difficult to scale-up in bandwidth, which is usually performed by increasing the number of data signal lines. More signal lines result in difficult clock-to-data skew management, creating complex PCB layout rules that make cost-effective implementations in the FR4 technology difficult. Increasing the number of signal lines also increases the power dissipation. The PCIe architecture was developed to help minimize I/O bus bottlenecks within systems and to provide the necessary bandwidth for high-speed, chip-to-chip, and board-to-board communications within a system. It is designed to replace the PCI-based shared, parallel-bus-signaling technology that is approaching its practical performance limits while simplifying the interface design. It includes cost, performance, and scalability advantages ensuring a long life span existence to applications, system designs and investments.

PCIe is a serial-based technology which uses low-voltage differential data signaling/lines (LVDS) to reduce the number of data signal lines and high-frequency clock signals in a point-to-point interconnect arrangement between two devices. It also serves to eliminate multiple host presences on the same bus.

17.1.2 Features

The PCIESS on the device supports an interface width of ×2 lanes. The following features are included:

- 250 MHz functional clock frequency operation (PIPE clock frequency)
- Supports a single bi-directional Link interface (that is, a single Ingress and a single Egress ports). Can directly connect to one device only with the possibility of 1 or 2 bi-directional lanes.
- Operates at a raw speed of 2.5Gbps or 5.0 Gbps per Lane per Direction
- Maximum outbound payload size of 128 bytes
- Maximum inbound payload size of 256 bytes
- Maximum remote read request size of 256 bytes
- Ultra-low transmit and receive latency
- Support for dynamic-width conversion
- Automatic Lane reversal
- Polarity inversion on receive
- Single Virtual Channel (VC)
- Single Traffic Class (TC)
- Automatic credit management
- Single Function in Endpoint (EP) mode
- ECRC generation and checking
- PCI Device Power Management with the exception of D3 cold with Vaux
- PCI Express Active State Power Management (ASPM) state L0s and L1
- PCI Express Link Power Management states except L2 state
- PCI Express Advanced Error Reporting

- PCI Express messages for both transmit and receive
- Filtering for Posted, Non-Posted, and Completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and Completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through BAR0 and through configuration access
- Legacy Interrupts reception (Root Complex (RC)) and generation (EP)
- MSI generation and reception
- PHY Loopback in RC mode

17.1.3 Features Not Supported

The following features are not supported by the PCIESS:

- Multiple VCs
- Multiple TCs
- Outbound transactions involving less than 4 bytes
- Function Level Reset
- PCI Express beacon for in-band wake
- Built-in hardware support for hot plug
- Vendor Messaging
- IO access in inbound direction
- Addressing modes other than incremental for burst transactions
- Using ×2 link as two ×1 links
- Auxiliary Power to maintain controller state to come out D3cold state
- Link state L2 support

17.1.4 Functional Block Diagram

The PCIESS is shown in Figure 17-1.

17.1.4.1 PCIe Core

The PCI Express core implements the three PCI Express protocol layers (Transaction Layer, Data Link Layer, and the MAC portion of the Physical Layer). The PCIe core is a Dual Mode core allowing it to operate either as an RC or as an EP. As an EP, it can operate as a Legacy Endpoint or native PCIe Endpoint. The role it assumes is based on the state of the PCIe Configuration register (within the Control Module) bit field PCIE_CFG [1:0] PCIE_DEVTYPE = 00b/ 01b/ 10b = EP/ Legacy Endpoint/ RC respectively. The user software or BOOTROM is required to initialize this field. During times PCIe is used as a Boot Device, then the state of Bootmode Pins will determine the Boot Type used (in this case it will be PCIe) and the address size to be used which is either 32bit or 64bit addressing. The bootloader software configures the PCIe core to operate in EP mode. No RC Bootmode is supported.

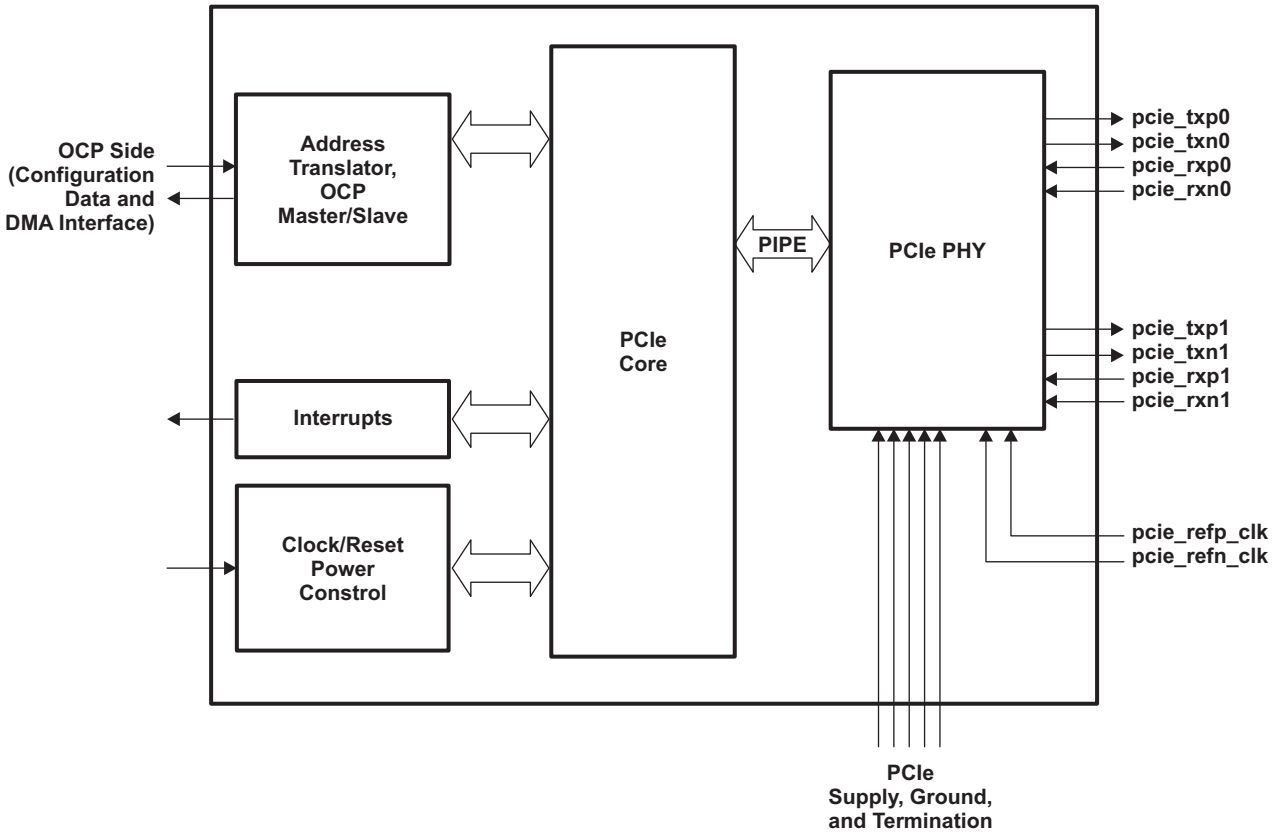
17.1.4.2 PCIe PHY

The PCI PHY (SERDES) contains the analog portion of the PHY which is the transmission line channel that is used to transmit and receive data. It contains a phase locked loop, analog transceiver, phase interpolation based clock/data recovery, parallel to serial converter, serial to parallel converter, scrambler, configuration and test logic.

17.1.4.3 OCP (Configuration and DMA Access Interface)

CPU side access, Configuration Registers, Data Access, and Remote EP DMA access is performed through the Configuration and DMA Access interface. The maximum amount of data burst access made through this port is 128 bytes.

Figure 17-1. PCIe Subsystem (PCIESS) Block Diagram



17.1.4.4 Clock, Reset, Power Control Logic

Several clock domains exist within PCIESS. These clocks are functional clocks used by the PCIe controller and interface bridges as well as receive and transmit clocks used to clock data in and out respectively. The clocks required for clocking data and PHY functional clocks are generated by the PHY through the supplied external input 100 MHz differential clock with no more than 300ppm tolerance. The PCIe controller functional clock frequency is generated from the internal PLL and should be programmed to generate a clock frequency of 250MHz.

The PCIESS supports the Conventional Reset mechanism that is specified within the PCI Express Specification. The reset shown on the block diagram pertains to a hardware reset (cold or warm reset).

In addition to automatic power down mode exercised and entered by the hardware (Active State Power Management) when no activity is present, PCIESS supports higher level power down modes controlled (activated and deactivated) by application software.

NOTE: Link state L2 is not supported.

17.1.4.5 Interrupts

The PCIESS is capable of generating multiple interrupts events via the four interrupt lines (INTA/B/C/D – Legacy Interrupts Combined, MSI, Error, and PM/Reset), connected to the Interrupt Controller. The user software is required to acknowledge the serviced interrupt by writing to the corresponding vector onto the EOI register.

17.1.4.6 PCIe Power/Ground/Termination

Several supplies, grounds, and termination exist to properly power up the PHY.

17.1.4.7 Differential Data Lines

A pair of differential data lines exists, for both transmit and receive paths, for each lane.

17.1.5 Supported Use Case Statement

The PCIe subsystem has only one interface link and this link can be used in a ×1 or ×2 lane arrangements connecting to only one single device. In other words, there exists no support for connecting to two devices in an ×1 arrangement since it has the support of a single interface link. It also means that it cannot be used as a switch. Lane 0 must always be connected and functioning, either alone or in conjunction with Lane 1, for the link to be established. Lane 1 cannot be used alone.

17.1.6 Industry Standard(s) Compliance Statement

The PCIESS complies with the following standards:

- Revision 2.0 of the PCI Express Base Specification
- Synopsys DWC PCIe Dual Core Version 3.51a
- TI SERDES 1.1.03

17.1.7 Terminology Used in this Document

The following is a brief explanation of some terms used in this document:

ADPLL— All Digital Phase Locked Loop

ASPM— Active state power management

AXI— AMBA AXI Bus Protocol

DBI— Direct Bus Interface

EP— End Point

LVDS— Low Voltage Differential Signaling

MMR— Memory Mapped Register

OCP— Open Core Protocol

OCM— On-Chip Memory

OCMC— On-Chip Memory Controller

PCI— Peripheral Component Interconnect

PCIe— PCI Express

PCIESS— PCI Express subsystem

PCISIG— PCI Special Interest Group

PIPE— Physical Interface for PCI Express

PME— Power Management Event

RC— Root Complex

TC— Traffic Class

TLP— Transaction Layer Packet

VC— Virtual Channel

VPD— Vital Product Data

17.2 Architecture

This section discusses the architecture of the PCIESS.

17.2.1 Clock Control

The PCIESS uses multiple clock domains. At the top level, there are only two functional clocks of relevance – a reference clock to the PCIE PHY and a clock for OCP interfaces of the subsystem.

The OCP interface functional clock is generated from the main PLL which in turn uses the 27-MHz crystal input. It is important that the PLL is programmed appropriately in such a way that a 250-MHz functional clock is present at SYSCLK5.

The other clock input to the PCIESS is the differential 100-MHz clock with a maximum frequency of deviation value of 300 ppm. This differential clock is used by the PHY PLL to generate the necessary functional and bit clock required by the PHY.

The PCIESS operation is completely dependent upon availability and stability of the clocks, more importantly the accuracy of the clock generated from the PLL that is inside the PHY. All registers in PCIESS are located in the clock domain that is dependent upon PLL proper configuration and lock status state prior to placing the PCIe in active state. Transactions initiated before ensuring PLL lock status will cause the PCIe subsystem to operate in an unpredictable manner. The SoC-level registers are used to enable PLL and to verify lock status.

17.2.2 Supported PCIe Transactions

All of the PCIe Transactions defined, Posted and Non-Posted, are supported except the Locked Memory Read request transaction and its subsequent completion Locked response transaction. In-bound I/O read/write transactions are also not supported.

Table 17-1. PCIe Transaction Layer Packets Supported

Transaction Packet Types	Posted/Non-posted
Memory Read	Non-posted
Memory Write	Posted
IO read (Outbound only supported in RC Mode)	Non-posted
IO Write (Outbound only supported in RC Mode)	Non-posted
Configuration Read (Type 0 and Type 1)	Non-posted
Configuration Write (Type 0 and Type 1)	Non-posted
Message Request without Data	Posted
Message Request with Data	Posted
Completion without Data	-
Completion with Data	-

17.2.3 Address Translations

PCI Express TLP transactions using Address Routing use PCIe addresses. To accommodate the mapping requirement that exists between a PCIe address and a local OCP/Internal address, a built-in hardware address translation mechanisms exists. That is, if the “Type” field of an outgoing or received TLP indicates the use of address routing, then an Outbound or Inbound address translation is required and is performed accordingly to map OCP/Internal address to PCIe address or vice-versa using hardware address translators. Address translations for Outbound and Inbound transactions are discussed below.

PCIe recognizes four address spaces, Memory, I/O, Configuration, and Message. Messages do not consume any Memory or I/O resource and no type of translation is required. I/O addressing is used by PCIe (only supported in RC configuration) in outbound access to a Legacy EP; this is not a mandatory feature by PCIe and when supported the I/O spaces is memory mapped to system memory. This implies that there exists a need to map only two types of device address spaces, Configuration and Memory address spaces. The address translators apply to translating Configuration and Memory addresses between PCIe address and OCP/Internal address.

The address space of the physical device is divided into two spaces (Range 0 and Range 1). Address space (Range 0) that is used for PCI configuration tasks, referred to as configuration space; and a second Address space (Range 1) that is used for accessing memory (non-configuration related), referred to as memory space.

NOTE: All I/O access use Address Routing. There is no-support for I/O access in Inbound direction. That is, when it comes to a transaction that performs I/O access only TLPs with Outbound transactions are supported.

17.2.3.1 Outbound Address Translations

Outgoing Transaction Layer Packets (TLP) associated with “Address Routing” would require the use of the Outbound address translator that creates a mapping between the OCP/Internal memory/address and external PCIe device memory/address on the PCIe fabric.

The PCIE Subsystem allows mapping of Physical device address to PCIe address on outgoing TLPs. This is accomplished by using outbound address translation logic. For each outbound read/write request, the address translation module within PCIESS converts an OCP address (OCP/Internal address) to a PCIE address (PCIe address) of Memory Read/Write type. The address translation logic uses information programmed within address translation registers to perform the mapping. The registers, OB_SIZE, OB_OFFSET_INDEXn, OB_OFFSETn_HI are used in conjunction with Out-bound address translator.

The physical memory range that PCIESS occupies in the devices internal address range is divided into 32 equally sized translation regions (Regions 0 to 31). These equally divided regions can be programmed to have a size of 1, 2, 4, or 8 MB and this size value is communicated with the Outbound Address Translator via the OB_SIZE register. Each such region (OCP/Internal address) can be remapped to a PCIE address range of same size as the size of translation region itself. The address translation logic identifies and extract the 5 bits (32 regions) from the OCP/Internal address and uses this value as an index to identify one of the 32 regions. The bit address position for these 5 bits depends on the size of the regions. Once the region is identified, the Address translation logic then generates PCIe base address, from the values provided within the corresponding configuration registers for that region, that is, the registers OB_OFFSET_INDEXn and OB_OFFSETn_HI [n = 0-31]. If 32-bit addressing is used, OB_OFFSETn_HI will always be programmed with zero.

Once the PCIe base address has been identified, the offset that is to be added to this base address is derived from the lower bit fields of the OCP/Internal address and the bit fields that make up this offset correspond to the size of the regions.

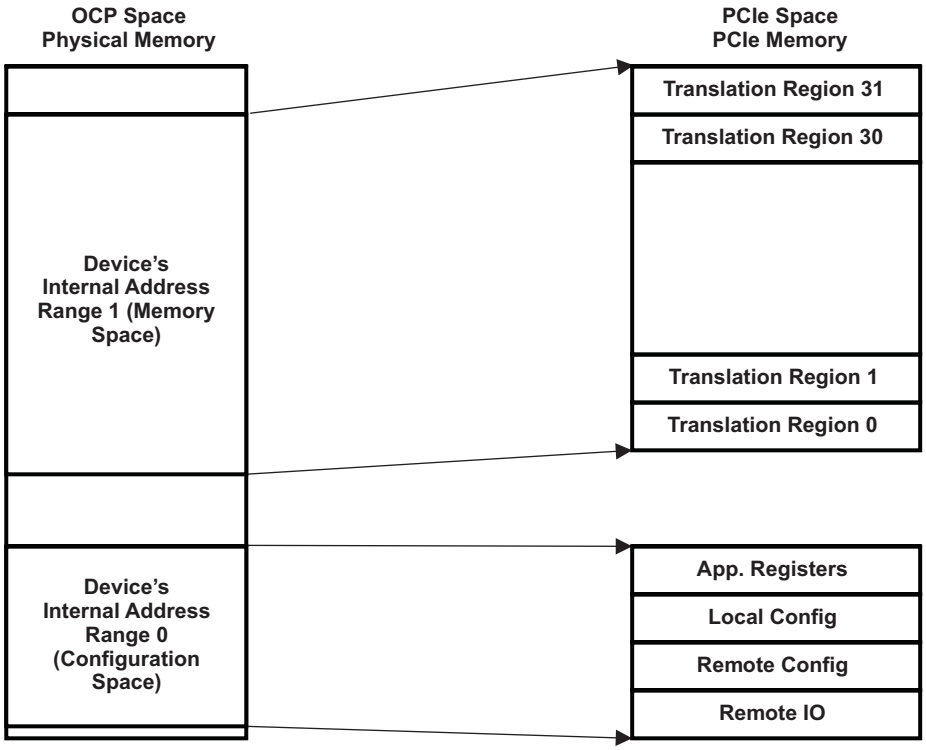
Application software is required to identify the desired physical memory that is to be accessible by the PCIe module and initialize the corresponding registers prior to enabling PCIe transactions. For Outbound translation the registers in use, initialization, and usage is discussed below.

- Outbound Size Register (OB_SIZE) — Application software initializes this register with the size value that applies to all 32 regions. OB_SIZE=0,1,2, and 3 correspond to region sizes of 1MB, 2MB, 4MB, and 8MB and the corresponding indexed regions for these sizes are identified from the OCP/Internal address. Bits[24:20], bits[25:21], bits[26:22], and bits[27:23] of the OCP/Internal address holds the Index value used to identify one of the 32 regions for the 1MB, 2MB, 4MB and 8MB regions respectively. Size of regions also affect the meaningful bit fields within OB_OFFSET_INDEXn [n=0-31] register. The lower bit fields corresponding to the size of the region are masked and not used in the mapping.
- Outbound Translation Region n Offset Low and Index Register (OB_OFFSET_INDEXn [n = 0-31]) — Application software initializes this register with the 32-bit PCIe address. The useful address bits used by the Outbound translator from this register depends upon the size of the region. If each region is 1MB, 2MB, 4MB, or 8MB, then the relevant address field bits used to create PCIe address are the

higher address bits, specifically bits[31:20], bits[31:21], bits[31:22], and bits[31:23], respectively.

- Outbound Address High Offset (OB_OFFSETn_HI [n = 0-31]) – Application software initializes this register if using 64-bit addressing with the higher 32-bit address. This register is required to be programmed with a Zero value if using 32-bit addressing.

Figure 17-2. Outbound Address Translation



The following example demonstrates the mapping of a given OCP/Internal address to a PCIe address.

Example 1:

For a given OCP/Internal Address of 9D3A_1234h; what would be the corresponding PCIe Address that would be used on an outgoing TLP Header (assume a 2MB region partition)?

For this example, further assume the followings: 64 bit addressing is to be used and for region 9, and application software has initialized OBOFFSET9_HI with 3344 5566h and OB_OFFSET9 with 56Ex xxxxh (where 'x' here is a don't care hexadecimal value). Note that bits[31:21] of OB_OFFSET9 register is the part of this register content that is meaningful for this example since the size of the regions is 2MB.

The procedure that is used to convert this OCP/Internal address to a PCIe address is as follows.

1. Extract the five bits Index and Offset from given input OCP/Internal address of 9D31 1234h: Since region size is given to be 2MB, bits [25:21] of address 9D3A 1234h is extracted to be used as an Index and this comes out to be 01001b, which is 9. Since size of all regions is 2MB, the offset address corresponds to bits[20:00] of the OCP/Internal address. Note that the offset of the OCP/Internal address, bits[20:00], is directly mapped to the PCIe address; that is, bits[20:00], and for this example that translates to XX1A 1234h. Since Index value is 9, translation registers contents for region 9 will be used.

   Index is now matched to Region 9 and Offset is 001A 1234h.
2. Generate PCIe Base address: Using the Index value identified above, 9, generate base address from register OBOFFSET9_HI (bits[63:32]) for 64-bit addressing and register OB_OFFSET9 (bits[31:20]). The PCIe Base Address for this example would results with: 3344 5566 56E0 0000h.
3. Compute translated address, PCIe address: Using the generated Base Address and Offset the PCIe address corresponding to a OCP/Internal address of 9D3A 1234h is 3344 5566 56FA 1234h.

NOTE: For this example, 2MB size region will allow unique address mapping for Physical Address values 0000 0000h to 03FF FFFFh. This allows a total of 2MB × 32 = 64MB unique Physical Address location to be mapped onto a corresponding unique virtual PCIe address. Any Physical address outside this 64MB space will not be uniquely mapped and the Physical address will be truncated to fall in within the 64MB space, which happens to be for this example. In other words, bits[31:26] of the given example Input/Physical Address is masked and did not contribute to the PCIe Address generation.

For this example, OCP/Internal addresses 9D3A 1234h, 913A 1234h, 953A 1234h, 993A 1234h, etc., are few of other OCP/Internal Physical values that will all map to the same PCIe address 3344 5566 56FA 1234h.

17.2.3.2 Inbound Address Translations

Incoming error free accepted Transaction Layer Packets (TLP) associated with “Address Routing” would require the use of the In-bound address translator to map received PCIe address to OCP/Internal address.

The PCIe Subsystem allows mapping of accepted PCI Express addresses to a Physical device address internal to the device using the Inbound Address Translation logic. For each Inbound read/write request, that results with incoming TLP, the address translation module within PCIESS can convert a PCIe address to OCP (internal/physical) address for Memory or Configuration Read/Write type transactions.

PCIESS is aware of two OCP Address Spaces (Internal/Physical Memory Spaces) within the device. The first address space, “Address Space Zero” (also known as region 0), is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote IO accesses (RC only). The second, address space, “Address Space One” (also known as region 1), is dedicated for data transfer. Details on this are captured in following sections.

Address Space Zero occupies a contiguous 16K Bytes of location. The first 4KB of this 16KB Space is the Configuration Space. “Address Space One” is used for data buffering and is large in size and not necessarily contiguous. To perform a mapping of a PCIe addresses that would land within Address Space One, four dedicated Regions, (Regions [0-3]) are available for the use of the Inbound Address Translator. Note that Outbound translation has 32 regions while Inbound translation has four regions.

This means that any Accepted TLP that has found a match with one of the BARs, BAR[0-5] will be mapped to one of the two address spaces, Address Space Zero or Address Space One. BAR0 is dedicated to Address Space Zero and implicit mapping is done and no region association is required. However BARs[1-5] are dedicated to Address Space One and association with one of the four regions, Regions[0-3], is required. Note that this is valid in the context of an accepted TLP with 32-bit Addressing. If 64-bit Addressing is used, then the association of the six BARs with the Address Spaces change to a total of three since a pair of adjacent BARs concatenated is required to hold the 64-bit Address. This implies that BAR0 and BAR1 will hold 64-bit Address with BAR0 holding the low 32-bit PCIe address to match while BAR1 holds the high 32-bit PCIe address to match (associated with Address Space Zero). The same holds for Address Space One association. BARs[2-3] and BARs[4-5] will hold the accepted 64-bit address that will be associated to Address Space One where mapping takes place between the BARs and Regions[0-3].

Address Translation for Address Space Zero does not exist since the internal location is unique and is contiguous. All is needed is the PCIe Address within the received TLP PCIe address matching BAR0, for 32-bit addressing, and BARs[0:1] for 64-bit addressing.

However, Address Translation for Address Space One requires the use of one of the four Regions (Regions[0-3]) to map accepted TLPs to Internal/Physical memory address. Four region specific memory mapped registers exist and used by the Inbound Address Translator.

Association between regions (Regions[0-3]) and BARs is made via the corresponding IB_BARn [n=0-3] register. IB_STARTn_HI [n = 0-3] and IB_STARTn_LO [n = 0-3] are used to hold the start address of a 64-bit PCIe Address to match, and IB_OFFSETn [n = 0-3] is used to hold the Offset for that particular Region (note that what is referred here as offset could be viewed as the physical Memory Base Address). Note also that for 32-bit addressing, IB_STARTn_HI[0-3] is programmed to zero.

The procedure used by the In-Bound Address Translator to perform the mapping between the PCIe Address and Address Space One is as follows:

1. Extract the Offset: PCIe Address – (IB_STARTn_HI : IB_STARTn_LO)
2. Compute absolute OCP/Internal address: Add Base Address IB_OFFSETn to the Offset extracted on step 1.

NOTE: When using TLPs with 64-bit addressing a pair of adjacent BARs are concatenated to hold the 64-bit Address. This implies that BAR0 and BAR1 will hold the 64-bit Address with BAR1 holding the high 32-bit PCIe address to match and BAR0 holding the low 32-bit PCIe address to match. Same argument holds for BAR3, BAR4 and BAR5, BAR6 where BAR3 and BAR5 hold the low 32-bit of the 64-bit addresses.

Example 2:

For a given 64-bit PCIe Address of 1234 5678 ABC5 0000h, that qualifies for acceptance; what would be the corresponding mapped Internal (Physical) Device Address be? (Assume that Region 1 registers are programmed to match BAR2, BAR3 RC programmed addresses).

Further assume that application software has programmed the set of registers corresponding to Region 1 with the values shown below.

- IB_BAR1 = 2. This assignment associates Region 1 with BAR2, or BAR3 for 64-bit Addressing. This value programmed as 2 associates the match between Region 1 (IB_BAR1) and Configuration Register BAR2/BAR3.
- IB_START1_HI = 1234 5678h
- IB_START1_LO = ABC0 0000h
- IB_OFFSET1 = 3340 0000h

The OCP/Internal address is computed by Subtracting the PCIe Base Address and extracting the Offset from the PCIe Address (Address within the TLP Header) and add the resultant to the start Address of the OCP/Internal address.

Extract the Offset from the PCIe Address:

- Extracted Offset = PCIe address – (IB_STARTn_HI : IB_STARTn_LO) => Extracted Offset = 1234 5678 ABC5 0000h – 1234 5678 ABC0 0000h = 0005 0000h

Compute the absolute OCP/Internal address:

- Add the extracted Offset to the Internal Base Address:

  Internal/Physical Absolute Address = 3340 0000h + 0005 0000h = 3345 0000h

In example 2, PCIe Address of 1234 5678 ABC5 0000h is translated or mapped to OCP/Internal address, 3345 0000h.

17.2.3.2.1 BAR0 Exception for In-Bound Address Translation

The memory space covered by BAR0 in inbound direction is completely dedicated to accessing the application registers, Address Space Zero. It implies that the BAR0 cannot be remapped to any other location but to application registers. Any remote inbound access matching the BAR0 region will automatically be routed to these registers. It allows RC devices to control EP devices in absence of dedicated software running on EP. For RC and EP, this mapping of BAR0 to registers allows the message signaled interrupts to work. There is no support to disable BAR0 accesses from reaching the application registers.

17.2.3.2.2 Mapping Multiple Non-contiguous Memory Ranges to One Region

A single inbound TLP address translation region (matching RC programmed PCIe BAR Address) can be used to map accesses to multiple non-contiguous internal address ranges, within Address Space One, by ensuring that the start addresses of these regions are programmed in ascending order in the inbound start address registers.

Example 3:

In this example, two BARs (BAR1 and BAR2) are remapped to four separate locations (four regions) that are non-contiguous using 32-bit addressing. The first two regions (Region 0 and Region 1) remap accesses landing in BAR1 space and the following two regions (Region 2 and Region 3) remap accesses landing in BAR2 space. Each BAR is treated as a 32-bit BAR.

Assumed RC programmed Value of Base Address Registers in Configuration Space:

- BAR1: 1111 0000h
- BAR2: 2222 0000h

NOTE: In case there are more than one matching BAR, then the highest start address that is greater than the TLP address is the one that is considered for translation.

Table 17-2. Example Demonstrating the Mapping of Non-contiguous Memories to a Single Region

Region (IB_BAR)	BAR	IB_Start_LO	IB_Offset	TLP Address	Translated Address
0	1	1111 0000h	3333 0000h	1111 0080h	[1111 0080h - 1111 0000h] + 3333 0000h = 3333 0080h
1	1	1111 8000h	4444 0000h	1111 9000h	[1111 9000h – 1111 8000h] + 4444 0000h = 4444 1000h
2	2	2222 0000h	5555 0000h	2222 0400h	[2222 0400h – 2222 0000h] + 5555 0000h = 5555 0400h
3	2	2222 0800h	6666 0000h	2223 1000h	[2223 1000h – 2222 0800h] + 6666 0000h = 6667 0800h

17.2.3.2.3 Using BAR1 Value as Start Address

The inbound address translation for BAR1 has additional capability of using the value of BAR1 register (from PCIe Configuration Space) as the start address for inbound address translation. This feature can be activated by leaving the start address of the corresponding inbound translation region (one of the four Regions associated to BAR1) programmed with zero. When an incoming read/write access matches BAR1 and the inbound region's BAR match (IB_BARn) is set to one with start address programmed to zero, the BAR1 value is used to compute the translated address. Note that if this feature is used, only one inbound translation window is available and it will be relative to BAR1 programmed value. No other BARs or inbound translation windows can be used if BAR1 is designated as the reference for inbound address translation.

17.2.3.2.4 BAR Mask Registers

The PCI Configuration Register BARs in End Point devices are programmed by RC during the PCI Configuration process while performing enumeration, device discovery. Since the PCIESS is a Dual Mode (DM) core, prior to the start of PCI Configuration, the PCIESS EP device firmware/application software has the opportunity to modify the behavior of BAR registers prior to RC starts the enumeration process and assignment of PCIe Base Addresses. Using the BAR Mask Registers which are overlaid on the BAR Registers, the software on the EP device can configure the amount of address space that the EP will request from the RC during configuration for each of its BARs. The software can also modify the BAR types and can enable/disable the BARs. That is, the read only bit fields of the Configuration Register BARs are user programmable and is required to be programmed prior to enumeration or device discovery process begins.

Note that the BAR Mask Registers are accessible, for configuration purposes of the BARs, only when operating as EP and at the same time only when CMD_STATUS[DBI_CS2] is set/ enabled. Firmware needs to always read back the data written after modification to ensure that the write has completed since the confirmation read will not happen until the write completion insuring the register update is made prior to use. Firmware needs to clear CMD_STATUS[DBI_CS2] after initial configuration prior to RC starts enumeration.

It is important to not attempt modification of BAR Mask Registers from serial link side as unpredictable behavior may occur and the system could become unstable and even worse unusable.

17.2.3.3 Address Alignment Requirement

As per PCIe standard, no transaction can cross a 4 KB-aligned address boundary. The limit on transaction size on the internal bus interface (OCP) is 128 bytes. So, the transactions must be 128 byte or smaller on the internal bus interface. If a transaction received in inbound direction crosses a 128 byte aligned address, then the PCIESS master interface can split such transaction into multiple transactions at the 128 byte boundary.

17.2.3.4 Byte Strobe Usage Requirements

For any type of write transactions, the byte enables can only have a single unbroken string of 1s. In other words, in a transaction, if a byte's write strobe is set, then all following bytes must have write strobe set until the last byte with write enabled. "Holes" or "Zeros" in between the byte enables are not allowed.

Since the internal bus width is greater that 32-bit, the TLP size will not be 1 (PCIe counts in 32-bit units) and therefore, it is through the FBE/LBE (First/Last Byte Enable) that the actual data transfer size is controlled.

17.2.3.5 Zero-Length Read/Write Transactions

Read transactions that request zero bytes are not supported by PCIESS. PCIESS will read issue a read with FBE field of PCIe TLP set to Fh. Writes of zero bytes are supported.

17.2.3.6 Transactions Crossing 4KB Boundary

Any single transaction that reads/writes data on locations crossing a 4KB aligned address are invalid as per PCIe Standard Section 2.2.7. If such a read is issued to PCIESS Slave, it will lead to two transactions on the serial link so that PCIe protocol is not violated. But if the completions do not return in order from remote PCIe link partner, then it may result in violation.

17.2.3.7 Outbound Transactions Involving Less than 4 Bytes

The PCIESS imposes a limitation on the minimum size of data, 4-bytes wide, to be accessed in outbound transactions. It is not possible to access less than 4 bytes. This could potentially be a problem when accessing non-prefetchable memory, resulting in accesses to an undesired memory location.

17.2.3.8 Transaction Address Alignment

The PCIESS imposes a limitation of a maximum of 128 byte outbound read/write command. However, if the starting address is not aligned to an 8 byte boundary, then the maximum transaction size is reduced to 120 bytes. Unspecified behavior will occur if misaligned transactions in outbound direction are not limited to a maximum of 120 bytes.

17.2.3.9 Read Interleaving

Read interleaving refers to the process of returning split read responses from multiple transactions. This implies that read data is not guaranteed to be sent in sequential order (data for one transaction to be sent completely before the next). PCIE core is guaranteed to not interleave read responses if the outbound read command/transaction size does not exceed the max transaction size configured in the PCIE core. Currently this is configured as 128 bytes.

17.2.3.10 Endian Mode

The PCIESS is configured to operate in Little Endian mode. Most of the peripherals within the devices are also configured in Little Endian mode.

17.2.4 Address Spaces

Internal Device addressable resources, from PCIESS perspective, are categorized in to two separate spaces. That is, PCIESS has two OCP Address Spaces or Regions. The first is dedicated for local application registers, local configuration accesses, remote configuration accesses and remote IO accesses (RC only). This space is referred as Address Space Zero. The second is dedicated for data transfer and it is referred as Address Space One.

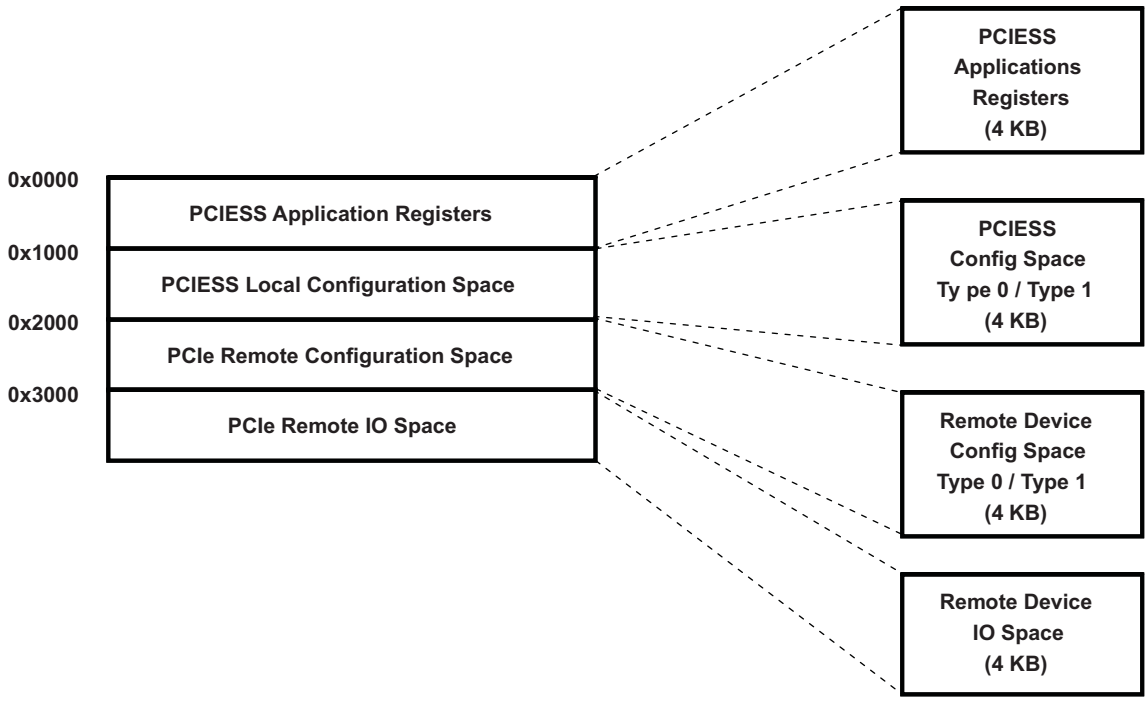
17.2.4.1 Address Spaces Zero

Address Space Zero is made of a contiguous 16 Kbytes of memory partitioned into four sections/regions with equal sizes (each 4 Kbytes long). These regions are:

1. PCIESS Application Registers
2. PCIe Local Configuration Registers
3. PCIe Remote Configuration Registers
4. PCIe IO Access Window

Figure 17-3 illustrates the relationship of the various address regions within the Address Space Zero.

Figure 17-3. Address Space Zero Relationships



Each of the four addresses space Zero regions is meant for accessing a set of registers.

1. PCIESS Application Registers – These registers are used to configure and monitor various settings within the PCIESS. These registers are specific to the application needs and are not related to the PCIE Configuration Registers. Note that all PCIESS Application registers should be accessed in 32-bit mode.

2. PCIe Local Configuration Registers – PCIESS local configuration registers are used to read the settings of configuration registers of the local PCIE Device. Prior to PCI Express configuration is complete, these registers can also be written to. Depending upon whether PCIESS is configured as RC or EP, the layout of these registers is either Config space Type 0 or Type 1. Note that all accesses on PCIe Local Configuration Registers must be made in 32-bit mode. In EP Mode, this is Type 0. In RC Mode, this is Type 1.
3. PCIe Remote Configuration Registers – Remote PCIe configuration registers are accessed by programming the bus number, device number and function number of the remote PCIE device in one of the application register and then accessing the PCI Remote configuration registers as if it were the PCIE Config space of a single PCIE function. The layout of the remote configuration registers varies based upon whether the device is an End Point or a PCIe Switch.
4. PCIe IO Access Window – A 4KB region is dedicated for remote IO accesses when PCIESS is in RC mode. Any access made on this space becomes an IO access. The actual address in the TLP gets its base address from the IO_BASE register value and an offset that is directly derived from the address of the OCP/VBUM access in this 4KB space.

None of the four address ranges described above support burst transactions. So, only single 32-bit transactions should be issued to these addresses. These addresses should also be configured as non-cacheable address space.

17.2.4.1.1 Remote Configuration and I/O Requests (Caution)

Since the remote configuration and IO transaction windows are directly mapped to internal bus space, the software must take caution not to access these spaces when there is no operational PCIe link. No response may be generated for such transactions. It is recommended that checks be built into software to avoid remote accesses in the absence of an operational link.

17.2.4.2 Address Space One

The second address space/region is used for data transfer. The BAR values setup within the PCIe Local Configuration Registers define where within the memory map of the CPU on Root Complex side are the End Points located. All locations other than what is setup in BAR registers of the End Points are on the Root Complex side.

The Address Space One is mapped to multiple devices in RC mode. Each remote device could be allocated a portion of this memory space and any transaction that is targeted to this address space gets converted to a PCIe transaction targeted to the appropriate remote PCIe device.

17.2.4.2.1 Organization of Configuration Registers

As shown in Table 17-3, the registers for various PCIe capabilities are linked to each other via address offsets specified in the registers.

Table 17-3. Register Blocks That Make Up the PCIe Configuration Registers

Offset From Start of Configuration Space	Register Block
00h	PCI-Compatible Header (Type 0/1)
40h	Power Management Capabilities Registers
50h	MSI Capabilities Registers
70h	PCI Express Capabilities Registers
100h	PCI Express Extended Capabilities Registers
700h	Port Logic Registers

17.2.5 Bus Mastering

An End Point that is capable of becoming a bus master and initiate transactions in upstream direction must have its Bus Master Enable bit set in configuration space registers (STATUS_COMMAND[BUS_MASTER]). If transactions are initiated (while assuming the role of a RC or EP) before enabling bus mastering capability, then transactions will not start until the bus master enable is set. There is no timeout or error response generated when transactions does not go out because of bus master bit not being set.

17.2.6 PCIe Loopback

The PCIe Specifications provides loopback support in two ways – through PIPE interface (Link Layer) and second through PHY loopback capability (PHY Layer).

The PIPE Interface Loopback requires for two PCIe Devices/Components to attached to each other in a Loopback Master and a Loopback Slave configuration. A Loopback Master is the component requesting Loopback. A Loopback Slave is the component looping back the data. Note that, regardless with the PCIESS role it assumes (RC or EP), it can assume a role of a Loopback Master or a Loopback Slave.

The Loopback, Loopback at the PHY Level, does not require another component.

17.2.6.1 PIPE Loopback

The procedure depends upon whether the device is operating in RC or EP Mode. In either case, the PCIESS can be loopback master or loopback slave as outlined in PCIe specifications. Note that this Loopback Mode cannot be used for looping back transactions. These modes are to be used with PCIe test equipment only for symbol level loopback.

The Loopback entry procedure when PCIESS is a Loopback Master:

RC Mode

1. Set Loopback Enable in the Port Link Control Register in Port Logic Register space.
2. The link retraining sequence must be initiated by writing to Link Retrain field in the Link Control Register in PCI Express Capabilities structure in the device's PCI Configuration Space.

EP Mode

1. Set Loopback Enable in the Port Link Control Register.
2. Force the LTSSM to be in recovery state via the Port Force Link register of the Port Logic registers.
3. Set Force Link bit to high in Port Force Link register in Port Logic Registers.

Once this is done, devices at the ends of a PCIe link enter PCIe LTSSM Loopback state. The initiator of loopback state is the loopback master and the other device is loopback slave. Note that it is not possible to send TLPs in this mode and return them via the loopback state of the other device.

The Loopback entry procedure when PCIESS is a Loopback Slave:

If the PCIESS is a Loopback slave, then the incoming serial data is routed back to the originating device from the PIPE interface as per PCIe loopback requirements. Typically, PCIe test equipment will be used as Loopback Master and it will transition PCIESS into Loopback Slave state following which the inbound transactions will be Loopback to the test equipment. There is no programming required on PCIESS to enter Loopback in slave mode. PHY support is not required to use this loopback mode.

17.2.6.2 PHY Loopback

The PHY loopback is accomplished by switching the PHY to loopback where the transmitted data is looped back to the receive path at the PHY level. This mode can be used to perform TLP loopback even if there is no link partner. It is, however, only possible to set up when PCIESS is used in RC mode. This limitation is because of the fact that link training cannot occur between two upstream ports; at least one port must be a downstream port.

The procedure is similar to the one for PIPE (Link Layer) interface but the PHY programming is used instead. This mode is entered by configuring the SERDES configuration registers. Both the Transmit and Receive paths must be set in loopback mode to enable PHY loopback mode.

Note that there are several other requirements for this to correctly work:

1. The PHY should be configured to operate in loopback mode before any transaction is sent out. Recommended approach is to set loopback before link training. Otherwise, any transactions that were not looped back will cause sequence numbers to increment on transmitter but not on receiver and all following transactions will be dropped because of sequence number mismatch.
2. The BAR0 and BAR1 values (if programmed) should not match the address for the transaction that is issued on slave interface. Otherwise, it will not get to the master port but to internal registers.
3. The memory base/limit registers should not be configured such that the address of the transaction lies in the range specified by the memory base/limit registers. Otherwise, the transaction will be discarded as a misrouted packet.
4. It is not possible to use configuration type transactions in this mode as RC cannot be a target of configuration transactions. Such transactions will be invalid and loopback will not work.

17.2.7 L3 Memory Map

The system memory mapping of the device is broken into three levels (Level 1, 2, and 3) of granularity for target address spaces allocation for easier address decoding capability. The address spaces required for PCIe usage lies within Level 3 (L3) Memory/Region. See the *Chip Level Resources* chapter or the data manual for more information.

Some processors within the device may re-map these targets to different PCIe addresses through an internal or external MMU. Processors without MMUs and other bus masters will use these OCP/Internal addresses to access L3 regions. Note that not all masters have access to all L3 regions but only those with defined connectivity. See the data manual or the Chip Level chapter for more information.

The OCP/Internal address block accessed by PCIESS is 256MB wide (within L3 region) with starting address of 2000 0000h and ending address of 2FFF FFFFh. This is also referred to Address Space One within PCIe.

Another OCP/Internal address block accessed by PCIESS is a16MB wide block (within L3 region) with starting address of 5100 0000h and ending address of 51FF FFFFh. This address region is referred to Address Space Zero within PCIe.

Two more additional registers within the Control Module (also within L3 region) PCIE_CFG and PCIE_TEST_CTRL are used by the PCIe to configure the PHY PLL, PCIe Mode of operation, Test Mode Patterns, etc.

Four more additional registers within the Power Reset and Control Module (also within L3 region) are used to control the PCIe controller reset status and release states as well as clock enable/disable capabilities. The PM_DEFAULT_PWRSTST and RM_DEFAULT_RSTCTRL registers are used to control reset related tasks while CM_DEFAULT_PCI_CLKSTCTRL and CM_DEFAULT_PCI_CLKCTRL are used to control clocking related functions.

17.2.8 Reset Considerations

The PCIESS supports the Conventional Reset mechanism that is specified within the PCI Express Specification. Both hardware and software reset are supported.

No support for the Functional Level reset is needed since the PCIESS supports a single function.

17.2.8.1 Software Reset Considerations

Software reset is issued via the transmission of TS1 Ordered Sets.

17.2.8.2 Hardware Reset Considerations

Hardware reset is caused while power is being sourced to the device. The SoC level Power On Reset acts as the power on reset for PCIESS.

17.2.8.3 PCIe Boot Capability

The device supports PCIe boot capability as an Endpoint. No support for RC bootmode. See Bootmode configuration details for the applicable settings of the Bootmode pins.

17.2.8.4 PCIe System Module Registers

Two configuration registers PCIE_CFG and PCIE_TEST_CTRL are used for configuring PCIe for operation as well as for Test mode generation. These registers exist within the Control Module space. These registers can only be accessed in Supervisory mode. See the System Module for more information. The base address for the Control Module registers is 4814 0000h.

Four registers within the Power, Reset, and Clock Management (PRCM) Module are used to control the PCIe controller reset status, reset release, and PCIe clock enable/disable capabilities. RM_DEFAULT_RSTST and RM_DEFAULT_RSTCTRL are used to control reset related control capabilities, and CM_DEFAULT_PCI_CLKSTCTRL and CM_DEFAULT_PCI_CLKCTRL are used to control clocking related tasks. The base address for the PRCM registers is 4818 0000h.

17.2.8.4.1 PCIe Configuration Register (PCIE_CFG)

The PCIE_CFG register, in the Control Module, is located at offset 640h and the register format and description are shown in Figure 17-4 and Table 17-4. The PCIE_CFG register is used to configure the PCIe role to be in RC or EP mode. It is also used to configure the PHY PLL multiplier value.

17.2.8.4.4 RM_DEFAULT_RSTST Register

The RM_DEFAULT_RSTST register, in the PRCM module, is located at offset B14h and the register format and description are shown in Figure 17-7 and Table 17-7. The RM_DEFAULT_RSTST register logs the different reset sources of the DEFAULT domain. Each bit is set upon release of the domain reset signal. Must be cleared by software, using RM_DEFAULT_RSTCTRL register, prior to setting the status bit.

17.2.8.4.5 CM_DEFAULT_PCI_CLKSTCTRL Register

The CM_DEFAULT_PCI_CLKSTCTRL register, in the PRCM module, is located at 4818_0510h and the register format and description is shown below. This register enables the domain power state transition. It controls the software supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

Table 17-9. CM_DEFAULT_PCI_CLKCTRL Register Field Descriptions

Bit	Field	Value	Description
31-21	Reserved	0	Read returns 0
18	STBYST		Module standby status.
		0	Module is functional (not in standby)
		1	Module is in standby
1-0	IDLEST		Module idle status.
		0	Module is fully functional, including OCP
		1h	Module is performing transition: wakeup, or sleep, or sleep abortion
		2h	Module is in Idle mode (only OCP part). It is functional if using separate functional clock
		3h	Module is disabled and cannot be accessed
15-2	Reserved	0	Read returns 0
1-0	MODULEMODE		Control the way mandatory clocks are managed.
		0	Module is disabled by software. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wake up).
		1h	Reserved
		2h	Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.
		3h	Reserved

17.2.9 Interrupt Support

The PCIESS provides a total of four interrupts to the device interrupt controller, that is, it generates four interrupt events aggregated. In other words, each of these interrupts has more than one underlying event that the interrupt represents. Once all pending interrupts have been cleared, the hardware EOI for the interrupt generic will be generated.

Both Message Signaled Interrupt (MSI) and Legacy Interrupt are handled by the PCIESS. When operating as an EP, the PCIESS is capable of generating MSI or Legacy Interrupt, depending on the role it is assuming. Note that one PCIe component can not generate both type of interrupts. It is either one or the other. The interrupt type an EP generates is configured during configuration time. When operating as RC, the PCIESS is capable of handling both MSI and Legacy Interrupts. This is because when operating as RC it should be able to service both PCIe endpoints as well as Legacy endpoints.

17.2.9.1 Interrupt Events and Requests

A total of four interrupt events are supported by the PCIESS. Some of the events are meaningful based on the role the PCIESS assumes (RC or EP). Table 17-10 captures the Interrupt events supported for both RC and EP modes.

Table 17-10. PCIESS Interrupt Events

Interrupt	Interrupt Description
0	PCIE Express Legacy Interrupt Mode (RC mode only)
	[0] INTA
	[1] INTB
	[2] INTC
	[3] INTD
1	MSI Interrupts 0 through 31 in PCI Express Mode (EP/RC Modes)
	[0] MSI Interrupt 0
	[1..30] MSI Interrupt 1 and so on
	[31] MSI Interrupt 31
2	Error Interrupts (EP, RC)
	[0] System Error (OR of Fatal, Nonfatal, Correctable errors)
	[1] PCIe Fatal Error
	[2] PCIe Non-fatal Error
	[3] PCIe Correctable Error
	[4] AXI Error due to fatal condition in AXI bridge
	[5] PCIe Advanced Error
3	Power Management and Reset Event Interrupts (EP, RC)
	[0] Power Management Turn-off Message Interrupt (EP only)
	[1] Power Management Ack Message Interrupt
	[2] Power Management Event Interrupt
	[3] Link Request Reset Interrupt (Hot reset or Link down)

17.2.9.2 Interrupt Generation

Since the PCIESS is capable of assuming a role of RC or EP, interrupt generation capability is dependant upon the role it is assuming.

17.2.9.2.1 Interrupt Generation in RC Mode

As per PCI Express Base Specifications, Root Complex ports only receive interrupts. There is no mechanism to generate interrupts from RC port to EP mode as per PCIe specification. However, PCIESS does support generation of interrupts from RC to EP. The behavior is similar to generation and reception of MSI interrupts in RC mode except for the fact that this functionality is enabled in EP mode as well.

The RC device can perform a memory write into the MSI IRQ register over the PCIe link to generate one of 32 EP interrupts. Note that the PCIESS will follow PCIe MSI rules and will not necessarily accumulate multiple writes to the same MSI vector. Only one of such writes is guaranteed to be processed and subsequent writes on the same vector arriving before the interrupt status is cleared may be lost.

17.2.9.2.2 Interrupt Generation in EP Mode

When PCIESS is operating as an EP, either the legacy interrupts or the MSI interrupts can be triggered to the upstream ports (eventually leading to an interrupt in RC device). As per PCIe Specifications, each PCIe function may generate only one of the Legacy or MSI interrupt types as decided during configuration period.

Legacy Interrupt Generation in EP Mode

The endpoint can trigger generation of a PCI Legacy Interrupt at the Root Complex via an in-band Assert_INTx / Deassert_INTx PCIe Message. The actual interrupt that is generated on RC port is based on the configuration of the EP that generates the interrupt and it could be one of INTA, INTB, INTC or INTD. See Interrupt related registers in configuration space registers.

To generate an interrupt, following steps are required:

1. Legacy interrupt generation should be enabled via EP_LEGACY_CONFIG register.
2. Write 1h to EP_IRQ_SET register to enable the legacy interrupt.
3. An ASSERT INTA/B/C/D message is automatically sent.
4. Write 1h to EP_IRQ_CLR register to disable the legacy interrupt by sending a DEASSERT INT A/B/C/D message.

Once an assert message has been generated, it cannot be generated again until a deassert message is generated. Thus, only one interrupt can be pending at a time. The pending status can be checked in EP_IRQ_STATUS register.

Note that the interrupt messaging mechanism makes it unfeasible to guarantee a time of delivery of the interrupt unlike in conventional designs where the interrupt line is often electrically connected to the final destination.

There is no hardware input port provided that will allow generation of legacy interrupts on the EP port.

MSI Interrupt Generation in EP Mode

MSI Interrupts are generated by a PCIe Write transaction that performs a 32-bit memory write to a pre-determined address with a pre-determined data. The PCIe system software configures the address and the data that is to be used in the memory write transaction at the time of initialization of the EP device. The MSI scheme supports multiple interrupts and each device can request up to 32 interrupt vectors even though the allotted interrupts may be less than the requested number.

To generate MSI interrupts, the following steps need to be taken:

1. Ensure that the MSI support has been enabled in the device.
2. Read the value of MSI Address Register in the local PCIe configuration space.
3. Read the value of MSI Data Register in the local PCIe configuration space.
4. Determine the number of MSI vectors allocated (and the number requested) to the device.
5. Depending upon the number of MSI interrupts allocated, issue a Memory Write transaction with the address same as MSI Address Register and Data same as MSI Data Register. In the data, the LSBs can be modified to reflect appropriate MSI event that needs to be notified to Root Complex.
6. The Memory Write transaction can also be optionally routed through the outbound address translation interface if the destination PCIe address is not directly accessible.

For more details about how MSI interrupts are expected to behave, refer to PCIe Standard Specifications.

17.2.9.3 Interrupt Reception

Since the PCIESS is capable of assuming a role of RC or EP, interrupt reception capability is dependant upon the role it is assuming.

17.2.9.3.1 Interrupt Reception in EP Mode

The PCIe specification does not have provision for End Points to receive legacy interrupts. As a result, only events other than PCIe related can cause interrupts. The MSI interrupts are not supported on EP devices as per PCIe Specification but PCIESS does support these interrupts. The MSI interrupt is generated as a result of the one of 32 events that are trigger by a write to MSI_IRQ register by the RC.

These interrupts, delivered via register writes over the serial link, could also be coming from another End Point that performs a write to the appropriate interrupt registers in the EP's BAR0 space. It is up to software designers to implement a way to determine the actual source of the interrupt.

17.2.9.3.1.1 Host Reset Request Interrupt Reception in EP Mode

When the link is down, the upstream port may request reset of the End Point. This request is terminated as an interrupt to the End Point host software. The PCIESS automatically disables LTSSM by de-asserting app_ltssm_enable bit in CMD_STATUS register and suspends LTSSM in DETECT QUIET state. All outstanding transactions are errored out on slave port and further transactions are no generated on master port. Once the transactions are completely stopped through OCP disconnect protocol, the software should issue a local reset to PCIESS. The re-initialization process may then be started.

17.2.9.3.2 Interrupt Reception in RC Mode

When PCIESS operates in RC Mode the Endpoints on the PCI fabric can be a Switch, PCIe EP or Legacy EP. For this reason, it should be able to handle both MSI and Legacy Interrupt.

17.2.9.3.2.1 MSI Interrupt Reception in RC Mode

A total of 32 MSI interrupts can be generated from one or more downstream devices. These MSI interrupts represent the MSI interrupts that have been allocated to various downstream devices during PCIe configuration/enumeration procedure. Before the End Point devices can issue MSI interrupts, the MSI address and data registers must be configured. Each End Point can either use MSI interrupts or legacy interrupts and not both at the same time. MSI interrupt have the same race condition hazard as the legacy interrupts. Hence, software drivers should take precaution.

17.2.9.3.2.2 Legacy Interrupt Reception in RC Mode

Any of the four legacy interrupts may be generated by the PCIESS. Each interrupt can originate from multiple End Point devices. The software should service these by probing the interrupt registers in each downstream device's configuration space. When all devices have been serviced, the last device serviced will send a interrupt deassert message which will clear the interrupt.

The interrupt request signal at the PCIESS boundary is a pulse signal that is triggered each time a assert interrupt message is received. The interrupt pending signal is a level signal that is high as long as the interrupt has not be serviced and the interrupt status not cleared through a register write.

Note that the traditional EOI procedure, although implemented, may not operate as expected if the deassert message arrives after the EOI has been issued. This can not be corrected but only worked around by doing a read on the interrupt register downstream before issuing EOI. If the EOI register is written to before the deassert message has reached the interrupt logic, the interrupt pending status will not have cleared and the interrupt will re-trigger.

In addition, the software drivers for downstream devices must ensure that the data transaction that is expected to complete before interrupt is triggered in RC device's CPU has completed. Since PCIe write transactions are posted, it is not necessary that a write from EP to system memory in RC has completed before a write to MSI interrupt generation register has completed. This could create a potential race condition.

It is optional to support Legacy Interrupts in PCI Express (non-legacy) devices.

17.2.10 DMA Support

The PCIESS has no built in DMA and makes use of the EDMA to move data in and out of the PCIESS with out the need of the CPU intervention. EDMA is only used when PCIESS is the initiator of a transaction and accessing other PCIe component. When another PCIe component is accessing a resource within the PCIESS, the PCIe in this case acts as a master and it makes use of the master port to directly access the necessary resource requiring no need for the EDMA usage. For details on EDMA, please consult the EDMA Peripheral Guide.

As an initiator only Cortex-A8 and EDMA can be used to move data in and out of the device resource. As a master (that is, external PCIe component accessing device resource), it is capable of accessing DDR (via DMM), Async EMIF (GPMC), C674x L2 Memory, and On-Chip Memory.

NOTE: Master/Slave reference here does not mean RC/EP mode. As an RC or EP, the PCIESS can act as both Master and Slave. It means as to who is generating the request. If the PCIESS is generating a request, it means that an external PCIe component is the actual entity generating the request and the PCIESS is now regarded as a Master. If the PCIESS is accessing external PCIe component, the PCIESS is regarded as a slave and only Cortex-A8 or EDMA is capable of moving data in and out internal resource.

17.2.10.1 DMA Support in RC Mode

When operating in Root Complex mode, the EDMA controller can perform DMA transfer between device internal resource and any remote device located on the PCI Express fabric. The memory address of such devices is available to the software via the PCI Express bus enumeration procedure. In addition, the PCIe subsystem has a provision to perform memory address translation on outbound requests. Thus, the software is able to map different memory regions in its memory map to correspond to different addresses (and different access types) on the PCI Express side.

There are bandwidth implications of using an external DMA. If the PCIe core has been programmed to establish a link in PCIe 2.5 Gbps rate, then the DMA controller that drives PCIESS Slave Port must be able to write/read data at about 85% of 2 Gbps bandwidth per PCIe link. For a PCIe link speed of 5.0 Gbps, the DMA controller must be able to provide bandwidth of about 85% of 4 Gbps per PCIe link.

In addition, the master port on PCIe port can issue read/write accesses that have been initiated by remote PCI Express device. The interconnect fabric should provide sufficient capacity to serve 85% of 2 Gbps (4 Gbps if operating in Gen2) per PCIe link in each direction.

17.2.10.2 DMA Support in EP Mode

When operating as a PCIe End Point, the device will be located in PCIe memory map at location programmed in the Base Address Registers by the PCIe Root device. In End Point mode, the PCIESS provides address translation functionality. It is possible to map IO, Config and Memory accesses originating on PCI Express side to memory accesses with different address on the OCP side. These address ranges are configurable through application registers.

The approximate data rate for each of these transactions will be about 85% of 2 Gbps (4Gbps in Gen2 mode) in each direction on each PCIe lane.

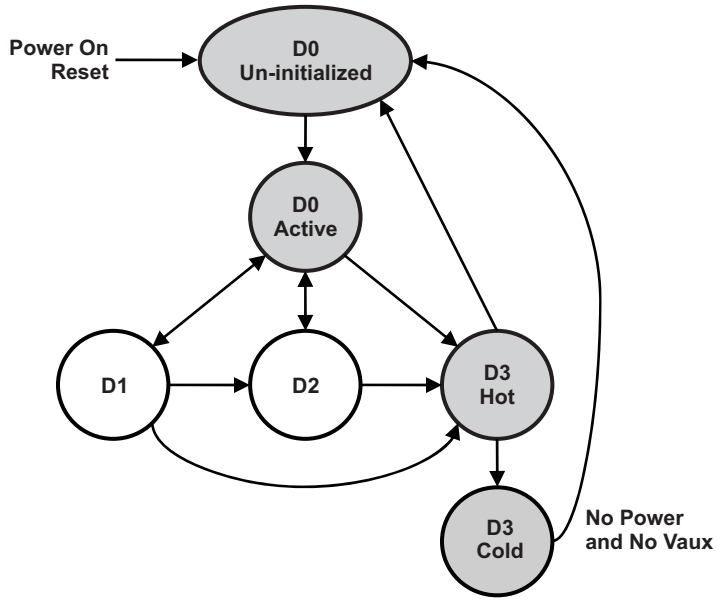
17.2.11 Power Management

PCI Express has multiple power management protocols. Some of these are invoked by the hardware solely, Advanced State Power Management (ASPM) feature, while others are activated at higher levels via software.

17.2.11.1 Device Power Management

The PCI Express protocol is compatible with all PCI power management functionality. The power states specified are D0, D1, D2, D3Hot and D3cold. All functions must support D0 and D3 states.

Figure 17-10. Device Power Management States



17.2.11.1.1 D0 Power State

Upon completion of a reset such a power-on or hot reset, the function is considered to be in D0 uninitialized state. Once the function is enumerated, configured and one or more of the memory space enable, IO space enable or bus master enable bits are set, it is considered to be in D0 active state. The D0 active state is the full-operation state of a PCI Express function.

17.2.11.1.2 D1 Power State

Support for D1 state is optional and is primarily driven by software. It is considered to be a light sleep state that provides some power savings compared to D0 state while still allowing transition to D0 state. While in the D1 state, a Function must not initiate any Request TLPs on the Link except for a PME Message. Configuration and Message Requests are the only TLPs accepted by a Function in the D1state. All other received Requests must be handled as Unsupported Requests, and all received Completions may optionally be handled as Unexpected Completions. A Function's software driver participates in the process of transitioning the Function from D0 to D1. It contributes to the process by saving any functional state (if necessary), and otherwise preparing the Function for the transition to D1. As part of this quiescence process the Function's software driver must ensure that any mid-transaction TLPs (Requests with outstanding Completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D1.

17.2.11.1.3 D2 Power State

Support for D2 state is optional in PCI Express and is primarily driven by software. It provides significant power savings while still retaining capability to transition back to previous condition. In this state, the PCI function can only initiate Power Management events and it can only respond to configuration accesses.

17.2.11.1.4 D3Hot and D3Cold Power State

All PCI Express functions are required to support D3 state. In D3hot state, power is still present while in D3cold there is no power. Devices in D3Hot state may be transitioned back to D0 state while the devices in D3Hot state need re-initialization to be brought back to D0 state.

Functions in D3hot respond to configuration space accesses as long as power and clock are supplied so that they can be returned to D0 by software. When programmed to D0, the function may return to the D0 Initialized or D0 Un-initialized state without PCIe reset being asserted. There is an option of either performing an internal reset or not performing an internal reset. If not performing an internal reset, upon completion of the D3hot to D0 Initialized state, no additional operating system intervention is required beyond writing the Power State bits. If the internal reset is performed, devices return to D0 Un-initialized and a full re-initialization is performed on the device. The full re-initialization sequence returns the device to D0 Initialized when normal operation may resume.

17.2.11.2 Link State Power Management

There are multiple states for the physical layer – L0, L0s, L1, L2 and L3 states that provide incrementally higher power savings as the states transition from L0 towards L3. PCIESS supports L0, L0s and L1 states. L3 state is power-off state and is supported by default. PCIESS does not support L2 power down states.

Some of the link power states are autonomously managed by hardware. This scheme is referred to as Active State Power Management (ASPM). Figure 17-11 illustrates the transitions between states L0, L0s and L1 that are managed by ASPM. The transitions between gray states are allowed in ASPM. These transitions can be enabled through registers in the PCI Express Configuration Space to allow either just L0s transition or both L0s and L1 transitions.

The L1 power state can also be entered via software control. When the device power state is D1, D2 or D3hot, then the link state must transition to L1 state. Figure 17-12 shows such state transition.

Figure 17-11. Transitions Between Link States

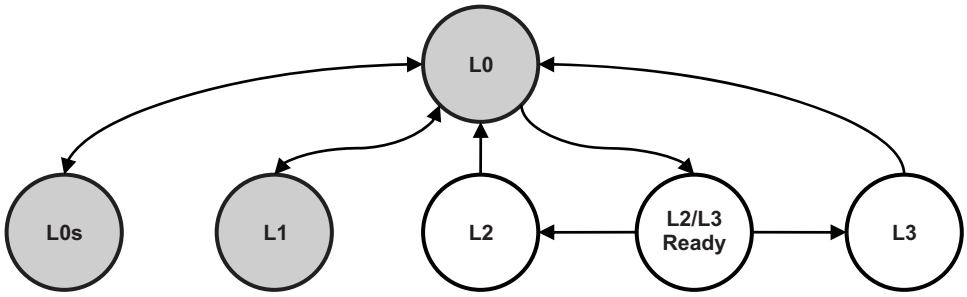


Figure 17-12. Link State Transition to L1 State

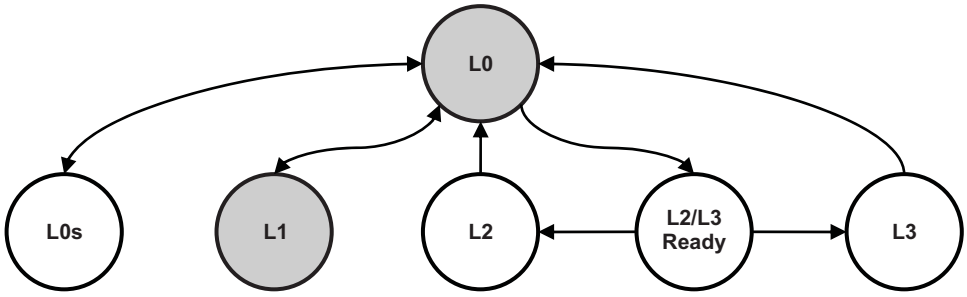

17.2.11.2.1 L0s State

L0s is a lower power state enabled by Active State Power Management. Each device can control its L0s transition on its transmitter. Receiver side is controlled by the remote device.

17.2.11.2.2 L1 State

The L1 state is reached either through ASPM timer mechanism or via the software initiated transition to a D state other than the D0 state. In L1 state, the link is in idle state and both receiver and transmitter in devices on both ends of a link are able to conserve energy.

17.2.11.2.3 L2/L3 Ready State

This state is a transitional state reached from L1 where from the link must either transition to L2 or to L3 state. The L3 state is a full power off state. The L2 state is also a power off state except that the WAKE signal can be used by End Point devices to request power and clock from the system.

17.2.11.2.4 L2 State

The L2 state is appropriate when a device needs to monitor an external event while in deep power down mode. In L2 state, auxiliary power is supplied and a minimal amount of current is drawn from the power source. Almost all of the logic is devoid of power. To recover, the wake signal is used.

17.2.11.2.5 L3 State

In this state, device is supplied no power from the PCIe fabric. There is no mechanism to communicate in L3 state. To recover, the system must re-establish power and reference clock followed by a fundamental reset.

17.2.12 Relationship Between Device and Link Power States

The device D-states are correlated to the link power states. For each D state, there are specific states that the PCIe link or interconnect can transition to. Table 17-11 shows the permissible state combinations.

Table 17-11. Device Power States and Link Power States Relations

Downstream Device State	Permissible Upstream Device State	Permissible Link State
D0	D0	L0 (required), L0s (required), L1 ASPM (optional)
D1	D0 – D1	L1
D2	D0 – D2	L1
D3hot	D0 – D3hot	L1, L2/L3 Ready
D3cold	D0 – D3cold	L2aux, L3

17.2.12.1 OCP Power Management

The OCP bus power management is accomplished by use of Idle and Standby Mode. The list of Idle/Standby states support by PCIESS are in Table 17-12

Table 17-12. Idle/Stand-by State Supported

IDLE/STANDBY Mode	Remarks
NO IDLE	Supported.
SMART IDLE	Default State
SMART IDLE w/ WAKE-UP	Supported
FORCE IDLE	Supported
NO STANDBY	Supported
SMART STANDBY	Default State
SMART STANDBY w/ WAKE	Not supported
FORCE STANDBY	Supported

Note that if Idle mode is reached in default state, the hardware will not request wakeup once in Idle mode. Software must ensure that it wakes up the hardware by exiting IDLE state in such situations. The compatibilities of various states are tabulated in Table 17-13.

Table 17-13. Relationships Between Power States and Link States

STANDBY Mode	Tested IDLE Mode(s)	Link States and transitions
NO STANDBY	NO IDLE	States: L0 and L1 Transitions: L0àL1, L1àL0
SMART STANDBY	SMART IDLE WITH WAKE	States: L0, L1 The valid transitions among these states are tested Transitions: L0àL1, L1àL0, L0àL2/L3 Ready The states L2 and L3 need fundamental reset to recover from.
SMART STANDBY	SMART IDLE	States: L0, L1, L2/L3 Ready Transitions: L0àL1, L0àL2/L3 Ready Valid transitions among these states are tested. Note that the Remote partner cannot wake up PCIESS if OCP wakeup is not enabled. A fundamental reset is always required to wake from L2 or L3 states.
SMART STANDBY	NO IDLE	States: L0, L1 Transitions: L0àL1 Only master port will enter standby. No clock gating is achievable in this configuration.
SMART STANDBY w/ WAKE	NA	Not supported
FORCE STANDBY	FORCE IDLE	States: Uninitialized Link, L0 Transitions: None It is not recommended to keep OCP in standby/idle and link in initialized state. This should be done only when the remote side is aware that the device interconnect in not operational and therefore, no transactions should be initiated.

17.3 Use Case

17.3.1 PCIe Root Complex

When the PCIESS is desired to operate as a Root Complex (RC), the following initialization sequence is recommended.

17.3.1.1 PCIe Root Complex Initialization Sequence

The initialization sequence is:

1. Configure PCIe Mode of operation to RC Mode by programming PCIE_CFG.PCIE_DEVTYPE with a value of 2h.
2. Bring PCIESS out of reset through the device level reset controller.
3. Enable and configure PCIe Clock (See PCIE_CFG Register Description). Note: The Default PLL Multiplier configuration value (PCIE_CFG.PCIE_CFGPLL = 1C9h) is most likely to be used if using a 100 MHz input clock source.
4. Wait for the PCIe PHY PLL to lock; wait for PCIe PLL Status (PCIE_CFG.PCIE_STSPLL) to change to 1h.
5. Insure that the link is idle. Disable link training by de-asserting the LTSSM Enable bit in PCIESS Control Register. Upon reset, the LTSSM Enable is de-asserted automatically by hardware, CMD_STATUS.LTSSM_EN is zero.
6. Configure core registers through OCP Slave interface address space 0.
7. Initiate link training can be initiated by asserting LTSSM Enable bit in PCIESS Control Register; programming CMD_STATUS.LTSSM_EN with a 1.
8. Insure link training completion and success by observing DEBUG0.LTSSM_STATE field change to 11h.
9. In conjunction with the system software, start bus enumeration and setup configuration space on downstream ports.
10. Continue software handshake and initialization on the remote devices. This includes setting up DMA protocols, interrupt procedures, etc.
11. With the completion of software initialization, DMA accesses can be started on various end points.

17.3.1.2 PCIe Root Complex Configuration Accesses

Configuration accesses are made by RC port to individual function in each downstream EP device to program the PCIe specific operating parameters. In particular, the configuration accesses are used to allocate memory ranges for each downstream device, configure those memory ranges as IO or Memory type, enable bus master capability on the device if necessary and also build a software database of PCIE attributes and capabilities of each downstream device. Each downstream device can be configured through the configuration access region of PCIESS. The PCIESS convert memory reads and writes on the configuration region of OCP interface into configuration access on the serial link.

17.3.1.3 PCIe Root Complex Memory Accesses

There are two types of memory accesses – the outbound memory accesses that are initiated by the DMA on the PCIESS Slave port and the inbound memory accesses that are initiated by the PCIESS Master port targeted to internal memory regions within the OCP Interconnect.

The outbound PCIe memory read and write accesses are made through the PCIESS slave port through the device memory range that is dedicated to data transfers. The read and write transactions on this region are directly mapped to PCI Express space by the PCIESS in conjunction with the outbound address translation mechanism. The completions to the bus transactions are generated by PCIESS when it receives completions from remote devices. In case of errors or timeouts, an error response is provided. For reads, the error responses span as many phases as there would be data phases if the error had not occurred.

The inbound memory accesses received by PCIESS on the serial link are initiated by remote PCIe End Points that are capable of bus mastership. Such accesses are converted to bus transactions on PCIESS master port and once a Response/Completion is received, the PCIESS sends data/response back to the PCIe bus master over the serial links. Typically, the inbound accesses will be targeted to memory space resident on the bus side of the RC port. The locations to which inbound memory accesses map are determined by software. The software must inform the remote devices about what protocol is to be followed so that the remote device will access the relevant memory regions to read or write data/control information. Not all End Points have the capability to initiate inbound accesses.

An inbound access cannot cross a 4 KB boundary as per PCIe specifications. In addition, any access that spans a 128 byte boundary in the device memory map can get split into two transactions at the 128 byte boundary.

17.3.1.4 PCIe Root Complex I/O Accesses

I/O accesses are optional in PCI Express. In PCIESS, these accesses can be made through a 4KB memory space and a programmable register. All accesses made to the 4KB space become IO accesses and the IO Base register determines the target address for such accesses. The IO accesses cannot be for more than 32-bits of data aligned at 4 byte boundary.

17.3.2 PCIe End Point

When the PCIESS is desired to operate as an Endpoint (EP), the following initialization sequence is recommended.

17.3.2.1 PCIe End Point Initialization Sequence

Upon de-assertion of reset, the PCIESS is configured as End Point by chip level setting of PCIESS inputs. Before a Root Complex is allowed to access the configuration space of the end point, the following initialization sequence should be followed:

1. Configure PCIe Mode of operation for EP Mode by programming PCIE_CFG.PCIE_DEVTYPE with a value of 0.
2. Bring PCIESS out of reset through the device level reset controller.
3. Enable and configure PCIe Clock (See PCIE_CFG Register Description). Note: The Default PLL Multiplier configuration value (PCIE_CFG.PCIE_CFGPLL= 1C9h) is most likely to be used if using a 100 MHz input clock source.
4. Wait for the PCIe PHY PLL to lock; wait for PCIe PLL Status (PCIE_CFG.PCIE_STSPLL) to change to 1h.
5. Insure that the link is idle. Disable link training by de-asserting the LTSSM Enable bit in PCIESS Control Register. Upon reset, the LTSSM Enable is de-asserted automatically by hardware, CMD_STATUS.LTSSM_EN is 0.
6. Program the configuration registers in the PCIESS to desired values.
7. Initiate link training can be initiated by asserting LTSSM Enable bit in PCIESS Control Register; programming CMD_STATUS.LTSSM_EN with a 1.
8. Insure link training completion and success by observing DEBUG0.LTSSM_STATE field change to 11h.
9. If further configuration register initialization is required, the Application Request Retry bit should be set. This will lead to incoming accesses to be responded with the retry response. This feature allows slow devices extra time before the Root Port assumes the devices to be inactive. Once programming is complete, de-assert Application Request Retry field to allow transactions from the Root Complex.
10. Once configuration setup is complete, DMA transactions can begin.
11. Inbound PCIe transactions will arrive at the master port of the PCIESS End Point. These will be responded to by the target slave devices and the PCIESS will relay the response back to the PCIE device that initiated the transaction.
12. Outbound PCIe transactions will be targeted to the slave port of the PCIESS End Point. These transactions will be serviced only if the PCIESS End Point has been given Bus Master Capability by the Root Complex.

17.3.2.2 PCIe End Point Configuration Accesses

As an endpoint, the PCIESS can only be a target of configuration accesses from upstream. Until the link is established and APP_RETRY_EN is disabled, the PCIESS will not respond to configuration accesses. When enabled, the PCIESS will respond to configuration accesses automatically and these accesses do not get relayed to the master interface on the device interconnect side.

End point is not capable to accessing configuration space of devices other than its own. The system software can initialize the read only fields in PCIESS Configuration Space via the slave port before the link training has been initiated. Once the configuration is complete by the PCI Express Root Complex, the system software should not modify the PCIESS configuration parameters. There is no explicit prevention mechanism in hardware to disallow such accesses though.

17.3.2.3 PCIe End Point Memory Accesses

There are two types of Memory Accesses – inbound and outbound memory accesses.

An inbound access is typically initiated by a Root Complex port or by another End Point that is reaching the PCIESS via a PCI Express switch that supports peer-to-peer access. In either case, the incoming PCIe transaction results in an access on the PCIESS master port. The response to the such accesses is relayed back to the originating PCIe device.

In an outbound access, a DMA module or a host CPU initiates a read/write access on the PCIESS Slave port. This request is converted into a PCIe memory read/write transaction over the PCIE link. Once the PCIESS receives completion from the remote device, it generates a completion on the OCP slave port. The software/hardware that initiates the request on the slave port must perform it in a memory region that has been determined previously through software protocols. For example, the software may get information about applicable memory regions from the software that is running on the Root Complex device.

17.3.2.4 PCIe End Point I/O Accesses

IO Accesses are not supported in PCIESS operating as a PCIe End Point.

17.4 PCIe Registers

17.4.1 Accessing Read-only Registers in Configuration Space

Some of the register fields provided in the configuration space can be written to prior to bus enumeration via the slave interface of PCIESS. Note that the hardware does not prevent modification of read only field after bus enumeration but it is strongly advised that read only fields not be written once the bus enumeration is complete.

In addition, the BAR Mask registers can also be programmed by first enabling the DBI_CS2 bit and then performing writes on the BAR registers. The BAR mask registers are overlaid on BAR registers. For the BAR mask registers to be writable, the respective BAR must first be enabled.

17.4.2 Accessing EP Application Registers from PCIe RC

The application registers are also mapped at 2K and above address, in the configuration space. The RC software can access these registers over PCIe link provided the registers are programmed to some default values by the BOOT code in the PCIESS host device that enables link training and TLP exchange.

17.4.3 Encoding of LTSSM State in DEBUG Registers

The LTSSM state value that is read from DEBUG registers is an encoded value. The literal names of the LTSSM states corresponding to the encoded values are tabulated in Table 17-14.

Table 17-14. Encoded Debug Registers Contents and Their Relation to LTSSM States

Code	LTSSM State
0h	DETECTQUIET
1h	DETECTACT
2h	POLLACTIVE
3h	POLLCOMPLIANCE
4h	POLLCONFIG
5h	PREDETECTQUIET
6h	DETECTWAIT
7h	CFGLINKWDSTART
8h	CFGLINKWDACEPT
9h	CFGLANENUMWAIT
Ah	CFGLANENUMACEPT
Bh	CFGCOMPLETE

1Bh	LPBKACTIVE
1Ch	LPBKEXIT
1Dh	LPBKEXITTIMEOUT
1Eh	HOTRESETENTRY
1Fh	HOTRESET

17.4.4 PCIe Application Registers

The Application registers are accessible in multiple ways depending on the point of origin of such accesses. When accessed from the OCP side (on board CPU or EDMA performing the access), these registers are accessed via the 4KB space in Address Space or Address Region Zero. When accessed from the PCIe serial link side, the application registers are mapped to BAR0 of an EP as well as RC. In other words, if a PCIe component desires access to the application registers, based on the address type used (memory or configuration) the right block of memory is accessed automatically. In addition, an RC can access these registers in a PCIESS EP via the upper 1 KB space of the PCIe configuration space. The offsets of the registers remain the same regardless with the access method used.

Table 17-15 lists the PCIe application registers. For the base address of these registers, see Table 1-11.

Table 17-15. PCIe Application Registers

Offset	Acronym	Register Name	Section

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-17. CMD_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved
11-10	OCP_STANDBY	0-3h	The **OCP standby mode bitfield** defines the local clock-management behavior of the PCIe module based on Standby (master) protocol with the device PRCM. **For more information on Standby states relations to the PCIe protocol link power states, refer to** Section 17.2.12.1, *OCP Power Management* .
			0h : Force standby / The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully **(should NOT be used in normal usage but for debug purposes only)** because it does not prevent loss of data at the time the clocks are gated. /
			1h : No standby / The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active; however, it is not efficient from a power-saving perspective because it never allows the PRCM module output clocks to be gated. /
			2h : Smart standby / The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module. Note that, this mode is NOT wake-up capable, i.e. the module can NOT generate (IRQ- or DMA request-related) wake-up events when in IDLE state. /
			3h : Reserved
9-8	OCP_IDLE	0-3h	The **OCP idle mode bitfield** defines the local clock-management behavior of the PCIe module based on Idle (Slave) protocol with the device PRCM. **For more information on Idle states relations to the PCIe protocol link power states, refer to** Section 17.2.12.1, *OCP Power Management*.
			0h : Force Idle / The module unconditionally acknowledges an IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully **(should NOT be used in normal usage but for debug purposes only)**, because it does not prevent loss of data at the time the clock is switched off. /
			1h : No Idle / The module never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state. /
			2h : Smart Idle / The module acknowledges an IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. Note that, this mode is NOT wake-up capable, i.e. the module can NOT generate (IRQ- or DMA request- related) wake-up events when in IDLE state. /
			3h : Smart Idle (wake-up capable) / The module acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA request- related) wake-up events when in IDLE state. /

Table 17-17. CMD_STATUS Register Field Descriptions (continued)

Bit	Field	Value	Description
7-6	Reserved	0	Reserved
5	DBI_CS2	0	Set to enable writing to BAR mask registers that are overlaid on BAR registers.
4	APP_RETRY_EN	0	Application Request Retry Enable—Setting this bit will enable all incoming PCIe transactions to be returned with a retry response. This feature can be used if initialization can take longer than PCIe stipulated time frame.
3	POSTED_WR_EN	0	Posted Write Enable—Setting this bit will cause the OCP master to use posted write commands. Default is zero with all OCP Master writes defaulting to non-posted.
2	IB_XLT_EN	0	Inbound Address Translation Enable—Setting this bit will enable translation of inbound memory/io read/write requests into memory read/write requests.
1	OB_XLT_EN	0	Outbound Address Translation Enable—Setting this bit will enable translation of outbound memory read/write requests into memory/io/cfg read/write requests.
0	LTSSM_EN	0	Link Transitioning Enable—Setting this bit will enable LTSSM in PCI Express Core and link negotiation with link partner will begin.

17.4.4.3 CFG_SETUP Register

The config transaction setup register (CFG_SETUP) is described in the figure and table below.

Figure 17-15. CFG_SETUP Register

31	25	24	23	16
Reserved		CFG_TYPE	CFG_BUS	
R-0		R/W-0	R/W-0	

15	13	12	8	7	3	2	0
Reserved		CFG_DEVICE		Reserved		CFG_FUNC	
R-0		R/W-0		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-18. CFG_SETUP Register Field Descriptions

Bit	Field	Value	Description
31-25	Reserved	0	Reserved
24	CFG_TYPE	0	Configuration Type for outbound configuration accesses. Set for Type 1 access and clear for Type 0 access.
23-16	CFG_BUS	0-FFh	PCIe Bus number for outbound configuration accesses
15-13	Reserved	0	Reserved
12-8	CFG_DEVICE	0-1Fh	PCIe Device number for outbound configuration accesses
7-3	Reserved	0	Reserved
2-0	CFG_FUNC	0-7h	PCIe Function number for outbound configuration accesses

17.4.4.4 IOBASE Register

The IO TLP base register (IOBASE) is described in the figure and table below.

Figure 17-16. IOBASE Register

31	16
IOBASE	
R/W-0	

15	12	11	0
IOBASE		Reserved	
R/W-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-19. IOBASE Register Field Descriptions

Bit	Field	Value	Description
31-12	IOBASE	0-F FFFFh	Bits 31-12 of outgoing IO TLP. RC mode only.
11-0	Reserved	0	Reserved

17.4.4.5 TLPCFG Register

The TLP attribute configuration register (TLPCFG) is described in the figure and table below.

Figure 17-17. TLPCFG Register

31	16
Reserved	
R-0	

15	2	1	0
Reserved		RELAXED	NO_SNOOP
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-20. TLPCFG Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	RELAXED	0	Enable Relaxed Ordering for all outgoing TLPs.
0	NO_SNOOP	0	Enable No Snoop attribute on all outgoing TLPs.

17.4.4.6 RSTCMD Register

The reset command and status register (RSTCMD) is described in the table and figure below.

Figure 17-18. RSTCMD Register

31	17	16
Reserved		FLUSH_N
R-0		R-1

15	1	0
Reserved		INIT_RST
R-0		W1S-0

LEGEND: R = Read only; W1S = Write 1 to set; -*n* = value after reset

Table 17-21. RSTCMD Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	FLUSH_N	1	Bridge Flush Status—Reads a zero when no transaction is pending. Used to ensure no pending transactions before issuing warm reset. Only applicable in PCIESS versions that use Designware core version 3.57 and newer.
15-1	Reserved	0	Reserved
0	INIT_RST	0	Write 1 to initiate a downstream hot reset sequence on downstream.

17.4.4.7 PMCMD Register

The power management command register (PMCD) is described in the figure and table below.

Figure 17-19. PMCMD Register

31	16
Reserved	
R-0	

15	2	1	0
Reserved		PM_XMT_TURNOFF	PM_XMT_PME
R-0		R/W1S -0	R/W1S -0

LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set; -*n* = value after reset

Table 17-22. PMCMD Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	PM_XMT_TURNOFF	0	Write 1 to transmit a PM_TURNOFF message. Reads zero. Applicable in RC mode only.
0	PM_XMT_PME	0	Write 1 to transmit a PM_PME message. Reads zero. Applicable to EP mode only.

17.4.4.8 PMCFG Register

The power management configuration register (PMCFG) is described in the figure and table below.

Figure 17-20. PMCFG Register

31	16
Reserved	
R-0	

15	3	2	1	0
Reserved		RDY_ENTR_L23	Reserved	ENTR_L23
R-0		R-0	R-0	W-0

LEGEND: R = Read only; W = Write only; -*n* = value after reset

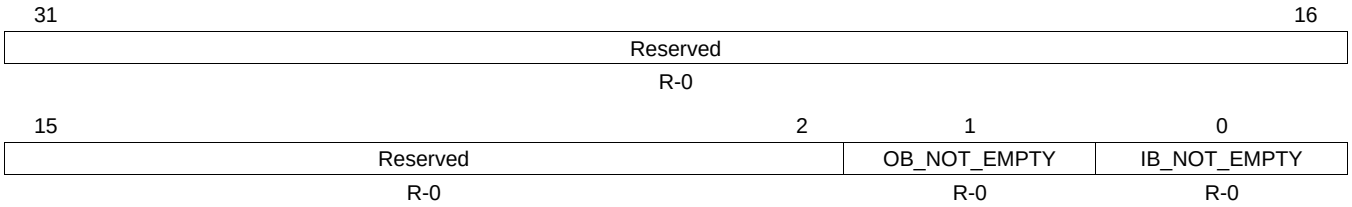
Table 17-23. PMCFG Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2	RDY_ENTR_L23	0	Read L2/L3 entry readiness. Applicable to RC and EP.
1	Reserved	0	Reserved
0	ENTR_L23	0	Write one to enable entry to L2/L3 ready state. Applicable to RC and EP.

17.4.4.9 ACT_STATUS Register

The activity status register (ACT_STATUS) is described in the figure and table below.

Figure 17-21. ACT_STATUS Register



LEGEND: R = Read only; -*n* = value after reset

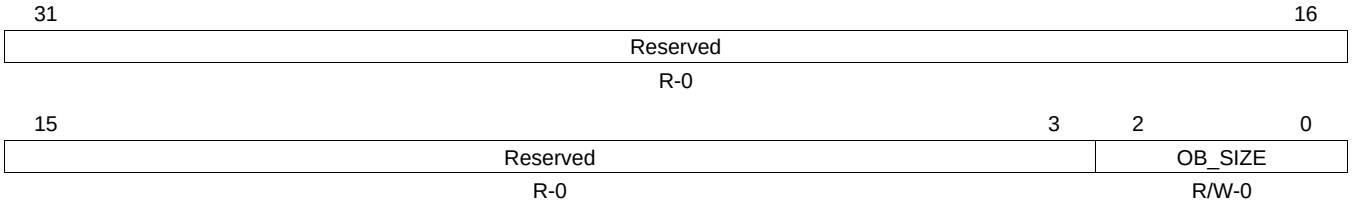
Table 17-24. ACT_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	OB_NOT_EMPTY	0	Outbound buffers are empty if this bit is read as 0.
0	IB_NOT_EMPTY	0	Inbound buffers are empty if this bit is read as 1.

17.4.4.10 OB_SIZE Register

The outbound size register (OB_SIZE) is described in the figure and table below.

Figure 17-22. OB_SIZE Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

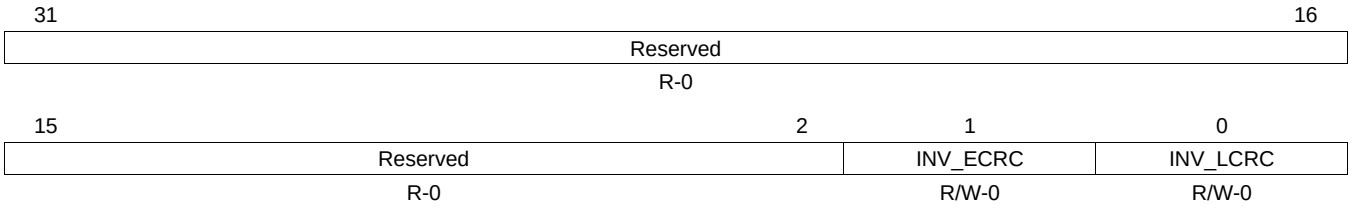
Table 17-25. OB_SIZE Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	OB_SIZE	0-7h	Write 0, 1, 2 and so on to set each outbound translation window size to 1, 2, 4 MB and so on. Applicable to RC and EP.

17.4.4.11 DIAG_CTRL Register

The diagnostic control register (DIAG_CTRL) is described in the figure and table below.

Figure 17-23. DIAG_CTRL Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

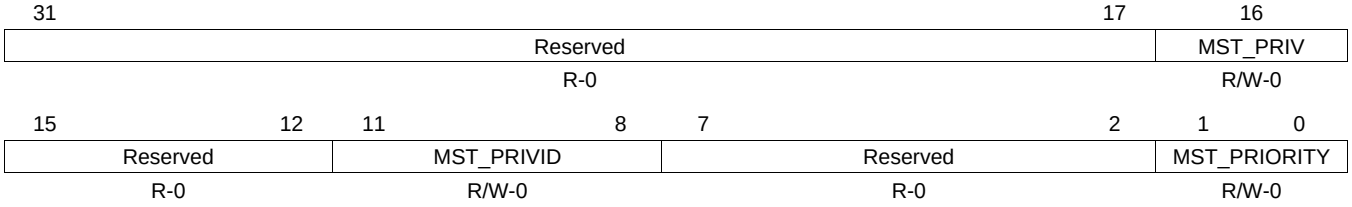
Table 17-26. DIAG_CTRL Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	INV_ECRC	0	Write 1 to force inversion of LSB of ECRC for next one packet. It is self-cleared when the ECRC error has been injected on one TLP.
0	INV_LCRC	0	Write 1 to force inversion of LSB of LCRC for next one packet. It is self-cleared when the ECRC error has been injected on one TLP.

17.4.4.12 PRIORITY Register

The CBA transaction priority register (PRIORITY) is described in the figure and table below.

Figure 17-24. PRIORITY Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

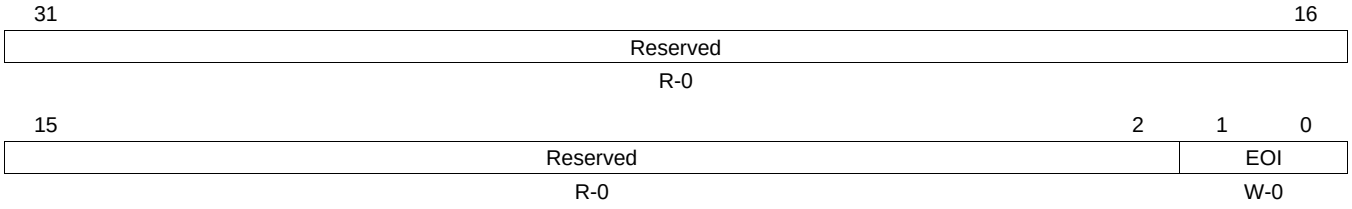
Table 17-27. PRIORITY Register Field Descriptions

Bit	Field	Value	Description
31-17	Reserved	0	Reserved
16	MST_PRIV	0	Value on master transactions
15-12	Reserved	0	Reserved
11-8	MST_PRIVID	0-Fh	Value on master transactions
7-2	Reserved	0	Reserved
1-0	MST_PRIORITY	0-3h	Priority level for each inbound transaction on the CBA master port. This field is not used for OCP interface.

17.4.4.13 IRQ_EOI Register

The end of interrupt register (IRQ_EOI) is described in the figure and table below.

Figure 17-25. IRQ_EOI Register



LEGEND: R = Read only; W = Write only; -*n* = value after reset

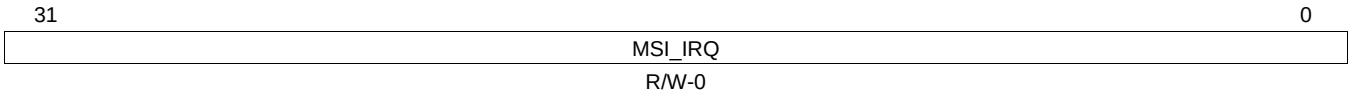
Table 17-28. EOI Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	EOI	0-3h	EOI for each interrupt. Write to indicate end-of-interrupt for the interrupt events. Write 0 to mark EOI for INTA/INTB/INTC/INTD, 1 to mark EOI for MSI interrupts and so on.

17.4.4.14 MSI_IRQ Register

The MSI interrupt IRQ register (MSI_IRQ) is described in the figure and table below.

Figure 17-26. MSI_IRQ Register



LEGEND: R/W = Read/Write; -*n* = value after reset

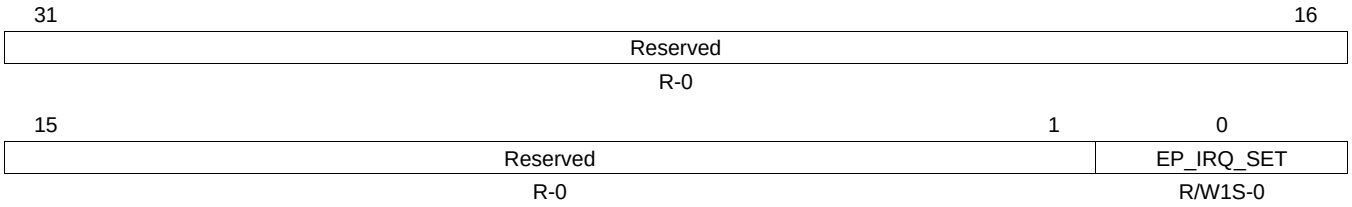
Table 17-29. MSI_IRQ Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI_IRQ	0-FFFF FFFFh	This register is written to by the remote device. Writes initiated by an EP over PCIe link that target BAR0 of the RC land to this register if the offset matches. To generate MSI Interrupt 0, the EP should write 0000 0000h to this register. It will result in a pulse on bit 0 triggering the MSI interrupt from PCIESS to the external processor.

17.4.4.15 EP_IRQ_SET Register

The endpoint interrupt request set register (EP_IRQ_SET) is described in the figure and table below.

Figure 17-27. EP_IRQ_SET Register



LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set; -*n* = value after reset

Table 17-30. EP_IRQ_SET Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_SET	0	Write 1 to generate assert interrupt message. If MSI is disabled, legacy interrupt assert message will be generated. On read, a 1 indicates currently asserted interrupt.

17.4.4.16 EP_IRQ_CLR Register

The endpoint interrupt request clear register (EP_IRQ_CLR) is described in the figure and table below.

Figure 17-28. EP_IRQ_CLR Register

31	16
Reserved	
R-0	

15	1	0
Reserved		EP_IRQ_CLR
R-0		R/W1C-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 17-31. EP_IRQ_CLR Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_CLR	0	Write 1 to generate deassert interrupt message. If MSI is disabled, legacy interrupt deassert message will be generated. On read, a 1 indicates currently asserted.

17.4.4.17 EP_IRQ_STATUS Register

The endpoint interrupt status register (EP_IRQ_STATUS) is described in the figure and table below.

Figure 17-29. EP_IRQ_STATUS Register

31	1
Reserved	
R-0	

15	1	0
Reserved		EP_IRQ_STATUS
R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

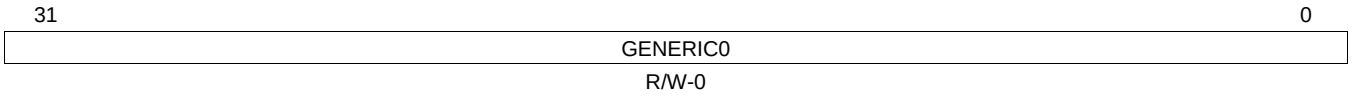
Table 17-32. EP_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-1	Reserved	0	Reserved
0	EP_IRQ_STATUS	0	Indicates whether interrupt for function 0 is asserted or not.

17.4.4.18 GPR0 Register

The general purpose 0 register (GPR0) is described in the figure and table below.

Figure 17-30. GPR0 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

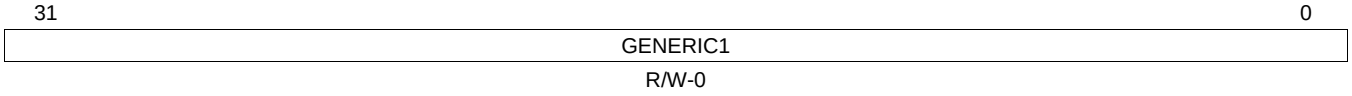
Table 17-33. GPR0 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC0	0-FFFF FFFFh	Generic Info field 0

17.4.4.19 GPR1 Register

The general purpose 1 register (GPR1) is described in the figure and table below.

Figure 17-31. GPR1 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

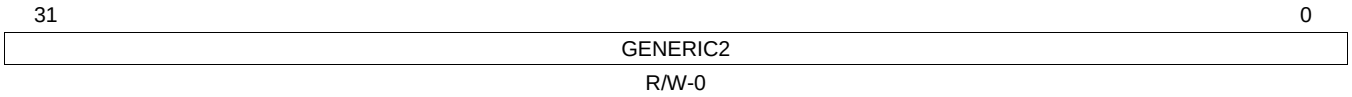
Table 17-34. GPR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC1	0-FFFF FFFFh	Generic Info field 1

17.4.4.20 GPR2 Register

The general purpose 2 register (GPR2) is described in the figure and table below.

Figure 17-32. GPR2 Register



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-35. GPR2 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC2	0-FFFF FFFFh	Generic Info field 2

17.4.4.21 GPR3 Register

The general purpose 3 register (GPR3) is described in the figure and table below.

Figure 17-33. GPR3 Register

31	0
GENERIC3	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-36. GPR3 Register Field Descriptions

Bit	Field	Value	Description
31-0	GENERIC3	0-FFFF FFFFh	Generic Info field 3

17.4.4.22 MSI0_IRQ_STATUS_RAW Register

The MSI 0 interrupt raw status register (MSI0_IRQ_STATUS_RAW) is described in the figure and table below.

Figure 17-34. MSI0_STATUS_RAW Register

31	0
MSI0_RAW_STATUS	
R/W1S-0	

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -*n* = value after reset

Table 17-37. MSI0_STATUS_RAW Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_RAW_STATUS	0-FFFF FFFFh	Each bit indicates raw status of MSI vector associated with the bit. Typically, writes to this register are only done for debug purposes.

17.4.4.23 MSI0_IRQ_STATUS Register

The MSI 0 interrupt enabled status register (MSI0_IRQ_STATUS) is described in the figure and table below.

Figure 17-35. MSI0_IRQ_STATUS Register

31	0
MSI0_IRQ_STATUS	
R/W0C-0	

LEGEND: R/W = Read/Write; W0C = Write 0 to clear; -*n* = value after reset

Table 17-38. MSI0_IRQ_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_STATUS	0-FFFF FFFFh	Each bit indicates raw status of MSI vector associated with the bit. Each of the bits can be written with a zero to clear the respective interrupt status bit.

17.4.4.24 MSI0_IRQ_ENABLE_SET Register

The MSI 0 interrupt enable set register (MSI0_IRQ_ENABLE_SET) is described in the figure and table below.

Figure 17-36. MSI0_IRQ_ENABLE_SET Register

31	0
MSI0_IRQ_ENABLE_SET	
R/W1S-0	

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -*n* = value after reset

Table 17-39. MSI0_IRQ_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_ENABLE_SET	0-FFFF FFFFh	Each bit, when written to, enables the MSI interrupt associated with the bit.

17.4.4.25 MSI0_IRQ_ENABLE_CLR Register

The MSI0 interrupt enable clear register (MSI0_IRQ_ENABLE_SET) is described in the figure and table below.

Figure 17-37. MSI0_IRQ_ENABLE_CLR Register

31	0
MSI0_IRQ_ENABLE_CLR	
R/W1C-0	

LEGEND: R/W = Read/Write; W1C = Write 1 to clear; -*n* = value after reset

Table 17-40. MSI0_IRQ_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-0	MSI0_IRQ_ENABLE_CLR	0-FFFF FFFFh	Each bit, when written to, disables the MSI interrupt associated with the bit.

17.4.4.26 IRQ_STATUS_RAW Register

The raw interrupt status register (IRQ_STATUS_RAW) is described in the figure and table below.

Figure 17-38. IRQ_STATUS_RAW Register

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt raw status
2	PM_PME	0	Power Management PME message received interrupt raw status
1	PM_TO_ACK	0	Power Management ACK received interrupt raw status
0	PM_TURNOFF	0	Power Management Turnoff message received raw status

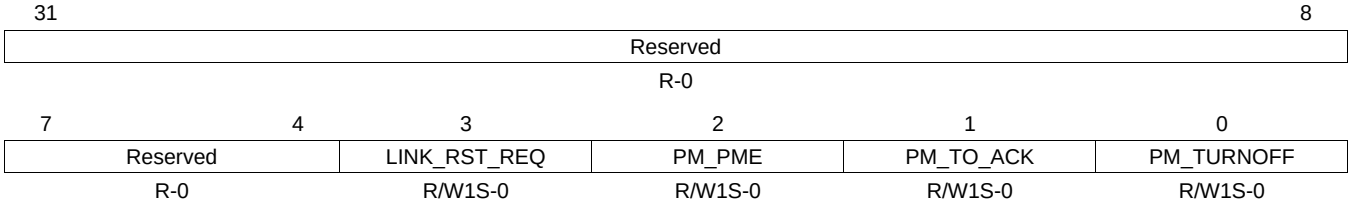
17.4.4.36 PMRST_ENABLE_SET Register

The power management and reset interrupt enabled set register (PMRST_ENABLE_SET) is described in the figure and table below.

Figure 17-48. PMRST_ENABLE_SET Register



LEGEND: R/W = Read/Write; R = Read only; W1S = Write 1 to set; -*n* = value after reset

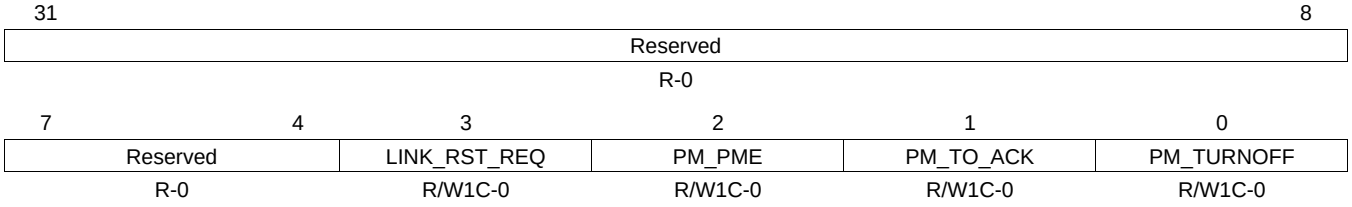
Table 17-51. PMRST_ENABLE_SET Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
2	PM_PME	0	Power Management PME message received interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
1	PM_TO_ACK	0	Power Management ACK received interrupt enable. Set to enable the interrupt. Read 1 means interrupt is enabled.
0	PM_TURNOFF	0	Power Management Turnoff message received enable. Set to enable the interrupt. Read 1 means interrupt is enabled.

17.4.4.37 PMRST_ENABLE_CLR Register

The power management and reset interrupt enabled clear register (PMRST_ENABLE_CLR) is described in the figure and table below.

Figure 17-49. PMRST_ENABLE_CLR Register



LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

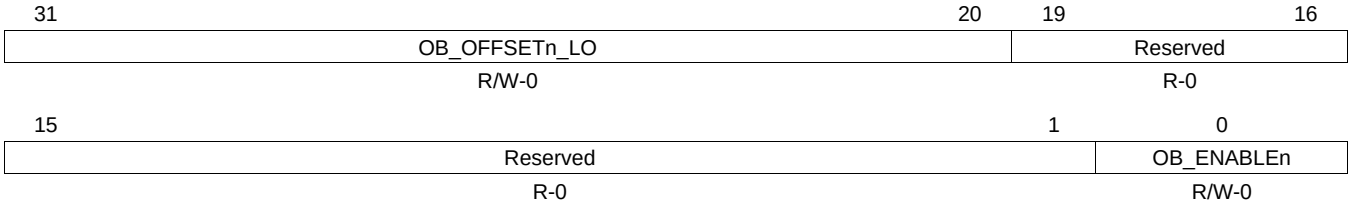
Table 17-52. PMRST_ENABLE_CLR Register Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	LINK_RST_REQ	0	Link Request Reset interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
2	PM_PME	0	Power Management PME message received interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
1	PM_TO_ACK	0	Power Management ACK received interrupt disable. Set to disable the interrupt. Read 1 means interrupt is enabled.
0	PM_TURNOFF	0	Power Management Turnoff message received disable. Set to disable the interrupt. Read 1 means interrupt is enabled.

17.4.4.38 OB_OFFSET_INDEXn Register

The outbound translation region N offset low and index register (OB_OFFSET_INDEXn) is described in the figure and table below.

Figure 17-50. OB_OFFSET_INDEXn Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-53. OB_OFFSET_INDEXn Register Field Descriptions

Bit	Field	Value	Description
31-20	OB_OFFSETn_LO	0-FFFh	Offset bits 31-20 for translation region N (N = 0-31)
19-1	Reserved	0	Reserved
0	OB_ENABLEn	0	Enable translation region N (N = 0-31)

17.4.4.39 OB_OFFSETn_HI Register

The outbound translation region N offset high register (OB_OFFSETn_HI) is described in the figure and table below.

Figure 17-51. OB_OFFSETn_HI Register

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

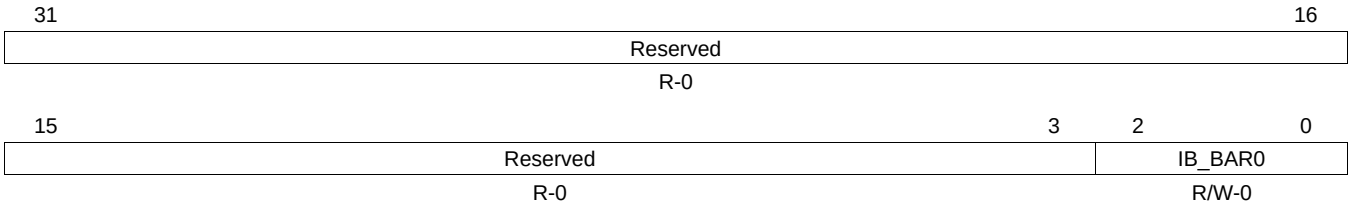
Table 17-54. OB_OFFSETn_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	OB_OFFSETn_HI	0-FFFF FFFFh	Offset bits 31-0 for translation region N (N = 0-31)

17.4.4.40 IB_BAR0 Register

The inbound translation bar match 0 register (IB_BAR0) is described in the figure and table below.

Figure 17-52. IB_BAR0 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

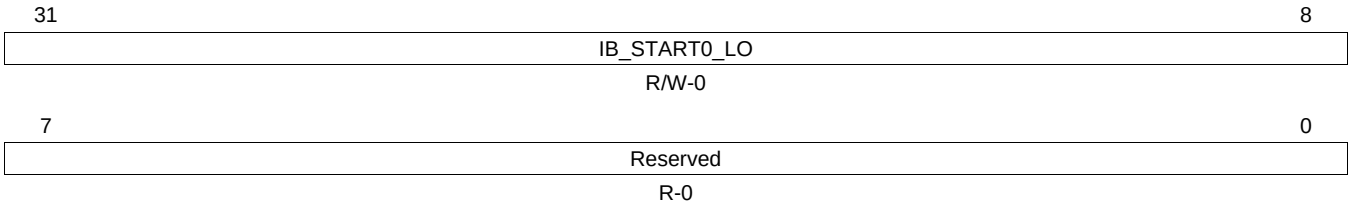
Table 17-55. IB_BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR0	0-7h	BAR number to match for inbound translation region 0

17.4.4.41 IB_START0_LO Register

The inbound translation 0 start address low register (IB_START0_LO) is described in the figure and table below.

Figure 17-53. IB_START0_LO Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-56. IB_START0_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START0_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 0.
7-0	Reserved	0	Reserved

17.4.4.42 IB_START0_HI Register

The inbound translation 0 start address high register (IB_START0_HI) is described in the figure and table below.

Figure 17-54. IB_START0_HI Register

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

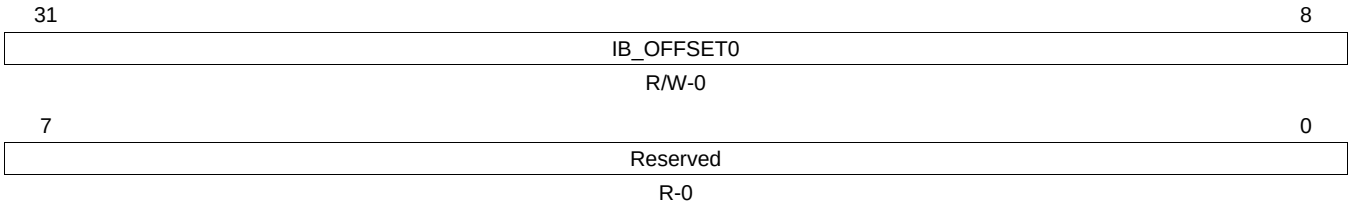
Table 17-57. IB_START0_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START0_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 0.

17.4.4.43 IB_OFFSET0 Register

The inbound translation 0 address offset register (IB_OFFSET0) is described in the figure and table below.

Figure 17-55. IB_OFFSET0 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

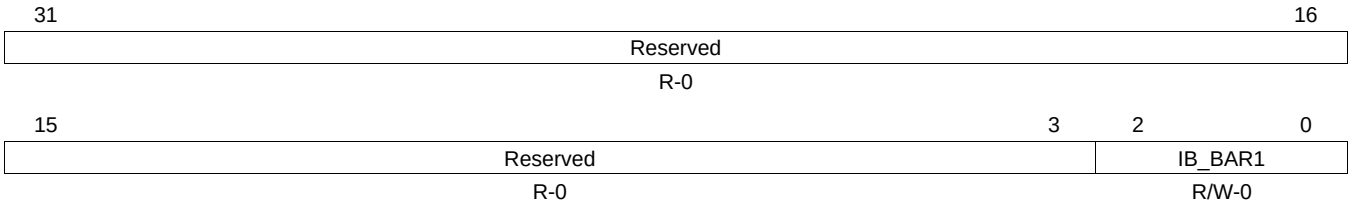
Table 17-58. IB_OFFSET0 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET0	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 0.
7-0	Reserved	0	Reserved

17.4.4.44 IB_BAR1 Register

The inbound translation bar match 1 register (IB_BAR1) is described in the figure and table below.

Figure 17-56. IB_BAR1 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

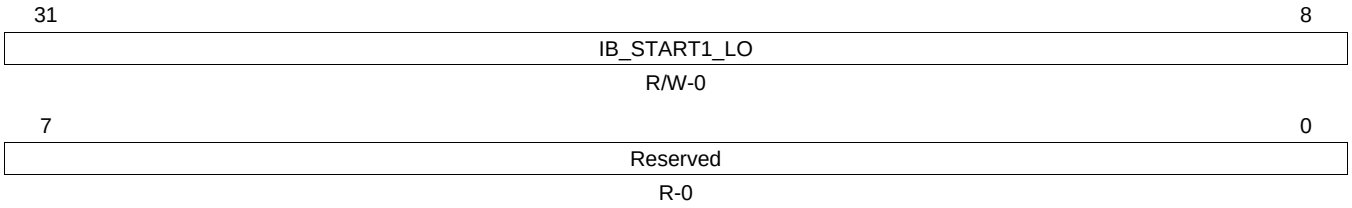
Table 17-59. IB_BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR1	0-7h	BAR number to match for inbound translation region 1

17.4.4.45 IB_START1_LO Register

The inbound translation 1 start address low register (IB_START1_LO) is described in the figure and table below.

Figure 17-57. IB_START1_LO Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

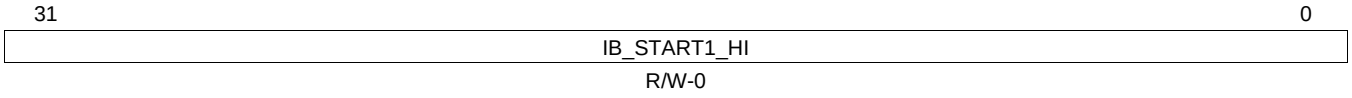
Table 17-60. IB_START1_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START1_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 1
7-0	Reserved	0	Reserved

17.4.4.46 IB_START1_HI Register

The inbound translation 1 start address high register (IB_START1_HI) is described in the figure and table below.

Figure 17-58. IB_START1_HI Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

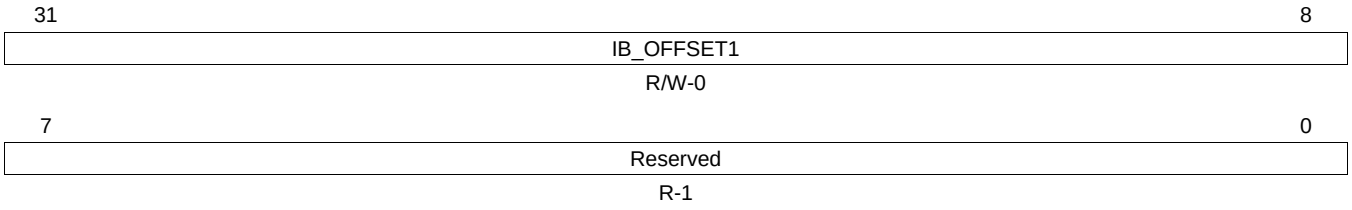
Table 17-61. IB_START1_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START1_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 1

17.4.4.47 IB_OFFSET1 Register

The inbound translation 1 address offset register (IB_OFFSET1) is described in the figure and table below.

Figure 17-59. IB_OFFSET1 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

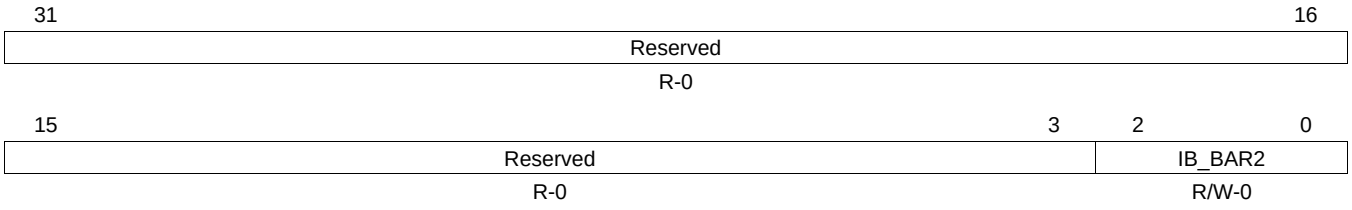
Table 17-62. IB_OFFSET 1 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET1	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 1
7-0	Reserved	0	Reserved

17.4.4.48 IB_BAR2 Register

The inbound translation bar match 2 register (IB_BAR2) is described in the figure and table below.

Figure 17-60. IB_BAR2 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

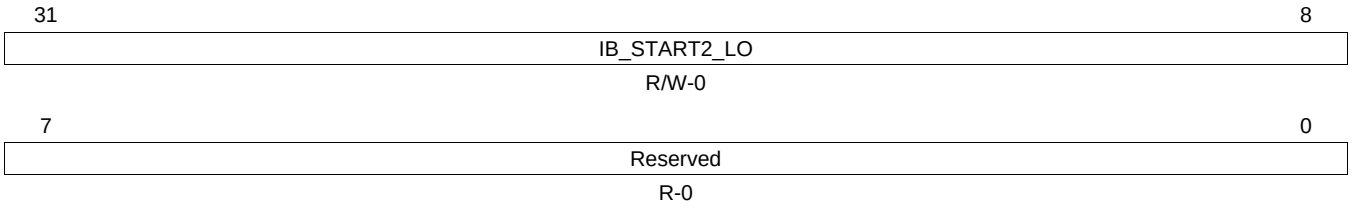
Table 17-63. IB_BAR2 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR2	0-7h	BAR number to match for inbound translation region 2

17.4.4.49 IB_START2_LO Register

The inbound translation 2 start address low register (B_START2_LO) is described in the figure and table below.

Figure 17-61. IB_START2_LO Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

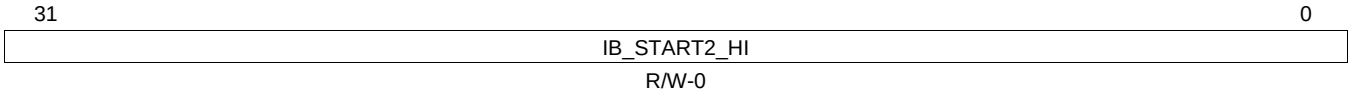
Table 17-64. IB_START2_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START2_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 2
7-0	Reserved	0	Reserved

17.4.4.50 IB_START2_HI Register

The inbound translation 2 start address low register (B_START2_HI) is described in the figure and table below.

Figure 17-62. IB_START2_HI Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

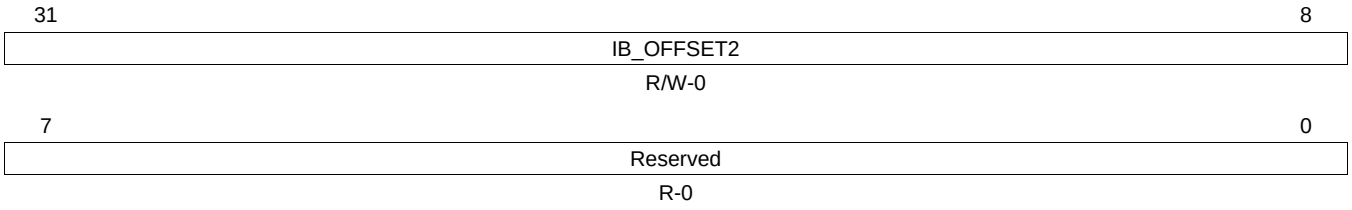
Table 17-65. IB_START2_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START2_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 2

17.4.4.51 IB_OFFSET2 Register

The inbound translation 2 address offset register (IB_OFFSET2) is described in the figure and table below.

Figure 17-63. IB_OFFSET2 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

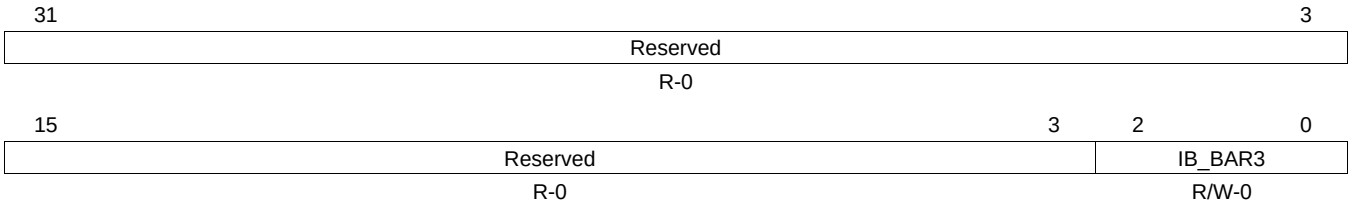
Table 17-66. IB_OFFSET2 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET2	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 2
7-0	Reserved	0	Reserved

17.4.4.52 IB_BAR3 Register

The inbound translation bar match 3 register (B_BAR3) is described in the figure and table below.

Figure 17-64. IB_BAR3 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

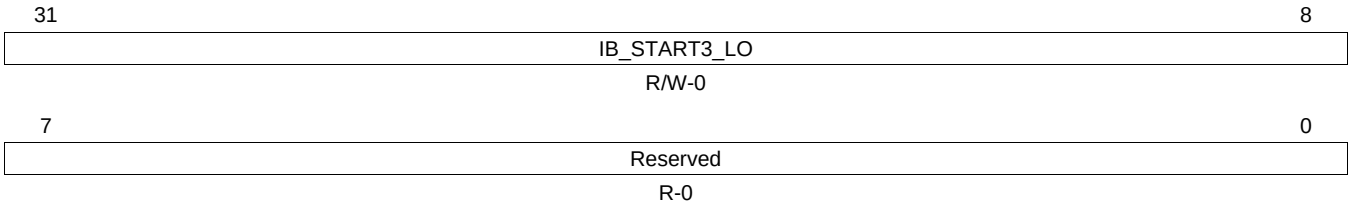
Table 17-67. IB_BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	IB_BAR3	0-7h	BAR number to match for inbound translation region 3

17.4.4.53 IB_START3_LO Register

The inbound translation 3 start address low register (IB_START3_LO) is described in the figure and table below.

Figure 17-65. IB_START3_LO Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

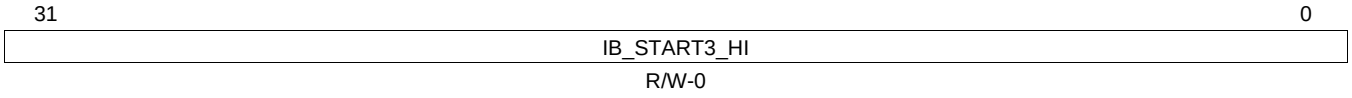
Table 17-68. IB_START3_LO Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_START3_LO	0-FF FFFFh	Start address bits 31-8 for inbound translation region 3
7-0	Reserved	0	Reserved

17.4.4.54 IB_START3_HI Register

The inbound translation 3 start address high register (IB_START3_HI) is described in the figure and table below.

Figure 17-66. IB_START3_HI Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

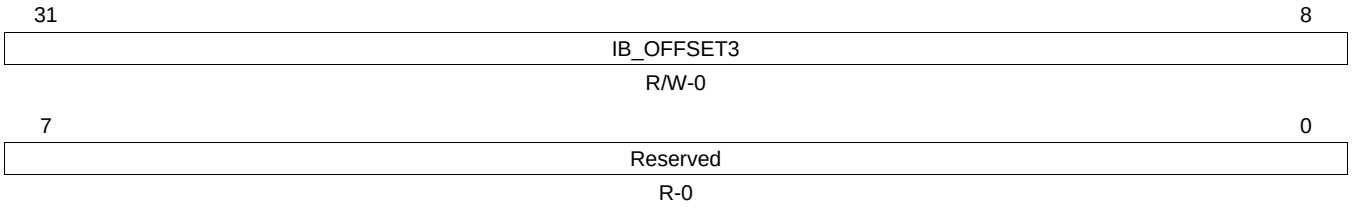
Table 17-69. IB_START3_HI Register Field Descriptions

Bit	Field	Value	Description
31-0	IB_START3_HI	0-FFFF FFFFh	Start address bits 63-0 for inbound translation region 3

17.4.4.55 IB_OFFSET3 Register

The inbound translation 3 address offset register (IB_OFFSET3) is described in the figure and table below.

Figure 17-67. IB_OFFSET3 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

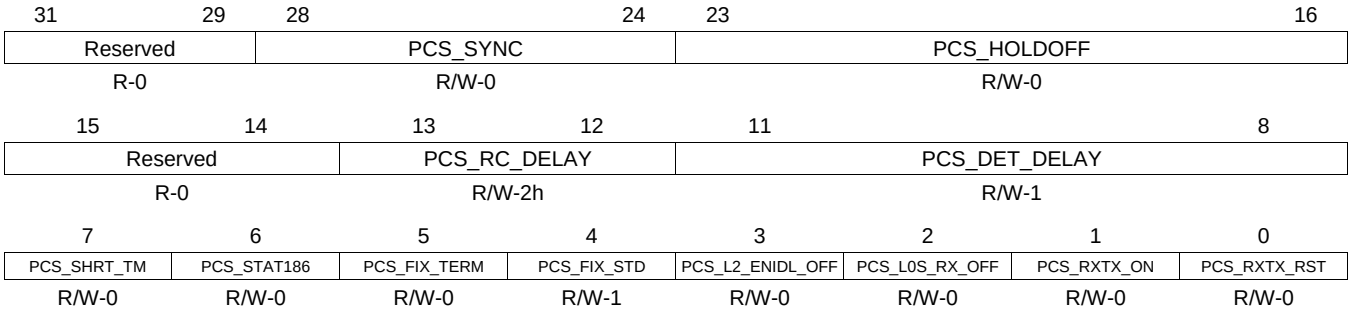
Table 17-70. IB_OFFSET3 Register Field Descriptions

Bit	Field	Value	Description
31-8	IB_OFFSET3	0-FF FFFFh	Offset address bits 31-8 for inbound translation region 3
7-0	Reserved	0	Reserved

17.4.4.56 PCS_CFG0 Register

The PCS configuration 0 (PCS_CFG0) register is described in the figure and table below

Figure 17-68. PCS_CFG0 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

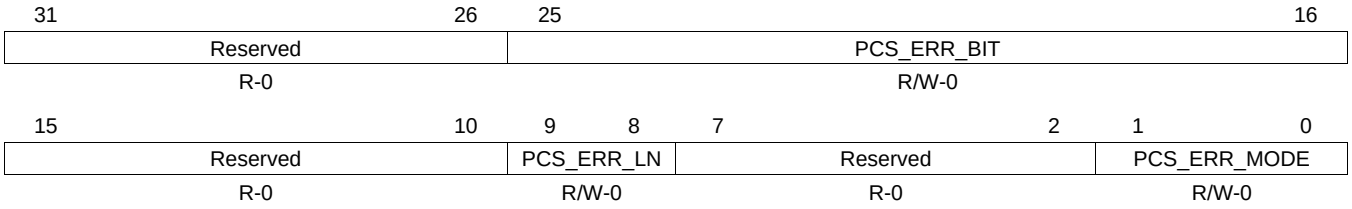
Table 17-71. PCS_CFG0 Register Field Descriptions

Bit	Field	Value	Description
31-29	Reserved	0	Reserved
28-24	PCS_SYNC	0-1Fh	Receiver Lock/Sync Control
23-16	PCS_HOLDOFF	0-FFh	Receiver Initialization Hold Off Control
15-14	Reserved	0	Reserved
13-12	PCS_RC_DELAY	0-3h	Rate Change Delay
11-8	PCS_DET_DELAY	0-Fh	Detection Delay
7	PCS_SHRT_TM	0	Enable short times for debug purposes.
6	PCS_STAT186	0	Enable PIPE Spec 1.86 for PHY status behavior
5	PCS_FIX_TERM	0	Fed term output to 3'b100 during reset.
4	PCS_FIX_STD	0	Fix std output to 2'b10
3	PCS_L2_ENIDL_OFF	0	Deassert ENIDL during L2 state.
2	PCS_L0S_RX_OFF	0	Deassert Rx Enable in L0s state.
1	PCS_RXTX_ON	0	RX and TX on during reset. TX also on in P1 state.
0	PCS_RXTX_RST	0	RX and TX on during reset

17.4.4.57 PCS_CFG1 Register

The PCS configuration 1 (PCS_CFG1) register is described in the figure and table below.

Figure 17-69. PCS_CFG1 Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

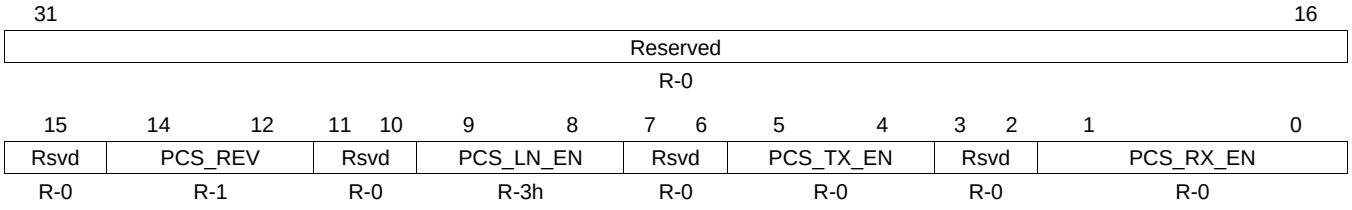
Table 17-72. PCS_CFG1 Register Field Descriptions

Bit	Field	Value	Description
31-26	Reserved	0	Reserved
25-16	PCS_ERR_BIT	0-3FFh	Error Bit enable
15-10	Reserved	0	Reserved
9-8	PCS_ERR_LN	0-3h	Error Lane enable
7-2	Reserved	0	Reserved
1-0	PCS_ERR_MODE	0-3h	Error Injection Mode

17.4.4.58 PCS_STATUS Register

The PCS status register is described in the figure and table below.

Figure 17-70. PCS_STATUS Register



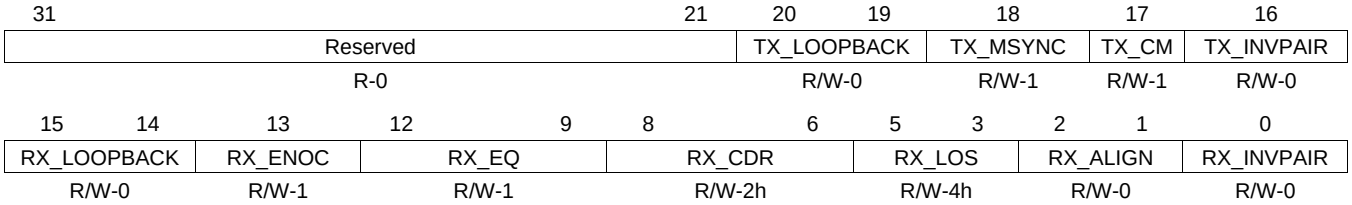
LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-73. PCS_STATUS Register Field Descriptions

Bit	Field	Value	Description
31-15	Reserved	0	Reserved
14-12	PCS_REV	0-7h	PCS RTL Revision
11-10	Reserved	0	Reserved
9-8	PCS_LN_EN	0-3h	PCS Lanes enabled status
7-6	Reserved	0	Reserved
5-4	PCS_TX_EN	0-3h	PCS Transmitters enabled status
3-2	Reserved	0	Reserved
1-0	PCS_RX_EN	0-3h	PCS Receivers enabled status

17.4.4.59 SERDES_CFG0 Register

Figure 17-71. SERDES_CFG0 Register



31	21	20	19	18	17	16

12-9	RX_EQ	0-Fh	Enable RX adaptive equalization (CFGRX1[22:19])
8-6	RX_CDR	0-7h	Enable RX clock data recovery (CFGRX1[18:16])
5-3	RX_LOS	0-7h	Enable RX loss of signal detection (CFGRX1[15:13])
2-1	RX_ALIGN	0-3h	Enable RX symbol alignment (CFGRX1[12:11])
0	RX_INVPAIR	0	Invert RX pair polarity (CFGRX1[7])

17.4.5 Configuration Registers Common to Type 0 and Type 1 Headers

Table 17-76. Configuration Registers Common to Type 0 and Type 1 Headers

Offset	Acronym	Section
0h	VENDOR_DEVICE_ID	Section 17.4.5.1
4h	STATUS_COMMAND	Section 17.4.5.2
8h	CLASSCODE_REVID	Section 17.4.5.3

17.4.5.1 VENDOR_DEVICE_ID Register

The vendor and device identification register (VENDOR_DEVICE_ID) is described in the figure and table below.

Figure 17-73. VENDOR_DEVICE_ID Register

31	16
device_id	
R-8888h	

15	0
vendor_id	
R-104Ch	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-77. VENDOR_DEVICE_ID Register Field Descriptions

Bit	Field	Value	Description
31-16	device_id	0-FFFFh	PCIe Device ID. Writable from internal bus interface.
15-0	vendor_id	0-FFFFh	PCIe Vendor ID. Writable from internal bus interface.

17.4.5.2 STATUS_COMMAND Register

The status and command register (STATUS_COMMAND) is described in the figure and table below.

Figure 17-74. STATUS_COMMAND Register

31	30	29	28	27	26	25	24
Parity Error	Signaled System Error	Received Master Abort	Received Target Abort	Signaled Target Abort	Reserved		Data Parity Error
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0		R/W1C-0

23	21	20	19	18	16
Reserved		Capabilities List	Interrupt Status	Reserved	
R-0		R-1	R-0	R-0	

15	11	10	9	8
Reserved		INTx Disable	Reserved	SERR Enable
R-0		R/W-0	R-0	R/W-0

7	6	5	3	2	1	0
Reserved	Parity Error	Reserved		Bus Master	Memory Space	IO Space
R-0	R/W-0	R-0		R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 17-78. STATUS_COMMAND Register Field Descriptions

Bit	Field	Value	Description
31	Parity Error	0	Set if function receives poisoned TLP.
30	Signaled System Error	0	Set if function sends a ERR_FATAL or ERR_NONFATAL message and SERR enable bit is set to one.
29	Received Master Abort	0	Set when a Requester receives a Completion with Unsupported Request Completion Status.
28	Received Target Abort	0	Set when a Requester receives a Completion with Completer Abort Status.
27	Signaled Target Abort	0	Set when a function acting as a Completer terminates a request by issuing Completer Abort Completion Status to the Requester.
26-25	Reserved	0	Reserved
24	Data Parity Error	0	This bit is set by a Requester if the Parity Error Enable bit is set in its Command register and either the condition that the requester receives a poisoned Completion or the condition that the requester poisons a write request are true.
23-21	Reserved	0	Reserved
20	Capabilities List	1	For PCIe, this field must be set to 1.
19	Interrupt Status	0	Indicates that the function has received an interrupt.
18-11	Reserved	0	Reserved
10	INTx Disable	0	Setting this bit disables generation of INTx messages.
9	Reserved	0	Reserved
8	SERR Enable	0	When set, it enables System Error reporting to the Root Complex.
7	Reserved	0	Reserved
6	Parity Error	0	This bit controls whether or not the device responds to detected parity errors. If this bit is set, the PCIESS will respond normally to parity errors. If this bit is cleared, the PCIES will ignore detected parity errors.
5-3	Reserved	0	Reserved
2	Bus Master	0	Enables mastership of the bus.
1	Memory Space	0	This bit is set to enable the device to respond to memory accesses.
0	IO Space	0	This bit is set to enable the device to respond to I/O accesses. This functionality is not supported in PCIESS and there this bit is set to zero.

17.4.5.3 CLASSCODE_REVID Register

The class code and revision ID register (CLASSCODE_REVID) is described in the figure and table below.

Figure 17-75. CLASSCODE_REVID Register

31							8
Class Code							
R-0							
7							0
Revision ID							
R-1							

LEGEND: R = Read only; -*n* = value after reset

Table 17-79. CLASSCODE_REVID Register Field Descriptions

Bit	Field	Value	Description
31-8	Class Code	0-FF FFFFh	PCIe Class Code per PCIe Base Specifications Revision 2.0. Writable from internal bus interface.
7-0	Revision ID	0-FFh	Updated with each revision of hardware. Writable from internal bus interface.

17.4.6 Configuration Type 0 Registers

Table 17-80. Configuration Type 0 Registers

Offset	Acronym	Section
Ch	BIST_HEADER	Section 17.4.6.1
10h	BAR0	Section 17.4.6.2
14h	BAR1	Section 17.4.6.3
18h	BAR2	Section 17.4.6.4

3Ch	INT_PIN	Section 17.4.6.11

17.4.6.1 BIST_HEADER Register

The BIST, Header Type, Latency Time and Cache Line Size register (BIST_HEADER) is described in the figure and table below.

Figure 17-76. BIST_HEADER Register

31	30	29 28	27 24	23	22 16
BIST Capable	Start BIST	Reserved	Completion Code	Multi-function Device	Header Type
R-0	R-0	R-0	R-0	R-0	R-0

15 8	7 0
Latency Timer	Cache Line Size
R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-81. BIST_HEADER Register Field Descriptions

Bit	Field	Value	Description
31	BIST Capable	0	Returns a 1 for BIST capability and 0 otherwise. Not supported by PCIESS.
30	Start BIST	0	Write a 1 to start BIST. Not supported by PCIESS.
29-28	Reserved	0	Reserved
27-24	Completion Mode	0-Fh	Completion Code. Not supported by PCIESS.
23	Multi-function Device	0	Returns 1 if it is a multi function device. Writable from internal bus interface.
22-16	Header Type	0-7Fh	Configuration Header Format. It is set to 1 for RC and cleared to 0 for EP.
15-8	Latency Timer	0-FFh	Not applicable in PCIe
7-0	Cache Line Size	0-FFh	Not applicable in PCIe

17.4.6.2 BAR0 Register

The base address register 0 (BAR0) is described in the figure and table below.

Figure 17-77. BAR0 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-0	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-82. BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.3 BAR1 Register

The base address register 1 (BAR1) is described in the figure and table below.

Figure 17-78. BAR1 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-1	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-83. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.3.1 BAR1 Register

The base address register 1 (BAR1) is described in the figure and table below.

Figure 17-79. BAR1 Register

31	0
Base Address	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-84. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR0 address

17.4.6.4 BAR2 Register

The base address register 2 (BAR2) is described in the figure and table below.

Figure 17-80. BAR2 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-1	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-85. BAR2 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.5 BAR3 Register

The base address register 3 (BAR3) is described in the figure and table below.

Figure 17-81. BAR3 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-1	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-86. BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.5.1 BAR3 Register

The base address register 3 (BAR3) is described in the figure and table below.

Figure 17-82. BAR3 Register

31	0
Base Address	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-87. BAR3 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR2 address

17.4.6.6 BAR4 Register

The base address register 4 (BAR4) is described in the figure and table below.

Figure 17-83. BAR4 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-1	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-88. BAR4 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.7 BAR5 Register

The base address register 5 (BAR5) is described in the figure and table below.

Figure 17-84. BAR5 Register

31	8
Base Address	
R/W-0	

7	6	4	3	2	1	0
Base Address	Reserved		Prefetchable	Type		Memory Space
R/W-0	R-0		R-1	R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-89. BAR5 Register Field Descriptions

Bit	Field	Value	Description
31-7	Base Address	0-1FF FFFFh	Base Address
6-4	Reserved	0	Reserved
3	Prefetchable	0	For memory BARs, it indicates whether the region is prefetchable. For IO Bars, it is used as second LSB of the base address. Writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.6.7.1 BAR5 Register

The base address register 5 (BAR5) is described in the figure and table below.

Figure 17-85. BAR5 Register

31	0
Base Address	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

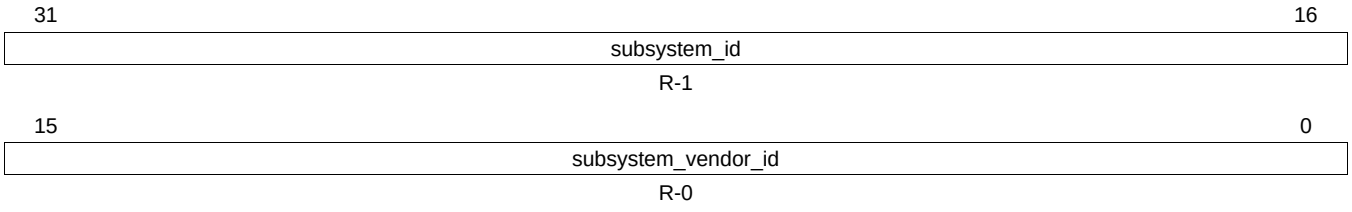
Table 17-90. BAR5 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of BAR4 address

17.4.6.8 SUBSYS_VNDR_ID Register

The subsystem and subsystem vendor ID register (SUBSYS_VNDR_ID) is described in the figure and table below.

Figure 17-86. SUBSYS_VNDR_ID Register



LEGEND: R = Read only; -*n* = value after reset

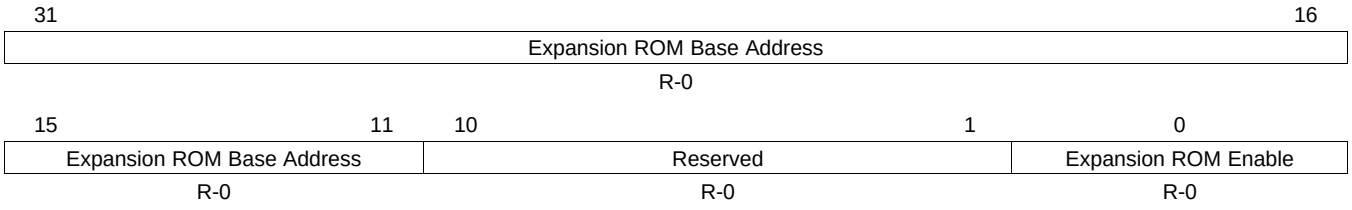
Table 17-91. SUBSYS_VNDR_ID Register Field Descriptions

Bit	Field	Value	Description
31-16	subsystem_id	0-FFFFh	PCIe Subsystem ID (TBD). Writable from internal bus interface.
15-0	subsystem_vendor_id	0-FFFFh	PCIe Subsystem Vendor ID (TBD). Writable from internal bus interface.

17.4.6.9 EXPNSN_ROM Register

The expansion ROM base address (EXPNSN_ROM) is described in the figure and table below.

Figure 17-87. EXPNSN_ROM Register



LEGEND: R = Read only; -*n* = value after reset

Table 17-92. EXPNSN_ROM Register Field Descriptions

Bit	Field	Value	Description
31-11	Expansion ROM Base Address	0-1F FFFFh	Address of Expansion ROM
10-1	Reserved	0	Reserved
0	Expansion ROM Enable	0	Expansion ROM Enable

17.4.6.10 CAP_PTR Register

The capabilities pointer register (CAP_PTR) is described in the figure and table below.

Figure 17-88. CAP_PTR Register

31	8
Reserved	
R-0	

7	0
cap_ptr	
R-40h	

LEGEND: R = Read only; -*n* = value after reset

Table 17-93. CAP_PTR Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	cap_ptr	0-FFh	First Capability Pointer. By default, it points to Power Management Capability structure. Writable from internal bus interface.

17.4.6.11 INT_PIN Register

Figure 17-89. INT_PIN Register

31	24	23	16
max_latency		min_grant	
R-0		R-0	

15	8	7	0
int_pin		int_line	
R-1		R/W-FFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-94. INT_PIN Register Field Descriptions

Bit	Field	Value	Description
31-24	max_latency	0-FFh	Not applicable to PCI Express
23-16	min_grant	0-FFh	Not applicable to PCI Express
15-8	int_pin	0-FFh	Interrupt Pin. Valid values at 00h, 01h, 02h, 03h and 04h for unused legacy interrupt, INTA, INTB, INTC or INTD respectively. For single function configuration, the core only uses INTA. Writable from internal bus interface.
7-0	int_line	0-FFh	Interrupt Line

17.4.7 Configuration Type 1 Registers

Table 17-95. Configuration Type 1 Registers

Offset	Acronym	Section
Ch	BIST_HEADER	Section 17.4.7.1
10h	BAR0	Section 17.4.7.2
14h	BAR1	Section 17.4.7.3
18h	BUSNUM	Section 17.4.7.4
1Ch	SECSTAT	Section 17.4.7.5
20h	MEMSPACE	Section 17.4.7.6
24h	PREFETCH_MEM	Section 17.4.7.7
28h	PREFETCH_BASE	Section 17.4.7.8
2Ch	PREFETCH_LIMIT	Section 17.4.7.9
30h	IOSPACE	Section 17.4.7.10
34h	CAP_PTR	Section 17.4.7.11
38h	EXPNSN_ROM	Section 17.4.7.12
3Ch	BRIDGE_INT	Section 17.4.7.13

17.4.7.1 BIST_HEADER Register

The BIST, Header Type, Latency Time and Cache Line Size register (BIST_HEADER) is described in the figure and table below.

Figure 17-90. BIST_HEADER Register

31	30	29 28	27 24	23	22 16
BIST Capable	Start BIST	Reserved	Completion Code	Multi-function Device	Header Type
R-0	R-0	R-0	R-0	R-0	R-1

15 8	7 0
Latency Timer	Cache Line Size
R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-96. BIST_HEADER Register Field Descriptions

Bit	Field	Value	Description
31	BIST Capable	0	Returns a 1 for BIST capability and 0 otherwise. Not supported by PCIESS.
30	Start BIST	0	Write a 1 to start BIST. Not supported by PCIESS.
29-28	Reserved	0	Reserved
27-24	Completion Code	0-Fh	Completion Code. Not supported by PCIESS.
23	Multi-function Device	0	Returns 1 if it is a multi function device. Writable from internal bus interface.
22-16	Header Type	0-7Fh	Configuration Header Format. It is set to 1 for RC and cleared to 0 for EP.
15-8	Latency Timer	0-FFh	Not applicable in PCIe.
7-0	Cache Line Size	0-FFh	Not applicable in PCIe.

17.4.7.2 BAR0 Register

The base address register 0 (64/32 bit mode) is described in the figure and table below.

Figure 17-91. BAR0 Register

31	8
Base Address	
R-0	

7	4	3	2	1	0
Base Address		Prefetchable	Type		Memory Space
R-0		R-0	R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 17-97. BAR0 Register Field Descriptions

Bit	Field	Value	Description
31-4	Base Address	0-FFF FFFFh	Base Address. Actual writable bits are determined by BAR0 Mask Register.
3	Prefetchable	0	Set to indicate prefetchable space. This field is writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.7.3 BAR1 Register

Figure 17-92. BAR1 Register

31	8
Base Address	
R-0	

7	4	3	2	1	0
Base Address		Prefetchable	Type		Memory Space
R-0		R-1	R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 17-98. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-4	Base Address	0-FFF FFFFh	Base Address. Actual writable bits are determined by BAR0 Mask Register.
3	Prefetchable	0	Set to indicate prefetchable space. This field is writable from internal bus interface.
2-1	Type	0-3h	Decode type. Writable from internal bus interface.
		0	32 bit decode
		1h	Reserved
		2h	64 bit decode
		3h	Reserved
0	Memory Space	0	Set to indicate Memory Space. Writable from internal bus interface.

17.4.7.3.1 BAR1 Register

The base address register 1(BAR1) is described in the figure and table below.

Figure 17-93. BAR1 Register

31	0
Base Address	
R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 17-99. BAR1 Register Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Base Address high 32 bits for BAR0. Actual writable bits are determined by BAR0 Mask Register.

17.4.7.4 BUSNUM Register

The latency timer and bus number register (BUSNUM) is described in the figure and table below.

Figure 17-94. BUSNUM Register

31	24	23	16
Secondary Latency Timer		Subordinate Bus Number	
R-0		R/W-0	

15	8	7	0
Secondary Bus Number		Primary Bus Number	
R/W-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-100. BUSNUM Register Field Descriptions

Bit	Field	Value	Description
31-24	Secondary Latency Timer	0-FFh	Not applicable in PCI Express.
23-16	Subordinate Bus Number	0-FFh	Subordinate Bus Number. This is highest bus number on downstream interface.
15-8	Secondary Bus Number	0-FFh	Secondary Bus Number. It is typically 1h for RC.
7-0	Primary Bus Number	0-FFh	Primary Bus Number. It is zero for RC and nonzero for switch devices only.

17.4.7.5 SECSTAT Register

The secondary status and IO base/limit register (SECSTAT) is described in the figure and table below.

Figure 17-95. SECSTAT Register

31	30	29	28	27	26	25	24
DTCT_PERROR	RX_SYS_ERROR	RX_MST_ABORT	RX_TGT_ABORT	TX_TGT_ABORT	Reserved		MST_DPERR
R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R/W1C-0	R-0		R/W1C-0

23	16
Reserved	
R-0	

15	12	11	9	8
IO Limit		Reserved		IO Addressing
R/W-0		R-0		R-0

7	4	3	1	0
IO Base		Reserved		IO Addressing
R/W-0		R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 17-101. SECSTAT Register Field Descriptions

Bit	Field	Value	Description
31	DTCT_PERROR	0	Detected Parity Error
30	RX_SYS_ERROR	0	Received System Error
29	RX_MST_ABORT	0	Received Master Abort
28	RX_TGT_ABORT	0	Received Target Abort
27	TX_TGT_ABORT	0	Signaled Target Abort
26-25	Reserved	0	Reserved
24	MST_DPERR	0	Master Data Parity Error
23-16	Reserved	0	Reserved
15-12	IO Limit	0-Fh	I/O Space Limit
11-9	Reserved	0	Reserved
8	IO Addressing	0	32 bit IO Space indication for IO Limit Register. Indicates 16 bit and 32 bit addressing for 0 and 1 respectively.
7-4	IO Base	0-Fh	IO Space Base
3-1	Reserved	0	Reserved
0	IO Addressing	0	Indicates 0 for 16 bit and 1 for 32 bit addressing for the IO Base Register. Writable from internal bus interface.

17.4.7.6 MEMSPACE Register

The memory limit and base register (MEMSPACE) is described in the figure and table below.

Figure 17-96. MEMSPACE Register

31	20	19	16
Memory Limit		Reserved	
R/W-0		R-0	

15	4	3	0
Memory Base		Reserved	
R/W-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-102. MEMSPACE Register Field Descriptions

Bit	Field	Value	Description
31-20	Memory Limit	0-FFFh	Memory Limit Address
19-16	Reserved	0	Reserved
15-4	Memory Base	0-FFFh	Memory Base Address
3-0	Reserved	0	Reserved

17.4.7.7 PREFETCH_MEM Register

The prefetchable memory limit and base register (PREFETCH_MEM) is described in the figure and table below.

Figure 17-97. PREFETCH_MEM Register

31	20	19	17	16
End Address		Reserved		Memory Addressing
R/W-0		R-0		R-0

15	4	3	1	0
Start Address		Reserved		Memory Addressing
R/W-0		R-0		R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-103. PREFETCH_MEM Register Field Descriptions

Bit	Field	Value	Description
31-20	End Address	0-FFFh	Upper 12 bits of 32 bit Prefetchable Memory End Address
19-17	Reserved	0	Reserved
16	Memory Addressing		Memory addressing. Writable from internal bus interface.
		0	32 bit memory addressing
		1	64 bit memory addressing
15-4	Start Address	0-FFFh	Upper 12 bits of 32 bit Prefetchable Memory Start Address
3-1	Reserved	0	Reserved
0	Memory Addressing		Memory addressing. Writable from internal bus interface.
		0	32 bit memory addressing
		1	64 bit memory addressing

17.4.7.8 PREFETCH_BASE Register

The prefetchable memory base upper 32 bits register (PREFETCH_BASE) is described in the figure and table below.

Figure 17-98. PREFETCH_BASE Register

31	0
Base Address	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-104. PREFETCH_BASE Field Descriptions

Bit	Field	Value	Description
31-0	Base Address	0-FFFF FFFFh	Upper 32 bits of base address of prefetchable memory space. Used when 64 bit addressing is enabled.

17.4.7.9 PREFETCH_LIMIT Register

The prefetchable limit upper 32 bits register (PREFETCH_LIMIT) is described in the figure and table below.

Figure 17-99. PREFETCH_LIMIT Register

31	0
Base Address	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 17-105. PREFETCH_LIMIT Register Field Descriptions

Bit	Field	Value	Description
31-0	Limit Address	0-FFFF FFFFh	Upper 32 bits of Limit Address of Prefetchable Memory Space. Used with 64 bit prefetchable memory addressing only.

17.4.7.10 IOSPACE Register

The IO base and limit upper 16 bits register (IOSPACE) is described in the figure and table below.

Figure 17-100. IOSPACE Register

31	16
IOBASE	
R/W-0	
15	0
IOLIMIT	
R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

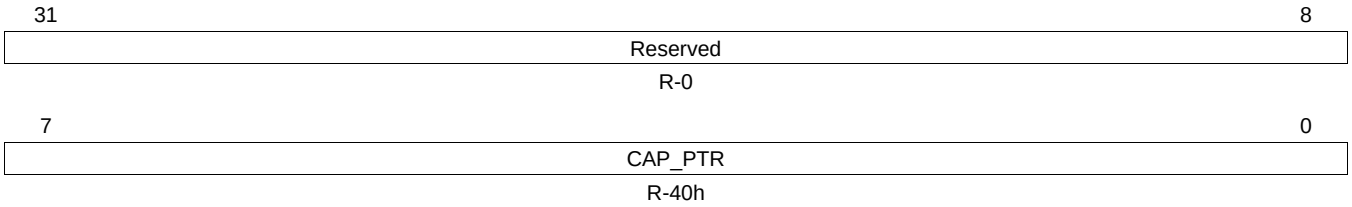
Table 17-106. IOSPACE Register Field Descriptions

Bit	Field	Value	Description
31-16	IOBASE	0-FFFFh	Upper 16 bits of IO Base
15-0	IOLIMIT	0-FFFFh	Upper 16 bits of IO Limit

17.4.7.11 CAP_PTR Register

The capabilities pointer register (CAP_PTR) is described in the figure and table below.

Figure 17-101. CAP_PTR Register



LEGEND: R = Read only; -*n* = value after reset

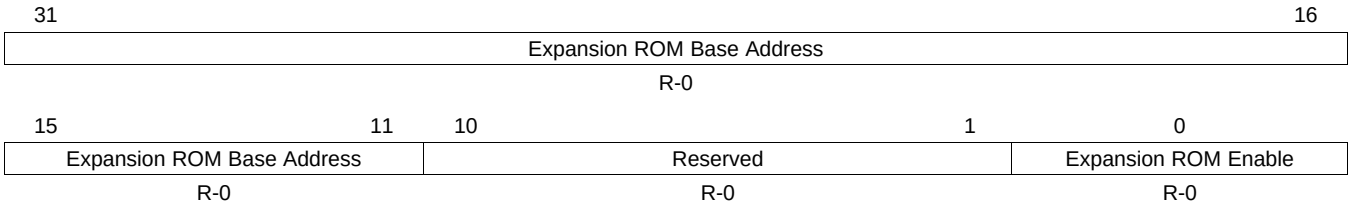
Table 17-107. CAP_PTR Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	CAP_PTR	0-FFh	First Capability Pointer. By default, it points to Power Management Capability structure. Writable from internal bus interface.

17.4.7.12 EXPNSN_ROM Register

The expansion ROM base address register (EXPNSN_ROM) is described in the figure and table below.

Figure 17-102. EXPNSN_ROM Register



LEGEND: R = Read only; -*n* = value after reset

Table 17-108. EXPNSN_ROM Register Field Descriptions

Bit	Field	Value	Description
31-11	Expansion ROM Base Address	0-1F FFFFh	Address of Expansion ROM
10-1	Reserved	0	Reserved
0	Expansion ROM Enable	0	Expansion ROM Enable

17.4.7.13 BRIDGE_INT Register

The bridge control register (BRIDGE_INT) is described in the figure and table below.

Figure 17-103. BRIDGE_INT Register

31	30	29	28	27	26	25	24
Reserved				SERREN_STATUS	TIMER_STATUS	SEC_TIMER	PRI_TIMER

R-1							
7	6	5	4	3	2	1	0
INT_LINE							
R/W-FFh							

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 17-109. BRIDGE_INT Register Field Descriptions

Bit	Field	Value	Description
31-28	Reserved	0	Reserved
27	SERREN_STATUS	0	Discard Timer SERR Enable Status. Not Applicable to PCI Express.
26	TIMER_STATUS	0	Discard Timer Status. Not applicable to PCI Express.
25	SEC_TIMER	0	Secondary Discard Timer. Not applicable to PCI Express
24	PRI_TIMER	0	Primary Discard Timer. Not applicable to PCI Express.
23	B2B_EN	0	Fast Back to Back Transactions Enable. Not applicable to PCI Express.
22	SEC_BUS_RST	0	Secondary Bus Reset
21	MST_ABORT_MODE	0	Master Abort Mode. Not applicable to PCI Express. Always zero.
20	VGA_DECODE	0	VGA 16 bit Decode
19	VGA_EN	0	VGA Enable
18	ISA_EN	0	ISA Enable
17	SERR_EN	0	SERR Enable
16	PERR_RESP_EN	0	Parity Error Response Enable
15-8	INT_PIN	0-FFh	Interrupt Pin. It identifies the legacy interrupt message that the device uses. Valid values are 00h for legacy interrupt not used and 01h, 02h, 03h and 04h for INTA, INTB, INTC or INTD respectively. For single function configuration, the core only uses INTA. This register is writable through internal bus interface.
7-0	INT_LINE	0-FFh	Interrupt Line. Value is system software specified.

17.4.8 PCIe Capability Registers

Table 17-110. PCIe Capability Registers

Offset	Acronym	Section
0h	PCIE_CAP	Section 17.4.8.1
4h	DEVICE_CAP	Section 17.4.8.2
8h	DEV_STAT_CTRL	Section 17.4.8.3
Ch	LINK_CAP	Section 17.4.8.4

Power, Reset, and Clock Management (PRCM) Module

Topic **Page**

18.1 Introduction

The device power-management architecture ensures maximum performance and operation time for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements. This introduction contains the following information:

- Power-management architecture building blocks for the device
- State-of-the-art power-management techniques supported by the power-management architecture of the device

18.1.1 Device Power-Management Architecture Building Blocks

To provide a versatile architecture supporting multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage management.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

18.1.1.1 Clock Management

The PRCM module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management.

Each module within the device has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks.

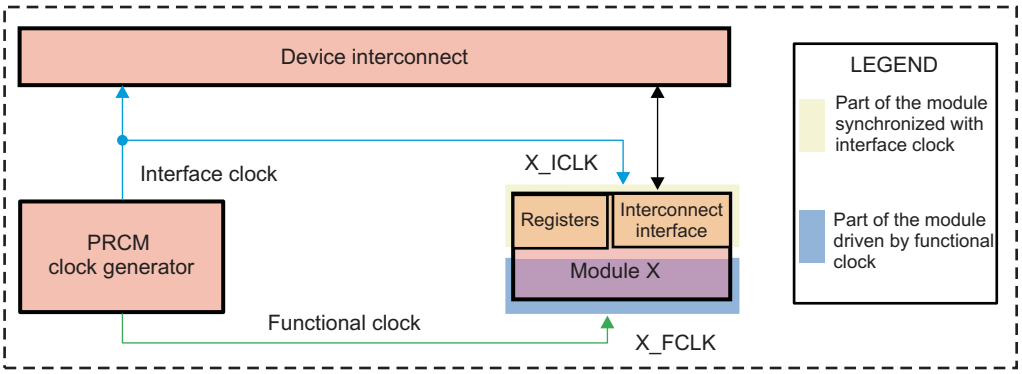
The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.
- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is identified by an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity.
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

Figure 18-1. Functional and Interface Clocks



18.1.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or may be gated otherwise. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks. The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module) or cannot initiate transactions and only responds to the transactions initiated by the master (called slave module). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules

18.1.2.1 Master Standby Protocol

This protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for the purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes. Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the module register bit field <Module>_SYSCONFIG. MIDLEMODE or >Module>_SYSCONFIG. STANDBYMODE (see Table 18-1). The behavior, identified by standby mode values, must be configured.

The standby status of a master module is indicated by the CM_<Power_domain>_<Module>_CLKCTRL[x].STBYST bit in the PRCM module. Table 18-2 describes the master module standby status.

Table 18-1. Master Module Standby-Mode Settings

Standby Mode Value	Selected Mode	Description
0	Force-standby	The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent the loss of data at the time the clocks are gated.
1h	No-standby	The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it never allows the output clocks of the PRCM module to be gated.
2h	Smart-standby	The module asserts the standby request based on its internal activity status.The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module.
3h	Smart-standby wakeup-capable mode	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in STANDBY state. The mode is relevant only if the appropriate module mwakeup output is implemented.

Table 18-2. Master Module Standby Status

STBYST Bit Value	Description
0	The module is functional.
1	The module is in standby mode.

18.1.2.2 Slave Idle Protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an idle request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module. Similarly, an idled slave module may need to be wakened because of a service request from a master module or as a result of an event (called a wake-up event; for example, interrupt or DMA request) received by the slave module. In this situation the PRCM module enables the clocks to the module and then deasserts the idle request to signal the module to wake up. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the module register bit field <Module>_SYSCONFIG. SIDLEMODE or <Module>_SYSCONFIG. IDLEMODE (see Table 18-3). The behavior, listed in the Idle Mode Value column, must be configured by software.

Table 18-3. Module Idle Mode Settings

Idle Mode Value	Selected Mode	Description
0	Force-idle	The module unconditionally acknowledges the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent the loss of data at the time the clock is switched off.
1h	No-idle	The module never acknowledges any idle request from the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state.
2h	Smart-idle	The module acknowledges the idle request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or direct memory access (DMA) requests are processed. This is the best approach to efficient system power management.

Table 18-3. Module Idle Mode Settings (continued)

Idle Mode Value	Selected Mode	Description
3h	Smart-idle wakeup-capable mode	The module acknowledges the idle request basing its decision on its internal wakeup-capable mode activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module swakeup output(s) is implemented.

The idle status of a slave module is indicated by the CM_<Powerdomain>_<Module>_CLKCTRL[x] IDLEST bit field in the PRCM module. Table 18-4 lists the possible idle status for a slave module.

Table 18-4. Slave Module Idle Status

IDLEST Bit	Idle Status	Description
0	Functional	The module is fully functional. The interface and functional clocks are active.
1h	In transition	The module is performing a wake-up or a sleep transition.
2h	Interface idle	The module interface clock is idled. The module may remain functional if using a separate functional clock.
3h	Full idle	The module is fully idle. The interface and functional clocks are gated.

For the idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM_<Powerdomain>_<Module>_CLKCTRL[x] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the idle request to the module unconditionally (that is, immediately when the software requests). Table 18-5 describes the configurable behavior of MODULEMODE.

Table 18-5. Slave Module Mode Settings in PRCM

MODULEMODE Bit	Selected Mode	Description
0	Disabled	The PRCM module unconditionally asserts the module idle request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled).
1h	Reserved	Reserved
2h	Enabled	This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module idle request based on the clock-domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module.
3h	Reserved	Reserved

In addition to the IDLE and STANDBY protocol, PRCM offers also the possibility to manage optional clocks, through a direct software control: “OptFclken” bit from programming register.

Table 18-6. Module Clock Enabling Condition

Clock Enabling Condition	Condition:	
	AND	OR
Clock associated with STANDBY protocol	Clock domain is ready	MStandby is de-asserted Mwakeup is asserted

Table 18-6. Module Clock Enabling Condition (continued)

Clock Enabling Condition	Condition: AND	Condition: OR
Clock associated with IDLE protocol, as interface clock	Clock domain is ready	Idle status = FUNCT Idle status = TRANS SWakeup is asserted
Clock associated with IDLE protocol, as functional clock	Clock domain is ready	Idle status = FUNCT Idle status = TRANS Idle status = IDLE SWakeup is asserted
Optional clock	Clock domain is ready	OptFclken=Enabled (1)

18.1.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module (see Figure 18-2). By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE (GATED) states). Thus, a clock domain allows control of the dynamic power consumption of the device. The device is partitioned into multiple clock domains, and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to individually activate and gate each clock domain of the device.

Figure 18-2. Generic Clock Domain

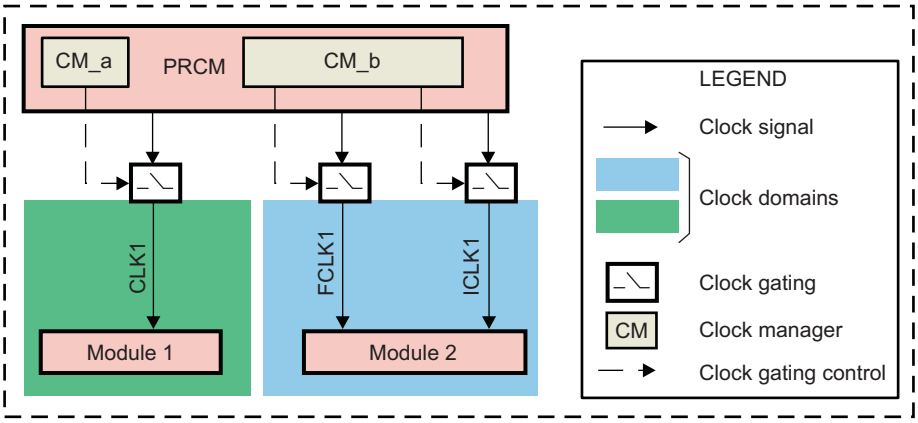


Figure 18-2 is an example of two clock managers: CM_a and CM_b. Each clock manager manages a clock domain. The clock domain of CM_b is composed of two clocks: a functional clock (FCLK2) and an interface clock (ICLK1), while the clock domain of CM_a consists of a clock (CLK1) that is used by the module as a functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use. The PRCM module lets software check the status of the clock domain functional clocks. The CM_<Clock_domain>_CLKSTCTRL[x] CLKACTIVITY_<FCLK/Clock name_FCLK> bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table 18-7 shows the possible states of the functional clock.

Table 18-7. Clock Domain Functional Clock States

CLKACTIVITY Bit	Status	Description
0	Gated	The functional clock of the clock domain is inactive
1	Active	The functional clock of the clock domain is running

18.1.3.1 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings. A clock domain can switch between three possible states: ACTIVE, IDLE_TRANSITION, and INACTIVE. Figure 18-3 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

Figure 18-3. Clock Domain State Transitions

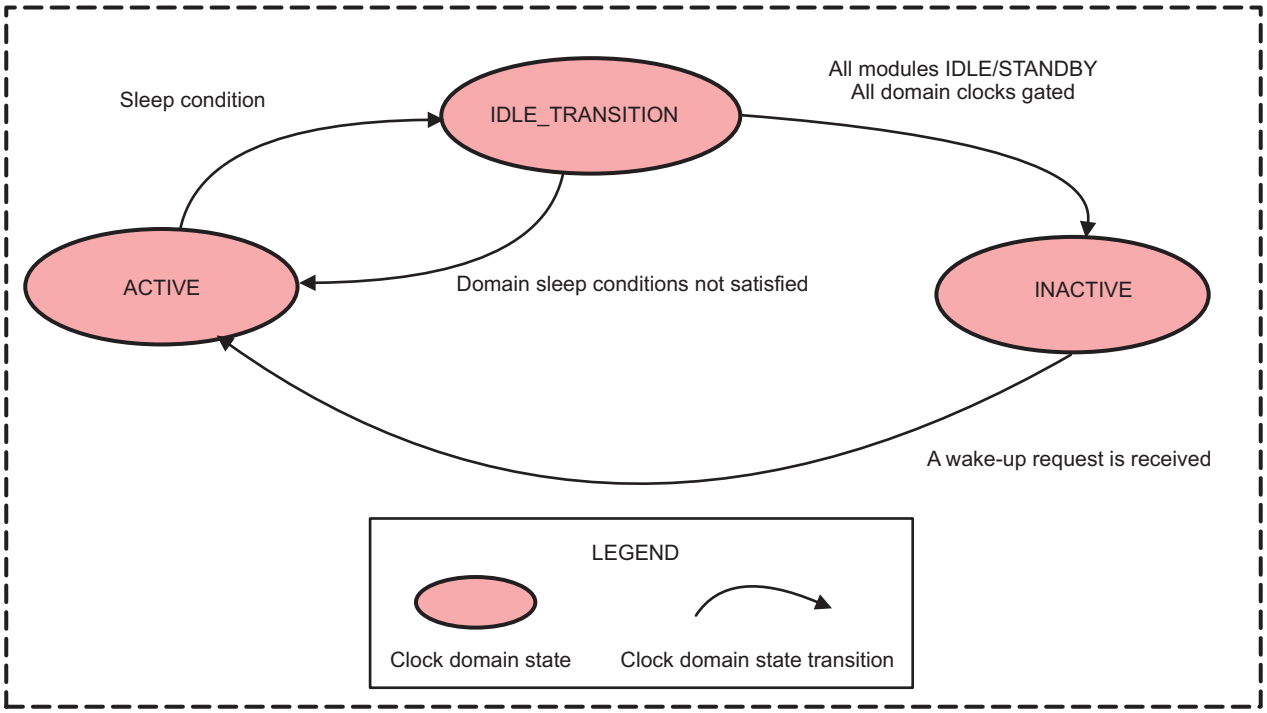

Table 18-8. Clock Domain States

State	Description
ACTIVE	Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state. · All interface clocks to the nondisabled slave modules in the clock domain are provided. All functional and interface clocks to the active master modules (that is, not in STANDBY) in the clock domain are provided.· All enabled optional clocks to the modules in the clock domain are provided.
IDLE_TRANSITION	This is a transitory state.· Every master module in the clock domain is in STANDBY state · Every idle request to all the slave modules in the clock domain is asserted.· The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active.· All enabled optional clocks to the modules in the clock domain are provided.
INACTIVE	All clocks within the clock domain are gated.· Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled or auto) is in IDLE state and set to disabled or auto mode.· Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled or auto) is in IDLE state and set to disabled or auto mode.· Every optional functional clock in the clock domain is gated.

Each clock domain transition behavior is managed by an associated register bit field in the CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL PRCM module. Table 18-9 describes the clock transition mode settings in the clock domain.

Table 18-9. Clock Transition Mode Settings

CLKTRCTRL Bit	Selected Mode	Description
0	Reserved	Reserved
1h	SW_SLEEP	A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied
2h	SW_WKUP	A software-forced clock domain wake-up transition is initiated
3h	Reserved	Reserved

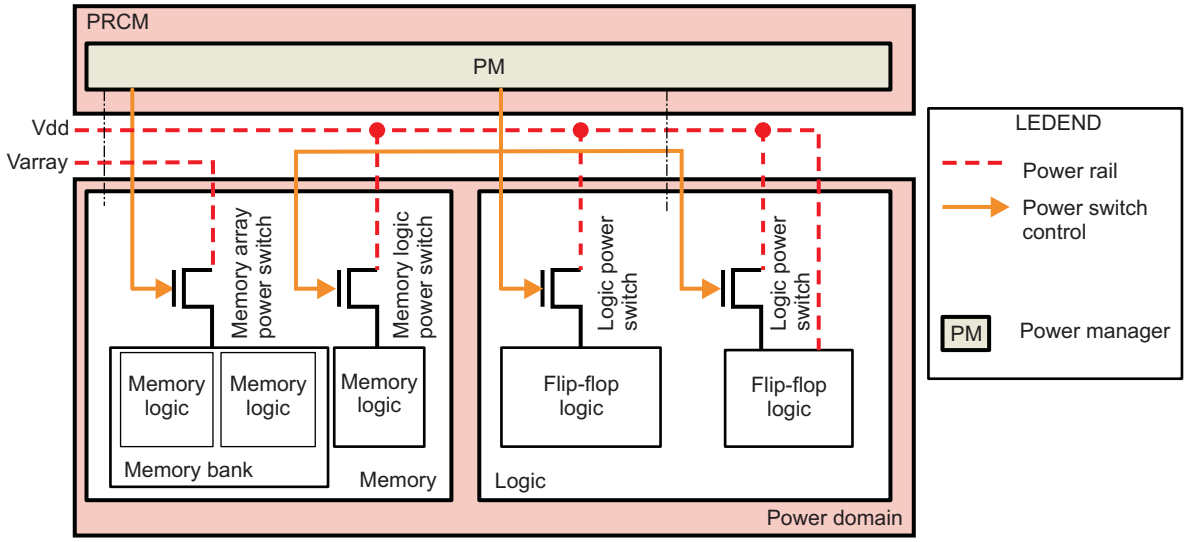
18.1.4 Power Management

The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allows the PRCM module to turn on and off specific sections of the device without affecting the others.

18.1.4.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see Figure 18-4). A power domain can be turned on and off without affecting the other parts of the device.

Figure 18-4. Power Domain Block Diagram



To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into a logic area (Table 18-10) and a memory area (Table 18-11).

Table 18-10. States of a Logic Area in a Power Domain

State	Description
On	Logic is fully powered
Off	Logic power switches are off. All the logic (DFF) is lost.

Table 18-11. States of a Memory Area in a Power Domain

State	Description
On	The memory array is powered and fully functional.
Off	The memory array is powered down.

18.1.4.2 Power Domain Management

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state.

Table 18-12. Power Domain Control and Status Registers

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE	Control	Selects the target power state of the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[1:0] POWERSTATEST	Status	Identifies the current state of the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[2] LOGICSTATEST	Status	Identifies the current state of the logic area in the power domain. It is OFF or ON.
PM_<Power domain>_PWRSTST[5:4] MEMSTATEST	Status	Identifies the current state of the memory area in the power domain. It is OFF or ON.

18.1.4.3 Power-Management Techniques

The following section describes the state-of-the-art power-management techniques supported by the device.

18.1.4.3.1 Adaptive Voltage Scaling

Adaptive voltage scaling (AVS) is a power-management technique based in Smart Reflex that is used for automatic control of the operating voltages of the device to reduce active power consumption. With Smart Reflex, power-supply voltage is adapted to silicon performance, either statically (based on performance points predefined in the manufacturing process of a given device) or dynamically (based on the temperature-induced real-time performance of the device). A comparison of these predefined performance points to the real-time on-chip measured performance determines whether to raise or lower the power-supply voltage. AVS achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variation. The device voltage is automatically adapted to maintain performance of the device.

18.2 Power Reset Clock Management Overview

18.2.1 Introduction

The PRCM is structured using the architectural concepts presented in the 5000x Power Management Framework. This framework provides:

A set of modular, re-usable FSM blocks to be assembled into the full clock and power management mechanism. A register set and associated programming model. Functional sub-block definitions for clock management, power management, system clock source generation, and master clock generation.

The device supports an enhanced power management scheme based on:

- 4 functional power domains:

Generic domains:

- Active
- AlwaysOn
- Default
- HDVICP2-0
- HDVICP2-1
- HDVICP2-2
- SGX

The PRCM provides the following functional features:

- Device power-up sequence control
- Device sleep / wake-up sequence control
- Centralized reset generation and management
- Centralized clock generation and management

The PRCM modules implement these general functional interfaces:

- OCP configuration ports
- Power switch control signals
- Device control signals
- Clocks control signals
- Resets signals
- A set of power management protocol signals for each module to control and monitor standby, idle and wake-up modes (CM and PRM)
- Emulation signals

18.2.2 Interfaces Description

This section lists and shortly describes the different interfaces that allow PRCM to communicate with other modules or external devices.

18.2.2.1 OCP Interfaces

The PRCM has 1 target OCP interfaces, compliant with respect to the OCP/IP2 standard. The OCP port, for the PRCM module is used to control power, reset and wake-up Management.

18.2.2.1.1 OCP Slave Interfaces

PRCM implements a 32-bit OCP target interface compliant to the OCP/IP2.0 standard. PRCM is specified to operate at “clkin (27 Mhz)” clock rate.

18.2.3 Power Control Interface

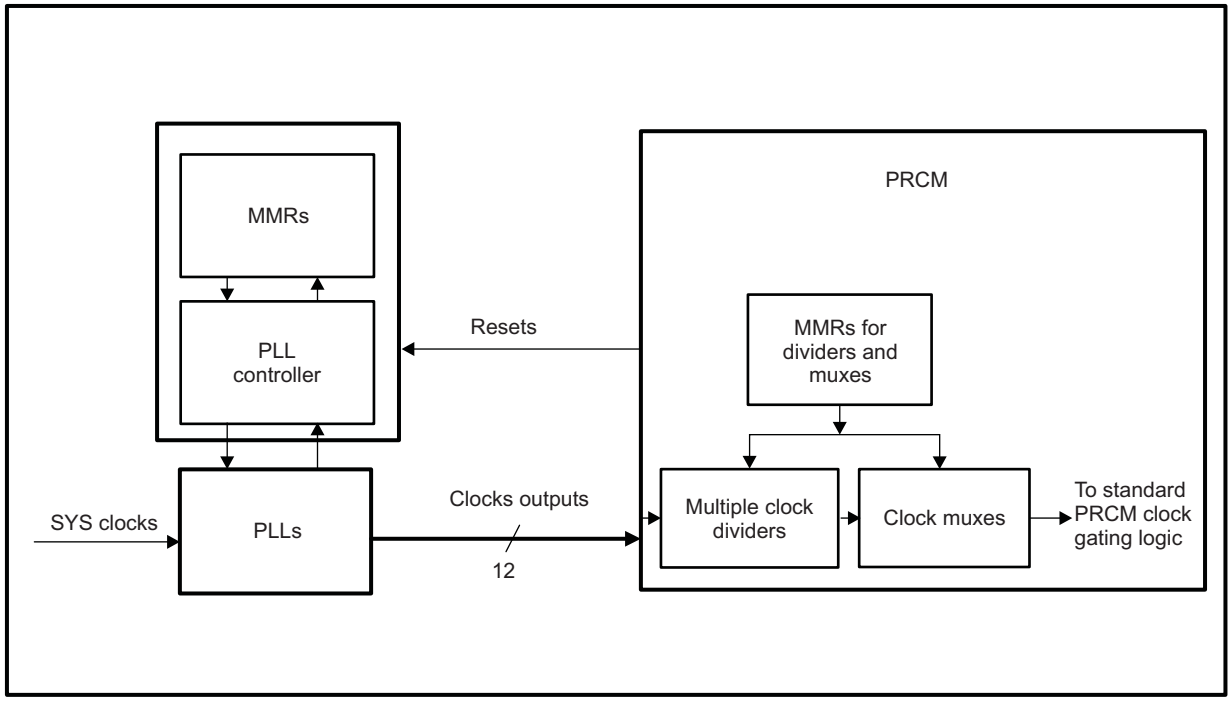
The Device does has power domain switches over the device, this interface provides PRCM control over power domain switches and receives responses from the power domains which indicate the switch status. It also controls the isolation signals. The control for power domain switches will be latched in PRCM Status Registers.

18.2.4 FAPLL interface

All Flying adder PLL control signals will be generated outside PRCM. Following diagram shows the overview of Flying adder PLLs with PRCM.

Figure 18-5 shows the proposed architecture of Device Flying-adder PLLs along with PRCM.

Figure 18-5. Device Flying-Adder PLLs



Following are the key points The PLLs (4 nos.) and PLL controllers are outside PRCM and all the controls required by PLLs will be generated by PLL controller. PLL controllers will be configured/controlled by chip level MMRs. All the resets required by these MMRs, PLL controllers will be generated by PRCM.

18.2.5 Device Control Interface

This interface provides PRM management of several device-level features which are not specific to any single power domain. This PRM interface controls signals to/from the device for global control:

- Device type coding
- I/Os isolation control

18.2.6 Clocks Interface

This interface gathers all clock inputs and outputs managed by PRCM modules.

18.2.7 Resets Interface

This interface gathers all resets inputs and outputs managed by PRCM module.

18.2.8 Modules Power Management Control Interface

Modules or sub-systems in the device are split over 2 categories:

Initiator: an initiator is a module able to generate traffic on the device interconnects (typically: processors, MMU, eDMA...).

Target: a target is a module that cannot generate traffic on the device interconnects, but that can generate interrupts or DMA request to the system (typically: peripherals). PRCM handles a power management handshake protocol with each module or sub-system. This protocol allows performing proper clock and power transition taking into account each module activity or state.

18.2.8.1 Initiator Modules Interface

PRCM module handle all initiator modules power management interfaces: MStandby signal MWait signal.

18.2.8.2 Targets Modules Interface

PRCM module handle all target modules power management interfaces: SIdleReq signal SIdleAck signal FCLKEN signal PRCM module handles all target modules wake-up: SWakeup signal.

18.3 Device Modules and Power-Management Attributes List

18.3.1 Active Power Domain Modules Attribute

Table 18-13. Active Power Domain Modules Attribute

Module Instance	Clock Domain Name	Module PM Ports
C674x DSP	GEM_GCLKIN	Master Slave
HD_DSS	HDSS_L3_GCLK	Master Slave

18.3.2 AlwaysOn Power Domain Modules Attribute

Table 18-14. AlwaysOn Power Domain Modules Attribute

Module Instance	Clock Domain Name	Module PM Ports
CONTRL	ALWON_L3_SLOW_GCLK	Slave

18.4 Clock Management

PRCM provides a centralized control for the generation, distribution and gating of most clocks in the device. PRCM gathers externally clocks and device internally generated clocks (FAPLL clocks) for distribution to the other modules in the device. PRCM module manages system clock generation.

18.4.1 Terminology

The PRCM produces two types of clock: interface and functional clocks.

Interface clocks: these clocks primarily provide clocking for the system interconnect modules and the portions of device's functional modules which interface to the system interconnect modules. In most cases, the interface clock supplies the functional module's system interconnect interface and registers. For some modules, interface clock is also used as functional clock. In this specification, interface clocks are represented by blue lines.

Functional clock: this clock supplies the functional part of a module or a sub-system. In some cases, a module or a subsystem may require several functional clocks: 1 or several main functional clock(s), 1 or several optional clock(s). A module needs its main clock(s) to be operational. Optional clocks are used for specific features and can be shutdown without stopping the module.

18.4.2 External Clock Sources to PRCM

The Device requires the following clocks: The 32 kHz frequency is used for low frequency operation. It supplies the clock to the RTC. The MAIN PLL CLOCKS are the source clocks for the C674x DSP, Cortex-A8, HDVICP2 and all the interconnect clocks. The DDR PLL CLOCKS are the source clocks for DDR. The VIDEO PLL CLOCKS are the source clocks for HD-DSS. The AUDIO PLL CLOCKS are the source clocks for McASPs, McBSPs. The Device delivers four clock signals to external devices:

Output clock SYSCLK_OUT can deliver clock outputs of each PLL. CM_CLKOUT_CTRL Register controls the Clock selection and division ratio.

Table 18-20. External Clock Sources to PR

Clock name	Source	Destination	Description
Main_pll_clock1	Main PLL	PRCM	Clock input from Main PLL (Flying adder Synthesizer 1)

18.4.4 Clock Generation

18.4.4.1 Main FAPLL Interface to PRCM

Figure 18-6 shows the interface between main FAPLL and PRCM.

CAUTION

"Glitch-free" muxes have an output which is free from any glitches. It requires the previously selected clock and the newly selected clock to both be freerunning for switch-over to occur. Switchover could take 1-2 clock cycles of previously selected and newly selected clock to complete. If newly selected clock is idle, a switchover never occurs (previously selected clock continues to pass through the mux). Do not switch to a non-existent clock.

18.5 Reset Management

18.5.1 Overview

The PRCM manages the resets to all power domains inside device. And, it manages generation of a single reset output signal through device pin, SYS_RESWARM_RST, for external use. The PRCM has no knowledge of or control over resets generated locally within a module, for example, via the OCP configuration register bit IPName_SYSCONFIG.SoftReset.

All PRM reset outputs are asynchronously asserted. These outputs are active-low except for the DPLL resets. Deassertion is synchronous to the clock which runs a counter used to stall, or delay, reset de-assertion upon source deactivation. This clock will be SYS_CLK used by all the reset managers. All modules receiving a PRCM generated reset are expected to treat the reset as asynchronous and implement local re-synchronization upon de-activation as needed.

One or more Reset Managers are required per power domain. Independent management of multiple reset domains is required to meet the reset sequencing requirements of all modules in the power domain.

18.5.2 Reset Concepts and Definitions

The PRCM collects many sources of reset. Here below is a list of qualifiers of the source of reset:

- Cold reset: it affects all the logic in a given entity
- Warm reset: it is a partial reset which doesn't affect all the logic in a given entity
- Global reset: it affects the entire device
- Local reset: it affects part of the device (1 power domain for example)
- Software reset: it is initiated by software
- Hardware reset: it is hardware driven

Each reset source is specified as being a cold or warm type. Cold types are synonymous with power-on-reset (POR) types. Such sources are applied globally within each receiving entity (sub-system, module, macro-cell) upon assertion. Cold reset events include: device power-up, power-domain power-up, and E-Fuse programming failures.

Warm reset types are not necessarily applied globally within each receiving entity. A module may use a warm reset to reset a subset of its logic. This is often done to speed-up reset recovery time, that is, the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include: software initiated per power-domain, watch-dog time-out, externally triggered, and emulation initiated.

Reset sources, warm or cold types, intended for device-wide effect are classified as global sources. Reset sources intended for regional effect are classified as local sources.

Each Reset Manager provides two reset outputs. One is a cold reset generated from the group of global and local cold reset sources it receives. The other is a warm+cold reset generated from the combined groups of, global and local, cold and warm reset sources it receives.

The Reset Manager asserts one, or both, of its reset outputs asynchronously upon reset source assertion. Reset deassertion is extended beyond the time the source gets de-asserted. The reset manager will then extend the active period of the reset outputs beyond the release of the reset source, according to the PRCM's internal constraints and device's constraints. Some reset durations can be software-configured. Most (but not all) reset sources are logged by PRCM's reset status registers. The same reset output can generally be activated by several reset sources and the same reset source can generally activate several reset outputs. All the reset signals output of the PRCM are active low. Several conventions are used in this document for signal and port names. They include:

- "_RST" in a signal or port name is used to denote reset signal.
- "_PWRN_RST" in a signal or port name is used to denote a cold reset source

Table 18-28. Reset Sources Overview

18.5.3 Global Power-On (Cold) Reset

The PRCM is required internally to generate the global power-on reset used by the domain Reset Managers from three cold reset sources: SYS_PWRN_RST, ICEPICK_POR_RST, GLOBAL_COLD_SW_RST.

Source SYS_PWRN_RST is received over a dedicated device input pin, typically driven by the same power IC that supplies device power and 27MHz clock. This is the normal system POR.

The internal emulation module, ICE-Pick, generates ICEPICK_POR_RST. This reset is used in emulation mode only.The PRCM is required to provide an output port, ACT_LIKE_SECURE, which is asynchronously set to a logic high upon ICEPICK_POR_RST assertion. This state is maintained until a normal system POR occurs.

Source GLOBAL_COLD_SW_RST is a PRM internally generated one. Activation is triggered upon setting PRM memory-mapped register bit, PRM_RSTCTRL.GLOBAL_COLD_SW_RST. This bit is self-clearing, it is automatically cleared by the hardware.

All the reset driven by the PRCM are asserted when any one of global power on reset sources above are active. The PRCM must stall the release of the global power-on reset until after de-assertion of all cold reset sources and until after receiving indication that the voltage domains, have all ramped to their operating levels and until after receiving an indication that the system clock is running and is stable. The PRCM implements a counter after all of these indications have occurred to provide a delay before releasing internal global power on reset signals. This requires use of a PM FW Reset Manager. The "always-on" 27 MHz clock must run the RM's stall-period timer. The max count is provided by PRM register RM_RSTTIME.RSTIME1 bit-field. During device power-up, this mechanism enforces the system requirement of a running 27 MHz clock.

18.5.3.1 Power-On Reset Sequence

The following sequence describes the main chronological steps during the power-on reset sequence of the device.

- The system settings are done (all the voltages are ramped-up, 27 MHz clock is stable, power domains are ramped up) and now SYS_PWRN_RST is de-asserted and the PRCM proceeds with the device power-up sequence.
- Following the de-assertion of this power on reset signal, the PRCM starts the power on reset sequence.
- SYS_WARM_OUT_RESET will be de-asserted by PRCM.
- The DPLLs are released from reset.
- The MPU is released from reset provided the MPU clock is running.
- Once MPU_RST_DONE is asserted by MPU, all other domain resets are released provided the domain clocks are running.
- All the software controlled resets, will either remain asserted/De-asserted as per the default MMR bit.

18.5.4 Global Warm Reset

The PRCM is required to generate the global reset used by the domain Reset Managers from the following warm reset input sources: SYS_WARM_IN_RST, MPU_WD_RST, GLOBAL_SW_WARM_RST, and ICEPICK_RST.

Source SYS_WARM_IN_RST is received over the input path from a dedicated device bidirectional pin. The source is typically hardware generated via a reset push-button switch. Source MPU_WDT_RST is generated from internal watchdog timer module. Activation is triggered by a timeout event. Source GLOBAL_WARM_SW_RST is PRCM internally generated. Activation is triggered upon setting PRM memory-mapped register bit. This bit is self-clearing, that is, it is automatically cleared by the hardware.

18.5.4.1 Global Warm Reset Sequence

The following sequence describes the main chronological steps during a global warm reset sequence: Assumptions are: Device V_{DD} is regulated at to the required voltage The system is running: Resets are released All the PLLs are locked.

- Upon assertion of any global warm reset source: The GLOBAL_WARM_RSTACTST signal is asserted High by the PRCM to indicate to the EMIF module that global warm reset event has occurred. Following the assertion of the status signal, EMIF starts putting its OCP interface into the idle state. The PRCM delays global warm reset to the device for minimum 16 L3 clock cycles until EMI puts its OCP interface properly in idle state.

  In parallel to this, the PRCM also asserts the EMIF_IDLEREQ driven to EMIF module so that EMIF can drain all its outstanding requests and starts putting the external SDRAM memory into the self-refresh mode. The EMIF asserts its IDLEACK high once memory is properly put in self-refresh mode.
- The device reset manager resets part of the device by asserting the global warm reset The external warm reset is asserted (SYS_NRES_WARM_OUT port) but gets de-asserted after approx 30 CLKIN cycles irrespective of SYS_WARMIN_RST state.
  - All the domain warm resets are asserted
  - The DPLL resets are not asserted
  - The system clock, CLKIN, is running at the system clock frequency
  - The registers sensitive to a warm reset are synchronously reset (PRCM registers sets)
  - The PRCM cuts all the clocks not requested by the registers reset value setting
- The global warm reset is released. The global warm reset is extended after release of the warm reset source until all the following conditions are met:

  Device reset manager counter overflowed (setup by the register PRM_RSTTIME.RSTTIME2) Voltages are stable
- The external warm reset is de-asserted.
- The MPU clock is running.
- The MPU domain is released from reset. The MPU re-boots.

NOTE: The C674x DSP, HDVICP2-0, HDVICP2-1, HDVICP2-2, are held under reset after global warm reset by assertion of software source of reset. Other domains such are held under reset after global warm reset until the MPU software enables their respective interface clock.

18.5.5 MPU Subsystem POR Sequence

The power on reset must be applied when MPU SS is first powered up. Following is the detailed description of MPU power on reset sequence.

During the initial power up sequence, the PRCM it asynchronously releases the DPLL_MAIN_RST signal for the main PLL and. Once the main PLL reset is released, it starts the PLL initialization. The PLL is configured in bypass mode and it provides the bypass output CLK to all the modules inside MPU SS.

The PRCM releases the reset to INTC module inside MPUSS, it asynchronously releases the MPU_AO_RST signal to MPUSS.

Before the MPU power on reset is de-asserted, the PRCM must ensure that the MPU CLK is running so that MPU can be reset properly

The PRCM releases MPU_PWRN_RST and it waits until MPUSS power on Reset done, MPU_PWRN_RSTDONE signal is asserted HIGH by the MPUSS.

Following the de-assertion of MPU_PWRN_RST signal, the MPU SS de-asserts the nPORESET signal to the Cortex-A8 CPU and after sufficient number of MPU CLK cycles MPU SS asserts the MPU_PWRN_RSTDONE signal high to indicate to the PRCM that synchronous power on reset sequence is completed inside MPU SS.

Once the PRCM sees that this MPU_PWRN_RSTDONE signal is asserted HIGH, PRCM de-asserts the MPU_RST signal and then the MPU starts booting.

18.5.6 MPU Subsystem Warm Sequence

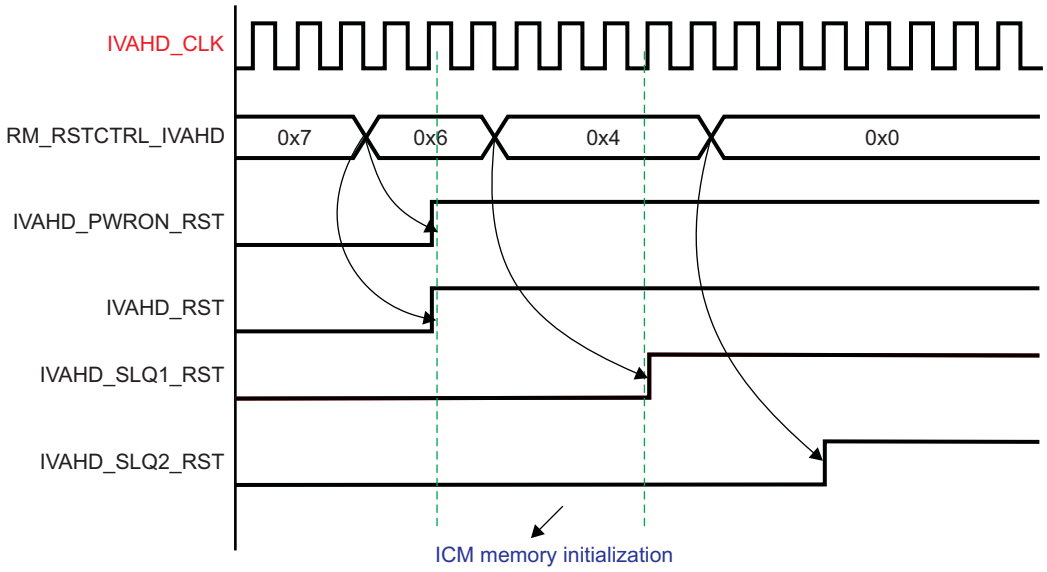
During the warm reset of MPU, the PRCM asserts the MPU_RST signal only and power on reset signal is not asserted.

The MPU_RST is kept asserted for minimum 32 MPU clock cycles, that is, SYS_CLK in this case since during warm the reset of MPU.

18.5.7 HDVICP2 Power-On Reset Sequence

Figure 18-12 illustrates the POR sequence of the HDVICP2.

Figure 18-12. POR Sequence of the HDVICP2



POR to HDVICP2 is applied when PD_IVAHD is powered up.

Whenever the HDVICP2 is enabled by software control, the following sequence happens:

- The PRCM module provides the functional clock IVAHDi_CLK to the HDVICP2
- The POR to HDVICP2 is de-asserted

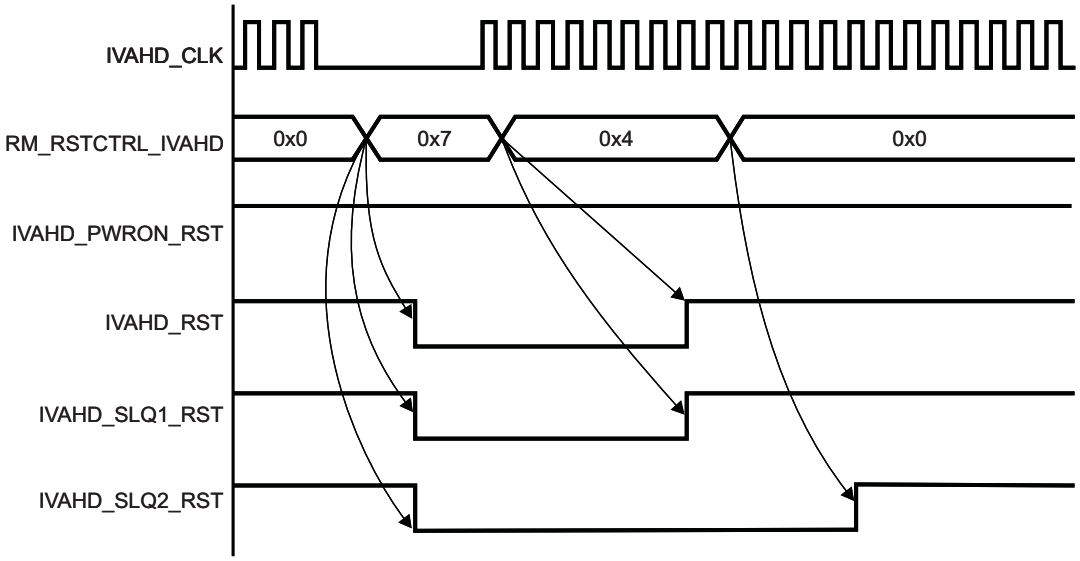
After POR de-assertion, the sequence is:

- Software clears the RM_IVAHDi_RSTCTRL[2] RST3 bit. This causes the PRCM module to release the IVAHDi_PWRN_RST reset, which is used inside HDVICP2 primarily to reset the emulation logic and the IVAHDi_RST reset, which is used to reset all logic inside HDVICP2. Then, software can download data into the TCM memory while keeping the sequencer CPUs under reset.
- Software clears the RM_IVAHDi_RSTCTRL[0] RST1 bit. This releases the IVAHDi_SEQ1_RST reset to the Sequencer1 CPU.
- Software can clear the RM_IVAHDi_RSTCTRL[1] RST2 bit. This releases the IVAHDi_SEQ2_RST reset to the Sequencer2 CPU.

18.5.8 HDVICP2 Software Warm Reset Sequence

Figure 18-13 illustrates the software warm reset sequence of the HDVICP2.

Figure 18-13. Software Warm Reset Sequence of the HDVICP2



Before asserting the software reset to the HDVICP2, the MPU software must ensure that:

- The HDVICP2 sequencer CPUs are in IDLE state (CM_IVAHDi_IVAHD_CLKCTRL[17:16] IDLEST).
- The HDVICP2 is in STANDBY state CM_IVAHDi_IVAHD_CLKCTRL[[18] STBYST).
- The functional clock to theHDVICP2 has been gated by the PRCM module (CM_IVAHDi_CLKSTCTRL[8] CLKACTIVITY_IVAHD_CLK).

The software reset sequence occurs when the MPU software:

1. Sets the RM_IVAHDi_RSTCTRL[2] RST3, RM_IVAHDi_RSTCTRL[1] RST2, and RM_IVAHDi_RSTCTRL[0] RST1 bits. This causes the PRCM module to assert the IVAHDi_RST, IVAHDi_SEQ1_RST, and IVAHDi_SEQ2_RST resets to the HDVICP2. IVAHDi_PWRN_RST remains deasserted.
2. Enables the functional clock to the HDVICP2.
3. clears the RM_IVAHDi_RSTCTRL[2] RST3 and RM_IVAHDi_RSTCTRL[0] RST1 bits. This causes the PRCM module to release the IVAHDi_RST and IVAHDi_SEQ1_RST resets to the HDVICP2.
4. clears the RM_IVAHDi_RSTCTRL[1] RST2 bit. This releases the IVAHDi_SEQ2_RST reset to the Sequencer2 CPU.

18.5.9 C674x DSP Power-On Reset Sequence

The assumptions about POR de-assertion are:

- The MPU software sets the CM_ACTIVE_GEM_CLKCTRL [1:0] MODULEMODE bit field to enabled.
- The MPU software sets the CM_ACTIVE_GEM_CLKSTCTRL [1:0] CLKTRCTRL bit field to SW_WKUP.
- The PRCM is providing the clocks to C674x DSP.

The POR sequence is:

- The PRCM module releases GEM_POR when the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) reaches its limit.
- The MPU software clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to release the DSP, MMU, and CACHE interface from reset.
- Once the reset manager counter (PRM_RSTTIME[14:10] RSTTIME2) expires, the PRCM module releases the GEM_GRST signal.
- On deassertion of the GEM_GRST signal, the C674x subsystem starts the initialization sequence. During the initialization sequence all the internal registers inside the C674x subsystem are properly reset and the reset for the DSP, MMU, and CACHE interface completes.
- The MPU software must configure the MMU once the MMU is out of reset. After the MMU is configured, the MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.

The PRCM module releases GEM_LRST, which causes the DSP to start booting.

18.5.10 C674x DSP Warm Reset Sequence

The assumptions about WARM reset de-assertion are:

- The DSP is in IDLE state

The sequence is:

1. The MPU software sets the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST and RM_ACTIVE_RSTCTRL[0] GEM_LRST bits.
2. The PRCM module asserts the GEM_GRST and GEM_LRST reset signals.GEM_POR remains deasserted in this case.
3. The MPU software re-enables the C674x DSP Clocks and clears the RM_ACTIVE_RSTCTRL[1] GEM_SW_RST bit in the PRCM module register to reset the DSP, MMU, and CACHE interface. The DSP subsystem starts the partial initialization sequence for the warm reset.
4. The MPU software clears the RM_ACTIVE_RSTCTRL[0] GEM_LRST bit in the PRCM module register.
5. The PRCM module releases GEM_LRST, which causes the DSP to start booting.

18.6 Power Management

18.6.1 Overview

The PRCM is responsible for managing power domain state transitions through generation of power-down controls to the following cells (for example, isolation latches, domain power switches), and other analog or mixed-signal cells (for example, memory, DPLLs, oscillator) in the device. See Figure 18-14.

Figure 18-14. Voltage and Power Domains

	1V AVS	1V	1.8V	3.3V	1.5V	0.9V
Always-on						
Default						
Active						
HDVICP2-0						
HDVICP2-1						
HDVICP2-2						
SGX						

18.6.2 Power Domains Management

PRCM contains a set of memory-mapped PM-type registers for those functional power domains. These registers allow software to configure define the states of the physical domains under each functional domain state. All domain transitions are fully software controllable. Always ON power domain is never transitioned from the ON power state.

18.6.3 Power Domain Transition Control

The Device has multiple power domains. All these power domains will be controlled by on-chip power switches.

18.6.3.1 Power-Down Sequence

Power-down sequence defined here assumes that IP with STANDBY interface is already in smart-standby mode and STANDBY is already asserted by the IP.

1. Software will request PRCM to put all modules in the specific power domain in “Disable” by programming “Module control Register: Disable” inside PRCM. CM_<Power domain>_<module>_CLKCTRL[x] MODULEMODE = 0 (DISABLED).
2. PRCM starts the power management handshake (IdleReq/IdleAck) with IPs.
3. FCLKEN will be driven LOW by PRCM. PRCM will gate-off all the clock to the functional clock domains.(ICLK and FCLK).
4. Software will request PRCM to put all Interface clock domains in the specific power domain in “force sleep” by programming “Functional clock Domain control register: force sleep” inside PRCM. CM_<Clock domain>_CLKSTCTRL[x] CLKTRCTRL = 1 (SW_SLEEP).
5. Software will request PRCM to put a specific power domain in OFF state by programming MMR (PWRSTCTRL: OFF) inside PRCM. PM_<Power domain>_PWRSTCTRL[POWERSTATE] = 0 (OFF).
6. Specific PSCON inside PRCM will assert the control signals for enabling Isolation cells.
7. PRCM asserts reset of the domain.
8. PSCON then will assert control signal to switch-off the actual power supply.
9. On Die switch will control the actual power supply to the Domain and the acknowledgement is fed back to PRCM.

18.6.3.2 Power-Up Sequence

1. One of the Always on domain IPs send a wake-up interrupt to the Cortex-A8. [All IPs that can generate wake-up are always enabled].
2. Software will request PRCM to put all Interface clock domains in the specific power domain in “force wakeup” by programming “Functional clock Domain control register: force wakeup” inside PRCM. CM_<Clock domain>_CLKSTCTRL[x] .CLKTRCTRL = 2h (SW_WKUP).
3. This will enable power as well as interface clocks.
4. Specific PSCON inside PRCM will assert the control signals to switch-on the actual power supply.
5. This On Die power switch will switch ON the power supply to the domain.
6. Once the power supply is switched ON, acknowledgement is fed back to PSCON.
7. PRCM de-asserts reset of the domain.
8. PRCM will then turn-off isolation cells.
9. Software will request PRCM to put all modules in the specific power domain in “Enable” by programming “Module control Register: Enable” inside PRCM. CM_<Power domain>_<module>_CLKCTRL[x] MODULEMODE = 2h (ENABLED).
10. PRCM will de-assert the “IdleReq” to the modules

NOTE:

- If only modules need to be disabled, then only power-down sequence steps 1, 2, 3 will be performed. (PRCM will clock gate clocks to the module, if all modules sharing that clock are disabled).
- Programming “PWRSTCTRL” can be skipped in both the sequnces. In such a scenario PWRSTCTRL:OFF should be in default state. Whenever Functional clock Domain control register: force sleep is programmed, it will automatically go to OFF state. Whenever Functional clock Domain control registers: force wakeup is programmed, it will automatically go to ON state.
- PWRSTCTRL: ON should be programmed only if there is any requirement of not to switch off the power but gate all the clocks.

18.7 PRCM Registers

Table 18-29 shows the base address offset for the PRCM module. For the base address of these registers, see Table 1-12.

Table 18-29. PRCM Modules

Base Address Offset	Module Name	Section
000h	PRM_DEVICE	Section 18.7.1
100h	CM_DEVICE	Section 18.7.2

18.7.1 PRM_DEVICE

Table 18-30 lists the PRMDEVICE registers.

Table 18-30. PRM_DEVICE Registers

Offset Address	Acronym	Section
A0h	PRM_RSTCTRL	Section 18.7.1.1
A4h	PRM_RSTTIME	Section 18.7.1.2
A8h	PRM_RSTST	Section 18.7.1.3

18.7.1.1 Reset Control (PRM_RSTCTRL) Register

The reset control (PRM_RSTCTRL) register is shown and described in the figure and table below.

Figure 18-15. Reset Control (PRM_RSTCTRL) Register

31	2	1	0
Reserved		RST_GLOBAL_COLD_SW	RST_GLOBAL_WARM_SW
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-31. Reset Control (PRM_RSTCTRL) Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1	RST_GLOBAL_COLD_SW		Global COLD software reset control. This bit is reset only upon a global cold source of reset.
		0	Global COLD software reset is cleared.
		1	Asserts a global COLD software reset. The software must ensure the SDRAM is properly put in sef-refresh mode before applying this reset.
0	RST_GLOBAL_WARM_SW		Global WARM software reset control. This bit is reset upon any global source of reset (warm and cold).
		0	Global warm software reset is cleared.
		1	Asserts a global warm software reset.

18.7.1.2 PRM_RSTTIME Register

The PRM_RSTTIME register is shown and described in the figure and table below.

Figure 18-16. PRM_RSTTIME Register

31	13	12	8	7	0
Reserved		RSTTIME2		RSTTIME1	
		R/W-10h		R/W-6h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-32. PRM_RSTTIME Register Field Descriptions

Bit	Field	Value	Description
31-13	Reserved	0	Reserved
12-8	RSTTIME2	0-1Fh	(Power domain) reset duration 2 (number of RM.SYSCLK clock cycles)
7-0	RSTTIME1	0-FFh	(Global) reset duration 1 (number of SYS_CLK clock cycles)

18.7.1.3 PRM_RSTST Register

The PRM_RSTST register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software. This register is shown and described in the figure and table below.

Figure 18-17. PRM_RSTST Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18-33. PRM_RSTST Register Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved
9	ICEPICK_RST		IcePick reset event. This is a source of global warm reset initiated by the emulation.
		0	No ICEPICK reset
		1	IcePick reset has occurred
8-6	Reserved	0	Reserved
5	EXTERNAL_WARM_RST		External warm reset event
		0	No global warm reset
		1	Global external warm reset has occurred
4	Reserved	0	Reserved
3	MPU_WDT_RST		MPU Watchdog timer reset event. This is a source of global WARM reset.
		0	No MPU watchdog reset
		1	MPU watchdog reset has occurred
2	Reserved	0	Reserved
1	GLOBAL_WARM_SW_RST		Global warm software reset event
		0	No global warm software reset
		1	Global warm software reset has occurred
0	GLOBAL_COLD_RST		Power-on (cold) reset event
		0	No power-on reset
		1	Power-on reset has occurred

18.7.2 CM_DEVICE

18.7.2.1 CM_CLKOUT_CTRL Register

The CM_CLKOUT_CTRL register provides the control over SYS_CCCLKOUT output. It is shown and described in the figure and table below.

Figure 18-18. CM_CLKOUT_CTRL Register

31 8	7	6	5 3	2 0
Reserved	CLKOUT2EN	Reserved	CLKOUT2DIV	CLKOUT2SOURCE
	R/W-0	R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-34. CM_CLKOUT_CTRL Register Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	CLKOUT2EN		This bit controls the external clock activity
		0	SYS_CLKOUT2 is disabled
		1	SYS_CLKOUT2 is enabled
6	Reserved	0	Reserved
5-3	CLKOUT2DIV		This field controls the external clock divison factor
		0	SYS_CLKOUT2/1
		1h	SYS_CLKOUT2/2
		2h	SYS_CLKOUT2/3
		3h	SYS_CLKOUT2/4
		4h	SYS_CLKOUT2/5
		5h	SYS_CLKOUT2/6
		6h	SYS_CLKOUT2/7
		7h	SYS_CLKOUT2/8
2-0	CLKOUT2SOURCE		This field selects the external output clock source
		0	Source clock is MAIN_PLL_CLK5
		1h	Source clock is DDR_PLL_CLK1
		2h	Source clock is VIDEO_PLL_CLK1
		3h	Source clock is AUDIO_PLL_CLK1

18.7.3 OCP_SOCKET_PRM Device

18.7.3.1 REVISION_PRM Register

The REVISION_PRM register contains the IP revision code for the PRM. It is shown and described in the figure and table below.

Figure 18-19. REVISION_PRM Register

31	8	7	0
Reserved		REV	
R-0		R-10h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

		7h	Select SYS_CLK divided by 8

18.7.4.11 CM_SYSCLK15_CLKSEL Register

The CM_SYSCLK15_CLKSEL register selects the divider value for SYSCLK13. It is shown and described in the figure and table below.

Figure 18-30. CM_SYSCLK15_CLKSEL Register

31	3	2	0
Reserved		CLKSEL	
R-0		R/W-3h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-47. CM_SYSCLK15_CLKSEL Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	CLKSEL		Selects the divider value [warm reset insensitive]
		0	Select SYS_CLK divided by 1
		1h	Select SYS_CLK divided by 2
		2h	Select SYS_CLK divided by 3
		3h	Select SYS_CLK divided by 4
		4h	Select SYS_CLK divided by 5
		5h	Select SYS_CLK divided by 6
		6h	Select SYS_CLK divided by 7
		7h	Select SYS_CLK divided by 8

18.7.4.12 CM_VPB3_CLKSEL Register

The CM_VPB3_CLKSEL register selects the divider value for video PLL B3 divider. It is shown and described in the figure and table below.

Figure 18-31. CM_VPB3_CLKSEL Register

31	2	1	0
Reserved		CLKSEL	
R-0		R/W-2h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-48. CM_VPB3_CLKSEL Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	CLKSEL		Selects the divider value [warm reset insensitive]
		0	Select SYS_CLK divided by 1
		1h	Select SYS_CLK divided by 2
		2h	Select SYS_CLK divided by 22
		3h	Reserved

18.7.4.13 CM_VPC1_CLKSEL Register

The CM_VPC1_CLKSEL register selects the divider value for video PLL B1 divider. It is shown and described in the figure and table below.

Figure 18-32. CM_VPC1_CLKSEL Register

31	2	1	0
Reserved		CLKSEL	
R-0		R/W-2h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-49. CM_VPC1_CLKSEL Register Field Descriptions

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	CLKSEL		Selects the divider value [warm reset insensitive]
		0	Select SYS_CLK divided by 1
		1h	Select SYS_CLK divided by 2
		2h	Select SYS_CLK divided by 22
		3h	Reserved

18.7.4.14 CM_VPD1_CLKSEL Register

The CM_VPD1_CLKSEL register selects the divider value for video PLL D1 divider. It is shown and described in the figure and table below.

Figure 18-33. CM_VPD1_CLKSEL Register

31	2	1	0
Reserved		CLKSEL	
R-0		R/W-7h	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-50. CM_VPD1_CLKSEL Register Field Descriptions

Bit	Field	Value	Description
31-3	Reserved	0	Reserved
2-0	CLKSEL		Selects the divider value [warm reset insensitive]
		0	Select SYS_CLK divided by 1
		1h	Select SYS_CLK divided by 2

10	CLKACTIVITY_SD_GCLK		This field indicates the state of the SD_GCLK clock in the domain.
		0	Corresponding clock is gated
		1	Corresponding clock is active
9	CLKACTIVITY_HD_VENC_A_GCLK		This field indicates the state of the HD_VENC_A_GCLK clock in the domain.
		0	Corresponding clock is gated
		1	Corresponding clock is active

Table 18-73. CM_HDDSS_CLKSTCTRL Register Field Descriptions (continued)

Bit	Field	Value	Description
8	CLKACTIVITY_HD_VENC_D_GCLK		This field indicates the state of the HD_VENC_D_GCLK clock in the domain.
		0	Corresponding clock is gated
		1	Corresponding clock is active
7-2	Reserved	0	Reserved
1-0	CLKTRCTRL		Controls the clock state transition of the HD-DSS clock domain.
		0	Reserved
		1h	SW_SLEEP: Start a software forced sleep transition on the domain.
		2h	SW_WKUP: Start a software forced wake-up transition on the domain.
		3h	Reserved

18.7.5.3 CM_ACTIVE_GEM_CLKCTRL Register

The CM_ACTIVE_GEM_CLKCTRL register manages the C674x DSP clocks. It is shown and described in the figure and table below.

Figure 18-56. CM_ACTIVE_GEM_CLKCTRL Register

31 19	18	17 16	15 2	1 0
Reserved	STBYST	IDLEST	Reserved	MODULEMODE
R-0	R-1	R-3h	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-74. CM_ACTIVE_GEM_CLKCTRL Register Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reserved
18	STBYST		Module standby status
		0	Module is functional (not in standby)
		1	Module is in standby
17-16	IDLEST		Module idle status
		0	Module is fully functional, including OCP
		1h	Module is performing transition: wakeup, or sleep, or sleep abortion
		2h	Module is in Idle mode (only OCP part). It is functional if using separate functional clock.
		3h	Module is disabled and cannot be accessed
15-2	Reserved	0	Reserved
1-0	MODULEMODE		Control the way mandatory clocks are managed
		0	Module is disabled by software. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).
		1h	Reserved
		2h	Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.
		3h	Reserved

18.7.5.4 CM_ACTIVE_HDDSS_CLKCTRL Register

The CM_ACTIVE_HDDSS_CLKCTRL register manages the HD_DSS clocks. It is shown and described in the figure and table below.

Figure 18-57. CM_ACTIVE_HDDSS_CLKCTRL Register

		0	Module is disabled by software. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).
		1h	Reserved
		2h	Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.
		3h	Reserved

18.7.17.37 CM_ALWON_MMUCFG_CLKCTRL Register

The CM_ALWON_MMUCFG_CLKCTRL register manages the MMU config clocks. It is shown and described in the figure and table below.

Figure 18-142. CM_ALWON_MMUCFG_CLKCTRL Register

31 18	17 16	15 2	1 0
Reserved	IDLEST	Reserved	MODULEMODE
R-0	R-3h	R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-172. CM_ALWON_MMUCFG_CLKCTRL Register Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved
17-16	IDLEST		Module idle status.
		0	Module is fully functional, including OCP
		1h	Module is performing transition: wakeup, or sleep, or sleep abortion
		2h	Module is in Idle mode (only OCP part). It is functional if using separate functional clock
		3h	Module is disabled and cannot be accessed
15-2	Reserved	0	Reserved
1-0	MODULEMODE		Control the way mandatory clocks are managed.
		0	Module is disabled by software. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).
		1h	Reserved
		2h	Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.
		3h	Reserved

18.7.17.38 CM_ALWON_SDIO_CLKCTRL Register

The CM_ALWON_SDIO_CLKCTRL register manages the SDIO clocks. It is shown and described in the figure and table below.

Figure 18-143. CM_ALWON_SDIO_CLKCTRL Register

31	18	17	16	15	2	1	0
Reserved		IDLEST		Reserved		MODULEMODE	
R-0		R-3h		R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 18-173. CM_ALWON_SDIO_CLKCTRL Register Descriptions

Bit	Field	Value	Description
31-18	Reserved	0	Reserved
17-16	IDLEST		Module idle status.
		0	Module is fully functional, including OCP
		1h	Module is performing transition: wakeup, or sleep, or sleep abortion
		2h	Module is in Idle mode (only OCP part). It is functional if using separate functional clock
		3h	Module is disabled and cannot be accessed
15-2	Reserved	0	Reserved
1-0	MODULEMODE		Control the way mandatory clocks are managed.
		0	Module is disabled by software. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup).
		1h	Reserved
		2h	Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen.
		3h	Reserved

18.7.17.39 CM_ALWON_OCMC_0_CLKCTRL Register

The CM_ALWON_OCMC_0_CLKCTRL register manages the OCMC_0 clocks. It is shown and described in the figure and table below.

Figure 18-144. CM_ALWON_OCMC_0_CLKCTRL Register

31 18	17 16	15 2	1 0

Real-Time Clock (RTC)

This chapter provides a functional presentation of real-time clock (RTC).

Topic **Page**

19.1 Introduction

19.1.1 Overview

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock itself can track the passage of real time for durations of several years, provided it has a sufficient power source the whole time.

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of RTC is to wake the rest of chip up from a power down state.

Alarms are available to interrupt the CPU at a particular time, or at periodic time intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

19.1.2 Features

The real-time clock (RTC) provides the following features:

- 100-year calendar (xx00 to xx99)
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded-decimal (BCD) representation of time, calendar, and alarm
- 12-hour clock mode (with AM and PM) or 24-hour clock mode
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the CPU

19.1.3 Functional Block Diagram

Figure 19-1 shows the RTC module block diagram. Figure 19-2 shows a functional block diagram of the RTC.

Figure 19-1. RTC Block Diagram

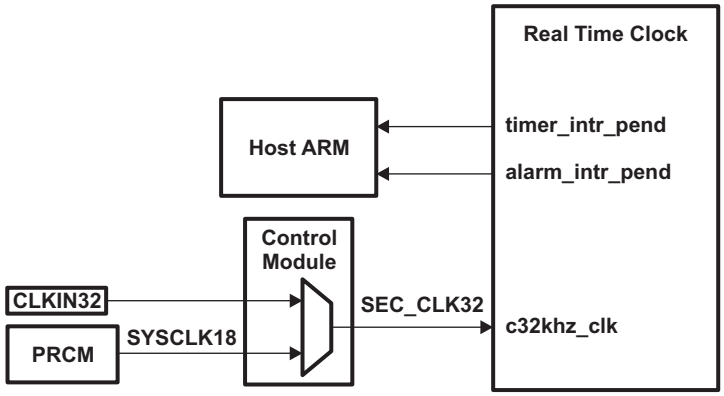

Figure 19-2. RTC Functional Block Diagram

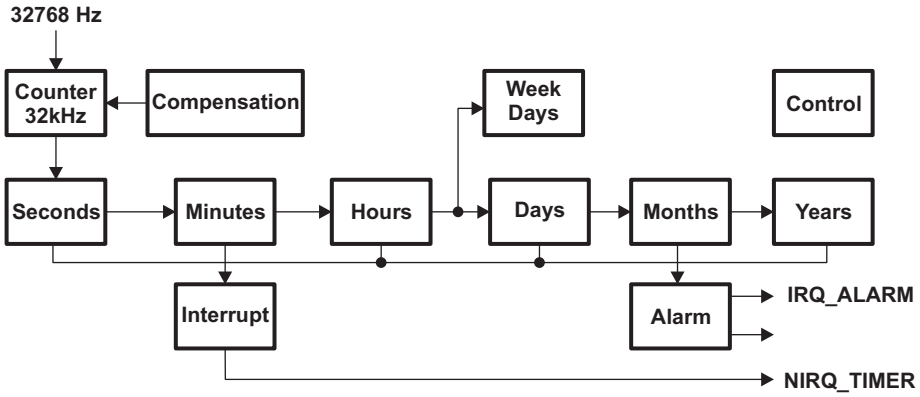


19.2 Architecture

This section defines the module interrupt capabilities and requirements.

19.2.1 Clock Source

The clock reference for the RTC is an internal 32.768-kHz clock signal (SYSCLK18) or an optional external clock source of the same frequency input on the CLKIN32 pin, as selected by the device Control Module. For more information about the optional CLKIN32 pin connection, see your device-specific data manual. If the CLKIN32 pin is not used, this pin should be held low.

The RTC_DISABLE bit in the control register (RTC_CTRL_REG) can be set to save power; however, the RTC_DISABLE bit should not be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP_RTC bit in RTC_CTRL_REG should be used instead.

19.2.2 Signal Descriptions

Table 19-1 lists the signals and their descriptions for the RTC.

Table 19-1. RTC Signals

Signal	I/O	Description
32.768 kHz Functional Clock	I	RTC clock input: SYSCLK18 or optional CLKIN32 pin

19.2.3 Interrupt Support

19.2.3.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer_intr is a timer interrupt.
- alarm_intr is an alarm interrupt.

NOTE: Both interrupt outputs support high-level and high-pulse.

19.2.3.2 Interrupt Description

19.2.3.2.1 Timer Interrupt (timer_intr)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see RTC_INTERRUPTS_REG[1:0] for a description of how to set this up). The IT_TIMER bit of RTC_INTERRUPTS_REG enables this interrupt. The timer interrupt is active-low.

The RTC_STATUS_REG[5:2] bits are only updated at each new interrupt and occur according to Table 19-2. For example, bit 2 (SEC) will always be set when one second has passed. It will also be set when one minute has passed since the completion of one minute also marks the completion of one second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them will also correspond to the passing of a second.

Conversely, bit 5 (DAY) will always be set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

Table 19-2. Interrupt Trigger Events

RTC_STATUS_REG bit	One day has passed	One hour has passed	One minute has passed	One second has passed
[5] (DAY)	1	0/1[(1)]	0/1[(1)]	0/1[(1)]
[4] (HOUR)	1	1	0/1[(1)]	0/1[(1)]
[3] (MIN)	1	1	1	0/1[(1)]
[2] (SEC)	1	1	1	1

(1) This event is only triggered when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

19.2.3.2.2 Alarm Interrupt (alarm_intr)

The alarm interrupt can be generated when the time set into the TC ALARM registers is exactly the same as in the TC registers. This interrupt is then generated, if the IT_ALARM bit in the interrupt register (RTC_INTERRUPTS_REG) is set. This interrupt is low-level sensitive. The RTC_STATUS_REG[6] bit indicates that IRQ_ALARM_CHIP has occurred. This interrupt is disabled by writing a 1 into the RTC_STATUS_REG[6] bit.

To set up an alarm:

- Modify the ALARM_SECONDS_REG, ALARM_MINUTES_REG, ALARM_HOURS_REG, ALARM_DAYS_REG, ALARM_MONTHS_REG, and ALARM_YEARS_REG registers to the exact time you want an alarm to generate.
- Set the IT_ALARM bit in RTC_INTERRUPTS_REG to enable the alarm interrupt.

19.2.4 Programming/Usage Guide

19.2.4.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Although most of the time/calendar registers have 4 bits assigned to each BCD digit, some of the register fields are shorter since the range of valid numbers may be limited. For example, only 3 bits are required to represent the day of the week (WEEK_REG) since only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

Note that the ALARM registers which share the names above also share the same BCD formatting.

- SECOND - Second Count (00-59)
- MINUTE - Minute Count (00-59)
- HOUR - Hour Count (12HR: 01-12; 24HR: 00-23)
- DAY - Day of the Month Count (01-31)
- WEEK - Day of the Week (0-6: SUN = 0)
- MONTH - Month Count (01-12; JAN = 1)
- YEAR - Year Count (00-99)

19.2.4.2 Register Access

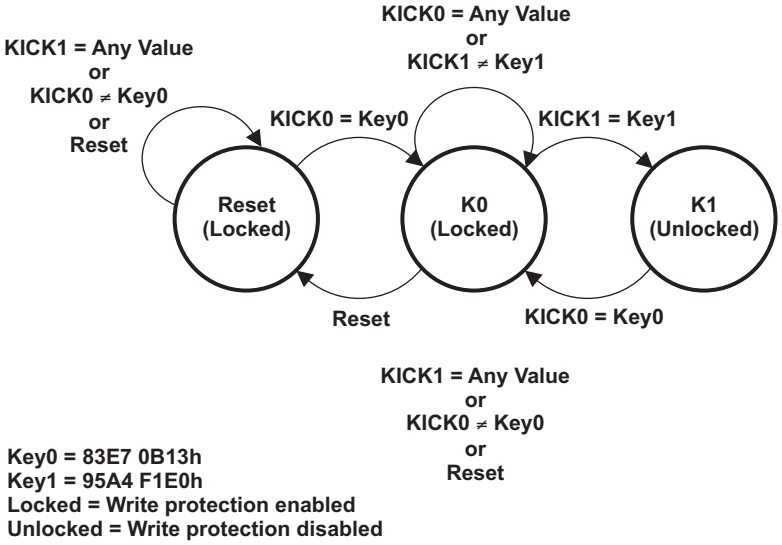
The three register types are as follows and each has its own access constraints:

- TC registers and TC alarm registers
- General registers
- Compensation registers

19.2.4.3 MMR Spurious Write Protection

The module also contains a kicker mechanism (Figure 19-3) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until a reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

Figure 19-3. Kick Register State Machine Diagram



19.2.4.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the SECONDS register will update all of the TC registers. For example, the Year will only get updated on a reading of the SECONDS register. The time/calendar registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values at the moment of the SECONDS read request and not be subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND_30S bit in the control register (RTC_CTRL_REG); the RTC automatically rounds the time values to the nearest minute upon the next read of the SECONDS register.

NOTE: Software should always read the SECONDS register first. However, the software does not have to poll any status bit to determine when to read the TC registers. Table 19-3 defines the TC set that gets shadowed.

Table 19-3. RTC Register Names and Values

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24 hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

19.2.4.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND_30S bit of the control register (RTC_CTRL_REG). When this bit is set, TC values are set to the closest minute value at the next second. The ROUND_30S bit is automatically cleared when rounding time is performed.

Example:

- If current time is 10H59M45S, round operation will change time to 11H00M00S.
- If current time is 10H59M29S, round operation will change time to 10H59M00S.

19.2.4.5 Modifying the TC Registers

To write correct data from/to the TC and TC alarm registers and read the TC alarm registers, the ARM must first read the BUSY bit of the status register (RTC_STATUS_REG) until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15 µs access period in which the ARM can program the TC and TC alarm registers. Once the 15 µs access period passes, the BUSY flag has to be read again from the STATUS register as described previously. If the ARM accesses the TC registers outside of the access period, then the access is not assured.

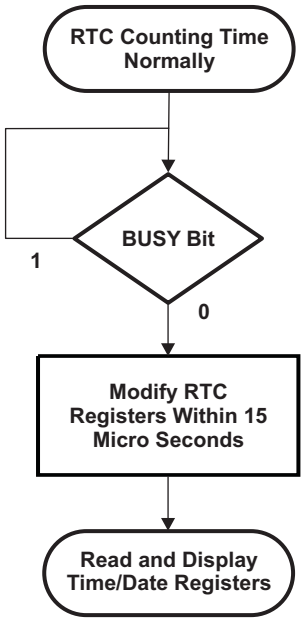
The ARM can access the RTC_STATUS_REG and the RTC_CTRL_REG registers at any time, with the exception of the RTC_CTRL_REG[5] bit, which can only be changed when the RTC is stopped. The ARM can stop the RTC by clearing the STOP_RTC bit of RTC_CTRL_REG. After clearing this bit, the RUN bit in RTC_STATUS_REG needs to be checked to verify the RTC has stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be re-started by resetting the STOP_RTC bit.

NOTE: After writing to a TC register, you must wait 4 clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

CAUTION

In order to remove any possibility of interrupting the register's read process, thus introducing a potential risk of violating the authorized 15 µs access period, it is recommended that you disable all incoming interrupts during the register read process.

Figure 19-4. Flow Control for Updating RTC Registers



19.2.4.5.1 General Registers

The ARM can access the RTC_STATUS_REG and the RTC_CTRL_REG registers at any time (except the RTC_CTRL_REG[5] bit, which must be changed only when the RTC is stopped). For the RTC_INTERRUPTS_REG, the ARM should respect the available access period to prevent spurious interrupt.

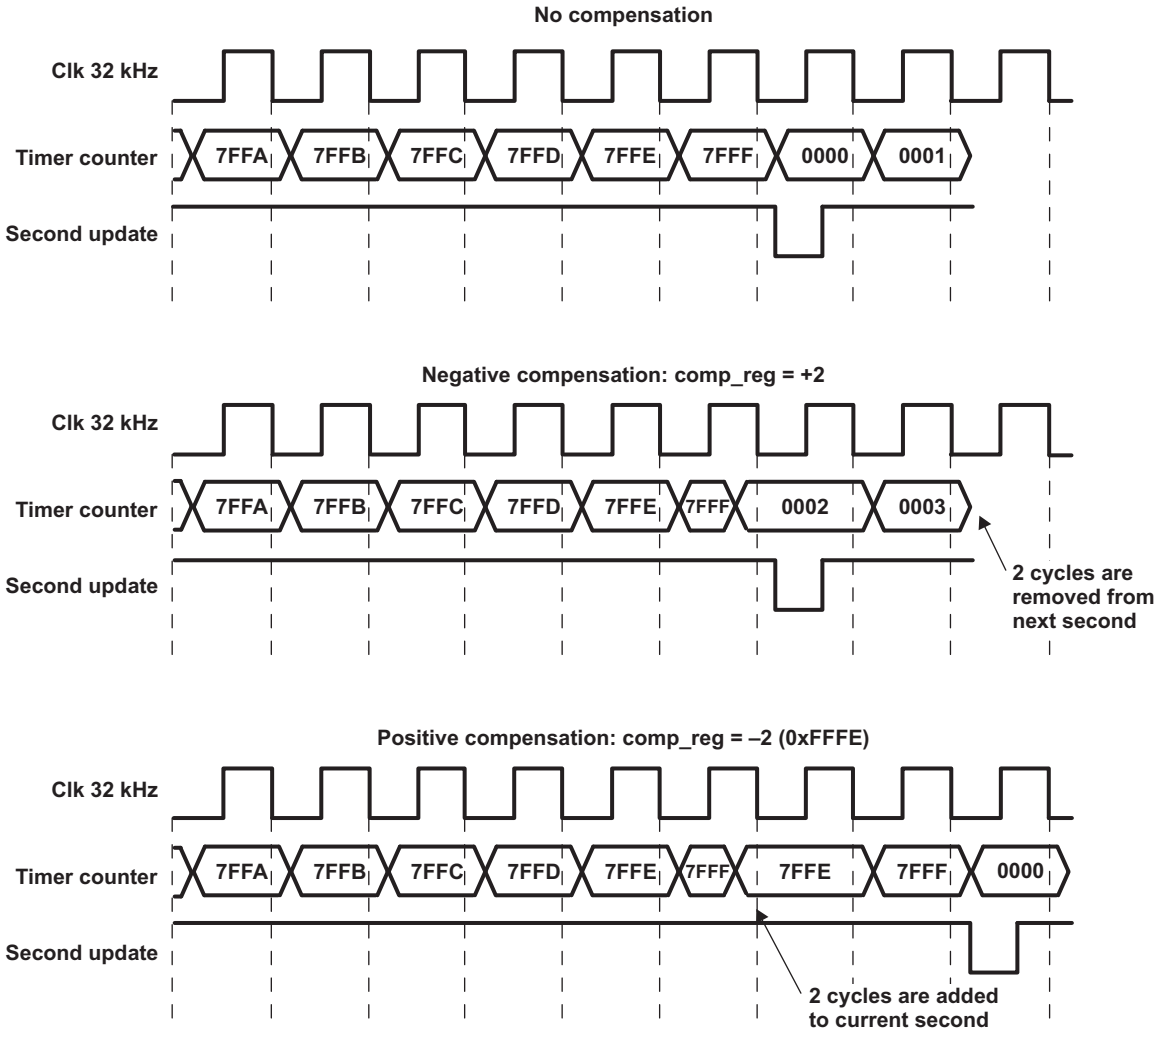
The RTC_DISABLE bit of RTC_CTRL_REG must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. In order to save power, this bit should only be used if the RTC function is unwanted in the application.

19.2.4.6 Crystal Compensation

To compensate for any inaccuracy of the 32 kHz oscillator, the ARM can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by the AUTO_COMP bit in the RTC_CTRL_REG register. If the RTC_COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the RTC_COMP_REG value is negative, compensation occurs before the second change event. RTC_COMP_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform below summarizes positive and negative compensation effect.

Access to the RTC_COMP_MSB_REG and the RTC_COMP_LSB_REG registers must respect the available access period. These registers should not be updated during compensation (first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the ARM could load the compensation value into these registers after each hour event, during an available access period.

Figure 19-5. Compensation Illustration



19.2.5 Scratch Registers

The RTC provides three general-purpose registers (RTC_SCRATCHx_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the RTC_SCRATCHx_REG registers to be useful in indicating RTC states. For example, the RTC_SCRATCHx_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the RTC_SCRATCHx_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the RTC_SCRATCHx_REG register. To indicate unintentional power downs, the software should write a unique value to one of the RTC_SCRATCHx_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the RTC_SCRATCHx_REG register is cleared.

19.2.6 Power Management

The RTC supports the power idle protocol. It has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read.

The Alarm SWakeup event can be used to wakeup the RTC when it is in IDLE state. In order to do so, the alarm needs to be set and enabled before RTC enters the IDLE state. Once this is done, the SWakeup will occur when the alarm event triggers.

NOTE: Since SWakeup is not periodic, using it to wake up the RTC when in IDLE state is not recommended, use Alarm SWakeup instead.

19.2.7 Reset Considerations

When the device is initially powered on, the RTC may issue spurious interrupt signals to the CPU. To avoid issues, a software reset should be performed on the RTC module before the CPU interrupt controller is initialized.

19.3 RTC Registers

Table 19-4 lists the registers for the RTC. For the base address of these registers, see Table 1-12.

Table 19-4. Real-Time Clock (RTC) Registers

Address Offset	Acronym	Register Description	Section
0h	SECONDS_REG	Seconds Register	Section 19.3.1
4h	MINUTES_REG	Minutes Register	Section 19.3.2

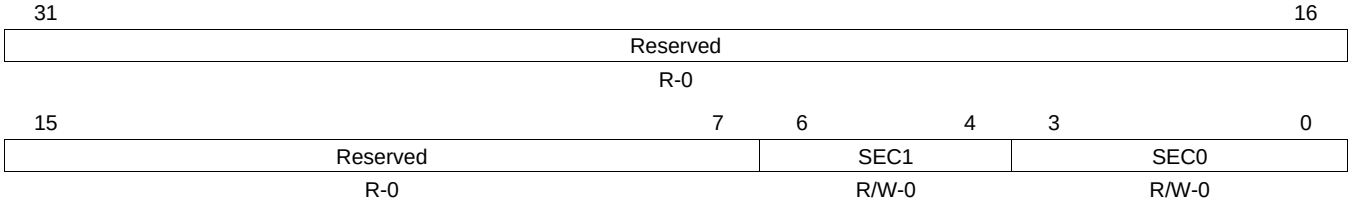
19.3.1 Seconds Register (SECONDS_REG)

The SECONDS_REG is used to program the required seconds value of the current time. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the seconds value is 45, then the value of SEC0 is 5 and value of SEC1 is 4.

Figure 19-6. Seconds Register (SECONDS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

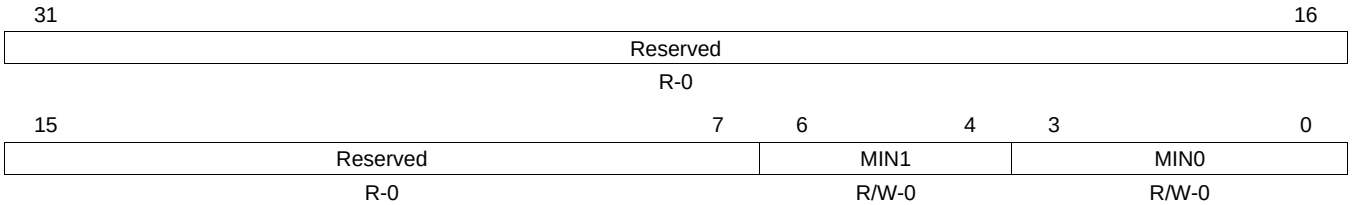
Table 19-5. Seconds Register (SECONDS_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6-4	SEC1	0-5h	2nd digit of seconds, Range is 0 to 5
3-0	SEC0	0-9h	1st digit of seconds, Range is 0 to 9

19.3.2 Minutes Register (MINUTES_REG)

The MINUTES_REG is used to program the minutes value of the current time. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the minutes value is 32, then the value of MIN0 is 2 and value of MIN1 is 3.

Figure 19-7. Minutes Register (MINUTES_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-6. Minutes Register (MINUTES_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6-4	MIN1	0-5h	2nd digit of minutes, Range is 0 to 5
3-0	MIN0	0-9h	1st digit of minutes, Range is 0 to 9

19.3.3 Hours Register (HOURS_REG)

The HOURS_REG is used to program the hours value of the current time. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. In 24Hr time mode if you want to set the hour as 18, then HOUR0 is set as 8 and HOUR1 is set as 1.

Figure 19-8. Hours Register (HOURS_REG)

3-0	HOUR0	0-9h	1st digit of hours, Range is 0 to 9

19.3.4 Day of the Month Register (DAYS_REG)

The DAYS_REG is used to program the day of the month value of the current date. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the day value of the date is 28, DAY0 is set as 8 and DAY1 is set as 2.

Figure 19-9. Days of the Month Register (DAYS_REG)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-8. Day of the Month (DAYS_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	DAY1	0-3h	2nd digit of days, Range is 0 to 3
3-0	DAY0	0-9h	1st digit of days, Range is 0 to 9

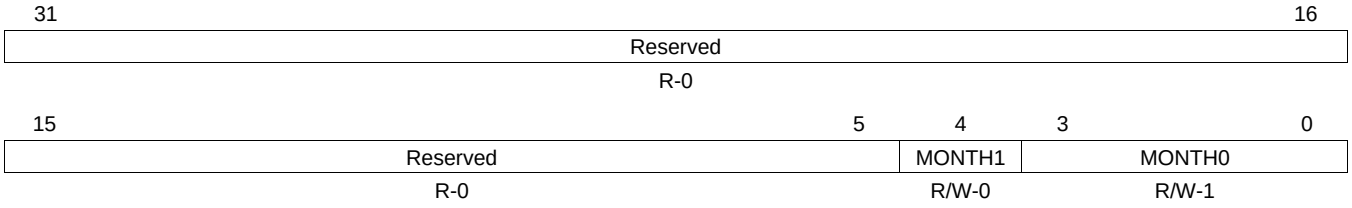
19.3.5 Month Register (MONTHS_REG)

The MONTHS_REG is used to set the month in the year value of the current date. Months are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Usual notation is taken for month value:

- 01 => January
- 02 => February
- ...
- 12 => December

Figure 19-10. Month Register (MONTHS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

3-0	MONTH0	0-9h	1st digit of months, Range is 0 to 9

19.3.6 Year Register (YEARS_REG)

The YEARS_REG is used to program the year value of the current date. The year value is represented by only the last 2 digits and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The year 1979 is programmed as 79 with YEAR0 set as 9 and YEAR1 set as 7.

3-0	YEAR0	0-9h	1st digit of years, Range is 0 to 9

19.3.7 Day of the Week Register (WEEKS_REG)

The WEEKS_REG is used to program the day of the week value of the current date. The day of the week is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

NOTE: Sunday is treated as 0, Monday 1, and ending at Saturday with 6.

Figure 19-12. Day of the Week Register (WEEKS_REG)

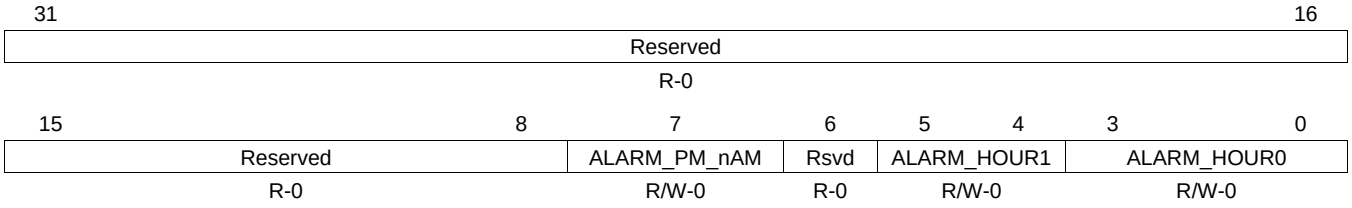
6-4	ALARM_MIN1	0-5h	2nd digit of minutes, Range is 0 to 5
3-0	ALARM_MIN0	0-9h	1st digit of minutes, Range is 0 to 9

19.3.10 Alarm Hours Register (ALARM_HOURS_REG)

The ALARM_HOURS_REG is used to program the hour value for the alarm interrupt. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 19-15. Alarm Hour Register (ALARM_HOURS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

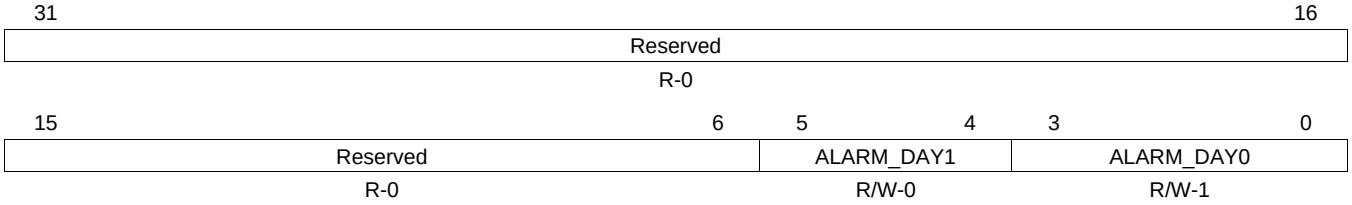
Table 19-14. Alarm Hour Register (ALARM_HOURS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved.
7	ALARM_PM_nAM		Only used in PM_AM mode (otherwise 0)
		0	AM
		1	PM
6	Reserved	0	Reserved.
5-4	ALARM_HOUR1	0-2h	2nd digit of hours, Range is 0 to 2
3-0	ALARM_HOUR0	0-9h	1st digit of hours, Range is 0 to 9

19.3.11 Alarm Day of the Month Register (ALARM_DAYS_REG)

The ALARM_DAYS_REG is used to program the day of the month value for the alarm interrupt. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 19-16. Alarm Day of the Month (ALARM_DAYS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

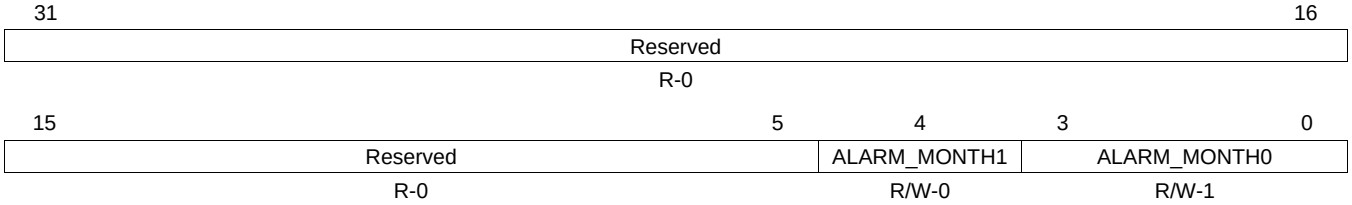
Table 19-15. Alarm Day of the Month Register (ALARM_DAYS_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5-4	ALARM_DAY1	0-3h	2nd digit for days, Range from 0 to 3
3-0	ALARM_DAY0	0-9h	1st digit for days, Range from 0 to 9

19.3.12 Alarm Months Register (ALARM_MONTHS_REG)

The ALARM_MONTHS_REG is used to program the month in the year value for the alarm interrupt. The month is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 19-17. Alarm Month Register (ALARM_MONTHS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

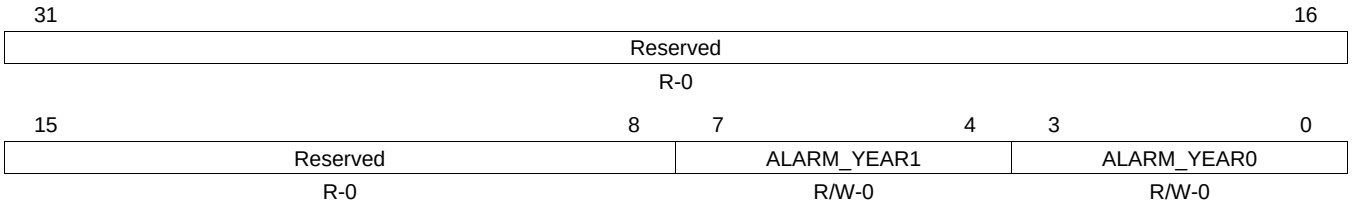
Table 19-16. Alarm Month Register (ALARM_MONTHS_REG) Field Descriptions

Bit	Field	Value	Description
31-5	Reserved	0	Reserved
4	ALARM_MONTH1	0-1h	2nd digit of months, Range from 0 to 1
3-0	ALARM_MONTH0	0-9h	1st digit of months, Range from 0 to 9

19.3.13 Alarm Years Register (ALARM_YEARS_REG)

The ALARM_YEARS_REG is used to program the year for the alarm interrupt. Only the last two digits are used to represent the year and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent.

Figure 19-18. Alarm Year Register (ALARM_YEARS_REG)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-17. Alarm Year Register (ALARM_YEARS_REG) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-4	ALARM_YEAR1	0-9h	2nd digit of years, Range from 0 to 9
3-0	ALARM_YEAR0	0-9h	1st digit of years, Range from 0 to 9

19.3.14 Control Register (RTC_CTRL_REG)

The RTC_CTRL_REG contains the controls to enable/disable the RTC, set the 12/24 hour time mode, to enable the 30 second rounding feature, and to STOP/START the RTC.

Figure 19-19. Control Register (RTC_CTRL_REG)

31							8
Reserved							
R-0							
7	6	5	4	3	2	1	0
Rsvd	RTC_DISABLE	SET_32_COUNTER	TEST_MODE	MODE_12_24	AUTO_COMP	ROUND_30S	STOP_RTC
R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 19-18. Control Register (RTC_CTRL_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved.
6	RTC_DISABLE		Disable RTC module and gate 32-kHz reference clock.
		0	RTC enable
		1	RTC disable (no 32 kHz clock)
5	SET_32_COUNTER		Set the 32-kHz counter with the value stored in the compensation registers when the SET_32_COUNTER bit is set.
		0	No action.
		1	Set the 32Khz counter with compensation registers value
4	TEST_MODE		Test mode.
		0	Functional mode
		1	Test mode (Auto compensation is enabled when the 32-kHz counter reaches its end)
3	MODE_12_24		Enable 12-hour mode for HOURS and ALARMHOURS registers.
		0	24-hr mode
		1	12-hour mode
2	AUTO_COMP		Enable oscillator compensation mode.
		0	No auto compensation
		1	Auto compensation enabled
1	ROUND_30S		Enable one-time rounding to nearest minute on next time register read.
		0	No update
		1	Time is rounded to the nearest minute
0	STOP_RTC		Stop the RTC 32-kHz counter.
		0	RTC is frozen
		1	RTC is running

NOTE:

- The SET_32_COUNTER bit must only be used when the RTC is frozen.
- The RTC_DISABLE bit must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. This bit should only be used if the RTC function is unwanted in the application, in order to save power.
- MODE_12_24: It is possible to switch between the two modes at any time without disturbing the RTC; read or write is always performed with the current mode.
- Auto compensation is enabled by the AUTO_COMP bit. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables it to compensate with one 32-kHz period accuracy each hour.
- The ROUND_30S bit is a toggle bit; the ARM can only write 1 and the RTC clears it. If the ARM sets the ROUND_30S bit and then reads it, the ARM reads 1 until the round-to-the-closest-minute is performed at the next second.
- The ARM can stop the RTC by clearing the STOP_RTC bit (owing to internal resynchronization, the RUN bit of the status register (RTC_STATUS_REG) must be checked to ensure that the RTC is frozen), then update TC values, and re-start the RTC by resetting the STOP_RTC bit.

19.3.15 Status Register (RTC_STATUS_REG)

The RTC_STATUS_REG contains bits that signal the status of interrupts, events to the processor. Status for the alarm interrupt and timer events are notified by the register.

Figure 19-20. Status Register (RTC_STATUS_REG)

31							16
Reserved

R-0		R/W-0	R-0	R-0	R-0	R-0	R-0	R-0

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 19-19. Status Register (RTC_STATUS_REG) Field Descriptions

Bit	Field	Value	Description
31-7	Reserved	0	Reserved
6	ALARM	0-1	Indicates that an alarm interrupt has been generated
5	1D_EVENT	0-1	One day has occurred
4	1H_EVENT	0-1	One hour has occurred
3	1M_EVENT	0-1	One minute has occurred
2	1S_EVENT	0-1	One second has occurred
1	RUN		RTC is frozen or is running.
		0	RTC is frozen
		1	RTC is running
0	BUSY		Status of RTC module.
		0	Updating event in more than 15 µs
		1	Updating event

NOTE:

- The alarm interrupt keeps its low level until the ARM writes 1 in the ALARM bit of the RTC_STATUS_REG register.
- ALARM: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt.
- 1D_EVENT1: This bit will indicate if a day event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1H_EVENT1: This bit will indicate if an hour event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1M_EVENT1: This bit will indicate if a minute event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- 1S_EVENT1: This bit will indicate if a second event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller.
- RUN: This bit will indicate if RTC is frozen or it is running. The RUN bit shows the real state of the RTC. Indeed, because the STOP_RTC signal is resynchronized on 32-kHz clock the action of this bit is delayed.
- BUSY: This bit will give the status of RTC module. The Time and alarm registers can be modified only when this bit is 0.
- The timer interrupt is a negative edge sensitive low-level pulse.

19.3.16 Interrupt Register (RTC_INTERRUPTS_REG)

The RTC_INTERRUPTS_REG is used to enable or disable the RTC from generating interrupts. The timer interrupt and alarm interrupt can be controlled using this register.

Figure 19-21. Interrupt Register (RTC_INTERRUPTS_REG)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 19-20. Interrupt Register (RTC_INTERRUPTS_REG) Field Descriptions

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	IT_ALARM	0	Enable one interrupt when the alarm value is reached (TC ALARM registers) by the TC registers
2	IT_TIMER		Enable periodic interrupt.
		0	Interrupt is disabled.
		1	Interrupt is enabled.
1-0	EVERY	0-3h	Interrupt period.
		0	Every second
		1h	Every minute
		2h	Every hour
		3h	Every day

NOTE:

- The ARM must respect the BUSY period to prevent spurious interrupt. To set a period timer interrupt, the respective period value must be set in the EVERY field. For example, to set a periodic timer interrupt for every hour, the EVERY field has to be set to 2h. Along with this, the IT_TIMER bit also has to be set for the periodic interrupt to be generated.
- The IT_ALARM bit has to be set to generate an alarm interrupt.

19.3.17 Compensation (LSB) Register (RTC_COMP_LSB_REG)

The RTC_COMP_LSB_REG is used to program the LSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The RTC_COMP_LSB_REG works together with the compensation (MSB) register (RTC_COMP_MSB_REG). The AUTO_COMP bit in the control register (RTC_CTRL_REG) must be enabled for compensation to take place.

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RTC_COMP_LSB	0-FFh	Indicates number of 32-kHz periods to be added into the 32-kHz counter every hour

NOTE: This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

19.3.18 Compensation (MSB) Register (RTC_COMP_MSB_REG)

The RTC_COMP_MSB_REG is used to program the MSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The RTC_COMP_MSB_REG works together with the compensation (LSB) register (RTC_COMP_LSB_REG) to set the hourly oscillator compensation value. The AUTO_COMP bit in the control register (RTC_CTRL_REG) must be enabled for compensation to take place.

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-0	RTC_COMP_MSB	0-FFh	Indicates number of 32-kHz periods to be added into the 32-kHz counter every hour

NOTE: This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

19.3.19 Oscillator Register (RTC_OSC_REG)

The RTC_OSC_REG is used to program the oscillator resistance value and the SWRESET bit can be used to reset the RTC. This is the only way to reset the RTC.

Figure 19-24. Oscillator Register (RTC_OSC_REG)

Table 19-23. Oscillator Register (RTC_OSC_REG) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	SWRESET	0-1	Software reset bit
4	OSC32KPWRDNR	0-1	Control of 32 kHz Oscillator powerdown
3-0	SWRESPROG	0-Fh	Value of the oscillator resistance

NOTE: The SWRESET bit is set to 1 to reset the RTC module. This bit is self-clearing, and is always read as 0. CPU must care of interrupt handling before RTC is reset. After setting the SWRESET bit, you must not access any of the RTC registers for three 32-kHz clock cycles.

19.3.20 Scratch Registers (RTC_SCRATCHx_REG)

The RTC_SCRATCH_REG is used to hold some required values for the RTC register.

Figure 19-25. Scratch Registers (RTC_SCRATCHx_REG)

Bit	Field	Value	Description
31-0	RTCSCRATCHx	0-FFFF FFFFh	Scratch registers, available to program

19.3.21 Kick Registers (KICK0R, KICK1R)

The kick registers (KICKnR) are used to enable and disable write protection on the RTC registers. Out of reset, the RTC registers are write-protected. To disable write protection, correct keys must be written to the KICKnR registers.

Kick0 Register (KICK0R)

The Kick0 register allows writing to unlock the kick0 data. To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R. RTC register write protection is enabled when any value is written to KICK0R.

Serial ATA (SATA) Controller

This chapter describes the Serial ATA Controller (SATA) in the device.

Topic **Page**

20.1 Introduction

The serial ATA is the successor of the Parallel ATA/ATAPI controller that has served as the choice of the communication medium between a portable computer (PC) and a hard-disk drive for several decades. During these times, the PATA interface has gone through changes to sustain the demands of the newly emerging applications needs and eventually reached its technical limitation creating a throughput bound. The PATA controller reached a point where it required major changes to satisfy the upcoming applications requirements and this led to its successor, the birth of the SATA controller. The SATA controller was designed to use the same logical command structures that PATA uses but with a whole new physical characteristic. The SATA controller makes use of 2 pairs of high-speed differential conductors as opposed to the parallel 16 bit low-speed interface. The device has a built in SATA controller with a dual HBA port operating in AHCI mode and is used to interface to data storage devices at both 1.5 Gbits/second and 3.0 Gbits/second line speeds per HBA port. AHCI describes a system memory structure which contains a generic area for control and status, and a table of entries describing a command list where each command list entry contains information necessary to program an SATA device, and a pointer to a descriptor table for transferring data between system memory and the device.

20.1.1 Purpose of the Peripheral

The SATA controller addresses the drawback of the PATA interface architecture, throughput, and protocol perspectives. PATA required 40/80 wire parallel cable with a length requirement not exceeding 18 inches. With the latest/final PATA hardware design, PATA's maximum transfer rate saturated to a 133 Mbytes/second of transfer. In addition to newly added features, like hot swapping and native command queuing, the SATA controller abandoned the parallel physical interface and transitioned to a high-speed serial format using two differential pairs supporting up to 3 Mbits/second transfer rate, translating to a 300 Mbytes/second raw throughput per HBA port.

With the intent on handling roles of the PATA controller and addressing the future needs, SATA controller is architected with the option of operating in a Legacy mode; a mode that behaves similar to the PATA controller from the protocol/driver perspective, and a new AHCI mode that is different from the Legacy mode allowing it to overcome the drawbacks of PATA protocol as well; extending PATAs capabilities. The SATA controller that is supported by the device supports AHCI mode of operation only. That is, the AHCI controller supported has no support for Legacy mode of operation. AHCI is a PCI class device that acts as a data movement engine between system memory and Serial ATA devices. However, the AHCI controller is integrated within the core chipset which usually is a common attribute for embedded devices.

Communication between a device and software moves from the PATA task file registers access made via byte-wide accesses to a structure based, command Frame Information Structure (FIS), located in system memory that is fetched by the HBA. This reduces command setup time significantly, allowing for many more devices to be added to a single host controller port (up to 15 of them via the use of a hardware Port Multiplier). Software no longer communicates directly to a device via the task file. In other words, all data transfers between the device and system memory occur through the HBA acting as a bus master to system memory. Whether the transaction is of a DMA type or a PIO type (the use of the PIO command type is strongly discouraged and all transfers should be performed using DMA unless a transaction is only performed via PIO command, which in this case is still done via the AHCI master port not the CPU), the HBA fetches and stores data to memory, offloading the CPU. No data port exists for moving data in and out of the system memory similar to the PATA offerings. Software written for AHCI is not allowed to utilize any of the legacy mechanisms to program devices.

The SATA controller uses a less massive thinner flexible cable that can be up to 3 feet (1 meter) in length allowing for easier routing and better air ventilation inside a case. Its power budget is significantly reduced to 250 mV compared to the required 5V and/or 3.3V power of PATA.

Like its predecessor the SATA controller is most commonly used by PCs, portable devices, and embedded devices to interface a host processor with external data storage or CD/audio devices. It also has the support for hot swapping capability and the ability of interfacing to a Port Multiplier (PM) to increase the number of devices that can be attached to a single HBA port by as many as fifteen devices. In other words, with the use of two PMs, a total of 30 devices can be connected to the two available HBA ports. Note that in the case where a PM is used, the bandwidth offered by a single HBA port will be shared amongst the total number of devices attached to the Port Multiplier. The device has two HBA ports rendering aggregated 6Gbits/second throughput of raw data capability.

20.1.2 Features Supported

The main features of the SATA controller are:

- Support for Synopsys DWH Serial ATA 1.5Gbps and 3Gbps speeds core
- Supports AHCI Controller (specification version 1.1)
- Support two HBA Ports
- Integrated TI SERDES PHY
- Built in/integrated Rx and Tx data buffers
- Supports all SATA power management features
- Internal DMA engine per port
- Hardware-assisted native command queuing (NCQ) for up to 32 entries
- 32-bit addressing
- Supports port multiplier with command-based switching
- Activity LED support (one for each Port)

20.1.3 Features Not Supported

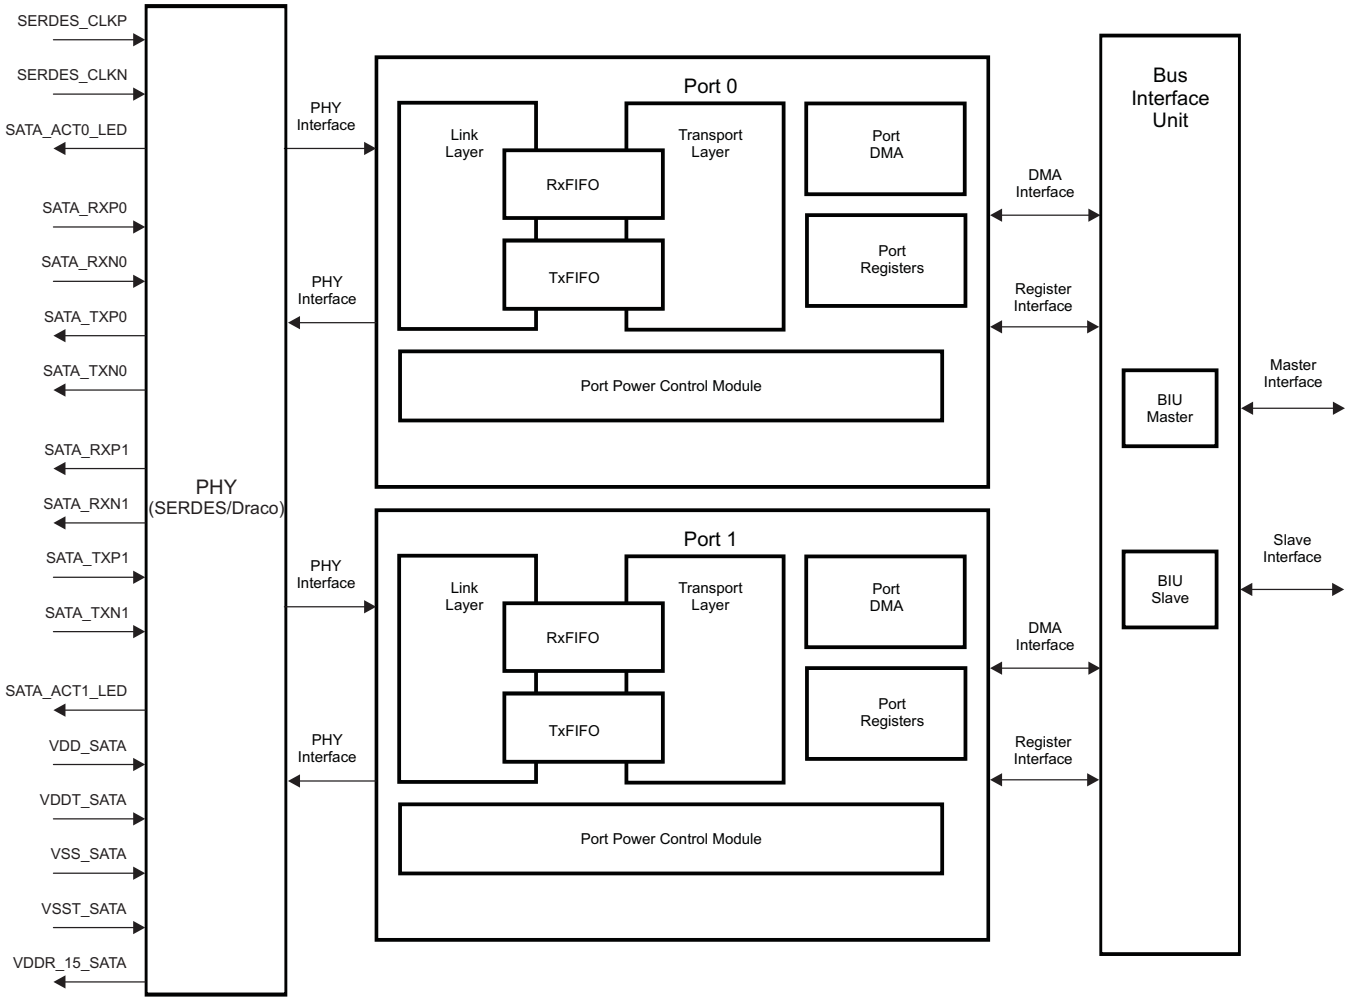
Features not supported in this SATA controller are:

- Legacy mode of operation
- Master/slave type of configuration
- Far-end analog loopback
- Message signaled interrupts
- 64-bit addressing
- Dedicated Mechanical Presence Switch Pin (GPIO usage is expected to supplement this task if necessary)
- Dedicated Cold Presence Detect Pin (GPIO usage is expected to supplement this task if necessary)

20.1.4 Functional Block Diagram

The SATASS is a fully contained Serial ATA host with built in DMA. It uses the AHCI standard for communication with a SATA device. It has no support for the Legacy mode of operation. Figure 20-1 shows a high level block diagram of the SATA Subsystem (core and the integrated TI PHY (SERDES)).

Figure 20-1. SATA Core Block Diagram



20.1.5 Industry Standard(s) Compliance

The SATA Subsystem complies with the following industry standards:

- SATA revision 2.6 Gold standard.
- AHCI revision 1.1 specification.

20.1.6 Non-Industry Standard(s) Compliance

The SATA Subsytem complies with the following proprietary standards:

- Synopsys Design Ware Core DWC AHCI Controller Version 1.30.
- TI SERDES PHY: wiz7c2xxn5x1px (Draco) Macro specification Revision 01.02.01.

20.1.7 Terminology Used in this Document

The following is a brief explanation of some terms used in this document:

AHCI — Advanced Host Controller Interface (necessary for implementing newly supported features like native command queuing). The device supports only this mode of operation and has no support for Legacy mode. It also reduces CPU/Software overhead when moving data in and out of the system memory. Note that system software is responsible to ensure that queued and non-queued commands are not mixed in the command list.

ATA/ATAPI— Advanced Technology (AT) attachment/ATA packet interface

CF— Compact Flash

Device— External SATA or ATAPI device attached to the SATA controller

DMA— DMA within the ATA controller, not the processor EDMA system

DWORD— DWORD is 32 bits of data.

Command List— Command List is a memory buffer for as much as 32 commands. Each command is entered in a command slot. This is a required feature when supporting command queuing.

Command Slot— A command slot is a subset of the command list. It is the memory buffer for a single command. A total of 32 command slots exist.

D2H— D2H is an acronym for “device to HBA” and is mostly used to indicate the direction of the transmission of FIS which is from device to the HBA (host).

FIS— FIS is an acronym for “Frame Information Structure”. A frame is made of a data payload with computed CRC and a start and end primitives.

H2D— H2D is an acronym for “HBA to device” and is mostly used to indicate the direction of the transmission of FIS which is from HBA (host) to device.

HBA — HBA is an acronym for “host bus adapter”. It is the SATA controller that implements the AHCI specification to communicate between system memory and Serial ATA devices.

Legacy Mode— This mode of operation makes the user access (application software or driver) to view the SATA controller in a similar fashion as a PATA controller. The device does not support Legacy mode of operation but AHCI mode of operation.

OOB — Out of Band. OOB signaling is used for during device detection and when recovering from power states.

PM — PM is an acronym for ‘Port Multiplier”. A Port Multiplier allows extending an HBA port connection capability to connect to multiple SATA Devices, a maximum of 15 Devices. Note that the operating bandwidth is shared amongst all the Devices when using this type of configuration.

PMP — Port Multiplier Port : A Port of a Port Multiplier (PM).

PORT— Refers to HBA Port mainly, within this document. However, the PORT is also be used to refer to a port of a PORT Multiplier.

PRD — PRD is an acronym for “physical region descriptor”. A PRD table is a data structure used by DMA engines that comply with the ATA/ATAPI Host Adapters standard. The PRD describes memory regions to be used as the source or destination of data during DMA transfers. A PRD table is often referred to as a scatter/gather list.

SATA Controller— Serial ATA controller, also HBA.

System Memory— The memory that is external from the SATA controller but is a memory that is accessible by the built in SATA controller DMA or the CPU.

20.2 Architecture

This section discusses the architecture of the Serial ATA Controller. The Serial ATA Controller supports Advanced Host Controller Interface (AHCI). The dual port SATA controller does not support the Legacy mode of operation. Since the controller complies with the AHCI standard (version 1.1) the details of its operation is captured within the AHCI version 1.1 specification. Please consult the specification for the general behavior of the SATA Core operation. The SATA controller supported within the device has two HBA ports.

20.2.1 Clock Control

The SATA controller makes use of one internal 250 MHz clock (SYSCLK5) for both functional and keep alive functions. During a Low Power down event, the keep alive clock is necessary to insure portion of the controller interface to remain up and running at all times keeping controller context in tact as well as clocking the h/w logic necessary used in detecting wake up events from power down modes. Access to the SATA controller and resources are implemented through, SYSCLK5 derived from the output of the main input 27MHz clock source. SYCLK5 to the SATA controller is gated by the PRCM (Power, Reset, and Clock Management) at the controller boundary and is required to be enabled prior to accessing the SATA controller. However, the keep alive clock is always ON, it can not be gated at the controller boundary, and can not be turned off so long as the device is in normal operation state.

A high quality low jitter external differential clock is required as a source clock input to the PHY and the frequency of the input clock should be between 60MHz and 375 MHz (depending upon the supported multiplier used). It is recommended to keep the input clock differential frequency selection to a frequency value that is desirable to both SATA and PCI Express peripherals and is highly recommended for the use of a 100 MHz input differential clock source since this input clock source frequency is expected by most, if not all, of the PCIe systems.

This input frequency requirement is dependent upon the supported PHY PLL multiplier value. A single PLL within the SERDES device exists that is shared amongst the two HBA Ports. The control for this PLL and PHY operation is done via P0PHYCR register. That is, the programming done for the clock setting using Port 0 PHY Control Register applies to both ports and the respective field within P1PHYCR is reserved. See P#PHYCR (# = 0 or 1) register field descriptions for more detail. The MPY field of the P0PHYCR register is programmed with the PLL multiplier value based on the input frequency clock. Note that the PHY PLL output frequency should be exactly 1.5GHz (for both 3 and 1.5 Gbits/second line rate) and its accuracy is very important to the operation of the SATA controller.

Table 20-1 shows the MPY bit field of P#PHYCR for supported PHY PLL multiplier values.

Table 20-1. MPY Bit Field of P0PHYCR

MPY Bit Field Value	Effect
0	4x
1h	5x
2h	6x
3h	8x
4h	8.25x
5h	10x
6h	12x
7h	12.5x
8h	15x
9h	16x
Ah	16.5x
Bh	20x
Ch	22x
Dh	25x
Eh	Reserved
Fh	Reserved

20.2.2 Signal Description

The device has bonded out the Data lines (two sets of differential data lines) and device activity per port indicators. Signals needed to detect device detection and attached device power indicators need to be implemented via GPIO if desired and no dedicated signals for these tasks exist. The power pins and logic necessary to power up a cold SATA device should be handled external to the device.

Table 20-2 summarizes the available SATA module signals.

Table 20-2. SATA Interface Signal Descriptions

Terminal Name	Direction from the HBA Perspective (In/Out)	Description
SATA_RXP0	Input	Receive Data Positive Differential Signal for Port 0
SATA_RXN0	Input	Receive Data Negative Differential Signal for Port 0
SATA_TXP0	Input	Transmit Data Positive Differential Signal for Port 0
SATA_TXN0	Input	Transmit Data Positive Differential Signal for Port 0
SATA_RXP1	Input	Receive Data Positive Differential Signal for Port 1
SATA_RXN1	Input	Receive Data Positive Differential Signal for Port 0
SATA_TXP1	Input	Transmit Data Positive Differential Signal for Port 1
SATA_TXN1	Input	Transmit Data Negative Differential Signal for Port 1
SERDES_CLKP	Input	PHY Reference Positive Differential Signal
SERDES_CLKN	Input	PHY Reference Negative Differential Signal
SATA_ACT0_LED	Output[1]	Device Activity Indicator for HBA Port 0
SATA_ACT1_LED	Output[2]	Device Activity Indicator for HBA Port 1
VDD_SATA		
VSS_SATA		
VDDT_SATA		
VSST_SATA		

(1) Multiplexed with GPIO 30.
(2) Multiplexed with GPIO 31.

20.2.3 DMA

Each HBA ports contain two DMA engines. One of the DMA engine is used to fetch command from the command list. The other DMA is used to move FISes in and out of system memory

The DMA used to move FISs in and out of system memory has a register, P#DMACR (one for each HBA port where # = 0 or 1), to control the burst transfer. This DMA is used to transfer all information between system memory and the attached SATA device, as well as configuration and status FISs.

The user can program the maximum burst size that will be issued on the system bus independently for both reads and writes. The DMA will issue transactions equaling the programmed size or smaller (in DWORD increments). This can be used to optimize burst size for over-all system throughput efficiency. Refer to Section 20.4.33 for details on legal values. Note that programming a burst size of greater than a transaction size (below), while is not invalid, is meaningless because the DMA maximizes out at the maximum transaction size.

The user can also program the transaction size for both receive and transmit (see Section 20.4.33). The transaction size is the minimum amount of data that the DMA will work on. For example, if there is an FIS coming from the device to the host, the DMA will not begin transferring data into system memory until there is at least RX_TRANSACTION_SIZE (RXTS) data in the receive FIFO. During transmit, the DMA will read data from system memory in TX_TRANSACTION_SIZE (TXTS) increments to put into the transmit FIFO. Note that transactions may be broken up into multiple bursts based on burst size, crossing of a 1k boundary, or end-of-frame.

20.2.4 Transport Layer

The transport layer handles all of the transport layer functions of the SATA protocol. During reception, it receives a FIS from the Link layer via the Rx FIFO, decodes the type, and routes it to the proper location via the port DMA. During transmission, it transfers a FIS constructed by the port DMA to the link layer via the Tx FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system.

20.2.5 FIFOs

The transport layer also contains the Tx and Rx FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystems ability to buffer data before flow control must be asserted. It also affects the maximum programmable transaction and burst sizes that can be programmed into the port DMA. The Tx FIFO size is 64 DWORDS (256 bytes) deep while the Rx FIFO size is 128 DWORDS (512 bytes) deep.

20.2.6 Link Layer

The link layer maintains the link and supports all SATA link layer functionality including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/de-framing
- CRC calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

20.2.7 PHY

The SATASS includes an integrated TI SERDES macro as a PHY. The PHY handles all of the serialization/de-serialization, symbol alignment, and Rx OOB signal detection.

20.2.8 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package; therefore, some of the SATA controller peripheral signals share SERDES clock input pins (SERDES_CLKP/N) with the PCI Express peripheral and GPIO Module (GPIO30/31). Since the same SERDES is used by SATA and PCI Express peripherals, it is recommended the use of a 100 MHz differential input clock source that is ideal for both peripherals. Refer to the device-specific data manual to determine how pin multiplexing affects the SATA.

20.2.9 Power Management

The SATA controller can be placed in reduced power modes to conserve power during periods of no activity or no use. The main power management of the peripheral is controlled by the Power, Reset, and Clock Management (PRCM) unit. The PRCM acts as a master controller for power management of all of the peripherals on the processor. For detailed information on power management procedures using the PRCM, see the *Power, Reset, and Clock Management (PRCM) Module* chapter.

During times that the SATA peripheral is in use, the SATASS supports the industry standard power down modes (both Partial and Slumber low power modes) as provided within the SATA specification. These modes allow for power savings by powering down part of the SERDES PHY and by providing the ability to gate off the clocks to the link layer. The Port Power Control Module is used to enter and exit this power down modes (that is power down mode is controlled at Port level) which may have the normal functional clocks gated off.

NOTE: When SATA communication is in the idle state, that is, when no disk activity takes place, the communication remains active with both the host and the device sending a logical sync primitive and scrambled data at the speed negotiated continuously. For power sensitive applications, the power consumed during the disk inactivity stage might be undesirable and it might be a desired task to place the communication interface into an electrical idle (Partial or Slumber) state until data transfer activity is needed in order to conserve power.

20.2.10 Reset

The SATA controller reset is handled via PRCM. Please consult the PRCM document for details on how to use the PRCM module. Other types of resets (HBA Reset, Port Reset, and Software Reset) supported by the SATA controller are part of the AHCI specification. See the AHCI Standard Specification 1.1 for details on HBA Reset, Port Rest, and Software Reset.

20.2.11 Interfacing to Single and Multiple Devices

The SATA controller supports dual HBA ports. This means that each HBA port can be used to interface directly to a single SATA device or to multiple SATA Devices via a Port Multiplier. Note that on a multiple target setup, the available bandwidth will be shared amongst all the attached devices.

Note that Port Multipliers and Power Supplies for external SATA devices, when needed, should be furnished external to the device. No dedicated signals for controlling power and device detection are not bonded out and usage of GPIO pins can be used to supplement this task. However, the controller supports the capability to spin-up-attached devices independently.

20.2.11.1 Interfacing to a Single Device

If need to interface directly to a Single Device, there is no need of populating a Port Multiplier. The software needs to ensure that the PMP field within the Command Header and the PM_PORT field of the FIS be cleared at all times.

If the external SATA device is not Self Powered, it is the responsibility of the System Designer to populate and furnish the right power supply needed. Consult the SATA Specification for details.

20.2.11.2 Interfacing to Multiple Devices

Interfacing to multiple devices is pretty much identical to interfacing with a single device except the addition of a hardware Port Multiplier and initialization on software side. User software is required to perform the additional task of detecting and configuring the PM prior to accessing the attached devices. The user software is required to populate the Port Multiplier Port (PMP) field of the FIS in order to select one of the fifteen devices that could be connected and accessed by the HBA. The details on this are fully captured within the AHCI specification Version 1.1.

20.2.12 Initialization

Proper initialization of the HBA is required after power up to ensure proper operation of the SATA controller peripheral. The initialization process starts by performing a write to one-time write only registers (this initialization step is documented as Firmware initialization within the AHCI specification) where the values programmed depend on the features that the applications support. Note that the features that are enabled by the Firmware initialization are subsets of the features supported by the SATA subsystem. This Firmware initialization is similar to what a PC BIOS does and allows the user to enable/disable some features by using software.

The software can then continue with the normal initialization that is required by the software. The details and sequence of initialization is documented within the AHCI specification. In general, everything that is achieved by the Software Initialization has to do with configuring and furnishing resources needed by the AHCI controller and these tasks include PHY Initialization, allocating structures and memories for Command Slots, FIS, and Data Memories and concludes by enabling the receive FIS DMA. The software will then Spin-Up the Device and ensure that a proper Device Detection and Speed Negotiation has completed prior to enabling the Command DMA.

Note that DMA Configuration/Initialization should take place after Device Detection and Speed Negotiation. If done earlier, the default value is used (which is the recommended setting) since RESET removes the user programmed values. The only time it is advisable to change the DMA Configuration is when you need to prioritize System Resource access. This still has to be done after "PHY Ready" status is set (in other words, after the device detection and speed negotiation has completed). It also requires that the Command DMA is not running (P0CMD.ST = 0) when modifying the value of the DMA Configuration fields.

20.2.12.1 Initialization (Firmware and Software)

Software reads the HBA capabilities register (CAP), ports implemented register (PI), AHCI version register (VS), global parameter 1 register (GPARAM1R), global parameter 2 register (GPARAM2R), and the port parameter register (PPARAMR) to obtain information about the subsystem's capabilities. The software should then take the following steps to configure each port for operation:

1. Do all firmware capability writes.
2. Setup all appropriate structures in memory as per the AHCI specification.
3. Configure the PHY using the port PHY control register (P#PHYCR):
   (a) Set the MPY bit field for the PLL multiply factor (multiply value selected should target a 1.5-GHz frequency that is good enough for both GEN1 and GEN2 speeds).
   (b) Set LOS = 1 (enable loss of signal detection)
   (c) Set ENPLL = 1 (enable the PLL)
4. Set the port command list base address register (P#CLB).
5. Set the port FIS base address register (P#FB).
6. Set appropriate bits in the port command register (P#CMD).
7. Program the port serial ATA control register (P#SCTL).
8. Wait for Device Detection and Speed Negotiation to end.
9. Program the port DMA control register (P#DMACR).
10. Enable the appropriate interrupts.
11. Enable FIS reception in P#CMD.
12. Spin-up the device(s), if necessary.

20.2.12.2 Issuing a Command

Once the host and device are configured, perform the following steps to issue a command:

1. Create the appropriate FIS in system memory.
2. Create the PRD.
3. Queue the command to the command queue list (location specified by the port command list base address register (P#CLB).

For detailed information, see the AHCI Specification Version 1.1.

20.2.13 Interrupt Support

The AHCI controller supports both standard interrupt sourcing, where interrupts are generated when enabled events occur, or a different type of method of generating interrupts that minimize interrupt loading by either generating interrupts in a batch or periodically. The latter method is handled using Command Completion Coalescing method and the details is captured within the AHCI Specification Version 1.1.

20.2.13.1 Command Completion Coalescing

Command Completion Coalescing (CCC) is a feature designed to reduce the interrupt and command completion overhead in a heavily loaded system. The feature enables the number of interrupts taken per completion to be reduced significantly, while ensuring a minimum quality of service for command completions. When software specified number of commands have completed or a software specified timeout has expired, an interrupt is generated by hardware to allow software to process completed commands. The command completion coalescing ports register (CCC_PORTS) should be programmed by setting the corresponding bit of the Port that is to be included in command completion coalescing feature. Note that the device supports 2 HBA ports.

For a detailed explanation of the CCC initialization and usage, see the AHCI Specification 1.1 Section 11.6.

20.2.13.1.1 CCC Interrupt Based on Timer Expiration

When CCC is enabled and the desired method to receive an interrupt is based on a timer elapse condition, then the user needs to communicate a resolution for a 1ms time by programming the TIMER1MS register with the OCP cycle count derived from the OCP clock frequency sourced to the SATA controller.

As an example, if a user desires for interrupt to be generated every 15 ms, for OCP bus Clock frequency of 250 MHz, the 1-ms cycle count should be programmed with a value of 250 000, that is, 250 MHz/1000 = 250 000, and CCC_CTL.TV is programmed with a non-zero value (15 in this case). When CCC_CTL.EN is set to 1 (CCC is enabled), the CCC will periodically generate interrupt every 15 ms or every 15 × 250 000 = 3,750,000 OCP cycles.

NOTE: Make sure the EN bit in the command completion coalescing control register (CCC_CTL) is cleared to 0 (CCC is disabled, prior to programming this field).

20.2.13.1.2 CCC Interrupt Based on Completion Count

When CCC is enabled and the desired method to receive an interrupt is based on a completion count, that is, the CC bit in the command completion coalescing control register (CCC_CTL) is programmed with a non-zero value and the CCC interrupt is enabled (EN bit in CCC_CTL is set to 1), an interrupt is sourced from the SATA controller when the programmed desired number of interrupt is received.

NOTE: Make sure the EN bit in the command completion coalescing control register (CCC_CTL) is cleared to 0 (CCC is disabled, prior to programming this field).

20.2.13.2 Non CCC Interrupt Configuration

For a standard interrupt handling method where every event that is enabled generates an interrupt, is handled as follows. For more information, see the AHCI Specification.

After insuring that CCC is disabled, the EN bit in the command completion coalescing control register (CCC_CTL) is 0, in order for the SATA Core to source interrupts, the interrupt should be enabled at both global level (the IE bit in the global HBA control register (GHC) is set to 1) and port level by enabling the bit fields for the desired interrupt. An enable bit at a Port level controls corresponding interrupt dispatch to the processor interrupt handling resource. So long as the CPU interrupt handler is configured properly, the CPU receives the interrupt when the enabled event occurs.

20.2.14 EDMA Event Support

The SATA controller makes use of its own built-in DMA and has no need for the use of the processor EDMA.

20.3 Use Cases

The following sections include some sample program snippets that can be used as a guide for software development. The example demonstrates one of the ways of creating the necessary structures; properly aligned system memory resources, initialization, as well as performing basic DMA Read/Write transfer using a couple of the Command Slots.

Section 20.3.1 contains examples in relations to System Memory resource allocations, Structures, and Subroutines used by the Initialization and Read/Write Transfer functions. The remaining sections include examples of basic Initialization, DMA Write transfer, and DMA Read transfer examples using Port 0.

```

20.4 SATA Registers

Due to the support of a standard controller, that is compliant with the AHCI 1.1 specifications, the memory-map of the controller and the register descriptions matches the memory-map documented within the standard. For features that are not part of the standard or are implementer specific, (for example, DMA burst control or built-in self test) the reserved locations are used to document the necessary registers required by the non-standard features.

The sub-system core contains register space for global host programming and space for port programming (the device supports two Host Ports and confirms to the AHCI specification calls for the support of multiple Host ports and the register space partitioning comes from this perspective). All registers that start below offset address 100h are global and meant to apply to the HBA, the registers settings entered at the global region applies to both HBA ports. The port control registers reside at offset 100h and above. Dedicated registers that pertains to the specific port reside within this space. There are as many register banks as there are ports (for the device two banks of registers are available for use).

The subsystem core contains register space for global host programming and space for port programming (the AHCI specification calls for the support of multiple Host ports and the register space partitioning comes from this perspective). All registers that start below offset address 100h are global and meant to apply to the entire HBA, the registers settings entered at the global region applies to both HBA ports. The Port 0 control registers reside at offset 100h and above while the Port 1 registers reside at offset 180h and above. Dedicated registers that pertains to the specific port reside within this space. There are as many register banks as there are ports (for this device, two banks of registers are available).

Table 20-3 lists the registers of the SATA. For the base address of these registers, see Table 1-13.

Table 20-3. SATA Controller Registers

Address Offset	Acronym	Register Description	Section
0h	CAP[1]	HBA Capabilities Register	Section 20.4.1
4h	GHC	Global HBA Control Register	Section 20.4.2
8h	IS	Interrupt Status Register	Section 20.4.3
Ch	PI	Ports Implemented Register	Section 20.4.4
10h	VS	AHCI Version Register	Section 20.4.5
14h	CCC_CTL	Command Completion Coalescing Control Register	Section 20.4.6
18h	CCC_PORTS	Command Completion Coalescing Ports Register	Section 20.4.7
A0h	BISTAFR	BIST Active FIS Register	Section 20.4.8
A4h	BISTCR	BIST Control Register	Section 20.4.9
A8h	BISTFCTR	BIST FIS Count Register	Section 20.4.10
ACh	BISTSR	BIST Status Register	Section 20.4.11
B0h	BISTDECR	BIST DWORD Error Count Register	Section 20.4.12
E0h	TIMER1MS[1]	BIST DWORD Error Count Register	Section 20.4.13
E8h	GPARAM1R	Global Parameter 1 Register	Section 20.4.14
ECh	GPARAM2R	Global Parameter 2 Register	Section 20.4.15
F0h	PPARAMR	Port Parameter Register	Section 20.4.16
F4h	TESTR	Test Register	Section 20.4.17
F8h	VERSIONR	Version Register	Section 20.4.18
FCh	IDR	ID Register	Section 20.4.19
100h	P0CLB	Port 0 Command List Base Address Register	Section 20.4.20
108h	P0FB	Port 0 FIS Base Address Register	Section 20.4.21

(1) This register requires a one-time initialization after power-up. The register is written once after a hard reset by firmware, and then remains as read-only thereafter. The register is not affected by software reset.

Table 20-3. SATA Controller Registers (continued)

Address Offset	Acronym	Register Description	Section
110h	P0IS	Port 0 Interrupt Status Register	Section 20.4.22
114h	P0IE	Port 0 Interrupt Enable Register	Section 20.4.23

20.4.1 HBA Capabilities Register (CAP)

The HBA capabilities register (CAP) indicates basic capabilities of the DWC SATA AHCI to the driver software.

The CAP register is shown in Figure 20-2 and described in Table 20-4.

Figure 20-2. HBA Capabilities Register (CAP)

31	30	29	28	27	26	25	24	23	20	19	18	17	16
S64A	SNCQ	SSNTF	SMPS	SSS	SALP	SAL	SCLO	ISS		SNZO	SAM	SPM	Rsvd
R-0	R-1	R-1	W/RO-0	W/RO-0	R-1	R-1	R-1	R-2h		R-0	R-1	R-1	R-0

15	14	13	12	8	7	6	5	4	0
PMD	SSC	PSC	NCS		CCCS	EMS	SXS	NP	
R-1	R-1	R-1	R-1Fh		R-1	R-0	R-0	R-1	

LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only; *-n* = value after reset

Table 20-4. HBA Capabilities Register (CAP) Field Descriptions

Bit	Field	Value	Description
31	S64A	0	Indicates Support for 64-Bit Addressing. The SATASS only supports 32-bit addressing so this bit is always 0.
30	SNCQ	1	Supports Native Command Queuing. SATASS supports SATA native command queuing by handling DMA Setup FIS natively.
29	SSNTF	1	Supports SNotification Register. SATASS supports P0SNTF (SNotification) register and its associated functionality.
28	SMPS	0	Supports Mechanical Presence Switch. This bit is set by firmware when the platform supports a mechanical presence switch for hot plug operation. This should be written with Zero value. Can use GPIO to supplement this task.
27	SSS	0	Supports Staggered Spin-Up. Only writable once after power up. Set this bit during Firmware Initialization prior to attempting to spin up device (P0CMD[SUD]).
26	SALP	1	Supports Aggressive Link Power Management. SATASS supports auto-generating (Port-initiated) Link Layer requests to the PARTIAL or SLUMBER power management states when there are no commands to process.
25	SAL	1	Supports Activity LED.
24	SCLO	1	Supports Command List Override. Supports the P0CMD.CLO bit functionality for Port Multiplier devices enumeration.
23-20	ISS	2h	Interface Speed Support. SATASS Supports 1.5 and 3 Gbps.
19	SNZO	0	Supports Non-Zero DMA Offsets. Not supported.
18	SAM	1	Supports AHCI Mode Only. SATASS supports AHCI mode only and does not support legacy, task-file based register interface.
17	SPM	1	Supports Port Multiplier. SATASS supports command-based switching Port Multiplier on any of its Ports.
16	Reserved	0	Reserved.
15	PMD	1	PIO Multiple DRQ Block. SATASS supports multiple DRQ block data transfers for the PIO command protocol.
14	SSC	1	Slumber State Capable. SATASS supports transitions to the interface SLUMBER power management state.
13	PSC	1	Partial State Capable. SATASS supports transitions to the interface PARTIAL power management state.
12-8	NCS	1Fh	Number of Command Slots. SATASS supports 32 command slots per Port.
7	CCCS	1	Command Completion Coalescing Supported. SATASS supports command completion coalescing.
6	EMS	0	Enclosure Management Supported. Enclosure Management is not supported.
5	SXS	1	Supports External SATA.

Table 20-4. HBA Capabilities Register (CAP) Field Descriptions (continued)

Bit	Field	Value	Description
4-0	NP		Number of Ports. 0's based value indicating the number of Ports supported by the SATSS.
		0	1 Port
		1	2 Ports
		2h - Fh	Reserved

20.4.2 Global HBA Control Register (GHC)

The global HBA control register (GHC) provides various global functions for the SATASS.

The GHC register is shown in Figure 20-3 and described in Table 20-5.

Figure 20-3. Global HBA Control Register (GHC)

31	30	16
AE	Reserved	
R-1	R-0	

15	2	1	0
Reserved		IE	HR
R-0		R/W-0	W-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 20-5. Global HBA Control Register (GHC) Field Descriptions

Bit	Field	Value	Description
31	AE	1	AHCI Enable. This bit is always set since SATASS supports only AHCI mode as indicated by the SAM bit in the HBA capabilities register (CAP) = 1.
30-2	Reserved	0	Reserved.
1	IE		Interrupt Enable. This global bit enables interrupts from the SATASS. This field is reset on Global reset (GHC.HR = 1).
		0	All interrupt sources from all the Ports are disabled (masked).
		1	Interrupts are enabled and any SATASS interrupt event causes interrupt output assertion.
0	HR	0	HBA Reset. When set by the software, this bit causes an internal Global reset of the SATASS. All state machines that relate to data transfers and queuing return to an idle state, and all the Ports are reinitialized by sending COMRESET if staggered spin-up is not supported. If staggered spin-up is supported, then it is the responsibility of the software to spin-up each Port after this reset has completed. The SATASS clears this bit when the reset action is done. A software write of 0 has no effect.

20.4.3 Interrupt Status Register (IS)

The interrupt status register (IS) indicates which port inside of the subsystem has a pending interrupt.

The IS register is shown in Figure 20-4 and described in Table 20-6.

Figure 20-4. Interrupt Status Register (IS)

31	16
Reserved	
R-0	

15	2	1	0
Reserved		IPS[*n*]	
R-0		R/W1C-0	

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 20-6. Interrupt Status Register (IS) Field Descriptions

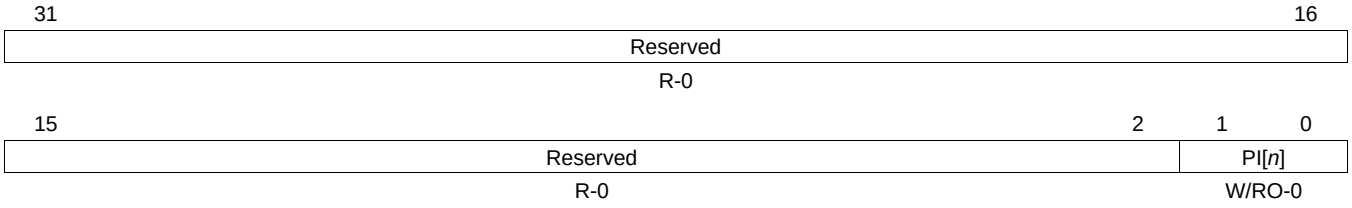
Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	IPS[*n*]	0-1	Interrupt Pending Status (IPS[0] is for Port 0 and IPS[1] is for Port[1]).. If a bit *n* is set to 1 If set, the corresponding Port has an interrupt pending. Software can use this information to determine which Ports require service after an interrupt. The bits of this field are set by the Ports that have interrupt events pending in the port interrupt status register (P#IS) bits and enabled by the port interrupt enable register (P#IE) bits. Set bits are cleared by the software writing 1 to all bits to clear.

20.4.4 Ports Implemented Register (PI)

The ports implemented register (PI) indicates which ports are exposed by the SATASS and are available for software to use. It is loaded by the BIOS. For example, the SATASS supports 2 Ports as indicated in the CAP.NP, only Port 1 could be available, while Port 0 is unavailable. During Firmware Initialization the software needs to indicate that Port 0 is not available by setting only PI[bit1] only. This means the Port Enabled is a subset of Port available. Note that a minimum of one port needs to be enabled.

The PI register is shown in Figure 20-5 and described in Table 20-7.

Figure 20-5. Ports Implemented Register (PI)



LEGEND: R/W = Read/Write; R = Read only; W/RO: written once after hard reset by firmware, then remain as read-only; -*n* = value after reset

Table 20-7. Ports Implemented Register (PI) Field Descriptions

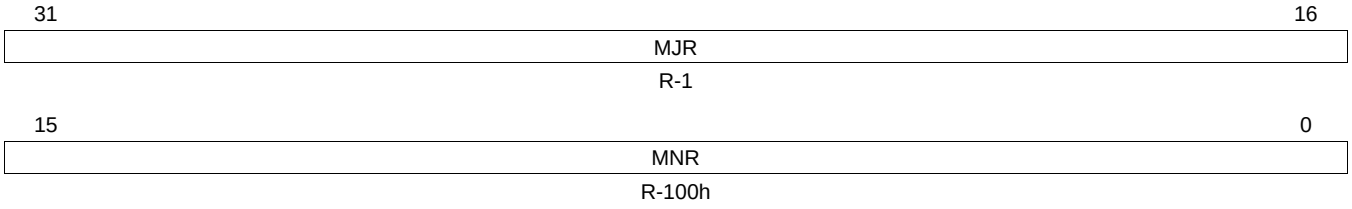
Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	PI[*n*]	0-1	Ports Implemented. This register is bit significant. If a bit *n* is set to 1, the corresponding Port is available for software to use. If a bit *n* is cleared to 0, the Port is not available for software to use. The maximum number of bits that can be set is 2 for a module with two HBA ports. **Note:** The contents of this register are relevant to the command completion coalescing ports register (CCC_PORTS).

20.4.5 AHCI Version Register (VS)

The AHCI version register (VS) indicates the version of the Synopsis AHCI core embedded in the SATASS.

The VS register is shown in Figure 20-6 and described in Table 20-8.

Figure 20-6. AHCI Version Register (VS)



LEGEND: R = Read only; -*n* = value after reset

Table 20-8. AHCI Version Register (VS) Field Descriptions

Bit	Field	Value	Description
31-16	MJR	1	Major Revision Number.
15-0	MNR	100h	Minor Revision Number.

20.4.6 Command Completion Coalescing Control Register (CCC_CTL)

The command completion coalescing control register (CCC_CTL) is used to configure the command completion coalescing (CCC) feature for the SATASS core. It is reset on Global reset.

The CCC_CTL register is shown in Figure 20-7 and described in Table 20-9.

Figure 20-7. Command Completion Coalescing Control Register (CCC_CTL)

31															16
TV															
R/W-1															
15							8	7				3	2	1	0
CC								INT					Reserved		EN
R/W-1								R-1					R-0		R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-9. Command Completion Coalescing Control Register (CCC_CTL) Field Descriptions

Bit	Field	Value	Description
31-16	TV	0-FFFFh	Time-out value. This bit field specifies the CCC time-out value in 1 ms intervals. Software loads this value prior to enabling CCC. This bit field is: • Read/Write (R/W) when EN = 0 • Read only (R) when EN = 1 A time-out value of 0 is reserved and should not be used.
15-8	CC	0-FFh	Command Completions. This bit field specifies the number of command completions that are necessary to cause a CCC interrupt. Software loads this value prior to enabling CCC. This bit field is: • Read/Write (R/W) when EN = 0 • Read only (R) when EN = 1 A value of 0 disables CCC interrupts being generated based on the number of commands completed, that is, CCC interrupts are only generated based on the timer in this case.
7-3	INT	0-1Fh	Interrupt. This bit field specifies the interrupt used by the CCC feature, using the number of ports configured for the core. For a single Port instantiation, INT should be programmed to 1. When a CCC interrupt occurs, the IS.IPS[INT] bit is set to 1.
2-1	Reserved	0	Reserved.
0	EN		CCC feature enable. When EN = 1, software can not change the bit fields: TV and CC.
		0	CCC feature is disabled and no CCC interrupts are generated.
		1	CCC feature is enabled and CCC interrupts may be generated based on the time-out or command completion conditions. **Note:** When EN = 1, software can not change the fields : CCC_CTL.TV and CCC_CTL.CC.

20.4.7 Command Completion Coalescing Ports Register (CCC_PORTS)

The command completion coalescing ports register (CCC_PORTS) specifies the Ports that are coalesced as part of the command completion coalescing (CCC) feature when CCC_CTL.EN = 1. It is reset on Global reset.

The CCC_PORTS register is shown in Figure 20-8 and described in Table 20-10.

Figure 20-8. Command Completion Coalescing Ports Register (CCC_PORTS)

31	2	1	0
Reserved		PRT	
R-0		R/W-0	

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 20-10. Command Completion Coalescing Ports Register (CCC_PORTS) Field Description

Bit	Field	Value	Description
31-2	Reserved	0	Reserved
1-0	PRT		This field is bit significant. Each bit corresponds to a particular Port, where bit 0 corresponds to Port 0 and bit 1 corresponds to Port 1. Bits set to 1 must also have the corresponding bit set to 1 in the ports implemented register (PI).
		0	The corresponding Port is not part of the CCC feature.
		1	The corresponding Port is part of the CCC feature.

20.4.8 BIST Active FIS Register (BISTAFR)

The BIST active FIS register (BISTAFR) is shown in Figure 20-9 and described in Table 20-11.

Figure 20-9. BIST Active FIS Register (BISTAFR)

31	16
Reserved	
R-0	

15	8	7	0
NCP		PD	
R-0		R-0	

LEGEND: R = Read only; -*n* = value after reset

Table 20-11. BIST Active FIS Register (BISTAFR) Field Descriptions

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-8	NCP	0-FFh	Non-Compliant Pattern. Least significant byte of the received BIST Activate FIS second DWORD (bits [7:0]). This value defines the required pattern for the far-end transmit only modes (PD=80h or A0h). If none of these values are decoded, the simultaneous switching pattern is transmitted by default.
		0-49h	Reserved
		4Ah	High frequency test pattern (HFTP)
		4Bh-77h	Reserved
		78h	Mid frequency test pattern (MFTP)
		79h-7Dh	Reserved
		7Eh	Low frequency test pattern (LFTP)
		7Fh	Simultaneous switching outputs pattern (SSOP)
		80h-8Ah	Reserved
		8Bh	Lone Bit pattern (LBP)
		8Ch-AAh	Reserved
		ABh	Low frequency spectral component pattern (LFSCP)
		ACh-B4h	Reserved
		B5h	High transition density pattern (HTDP)
		B6h-F0h	Reserved
		F1h	Low transition density pattern (LTDP)
		F2h-FFh	Reserved
7-0	PD	0-FFh	Pattern Definition. Indicates the pattern definition field of the received BIST Activate FIS (bits [23:16]) of the first DWORD. It is used to put the SATASS in one of the following BIST modes. All reserved values should not be used by the device; otherwise, the FIS is negatively acknowledged with R_ERRp. For far-end transmit only modes, the NCP bit field contains the required data pattern.
		0-7h	Reserved
		8h	Far-end analog (if PHY supports this mode)
		9h-Fh	Reserved
		10h	Far-end retimed
		11h-7Fh	Reserved
		80h	Far-end transmit only
		81h-9Fh	Reserved
		A0h	Far-end transmit only with scrambler bypassed
		A1h-FFh	Reserved

20.4.9 BIST Control Register (BISTCR)

The BIST control register (BISTCR) is shown in Figure 20-10 and described in Table 20-12.

Figure 20-10. BIST Control Register (BISTCR)

31							24
Reserved							
R-0							
23				19	18	17	16
Reserved					TXO	CNTCLR	NEALB
R-0					W-0	W-0	R/W-0
15				11	10		8
Reserved					LLC		
R-0					R/W-7h		
7	6	5	4	3			0
Reserved	ERREN	FLIP	PV	PATTERN			
R-0	R/W-0	R/W-0	R/W-0	R/W-0			

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 20-12. BIST Control Register (BISTCR) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reserved.
18	TXO	0	Transmit Only. This bit is used to initiate transmission of one of the non-compliant patterns defined by the BISTCR.PATTERN value when the device is disconnected.
17	CNTCLR	0	Counter Clear. This bit clears BIST error count registers. Writing a 1 clears BISTFCTR, BISTSR, and BISTDECR registers.
16	NEALB		Near-end Analog Loopback. Places the Port PHY into near-end analog loopback mode.
		0	Near-end analog loopback is not requested.
		1	Initiates a near-end analog loopback request. BISTCR.CP field contains the appropriate pattern. This mode should be initiated either in the PARTIAL or SLUMBER power mode, or with the device disconnected from the Port PHY (Link NOCOMM state). BIST Activate FIS is not sent to the device in this mode.
15-11	Reserved	0	Reserved.
10-8	LLC	0-7h	Link Layer Control. This bit field controls the Port Link Layer functions: scrambler, descrambler, and repeat primitive drop (RPD). In normal mode, the functions scrambler, descrambler, or RPD are changed only during Port reset (P0SCTL.DET = 1). Note the different meanings for normal and BIST modes of operation:
			Bit 10 (RPD):
		0	Repeat primitive drop function is disabled in normal mode, enabled in BIST mode.
		1	Repeat primitive drop function is enabled in normal mode, disabled in BIST mode.
			Bit 9 (DESCRAM):
		0	Descrambler is disabled in normal mode, enabled in BIST mode.
		1	Descrambler is enabled in normal mode, disabled in BIST mode.
			Bit 8 (SCRAM):
		0	Scrambler is disabled in normal mode, enabled in BIST mode.
		1	Scrambler is enabled in normal mode, disabled in BIST mode.
			The SCRAM bit is cleared (enabled) by the Port when the Port enters a responder far-end transmit BIST mode with scrambling enabled (BISTAFR.PD = 80h).
7	Reserved	0	Reserved.
6	ERREN		Error Enable. Used to allow or filter (disable) PHY internal errors outside the FIS boundary to set corresponding port serial ATA error register (P0SERR) bits.
		0	Filter errors outside the FIS, allow errors inside the FIS.
		1	Allow errors outside or inside the FIS.
5	FLIP	0-1	Flip Disparity. Enables changing disparity of the current test pattern to the opposite every time its state is changed by software.

Table 20-12. BIST Control Register (BISTCR) Field Descriptions (continued)

Bit	Field	Value	Description
4	PV		Pattern Version. Selects either short or long version of the SSOP, HTDP, LTDP, LFSCP, and COMP patterns.
		0	Short pattern version
		1	Long pattern version
3-0	PATTERN	0-Fh	Defines one of the following SATA compliant patterns for far-end retimed/ far-end analog/near-end analog initiator modes, or non-compliant patterns for transmit-only responder mode when initiated by software writing to the BISTCR.TXO bit.
		0	Simultaneous switching outputs pattern (SSOP)
		1h	High-transition density pattern
		2h	Low-transition density pattern
		3h	Low-frequency spectral component pattern (LFSCP)
		4h	Composite pattern (COMP)
		5h	Lone bit pattern (LBP)
		6h	Mid-frequency test pattern (MFTP)
		7h	High-frequency test pattern (HFTP)
		8h	Low-frequency test pattern (LFTP)
		9h-Fh	Reserved.

20.4.10 BIST FIS Count Register (BISTFCTR)

The BIST FIS count register (BISTFCTR) contains the received BIST FIS count in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. This register does not roll over and freezes when the FFFF FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value.

The BISTFCTR register is shown in Figure 20-11 and described in Table 20-13.

Figure 20-11. BIST FIS Count Register (BISTFCTR)

31	0
BISTFCTR	
R/W-0

Table 20-13. BIST FIS Count Register (BISTFCTR) Field Description

Bit	Field	Value	Description
31-0	BISTFCTR	0-FFFF FFFFh	Received BIST FIS Count.

20.4.11 BIST Status Register (BISTSR)

The BIST status register (BISTSR) contains errors detected in the received BIST FIS in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is not meaningful in responder mode. It is updated each time a new BIST FIS is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit.

The BISTSR register is shown in Figure 20-12 and described in Table 20-14.

Figure 20-12. BIST Status Register (BISTSR)

31	24	23	16
Reserved		BRSTERR	
R-0		R-0	

15	0
FRAMERR	
W-0	

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 20-14. BIST Status Register (BISTSR) Field Description

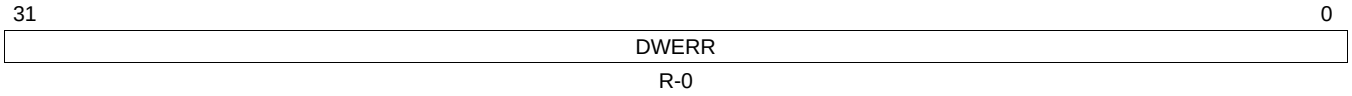
Bit	Field	Value	Description
31-24	Reserved	0	Reserved.
23-16	BRSTERR	0-FFh	Burst Error. This bit field contains the burst error count. It is accumulated each time a burst error condition is detected: DWORD error is detected in the received frame and 1.5 seconds (27,000 frames) passed since the previous burst error was detected. The BRSTERR value does not roll over and freezes at FFh. This bit field is updated if BIST_MODE = DWORD.
15-0	FRAMERR	0-FFFFh	Frame Error. This bit field contains the frame error count. It is accumulated (new value is added to the old value) each time a new BIST frame with a CRC error is received. The FRAMERR value does not roll over and freezes at FFFFh.

20.4.12 BIST DWORD Error Count Register (BISTDECR)

The BIST DWORD error count register (BISTDECR) contains the number of DWORD errors detected in the received BIST frame in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. It is updated each time a new BIST frame is received. It is reset by Global reset, Port reset (COMRESET) or by setting the BISTCR.CNTCLR bit. This register is updated only when the parameter BIST_MODE=DWORD.

The BISTDECR register is shown in Figure 20-13 and described in Table 20-15.

Figure 20-13. BIST DWORD Error Count Register (BISTDECR)



LEGEND: R = Read only; -*n* = value after reset

Table 20-15. BIST DWORD Error Count Register (BISTDECR) Field Description

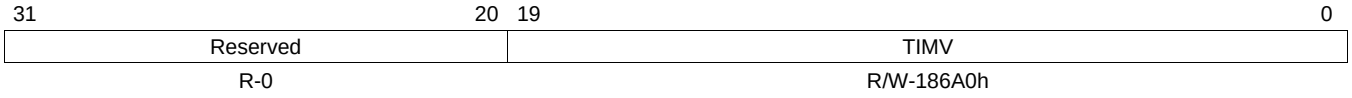
Bit	Field	Value	Description
31-0	DWERR	0-FFFF FFFFh	DWORD Error Count. This bit field contains the DWORD error count. It is accumulated (new value is added to the old value) each time a new BIST frame is received. The DWERR value does not roll over and freezes if it exceeds FFFF F000h.

20.4.13 BIST DWORD Error Count Register (TIMER1MS)

The BIST DWORD error count register (TIMER1MS) is used to generate 1ms tick for the command completion coalescing (CCC) logic based on the OCP clock frequency sourced to the SATA controller. Software must initialize this register with the required value after power up before using the CCC feature. This register is reset to 100,000d (corresponding to a VBUS Clock frequency of 100 MHz hclk) on power up and is not affected by Global reset.

The TIMER1MS register is shown in Figure 20-14 and described in Table 20-16.

Figure 20-14. BIST DWORD Error Count Register (TIMER1MS)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-16. BIST DWORD Error Count Register (TIMER1MS) Field Description

Bit	Field	Value	Description
31-20	Reserved	0	Reserved.
19-0	TIMV	0-F FFFFh	1ms Timer Value. This bit field contains the cycle count of the SATA VBUS Clock Cycle generating 1ms tick. This bit field is: • Read/Write (R/W) when CCC_CTL.EN = 0 • Read only (R) when CCC_CTL.EN = 1

20.4.14 Global Parameter 1 Register (GPARAM1R)

The global parameter 1 register (GPARAM1R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core.

The GPARAM1R register is shown in Figure 20-15 and described in Table 20-17.

Figure 20-15. Global Parameter 1 Register (GPARAM1R)

Table 20-17. Global Parameter 1 Register (GPARAM1R) Field Descriptions

Bit	Field	Value	Description
31	ALIGN_M	1	Rx Data Alignment. Data is always aligned.
30	RX_BUFFER	1	Rx Data Buffer. Core includes an Rx Data Buffer.
29-28	PHY_DATA	0	PHY Data Width. Indicates width = 0 (8-bits).
27	PHY_RST	0	PHY Reset Mode. Indicates that the PHY reset output is active-low.
26-21	PHY_CTRL	1Ah	PHY Control Width. Indicates that there are 32-bits of PHY control.
20-15	PHY_STAT	2h	PHY Status Width. Indicates that there are 32-bits of PHY status.
14	LATCH_M	0	Latch Mode. Indicates that the subsystem does not include latches.
13	BIST_M	0	BIST Loopback Checking Depth. Checks errors per FIS not DWORD.
12	PHY_TYPE	0	PHY Interface Type. Indicates a non-Synopsis PHY.
11	Reserved	0	Reserved.
10	RETURN_ERR	1	AHB Error Response. Indicates AHB Errors are returned.
9-8	AHB_ENDIAN	2h	Bus Endianness. Indicates that endianness may be configured by input pin.
7	S_HADDR	0	Slave address bus width. Indicates 32-bit wide address bus.
6	M_HADDR	0	Master address bus width. Indicates 32-bit wide address bus.
5-3	S_HDATA	0	Slave Data Bus Width. Indicates 32-bit data bus.
2-0	M_HDATA	0	Master Data Bus Width. Indicates 32-bit data bus.

20.4.15 Global Parameter 2 Register (GPARAM2R)

The global parameter 2 register (GPARAM2R) is a read-only register that contains encoded information about the configuration of the embedded Synopsis AHCI SATA Core.

The GPARAM2R register is shown in Figure 20-16 and described in Table 20-18.

Figure 20-16. Global Parameter 2 Register (GPARAM2R)

LEGEND: R = Read only; -*n* = value after reset

Table 20-18. Global Parameter 2 Register (GPARAM2R) Field Descriptions

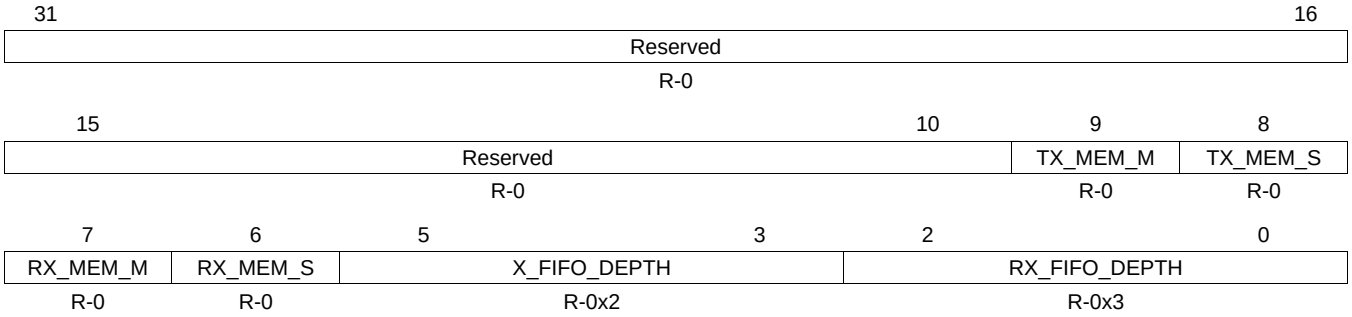
Bit	Field	Value	Description
31-15	Reserved	0	Reserved.
14	DEV_CP	0	Cold Presence Detect. CPD is supported in SATASS.
13	DEV_MP	0	Mechanical Presence Switch. MP is supported in SATASS.
12	ENCODE_M	1	8b/10b Encoding/Decoding. Indicates 8-bit/10-bit encoding and decoding are done in the Synopsis core.
11	RXOOB_CLK_M	0	Rx OOB Clock Mode. Indicates that the Rx OOB Functions are on the Rx Clock.
10	RX_OOB_M	1	Rx OOB Mode. Indicates that Rx Out-of-Band signals are detected in the PHY.
9	TX_OOB_M	1	Tx OOB Mode. Indicates that Tx Out-of-Band signaling is done by the Synopsis Core.
8-0	RXOOB_CLK	96h	Rx OOB Clock Frequency. Reflects the hexadecimal value of the RXOOB_CLK_FREQ parameter.

20.4.16 Port Parameter Register (PPARAMR)

The port parameter register (PPARAMR) is a read-only register that contains encoded information about the selected Port configuration parameters settings. The Port is selected by the TESTR.PSEL field. Note, there are two HBA ports on this sub-system and the configuration setting applies to both ports.

The PPARAMR register is shown in Figure 20-17 and described in Table 20-19.

Figure 20-17. Port Parameter Register (PPARAMR)



LEGEND: R = Read only; -*n* = value after reset

Table 20-19. Port Parameter Register (PPARAMR) Field Descriptions

Bit	Field	Value	Description
31-10	Reserved	0	Reserved.
9	TX_MEM_M	0	Tx FIFO Memory Read Port Type. Indicates that the Tx FIFO memory is asynchronous read.
8	TX_MEM_S	0	Tx FIFO Memory Type. Indicates that the Tx FIFO memory is outside of the core (but still inside the subsystem wrapper).
7	RX_MEM_M	0	Rx FIFO Memory Read Port Type. Indicates that the Rx FIFO memory is asynchronous read.
6	RX_MEM_S	0	Rx FIFO Memory Type. Indicates that the Rx FIFO memory is outside of the core (but still inside the subsystem wrapper).
5-3	TX_FIFO_DEPTH	2h	Tx FIFO Depth. Indicates that the depth of the Tx FIFO is 64 DWORDS.
2-0	RX_FIFO_DEPTH	3h	Rx FIFO Depth. Indicates that the depth of the Rx FIFO is 128 DWORDS.

20.4.17 Test Register (TESTR)

The test register (TESTR) is used to put the SATASS slave interface into a test mode and to select a Port for BIST operation.

The TESTR register is shown in Figure 20-18 and described in Table 20-20.

Figure 20-18. Test Register (TESTR)

31	19	18	16
Reserved		PSEL	
R-0		R/W-0	

15	0
Reserved	TEST_IF
R-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-20. Test Register (TESTR) Field Descriptions

Bit	Field	Value	Description
31-19	Reserved	0	Reserved.
18-16	PSEL	0	Port Select. Selects the port for BIST operation. Note that there are two ports in this subsystem, so 0 and 1 are valid values.
15-1	Reserved	0	Reserved.
0	TEST_IF		Test Interface. Places the DWC SATA AHCI slave interface into the test mode.
		0	Normal mode: the read back value of some registers is a function of the DWC SATA AHCI state and does not match the value written.
		1	Test mode: the read back value of the registers matches the value written. Normal operation is disabled. The following registers are accessed in this mode: • GHC register: IE bit • BISTAFR register: NCP and PD bits become read/write • BISTCR register: LLC, ERREN, FLIP, PV, PATTERN • BISTFCTR, BISTSR, BISTDECR registers become read/write • P#CLB (# = 0 or 1)/CLBU, P#FB (# = 0 or 1)/FBU registers • P#IS (# = 0 or 1) register: RW1C and UFS bits become read/write • P#IE (# = 0 or 1) register • P#CMD (# = 0 or 1) register: ASP, ALPE, DLAE, ATAPI, PMA bits • P#TFD (# = 0 or 1), P#SIG (# = 0 or 1) registers become read/write • P#SCTL (# = 0 or 1) register • P#SERR (# = 0 or 1) register: R/W1C bits become read/write bits • P#SACT (# = 0 or 1), P#CI (# = 0 or 1), P#SNTF (# = 0 or 1) registers become read/write • P#DMACR (# = 0 or 1) register • P#PHYCR (# = 0 or 1) register • P#PHYSR (# = 0 or 1) register becomes read/write Notes: Where # = Port 0 or Port 1 above, the PSEL field will select the Port Number under test. Interrupt is asserted if any of the IS register bits is set after setting the corresponding P0IS and P0IE registers and GHC.IE = 1. CAP.SMPS/SSS, PI, P0CMD.ESP/CPD/MPSP/ HPCP register bits are W/RO (written once after power-on reset, then remain as read-only) type and can not be used in test mode. Global DWC SATA AHCI reset must be issued (GHC.HR = 1) after TEST_IF bit is cleared following the test mode operation.

20.4.18 Version Register (VERSIONR)

The version register (VERSIONR) contains the 32-bit SATASS version.

The VERSIONR register is shown in Figure 20-19 and described in Table 20-21.

Figure 20-19. Version Register (VERSIONR)

LEGEND: R = Read only; -*n* = value after reset

Table 20-21. Version Register (VERSIONR) Field Description

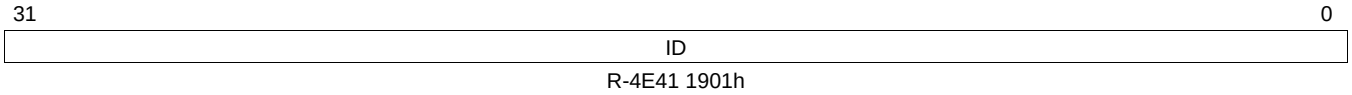
Bit	Field	Value	Description
31-0	VERSION	3134 302Ah	32-bit version of SATASS.

20.4.19 ID Register (IDR)

The ID register (IDR) contains the 32-bit SATASS ID.

The IDR register is shown in Figure 20-20 and described in Table 20-22.

Figure 20-20. ID Register (IDR)



LEGEND: R = Read only; -*n* = value after reset

Table 20-22. ID Register (IDR) Field Description

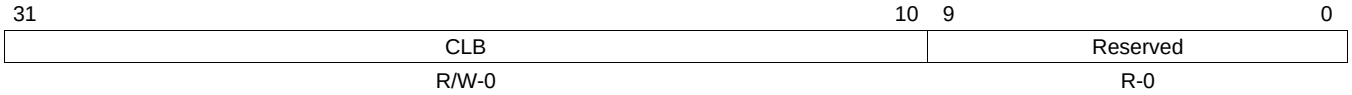
Bit	Field	Value	Description
31-0	ID	4E41 1901h	32-bit ID of SATASS.

20.4.20 Port Command List Base Address Register (P#CLB) (# = 0 or 1)

The port command list base address register (P#CLB) contains the 32-bit base address of the command list.

The P#CLB register is shown in Figure 20-21 and described in Table 20-23.

Figure 20-21. Port Command List Base Address Register (P#CLB)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-23. Port Command List Base Address Register (P#CLB) Field Description

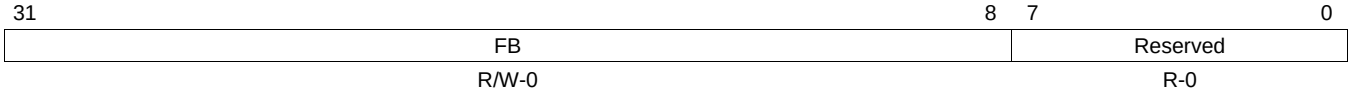
Bit	Field	Value	Description
31-10	CLB	0-3F FFFFh	Command List Base Address. Indicates the 32-bit base physical address for the command list for this port. This base is used when fetching commands to execute. The structure pointed to by this address range is 1Kbyte in length. This address must be 1Kbyte-aligned as indicated by bits [9:0] being read-only.
9-0	Reserved	0	Reserved.

20.4.21 Port FIS Base Address Register (P#FB) (# = 0 or 1)

The port FIS base address register (P#FB) contains the 32-bit base address of the destination for incoming received FISes.

The P#FB register is shown in Figure 20-22 and described in Table 20-24.

Figure 20-22. Port FIS Base Address Register (P#FB)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 20-24. Port FIS Base Address Register (P#FB) Field Description

Bit	Field	Value	Description
31-8	FB	0-FF FFFFh	FIS Base Address. Indicates the 32-bit base physical address for received FISes. The structure pointed to by this address range is 256 bytes in length. This address must be 256 byte-aligned as indicated by bits [7:0] being read-only.
7-0	Reserved	0	Reserved.

20.4.22 Port Interrupt Status Register (P#IS) (# = 0 or 1)

The port interrupt status register (P#IS) is used to generate SATASS interrupts when any of the bits are set. Bits in this register are set by some internal conditions, and cleared by software writing ones in the positions it wants to clear. This register is reset on Global reset.

The P#IS register is shown in Figure 20-23 and described in Table 20-25.

Figure 20-23. Port Interrupt Status Register (P#IS)

31	30	29	28	27	26	25	24	23	22	21	16

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 20-25. Port Interrupt Status Register (P#IS) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. Since no dedicated pins for CPD detection/control exist for the device, this bit is reserved. If need to support this feature, use of GPIO is recommended.
30	TFES	0-1	Task File Error Status. This bit is set whenever the P0TFD register is updated by the device and the error bit (P0TFD.STS[0]) is set.
29	HBFS	0-1	Host Bus Fatal Error Status. This bit is set when SATASS bus master detects an ERROR response from the slave.
28	HBDS	0-1	Host Bus Data Error Status. This bit is always cleared to 0.
27	IFS	0-1	Interface Fatal Error Status. This bit is set if any of the following conditions is detected: • SYNC escape is received from the device during H2D Register or Data FIS transmission. • One or more of the following errors are detected during Data FIS transfer: Protocol (P0SERR.ERR_P), CRC (P0SERR.DIAG_C), Handshake (P0SERR.DIAG_H), PHY Not Ready (P0SERR.ERR_C). • Unknown FIS is received with good CRC, but the length exceeds 64 bytes. • PRD table byte count is zero. Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.
26	INFS	0-1	Interface Non-fatal Error Status. This bit is set if any of the following conditions is detected: • One or more of the following errors are detected during non-data FIS transfer: Protocol (P0SERR.ERR_P), CRC (P0SERR.DIAG_C), Handshake (P0SERR.DIAG_H), PHY Not Ready (P0SERR.ERR_C). • Command list underflow during read operation (DMA read) when software builds command table that has more total bytes than the transaction given to the device. In both cases, Port operation continues normally. If error is detected during non-data FIS transmission, this FIS is retransmitted continuously until it succeeds or software times out and resets the interface.
25	Reserved	0	Reserved.
24	OFS	0-1	Overflow Status. This bit is set if command list overflow is detected during read or write operation when software builds a command table that has fewer total bytes than the transaction given to the device. Port DMA transitions to a fatal state until software clears P0CMD.ST bit or resets the interface by way of Port or Global reset.
23	IPMS	0-1	Incorrect Port Multiplier Status. Indicates that the HBA received a FIS from a device whose Port Multiplier field did not match what was expected. This bit may be set during enumeration of devices on a Port Multiplier due to the normal Port Multiplier enumeration process. The software should only use the IPMS bit after enumeration is complete on the Port Multiplier.
22	PRCS	0-1	PHY Ready Change Status. When set to 1, indicates the internal PHY Ready signal changed state. This bit reflects the state of the P0SERR.DIAG_N bit. To clear this bit, the software must clear the P0SERR.DIAG_N bit to 0.
21-8	Reserved	0	Reserved.

Table 20-25. Port Interrupt Status Register (P#IS) Field Descriptions (continued)

Bit	Field	Value	Description
7	DMPS	0-1	Device Mechanical Presence Status. This bit is set when the state of SATA_MP_SWITCH input pin changes as a result of a mechanical switch attached to this port being opened or closed. This bit is only valid if both CAP.SMPS and P0CMD.MPSP are set to 1.
6	PCS		Port Connect Change Status. This bit reflects the state of the P0SERR.DIAG_X bit. This bit is only cleared when P0SERR.DIAG_X is cleared.
		0	No change in Current Connect Status
		1	Change in Current Connect Status
5	DPS	0-1	Descriptor Processed. A PRD with the I bit set has transferred all of its data. Note: This is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts could happen close in time together such that the second interrupt is missed when the first PRD interrupt is being cleared.
4	UFS	0-1	Unknown FIS Interrupt. When set to 1, indicates that an unknown FIS was received and has been copied into system memory. This bit is cleared to 0 by software clearing the P0SERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the P0SERR.DIAG_F bit. P0SERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. Software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync.
3	SDBS	0-1	Set Device Bits Interrupt. A Set Device Bits FIS has been received with the I bit set and has been copied into system memory.
2	DSS	0-1	DMA Setup FIS Interrupt. A DMA Setup FIS has been received with the I bit set and has been copied into system memory.
1	PSS	0-1	PIO Setup FIS Interrupt. A PIO Setup FIS has been received with the I bit set, it has been copied into system memory, and the data related to that FIS has been transferred.
0	DHRS	0-1	Device to Host Register FIS Interrupt. A D2H Register FIS has been received with the I bit set, and has been copied into system memory.

20.4.23 Port Interrupt Enable Register (P#IE) (# = 0 or 1)

The port interrupt enable register (P#IE) enables and disables the reporting of the corresponding interrupt to system software. When a bit is set (1), and the corresponding interrupt condition is active, then the SATASS intrq output is asserted. Interrupt sources that are disabled (0) are still reflected in the status registers. This register is symmetrical with the P#IS register. This register is reset on Global reset.

The P#IE register is shown in Figure 20-24 and described in Table 20-26.

Figure 20-24. Port Interrupt Enable Register (P#IE)

Table 20-26. Port Interrupt Enable Register (P#IE) Field Descriptions

Bit	Field	Value	Description
31	Reserved	0	Reserved. No CPD capability exist since CPD related pins are not bonded out for the device. If need this feature, use of GPIO is recommended.
30	TFEE	0-1	Task File Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the intrq output is asserted.
29	HBFE	0-1	Host Bus Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBFS = 1, the interq output is asserted.
28	HBDE	0-1	Host Bus Data Error Enable. When set to 1, GHC.IE = 1, and P0IS.HBDS = 1, the intrq output is asserted.
27	IFE	0-1	Interface Fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.IFS = 1, the intrq output is asserted.
26	INFE	0-1	Interface Non-fatal Error Enable. When set to 1, GHC.IE = 1, and P0IS.INFS = 1, the intrq output is asserted.
25	Reserved	0	Reserved.
24	OFE	0-1	Overflow Enable. When set to 1, GHC.IE = 1, and P0IS.OFS = 1, the intrq output is asserted.
23	IPME	0-1	Incorrect Port Multiplier Enable. When set to 1, GHC.IE = 1, and P0IS.IPMS = 1, the intrq output is asserted.
22	PRCE	0-1	PHY Ready Change Enable. When set to 1, GHC.IE = 1, and P0IS.PRCS = 1, the intrq output is asserted.
21-8	Reserved	0	Reserved.
7	DMPE	0-1	Device Mechanical Presence Enable. When set to 1, GHC.IE = 1, and P0IS.DMPS = 1, the intrq output is asserted.
6	PCE	0-1	Port Change Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PCS = 1, the intrq output is asserted.
5	DPE	0-1	Descriptor Processed Interrupt Enable. When set to 1, GHC.IE = 1 and P0IS.DPS = 1, the intrq output is asserted.
4	UFE	0-1	Unknown FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.UFS = 1, the intrq output is asserted.
3	SDBE	0-1	Set Device Bits FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.SDBS = 1, the intrq output is asserted.
2	DSE	0-1	DMA Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.
1	PSE	0-1	PIO Setup FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.PSS = 1, the intrq output is asserted.
0	DHRE	0-1	Device Host Register FIS Interrupt Enable. When set to 1, GHC.IE = 1, and P0IS.DHRS = 1, the intrq output is asserted.

20.4.24 Port Command Register (P#CMD) (# = 0 or 1)

The port command register (P#CMD) contains bits controlling various Port functions. All read/write bits are reset on Global reset.

The P#CMD register is shown in Figure 20-25 and described in Table 20-27.

Figure 20-25. Port Command Register (P#CMD)

Table 20-27. Port Command Register (P#CMD) Field Descriptions

Bit	Field	Value	Description
31-28	ICC	0-Fh	Interface Communication Control. Controls power management states of the interface. If the Link layer is currently in the L_IDLE state, writes to this bit field causes the Port to initiate a transition to the interface power management state requested. If the Link layer is not currently in the L_IDLE state, writes to this bit field have no effect. When system software writes a nonreserved value other than No-Op (0), the Port performs the action and updates this bit field back to Idle (0). If software writes to this bit field to change the state to a state the link is already in (that is, interface is in the active state and a request is made to go to the active state), the Port takes no action and returns this bit field to Idle. If the interface is in a low power state and software wants to transition to a different low power state, software must first bring the link to active and then initiate the transition to the desired low power state.
		0	No-Op/ Idle: When software reads this value, it indicates the Port is ready to accept a new interface control command, although the transition to the previously selected state may not yet have occurred.
		1h	Active: Causes the Port to request a transition of the interface into the active state.
		2h	Partial: Causes the Port to request a transition of the interface to the Partial state. The SATA device may reject the request and the interface remains in its current state.
		3h-5h	Reserved
		6h	Slumber: Causes the Port to request a transition of the interface to the Slumber state. The SATA device may reject the request and the interface remains in its current state.
		7h-Fh	Reserved
27	ASP		Aggressive Slumber/Partial.
		0	When cleared to 0 and P0CMD.ALPE = 1, the Port aggressively enters the PARTIAL state when it clears the P0CI register, and the P0SACT register is cleared when it clears the P0SACT register and P0CI is cleared.
		1	When set to 1 and P0CMD.ALPE = 1, the Port aggressively enters the SLUBMER state when it clears the P0CI register and the P0SACT register is cleared, or when it clears the P0SACT register and P0CI is cleared.
26	ALPE		Aggressive Link Power Management Enable.
		0	Aggressive power management state transition is disabled.
		1	Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of the P0CMD.ASP bit.
25	DLAE	0-1	Drive LED on ATAPI Enable. When set to 1, P0CMD.ATAPI = 1, and commands are active, the Port asserts P0_act_led output.
24	ATAPI	0-1	Device is ATAPI. When set to 1, the connected device is an ATAPI device. This bit is used by the Port to control whether or not to assert P0_act_led output when commands are active.
23-22	Reserved	0	Reserved.
21	ESP		External SATA Port. The ESP bit is mutually exclusive with the P0CMD.HPCP bit.
		0	Ports signal only connector is not externally accessible.
		1	Ports signal only connector is externally accessible. When set to 1, CAP.SXS is also set to 1.

Table 20-27. Port Command Register (P#CMD) Field Descriptions (continued)

Bit	Field	Value	Description
20	Reserved	0	Reserved. Since no CPD pins are bonded out for the device, this bit should be written with a zero value. If need to implement CPD functionality, GPIO usage is recommended.
19	MPSP		Mechanical Presence Switch Attached to Port.
		0	Platform does not support a mechanical presence switch on this port.
		1	Platform supports a mechanical presence switch attached to this port. When this bit is set to 1, P0CMD.HPCP should also be set to 1.
18	HPCP		Hot Plug.
		0	Ports signal and power connectors are not externally accessible.
		1	Ports signal and power connectors are externally accessible via a joint signal-power connector for blindmate device hot plug.
17	PMA		Port Multiplier Attached.
			Note: Software is responsible for detecting whether a Port Multiplier is present. There is no auto detection.
		0	When cleared to 0 by software, indicates that a Port Multiplier is not attached to this Port.
		1	When set to 1 by software, indicates that a Port Multiplier is attached to this Port.
16	CPD	0	Since no CPD pins are bonded out for the device, this bit is always zero. if need to implement CPD usage of GPIO is recommended.
15	CR	0-1	Command List Running. When this bit is set to 1, the command list DMA engine for this Port is running. See Synopsys spec for more detail.
14	FR	0-1	FIS Receive Running. When set to 1, the FIS Receive DMA engine for this port is running. Refer to the AHCI specification section 10.3.2 for details on when this bit is set and cleared by the Port.
13	MPSS		Mechanical Presence Switch State. Reports the state of a mechanical presence switch attached to this port as indicated by the P0_mp_switch input state (assuming CAP.SMPS = 1 and P0CMD.MPSP = 1). If CAP.SMPS = 0, then this bit is cleared to 0. Software should only use this bit if both CAP.SMPS and P0CMD.MPSP are set to 1.
			Note: The reset of this bit may change based on the SATA_MP_SWITCH state at reset.
		0	Switch is closed.
		1	Switch is open.
12-8	CCS	0-1Fh	Current Command Slot. This field is valid when P0CMD.ST is set to 1 and is set to the command slot value of the command that is currently being issued by the Port. When P0CMD.ST transitions from 1 to 0, this field is reset to 0x00. After P0CMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is P0CMD.CCS+1. For example, after the Port has issued its first command, if CCS=0x00 and P0CI is set to 0x3, the next command that will be issued is from command slot 1.
7-5	Reserved	0	Reserved.
4	FRE	0-1	FIS Receive Enable. When set to 1, the Port may post received FISes into the FIS receive area pointed to by P#FB. When cleared, received FISes are not accepted by the Port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area.
			System software must not set this but until P#FB has been programmed with a valid pointer to the FIS receive area, and if software wishes to move the base, this bit must first be cleared, and software must wait for the P0CMD.FR bit to be cleared. Refer to the Synopsis spec for important restrictions on changing P0CMD.FRE.
3	CLO	1	Command List Override. Setting this bit to 1 causes P0TFD.STS.BSY and P0TFD.STS.DRQ to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the P0TFD.STS register. This bit is cleared to 0 when P0TFD.STS.BSY and P0TFD.STS.DRQ have been cleared to 0. A write to this register with a value of 0 has no effect.
			This bit should only be set to 1 immediately prior to setting P0CMD.ST bit to 1 from a previous value of 0. Setting this bit to 1 at any other time is not supported and results in indeterminate behavior.
2	POD	0-1	Power On Device. This bit is RW if cold presence detection is supported on this port as indicated by P0CMD.CPD=1. This bit is RO 1 if cold presence detection is not supported and P0CMD.CPD=0. Note: Since no CPD control/status related pins are bonded out on the device, this bit is read only. Usage of GPIO is recommended if need to supplement CPD feature.
1	SUD	0-1	Spin-Up Device. This bit is read/write if staggered spin-up is supported as indicated by the CAP.SSS = 1. This bit is read-only 1 if staggered spin-up is not supported and CAP.SSS = 0. On an edge detect from 0 to 1, the Port starts a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface.
			Note: the SUD bit is read-only 0 on power-up until CAP.SSS bit is written with the required value.

Table 20-27. Port Command Register (P#CMD) Field Descriptions (continued)

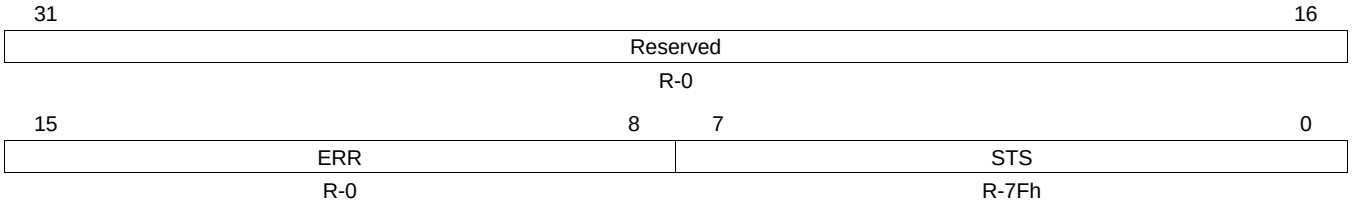
Bit	Field	Value	Description
0	ST	0-1	Start. When set to 1, the Port processes the command list. When cleared, the Port does not process the command list. Whenever this bit is changed from a 0 to a 1, the Port starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, the P0CI register is cleared by the Port upon transition into an idle state. Refer to the AHCI specification for important restrictions on when this bit can be set to 1.

20.4.25 Port Task File Data Register (P#TFD) (# = 0 or 1)

The port task file data register (P#TFD) contains Error and Status registers updated every time a new Register FIS.

The P#TFD register is shown in Figure 20-26 and described in Table 20-28.

Figure 20-26. Port Task File Data Register (P#TFD)



LEGEND: R = Read only; -*n* = value after reset

Table 20-28. Port Task File Data Register (P#TFD) Field Descriptions

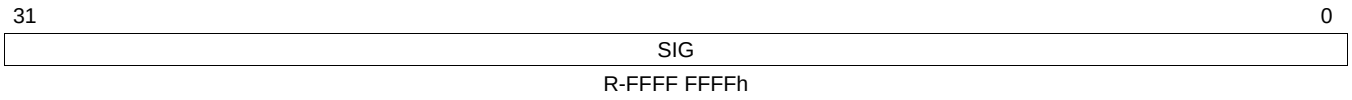
Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-8	ERR	0-FFh	Error. Contains the latest copy of the task file error register.
7-0	STS	0-FFh	Status. Contains the latest copy of the task file status register.
			Note: the HBA updates the entire 8-bit field not just the bits listed.
		0	ERR – Indicates an error during the transfer
		1h-2h	Reserved
		3h	DRQ – Indicates a data transfer is requested
		4h-6h	Reserved
		7h	BSY – Indicates the interface is busy
		8h-FFh	Reserved

20.4.26 Port Signature Register (P#SIG) (# = 0 or 1)

The port signature register (P#SIG) contains the Device Signature information.

The P#SIG register is shown in Figure 20-27 and described in Table 20-29.

Figure 20-27. Port Signature Register (P#SIG)



LEGEND: R = Read only; -*n* = value after reset

Table 20-29. Port Signature Register (P#SIG) Field Description

Bit	Field	Value	Description
31-0	SIG	0-FFFF FFFFh	Signature. Contains the signature received from a device on the first D2H Register FIS. This register is updated once after a reset sequence. Reset on Global or Port reset. The bit order as is:
			Bits 31-24: LBA High (Cylinder High) Register
			Bits 23-16: LBA Mid (Cylinder Low) Register
			Bits 15-8: LBA Low (Sector Number) Register
			Bits 7-0: Sector Count Register

20.4.27 Port Serial ATA Status Register (P#SSTS) (# = 0 or 1)

The port serial ATA status register (P#SSTS) conveys the current state of the interface and host. The Port updates it continuously and asynchronously. When the Port transmits a COMRESET to the device, this register is updated to its reset values (Global reset, Port reset, or COMINIT from the device).

The P#SSTS register is shown in Figure 20-28 and described in Table 20-30.

Bit	Field	Value	Description
31-12	Reserved	0	Reserved.
11-8	IPM	0-Fh	Interface Power Management. Indicates the current interface state.
		0	Device is not present or communication is not established.
		1h	Interface in active state
		2h	Interface in Partial power management state.
		3h-5h	Reserved
		6h	Interface in Slumber power management state.
		7h-Fh	Reserved
7-4	SPD	0-Fh	Current Interface Speed. Indicates the negotiated interface communication speed.
		0	Device is not present or communication is not established.
		1h	Generation 1 (1.5 Gbps) negotiated
		2h	Generation 2 (3 Gbps) negotiated
		3h-Fh	Reserved
3-0	DET	0-Fh	Device Detection. Indicates the interface device detection and PHY state.
		0	No device detected and PHY communication is not established.
		1h	Device presence detected but PHY communication is not established (COMINIT is detected).
		2h	Reserved
		3h	Device presence detected and PHY communication is established (PHY Ready is detected).
		4h	PHY in offline mode as a result of the interface being disabled or running in BIST loopback mode.
		5h-Fh	Reserved

20.4.28 Port Serial ATA Control Register (P#SCTL) (# = 0 or 1)

The port serial ATA control register (P#SCTL) is used by software to control SATA interface capabilities. Writes to this register result in an action being taken by the Port PHY interface. Reads from the register return the last value written to it. Reset on Global reset.

These bits are static and should not be changed frequently due to the clock crossing between the Transport and Link Layers. Software must wait for at least seven periods of the slower clock (clk_asic or OCP clock) before changing this register.

The P#SCTL register is shown in Figure 20-29 and described in Table 20-31.

Figure 20-29. Port Serial ATA Control Register (P#SCTL)

Table 20-31. Port Serial ATA Control Register (P#SCTL) Field Descriptions

Bit	Field	Value	Description
31-12	Reserved	0	Reserved.
11-8	IPM	0-Fh	Interface Power Management Transitions Allowed. Indicates which power states the Port PHY interface is allowed to transition to. If an interface power management state is disabled, the Port does not initiate that state and any request from the device to enter that state is rejected via PMNAKp.
		0	No interface power management state restrictions.
		1h	Transitions to the Partial state are disabled.
		2h	Transitions to the Slumber state are disabled.
		3h	Transitions to both Partial and Slumber states are disabled.
		4h-Fh	Reserved
7-4	SPD	0-Fh	Speed Allowed. Indicates the highest allowable speed of the Port PHY interface. Note: When host software must change this bit field value, the host must also reset the Port (DET = 1) at the same time to ensure proper speed negotiation.
		0	No speed negotiation restrictions.
		1h	Limit speed negotiation to Generation 1 (1.5 Gbps) communication rate.
		2h	Limit speed negotiation to Generation 2 (3 Gbps) communication rate.
		3h-Fh	Reserved
3-0	DET	0-Fh	Device Detection Initialization. Controls the Ports device detection and interface initialization. Note: This bit field may only be modified when P0CMD.ST = 0; changing this bit field while P0CMD.ST = 1 results in undefined behavior. When P0CMD.ST is set to 1, this bit field should have a value of 0.
		0	No device detection or initialization action is requested.
		1h	Perform interface initialization sequence to establish communication. This results in the interface being reset and communication re-initialized.
		2h-3h	Reserved
		4h	Disable the Serial ATA interface and put the Port PHY in offline mode.
		5h-Fh	Reserved

20.4.29 Port Serial ATA Error Register (P#SERR) (# = 0 or 1)

The port serial ATA error register (P#SERR) represents all the detected interface errors accumulated since the last time it was cleared. The set bits in the P#SERR register indicate that the corresponding error condition became true one or more times since the last time the bit was cleared. The set bits in this register are explicitly cleared by a write operation to the register, Global reset, or Port reset (COMRESET). The value written to clear the set error bits should have ones encoded in the bit positions corresponding to the bits that are to be cleared. All bits in the following table have a reset value of 0.

The P#SERR register is shown in Figure 20-30 and described in Table 20-32.

Figure 20-30. Port Serial ATA Error Register (P#SERR)

LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 20-32. Port Serial ATA Error Register (P#SERR) Field Descriptions

Bit	Field	Value	Description
31-27	Reserved	0	Reserved.
26	DIAG_X	0-1	Exchanged. This bit is set to 1 when PHY COMINIT signal is detected. This bit is reflected in the P0IS.PCS bit.
25	DIAG_F	0-1	Unknown FIS Type. Indicates that one or more FISes were received by the Transport layer with good CRC, but had a type field that was not recognized/known and the length was less than or equal to 64 bytes. Note: If the Unknown FIS length exceeds 64 bytes, the DIAG_F bit is not set and the DIAG_T bit is set instead.
24	DIAG_T	0-1	Transport State Transition Error. Indicates that a Transport Layer protocol violation was detected.
23	DIAG_S	0-1	Link Sequence Error. Indicates that one or more Link state machine error conditions was encountered. One of the conditions that cause this bit to be set is the device doing SYNC escape during FIS transmission.
22	DIAG_H	0-1	Handshake Error. Indicates that one or more R-ERRp was received in response to frame transmission. Such errors may be the result of a CRC error detected by the device, a disparity or 8-bit/10-bit decoding error, or other error condition leading to a negative handshake on a transmitted frame.
21	DIAG_C	0-1	CRC Error. Indicates that one ore more CRC errors were detected by the Link layer during FIS reception.
20	DIAG_D	0	Disparity Error. This bit is always 0 since it is not used by the AHCI specification.
19	DIAG_B	0-1	10B to 8B Decode Error. Indicates errors were detected by 10b8b decoder. Note: This bit is set only when an error is detected on the received FIS data word. This bit is not set when an error is detected on the primitive, regardless of whether it is inside or outside the FIS.
18	DIAG_W	0-1	Comm Wake. This bit is set when the PHY COMWAKE signal is detected.
17	DIAG_I	0-1	PHY Internal Error. This bit is set when the PHY detects some internal error. Note: The TI PHY does not support any errors so this bit will never be set.
16	DIAG_N	0-1	PHY Ready Change. Indicates that the PHY Ready signal changed state. This bit is reflected in the P0IS.PRCS bit.
15-12	Reserved	0	Reserved.

Table 20-32. Port Serial ATA Error Register (P#SERR) Field Descriptions (continued)

Bit	Field	Value	Description
11	ERR_E	0-1	Internal Error. This bit is set to 1 when one or more AHB bus ERROR responses are detected on the master or the slave interfaces.
10	ERR_P	0-1	Protocol Error. This bit is set to 1 when any of the following conditions are detected: • Transport state transition error (DIAG_T) • Link sequence error (DIAG_S) • RxFIFO overflow • Link bad end error (WTRM instead of EOF is received)
9	ERR_C	0-1	Non-recovered Persistent Communication Error. This bit is set to 1 when the PHY Ready signal is negated due to the loss of communication with the device or problems with the interface, but not after transition from active to Partial or Slumber power management state.
8	ERR_T	0-1	Non-recovered Transient Data Integrity Error. This bit is set if any of the following P0SERR register bits is set during Data FIS transfer: • ERR_P (Protocol) • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C (PHY Ready negation)
7-2	Reserved	0	Reserved.
1	ERR_M	0-1	Recovered Communication Error. This bit is set to 1 when the PHY Ready condition is detected after interface initialization, but not after transition from partial or Slumber power management state to active state.
0	ERR_I	0-1	Recovered Data Integrity. This bit is set if any of the following P0SERR register bits is set during non-Data FIS transfer: • ERR_P (Protocol) • DIAG_C (CRC) • DIAG_H (Handshake) • ERR_C (PHY Ready negation)

20.4.30 Port Serial ATA Active Register (P#SACT) (# = 0 or 1)

The port serial ATA active register (P#SACT) is used to indicate what command slots have commands in them.

The P#SACT register is shown in Figure 20-31 and described in Table 20-33.

Figure 20-31. Port Serial ATA Active Register (P#SACT)

31	0
DS[*n*]	
R/W1S-0	

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -*n* = value after reset

Table 20-33. Port Serial ATA Active Register (P#SACT) Field Description

Bit	Field	Value	Description
31-0	DS[*n*]	0-1	This field is bit significant. Each bit *n* corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. This field is set by software prior to issuing a native queued command for a particular command slot. Prior to writing P0CI[TAG] to 1, software will set DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits in this field by sending a Set Device Bits FIS to the Port. The Port clears bits in this field that are set to 1 in the SActive field of the Set Device Bits FIS. The Port only clears bits that correspond to native queued commands that have completed successfully. Software should only write to this bit field when P0CMD.ST bit is set to 1. This bit field is cleared when P0CMD.ST is written from a 1 to a 0 by software. This bit field is not cleared by a Port reset (COMRESET) or a software reset.

20.4.31 Port Command Issue Register (P#CI) (# = 0 or 1)

The port command issue register (P#CI) is used to indicate what that a command has been constructed and may be carried out.

The P#CI register is shown in Figure 20-32 and described in Table 20-34.

Figure 20-32. Port Command Issue Register (P#CI)

31	0
CI[*n*]	
R/W1S-0	

LEGEND: R/W = Read/Write; W1S = Write 1 to set; -*n* = value after reset

Table 20-34. Port Command Issue Register (P#CI) Field Description

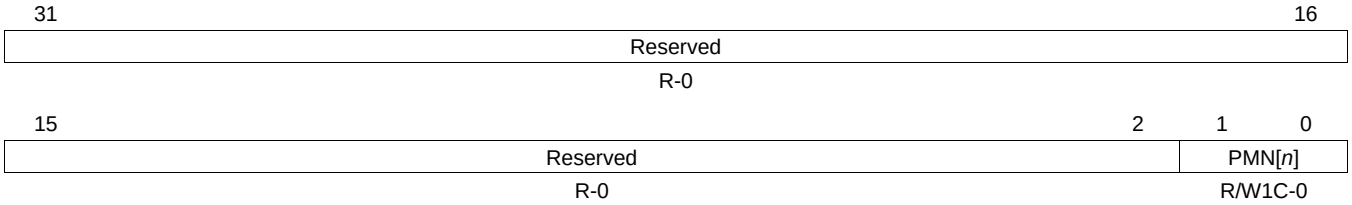
Bit	Field	Value	Description
31-0	CI[*n*]	0-1	Command Issued. This field is bit significant. Each bit *n* corresponds to a command slot, where bit 0 corresponds to command slot 0. This bit field is set by software to indicate to the Port that a command has been built in system memory for a command slot and may be sent to the device. When the Port receives a FIS that clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit *n* in this register for that command slot. Bits in this field can only be set to 1 by software when P0CMD.ST is set to 1.

20.4.32 Port Serial ATA Notification Register (P#SNTF) (# = 0 or 1)

The port serial ATA notification register (P#SNTF) is used to determine if asynchronous notification events have occurred for directly connected devices and devices connected to a Port Multiplier.

The P#SNTF register is shown in Figure 20-33 and described in Table 20-35.

Figure 20-33. Port Serial ATA Notification Register (P#SNTF)



LEGEND: R/W = Read/Write; R = Read only; W1C = Write 1 to clear; -*n* = value after reset

Table 20-35. Port Serial ATA Notification Register (P#SNTF) Field Description

Bit	Field	Value	Description
31-2	Reserved	0	Reserved.
1-0	PMN[*n*]	0-1	PM Notify. Indicates whether a particular device with the corresponding PM Port number issued a Set Device Bits FIS to the SATASS Port with the Notification bit set. Individual bits are cleared by software writing 1s to the corresponding bit *n* positions. This bit field is reset on Global reset, but it is not reset by Port reset (COMRESET) or software reset. • PM Port 0 sets bit 0 • PM Port 1 sets bit 1 Note that two different types of ports exist. HBA Port (the device has the support for 2 HBA Ports) and Port Multiplier Port (PMP). A Port of a Port Multiplier (PMP) connects a single device to a PM. As many as 15 devices can be connected to a single HBA Port.

20.4.33 Port DMA Control Register (P#DMACR) (# = 0 or 1)

The port DMA control register (P#DMACR) contains bits for controlling the Port DMA engine. The software can change the fields of this register only when P0CMD.ST=0. Power-up (system reset), Global reset, or Port reset (COMRESET) reset this register to the default value.

The P#DMACR register is shown in Figure 20-34 and described in Table 20-36.

Figure 20-34. Port DMA Control Register (P#DMACR)

Table 20-36. Port DMA Control Register (P#DMACR) Field Description

Bit	Field	Value	Description
31-16	Reserved	0	Reserved.
15-12	RXABL	0-Fh	Receive Burst Limit. Allows software to limit the OCP master write burst size.
			Note: SATASS master breaks the burst at 1Kbyte address boundaries regardless of the RXABL value.
		0	Limit OCP burst size to 256 DWORDS
		1h	Limit OCP Burst size to 1 DWORD
		2h	Limit OCP Burst size to 2 DWORDs
		3h	Limit OCP Burst size to 4 DWORDs
		4h	Limit OCP Burst size to 8 DWORDs
		5h	Limit OCP Burst size to 16 DWORDs
		6h	Limit OCP Burst size to 32 DWORDs
		7h	Limit OCP Burst size to 64 DWORDs
		9h-Fh	Limit OCP Burst size to 256 DWORDS
			Note: The maximum sized burst that will be issued on the OCP is 64 bytes; for this reason higher programmed values than 0x7 will still result with 64 bytes burst.
			Note: This field is read-write when P0CMD.ST=0 and read-only when P0CMD.ST=1.
11-8	TXABL	0-Fh	Transmit Burst Limit. This field allows software to limit the OCP master read burst size. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1.
			Note: SATASS master breaks the burst at 1Kbyte address boundaries regardless of the TXABL value.
		0	Limit OCP burst size to 256 DWORDS
		1h	Limit OCP Burst size to 1 DWORD
		2h	Limit OCP Burst size to 2 DWORDs
		3h	Limit OCP Burst size to 4 DWORDs
		4h	Limit OCP Burst size to 8 DWORDs
		5h	Limit OCP Burst size to 16 DWORDs
		6h	Limit OCP Burst size to 32 DWORDs
		7h	Limit OCP Burst size to 64 DWORDs
		9h-Fh	Limit OCP Burst size to 256 DWORDs
			Note: The maximum sized burst that will be issued on the OCP is 64 bytes; for this reason higher programmed values than 0x7 will still result with 64 bytes burst.

Table 20-36. Port DMA Control Register (P#DMACR) Field Description (continued)

Bit	Field	Value	Description
7-4	RXTS	0-Fh	Receive Transaction Size (RX_TRANSACTION_SIZE). This field defines the Port DMA transaction size in DWORDs for receive (system bus write, device read) operation. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. The maximum value of this bit field is determined by the Rx FIFO Depth (P0_RXFIFO_DEPTH). If software attempts to write a value exceeding this maximum value, the maximum value would be set instead.
		0	1 DWORD
		1h	2 DWORDs
		2h	4 DWORDs
		3h	8 DWORDs
		4h	16 DWORDS
		5h	32 DWORDs
		6h	64 DWORDs
		7h-Fh	Reserved
3-0	TXTS	0-Fh	Transmit Transaction Size (TX_TRANSACTION_SIZE). This field defines the DMA transaction size in DWORDs for transmit (system bus read, device write) operation. This bit field is read/write when P0CMD.ST = 0 and read-only when P0CMD.ST = 1. The maximum value of this bit field is determined by the Tx FIFO Depth (P0_TXFIFO_DEPTH). If software attempts to write a value exceeding this maximum value, the maximum value would be set instead.
		0	1 DWORD
		1h	2 DWORDs
		2h	4 DWORDs
		3h	8 DWORDs
		4h	16 DWORDS
		5h	32 DWORDs
		6h-Fh	Reserved

20.4.34 Port PHY Control Register (P#PHYCR) (# = 0 or 1)

The port PHY control register (P#PHYCR) is used to control the PHY. These ports are configured for the WIZ6C2B2N5W0M (Maverick B2) macro. Refer to that spec for further details.

Note: This description is only valid for configuration GS60. See the corresponding P0PHYSR Register description for each configuration.

The P#PHYCR register is shown in Figure 20-35 and described in Table 20-37.

Figure 20-35. Port PHY Control Register (P#PHYCR)

Table 20-37. Port PHY Control Register (P#PHYCR) Field Descriptions (continued)

Bit	Field	Value	Description
15-13	RXCDR	0-7h	Receiver Clock/data Recovery. Configures the clock/data recovery algorithm.
		0	First order, threshold of 1. Phase offset tracking up to +/-488ppm. Suitable for use in asynchronous systems with low frequency offset.
		1h	First order, threshold of 17. Phase offset tracking up to +/-325ppm. Suitable for use in synchronous systems. Offers superior rejection of random jitter, but is less responsive to systematic variation such as sinusoidal jitter.
		2h	Second order, high precision, threshold of 1. Highest precision frequency offset matching but relatively poor response to changes in frequency offset, and long lock time. Suitable for use in systems with fixed frequency offset.
		3h	Second order, high precision, threshold of 1. Highest precision frequency offset matching but relatively poor response to changes in frequency offset, and long lock time. Suitable for use in systems with fixed frequency offset.
		4h	Second order, high precision, threshold of 1. Highest precision frequency offset matching but relatively poor response to changes in frequency offset, and long lock time. Suitable for use in systems with fixed frequency offset.
		5h	Second order, high precision, threshold of 1. Highest precision frequency offset matching but relatively poor response to changes in frequency offset, and long lock time. Suitable for use in systems with fixed frequency offset.
		6h	Reserved.
		7h	Reserved.
12	RXLOS		Loss of Signal Detection.
			Note: This must be enabled by software before initialization is started on the device.
			Note: Refer to PHY CFGR2 Register for what value is actually programmed into the SERDES. In most cases, only the default will have to be used.
		0	Disabled.
		1	Enabled.
11-10	LOOPBACK		Transmitter and Receiver Loopback Selection.
		0	Transmitter – Disabled
			Receiver – Disabled
		1h	Transmitter – Reserved
			Receiver – Reserved
		2h	Transmitter – Loopback, TX Driver Disabled. The loopback path covers all the stages of the transmitter except the TX output itself. A differential current is passed to the receiver. The magnitude of this current is dependent on SWING. The transmitter driver itself is disabled.
			Receiver – Reserved (N/A)
		3h	Transmitter – Loopback, TX Driver Enabled. As above, but the transmit driver operates normally.
			Receiver – Loopback. The differential current from the transmitter is converted to a voltage and applied to the receiver input if LOS is disabled, or to the Loss of Signal detector if LOS is enabled.
9	RXINVPAIR	0	Receiver Invert Polarity. Inverts the polarity of RXP# and RXN#.
8-7	CLKBYP		Clock Bypass. Facilitates bypassing of the PLL with either REFCLKP/N or TESTCLKT, and bypassing of the recovered receiver clock with TESTCLKR.
			Note: This field applies to Port 0 only, P0PHYCR. This bit is reserved for Port 1, P1PHYCR.
		0	No bypass. Macro operates normally from the PLL.
		1h	Reserved.
		2h	Functional Bypass. The macro operates functionally at low speed using TESTCLKT and TESTCLKR.
		3h	REFCLK Observe. The PLL is bypassed by REFCLKP/N. This diagnostic capability is designed to facilitate observation of the reference clock from macros containing transmitters

Table 20-37. Port PHY Control Register (P#PHYCR) Field Descriptions (continued)

Bit	Field	Value	Description
6-5	LB		Loopback. Enables Loopback.
			Note: This field applies to Port 0 only, P0PHYCR. This bit is reserved for Port 1, P1PHYCR.
		0	Disabled.
		1h	Reserved.
		2h	Inner loopback, CML driver disabled. The loopback path is fully digital and excludes the transmit CML driver and receive sense amps. The transmit CML driver is disabled.
		3h	Inner loopback, CML driver enabled. As above, but the CML driver operates normally.
4-1	MPY	0-Fh	PLL Multiply. Select PLL multiply factors between 5 and 20.
			The MPY factor along with the SERDES_CLKP/N frequency is what determines the required data rate. Full Rate corresponds to 3Gbps Line Rate (Gen2) and Half Rate corresponds to 1.5Gbps Line Rate (Gen1).
			Example: If SERDES_CLKP/N is300MHz, then MPY=4'b0001 (5x).
			Note: This field should only be written before or at the same time while enabling the ENPLL field. You should not change MPY field after the PLL is enabled.
			Note: This field applies to Port 0 only, P0PHYCR. This field is reserved for Port 1, P1PHYCR.
		0	4x
		1h	5x
		2h	6x
		3h	8x
		4h	8.25x
		5h	10x
		6h	12x
		7h	12.5x
		8h	15x
		9h	16x
		Ah	16.5x
		Bh	20x
		Ch	22x
		Dh	25x
		Eh	Reserved.
		Fh	Reserved.
0	ENPLL		Enable PHY PLL. This bit must be written to 1 to enable the PHY's PLL and use the link.
			Note: This must be enabled by software before initialization is started on the device.
			Note: This bit should not be enabled unless the MPY field has been previously set or is being set in the same write. Changing the MPY field while the PLL is enabled disrupts the link clocks and may disrupt the link, requiring a port reset to fix.
			Note: This field applies to Port 0 only, P0PHYCR. This bit is reserved for Port 1, P1PHYCR.
		0	Disabled.
		1	Enabled.

20.4.35 Port PHY Status Register (P#PHYSR) (# = 0 or 1)

The port PHY status register (P#PHYSR) is used to reflect the PHY status. Note: In multi-port configurations, each of these registers will read identically, P0PHYSR and P1PHYSR have the same value.

The P#PHYSR register is shown in Figure 20-36 and described in Table 20-38.

Figure 20-36. Port PHY Status Register (P#PHYSR)

31	16
Reserved	
R-0

LEGEND: R = Read only; -*n* = value after reset

Table 20-39. Idle Register (IDLE) Field Description

Bit	Field	Value	Description
31-18	Reserved	0	Reserved.
17	OVERRIDE1		Override for Clock Stopping. Normally the functional clock can only be stopped if the link is put into partial or slumber power mode. However, if there is no device attached (such as in a removable media situation) or the device has not been started the user may wish to stop the functional clocks but not be able to enter a low power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low power state. **WARNING:** If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low power state it will ruin the link and cause undetermined behavior. A port reset or full SATASS reset may be required to recover.
		0	Normal.
		1	Override.
16	OVERRIDE0		Override for Clock Stopping. Normally the functional clock can only be stopped if the link is put into partial or slumber power mode. However, if there is no device attached (such as in a removable media situation) or the device has not been started the user may wish to stop the functional clocks but not be able to enter a low power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low power state. **WARNING:** If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low power state it will ruin the link and cause undetermined behavior. A port reset or full SATASS reset may be required to recover.
		0	Normal.
		1	Override.
15-4	Reserved	0	Reserved.
3-2	STANDBYMODE		This gives direct control to the standby_mode control of the standby generic.
1-0	IDLEMODE		This gives direct control to the idle_mode control of the idle generic. **Note:** Only force idle mode is supported.

20.4.37 PHY Configuration Register 2 (PHYCFGR2)

The Idle Register (IDLE) is used to control the idle and standby modes.

The Idle Register (IDLE) is shown in Figure 20-38 and described in Table 20-40.

Figure 20-38. PHY Configuration Register 2 (PHYCFGR2)

Table 20-40. PHY Configuration Register 2 (PHYCFGR2) Field Description

Bit	Field	Value	Description
31-10	Reserved	0	Reserved.
9-8	P1ALIGN		Port 1 ALIGN –this register is used to directly control the ALIGN (comma alignment enable) on the SERDES. Comma alignment defaults to 0x1 (ON) and in most cases will never have to be changed. However, if a system is experiencing a large amount of incorrect commas detected, software may use this register to disable comma alignment after a link has been negotiated.
		0	Alignment Disabled.
		1h	Comma Alignment Enabled.
		2h	Alignment Jog.
		3h	Reserved.
7-6	P0ALIGN		Port 0 ALIGN – this register is used to directly control the ALIGN (comma alignment enable) on the SERDES. Comma alignment defaults to 0x1 (ON) and in most cases will never have to be changed. However, if a system is experiencing a large amount of incorrect commas detected, software may use this register to disable comma alignment after a link has been negotiated.
		0	Alignment Disabled.
		1h	Comma Alignment Enabled.
		2h	Alignment Jog.
		3h	Reserved.
5-3	P1LOS		Port 1 LOS –This register is used to directly control the Loss-of-Signal configuration for the SERDES macro on port 1. When the LOS detection is enabled in the **Error! Reference source not found.** based on the LOS bit, this is the value that will be fed directly into the SERDES. Usually, only the default will need to be used. However, if silicon variations cause the LOS detection threshold to need to be adjusted, this register can be used to do so.
2-0	P0LOS		Port 0 LOS –This register is used to directly control the Loss-of-Signal configuration for the SERDES macro on port 1. When the LOS detection is enabled in the **Error! Reference source not found.** based on the LOS bit, this is the value that will be fed directly into the SERDES. Usually, only the default will need to be used. However, if silicon variations cause the LOS detection threshold to need to be adjusted, this register can be used to do so.

Timers

This chapter describes the operation of the software-programmable timer.

Topic **Page**

21.1 Introduction

21.1.1 Overview

The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written in real-time (while counting). The timer module includes compare logic to allow an interrupt event on a programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and a matched event. This output can be used as a timing stamp trigger signal or PWM (pulse-width modulation) signal source. An additional dedicated output signal (PORGPOCFG) can be used for general-purpose IO, directly driven by bit 14 of the Timer Control Register (TCLR). Based on the programmable input signal transition type, a dedicated signal can be used to trigger an automatic timer counter capture event and generate an interrupt. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled or disabled.

This module is controllable through the OCP peripheral bus.

As two clock domains are managed inside this module, resynchronization is done by special logic between the OCP clock domain and the Timer clock domain. At reset, synchronization logic allows utilization of all ratios between the OCP clock and the Timer clock. A drawback of this mode is that the full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clock ratios, write-posted mode can be used by setting the POSTED bit of the Timer Synchronous Interface Control Register (TSICR). Under posted mode, the OCP write command is granted before the write process is complete in the timer clock domain. This mode allows software to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at the software level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

21.1.2 Features

The timer consists of the following features:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Programmable divider clock source
- 16-32 bit addressing
- “On the fly” read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

The Timer resolution and interrupt period are dependent on the selected input clock and clock prescale value. Example resolutions for common clock values are shown in Table 21-1.

Table 21-1. Timer Resolution and Maximum Range

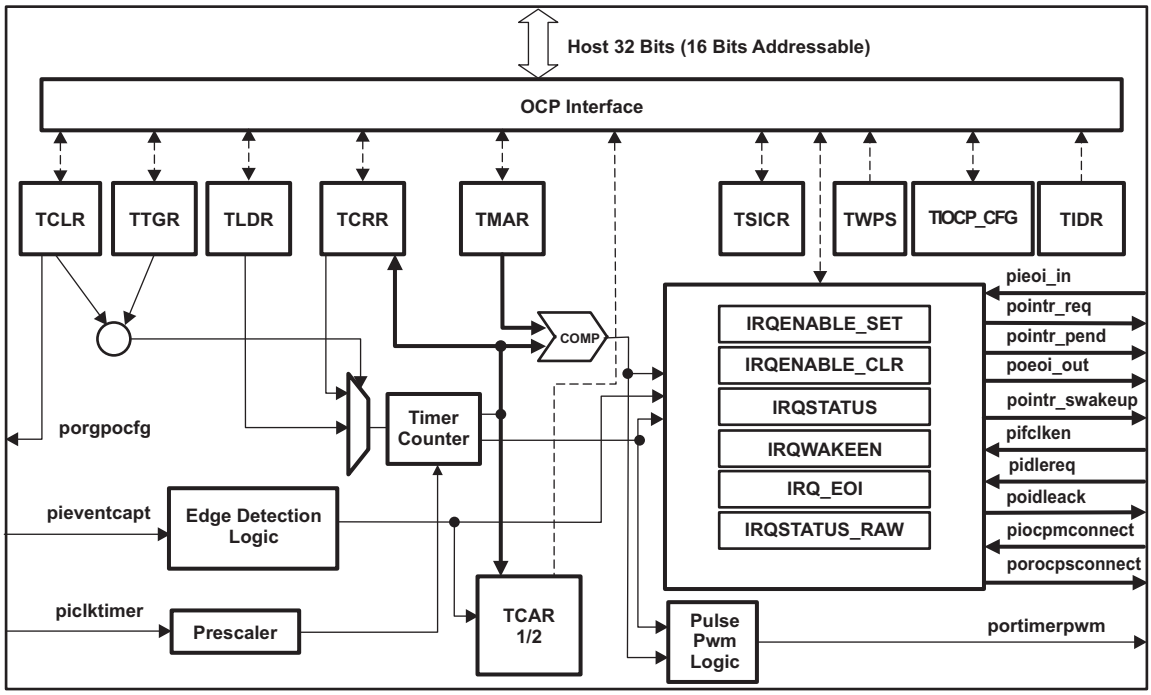
Clock	Prescaler	Resolution	Interrupt Period Range[1]
32 KHz	1 (min)	31.25 us	62.5 us to ~37h 17m
	256 (max)	8 ms	16 ms to ~397d 16h 22m
27 MHz	1 (min)	~37 ns	~74 ns to ~159s
	256 (max)	~9.48 us	~18.9 us to ~11h 18m
38.4 MHz	1 (min)	~26 ns	~52 ns to ~112 s
	256 (max)	~6.7 us	~13.3 us to ~7h 57m

(1) Minimum calculation adheres to recommendation of 2 clock cycle minimum between interrupts.

21.1.3 Functional Block Diagram

Figure 21-1 shows a block diagram of the timer.

Figure 21-1. Timer Block Diagram

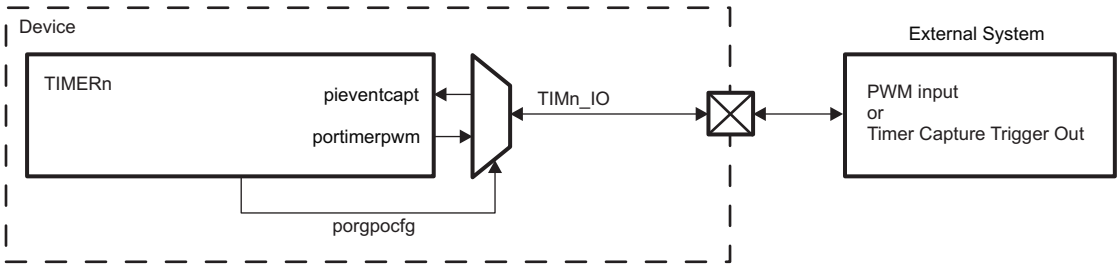


21.1.4 GP Timer External System Interface

The general-purpose (GP) timer can send or receive stimulus to/from the external (off-chip) system. In the device, however, only certain timers are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. See the device-specific data manual details on which timers have IO capabilities.

Figure 21-2 shows the external system interface for the GP timers.

Figure 21-2. GP Timers External System Interface



NOTE: For the timers with IO capabilities, the PORGPOCFG output signal selects the timer PWM output or the timer capture input signal to the TIMn_IO pad at the top level. When TCLR[GPO_CFG] = 1, TIMn_IO functions as a capture input. When TCLR[GPO_CFG] = 0, TIMn_IO functions as a PWM output.

21.2 Architecture

21.2.1 Functional Description

The general-purpose timer is an upward counter. It supports 3 functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

21.2.1.1 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the ST bit of the Timer Control Register (TCLR). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register (TLDR), due to a write access to the Timer Trigger Register (TTGR). TCRR is loaded regardless of the TTGR written value. The TCRR value can be read when stopped or captured on-the-fly by a TCRR read access. The timer is stopped and the counter value is cleared to “0” when the module’s reset is asserted. The timer is maintained in a stopped state after reset is released. When the timer is stopped, TCRR does not increment. The counter can be restarted from the frozen value unless TCRR has been reloaded with a new value.

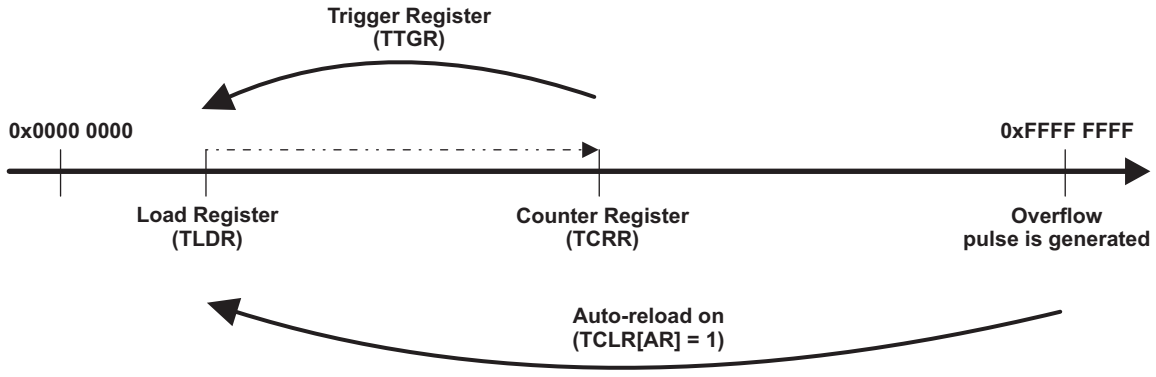
When the one-shot mode is enabled (TCLR[AR] = 0), the counter is stopped after a counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR[AR] = 1), TCRR is reloaded with the Timer Load Register (TLDR) value after a counting overflow.

It is not recommended to put the overflow value (FFFF FFFFh) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow, if the overflow interrupt enable bit is set in the Timer IRQENABLE Set Register (IRQENABLE_SET[OVF_EN_FLAG] = 1). In addition, a dedicated output pin can be used to generate one positive pulse (piclktimer duration) or to invert the current value (toggle mode) when an overflow occurs. Refer to Section 21.2.1.5 for more details related to the dedicated pulse-width modulation (PWM) output pin.

Figure 21-3. TCRR Timing Value



21.2.1.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trig the timer counter capture. The module sets the IRQSTATUS (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

- If TCLR's CAPT_MODE field is 0 then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it.
- If TCLR's CAPT_MODE field is 1 then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served - TCAR_IT_FLAG bit of IRQSTATUS (previously 1) is cleared. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Input negative or positive pulse can be detected when pulse time is above functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register IRQENABLE_SET (TCAR_IT_FLAG bit).

In Figure 21-4, the TCM value is 01 and CAPT_MODE is 0 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

In Figure 21-5, the TCM value is 01 and CAPT_MODE is 1 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 21-4. Capture Wave Example for CAPT_MODE = 0

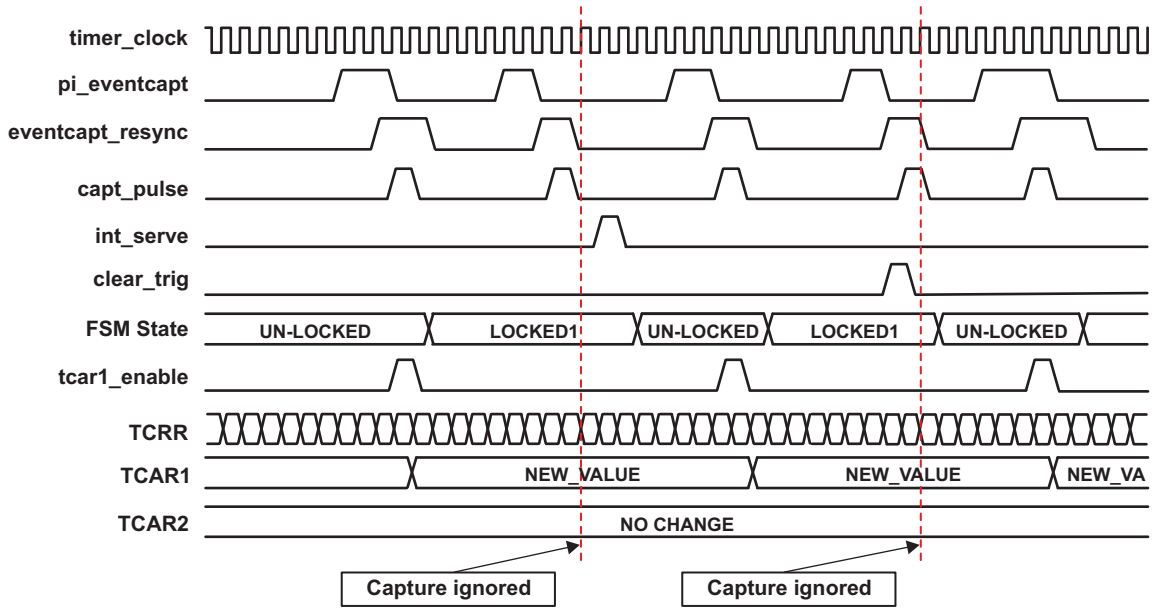


Figure 21-5. Capture Wave Example for CAPT_MODE = 1

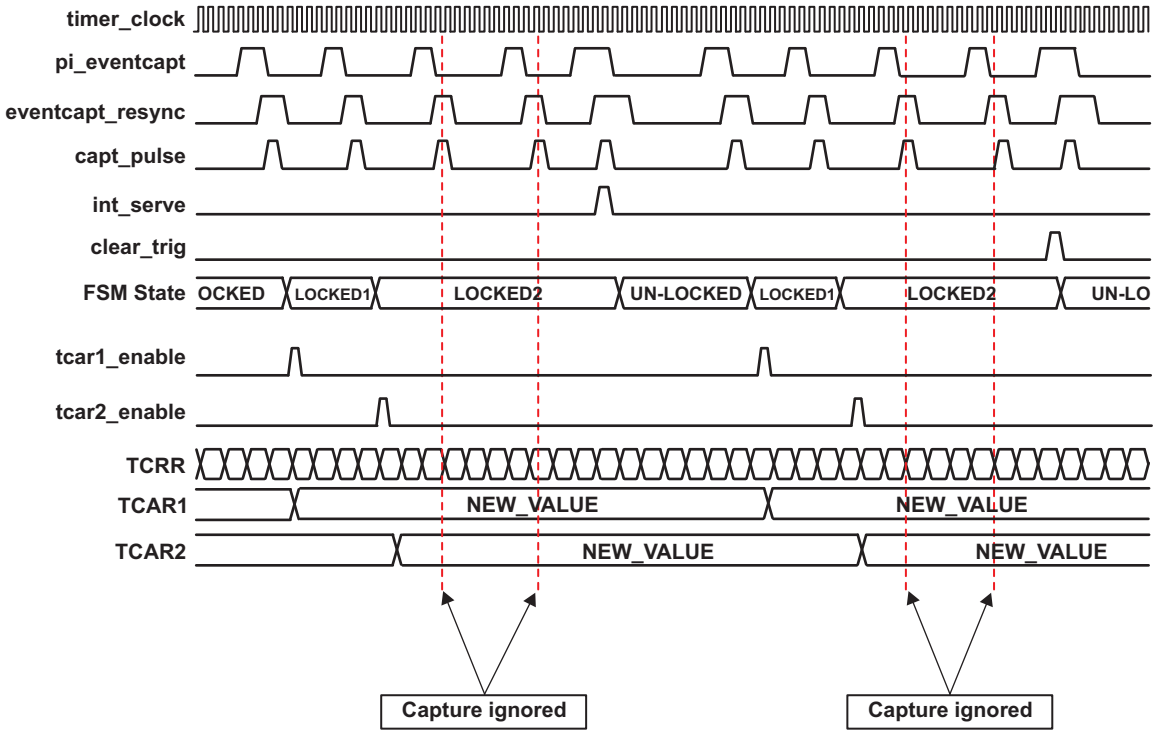

21.2.1.3 Compare Mode Functionality

When the Compare Enable bit of the Timer Control Register (TCLR[CE]) is set to 1, the timer value in the Timer Counter Register (TCRR) is permanently compared to the value held in the Timer Match Register (TMAR). The TMAR value can be loaded at any time (timer counting or stopped). When the TCRR and the TMAR values match, an interrupt can be issued if the match interrupt enable bit is set in the Timer IRQENABLE Set Register (IRQENABLE_SET[MAT_EN_FLAG] = 1). Software should write a compare value in the TMAR register before setting the TCLR[CE] bit to avoid any unwanted interrupt due to a reset value matching effect.

A dedicated output pin can be used to generate one positive pulse (piclktimer duration) or to invert the current value (toggle mode) when an overflow and a match occur. Refer to Section 21.2.1.5 for more details related to the dedicated pulse-width modulation (PWM) output pin.

21.2.1.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when the PRE bit of the Timer Control Register (TCLR[PRE]) is set. The 2^n division ratio value (PTV) can be configured in the TCLR register. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly. Refer to Section 21.2.1.6 for more details on the prescaler clock ratio values.

Table 21-2. Prescaler Functionality

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	Reset	TLDR
TCRR Write	Reset	TCRR
TTGR Write	Reset	TLDR
Stop	Reset	Frozen

21.2.1.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PWM) output on a dedicated output pin (PORTIMERPWM). The PORTIMERPWM output pin can be configured to toggle on a specified event. The TRG field of the Timer Control Register (TCLR[TRG]) determines the trigger event when the PORTIMERPWM pin toggles. Either overflow or the combination of both overflow and match can be used to toggle the PORTIMERPWM pin.

When both overflow and match are configured to trigger the PWM pin, the matched event will be ignored from the moment the mode was set-up until the first overflow event occurs (see Figure 21-7).

The SCPWM bit in the TCLR register can be programmed to set or clear the PORTIMERPWM output signal only while the counter is stopped or the triggering is disabled. This allows fixing a deterministic state of the output pin while modulation is stopped. The modulation is synchronously stopped when the TRG bit is cleared and overflow occurs.

In the following timing diagrams, the internal overflow pulse is set each time an overflow occurs in the Timer Counter Register (TCRR), and the internal match pulse is set when the counter reaches the Timer Match Register (TMAR) value. Depending on the configured value of the TRG and PT bits of the TCLR register, the timer generates one pulse or inverts the current value on the output pin (PORTIMERPWM).

The Timer Load Register (TLDR) and Timer Match Register (TMAR) must keep values smaller than the overflow value (FFFF FFFFh) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the TLDR and TMAR registers must be at least 2 units. When match event is used, the CE bit of the TCLR register must be set.

In Figure 21-6, TCLR[SCPWM] is cleared to 0. In Figure 21-7, TCLR[SCPWM] is set to 1.

Figure 21-6. Timing Diagram of Pulse-Width Modulation with SCPWM = 0

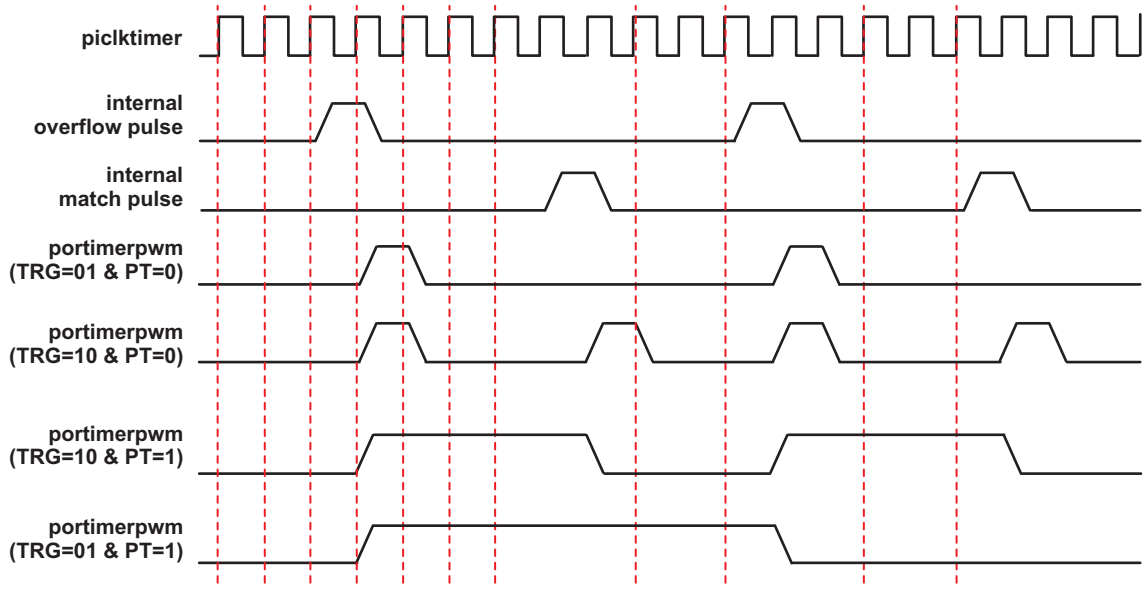

Figure 21-7. Timing Diagram of Pulse-Width Modulation with SCPWM = 1

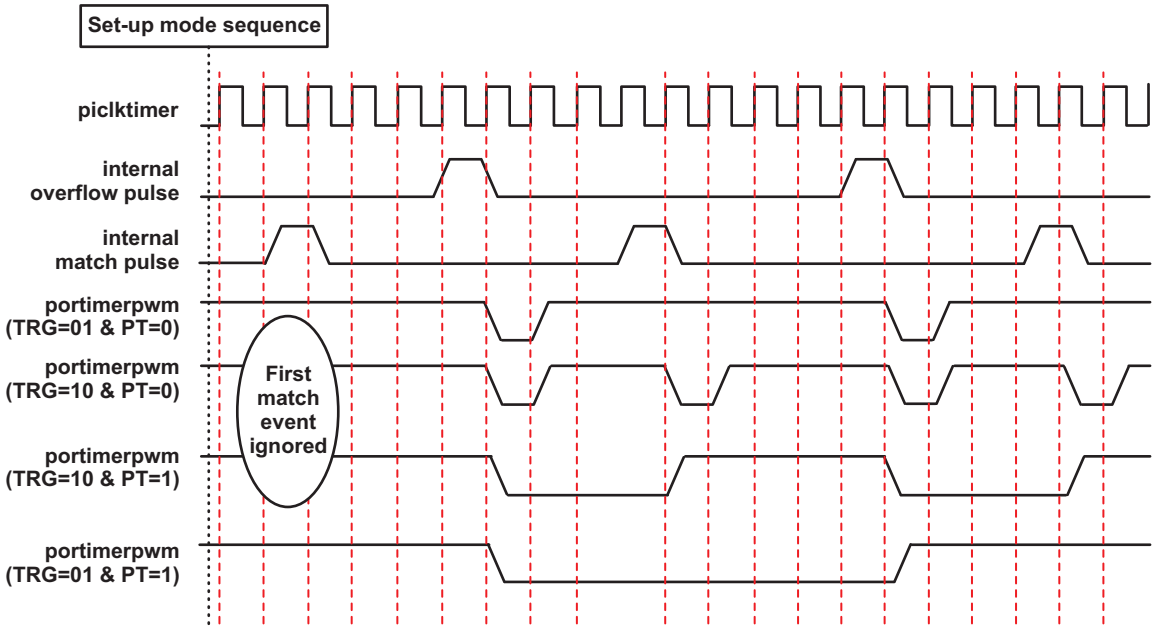

21.2.1.6 Timer Counting Rate

The timer counter is composed of a prescaler stage and a timer counter. The prescaler stage is clocked with the timer input clock and acts as a clock divider for the timer counter stage. The ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR). See Table 21-3.

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 21-3. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

(FFFF FFFFh – TLDR + 1) × timer Clock period × Clock Divider (PS)

With timer Clock period = 1/ timer Clock frequency and PS = $2^{(PTV + 1)}$.

As an example, if we consider a timer clock input of 32 kHz, with a PRE field equal to 0, the timer output period is:

Table 21-4. Value and Corresponding Interrupt Period

TLDR	Interrupt period
0000 0000h	~37 h
FFFF 0000h	~2 s
FFFF FFF0h	500 µs
FFFF FFFEh	62.5 µs

21.2.1.7 Dual Mode Timer Under Emulation

During emulation mode (when PINSUSPENDN signal is active), the timer can/cannot continue running according to the value of the EmuFree bit of the timer OCP configuration register (TIOCP_CFG).

If EmuFree is 1, timer execution is not stopped and, regardless of the value of PINSUSPENDN signal, and the interrupt assertion is still generated when overflow is reached.

If EmuFree is 0, counters (prescaler/timer) are frozen and an increment start occurs again as soon as PINSUSPENDN becomes inactive. The asynchronous input pin is internally synchronized on 2 TIMER clock rising edges.

21.2.2 Accessing Registers

All registers are 32-bit wide, accessible via OCP interface with 16-bit or 32-bit OCP access (Read/Write). The 32-bit registers write update in 16 bits access must be LSB16 first and the second write access must be MSB16. For the write operation, the module allows skipping the MSB access if the user does not need to update the 16 MSB bits of the register, but only for the OCP registers (TIDR, TIOCP_CFG, IRQ_EOI, IRQSTATUS_RAW, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN and TSICR). The write operation on any functional register (TCLR, TCRR, TLDR, TTGR and TMAR) must be complete (the MSB must be written even if the MSB data is not used).

21.2.2.1 Programming the Timer Registers

The TLDR, TCRR, TCLR, TIOCP_CFG, IRQ_EOI, IRQSTATUS, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TTGR, TSICR and TMAR registers write is done synchronously with OCP clock, by the host, using the OCP bus protocol.

21.2.2.2 Reading the Timer Registers

The counter register (TCRR) is a 32-bit “atomic datum” and 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. Atomic capture is also performed for the TCAR1 and TCAR2 registers as they may change due to internal processes. DSP 16 bit accesses can be interleaved with MCU 32 bit accesses.

21.2.2.3 OCP Error Generation

The timer module responds with error indication in the following cases:

Error on write transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase.

Error on read transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase. PORSDATA in this case is not valid.

Table 21-5. OCP Error Reporting

Error Type	Response: SRESP = ERR
Unsupported PIOCPMCMD command	Yes
Address error: Read or write to a non-existing internal address	No
Read to write-only registers and write to read-only registers	No
Unaligned address (PIOCPMADDR ≠ 00) on read/write transaction	Yes
Unsupported PIOCPMBYTEEN on read/write transaction	Yes

NOTE: Byte enable “0000” is a supported byte enable.

21.2.3 Posted Mode Selection

A choice between the two synchronization modes will be made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to functional registers that require synchronization on/from timer clock domain. For write operation the registers affected by this posted/non-posted selection are: TCLR, TLDR, TCRR, TTGR and TMAR. For read operation the register affected by this posted/non-posted selection are: TCRR, TCAR1 and TCAR2.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, TISTAT, IRQ_EOI,IRQSTATUS,IRQSTATUS_RAW, IRQENABLE_SET, IRQENABLE_CLR, IRQWAKEEN, TWPS and TSICR are not affected by the posted/non-posted mode selection; the write/read operation is effective and acknowledged (command accepted) after one OCP clock cycle from the command assertion.

The configuration posted/non-posted is made by setting the PIFREQRATIO when the module is integrated. The PIFREQRATIO signal should be tied to '1' when the freq (timer) < freq (OCP)/4 frequency, and tied to 0 when it is the opposite frequency ratio. The PIFREQRATIO represent the reset value of the TSICR (POSTED bit). The configuration can be changed (overwritten) by software, writing the TSICR (POSTED bit) register.

The following cases are possible:

- Posted Mode can be used when the functional frequency range is: freq (timer) < freq (OCP)/4.
- Non-Posted Mode can be used regardless of the frequency range. Recommended frequency is: freq (timer) >= freq (OCP)/4.

NOTE: The Non-Posted Mode can be also used when freq (timer) < freq (OCP)/4, but it is recommended to use the Posted Mode. Using Non-Posted Mode will delay the command accept and the transaction latency will be as described in the below chapters. Posted mode offers an OCP interface latency improvement and can be used only if the frequencies respect the freq (timer) < freq (OCP)/4 formula.

21.2.4 Write Registers Access

21.2.4.1 Write Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-write scheme to update any internal register. The write transaction is immediately acknowledged on the OCP interface, although the effective write operation will occur later, due to a resynchronisation in the timer clock domain. This has the advantage of not stalling either the interconnect system, or the CPU that requested the write transaction. For each register, a status bit is provided, that is set if there is a pending write access to this register.

In this mode, it is mandatory that the CPU checks the status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can lead to unexpected results also).

There is one status bit per register, accessible in the Timer Write Posted Status Register. When the timer module operates in this mode, there is an automatic sampling of the current timer counter value, in an OCP-synchronized capture register. Consequently, any read access to the timer counter register does not add any re-synchronization latency; the current value is always available.

A register read following a write posted register (on the same register) is not insured to read the previous write value if the write posted process is not completed. Software synchronization should be used to avoid non-coherent read.

The drawback of this automatic update mechanism is that it assumes a given relationship between the OCP interface frequency and the timer functional frequency.

This posted period is defined as the interval between the posted write access request and the reset of the posted bit in TWPS register, and can be quantified:

T (reset posted max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

21.2.4.2 Write Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-write scheme to update any internal register. That means the write transaction will not be acknowledged on the OCP interface, until the effective write operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and CPU are stalled.
- An interconnect logic, including time-out logic to detect erroneous transactions, can generate an unwanted system abort event.

The stall period is defined as the interval between the non-posted write access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

A register read following a write to the same register is always coherent.

21.2.5 Read Registers Access

21.2.5.1 Read Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-read scheme, for reading any internal register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been previously resynchronised. This has the advantage of not stalling either the interconnect system, or the CPU that requested the read transaction.

21.2.5.2 Read Non-Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-read scheme, for reading any internal register. The read transaction will not be acknowledged on the OCP interface, until the effective read operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and the CPU are stalled.
- An interconnect system including time-out logic to detect erroneous transactions can generate an unwanted system abort event.

This mode only applies only to three registers: TCRR, TCAR1 and TCAR2, which need resynchronisation from functional to OCP clock domains.

The stall period is defined as the interval between the non-posted read access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the value is sampled is:

T (read sample) = 1 OCP clock + 2.5 TIMER clock

21.3 Timer Registers

The timer registers are listed in Table 21-6. All registers are:

- 32-bit register accessible in 16-bit mode
- Little-endian addressing

Table 21-6. Timer Registers

Offset	Acronym	Register Name	Section
00h	TIDR	Identification Register	Section 21.3.1
10h	TIOCP_CFG	Timer OCP Configuration Register	Section 21.3.2

0	ST	R/W	0	In the case of one-shot mode selected (AR = 0), this bit is automatically reset by internal logic when the counter is overflowed. 0 = Stop timer: Only the counter is frozen 1 = Start timer

21.3.10 TCRR Register

The TCRR register is a 32-bit register, 16-bit addressable. The MCU can perform a 32-bit access or two 16-bit accesses to access the register while the DSP performs 2 consecutive 16-bit transactions. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCRR value is not read while it is being incremented.

In 16-bit mode the following sequence must be followed to read the TCRR register properly:

First, perform an OCP Read Transaction to Read the lower 16-bit of the TCRR register (offset = 3Ch). When the TCRR is read and synchronized, the lower 16-bit LSBs are driven onto the output OCP data bus and the upper 16-bit MSBs of the TCRR register are stored in a temporary register.

Second, perform an OCP Read Transaction to read the upper 16-bit of the TCRR register (offset = 3Eh). During this Read, the value of the upper 16-bit MSBs that has been temporary register is forwarded onto the output OCP data bus.

So, to read the value of TCRR correctly, the first OCP read access has to be to the lower 16-bit (offset = 3Ch), followed by OCP read access to the upper 16-bit (offset = 3Eh).

As the TCRR is updated using more sources (shadow_in_tcrr, incremented value of tcrr, TLDR and “0”), a priority order will be defined:

The first priority is the OCP update.

The second is the reload way (triggered through TTGR reg. or following an auto-reload overflow).

The third is the one-shot overflow reset to 0.

The last is the incremented value.

31-0	TTGR_VALUE	R/W	FFFF FFFFh	Any write to the TTGR register will load the value from TLDR into TCRR and clear the prescaler counter. This will occur regardless of the AR field value in the TCLR register. A read access of TTGR will always return FFFF FFFFh.

21.3.13 TWPS Register

In posted mode the software must read the pending write status bits (Timer Write Posted Status register bits [4:0]) to insure that following write access will not be discarded due to on going write synchronization process. These bits are automatically cleared by internal logic when the write to the corresponding register is acknowledged.

Table 21-20. TMAR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	COMPARE_VALUE	R/W	0	Value to be compared to the timer counter

21.3.15 TCAR1 Register

When the appropriate (rising, falling or both) transition is detected in the edge detection logic the current counter value is stored to the TCAR1 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR1 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR1 register properly:

First, perform an OCP Read Transaction to Read the lower 16-bits of the TCAR1 register.

Second, perform an OCP Read Transaction to read the upper 16-bits of the TCAR1 register.

21.3.16 TSICR Register

Access to this register is not stalled even if the timer is in non-posted mode configuration. To abort any wrong behavior, software can permanently reset the functional part of the module. Also in case of a wrong hardware PIFREQRATIO tied the POSTED field can be reprogrammed on the fly, so deadlock situation cannot happen.

Reset value of POSTED depends on hardware integration module at design time. Software must read POSTED field to get the hardware module configuration.

21.3.17 TCAR2 Register

When the appropriate (rising, falling or both) transition is detected in the edge detection logic and the capture on second event is activated from the control register (TCLR), the current counter value is stored to the TCAR2 register. Note that since the OCP clock is completely asynchronous with the timer clock, some synchronization is done in order to make sure that the TCAR2 value is not read while it is being updated due to some capture event.

In 16-bit mode the following sequence must be followed to read the TCAR2 register properly:

First, perform an OCP Read Transaction to Read the lower 16-bits of the TCAR2 register.

Second, perform an OCP Read Transaction to read the upper 16-bits of the TCAR2 register.

Watchdog Timer

This chapter describes the watchdog timer.

Topic **Page**

22.1 Introduction

22.1.1 Overview

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The watchdog timer serves resets to the PRCM module and serves watchdog interrupts to the host subsystem. The reset of the PRCM module causes warm reset of the device.

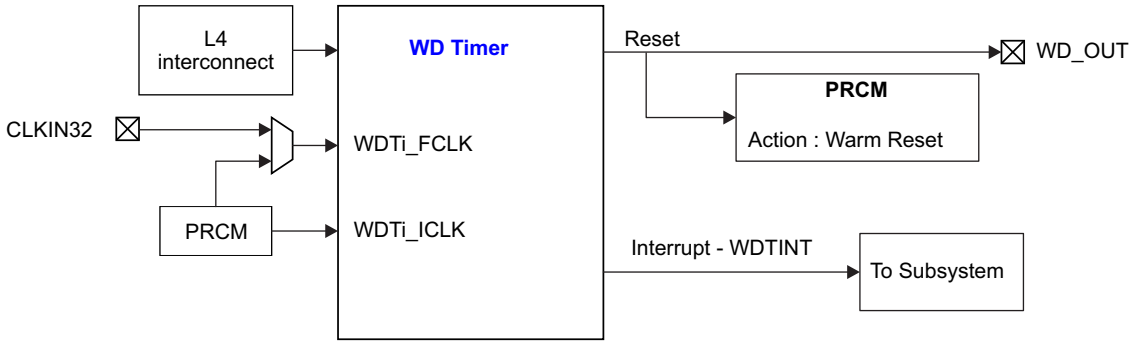
The watchdog timer can be accessed, loaded, and cleared by registers through the L4 interface. The watchdog timer has the 32-kHz clock for its timer clock input.

The watchdog timer connects to a single target agent port on the L4 interconnect. The default state of the watchdog timer is enabled and not running.

22.1.2 Functional Block Diagram

Figure 22-1 shows a block diagram of the watchdog timer.

Figure 22-1. Watchdog Timer Block Diagram



22.1.3 Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where n = 0-7)
- On-the-fly read/write register (while counting)
- Subset programming model of the timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration.

22.1.4 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

22.2 Architecture

22.2.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is a 32 kHz watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is a 125 MHz watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

In this device, the watchdog timer clocks are always On. The clocks cannot be turned off, if the watchdog timer is not being used.

22.2.2 Interrupts

Table 22-1 list the event flags, and their masks, that cause module interrupts.

Table 22-1. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTINT	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTINT	Watchdog delay value reached

22.2.3 General Watchdog Timer Operation

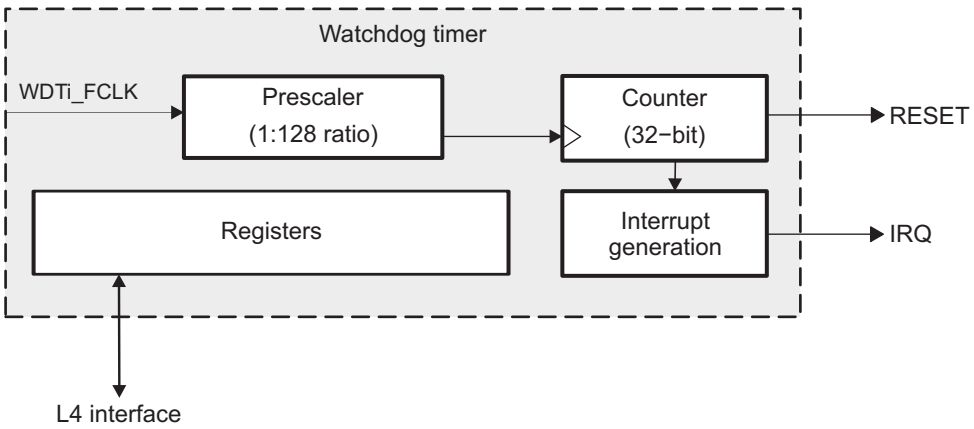
The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. Figure 22-2 is a functional block diagram of the watchdog timer.

The interrupt generation mechanism is controlled through the WDT_WIRQENSET/WDT_WIRQENCLR and WDT_WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WDT_WCLR[4:2] PTV bit field and the WDT_WCLR[5] PRE bit of the watchdog control register (WDT_WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WDT_WCRR), can be modified by accessing the watchdog timer load register (WDT_WLDR) (no on-the-fly update), or can be reloaded by following a specific reload sequence on the watchdog timer trigger register (WDT_WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WDT_WSPR) can start and stop the watchdog timers.

Figure 22-2. 32-Bit Watchdog Timer Functional Block Diagram



22.2.4 Reset Context

The watchdog timers are enabled after reset. Table 22-2 lists the default reset values of the two watchdog timer load registers (the WDT_WLDR) and prescaler ratios (the WDT_WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WDT_WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 22-2. Count and Prescaler Default Reset Values

Timer	WDT_WLDR Reset Value	PTV Reset Value
WDT	FFFF FFBEh	0

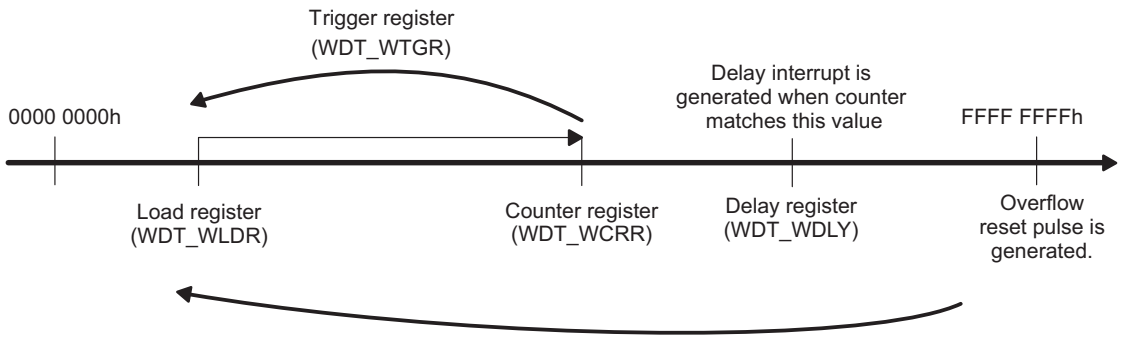
22.2.5 Overflow/Reset Generation

When the watchdog timer counter register (WDT_WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This RESET pulse causes the PRCM module to generate global WARM reset of the device. It is also driven out of the device through the WD_OUT pin. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDT_WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 22-3 shows a general functional view of the watchdog timers.

Figure 22-3. Watchdog Timers General Functional View



22.2.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDT_WCLR[5] PRE bit and the WDT_WCLR[4:2] PTV bit field)
- Value loaded into the timer load register (WDT_WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDT_WCLR[4:2] PTV bit field) and is enabled with the WDT_WCLR[5] PRE bit.

Table 22-3 lists the prescaler clock ratio values.

Table 22-3. Prescaler Clock Ratio Values

WDT_WCLR[5] PRE	WDT_WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (FFFF FFFFh – WDT_WLDR + 1) × (wd-functional clock period) × PS

where wd-functional clock period = 1/(wd-functional clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WDT_WSPR before WDT_WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WDT_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 1 (clock divided by 2) and WDT_WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 22-4.

Table 22-4. Reset Period Examples

WDT_WLDR Value	Reset Period
0000 0000h	74 h 56 min
FFFF 0000h	4 s
FFFF FFF0h	1 ms
FFFF FFFFh	62.5 us

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WDT_WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDT_WLDR[31:0] = FFFF FFFFh is a special case, although such a value of WDT_WLDR is meaningless. When WDT_WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 22-5 lists the default reset periods for the watchdog timers.

Table 22-5. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
WDT	32 kHz	2 s

22.2.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (WDT_WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT_WTGR register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WDT_WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

22.2.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register (WDT_WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write XXXX AAAAh in WDT_WSPR.
2. Write XXXX 5555h in WDT_WSPR.

To enable the timer, follow this sequence:

1. Write XXXX BBBBh in WDT_WSPR.
2. Write XXXX 4444h in WDT_WSPR.

All other write sequences on the WDT_WSPR register have no effect on the start/stop feature of the module.

22.2.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WDT_WCRR register), prescaler ratio (the WDT_WCLR[4:2] PTV bit field), delay configuration value (the WDT_WDLY[31:0] DLY_VALUE bit field), or the load value (the WDT_WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WDT_WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WDT_WTGR register).

22.2.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the WDT_WCRR register because the WDT_WCRR register is directly related to the timer counter value and is updated on the timer clock (WDT_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDT_ICLK) is completely asynchronous with the timer clock (WDT_FCLK), some synchronization is performed to ensure that the value of the WDT_WCRR register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside WDT_WCRR, the first read access is to the lower 16 bits (offset = 8h), followed by read access to the upper 16 bits (offset = Ah).

22.2.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF or WDT_WIRQSTAT[1] EVENT_DLY bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDT_WIRQSTAT register. Reading the WDT_WIRQSTAT register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register (WDT_WIRQENSET[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF bit) is set to 1. The output interrupt line (WDT_IRQ) is asserted (active low) when status (EVENT_OVF) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register (WDT_WIRQENSET[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDT_WDLY), the corresponding interrupt status bit is set in the watchdog status register (WDT_WIRQSTAT) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the WDT_WIRQSTAT and WDT_WIRQENSET registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WDT_WIRQSTAT[0] EVENT_OVF bit or the WDT_WIRQSTAT[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register (WDT_WIRQSTAT).

The WDT_WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WDT_WLDR) and the programmed value in this register (WDT_WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDT_WDLY – WDT_WLDR + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WDT_WCRR) reaches the programmed value (WDT_WDLY), the status bit (EVENT_DLY) gets set in the interrupt status register (WDT_WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WDT_WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (WDT_WDLY[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register (WDT_WDLY) is less than the value stored in the counter load register (WDT_WLDR).

22.2.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can/cannot continue running, according to the value of the WDT_WDSC[5] EMUFREE bit of the system configuration register (WDT_WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

22.2.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WWPS

NOTE: Accesses to WDT2 and WDT3 are posted.

22.3 Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

22.3.1 Global Initialization

22.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 22-6).

Table 22-6. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled.
Control module	Module-specific pad multiplexing must be set in the control module.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer.

22.3.1.2 Main Sequence – Watchdog Timer Module Global Initialization

Table 22-7 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 22-7. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	1

22.3.2 Operational Mode Configuration

22.3.2.1 Main Sequence – Watchdog Timer Basic Configuration

Table 22-8 lists the steps for the basic configuration of the watchdog timer.

Table 22-8. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 22.3.2.2.	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 22.3.2.3.	

22.3.2.2 Subsequence – Disable the Watchdog Timer

Table 22-9 lists the steps to disable the watchdog timer.

Table 22-9. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WDT_WSPR	XXXX AAAAh
Write disable sequence Data2.	WDT_WSPR	XXXX 5555h

22.3.2.3 Subsequence – Enable the Watchdog Timer

Table 22-10 lists the steps to enable the watchdog timer.

Table 22-10. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WDT_WSPR	XXXX BBBBh
Write enable sequence Data2.	WDT_WSPR	XXXX 4444h

22.4 Watchdog Timer Registers

The watchdog timer registers are listed in Table 22-11. For the base address of these registers, see Table 1-12.

CAUTION

The watchdog timers registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

NOTE:

- The WDT_WISR and WDT_WIRQSTATRAW registers have the same functionality. The WDT_WISR register is used for software backward compatibility.
- The WDT_WIER and WDT_WIRQENSET/WDT_WIRQENCLR registers have the same functionality. The WDT_WIER register is used for software backward compatibility.
- The WDT_WIRQSTATRAW and WDT_WIRQSTAT registers give the same information when read. The WDT_WIRQSTATRAW register is used for debug.

Table 22-11. Watchdog Timer Registers

Bit	Field	Type	Reset	Description
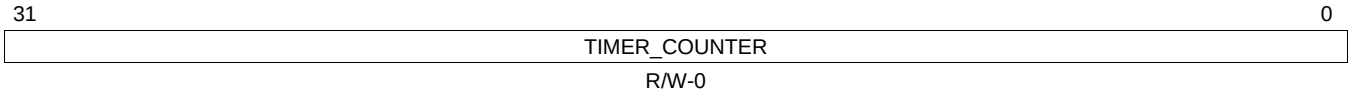
31-6	Reserved	R	0	Reads return 0.
5	PRE	R/W	1	Prescaler enable/disable configuration 0 = Prescaler disabled 1 = Prescaler enabled
4-2	PTV	R/W	0	Prescaler value The timer counter is prescaled with the value: 2**PTV. Example: PTV = 3 then counter increases value if started after 8 functional clock periods. On reset, it is loaded from PI_PTV_RESET_VALUE input port.
1-0	Reserved	R	0	Write 0s for future compatibility. Reads return 0.

22.4.7 WDT_WCRR Register

The WDT_WCRR register holds the value of the internal counter.

It is shown and described in the figure and table below.

Figure 22-10. WDT_WCRR Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-18. WDT_WCRR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TIMER_COUNTER	R/W	0	Value of the timer counter register

22.4.8 WDT_WLDR Register

The WDT_WLDR register holds the timer load value.

It is shown and described in the figure and table below.

Figure 22-11. WDT_WLDR Register

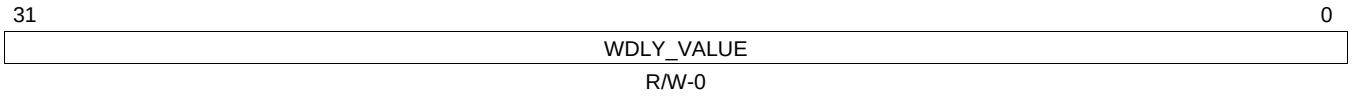
22.4.11 WDT_WDLY Register

ThE WDT_WDLY register holds the delay value that controls the internal pre-overflow event detection.

Figure 22-14. WDT_WDLY



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

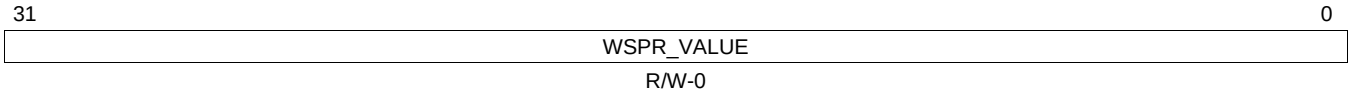
Table 22-22. WDT_WDLY Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	WDLY_VALUE	R/W	0	Value of the delay register

22.4.12 WDT_WSPR Register

The WDT_WSPR register holds the start-stop value that controls the internal start-stop FSM.

Figure 22-15. WDT_WSPR Register



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 22-23. WDT_WSPR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	WSPR_VALUE	R/W	0	Value of the start-stop register

22.4.13 WDT_WIRQSTATRAW Register

IRQ unmasked status, status set per-event raw interrupt status vector, line 0. Raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug.

Figure 22-16. WDT_WIRQSTATRAW Register

31	2	1	0
Reserved		EVENT_DLY	EVENT_OVF
R-0		R/W1S-0	R/W1S-0

UART/IrDA/CIR Module

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module.

Topic **Page**

23.1 Introduction

23.1.1 Main Features

The main features of each of the UARTs are:

- Selectable UART/IrDA/CIR modes
- 16C750 compatibility
- Dual 64 entry FIFOs for received and transmitted data payload
- Programmable and selectable transmit and receive FIFO trigger levels for DMA and interrupt generation
- Programmable sleep mode
- Complete status reporting capabilities in both normal and sleep mode
- Frequency prescaler values from 0 to 16383 to generate the appropriate baud rates
- Internal system clock reference for baud setting (In this document, a 48 MHz reference clock is considered. For more information on reference clock support, see your device-specific data manual)
- Two DMA requests, 1 interrupt request to the system
- Break character detection and generation
- Configurable data format
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART/IrDA module can operate in six different modes:

- UART 16× mode
- UART 16× mode with autobauding (greater than or equal to 1200 bits/s and less than or equal to 115.2 Kbits/s)
- UART 13× mode
- IrDA SIR mode (less than or equal to 115.2 Kbits/s)
- IrDA MIR mode (0.576 and 1.152 Mbits/s)
- IrDA FIR mode (4 Mbits/s)
- CIR mode (programmable modulation rates specific to remote control applications)

23.1.2 UART/Modem Functions

The UART/Modem has the following functions:

- Baud-rate from 300 bits/s up to 3.6864 Mbits/s (with a 48 MHz reference clock)
- Auto-baud between 1200 bits/s and 115.2 Kbits/s
- Software/Hardware flow control
  - Programmable Xon/Xoff characters
  - Programmable auto-RTS and auto-CTS
- Programmable serial interface characteristics
  - 5, 6, 7, or 8 bit characters
  - Even, odd, mark (always = 1), space (always = 0) or no parity (non parity bit frame) bit generation and detection
  - 1, 1.5, or 2 stop bit generation
- False start bit detection
- Line break generation and detection
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities
- Modem control functions ($\overline{\text{CTS}}$, $\overline{\text{RTS}}$, $\overline{\text{DSR}}$, $\overline{\text{DTR}}$, RIN, and $\overline{\text{DCD}}$)

23.1.3 IrDA Functions

The IrDA has the following functions:

- Slow infrared (SIR 115.2 KBAUD), medium infrared (MIR 0.576 MBAUD) and fast infrared (FIR 4.0 MBAUD) operations (very fast infrared (VFIR) is not supported)
- Framing error, cyclic redundancy check (CRC) error, illegal symbol (FIR), abort pattern (SIR, MIR) detection
- 8-entry status FIFO (with selectable trigger levels) available to monitor frame length and frame errors

23.1.4 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR includes the following key features to provide CIR support for remote control applications:

- Consumer Infrared remote control mode with programmable data encoding
- Transmit and receive modes supported
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

23.2 Architecture

23.2.1 UART Signal Descriptions

Table 23-1 describes the UART interface.

Table 23-1. UART Signal Description

Signal	I/O	Description	Reset
RX	I	Serial data input for all modes.	Unknown
TX	O	Serial data output in UART modes. In other modes, this pin is set to the reset value (inactive state).	1
IRTX	O	Serial data output in IrDA modes (SIR, MIR and FIR). In other modes, this pin is set to the reset value (inactive state).	0
RCTX	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
$\overline{CTS}$	I	Clear to send. Active-low modem status signal. Reading bit 4 of the modem status register checks the condition of $\overline{CTS}$. Reading bit 0 of that register checks a change of state of $\overline{CTS}$ since the last read of the modem status register. $\overline{CTS}$ is used in auto-CTS mode to control the transmitter.	Unknown
$\overline{RTS}$	O	Request to send. When active (low), the module is ready to receive data. Setting modem control register bit 1 activates $\overline{RTS}$. It becomes inactive as a result of a module reset, loop back mode or by clearing the MCR[1]. In auto-RTS mode, it becomes inactive as a result of the receiver threshold logic.	1
SD	O	SD mode is used to configure the transceivers. The SD pin out is an inverted value of ACREG[6].	1
$\overline{DSR}$	I	Data set ready: Active-low modem status signal. Reading bit 5 of the modem status register checks the condition of $\overline{DSR}$. Reading bit 1 of that register checks a change of state of $\overline{DSR}$ since the last read of the modem status register.	Unknown
$\overline{DTR}$	O	Data terminal ready: When active (low), this signal informs the modem that the module is ready to communicate. It is activated by setting bit 0 of the modem control register.	1
$\overline{DCD}$	I	Data carrier detect: Active-low modem status signal. The condition of $\overline{DCD}$ can be checked by reading bit 7 of the modem status register and any change in its state can be detected by reading bit 3 of that register.	Unknown
RIN	I	Ring indicator: Active-low modem status signal. The condition of RIN can be checked by reading bit 6 of the modem status register and any change in its state can be detected by reading bit 2 of that register.	Unknown

NOTE: Not all UART instances on a specific device support the full pinout shown here. Refer to the device data manual for details

23.2.2 UART/IrDA/CIR Mode Selection

To select a mode, set the MODESELECT field in MDR1[2:0] (see Table 23-2).

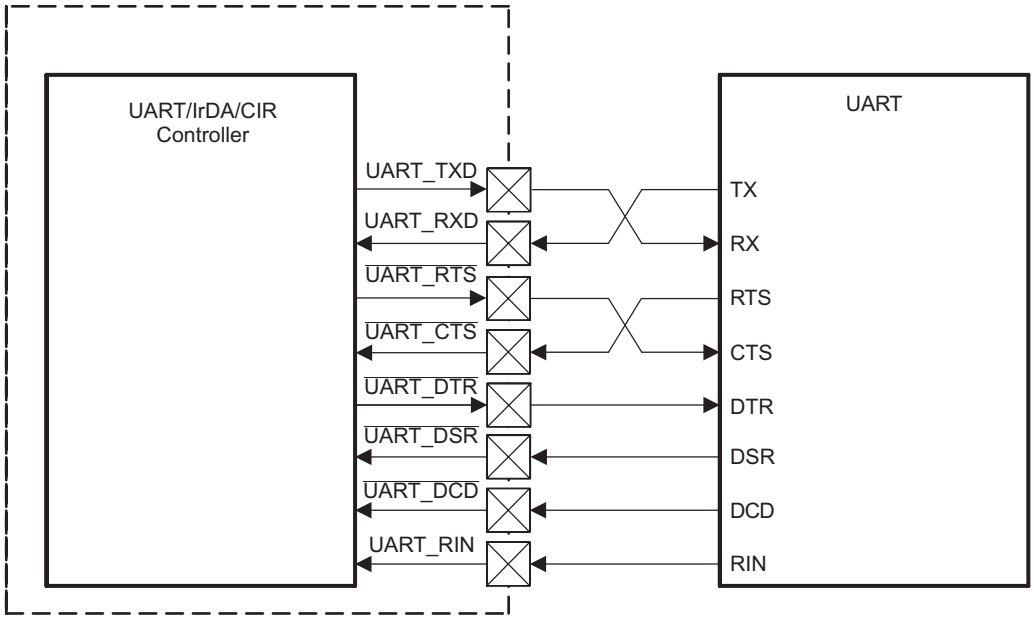
Table 23-2. UART Mode Selection

MDR1[2:0] Value	Mode
0h	UART 16x mode
1h	SIR mode
2h	UART 16x auto-baud
3h	UART 13x mode
4h	MIR mode
5h	FIR mode
6h	CIR mode
7h	Disable (default state)

23.2.3 UART Mode

This section describes how the UART functions in UART wired mode. Figure 23-1 shows how to connect the UART operating in UART mode to another UART on an external device.

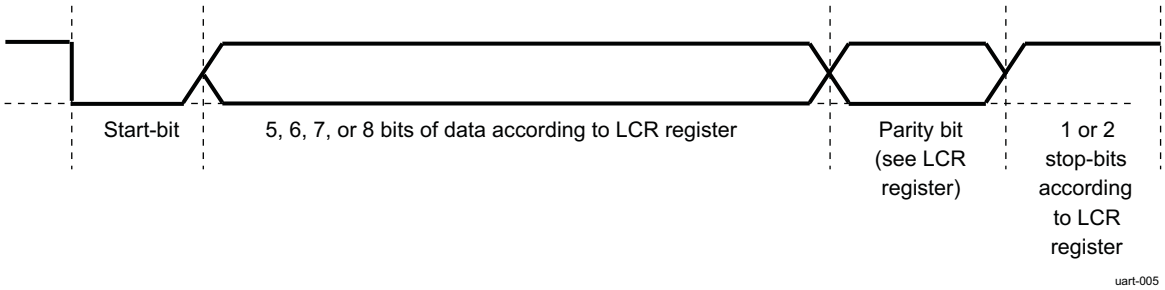
Figure 23-1. UART to UART Connection With Full Handshaking



The UART uses a wired interface for serial communication with a remote device. It can use hardware or software flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the $\overline{\text{RTS}}$ output and $\overline{\text{CTS}}$ input signals. Software flow control automatically controls data flow by using programmable XON/XOFF characters.

The UART modem module is enhanced with an autobauding functionality, which in control mode allows to automatically set the speed, the number of bit per character, and the parity selected. Figure 23-2 shows the UART frame data format. Each frame consists of a start bit, 5 to 8 data bits (user configurable), an optional parity bit (user configurable), and 1 or 2 stop bits (user configurable).

Figure 23-2. UART Frame Data Format



23.2.3.1 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming EFR[7:6]. With auto-CTS, $\overline{CTS}$ must be active before the module can transmit data.

Auto-RTS only activates the $\overline{RTS}$ output when there is enough room in the RX FIFO to receive data and de-activates the $\overline{RTS}$ output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the TCR determine the levels at which $\overline{RTS}$ is activated/de-activated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

23.2.3.1.1 Auto-RTS

Auto-RTS data flow control originates in the receiver block (see functional block diagram). The receiver FIFO trigger levels used in auto-RTS are stored in the TCR. $\overline{RTS}$ is active if the RX FIFO level is below the HALT trigger level in TCR[3:0]. When the receiver FIFO HALT trigger level is reached, $\overline{RTS}$ is de-asserted. The sending device (for example, another UART) may send an additional byte after the trigger level is reached because it may not recognize the de-assertion of $\overline{RTS}$ until it has begun sending the additional byte. $\overline{RTS}$ is automatically reasserted once the receiver FIFO reaches the RESUME trigger level programmed via TCR[7:4]. This reassertion requests the sending device to resume transmission.

23.2.3.1.2 Auto-CTS

The transmitter circuitry checks $\overline{CTS}$ before sending the next data byte. When $\overline{CTS}$ is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, $\overline{CTS}$ must be de-asserted before the middle of the last stop bit that is currently being sent. The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the $\overline{CTS}$ state changes need not trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO and a receiver overrun error can result.

23.2.3.2 Software Flow Control

Software flow control is enabled through the enhanced feature register (EFR) and the modem control register (MCR). Different combinations of software flow control can be enabled by setting different combinations of EFR[3:0]. There are two other enhanced features relating to software flow control:

- XON any function (MCR[5]): operation will resume after receiving any character after recognizing the XOFF character. The XON-any character is written into the RX FIFO even if it is a software flow character.
- Special character (EFR[5]): Incoming data is compared to XOFF2. Detection of the special character sets the XOFF interrupt (IIR[4]) but does not halt transmission. The XOFF interrupt is cleared by a read of the IIR. The special character is transferred to the RX FIFO.

23.2.3.2.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission is halted after completing transmission of the current character. XOFF detection also sets IIR[4] (if enabled via IER[5]) and causes the interrupt line to go low. To resume transmission a XON1/2 character must be received (in certain cases XON1 and XON2 must be received sequentially). When the correct XON characters are received IIR[4] is cleared and the XOFF interrupt disappears.

NOTE: If a parity, framing or break error occurs while receiving a software flow control character, this character will be treated as normal data and will be written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled no valid XON or XOFF characters are written to the RX FIFO. For example, EFR[1:0] = 10, if XON1 and XOFF1 characters are received they do not get written to the RX FIFO. In the case where pairs of software flow characters are programmed to be received sequentially (EFR[1:0] = 11) the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

23.2.3.2.2 Transmit (TX)

- XOFF1: Two characters are transmitted when the RX FIFO has passed the programmed trigger level TCR[3:0].
- XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed via TCR[7:4].

NOTE: If after an XOFF character has been sent, software flow control is disabled, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF/XON (s) follows the exact same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to be 5, 6 or 7 characters then the 5, 6 or 7 least significant bits of XOFF1,2/XON1,2 are transmitted. Note that the transmission of 5, 6, or 7 bits of a character is seldom done but this functionality is included to maintain compatibility with earlier designs. It is assumed that software flow control and hardware flow control will never be enabled simultaneously.

23.2.3.3 Break and Time-Out Conditions

23.2.3.3.1 Time-Out Counter

An RX idle condition is detected when the receiver line, RX, has been high for a time equivalent to 4X programmed word length+12 bits. The receiver line is sampled midway through each bit. For sleep mode the counter is reset when there is activity on the RX line. For the timeout interrupt, the counter only counts when there is data in the RX FIFO and the count is reset when there is activity on the RX line or when the RHR is read.

23.2.3.3.2 Break Condition

When a break condition occurs, the TX line is pulled low. A break condition is activated by setting LCR[6]. Be aware that the break condition is not aligned on word stream; that is, a break condition can occur in the middle of a character. The only way to send a break condition on a full character, is:

- Reset transmit FIFO (if enabled)
- Wait for transmit shift register becomes empty (LSR[6] = 1)
- Take a guard time according to stop bit definition
- Set LCR[6] to 1

A break condition is asserted as long as LCR[6] is set to 1. The above functionality (timeout counter and break condition) only applies to the UART Modem operation and does not extend to the IrDA/CIR modes of operation.

NOTE: A break condition is asserted irrespective of CTS state when auto-CTS is programmed.

23.2.3.4 UART Configuration Example

This section proposes outlines the programming stages to operate one UART module with FIFO, interrupt and no DMA capabilities. This is a three-step procedure that ensures quick start of these modules (obviously it does not cover every UART module feature). The first stage covers SW reset of the module (interrupts, status and controls); the second stage deals with FIFO configuration and enable. Finally, last stage deals with the baud rate data and stop configuration. The procedure below is programming language agnostic.

23.2.3.4.1 UART Software Reset

Goal: To clear IER and MCR registers: remove UART breaks (LCR[6] = 0) and put module in reset (MDR1[2:0] = 7h).

Procedure: To write into both the IER and MCR register, EFR[4] must first be set to 1. To be able to access the EFR register, BFh must first be written to LCR register. Hence LCR = BFh; first write to the LCR register EFR[4] = 1. When LCR = BFh, enable the enhanced feature register LCR[7] = 0. Here, access to IER and MCR is allowed. IER = 0; disable interrupt MCR = 0. Force control signals inactive LCR[6] = 0. Here, UART breaks are removed MDR1 = 7h. Here, UART is in reset or disabled. Alternatively, the SYSC[1] can be set to 1 to start a hardware reset from the generic synchronous reset module. The reset progress can be monitored via the SYSS[0]. Once complete the above sequence should ensure the UART is in the equivalent disabled mode with reference to MDR1[2:0].

23.2.3.4.2 UART FIFO Configuration

Goal: To set trigger level for halt/restore (TCR register), set trigger level for transmit/receive (TLR register), and configure FIFO (FCR register).

Procedure: To write into both the TLR and TCR registers, EFR[4] must be set to 1 and MCR[6] to 1. To write into FCR, EFR[4] must be set to 1. Note that EFR[4] = 1 has already been done in the previous section, hence a write to MCR[6] is necessary. MCR[6] = 1; set TCR, TLR, and FCR to the desired value. Here, accesses to TCR, TLR, and FCR must be disabled to avoid any further undesired writes to these registers. Hence, LCR = BFh, provides access to EFR, EFR[4] = 0; LCR[7] = 0; MCR[6] = 0.

23.2.3.4.3 Baud Rate Data and Stop Configuration

Goal: To configure UART data and stop (LCR register). baud rate (DLH and DLL registers), and enable UART operation. In case interrupt capability is added, configuration must be added right before UART enable.

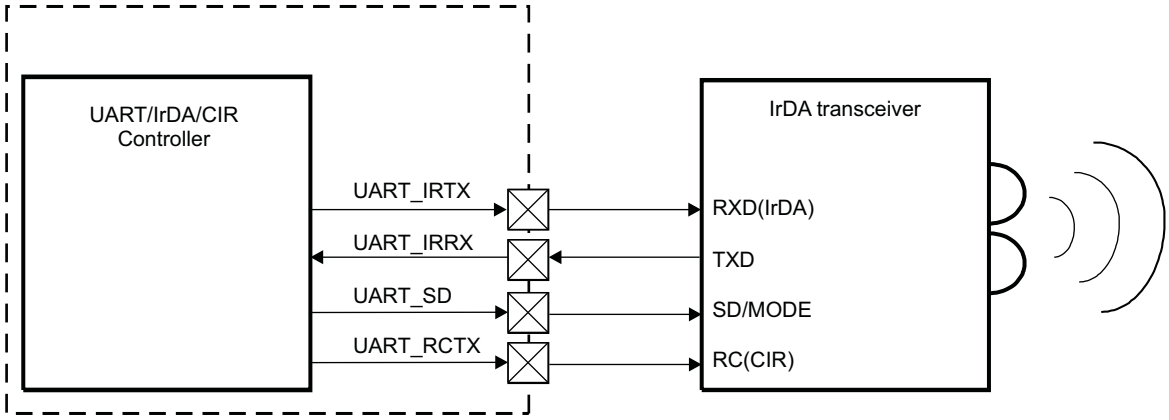
Procedure: Set LCR to desired value; LCR[7] to 1, gives access to DLH and DLL registers. Set DLH and DLL; LCR[7] = 0, removes access to DLH and DLL registers. Set IER to desired value. Set interrupts MDR1[2:0] = 0; enables UART without autobauding.

The UART module is operational.

23.2.4 IrDA Mode

This section describes the IrDA connection with an external device. Figure 23-3 shows how UART3 can be connected to an external infrared transceiver in the IrDA mode.

Figure 23-3. UART IrDA to External IR Device



The module performs serial-to-parallel conversion on received data characters and parallel-to-serial conversion on transmitted data characters by the processor. The complete status of each channel of the module and each received character/frame can be read at any time during functional operation via the line status register (LSR).

The module can be placed in an alternate mode (FIFO mode) relieving the processor of excessive software overhead by buffering received/transmitted characters. Both the receiver and transmitter FIFOs can store up to 64 bytes of data (plus three additional bits of error status per byte for the receiver FIFO) and have selectable trigger levels. Both interrupts and DMA are available to control the data-flow between the LH and the module.

23.2.4.1 SIR Mode

In slow infrared (SIR) mode, data transfer takes place between the LH and peripheral devices at speeds of up to 115200 bauds speed. A SIR transmit frame starts with start flags (either a single C0h, multiple C0h, or a single C0h preceded by a number of FFh flags), followed by frame data, CRC-16 and ends with a stop flag (C1h). The bit format for a single word uses a single start bit, eight data bits and one stop bit and is unaffected by the use and settings of the LCR register.

Note that BLR[6] is used to select whether C0h or FFh start patterns is to be used, when multiple start flags are required. The SIR transmit state machine attaches start flags, CRC-16 and stop flags. It checks the outgoing data to establish if data transparency is required. SIR transparency is carried out if the outgoing data, between the start and stop flags, contains C0h, C1h, or 7Dh. If one of these is about to be transmitted, then the SIR state machine sends an escape character (7Dh) first, then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 7Dh character.

The SIR receive state machine recovers the receive clock, removes the start flags, removes any transparency from the incoming data and determines frame boundary with reception of the stop flag. It also checks for errors such as: frame abort (0x7D character followed immediately by a C1h stop flag, without transparency), CRC error and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

NOTE: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

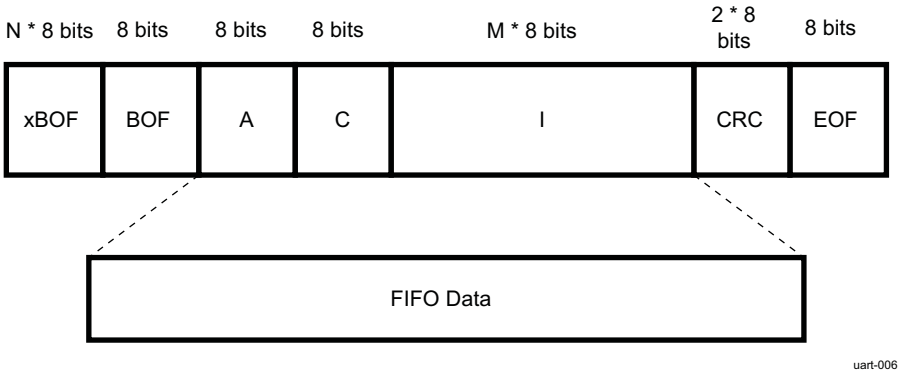
The infrared output in SIR mode can either be 1.6 µs or 3/16 encoding, selected by the PULSETYPE bit of the auxiliary control register (ACREG[7]). In 1.6 µs encoding, the infrared pulse width is 1.6 µs and in 3/16 encoding the infrared pulse width is 3/16 of a bit duration (1/baud-rate). The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

NOTE: Reception supports variable-length stop-bits.

23.2.4.1.1 Frame Format

Figure 23-4 shows the IrDA SIR frame format.

Figure 23-4. IrDA SIR Frame Format



The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

23.2.4.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to C0h (BOF), C1h (EOF), or 7Dh (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 20h)

  The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 20h).
- In reception:

  For the A, C, I, CRC field:
  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

23.2.4.1.3 Abort Sequence

The transmitter may decide to prematurely close a frame. The transmitter aborts by sending following sequence: 7DC1h. The abort pattern closes the frame without a CRC field or an ending flag. It is possible to abort a transmission frame by programming the ABORTEN bit of the auxiliary control register (ACREG[1]). When this bit is set to 1, 7Dh and C1h are transmitted and the frame is not terminated with CRC or stop flags. The receiver treats a frame as an aborted frame when a 7Dh character followed immediately by a C1h character have been received without transparency.

23.2.4.1.4 Pulse Shaping

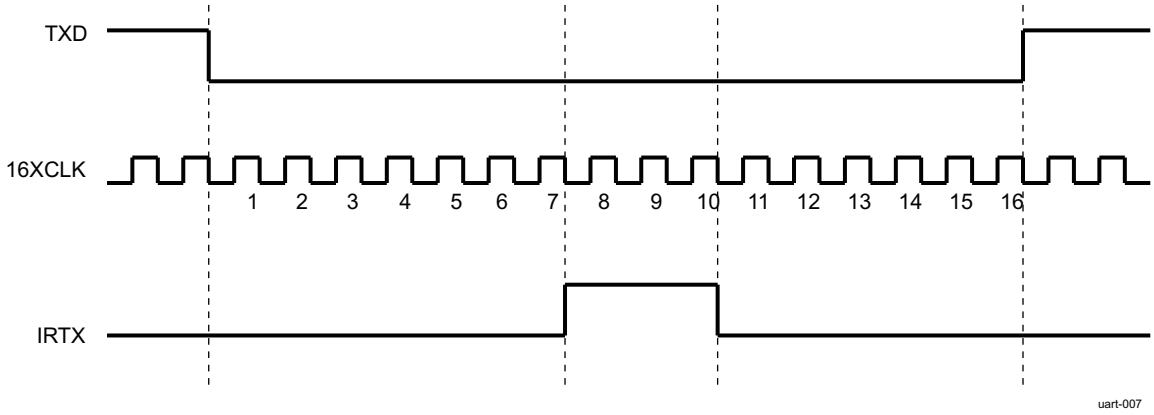
The SIR mode supports both the 3/16th and the 1.6-µs pulse duration methods. The PULSETYPE bit of the auxiliary control register (ACREG[7]) selects the pulse width method in transmit mode.

23.2.4.1.5 Encoder

Serial data from transmit state-machine is encoded to transmit data to the optoelectronics. While the serial data input to the (TXD) is high, the output (IRTX) is always low, and the counter used to form a pulse on IRTX is continuously cleared. After TXD resets to 0, IRTX rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, IRTX falls, creating a 3-clock-wide pulse. While TXD stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 23-5 shows the IrDA SIR encoding mechanism.

Figure 23-5. IrDA SIR Encoding Mechanism

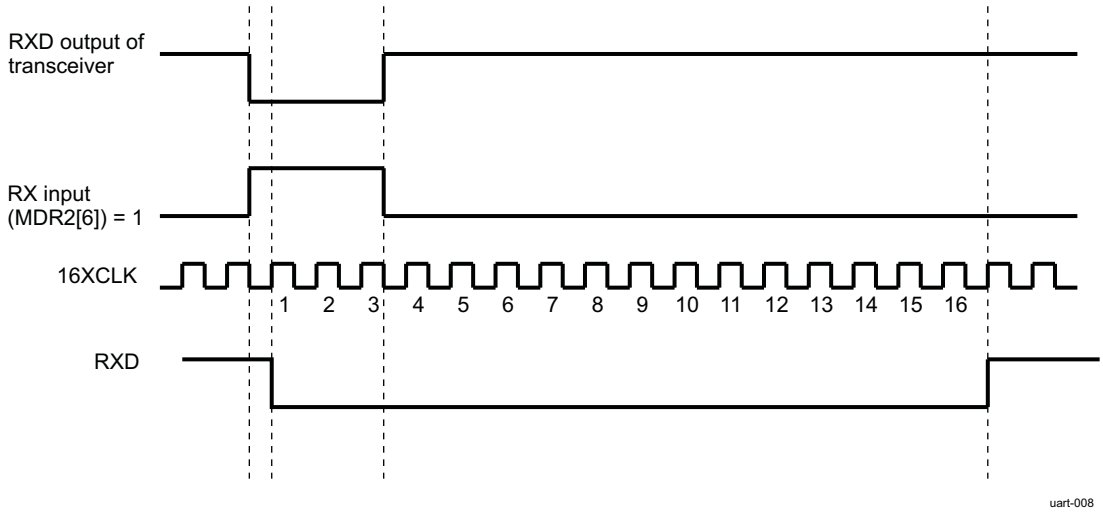


23.2.4.1.6 Decoder

After reset, RXD is high and the 4-bit counter is cleared. When a rising edge is detected on RX, RXD falls on the next rising edge of 16XCLK with sufficient setup time. RXD stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, RXD remains high.

Figure 23-6 shows the IrDA SIR decoding mechanism.

Figure 23-6. IrDA SIR Decoding Mechanism



The operation of the RX input can be disabled with DISIRRX bit of the auxiliary control register (ACREG[5]). Furthermore, the MDR2[6] can be used to invert the signal from the transceiver (RX output) pin to the IRRX logic inside the UART.

23.2.4.1.7 IR Address Checking

In all IR modes, if address checking is enabled, only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multi-point infrared environment. It is possible to program two frame addresses that the UART IrDA receives with XON1/ADDR1 and XON2/ADDR2 registers.

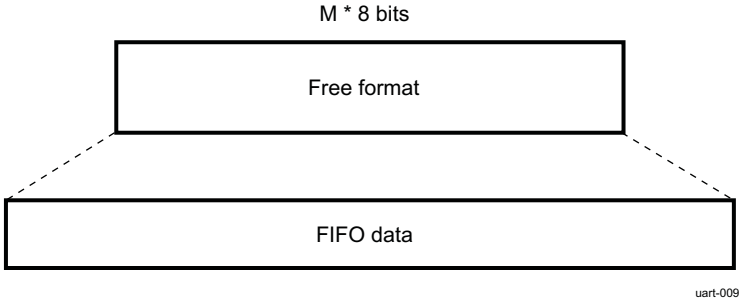
Selecting address1 checking is done by setting EFR[0] to 1; selecting address2 checking is done by setting EFR[1] to 1. Clearing EFR[1:0] to 0 disables all address checking operations. If both bits are set, then the incoming frame is checked for both private and public addresses. If address checking is disabled, then all received frames are written into the reception FIFO.

23.2.4.1.8 SIR Free Format Mode

To allow complete software flexibility in the transmission and reception of Infrared data packets, the SIR Free Format mode is a sub function of the existing SIR mode such that all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values. In transmission phase, it uses the IRTX pin as in SIR mode.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud-rate pulse width. For example, a normal SIR packet has BOF control and CRC error checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs. In SIR Free Format mode only the data termed the FIFO DATA area as shown in Figure 23-7 (and in Figure 23-4) would be transmitted and received.

Figure 23-7. SIR Free Format Mode



In this mode, the entire FIFO data packet is to be constructed (encoded and decoded) by the LH software.

The SIR Free Format mode is selected by setting the module in UART mode (MDR1[2:0] = 000) and the MDR2[3] register bit to one to allow the pulse shaping.

As the bit format is to remain the same, some UART mode configuration register need to be set at specific value:

- LCR[1:0] = 11 (8 data bits)
- LCR[2] = 0 (1 stop bit)
- LCR[3] = 0 (no parity)
- ACREG[7] = 0 (3/16 of baud-rate pulse width)

The features defined through MDR2[6] and ACREG[5] are also supported.

NOTE: All other configuration registers need to be at the reset value.

The UART mode interrupts are used for the SIR Free Format mode but many of them are not relevant (XOFF, RTS, CTS, Modem status register, …….).

23.2.4.1.9 Programming Models

Example 23-1. Receive IrDA

Receive IrDA frame with parity forced to 1, baud-rate = 112.5Kbs, FIFOs disabled.

- MDR1 = 01h
  - MDR1[2:0] = 001b: SIR mode
- LCR = A8h
  - LCR[7] = 1: access to write DLL and DLH
  - LCR[5:3] = 101: set parity type to forced 1 (default: no parity).
  - optional: LCR[2] = 1: set number of stop bits to 2 (default: 1)
  - optional: LCR[1:0] = 11b: set word length to 8 bits (default: 5)
- DLL = 1Ah: 115.2 Kbs
- DLH = 0h: 115.2 Kbs
- LCR = 28h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, RHR
- optional: IER = 1: enable RHR interrupt

Example 23-2. Transmit IrDA

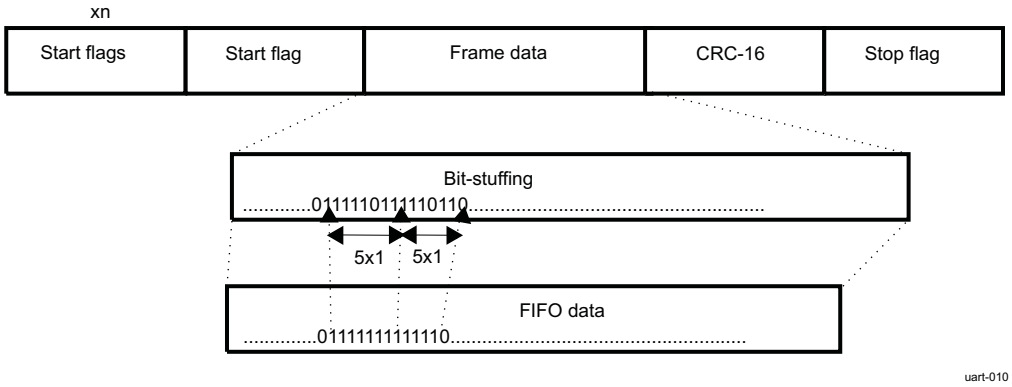
Transmit IrDA 6bytes frame with no parity, baud-rate = 112.5Kbs, FIFOs disabled, 3/16 encoding.

- MDR1 = 41h
  - MDR1[2:0] = 001b: SIR mode
  - MDR1[6] = 1: SIP is generated automatic after each transmission
- LCR = BFh: gives you access to EFR
- EFR = 10h: enhanced functions write enable
- LCR = 86h
  - LCR[7] = 1: access to write DLL and DLH
  - LCR[2] = 1: set number of stop bits to 2 (default: 1)
  - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
- DLL = 1Ah: 115.2 Kbs
- DLH = 0h: 115.2 Kbs
- LCR = 06h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, THR
- MCR =01h: force $\overline{\text{DTR}}$ output to active (low)
- optional: IER = 02h: enable THR interrupt
- TXFLL = 06h: transmit frame length is 6 bytes
- EBLR = 08: transmit 7 starts of frame
- optional: set ACREG[7] = 1: selects SIR pulse width to be 1.6 µs (default 3/16 bit period).
- THR = desired data to be transmitted

23.2.4.2 MIR Mode

In medium infrared (MIR) mode, data transfer takes place between LH and peripheral devices at 0.576 or 1.152 Mbits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16 and ends with a stop flag (see Figure 23-8).

Figure 23-8. MIR Transmit Frame Format



On transmit, the MIR state machine attaches start flags, CRC-16, and stop flags. It also looks for 5 consecutive 1s in the frame data and automatically inserts 0 after 5 consecutive 1s (this is called bit stuffing).

On receive, the MIR receive state machine recovers the receive clock, removes the start flags, de-stuffs the incoming data and determines frame boundary with reception of the stop flag. It also checks for errors such as: frame abort, CRC error or frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of received frame.

Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. Refer to the DISIRRX bit of the auxiliary control register (ACREG[5]) for a description of the logical operation.

NOTE: This applies to all three modes SIR, MIR, and FIR.

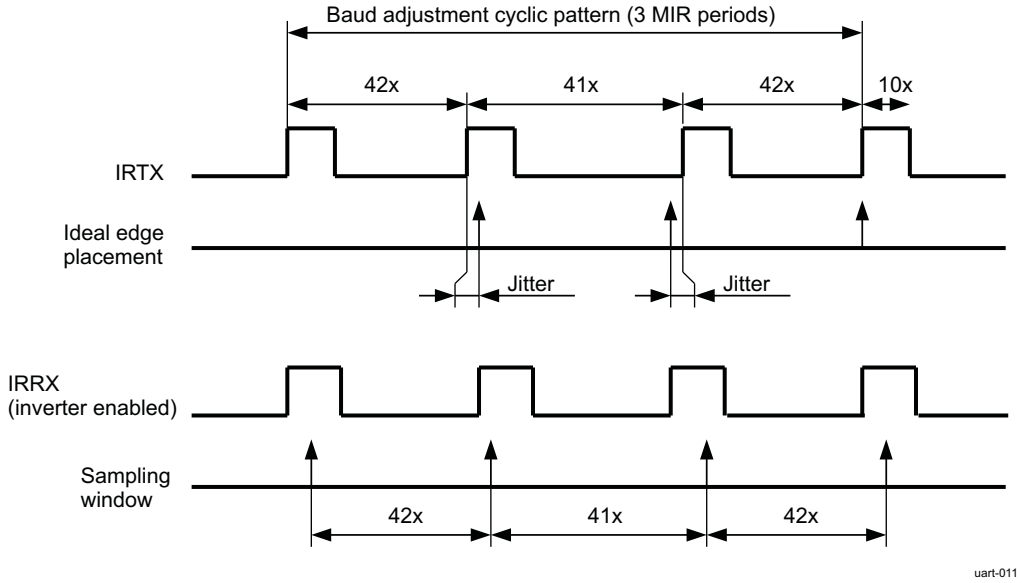
23.2.4.2.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of +/–0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 23-9 shows the MIR baud rate adjustment mechanism.

Figure 23-9. MIR Baud Rate Adjustment Mechanism



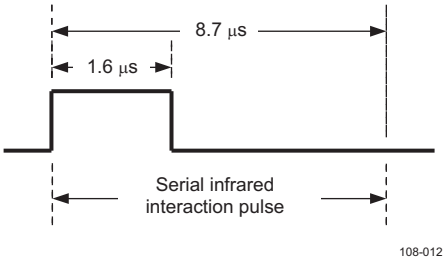
23.2.4.2.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

When the SIPMODE bit of the mode definition register 1 (MDR1[6]) equals 1, the TX state machine always sends one SIP at the end of a transmission frame. But when MDR1[6] = 0, the transmission of the SIP depends on the SENDSIP bit of the auxiliary control register (ACREG[3]). The system (LH) can set ACREG[3] at least once every 500 ms. The advantage of this approach over the default approach is that the TX state machine does not need to send the SIP at the end of each frame which may reduce the overhead required.

Figure 23-10 shows the SIP.

Figure 23-10. Serial Infrared Interaction Pulse (SIP)



23.2.4.2.3 Programming Models

Example 23-3. Receive IrDA

Receive IrDA frame with no parity, baud-rate = 1.152 Mbs, FIFOs disabled.

- MDR1 = 04h
  - MDR1[2:0] = 100b: MIR mode
- LCR = 86h
  - LCR[7] = 1: access to write DLL and DLH
  - LCR[2] = 1: set number of stop bits to 2 (default: 1)
  - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
- DLL = 01h: 1.152 Mbs
- DLH = 0h: 1.152 Mbs
- LCR = 06h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, RHR
- MCR =03h: forces $\overline{\text{DTR}}$ and $\overline{\text{RTS}}$ output to active (low).
- optional: IER = 1: enable RHR interrupt

Example 23-4. Transmit IrDA

Transmit IrDA 60 bytes frame with no parity, baud-rate = 1.152 Mbs, FIFOs disabled.

- MDR1 = 04h
  - MDR1[2:0] = 100b: MIR mode
- LCR = 82h
  - LCR[7] = 1: access to write DLL and DLH
  - LCR[1:0] = 10b: set word length to 7 bits (default: 5)
  - optional: LCR[2] = 1: set number of stop bits to 2 (default: 1)
- DLL = 01h: 1.152 Mbs
- DLH = 0h: 1.152 Mbs
- LCR = 02h: LCR[7] = 0 disables access to DLL and DLH and gives access to MCR, FCR, IER, BLR, EBLR, THR
- MCR =01h: force $\overline{\text{DTR}}$ output to active (low)
- optional: IER = 02h: enable THR interrupt
- TXFLL = 3Ch: transmit frame length is 60 bytes
- optional: EBLR = 08: transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)
- optional: set ACREG[3] = 1: SIP sends at the end of transmission
- THR = desired data to be transmitted

23.2.4.3 FIR Mode

In fast infrared mode (FIR), data transfer takes place between LH and peripheral devices at 4 Mbits/s speed. A FIR transmit frame starts with preamble, followed by a start flag, frame data, CRC-32 and ends with a stop flag.

Table 23-3 shows the FIR transmit frame format.

Table 23-3. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag

On transmit, the FIR transmit state machine attaches the preamble, start flag, CRC-32, and stop flag. It also encodes the transmit data into 4PPM format. It also generates the serial infrared interaction pulse (SIP).

On receive, the FIR receive state machine recovers the receive clock, removes start flag, decodes the 4PPM incoming data and determines frame boundary with reception of stop flag. It also checks for errors such as: illegal symbol, CRC error and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. Refer to the DISIRRX bit of the auxiliary control register (ACREG[5]) for a description of the logical operation.

NOTE: This applies to all three modes SIR, MIR, and FIR.

23.2.5 CIR Mode

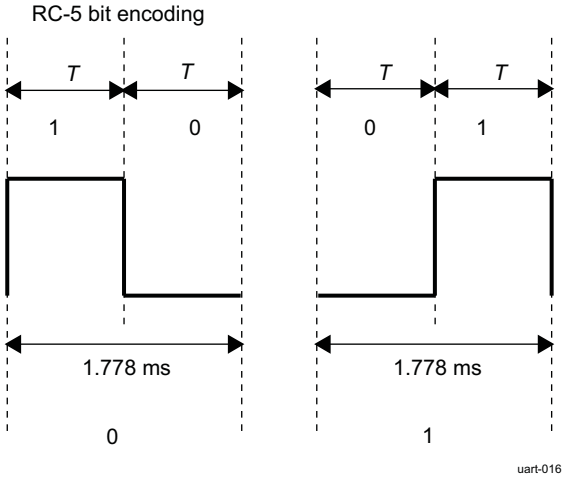
In consumer infrared (CIR) mode, the infrared operation is designed to function as a programmable (universal) remote control. By setting the MDR1 register, the UART can be set to CIR mode in the same way as the other IrDA modes are set using the MDR1 register. The CIR mode uses a variable pulse width modulation technique (based on multiples of a programmable T period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic is to transmit and receive data packets according to the user definable frame structure and packet content.

23.2.5.1 Consumer IR Encoding

There are two distinct methods of encoding for remote control applications. The first uses time extended bit forms, that is, a variable pulse distance (or duration) whereby the difference between a logic 1 and logic 0 is the length of the pulse width; and the second is the use of a bi-phase where the encoding of the logic 0 and logic 1 is in the change of signal level from 1 -> 0 or 0 -> 1, respectively. Japanese manufacturers tend to favor the use of pulse duration encoding whereas European manufacturers favor the use of bi-phase encoding.

The CIR mode is designed to use a completely flexible free format encoding where a digit ‘1’ from the TX/RX FIFO is to be transmitted/received as a modulated pulse with duration T. Equally, a ‘0’ is to be transmitted/received as a blank duration T. The protocol of the data is to be constructed and deciphered by the host CPU. For example, the RC-5 protocol (Figure 23-11) using Manchester encoding can be emulated as using a “01” pair for one and “10” pair for a zero.

Figure 23-11. RC-5 Bit Encoding



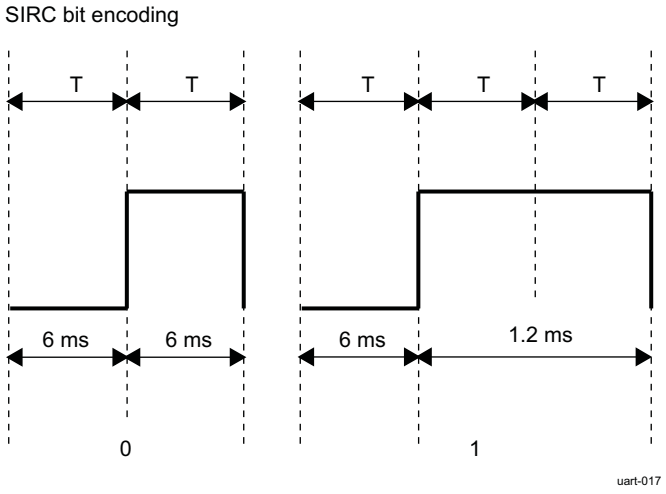
Since the CIR mode logic does not impose a fixed format for infrared packets of data, the CPU software is at liberty to define the format through the use of simple data structures that will then be modulated into an industry standard such as RC-5 or SIRC to name a few. To send a sequence of “0101” in RC-5, the host software must write an eight bit binary character of “10011001” to the data TX FIFO of the UART.

For SIRC, the modulation length (multiples of T) is the method to distinguish between a “1” or a “0”. The following SIRC digits show the difference in encoding between this and RC-5 for example.

NOTE: The pulse width is extended for “1” digits.

Figure 23-12 shows SIRC bit encoding.

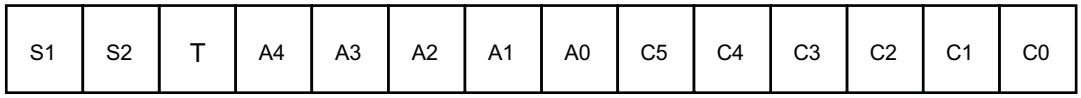
Figure 23-12. SIRC Bit Encoding



To construct comprehensive packets that constitute remote control commands, the host software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 23-13 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 23-13. RC-5 Standard Packet Format



Where:

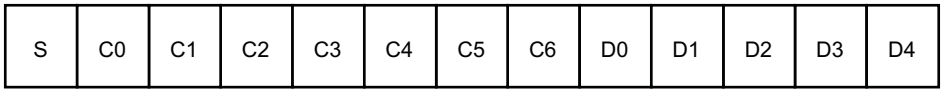
S1, S2:	Start bits (always 1)
T:	Toggle bit
A4..A0:	Address (or system) bits
C5..C0:	Command bits

The toggle bit T changes each time a new command is transmitted to allow detection of pressing the same key twice (or effectively receiving the same data from the host consecutively). Since a code is being sent as long as the CPU transmits characters to the UART for transmission, a brief delay in the transmission of the same command would be detected by the use of the toggle bit. The address bits define the machine or device that the Infrared transmission is intended for and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

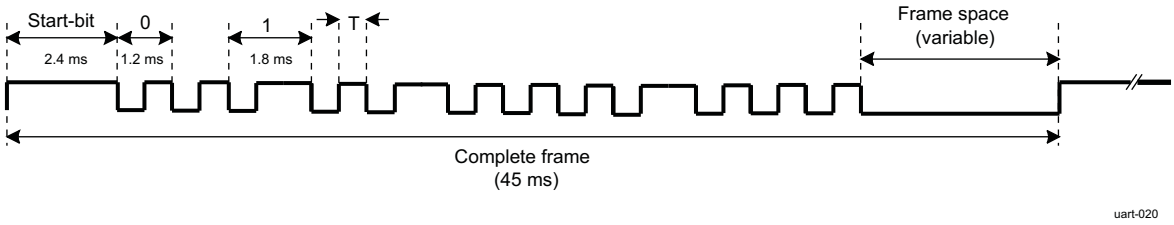
The SIRC encoding uses the duration of modulation for mark and space; hence the duration of data bits inside the standard frame length will vary depending upon the logic 1 content. Figure 23-14 shows the packet format and bit encoding. As Figure 23-14 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 23-14. SIRC Packet Format



NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 23-15. SIRC Bit Transmission Example



This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

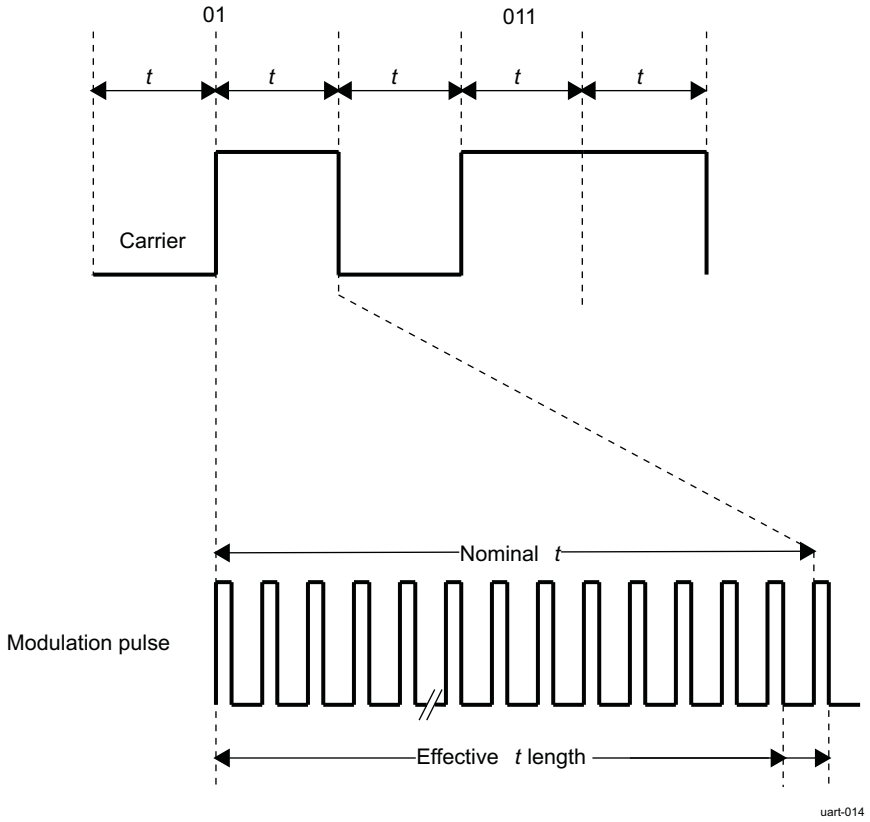
23.2.5.2 CIR Mode Operation

In CIR mode, the infrared operation functions as a programmable (universal) remote control. CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

23.2.5.3 Carrier Modulation

Looking closely at the actual modulation pulses of the infrared data stream, each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 23-16).

Figure 23-16. CIR Pulse Modulation



A minimum of 4 modulation pulses per bit is required by the module. Based on the requested modulation frequency, the CFPS register must be set with the correct dividing value to provide the more accurate pulse frequency:

Dividing value = (FCLK/12)/MODfreq

Where:

FCLK = System clock frequency (48 MHz)
12 = real value of BAUD multiple
MODfreq = Effective frequency of the modulation (MHz)

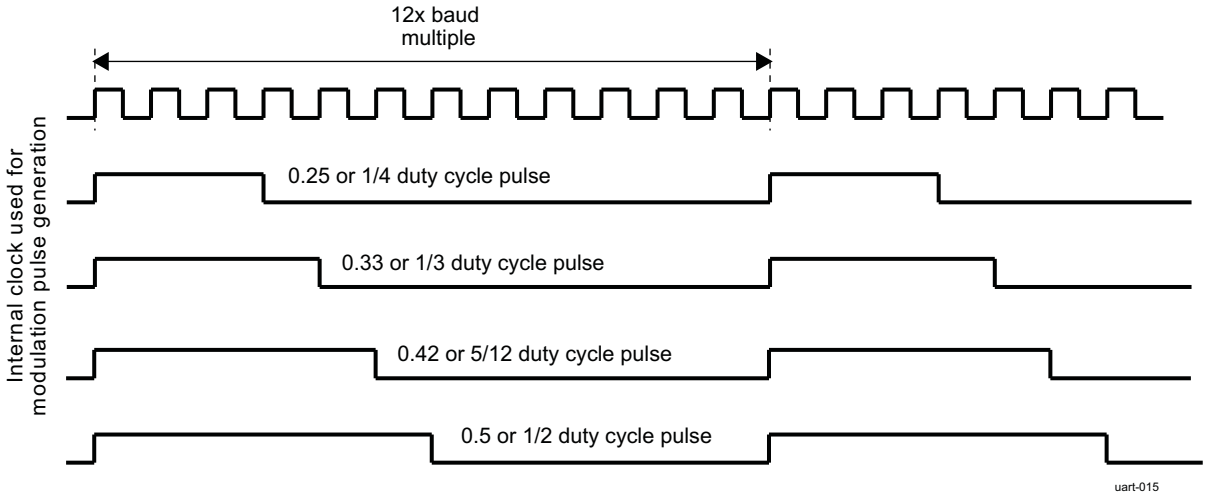
For example, for a targeted modulation frequency of 36 kHz, the CFPS value must be set to 111 in decimal, which provides a modulation frequency of 36.04 kHz.

NOTE: The CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the CIRPULSEMODE field in the mode definition register 2 (MDR2[5:4]).

Figure 23-17 shows the CIR modulation duty cycles.

Figure 23-17. CIR Modulation Duty Cycle



The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes.

NOTE: The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit. This bit will not affect the transmission modulation.

23.2.5.4 Frequency Divider Values

As previously explained, the data transferred is a succession of pulses with a T period. Depending on the standards used, the T period is defined through the DLL and DLH registers, which defined the value to divide the functional clock (48 MHz):

Dividing value = (FCLK/16)/Tfreq

Where:

FCLK =	System clock frequency (48 MHz)
16 =	real value of BAUD multiple
Tfreq =	Effective frequency of the T pulse (MHz)

23.2.6 FIFO Management

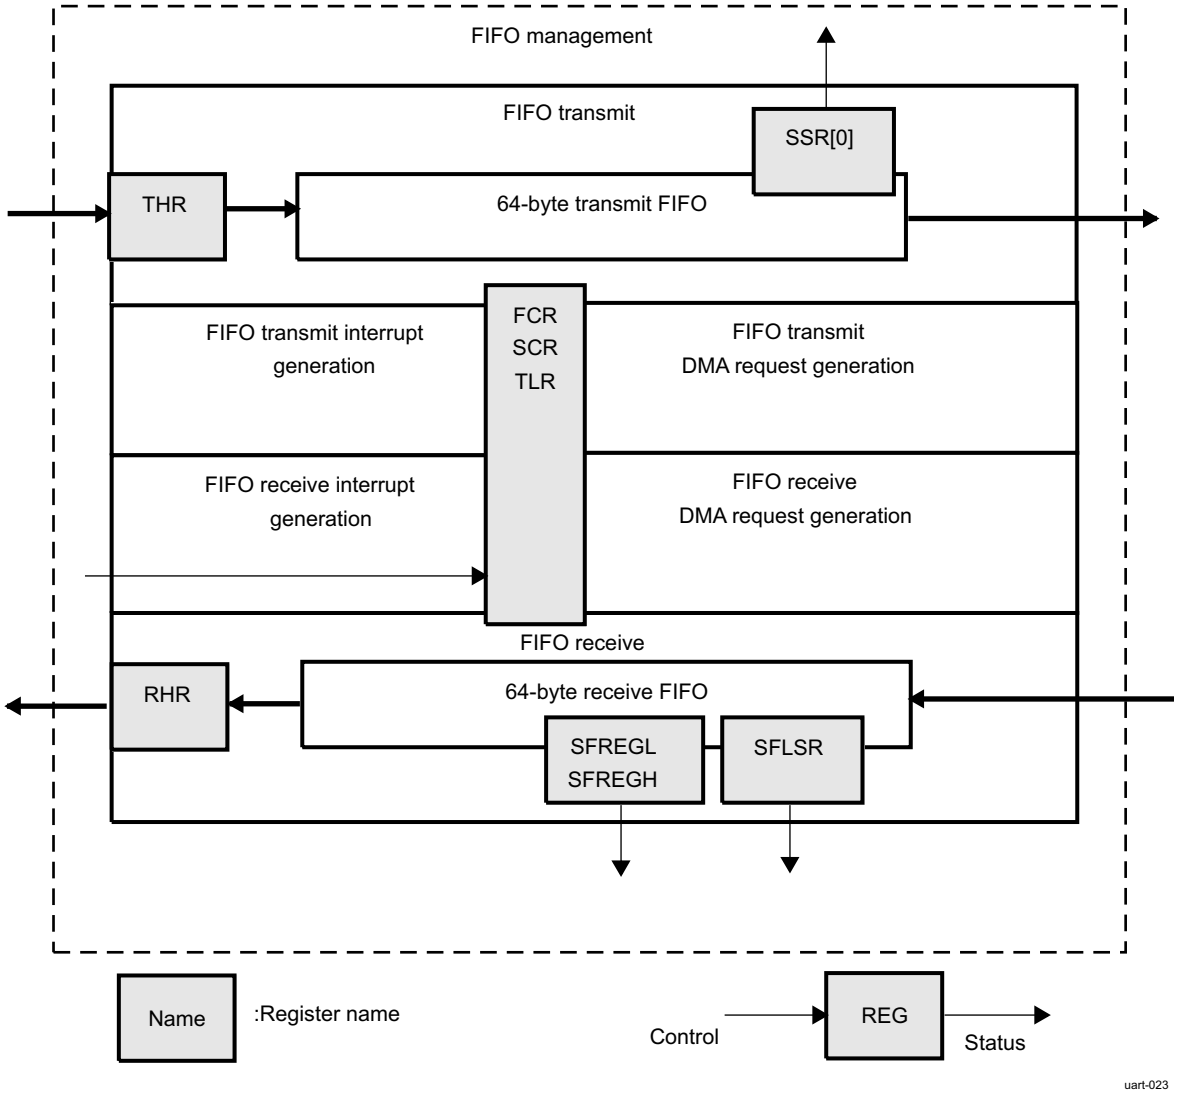
The FIFO is accessed by reading/writing the RHR and THR registers. Parameters are controlled using the FIFO control register (FCR) and supplementary control register (SCR). Reading the TXFIFOFULL bit in SSR[0] as 1 means the FIFO is full.

The TLR register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. Figure 23-18 shows the FIFO management registers.

NOTE: Data in the RHR register is not overwritten when an overflow occurs.

The SFLSR, SFREGL, and SFREGH status registers are used in IrDA mode only.

Figure 23-18. FIFO Management

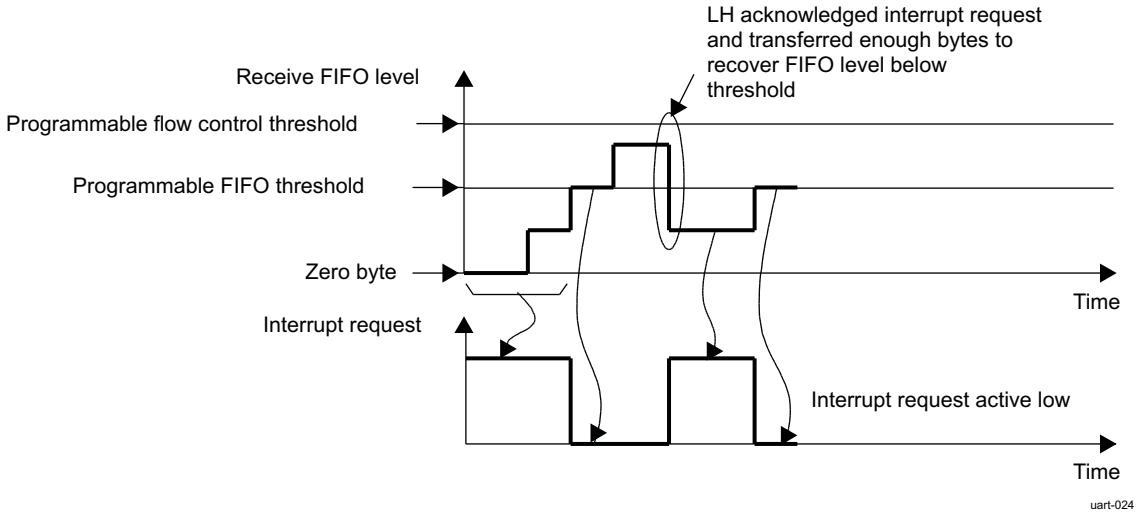


23.2.6.1 FIFO Interrupt Mode

In the FIFO interrupt mode (FIFO_EN bit in the FIFO control register (FCR[0]) is set to 1 and relevant interrupts are enabled via the interrupt enable register (IER)), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (TLR[7:4] and TLR[3:0] fields or the FCR[7:6] and FCR[5:4] fields, respectively) are reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode). Note also that in the case of the UART flow control being enabled along with the interrupt capabilities, the user must ensure that the UART flow control FIFO threshold (TCR[3:0]) is greater than or equal to the receive FIFO threshold.

Figure 23-19 shows the generation of the receive FIFO interrupt request.

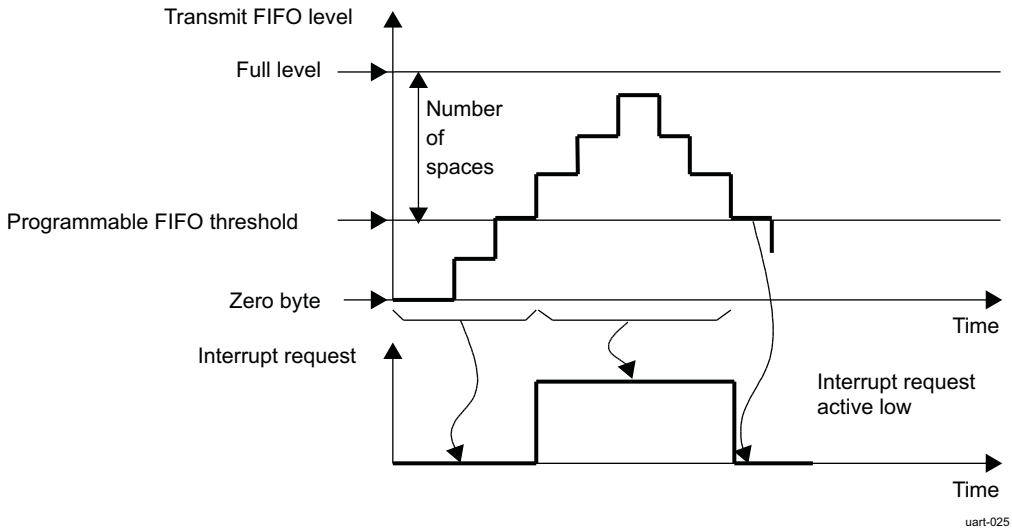
Figure 23-19. Receive FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be de-asserted only when the Local Host has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 23-20 shows the generation of the transmit FIFO interrupt request.

Figure 23-20. Transmit FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is de-asserted when the TX FIFO crosses the threshold level. The interrupt line is de-asserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

23.2.6.2 FIFO Polled Mode Operation

In FIFO polled mode (FCR[0] = 0, relevant interrupts disabled via interrupt enable register (IER)) the status of the receiver and transmitter can then be checked by polling the line status register (LSR). This mode is an alternative to the FIFO interrupt mode of operation where the status of the receiver and transmitter is automatically known by means of interrupts sent to the LH.

23.2.6.3 FIFO DMA Mode Operation

23.2.6.3.1 DMA Signaling

There are four modes of DMA operation, DMA mode 0/1/2/3. They can be selected as follows:

- When SCR[0] = 0: setting FCR[3] to 0 enables DMA mode 0, setting FCR[3] to 1 enables DMA mode 1.
- When SCR[0] = 1: SCR[2:1] determines DMA mode 0 to 3, according to supplementary control register (SCR).

So for instance:

- if no DMA operation is desired: set SCR[0] to 1 and SCR[2:1] to 00 (FCR[3] is discarded)
- if DMA mode 1 is desired: either set SCR[0] to 0 and FCR[3] to 1 or set SCR[0] to 1 and SCR[2:1] to 01 (FCR[3] is discarded)

If the FIFOs are disabled (FCR[0] = 0), DMA occurs in single character transfers.

NOTE: Note that when DMA mode 0 has been programmed, the signals associated with DMA operation are not active.

23.2.6.3.2 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 23-21, Figure 23-22, Figure 23-23, and Figure 23-24 show the supported DMA operations.

In receive mode, a DMA request is generated as soon as the receive FIFO reaches its threshold level defined in the trigger level register (TLR). This request is de-asserted when the number of bytes defined by the threshold level has been read by the system DMA.

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is de-asserted when the number of bytes defined by the number of spaces in the trigger level register (TLR) has been written by the system DMA. If an insufficient number of characters are written, then the DMA request will remain active.

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the TLR register.

There are a number of ways the threshold can be programmed. The example in Figure 23-22 is of a DMA transfer that operates with a space setting of 56, which could arise from the use of the auto settings in the FCR[5:4] or the use of the TLR[3:0] concatenated with the FCR[5:4]. The setting of 56 spaces in the UART/IrDA/CIR module should correlate with settings of the system DMA so that the buffer does not overflow (program the DMA request size of the Local Host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

Figure 23-21. Receive FIFO DMA Request Generation (32 Characters)

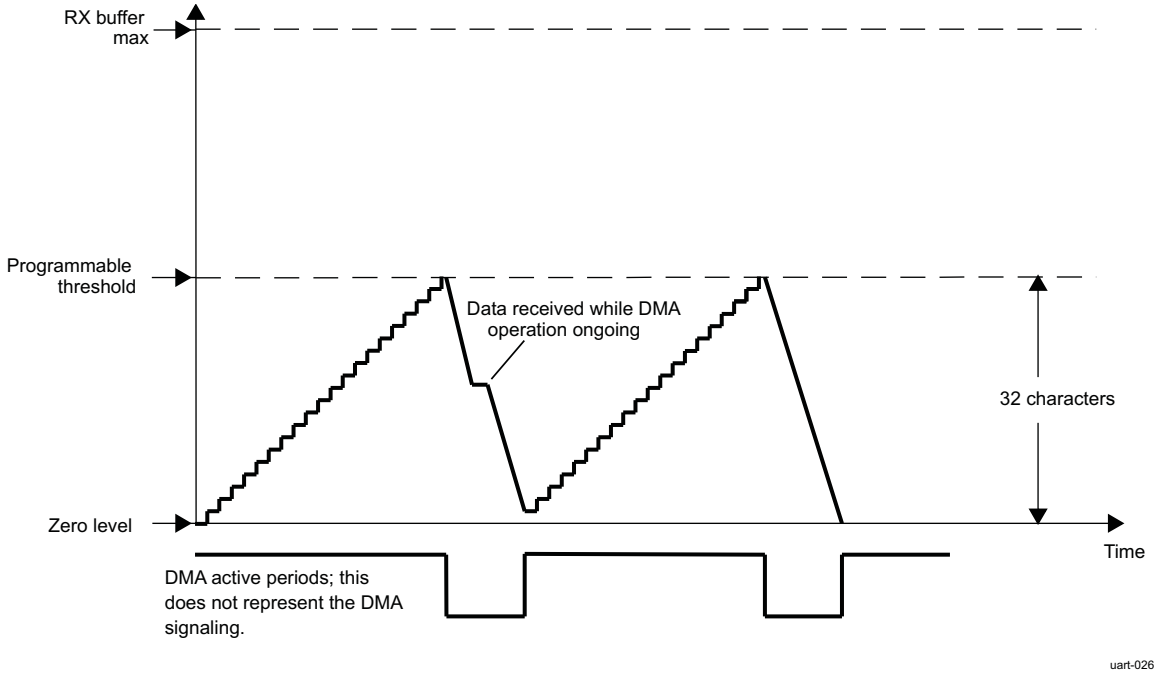


Figure 23-22. Transmit FIFO DMA Request Generation (56 Spaces)

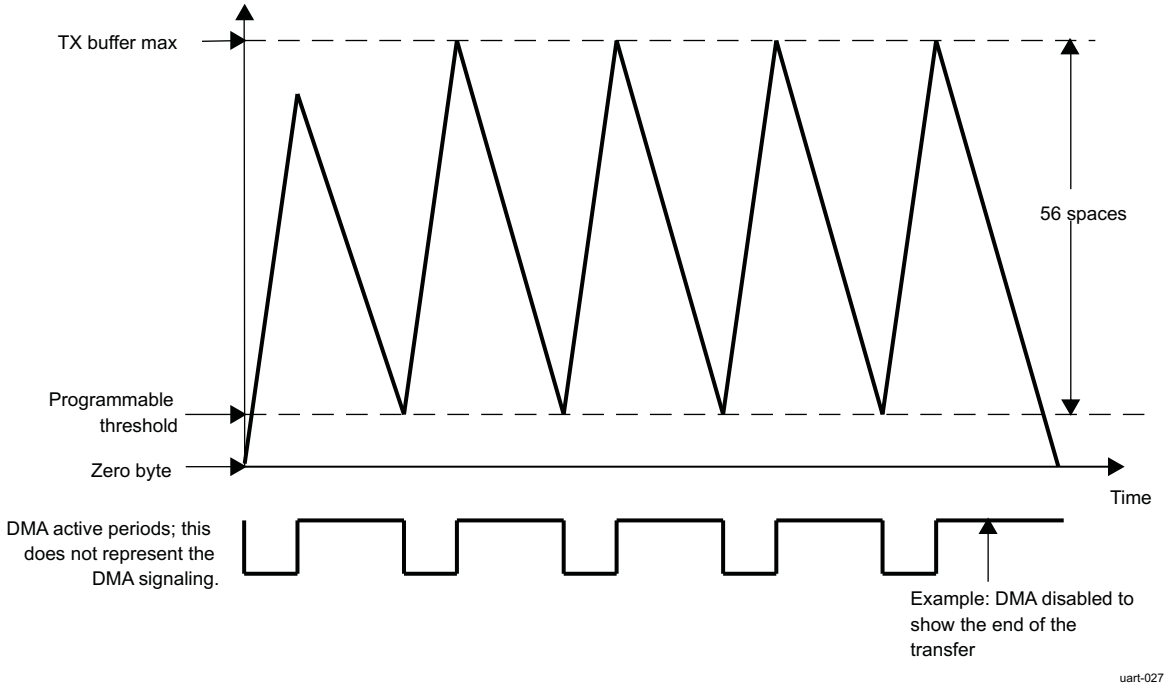

Figure 23-23 shows an example with 8 spaces to show the buffer level crossing the space threshold. Again, the Local Host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

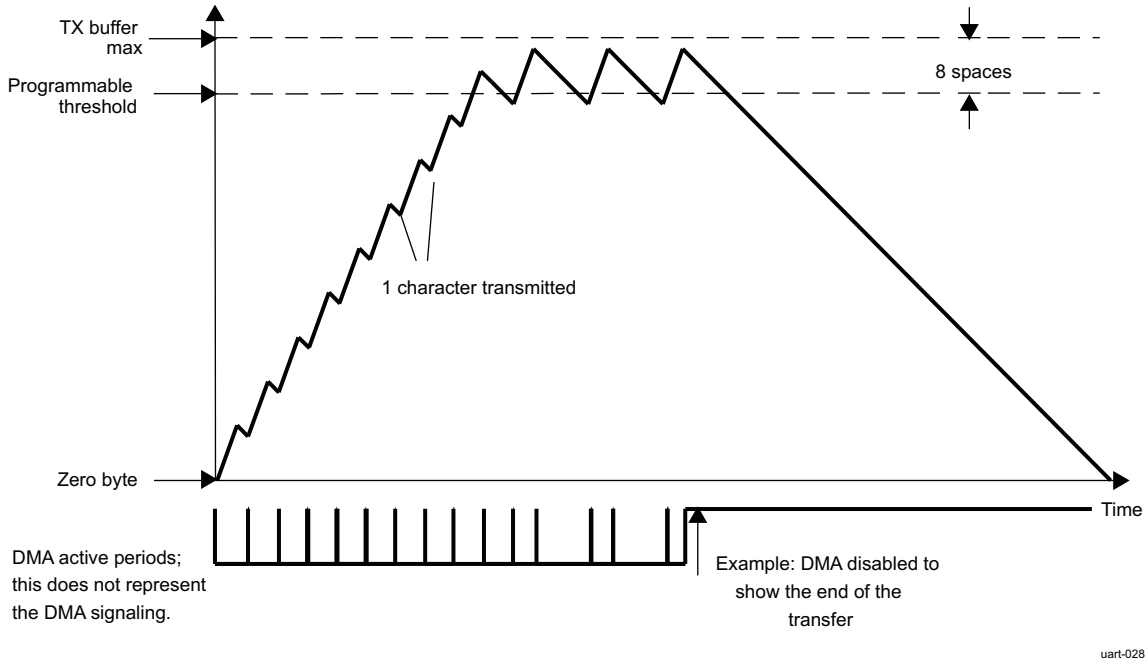
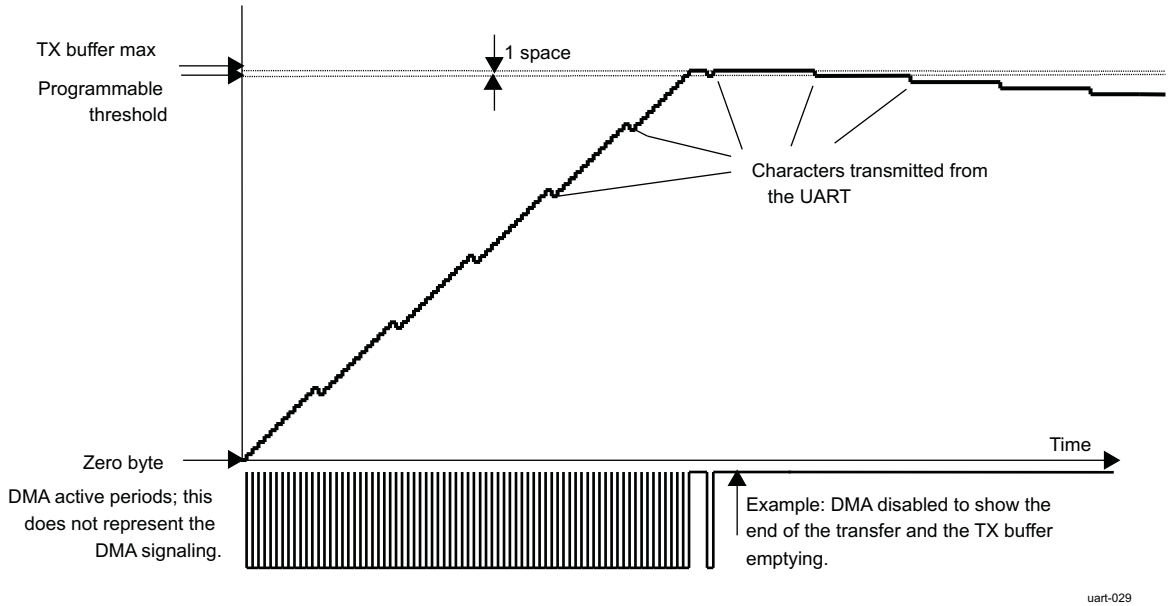
Figure 23-23. Transmit FIFO DMA Request Generation (8 Spaces)



The final example illustrates the setting of one space which uses the DMA for each transfer of one character to the transmit buffer (see Figure 23-24). The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer. There are two occasions where the buffer holds the maximum amount of data words, shortly after this, the DMA is disabled to illustrate the slower transmission of the data words to the TX pin. Eventually, the buffer will be emptied at the rate specified by the BAUD Rate Settings of the DLL and DLH registers. Again, the DMA settings should correspond to the system's Local Host DMA controller settings in order to ensure the correct operation of this logic.

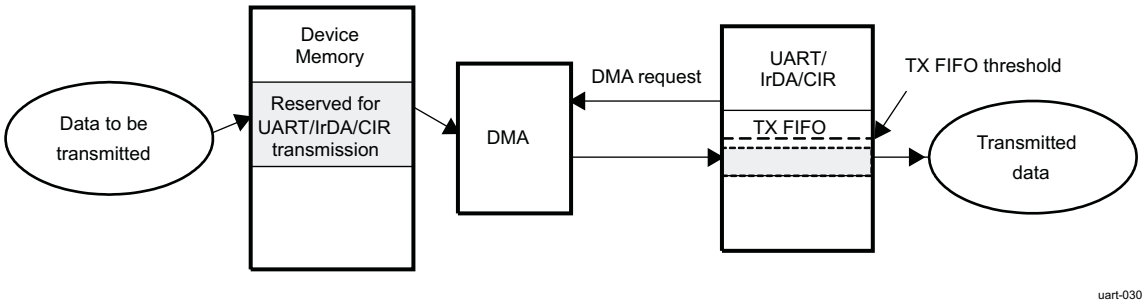
Figure 23-24. Transmit FIFO DMA Request Generation (1 Space)



23.2.6.3.3 DMA Transmission

Figure 23-25 shows the DMA transmission process.

Figure 23-25. Transmission Process



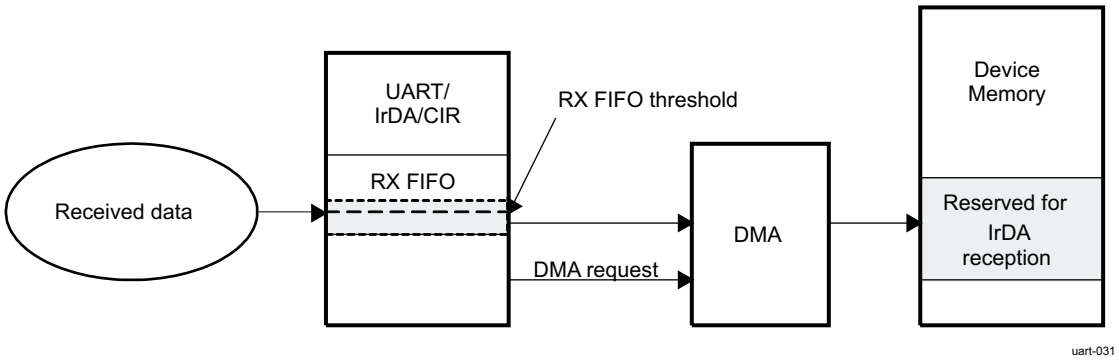
- Data to be transmitted are put in the memory reserved for UART/IrDA/CIR transmission by the DMA:
  - Until the TX FIFO trigger level is not reached, a DMA request is generated.
  - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR register empties.

23.2.6.3.4 DMA Reception

Figure 23-26 shows the DMA reception process.

Figure 23-26. Reception Process



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
   - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

23.2.6.4 IrDA Status FIFO

In IrDA modes, a status FIFO is used to record the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written into the status FIFO. The frame length and error status can be read by reading SFREGL/H and SFLSR. Reading the SFLSR causes the read pointer to be incremented. The status FIFO is eight entries deep and therefore can hold the status of eight frames. The LH uses the frame-length information to locate the frame-boundary in the received frame data. The LH can screen bad frames using the error-status information and later request the sender to resend only the bad frames. This status FIFO can be used very effectively in DMA as the LH need not be interrupted every time a frame is received but only whenever the programmed status FIFO trigger level is reached.

23.2.6.5 Frame Closing

There are two ways by which a transmission-frame can be properly terminated:

- Frame-length method: Frame-length method is selected when MDR1[7] = 0. The LH writes the frame-length value to TXFLH and TXFLL registers. The device automatically attaches end flags to the frame once the number of bytes transmitted becomes equal to the frame-length value.
- Set-EOT bit Method: Set-EOT bit method is selected when MDR1[7] = 1. The LH writes 1 to ACREG[0] (EOT bit) just before it writes the last byte to the TX FIFO. When the LH writes the last byte to the TX FIFO, the device internally sets the tag bit for that particular character in the TX FIFO. As the TX state machine reads data from the TX FIFO it uses this tag-bit information to attach end flags and properly terminate the frame.

23.2.6.6 Store and Controlled Transmission (SCT)

In SCT the LH first starts writing data into the TX FIFO. Then, after it writes a part of a frame (for a bigger frame) or a whole frame (a small frame, that is, supervisory frame), it writes a 1 to ACREG[2] (deferred TX start) to start transmission. SCT is enabled when MDR1[5] = 1. This method of transmission is different from the normal mode, where transmission of data starts immediately after data is written to the TX FIFO. SCT is useful to send short frames without TX underrun.

23.2.6.7 Underrun During Transmission

Underrun in transmission occurs when the TX FIFO becomes empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end-flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a re-transmission. Underrun also causes an internal flag to be set which disables further transmission. Before the next frame can be transmitted the system (LH) must:

- Reset the TX FIFO
- Read the RESUME register. This clears the internal flag.

This functionality can be disabled with ACREG[4], compensated by the extension of the stop bit in transmission in case the TX FIFO is empty.

23.2.6.8 Overrun During Receive

Overrun occurs during receive if the RX state machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the LH with IIR[3] and discards the remaining portion of the frame. Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received the system (LH) must:

- Reset the RX FIFO
- Read the RESUME register. This clears the internal flag.

23.2.7 Interrupts

The UART/IrDA/CIR module generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (IER). The interrupt status of the device can be checked at any time by reading the interrupt identification register (IIR). The UART, IrDA and CIR modes have different interrupts in the UART/IrDA/CIR module and therefore different IER and IIR mappings according to the selected mode.

23.2.7.1 Trigger Levels

The UART provides programmable trigger levels for both receiver and transmitter DMA and Interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of one byte. The programmable trigger levels are an enhanced feature available via the trigger level register (TLR).

23.2.7.2 UART Mode Interrupts

In UART modes, there are seven possible interrupts. These interrupts are prioritized to six different levels. When an interrupt is generated, the interrupt identification register (IIR) indicates that an interrupt is pending by bringing IIR[0] to 0 and provides the type of interrupt through IIR[5-1]. Table 23-4 summarizes the interrupt control functions.

It is important to note that for the receiver line status interrupt, RX_FIFO_STS bit (LSR[7]) generates the interrupt. For the XOFF interrupt, if a XOFF flow character detection caused the interrupt, the interrupt is cleared by a XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the IIR.

Table 23-4. UART Mode Interrupts

IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
00 0001	None	None	None	None
00 0110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read RHR register. OE: Read LSR register.
00 1100	2	RX time-out	Stale data in RX FIFO	Read RHR register.
00 0100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
00 0010	3	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
00 0000	4	Modem status	See the MSR register.	Read MSR register.
01 0000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt. Read IIR register, if special character interrupt.
10 0000	6	CTS, RTS, DSR	$\overline{\text{RTS}}$ pin, $\overline{\text{CTS}}$ pin, or $\overline{\text{DSR}}$ pin changes state from active (low) to inactive (high).	Read IIR register.

23.2.7.3 IrDA Mode Interrupts

In IrDA modes, there are eight possible interrupts. The interrupt line is activated when any of the eight interrupts is generated (there is no priority). For IIR[5], interrupt source 1 is used with interrupt reset method 1 and interrupt source 2 is used with interrupt reset method 2. Table 23-5 summarizes the interrupt control functions.

Table 23-5. IrDA Mode Interrupts

IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read RHR register.
3	RX overrun	Write to RHR register when RX FIFO full.	Read RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read SFREGL/H, SFLSR. Status FIFO read pointer is incremented only when reading SFLSR.
5	TX status (indicated by MDR2[0] (IRTX_UNDERRUN)	1. THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read RESUME register. OR 2. Read IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into STATUS FIFO.	Read STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame.	Read IIR register.

23.2.7.4 CIR Mode Interrupts

The CIR mode uses a subset of the existing IrDA mode interrupts. Table 23-6 summarizes the interrupt modes that are to be maintained. In CIR mode, IIR bit 5 has a single purpose of indicating that the last bit of infrared data has been passed to the IR TX pin.

Table 23-6. CIR Mode Interrupts

IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read RHR register until interrupt condition disappears.
1	THR interrupt	TFE (THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to THR register until interrupt condition disappears.
2	RXSTOPIT interrupt	Receive stop interrupt (depending on value set in the BOF length register (EBLR))	Read IIR register.
3	RXOEIT interrupt	Write to RHR register when RX FIFO full.	Read RESUME register.
4	N/A for CIR mode		
5	TX status	Transmission of the last bit of the frame is completed successfully.	Read IIR register.
6-7	N/A for CIR mode		

23.2.7.5 Wake-Up Interrupt

Wake-up interrupt is a special interrupt, which is not designed in the same way than previous ones. This interrupt is enabled when the RX_CTS_DSR_WAKE_UP_ENABLE bit of the supplementary control register (SCR[4]) is set to one. The IIR register is not modified when it occurs, SSR[1] must be checked to detect a wake-up-event. When wake-up interrupt occurs, the only way to clear it, is to reset SCR[4] to 0. Wake-up can also occur if the WER[7] TX_WAKEUP_EN is set to 1 and one of the followings occurred:

- THR interrupt occurred if it is enabled (omitted if TX DMA request is enabled)
- TX DMA request occurred if it is enabled
- TX_STATUS_IT occurred if it is enabled (only IrDA and CIR modes). Can not be used with THR interrupt

23.2.8 Sleep Modes

23.2.8.1 When in UART Mode

In UART modes, sleep mode is enabled by writing a 1 to IER[4] (when EFR[4] = 1). Sleep mode is entered when:

- The serial data input line, RX is idle
- The TX FIFO and TX shift register are empty
- The RX FIFO is empty
- There are no interrupts pending except THR interrupts

It should be noted that sleep mode is a good way to lower power consumption of UART but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode. In sleep mode the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks the power consumption is greatly reduced. The module wakes up when any change is detected on the RX line, if data is written to the TX FIFO, when there is any change in the state of the modem input pins. Note that an interrupt can be generated on a wake up event by setting SCR[4] to 1. See interrupt section to know how to manage it.

NOTE: Writing to the divisor latches, DLL and DLH, to set the baud clock, BCLK, must not be done during sleep mode. Therefore, it is advisable to disable sleep mode using IER[4] before writing to DLL or DLH.

23.2.8.2 When in IR-IrDA and CIR Modes

In IrDA/CIR modes, sleep mode is enabled by writing a 1 to MDR1[3]. Sleep mode is entered when:

- The serial data input line, RX is idle
- The TX FIFO and TX shift register are empty
- The RX FIFO is empty
- There are no interrupts pending except THR interrupts

The module wakes up when any change is detected on the RX line or if data is written to the TX FIFO.

23.2.9 Idle Modes

Sleep and AutoIdle modes are embedded power-saving features. At the system level, power reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

- The UART supports an idle req - idle ack handshaking protocol. This protocol is used at system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from the interrupt generation mode to a wakeup generation mode for unmasked events (Refer to SYSC[2] and WER).
- In the wakeup generation mode, interrupt request generation and DMA request generation are disabled.

23.2.10 Programmable Baud Rate Generator

The UART/rRDA/CIR module contains a programmable baud generator and a set of fixed dividers that takes the 48 MHz clock input and divides it down to the expected baud-rate. The baud rate generator and associated controls is shown in Figure 23-27.

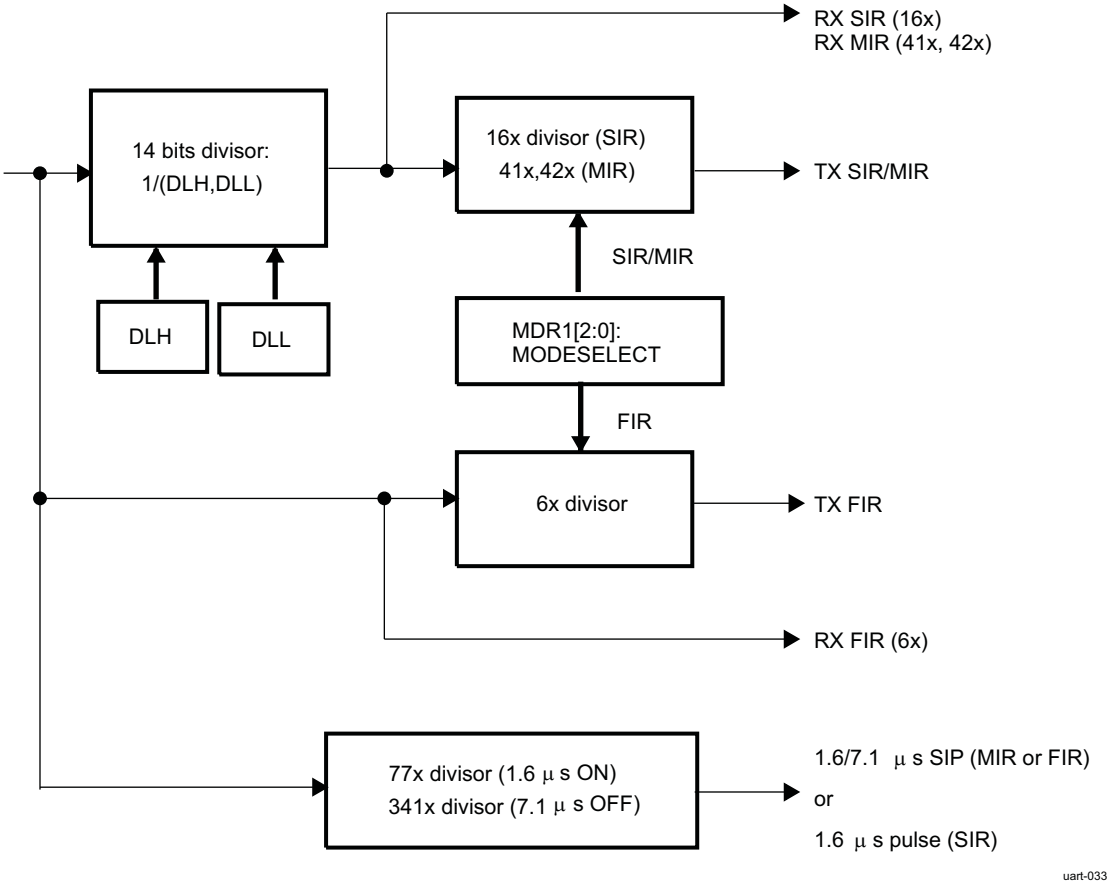
CAUTION

It is mandatory that the MODESELECT bit in MDR1[2:0] = 7h (disable) before initializing or modifying clock parameter controls (DLH and DLL). Failure to observe this rule can result in unpredictable module behavior.

Choosing the appropriate divisor value:

- UART 16× mode: Divisor value = Operating Frequency/(16× baud rate)
- UART 13× mode: Divisor value = Operating Frequency/(13× baud rate)
- SIR mode: Divisor value = Operating Frequency/(16× baud-rate)
- MIR mode: Divisor value = Operating Frequency/(41×/42× baud-rate)
- FIR mode: Divisor value = none

Figure 23-27. BAUD Rate Generator



23.2.10.1 UART Baud Rates (48 MHz Clock)

Table 23-7 describes the UART baud rate settings.

Table 23-7. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH, DLL (Decimal)	DLH, DLL (Hex)	Actual Baud Rate	Error (%)
0.3 Kbps	16x	10000	27h, 10h	0.3 Kbps	0
0.6 Kbps	16x	5000	13h, 88h	0.6 Kbps	0
1.2 Kbps	16x	2500	09h, C4h	1.2 Kbps	0
2.4 Kbps	16x	1250	04h, E2h	2.4 Kbps	0
4.8 Kbps	16x	625	02h, 71h	4.8 Kbps	0
9.6 Kbps	16x	312	01h, 38h	9.6153 Kbps	+0.16
14.4 Kbps	16x	208	00h, D0h	14.423 Kbps	+0.16
19.2 Kbps	16x	156	00h, 9Ch	19.231 Kbps	+0.16
28.8 Kbps	16x	104	00h, 68h	28.846 Kbps	+0.16
38.4 Kbps	16x	78	00h, 4Eh	38.462 Kbps	+0.16
57.6 Kbps	16x	52	00h, 34h	57.692 Kbps	+0.16
115.2 Kbps	16x	26	00h, 1Ah	115.38 Kbps	+0.16

1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps(2)	0	-2.0375	208 ns
4 Mbps	FIR	6x	4PPM	-	4 Mbps	0	0	125 ns

(1) Baud rate error and source jitter table values do not include 48 MHz reference clock error and jitter
(2) Average value

23.2.10.3 Autobauding Modes

In autobauding mode, the UART extracts transfer characteristics (speed, length, and parity) from an AT command. These characteristics are used to receive data after an “at” (AT) and to send data.

The valid AT commands follow:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware. A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0Dh), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UASR register reflects the correct settings for the baud rate detected. The interrupt activity continues in this way each time a subsequent character is received. Therefore, it is recommended that the software enables the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character + space parity is not supported.

The method used to identify the speed is:

- Detect the transition 1->0 on the received data. This happens as soon as a stop to start bit transition occurs. The transition is valid after a majority vote on 3 sampling period.
- Sample the start bit duration with 115 200 × 16 Hz clock frequency as long as there is no rising edge. A transition 0->1 is considered as valid after a majority vote on 3 sampling period.
- Compare the sampled value with a table. If the sampled value is outside a valid range an error is reported (no speed identified). And the hardware goes back to the first state (1).
- Else store the first data bit in the received register (for serial to parallel conversion) and go to frame format identification.

The next received bits are sampled according to the programmed baud rate. However, after seven bits reception, the speed identification must be restarted since we may receive several “a” or “A” character before a valid “t” or “T” character.

Autobauding mode is selected when the MODESELECT field in MDR1[2:0] is set to 2h. In the UART autobauding mode, DLL, DLH, and LCR[5:0] settings are not used; instead, UASR is updated with the configuration detected by the autobauding logic.

23.3 UART Registers

Each register is selected using a combination of address and, for some, LCR register bit settings as shown in Table 23-9. For the base address of these registers, see Table 1-12. The following registers are accessible by the local host (LH) at address = module base address + address offset. The module base address is the module start address. Note that register address offsets depends upon the module address alignment at the system top level.

Table 23-9. UART Registers

Address Offset	Registers					
	LCR[7] = 0		LCR[7:0] ≠ BFh		LCR[7:0] = BFh	
	Read	Write	Read	Write	Read	Write
0h	RHR	THR	DLL	DLL	DLL	DLL
4h	IER(1)	IER(1)	DLH	DLH	DLH	DLH
8h	IIR	FCR(2)	IIR	FCR(2)	EFR	EFR
Ch	LCR	LCR	LCR	LCR	LCR	LCR
10h	MCR(2)	MCR(2)	MCR(2)	MCR(2)	XON1/ADDR1	XON1/ADDR1
14h	LSR	-	LSR	-	XON2/ADDR2	XON2/ADDR2
18h	MSR/TCR(3)	TCR(3)	MSR/TCR(3)	TCR(3)	XOFF1/TCR(3)	XOFF1/TCR(3)
1Ch	SPR/TLR(3)	SPR/TLR(3)	SPR/TLR(3)	SPR/TLR(3)	XOFF2/TLR(3)	XOFF2/TLR(3)
20h	MDR1	MDR1	MDR1	MDR1	MDR1	MDR1
24h	MDR2	MDR2	MDR2	MDR2	MDR2	MDR2
28h	SFLSR	TXFLL	SFLSR	TXFLL	SFLSR	TXFLL
2Ch	RESUME	TXFLH	RESUME	TXFLH	RESUME	TXFLH
30h	SFREGL	RXFLL	SFREGL	RXFLL	SFREGL	RXFLL
34h	SFREGH	RXFLH	SFREGH	RXFLH	SFREGH	RXFLH
38h	BLR	BLR	UASR	-	UASR	-
3Ch	ACREG	ACREG	-	-	-	-
40h	SCR	SCR	SCR	SCR	SCR	SCR
44h	SSR	SSR[2]	SSR	SSR[2]	SSR	SSR[2]
48h	EBLR	EBLR	-	-	-	-
50h	MVR	-	MVR	-	MVR	-
54h	SYSC	SYSC	SYSC	SYSC	SYSC	SYSC
58h	SYSS	-	SYSS	-	SYSS	-
5Ch	WER	WER	WER	WER	WER	WER
60h	CFPS	CFPS	CFPS	CFPS	CFPS	CFPS
80h	MDR3	MDR3	MDR3	MDR3	MDR3	MDR3

(1) In UART modes, IER[7:4] can only be written when EFR[4] = 1; in IrDA/CIR modes, EFR[4] has no impact on the access to IER[7:4].
(2) MCR[7:5] and FCR[5:4] can only be written when EFR[4] = 1.
(3) Transmission control register (TCR) and trigger level register (TLR) are accessible only when EFR[4] = 1 and MCR[6] = 1.

23.3.1 Receiver Holding Register (RHR)

The receiver section consists of the receiver holding register and the receiver shift register. The RHR is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location zero of the FIFO is used to store the single data character.

NOTE: If an overflow occurs, the data in the RHR is not overwritten.

The receiver holding register (RHR) register is shown in Figure 23-28 and described in Table 23-10.

Figure 23-28. Receiver Holding Register (RHR)

15	8	7	0
Reserved		RHR	
R-0		R-unknown

Table 23-10. Receiver Holding Register (RHR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	RHR	0-FFh	Receive holding register.

23.3.2 Transmit Holding Register (THR)

The transmitter section consists of the transmit holding register and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.

The transmit holding register (THR) is shown in Figure 23-29 and described in Table 23-11.

Figure 23-29. Transmit Holding Register (THR)

7-0	THR	0-FFh	Transmit holding register.

23.3.3 Interrupt Enable Register (IER) - UART Mode

The interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are seven types of interrupt in this mode: receiver error, RHR interrupt, THR interrupt, XOFF received and $\overline{CTS}$/$\overline{RTS}$ change of state from low to high. Each interrupt can be enabled/disabled individually. There is also a sleep mode enable bit. The UART interrupt enable register (IER) is shown in Figure 23-30 and described in Table 23-12.

Table 23-12. UART Interrupt Enable Register (IER) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	CTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{CTS}$ interrupt.
		1	Enables the $\overline{CTS}$ interrupt.
6	RTSIT		Can be written only when EFR[4] = 1.
		0	Disables the $\overline{RTS}$ interrupt.
		1	Enables the $\overline{RTS}$ interrupt.
5	XOFFIT		Can be written only when EFR[4] = 1.
		0	Disables the XOFF interrupt.
		1	Enables the XOFF interrupt.
4	SLEEPMODE		Can be only written when EFR[4] = 1.
		0	Disables sleep mode.
		1	Enables sleep mode (stop baud rate clock when the module is inactive).
3	MODEMSTSIT	0	Disables the modem status register interrupt.
		1	Enables the modem status register interrupt
2	LINESTSIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt and time out interrupt.
		1	Enables the RHR interrupt and time out interrupt.

23.3.4 Interrupt Enable Register (IER) - IrDA Mode

The IrDA interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 8 types of interrupt in these modes, received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The IrDA interrupt enable register (IER) is shown in Figure 23-31 and described in Table 23-13.

NOTE: The TXSTATUSIT interrupt reflects two possible conditions. The MDR2[0] bit should be read to determine the status in the event of this interrupt.

6	LINESTSIT	0	Disables the receiver line status interrupt.
		1	Enables the receiver line status interrupt.
5	TXSTATUSIT	0	Disables the TX status interrupt.
		1	Enables the TX status interrupt.
4	STSFIFOTRIGIT	0	Disables status FIFO trigger level interrupt.
		1	Enables status FIFO trigger level interrupt.
3	RXOVERRUNIT	0	Disables the RX overrun interrupt.
		1	Enables the RX overrun interrupt.
2	LASTRXBYTEIT	0	Disables the last byte of frame in RX FIFO interrupt.
		1	Enables the last byte of frame in RX FIFO interrupt.
1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt.
		1	Enables the RHR interrupt.

23.3.5 Interrupt Enable Register (IER) - CIR Mode

The CIR interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 5 types of interrupt in these modes, TX status, RX overrun, RX stop interrupt, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The CIR interrupt enable register (IER) is shown in Figure 23-32 and described in Table 23-14.

NOTE: In CIR mode, the TXSTATUSIT bit has only one meaning corresponding to the case MDR2[0] = 0.

The RXSTOPIT interrupt is generated based on the value set in the BOF Length register (EBLR).

1	THRIT	0	Disables the THR interrupt.
		1	Enables the THR interrupt.
0	RHRIT	0	Disables the RHR interrupt.
		1	Enables the RHR interrupt.

23.3.6 Interrupt Identification Register (IIR) - UART Mode

The UART interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The UART interrupt identification register (IIR) is shown in Figure 23-33 and described in Table 23-15.

NOTE: An interrupt source can be flagged only if enabled in the IER register.

Figure 23-33. UART Interrupt Identification Register (IIR)

		11h-1Fh	Reserved
0	IT_PENDING		Interrupt pending.
		0	An interrupt is pending.
		1	No interrupt is pending.

23.3.7 Interrupt Identification Register (IIR) - IrDA Mode

The IrDA interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The IrDA interrupt identification register (IIR) is shown in Figure 23-34 and described in Table 23-16.

NOTE: An interrupt source can be flagged only if enabled in the IER register.

		1	RHR interrupt active.

23.3.8 Interrupt Identification Register (IIR) - CIR Mode

The CIR interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. The CIR interrupt identification register (IIR) is shown in Figure 23-35 and described in Table 23-17.

NOTE: An interrupt source can be flagged only if enabled in the IER register.

Table 23-18. FIFO Control Register (FCR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-6	RX_FIFO_TRIG	0-3h	Sets the trigger level for the RX FIFO: If SCR[7] = 0 and TLR[7:4] ≠ 0000, RX_FIFO_TRIG is not considered. If SCR[7] = 1, RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with the granularity 1. If SCR[7] = 0 and TLR[7:4] = 0000:
		0	8 characters
		1h	16 characters
		2h	56 characters
		3h	60 characters
5-4	TX_FIFO_TRIG	0-3h	Can be written only if EFR[4] = 1. Sets the trigger level for the TX FIFO: If SCR[6] = 0 and TLR[3:0] ≠ 0000, TX_FIFO_TRIG is not considered. If SCR[6] = 1, TX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR[6] = 0 and TLR[3:0] = 0000:
		0	8 characters
		1h	16 characters
		2h	32 characters
		3h	56 characters
3	DMA_MODE		Can be changed only when the baud clock is not running (DLL and DLH cleared to 0). If SCR[0] = 0, this register is considered.
		0	DMA_MODE 0 (No DMA).
		1	DMA_MODE 1 (UART_NDMA_REQ[0] in TX, UART_NDMA_REQ[1] in RX).
2	TX_FIFO_CLEAR	0	No change.
		1	Clears the transmit FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
1	RX_FIFO_CLEAR	0	No change.
		1	Clears the receive FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
0	FIFO_EN		Can be changed only when the baud clock is not running (DLL and DLH cleared to 0).
		0	Disables the transmit and receive FIFOs. The transmit and receive holding registers are 1-byte FIFOs.
		1	Enables the transmit and receive FIFOs. The transmit and receive holding registers are 64-byte FIFOs.

23.3.10 Line Control Register (LCR)

The line control register (LCR) is shown in Figure 23-37 and described in Table 23-19.

NOTE: As soon as LCR[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR[6] = 1.

		0	Normal operating condition.
		1	Divisor latch enable. Allows access to DLL and DLH.
6	BREAK_EN		Break control bit.
			Note: When LCR[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR[6] = 1.
		0	Normal operating condition.
		1	Forces the transmitter output to go low to alert the communication terminal.
5	PARITY_TYPE2		If LCR[3] = 1:
		0	If LCR[5] = 0, LCR[4] selects the forced parity format.
		1	If LCR[5] = 1 and LCR[4] = 0, the parity bit is forced to 1 in the transmitted and received data.
		1	If LCR[5] = 1 and LCR[4] = 1, the parity bit is forced to 0 in the transmitted and received data.
4	PARITY_TYPE1		If LCR[3] = 1:
		0	Odd parity is generated.
		1	Even parity is generated.
3	PARITY_EN		Parity bit.
		0	No parity.
		1	A parity bit is generated during transmission, and the receiver checks for received parity.
2	NB_STOP		Specifies the number of stop bits.
		0	1 stop bit (word length = 5, 6, 7, 8).
		1	1.5 stop bits (word length = 5) or 2 stop bits (word length = 6, 7, 8).
1-0	CHAR_LENGTH	0-3h	Specifies the word length to be transmitted or received.
		0	5 bits
		1h	6 bits
		2h	7 bits
		3h	8 bit

23.3.11 Modem Control Register (MCR)

Bits 3-0 control the interface with the modem, data set, or peripheral device that is emulating the modem. The modem control register (MCR) is shown in Figure 23-38 and described in Table 23-20.

Figure 23-38. Modem Control Register (MCR)

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 23-20. Modem Control Register (MCR) Field Descriptions

Bit	Field	Value	Description
15-7	Reserved	0	Reserved.
6	TCRTLR		Can be written only when EFR[4] = 1.
		0	No action.
		1	Enables access to the TCR and TLR registers.
5	XONEN		Can be written only when EFR[4] = 1.
		0	Disable XON any function.
		1	Enable XON any function.
4	LOOPBACKEN		Loopback mode enable.
		0	Normal operating mode.
		1	Enable local loopback mode (internal). In this mode, the MCR[3:0] signals are looped back into MSR[7:4]. The transmit output is looped back to the receive input internally.
3	CDSTSCH	0	In loopback mode, forces $\overline{\text{DCD}}$ input high and IRQ outputs to INACTIVE state.
		1	In loopback mode, forces $\overline{\text{DCD}}$ input low and IRQ outputs to INACTIVE state.
2	RISTSCH	0	In loopback mode, forces $\overline{\text{RI}}$ input inactive (high).
		1	In loopback mode, forces $\overline{\text{RI}}$ input active (low).
1	RTS		In loopback mode, controls MSR[4]. If auto-RTS is enabled, the $\overline{\text{RTS}}$ output is controlled by hardware flow control.
		0	Force $\overline{\text{RTS}}$ output to inactive (high).
		1	Force $\overline{\text{RTS}}$ output to active (low).
0	DTR	0	Force $\overline{\text{DTR}}$ output (used in loopback mode) to inactive (high).
		1	Force $\overline{\text{DTR}}$ output (used in loopback mode) to active (low).

23.3.12 Line Status Register (LSR) - UART Mode

When the UART line status register (LSR) is read, LSR[4:2] reflect the error bits (BI, FE, PE) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the LSR and then reading the RHR identifies errors in a character. Reading RHR updates BI, FE, and PE. LSR [7] is set when there is an error anywhere in the RX FIFO and is cleared only when there are no more errors remaining in the RX FIFO. The UART line status register (LSR) is shown in Figure 23-39 and described in Table 23-21.

NOTE: Reading the LSR does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the RHR. Reading LSR clears OE if set.

Figure 23-39. UART Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 23-21. UART Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	RXFIFOSTS	0	Normal operation.
		1	At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO.
6	TXSRE	0	Transmitter hold (TX FIFO) and shift registers are not empty.
		1	Transmitter hold (TX FIFO) and shift registers are empty.
5	TXFIFOE	0	Transmit hold register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
4	RXBI	0	No break condition.
		1	A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame).
3	RXFE	0	No framing error in data being read from RX FIFO.
		1	Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit).
2	RXPE	0	No parity error in data being read from RX FIFO.
		1	Parity error in data being read from RX FIFO.
1	RXOE	0	No overrun error.
		1	Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full.
0	RXFIFOE	0	No data in the receive FIFO.
		1	At least one data character in the RX FIFO.

23.3.13 Line Status Register (LSR) - IrDA Mode

When the IrDA line status register (LSR) is read, LSR[4:2] reflect the error bits (FL, CRC, ABORT) of the frame at the top of the status FIFO (next frame status to be read). The IrDA line status register (LSR) is shown in Figure 23-40 and described in Table 23-22.

Figure 23-40. IrDA Line Status Register (LSR)

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 23-22. IrDA Line Status Register (LSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	THR_EMPTY	0	Transmit holding register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
6	STS_FIFO_FULL	0	Status FIFO is not full.
		1	Status FIFO is full.
5	RX_LAST_BYTE	0	The RX FIFO (RHR) does not contain the last byte of the frame to be read.
		1	The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set to 1 only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR register.
4	FRAME_TOO_LONG	0	No frame-too-long error in frame.
		1	Frame-too-long error in the frame at the top of the status FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.
3	ABORT	0	No abort pattern error in frame.
		1	Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol.
2	CRC	0	No CRC error in frame.
		1	CRC error in the frame at the top of the status FIFO (next character to be read).
1	STS_FIFO_E	0	Status FIFO is not empty.
		1	Status FIFO is empty.
0	RX_FIFO_E	0	At least one data character in the RX FIFO.
		1	No data in the receive FIFO.

23.3.14 Line Status Register (LSR) - CIR Mode

The CIR line status register (LSR) is shown in Figure 23-41 and described in Table 23-23.

7	THREMPTY	0	Transmit holding register (TX FIFO) is not empty.
		1	Transmit hold register (TX FIFO) is empty. The transmission is not necessarily completed.
6	Reserved	0	Reserved.
5	RXSTOP		The RXSTOP is generated based on the value set in the BOF Length register (EBLR).
		0	Reception is on going or waiting for a new frame.
		1	Reception is completed. It is cleared on a single read of the LSR register.
4-1	Reserved	0	Reserved
0	RXFIFOE	0	At least one data character in the RX FIFO.
		1	No data in the receive FIFO.

23.3.15 Modem Status Register (MSR)

The modem status register (MSR) provides information about the current state of the control lines from the modem, data set, or peripheral device to the Local Host. It also indicates when a control input from the modem changes state. The modem status register (MSR) is shown in Figure 23-42 and described in Table 23-24.

Figure 23-42. Modem Status Register (MSR)

Table 23-24. Modem Status Register (MSR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	NCD_STS		This bit is the complement of the $\overline{DCD}$ input. In loopback mode, it is equivalent to MCR[3].
6	NRI_STS		This bit is the complement of the $\overline{RI}$ input. In loopback mode, it is equivalent to MCR[2].
5	NDSR_STS		This bit is the complement of the $\overline{DSR}$ input. In loopback mode, it is equivalent to MCR[0].
4	NCTS_STS		This bit is the complement of the $\overline{CTS}$ input. In loopback mode, it is equivalent to MCR[1].
3	DCD_STS	0	No change.
		1	Indicates that $\overline{DCD}$ input (or MCR[3] in loopback mode) has changed. Cleared on a read.
2	RI_STS	0	No change.
		1	Indicates that $\overline{RI}$ input (or MCR[2] in loopback mode) changed state from low to high. Cleared on a read.
1	DSR_STS	0	No change.
		1	Indicates that $\overline{DSR}$ input (or MCR[0] in loopback mode) changed state. Cleared on a read.
0	CTS_STS	0	No change.
		1	Indicates that $\overline{CTS}$ input (or MCR[1] in loopback mode) changed state. Cleared on a read.

23.3.16 Transmission Control Register (TCR)

The transmission control register (TCR) stores the receive FIFO threshold levels to start/stop transmission during hardware flow control. The transmission control register (TCR) is shown in Figure 23-43 and described in Table 23-25.

NOTE:

- Trigger levels from 0-60 bytes are available with a granularity of 4.
- Trigger level = 4 × [4-bit register value]
- You must ensure that TCR[3:0] > TCR[7:4], whenever auto-RTS or software flow control is enabled to avoid a misoperation of the device. In FIFO interrupt mode with flow control, you have to also ensure that the trigger level to HALT transmission is greater or equal to receive FIFO trigger level (either TLR[7:4] or FCR[7:6]); otherwise, FIFO operation stalls.
- In FIFO DMA mode with flow control, this concept does not exist because the DMA request is sent each time a byte is received.

Figure 23-43. Transmission Control Register (TCR)

7-4	RXFIFOTRIGSTART	0-Fh	RX FIFO trigger level to RESTORE transmission (0 to 60).
3-0	RXFIFOTRIGHALT	0-Fh	RX FIFO trigger level to HALT transmission (0 to 60).

23.3.17 Scratchpad Register (SPR)

The scratchpad register (SPR) is a read/write register that does not control the module. It is a scratchpad register used to hold temporary data. The scratchpad register (SPR) is shown in Figure 23-44 and described in Table 23-26.

Figure 23-44. Scratchpad Register (SPR)

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-4	RX_FIFO_TRIG_ DMA	0-Fh	Receive FIFO trigger level. See Table 23-28.
3-0	TX_FIFO_TRIG_ DMA	0-Fh	Transmit FIFO trigger level. See Table 23-29.

Table 23-28. RX FIFO Trigger Level Setting Summary

SCR[7]	TLR[7:4]	Description
0	0	Defined by FCR[7:6] (either 8, 16, 56, 60 characters).
0	≠ 0000	Defined by TLR[7:4] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[7:4] and FCR[7:6] (from 1 to 63 characters with a granularity of 1 character). **Note:** the combination of TLR[7:4] = 0000 and FCR[7:6] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

Table 23-29. TX FIFO Trigger Level Setting Summary

SCR[6]	TLR[3:0]	Description
0	0	Defined by FCR[5:4] (either 8, 16, 32, 56 characters).
0	≠ 0000	Defined by TLR[3:0] (from 4 to 60 characters with a granularity of 4 characters).
1	any value	Defined by the concatenated value of TLR[3:0] and FCR[5:4] (from 1 to 63 characters with a granularity of 1 character). **Note:** the combination of TLR[3:0] = 0000 and FCR[5:4] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

23.3.19 Mode Definition Register 1 (MDR1)

The mode of operation is programmed by writing to MDR1[2:0]; therefore, the mode definition register 1 (MDR1) must be programmed on startup after configuration of the configuration registers (DLL, DLH, and LCR). The value of MDR1[2:0] must not be changed again during normal operation. The mode definition register 1 (MDR1) is shown in Figure 23-46 and described in Table 23-30.

NOTE: If the module is disabled by setting the MODESELECT field to 7h, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows the UART mode interrupt flags.

		1	SIR mode.
		2h	UART 16× auto-baud.
		3h	UART 13× mode.
		4h	MIR mode.
		5h	FIR mode.
		6h	CIR mode.
		7h	Disable (default state).

23.3.20 Mode Definition Register 2 (MDR2)

The MDR2[0] bit describes the status of the TX status interrupt in IIR[5]. The IRTXUNDERRUN bit must be read after a TX status interrupt occurs. The MDR2[2:1] bits set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1[2:0]. The mode definition register 2 (MDR2) is shown in Figure 23-47 and described in Table 23-31.

NOTE: The MDR2[6] bit gives the flexibility to invert the RX pin inside the UART module to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most of transceiver invert the IR receive pin.

		1	Alternate mode for SETTXIR
6	IRRXINVERT		Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes.
		0	Inversion is performed.
		1	No inversion is performed.
5-4	CIRPULSEMODE	0-3h	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit:
		0	Pulse width of 3 from 12 cycles.
		1h	Pulse width of 4 from 12 cycles.
		2h	Pulse width of 5 from 12 cycles.
		3h	Pulse width of 6 from 12 cycles.
3	UARTPULSE		UART mode only. Used to allow pulse shaping in UART mode.
		0	Normal UART mode.
		1	UART mode with pulse shaping.
2-1	STSFIFOTRIG	0-3h	Only for IrDA mode. Frame status FIFO threshold select:
		0	1 entry
		1h	4 entries
		2h	7 entries
		3h	8 entries
0	IRTXUNDERRUN		IrDA transmission status interrupt. When the TX status interrupt (IIR[5]) occurs, the meaning of the interrupt is:
		0	The last bit of the frame was transmitted successfully without error.
		1	An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME register is read.

23.3.21 Mode Definition Register 3 (MDR3)

The MDR3[0] DISABLE_CIR_RX_DEMOD bit will force the CIR receiver to bypass demodulation of received data if set.

The MDR3[1] NONDEFAULT_FREQ bit allows the user to set sample per bi. Set this bit if non default (48MHz) clock frequency is used to achieve less than 2 % error rate. Changing this bit automatically disables the device by setting MDR1[2:0] to 3h.

MDR3[2] SET_DMA_THRESHOLD bit enables the usage of different TX DMA threshold then 64-trigger, when set to 1h.

The mode definition register 3 (MDR3) is shown in Figure 23-48 and described in Table 23-32.

Figure 23-48. Mode Definition Register 3 (MDR3)

2	SET_DMA_THRESHOLD	0	Use the value of 64-tx trigger.
		1h	Sets different TX DMA threshold then 64-trigger
1	NONDEFAULT_FREQ	0	Default fclk frequencies
		1h	Nondefault fclk frequencies
0	DISABLE_CIR_RX_DEMOD	0	Enalbes CIR RX demodulation
		1h	Disables CIR RX demodulation

23.3.22 Status FIFO Line Status Register (SFLSR)

Reading the status FIFO line status register (SFLSR) effectively reads frame status information from the status FIFO. This register does not physically exist. Reading this register increments the status FIFO read pointer (SFREGL and SFREGH must be read first). The status FIFO line status register (SFLSR) is shown in Figure 23-49 and described in Table 23-33.

NOTE: Top of RX FIFO = Next frame to be read from RX FIFO.

Figure 23-49. Status FIFO Line Status Register (SFLSR)

15-5	Reserved	0	Reserved.
4	OE_ERROR	0	No error
		1	Overrun error in RX FIFO when frame at top of RX FIFO was received.
3	FRAME_TOO_LONG_ERROR	0	No error
		1	Frame-length too long error in frame at top of RX FIFO.
2	ABORT_DETECT	0	No error
		1	Abort pattern detected in frame at top of RX FIFO.
1	CRC_ERROR	0	No error
		1	CRC error in frame at top of RX FIFO.
0	Reserved	0	Reserved.

23.3.23 RESUME Register

The RESUME register is used to clear internal flags, which halt transmission/reception when an underrun/overrun error occurs. Reading this register resumes the halted operation. This register does not physically exist and always reads as 00. The RESUME register is shown in Figure 23-50 and described in Table 23-34.

Figure 23-50. RESUME Register

Table 23-34. RESUME Register Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	RESUME	0-FFh	Dummy read to restart the TX or RX.

23.3.24 Status FIFO Register Low (SFREGL)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register low (SFREGL) is shown in Figure 23-51 and described in Table 23-35.

Figure 23-51. Status FIFO Register Low (SFREGL)

7-0	SFREGL	0-FFh	LSB part of the frame length.

23.3.25 Status FIFO Register High (SFREGH)

The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR. The status FIFO register high (SFREGH) is shown in Figure 23-52 and described in Table 23-36.

Figure 23-52. Status FIFO Register High (SFREGH)

Bit	Field	Value	Description
15-4	Reserved	0	Reserved.
3-0	SFREGH	0-Fh	MSB part of the frame length.

23.3.26 BOF Control Register (BLR)

The BLR[6] bit is used to select whether C0h or FFh start patterns are to be used, when multiple start flags are required in SIR mode. If only one start flag is required, this is always C0h. If *n* start flags are required, either (n – 1) C0h or (n –1) FFh flags are sent, followed by a single C0h flag (immediately preceding the first data byte). The BOF control register (BLR) is shown in Figure 23-53 and described in Table 23-37.

Figure 23-53. BOF Control Register (BLR)

6	XBOFTYPE		SIR xBOF select.
		0	FFh start pattern is used.
		1	C0h start pattern is used.
0	Reserved	0	Reserved.

23.3.27 Auxiliary Control Register (ACREG)

The auxiliary control register (ACREG) is shown in Figure 23-54 and described in Table 23-38.

NOTE:

- If transmit FIFO is not empty and MDR1[5] = 1, IrDA starts a new transfer with data of previous frame as soon as abort frame has been sent. Therefore, TX FIFO must be reset before sending an abort frame.
- It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, unknown data is sent over TX line.

Figure 23-54. Auxiliary Control Register (ACREG)

15							8

PULSETYPE	SDMOD	DISIRRX	DISTXUNDERRUN	SENDSIP	SCTXEN	ABORTEN	EOTEN
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 23-38. Auxiliary Control Register (ACREG) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	PULSETYPE		SIR pulse-width select:
		0	3/16 of baud-rate pulse width
		1	1.6 µs
6	SDMOD		Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers.
		0	SD pin is set to high.
		1	SD pin is set to low.
5	DISIRRX		Disable RX input.
		0	Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation).
		1	Disables RX input (permanent state; independent of transmit).
4	DISTXUNDERRUN		Disable TX underrun.
		0	Long stop bits cannot be transmitted. TX underrun is enabled.
		1	Long stop bits can be transmitted.
3	SENDSIP		MIR/FIR modes only. Send serial infrared interaction pulse (SIP).
			If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission.
		0	No action.
		1	Send SIP pulse.
2	SCTXEN		Store and control TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.
1	ABORTEN		Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.
0	EOTEN		EOT (end-of-transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the LH writes to the THR (TX FIFO).

23.3.28 Supplementary Control Register (SCR)

The supplementary control register (SCR) is shown in Figure 23-55 and described in Table 23-39.

NOTE: Bit 4 enables the wake-up interrupt, but this interrupt is not mapped into the IIR register. Therefore, when an interrupt occurs and there is no interrupt pending in the IIR register, the SSR[1] bit must be checked. To clear the wake-up interrupt, bit SCR[4] must be reset to 0.

		1	Enables the granularity of 1 for trigger RX level.
6	TXTRIGGRANU1	0	Disables the granularity of 1 for trigger TX level.
		1	Enables the granularity of 1 for trigger TX level.
5	DSRIT	0	Disables $\overline{\text{DSR}}$ interrupt.
		1	Enables $\overline{\text{DSR}}$ interrupt.
4	RXCTSDSRWAKEUPENABLE		RX CTS wake-up enable.
		0	Disables the WAKE UP interrupt and clears SSR[1].
		1	Waits for a falling edge of RX, $\overline{\text{CTS}}$, or $\overline{\text{DSR}}$ pins to generate an interrupt.
3	TXEMPTYCTLIT	0	Normal mode for THR interrupt.
		1	THR interrupt is generated when TX FIFO and TX shift register are empty.
2-1	DMAMODE2	0-3h	Specifies the DMA mode valid if SCR[0] = 1:
		0	DMA mode 0 (no DMA).
		1h	DMA mode 1 (UARTnDMAREQ[0] in TX, UARTnDMAREQ[1] in RX)
		2h	DMA mode 2 (UARTnDMAREQ[0] in RX)
		3h	DMA mode 3 (UARTnDMAREQ[0] in TX)
0	DMAMODECTL	0	The DMAMODE is set with FCR[3].
		1	The DMAMODE is set with SCR[2:1].

23.3.29 Supplementary Status Register (SSR)

The supplementary status register (SSR) is shown in Figure 23-56 and described in Table 23-40.

NOTE: Bit 1 is reset only when SCR[4] is reset to 0.

Figure 23-56. Supplementary Status Register (SSR)

Bit	Field	Value	Description
15-3	Reserved	0	Reserved.
2	DMACOUNTERRST	0	The DMA counter will not be reset, if the corresponding FIFO is reset (via FCR[1] or FCR[2]).
		1	The DMA counter will be reset, if the corresponding FIFO is reset (via FCR[1] or FCR[2]).
1	RXCTSDSRWAKEUPSTS		Pin falling edge detection: Reset only when SCR[4] is reset to 0.
		0	No falling-edge event on RX, $\overline{CTS}$, and $\overline{DSR}$.
		1	A falling edge occurred on RX, $\overline{CTS}$, or $\overline{DSR}$.
0	TXFIFOFULL	0	TX FIFO is not full.
		1	TX FIFO is full.

23.3.30 BOF Length Register (EBLR)

In IrDA SIR operation, the BOF length register (EBLR) specifies the number of BOF + xBOFs to transmit. The value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with *n* XBOFs, this register must be set to *n* + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOFs.

In IrDA MIR mode, the BOF length register (EBLR) specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags).

In CIR mode, the BOF length register (EBLR) specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]). All the received zeros are stored in the RX FIFO. When the register is cleared to 0, this feature is deactivated and always in reception state, which is disabled by setting the ACREG[5] bit to 1.

The BOF length register (EBLR) is shown in Figure 23-57 and described in Table 23-41.

NOTE: If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

15-8	Reserved	0	Reserved.
7-0	EBLR		IrDA mode: This register allows definition of up to 176 xBOFs, the maximum required by IrDA specification. CIR mode: This register specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]).
		0	Feature disabled.
		1h	Generate RXSTOP interrupt after receiving 1 zero bit.
		...	
		FFh	Generate RXSTOP interrupt after receiving 255 zero bits.

23.3.31 Module Version Register (MVR)

The reset value is fixed by hardware and corresponds to the RTL revision of this module. A reset has no effect on the value returned. The module version register (MVR) is shown in Figure 23-58 and described in Table 23-42.

Figure 23-58. Module Version Register (MVR)

7-4	MAJORREV	0-Fh	Major revision number of the module.
3-0	MINORREV	0-Fh	Minor revision number of the module.

23.3.32 System Configuration Register (SYSC)

The AUTOIDLE bit controls a power-saving technique to reduce the logic power consumption of the module interface; that is, when the feature is enabled, the interface clock is gated off until the module interface is accessed. When the SOFTRESET bit is set high, it causes a full device reset. The system configuration register (SYSC) is shown in Figure 23-59 and described in Table 23-43.

Figure 23-59. System Configuration Register (SYSC)

15	5	4	3	2	1	0

15-1	Reserved	0	Reserved.
0	RESETDONE		Internal reset monitoring.
		0	Internal module reset is ongoing.
		1	Reset complete.

23.3.34 Wake-Up Enable Register (WER)

The wake-up enable register (WER) is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such. The wake-up enable register (WER) is shown in Figure 23-61 and described in Table 23-45.

		1	Event can wake up the system.
0	CTS_ ACTIVITY	0	Event is not allowed to wake up the system.
		1	Event can wake up the system.

23.3.35 Carrier Frequency Prescaler Register (CFPS)

Since the consumer IR (CIR) works at modulation rates of 30–56.8 kHz, the 48 MHz clock must be prescaled before the clock can drive the IR logic. The carrier frequency prescaler register (CFPS) sets the divisor rate to give a range to accommodate the remote control requirements in BAUD multiples of 12×. The value of the CFPS at reset is 105 decimal (69h), which equates to a 38.1 kHz output from starting conditions. The 48 MHz carrier is prescaled by the CFPS that is then divided by the 12× BAUD multiple. The carrier frequency prescaler register (CFPS) is shown in Figure 23-62 and described in Table 23-46.

Figure 23-62. Carrier Frequency Prescaler Register (CFPS)

15	8	7	0
Reserved		CFPS	
R-0		R/W-69h

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	CFPS	0-FFh	System clock frequency prescaler at (12× multiple). CFPS = 0 is not supported. Examples for CFPS values:

Target Frequency (kHz)	CFPS (decimal)	Actual Frequency (kHz)
30	133	30.08
32.75	122	32.79
36	111	36.04
36.7	109	36.69
38	105	38.1
40	100	40
56.8	70	57.14

23.3.36 Divisor Latches Low Register (DLL)

The divisor latches low register (DLL) with the DLH register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. The DLL register is shown in Figure 23-63 and described in Table 23-47.

NOTE: DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

Figure 23-63. Divisor Latches Low Register (DLL)

15	8	7	0
Reserved		CLOCK_LSB

5-0	CLOCK_MSB	0-3Fh	Divisor latches high. Stores the 6 MSB divisor value.

23.3.38 Enhanced Feature Register (EFR)

The enhanced feature register (EFR) enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR[4] enables write accesses to FCR[5:4], the TX trigger level, which is also used in IrDA modes. The enhanced feature register (EFR) is shown in Figure 23-65 and described in Table 23-49.

Figure 23-65. Enhanced Feature Register (EFR)

15					8

Table 23-49. Enhanced Feature Register (EFR) Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7	AUTOCTSEN		Auto-CTS enable bit (UART mode only).
		0	Normal operation.
		1	Auto-CTS flow control is enabled; transmission is halted when the $\overline{CTS}$ pin is high (inactive).
6	AUTORTSEN		Auto-RTS enable bit (UART mode only).
		0	Normal operation.
		1	Auto-RTS flow control is enabled; $\overline{RTS}$ pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.
5	SPECIALCHARDETECT		Special character detect (UART mode only).
		0	Normal operation.
		1	Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and the IIR[4] bit is set to 1 to indicate that a special character was detected.
4	ENHANCEDEN		Enhanced functions write enable bit.
		0	Disables writing to IER[7:4], FCR[5:4], and MCR[7:5].
		1	Enables writing to IER[7:4], FCR[5:4], and MCR[7:5].
3-0	SWFLOWCONTROL	0-Fh	Combinations of software flow control can be selected by programming this bit. XON1 and XON2 should be set to different values if the software flow control is enabled. See Table 23-50. In IrDA mode, EFR[1:0] selects the IR address to check. See *IR Address Checking*.

Table 23-50. EFR[3:0] Software Flow Control Options

EFR[3:0]				
Bit 3	Bit 2	Bit 1	Bit 0	TX/RX Software Flow Control
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) The XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.

23.3.39 XON1/ADDR1 Register

In UART mode, XON1 character; in IrDA mode, ADDR1 address 1. The XON1/ADDR1 register is shown in Figure 23-66 and described in Table 23-51.

Figure 23-66. XON1/ADDR1 Register

15	8	7	0
Reserved		XONWORD1	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 23-51. XON1/ADDR1 Register Field Descriptions

Bit	Field	Value	Description
15-8	Reserved	0	Reserved.
7-0	XONWORD1	0-FFh	Stores the 8-bit XON1 character in UART modes and ADDR1 address 1 in IrDA modes.

23.3.40 XON2/ADDR2 Register

In UART mode, XON2 character; in IrDA mode, ADDR2 address 2. The XON2/ADDR2 register is shown in Figure 23-67 and described in Table 23-52.

Figure 23-67. XON2/ADDR2 Register

15	8	7	0

7-0	XOFFWORD2	0-FFh	Stores the 8-bit XOFF2 character in UART modes.

23.3.43 Transmit Frame Length Low Register (TXFLL)

The transmit frame length low register (TXFLL) and the TXFLH register hold the 13-bit transmit frame length (expressed in bytes). TXFLL holds the LSBs and TXFLH holds the MSBs. The frame length value is used if the frame length method of frame closing is used. The transmit frame length low register (TXFLL) is shown in Figure 23-70 and described in Table 23-55.

Figure 23-70. Transmit Frame Length Low Register (TXFLL)

23.3.45 Received Frame Length Low Register (RXFLL)

The received frame length low register (RXFLL) and the RXFLH register hold the 12-bit receive maximum frame length. RXFLL holds the LSBs and RXFLH holds the MSBs. If the intended maximum receive frame length is *n* bytes, program RXFLL and RXFLH to be *n* + 3 in SIR or MIR modes and *n* + 6 in FIR mode (+3 and +6 are the result of frame format with CRC and stop flag; two bytes are associated with the FIR stop flag). The received frame length low register (RXFLL) is shown in Figure 23-72 and described in Table 23-57.

Figure 23-72. Received Frame Length Low Register (RXFLL)

Table 23-58. Received Frame Length High Register (RXFLH) Field Descriptions

Bit	Field	Value	Description
15-4	Reserved	0	Reserved.
3-0	RXFLH	0-Fh	MSB register used to specify the frame length in reception.

23.3.47 UART Autobauding Status Register (UASR)

The UART autobauding status register (UASR) returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. The UART autobauding status register (UASR) is shown in Figure 23-74 and described in Table 23-59.

NOTE:

- This register is used to set up transmission according to characteristics of previous reception, instead of LCR, DLL, and DLH registers when UART is in autobauding mode.
- To reset the autobauding hardware (to start a new “AT” detection) or to set the UART in standard mode (no autobaud), MDR1[2:0] must be set to 7h (reset state), then set to 2h (UART in autobaud mode) or cleared to 0 (UART in standard mode).

Usage limitation:

- Only 7 and 8 bits character (5 and 6 bits not supported).
- 7 bits character with space parity not supported.
- Baud rate between 1200 and 115 200 bp/s (10 possibilities).

Figure 23-74. UART Autobauding Status Register (UASR)

		7h	9600 baud
		8h	4800 baud
		9h	2400 baud
		Ah	1200 baud
		Bh-1Fh	Reserved

Universal Serial Bus (USB)

The universal serial bus (USB) is an external serial bus supporting a data transfer speed rates ranging up to 480 Mbits/second. The device supports a dual port USB controller with both ports complying with USB2.0 standard. Both ports support dual role functionality and as such they are both configurable as Host or Device. Even though both ports are made of OTG Controllers, OTG feature is not supported. The two ports operate independent of each other.

Topic **Page**

24.1 Introduction

24.1.1 Overview

The USB controller provides a low-cost connectivity solution for numerous consumer portable devices by providing a mechanism for data transfer between USB devices with a line/bus speed up to 480 Mbps. The device USB subsystem has two independent USB 2.0 Modules built around two OTG controllers. Even though the controllers are OTG controllers, OTG features are not supported by any of the ports. Each port has the support for a dual-role feature allowing for additional versatility enabling operation capability as a host or peripheral. Both ports have identical capabilities and operate independent of each other.

Each USB controller is built around the Mentor USB OTG controller (musbmhdrc) and Synopsys SR70LX PHY. Each USB controller has user configurable 32K Bytes of Endpoint FIFO and has the support for 15 'Transmit' endpoints and 15 'Receive' endpoints in addition to Endpoint 0. The USB subsystem makes use of the CPPI 4.1 DMA for accelerating data movement via a dedicated DMA hardware.

The two USB modules share the CPPI DMA controller and accompanying Queue Manager, Interrupt Pacer, Power Management module, and PHY/UTMI clock.

Within the descriptions of the USB subsystem that would follow, the term USB controller or USB PHY is used to mean/refer to any of the two USB controllers or PHYs existing within the USB subsystem. The term USB module is used to mean/refer to any of the two USB modules. USB0(1) is used to refer to one of the two USB Modules.

24.1.2 Features Supported

The main features of the USB Subsystem are:

- Has two USB modules where each USB module is built around a mentor USB controller and Synopsys PHY.
- Includes SR70LX Synopsys USB 2.0 OTG nanoPHY per module in C014.P process.
- Supports USB 2.0 device operations at HS (480 Mb/s) and FS (12 Mb/s).
- Supports USB 2.0 Host operations at HS (480 Mb/s), FS (12 Mb/s) and LS (1.5Mb/s).
- Supports all modes of transfers (control, bulk, interrupt, and isochronous) in both host and device mode.
- Supports high bandwidth ISO mode.
- Supports 15 Transmit (Tx) and 15 Receive (Rx) Endpoints including Endpoint 0.
- Includes a 32KB Endpoint FIFO RAM per Module (64Kbytes per USB Subsystem) with user programmable FIFO sizes.
- Includes RNDIS mode for accelerating RNDIS type protocols using short packet termination over USB.
- Includes CDC Linux mode for accelerating CDC type protocols using short packet termination over USB.
- Includes Generic RNDIS mode, an RNDIS like mode for terminating RNDIS type protocols without using short packet termination for support for MSC class applications.
- Includes a CPPI 4.1 compliant DMA controller sub-module with 30 Rx and 30 Tx simultaneous data connections/channels.
- Includes CPPI 4.1 DMA scheduler.
- DMA supports host and packet descriptors formats.
- DMA supports stall on buffer starvation.
- DMA supports capability of allocating data buffer sizes up to 4Mbytes per single transfer.
- Provides a CPPI Queue Manager Module with 156 Queues for Queueing and De-Queueing packets.
- Supports DMA pacing logic for interrupts.
- Supports Loopback MGC test using at the UTMI interface level.

24.1.3 Features Not Supported

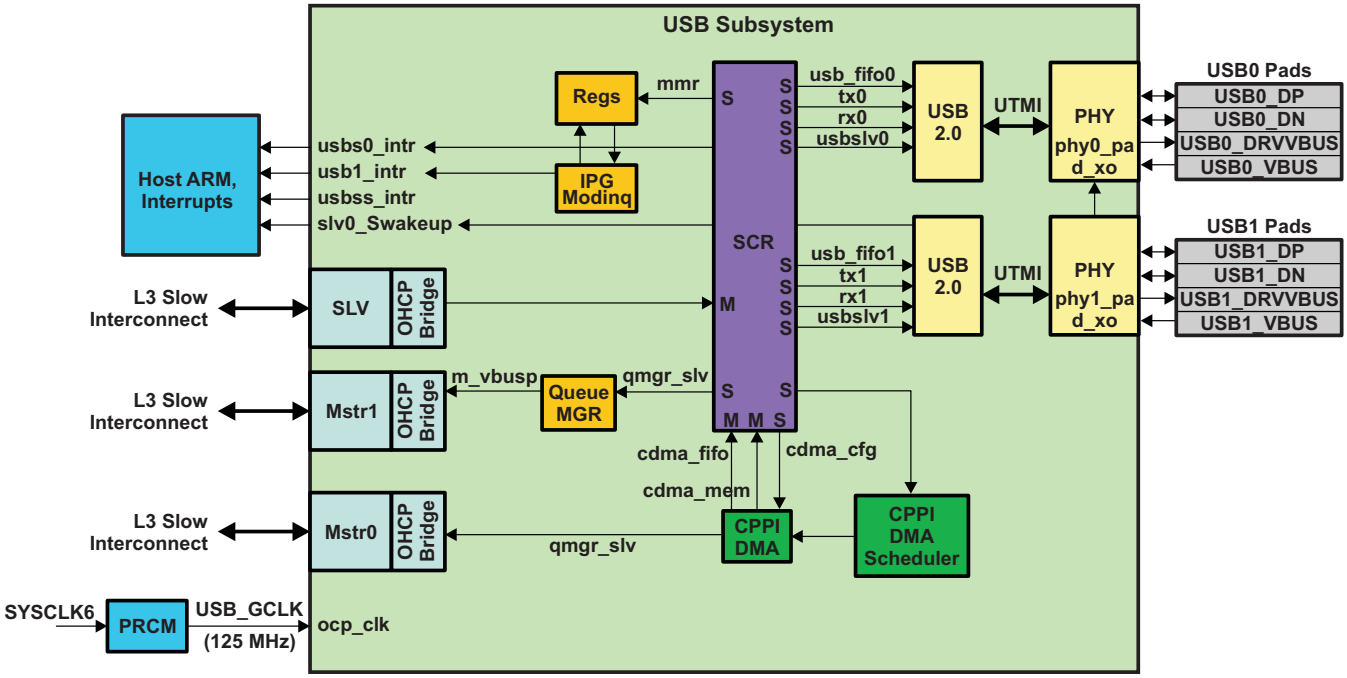
- USB2.0 extensions for OTG Session Request Protocol (SRP)
- USB2.0 extensions for OTG Host Request Protocol (HRP)

NOTE: The USB subsystem is built around two USB OTG controllers. However, OTG functionalities are not supported. What this means is that the USB Modules support mini-host and device capabilities but is not capable of changing roles (device/host) on the fly.

24.1.4 Functional Block Diagram

Figure 1 displays a high-level functional block diagram covering the major blocks of the USB subsystem. It captures the general data paths and displays the interaction between each blocks of the subsystem at a high level.

Figure 24-1. USB Subsystem Block Diagram



24.1.4.1 L3 Slow Interconnect

This is the OCP interface to the MMRs and system resource. CPPI DMA and Queue Manager have also their own dedicated interface to the system resource through the master interfaces. Cortex-A8 accesses the USB peripheral through the save OCP Interface.

24.1.4.2 Reg

The USB register file (USB core and subsystem registers and CPPI DMA registers are accessible to the Cortex-A8) reside in a block within the USBSS.

24.1.4.3 USB2.0 Controller

The USB subsystem supports two independent USB Modules. Each USB module comprises of a Dual Role USB2.0 compliant Mentor OTG controller without the support for OTG functionality.

24.1.4.4 USB PHY

The USB subsystem is made of two USB modules. Each USB module comprises a Synopsys Designware core USB 2.0 PHY. The PHY is connected to the USB controller via 8-bit UTMI Interface. The PHY does not have a built-in charge pump and an external power source is required to source the 5V VBUS power when operating as a Host.

24.1.4.5 USB Pads

The USB subsystem external interface signals comprises two differential data lines, two Voltage Buses (VBUS), and two USB DRVVBUS signals (enable/disable external 5V Power Source). No USB ID pad exists. The Register field that is user software controlled is used as a replacement for the ID pad usage. For more details about the USB0 and USB1 mode registers, see Section 24.9.2.1.22 and Section 24.9.2.2.22, respectively.

24.1.4.6 DMA Resources

The CPPI DMA alongside with the Queue Manager and the Scheduler are used to perform data transfer for Endpoints 1 to 15.

24.1.4.7 Interrupts

There are three interrupt interfaces: one for the USB subsystem, one for the USB0 controller, and one for the USB1 controller. All interrupts for that specific unit are aggregated into one interrupt interface.

Each interrupt has two basic registers: STATUS and ENABLE. Hardware can set the register via internal logic. Software can set or clear the register by accessing the appropriate locations in the memory map. The enabling (or masking) of the interrupt is controlled via software. Writing 1's (WR1) to either the IRQENABLE_SET or IRQENABLE_CLR addresses will enable or disable the interrupt respectively. An EOI function exists to re-enable the detection of active interrupts. If the system attempts to write to any of the interrupt registers, any still active interrupts will trigger the EOI output signal. The EOI input signal indicates when external logic requires the USB to re-evaluate its pending sources and send another pulse. For more information see section "Interrupt Support."

Note: When generating an interrupt by writing to one of the IRQ_ENABLE_SET registers; the interrupt can occur several cycles before the OCP write status complete has occurred.

24.1.5 Supported Use Case(s)

The USB subsystem supports two USB OTG modules that are capable of operating as a mini-host and device. OTG features are not supported.

24.1.6 Industry Standard(s) Compliance

The USB subsystem complies with the following standards:

- Complies with the USB 2.0 standard for high-speed (480 Mbps) functions and with the On-The-Go supplement to the USB 2.0 Specification. However it does not support OTG functionality.

24.1.7 Non-Industry Standard(s)

The USB subsystem complies with the following proprietary standards:

- Mentor Dual Role Controller (MUSBMHDRC) – USB Controller
- SR70LX – Physical Layer: Synopsys DesignWare Core USB 2.0 nanoPHY
- TI CPPI 4.1 – Built in 1st party DMA and Structure

24.1.8 Terminology Used in This Document

The following is a brief explanation of some terms that are used in this document:

AHB— Advanced High-Performance Bus

CBA— Common Bus Architecture

CDC— Change Data Capture

CPPI— Communications Port Programming Interface

DFT— Design for Test

DMA— Direct Memory Access

DV— Design Verification

EOI— End of Interrupt

EOP— End of Packet

FIFO— First-In First-Out

FS— Full-Speed USB data rate

HNP— Host Negotiation

HS— High-Speed USB data rate

INTD— Interrupt Distributor

IP— Intellectual Property

ISO— Isochronous transfer type

LS— Low-Speed USB data rate

MP— Middle of Packet

OCP— Open Core Protocol

OCP HD— OCP High Performance

OCP MMR— OCP Memory-Mapped Registers

OTG— On-the-Go

PDR— Physical Design Requirements

PHY— Physical Layer Device

PPU— Packet Processing Unit

RNDIS— Remote Network Driver Interface Specification

RX— Receive

SCR— Switched Central Resource

SOC— System On a Chip

SOP— Start of Packet

SRP— Session Resume

TX— Transmit

USB— Universal Serial Bus

USB0— One of the two USB 2.0-Compliant USB Module

USB1— One of the two USB2.0-Compliant USB Module

USBSS— USB Subsystem (contains USB0 and USB1)

UTMI— USB 2.0 Transceiver Macrocell Interface

XDMA— Transfer DMA (DMA other than CPPI DMA used within the Controller)

24.2 Architecture

The USB controller within the device supports 15 Transmit endpoints and 15 Receive endpoints in addition to Endpoint 0. (The use of these endpoints for IN and OUT transactions depends on whether the USB controller is being used as a device/peripheral or as a host. When used as a peripheral, IN transactions are processed through TX endpoints and OUT transactions are processed through Rx endpoints. When used as a host, IN transactions is processed through Rx endpoints and OUT transactions is processed through TX endpoints.)

These additional endpoints can be individually configured in software to handle either Bulk transfers (which also allows them to handle Interrupt transfers), Isochronous transfers or Control transfers. Further, the endpoints can also be allocated to different target device functions on the fly – maximizing the number of devices that can be simultaneously supported.

Each endpoint requires a chunk of memory allocated within the FIFO to be associated with it. The USB module has a single block of FIFO RAM (32 Kbytes in size) to be shared by all endpoints. The FIFO for Endpoint 0 is required to be 64 bytes deep and will buffer 1 packet. The first 64 Bytes of the FIFO RAM is reserved by hardware for Endpoint 0 usage and for this reason user software does not need (nor has the capability) to allocate FIFO for Endpoint 0. The rest of the FIFO RAM is user configurable with regard to the other endpoint FIFOs, which may be from 8 to 8192 bytes in size and can buffer either 1 or 2 packets.

Separate FIFOs may be associated with each endpoint: alternatively a TX endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO, for example to reduce the size of RAM block needed, provided they can never be active at the same time.

The role (host or device) that the USB controller assumes is chosen by user firmware programming the respective USB controller MODE register defined within the USB subsystem space. Note that some USB pins have not been bonded out and the functions of these pins are controlled by user software via dedicated registers.

The user has access to the controller through the OCP slave interface via the CPU. The user can process USB transactions entirely from the CPU or can also use the DMA to perform data transfer. The CPPI DMA can be used to service Endpoints 1 to 15 not Endpoint 0. CPU access method is used to service Endpoint 0 transactions.

24.2.1 Clock Control

Two main clocks are used to by the USB subsystem, the OCP clock and the UTMI/PHY clock.

The OCP clock (SYSCLK6), also referred as the System Clock, is the clock that is used to clock the controller and all other blocks of the USB subsystem with the exception of the PHY. This clock is controlled by the PRCM. A clock rate of 60 MHz or greater must be used to guarantee core operation can deliver full USB 2.0 bandwidth (480 Mb/s). In other words, SYSCLK6 should not be less than 60 MHz. SYSCLK6 is derived from the main PLL.

The UTMI/PHY clock is derived from a 24 MHz clock sourced to the PHY. PHY internal PLL will derive the necessary bit clock and 60MHz UTMI clock

24.2.2 Signal Descriptions

The USB subsystem external interface signals are displayed within Table 24-1.

Table 24-1. USBSS Interface Signals

Pin (x=0/1)	Type	Description
USBx_DP USBx_DN	I/O	USBx data differential pair
USBx_DRVVBUS	O	USBx VBUS supply control
USBx_VBUS	I	USBx VBUS (input only for voltage sensing)

24.2.3 VBUS Voltage Sourcing Control

When any of the USB controllers assumes the role of a host, the USB is required to supply a 5V power source to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of an external power logic (or charge pump) capable of sourcing 5V power. A USB_DRVVBUS is used as a control signal to enable/disable this external power logic to either source or disable power on the VBUS line. The control on the USB_DRVVBUS is automatic and is handled by the USB controller. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB_DRVVBUS signal high when it assumes the role of a host while the controller is in session. When assuming the role of a device, the controller drives the USB_DRVVBUS signal low disabling the external charge pump/power logic; hence, no power is driven on the VBUS line (in this case, power is expected to be sourced by the external host).

Note that both USBs are self-powered and the device does not rely on the voltage on the VBUS line sourced by an external host for controller operation when assuming the role of a device. The power on the VBUS is used to identify the presence of a Host. It is also used to power up the pull-up on the D+ line. The USB PHY would continually monitor the voltage on the VBUS and report the status to USB controller.

24.2.4 Pull-up/Pull-Down Resistors

Since the USB controllers are dual role controllers, capable of assuming a role of a host or device, the necessary required pull-up/pull-down resistors can not exist external to the device. These pull-up/pull-down resistors exist internal to the device, within the PHY to be more specific, and are enabled and disabled based on the role the controller assumes allowing dynamic hardware configuration.

When assuming the role of a host, the data lines are pulled low by the PHY enabling the internal 15KOhms resistors. When assuming the role of a device the required 1.5Kohm pull-up resistor on the D+ line is enabled automatically to signify the USB capability to the external host as a FS device (HS operation is negotiated during reset bus condition).

24.2.5 Role Assuming Method

For an OTG controller, the usual method followed by the controller to assume the role of a host or a device is governed by the state of the ID pin which in turn is controlled by the USB cable connector type. Since no ID pin signal has been bonded out on the device, there exists a register field within the USB subsystem register file that is programmed by the user indirectly controlling the state of the ID pin and ultimately selecting the role of the USB controller.

Two registers, USB0 Mode Register at offset 10E8h and USB1 Mode Register at offset 18E8h, are used for a user to select the role the USB controller assumes. The user is required to program the corresponding register prior to the USB controller is in session.

24.2.6 USB Signal Conditioning

The device supports a built in logic to condition the signal quality of the transmit signal by adjusting transmit parameters including transmit level, pre-emphasis, etc using the USB_CTRL0/1 Registers.

24.2.7 USB PHY Initialization

Prior to configuring the USB Module Registers, release the USB SubSystem and PHY from reset, enable the interconnect and controller clocks, and as configure PHY values. Registers related for this task are captured within this doc for ease of reference. Only related information for this task is included within this document. The actual program values are shown at the end.

The USB registers within Device Configuration register space are used to control the PHY. The Cortex-A8 CPU must be in Supervisory Mode when accessing the USB related registers within the Device Configuration Spaces. The registers used to control the PHY are USB_CTRL, USBPHY_CTRL0, and USBPHY_CTRL1. See USB Related Clock/PHY Control Registers for the definitions of these registers. Consult the device manual for more information.

```
*0x48180B10 &= 0xFFFFFF9F; // RSTCTRL (Release USB Module from Reset)
while ((0x48180B14 & 0x00000060)>>5)!=0x3); // Wait until Modules come out Reset
*0x48180B14 |= 0x00000060; // RSTST (Clear Reset Presence)
*0x48180514 |= 0x2; // L3_SLOW_CLKSTCTRL (Enable Interconnect Clock)
*0x48180558 |= 0x2; // USB_CLKCTRL (Enable USB OCP Clock)
while(((*0x48180558) & 0x70000)>>16)==0x7); // Wait until USB Module is Ready

// Configure Access Capability to be in Supervisory Mode
*0x48140620 =0x0000_0003 //USB_CTRL Use PLL Ref Clock, Wake USB PHY1/00

USBPHY_CTRL0 default configuration is good as is and works with out the need for
adjusting parameters for most boards (boards with good h/w design).

USBPHY_CTRL1 default configuration is good as is and works with out the need for
adjusting parameters for most boards (boards with good h/w design).

// USB0 Controller Role Assumption Configuration
*0x4740_10E8 = 0x0000_0000. //A-Type, Normal Phy Mode, Normal Loopback Mode
*0x4740_10E8 = 0x0000_0100. //B-Type, Normal Phy Mode, Normal Loopback Mode

// USB1 Controller Role Assumption Configuration
*0x4740_18E8 = 0x0000_0000. //A-Type, Normal Phy Mode, Normal Loopback Mode
*0x4740_18E8 = 0x0000_0100. //B-Type, Normal Phy Mode, Normal Loopback Mode
```

24.2.8 Indexed and Non-Indexed Register Spaces

The USB controller provides two mechanisms for accessing endpoint control and status registers; Indexed and Non-Indexed method.

Indexed Endpoint Control/Status Register Space. This register space can be thought of as a region populated with Proxy Registers. This register space is a memory-mapped region at offset 1410h to 141Fh for USB0 and 1C10h to 1C1Fh for USB1. The endpoint register space mapped at this region is selected by programming the corresponding INDEX register (@ offsets 140Eh and 1C0Eh for USB0 and USB1 respectively) of the controller.

By programming the INDEX register with the corresponding endpoint number, the control and status register corresponding to that particular endpoint is accessible from this Indexed Region. In other words, Index Register region behaves as a proxy to access a selected endpoint registers.

Non-indexed Endpoint Control/Status Register Space. These regions are dedicated endpoint registers memory-mapped residing at offsets 1500h to 16FFh for USB0 and 1D00h to 1EFFh for USB1. Registers at offset 1500h to 150Fh belong to Endpoint 0; registers at offset 1510h to 151Fh belong to Endpoint 1… and lastly registers at offset 16F0h to 16FFh belong to Endpoint 15 for USB0. Similarly registers at offset 1D00h to 1E0Fh belong to Endpoint 0; registers at offset 1D10h to 1D1Fh belong to Endpoint 1… and finally registers at offset 1DF0h to 1DFFh belong to Endpoint 15 for USB1.

This allows the user/firmware to access an endpoint register region directly from its unique space, as specified within a non-indexed region or from a proxy space by programming the corresponding Index register.

Note: The control and status registers/regions apply to both Tx and Rx of a given Endpoint. That is, Endpoint 1 Tx and Endpoint 1 Rx registers occupy the same register space.

For detailed information about the USB controller registers, see Section 24.9.

24.2.9 Dynamic FIFO Sizing

Each USB module supports a total of 32K bytes of FIFO RAM to dynamically allocate FIFO to all endpoints in use. Each endpoint requires a FIFO to be associated with it. There is one set of register per endpoint available for FIFO allocation, excluding endpoint 0. FIFO configuration registers are Indexed registers and cannot be accessed directly; configuration takes place via accessing proxy registers. The INDEX register at addresses 140Eh or 1C0Eh must be set to the appropriate endpoint. In other words, the Endpoint FIFO configuration registers do not have non-indexed regions.

The allocation of FIFO space to the different endpoints requires programming for each Tx and Rx endpoint with the following information:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

(These last two together define the amount of space that needs to be allocated to the FIFO.)

It is the responsibility of the firmware to ensure that all the Tx and Rx endpoints (other than endpoint 0) that are active in the current USB configuration have a block of FIFO RAM allocated for their use. The maximum FIFO size for endpoint 0 required is 64 bytes deep and which is large enough to buffer one packet. For this reason, the first 64 bytes of FIFO memory is reserved for Endpoint 0 usage and this resource allocation is implied to be available at all times and no FIFO allocation is required for Endpoint 0. For endpoints other than endpoint 0, the FIFO RAM interface is configurable and must have a minimum size of 8 bytes and should be capable of buffering either 1 or 2 packets. Separate FIFOs may be associated with each endpoint: alternatively a Tx endpoint and the Rx endpoint with the same Endpoint number can be configured to use the same FIFO, to reduce the size of RAM block needed, provided they can never be active at the same time.

NOTE: The option of dynamically setting FIFO sizes only applies to Endpoints 1-15. Endpoint 0 FIFO has a fixed size (64 bytes) and a fixed location which is the first 64 Bytes of FIFO (FIFO addresses 0-63).

24.2.10 USB Controller Host and Peripheral Modes Operation

The two USB modules can be used in a range of different environments. They can be used as either a high-speed or a full-speed USB peripheral device attached to a conventional USB host (such as a PC) in a point-to-point type of arrangement. As a host, the USB modules can also be used with another peripheral device of any speed (high-,full-, or low-speed) in a point-to-point arrangement or can be used as the host to a range of peripheral devices in a multi-point setup; one-to-many via hub. Note that the role each USB controller is assuming is independent of each other.

Since no USB ID pin has been bonded out on the device, the USB2.0 controller role adaptation of a host or peripheral (device) is dependent upon the setting made by the firmware to the respective USB Mode Register IDDIG field. If the IDDIG field is programmed by the firmware with a value of ‘1’ prior to the USB going into session, it would assume the role of a peripheral/device. However, if the IDDIG field is programmed with the value of ‘0’, the USB controller will assume the role of a host. What this means is that the USB cable end, connector, will not be able to control the role of the OTG controller and the user needs to be aware of the firmware program setting prior to performing a USB connection.

The procedure for the USB2.0 OTG controller determining its operating modes (usb controller assuming a role of a host or a peripheral) starts when the USB 2.0 controller goes to session. The USB 2.0 controller is in session when either it senses a voltage (>= 4.4V) on the USB0_VBUS pin and the controller sets DEVCTL[SESSION] or when the firmware sets the DEVCTL[SESSION] bit; assuming that it will operating as a host.

When the SESSION bit is set, the controller will start sensing the state of the Iddig signal controlled by the IDDIG bit field of the MODE Register. If the state of the iddig signal is found to be low (IDDIG is programmed with ‘0’) then the USB2.0 controller will assume the role of a host and when it finds the iddig signal to be high (IDDIG is programmed with ‘1’) then it will assume the role of a device. Note that iddig is an internal signal that could be driven to high or low via firmware from dedicated registers.

Upon the USB controller determining its role as a host, it will drive the USB0/1_DRVVBUS pin high to enable the external power logic so that it start sourcing the required 5V power (must be ≥ 4.4V to account for the voltage drop on the cable it is suggested to be in the neighborhood of 4.75V). The USB2.0 controller will then wait for the voltage of the USB0/1_VBUS to go high. Upon sampling a little time later, if it does not see the voltage on the USB0/1_VBUS pin to be greater than Vbus Valid voltage (4.4V), it will generate a Vbus error interrupt. Assuming that the voltage level of the USB0/1_VBUS is found to be above Vbus Valid, the USB 2.0 host controller will wait for a device to connect; that is for it to see one of its data lines USB0/1_DP/DM be pulled high.

When assuming the role of a peripheral, assuming that the firmware has set the POWER[SOFTCONN] bit, and the USB0/1 Mode Register IDDIG bit field is programmed with '1' and an external host is sourcing power on the USB0/1_VBUS line then the USB2.0 controller will set the DEVCTL[SESSION] bit instructing the controller to go into session. Note that the voltage on the USB0/1_VBUS pin must be greater or equal to 4.4V. When the controller goes into session, it will force the USB2.0 Controller to sense the state of the iddig signal. Once it senses iddig signal to be high, it will enable its 1.5 Kohm pull-up resistor to signify the external host that it is a Full-Speed device. Note that even when operating as a High-Speed peripheral; the USB controller has to first come up as Full-Speed and then later transition to High-Speed. The USB2.0 controller will then waits for a reset bus condition from the external host. Then after, if High-Speed option has been selected it will negotiate for a High-Speed operation and if its request has been accepted by the host, it will enable its precision 45 ohm resistors on its data lines and disable the 1.5 Kohm resistor.

24.3 Protocol Description(s)

This section describes the implementation of the USB protocol(s) by the USB modules.

24.3.1 USB Controller Peripheral Mode Operation

The USB controller assumes the role of a peripheral when the USB Mode Register[iddig=bit8] is set to 1 by the user application prior to the controller goes into session. When the USB controller go into session it will assume the role of a device.

Soft connect –After a POR or USB Module soft reset, the SOFTCONN bit of POWER register (bit 6) is cleared to 0. The controller will therefore appear disconnected until the software has set the SOFTCONN bit to 1. The application software can then choose when to set the PHY into its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the SOFTCONN bit has been set, the software can also simulate a disconnect by clearing this bit to 0.

Entry into suspend mode –When operating as a peripheral device, the controller monitors activity on the bus and when no activity has occurred for 3 ms, it goes into Suspend mode. If the Suspend interrupt has been enabled, an interrupt will be generated at this time.

At this point, the controller can then be left active (and hence able to detect when Resume signaling occurs on the USB), or the application may arrange to disable the controller by stopping its clock. However, the controller will not then be able to detect Resume signaling on the USB if clocks are not running. If such is the case, external hardware will be needed to detect Resume signaling (by monitoring the DM and DP signals), so that the clock to the controller can be restarted.

Resume Signaling –When resume signaling occurs on the bus, first the clock to the controller must be restarted if necessary. Then the controller will automatically exit Suspend mode. If the Resume interrupt is enabled, an interrupt will be generated.

Initiating a remote wakeup –If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should set the POWER[RESUME] bit to 1. The software should leave then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0.

NOTE: No resume interrupt will be generated when the software initiates a remote wakeup.

Reset Signaling –When reset signaling or bus condition occurs on the bus, the controller performs the following actions:

- Clears FADDR register to 0
- Clears INDEX register to 0
- Flushes all endpoint FIFOs

- Clears all controller control/status registers
- Generates a reset interrupt
- Enables all interrupts at the core level.

If the HSENA bit within the POWER register (bit 5) is set, the controller also tries to negotiate for high-speed operation. Whether high-speed operation is selected is indicated by HSMODE bit of POWER register (bit 4). When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

24.3.1.1 Control Transactions:Peripheral Mode

Endpoint 0 is the main control endpoint of the core. The software is required to handle all the standard device requests that may be sent or received via endpoint 0. These are described in Universal Serial Bus Specification, Revision 2.0, Chapter 9. The protocol for these device requests involves different numbers and types of transactions per request/command. To accommodate this, the software needs to take a state machine approach to command decoding and handling.

The Standard Device Requests received by a USB peripheral device can be divided into three categories: Zero Data Requests (in which all the information is included in the command; no additional data is required), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

NOTE: The Setup packet associated with any standard device request should include an 8-byte command. Any setup packet containing a command field other than 8 bytes will be automatically rejected by the controller.

24.3.1.1.1 Zero Data Requests: Peripheral Mode

Zero data requests have all their information included in the 8-byte command and require no additional data to be transferred. Examples of Zero Data standard device requests are:

- SET_FEATURE
- CLEAR_FEATURE
- SET_ADDRESS
- SET_CONFIGURATION
- SET_INTERFACE

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO, decoded and the appropriate action taken.

For example, if the command is SET_ADDRESS, the 7-bit address value contained in the command should be written to the FADDR register at the completion of the command. The PERI_CSR0 register should be written by setting the SERV_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) and also setting the DATAEND bit (bit 3) (indicating that no further data is expected for this request). The interval between setting SERV_RXPKTRDY bit and DATAEND bit should be very small to avoid getting a SETUPEND error condition. It is highly recommended to set both bits at the same time.

When the host moves to the status stage of the request, a second endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software. The second interrupt is just a confirmation that the request completed successfully. For SET_ADDRESS command, the address should be written to FADDR register at the completion of the command, that is, when the status stage interrupt is received.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host moves to the status stage of the request, the controller will send a STALL packet telling the host that the request was not executed. A second endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI_CSR0) will be set.

If the host sends more data after the DATAEND bit has been set, then the controller will send a STALL packet automatically. An endpoint 0 interrupt will be generated and the SENTSTALL bit (bit 2 of PERI_CSR0) will be set.

NOTE: DMA is not supported for endpoint 0; endpoint 0 is always serviced via CPU.

24.3.1.1.2 Write Requests: Peripheral Mode

Write requests involve an additional packet (or packets) of data being sent from the host after the 8-byte command. An example of a Write standard device request is: SET_DESCRIPTOR.

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI_CSR0 will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded.

As with a zero data request, the PERI_CSR0 register should then be written to set the SERV_RXPKTRDY bit (bit 6) (indicating that the command has been read from the FIFO) but in this case the DATAEND bit (bit 3) should not be set (indicating that more data is expected).

When a second endpoint 0 interrupt is received, the PERI_CSR0 register should be read to check the endpoint status. The RXPKTRDY bit of PERI_CSR0 should be set to indicate that a data packet has been received. The COUNT0 register should then be read to determine the size of this data packet. The data packet can then be read from the endpoint 0 FIFO.

If the length of the data associated with the request (indicated by the wLength field in the command) is greater than the maximum packet size for endpoint 0, further data packets will be sent. In this case, PERI_CSR0 should be written to set the SERV_RXPKTRDY bit, but the DATAEND bit should not be set.

When all the expected data packets have been received, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit and to set the DATAEND bit (indicating that no more data is expected).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software, the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host sends more data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 (bit 2) will be set.

If the host sends more data after the DATAEND has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 (bit 2) will be set.

24.3.1.1.3 Read Requests: Peripheral Mode

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Read Standard Device Requests are:

- GET_CONFIGURATION
- GET_INTERFACE
- GET_DESCRIPTOR
- GET_STATUS
- SYNCH_FRAME

The sequence of events will begin, as with all requests, when the software receives an endpoint 0 interrupt. The RXPKTRDY bit of PERI_CSR0 (bit 0) will also have been set. The 8-byte command should then be read from the endpoint 0 FIFO and decoded. The PERI_CSR0 register should then be written to set the SERV_RXPKTRDY bit (bit 6) (indicating that the command has read from the FIFO).

The data to be sent to the host should then be written to the endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for endpoint 0, only the maximum packet size should be written to the FIFO. The PERI_CSR0 register should then be written to set the TXPKTRDY bit (bit 1) (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, another endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the PERI_CSR0 register should be written to set the TXPKTRDY bit and to set the DATAEND bit (bit 3) (indicating that there is no more data after this packet).

When the host moves to the status stage of the request, another endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software: the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the PERI_CSR0 register should be written to set the SERV_RXPKTRDY bit (bit 6) and to set the SENDSTALL bit (bit 5). When the host requests data, the controller will send a STALL to tell the host that the request was not executed. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 (bit 2) will be set.

If the host requests more data after DATAEND (bit 3) has been set, then the controller will send a STALL. An endpoint 0 interrupt will be generated and the SENTSTALL bit of PERI_CSR0 (bit 2) will be set.

24.3.1.1.4 Endpoint 0 States: Peripheral Mode

When the USB controller is operating as a peripheral device, the endpoint 0 control needs three modes – IDLE, TX and RX – corresponding to the different phases of the control transfer and the states endpoint 0 enters for the different phases of the transfer (described in later sections).

The default mode on power-up or reset should be IDLE. RXPKTRDY bit of PERI_CSR0 (bit 0) becoming set when endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the controller decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction). See Figure 24-2.

Depending on the direction of the data phase, endpoint 0 goes into either TX state or RX state. If there is no Data phase, endpoint 0 remains in IDLE state to accept the next device request

The actions that the CPU needs to take at the different phases of the possible transfers (for example, loading the FIFO, setting TXPKTRDY) are indicated in Figure 24-3.

Figure 24-2. CPU Actions at Transfer Phases

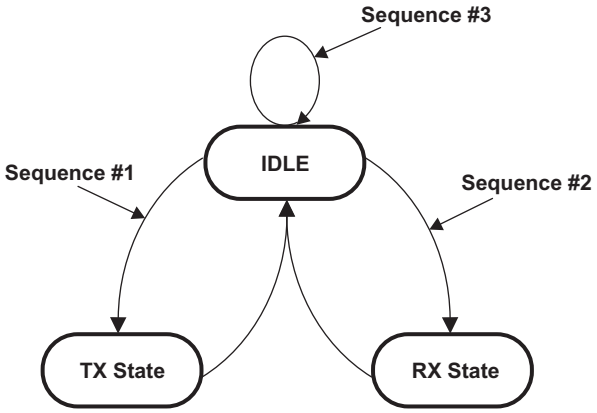


Figure 24-3. Sequence of Transfer

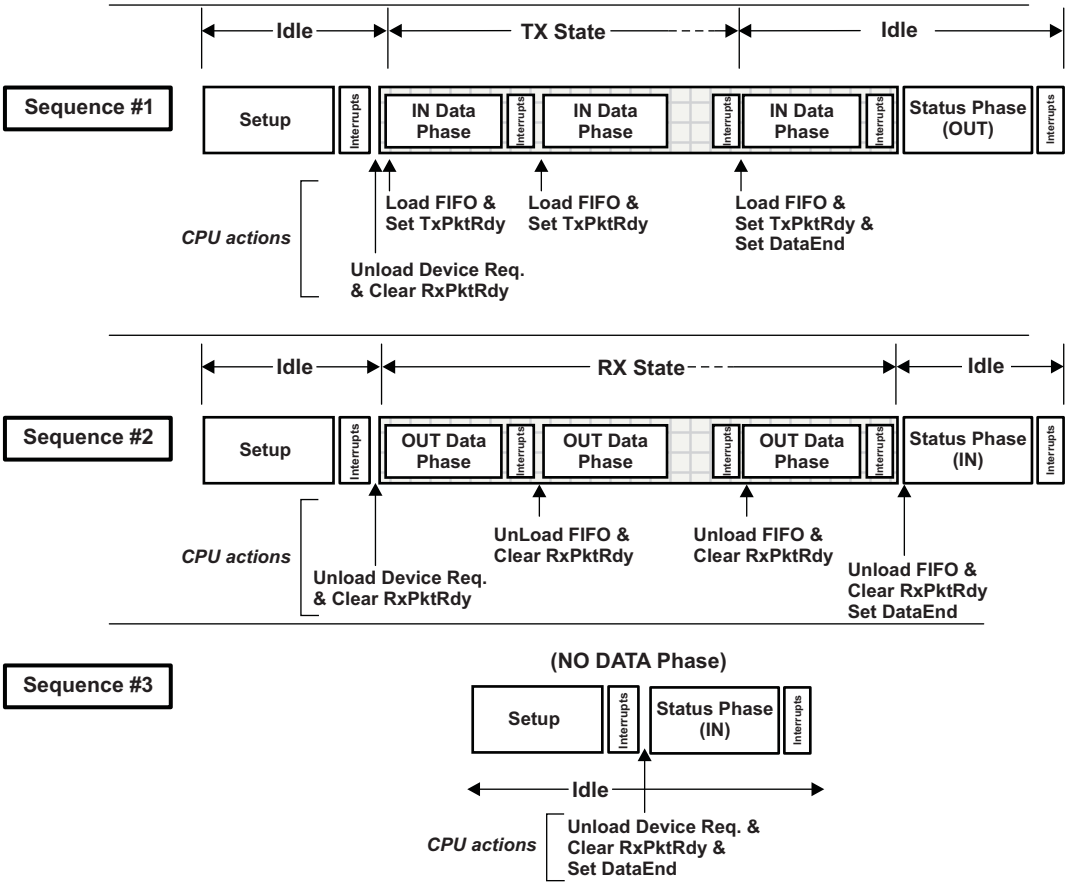


24.3.1.1.4.1 Endpoint 0 Interrupt Generating Events: Peripheral Mode

An Endpoint 0 interrupt is generated when any of the below events occur and Interrupt Service handler should determine the right event and launch the proper handler

The following events will cause Endpoint 0 Interrupt to be generated while the controller is operating assuming the role of a device/peripheral:

- The controller sets the RXPKTRDY bit of PERI_CSR0 (bit 0) after a valid token has been received and data has been written to the FIFO (legal status condition).
- The controller clears the TXPKTRDY bit of PERI_CSR0 (bit 1) after the packet of data in the FIFO has been successfully transmitted to the host (legal status condition).
- The controller sets the SENTSTALL bit of PERI_CSR0 (bit 2) after a control transaction is ended due to a protocol violation (illegal status condition).
- The controller sets the SETUPEND bit of PERI_CSR0 (bit 4) because a control transfer has ended before DATAEND (bit 3 of PERI_CSR0) is set (illegal status condition).

In order to determine the cause of the interrupt, the detail below recommends the order of cause determination and execution.

Whenever the endpoint 0 service routine is entered, the software must first check to see if the current control transfer has been ended due to either a STALL condition or a premature end of control transfer. If the control transfer ends due to a STALL condition, the SENTSTALL bit would be set. If the control transfer ends due to a premature end of control transfer, the SETUPEND bit would be set. In either case, the software should abort processing the current control transfer and set the state to IDLE.

Once the software has determined that the interrupt was not generated by an illegal bus state, the next action taken depends on the endpoint state.

If endpoint 0 is in IDLE state, the only valid reason an interrupt can be generated is as a result of the controller receiving data from the bus. The service routine must check for this by testing the RXPKTRDY bit of PERI_CSR0 (bit 0). If this bit is set, then the controller has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the controller must take. Depending on the command contained within the SETUP packet, endpoint 0 will enter one of three states:

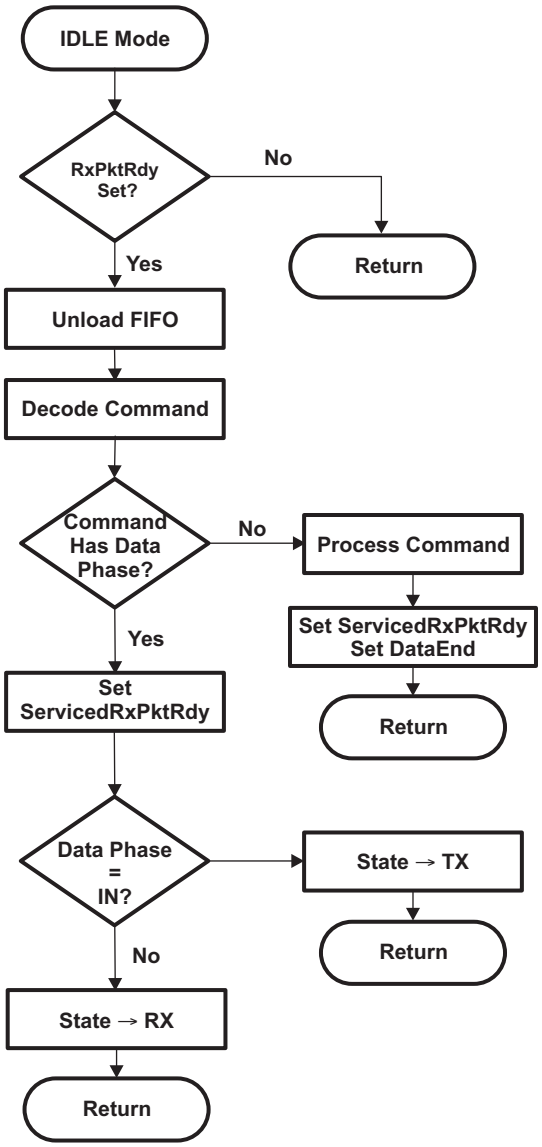
- If the command is a single packet transaction (SET_ADDRESS, SET_INTERFACE etc.) without any data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (SET_DESCRIPTOR etc.), the endpoint will enter RX state.
- If the command has an IN data phase (GET_DESCRIPTOR etc.), the endpoint will enter TX state.
- If the endpoint 0 is in TX state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The software must respond to this either by placing more data in the FIFO if the host is still expecting more data or by setting the DATAEND bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, endpoint 0 should be returned to IDLE state to await the next control transaction (status stage).
- If the endpoint is in RX state, the interrupt indicates that a data packet has been received. The software must respond by unloading the received data from the FIFO. The software must then determine whether it has received all of the expected data. If it has, the software should set the DATAEND bit and return endpoint 0 to IDLE state. If more data is expected, the firmware should set the SERV_RXPKTRDY bit of PERI_CSR0 (bit 6) to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

24.3.1.1.4.2 Idle Mode: Control Transfer of Peripheral Mode

IDLE mode is the mode the Endpoint 0 control needs to select at power-on or reset and is the mode to which the Endpoint 0 control should return when the RX and TX modes are terminated.

It is also the mode in which the SETUP phase of control transfer is handled (as outlined in Figure 24-4).

Figure 24-4. Flow Chart of Setup Stage of a Control Transfer in Peripheral Mode



24.3.1.1.4.3 TX Mode: Control Transfer of Peripheral Mode

When the endpoint is in TX state, all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, this will cause a SETUPEND condition to occur as the core expects only IN tokens.

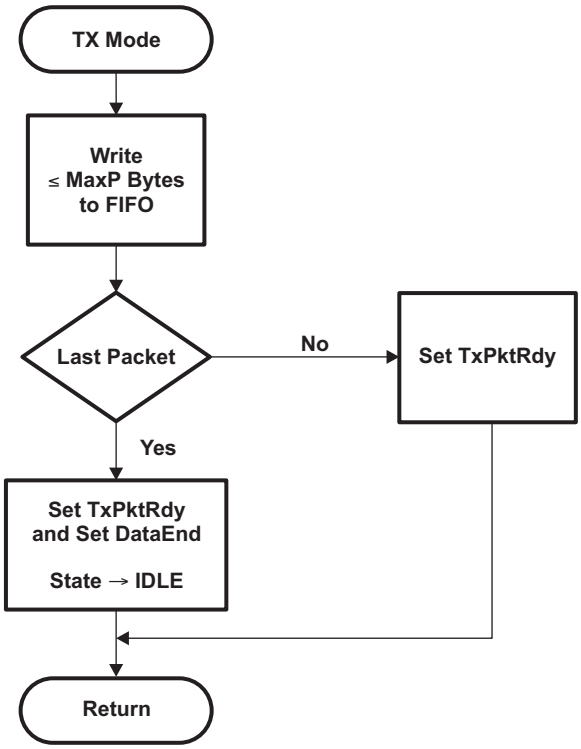
Three events can cause TX mode to be terminated before the expected amount of data has been sent as shown in Figure 24-5:

1. The host sends an invalid token causing a SETUPEND condition (bit 4 of PERI_CSR0 is set).
2. The firmware sends a packet containing less than the maximum packet size for Endpoint 0.
3. The firmware sends an empty data packet.

Until the transaction is terminated, the firmware simply needs to load the FIFO when it receives an interrupt which indicates that a packet has been sent from the FIFO. An interrupt is generated when TXPKTRDY is cleared.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it should set the DATAEND bit of PERI_CSR0 (bit 3) to indicate to the core that the data phase is complete and that the core should next receive an acknowledge packet.

Figure 24-5. Flow Chart of Transmit Data Stage of a Control Transfer in Peripheral Mode



24.3.1.1.4.4 Rx Mode: Control Transfer of Peripheral Mode

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SETUPEND condition will occur as the controller expects only OUT tokens.

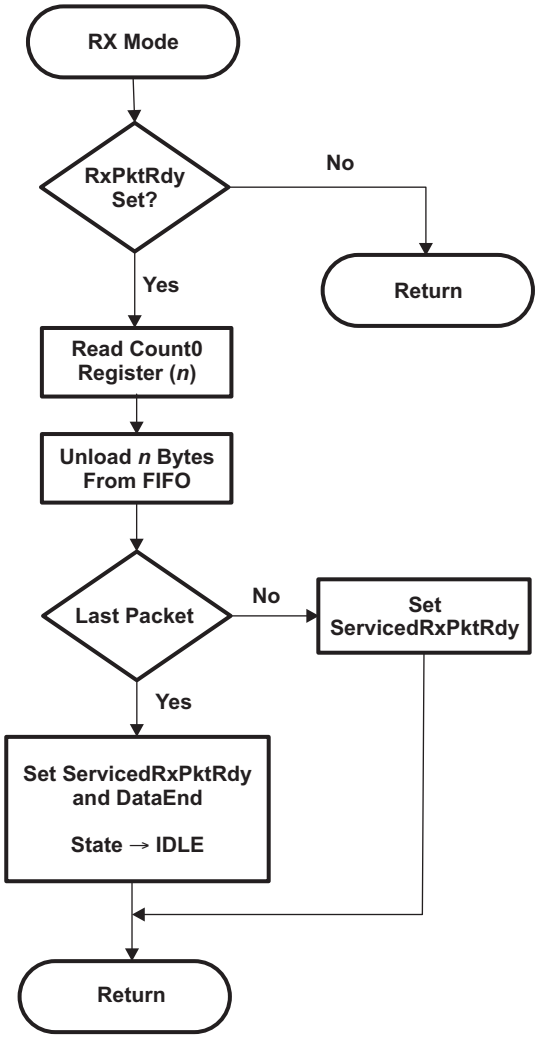
Three events can cause RX mode to be terminated before the expected amount of data has been received as shown in Figure 24-6:

1. The host sends an invalid token causing a SETUPEND condition (setting bit 4 of PERI_CSR0).
2. The host sends a packet which contains less than the maximum packet size for endpoint 0.
3. The host sends an empty data packet.

Until the transaction is terminated, the software unloads the FIFO when it receives an interrupt that indicates new data has arrived (setting RXPKTRDY bit of PERI_CSR0) and to clear RXPKTRDY by setting the SERV_RXPKTRDY bit of PERI_CSR0 (bit 6).

When the software detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DATAEND bit (bit 3 of PERI_CSR0) to indicate to the controller that the data phase is complete and that the core should receive an acknowledge packet next.

Figure 24-6. Flow Chart of Receive Data Stage of a Control Transfer in Peripheral Mode



24.3.1.1.4.5 Error Handling: Control Transfer of Peripheral Mode

A control transfer may be aborted due to a protocol error on the USB, the host prematurely ending the transfer, or if the software wishes to abort the transfer (for example, because it cannot process the command).

The controller automatically detects protocol errors and sends a STALL packet to the host under the following conditions:

- The host sends more data during the OUT Data phase of a write request than was specified in the command. This condition is detected when the host sends an OUT token after the DATAEND bit (bit 3 of PERI_CSR0) has been set.
- The host requests more data during the IN Data phase of a read request than was specified in the command. This condition is detected when the host sends an IN token after the DATAEND bit in the PERI_CSR0 register has been set.
- The host sends more than Max Packet Size data bytes in an OUT data packet.
- The host sends a non-zero length DATA1 packet during the STATUS phase of a read request.

When the controller has sent the STALL packet, it sets the SENTSTALL bit (bit 2 of PERI_CSR0) and generates an interrupt. When the software receives an endpoint 0 interrupt with the SENTSTALL bit set, it should abort the current transfer, clear the SENTSTALL bit, and return to the IDLE state.

If the host prematurely ends a transfer by entering the STATUS phase before all the data for the request has been transferred, or by sending a new SETUP packet before completing the current transfer, then the SETUPEND bit (bit 4 of PERI_CSR0) will be set and an endpoint 0 interrupt generated. When the software receives an endpoint 0 interrupt with the SETUPEND bit set, it should abort the current transfer, set the SERV_SETUPEND bit (bit 7 of PERI_CSR0), and return to the IDLE state. If the RXPKTRDY bit (bit 0 of PERI_CSR0) is set this indicates that the host has sent another SETUP packet and the software should then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the SENDSTALL bit (bit 5 of PERI_CSR0). The controller will then send a STALL packet to the host, set the SENTSTALL bit (bit 2 of PERI_CSR0) and generate an endpoint 0 interrupt.

24.3.1.1.5 Additional Conditions: Control transfer of Peripheral Mode

When working as a peripheral device, the controller automatically responds to certain conditions on the USB bus or actions by the host. The details are:

- Stall Issued to Control Transfers
  1. The host sends more data during an OUT Data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an OUT token (instead of an IN token) after the software has unloaded the last OUT packet and set DATAEND.
  2. The host requests more data during an IN data phase of a Control transfer than was specified in the device request during the SETUP phase. This condition is detected by the controller when the host sends an IN token (instead of an OUT token) after the software has cleared TXPKTRDY and set DATAEND in response to the ACK issued by the host to what should have been the last packet.
  3. The host sends more than MaxPktSize data with an OUT data token.
  4. The host sends the wrong PID for the OUT Status phase of a Control transfer.
  5. The host sends more than a zero length data packet for the OUT Status phase.
- Zero Length Out Data Packets In Control Transfer
  A zero length OUT data packet is used to indicate the end of a Control transfer. In normal operation, such packets should only be received after the entire length of the device request has been transferred (after the software has set DataEnd). If, however, the host sends a zero length OUT data packet before the entire length of device request has been transferred, this signals the premature end of the transfer. In this case, the controller will automatically flush any IN token loaded by software ready for the Data phase from the FIFO and set SETUPEND bit (bit 4 of PERI_CSR0).

24.3.1.2 Bulk Transfer: Peripheral Mode

Bulk transactions are handled by endpoints other than endpoint 0. It is used to handle non-periodic, large bursty communication typically used for a transfer that use any available bandwidth and can also be delayed until bandwidth is available.

24.3.1.2.1 Bulk IN Transactions: Peripheral Mode

A Bulk IN transaction is used to transfer non-periodic data from the USB peripheral device to the host.

The following optional features are available for use with a Tx endpoint used in peripheral mode for Bulk IN transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention

24.3.1.2.1.1 Bulk IN Transaction Setup: Peripheral Mode

In configuring a TX endpoint for bulk transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint and the PERI_TXCSR register (DMAEN and DMAMODE bit fields should be set when using DMA. Table 24-2 displays the PERI_TXCSR setting when used for Bulk transfer.

Table 24-2. PERI_TXCSR Register Bit Configuration for Bulk IN Transactions

Bit	Bit Name	Description
Bit 15	AUTOSET	Cleared to 0 if using DMA. For CPU Mode use, if AUTOSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO.
Bit 14	ISO	Cleared to 0 for bulk mode operation.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage; not needed if CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.

When the endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_TXCSR should be written to set the CLRDATATOG bit (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state.

Also if there are any data packets in the FIFO, indicated by the FIFONOTEMPTY bit (bit 1 of PERI_TXCSR) being set, they should be flushed by setting the FLUSHFIFO bit (bit 3 of PERI_TXCSR).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

24.3.1.2.1.2 Bulk IN Operation: Peripheral Mode

When data is to be transferred over a Bulk IN pipe, a data packet needs to be loaded into the FIFO and the PERI_TXCSR register written to set the TXPKTRDY bit (bit 0). When the packet has been sent, the TXPKTRDY bit will be cleared by the USB controller and an interrupt generated to signify to the user/application that the next packet can be loaded into the FIFO. If double packet buffering is enabled, then after the first packet has been loaded and the TXPKTRDY bit set, the TXPKTRDY bit will immediately be cleared (will not wait for the loaded first packet to be driven out) by the USB controller and an interrupt generated so that a second packet can be loaded into the FIFO. The software should operate in the same way, loading a packet when it receives an interrupt, regardless of whether double packet buffering is enabled or not.

In the general case, the packet size must not exceed the size specified by the lower 11 bits of the TXMAXP register. This part of the register defines the payload (packet size) for transfers over the USB and is required by the USB Specification to be either 8, 16, 32, 64 (Full-Speed or High-Speed) or 512 bytes (High-Speed only).

The host may determine that all the data for a transfer has been sent by knowing the total amount of data that is expected. Alternatively it may infer that all the data has been sent when it receives a packet which is smaller than the maximum packet size configuration for that particular endpoint (TXMAXP[10-0]). In the latter case, if the total size of the data block is a multiple of this payload, it will be necessary for the function to send a null packet after all the data has been sent. This is done by setting TXPKTRDY when the next interrupt is received, without loading any data into the FIFO.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using the CPPI DMA. A separate section detailing the use of the DMA is discussed within a latter section. Suffix is to say that the PERI_TXCSR (DMAEN and DMAMODE) bit fields need to be set and the PERI_TXCSR[AUTOSET] bit cleared at the core level when using the DMA with an endpoint configured for any IN transaction/transfer.

24.3.1.2.1.3 Error Handling of Bulk IN Transfer: Peripheral Mode

If the software wants to shut down the Bulk IN pipe, it should set the SENDSTALL bit (bit 4 of PERI_TXCSR). When the controller receives the next IN token, it will send a STALL to the host, set the SENTSTALL bit (bit 5 of PERI_TXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 5 of PERI_TXCSR) set, it should clear the SENTSTALL bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk IN pipe.

NOTE: If the host failed to receive the STALL packet for some reason, it will send another IN token, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk IN pipe. When a pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit in the PERI_TXCSR register (bit 6).

24.3.1.2.2 Bulk OUT Transfer: Peripheral Mode

A Bulk OUT transaction is used to transfer non-periodic data from the host to the function controller.

The following optional features are available for use with an Rx endpoint used in peripheral mode for Bulk OUT transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of the RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.

NOTE: When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

24.3.1.2.2.1 Bulk OUT Transfer Setup: Peripheral Mode

In configuring an Rx endpoint for Bulk OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. When using DMA for Rx Endpoints, the PERI_RXCSR needs to have its DMAEN bit set and have its AUTOCLEAR and DMAMODE bits cleared. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in Table 24-3.

Table 24-3. PERI_RXCSR Register Bit Configuration for Bulk OUT Transactions

Bit	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Cleared to 0 to enable Bulk protocol.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Cleared to 0 to allow normal PING flow control. This will affect only high speed transactions.
Bit 11	DMAMODE	Always clear this bit to 0.

When the Rx endpoint is first configured (following a SET_CONFIGURATION or SET_INTERFACE command on Endpoint 0), the lower byte of PERI_RXCSR should be written to set the CLRDATATOG bit (bit 7). This will ensure that the data toggle (which is handled automatically by the USB controller) starts in the correct state.

Also if there are any data packets in the FIFO (indicated by the RXPKTRDY bit (bit 0 of PERI_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit (bit 4 of PERI_RXCSR).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

24.3.1.2.2.2 Bulk OUT Operation: Peripheral Mode

When a data packet is received by a Bulk Rx endpoint, the RXPKTRDY bit (bit 0 of PERI_RXCSR) is set and an interrupt is generated. The software should read the RXCOUNT register for the endpoint to determine the size of the data packet. The data packet should be read from the FIFO, and then the RXPKTRDY bit should be cleared.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host). When a block of data larger than wMaxPacketSize needs to be sent to the function, it will be sent as multiple packets. All the packets will be wMaxPacketSize in size, except the last packet which will contain the residue. The software may use an application specific method of determining the total size of the block and hence when the last packet has been received. Alternatively it may infer that the entire block has been received when it receives a packet which is less than wMaxPacketSize in size. (If the total size of the data block is a multiple of wMaxPacketSize, a null data packet will be sent after the data to signify that the transfer is complete.)

In the general case, the application software will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

24.3.1.2.2.3 Bulk OUT Error Handling: Peripheral Mode

If the software wants to shut down the Bulk OUT pipe, it should set the SENDSTALL bit (bit 5 of PERI_RXCSR). When the controller receives the next packet it will send a STALL to the host, set the SENTSTALL bit (bit 6 of PERI_RXCSR) and generate an interrupt.

When the software receives an interrupt with the SENTSTALL bit (bit 6 of PERI_RXCSR) set, it should clear this bit. It should however leave the SENDSTALL bit set until it is ready to re-enable the Bulk OUT pipe.

NOTE: If the host failed to receive the STALL packet for some reason, it will send another packet, so it is advisable to leave the SENDSTALL bit set until the software is ready to re-enable the Bulk OUT pipe. When a Bulk OUT pipe is re-enabled, the data toggle sequence should be restarted by setting the CLRDATATOG bit (bit 7) in the PERI_RXCSR register.

24.3.1.3 Interrupt Transfer: Peripheral Mode

An Interrupt IN transaction uses the same protocol as a Bulk IN transaction and the configuration and operation mentioned on prior sections apply to Interrupt transfer too with minor changes. Similarly, an Interrupt OUT transaction uses almost the same protocol as a Bulk OUT transaction and can be used the same way.

Tx endpoints in the USB controller have one feature for Interrupt IN transactions that they do not support in Bulk IN transactions. In Interrupt IN transactions, the endpoints support continuous toggle of the data toggle bit.

This feature is enabled by setting the FRCDATATOG bit in the PERI_TXCSR register (bit 11). When this bit is set, the controller will consider the packet as having been successfully sent and toggle the data bit for the endpoint, regardless of whether an ACK was received from the host.

Another difference is that interrupt endpoints do not support PING flow control. This means that the controller should never respond with a NYET handshake, only ACK/NAK/STALL. To ensure this, the DISNYET bit in the PERI_RXCSR register (bit 12) should be set to disable the transmission of NYET handshakes in high-speed mode.

Though DMA can be used with an interrupt OUT endpoint, it generally offers little benefit as interrupt endpoints are usually expected to transfer all their data in a single packet.

24.3.1.4 Isochronous Transfer: Peripheral Mode

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

24.3.1.4.1 Isochronous IN Transactions: Peripheral Mode

An Isochronous IN transaction is used to transfer periodic data from the function controller to the host.

The following optional features are available for use with a Tx endpoint used in Peripheral mode for Isochronous IN transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the host. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

  NOTE: Double packet buffering is generally advisable for isochronous transactions in order to avoid underrun errors as described in later section.
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature allows the DMA controller to load packets into the FIFO without processor intervention.
  However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_TXCSR register needs to be accessed following every packet to check for Underrun errors.
  When DMA is enabled and DMAMODE bit of PERI_TXCSR is set, endpoint interrupt will not be generated for completion of packet transfer. Endpoint interrupt will be generated only in the error conditions.

24.3.1.4.1.1 Isochronous IN Transfer Setup: Peripheral Mode

In configuring a Tx endpoint for Isochronous IN transactions, the TXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint) and the PERI_TXCSR register should be set as shown in Table 24-4.

Table 24-4. PERI_TXCSR Register Bit Configuration for Isochronous IN Transactions

Bit	Bit Name	Description
Bit 14	ISO	Set to 1 to enable Isochronous transfer protocol.
Bit 13	MODE	Set to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
Bit 12	DMAEN	Set to 1 if DMA Requests have to be enabled.
Bit 11	FRCDATATOG	Ignored in Isochronous mode.
Bit 10	DMAMODE	Set to 1 when DMA is enabled.

24.3.1.4.1.2 Isochronous IN Transfer Operation: Peripheral Mode

An isochronous endpoint does not support data retries, so if data underrun is to be avoided, the data to be sent to the host must be loaded into the FIFO before the IN token is received. The host will send one IN token per frame (or microframe in High-speed mode), however the timing within the frame (or microframe) can vary. If an IN token is received near the end of one frame and then at the start of the next frame, there will be little time to reload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is sent to the host and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the PERI_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame(/microframe) before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using either the SOF interrupt or the external SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to set the TXPKTRDY bit in PERI_TXCSR (bit 0) and to check for data overruns/underruns.

Starting up a double-buffered Isochronous IN pipe can be a source of problems. Double buffering requires that a data packet is not transmitted until the frame(/microframe) after it is loaded. There is no problem if the function loads the first data packet at least a frame(/microframe) before the host sets up the pipe (and therefore starts sending IN tokens). But if the host has already started sending IN tokens by the time the first packet is loaded, the packet may be transmitted in the same frame(/microframe) as it is loaded, depending on whether it is loaded before, or after, the IN token is received. This potential problem can be avoided by setting the ISOUPDATE bit in the POWER register (bit 7). When this bit is set, any data packet loaded into an Isochronous Tx endpoint FIFO will not be transmitted until after the next SOF packet has been received, thereby ensuring that the data packet is not sent too early.

24.3.1.4.1.3 Isochronous IN Error Handling: Peripheral Mode

If the endpoint has no data in its FIFO when an IN token is received, it will send a null data packet to the host and set the UNDERRUN bit in the PERI_TXCSR register (bit 2). This is an indication that the software is not supplying data fast enough for the host. It is up to the application to determine how this error condition is handled.

If the software is loading one packet per frame(/microframe) and it finds that the TXPKTRDY bit in the PERI_TXCSR register (bit 0) is set when it wants to load the next packet, this indicates that a data packet has not been sent (perhaps because an IN token from the host was corrupted). It is up to the application how it handles this condition: it may choose to flush the unsent packet by setting the FLUSHFIFO bit in the PERI_TXCSR register (bit 3), or it may choose to skip the current packet.

24.3.1.4.2 Isochronous OUT Transactions: Peripheral Mode

An isochronous OUT transaction is used to transfer periodic data from the host to the function controller.

Following optional features are available for use with an Rx endpoint used in Peripheral mode for Isochronous OUT transactions:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
  NOTE: Double packet buffering is generally advisable for Isochronous transactions in order to avoid overrun errors.
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.
  However, this feature is not particularly useful with Isochronous endpoints because the packets transferred are often not maximum packet size and the PERI_RXCSR register needs to be accessed following every packet to check for Overrun or CRC errors.
  When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

24.3.1.4.2.1 Isochronous OUT Setup: Peripheral Mode

In configuring an Rx endpoint for Isochronous OUT transactions, the RXMAXP register must be written with the maximum packet size (in bytes) for the endpoint. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the endpoint. In addition, the relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint) and the PERI_RXCSR register should be set as shown in Table 24-5.

Table 24-5. PERI_RXCSR Register Bit Configuration for Isochronous OUT Transactions

Bit	Bit Name	Description
Bit 15	AUTOCLEAR	Cleared to 0 if using DMA. In CPU Mode of usage, if the CPU sets AUTOCLEAR bit, the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO.
Bit 14	ISO	Set to 1 to configure endpoint usage for Isochronous transfer.
Bit 13	DMAEN	Set to 1 if a DMA request is required for this Rx endpoint.
Bit 12	DISNYET	Ignored in Isochronous Mode.
Bit 11	DMAMODE	Always clear this bit to 0.

24.3.1.4.2.2 Isochronous OUT Operation: Peripheral Mode

An Isochronous endpoint does not support data retries so, if a data overrun is to be avoided, there must be space in the FIFO to accept a packet when it is received. The host will send one packet per frame (or microframe in High-speed mode); however, the time within the frame can vary. If a packet is received near the end of one frame(/microframe) and another arrives at the start of the next frame, there will be little time to unload the FIFO. For this reason, double buffering of the endpoint is usually necessary.

An interrupt is generated whenever a packet is received from the host and the software may use this interrupt to unload the packet from the FIFO and clear the RXPKTRDY bit in the PERI_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), depending on when the host has scheduled the transaction, the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame(/microframe) before unloading the FIFO. This can be done by using either the SOF interrupt or the external SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe) when a SOF packet is received. (The controller also maintains an external frame(/microframe) counter so it can still generate a SOF_PULSE when the SOF packet has been lost.) The interrupts may still be used to clear the RXPKTRDY bit in PERI_RXCSR and to check for data overruns/underruns.

24.3.1.4.2.3 Isochronous OUT Error Handling: Peripheral Mode

If there is no space in the FIFO to store a packet when it is received from the host, the OVERRUN bit in the PERI_RXCSR register (bit 2) will be set. This is an indication that the software is not unloading data fast enough for the host. It is up to the application to determine how this error condition is handled

If the controller finds that a received packet has a CRC error, it will still store the packet in the FIFO and set the RXPKTRDY bit (bit 0 of PERI_RXCSR) and the DATAERROR bit (bit 3 of PERI_RXCSR). It is left up to the application to determine how this error condition is handled.

The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a microframe, the INCOMPRX bit (bit 8) bit in the PERI_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit is the PERI_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

Note: The circumstances in which a PID Error or INCOMPRX is reported depends on the precise sequence of packets received.

When the core is operating in peripheral mode, the details are in Isochronous OUT Error Handling: Peripheral Mode.

Isochronous OUT Error Handling: Peripheral Mode

No. Packet(s) Expected	Data Packet(s) Received	Response
1	DATA0	OK
	DATA1	PID Error set
	DATA2	PID Error set
	MDATA	PID Error set
2	DATA0	OK
	DATA1	INCOMPRX Set
	DATA2	INCOMPRX Set + PID Error set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error Set
	MDATA DATA1	OK
	MDATA DATA2	PID Error Set
	MDATA MDATA	PID Error Set

Isochronous OUT Error Handling: Peripheral Mode (continued)

No. Packet(s) Expected	Data Packet(s) Received	Response
3	DATA0	OK
	DATA1	INCOMPRX Set
	DATA2	INCOMPRX Set
	MDATA	INCOMPRX Set
	MDATA DATA0	PID Error set
	MDATA DATA1	OK
	MDATA DATA2	INCOMPRX Set
	MDATA MDATA	INCOMPRX Set
	MDATA MDATA DATA0	PID Error set
	MDATA MDATA DATA1	PID Error set
	MDATA MDATA DATA2	OK
	MDATA MDATA MDATA	PID Error set

24.3.2 USB Controller Host Mode Operation

The USB controller assumes the role of a host when the USB Mode Register[iddig=bit8] is cleared to 0 by the firmware prior to the controller goes into session. When the USB controller go into session, application/firmware sets the DEVCTL[SESSION] bit to 1, it will assume the role of a host.

- Entry into Suspend mode. When operating as a host, the USB controller can be prompted to go into Suspend mode by setting the SUSPENDM bit in the POWER register. When this bit is set, the controller will complete the current transaction then stop the transaction scheduler and frame counter. No further transactions will be started and no SOF packets will be generated.
  If the ENSUSPM bit (bit 0 of POWER register) is set, the UTMI+ PHY will go into low-power mode when the controller goes into suspend mode.
- Sending Resume Signaling. When the application requires the controller to leave suspend mode, it needs to clear the SUSPENDM bit in the POWER register, set the RESUME bit and leave it set for 20ms. While the RESUME bit is high, the controller will generate Resume signaling on the bus. After 20 ms, the CPU should clear the RESUME bit, at which point the frame counter and transaction scheduler will be started.
- Responding to Remote Wake-up. If Resume signaling is detected from the target while the controller is in suspend mode, the UTMI+ PHY will be brought out of low-power mode and UTMI clock is restarted. The controller will then exit suspend mode and automatically set the RESUME bit in the POWER register (bit 2) to ‘1’ to take over generating the Resume signaling from the target. If the resume interrupt is enabled, an interrupt will be generated.
- Reset Signaling. If the RESET bit in the POWER register (bit 3) is set while the controller is in Host mode, it will generate Reset signaling on the bus. If the HSENAB bit in the POWER register (bit 5) was set, it will also try to negotiate for high-speed operation. The software should keep the RESET bit set for at least 20 ms to ensure correct resetting of the target device. After the software has cleared the bit, the controller will start its frame counter and transaction scheduler. Whether high-speed operation is selected will be indicated by HSMODE bit of POWER register (bit 4).

24.3.2.1 Control Transactions: Host Mode

Host control transactions are conducted through Endpoint 0 and the software is required to handle all the Standard Device Requests that may be sent or received via Endpoint 0 (as described in Universal Serial Bus Specification, Revision 2.0). Endpoint 0 can only be serviced via CPU and DMA mode can not be used.

There are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the command); Write Requests (in which the command will be followed by additional data); and Read Requests (in which the device is required to send data back to the host).

1. Zero Data Requests comprise a SETUP command followed by an IN Status Phase.
2. Write Requests comprise a SETUP command, followed by an OUT Data Phase which is in turn followed by an IN Status Phase.
3. Read Requests comprise a SETUP command, followed by an IN Data Phase which is in turn followed by an OUT Status Phase.

A timeout may be set to limit the length of time for which the host controller will retry a transaction which is continually NAKed by the target. This limit can be between 2 and 2 15 frames/microframes and is set through the NAKLIMIT0 register.

The following sections describe the actions that the CPU needs to take in issuing these different types of request through looking at the steps to take in the different phases of a control transaction.

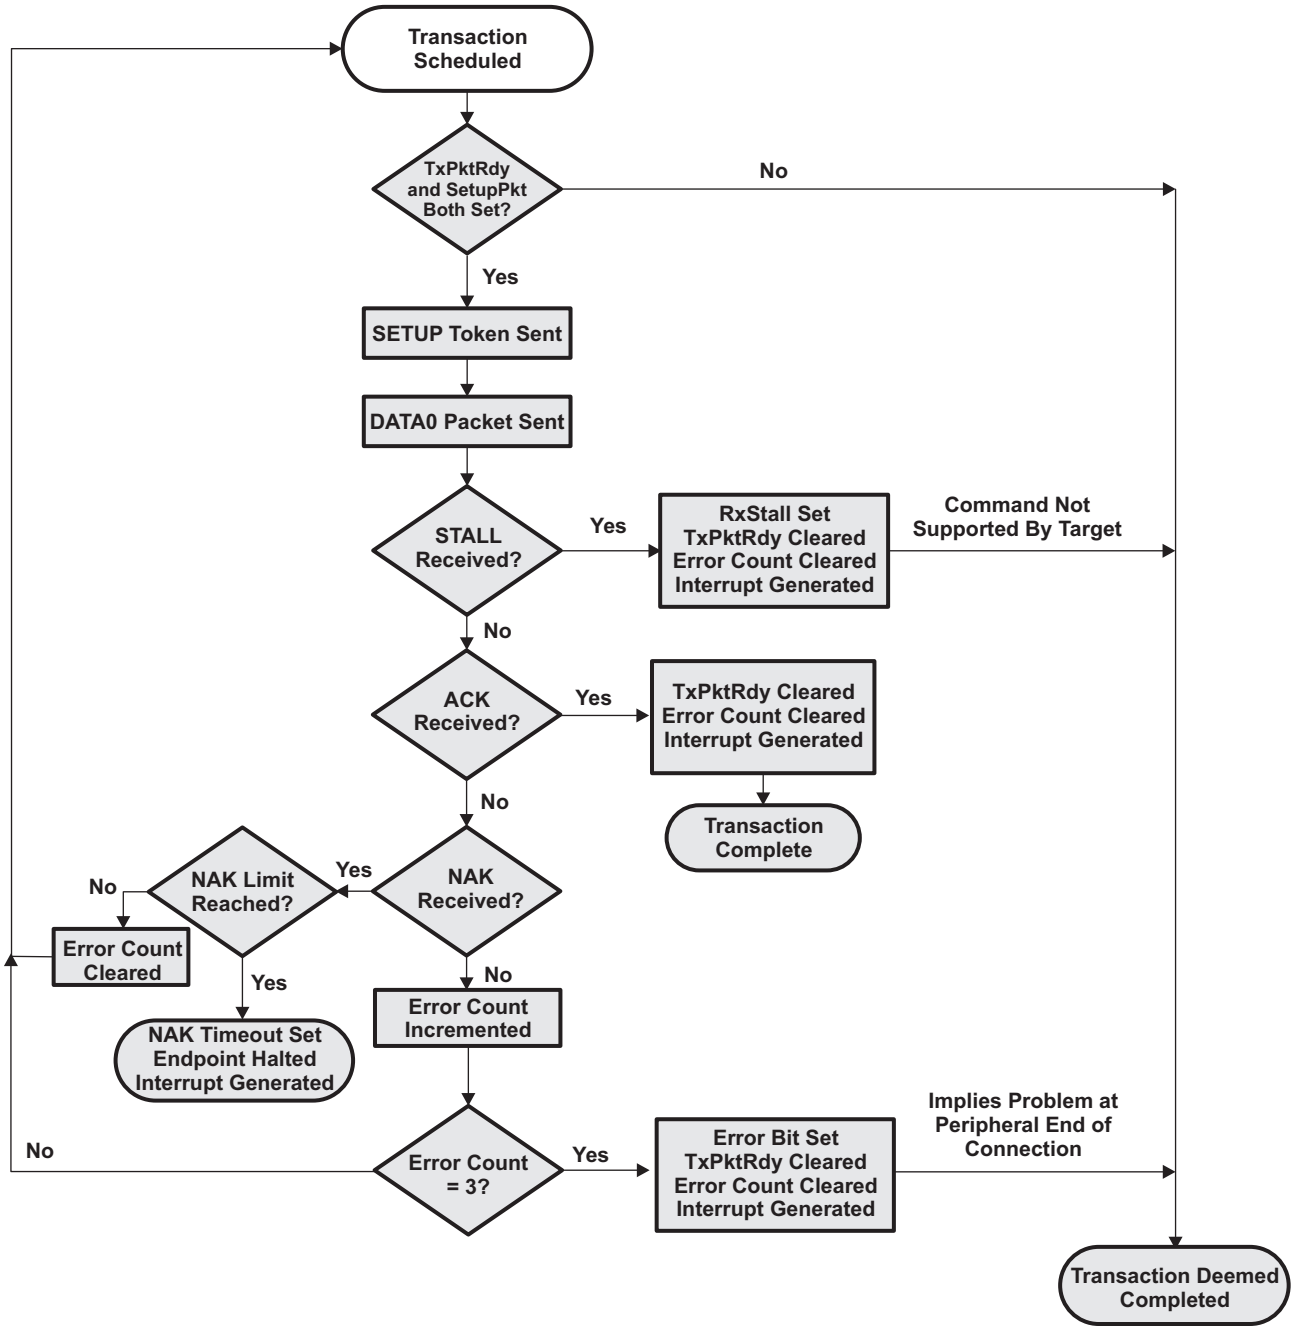
Note: Before initiating any transactions as a Host, the FADDR register needs to be set to address the peripheral device. When the device is first connected, FADDR should be cleared to 0. After a SET_ADDRESS command is issued, FADDR should be set the target's new address.

24.3.2.1.1 Setup Phase of Control Transaction: Host Mode

For the SETUP Phase of a control transaction (Figure 24-7), the software driving the USB host device needs to:

1. Load the 8 bytes of the required Device request command into the Endpoint 0 FIFO
2. Set SETUPPKT and TXPKTRDY (bits 3 and 1 of HOST_CSR0, respectively).
   NOTE: These bits must be set together.
   The controller then proceeds to send a SETUP token followed by the 8-byte command/request to Endpoint 0 of the addressed device, retrying as necessary. *Note:* On errors, the controller retries the transaction three times.
3. At the end of the attempt to send the 8-byte request data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
   If RXSTALL is set, it indicates that the target did not accept the command (for example, because it is not supported by the target device) and so has issued a STALL response. If ERROR is set, it means that the controller has tried to send the SETUP Packet and the following data packet three times without getting any response.
   If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK_TIMEOUT is set, the SETUP Phase has been correctly ACKed and the software should proceed to the following IN Data Phase, OUT Data Phase or IN Status Phase specified for the particular Standard Device Request.

Figure 24-7. Flow Chart of Setup Stage of a Control Transfer in Host Mode



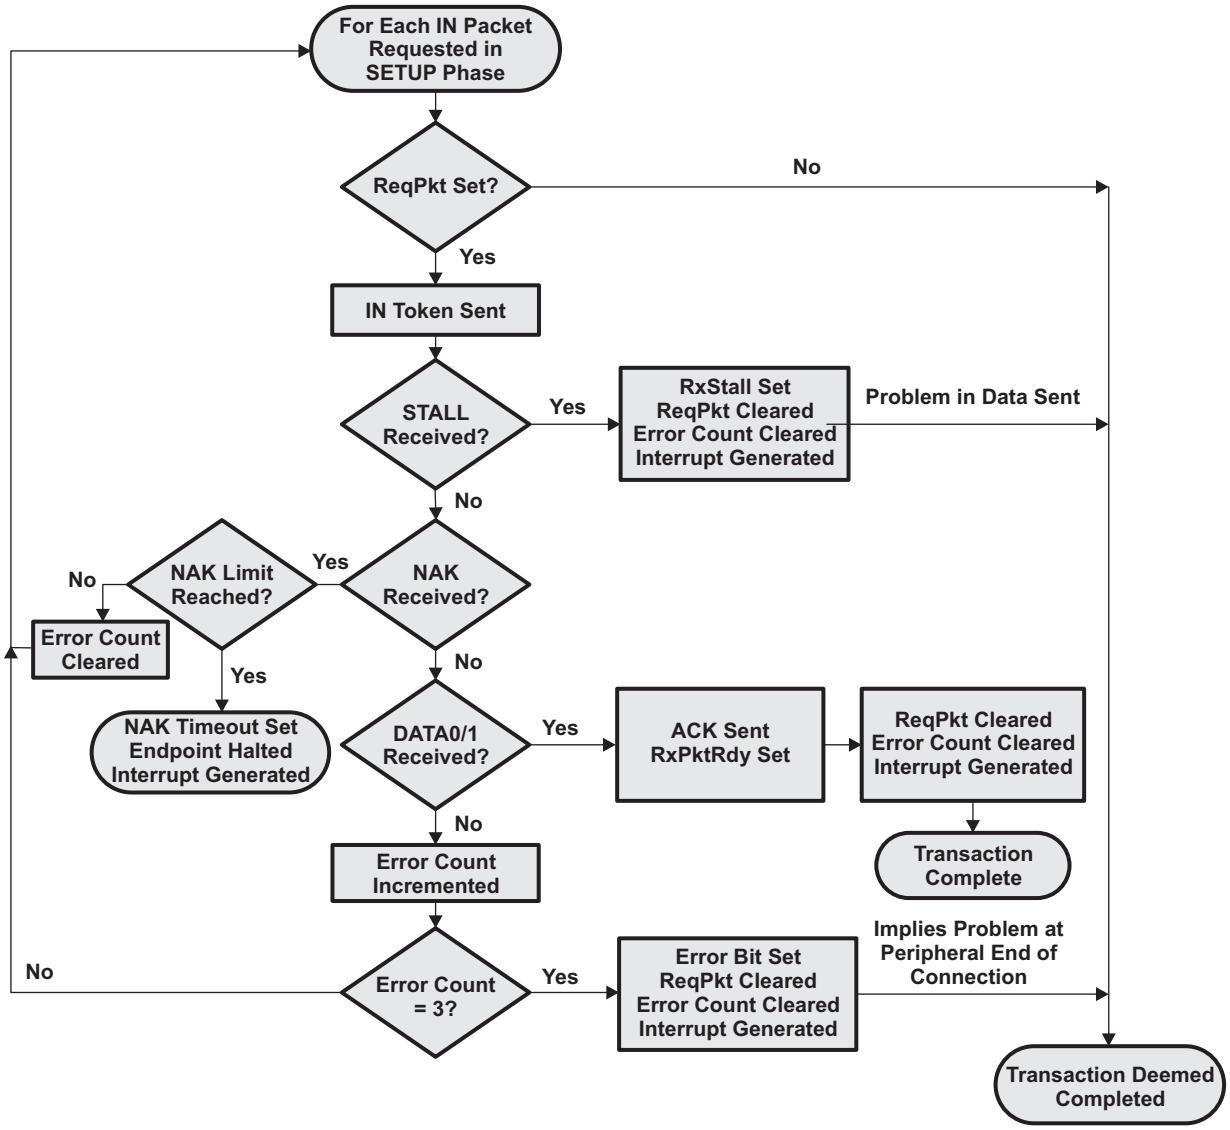
24.3.2.1.2 Data Phase (IN Data Phase) of a Control Transaction: Host Mode

For the IN Data Phase of a control transaction (Figure 24-8), the software driving the USB host device needs to

1. Set REQPKT bit of HOST_CSR0 (bit 5)
2. Wait while the controller sends the IN token and receives the required data back.
3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPKTRDY bit (bit 0) has been set.
   If RXSTALL is set, it indicates that the target has issued a STALL response.
   If ERROR is set, it means that the controller has tried to send the required IN token three times without getting any response. If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in HOST_NAKLIMIT0. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT before clearing the NAK_TIMEOUT bit
4. If RXPKTRDY has been set, the software should read the data from the Endpoint 0 FIFO, then clear RXPKTRDY.
5. If further data is expected, the software should repeat Steps 1-4.

When all the data has been successfully received, the CPU should proceed to the OUT Status Phase of the Control Transaction.

Figure 24-8. Flow Chart of Data Stage (IN Data Phase) of a Control Transfer in Host Mode

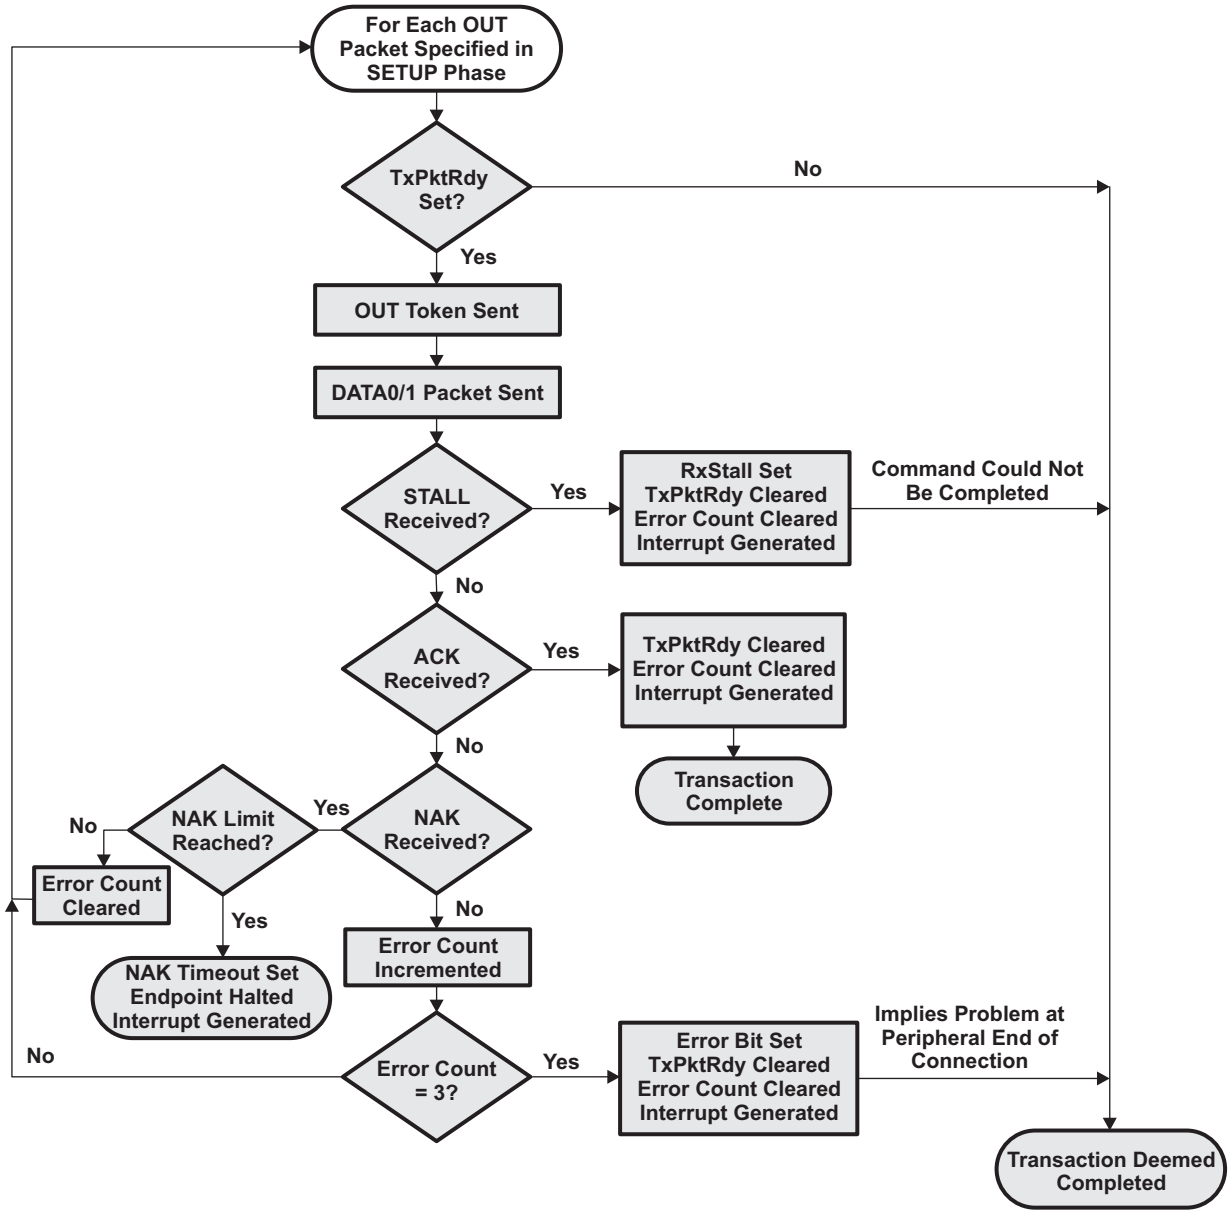


24.3.2.1.3 Data Phase (OUT Data Phase) of a Control Transaction: Host Mode

For the OUT Data Phase of a control transaction (Figure 24-9), the software driving the USB host device needs to:

1. Load the data to be sent into the endpoint 0 FIFO.
2. Set the TXPKTRDY bit of HOST_CSR0 (bit 1). The controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
   If RXSTALL bit is set, it indicates that the target has issued a STALL response.
   If ERROR bit is set, it means that the controller has tried to send the OUT token and the following data packet three times without getting any response. If NAK_TIMEOUT is set, it means that the controller has received a NAK response to each attempt to send the OUT token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
   If none of RXSTALL, ERROR or NAKLIMIT is set, the OUT data has been correctly ACKed.
4. If further data needs to be sent, the software should repeat Steps 1-3.
   When all the data has been successfully sent, the software should proceed to the IN Status Phase of the Control Transaction.

Figure 24-9. Flow Chart of Data Stage (OUT Data Phase) of a Control Transfer in Host Mode



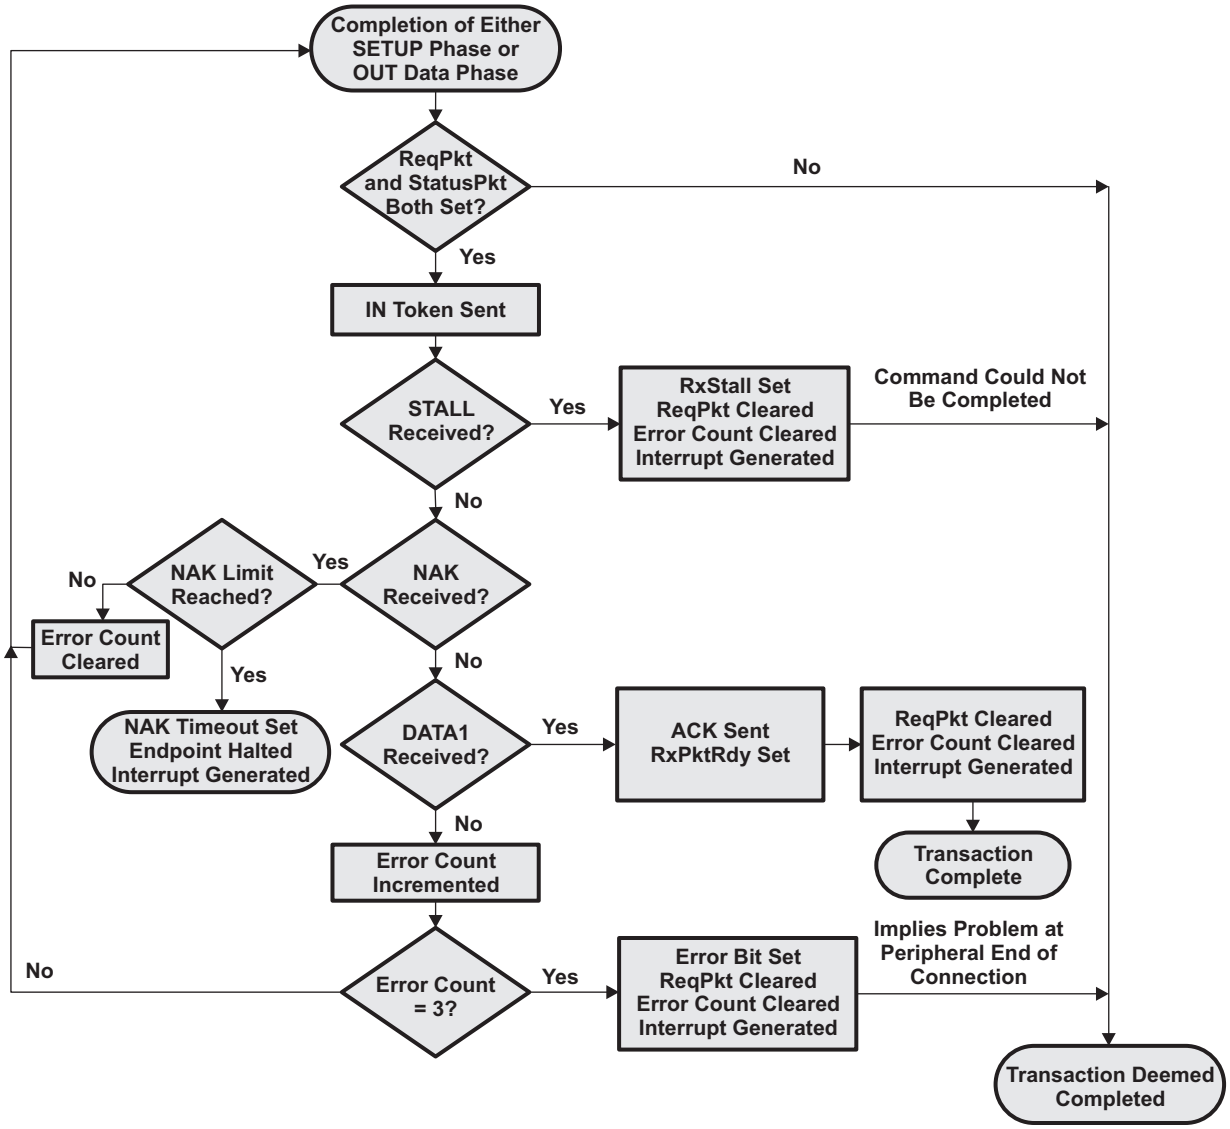
24.3.2.1.4 Status Phase (Status for OUT Data Phase or Setup Phase) of a Control Transaction: Host Mode

IN Status Phase of a control transfer exists for a Zero Data Request or for a Write Request of a control transfer. The IN Status Phase follows the Setup Stage, if no Data Stage of a control transfer exists, or OUT Data Phase of a Data Stage of a control transfer.

For the IN Status Phase of a control transaction (Figure 24-10), the software driving the USB Host device needs to:

1. Set the STATUSPKT and REQPKT bits of HOST_CSR0 (bit 6 and bit 5, respectively).
2. Wait while the controller sends an IN token and receives a response from the USB peripheral device.
3. When the controller generates the Endpoint 0 interrupt, read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4), the NAK_TIMEOUT bit (bit 7) or RXPKTRDY bit (bit 0) has been set.
   If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
   If ERROR bit is set, it means that the controller has tried to send the required IN token three times without getting any response.
   If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by clearing REQPKT bit and STATUSPKT bit before clearing the NAK_TIMEOUT bit.
4. The CPU should clear the STATUSPPKT bit of HOST_CSR0 together with (in the same write operation as) RxPktRdy if this has been set.

Figure 24-10. Flow Chart of Status Stage of Zero Data Request or Write Request of a Control Transfer in Host Mode



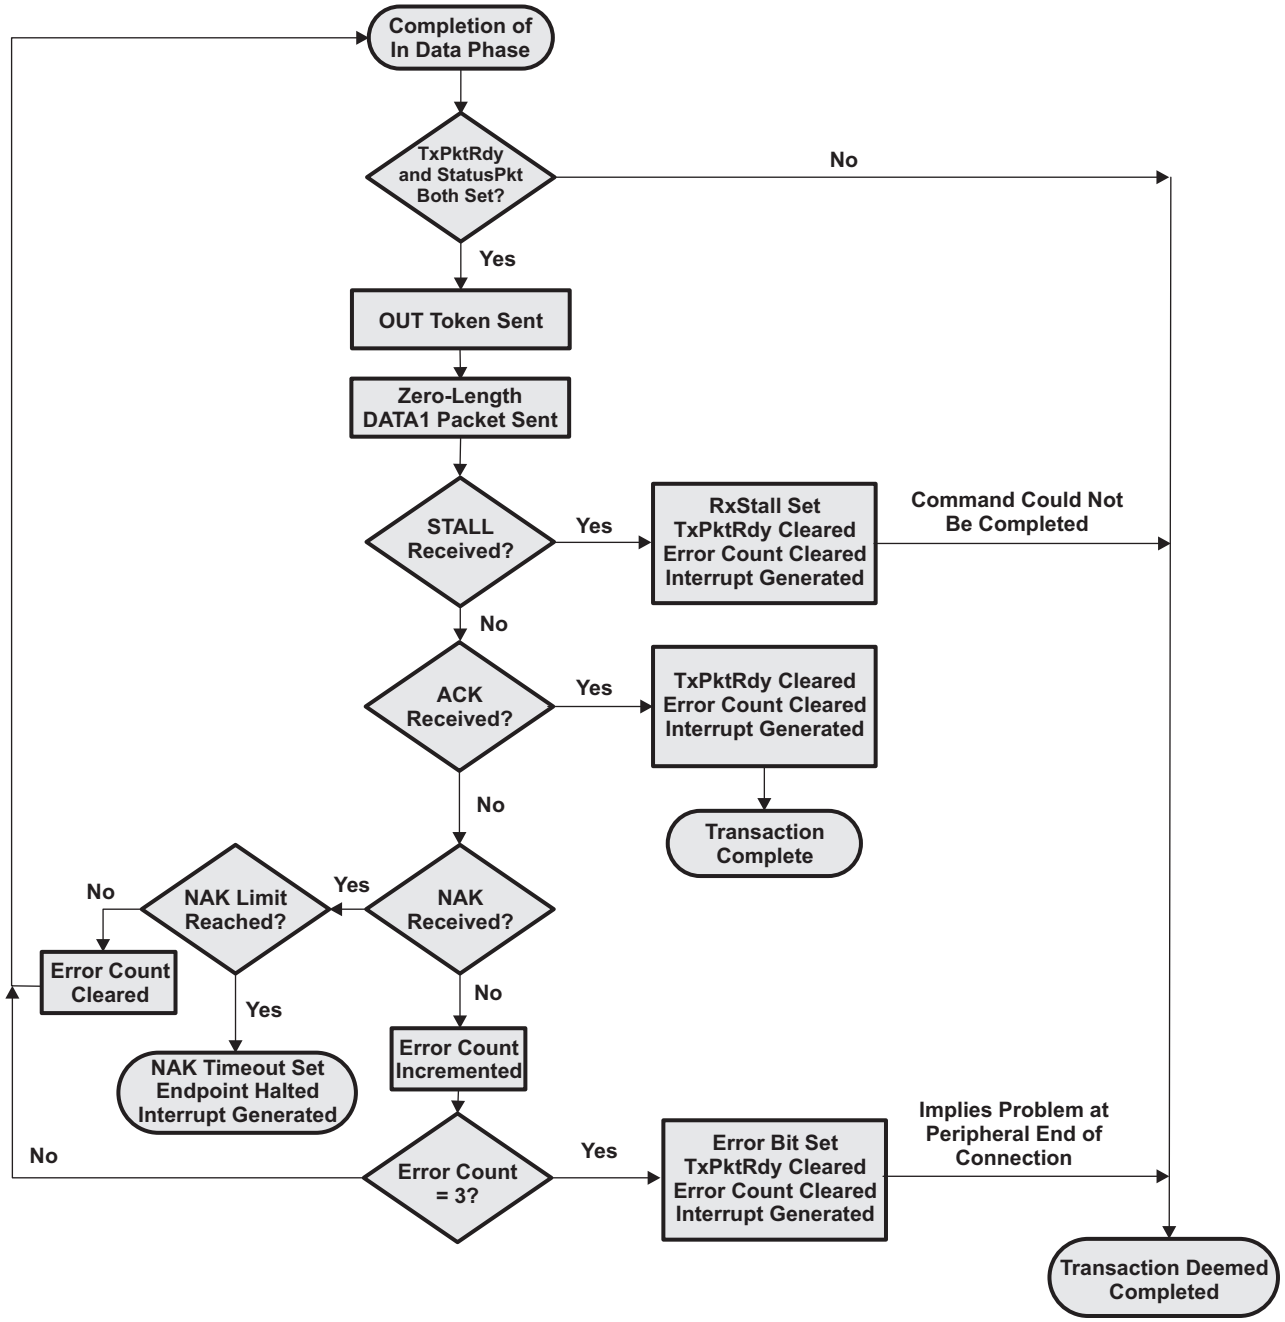
24.3.2.1.5 Status Phase for a Read Request of a Control Transaction: Host Mode

OUT Status Phase of a control transfer exist for a Read Request or a control transfer where data was received by the host controller. The OUT Status phase follows the IN Data Stage of a control transfer.

For the OUT Status Phase of a control transaction (Figure 24-11), the CPU driving the host device needs to:

1. Set STATUSPKT and TXPKTRDY bits of HOST_CSR0 (bit 6 and bit 1, respectively).
   NOTE: These bits need to be set together
2. Wait while the controller sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the controller will generate an Endpoint 0 interrupt. The software should then read HOST_CSR0 to establish whether the RXSTALL bit (bit 2), the ERROR bit (bit 4) or the NAK_TIMEOUT bit (bit 7) has been set.
   If RXSTALL bit is set, it indicates that the target could not complete the command and so has issued a STALL response.
   If ERROR bit is set, it means that the controller has tried to send the STATUS Packet and the following data packet three times without getting any response.
   If NAK_TIMEOUT bit is set, it means that the controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the HOST_NAKLIMIT0 register. The controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.
4. If none of RXSTALL, ERROR or NAK_TIMEOUT bits is set, the STATUS Phase has been correctly ACKed.

Figure 24-11. Chart of Status Stage of a Read Request of a Control Transfer in Host Mode



24.3.2.2 Bulk Transfer: Host Mode

Bulk transactions are handled by endpoints other than endpoint 0. It is used to handle non-periodic, large bursty communication typically used for a transfer that use any available bandwidth and can also be delayed until bandwidth is available.

24.3.2.2.1 Bulk IN Transactions: Host Mode

A Bulk IN transaction may be used to transfer non-periodic data from the external USB peripheral to the host.

The following optional features are available for use with an Rx endpoint used in host mode to receive the data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention.
  When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions. For more information see section on CPPI DMA

24.3.2.2.1.1 Bulk IN Setup: Host Mode

Before initiating any Bulk IN Transactions in Host mode:

- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 10 (binary value) in the PROT field for bulk transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or cleared to 0 if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).

  Note: Whether interrupt is handled from PDR level or Core level, interrupt is required to be enabled at the core level. See details on Core Interrupt registers, CTRLR register, and sections on Interrupt Handling
- The AUTOREQ bit field should be used only when servicing transfers using CPU mode and must be cleared when using DMA Mode. For DMA Mode, dedicated registers USB0/1 Req Registers exist and the HOST_RXCSR[AUTOREQ] should be cleared.
  When DMA is enabled, the following bits of HOST_RXCSR register should be set as:
  - Clear AUTOCLEAR.
  - Set DMAEN (bit 13) to 1 if a DMA request is required for this endpoint.
  - Clear DSINYET (bit 12) to 0 to allow normal PING flow control. This will affect only High Speed transactions.
  - Clear DMAMODE (bit 11) to 0.

    Note: If DMA is enabled, the USB0/1 Auto Req register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn_AUTOREQ (where n is the endpoint number) with binary value 01 or 11.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN and DATATOG bits of HOST_RXCSR (bit 10 and bit 9) to toggle the current setting or by setting the CLRDATATOG bit of HOST_RXCSR (bit 7). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also if there are any data packets in the FIFO (indicated by the RXPKTRDY bit (bit 0 of HOST_RXCSR) being set), they should be flushed by setting the FLUSHFIFO bit of HOST_RXCSR (bit 4).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

24.3.2.2.1.2 Bulk IN Operation: Host Mode

When Bulk data is required from the USB peripheral device, the software should set the REQPKT bit in the corresponding HOST_RXCSR register (bit 5). The controller will then send an IN token to the selected peripheral endpoint and waits for data to be returned.

If data is correctly received, RXPKTRDY bit of HOST_RXCSR (bit 0) is set. If the USB peripheral device responds with a STALL, RXSTALL bit (bit 6 of HOST_RXCSR) is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the POLINTVL_NAKLIMIT set in the HOST_RXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting the ERROR bit of HOST_RXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_RXCSR register to determine whether the RXPKTRDY, RXSTALL, ERROR or DATAERR_NAKTIMEOUT bit is set and act accordingly. If the DATAERR_NAKTIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the DATAERR_NAKTIMEOUT bit or to abort the transaction by clearing REQPKT bit before clearing the DATAERR_NAKTIMEOUT bit.

The packets received should not exceed the size specified in the RXMAXP register (as this should be the value set in the wMaxPacketSize field of the endpoint descriptor sent to the host).

In the general case, the application software (if CPU is servicing the endpoint) will need to read each packet from the FIFO individually. If large blocks of data are being transferred, the overhead of calling an interrupt service routine to unload each packet can be avoided by using DMA.

Note: When using DMA, see CPPI DMA section for the proper configuration of the core register, HOST_RXCSR.

24.3.2.2.1.3 Bulk IN Error Handling: Host Mode

If the target wants to shut down the Bulk IN pipe, it will send a STALL response to the IN token. This will result in the RXSTALL bit of HOST_RXCSR (bit 6) being set.

24.3.2.2.2 Bulk OUT Transactions: Host Mode

A Bulk OUT transaction may be used to transfer non-periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).
- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention. For more information on using DMA, consult the section discussing CPPI DMA.
  When DMA is enabled and DMAMODE bit in HOST_TXCSR register is set, an endpoint interrupt will not be generated for completion of packet reception. An endpoint interrupt will be generated only in the error conditions.

24.3.2.2.2.1 Bulk OUT Setup: Host Mode

Before initiating any bulk OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint. (TXFUNCADDR register is available for all endpoints from EP0 to EP15.)
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set PROT field to 10b for bulk transfer.
  - Enter Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required value for the NAK limit (2-215 frames/microframes), or cleared to 0 if the NAK timeout feature is not required.
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Clear the FRCDATATOG bit (bit 11) to 0 to allow normal data toggle operations.
  - Clear/Set AUTOSET bit (bit 15). The setting of this bit depends on the desire of the user/application in automatically setting the TXPKTRDY bit when servicing transactions using CPU.

Note: If DMA needs to be used in place of the CPU, HOST_TXCSR Register Bit Configuration in Host Mode displays the setting of the HOST_TXCSR register in Host mode. For the CPPI DMA registers settings, see Section 24.4.

HOST_TXCSR Register Bit Configuration in Host Mode

Bit	Bit Name	Description
Bit 15	AUTOSET	Cleared to 0 if using DMA. For CPU Mode use, if AUTOSET bit is set, the TXPKTRDY bit will be automatically set when data of the maximum packet size is loaded into the FIFO.
Bit 14	ISO	Cleared to 0 for bulk mode operation.
Bit 13	MODE	Set to 1 to make sure the FIFO is enabled (only necessary if the FIFO is shared with an RX endpoint)
Bit 12	DMAEN	Set to 1 to enable DMA usage; not needed if CPU is being used to service the Tx Endpoint
Bit 11	FRCDATATOG	Cleared to 0 to allow normal data toggle operations.
Bit 10	DMAMODE	Set to 1 when DMA is used to service Tx FIFO.

When the endpoint is first configured, the endpoint data toggle should be cleared to 0 either by using the DATATOGWREN bit and DATATOG bit of HOST_TXCSR (bit 9 and bit 8) to toggle the current setting or by setting the CLRDATATOG bit of HOST_TXCSR (bit 6). This will ensure that the data toggle (which is handled automatically by the controller) starts in the correct state. Also, if there are any data packets in the FIFO (indicated by the FIFONOTEMPTY bit of HOST_TXCSR register (bit 1) being set), they should be flushed by setting the FLUSHFIFO bit (bit 3 of HOST_TXCSR).

NOTE: It may be necessary to set this bit twice in succession if double buffering is enabled.

24.3.2.2.2.2 Bulk OUT Operation: Host Mode

When Bulk data is required to be sent to the USB peripheral device, the software should write the first packet of the data to the FIFO (or two packets if double-buffered) and set the TXPKTRDY bit in the corresponding HOST_TXCSR register (bit 0). The controller will then send an OUT token to the selected peripheral endpoint, followed by the first data packet from the FIFO.

If data is correctly received by the peripheral device, an ACK should be received whereupon the controller will clear TXPKTRDY bit of HOST_TXCSR (bit 0). If the USB peripheral device responds with a STALL, the RXSTALL bit (bit 5) of HOST_TXCSR is set. If a NAK is received, the controller tries again and continues to try until either the transaction is successful or the NAK limit set in the HOST_TXINTERVAL register is reached. If no response at all is received, two further attempts are made before the controller reports an error by setting ERROR bit in HOST_TXCSR (bit 2).

The controller then generates the appropriate endpoint interrupt, whereupon the software should read the corresponding HOST_TXCSR register to determine whether the RXSTALL (bit 5), ERROR (bit 2) or NAK_TIMEOUT (bit 7) bit is set and act accordingly. If the NAK_TIMEOUT bit is set, the controller can be directed either to continue trying this transaction (until it times out again) by clearing the NAK_TIMEOUT bit or to abort the transaction by flushing the FIFO before clearing the NAK_TIMEOUT bit.

If large blocks of data are being transferred, then the overhead of calling an interrupt service routine to load each packet can be avoided by using DMA.

24.3.2.2.2.3 Bulk OUT Error Handling: Host Mode

If the target wants to shut down the Bulk OUT pipe, it will send a STALL response. This is indicated by the RXSTALL bit of HOST_TXCSR register (bit 5) being set.

24.3.2.3 Interrupt Transfer: Host Mode

When the controller is operating as the host, interactions with an Interrupt endpoint on the USB peripheral device are handled in very much the same way as the equivalent Bulk transactions (described in previous sections).

The principal difference as far as operational steps are concerned is that the PROT field of HOST_RXTYPE and HOST_TXTYPE (bits 5-4) need to be set (binary value) to represent an Interrupt transaction. The required polling interval also needs to be set in the HOST_RXINTERVAL and HOST_TXINTERVAL registers.

24.3.2.4 Isochronous Transfer: Host Mode

Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device.

An Isochronous IN transaction is used to transfer periodic data from the USB peripheral to the host.

24.3.2.4.1 Isochronous IN Transactions: Host Mode

The following optional features are available for use with an Rx endpoint used in Host mode to receive this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO on reception from the host. This allows that one packet can be received while another is being read. Double packet buffering is enabled by setting the DPB bit of RXFIFOSZ register (bit 4).
- AutoRequest: When the AutoRequest feature is enabled, the REQPKT bit of HOST_RXCSR (bit 5) will be automatically set when the RXPKTRDY bit is cleared. This only applies when the CPU is being used to service the endpoint. When using DMA, this bit field needs to be cleared to Zero. CPPI DMA has its own configuration registers that renders a similar task, USB0/1 Auto Req registers, that needs to be used to have a similar effect. For more information, see section on CPPI DMA.

- DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint has a packet in its FIFO. This feature can be used to allow the DMA controller to unload packets from the FIFO without processor intervention. However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.
- When DMA is enabled, endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

24.3.2.4.1.1 Isochronous IN Transfer Setup: Host

Before initiating an Isochronous IN Transactions in Host mode:

- The target function address needs to be set in the RXFUNCADDR register for the selected controller endpoint (RXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_RXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in RENDPN field. This is the endpoint number contained in the Rx endpoint descriptor returned by the target device during enumeration.
- The RXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_RXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRRXE register should be set (if an interrupt is required for this endpoint).
- The following bits of HOST_RXCSR register should be set as:
  - Clear AUTOCLEAR
  - Set the DMAEN bit (bit 13) to 1 if a DMA request is required for this endpoint.
  - Clear the DISNYET it (bit 12) to 0 to allow normal PING flow control. This will only affect High Speed transactions.
  - Clear DMAMODE bit (bit 11) to 0.
- If DMA is enabled, AUTOREQ register can be set for generating IN tokens automatically after receiving the data. Set the bit field RXn_AUTOREQ (where n is the endpoint number) with binary value 01 or 11. For detailed information on using CPPI DMA, consult related section within this document.

24.3.2.4.1.2 Isochronous IN Operation: Host Mode

The operation starts with the software setting REQPKT bit of HOST_RXCSR (bit 5). This causes the controller to send an IN token to the target.

When a packet is received, an interrupt is generated which the software may use to unload the packet from the FIFO and clear the RXPKTRDY bit in the HOST_RXCSR register (bit 0) in the same way as for a Bulk Rx endpoint. As the interrupt could occur almost any time within a frame(/microframe), the timing of FIFO unload requests will probably be irregular. If the data sink for the endpoint is going to some external hardware, it may be better to minimize the requirement for additional buffering by waiting until the end of each frame before unloading the FIFO. This can be done by using the SOF_PULSE signal from the controller to trigger the unloading of the data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to clear the RXPKTRDY bit in HOST_RXCSR.

24.3.2.4.1.3 Isochronous IN Error Handling: Host Mode

If a CRC or bit-stuff error occurs during the reception of a packet, the packet will still be stored in the FIFO but the DATAERR_NAKTIMEOUT bit of HOST_RXCSR (bit 3) is set to indicate that the data may be corrupt.

Note: The number of USB packets sent in any microframe will depend on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated numbers of packets have not been received by the end of a microframe, the INCOMPRX bit in the HOST_RXCSR register will be set to indicate that the data in the FIFO is incomplete. Equally, if a packet of the wrong data type is received, then the PID Error bit is the HOST_RXCSR register will be set. In each case, an interrupt will, however, still be generated to allow the data that has been received to be read from the FIFO.

24.3.2.4.2 Isochronous OUT Transactions: Host Mode

An Isochronous OUT transaction may be used to transfer periodic data from the host to the USB peripheral.

Following optional features are available for use with a Tx endpoint used in Host mode to transmit this data:

- Double packet buffering: When enabled, up to two packets can be stored in the FIFO awaiting transmission to the peripheral device. Double packet buffering is enabled by setting the DPB bit of TXFIFOSZ register (bit 4).

DMA: If DMA is enabled for the endpoint, a DMA request will be generated whenever the endpoint is able to accept another packet in its FIFO. This feature can be used to allow the DMA controller to load packets into the FIFO without processor intervention.

However, this feature is not particularly useful with isochronous endpoints because the packets transferred are often not maximum packet size.

When DMA is enabled and endpoint interrupt will not be generated for completion of packet reception. Endpoint interrupt will be generated only in the error conditions.

24.3.2.4.2.1 Isochronous OUT Transfer Setup: Host Mode

Before initiating any Isochronous OUT transactions:

- The target function address needs to be set in the TXFUNCADDR register for the selected controller endpoint (TXFUNCADDR register is available for all endpoints from EP0 to EP4).
- The HOST_TXTYPE register for the endpoint that is to be used needs to be programmed as:
  - Operating speed in the SPEED bit field (bits 7 and 6).
  - Set 01 (binary value) in the PROT field for isochronous transfer.
  - Endpoint Number of the target device in TENDPN field. This is the endpoint number contained in the OUT(Tx) endpoint descriptor returned by the target device during enumeration.
- The TXMAXP register for the controller endpoint must be written with the maximum packet size (in bytes) for the transfer. This value should be the same as the wMaxPacketSize field of the Standard Endpoint Descriptor for the target endpoint.
- The HOST_TXINTERVAL register needs to be written with the required transaction interval (usually one transaction per frame/microframe).
- The relevant interrupt enable bit in the INTRTXE register should be set (if an interrupt is required for this endpoint).

- The following bits of HOST_TXCSR register should be set as:
  - Set the MODE bit (bit 13) to 1 to ensure the FIFO is enabled (only necessary if the FIFO is shared with an Rx endpoint).
  - Set the DMAEN bit (bit 12) to 1 if a DMA request is required for this endpoint
  - The FRCDATATOG bit (bit 11) is ignored for isochronous transactions.
  - Set the DMAMODE bit (bit 10) to 1 when DMA is enabled.
    For more details in using DMA, consult CPPI DMA section within this document.

24.3.2.4.2.2 Isochronous OUT Transfer Operation: Host Mode

The operation starts when the software writes to the FIFO and sets TXPKTRDY bit of HOST_TXCSR (bit 0). This triggers the controller to send an OUT token followed by the first data packet from the FIFO.

An interrupt is generated whenever a packet is sent and the software may use this interrupt to load the next packet into the FIFO and set the TXPKTRDY bit in the HOST_TXCSR register (bit 0) in the same way as for a Bulk Tx endpoint. As the interrupt could occur almost any time within a frame, depending on when the host has scheduled the transaction, this may result in irregular timing of FIFO load requests. If the data source for the endpoint is coming from some external hardware, it may be more convenient to wait until the end of each frame before loading the FIFO as this will minimize the requirement for additional buffering. This can be done by using the SOF_PULSE signal from the controller to trigger the loading of the next data packet. The SOF_PULSE is generated once per frame(/microframe). The interrupts may still be used to set the TXPKTRDY bit in HOST_TXCSR.

24.4 Communications Port Programming Interface (CPPI) 4.1 DMA

The CPPI DMA module supports the transmission and reception of USB packets. The CPPI DMA is designed to facilitate the segmentation and reassembly of CPPI compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. Multiple Tx and Rx channels are provided for all endpoints (excluding endpoint 0) within the DMA allowing multiple segmentation or reassembly operations to be effectively performed in parallel (but not actually simultaneously). The DMA controller maintains state information for each of the ports/channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

The CPPI (version 4.1) DMA controller sub-module is a common 15 port DMA controller. It supports 15 Tx and 15 Rx channels and each port attaches to the associated endpoint in the controller. Port 1 maps to endpoint 1 and Port 2 maps to endpoint 2 and so on with Port 15 mapped to endpoint 15; endpoint 0 can not utilize the DMA and the firmware is responsible to load or offload the endpoint 0 FIFO via CPU.

24.4.1 CPPI Terminology

Host — The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port interrupts.

Main Memory — The area of data storage managed by the CPU. The CPPI DMA (CDMA) reads and writes CPPI packets from and to main memory. This memory can exist internal or external from the device.

Queue Manager (QM) — The QM is responsible for accelerating management of a variety of Packet Queues and Free Descriptor / Buffer Queues. It provides status indications to the CDMA Scheduler when queues are empty or full.

CPPI DMA (CDMA) — The CDMA is responsible for transferring data between the CPPI FIFO and Main Memory. It acquires free Buffer Descriptor from the QM (Receive Submit Queue) for storage of received data, posts received packets pointers to the Receive Completion Queue, transmits packets stored on the Transmit Submit Queue (Transmit Queue) , and posts completed transmit packets to the Transmit Completion Queue.

CDMA Scheduler (CDMAS) — The CDMAS is responsible for scheduling CDMA transmit and receive operations. It uses Queue Indicators from the QM and the CDMA to determine the types of operations to schedule.

CPPI FIFO — The CPPI FIFO provides FIFO interfaces (for each of the 15 transmit and 15 receive endpoints).

Transfer DMA (XDMA) — The XDMA receives DMA requests from the Mentor USB 2.0 Core and initiates DMAs to the CPPI FIFO.

Endpoint FIFOs — The Endpoint FIFOs are the USB packet storage elements used by the Mentor USB 2.0 Core for packet transmission or reception. The XDMA transfers data between the CPPI FIFO and the Endpoint FIFOs for transmit operations and between the Endpoint FIFOs and the CPPI FIFO for receive operations.

Port — A port is the communications module (peripheral hardware) that contains the control logic for Direct Memory Access for a single transmit/receive interface or set of interfaces. Each port may have multiple communication channels that transfer data using homogenous or heterogeneous protocols. A port is usually subdivided into transmit and receive pairs which are independent of each other. Each endpoint, excluding endpoint 0, has its own dedicated port.

Channel — A channel refers to the sub-division of information (flows) that is transported across ports. Each channel has associated state information. Channels are used to segregate information flows based on the protocol used, scheduling requirements (example: CBR, VBR, ABR), or concurrency requirements (that is, blocking avoidance). All fifteen ports per USB Module have dedicated single channels, channel 0, associated for their use in a USB application.

Data Buffer — A data buffer is a single data structure that contains payload information for transmission to or reception from a port. A data buffer is a byte aligned contiguous block of memory used to store packet payload data. A data buffer may hold any portion of a packet and may be linked together (via descriptors) with other buffers to form packets. Data buffers may be allocated anywhere within the 32-bit memory space. The Buffer Length field of the packet descriptor indicates the number of valid data bytes in the buffer. There may be from 1 to 4M-1 valid data bytes in each buffer.

Host Buffer Descriptor (Buffer Descriptor) — A buffer descriptor is a single data structure that contains information about one or more data buffers. This type of descriptor is required when more than one descriptor is needed to define an entire packet, that is, it either defines the middle of a packet or end of a packet.

Start of Packet (SOP) — Packet along side Buffer Descriptors are used to hold information about Packets. When multiple Descriptors are used to hold a single packet information or a single Descriptor is used to hold a single packet information, the first descriptor is referred to as a Packet Descriptor which is also Start-of-Packet Descriptor.

Host Packet Descriptor (Packet Descriptor) — A packet descriptor is another name for the first buffer descriptor within a packet. Some fields within a data buffer descriptor are only valid when it is a packet descriptor including the tags, packet length, packet type, and flags. This type of descriptor is always used to define a packet since it provides packet level information that is useful to both the ports and the Host in order to properly process the packet. It is the only descriptor used when single descriptor solely defines a packet. When multiple descriptors are needed to define a packet, the packet descriptor is the first descriptor used to define a packet.

Free Descriptor/Buffer Queue — A free descriptor/buffer queue is a hardware managed list of available descriptors with pre-linked empty buffers that are to be used by the receive ports for host type descriptors. Free Descriptor/Buffer Queues are implemented by the Queue Manager.

Teardown Descriptor — Teardown Descriptor is a special structure which is not used to describe either a packet or a buffer but is instead used to describe the completion of a channel halt and teardown event. Channel teardown is an important function because it ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the Host without the possibility of losing buffer or descriptor references (which results in a memory leak).

Packet Queue — A packet queue is hardware managed list of valid (populated) packet descriptors that is used for forwarding a packet from one entity to another for any number of purposes.
NOTE: All descriptors (regardless of type) must be allocated at addresses that are naturally aligned to the smallest power of 2 that is equal to or greater than the descriptor size.

24.4.2 Data Structures

Two data structures are mainly used to identify data buffers used by packet and buffer descriptors. A third Descriptor, Teardown Descriptor, exists. The purpose of this Descriptor is a channel halt and teardown event. Each of these Descriptor layouts as well as bit fields are shown below.

24.4.2.1 Host Packet Descriptor/ Packet Descriptor (SOP Descriptor)

Descriptors are designed to be used when USB like application requires support for true, unlimited fragment count scatter/gather type operations. The Packet Descriptor is the first descriptor on multiple descriptors setup or the only descriptor in a single descriptors setup. The Packet Descriptor contains the following information:

- Indicator which identifies the descriptor as a packet descriptor (always 10h
- Source and destination tags (reserved)
- Packet type
- Packet length
- Protocol specific region size
- Protocol specific control/statusbits
- Pointer to the first valid byte in the SOP data buffer
- Length of the SOP data buffer
- Pointer to the next buffer descriptor in the

Packet descriptors can vary in size by design of their defined fields from 32 bytes up to 104 bytes. Within this range, packet descriptors always contain 32 bytes of required information and may also contain 8 bytes of software specific tagging information and up to 64 bytes (indicated in 4 byte increments) of protocol specific information. How much protocol specific information (and therefore the allocated size of the descriptors) is application dependent. Port will make use of the first 32 bytes only.

From a general USB use perspective, a 32-byte descriptor size is suffix and the use of this size is expected for a normal USB usage.

The packet descriptor layout is shown in Figure 24-12 and described within Table 24-6 through Table 24-13.

Figure 24-12. Packet Descriptor Layout

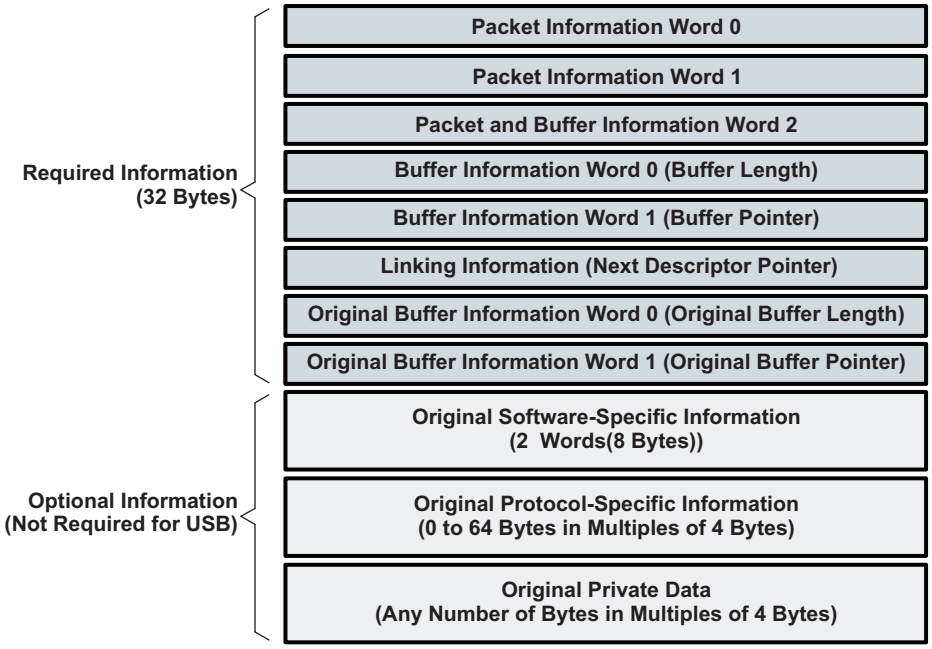


Table 24-6. Packet Descriptor Word 0 (PD0) Bit Field Descriptions

Bits	Field	Description
31-27	Descriptor type	The host packet descriptor type is 16 decimal (10h). The CPU initializes this field.
26-22	Protocol-specific valid word count	This field indicates the valid number of 32-bit words in the protocol-specific region. The CPU initializes this field. This is encoded in increments of 4 bytes as: 0 = 0 byte 1 = 4 bytes ... 16 = 64 bytes 17-31 = Reserved
21-0	Packet length	The length of the packet in bytes. If the packet length is less than the sum of the buffer lengths, then the packet data will be truncated. A packet length greater than the sum of the buffers is an error. The valid range for the packet length is 0 to (4M - 1) bytes. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 24-7. Packet Descriptor Word 1 (PD1) Bit Field Descriptions

Bits	Field	Description
31-27	Source Tag; Port #	This field indicates the port number (0-31) from which the packet originated. The DMA overwrites this field on packet reception. This is the RX Endpoint number from which the packet originated.
26-21	Source Tag; Channel #	This field indicates the channel number within the port from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0-67.
20-16	Source Tag: Sub-channel #	This field indicates the sub-channel number (0-31) within the channel from which the packet originated. The DMA overwrites this field on packet reception. This field is always 0.
15-0	Destination Tag	This field is application-specific. This field is always 0.

Table 24-8. Packet Descriptor Word 2 (PD2) Bit Field Descriptions

Bits	Field	Description
31	Packet error	This bit indicates if an error occurred during reception of this packet (0 = no error occurred; 1 = error occurred). The DMA overwrites t his field on packet reception. Additional information about different errors may be encoded in the protocol specific fields in the descriptor.
30-26		This field indicates the type of this packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception. This field is encoded as: 5 = USB 8-31 = Reserved
25-20	Reserved	Reserved
19	Zero-length packet indicator	If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit is set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.
18-16	Protocol-specific	This field contains protocol-specific flags/information that can be assigned based on the packet type. Not used for USB.
15	Return policy	This field indicates the return policy for this packet. The CPU initializes this field. 0 = Entire packet (still linked together) should be returned to the queue specified in bits 13-0. 1 = Each buffer should be returned to the queue specified in bits 13-0 of Word 2 in their respective descriptors. The Tx DMA will return each buffer in sequence.
14	On-chip	This field indicates whether or not this descriptor is in a region which is in on-chip memory space (1) or in external memory (0).
31-12	Packet return queue mgr #	This field indicates which queue manager in the system the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmissionor reception and is initialized by the CPU. There is only one queue manager in the USB HS/FS device controller. This field must always be 0.
11-0	Packet return queue #	This field indicates the queue number within the selected queue manager that the descriptor is to be returned to after transmission is complete. This field is not altered by the DMA during transmission or reception and is initialized by the CPU.

Table 24-9. Packet Descriptor Word 3 (PD3) Bit Field Descriptions

Bits	Field	Description
31-22	Reserved	Reserved
21-0	Buffer 0 length	The buffer length field indicates how many valid data bytes are in the buffer. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 24-10. Packet Descriptor Word 4 (PD4) Bit Field Descriptions

Bits	Field	Description
31-0	Buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 24-11. Packet Descriptor Word 5 (PD5) Bit Field Descriptions

Bits	Field	Description
31-0	Next descriptor pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current buffer is the last buffer in the packet. The CPU initializes this field for transmitted packets; the DMA overwrites this field on packet reception.

Table 24-12. Packet Descriptor Word 6 (PD6) Bit Field Descriptions

Bits	Field	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

Table 24-13. Packet Descriptor Word 7 (PD7) Bit Field Descriptions

Bits	Field	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

24.4.2.2 Host Buffer Descriptor/Buffer Descriptor (BD)

The buffer descriptor is identical in size and organization to a Packet Descriptor but does not include valid information in the packet level fields and does not include a populated region for protocol specific information. The packet level fields are not needed since the SOP descriptor contains this information and additional copy of this data is not needed/necessary.

Host buffer descriptors are designed to be linked onto a host packet descriptor or another host buffer descriptor to provide support for unlimited scatter / gather type operations. Host buffer descriptors provide information about a single corresponding data buffer. Every host buffer descriptor stores the following information:

- Pointer to the first valid byte in the data
- Length of the data buffer
- Pointer to the next buffer descriptor in the packet

Buffer descriptors always contain 32 bytes of required information. Since it is a requirement that it is possible to convert a descriptor between a Buffer Descriptor and a Packet Descriptor (by filling in the appropriate fields) in practice, Buffer Descriptors will be allocated using the same sizes as Packet Descriptors. In addition, since the 5 LSBs of the Descriptor Pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is always 32 bytes

The buffer descriptor layout is shown in Figure 24-13 and described within Table 24-14 through Table 24-21 .

Bits	Field	Description
31-0	Next description pointer	The 32-bit word aligned memory address of the next buffer descriptor in the packet. If the value of this pointer is zero, then the current descriptor is the last descriptor in the packet. The CPU initializes this field for transmitted packets. The DMA overwrites this field upon packet reception.

Table 24-20. Buffer Descriptor Word 6 (BD6) Bit Field Descriptions

Bits	Field	Description
31-22	Reserved	Reserved
21-0	Original buffer 0 length	The buffer length field indicates the original size of the buffer in bytes. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer size as allocated by the CPU at initialization. Since the buffer length in Word 3 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer size information.

Table 24-21. Buffer Descriptor Word 7 (BD7) Bit Field Descriptions

Bits	Field	Description
31-0	Original buffer 0 pointer	The buffer pointer is the byte-aligned memory address of the buffer associated with the buffer descriptor. This value is not overwritten during reception. This value is read by the Rx DMA to determine the actual buffer location as allocated by the CPU at initialization. Since the buffer pointer in Word 4 is overwritten by the Rx port during reception, this field is necessary to permanently store the buffer pointer information.

24.4.2.3 Teardown Descriptor

The Teardown Descriptor is not like the packet or buffer descriptors since it is not used to describe either a packet or a buffer. The teardown descriptor is always 32 bytes long and is comprised of 4 bytes of actual teardown information and 28 bytes of pad. The teardown descriptor layout and associated bit field descriptions are shown in the Figure below and Tables that follows. Since the 5 LSBs of the descriptor pointers are used in CPPI 4.1 for the purpose of indicating the length of the descriptor, the minimum size of a descriptor is 32 bytes.

The teardown descriptor is used to describe a channel halt and teardown event. Channel teardown ensures that when a connection is no longer needed that the hardware can be reliably halted and any remaining packets which had not yet been transmitted can be reclaimed by the host without the possibility of losing buffer or descriptor references (which results in a memory leak).

Theteardown descriptor contains the following information:

- Indicator which identifies the descriptor as a teardown packet descriptor
- DMA controller number where teardown
- Channel number within DMA where teardown occurred
- Indicator of whether this teardown was for the Tx or Rx channel

Figure 24-14. Teardown Descriptor Layout

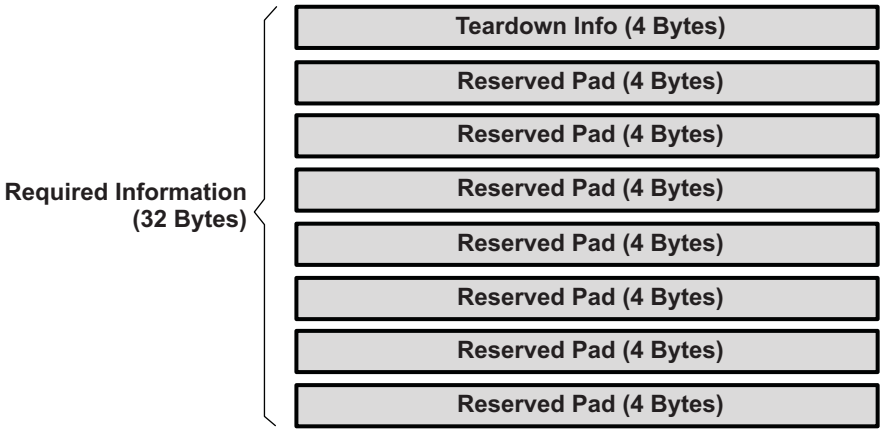

Table 24-22. Teardown Descriptor Word 0 Bit Field Descriptions

Bits	Field	Description
31-27	Descriptor type	The teardown descriptor type is 19 decimal (13h)
26-17	Reserved	Reserved
16	TX_RX	Indicates whether teardown is a TX (0) or RX (1).
15-10	DMA number	Indicates the DMA number for this teardown.
9-6	Reserved	Reserved
5-0	Channel number	Indicates the channel number within the DMA that was torn down.

Table 24-23. Teardown Descriptor Words 1 to 7 Bit Field Descriptions

Bits	Field	Description
31-0	Reserved	Reserved

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in TEARDOWN of the USB module must be set, and the FlushFIFO bit in the Mentor USB controller Tx/RxCSR register must be set.

The following is the Transmit teardown procedure highlighting the steps required to be followed:

1. Set the TX_TEARDOWN bit in the CPPI DMA TX channel n global configuration register (TXGCRn).
2. Set the appropriate TX_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Write Tx Endpoint Number to teardown to TEARDOWN[TX_TDOWN] field.
3. Check if the teardown descriptor has been received on the teardown queue: The completion queue (see Queue Assignment table) is usually used as the Teardown queue when the Teardown descriptor has been received, the descriptor address will be loaded onto CTRLD[Completion Queue #] register:
   (a) If not, go to step 2
   (b) If so, go to step 4
4. Set the appropriate TX_TDOWN bit in the USBOTG controller's USB teardown register (TEARDOWN). Set the bit corresponding to the Channel Number within TEARDOWN[TX_TDOWN] field.
5. Flush the TX FIFO in the Mentor OTG core: Set PERI_TXCSR[FLUSHFIFO] for the corresponding Endpoint.
6. Re-enable the Tx DMA channel.
   (a) Clear TXGCRn[TX_TEARDOWN and TX_ENABLE] bit.
   (b) Set TXGCRn[TX_ENABLE] bit.

24.4.3 Queue Manager

The queue manager (QM) is a hardware module that is responsible for accelerating management of the queues, that is, queues are maintained within a queue manager module. Packets are added to a queue by writing the 32-bit descriptor address to a particular memory mapped location in the queue manager module. Packets are de-queued by reading the same location for that particular queue. A single queue manager exists within the device and handles all available 156 queues within the USB subsystem

Descriptors are queued onto a logical queue (pushed) by writing the descriptor pointer to the Queue N Register D. When the Queue N Register D is written, this kicks off the queue manager causing it to add the descriptor to the tail of queue.

The QM keeps track of the order of the descriptors pushed within a queue or the linking status of the descriptors. To accomplish this linking status, QM will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking a queue pointer purposes. Once the address to index computation is performed, that is, the physical index information is determined, the QM will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. More on linking RAM discussion would follow in latter sections. The QM will also update the queue tail pointers appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

24.4.3.1 Queue Types

Several types of queues exist (a total of 156 queues) within the CPPI 4.1 DMA. Regardless of the type of queue, queues are used to hold pointers to Packet or Buffer Descriptors while they are being passed between the Host and / or any of the ports in the system. All queues are maintained within the single Queue Manager module.

The following types of Queues exist:

- Free descriptor queue (unassigned to specific endpoint but assigned to specific endpoint type; receive endpoints – can be used as a receive submit queue)
- Transmit submit queue
- Transmit completion (return) queue
- Receive completion (return) queue
- Teardown queue

Dedicated queues exist where one or more queues are assigned for the use of a single endpoint and non-dedicated queues exist where no specific queue assignment to an endpoint is required (but pertains to receive endpoints only). Transmit endpoints are not allowed to use free descriptor queues.

Dedicated queues exist for each specific endpoint use and non-dedicated queues exist that can be used by any/all receive endpoints. Three queues are reserved for each endpoint/port for transmit actions with two of the three queues being transmit submit queues while the remaining queue is used as a completion/return queue. For receive actions, the only dedicated queues are completion/return queues; one queue is assigned/reserved for each receive endpoint. 32 free descriptor queues that do not have dedicated endpoint-queue assignment exist and these queues are used to service any receive endpoint as receive submit queues.

Table 24-24 displays queue-endpoint assignments.

Table 24-24. Queue-Endpoint Assignments

Queue Start Number	Queue Count	Queue-Endpoint Association
0	32	Free Descriptor Queues/Rx Submit Queues (USB0/1 Rx Endpoints)
32	2	USB0 Tx Endpoint 1
34	2	USB0 Tx Endpoint 2
36	2	USB0 Tx Endpoint 3
38	2	USB0 Tx Endpoint 4

154	1	USB1 Rx Endpoint 14 completion queue
155	1	USB1 Rx Endpoint 15 completion queue

24.4.3.2 Free Descriptor Queue (Receive Submit Queue)

Receive endpoints/channels use queues, referred to as free descriptor queues, or receive submit queues, to forward completed receive packets to the host. The entries on the free descriptor queues have pre-attached empty buffers whose size and location are described in the original buffer information fields in the descriptor. The host is required to allocate both the descriptor and buffer and pre-link them prior to adding (submitting) a descriptor to one of the available free descriptor queue. The first 32 queues (queue 0 up to queue 31) are reserved for all 30 USB0/1 (endpoints 1 to 15 of each USB module) receive endpoints/channels to handle incoming packets to the device.

24.4.3.3 Transmit Submit Queue

Transmit ports use packet queues, referred to as transmit submit queues, to store the packets that are waiting to be transmitted. Each transmit endpoint has dedicated queues (2 queues per port) that are reserved exclusively for a use by a single endpoint. Multiple queues per port/channel are allocated to facilitate quality of service (QoS) for applications that require QoS. The first 30 queues, queue 32 up to queue 61, are allocated for USB0 transmit endpoints 1 to 15 with two queues per endpoint.queues 62 up to queue 91, are allocated for transmit USB1 endpoints 1 to 15.

24.4.3.4 Transmit Completion (Return) Queue

Transmit ports use packet queues, referred to as "transmit completion queues, to return packet descriptors to the host after packets have been transmitted. A singe queue is reserved to be used by a single transmit endpoint. Application s/w needs to insure that the right set of queues is used to return the Descriptors after the completion of a packet transmission based on the endpoint number used. For USB0 transmit endpoints 1 to 15 Queues 92 up to queue 106 are reserved/assigned for use as a completion queue respectively. Similarly for USB1 transmit endpoints 1 to 15, queues 107 up to queue 121 is used as completion queue, respectively.

Transmit Completion Queues are also used to return packet Descriptors when performing a Transmit channel teardown operation.

24.4.3.5 Receive Completion (Return) Queue

Receive ports use packet queues, referred to as receive completion queues, to return packet descriptors to the port after packets have been received. A singe queue is reserved to be used by a single receive endpoint. Application s/w needs to insure that the right set of queues is used to return the descriptors after the completion of a packet reception based on the endpoint number used. For USB0 receive endpoints 1 to 15 queues 122 up to queue 136 are reserved/assigned for use as a receive completion queue respectively. Similarly for USB1 receive endpoints 1 to 15, queues 137 up to queue 151 is used as completion queue respectively.

Receive channel teardown is not necessary for receive transactions and no channel teardown information nor resource is available

24.4.3.6 Diverting Queue Packets from one Queue to Another

The host can move the entire contents of one queue to another queue by writing the source queue number and the destination queue number to the Queue Diversion register. When diverting packets, the descriptors are pushed onto the tail of the destination queue.

24.4.3.7 Teardown Queue

The Teardown Queue is used by the DMA to communicate a completion of a channel teardown after a channel teardown is invoked on to a channel. The pointer to the teardown descriptor is written to the teardown queue, which is also the Completion Queue, when the channel teardown completes.

24.4.4 Memory Regions and Linking RAM

In addition to allocating buffer for raw data and memory for Descriptors, the host is responsible for allocating additional memory for exclusive use of the CPPI DMA Queue Manager to be used as a scratch PAD RAM. The queue manager uses this memory to manage states of descriptors submitted within the submit queues. In other words, this memory needs not to be managed by the user software and firmware responsibility lies only for allocation/reserving a chunk of memory for the use of the queue manager. The allocated memory can be a single block of memory that is contiguous or two blocks of memory that are not contiguous. These two blocks of memory are referred to as a Linking RAM Regions and should not be confused with memory regions that are used to store descriptors. That is, the use of the term *region* should be used in the context of its use.

To accomplish the linking of submitted descriptors, the queue manager will first resolve the 32-bit descriptor pointer into a 16-bit index which is used for linking and queue pointer purposes. Once the physical index information is determined, the queue manager will link that descriptor onto the descriptor chain that is maintained for that logical queue by writing the linking information out to a linking RAM which is external to the queue manager. The queue manager will also update the queue tail pointer appropriately. Since logical queues within the queue manager are maintained using linked lists, queues cannot become full and no check for fullness is required before queuing a packet descriptor.

The actual physical size of the Linking RAM region(s) to be allocated depends on the total number of descriptors defined within all memory regions. A minimum of four bytes of memory needs to be allocated for each Descriptor defined within all 16 memory regions.

The queue manager has the capability of managing up to 16 memory regions. These memory regions are used to store descriptors of variable sizes. The total number of descriptors that can be managed by the queue manager should not exceed 64K. Each memory region has descriptors of one configurable size, that is, descriptors with different sizes cannot be housed within a single memory region. These 64K descriptors are referenced internally in the queue manager by a 16-bit quantity index.

The information about the Linking RAM regions and the size that are allocated is communicated to the CPPI DMA via three registers dedicated for this purpose. Two of the three registers are used to store the 32-bit aligned start addresses of the Linking RAM regions. The remaining one register is used to store the size of the first Linking RAM. The linking RAM size value stored here is the number of descriptors that is to be managed by the queue manager within that region not the physical size of the buffer, which is four times the number of descriptors.

Note that application is not required to use both linking RAM regions, if the size of the Linking RAM for the first region is large enough to accommodate all descriptors defined. No linking RAM size register for linking RAM region 2 exists. The size of the second linking RAM, when used, is indirectly computed from the total number of descriptors defined less the number of descriptors managed by the first linking RAM

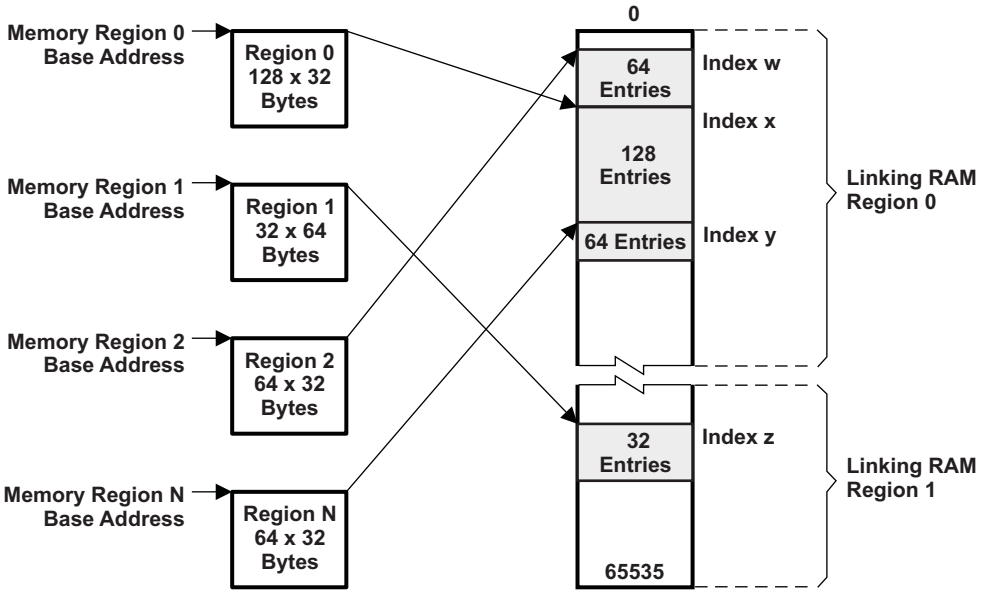
Figure 24-15 displays the relationship between several memory regions and linking RAM.

24.4.5 Zero Length Packets

A special case is the handling of null packets with the CPPI 4.1 compliant DMA controller. Upon receiving a zero length USB packet, the XFER DMA will send a data block to the DMA controller with byte count of zero and the zero byte packet bit of INFO Word 2 set. The DMA controller will then perform normal End of Packet termination of the packet, without transferring data.

If a zero-length USB packet is received, the XDMA will send the CDMA a data block with a byte count of 0 and this bit set. The CDMA will then perform normal EOP termination of the packet without transferring data. For transmit, if a packet has this bit set, the XDMA will ignore the CPPI packet size and send a zero-length packet to the USB controller.

Figure 24-15. Relationship Between Memory Regions and Linking RAM



24.4.6 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads/transfers that are provided in the CPPI DMA controller. The scheduler table RAM exists within the scheduler.

The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs.

24.4.6.1 CPPI DMA Scheduler Operation

Once the scheduler is enabled it will begin processing the entries in the table. When appropriate the scheduler will pass credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled it begins with the table index cleared to 0.
2. The scheduler reads the entry pointed to by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted.
   (a) The DMA channel must be enabled AND
   (b) The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted)
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface which is a point to point connection between the DMA Scheduler and the DMA Controller.
   (a) The DMA controller may not be ready to accept the credit immediately and is provided a sched_ready signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the sched_ready signal when it is in the IDLE state.
   (b) Once a credit has been accepted (indicated by sched_req and sched_ready both asserted), the scheduler will increment the index to the next entry and will start again at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
5. Note that when the scheduler attempts to increment its index, to the value programmed in the table size register, the index will be reset to 0.

24.4.6.1.1 CPPI DMA Scheduler Initialization

Before the scheduler can be used, the host is required to initialize and enable the block. This initialization is performed as follows:

1. The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries (4 entries per table word n where n=0-63) and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
2. If the application does not need to use the entire 256 entries, firmware can initialize the portion of the 256 entries and indicate the size of the entries used by writing onto an internal register in the scheduler which sets the actual size of the array (it can be less than 256 entries).
3. The host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

24.4.6.1.2 CPPI DMA Scheduler Programming Examples

Consider a three endpoints use on a system with the following configurations: EP1-Tx, EP2-Rx, and EP2-Tx. Two assumptions are considered:

Case 1: Assume that you would like to service each enabled endpoints (EP1-Tx, EP2-Rx, and EP2-Tx) with equal priority.

The scheduler handles the rate at which an endpoint is serviced by the number of credits programmed (entries) for that particular endpoint within the scheduler Table Words. The scheduler has up to 256 credits that it can grant and for this example the user can configure the number of entries/credits to be anywhere from 3 to 256 with a set of 3 entries.

However, the optimum and direct programming for this scenario would be programming only the first three entries of the scheduler via scheduler Table WORD[0]. Since this case expects the Scheduler to use only the first three entries, you communicate that by programming DMA_SCHED_CTRL.LAST_ENTRY with 2 (that is, 3 -1). The Enabled Endpoint numbers and the data transfer direction is then communicated by programming the first three entries of WORD[0] (ENTRY0_CHANNEL = 1: ENTRY0_RXTX = 0; ENTRY1_CHANNEL = 2: ENTRY1_RXTX = 1;ENTRY2_CHANNEL = 2: ENTRY2_RXTX = 0). With this programming, the Scheduler will only service the first three entries in a round-robin fashion, checking each credited endpoint for transfer one after the other, and servicing the endpoint that has data to transfer.

Case 2: Enabled endpoint EP1-Tx is serviced at twice the rate as the other enabled endpoints (EP2-Rx and EP2-Tx).

The number of entries/credit that has to be awarded to EP1-Tx has to be twice as much of the others. Four entries/credits would suffix to satisfy our requirement with two credits for EP1-Tx, one credit for EP2-Rx, and one credit for EP2-Tx. This requirement is satisfied by allocating any 2 of the 4 entries to EP1-Tx endpoint. Again for this example, scheduler Table WORD[0] would suffice since it can handle the first 4 entries. Even though several scenarios exist to programming the order of service for this case, one scenario would be to allow servicing EP1-Tx to back-to-back followed by the other enabled endpoints. Program DMA_SCHED_CTRL.LAST_ENTRY with 3 (that is, 4 -1). Program WORD[0] (ENTRY0_CHANNEL = 1: ENTRY0_RXTX = 0; ENTRY1_CHANNEL = 1: ENTRY1_RXTX = 0; ENTRY2_CHANNEL = 2: ENTRY2_RXTX = 1; ENTRY3_CHANNEL = 2: ENTRY3_RXTX = 0).

24.4.7 CPPI DMA State Registers

The port must store and maintain state information for each transmit and receive port/channel. The state information is referred to as the Tx DMA State and Rx DMA State.

24.4.7.1 Transmit DMA State Registers

The Tx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures and transmit packets. Each transmit channel has two queues. Each queue has a one head descriptor pointer and one completion pointer. There are thirty Tx DMA State registers; one for each port/channel.

The following information is stored in the Tx DMA State:

- Tx Queue Head Descriptor Pointer(s)
- Tx Completion Pointer(s)
- Protocol specific control/status (port scratchpad)

24.4.7.2 Receive DMA State Registers

The Rx DMA State is a combination of control fields and protocol specific port scratchpad space used to manipulate data structures in order to receive packets. Each receive channel has only one queue. Each channel queue has one head descriptor pointer and one completion pointer. There are thirty Rx DMA State registers; one for each port/channel.

The following information is stored in the Rx DMA State:

- Rx Queue Head Descriptor Pointer
- Rx Queue Completion Pointer
- Rx Buffer Offset

24.4.8 CPPI DMA Protocols Supported

Four different type of DMA transfers are supported by the CPPI 4.1 DMA; Transparent, RNDIS, Generic RNDIS, and Linux CDC. The following sections will outline the details on these DMA transfer types.

24.4.8.1 Transparent DMA Transfer

Transparent Mode DMA operation is the default DMA mode where DMA interrupt is generated whenever a DMA packet is transferred. In the transparent mode, DMA packet size cannot be greater than USB MaxPktSize for the endpoint. This transfer type is ideal for transfer (not packet) sizes that are less than a max packet size.

24.4.8.1.1 Transparent DMA Transfer Setup

The following will configure all 30 ports/channels for Transparent DMA Transfer type.

Make sure that RNDIS Mode is disabled globally. This allows the application to configure the CPPI DMA protocol in use to be configured per endpoint need. To disable RNDIS operation, clear RNDIS bit in the USB Control Registers corresponding to the USB Module (default setting), that is, CTRL0[RNDIS] = 0 and CTRL1[RNDIS] = 0.

Configure the USB0/1 Tx/Rx DMA Mode Registers (USB0/1 TX(RX)MODE0/1) for the Endpoint field in use is programmed for Transparent Mode (TXMODE0/1[TXn_MODE] = 00b and RXMODE0/1[RXn_MODE] = 00b).

24.4.8.2 RNDIS DMA Transfer

RNDIS mode DMA is used for large transfers (total data size to be transferred is greater than USB MaxPktSize where the MzxPktSize is a multiple of 64 bytes) that requires multiple USB packets. This is accomplished by breaking the larger packet into smaller packets, where each packet size being USB MaxPktSize except the last packet where its size is less than USB MaxPktSize, including zero bytes. This implies that multiple USB packets of MaxPktSize will be received and transferred together as a single large DMA transfer and the DMA interrupt is generated only at the end of the complete reception of DMA transfer. The protocol defines the end of the complete transfer by receiving a short USB packet (smaller than USB MaxPktSize as mentioned in USB specification 2.0). If the DMA packet size is an exact multiple of USB MaxPktSize, the DMA controller waits for a zero byte packet at the end of complete transfer to signify the completion of the transfer.

NOTE: RNDIS Mode DMA is supported only when USB MaxPktSize is an integral multiple of 64 bytes.

24.4.8.2.1 RNDIS DMA Transfer Setup

If all endpoints in use are desired to operate in RNDIS mode, it is only suffix to configure RNDIS DMA operation in RNDIS mode at the global level and application can ignore individual endpoint DMA mode configuration. This is achieved by programming CTRLR0/1[RNDIS] = 1.

However if DMA mode is required to be configured at the endpoint level, it is required to disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS] = 0), since global configuration over-rides endpoint configuration.

To configure RNDIS DMA mode use, configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register (TXMODE0/1[TXn_MODE] = 01b and RXMODE0/1[RXn_MODE] = 01b).

24.4.8.3 Generic RNDIS DMA Transfer

Generic RNDIS DMA transfer mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where the last packet of the transfer can either be a short packet or the MaxPktSize. When the last packet size is equal to the MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. Generic RNDIS transfer makes use of a USB0/1 GENERIC RNDIS EPn Size register (there exists a register for each endpoint) that must be programmed with the transfer size (in bytes) of the transfer for the USB Module (USB0 or USB1) prior to posting a transfer transaction. If the transfer size is an integer multiple of USB MaxPktSize then no additional zero-byte packet is sent when using Generic RNDIS transfer. However, if the a short packet has been sent prior to programmed size count, the transfer would end in a similar fashion an RDIS transfer would behave. For example, it the USB MaxPktSize (Tx/RxMaxP) is programmed with a value of 64, the Generic RNDIS EP Size register for that endpoint must be programmed with a value that is an integer multiple of 64 (for example, 64, 128, 192, 256, etc.) for it behave differently than RNDIS transfer. In other words, when using Generic RNDIS mode and the DMA is tasked to transfer data transfer size that is less or equal the size value programmed within the USB0/1 GENERIC RNDIS EPn Size register.

This means that Generic RNDIS mode will perform data transfer in the same manner as RNDIS mode, closing the CPPI packet if a USB packet with a size less than the USB MaxPktSize size value is received. Otherwise, the packet will be closed when the value in the Generic RNDIS EP Size register is reached.

Using USB0/1 GENERIC RNDIS EPn Size register, a packet of up to 64K bytes (65536 bytes) can be transferred. This is to allow the host software to program the USB module to transfer data that is an exact multiple of the USB MaxPktSize (Tx/RxMaxP programmed value) without having to send an additional short packet to terminate.

NOTE: As in RNDIS mode, the USB max packet size (Tx/RxMaxp programmed value) of any Generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

24.4.8.3.1 Generic RNDIS DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register (TXMODE0/1[TXn_MODE] = 11b and RXMODE0/1[RXn_MODE] = 11b).

24.4.8.4 Linux CDC DMA Transfer

Linux CDC DMA transfer mode acts in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size requiring additional zero-byte packet transfer in RNDIS mode and this is not the case for Linux CDC. If the last data packet of a transfer is a short packet where the data size is greater than zero and less the USB MaxPktSize, then the behavior of the Linux CDC DMA transfer type is identical with the RNDIS DMA transfer type. The only exception is when the short packet length terminating the transfer is a Null Packet. In this case, instead of transferring the Null Packet, it will transfer a data packet of size 1 byte with the data value of 00h.

In transmit operation, if an endpoint is configured or CDC Linux mode, upon receiving a Null Packet from the CPPI DMA, the XFER DMA will then generate a packet containing 1 byte of data, whose value is 00h, indicating the end of the transfer. During receive operation, the XFER DMA will recognize the one byte zero packet as a termination of the data transfer, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller. The CPPI DMA realizing the end of the transfer termination will not update/increase the packet size count of the Host Packet Descriptor.

24.4.8.4.1 Linux CDC DMA Transfer Setup

Disable the use of RNDIS at the global level, this is achieved by clearing RNDIS bit field (CTRLR0/1[RNDIS]=0), since global configuration over-rides endpoint configuration.

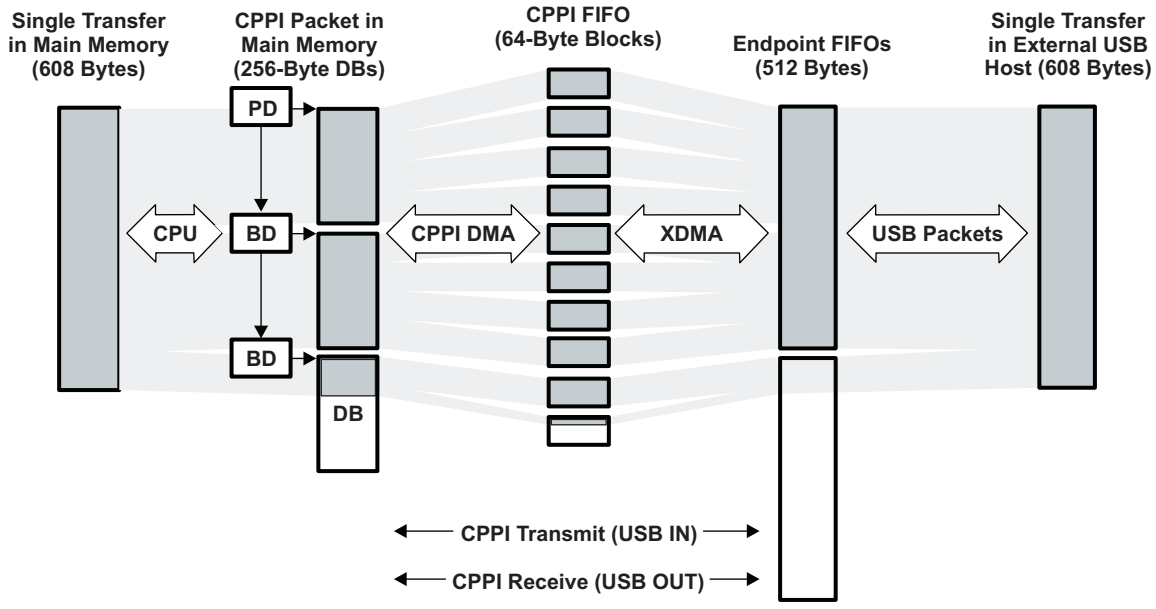
Configure the field that correspond to the USB module endpoint using the corresponding USB0/1 TX(RX) Mode Register (TXMODE0/1[TXn_MODE] = 10b and RXMODE0/1[RXn_MODE] = 10b).

24.4.9 USB Data Flow Using DMA

The necessary steps required to perform a USB data transfer using the CPPI 4.1 DMA is expressed using an example for both transmit and receive cases. Assume USB0 is ready to perform a USB data transfer of size 608 bytes (see Figure 24-16).

The 608 bytes data to be transferred is described using three descriptors. Since each data buffer defined within a single descriptor has a size of 256 bytes, a 608 bytes data buffer would require three descriptors.

Figure 24-16. High-level Transmit and Receive Data Transfer Example



Example assumptions:

- The CPPI data buffers are 256 bytes in length.
- USB0 module is to be used to perform this transfer. Note that the steps required is similar for USB1 use.
- The USB0 endpoint 1 Tx and Rx endpoint 1 size are programmed to handle max USB packet size of 512 bytes.
- A single transfer length is 608 bytes.
- The SOP offset is 0.

The previous example translates to the following multi-descriptor setup:

Transmit Case

Transmit setup is as follows:

- One packet descriptor with packet length (this is NOT data buffer length, the term packet used here is to mean a transfer length not USB packet) field of 608 bytes and a Data Buffer of size 256 Bytes linked to the 1st host buffer descriptor.
- Two buffer descriptors with first buffer descriptor (this is the one linked to the packet descriptor) defining the second data buffer size of 256 Bytes which in turn is linked to the next (second) buffer descriptor.
- Second buffer fescriptor with a fata buffer size of 96 bytes (can be greater, the packet descriptor contain the size of the packet) linked to no other descriptor (NULL).

Receive Case

For this example since each data buffer size is 256 bytes, we would require a minimum of three descriptors that would define data buffer size of 608 bytes. The receive setup is as follows:

- Two buffer descriptors with 256 bytes of data buffer size
- One buffer descriptor with 96 bytes (can be greater) of data buffer size

Within the rest of this section, the following nomenclature is used:

BD — Buffer Descriptor or Host Buffer Descriptor

DB — Data Buffer Size of 256 Bytes

PBD — Pointer to Host Buffer Descriptor

PD — Host Packet Descriptor

PPD — Pointer to Host Packet Descriptor

TXSQ — Transmit Queue or Transmit Submit Queue (for USB0 EP1, use Queues 32 or 33, for USB1 EP1 use Queues 62 or 63)

TXCQ — Transmit Completion Queue or Transmit Return Queue (for USB0 Tx EP1, use Queue 93, and for USB1 Tx EP1 use Queue 125)

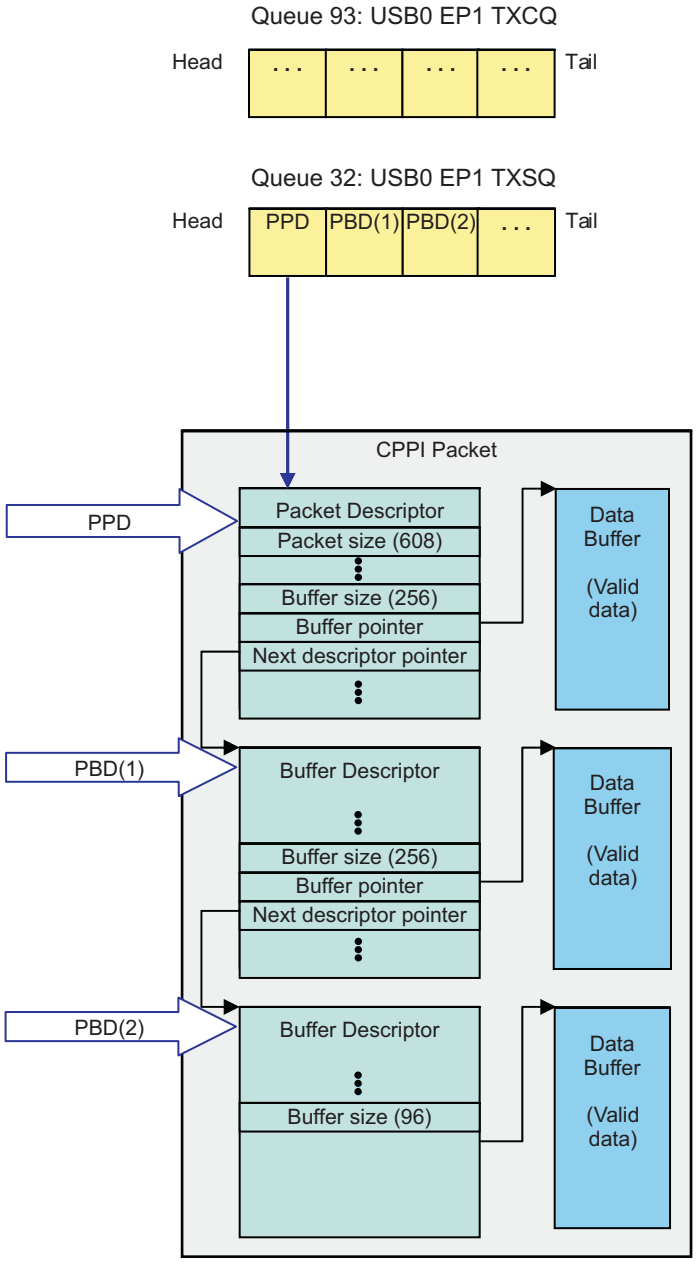
RXCQ — Receive Completion Queue or Receive Return Queue (for USB0 Rx EP1, use Queue 109, for USB1 Rx EP1 use Queue 141)

RXSQ — Receive Free/Buffer Descriptor Queue or Receive Submit Queue. (For USB0 Rx EP1 Queue 0 is used and for USB1 Rx EP1 Queue 16 should be used

24.4.9.1 Transmit USB Data Flow Using DMA

The transmit descriptors and queue status configuration prior to the transfer taking place is shown in Figure 24-17.

Figure 24-17. Transmit Descriptors and Queue Status Configuration



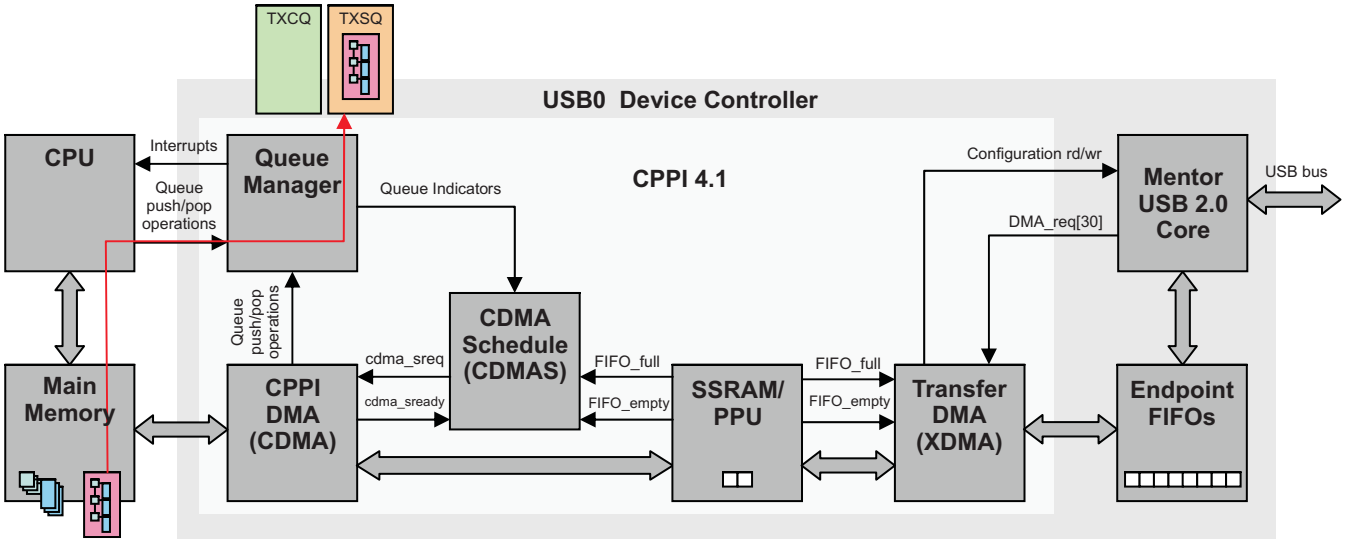
24.4.9.1.1 Transmit Initialization (Step 1)

The CPU performs the following steps for transmit initialization:

1. Initializes Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. Creates PD, BDs, and DBs in main memory and link as indicated in Figure 24-18.
3. Initializes and configures the Queue Manager, Channel Setup, DMA Scheduler, and Mentor USB 2.0 Core.
4. Adds (pushes) the PPD and the two PBDs to the TXSQ by writing the Packet Descriptor address to the TXSQ CTRL D Register.

Figure 24-18 captures the BD/DB pair in main memory and later submitted within the TXSQ.

Figure 24-18. Transmit USB Data Flow Example (Initialization)



24.4.9.1.2 CDMA and XDMA Transfer Packet Data Into Endpoint FIFO (Step 2)

The steps for CDMA and XDMA to transfer packet data into endpoint FIFO are as follows:

1. The Queue Manager informs the CDMAS that the TXSQ is not empty.
2. CDMAS checks that the CPPI FIFO FIFO_full is not asserted, then issues a credit to the CDMA.
3. CDMA reads the Packet Descriptor pointer (PPD) and descriptor size hint from the queue manager
4. For each 64-byte block of data in the packet data payload (note that packet refers here to CPPI packet which is not the same as USB packet and it means to refer to data transfer size):
   (a) The CDMA transfers a max burst of 64-byte block (OCP burst) from the data to be transferred in main memory to the CPPI FIFO
   (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
   (c) The CDMA performs the above 2 steps (‘a’ and ‘b’) 3 more times since the data size of the HPD is 256 bytes.
5. The CDMA reads the first buffer descriptor pointer (PBD).
6. For each 64-byte block of data in the packet data payload:
   (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
   (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
   (c) The CDMA performs the above 2 steps (‘a’ and ‘b’) 2 more times since data size of the HBD is 256 bytes.
7. The CDMA reads the second Buffer Descriptor pointer (PBD
8. For each 64-byte block of data in the packet data payload:
   (a) The CDMA transfers a max burst of 64-byte block from the data to be transferred in main memory to the CPPI FIFO.
   (b) The XDMA sees FIFO_empty not asserted and transfers 64-byte block from CPPI FIFO to Endpoint FIFO.
   (c) The CDMA transfers the last remaining 32-byte from the data to be transferred in main memory to the CPPI FIFO.
   (d) The XDMA sees FIFO_empty not asserted and transfers 32-byte block from CPPI FIFO to Endpoint FIFO.

24.4.9.1.3 USB 2.0 Core Transmits USB Packets for Tx (Step 3)

1. Once the XDMA has transferred enough 64-byte blocks of burst of data from the CPPI FIFO to fill the Endpoint FIFO (accumulated 512 bytes), it signals the Mentor USB 2.0 Core that a TX packet is ready (sets the endpoint's TxPktRdy bit).
2. The USB 2.0 Core will transmit the packet from the Endpoint FIFO out on the USB BUS when it receives a corresponding IN request from the attached USB Host.
3. After the USB packet is transferred, the USB 2.0 Core issues a TX DMA_req to the XDMA.
4. This process is repeated until (the above steps '1', '2', and '3') the entire packet has been transmitted. The XDMA will also generate the required termination packet depending on the termination mode configured for the endpoint.

24.4.9.1.4 Return Packet to Completion Queue and Interrupt CPU for Tx (Step 4)

1. After all data for the packet has been transmitted (as specified by the packet size field), the CDMA will write the pointer of the Packet Descriptor only to the TX Completion Queue specified in the return queue manager / queue number fields of the packet descriptor.
2. The Queue Manager then indicates the status of the TXSQ (empty) to the CDMAS and the TXCQ to the CPU via an interrupt.

24.4.9.2 Receive USB Data Flow Using DMA

The receive buffer descriptors and queue status configuration prior to the transfer taking place is shown in Figure 24-19.

24.4.9.2.1 Receive Initialization (Step 1)

1. The CPU initializes Queue Manager with the Memory Region 0 base address and Memory Region 0 size, Link RAM0 Base address, Link RAM0 data size, and Link RAM1 Base address.
2. The CPU creates BDs, and DBs in main memory and link them creating a BD and DB pairs.
3. CPU then initializes the RXCQ queue and configures the Queue Manager, Channel Setup, DMA Scheduler, and USB 2.0 Core.
4. It then adds (pushes) the address of the addresses/pointers of three Buffer Descriptors (PBDs) into the RXSQ by writing onto CTRL D register.

Figure 24-20 displays receive operation Initialization.

24.4.9.2.2 USB 2.0 Core Receives a Packet, XDMA Starts Data Transfer for Receive (Step 2)

1. The USB 2.0 Core receives a USB packet from the USB Host and stores it in the Endpoint FIFO.
2. It then asserts a DMA_req to the XDMA informing it that data is available in the Endpoint FIFO.
3. The XDMA verifies the corresponding CPPI FIFO is not full via the FIFO_full signal, then starts transferring 64-byte data blocks (burst) from the Endpoint FIFO into the CPPI FIFO.

Figure 24-19. Receive Buffer Descriptors and Queue Status Configuration

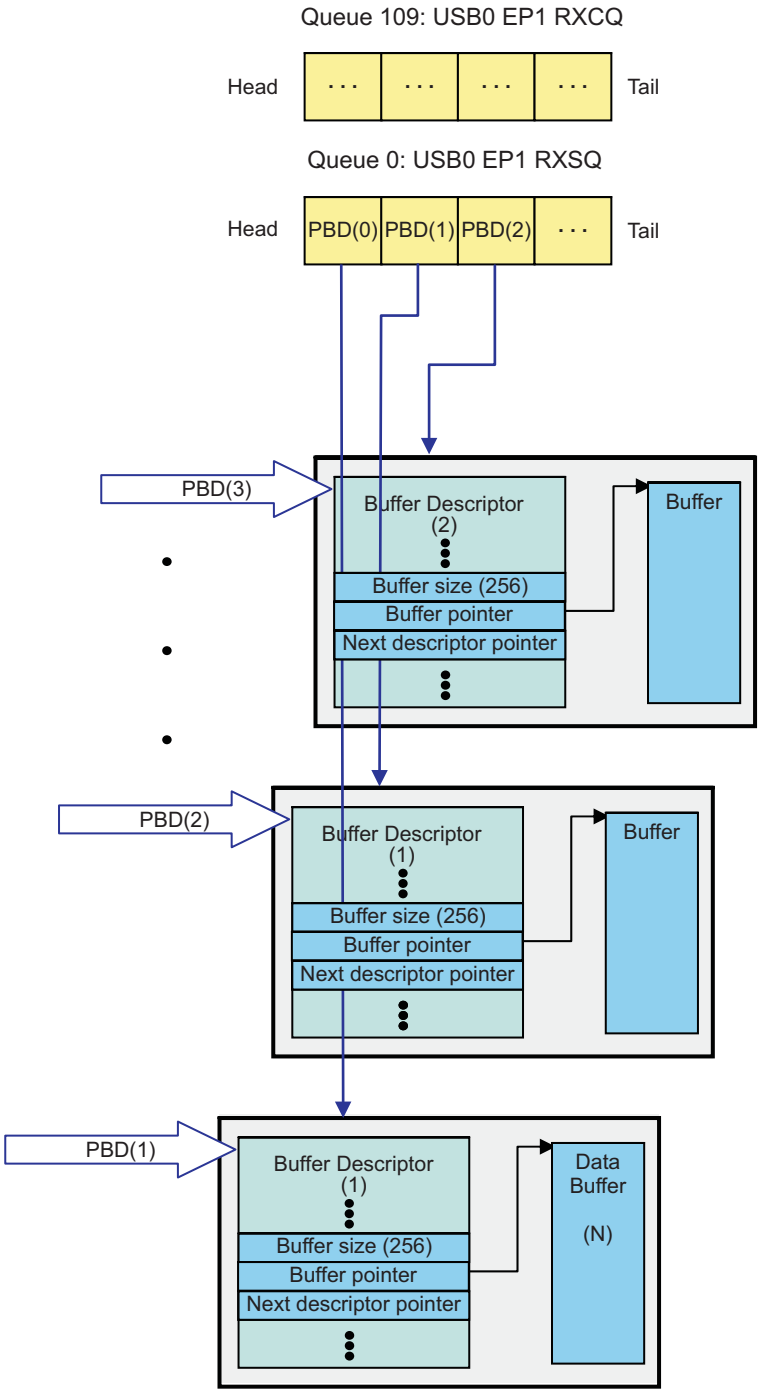


Figure 24-20. Receive USB Data Flow Example (Initialization)

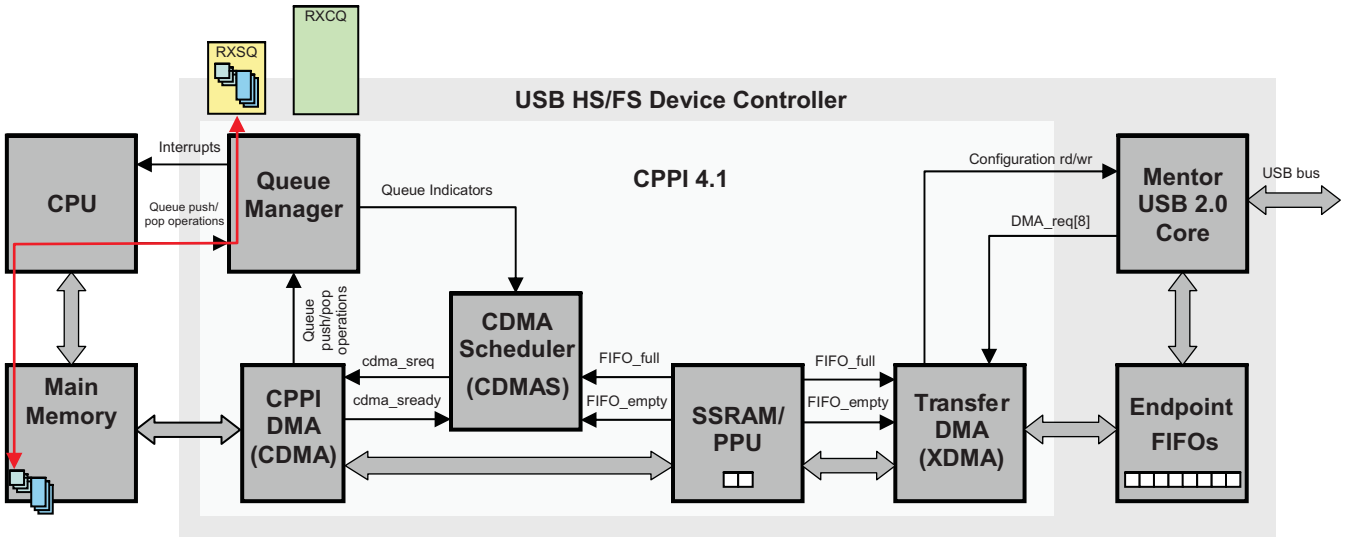


24.4.9.2.3 CDMA Transfers Data from SSRAM / PPU to Main Memory for Receive (Step 3)

1. The CDMAS see FIFO_empty de-asserted (there is RX data in the FIFO) and issues a transaction credit to the CDMA.
2. The CDMA begins packet reception by fetching the first PBD from the Queue Manager using the Free Descriptor / Buffer Queue 0 (Rx Submit Queue) index that was initialized in the RX port DMA state for that channel.
3. The CDMA will then begin writing the 64-byte block of packet data into this DB.
4. The CDMA will continue filling the buffer with additional 64-byte blocks of data from the CPPI FIFO and will fetch additional PBD as needed using the Free Descriptor / Buffer Queue 1, 2, and 3 indexes for the 2nd, 3rd, and remaining buffers in the packet. After each buffer is filled, the CDMA writes the buffer descriptor to main memory.

24.4.9.2.4 CDMA Completes the Packet Transfer for Receive (Step 4)

1. After the entire packet has been received, the CDMA writes the packet descriptor to main memory.
2. The CDMA then writes the packet descriptor to the RXCQ specified in the Queue Manager / Queue Number fields in the RX Global Configuration Register.
3. The Queue Manager then indicates the status of the RXCQ to the CPU via an interrupt.
4. The CPU can then process the received packet by popping the received packet information from the RXCQ and accessing the packet's data from main memory.

24.5 USB 2.0 Test Modes

The USB2.0 controller supports the four USB 2.0 test modes (Test_SE0_NAK, Test_J, Test_K, and Test_Packet) defined for high-speed functions. It also supports an additional “FIFO access” test mode that can be used to test the operation of the CPU interface, the DMA controller and the RAM block.

The test modes are entered by writing to the TESTMODE register. A test mode is usually requested by the host sending a SET_FEATURE request to Endpoint 0. When the software receives the request, it should wait until the Endpoint 0 transfer has completed (when it receives the Endpoint 0 interrupt indicating the status phase has completed) then write to the TESTMODE register.

Note: These test modes have no purpose in normal operation.

24.5.1 TEST_SE0_NAK

To enter the Test_SE0_NAK test mode, the software should set the TEST_SE0_NAK bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it responds to any valid IN token with a NAK.

24.5.2 TEST_J

To enter the Test_J test mode, the software should set the TEST_J bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous J on the bus.

24.5.3 TEST_K

To enter the Test_K test mode, the software should set the TEST_K bit in the TESTMODE register to 1. The USB controller will then go into a mode in which it transmits a continuous K on the bus.

24.5.4 TEST_PACKET

To execute the Test_Packet, the software should:

1. Start a session (if the core is being used in Host mode.
2. Write the standard test packet (shown below) to the Endpoint 0 FIFO.
3. Write 8h to the TESTMODE register (TEST_PACKET = 1) to enter Test_Packet test mode.
4. Set the TxPktRdy bit in the HOST/PERI_CSR0 register (bit 1).

The 53 byte test packet to load is as follows (all bytes in hex). The test packet only has to be loaded once; the USB controller will keep re-sending the test packet without any further intervention from the software.

Table 24-25 displays the 53 Bytes test packet content.

Table 24-25. 53 Bytes Test Packet Content

0	0	0	0	0	0	0	0
0	AA	AA	AA	AA	AA	AA	AA
AA	EE	EE	EE	EE	EE	EE	EE
EE	FE	FF	FF	FF	FF	FF	FF
FF	FF	FF	FF	FF	7F	BF	DF
EF	F7	FB	FD	FC	7E	BF	DF
EF	F7	FB	FD	7E			

This data sequence is defined in Universal Serial Bus Specification Revision 2.0, Section 7.1.20. The USB controller will add the DATAA0 PID to the head of the data sequence and the CRC to the end.

24.5.5 FIFO_ACCESS

The FIFO Access test mode allows you to test the operation of CPU Interface, the DMA controller (if configured), and the RAM block by loading a packet of up to 64 bytes into the Endpoint 0 FIFO and then reading it back out again. Endpoint 0 is used because it is a bidirectional endpoint that uses the same area of RAM for its Tx and Rx FIFOs.

NOTE: The core does not need to be connected to the USB bus to run this test. If it is connected, then no session should be in progress when the test is run.

The test procedure is as follows:

1. Load a packet of up to 64 bytes into the Endpoint 0 Tx FIFO.
2. Set HOST/PERI_CSR0[TXPKTRDY].
3. Write 40h to the TESTMODE register (FIFO_ACCESS = 1).
4. Unload the packet from the Endpoint Rx FIFO, again.
5. Set HOST/PERI_CSR0[SERVICEDRXPKTRDY].

Writing 40h to the TESTMODE register causes the following sequence of events:

The Endpoint 0 CPU pointer (that records the number of bytes to be transmitted) is copied to the Endpoint 0 USB pointer (that records the number of bytes received).

1. The Endpoint 0 CPU pointer is reset.
2. HOST/PERI_CSR0[TXPKTRDY] is cleared.
3. HOST/PERI_CSR0[RXPKTRDY] is set.
4. An Endpoint 0 interrupt is generated (if enabled).

The effect of these steps is to make the Endpoint 0 controller act as if the packet loaded into the Tx FIFO has flushed and the same packet received over the USB. The data that was loaded in the Tx FIFO can now be read out of the Rx FIFO.

24.5.6 FORCE_HOST

The Force Host test mode enables you to instruct the core to operate in Host mode, regardless of whether it is actually connected to any peripheral; that is, the state of the CID input and the LINESTATE and HOSTDISCON signals are ignored. (While in this mode, the state of the HOSTDISCON signal can be read from the BDEVICE bit in the device control register (DEVCTL)) .

This mode, which is selected by writing 80h to the TESTMODE register (FORCE_HOST = 1), allows implementation of the USB Test_Force_Enable (USB 2.0 Specification Section 7.1.20). It can also be used for debugging PHY problems in hardware.

While the FORCE_HOST bit remains set, the core enters the Host mode when the SESSION bit in DEVCTL is set to 1 and remains in the Host mode until the SESSION bit is cleared to 0 even if a connected device is disconnected during the session. The operating speed while in this mode is determined by the FORCE_HS and FORCE_FS bits in the TESTMODE register.

24.6 Reset Considerations

The USB controller has two reset sources: hardware reset and the soft reset.

24.6.1 Software Reset Considerations

When the RESET bit in the control register (CTRLR) is set, all the USB controller registers and DMA operations are reset. The bit is cleared automatically.

A software reset on the DSP or ARM CPU does not affect the register values and operation of the USB controller.

24.6.2 Hardware Reset Considerations

When a hardware reset is asserted, all the registers are set to their default values.

24.7 Interrupt Support

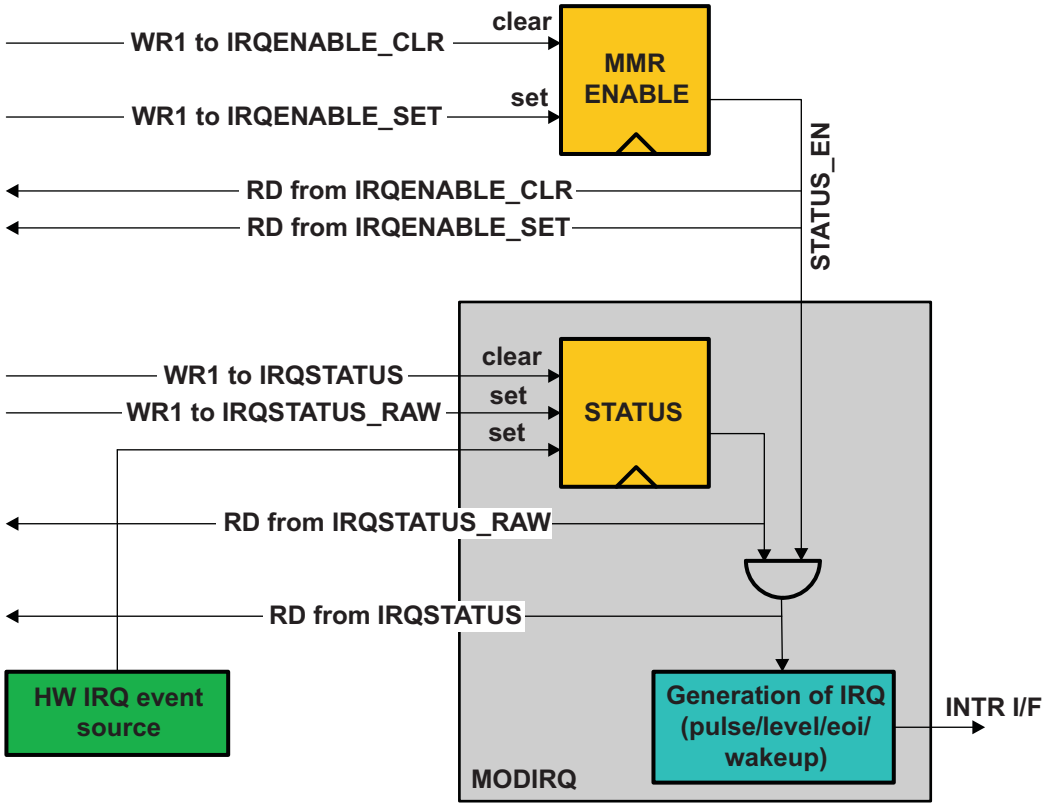
This section defines the module interrupt capabilities and requirements.

24.7.1 CPU Interrupts

There are three interrupt interfaces: one for the USB subsystem, one for USB0 controller, and one for USB1 controller. All interrupts for that specific unit are aggregated into one interrupt interface.

Each interrupt interface will use the IP generic MODIRQ as shown in Figure 24-21 which is shown with the grey box. Each interrupt has two basic registers: STATUS and ENABLE. The STATUS register is located in the MODIRQ module and can be set two ways. Hardware can set the register via internal logic. Software can set or clear the register by accessing the appropriate locations in the memory map. The enabling (or masking) of the interrupt is controlled via software. Writing 1's (WR1) to either the IRQENABLE_SET or IRQENABLE_CLR addresses will enable or disable the interrupt.

Figure 24-21. Functional Representation of Interrupts



The output interrupt interface has both a pulse and a level output. The pulse signal is active for one OCP clock; while the level output will be active high when asserted. An EOI function exists to re-enable the detection of active interrupts. If the system attempts to write to any of the interrupt registers, any still active interrupts will trigger the EOI output signal. The EOI input signal indicates when external logic requires the USB to re-evaluate its pending sources and send another pulse.

NOTE: When generating an interrupt by writing to one of the IRQ_ENABLE_SET registers; the interrupt can occur several cycles before the OCP write status complete has occurred.

Subsystem Interrupts

USB Subsystem Interrupts lists the interrupts generated by the USB subsystem.

USB Subsystem Interrupts

Interrupt	Description
rx_sop_starvation	Queue Manager cannot obtain a valid descriptor at SOP and has starvation status.
rx_mop_starvation	Queue Manager cannot obtain a valid descriptor during MOP and has starvation status.
pd_cmp_flag	When the packet is completed and the Packet Descriptor is pushed into the Queue Manager.
tx_pkt_cmp_0	USB0 Tx CPPI DMA Packet completion status
rx_pkt_cmp_0	USB0 Rx CPPI DMA Packet completion status
tx_pkt_cmp_1	USB1 Tx CPPI DMA Packet completion status
rx_pkt_cmp_1	USB1 Rx CPPI DMA Packet completion status

The pd_cmp_flag is only set when bit 31 of the original buffer length word (word 6) of a packet descriptor (not buffer descriptor) has been set.

The USBSS QMGR outputs 60 packet completion signals for the four Tx/Rx CPPI DMA Packet Completion Status interrupts as shown in USB Subsystem Interrupts. The mapping of the packet completion signals is shown in CPPI DMA Packet Completion Hardware Interrupt Groupings. Therefore, each packet completion consists of the combination of the data from the 15 individual packet completion signals. When one of the 15 packet completion signals was active (level high) then an interrupt would be generated (if enabled).

CPPI DMA Packet Completion Hardware Interrupt Groupings

Interrupt	CPPI DMA Packet Completion Grouping (EP)	Description
tx_pkt_cmp_0	1, 2, …, 15	USB0 Tx CPPI DMA Packet completion status
rx_pkt_cmp_0	1, 2, …, 15	USB0 Rx CPPI DMA Packet completion status
tx_pkt_cmp_1	1, 2, …, 15	USB1 Tx CPPI DMA Packet completion status
rx_pkt_cmp_1	1, 2, …, 15	USB1 Rx CPPI DMA Packet completion status

In order to control the frequency of the generated interrupts, interrupt pacing has been added to each of the 60 individual packet completions. Each packet completion has its own 8-bit unsigned threshold. Each threshold can range from 0 to 255. The packet descriptor for each of the packet completion signals will have a differed bit. This bit will indicate whether the packet completion will be incremented or not. If the count of the packet completion exceeds the threshold; then an interrupt will be generated. This assumes that the packet completion is enabled. The thresholds for the 60 packet completions are stored in one of the following registers: USBSS IRQ_DMA_THRESHOLD_ab_c. Where:

(a) Tx or Rx

(b) 0 or 1

(c) 0, 1, 2, or 3

The 60 DMA enables are stored in registers: USBSS IRQ_DMA_ENABLE_0 and USBSS IRQ_DMA_ENABLE_1.

The individual packet completion count registers will be reset to zero when one of the below conditions occurs:

- Reset signal is active.
- Packet completion threshold has been exceeded.
- Packet completion count is equal to 255.
- Frame count threshold has been exceeded.
- Frame count is equal to 255.

It is possible that the generation of interrupts has been reduced to an unacceptable delay due a lack of differed bits or thresholds set to too large of a number. A watch dog timer has been added to the design which provides a secondary method of generating the interrupts. This system uses the USB start of frame pulse from the Mentor core, a counter, a threshold, and an enable. This logic is similar as compared with the differed bit logic. The frame sync pulse frequency is 1kHz in full-speed or low-speed mode, or 8kHz is high-speed mode.

Example 1: The DMA threshold is set to 10 and the frame threshold is set to 3 for a specific endpoint. Let's assume that the expected packet completion frequency is 5 completed packets per frame. In this example the first frame had 5 packets completed. The second frame had 5 packets completed. An interrupt is generated after the 2nd frame.

Example 2: The DMA threshold is set to 10 and the frame threshold is set to 3 for a specific endpoint. Let's assume that the expected packet completion frequency is 5 completed packets per frame. In this example the first frame had 5 packets completed. The second frame had only 2 packets completed and the third frame had 0 packets completed. There was some error or delay that caused the remaining packets to not complete. An interrupt is generated after the 3rd frame.

In both examples software will not be able to determine whether the interrupt was generated due to DMA threshold or frame threshold.

Each of the 60 Packet completions will have a frame counter, frame threshold, and frame enable. If the frame counter exceeds the frame threshold; then an interrupt will be generated. This assumes the frame enable counter has been enabled.

The registers for the 60 frame thresholds are stored in: USBSS_IRQ_FRAME_THRESHOLD_ab_c. Where:

(a) Tx or Rx

(b) 0 or 1

(c) 0, 1, 2, or 3

The 60 frame enables are stored in registers: USBSS IRQ_FRAME_ENABLE_0 and USBSS IRQ_FRAME_ENABLE_1.

The individual frame count registers will be reset to zero when one of the below conditions occurs:

- Reset signal is active.
- Packet completion threshold has been exceeded.
- Packet completion count is equal to 255.
- Frame count threshold has been exceeded.
- Frame count is equal to 255.

When the low to high transition occurs for any of the four CPPI DMA Packet completions, a hardware signal is sent to the MODIRQ module. This will cause an interrupt (if enabled via software). When all packets have been removed from the queue, the pending signal is returned to a 0. Software may choose to use one of the unassigned queues if an interrupt is not wanted upon the completion of a packet.

The starvation interrupts occur when the queue manager cannot allocate a buffer for an Rx buffer. This can occur either at the start of a packet or in the middle of a series of packets.

The interrupts listed in USB Subsystem Interrupts can be enabled (or disabled) by setting (or clearing) the appropriate IRQENABLE_SET (or IRQENABLE_CLR) bits in the MMR registers.

To clear the interrupts it is required to write 1's to the IRQSTAUS registers. It is possible to manually set the interrupts by writing 1's to the IRQSTATUS_RAW registers.

Controller Interrupts

Each of the controllers has 42 interrupts that are generated by the USB 2.0 OTG Controller. Actually, there are only 41 real interrupts; but 42 are designed into the logic. This makes the logic easier to build. RX_ENDP[0] will never be used.

Controller Interrupts

Interrupt	Description
TX_ENDP[15:0]	TX endpoint ready or error for endpoints 15 to 0 (endpoint 0 is used for both TX and RX)
RX_ENDP[15:1]	RX endpoint ready or error for endpoints 15 to 0 (there is no interrupt for endpoint 0)
USB[8] DRVVBUS level change	Signal from the Mentor core
USB[7:0]	8 USB conditions
USB_INT	Single interrupt signal from the Mentor core
TX_FIFO[15:0]	TX FIFO endpoint ready for endpoints 15 to 0

The interrupts listed in Controller Interrupts are generated by the Mentor core (assumes that DMAReqEnab and DMAReqMode are not both set) and follow the following procedure to generate the interrupt (for all interrupts except USB[8] and TX_FIFO[15:0]):

- Mentor core will signal F_INTR module that there is an interrupt via the USB_INT signal.
- F_INTR will generate 3 VBUSP read transactions for the Mentor core.
  - Read INTRTX register
  - Read INTRRX register
  - Read INTRUSB register
- F_INTR will temporary store the results and transfer the data to the F_REGS module.
- The F_REGS module will generate the hardware IRQ event source.

Interrupts for TX_ENDP[15:0] and RX_ENDP[15:1] are not generated when both DMAReqEnab and DMAReqMode are both set. This is the typical case when the USBSS DMA is used (CPPI).

Interrupts for TX_FIFO[15:0] are derived from the Mentor controller and sent directly to the F_REGS module which generates the hardware interrupts event source. These interrupts indicate when the TX Fifo is ready to accept new data.

The interrupt for USB[8] is from the signal DRVVBUS. This interrupt comes from the Mentor core; but does not have an internal register within the Mentor core. The signal DRVVBUS goes directly to the F_REGS module which generates the hardware interrupt event source.

The interrupts listed in Controller Interrupts can be enabled (or disabled) by setting (or clearing) the appropriate IRQENABLE_SET (or IRQENABLE_CLR) bits in the MMR registers.

To clear the interrupts it is required to write 1's to the IRQSTAUS registers. It is possible to manually set the interrupts by writing 1's to the IRQSTATUS_RAW registers.

The interrupt registers for all the interrupts in Table 132 are listed in both the USB0 and USB1 controller memory maps. The interrupt registers for TX_ENDP[15:0], RX_ENDP[15:1], and USB[7:0] are listed in the Mentor Core memory map.

Interrupt Description

USB Core Highlander Interrupts

There are 15 general-purpose TX endpoints supported in addition to control endpoint 0, whose interrupt encapsulates both TX and RX readiness. The core will generate a corresponding EP0 or TXEPn (n=1…15) interrupt when that TX endpoint successfully completes transmitting a packet and the buffer is empty and ready to send another packet or when the TX endpoint had an error condition. If the TXCSR is setup as required for the DMA (with DMAReqEnab and DMAReqMode set) then the TX endpoint interrupt will only generate error condition interrupts, and not packet completion interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions. This is the setup when the USBSS CPPI DMA controller is used.

There are 15 general-purpose RX endpoints supported. The core will generate a corresponding RXEPn (n=1…15) interrupt when that RX endpoint successfully receives a packet and all the data is ready in the RX endpoint FIFO or when a receive error occurs. If the RXCSR is setup as required for the DMA (with DMAReqEnab set and DMAReqMode clear) then the RX endpoint interrupt will only generate error condition interrupts, and not packet readiness interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions.

Interrupts USB[0] to USB[7] are generated by the Mentor controller, and converted to HIGHLANDER 0.8 format by the Highlander interrupt sub-module. Refer to the Mentor core documentation for more details on these interrupts. Interrupt USB[8] is generated outside the Mentor core by the interrupt sub-module whenever the level of DRVVBUS changes. This is usually due to entering or leaving host mode, or entering or leaving power saving mode.

It is important to clear the Mentor controller interrupts by reading the respective Mentor controller INTRUSB Register before clearing the IRQ_ENABLE_CLR Register and setting the IRQ_EOI Register.

16 TX FIFO endpoint interrupts exist one for each endpoint. These interrupts indicate when the TX FIFO is ready to accept new data.

The USB20OTG interrupts are also aggregated by the MODIRQ module. Refer to the memory mapped registers for a list of USB Interrupts that the MODIRQ processes. Only one USB interrupt interface is provided on the outside for each USB controller and MODIRQ provides the interrupt aggregation logic for these interrupts. When the EOI register in the USB module is written to, the eoi_write signal is sent to MODIRQ which in turn re-evaluates the interrupt and triggers it if necessary.

USB Core (Non-Highlander) Interrupts

If the non-Highlander interrupt mode is selected for the USB interrupts, then the previous list of USB Highlander sources are not valid, and the core generates the CPU interrupt directly. The signal from the core will be connected to the module F_REGS and all interactions to clear and mask interrupts must be done with the core registers.

The additional USB interrupt for DRVVBUS level changes is not part of the core interrupt set, and therefore is not available when using non-Highlander interrupt mode.

Interrupt Condition Control

USB Core Interrupts

The USB core interrupts are originally generated inside the Mentor core. The core provides enable registers for each of the three types of interrupts. The INTRTXE register allows enabling of each TX endpoint interrupt The INTRRXE register allows enabling of each RX endpoint interrupt. The INTRUSBE register allows enabling of each general USB interrupt. Any enabled interrupt will generate CPU interrupts in the form of the corresponding interrupt source, the module generated interrupt pulse, and the interrupt pulse from the Mentor core directly.

To comply with Highlander interrupts, additional logic is built around the core. This adds a mask register along with mask set and mask clear registers. The USB Interrupt Mask register shows the current mask value, where each bit enables the corresponding interrupt source in the USB Interrupt Source register. The USB Interrupt Mask Set register allows writing a '1' in bit positions to enable the corresponding interrupt source. Those bits written with a '0' will not be modified. The USB Interrupt Mask Clear register allows writing a '1' in bit positions to disable the corresponding interrupt source. Those bit written with a '0' will not be modified. The mask is used to enable interrupt sources and generate the masked interrupt sources which are used to generate the CPU interrupt or by external logic to generate CPU interrupts.

24.8 Supported Use Cases

The USB Subsystem supports two independent USB Modules where each USB module can operate as a host or peripheral. When operating as a host, it is capable of interfacing to a single target/peripheral directly or to multiple targets via hub at low-, full-, or high-speed. When operating as a peripheral, it is capable of interfacing to a host at a full- or high-speed.

24.9 USB Registers

The USB20OTG_REGS submodule contains the MMRs that are used in the submodules within the USB controller. The registers required to access and control the USBSS are partitioned in blocks based on their functions. Table 24-26 lists the base address offset of the USBSS and its submodules. For the base address of these registers, see Table 1-11.

Table 24-26. USBSS Submodule Base Addresses and Size

Submodule Name	Base Address Offset	Section
USBSS Registers	0000h	Section 24.9.1
USB0 Controller Registers	1000h	Section 24.9.2.1
USB1 Controller Registers	1800h	Section 24.9.2.2
CPPI DMA Controller Registers	2000h	Section 24.9.3
CPPI DMA Scheduler Registers	3000h	Section 24.9.4
CPPI DMA Queue Manager Registers	4000h	Section 24.9.5

24.9.1 USBSS Registers

The USBSS registers contain the registers that are used to control at the global level and apples to all submodules. Table 24-27 lists the registers for the USBSS submodule.

Table 24-27. USBSS Registers

Address Offset	Acronym	USBSS Register
0h	REVREG	USBSS REVISION
10h	SYSCONFIG	USBSS SYSCONFIG

24.9.1.1 USBSS Revision Register (REVREG)

The USBSS revision register (REVREG) contains the major and minor revisions for the USB subsystem module. This register is shown in Figure 24-22 and described in Table 24-28.

Figure 24-22. USBSS Revision Register (REVREG)

31–30	29–28	27–16
Scheme	Reserved	func
R-1	R-0	R-EA2h

15–11	10–8	7–6	5–0

Bits	Field	Value	Description
31-30	Scheme	0-3h	Used to distinguish between old scheme and current.
29-28	Reserved	0	Reserved
27-16	func	0-FFFh	Function indicates a software compatible module family.
15-11	R_rtl	0-1Fh	RTL revision. Will vary depending on release.
10-8	X_major	0-7h	Major revision.
7-6	Custom	0-3h	Custom revision
5-0	Y_minor	0-3Fh	Minor revision.

24.9.1.2 USBSS SYSCONFIG Register (SYSCONFIG)

The USBSS SYSCONFIG register (SYSCONFIG) is the clock management configuration register for the USBSS.

The clock enable bits 8 to 11 should only be configured/modified during the firmware initialization stage of the USBSS. In other words, these bits should not be modified while the system is running or after enabling the clock. These bits control the clock generation modules. Dynamically setting these bits can disable the power management logic.

The USBSS SYSCONFIG register is shown in shown in Figure 24-23 and described in Table 24-29.

Figure 24-23. USBSS SYSCONFIG Register (SYSCONFIG)

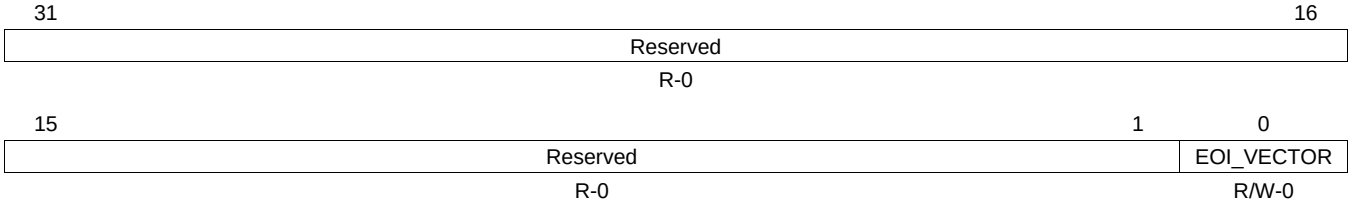
24.9.1.3 USBSS End of Interrupt Register (EOI)

The USBSS end of interrupt register (EOI) allows the CPU to acknowledge completion of an interrupt by writing 0, zero, to the EOI_VECTOR field. An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain.

This register will be reset one cycle after it has been written to. The USBSS end of interrupt register is shown in Figure 24-24 and described in Table 24-30.

Figure 24-24. USBSS End of Interrupt Register (EOI)



LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-30. USBSS End of Interrupt Register (EOI) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	EOI_VECTOR	EOI for USBSS interrupt.

24.9.1.4 USBSS IRQ_STATUS_RAW (IRQSTATRAW)

The USBSS IRQSTATRAW register allows the USBSS interrupt sources to be manually triggered when writing a 1 to a specific bit. A read from this register returns the USBSS interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Set event
Read 0: No event pending
Read 1: Event pending

This register is shown in Figure 24-25 and described in Table 24-31.

Figure 24-25. USBSS IRQ_STATUS_RAW (IRQSTATRAW)

31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt status for USB1 Rx CPPI DMA packet completion status.
10	tx_pkt_cmp_1	Interrupt status for USB1 Tx CPPI DMA packet completion status.
9	rx_pkt_cmp_0	Interrupt status for USB0 Rx CPPI DMA packet completion status.
8	tx_pkt_cmp_0	Interrupt status for USB0 Tx CPPI DMA packet completion status.
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt status when the packet is completed and the packet descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer at the start of a packet.

24.9.1.5 USBSS IRQ_STATUS Register (IRQSTAT)

The USBSS IRQSTAT register contains the interrupt sources status of the enabled interrupt. IRQSTAT register is a subset of IRQSTATRAW register. Writing a '1' to a bit field will clear a pending interrupt event.

General actions per bit:
Write 0: No action
Write 1: Clear event
Read 0: No event pending
Read 1: Event pending

This register is shown in Figure 24-26 and described in Table 24-32.

Figure 24-26. USBSS IRQ_STATUS (IRQSTAT)

10	tx_pkt_cmp_1	Interrupt status for USB1 Tx CPPI DMA packet completion status.
9	rx_pkt_cmp_0	Interrupt status for USB0 Rx CPPI DMA packet completion status.
8	tx_pkt_cmp_0	Interrupt status for USB0 Tx CPPI DMA packet completion status.
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt status when the packet is completed and the packet descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt status when queue manager cannot allocate an Rx buffer at the start of a packet.

24.9.1.6 USBSS IRQ_ENABLE_SET Register (IRQENABLER)

The USB interrupt mask set register (IRQENABLER) allows the USB interrupts to be enabled (unmasked). A read from this register returns the USB interrupts enabled.

General actions per bit:
Write 0: No action
Write 1: Interrupt enabled
Read 0: Interrupt disabled
Read 1: Interrupt enabled

The USBSS IRQ_ENABLE_SET register is shown in Figure 24-27 and described in Table 24-33.

31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt enable for USB1 Rx CPPI DMA packet completion status.
10	tx_pkt_cmp_1	Interrupt enable for USB1 Tx CPPI DMA packet completion status.
9	rx_pkt_cmp_0	Interrupt enable for USB0 Rx CPPI DMA packet completion status.
8	tx_pkt_cmp_0	Interrupt enable for USB0 Tx CPPI DMA packet completion status.
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt enable when the packet is completed and the packet descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer at the start of a packet.

24.9.1.7 USBSS IRQ_ENABLE_CLR Register (IRQCLEARR)

The USBSS IRQCLEARR register allows the USBSS interrupt sources to be masked when writing a 1 to a specific bit. A read of this register returns the USBSS interrupt enabled value.

General actions per bit:
Write 0: No action
Write 1: Disable interrupt
Read 0: Interrupt disabled
Read 1: Interrupt enabled

The USBSS IRQ_ENABLE_CLR register is shown in Figure 24-28 and described in Table 24-34.

Figure 24-28. USBSS IRQ_ENABLE_CLR Register (IRQCLEARR)

Table 24-34. USBSS IRQ_ENABLE_CLR Register (IRQCLEARR) Field Descriptions

Bits	Field	Description
31-12	Reserved	Always read as 0. Writes have no effect.
11	rx_pkt_cmp_1	Interrupt enable for USB1 Rx CPPI DMA packet completion status.
10	tx_pkt_cmp_1	Interrupt enable for USB1 Tx CPPI DMA packet completion status
9	rx_pkt_cmp_0	Interrupt enable for USB0 Rx CPPI DMA packet completion status.
8	tx_pkt_cmp_0	Interrupt enable for USB0 Tx CPPI DMA packet completion status.
7-3	Reserved	Always read as 0. Writes have no effect.
2	pd_cmp_flag	Interrupt enable when the packet is completed and the packet descriptor is pushed into the queue manager.
1	rx_mop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer in the middle of a packet.
0	rx_sop_starvation	Interrupt enable when queue manager cannot allocate an Rx buffer at the start of a packet.

24.9.1.8 USBSS IRQ_DMA_THRESHOLD_TX0_0 Register (IRQDMATHOLDTX00)

The USBSS IRQ_DMA_THRESHOLD_TX0_0 register (IRQDMATHOLDTX00) defines the size of the four DMA thresholds for interrupt pacing for USB0. Each threshold contains an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_DMA_THRESHOLD_TX0_0 register is shown in Figure 24-29 and described in Table 24-35.

Figure 24-29. USBSS IRQ_DMA_THRESHOLD_TX0_0 Register (IRQDMATHOLDTX00)

15-8	dma_thres_rx1_9	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 9.
7-0	dma_thres_rx1_8	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 8.

24.9.1.23 USBSS IRQ_DMA_THRESHOLD_RX1_3 Register (IRQDMATHOLDRX13)

The USBSS IRQ_DMA_THRESHOLD_RX1_3 register (IRQDMATHOLDRX13) defines the size of the four DMA thresholds for interrupt pacing for USB1. Each threshold contains an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_DMA_THRESHOLD_RX1_3 register is shown in Figure 24-44 and described in Table 24-50.

Bits	Field	Description
31-24	dma_thres_rx1_15	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 15.
23-16	dma_thres_rx1_14	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 14.
15-8	dma_thres_rx1_13	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 13.
7-0	dma_thres_rx1_12	DMA threshold value for rx_pkt_cmp_0 for USB1 endpoint 12.

24.9.1.24 USBSS IRQ_DMA_ENABLE_0 Register (IRQDMAENABLE0)

The USBSS IRQ_DMA_ENABLE_0 register (IRQDMAENABLE0) contains 32 enables. Sixteen enables are assigned to the 16 endpoints associated with the tx_pkt_cmp_0 interrupt and 16 enables are assigned to the 16 endpoints associated with the rx_pkt_cmp_0 interrupt. Endpoint 0 for both the tx and rx does not exist; but it is included for completeness of this register.

If the enable is set; then that specific endpoint can generate an interrupt if the event pending count has exceeded the threshold.

If the enable is cleared; then that specific endpoint cannot generate an interrupt regardless if the event pending count has exceeded the threshold or not. The USBSS IRQ_DMA_ENABLE_0 Register is shown in Figure 24-45 and described in Table 24-51.

7-0	frame_thres_tx1_12	FRAME threshold value for tx_pkt_cmp_0 for USB1 endpoint 12.

24.9.1.38 USBSS IRQ_FRAME_THRESHOLD_RX1_0 Register (IRQFRAMETHOLDRX10)

The USBSS IRQ_FRAME_THRESHOLD_RX1_0 register (IRQFRAMETHOLDRX10) defines the size of the four FRAME thresholds for interrupt pacing for USB1. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_RX1_0 register is shown in Figure 24-59 and described in Table 24-65.

7-0	Reserved	Always read as 0. Writes have no effect.

24.9.1.39 USBSS IRQ_FRAME_THRESHOLD_RX1_1 Register (IRQFRAMETHOLDRX11)

The USBSS IRQ_FRAME_THRESHOLD_RX1_1 register (IRQFRAMETHOLDRX11) defines the size of the four FRAME thresholds for interrupt pacing for USB1. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_RX1_1 register is shown in Figure 24-60 and described in Table 24-66.

24.9.1.40 USBSS IRQ_FRAME_THRESHOLD_RX1_2 Register (IRQFRAMETHOLDRX12)

The USBSS IRQ_FRAME_THRESHOLD_RX1_2 register (IRQFRAMETHOLDRX12) defines the size of the four FRAME thresholds for interrupt pacing for USB1. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_RX1_2 register is shown in Figure 24-61 and described in Table 24-67.

24.9.1.41 USBSS IRQ_FRAME_THRESHOLD_RX1_3 Register (IRQFRAMETHOLDRX13)

The USBSS IRQ_FRAME_THRESHOLD_RX1_3 register (IRQFRAMETHOLDRX13) defines the size of the four FRAME thresholds for interrupt pacing for USB1. Each threshold contains is an 8-bit unsigned number and can range from 0 to 255. A possible interrupt can be triggered if the count for that specific endpoint has exceeded the value of the threshold. The counter for the compared value is also an 8-bit unsigned number; therefore, setting the threshold to 255 prevents the possibility of a trigger.

The USBSS IRQ_FRAME_THRESHOLD_RX1_3 register is shown in Figure 24-62 and described in Table 24-68.

Bits	Field	Description
31-24	frame_thres_rx1_15	FRAME threshold value for rx_pkt_cmp_0 for USB1 endpoint 15.
23-16	frame_thres_rx1_14	FRAME threshold value for rx_pkt_cmp_0 for USB1 endpoint 14.
15-8	frame_thres_rx1_13	FRAME threshold value for rx_pkt_cmp_0 for USB1 endpoint 13.
7-0	frame_thres_rx1_12	FRAME threshold value for rx_pkt_cmp_0 for USB1 endpoint 12.

24.9.1.42 USBSS IRQ_FRAME_ENABLE_0 Register (IRQFRAMEENABLE0)

The USBSS IRQ_FRAME_ENABLE_0 register (IRQFRAMEENABLE0) contains 30 enables for USB0. Fifteen enables are assigned to the 15 endpoints associated with the tx_pkt_cmp_0 interrupt and 15 enables are assigned to the 15 endpoints associated with the rx_pkt_cmp_0 interrupt. Endpoint 0 for both the tx and rx does not exist; but it is included for completeness of this register.

If the enable is set; then that specific endpoint can generate an interrupt if the frame count has exceeded the threshold.

If the enable is not set; then no hardware interrupt will be generated for that specific endpoint. It is still possible to generate the interrupt via software. If the enable is cleared; then that specific endpoint cannot generate an interrupt regardless if the frame count has exceeded the threshold or not. The USBSS IRQ_FRAME_ENABLE_0 register is shown in Figure 24-63 and described in Table 24-69.

17	frame_en_rx0_1	FRAME threshold enable value for rx_pkt_cmp_0 for USB0 endpoint 1.
16	Reserved	Always read as 0. Writes have no effect.
15-2	frame_en_tx0_15	FRAME threshold enable value for tx_pkt_cmp_0 for USB0 endpoint 15.
1	frame_en_tx0_1	FRAME threshold enable value for tx_pkt_cmp_0 for USB0 endpoint 1.
0	Reserved	Always read as 0. Writes have no effect.

24.9.1.43 USBSS IRQ_FRAME_ENABLE_1 Register (IRQFRAMEENABLE1)

The USBSS IRQ_FRAME_ENABLE_1 register (IRQFRAMEENABLE1) contains 30 enables for USB1. Fifteen enables are assigned to the 15 endpoints associated with the tx_pkt_cmp_1 interrupt and 15 enables are assigned to the 15 endpoints associated with the rx_pkt_cmp_1 interrupt. Endpoint 0 for both the tx and rx does not exist; but it is included for completeness of this register.

If the enable is set; then that specific endpoint can generate an interrupt if the frame count has exceeded the threshold. If the enable is not set; then no hardware interrupt will be generated for that specific endpoint. It is still possible to generate the interrupt via software.

If the enable is cleared; then that specific endpoint cannot generate an interrupt regardless if the frame count has exceeded the threshold or not. The USBSS IRQ_FRAME_ENABLE_1 register is shown in Figure 24-64 and described in Table 24-70.

Table 24-72. USB0 Revision Register (USB0REV) Field Descriptions

Bits	Field	Value	Description
31-30	Scheme	0-3h	Used to distinguish between old scheme and current.
29-28	Reserved	0	Reserved
27-16	func	0-FFFh	Function indicates a software compatible module family.
15-11	R_rtl	0-1Fh	RTL revision.
10-8	X_major	0-7h	Major revision.
7-6	Custom	0-3h	Custom revision
5-0	Y_minor	0-3Fh	Minor revision

24.9.2.1.2 USB0 Control Register (USB0CTRL)

The USB0 control register (USB0CTRL) allows the CPU to control various aspects of the module. If uint is set high, then the Mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires software to read the Mentor controller's registers to determine which interrupt USB[0] to USB[7] occurred. If uint is set low, then the usb20otg_f module will automatically read the Mentor controller's registers and set the appropriate interrupt USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.

The USB0 control register is shown in Figure 24-66 and described in Table 24-73.

Figure 24-66. USB0 Control Register (USB0CTRL)

Table 24-73. USB0 Control Register (USB0CTRL) Field Descriptions

Bits	Field	Value	Description
31	dis_deb	0-1	Disable the VBUS debouncer circuit fix
30	dis_srp	0-1	Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0) this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB0 SRP Fix time register.
29-6	Reserved	0	Always read as 0. Writes have no effect.
5	soft reset isolation	0-1	Soft reset isolation. When high, this bit forces all USB0 signals that connect to the USBSS to zeros during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	rndis	0-1	Global RNDIS mode enable for all endpoints.
3	uint		USB non-highlander interrupt enable
		1	Non-highlander
		0	Highlander
2	Reserved	0	Always read as 0. Writes have no effect.
1	clkfack	0-1	Clock stop fast ack enable.
0	soft reset		Software reset of USB0.
		Write 0	No action
		Write 1	Initiate software reset
		Read 0	Reset done, no action
		Read 1	Reset ongoing

24.9.2.1.3 USB0 Status Register (USB0STAT)

The USB0 status register (USB0STAT) allows the CPU to check the voltage state level of USB0_DRVVBUS pin. The USB0 status register is shown in Figure 24-67 and described in Table 24-74.

Figure 24-67. USB0 Status Register (USB0STAT)

31	1	0
Reserved		drvvbus
R-0		R-0

LEGEND: R = Read only; -*n* = value after reset

Table 24-74. USB0 Status Register (USB0STAT) Field Descriptions

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	drvvbus	Current USB0_DRVVBUS value

24.9.2.1.4 USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT)

The USB0 IRQ_MERGED_STATUS register (USB0IRQMSTAT) contains a merged status for all the events for USB0. This register optimizes software accesses in a module where a large number of events are associated to one IRQ line. The merged status is read-only, and does not need to be actively cleared like the IRQ status. It will clear automatically.

The USB0 IRQ_MERGED_STATUS register is shown in Figure 24-68 and described in Table 24-75.

Figure 24-68. USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT)

31	1	2	1	0
Reserved			Bank1	Bank1

LEGEND: R = Read only; -*n* = value after reset

Table 24-75. USB0 IRQ_MERGED_STATUS Register (USB0IRQMSTAT) Field Descriptions

Bits	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no effect.
1	Bank1	0	No events pending from IRQ_STATUS_1
		1	At least one event is pending from IRQ_STATUS_1
0	Bank0	0	No events pending from IRQ_STATUS_0
		1	At least one event is pending from IRQ_STATUS_0

24.9.2.1.5 USB0 IRQ_EOI Register (USB0IRQEOI)

The USB0 IRQ_EOI register (USB0IRQEOI) allows the CPU to acknowledge completion of an interrupt by writing to the EOI. An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain.

This register will be reset one cycle after it has been written to.

The USB0 IRQ_EOI register is shown in Figure 24-69 and described in Table 24-76.

Figure 24-69. USB0 IRQ_EOI Register (USB0IRQEOI)

Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	EOI for USB0	EOI for USB0 interrupt

24.9.2.1.6 USB0 IRQ_STATUS_RAW_0 Register (USB0IRQSTATRAW0)

The USB0 IRQ_STATUS_RAW_0 register (USB0IRQSTATRAW0) allows the USB0 interrupt sources to be manually triggered when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Set event
Read 0: No event pending
Read 1: Event pending

The USB0 IRQ_STATUS_RAW_0 register is shown in Figure 24-70 and described in Table 24-77.

15-0	TXEP*n*	Interrupt status for TX endpoint *n*

24.9.2.1.7 USB0 IRQ_STATUS_RAW_1 Register (USB0IRQSTATRAW1)

The USB0 IRQ_STATUS_RAW_1 register (USB0IRQSTATRAW1) allows the USB0 interrupt sources to be manually triggered when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Set event
Read 0: No event pending
Read 1: Event pending

The USB0 IRQ_STATUS_RAW_1 register is shown in Figure 24-71 and described in Table 24-78.

1	USB[1]	Interrupt status for Resume signaling detected
0	USB[0]	Interrupt status for Suspend signaling detected

24.9.2.1.8 USB0 IRQ_STATUS_0 Register (USB0IRQSTAT0)

The USB0 IRQ_STATUS_0 register (USB0IRQSTAT0) allows the USB0 interrupt sources to be manually cleared when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Clear event
Read 0: No event pending
Read 1: Event pending

The USB0 IRQ_STATUS_0 register is shown in Figure 24-72 and described in Table 24-79.

16	Reserved	Always read 0. Writes have no effect.
15-0	TXEP*n*	Interrupt status for TX endpoint *n*

24.9.2.1.9 USB0 IRQ_STATUS_1 Register (USB0IRQSTAT1)

The USB0 IRQ_STATUS_1 register (USB0IRQSTAT1) allows the USB0 interrupt sources to be manually cleared when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Clear event
Read 0: No event pending
Read 1: Event pending

The USB0 IRQ_STATUS_1 register is shown in Figure 24-73 and described in Table 24-80.

0	USB[0]	Interrupt status for Suspend signaling detected

24.9.2.1.10 USB0 IRQ_ENABLE_SET_0 Register (USB0IRQENABLESET0)

The USB0 IRQ_ENABLE_SET_0 register (USB0IRQENABLESET0) allows the USB0 interrupt sources to be manually enabled when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt enabled value. General actions per bit:
Write 0: No action
Write 1: Interrupt enabled
Read 0: Interrupt disabled
Read 1: Interrupt enabled

The USB0 IRQ_ENABLE_SET_0 register is shown in Figure 24-74 and described in Table 24-81.

24.9.2.1.12 USB0 IRQ_ENABLE_CLR_0 Register (USB0IRQENABLECLR0)

The USB0 IRQ_ENABLE_CLR_0 register (USB0IRQENABLECLR0) allows the USB0 interrupt sources to be manually disabled when writing a 1 to a specific bit. A read of this register returns the USB0 interrupt enabled value. General actions per bit:
Write 0: No action
Write 1: Disable interrupt
Read 0: Interrupt disabled
Read 1: Interrupt enabled

The USB0 IRQ_ENABLE_CLR_0 register is shown in Figure 24-76 and described in Table 24-83.

24.9.2.1.14 USB0 Tx Mode Register (USB0TXMODE)

The USB0 Tx mode register (USB0TXMODE) allows the CPU to individually enable RNDIS/Generic/CDC modes for each endpoint. Using the global RNDIS enable (rndis) bit in the control register (USB0CTRL) overrides this register and enables the RNDIS mode for all endpoints.

The USB0 Tx mode register is shown in Figure 24-78 and described in Table 24-85.

24.9.2.1.16 USB0 Generic RNDIS EPn Size Register (USB0GENRNDISEPn)

The USB0 generic RNDIS EPn size register (USB0GENRNDISEPn) is programmed with a RNDIS packet size in bytes. When EP(n) is in Generic RNDIS mode, the received USB packets will be collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a “short” packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 10000h, or 65536. N can range from 1 to 15.

The USB0 generic RNDIS EPn size register is shown in Figure 24-80 and described in Table 24-87.

Bits	Field	Description
31-17	Reserved	Always read as 0. Writes have no effect.
16-0	Ep(n)_size	Generic RNDIS packet size. n = 1-15

24.9.2.1.17 USB0 Auto Req Register (USB0AUTOREQ)

The USB0 auto req register (USB0AUTOREQ) allows the CPU to enable an automatic IN token request generation for host mode RX operation per each RX endpoint. This features has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU will have to manually set the ReqPkt bit for every USB packet.

There are two modes that Auto Req can function: always or all except an EOP. The always mode will set the ReqPkt bit after every USB packet the DMA receives thus generating a new IN token after each USB packet. The EOP mode will set the ReqPkt bit after every USB packet that isn’t an EOP (end of packet) in the CPPI descriptor. For RNDIS, CDC, and Generic RNDIS modes the auto req will stop when the EOP is received (either via a short packet for RNDIS,CDC, and Generic RNDIS or the count is reached for Generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode every USB packet is an EOP CPPI packet so the auto req never functions and acts like auto req is disabled.

The USB0 auto req register is shown in Figure 24-81 and described in Table 24-88.

24.9.2.1.18 USB0 SRP Fix Time Register (USB0SRPFIXTIME)

The USB0 SRP fix time register (USB0SRPFIXTIME) allows the CPU to configure the maximum amount of time the SRP fix logic blocks the AVAID from the PHY to the OTG core. This time allows the VBUS signal the ability to get below the thresholds and therefore remove the chance of voltage bounces which could give false threshold measurements.

The USB0 SRP fix time register is shown in Figure 24-82 and described in Table 24-89.

Figure 24-82. USB0 SRP Fix Time Register (USB0SRPFIXTIME)

Bits	Field	Description
31-0	srpfixtime	SRP Fix maximum time in 60 MHz cycles. Default is 700 ms.

24.9.2.1.19 USB0 Teardown Register (USB0TDOWN)

The USB0 teardown register (USB0TDOWN) controls the tearing down of Rx and Tx FIFOs in the USB controller. When a 1 is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared, and the register automatically clears itself after 1 clock cycle. This register must be used in conjunction with the CPPI DMA Teardown mechanism. The host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB Controller registers to ensure a complete teardown of the endpoint (see the Mentor specification for details).

The USB0 teardown register is shown in Figure 24-83 and described in Table 24-90.

24.9.2.1.20 USB0 PHY UTMI Register (USB0UTMI)

The USB0 PHY UTMI register (USB0UTMI) controls various PHY UTMI signals. The UTMI interface is located between the PHY module and the Mentor Graphics Controller. These signals are inputs to the PHY but are not outputs from the Mentor Graphics Controller.

It is important to set the otgdisable bit in to a high value to operate the PHY in a non-OTG mode. The USB0 PHY UTMI register is shown in Figure 24-84 and described in Table 24-91.

24.9.2.1.21 USB0 MGC UTMI Loopback Register (USB0UTMILB)

The USB0 MGC UTMI loopback register (USB0UTMILB) contains most of the input and output UTMI signals for the Mentor Graphics Controller. The UTMI interface is located between the PHY module and the Mentor Graphics Controller.

In the loopback mode, test register bits 11 to 0 control various UTMI signals that are input to the Mentor Graphics Controller.

In the loopback mode, test register bits 28 to 16 observe various UTMI signals that are output from the Mentor Graphics Controller.

The USB0 MGC UTMI loopback register is shown in Figure 24-85 and described in Table 24-92.

1-0	Reserved	Always read as 0. Writes have no effect.

24.9.2.1.22 USB0 Mode Register (USB0MODE)

The USB0 mode register (USB0MODE) supports operating the PHY in a non-OTG mode. This requires the user to set the MGC UTMI input signal iddig. OTG interfaces have an id external pin which control UTMI signal iddig. Since this external pin is not available, the user should set iddig to either a 0 (A-type) or 1 (B-type). This value will be the initial setting for the Mentor controller. But, the controller will determine whether it is operating as a host or device via its protocols. To determine the function of the controller this information can be found by reading the Mentor Controller DEVCTL register (80h) bit 2.

The loopback bit enables the loopback test. This test allows MGC0 to be connected to MGC1. It is important to set both loopback bits in both USB0/1 Mode registers. The USB0 MGC UTMI loopback register contains the various UTMI signals to be controlled and observed during loopback test.

The phy_test bit enables the phy_test mode. This test mode is intended to allow additional control of the UTMI inputs to the PHY. Currently, these inputs are drvvbus, dppulldown, dmpulldown, and idpullup. When phy_test is high, then the pin inputs for these signals control the inputs to the PHY instead of the Mentor controller outputs. The phy_test mode is not active with loopback mode is active.

When phy_test is active than the PHY inputs datainh is equal to datain. And txvalidh is equal to txvalid.

The USB0 mode register is shown in Figure 24-86 and described in Table 24-93.

24.9.2.1.23 USB0 Mentor Core Registers

A description of the Mentor core registers is available in Section 24.9.6. Two instantiations of the USB core exists, USB0 and USB1. These registers reside back to back within USB0 space. The core registers that are used by USB0 subsystem are defined within offsets 1400h-159Ch, while the core registers that are used by USB1 subsystem are defined within offset 1C00h-1D9Ch.

24.9.2.2 USB1 Controller Registers

Table 24-94 lists the registers for the USB1 controller submodule.

Table 24-94. USB1 Controller Registers

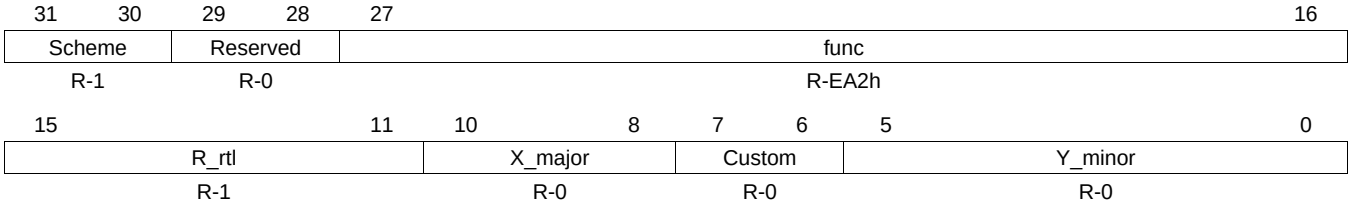
24.9.2.2.1 USB1 Revision Register (USB1REV)

The USB1 revision register (USB1REV) contains the major and minor revisions for the USB1 module.

The USB1 revision register is shown in Figure 24-87 and described in Table 24-95.

Figure 24-87. USB1 Revision Register (USB1REV)



LEGEND: R = Read only; -*n* = value after reset

Table 24-95. USB1 Revision Register (USB1REV) Field Descriptions

Bits	Field	Value	Description
31-30	Scheme	0-3h	Used to distinguish between old scheme and current.
29-28	Reserved	0	Reserved
27-16	func	0-FFFh	Function indicates a software compatible module family.
15-11	R_rtl	0-1Fh	RTL revision.
10-8	X_major	0-7h	Major revision.
7-6	Custom	0-3h	Custom revision
5-0	Y_minor	0-3Fh	Minor revision.

24.9.2.2.2 USB1 Control Register (USB1CTRL)

The USB1 control register (USB1CTRL) allows the CPU to control various aspects of the module. If uint is set high, then the Mentor controller generic interrupt for USB[9] will be generated (if enabled). This requires S/W to read the Mentor controller's registers to determine which interrupt USB[0] to USB[7] occurred. If uint is set low, then the usb20otg_f module will automatically read the Mentor controller's registers and set the appropriate interrupt USB[0] to USB[7] (if enabled). The generic interrupt for USB[9] will not be generated.

The USB1 control register is shown in Figure 24-88 and described in Table 24-96.

Figure 24-88. USB1 Control Register (USB1CTRL)

Table 24-96. USB1 Control Register (USB1CTRL) Field Descriptions

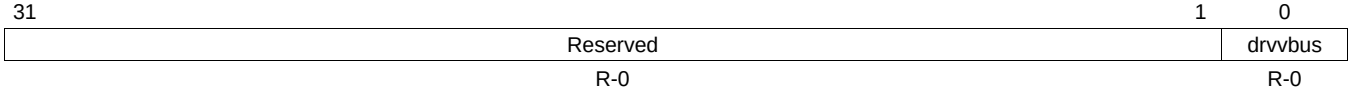
Bits	Field	Value	Description
31	dis_deb	0-1	Disable the VBUS debouncer circuit fix
30	dis_srp	0-1	Disable the OTG Session Request Protocol (SRP) AVALID circuit fix. When enabled (=0), this allows additional time for the VBUS signal to be measured against the VBUS thresholds. The time is specified in the USB1 SRP Fix Time Register.
29-6	Reserved	0	Always read as 0. Writes have no effect.
5	soft reset isolation	0-1	Soft reset isolation. When high, this bit forces all USB1 signals that connect to the USBSS to zeros during a soft reset via bit 0 of this register. This bit should be set high prior to setting bit 0 and cleared after bit 0 is cleared.
4	rndis	0-1	Global RNDIS mode enable for all endpoints.
3	uint		USB non-highlander interrupt enable
		0	Highlander
		1	Non-highlander
2	Reserved	0	Always read as 0. Writes have no effect.
1	clkfack	0-1	Clock stop fast ack enable.
0	soft reset		Software reset of USB1.
		Write 0	No action
		Write 1	Initiate software reset
		Read 0	Reset done, no action
		Read 1	Reset ongoing

24.9.2.2.3 USB1 Status Register (USB1STAT)

The USB1 status register (USB1STAT) allows the CPU to check the voltage state level of USB1_DRVVBUS pin.

Ths USB1 status register is shown in Figure 24-89 and described in Table 24-97.

Figure 24-89. USB1 Status Register (USB1STAT)



LEGEND: R = Read only; -*n* = value after reset

Table 24-97. USB1 Status Register (USB1STAT) Field Descriptions

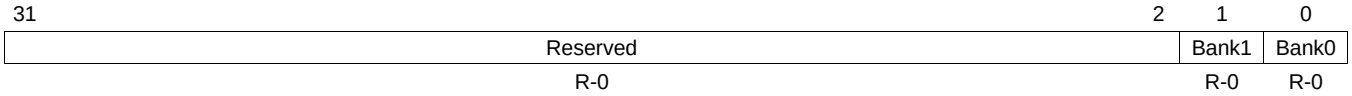
Bits	Field	Description
31-1	Reserved	Always read as 0. Writes have no effect.
0	drvvbus	Current USB1_DRVVBUS value

24.9.2.2.4 USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT)

The USB1 IRQ_MERGED_STATUS register (USB1IRQMSTAT) contains a merged status for all the events for USB1. This register optimizes software accesses in a module where a large number of events are associated to one IRQ line. The merged status is read-only, and does not need to be actively cleared like the IRQ status. It will clear automatically.

The USB1 IRQ_MERGED_STATUS register is shown in Figure 24-90 and described in Table 24-98.

Figure 24-90. USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT)



LEGEND: R = Read only; -*n* = value after reset

Table 24-98. USB1 IRQ_MERGED_STATUS Register (USB1IRQMSTAT) Field Descriptions

Bits	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no effect.
1	Bank1	0	No events pending from IRQ_STATUS_1
		1	At least one event is pending from IRQ_STATUS_1
0	Bank0	0	No events pending from IRQ_STATUS_0
		1	At least one event is pending from IRQ_STATUS_0

24.9.2.2.5 USB1 IRQ_EOI Register (USB1IRQEOI)

The USB1 IRQ_EOI register (USB1IRQEOI) allows the CPU to acknowledge completion of an interrupt by writing to the end of interrupt (EOI). An eoi_write signal will be generated and another interrupt will be triggered if interrupt sources remain. This register will be reset one cycle after it has been written to.

The USB1 IRQ_EOI register is shown in Figure 24-91 and described in Table 24-99.

Figure 24-91. USB1 IRQ_EOI Register (USB1IRQEOI)

24.9.2.2.6 USB1 IRQ_STATUS_RAW_0 Register (USB1IRQSTATRAW0)

The USB1 IRQ_STATUS_RAW_0 register (USB1IRQSTATRAW0) allows the USB1 interrupt sources to be manually triggered when writing a 1 to a specific bit. A read of this register returns the USB1 interrupt event pending value.

General actions per bit:
Write 0: No action
Write 1: Set event
Read 0: No event pending
Read 1: Event pending

The USB1 IRQ_STATUS_RAW_0 register is shown in Figure 24-92 and described in Table 24-100.

24.9.2.2.14 USB1 Tx Mode Register (USB1TXMODE)

The USB1 Tx mode register (USB1TXMODE) allows the CPU to individually enable RNDIS/Generic/CDC modes for each endpoint. Using the global RNDIS enable (rndis) bit in the control register (USB1CTRL) overrides this register and enables the RNDIS mode for all endpoints.

The USB1 Tx mode register is shown in Figure 24-100 and described in Table 24-108.

		3h	Generic RNDIS Mode on TX endpoint 1

24.9.2.2.15 USB1 Rx Mode Register (USB1RXMODE)

The USB1 Rx mode register (USB1RXMODE) allows the CPU to individually enable RNDIS/Generic/CDC modes for each endpoint. Using the global RNDIS enable (rndis) bit in the control register (USB1CTRL) overrides this register and enables the RNDIS mode for all endpoints.

The USB1 Rx mode register is shown in Figure 24-101 and described in Table 24-109.

24.9.2.2.16 USB1 Generic RNDIS EP N Size Register (USB1GENRNDISEPn)

The USB1 generic RNDIS EP N size register (USB1GENRNDISEPn) is programmed with a RNDIS packet size in bytes. When EP(N) is in Generic RNDIS mode, the received USB packets will be collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a “short” packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. N can range from 1 to 15.

The USB1 generic RNDIS EP N size register is shown in Figure 24-102 and described in USB1 Generic RNDIS EP N Size Register (USB1GENRNDISEPn) Field Descriptions.

24.9.2.2.17 USB1 Auto Req Register (USB1AUTOREQ)

The USB1 auto req register (USB1AUTOREQ) allows the CPU to enable an automatic IN token request generation for host mode RX operation per each RX endpoint. This features has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU will have to manually set the ReqPkt bit for every USB packet.

There are two modes that Auto Req can function: always or all except an EOP. The always mode will set the ReqPkt bit after every USB packet the DMA receives thus generating a new IN token after each USB packet. The EOP mode will set the ReqPkt bit after every USB packet that isn’t an EOP (end of packet) in the CPPI descriptor. For RNDIS, CDC, and Generic RNDIS modes the auto req will stop when the EOP is received (either via a short packet for RNDIS,CDC, and Generic RNDIS or the count is reached for Generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode, every USB packet is an EOP CPPI packet, so the auto req never functions and acts like auto req is disabled.

The USB1 auto req register is shown in Figure 24-103 and described in Table 24-110.

24.9.2.2.18 USB1 SRP Fix Time Register (USB1SRPFIXTIME)

The USB1 SRP fix time register (USB1SRPFIXTIME) allows the CPU to configure the maximum amount of time the SRP fix logic blocks the AVAID from the PHY to the OTG core. This time allows the VBUS signal the ability to get below the thresholds and therefore remove the chance of voltage bounces which could give false threshold measurements.

The USB1 SRP fix time register is shown in Figure 24-104 and described in Table 24-111.

Figure 24-104. USB1 SRP Fix Time Register (USB1SRPFIXTIME)

Bits	Field	Description
31-0	srpfixtime	SRP Fix maximum time in 60 MHz cycles. Default is 700 ms.

24.9.2.2.19 USB1 Teardown Register (USB1TDOWN)

The USB1 teardown register (USB1TDOWN) controls the tearing down of rx and tx fifos in the USB controller. When a '1' is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared , and the register automatically clears itself after 1 clock cycle. This register must be used in conjunction with the CPPI DMA Teardown mechanism. The Host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB Controller registers to ensure a complete teardown of the endpoint. See the Mentor specification for details.

The USB1 teardown register is shown in Figure 24-105 and described in Table 24-112.

24.9.2.2.20 USB1 PHY UTMI Register (USB1UTMI)

The USB1 PHY UTMI register (USB1UTMI) controls various PHY UTMI signals. The UTMI interface is located between the PHY module and the Mentor Graphics Controller. These signals are inputs to the PHY but are not outputs from the Mentor Graphics Controller. It is important to set the otgdisable bit in to a high value to operate the PHY in a non-OTG mode.

The USB1 PHY UTMI register is shown in Figure 24-106 and described in Table 24-113.

24.9.2.2.21 USB1 MGC UTMI Loopback Register (USB1UTMILB)

The USB1 MGC UTMI loopback register (USB1UTMILB) contains most of the input and output UTMI signals for the Mentor Graphics Controller. The UTMI interface is located between the PHY module and the Mentor Graphics Controller.

In the loopback mode, test register bits 11 to 0 control various UTMI signals that are input to the Mentor Graphics Controller.

In the loopback mode, test register bits 28 to 16 observe various UTMI signals that are output from the Mentor Graphics Controller.

The USB1 MGC UTMI loopback register is shown in Figure 24-107 and described in Table 24-114.

24.9.2.2.22 USB1 Mode Register (USB1MODE)

The USB1 mode register (USB1MODE) supports operating the PHY in a non-OTG mode. This requires the user to set the MGC UTMI input signal iddig. OTG interfaces have an id external pin which control UTMI signal iddig. Since this external pin is not available, the user should set iddig to either a 0 (A-type) or 1 (B-type). This value will be the initial setting for the Mentor controller. But, the controller will determine whether it is operating as a host or device via its protocols. To determine the function of the controller this information can be found by reading the Mentor Controller DEVCTL register (80h) bit 2.

The loopback bit enables the loopback test. This test allows MGC1 to be connected to MGC0. It is important to set both loopback bits in both USB0/1 Mode registers. The USB0 MGC UTMI Loopback Register contains the various UTMI signals to be controlled and observed during loopback test.

The phy_test bit enables the phy_test mode. This test mode is intended to allow additional control of the UTMI inputs to the PHY. Currently, these inputs are drvvbus, dppulldown, dmpulldown, and idpullup. When phy_test is high, then the pin inputs for these signals control the inputs to the PHY instead of the Mentor controller outputs. The phy_test mode is not active with loopback mode is active.

When phy_test is active than the PHY inputs datainh is equal to datain. And txvalidh is equal to txvalid.

The USB1 mode register is shown in Figure 24-108 and described in Table 24-115.

24.9.2.2.23 USB1 Mentor Core Registers

A description of the mentor core registers is available in Section 24.9.6. Two instantiations of the USB core exists, USB0 and USB1. These registers reside back to back within USB0 space. The core registers that are used by USB0 subsystem are defined within offsets 1400h-159Ch, while the core registers that are used by USB1 subsystem are defined within offsets 1C00h–1D9Ch.

24.9.3 CPPI DMA Controller Registers

Table 24-116 lists the registers for the CPPI DMA Controller submodule.

Table 24-116. CPPI DMA Controller Registers

Address Offset	Acronym	CPPI DMA Controller Register

Bits	Field	Value	Description
31-30	Reserved	0	Always read as 0. Writes have no effect.
29-16	modID	0-3FFFh	Module ID field
15-11	revrtl	0-1Fh	RTL revision.
10-8	revmaj	0-7h	Major revision.
7-0	revmin	0-FFh	Minor revision.

24.9.3.2 CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ)

The CPPI DMA teardown free descriptor queue control register (TDFDQ) is used to inform the DMA of the location in memory or descriptor array which is to be used for signaling of a teardown complete for each Tx and Rx channel. The CPPI DMA teardown free descriptor queue control register is shown in Figure 24-110 and described in Table 24-118.

Figure 24-110. CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ)

31 14	13 12	11 0
Reserved	td_desc_qmgr	td_desc_qnum
R-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-118. CPPI DMA Teardown Free Descriptor Queue Control Register (TDFDQ) Field Descriptions

Bits	Field	Description
31-14	Reserved	Reserved
13-12	td_desc_qmgr	This field controls which of the 4 Queue Managers the DMA will access in order to allocate a channel teardown descriptor from the teardown descriptor queue.
11-0	td_desc_qnum	This field controls which of the 2K queues in the indicated queue manager should be read in order to allocate channel teardown descriptors.

24.9.3.3 CPPI DMA Emulation Control Register (DMAEMU)

The CPPI DMA emulation control register (DMAEMU) is used to control the behavior of the DMA when the emususp input is asserted. The CPPI DMA emulation control register is shown in Figure 24-111 and described in Table 24-119.

Figure 24-111. CPPI DMA Emulation Control Register (DMAEMU)

31	2	1	0
Reserved		soft	free
R-0		R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-119. CPPI DMA Emulation Control Register (DMAEMU) Field Descriptions

Bits	Field	Value	Description
31-2	Reserved	0	Always read as 0. Writes have no effect.
1	soft		Control for emulation pause request
		0	Forces emu_pause_req low
		1	Does not force emu_pause_req low
0	free	0-1	Enable for emulation suspend

24.9.3.4 CPPI Mem1 Base Address Register (DMAMEM1BA)

The CPPI Mem1 base address register (DMAMEM1BA) is the base address for the CPPI mem1 accesses. This base address points to the location of the data that will be transferred from external memory to the USB DMA RAM. This 16-bit field is the 16 most-significant bits of the 32-bit base address.

The CPPI Mem1 base address register is shown in Figure 24-112 and described in Table 24-120.

Figure 24-112. CPPI Mem1 Base Address Register (DMAMEM1BA)

31	16	15	0
mem1_base		Reserved	
R/W-0		R-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-120. CPPI Mem1 Base Address Register (DMAMEM1BA) Field Descriptions

Bits	Field	Description
31-16	mem1_base	CPPI mem1 base address
15-0	Reserved	Always read as 0. Writes have no effect.

24.9.3.5 CPPI Mem1 Mask Address Register (DMAMEM1MASK)

The CPPI Mem1 mask address register (DMAMEM1MASK) is the mask address for the CPPI mem1 base register (DMAMEM1BA). The 16-bit mem1_mask is ANDed with the 16-bit mem1_base register. The 16-bit resultant signal is the 16 most-significant bits of the 32-bit address for external memory accesses during DMA transactions.

The CPPI Mem1 mask address register is shown in Figure 24-113 and described in Table 24-121.

Figure 24-113. CPPI Mem1 Mask Address Register (DMAMEM1MASK)

31-16	mem1_mask	CPPI mem1 mask address
15-0	Reserved	Always read as 0. Writes have no effect.

24.9.3.6 Tx Channel N Global Configuration Register (TXGCRn)

The Tx channel N global configuration register (TXGCRn) are used to initialize the behavior of each of the Tx CPPI DMA channels. N,n ranges from 0 to 14. The Tx channel N global configuration register is shown in Figure 24-114 and described in Table 24-122.

Figure 24-114. Tx Channel N Global Configuration Register (TXGCRn)

Reserved		tx_default_qmgr		tx_default_qnum	
R-0		W-0		W-0	

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-122. Tx Channel N Global Configuration Register (TXGCRn) Field Descriptions

Bits	Field	Value	Description
31	tx_enable		This field enables or disables the channel
		0	Channel is disabled
		1	Channel is enabled
			This field will be cleared after a channel teardown is complete.
30	tx_teardown	0-1	Setting this bit will request the channel to be torn down. This field will remain set after a channel teardown is complete.
29-14	Reserved	0	Reserved
13-12	tx_default_qmgr	0-3h	This field controls the default queue manager number that will be used to queue teardown descriptors back to the host.
11-0	tx_default_qnum	0-FFFh	This field controls the default queue number within the selected queue manager onto which teardown descriptors will be queued back to the host.

24.9.3.7 Rx Channel N Global Configuration Register (RXGCRn)

The Rx channel N global configuration register (RXGCRn) are used to initialize the global (non descriptor type specific) behavior of each of the Rx CPPI DMA channels. If the enable bit is being set, the Rx Channel Global Configuration Register should only be written after all of the other Rx Configuration Registers have been initialized. N,n ranges from 0 to 14.

The Rx channel N global configuration register is shown in Figure 24-115 and described in Table 24-123.

Figure 24-115. Rx Channel N Global Configuration Register (RXGCRn)

31	30	29 25	24	23 16
rx_enable	rx_teardown	Reserved	rx_error_handling	rx_sop_offset
R/W-0	R/W-0	R-0	W-0	W-0

15 14	13 12	11 0
rx_default_desc_type	rx_default_rq_qmgr	rx_default_rq_qnum
W-0	W-0	W-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-123. Rx Channel N Global Configuration Register (RXGCRn) Field Descriptions

Bits	Field	Value	Description
31	rx_enable		This field enables or disables the channel
		0	Channel is disabled
		1	Channel is enabled
			This field will be cleared after a channel teardown is complete.
30	rx_teardown	0-1	This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field will be set after a channel teardown is complete.
29-25	Reserved	0	Reserved
24	rx_error_handling		This bit controls the error handling mode for the channel and is only used when channel errors (descriptor or buffer starvation occurs):
		0	Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to
		1	Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA will return to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added.
			Regardless of the value of this bit, the DMA will assert the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when
23-16	rx_sop_offset	0-FFh	This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 – 255 bytes.
15-14	rx_default_desc_type		This field indicates the default descriptor type to use:
		0	Reserved
		1h	Host
		2h-3h	Reserved
			The actual descriptor type that will be used for reception can be overridden by information provided in the CPPI FIFO data block.
13-12	rx_default_rq_qmgr	0-3h	This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block.
11-0	rx_default_rq_qnum	0-FFFh	This field indicates the default receive queue that this channel should use. The actual receive queue that will be used for reception can be overridden by information provided in the CPPI FIFO data block.

24.9.3.8 Rx Channel N Host Packet Configuration Register A (RXHPCRAn)

The Rx channel N host packet configuration register A (RXHPCRAn) are used to initialize the behavior of each of the Rx CPPI DMA channels for reception of host type packets. N,n ranges from 0 to 14. The Rx channel N host packet configuration register A is shown in Figure 24-116 and described in Figure 24-116.

Figure 24-116. Rx Channel N Host Packet Configuration Register A (RXHPCRAn)

Table 24-124. Rx Channel N Host Packet Configuration Register A (RXHPCRAn) Field Descriptions

Bits	Field	Description
31-30	Reserved	Reserved
29-28	rx_host_fdq1_qmgr	This field specifies which Buffer Manager should be used for the 2nd Rx buffer in a host type packet
27-16	rx_host_fdq1_qnum	This field specifies which Free Descriptor / Buffer Pool should be used for the 2nd Rx buffer in a host type packet
15-14	Reserved	Reserved
13-12	rx_host_fdq0_qmgr	This field specifies which Buffer Manager should be used for the 1st Rx buffer in a host type packet
11-0	rx_host_fdq0_qnum	This field specifies which Free Descriptor / Buffer Pool should be used for the 1st Rx buffer in a host type packet

24.9.3.9 Rx Channel N Host Packet Configuration Register B (RXHPCRBn)

The Rx channel N host packet configuration register B (RXHPCRBn) are used to initialize the behavior of each of the Rx CPPI DMA channels for reception of host type packets. N,n ranges from 0 to 14. The Rx channel N host packet configuration register B is shown in Figure 24-117 and described in Table 24-125.

Figure 24-117. Rx Channel N Host Packet Configuration Register B (RXHPCRBn)

R-0	W-0	W-0

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 24-125. Rx Channel N Host Packet Configuration Register B (RXHPCRBn) Field Descriptions

Bits	Field	Description
31-30	Reserved	Reserved
29-28	rx_host_fdq3_qmgr	This field specifies which Manager should be used for the 4th or later Rx buffers in a host type packet
27-16	rx_host_fdq3_qnum	This field specifies which Free Descriptor Queue should be used for the 4th or later Rx buffers in a host type packet
15-14	Reserved	Reserved
13-12	rx_host_fdq2_qmgr	This field specifies which Buffer Manager should be used for the 3rd Rx buffer in a host type packet
11-0	rx_host_fdq2_qnum	This field specifies which Free Descriptor / Buffer Pool should be used for the 3rd Rx buffer in a host type packet

24.9.4 CPPI DMA Scheduler Registers

Table 24-126 lists the registers for the CPPI DMA Scheduler submodule.

Table 24-126. CPPI DMA Scheduler Registers

Address Offset	Acronym	CPPI DMA Scheduler Register
3000h	DMA_SCHED_CTRL	CPPI DMA Scheduler Control Register
3800h-38FCh	WORD0-WORD63	CPPI DMA Scheduler Table Word 0-Word 63

24.9.4.1 CPPI DMA Scheduler Control Register (DMA_SCHED_CTRL)

The CPPI DMA scheduler control register (DMA_SCHED_CTRL) contains the major and minor revisions for the module. This register is shown in Figure 24-118 and described in Table 24-127.

Figure 24-118. CPPI DMA Scheduler Control Register (DMA_SCHED_CTRL)

31	30	16
enable	Reserved	
R/W-0	R-0	

15	8	7	0
Reserved		last_entry	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-127. CPPI DMA Scheduler Control Register (DMA_SCHED_CTRL) Field Descriptions

Bits	Field	Value	Description
31	enable		This is the enable bit for the scheduler and is encoded as follows:
		0	Scheduler is disabled and will no longer fetch entries from the scheduler table or pass credits to the DMA controller
		1	Scheduler is enabled
			This bit should only be set after the table has been initialized.
30-8	Reserved	0	Reserved
7-0	last_entry		This field indicates the last valid entry in the scheduler table. There are 64 words in the table and there are 4 entries in each word. The table can be programmed with any integer number of entries from 1 to 256. The corresponding encoding for this field is as follows:
		0	1 entry
		1h	2 entries
		…	
		FEh	255 entries
		FFh	256 entries

24.9.4.2 CPPI DMA Scheduler Table Word N (WORDn)

The Tx channel configuration registers are used to initialize the behavior of each of the Tx DMA channels. N ranges from 0 to 63. The CPPI DMA scheduler table word N register (WORDn) is shown in Figure 24-119 and described in Table 24-128.

Figure 24-119. CPPI DMA Scheduler Table Word N Register (WORDn)

31	30 29	28 24	23	22 21	20 16
entry3_rxtx	Reserved	entry3_channel	entry2_rxtx	Reserved	entry2_channel
W-0	R-0	W-0	W-0	R-0	W-0

15	14 13	12 8	7	6 5	4 0
entry1_rxtx	Reserved	entry1_channel	entry0_rxtx	Reserved	entry0_channel
W-0	R-0	W-0	W-0	R-0	W-0

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 24-128. CPPI DMA Scheduler Table Word N Register (WORDn) Field Descriptions

Bits	Field	Value	Description
31	entry3_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
30-29	Reserved	0	Reserved
28-24	entry3_channel	0-1Fh	This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
23	entry2_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
22-21	Reserved	0	Reserved
20-16	entry2_channel	0-1Fh	This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
15	entry1_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
14-13	Reserved		Reserved
12-8	entry1_channel	0-1Fh	This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.
7	entry0_rxtx		This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows:
		0	Tx Channel
		1	Rx Channel
6-5	Reserved	0	Reserved

Table 24-128. CPPI DMA Scheduler Table Word N Register (WORDn) Field Descriptions (continued)

Bits	Field	Value	Description
4-0	entry0_channel	0-1Fh	This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA will be presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA will be presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit will actually be the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry.

24.9.5 CPPI DMA Queue Manager Registers

Table 24-129 lists the registers for the CPPI DMA Queue Manager submodule.

Table 24-129. CPPI DMA Queue Manager Registers

Address Offset	Acronym	CPPI DMA Queue Manager Register
4000h	QMGRREVID	Revision Register
4008h	DIVERSIO	Queue Diversion Register
4020h	FDBSC0	Free Descriptor/Buffer Starvation Count Qmgr Register 0
4024h	FDBSC1	Free Descriptor/Buffer Starvation Count Register 1
4028h	FDBSC2	Free Descriptor/Buffer Starvation Count Register 2
402Ch	FDBSC3	Free Descriptor/Buffer Starvation Count Register 3
4030h	FDBSC4	Free Descriptor/Buffer Starvation Count Register 4
4034h	FDBSC5	Free Descriptor/Buffer Starvation Count Register 5
4038h	FDBSC6	Free Descriptor/Buffer Starvation Count Register 6

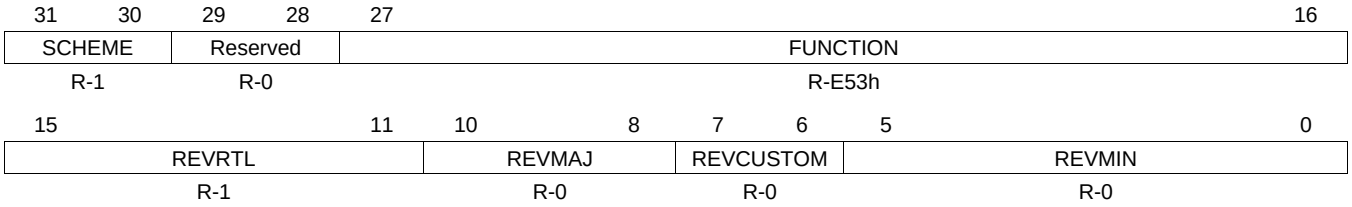
5000h + 16 x R	QMEMRBASEr	Memory Region R Base Address Register
5000h + 16 x R + 4	QMEMRCTRLr	Memory Region R Control Register
6000h + 16 x N	CTRLAn	Queue Manager Queue N Register A
6004h + 16 x N	CTRLBn	Queue Manager Queue N Register B
6008h + 16 x N	CTRLCn	Queue Manager Queue N Register C
600Ch + 16 x N	CTRLDn	Queue N Register D
7000h + 16 x N	QSTATAn	Queue N Status Register A
7004h + 16 x N	QSTATBn	Queue N Status Register B
7008h + 16 x N	QSTATCn	Queue N Status Register C

24.9.5.1 Queue Manager Revision Register (QMGRREVID)

The queue manager revision register (QMGRREVID) contains the major and minor revisions for the module. It does not support byte accesses. This register is shown in Figure 24-120 and described in Table 24-130.

Figure 24-120. Queue Manager Revision Register (QMGRREVID)



LEGEND: R = Read only; -*n* = value after reset

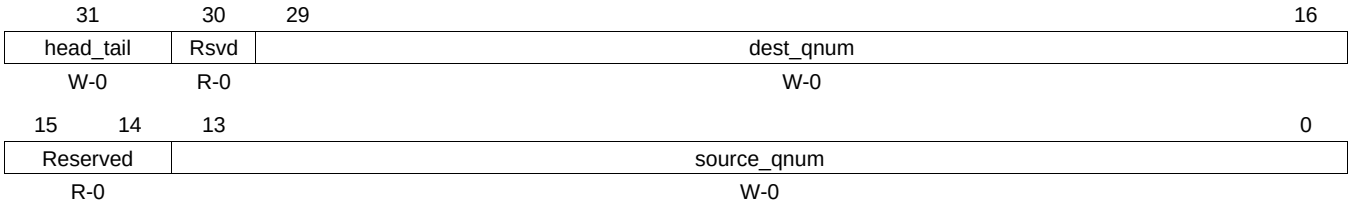
Table 24-130. Queue Manager Revision Register (QMGRREVID) Field Descriptions

Bits	Field	Value	Description
31-30	SCHEME	0-3h	Used to distinguish between old scheme and current.
29-28	Reserved	0	Reserved
27-16	FUNCTION	0-FFFh	Function indicates a software compatible module family.
15-11	REVRTL	0-1Fh	RTL revision
10-8	REVMAJ	0-7h	Major revision
7-6	REVCUSTOM	0-3h	Custom revision
5-0	REVMIN	0-3Fh	Minor revision

24.9.5.2 Queue Manager Queue Diversion Register (DIVERSION)

The queue manager queue diversion register (DIVERSION) is used to transfer the contents of one queue onto another queue. It does not support byte accesses. This register is shown in Figure 24-121 and described in Table 24-131.

Figure 24-121. Queue Manager Queue Diversion Register (DIVERSION)



LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 24-131. Queue Manager Queue Diversion Register (DIVERSION) Field Descriptions

Bits	Field	Description
31	head_tail	Indicates whether queue contents should be merged on to head or tail of destination queue. Clear this field for head and set for tail.
30	Reserved	Reserved
29-16	dest_qnum	Destination Queue Number
15-14	Reserved	Reserved
13-0	source_qnum	Source Queue Number

24.9.5.3 Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)

The queue manager free descriptor/buffer starvation count register 0 (FDBSC0) provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses. This register is shown in Figure 24-122 and described in Table 24-132.

Figure 24-122. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0)

31 24	23 16	15 8	7 0
fdbq3_starve_cnt	fdbq2_starve_cnt	fdbq1_starve_cnt	fdbq0_starve_cnt
RC-0	RC-0	RC-0	RC-0

LEGEND: RC = Clear on read; -*n* = value after reset

Table 24-132. Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (FDBSC0) Field Descriptions

Bits	Field	Description
31-24	fdbq3_starve_cnt	This field increments each time the free descriptor/buffer queue 3 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
23-16	fdbq2_starve_cnt	This field increments each time the free descriptor/buffer queue 2 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
15-8	fdbq1_starve_cnt	This field increments each time the free descriptor/buffer queue 1 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
7-0	fdbq0_starve_cnt	This field increments each time the free descriptor/buffer queue 0 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.

24.9.5.4 Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)

The queue manager free descriptor/buffer starvation count register 1 (FDBSC1) provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses. This register is shown in Figure 24-123 and described in Table 24-133.

Figure 24-123. Queue Manager Free Descriptor/Buffer Starvation Count Register 1 (FDBSC1)

Table 24-134. Queue Manager Free Descriptor/Buffer Starvation Count Register 2 (FDBSC2) Field Descriptions

Bits	Field	Description
31-24	fdbq11_starve_cnt	This field increments each time the free descriptor/buffer queue 11 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
23-16	fdbq10_starve_cnt	This field increments each time the free descriptor/buffer queue 10 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
15-8	fdbq9_starve_cnt	This field increments each time the free descriptor/buffer queue 9 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.
7-0	fdbq8_starve_cnt	This field increments each time the free descriptor/buffer queue 8 is read while it is empty via the CPPI DMA. This field is cleared when read via the CPU.

24.9.5.6 Queue Manager Free Descriptor/Buffer Starvation Count Register 3 (FDBSC3)

The queue manager free descriptor/buffer starvation count register 3 (FDBSC3) provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses. This register is shown in Figure 24-125 and described in Table 24-135.

Figure 24-125. Queue Manager Free Descriptor/Buffer Starvation Count Register 3 (FDBSC3)

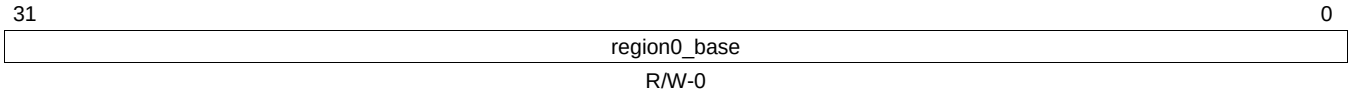
24.9.5.11 Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)

The queue manager linking RAM region 0 base address register (LRAM0BASE) is used to set the base address for the first portion of the Linking RAM. This address must be 32-bit aligned. It is used by the queue manager to calculate the 32-bit linking address for a given descriptor index. It does not support byte accesses.

The queue manager linking RAM region 0 base address register is shown in Figure 24-130 and described in Table 24-140.

Figure 24-130. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE)



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 24-140. Queue Manager Linking RAM Region 0 Base Address Register (LRAM0BASE) Field Descriptions

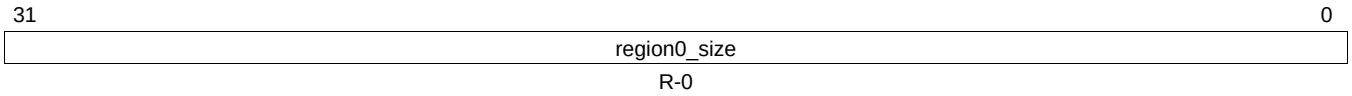
Bits	Field	Description
31-0	region0_base	This field stores the base address for the first region of the linking RAM. This may be anywhere in 32-bit address space but would be typically located in on-chip memory.

24.9.5.12 Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE)

The queue manager linking RAM region 0 size register (LRAM0SIZE) is used to set the size of the array of linking pointers that are located in region 0 of linking RAM. The size specified the number of descriptors for which linking information is stored in this region. It does not support byte accesses.

The queue manager linking RAM region 0 size register is shown in Figure 24-131 and described in Table 24-141.

Figure 24-131. Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE)



LEGEND: R = Read only; -*n* = value after reset

Table 24-141. Queue Manager Linking RAM Region 0 Size Register (LRAM0SIZE) Field Descriptions

Bits	Field	Description
31-0	region0_size	This field indicates the number of entries that are contained in the linking RAM region 0. A descriptor with index less than region0_size value has its linking location in region 0. A descriptor with index greater than region0_size has its linking location in region 1. The queue manager adds the index (left shifted by 2 bits) to the appropriate regionX_base_addr to get the absolute 32-bit address to the linking location for a descriptor.

24.9.5.13 Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE)

The queue manager linking RAM region 1 base address register (LRAM1BASE) is used to set the base address for the second portion of the linking RAM. This base address is used by the queue manager to calculate the 32-bit linking address from the descriptor index. All descriptors with index higher than that given in linking RAM 0 size register have linking information stored in linking RAM region 1. It does not support byte accesses.

The queue manager linking RAM region 1 base address register is shown in Figure 24-132 and described in Table 24-142.

Figure 24-132. Queue Manager Linking RAM Region 1 Base Address Register (LRAM1BASE)

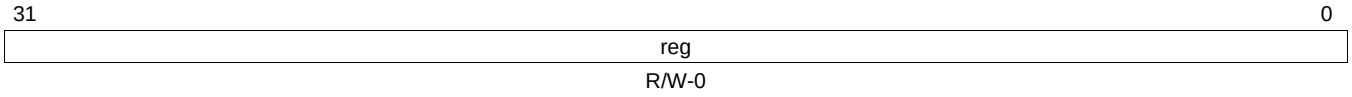
24.9.5.19 Queue Manager Memory Region R Base Address Register (QMEMRBASEr)

The queue manager memory region R base address register (QMEMRBASEr) is written by the Host to set the base address of memory region R. This memory region stores a number of descriptors of a particular size as determined by the memory region R control register. It does not support byte accesses. R ranges from 0 to 15.

The queue manager memory region R base address register is shown in Figure 24-138 and described in Table 24-148.

Figure 24-138. Queue Manager Memory Region R Base Address Register (QMEMRBASEr)



LEGEND: R/W = Read/Write; -*n* = value after reset

Table 24-148. Queue Manager Memory Region R Base Address Register (QMEMRBASEr) Field Descriptions

Bits	Field	Description
31-0	reg	This field contains the base address of the memory region R.

24.9.5.20 Queue Manager Memory Region R Control Register (QMEMRCTRLr)

The queue manager memory region R control register (QMEMRCTRLr) is written by the Host to configure various parameters of this memory region. It does not support byte accesses. R ranges from 0 to 15. This register is shown in Figure 24-139 and described in Table 24-149.

Figure 24-139. Queue Manager Memory Region R Control Register (QMEMRCTRLr)

Table 24-149. Queue Manager Memory Region R Control Register (QMEMRCTRLr) Field Descriptions

Bits	Field	Description
31-30	Reserved	Reserved
29-16	start_index	This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts.
15-12	Reserved	Reserved
11-08	desc_size	This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as 2^(5+desc_size) number of bytes. The settings of desc_size from 9-15 are reserved.
7-3	Reserved	Reserved
2-0	reg_size	This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as 2^(5+reg_size) number of descriptors.

24.9.5.21 Queue Manager Queue N Register A (CTRLAn)

The queue manager queue N register A (CTRLAn) is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N register A is shown in Figure 24-140 and described in Table 24-150.

Figure 24-140. Queue Manager Queue N Register A (CTRLAn)

31–14	13–0
Reserved	queue_entry_count
R-0	R-0

Table 24-150. Queue Manager Queue N Register A (CTRLAn) Field Descriptions

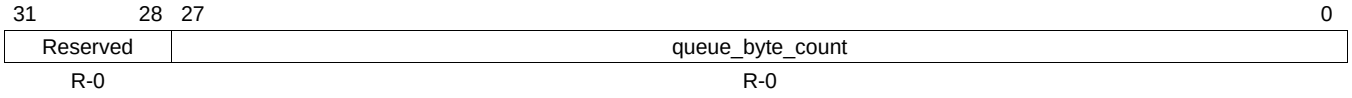
Bits	Field	Description
31-14	Reserved	Reserved
13-0	queue_entry_count	This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue.

24.9.5.22 Queue Manager Queue N Register B (CTRLBn)

The queue manager queue N register B (CTRLBn) is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. This register must be read prior to reading queue N register D during packet pop operation if the total size information is desired. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N register B is shown in Figure 24-141 and described in Table 24-151.

Figure 24-141. Queue Manager Queue N Register B (CTRLBn)



LEGEND: R = Read only; -*n* = value after reset

Table 24-151. Queue Manager Queue N Register B (CTRLBn) Field Descriptions

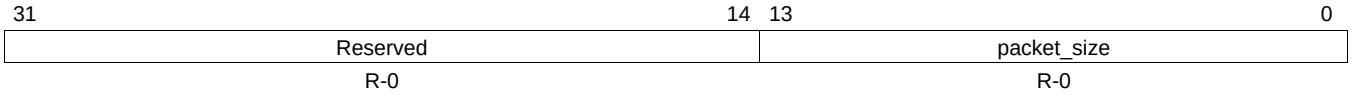
Bits	Field	Description
31-28	Reserved	Reserved
27-0	queue_byte_count	This field indicates how many bytes total are contained in all of the packets that are currently queued on this queue.

24.9.5.23 Queue Manager Queue N Register C (CTRLCn)

The queue manager queue N register C (CTRLCn) is used to provide additional information about the packet that is being pushed or popped from the queue. This register provides an option for the packet to be pushed onto either the tail of the queue (default) or the head of the queue (override). This register must be written prior to writing the queue N register D during packet write operations. This register must be read prior to reading queue N register D during pop operations if the packet size information is desired. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N register C is shown in Figure 24-142 and described in Table 24-152.

Figure 24-142. Queue Manager Queue N Register C (CTRLCn)



LEGEND: R = Read only; -*n* = value after reset

Table 24-152. Queue Manager Queue N Register C (CTRLCn) Field Descriptions

Bits	Field	Description
31-14	Reserved	Reserved
13-0	packet_size	This field indicates packet size of the head element of a queue. This field indicates packet size for packet pop operation.

24.9.5.24 Queue Manager Queue N Register D (CTRLDn)

The queue manager queue N register D (CTRLDn) is written to add a packet to the queue and read to pop a packets off a queue. The packet is only pushed or popped to/from the queue when the queue register D is written. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N register D is shown in Figure 24-143 and described in Table 24-153.

Figure 24-143. Queue Manager Queue N Register D (CTRLDn)

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 24-153. Queue Manager Queue N Register D (CTRLDn) Field Descriptions

Bits	Field	Description
31-5	desc_ptr	Descriptor pointer. It is read as zero if the queue is empty. It indicates a 32-bit aligned address that points to a descriptor when the queue is not empty.
4-0	desc_size	Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field returns a 0x0 when an empty queue is read.

24.9.5.25 Queue Manager Queue N Status Register A (QSTATAn)

The queue manager queue N status register A (QSTATAn) is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N status register A is shown in Figure 24-144 and described in Table 24-154.

Figure 24-144. Queue Manager Queue N Status Register A (QSTATAn)

24.9.5.26 Queue Manager Queue N Status Register B (QSTATBn)

The queue manager queue N status register B (QSTATBn) is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. It does not support byte accesses. N ranges from 0 to 155.

The queue manager queue N status register B is shown in Figure 24-145 and described in Table 24-155.

Figure 24-145. Queue Manager Queue N Status Register B (QSTATBn)

13-0	packet_size	This field indicates packet size of the head element of a queue.

24.9.6 USB Mentor Core Registers

The Mentor Control register map is divided into the following sections:

- **Common USB registers (0h–Fh)** – These registers provide control and status for the complete core.
- **Indexed Endpoint Control/Status registers (10h–1Fh)** – These registers provide control and status for the currently selected endpoint. The registers mapped into this section depend on whether the core is in Peripheral mode or in Host mode and on the value of the Index register.
- **FIFOs (20h–5Fh)** – This address range provides access to the endpoint FIFOs.
- Additional Control and Configuration registers (60h–7Fh) – These registers provide additional device status and control.
- **Target Endpoint Control Registers (80h–FFh)** – These registers provide target function and hub address details for each of the endpoints.
- **Non-Indexed Endpoint Control/Status registers (100h and above)** – The registers available at 10h–1Fh, accessible independently of the setting of the Index register. 100h–10Fh, EP0 registers; 110h–11Fh, EP1 registers; 120h–12Fh, EP2; and so on.

Two instances of the mentor core registers exist within USB0 space. Since both USB modules operate independent of each other, each USB core has its own set of registers. USB0 mentor base address is 4740 1400h; USB1 mentor core registers base address is 4740 1C00h. The core registers the absolute address is computed by summing the CORE_OFFSET with USBn_OFFSET.

24.9.6.1 Common USB Registers

These registers provide control and status for the complete core. Table 24-157 lists the registers.

Table 24-157. Common USB Registers

Core Address Offset	Acronym	Common USB Registers
0h	USBn_FADDR	Function Address Register
1h	USBn_POWER	Power Management Register
2h	USBn_INTRTX	Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15
4h	INTRRX	Interrupt Register for Receive Endpoints 1 to 15
6h	INTRTXE	Interrupt Enable Register for INTRTX
8h	INTRRXE	Interrupt Enable Register for INTRRX
Ah	USBn_INTRUSB	Interrupt Register for Common USB Interrupts
Bh	USBn_INTRUSBE	Interrupt Enable Register for INTRUSB
Ch	USBn_FRAME	Frame Number Register
Eh	USBn_INDEX	Index Register for Selecting the Endpoint Status and Control Registers
Fh	USBn_TESTMODE	Register to Enable the USB 2.0 Test Modes

24.9.6.1.1 Function Address Register (USBn_FADDR)

The function address register (USBn_FADDR) is an 8-bit register that should be written with the 7-bit address of the peripheral part of the transaction.

Since USB cores are configured with multipoint support, this register only applies to operations carried out when the controller is in peripheral mode. In Host mode, this register is ignored.

The function address register is shown in Figure 24-147 and described in Table 24-158.

Figure 24-147. Function Address Register (USBn_FADDR)

7	6	0
Reserved	FUNCADDR	
R-0	W-0	

LEGEND: R = Read only; W = Write only; -*n* = value after reset

Table 24-158. Function Address Register (USBn_FADDR) Field Descriptions

Bits	Field	Description
7	Reserved	Reserved
6-0	FUNCADDR	7_bit address of the peripheral part of the transaction. When used in peripheral mode, this register should be written with the address received through a SET_ADDRESS command, which is then used for decoding the function address in subsequent token packets.

24.9.6.1.2 Power Management Register (USBn_POWER)

The power management register (USBn_POWER) is an 8-bit register that is used for controlling suspend and resume signaling, and some basic operational aspects of the USB core. This register is shown in Figure 24-148 and described in Table 24-159.

Figure 24-148. Power Management Register (USBn_POWER)

LEGEND: R/W = Read/Write; -*n* = value after reset

Table 24-159. Power Management Register (USBn_POWER) Field Descriptions

Bits	Field	Description
7	ISOUPDATE	When set, the USB controller will wait for an SOF token from the time TxPktRdy is set before sending the packet. If an IN token is received before an SOF token, then a zero length data packet will be sent. Note: this is only valid in Peripheral Mode. This bit only affects endpoints performing Isochronous transfers.
6	SOFTCONN	If Soft Connect/Disconnect feature is enabled, then the USB D+/D-lines are enabled when this bit is set and tri-stated when this bit is cleared. Note: This is only valid in Peripheral Mode.
5	HSEN	When set, the USB controller negotiates for high-speed mode when the device is reset by the hub. If not set, the device will only operate in full-speed mode.
4	HSMODE	This bit is set when the USB controller has successfully negotiated for high-speed mode.
3	RESET	This bit is set when reset signaling is present on the bus. Note: this bit is Read/Write in Host Mode, but read-only in peripheral mode.
2	RESUME	Set to generate resume signaling when the controller is in suspend mode. The bit should be cleared after 10 ms (a maximum of 15 ms) to end resume signaling. In Host mode, this bit is also automatically set when resume signaling from the target is detected while the USB controller is suspended.
1	SUSPENDM	In Host mode, this bit should be set to enter suspend mode. In peripheral mode, this bit is set on entry into suspend mode. It is cleared when the interrupt register is read, or the RESUME bit is set.
0	ENSUSPM	Set to enable the SUSPENDM output.

24.9.6.1.3 Interrupt Register for Endpoint 0 Plus Transmit Endpoints 1 to 15 (USBn_INTRTX)

The interrupt register for endpoint 0 plus transmit endpoints 1 to 15 (USBn_INTRTX) is a 16-bit read-only register that indicates which interrupts are currently active for endpoint 0 and the TX endpoints 1-15. Note also that all active interrupts are cleared when this register is read.

The interrupt register for endpoint 0 plus transmit endpoints 1 to 15 is shown in Figure 24-149 and described in Table 24-160.

24.9.6.1.4 Interrupt Register for Receive Endpoints 1 to 15 (INTRRX)

The interrupt register for receive endpoints 1 to 15 (INTRRX) is a 16-bit read-only register that indicates which of the interrupts for Rx Endpoints 1-15 are currently active. Note also that all active interrupts are cleared when this register is read.

The interrupt register for receive endpoints 1 to 15 is shown in Figure 24-150 and described in Table 24-161.

24.9.6.1.5 Interrupt Enable Register for INTRTX (INTRTXE)

The interrupt enable register for INTRTX (INTRTXE) is a 16-bit register that provides interrupt enable bits for the interrupts in IntrTx. On reset, the bits corresponding to endpoint 0 and the TX endpoints are set to 1. This register is shown in Figure 24-151 and described in Table 24-162.

24.9.6.1.7 Interrupt Register for Common USB Interrupts (USBn_INTRUSB)

The interrupt register for common USB interrupts (USBn_INTRUSB) is an 8-bit read-only register that indicates which USB interrupts are currently active. All active interrupts will be cleared when this register is read. This register is shown in Figure 24-153 and described in Table 24-164.

Figure 24-153. Interrupt Register for Common USB Interrupts (USBn_INTRUSB)

Table 24-164. Interrupt Register for Common USB Interrupts (USBn_INTRUSB) Field Descriptions

Bits	Field	Description
7	VBUSERR	Set when VBus drops below the VBus valid threshold during a session. Only valid when the USB controller is 'A' device. All active interrupts will be cleared when this register is read.
6	SESSREQ	Set when session request signaling has been detected. Only valid when USB controller is 'A' device.
5	DISCON	Set in host mode when a device disconnect is detected. Set in peripheral mode when a session ends.
4	CONN	Set when a device connection is detected. Only valid in host mode.
3	SOF	Set when a new frame starts.
2	RESET_BABBLE	Set in peripheral mode when reset signaling is detected on the bus set in host mode when babble is detected.
1	RESUME	Set when resume signaling is detected on the bus while the USB controller is in suspend mode.
0	SUSPEND	Set when suspend signaling is detected on the bus only valid in peripheral mode.

24.9.6.1.8 Interrupt Enable Register for INTRUSB (USBn_INTRUSBE)

The interrupt enable register for INTRUSB (USBn_INTRUSBE) is an 8-bit register that provides interrupt enable bits for each of the interrupts in USBn_INTRUSB. This register is shown in Figure 24-154 and described in Table 24-165.

Figure 24-154. Interrupt Enable Register for INTRUSB (USBn_INTRUSBE)

2	RESET_BABBLE	Reset interrupt enable
1	RESUME	Resume interrupt enable
0	SUSPEND	Suspend interrupt enable

24.9.6.1.9 Frame Number Register (USBn_FRAME)

The frame number register (USBn_FRAME) is a 16-bit read-only register that holds the last received frame number. This register is shown in Figure 24-155 and described in Table 24-166.

Figure 24-155. Frame Number Register (USBn_FRAME)

Bits	Field	Description
15-11	Reserved	Reserved
10-0	FRAMENUMBER	Last received frame number

24.9.6.1.10 Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX)

Each TX endpoint and each Rx endpoint have their own set of control/status registers located between Core_Offset 100h-1FFh. In addition one set of TX control/status and one set of Rx control/status registers appear at Core_Offset 10h-19h. This block of memory can be used as a proxy to access endpoint configuration registers. Index is a 4-bit register that determines which endpoint control/status registers are accessed.

Before accessing an endpoint's control/status registers at Core_Offset 10h-19h, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory map.

The index register for selecting the endpoint status and control registers is shown in Figure 24-156 and described in Table 24-167.

Figure 24-156. Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX)

7	4	3	0
Reserved		EPSEL	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-167. Index Register for Selecting the Endpoint Status and Control Registers (USBn_INDEX) Field Descriptions

Bits	Field	Description
7-4	Reserved	Reserved
3-0	EPSEL	Each transmit endpoint and each receive endpoint have their own set of control/status registers. EPSEL determines which endpoint control/status registers are accessed. Before accessing an endpoint's control/status registers, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory-map.

24.9.6.1.11 Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE)

The register to enable the USB 2.0 test modes (USBn_TESTMODE) is an 8-bit register that is primarily used to put the USB controller into one of the four test modes for high-speed operation described in the USB 2.0 specification – in response to a SET FEATURE: TESTMODE command. It is not used in normal operation.

The register to enable the USB 2.0 test modes is shown in Figure 24-157 and described in Table 24-168.

Figure 24-157. Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE)

7	6	5	4	3	2	1	0
FORCE_HOST	FIFO_ACCESS	FORCE_FS	FORCE_HS	TEST_PACKET	TEST_K	TEST_J	TEST_SE0_NAK
R/W-0	W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-168. Register to Enable the USB 2.0 Test Modes (USBn_TESTMODE) Field Descriptions

Bits	Field	Description
7	FORCE_HOST	Set this bit to forcibly put the USB controller into Host mode when SESSION bit is set, regardless of whether it is connected to any peripheral. The controller remains in Host mode until the session bit is cleared, even if a device is disconnected. And if the FORCE_HOST but remains set, it re-enters Host mode next time the SESSION bit is set. The operating speed is determined using the FORCE_HS and FORCE_FS bits.
6	FIFO_ACCESS	Set this bit to transfer the packet in EP0 Tx FIFO to EP0 Receive FIFO. It is cleared automatically.
5	FORCE_FS	Set this bit to force the USB controller into full-speed mode when it receives a USB reset.
4	FORCE_HS	Set this bit to force the USB controller into high-speed mode when it receives a USB reset.
3	TEST_PACKET	Set this bit to enter the Test_Packet test mode. In this mode, the USB controller repetitively transmits a 53-byte test packet on the bus, the form of which is defined in the Universal Serial Bus Specification Revision 2.0. Note: The test packet has a fixed format and must be loaded into the endpoint 0 FIFO before the test mode is entered.
2	TEST_K	Set this bit to enter the Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.
1	TEST_J	Set this bit to enter the Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.
0	TEST_SE0_NAK	Set this bit to enter the Test_SE0_NAK test mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK.

24.9.6.2 Indexed Register Space

This is a block of the core register space that is used as a proxy to access the configuration and status registers of an endpoint. Mapping is done by programming the INDEX register with the endpoint number. Table 24-169 lists the registers.

Table 24-169. Indexed Region Registers

Core Address Offset	Acronym	Indexed Region Registers
10h	USBn_TXMAXP	Maximum Packet Size for Peripheral/Host Transmit Endpoint
12h	USBn_PERI_CSR0	Control Status Register for Endpoint 0 in Peripheral Mode
12h	USBn_HOST_CSR0	Control Status Register for Endpoint 0 in Host Mode
12h	USBn_PERI_TXCSR	Control Status Register for Peripheral Transmit Endpoint
12h	USBn_HOST_TXCSR	Control Status Register for Host Transmit Endpoint
14h	USBn_RXMAXP	Maximum Packet Size for Peripheral/Host Receive Endpoint
16h	USBn_PERI_RXCSR	Control Status Register for Peripheral Receive Endpoint
16h	USBn_HOST_RXCSR	Control Status Register for Host Receive Endpoint
18h	USBn_COUNT0	Count 0 Register
18h	USBn_RXCOUNT	Receive Count Register
1Ah	USBn_HOST_TYPE0	Type Register (Host mode only)
1Ah	USBn_HOST_TXTYPE	Transmit Type Register (Host mode only)
1Bh	USBn_HOST_NAKLIMIT0	NAKLimit0 Register (Host mode only)
1Bh	USBn_HOST_TXINTERVAL	Transmit Interval Register (Host mode only)
1Ch	USBn_HOST_RXTYPE	Receive Type Register (Host mode only)
1Dh	USBn_HOST_RXINTERVAL	Receive Interval Register (Host mode only)
1Fh	USBn_CONFIGDATA	Configuration Data Register

24.9.6.2.1 Maximum Packet Size for Peripheral/Host Transmit Endpoint Register (USBn_TXMAXP)

The maximum packet size for peripheral/host transmit endpoint register (USBn_TXMAXP) defines the maximum amount of data that can be transferred through the selected Tx endpoint in a single operation. There is a TXMAXP register for each Tx endpoint (except Endpoint 0). Endpoint 0 resource is hardened in design and max packet size is set to 64 bytes and no user configuration is required or does not exist.

The maximum packet size for peripheral/host transmit endpoint register is shown in Figure 24-158 and described in Table 24-170.

Figure 24-158. Maximum Packet Size for Peripheral/Host Transmit Endpoint Register (USBn_TXMAXP)

15	11	10	0
Reserved		MAXPAYLOAD	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-170. Maximum Packet Size for Peripheral/Host Transmit Endpoint (USBn_TXMAXP) Field Descriptions

Bits	Field	Description
15-11	Reserved	Reserved

Table 24-170. Maximum Packet Size for Peripheral/Host Transmit Endpoint (USBn_TXMAXP) Field Descriptions (continued)

Bits	Field	Description
10-0	MAXPAYLOAD	The maximum payload transmitted in a single transaction. The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB specification on packet sizes for bulk, interrupt, and isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the standard endpoint descriptor for the associated endpoint. A mismatch could cause unexpected results.

24.9.6.2.2 Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0)

The control status register for endpoint 0 in peripheral mode (USBn_PERI_CSR0) is a 16-bit register that provides control and status bits for endpoint 0 when USB controller assumes the role of a peripheral. This register is shown in Figure 24-159 and described in Table 24-171.

Figure 24-159. Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0)

15						9	8
Reserved							FLUSHFIFO
R-0							W-0
7	6	5	4	3	2	1	0
SERV_ SETUPEND	SERV_ RXPKTRDY	SENDSTALL	SETUPEND	DATAEND	SENTSTALL	TXPKTRDY	RXPKTRDY
W-0	W-0	W-0	R-0	W-0	R/W-0	R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-171. Control Status Register for Endpoint 0 in Peripheral Mode (USBn_PERI_CSR0) Field Descriptions

Bits	Field	Description
15-9	Reserved	Reserved
8	FLUSHFIFO	Set this bit to flush the next packet to be transmitted/read from the endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.
7	SERV_SETUPEND	Set this bit to clear the SETUPEND bit. It is cleared automatically.
6	SERV_RXPKTRDY	Set this bit to clear the RXPKTRDY bit. It is cleared automatically.
5	SENDSTALL	Set this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically.
4	SETUPEND	This bit will be set when a control transaction ends before the DATAEND bit has been set. An interrupt is generated, and the FIFO will be flushed at this time. The bit is cleared by the writing a 1 to the SERV_SETUPEND bit.
3	DATAEND	Set this bit to 1: • When setting TXPKTRDY for the last data packet. • When clearing RXPKTRDY after unloading the last data packet. • When setting TXPKTRDY for a zero length data packet. It is cleared automatically.
2	SENTSTALL	This bit is set when a STALL handshake is transmitted. This bit should be cleared.
1	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPKTRDY	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. This bit is cleared by setting the SERV_RXPKTRDY bit.

24.9.6.2.3 Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0)

The control status register for endpoint 0 in host mode (USBn_HOST_CSR0) is a 16-bit register that provides control and status bits for endpoint 0 when USB controller assumes the role of a host. This register is shown in Figure 24-160 and described in Table 24-172.

Figure 24-160. Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0)

15	14	13	12	11	10	9	8

NAK_TIMEOUT	STATUSPKT	REQPKT	ERROR	SETUPPKT	RXSTALL	TXPKTRDY	RXPKTRDY
W-0	R/W-0	R/W-0	W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-172. Control Status Register for Endpoint 0 in Host Mode (USBn_HOST_CSR0) Field Descriptions

Bits	Field	Description
15-12	Reserved	Reserved
11	DSPING	The CPU writes a 1 to the DSPING bit to instruct the core not to issue PING tokens in the data and status phases of a high-speed control transfer (for use with devices that do not respond to PING).
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the EP0 data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	FLUSHFIFO	Write 1 to this bit to flush the next packet to be transmitted/read from the Endpoint 0 FIFO. The FIFO pointer is reset and the TXPKTRDY/RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless TXPKTRDY/RXPKTRDY is set.
7	NAK_TIMEOUT	This bit will be set when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the NAKLIMIT0 register. This bit should be cleared to allow the endpoint to continue.
6	STATUSPKT	Set this bit at the same time as the TXPKTRDY or REQPKT bit is set, to perform a status stage transaction. Setting this bit ensures that the data toggle is set so that a DATA1 packet is used for the Status Stage transaction.
5	REQPKT	Set this bit to request an IN transaction. It is cleared when RXPKTRDY is set.
4	ERROR	This bit is set when three attempts have been made to perform a transaction with no response from the peripheral. You should clear this bit. An interrupt is generated when this bit is set.
3	SETUPPKT	Set this bit, at the same time as the TXPKTRDY bit is set, to send a SETUP token instead of an OUT token for the transaction.
2	RXSTALL	This bit is set when a STALL handshake is received. You should clear this bit.
1	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.
0	RXPKTRDY	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. Clear this bit by setting the SERV_RXPKTRDY bit.

24.9.6.2.4 Control Status Register for Peripheral Transmit Endpoint (USBn_PERI_TXCSR)

The control status register for peripheral transmit endpoint (USBn_PERI_TXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a peripheral. There is a TXCSR register for each configured Tx endpoint (not including Endpoint 0).

The control status register for peripheral transmit endpoint is shown in Figure 24-161 and described in Table 24-173.

Figure 24-161. Control Status Register for Peripheral Transmit Endpoint (USBn_PERI_TXCSR)

15	14	13	12	11	10	9	8

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0	
7	6	5	4	3	2	1	0
Reserved	CLRDATATOG	SENTSTALL	SENDSTALL	FLUSHFIFO	UNDERRUN	FIFO NOTEMPTY	TXPKTRDY
R-0	W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-173. Control Status Register for Peripheral Transmit Endpoint (USBn_PERI_TXCSR) Field Descriptions

Bits	Field	Description
15	AUTOSET	DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA. CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually.
14	ISO	Set this bit to enable the Tx endpoint for Isochronous transfers, and clear it to enable the Tx endpoint for Bulk or Interrupt transfers.
13	MODE	Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	This bit should always be set to 1 when the DMA is enabled.
9-7	Reserved	Reserved
6	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
5	SENTSTALL	This bit is set automatically when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
4	SENDSTALL	Write a 1 to this bit to issue a STALL handshake to an IN token. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
3	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit is cleared. Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FlushFIFO may need to be set twice to completely clear the FIFO.
2	UNDERRUN	This bit is set automatically if an IN token is received when TXPKTRDY is not set. You should clear this bit.
1	FIFONOTEMPTY	This bit is set when there is at least 1 packet in the Tx FIFO. You should clear this bit.
0	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

24.9.6.2.5 Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR)

The control status register for host transmit endpoint (USBn_HOST_TXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a host. There is a TXCSR register for each configured Tx endpoint (not including Endpoint 0).

The control status register for host transmit endpoint is shown in Figure 24-162 and described in Figure 24-162.

Figure 24-162. Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR)

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-174. Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR) Field Descriptions

Bits	Field	Description
15	AUTOSET	DMA Mode: The CPU needs to set the AUTOSET bit prior to enabling the Tx DMA. CPU Mode: If the CPU sets the AUTOSET bit, the TXPKTRDY bit will be automatically set when data of the maximum packet size (value in TXMAXP) is loaded into the Tx FIFO. If a packet of less than the maximum packet size is loaded, then the TXPKTRDY bit will have to be set manually.
14	Reserved	Reserved
13	MODE	Set this bit to enable the endpoint direction as Tx, and clear the bit to enable it as Rx. Note: This bit has any effect only where the same endpoint FIFO is used for both Transmit and Receive transactions.
12	DMAEN	Set this bit to enable the DMA request for the Tx endpoint.
11	FRCDATATOG	Set this bit to force the endpoint data toggle to switch and the data packet to be cleared from the FIFO, regardless of whether an ACK was received. This can be used by Interrupt Tx endpoints that are used to communicate rate feedback for Isochronous endpoints.
10	DMAMODE	This bit should always be set to 1 when the DMA is enabled.
9	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
8	DATATOG	When read, this bit indicates the current state of the Tx EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
7	NAK_TIMEOUT	This bit will be set when the Tx endpoint is halted following the receipt of NAK responses for longer than the time set as the NAKLIMIT by the TXINTERVAL register. It should be cleared to allow the endpoint to continue. Note: This is valid only for Bulk endpoints.
6	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
5	RXSTALL	This bit is set when a STALL handshake is received. The FIFO is flushed and the TXPKTRDY bit is cleared (see below). You should clear this bit.
4	SETUPPKT	Set this bit at the same time as TXPKTRDY is set, to send a SETUP token instead of an OUT token for the transaction. Note: Setting this bit also clears the DATATOG bit.
3	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be transmitted from the endpoint Tx FIFO. The FIFO pointer is reset and the TXPKTRDY bit (below) is cleared. Note: FlushFIFO has no effect unless the TXPKTRDY bit is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
2	ERROR	The USB controller sets this bit when 3 attempts have been made to send a packet and no handshake packet has been received. You should clear this bit. An interrupt is generated when the bit is set. This is valid only when the endpoint is operating in Bulk or Interrupt mode.
1	FIFONOTEMPTY	The USB controller sets this bit when there is at least 1 packet in the Tx FIFO.

Table 24-174. Control Status Register for Host Transmit Endpoint (USBn_HOST_TXCSR) Field Descriptions (continued)

Bits	Field	Description
0	TXPKTRDY	Set this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

24.9.6.2.6 Maximum Packet Size for Peripheral/Host Receive Endpoint Register (USBn_RXMAXP)

The maximum packet size for peripheral/host receive endpoint register (USBn_RXMAXP) defines the maximum amount of data that can be transferred through the selected Rx endpoint in a single operation. There is a RXMAXP register for each Rx endpoint (except Endpoint 0). Endpoint 0 resource is hardened in design and max packet size is set to 64 bytes and no user configuration is required or does not exist.

The maximum packet size for peripheral/host receive endpoint register is shown in Figure 24-163 and described in Table 24-175.

Figure 24-163. Maximum Packet Size for Peripheral/Host Receive Endpoint Register (USBn_RXMAXP)

Reserved		MAXPAYLOAD	
R-0		RW-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-175. Maximum Packet Size for Peripheral Host Receive Endpoint (USBn_RXMAXP) Field Descriptions

Bit	Field	Description
15-11	Reserved	Reserved
10-0	MAXPAYLOAD	Defines the maximum amount of data that can be transferred through the selected Receive endpoint in a single frame/microframe (high-speed transfers). The value set can be up to 1024 bytes, but is subject to the constraints placed by the USB specification on packet sizes for bulk, interrupt, and isochronous transfers in full-speed and high-speed operations. The value written to this register should match the wMaxPacketSize field of the standard endpoint descriptor for the associated endpoint. A mismatch could cause unexpected results.

24.9.6.2.7 Control Status Register for Peripheral Receive Endpoint (USBn_PERI_RXCSR)

The control status register for peripheral receive endpoint (USBn_PERI_RXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Tx endpoint when controller assumes the role of a peripheral. There is a RXCSR register for each configured Rx endpoint (not including endpoint 0).

The control status register for peripheral receive endpoint is shown in Figure 24-164 and described in Table 24-176.

Figure 24-164. Control Status Register for Peripheral Receive Endpoint (USBn_PERI_RXCSR)

LEGEND: R/W = Read/Write; R = Read only; W = Write only; -*n* = value after reset

Table 24-176. Control Status Register for Peripheral Receive Endpoint (USBn_PERI_RXCSR) Field Descriptions

Bit	Field	Description
15	AUTOCLEAR	DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA. CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually.
14	ISO	Set this bit to enable the Receive endpoint for Isochronous transfers, and clear it to enable the Receive endpoint for bulk/interrupt transfers.
13	DMAEN	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	DISNYET: Applies only for bulk/interrupt transactions: The CPU sets this bit to disable the sending of NYET handshakes. When set, all successfully received Rx packets are ACK'd including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints. PID_ERROR: Applies only for ISO Transactions: The core sets this bit to indicate a PID error in the received packet.
11	DMAMODE	Always clear this bit to 0.
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	Reserved	Reserved
7	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
6	SENTSTALL	This bit is set when a STALL handshake is transmitted. The FIFO is flushed and the TXPKTRDY bit is cleared. You should clear this bit.
5	SENDSTALL	Write a 1 to this bit to issue a STALL handshake. Clear this bit to terminate the stall condition. Note: This bit has no effect where the endpoint is being used for Isochronous transfers.
4	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
3	DATAERROR	This bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error. It is cleared when RXPKTRDY is cleared. Note: This bit is only valid when the endpoint is operating in ISO mode. In Bulk mode, it always returns zero.
2	OVERRUN	This bit is set if an OUT packet cannot be loaded into the Receive FIFO. You should clear this bit. Note: This bit is only valid when the endpoint is operating in ISO mode. In bulk mode, it always returns zero.
1	FIFOFULL	This bit is set when no more packets can be loaded into the Receive FIFO.

Table 24-176. Control Status Register for Peripheral Receive Endpoint (USBn_PERI_RXCSR) Field Descriptions (continued)

Bit	Field	Description
0	RXPKTRDY	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

24.9.6.2.8 Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR)

The control status register for host receive endpoint (USBn_HOST_RXCSR) is a 16-bit register that provides control and status bits for transfers through the currently-selected Rx endpoint when controller assumes the role of a host. There is a RXCSR register for each configured Rx endpoint (not including endpoint 0).

The control status register for host receive endpoint is shown in Figure 24-165 and described in Table 24-177.

Table 24-177. Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR) Field Descriptions

Bit	Field	Description
15	AUTOCLEAR	DMA Mode: The CPU sets the AUTOCLEAR bit prior to enabling the Rx DMA. CPU Mode: If the CPU sets the AUTOCLEAR bit, then the RXPKTRDY bit will be automatically cleared when a packet of RXMAXP bytes has been unloaded from the Receive FIFO. When packets of less than the maximum packet size are unloaded, RXPKTRDY will have to be cleared manually.
14	AUTOREQ	If the CPU sets the AUTOREQ bit, then the REQPKT bit will be automatically set when the RXPKTRDY bit is cleared. Note: This bit is automatically cleared when a short packet is received.
13	DMAEN	Set this bit to enable the DMA request for the Receive endpoints.
12	DISNYET	Set this bit to disable the sending of NYET handshakes. When set, all successfully received Receive packets are ACKED including at the point at which the FIFO becomes full. Note: This bit only has any effect in high-speed mode, in which mode it should be set for all Interrupt endpoints.
11	DMAMODE	Always clear this bit to 0.
10	DATATOGWREN	Write 1 to this bit to enable the DATATOG bit to be written. This bit is automatically cleared once the new value is written to DATATOG.
9	DATATOG	When read, this bit indicates the current state of the Receive EP data toggle. If DATATOGWREN is high, this bit can be written with the required setting of the data toggle. If DATATOGWREN is low, any value written to this bit is ignored.
8	Reserved	Reserved
7	CLRDATATOG	Write a 1 to this bit to reset the endpoint data toggle to 0.
6	RXSTALL	When a STALL handshake is received, this bit is set and an interrupt is generated. You should clear this bit.
5	REQPKT	Write a 1 to this bit to request an IN transaction. It is cleared when RXPKTRDY is set.

Table 24-177. Control Status Register for Host Receive Endpoint (USBn_HOST_RXCSR) Field Descriptions (continued)

Bit	Field	Description
4	FLUSHFIFO	Write a 1 to this bit to flush the next packet to be read from the endpoint Receive FIFO. The FIFO pointer is reset and the RXPKTRDY bit is cleared. Note: FLUSHFIFO has no effect unless RXPKTRDY is set. Also note that, if the FIFO is double-buffered, FLUSHFIFO may need to be set twice to completely clear the FIFO.
3	DATAERR_NAKTIMEOUT	When operating in ISO mode, this bit is set when RXPKTRDY is set if the data packet has a CRC or bit-stuff error and cleared when RXPKTRDY is cleared. In Bulk mode, this bit will be set when the Receive endpoint is halted following the receipt of NAK responses for longer than the time set as the NAK Limit by the RXINTERVAL register. You should clear this bit to allow the endpoint to continue.
2	ERROR	The USB controller sets this bit when 3 attempts have been made to receive a packet and no data packet has been received. You should clear this bit. An interrupt is generated when the bit is set. Note: This bit is only valid when the transmit endpoint is operating in Bulk or Interrupt mode. In ISO mode, it always returns zero.
1	FIFOFULL	This bit is set when no more packets can be loaded into the Receive FIFO.
0	RXPKTRDY	This bit is set when a data packet has been received. You should clear this bit when the packet has been unloaded from the Receive FIFO. An interrupt is generated when the bit is set.

24.9.6.2.9 Count 0 Register (USBn_COUNT0)

The count 0 register (USBn_COUNT0) is a 7-bit read-only register that indicates the number of received data bytes in the Endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the RXPKTRDY bit in the control status register for host receive endpoint (USBn_HOST_RXCSR) is set. This register is shown in Figure 24-166 and described in Table 24-178.

Figure 24-166. Count 0 Register (USBn_COUNT0)

Bit	Field	Description
15-7	Reserved	Reserved
6-0	EP0RXCOUNT	Indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPKTRDY of USBn_PERI_CSR0 or USBn_HOST_CSR0 is set.

24.9.6.2.10 Receive Count Register (USBn_RXCOUNT)

The receive count register (USBn_RXCOUNT) is a 13-bit read-only register that holds the number of received data bytes in the packet currently in line to be read from the Rx FIFO for endpoints other than endpoint 0. The value returned changes as the FIFO is unloaded and is only valid while the RXPKTRDY bit in the control status register for host receive endpoint (USBn_HOST_RXCSR) is set.

The receive count register is shown in Figure 24-167 and described in Table 24-179.

Bit	Field	Description
15-13	Reserved	Reserved
12-0	EPRXCOUNT	Holds the number of received data bytes in the packet in the Receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while RXPKTRDY of PERI_RXCSR or HOST_RXCSR is set.

24.9.6.2.11 Type Register (Host mode only) (USBn_HOST_TYPE0)

The type register (Host mode only) (USBn_HOST_TYPE0) is an 8-bit register, meaningful only when controller assumes the role of a host, of which only bits 6 and 7 are implemented. These bits should be written with the operating speed of the targeted device. This register is shown in Figure 24-168 and described in Table 24-180.

		2h	Full
		3h	Low
5-0	Reserved	0	Reserved

24.9.6.2.12 Transmit Type Register (Host mode only) (USBn_HOST_TXTYPE)

The transmit type register (Host mode only) (USBn_HOST_TXTYPE) is an 8-bit register that should be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently-selected Tx endpoint, and its operating speed. There is a TXTYPE register for each configured Tx endpoint (except Endpoint 0).

The transmit type register is shown in Figure 24-169 and described in Table 24-181.

		0	Control
		1h	Isochronous
		2h	Bulk
		3h	Interrupt
3-0	TENDPN	0-Fh	Set this value to the endpoint number contained in the transmit endpoint descriptor returned to the USB controller during device enumeration.

24.9.6.2.13 NAKLimit0 Register (Host mode only) (USBn_HOST_NAKLIMIT0)

The NAKLIMIT0 register (Host mode only) (USBn_HOST_NAKLIMIT0) is a 5-bit register that sets the number of frames/microframes (high-speed transfers) after which endpoint 0 should timeout on receiving a stream of NAK responses. (Equivalent settings for other endpoints can be made through their TXINTERVAL and RXINTERVAL registers.) The number of frames/microframes selected is 2(m - 1) (where m is the value set in the register, valid values 2-16). If the host receives NAK responses from the target for more frames than the number represented by the Limit set in this register, the endpoint will be halted. Note: A value of 0 or 1 disables the NAK timeout function.

The NAKLIMIT0 register is shown in Figure 24-170 and described in Table 24-182.

Figure 24-170. NAKLimit0 Register (Host mode only) (USBn_HOST_NAKLIMIT0)

7	5	4	0
Reserved		EP0NAKLIMIT	
R-0		R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-182. NAKLimit0 Register (Host mode only) (USBn_HOST_NAKLIMIT0) Field Descriptions

Bit	Field	Description
7-5	Reserved	Reserved
4-0	EP0NAKLIMIT	Sets the number of frames/microframes (high-speed transfers) after which endpoint 0 should time out on receiving a stream of NAK responses. The number of frames/microframes selected is 2(-1) (where m is the value set in the register, valid values 2-16). If the host receives NAK responses from the target for more frames than the number represented by the Limit set in this register, the endpoint will be halted. Note: A value of 0 or 1 disables the NAK timeout function.

24.9.6.2.14 Transmit Interval Register (Host mode only) (USBn_HOST_TXINTERVAL)

The transmit interval register (Host mode only) (USBn_HOST_TXINTERVAL) is an 8-bit register (meaningful only when controller assumes the role of a host) that, for interrupt and isochronous transfers, defines the polling interval for the currently-selected Tx endpoint. For bulk endpoints, this register sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a TXINTERVAL register for each configured Tx endpoint (except endpoint 0).

The transmit interval register is shown in Figure 24-171 and described in Table 24-183.

Figure 24-171. Transmit Interval Register (Host mode only) (USBn_HOST_TXINTERVAL)

7							0

Table 24-183. Transmit Interval Register (Host mode only) (USBn_HOST_TXINTERVAL) Field Descriptions

Bit	Field	Description			
7-0	POLINTVL_ NAKLIMIT	For interrupt and isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except endpoint 0). In each case, the value that is set defines a number of frames/microframes (high-speed transfers), as follows:			
		Transfer Type	Speed	Valid values (m)	Interpretation
		Interrupt	Low Speed or Full Speed	1-255	Polling interval is m frames
				1-16	Polling interval is 2(-1) microframes
		Isochronous	Full Speed or High Speed	1-16	Polling interval is 2(-1) frames/microframes
		Bulk	Full Speed or High Speed	2-16	NAK Limit is 2(-1)frames/microframes
		Note: A value of 0 or 1 disables the NAK timeout function.			

24.9.6.2.15 Receive Type Register (Host mode only) (USBn_HOST_RXTYPE)

The receive type register (Host mode only) (USBn_HOST_RXTYPE) is an 8-bit register that should be written with the endpoint number to be targeted by the endpoint, the transaction protocol to use for the currently-selected Rx endpoint, and its operating speed. There is a RXTYPE register for each configured Rx endpoint (except endpoint 0).

The receive type register is shown in Figure 24-172 and described in Figure 24-172.

24.9.6.2.16 Receive Interval Register (Host mode only) (USBn_HOST_RXINTERVAL)

The receive interval register (Host mode only) (USBn_HOST_RXINTERVAL) is an 8-bit register (only meaningful in host mode only) that, for Interrupt and Isochronous transfers, defines the polling interval for the currently-selected Rx endpoint. For bulk endpoints, this register sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a RXINTERVAL register for each configured Rx endpoint (except endpoint 0).

The receive interval register is shown in Figure 24-173 and described in Table 24-185.

Bit	Field	Description			
7-0	POLINTVL_ NAKLIMIT	For interrupt and isochronous transfers, defines the polling interval for the currently-selected transmit endpoint. For bulk endpoints, sets the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses. There is a transmit interval register for each configured transmit endpoint (except endpoint 0). In each case, the value that is set defines a number of frames/microframes (high-speed transfers), as follows:			
		Transfer Type	Speed	Valid values (m)	Interpretation
		Interrupt	Low Speed or Full Speed	1-255	Polling interval is m frames
			High Speed	1-16	Polling interval is 2(-1) microframes
		Isochronous	Full Speed or High Speed	1-16	Polling interval is 2(-1) frames/microframes
		Bulk	Full Speed or High Speed	2-16	NAK Limit is 2(-1)frames/microframes
		Note: A value of 0 or 1 disables the NAK timeout function.			

24.9.6.2.17 Configuration Data Register (USBn_CONFIGDATA)

The configuration data register (USBn_CONFIGDATA) is an 8-bit read-only register that returns information about the selected core configuration. This register information can only be accessed from Indexed Region and INDEX has to be programmed, with zero, selecting endpoint 0. This register is shown in Figure 24-174 and described in Table 24-186.

Figure 24-174. Configuration Data Register (USBn_CONFIGDATA)

		0	High-bandwidth Tx ISO endpoint support is not selected.
		1	High-bandwidth Tx ISO endpoint support is selected.
2	DYNFIFO		Indicates dynamic FIFO sizing. (INDEX register needs to be cleared to 0.)
		0	Dynamic FIFO sizing option is not selected.
		1	Dynamic FIFO sizing option is selected.
1	SOFTCONE		Indicates soft connect/disconnect. (INDEX register needs to be cleared to 0.)
		0	Soft connect/disconnect option is not selected.
		1	Soft connect/disconnect option is selected.
0	UTMIDATAWIDTH		Indicates selected UTMI data width. (INDEX register needs to be cleared to 0.)
		0	8 bits
		1	16 bits

24.9.7 FIFOs

This address range provides access to the endpoint FIFOs. Register offset addresses for this block is 20h to 5Fh.

24.9.7.1 Transmit and Receive FIFO Register for Endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15)

This address range provides 16 addresses for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the TxFIFO for the corresponding endpoint. Reading from these addresses unloads data from the RxFIFO for the corresponding endpoint. The address range is 20h – 5Fh and the FIFOs are located on 32-bit double-word boundaries (endpoint 0 at 20h, endpoint 1 at 24h ... Endpoint 15 at 5Ch).

Note 1: Transfers to and from FIFOs may be 8-bit, 16-bit or 32-bit as required, and any combination of access is allowed provided the data accessed is contiguous. However, all the transfers associated with one packet must be of the same width so that the data is consistently byte-, word- or double-word-aligned. The last transfer may however contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

Note 2: Depending on the size of the FIFO and the expected maximum packet size, the FIFOs support either single-packet or doublepacket buffering. However, burst writing of multiple packets is not supported as flags need to be set after each packet is written.

Note 3: Following a STALL response or a Tx strike out error on dndpoint 1 – 15, the associated FIFO is completely flushed.

The transmit and receive FIFO register for endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15) is shown in Figure 24-175 and described in Table 24-187.

Figure 24-175. Transmit and Receive FIFO Register for Endpoint 0 - 15 (USBn_FIFO0 – USBn_FIFO15)

24.9.7.2 Additional Control and Configuration Registers

Table 24-188 lists the additional Control and Configuration registers.

Table 24-188. Additional Control and Configuration Registers

Core Address Offset	Acronym	Control and Configuration Registers
60h	USBn_DEVCTL	Device Control Register
62h	USBn_TXFIFOSZ	Transmit Endpoint FIFO Size Register
63h	USBn_RXFIFOSZ	Receive Endpoint FIFO Size Register
64h	USBn_TXFIFOADDR	Transmit Endpoint FIFO Address Register
66h	USBn_RXFIFOADDR	Receive Endpoint FIFO Address Register
6Ch	USBn_HWVERS	Hardware Version Register

24.9.7.2.1 Device Control Register (USBn_DEVCTL)

The device control register (USBn_DEVCTL) is an 8-bit read-only register that is used to select whether the USB controller is operating in peripheral mode or in host mode, and for controlling and monitoring the USB VBus line. If the PHY is suspended no PHY clock is received and the VBus is not sampled. This register is shown in Figure 24-176 and described in Table 24-189.

Figure 24-176. Device Control Register (USBn_DEVCTL)

7	6	5	4	3	2	1	0
BDEVICE	FSDEV	LSDEV	VBUS		HOSTMODE	HOSTREQ	SESSION
R-0	R-0	R-0	R-0		R-0	R-0	R-0

LEGEND: R = Read only; -*n* = value after reset

Table 24-189. Device Control Register (USBn_DEVCTL) Field Descriptions

Bit	Field	Value	Description
7	BDEVICE		This read-only bit indicates whether the USB controller is operating as the 'A' device or the 'B' device.
		0	A device
		1	B device
6	FSDEV	0-1	This read-only bit is set when a full-speed or high-speed device has been detected being connected to the port (high-speed devices are distinguished from full-speed by checking for high-speed chirps when the device is reset). Only valid in Host mode.
5	LSDEV	0-1	This read-only bit is set when a low-speed device has been detected being connected to the port. Only valid in Host mode.
4-3	VBUS		These read-only bits encode the current VBus level as follows:
		0	Below session end
		1h	Above session dnd, below AValid
		2h	Above AValid, below VBusValid
		3h	Above VBusValid
2	HOSTMODE	0-1	This read-only bit is set when the USB controller is acting as a Host.
1	HOSTREQ	0-1	When set, the USB controller initiates the Host negotiation when suspend mode is entered. It is cleared when Host negotiation is completed. ('B' device only)
0	SESSION	0-1	When operating as an 'A' device, you must set or clear this bit start or end a session. When operating as a 'B' device, this bit is set/cleared by the USB controller when a session starts/ends. You must also set this bit to initiate the session request protocol. When the USB controller is in suspend mode, you may clear the bit to perform a software disconnect. A special software routine is required to perform SRP. Details will be made available in a later document version.

24.9.7.2.2 Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ)

The allocation of FIFO space to the different endpoints requires the specification for each Tx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The transmit endpoint FIFO size register (USBn_TXFIFOSZ) defines the amount of space that needs to be allocated to the FIFO in either single or double buffering context.

The transmit endpoint FIFO size register is shown in Figure 24-177 and described in Table 24-190.

Figure 24-177. Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ)

7	5	4	3	0
Reserved		DPB	SZ	
R-0		R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-190. Transmit Endpoint FIFO Size Register (USBn_TXFIFOSZ) Field Descriptions

Bit	Field	Description
7-5	Reserved	Reserved
4	DPB	Double packet buffering enable. Single packet buffering is supported. Double packet buffering is enabled
3-0	SZ	Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as 2(m+3) for single packet buffering and 2(m+4) for dual packet buffering.

24.9.7.2.3 Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ)

The allocation of FIFO space to the different endpoints requires the specification for each Rx endpoint

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The receive endpoint FIFO size register (USBn_RXFIFOSZ) defines the amount of space that needs to be allocated to the FIFO in either single or double buffering context.

The receive endpoint FIFO size register is shown in Figure 24-178 and described in Table 24-191.

Figure 24-178. Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ)

7	6	5	4	3	0
Reserved			DPB	SZ	
R-0			R/W-0	R/W-0	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-191. Receive Endpoint FIFO Size Register (USBn_RXFIFOSZ) Field Descriptions

Bit	Field	Description
7-5	Reserved	Reserved
4	DPB	Double packet buffering enable. Single packet buffering is supported. Double packet buffering is enabled
3-0	SZ	Maximum packet size to be allowed (before any splitting within the FIFO of Bulk packets prior to transmission). If m = SZ, the FIFO size is calculated as 2(m+3) for single packet buffering and 2(m+4) for dual packet buffering.

24.9.7.2.4 Transmit Endpoint FIFO Address Register (USBn_TXFIFOADDR)

The allocation of FIFO space to the different endpoints requires the specification for each Tx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The transmit endpoint FIFO address register (USBn_TXFIFOADDR) the coding for the start address of the FIFO. Note that the 1st 64 bytes of the FIFO RAM is reserved for the use of endpoint 0. Allocation of FIFO should exclude this reserved location.

The transmit endpoint FIFO address register is shown in Figure 24-179 and described in Table 24-192.

Figure 24-179. Transmit Endpoint FIFO Address Register (USBn_TXFIFOADDR)

15	13	12	0
Reserved		ADDR	
R-0		R/W-1FFFh	

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

Table 24-192. Transmit Endpoint FIFO Address Register (USBn_TXFIFOADDR) Field Descriptions

Bit	Field	Description
15-13	Reserved	Reserved
12-0	ADDR	Start address of endpoint FIFO in units of 8 bytes If m = ADDR, then the start address is 8 × m

24.9.7.2.5 Receive Endpoint FIFO Address Register (USBn_RXFIFOADDR)

The allocation of FIFO space to the different endpoints requires the specification for each Rx endpoint:

- The start address of the FIFO within the RAM block
- The maximum size of packet to be supported
- Whether double-buffering is required

The receive endpoint FIFO address register (USBn_RXFIFOADDR) the coding for the start address of the FIFO. Note that the 1st 64 bytes of the FIFO RAM is reserved for the use of endpoint 0. Allocation of FIFO should exclude this reserved location.

The receive endpoint FIFO address register is shown in Figure 24-180 and described in Table 24-193.

Figure 24-180. Receive Endpoint FIFO Address Register (USBn_RXFIFOADDR)

Bit	Field	Description
15-13	Reserved	Reserved
12-0	ADDR	Start address of endpoint FIFO in units of 8 bytes If m = ADDR, then the start address is 8 × m

24.9.7.2.6 Hardware Version Register (USBn_HWVERS)

The hardware version register (USBn_HWVERS) is a 16-bit read-only register that returns information about the version of the RTL from which the core hardware was generated, in particular the RTL version number (REVMAJ.REVMIN). This register is shown in Figure 24-181 and described in Table 24-194.

Figure 24-181. Hardware Version Register (USBn_HWVERS)

15	14 10	9 0
RC	REVMAJ	REVMIN
R-0	R-1Fh	R-3E7h

LEGEND: R = Read only; -*n* = value after reset

Table 24-194. Hardware Version Register (USBn_HWVERS) Field Descriptions

Bit	Field	Description
15	RC	Set to 1 if RTL is used from a Release Candidate, rather than from a full release of the core.
14-10	REVMAJ	Major version of RTL. Range is 0-31.
9-0	REVMIN	Minor version of RTL. Range is 0-999.

24.9.7.3 Target Endpoint Control Registers

Table 24-195 lists the target endpoint control registers. These registers provide target function and hub address details for each of the endpoints. Register addresses consumed by this block is 0x0080 to 0x00FF.

Table 24-195. Target Endpoint Control Registers

Core Address Offset	Acronym	Target Endpoint Control Registers
80h	USBn_TXFUNCADDRm	Transmit Function Address Register
82h	USBn_TXHUBADDRm	Transmit Hub Address Register
83h	USBn_TXHUBPORTm	Transmit Hub Port Register
84h	USBn_RXFUNCADDRm	Receive Function Address Register
86h	USBn_RXHUBADDRm	Receive Hub Address Register
87h	USBn_RXHUBPORTm	Receive Hub Port Register

24.9.7.3.1 Transmit Function Address Register (USBn_TXFUNCADDRm)

The transmit function address register (USBn_TXFUNCADDRm) is a 7-bit register (meaningful in host mode operation only) that records the address of the target function that is to be accessed through the associated endpoint (EPn). USBn_ TXFUNCADDR needs to be defined for each Tx endpoint that is used.

USBn_TXFUNCADDRm needs to be defined for endpoint 0. This register, with the USBn_TXHUBADDRm and USBn_TXHUBPORTm registers, allows the allocation of multiple devices to the USB controller endpoints.

The transmit function address register is shown in Figure 24-182 and described in Table 24-196.

Figure 24-182. Transmit Function Address Register (USBn_TXFUNCADDRm)

7	6	0
Reserved	FUNCADDR	
R-0	R/W-7Fh	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 24-196. Transmit Function Address (USBn_TXFUNCADDRm) Field Descriptions

Bit	Field	Description
7	Reserved	Reserved
6-0	FUNCADDR	Address of target function

24.9.7.3.2 Transmit Hub Address Register (USBn_TXHUBADDRm)

The transmit hub address register (USBn_TXHUBADDRm) is an 8-bit register, like USBn_TXHUBPORTm, that only needs to be written where a full- or low-speed device is connected to Tx endpoint EPn via a high-speed USB 2.0 hub that carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- The lower 7 bits should record the address of this USB 2.0 hub
- The top bit should record whether the hub has multiple transaction translators (clear to 0 if single transaction translator; set to 1 if multiple transaction translators).

If endpoint 0 is connected to a hub, then USBn_TXHUBADDRm need to be defined for this endpoint.

The transmit hub address register is shown in Figure 24-183 and described in Table 24-197.

Figure 24-183. Transmit Hub Address Register (USBn_TXHUBADDRm)

7	6	0
MULT_TRANS	HUBADDR

Bit	Field	Description
7	MULT_TRANS	Set to 1 if hub has multiple transaction translators. Cleared to 0 if only single transaction translator is available.
6-0	HUBADDR	Address of hub

24.9.7.3.3 Transmit Hub Port Register (USBn_TXHUBPORTm)

The transmit hub port register (USBn_TXHUBPORTm) (meaningful in host mode operation only) only needs to be written where a full- or low-speed device is connected to Tx endpoint EPn via a high-speed USB 2.0 hub, which carries out the necessary transaction translation. In such circumstances, these 7-bit read/write registers need to be used to record the port of that USB 2.0 hub through which the target associated with the endpoint is accessed.

If Endpoint 0 is connected to a hub, then USBn_TXHUBPORT needs to be defined for this endpoint.

The transmit hub port register is shown in Figure 24-184 and described in Table 24-198.

Figure 24-184. Transmit Hub Port (USBn_TXHUBPORTm)

7	6	0
Reserved	HUBPORT	
R-0	R/W-7Fh	

LEGEND: R/W = Read/Write; R = Read only; *-n* = value after reset

Table 24-198. Transmit Hub Port Register (USBn_TXHUBPORTm) Field Descriptions

Bit	Field	Description
7	Reserved	Reserved
6-0	HUBPORT	Port number of the hub

24.9.7.3.4 Receive Function Address Register (USBn_RXFUNCADDRm)

The receive function address register (USBn_RXFUNCADDRm) is a 7-bit register (meaningful in host mode operation only) that records the address of the target function that is to be accessed through the associated endpoint (EPn). USBn_ RXFUNCADDR needs to be defined for each Rx endpoint that is used.

USBn_RXFUNCADDRm needs to be defined for endpoint 0. This register, with the USBn_RXHUBADDRm and USBn_RXHUBPORTm registers, allows the allocation of multiple devices to the USB controller endpoints.

The receive function address register is shown in Figure 24-185 and described in Table 24-199.

Figure 24-185. Receive Function Address Register (USBn_RXFUNCADDRm)

7	6	0
Reserved	FUNCADDR	
R-0	R/W-7Fh

Bit	Field	Description
7	Reserved	Reserved
6-0	FUNCADDR	Address of target function.

24.9.7.3.5 Receive Hub Address Register (USBn_RXHUBADDRm)

The receive hub address register (USBn_RXHUBADDRm) is an 8-bit register (meaningful in host mode operation only), like USBn_RXHUBPORTm, that only needs to be written where a full- or low-speed device is connected to Rx endpoint EPn via a high-speed USB 2.0 hub that carries out the necessary transaction translation to convert between high-speed transmission and full-/low-speed transmission. In such circumstances:

- The lower 7 bits should record the address of this USB 2.0 hub
- The top bit should record whether the hub has multiple transaction translators (clear to 0 if single transaction translator; set to 1 if multiple transaction translators).

If endpoint 0 is connected to a hub, then USBn_RXHUBADDRm need to be defined for this endpoint.

The receive hub address register is shown in Figure 24-186 and described in Table 24-200.

Figure 24-186. Receive Hub Address Register (USBn_RXHUBADDRm)

7	6	0
MULT_TRANS	HUBADDR	
R/W-0	R/W-7Fh

Bit	Field	Description
7	MULT_TRANS	Set to 1 if hub has multiple transaction translators. Cleared to 0 if only single transaction translator is available.
6-0	HUBADDR	Address of HUB.

24.9.7.3.6 Receive Hub Port Register (USBn_RXHUBPORTm)

The receive hub port register (USBn_RXHUBPORTm) (meaningful in host mode operation only) only needs to be written where a full- or low-speed device is connected to Rx endpoint EPn via a high-speed USB 2.0 hub that carries out the necessary transaction translation. In such circumstances, these 7-bit read/write registers need to be used to record the port of that USB 2.0 hub through which the target associated with the endpoint is accessed.

Note: If endpoint 0 is connected to a hub, then USBn_RXHUBPORT needs to be defined for this endpoint.

The receive hub port register is shown in Figure 24-187 and described in Table 24-201

Figure 24-187. Receive Hub Port Register (USBn_RXHUBPORTm)

7	Reserved	Reserved
6-0	HUBPORT	Port number of HUB.

24.9.7.4 Non-Indexed Endpoint Control/Status Registers

The registers available at indexed region, offset 10h–1Fh, are accessible independently of the setting of the Index register. The Non-Indexed region has dedicated block of register space for each endpoint with memory block between 100h–10Fh are reserved for endpoint 0 registers; memory block between 110h–11Fh are reserved for endpoint 1 registers; memory block between 120h–12Fh are reserved for endpoint 2 registers; and so on.

Table 24-202 and Table 24-203 display the set of endpoint registers that are accessible from their dedicated block of memory in both peripheral and host mode, respectively. Note that the definitions of these register is discussed in detail in Section 24.9.6.2.

Table 24-202. Peripheral Mode Configuration and Status Register Mapping where n = 0,1 (USB0 or USB1) and m = 1-15 (endpoint number)

USB Related Clock/PHY Control Registers

This section contains information on USB PHY registers, which are also used for USB Interface Clocking and USB Controller Clocking. For details on USB Interface Clocking and USB Controller Clocking, see the appropriate chapter.

24.9.7.1 CM_DEFAULT_L3_SLOW_CLKSTCTRL Register

The CM_DEFAULT_L3_SLOW_CLKSTCTRL register enables the domain power state transition. It controls the software supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also holds one status bit per clock input of the domain.

This register is shown in Figure 24-188 and described in Table 24-204.

Figure 24-188. CM_DEFAULT_L3_SLOW_CLKSTCTRL Register

ROM Code Memory and Peripheral Booting

This chapter describes the booting functionality of the ROM Code. The booting functionality covers the following features:

- *Memory Booting* – booting the device by starting code stored on permanent memories like flash-memory or memory cards. This process is usually performed after either device cold or warm reset.
- *Peripheral Booting* – booting the device by downloading the executable code over a communication interface like UART or Ethernet. This process is intended for flashing a device.

This chapter is intended for all who design systems based on this device, develop boot loader images and flashing tools.

Topic **Page**

25.1 Introduction

25.1.1 Acronyms

Table 25-1. Acronyms and Abbreviations

Acronym/Abbreviation	Definition
ASIC	Application Specific Integrated Circuit
B	Byte (8 bits)
CS	Chip Select
CH	Configuration Header
DPLL	Digital PLL
EMIF	External Memory InterFace (SDRAM Controller)
FIQ	Fast Interrupt Request
FS USB	Full Speed USB
GPMC	General Purpose Memory Controller
HLOS	High Level Operating System
HS USB	High Speed USB
HW	Hardware
HWA	Hardware Accelerator
I2C	Inter-Integrated Circuit
IRQ	Interrupt
ISR	Interrupt Service Routine
JTAG	Joint Test Action Group. This term is used to refer to the Debugging and Testing interface.
Kbps	Kilobits per second
KB	Kilobyte, 1024 B
MB	Megabyte, 1024 KB
MPU	Micro Processor Unit
OCM	On-Chip Memory
OneNAND™	A type of Flash memory
PLL	Phase Locked Loop
POR	Power On Reset
PMU	Power Management Unit
PRCM	Power, Reset and Clock Management module
RAM	Random Access Memory. Refers to the internal static RAM.
ROM	Read Only Memory
RSA	Rivest, Shamir, Adleman encryption algorithm
SAR	Save & Restore
SD card	Secure Digital card
SDRAM	Synchronous Dynamic Random Access Memory
SWI	Software Interrupt
TOC	Table Of Contents – a structure within an executable image
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
XIP	Execute In Place
WDT	Watchdog timer

25.1.2 Naming Conventions

The following is a brief explanation of some terms used in this document:

Bootstrap— Initial software that is launched by the ROM Code during the Memory Booting phase.

Downloaded SW— Initial software that is downloaded into internal RAM by the ROM Code during Peripheral Booting phase.

E-Fuse— A one-time programmable memory location usually set at the factory.

Emulator Device— A type of device where some of the security rules are relaxed. Intended for development only.

Flash Loader— Downloaded software launched by the ROM Code in Pre-Flashing and which programs an image into external memories.

Initial SW— Software that is executed by any of the ROM Code mechanisms (Memory Booting or Peripheral Booting). Initial SW is a generic term for Bootstrap and Downloaded SW.

Manager— A modular software component with finite and focused functionality.

Memory Booting— ROM Code mechanism that consists of executing an Initial SW from external memory.

Peripheral Booting— ROM Code mechanism that consists of polling selected interfaces, downloading and executing an Initial SW (in this case called Downloaded SW) in internal RAM.

Pre-Flashing— Specific case of Peripheral Booting, where the ROM Code mechanism is used to program external Flash memories.

25.2 Overview

25.2.1 Architecture

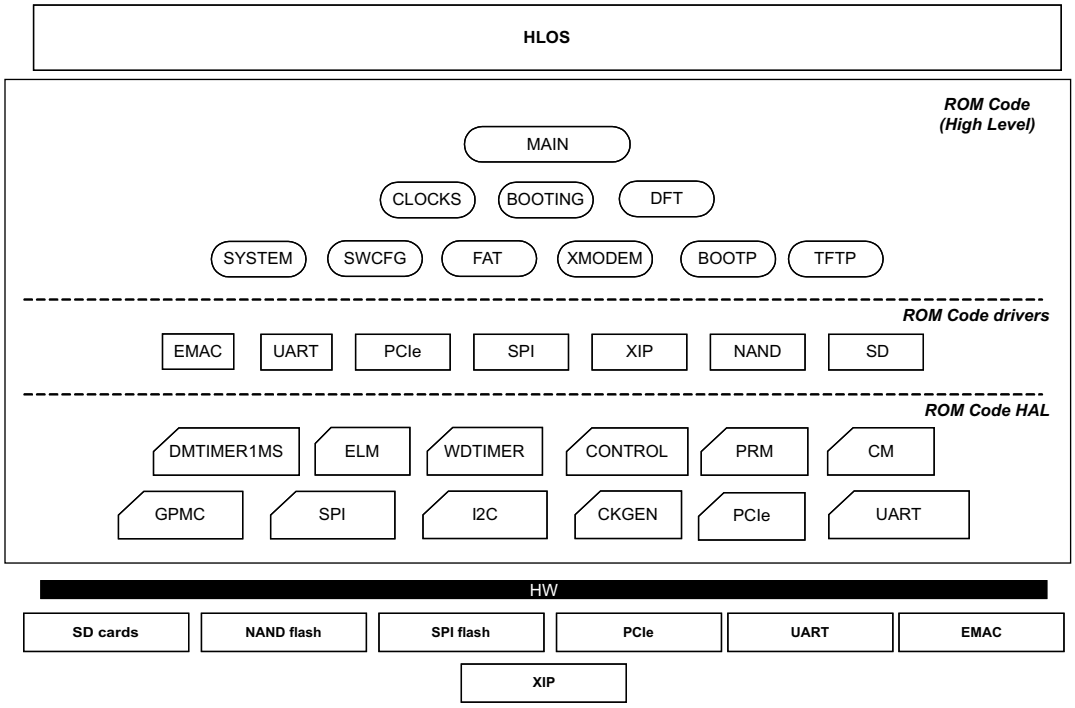
The architecture of the ROM Code is shown in Figure 25-1. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower level layer through a unified interface.

The high-level layer is in charge of the main tasks of the ROM Code: watchdog and clocks configuration and main booting routine.

The drivers layer implements the logical and communication protocols for any booting device in accordance with the interface specification.

Finally the HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to device IO pads.

Figure 25-1. ROM Code Architecture



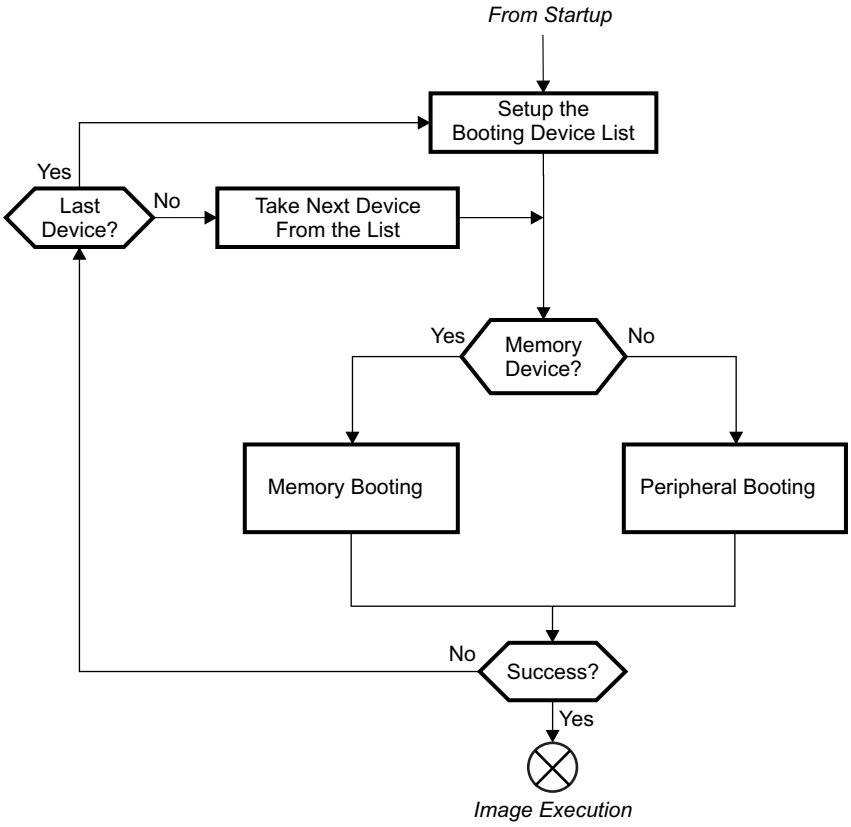
25.2.2 Functionality

Figure 25-2 illustrates the high-level flow for the ROM Code booting procedure. The ROM Code performs platform configuration and initialization as part of the start-up procedure.

The booting device list is created based on the MBOOT.A booting device can be a memory booting device (soldered flash memory or temporarily booting device like memory card) or a peripheral interface connected to a host.

The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration.

Figure 25-2. ROM Code Boot Procedure



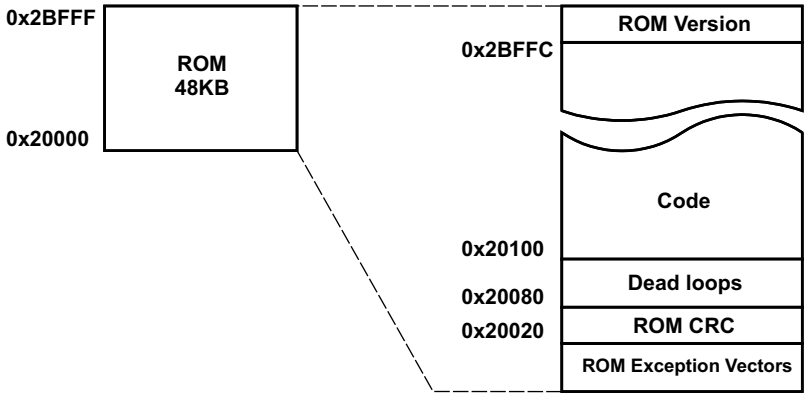
25.3 Memory Map

25.3.1 ROM Memory Map

The on-chip ROM memory map is shown in Figure 25-3. The ROM Code mapping consists of the following:

- ROM Exception vectors
- CRC
- Dead loops collection
- Code and const data sections
- API Table
- ROM Version

Figure 25-3. ROM Memory Map



25.3.1.1 ROM Exception Vectors

Table 25-2 lists the ROM exception vectors. The reset exception is redirected to the ROM Code startup. Other exceptions are redirected to their RAM handlers by loading appropriate addresses into the PC register.

Table 25-2. ROM Exception Vectors

Address	Exception	Content
20000h	Reset	Branch to the ROM Code startup
20004h	Undefined	PC = 4030 D004h
20008h	SWI	PC = 4030 D008h
2000Ch	Pre-fetch abort	PC = 4030 D00Ch
20010h	Data abort	PC = 4030 D010h
20014h	Unused	PC = 4030 D014h
20018h	IRQ	PC = 4030 D018h
2001Ch	FIQ	PC = 4030 D01Ch

25.3.1.2 ROM Code CRC

The ROM Code CRC is calculated as 32 bit CRC code (CRC-32-IEEE 802.3) for the address range 20000h–2BFFFh. The four bytes CRC code is stored at location 20020h.

25.3.1.3 Dead Loops

Built-in dead loops are used for different purposes as shown in Table 25-3. All dead loops are branch instructions coded in ARM mode. The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors. The dead loops might be called directly from the user code. However there exists a special function which can be called from ROM Code in order to execute a dead loop. The function is an assembly code in ARM mode which takes the dead loop address from R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. The function is located at address 200C0h. In addition, the function clears global cold reset status upon issuing the global SW reset.

Table 25-3. Dead Loops

Address	Purpose
20080h	Undefined exception default handler
20084h	SWI exception default handler
20088h	Pre-fetch abort exception default handler
2008Ch	Data abort exception default handler
20090h	Unused exception default handler
20094h	IRQ exception default handler
20098h	FIQ exception default handler
2009Ch	Validation tests PASS
200A0h	Validation tests FAIL
200A4h	Reserved
200A8h	Image not executed or returned.
200ACh	Reserved
200B0h	Reserved
200B4h	Reserved
200B8h	Reserved
200BCh	Reserved

25.3.1.4 Code

This space is used to hold code and constant data

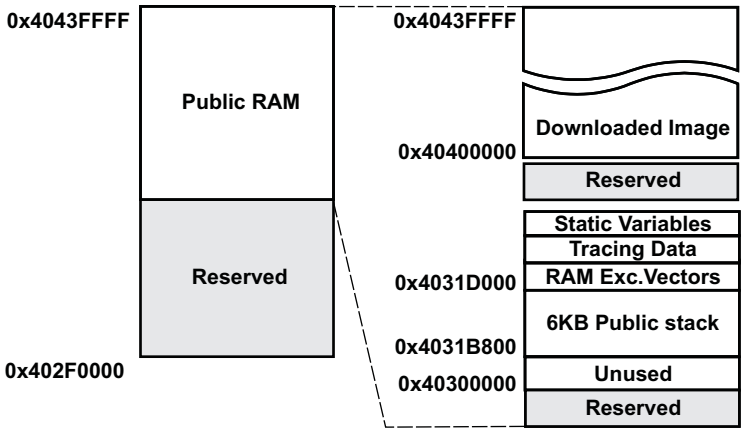
25.3.1.5 ROM Code Version

The ROM Code version consists of two decimal numbers: major and minor. It can be used to identify the ROM Code release version burned in a given IC (for example, useful to identify an IC version). The ROM Code version is a 32-bit hexadecimal value located at address 2BFFCh.

25.3.2 RAM Memory Map

The ROM Code makes use of the on-chip RAM module connected to the L3 interconnect (referred to as L3 RAM in this document). Its usage is shown in Figure 25-4. The RAM memory-map ranges from address 4030 0000h to 4043 FFFFh.

Figure 25-4. RAM Memory Map



25.3.2.1 Downloaded Image

This area is used by the ROM Code to store the downloaded boot image. It can be up to 255 KB.

25.3.2.2 Public Stack

Space reserved for stack.

25.3.2.3 RAM Exception Vectors

The RAM exception vectors enable a simple means for redirecting exceptions to custom handlers. Table 25-4 shows content of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load the value located in the subsequent seven addresses into the PC register. Theses instructions are executed when an exception occurs since they are called from the ROM exception vectors. Undefined, SWI, Unused and FIQ exceptions are redirected to a hardcoded dead loop. Pre-fetch abort, data abort, and IRQ exception are redirected to pre-defined ROM handlers. User code can redirect any exception to a custom handler either by writing its address to the appropriate location from 4031 D024h to 4031 D03Ch or by overriding the branch (load into PC) instruction between addresses from 4031 D004h to 4031 D01Ch.

Table 25-4. RAM Exception Vectors

Address	Exception	Content
4031 D000h	Reserved	Reserved
4031 D004h	Undefined	PC = [4031 D024h]
4031 D008h	SWI	PC = [4031 D028h]
4031 D00Ch	Pre-fetch abort	PC = [4031 D02Ch]
4031 D010h	Data abort	PC = [4031 D030h]
4031 D014h	Unused	PC = [4031 D034h]
4031 D018h	IRQ	PC = [4031 D038h]
4031 D01Ch	FIQ	PC = [4031 D03Ch]
4031 D020h	Reserved	20090h

Table 25-4. RAM Exception Vectors (continued)

Address	Exception	Content
4031 D024h	Undefined	20080h
4031 D028h	SWI	20084h
4031 D02Ch	Pre-fetch abort	Address of default pre-fetch abort handler (*)
4031 D030h	Data abort	Address of default data abort handler (*)
4031 D034h	Unused	20090h
4031 D038h	IRQ	Address of default IRQ handler
4031 D03Ch	FIQ	20098h

(*) the default handlers for pre-fetch and data abort are performing reads from CP15 debug registers to retrieve the reason of the abort:

- In case of pre-fetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM Code jumps to the pre-fetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM Code jumps to the data abort dead loop (2008Ch).

25.3.2.4 Tracing Data

This section contains trace vectors reflecting the execution path of the boot. Section 25.12 describes the usage of the different trace vectors and lists all the possible trace codes.

Table 25-5. Tracing Data

Address	Size [bytes]	Description
4031 D040h	4	Current tracing vector, word 1
4031 D044h	4	Current tracing vector, word 2
4031 D048h	4	Current tracing vector, word 3
4031 D04Ch	4	Current copy of the PRM_RSTST register (reset reasons)
4031 D050h	4	Cold reset run tracing vector, word 1
4031 D054h	4	Cold reset run tracing vector, word 2
4031 D058h	4	Cold reset run tracing vector, word 3
4031 D05Ch	4	Reserved
4031 D060h	4	Reserved
4031 D064h	4	Reserved

25.3.2.5 Static Variables

This area contains the ROM Code static variables used during boot time (and possibly during run-time, if calling the ROM API functions).

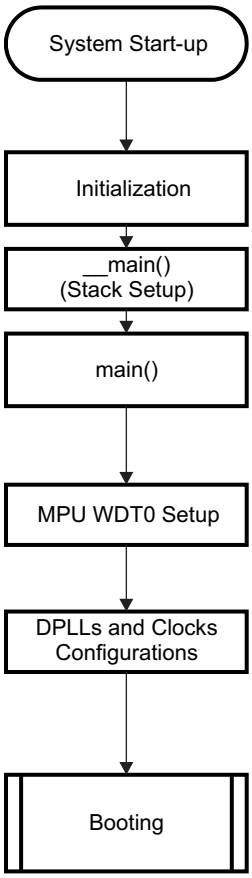
25.4 Startup and Configuration

25.4.1 ROM Code Start-up

The ROM Code is physically located at the address 20000h.

The CPU performs the initialization and stack setup (compiler auto-generated C-initialization or “scatter loading”) as shown in Figure 25-5. Then it configures the watchdog timer (set to 3 minutes) and performs system clocks configuration. Finally, it jumps to the booting routine.

Figure 25-5. ROM Code Start-up Sequence



25.4.2 CPU State at Startup

The CPU L1 instruction cache and branch prediction mechanisms are not activated as part of the boot process. The vector base address is configured to the reset vector of the ROM Code (20000h). The MMU is left switched off during the boot (hence, L1 data cache off).

No specific configuration is performed for the slave CPU which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of vectors base address).

25.4.3 Clocking Configuration

The supported system clock frequencies are DEV_CLKIN = 27 MHz.

The ROM Code configures the clocks and DPLLs that are necessary for ROM Code execution:

- MAIN PLL locked to provide 220 MHz clocks for ARM and peripheral blocks.
- DDR DPLL locked to provide 400 MHz for L3, UART clocks.

Table 25-6 summarizes the ROM Code default settings for clocks. This default configuration enables all the ROM Code functionalities with minimized needs on power during boot.

CAUTION

The SYSCLK10 divisor that the ROM Code configures is different between PG1.x and PG2.x devices. If SYSCLK10 is used, the original default POR values described in this document should not be depended on, but the PLLs and divisors must be explicitly configured. This is applicable for both PG1.x and PG2.x devices.

The DPLLs and PRCM clock dividers are configured with the ROM Code default values after cold or warm reset in order to give the same working conditions to the ROM Code sequence.

Table 25-6. ROM Code Default Clock Settings

Clock	Frequency (MHz)	Source
SYSCLK2	1000	MAIN PLL
SYSCLK5	250	MAIN PLL
SYSCLK6	125	MAIN PLL
SYSCLK10	48	DDR PLL

25.5 Booting

25.5.1 Overview

Figure 25-6 shows the booting procedure. First, a booting device list is created. The list consists of all devices which will be searched for a booting image. The list is filled in based on the SYSBOOT.

Once the booting device list is set up, the booting routine examines the devices enumerated in the list sequentially and either executes the memory booting or peripheral booting procedure depending on the booting device type. The memory booting procedure is executed when the booting device type is one of NOR, NAND, or SPI-EEPROM. The peripheral booting is executed when the booting device type is Ethernet, PCIe or UART.

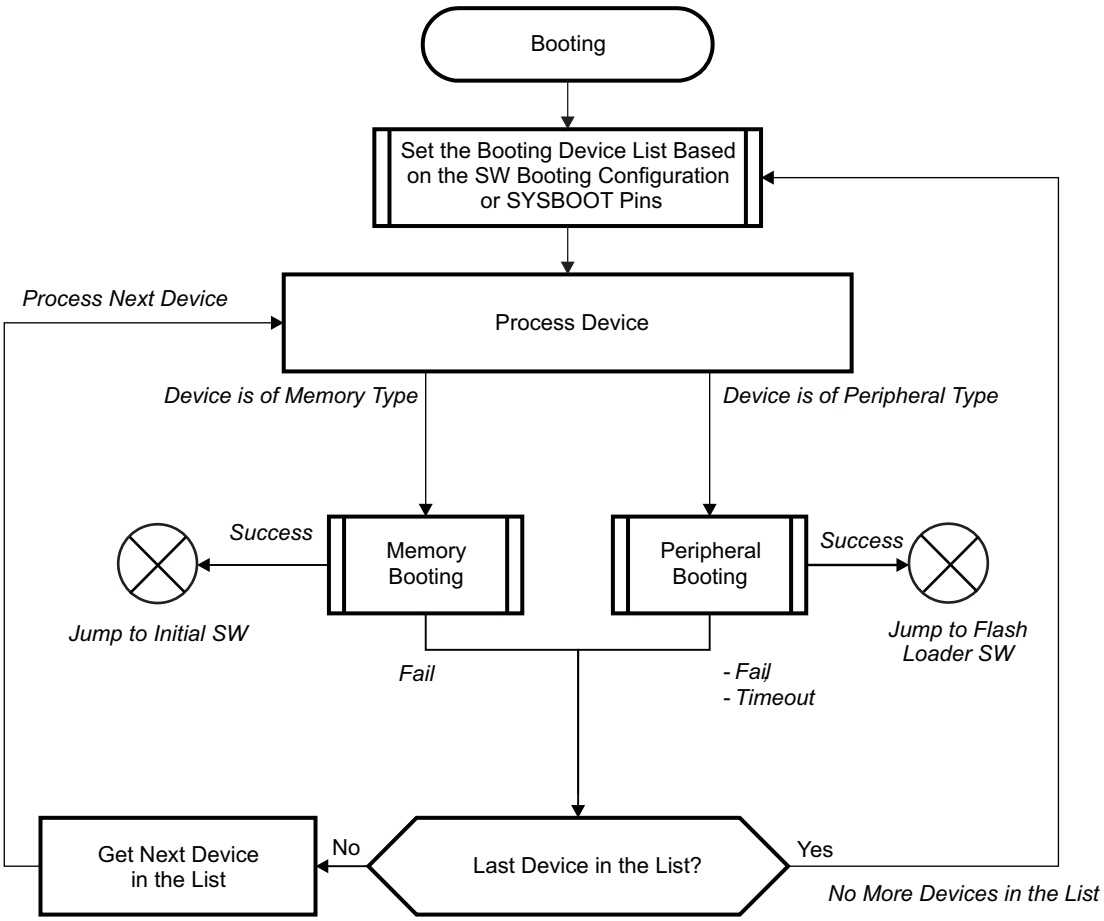
The memory booting procedure reads data from a memory type device. If a valid booting image is found and successfully read from the external memory:

- the Initial SW is simply started.

The peripheral booting procedure downloads data from a host (commonly a PC) to the device by means of Ethernet, PCIe or UART links. The ROM Code uses a host-slave logical protocol for synchronization. Upon successful PCIe enumeration (or UART or Ethernet connection) the host sends the image binary contents. The peripheral booting procedure is described in detail in Section 25.8.

If the memory or peripheral booting fails for all devices enumerated in the device list, then the ROM Code gets back to the first device in the list. The device list is then processed again in a loop. This loop shall be further interrupted by the MPU.

Figure 25-6. . ROM Code Booting Procedure



25.5.2 Device List

The ROM Code creates the device list based on information gathered from the SYSBOOT configuration pins sensed in the control module. The pins are used to index the device table from which the list of devices is extracted.

25.5.2.1 MBOOT Configuration Pins

Table 25-7. MBOOT Configuration Pins

Boot Modes				MBOOT[4:0]
1st	2nd	3rd	4th	
reserved	reserved	reserved	reserved	0

reserved	reserved	reserved	reserved	11110
Fast External Boot	Ethernet(GMII)	UART	PCIE_32	11111

The ROM Code uses the row pointed by the MBOOT configuration value .The device list is filled in with the 1st to 4th devices.

Table 25-7 is the decoding table for MBOOT configuration pins. The following shortcuts are used in the table:

NAND / NANDI2C	NAND flash memory / read flash geometry from I2C EEPROM
XIP / XIP w/ WAIT	NOR or other XIP device with or without wait monitoring
UART	UART interface (UART port 0)
Ethernet	Ethernet GMII0 interface (EMAC port 0)
SPI	SPI EEPROM (SPI 0, CS0)
PCIE_32 / PCIE_64	PCI Express interface with 32 bit / 64 bit addressing

Fast XIP boot mechanism (as described in Section 25.6) is provided where minimal execution is performed from ROM Code for configuring the GPMC interface and then directly jump to the code contained in the connected NOR flash device.

The NOR device must fulfill the following requirements for EMU external boot mode and fast XIP mode:

- Addr/Data muxed device or a non-muxed device connected in MUX0 configuration
- Bus width
- CS0 chip select
- Device wait signal connected to the WAIT0 GPMC signal (if used)
- Wait monitoring enable/disable

25.6 Fast Internal Booting

25.6.1 Overview

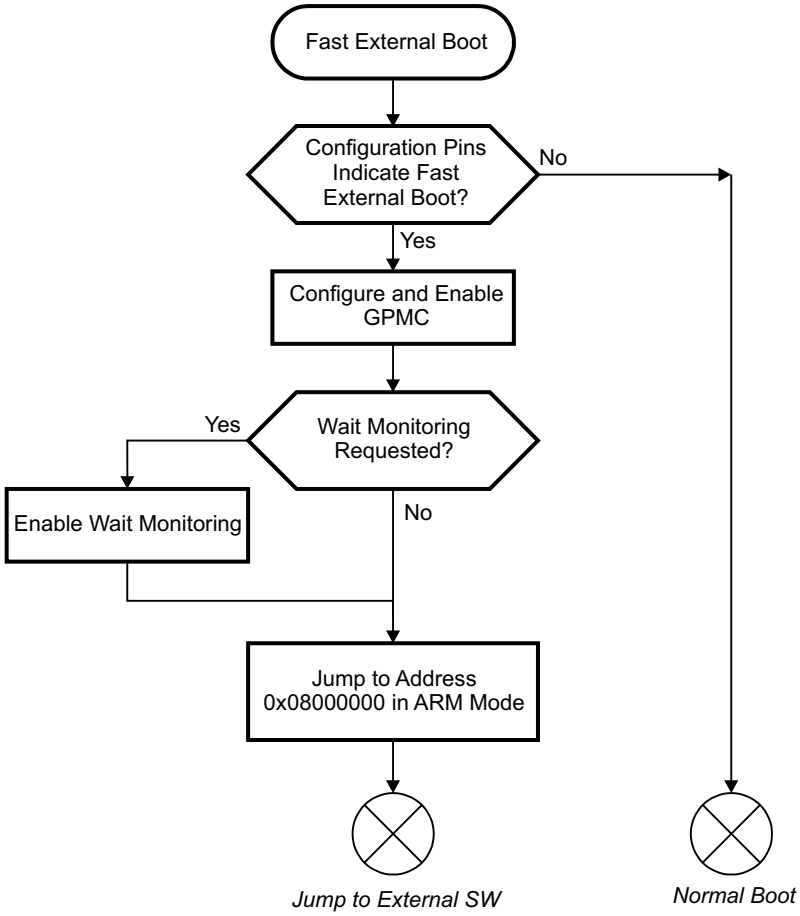
The fast external boot feature:

- Consists of a blind jump in ARM mode to a code located in an external XIP device connected to CS0
- The jump is performed with minimum on-chip ROM Code execution, without configuring any PLL
- Allows the customer to create its own booting code
- Is set up by means of the configuration pins, see Table 25-7

25.6.2 External Booting

Figure 25-7 shows the Fast External Boot procedure. The code does not make use of RAM and is designed for fast execution.

Figure 25-7. Fast External Boot

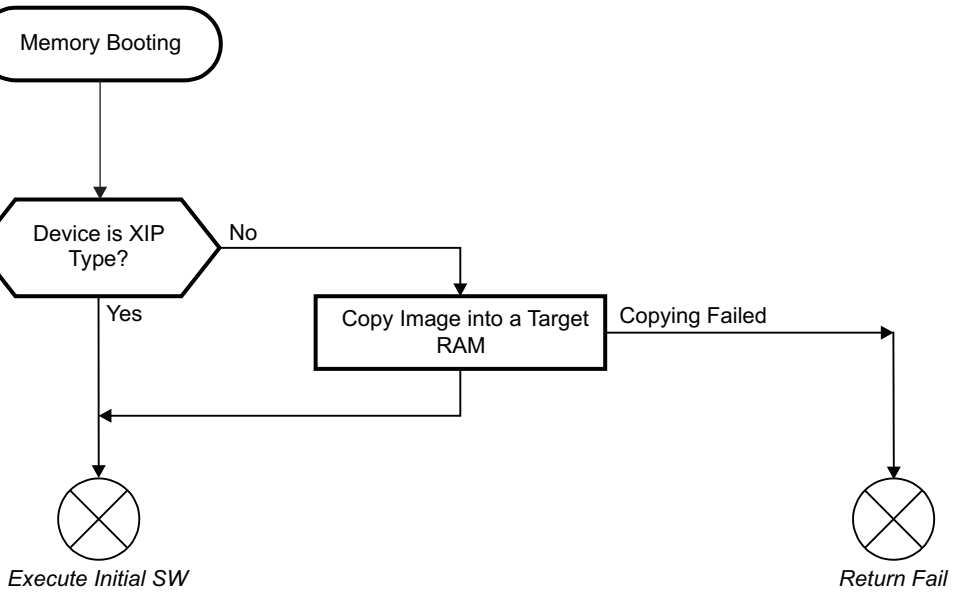


25.7 Memory Booting

25.7.1 Overview

The Memory Booting procedure takes care of starting an external code located in memory device types. These devices are also called permanent booting devices since they are used for booting permanently.

Figure 25-8. Memory Booting



The permanent booting devices supported are:

- SD cards
- NOR flash
- NAND flash
- SPI EEPROMs

There are two groups of permanent booting devices distinguished by the need of code shadowing. The code shadowing means copying a code from a non-directly addressable device into a location (typically a RAM area) from where the code can be executed. Devices that are directly addressable are called eXecute In Place (XIP) devices.

The memory booting flowchart is shown in Figure 25-8. The second step is about performing the shadowing of the image, that is copying the image from external mass storage (non-XIP) into internal RAM. Failure in image copy results in memory booting returning to the main booting procedure that will select the next device for booting. The next sections detail procedures for device initialization and detection in addition to the description of the sector read routine for each supported device type. A sector is a logical unit of 512 bytes. A booting image is considered to be present when the first 4 bytes word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector call, sectors are copied to a temporary RAM buffer. Once the image is found and destination address is known, the content of the temporary buffer is moved to the target RAM location so it is needed to re-read the first image sector.The header is discarded, therefore only executable code is located in RAM with the first executable instruction located at the destination address.

The image execution is detailed in Section 25.10. For more information about image formats and contents refer to Section 25.9.

SD cards and NAND devices can hold up to four copies of the booting image. Therefore, the ROM Code searches for one valid image out of the four if present by walking over the first four blocks of the mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

25.7.2 XIP Memory

The ROM Code can boot directly from XIP devices. A typical XIP device is a NOR flash memory. Support for XIP devices is performed under the following assumptions:

- Uses GPMC as the communication interface
- Can connect up to 1 Gbit (128 Mbytes) memories
- Uses both ×8 and ×16 data bus width
- Follows asynchronous protocol
- Supports address / data multiplexed mode and non-multiplexed mode
- GPMC clock is 55 MHz
- Device is connected to CS0 mapped to address 800 0000h
- Wait pin signal WAIT0 is monitored depending on the MBOOT configuration pins (XIP/XIPWAIT).

Depending on the MBOOT option the GPMC is configured to use the WAIT signal connected on the WAIT0 pin or not. Wait pin polarity is set to stall accessing memory when the WAIT0 pin is low. The wait monitoring is intended to be used with memories which require long time for initialization after reset or need to pause while reading data. The boot procedure from XIP device can be described as such:

1. Configure GPMC for XIP device access
2. Set the image location to 800 0000h
3. Verify if bootable image is present at the image location.
4. If the image has been found, start it.
5. If the image has not been found, return from XIP booting to the main booting loop.

25.7.2.1 XIP Initialization and Detection

GPMC Initialization

Figure 25-9 and Table 25-8 describes the GPMC timing settings set for XIP boot and other address-data accessible devices (for example, OneNAND).

Figure 25-9. GPMC XIP Timings

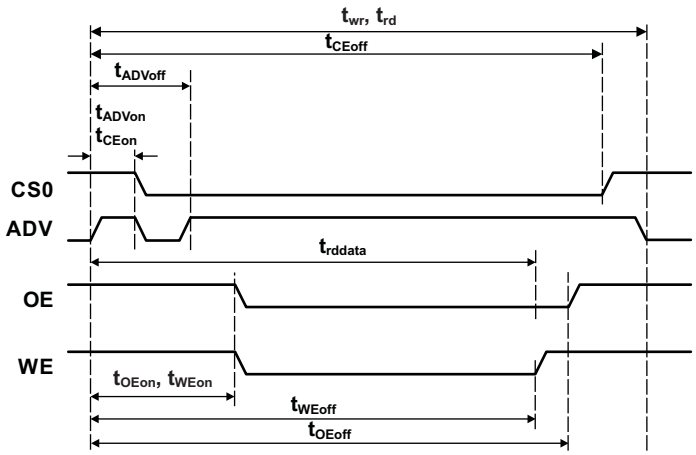


Table 25-8. XIP Timings Parameters

Parameter	Description	Value [clock cycles]
twr	write cycle period	17
trd	read cycle period	17
tCEon	CE low time	1
tCEoff	CE high time	16
tADVon	ADV low time	1
tADVoff	ADV high time	2
tOEon	OE low time	3
tWEon	WE low time	3
trddata	data latch time	15
tOEoff	OE high time	16
tWEoff	WE high time	15

The one clock cycle is 18.182 ns which corresponds to 55 MHz frequency.

There is no specific identification routine executed prior to booting from an XIP device.

The list of pins that are configured by the ROM in the case of NOR boot mode are listed in Table 25-9. Note that all the pins might not be driven at boot time. The decision as to which pins need to be driven is done based on the type of NOR flash selected.

The pins that are not listed in Table 25-9 are not configured by the ROM code, and are left at power on defaults. Specifically, external logic is needed to isolate the upper address lines (A12-A27) of the NOR flash from the device pins and drive them low during boot. Once the Initial Software starts running, it can configure the pinmux setting appropriately for the lines and remove the isolation to allow the GPMC to drive all the address lines.

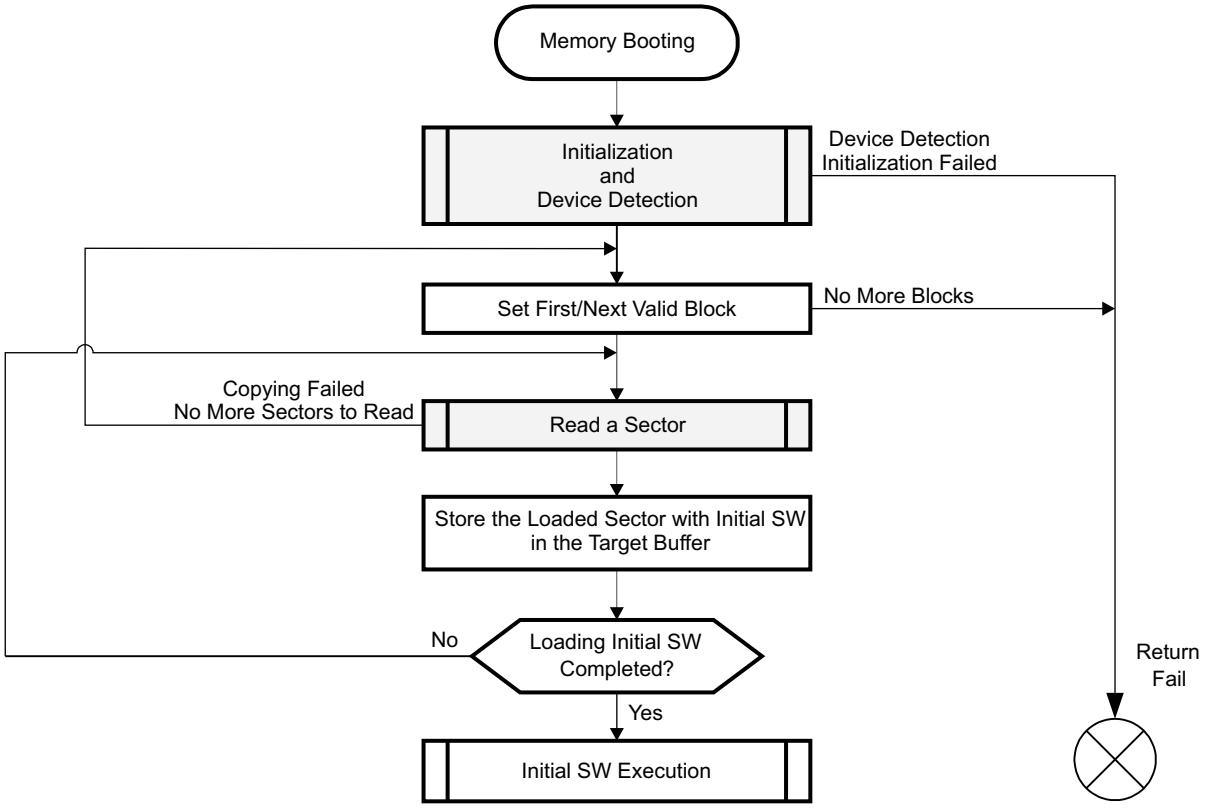
Table 25-9. Pins Used for NOR Boot

Signal Name	Pin Used in XIP Mode
cs0	$\overline{\text{GPMC\_CS[0]}}$
advn_ale	GPMC_$\overline{\text{ADV}}$_ALE
oen_ren	$\overline{\text{GPMC\_OE\_RE}}$
be0n_cle	GPMC_$\overline{\text{BE0}}$_CLE
Wen	$\overline{\text{GPMC\_WE}}$
Wait	GPMC_WAIT
Clk	GPMC_CLK
ad0 - ad15	GPMC_D[15:0]
a0	GPMC_A[0]
a1	GPMC_A[1]
a2	GPMC_A[2]
a3	GPMC_A[3]
a4	GPMC_A[4]
a5	GPMC_A[5]
a6	GPMC_A[6]
a7	GPMC_A[7]
a8	GPMC_A[8]
a9	GPMC_A[9]
a10	GPMC_A[10]
a11	GPMC_A[11]

Image Shadowing for non-XIP memories

- The image shadowing uses the approach shown in Figure 25-10.

Figure 25-10. Image Shadowing



25.7.3 NAND

NOTE: For PG2.x devices, CS0BW is not needed for NAND boot. The boot ROM detects the size of the NAND device and configures itself appropriately.

The NAND flash memory is not XIP and requires shadowing before the code can be executed. The features include:

- GPMC as the communication interface
- Device from 512Mbit (64 MByte)
- ×8 and ×16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128 / 218 spare bytes)
- CE don't care devices only
- Single Level Cell (SLC) and Multiple Level Cell (MLC) devices
- Device Identification based on ONFI or ROM table
- ECC correction : 8 bits/sector for most devices (16b/sector for devices with large spare area)
- GPMC timings adjusted for NAND access
- 55 MHz GPMC clock
- Device connected to CS0
- Wait pin signal WAITPIN0 connected to NAND BUSY output
- Four physical blocks are searched for an image. The block size depends on device.

The initialization routine for NAND devices consists in three parts: GPMC initialization, device detection with parameters determination and finally bad block detection.

- **ONFI support.** The NAND identification starts with ONFI detection.
- **GPMC initialization.** The GPMC interface is configured as such it can be used for accessing NAND devices. The address bus is released since a NAND device does not use it. The data bus width is initially set to 8 bits; and changed to 16 bits if needed after device parameters determination. The following scheme is applied since NAND devices require different timings when compared to regular NOR devices:

Figure 25-11 and Table 25-10 describes the timings configured for NAND device access. The one clock cycle is 18.181 ns which correspond to 55 MHz frequency.

Figure 25-11. GPMC NAND Timings

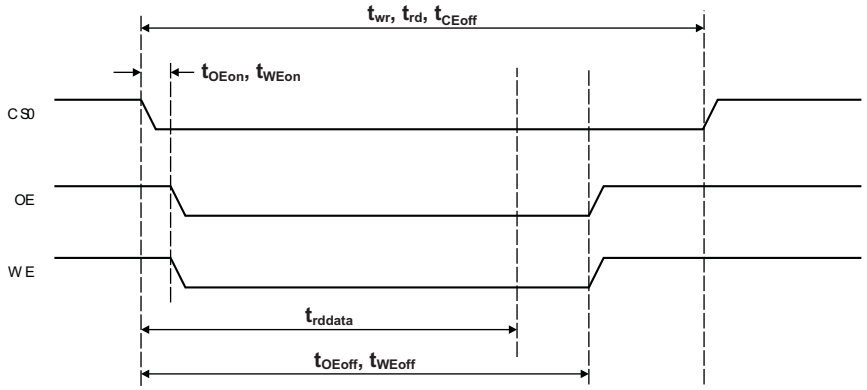


Table 25-10. NAND Timings Parameters

Parameter	Description	Value [clock cycles]
twr	write cycle period	30
trd	read cycle period	30
tCEon	CE low (not marked on the figure)	0
tOEon	CE low to OE low time	7
tWEon	CE low to WE low time	5
trddata	CE low to data latch time	21
tOEoff	CE low to OE high time	24
tWEoff	CE low to WE high time	22

- **Device detection and parameters.** The ROM Code first performs an initial wait for device auto initialization (with 250 ms timeout) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100 ms timeout). The ONFI Read ID (command 90h / address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes), then a Read parameters page (command ECh) is sent. The information shown in Table 25-11 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameters page stream are simply ignored.

NOTE: PG2.x devices also check for the ONFI signature on the parameters page. Some NAND devices that did not work properly with PG1.x devices could work with PG2.x devices.

Table 25-11. ONFI Parameters Page Description

Offset	Description	Size (bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 100ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM Code table. The list of supported devices is shown in Table 25-12.

Table 25-12. Supported NAND Devices

Capacity	Device ID	Bus Width	Page size
512 Mb	F0	x8	2048
512 Mb	C0	x16	2048
512 Mb	A0	x8	2048
512 Mb	B0	x16	2048
512 Mb	F2	x8	2048
512 Mb	C2	x16	2048
512 Mb	A2	x8	2048
512 Mb	B2	x16	2048
1 Gb	F1	x8	2048

Table 25-12. Supported NAND Devices (continued)

Capacity	Device ID	Bus Width	Page size
1 Gb	C1	x16	2048
1 Gb	A1	x8	2048
1 Gb	B1	x16	2048
2 Gb	DA	x8	2048
2 Gb	CA	x16	2048
2 Gb	AA	x8	2048
2 Gb	BA	x16	2048
2 Gb	83	x8	2048
2 Gb	93	x16	2048

64 Gb	AE	x8	2048/4096
64 Gb	BE	x16	2048/4096

When the parameters are retrieved from the ROM table: page size and block size is updated based on 4th byte of NAND ID data. Due to inconsistency amongst different manufacturers, only devices which has been recognized to be at least 2Gb (included) have these parameters updated. Therefore, the ROM Code supports 4kB page devices but only if their size, according to the table, is at least 2Gb. Devices which are smaller than 2Gb have the block size parameter set to 128kB (when page size is 2KB). Table 25-13 shows the 4th ID Data byte encoding used in ROM Code.

Table 25-13. 4th NAND ID Data Byte

Item	Description	I/O #							
		7	6	5	4	3	2	1	0
Page Size	1kB							0	0
	2kB							0	1
	4kB							1	0
	8kB							1	1
Cell type	2 levels					0	0		
	4 levels					0	1		
	8 levels					1	0		
	16 levels					1	1		
Block Size	64kB			0	0				
	128kB			0	1				
	256kB			1	0				
	512kB			1	1				

- **Reading NAND geometry from I2C EEPROM.** ROM supports a special boot mode called NANDI2C to support NAND devices whose geometry cannot be detected by the ROM automatically using methods described in the previous section (Figure 25-12). If this boot mode is selected, the ROM code tries to read NAND geometry from an I2C EEPROM. If the read is successful, ROM code then proceeds to next steps of NAND boot, beginning with reading bad blocks information.

  The list of pins that are configured by the ROM incase of NANDI2C boot mode (This is in addition to the NAND boot pins described in Table 25-16).

Table 25-14. Pins used for NANDI2C boot for I2C EEPROM access

Signal name	Pin used
I2C SCL	iic0_scl
I2C SDA	iic0_sda

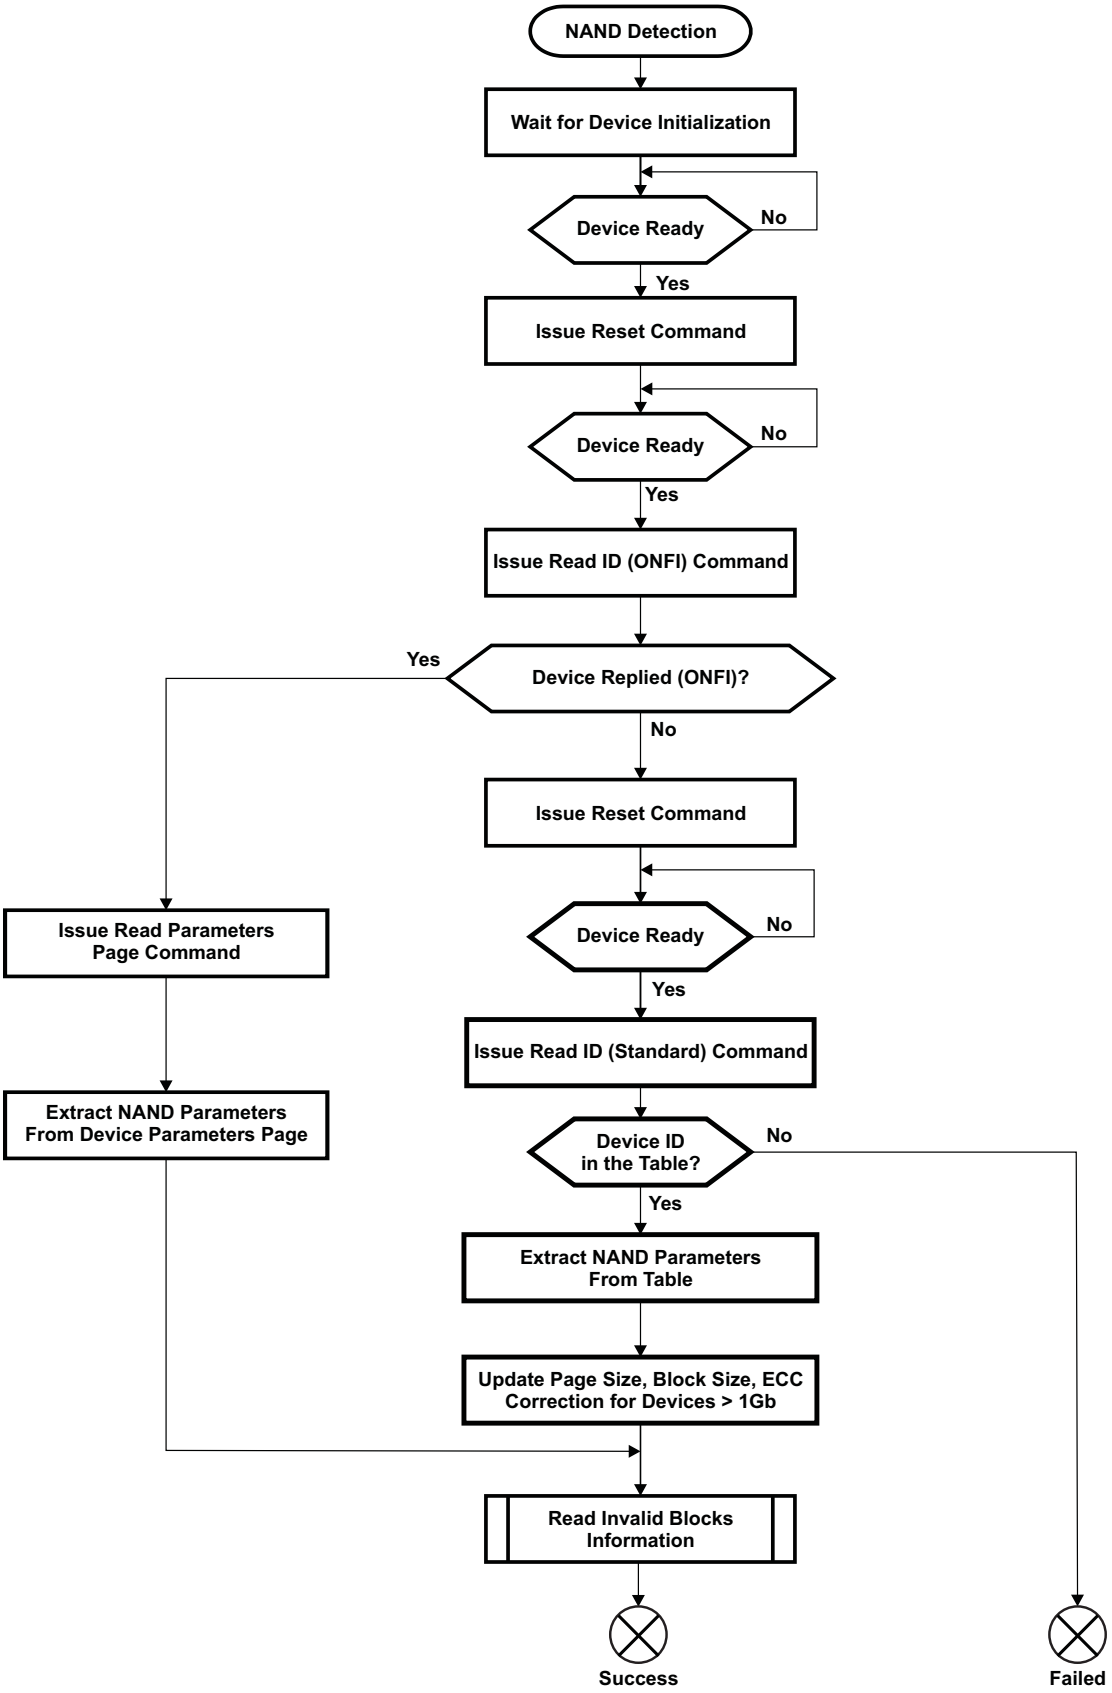
ROM accesses the I2C EEPROM at I2C slave address 50h and reads 7 bytes starting from address offset 80h. The format of this (NAND geometry information) is shown in Table 25-15.

The detection procedure is described in Figure 25-12. Once the device has been successfully detected, the ROM Code changes GPMC to 16-bit bus width if necessary.

Table 25-15. NAND Geometry Information on I2C EEPROM

Byte address	Information	
	Upper nibble	Lower nibble
80h	Magic Number – 10h	
81h	Magic Number – B3h	
82h	Magic Number – 57h	
83h	Magic Number – A6h	
84h	NAND column address (word/byte offset within a page) size in bytes, Example: 2	NAND row address (page offset) size in bytes. Example: 3
85h	Page size (2N) exponent “N”. Example (for page size of 2048): 11	Pages per block (2N) exponent “N” Example (for number of blocks 64): 6
86h	NAND bus width 0 → 8-bit, 1 → 16-bit	ECC Type 0→ No ECC, 1 → BCH8, 2 → BCH16

Figure 25-12. NAND Device Detection

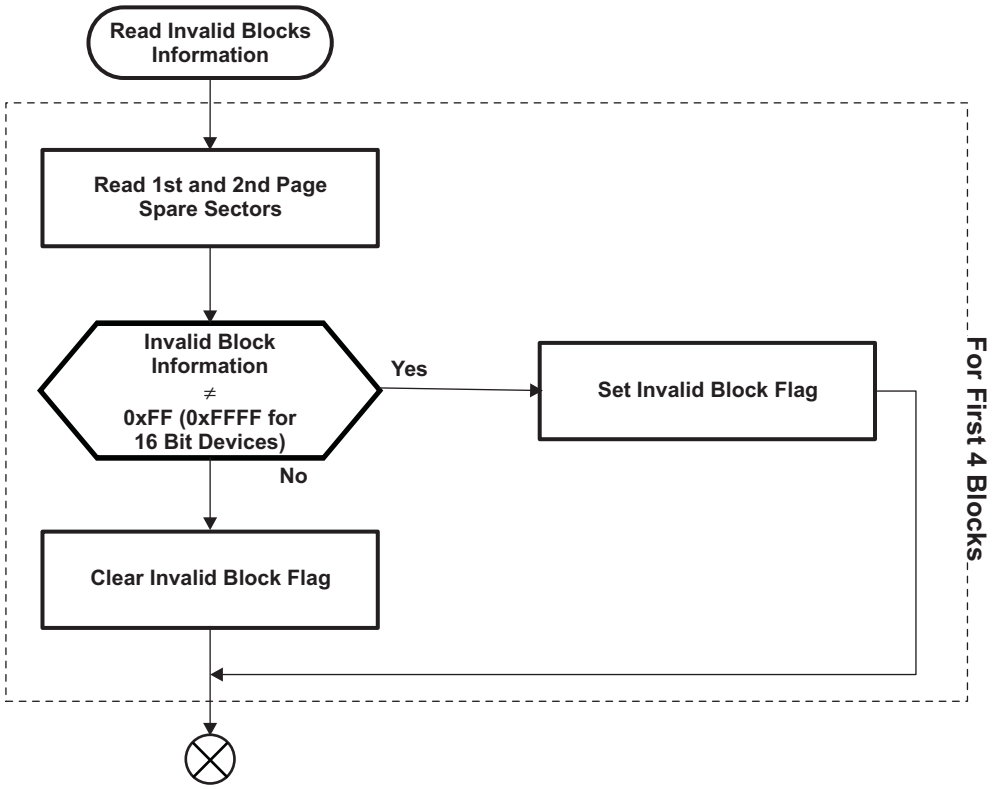


- **ECC correction.** The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

  For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when manufacturer code (first ID byte) is 98h the Cell type information is checked in the 4th byte of ID data. If it is equal to 10b then the ECC correction applied is BCH 16b/sector.
- **Bad block verification.** Invalid blocks are blocks which contain invalid bits whose reliability cannot be guaranteed by the manufacturer. Those bits are identified in the factory or during the programming and reported in the initial invalid block information located in the spare area on the 1st and 2nd page of each block. Since the ROM Code is looking for an image in the first four blocks, it must detect block validity status of these blocks. Blocks which are detected as invalid are not accessed later on. Blocks validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in 1st and 2nd pages for an 8 bits device / first word equal to FFFFh in 1st and 2nd page for a 16-bit device).

  Figure 25-13 depicts the invalid block detection routine. The routine consists in reading spare areas and checking validity data pattern.

Figure 25-13. NAND Invalid Blocks Detection



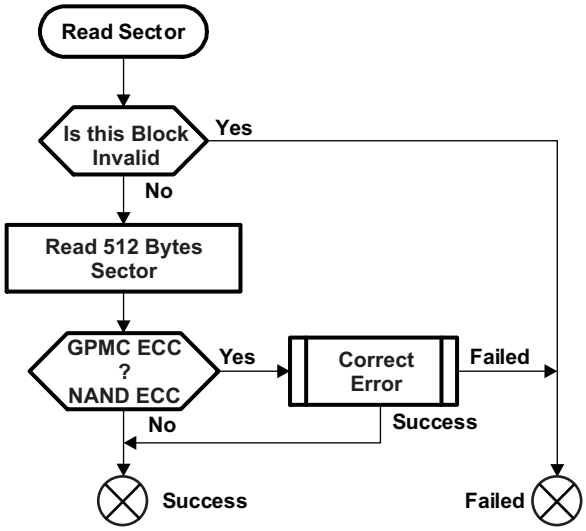
25.7.3.1 NAND Read Sector Procedure

The ROM Code reads data from NAND devices in 512 bytes sectors. The read function fails in two cases:

- The accessed sector is within a block marked as invalid
- The accessed sector contains an error which cannot be corrected with ECC

Figure 25-14 shows the read sector routine for NAND devices. The ROM Code uses normal read (command 00h 30h) for reading NAND page data.

Figure 25-14. NAND Read Sector Procedure



Page data can contain errors due to memory alteration. The ROM Code uses an ECC correction algorithm to detect and possibly correct those errors. The ECC algorithm used is BCH with capability for correcting 8b or 16b errors per sector.

The BCH data is automatically calculated by the GPMC on reading each 512 bytes sector. The computed ECC is compared against ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 25-15 and Figure 25-16 show the mapping of ECC data inside the spare area for 2KB-page and 4KB-page devices, respectively. If both ECC data are equal then the Read Sector function returns the read 512 bytes sector without error. Otherwise, the ROM Code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

The first two bytes in the spare area are always reserved for block state information:

- First word equal to FFFFh for a 16-bit device to check block validity
- First byte equal to FFh for an 8-bit device to check block validity and the second byte is a padding

Concerning the length of ECC section in bytes, extra bytes can be added to make the access ×16 compatible:

- For 8b BCH, there are 14 bytes ECC for each 512 bytes sector (that is, 13 bytes ECC + 1 byte padding)
- For 16b BCH, there are 26 bytes ECC for each 512 bytes sector (that is, no padding is needed)

Figure 25-15. ECC Data Mapping for 2KB Page and 8b BCH Encoding

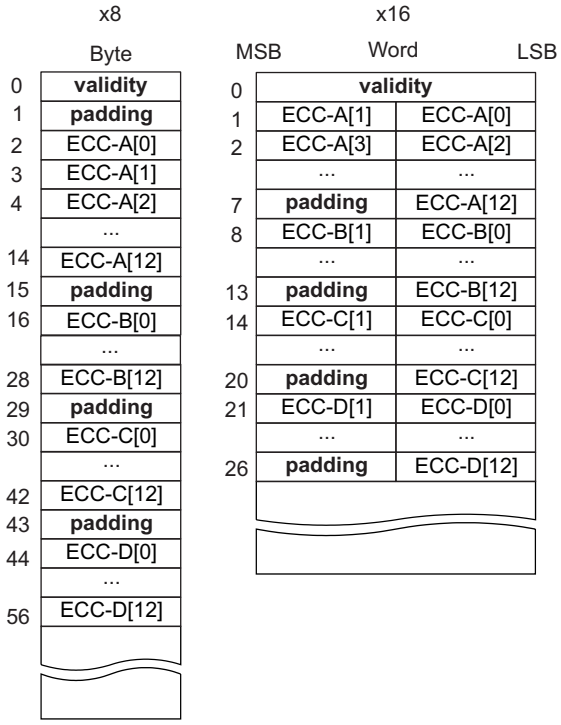


Figure 25-16. ECC Data Mapping for 4KB Page and 16b BCH Encoding

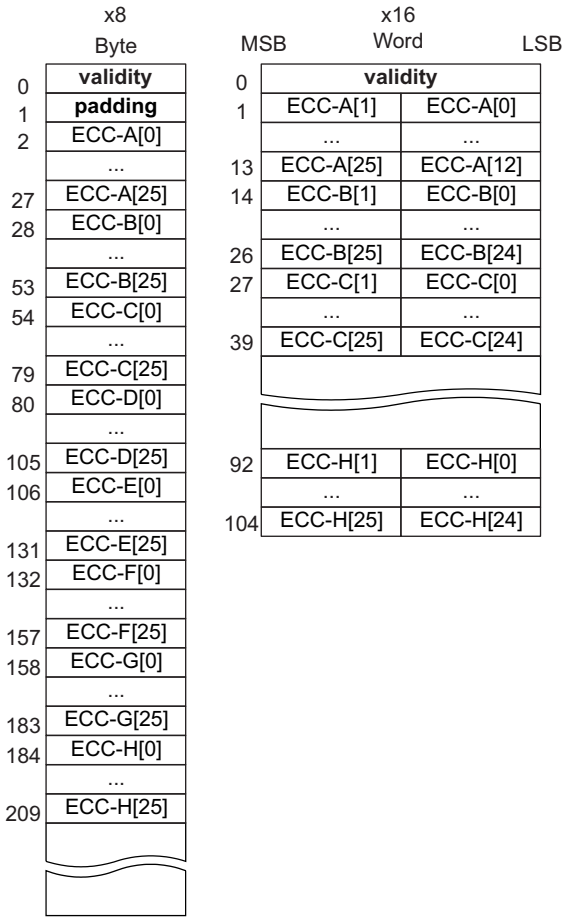


25.7.3.2 Pins Used

The list of pins that are configured by the ROM in case of NAND boot mode are in Table 25-16. Note that all the pins might not be driven at boot time.

Table 25-16. Pins Used for NAND Boot

Signal Name	Pin Used
cs0	$\overline{\text{GPMC\_CS[0]}}$
advn_ale	GPMC_$\overline{\text{ADV}}$_ALE
oen_ren	$\overline{\text{GPMC\_OE\_RE}}$
be0n_cle	GPMC_$\overline{\text{BE0}}$_CLE
wen	$\overline{\text{GPMC\_WE}}$
wait	GPMC_WAIT
clk	GPMC_CLK
ad0 - ad15	GPMC_D[15:0]

25.7.4 SD Cards

NOTE: PG2.x devices support booting from SD cards larger than 4 GB in size.

25.7.4.1 Overview

The ROM code supports booting from SD cards in the following conditions:

- SD cards compliant to low and high capacities.
- SD cards connected to interface #1.
- 3V VCC power supply, support for 3V I/O voltages.
- Clock Frequency: identification mode: 400 kHz; data transfer mode up to 10 MHz.
- Only one card connected to the bus.
- Raw mode, image data read directly from sectors in the user area.
- File system mode (FAT12/16/32 supported with or without Master Boot Record), image data is read from a booting file.

25.7.4.2 System Interconnection

An SD card can be connected to interface #1 typically through a card cage.

Notes:

- It may be possible to design the system so that an eSD memory type is connected to interface #1. However, the dual voltage IOs feature of interface #1 dedicates it preferably to cards.
- The ROM Code does not handle the card detection feature on card cage.

25.7.4.3 Pins Used

The list of device pins that are configured by the ROM in the case of SD boot mode are shown in Table 25-17. Note that all the pins might not be driven at boot time.

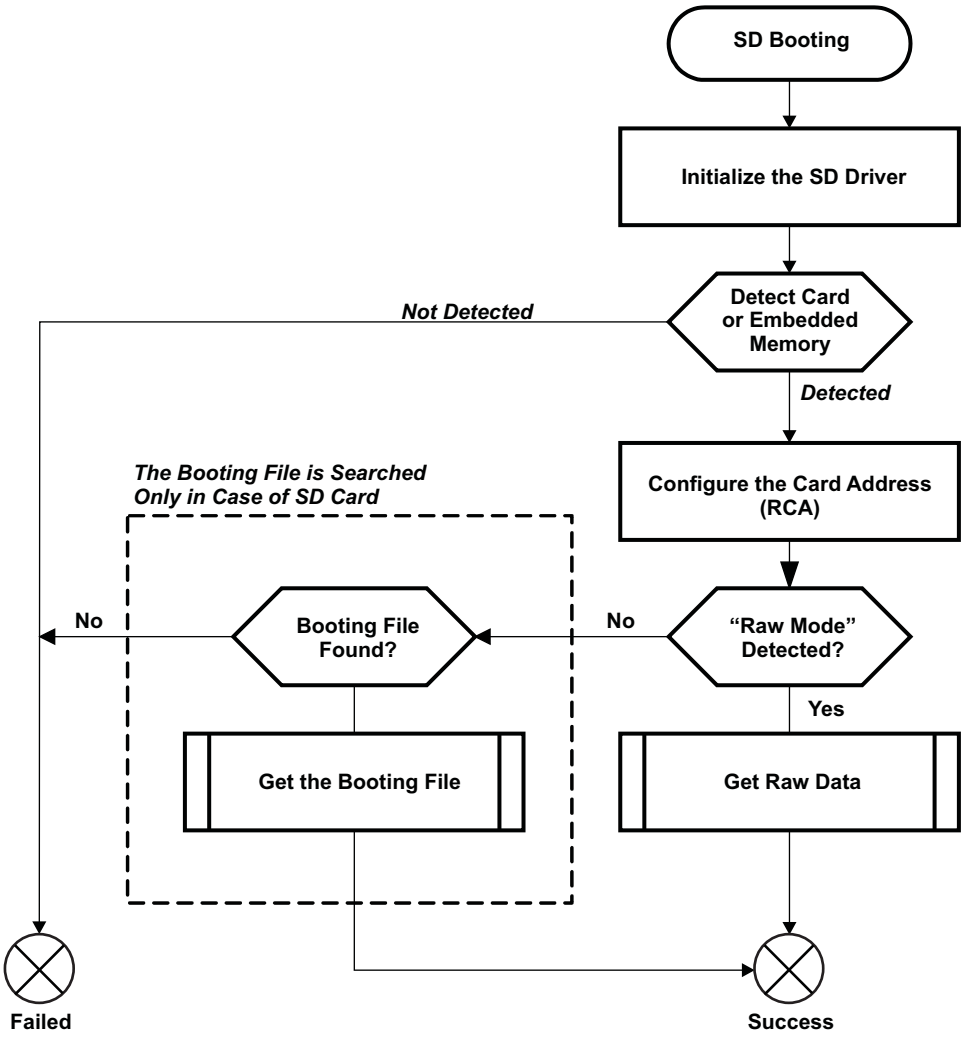
Table 25-17. Pins Used for SD Card Boot

Signal Name	Pin Used
clk	SD_CLK
cmd	SD_CMD
dat0	SD_DAT[0]
dat1	SD_DAT[1]
dat2	SD_DAT[2]
dat3	SD_DAT[3]

25.7.4.4 Booting Procedure

The high level flowchart of the eSD and SD booting procedure is depicted in Figure 25-17. The booting file is searched only in case of booting from a card. eSD embedded memories only support raw mode.

Figure 25-17. SD Booting



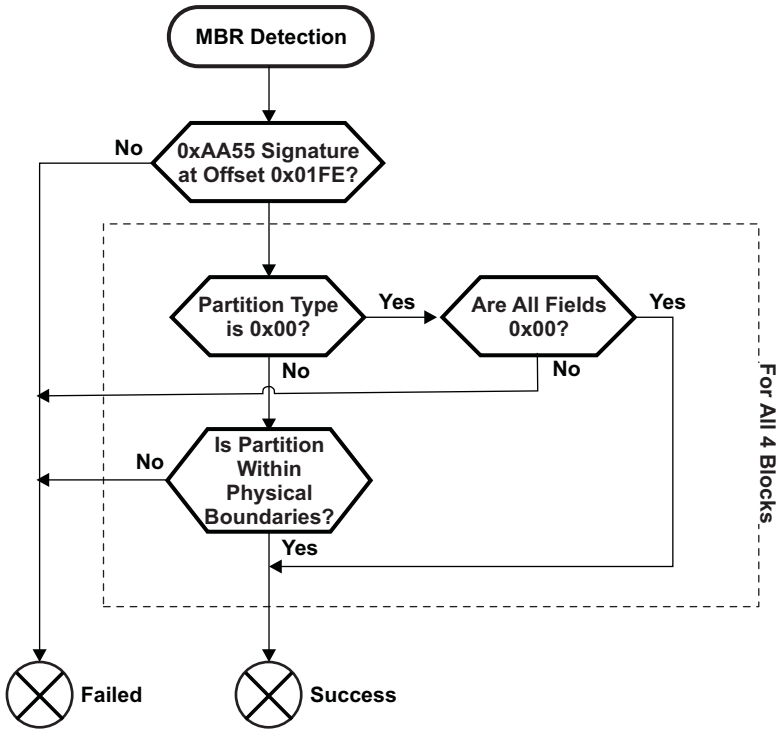
25.7.4.5 Initialization and Detection

The ROM Code initializes the memory device or card connected on interface #1 using the standard High-Voltage range (3.0V). If neither memory device nor card is detected then the ROM Code carries on to the next booting device. The standard identification process and Relative Card Address (RCA) assignment are used. However, the ROM Code assumes that only one memory or card is present on the bus. This first sequence is done using the CMD signal that is common to SD devices.

SD standards detail this phase as initialization phase. ACMD41 is only supported by the SD standard. ACMD41 (ACMD41 is made out of CMD55 and ACMD41) is sent and a response is expected from an SD device. If no response is received then it is assumed that no device is connected and the ROM Code exits the SD Booting procedure with FAIL. This is detection procedure is shown in Figure 25-18.

As previously mentioned, the contents of an SD card may be formatted as raw binary or within a FAT file system. eSD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

Figure 25-18. SD Detection Procedure



25.7.4.6 SD Read Sector Procedure in Raw Mode

In raw mode the booting image can be located at one of the four consecutive locations in the main area: offset 0/20000h (128KB)/40000h (256KB)/60000h (384KB). For this reason a booting image shall not exceed 128KB in size. However it is possible to flash a device with an image greater than 128KB starting at one of the aforementioned locations. Therefore the ROM Code does not check the image size. The only drawback is that the image will cross the subsequent image boundary.

The raw mode is detected by reading sectors #0, #256, #512, #768. The content of these sectors is then verified for presence of a TOC structure as described in Section 25.10. The Configuration Header (CH) must be located in the first sector followed by a header. The CH might be void (only containing a CHSETTINGS item for which the Valid field is zero).

25.7.4.7 SD Read Sector Procedure in FAT Mode

SD cards may hold a FAT file system which ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named “MLO”. This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An SD card can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any master boot record (MBR) holding a partition table
- When acting as hard-drive-like, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary and active.

The card should always hold an MBR. However, depending on the operating system, the SD card will be formatted either with partition(s) (using an MBR) or without. The ROM Code supports both types; this is described in the following section.

The ROM Code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512 byte sector within the booting file without involving ROM Code FAT module.

The sector read procedure utilizes standard SD raw data read function. The sector address is generated based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

25.7.4.8 FAT File System

This paragraph describes functionalities which are used by the ROM Code. It is not intended to fully describe the Master Boot Record and the FAT file system, but does include:

- How to recognize if a sector is the 1st sector of an MBR
- How to recognize if a sector is the 1st sector of a FAT12/16/32
- How to find the 1st cluster of the booting file
- How to buffer the booting file FAT entries

Some memory devices which support file systems can be formatted with or without MBR, therefore the first task of the ROM Code is to detect whether or not the device is holding an MBR in the first sector. If this is the case, an active FAT12/16/32 partition is searched in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no useable partition is found then the ROM Code returns to the Booting procedure with FAIL. The Extended partitions are not checked, the booting file must reside in a primary partition.

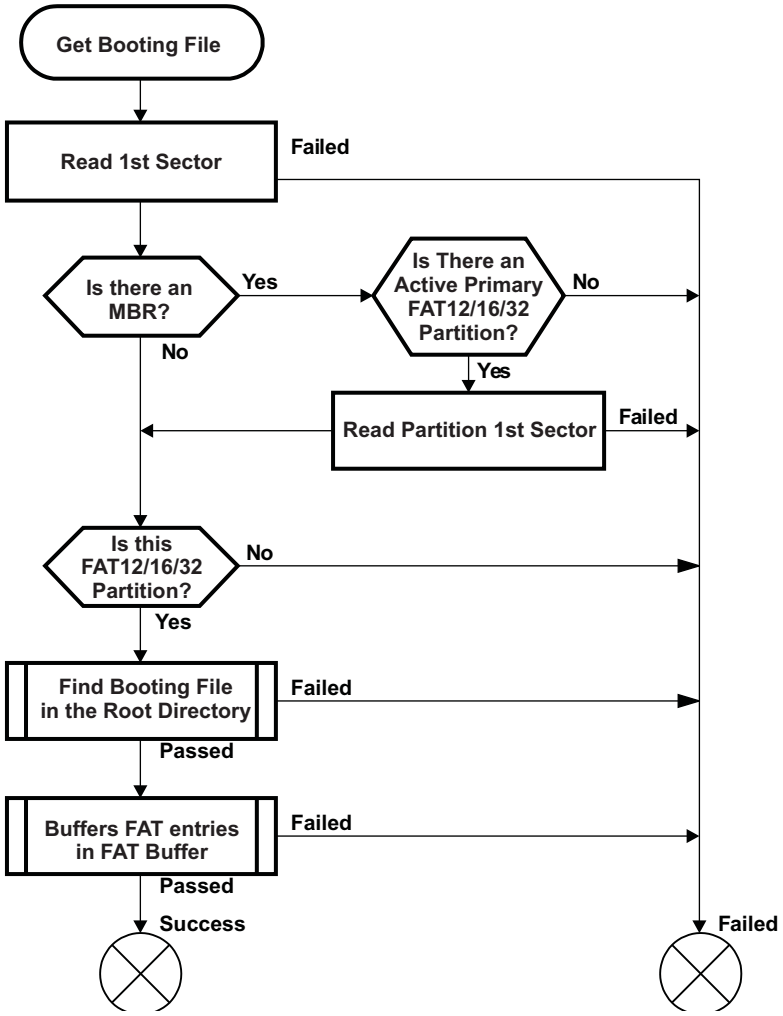
If a partition is found then its first sector is read and used further on. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used further on. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, in case another partition type is used (Linux FS or any other) or if the partition is not valid, the ROM Code returns with FAIL.

Otherwise, the Root Directory entries are searched for a file named depending on the booting device. The Long File Names (LFN) format is not used and only File Names in 8.3 Format are searched for. If no valid file is found, the ROM Code returns with FAIL.

Once the file has been found, the ROM Code reads the File Allocation Table (FAT) and buffers the singly-linked chain of clusters in a FAT Buffer which will be used by the Booting Procedure to access the file directly sector by sector. For FAT12/16 and for FAT32 (valid if a specific flag has been set in the FAT32 Boot Sector), there exist multiples copies of the FAT (ROM Code supports only two copies). When buffering FAT entries, the two FATs are compared. If they are not the same, only entries from the last FAT are used. The FAT Buffer holds sector numbers and not cluster numbers. The ROM Code converts each cluster entry to one or several sector entries if applicable.

The whole process is described in Figure 25-19. Every part related to MBR or FAT12/16/32 is described in the next paragraph.

Figure 25-19. SD Booting, Get Booting File



25.7.4.8.1 Master Boot Record: MBR

The Master Boot Record is the 1st sector of a memory device. It is made out of some executable code and four partition entries. The aim of such a structure is to be able to divide the hard disk in partitions mostly used to boot different systems (Microsoft Windows™, Linux, …). Its structure is described in Table 25-18 and Table 25-19. The valid partition types searched by the ROM Code are described in Table 25-20.

Table 25-18. Master Boot Record Structure

Offset	Length [bytes]	Entry Description	Value
0000h	446	Optional Code	
01BEh	16	Partition Table Entry	(see Table 25-19)
01CEh	16	Partition Table Entry	(see Table 25-19)
01DEh	16	Partition Table Entry	(see Table 25-19)
01EEh	16	Partition Table Entry	(see Table 25-19)
01FEh	2	Signature	AA55h

Table 25-19. Partition Entry

Offset	Length [bytes]	Entry Description	Value
0000h	1	Partition State	00h: Inactive 80h: Active
0001h	1	Partition Start Head	H_s
0002h	2	Partition Start Cylinder and Sector	$C_s[7:0]$-$C_s[9:8]$-$S_s[5:0]$
0004h	1	Partition Type	Refer to Table 25-20 for partial partition types
0005h	16	Partition End Head	H_e
0006h	2	Partition End Cylinder and Sector	$C_e[7:0]$ - $C_e[9:8]$ - $S_e[5:0]$
0008h	4	First sector position relative to the beginning of media	$LBA_s = C_s.H.S + H_s.S + S_s - 1$
000Ch	4	Number of sectors in partition	$LBA_e = C_e.H.S + H_e.S + S_e - 1$ $Nb_s = LBA_e - LBA_s + 1$

Table 25-20. Partition Types

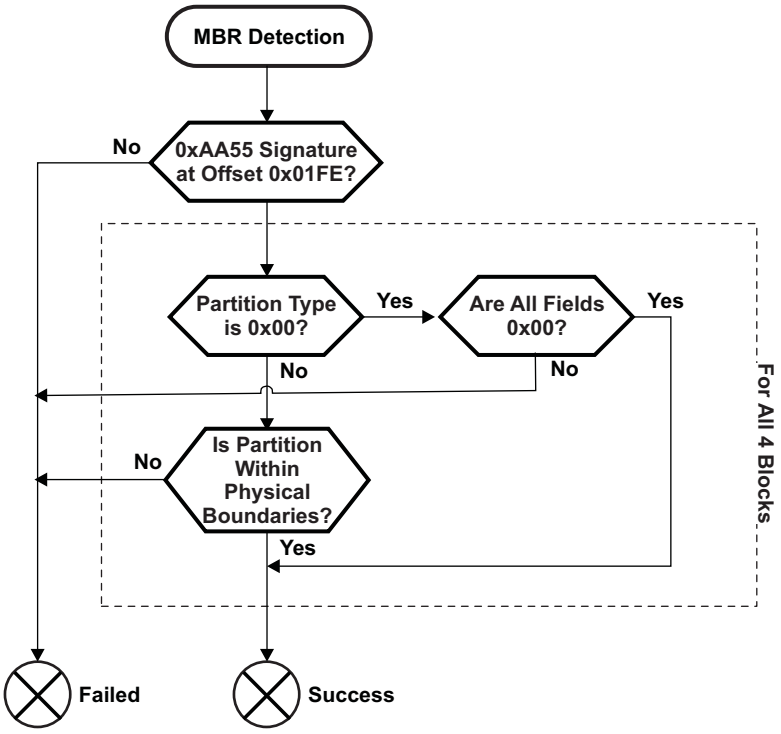
Partition Type	Description
01h	FAT12
04h, 06h, 0Eh	FAT16
0Bh, 0Ch, 0Fh	FAT32

The way the ROM Code detects whether a sector is the 1st sector of an MBR or not is described in Figure 25-20.

The ROM Code first checks if the signature is present. Each partition entry is checked:

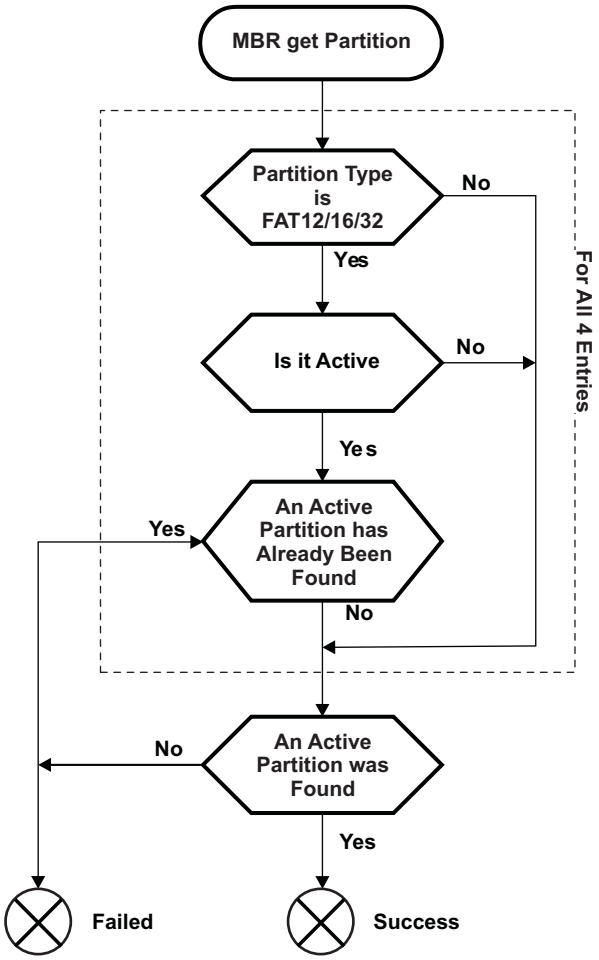
- If its type is set to 00h then all fields in the entry must be 00h
- The partition is checked to be within physical boundaries (the partition is located inside and its size fits the total physical sectors)

Figure 25-20. MBR Detection Procedure



Once identified, the ROM Code gets the partition using the procedure described in Figure 25-21. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h or 80h (if there is more than one active partition the test fails). The ROM Code returns with FAIL if no active primary FAT12/16/32 could be found.

Figure 25-21. MBR, Get Partition



25.7.4.8.2 FAT12/16/32 Boot Sector

The FAT file system is made out of several parts:

- Boot Sector which holds the BIOS Parameter Block (BPB)
- File Allocation Table (FAT) which describes the use of each cluster of the partition
- Data Area which holds the Files, Directories and Root Directory (for FAT12/16, the Root Directory has a specific fixed location)

The boot sector is described in Table 25-21. In the following description, all the fields whose names start with BPB_ are part of the BPB. All the fields whose names start with BS_ are part of the Boot Sector and not really part of the BPB (not mandatory); they are not used at all by the ROM Code.

Table 25-21. FAT Boot Sector

	Offset	Length [bytes]	Name	Description
	0000h	3	BS_jmpBoot	Jump Instruction to Boot Code (not used)
	0003h	8	BS_OEMName	Name of the System which created the partition
	000Bh	2	BPB_BytsPerSec	Counts of Bytes per sector (usually 512)
	000Dh	1	BPB_SecPerClus	Number of sectors per allocation unit
	000Eh	2	BPB_RsvdSecCnt	Number of reserved sectors for the Boot Sector For FAT12/16 is 1, for FAT32, usually 32
	0010h	1	BPB_NumFATs	Number of copies of FAT, usually 2
	0011h	2	BPB_RootEntCnt	For FAT12/16, number of 32 bytes entries in the Root Directory (multiple of BPB_BytsPerSec/32) For FAT32 this value is 0
	0013h	2	BPB_TotSec16	Total Count of sectors on the volume. If the size is bigger than 10000h or for FAT32, this field is 0 and BPB_TotSec32 holds the value
	0015h	1	BPB_Media	Media Type, usually F8h: fixed, non-removable
	0016h	2	BPB_FATSz16	For FAT12/16, size in sectors of one FAT For FAT32, holds 0
	0018h	2	BPB_SecPerTrk	Number of sectors per track, 63 for SD
	001Ah	2	BPB_NumHeads	Number of heads, 255 for SD
	001Ch	4	BPB_HiddSec	Number of sectors preceding the partition
	0020h	4	BPB_TotSec32	Total Count of sectors on the volume. If the size is smaller than 10000h (for FAT12/16), this field is 0 and BPB_TotSec16 is valid
FAT12/16	0024h	1	BS_DrvNum	Drive Number
	0025h	1	BS_Reserved1	00h
	0026h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0027h	4	BS_VolID	Volume Serial Number
	002Bh	11	BS_VolLab	Volume Label
	0036h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”. Note: This field is not mandatory (BS_), it cannot be used to indentify the partition type.
FAT32	0024h	4	BPB_FATSz32	Size in sectors of one FAT. Field BPB_FATSz16 must be 0
	0028h	2	BPB_ExtFlags	FAT Flags: [7]: 0 = FAT is mirrored; 1 = Only one FAT is used [3:0]: Number of used FAT if no mirroring used
	002Ah	2	BPB_FSVer	File system Version Number
	002Ch	4	BPB_RootClus	First Cluster number of the Root Directory
	0030h	2	BPB_FSInfo	Sector number of FSINFO Structure in the reserved-area, usually 1
	0032h	2	BPB_BkBootSec	If non-zero, indicates the sector number in the reserved-area of a copy of the Boot Sector
	0034h	12	BPB_Reserved	Reserved, set to 00h
	0040h	1	BS_DrvNum	Drive Number
	0041h	1	BS_Reserved1	00h
	0042h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0043h	4	BS_VolID	Volume Serial Number
	0047h	11	BS_VolLab	Volume Label
	0052h	8	BS_FilSysType	File system Type: “FAT12”, “FAT16”, “FAT32”. Note: This field is not mandatory (BS_), it cannot be used to indentify the partition type.
	01FEh	2	BPB_Signature	AA55h

25.7.5 SPI

SPI EEPROMs or SPI flashes have an EEPROM or NOR Flash back-end and they connect to the device using the serial SPI protocol. These typical devices operate in three stages – the command stage, the address stage, and the data transfer stage. The command is usually an 8-bit value followed by the address (depending on the size of the device), followed by the data to be read or written. Because of the need for fewer pins, these devices are comparatively inexpensive, easy for board layout, and are the devices of choice when cost, complexity, and form factor are critical considerations.

25.7.5.1 Features

- Supports 12 MHz clock (50% duty cycle)
- Supports only SPI Mode 3 (clock polarity = 1, clock phase = 1)
- Supports only 24-bit addressable EEPROMs
- Supports only 4-pin SPI mode (CS, CLK, Serial Input, Serial Output)
- The boot devices must be connected to channel 0 and must support the Read Command (03h)
- The boot image is copied into internal memory and then executed

25.7.5.2 Initialization and Detection

The ROM Code initializes the SPI controller, pin muxing, and clocks for communicating with the SPI device. The controller is initialized in Mode 3 and the clock is setup to operate at 12 MHz. There is no specific device identification routine that is executed by the ROM code to identify whether a boot device is preset or not. If no SPI device is present, the sector read will return only FFFF FFFFh and the SPI boot will be treated as failed.

25.7.5.3 SPI Read Sector Procedure

The ROM Code reads SPI data from the boot device in 512-byte sectors. For each call to the SPI Read Sector routine, the SPI Read Command (03h) is sent along with the 24-bit start address of the data to be read.

From the next iteration onwards, a dummy value is transmitted on the master out line and the data is received on the master in line. This needs to be done because the SPI protocol always operates in full duplex mode. The dummy data transmitted by the ROM is the Read Command appended to the start address. The data from the boot device is received MSB first.

As the Cortex-A8 is a little-endian processor and the SPI operates in a big-endian format, this means that while writing to the Flash, care needs to be taken to write the image in a big-endian format. This avoids doing the endian conversion at boot time, thus improving boot performance.

25.7.5.4 Pins Used

The list of device pins that are configured by the ROM in the case of SPI boot mode are shown in Table 25-22. Note that all the pins might not be driven at boot time. The default state of the other SPI chip select pins could be low at POR, so care must be taken if any other devices are connected to CS[1], CS[2], or CS[3]. External logic must be used to ensure that the chip select to these devices are not enabled by default.

Table 25-22. Pins Used for SPI Boot

Signal Name	Pin Used
cs	$\overline{\text{SPI\_SCS[0]}}$
miso	SPI_D[0]
mosi	SPI_D[1]
clk	SPI_SCLK

25.7.5.5 Blocks and Sectors Search Summary

Table 25-23 summarizes the number of blocks and sectors that are searched during the memory booting from devices requiring image shadowing. NAND is organized with blocks, which are erasable units.

Table 25-23. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Blocks Checked	Number of Sectors Searched
NAND	First 4	Number of sectors in one block(1)
SPI, eSD and SD cards (raw mode)	First 4	1(2)

(1) Depends on NAND geometry
(2) Regarding SD card booting in FAT mode, the file system area is searched for one file.

25.8 Peripheral Booting

25.8.1 Overview

The ROM Code can boot from three different peripheral interfaces:

- ETHERNET: 1000/100/10 Mbps Ethernet, using standard TCP/IP network boot protocols BOOTP and TFTP over the GMII interface
- PCIe: Two lanes at 250 MB/s
- UART: 115.2Kbps, 8 bits, even parity, 1 stop bit, no flow control

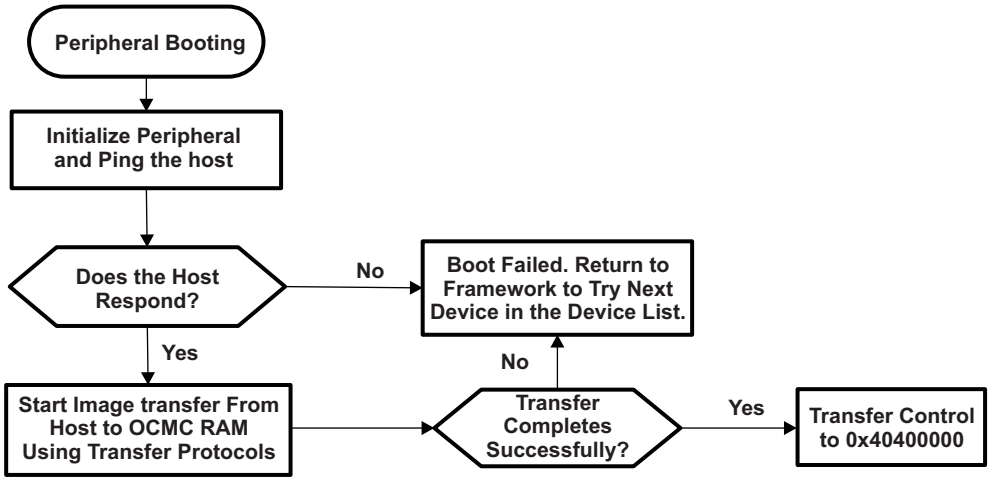
The purpose of booting from a peripheral interface is to download a boot image from an external host (typically a PC). This booting method is mostly used for programming flash memories connected to the device (for example, in the case of initial flashing, firmware update or servicing).

25.8.2 Boot Image Location and Size

The boot image is downloaded directly into internal RAM at the location 40400000h. The maximum size of downloaded image is 256KB.

25.8.3 Peripheral Boot Procedure Overview

Figure 25-22. Peripheral Booting Procedure



25.8.4 Ethernet Boot Procedure

25.8.4.1 Device Initialization

- Ethernet boot uses the CPGMAC0 subsystem of the device, connected to external Ethernet PHY using the GMII0 and MDIO pins.
- Device uses EFUSE register MAC_ID0 for Ethernet MAC address of the device.
- Device detects if the PHY is alive on the MDIO interface and
  - Reads the STATUS register to check if Ethernet link is active
  - Reads the CONTROL register to detect the auto-negotiated mode of operation
    - Is the mode full-duplex or half duplex
    - Speed of operation, 1000/100/10 Mbps

25.8.4.2 BOOTP (RFC 951)

The device then proceeds to obtain the IP and Boot information using BOOTP protocol. The device prepares and broadcasts the BOOTP message that has the following information:

- Device MAC address in “chaddr” field – to uniquely identify the device to the server.
- “Vender-class-identifier” option number 60 (RFC 1497, RFC 1533). Servers could use this information to identify the device type. The value present is "DM816x ROM v1.0"
- ”Client-identifier” option number 61 (RFC 1497, RFC 1533). This has the ASIC-ID structure which contains additional info for the device.

The device then expects a BOOTP response that provides the following information for the booting to proceed:

- Device IP address from “yiaddr” field
- Subnetmask from extended option 1 (RFC 1497, RFC 1533)
- Gateway IP from extended option number 3 (RFC 1497, RFC 1533) or from “giaddr” field of BOOTP response.
- Boot image filename from “file” field

  Timeouts and retries
- Exponentially increasing timeouts starting from 4s
- Five retries

25.8.4.3 FTP (RFC 1350)

After a successful BOOTP completion, the device initiates the TFTP download of the boot image into SRAM. The device has the capability to reach TFTP server within the local subnet or outside, though the gateway.

Timeouts and retries

- Timeout of 1s to receive a response for the READ request
- 5 retries for the READ request
- Retries are managed by server once data transfer starts (server re-sends a data packet if the ACK was not received within a timeout value)
- Device has a 60s timeout to complete the data transfer, to handle the scenario if the server dies in the middle of a data transfer

25.8.4.4 Pins Used

The list of pins that are configured by the ROM in case of Ethernet boot mode are in Table 25-24. Note that all the pins might not be driven at boot time.

Table 25-24. Pins Used for Ethernet Boot

Signal Name	Pin Used
col	gmii0_col
crs	gmii0_crs
gtx_clk	gmii0_gtxclk
rx_clk	gmii0_rxclk
rxd0-rxd7	gmii0_rxd0-rxd7
rxdv	gmii0_rxdv
rxer	gmii0_rxer
tx_clk	gmii0_txclk
txd_0-txd7	gmii0_txd0-txd7
txen	gmii0_txen
mclk	gmii0_mclk
mdio	gmii0_mdio

25.8.5 PCIe Boot Procedure

25.8.5.1 Device Initialization

- ROM code configures the PCIe vendor ID as 104Ch
- ROM code configures the PCIe device ID as B800h.
- The BAR window sizes for inbound translation are configurable as per the following tables.
- Only legacy interrupt A is enabled. MSI is disabled.
- The device is configured in the D0 power state.
- The link and device capability is configured for maximum flexibility.
- The PCIe settings used by the ROM can be overridden after boot by the Root Complex.

Figure 25-23. PCIe Peripheral Booting Procedure

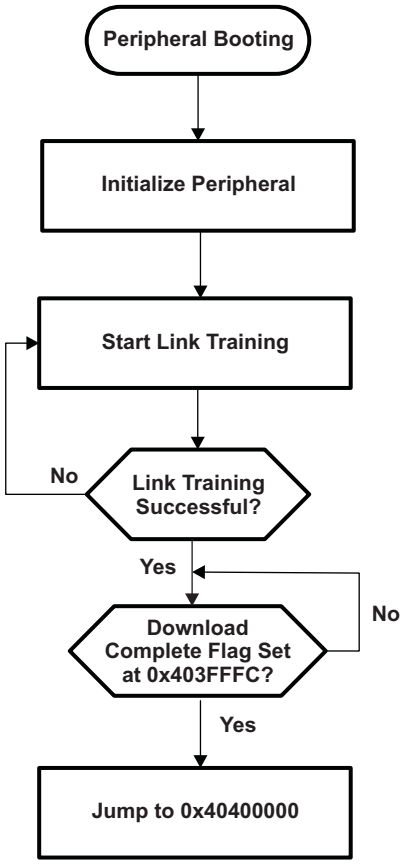


Table 25-25. PCIe 32 BAR Window Size Configuration (PG1.x Devices)

BAR0	BAR1	BAR2		BAR3		BAR4

	01	256 MB	01	1 GB
	10	512 MB	10	2 GB
	11	1 GB	11	4 GB

Table 25-29. PCIe BAR Window Base Address and Offset Configuration

BAR	Base Address	Offset	Comments
0	0000 0000h	0000 0000h	
1 (64bit BAR0)	8080 0000h	4040 0000h	OCMC RAM1
2	8100 0000h	0800 0000h	GPMC
3 (64 Bit BAR2)	8180 0000h	8000 0000h	DDR 0
4	8200 0000h	C000 0000h	DDR 1

Note that the Base Address and Offset configurations can be changed from the host after the enumeration is complete.

25.8.6 UART Boot Procedure

25.8.6.1 Device Initialization

- UART boot uses UART0
- UART0 is configured to run at 115200 baud, 8-bits, even parity, 1 stop bit and no flow control.

25.8.6.2 Boot Image Download

- UART boot uses x-modem client protocol to receive the boot image.
- Utilities like hyperterm, teraterm, minicom can be used on the PC side to download the boot image to the board
- With x-modem packet size of 1K throughout is roughly about 4KBytes/Sec.
- The ROM code will ping the host 10 times in 3s to start x-modem transfer. If host does not respond, UART boot will timeout.
- Once the transfer has started, if the host does not send any packet for 3s, UART boot will time out
- If the delay between two consecutive bytes of the same packet is more than 2ms, the host is requested to re-transmit the entire packet again
- Error checking using the CRC-16 support in x-modem. If an error is detected, the host is requested to re-transmit the packet again

25.8.6.3 Pins Used

The list of pins that are configured by the ROM incase of UART boot mode are in Table 25-30. Note that all the pins might not be driven at boot time

Table 25-30. Pins Used for UART Boot

Signal Name	Pin Used
rx	UART0_RXD
tx	UART0_TXD

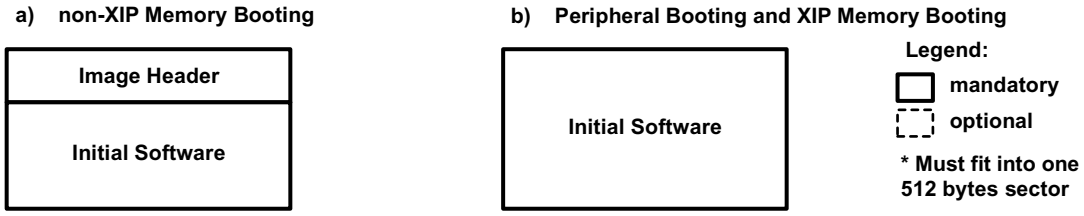
25.9 Image Format

25.9.1 Overview

All preceding sections describe how the ROM Code searches and detects a boot image from a memory or a peripheral device type. This section describes the format of the boot image. A boot image is a header containing the destination address and size of the image for non-XIP memory devices.

The mandatory section of a boot image contains the software that will be loaded into the memory and executed. An overview of the image formats is shown in Figure 25-24.

Figure 25-24. Image Formats



(a) Non-XIP Memory Booting: Image must begin with a header that contains information on image size and destination address

(b) Peripheral Booting and XIP Memory Booting: When memory device is of XIP type (for example, NOR), the header is not needed and the image can contain code for direct execution. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

25.9.1.1 Image Format

When the booting memory device is non-XIP, the image must contain a small header with the size of the software to load and the destination address where to store it.

The header is not needed when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 25-31. Image Format

Field	Non-XIP Device (offset)	XIP Device (offset)	Size (bytes)	Description
Size	0000h	-	4	Size of the image
Destination	0004h	-	4	Address where to store the image / code entry point
Image	0008h	0000h	x	Executable code

Note: the “Destination” address field stands for both:

- • Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- • Entry point for image code

In other words, you must take care to locate the code entry point to the target address for image copy.

25.10 Image Execution

25.10.1 Overview

One of the early steps of the ROM Code execution is to search for a boot image from the requested medium (configured by the MBOOT pins) and copy it to RAM if needed. If the boot interface is non-XIP, then the image is simply copied to the provided destination address (internal or external RAM) and then executed. If the boot interface is of XIP type, then the image copy is not needed and execution is directly given to the XIP memory.

25.10.2 Execution

The image is executed at the time the ROM Code performs the branch to the first executable instruction inside the Initial SW. In non-XIP, the execution address is the first word after the header. The branch is performed in public ARM supervisor mode. The R0 register points to the Booting Parameters structure which contains various information about the booting execution. Table 25-32 details this structure.

Table 25-32. Booting Parameters Structure

Offset	Field	Size (bytes)	Description
0h	Booting Message	4	Last received Booting Message.
4h	Memory booting device descriptor address	4	Pointer to the memory device descriptor that has been used during the memory booting process
5h	Current Booting Device	1	Code of device used for booting 0h – void, no device 1h – XIP memory 2h – XIPWAIT memory (wait monitoring on) 3h – NAND 4h – OneNAND 5h – SD port 1 (Card) 6h – SD port 2 (JC64) 7h – EMIF NVM 43h – UART3 45h – USB (internal) 46h – USB-ULPI
6h	Reset Reason	1	Current reset reason bit mask (bit = 1-event present) [0] – power-on reset [1] – global software reset [4] – MPU watchdog reset [6] – external warm reset Other bits – reserved
7h	Reserved	1	Reserved

25.11 Services for HLOS Support

The Cortex-A8 in the device restrict accesses to few ARM coprocessor registers. In order for the HLOS to access secure registers for L2 cache maintenance and wake up of slave CPU(s), the ROM Code provides primitives that can be called.

The list of services is:

- L2 cache maintenance
  - L2 Cache Set Debug Register
  - L2 Cache Clean & Invalidate Range of PA
  - L2 Cache Set Control Register
- Multicore infrastructure maintenance
  - Read AuxCoreBoot 0 and 1 Register
  - Modify AuxCoreBoot 0
  - Write AuxCoreBoot 1
  - Read Control and Status Register
  - Clear Control and Status Register

25.12 Tracing

Tracing in the ROM Code consist in three 32 bit vectors for which each bit corresponds to a particular “way point” in the ROM Code execution sequence (refer to Table 25-5). Tracing vectors are initialized at the very beginning of the startup phase and updated all along the boot process.

There are two sets of tracing vectors. The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM Code run after cold reset. As a consequence after a warm reset, it is possible to have visibility on the boot scenario that occurred during cold reset.

Table 25-33. Tracing Vectors

Trace vector	Bit #	Group	Meaning
1	0	General	Passed the public reset vector
1	1	General	Entered main function
1	2	General	Running after the cold reset
1	3	Boot	Main booting routine entered
1	4	Memory Boot	Memory booting started
1	5	Peripheral Boot	Peripheral booting started
1	6	Boot	Booting loop reached last device
1	7	Boot	Header found
1	8	Boot	Booting Message “Skip Peripheral Booting” received
1	9	Boot	Booting Message “Change Device” received
1	10	Peripheral Boot	Booting Message “Peripheral booting” received
1	11	Peripheral Boot	Booting Message “Get Asic Id”
1	12	Peripheral Boot	Device initialized
1	13	Peripheral Boot	Asic Id sent
1	14	Peripheral Boot	Image received
1	15	Peripheral Boot	Peripheral booting failed

On-Chip Debug Support

This chapter describes the on-chip debug support.

Topic **Page**

26.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software running on a host computer, to a low-level debug interface supported by the target device. An emulator device facilitates communication between the host debugger and the emulation logic on the target chip.

The emulation layer is a combination of hardware and software that connects the host debugger to the target system. It utilizes one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG commands and scans that exercise the core hardware.

The device implements the following debug features:

- Debug interface with 5 standard JTAG pins + RTCK pin + EMU[4:0] pins, which supports:
  - Standard JTAG (IEEE1149.1) protocol, and adaptive clocking scheme of ARM® ARM9™ processor
  - Cross-triggering between devices, and debug boot mode control via EMU[1:0] pins
  - Export of system trace data over EMU[4:0] pins
- Support debug capabilities of individual processor, including:
  - Advanced Event Triggering (AET) for C674x DSP
  - Six ARM968™ processor cores enhanced with TI's ICECrusher-9 modules, residing in the three HDVICP subsystems
  - Cortex-A8 core enhanced with TI's ICECrusher-CS module, residing in the MPU subsystem
  - Debug activities shall not been interrupted by events of clock-gate or power-down of an individual subsystem.
- Support limited debug capabilities of Hardware Accelerators (HWAs), residing in the three HDVICP subsystems (6 HWAs per HDVICP)
- Support multi-core debug capabilities, including:
  - Two cross-triggering channels (Trigger0, and Trigger1), shared by:
    - All processors in the device
    - External device (via EMU[1:0] pins)
    - Other debug modules that have only input trigger line - L3 Statistics Collector, MIPI® System Trace Module (STM), and HDVICP HWAs + Software Message and System Event Trace (SMSET) module
  - Synchronized (global) run with C674x DSP, Cortex-A8, Media Controller, ARM968s, and all HWAs
- Support debug related reset features, including:
  - Debugger-generated system reset and subsystem resets via ICEPick-D
  - Debugger-generated local resets to individual processor (both DSP Subsystem and ICECrusher can generate a local reset)
  - Blocking certain system reset generated by applications
  - Blocking subsystem local resets generated by applications
  - Debug logics shall survive all resets except global cold resets or nTRST/TLR
  - nTRST/TLR resets only affect debug and test logics. It does not affect any functional operation of the device
  - Wait-In-Reset (WIR) debug boot mode
- Support system memory accesses and debug components access via the DAP port without halting any processors
- Support Embedded Trace Buffer (ETB) based CPU trace for Cortex-A8 and C674x DSP, including:
  - Support Cortex-A8 program trace, timing trace, and data trace (address only)
  - Support C674x DSP program trace, timing trace, and data trace
  - A single 32KB ETB shared by Cortex-A8, C674x DSP, and system trace

- Support STM-based system trace as following:
  - SW messages generated by application code running on each processor
  - HW messages generated by bus monitors and system event monitors
  - Trace data can be exported to either EMU[4:0] pins or ETB buffer
- Peripherals, memories, as well as MMU units are aware of debug activities:
  - Debug access to invalid memory locations, which might be reserved, clock-gated, or powered-down, does not cause system hang
  - Debug activities does not affect the correctness of an application:
    - Peripheral, which is sensitive to a debug access, distinguishes access initiated from debugger versus from application
    - Peripheral, which is sensitive to a debug event (CPU halt), behaves properly during processor suspension
    - Errors triggered by a debug access does not cause any undesired interrupt or exception to the normal execution of a processor
    - The result of MMU table-walk caused by a debug access is not written into TLB; MMU translation fault caused by debug access does not trigger the translation fault interrupt/exception

The following commonly used debug features are not supported in the device:

- Off-chip trace of C674x DSP (via pins)
- Off-chip trace of Cortex-A8 (via pins)

26.2 Debug Interface

26.2.1 IEEE1149.1 JTAG Mode

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals:
  - nTRST
  - TCK
  - TMS
  - TDI
  - TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968 processor
- Two EMU[1:0] or five EMU[4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 26-1 describes the IEEE1149.1 signals.

Table 26-1. IEEE1149.1 Signals

Device Pin Name	Internal Signal Name	Type[1]	Function	Description
$\overline{\text{TRST}}$	nTRST	I	Test reset	When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE1149.1 interface
TCLK	TCK	I	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. Depending on the emulator attached to the device, this is a free running clock or a gated clock depending on RTCK monitoring.
RTCK	RTCK	O	Returned (synchronized) test clock	Depending on the emulator attached to the device, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
TMS	TMS	I	Test mode select	Directs the next state of the IEEE1149.1 TAP state-machine
TDI	TDI	I	Test data input	Scan data input to the device
TDO	TDO	O	Test data output	Scan data output by the device
EMU0	EMU0	I/O	Emulation 0	Channel 0 trigger, debug boot mode, or system trace port
EMU1	EMU1	I/O	Emulation 1	Channel 0 trigger, debug boot mode, or system trace port
EMU2[2]	EMU2	I/O	Emulation 2	System trace port
EMU3[2]	EMU3	I/O	Emulation 3	
EMU4[2]	EMU4	I/O	Emulation 4	

(1) I = Input; O = Output; I/O = Bidirectional
(2) 20-pin JTAG header only

For information about internal pullup/pulldown resistors on the debug interface pins, see the device datasheet.

For information about the JTAG ID code value, see the *TMS320DM816x DaVinci Digital Media Processors Silicon Errata* (SPRZ329).

26.2.2 Trace Connector and Board Layout Considerations

For information about board design guidelines for Trace Advanced Emulation, see *Emulation and Trace Headers Technical Reference Manual* (SPRU655).

26.3 Debugger Connection

26.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the ICEPick module embedded in the Debug Subsystem.

NOTE: ICEPick version D (ICEPick-D) is used in the device.

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view, and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion:
  - Serially linking up to 32 TAP controllers
  - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management:
  - Provides the power and clock states of each domain
  - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  - Applies system reset
  - Provides wait-in-reset (WIR) boot mode
  - Provides global and local WIR release
  - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. When the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see Section 26.3.3.

For more information about ICEPick power, reset, and clock management features, see Section 26.6.

26.3.2 Debug Boot Modes

ICEPick supports debug boot modes determined by the level of the EMU0 and EMU1 pins upon a rising edge of the Power-On Reset (POR) signal. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins are free when POR is released.

Table 26-2 summarizes the debug boot modes.

Table 26-2. Debug Boot Modes Upon POR

EMU1	EMU0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + WIR mode
1	1	ICEPick	TAP only (default mode)

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

The device can also boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

26.3.3 Dynamic TAP Insertion

To include secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the emulator selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Table 26-3 shows the secondary debug and test TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP ID indicates the position of the TAP in the scan chain.

Table 26-3. ICEPick Secondary Debug and Test TAP Mapping

Secondary JTAG Port	TAP ID	IR Scan Length	Modules Accessed Through That JTAG Port
Test Bank

NOTE:

- The DAP provides a way for the debugger to access:
  - Debug peripherals inside and outside the DebugSS for configuration purposes (through the APB port)
  - Device-level resources for program downloading and access to application peripherals without any requirement to halt or be intrusive to a CPU in the device (through the AHB port)

Besides secondary debug TAPs, ICEPick supports also power, reset, and clock controls for non-JTAG debug cores. The debug cores are accessible through the Debug Access Port (DAP).

Table 26-4 summarizes the ICEPick debug core mapping.

26.4 Basic Debug Support

26.4.1 Processors Native Debug Support

26.4.1.1 Cortex-A8

The Cortex-A8 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six hardware breakpoints and two watchpoints
- Performance monitoring
- Trace

For more information about Cortex-A8 native debug features, refer to the ARM® Cortex®-A8 Technical Reference Manual.

Additionally, the native debug features of Cortex-A8 are enhanced by an ICECrusher-CS module as follows:

- Two cross-triggering channels
- Debug reset support

26.4.1.2 C674x

The C674x processor supports the following debug features through the ICEMaker module:

- Run/halt/single-step the target
- Total of ten hardware breakpoints (four from ICEMaker, six from AET)
- Download code
- Access to memory and registers
- Real-time capabilities which include:
  - Access to memory or registers while CPU is running
  - Time-critical interrupts can still be serviced during CPU halt at a debug event
- Trace

26.4.1.3 ARM968

The ARM968E-S processor supports the following native debug features through its EmbeddedICE-RT logic:

- Basic debug functions – run, halt, step, and software breakpoint (SWBP)
- Non-real-time debug – access to register/memory while CPU halt
- Real-time debug (a debug event will trigger a debug interrupt instead of halting CPU)
- Two hardware breakpoints (HWBP) which can used as data watchpoints (WP) as well
- Maskable cycle type and address and data comparison for HWBPs and WPs

For more information about ARM968 native debug features, refer to the ARM968E-S™ Technical Reference Manual.

Additionally, the native debug features of ARM968 are enhanced by an ICECrusher-9 module as follows:

- Two cross-triggering channels
- Bus hang detection and CPU force ready
- Two multi-mode performance/benchmark counters
- JTAG clock synchronization
- Adaptive clocking
- Debug reset support

26.4.1.4 HDVICP Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SyncBox module:

- Manual halt: Halt occurs at the SYNCBOX task boundary, when requested by the debugger
- Single-step execution at SYNCBOX task level (from 1 to *n* macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt, after the execution of current SYNCBOX task, based on trigger event detection
- Global run

Table 26-5 summarizes the debug capabilities of the hardware accelerators.

Table 26-5. Hardware Accelerators Debug Capability Options

Feature	iME3	iPE3	MC3	CALC3	iLF3	ECD3
Core reset	–	–	–	–	–	–
Execution request	–	–	–	–	–	–
Trigger output	–	–	–	–	–	–
Trigger input	✓	✓	✓	✓	✓	✓
Number of trigger channels	1	1	1	1	1	1
Number of counters	0	0	0	0	0	0
Number of watchpoints	0	0	0	0	0	0
Number of hardware breakpoints	0	0	0	0	0	0

26.4.2 Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, *Subsystem A* can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another *Subsystem B* can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

The device implements two global cross-triggering lines: Trigger0 and Trigger1.

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

NOTE: XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

The Trigger0 and Trigger1 lines can also be configured as external triggers and contribute to cross-triggering.

Table 26-6 summarizes the cross-triggering connections in the device.

Table 26-6. Cross-Triggering Connections in the Device

Module	Channels	Generate/Take Triggers	Comments
Inside DebugSS			
Device to device via pins	Trigger0 / Trigger1	yes / yes	Device to device trigger via EMU[1:0] pins. This is fixed (not affected by configuration)
STM	Trigger0 / Trigger1	no / yes	Trigger generated by STM
Outside DebugSS

Media Controller (HDVICP control)	Trigger0 / Trigger1	yes / yes	–
Media Controller (HDVPSS control)	Trigger0 / Trigger1	yes / yes	–
OCP_WP	Trigger0 / Trigger1	yes / yes	–
SMSET_HDVICP2-0	Trigger0 / Trigger1	no / yes	Shared with IME3_HDVICP2-0, ILF3_HDVICP2-0, IPE3_HDVICP2-0, ECD3_HDVICP2-0, MC3_HDVICP2-0, CALC3_HDVICP2-0. It can only take triggers.
SMSET_HDVICP2-1	Trigger0 / Trigger1	no / yes	Shared with IME3_HDVICP2-1, ILF3_HDVICP2-1, IPE3_HDVICP2-1 ECD3_HDVICP2-1, MC3_HDVICP2-1, CALC3_HDVICP2-1. It can only take triggers
SMSET_HDVICP2-2	Trigger0 / Trigger1	no / yes	Shared with IME3_HDVICP2-2, ILF3_HDVICP2-2, IPE3_HDVICP2-2 ECD3_HDVICP2-2, MC3_HDVICP2-2, CALC3_HDVICP2-2. It can only take triggers
L3 Debug Port	Trigger0 / Trigger1	no / yes	Entire L3 NoC (including statistics collectors) can only take triggers

26.4.3 Debug Suspend

The device supports a debug suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters a debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors. For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and therefore is coded using 1 bit, usually named EMUFREE or FREEEMU):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

Peripherals might be used by multiple host processors. The Debug Resource Manager (DRM) in DebugSS provides a MUX for each peripheral for user to select the suspend source.

Table 26-7 lists the mapping of the device processors to the DRM suspend control input lines.

Table 26-7. Debug Suspend Host Processors Mapping

Suspend Input Line	Host Processor
0	Cortex-A8
1	DSP

(1) One common suspension input signal (and one FREEEMU control bit) for the two USB2.0 modules

26.5 Real-Time Debug Events

A few device interrupt channels are dedicated to debug support. Table 26-9 summarizes the debug interrupt events.

Table 26-9. Debug Interrupts

Interrupt Request	Subsystem	Source	Description
EMUINT	Cortex-A8 MPU subsystem	Cortex-A8 ICECrusher-CS	ICECrusher-CS emulation interrupt (EMUINTR)
COMMTX			Cortex-A8 communication transmit channel (COMMTX)
COMMRX			Cortex-A8 communication receive channel (COMMRX)
BENCH			Cortex-A8 PMU (nPMUIRQ)
EMU_DTDMA	DSP subsystem	C674x ICEMaker	ECM interrupt (host scan access, DTDMA)
IC_NINTR1	HDVICP subsystems	ARM968 ICECrusher-9	Combined iCONT1 ICECrusher-9 interrupts (EMUINTR, COMMRX, COMMTX, counters overflow)
IC_NINTR2		ARM968 ICECrusher-9	Combined iCONT2 ICECrusher-9 interrupts (EMUINTR, COMMRX, COMMTX, counters overflow)

NOTE: The debug interrupts are contained within their respective subsystems and do not require additional handling at the SoC level.

26.6 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
  - Current power setting indicating whether the power domain is on or off
  - Loss of power detected since software last checked the status
  - Current clock setting indicating whether the clock domain is on or off
  - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  - Subsystem reset state
  - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

26.6.1 Power and Clock Management

26.6.1.1 Power and Clock Control Override From Debugger

The debugger can override the application software power and clock management settings through the ICEPick module. It can configure ICEPick to force a domain active or prevent it from going to sleep once it is active. This can be achieved through the FORCEACTIVE and INHIBITSLEEP debugger directives.

26.6.1.1.1 Debugger Directives

26.6.1.1.1.1 FORCEACTIVE Debugger Directive

To ensure that the subsystem debug registers can always be accessed, regardless of the application power-management scenarios, a FORCEACTIVE directive can be issued through the debugger during the entire debug session. From an application standpoint, the system state, status, and timing are preserved, but the subsystem power domain is never shut down. Therefore, the emulation setup is preserved across power transitions, regardless of where the debug hardware is implemented.

If the debugger connects and the subsystems were previously powered down, a FORCEACTIVE directive wakes the system and allows the debugger to take control.

26.6.1.1.1.2 INHIBITSLEEP Debugger Directive

The debugger can use the INHIBITSLEEP directive to keep a subsystem powered and clocked, even if the relevant settings request that this subsystem go to sleep. Unlike the FORCEACTIVE directive, the INHIBITSLEEP command does not wake up a subsystem that is already powered down by the application.

The typical use of the INHIBITSLEEP directive is to prevent power and clock transitions on the subsystem during a debug session. In this situation, when the relevant scenario initiates a transition, the transition does not occur, but from an application standpoint the subsystem is not accessible.

26.6.1.1.2 Intrusive Debug Model

The use of debugger directives is intrusive from the standpoint of the power and clock controls, because they affect the power-management behavior of the application.

26.6.1.2 Debug Across Power Transition

26.6.1.2.1 Nonintrusive Debug Model

To preserve the power-management behavior of the device and allow the subsystem power and clock to be switched off by application software, the subsystem TAP must be disconnected from the ICEPick scan chain. The subsystem is then completely ignored by the debugger and the host-to-target communication is no longer affected by the state of the subsystem power and clocks. The debugger can still be informed that the disconnected subsystem entered the debug state by polling the Debug Attention status bit from ICEPick. The debugger can then insert the TAP, take control of the subsystem power and clock, and examine the system state.

This debug model is nonintrusive, because it can preserve the power-management behavior of the application.

26.6.1.2.2 Debug Context Save and Restore

26.6.1.2.2.1 Debug Context Save

The device partitioning is such that not all the debug components are mapped to an always-on domain. Typically, the programmer wants the debug setup to be preserved along a debug session, including subsystem power cycling. When debug registers are memory-mapped and not implemented within the PD_EMU power domain, the application software must save the state of the debug registers before going to sleep and restore them upon wakeup.

26.6.1.2.2.2 Debug Context Restore

When the application software performs a context restore, it must be able to write to all the debug registers to restore their contents, regardless of the previous ownership. After the subsystem power domain ramps up, the debug resources are in the available state, and ownership is restored. The debug context save and restore sequences are protected. All debug functionality is disabled and debugger accesses are blocked.

26.6.2 Reset Management

The debugger can take control of the system reset for each subsystem through ICEPick. The debugger can configure ICEPick to assert, block, or extend the subsystem reset.

26.6.2.1 Debugger Directives

26.6.2.1.1 Assert Reset

The debugger can program ICEPick to generate a subsystem reset request to the device reset management module. The debugger reset event is then merged with system reset events.

26.6.2.1.2 Block Reset

The debugger can program ICEPick to request the device reset management module to block an unsafe application system or subsystem reset event.

A reset originated by some safe reset sources cannot be blocked by the debugger.

26.6.2.1.3 Wait-In-Reset

Wait-in-reset (WIR) mode is latched from boot mode (see Section 26.3.2) and lets the user hold a secondary TAP module in a reset state when a reset is applied (and thus, extend the reset). This mode lets the user:

- Gain emulation control of any processor in a power domain at POR
- Capture and extend system-generated functional resets while running (under emulation control or not)
- Hold an entire power domain in reset until emulation control of the subsystem can be established
- Stall the entire system while reset is extended to a power domain
- Reset extensions visible external to the power domain
- Debug execution of code from the first cycle of execution
- Prevent processor execution of random instructions in uninitialized program memory at power up
- Download code before any code execution occurs
- Coordinate debug initialization across multiple cores before code execution begins

WIR mode extends only the processor reset. During reset extension, the debugger can still access modules such as L2 memory and MMU, even if they are embedded in the device subsystem affected by WIR.

When the debugger task is complete, the emulator releases the subsystem reset by programming the corresponding ICEPick TAP control register.

26.7 Performance Monitoring

26.7.1 Cortex-A8 MPU Subsystem Performance Monitoring

The Cortex-A8 processor includes a Performance Monitoring Unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides four counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A8. Upon counter overflow, PMU can generate an interrupt on its nPMUIRQ output. This interrupt signal is mapped to the CTI TRIGIN[1] input and also routed to interrupt line #3 (BENCH event) of the Cortex-A8 MPU AINTC.

For Cortex-A8 PMU event mapping, refer to the ARM® Cortex®-A8 Technical Reference Manual.

26.8 Trace Support

The device supports trace at the Cortex-A8, C674x DSP, and system levels. Trace is a debug technology that provides a detailed, historical account of application code execution, timing, and data accesses. Trace collects, compresses, and exports debug information for analysis. The debug information can be exported to the ETB, or to the 5-pin (EMU[4:0]) trace interface (system trace only). Trace works in real-time and does not impact the execution of the system.

26.8.1 Processor Trace

The device supports two CPU traces: ARM Cortex-A8 and C674x DSP.

The Cortex-A8 processor trace is only stored to ETB and is not exported off chip. It is supported by ETM module, which generates a real-time trace that can be configured to include: program (instruction) trace, and data trace (address only). Tracing of data values is not supported by Cortex-A8 ETM. The ETM outputs trace to the ETB via its ATB interface.

The DSP processor trace is also only stored to ETB and is not exported off chip. It is supported by ADTF module, which needs to be programmed to convert the DSP trace format to ATB format (for ETB storage).

The CPU traces are routed to the ETB via a CoreSight Trace Funnel (CS_TF). The CS_TF combines multiple trace streams onto a single ATB bus.

The ETB supports on-chip buffering in two modes: circular buffer and one-shot mode.

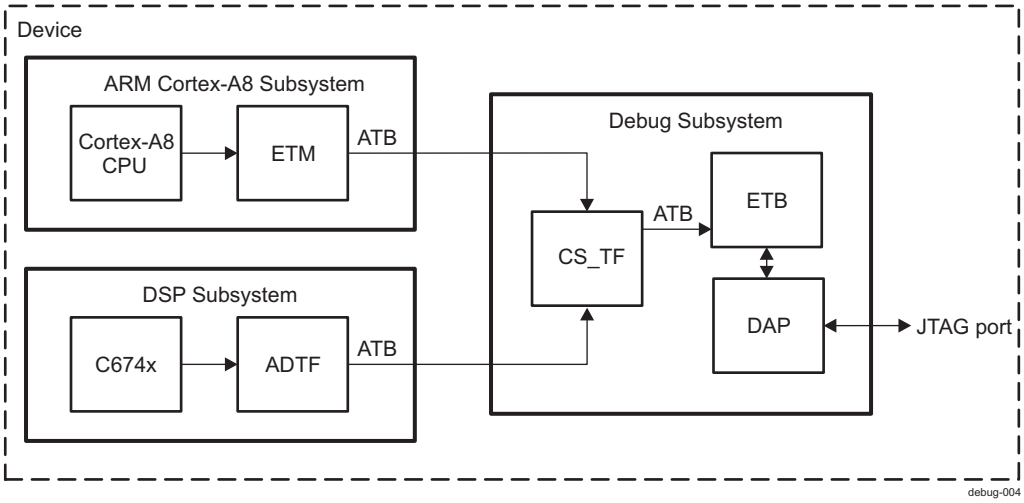
In circular buffer mode, the ETB continuously captures and writes data into memory when trace capture is enabled and its trigger counter is static at 0 (or has not yet decremented to 0). The trace window can be adjusted around a specific trigger spot (trace before, trace after, or trace around) using the ETB trigger counter.

The one-shot mode is not natively supported by the ETB and is actually a TI addition.

For more information about ETB, see the ARM® CoreSight™ Components Technical Reference Manual.

Figure 26-1 shows an overview of the processor traces flow.

Figure 26-1. Processor Traces Flow



26.8.2 System Trace

26.8.2.1 MIPI STM

The STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages. See Section 26.9.5.1 for the list of software masters
  - Hardware messages. See Section 26.9.5.2 for the list of hardware masters
- Exports trace data to:
  - External trace receiver
  - On-chip trace buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Timestamps:
  - Calculated by the trace receiver if exported off-chip
  - Can use local relative timestamp if exported to the on-chip ETB buffer
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 256 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

26.8.2.2 Trace Exported to an External Trace Receiver

System trace data can be exported to an external trace receiver through the STM module. The debugger or application software must take care to program the DRM module according to Table 26-24.

The STM has configurable export width of 1, 2, or 4 data pins (STM_DATA), plus a dedicated export clock (STM_CLK).

26.8.2.3 Trace Captured Into On-Chip Trace Buffer

The user can also configure the STM module to redirect the STP trace stream to the on-chip trace buffer (ETB) and enable local timestamp. This is accomplished by outputting a local timestamp granularity (LTSG) message, which is a TI addition to the MIPI standard messages.

26.9 System Instrumentation

The device supports the following system instrumentation features (that can generate system trace messages):

- Real-time software trace (see Section 26.9.1)
- OCP target traffic monitoring (see Section 26.9.2.1)
- System events (see Section 26.9.2.2)
- L3 target load and master latency monitoring (see Section 26.9.4)
- HWA load monitoring (see Section 26.9.3)

26.9.1 Software Instrumentation

The device provides support for real-time software trace through user-defined (that is, by application code) message writes to specific STM memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the STP protocol. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The format of a software message can be defined by specific application. On the receiver side, master ID (associated with individual processor) and channel ID (associated with specific memory mapped address of STM) are both inserted in the exported trace data by STM, and are used to decode the received messages.

Moreover, by carefully assigning channel IDs, the use of semaphore or mutex could be avoided, which would dramatically reduce the intrusiveness to an application.

The software masters supported in the device are:

- Cortex-A8 CPU (via L3)
- DAP (via L3); for testing purpose
- C674x DSP (via L3)
- Media Controller Subsystem (via L3)
- ARM968 of each HDVICP subsystem (via L3, and via SMSET)
- EDMA transfer controller write ports 1 and 2 (TPTC_WR1, and TPTC_WR2)

Each software master has a master-ID assigned to it (see Section 26.9.5.1).

Software messages can be interleaved with hardware messages.

26.9.2 OCP Bus Traffic Monitor (OCP_WP)

26.9.2.1 OCP Target Traffic Monitoring

The device instantiates one OCP watchpoint (OCP_WP) module and five OCP traffic probes inside the L3 NoC for OCP traffic monitoring. The probes are attached to the following L3 targets:

- GPMC
- L4_HS
- L4_LS
- OCMC_RAM0
- OCMC_RAM1

The outputs of the probes are muxed together and then sent to the L3 debug port. The OCP_WP is used to collect data from the OCP traffic probes and then transmit captured data to the STM module. The OCP_WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP_WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
  - Address range
  - Initiator-ID (also named ConnID). For ConnID values of the various L3 initiators, see the *Bus Interconnect* section of the *Chip Level Resources* chapter.
  - Transaction type
  - Transaction qualifier
- Generating a trigger upon WP match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- Generating hardware message upon system event (see Section 26.9.2.2)
- OCP_WP messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

NOTE: The OCP_WP is restricted to monitor request flow only.

The user can program the OCP_WP to extract the traffic from a specific set of initiators (maximum four).

Table 26-10 summarizes the OCP targets that can be monitored by the OCP_WP and their respective probe-ID.

Table 26-10. OCP Traffic Probes Mapping

Probe-ID	L3 OCP Target
000	Reserved(1)
001	GPMC
010	L4_HS
011	L4_FS
100	OCMC_RAM0
101	OCMC_RAM1
110	Reserved
111	Reserved

(1) No selection. This is also for power saving.

26.9.2.2 Messages Triggered from System Events

The OCP_WP can be programmed to export a hardware message through the STM upon detection of a system event (interrupt, DMA request). A bus of 16 system events pre-selected at SoC level from a total of 256 system events is routed to the OCP_WP. An event selector controlled by the device Control Module is used to select the system events to be traced.

To simplify the design of the event selector and maintain the flexibility of event selection, the 256 events are grouped into four groups of 64. For each group, a 64-bits configuration register (HW_EVT_SEL_GRPx, where x = 1 to 4) is used to select 4 events out of 64. For the description of the HW_EVT_SEL_GRPx registers, refer to the *Control Module* section of the *Chip Level Resources* chapter.

26.9.3 HDVICP Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding HDVICP micro-task sequencing. This is supported through a SMSET module instantiated in each of the three HDVICP subsystems. The micro-task boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the MIPI-STM module.

The HDVICP instrumentation scheme allows the user to understand micro-task dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as HDVICP events. Software messages from ARM968 execution can be interleaved with HDVICP events.

The HDVICP subsystem provides an instrumentation master port that interfaces directly with the debug subsystem. This ensures that the HDVICP instrumentation is not intrusive and does not affect the L3 application traffic.

26.9.4 L3 Load and Latency Monitors

The L3 interconnect supports a built-in performance monitoring feature by implementing a number of performance probes, as well as a statistics collector (SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI_STM interface. Four SC instances are instantiated in the device:

- One statistics collector dedicated to DDR2/3 SDRAM load monitoring – SC_SDRAM (see Section 26.9.4.1). The probes connected to this SC are of OCP type.
- Three statistics collectors dedicated to master latency monitoring – SC_LAT0, SC_LAT1, and SC_LAT2 (see Section 26.9.4.2). The probes connected to this SC are of NTTP type.

Statistics collectors (SDRAM and LAT0/1/2) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- % Link occupancy on the request link (for store transactions) during a sampling window
- % Link occupancy on the response link (for load transactions) during a sampling window
- % Arbitration conflict cycles on the request link
- % Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16 , 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for HDVICP initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in Table 26-11.

Table 26-11. Performance Monitoring Events Detection

Link Event	NTTP	OCP	Definition
NONE	✓	✓	No event selected
ANY	✓	✓	Any clock cycles
TRANSFER	✓	✓	Word has been accepted by the receiver.
WAIT	✓	–	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	✓	✓	Receiver applies flow control
PKT	✓	✓	Transfer of a new packet header
DATA	✓	✓	Transfer of a payload word
IDLES	✓	✓	No communication over the link

Table 26-11. Performance Monitoring Events Detection (continued)

Link Event	NTTP	OCP	Definition
LATENCY	✓	–	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in Table 26-12.

Table 26-12. Performance Filtering Options

Probe Filtering Options	Description
Master address	Mask and match
Slave address[1]	
UserInfo	
Read	
Write	
Error	
OCP address[2]	

(1) SC_LAT0/1/2 only
(2) SC_SDRAM only

For master address mapping (all statistics collectors) and slave address mapping (SC_LAT0/1/2 only), see the *Bus Interconnect* section of the *Chip Level Resources* chapter.

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are not accessible by application software.

Table 26-13 summarizes the performance probe aggregation modes.

Table 26-13. Aggregation Modes

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range. - Payload length (bytes) - Pressure value - Request/response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits. - Payload length (bytes) - Pressure value - Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

26.9.4.1 L3 Target Load Monitoring

The L3 interconnect implements two performance monitoring probes on DDR2/3 memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the STM interface.

SC_SDRAM supports the following main features:

- Two probe inputs
  - Probe 0 – EMIF1 (DMM-EMIF1 128-bit port)
  - Probe 1 – EMIF2 (DMM-EMIF2 128-bit port)
- Two 32-bit counters/filters shared concurrently
  - Counter 0 with two elements
  - Counter 1 with two elements
- Filtering according to:
  - Initiator of traffic
  - Access priorities
- No latency counter. Only bandwidth measurement on this collector
- 32-bit collecting window counter
- Dump Identifier is 0x0 (tie-off value)
- Dumps frames at L3 interconnect slave address 0x1F (DEBUGSS)

Table 26-14 summarizes the SC_SDRAM configuration.

Table 26-14. SC_SDRAM Configuration

Counters	Min/ Max	Filter Elements	L3 Target	
Counter 0	Yes	2	EMIF1	EMIF2
Counter 1	Yes	2	EMIF1	EMIF2

Table 26-15 shows the SC_SDRAM port mapping.

Table 26-15. SC_SDRAM Port Mapping

Probe #	Description	Link	Port #
0	EMIF1	OCP REQ	0
		OCP RSP	1
1	EMIF2	OCP REQ	2
		OCP RSP	3

26.9.4.2 L3 Master Latency Monitoring

The device L3 interconnect implements a number of performance monitoring probes on the main L3 initiators:

- MPU subsystem
- DSP subsystem (MDMA port)
- HDVICP2-0
- HDVICP2-1
- HDVICP2-2
- MMU

- HDVPSS M0
- HDVPSS M1
- EDMA TPTC1 read channel (TPTC_RD1)
- EDMA TPTC2 read channel (TPTC_RD2)
- EDMA TPTC3 read channel (TPTC_RD3)
- EDMA TPTC4 read channel (TPTC_RD4)
- SGX
- Media Controller
- PCIe
- CPGMAC0
- CPGMAC1
- SATA

The master latency statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with on-going execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

26.9.4.2.1 SC_LAT0 Configuration

SC_LAT0 supports the following main features:

- Eight probe inputs:
  - Probe 0: MPU subsystem
  - Probe 1: DSP MDMA
  - Probe 2: HDVPSS M0
  - Probe 3: HDVPSS M1
  - Probe 4: MMU
  - Probe 5: HDVICP2-0
  - Probe 6: HDVICP2-1
  - Probe 7: HDVICP2-2
- Eight 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
  - Counter 4 with one filter
  - Counter 5 with one filter
  - Counter 6 with one filter
  - Counter 7 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 12-bit counter for latency measurement

- 32-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x1F (DEBUGSS)

Table 26-16 summarizes the SC_LAT0 configuration.

Table 26-16. SC_LAT0 Configuration

Counters	Min/ Max	Filter Elements	L3 Master							
Counter 0	Yes	1	MPU	DSP	HDVPSS M0	HDVPSS M1	MMU	HDVICP2-0	HDVICP2-1	HDVICP2-2
Counter 1	Yes	1	MPU	DSP	HDVPSS M0	HDVPSS M1	MMU	HDVICP2-0	HDVICP2-1	HDVICP2-2
Counter 2	Yes	1	MPU	DSP	HDVPSS M0	HDVPSS M1	MMU	HDVICP2-0	HDVICP2-1	HDVICP2-2

26.9.4.2.2 SC_LAT1 Configuration

SC_LAT1 supports the following main features:

- Eight probe inputs:
  - Probe 0: TPTC_RD1
  - Probe 1: TPTC_RD2
  - Probe 2: TPTC_RD3
  - Probe 3: TPTC_RD4
  - Probe 4: HDVICP2-0 SL2
  - Probe 5: HDVICP2-1 SL2
  - Probe 6: HDVICP2-2 SL2
  - Probe 7: C674x DSP SDMA
- Eight 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
  - Counter 4 with one filter
  - Counter 5 with one filter
  - Counter 6 with one filter
  - Counter 7 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 12-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x1F (DEBUGSS)

Table 26-18 summarizes the SC_LAT1 configuration.

26.9.4.2.3 SC_LAT2 Configuration

SC_LAT2 supports the following main features:

- Seven probe inputs:
  - Probe 0: SGX530
  - Probe 1: Media Controller
  - Probe 2: Reserved
  - Probe 3: Reserved
  - Probe 4: CPGMAC0
  - Probe 5: CPGMAC1
  - Probe 6: PCIe
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 12-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x3 (tie-off value)
- Dumps frames at slave address 0x1F (DEBUGSS)

Table 26-18 summarizes the SC_LAT2 configuration.

Table 26-20. SC_LAT2 Configuration

Counters	Min/ Max	Filter Elements	L3 Master						
Counter 0	Yes	1	SGX530	Media Controller	Reserved	Reserved	CPGMAC0	CPGMAC1	PCIe

6	PCIe	NTTP REQ	12
		NTTP RSP	13

26.9.5 Master-ID Encoding

A master-ID (MReqMstID[7:0]) field is used by the STM to encode a MASTER type of message:

- MReqMstID[7] – Differentiates software versus hardware masters (0 for software masters; 1 for hardware masters)
- MReqMstID[6:2] – Master address exported by the L3 interconnect debug subsystem target
- MReqMstID[1:0] – Additional qualifier for multicore masters

26.9.5.1 Software Masters

The STM module allows:

- Enabling a maximum of four SoC software masters
- Masking MReqMstID[1:0]
- Differentiating multicore software masters through MReqMstID[1:0]

Table 26-22 summarizes the software initiators that can export trace messages through the STM.

Table 26-22. STM Message Software Masters

Initiator	MReqMstID			Description
	[7]	[6:2]	[1:0]	
Cortex-A8 MPU subsystem	0	00000	00	SW messages routed through L3 DebugSS target port
DebugSS (DAP)	0	00100	–	STP link testing; SW messages routed through L3 DebugSS target port
DSP subsystem	0	01000	–	SW messages routed through L3 DebugSS target port
HDVICP2-0 iCONT1	0	00010	00	SW messages routed through L3 DebugSS target port
HDVICP2-0 iCONT2 (via SMSET)	0	00011	00	SW messages routed through HDVICP2-0 instrumentation port
HDVICP2-1 iCONT1	0	00110	00	SW messages routed through L3 DebugSS target port
HDVICP2-1 iCONT2 (via SMSET)	0	00111	00	SW messages routed through HDVICP2-1 instrumentation port
HDVICP2-2 iCONT1	0	01100	00	SW messages routed through L3 DebugSS target port
HDVICP2-2 iCONT2 (via SMSET)	0	01101	00	SW messages routed through HDVICP2-2 instrumentation port
Reserved	0	10000	00	Reserved
Media Controller (HDVPSS and HDVICP control)	0	10001	00	HDVPSS control; SW messages routed through L3 DebugSS target port
	0	10001	01	HDVICP control; SW messages routed through L3 DebugSS target port
Reserved	0	10100	00	Reserved
TPTC_WR1	0	11001	00	Data logging; SW messages routed through L3 DebugSS target port
TPTC_WR2	0	11011	–	Data logging; SW messages routed through L3 DebugSS target port

26.9.5.2 Hardware Masters

The STM module allows enabling a subset of SoC hardware masters (maximum = 4).

Table 26-23 summarizes the hardware initiators that can export trace messages through the STM.

Table 26-23. STM Message Hardware Masters

Initiator	MReqMstID		
	[7]	[6:2]	[1:0]
OCP_WP Traffic Probe	1	00001	00
OCP_WP System Events	1	00010	00
Statistics collector 0	1	11100	00
Statistics collector 1	1	11101	00
Statistics collector 2	1	11110	00
Statistics collector 3	1	11111	00
HDVICP2-0 (via SMSET)	1	01001	00
HDVICP2-1 (via SMSET)	1	01010	00
HDVICP2-2 (via SMSET)	1	01011	00

26.10 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each debug interface pin.

Because of the limited number of pins allocated to debug and trace, a muxing of signals is implemented (at DRM level).

Table 26-24 summarizes the trace port configuration.

Table 26-24. Trace Port Configuration

Device Pin Name	Triggers	STM (System Trace)
EMU4	–	STM_DATA[3]
EMU3	–	STM_DATA[2]
EMU2	–	STM_CLK
EMU1	Trigger1	STM_DATA[1]
EMU0	Trigger0	STM_DATA[0]

Table 26-25 summarizes the concurrent debug and trace in the device.

Table 26-25. Concurrent Debug and Trace

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock
0	STM		4	–	1
	Triggers	–			
1	STM		2	–	1
	Triggers	2			

26.11 Debug Components Memory Mapping

Table 26-26 summarizes the base addresses for the debug components.

Table 26-26. Debug Modules Memory Mapping

Region Name	Block Name	Start Address	End Address	Size	Description
L3 Target Space	Instrumentation	0x4B00 0000	0x4BFF FFFF	16MB	Debug Instrumentation Interconnect region
	OCP_WP	0x4818 C000	0x4818 CFFF	4KB	OCP_WP register space

26.11.1 Debug Instrumentation Interconnect Address Space

The instrumentation address space is driven by the L3 or HW master access ports and targets the STM module. The address space is detailed in Table 26-27.

Table 26-27. Debug Instrumentation Interconnect Address Space

Region Name	Module Name	Start Address Offset(1)	End Address Offset(1)	Size	Description
Debug Instrumentation Interconnect	MIPI_STM [256 × 4K channels] (OCP – AddrSpace 0)	0x000000	0x0FFFFF	1MB	STM [256 × 4K channels]
	MIPI_STM [256 × 1K channels] (OCP – AddrSpace 1)	0x100000	0x13FFFF	256KB	STM [256 × 1K channels]
	Debug Configuration Interconnect	0x140000	0x17FFFF	256KB	Debug Configuration Interconnect
	Reserved	0x181000	0x1FFFFF	508KB	If accessed, returns error response

(1) Offset from the base address of the region

26.11.2 Debug Configuration Interconnect Address Space

The following modules may be accessible in the configuration address space of an application initiator to the configuration bus or from the DAP APB port:

Table 26-28. Debug Configuration Interconnect Address Space

Region Name	Module Name / Interface Type	Start Address Offset(1)	End Address Offset(1)	Size	Description
Debug Configuration Interconnect	External port (OCP) for Cortex-A8 MPU Subsystem	0x00000	0x1FFFF	128KB	MPU subsystem register space
	DRM (OCP)	0x20000	0x20FFF	4KB	DRM register space
	MIPI_STM (OCP)	0x21000	0x21FFF	4KB	MIPI_STM register space
	ETB (APBv3)	0x22000	0x22FFF	4KB	ETB register space
	Reserved	0x23000	0x23FFF	4KB	Reserved
	CS_TF (APBv3)	0x24000	0x24FFF	4KB	CS_TF register space
	Reserved	0x25000	0x25FFF	4KB	Reserved
	External port (OCP) for ADTF	0x26000	0x26FFF	4KB	ADTF register space
	Technology Specific Interconnect Registers	0x27000	0x27FFF	4KB	Note: Not all space may be used
	Reserved	0x28000	0x3FFFF	96K	If accessed, returns error response

(1) Offset from the base address of the region

26.11.3 Cortex-A8 MPU Subsystem Address Space

The base address for the debug components at the MPUSS (Cortex-A8) are described in Table 26-29.

Table 26-29. Cortex-A8 MPU Subsystem Address Space

Region Name	Module Name	Start Address Offset(1)	End Address Offset(1)	Size	Description
DAP-APB	Cortrex-A8 ETM unit	0x0000	0x0FFF	4KB	Cortrex-A8 ETM register space
	Cortex-A8 Debug unit	0x1000	0x1FFF	4KB	Cortex-A8 Debug unit register space
	Cortex-A8 CTI unit	0x2000	0x2FFF	4KB	Cortex-A8 CTI register space
	ICECrusher-CS APB	0x3000	0x3FFF	4KB	ICECrusher-CS register space
	Timeout Register for the CortexA8 APB Port	0x4000	0x43FF	1KB	–
	AP registers	0x4400	0x47FF	1KB	Reserved
	LA registers	0x4800	0x4BFF	1KB	Reserved. Writing to this range may cause unpredictable behavior in the bridge
	Reserved	0x4C00	0x4FFF	1KB	If accessed, returns error response
	Timeout Register for the ICECrusher-CS APB Port	0x5000	0x53FF	1KB	–
	Reserved	0x5400	0x7FFF	8KB	If accessed, returns error response

(1) Offset from the base address of the region

The MPUSS debug components are accessible via the external subsystem port (for Cortex-A8) of the configuration interconnect in DebugSS.

The physical address of a certain MPU debug module (for example, Cortex-A8 debug unit) can be calculated as follows:

- The SoC level address for DebugSS is 0x4B000000 (see Table 26-26).
- The offset of the configuration interconnect in DebugSS is 0x140000 (see Table 26-27).
- The offset of the external subsystem port (for Cortex-A8) from the configuration interconnect is 0x0 (see Table 26-28).
- Therefore, the SoC level address for Cortex-A8 debug unit is 0x4B141000 (0x4B000000 + 0x140000 + 0x1000).

26.11.4 DAP-APB Address Space

The DAP-APB port has a 32-bit address space.

The address map as seen by the APB interface of the CoreSight DAP is described in Table 26-30.

Any accesses made to the "no mapping" region return implementation defined data. In fact, the current implementation allows the address of such accesses to wrap around a 256KB address boundary.

MSB of the address allows the access on the APB interface to be qualified as an application (when not set) or debugger one (when set).

Table 26-30. DAP-APB Address Map

Region Name	Module Name	Start Address (hex)	End Address (hex)	Size	Description
DAP-APB	Debug Configuration Interconnect	0x00000000	0x0003FFFF	256KB	Debug Configuration Interconnect [application access]
	DAP ROM Table	0x00040000	0x00040FFF	4KB	DAP ROM Table [application access]
	No Mapping	0x00041000	0x7FFFFFFF	2MB	–
	Debug Configuration Interconnect	0x80000000	0x8003FFFF	256KB	Debug Configuration Interconnect [debugger access]
	DAP ROM Table	0x80040000	0x80040FFF	4KB	DAP ROM Table [debugger access]
	No Mapping	0x80041000	0x7FFFFFFF	2MB	–

Revision History

Changes from March 26, 2013 to March 6, 2015 (from B Revision (March 2013) to C Revision) **Page**

- **Chapter 1: Chip Level Resources** 109
- Figure 1-1: Removed all frequencies 111
- Table 1-1: Deleted frequency from Comments column 115
- Table 1-2: Deleted Maximum Frequency column 115
- Section 1.2.6.2: Deleted first bulleted item 118
- Section 1.7.2.1.1: Deleted last sentence in fourth paragraph 178
- Figure 1-67: Changed 432 MHz to Audio reference clock 205
- Table 1-73: Deleted Frequency column 206
- Table 1-73: Changed DDRPLL to MAINPLL for DDR2/DDR3 SYSCLK4 206
- Section 1.10.3: Changed $_{fvco}$ to f_{vco} in f_s frequency 210
- Section 1.10.3: Changed fractional range to FF FFFFh in FREQ 210
- Section 1.10.3: Added NOTE 210
- Section 1.10.3.1.1: Changed third paragraph 211
- Figure 1-70: Deleted 432 MHz 211
- Table 1-76: Changed table 212
- Table 1-77: Changed table 213
- Table 1-78: Added Main PLL Frequencies for Speed Grade 2 table. Subsequent tables renumbered 213
- Table 1-79: Added Main PLL Frequencies for Speed Grade 4 table. Subsequent tables renumbered 214

- Figure 1-75: Deleted all frequencies 232
- Section 1.16.1.2.20: Changed 380 MHz to 364 MHz. Deleted the last sentence 324
- Section 1.16.1.2.34: Changed 432 MHz to the audio reference clock 332
- Section 1.16.1.3: Deleted USB Control Register 1 (USB_CTRL1) subsection. Subsequent subsections renumbered 338
- Table 1-212: Changed USB_CTRL0 to USB_CTRL. 338
- Table 1-212: Changed address offset 628h to Reserved. Deleted USB Control Register 1 (USB_CTRL1) 338
- Figure 1-170: Changed figure 346
- Table 1-220: Changed table 346
- Figure 1-171: Changed figure 347
- Table 1-221: Changed table 347
- Figure 1-172: Changed figure 348
- Table 1-222: Changed table 348
- **Chapter 4: DMM/TILER** 415
- Figure 4-1: Deleted frequencies 416
- Figure 4-1: Connected DMM to EMIF and DDR Bank 416
- **Chapter 9: General-Purpose Memory Controller (GPMC)** 859
- Section 9.2.4.9.6: Changed first bullet in second paragraph (RDCYCLETIME - CLKACTIVATIONTIME) 885
- Table 9-80: Changed Description of ECCTOPSECTOR bit 996

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have ***not*** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
